\forall i \sum_{j=1}^{k_1} b_{j,i} = p_{2,j} \\
\]

\( b_{i,j} \) is a binary variable

Ryser’s Algorithm:

(Ryser [Ryser63]): The construction of an \( m \times n \) matrix \( A = A_{r,s} \), due to Ryser, is described as follows. The construction works if and only if have \( s \preceq r^* \).

\bullet \) Construct the \( m \times n \) matrix \( B \) from \( r \) by defining the \( i \)-th row of \( B \) to be the vector whose first \( r_i \) entries are 1, and the remainder are 0’s, \( 1 \leq i \leq m \). This maximal matrix \( B \) with row sum \( r \) and ones left justified has column sum \( r^* \).

\bullet \) Shift the last 1 in certain rows of \( B \) to column \( n \) in order to achieve the sum \( s_n \). Call this \( B \) again.

\quad \) The 1’s in column \( n \) are to appear in those rows in which \( A \) has the largest row sums, giving preference to the bottom-most positions in case of ties.

\quad \) Note: When this step automatically “fixes” other columns, one must skip ahead to the first column index with a wrong sum in the step below.

\bullet \) Proceed inductively to construct columns \( n - 1, \ldots, 2, 1 \). Note: when performing the induction on step \( k \), we consider the row sums of the first \( k \) columns.

\bullet \) Set \( A = B \). Return \( A \).

EXAMPLES:
Computing the matrix for \( p_1 = p_2 = 2 + 2 + 1 \):

```
sage: from sage.combinat.integer_vector import gale_ryser_theorem
sage: p1 = [2,2,1]
sage: p2 = [2,2,1]
sage: print(gale_ryser_theorem(p1, p2))        # not tested
[1 1 0]
[1 0 1]
[0 1 0]
sage: A = gale_ryser_theorem(p1, p2)
sage: rs = [sum(x) for x in A.rows()]
sage: cs = [sum(x) for x in A.columns()]
sage: p1 == rs; p2 == cs
True
True
```

Or for a non-square matrix with \( p_1 = 3 + 3 + 2 + 1 \) and \( p_2 = 3 + 2 + 2 + 1 + 1 \), using Ryser’s algorithm:
```python
sage: from sage.combinat.integer_vector import gale_ryser_theorem
sage: p1 = [3,3,1,1]
sage: p2 = [3,3,1,1]
sage: gale_ryser_theorem(p1, p2, algorithm = "ryser")
[1 1 1 0]
[1 1 0 1]
[1 0 0 0]
[0 1 0 0]
sage: p1 = [4,2,2]
sage: p2 = [3,3,1,1]
sage: gale_ryser_theorem(p1, p2, algorithm = "ryser")
[1 1 1 1]
[1 1 0 0]
[1 1 0 0]
sage: p1 = [4,2,2,0]
sage: p2 = [3,3,1,1,0,0]
sage: gale_ryser_theorem(p1, p2, algorithm = "ryser")
[1 1 1 1 0 0]
[1 1 0 0 0 0]
[1 1 0 0 0 0]
[0 0 0 0 0 0]
sage: p1 = [3,3,2,1]
sage: p2 = [3,2,2,1,1]
sage: print(gale_ryser_theorem(p1, p2, algorithm = "gale"))  # not tested
[1 1 1 0 0]
[1 1 0 0 1]
[1 0 1 0 0]
[0 1 0 0 0]
With 0 in the sequences, and with unordered inputs:
```

```python
sage: from sage.combinat.integer_vector import gale_ryser_theorem
sage: gale_ryser_theorem([3,3,0,1,1,0], [3,1,3,1,0], algorithm = "ryser")
[1 1 1 0 0]
[1 0 1 1 0]
[0 0 0 0 0]
[1 0 0 0 0]
[0 0 1 0 0]
[0 0 0 0 0]
sage: p1 = [3,1,1,1,1]; p2 = [3,2,2,0]
sage: gale_ryser_theorem(p1, p2, algorithm = "ryser")
[1 1 1 0]
[1 0 0 0]
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
```

REFERENCES:
sage.combinat.integer_vector.integer_vectors_nk_fast_iter(n, k)
A fast iterator for integer vectors of n of length k which yields Python lists filled with Sage Integers.

EXAMPLES:
We check some corner cases:

\[
\begin{align*}
\text{sage: } & \text{list(integer_vectors_nk_fast_iter(5, 1))} \\
& \text{[[5]]} \\
\text{sage: } & \text{list(integer_vectors_nk_fast_iter(1, 1))} \\
& \text{[[1]]} \\
\text{sage: } & \text{list(integer_vectors_nk_fast_iter(2, 0))} \\
& [] \\
\text{sage: } & \text{list(integer_vectors_nk_fast_iter(0, 2))} \\
& [[0, 0]]
\end{align*}
\]

\[
\begin{align*}
\text{sage: } & \text{list(integer_vectors_nk_fast_iter(0, 0))} \\
& [[]]
\end{align*}
\]

\[
\begin{align*}
\text{sage.combinat.integer_vector.is_gale_ryser}(r, s)
\end{align*}
\]

Tests whether the given sequences satisfy the condition of the Gale-Ryser theorem.

Given a binary matrix $B$ of dimension $n \times m$, the vector of row sums is defined as the vector whose $i^{th}$ component is equal to the sum of the $i^{th}$ row in $A$. The vector of column sums is defined similarly.

If, given a binary matrix, these two vectors are easy to compute, the Gale-Ryser theorem lets us decide whether, given two non-negative vectors $r, s$, there exists a binary matrix whose row/column sums vectors are $r$ and $s$.

This function answers accordingly.

INPUT:

• $r, s$ – lists of non-negative integers.

ALGORITHM:

Without loss of generality, we can assume that:

• The two given sequences do not contain any 0 (which would correspond to an empty column/row)

• The two given sequences are ordered in decreasing order (reordering the sequence of row (resp. column) sums amounts to reordering the rows (resp. columns) themselves in the matrix, which does not alter the columns (resp. rows) sums.

We can then assume that $r$ and $s$ are partitions (see the corresponding class \texttt{Partition}).

If $r^*$ denote the conjugate of $r$, the Gale-Ryser theorem asserts that a binary Matrix satisfying the constraints exists if and only if $s \preceq r^*$, where $\preceq$ denotes the domination order on partitions.

EXAMPLES:

\[
\begin{align*}
\text{sage: } & \text{from sage.combinat.integer_vector import is_gale_ryser} \\
\text{sage: } & \text{is_gale_ryser([4,2,2],[3,3,1,1])} \\
& \text{True} \\
\text{sage: } & \text{is_gale_ryser([4,2,1,1],[3,3,1,1])} \\
& \text{True}
\end{align*}
\]

(continues on next page)
REMARK: In the literature, what we are calling a Gale-Ryser sequence sometimes goes by the (rather generic-sounding) term “realizable sequence”.

```python
sage.combinat.integer_vector.list2func(l, default=None)
```

Given a list `l`, return a function that takes in a value `i` and return `l[i]`. If default is not None, then the function will return the default value for out of range `i`’s.

EXAMPLES:

```python
sage: f = sage.combinat.integer_vector.list2func([1, 2, 3])
sage: f(0)
1
sage: f(1)
2
sage: f(2)
3
sage: f(3)
Traceback (most recent call last):
... IndexError: list index out of range
```

```python
sage: f = sage.combinat.integer_vector.list2func([1, 2, 3], 0)
sage: f(2)
3
sage: f(3)
0
```

### 5.1.126 Weighted Integer Vectors

AUTHORS:

- Mike Hansen (2007): initial version, ported from MuPAD-Combinat
- Nicolas M. Thiery (2010-10-30): WeightedIntegerVectors(weights) + cleanup

```python
class sage.combinat.integer_vector_weighted.WeightedIntegerVectors(n, weight)
```

Bases: `Parent, UniqueRepresentation`

The class of integer vectors of `n` weighted by `weight`, that is, the nonnegative integer vectors \((v_1, \ldots, v_\ell)\) satisfying \(\sum_{i=1}^\ell v_i w_i = n\) where \(\ell\) is `length(weight)` and \(w_i\) is `weight[i]`.

INPUT:

- `n` – a non negative integer (optional)
- `weight` – a tuple (or list or iterable) of positive integers

EXAMPLES:

```python
sage: WeightedIntegerVectors(8, [1,1,2])
Integer vectors of 8 weighted by [1, 1, 2]
sage: WeightedIntegerVectors(8, [1,1,2]).first()
```

(continues on next page)
\begin{verbatim}
[0, 0, 4]
sage: WeightedIntegerVectors(8, [1,1,2]).last()
[8, 0, 0]
sage: WeightedIntegerVectors(8, [1,1,2]).cardinality()
25
sage: w = WeightedIntegerVectors(8, [1,1,2]).random_element()
sage: w.parent() is WeightedIntegerVectors(8, [1,1,2])
True
sage: WeightedIntegerVectors([1,1,2])
Integer vectors weighted by [1, 1, 2]
sage: WeightedIntegerVectors([1,1,2]).cardinality()
+Infinity
sage: WeightedIntegerVectors([1,1,2]).first()
[0, 0, 0]
\end{verbatim}

**Todo:** Should the order of the arguments \texttt{n} and \texttt{weight} be exchanged to simplify the logic?

**Element**
alias of \texttt{IntegerVector}

\begin{classdef}
\begin{verbatim}
class sage.combinat.integer_vector_weighted.Weight\_Integer\_Vectors\_all(weight)
Bases: DisjointUnionEnumeratedSets
Set of weighted integer vectors.
\end{verbatim}
\end{classdef}

**EXAMPLES:**
\begin{verbatim}
sage: W = WeightedIntegerVectors([3,1,1,2,1]); W
Integer vectors weighted by [3, 1, 1, 2, 1]
sage: W.cardinality()
+Infinity
sage: W12 = W.graded_component(12)
sage: W12.an_element()
[4, 0, 0, 0, 0]
sage: W12.last()
[0, 12, 0, 0, 0]
sage: W12.cardinality()
441
sage: for w in W12: print(w)
[4, 0, 0, 0, 0]
[3, 0, 0, 1, 1]
[3, 0, 1, 1, 0]
...
[0, 11, 1, 0, 0]
[0, 12, 0, 0, 0]
\end{verbatim}

**grading(x)**
EXAMPLES:
sage: C = WeightedIntegerVectors([2,1,3])
sage: C.grading((2,1,1))
8

subset(size=None)
EXAMPLES:

sage: C = WeightedIntegerVectors([2,1,3])
sage: C.subset(4)
Integer vectors of 4 weighted by [2, 1, 3]

sage.combinat.integer_vector_weighted.iterator_fast(n, l)
Iterate over all l weighted integer vectors with total weight n.

INPUT:
• n – an integer
• l – the weights in weakly decreasing order

EXAMPLES:

sage: from sage.combinat.integer_vector_weighted import iterator_fast
sage: list(iterator_fast(3, [2,1,1]))
[[1, 1, 0], [1, 0, 1], [0, 3, 0], [0, 2, 1], [0, 1, 2], [0, 0, 3]]
sage: list(iterator_fast(2, [2]))
[[1]]

Test that github issue #20491 is fixed:

sage: type(list(iterator_fast(2, [2]))[0][0])
<class 'sage.rings.integer.Integer'>

5.1.127 Integer vectors modulo the action of a permutation group

class sage.combinat.integer_vectors_mod_permgroup.IntegerVectorsModPermutationGroup
Bases: UniqueRepresentation

Returns an enumerated set containing integer vectors which are maximal in their orbit under the action of the permutation group G for the lexicographic order.

In Sage, a permutation group G is viewed as a subgroup of the symmetric group Sn of degree n and n is said to be the degree of G. Any integer vector v is said to be canonical if it is maximal in its orbit under the action of G. v is canonical if and only if

\[ v = \max_{\text{lex order}} \{ g \cdot v | g \in G \} \]

The action of G is on position. This means for example that the simple transposition s1 = (1, 2) swaps the first and the second entries of any integer vector

\[ v = [a_1, a_2, a_3, \ldots, a_n] \]

\[ s_1 \cdot v = [a_2, a_1, a_3, \ldots, a_n] \]

This function returns a parent which contains a single integer vector by orbit under the action of the permutation group G. The approach chosen here is to keep the maximal integer vector for the lexicographic order in each orbit. Such maximal vector will be called canonical integer vector under the action of the permutation group G.

INPUT:
• $G$ - a permutation group
• $\text{sum}$ - (default: None) - a nonnegative integer
• $\text{max\_part}$ - (default: None) - a nonnegative integer setting the maximum of entries of elements
• $\text{sgs}$ - (default: None) - a strong generating system of the group $G$. If you do not provide it, it will be calculated at the creation of the parent

OUTPUT:
• If $\text{sum}$ and $\text{max\_part}$ are None, it returns the infinite enumerated set of all integer vectors (list of integers) maximal in their orbit for the lexicographic order.
• If $\text{sum}$ is an integer, it returns a finite enumerated set containing all integer vectors maximal in their orbit for the lexicographic order and whose entries sum to $\text{sum}$.

EXAMPLES:
Here is the set enumerating integer vectors modulo the action of the cyclic group of 3 elements:

```sage
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3)]]))
sage: I.category()
Category of infinite enumerated quotients of sets
sage: I.cardinality()
+Infinity
sage: I.list()
Traceback (most recent call last):
... 
NotImplementedError: cannot list an infinite set
sage: p = iter(I)
sage: for i in range(10): next(p)
[0, 0, 0]
[1, 0, 0]
[2, 0, 0]
[1, 1, 0]
[3, 0, 0]
[2, 1, 0]
[2, 0, 1]
[1, 1, 1]
[4, 0, 0]
[3, 1, 0]
```

The method $\text{is\_canonical()}$ tests if any integer vector is maximal in its orbit. This method is also used in the containment test:

```sage
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: I.is_canonical([5,2,0,4])
True
sage: I.is_canonical([5,0,6,4])
False
sage: I.is_canonical([5,0,6,4])
True
sage: [2,3,1,0] in I
False
sage: [5,0,5,0] in I
True
sage: 'Bla' in I
```

(continues on next page)
Combinatorics, Release 10.0

False
sage: I.is_canonical('bla')
Traceback (most recent call last):
...
AssertionError: bla should be a list or an integer vector

If you give a value to the extra argument sum, the set returned will be a finite set containing only canonical vectors whose entries sum to sum:

sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3]]), sum=6)
sage: I.cardinality()
10
sage: I.list()
[[6, 0, 0], [5, 1, 0], [5, 0, 1], [4, 2, 0], [4, 1, 1],
 [4, 0, 2], [3, 3, 0], [3, 2, 1], [3, 1, 2], [2, 2, 2]]
sage: I.category()
Join of Category of finite enumerated sets and Category of subquotients of finite...
\rightarrow sets and Category of quotients of sets

To get the orbit of any integer vector \(v\) under the action of the group, use the method \texttt{orbit()}; we convert the returned set of vectors into a list in increasing lexicographic order, to get a reproducible test:

sage: sorted(I.orbit([6,0,0]))
[[0, 0, 6], [0, 6, 0], [6, 0, 0]]
sage: sorted(I.orbit([5,1,0]))
[[0, 5, 1], [1, 0, 5], [5, 1, 0]]
sage: I.orbit([2,2,2])
{[2, 2, 2]}

class \texttt{sage.combinat.integer_vectors_mod_permgroup.IntegerVectorsModPermutationGroup\_All}(G, sgs=None)

Bases: \texttt{UniqueRepresentation}, \texttt{RecursivelyEnumeratedSet\_forest}

A class for integer vectors enumerated up to the action of a permutation group.

A Sage permutation group is viewed as a subgroup of the symmetric group \(S_n\) for a certain \(n\). This group has a natural action by position on vectors of length \(n\). This class implements a set which keeps a single vector for each orbit. We say that a vector is canonical if it is the maximum in its orbit under the action of the permutation group for the lexicographic order.

EXAMPLES:

sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]))
sage: I
Integer vectors of length 4 enumerated up to the action of Permutation Group with...
\rightarrow generators [(1,2,3,4)]
sage: I.cardinality()
+Infinity
sage: TestSuite(I).run()
sage: it = iter(I)
sage: [next(it), next(it), next(it), next(it), next(it)]
[[0, 0, 0, 0], [1, 0, 0, 0], [2, 0, 0, 0],...
class Element

Bases: ClonableIntArray

Element class for the set of integer vectors of given sum enumerated modulo the action of a permutation group. These vectors are clonable lists of integers which must satisfy conditions coming from the parent appearing in the method `check()`.

`check()`

Checks that `self` verify the invariants needed for living in `self.parent()`.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]))
sage: v = I.an_element()
sage: v.check()
sage: w = I([0,4,0,0], check=False); w
[0, 4, 0, 0]
sage: w.check()
Traceback (most recent call last):
  ...  AssertionError
```

`ambient()`

Return the ambient space from which `self` is a quotient.

EXAMPLES:

```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]))
sage: S.ambient()
Integer vectors of length 4
```

`children(x)`

Returns the list of children of the element `x`. This method is required to build the tree structure of `self` which inherits from the class `RecursivelyEnumeratedSet_forest`.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]))
sage: I.children(I([2,1,0,0], check=False))
[[2, 2, 0, 0], [2, 1, 1, 0], [2, 1, 0, 1]]
```

`is_canonical(v, check=True)`

Returns `True` if the integer list `v` is maximal in its orbit under the action of the permutation group given to define `self`. Such integer vectors are said to be canonical. A vector `v` is canonical if and only if

\[
v = \max_{\text{lex order}} \{ g \cdot v | g \in G \}\]

EXAMPLES:
lift(elt)
Lift the element elt inside the ambient space from which self is a quotient.

EXAMPLES:

\begin{verbatim}
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: v = S.lift(S([4,3,0,1])); v
[4, 3, 0, 1]
sage: type(v)
<class 'list'>
\end{verbatim}

orbit(v)
Returns the orbit of the integer vector v under the action of the permutation group defining self. The result is a set.

EXAMPLES:
In order to get reproducible doctests, we convert the returned sets into lists in increasing lexicographic order:

\begin{verbatim}
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: sorted(I.orbit([2,2,0,0]))
[[0, 0, 2, 2], [0, 2, 2, 0], [2, 0, 0, 2], [2, 2, 0, 0]]
sage: sorted(I.orbit([2,1,0,0]))
[[0, 0, 2, 1], [0, 2, 1, 0], [1, 0, 0, 2], [2, 1, 0, 0]]
sage: sorted(I.orbit([2,0,1,0]))
[[0, 1, 0, 2], [0, 2, 0, 1], [1, 0, 2, 0], [2, 0, 1, 0]]
sage: sorted(I.orbit([2,0,2,0]))
[[0, 2, 0, 2], [2, 0, 2, 0]]
sage: I.orbit([1,1,1,1])
[[1, 1, 1, 1]]
\end{verbatim}

permutation_group()
Returns the permutation group given to define self.

EXAMPLES:

\begin{verbatim}
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: I.permutation_group()
Permutation Group with generators [(1,2,3,4)]
\end{verbatim}

retract(elt)
Return the canonical representative of the orbit of the integer elt under the action of the permutation group defining self.
If the element elt is already maximal in its orbit for the lexicographic order, elt is thus the good representative for its orbit.

EXAMPLES:

```python
sage: [0,0,0,0] in IntegerVectors(0,4)
True
sage: [1,0,0,0] in IntegerVectors(1,4)
True
sage: [0,1,0,0] in IntegerVectors(1,4)
True
sage: [1,0,1,0] in IntegerVectors(2,4)
True
sage: [0,1,0,1] in IntegerVectors(2,4)
True
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]))
sage: S.retract([0,0,0,0])
[0, 0, 0, 0]
sage: S.retract([1,0,0,0])
[1, 0, 0, 0]
sage: S.retract([0,1,0,0])
[1, 0, 0, 0]
sage: S.retract([1,0,1,0])
[1, 0, 1, 0]
sage: S.retract([0,1,0,1])
[1, 0, 1, 0]
```

```
roots()

Returns the root of generation of self. This method is required to build the tree structure of self which inherits from the class RecursivelyEnumeratedSet_forest.

EXAMPLES:

```python
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]))
sage: I.roots()
[[0, 0, 0, 0]]
```

```
subset(sum=None, max_part=None)

Returns the subset of self containing integer vectors whose entries sum to sum.

EXAMPLES:

```python
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]))
sage: S.subset(4)
Integer vectors of length 4 and of sum 4 enumerated up to the action of Permutation Group with generators
[(1,2,3,4)]
```

```
class sage.combinat.integer_vectors_mod_permgroup.IntegerVectorsModPermutationGroup_with_constraints(G, d, max_part, sgs)

Bases: UniqueRepresentation, RecursivelyEnumeratedSet_forest

This class models finite enumerated sets of integer vectors with constraint enumerated up to the action of a permutation group. Integer vectors are enumerated modulo the action of the permutation group. To implement
that, we keep a single integer vector by orbit under the action of the permutation group. Elements chosen are vectors maximal in their orbit for the lexicographic order.

For more information see \texttt{IntegerVectorsModPermutationGroup}.

**EXAMPLES:**

```python
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]), max_part=1)
sage: I.list()
[[0, 0, 0, 0], [1, 0, 0, 0], [1, 1, 0, 0], [1, 0, 1, 0], [1, 1, 1, 0], [1, 1, 1, 1]]
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]), sum=6, max_part=4)
sage: I.list()
[[4, 2, 0, 0], [4, 1, 1, 0], [4, 1, 0, 1], [4, 0, 2, 0], [4, 0, 1, 1],
 [4, 0, 0, 2], [3, 3, 0, 0], [3, 2, 1, 0], [3, 2, 0, 1], [3, 1, 2, 0],
 [3, 1, 1, 1], [3, 1, 0, 2], [3, 0, 3, 0], [3, 0, 2, 1], [3, 0, 1, 2],
 [2, 2, 2, 0], [2, 2, 1, 1], [2, 1, 2, 1]]
```

Here is the enumeration of unlabeled graphs over 5 vertices:

```python
sage: G = IntegerVectorsModPermutationGroup(TransitiveGroup(10,12), max_part=1)
sage: G.cardinality()
34
```

**class Element**

Bases: \texttt{ClonableIntArray}

Element class for the set of integer vectors with constraints enumerated modulo the action of a permutation group. These vectors are clonable lists of integers which must satisfy conditions coming from the parent as in the method \texttt{check()}.

\texttt{check()} Checks that \texttt{self} meets the constraints of being an element of \texttt{self.parent()}.

**EXAMPLES:**

```python
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]), 4)
sage: v = I.an_element()
sage: v.check()
sage: w = I([0,4,0,0], check=False); w
[0, 4, 0, 0]
sage: w.check()
Traceback (most recent call last):
  ... AssertionError
```

\texttt{ambient()} Return the ambient space from which \texttt{self} is a quotient.

**EXAMPLES:**

```python
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]), 6);
sage: S.ambient()
Integer vectors that sum to 6
```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]), 6, max_part=12); S.ambient()
Integer vectors that sum to 6 with constraints: max_part=12
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]), max_part=12); S.ambient()
Integer vectors with constraints: max_part=12

an_element()
Returns an element of self or raises an EmptySetError when self is empty.

EXAMPLES:

sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]), sum=0, max_part=1); S.an_element()
[0, 0, 0, 0]
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]), sum=1, max_part=1); S.an_element()
[1, 0, 0, 0]
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]), sum=2, max_part=1); S.an_element()
[1, 1, 0, 0]
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]), sum=3, max_part=1); S.an_element()
[1, 1, 1, 0]
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]), sum=4, max_part=1); S.an_element()
[1, 1, 1, 1]
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]), sum=5, max_part=1); S.an_element()
Traceback (most recent call last):
... EmptySetError

children(x)
Returns the list of children of the element x. This method is required to build the tree structure of self which inherits from the class RecursivelyEnumeratedSet_forest.

EXAMPLES:

sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]), max_part=3)
sage: I.children(I([2,1,0,0], check=False))
[[2, 2, 0, 0], [2, 1, 1, 0], [2, 1, 0, 1]]

is_canonical(v, check=True)
Returns True if the integer list v is maximal in its orbit under the action of the permutation group given to define self. Such integer vectors are said to be canonical. A vector v is canonical if and only if

\[ v = \max_{\text{lex order}} \{ g \cdot v | g \in G \} \]

EXAMPLES:

sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]), max_part=3)
lift(elt)
Lift the element elt inside the ambient space from which self is a quotient.

EXAMPLES:

```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup(
            [[(1,2,3,4)]]), \n            -> max_part=1)
sage: v = S.lift([1,0,1,0]); v
[1, 0, 1, 0]
sage: v in IntegerVectors(2,4,max_part=1)
True
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup(
            [[(1,2,3,4)]]), \n            -> sum=6)
sage: v = S.lift(S.list()[5]); v
[4, 1, 1, 0]
sage: v in IntegerVectors(n=6)
True
```

orbit(v)
Returns the orbit of the vector v under the action of the permutation group defining self. The result is a set.

INPUT:

* v - an element of self or any list of length the degree of the permutation group.

EXAMPLES:

We convert the result in a list in increasing lexicographic order, to get a reproducible doctest:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup(
            [[(1,2,3,4)]], 4)
sage: I.orbit([1,1,1,1])
{(1, 1, 1, 1)}
sage: sorted(I.orbit([3,0,0,1]))
[[0, 0, 1, 3], [0, 1, 3, 0], [1, 3, 0, 0], [3, 0, 0, 1]]
```

permutation_group()
Returns the permutation group given to define self.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup(
            [[(1,2,3,4)]], 5)
sage: I.permutation_group()
Permutation Group with generators [(1,2,3)]
```

retract(elt)
Return the canonical representative of the orbit of the integer elt under the action of the permutation group defining self.
If the element \( \texttt{elt} \) is already maximal in its orbits for the lexicographic order, \( \texttt{elt} \) is thus the good representative for its orbit.

**EXAMPLES:**

```python
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]),
      sum=2, max_part=1)
sage: S.retract([1,1,0,0])
[1, 1, 0, 0]
sage: S.retract([1,0,1,0])
[1, 0, 1, 0]
sage: S.retract([1,0,0,1])
[1, 1, 0, 0]
sage: S.retract([0,1,1,0])
[1, 1, 0, 0]
sage: S.retract([0,1,0,1])
[1, 0, 1, 0]
sage: S.retract([0,0,1,1])
[1, 1, 0, 0]
```

**roots()**

Returns the root of generation of \( \texttt{self} \). This method is required to build the tree structure of \( \texttt{self} \) which inherits from the class \( \text{RecursivelyEnumeratedSet\_forest} \).

**EXAMPLES:**

```python
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]))
sage: I.roots()
[[0, 0, 0, 0]]
```

### 5.1.128 Tamari Interval-posets

This module implements Tamari interval-posets: combinatorial objects which represent intervals of the Tamari order. They have been introduced in [CP2015] and allow for many combinatorial operations on Tamari intervals. In particular, they are linked to \( \text{DyckWords} \) and \( \text{BinaryTrees} \). An introduction into Tamari interval-posets is given in Chapter 7 of [Pons2013].

The Tamari lattice can be defined as a lattice structure on either of several classes of Catalan objects, especially binary trees and Dyck paths [Tam1962] [HT1972] [Sta-EC2]. An interval can be seen as a pair of comparable elements. The number of intervals has been given in [Cha2008].

**AUTHORS:**

- Viviane Pons 2014: initial implementation
- Frédéric Chapoton 2014: review
- Darij Grinberg 2014: review
- Travis Scrimshaw 2014: review

```python
sage.combinat.interval_posets.TIP
alias of TamariIntervalPoset
class sage.combinat.interval_posets.TamariIntervalPoset(parent, size, relations=None, check=True)
              Bases: Element

The class of Tamari interval-posets.
```
An interval-poset is a labelled poset of size \( n \), with labels \( 1, 2, \ldots, n \), satisfying the following conditions:

- if \( a < c \) (as integers) and \( a \) precedes \( c \) in the poset, then, for all \( b \) such that \( a < b < c \), \( b \) precedes \( c \),
- if \( a < c \) (as integers) and \( c \) precedes \( a \) in the poset, then, for all \( b \) such that \( a < b < c \), \( b \) precedes \( a \).

We use the word “precedes” here to distinguish the poset order and the natural order on numbers. “Precedes” means “is smaller than with respect to the poset structure”; this does not imply a covering relation.

Interval-posets of size \( n \) are in bijection with intervals of the Tamari lattice of binary trees of size \( n \). Specifically, if \( P \) is an interval-poset of size \( n \), then the set of linear extensions of \( P \) (as permutations in \( S_n \)) is an interval in the right weak order (see \texttt{permutohedron_lequal()}, and is in fact the preimage of an interval in the Tamari lattice (of binary trees of size \( n \)) under the operation which sends a permutation to its right-to-left binary search tree (\texttt{binary_search_tree()} with the \texttt{left_to_right} variable set to \texttt{False}) without its labelling.

INPUT:

- \texttt{size} – an integer, the size of the interval-posets (number of vertices)
- \texttt{relations} – a list (or tuple) of pairs \((a, b)\) (themselves lists or tuples), each representing a relation of the form ‘\( a \) precedes \( b \)’ in the poset.
- \texttt{check} – (default: True) whether to check the interval-poset condition or not.

\textbf{Warning:} The \texttt{relations} input can be a list or tuple, but not an iterator (nor should its entries be iterators).

\textbf{NOTATION:}

Here and in the following, the signs \(<\) and \(>\) always refer to the natural ordering on integers, whereas the word “precedes” refers to the order of the interval-poset. “Minimal” and “maximal” refer to the natural ordering on integers.

The \textit{increasing relations} of an interval-poset \( P \) mean the pairs \((a, b)\) of elements of \( P \) such that \( a < b \) as integers and \( a \) precedes \( b \) in \( P \). The \textit{initial forest} of \( P \) is the poset obtained by imposing (only) the increasing relations on the ground set of \( P \). It is a sub-interval poset of \( P \), and is a forest with its roots on top. This forest is usually given the structure of a planar forest by ordering brother nodes by their labels; it then has the property that if its nodes are traversed in post-order (see \texttt{post_order_traversal()}, and traverse the trees of the forest from left to right as well), then the labels encountered are \( 1, 2, \ldots, n \) in this order.

The \textit{decreasing relations} of an interval-poset \( P \) mean the pairs \((a, b)\) of elements of \( P \) such that \( b < a \) as integers and \( a \) precedes \( b \) in \( P \). The \textit{final forest} of \( P \) is the poset obtained by imposing (only) the decreasing relations on the ground set of \( P \). It is a sub-interval poset of \( P \), and is a forest with its roots on top. This forest is usually given the structure of a planar forest by ordering brother nodes by their labels; it then has the property that if its nodes are traversed in pre-order (see \texttt{pre_order_traversal()}, and traverse the trees of the forest from left to right as well), then the labels encountered are \( 1, 2, \ldots, n \) in this order.

\textbf{EXAMPLES:}

\texttt{sage:} TamariIntervalPoset(0, [])
The Tamari interval of size 0 induced by relations []
\texttt{sage:} TamariIntervalPoset(3, [])
The Tamari interval of size 3 induced by relations []
\texttt{sage:} TamariIntervalPoset(3, [(1,2)])
The Tamari interval of size 3 induced by relations [(1, 2)]
\texttt{sage:} TamariIntervalPoset(3, [(1,2),(2,3)])
The Tamari interval of size 3 induced by relations [(1, 2), (2, 3)]
\texttt{sage:} TamariIntervalPoset(3, [(1,2),(2,3),(1,3)])
The Tamari interval of size 3 induced by relations [(1, 2), (2, 3)]
sage: TamariIntervalPoset(3,[(1,2),(3,2)])
The Tamari interval of size 3 induced by relations [(1, 2), (3, 2)]
sage: TamariIntervalPoset(3,[[1,2],[2,3]])
The Tamari interval of size 3 induced by relations [(1, 2), (2, 3)]
sage: TamariIntervalPoset(3,[[1,2],[2,3],[1,2],[1,3]])
The Tamari interval of size 3 induced by relations [(1, 2), (2, 3)]
sage: TamariIntervalPoset(3,[(3,4)])
Traceback (most recent call last):
    ...
ValueError: the relations do not correspond to the size of the poset
sage: TamariIntervalPoset(2,[(2,1),(1,2)])
Traceback (most recent call last):
    ...
ValueError: The graph is not directed acyclic
sage: TamariIntervalPoset(3,[(1,3)])
Traceback (most recent call last):
    ...
ValueError: this does not satisfy the Tamari interval-poset condition

It is also possible to transform a poset directly into an interval-poset:

sage: TIP = TamariIntervalPosets()
sage: p = Poset(((1,2,3), [(1,2)]))
sage: TIP(p)
The Tamari interval of size 3 induced by relations [(1, 2)]
sage: TIP(Poset({1: []}))
The Tamari interval of size 1 induced by relations []
sage: TIP(Poset({}))
The Tamari interval of size 0 induced by relations []

binary_trees()
Return an iterator on all the binary trees in the interval represented by self.

See also:
interval_cardinality()

EXAMPLES:

sage: list(TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)]).binary_trees())
[[[., [[., .], .]], .], [[., [[., .], .]], .], [[., [[., .], .]], .], [[., [[., .], .]], .]]
sage: set(TamariIntervalPoset(4,[]).binary_trees()) == set(BinaryTrees(4))
True

complement()
Return the complement of the interval-poset self.

If \( P \) is a Tamari interval-poset of size \( n \), then the complement of \( P \) is defined as the interval-poset \( Q \) whose base set is \( \{1, 2, \ldots, n\} \) (just as for \( P \)), but whose order relation has \( a \) precede \( b \) if and only if

5.1. Comprehensive Module List

1223
\( n + 1 - a \) precedes \( n + 1 - b \) in \( P \).

In terms of the Tamari lattice, the complement is the symmetric of self. It is formed from the left-right symmetrized of the binary trees of the interval (switching left and right subtrees, see \texttt{left_right_symmetry()}). In particular, initial intervals are sent to final intervals and vice-versa.

EXAMPLES:

```
sage: TamariIntervalPoset(3, [(2, 1), (3, 1)]).complement()
The Tamari interval of size 3 induced by relations [(1, 3), (2, 3)]
sage: TamariIntervalPoset(0, []).complement()
The Tamari interval of size 0 induced by relations []
sage: ip = TamariIntervalPoset(4, [(1, 2), (2, 4), (3, 4)])
sage: ip.complement() == TamariIntervalPoset(4, [(2, 1), (3, 1), (4, 3)])
True
sage: ip.lower_binary_tree() == ip.complement().upper_binary_tree().left_right_symmetry()
True
sage: ip.upper_binary_tree() == ip.complement().lower_binary_tree().left_right_symmetry()
True
sage: ip.is_initial_interval()
True
sage: ip.complement().is_final_interval()
True
```

\texttt{contains_binary_tree(binary_tree)}

Return whether the interval represented by self contains the binary tree \texttt{binary_tree}.

INPUT:

- \texttt{binary_tree} – a binary tree

See also:

\texttt{contains_dyck_word()}  

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4, [(2, 4), (3, 4), (2, 1), (3, 1)])
sage: ip.contains_binary_tree(BinaryTree([[None, [None, []]], None]))
True
sage: ip.contains_binary_tree(BinaryTree([[None, [[]], None]]))
True
sage: ip.contains_binary_tree(BinaryTree([[], [[]], None]))
False
sage: ip.contains_binary_tree(ip.lower_binary_tree())
True
sage: ip.contains_binary_tree(ip.upper_binary_tree())
True
sage: all(ip.contains_binary_tree(bt) for bt in ip.binary_trees())
True
```

\texttt{contains_dyck_word(dyck_word)}

Return whether the interval represented by self contains the Dyck word \texttt{dyck_word}.

INPUT:
• dyck_word – a Dyck word

See also:

contains_binary_tree()

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4, [(2,4),(3,4),(2,1),(3,1)])
sage: ip.contains_dyck_word(DyckWord([1,1,1,0,0,0,1,0]))
True
sage: ip.contains_dyck_word(DyckWord([1,1,0,1,0,1,0,0]))
True
sage: ip.contains_dyck_word(DyckWord([1,0,1,1,0,1,0,0]))
False
sage: ip.contains_dyck_word(ip.lower_dyck_word())
True
sage: ip.contains_dyck_word(ip.upper_dyck_word())
True
sage: all(ip.contains_dyck_word(bt) for bt in ip.dyck_words())
True
```

contains_interval(other)

Return whether the interval represented by other is contained in self as an interval of the Tamari lattice. In terms of interval-posets, it means that all relations of self are relations of other.

INPUT:

• other – an interval-poset

EXAMPLES:

```python
sage: ip1 = TamariIntervalPoset(4, [(1,2),(2,3),(3,4)])
sage: ip2 = TamariIntervalPoset(4, [(2,3)])
sage: ip2.contains_interval(ip1)
True
sage: ip3 = TamariIntervalPoset(4, [(2,1)])
sage: ip2.contains_interval(ip3)
False
sage: ip4 = TamariIntervalPoset(3, [(2,3)])
sage: ip2.contains_interval(ip4)
False
```

cubical_coordinates()

Return the cubical coordinates of self.

This provides a fast and natural way to order the set of interval-posets of a given size.

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4, [(1,2),(2,3)])
sage: ip.cubical_coordinates()
(-1, -2, 0)
```

REFERENCES:

• [Com2019]
decomposition_to_triple()
Decompose an interval-poset into a triple \((\text{left}, \text{right}, r)\).
For the inverse method, see \texttt{TamariIntervalPosets.recomposition_from_triple().}

OUTPUT:
a triple \((\text{left}, \text{right}, r)\) where \text{left} and \text{right} are interval-posets and \text{r} (an integer) is the parameter of the decomposition.

EXAMPLES:

\begin{verbatim}
sage: tip = TamariIntervalPoset(8, [(1,2), (2,4), (3,4), (6,7), (3,2), (5,4),
(6,4), (8,7)])
sage: tip.decomposition_to_triple()
(The Tamari interval of size 3 induced by relations [(1, 2), (3, 2)],
The Tamari interval of size 4 induced by relations [(2, 3), (4, 3)],
2)
sage: tip == TamariIntervalPosets.recomposition_from_triple(*tip.decomposition_to_triple())
True
\end{verbatim}

REFERENCES:
• [CP2015]

decreasing_children\((v)\)
Return the children of \(v\) in the final forest of \text{self}.

INPUT:
• \(v\) – an integer representing a vertex of \text{self} (between 1 and size)

OUTPUT:
The list of all children of \(v\) in the final forest of \text{self}, in increasing order.

EXAMPLES:

\begin{verbatim}
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,5)])
sage: ip.decreasing_children(2)
[3, 5]
sage: ip.decreasing_children(3)
[4]
sage: ip.decreasing_children(1)
[]
\end{verbatim}

decreasing_cover_relations()
Return the cover relations of the final forest of \text{self}.
This is the poset formed by keeping only the relations of the form \(a\) precedes \(b\) with \(a > b\).
The final forest of \text{self} is a forest with its roots being on top. It is also called the decreasing poset of \text{self}.

\textbf{Warning:} This method computes the cover relations of the final forest. This is not identical with the cover relations of \text{self} which happen to be decreasing!
See also:

*final_forest()*

EXAMPLES:

```python
sage: TamariIntervalPoset(4,[(2,1),(3,2),(3,4),(4,2)]).decreasing_cover_relations()
[(4, 2), (3, 2), (2, 1)]
```

```python
sage: TamariIntervalPoset(4,[(2,1),(4,3),(2,3)]).decreasing_cover_relations()
[(4, 3), (2, 1)]
```

```python
sage: TamariIntervalPoset(3,[(2,1),(3,1),(3,2)]).decreasing_cover_relations()
[(3, 2), (2, 1)]
```

decreasing_parent(v)

Return the vertex parent of *v* in the final forest of *self*.

This is the highest (as integer!) vertex *a* < *v* such that *v* precedes *a*. If there is no such vertex (that is, *v* is a decreasing root), then None is returned.

INPUT:

* • v – an integer representing a vertex of *self* (between 1 and size)

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,5)]);
ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.decreasing_parent(4)
3
sage: ip.decreasing_parent(3)
2
sage: ip.decreasing_parent(5)
2
sage: ip.decreasing_parent(2) is None
True
```

decreasing_roots()

Return the root vertices of the final forest of *self*.

These are the vertices *b* such that there is no *a* < *b* with *b* preceding *a*.

OUTPUT:

The list of all roots of the final forest of *self*, in increasing order.

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,5)]);
ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.decreasing_roots()
[1, 2]
sage: ip.final_forest().decreasing_roots()
[1, 2]
```
dyck_words()

Return an iterator on all the Dyck words in the interval represented by self.

EXAMPLES:

```python
sage: list(TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)]).dyck_words())
[[1, 1, 1, 0, 0, 1, 0, 0],
 [1, 1, 1, 0, 0, 0, 1, 0],
 [1, 1, 0, 1, 0, 1, 0, 0],
 [1, 1, 0, 1, 0, 0, 1, 0]]
sage: set(TamariIntervalPoset(4,[]).dyck_words()) == set(DyckWords(4))
True
```

factor()

Return the unique decomposition as a list of connected components.

EXAMPLES:

```python
sage: factor(TamariIntervalPoset(2,[]))  # indirect doctest
[The Tamari interval of size 1 induced by relations [],
The Tamari interval of size 1 induced by relations []]
```

See also:

is_connected()

final_forest()

Return the final forest of self, i.e., the interval-poset formed with only the decreasing relations of self.

See also:

initial_forest()

EXAMPLES:

```python
sage: TamariIntervalPoset(4,[(2,1),(3,2),(3,4),(4,2)]).final_forest()
The Tamari interval of size 4 induced by relations [(4, 2), (3, 2), (2, 1)]
sage: ip = TamariIntervalPoset(3,[(2,1),(3,1)])
sage: ip.final_forest() == ip
True
```

ge(e1, e2)

Return whether e2 precedes or equals e1 in self.

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3)])
sage: ip.ge(2,1)
True
sage: ip.ge(3,1)
True
sage: ip.ge(3,2)
True
sage: ip.ge(4,3)
False
sage: ip.ge(1,1)
True
```
grafting_tree()

Return the grafting tree of the interval-poset.

For the inverse method, see TamariIntervalPosets.from_grafting_tree().

EXAMPLES:

```python
sage: tip = TamariIntervalPoset(8, [(1,2), (2,4), (3,4), (6,7), (3,2), (5,4), (6,4), (8,7)])
```
```
sage: tip.grafting_tree()
2[1[0[., .], 0[., .]], 0[., 1[0[., .], 0[., .]]]]
```
```
sage: tip == TamariIntervalPosets.from_grafting_tree(tip.grafting_tree())
True
```

REFERENCES:

• [Pons2018]

gt(e1, e2)

Return whether e2 strictly precedes e1 in self.

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3)])
```
```
sage: ip.gt(2,1)
True
```
```
sage: ip.gt(3,1)
True
```
```
sage: ip.gt(3,2)
True
```
```
sage: ip.gt(4,3)
False
```
```
sage: ip.gt(1,1)
False
```

increasing_children(v)

Return the children of v in the initial forest of self.

INPUT:

• v – an integer representing a vertex of self (between 1 and size)

OUTPUT:

The list of all children of v in the initial forest of self, in decreasing order.

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,5)]);
```
```
sage: ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
```
```
sage: ip.increasing_children(2)
[1]
```
```
sage: ip.increasing_children(5)
[4, 3]
```
```
sage: ip.increasing_children(1)
[]
```
**increasing_cover_relations()**

Return the cover relations of the initial forest of self.

This is the poset formed by keeping only the relations of the form \(a \lessdot b\) with \(a < b\).

The initial forest of self is a forest with its roots being on top. It is also called the increasing poset of self.

**Warning:** This method computes the cover relations of the initial forest. This is not identical with the cover relations of self which happen to be increasing!

See also:

* initial_forest()

**EXAMPLES:**

```sage
tamari = IntervalPoset(4, [(1,2),(3,2),(2,4),(3,4)]).increasing_cover_relations()
tamari
```

```text
[(1, 2), (2, 4), (3, 4)]
```

```sage
tamari = IntervalPoset(3, [(1,2),(1,3),(2,3)]).increasing_cover_relations()
tamari
```

```text
[(1, 2), (2, 3)]
```

**increasing_parent(v)**

Return the vertex parent of v in the initial forest of self.

This is the lowest (as integer!) vertex \(b > v\) such that \(v \lessdot b\). If there is no such vertex (that is, \(v\) is an increasing root), then None is returned.

**INPUT:**

* v – an integer representing a vertex of self (between 1 and size)

**EXAMPLES:**

```sage
ip = IntervalPoset(6, [(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,5)]);
ip
```

```
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
```

```sage
ip.increasing_parent(1)
ip.increasing_parent(3)
ip.increasing_parent(4)
ip.increasing_parent(5)
```

```text
2
5
5
None
```

**increasing_roots()**

Return the root vertices of the initial forest of self.

These are the vertices \(a\) of self such that there is no \(b > a\) with \(a \lessdot b\).

**OUTPUT:**

The list of all roots of the initial forest of self, in decreasing order.

**EXAMPLES:**

```sage
root = increasing_roots()
root
```

```text
[5, 4, 3, 2, 1]
```
 sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,5)]);
      ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5), (6, 
      5), (5, 2), (4, 3), (3, 2)]
sage: ip.increasing_roots()
[6, 5, 2]
sage: ip.initial_forest().increasing_roots()
[6, 5, 2]

`initial_forest()`

Return the initial forest of `self`, i.e., the interval-poset formed from only the increasing relations of `self`.

See also:

`final_forest()`

EXAMPLES:

 sage: TamariIntervalPoset(4,[(1,2),(3,2),(2,4),(3,4)]).initial_forest()
The Tamari interval of size 4 induced by relations [(1, 2), (2, 4), (3, 4)]
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3)])
sage: ip.initial_forest() == ip
True

`insertion(i)`

Return the Tamari insertion of an integer `i` into the interval-poset `self`.

If `P` is a Tamari interval-poset of size `n` and `i` is an integer with `1 ≤ i ≤ n + 1`, then the Tamari insertion of `i` into `P` is defined as the Tamari interval-poset of size `n + 1` which corresponds to the interval `[C_1, C_2]` on the Tamari lattice, where the binary trees `C_1` and `C_2` are defined as follows: We write the interval-poset `P` as `[B_1, B_2]` for two binary trees `B_1` and `B_2`. We label the vertices of each of these two trees with the integers `1, 2, ..., i − 1, i + 1, i + 2, ..., n + 1` in such a way that the trees are binary search trees (this labelling is unique). Then, we insert `i` into each of these trees (in the way as explained in `binary_search_insert()`). The shapes of the resulting two trees are denoted `C_1` and `C_2`.

An alternative way to construct the insertion of `i` into `P` is by relabeling each vertex `u` of `P` satisfying `u ≥ i` (as integers) as `u + 1`, and then adding a vertex `i` which should precede `i − 1` and `i + 1`.

Todo: To study this, it would be more natural to define interval-posets on arbitrary ordered sets rather than just on `{1, 2, ..., n}`.

EXAMPLES:

 sage: ip = TamariIntervalPoset(4, [(2, 3), (4, 3)]); ip
The Tamari interval of size 4 induced by relations [(2, 3), (4, 3)]
sage: ip.insertion(1)
The Tamari interval of size 5 induced by relations [(1, 2), (3, 4), (5, 4)]
sage: ip.insertion(2)
The Tamari interval of size 5 induced by relations [(2, 3), (3, 4), (5, 4), (2, 
      ˓→1)]
sage: ip.insertion(3)
The Tamari interval of size 5 induced by relations [(2, 4), (3, 4), (5, 4), (3, 
      ˓→2)]
sage: ip.insertion(4)

(continues on next page)
The Tamari interval of size 5 induced by relations \[[2, 3), (4, 5), (5, 3), (4, \rightarrow 3)\]
\sage: ip.insertion(5)
The Tamari interval of size 5 induced by relations \[[2, 3), (5, 4), (4, 3)\]
\sage: ip = TamariIntervalPoset(0, [])
\sage: ip.insertion(1)
The Tamari interval of size 1 induced by relations []
\sage: ip = TamariIntervalPoset(1, [])
\sage: ip.insertion(1)
The Tamari interval of size 2 induced by relations \[[1, 2]\]
\sage: ip.insertion(2)
The Tamari interval of size 2 induced by relations \[[2, 1]\]

intersection\(other\)
Return the interval-poset formed by combining the relations from both \self and \other. It corresponds to the intersection of the two corresponding intervals of the Tamari lattice.

**INPUT:**

- \other – an interval-poset of the same size as \self

**EXAMPLES:**

\sage: ip1 = TamariIntervalPoset(4,\[(1,2),(2,3)\])
\sage: ip2 = TamariIntervalPoset(4,\[(4,3)\])
\sage: ip1.intersection(ip2)
The Tamari interval of size 4 induced by relations \[[1, 2), (2, 3), (4, 3)\]
\sage: ip3 = TamariIntervalPoset(4,\[(2,1)\])
\sage: ip1.intersection(ip3)
Traceback (most recent call last):
... ValueError: this intersection is empty, it does not correspond to an interval-poset
\sage: ip4 = TamariIntervalPoset(3,\[(2,3)\])
\sage: ip2.intersection(ip4)
Traceback (most recent call last):
... ValueError: intersections are only possible on interval-posets of the same size

interval_cardinality()
Return the cardinality of the interval, i.e., the number of elements (binary trees or Dyck words) in the interval represented by \self.

Not to be confused with \size which is the number of vertices.

**See also:**

\binary_trees()

**EXAMPLES:**

\sage: TamariIntervalPoset(4,\[(2,4),(3,4),(2,1),(3,1)\]).interval_cardinality()
4
sage: TamariIntervalPoset(4,[]).interval_cardinality()
14
sage: TamariIntervalPoset(4,[(1,2),(2,3),(3,4)]).interval_cardinality()
1

**is_connected()**
Return whether `self` is a connected Tamari interval.

This means that the Hasse diagram is connected.

This condition is invariant under complementation.

See also:
- `is_indecomposable()`, `factor()`

EXAMPLES:

```python
sage: len([T for T in TamariIntervalPosets(3) if T.is_connected()])
8
```

**is_dexter()**
Return whether `self` is a dexter Tamari interval.

This is defined by an exclusion pattern in the Hasse diagram. See the code for the exact description.

This condition is not invariant under complementation.

EXAMPLES:

```python
sage: len([T for T in TamariIntervalPosets(3) if T.is_dexter()])
12
```

**is_exceptional()**
Return whether `self` is an exceptional Tamari interval.

This is defined by exclusion of a simple pattern in the Hasse diagram, namely there is no configuration \( y \prec x \prec z \) with \( 1 \leq y < x < z \leq n \).

This condition is invariant under complementation.

EXAMPLES:

```python
sage: len([T for T in TamariIntervalPosets(3) if T.is_exceptional()])
12
```

**is_final_interval()**
Return if `self` corresponds to a final interval of the Tamari lattice.

This means that its upper end is the largest element of the lattice. It consists of checking that `self` does not contain any increasing relations.

See also:
- `is_initial_interval()`

EXAMPLES:
Combinatorics, Release 10.0

```python
sage: ip = TamariIntervalPoset(4, [(4, 3), (3, 1), (2, 1)])
sage: ip.is_final_interval()
True
sage: ip.upper_dyck_word()
[1, 1, 1, 1, 0, 0, 0, 0]
sage: ip = TamariIntervalPoset(4, [(4, 3), (3, 1), (2, 1), (2, 3)])
sage: ip.is_final_interval()
False
sage: ip.upper_dyck_word()
[1, 1, 0, 1, 1, 0, 0, 0]
sage: all(dw.tamari_interval(DyckWord([1, 1, 1, 0, 0, 0])).is_final_interval() for dw in DyckWords(3))
True
```

**is_indecomposable()**

Return whether self is an indecomposable Tamari interval.

This is the terminology of [Cha2008].

This means that the upper binary tree has an empty left subtree.

This condition is not invariant under complementation.

See also:

`is_connected()`

EXAMPLES:

```python
sage: len([T for T in TamariIntervalPosets(3) if T.is_indecomposable()])
8
```

**is_ininitely_modern()**

Return whether self is an infinitely-modern Tamari interval.

This is defined by the exclusion of the configuration $i \rightarrow i + 1$ and $j + 1 \rightarrow j$ with $i < j$.

This condition is invariant under complementation.

See also:

`is_new()`, `is_modern()`

EXAMPLES:

```python
sage: len([T for T in TamariIntervalPosets(3) if T.is_ininitely_modern()])
12
```

REFERENCES:

- [Rog2018]

**is_initial_interval()**

Return if self corresponds to an initial interval of the Tamari lattice.

This means that its lower end is the smallest element of the lattice. It consists of checking that self does not contain any decreasing relations.
See also:

is_final_interval()

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4, [(1, 2), (2, 4), (3, 4)])
sage: ip.is_initial_interval()
True
sage: ip.lower_dyck_word()
[1, 0, 1, 0, 1, 0]
sage: ip = TamariIntervalPoset(4, [(1, 2), (2, 4), (3, 4), (3, 2)])
sage: ip.is_initial_interval()
False
sage: ip.lower_dyck_word()
[1, 0, 1, 1, 0, 0]
sage: all(DyckWord([1,0,1,0,1,0]).tamari_interval(dw).is_initial_interval() for dw in DyckWords(3))
True
```

is_linear_extension(perm)

Return whether the permutation `perm` is a linear extension of `self`.

INPUT:

• `perm` – a permutation of the size of `self`

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4, [(1, 2), (2, 3), (4, 3)])
sage: ip.is_linear_extension([1, 4, 2, 3])
True
sage: ip.is_linear_extension(Permutation([1, 4, 2, 3]))
True
sage: ip.is_linear_extension(Permutation([1, 4, 3, 2]))
False
```

is_modern()

Return whether `self` is a modern Tamari interval.

This is defined by exclusion of a simple pattern in the Hasse diagram, namely there is no configuration \( y \rightarrow x \leftarrow z \) with \( 1 \leq y < x < z \leq n \).

This condition is invariant under complementation.

See also:

is_new(), is_ininitely_modern()

EXAMPLES:

```python
sage: len([T for T in TamariIntervalPosets(3) if T.is_modern()])
12
```

REFERENCES:

• [Rog2018]
**is_new()**

Return whether `self` is a new Tamari interval.

Here ‘new’ means that the interval is not contained in any facet of the associahedron. This condition is invariant under complementation.

They have been considered in section 9 of [Cha2008].

See also:

`is_modern()`

**EXAMPLES:**

```
sage: TIP4 = TamariIntervalPosets(4)
sage: len([u for u in TIP4 if u.is_new()])
12
sage: TIP3 = TamariIntervalPosets(3)
sage: len([u for u in TIP3 if u.is_new()])
3
```

**is_simple()**

Return whether `self` is a simple Tamari interval.

Here ‘simple’ means that the interval contains a unique binary tree.

These intervals define the simple modules over the incidence algebras of the Tamari lattices.

See also:

`is_final_interval(), is_initial_interval()`

**EXAMPLES:**

```
sage: TIP4 = TamariIntervalPosets(4)
sage: len([u for u in TIP4 if u.is_simple()])
14
sage: TIP3 = TamariIntervalPosets(3)
sage: len([u for u in TIP3 if u.is_simple()])
5
```

**is_synchronized()**

Return whether `self` is a synchronized Tamari interval.

This means that the upper and lower binary trees have the same canopee. This condition is invariant under complementation.

This has been considered in [FPR2015]. The numbers of synchronized intervals are given by the sequence OEIS sequence A000139.

**EXAMPLES:**

```
sage: len([T for T in TamariIntervalPosets(3) if T.is_synchronized()])
6
```
latex_options()

Return the latex options for use in the \_latex\_ function as a dictionary.

The default values are set using the options.

- **tikz_scale** – (default: 1) scale for use with the tikz package
- **line_width** – (default: 1) value representing the line width (additionally scaled by \texttt{tikz_scale})
- **color_decreasing** – (default: 'red') the color for decreasing relations
- **color_increasing** – (default: 'blue') the color for increasing relations
- **hspace** – (default: 1) the difference between horizontal coordinates of adjacent vertices
- **vspace** – (default: 1) the difference between vertical coordinates of adjacent vertices

EXAMPLES:

```sage
ip = TamariIntervalPoset(4, [(2,4),(3,4),(2,1),(3,1)])
ip.latex_options()['color_decreasing']
'red'
ip.latex_options()['hspace']
1
```

le(e1, e2)

Return whether e1 precedes or equals e2 in self.

EXAMPLES:

```sage
ip = TamariIntervalPoset(4, [(1,2),(2,3)])
ip.le(1,2)
True
ip.le(1,3)
True
ip.le(2,3)
True
ip.le(3,4)
False
ip.le(1,1)
True
```

left_branch_involution()

Return the image of self by the left-branch involution.

OUTPUT: an interval-poset

See also:

\texttt{rise_contact_involution()}

EXAMPLES:

```sage
tip = TamariIntervalPoset(8 , [(1,2), (2,4), (3,4), (6,7), (3,2), (5,4), ...
→(6,4), (8,7)])
t = tip.left_branch_involution(); t
The Tamari interval of size 8 induced by relations [(1, 6), (2, 6),
(3, 5), (4, 5), (5, 6), (6, 8), (7, 8), (7, 6), (4, 3), (3, 1),
(2, 1)]
```

(continues on next page)
REFERENCES:

- [Pons2018]

linear_extensions()

Return an iterator on the permutations which are linear extensions of self.

They form an interval of the right weak order (also called the right permutahedron order – see permutohedron_lequal() for a definition).

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(3,[(1,2),(3,2)])
sage: list(ip.linear_extensions())
[[3, 1, 2], [1, 3, 2]]
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3),(4,3)])
sage: list(ip.linear_extensions())
[[4, 1, 2, 3], [1, 2, 4, 3], [1, 4, 2, 3]]
```

lower_binary_tree()

Return the lowest binary tree in the interval of the Tamari lattice represented by self.

This is a binary tree. It is the shape of the unique binary search tree whose left-branch ordered forest (i.e., the result of applying to_ordered_tree_left_branch() and cutting off the root) is the final forest of self.

See also:

lower_dyck_word()

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(4,5)])
```

lower_contained_intervals()

If self represents the interval \([t_1, t_2]\) of the Tamari lattice, return an iterator on all intervals \([t_1, t]\) with \(t \leq t_2\) for the Tamari lattice.

In terms of interval-posets, it corresponds to adding all possible relations of the form \(n\) precedes \(m\) with \(n < m\).

EXAMPLES:
Combinatorics, Release 10.0

sage: ip = TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)])
sage: list(ip.lower_contained_intervals())

The Tamari interval of size 4 induced by relations [(2, 4), (3, 4), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations [(1, 4), (2, 4), (3, 4), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations [(2, 3), (3, 4), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations [(1, 4), (2, 3), (3, 4), (3, 1), (2, 1)]

sage: ip = TamariIntervalPoset(4,[])
sage: len(list(ip.lower_contained_intervals()))
14

lower_contains_interval(other)
Return whether the interval represented by other is contained in self as an interval of the Tamari lattice and if they share the same lower bound.

As interval-posets, it means that other contains the relations of self plus some extra increasing relations.

INPUT:
• other -- an interval-poset

EXAMPLES:
sage: ip1 = TamariIntervalPoset(4,[(1,2),(2,3),(4,3)])
sage: ip2 = TamariIntervalPoset(4,[(4,3)])
sage: ip2.lower_contains_interval(ip1)
True
sage: ip2.contains_interval(ip1) and ip2.lower_binary_tree() == ip1.lower_binary_tree()
True
sage: ip3 = TamariIntervalPoset(4,[(4,3),(2,1)])
sage: ip2.contains_interval(ip3)
True
sage: ip2.lower_binary_tree() == ip3.lower_binary_tree()
False
sage: ip2.lower_contains_interval(ip3)
False

lower_dyck_word()
Return the lowest Dyck word in the interval of the Tamari lattice represented by self.

See also:
lower_binary_tree()

EXAMPLES:
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(4,5)]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (4, 5), (6, 5), (5, 1), (2, 4), (3, 2)]
sage: ip.lower_dyck_word()
[1, 0, 1, 1, 1, 0, 0, 1, 1, 0, 0, 0]
sage: TamariIntervalPosets.final_forest(ip.lower_dyck_word()) == ip.final_

(continues on next page)
Combinatorics, Release 10.0

\[\Box\] forest()
True
\[\Box\]

\[\Box\]
sage: ip == TamariIntervalPosets.from_dyck_words(ip.lower_dyck_word(),ip.upper_dyck_word())
True

lt(e1, e2)
Return whether e1 strictly precedes e2 in self.

EXAMPLES:
\[\Box\]

\[\Box\]

\[\Box\]

max_linear_extension()
Return the maximal permutation for the right weak order which is a linear extension of self.

This is also the maximal permutation in the sylvester class of self.upper_binary_tree() and is a 132-avoiding permutation.

The right weak order is also known as the right permutohedron order. See permutohedron_lequal() for its definition.

EXAMPLES:
\[\Box\]

\[\Box\]

maximal_chain_binary_trees()
Return an iterator on the binary trees forming a longest chain of self (regarding self as an interval of the Tamari lattice).
EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)])
sage: list(ip.maximal_chain_binary_trees())[['[[., .], .], .], [[., [[., .], .]], .], [[., [[., .]], .], .], [[., [[., .]], .], .]]
sage: ip = TamariIntervalPoset(4,[])
sage: list(ip.maximal_chain_binary_trees())[['[[., .], .], .], [[., [[., .], .]], .], [[., [[., .]], .], .], [[., [[., .]], .], .]]
```

```python
maximal_chain_dyck_words()  
Return an iterator on the Dyck words forming a longest chain of self (regarding self as an interval of the Tamari lattice).

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)])
sage: list(ip.maximal_chain_dyck_words())[[1, 1, 0, 1, 0, 0, 1, 0], [1, 1, 0, 1, 0, 1, 0, 0], [1, 1, 1, 0, 0, 1, 0, 0]]
sage: ip = TamariIntervalPoset(4,[])
sage: list(ip.maximal_chain_dyck_words())[[1, 0, 1, 0, 1, 0, 1, 0], [1, 1, 0, 1, 0, 0, 1, 0], [1, 1, 0, 1, 0, 1, 0, 0], [1, 1, 1, 0, 0, 1, 0, 0], [1, 1, 1, 1, 0, 0, 0, 0]]
```

```python
maximal_chain_tamari_intervals()  
Return an iterator on the upper contained intervals of one longest chain of the Tamari interval represented by self.

If self represents the interval $[T_1, T_2]$ of the Tamari lattice, this returns intervals $[T', T_2]$ with $T'$ following one longest chain between $T_1$ and $T_2$.

To obtain a longest chain, we use the Tamari inversions of self. The elements of the chain are obtained by adding one by one the relations $(b, a)$ from each Tamari inversion $(a, b)$ to self, where the Tamari inversions are taken in lexicographic order.

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)])
sage: list(ip.maximal_chain_tamari_intervals())[[The Tamari interval of size 4 induced by relations [(2, 4), (3, 4), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations [(2, 4), (3, 4), (4, 1), (3, 2), (2, 1)],
The Tamari interval of size 4 induced by relations [(2, 4), (3, 4), (4, 1), (3, 2), (2, 1)]]
```
**min_linear_extension()**

Return the minimal permutation for the right weak order which is a linear extension of `self`.

This is also the minimal permutation in the sylvester class of `self.lower_binary_tree()` and is a 312-avoiding permutation.

The right weak order is also known as the right permutohedron order. See `permutohedron_lequal()` for its definition.

**EXAMPLES:**

```python
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3),(4,3)])
sage: ip.min_linear_extension()
[1, 2, 3, 4]
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(4,5)])
sage: ip.min_linear_extension()
[1, 2, 3, 4, 5, 6]
sage: ip = TamariIntervalPoset(0,[])
sage: ip.min_linear_extension()
[]
sage: ip = TamariIntervalPoset(5, [(1, 4), (2, 4), (3, 4), (5, 4)]); ip
The Tamari interval of size 5 induced by relations [(1, 4), (2, 4), (3, 4), (5, 4)]
sage: ip.min_linear_extension()
[1, 2, 3, 4, 5]
```

**new_decomposition()**

Return the decomposition of the interval-poset into new interval-posets.

Every interval-poset has a unique decomposition as a planar tree of new interval-posets, as explained in [Cha2008]. This function computes the terms of this decomposition, but not the planar tree.

For the number of terms, you can use instead the method `number_of_new_components()`.

**OUTPUT:**

a list of new interval-posets.

**See also:**

`number_of_new_components()`, `is_new()`

**EXAMPLES:**

```python
sage: ex = TamariIntervalPosets(4)[11]
sage: ex.number_of_new_components()
3
```
sage: ex.new_decomposition()
[The Tamari interval of size 1 induced by relations [],
The Tamari interval of size 2 induced by relations [],
The Tamari interval of size 1 induced by relations []]

number_of_new_components()
Return the number of terms in the decomposition in new interval-posets.

Every interval-poset has a unique decomposition as a planar tree of new interval-posets, as explained in [Cha2008]. This function just computes the number of terms, not the planar tree nor the terms themselves.

See also:
is_new(), new_decomposition()

EXAMPLES:

```
sage: TIP4 = TamariIntervalPosets(4)
sage: nb = [u.number_of_new_components() for u in TIP4]
sage: [nb.count(i) for i in range(1, 5)]
[12, 21, 21, 14]
```

count_of_intermediate_posets()
Return the number of Tamari inversions of self.

This is also the length the longest chain of the Tamari interval represented by self.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)])
sage: ip.number_of_tamari_inversions()
2
sage: ip = TamariIntervalPoset(4,[])
sage: ip.number_of_tamari_inversions()
6
sage: ip = TamariIntervalPoset(3,[])
sage: ip.number_of_tamari_inversions()
3
```

plot(**kwds)
Return a picture.

The picture represents the Hasse diagram, where the covers are colored in blue if they are increasing and in red if they are decreasing.

This uses the same coordinates as the latex view.

EXAMPLES:

```
sage: ti = TamariIntervalPosets(4)[2]
sage: ti.plot()
Graphics object consisting of 6 graphics primitives
```

poset()
Return self as a labelled poset.

An interval-poset is indeed constructed from a labelled poset which is stored internally. This method allows to access the poset and all the associated methods.
EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4, [(1,2), (3,2), (2,4), (3,4)])
sage: pos = ip.poset(); pos
Finite poset containing 4 elements
sage: pos.maximal_chains()
[[3, 2, 4], [1, 2, 4]]
sage: pos.maximal_elements()
[4]
sage: pos.is_lattice()
False
```

**rise_contact_involution()**

Return the image of `self` by the rise-contact involution.

**OUTPUT:** an interval-poset

This is defined by conjugating the complement involution by the left-branch involution.

**See also:**

`left_branch_involution()`, `complement()`

EXAMPLES:

```python
sage: tip = TamariIntervalPoset(8, [(1,2), (2,4), (3,4), (6,7), (3,2), (5,4), (6,4), (8,7)])
sage: t = tip.rise_contact_involution(); t
The Tamari interval of size 8 induced by relations [(2, 8), (3, 8), (4, 5), (5, 7), (6, 7), (7, 8), (8, 1), (7, 2), (6, 2), (5, 3), (4, 3), (3, 2), (2, 1)]
sage: t.rise_contact_involution() == tip
True
sage: tip.lower_dyck_word().number_of_touch_points() == t.upper_dyck_word().number_of_initial_rises()
True
sage: tip.number_of_tamari_inversions() == t.number_of_tamari_inversions()
True
```

REFERENCES:

- [Pons2018]

**set_latex_options(D)**

Set the latex options for use in the `_latex_` function.

The default values are set in the `__init__` function.

- `tikz_scale` – (default: 1) scale for use with the tikz package
- `line_width` – (default: 1 * `tikz_scale`) value representing the line width
- `color_decreasing` – (default: red) the color for decreasing relations
- `color_increasing` – (default: blue) the color for increasing relations
- `hspace` – (default: 1) the difference between horizontal coordinates of adjacent vertices
- `vspace` – (default: 1) the difference between vertical coordinates of adjacent vertices

INPUT:
Combinatorics, Release 10.0

• D – a dictionary with a list of latex parameters to change

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)])
sage: ip.latex_options()['color_decreasing']
'red'
sage: ip.set_latex_options({'color_decreasing':'green'})
sage: ip.latex_options()['color_decreasing']
'green'
sage: ip.set_latex_options({'color_increasing':'black'})
sage: ip.latex_options() ['color_increasing']
'black'
```

To change the default options for all interval-posets, use the parent’s latex options:

```python
sage: ip = TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)])
sage: ip2 = TamariIntervalPoset(4,[(1,2),(2,3)])
sage: ip.latex_options() ['color_decreasing']
'red'
sage: ip2.latex_options() ['color_decreasing']
'red'
sage: TamariIntervalPosets.options(latex_color_decreasing='green')
sage: ip.latex_options() ['color_decreasing']
'green'
sage: ip2.latex_options() ['color_decreasing']
'green'
```

Next we set a local latex option and show the global option does not override it:

```python
sage: ip.set_latex_options({'color_decreasing': 'black'})
sage: ip.latex_options() ['color_decreasing']
'black'
sage: TamariIntervalPosets.options(latex_color_decreasing='blue')
sage: ip.latex_options() ['color_decreasing']
'black'
sage: ip2.latex_options() ['color_decreasing']
'blue'
sage: TamariIntervalPosets.options._reset()
```

`size()`

Return the size (number of vertices) of the interval-poset.

EXAMPLES:

```python
sage: TamariIntervalPoset(3,[(2,1),(3,1)]).size()
3
```

`sub_poset(start, end)`

Return the renormalized subposet of self consisting solely of integers from start (inclusive) to end (not inclusive).

“Renormalized” means that these integers are relabelled 1, 2, . . . , k in the obvious way (i.e., by subtracting start - 1).

INPUT:
Combinatorics, Release 10.0

- start – an integer, the starting vertex (inclusive)
- end – an integer, the ending vertex (not inclusive)

EXAMPLES:

```
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,5)]);
    → ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
```

```
sage: ip.subposet(1,3)
The Tamari interval of size 2 induced by relations [(1, 2)]
```

```
sage: ip.subposet(1,4)
The Tamari interval of size 3 induced by relations [(1, 2), (3, 2)]
```

```
sage: ip.subposet(1,5)
The Tamari interval of size 4 induced by relations [(1, 2), (4, 3), (3, 2)]
```

```
sage: ip.subposet(1,7) == ip
True
```

```
sage: ip.subposet(1,1)
The Tamari interval of size 0 induced by relations []
```

subposet(start, end)

Return the renormalized subposet of self consisting solely of integers from start (inclusive) to end (not inclusive).

“Renormalized” means that these integers are relabelled 1, 2, ..., k in the obvious way (i.e., by subtracting start - 1).

INPUT:

- start – an integer, the starting vertex (inclusive)
- end – an integer, the ending vertex (not inclusive)

EXAMPLES:

```
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,5)]);
    → ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
```

```
sage: ip.subposet(1,3)
The Tamari interval of size 2 induced by relations [(1, 2)]
```

```
sage: ip.subposet(1,4)
The Tamari interval of size 3 induced by relations [(1, 2), (3, 2)]
```

```
sage: ip.subposet(1,5)
The Tamari interval of size 4 induced by relations [(1, 2), (4, 3), (3, 2)]
```

```
sage: ip.subposet(1,7) == ip
True
```

```
sage: ip.subposet(1,1)
The Tamari interval of size 0 induced by relations []
```

tamari_inversions()

Return the Tamari inversions of self.

A Tamari inversion is a pair of vertices (a, b) with a < b such that:

- the decreasing parent of b is strictly smaller than a (or does not exist), and
- the increasing parent of a is strictly bigger than b (or does not exist).
“Smaller” and “bigger” refer to the numerical values of the elements, not to the poset order.

This method returns the list of all Tamari inversions in lexicographic order.

The number of Tamari inversions is the length of the longest chain of the Tamari interval represented by self.

Indeed, when an interval consists of just one binary tree, it has no inversion. One can also prove that if a Tamari interval \( I' = [T'_1, T'_2] \) is a proper subset of a Tamari interval \( I = [T_1, T_2] \), then the inversion number of \( I' \) is strictly lower than the inversion number of \( I \). And finally, by adding the relation \((b, a)\) to the interval-poset where \((a, b)\) is the first inversion of \( I \) in lexicographic order, one reduces the inversion number by exactly 1.

See also:

tamari_inversions_iter(), number_of_tamari_inversions()

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(3,[])
sage: ip.tamari_inversions()
[(1, 2), (1, 3), (2, 3)]
```

```python
sage: ip = TamariIntervalPoset(3,[(2,1)])
sage: ip.tamari_inversions()
[(1, 3), (2, 3)]
```

```python
sage: ip = TamariIntervalPoset(3,[(1,2)])
sage: ip.tamari_inversions()
[(2, 3)]
```

```python
sage: ip = TamariIntervalPoset(3,[(1,2),(3,2)])
sage: ip.tamari_inversions()
[]
```

```python
sage: ip = TamariIntervalPoset(3,[(1,2),(3,2)])
sage: ip.tamari_inversions()
[(2, 3)]
```

```python
sage: ip = TamariIntervalPoset(3,[(1,2),(3,2)])
sage: ip.tamari_inversions()
[]
```

```python
sage: all(len(TamariIntervalPosets.from_binary_trees(bt,bt).tamari_inversions())==0 for bt in BinaryTrees(3))
True
```

```python
sage: all(len(TamariIntervalPosets.from_binary_trees(bt,bt).tamari_inversions())==0 for bt in BinaryTrees(4))
True
```

```
tamari_inversions_iter()
Iterate over the Tamari inversions of self, in lexicographic order.

See tamari_inversions() for the definition of the terms involved.

EXAMPLES:
```
```
sage: list(T.tamari_inversions_iter())
[(1, 2), (1, 7), (5, 6)]

sage: T = TamariIntervalPoset(1, [])

sage: list(T.tamari_inversions_iter())
[]

sage: T = TamariIntervalPoset(0, [])

sage: list(T.tamari_inversions_iter())
[]

\textbf{upper\textunderscore binary\textunderscore tree()}

Return the highest binary tree in the interval of the Tamari lattice represented by \texttt{self}.

This is a binary tree. It is the shape of the unique binary search tree whose right-branch ordered forest (i.e., the result of applying \texttt{to\_ordered\_tree\_right\_branch()} and cutting off the root) is the initial forest of \texttt{self}.

\textbf{See also:}

to\textunderscore ordered\textunderscore tree\textunderscore right\textunderscore branch()

\textbf{EXAMPLES:}

sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(4,5)]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (4, 5), (6, 5), (5, ˓→2), (4, 3), (3, 2)]

sage: ip.upper_binary_tree()
[[., .], [[., .], [[., .], [[., .], [[., .], [[., .], [[., .], [[., .], [[., .], [[., .], [[., .], [[., .], [[., .], [[., .], [[., .]]]]]]]]]]]]

sage: TamariIntervalPosets.initial_forest(ip.upper_binary_tree()) == ip.initial_˓→forest()
True

sage: ip == TamariIntervalPosets.from_binary_trees(ip.lower_binary_tree(),ip.˓→upper_binary_tree())
True

\textbf{upper\textunderscore contains\textunderscore interval(\texttt{other})}

Return whether the interval represented by \texttt{other} is contained in \texttt{self} as an interval of the Tamari lattice and if they share the same upper bound.

As interval-posets, it means that \texttt{other} contains the relations of \texttt{self} plus some extra decreasing relations.

\textbf{INPUT:}

\indent * \texttt{other} – an interval-poset

\textbf{EXAMPLES:}

sage: ip1 = TamariIntervalPoset(4,[(1,2),(2,3),(4,3)])
sage: ip2 = TamariIntervalPoset(4,[(1,2),(2,3)])
sage: ip2.upper\textunderscore contains\textunderscore interval(ip1)
True

sage: ip2.contains\textunderscore interval(ip1) and ip2.upper\textunderscore binary\textunderscore tree() == ip1.upper_˓→binary\textunderscore tree()
True

sage: ip3 = TamariIntervalPoset(4,[(1,2),(2,3),(3,4)])
upper_dyck_word()

Return the highest Dyck word in the interval of the Tamari lattice represented by self.

See also:

upper_binary_tree()

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(4,5)]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (4, 5), (6, 5), (5, ˓→2), (4, 3), (3, 2)]
sage: ip.upper_dyck_word()
[1, 0, 1, 1, 1, 0, 1, 1, 0, 0, 0, 0]
sage: TamariIntervalPosets.initial_forest(ip.upper_dyck_word()) == ip.initial_ ˓→forest()
True
sage: ip == TamariIntervalPosets.from_dyck_words(ip.lower_dyck_word(),ip.upper_ ˓→dyck_word())
True
```

class sage.combinat.interval_posets.TamariIntervalPosets

Factory for interval-posets.

INPUT:

• size – (optional) an integer

OUTPUT:

• the set of all interval-posets (of the given size if specified)

EXAMPLES:

```python
sage: TamariIntervalPosets()
Interval-posets

sage: TamariIntervalPosets(2)
Interval-posets of size 2
```

Note: This is a factory class whose constructor returns instances of subclasses.

```python
static check_poset(poset)

Check if the given poset poset is a interval-poset, that is, if it satisfies the following properties:

• Its labels are exactly 1, \ldots, n where n is its size.
```
• If $a < c$ (as numbers) and $a$ precedes $c$, then $b$ precedes $c$ for all $b$ such that $a < b < c$.
• If $a < c$ (as numbers) and $c$ precedes $a$, then $b$ precedes $a$ for all $b$ such that $a < b < c$.

INPUT:
• poset – a finite labeled poset

EXAMPLES:

```
sage: p = Poset(([1,2,3],[[1,2],[3,2]]))
sage: TamariIntervalPosets.check_poset(p)
True
sage: p = Poset(([2,3],[[3,2]]))
sage: TamariIntervalPosets.check_poset(p)
False
sage: p = Poset(([1,2,3],[[3,1]]))
sage: TamariIntervalPosets.check_poset(p)
False
sage: p = Poset(([1,2,3],[[1,3]]))
sage: TamariIntervalPosets.check_poset(p)
False
```

```
static final_forest(element)

Return the final forest of a binary tree, an interval-poset or a Dyck word.

A final forest is an interval-poset corresponding to a final interval of the Tamari lattice, i.e., containing only decreasing relations.

It can be constructed from a binary tree by its binary search tree labeling with the rule: $b$ precedes $a$ in the final forest iff $b$ is in the right subtree of $a$ in the binary search tree.

INPUT:
• element – a binary tree, a Dyck word or an interval-poset

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3),(4,3)])
sage: TamariIntervalPosets.final_forest(ip)
The Tamari interval of size 4 induced by relations [(4, 3)]
```

From binary trees:

```
sage: bt = BinaryTree(); bt
 .
sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 0 induced by relations []
sage: bt = BinaryTree([]); bt
[[], .]
sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 1 induced by relations []
sage: bt = BinaryTree([[],None]); bt
[[., .], .]
sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 2 induced by relations []
sage: bt = BinaryTree([None,[]]); bt
[[., [., .]], .]
```

(continues on next page)
Combinatorics, Release 10.0

(continued from previous page)

```
sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 2 induced by relations [(2, 1)]
sage: bt = BinaryTree([[],[]]); bt
[[., .], [., .]]
sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 3 induced by relations [(3, 2)]
sage: bt = BinaryTree([None,[[None],[None]],[]]); bt
[[., [[., .], .]], [., .]]
sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 5 induced by relations [(5, 4), (3, 1), (2, 1)]
```

From Dyck words:

```
sage: dw = DyckWord([1,0])
sage: TamariIntervalPosets.final_forest(dw)
The Tamari interval of size 1 induced by relations []
sage: dw = DyckWord([1,0,1,0,0,1,0,0,1,0,0])
sage: TamariIntervalPosets.final_forest(dw)
The Tamari interval of size 5 induced by relations [(5, 4), (3, 1), (2, 1)]
```

```
static from_binary_trees(tree1, tree2)
Return the interval-poset corresponding to the interval [tree1, tree2] of the Tamari lattice.
Raise an exception if tree1 is not ≤ tree2 in the Tamari lattice.

INPUT:

• tree1 – a binary tree

• tree2 – a binary tree greater or equal than tree1 for the Tamari lattice

EXAMPLES:

```
sage: tree1 = BinaryTree([[],None])
sage: tree2 = BinaryTree([None,[]])
sage: TamariIntervalPosets.from_binary_trees(tree1,tree2)
The Tamari interval of size 2 induced by relations []
sage: TamariIntervalPosets.from_binary_trees(tree1,tree1)
The Tamari interval of size 2 induced by relations [(1, 2)]
sage: TamariIntervalPosets.from_binary_trees(tree2,tree2)
The Tamari interval of size 2 induced by relations [(2, 1)]
sage: tree1 = BinaryTree([[],[[None],[]]])
sage: tree2 = BinaryTree([None,[None,[None],[[],[]]]])
sage: TamariIntervalPosets.from_binary_trees(tree1,tree2)
The Tamari interval of size 6 induced by relations [(4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
sage: tree3 = BinaryTree([None,[None,[[None],[]]]])
sage: TamariIntervalPosets.from_binary_trees(tree1,tree3)
Traceback (most recent call last):
...
ValueError: the two binary trees are not comparable on the Tamari lattice
```

(continues on next page)
... ValueError: the two binary trees are not comparable on the Tamari lattice

**static from_dyck_words**(\(dw1, dw2\))

Return the interval-poset corresponding to the interval \([dw1, dw2]\) of the Tamari lattice.

Raise an exception if the two Dyck words \(dw1\) and \(dw2\) do not satisfy \(dw1 \leq dw2\) in the Tamari lattice.

**INPUT:**

- \(dw1\) – a Dyck word
- \(dw2\) – a Dyck word greater or equal than \(dw1\) for the Tamari lattice

**EXAMPLES:**

```python
sage: dw1 = DyckWord([1,0,1,0])
sage: dw2 = DyckWord([1,1,0,0])
sage: TamariIntervalPosets.from_dyck_words(dw1,dw2)
The Tamari interval of size 2 induced by relations []
sage: TamariIntervalPosets.from_dyck_words(dw1,dw1)
The Tamari interval of size 2 induced by relations [(1, 2)]
sage: TamariIntervalPosets.from_dyck_words(dw2,dw2)
The Tamari interval of size 2 induced by relations [(2, 1)]
sage: dw1 = DyckWord([1,0,1,1,1,0,0,1,1,0,0,0])
sage: dw2 = DyckWord([1,1,1,1,0,1,1,0,0,0,0,0])
sage: TamariIntervalPosets.from_dyck_words(dw1,dw2)
The Tamari interval of size 6 induced by relations [(4, 5), (6, 5), (5, 2), (4, \to 3), (3, 2)]
sage: dw3 = DyckWord([1,1,0,1,1,1,0,0,0,0,0])
sage: TamariIntervalPosets.from_dyck_words(dw1,dw3)
Traceback (most recent call last):
... ValueError: the two Dyck words are not comparable on the Tamari lattice
```

**static from_grafting_tree**(\(tree\))

Return an interval-poset from a grafting tree.

For the inverse method, see `TamariIntervalPoset.grafting_tree()`.

**EXAMPLES:**

```python
sage: tip = TamariIntervalPoset(8, [(1,2), (2,4), (3,4), (6,7), (3,2), (5,4), \to (6,4), (8,7)])
sage: t = tip.grafting_tree()
sage: TamariIntervalPosets.from_grafting_tree(t) == tip
True
```

**REFERENCES:**

- [Pons2018]
static from_minimal_schnyder_wood(graph)
Return a Tamari interval built from a minimal Schnyder wood.

This is an implementation of Bernardi and Bonichon’s bijection [BeBo2009].

INPUT:

a minimal Schnyder wood, given as a graph with colored and oriented edges, without the three exterior unoriented edges

The three boundary vertices must be -1, -2 and -3.

One assumes moreover that the embedding around -1 is the list of neighbors of -1 and not just a cyclic permutation of that.

Beware that the embedding convention used here is the opposite of the one used by the plot method.

OUTPUT:

a Tamari interval-poset

EXAMPLES:

A small example:

```
sage: TIP = TamariIntervalPosets
sage: G = DiGraph([(0,-1,0),(0,-2,1),(0,-3,2)], format='list_of_edges')
sage: G.set_embedding({-1:[0],-2:[0],-3:[0],0:[-1,-2,-3]})
sage: TIP.from_minimal_schnyder_wood(G)
The Tamari interval of size 1 induced by relations []
```

An example from page 14 of [BeBo2009]:

```
sage: c0 = [(0,-1),(1,0),(2,0),(4,3),(3,-1),(5,3)]
sage: c1 = [(5,-2),(3,-2),(4,5),(1,3),(2,3),(0,3)]
sage: c2 = [(0,-3),(1,-3),(3,-3),(4,-3),(5,-3),(2,1)]
sage: ed = [(u,v,0) for u,v in c0]
sage: ed += [(u,v,1) for u,v in c1]
sage: ed += [(u,v,2) for u,v in c2]
sage: G = DiGraph(ed, format='list_of_edges')
sage: embed = {-1:[3,0],-2:[5,3],-3:[0,1,3,4,5]}
sage: data_emb = [-2,5,4,-3,1,2,0,-1]
sage: data_emb += [5,-3,3]
sage: data_emb += [-2,-3,4,3]
sage: for k in range(6):
    ....:     embed[k] = data_emb[k]
sage: G.set_embedding(embed)
sage: TIP.from_minimal_schnyder_wood(G)
The Tamari interval of size 6 induced by relations [(1, 4), (2, 4), (3, 4), (5, ˓→6), (6, 4), (5, 4), (3, 1), (2, 1)]
```

An example from page 18 of [BeBo2009]:

```
sage: c0 = [(0,-1),(1,0),(2,-1),(3,2),(4,2),(5,-1)]
sage: c1 = [(5,-2),(2,-2),(4,-2),(3,4),(1,2),(0,2)]
sage: c2 = [(0,-3),(1,-3),(3,-3),(4,-3),(2,-3),(5,2)]
sage: ed = [(u,v,0) for u,v in c0]
sage: ed += [(u,v,1) for u,v in c1]
sage: ed += [(u,v,2) for u,v in c2]
(continues on next page)
Combinatorics, Release 10.0

sage: G = DiGraph(ed, format='list_of_edges')
sage: embed = {-1:[5,2,0],-2:[4,2,5],-3:[0,1,2,3,4]}
sage: data_emb = [[2,1,-3,-1],[2,-3,0],[3,-3,1,0,-1,5,-2,4]]
sage: data_emb += [[4,-3,2],[-2,-3,2],[-2,2,-1]]
sage: for k in range(6):
    ....:     embed[k] = data_emb[k]
sage: G.set_embedding(embed)
sage: TIP.from_minimal_schnyder_wood(G)
The Tamari interval of size 6 induced by relations [(1, 3), (2, 3), (4, 5), (5, \rightarrow 3), (4, 3), (2, 1)]

Another small example:

sage: c0 = [(0,-1),(2,-1),(1,0)]
sage: c1 = [(2,-2),(1,-2),(0,2)]
sage: c2 = [(0,-3),(1,-3),(2,1)]
sage: ed = [(u,v,0) for u,v in c0]

sage: for k in range(3):
    ....:     embed[k] = data_emb[k]
sage: G.set_embedding(embed)
sage: TIP.from_minimal_schnyder_wood(G)
The Tamari interval of size 3 induced by relations [(2, 3), (2, 1)]

static initial_forest(element)

Return the initial forest of a binary tree, an interval-poset or a Dyck word.

An initial forest is an interval-poset corresponding to an initial interval of the Tamari lattice, i.e., containing only increasing relations.

It can be constructed from a binary tree by its binary search tree labeling with the rule: \( a \) precedes \( b \) in the initial forest iff \( a \) is in the left subtree of \( b \) in the binary search tree.

INPUT:

- element -- a binary tree, a Dyck word or an interval-poset

EXAMPLES:

sage: ip = TamariIntervalPoset(4,[(1,2),(2,3),(4,3)])
sage: TamariIntervalPosets.initial_forest(ip)
The Tamari interval of size 4 induced by relations [(1, 2), (2, 3)]

with binary trees:

sage: bt = BinaryTree(); bt
sage: TamariIntervalPosets.initial_forest(bt)
The Tamari interval of size 0 induced by relations []
sage: bt = BinaryTree([]); bt
[., .]
The Tamari interval of size 1 induced by relations []

```sage```
```
bt = BinaryTree([[], None]); bt
[[., .], .]
```
```sage```
```
TamariIntervalPosets.initial_forest(bt)
The Tamari interval of size 2 induced by relations [(1, 2)]
```
```sage```
```
b = BinaryTree([None, []]); btt
[., [., .]]
```
```sage```
```
TamariIntervalPosets.initial_forest(bt)
The Tamari interval of size 2 induced by relations []
```
```sage```
```
b = BinaryTree([[], []]); btt
[[., .], [., .]]
```
```sage```
```
TamariIntervalPosets.initial_forest(bt)
The Tamari interval of size 2 induced by relations [(1, 2)]
```
```sage```
```
bt = BinaryTree([[None, [[], None]], []]); bt
[[., [., .]], [., .], [., .]]
```
```sage```
```
TamariIntervalPosets.initial_forest(bt)
The Tamari interval of size 5 induced by relations [(1, 4), (2, 3), (3, 4)]
```
```sage```
```
dw = DyckWord([1, 0])
```
```sage```
```
TamariIntervalPosets.initial_forest(dw)
The Tamari interval of size 1 induced by relations []
```
```sage```
```
dw = DyckWord([1, 1, 0, 1, 0, 0, 1, 1, 0, 0])
```
```sage```
```
TamariIntervalPosets.initial_forest(dw)
The Tamari interval of size 5 induced by relations [(1, 4), (2, 3), (3, 4)]
```
```sage```
```
de1, de2
```
```sage```
```
le(el1, el2)
Poset structure on the set of interval-posets.
```
The comparison is first by size, then using the cubical coordinates.
```
See also:
```
cubical_coordinates()
```
```
INPUT:
```
• el1 -- an interval-poset
• el2 -- an interval-poset
```
```
EXAMPLES:
```
```sage```
```
ip1 = TamariIntervalPoset(4, [(1, 2), (2, 3), (4, 3)])
```
```sage```
```
ip2 = TamariIntervalPoset(4, [(1, 2), (2, 3)])
```
```sage```
```
TamariIntervalPosets().le(ip1, ip2)
False
```
```sage```
```
TamariIntervalPosets().le(ip2, ip1)
True

static recomposition_from_triple(\(left, right, r\))

Recompose an interval-poset from a triple \((left, right, r)\).

For the inverse method, see \(TamariIntervalPoset.decomposition_to_triple()\).

INPUT:
- \(left\) – an interval-poset
- \(right\) – an interval-poset
- \(r\) – the parameter of the decomposition, an integer

OUTPUT: an interval-poset

EXAMPLES:

```
sage: T1 = TamariIntervalPoset(3, [(1, 2), (3, 2)])
sage: T2 = TamariIntervalPoset(4, [(2, 3), (4, 3)])
sage: TamariIntervalPosets.recomposition_from_triple(T1, T2, 2)
The Tamari interval of size 8 induced by relations [(1, 2), (2, 4), (3, 4), (6, 7), (8, 7), (6, 4), (5, 4), (3, 2)]
```

REFERENCES:
- [Pons2018]

class sage.combinat.interval_posets.TamariIntervalPosets_all

Bases: DisjointUnionEnumeratedSets, TamariIntervalPosets

The enumerated set of all Tamari interval-posets.

Element

alias of TamariIntervalPoset

one()

Return the unit of the monoid.

This is the empty interval poset, of size 0.

EXAMPLES:

```
sage: TamariIntervalPosets().one()
The Tamari interval of size 0 induced by relations []
```

class sage.combinat.interval_posets.TamariIntervalPosets_size(size)

Bases: TamariIntervalPosets

The enumerated set of interval-posets of a given size.

cardinality()

The cardinality of self. That is, the number of interval-posets of size \(n\).

The formula was given in [Cha2008]:

\[
\frac{2(4n+1)!}{(n+1)!(3n+2)!} = \frac{2}{n(n+1)} \binom{4n+1}{n-1}.
\]

EXAMPLES:

```
sage: [TamariIntervalPosets(i).cardinality() for i in range(6)]
[1, 1, 3, 13, 68, 399]
```
**element_class()**

**random_element()**

Return a random Tamari interval of fixed size.

This is obtained by first creating a random rooted planar triangulation, then computing its unique minimal Schnyder wood, then applying a bijection of Bernardi and Bonichon [BeBo2009].

Because the random rooted planar triangulation is chosen uniformly at random, the Tamari interval is also chosen according to the uniform distribution.

**EXAMPLES:**

```python
sage: T = TamariIntervalPosets(4).random_element()
sage: T.parent()
Interval-posets
sage: u = T.lower_dyck_word(); u  # random
[1, 1, 0, 1, 0, 0, 1, 0]
sage: v = T.lower_dyck_word(); v  # random
[1, 1, 0, 1, 0, 0, 1, 0]
sage: len(u)
8
```

### 5.1.1.29 $k$-regular Sequences

An introduction and formal definition of $k$-regular sequences can be found, for example, on the Wikipedia article *k-regular_sequence* or in [AS2003].

**Warning:** As this code is experimental, warnings are thrown when a $k$-regular sequence space is created for the first time in a session (see `sage.misc.superseded.experimental`).

#### Examples

**Binary sum of digits**

The binary sum of digits $S(n)$ of a nonnegative integer $n$ satisfies $S(2n) = S(n)$ and $S(2n + 1) = S(n) + 1$. We model this by the following:

```python
sage: Seq2 = kRegularSequenceSpace(2, ZZ)
sage: S = Seq2((Matrix([[1, 0], [0, 1]]), Matrix([[1, 0], [1, 1]])),
            ....:     left=vector([0, 1]), right=vector([1, 0]))
sage: S
2-regular sequence 0, 1, 1, 2, 1, 2, 2, 3, 1, 2, ...
sage: all(S[n] == sum(n.digits(2)) for n in srange(10))
True
```
Number of odd entries in Pascal’s triangle

Let us consider the number of odd entries in the first $n$ rows of Pascal's triangle:

```
sage: @cached_function
....: def u(n):
....:     if n <= 1:
....:         return n
....:     return 2 * u(n // 2) + u((n+1) // 2)
sage: tuple(u(n) for n in srange(10))
(0, 1, 3, 5, 9, 11, 15, 19, 27, 29)
```

There is a 2-recursive sequence describing the numbers above as well:

```
sage: U = Seq2((Matrix([[3, 2], [0, 1]]), Matrix([[2, 0], [1, 3]])),
....:         left=vector([0, 1]), right=vector([1, 0])).transposed()
sage: all(U[n] == u(n) for n in srange(30))
True
```

Classes and Methods

class sage.combinat.k_regular_sequence.RecurrenceParser($k$, coefficient_ring)

Bases: object

A parser for recurrence relations that allow the construction of a $k$-linear representation for the sequence satisfying these recurrence relations.

This is used by kRegularSequenceSpace.from_recurrence() to construct a kRegularSequence.

ind($M$, $m$, $ll$, $uu$)

Determine the index operator corresponding to the recursive sequence as defined in [HKL2021].

INPUT:

• $M$, $m$ – parameters of the recursive sequences, see [HKL2021], Definition 3.1
• $ll$, $uu$ – parameters of the resulting linear representation, see [HKL2021], Theorem A

OUTPUT:

A dictionary which maps both row numbers to subsequence parameters and vice versa, i.e.,
• \(\text{ind}[i]\) – a pair \((j, d)\) representing the sequence \(x(k^j n + d)\) in the \(i\)-th component (0-based) of the resulting linear representation,

• \(\text{ind}[(j, d)]\) – the (0-based) row number of the sequence \(x(k^j n + d)\) in the linear representation.

EXAMPLES:

```python
sage: from sage.combinat.k_regular_sequence import RecurrenceParser
sage: RP = RecurrenceParser(2, ZZ)
sage: RP.ind(3, 1, -3, 3)
{(0, 0): 0, (1, -1): 3, (1, -2): 2, (1, -3): 1,
 (1, 0): 4, (1, 1): 5, (1, 2): 6, (1, 3): 7, (2, -1): 10,
 (2, -2): 9, (2, -3): 8, (2, 0): 11, (2, 1): 12, (2, 2): 13,
 (2, 3): 14, (2, 4): 15, (2, 5): 16, 0: (0, 0), 1: (1, -3),
 10: (2, -1), 11: (2, 0), 12: (2, 1), 13: (2, 2), 14: (2, 3),
 15: (2, 4), 16: (2, 5), 2: (1, -2), 3: (1, -1), 4: (1, 0),
 5: (1, 1), 6: (1, 2), 7: (1, 3), 8: (2, -3), 9: (2, -2)}
```

See also:

`kRegularSequenceSpace.from_recurrence()`

\(\text{left}(\text{recurrence rules})\)

Construct the vector \(\text{left}\) of the linear representation of recursive sequences.

INPUT:

• recurrence_rules – a namedtuple generated by `parameters()`: it only needs to contain a field \(\text{dim}\) (a positive integer)

OUTPUT: a vector

EXAMPLES:

```python
sage: from collections import namedtuple
sage: from sage.combinat.k_regular_sequence import RecurrenceParser
sage: RP = RecurrenceParser(2, ZZ)
sage: RRD = namedtuple('recurrence_rules_dim', 'dim', 'inhomogeneities')
sage: recurrence_rules = RRD(dim=5, inhomogeneities={})
sage: RP.left(recurrence_rules)
(1, 0, 0, 0, 0)
```

```python
sage: Seq2 = kRegularSequenceSpace(2, ZZ)
sage: RRD = namedtuple('recurrence_rules_dim', 'M', 'm', 'll', 'uu', 'dim', 'inhomogeneities')
sage: recurrence_rules = RRD(M=3, m=2, ll=0, uu=9, dim=5,
.....: inhomogeneities={0: Seq2.one_hadamard()})
sage: RP.left(recurrence_rules)
(1, 0, 0, 0, 0, 0, 0, 0)
```

See also:

`kRegularSequenceSpace.from_recurrence()`

\(\text{matrix}(\text{recurrence rules}, \text{rem}, \text{correct_offset=True})\)

Construct the matrix for remainder \(\text{rem}\) of the linear representation of the sequence represented by recurrence_rules.
INPUT:

• **recurrence_rules** – a namedtuple generated by `parameters()`
• **rem** – an integer between 0 and \( k - 1 \)
• **correct_offset** – (default: True) a boolean. If True, then the resulting linear representation has no offset. See [HKL2021] for more information.

OUTPUT: a matrix

EXAMPLES:

The following example illustrates how the coefficients in the right-hand sides of the recurrence relations correspond to the entries of the matrices.

```python
from sage.combinat.k_regular_sequence import RecurrenceParser
sage: RP = RecurrenceParser(2, ZZ)

sage: var('n')
n
sage: function('f')
f

sage: M, m, coeffs, initial_values = RP.parse_recurrence([  
...:     f(8*n) == -1*f(2*n - 1) + 1*f(2*n + 1),
...:     f(8*n + 1) == -11*f(2*n - 1) + 10*f(2*n) + 11*f(2*n + 1),
...:     f(8*n + 2) == -21*f(2*n - 1) + 20*f(2*n) + 21*f(2*n + 1),
...:     f(8*n + 3) == -31*f(2*n - 1) + 30*f(2*n) + 31*f(2*n + 1),
...:     f(8*n + 4) == -41*f(2*n - 1) + 40*f(2*n) + 41*f(2*n + 1),
...:     f(8*n + 5) == -51*f(2*n - 1) + 50*f(2*n) + 51*f(2*n + 1),
...:     f(8*n + 6) == -61*f(2*n - 1) + 60*f(2*n) + 61*f(2*n + 1),
...:     f(8*n + 7) == -71*f(2*n - 1) + 70*f(2*n) + 71*f(2*n + 1),
...:     f(0) == 0, f(1) == 1, f(2) == 2, f(3) == 3, f(4) == 4,
...:     f(5) == 5, f(6) == 6, f(7) == 7], f, n)

sage: rules = RP.parameters(
...:     M, m, coeffs, initial_values, 0)

sage: RP.matrix(rules, 0, False)

```

(continues on next page)
Stern–Brocot Sequence:

```
sage: SB_rules = RP.parameters(
    ....:    1, 0, {(0, 0): 1, (1, 0): 1, (1, 1): 1},
    ....:    {0: 0, 1: 1, 2: 1}, 0)
sage: RP.matrix(SB_rules, 0)

[1 0 0]
[1 1 0]
[0 1 0]
sage: RP.matrix(SB_rules, 1)

[1 1 0]
[0 1 0]
[0 1 1]
```

Number of Unbordered Factors in the Thue–Morse Sequence:

```
sage: M, m, coeffs, initial_values = RP.parse_recurrence([f(8*n) == 2*f(4*n),
    ....:    f(8*n + 1) == f(4*n + 1),
    ....:    f(8*n + 2) == f(4*n + 1) + f(4*n + 3),
    ....:    f(8*n + 3) == -f(4*n + 1) + f(4*n + 2),
    ....:    f(8*n + 4) == 2*f(4*n + 2),
    ....:    f(8*n + 5) == f(4*n + 3),
    ....:    f(8*n + 6) == -f(4*n + 1) + f(4*n + 2) + f(4*n + 3),
    ....:    f(8*n + 7) == 2*f(4*n + 1) + f(4*n + 3),
    ....:    f(9) == 1, f(1) == 2, f(2) == 2, f(3) == 4, f(4) == 2,
    ....:    f(5) == 4, f(6) == 6, f(7) == 0, f(8) == 4, f(9) == 4,
    ....:    f(10) == 4, f(11) == 4, f(12) == 12, f(13) == 0, f(14) == 4,
    ....:    f(15) == 4, f(16) == 8, f(17) == 4, f(18) == 8, f(19) == 0,
    ....:    f(20) == 8, f(21) == 4, f(22) == 4, f(23) == 8], f, n)
sage: UB_rules = RP.parameters(
    ....:    M, m, coeffs, initial_values, 3)
sage: RP.matrix(UB_rules, 0)

[ 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
[ 0 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0]
[ 0 0 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0]```

(continues on next page)
See also:

\texttt{kRegularSequenceSpace.from_recurrence()}

\texttt{parameters(}\texttt{M, m, coeffs, initial_values, offset=0, inhomogeneities={})}

Determine parameters from recurrence relations as admissible in \texttt{kRegularSequenceSpace.from_recurrence()}. 

**INPUT:**

All parameters are explained in the high-level method \texttt{kRegularSequenceSpace.from_recurrence()}. 

**OUTPUT:** a namedtuple \texttt{recurrence_rules} consisting of

- M, m, l, u, offset – parameters of the recursive sequences, see [HKL2021], Definition 3.1
- l1, uu, n1, dim – parameters and dimension of the resulting linear representation, see [HKL2021], Theorem A
- coeffs – a dictionary mapping (r, j) to the coefficients \(c_{r,j}\) as given in [HKL2021], Equation (3.1). If coeffs[(r, j)] is not given for some r and j, then it is assumed to be zero.
- initial_values – a dictionary mapping integers n to the n-th value of the sequence
- inhomogeneities – a dictionary mapping integers r to the inhomogeneity \(g_r\) as given in [HKL2021], Corollary D.
EXAMPLES:

```
sage: from sage.combinat.k_regular_sequence import RecurrenceParser
g sage: RP = RecurrenceParser(2, ZZ)
sage: RP.parameters(2, 1,
  ....:   {(-2): 3, (0, 0): 1, (0, 1): 2, (1, -2): 6, (1, 0): 4,
  ....:    (1, 1): 5, (2, -2): 9, (2, 0): 7, (2, 1): 8, (3, -2): 12,
  ....:    (3, 0): 10, (3, 1): 11}, {0: 1, 1: 2, 2: 1, 3: 4}, 0, {0: 1})
  recurrence_rules(M=2, m=1, l=-2, u=1, lL=-6, uu=3, dim=14,
  coeffs={(0, -2): 3, (0, 0): 1, (0, 1): 2, (1, -2): 6, (1, 0): 4,
  (1, 1): 5, (2, -2): 9, (2, 0): 7, (2, 1): 8, (3, -2): 12,
  (3, 0): 10, (3, 1): 11}, initial_values={0: 1, 1: 2, 2: 1},
  offset=1, n1=3, inhomogeneities={0: 2-regular sequence 1, 1, 1, 1,
  1, 1, 1, 1, ...})
```

See also:

```
  kRegularSequenceSpace.from_recurrence()
```

`parse_direct_arguments(M, m, coeffs, initial_values)`

Check whether the direct arguments as admissible in `kRegularSequenceSpace.from_recurrence()` are valid.

INPUT:

All parameters are explained in the high-level method `kRegularSequenceSpace.from_recurrence()`.

OUTPUT: a tuple consisting of the input parameters

EXAMPLES:

```
sage: from sage.combinat.k_regular_sequence import RecurrenceParser
g sage: RP = RecurrenceParser(2, ZZ)
sage: RP.parse_direct_arguments(2, 1,
  ....:   {(-2): 3, (0, 0): 1, (0, 1): 2,
  ....:    (1, -2): 6, (1, 0): 4, (1, 1): 5,
  ....:    (2, -2): 9, (2, 0): 7, (2, 1): 8,
  ....:    (3, -2): 12, (3, 0): 10, (3, 1): 11},
  ....:   {0: 1, 1: 2, 2: 1})
(2, 1, {(0, -2): 3, (0, 0): 1, (0, 1): 2,
(1, -2): 6, (1, 0): 4, (1, 1): 5,
(2, -2): 9, (2, 0): 7, (2, 1): 8,
(3, -2): 12, (3, 0): 10, (3, 1): 11},
{0: 1, 1: 2, 2: 1})
```

Stern–Brocot Sequence:

```
sage: RP.parse_direct_arguments(1, 0,
  ....:   {(-2): 3, (0, 0): 1, (0, 1): 2,
  ....:    (1, -2): 6, (1, 0): 4, (1, 1): 5,
  ....:    (2, -2): 9, (2, 0): 7, (2, 1): 8,
  ....:    (3, -2): 12, (3, 0): 10, (3, 1): 11},
  {0: 1, 1: 2, 2: 1})
```

See also:

```
  kRegularSequenceSpace.from_recurrence()
```
parse_recurrence(equations, function, var)

Parse recurrence relations as admissible in kRegularSequenceSpace.from_recurrence().

INPUT:

All parameters are explained in the high-level method kRegularSequenceSpace.from_recurrence().

OUTPUT: a tuple consisting of

• M, m – see kRegularSequenceSpace.from_recurrence()
• coeffs – see kRegularSequenceSpace.from_recurrence()
• initial_values – see kRegularSequenceSpace.from_recurrence()

EXAMPLES:

sage: from sage.combinat.k_regular_sequence import RecurrenceParser
sage: RP = RecurrenceParser(2, ZZ)
sage: var('n')
n
sage: function('f')
f
sage: RP.parse_recurrence([....: f(4*n) == f(2*n) + 2*f(2*n + 1) + 3*f(2*n - 2),
....: f(4*n + 1) == 4*f(2*n) + 5*f(2*n + 1) + 6*f(2*n - 2),
....: f(4*n + 2) == 7*f(2*n) + 8*f(2*n + 1) + 9*f(2*n - 2),
....: f(4*n + 3) == 10*f(2*n) + 11*f(2*n + 1) + 12*f(2*n - 2),
....: f(0) == 1, f(1) == 2, f(2) == 1], f, n)

Stern–Brocot Sequence:

sage: RP.parse_recurrence([....: f(2*n) == f(n), f(2*n + 1) == f(n) + f(n + 1),
....: f(0) == 0, f(1) == 1], f, n)
(1, 0, {(0, 0): 1, (1, 0): 1, (1, 1): 1}, {0: 0, 1: 1})

See also:

kRegularSequenceSpace.from_recurrence()

right(recurrence_rules)

Construct the vector right of the linear representation of the sequence induced by recurrence_rules.

INPUT:

• recurrence_rules – a namedtuple generated by parameters()

OUTPUT: a vector

See also:

kRegularSequenceSpace.from_recurrence()

shifted_inhomogeneities(recurrence_rules)

Return a dictionary of all needed shifted inhomogeneities as described in the proof of Corollary D in [HKL2021].

INPUT:
• recurrence_rules – a namedtuple generated by `parameters()`

OUTPUT:

A dictionary mapping \( r \) to the regular sequence \( \sum_{i} g_r(n+i) \) for \( g_r \) as given in [HKL2021], Corollary D, and \( i \) between \( \lfloor \frac{\ell}{k^M} \rfloor \) and \( \lfloor (k^M-1-k^m+u')/k^M \rfloor + 1 \); see [HKL2021], proof of Corollary D. The first blocks of the corresponding vector-valued sequence (obtained from its linear representation) correspond to the sequences \( g_r(n+i) \) where \( i \) is as in the sum above; the remaining blocks consist of other shifts which are required for the regular sequence.

EXAMPLES:

```python
sage: from collections import namedtuple
sage: from sage.combinat.k_regular_sequence import RecurrenceParser
sage: RP = RecurrenceParser(2, ZZ)
```

```python
sage: Seq2 = kRegularSequenceSpace(2, ZZ)
```

```python
sage: S = Seq2((Matrix([[1, 0], [0, 1]]), Matrix([[1, 0], [1, 1]])), ....: left=vector([0, 1]), right=vector([1, 0]))
```

```python
sage: S 2-regular sequence 0, 1, 1, 2, 1, 2, 2, 3, 1, 2, ...
```

```python
sage: RR = namedtuple('recurrence_rules', ....: [M, m, ll, uu, 'inhomogeneities'])
```

```python
sage: recurrence_rules = RR(M=3, m=0, ll=-14, uu=14, ....: inhomogeneities={0: S, 1: S})
```

```python
sage: SI = RP.shifted_inhomogeneities(recurrence_rules)
```

```python
sage: SI {0: 2-regular sequence 4, 5, 7, 9, 11, 11, 11, 12, 13, 13, ..., 1: 2-regular sequence 4, 5, 7, 9, 11, 11, 11, 12, 13, 13, ...}
```

The first blocks of the corresponding vector-valued sequence correspond to the corresponding shifts of the inhomogeneity. In this particular case, there are no other blocks:

```python
sage: lower = -2
sage: upper = 3
sage: SI[0].dimension() == S.dimension() * (upper - lower + 1)
True
```

```python
sage: all( ....: Seq2( ....: SI[0].mu, ....: vector((i - lower)*[0, 0] + list(S.left) + (upper - i)*[0, 0]), ....: SI[0].right) ....: == S.subsequence(1, i) ....: for i in range(lower, upper+1))
True
```

See also:

`kRegularSequenceSpace.from_recurrence()`

`v_eval_n(recurrence_rules, n)`

Return the vector \( v(n) \) as given in [HKL2021], Theorem A.

INPUT:

• recurrence_rules – a namedtuple generated by `parameters()`

• n – an integer
OUTPUT: a vector

EXAMPLES:

Stern–Brocot Sequence:

```python
sage: from sage.combinat.k_regular_sequence import RecurrenceParser
sage: RP = RecurrenceParser(2, ZZ)
sage: SB_rules = RP.parameters(
    ....: 1, 0, {(0, 0): 1, (1, 0): 1, (1, 1): 1},
    ....: {0: 0, 1: 1, 2: 1}, 0)
sage: RP.v_eval_n(SB_rules, 0)
(0, 1, 1)
```

See also:

```
kRegularSequenceSpace.from_recurrence()
```

values($M, m, l, u, ll, coeffs, initial_values, last_value_needed, offset, inhomogeneities$)

Determine enough values of the corresponding recursive sequence by applying the recurrence relations given in $kRegularSequenceSpace.from_recurrence()$ to the values given in initial_values.

INPUT:

- $M, m, l, u, offset$ – parameters of the recursive sequences, see [HKL2021], Definition 3.1
- $ll$ – parameter of the resulting linear representation, see [HKL2021], Theorem A
- $coeffs$ – a dictionary where $coeffs[(r, j)]$ is the coefficient $c_{r,j}$ as given in $kRegularSequenceSpace.from_recurrence()$. If $coeffs[(r, j)]$ is not given for some $r$ and $j$, then it is assumed to be zero.
- $initial_values$ – a dictionary mapping integers $n$ to the $n$-th value of the sequence
- $last_value_needed$ – last initial value which is needed to determine the linear representation
- $inhomogeneities$ – a dictionary mapping integers $r$ to the inhomogeneity $g_r$ as given in [HKL2021], Corollary D.

OUTPUT:

A dictionary mapping integers $n$ to the $n$-th value of the sequence for all $n$ up to last_value_needed.

EXAMPLES:

Stern–Brocot Sequence:

```python
sage: from sage.combinat.k_regular_sequence import RecurrenceParser
sage: RP = RecurrenceParser(2, ZZ)
sage: RP.values(M=1, m=0, l=0, u=1, ll=0,
    ....: coeffs={(0, 0): 1, (1, 0): 1, (1, 1): 1},
    ....: initial_values={0: 0, 1: 1, 2: 1}, last_value_needed=20,
    ....: offset=0, inhomogeneities={})
{0: 0, 1: 1, 2: 1, 3: 2, 4: 1, 5: 3, 6: 2, 7: 3, 8: 1, 9: 4, 10: 3, 11: 5, 12: 2, 13: 5, 14: 3, 15: 4, 16: 1, 17: 5, 18: 4, 19: 7, 20: 3}
```

See also:

```
kRegularSequenceSpace.from_recurrence()
```
class sage.combinat.k_regular_sequence.kRegularSequence(parent, mu, left=None, right=None)

Bases: RecognizableSeries

A \(k\)-regular sequence.

INPUT:

- **parent** – an instance of \(k\)RegularSequenceSpace
- **mu** – a family of square matrices, all of which have the same dimension. The indices of this family are 0, ..., \(k - 1\). \(mu\) may be a list or tuple of cardinality \(k\) as well. See also \(mu()\).
- **left** – (default: None) a vector. When evaluating the sequence, this vector is multiplied from the left to the matrix product. If None, then this multiplication is skipped.
- **right** – (default: None) a vector. When evaluating the sequence, this vector is multiplied from the right to the matrix product. If None, then this multiplication is skipped.

EXAMPLES:

sage: Seq2 = kRegularSequenceSpace(2, ZZ)
sage: S = Seq2((Matrix([[3, 6], [0, 1]]), Matrix([[0, -6], [1, 5]])),
                      vector([0, 1]), vector([1, 0])).transposed(); S

2-regular sequence 0, 1, 3, 5, 9, 11, 15, 19, 27, 29, ...

We can access the coefficients of a sequence by

sage: S[5]
11

or iterating over the first, say 10, by

sage: from itertools import islice
sage: list(islice(S, 10))
[0, 1, 3, 5, 9, 11, 15, 19, 27, 29]

See also:

\(k\)-regular sequence, \(k\)RegularSequenceSpace.

backward_differences(**kwds)

Return the sequence of backward differences of this \(k\)-regular sequence.

INPUT:

- **minimize** – (default: None) a boolean or None. If True, then \(minimized()\) is called after the operation, if False, then not. If this argument is None, then the default specified by the parent’s minimize_results is used.

OUTPUT:

A kRegularSequence

Note: The coefficient to the index \(-1\) is \(0\).

EXAMPLES:
Combinatorics, Release 10.0

```
sage: Seq2 = kRegularSequenceSpace(2, ZZ)
sage: C = Seq2((Matrix([[2, 0], [2, 1]]), Matrix([[0, 1], [-2, 3]])),
                ....: vector([1, 0]), vector([0, 1]))
sage: C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
sage: C.backward_differences()
2-regular sequence 0, 1, 1, 1, 1, 1, 1, 1, 1, 1, ...

sage: E = Seq2((Matrix([[0, 1], [0, 1]]), Matrix([[0, 0], [0, 1]])),
                ....: vector([1, 0]), vector([1, 1]))
sage: E
2-regular sequence 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, ...
sage: E.backward_differences()
2-regular sequence -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, ...
```

**forward_differences(**kwds**)

Return the sequence of forward differences of this $k$-regular sequence.

**INPUT:**

- `minimize` – (default: None) a boolean or None. If True, then `minimized()` is called after the operation, if False, then not. If this argument is None, then the default specified by the parent's `minimize_results` is used.

**OUTPUT:**

A `kRegularSequence`

**EXAMPLES:**

```
sage: Seq2 = kRegularSequenceSpace(2, ZZ)
sage: C = Seq2((Matrix([[2, 0], [2, 1]]), Matrix([[0, 1], [-2, 3]])),
                ....: vector([1, 0]), vector([0, 1]))
sage: C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
sage: C.forward_differences()
2-regular sequence 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, ...

sage: E = Seq2((Matrix([[0, 1], [0, 1]]), Matrix([[0, 0], [0, 1]])),
                ....: vector([1, 0]), vector([1, 1]))
sage: E
2-regular sequence 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, ...
sage: E.forward_differences()
2-regular sequence -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, ...
```

**partial_sums(**args, **kwds**)

Return the sequence of partial sums of this $k$-regular sequence. That is, the $n$’th entry of the result is the sum of the first $n$ entries in the original sequence.

**INPUT:**

- `include_n` – (default: False) a boolean. If set, then the $n$-th entry of the result is the sum of the entries up to index $n$ (included).
- `minimize` – (default: None) a boolean or None. If True, then `minimized()` is called after the operation, if False, then not. If this argument is None, then the default specified by the parent’s `minimize_results` is used.
OUTPUT:

A $k$-RegularSequence

EXAMPLES:

```python
sage: Seq2 = kRegularSequenceSpace(2, ZZ)
sage: E = Seq2((Matrix([[0, 1], [0, 1]]), Matrix([[0, 0], [0, 1]])),
...:     vector([1, 0]), vector([1, 1]))
sage: E
2-regular sequence 1, 0, 1, 0, 1, 0, 1, 0, ...
sage: E.partial_sums()
2-regular sequence 0, 1, 1, 2, 2, 3, 3, 4, 4, ...
sage: E.partial_sums(include_n=True)
2-regular sequence 1, 1, 2, 2, 3, 3, 4, 4, 5, ...
```

```python
sage: C = Seq2((Matrix([[2, 0], [2, 1]]), Matrix([[0, 1], [-2, 3]])),
...:     vector([1, 0]), vector([0, 1])); C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
sage: C.partial_sums()
2-regular sequence 0, 0, 1, 3, 6, 10, 15, 21, 28, 36, ...
sage: C.partial_sums(include_n=True)
2-regular sequence 0, 1, 3, 6, 10, 15, 21, 28, 36, 45, ...
```

**shift_left**($b=1, \text{**kwds}}$

Return the sequence obtained by shifting this $k$-regular sequence $b$ steps to the left.

INPUT:

- $b$ – an integer
- minimize – (default: None) a boolean or None. If True, then `minimized()` is called after the operation, if False, then not. If this argument is None, then the default specified by the parent's `minimize_results` is used.

OUTPUT:

A $k$-RegularSequence

Note: If $b$ is negative (i.e., actually a right-shift), then the coefficients when accessing negative indices are 0.

EXAMPLES:

```python
sage: C = Seq2((Matrix([[2, 0], [2, 1]]), Matrix([[0, 1], [-2, 3]])),
...:     vector([1, 0]), vector([0, 1])); C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
sage: C.shift_left()
2-regular sequence 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, ...
sage: C.shift_left(3)
2-regular sequence 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, ...
```

(continues on next page)
\textbf{shift_right}(b=1,**kwds)

Return the sequence obtained by shifting this $k$-regular sequence $b$ steps to the right.

\begin{itemize}
  \item $b$ – an integer
  \item minimize – (default: None) a boolean or None. If True, then \texttt{minimized()} is called after the operation, if False, then not. If this argument is None, then the default specified by the parent’s \texttt{minimize_results} is used.
\end{itemize}

\textbf{OUTPUT:}

A \texttt{kRegularSequence}

\textbf{Note:} If $b$ is positive (i.e., indeed a right-shift), then the coefficients when accessing negative indices are 0.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Seq2 = kRegularSequenceSpace(2, ZZ)
sage: C = Seq2((Matrix([[2, 0], [0, 1]]), Matrix([[2, 1], [0, 1]])), ....:     vector([1, 0]), vector([0, 1])); C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
sage: C.shift_right()
2-regular sequence 0, 0, 1, 2, 3, 4, 5, 6, 7, 8, ...
sage: C.shift_right(3)
2-regular sequence 0, 0, 0, 1, 2, 3, 4, 5, 6, ...
sage: C.shift_right(-2)
2-regular sequence 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, ...
\end{verbatim}

\textbf{subsequence}(*args,**kwds)

Return the subsequence with indices $an + b$ of this $k$-regular sequence.

\begin{itemize}
  \item $a$ – a nonnegative integer
  \item $b$ – an integer
  
  Alternatively, this is allowed to be a dictionary $b_j \mapsto c_j$. If so and applied on $f(n)$, the result will be the sum of all $c_j \cdot f(an + bj)$.
  
  minimize – (default: None) a boolean or None. If True, then \texttt{minimized()} is called after the operation, if False, then not. If this argument is None, then the default specified by the parent’s \texttt{minimize_results} is used.
\end{itemize}

\textbf{OUTPUT:}

A \texttt{kRegularSequence}

\textbf{Note:} If $b$ is negative (i.e., right-shift), then the coefficients when accessing negative indices are 0.
EXAMPLES:

```
sage: Seq2 = kRegularSequenceSpace(2, ZZ)
```

We consider the sequence $C$ with $C(n) = n$ and the following linear representation corresponding to the vector $(n, 1)$:

```
sage: C = Seq2((Matrix([[2, 0], [0, 1]]), Matrix([[2, 1], [0, 1]])),
....:    vector([1, 0]), vector([0, 1])); C
```

2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...

We now extract various subsequences of $C$:

```
sage: C.subsequence(2, 0)
2-regular sequence 0, 2, 4, 6, 8, 10, 12, 14, 16, 18, ...

sage: S31 = C.subsequence(3, 1); S31
2-regular sequence 1, 4, 7, 10, 13, 16, 19, 22, 25, 28, ...

sage: S31.linear_representation()
((1, 0),
 Finie family {0: [ 0 1]
     [-2 3],
     1: [ 6 -2]
     [10 -3]},
 (1, 1))

sage: C.subsequence(3, 2)
2-regular sequence 2, 5, 8, 11, 14, 17, 20, 23, 26, 29, ...

sage: Srs = C.subsequence(1, -1); Srs
2-regular sequence 0, 0, 1, 2, 3, 4, 5, 6, 7, 8, ...

sage: Srs.linear_representation()
((1, 0, 0),
 Finie family {0: [ 0 1 0]
     [-2 3 0]
     [-4 4 1],
     1: [ -2 2 0]
     [ 0 0 1]
     [12 -12 5]},
 (0, 0, 1))
```

We can build `backward_differences()` manually by passing a dictionary for the parameter $b$:

```
sage: Sbd = C.subsequence(1, {0: 1, -1: -1}); Sbd
2-regular sequence 0, 1, 1, 1, 1, 1, 1, 1, 1, 1, ...
```

```
class sage.combinat.k_regular_sequence.kRegularSequenceSpace(k, *args, **kwds)
    Bases: RecognizableSeriesSpace

    The space of $k$-regular Sequences over the given coefficient_ring.

    INPUT:
    - $k$ – an integer at least 2 specifying the base
    - coefficient_ring – a (semi-)ring
```
• category – (default: None) the category of this space

**EXAMPLES:**

```python
sage: kRegularSequenceSpace(2, ZZ)
Space of 2-regular sequences over Integer Ring
sage: kRegularSequenceSpace(3, ZZ)
Space of 3-regular sequences over Integer Ring
```

See also:

`k-regular sequence`, `kRegularSequence`.

**Element**

alias of `kRegularSequence`

**from_recurrence(**args, **kwds)**

Construct the unique $k$-regular sequence which fulfills the given recurrence relations and initial values. The recurrence relations have to have the specific shape of $k$-recursive sequences as described in [HKL2021], and are either given as symbolic equations, e.g.,

```python
sage: Seq2 = kRegularSequenceSpace(2, ZZ)
sage: var('n')
sage: function('f')
f
sage: Seq2.from_recurrence([
    ....: f(2*n) == 2*f(n), f(2*n + 1) == 3*f(n) + 4*f(n - 1),
    ....: f(0) == 0, f(1) == 1], f, n)
2-regular sequence 0, 0, 0, 1, 2, 3, 4, 10, 6, 17, ...
```

or via the parameters of the $k$-recursive sequence as described in the input block below:

```python
sage: Seq2.from_recurrence(M=1, m=0,
    ....: coeffs={(0, 0): 2, (1, 0): 3, (1, -1): 4},
    ....: initial_values={0: 0, 1: 1})
2-regular sequence 0, 0, 0, 1, 2, 3, 4, 10, 6, 17, ...
```

**INPUT:**

Positional arguments:

If the recurrence relations are represented by symbolic equations, then the following arguments are required:

- **equations** – A list of equations where the elements have either the form
  
  $f(k^M n + r) = c_{r,l} f(k^m n + l) + c_{r,t+1} f(k^m n + l + 1) + ... + c_{r,u} f(k^m n + u)$
  
  for some integers $0 \leq r < k^M$, $M > m \geq 0$ and $l \leq u$, and some coefficients $c_{r,j}$ from the (semi)ring coefficients of the corresponding $kRegularSequenceSpace$, valid for all integers $n \geq$ offset for some integer offset $\geq \max(-l/k^m, 0)$ (default: 0), and there is an equation of this form (with the same parameters $M$ and $m$) for all $r$

  or the form
  
  $f(k) = t$ for some integer $k$ and some $t$ from the (semi)ring coefficient_ring.

The recurrence relations above uniquely determine a $k$-regular sequence; see [HKL2021] for further information.

- **function** – symbolic function $f$ occurring in the equations
• var – symbolic variable (n in the above description of equations)

The following second representation of the recurrence relations is particularly useful for cases where coefficient_ring is not compatible with sage.symbolic.ring.SymbolicRing. Then the following arguments are required:

• M – parameter of the recursive sequences, see [HKL2021], Definition 3.1, as well as in the description of equations above
• m – parameter of the recursive sequences, see [HKL2021], Definition 3.1, as well as in the description of equations above
• coeffs – a dictionary where coeffs[(r, j)] is the coefficient $c_{r,j}$ as given in the description of equations above. If coeffs[(r, j)] is not given for some r and j, then it is assumed to be zero.
• initial_values – a dictionary mapping integers n to the n-th value of the sequence

Optional keyword-only argument:

• offset – (default: 0) an integer. See explanation of equations above.
• inhomogeneities – (default: {}) a dictionary mapping integers r to the inhomogeneity $g_r$ as given in [HKL2021], Corollary D. All inhomogeneities have to be regular sequences from self or elements of coefficient_ring.

OUTPUT: a $k$RegularSequence

EXAMPLES:

Stern–Brocot Sequence:

Sage:
```plaintext
sage: Seq2 = kRegularSequenceSpace(2, ZZ)
sage: var('n')
n
sage: function('f')
f
sage: SB = Seq2.from_recurrence([
    ....: f(2*n) == f(n), f(2*n + 1) == f(n) + f(n + 1),
    ....: f(0) == 0, f(1) == 1], f, n)
sage: SB
2-regular sequence 0, 1, 1, 2, 1, 3, 2, 3, 1, 4, ...
```

Number of Odd Entries in Pascal’s Triangle:

Sage:
```plaintext
sage: Seq2. from_recurrence([ 
    ....: f(2*n) == 3*f(n), f(2*n + 1) == 2*f(n) + f(n + 1),
    ....: f(0) == 0, f(1) == 1], f, n)
2-regular sequence 0, 1, 3, 5, 9, 11, 15, 19, 27, 29, ...
```

Number of Unbordered Factors in the Thue–Morse Sequence:

Sage:
```plaintext
sage: UB = Seq2. from_recurrence([ 
    ....: f(8*n) == 2*f(4*n),
    ....: f(8*n + 1) == f(4*n + 1),
    ....: f(8*n + 2) == f(4*n + 1) + f(4*n + 3),
    ....: f(8*n + 3) == -f(4*n + 1) + f(4*n + 2),
    ....: f(8*n + 4) == 2*f(4*n + 2),
    ....: f(8*n + 5) == f(4*n + 3),
    ....: f(8*n + 6) == -f(4*n + 1) + f(4*n + 2) + f(4*n + 3),
```
\(\vdots\) \(f(8n + 7) = 2^4 f(4n + 1) + f(4n + 3),\)
\(\vdots\) \(f(0) = 1, f(1) = 2, f(2) = 2, f(3) = 4, f(4) = 2,\)
\(\vdots\) \(f(5) = 4, f(6) = 6, f(7) = 0, f(8) = 4, f(9) = 4,\)
\(\vdots\) \(f(10) = 4, f(11) = 4, f(12) = 12, f(13) = 0, f(14) = 4,\)
\(\vdots\) \(f(15) = 4, f(16) = 8, f(17) = 4, f(18) = 8, f(19) = 0,\)
\(\vdots\) \(f(20) = 8, f(21) = 4, f(22) = 4, f(23) = 8, f, n, offset=3)\)

**sage:** UB
2-regular sequence 1, 2, 2, 4, 2, 4, 6, 0, 4, 4, ...

Binary sum of digits \(S(n),\) characterized by the recurrence relations \(S(4n) = S(2n), S(4n+1) = S(2n+1), S(4n+2) = S(2n+1)\) and \(S(4n+3) = -S(2n) + 2S(2n+1):\)

**sage:** S = Seq2.from_recurrence(
\(\vdots\) \(f(4n) = f(2n),\)
\(\vdots\) \(f(4n + 1) = f(2n + 1),\)
\(\vdots\) \(f(4n + 2) = f(2n + 1),\)
\(\vdots\) \(f(4n + 3) = -f(2n) + 2f(2n + 1),\)
\(\vdots\) \(f(0) = 0, f(1) = 1)\)

**sage:** S
2-regular sequence 0, 1, 1, 2, 1, 2, 2, 3, 1, 2, ...

In order to check if this sequence is indeed the binary sum of digits, we construct it directly via its linear representation and compare it with \(S:\)

**sage:** S2 = Seq2(\n\(\vdots\) \((\text{Matrix([[1, 0], [0, 1]]), \text{Matrix([[1, 0], [1, 1]])}),\)
\(\vdots\) \(\text{left=vector([0, 1]), right=vector([1, 0]))})\)
**sage:** (S - S2).is_trivial_zero()
True

Alternatively, we can also use the simpler but inhomogeneous recurrence relations \(S(2n) = S(n)\) and \(S(2n + 1) = S(n) + 1\) via direct parameters:

**sage:** S3 = Seq2.from_recurrence(M=1, m=0,\n\(\vdots\) \(\text{coeffs=}\{(0, 0): 1, (1, 0): 1,\}
\(\vdots\) \(\text{initial_values=}\{0: 0, 1: 1,\}
\(\vdots\) \(\text{inhomogeneities=}\{1: 1\})\)
**sage:** S3
2-regular sequence 0, 1, 1, 2, 1, 2, 2, 3, 1, 2, ...
**sage:** (S3 - S2).is_trivial_zero()
True

Number of Non-Zero Elements in the Generalized Pascal’s Triangle (see [LRS2017]):

**sage:** Seq2 = kRegularSequenceSpace(2, QQ)
**sage:** P = Seq2.from_recurrence([\n\(\vdots\) \(f(4n) = 5/3 f(2n) - 1/3 f(2n + 1),\)
\(\vdots\) \(f(4n + 1) = 4/3 f(2n) + 1/3 f(2n + 1),\)
\(\vdots\) \(f(4n + 2) = 1/3 f(2n) + 4/3 f(2n + 1),\)
\(\vdots\) \(f(4n + 3) = -1/3 f(2n) + 5/3 f(2n + 1),\)
\(\vdots\) \(f(0) = 1, f(1) = 2)\)
**sage:** P
2-regular sequence 1, 2, 3, 3, 4, 5, 5, 4, 5, 7,
Finally, the same sequence can also be obtained via direct parameters without symbolic equations:

\[
\text{sage: Seq2.from_recurrence(M=2, m=1, coeffs={(0, 0): 5/3, (0, 1): -1/3, (1, 0): 4/3, (1, 1): 1/3, (2, 0): 1/3, (2, 1): 4/3, (3, 0): -1/3, (3, 1): 5/3), initial_values={0: 1, 1: 2})}
\]

2-regular sequence 1, 2, 3, 3, 4, 5, 5, 4, 5, 7, ...

5.1.130 Strong and weak tableaux

There are two types of \(k\)-tableaux: strong \(k\)-tableaux and weak \(k\)-tableaux. Standard weak \(k\)-tableaux correspond to saturated chains in the weak order, whereas standard strong \(k\)-tableaux correspond to saturated chains in the strong Bruhat order. For semistandard tableaux, the notion of weak and strong horizontal strip is necessary. More information can be found in [LLMS2006].

See also:

\texttt{sage.combinat.k_tableau.StrongTableau()}, \texttt{sage.combinat.k_tableau.WeakTableau()}

Authors:

- Anne Schilling and Mike Zabrocki (2013): initial version
- Avi Dalal and Nate Gallup (2013): implementation of \(k\)-charge

\textbf{class} \texttt{sage.combinat.k_tableau.StrongTableau(parent, T)}

Bases: \texttt{ClonableList}

A (standard) strong \(k\)-tableau is a (saturated) chain in Bruhat order.

Combinatorially, it is a sequence of embedded \(k+1\)-cores (subject to some conditions) together with a set of markings.

A strong cover in terms of cores corresponds to certain translated ribbons. A marking corresponds to the choice of one of the translated ribbons, which is indicated by marking the head (southeast most cell in French notation) of the chosen ribbon. For more information, see [LLMS2006] and [LLMSSZ2013].

In Sage, a strong \(k\)-tableau is created by specifying \(k\), a standard strong tableau together with its markings, and a weight \(\mu\). Here the standard tableau is represented by a sequence of \(k+1\)-cores

\[
\lambda^{(0)} \subseteq \lambda^{(1)} \subseteq \cdots \subseteq \lambda^{(m)}
\]

where each of the \(\lambda^{(i)}\) is a \(k+1\)-core. The standard tableau is a filling of the diagram for the core \(\lambda^{(m)}/\lambda^{(0)}\) where a strong cover is represented by letters \(\pm i\) in the skew shape \(\lambda^{(i)}/\lambda^{(i-1)}\). Each skew \((k+1)\)-core \(\lambda^{(i)}/\lambda^{(i-1)}\) is a ribbon or multiple copies of the same ribbon which are separated by \(k+1\) diagonals. Precisely one of the copies of the ribbons will be marked in the largest diagonal of the connected component (the ‘head’ of the ribbon). The marked cells are indicated by negative signs.

The strong tableau is stored as a standard strong marked tableau (referred to as the standard part of the strong tableau) and a vector representing the weight.

\textbf{EXAMPLES}:

\texttt{sage: StrongTableau([[-1, -2, -3], [3]], 2, [3])}
\texttt{[-1, -1, -1], [1]}
\texttt{sage: StrongTableau([[1, 2, 4, 7], [-3, 6, -6, 8], [4, 7], [-5, -8]], 3, [2, 2, 3, 1])}
\texttt{[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4]}

5.1. Comprehensive Module List
Alternatively, the strong $k$-tableau can also be entered directly in semistandard format and then the standard tableau and the weight are computed and stored:

\begin{verbatim}
sage: T = StrongTableau([[-1,-1,-1],[1]], 2); T
[[[-1, -1, -1], [1]]]
sage: T.to_standard_list()
[[[-1, -2, -3], [3]]]
sage: T.weight()
(3,)
sage: T = StrongTableau([[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4]], 3); T
[[[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4]]]
sage: T.to_standard_list()
[[[-1, -2, -4, -7], [-3, 6, -6, 8], [4, 7], [-5, -8]]]
sage: T.weight()
(2, 2, 3, 1)
\end{verbatim}

\section*{cell_of_highest_head(v)}

Return the cell of the highest head of label $v$ in the standard part of self.

Return the cell where the head of the ribbon in the highest row is located in the underlying standard tableau. If there is no cell with entry $v$ then the cell returned is $(0, r)$ where $r$ is the length of the first row.

This cell is calculated by iterating through the diagonals of the tableau.

\textbf{INPUT:}

\begin{itemize}
  \item $v$ – an integer indicating the label in the standard tableau
\end{itemize}

\textbf{OUTPUT:}

\begin{itemize}
  \item a pair of integers indicating the coordinates of the head of the highest ribbon with label $v$
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: T = StrongTableau([[-1,2,-3],[-2,3],[-3]], 1)
sage: [T.cell_of_highest_head(v) for v in range(1,5)]
[(0, 0), (1, 0), (2, 0), (0, 3)]
sage: T = StrongTableau([[None,None,-3,4],[3,-4]],2)
sage: [T.cell_of_highest_head(v) for v in range(1,5)]
[(1, 0), (1, 1), (0, 4), (0, 4)]
\end{verbatim}

\section*{cell_of_marked_head(v)}

Return location of marked head labeled by $v$ in the standard part of self.

Return the coordinates of the $v$-th marked cell in the strong standard tableau self. If there is no mark, then the value returned is $(0, r)$ where $r$ is the length of the first row.

\textbf{INPUT:}

\begin{itemize}
  \item $v$ – an integer representing the label in the standard tableau
\end{itemize}

\textbf{OUTPUT:}

\begin{itemize}
  \item a pair of the coordinates of the marked cell with entry $v$
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: T = StrongTableau([[1,2,-3],[-2,3],[3]], 1)
sage: [T.cell_of_marked_head(i) for i in range(1,7)]
[(0, 0), (1, 0), (0, 1), (2, 0), (0, 3), (0, 4)]
sage: T = StrongTableau([[None,None,-3,4],[3,-4]],2)
sage: [T.cell_of_marked_head(v) for v in range(1,5)]
[(1, 0), (1, 1), (0, 4), (0, 4)]
\end{verbatim}

(continues on next page)
cells_head_dictionary()
Returns a dictionary with the locations of the heads of all markings.

OUTPUT:
- a dictionary with keys the entries in the tableau and values are the coordinates of the heads with those entries

EXAMPLES:

```sage
T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
                   [-3, [3], [3], [3]], 4])
sage: T.cell_of_marked_head(i) for i in range(1,7)]
[(2, 0), (0, 2), (2, 1), (0, 3), (4, 0), (0, 4)]
sage: T.cells_head_dictionary()
{1: [(0, 0)], 2: [(0, 1)], 3: [(1, 0)], 4: [(2, 0), (0, 2)], 5: [(3, 0)],
  6: [(1, 2)], 7: [(2, 1), (0, 3)], 8: [(3, 1), (1, 3)]}
sage: T = StrongTableau([[None, 4, -4, -6, -7, 8, 8, -8],
                      [-3, 6], 3])
sage: T.cells_head_dictionary()
{1: [(2, 0)], 2: [(0, 2)], 3: [(1, 1)], 4: [(2, 1), (0, 3)], 5: [(0, 4)],
  6: [(1, 4), (0, 7)]}
sage: StrongTableau([[None, None], [None, -1]], 4).cells_head_dictionary()
{1: [(1, 1)]}
```

cells_of_heads(v)
Returns a list of cells of the heads with label v in the standard part of self.

A list of cells which are heads of the ribbons with label v in the standard part of the tableau self. If there is no cell labelled by v then return the empty list.

INPUT:
- v – an integer label

OUTPUT:
- a list of pairs of integers of the coordinates of the heads of the ribbons with label v

EXAMPLES:

```sage
T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
                   [-3, [3], [3], [3]], 4])
sage: T.cell_of_marked_head(i) for i in range(1,7)]
[(2, 0), (0, 2), (2, 1), (0, 3), (4, 0), (0, 4)]
sage: T.cells_head_dictionary()
{1: [(0, 0)], 2: [(0, 1)], 3: [(1, 0)], 4: [(2, 0), (0, 2)], 5: [(3, 0)],
  6: [(1, 2)], 7: [(2, 1), (0, 3)], 8: [(3, 1), (1, 3)]}
sage: T = StrongTableau([[None, 4, -4, -6, -7, 8, 8, -8],
                      [-3, 6], 3])
sage: T.cells_head_dictionary()
{1: [(2, 0)], 2: [(0, 2)], 3: [(1, 1)], 4: [(2, 1), (0, 3)], 5: [(0, 4)],
  6: [(1, 4), (0, 7)]}
sage: StrongTableau([[None, None], [None, -1]], 4).cells_head_dictionary()
{1: [(1, 1)]}
```

5.1. Comprehensive Module List 1277
cells_of_marked_ribbon($v$)

Return a list of all cells the marked ribbon labeled by $v$ in the standard part of self.

Return the list of coordinates of the cells which are in the marked ribbon with label $v$ in the standard part of the tableau. Note that the result is independent of the weight of the tableau.

The cells are listed from largest content (where the mark is located) to the smallest. Hence, the first entry in this list will be the marked cell.

INPUT:

• $v$ – the entry of the standard tableau

OUTPUT:

• a list of pairs representing the coordinates of the cells of the marked ribbon

EXAMPLES:

```python
sage: T = StrongTableau([[-1, -1, -2, -2, 3], [2, -3], [-3]], 3)
sage: T.to_standard_list()
[[0, 0], [1, -1], [1, -2], [2, 3], [3, -1], [3, -2], [3, -3]]
sage: T.cells_of_marked_ribbon(1)
[[(0, 0)]]
sage: T.cells_of_marked_ribbon(4)
[[(0, 3)]]
sage: T = StrongTableau([[-1, -2, -4, -7], [3, -6, -6, 8], [4, 7], [5, -8]], 3)
sage: T.cells_of_marked_ribbon(6)
[[(1, 2), (1, 1)]]
sage: T.cells_of_marked_ribbon(9)
[]
```

check()

Check that self is a valid strong $k$-tableau.

This function verifies that the outer and inner shape of the parent class is equal to the outer and inner shape of the tableau, that the tableau portion of self is a valid standard tableau, that the marks are placed correctly and that the size and weight agree.
EXAMPLES:

```python
sage: T = StrongTableau([[-1, -1, -2], [2]], 2)
sage: T.check()
sage: T = StrongTableau([[None, None, 2, -4, -4], [-1, 4], [-2]], 3)
sage: T.check()
```

**content_of_highest_head(v)**

Return the diagonal of the highest head of the cells labeled v in the standard part of self.

Return the content of the cell of the head in the highest row of all ribbons labeled by v of the underlying standard tableau. If there is no cell with entry v then the value returned is the length of the first row.

INPUT:

• v – an integer representing the label in the standard tableau

OUTPUT:

• an integer representing the content of the head of the highest ribbon with label v

EXAMPLES:

```python
sage: [StrongTableau([[-1,2,-3],[1,-3],[3]], 1).content_of_highest_head(v) for v in range(1,5)]
[0, -1, -2, 3]
```

**content_of_marked_head(v)**

Return the diagonal of the marked label v in the standard part of self.

Return the content (the \(j - i\) coordinate of the cell) of the v-th marked cell in the strong standard tableau self. If there is no mark, then the value returned is the size of first row.

INPUT:

• v – an integer representing the label in the standard tableau

OUTPUT:

• an integer representing the residue of the location of the mark

EXAMPLES:

```python
sage: [StrongTableau([[None, None, -1, -2], None, None], [[1, 2], [-3], [3]], [3], [3], [4])
[0, -1, 3, 4]
```

**contents_of_heads(v)**

A list of contents of the cells which are heads of the ribbons with label v.

If there is no cell labelled by v then return the empty list.

INPUT:

• v – an integer label

OUTPUT:
• a list of integers of the content of the heads of the ribbons with label \( v \)

EXAMPLES:

```python
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], [3]], 4)
sage: T.contents_of_heads(1)
[-2]
sage: T.contents_of_heads(2)
[-3, 2]
sage: T.contents_of_heads(3)
[-1]
sage: T.contents_of_heads(4)
[-2, 3]
sage: T.contents_of_heads(5)
[-4]
sage: T.contents_of_heads(6)
[]
```

**entries_by_content**(*diag*)

Return the entries on the diagonal of *self*.

Return the entries in the tableau that are in the cells \((i, j)\) with \(j - i\) equal to *diag* (that is, with content equal to *diag*).

**INPUT:**

• *diag* – an integer indicating the diagonal

**OUTPUT:**

• a list (perhaps empty) of labels on the diagonal *diag*

**EXAMPLES:**

```python
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], [3]], 4)
sage: T.entries_by_content(0)
[]
sage: T.entries_by_content(1)
[]
sage: T.entries_by_content(2)
[-1]
sage: T.entries_by_content(-2)
[-1, 2]
```

**entries_by_content_standard**(*diag*)

Return the entries on the diagonal of the standard part of *self*.

Return the entries in the tableau that are in the cells \((i, j)\) with \(j - i\) equal to *diag* (that is, with content equal to *diag*) in the standard tableau.

**INPUT:**

• *diag* – an integer indicating the diagonal

**OUTPUT:**

• a list (perhaps empty) of labels on the diagonal *diag*
EXAMPLES:

```
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
                      [-3], [3], [3], [3]], 4)
sage: T.entries_by_content_standard(0)
[]
sage: T.entries_by_content_standard(1)
[]
sage: T.entries_by_content_standard(2)
[-2]
sage: T.entries_by_content_standard(-2)
[-1, 4]
```

`follows_tableau()`

Return a list of strong marked tableaux with length one longer than `self`.

Return list of all strong tableaux obtained from `self` by extending to a core which follows the shape of `self` in the strong order.

OUTPUT:

- a list of strong tableaux which follow `self` in strong order

EXAMPLES:

```
sage: T = StrongTableau([[[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,1]])
sage: T.follows_tableau()
[[[-1, -1, -2, -3, 5, 5, -5], [-2, 3, -3, 4], [2, 3], [-3, -4]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [-5]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [5]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [5]],
 [[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4], [-5], [5]],
]
sage: StrongTableau([[[-1,-2],[-3,-4]],3]).follows_tableau()
[[[-1, -2, 5, 5, -5], [-3, -4]], [[-1, -2, 5], [-3, -4], [-5]],
 [[-1, -2, -5], [-3, -4], [5]], [[-1, -2], [-3, -4], [-5], [5], [5]]
```

`height_of_ribbon(v)`

The number of rows occupied by one of the ribbons with label `v`.

The number of rows occupied by the marked ribbon with label `v` (and by consequence the number of rows occupied by any ribbon with the same label) in the standard part of `self`.

INPUT:

- `v` – the label of the standard marked tableau

OUTPUT:

- a non-negative integer representing the number of rows occupied by the ribbon which is marked

EXAMPLES:

```
sage: T = StrongTableau([[-1, -1, -2, -2, 3], [2, -3], [-3]])
sage: T.to_standard_list()
[[-1, -2, -3, -4, 6], [4, -6], [-5]]
sage: T.height_of_ribbon(1)
1
sage: T.height_of_ribbon(4)
(continues on next page)
```
inner_shape()  
Return the inner shape of self.

If self is a strong skew tableau, then this method returns the inner shape (the shape of the cells labelled with None). If self is not skew, then the inner shape is empty.

OUTPUT:  
• a \((k + 1)\)-core

EXAMPLES:

```python
sage: StrongTableau([[-1, None], [2], [-3]], 3).inner_shape()
[2, 2]
```

intermediate_shapes()  
Return the intermediate shapes of self.

A (skew) tableau with letters 1, 2, \ldots, \ell can be viewed as a sequence of shapes, where the \(i\)-th shape is given by the shape of the subtableau on letters 1, 2, \ldots, \(i\).

The output is the list of these shapes. The marked cells are ignored so to recover the strong tableau one would need the intermediate shapes and the \textit{content_of_marked_head()} for each pair of adjacent shapes in the list.

OUTPUT:

• a list of lists of integers representing \(k + 1\)-cores

EXAMPLES:

```python
sage: T = StrongTableau([[None, None, -1, -2], [None, None, -1, -2], [1, 2], [-3], [-3], [3], [3], [3]], 4)
sage: T.intermediate_shapes()

sage: T = StrongTableau([[-1, -2, -4, -7], [-3, 6, -6, 8], [4, 7, -5, -8]], 3, [2, 2, 3, 1])
sage: T.intermediate_shapes()

sage: T = StrongTableau([[-1, None], [2], [-3]], 3)
sage: T.intermediate_shapes()
```

is_column_strict_with_weight(mu)  
Test if self is a column strict tableau with respect to the weight \(mu\).

INPUT:

• \(mu\) – a vector of weights

OUTPUT:
• a boolean, True means the underlying column strict strong marked tableau is valid

EXAMPLES:

```python
sage: StrongTableau([[-1, -2, -3], [3]], 2).is_column_strict_with_weight([3])
True
sage: StrongTableau([[-1, -2, 3], [-3]], 2).is_column_strict_with_weight([3])
False
```

**left_action(tij)**

Action of transposition tij on self by adding marked ribbons.

Computes the left action of the transposition tij on the tableau. If tij acting on the element of the affine Grassmannian raises the length by 1, then this function will add a cell to the standard tableau.

INPUT:

• tij – a transposition represented as a pair (i, j).

OUTPUT:

• self after it has been modified by the action of the transposition tij

EXAMPLES:

```python
sage: StrongTableau([[None, -1, -2, -3], [3], [-4]], 3, weight=[1,1,1,1]).left_action([0,1])
[[None, -1, -2, -3, 5], [3, -5], [-4]]
sage: T = StrongTableau([[None, -1, -2, -3], [3], [-4]], 3, weight=[1,1,1,1])
sage: T.left_action([-3,-2])
[[None, -1, -2, -3], [3, [-4], [-5]]]
sage: T = StrongTableau([[None, -1, -2, -3], [3], [-4]], 3, weight=[3,1])
sage: T.left_action([-3,-2])
[[None, -1, -1, -1], [1], [-2], [-3]]
sage: T
[[None, -1, -1, -1], [1], [-2]]
sage: T.check()
sage: T.weight()
((3, 1))
```

**number_of_connected_components(v)**

Number of connected components of ribbons with label v in the standard part.

The number of connected components is calculated by finding the number of cells with label v in the standard part of the tableau and dividing by the number of cells in the ribbon.

INPUT:

• v – the label of the standard marked tableau

OUTPUT:

• a non-negative integer representing the number of connected components

EXAMPLES:
Combinatorics, Release 10.0

sage: T = StrongTableau(
[-1, -2, -2, 3], [2, -3], [-3], 3
sage: T.to_standard_list()
[[[-1, -2, -3, -4, 6], [4, -6], [-5]]

sage: T.number_of_connected_components(1)
1
sage: T.number_of_connected_components(4)
2
sage: T = StrongTableau([[[-1, -2, -4, -7], [-3, 6, -6, 8], [4, 7], [-5, -8]], 3
sage: T.number_of_connected_components(6)
1
sage: T.number_of_connected_components(9)
0

outer_shape()

Return the outer shape of self.

This method returns the outer shape of self as viewed as a Core. The outer shape of a strong tableau is always a \((k + 1)\)-core.

OUTPUT:

• a \((k + 1)\)-core

EXAMPLES:

sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3],
\[3], [3], [3]], 4).outer_shape()
[4, 2, 2, 2, 1, 1, 1, 1]

sage: StrongTableau([[[-1, -2, -4, -7], [-3, 6, -6, 8], [4, 7], [-5, -8]], 3, [2, 2, 3, 1]).
\[outer_shape()
[4, 4, 2, 2]

pp()

Print the strong tableau self in pretty print format.

EXAMPLES:

sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3],
\[3], [3], [3]], 4)
\[\[outer_shape()
[4, 4, 2, 2]

sage: Tableaux.options(convention="French")
restrict($r$)

Restrict the standard part of the tableau to the labels 1, 2, ..., $r$.

Return the tableau consisting of the labels of the standard part of self restricted to the labels of 1 through $r$. The result is another StrongTableau object.

INPUT:

• $r$ – an integer

OUTPUT:

• A strong tableau

EXAMPLES:

sage: T = StrongTableau([[None, None, -4, 5, -5], [None, None], [-1, -3], [-2], [2], [2], [3]], 4, weight=[1,1,1,1,1])
sage: T.restrict(3)
[[None, None], [None, None], [-1, -3], [-2], [2], [2], [3]]
sage: TT = T.restrict(0)
sage: TT
[[None, None], [None, None]]
sage: TT == StrongTableau([[None, None], [None, None]], 4)
True
sage: T.restrict(5) == T
True

ribbons_above_marked($v$)

Number of ribbons of label $v$ higher than the marked ribbon in the standard part.

Return the number of copies of the ribbon with label $v$ in the standard part of self which are in a higher row than the marked ribbon. Note that the result is independent of the weight of the tableau.

INPUT:

• $v$ – the entry of the standard tableau

OUTPUT:

• an integer representing the number of copies of the ribbon above the marked ribbon

EXAMPLES:

sage: T = StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[5,-8]], 3)
sage: T.ribbons_above_marked(4)
1

(continues on next page)
sage: T.ribbons_above_marked(6)
0
sage: T.ribbons_above_marked(9)
0
sage: StrongTableau([[[-1, -2, -3, -4], [2, 3, 4], [3, 4], [4]], 1]).ribbons_above_marked(4)
3

set_weight(mu)

Sets a new weight mu for self.

This method first tests if the underlying standard tableau is column-strict with respect to the weight mu. If it is, then it changes the weight and returns the tableau; otherwise it raises an error.

INPUT:

- mu – a list of non-negative integers representing the new weight

EXAMPLES:

sage: StrongTableau([[[-1, -2, -3]], [3]], 2).set_weight([3])
[[[-1, -1, -1]], [1]]
sage: StrongTableau([[[-1, -2, -3]], [3]], 2).set_weight([0, 3])
[[[-2, -2, -2]], [2]]
sage: StrongTableau([[[-1, -2, -3]], [3]], 2).set_weight([2, 0, 1])
[[[-1, -1, 3]], [-3]]
sage: StrongTableau([[[-1, -2, -3]], [3]], 2).set_weight([3])
Traceback (most recent call last):
  ... ValueError: \([-1, -2, 3], [-3]\) is not a semistandard strong tableau with respect to the partition [3]

shape()

Return the shape of self.

If self is a skew tableau then return a pair of \(k+1\)-cores consisting of the outer and the inner shape. If self is strong tableau with no inner shape then return a \(k+1\)-core.

INPUT:

- form - optional argument to indicate ‘inner’, ‘outer’ or ‘skew’ (default : ‘outer’)

OUTPUT:

- a \(k+1\)-core or a pair of \(k+1\)-cores if form is not ‘inner’ or ‘outer’

EXAMPLES:

sage: T = StrongTableau([[[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], [3]], 4])
sage: T.shape()
([4, 2, 2, 2, 1, 1, 1, 1], [2, 2])
sage: StrongTableau([[-1, -2, 3], [-3]], 2).shape()
[3, 1]
sage: type(StrongTableau([[-1, -2, 3], [-3]], 2).shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
size()

Return the size of the strong tableau.

The size of the strong tableau is the sum of the entries in the weight(). It will also be equal to the length of the outer shape (as a \(k + 1\)-core) minus the length of the inner shape.

See also:

\texttt{sage.combinat.core.Core.length()}

OUTPUT:

• a non-negative integer

EXAMPLES:

\begin{verbatim}
 sage: StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3).size()
 5
 sage: StrongTableau([[\texttt{None}, \texttt{None}, -1, 2], [-2], [-3]], 3).size()
 3
\end{verbatim}

spin()

Return the spin statistic of the tableau \(self\).

The spin is an integer statistic on a strong marked tableau. It is the sum of \((h - 1)r + \text{number of connected components above the marked one} \) where \(h\) is the height of the marked ribbon and \(r\) is the number of connected components.

See also:

\texttt{height_of_ribbon()}, \texttt{number_of_connected_components()}, \texttt{ribbons_above_marked()}

The \(k\)-Schur functions with a parameter \(t\) can be defined as

\[ s^{(k)}_{\lambda}[X; t] = \sum T \cdot t^{\text{spin}(T)} m_{\text{weight}(T)}[X] \]

where the sum is over all column strict marked strong \(k\)-tableaux of shape \(\lambda\) and partition content.

OUTPUT:

• an integer value representing the spin.

EXAMPLES:

\begin{verbatim}
 sage: StrongTableau([[-1,-2,5,6],[-4,7,-8]], 3, [2,2,3,1]).spin()
 1
 sage: StrongTableau([[-1,-2,6,-4],[3,-7,-6]], 3, [2,2,3,1]).spin()
 2
 sage: StrongTableau([[\texttt{None}, \texttt{None}, -1, -3],[2,3,\texttt{None}],[\texttt{None}, \texttt{None}, -3,-4]], 3).spin()
 2
 sage: ks3 = SymmetricFunctions(QQ['t']).fraction_field()).kschur(3)
sage: t = ks3.realization_of().t
tsage: m = ks3.ambient().realization_of().m()
sage: myks221 = sum(sum(t**T.spin() for T in StrongTableaux(3,[3,2,1], weight=mu))*m(mu) for mu in Partitions(5, max_part=3))
sage: myks221 == m(ks3[2,2,1])
True
\end{verbatim}

(continues on next page)
spin_of_ribbon(v)

Return the spin of the ribbon with label v in the standard part of self.

The spin of a ribbon is an integer statistic. It is the sum of \((h - 1)r\) plus the number of connected components above the marked one where \(h\) is the height of the marked ribbon and \(r\) is the number of connected components.

See also:

height_of_ribbon(), number_of_connected_components(), ribbons_above_marked()

INPUT:

• v – a label of the standard part of the tableau

OUTPUT:

• an integer value representing the spin of the ribbon with label v.

EXAMPLES:

sage: T = StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3)
sage: [T.spin_of_ribbon(v) for v in range(1,9)]
[0, 0, 0, 0, 0, 0, 1, 0]
sage: T = StrongTableau([[None, None, -1, -3],[None, 3, -3, 4],[2,3],[-3,-4]], 3)
sage: [T.spin_of_ribbon(v) for v in range(1,7)]
[0, 1, 0, 0, 1, 0]

to_list()

Return the marked column strict (possibly skew) tableau as a list of lists.

OUTPUT:

• a list of lists of integers or None

EXAMPLES:

sage: StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3).set_weight([2,1,1,1]).to_list()
[[-1, -1, -2, 3], [-3], [-4]]
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3],
                  → [3], [3], [3]], 4).to_list()
[[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], [3]]
sage: StrongTableau([[-1, -1, -2, -3, 4], [-4], [-5]], 3, [3,1,1]).to_list()
[[-1, -1, -1, 2], [-2], [-3]]

to_standard_list()

Return the underlying standard strong tableau as a list of lists.

Internally, for a strong tableau the standard strong tableau and its weight is stored separately. This method returns the underlying standard part.
OUTPUT:

• a list of lists of integers or None

EXAMPLES:

```
sage: StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1]).to_standard_list()
[[-1, -2, -3, 4], [-4], [-5]]
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], → [3], [3], [3]], 4).to_standard_list()
[[None, None, -2, -4], [None, None], [-1, -3], [2, 4], [-5], [5], [5], [5]]
```

to_standard_tableau()

Return the underlying standard strong tableau as a StrongTableau object.

Internally, for a strong tableau the standard strong tableau and its weight is stored separately. This method returns the underlying standard part as a StrongTableau.

OUTPUT:

• a strong tableau with standard weight

EXAMPLES:

```
sage: T = StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1])
sage: T.to_standard_tableau() == T.to_standard_list()
False
```

to_transposition_sequence()

Return a list of transpositions corresponding to self.

Given a strong column strict tableau self returns the list of transpositions which when applied to the left of an empty tableau gives the corresponding strong standard tableau.

OUTPUT:

• a list of pairs of values \([i,j]\) representing the transpositions \(t_{ij}\)

EXAMPLES:

```
sage: T = StrongTableau([[-1, -1, -1], [1]],2)
sage: T.to_transposition_sequence()
[[2, 3], [1, 2], [0, 1]]
sage: T = StrongTableau([[-1, -1, 2], [-2]],2)
sage: T.to_transposition_sequence()
[[-1, 0], [1, 2], [0, 1]]
sage: T = StrongTableau([[None, 1, 2], [-3]],2)
sage: T.to_transposition_sequence()
[[3, 4], [-1, 0], [1, 2]]
```

to_unmarked_list()

Return the tableau as a list of lists with markings removed.
Return the list of lists of the rows of the tableau where the markings have been removed.

OUTPUT:

• a list of lists of integers or None

EXAMPLES:

```python
sage: T = StrongTableau( [[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1])
sage: T.to_unmarked_list()
[[1, 1, 1], [2], [3]]
sage: TT = T.set_weight([2,1,1])
sage: TT.to_unmarked_list()
[[1, 1, 2], [3], [4]]
sage: StrongTableau( [[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], [3], 4]).to_unmarked_list()
[[None, None, 1, 2], [None, None], [1, 2], [1, 2], [3], [3], [3], [3]]
```

to_unmarked_standard_list()

Return the standard part of the tableau as a list of lists with markings removed.

Return the list of lists of the rows of the tableau where the markings have been removed.

OUTPUT:

• a list of lists of integers or None

EXAMPLES:

```python
sage: StrongTableau( [[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1]).to_unmarked_standard_list()
[[1, 2, 3, 4], [4], [5]]
sage: StrongTableau( [[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], [3], 4]).to_unmarked_standard_list()
[[None, None, 2, 4], [None, None], [1, 3], [2, 4], [5], [5], [5], [5]]
```

weight()

Return the weight of the tableau.

The weight is a list of non-negative integers indicating the number of 1s, number of 2s, number of 3s, etc.

OUTPUT:

• a list of non-negative integers

EXAMPLES:

```python
sage: T = StrongTableau([[1, -1, -2, -3, 4], [-4], [-5]], 3); T.weight()
(1, 1, 1, 1, 1)
sage: T.set_weight([3,1,1]).weight()
(3, 1, 1)
sage: StrongTableau([[1, -1, -2, -3], [-2,3, -3,4],[2,3],[-3,-4]], 3).weight()
(2, 2, 3, 1)
```

class sage.combinat.k_tableau.StrongTableaux(k, shape, weight)

Bases: UniqueRepresentation, Parent

Element

alias of StrongTableau
classmethod add_marking(unmarkedT, marking, k, weight)
Add markings to a partially marked strong tableau.

Given an partially marked standard tableau and a list of cells where the marks should be placed along with a weight, return the semi-standard marked strong tableau. The marking should complete the marking so that the result is a strong standard marked tableau.

INPUT:
• unmarkedT - a list of lists which is a partially marked strong $k$-tableau
• marking - a list of pairs of coordinates where cells are to be marked
• k - a positive integer
• weight - a tuple of the weight of the output tableau

OUTPUT:
• a StrongTableau object

EXAMPLES:

sage: StrongTableaux.add_marking([[None,1,2],[2]], [(0,1), (1,0)], 2, [1,1])
[[None, -1, 2], [-2]]

sage: StrongTableaux.add_marking([[None,1,2],[2]], [(0,1), (1,0)], 2, [2])
Traceback (most recent call last):
... ValueError: The weight=(2,) and the markings on the standard tableau=[[None, -1, → 2], [-2]] do not agree.

sage: StrongTableaux.add_marking([[None,1,2],[2]], [(0,1), (0,2)], 2, [2])
[[None, -1, -1], [1]]

an_element()
Return the first generated element of the class of StrongTableaux.

EXAMPLES:

sage: ST = StrongTableaux(3, [3], weight=[3])
sage: ST.an_element()
[[−1, −1, −1]]

classmethod cells_head_dictionary(T)
Return a dictionary with the locations of the heads of all markings.

Return a dictionary of values and lists of cells where the heads with the values are located in a strong standard unmarked tableau T.

INPUT:
• T – a strong standard unmarked tableau as a list of lists

OUTPUT:
• a dictionary with keys the entries in the tableau and values are the coordinates of the heads with those entries

EXAMPLES:
class method follows_tableau_unsigned_standard(Tlist, k)

Return a list of strong tableaux one longer in length than Tlist.

Return list of all standard strong tableaux obtained from Tlist by extending to a core which follows the shape of Tlist in the strong order. It does not put the markings on the last entry that it adds but it does keep the markings on all entries smaller. The objects returned are not StrongTableau objects (and cannot be) because the last entry will not properly marked.

INPUT:

• Tlist – a filling of a $k + 1$-core as a list of lists

• k - an integer

OUTPUT:

• a list of strong tableaux which follow Tlist in strong order

EXAMPLES:

\[
\text{sage: StrongTableaux.follows_tableau_unsigned_standard([[-1, -1, -2, -3], [-2, -3, -4], [2, 3], [-3, -4]], 3)}
\]
\[
[[[-1, -1, -2, -3, 5, 5, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4]], [5], [5], [5]]
\]

inner_shape()

Return the inner shape of the class of strong tableaux.

OUTPUT:

• a $k + 1$-core

EXAMPLES:
sage: StrongTableaux( 2, [3,1] ).inner_shape()
[]
sage: type(StrongTableaux( 2, [3,1] ).inner_shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: StrongTableaux( 4, [[2,1], [1]] ).inner_shape()
[1]

classmethod marked_CST_to_transposition_sequence(T, k)

Return a list of transpositions corresponding to T.

Given a strong column strict tableau T returns the list of transpositions which when applied to the left of an empty tableau gives the corresponding strong standard tableau.

INPUT:

• T – a non-empty column strict tableau as a list of lists

• k – a positive integer

OUTPUT:

• a list of pairs of values [i, j] representing the transpositions t_{ij}

EXAMPLES:

sage: CST_to_trans = StrongTableaux.marked_CST_to_transposition_sequence
sage: CST_to_trans([[[-1, -1, -1], [1]], 2]
[[2, 3], [1, 2], [0, 1]])
sage: CST_to_trans([], 2)
[]
sage: CST_to_trans([[[-2, -2, -2], [2]], 2]
[[2, 3], [1, 2], [0, 1]])
sage: CST_to_trans([[[-1, -2, -2, -2], [-2, 2]], 3]
[[4, 5], [3, 4], [2, 3], [1, 2], [-1, 0], [0, 1]])
sage: CST_to_trans([[[-1, -2, -5, 5, -5, 5, -5], [-3, -4, 5, 5]], 3)
[[5, 7], [3, 5], [2, 3], [0, 1], [-1, 0], [1, 2], [0, 1]])
sage: CST_to_trans([[[-1, -2, -3, 4, -7], [-4, -6], [-5, 6]], 3)
[[4, 5], [-1, 1], [-2, -1], [-1, 0], [2, 3], [1, 2], [0, 1]]

classmethod marked_given_unmarked_and_weight_iterator(unmarkedT, k, weight)

An iterator generating strong marked tableaux from an unmarked strong tableau.

Iterator which lists all marked tableaux of weight weight such that the standard unmarked part of the tableau is equal to unmarkedT.

INPUT:

• unmarkedT - a list of lists representing a strong unmarked tableau

• k - a positive integer

• weight - a list of non-negative integers indicating the weight

OUTPUT:

• an iterator that returns StrongTableau objects

EXAMPLES:
options = Current options for Tableaux - ascii_art: repr - convention: English - display: list - latex: diagram

outer_shape()

Return the outer shape of the class of strong tableaux.

OUTPUT:

• a \( k + 1 \)-core

EXAMPLES:

```
sage: StrongTableaux( 2, [3,1] ).outer_shape()
[3, 1]
sage: type(StrongTableaux( 2, [3,1] ).outer_shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: StrongTableaux( 4, [[2,1], [1]] ).outer_shape()
[2, 1]
```

shape()

Return the shape of self.

If the self has an inner shape return a pair consisting of an inner and an outer shape. If the inner shape is empty then return only the outer shape.

OUTPUT:

• a \( k + 1 \)-core or a pair of \( k + 1 \)-cores

EXAMPLES:
classmethod standard_marked_iterator\((k, size, outer_shape=None, inner_shape=[])\)

An iterator for generating standard strong marked tableaux.

An iterator which generates all standard marked \(k\)-tableaux of a given size which are contained in outer_shape and contain the inner_shape. If outer_shape is None then there is no restriction on the shape of the tableaux which are created.

**INPUT:**
- \(k\) - a positive integer
- \(size\) - a positive integer
- outer_shape - a list which is a \(k + 1\)-core (default: None)
- inner_shape - a list which is a \(k + 1\)-core (default: [])

**OUTPUT:**
- an iterator which returns the standard marked tableaux with size cells and that are contained in outer_shape and contain inner_shape

**EXAMPLES:**

```sage
sage: list(StrongTableaux.standard_marked_iterator(2, 3))
[[[[-1, -2, 3], [-3]], [[-1, -2, -3], [3]], [[-1, -2], [-3], [3]], [[-1, 3, -3], [-2]], [[-1, 3, [-2], [-3]], [[-1, -3], [-2], [3]]]
sage: list(StrongTableaux.standard_marked_iterator(2, 1, inner_shape=[1,1]))
[[[None, 1, -1], [None]], [[None, 1], [None], [-1]], [[None, -1], [None], [1]]
sage: len(list(StrongTableaux.standard_marked_iterator(4,4)))
10
sage: len(list(StrongTableaux.standard_marked_iterator(4,6)))
140
sage: len(list(StrongTableaux.standard_marked_iterator(4,4, inner_shape=[2,2])))
200
sage: len(list(StrongTableaux.standard_marked_iterator(4,4, outer_shape=[5,2,2, -1], inner_shape=[2,2])))
24
```

classmethod standard_unmarked_iterator\((k, size, outer_shape=None, inner_shape=[])\)

An iterator for standard unmarked strong tableaux.

An iterator which generates all unmarked tableaux of a given size which are contained in outer_shape and which contain the inner_shape. These are built recursively by building all standard marked strong tableaux of size size −1 and adding all possible covers.

If outer_shape is None then there is no restriction on the shape of the tableaux which are created.

**INPUT:**
- \(k, size\) - a positive integers
• outer_shape - a list representing a $k + 1$-core (default: None)
• inner_shape - a list representing a $k + 1$-core (default: [])

OUTPUT:
• an iterator which lists all standard strong unmarked tableaux with size $n$ and which are contained in outer_shape and contain inner_shape

EXAMPLES:

```python
sage: list(StrongTableaux.standard_unmarked_iterator(2, 3))
[[[1, 2, 3], [3]], [[1, 2], [3], [3]], [[1, 3, 3], [2]], [[1, 3], [2], [3]]]
sage: list(StrongTableaux.standard_unmarked_iterator(2, 1, inner_shape=[1,1]))
[[[None, 1, 1], [None]], [[None, 1], [None], [1]]]
sage: len(list(StrongTableaux.standard_unmarked_iterator(4,4)))
10
sage: len(list(StrongTableaux.standard_unmarked_iterator(4,6)))
98
sage: len(list(StrongTableaux.standard_unmarked_iterator(4,4, inner_shape=[2, 2])))
92
sage: len(list(StrongTableaux.standard_unmarked_iterator(4,4, outer_shape=[5,2, 2,1], inner_shape=[2,2])))
10
```

classmethod transpositions_to_standard_strong(transeq, k, emptyTableau=[])

Return a strong tableau corresponding to a sequence of transpositions.

This method returns the action by left multiplication on the empty strong tableau by transpositions specified by transeq.

INPUT:
• transeq – a sequence of transpositions $t_{ij}$ (a list of pairs).
• emptyTableau – (default: []) an empty list or a skew strong tableau possibly consisting of None entries

OUTPUT:
• a StrongTableau object

EXAMPLES:

```python
sage: StrongTableaux.transpositions_to_standard_strong([[0,1]], 2)
[[[-1]]]
sage: StrongTableaux.transpositions_to_standard_strong([[2, 3], [1, 2], [0, 1]], 2)
[[[-1, -2, -3], [3]]]
sage: StrongTableaux.transpositions_to_standard_strong([[0, -1], [1, 2], [0, -1]], 2)
[[[-1, -2, 3], [-3]]]
sage: StrongTableaux.transpositions_to_standard_strong([[3, 4], [-1, 0], [1, -2]], 2, [[None]])
[[None, -1, 2, -3], [-2, 3]]
```
This is the dispatcher method for the element class of weak $k$-tableaux.

Standard weak $k$-tableaux correspond to saturated chains in the weak order. There are three formulations of weak tableaux, one in terms of cores, one in terms of $k$-bounded partitions, and one in terms of factorizations of affine Grassmannian elements. For semistandard weak $k$-tableaux, all letters of the same value have to satisfy the conditions of a horizontal strip. In the affine Grassmannian formulation this means that all factors are cyclically decreasing elements. For more information, see for example [LLMSSZ2013].

**INPUT:**

- $t$ – a weak $k$-tableau in the specified representation:
  - for the ‘core’ representation $t$ is a list of lists where each subtableaux should have a $k + 1$-core shape; `None` is allowed as an entry for skew weak $k$-tableaux
  - for the ‘bounded’ representation $t$ is a list of lists where each subtableaux should have a $k$-bounded shape; `None` is allowed as an entry for skew weak $k$-tableaux
  - for the ‘factorized_permutation’ representation $t$ is either a list of cyclically decreasing Weyl group elements or a list of reduced words of cyclically decreasing Weyl group elements; to indicate a skew tableau in this representation, `inner_shape` should be the inner shape as a $(k + 1)$-core

- $k$ – positive integer

- `inner_shape` – this entry is only relevant for the ‘factorized_permutation’ representation and specifies the inner shape in case the tableau is skew (default: `[]`)

- `representation` – ‘core’, ‘bounded’, or ‘factorized_permutation’ (default: ‘core’)

**EXAMPLES:**

Here is an example of a weak 3-tableau in core representation:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.shape()
[5, 2, 1]
sage: t.weight()
(2, 2, 2)
sage: type(t)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
```

And now we give a skew weak 3-tableau in core representation:

```
sage: ts = WeakTableau([[None, 1, 1, 2, 2], [None, 2], [1]], 3)
sage: ts.shape()
([5, 2, 1], [1, 1])
sage: ts.weight()
(2, 2)
sage: type(ts)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
```

Next we create the analogue of the first example in bounded representation:

```
sage: tb = WeakTableau([[1,1,2],[2,3],[3]], 3, representation="bounded")
sage: tb.shape()
[3, 2, 1]
sage: tb.weight()
(2, 2, 2)
```

(continues on next page)
sage: type(tb)
<class 'sage.combinat.k_tableau.WeakTableaux_bounded_with_category.element_class'>
sage: tb.to_core_tableau()
[[1, 1, 2, 2, 3], [2, 3], [3]]
sage: t == tb.to_core_tableau()
True

And the analogue of the skew example in bounded representation:

sage: tbs = WeakTableau([[None, 1, 2], [None, 2], [1]], 3, representation="bounded →")
sage: tbs.shape()
([3, 2, 1], [1, 1])
sage: tbs.weight()
(2, 2)
sage: tbs.to_core_tableau()
[[None, 1, 1, 2, 2], [None, 2], [1]]
sage: ts.to_bounded_tableau() == tbs
True

Finally we do the same examples for the factorized permutation representation:

sage: tf = WeakTableau([[2,0],[3,2],[1,0]], 3, representation="factorized_˓→permutation")

Finally we do the same examples for the factorized permutation representation:

sage: tf = WeakTableau([[2,0],[3,2],[1,0]], 3, representation="factorized_˓→permutation")

sage: tf.shape()
[5, 2, 1]
sage: tf.weight()
(2, 2, 2)
sage: type(tf)
<class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_category.˓→element_class'>
sage: tf.to_core_tableau() == t
True

sage: tfs = WeakTableau([[0,3],[2,1]], 3, inner_shape = [1,1], representation = ˓→'factorized_permutation'

Another way to pass from one representation to another is as follows:

sage: ts
[[None, 1, 1, 2, 2], [None, 2], [1]]
sage: ts.parent()._representation
'core'
To test whether a given semistandard tableau is a weak $k$-tableau in the bounded representation, one can ask:

```python
sage: t = Tableau([[1,1,2],[2,3],[3]])
sage: t.is_k_tableau(3)
True
sage: t = SkewTableau([[None, 1, 2], [None, 2], [1]])
sage: t.is_k_tableau(3)
True
sage: t = SkewTableau([[None, 1, 1], [None, 2], [2]])
sage: t.is_k_tableau(3)
False
```

### class sage.combinat.k_tableau.WeakTableau_abstract

Bases: `ClonableList`

Abstract class for the various element classes of WeakTableau.

#### intermediate_shapes()

Return the intermediate shapes of self.

A (skew) tableau with letters $1, 2, \ldots, \ell$ can be viewed as a sequence of shapes, where the $i$-th shape is given by the shape of the subtableau on letters $1, 2, \ldots, i$. The output is the list of these shapes.

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.intermediate_shapes()
[[], [2], [4, 1], [5, 2, 1]]

sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.intermediate_shapes()
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]

sage: t = WeakTableau([[1,1,1],[2,2],[3],[3]], 3, representation = 'bounded')
sage: t.intermediate_shapes()
[[], [3], [3, 2], [3, 2, 1]]

sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation = 'bounded')
sage: t.intermediate_shapes()
[[2], [3], [3, 1], [3, 1, 1], [3, 2, 1]]

sage: t = WeakTableau([[None, 0],[3],[2],[3]], 3, inner_shape = [2], representation = 'factorized_permutation')
sage: t.intermediate_shapes()
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]
```

#### pp()

Return a pretty print string of the tableau.

**EXAMPLES:**
\begin{verbatim}
sage: t = WeakTableau([[None, 1, 1, 2, 2], [None, 2], [1]], 3)
sage: t.pp()
 . 1 1 2 2
 . 2

1

sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation = \texttt{factorized_permutation})

sage: t.pp()
[s2*s0, s3*s2]

representation\texttt{(representation='core')}

Return the analogue of self in the specified representation.

\textbf{INPUT:}

\begin{itemize}
  \item representation – 'core', 'bounded', or 'factorized_permutation' (default: 'core')
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: t = WeakTableau([[1, 1, 2, 4], [2, 3, 5], [3, 4], [5, 6], [6], [7]], 4)
sage: t.parent()._representation
'core'
sage: t.representation('bounded')
[[1, 1, 2, 4], [2, 3, 5], [3, 4], [5, 6], [6], [7]]
sage: t.representation('factorized_permutation')
[s0*s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]
sage: tb = WeakTableau([[1, 1, 2, 4], [2, 3, 5], [3, 4], [5, 6], [6], [7]], 4, representation = 'bounded')
sage: tb.parent()._representation
'bounded'
sage: tb.representation('core') == t
True
sage: tb.representation('factorized_permutation')
[s0*s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]
sage: tp = WeakTableau([[0],[3,1],[2,1],[0,4],[3,0],[4,2],[1,0]], 4, representation = 'factorized_permutation')
sage: tp.parent()._representation
'factorized_permutation'
sage: tp.representation('core') == t
True
sage: tp.representation('bounded') == tb
True
\end{verbatim}

shape()

Return the shape of self.

When the tableau is straight, the outer shape is returned. When the tableau is skew, the tuple of the outer and inner shape is returned.

\textbf{EXAMPLES:}

\begin{verbatim}
\end{verbatim}
\end{verbatim}
size()

Return the size of the shape of self.

In the bounded representation, the size of the shape is the number of boxes in the outer shape minus the number of boxes in the inner shape. For the core and factorized permutation representation, the size is the length of the outer shape minus the length of the inner shape.

See also:

sage.combinat.core.Core.length()

EXAMPLES:

```python
sage: t = WeakTableau([[None, 1, 1, 2], [None, 2], [1]], 3)
sage: t.shape()
([5, 2, 1], [1, 1])
sage: t.size()
4
sage: t = WeakTableau([[1, 1, 2], [2, 3], [3]], 3, representation="bounded")
sage: t.shape()
([5, 2, 1], [1])
sage: t.size()
6
```

weight()

Return the weight of self.

The weight is a tuple whose $i$-th entry is the number of labels $i$ in the bounded representation of self.

EXAMPLES:
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.weight()
(2, 2, 2)
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.weight()
(1, 1, 1, 1)
sage: t = WeakTableau([[None, 2, 3], [3]], 2)
sage: t.weight()
(0, 1, 1)

sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.weight()
(3, 2, 1)
sage: t = WeakTableau([[1,1,2],[2,3],[3]], 3, representation = 'bounded')
sage: t.weight()
(2, 2, 2)
sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation = 'bounded')
sage: t.weight()
(1, 1, 1, 1)

sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_permutation')
sage: t.weight()
(3, 2, 1)
sage: t = WeakTableau([[2,0],[3,2],[1,0]], 3, representation = 'factorized_permutation')
sage: t.weight()
(2, 2, 2)
sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation = 'factorized_permutation')
sage: t.weight()
(2, 2)

class sage.combinat.k_tableau.WeakTableau_bounded(parent, t)
Bases: WeakTableau_abstract

A (skew) weak k-tableau represented in terms of k-bounded partitions.

check()
Check that self is a valid weak k-tableau.

EXAMPLES:

sage: t = WeakTableau([[1,1],[2]], 2, representation = 'bounded')
sage: t.check()

sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation = 'bounded')
sage: t.check()

classmethod from_core_tableau(t, k)
Construct weak k-bounded tableau from in k-core tableau.

EXAMPLES:
sage: from sage.combinat.k_tableau import WeakTableau_bounded
sage: WeakTableau_bounded.from_core_tableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
[[1, 1, 2], [2, 3], [3]]
sage: WeakTableau_bounded.from_core_tableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
[[None, None, 3], [1, 4], [2]]
sage: WeakTableau_bounded.from_core_tableau([[None, 2, 3], [3]], 2)
[[None, 2], [3]]

\textbf{\texttt{k\_charge}}(algorith\texttt{m}=I)

Return the \(k\)-charge of \texttt{self}.

\textbf{INPUT:}

\begin{itemize}
  \item \texttt{algorithm} – (default: “I”) if “I”, computes \(k\)-charge using the \(I\) algorithm, otherwise uses the \(J\)-algorithm
\end{itemize}

\textbf{OUTPUT:}

\begin{itemize}
  \item a nonnegative integer
\end{itemize}

For the definition of \(k\)-charge and the various algorithms to compute it see Section 3.3 of [LLMSSZ2013].

\textbf{EXAMPLES:}

sage: t = WeakTableau([[1, 1, 2], [2, 3], [3]], 3, representation = 'bounded')
sage: t.k_charge()
2
sage: t = WeakTableau([[1, 3, 5], [2, 6], [4]], 3, representation = 'bounded')
sage: t.k_charge()
8
sage: t = WeakTableau([[1, 1, 2, 4], [2, 3, 5], [3, 4], [5, 6], [6], [7]], 4, \rightarrow representation = 'bounded')
sage: t.k_charge()
12

\textbf{\texttt{shape\_bounded}}()

Return the shape of \texttt{self} as \(k\)-bounded partition.

When the tableau is straight, the outer shape is returned as a \(k\)-bounded partition. When the tableau is skew, the tuple of the outer and inner shape is returned as \(k\)-bounded partitions.

\textbf{EXAMPLES:}

sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.shape_bounded()
[3, 2, 1]
sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation = \rightarrow 'bounded')
sage: t.shape_bounded()
([3, 2, 1], [2])

\textbf{\texttt{shape\_core}}()

Return the shape of \texttt{self} as \((k+1)\)-core.
When the tableau is straight, the outer shape is returned as a \((k+1)\)-core. When the tableau is skew, the tuple of the outer and inner shape is returned as \((k+1)\)-cores.

**EXAMPLES:**

```python
t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
t.shape_core()
[5, 2, 1]

t = WeakTableau([[None, None, 1],[2, 4],[3]], 3, representation = 'bounded')
t.shape_core()
([5, 2, 1], [2])
```

**to_core_tableau()**

Return the weak \(k\)-tableau \(self\) where the shape of each restricted tableau is a \((k+1)\)-core.

**EXAMPLES:**

```python
t = WeakTableau([[1,1,2,4],[2,3,5],[3,4],[5,6],[6],[7]], 4, representation = 'bounded')
t.to_core_tableau(); c
[[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]]
type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
t = WeakTableau([], 4, representation = 'bounded')
t.to_core_tableau()
[]

t = WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),3)
[[1, 1, 2], [2, 3], [3]]
```

**class** `sage.combinat.k_tableau.WeakTableau_core` *(parent, t)*

**Bases:** `WeakTableau_abstract`

A (skew) weak \(k\)-tableau represented in terms of \((k+1)\)-cores.

**check()**

Check that \(self\) is a valid weak \(k\)-tableau.

**EXAMPLES:**

```python
t = WeakTableau([[1, 1, 2], [2]], 2)
t.check()
```
dictionary_of_coordinates_at_residues(v)

Return a dictionary assigning to all residues of self with label v a list of cells with the given residue.

INPUT:

• v – a label of a cell in self

OUTPUT:

• dictionary assigning coordinates in self to residues

EXAMPLES:

```python
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.dictionary_of_coordinates_at_residues(3)
{2: [(0, 3), (1, 0)]}
```

k_charge(algorithm='I')

Return the $k$-charge of self.

INPUT:

• algorithm – (default: “I”) if “I”, computes $k$-charge using the $I$ algorithm, otherwise uses the $J$-algorithm

OUTPUT:

• a nonnegative integer

For the definition of $k$-charge and the various algorithms to compute it see Section 3.3 of [LLMSSZ2013].

See also:

k_charge_I() and k_charge_J()

EXAMPLES:

```python
sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]], 4)
sage: t.k_charge()
12
```
**k_charge_I()**

Return the $k$-charge of `self` using the $I$-algorithm.

For the definition of $k$-charge and the $I$-algorithm see Section 3.3 of [LLMSSZ2013].

**OUTPUT:**

• a nonnegative integer

**See also:**

`k_charge()` and `k_charge_J()`

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.k_charge_I()
2
sage: t = WeakTableau([[1, 3, 4, 5, 6], [2, 6], [4]], 3)
sage: t.k_charge_I()
8
sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]], 4)
sage: t.k_charge_I()
12
```

**k_charge_J()**

Return the $k$-charge of `self` using the $J$-algorithm.

For the definition of $k$-charge and the $J$-algorithm see Section 3.3 of [LLMSSZ2013].

**OUTPUT:**

• a nonnegative integer

**See also:**

`k_charge()` and `k_charge_I()`

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.k_charge_J()
2
sage: t = WeakTableau([[1, 3, 4, 5, 6], [2, 6], [4]], 3)
sage: t.k_charge_J()
8
sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]], 4)
sage: t.k_charge_J()
12
```

**list_of_standard_cells()**

Return a list of lists of the coordinates of the standard cells of `self`.

**INPUT:**

• `self` – a weak $k$-tableau in core representation with partition weight

**OUTPUT:**

• a list of lists of coordinates
Warning: This method currently only works for straight weak tableaux with partition weight.

EXAMPLES:

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.list_of_standard_cells()
[[[0, 1], (1, 0), (2, 0)], [[0, 0], (0, 2), (1, 1)]

sage: t = WeakTableau([[1, 1, 1, 2], [2, 2, 3]], 5)
sage: t.list_of_standard_cells()
[[[0, 2], (1, 1), (1, 2)], [[0, 1], (1, 0)], [[0, 0], (0, 3)]

sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]], 4)
sage: t.list_of_standard_cells()
[[[0, 1], (1, 0), (2, 0), (3, 0), (4, 0), (5, 0)], [[0, 0], (0, 2), (1, 0), (2, 1), (1, 2), (3, 1)])
```

residues_of_entries(v)

Return a list of residues of cells of weak k-tableau self labeled by v.

INPUT:

- v – a label of a cell in self

OUTPUT:

- a list of residues

EXAMPLES:

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.residues_of_entries(1)
[0, 1]

sage: t = WeakTableau([[None, None, 1, 1, 4], [1, 4], [3]], 3)
sage: t.residues_of_entries(1)
[2, 3]
```

shape_bounded()  

Return the shape of self as a k-bounded partition.

When the tableau is straight, the outer shape is returned as a k-bounded partition. When the tableau is skew, the tuple of the outer and inner shape is returned as k-bounded partitions.

EXAMPLES:

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.shape_bounded()
[3, 2, 1]

sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.shape_bounded()
[[3, 2, 1], [2]]
```

shape_core()  

Return the shape of self as a (k + 1)-core.
When the tableau is straight, the outer shape is returned as a core. When the tableau is skew, the tuple of the outer and inner shape is returned as cores.

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.shape_core()
[5, 2, 1]
```

```python
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.shape_core()
([5, 2, 1], [2])
```

to_bounded_tableau()

Return the bounded representation of the weak \(k\)-tableau self.

Each restricted subtableau of the output is a \(k\)-bounded partition.

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: c = t.to_bounded_tableau(); c
[[1, 1, 2], [2, 3], [3]]
sage: type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_bounded_with_category.element_class'>
```

```python
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.to_bounded_tableau() == t
True
```

to_factorized_permutation_tableau()

Return the factorized permutation representation of the weak \(k\)-tableau self.

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: c = t.to_factorized_permutation_tableau(); c
[s2*s0, s3*s2, s1*s0]
sage: type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_category.element_class'>
sage: c.to_core_tableau() == t
True
```

```python
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: c = t.to_factorized_permutation_tableau(); c
[s0, s3, s2, s3]
sage: c._inner_shape
[2]
sage: c.to_core_tableau() == t
True
```
class sage.combinat.k_tableau.WeakTableau_factorized_permutation(parent, t)

Bases: WeakTableau_abstract

A weak (skew) $k$-tableau represented in terms of factorizations of affine permutations into cyclically decreasing elements.

check()

Check that self is a valid weak $k$-tableau.

EXAMPLES:

```python
sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_permutation')
sage: t.check()
```

classmethod from_core_tableau(t, k)

Construct weak factorized affine permutation tableau from a $k$-core tableau.

EXAMPLES:

```python
sage: from sage.combinat.k_tableau import WeakTableau_factorized_permutation
sage: WeakTableau_factorized_permutation.from_core_tableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
[s2*s0, s3*s2, s1*s0]
sage: WeakTableau_factorized_permutation.from_core_tableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]], 4)
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]
sage: WeakTableau_factorized_permutation.from_core_tableau([[None, 1, 1, 2, 2], [None, 2], [1]], 3)
[s0*s3, s2*s1]
```

k_charge(algorithm='I')

Return the $k$-charge of self.

OUTPUT:

- a nonnegative integer

EXAMPLES:

```python
sage: t = WeakTableau([[2,0],[3,2],[1,0]], 3, representation = 'factorized_permutation')
sage: t.k_charge()
2
sage: t = WeakTableau([[0],[3],[2],[1],[3],[0]], 3, representation = 'factorized_permutation')
sage: t.k_charge()
8
sage: t = WeakTableau([[0],[3,1],[2,1],[0,4],[3,0],[4,2],[1,0]], 4, representation = 'factorized_permutation')
sage: t.k_charge()
12
```

shape_bounded()

Return the shape of self as a $k$-bounded partition.

When the tableau is straight, the outer shape is returned as a $k$-bounded partition. When the tableau is skew, the tuple of the outer and inner shape is returned as $k$-bounded partitions.
EXAMPLES:

```
sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_permutation')
sage: t.shape_bounded()
[3, 2, 1]
```

```
sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation = 'factorized_permutation')
sage: t.shape_bounded()
([3, 2, 1], [2])
```

```
shape_core()

Return the shape of self as a \((k + 1)\)-core.

When the tableau is straight, the outer shape is returned as a core. When the tableau is skew, the tuple of the outer and inner shape is returned as cores.

EXAMPLES:

```
sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_permutation')
sage: t.shape_core()
[5, 2, 1]
```

```
sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation = 'factorized_permutation')
sage: t.shape()
([5, 2, 1], [2])
```

```
station straighten_input\(t, k\)

Straightens input.

INPUT:

• \(t\) – a list of reduced words or a list of elements in the Weyl group of type \(A_k^{(1)}\)

• \(k\) – a positive integer

EXAMPLES:

```
sage: from sage.combinat.k_tableau import WeakTableau_factorized_permutation
sage: WeakTableau_factorized_permutation.straighten_input([[2,0],[3,2],[1,0]], 3)
(s2*s0, s3*s2, s1*s0)
sage: W = WeylGroup(['A',4,1])
sage: WeakTableau_factorized_permutation.straighten_input([W.an_element(),W.an_element()], 4)
(s0*s1*s2*s3*s4, s0*s1*s2*s3*s4)
```

```
to_core_tableau()

Return the weak \(k\)-tableau self where the shape of each restricted tableau is a \((k + 1)\)-core.

EXAMPLES:

```
sage: t = WeakTableau([[0], [3,1], [2,1], [0,4], [3,0], [4,2], [1,0]], 4, representation = 'factorized_permutation'); t
```
\[[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]\]

\[\texttt{sage: c = t.to_core_tableau(); c} \]
\[
\begin{bmatrix}
1, 1, 2, 3, 4, 5, 5, 6, 6, 5, 7, 7, 6, 6, 6, 7
\end{bmatrix}
\]

\[\texttt{sage: type(c)} \]
\[
\texttt{<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>} \]

\[\texttt{sage: t = WeakTableau([[]], 4, representation = 'factorized_permutation'); t} \]
\[
\begin{bmatrix}
1
\end{bmatrix}
\]

\[\texttt{sage: t.to_core_tableau()} \]
\[
\emptyset
\]

\[\texttt{sage: from sage.combinat.k_tableau import WeakTableau_factorized_permutation} \]

\[\texttt{sage: t = WeakTableau([[[2,0],[3,2],[1,0]], 3, representation = 'factorized_permutation'}) \]

\[\texttt{sage: WeakTableau_factorized_permutation.from_core_tableau(t.to_core_tableau(), 3)} \]

\[
\begin{bmatrix}
\texttt{[s2*s0, s3*s2, s1*s0]} \\
\texttt{t == WeakTableau_factorized_permutation.from_core_tableau(t.to_core_tableau(), 3)} \]

\[
\texttt{True}
\]

\[\texttt{sage: t = WeakTableau([[[2,0],[3,2]], 3, inner_shape = [2], representation = 'factorized_permutation'}) \]

\[\texttt{sage: t.to_core_tableau()} \]
\[
\begin{bmatrix}
\texttt{[[None, None, 1, 1, 2], [1, 2, 2]]} \\
\texttt{t == WeakTableau_factorized_permutation.from_core_tableau(t.to_core_tableau(), 3)} \]

\[
\texttt{True}
\]\n
\[\texttt{sage.combinat.k_tableau.WeakTableaux(k, shape, weight, representation='core')}\]

This is the dispatcher method for the parent class of weak \(k\)-tableaux.

**INPUT:**

- \(k\) – positive integer
- \(\text{shape}\) – shape of the weak \(k\)-tableaux; for the ‘core’ and ‘factorized_permutation’ representation, the shape is inputted as a \(k+1\)-core; for the ‘bounded’ representation, the shape is inputted as a \(k\)-bounded partition; for skew tableaux, the shape is inputted as a tuple of the outer and inner shape
- \(\text{weight}\) – the weight of the weak \(k\)-tableaux as a list or tuple
- \(\text{representation}\) – ‘core’, ‘bounded’, or ‘factorized_permutation’ (default: ‘core’)

**EXAMPLES:**

\[\texttt{sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1,1])} \]

\[\texttt{sage: T.list()} \]
\[
\begin{bmatrix}
[[1, 3, 4, 5, 6], [2, 6], [4]], \\
[[1, 2, 4, 5, 6], [3, 6], [4]], \\
[[1, 2, 3, 4, 6], [4, 6], [5]], \\
[[1, 2, 3, 4, 5], [4, 5], [6]]
\end{bmatrix}
\]

\[\texttt{sage: T.cardinality()} \]
\[
4
\]

\[\texttt{sage: T = WeakTableaux(3, [[5,2,1], [2]], [1,1,1,1])} \]

(continues on next page)
Combinatorics, Release 10.0

sage: T.list()
[[[None, None, 2, 3, 4], [1, 4], [2]],
[[None, None, 1, 2, 4], [2, 4], [3]],
[[None, None, 1, 2, 3], [2, 3], [4]]]

sage: T = WeakTableaux(3, [3,2,1], [1,1,1,1,1,1], representation = 'bounded')
sage: T.list()

class sage.combinat.k_tableau.WeakTableaux_abstract

Bases: UniqueRepresentation, Parent

Abstract class for the various parent classes of WeakTableaux.

representation(representation='core')

Return the analogue of self in the specified representation.

INPUT:

• representation – ‘core’, ‘bounded’, or ‘factorized_permutation’ (default: ‘core’)

EXAMPLES:

sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1,1])
sage: T._representation
'core'
sage: T.representation('bounded')
Bounded weak 3-Tableaux of (skew) 3-bounded shape [5, 2, 1] and weight (1, 1, 1, 1, 1, 1)
sage: T.representation('factorized_permutation')
Factorized permutation (skew) weak 3-Tableaux of shape [5, 2, 1] and weight (1, 1, 1, 1, 1, 1)
Combinatorics, Release 10.0

sage: T = WeakTableaux(3, [3,2,1], [1,1,1,1,1,1], representation = 'bounded')
sage: T._representation
'bounded'
sage: T.representation('core')
Core weak 3-Tableaux of (skew) core shape [5, 2, 1] and weight (1, 1, 1, 1, 1)
sage: T.representation('bounded')
Bounded weak 3-Tableaux of (skew) 3-bounded shape [3, 2, 1] and weight (1, 1, 1, 1, 1)
sage: T.representation('bounded') == T
True
sage: T.representation('factorized_permutation')
Factorized permutation (skew) weak 3-Tableaux of shape [5, 2, 1] and weight (1, 1, 1, 1, 1)
sage: T.representation('factorized_permutation') == T
False

shape()

Return the shape of the tableaux of self.

When self is the class of straight tableaux, the outer shape is returned. When self is the class of skew tableaux, the tuple of the outer and inner shape is returned.

Note that in the ‘core’ and ‘factorized_permutation’ representation, the shapes are (k + 1)-cores. In the ‘bounded’ representation, the shapes are k-bounded partitions.

If the user wants to access the skew shape (even if the inner shape is empty), please use self._shape.

EXAMPLES:

sage: T = WeakTableaux(3, [5,2,2], [2,2,2,1])
sage: T.shape()
[5, 2, 2]
sage: T._shape
([5, 2, 2], [])
sage: T = WeakTableaux(3, [[5,2,2], [1]], [2,1,2,1])
sage: T.shape()
([5, 2, 2], [1])

(continues on next page)
sage: T = WeakTableaux(3, [3,2,2], [2,2,1], representation = 'bounded')
sage: T.shape()
[3, 2, 2]
sage: T._shape
([3, 2, 2], [])
sage: T = WeakTableaux(3, [[3,2,2], [1]], [2,1,2,1], representation = 'bounded')
sage: T.shape()
([3, 2, 2], [1])
sage: T = WeakTableaux(3, [4,1], [2,2], representation = 'factorized_permutation →')
sage: T.shape()
([4, 1], [])
sage: T = WeakTableaux(4, [[6,2,1], [2]], [2,1,1,1], representation = 'factorized_permutation')
sage: T.shape()
([6, 2, 1], [2])

size()

Return the size of the shape.

In the bounded representation, the size of the shape is the number of boxes in the outer shape minus the number of boxes in the inner shape. For the core and factorized permutation representation, the size is the length of the outer shape minus the length of the inner shape.

EXAMPLES:

sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1])
sage: T.size()
6
sage: T = WeakTableaux(3, [3,2,1], [1,1,1,1,1], representation = 'bounded')
sage: T.size()
6
sage: T = WeakTableaux(4, [[6,2,1], [2]], [2,1,1,1], 'factorized_permutation')
sage: T.size()
5

class sage.combinat.k_tableau.WeakTableaux_bounded(k, shape, weight)

Bases: WeakTableaux_abstract

The class of (skew) weak $k$-tableaux in the bounded representation of shape $shape$ (as $k$-bounded partition or tuple of $k$-bounded partitions in the skew case) and weight $weight$.

INPUT:

- $k$ – positive integer
- $shape$ – the shape of the $k$-tableaux represented as a $k$-bounded partition; if the tableaux are skew, the shape is a tuple of the outer and inner shape each represented as a $k$-bounded partition
- $weight$ – the weight of the $k$-tableaux

EXAMPLES:
```python
sage: T = WeakTableaux(3, [3,1], [2,2], representation = 'bounded')
sage: T.list()
[[[1, 1, 2], [2]]]

sage: T = WeakTableaux(3, [[3,2,1], [2]], [1,1,1,1], representation = 'bounded')
sage: T.list()
[[[None, None, 3], [1, 4], [2]],
[[None, None, 1], [2, 4], [3]],
[[None, None, 1], [2, 3], [4]]]
```

**Element**

alias of *WeakTableau_bounded*

```python
class sage.combinat.k_tableau.WeakTableaux_core(k, shape, weight)
Bases: WeakTableaux_abstract

The class of (skew) weak \( k \)-tableaux in the core representation of shape \( \text{shape} \) (as \( k+1 \)-core) and weight \( \text{weight} \).

**INPUT:**
- \( k \) – positive integer
- \( \text{shape} \) – the shape of the \( k \)-tableaux represented as a \( (k+1) \)-core; if the tableaux are skew, the shape is a tuple of the outer and inner shape (both as \( (k+1) \)-cores)
- \( \text{weight} \) – the weight of the \( k \)-tableaux

**EXAMPLES:**

```python
sage: T = WeakTableaux(3, [4,1], [2,2])
sage: T.list()
[[[1, 1, 2, 2], [2]]]

sage: T = WeakTableaux(3, [[5,2,1], [2]], [1,1,1,1])
sage: T.list()
[[[None, None, 2, 3, 4], [1, 4], [2]],
[[None, None, 1, 2, 4], [2, 4], [3]],
[[None, None, 1, 2, 3], [2, 3], [4]]]
```

**Element**

alias of *WeakTableau_core*

```python
circular_distance(cr, r)

Return the shortest counterclockwise distance between \( cr \) and \( r \) modulo \( k + 1 \).

**INPUT:**
- \( cr, r \) – nonnegative integers between 0 and \( k \)

**OUTPUT:**
- a positive integer

**EXAMPLES:**

```python
sage: T = WeakTableaux(10, [], [])
sage: T.circular_distance(8, 6)
2
```
```
sage: T.circular_distance(8, 8)
0
sage: T.circular_distance(8, 9)
10

diag(c, ha)
Return the number of diagonals strictly between cells c and ha of the same residue as c.

INPUT:
• c – a cell in the lattice
• ha – another cell in the lattice with bigger row and smaller column than c

OUTPUT:
• a nonnegative integer

EXAMPLES:

sage: T = WeakTableaux(4, [5,2,2], [2,2,2,1])
sage: T.diag((1,2),(4,0))
0

class sage.combinat.k_tableau.WeakTableaux_factorized_permutation(k, shape, weight)

Bases: WeakTableaux_abstract

The class of (skew) weak k-tableaux in the factorized permutation representation of shape shape (as k + 1-core or tuple of (k + 1)-cores in the skew case) and weight weight.

INPUT:
• k – positive integer
• shape – the shape of the k-tableaux represented as a (k + 1)-core; in the skew case the shape is a tuple of the outer and inner shape both as (k + 1)-cores
• weight – the weight of the k-tableaux

EXAMPLES:

sage: T = WeakTableaux(3, [4,1], [2,2], representation = 'factorized_permutation')
sage: T.list()
[[s3*s2, s1*s0]]
sage: T = WeakTableaux(4, [[6,2,1], [2]], [2,1,1,1], representation = 'factorized_permutation')
sage: T.list()
[[s0, s4, s3, s4*s2], [s0, s3, s4, s3*s2], [s3, s0, s4, s3*s2]]

Element
alias of WeakTableau_factorized_permutation

sage.combinat.k_tableau.intermediate_shapes(t)

Return the intermediate shapes of tableau t.

A (skew) tableau with letters 1, 2, ..., ℓ can be viewed as a sequence of shapes, where the i-th shape is given by the shape of the subtableau on letters 1, 2, ..., i. The output is the list of these shapes.

OUTPUT:
• a list of lists representing partitions

EXAMPLES:

```
sage: from sage.combinat.k_tableau import intermediate_shapes
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: intermediate_shapes(t)
[[], [2], [4, 1], [5, 2, 1]]
```

```
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: intermediate_shapes(t)
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]
```

```
sage.combinat.k_tableau.nabs(v)

Return the absolute value of v or None.

INPUT:

• v – either an integer or None

OUTPUT:

• either a non-negative integer or None

EXAMPLES:

```
sage: from sage.combinat.k_tableau import nabs
sage: nabs(None)
sage: nabs(-3)
3
sage: nabs(None)
```

5.1.131 Kazhdan-Lusztig Polynomials

AUTHORS:

• Daniel Bump (2008): initial version

```
class sage.combinat.kazhdan_lusztig.KazhdanLusztigPolynomial(W, q, trace=False)

Bases: UniqueRepresentation, SageObject

A Kazhdan-Lusztig polynomial.

INPUT:

• \( W \) – a Weyl Group
• q – an indeterminate

OPTIONAL:

• trace – if True, then this displays the trace: the intermediate results. This is instructive and fun.

The parent of q may be a PolynomialRing or a LaurentPolynomialRing.

EXAMPLES:
```
Combinatorics, Release 10.0

```sage
sage: W = WeylGroup("B3", prefix="s")
sage: [s1, s2, s3] = W.simple_reflections()
sage: R.<q> = LaurentPolynomialRing(QQ)
sage: KL = KazhdanLusztigPolynomial(W, q)
sage: KL.P(s2, s3*s2*s3*s1*s2)
1 + q
```

A faster implementation (using the optional package Coxeter 3) is given by:

```sage
sage: W = CoxeterGroup(['B', 3], implementation='coxeter3') # optional - coxeter3
coxeter3
sage: W.kazhdan_lusztig_polynomial([2], [3, 2, 3, 1, 2]) # optional - coxeter3
coxeter3
```

$P(x, y)$

Return the Kazhdan-Lusztig $P$ polynomial.

If the rank is large, this runs slowly at first but speeds up as you do repeated calculations due to the caching.

**INPUT:**

- $x, y$ – elements of the underlying Coxeter group

**See also:**

kazhdan_lusztig_polynomial for a faster implementation using Fokko Ducloux’s Coxeter3 C++ library.

**EXAMPLES:**

```sage
sage: R.<q> = QQ[]
sage: W = WeylGroup("A3", prefix="s")
sage: [s1, s2, s3] = W.simple_reflections()
sage: KL = KazhdanLusztigPolynomial(W, q)
sage: KL.P(s2, s2*s1*s3*s2)
```

$R(x, y)$

Return the Kazhdan-Lusztig $R$ polynomial.

**INPUT:**

- $x, y$ – elements of the underlying Coxeter group

**EXAMPLES:**

```sage
sage: R.<q> = QQ[]
sage: W = WeylGroup("A2", prefix="s")
sage: [s1, s2] = W.simple_reflections()
sage: KL = KazhdanLusztigPolynomial(W, q)
sage: [KL.R(x, s2*s1) for x in [1, s1, s2, s1*s2]]
```

$R_{\tilde{}}(x, y)$

Return the Kazhdan-Lusztig $\tilde{R}$ polynomial.

Information about the $\tilde{R}$ polynomials can be found in [Dy1993] and [BB2005].

**INPUT:**
\* x, y – elements of the underlying Coxeter group

**EXAMPLES:**

```python
sage: R.<q> = QQ[]
sage: W = WeylGroup("A2", prefix="s")
sage: [s1,s2] = W.simple_reflections()
sage: KL = KazhdanLusztigPolynomial(W, q)
```

```python
sage: [KL.R_tilde(x,s2*s1) for x in [1,s1,s2,s1*s2]]
[q^2, q, q, 0]
```

### 5.1.132 Key polynomials

Key polynomials (also known as type A Demazure characters) are defined by applying the divided difference operator \( \pi_\sigma \), where \( \sigma \) is a permutation, to a monomial corresponding to an integer partition \( \mu \vdash n \).

**See also:**

For Demazure characters in other types, see

- `sage.combinat.root_system.weyl_characters.WeylCharacterRing.demazure_character()`

**AUTHORS:**

- Trevor K. Karn (2022-08-17): initial version

**class** `sage.combinat.key_polynomial.KeyPolynomial`

**Bases:** `IndexedFreeModuleElement`

A key polynomial.

Key polynomials are polynomials that form a basis for a polynomial ring and are indexed by weak compositions.

Elements should be created by first creating the basis `KeyPolynomialBasis` and passing a list representing the indexing composition.

**EXAMPLES:**

```python
sage: k = KeyPolynomials(QQ)
sage: f = k([4,3,2,1]) + k([1,2,3,4]); f
k[4, 3, 2, 1] + k[1, 2, 3, 4]
sage: f in k
True
```

**divided_difference(w)**

Apply the divided difference operator \( \partial_w \) to `self`.

The convention is to apply from left to right so if \( w = [w_1, w_2, \ldots, w_m] \) then we apply \( \partial_{w_2 \cdots w_m} \circ \partial_{w_1} \)

**EXAMPLES:**

```python
sage: k = KeyPolynomials(QQ)
sage: k([3,2,1]).divided_difference(2)
k[3, 1, 1]
sage: k([3,2,1]).divided_difference([2,3])
k[3, 1]
```

(continues on next page)
sage: k = KeyPolynomials(QQ, 4)
sage: k([3,2,1,0]).divided_difference(2)
k[3, 1, 1, 0]

expand()

Return self written in the monomial basis (i.e., as an element in the corresponding polynomial ring).

EXAMPLES:

sage: k = KeyPolynomials(QQ)
sage: f = k([4,3,2,1])
sage: f.expand()
z_3*z_2^2*z_1^3*z_0^4

sage: f = k([1,2,3])
sage: f.expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^2*z_1^3*z_0^3 + 2*z_2^2*z_1^2*z_0^2 + z_2*z_1^3*z_0^2 + z_2*z_1^2*z_0^3

isobaric_divided_difference(w)

Apply the operator $\pi_w$ to self.

w may be either a Permutation or a list of indices of simple transpositions (1-based).

The convention is to apply from left to right so if $w = [w_1, w_2, \ldots, w_m]$ then we apply $\pi_{w_2} \cdots \pi_{w_m} \circ \pi_{w_1}$

EXAMPLES:

sage: k = KeyPolynomials(QQ)
sage: k([3,2,1]).pi(2)
k[3, 1, 2]
sage: k([3,2,1]).pi([2,1])
k[1, 3, 2]
sage: k([3,2,1]).pi(Permutation([3,2,1]))
k[1, 2, 3]
sage: f = k([3,2,1]) + k([3,2,1,1])
sage: f.pi(2)
k[3, 1, 2] + k[3, 1, 2, 1]
sage: k.one().pi(1)
k[]
sage: k([3,2,1,0]).pi(2).pi(2)
k[3, 1, 2]
sage: (-k([3,2,1,0]) + 4*k([3,1,2,0])).pi(2)
3*k[3, 1, 2]
pi(w)

Apply the operator $\pi_w$ to self.

$w$ may be either a Permutation or a list of indices of simple transpositions (1-based).

The convention is to apply from left to right so if $w = [w_1, w_2, \ldots, w_m]$ then we apply $\pi_{w_m} \circ \pi_{w_{m-1}} \circ \cdots \circ \pi_{w_1}$.

EXAMPLES:

```python
sage: k = KeyPolynomials(QQ)
sage: k([3,2,1]).pi(2)
k[3, 1, 2]
sage: k([3,2,1]).pi([2,1])
k[1, 3, 2]
sage: k([3,2,1]).pi(Permutation([3,2,1]))
k[1, 2, 3]
sage: f = k([3,2,1]) + k([3,2,1,1])
sage: f.pi(2)
k[3, 1, 2] + k[3, 1, 2, 1]
sage: k.one().pi(1)
k[0, 0, 0, 0]
```

```python
sage: to_polynomial()
Return self written in the monomial basis (i.e., as an element in the corresponding polynomial ring).

EXAMPLES:

```python
sage: k = KeyPolynomials(QQ)
sage: f = k([4,3,2,1])
```

(continues on next page)
Combinatorics, Release 10.0

```
sage: f.expand()
z_3*z_2^2*z_1^3*z_0^4

sage: f = k([1,2,3])
sage: f.expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^2*z_1^3*z_0^3 + z_2^2*z_1^2*z_0^3 + 2*z_2^2*z_1*z_0^3 + z_2*z_1^3*z_0^2 + z_2*z_1^2*z_0^3
```

```python
class sage.combinat.key_polynomial.KeyPolynomialBasis(R=None, k=None, poly_ring=None):
    Bases: CombinatorialFreeModule

    The key polynomial basis for a polynomial ring.

    For a full definition, see SymmetricFunctions.com. Key polynomials are indexed by weak compositions with no trailing zeros, and \( \sigma \) is the permutation of shortest length which sorts the indexing composition into a partition.

    EXAMPLES:

    Key polynomials are a basis, indexed by (weak) compositions, for polynomial rings:

    ```python
    sage: k = KeyPolynomials(QQ)
sage: k([3,0,1,2])
k[3, 0, 1, 2]
sage: k([3,0,1,2])/2
    1/2*k[3, 0, 1, 2]
sage: R = k.polynomial_ring(); R
    Infinite polynomial ring in z over Rational Field
    sage: K = KeyPolynomials(GF(5)); K
    Key polynomial basis over Finite Field of size 5
    sage: 2*K([3,0,1,2])
    2*k[3, 0, 1, 2]
sage: 5*(K([3,0,1,2]) + K([3,1,1]))
    0
    ```

    We can expand them in the standard monomial basis:

    ```python
    sage: k([3,0,1,2]).expand()
z_3^2*z_2*z_0^3 + z_3^2*z_1*z_0^3 + z_3^2*z_2^2*z_0^2 + z_3^2*z_1^2*z_0^2 + z_3*z_2^2*z_0^2 + z_3*z_1^2*z_0^2 + z_2^2*z_1*z_0^2 + z_2^2*z_1^2*z_0^2 + z_2*z_1^2*z_0^2 + z_2*z_1*z_0^2 + z_1^2*z_0^2 + z_1*z_0^2 + z_0^2
    ```

    If we have a polynomial, we can express it in the key basis:

    ```python
    sage: z = R.gen()
sage: k.from_polynomial(z[2]^2*z[1]*z[0])
k[1, 1, 2] - k[1, 2, 1]
sage: f = z[3]^2*z[2]*z[0]^3 + z[3]^2*z[1]*z[0]^3 + z[3]*z[2]^2*z[0]^2 + z[3]*z[1]^2*z[0]^2 + z[2]^2*z[0]^2 + z[2]*z[1]*z[0]^2 + z[1]*z[0]^2 + z[0]*z_2^2 + z[0]*z_1^2 + z[0]*z_0 + z[0]^2
    ```
```
Since the ring of key polynomials may be regarded as a different choice of basis for a polynomial ring, it forms an algebra, so we have multiplication:

\[
sage: k([10, 5, 2]) \cdot k([1, 1, 1])
\]
\[
k[11, 6, 3]
\]

We can also multiply by polynomials in the monomial basis:

\[
sage: k([10, 9, 1]) \cdot z[0]
\]
\[
k[11, 9, 1]
\]

\[
sage: z[0] \cdot k([10, 9, 1])
\]
\[
k[11, 9, 1]
\]

\[
sage: k([10, 9, 1]) \cdot (z[0] + z[3])
\]
\[
k[10, 9, 1, 1] + k[11, 9, 1]
\]

When the sorting permutation is the longest element, the key polynomial agrees with the Schur polynomial:

\[
sage: s = SymmetricFunctions(QQ).schur()
sage: k([1, 2, 3]).expand()
\]
\[
z_2^3 z_1^2 z_0 + z_2^3 z_1 z_0^2 + z_2^2 z_1^3 z_0^2 + 2 z_2^2 z_1^2 z_0^3 + z_2 z_1^3 z_0^3
\]

The polynomial expansions can be computed using crystals and expressed in terms of the key basis:

\[
sage: T = crystals.Tableaux(['A', 3], shape=[2, 1])
sage: f = T.demazure_character([3, 2, 1])
sage: k.from_polynomial(f)
\]
\[
k[1, 0, 0, 2]
\]

The default behavior is to work in a polynomial ring with infinitely many variables. One can work in a specified number of variables:

\[
sage: k = KeyPolynomials(QQ, 4)
sage: k([3, 0, 1, 2]).expand()
\]
\[
z_0^3 z_1^2 z_2 + z_0^3 z_1 z_2^2 + z_0^3 z_1^2 z_3 + 2 z_0^2 z_1^2 z_3 + z_0^2 z_1 z_3^2 + z_0^2 z_2 z_3^2 + z_0^2 z_1^2 z_2^2
\]

\[
sage: k([0, 0, 2, 0]).expand()
\]
\[
z_0^2 + z_0 z_1 + z_1^2 + z_0 z_2 + z_1 z_2 + z_2^2
\]

\[
sage: k([0, 0, 2, 0]).expand().parent()
\]
\[
Multivariate Polynomial Ring in z_0, z_1, z_2, z_3 over Rational Field
\]

If working in a specified number of variables, the length of the indexing composition must be the same as the number of variables:
One can also work in a specified polynomial ring:

```
sage: k = KeyPolynomials(QQ['x0', 'x1', 'x2', 'x3'])
sage: k([0,2,0,0])
```

If one wishes to use a polynomial ring as coefficients for the key polynomials, pass the keyword argument `poly_coeffs=True`:

```
sage: k = KeyPolynomials(QQ['q'], poly_coeffs=True)
sage: R = k.base_ring(); R
Univariate Polynomial Ring in q over Rational Field
sage: R.inject_variables()
Defining q
sage: (q^2 + q + 1)*k([0,2,2,0,3,2])
(q^2+q+1)*k[0, 2, 2, 0, 3, 2]
```

**Element**

With `Element` alias of `KeyPolynomial`.

**degree_on_basis(alpha)**

Return the degree of the basis element indexed by `alpha`.

**from_polynomial(f)**

Expand a polynomial in terms of the key basis.

**EXAMPLES:**

```
sage: k = KeyPolynomials(QQ)
sage: k.from_polynomial(k(c).expand())
```

(continues on next page)
from_schubert_polynomial(s)

Expand a Schubert polynomial in the key basis.

EXAMPLES:

```python
sage: k = KeyPolynomials(ZZ)
sage: X = SchubertPolynomialRing(ZZ)
```

```python
sage: f = X([2,1,5,4,3])
```

```python
sage: k.from_schubert_polynomial(f)
k[1, 0, 2, 1] + k[2, 0, 2] + k[3, 0, 0, 1]
```

```python
sage: k.from_schubert_polynomial(2)
2*k[]
```

```python
sage: k = KeyPolynomials(GF(7), 4)
```

```python
sage: k.from_schubert_polynomial(f)
k[1, 0, 2, 1] + k[2, 0, 2, 0] + k[3, 0, 0, 1]
```

one_basis()

Return the basis element indexing the identity.

EXAMPLES:

```python
sage: k = KeyPolynomials(QQ)
```

```python
sage: k.one_basis()
[]
```

```python
sage: k = KeyPolynomials(QQ, 4)
```

```python
sage: k.one_basis()
[0, 0, 0, 0]
```

poly_gens()

Return the polynomial generators for the polynomial ring associated to self.

EXAMPLES:

```python
sage: k = KeyPolynomials(QQ)
```

```python
sage: k.poly_gens()
(z_0, z_1, z_2, z_3)
```

polynomial_ring()

Return the polynomial ring associated to self.
EXAMPLES:

```python
sage: k = KeyPolynomials(QQ)
sage: k.polynomial_ring()
Infinite polynomial ring in z over Rational Field
sage: k = KeyPolynomials(QQ, 4)
sage: k.polynomial_ring()
Multivariate Polynomial Ring in z_0, z_1, z_2, z_3 over Rational Field
```

```python
sage.combinat.key_polynomial.divided_difference(f, i)
Apply the i-th divided difference operator to the polynomial f.
```

EXAMPLES:

```python
sage: from sage.combinat.key_polynomial import divided_difference
sage: k = KeyPolynomials(QQ)
sage: z = k.poly_gens()
sage: divided_difference(f, 3)
   z_3^2*z_1 + z_3*z_2*z_1 + z_2^2*z_1
sage: k = KeyPolynomials(QQ, 4)
sage: z = k.poly_gens()
sage: divided_difference(f, 3)
   z_1*z_2^2 + z_1*z_2*z_3 + z_1*z_3^2
sage: k = KeyPolynomials(QQ)
sage: R = k.polynomial_ring(); R
Infinite polynomial ring in z over Rational Field
sage: z = R.gen()
sage: divided_difference(z[1]*z[2]^3, 2)
   -z_2^2*z_1 - z_2*z_1^2

   0
sage: divided_difference(z[1]*z[2]*z[3], 4)
   z_1*z_2
sage: divided_difference(z[1]*z[2]*z[4], 4)
   -z_1*z_2
```
w may be either a single index or a list of indices of simple transpositions.

**Warning:** The simple transpositions should be applied from left to right.

**EXAMPLES:**

```python
sage: from sage.combinat.key_polynomial import isobaric_divided_difference as idd
sage: R.<z> = InfinitePolynomialRing(GF(3))
```
```
0
z_4^2*z_3*z_2^2*z_1^4 + z_4*z_3*z_2^2*z_1^4
sage: idd(z[1]^4*z[2]^2*z[3]*z[4], [3, 4])
z_4^2*z_3*z_2^2*z_1^4 + z_4*z_3^2*z_2^2*z_1^4
sage: idd(z[1]^4*z[2]^2*z[3]*z[4], [4, 3])
z_4^2*z_3^2*z_2^2*z_1^4 + z_4*z_3*z_2^2*z_1^4
sage: idd(z[1]^2*z[2], [3, 2])
z_3^2 + z_3*z_2 + z_3*z_2^2 + z_2^2*z_1 + z_2*z_1^2
```

`sage.combinat.key_polynomial.sorting_word(alpha)`

Get a reduced word for the permutation which sorts alpha into a partition.

The result is a list \( l = [i_0, i_1, i_2, \ldots] \) where each \( i_j \) is a positive integer such that it applies the simple transposition \((i_j, i_j + 1)\). The transpositions are applied starting with \( i_0 \), then \( i_1 \) is applied, followed by \( i_2 \), and so on. See `sage.combinat.permutation.Permutation.reduced_words()` for the convention used.

**EXAMPLES:**

```python
sage: IV = IntegerVectors()
```
```
sage: from sage.combinat.key_polynomial import sorting_word
sage: list(sorting_word(IV([2,3,2]))[0])
[1]
sage: list(sorting_word(IV([2,3,2]))[1])
[3, 2]
sage: list(sorting_word(IV([5,6,7]))[0])
[1, 2, 1]
sage: list(sorting_word(IV([0,3,2]))[0])
[2, 1]
sage: list(sorting_word(IV([0,3,0,2]))[0])
[2, 3, 1]
sage: list(sorting_word(IV([3,2,1]))[0])
[]
sage: list(sorting_word(IV([2,3,3]))[0])
[2, 1]
```
5.1.133 Knutson-Tao Puzzles

This module implements a generic algorithm to solve Knutson-Tao puzzles. An instance of this class will be callable: the arguments are the labels of north-east and north-west sides of the puzzle boundary; the output is the list of the fillings of the puzzle with the specified pieces.

Acknowledgements

This code was written during Sage Days 45 at ICERM with Franco Saliola, Anne Schilling, and Avinash Dalal in discussions with Allen Knutson. The code was tested afterwards by Liz Beazley and Ed Richmond.

Todo: Functionality to add:

- plotter will not plot edge labels higher than 2; e.g. in BK puzzles, the labels are 1, ..., n and so in 3-step examples, none of the edge labels with 3 appear
- we should also have a 3-step puzzle pieces constructor, taken from p22 of arXiv math/0610538
- implement the bijection from puzzles to tableaux; see for example R. Vakil, A geometric Littlewood-Richardson rule, arXiv math/0302294 or K. Purbhoo, Puzzles, Tableaux and Mosaics, arXiv 0705.1184.

sage.combinat.knutson_tao_puzzles.BK_pieces(max_letter)

The puzzle pieces used in computing the Belkale-Kumar coefficients for any partial flag variety in type $A$.

There are two types of puzzle pieces:

- a triangle, with each edge labeled with the same letter;
- a rhombus, with edges labeled $i, j, i, j$ in clockwise order with $i > j$.

Each of these is rotated by 60 degrees, but not reflected.

We model the rhombus pieces as two triangles: a delta piece north-west label $i$, north-east label $j$ and south label $i(j)$; and a nabla piece with south-east label $i$, south-west label $j$ and north label $i(j)$.

INPUT:

- max_letter – positive integer specifying the number of steps in the partial flag variety, equivalently, the number of elements in the alphabet for the edge labels. The smallest label is 1.

REFERENCES:

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import BK_pieces
sage: BK_pieces(3)
Nablas : [1\1/1, 1\2(1)/2, 1\3(1)/3, 2(1)/2\1, 2\1/2(1), 2\2/2, 2\3(2)/3, 3(1)/3\1, ˓→3(2)/3\2, 3\1/3(1), 3\2/3(2), 3\3/3]
Deltas : [1/1\1, 1/2\2(1), 1/3\3(1), 2(1)/1\2, 2\1/2(1), 2\2/2, 2\3(2)/3, 3(1)/1\3, ˓→3(2)/2\3, 3\3(1)/1, 3\3(2)/2, 3\3/3]
```

class sage.combinat.knutson_tao_puzzles.DeltaPiece(south, north_west, north_east)

Bases: PuzzlePiece

Delta Piece takes as input three labels, inputted as strings. They label the South, Northwest and Northeast edges, respectively.

EXAMPLES:
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: DeltaPiece('a', 'b', 'c')
b/a\c

clockwise_rotation()

Rotate the Delta piece by 120 degree clockwise.

OUTPUT:

• Delta piece

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('1', '2', '3')
sage: delta.clockwise_rotation()
1/3\2

edges()

Return the tuple of edge names.

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('1', '2', '3')
sage: delta.edges()
('south', 'north_west', 'north_east')

half_turn_rotation()

Rotate the Delta piece by 180 degree.

OUTPUT:

• Nabla piece

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('1', '2', '3')
sage: delta.half_turn_rotation()
3\1/2

sage.combinat.knutson_tao_puzzles.HT_grassmannian_pieces()

Define the puzzle pieces used in computing the torus-equivariant cohomology of the Grassmannian.

REFERENCES:

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import HT_grassmannian_pieces
sage: HT_grassmannian_pieces()
Nablas : [0/0, 0/10, \[10/1, 1/10, 1/1, 1/T0|1/0]
Deltas : [0/0\0, 0/10, 0/T0|1/1, 1/10\0, 1/1, 10/0\1]

sage.combinat.knutson_tao_puzzles.HT_two_step_pieces()

Define the puzzle pieces used in computing the equivariant two step puzzle pieces.

For the puzzle pieces, see Figure 26 on page 22 of [CoskunVakil06].
REFERENCES:

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import HT_two_step_pieces
sage: HT_two_step_pieces()
Nablas : [(21)0/21, 0\21/0, 0\21/0, 0\0/0, 0\10/1, 0\20/2, 10\1/0, 10\2(10)/2,
1\0/10, 1\1/1, 1\2/2, 1\T0|1/0, 2\(10)/2, 20\2/0, 2\T0|2\0, 2\T0|2\2, 2\T1|2/1]
Deltas : [(21)0/0\21, 0/0\0, 0/1\10, 0/21\2(10), 0/2\20, 0/T0|1\1, 0/T0|2\1, 0/ →
T0|2]\2, 1/10\0, 1/1\1, 1/2\21, 1/T1|2\2, 10\0/1, 10\2\2(10), 10/T10|2\21, 10/T10|2\21, →
2(10)/10\2, 2/2(10)|10, 2/20\0, 2/21\2, 20/0\2, 21/(21)0\0, 21/1\2]
```

```
sage.combinat.knutson_tao_puzzles.H_grassmannian_pieces()
Define the puzzle pieces used in computing the cohomology of the Grassmannian.

REFERENCES:

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import H_grassmannian_pieces
sage: H_grassmannian_pieces()
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

```
sage.combinat.knutson_tao_puzzles.H_two_step_pieces()
Define the puzzle pieces used in two step flags.

This rule is currently only conjecturally true. See [BuchKreschTamvakis03].

REFERENCES:

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import H_two_step_pieces
sage: H_two_step_pieces()
Nablas : [(21)0/21, 0\21/0, 0\21/0, 0\0/0, 0\10/1, 0\20/2, 10\1/0, 10\2(10)/2,
1\0/10, 1\1/1, 1\2/2, 2(10)\2/10, 20\2/0, 2\0/2(10), 21\2/1, 2\0/20, 2\1/21, 2\10/2(10), 2\2/2]
Deltas : [(21)0/0\21, 0/0\0, 0/1\10, 0/21\2(10), 0/2\20, 10\1/0, 1\1/1, 2\2/1, 10/ →
0\1, 10\2\2(10), 2\10/10\2, 2/2(10)|10, 2/20\0, 2/21\2, 20/0\2, 21/(21)0\0, 21/1\2]
```

```
sage.combinat.knutson_tao_puzzles.K_grassmannian_pieces()
Define the puzzle pieces used in computing the K-theory of the Grassmannian.

REFERENCES:

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import K_grassmannian_pieces
sage: K_grassmannian_pieces()
Nablas : [0\0/0, 0\10/1, 0\K/1, 10\1/0, 1\0/10, 1\0/K, 1\1/1, K\1/0]
Deltas : [0/0\0, 0/1\10, 1/0/10, 1/1/1, 10/0/1, K/K/K]
```

class sage.combinat.knutson_tao_puzzles.KnutsonTaoPuzzleSolver(puzzle_pieces)
    Bases: UniqueRepresentation

Return puzzle solver function used to create all puzzles with given boundary conditions.

This class implements a generic algorithm to solve Knutson-Tao puzzles. An instance of this class will be
callable: the arguments are the labels of north-east and north-west sides of the puzzle boundary; the output is the
list of the fillings of the puzzle with the specified pieces.

INPUT:

• puzzle_pieces – takes either a collection of puzzle pieces or a string indicating a pre-programmed col-
  lection of puzzle pieces:
    – H – cohomology of the Grassmannian
    – HT – equivariant cohomology of the Grassmannian
    – K – K-theory
    – H2step – cohomology of the 2-step Grassmannian
    – HT2step – equivariant cohomology of the 2-step Grassmannian
    – BK – Belkale-Kumar puzzle pieces
• max_letter – (default: None) None or a positive integer. This is only required only for Belkale-Kumar
  puzzles.

EXAMPLES:

Each puzzle piece is an edge-labelled triangle oriented in such a way that it has a south edge (called a delta piece)
or a north edge (called a nabla piece). For example, the puzzle pieces corresponding to the cohomology of the
Grassmannian are the following:

```sage
from sage.combinat.knutson_tao_puzzles import H_grassmannian_pieces
sage: H_grassmannian_pieces()
Nablas : [0\0/0, 0\1/1, 1\0/10, 1\1/0, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

In the string representation, the nabla pieces are depicted as c\a/b, where a is the label of the north edge, b is
the label of the south-east edge, c is the label of the south-west edge. A similar string representation exists for
the delta pieces.

To create a puzzle solver, one specifies a collection of puzzle pieces:

```sage
KnutsonTaoPuzzleSolver(H_grassmannian_pieces())
Knutson-Tao puzzle solver with pieces:
Nablas : [0\0/0, 0\1/10, 1\0/10, 1\1/0, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

The following shorthand to create the above puzzle solver is also supported:

```sage
KnutsonTaoPuzzleSolver('H')
Knutson-Tao puzzle solver with pieces:
Nablas : [0\0/0, 0\1/10, 1\0/10, 1\1/0, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

The solver will compute all fillings of the puzzle with the given puzzle pieces. The user specifies the labels of
north-east and north-west sides of the puzzle boundary and the output is a list of the fillings of the puzzle with
the specified pieces. For example, there is one solution to the puzzle whose north-west and north-east edges are both labeled ‘0’:

```
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: ps('0', '0')
[[{(1, 1): 0/0\0}]]
```

There are two solutions to the puzzle whose north-west and north-east edges are both labeled ‘0101’:

```
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: solns = ps('0101', '0101')
sage: len(solns)
2
sage: solns.sort(key=str)
sage: solns
[[{(1, 1): 0/0\0,
   (1, 2): 1/\0 0\/1,
   (1, 3): 0\/0 0\/0,
   (1, 4): 1\/0 0\/1,
   (2, 2): 1/1\1,
   (2, 3): 0\/10 1\/1,
   (2, 4): 1/1 10\/0,
   (3, 3): 1/1\1,
   (3, 4): 0\/0 1\/10,
   (4, 4): 10/0\1}, {(1, 1): 0/1\10,
   (1, 2): 1\/1 10\/0,
   (1, 3): 0\/0 1\/10,
   (1, 4): 1\/0 0\/1,
   (2, 2): 0/0\0,
   (2, 3): 10/\1 0\/0,
   (2, 4): 1/1 1\/1,
   (3, 3): 0/0\0,
   (3, 4): 1/0 0\/1,
   (4, 4): 1/1\1}]
```

The pieces in a puzzle filling are indexed by pairs of non-negative integers \((i, j)\) with \(1 \leq i \leq j \leq n\), where \(n\) is the length of the word labelling the triangle edge. The pieces indexed by \((i, i)\) are the triangles along the south edge of the puzzle.

```
sage: f = solns[0]
sage: [f[i, i] for i in range(1,5)]
[0/0\0, 1/1\1, 1/1\1, 10/0\1]
```

The pieces indexed by \((i, j)\) for \(j > i\) are a pair consisting of a delta piece and nabla piece glued together along the south edge and north edge, respectively (these pairs are called rhombi).

```
sage: f = solns[0]
sage: f[1, 2]
1/\0 0\/1
```

There are various methods and options to display puzzle solutions. A single puzzle can be displayed using the plot method of the puzzle:
To plot several puzzle solutions, use the plot method of the puzzle solver:

```python
sage: ps = KnutsonTaoPuzzleSolver('K')
sage: solns = ps('0101', '0101')
sage: ps.plot(solns)  # not tested
```

The code can also generate a PDF of a puzzle (using LaTeX and `tikz`):

```python
sage: latex.extra_preamble(r'''
\usepackage{tikz}''')
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: solns = ps('0101', '0101')
sage: view(solns[0], viewer='pdf')  # not tested
```

Below are examples of using each of the currently supported puzzles.

Cohomology of the Grassmannian:

```python
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: solns = ps('0101', '0101')
sage: sorted(solns, key=str)
[[(1, 1): 0/0\0, (1, 2): 1\0 0\1, (1, 3): 0\0 0/0, (1, 4): 1\0 0\1, (2, 2): 1/1\1, (2, 3): 0\10 1\1, (2, 4): 1\1 10\/0, (3, 3): 1/1\1, (3, 4): 0\0 1\10, (4, 4): 10/0\1}, {(1, 1): 0/1\10, (1, 2): 1\1 10\/0, (1, 3): 0\0 1\10, (1, 4): 1\0 0\1, (2, 2): 0/0\0, (2, 3): 10/1 0\/0, (2, 4): 1\1 1\1, (3, 3): 0\0\0, (3, 4): 1\0 0\1, (4, 4): 1/1\1}]
```

Equivariant puzzles:

```python
sage: ps = KnutsonTaoPuzzleSolver('HT')
sage: solns = ps('0101', '0101')
sage: sorted(solns, key=str)
[[(1, 1): 0/0\0, (1, 2): 1\0 0\1, (1, 3): 0/0 0\0, (1, 4): 1\0 0\1, (2, 2): 1/1\1, (2, 3): 0\10 1\1, (2, 4): 1\1 10\/0, (3, 3): 1/1\1, (3, 4): 0\0 1\10, (4, 4): 10/0\1}, {(1, 1): 0/1\10, (1, 2): 1\1 10\/0, (1, 3): 0\0 1\10, (1, 4): 1\0 0\1, (2, 2): 0/0\0, (2, 3): 10/1 0\/0, (2, 4): 1\1 1\1, (3, 3): 0\0\0, (3, 4): 1\0 0\1, (4, 4): 1/1\1}]
```

(continues on next page)
(1, 4): 1\0 0\1,
(2, 2): 1/1\1,
(2, 3): 0\1 1\0,
(2, 4): 1/1 1\1,
(3, 3): 0\0\0,
(3, 4): 1\0 0\1,
(4, 4): 1/1\1}, {(1, 1): 0/0\0,
(1, 2): 1\0 0\1,
(1, 3): 0\0 0\0,

Belkale-Kumar puzzles (the following example is Figure 2 of [KnutsonPurbhoo10]):

```
sage: ps = KnutsonTaoPuzzleSolver('BK', 3)
sage: solns = ps('12132', '23112')
```
sage: len(solns)
1
sage: solns[0].south_labels()
('3', '2', '1', '2', '1')

sage: solns
[[(1, 1): 1/3\3(1),
  (1, 2): 2\3(2) 3(1)\1,
  (1, 3): 1/3(1) 3(2)\2,
  (1, 4): 3\3 3(1)\1,
  (1, 5): 2\2 3\3(2),
  (2, 2): 1/2\2(1),
  (2, 3): 2\2 2(1)\1,
  (2, 4): 1/2(1) 2\2,
  (2, 5): 3(2)/3 2(1)\1,
  (3, 3): 1/1\1,
  (3, 4): 2\1 1\2,
  (3, 5): 1/1 1/1,
  (4, 4): 2\2,]

plot(puzzles)

Return plot of puzzles.

INPUT:

  • puzzles – list of puzzles

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver('K')
```

```python
sage: solns = ps('0101', '0101')
sage: ps.plot(solns)  # not tested
```

puzzle_pieces()

The puzzle pieces used for filling in the puzzles.

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: ps.puzzle_pieces()
```

```python
Nablas : [\0/0/0, \0/10/1, 10\1/0, 1/0/10, 1/1/1]
Deltas : [\0/0/0, \0/1/10, 1/10\0, 1/1\1, 10/0\1]
```

solutions(lambda, mu, algorithm='strips')

structure_constants(lambda, mu, nu=None)

Compute cohomology structure coefficients from puzzles.

INPUT:

  • pieces – puzzle pieces to be used
  • lambda, mu – edge labels of puzzle for northwest and north east side
• nu – (default: None) If nu is not specified a dictionary is returned with the structure coefficients corresponding to all south labels; if nu is given, only the coefficients with the specified label is returned.

OUTPUT: dictionary

EXAMPLES:

Note: In order to standardize the output of the following examples, we output a sorted list of items from the dictionary instead of the dictionary itself.

Grassmannian cohomology:

```python
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: cp = ps.structure_constants('0101', '0101')
sage: sorted(cp.items(), key=str)
[(('0', '1', '1', '0'), 1), (('1', '0', '0', '1'), 1)]
```

Equivariant cohomology:

```python
sage: ps = KnutsonTaoPuzzleSolver('HT')
sage: cp = ps.structure_constants('0101', '0101')
sage: sorted(cp.items(), key=str)
[(('0', '1', '1', '0'), y2 - y3),
 ('(1', '0', '0', '1'), 1),
 ('(1', '0', '0', '1'), 1)]
```

K-theory:

```python
sage: ps = KnutsonTaoPuzzleSolver('K')
sage: cp = ps.structure_constants('0101', '0101')
sage: sorted(cp.items(), key=str)
[(('0', '1', '1', '0'), 1), (('1', '0', '0', '1'), 1), (('1', '0', '0', '1'), -1)]
```

Two-step:

```python
sage: ps = KnutsonTaoPuzzleSolver('H2step')
sage: cp = ps.structure_constants('01122', '01122')
sage: sorted(cp.items(), key=str)
[(('0', '1', '1', '0'), 1),
 ('(1', '2', '0', '1'), 1),
 ('(1', '2', '0', '1'), 1)]
```

Two-step equivariant:

```python
sage: ps = KnutsonTaoPuzzleSolver('HT2step')
sage: cp = ps.structure_constants('10212', '12012')
sage: sorted(cp.items(), key=str)
[(('1', '2', '0', '1', '2'), y1*y2 - y2*y3 - y1*y4 + y3*y4),
 ('(1', '2', '0', '2', '1'), y1 - y3),
 ('(1', '2', '0', '2', '1'), y2 - y4),
 (continues on next page)
```
class sage.combinat.knutson_tao_puzzles.NablaPiece(north, south_east, south_west)

Bases: PuzzlePiece

Nabla Piece takes as input three labels, inputted as strings. They label the North, Southeast and Southwest edges, respectively.

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: NablaPiece('a','b','c')
c/a/b

clockwise_rotation()

Rotate the Nabla piece by 120 degree clockwise.

OUTPUT:

• Nabla piece

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: nabla = NablaPiece('1','2','3')
sage: nabla.clockwise_rotation()
2\3/1

edges()

Return the tuple of edge names.

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: nabla = NablaPiece('1','2','3')
sage: nabla.edges()
('north', 'south_east', 'south_west')

half_turn_rotation()

Rotate the Nabla piece by 180 degree.

OUTPUT:

• Delta piece

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: nabla = NablaPiece('1','2','3')
sage: nabla.half_turn_rotation()
2/1\3
class sage.combinat.knutson_tao_puzzles.PuzzleFilling(north_west_labels, north_east_labels)
    Bases: object

    Create partial puzzles and provides methods to build puzzles from them.

    add_piece(piece)
        Add piece to partial puzzle.

        EXAMPLES:
        sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
        sage: piece = DeltaPiece('0', '1', '0')
        sage: P = PuzzleFilling('0101', '0101'); P
        {}
        sage: P.add_piece(piece); P
        {(1, 4): 1/0\0}

    add_pieces(pieces)
        Add piece to partial puzzle.

        INPUT:
        • pieces – tuple of pieces

        EXAMPLES:
        sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
        sage: piece = DeltaPiece('0', '1', '0')
        sage: pieces = [piece, piece]
        sage: P.add_pieces(pieces)
        sage: P
        {(1, 4): 1/0\0, (2, 4): 1/0\0}

    contribution()
        Return equivariant contributions from self in polynomial ring.

        EXAMPLES:
        sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
        sage: ps = KnutsonTaoPuzzleSolver("HT")
        sage: puzzles = ps('0101', '1001')
        sage: sorted([p.contribution() for p in puzzles], key=str)
        [1, y1 - y3]

    copy()
        Return copy of self.

        EXAMPLES:
        sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
        sage: piece = DeltaPiece('0', '1', '0')
        sage: P = PuzzleFilling('0101', '0101'); P
        {}
        sage: PP = P.copy()
        sage: PP
        {}
        sage: P.add_piece(piece); P
        {(1, 4): 1/0\0}
Combinatorics, Release 10.0

{(1, 4): 1/0\0}

sage: PP
{}

is_completed()

Whether partial puzzle is complete (completely filled) or not.

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P.is_completed()
False

sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: puzzle = ps('0101','1001')[0]
sage: puzzle.is_completed()
True

is_in_south_edge()

Check whether kink coordinates of partial puzzle is in south corner.

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P.is_in_south_edge()
False

kink_coordinates()

Provide the coordinates of the kinks.

The kink coordinates are the coordinates up to which the puzzle has already been built. The kink starts in
the north corner and then moves down the diagonals as the puzzles is built.

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P
{}
{sage: P.kink_coordinates()
(1, 4)

north_east_label_of_kink()

Return north east label of kink.

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P.north_east_label_of_kink()
'0'
**north_west_label_of_kink()**

Return north-west label of kink.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101', '0101')
sage: P.north_west_label_of_kink()
'1'
```

**plot(labels=True, style='fill')**

Plot completed puzzle.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: puzzle = ps('0101', '1001')[0]
sage: puzzle.plot()  #not tested
sage: puzzle.plot(style='fill')  #not tested
sage: puzzle.plot(style='edges')  #not tested
```

**south_labels()**

Return south labels for completed puzzle.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: ps('0101', '1001')[0].south_labels()
('1', '0', '1', '0')
```

**class sage.combinat.knutson_tao_puzzles.PuzzlePiece**

Bases: object

Abstract class for puzzle pieces.

This abstract class contains information on how to test equality of puzzle pieces, and sets color and plotting options.

**border()**

Return the border of self.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('a', 'b', 'c')
sage: sorted(delta.border())
['a', 'b', 'c']
```

**color()**

Return the color of self.

EXAMPLES:
```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('a','b','c')
sage: delta.color()
'white'
sage: delta = DeltaPiece('0','0','0')
sage: delta.color()
'red'
sage: delta = DeltaPiece('1','1','1')
sage: delta.color()
'blue'
sage: delta = DeltaPiece('2','2','2')
sage: delta.color()
'green'
sage: delta = DeltaPiece('2','K','2')
sage: delta.color()
'orange'
sage: delta = DeltaPiece('2','T1/2','2')
sage: delta.color()
'yellow'
```

**edge_color**(edge)

Color of the specified edge of self (to be used when plotting the piece).

**edge_label**(edge)

Return the edge label of edge.

**class** `sage.combinat.knutson_tao_puzzles.PuzzlePieces` *(forbidden_border_labels=None)*

Bases: object

Construct a valid set of puzzle pieces.

This class constructs the set of valid puzzle pieces. It can take a list of forbidden border labels as input. These labels are forbidden from appearing on the south edge of a puzzle filling. The user can add valid nabla or delta
Combinatorics, Release 10.0

pieces and specify which rotations of these pieces are legal. For example, \texttt{rotations=0} does not add any additional pieces (only the piece itself), \texttt{rotations=60} adds six pieces (the pieces and its rotations by 60, 120, 180, 240, 300), etc..

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, NablaPiece
sage: forbidden_border_labels = ['10']
sage: pieces = PuzzlePieces(forbidden_border_labels)
sage: pieces.add_piece(NablaPiece('0','0','0'), rotations=60)
sage: pieces.add_piece(NablaPiece('1','1','1'), rotations=60)
sage: pieces.add_piece(NablaPiece('1','0','10'), rotations=60)
sage: pieces
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/\10, 1/10\0, 1/1\1, 10/0\1]
```

The user can obtain the list of valid rhombi pieces as follows:

```python
sage: sorted([p for p in pieces.rhombus_pieces()], key=str)
[0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1, 0\0/1, 1\1/1, 0\10/1, 1/10\0, 1/1\1, 10/0\1]
```

\texttt{add\_T\_piece(label1\textup{,} label2)}

Add a nabla and delta piece with \texttt{label1} and \texttt{label2}.

This method adds a nabla piece with edges \texttt{label2T``\textbackslash label1``\textbackslash label2``/ label1.} and a delta piece with edges \texttt{label1\textbackslash T``\textbackslash label1``\textbackslash label2`` label2.} It also adds \texttt{T``\textbackslash label1``\textbackslash label2``} to the forbidden list.

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces
sage: pieces = PuzzlePieces()
sage: pieces.add_T_piece('1', '3')
sage: pieces
Nablas : [3\T1\3/1]
Deltas : [1/T1\3/3]
sage: pieces._forbidden_border_labels
['T1\3']
```

\texttt{add\_forbidden\_label(label)}

Add forbidden border labels.

INPUT:

- \texttt{label} – string specifying a new forbidden label

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces
sage: pieces = PuzzlePieces()
sage: pieces.add_forbidden_label('1')
sage: pieces
Nablas : [\3\T1\3/1]
Deltas : [1/T1\3/3]
sage: pieces._forbidden_border_labels
['T1\3']
```

1346 Chapter 5. Comprehensive Module List
add_piece(piece, rotations=120)

Add piece to the list of pieces.

INPUT:

• piece – a nabla piece or a delta piece
• rotations – (default: 120) 0, 60, 120, 180

The user can add valid nabla or delta pieces and specify which rotations of these pieces are legal. For example, rotations=0 does not add any additional pieces (only the piece itself), rotations=60 adds six pieces (namely three delta and three nabla pieces), while rotations=120 adds only delta or nabla (depending on which piece self is). rotations=180 adds the piece and its 180 degree rotation, i.e. one delta and one nabla piece.

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: delta = DeltaPiece('a', 'b', 'c')
sage: pieces = PuzzlePieces()
sage: pieces.add_piece(delta)
sage: pieces
Nablas : []
Deltas : [a/c\b, b/a\c, c/b\a]

sage: pieces = PuzzlePieces()
sage: pieces.add_piece(delta, rotations=0)
sage: pieces
Nablas : []
Deltas : [b/a\c]

sage: pieces = PuzzlePieces()
sage: pieces.add_piece(delta, rotations=60)
sage: pieces
Nablas : [a\b/c, b/c/a, c/a/b]
Deltas : [a/c\b, b/a\c, c/b\a]
```

boundary_deltas()

Return deltas with south edges not in the forbidden list.

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: pieces = PuzzlePieces(['a'])
sage: delta = DeltaPiece('a', 'b', 'c')
sage: pieces.add_piece(delta, rotations=60)
sage: sorted([p for p in pieces.boundary_deltas()], key=str)
[a/c\b, c/b\a]
```

delta_pieces()

Return the delta pieces as a set.

EXAMPLES:
```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: pieces = PuzzlePieces()
sage: delta = DeltaPiece('a', 'b', 'c')
sage: pieces.add_piece(delta, rotations=60)
sage: sorted([p for p in pieces.delta_pieces()], key=str)
[a/c\b, b/a\c, c/b\a]
```

```
nabla_pieces()
Return the nabla pieces as a set.
EXAMPLES:
```
```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: pieces = PuzzlePieces()
sage: delta = DeltaPiece('a', 'b', 'c')
sage: pieces.add_piece(delta, rotations=60)
sage: sorted([p for p in pieces.nabla_pieces()], key=str)
[a\b/c, b\c/a, c\a/b]
```

```
rhombus_pieces()
Return a set of all allowable rhombus pieces.
Allowable rhombus pieces are those where the south edge of the delta piece equals the north edge of the
nabla piece.
EXAMPLES:
```
```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: pieces = PuzzlePieces()
sage: delta = DeltaPiece('a', 'b', 'c')
sage: pieces.add_piece(delta, rotations=60)
sage: sorted([p for p in pieces.rhombus_pieces()], key=str)
[a/b\c, b\c/a, c\a/b]
```

```
class sage.combinat.knutson_tao_puzzles.RhombusPiece(north_piece, south_piece)
Bases: PuzzlePiece
Class of rhombi pieces.
To construct a rhombus piece we input a delta and a nabla piece. The delta and nabla pieces are joined along the
south and north edge, respectively.
EXAMPLES:
```
```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,
...RhombusPiece
sage: delta = DeltaPiece('1', '2', '3')
sage: nabla = NablaPiece('4', '5', '6')
sage: RhombusPiece(delta, nabla)
2\3 6\5
```
```
edges()
Return the tuple of edge names.
EXAMPLES:
```
```python
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,
    RhombusPiece
sage: delta = DeltaPiece('1', '2', '3')
```

```python
sage: nabla = NablaPiece('4', '5', '6')
```

```python
sage: RhombusPiece(delta, nabla).edges()
('north_west', 'north_east', 'south_east', 'south_west')
```

**north_piece()**

Return the north piece.

**EXAMPLES:**

```python
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,
    RhombusPiece
sage: delta = DeltaPiece('1', '2', '3')
```

```python
sage: nabla = NablaPiece('4', '5', '6')
```

```python
sage: r = RhombusPiece(delta, nabla)
```

```python
sage: r.north_piece()
```

```latex
\frac{2}{1} \frac{3}{1}
```

**south_piece()**

Return the south piece.

**EXAMPLES:**

```python
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,
    RhombusPiece
sage: delta = DeltaPiece('1', '2', '3')
```

```python
sage: nabla = NablaPiece('4', '5', '6')
```

```python
sage: r = RhombusPiece(delta, nabla)
```

```python
sage: r.south_piece()
```

```latex
\frac{6}{4} \frac{5}{5}
```

### 5.1.134 Combinatorics on matrices

- *Dancing Links internal pxy code*
- *Dancing links C++ wrapper*
- *Hadamard matrices*
- *Latin Squares*

### 5.1.135 Dancing Links internal pxy code

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0, 1, 2], [3, 4, 5], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
```

```python
sage: x = dlx_solver(rows)
```

```python
sage: x
```

```
Dancing links solver for 6 columns and 6 rows
```

The number of solutions:
sage: x.number_of_solutions()
3

Iterate over the solutions:

```python
sage: sorted(map(sorted, x.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

All solutions (computed in parallel):

```python
sage: sorted(map(sorted, x.all_solutions()))
[[0, 1], [2, 3], [4, 5]]
```

Return the first solution found when the computation is done in parallel:

```python
sage: sorted(x.one_solution(ncpus=2)) # random
[0, 1]
```

Find all solutions using some specific rows:

```python
sage: x_using_row_2 = x.restrict([2])
sage: x_using_row_2
Dancing links solver for 7 columns and 6 rows
sage: sorted(map(sorted, x_using_row_2.solutions_iterator()))
[[2, 3]]
```

The two basic methods that are wrapped in this class are `search` which returns 1 if a solution is found or 0 otherwise and `get_solution` which return the current solution:

```python
sage: x = dlx_solver(rows)
sage: x.search()
1
sage: x.get_solution()
[0, 1]
sage: x.search()
1
sage: x.get_solution()
[2, 3]
sage: x.search()
1
sage: x.get_solution()
[4, 5]
sage: x.search()
0
```

There is also a method `reinitialize` to reinitialize the algorithm:

```python
sage: x.reinitialize()
sage: x.search()
1
sage: x.get_solution()
[0, 1]
```

```python
class sage.combinat.matrices.dancing_links.dancing_linksWrapper
   Bases: object
```
A simple class that implements dancing links.

The main methods to list the solutions are `search()` and `get_solution()`. You can also use `number_of_solutions()` to count them.

This class simply wraps a C++ implementation of Carlo Hamalainen.

**all_solutions**(ncpus=None, column=None)

Return all solutions found after splitting the problem to allow parallel computation.

**INPUT:**

- ncpus – integer (default: None), maximal number of subprocesses to use at the same time. If None, it detects the number of effective CPUs in the system using `sage.parallel.ncpus.ncpus()`.
- column – integer (default: None), the column used to split the problem, if None a random column is chosen

**OUTPUT:**

list of solutions

**EXAMPLES:**

```sage
def dlx_solver(rows):
    d = dlx_solver(rows)
    S = d.all_solutions()
    return sorted(sorted(s) for s in S)

dlx = dlx_solver(result)
dlx
Dancing links solver for 4 columns and 16 rows
dlx.number_of_solutions()
15
dlx.sorted(sorted(s) for s in dlx.all_solutions(ncpus=2))
[[1, 2, 3, 4],
 [1, 2, 10],
 [1, 3, 9],
 [1, 4, 8],
 [1, 14],
 [2, 3, 7],
 [2, 4, 6],
 [2, 13],
 [3, 4, 5],
 [3, 12],
 [4, 11],
 [5, 10],
 [6, 9],
 [7, 8],
 [15]]
```

If ncpus=1, the computation is not done in parallel:
get_solution()

Return the current solution.

After a new solution is found using the method search() this method return the rows that make up the current solution.

ncols()

Return the number of columns.

EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[[0,1,2], [1,2], [0], [3,4,5]]
```
OUTPUT:

integer

EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2]]
sage: rows += [[0,2]]
sage: rows += [[1]]
sage: rows += [[3]]
sage: x = dlx_solver(rows)
sage: x.number_of_solutions()
2
```

The number of CPUs can be specified as input:

```python
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: x = dlx_solver(rows)
sage: x.number_of_solutions(ncpus=2, column=3)
3
```

```python
sage: S = Subsets(range(5))
sage: rows = map(list, S)
sage: d = dlx_solver(rows)
sage: d.number_of_solutions()
52
```

```python
one_solution(ncpus=None, column=None)

Return the first solution found.

This method allows parallel computations which might be useful for some kind of problems when it is very hard just to find one solution.

INPUT:

• ncpus – integer (default: None), maximal number of subprocesses to use at the same time. If None, it detects the number of effective CPUs in the system using `sage.parallel.ncpus.ncpus()`. If ncpus=1, the first solution is searched serially.

• column – integer (default: None), the column used to split the problem (see `restrict()`). If None, a random column is chosen. This argument is ignored if ncpus=1.

OUTPUT:

list of rows or None if no solution is found

Note: For some case, increasing the number of cpus makes it faster. For other instances, ncpus=1 is faster. It all depends on problem which is considered.

EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: solutions = [[0,1], [2,3], [4,5]]
```

The number of CPUs can be specified as input:

```python
sage: sorted(d.one_solution(ncpus=2)) in solutions
True
```

The column used to split the problem for parallel computations can be given:

```python
sage: sorted(d.one_solution(ncpus=2, column=4)) in solutions
True
```

When no solution is found:

```python
sage: rows = [[0,1,2], [2,3,4,5], [0,1,2,3]]
sage: d = dlx_solver(rows)
sage: d.one_solution() is None
True
```

**one_solution_using_milp_solver**(*solver=None, integrality_tolerance=0.001*)

Return a solution found using a MILP solver.

**INPUT:**

- solver – string or None (default: None), possible values include 'GLPK', 'GLPK/exact', 'Coin', 'CPLEX', 'Gurobi', 'CVXOPT', 'PPL', 'InteractiveLP'.

**OUTPUT:**

list of rows or None if no solution is found

**Note:** When comparing the time taken by method one_solution, have in mind that one_solution_using_milp_solver first creates (and caches) the MILP solver instance from the dancing links solver. This copy of data may take many seconds depending on the size of the problem.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: solutions = [[0,1], [2,3], [4,5]]
sage: d.one_solution_using_milp_solver() in solutions
True
```

Using optional solvers:

```python
sage: s = d.one_solution_using_milp_solver('gurobi') # optional - gurobi sage_numerical_backends_gurobi
sage: s in solutions # optional - gurobi sage_numerical_backends_gurobi
True
```

When no solution is found:
sage: rows = [[0,1,2], [2,3,4,5], [0,1,2,3]]
sage: d = dlx_solver(rows)
sage: d.one_solution_using_milp_solver() is None
True

one_solution_using_sat_solver(solver=None)

Return a solution found using a SAT solver.

INPUT:

• solver – string or None (default: None), possible values include 'picosat', 'cryptominisat', 'LP', 'glucose', 'glucose-syrup'.

OUTPUT:

list of rows or None if no solution is found

Note: When comparing the time taken by method one_solution, have in mind that one_solution_using_sat_solver first creates the SAT solver instance from the dancing links solver. This copy of data may take many seconds depending on the size of the problem.

EXAMPLES:

sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: solutions = [[0,1], [2,3], [4,5]]
sage: d.one_solution_using_sat_solver() in solutions
True

Using optional solvers:

sage: s = d.one_solution_using_sat_solver('glucose') # optional - glucose
sage: s in solutions # optional - glucose
True

When no solution is found:

sage: rows = [[0,1,2], [2,3,4,5], [0,1,2,3]]
sage: d = dlx_solver(rows)
sage: d.one_solution_using_sat_solver() is None
True

reinitialize()

Reinitialization of the search algorithm

This recreates an empty dancing_links object and adds the rows to the instance of dancing_links.

EXAMPLES:

sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: x = dlx_solver(rows)
sage: x.get_solution() if x.search() else None
[0, 1]
Reinitialization of the algorithm:

```python
sage: x.reinitialize()
sage: x.get_solution() if x.search() else None
[0, 1]
sage: x.get_solution() if x.search() else None
[2, 3]
sage: x.get_solution() if x.search() else None
[4, 5]
sage: x.get_solution() if x.search() else None
```

Reinitialization works after solutions are exhausted:

```python
sage: x.reinitialize()
sage: x.get_solution() if x.search() else None
[0, 1]
sage: x.get_solution() if x.search() else None
[2, 3]
sage: x.get_solution() if x.search() else None
[4, 5]
sage: x.get_solution() if x.search() else None
```

\texttt{restrict(indices)}

Return a dancing links solver solving the subcase which uses some given rows.

For every row that is wanted in the solution, we add a new column to the row to make sure it is in the solution.

INPUT:

\begin{itemize}
\item \texttt{indices} – list, row indices to be found in the solution
\end{itemize}

OUTPUT:

dancing links solver

EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: d
Dancing links solver for 6 columns and 6 rows
sage: sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

To impose that the 0th row is part of the solution, the rows of the new problem are:

```python
sage: d_using_0 = d.restrict([0])
sage: d_using_0
Dancing links solver for 7 columns and 6 rows
sage: d_using_0.rows()
[[0, 1, 2, 6], [3, 4, 5], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
```
After restriction the subproblem has one more columns and the same number of rows as the original one:

```
sage: d.restrict([1]).rows()
[[0, 1, 2], [3, 4, 5, 6], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
sage: d.restrict([2]).rows()
[[0, 1, 2], [3, 4, 5], [0, 1, 6], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
```

This method allows to find solutions where the 0th row is part of a solution:

```
sage: sorted(map(sorted, d.restrict([0]).solutions_iterator()))
[[0, 1]]
```

Some other examples:

```
sage: sorted(map(sorted, d.restrict([1]).solutions_iterator()))
[[0, 1]]
sage: sorted(map(sorted, d.restrict([2]).solutions_iterator()))
[[2, 3]]
sage: sorted(map(sorted, d.restrict([3]).solutions_iterator()))
[[2, 3]]
```

Here there are no solution using both 0th and 3rd row:

```
sage: list(d.restrict([0,3]).solutions_iterator())
[]
```

```
rows()
Return the list of rows.
EXAMPLES:
```
```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [1,2], [0]]
sage: x = dlx_solver(rows)
sage: x.rows()
[[0, 1, 2], [1, 2], [0]]
```

```
search()
Search for a new solution.
Return 1 if a new solution is found and 0 otherwise. To recover the solution, use the method get_solution().
EXAMPLES:
```
```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2]]
sage: rows+= [[0,2]]
sage: rows+= [[1]]
sage: rows+= [[3]]
sage: x = dlx_solver(rows)
sage: print(x.search())
1
sage: print(x.get_solution())
[3, 0]
```
solutions_iterator()
Return an iterator of the solutions.

EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
dsage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
dsage: d = dlx_solver(rows)
dsage: sorted(map(sorted, d.solutions_iterator()))
[[[0, 1], [2, 3], [4, 5]]
```

split(column)
Return a dict of independent solvers.

For each i-th row containing a 1 in the column, the dict associates the solver giving all solution using the i-th row.

This is used for parallel computations.

INPUT:
- column – integer, the column used to split the problem into independent subproblems

OUTPUT:
- dict where keys are row numbers and values are dlx solvers

EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
dsage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
dsage: d = dlx_solver(rows)
dsage: d
Dancing links solver for 6 columns and 6 rows

dsage: sorted(map(sorted, d.solutions_iterator()))
[[[0, 1], [2, 3], [4, 5]]
```

After the split each subproblem has one more column and the same number of rows as the original problem:

```python
sage: D = d.split(0)
dsage: D
{0: Dancing links solver for 7 columns and 6 rows, 2: Dancing links solver for 7 columns and 6 rows, 4: Dancing links solver for 7 columns and 6 rows}
```

The (disjoint) union of the solutions of the subproblems is equal to the set of solutions shown above:

```python
sage: for x in D.values(): sorted(map(sorted, x.solutions_iterator()))
[[[0, 1]]
[[2, 3]]
[[4, 5]]
```

to_milp(solver=None)
Return the mixed integer linear program (MILP) representing an equivalent problem.

See also sage.numerical.mip.MixedIntegerLinearProgram.

INPUT:
• solver – string or None (default: None), possible values include 'GLPK', 'GLPK/exact', 'Coin', 'CPLEX', 'Gurobi', 'CVXOPT', 'PPL', 'InteractiveLP'.

OUTPUT:
• MixedIntegerLinearProgram instance
• MIPVariable with binary components

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
dsage: rows = [[0,1,2], [0,2], [1], [3]]
dsage: d = dlx_solver(rows)
dsage: p,x = d.to_milp()
dsage: p
Boolean Program (no objective, 4 variables, ... constraints)
dsage: x
MIPVariable with 4 binary components
```

In the reduction, the boolean variable $x_i$ is True if and only if the $i$-th row is in the solution:

```
sage: p.show()
Maximization:

Constraints:...
  one 1 in 0-th column: 1.0 <= x_0 + x_1 <= 1.0
  one 1 in 1-th column: 1.0 <= x_0 + x_2 <= 1.0
  one 1 in 2-th column: 1.0 <= x_0 + x_1 <= 1.0
  one 1 in 3-th column: 1.0 <= x_3 <= 1.0

Variables:
  x_0 is a boolean variable (min=0.0, max=1.0)
  x_1 is a boolean variable (min=0.0, max=1.0)
  x_2 is a boolean variable (min=0.0, max=1.0)
  x_3 is a boolean variable (min=0.0, max=1.0)
```

Using some optional MILP solvers:

```
sage: d.to_milp('gurobi') # optional - gurobi sage_numerical_backends_gurobi
(Boolean Program (no objective, 4 variables, 4 constraints), MIPVariable with 4 binary components)
```

**to_sat_solver**(solver=None)

Return the SAT solver solving an equivalent problem.

Note that row index $i$ in the dancing links solver corresponds to the boolean variable index $i+1$ for the SAT solver to avoid the variable index 0.

See also *sage.sat.solvers.satsolver*.

INPUT:
• solver – string or None (default: None), possible values include 'picosat', 'cryptominisat', 'LP', 'glucose', 'glucose-syrup'.

OUTPUT:
SAT solver instance
**Examples:**

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [0,2], [1], [3]]
```

```python
sage: x = dlx_solver(rows)
```

```python
sage: s = x.to_sat_solver()
```

Using some optional SAT solvers:

```python
sage: x.to_sat_solver('cryptominisat')  # optional - pycryptosat
```

CryptoMiniSat solver: 4 variables, 7 clauses.

---

**sage.combinat.matrices.dancing_links.dlx_solver(rows)**

Internal-use wrapper for the dancing links C++ code.

**Examples:**

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2]]
```

```python
sage: rows+= [[0,2]]
```

```python
sage: rows+= [[1]]
```

```python
sage: rows+= [[3]]
```

```python
sage: x = dlx_solver(rows)
```

```python
sage: print(x.search())
```

```
1
```

```python
sage: print(x.get_solution())
```

```
[3, 0]
```

```python
sage: print(x.search())
```

```
1
```

```python
sage: print(x.get_solution())
```

```
[3, 1, 2]
```

```python
sage: print(x.search())
```

```
0
```

**sage.combinat.matrices.dancing_links.make_dlxwrapper(s)**

Create a dlx wrapper from a Python string s.

This was historically used in unpickling and is kept for backwards compatibility. We expect s to be dumps(rows) where rows is the list of rows used to instantiate the object.

---

**5.1.136 Dancing links C++ wrapper**

**sage.combinat.matrices.dlxcpp.AllExactCovers(M)**

Solves the exact cover problem on the matrix M (treated as a dense binary matrix).

**Examples:** No exact covers:

```python
sage: M = Matrix([[1,1,0], [1,0,1], [0,1,1]])
```

```python
sage: [cover for cover in AllExactCovers(M)]
```

```
[]
```

Two exact covers:
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]])
sage: [cover for cover in AllExactCovers(M)]

[[[1, 1, 0], (0, 0, 1)], [[1, 0, 1], (0, 1, 0)]]

sage.combinat.matrices.dlxcpp.DLXCPP(rows)
Solves the Exact Cover problem by using the Dancing Links algorithm described by Knuth.

Consider a matrix \( M \) with entries of 0 and 1, and compute a subset of the rows of this matrix which sum to the vector of all 1's.

The dancing links algorithm works particularly well for sparse matrices, so the input is a list of lists of the form:

\[
[ \\
[ i_{11}, i_{12}, \ldots, i_{1r} ] \\
\ldots \\
[ i_{m1}, i_{m2}, \ldots, i_{ms} ] \\
]
\]

where \( M[j][i_{jk}] = 1 \).

The first example below corresponds to the matrix:

\[
\begin{array}{cccc}
1 & 1 & 1 & 0 \\
1 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 \\
\end{array}
\]

which is exactly covered by:

\[
\begin{array}{cccc}
1 & 1 & 0 \\
0 & 0 & 1 \\
\end{array}
\]

and

\[
\begin{array}{cccc}
1 & 0 & 1 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
\end{array}
\]

If soln is a solution given by DLXCPP(rows) then
\[
[ \text{rows[soln[0]]}, \text{rows[soln[1]]}, \ldots, \text{rows[soln[len(soln)-1]]} ]
\]

is an exact cover.

Solutions are given as a list.

EXAMPLES:

```
sage: rows = [[[0,1,2]]
sage: rows+= [[[0,2]]
sage: rows+= [[[1]]
sage: rows+= [[[3]]
sage: [x for x in DLXCPP(rows)]
[[[3, 0], [3, 1, 2]]]
```
EXAMPLES:

```python
sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]])  # no exact covers
sage: print(OneExactCover(M))
None
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]])  # two exact covers
sage: OneExactCover(M)
[(1, 1, 0), (0, 0, 1)]
```

5.1.137 Hadamard matrices

A Hadamard matrix is an $n \times n$ matrix $H$ whose entries are either $+1$ or $-1$ and whose rows are mutually orthogonal. For example, the matrix $H_2$ defined by

\[
\begin{pmatrix}
1 & 1 \\
1 & -1
\end{pmatrix}
\]

is a Hadamard matrix. An $n \times n$ matrix $H$ whose entries are either $+1$ or $-1$ is a Hadamard matrix if and only if:

(a) $|\det(H)| = n^{n/2}$ or

(b) $H = H^\dagger = n \cdot I_n$, where $I_n$ is the identity matrix.

In general, the tensor product of an $m \times m$ Hadamard matrix and an $n \times n$ Hadamard matrix is an $(mn) \times (mn)$ matrix. In particular, if there is an $n \times n$ Hadamard matrix then there is a $(2n) \times (2n)$ Hadamard matrix (since one may tensor with $H_2$). This particular case is sometimes called the Sylvester construction.

The Hadamard conjecture (possibly due to Paley) states that a Hadamard matrix of order $n$ exists if and only if $n = 1$, 2 or $n$ is a multiple of 4.

The module below implements constructions of Hadamard and skew Hadamard matrices for all known orders $\leq 1000$, plus some more greater than 1000. It also allows you to pull a Hadamard matrix from the database at [SloaHada].

The following code will test that a construction for all known orders $\leq 4k$ is implemented. The assertion above can be verified by setting $k=250$ (note that it will take a long time to run):

```python
sage: from sage.combinat.matrices.hadamard_matrix import (hadamard_matrix,
    ....: skew_hadamard_matrix, is_hadamard_matrix,
    ....: is_skew_hadamard_matrix)

sage: k = 20
sage: unknown_hadamard = [668, 716, 892]
```

AUTHORS:

- David Joyner (2009-05-17): initial version
- Matteo Cati (2023-03-18): implemented more constructions for Hadamard and skew Hadamard matrices, to cover all known orders up to 1000.

sage.combinat.matrices.hadamard_matrix.GS_skew_hadamard_smallcases(n, existence=False, check=True)

Data for Williamson-Goethals-Seidel construction of skew Hadamard matrices

Here we keep the data for this construction. Namely, it needs 4 circulant matrices with extra properties, as described in sage.combinat.matrices.hadamard_matrix. williamson_goethals_seidel_skew_hadamard_matrix(). Matrices are taken from:

- \( n = 36, 52 \): [GS70s]
- \( n = 92 \): [Wall71]
- \( n = 188 \): [Djo2008a]
- \( n = 236 \): [FKS2004]
- \( n = 276 \): [Djo2023a]

Additional data is obtained from skew supplementary difference sets contained in sage.combinat.designs. difference_family.skew_supplementary_difference_set(), using the construction described in [Djo1992a].

INPUT:

• \( n \) – integer; the order of the matrix
• \( \text{existence} \) – boolean (default: True); if True, only check that we can do the construction
• \( \text{check} \) – boolean (default: False): if True, check the result

sage.combinat.matrices.hadamard_matrix.RSHCD_324(\( e \))

Return a size 324x324 Regular Symmetric Hadamard Matrix with Constant Diagonal.

We build the matrix \( M \) for the case \( n = 324, \epsilon = 1 \) directly from JankoKharaghaniTonchevGraph and for the case \( \epsilon = -1 \) from the “twist” \( M' \) of \( M \), using Lemma 11 in [HX2010]. Namely, it turns out that the matrix

\[
M' = \begin{pmatrix}
M_{12} & M_{11} \\
M_{11}^T & M_{21}
\end{pmatrix}, \quad \text{where} \quad M = \begin{pmatrix}
M_{11} & M_{12} \\
M_{21} & M_{22}
\end{pmatrix},
\]

and the \( M_{ij} \) are 162x162-blocks, also RSHCD, its diagonal blocks having zero row sums, as needed by [loc.cit.]. Interestingly, the corresponding (324, 152, 70, 72)-strongly regular graph has a vertex-transitive automorphism group of order 2592, twice the order of the (intransitive) automorphism group of the graph corresponding to \( M \). Cf. [CP2016].

INPUT:

• \( e = -1 \) or \( +1 \); the value of \( \epsilon \)

REFERENCE:

• [CP2016]

sage.combinat.matrices.hadamard_matrix.amicable_hadamard_matrices(n, existence=False, check=True)

Construct amicable Hadamard matrices of order \( n \) using the available methods.

INPUT:
• \(n\) – positive integer; the order of the amicable Hadamard matrices
• existence – boolean (default: \texttt{False}); if \texttt{True}, only return whether amicable Hadamard matrices of order \(n\) can be constructed
• check – boolean (default: \texttt{True}); if \texttt{True}, check that the matrices are amicable Hadamard matrices before returning them

OUTPUT:
If existence is true, the function returns a boolean representing whether amicable Hadamard matrices of order \(n\) can be constructed. If existence is false, returns two amicable Hadamard matrices, or raises an error if the matrices cannot be constructed.

EXAMPLES:
```
sage: from sage.combinat.matrices.hadamard_matrix import amicable_hadamard_matrices
sage: amicable_hadamard_matrices(2)
(\[
[ 1 1 ]
[ 1 1 ]
[-1 1] [ 1 -1 ]
\])
```
If existence is true, the function returns a boolean:
```
sage: amicable_hadamard_matrices(16, existence=True)
False
```

\texttt{sage.combinat.matrices.hadamard_matrix.amicable_hadamard_matrices_wallis}(n, check=True)
Construct amicable Hadamard matrices of order \(n = q + 1\) where \(q\) is a prime power.
If \(q\) is a prime power \(\equiv 3 \mod 4\), then amicable Hadamard matrices of order \(q + 1\) can be constructed as described in [Wal1970b].

INPUT:
• \(n\) – integer; the order of the matrices to be constructed
• check – boolean (default: \texttt{True}); if \texttt{True}, check that the resulting matrices are amicable Hadamard before returning them

OUTPUT:
The function returns two amicable Hadamard matrices, or raises an error if such matrices cannot be created using this construction.

EXAMPLES:
```
sage: from sage.combinat.matrices.hadamard_matrix import amicable_hadamard_matrices_wallis
sage: M, N = amicable_hadamard_matrices_wallis(28)
sage.combinat.matrices.hadamard_matrix.amicable_hadamard_matrices_wallis
```

\texttt{sage.combinat.matrices.hadamard_matrix.are_amicable_hadamard_matrices}(M, N, verbose=False)
Check if \(M\) and \(N\) are amicable Hadamard matrices.
Two matrices \(M\) and \(N\) of order \(n\) are called amicable if they satisfy the following conditions (see [Seb2017]):
• \(M\) is a skew Hadamard matrix
• \(N\) is a symmetric Hadamard matrix
• \(MN^T = NM^T\)
INPUT:

- M – a square matrix
- N – a square matrix
- verbose – boolean (default False); whether to be verbose when the matrices are not amicable Hadamard matrices

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import are_amicable_hadamard_matrices
sage: M = matrix([[1, 1], [-1, 1]])
sage: N = matrix([[1, 1], [1, -1]])
sage: are_amicable_hadamard_matrices(M, N)
True
```

If verbose is true, the function will be verbose when returning False:

```python
sage: N = matrix([[1, 1], [1, 1]])
sage: are_amicable_hadamard_matrices(M, N, verbose=True)
The second matrix is not Hadamard
False
```

```
sage.combinat.matrices.hadamard_matrix.construction_four_symbol_delta_code_I(X, Y, Z, W)
Construct 4-symbol δ code of length 2n + 1.

The 4-symbol δ code is constructed from sequences X, Y, Z, W of length \( n + 1 \), \( n + 1 \), \( n \), \( n \) satisfying for all \( s > 0 \):

\[
N_X(s) + N_Y(s) + N_Z(s) + N_W(s) = 0
\]

where \( N_A(s) \) is the nonperiodic correlation function:

\[
N_A(s) = \sum_{i=1}^{n-s} a_i a_{i+s}
\]

The construction (detailed in [Tur1974]) is as follows:

- \( T_1 = X; Z \)
- \( T_2 = X; -Z \)
- \( T_3 = Y; W \)
- \( T_4 = Y; -W \)

INPUT:

- X – list; the first sequence (length \( n + 1 \))
- Y – list; the second sequence (length \( n + 1 \))
- Z – list; the third sequence (length \( n \))
- W – list; the fourth sequence (length \( n \))

OUTPUT:

A tuple containing the 4-symbol δ code of length 2n + 1.

EXAMPLES:
sage: from sage.combinat.matrices.hadamard_matrix import construction_four_symbol_delta_code_I
sage: construction_four_symbol_delta_code_I([1, 1], [1, -1], [1], [1])
([1, 1, 1], [1, 1, -1], [1, -1, 1], [1, -1, -1])

sage.combinat.matrices.hadamard_matrix.construction_four_symbol_delta_code_II(X, Y, Z, W)
Construct 4-symbol δ code of length 4n + 3.
The 4-symbol δ code is constructed from sequences X, Y, Z, W of length n + 1, n + 1, n, n satisfying for all s > 0:

\[ N_X(s) + N_Y(s) + N_Z(s) + N_W(s) = 0 \]

where \( N_A(s) \) is the nonperiodic correlation function:

\[ N_A(s) = \sum_{i=1}^{n-s} a_i a_{i+s} \]

The construction (detailed in [Tur1974]) is as follows (writing A/B to mean A alternated with B):

\[ T_1 = X/Z; Y/W; 1 \]
\[ T_2 = X/Z; Y/W; -1 \]
\[ T_3 = X/Z; Y/W; 1 \]
\[ T_4 = X/Z; Y/W; -1 \]

INPUT:
- \( X \) – list; the first sequence (length \( n + 1 \))
- \( Y \) – list; the second sequence (length \( n + 1 \))
- \( Z \) – list; the third sequence (length \( n \))
- \( W \) – list; the fourth sequence (length \( n \))

OUTPUT:
A tuple containing the four 4-symbol δ code of length 4n + 3.

EXAMPLES:

sage: from sage.combinat.matrices.hadamard_matrix import construction_four_symbol_delta_code_II
sage: construction_four_symbol_delta_code_II([1, 1], [1, -1], [1], [1])
([1, 1, 1, 1, 1, -1, 1], [1, 1, 1, 1, -1, -1, -1], [1, 1, 1, -1, -1, 1, 1], [1, 1, 1, -1, 1, 1, -1])

sage.combinat.matrices.hadamard_matrix.four_symbol_delta_code_smallcases(n, existence=False)
Return the 4-symobl δ code of length \( n \) if available.
The 4-symbol δ codes are constructed using \( \text{construction_four_symbol_delta_code_I()} \) or \( \text{construction_four_symbol_delta_code_II()} \). The base sequences used are taken from [Tur1974].

INPUT:
- \( n \) – integer; the length of the desired 4-symbol δ code
sage.combinat.matrices.hadamard_matrix.hadamard_matrix(n, existence=False, check=True)

This function is available as hadamard_matrix(...) and matrix.hadamard(...).

Tries to construct a Hadamard matrix using the available methods.

Currently all orders ≤ 1000 for which a construction is known are implemented. For n > 1000, only some orders are available.

INPUT:

• n – integer; dimension of the matrix

• existence – boolean (default: False); whether to build the matrix or merely query if a construction is available in Sage. When set to True, the function returns:
  – True – meaning that Sage knows how to build the matrix
  – Unknown – meaning that Sage does not know how to build the matrix, although the matrix may exist (see sage.misc.unknown).
  – False – meaning that the matrix does not exist.

• check – boolean (default: True); whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed.

EXAMPLES:

sage: hadamard_matrix(12).det()
2985984
sage: 12^6
2985984
sage: hadamard_matrix(1)
[1]
sage: hadamard_matrix(2)
[ 1 1
 [ 1 -1]
sage: hadamard_matrix(8) # random
[ 1 1 1 1 1 1 1 1
 [ 1 -1 1 -1 1 -1 1 -1]
 [ 1 1 -1 -1 1 1 -1 -1]
 [ 1 -1 -1 1 1 -1 -1 1]
 [ 1 1 1 1 -1 -1 -1 -1]
 [ 1 -1 1 -1 -1 1 -1 1]
 [ 1 1 -1 -1 -1 1 1 1]
 [ 1 -1 -1 1 1 1 -1]
sage: hadamard_matrix(8).det() == 8^4
True
We note that `hadamard_matrix()` returns a normalised Hadamard matrix (the entries in the first row and column are all +1).

```python
sage: hadamard_matrix(12) # random
[ 1  1| 1  1| 1  1| 1  1| 1  1| 1  1]
[ 1 -1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1]
[-------------------------+-------------------------]
[ 1 -1| 1  1| 1  1| 1  1| 1  1| 1  1]
[ 1  1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1]
[-------------------------+-------------------------]
[ 1 -1| 1  1| 1  1| 1  1| 1  1| 1  1]
[ 1  1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1]
[-------------------------+-------------------------]
[ 1 -1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1]
[ 1  1| 1  1| 1  1| 1  1| 1  1| 1  1]
[-------------------------+-------------------------]
[ 1 -1| 1  1| 1  1| 1  1| 1  1| 1  1]
[ 1  1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1]
[-------------------------+-------------------------]
[ 1 -1| 1  1| 1  1| 1  1| 1  1| 1  1]
[ 1  1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1]
[-------------------------+-------------------------]
[ 1 -1| 1  1| 1  1| 1  1| 1  1| 1  1]
[ 1  1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1]
```

`sage.combinat.matrices.hadamard_matrix.hadamard_matrix_156()`

Construct an Hadamard matrix of order 156.

The matrix is created using the construction detailed in [BH1965]. This uses four circulant matrices of size $13 \times 13$, which are composed into a $156 \times 156$ block matrix.

`sage.combinat.matrices.hadamard_matrix.hadamard_matrix_cooper_wallis_construction(x1, x2, x3, x4, A, B, C, D, check=True)`

Create an Hadamard matrix using the construction detailed in [CW1972].

Given four circulant matrices $X_1, X_2, X_3, X_4$ of order $n$ with entries $(0, 1, -1)$ such that the entrywise product of two distinct matrices is always equal to 0 and that $\sum_{i=1}^{4} X_i X_i^\top = n I_n$ holds, and four matrices $A, B, C, D$ of order $m$ with elements $(1, -1)$ such that $MN^\top = NM^\top$ for all distinct $M, N$ and $AA^\top + BB^\top + CC^\top + DD^\top = 4m I_m$ holds, we construct an Hadamard matrix of order $4nm$.

**INPUT:**

- `x1` – list or vector; the first row of the circulant matrix $X_1$
- `x2` – list or vector; the first row of the circulant matrix $X_2$
- `x3` – list or vector; the first row of the circulant matrix $X_3$
- `x4` – list or vector; the first row of the circulant matrix $X_4$
- `A` – the matrix described above
- `B` – the matrix described above
- `C` – the matrix described above
- `D` – the matrix described above
- `check` – boolean (default: `True`); if `True`, check that the resulting matrix is Hadamard before returning it.

**EXAMPLES:**
Construct Hadamard matrices using the Cooper-Wallis construction for some small values of \( n \).

This function calls the function `hadamard_matrix_cooper_wallis_construction()` with the appropriate arguments. It constructs the matrices \( X_1, X_2, X_3, X_4 \) using either T-matrices or the T-sequences from `sage.combinat.t_sequences.T_sequences_smallcases()`. The matrices \( A, B, C, D \) are taken from `williamson_type_quadruples_smallcases()`.

Data for T-matrices of order 67 is taken from [Saw1985].

**INPUT:**
- \( n \) – integer; the order of the matrix to be constructed
- \( \text{check} \) – boolean (default: True); if True, check that the matrix is an Hadamard matrix before returning
- \( \text{existence} \) – boolean (default: False); if True, only check if the matrix exists.

**OUTPUT:**
If \( \text{existence}=False \), returns the Hadamard matrix of order \( n \). It raises an error if no data is available to construct the matrix of the given order. If \( \text{existence}=True \), returns a boolean representing whether the matrix can be constructed or not.

**See also:**
`hadamard_matrix_cooper_wallis_construction()`

**EXAMPLES:**

By default, the function returns the Hadamard matrix

```python
sage: hadamard_matrix_cooper_wallis_smallcases(28)
28 x 28 dense matrix over Integer Ring...
```

If \( \text{existence} \) is set to True, the function returns a boolean

```python
sage: hadamard_matrix_cooper_wallis_smallcases(20, existence=True)
True
```

**Construction of Hadamard matrices from supplementary difference sets.**

Given four SDS with parameters \( 4 - \{n; n_1, n_2, n_3, n_4; \lambda \} \) with \( n_1 + n_2 + n_3 + n_4 = n + \lambda \) we can construct four \((-1,+1)\) sequences \( a_i = (a_{i,0}, ..., a_{i,n-1}) \) where \( a_{i,j} = -1 \) iff \( j \in S_i \). These will be the first rows of four circulant matrices \( A_1, A_2, A_3, A_4 \) which, when plugged into the Goethals-Seidel array, create an Hadamard matrix of order \( 4n \) (see [Djo1994b]).
The supplementary difference sets are taken from `sage.combinat.designs.difference_family.supplementary_difference_set()`.

**INPUT:**
- `n` – integer; the order of the matrix to be constructed
- `check` – boolean (default: `True`); if `True`, check that the matrix is a Hadamard before returning
- `existence` – boolean (default: `False`); if `True`, only check if the matrix exists

**OUTPUT:**
If `existence=False`, returns the Hadamard matrix of order `n`. It raises an error if no data is available to construct the matrix of the given order, or if `n` is not a multiple of 4. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

**EXAMPLES:**
By default The function returns the Hadamard matrix

```python
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_from_sds
sage: hadamard_matrix_from_sds(148)
```

```python
148 x 148 dense matrix over Integer Ring...
```

If `existence` is set to `True`, the function returns a boolean

```python
sage: hadamard_matrix_from_sds(764, existence=True)
```

```python
True
```

`sage.combinat.matrices.hadamard_matrix.hadamard_matrix_miyamoto_construction(n, existence=False, check=True)`

Construct Hadamard matrix using the Miyamoto construction.

If \( q = n/4 \) is a prime power, and there exists an Hadamard matrix of order \( q - 1 \), then a Hadamard matrix of order \( n \) can be constructed (see [Miy1991]).

**INPUT:**
- `n` – integer; the order of the matrix to be constructed
- `check` – boolean (default: `True`); if `True`, check that the matrix is a Hadamard before returning
- `existence` – boolean (default: `False`); if `True`, only check if the matrix exists

**OUTPUT:**
If `existence=False`, returns the Hadamard matrix of order `n`. It raises an error if no data is available to construct the matrix of the given order, or if `n` does not satisfies the constraints. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

**EXAMPLES:**
By default the function returns the Hadamard matrix

```python
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_miyamoto_construction
sage: hadamard_matrix_miyamoto_construction(20)
```

```python
20 x 20 dense matrix over Integer Ring...
```

If `existence` is set to `True`, the function returns a boolean
sage: hadamard_matrix_miyamoto_construction(36, existence=True)
True

sage.combinat.matrices.hadamard_matrix.hadamard_matrix_paleyI(n, normalize=True)
Implement the Paley type I construction.
The Paley type I case corresponds to the case \( p = n - 1 \equiv 3 \mod 4 \) for a prime power \( p \) (see [Hora]).

INPUT:
- \( n \) – the matrix size
- \( \text{normalize} \) – boolean (default: True); whether to normalize the result

EXAMPLES:
We note that this method by default returns a normalised Hadamard matrix

\[
\begin{bmatrix}
1 & 1 & 1 & 1 \\
1 & -1 & -1 & 1 \\
1 & -1 & 1 & 1 \\
1 & 1 & 1 & -1
\end{bmatrix}
\]

Otherwise, it returns a skew Hadamard matrix \( H \), i.e. \( H = S + I \), with \( S = -S^T \)

\[
\begin{bmatrix}
1 & 1 & 1 & 1 \\
1 & 1 & -1 & -1 \\
1 & -1 & 1 & -1 \\
1 & -1 & -1 & 1
\end{bmatrix}
\]

sage: M = hadamard_matrix_paleyI(4, normalize=False); M
\[
\begin{bmatrix}
1 & 1 & 1 & 1 \\
1 & -1 & 1 & -1 \\
1 & -1 & 1 & 1 \\
1 & 1 & -1 & 1
\end{bmatrix}
\]

sage: S = M - identity_matrix(4); -S == S.T

True

sage.combinat.matrices.hadamard_matrix.hadamard_matrix_paleyII(n)
Implement the Paley type II construction.
The Paley type II case corresponds to the case \( p = n/2 - 1 \equiv 1 \mod 4 \) for a prime power \( p \) (see [Hora]).

EXAMPLES:
We note that the method returns a normalised Hadamard matrix

\[
\begin{bmatrix}
1 & 1 & 1 & 1 & 1 & 1 \ 1 & -1 & 1 & -1 & 1 & -1 \ 1 & -1 & -1 & -1 & 1 & 1 \ 1 & -1 & 1 & 1 & -1 & 1 \\
\end{bmatrix}
\]

(continues on next page)
sage.combinat.matrices.hadamard_matrix.hadamard_matrix_spence_construction(n,  
existence=False,  
check=True)

Create an Hadamard matrix of order \( n \) using the Spence construction.

This construction (detailed in [Spe1975]), uses supplementary difference sets implemented in `sage.combinat.designs.difference_family.supplementary_difference_set_from_rel_diff_set()` to create the desired matrix.

**INPUT:**

- \( n \) – integer; the order of the matrix to be constructed
- \( \text{existence} \) – boolean (default: `False`); if `True`, only check if the matrix exists
- \( \text{check} \) – boolean (default: `True`); if `True`, check that the matrix is an Hadamard matrix before returning

**OUTPUT:**

If `existence=True`, returns a boolean representing whether the Hadamard matrix can be constructed. Otherwise, returns the Hadamard matrix, or raises an error if it cannot be constructed.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_spence_construction
sage: hadamard_matrix_spence_construction(36)
36 x 36 dense matrix over Integer Ring...
```

If `existence` is `True`, the function returns a boolean

```python
sage: hadamard_matrix_spence_construction(52, existence=True)
True
```

sage.combinat.matrices.hadamard_matrix.hadamard_matrix_turyn_type(a, b, c, d, e1, e2, e3, e4,  
check=True)

Construction of Turyn type Hadamard matrix.

Given \( n \times n \) circulant matrices \( A, B, C, D \) with 1,-1 entries, satisfying \( A A^\top + B B^\top + C C^\top + D D^\top = 4n I \), and a set of Baumert-Hall units of order \( 4t \), one can construct a Hadamard matrix of order \( 4tn \) as detailed by Turyn in [Tur1974].

**INPUT:**

- \( a \) – 1,-1 list; the 1st row of \( A \)
- \( b \) – 1,-1 list; the 1st row of \( B \)
• d – 1,-1 list; the 1st row of C
• c – 1,-1 list; the 1st row of D
• e1 – Matrix; the first Baumert-Hall unit
• e2 – Matrix; the second Baumert-Hall unit
• e3 – Matrix; the third Baumert-Hall unit
• e4 – Matrix; the fourth Baumert-Hall unit
• check – boolean (default: True); whether to check that the output is an Hadamard matrix before returning it

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_turyn_type, _get_baumert_hall_units
sage: A, B, C, D = _get_baumert_hall_units(28)
sage: hadamard_matrix_turyn_type([1], [1], [1], [1], A, B, C, D)
28 x 28 dense matrix over Integer Ring...
```

sage.combinat.matrices.hadamard_matrix.hadamard_matrix_williamson_type(a, b, c, d, check=True)
Construction of Williamson type Hadamard matrix.

Given $n \times n$ circulant matrices $A, B, C, D$ with 1,-1 entries, and satisfying $AA^T + BB^T + CC^T + DD^T = 4nI$,
one can construct a Hadamard matrix of order $4n$, cf. [Ha83].

INPUT:
• a – (1,-1) list; the 1st row of $A$
• b – (1,-1) list; the 1st row of $B$
• d – (1,-1) list; the 1st row of $C$
• c – (1,-1) list; the 1st row of $D$
• check – boolean (default: True); whether to check that the output is an Hadamard matrix before returning it

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_williamson_type
sage: a = [1, 1, 1]
sage: b = [1, -1, -1]
sage: c = [1, -1, -1]
sage: d = [1, -1, -1]
sage: M = hadamard_matrix_williamson_type(a, b, c, d, check=True)
```

sage.combinat.matrices.hadamard_matrix.hadamard_matrix_www(url_file, comments=False)
Pull file from Sloane's database and return the corresponding Hadamard matrix as a Sage matrix.

You must input a filename of the form “had.n.xxx.txt” as described on the webpage http://neilsloane.com/hadamard/, where “xxx” could be empty or a number of some characters.

If comments=True then the “Automorphism…” line of the had.n.xxx.txt file is printed if it exists. Otherwise nothing is done.

EXAMPLES:
```python
sage: hadamard_matrix_www("had.4.txt")  # optional - internet
[ 1 1 1 1]
[ 1 -1 1 -1]
[ 1 1 -1 -1]
[ 1 -1 -1 1]
sage: hadamard_matrix_www("had.16.2.txt", comments=True)  # optional - internet
Automorphism group has order = 49152 = 2^14 * 3
[ 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1]
[ 1 -1 1 -1 1 -1 1 -1 1 -1 1 -1 1 -1 1 -1]
[ 1 1 -1 1 1 -1 1 -1 1 -1 1 -1 1 -1 1 -1]
[ 1 1 1 1 -1 -1 -1 -1 1 1 1 -1 -1 -1 -1 -1]
[ 1 -1 1 1 -1 -1 1 -1 1 -1 1 -1 1 -1 1 -1]
[ 1 1 1 1 1 -1 -1 -1 1 1 1 -1 -1 -1 -1 -1]
[ 1 -1 -1 1 1 -1 -1 -1 1 1 1 -1 -1 -1 -1 -1]
[ 1 1 1 1 1 1 1 1 1 1 -1 -1 -1 1 1 1]
[ 1 1 1 1 1 -1 -1 -1 -1 1 1 1 -1 -1 -1 -1]
[ 1 1 -1 1 -1 -1 -1 1 1 -1 -1 -1 1 -1 -1 1]
[ 1 1 -1 -1 -1 -1 -1 -1 1 1 -1 -1 1 -1 -1 1]
[ 1 1 -1 -1 -1 1 1 1 -1 -1 1 1 1 -1 -1 1]
[ 1 -1 1 1 -1 1 1 -1 -1 -1 1 1 1 -1 -1 1]
[ 1 1 1 1 -1 -1 -1 -1 -1 -1 1 1 1 -1 -1 1]
[ 1 -1 -1 1 -1 -1 -1 1 1 -1 -1 1 1 1 -1 -1]
[ 1 1 -1 -1 -1 -1 -1 -1 -1 -1 1 1 1 -1 -1 1]
[ 1 1 -1 -1 -1 -1 1 1 -1 -1 1 1 1 -1 -1 1]
[ 1 -1 -1 1 1 -1 -1 1 1 -1 1 1 1 -1 -1 1]
[ 1 -1 -1 1 -1 1 -1 -1 -1 1 1 -1 -1 -1 -1 1]
```

sage.combinat.matrices.hadamard_matrix.is_hadamard_matrix(M, normalized=False, skew=False, verbose=False)

Test if $M$ is a Hadamard matrix.

**INPUT:**

- $M$ – a matrix
- normalized – boolean (default: False); whether to test if $M$ is a normalized Hadamard matrix, i.e. has its first row/column filled with $+1$
- skew – boolean (default: False); whether to test if $M$ is a skew Hadamard matrix, i.e. $M = S + I$ for $-S = S^\top$, and $I$ the identity matrix
- verbose – boolean (default: False); whether to be verbose when the matrix is not Hadamard

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.hadamard_matrix import is_hadamard_matrix
sage: h = matrix.hadamard(12)
sage: is_hadamard_matrix(h)
True
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix
sage: h = skew_hadamard_matrix(12)
sage: is_hadamard_matrix(h, skew=True)
True
sage: h = matrix.hadamard(12)
sage: h[0,0] = 2
sage: is_hadamard_matrix(h, verbose=True)
The matrix does not only contain +1 and -1 entries, e.g. 2
False
```
sage: h = matrix.hadamard(12)
sage: for i in range(12):
.....: h[i,2] = -h[i,2]
sage: is_hadamard_matrix(h, verbose=True, normalized=True)
The matrix is not normalized
False

sage.combinat.matrices.hadamard_matrix.is_skew_hadamard_matrix(M, normalized=False, verbose=False)

Test if \( M \) is a skew Hadamard matrix.

this is a wrapper around the function is_hadamard_matrix()

INPUT:

• \( M \) – a matrix

• normalized – boolean (default: False); whether to test if \( M \) is a skew-normalized Hadamard matrix, i.e. has its first row filled with +1

• verbose – boolean (default: False); whether to be verbose when the matrix is not skew Hadamard

EXAMPLES:

sage: from sage.combinat.matrices.hadamard_matrix import is_skew_hadamard_matrix, skew_hadamard_matrix
sage: h = matrix.hadamard(12)
sage: is_skew_hadamard_matrix(h, verbose=True)
The matrix is not skew
False
sage: h = skew_hadamard_matrix(12)
sage: is_skew_hadamard_matrix(h)
True
sage: from sage.combinat.matrices.hadamard_matrix import normalise_hadamard
sage: h = normalise_hadamard(skew_hadamard_matrix(12), skew=True)
sage: is_hadamard_matrix(H, skew=True, normalized=True)
True

sage.combinat.matrices.hadamard_matrix.normalise_hadamard(H, skew=False)

Return the normalised Hadamard matrix corresponding to \( H \).

The normalised Hadamard matrix corresponding to a Hadamard matrix \( H \) is a matrix whose every entry in the first row and column is +1.

If skew is True, the matrix returned will be skew-normal: a skew Hadamard matrix with first row of all +1.

EXAMPLES:

sage: from sage.combinat.matrices.hadamard_matrix import normalise_hadamard, is_hadamard_matrix, skew_hadamard_matrix
sage: H = normalise_hadamard(hadamard_matrix(4))
sage: H == hadamard_matrix(4)
True
sage: H = normalise_hadamard(skew_hadamard_matrix(20), skew=True)
sage: is_hadamard_matrix(H, skew=True, normalized=True)
True
If `skew` is True but the Hadamard matrix is not skew, the matrix returned will not be normalized:

```
sage: H = normalise_hadamard(hadamard_matrix(92), skew=True)
sage: is_hadamard_matrix(H, normalized=True)
False
```

Return a Regular Symmetric Hadamard Matrix with Constant Diagonal.

A Hadamard matrix is said to be regular if its rows all sum to the same value.

For $\epsilon \in \{-1, +1\}$, we say that $M$ is a $(n, \epsilon)$ – $RSHCD$ if $M$ is a regular symmetric Hadamard matrix with constant diagonal $\delta \in \{-1, +1\}$ and row sums all equal to $\delta \epsilon \sqrt{n}$. For more information, see [HX2010] or 10.5.1 in [BH2012]. For the case $n = 324$, see `RSHCD_324()` and [CP2016].

**INPUT:**

- `n` – integer; side of the matrix
- `e` – $-1$ or $+1$; the value of $\epsilon$

**EXAMPLES:**

```
sage: from sage.combinat.matrices.hadamard_matrix import regular_symmetric_hadamard_matrix_with_constant_diagonal
sage: regular_symmetric_hadamard_matrix_with_constant_diagonal(4,1)
[ 1 1 1 -1]
[ 1 1 -1 1]
[ 1 -1 1 1]
[ 1 -1 1 1]
sage: regular_symmetric_hadamard_matrix_with_constant_diagonal(4,-1)
[ 1 -1 -1 -1]
[-1 1 -1 -1]
[-1 -1 1 -1]
[-1 -1 -1 1]
```

Other hardcoded values:

```
sage: for n,e in [(36,1),(36,-1),(100,1),(100,-1),(196,1)]:  # long time
....:     print(repr(regular_symmetric_hadamard_matrix_with_constant_diagonal(n,e)))
36 x 36 dense matrix over Integer Ring
36 x 36 dense matrix over Integer Ring
100 x 100 dense matrix over Integer Ring
100 x 100 dense matrix over Integer Ring
196 x 196 dense matrix over Integer Ring
```

```
sage: for n,e in [(324,1),(324,-1)]:  # not tested - long time, tested in `RSHCD_324`
....:
....:     print(repr(regular_symmetric_hadamard_matrix_with_constant_diagonal(n,e)))
324 x 324 dense matrix over Integer Ring
324 x 324 dense matrix over Integer Ring
```

From two close prime powers:
sage: regular_symmetric_hadamard_matrix_with_constant_diagonal(64,-1)
64 x 64 dense matrix over Integer Ring (use the '.str()' method to see the entries)

From a prime power and a conference matrix:

sage: regular_symmetric_hadamard_matrix_with_constant_diagonal(676,1)  # long time
676 x 676 dense matrix over Integer Ring (use the '.str()' method to see the entries)

Recursive construction:

sage: regular_symmetric_hadamard_matrix_with_constant_diagonal(144,-1)
144 x 144 dense matrix over Integer Ring (use the '.str()' method to see the entries)

REFERENCE:

• [BH2012]
• [HX2010]

sage.combinat.matrices.hadamard_matrix.rshcd_from_close_prime_powers(n)
Return a \((n^2,1)\)-RSHCD when \(n - 1\) and \(n + 1\) are odd prime powers and \(n = 0 \pmod{4}\).

The construction implemented here appears in Theorem 4.3 from [GS1970].

Note that the authors of [SWW1972] claim in Corollary 5.12 (page 342) to have proved the same result without the \(n = 0 \pmod{4}\) restriction with a very similar construction. So far, however, I (Nathann Cohen) have not been able to make it work.

INPUT:

• \(n\) – an integer congruent to 0 \(\pmod{4}\)

See also:

regular_symmetric_hadamard_matrix_with_constant_diagonal()

EXAMPLES:

sage: from sage.combinat.matrices.hadamard_matrix import rshcd_from_close_prime_powers
sage: rshcd_from_close_prime_powers(4)
[-1 -1 1 -1 1 -1 -1 1 -1 1 -1 1 -1 1 -1 1 -1]
[-1 -1 -1 1 1 -1 -1 1 -1 -1 1 -1 1 -1 -1 1 -1]
[ 1 -1 -1 1 1 1 -1 -1 -1 -1 -1 -1 -1 -1 -1 1 -1]
[ 1 1 1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 1]
[-1 -1 -1 1 1 -1 -1 1 -1 -1 -1 -1 -1 -1 -1 -1 -1]
[ 1 1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 1 -1]
[-1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1]
[-1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1]
[ 1 -1 -1 -1 -1 -1 -1 -1 1 -1 -1 -1 1 -1 -1 -1 -1]
[ 1 -1 -1 -1 -1 -1 -1 -1 1 -1 -1 -1 1 -1 -1 -1 -1]
[-1 -1 -1 -1 -1 -1 -1 1 -1 -1 -1 -1 1 -1 -1 -1 -1]
[-1 -1 -1 -1 -1 -1 -1 -1 1 -1 -1 -1 1 -1 -1 -1 -1]
[-1 1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1]
[-1 -1 1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1]
[ 1 1 -1 -1 -1 -1 -1 -1 1 -1 -1 -1 1 -1 -1 -1 -1]
[-1 -1 -1 -1 -1 -1 -1 -1 1 -1 -1 -1 1 -1 -1 -1 -1]
[ 1 -1 -1 -1 -1 -1 -1 -1 1 1 1 1 1 1 -1 -1 -1]
[-1 1 -1 -1 -1 -1 -1 1 -1 -1 -1 -1 -1 -1 -1 -1 -1]
[-1 -1 -1 -1 -1 -1 1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1]
[ 1 -1 -1 -1 -1 -1 -1 -1 1 1 1 1 1 1 -1 -1 -1]
[-1 1 -1 -1 -1 -1 -1 1 -1 -1 -1 -1 -1 -1 -1 -1 -1]
[ 1 -1 -1 -1 -1 -1 -1 -1 1 1 1 1 1 1 -1 -1 -1]
[-1 1 -1 -1 -1 -1 -1 1 -1 -1 -1 -1 -1 -1 -1 -1 -1]
REFERENCE:

- [SWW1972]

```
sage.combinat.matrices.hadamard_matrix.rshcd_from_prime_power_and_conference_matrix(n)
```

Return a \((n - 1)^2, 1\)-RSHCD if \(n\) is prime power, and symmetric \((n - 1)\)-conference matrix exists.

The construction implemented here is Theorem 16 (and Corollary 17) from [WW1972].

In [WW1972] this construction (Theorem 5.15 and Corollary 5.16) is reproduced with a typo. Note that [WW1972] refers to [Sz1969] for the construction, provided by `szekeres_difference_set_pair()`, of complementary difference sets, and the latter has a typo.

From a `symmetric_conference_matrix()`, we only need the Seidel adjacency matrix of the underlying strongly regular conference (i.e. Paley type) graph, which we construct directly.

**INPUT:**

- \(n\) – an integer

**See also:**

`regular_symmetric_hadamard_matrix_with_constant_diagonal()`

**EXAMPLES:**

A 36x36 example

```
sage: from sage.combinat.matrices.hadamard_matrix import rshcd_from_prime_power_and_conference_matrix
sage: from sage.combinat.matrices.hadamard_matrix import is_hadamard_matrix
sage: H = rshcd_from_prime_power_and_conference_matrix(7); H
36 x 36 dense matrix over Integer Ring (use the '.str()' method to see the entries)
```

```
sage: H == H.T and is_hadamard_matrix(H) and H.diagonal() == [1]*36 and list(sum(H)) == [6]*36
True
```

Bigger examples, only provided by this construction

```
sage: H = rshcd_from_prime_power_and_conference_matrix(27) # long time
sage: H == H.T and is_hadamard_matrix(H)                     # long time
True
`sage: H.diagonal() == [1]*676 and list(sum(H)) == [26]*676   # long time
True
```

In this example the conference matrix is not Paley, as 45 is not a prime power

```
sage: H = rshcd_from_prime_power_and_conference_matrix(47) # not tested (long time)
```

**REFERENCE:**

- [WW1972]

```
sage.combinat.matrices.hadamard_matrix.skew_hadamard_matrix(n, existence=False, skew_normalize=True, check=True)
```

Tries to construct a skew Hadamard matrix.
A Hadamard matrix $H$ is called skew if $H = S - I$, for $I$ the identity matrix and $-S = S^T$. Currently all orders $\leq 1000$ for which a construction is known are implemented. For $n > 1000$, only some orders are available.

**INPUT:**

- **n** – integer; dimension of the matrix
- **existence** – boolean (default: False); whether to build the matrix or merely query if a construction is available in Sage. When set to True, the function returns:
  - **True** – meaning that Sage knows how to build the matrix
  - **Unknown** – meaning that Sage does not know how to build the matrix, but that the design may exist (see sage.misc.unknown).
  - **False** – meaning that the matrix does not exist.
- **skew_normalize** – boolean (default: True); whether to make the 1st row all-one, and adjust the 1st column accordingly
- **check** – boolean (default: True); whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix
sage: skew_hadamard_matrix(12).det()
2985984
sage: 12^6
2985984
sage: skew_hadamard_matrix(1)
[1]
sage: skew_hadamard_matrix(2)
[ 1  1]
[ -1  1]
```

**REFERENCES:**

- [Ha83]

sage.combinat.matrices.hadamard_matrix.skew_hadamard_matrix_from_complementary_difference_sets($n$, $\text{existence}=$False, $\text{check}=$True)

Construct a skew Hadamard matrix of order $n = 4(m + 1)$ from complementary difference sets.

If $A, B$ are complementary difference sets over a group of order $2m + 1$, then they can be used to construct a skew Hadamard matrix, as described in [BS1969].

The complementary difference sets are constructed using the function sage.combinat.designs.difference_family.complementary_difference_sets().

**INPUT:**

- **n** – positive integer; the order of the matrix to be constructed
- **existence** – boolean (default: False); if True, only return whether the skew Hadamard matrix can be constructed
- **check** – boolean (default: True); if True, check that the result is a skew Hadamard matrix before returning it
OUTPUT:

If `existence=False`, returns the skew Hadamard matrix of order `n`. It raises an error if `n` does not satisfy the required conditions. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_from_complementary_difference_sets
sage: skew_hadamard_matrix_from_complementary_difference_sets(20)
20 x 20 dense matrix over Integer Ring...
sage: skew_hadamard_matrix_from_complementary_difference_sets(52, existence=True)
True
```

```python
sage.combinat.matrices.hadamard_matrix.skew_hadamard_matrix_from_good_matrices(a, b, c, d, check=True)
```

Construct skew Hadamard matrix from good matrices.

Given good matrices `A, B, C, D` (`A` circulant, `B, C, D` back-circulant) they can be used to construct a skew Hadamard matrix using the following block matrix (as described in [Sze1988]):

\[
\begin{pmatrix}
A & B & C & D \\
-B & A & D & -C \\
-C & -D & A & B \\
-D & C & -B & A
\end{pmatrix}
\]

INPUT:

- `a` – `(1,-1)` list; the 1st row of `A`
- `b` – `(1,-1)` list; the 1st row of `B`
- `d` – `(1,-1)` list; the 1st row of `C`
- `c` – `(1,-1)` list; the 1st row of `D`
- `check` – boolean (default: True); if True, check that the matrix is a skew Hadamard matrix before returning it

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_from_good_matrices
sage: a, b, c, d = ([1, 1, 1, -1, -1], [1, -1, 1, 1, -1], [1, -1, -1, -1, -1], [1, -1, -1, -1, -1])
sage: skew_hadamard_matrix_from_good_matrices(a, b, c, d)
20 x 20 dense matrix over Integer Ring...
```

```python
sage.combinat.matrices.hadamard_matrix.skew_hadamard_matrix_from_good_matrices_smallcases(n, existence=False, check=True)
```

Construct skew Hadamard matrices from good matrices for some small values of `n = 4m`, with `m` odd.

The function stores good matrices of odd orders \( \leq 31 \), taken from [Sze1988]. These are used to create skew Hadamard matrices of order \( 4m, 1 \leq m \leq 31 \) (\( m \) odd), using the function `skew_hadamard_matrix_from_good_matrices()`.

1380 Chapter 5. Comprehensive Module List
ALGORITHM:

Given four sequences (stored in \(E_{\text{sequences}}\)) of length \(m\), they can be used to construct four \(E\) \(-\) \(sequences\) of length \(n = 2m + 1\), as follows:

\[
\begin{align*}
  a &= 1, a_0, a_1, ..., a_m, -a_m, -a_{m-1}, ..., -a_0 \\
  b &= 1, b_0, b_1, ..., b_m, b_{m-1}, ..., b_0 \\
  c &= 1, c_0, c_1, ..., c_m, c_{m-1}, ..., c_0 \\
  d &= 1, d_0, d_1, ..., d_m, d_{m-1}, ..., d_0
\end{align*}
\]

These E-sequences will be the first rows of the four good matrices needed to construct a skew Hadamard matrix of order \(4n\).

INPUT:

- \(n\) – integer; the order of the skew Hadamard matrix to be constructed
- \(\text{existence}\) – boolean (default: False); If True, only return whether the Hadamard matrix can be constructed
- \(\text{check}\) – boolean (default: True); if True, check that the matrix is an Hadamard matrix before returning it

OUTPUT:

If \(\text{existence}=\)False, returns the skew Hadamard matrix of order \(n\). It raises an error if no data is available to construct the matrix of the given order. If \(\text{existence}=\)True, returns a boolean representing whether the matrix can be constructed or not.

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_from_good_matrices_smallcases
sage: skew_hadamard_matrix_from_good_matrices_smallcases(20)
20 x 20 dense matrix over Integer Ring...
sage: skew_hadamard_matrix_from_good_matrices_smallcases(20, existence=True)
True
```

Construct skew Hadamard matrices of order \(mn(n - 1)\) if suitable orthogonal designs exist.

In [Seb1978] is proved that if amicable Hadamard matrices of order \(n\) and an orthogonal design of type \((1, m, mn - m - 1)\) in order \(mn\) exist, then a skew Hadamard matrix of order \(mn(n - 1)\) can be constructed. The paper uses amicable orthogonal designs instead of amicable Hadamard matrices, but the two are equivalent (see [Seb2017]).

Amicable Hadamard matrices are constructed using \texttt{amicable_hadamard_matrices()}. and the orthogonal designs are constructed using the Goethals-Seidel array, with data taken from [Seb2017].

INPUT:

- \(n\) – positive integer; the order of the matrix to be constructed
- \(\text{existence}\) – boolean (default: False); if True, only return whether the skew Hadamard matrix can be constructed
- \(\text{check}\) – boolean (default: True); if True, check that the result is a skew Hadamard matrix before returning it
OUTPUT:
If \( \text{existence=False} \), returns the skew Hadamard matrix of order \( n \). It raises an error if a construction for order \( n \) is not yet implemented, or if \( n \) does not satisfy the constraint. If \( \text{existence=True} \), returns a boolean representing whether the matrix can be constructed or not.

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_from_orthogonal_design
sage: skew_hadamard_matrix_from_orthogonal_design(756)
756 x 756 dense matrix over Integer Ring...
```

If \( \text{existence is True} \), the function returns a boolean:

```python
sage: skew_hadamard_matrix_from_orthogonal_design(200, existence=True)
False
```

sage.combinat.matrices.hadamard_matrix.skew_hadamard_matrix_spence_1975(\( n \), \( \text{existence=False} \), \( \text{check=True} \))

Construct a skew Hadamard matrix of order \( n = 4(1 + q + q^2) \) using the Spence construction.

If \( n = 4(1 + q + q^2) \) where \( q \) is a prime power such that either \( 1 + q + q^2 \) is a prime congruent to 3, 5, 7 mod 8 or \( 3 + 2q + 2q^2 \) is a prime power, then a skew Hadamard matrix of order \( n \) can be constructed using the Goethals Seidel array. The four matrices \( A, B, C, D \) plugged into the GS-array are created using complementary difference sets of order \( 1 + q + q^2 \) (which exist if \( q \) satisfies the conditions above), and a cyclic planar difference set with parameters \( (1 + q^2 + q^4, 1 + q^2, 1) \). These are constructed by the functions sage.combinat.designs.difference_family.complementary_difference_sets() and sage.combinat.designs.difference_family.difference_family().

For more details, see [Spe1975b].

INPUT:
- \( n \) – positive integer; the order of the matrix to be constructed
- \( \text{existence} \) – boolean (default: False); if True, only return whether the Hadamard matrix can be constructed
- \( \text{check} \) – boolean (default: True); check that the result is a skew Hadamard matrix before returning it

OUTPUT:
If \( \text{existence=False} \), returns the skew Hadamard matrix of order \( n \). It raises an error if \( n \) does not satisfy the required conditions. If \( \text{existence=True} \), returns a boolean representing whether the matrix can be constructed or not.

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_spence_1975
sage: skew_hadamard_matrix_spence_1975(52, existence=False, check=True)
52 x 52 dense matrix over Integer Ring...
```

If \( \text{existence is True} \), the function returns a boolean:

```python
sage: skew_hadamard_matrix_spence_1975(52, existence=True)
True
```
Construct skew Hadamard matrix of order $n$ using Spence construction.

This function will construct skew Hadamard matrix of order $n = 2(q + 1)$ where $q$ is a prime power with $q = 5 \pmod{8}$. The construction is taken from [Spe1977], and the relative difference sets are constructed using `sage.combinat.designs.difference_family.relative_difference_set_from_homomorphism()`.

INPUT:

- $n$ – positive integer
- check – boolean (default: True); if True, check that the resulting matrix is Hadamard before returning it

OUTPUT:

If $n$ satisfies the requirements described above, the function returns a $n \times n$ Hadamard matrix. Otherwise, an exception is raised.

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_spence_construction
sage: skew_hadamard_matrix_spence_construction(28)
28 x 28 dense matrix over Integer Ring...
```

Construct a skew Hadamard matrix of order $n = 2(q + 1)$ where $q = p^t$ is a prime power with $p \equiv 5 \pmod{8}$ and $t \equiv 2 \pmod{4}$.

Assuming $n$ satisfies the conditions above, it is possible to construct two supplementary difference sets $A, B$ (see [Whi1971]), and these can be used to construct a skew Hadamard matrix, as described in [BS1969].

INPUT:

- $n$ – positive integer; the order of the matrix to be constructed
- existence – boolean (default: False); If True, only return whether the Hadamard matrix can be constructed
- check – boolean (default: True); if True, check that the result is a skew Hadamard matrix before returning it

OUTPUT:

If existence=False, returns the skew Hadamard matrix of order $n$. It raises an error if $n$ does not satisfy the required conditions. If existence=True, returns a boolean representing whether the matrix can be constructed or not.

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_whiteman_construction
sage: skew_hadamard_matrix_whiteman_construction(52)
52 x 52 dense matrix over Integer Ring...
sage: skew_hadamard_matrix_whiteman_construction(52, existence=True)
True
```
Combinatorics, Release 10.0

Note: A more general version of this construction is \texttt{skew_hadamard_matrix_from_complementary_difference_sets()}. sage.combinat.matrices.hadamard_matrix.symmetric_conference_matrix\(n, \text{check}=\text{True}\)

Tries to construct a symmetric conference matrix

A conference matrix is an \(n \times n\) matrix \(C\) with 0s on the main diagonal and 1s and -1s elsewhere, satisfying \(CC^\top = (n - 1)I\). If \(C = C^\top\) then \(n \equiv 2 \mod 4\) and \(C\) is Seidel adjacency matrix of a graph, whose descendent graphs are strongly regular graphs with parameters \((n - 1, (n - 2)/2, (n - 6)/4, (n - 2)/4)\), see Sec.10.4 of [BH2012]. Thus we build \(C\) from the Seidel adjacency matrix of the latter by adding row and column of 1s.

INPUT:

- \(n\) – integer; dimension of the matrix
- \(\text{check}\) – boolean (default: True); whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.matrices.hadamard_matrix import symmetric_conference_matrix sage: C = symmetric_conference_matrix(10); C
\[ 0 1 1 1 1 1 1 1 1 1
 1 0 -1 -1 1 -1 1 1 1 -1
 1 -1 0 -1 1 -1 -1 1 1 1
 1 -1 -1 0 -1 1 1 1 -1 1
 1 1 1 -1 0 -1 -1 1 -1 1
 1 -1 1 1 -1 0 -1 1 1 1
 1 1 -1 1 -1 -1 0 -1 1 1
 1 1 -1 1 1 -1 0 -1 -1 1
 1 1 -1 1 1 1 -1 0 -1 -1
 1 -1 1 1 1 -1 1 -1 1 -1 0\]
sage: C^2 == 9*identity_matrix(10) and C == C.T
True
\end{verbatim}

\begin{verbatim}
sage.combinat.matrices.hadamard_matrix.symmetric_conference_matrix_paley\(n)\)

Construct a symmetric conference matrix of order \(n\).

A conference matrix is an \(n \times n\) matrix \(C\) with 0s on the main diagonal and 1s and -1s elsewhere, satisfying \(CC^\top = (n - 1)I\). This construction assumes that \(q = n - 1\) is a prime power, with \(q \equiv 1 \mod 4\). See [Hora] or [Lon2013].

These matrices are used in \texttt{hadamard_matrix_paleyII()}. INPUT:

- \(n\) – integer; the order of the symmetric conference matrix to construct

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.matrices.hadamard_matrix import symmetric_conference_matrix_paley
sage: symmetric_conference_matrix_paley(6)
\[ 0 1 1 1 1 1
 1 0 -1 -1 -1 1
 1 1 0 1 -1 -1
 1 1 0 1 -1 -1
 1 -1 1 0 1 -1
\]
\end{verbatim}
sage.combinat.matrices.hadamard_matrix.szekeres_difference_set_pair\((m, \text{check}=\text{True})\)

Construct Szekeres \((2m+1, m, 1)\)-cyclic difference family

Let \(4m + 3\) be a prime power. Theorem 3 in [Sz1969] contains a construction of a pair of complementary difference sets \(A, B\) in the subgroup \(G\) of the quadratic residues in \(F_{4m+3}^*\). Namely \(|A| = |B| = m\), \(a \in A\) whenever \(a - 1 \in G\), \(b \in B\) whenever \(b + 1 \in G\). See also Theorem 2.6 in [SWW1972] (there the formula for \(B\) is correct, as opposed to (4.2) in [Sz1969], where the sign before 1 is wrong.

In modern terminology, for \(m > 1\) the sets \(A\) and \(B\) form a difference family with parameters \((2m+1, m, 1)\). I.e. each non-identity \(g \in G\) can be expressed uniquely as \(xy^{-1}\) for \(x, y \in A\) or \(x, y \in B\). Other, specific to this construction, properties of \(A\) and \(B\) are: for \(a\) in \(A\) one has \(a - 1\) not in \(A\), whereas for \(b\) in \(B\) one has \(b^{-1}\) in \(B\).

INPUT:

- \(m\) – integer; dimension of the matrix
- \(\text{check}\) – boolean (default: \(\text{True}\)); whether to check \(A\) and \(B\) for correctness

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.matrices.hadamard_matrix import szekeres_difference_set_pair
sage: G,A,B=szekeres_difference_set_pair(6)
sage: G,A,B=szekeres_difference_set_pair(7)
\end{verbatim}

REFERENCE:

- [Sz1969]

sage.combinat.matrices.hadamard_matrix.turyn_type_hadamard_matrix_smallcases\((n, \text{existence}=\text{False, check}=\text{True})\)

Construct an Hadamard matrix of order \(n\) from available 4-symbol \(\delta\) codes and Williamson quadruples.

The function looks for Baumert-Hall units and Williamson type matrices from \texttt{four_symbol_delta_code_smallcases()} and \texttt{williamson_type_quadruples_smallcases()} and use them to construct an Hadamard matrix with the Turyn construction defined in \texttt{hadamard_matrix_turyn_type()}.

INPUT:

- \(n\) – integer; the order of the matrix to be constructed
- \(\text{existence}\) – boolean (default: \(\text{False}\)): if \(\text{True}\), only check if the matrix exists
- \(\text{check}\) – boolean (default: \(\text{True}\)): if \(\text{True}\), check that the matrix is an Hadamard matrix before returning

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.matrices.hadamard_matrix import turyn_type_hadamard_matrix_smallcases
sage: turyn_type_hadamard_matrix_smallcases(28, existence=True)
  True
sage: turyn_type_hadamard_matrix_smallcases(28)
  28 x 28 dense matrix over Integer Ring...
\end{verbatim}
sage.combinat.matrices.hadamard_matrix.typeI_matrix_difference_set(G, A)

(1,-1)-incidence type I matrix of a difference set $A$ in $G$

Let $A$ be a difference set in a group $G$ of order $n$. Return $n \times n$ matrix $M$ with $M_{ij} = 1$ if $A_iA_j^{-1} \in A$, and $M_{ij} = -1$ otherwise.

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import szekeres_difference_set_pair
sage: G, A, B = szekeres_difference_set_pair(2)
sage: typeI_matrix_difference_set(G, A)
[-1  1 -1 -1  1]
[-1 -1  1  1  1]
[ 1  1 -1 -1 -1]
[ 1 -1  1  1 -1]
[-1 -1  1  1 -1]
```

sage.combinat.matrices.hadamard_matrix.williamson_goethals_seidel_skew_hadamard_matrix(a, b, c, d, check=True)

Williamson-Goethals-Seidel construction of a skew Hadamard matrix

Given $n \times n$ (anti)circulant matrices $A, B, C, D$ with 1,-1 entries, and satisfying $A + A^\top = 2I$, $AA^\top + BB^\top + CC^\top + DD^\top = 4nI$, one can construct a skew Hadamard matrix of order $4n$, cf. [GS70s].

INPUT:

- $a$ – 1,-1 list; the 1st row of $A$
- $b$ – 1,-1 list; the 1st row of $B$
- $c$ – 1,-1 list; the 1st row of $C$
- $d$ – 1,-1 list; the 1st row of $D$
- check – boolean (default: True); if True, check that the resulting matrix is skew Hadamard before returning it

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import williamson_goethals_seidel_skew_hadamard_matrix as WGS
sage: a = [ 1, 1, 1, -1, 1, -1, -1, 1, -1]
sage: b = [ 1, -1, 1, 1, -1, -1, 1, 1, -1]
sage: c = [-1, -1]+[1]*6+[1]
sage: d = [ 1, 1, 1, -1, 1, 1, -1, 1, 1]
sage: M = WGS(a, b, c, d, check=True)
```

REFERENCES:

- [GS70s]
- [Wall71]
- [KoSt08]
sage.combinat.matrices.hadamard_matrix.williamson_hadamard_matrix_smallcases(n, existence=False, check=True)

Construct Williamson type Hadamard matrices for some small values of n.

This function uses the data contained in sage.combinat.matrices.hadamard_matrix.williamson_type_quadruples_smallcases() to create Hadamard matrices of the Williamson type, using the construction from sage.combinat.matrices.hadamard_matrix.hadamard_matrix_williamson_type().

INPUT:

• n – integer; the order of the matrix
• existence – boolean (default: False); if True, only check that we can do the construction
• check – boolean (default: True); if True check the result

sage.combinat.matrices.hadamard_matrix.williamson_type_quadruples_smallcases(n, existence=False)

Quadruples of matrices that can be used to construct Williamson type Hadamard matrices.

This function contains for some values of n, four \( n \times n \) matrices used in the Williamson construction of Hadamard matrices. Namely, the function returns the first row of 4 \( n \times n \) circulant matrices with the properties described in sage.combinat.matrices.hadamard_matrix.hadamard_matrix_williamson_type(). The matrices for \( n = 3, 5, \ldots, 29, 37, 43 \) are given in [Ha83]. The matrices for \( n = 31, 33, 39, 41, 45, 49, 51, 55, 57, 61, 63 \) are given in [Lon2013].

INPUT:

• n – integer; the order of the matrices to be returned
• existence – boolean (default: False); if True, only check that we have the quadruple

OUTPUT:

If existence is false, returns a tuple containing four vectors, each being the first line of one of the four matrices. It raises an error if no such matrices are available. If existence is true, returns a boolean representing whether the matrices are available or not.

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import williamson_type_quadruples_smallcases
sage: williamson_type_quadruples_smallcases(29)
((1, 1, 1, -1, -1, 1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1),
 (1, -1, 1, -1, -1, 1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1),
 (1, 1, 1, 1, -1, 1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1),
 (1, 1, 1, 1, -1, 1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, 1))
```

```
sage: williamson_type_quadruples_smallcases(43, existence=True)
True
```
5.1.138 Latin Squares

A Latin square of order \( n \) is an \( n \times n \) array such that each symbol \( s \in \{0, 1, \ldots, n-1\} \) appears precisely once in each row, and precisely once in each column. A partial Latin square of order \( n \) is an \( n \times n \) array such that each symbol \( s \in \{0, 1, \ldots, n-1\} \) appears at most once in each row, and at most once in each column. Empty cells are denoted by \(-1\). A Latin square \( L \) is a completion of a partial Latin square \( P \) if \( P \subseteq L \). If \( P \) completes to just \( L \) then \( P \) has unique completion.

A Latin bitrade \((T_1, T_2)\) is a pair of partial Latin squares such that:

1. \( \{ (i, j) \mid (i, j, k) \in T_1 \text{ for some symbol } k \} = \{ (i, j) \mid (i, j, k') \in T_2 \text{ for some symbol } k' \}; \)
2. for each \( (i, j, k) \in T_1 \) and \( (i, j, k') \in T_2, k \neq k' \);
3. the symbols appearing in row \( i \) of \( T_1 \) are the same as those of row \( i \) of \( T_2 \); the symbols appearing in column \( j \) of \( T_1 \) are the same as those of column \( j \) of \( T_2 \).

Intuitively speaking, a bitrade gives the difference between two Latin squares, so if \((T_1, T_2)\) is a bitrade for the pair of Latin squares \((L_1, L_2)\), then \( L_1 = (L_2 \setminus T_1) \cup T_2 \) and \( L_2 = (L_1 \setminus T_2) \cup T_1 \).

This file contains:

1. LatinSquare class definition;
2. some named Latin squares (back circulant, forward circulant, abelian 2-group);
3. functions is_partial_latin_square and is_latin_square to test if a LatinSquare object satisfies the definition of a Latin square or partial Latin square, respectively;
4. tests for completion and unique completion (these use the C++ implementation of Knuth’s dancing links algorithm to solve the problem as an instance of \(0-1\) matrix exact cover);
5. functions for calculating the \( \tau_i \) representation of a bitrade and the genus of the associated hypermap embedding;
6. Markov chain of Jacobson and Matthews (1996) for generating Latin squares uniformly at random (provides a generator interface);
7. a few examples of \( \tau_i \) representations of bitrades constructed from the action of a group on itself by right multiplication, functions for converting to a pair of LatinSquare objects.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(5)
sage: B
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
sage: B.is_latin_square()
True
sage: B[0, 1] = 0
sage: B.is_latin_square()
False

sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[ 0 -1 3 1]
```
Todo:

1. Latin squares with symbols from a ring instead of the integers \(\{0, 1, \ldots, n-1\}\).
2. Isotopism testing of latin squares and bitrades via graph isomorphism (naity?).
3. Combinatorial constructions for bitrades.

AUTHORS:

- Carlo Hamalainen (2008-03-23): initial version

**class** `sage.combinat.matrices.latin.LatinSquare(*args)`

Bases: `object`

Latin squares.

This class implements a latin square of order \(n\) with rows and columns indexed by the set \(0, 1, \ldots, n-1\) and symbols from the same set. The underlying latin square is a matrix(ZZ, \(n, n\)). If \(L\) is a latin square, then the cell at row \(r\), column \(c\) is empty if and only if \(L[r, c] < 0\). In this way we allow partial latin squares and can speak of completions to latin squares, etc.

There are two ways to declare a latin square:

Empty latin square of order \(n\):

```python
sage: n = 3
sage: L = LatinSquare(n)
sage: L
[-1 -1 -1]
[-1 -1 -1]
[-1 -1 -1]
```

Latin square from a matrix:

```python
sage: M = matrix(ZZ, [[0, 1], [2, 3]])
sage: LatinSquare(M)
[0 1]
[2 3]
```

**actual_row_col_sym_sizes()**

Bitrades sometimes end up in partial latin squares with unused rows, columns, or symbols. This function works out the actual number of used rows, columns, and symbols.
Warning: We assume that the unused rows/columns occur in the lower right of self, and that the used symbols are in the range \( \{0, 1, \ldots, m\} \) (no holes in that list).

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(3)
sage: B[0,0] = B[2,1] = -1
sage: B
[-1  1 -1]
[ 1  2 -1]
[ 2 -1 -1]
sage: B.actual_row_col_sym_sizes()
(3, 2, 2)
```

apply_isotopism\((row\_perm, col\_perm, sym\_perm)\)

An isotopism is a permutation of the rows, columns, and symbols of a partial latin square self. Use isotopism() to convert a tuple (indexed from 0) to a Permutation object.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(5)
sage: B
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
sage: alpha = isotopism((0,1,2,3,4))
sage: beta = isotopism((1,0,2,3,4))
sage: gamma = isotopism((2,1,0,3,4))
sage: B.apply_isotopism(alpha, beta, gamma)
[3 4 2 0 1]
[0 2 3 1 4]
[1 3 0 4 2]
[4 0 1 2 3]
[2 1 4 3 0]
```

clear_cells()

Mark every cell in self as being empty.

EXAMPLES:

```python
sage: A = LatinSquare(matrix(ZZ, [[0, 1], [2, 3]]))
sage: A.clear_cells()
sage: A
[-1 -1]
[-1 -1]
```

column\((x)\)

Return column \(x\) of the latin square.
EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(3).column(0)
(0, 1, 2)
```

`contained_in(Q)`

Return True if self is a subset of Q?

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: P = elementary_abelian_2group(2)
sage: P[0, 0] = -1
sage: P.contained_in(elementary_abelian_2group(2))
True
sage: back_circulant(4).contained_in(elementary_abelian_2group(2))
False
```

`disjoint_mate_dlxcpp_rows_and_map(allow_subtrade)`

Internal function for find_disjoint_mates.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(4)
sage: B.disjoint_mate_dlxcpp_rows_and_map(allow_subtrade = True)

`dlxcpp_has_unique_completion()`

Check if the partial latin square self of order n can be embedded in precisely one latin square of order n.

5.1. Comprehensive Module List 1393
EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(2).dlcpp_has_unique_completion()
True
sage: P = LatinSquare(2)
sage: P.dlxcpp_has_unique_completion()
False
sage: P[0, 0] = 0
sage: P.dlxcpp_has_unique_completion()
True
```

dumps()
Since the latin square class does not hold any other private variables we just call dumps on self.square:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(2) == loads(dumps(back_circulant(2)))
True
```

filled_cells_map()
Number the filled cells of self with integers from \{1, 2, 3,\ldots\}.

INPUT:

• self – partial latin square self (empty cells have negative values)

OUTPUT:

A dictionary cells_map where cells_map[(i,j)] = m means that (i,j) is the m-th filled cell in P, while cells_map[m] = (i,j).

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: D = T1.filled_cells_map()
sage: {i: v for i,v in D.items() if i in ZZ}
{1: (0, 0),
 2: (0, 2),
 3: (0, 3),
 4: (1, 1),
 5: (1, 2),
 6: (1, 3),
 7: (2, 0),
 8: (2, 1),
 9: (2, 2),
10: (3, 0),
11: (3, 1),
12: (3, 3)}
sage: {i: v for i,v in D.items() if i not in ZZ}
{(0, 0): 1,
 (0, 2): 2,
 (0, 3): 3,
(continues on next page)
1. 1: 4,  
(1, 2): 5,  
(1, 3): 6,  
(2, 0): 7,  
(2, 1): 8,  
(2, 2): 9,  
(3, 0): 10,  
(3, 1): 11,  
(3, 3): 12}

\(\text{find_disjoint_mates}(nr\_\_to\_\_find=\text{None}, allow\_\_subtrade=\text{False})\)

**Warning:** If allow\_subtrade is True then we may return a partial latin square that is not disjoint to self. In that case, use bitrade(P, Q) to get an actual bitrade.

**EXAMPLES:**

```
sage: from sage.combinat.matrices.latin import *  
sage: B = back_circulant(4)  
sage: g = B.find_disjoint_mates(allow_subtrade = True)  
sage: B1 = next(g)  
sage: B0, B1 = bitrade(B, B1)  
sage: assert is_bitrade(B0, B1)  
sage: print(B0)  
[-1 1 2 -1]  
[-1 2 -1 0]  
[-1 -1 -1 -1]  
[-1 0 1 2]  
sage: print(B1)  
[-1 2 1 -1]  
[-1 0 -1 2]  
[-1 -1 -1 -1]  
[-1 1 2 0]
```

\(\text{gcs()}\)

A greedy critical set of a latin square self is found by successively removing elements in a row-wise (bottom-up) manner, checking for unique completion at each step.

**EXAMPLES:**

```
sage: from sage.combinat.matrices.latin import *  
sage: A = elementary_abelian_2group(3)  
sage: G = A.gcs()  
sage: A  
\[
\begin{bmatrix}
0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 \\
1 & 0 & 3 & 2 & 5 & 4 & 7 & 6 \\
2 & 3 & 0 & 1 & 6 & 7 & 4 & 5 \\
3 & 2 & 1 & 0 & 7 & 6 & 5 & 4 \\
4 & 5 & 6 & 7 & 0 & 1 & 2 & 3 \\
5 & 4 & 7 & 6 & 1 & 0 & 3 & 2 \\
6 & 7 & 4 & 5 & 2 & 3 & 0 & 1 \\
\end{bmatrix}
\]
```
is_completable()
Return True if the partial latin square can be completed to a latin square.

EXAMPLES:
The following partial latin square has no completion because there is nowhere that we can place the symbol 0 in the third row:

```
sage: B = LatinSquare(3)
sage: B[0, 0] = 0
sage: B[1, 1] = 0
sage: B[2, 2] = 1
sage: B
[ 0 -1 -1]
[-1 0 -1]
[-1 -1 1]
sage: B.is_completable()
False
sage: B[2, 2] = 0
sage: B.is_completable()
True
```

is_empty_column(c)
Check if column c of the partial latin square self is empty.

EXAMPLES:
```
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(4)
sage: L.is_empty_column(0)
False
sage: L[0,0] = L[1,0] = L[2,0] = L[3,0] = -1
sage: L.is_empty_column(0)
True
```

is_empty_row(r)
Check if row r of the partial latin square self is empty.

EXAMPLES:
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(4)
sage: L.is_empty_row(0)
False
sage: L[0,0] = L[0,1] = L[0,2] = L[0,3] = -1
sage: L.is_empty_row(0)
True

is_latin_square()

self is a latin square if it is an n by n matrix, and each symbol in \([0, 1, \ldots, n-1]\) appears exactly once in each row, and exactly once in each column.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *
sage: elementary_abelian_2group(4).is_latin_square()
True
sage: forward_circulant(7).is_latin_square()
True

is_partial_latin_square()

self is a partial latin square if it is an n by n matrix, and each symbol in \([0, 1, \ldots, n-1]\) appears at most once in each row, and at most once in each column.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *
sage: LatinSquare(4).is_partial_latin_square()
True
sage: back_circulant(3).gcs().is_partial_latin_square()
True
sage: back_circulant(6).is_partial_latin_square()
True

is_uniquely_completable()

Return True if the partial latin square self has exactly one completion to a latin square. This is just a wrapper for the current best-known algorithm, Dancing Links by Knuth. See dancing_links.spyx

EXAMPLES:

sage: from sage.combinat.matrices.latin import *
sage: back_circulant(4).gcs().is_uniquely_completable()
True
sage: G = elementary_abelian_2group(3).gcs()
sage: G.is_uniquely_completable()
True
sage: G[0, 0] = -1
sage: G.is_uniquely_completable()
False
latex()

Return LaTeX code for the latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: print(back_circulant(3).latex())
\begin{array}{|c|c|c|}
\hline
0 & 1 & 2 \\
\hline
1 & 2 & 0 \\
\hline
2 & 0 & 1 \\
\end{array}
```

list()

Convert the latin square into a list, in a row-wise manner.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(3).list()
[0, 1, 2, 1, 2, 0, 2, 0, 1]
```

ncols()

Number of columns in the latin square.

EXAMPLES:

```
sage: LatinSquare(3).ncols()
3
```

nr_distinct_symbols()

Return the number of distinct symbols in the partial latin square self.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(5).nr_distinct_symbols()
5
sage: L = LatinSquare(10)
sage: L.nr_distinct_symbols()
0
sage: L[0, 0] = 0
sage: L[0, 1] = 1
sage: L.nr_distinct_symbols()
2
```

nr_filled_cells()

Return the number of filled cells (i.e. cells with a positive value) in the partial latin square self.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: LatinSquare(matrix([[0, -1], [-1, 0]])).nr_filled_cells()
2
```

nrows()

Number of rows in the latin square.

EXAMPLES:
permissible_values(r, c)

Find all values that do not appear in row r and column c of the latin square self. If self[r, c] is filled then we return the empty list.

INPUT:

• self - LatinSquare
• r - int; row of the latin square
• c - int; column of the latin square

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(5)
sage: L[0, 0] = -1
sage: L.permissible_values(0, 0)
[0]
```

random_empty_cell()

Find an empty cell of self, uniformly at random.

INPUT:

• self - LatinSquare

OUTPUT:

• [r, c] - cell such that self[r, c] is empty, or returns None if self is a (full) latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: P = back_circulant(2)
sage: P[1,1] = -1
sage: P.random_empty_cell()
[1, 1]
```

row(x)

Return row x of the latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(3).row(0)
(0, 1, 2)
```

set_immutable()

A latin square is immutable if the underlying matrix is immutable.

EXAMPLES:

```
sage: L = LatinSquare(matrix(ZZ, [[0, 1], [2, 3]]))
sage: L.set_immutable()
```
top_left_empty_cell()
Return the least [r, c] such that self[r, c] is an empty cell. If all cells are filled then we return None.

INPUT:
• self - LatinSquare

EXAMPLES:

vals_in_col(c)
Return a dictionary with key e if and only if column c of self has the symbol e.

EXAMPLES:

vals_in_row(r)
Return a dictionary with key e if and only if row r of self has the symbol e.

EXAMPLES:

sage.combinat.matrices.latin.LatinSquare_generator(L_start, check_assertions=False)
Generator for a sequence of uniformly distributed latin squares, given L_start as the initial latin square.

This code implements the Markov chain algorithm of Jacobson and Matthews (1996), see below for the BibTex entry. This generator will never throw the StopIteration exception, so it provides an infinite sequence of latin squares.

EXAMPLES:

Use the back circulant latin square of order 4 as the initial square and print the next two latin squares given by the Markov chain:

sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(3)
sage: B[0, 0] = -1
sage: B vals_in_col(0)
{0: True, 1: True, 2: True}

sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(3)
sage: B[0, 0] = -1
dsage: back_circulant(3).vals_in_row(0)
{0: True, 1: True, 2: True}

sage.combinat.matrices.latin.LatinSquare_generator(L_start, check_assertions=False)
Generator for a sequence of uniformly distributed latin squares, given L_start as the initial latin square.

This code implements the Markov chain algorithm of Jacobson and Matthews (1996), see below for the BibTex entry. This generator will never throw the StopIteration exception, so it provides an infinite sequence of latin squares.

EXAMPLES:

Use the back circulant latin square of order 4 as the initial square and print the next two latin squares given by the Markov chain:

sage: from sage.combinat.matrices.latin import *
sage: g = LatinSquare_generator(back_circulant(4))

(continues on next page)
REFERENCES:
sage.combinat.matrices.latin.alternating_group_bitrade_generators(m)
Construct generators a, b, c for the alternating group on 3m+1 points, such that a*b*c = 1.

EXAMPLES:
```python
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (a, b, c, G)
((1,2,3), (1,4,2), (2,4,3), Permutation Group with generators [(1,2,3), (1,4,2)])
sage: a*b*c
False
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[ 0 -1  3  1]
[-1  1  0  2]
[ 1  3  2 -1]
[ 2  0 -1  3]
sage: T2
[ 1 -1  0  3]
[-1  0  2  1]
[ 2  1  3 -1]
[ 0  3 -1  2]
```
sage.combinat.matrices.latin.back_circulant(n)
The back-circulant latin square of order n is the Cayley table for (Z_n, +), the integers under addition modulo n.

INPUT:
• n – int; order of the latin square.

EXAMPLES:
```python
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(5)
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
```
sage.combinat.matrices.latin.beta1(rce, T1, T2)
Find the unique (x, c, e) in T2 such that (r, c, e) is in T1.

INPUT:
• rce - tuple (or list) (r, c, e) in T1
• T1, T2 - latin bitrade

OUTPUT: (x, c, e) in T2.
EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( [0,1,2,3,4] )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: beta1([0, 0, 0], T1, T2)
(1, 0, 0)
```

`sage.combinat.matrices.latin.beta2(rce, T1, T2)`

Find the unique \((r, x, e)\) in \(T2\) such that \((r, c, e)\) is in \(T1\).

**INPUT:**
- \(rce\) - tuple (or list) \((r, c, e)\) in \(T1\)
- \(T1, T2\) - latin bitrade

**OUTPUT:**
- \((r, x, e)\) in \(T2\).

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( [0,1,2,3,4] )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: beta2([0, 0, 0], T1, T2)
(0, 1, 0)
```

`sage.combinat.matrices.latin.beta3(rce, T1, T2)`

Find the unique \((r, c, x)\) in \(T2\) such that \((r, c, e)\) is in \(T1\).

**INPUT:**
- \(rce\) - tuple (or list) \((r, c, e)\) in \(T1\)
- \(T1, T2\) - latin bitrade

**OUTPUT:**
- \((r, c, x)\) in \(T2\).

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( [0,1,2,3,4] )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: beta3([0, 0, 0], T1, T2)
(0, 1, 0)
```
sage.combinat.matrices.latin.bitrade(T1, T2)

Form the bitrade (Q1, Q2) from (T1, T2) by setting empty the cells (r, c) such that T1[r, c] == T2[r, c].

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: B1 = back_circulant(5)
sage: alpha = isotopism((0,1,2,3,4))
sage: beta = isotopism((1,0,2,3,4))
sage: gamma = isotopism((2,1,0,3,4))
sage: B2 = B1.apply_isotopism(alpha, beta, gamma)
sage: T1, T2 = bitrade(B1, B2)

sage: T1
[[0 1 -1 3 4]
 [1 -1 -1 4 0]
 [2 -1 4 0 1]
 [3 4 0 1 2]
 [4 0 1 2 3]]

sage: T2
[[3 4 -1 0 1]
 [-1 0 2 1]
 [2 1 4 3 0]
 [0 3 -1 2]]
```

sage.combinat.matrices.latin.bitrade_from_group(a, b, c, G)

Given group elements a, b, c in G such that abc = 1 and the subgroups a, b, c intersect (pairwise) only in the identity, construct a bitrade (T1, T2) where rows, columns, and symbols correspond to cosets of a, b, and c, respectively.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)

sage: T1
[[0 -1 3 1]
 [-1 1 0 2]
 [1 3 2 -1]
 [2 0 -1 3]]

sage: T2
[[1 -1 0 3]
 [-1 0 2 1]
 [2 1 3 -1]
 [0 3 -1 2]]
```

sage.combinat.matrices.latin.cells_map_as_square(cells_map, n)

Return a LatinSquare with cells numbered from 1, 2, ..., to given the dictionary cells_map.
EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[[ 0 -1  3  1]
 [ -1  1  0  2]
 [ 1  3  2 -1]
 [ 2  0 -1  3]]
```

There are 12 filled cells in T:

```python
sage: cells_map_as_square(T1.filled_cells_map(), max(T1.nrows(), T1.ncols()))
[[ 1 -1  2  3]
 [ -1  4  5  6]
 [ 7  8  9 -1]
 [10 11 -1 12]]
```

`sage.combinat.matrices.latin.check_bitrade_generators(a, b, c)`

Three group elements a, b, c will generate a bitrade if a*b*c = 1 and the subgroups a, b, c intersect (pairwise) in just the identity.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = p3_group_bitrade_generators(3)
sage: check_bitrade_generators(a, b, c)
True
sage: check_bitrade_generators(a, b, gap('()'))
False
```

`sage.combinat.matrices.latin.coin()`

Simulate a fair coin (returns True or False) using ZZ.random_element(2).

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import coin
sage: x = coin()
sage: x == 0 or x == 1
True
```

`sage.combinat.matrices.latin.column_containing_sym(L, r, x)`

Given an improper latin square L with \(L[r, c1] = L[r, c2] = x\), return \(c1\) or \(c2\) with equal probability. This is an internal function and should only be used in LatinSquare_generator().

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: L = matrix([(1, 0, 2, 3), (0, 2, 3, 0), (2, 3, 0, 1), (3, 0, 1, 2)])
```

(continues on next page)
sage: L
[[1 0 2 3]
[0 2 3 0]
[2 3 0 1]
[3 0 1 2]]
sage: c = column_containing_sym(L, 1, 0)
sage: c == 0 or c == 3
True

sage.combinat.matrices.latin.direct_product(L1, L2, L3, L4)
The ‘direct product’ of four latin squares L1, L2, L3, L4 of order n is the latin square of order 2n consisting of

|  
|  
|  

where the subsquares L2 and L3 have entries offset by n.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *
sage: direct_product(back_circulant(4), back_circulant(4), elementary_abelian_2group(2), elementary_abelian_2group(2))
[[0 1 2 3 4 5 6 7]
[1 2 3 0 5 6 7 4]
[2 3 0 1 6 7 4 5]
[3 0 1 2 7 4 5 6]
[4 5 6 7 0 1 2 3]
[5 4 7 6 1 0 3 2]
[6 7 4 5 2 3 0 1]
[7 6 5 4 3 2 1 0]]

sage.combinat.matrices.latin.dlxcpp_find_completions(P, nr_to_find=None)
Return a list of all latin squares L of the same order as P such that P is contained in L. The optional parameter nr_to_find limits the number of latin squares that are found.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *
sage: dlxcpp_find_completions(LatinSquare(2))
[[[0 1]
  [1 0]]
[[0 1], [1 0]]
[[[0 1]
  [1 0]]

sage.combinat.matrices.latin.dlxcpp_rows_and_map(P)
Internal function for dlxcpp_find_completions. Given a partial latin square P we construct a list of rows of a 0-1 matrix M such that an exact cover of M corresponds to a completion of P to a latin square.
EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: dlxcpp_rows_and_map(LatinSquare(2))
([[0, 4, 8],
  [1, 5, 8],
  [2, 4, 9],
  [3, 5, 9],
  [0, 6, 10],
  [1, 7, 10],
  [2, 6, 11],
  [3, 7, 11]],
  {(0, 4, 8): (0, 0, 0),
   (0, 6, 10): (1, 0, 0),
   (1, 5, 8): (0, 0, 1),
   (1, 7, 10): (1, 0, 1),
   (2, 4, 9): (0, 1, 0),
   (2, 6, 11): (1, 1, 0),
   (3, 5, 9): (0, 1, 1),
   (3, 7, 11): (1, 1, 1)})
```

`sage.combinat.matrices.latin.elementary_abelian_2group(s)`
Return the latin square based on the Cayley table for the elementary abelian 2-group of order 2s.

INPUT:

• s – int; order of the latin square will be 2s.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: elementary_abelian_2group(3)
[0 1 2 3 4 5 6 7]
[1 0 3 2 5 4 7 6]
[2 3 0 1 6 7 4 5]
[3 2 1 0 7 6 5 4]
[4 5 6 7 0 1 2 3]
[5 4 7 6 1 0 3 2]
[6 7 4 5 2 3 0 1]
[7 6 5 4 3 2 1 0]
```

`sage.combinat.matrices.latin.forward_circulant(n)`
The forward-circulant latin square of order n is the Cayley table for the operation \( r + c = (n-c+r) \mod n \).

INPUT:

• n – int; order of the latin square.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: forward_circulant(5)
[0 4 3 2 1]
[1 0 4 3 2]
[2 1 0 4 3]
[3 2 1 0 4]
[4 3 2 1 0]
```
sage.combinat.matrices.latin.genus(T1, T2)

Return the genus of hypermap embedding associated with the bitrade \((T1, T2)\).

Informally, we compute the \([\tau_1, \tau_2, \tau_3]\) permutation representation of the bitrade. Each cycle of \(\tau_1, \tau_2, \text{ and } \tau_3\) gives a rotation scheme for a black, white, and star vertex (respectively). The genus then comes from Euler’s formula.

For more details see Carlo Hamalainen: *Partitioning 3-homogeneous latin bitrades*. To appear in Geometriae Dedicata, available at arXiv 0710.0938

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: genus(T1, T2)
1
sage: (a, b, c, G) = pq_group_bitrade_generators(3, 7)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: genus(T1, T2)
3
```

sage.combinat.matrices.latin.group_to_LatinSquare(G)

Construct a latin square on the symbols \([0, 1, \ldots, n-1]\) for a group with an \(n \times n\) Cayley table.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import group_to_LatinSquare
sage: group_to_LatinSquare(DihedralGroup(2))
[0 1 2 3]
[1 0 3 2]
[2 3 0 1]
[3 2 1 0]
```

```python
sage: G = gap.Group(PermutationGroupElement((1,2,3)))
sage: group_to_LatinSquare(G)
[0 1 2]
[1 2 0]
[2 0 1]
```

sage.combinat.matrices.latin.is_bitrade(T1, T2)

Combinatorially, a pair \((T1, T2)\) of partial latin squares is a bitrade if they are disjoint, have the same shape, and have row and column balance. For definitions of each of these terms see the relevant function in this file.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism((0, 1, 2, 3, 4))
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
```
sage.combinat.matrices.latin.is_disjoint(T1, T2)

The partial latin squares T1 and T2 are disjoint if T1[r, c] != T2[r, c] or T1[r, c] == T2[r, c] == -1 for each cell [r, c].

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import is_disjoint, back_circulant,
    isotopism
sage: is_disjoint(back_circulant(2), back_circulant(2))
False
```

```python
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_disjoint(T1, T2)
True
```

sage.combinat.matrices.latin.is_primary_bitrade(a, b, c, G)

A bitrade generated from elements a, b, c is primary if a, b, c = G.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = p3_group_bitrade_generators(5)
sage: is_primary_bitrade(a, b, c, G)
True
```

sage.combinat.matrices.latin.is_row_and_col_balanced(T1, T2)

Partial latin squares T1 and T2 are balanced if the symbols appearing in row r of T1 are the same as the symbols appearing in row r of T2, for each r, and if the same condition holds on columns.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: T1 = matrix([[0,1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
sage: T2 = matrix([[0,1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
sage: is_row_and_col_balanced(T1, T2)
True
```

```python
sage: T2 = matrix([[0,3,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
sage: is_row_and_col_balanced(T1, T2)
False
```

sage.combinat.matrices.latin.is_same_shape(T1, T2)

Two partial latin squares T1, T2 have the same shape if T1[r, c] = 0 if and only if T2[r, c] = 0.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: is_same_shape(elementary_abelian_2group(2), back_circulant(4))
True
```

```python
sage: is_same_shape(LatinSquare(5), LatinSquare(5))
True
```
sage: is_same_shape(forward_circulant(5), LatinSquare(5))
False

sage.combinat.matrices.latin.isotopism(p)

Return a Permutation object that represents an isotopism (for rows, columns or symbols of a partial Latin square).

Technically, all this function does is take as input a representation of a permutation of 0, ..., n - 1 and return a Permutation object defined on 1, ..., n.

For a definition of isotopism, see the Wikipedia section on isotopism.

INPUT:

According to the type of input (see examples below):

- an integer n – the function returns the identity on 1, ..., n.
- a string representing a permutation in disjoint cycles notation, e.g. (0, 1, 2)(3, 4, 5) – the corresponding permutation is returned, shifted by 1 to act on 1, ..., n.
- list/tuple of tuples – assumes disjoint cycle notation, see previous entry.
- a list of integers – the function adds 1 to each member of the list, and returns the corresponding permutation.
- a PermutationGroupElement p – returns a permutation describing p without any shift.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *
sage: isotopism(5) # identity on 5 points
[1, 2, 3, 4, 5]

sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: g = G.gen(0)
sage: isotopism(g)
[2, 3, 1, 5, 4]

sage: isotopism([0,3,2,1]) # 0 goes to 0, 1 goes to 3, etc.
[1, 4, 3, 2]

sage: x = isotopism((0,1,2)) # single cycle, presented as a tuple
[2, 3, 1]

sage: x = isotopism(((0,1,2), (3,4))) # tuple of cycles
[2, 3, 1, 5, 4]

sage.combinat.matrices.latin.next_conjugate(L)

Permute L[r, c] = e to the conjugate L[c, e] = r.

We assume that L is an n by n matrix and has values in the range 0, 1, ..., n-1.

EXAMPLES:
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(6)
sage: L
[[0, 1, 2, 3, 4, 5],
 [1, 2, 3, 4, 5, 0],
 [2, 3, 4, 5, 0, 1],
 [3, 4, 5, 0, 1, 2],
 [4, 5, 0, 1, 2, 3],
 [5, 0, 1, 2, 3, 4]]
sage: next_conjugate(L)
[[0, 1, 2, 3, 4, 5],
 [5, 0, 1, 2, 3, 4],
 [4, 5, 0, 1, 2, 3],
 [3, 4, 5, 0, 1, 2],
 [2, 3, 4, 5, 0, 1],
 [1, 2, 3, 4, 5, 0]]
sage: L == next_conjugate(next_conjugate(next_conjugate(L)))
True

sage.combinat.matrices.latin.p3_group_bitrade_generators(p)
Generators for a group of order p^3 where p is a prime.

EXAMPLES:
sage: from sage.combinat.matrices.latin import *
sage: p3_group_bitrade_generators(3)
((2,6,7)(3,8,9), (1,2,3)(4,7,8)(5,6,9), (1,9,2)(3,7,4)(5,8,6), Permutation Group with generators [(2,6,7)(3,8,9), (1,2,3)(4,7,8)(5,6,9)])

sage.combinat.matrices.latin.pq_group_bitrade_generators(p, q)
Generators for a group of order pq where p and q are primes such that (q % p) == 1.

EXAMPLES:
sage: from sage.combinat.matrices.latin import *
sage: pq_group_bitrade_generators(3,7)
((2,3,5)(4,7,6), (1,2,3,4,5,6,7), (1,4,2)(3,5,6), Permutation Group with generators [(2,3,5)(4,7,6), (1,2,3,4,5,6,7)])

sage.combinat.matrices.latin.row_containing_sym(L, c, x)
Given an improper latin square L with L[r1, c] = L[r2, c] = x, return r1 or r2 with equal probability. This is an internal function and should only be used in LatinSquare_generator().

EXAMPLES:
sage: from sage.combinat.matrices.latin import *
sage: L = matrix([[0, 1, 0, 3], [3, 0, 2, 1], [1, 0, 3, 2], [2, 3, 1, 0]])
sage: L
[[0, 1, 0, 3],
 [3, 0, 2, 1],
 [1, 0, 3, 2],
 [2, 3, 1, 0]]
sage: c = row_containing_sym(L, 1, 0)
sage: c == 1 or c == 2
True
sage.combinat.matrices.latin.tau1(T1, T2, cells_map)

The definition of \( \tau_1 \) is

\[
\tau_1 : T1 \rightarrow T1 \\
\tau_1 = \beta_2^{-1} \beta_3
\]

where the composition is left to right and \( \beta_i : T2 \rightarrow T1 \) changes just the \( i^{th} \) coordinate of a triple.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)

sage: is_bitrade(T1, T2)
True
sage: (cells_map, t1, t2, t3) = tau123(T1, T2)
sage: t1

[2, 3, 4, 5, 1, 7, 8, 9, 10, 6, 12, 13, 14, 15, 11, 17, 18, 19, 20, 16, 22, 23, 24, ...
   ˓→ 25, 21]
sage: t1.to_cycles()

[(1, 2, 3, 4, 5), (6, 7, 8, 9, 10), (11, 12, 13, 14, 15), (16, 17, 18, 19, 20), (21, ˓→ 22, 23, 24, 25)]
```

sage.combinat.matrices.latin.tau123(T1, T2)

Compute the \( \tau_i \) representation for a bitrade \((T1, T2)\).

See the functions tau1, tau2, and tau3 for the mathematical definitions.

OUTPUT:

- \((\text{cells\_map, t1, t2, t3})\)

where \(\text{cells\_map}\) is a map to/from the filled cells of \(T1\), and \(t1, t2, t3\) are the \(\tau1, \tau2, \tau3\) permutations.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = pq_group_bitrade_generators(3, 7)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1

[ [0 1 3 -1 -1 -1 -1]
 [1 2 4 -1 -1 -1 -1]
 [2 3 5 -1 -1 -1 -1]
 [3 4 6 -1 -1 -1 -1]
 [4 5 0 -1 -1 -1 -1]
 [5 6 1 -1 -1 -1 -1]
 [6 0 2 -1 -1 -1 -1]]
sage: T2

[ [1 3 0 -1 -1 -1 -1]
 [2 4 1 -1 -1 -1 -1]
 [3 5 2 -1 -1 -1 -1]
 [4 6 3 -1 -1 -1 -1]
```
\[
\begin{bmatrix}
5 & 0 & 4 & -1 & -1 & -1 & -1 \\
6 & 1 & 5 & -1 & -1 & -1 & -1 \\
0 & 2 & 6 & -1 & -1 & -1 & -1 \\
\end{bmatrix}
\]

\texttt{sage: (cells_map, t1, t2, t3) = tau123(T1, T2)}

\texttt{sage: D = cells_map}

\texttt{sage: \{i: v for i,v in D.items() if i in ZZ\}}

\{
1: (0, 0),
2: (0, 1),
3: (0, 2),
4: (1, 0),
5: (1, 1),
6: (1, 2),
7: (2, 0),
8: (2, 1),
9: (2, 2),
10: (3, 0),
11: (3, 1),
12: (3, 2),
13: (4, 0),
14: (4, 1),
15: (4, 2),
16: (5, 0),
17: (5, 1),
18: (5, 2),
19: (6, 0),
20: (6, 1),
21: (6, 2)
\}

\texttt{sage: \{i: v for i,v in D.items() if not i in ZZ\}}

\{
(0, 0): 1,
(0, 1): 2,
(0, 2): 3,
(1, 0): 4,
(1, 1): 5,
(1, 2): 6,
(2, 0): 7,
(2, 1): 8,
(2, 2): 9,
(3, 0): 10,
(3, 1): 11,
(3, 2): 12,
(4, 0): 13,
(4, 1): 14,
(4, 2): 15,
(5, 0): 16,
(5, 1): 17,
(5, 2): 18,
(6, 0): 19,
(6, 1): 20,
(6, 2): 21
\}

\texttt{sage: cells_map_as_square(cells_map, max(T1.nrows(), T1.ncols()))}

\[
\begin{bmatrix}
1 & 2 & 3 & -1 & -1 & -1 & -1 \\
4 & 5 & 6 & -1 & -1 & -1 & -1 \\
\end{bmatrix}
\]
The product $t_1 \ast t_2 \ast t_3$ is the identity, i.e. it fixes every point:

```
sage: len((t1*t2*t3).fixed_points()) == T1.nr_filled_cells()
True
```

The definition of $\tau_2$ is

$$
\tau_2 : T1 \to T1
\tau_2 = \beta_3^{-1} \beta_1
$$

where the composition is left to right and $\beta_i : T2 \to T1$ changes just the $i^{th}$ coordinate of a triple.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: (cells_map, t1, t2, t3) = tau123(T1, T2)
sage: t2 = tau2(T1, T2, cells_map)
sage: t2
[21, 22, 23, 24, 25, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18,]
\rightarrow 19, 20]
sage: t2.to_cycles()
[(1, 21, 16, 11, 6), (2, 22, 17, 12, 7), (3, 23, 18, 13, 8), (4, 24, 19, 14, 9), (5,]
\rightarrow 25, 20, 15, 10)]
```
The definition of $\tau_3$ is
\[
\tau_3 : T1 \to T1
\]
\[
\tau_3 = \beta_1^{-1}\beta_2
\]
where the composition is left to right and $\beta_i : T2 \to T1$ changes just the $i^{th}$ coordinate of a triple.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5)  # identity
sage: z = isotopism(5)  # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: (cells_map, t1, t2, t3) = tau123(T1, T2)
sage: t3 = tau3(T1, T2, cells_map)
sage: t3
[10, 6, 7, 8, 9, 15, 11, 12, 13, 14, 20, 16, 17, 18, 19, 25, 21, 22, 23, 24, 5, 1, ...
˓→2, 3, 4]
sage: t3.to_cycles()
[(1, 10, 14, 18, 22), (2, 6, 15, 19, 23), (3, 7, 11, 20, 24), (4, 8, 12, 16, 25), ...
˓→(5, 9, 13, 17, 21)]
```

**sage.combinat.matrices.latin.tau_to_bitrade(t1, t2, t3)**

Given permutations $t1, t2, t3$ that represent a latin bitrade, convert them to an explicit latin bitrade $(T1, T2)$. The result is unique up to isotopism.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5)  # identity
sage: z = isotopism(5)  # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: _, t1, t2, t3 = tau123(T1, T2)
sage: U1, U2 = tau_to_bitrade(t1, t2, t3)
sage: assert is_bitrade(U1, U2)
sage: U1
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
sage: U2
[4 0 1 2 3]
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
```
5.1.139 Miscellaneous

class sage.combinat.misc.DoublyLinkedList(l)
   Bases: object
   A doubly linked list class that provides constant time hiding and unhideing of entries.
   Note that this list's indexing is 1-based.
   EXAMPLES:

   sage: dll = sage.combinat.misc.DoublyLinkedList([1,2,3]); dll
   Doubly linked list of [1, 2, 3]: [1, 2, 3]
   sage: dll.hide(1); dll
   Doubly linked list of [1, 2, 3]: [2, 3]
   sage: dll.unhide(1); dll
   Doubly linked list of [1, 2, 3]: [1, 2, 3]
   sage: dll.hide(2); dll
   Doubly linked list of [1, 2, 3]: [1, 3]
   sage: dll.unhide(2); dll
   Doubly linked list of [1, 2, 3]: [1, 2, 3]

head()
hide(i)
next(j)
prev(j)
unhide(i)

class sage.combinat.misc.IterableFunctionCall(f, *args, **kwargs)
   Bases: object
   This class wraps functions with a yield statement (generators) by an object that can be iterated over. For example,
   EXAMPLES:

   sage: def f():
   ...    yield 'a'; yield 'b'
   This does not work:
   sage: for z in f: print(z)
   Traceback (most recent call last):
   ...    TypeError: 'function' object is not iterable

   Use IterableFunctionCall if you want something like the above to work:
   sage: from sage.combinat.misc import IterableFunctionCall
   sage: g = IterableFunctionCall(f)
   sage: for z in g: print(z)
   a
   b
   If your function takes arguments, just put them after the function name. You needn't enclose them in a tuple or anything, just put them there:
```python
sage: def f(n, m):
    yield 'a' * n;
    yield 'b' * m;
    yield 'foo'
sage: g = IterableFunctionCall(f, 2, 3)
sage: for z in g: print(z)
  aa
  bbb
  foo
```

`sage.combinat.misc.check_integer_list_constraints(l, **kwargs)`

**EXAMPLES:**

```python
sage: from sage.combinat.misc import check_integer_list_constraints
sage: cilc = check_integer_list_constraints
sage: l = [[2,1,3],[1,2],[3,3],[4,1,1]]
sage: cilc(l, min_part=2)
[[3, 3]]
sage: cilc(l, max_part=2)
[[1, 2]]
sage: cilc(l, length=2)
[[1, 2], [3, 3]]
sage: cilc(l, max_length=2)
[[1, 2], [3, 3]]
sage: cilc(l, min_length=3)
[[2, 1, 3], [4, 1, 1]]
sage: cilc(l, max_slope=0)
[[3, 3], [4, 1, 1]]
sage: cilc(l, min_slope=1)
[[1, 2]]
sage: cilc(l, outer=[2,2])
[[1, 2]]
sage: cilc(l, inner=[2,2])
[[3, 3]]
```

```python
sage: cilc([1,2,3], length=3, singleton=True)
[1, 2, 3]
sage: cilc([1,2,3], length=2, singleton=True) is None
True
```

`sage.combinat.misc.umbral_operation(poly)`

Returns the umbral operation $\downarrow$ applied to poly.

The umbral operation replaces each instance of $x_i^{a_i}$ with $x_i \ast (x_i - 1) \ast \cdots \ast (x_i - a_i + 1)$.

**EXAMPLES:**

```python
sage: P = PolynomialRing(QQ, 2, 'x')
sage: x = P.gens()
sage: from sage.combinat.misc import umbral_operation
sage: umbral_operation(x[0]**3) == x[0]**(x[0]-1)**(x[0]-2)
True
sage: umbral_operation(x[0]**x[1])
x0**x1
sage: umbral_operation(x[0]+x[1])
x0 + x1
```

(continues on next page)
5.1.140 Ordered Multiset Partitions into Sets and the Minimaj Crystal

This module provides element and parent classes for ordered multiset partitions. It also implements the minimaj crystal of Benkart et al. [BCHOPSY2017]. (See \texttt{MinimajCrystal}.)

AUTHORS:

• Aaron Lauve (2018): initial implementation. First draft of minimaj crystal code provided by Anne Schilling.

REFERENCES:

• [BCHOPSY2017]
• [HRW2015]
• [HRS2016]
• [LM2018]

EXAMPLES:

An ordered multiset partition into sets of the multiset \{1, 3, 3, 5\}:

\begin{verbatim}
sage: OrderedMultisetPartitionIntoSets([5, 3], [1, 3])
\end{verbatim}

\begin{verbatim}
[[3, 5], [1, 3]]
\end{verbatim}

Ordered multiset partitions into sets of the multiset \{1, 3, 3\}:

\begin{verbatim}
sage: OrderedMultisetPartitionsIntoSets([1, 1, 3]).list()
\end{verbatim}

\begin{verbatim}
[[[1], [1], [3]], [[1], [1, 3]], [[1], [3], [1]], [[1, 3], [1], [1]]
\end{verbatim}

Ordered multiset partitions into sets of the integer 4:

\begin{verbatim}
sage: OrderedMultisetPartitionsIntoSets([1, 4, 3]).list()
\end{verbatim}

\begin{verbatim}
[[[1], [1], [4], [4]], [[1], [1, 4]], [[1, 4], [1]], [[1, 1], [4]], [[1], [4], [1]], [[1], [1], [4], [4]], [[1], [1], [4], [1]]
\end{verbatim}

Ordered multiset partitions into sets on the alphabet \{1, 4\} of order 3:

\begin{verbatim}
sage: OrderedMultisetPartitionsIntoSets([1, 4], 3).list()
\end{verbatim}

\begin{verbatim}
[[[1, 4], [1], [[1, 4], [4], [1], [4], [1]], [[1, 1], [4], [4], [1]]]
\end{verbatim}

Crystal of ordered multiset partitions into sets on the alphabet \{1, 2, 3\} with 4 letters divided into 2 blocks:

\begin{verbatim}
sage: crystals.Minimaj(3, 4, 2).list()
\end{verbatim}

\begin{verbatim}
[((2, 3, 1), (1,)), ((2, 3), (1, 2)), ((2, 3), (1, 3)), ((2, 1), (1, 2)), ((3, 1), (1, 2)), ((3, 1, 2), (2,)), ((3, 1), (1, 3)), ((3, 1), (2, 3)), ((3, 2), (2, 3)), ((2, 1), (1, 3)), ((2, 1), (1, 2, 3)), ((3,), (1, 2, 3)), ((1,), (1, 2, 3)), ((1, 2), (2, 3)), ((1, 2, 3), (3,))]
\end{verbatim}
class sage.combinat.multipartition_into_sets_ordered.MinimajCrystal(n, ell, k)

Bases: UniqueRepresentation, Parent

Crystal of ordered multiset partitions into sets with \(ell\) letters from alphabet \(\{1, 2, \ldots, n\}\) divided into \(k\) blocks. Elements are represented in the minimaj ordering of blocks as in Benkart et al. [BCHOPSY2017].

Note: Elements are not stored internally as ordered multiset partitions into sets, but as certain (pairs of) words stemming from the minimaj bijection \(\phi\) of [BCHOPSY2017]. See sage.combinat.multipartition_into_sets_ordered.MinimajCrystal.Element for further details.

AUTHORS:

• Anne Schilling (2018): initial draft
• Aaron Lauve (2018): changed to use Letters crystal for elements

EXAMPLES:

```
sage: list(crystals.Minimaj(2,3,2))
[((2, 1), (1,)), ((2,), (1, 2)), ((1,), (1, 2)), ((1, 2), (2,))]
sage: b = crystals.Minimaj(3, 5, 2).an_element(); b
((2, 3, 1), (1, 2))
sage: b.f(2)
((2, 3, 1), (1, 3))
sage: b.e(2)
```

class Element

Bases: ElementWrapper

An element of a Minimaj crystal.

Note: Minimaj elements \(b\) are stored internally as pairs \((w, \text{breaks})\), where:

• \(w\) is a word of length self.parent().ell over the letters 1 up to self.parent().n;
• \(\text{breaks}\) is a list of de-concatenation points to turn \(w\) into a list of row words of (skew-)tableaux that represent \(b\) under the minimaj bijection \(\phi\) of [BCHOPSY2017].

The pair \((w, \text{breaks})\) may be recovered via b.value.

\(e(i)\)

Return \(e_i\) on self.

EXAMPLES:

```
sage: B = crystals.Minimaj(4,3,2)
sage: b = B([[2,3], [3]]); b
((2, 3), (3,))
sage: [b.e(i) for i in range(1,4)]
[[(1, 3), (3,)], [(2,), (2, 3)], None]
```

\(f(i)\)

Return \(f_i\) on self.

EXAMPLES:
```python
sage: B = crystals.Minimaj(4,3,2)
sage: b = B([[2,3], [3]]); b
((2, 3), (3,))
sage: [b.f(i) for i in range(1,4)]
[None, None, ((2, 3), (4,))]
```

**to_tableaux_words()**

Return the image of the ordered multiset partition into sets `self` under the minimaj bijection \( \phi \) of [BCHOPSY2017].

**EXAMPLES:**

```python
sage: B = crystals.Minimaj(4,5,3)
sage: b = B.an_element(); b
((2, 3, 1), (1,), (1,))
sage: b.to_tableaux_words()
[[1], [3], [2, 1, 1]]
sage: b = B([[1,3,4], [3], [3]]); b
((4, 1, 3), (3,), (3,))
sage: b.to_tableaux_words()
[[3, 1], [], [4, 3, 3]]
```

**from_tableau(t)**

Return the bijection \( \phi^{-1} \) of [BCHOPSY2017] applied to \( t \).

**INPUT:**

- \( t \) – a sequence of column tableaux and a ribbon tableau

**EXAMPLES:**

```python
sage: B = crystals.Minimaj(3,6,3)
sage: b = B.an_element(); b
((3, 1, 2), (2, 1), (1,))
sage: t = b.to_tableaux_words(); t
[[1], [2, 1], [], [3, 2, 1]]
sage: B.from_tableau(t)
((3, 1, 2), (2, 1), (1,))
sage: B.from_tableau(t) == b
True
```

**val(q=’q’)**

Return the \( Val \) polynomial corresponding to \( self \).

**EXAMPLES:**

Verifying Example 4.5 from [BCHOPSY2017]:

```python
sage: B = crystals.Minimaj(3, 4, 2) # for 'Val_{4,1}^{(3)}'
sage: B.val()
(q^2+q+1)*s[2, 1, 1] + q*s[2, 2]
```

**class** `sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionIntoSets(parent, data)`

**Bases:** `ClonableArray`
Ordered Multiset Partition into sets

An ordered multiset partition into sets \( c \) of a multiset \( X \) is a list \( [c_1, \ldots, c_r] \) of nonempty subsets of \( X \) (note: not sub-multisets), called the blocks of \( c \), whose multi-union is \( X \).

EXAMPLES:
The simplest way to create an ordered multiset partition into sets is by specifying its blocks as a list or tuple:

```sage
sage: OrderedMultisetPartitionIntoSets([[3], [2, 1]])
[[3], [1, 2]]
sage: OrderedMultisetPartitionIntoSets(((3,), (1, 2)))
[[3], [1, 2]]
sage: OrderedMultisetPartitionIntoSets([set([i]) for i in range(2, 5)])
[[2], [3], [4]]
```

REFERENCES:

- [HRW2015]
- [HRS2016]
- [LM2018]

`check()`

Check that we are a valid ordered multiset partition into sets.

EXAMPLES:

```sage
sage: c = OrderedMultisetPartitionsIntoSets(4)([[1], [1, 2]])
sage: c.check()
sage: OMPs = OrderedMultisetPartitionsIntoSets()
sage: c = OMPs([[1], [1], ['a']])
sage: c.check()
```

`deconcatenate(k=2)`

Return the list of \( k \)-deconcatenations of \( self \).

A \( k \)-tuple \( (C_1, \ldots, C_k) \) of ordered multiset partitions into sets represents a \( k \)-deconcatenation of an ordered multiset partition into sets \( C \) if \( C_1 + \cdots + C_k = C \).

**Note:** This is not to be confused with `self.split_blocks()`, which splits each block of \( self \) before making \( k \)-tuples of ordered multiset partitions into sets.

EXAMPLES:

```sage
sage: OrderedMultisetPartitionIntoSets([[7, 1], [3, 4, 5]]).deconcatenate()
[[[1, 7], [3, 4, 5]], []], [[1, 7], [[3, 4, 5]]], [[], [[1, 7], [3, 4, 5]]]
sage: OrderedMultisetPartitionIntoSets(['b', 'c', ['a']]).deconcatenate()
[[['b', 'c'], ['a']], []], [[['b', 'c'], ['a']]], [[], [[b', 'c'], ['a']]]
sage: OrderedMultisetPartitionIntoSets(['a', 'b', 'c']).deconcatenate(3)
[[['a', 'b', 'c']], [], []], [[], [], [[a', 'b', 'c']]], [[], [], [[a', 'b', 'c']]]
```
**fatten**(grouping)

Return the ordered multiset partition into sets fatter than self, obtained by grouping together consecutive parts according to grouping (whenever this does not violate the strictness condition).

**INPUT:**

- grouping – a composition (or list) whose sum is the length of self

**EXAMPLES:**

Let us start with the composition:

```sage
C = OrderedMultisetPartitionIntoSets([[4,1,5], [2], [7,1]]); C
```

```
[{1,4,5}, {2}, {1,7}]
```

With grouping equal to (1, 1, 1), C is left unchanged:

```sage
C.fatten([1,1,1])
```

```
[{1,4,5}, {2}, {1,7}]
```

With grouping equal to (2, 1) or (1, 2), a union of consecutive parts is achieved:

```sage
C.fatten([2,1])
```

```
[{1,2,4,5}, {1,7}]
```

```sage
C.fatten([1,2])
```

```
[{1,4,5}, {1,2,7}]
```

However, the grouping (3) will throw an error, as 1 cannot appear twice in any block of C:

```sage
C.fatten(Composition([3]))
```

Traceback (most recent call last):
...
ValueError: [{1,4,5,2,1,7}] is not a valid ordered multiset partition into sets

**fatter()**

Return the set of ordered multiset partitions into sets which are fatter than self.

An ordered multiset partition into sets A is fatter than another B if, reading left-to-right, every block of A is the union of some consecutive blocks of B.

**EXAMPLES:**

```sage
C = OrderedMultisetPartitionIntoSets([[1,4,5], {2}, {1,7}]).fatter()
```

```
3
```

```sage
len(C)
```

```
3
```

```sage
sorted(C)
```

```
[[{1,4,5}, {2}, {1,7}], [{1,4,5}, {1,2,7}], [{1,2,4,5}, {1,7}]]
```

```sage
sorted(OrderedMultisetPartitionIntoSets([['a','b'],['c'],['a']]).fatter())
```

```
[['a','b'], ['c'], ['a']]
```

```sage
sorted(OrderedMultisetPartitionIntoSets([['a','b'],['c'],['a']]).fatter())
```

```
[['a','b'], ['c'], ['a']]
```

Some extreme cases:

```sage
list(OrderedMultisetPartitionIntoSets([['a','b'],['c']]).fatter())
```

```
[['a','b'], ['c']]    
```

```sage
list(OrderedMultisetPartitionIntoSets([]).fatter())
```

```
[[]]
```

```sage
A = OrderedMultisetPartitionIntoSets([[1], [2], [3], [4]]))
```

(continues on next page)
sage: B = OrderedMultisetPartitionIntoSets([[1,2,3,4]])
sage: A.fatter().issubset(B.finer())
True

**finer**(strong=False)

Return the set of ordered multiset partitions into sets that are finer than `self`.

An ordered multiset partition into sets `A` is finer than another `B` if, reading left-to-right, every block of `B` is the union of some consecutive blocks of `A`.

If optional argument `strong` is set to `True`, then return only those `A` whose blocks are deconcatenations of blocks of `B`. (Here, we view blocks of `B` as sorted lists instead of sets.)

**EXAMPLES:**

```python
sage: C = OrderedMultisetPartitionIntoSets([[3,2]]).finer()
sage: len(C)
3
sage: sorted(C, key=str)
[[[2,3]], [[2], [3]], [[3], [2]]]
sage: OrderedMultisetPartitionIntoSets([]).finer()
[[[]]]
sage: O = OrderedMultisetPartitionsIntoSets([1, 1, 'a', 'b'])
sage: o = O([{'1'}, {'a', 'b'}, {'1'}])
sage: sorted(o.finer(), key=str)
[[{'1'}, {'a', 'b'}, {'1'}], [{'1'}, {'a'}, {'b'}, {'1'}], [{'1'}, {'b'}, {'a'}, {'1'}]]
sage: o.finer() & o.fatter() == set([o])
True
```

**is_finer**(co)

Return `True` if the ordered multiset partition into sets `self` is finer than the composition `co`; otherwise, return `False`.

**EXAMPLES:**

```python
sage: OrderedMultisetPartitionIntoSets([[4],[1],[2]]).is_finer([[1,4],[2]])
True
sage: OrderedMultisetPartitionIntoSets([[1],[4],[2]]).is_finer([[1,4],[2]])
True
sage: OrderedMultisetPartitionIntoSets([[1,4],[1],[1]]).is_finer([[1,4],[2]])
False
```

**length()**

Return the number of blocks of `self`.

**EXAMPLES:**

```python
sage: OrderedMultisetPartitionIntoSets([[7,1],[3]]).length()
2
```

**letters()**

Return the set of distinct elements occurring within the blocks of `self`.

**EXAMPLES:**
```python
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]]);
C
frozenset({1, 2, 3, 4, 7})
sage: C.letters()
{'1,3,4', '2', '1,2,3,7'}
major_index()
Return the major index of self.
The major index is a statistic on ordered multiset partitions into sets, which we define here via an example.
1. Sort each block in the list self in descending order to create a word w, keeping track of the original separation into blocks:

| in: | [[3,4,5], {2,3,4}, {1}, {4,5}] |
| out: | [ 5,4,3 , 4,3,2 , 1 , 5,4 ] |

2. Create a sequence v = (v₀, v₁, v₂,...) of length self.order()+1, built recursively by:
   1. v₀ = 0
   2. v_j = v_j−1 + δ(j), where δ(j) = 1 if j is the index of an end of a block, and zero otherwise.

| in: | [ 5,4,3 , 4,3,2 , 1 , 5,4 ] |
| out: | (0, 0, 0, 1, 1, 1, 2, 3, 3, 4) |

3. Compute ∑ j v_j, restricted to descent positions in w, i.e., sum over those j with w_j > w_{j+1}:

| in: | w: [5, 4, 3, 4, 3, 2, 1, 5, 4] |
| v: | (0, 0, 0, 1, 1, 1, 2, 3, 3, 4) |
| maj := | 0 +0 +1 +1 +2 +3 = 7 |

REFERENCES:
• [HRW2015]

EXAMPLES:
```
```
minimaj()

Return the minimaj statistic on ordered multiset partitions into sets.

We define minimaj via an example:

1. Sort the block in self as prescribed by self.minimaj_word(), keeping track of the original separation into blocks:

   | in: | {{1,5,7}, {2,4}, {5,6}, {4,6,8}, {1,3}, {1,2,3}} |
   | out: | (5,7,1 / 2,4 / 5,6 / 4,6,8 / 3,1 / 1,2,3) |

2. Record the indices where descents in this word occur:

   | word: | (5, 7, 1 / 2, 4 / 5, 6 / 4, 6, 8 / 3, 1 / 1, 2, 3) |
   | indices: | 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 |
   | descents: | {2, 7, 10, 11} |

3. Compute the sum of the descents:

   minimaj = 2 + 7 + 10 + 11 = 30

REFERENCES:

- [HRW2015]

EXAMPLES:

```
sage: C = OrderedMultisetPartitionIntoSets([{{1,5,7}, {2,4}, {5,6}, {4,6,8}, {1,3}, {1,2,3}}])
sage: C.minimaj()
30
```

minimaj_blocks()

Return the minimaj ordering on blocks of self.

We define the ordering via the example below.

Sort the blocks \([B_1, ..., B_k]\) of self from right to left via:
1. Sort the last block $B_k$ in increasing order, call it the word $W_k$
2. If blocks $B_{i+1}, \ldots, B_k$ have been converted to words $W_{i+1}, \ldots, W_k$, use the letters in $B_i$ to make the unique word $W_i$ that has a factorization $W_i = (u, v)$ satisfying:
   - letters of $u$ and $v$ appear in increasing order, with $v$ possibly empty;
   - letters in $vu$ appear in increasing order;
   - $v[-1]$ is the largest letter $a \in B_i$ satisfying $a \leq W_{i+1}[0]$.

**EXAMPLES:**

```
sage: OrderedMultisetPartitionIntoSets([[1,5,7], [2,4], [5,6], [4,6,8], [1,3], ...
   --> [1,2,3]])
[[1,5,7], {2,4}, {5,6}, {4,6,8}, {1,3}, {1,2,3}]
sage: _.minimaj_blocks()
((5, 7, 1), (2, 4), (5, 6), (4, 6, 8), (3, 1), (1, 2, 3))
sage: OrderedMultisetPartitionIntoSets([]).minimaj_blocks()
()```

```
minimaj_word()
Return an ordering of self._multiset derived from the minimaj ordering on blocks of self.

See also:
OrderedMultisetPartitionIntoSets.minimaj_blocks().

**EXAMPLES:**

```
sage: C = OrderedMultisetPartitionIntoSets([[2,1], [1,2,3], [1,2], [3], [1]]);
C
[[1,2], {1,2,3}, {1,2}, {3}, {1}]
sage: C.minimaj_blocks()
((1, 2), (2, 3, 1), (1, 2), (3,), (1,))
sage: C.minimaj_word()
(1, 2, 2, 3, 1, 1, 2, 3, 1)```

```
multiset(as_dict=False)
Return the multiset corresponding to self.

INPUT:
   - as_dict – (default: False) whether to return the multiset as a tuple of a dict of multiplicities

**EXAMPLES:**

```
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]]);
C
[[1,3,4], {2}, {1,2,3,7}]
sage: C.multiset()
(1, 1, 2, 2, 3, 3, 4, 7)
sage: C.multiset(as_dict=True)
{1: 2, 2: 2, 3: 2, 4: 1, 7: 1}
sage: OrderedMultisetPartitionIntoSets([]).multiset() == ()
True```

```
order()
Return the total number of elements in all blocks of self.

**EXAMPLES:**
From the code snippet provided, we can infer the following methods and their descriptions:

- **reversal()**: Returns the reverse ordered multiset partition into sets of self.
  
  Given an ordered multiset partition into sets \((B_1, B_2, \ldots, B_k)\), its reversal is defined to be the ordered multiset partition into sets \((B_k, \ldots, B_2, B_1)\).

- **shape_from_cardinality()**: Returns a composition that records the cardinality of each block of self.

- **shape_from_size()**: Returns a composition that records the sum of entries of each block of self.

- **shuffle_product(other, overlap=False)**: Returns the shuffles (with multiplicity) of blocks of self with blocks of other.
  
  In case optional argument overlap is True, instead return the allowable overlapping shuffles. An overlapping shuffle \(C\) is allowable if, whenever one of its blocks \(c\) comes from the union \(c = a \cup b\) of a block of self and a block of other, then this union is disjoint.

See also:

- Composition.shuffle_product()
EXAMPLES:

```python
sage: A = OrderedMultisetPartitionIntoSets([[2,1,3], [1,2]]);
    A
[[1,2,3], [1,2]]
sage: B = OrderedMultisetPartitionIntoSets([[3,4]]);
    B
[[3,4]]
sage: C = OrderedMultisetPartitionIntoSets([[4,5]]);
    C
[[4,5]]
sage: list(A.shuffle_product(B))
[[[1,2,3], [1,2], [3,4]],
 [[3,4], [1,2,3], [1,2]]]
sage: list(A.shuffle_product(B, overlap=True))
[[[1,2,3], [1,2], [3,4]],
 [[1,2,3], [3,4], [1,2]],
 [[3,4], [1,2,3], [1,2]],
 [[1,2,3], [1,2,3,4]]]
sage: list(A.shuffle_product(C, overlap=True))
[[[1,2,3], [1,2], [4,5]],
 [[1,2,3], [4,5], [1,2]],
 [[4,5], [1,2,3], [1,2]],
 [[1,2,3,4,5], [1,2]],
 [[1,2,3], [1,2,4,5]]]
```

size()

Return the size of `self` (that is, the sum of all integers in all blocks) if `self` is a list of subsets of positive integers.

Else, return None.

EXAMPLES:

```python
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]]);
    C
[[1,3,4], [2], [1,2,3,7]]
sage: C.size()
23
sage: C.size() == sum(k for k in C.shape_from_size())
True
sage: OrderedMultisetPartitionIntoSets([[7,1],[3]]).size()
11
```

split_blocks(k=2)

Return a dictionary representing the k-splittings of `self`.

A k-tuple \((A^1, \ldots, A^k)\) of ordered multiset partitions into sets represents a k-splitting of an ordered multiset partition into sets \(A = \{b_1, \ldots, b_r\}\) if one can express each block \(b_i\) as an (ordered) disjoint union of sets \(b_i = b_{i1} \sqcup \cdots \sqcup b_{ik}\) (some possibly empty) so that each \(A^j\) is the ordered multiset partition into sets corresponding to the list \([b_{i1}, b_{i2}, \ldots, b_{ik}]\), excising empty sets appearing therein.

This operation represents the coproduct in Hopf algebra of ordered multiset partitions into sets in its natural basis [LM2018].

EXAMPLES:

```python
sage: sorted(OrderedMultisetPartitionIntoSets([[1,2],[3,4]]).split_blocks(),
        key=str)
[[], [[1,2], [3,4]],
 [[1,2], [3,4]], [[],
 [[1,2], [3]], [[4]],
 [[1,2], [4]], [[3]],
 [[1,2], [3,4]],
 [[1], [3,4]], [[2]],
 [[1], [3]], [[2], [4]]],
(continues on next page)
```
Combinatorics, Release 10.0

(continued from previous page)

\[
\begin{align*}
&([\{1\}, \{4\}], [\{2\}, \{3\}]), \\
&([\{1\}], [\{2\}, \{3,4\}]), \\
&([\{2\}, \{3\}], [\{1\}, \{4\}]), \\
&([\{2\}, \{4\}], [\{1\}, \{3\}]), \\
&([\{2\}], [\{1\}, \{3,4\}]), \\
&([\{3\}], [\{1\}, \{2\}]), \\
&([\{4\}], [\{1\}, \{3\}]), \\
&([\{2\}], [\{1\}, \{3,4\}]), \\
&([\{2\}], [\{1\}, \{3\}], [\{4\}])
\end{align*}
\]

```
sage: sorted(OrderedMultisetPartitionIntoSets([[1,2]]).split_blocks(3), key=str)
[(\[]], [\[]], [\{1,2\}]), ([\[]], [\{1\}], [\{2\}]), 
([\[1\]], [\[]], [\{2\}]), 
([\[]], [\{1\}], [\{2\}]), 
([\[]], [\{1\}], [\{2\}]), 
([\[]], [\{1\}], [\{2\}]), 
([\[]], [\{1\}], [\{2\}], [\[]])
```

```
sage: OrderedMultisetPartitionIntoSets([[4],[4]]).split_blocks()
{([\[]], [\{4\}], [\{4\}]): 1, ([\{4\}], [\{4\}]): 2, ([\{4\}], [\{4\}], [\[]]): 1}
```

**to_tableaux_words()**

Return a sequence of lists corresponding to row words of (skew-)tableaux.

**OUTPUT:**

The minimaj bijection \( \phi \) of [BCHOPSY2017] applied to self.

**Todo:** Implement option for mapping to sequence of (skew-)tableaux?

**EXAMPLES:**

```
sage: co = ((1,2,4),(4,5),(3,), (4,6,1),(2,3,1),(1,),(2,5))
sage: OrderedMultisetPartitionIntoSets(co).to_tableaux_words()
[[5, 1], [3, 1], [6], [5, 4, 2], [1, 4, 3, 4, 2, 1, 2]]
```

**weight(as_weak_comp=False)**

Return a dictionary, with keys being the letters in self.letters() and values being their (positive) frequency.

Alternatively, if as weak comp is True, count the number of instances \( n_i \) for each distinct positive integer \( i \) across all blocks of self. Return as a list \([n_1, n_2, n_3, ..., n_k]\), where \( k \) is the max letter appearing in self.letters().

**EXAMPLES:**

```
sage: c = OrderedMultisetPartitionIntoSets([[6,1],[1,3],[1,3,6]])
sage: c.weight()
\{1: 3, 3: 2, 6: 2\}
sage: c.weight(as_weak_comp=True)
\[3, 0, 2, 0, 0, 2\]
```

**class** sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets(is_finite=None, **constraints)**

**Bases:** UniqueRepresentation, Parent

Ordered Multiset Partitions into Sets.
An ordered multiset partition into sets $c$ of a multiset $X$ is a list of nonempty subsets (not multisets), called the blocks of $c$, whose multi-union is $X$.

The number of blocks of $c$ is called its length. The order of $c$ is the cardinality of the multiset $X$. If, additionally, $X$ is a multiset of positive integers, then the size of $c$ is the sum of all elements of $X$.

The user may wish to focus on ordered multiset partitions into sets of a given size, or over a given alphabet. Hence, this class allows a variety of arguments as input.

INPUT:

Expects one or two arguments, with different behaviors resulting:

- One Argument:
  - $X$ – a dictionary or list or tuple (representing a multiset for $c$), or an integer (representing the size of $c$)

- Two Arguments:
  - $A$ – a list (representing allowable letters within blocks of $c$), or a positive integer (representing the maximal allowable letter)
  - $n$ – a nonnegative integer (the total number of letters within $c$)

Optional keyword arguments are as follows: (See corresponding methods in see `OrderedMultisetPartitionIntoSets` for more details.)

- `weight=X` (list or dictionary $X$) specifies the multiset for $c$
- `size=n` (integer $n$) specifies the size of $c$
- `alphabet=A` (iterable $A$) specifies allowable elements for the blocks of $c$
- `length=k` (integer $k$) specifies the number of blocks in the partition
- `min_length=k` (integer $k$) specifies minimum number of blocks in the partition
- `max_length=k` (integer $k$) specifies maximum number of blocks in the partition
- `order=n` (integer $n$) specifies the cardinality of the multiset that $c$ partitions
- `min_order=n` (integer $n$) specifies minimum number of elements in the partition
- `max_order=n` (integer $n$) specifies maximum number of elements in the partition

EXAMPLES:

Passing one argument to `OrderedMultisetPartitionsIntoSets`:

There are 5 ordered multiset partitions into sets of the multiset $\{1, 1, 4\}$:

```python
sage: OrderedMultisetPartitionsIntoSets([1,1,4]).cardinality()
5
```

Here is the list of them:

```python
sage: OrderedMultisetPartitionsIntoSets([1,1,4]).list()
[[[1], [1], {4}], [[1], {1,4}], [[1], {4}, {1}], [{1}, {4}, {1}], [{1,4}, {1}]]
```

By chance, there are also 5 ordered multiset partitions into sets of the integer 3:

```python
sage: OrderedMultisetPartitionsIntoSets(3).cardinality()
5
```

Here is the list of them:
Passing two arguments to `OrderedMultisetPartitionsIntoSets`

There are also 5 ordered multiset partitions into sets of order 2 over the alphabet `{1, 4}`:

```
sage: OrderedMultisetPartitionsIntoSets([1, 4], 2)
```

Ordered Multiset Partitions into Sets of order 2 over alphabet `{1, 4}`
```
sage: OrderedMultisetPartitionsIntoSets([1, 4], 2).cardinality()
```

5

Here is the list of them:

```
sage: OrderedMultisetPartitionsIntoSets([1, 4], 2).list()
```

```
[[1, 4]], [[1], {1}], [[1], {4}], [{4}, {1}], [{4}, {4}]
```

If no arguments are passed to `OrderedMultisetPartitionsIntoSets`, then the code returns all ordered multiset partitions into sets:

```
sage: OrderedMultisetPartitionsIntoSets()  
```

Ordered Multiset Partitions into Sets
```
sage: [] in OrderedMultisetPartitionsIntoSets()  
```

True
```
sage: [[2, 3], [1]] in OrderedMultisetPartitionsIntoSets()  
```

True
```
sage: [['a', 'b'], ['a']] in OrderedMultisetPartitionsIntoSets()  
```

True
```
sage: [[-2, 3], [3]] in OrderedMultisetPartitionsIntoSets()  
```

True
```
sage: [[2], [3, 3]] in OrderedMultisetPartitionsIntoSets()  
```

False

The following examples show how to test whether or not an object is an ordered multiset partition into sets:

```
sage: [[3, 2], [2]] in OrderedMultisetPartitionsIntoSets()  
```

True
```
sage: [[3, 2], [2]] in OrderedMultisetPartitionsIntoSets(7)  
```

True
```
sage: [[3, 2], [2]] in OrderedMultisetPartitionsIntoSets([2, 2, 3])  
```

True
```
sage: [[3, 2], [2]] in OrderedMultisetPartitionsIntoSets(5)  
```

False
Optional keyword arguments

Passing keyword arguments that are incompatible with required requirements results in an error; otherwise, the collection of ordered multiset partitions into sets is restricted accordingly:

The weight keyword:

This is used to specify which multiset $X$ is to be considered, if this multiset was not passed as one of the required arguments for `OrderedMultisetPartitionsIntoSets`. In principle, it is a dictionary, but weak compositions are also allowed. For example, the ordered multiset partitions into sets of integer 4 are listed by weight below:

```
sage: OrderedMultisetPartitionsIntoSets(4, weight=[0,0,0,1])
Ordered Multiset Partitions into Sets of integer 4 with constraint: weight={4: 1}
sage: OrderedMultisetPartitionsIntoSets(4, weight=[0,0,0,1]).list()
[[[4]]]
sage: OrderedMultisetPartitionsIntoSets(4, weight=[1,0,1]).list()
[[[1]], [[3]], [[1,3]], [[3], [1]]]
sage: OrderedMultisetPartitionsIntoSets(4, weight=[0,2]).list()
[[[2], [2]]]
sage: OrderedMultisetPartitionsIntoSets(4, weight=[0,1,1]).list()
[]
sage: OrderedMultisetPartitionsIntoSets(4, weight=[2,1]).list()
[[[1], [1]], [[2]], [[1], [1,2]], [[1,2], [2]], [[2], [1], [1]], [[2], [2]]]
sage: O1 = OrderedMultisetPartitionsIntoSets(weight=[2,0,1])
sage: O2 = OrderedMultisetPartitionsIntoSets(weight={1:2, 3:1})
sage: O1 == O2
True
sage: OrderedMultisetPartitionsIntoSets(4, weight=[4]).list()
[[[1], [1], [1], [1]]]
```

The size keyword:

This is used to constrain the sum of entries across all blocks of the ordered multiset partition into sets. (This size is not pre-determined when alphabet $A$ and order $d$ are passed as required arguments.) For example, the ordered multiset partitions into sets of order 3 over the alphabet $\{1, 2, 4\}$ that have size equal to 5 are as follows:

```
sage: OMPs = OrderedMultisetPartitionsIntoSets
sage: OMPs([1,2,4], 3, size=5).list()
[[[1,2], [2]], [[2], [1,2]], [[2], [2], [1]],
 [[2], [1], [2]], [[1], [2], [2]], [[1], [2], [2]]]
```

The alphabet option:

This is used to constrain which integers appear across all blocks of the ordered multiset partition into sets. For example, the ordered multiset partitions into sets of integer 4 are listed for different choices of alphabet below. Note that alphabet is allowed to be an integer or an iterable:

```
sage: OMPs = OrderedMultisetPartitionsIntoSets
sage: OMPs(4, alphabet=3).list()
[[[1,3]], [[3], [1]],
 [[1,2], [1]], [[2], [2]],
 [[2], [1], [1]], [[1], [3]],
 [[1], [1,2]], [[1], [2], [1]],
 [[1], [1], [2]], [[1], [1], [1], [1]]]
sage: OMPs(4, alphabet=3) == OMPs(4, alphabet=[1,2,3])
True
```

(continues on next page)
Combinatorics, Release 10.0

sage: OMPs(4, alphabet=[3]).list()
[]
sage: OMPs(4, alphabet=[1,3]).list()
[[{1,3}, {1}], [{1}, {1}], [{1}, {3}]]
sage: OMPs(4, alphabet=[2]).list()
[[{2}, {2}]]
sage: OMPs(4, alphabet=[1,2]).list()
[[{1,2}, {1}], [{2}, {1}], [{1}, {1}], [{1}, {2}]]
sage: OMPs(4, alphabet=4).list() == OMPs(4).list()
True

The length, min_length, and max_length options:

These are used to constrain the number of blocks within the ordered multiset partitions into sets. For example, the ordered multiset partitions into sets of integer 4 of length exactly 2, at least 2, and at most 2 are given by:

sage: OrderedMultisetPartitionsIntoSets(4, length=2).list()
[[{1}, {1}], [{1,2}, {1}], [{2}, {2}], [{1}, {3}]]
sage: OrderedMultisetPartitionsIntoSets(4, min_length=3).list()
[[{1,2}, {1}], [{2}, {1}], [{1}, {1}], [{2}, {1}], [{1}, {1}, {1}]]
sage: OrderedMultisetPartitionsIntoSets(4, max_length=2).list()
[[{2}, {2}], [{1}, {1}], [{1}, {1}, {1}]]

The order, min_order, and max_order options:

These are used to constrain the number of elements across all blocks of the ordered multiset partitions into sets. For example, the ordered multiset partitions into sets of integer 4 are listed by order below:

sage: OrderedMultisetPartitionsIntoSets(4, order=1).list()
[[{4}]]
sage: OrderedMultisetPartitionsIntoSets(4, order=2).list()
[[{1,3}], [{1}, {1}], [{2}, {2}], [{1}, {3}]]
sage: OrderedMultisetPartitionsIntoSets(4, order=3).list()
[[{1,2}, {1}], [{2}, {1}], [{1}, {1}], [{1}, {2}], [{1}, {1}, {1}]]
sage: OrderedMultisetPartitionsIntoSets(4, order=4).list()
[[{1}, {1}, {1}, {1}]]

Also, here is a use of max_order, giving the ordered multiset partitions into sets of integer 4 with order 1 or 2:

sage: OrderedMultisetPartitionsIntoSets(4, max_order=2).list()
[[{4}], [{1,3}], [{3}, {1}], [{2}, {2}], [{1}, {3}]]

Element

alias of OrderedMultisetPartitionIntoSets

subset(size)

Return a subset of all ordered multiset partitions into sets.

INPUT:

- size – an integer representing a slice of all ordered multiset partitions into sets

The slice alluded to above is taken with respect to length, or to order, or to size, depending on the constraints of self.
EXAMPLES:

```python
sage: C = OrderedMultisetPartitionsIntoSets(weight={2:2, 3:1, 5:1})
sage: C.subset(3)
Ordered Multiset Partitions into Sets of multiset \{\{2, 2, 3, 5\}\} with constraint: length=3
sage: C = OrderedMultisetPartitionsIntoSets(weight={2:2, 3:1, 5:1}, min_length=2)
sage: C.subset(3)
Ordered Multiset Partitions into Sets of multiset \{\{2, 2, 3, 5\}\} with constraint: length=3
sage: C = OrderedMultisetPartitionsIntoSets(alphabet=[2,3,5])
sage: C.subset(3)
Ordered Multiset Partitions into Sets of order 3 over alphabet \{2, 3, 5\}
sage: C = OrderedMultisetPartitionsIntoSets(order=5)
sage: C.subset(3)
Ordered Multiset Partitions into Sets of integer 3 with constraint: order=5
sage: C = OrderedMultisetPartitionsIntoSets(alphabet=[2,3,5], order=5, length=3)
sage: C.subset(3)
Ordered Multiset Partitions into Sets of order 3 over alphabet \{2, 3, 5\} with constraint: length=3
sage: C = OrderedMultisetPartitionsIntoSets()  
sage: C.subset(3)
Ordered Multiset Partitions into Sets of integer 3
sage: C.subset(3) == OrderedMultisetPartitionsIntoSets(3)
True
```

class sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets_X(X):

Bases: `OrderedMultisetPartitionsIntoSets`

Class of ordered multiset partitions into sets of a fixed multiset $X$.

**cardinality()**

Return the number of ordered partitions of multiset $X$.

**random_element()**

Return a random element of self.

This method does not return elements of self with uniform probability, but it does cover all elements. The scheme is as follows:

- produce a random permutation $p$ of the multiset;
- create blocks of an OMP fat by breaking $p$ after non-ascents;
- take a random element of fat.finer().

EXAMPLES:

```python
sage: OrderedMultisetPartitionsIntoSets([1,1,3]).random_element()  # random
[[1], [1, 3]]
sage: OrderedMultisetPartitionsIntoSets([1,1,3]).random_element()  # random
[[3], [1], [1]]
sage: OMP = OrderedMultisetPartitionsIntoSets([1,1,3,3])
sage: d = {}
sage: for _ in range(1000):
    d[C.subset(3)] += 1
```

(continues on next page)
class sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets_X_constraints

Bases: OrderedMultisetPartitionsIntoSets

Class of ordered multiset partitions into sets of a fixed multiset $X$ satisfying constraints.

class sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets_all_constraints

Bases: OrderedMultisetPartitionsIntoSets

All ordered multiset partitions into sets (with or without constraints).

EXAMPLES:

sage: C = OrderedMultisetPartitionsIntoSets(); C
Ordered Multiset Partitions into Sets
sage: [[1], [1, 'a']] in C
True
sage: OrderedMultisetPartitionsIntoSets(weight=[2,0,1], length=2)
Ordered Multiset Partitions into Sets of multiset {{1, 1, 3}} with constraint:
- length=2

class sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets_alph_d(A, d)

Bases: OrderedMultisetPartitionsIntoSets

Class of ordered multiset partitions into sets of specified order $d$ over a fixed alphabet $A$.

cardinality()

Return the number of ordered partitions of order self._order on alphabet self._alphabet.

random_element()

Return a random element of self.

This method does not return elements of self with uniform probability, but it does cover all elements. The scheme is as follows:

- produce a random composition $C$;
- choose random subsets of self._alphabet of size $c$ for each $c$ in $C$.

EXAMPLES:

sage: OrderedMultisetPartitionsIntoSets([1,4], 3).random_element()  # random
[[4], [1, 4]]
sage: OrderedMultisetPartitionsIntoSets([1,3], 4).random_element()  # random
[[1, 3], [1], [3]]
sage: OMP = OrderedMultisetPartitionsIntoSets([2,3,4], 2)
sage: d = {} 
sage: for _ in range(1200):
    ....:     x = OMP.random_element()
    ....:     d[x] = d.get(x, 0) + 1
sage: d.values() # random
[192, 68, 73, 61, 69, 60, 77, 204, 210, 66, 53, 67]

class sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets_alph_d_constraints

Bases: OrderedMultisetPartitionsIntoSets

Class of ordered multiset partitions into sets of specified order \(d\) over a fixed alphabet \(A\) satisfying constraints.

class sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets_n(n)

Bases: OrderedMultisetPartitionsIntoSets

Ordered multiset partitions into sets of a fixed integer \(n\).

cardinality()

Return the number of elements in \(self\).

random_element()

Return a random element of \(self\). This method does not return elements of \(self\) with uniform probability, but it does cover all elements. The scheme is as follows:

- produce a random composition \(C\);
- choose a random partition of \(c\) into distinct parts for each \(c\) in \(C\).

EXAMPLES:

sage: OrderedMultisetPartitionsIntoSets(5).random_element() # random
[[1,2], [1], [1]]
sage: OrderedMultisetPartitionsIntoSets(5).random_element() # random
[[2], [1,2]]

sage: OMP = OrderedMultisetPartitionsIntoSets(5)
sage: d = {} 
sage: for _ in range(1100):
    ....:     x = OMP.random_element()
    ....:     d[x] = d.get(x, 0) + 1
sage: d.values() # random
[72, 73, 162, 78, 135, 75, 109, 65, 135, 134, 62]

class sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets_n_constraints

Bases: OrderedMultisetPartitionsIntoSets

Class of ordered multiset partitions into sets of a fixed integer \(n\) satisfying constraints.

5.1.142 Common combinatorial tools

REFERENCES:
sage.combinat.ncsf_qsym.combinatorics.coeff_dab(I, J)
Return the number of standard composition tableaux of shape $I$ with descent composition $J$.

INPUT:
- $I$, $J$ – compositions

OUTPUT:
- An integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_dab
sage: coeff_dab(Composition([2,1]),Composition([2,1]))
1
sage: coeff_dab(Composition([1,1,2]),Composition([1,2,1]))
0
```

sage.combinat.ncsf_qsym.combinatorics.coeff_ell(J, I)
Returns the coefficient $\ell_{J,I}$ as defined in [NCSF].

INPUT:
- $J$ – a composition
- $I$ – a composition refining $J$

OUTPUT:
- integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_ell
sage: coeff_ell(Composition([1,1,1]), Composition([2,1]))
2
sage: coeff_ell(Composition([2,1]), Composition([3]))
2
```

sage.combinat.ncsf_qsym.combinatorics.coeff_lp(J, I)
Returns the coefficient $lp_{J,I}$ as defined in [NCSF].

INPUT:
- $J$ – a composition
- $I$ – a composition refining $J$
OUTPUT:
• integer
EXAMPLES:
```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_lp
sage: coeff_lp(Composition([1,1,1]), Composition([2,1]))
1
sage: coeff_lp(Composition([2,1]), Composition([3]))
1
```
sage.combinat.ncsf_qsym.combinatorics.coeff_pi(J,I)

Returns the coefficient $\pi_{J,I}$ as defined in [NCSF].

INPUT:
• J – a composition
• I – a composition refining J

OUTPUT:
• integer

EXAMPLES:
```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_pi
sage: coeff_pi(Composition([1,1,1]), Composition([2,1]))
2
sage: coeff_pi(Composition([2,1]), Composition([3]))
6
```
sage.combinat.ncsf_qsym.combinatorics.coeff_sp(J,I)

Returns the coefficient $sp_{J,I}$ as defined in [NCSF].

INPUT:
• J – a composition
• I – a composition refining J

OUTPUT:
• integer

EXAMPLES:
```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_sp
sage: coeff_sp(Composition([1,1,1]), Composition([2,1]))
2
sage: coeff_sp(Composition([2,1]), Composition([3]))
4
```
sage.combinat.ncsf_qsym.combinatorics.compositions_order(n)

Return the compositions of $n$ ordered as defined in [QSCHUR].

Let $S(\gamma)$ return the composition $\gamma$ after sorting. For compositions $\alpha$ and $\beta$, we order $\alpha \triangleright \beta$ if
1) $S(\alpha) > S(\beta)$ lexicographically, or
2) $S(\alpha) = S(\beta)$ and $\alpha > \beta$ lexicographically.
INPUT:
• \( n \) – a positive integer

OUTPUT:
• A list of the compositions of \( n \) sorted into decreasing order by \( \triangleright \)

EXAMPLES:
```python
sage: from sage.combinat.ncsf_qsym.combinatorics import compositions_order
sage: compositions_order(3)
[[3], [2, 1], [1, 2], [1, 1, 1]]
sage: compositions_order(4)
[[4], [3, 1], [1, 3], [2, 2], [2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

\texttt{sage.combinat.ncsf_qsym.combinatorics.m\_to\_s\_stat}(\( R, I, K \))

Return the coefficient of the complete non-commutative symmetric function \( S^K \) in the expansion of the monomial non-commutative symmetric function \( M^I \) with respect to the complete basis over the ring \( R \). This is the coefficient in formula (36) of Tevlin’s paper [Tev2007].

INPUT:
• \( R \) – A ring, supposed to be a \( \mathbb{Q} \)-algebra
• \( I, K \) – compositions

OUTPUT:
• The coefficient of \( S^K \) in the expansion of \( M^I \) in the complete basis of the non-commutative symmetric functions over \( R \).

EXAMPLES:
```python
sage: from sage.combinat.ncsf_qsym.combinatorics import m_to_s_stat
sage: m_to_s_stat(QQ, Composition([2,1]), Composition([1,1,1]))
-1
sage: m_to_s_stat(QQ, Composition([3]), Composition([1,2]))
-2
sage: m_to_s_stat(QQ, Composition([2,1,2]), Composition([2,1,2]))
8/3
```

\texttt{sage.combinat.ncsf_qsym.combinatorics.number\_of\_SSRCT}(\text{shape\_comp})

The number of semi-standard reverse composition tableaux.

The dual quasisymmetric-Schur functions satisfy a left Pieri rule where \( S_\nu dQS_\alpha \) is a sum over dual quasisymmetric-Schur functions indexed by compositions which contain the composition \( \gamma \). The definition of an SSRCT comes from this rule. The number of SSRCT of content \( \beta \) and shape \( \alpha \) is equal to the number of SSRCT of content \( (\beta_2, \ldots, \beta_\ell) \) and shape \( \gamma \) where \( dQS_\alpha \) appears in the expansion of \( S_\beta dQS_\gamma \).

In sage the recording tableau for these objects are called \texttt{CompositionTableaux}.

INPUT:
• \text{content\_comp, shape\_comp} – compositions

OUTPUT:
• An integer

EXAMPLES:
```python
sage: from sage.combinat.ncsf_qsym.combinatorics import number_of_SSRCT
sage: number_of_SSRCT(Composition([3,1]), Composition([1,3]))
0
sage: number_of_SSRCT(Composition([1,2,1]), Composition([1,3]))
1
sage: number_of_SSRCT(Composition([1,1,2,2]), Composition([3,3]))
2
sage: all(CompositionTableaux(be).cardinality()
    == sum(number_of_SSRCT(al, be)*binomial(4, len(al))
    for al in Compositions(4))
    for be in Compositions(4))
True
```

```python
sage.combinat.ncsf_qsym.combinatorics.number_of_fCT(shape_comp)
```

Return the number of Immaculate tableaux of shape `shape_comp` and content `content_comp`.

See [BBSSZ2012], Definition 3.9, for the notion of an immaculate tableau.

**INPUT:**

- `content_comp, shape_comp` – compositions

**OUTPUT:**

- An integer

**EXAMPLES:**

```python
sage: from sage.combinat.ncsf_qsym.combinatorics import number_of_fCT
sage: number_of_fCT(Composition([3,1]), Composition([1,3]))
0
sage: number_of_fCT(Composition([1,2,1]), Composition([1,3]))
1
sage: number_of_fCT(Composition([1,1,3,1]), Composition([2,1,3]))
2
```

### 5.1.143 Generic code for bases

This is a collection of code that is shared by bases of noncommutative symmetric functions and quasisymmetric functions.

**AUTHORS:**

- Jason Bandlow
- Franco Saliola
- Chris Berg

```python
class sage.combinat.ncsf_qsym.generic_basis_code.AlgebraMorphism(domain, on_generators, position=0, codomain=None, category=None, anti=False)
```

**Bases:** `ModuleMorphismByLinearity`

A class for algebra morphism defined on a free algebra from the image of the generators
class sage.combinat.ncsf_qsym.generic_basis_code.BasesOfQSymOrNCSF(parent_with_realization)

Bases: Category_realization_of_parent

class ElementMethods
Bases: object

degree()

The maximum of the degrees of the homogeneous summands.

See also:

homogeneous_degree()

EXAMPLES:

sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: (x, y) = (S[2], S[3])
sage: x.degree()
2
sage: (x^3 + 4*y^2).degree()
6
sage: ((1 + x)^3).degree()
6

sage: F = QuasiSymmetricFunctions(QQ).F()
sage: (x, y) = (F[2], F[3])
sage: x.degree()
2
sage: (x^3 + 4*y^2).degree()
6
sage: ((1 + x)^3).degree()
6

degree_negation()

Return the image of self under the degree negation automorphism of the parent of self.

The degree negation is the automorphism which scales every homogeneous element of degree $k$ by $(-1)^k$ (for all $k$).

Calling degree_negation(self) is equivalent to calling self.parent().degree_negation(self).

EXAMPLES:

sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: f = 2*S[2, 1] + 4*S[1, 1] - 5*S[1, 2] - 3*S[]
sage: f.degree_negation()
-3*S[] + 4*S[1, 1] + 5*S[1, 2] - 2*S[2, 1]

sage: QSym = QuasiSymmetricFunctions(QQ)
sage: dI = QSym.dualImmaculate()
sage: f.degree_negation()
Todo: Generalize this to all graded vector spaces?

duality_pairing(y)
The duality pairing between elements of \(N\text{Sym}\) and elements of \(Q\text{Sym}\).
The complete basis is dual to the monomial basis with respect to this pairing.

INPUT:

\* \(y\) – an element of the dual Hopf algebra of \(self\)

OUTPUT:

\* The result of pairing \(self\) with \(y\).

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).Ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R[1,1,2].duality_pairing(F[1,1,2])
1
sage: R[1,2,1].duality_pairing(F[1,1,2])
0
```

skew_by(y, side='left')
The operation which is dual to multiplication by \(y\), where \(y\) is an element of the dual space of \(self\).
This is calculated through the coproduct of \(self\) and the expansion of \(y\) in the dual basis.

INPUT:

\* \(y\) – an element of the dual Hopf algebra of \(self\)
\* \(side\) – (Default='left') Either 'left' or 'right'

OUTPUT:

\* The result of skewing \(self\) by \(y\), on the side \(side\)

EXAMPLES:

Skewing an element of NCSF by an element of QSym:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R[1,2,2].skew_by(F[1,1])
sage: R[1,2,2].skew_by(F[2])
```

Skewing an element of QSym by an element of NCSF:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F[3,2].skew_by(R[1,1])
```

(continues on next page)
class ParentMethods

    Bases: object

    alternating_sum_of_compositions(n)

        Alternating sum over compositions of n.

        Note that this differs from the method alternating_sum_of_finer_compositions() because the
        coefficient of the composition 1^n is positive. This method is used in the expansion of the elementary
        generators into the complete generators and vice versa.

        INPUT:
        • n - a positive integer

        OUTPUT:
        • The expansion of the complete generator indexed by n into the elementary basis.

        EXAMPLES:

        sage: L = NonCommutativeSymmetricFunctions(QQ).L()
        sage: L.alternating_sum_of_compositions(0)
        L[]
        sage: L.alternating_sum_of_compositions(1)
        L[1]
        sage: L.alternating_sum_of_compositions(2)
        L[1, 1] - L[2]
        sage: L.alternating_sum_of_compositions(3)
alternating_sum_of_fatter_compositions(\texttt{composition})

Return the alternating sum of fatter compositions in a basis of the non-commutative symmetric functions.

INPUT:
• \texttt{composition} – a composition

OUTPUT:
• The alternating sum of the compositions fatter than \texttt{composition}, in the basis \texttt{self}. The alternation is upon the length of the compositions, and is normalized so that \texttt{composition} has coefficient 1.

EXAMPLES:

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: elementary = NCSF.elementary()
sage: elementary.alternating_sum_of_fatter_compositions(Composition([2, 2, 1]))
sage: elementary.alternating_sum_of_fatter_compositions(Composition([1, 2]))
-L[1, 1, 1] + L[1, 2]
```

alternating_sum_of_finer_compositions(\texttt{composition, conjugate=False})

Return the alternating sum of finer compositions in a basis of the non-commutative symmetric functions.

INPUT:
• \texttt{composition} – a composition
• \texttt{conjugate} – (default: \texttt{False}) a boolean

OUTPUT:
• The alternating sum of the compositions finer than \texttt{composition}, in the basis \texttt{self}. The alternation is upon the length of the compositions, and is normalized so that \texttt{composition} has coefficient 1. If the variable \texttt{conjugate} is set to \texttt{True}, then the conjugate of \texttt{composition} is used instead of \texttt{composition}.

EXAMPLES:

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: elementary = NCSF.elementary()
sage: elementary.alternating_sum_of_finer_compositions(Composition([2, 2, 1]))
L[1, 1, 1, 1, 1] - L[1, 1, 2, 1] - L[2, 1, 1, 1] + L[2, 2, 1]
sage: elementary.alternating_sum_of_finer_compositions(Composition([1, 2]))
-L[1, 1, 1] + L[1, 2]
```

counit_on_basis(I)

The counit is defined by sending all elements of positive degree to zero.

EXAMPLES:

```python
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.counit_on_basis([1, 3])
0
```
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.counit_on_basis([1,3])
0

degree_negation(element)

Return the image of element under the degree negation automorphism of self.

The degree negation is the automorphism which scales every homogeneous element of degree \(k\) by \((-1)^k\) (for all \(k\)).

INPUT:

- element – element of self

EXAMPLES:

sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: f = 2*S[2,1] + 4*S[1,1] - 5*S[1,2] - 3*S[]
sage: S.degree_negation(f)
-3*S[] + 4*S[1, 1] + 5*S[1, 2] - 2*S[2, 1]

sage: QSym = QuasiSymmetricFunctions(QQ)
sage: dI = QSym.dualImmaculate()
sage: dI.degree_negation(f)

Todo: Generalize this to all graded vector spaces?

degree_on_basis(I)

Return the degree of the basis element indexed by \(I\).

INPUT:

- \(I\) – a composition

OUTPUT:

- The degree of the non-commutative symmetric function basis element of self indexed by \(I\). By definition, this is the size of the composition \(I\).

EXAMPLES:

sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R.degree_on_basis(Composition([2,3]))
5
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: M.degree_on_basis(Composition([3,2]))
5
sage: M.degree_on_basis(Composition([]))
0

duality_pairing(x, y)

The duality pairing between elements of \(NSym\) and elements of \(QSym\).

This is a default implementation that uses self.realizations_of().a_realization() and its dual basis.

INPUT:
• $x$ – an element of `self`
• $y$ – an element in the dual basis of `self`

**OUTPUT:**

• The result of pairing the function $x$ from `self` with the function $y$ from the dual basis of `self`

**EXAMPLES:**

```sage
code here...
```

**duality_pairing_by_coercion**($x$, $y$)

The duality pairing between elements of NSym and elements of QSym.

This is a default implementation that uses `self.realizations_of().a_realization()` and its dual basis.

**INPUT:**

• $x$ – an element of `self`
• $y$ – an element in the dual basis of `self`

**OUTPUT:**

• The result of pairing the function $x$ from `self` with the function $y$ from the dual basis of `self`

**EXAMPLES:**

```sage
code here...
```
The matrix of scalar products between elements of NSym and elements of QSym.

`duality_pairing_matrix(basis, degree)`

The matrix of scalar products between elements of NSym and elements of QSym.

**INPUT:**
- `basis` – A basis of the dual Hopf algebra
- `degree` – a non-negative integer

**OUTPUT:**
- The matrix of scalar products between the basis `self` and the basis `basis` in the dual Hopf algebra in degree `degree`.

**EXAMPLES:**

The ribbon basis of NCSF is dual to the fundamental basis of QSym:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R.duality_pairing_matrix(F, 3)

[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

```
sage: F.duality_pairing_matrix(R, 3)

[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

The complete basis of NCSF is dual to the monomial basis of QSym:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: S.duality_pairing_matrix(M, 3)

[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

```
sage: M.duality_pairing_matrix(S, 3)

[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

The matrix between the ribbon basis of NCSF and the monomial basis of QSym:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: R.duality_pairing_matrix(M, 3)

[ 1 -1 -1  1]
[ 0  1  0 -1]
[ 0  0  1 -1]
[ 0  0  0  1]
```

(continues on next page)
The matrix between the complete basis of NCSF and the fundamental basis of QSym:

```python
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: S.duality_pairing_matrix(F, 3)
```

```
[1 1 1 1]
[0 1 0 1]
[0 0 1 1]
[0 0 0 1]
```

A base case test:

```python
sage: R.duality_pairing_matrix(M, 0)
```

```
[1]
```

### one_basis()

Return the empty composition.

**OUTPUT:**

- The empty composition.

**EXAMPLES:**

```python
sage: L = NonCommutativeSymmetricFunctions(QQ).L()
sage: parent(L)
<class 'sage.combinat.ncsf_qsym.ncsf.NonCommutativeSymmetricFunctions.Elementary_with_category'>
sage: parent(L).one_basis()
[]
```

### skew(x, y, side='left')

Return a function x in self skewed by a function y in the Hopf dual of self.

**INPUT:**

- x – a non-commutative or quasi-symmetric function; it is an element of self
- y – a quasi-symmetric or non-commutative symmetric function; it is an element of the dual algebra of self
- side – (default: 'left') either 'left' or 'right'

**OUTPUT:**

- The result of skewing the element x by the Hopf algebra element y (either from the left or from the right, as determined by side), written in the basis self.

**EXAMPLES:**

```python
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: S.skew(S[2,2,2], F[1,1])
S[1, 1, 2] + S[1, 2, 1] + S[2, 1, 1]
sage: F[2]
S[1, 1, 2] + S[1, 2, 1] + S[2, 1, 1] + 3*S[2, 2]
```
Combinatorics, Release 10.0

```python
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R.skew(R[2,2,2], F[1,1])
sage: R.skew(R[2,2,2], F[2])
```

```python
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.skew(M[3,2], S[2])
0
sage: M.skew(M[3,2], S[2], side='right')
M[3]
sage: M.skew(M[3,2], S[3])
M[2]
sage: M.skew(M[3,2], S[3], side='right')
0
```

**sum_of_fatter_compositions**(*composition*)

Return the sum of all fatter compositions.

**INPUT:**

- *composition* – a composition

**OUTPUT:**

- the sum of all basis elements which are indexed by compositions fatter (coarser?) than *composition*.

**EXAMPLES:**

```python
sage: L = NonCommutativeSymmetricFunctions(QQ).L()
sage: L.sum_of_fatter_compositions(Composition([2,1]))
L[1, 1, 1] + L[2, 1]
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: R.sum_of_fatter_compositions(Composition([1,3]))
R[1, 1, 1, 1] + R[1, 1, 2] + R[1, 2, 1] + R[1, 3]
```

**sum_of_finer_compositions**(*composition*)

Return the sum of all finer compositions.

**INPUT:**

- *composition* – a composition

**OUTPUT:**

- The sum of all basis elements which are indexed by compositions finer than *composition*.

**EXAMPLES:**

```python
sage: L = NonCommutativeSymmetricFunctions(QQ).L()
sage: L.sum_of_finer_compositions(Composition([2,1]))
L[1, 1, 1] + L[2, 1]
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: R.sum_of_finer_compositions(Composition([1,3]))
R[1, 1, 1, 1] + R[1, 1, 2] + R[1, 2, 1] + R[1, 3]
```

**sum_of_partition_rearrangements**(*par*)

Return the sum of all basis elements indexed by compositions which can be sorted to obtain a given...
Combinatorics, Release 10.0

**partition.**

**INPUT:**
- \( \text{par} \) – a partition

**OUTPUT:**
- The sum of all self basis elements indexed by compositions which are permutations of \( \text{par} \) (without multiplicity).

**EXAMPLES:**

```python
sage: NCSF=NonCommutativeSymmetricFunctions(QQ)
sage: elementary = NCSF.elementary()
sage: elementary.sum_of_partition_rearrangements(Partition([2,2,1]))
L[1, 2, 2] + L[2, 1, 2] + L[2, 2, 1]
sage: elementary.sum_of_partition_rearrangements(Partition([3,2,1]))
L[1, 2, 3] + L[1, 3, 2] + L[2, 1, 3] + L[2, 3, 1] + L[3, 1, 2] + L[3, 2, 1]
sage: elementary.sum_of_partition_rearrangements(Partition([]))
L[]
```

**super_categories()**

**class** sage.combinat.ncsf_qsym.generic_basis_code.GradedModulesWithInternalProduct(*base, name=None)*

**Bases:** Category_over_base_ring

Constructs the class of modules with internal product. This is used to give an internal product structure to the non-commutative symmetric functions.

**EXAMPLES:**

```python
sage: from sage.combinat.ncsf_qsym.generic_basis_code import GradedModulesWithInternalProduct
sage: GradedModulesWithInternalProduct(QQ)
```

**class** ElementMethods

**Bases:** object

**internal_product**(other)

Return the internal product of two non-commutative symmetric functions.

The internal product on the algebra of non-commutative symmetric functions is adjoint to the internal coproduct on the algebra of quasisymmetric functions with respect to the duality pairing between these two algebras. This means, explicitly, that any two non-commutative symmetric functions \( f \) and \( g \) and any quasi-symmetric function \( h \) satisfy

\[
\langle f \ast g, h \rangle = \sum_i \langle f, h'_i \rangle \langle g, h''_i \rangle,
\]

where we write \( \Delta^X(h) \) as \( \sum_i h'_i \otimes h''_i \). Here, \( f \ast g \) denotes the internal product of the non-commutative symmetric functions \( f \) and \( g \).

If \( f \) and \( g \) are two homogeneous elements of \( NSym \) having distinct degrees, then the internal product \( f \ast g \) is zero.

Explicit formulas can be given for internal products of elements of the complete and the Psi bases. First, the formula for the Complete basis ([NCSF1] Proposition 5.1): If \( I \) and \( J \) are two compositions...
of lengths \( p \) and \( q \), respectively, then the corresponding Complete homogeneous non-commutative symmetric functions \( S^I \) and \( S^J \) have internal product

\[
S^I \ast S^J = \sum \text{comp} M,
\]

where the sum ranges over all \( p \times q \)-matrices \( M \in \mathbb{N}^{p \times q} \) (with nonnegative integers as entries) whose row sum vector is \( I \) (that is, the sum of the entries of the \( r \)-th row is the \( r \)-th part of \( I \) for all \( r \)) and whose column sum vector is \( J \) (that is, the sum of all entries of the \( s \)-th row is the \( s \)-th part of \( J \) for all \( s \)). Here, for any \( M \in \mathbb{N}^{p \times q} \), we denote by \( \text{comp} M \) the composition obtained by reading the entries of the matrix \( M \) in the usual order (row by row, proceeding left to right in each row, traversing the rows from top to bottom).

The formula on the Psi basis ([NCSF2] Lemma 3.10) is more complicated. Let \( I \) and \( J \) be two compositions of lengths \( p \) and \( q \), respectively, having the same size \( |I| = |J| \). We denote by \( \Psi^K \) the element of the Psi basis corresponding to any composition \( K \).

- If \( p > q \), then \( \Psi^I \ast \Psi^J \) is plainly 0.
- Assume that \( p = q \). Let \( \delta_{I,J} \) denote the integer 1 if the compositions \( I \) and \( J \) are permutations of each other, and the integer 0 otherwise. For every positive integer \( i \), let \( m_i \) denote the number of parts of \( I \) equal to \( i \). Then, \( \Psi^I \ast \Psi^J = \delta_{I,J} \prod_{i \geq 0} i^{m_i} \Psi^I \).
- Now assume that \( p < q \). Write the composition \( I \) as \( I = (i_1,i_2,\ldots,i_p) \). For every nonempty composition \( K = (k_1,k_2,\ldots,k_q) \), denote by \( \Gamma_K \) the non-commutative symmetric function \( k_1\cdot\ldots\cdot[k_{k_1},\Psi_{k_2},\Psi_{k_3},\ldots,\Psi_{k_q}] \). For any subset \( A \) of \( \{1,2,\ldots,q\} \), let \( J_A \) be the composition obtained from \( J \) by removing the \( r \)-th parts for all \( r \notin A \) (while keeping the \( r \)-th parts for all \( r \in A \) in order). Then, \( \Psi^I \ast \Psi^J \) equals the sum of \( \Gamma_{J_{K_1}} \Gamma_{J_{K_2}} \cdots \Gamma_{J_{K_p}} \) over all ordered set partitions \( (K_1,K_2,\ldots,K_p) \) of \( \{1,2,\ldots,q\} \) into \( p \) parts such that each \( 1 \leq k \leq p \) satisfies \( |J_{K_k}| = i_k \).

(See OrderedSetPartition() for the meaning of “ordered set partition.”)

Aliases for internal_product() are itensor() and kronecker_product().

INPUT:
- other – another non-commutative symmetric function

OUTPUT:
- The result of taking the internal product of self with other.

EXAMPLES:

```sage
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: x = S.an_element(); x
2*S[] + 2*S[1] + 3*S[1, 1]
sage: x.internal_product(S[2])
3*S[1, 1]
sage: x.internal_product(S[1])
2*S[1]
sage: S[1,2].internal_product(S[1,2])
S[1, 1, 1] + S[1, 2]
```

Let us check the duality between the inner product and the inner coproduct in degree 4:

```sage
sage: M = QuasiSymmetricFunctions(FiniteField(29)).M()
sage: S = NonCommutativeSymmetricFunctions(FiniteField(29)).S()
sage: def tensor_incorp(f, g, h): # computes \sum_i \left< f, h_i \right> \cdot \left< h_i, g \right>
    result = h.base_ring().zero()
    h_parent = h.parent()
    for partition_pair, coeff in h.internal_coproduct().monomial_coefficients().items():
        result += coeff * h_parent(left< g, h"^i \right> \\left< f, h_i \right>)
    return result
    ....:
    ....:
    ....:
    ....:
```

(continues on next page)
The internal product on the algebra of non-commutative symmetric functions commutes with the canonical commutative projection on the symmetric functions:

```python
sage: S = NonCommutativeSymmetricFunctions(ZZ).S()
sage: e = SymmetricFunctions(ZZ).e()
sage: def int_pr_of_S_in_e(I, J):
    ....:     return (S[I].internal_product(S[J])).to_symmetric_function()
sage: all( all( int_pr_of_S_in_e(I, J)
    ....:         == S[I].to_symmetric_function().internal_product(S[J].to_
    ....:             symmetric_function())
    ....:     for I in Compositions(3) )
    ....:     for J in Compositions(3) )
True
```

`itensor`(*other*)

Return the internal product of two non-commutative symmetric functions.

The internal product on the algebra of non-commutative symmetric functions is adjoint to the internal coproduct on the algebra of quasisymmetric functions with respect to the duality pairing between these two algebras. This means, explicitly, that any two non-commutative symmetric functions $f$ and $g$ and any quasi-symmetric function $h$ satisfy

$$\langle f \ast g, h \rangle = \sum_i \langle f, h'_i \rangle \langle g, h''_i \rangle,$$

where we write $\Delta^\times(h)$ as $\sum_i h'_i \otimes h''_i$. Here, $f \ast g$ denotes the internal product of the non-commutative symmetric functions $f$ and $g$.

If $f$ and $g$ are two homogeneous elements of $NSym$ having distinct degrees, then the internal product $f \ast g$ is zero.

Explicit formulas can be given for internal products of elements of the complete and the Psi bases. First, the formula for the Complete basis ([NCSF1] Proposition 5.1): If $I$ and $J$ are two compositions of lengths $p$ and $q$, respectively, then the corresponding Complete homogeneous non-commutative symmetric functions $S^I$ and $S^J$ have internal product

$$S^I \ast S^J = \sum M^{\text{comp}},$$

where the sum ranges over all $p \times q$-matrices $M \in \mathbb{N}^{p \times q}$ (with nonnegative integers as entries) whose row sum vector is $I$ (that is, the sum of the entries of the $r$-th row is the $r$-th part of $I$ for all $r$) and...
whose column sum vector is $J$ (that is, the sum of all entries of the $s$-th row is the $s$-th part of $J$ for all $s$). Here, for any $M \in \mathbb{N}^{n \times q}$, we denote by $\text{comp} M$ the composition obtained by reading the entries of the matrix $M$ in the usual order (row by row, proceeding left to right in each row, traversing the rows from top to bottom).

The formula on the Psi basis ([NCSF2] Lemma 3.10) is more complicated. Let $I$ and $J$ be two compositions of lengths $p$ and $q$, respectively, having the same size $|I| = |J|$. We denote by $\Psi^K$ the element of the Psi basis corresponding to any composition $K$.

- If $p > q$, then $\Psi^I \ast \Psi^J$ is plainly $0$.
- Assume that $p = q$. Let $\delta_{I,J}$ denote the integer $1$ if the compositions $I$ and $J$ are permutations of each other, and the integer $0$ otherwise. For every positive integer $i$, let $m_i$ denote the number of parts of $I$ equal to $i$. Then, $\Psi^I \ast \Psi^J$ equals $\delta_{I,J} \prod_{i>0} i^{m_i} m_i! \Psi^I$.
- Now assume that $p < q$. Write the composition $I$ as $I = (i_1, i_2, \ldots, i_p)$. For every nonempty composition $K = (k_1, k_2, \ldots, k_s)$, denote by $\Gamma_K$ the non-commutative symmetric function $k_1 [\ldots [\Psi_{k_1}, \Psi_{k_2}], \ldots, \Psi_{k_s}]$. For any subset $A$ of $\{1, 2, \ldots, q\}$, let $J_A$ be the composition obtained from $J$ by removing the $r$-th parts for all $r \notin A$ (while keeping the $r$-th parts for all $r \in A$ in order). Then, $\Psi^I \ast \Psi^J$ equals the sum of $\Gamma_{J_{K_1}} \Gamma_{J_{K_2}} \cdots \Gamma_{J_{K_p}}$ over all ordered set partitions $(K_1, K_2, \ldots, K_p)$ of $\{1, 2, \ldots, q\}$ into $p$ parts such that each $1 \leq k \leq p$ satisfies $|J_{K_k}| = i_k$. (See OrderedSetPartition() for the meaning of “ordered set partition”.)

Aliases for internal_product() are itensor() and kronecker_product().

**INPUT:**
- other – another non-commutative symmetric function

**OUTPUT:**
- The result of taking the internal product of self with other.

**EXAMPLES:**

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: x = S.an_element(); x
2*S[] + 2*S[1] + 3*S[1, 1]
sage: x.internal_product(S[2])
3*S[1, 1]
sage: x.internal_product(S[1])
2*S[1]
sage: S[1,2].internal_product(S[1,2])
S[1, 1, 1] + S[1, 2]
```

Let us check the duality between the inner product and the inner coproduct in degree 4:

```python
sage: M = QuasiSymmetricFunctions(FiniteField(29)).M()
sage: S = NonCommutativeSymmetricFunctions(FiniteField(29)).S()
sage: def tensor_incorp(f, g, h):
...: # computes \sum_i \left< f, h'_i \right> \left< g, h'_i \right>
...: result = h.base_ring().zero()
...: h_parent = h.parent()
...: for partition_pair, coeff in h.internal_coproduct().monomial_coefficients().items():
...: result += coeff * f.duality_pairing(h_parent[partition_pair[0]]) * g.duality_pairing(h_parent[partition_pair[1]])
...: return result
sage: def testall(n):
...: return all( all( all( tensor_incorp(S[u], S[v], M[w]) == (S[u].itensor(S[v])).duality_pairing(M[w])
...: for u in S) for v in S) for w in M)
```

(continues on next page)
The internal product on the algebra of non-commutative symmetric functions commutes with the canonical commutative projection on the symmetric functions:

\[
\langle f \ast g, h \rangle = \sum_{i} \langle f, h'_i \rangle \langle g, h''_i \rangle,
\]

where we write \( \Delta^\times(h) \) as \( \sum_{i} h'_i \otimes h''_i \). Here, \( f \ast g \) denotes the internal product of the non-commutative symmetric functions \( f \) and \( g \).

If \( f \) and \( g \) are two homogeneous elements of \( NSym \) having distinct degrees, then the internal product \( f \ast g \) is zero.

Explicit formulas can be given for internal products of elements of the complete and the \Psi\) bases. First, the formula for the Complete basis ([NCSF1] Proposition 5.1): If \( I \) and \( J \) are two compositions of lengths \( p \) and \( q \), respectively, then the corresponding Complete homogeneous non-commutative symmetric functions \( S^I \) and \( S^J \) have internal product

\[
S^I \ast S^J = \sum S^{\text{comp } M},
\]

where the sum ranges over all \( p \times q \)-matrices \( M \in \mathbb{N}^{p \times q} \) (with nonnegative integers as entries) whose row sum vector is \( I \) (that is, the sum of the entries of the \( r \)-th row is the \( r \)-th part of \( I \) for all \( r \)) and whose column sum vector is \( J \) (that is, the sum of all entries of the \( s \)-th row is the \( s \)-th part of \( J \) for all \( s \)). Here, for any \( M \in \mathbb{N}^{p \times q} \), we denote by \( \text{comp } M \) the composition obtained by reading the entries of the matrix \( M \) in the usual order (row by row, proceeding left to right in each row, traversing the rows from top to bottom).
The formula on the Psi basis (\texttt{[NCSF2]} Lemma 3.10) is more complicated. Let \( I \) and \( J \) be two compositions of lengths \( p \) and \( q \), respectively, having the same size \(| I | = | J |\). We denote by \( \Psi^K \) the element of the Psi basis corresponding to any composition \( K \).

• If \( p > q \), then \( \Psi^I \star \Psi^J \) is plainly 0.

• Assume that \( p = q \). Let \( \delta_{I,J} \) denote the integer 1 if the compositions \( I \) and \( J \) are permutations of each other, and the integer 0 otherwise. For every positive integer \( i \), let \( m_i \) denote the number of parts of \( I \) equal to \( i \). For all \( i > 0 \), \( \Psi^I \star \Psi^J \) equals \( \delta_{I,J} \prod_{i>0} i^{m_i} m_i! \Psi^I \).

• Now assume that \( p < q \). Write the composition \( I \) as \( I = (i_1, i_2, \ldots, i_p) \). For every nonempty composition \( K = (k_1, k_2, \ldots, k_s) \), denote by \( \Gamma_K \) the non-commutative symmetric function \( k_1 \Psi^{i_1} \cdots \Psi^{i_{k_1}} \cdots k_2 \Psi^{i_{k_1+i_2}} \cdots \cdots \cdots \cdots k_s \Psi^{i_{k_1+i_2+\cdots+i_{k_{s-1}}}} \).

  For any subset \( A \) of \( \{1, 2, \ldots, q\} \), let \( J_A \) be the composition obtained from \( J \) by removing the \( r \)-th parts for all \( r \not\in A \) (while keeping the \( r \)-th parts for all \( r \in A \) in order). Then, \( \Psi^I \star \Psi^J \) equals the sum of \( \Gamma_{J_A} \Gamma_{K_{i_1}} \Gamma_{K_{i_2}} \cdots \Gamma_{K_{i_p}} \) over all ordered set partitions \((K_1, K_2, \ldots, K_p)\) of \( \{1, 2, \ldots, q\} \) into \( p \) parts such that each \( 1 \leq k \leq p \) satisfies \(|J_{K_k}| = i_k\).

(See \texttt{OrderedSetPartition()} for the meaning of “ordered set partition”.)

Aliases for \texttt{internal_product()} are \texttt{itensor()} and \texttt{kronecker_product()}.
The internal product on the algebra of non-commutative symmetric functions commutes with the canonical commutative projection on the symmetric functions:

```python
sage: S = NonCommutativeSymmetricFunctions(ZZ).S()
sage: e = SymmetricFunctions(ZZ).e()
sage: def int_pr_of_S_in_e(I, J):
    ....:     return (S[I].internal_product(S[J])).to_symmetric_function()
sage: all( all( int_pr_of_S_in_e(I, J)
    ....:         == S[I].to_symmetric_function().internal_product(S[J].to_symmetric_function())
    ....:         for I in Compositions(3) )
    ....:         for J in Compositions(3) )
True
```

```python
class ParentMethods
    Bases: object
    internal_product()
    The bilinear product inherited from the isomorphism with the descent algebra.

    This is constructed by extending the method internal_product_on_basis() bilinearly, if available, or using the method internal_product_by_coercion().

    OUTPUT:
    • The internal product map of the algebra the non-commutative symmetric functions.

    EXAMPLES:
    sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product
    Generic endomorphism of Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
    sage: S.internal_product(S[2,2], S[1,2,1])
    2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product(S[2,2], S[1,2])
    0
    sage: R = N.ribbon()
sage: R.internal_product
    <bound method ....internal_product_by_coercion ...>
    sage: R.internal_product_by_coercion(R[1, 1], R[1,1])
    R[2]
sage: R.internal_product(R[2,2], R[1,2])
    0
```

```python
internal_product_on_basis(I, J)
    The internal product of the two basis elements indexed by I and J (optional)
```
INPUT:
• \(I, J\) – compositions indexing two elements of the basis of self

Returns the internal product of the corresponding basis elements. If this method is implemented, the internal product is defined from it by linearity.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product_on_basis([2,2], [1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product_on_basis([2,2], [2,1])
0
```

**itensor()**

The bilinear product inherited from the isomorphism with the descent algebra.

This is constructed by extending the method `internal_product_on_basis()` bilinearly, if available, or using the method `internal_product_by_coercion()`.

OUTPUT:
• The internal product map of the algebra the non-commutative symmetric functions.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product(S[2,2], S[1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product(S[2,2], S[1,2])
0
```

**kronecker_product()**

The bilinear product inherited from the isomorphism with the descent algebra.

This is constructed by extending the method `internal_product_on_basis()` bilinearly, if available, or using the method `internal_product_by_coercion()`.

OUTPUT:
• The internal product map of the algebra the non-commutative symmetric functions.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: R.internal_product
<bound method ....internal_product_by_coercion ...>
sage: R.internal_product_by_coercion(R[1, 1], R[1,1])
R[2]
sage: R.internal_product(R[2,2], R[1,2])
0
```
Generic endomorphism of Non-Commutative Symmetric Functions over the Rational Field in the Complete basis

```sage```
```
sage: S.internal_product(S[2,2], S[1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product(S[2,2], S[1,2])
0
```
```python```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: R.internal_product
<bound method ....internal_product_by_coercion ...>
sage: R.internal_product_by_coercion(R[1, 1], R[1,1])
R[2]
sage: R.internal_product(R[2,2], R[1,2])
0
```

```python```
class Realizations(category, *args):
    Bases: RealizationsCategory
class ParentMethods
    Bases: object
    internal_product_by_coercion(left, right)
    Internal product of left and right.
    This is a default implementation that computes the internal product in the realization specified by self.realization_of().a_realization().
    INPUT:
    • left – an element of the non-commutative symmetric functions
    • right – an element of the non-commutative symmetric functions
    OUTPUT:
    • The internal product of left and right.
    EXAMPLES:
    ```sage```
    ```python```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.internal_product_by_coercion(S[2,1], S[3])
S[2, 1]
sage: S.internal_product_by_coercion(S[2,1], S[4])
0
```
```python```
super_categories()```
EXAMPLES:
```sage```
```python```
sage: from sage.combinat.ncsf_qsym.generic_basis_code import ...
sage: GradedModulesWithInternalProduct
sage: GradedModulesWithInternalProduct(ZZ).super_categories()
[Category of graded modules over Integer Ring]```
5.1.144 Non-Commutative Symmetric Functions

```python
class sage.combinat.ncsf_qsym.ncsf.NonCommutativeSymmetricFunctions(R)
    Bases: UniqueRepresentation, Parent

The abstract algebra of non-commutative symmetric functions.

We construct the abstract algebra of non-commutative symmetric functions over the rational numbers:

```sage```
NCSF = NonCommutativeSymmetricFunctions(QQ)
```
NCSF
Non-Commutative Symmetric Functions over the Rational Field
```
```
sage: S = NCSF.complete()
sage: R = NCSF.ribbon()
sage: S[2,1]*R[1,2]
S[2, 1, 1, 2] - S[2, 1, 3]
```
NCSF is the unique free (non-commutative!) graded connected algebra with one generator in each degree:

```sage```
NCSF.category()
Join of Category of hopf algebras over Rational Field
    and Category of graded algebras over Rational Field
    and Category of monoids with realizations
    and Category of graded coalgebras over Rational Field
    and Category of coalgebras over Rational Field with realizations
    and Category of cocommutative coalgebras over Rational Field
```
```
sage: [S[i].degree() for i in range(10)]
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```
We use the Sage standard renaming idiom to get shorter outputs:

```sage```
NCSF.rename("NCSF")
```
NCSF
```
NCSF has many representations as a concrete algebra. Each of them has a distinguished basis, and its elements are expanded in this basis. Here is the $\Psi (\Psi)$ representation:

```sage```
Psi = NCSF.Psi()
```
```
sage: Psi.an_element()
2*Psi[] + 2*Psi[1] + 3*Psi[1, 1]
```
The basis itself is accessible through:

```sage```
Psi.basis()
Lazy family (Term map from Compositions of non-negative integers...
```
```
sage: Psi.basis().keys()
Compositions of non-negative integers
```
To construct an element one can therefore do:
As this is rather cumbersome, the following abuses of notation are allowed:

```
sage: Psi[Composition([2, 1, 3])]
Psi[2, 1, 3]
sage: Psi[2, 1, 3]
Psi[2, 1, 3]
sage: Psi[2, 1, 3]
Psi[2, 1, 3]
```

or even:

```
sage: Psi[(i for i in [2, 1, 3])]
Psi[2, 1, 3]
```

Unfortunately, due to a limitation in Python syntax, one cannot use:

```
sage: Psi[]  # not implemented
```

Instead, you can use:

```
sage: Psi[[]]
Psi[]
```

Now, we can construct linear combinations of basis elements:

```
```

**Algebra structure**

To start with, \( \Psi \) is a graded algebra, the grading being induced by the size of compositions. The one is the basis element indexed by the empty composition:

```
sage: Psi.one()
Psi[]
sage: S.one()
S[]
sage: R.one()
R[]
```

As we have seen above, the \( \Psi \) basis is multiplicative; that is multiplication is induced by linearity from the concatenation of compositions:

```
sage: Psi[1, 3] * Psi[2, 1]
Psi[1, 3, 2, 1]
sage: (Psi.one() + 2 * Psi[1, 3]) * Psi[2, 4]
2*Psi[1, 3, 2, 4] + Psi[2, 4]
```
Hopf algebra structure

Psi is further endowed with a coalgebra structure. The coproduct is an algebra morphism, and therefore determined by its values on the generators; those are primitive:

```
sage: Psi[1].coproduct()
Psi[] # Psi[1] + Psi[1] # Psi[]
sage: Psi[2].coproduct()
```

The coproduct, being cocommutative on the generators, is cocommutative everywhere:

```
sage: Psi[1,2].coproduct()
```

The algebra and coalgebra structures on Psi combine to form a bialgebra structure, which cooperates with the grading to form a connected graded bialgebra. Thus, as any connected graded bialgebra, Psi is a Hopf algebra. Over QQ (or any other Q-algebra), this Hopf algebra Psi is isomorphic to the tensor algebra of its space of primitive elements.

The antipode is an anti-algebra morphism; in the Psi basis, it sends the generators to their opposites and changes their sign if they are of odd degree:

```
sage: Psi[3].antipode()
-Psi[3]
sage: Psi[1,3,2].antipode()
-Psi[2, 3, 1]
sage: Psi[1,3,2].coproduct().apply_multilinear_morphism(lambda be,ga:
    -Psi(be)*Psi(ga).antipode())
0
```

The counit is defined by sending all elements of positive degree to zero:

```
sage: S[3].degree(), S[3,1,2].degree(), S.one().degree()
(3, 6, 0)
sage: S[3].counit()
0
sage: S[3,1,2].counit()
0
sage: S.one().counit()
1
7
7
```

It is possible to change the prefix used to display the basis elements using the method `print_options()`. Say that for instance one wanted to display the Complete basis as having a prefix H instead of the default S:

```
sage: H = NCSF.complete()
sage: H.an_element()
2*S[] + 2*S[1] + 3*S[1, 1]
sage: H.print_options(prefix='H')
sage: H.an_element()
```

(continues on next page)
Concrete representations

NCSF admits the concrete realizations defined in [NCSF1]:

```
sage: Phi = NCSF.Phi()
sage: Psi = NCSF.Psi()
sage: ribbon = NCSF.ribbon()
sage: complete = NCSF.complete()
sage: elementary = NCSF.elementary()
```

To change from one basis to another, one simply does:

```
sage: Phi(Psi[1])
Phi[1]
sage: Phi(Psi[3])
-1/4*Phi[1, 2] + 1/4*Phi[2, 1] + Phi[3]
```

In general, one can mix up different bases in computations:

```
sage: Phi[1] * Psi[1]
Phi[1, 1]
```

Some of the changes of basis are easy to guess:

```
sage: ribbon(complete[1,3,2])
```

This is the sum of all fatter compositions. Using the usual Möbius function for the boolean lattice, the inverse change of basis is given by the alternating sum of all fatter compositions:

```
sage: complete(ribbon[1,3,2])
```

The analogue of the elementary basis is the sum over all finer compositions than the ‘complement’ of the composition in the ribbon basis:

```
sage: Composition([1,3,2]).complement()
[2, 1, 2, 1]
sage: ribbon(elementary([1,3,2]))
R[1, 1, 1, 1, 1, 1] + R[1, 1, 1, 2, 1] + R[2, 1, 1, 1, 1] + R[2, 1, 2, 1]
```

By Möbius inversion on the composition poset, the ribbon basis element corresponding to a composition \( I \) is then the alternating sum over all compositions fatter than the complement composition of \( I \) in the elementary basis:

```
sage: elementary(ribbon[2,1,2,1])
```
The $\Phi$ ($\Phi$) and $\Psi$ bases are computed by changing to and from the Complete basis. The expansion of $\Psi$ basis is given in Proposition 4.5 of [NCSF1] by the formulae

$$S^I = \sum_{J \geq I} \frac{1}{\pi_u(J, I)} \Psi^J$$

and

$$\Psi^I = \sum_{J \geq I} (-1)^{\ell(J) - \ell(I)} l_p(J, I) S^J$$

where the coefficients $\pi_u(J, I)$ and $l_p(J, I)$ are coefficients in the methods $\text{coeff\_pi()}$ and $\text{coeff\_lp()}$ respectively. For example:

```sage
sage: Psi(complete[3])
1/6*Psi[1, 1, 1] + 1/3*Psi[1, 2] + 1/6*Psi[2, 1] + 1/3*Psi[3]
sage: complete(Psi[3])
```

The $\Phi$ basis is another analogue of the power sum basis from the algebra of symmetric functions and the expansion in the Complete basis is given in Proposition 4.9 of [NCSF1] by the formulae

$$S^I = \sum_{J \geq I} \frac{1}{sp(J, I)} \Phi^J$$

and

$$\Phi^I = \sum_{J \geq I} (-1)^{\ell(J) - \ell(I)} \prod_{i | I} I_i S^J$$

where the coefficients $sp(J, I)$ and $\ell(J, I)$ are coefficients in the methods $\text{coeff\_sp()}$ and $\text{coeff\_ell()}$ respectively. For example:

```sage
sage: Phi(complete[3])
1/6*Phi[1, 1, 1] + 1/4*Phi[1, 2] + 1/4*Phi[2, 1] + 1/3*Phi[3]
sage: complete(Phi[3])
```

Here is how to fetch the conversion morphisms:

```sage
sage: f = complete.coerce_map_from(elementary); f
Generic morphism:
  From: NCSF in the Elementary basis
  To: NCSF in the Complete basis
sage: g = elementary.coerce_map_from(complete); g
Generic morphism:
  From: NCSF in the Complete basis
  To: NCSF in the Elementary basis
sage: f.category()
Category of homsets of unital magmas and right modules over Rational Field and left modules over Rational Field
sage: f(elementary[1,2,2])
S[1, 1, 1, 1, 1] - S[1, 1, 1, 2] - S[1, 2, 1, 1] + S[1, 2, 2]
sage: g(complete[1,2,2])
L[1, 1, 1, 1, 1] - L[1, 1, 1, 2] - L[1, 2, 1, 1] + L[1, 2, 2]
```

(continues on next page)
sage: h = f*g; h

Composite map:
  From: NCSF in the Complete basis
  To:   NCSF in the Complete basis
Defn:  Generic morphism:
    From: NCSF in the Complete basis
    To:   NCSF in the Elementary basis
    then
    Generic morphism:
    From: NCSF in the Elementary basis
    To:   NCSF in the Complete basis

sage: h(complete[1,3,2])
S[1, 3, 2]

Additional concrete representations

NCSF has some additional bases which appear in the literature:

sage: Monomial = NCSF.Monomial()
sage: Immaculate = NCSF.Immaculate()
sage: dualQuasisymmetric_Schur = NCSF.dualQuasisymmetric_Schur()

The Monomial basis was introduced in [Tev2007] and the Immaculate basis was introduced in [BBSSZ2012].
The Quasisymmetric_Schur were defined in [QSCHUR] and the dual basis is implemented here as
dualQuasisymmetric_Schur. Refer to the documentation for the use and definition of these bases.

Todo:

• implement fundamental, forgotten, and simple (coming from the simple modules of HS_n) bases.

We revert back to the original name from our custom short name NCSF:

sage: NCSF
NCSF
sage: NCSF.rename()
sage: NCSF
Non-Commutative Symmetric Functions over the Rational Field

class Bases(parent_with_realization)

   Bases: Category_realization_of_parent

   Category of bases of non-commutative symmetric functions.

   EXAMPLES:

sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.Bases()
Category of bases of Non-Commutative Symmetric Functions over the Rational Field
sage: R = N.Ribbon()
sage: R in N.Bases()
True
class ElementMethods

Bases: object

bernstein_creation_operator(n)

Return the image of self under the n-th Bernstein creation operator.

Let \( n \) be an integer. The \( n \)-th Bernstein creation operator \( B_n \) is defined as the endomorphism of the space \( NSym \) of noncommutative symmetric functions which sends every \( f \) to

\[
\sum_{i \geq 0} (-1)^i H_{n+i} F_{1+i}^\perp,
\]

where usual notations are in place (the letter \( H \) stands for the complete basis of \( NSym \), the letter \( F \) stands for the fundamental basis of the algebra \( QSym \) of quasisymmetric functions, and \( F_{1+i}^\perp \) means skewing \((\text{skew}_by())\) by \( F_1 \)). Notice that \( F_1 \) is nothing other than the elementary symmetric function \( e_i \).

This has been introduced in [BBSSZ2012], section 3.1, in analogy to the Bernstein creation operators on the symmetric functions \((\text{bernstein_creation_operator}())\), and studied further in [BBSSZ2012], mainly in the context of immaculate functions \((\text{Immaculate})\). In fact, if \((\alpha_1, \alpha_2, \ldots, \alpha_m)\) is an \( m \)-tuple of integers, then

\[
B_n I_{\alpha_1, \alpha_2, \ldots, \alpha_m} = I_{n, \alpha_1, \alpha_2, \ldots, \alpha_m},
\]

where \( I_{\alpha_1, \alpha_2, \ldots, \alpha_m} \) is the immaculate function associated to the \( m \)-tuple \((\alpha_1, \alpha_2, \ldots, \alpha_m)\) (see \(\text{immaculate_function}()\)).

EXAMPLES:

We get the immaculate functions by repeated application of Bernstein creation operators:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: I = NSym.I()
sage: S = NSym.S()
sage: def immaculate_by_bernstein(xs):
    ...:     # immaculate function corresponding to integer
    ...:     # tuple \( `xs`\), computed by iterated application
    ...:     # of Bernstein creation operators.
    ...:     res = S.one()
    ...:     for i in reversed(xs):
    ...:         res = res.bernstein_creation_operator(i)
    ...:     return res

sage: import itertools
sage: all( immaculate_by_bernstein(p) == I.immaculate_function(p)
    ...:      for p in itertools.product(range(-1, 3), repeat=3))
True
```

Some examples:

```
sage: S[3,2].bernstein_creation_operator(-2)
S[2, 1]
sage: S[3,2].bernstein_creation_operator(-1)
S[1, 2, 1] - S[2, 2] - S[3, 1]
sage: S[3,2].bernstein_creation_operator(0)
-S[1, 2, 2] - S[1, 3, 1] + S[2, 2, 1] + S[3, 2]
sage: S[3,2].bernstein_creation_operator(1)
```

(continues on next page)
\[
sage: S[3, 2].bernstein_creation_operator(2)
\]

\(\chi()\)

Return the commutative image of a non-commutative symmetric function.

**OUTPUT:**
- The commutative image of self. This will be a symmetric function.

**EXAMPLES:**

\[
sage: N = NonCommutativeSymmetricFunctions(QQ) \\
sage: R = N.ribbon() \\
sage: x = R.an_element(); x \\
sage: x.to_symmetric_function() \\
2*s[] + 2*s[1] + 3*s[1, 1] \\
sage: y = N.Phi()[1,3] \\
sage: y.to_symmetric_function() \\
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1] \\
\]

\(\text{expand}(n, \text{alphabet=}'x')\)

Expand the noncommutative symmetric function into an element of a free algebra in \(n\) indeterminates of an alphabet, which by default is ‘\(x\)’.

**INPUT:**
- \(n\) – a nonnegative integer; the number of variables in the expansion
- \(\text{alphabet}\) – (default: ‘\(x\)’); the alphabet in which self is to be expanded

**OUTPUT:**
- An expansion of self into the \(n\) variables specified by alphabet.

**EXAMPLES:**

\[
sage: NSym = NonCommutativeSymmetricFunctions(QQ) \\
sage: S = NSym.S() \\
sage: S[3].expand(3) \\
x0^3 + x0^2*x1 + x0^2*x2 + x0*x1^2 + x0*x1*x2 + x0*x2^2 + x1^3 + x1^2*x2 + x1*x2^2 + x2^3 \\
sage: L = NSym.L() \\
sage: L[3].expand(3) \\
x2*x1*x0 \\
sage: L[2].expand(3) \\
x1*x0 + x2*x0 + x2*x1 \\
sage: L[3].expand(4) \\
x2*x1*x0 + x3*x1*x0 + x3*x2*x0 + x3*x2*x1 \\
sage: Psi = NSym.Psi() \\
sage: Psi[2, 1].expand(3) \\
x0^3 + x0^2*x1 + x0^2*x2 + x0*x1^2 + x0*x1*x2 + x0*x2^2 + x1^3 + x1^2*x2 + x1*x2^2 + x2^3 \\
\]

One can use a different set of variables by adding an optional argument alphabet=...
sage: L[3].expand(4, alphabet="y")
y2*y1*y0 + y3*y1*y0 + y3*y2*y0 + y3*y2*y1

Todo: So far this is only implemented on the elementary basis, and everything else goes through coercion. Maybe it is worth shortcutting some of the other bases?

left_padded_kronecker_product(x)

Return the left-padded Kronecker product of self and x in the basis of self.

The left-padded Kronecker product is a bilinear map mapping two non-commutative symmetric functions to another, not necessarily preserving degree. It can be defined as follows: Let \( \ast \) denote the internal product (internal_product()) on the space of non-commutative symmetric functions. For any composition \( I \), let \( S^I \) denote the complete homogeneous symmetric function indexed by \( I \). For every composition \( I = (i_1, i_2, \ldots, i_k) \) and every integer \( n > |I| \), define the \( n \)-completion of \( I \) to be the composition \( (n - |I|, i_1, i_2, \ldots, i_k) \); this \( n \)-completion is denoted by \( I[n] \). Then, for any compositions \( \alpha \) and \( \beta \) and every integer \( n > |\alpha| + |\beta| \), we can write the internal product \( S^\alpha[n] \ast S^\beta[n] \) in the form

\[
S^\alpha[n] \ast S^\beta[n] = \sum_\gamma g^{\gamma[n]}_{\alpha[n], \beta[n]} S^\gamma[n]
\]

with \( \gamma \) ranging over all compositions. The coefficients \( g^{\gamma[n]}_{\alpha[n], \beta[n]} \) are independent on \( n \). These coefficients \( g^{\gamma[n]}_{\alpha[n], \beta[n]} \) are denoted by \( \tilde{g}^{\gamma}_{\alpha, \beta} \), and the non-commutative symmetric function

\[
\sum_\gamma \tilde{g}^{\gamma}_{\alpha, \beta} S^\gamma
\]

is said to be the left-padded Kronecker product of \( S^\alpha \) and \( S^\beta \). By bilinearity, this extends to a definition of a left-padded Kronecker product of any two non-commutative symmetric functions.

The left-padded Kronecker product on the non-commutative symmetric functions lifts the left-padded Kronecker product on the symmetric functions. More precisely, let \( \pi \) denote the canonical projection (to_symmetric_function()) from the non-commutative symmetric functions to the symmetric functions. Then, any two non-commutative symmetric functions \( f \) and \( g \) satisfy

\[
\pi(f \ast g) = \pi(f) \pi(g),
\]

where the \( \pi \) on the left-hand side denotes the left-padded Kronecker product on the non-commutative symmetric functions, and the \( \pi \) on the right-hand side denotes the left-padded Kronecker product on the symmetric functions.

INPUT:
• \( x \) – element of the ring of non-commutative symmetric functions over the same base ring as self

OUTPUT:
• the left-padded Kronecker product of self with x (an element of the ring of non-commutative symmetric functions in the same basis as self)

AUTHORS:
• Darij Grinberg (15 Mar 2014)

EXAMPLES:
```sage
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: S[2,1].left_padded_kronecker_product(S[3])
sage: S[2,1].left_padded_kronecker_product(S[1])
S[1, 1, 1] + S[1, 2, 1] + S[2, 1]
sage: S[1].left_padded_kronecker_product(S[2,1])
S[1, 1, 1] + S[2, 1] + S[2, 1, 1]
sage: S[1,1].left_padded_kronecker_product(S[2])
S[1, 1] + 2*S[1, 1, 1] + S[2, 1, 1]
sage: S[1].left_padded_kronecker_product(S[1,2,1])
S[1, 1, 1] + S[1, 2, 1] + S[1, 2, 1, 1] + S[2, 1, 1]
sage: S[2].left_padded_kronecker_product(S[3])
S[1, 2] + S[2, 1, 1] + S[3, 2]
```

Taking the left-padded Kronecker product with $1 = S$ is the identity map on the ring of noncommutative symmetric functions:

```sage
sage: all( S[Composition([])].left_padded_kronecker_product(S[lambda])
...: == S[lambda].left_padded_kronecker_product(S[Composition([])])
...: == S[lambda]
...: for i in range(4)
...: for lambda in Compositions(i) )
True
```

Here is a rule for the left-padded Kronecker product of $S_1$ (this is the same as $S^{(1)}$) with any complete homogeneous function: Let $I$ be a composition. Then, the left-padded Kronecker product of $S_1$ and $S^I$ is $\sum K a_K S^K$, where the sum runs over all compositions $K$, and the coefficient $a_K$ is defined as the number of ways to obtain $K$ from $I$ by one of the following two operations:

• Insert a 1 at the end of $I$.
• Subtract 1 from one of the entries of $I$ (and remove the entry if it thus becomes 0), and insert a 1 at the end of $I$.

We check this for compositions of size $\leq 4$:

```sage
def mults1(I):
    # Left left-padded Kronecker multiplication by S[1].
    res = S[I[:1] + [1]]
    for k in range(len(I)):
        I2 = I[:]
        if I2[k] == 1:
            I2 = I2[:k] + I2[k+1:]
        else:
            I2[k] -= 1
        res += S[I2 + [1]]
    return res
sage: all( mults1(I) == S[1].left_padded_kronecker_product(S[I])
...: for i in range(5) for I in Compositions(i) )
True
```

A similar rule can be made for the left-padded Kronecker product of any complete homogeneous function with $S_1$: Let $I$ be a composition. Then, the left-padded Kronecker product of $S^I$ and $S_1$ is $\sum K b_K S^K$, where the sum runs over all compositions $K$, and the coefficient $b_K$ is defined as the number of ways to obtain $K$ from $I$ by one of the following two operations:

• Insert a 1 at the front of $I$.
• Subtract 1 from one of the entries of \( I \) (and remove the entry if it thus becomes 0), and insert a 1 right after this entry.

We check this for compositions of size \( \leq 4 \):

```python
sage: def mults2(I):
    # Left left-padded Kronecker multiplication by S[1].
    res = S[[1] + I[:]]
    for k in range(len(I)):
        I2 = I[:]
        i2k = I2[k]
        if i2k != 1:
            I2 = I2[:k] + [i2k-1, 1] + I2[k+1:]
        res += S[I2]
    return res

sage: all( mults2(I) == S[I].left_padded_kronecker_product(S[1])
    for i in range(5) for I in Compositions(i) )
True
```

Checking the \( \pi(fg) = \pi(f)\pi(g) \) equality:

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: R = NSym.R()

sage: def testpi(n):
    for I in Compositions(n):
        for J in Compositions(n):
            a = R[I].to_symmetric_function()
            b = R[J].to_symmetric_function()
            x = a.left_padded_kronecker_product(b)
            y = R[I].left_padded_kronecker_product(R[J])
            y = y.to_symmetric_function()
            if x != y:
                return False
    return True

sage: testpi(3)
True
```

_omega_involution()_

Return the image of the noncommutative symmetric function \( \text{self} \) under the omega involution.

The omega involution is defined as the algebra antihomomorphism \( NCSF \to NCSF \) which, for every positive integer \( n \), sends the \( n \)-th complete non-commutative symmetric function \( S_n \) to the \( n \)-th elementary non-commutative symmetric function \( \Lambda_n \). This omega involution is denoted by \( \omega \). It can be shown that every composition \( I \) satisfies

\[
\omega(S^I) = \Lambda^{I^\prime}, \quad \omega(\Lambda^I) = S^{I^\prime}, \quad \omega(R_I) = R_{I^\prime}, \quad \omega(\Phi^I) = (-1)^{|I|-\ell(I)}\Phi^{I^\prime}, \omega(\Psi^I) = (-1)^{|I|-\ell(I)}\Psi^{I^\prime},
\]

where \( I^\prime \) denotes the reversed composition of \( I \), and \( I^\prime \) denotes the conjugate composition of \( I \), and \( \ell(I) \) denotes the length of the composition \( I \), and standard notations for classical bases of \( NCSF \) are being used (\( S \) for the complete basis, \( \Lambda \) for the elementary basis, \( R \) for the ribbon basis, \( \Phi \) for that of the power-sums of the second kind, and \( \Psi \) for that of the power-sums of the first kind). More generally, if \( f \) is a homogeneous element of \( NCSF \) of degree \( n \), then

\[
\omega(f) = (-1)^n S(f),
\]

where \( S \) denotes the antipode of \( NCSF \).
The omega involution $\omega$ is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. If $\pi$ denotes the projection from $NCSF$ to the ring of symmetric functions ($\text{to_symmetric_function()}$), then $\pi(\omega(f)) = \omega(\pi(f))$ for every $f \in NCSF$, where the $\omega$ on the right hand side denotes the omega automorphism of $Sym$.

The omega involution on $NCSF$ is adjoint to the omega involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The omega involution has been denoted by $\omega$ in [LMvW13], section 3.6. See [NCSF1], section 3.1 for the properties of this map.

See also:

omega involution of QSym, psi involution of NCSF, star involution of NCSF.

EXAMPLES:

```sage
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: L = NSym.L()
sage: L(S[3,2].omega_involution())
L[2, 3]
sage: L(S[6,3].omega_involution())
L[3, 6]
sage: L(S[1,3].omega_involution())
L[3, 1]
# long time
sage: L(S([4,2]).omega_involution())
L[2, 4]
sage: R = NSym.R()
sage: R([4,2]).omega_involution()
R[1, 2, 1, 1, 1]
sage: R.zero().omega_involution()
0
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NSym.Phi()
sage: Phi([2,1]).omega_involution()
-Phi[1, 2]
sage: Psi = NSym.Psi()
sage: Psi([2,1]).omega_involution()
-Psi[1, 2]
sage: Psi([3,1]).omega_involution()
Psi[1, 3]
```

Testing the $\pi(\omega(f)) = \omega(\pi(f))$ relation noticed above:

```sage
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: R = NSym.R()
sage: all( R(I).omega_involution().to_symmetric_function() == R(I).to_symmetric_function().omega_involution() for I in Compositions(4) )
True
```
The omega involution on $QSym$ is adjoint to the omega involution on $NSym$ with respect to the duality pairing:

```sage
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: all( all( M(I).omega_involution().duality_pairing(S(J)) == M(I).duality_pairing(S(J).omega_involution()) for I in Compositions(2) ) for J in Compositions(3) )
True
```

```
psi_involution()
```

Return the image of the noncommutative symmetric function `self` under the involution $\psi$.

The involution $\psi$ is defined as the linear map $NCSF \rightarrow NCSF$ which, for every composition $I$, sends the complete noncommutative symmetric function $S^I$ to the elementary noncommutative symmetric function $\Lambda^I$. It can be shown that every composition $I$ satisfies

$$\psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I| - \ell(I)} \Phi^I$$

where $I^c$ denotes the complement of the composition $I$, and $\ell(I)$ denotes the length of $I$, and where standard notations for classical bases of $NCSF$ are being used ($S$ for the complete basis, $\Lambda$ for the elementary basis, $\Phi$ for the basis of the power sums of the second kind, and $R$ for the ribbon basis).

The map $\psi$ is an involution and a graded Hopf algebra automorphism of $NCSF$. If $\pi$ denotes the projection from $NCSF$ to the ring of symmetric functions (`to_symmetric_function()`), then $\pi(\psi(f)) = \omega(\pi(f))$ for every $f \in NCSF$, where the $\omega$ on the right hand side denotes the omega automorphism of $Sym$.

The involution $\psi$ of $NCSF$ is adjoint to the involution $\psi$ of $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The involution $\psi$ has been denoted by $\psi$ in [LMvW13], section 3.6.

See also:

- `psi_involution of QSym`
- `star_involution of NCSF`

**EXAMPLES:**

```sage
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: R = NSym.R()
sage: R[3,2].psi_involution()
R[1, 1, 2, 1]
sage: R[6,3].psi_involution()
R[1, 1, 1, 1, 2, 1, 1]
4*R[] - 2*R[1, 1] + R[1, 1, 2, 1, 1]
sage: (R[3,3] - 2*R[2]).psi_involution()
-2*R[1, 1] + R[1, 1, 2, 1, 1]
sage: R([2,1,1]).psi_involution()
R[1, 3]
sage: S = NSym.S()
sage: S([2,1]).psi_involution()
S[1, 1, 1] - S[2, 1]
```

(continues on next page)
The Psi basis doesn’t behave as nicely:

```python
sage: Psi = NSym.Psi()
sage: Psi([2,1]).psi_involution()
1/2*Psi[1, 2, 1] - 1/2*Psi[2, 1, 1] + Psi[3, 1]
```

The involution $\psi$ commutes with the antipode:

```python
sage: all( R(I).psi_involution().antipode()
....:     == R(I).antipode().psi_involution()
....:     for I in Compositions(4) )
True
```

Testing the $\pi(\psi(f)) = \omega(\pi(f))$ relation noticed above:

```python
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: R = NSym.R()
sage: all( R(I).psi_involution().to_symmetric_function()
....:     == R(I).to_symmetric_function().omega()
....:     for I in Compositions(4) )
True
```

The involution $\psi$ of $QSym$ is adjoint to the involution $\psi$ of $NSym$ with respect to the duality pairing:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: all( all( M(I).psi_involution().duality_pairing(S(J))
....:         == M(I).duality_pairing(S(J).psi_involution())
....:         for I in Compositions(2) )
....:         for J in Compositions(3) )
True
```

**star_involution()**

Return the image of the noncommutative symmetric function self under the star involution.

The star involution is defined as the algebra antihomomorphism $NCSF \rightarrow NCSF$ which, for every positive integer $n$, sends the $n$-th complete non-commutative symmetric function $S_n$ to $S_n$. Denoting by $f^*$ the image of an element $f \in NCSF$ under this star involution, it can be shown...
that every composition $I$ satisfies

$$(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R^I_j = R_{I^r}, \quad (\Phi^I)^* = \Phi^{I^r},$$

where $I^r$ denotes the reversed composition of $I$, and standard notations for classical bases of $NCSF$ are being used ($S$ for the complete basis, $\Lambda$ for the elementary basis, $R$ for the ribbon basis, and $\Phi$ for that of the power-sums of the second kind). The star involution is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. Under the canonical isomorphism between the $n$-th graded component of $NCSF$ and the descent algebra of the symmetric group $S_n$ (see to_descent_algebra()), the star involution (restricted to the $n$-th graded component) corresponds to the automorphism of the descent algebra given by $x \mapsto \omega_n x \omega_n$, where $\omega_n$ is the permutation $(n, n-1, \ldots, 1) \in S_n$ (written here in one-line notation). If $\pi$ denotes the projection from $NCSF$ to the ring of symmetric functions (to_symmetric_function()), then $\pi(f^*) = \pi(f)$ for every $f \in NCSF$.

The star involution on $NCSF$ is adjoint to the star involution on $\text{QSym}$ by the standard adjunction between $NCSF$ and $\text{QSym}$.

The star involution has been denoted by $\rho$ in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

See also:

star involution of $\text{QSym}$, psi involution of $NCSF$.

**EXAMPLES:**

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: S[3,2].star_involution()
S[2, 3]
sage: S[6,3].star_involution()
S[3, 6]
sage: (S[3,3] - 2*S[2]) . star_involution()
sage: S[[4,2]] . star_involution()
S[2, 4]
sage: R = NSym.R()
sage: R[[4,2]].star_involution()
R[2, 4]
sage: R.zero().star_involution()
0
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NSym.Phi()
sage: Phi[[2,1]].star_involution()
Phi[1, 2]
```

The Psi basis doesn’t behave as nicely:

```python
sage: Psi = NSym.Psi()
sage: Psi([2,1]).star_involution()
Psi[1, 2]
sage: Psi([3,1]).star_involution()
1/2*Psi[1, 1, 2] - 1/2*Psi[1, 2, 1] + Psi[1, 3]
```
The star involution commutes with the antipode:

```python
sage: all( R(I).star_involution().antipode()
.....:     == R(I).antipode().star_involution()
.....:     for I in Compositions(4) )
True
```

Checking the relation with the descent algebra described above:

```python
sage: def descent_test(n):
.....:     DA = DescentAlgebra(QQ, n)
.....:     NSym = NonCommutativeSymmetricFunctions(QQ)
.....:     S = NSym.S()
.....:     DAD = DA.D()
.....:     w_n = DAD(set(range(1, n)))
.....:     for I in Compositions(n):
.....:         if not (S[I].star_involution()
.....:                      == w_n * S[I].to_descent_algebra(n) * w_n):
.....:             return False
.....:     return True

sage: all( descent_test(i) for i in range(4) )
True
sage: all( descent_test(i) for i in range(6) )
# long time
True
```

Testing the \(\pi(f^*) = \pi(f)\) relation noticed above:

```python
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: R = NSym.R()
sage: all( R(I).star_involution().to_symmetric_function()
.....:     == R(I).to_symmetric_function()
.....:     for I in Compositions(4) )
True
```

The star involution on \(QSym\) is adjoint to the star involution on \(NSym\) with respect to the duality pairing:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: all( all( M(I).star_involution().duality_pairing(S(J))
.....:         == M(I).duality_pairing(S(J).star_involution())
.....:         for I in Compositions(2) )
.....:         for J in Compositions(3) )
True
```

---

**to_descent_algebra\(n=\text{None}\)**

Return the image of the \(n\)-th degree homogeneous component of \(\text{self}\) in the descent algebra of \(S_n\) over the same base ring as \(\text{self}\).

This is based upon the canonical isomorphism from the \(n\)-th degree homogeneous component of the algebra of noncommutative symmetric functions to the descent algebra of \(S_n\). This isomorphism maps the inner product of noncommutative symmetric functions either to the product in the descent algebra of \(S_n\) or to its opposite (depending on how the latter is defined).
If \( n \) is not specified, it will be taken to be the highest homogeneous component of \( \text{self} \).

**OUTPUT:**
- The image of the \( n \)-th homogeneous component of \( \text{self} \) under the isomorphism into the descent algebra of \( S_n \) over the same base ring as \( \text{self} \).

**EXAMPLES:**

```python
sage: S = NonCommutativeSymmetricFunctions(ZZ).S()
sage: S[2,1].to_descent_algebra(3)
B[2, 1]
sage: (S[1,2,1] - 3 * S[1,1,2]).to_descent_algebra(4)
-3*R[1, 1, 2] + B[1, 2, 1]
sage: S[2,1].to_descent_algebra(2)
0
sage: S[2,1].to_descent_algebra()
B[2, 1]
sage: S.zero().to_descent_algebra().parent()
Descent algebra of 0 over Integer Ring in the subset basis
sage: (S[1,2,1] - 3 * S[1,1,2]).to_descent_algebra(1)
0
```

**to_fqsym()**

Return the image of the non-commutative symmetric function \( \text{self} \) under the morphism \( \iota : NSym \to FQSym \).

This morphism is the injective algebra homomorphism \( NSym \to FQSym \) that sends each Complete generator \( S_n \) to \( F_{[1,2,...,n]} \). It is the inclusion map, if we regard both \( NSym \) and \( FQSym \) as rings of noncommutative power series.

**See also:**

*FreeQuasisymmetricFunctions* for a definition of \( FQSym \).

**EXAMPLES:**

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x.to_fqsym()
sage: R[2,1].to_fqsym()
F[1, 3, 2] + F[3, 1, 2]
sage: x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
sage: x.to_fqsym()

sage: y = N.Phi()[1,2]
sage: y.to_fqsym()
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S[2].to_fqsym()
F[1, 2]
sage: S[1,2].to_fqsym()
```

(continues on next page)
Combinatorics, Release 10.0

(continued from previous page)

\[ F[1, 2, 3] + F[2, 1, 3] + F[2, 3, 1] \]

\[ \text{sage: } S[2, 1].to_fsym() \]

\[ F[1, 2, 3] + F[1, 3, 2] + F[3, 1, 2] \]

\[ \text{sage: } S[1, 2, 1].to_fsym() \]

\[ \text{to_fsym}() \]

Return the image of \texttt{self} under the natural map to \( FSym \).

There is an injective Hopf algebra morphism from \( NSym \) to \( FSym \) (see \texttt{FreeSymmetricFunctions}), which maps the ribbon \( R_\alpha \) indexed by a composition \( \alpha \) to the sum of all tableaux whose descent composition is \( \alpha \). If we regard \( NSym \) as a Hopf subalgebra of \( FQSym \) via the morphism \( \iota : NSym \to FQSym \) (implemented as \texttt{to_fqsym()}), then this injective morphism is just the inclusion map.

**EXAMPLES:**

\[ \text{sage: } N = \text{NonCommutativeSymmetricFunctions}(\QQ) \]
\[ \text{sage: } R = N.\text{ribbon()} \]
\[ \text{sage: } x.\text{to_fsym()} \]
\[ \text{sage: } R[2, 1].\text{to_fsym()} \]
\[ G[12|3] \]
\[ \text{sage: } R[1, 2].\text{to_fsym()} \]
\[ G[13|2] \]
\[ \text{sage: } R[2, 1, 2].\text{to_fsym()} \]
\[ \text{sage: } x = R.\text{an_element(); }x \]
\[ 2^*R[] + 2^*R[1] + 3^*R[1, 1] \]
\[ \text{sage: } x.\text{to_fsym()} \]

\[ \text{sage: } y = N.\text{Phi()}[1, 2] \]
\[ \text{sage: } y.\text{to_fsym()} \]

\[ \text{sage: } S = \text{NonCommutativeSymmetricFunctions}(\QQ).S() \]
\[ \text{sage: } S[2].\text{to_fsym()} \]
\[ G[12] \]
\[ \text{sage: } S[2, 1].\text{to_fsym()} \]
\[ G[12|3] + G[123] \]

\[ \text{to_ncsym}() \]

Return the image of \texttt{self} under the injective algebra homomorphism \( \kappa : NSym \to NCSym \) that fixes the symmetric functions.

As usual, \( NCSym \) denotes the ring of symmetric functions in non-commuting variables. Let \( S_n \) denote a generator of the complete basis. The algebra homomorphism \( \kappa : NSym \to NCSym \) is

5.1. Comprehensive Module List

1475
defined by

\[ S_n \mapsto \sum_{A \vdash n} \frac{\lambda(A)! \lambda(A)!}{n!} m_A. \]

It has the property that the canonical maps \( \chi : NCsym \to Sym \) and \( \rho : NSym \to Sym \) satisfy \( \chi \circ \kappa = \rho \).

**Note:** A remark in [BRRZ08] makes it clear that the embedding of \( NSym \) into \( NCsym \) that preserves the projection into the symmetric functions is not unique. While this seems to be a natural embedding, any free set of algebraic generators of \( NSym \) can be sent to a set of free elements in \( NCsym \) to form another embedding.

**See also:**

*NonCommutativeSymmetricFunctions* for a definition of \( NCsym \).

**EXAMPLES:**

```sage
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S[2].to_ncsym()
1/2*m\{1\} + m\{2\}
sage: S[1,2,1].to_ncsym()
1/2*m\{1\} + 1/2*m\{2\} + 1/2*m\{3\} + 1/2*m\{4\} + m\{1, 2\}
sage: S[2,1,1].to_ncsym()
1/2*m\{1\} + 1/2*m\{2\} + 1/2*m\{3\} + 1/2*m\{4\}
sage: S[1,2].to_ncsym()
1/2*m\{1\} + 1/2*m\{2\} + 1/2*m\{3\}
sage: S[1,3].to_ncsym()
1/2*m\{1\} + 1/2*m\{2\}
sage: R = N.ribbon()
sage: x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
sage: x.to_ncsym()
2*m\{\} + 2*m\{1\} + 3/2*m\{2\}
sage: R[2,1].to_ncsym()
1/3*m\{1\} + 1/3*m\{2\} + 1/6*m\{1, 2\}
sage: Phi = N.Phi()
sage: Phi[1,2].to_ncsym()
m\{1\} + m\{2\}, 3\}
sage: Phi[1,3].to_ncsym()
m\{1\}, 3\}
sage: Phi[1,3].to_ncsym()
-1/4*m\{1\} + 1/4*m\{2\} + 1/4*m\{3\} + 1/4*m\{4\}
- 1/4*m\{1\} + 1/4*m\{2\} + 1/4*m\{3\} + 1/4*m\{4\}
```
to_symmetric_function()

Return the commutative image of a non-commutative symmetric function.

OUTPUT:

- The commutative image of self. This will be a symmetric function.

EXAMPLES:

```sage
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
sage: x.to_symmetric_function()
2*s[] + 2*s[1] + 3*s[1, 1]
sage: y = N.Phi()[1,3]
sage: y.to_symmetric_function()
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
```

to_symmetric_group_algebra()

Return the image of a non-commutative symmetric function into the symmetric group algebra
where the ribbon basis element indexed by a composition is associated with the sum of all per-
mutations which have descent set equal to said composition. In compliance with the anti- iso-
morphism between the descent algebra and the non-commutative symmetric functions, we index
descent positions by the reversed composition.

OUTPUT:

- The image of self under the embedding of the \( n \)-th degree homogeneous component of the
  non-commutative symmetric functions in the symmetric group algebra of \( S_n \). This can behave
  unexpectedly when self is not homogeneous.

EXAMPLES:

```sage
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: R[2,1].to_symmetric_group_algebra()
[1, 3, 2] + [2, 3, 1]
sage: R([]).to_symmetric_group_algebra()
[]
```

verschiebung\((n)\)

Return the image of the noncommutative symmetric function self under the \( n \)-th Verschiebung operator.

The \( n \)-th Verschiebung operator \( V_n \) is defined to be the map from the \( k \)-algebra of noncommuta-
tive symmetric functions to itself that sends the complete function \( S^I \) indexed by a composition
\( I = (i_1, i_2, \ldots, i_k) \) to \( S^{(i_1/n, i_2/n, \ldots, i_k/n)} \) if all of the numbers \( i_1, i_2, \ldots, i_k \) are divisible by \( n \),
and to 0 otherwise. This operator \( V_n \) is a Hopf algebra endomorphism. For every positive integer
\( r \) with \( n \mid r \), it satisfies

\[
V_n(S_r) = S_{r/n}, \quad V_n(\Lambda_r) = (-1)^{r-n/n} \Lambda_{r/n}, \quad V_n(\Psi_r) = n \Psi_{r/n}, \quad V_n(\Phi_r) = n \Phi_{r/n}
\]

(where \( S_r \) denotes the \( r \)-th complete non-commutative symmetric function, \( \Lambda_r \) denotes the \( r \)-th el-
ementary non-commutative symmetric function, \( \Psi_r \) denotes the \( r \)-th power-sum non-commutative
symmetric function of the first kind, and \( \Phi_r \) denotes the \( r \)-th power-sum non-commutative sym-
metric function of the second kind). For every positive integer \( r \) with \( n \nmid r \), it satisfies

\[
V_n(S_r) = V_n(\Lambda_r) = V_n(\Psi_r) = V_n(\Phi_r) = 0.
\]

The \( n \)-th Verschiebung operator is also called the \( n \)-th Verschiebung endomorphism.

5.1. Comprehensive Module List 1477
It is a lift of the $n$-th Verschiebung operator on the ring of symmetric functions ($\text{verschiebung}(\cdot)$) to the ring of noncommutative symmetric functions.

The action of the $n$-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition $I$ of size $n\ell$ satisfies

$$V_n(R_I) = (-1)^{\ell(I) - \ell(J)} \cdot R_{J/n},$$

where $J$ denotes the meet of the compositions $I$ and $(n, n, \ldots, n)$, where $\ell(I)$ is the length of $I$, and where $J/n$ denotes the composition obtained by dividing every entry of $J$ by $n$. For a composition $I$ of size not divisible by $n$, we have $V_n(R_I) = 0$.

**See also:**

- frobenius method of $QSym$
- verschiebung method of $Sym$

**INPUT:**

- $n$ – a positive integer

**OUTPUT:**

The result of applying the $n$-th Verschiebung operator (on the ring of noncommutative symmetric functions) to `self`.

**EXAMPLES:**

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: S[3,2].verschiebung(2)
0
sage: S[6,4].verschiebung(2)
S[3, 2]
4*S [[]] + 2*S[3, 2] - S[4, 1]
sage: (S[3,3] - 2*S[2]).verschiebung(3)
S[1, 1]
sage: S([4,2]).verschiebung(1)
S[4, 2]
sage: R = NSym.R()
sage: R([4,2]).verschiebung(2)
R[2, 1]
```

Being Hopf algebra endomorphisms, the Verschiebung operators commute with the antipode:

```python
sage: all( R(I).verschiebung(2).antipode() == R(I).antipode().verschiebung(2) for I in Compositions(4) )
True
```

They lift the Verschiebung operators of the ring of symmetric functions:

```python
sage: all( S(I).verschiebung(2).to_symmetric_function() == S(I).to_symmetric_function().verschiebung(2) for I in Compositions(4) )
True
```

The Frobenius operators on $QSym$ are adjoint to the Verschiebung operators on $NSym$ with respect to the duality pairing:
Combinatorics, Release 10.0

```python
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: all( all( M(I).frobenius(3).duality_pairing(S(J))
            == M(I).duality_pairing(S(J).verschiebung(3))
            for I in Compositions(2) )
            for J in Compositions(3) )
True
```

```python
class ParentMethods
    Bases: object

    immaculate_function(xs)
    Return the immaculate function corresponding to the integer vector xs, written in the basis self.
    If \( \alpha \) is any integer vector – i.e., an element of \( \mathbb{Z}^m \) for some \( m \in \mathbb{N} \) –, the "immaculate function corresponding to \( \alpha \) is a non-commutative symmetric function denoted by \( S_\alpha \). One way to define this function is by setting

    \[
    S_\alpha = \sum_{\sigma \in S_m} (-1)^\sigma S_{\alpha_1 + \sigma(1) - 1} S_{\alpha_2 + \sigma(2) - 2} \cdots S_{\alpha_m + \sigma(m) - m},
    \]

    where \( \alpha \) is written in the form \((\alpha_1, \alpha_2, \ldots, \alpha_m)\), and where \( S \) stands for the complete basis (Complete).
    The immaculate function \( S_\alpha \) first appeared in [BBSSZ2012] (where it was defined differently, but the definition we gave above appeared as Theorem 3.27).
    The immaculate functions \( S_\alpha \) for \( \alpha \) running over all compositions (i.e., finite sequences of positive integers) form a basis of \( NCSF \). This is the "immaculate basis" (Immaculate).

    INPUT:
    • xs – list (or tuple or any iterable – possibly a composition) of integers
    OUTPUT:

    The immaculate function \( S_{xs} \) written in the basis self.

    EXAMPLES:

    Let us first check that, for xs a composition, we get the same as the result of self.realization_of().I()[xs]:

    ```python
    sage: def test_comp(xs):
    ....:     NSym = NonCommutativeSymmetricFunctions(QQ)
    ....:     I = NSym.I()
    ....:     return I[xs] == I.immaculate_function(xs)
    sage: def test_allcomp(n):
    ....:     return all( test_comp(c) for c in Compositions(n) )
    sage: test_allcomp(1)
    True
    sage: test_allcomp(2)
    True
    sage: test_allcomp(3)
    True
    ```

    Now some examples of non-composition immaculate functions:
```
```python
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: I = NSym.I()
sage: I.immaculate_function([0, 1])
0
sage: I.immaculate_function([0, 2])
-I[1, 1]
sage: I.immaculate_function([-1, 1])
-I[]
0
sage: I.immaculate_function([2, -1])
0
sage: I.immaculate_function([2, 0])
I[2]
sage: I.immaculate_function([2, 0, 1])
0
sage: I.immaculate_function([1, 0, 2])
-I[1, 1] + I[2, 1, 1]
sage: I.immaculate_function([2, 0, 2])
```

**to_symmetric_function()**

Morphism to the algebra of symmetric functions.

This is constructed by extending the computation on the basis or by coercion to the complete basis.

**OUTPUT:**

- The module morphism from the basis `self` to the symmetric functions which corresponds to taking a commutative image.

**EXAMPLES:**

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
sage: R.to_symmetric_function(x)
2*s[] + 2*s[1] + 3*s[1, 1]
sage: nM = N.Monomial()
sage: nM.to_symmetric_function(nM[3, 1])
```

**to_symmetric_function_on_basis()**

The image of the basis element indexed by `I` under the map to the symmetric functions.

This default implementation does a change of basis and computes the image in the complete basis.

**INPUT:**

- `I` – a composition

**OUTPUT:**

- The image of the non-commutative basis element of `self` indexed by the composition `I` under the map from non-commutative symmetric functions to the symmetric functions. This will be a symmetric function.

**EXAMPLES:**
```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: I = N.Immaculate()
sage: I.to_symmetric_function(I[1,3])
-h[2,2] + h[3,1]
sage: I.to_symmetric_function(I[1,2])
0
sage: Phi = N.Phi()
sage: Phi.to_symmetric_function_on_basis([3,1,2])==Phi.to_symmetric_function(Phi[3,1,2])
True
sage: Phi.to_symmetric_function_on_basis([])
h[]
```

**super_categories()**

Return the super categories of the category of bases of the non-commutative symmetric functions.

OUTPUT:
- list

**class Complete(NCSF)**

Bases: `CombinatorialFreeModule`, `BindableClass`

The Hopf algebra of non-commutative symmetric functions in the Complete basis.

The Complete basis is defined in Definition 3.4 of [NCSF1], where it is denoted by \((S^I)_I\). It is a multiplicative basis, and is connected to the elementary generators \(\Lambda_i\) of the ring of non-commutative symmetric functions by the following relation: Define a non-commutative symmetric function \(S_n\) for every nonnegative integer \(n\) by the power series identity

\[
\sum_{k \geq 0} t^k S_k = \left( \sum_{k \geq 0} (-t)^k \Lambda_k \right)^{-1}
\]

with \(\Lambda_0\) denoting 1. For every composition \((i_1, i_2, \ldots, i_k)\), we have \(S^{(i_1, i_2, \ldots, i_k)} = S_{i_1} S_{i_2} \cdots S_{i_k}\).

**EXAMPLES:**

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: S = NCSF.Complete(); S
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
sage: S.an_element()
2*S[] + 2*S[1] + 3*S[1, 1]
```

The following are aliases for this basis:

```python
sage: NCSF.complete()
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
sage: NCSF.S()
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
```

**class Element**

Bases: `IndexedFreeModuleElement`

An element in the Complete basis.

---

5.1. Comprehensive Module List 1481
psi_involution()  

Return the image of the noncommutative symmetric function `self` under the involution \( \psi \).

The involution \( \psi \) is defined as the linear map \( NCSF \to NCSF \) which, for every composition \( I \), sends the complete noncommutative symmetric function \( S^I \) to the elementary noncommutative symmetric function \( \Lambda^I \). It can be shown that every composition \( I \) satisfies

\[
\psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I| - \ell(I)} \Phi^I
\]

where \( I^c \) denotes the complement of the composition \( I \), and \( \ell(I) \) denotes the length of \( I \), and where standard notations for classical bases of \( NCSF \) are being used (\( S \) for the complete basis, \( \Lambda \) for the elementary basis, \( \Phi \) for the basis of the power sums of the second kind, and \( R \) for the ribbon basis). The map \( \psi \) is an involution and a graded Hopf algebra automorphism of \( NCSF \). If \( \pi \) denotes the projection from \( NCSF \) to the ring of symmetric functions \( \text{to_symmetric_function()} \), then \( \pi(\psi(f)) = \omega(\pi(f)) \) for every \( f \in NCSF \), where the \( \omega \) on the right hand side denotes the omega automorphism of \( Sym \).

The involution \( \psi \) of \( NCSF \) is adjoint to the involution \( \psi \) of \( QSym \) by the standard adjunction between \( NCSF \) and \( QSym \).

The involution \( \psi \) has been denoted by \( \psi \) in [LMvW13], section 3.6.

**See also:**  

\( psi \) involution of \( NCSF \), \( psi \) involution of \( QSym \), star involution of \( NCSF \).

**EXAMPLES:**

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)

sage: S = NSym.S()

sage: L = NSym.L()

sage: S[3,1].psi_involution()
S[1, 1, 1] - S[1, 2, 1] - S[2, 1, 1] + S[3, 1]

sage: L(S[3,1].psi_involution())
L[3, 1]

sage: S[[]].psi_involution()
S[]

sage: S[1,1].psi_involution()
S[1, 1]

sage: (S[2,1] - 2*S[2]).psi_involution()
```

The implementation at hand is tailored to the complete basis. It is equivalent to the generic implementation via the ribbon basis:

```python
sage: R = NSym.R()

sage: all( R(S[I].psi_involution()) == R(S[I]).psi_involution()  
.....:     for I in Compositions(4) )
True
```

dual()  

Return the dual basis to the complete basis of non-commutative symmetric functions. This is the Monomial basis of quasi-symmetric functions.

**OUTPUT:**

- The Monomial basis of quasi-symmetric functions.

**EXAMPLES:**
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.dual()
Quasisymmetric functions over the Rational Field in the Monomial basis

**internal_product_on_basis(I, J)**

The internal product of two non-commutative symmetric complete functions.

See `internal_product()` for a thorough documentation of this operation.

**INPUT:**
- I, J – compositions

**OUTPUT:**
- The internal product of the complete non-commutative symmetric function basis elements indexed by I and J, expressed in the complete basis.

**EXAMPLES:**

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product_on_basis([2,2],[1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product_on_basis([2,2],[1,2])
0
```

**to_symmetric_function()**

Morphism to the algebra of symmetric functions.

This is constructed by extending the computation on the complete basis.

**OUTPUT:**
- The module morphism from the basis `self` to the symmetric functions which corresponds to taking a commutative image.

**EXAMPLES:**

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.to_symmetric_function(S[3,1,2])
h[3, 2, 1]
sage: S.to_symmetric_function(S[])  
h[]
```

**to_symmetric_function_on_basis(I)**

The commutative image of a complete element

The commutative image of a basis element is obtained by sorting the indexing composition of the basis element and the output is in the complete basis of the symmetric functions.

**INPUT:**
- I – a composition

**OUTPUT:**
- The commutative image of the complete basis element indexed by I. The result is the complete symmetric function indexed by the partition obtained by sorting I.

**EXAMPLES:**

```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: S.to_symmetric_function_on_basis([2,1,3])
```
class Elementary(NCSF)

    Bases: CombinatorialFreeModule, BindableClass

    The Hopf algebra of non-commutative symmetric functions in the Elementary basis.

    The Elementary basis is defined in Definition 3.4 of [NCSF1], where it is denoted by \((\Lambda^I)_I\). It is a multiplicative basis, and is obtained from the elementary generators \(\Lambda_i\) of the ring of non-commutative symmetric functions through the formula \(\Lambda(i_1, i_2, \ldots, i_k) = \Lambda_{i_1} \Lambda_{i_2} \cdots \Lambda_{i_k}\) for every composition \((i_1, i_2, \ldots, i_k)\).

    EXAMPLES:

    sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: L = NCSF.Elementary(); L
    Non-Commutative Symmetric Functions over the Rational Field in the Elementary\_basis
sage: L.an_element()

    The following are aliases for this basis:

    sage: NCSF.elementary()
    Non-Commutative Symmetric Functions over the Rational Field in the Elementary\_basis
sage: NCSF.L()
    Non-Commutative Symmetric Functions over the Rational Field in the Elementary\_basis

class Element

    Bases: IndexedFreeModuleElement

    psi_involution()

    Return the image of the noncommutative symmetric function self under the involution \(\psi\).

    The involution \(\psi\) is defined as the linear map \(NCSF \to NCSF\) which, for every composition \(I\), sends the complete noncommutative symmetric function \(S^I\) to the elementary noncommutative symmetric function \(\Lambda^I\). It can be shown that every composition \(I\) satisfies

    \[
    \psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I| - \ell(I)} \Phi^I
    \]

    where \(I^c\) denotes the complement of the composition \(I\), and \(\ell(I)\) denotes the length of \(I\), and where standard notations for classical bases of \(NCSF\) are being used (\(S\) for the complete basis, \(\Lambda\) for the elementary basis, \(\Phi\) for the basis of the power sums of the second kind, and \(R\) for the ribbon basis).

    The map \(\psi\) is an involution and a graded Hopf algebra automorphism of \(NCSF\). If \(\pi\) denotes the projection from \(NCSF\) to the ring of symmetric functions \(to_symmetric_function()\), then \(\pi(\psi(f)) = \omega(\pi(f))\) for every \(f \in NCSF\), where the \(\omega\) on the right hand side denotes the omega automorphism of \(Sym\).

    The involution \(\psi\) of \(NCSF\) is adjoint to the involution \(\psi\) of \(QSym\) by the standard adjunction between \(NCSF\) and \(QSym\).

    The involution \(\psi\) has been denoted by \(\psi\) in [LMvW13], section 3.6.
See also:

\textit{psi involution of NCSF, psi involution of QSym, star involution of NCSF.}

**EXAMPLES:**

```python
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: L = NSym.L()
sage: L[3,1].psi_involution()
L[1, 1, 1, 1] - L[1, 2, 1] - L[2, 1, 1] + L[3, 1]
sage: S(L[3,1].psi_involution())
S[3, 1]
sage: L[].psi_involution()
L[]
sage: L[1,1].psi_involution()
L[1, 1]
sage: (L[2,1] - 2*L[2]).psi_involution()
```

The implementation at hand is tailored to the elementary basis. It is equivalent to the generic implementation via the ribbon basis:

```python
sage: R = NSym.R()
sage: all( R(L[I].psi_involution()) == R(L[I]).psi_involution() for I in Compositions(3) )
True
sage: all( R(L[I].psi_involution()) == R(L[I]).psi_involution() for I in Compositions(4) )
True
```

**star_involution()**

Return the image of the noncommutative symmetric function \( \text{self} \) under the star involution.

The star involution is defined as the algebra antihomomorphism \( \text{NCSF} \to \text{NCSF} \) which, for every positive integer \( n \), sends the \( n \)-th complete non-commutative symmetric function \( S_n \) to \( S_n \).

Denoting by \( f^* \) the image of an element \( f \in \text{NCSF} \) under this star involution, it can be shown that every composition \( I \) satisfies

\[
(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R_I^* = R_{I^r}, \quad (\Phi^I)^* = \Phi^{I^r},
\]

where \( I^r \) denotes the reversed composition of \( I \), and standard notations for classical bases of \( \text{NCSF} \) are being used (\( S \) for the complete basis, \( \Lambda \) for the elementary basis, \( R \) for the ribbon basis, and \( \Phi \) for that of the power-sums of the second kind). The star involution is an involution and a coalgebra automorphism of \( \text{NCSF} \). It is an automorphism of the graded vector space \( \text{NCSF} \). Under the canonical isomorphism between the \( n \)-th graded component of \( \text{NCSF} \) and the descent algebra of the symmetric group \( S_n \) (see \texttt{to_descent_algebra()}), the star involution (restricted to the \( n \)-th graded component) corresponds to the automorphism of the descent algebra given by \( x \mapsto \omega_n x \omega_n \), where \( \omega_n \) is the permutation \( (n, n-1, \ldots, 1) \in S_n \) (written here in one-line notation). If \( \pi \) denotes the projection from \( \text{NCSF} \) to the ring of symmetric functions (\texttt{to_symmetric_function()}), then \( \pi(f^*) = \pi(f) \) for every \( f \in \text{NCSF} \).

The star involution on \( \text{NCSF} \) is adjoint to the star involution on \( \text{QSym} \) by the standard adjunction between \( \text{NCSF} \) and \( \text{QSym} \).

The star involution has been denoted by \( \rho \) in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

5.1. Comprehensive Module List

1485
See also:

* star involution of NCSF, psi involution of NCSF, star involution of QSym.

**EXAMPLES:**

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: L = NSym.L()
sage: L[3,3,2,3].star_involution()
L[3, 2, 3, 3]
sage: L[6,3,3].star_involution()
L[3, 3, 6]
sage: (L[3,3] - 2*L[2]).star_involution()
sage: L([4,1]).star_involution()
L[1, 4]
```

The implementation at hand is tailored to the elementary basis. It is equivalent to the generic implementation via the complete basis:

```python
sage: S = NSym.S()
sage: all( S(L[I].star_involution()) == S(L[I]).star_involution()
    ....:     for I in Compositions(4) )
True
```

**verschiebung**(n)

Return the image of the noncommutative symmetric function self under the \( n \)-th Verschiebung operator.

The \( n \)-th Verschiebung operator \( V_n \) is defined to be the map from the \( k \)-algebra of noncommutative symmetric functions to itself that sends the complete function \( S^I \) indexed by a composition \( I = (i_1, i_2, \ldots, i_k) \) to \( S^{(i_1/n, i_2/n, \ldots, i_k/n)} \) if all of the numbers \( i_1, i_2, \ldots, i_k \) are divisible by \( n \), and to 0 otherwise. This operator \( V_n \) is a Hopf algebra endomorphism. For every positive integer \( r \) with \( n \mid r \), it satisfies

\[
V_n(S_r) = S_{r/n}, \quad V_n(\Lambda_r) = (-1)^{r-n/n} \Lambda_{r/n}, \quad V_n(\Psi_r) = n \Psi_{r/n}, \quad V_n(\Phi_r) = n \Phi_{r/n}
\]

(where \( S_r \) denotes the \( r \)-th complete non-commutative symmetric function, \( \Lambda_r \) denotes the \( r \)-th elementary non-commutative symmetric function, \( \Psi_r \) denotes the \( r \)-th power-sum non-commutative symmetric function of the first kind, and \( \Phi_r \) denotes the \( r \)-th power-sum non-commutative symmetric function of the second kind). For every positive integer \( r \) with \( n \nmid r \), it satisfies

\[
V_n(S_r) = V_n(\Lambda_r) = V_n(\Psi_r) = V_n(\Phi_r) = 0.
\]

The \( n \)-th Verschiebung operator is also called the \( n \)-th Verschiebung endomorphism.

It is a lift of the \( n \)-th Verschiebung operator on the ring of symmetric functions (verschiebung()) to the ring of noncommutative symmetric functions.

The action of the \( n \)-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition \( I \) of size \( n \ell \) satisfies

\[
V_n(R_I) = (-1)^{\ell(I) - \ell(J)} \cdot R_{J/n},
\]
where $J$ denotes the meet of the compositions $I$ and $(n, n, \ldots, n)$, where $\ell(I)$ is the length of $I$, and where $J/n$ denotes the composition obtained by dividing every entry of $J$ by $n$. For a composition $I$ of size not divisible by $n$, we have $V_n(R_I) = 0$.

**See also:**

*verschiebung method of NCSF*, *frobenius method of QSym*, *verschiebung method of Sym*

**INPUT:**

- $n$ – a positive integer

**OUTPUT:**

The result of applying the $n$-th Verschiebung operator (on the ring of noncommutative symmetric functions) to `self`.

**EXAMPLES:**

```sage
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: L = NSym.L()
sage: L([4,2]).verschiebung(2)
-L[2, 1]
sage: L([2,4]).verschiebung(2)
-L[1, 2]
sage: L([6]).verschiebung(2)
-L[3]
sage: L([2,1]).verschiebung(3)
0
sage: L([3]).verschiebung(2)
0
sage: L([]).verschiebung(2)
L[]
sage: L([5, 1]).verschiebung(3)
0
sage: L([5, 1]).verschiebung(6)
0
sage: L([5, 1]).verschiebung(2)
0
sage: L([1, 2, 3, 1]).verschiebung(7)
0
sage: L([7]).verschiebung(7)
L[1]
sage: L([1, 2, 3, 1]).verschiebung(5)
0
```

**I**

alias of `Immaculate`

**class Immaculate(NCSF)**

**Bases:** `CombinatorialFreeModule`, `BindableClass`

The immaculate basis of the non-commutative symmetric functions.

The immaculate basis first appears in Berg, Bergeron, Saliola, Serrano and Zabrocki’s [BBSSZ2012].
can be described as the family $(\mathcal{S}_\alpha)$, where $\alpha$ runs over all compositions, and $\mathcal{S}_\alpha$ denotes the immaculate function corresponding to $\alpha$ (see `immaculate_function()`).

If $\alpha$ is a composition $(\alpha_1, \alpha_2, \ldots, \alpha_m)$, then

$$\mathcal{S}_\alpha = \sum_{\sigma \in S_m} (-1)^\sigma S_{\sigma_1 + \sigma(1) - 1} S_{\sigma_2 + \sigma(2) - 2} \cdots S_{\sigma_m + \sigma(m) - m}.$$ 

**Warning:** This *basis* contains only the immaculate functions indexed by compositions (i.e., finite sequences of positive integers). To obtain the remaining immaculate functions (sensu lato), use the `immaculate_function()` method. Calling the immaculate *basis* with a list which is not a composition will currently return garbage!

**EXAMPLES:**

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: I = NCSF.I()
sage: I([1, 3, 2])*I([1])
I[1, 3, 2, 1] + I[1, 3, 3] + I[1, 4, 2] + I[2, 3, 2]
sage: I([1])^2*I([1, 3, 2])
sage: I([1, 3])^2*I([1, 1])
I[1, 1, 3, 1] + I[1, 4, 1] + I[2, 3, 1] + I[2, 4]
sage: I([3, 1, 1])^3*I([2, 1])
```

```
sage: R = NCSF.ribbon()
sage: I(R([1, 3, 1]))
sage: R(I(R([2, 1, 3])))
R[2, 1, 3]
```

**class Element**

- **Bases:** `IndexedFreeModuleElement`

An element in the Immaculate basis.

**bernstein_creation_operator**(n)**

Return the image of self under the $n$-th Bernstein creation operator.

Let $n$ be an integer. The $n$-th Bernstein creation operator $B_n$ is defined as the endomorphism of the space $NSym$ of noncommutative symmetric functions given by

$$B_n I_{(\alpha_1, \alpha_2, \ldots, \alpha_m)} = I_{(n, \alpha_1, \alpha_2, \ldots, \alpha_m)},$$

where $I_{(\alpha_1, \alpha_2, \ldots, \alpha_m)}$ is the immaculate function associated to the $m$-tuple $(\alpha_1, \alpha_2, \ldots, \alpha_m) \in \mathbb{Z}^m$.

This has been introduced in [BBSSZ2012], section 3.1, in analogy to the Bernstein creation operators on the symmetric functions.

For more information on the $n$-th Bernstein creation operator, see `bernstein_creation_operator()`.

**EXAMPLES:**
Combinatorics, Release 10.0

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: I = NSym.I()
sage: b = I[1,3,2,1]
sage: b.bernstein_creation_operator(3)
I[3, 1, 3, 2, 1]
sage: b.bernstein_creation_operator(5)
I[5, 1, 3, 2, 1]
sage: elt = b + 3*I[4,1,2]
sage: elt.bernstein_creation_operator(1)
I[1, 1, 3, 2, 1] + 3*I[1, 4, 1, 2]
```

We check that this agrees with the definition on the Complete basis:

```
sage: S = NSym.S()
sage: S(elt).bernstein_creation_operator(1) == S(elt.bernstein_creation_operator(1))
True
```

Check on non-positive values of $n$:

```
sage: I[2,2,2].bernstein_creation_operator(-1)
I[1, 1, 1, 2] + I[1, 1, 2, 1] + I[1, 2, 1, 1] - I[1, 2, 2]
sage: I[2,3,2].bernstein_creation_operator(0)
-I[1, 1, 3, 2] - I[1, 2, 2, 2] - I[1, 2, 3, 1] + I[2, 3, 2]
```

dual()

Return the dual basis to the Immaculate basis of NCSF.

The basis returned is the dualImmaculate basis of QSym.

OUTPUT:

• The dualImmaculate basis of the quasi-symmetric functions.

EXAMPLES:

```
sage: I = NonCommutativeSymmetricFunctions(QQ).Immaculate()
sage: I.dual()
Quasisymmetric functions over the Rational Field in the dualImmaculate basis
```

L

alias of Elementary

class Monomial(NCSF)

Bases: CombinatorialFreeModule, BindableClass

The monomial basis defined in Tevlin’s paper [Tev2007].

The monomial basis is well-defined only when the base ring is a $\mathbb{Q}$-algebra. It is the basis denoted by $(M')_i$ in [Tev2007].

class MultiplicativeBases(parent_with_realization)

Bases: Category_realization_of_parent

Category of multiplicative bases of non-commutative symmetric functions.

EXAMPLES:
The complete basis is a multiplicative basis, but the ribbon basis is not:

```
sage: N.Complete() in N.MultiplicativeBases()
True
sage: N.Ribbon() in N.MultiplicativeBases()
False
```

### class ParentMethods

**Bases:** object

#### algebra_generators()

Return the algebra generators of a given multiplicative basis of non-commutative symmetric functions.

**OUTPUT:**

- The family of generators of the multiplicative basis `self`.

**EXAMPLES:**

```
sage: Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
sage: f = Psi.algebra_generators()
sage: f
Lazy family (lambda i: Psi[i])_{i in Positive integers}
sage: f[1], f[2], f[3]
(Psi[1], Psi[2], Psi[3])
```

#### algebra_morphism(on_generators, **keywords)

Given a map defined on the generators of the multiplicative basis `self`, return the algebra morphism that extends this map to the whole algebra of non-commutative symmetric functions.

**INPUT:**

- `on_generators` – a function defined on the index set of the generators (that is, on the positive integers)
- `anti` – a boolean; defaults to `False`
- `category` – a category; defaults to `None`

**OUTPUT:**

- The algebra morphism of `self` which is defined by `on_generators` in the basis `self`. When `anti` is set to `True`, an algebra anti-morphism is computed instead of an algebra morphism.

**EXAMPLES:**

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: Psi = NCSF.Psi()
sage: double = lambda i: Psi[i,i]
sage: f = Psi.algebra_morphism(double, codomain = Psi)
sage: f
Generic endomorphism of Non-Commutative Symmetric Functions over the Rational Field in the Psi basis
sage: f(2*Psi[] + 3 * Psi[1,3,2] + Psi[2,4] )
2*Psi[] + 3*Psi[1, 1, 3, 3, 2, 2] + Psi[2, 2, 4, 4]
sage: f.category()
```

(continues on next page)
When extra properties about the morphism are known, one can specify the category of which it is a morphism:

```
sage: negate = lambda i: -Psi[i]
sage: f = Psi.algebra_morphism(negate, codomain = Psi, category =
        GradedHopfAlgebrasWithBasis(QQ))
sage: f
Generic endomorphism of Non-Commutative Symmetric Functions over the
    Rational Field in the Psi basis
sage: f(2*Psi[[]] + 3 * Psi[1,3,2] + Psi[2,4] )
2*Psi[[]] - 3*Psi[1, 3, 2] + Psi[2, 4]
sage: f.category()
Category of endsets of hopf algebras over Rational Field and graded,
    modules over Rational Field
```

If `anti` is true, this returns an anti-algebra morphism:

```
sage: f = Psi.algebra_morphism(double, codomain = Psi, anti=True)
sage: f
Generic endomorphism of Non-Commutative Symmetric Functions over the
    Rational Field in the Psi basis
sage: f(2*Psi[[]] + 3 * Psi[1,3,2] + Psi[2,4] )
2*Psi[[]] + 3*Psi[2, 2, 3, 3, 1, 1] + Psi[4, 4, 2, 2]
sage: f.category()
Category of endsets of modules with basis over Rational Field
```

`antipode()`

Return the antipode morphism on the basis `self`.

The antipode of `NSym` is closely related to the omega involution; see `omega_involution()` for the latter.

**OUTPUT:**

- The antipode module map from non-commutative symmetric functions on basis `self`.

**EXAMPLES:**

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.antipode
Generic endomorphism of Non-Commutative Symmetric Functions over the
    Rational Field in the Complete basis
```

`coproduct()`

Return the coproduct morphism in the basis `self`.

**OUTPUT:**

- The coproduct module map from non-commutative symmetric functions on basis `self`.

**EXAMPLES:**

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.coproduct
Generic morphism:
```
product_on_basis(composition1, composition2)

Return the product of two basis elements from the multiplicative basis. Multiplication is just concatenation on compositions.

INPUT:
• composition1, composition2 – integer compositions

OUTPUT:
• The product of the two non-commutative symmetric functions indexed by composition1 and composition2 in the multiplicative basis self. This will be again a non-commutative symmetric function.

EXAMPLES:

sage: Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
sage: Psi[3,1,2] * Psi[4,2] == Psi[3,1,2,4,2]
True
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.product_on_basis(Composition([2,1]), Composition([1,2]))
S[2, 1, 1, 2]

to_symmetric_function()

Morphism to the algebra of symmetric functions.

This is constructed by extending the algebra morphism by the image of the generators.

OUTPUT:
• The module morphism from the basis self to the symmetric functions which corresponds to taking a commutative image.

EXAMPLES:

sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.to_symmetric_function(S[1,3])
h[3, 1]
sage: Phi = N.Phi()
sage: Phi.to_symmetric_function(Phi[1,3])
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
sage: Psi = N.Psi()
sage: Psi.to_symmetric_function(Psi[1,3])
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]

to_symmetric_function_on_generators()

Morphism of the generators to symmetric functions.

This is constructed by coercion to the complete basis and applying the morphism.

OUTPUT:
• The module morphism from the basis self to the symmetric functions which corresponds to taking a commutative image.

EXAMPLES:
```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = N.Phil(3)
\text{h}[1, 1, 1] - 3^{3}\text{h}[2, 1] + 3^{3}\text{h}[3]
sage: Phi.to_symmetric_function_on_generators(0)
\text{h}[]
```

```
sage: Psi = N.Psi()
\text{h}[1, 1, 1] - 3^{3}\text{h}[2, 1] + 3^{3}\text{h}[3]
```

```
sage: L = N.elementary()
\text{h}[1, 1, 1] - 2^{3}\text{h}[2, 1] + \text{h}[3]
```

```python
super_categories()
Return the super categories of the category of multiplicative bases of the non-commutative symmetric functions.

OUTPUT:
- list
class MultiplicativeBasesOnGroupLikeElements(parent_with_realization)
Bases: Category_realization_of_parent

Category of multiplicative bases on grouplike elements of non-commutative symmetric functions.

Here, a “multiplicative basis on grouplike elements” means a multiplicative basis whose generators $(f_1, f_2, f_3, \ldots)$ satisfy

\[ \Delta(f_i) = \sum_{j=0}^{i} f_j \otimes f_{i-j} \]

with $f_0 = 1$. (In other words, the generators are to form a divided power sequence in the sense of a coalgebra.) This does not mean that the generators are grouplike, but means that the element $1 + f_1 + f_2 + f_3 + \cdots$ in the completion of the ring of non-commutative symmetric functions with respect to the grading is grouplike.

EXAMPLES:
```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.MultiplicativeBasesOnGroupLikeElements()
Category of multiplicative bases on group like elements of Non-Commutative\text{\_}Symmetric Functions over the Rational Field
```

The complete basis is a multiplicative basis, but the ribbon basis is not:
```python
sage: N.Complete() in N.MultiplicativeBasesOnGroupLikeElements()
True
sage: N.Ribbon() in N.MultiplicativeBasesOnGroupLikeElements()
False
```

class ParentMethods
Bases: object
```
\text{antipode_on_basis}(composition)
Return the application of the antipode to a basis element.
```
```
• composition – a composition

OUTPUT:
• The image of the basis element indexed by composition under the antipode map.

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: S.antipode_on_basis(Composition([2,1]))
-S[1, 1, 1] + S[1, 2]
sage: S[1].antipode() # indirect doctest
-S[1]
sage: S[2].antipode() # indirect doctest
S[1, 1] - S[2]
sage: S[3].antipode() # indirect doctest
-S[1, 1, 1] + S[1, 2] + S[2, 1] - S[3]
sage: S[2,3].coproduct().apply_multilinear_morphism(lambda be,ga: S(be)*S(ga).antipode())
0
sage: S[2,3].coproduct().apply_multilinear_morphism(lambda be,ga: S(be).antipode()*S(ga))
0
```

coproduct_on_generators(i)

Return the image of the $i^{th}$ generator of the algebra under the coproduct.

INPUT:
• $i$ – a positive integer

OUTPUT:
• The result of applying the coproduct to the $i^{th}$ generator of self.

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: S.coproduct_on_generators(3)
```

super_categories()

Return the super categories of the category of multiplicative bases of group-like elements of the non-commutative symmetric functions.

OUTPUT:
• list

class MultiplicativeBasesOnPrimitiveElements(parent_with_realization)

Bases: Category_realization_of_parent

Category of multiplicative bases of the non-commutative symmetric functions whose generators are primitive elements.

An element $x$ of a bialgebra is primitive if $\Delta(x) = x \otimes 1 + 1 \otimes x$, where $\Delta$ is the coproduct of the bialgebra.

Given a multiplicative basis and knowing the coproducts and antipodes of its generators, one can compute the coproduct and the antipode of any element, since they are respectively algebra morphisms and antimorphisms. See antipode_on_generators() and coproduct_on_generators().

Todo: this could be generalized to any free algebra.

EXAMPLES:
Combinatorics, Release 10.0

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.MultiplicativeBasesOnPrimitiveElements()
Category of multiplicative bases on primitive elements of Non-Commutative
  Symmetric Functions over the Rational Field
```

The Phi and Psi bases are multiplicative bases whose generators are primitive elements, but the complete and ribbon bases are not:

```python
sage: N.Phi() in N.MultiplicativeBasesOnPrimitiveElements()
True
sage: N.Psi() in N.MultiplicativeBasesOnPrimitiveElements()
True
sage: N.Complete() in N.MultiplicativeBasesOnPrimitiveElements()
False
sage: N.Ribbon() in N.MultiplicativeBasesOnPrimitiveElements()
False
```

```python
class ParentMethods
    Bases: object

    antipode_on_generators(i)
    Return the image of a generator of a primitive basis of the non-commutative symmetric functions under the antipode map.
    INPUT:
    • i – a positive integer
    OUTPUT:
    • The image of the i-th generator of the multiplicative basis self under the antipode of the algebra of non-commutative symmetric functions.
    EXAMPLES:

    sage: Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
sage: Psi.antipode_on_generators(2)
-Psi[2]
```

```python
coprocess_on_generators(i)
    Return the image of the i-th generator of the multiplicative basis self under the coproduct.
    INPUT:
    • i – a positive integer
    OUTPUT:
    • The result of applying the coproduct to the i-th generator of self.
    EXAMPLES:

    sage: Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
sage: Psi.coprocess_on_generators(3)
```

```python
super_categories()
    Return the super categories of the category of multiplicative bases of primitive elements of the non-commutative symmetric functions.
    OUTPUT:
    • list
```

5.1. Comprehensive Module List
class Phi(NCSF)
Bases: CombinatorialFreeModule, BindableClass

The Hopf algebra of non-commutative symmetric functions in the Phi basis.

The Phi basis is defined in Definition 3.4 of [NCSF1], where it is denoted by \((\Phi^I)_I\). It is a multiplicative basis, and is connected to the elementary generators \(\Lambda_i\) of the ring of non-commutative symmetric functions by the following relation: Define a non-commutative symmetric function \(\Phi_n\) for every positive integer \(n\) by the power series identity

\[
\sum_{k \geq 1} \frac{t^k}{k} \Phi_k = -\log \left( \sum_{k \geq 0} (-t)^k \Lambda_k \right),
\]

with \(\Lambda_0\) denoting 1. For every composition \((i_1, i_2, \ldots, i_k)\), we have \(\Phi^{(i_1, i_2, \ldots, i_k)} = \Phi_{i_1} \Phi_{i_2} \cdots \Phi_{i_k}\).

The \(\Phi\)-basis is well-defined only when the base ring is a \(\mathbb{Q}\)-algebra. The elements of the \(\Phi\)-basis are known as the “power-sum non-commutative symmetric functions of the second kind”.

The generators \(\Phi_n\) are related to the (first) Eulerian idempotents in the descent algebras of the symmetric groups (see [NCSF1], 5.4 for details).

EXAMPLES:

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NCSF.Phi(); Phi
Non-Commutative Symmetric Functions over the Rational Field in the Phi basis
sage: Phi.an_element()
2*Phi[] + 2*Phi[1] + 3*Phi[1, 1]
```

class Element
Bases: IndexedFreeModuleElement

psi_involution()
Return the image of the noncommutative symmetric function self under the involution \(\psi\).

The involution \(\psi\) is defined as the linear map \(NCSF \to NCSF\) which, for every composition \(I\), sends the complete noncommutative symmetric function \(S^I\) to the elementary noncommutative symmetric function \(\Lambda^I\). It can be shown that every composition \(I\) satisfies

\[
\psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I| - \ell(I)} \Phi^I
\]

where \(I^c\) denotes the complement of the composition \(I\), and \(\ell(I)\) denotes the length of \(I\), and where standard notations for classical bases of \(NCSF\) are being used (\(S\) for the complete basis, \(\Lambda\) for the elementary basis, \(\Phi\) for the basis of the power sums of the second kind, and \(R\) for the ribbon basis).

The map \(\psi\) is an involution and a graded Hopf algebra automorphism of \(NCSF\). If \(\pi\) denotes the projection from \(NCSF\) to the ring of symmetric functions \(\text{to_symmetric_function()}\), then \(\pi(\psi(f)) = \omega(\pi(f))\) for every \(f \in NCSF\), where the \(\omega\) on the right hand side denotes the omega automorphism of \(Sym\).

The involution \(\psi\) of \(NCSF\) is adjoint to the involution \(\psi\) of \(QSym\) by the standard adjunction between \(NCSF\) and \(QSym\).

The involution \(\psi\) has been denoted by \(\psi\) in [LMvW13], section 3.6.

See also:
psi involution of NCSF, psi involution of QSym, star involution of NCSF.

EXAMPLES:
The implementation at hand is tailored to the Phi basis. It is equivalent to the generic implementation via the ribbon basis:

```
sage: R = NSym.R()
sage: all( R(Phi[I].psi_involution()) == R(Phi[I]).psi_involution() 
        ....:    for I in Compositions(4) )
True
```

**star_involution()**

Return the image of the noncommutative symmetric function self under the star involution.

The star involution is defined as the algebra antihomomorphism $NCSF \to NCSF$ which, for every positive integer $n$, sends the $n$-th complete non-commutative symmetric function $S_n$ to $S_n$. Denoting by $f^*$ the image of an element $f \in NCSF$ under this star involution, it can be shown that every composition $I$ satisfies

$$(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R_i^r = R_{i^r}, \quad (\Phi^I)^* = \Phi^{I^r},$$

where $I^r$ denotes the reversed composition of $I$, and standard notations for classical bases of $NCSF$ are being used ($S$ for the complete basis, $\Lambda$ for the elementary basis, $R$ for the ribbon basis, and $\Phi$ for that of the power-sums of the second kind). The star involution is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. Under the canonical isomorphism between the $n$-th graded component of $NCSF$ and the descent algebra of the symmetric group $S_n$ (see to_descent_algebra()), the star involution (restricted to the $n$-th graded component) corresponds to the automorphism of the descent algebra given by $x \mapsto \omega_n x \omega_n$, where $\omega_n$ is the permutation $(n, n-1, \ldots, 1) \in S_n$ (written here in one-line notation). If $\pi$ denotes the projection from $NCSF$ to the ring of symmetric functions (to_symmetric_function()), then $\pi(f^*) = \pi(f)$ for every $f \in NCSF$.

The star involution on $NCSF$ is adjoint to the star involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by $\rho$ in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

**See also:**

- star involution of $NCSF$
- psi involution of $NCSF$
- star involution of $QSym$

**EXAMPLES:**

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NSym.Phi()
sage: Phi[3,2].psi_involution() -Phi[3, 2]
sage: Phi[2,2].psi_involution() Phi[2, 2]
sage: Phi[].psi_involution() Phi[]
sage: Phi(0).psi_involution() 0
```
sage: Phi[3,1,1,4].star_involution()
Phi[4, 1, 1, 3]
sage: Phi[4, 2, 1].star_involution()
Phi[1, 2, 4]
sage: (Phi[3, 3] + 3*Phi[1]).star_involution()
3*Phi[1] + Phi[3, 3]
sage: Phi([2,1]).star_involution()
Phi[1, 2]

The implementation at hand is tailored to the Phi basis. It is equivalent to the generic implementation via the complete basis:

sage: S = NSym.S()
sage: all( S(Phi[I].star_involution()) == S(Phi[I]).star_involution() 
....:     for I in Compositions(4) )
True

verschiebung(n)

Return the image of the noncommutative symmetric function self under the n-th Verschiebung operator.

The n-th Verschiebung operator $V_n$ is defined to be the map from the $k$-algebra of noncommutative symmetric functions to itself that sends the complete function $S^I$ indexed by a composition $I = (i_1, i_2, \ldots, i_k)$ to $S^{i_1/n, i_2/n, \ldots, i_k/n}$ if all of the numbers $i_1, i_2, \ldots, i_k$ are divisible by $n$, and to 0 otherwise. This operator $V_n$ is a Hopf algebra endomorphism. For every positive integer $r$ with $n \mid r$, it satisfies

$$V_n(S_r) = S_{r/n}, \quad V_n(\Lambda_r) = (-1)^{r-r/n} \Lambda_{r/n}, \quad V_n(\Psi_r) = n \Psi_{r/n}, \quad V_n(\Phi_r) = n \Phi_{r/n}$$

(where $S_r$ denotes the $r$-th complete non-commutative symmetric function, $\Lambda_r$ denotes the $r$-th elementary non-commutative symmetric function, $\Psi_r$ denotes the $r$-th power-sum non-commutative symmetric function of the first kind, and $\Phi_r$ denotes the $r$-th power-sum non-commutative symmetric function of the second kind). For every positive integer $r$ with $n \nmid r$, it satisfies

$$V_n(S_r) = V_n(\Lambda_r) = V_n(\Psi_r) = V_n(\Phi_r) = 0.$$ 

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism.

It is a lift of the n-th Verschiebung operator on the ring of symmetric functions (verschiebung()) to the ring of noncommutative symmetric functions.

The action of the n-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition $I$ of size $n\ell$ satisfies

$$V_n(R_I) = (-1)^{\ell(I)-\ell(J)} \cdot R_{J/n},$$

where $J$ denotes the meet of the compositions $I$ and $\underbrace{(n, n, \ldots, n)}_{|I|/n}$ times, where $\ell(I)$ is the length of $I$, and where $J/n$ denotes the composition obtained by dividing every entry of $J$ by $n$. For a composition $I$ of size not divisible by $n$, we have $V_n(R_I) = 0.$

```

class Psi(NCSF)

Bases: CombinatorialFreeModule, BindableClass

The Hopf algebra of non-commutative symmetric functions in the Psi basis.

The Psi basis is defined in Definition 3.4 of [NCSF1], where it is denoted by $(\Psi^i)_t$. It is a multiplicative basis, and is connected to the elementary generators $\Lambda_i$ of the ring of non-commutative symmetric functions by the following relation: Define a non-commutative symmetric function $\Psi_n$ for every positive integer $n$ by the power series identity

\[
\frac{d}{dt} \sigma(t) = \sigma(t) \cdot \left( \sum_{k \geq 1} t^{k-1} \Psi_k \right),
\]
where
\[
\sigma(t) = \left( \sum_{k \geq 0} (-t)^k \Lambda_k \right)^{-1}
\]
and where \( \Lambda_0 \) denotes 1. For every composition \((i_1, i_2, \ldots, i_k)\), we have \( \Psi^{(i_1, i_2, \ldots, i_k)} = \Psi_{i_1} \Psi_{i_2} \cdots \Psi_{i_k} \).

The \( \Psi \)-basis is a basis only when the base ring is a \( \mathbb{Q} \)-algebra (although the \( \Psi^I \) can be defined over any base ring). The elements of the \( \Psi \)-basis are known as the "power-sum non-commutative symmetric functions of the first kind". The generators \( \Psi_n \) correspond to the Dynkin (quasi-)idempotents in the descent algebras of the symmetric groups (see [NCSF1], 5.2 for details).

Another (equivalent) definition of \( \Psi_n \) is
\[
\Psi_n = \sum_{i=0}^{n-1} (-1)^i R_{1^i, n-i},
\]
where \( R \) denotes the ribbon basis of \( NCSF \), and where \( 1^i \) stands for \( i \) repetitions of the integer 1.

EXAMPLES:

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: Psi = NCSF.Psi(); Psi
Non-Commutative Symmetric Functions over the Rational Field in the Psi basis
sage: Psi.an_element()
2*Psi[] + 2*Psi[1] + 3*Psi[1, 1]
```

Checking the equivalent definition of \( \Psi_n \):

```python
sage: def test_psi(n):
....:     NCSF = NonCommutativeSymmetricFunctions(ZZ)
....:     R = NCSF.R()
....:     Psi = NCSF.Psi()
....:     a = R.sum([(-1) ** i * R[[1]*i + [n-i]]
....:                for i in range(n)]))
....:     return a == R(Psi[n])
sage: test_psi(2)
True
sage: test_psi(3)
True
sage: test_psi(4)
True
```

class Element

Bases: IndexedFreeModuleElement

```
verschiebung(n)
```

Return the image of the noncommutative symmetric function \( \text{self} \) under the \( n \)-th Verschiebung operator.

The \( n \)-th Verschiebung operator \( V_n \) is defined to be the map from the \( k \)-algebra of noncommutative symmetric functions to itself that sends the complete function \( S^I \) indexed by a composition \( I = (i_1, i_2, \ldots, i_k) \) to \( S^{(i_1/n, i_2/n, \ldots, i_k/n)} \) if all of the numbers \( i_1, i_2, \ldots, i_k \) are divisible by \( n \), and to 0 otherwise. This operator \( V_n \) is a Hopf algebra endomorphism. For every positive integer \( r \) with \( n \mid r \), it satisfies

\[
V_n(S_r) = S_{r/n}, \quad V_n(\Lambda_r) = (-1)^{r-r/n} \Lambda_{r/n}, \quad V_n(\Psi_r) = n\Psi_{r/n}, \quad V_n(\Phi_r) = n\Phi_{r/n}
\]
(where $S_r$ denotes the $r$-th complete non-commutative symmetric function, $\Lambda_r$ denotes the $r$-th elementary non-commutative symmetric function, $\Psi_r$ denotes the $r$-th power-sum non-commutative symmetric function of the first kind, and $\Phi_r$ denotes the $r$-th power-sum non-commutative symmetric function of the second kind). For every positive integer $r$ with $n \nmid r$, it satisfies

$$V_n(S_r) = V_n(\Lambda_r) = V_n(\Psi_r) = V_n(\Phi_r) = 0.$$

The $n$-th Verschiebung operator is also called the $n$-th Verschiebung endomorphism.

It is a lift of the $n$-th Verschiebung operator on the ring of symmetric functions (verschiebung()) to the ring of noncommutative symmetric functions.

The action of the $n$-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition $I$ of size $n \ell$ satisfies

$$V_n(R_I) = (-1)^{\ell(I)-\ell(J)} \cdot R_{J/n},$$

where $J$ denotes the meet of the compositions $I$ and $(n, n, \ldots, n)$, where $\ell(I)$ is the length of $I$, and where $J/n$ denotes the composition obtained by dividing every entry of $J$ by $n$. For a composition $I$ of size not divisible by $n$, we have $V_n(R_I) = 0$.

(continues on next page)```
internal_product_on_basis_by_bracketing(I, J)

The internal product of two elements of the Psi basis.

See internal_product() for a thorough documentation of this operation.

This is an implementation using [NCSF2] Lemma 3.10. It is fast when the length of \( I \) is small, but can get very slow otherwise. Therefore it is not being used by default for internally multiplying Psi functions.

INPUT:
• \( I, J \) – compositions

OUTPUT:
• The internal product of the elements of the Psi basis of \( NSym \) indexed by \( I \) and \( J \), expressed in the Psi basis.

AUTHORS:
• Travis Scrimshaw, 29 Mar 2014

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: Psi = N.Psi()
sage: Psi.internal_product_on_basis_by_bracketing([2,2],[1,2,1])
0
sage: Psi.internal_product_on_basis_by_bracketing([1,2,1],[2,1,1])
4*Psi[1, 2, 1]
sage: Psi.internal_product_on_basis_by_bracketing([2,1,1],[1,2,1])
4*Psi[2, 1, 1]
sage: Psi.internal_product_on_basis_by_bracketing([1,2,1],[1,1,1,1])
0
sage: Psi.internal_product_on_basis_by_bracketing([3,1],[1,2,1])
-Psi[1, 2, 1] + Psi[2, 1, 1]
sage: Psi.internal_product_on_basis_by_bracketing([1,2,1],[3,1])
0
sage: Psi.internal_product_on_basis_by_bracketing([2,2],[1,2])
0
sage: Psi.internal_product_on_basis_by_bracketing([4],[1,2,1])
-Psi[1, 1, 2] + 2*Psi[1, 2, 1] - Psi[2, 1, 1]
```
every composition $I$, we have
\[ R_I = \sum_J (-1)^{\ell(I) - \ell(J)} S_J, \]
where the sum is over all compositions $J$ which are coarser than $I$ and $\ell(I)$ denotes the length of $I$. (See the proof of Proposition 4.13 in [NCSF1].)

The elements of the Ribbon basis are commonly referred to as the ribbon Schur functions.

EXAMPLES:

```sage
NCSF = NonCommutativeSymmetricFunctions(QQ)
R = NCSF.Ribbon(); R
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon basis
sage: R.an_element()
2*R[] + 2*R[1] + 3*R[1, 1]
```

The following are aliases for this basis:

```sage
NCSF.ribbon()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon basis
sage: NCSF.R()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon basis
```

class Element

Bases: IndexedFreeModuleElement

star_involution()

Return the image of the noncommutative symmetric function self under the star involution.

The star involution is defined as the algebra antihomomorphism $NCSF \to NCSF$ which, for every positive integer $n$, sends the $n$-th complete non-commutative symmetric function $S_n$ to $S_n$. Denoting by $f^*$ the image of an element $f \in NCSF$ under this star involution, it can be shown that every composition $I$ satisfies
\[ (S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R_I^* = R_{I^r}, \quad (\Phi^I)^* = \Phi^{I^r}, \]
where $I^r$ denotes the reversed composition of $I$, and standard notations for classical bases of $NCSF$ are being used ($S$ for the complete basis, $\Lambda$ for the elementary basis, $R$ for the ribbon basis, and $\Phi$ for that of the power-sums of the second kind). The star involution is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. Under the canonical isomorphism between the $n$-th graded component of $NCSF$ and the descent algebra of the symmetric group $S_n$ (see to_descent_algebra()), the star involution (restricted to the $n$-th graded component) corresponds to the automorphism of the descent algebra given by $x \mapsto \omega_n x \omega_n$, where $\omega_n$ is the permutation $(n, n-1, \ldots, 1) \in S_n$ (written here in one-line notation). If $\pi$ denotes the projection from $NCSF$ to the ring of symmetric functions (to_symmetric_function()), then $\pi(f^*) = \pi(f)$ for every $f \in NCSF$.

The star involution on $NCSF$ is adjoint to the star involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by $\rho$ in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

See also:

* star involution of NCSF, star involution of QSym, psi involution of NCSF.

EXAMPLES:
The implementation at hand is tailored to the ribbon basis. It is equivalent to the generic implementation via the complete basis:

```
sage: S = NSym.S()
sage: all( S(R[I].star_involution()) == S(R[I]).star_involution()
       ....: for I in Compositions(4) )
True
```

**verschiebung**$(n)$

Return the image of the noncommutative symmetric function self under the $n$-th Verschiebung operator.

The $n$-th Verschiebung operator $V_n$ is defined to be the map from the $k$-algebra of noncommutative symmetric functions to itself that sends the complete function $S^I$ indexed by a composition $I = (i_1, i_2, \ldots, i_k)$ to $S^{(i_1/n, i_2/n, \ldots, i_k/n)}$ if all of the numbers $i_1, i_2, \ldots, i_k$ are divisible by $n$, and to 0 otherwise. This operator $V_n$ is a Hopf algebra endomorphism. For every positive integer $r$ with $n \mid r$, it satisfies

\[
V_n(S_r) = S_{r/n}, \quad V_n(\Lambda_r) = (-1)^{r-r/n} \Lambda_{r/n}, \quad V_n(\Psi_r) = n\Psi_{r/n}, \quad V_n(\Phi_r) = n\Phi_{r/n}
\]

(where $S_r$ denotes the $r$-th complete non-commutative symmetric function, $\Lambda_r$ denotes the $r$-th elementary non-commutative symmetric function, $\Psi_r$ denotes the $r$-th power-sum non-commutative symmetric function of the first kind, and $\Phi_r$ denotes the $r$-th power-sum non-commutative symmetric function of the second kind). For every positive integer $r$ with $n \nmid r$, it satisfies

\[
V_n(S_r) = V_n(\Lambda_r) = V_n(\Psi_r) = V_n(\Phi_r) = 0.
\]

The $n$-th Verschiebung operator is also called the $n$-th Verschiebung endomorphism.

It is a lift of the $n$-th Verschiebung operator on the ring of symmetric functions (verschiebung()) to the ring of noncommutative symmetric functions.

The action of the $n$-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition $I$ of size $n\ell$ satisfies

\[
V_n(R_I) = (-1)^{\ell(I)-\ell(J)} \cdot R_{J/n},
\]

where $J$ denotes the meet of the compositions $I$ and $(n, n, \ldots, n)$, where $\ell(I)$ is the length of $I$, and where $J/n$ denotes the composition obtained by dividing every entry of $J$ by $n$. For a composition $I$ of size not divisible by $n$, we have $V_n(R_I) = 0$. 

See also:

verschiebung method of NCSF, frobenius method of QSym, verschiebung method of Sym

INPUT:
• n – a positive integer

OUTPUT:

The result of applying the \( n \)-th Verschiebung operator (on the ring of noncommutative symmetric functions) to \( \text{self} \).

EXAMPLES:

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: R = NSym.R()
sage: R([4,2]).verschiebung(2)
R[2, 1]
sage: R([2,1]).verschiebung(3)
-R[1]
sage: R([3]).verschiebung(2)
0
sage: R([]).verschiebung(2)

sage: R([5, 1]).verschiebung(3)
-R[2]
sage: R([5, 1]).verschiebung(6)
-R[1]
sage: R([5, 1]).verschiebung(2)
-R[3]
sage: R([1, 2, 3, 1]).verschiebung(7)
-R[1]
sage: R([1, 2, 3, 1]).verschiebung(5)
0
```

\texttt{antipode\_on\_basis}(\texttt{composition})

Return the application of the antipode to a basis element of the ribbon basis \texttt{self}.

INPUT:
• \texttt{composition} – a composition

OUTPUT:
• The image of the basis element indexed by \texttt{composition} under the antipode map.

EXAMPLES:

```python
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R.antipode_on_basis(Composition([2,1]))
-R[2, 1]
sage: R[3,1].antipode() # indirect doctest
R[2, 1, 1]
sage: R([]).antipode() # indirect doctest
R[]
```

We check that the implementation of the antipode at hand does not contradict the generic one:
Combinatorics, Release 10.0

```python
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: all( S(R[I].antipode()) == S(R[I]).antipode() 
....:    for I in Compositions(4) )
True
```

dual()

Return the dual basis to the ribbon basis of the non-commutative symmetric functions. This is the Fundamental basis of the quasi-symmetric functions.

**OUTPUT:**
- The fundamental basis of the quasi-symmetric functions.

**EXAMPLES:**

```python
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R.dual()
Quasisymmetric functions over the Rational Field in the Fundamental basis
```

product_on_basis(I, J)

Return the product of two ribbon basis elements of the non-commutative symmetric functions.

**INPUT:**
- I, J - compositions

**OUTPUT:**
- The product of the ribbon functions indexed by I and J.

**EXAMPLES:**

```python
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R[R[1,2,1] * R[3,1]]
R[1, 2, 1, 3, 1] + R[1, 2, 4, 1]
sage: ( R[R[1,2]] + R[R[3,1]] ) * ( R[R[3,1]] + R[R[1,2,1]] )
```

to_symmetric_function_on_basis(I)

Return the commutative image of a ribbon basis element of the non-commutative symmetric functions.

**INPUT:**
- I - a composition

**OUTPUT:**
- The commutative image of the ribbon basis element indexed by I. This will be expressed as a symmetric function in the Schur basis.

**EXAMPLES:**

```python
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: R.to_symmetric_function_on_basis(Composition([3,1,1]))
s[3, 1, 1]
sage: R.to_symmetric_function_on_basis(Composition([4,2,1]))
s[4, 2, 1] + s[5, 1, 1] + s[5, 2]
sage: R.to_symmetric_function_on_basis(Composition([]))
s[]
```

S

alias of Complete
Combinatorics, Release 10.0

**ZL**
alias of `Zassenhaus_left`

**ZR**
alias of `Zassenhaus_right`

**class Zassenhaus_left(NCSF)**

Bases: `CombinatorialFreeModule`, `BindableClass`

The Hopf algebra of non-commutative symmetric functions in the left Zassenhaus basis.

This basis is the left-version of the basis defined in Section 2.5.1 of [HLNT09]. It is multiplicative, with $Z_n$ defined as the element of $NCSF_n$ satisfying the equation

$$\sigma_1 = \cdots \exp(Z_n) \cdots \exp(Z_2) \exp(Z_1),$$

where

$$\sigma_1 = \sum_{n \geq 0} S_n.$$  

It can be recursively computed by the formula

$$S_n = \sum_{\lambda \vdash n} \frac{1}{m_1(\lambda)!m_2(\lambda)!m_3(\lambda)! \cdots Z_{\lambda_1} Z_{\lambda_2} Z_{\lambda_3} \cdots}$$

for all $n \geq 0$.

**class Zassenhaus_right(NCSF)**

Bases: `CombinatorialFreeModule`, `BindableClass`

The Hopf algebra of non-commutative symmetric functions in the right Zassenhaus basis.

This basis is defined in Section 2.5.1 of [HLNT09]. It is multiplicative, with $Z_n$ defined as the element of $NCSF_n$ satisfying the equation

$$\sigma_1 = \exp(Z_1) \exp(Z_2) \exp(Z_3) \cdots \exp(Z_n) \cdots$$

where

$$\sigma_1 = \sum_{n \geq 0} S_n.$$  

It can be recursively computed by the formula

$$S_n = \sum_{\lambda \vdash n} \frac{1}{m_1(\lambda)!m_2(\lambda)!m_3(\lambda)! \cdots Z_{\lambda_1} Z_{\lambda_2} Z_{\lambda_3} \cdots}$$

for all $n \geq 0$.

Note that there is a variant (called the “noncommutative power sum symmetric functions of the third kind”) in Definition 5.26 of [NCSF2] that satisfies:

$$\sigma_1 = \exp(Z_1) \exp(Z_2/2) \exp(Z_3/3) \cdots \exp(Z_n/n) \cdots.$$  

**a_realization()**

Gives a realization of the algebra of non-commutative symmetric functions. This particular realization is the complete basis of non-commutative symmetric functions.

OUTPUT:
• The realization of the non-commutative symmetric functions in the complete basis.

EXAMPLES:

```python
sage: NonCommutativeSymmetricFunctions(ZZ).a_realization()
Non-Commutative Symmetric Functions over the Integer Ring in the Complete basis
```

**complete**

alias of **Complete**

**dQS**

alias of **dualQuasisymmetric_Schur**

**dYQS**

alias of **dualYoungQuasisymmetric_Schur**

**dual()**

Return the dual to the non-commutative symmetric functions.

**OUTPUT:**

• The dual of the non-commutative symmetric functions over a ring. This is the algebra of quasi-

symmetric functions over the ring.

**EXAMPLES:**

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: NCSF.dual()
Quasisymmetric functions over the Rational Field
```

class **dualQuasisymmetric_Schur**(NCSF)

**Bases:** **CombinatorialFreeModule**, **BindableClass**

The basis of NCSF dual to the Quasisymmetric-Schur basis of QSym.

The **Quasisymmetric_Schur** functions are defined in [QSCHUR] (see also Definition 5.1.1 of

[LMvW13]). The dual basis in the algebra of non-commutative symmetric functions is defined by the

following formula:

\[ R_\alpha = \sum_T dQ_{\text{shape}(T)}, \]

where the sum is over all standard composition tableaux with descent composition equal to \( \alpha \). The **Quasisymmetric_Schur** basis \( QS_\alpha \) has the property that

\[ s_\lambda = \sum_{\text{sort}(\alpha) = \lambda} QS_\alpha. \]

As a consequence the commutative image of a dual Quasisymmetric-Schur element in the algebra of symmetric functions (the map defined in the method to_symmetric_function()) is equal to the Schur function indexed by the decreasing sort of the indexing composition.

**See also:**

**CompositionTableaux**, **CompositionTableau**.

**EXAMPLES:**
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: dQS = NCSF.dQS()
sage: dQS([1,3,2])*dQS([1])
dQS[1, 2, 4] + dQS[1, 3, 2, 1] + dQS[1, 3, 3] + dQS[3, 2, 2]
sage: dQS([1])^2
2 * dQS[1, 3, 2]
sage: dQS([1, 3, 2])*dQS([1, 1])
sage: dQS([3,1])*dQS([2,1])
sage: dQS([1,1]).coproduct()
dQS[] # dQS[1, 1] + dQS[1] # dQS[1, 1] # dQS[]
sage: dQS([3,3]).coproduct().monomial_coefficients()[(Composition([1,2]),
Composition([1,2]))]
-1
sage: S = NCSF.complete()
sage: dQS(S[1,3,1])
sage: S(dQS([1,3,1]))
sage: s = SymmetricFunctions(QQ).s()
sage: s(S(dQS([2,1,3])).to_symmetric_function())
s[3, 2, 1]

dual()
The dual basis to the dual Quasisymmetric-Schur basis of NCSF.

The basis returned is the Quasisymmetric_Schur basis of QSym.

OUTPUT:

- the Quasisymmetric-Schur basis of the quasi-symmetric functions

EXAMPLES:

sage: dQS=NonCommutativeSymmetricFunctions(QQ).dualQuasisymmetric_Schur()
sage: dQS.dual()
Quasisymmetric functions over the Rational Field in the Quasisymmetric
Schur basis
sage: dQS.duality_pairing_matrix(dQS.dual(),3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]

to_symmetric_function_on_basis(I)
The commutative image of a dual quasi-symmetric Schur element

The commutative image of a basis element is obtained by sorting the indexing composition of the basis element.

INPUT:

- I -- a composition

OUTPUT:

- The commutative image of the dual quasi-Schur basis element indexed by I. The result is the Schur symmetric function indexed by the partition obtained by sorting I.
EXAMPLES:

```python
sage: dQS = NonCommutativeSymmetricFunctions(QQ).dQS()
sage: dQS.to_symmetric_function_on_basis([2,1,3])
s[3, 2, 1]
sage: dQS.to_symmetric_function_on_basis([])
s[]
```

class `dualYoungQuasisymmetric_Schur`(`NCSF`)

Bases: `CombinatorialFreeModule`, `BindableClass`

The basis of NCSF dual to the Young Quasisymmetric-Schur basis of QSym.

The `YoungQuasisymmetric_Schur` functions are given in Definition 5.2.1 of [LMvW13]. The dual basis in the algebra of non-commutative symmetric functions are related by an involution reversing the indexing composition of the complete expansion of a quasi-Schur basis element. This basis has many of the same properties as the Quasisymmetric Schur basis and is related to that basis by an algebraic transformation.

EXAMPLES:

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: dYQS = NCSF.dYQS()
sage: dYQS([1,3,2])*dYQS([1])
sage: dYQS([1,3])*dYQS([1,3,2])
sage: dYQS([1,3])*dYQS([1,1])
sage: dYQS([3,1])*dYQS([2,1])
sage: dYQS([1,1]).coproduct()
sage: dYQS([3,3]).coproduct().monomial_coefficients()[(Composition([1,2]), Composition([2,1]))]
1
sage: S = NCSF.complete()
sage: dYQS(S[1,3,1])
sage: S(dYQS([1,3,1]))
sage: s = SymmetricFunctions(QQ).s()
sage: s(S(dYQS([2,1,3])).to_symmetric_function())
s[3, 2, 1]
dual()

The dual basis to the dual Quasisymmetric-Schur basis of NCSF.

The basis returned is the `Quasisymmetric_Schur` basis of QSym.

OUTPUT:

- the Young Quasisymmetric-Schur basis of quasi-symmetric functions

EXAMPLES:
\begin{verbatim}
sage: dYQS=NonCommutativeSymmetricFunctions(QQ).dualYoungQuasisymmetric_.→Schur()
sage: dYQS.dual()
Quasisymmetric functions over the Rational Field in the Young Quasisymmetric Schur basis
sage: dYQS.duality_pairing_matrix(dYQS.dual(),3)
\begin{bmatrix}
 1 & 0 & 0 & 0 \\
 0 & 1 & 0 & 0 \\
 0 & 0 & 1 & 0 \\
 0 & 0 & 0 & 1
\end{bmatrix}

to\_symmetric\_function\_on\_basis(I)
The commutative image of a dual Young quasi-symmetric Schur element.
The commutative image of a basis element is obtained by sorting the indexing composition of the basis element.

INPUT:
• I – a composition

OUTPUT:
• The commutative image of the dual Young quasi-Schur basis element indexed by I. The result is the Schur symmetric function indexed by the partition obtained by sorting I.

EXAMPLES:
\begin{verbatim}
sage: dYQS=NonCommutativeSymmetricFunctions(QQ).dYQS() sage: dYQS.to_symmetric_function_on_basis([2,1,3]) s[3, 2, 1]
sage: dYQS.to_symmetric_function_on_basis([]) s[]

class sage.combinat.ncsf_qsym.qsym.QuasiSymmetricFunctions(R)
Bases: UniqueRepresentation, Parent

The Hopf algebra of quasisymmetric functions.

Let \( R \) be a commutative ring with unity. The \( R \)-algebra of quasi-symmetric functions may be realized as an \( R \)-subalgebra of the ring of power series in countably many variables \( R[[x_1, x_2, x_3, \ldots]] \). It consists of those formal power series \( p \) which are degree-bounded (i.e., the degrees of all monomials occurring with nonzero coefficient in \( p \) are bounded from above, although the bound can depend on \( p \)) and satisfy the following condition: For every tuple \((a_1, a_2, \ldots, a_m)\) of positive integers, the coefficient of the monomial \( x_1^{a_1} x_2^{a_2} \cdots x_m^{a_m} \) in \( p \) is the same for all strictly increasing sequences \((i_1 < i_2 < \cdots < i_m)\) of positive integers. (In other words, the coefficient of a monomial in \( p \) depends only on the sequence of nonzero exponents in the monomial. If “sequence” were to be replaced by “multiset” here, we would obtain the definition of a symmetric function.)

The \( R \)-algebra of quasi-symmetric functions is commonly called \( \text{QSym}_R \) or occasionally just \( \text{QSym} \) (when \( R \) is clear from the context or \( \mathbb{Z} \) or \( \mathbb{Q} \)). It is graded by the total degree of the power series. Its homogeneous elements of degree \( k \) form a free \( R \)-submodule of rank equal to the number of compositions of \( k \) (that is, \( 2^k - 1 \) if \( k \geq 1 \), else 1).

The two classical bases of \( \text{QSym} \), the monomial basis \((M_I)_I\) and the fundamental basis \((F_I)_I\), are indexed by compositions \( I = (I_1, I_2, \cdots, I_\ell) \) and defined by the formulas:

\[
M_I = \sum_{1 \leq i_1 < i_2 < \cdots < i_\ell} x_1^{I_1} x_2^{I_2} \cdots x_\ell^{I_\ell}
\]

and

\[
F_I = \sum_{(j_1, j_2, \ldots, j_n)} x_{j_1} x_{j_2} \cdots x_{j_n}
\]

where in the second equation the sum runs over all weakly increasing \( n \)-tuples \((j_1, j_2, \ldots, j_n)\) of positive integers (where \( n \) is the size of \( I \)) which increase strictly from \( j_r \) to \( j_{r+1} \) if \( r \) is a descent of the composition \( I \).

These bases are related by the formula

\[
F_I = \sum_{J \leq I} M_J
\]

where the inequality \( J \leq I \) indicates that \( J \) is finer than \( I \).

The \( R \)-algebra of quasi-symmetric functions is a Hopf algebra, with the coproduct satisfying

\[
\Delta M_I = \sum_{k=0}^{\ell} M_{(I_1, I_2, \cdots, I_k)} \otimes M_{(I_{k+1}, I_{k+2}, \cdots, I_\ell)}
\]

for every composition \( I = (I_1, I_2, \cdots, I_\ell) \).

It is possible to define an \( R \)-algebra of quasi-symmetric functions in a finite number of variables as well (but it is not a bialgebra). These quasi-symmetric functions are actual polynomials then, not just power series.

Chapter 5 of [GriRei18] and Section 11 of [HazWitt1] are devoted to quasi-symmetric functions, as are Malvenuto’s thesis [Mal1993] and part of Chapter 7 of [Sta-EC2].
The implementation of the quasi-symmetric function Hopf algebra

We realize the \( R \)-algebra of quasi-symmetric functions in Sage as a graded Hopf algebra with basis elements indexed by compositions:

\[
sage: \text{QSym} = \text{QuasiSymmetricFunctions}(\mathbb{Q})
\]
\[
sage: \text{QSym}.\text{category()}
\]
Join of Category of hopf algebras over Rational Field
and Category of graded algebras over Rational Field
and Category of commutative algebras over Rational Field
and Category of monoids with realizations
and Category of graded coalgebras over Rational Field
and Category of coalgebras over Rational Field with realizations

The most standard two bases for this \( R \)-algebra are the monomial and fundamental bases, and are accessible by the \( \text{M() and F()} \) methods:

\[
sage: \text{M} = \text{QSym.M()}
\]
\[
sage: \text{F} = \text{QSym.F()}
\]
\[
sage: \text{M}(\text{F}[2,1,2])
\]
\[\text{M}[1, 1, 1, 1, 1] + \text{M}[1, 1, 1, 2] + \text{M}[2, 1, 1, 1] + \text{M}[2, 1, 2]\]
\[
sage: \text{F}(\text{M}[2,1,2])
\]
\[\text{F}[1, 1, 1, 1, 1] - \text{F}[1, 1, 1, 2] - \text{F}[2, 1, 1, 1] + \text{F}[2, 1, 2]\]

The product on this space is commutative and is inherited from the product on the realization within the ring of power series:

\[
sage: \text{M}[3]*\text{M}[1,1] == \text{M}[1,1]*\text{M}[3]
\]
True
\[
sage: \text{M}[3]*\text{M}[1,1]
\]
\[\text{M}[1, 1, 3] + \text{M}[1, 3, 1] + \text{M}[1, 4] + \text{M}[3, 1, 1] + \text{M}[4, 1]\]
\[
sage: \text{F}[3]*\text{F}[1,1]
\]
\[\text{F}[1, 1, 3] + \text{F}[1, 2, 2] + \text{F}[1, 3, 1] + \text{F}[1, 4] + \text{F}[2, 1, 2] + \text{F}[2, 2, 1] + \text{F}[3, 1, 1] + \text{F}[3, 2] + \text{F}[4, 1]\]
\[
sage: \text{M}[3]*\text{F}[2]
\]
\[\text{M}[1, 1, 3] + \text{M}[1, 3, 1] + \text{M}[1, 4] + \text{M}[2, 3] + \text{M}[3, 1, 1] + \text{M}[3, 2] + \text{M}[4, 1] + \text{M}[5]\]
\[
sage: \text{F}[2]*\text{M}[3]
\]
\[\text{F}[1, 1, 1, 2] - \text{F}[1, 2, 2] + \text{F}[2, 1, 1, 1] - \text{F}[2, 1, 2] - \text{F}[2, 2, 1] + \text{F}[5]\]

There is a coproduct on \( \text{QSym} \) as well, which in the Monomial basis acts by cutting the composition into a left half and a right half. The coproduct is not co-commutative:

\[
sage: \text{M}[1,3,1].\text{coproduct()}
\]
\[\text{M}[1, 3, 1] \# \text{M}[1, 3, 1] + \text{M}[1, 3] \# \text{M}[1] + \text{M}[1, 3, 1] \# \text{M}[1] \]
\[
sage: \text{F}[1,3,1].\text{coproduct()}
\]
\[\text{F}[1, 3, 1] \# \text{F}[1, 3, 1] + \text{F}[1, 3] \# \text{F}[1, 1] + \text{F}[1, 3, 1] \# \text{F}[2, 1] + \text{F}[1, 2] \# \text{F}[1, 1] + \text{F}[1, 3] \# \text{F}[1] + \text{F}[1, 3, 1] \# \text{F}[\_] + \text{F}[\_] \# \text{F}[\_] + \text{F}[1, 2] \# \text{F}[1] + \text{F}[1, 3] \# \text{F}[1] + \text{F}[1, 3, 1] \# \text{F}[\_] + \text{F}[\_] \# \text{F}[\_] + \text{F}[1, 2] \# \text{F}[\_] + \text{F}[1, 3] \# \text{F}[\_] + \text{F}[1, 3, 1] \# \text{F}[\_] + \text{F}[\_] \# \text{F}[\_] + \text{F}[1, 2] \# \text{F}[\_] + \text{F}[1, 3] \# \text{F}[\_] + \text{F}[1, 3, 1] \# \text{F}[\_] + \text{F}[\_] \# \text{F}[\_] + \text{F}[1, 2] \# \text{F}[\_] + \text{F}[1, 3] \# \text{F}[\_] + \text{F}[1, 3, 1] \# \text{F}[\_] + \text{F}[\_] \# \text{F}[\_] + \text{F}[1, 2] \# \text{F}[\_] + \text{F}[1, 3] \# \text{F}[\_] + \text{F}[1, 3, 1] \# \text{F}[\_] + \text{F}[\_] \# \text{F}[\_] + \text{F}[1, 2] \# \text{F}[\_] + \text{F}[1, 3] \# \text{F}[\_] + \text{F}[1, 3, 1] \# \text{F}[\_] + \text{F}[\_] \# \text{F}[\_] + \text{F}[1, 2] \# \text{F}[\_] + \text{F}[1, 3] \# \text{F}[\_] + \text{F}[1, 3, 1] \# \text{F}[\_] + \text{F}[\_] \# \text{F}[\_] + \text{F}[1, 2] \# \text{F}[\_] + \text{F}[1, 3] \# \text{F}[\_] + \text{F}[1, 3, 1] \# \text{F}[\_] + \text{F}[\_] \# \text{F}[\_] + \text{F}[1, 2] \# \text{F}[\_] + \text{F}[1, 3] \# \text{F}[\_] + \text{F}[1, 3, 1] \# \text{F}[\_] + \text{F}[\_] \# \text{F}[\_] + \text{F}[1, 2] \# \text{F}[\_] + \text{F}[1, 3] \# \text{F}[\_] + \text{F}[1, 3, 1] \# \text{F}[\_] + \text{F}[\_] \# \text{F}[\_] + \text{F}[1, 2] \# \text{F}[\_] + \text{F}[1, 3] \# \text{F}[\_] + \text{F}[1, 3, 1] \# \text{F}[\_] + \text{F}[\_] \# \text{F}[\_] + \text{F}[1, 2] \# \text{F}[\_] + \text{F}[1, 3] \# \text{F}[\_] + \text{F}[1, 3, 1] \# \text{F}[\_] + \text{F}[\_] \# \text{F}[\_]
The duality pairing with non-commutative symmetric functions

These two operations endow the quasi-symmetric functions \( \text{QSym} \) with the structure of a Hopf algebra. It is the graded dual Hopf algebra of the non-commutative symmetric functions \( \text{NCSF} \). Under this duality, the Monomial basis of \( \text{QSym} \) is dual to the Complete basis of \( \text{NCSF} \), and the Fundamental basis of \( \text{QSym} \) is dual to the Ribbon basis of \( \text{NCSF} \) (see [MR]).

\[
\text{sage: } S = M.dual(); S
\]
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
\[
\text{sage: } M[1,3,1].duality_pairing( S[1,3,1] )
1
\]
\[
\text{sage: } M.duality_pairing_matrix( S, degree=4 )
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0
\end{bmatrix}
\]
\[
\text{sage: } F.duality_pairing_matrix( S, degree=4 )
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 \\
1 & 1 & 0 & 1 & 1 & 0 & 0 & 0 \\
1 & 0 & 1 & 1 & 0 & 1 & 0 & 0 \\
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1
\end{bmatrix}
\]
\[
\text{sage: } NCSF = M.realization_of().dual()
\]
\[
\text{sage: } R = NCSF.Ribbon()
\]
\[
\text{sage: } F.duality_pairing_matrix( R, degree=4 )
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1
\end{bmatrix}
\]
\[
\text{sage: } M.duality_pairing_matrix( R, degree=4 )
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
-1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
-1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
1 & -1 & -1 & 1 & 0 & 0 & 0 & 0 \\
-1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\
1 & -1 & 0 & 0 & -1 & 1 & 0 & 0 \\
1 & 0 & -1 & 0 & -1 & 0 & 1 & 0 \\
-1 & 1 & 1 & -1 & 1 & -1 & -1 & 1
\end{bmatrix}
\]

Let \( H \) and \( G \) be elements of \( \text{QSym} \), and \( h \) an element of \( \text{NCSF} \). Then, if we represent the duality pairing with the mathematical notation \( [\cdot, \cdot] \),

\[
[HG, h] = [H \otimes G, \Delta(h)].
\]
For example, the coefficient of $M[2,1,4,1]$ in $M[1,3]*M[2,1,1]$ may be computed with the duality pairing:

```
sage: I, J = Composition([1,3]), Composition([2,1,1])
sage: (M[I]*M[J]).duality_pairing(S[2,1,4,1])
1
```

And the coefficient of $S[1,3] \# S[2,1,1]$ in $S[2,1,4,1].coproduct()$ is equal to this result:

```
sage: S[2,1,4,1].coproduct()
```

The duality pairing on the tensor space is another way of getting this coefficient, but currently the method `duality_pairing` is not defined on the tensor squared space. However, we can extend this functionality by applying a linear morphism to the terms in the coproduct, as follows:

```
sage: X = S[2,1,4,1].coproduct()
sage: def linear_morphism(x, y):
...:     return x.duality_pairing(M[1,3]) * y.duality_pairing(M[2,1,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

Similarly, if $H$ is an element of $QSym$ and $g$ and $h$ are elements of $NCSF$, then

$$[H, gh] = [\Delta(H), g \otimes h].$$

For example, the coefficient of $R[2,3,1]$ in $R[2,1]*R[2,1]$ is computed with the duality pairing by the following command:

```
sage: (R[2,1]*R[2,1]).duality_pairing(F[2,3,1])
1
```

This coefficient should then be equal to the coefficient of $F[2,1] \# F[2,1]$ in $F[2,3,1].coproduct()$:

```
sage: F[2,3,1].coproduct()
```

This can also be computed by the duality pairing on the tensor space, as above:

```
sage: X = F[2,3,1].coproduct()
sage: def linear_morphism(x, y):
...:     return x.duality_pairing(R[2,1]) * y.duality_pairing(R[2,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```
The operation dual to multiplication by a non-commutative symmetric function

Let \( g \in NCSF \) and consider the linear endomorphism of \( NCSF \) defined by left (respectively, right) multiplication by \( g \). Since there is a duality between \( QSym \) and \( NCSF \), this linear transformation induces an operator \( g^\perp \) on \( QSym \) satisfying

\[
[g^\perp(H), h] = [H, gh].
\]

for any non-commutative symmetric function \( h \).

This is implemented by the method \( \text{skew\_by()} \). Explicitly, if \( H \) is a quasi-symmetric function and \( g \) a non-commutative symmetric function, then \( H.\text{skew\_by}(g) \) and \( H.\text{skew\_by}(g, \text{side='right'}) \) are expressions that satisfy, for any non-commutative symmetric function \( h \), the following equalities:

\[
H.\text{skew\_by}(g).\text{duality\_pairing}(h) \equiv H.\text{duality\_pairing}(g*h)
\]
\[
H.\text{skew\_by}(g, \text{side='right'}).\text{duality\_pairing}(h) \equiv H.\text{duality\_pairing}(h*g)
\]

For example, \( M[J].\text{skew\_by}(S[I]) \) is 0 unless the composition \( J \) begins with \( I \) and \( M[J].\text{skew\_by}(S[I], \text{side='right'}) \) is 0 unless the composition \( J \) ends with \( I \). For example:

```sage
sage: M[3,2,2].skew_by(S[3])
M[2, 2]
sage: M[3,2,2].skew_by(S[2])
0
tsage: M[3,2,2].coproduct().apply_multilinear_morphism( lambda x,y: x.duality_˓→pairing(S[3])*y )
M[2, 2]
tsage: M[3,2,2].skew_by(S[3], side='right')
0
tsage: M[3,2,2].skew_by(S[2], side='right')
M[3, 2]
```

The counit

The counit is defined by sending all elements of positive degree to zero:

```sage
sage: M[3].degree(), M[3,1,2].degree(), M.one().degree()
(3, 6, 0)
sage: M[3].counit()
0
tsage: M[3,1,2].counit()
0
tsage: M.one().counit()
1
7
7
```
### The antipode

The antipode sends the Fundamental basis element indexed by the composition $I$ to $(-1)^{|I|}$ times the Fundamental basis element indexed by the conjugate composition to $I$ (where $|I|$ stands for the size of $I$, that is, the sum of all entries of $I$).

```
sage: F[3,2,2].antipode()
-F[1, 2, 2, 1, 1]
sage: Composition([3,2,2]).conjugate()
[1, 2, 2, 1, 1]
```

The antipodes of the Monomial quasisymmetric functions can also be computed easily: Every composition $I$ satisfies

$$\omega(M_I) = (-1)^{\ell(I)} \sum M_J,$$

where the sum ranges over all compositions $J$ of $|I|$ which are coarser than the reversed composition $I^r$ of $I$. Here, $\ell(I)$ denotes the length of the composition $I$ (that is, the number of its parts).

```
sage: M[3,2,1].antipode()
sage: M[3,2,2].antipode()
```

We demonstrate here the defining relation of the antipode:

```
sage: X = F[3,2,2].coproduct()
sage: X.apply_multilinear_morphism(lambda x,y: x*y.antipode())
0
sage: X.apply_multilinear_morphism(lambda x,y: x.antipode()*y)
0
```

### The relation with symmetric functions

The quasi-symmetric functions are a ring which contain the symmetric functions as a subring. The Monomial quasi-symmetric functions are related to the monomial symmetric functions by

$$m_{\lambda} = \sum_{\text{sort}(I) = \lambda} M_I$$

(where sort($I$) denotes the result of sorting the entries of $I$ in decreasing order).

There are methods to test if an expression in the quasi-symmetric functions is a symmetric function and, if it is, send it to an expression in the symmetric functions:

```
sage: f = M[1,1,2] + M[1,2,1]
sage: f.is_symmetric()
False
sage: g = M[3,1] + M[1,3]
sage: g.is_symmetric()
True
sage: g.to_symmetric_function()
m[3, 1]
```
The expansion of the Schur function in terms of the Fundamental quasi-symmetric functions is due to [Ges]. There is one term in the expansion for each standard tableau of shape equal to the partition indexing the Schur function.

```sage
f.is_symmetric()
True
f.to_symmetric_function()
5*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + 2*m[2, 2, 1] + m[3, 1, 1] + m[3, 2]
s = SymmetricFunctions(QQ).s()
s(f.to_symmetric_function())
s[3, 2]
```

It is also possible to convert a symmetric function to a quasi-symmetric function:

```sage
m = SymmetricFunctions(QQ).m()
M[1, 1, 3] + M[1, 3, 1] + M[3, 1, 1]
F[1, 1, 2, 1] + F[1, 2, 1, 1] + F[1, 2, 2] + F[2, 1, 2] + F[2, 1, 2] + F[2, 2, 1]
```

It is possible to experiment with the quasi-symmetric function expansion of other bases, but it is important that the base ring be the same for both algebras.

```sage
R = QQ['t']
Qp = SymmetricFunctions(R).hall_littlewood().Qp()
QSymt = QuasiSymmetricFunctions(R)
Ft = QSymt.F()
Ft( Qp[2,2] )
```

```sage
K = QQ['q','t'].fraction_field()
Ht = SymmetricFunctions(K).macdonald().Ht()
Fqt = QuasiSymmetricFunctions(Ht.base_ring()).F()
Fqt(Ht[2,1])
q^t*F[1, 1, 1] + (q+t)*F[1, 2] + (q+t)*F[2, 1] + F[3]
```

The following will raise an error because the base ring of F is not equal to the base ring of Ht:

```sage
F(Ht[2,1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= McdHt[2, 1]) an element of self
```

(Quasisymmetric functions over the Rational Field in the Fundamental basis)
The map to the ring of polynomials

The quasi-symmetric functions can be seen as an inverse limit of a subring of a polynomial ring as the number of variables increases. Indeed, there exists a projection from the quasi-symmetric functions onto the polynomial ring \( R[x_1, x_2, \ldots, x_n] \). This projection is defined by sending the variables \( x_{n+1}, x_{n+2}, \ldots \) to 0, while the remaining \( n \) variables remain fixed. Note that this projection sends \( M_I \) to 0 if the length of the composition \( I \) is higher than \( n \).

```
sage: M[1,3,1].expand(4)
x0*x1^3*x2 + x0*x1^3*x3 + x0*x2^3*x3 + x1*x2^3*x3
sage: F[1,3,1].expand(4)
x0*x1^3*x2 + x0*x1^3*x3 + x0*x1^2*x2*x3 + x0*x1*x2^2*x3 + x0*x2^3*x3 + x1*x2^3*x3
sage: M[1,3,1].expand(2)
0
```

class ElementMethods
    Bases: object
    Methods common to all elements of QuasiSymmetricFunctions.

dendriform_leq(other)
    Return the result of applying the dendriform smaller-or-equal operation to the two quasi-symmetric functions self and other.

    The dendriform smaller-or-equal operation is a binary operation, denoted by \( \preceq \) and written infix, on the ring of quasi-symmetric functions. It can be defined as a restriction of a binary operation (denoted by \( \preceq \) and written infix as well) on the ring of formal power series \( R[[x_1, x_2, x_3, \ldots]] \), which is defined as follows: If \( m \) and \( n \) are two monomials in \( x_1, x_2, x_3, \ldots \), then we let \( m \preceq n \) be the product \( mn \) if the smallest positive integer \( i \) for which \( x_i \) occurs in \( m \) is smaller or equal to the smallest positive integer \( j \) for which \( x_j \) occurs in \( n \) (this is understood to be false when \( m = 1 \) and \( n \neq 1 \), and true when \( n = 1 \)), and we let \( m \preceq n \) be 0 otherwise. Having thus defined \( \preceq \) on monomials, we extend \( \preceq \) to a binary operation on \( R[[x_1, x_2, x_3, \ldots]] \) by requiring it to be continuous (in both inputs) and \( R \)-bilinear. It is easily seen that \( QSym \preceq QSym \subseteq QSym \), so that \( \preceq \) restricts to a binary operation on \( QSym \).

    This operation \( \preceq \) is related to the dendriform smaller relation \( \prec \) (\textit{dendriform_less()}). Namely, if we define a binary operation \( \succ \) on \( QSym \) by \( a \succ b = b \prec a \), then \( QSym, \preceq, \succ \) is a dendriform \( R \)-algebra. Thus, any \( a, b \in QSym \) satisfy \( a \preceq b = ab - b \prec a \).

    See also:

dendriform_less()
    INPUT:
    • other – a quasi-symmetric function over the same base ring as self
    OUTPUT:
    The quasi-symmetric function self \( \preceq \) other, written in the basis of self.
```
EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: M[2, 1].dendriform_leq(M[1, 2])
sage: F = QSym.F()
sage: F[2, 1].dendriform_leq(F[1, 2])
```

dendriform_less(other)

Return the result of applying the dendriform smaller operation to the two quasi-symmetric functions self and other.

The dendriform smaller operation is a binary operation, denoted by \( \prec \) and written infix, on the ring of quasi-symmetric functions. It can be defined as a restriction of a binary operation (denoted by \( \prec \) and written infix as well) on the ring of formal power series \( R[[x_1, x_2, x_3, \ldots]] \), which is defined as follows: If \( m \) and \( n \) are two monomials in \( x_1, x_2, x_3, \ldots \), then we let \( m \prec n \) be the product \( mn \) if the smallest positive integer \( i \) for which \( x_i \) occurs in \( m \) is smaller than the smallest positive integer \( j \) for which \( x_j \) occurs in \( n \) (this is understood to be false when \( m = 1 \), and true when \( m \neq 1 \) and \( n = 1 \)), and we let \( m \prec n = 0 \) otherwise. Having thus defined \( \prec \) on monomials, we extend \( \prec \) to a binary operation on \( R[[x_1, x_2, x_3, \ldots]] \) by requiring it to be continuous (in both inputs) and \( R \)-bilinear. It is easily seen that \( QSym \prec QSym \subseteq QSym \), so that \( \prec \) restricts to a binary operation on \( QSym \).

See also:

dendriform_leq()

INPUT:

- other – a quasi-symmetric function over the same base ring as self

OUTPUT:

The quasi-symmetric function \( self \prec other \), written in the basis of self.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: M[2, 1].dendriform_less(M[1, 2])
sage: F = QSym.F()
sage: F[2, 1].dendriform_less(F[1, 2])
```

The operation \( \prec \) can be used to recursively construct the dual immaculate basis: For every positive integer \( m \) and every composition \( I \), the dual immaculate function \( dI_{[m, I]} \) of the composition \( [m, I] \) (this composition is \( I \) with \( m \) prepended to it) is \( F_{[m]} \prec dI_{I} \).

```
sage: dI = QSym.dI()
sage: dI(F[2]).dendriform_less(dI[1, 2])
dI[2, 1, 2]
```
We check with the identity element:

\begin{verbatim}
sage: M.one().dendriform_less(M[1,2])
0
sage: M[1,2].dendriform_less(M.one())
M[1, 2]
\end{verbatim}

The operation $\prec$ is not symmetric, nor if $a \prec b \neq 0$, then $b \prec a = 0$ (as it would be for a single monomial):

\begin{verbatim}
sage: M[1,2,1].dendriform_less(M[1,2])
M[1, 1, 2, 1, 2] + 2*M[1, 1, 2, 2, 1] + M[1, 1, 2, 3] + M[1, 1, 4, 1] + 2*M[1, 2, 1, 1, 2] + M[1, 2, 1, 2, 1] + M[1, 2, 1, 3] + M[1, 2, 2, 2] + M[1, 3, 1, 2] + M[1, 3, 2, 1] + M[1, 3, 3]
sage: M[1,2].dendriform_less(M[1,2,1])
M[1, 1, 2, 1, 2] + 2*M[1, 1, 2, 2, 1] + M[1, 1, 2, 3] + M[1, 1, 4, 1] + M[1, 2, 1, 2, 1] + M[1, 3, 2, 1]
\end{verbatim}

\textbf{expand}(n, alphabet='x')

Expand the quasi-symmetric function into n variables in an alphabet, which by default is 'x'.

\textbf{INPUT:}
- n – A nonnegative integer; the number of variables in the expansion
- alphabet – (default: 'x'); the alphabet in which \textbf{self} is to be expanded

\textbf{OUTPUT:}
- An expansion of \textbf{self} into the n variables specified by alphabet.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: F[3].expand(3)
x0^3 + x0^2*x1 + x0*x1^2 + x1^3 + x0^2*x2 + x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2 + x2^3
sage: F[2,1].expand(3)
x0^2*x1 + x0^2*x2 + x0*x1*x2 + x1^2*x2 + x1^2*x2 + x0^2*x2 + x1^2*x2
\end{verbatim}

One can use a different set of variable by adding an optional argument alphabet=...

\begin{verbatim}
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: F[3].expand(2,alphabet='y')
y0^3 + y0^2*y1 + y0*y1^2 + y1^3
\end{verbatim}

\textbf{frobenius}(n)

Return the image of the quasi-symmetric function \textbf{self} under the n-th Frobenius operator.

The n-th Frobenius operator $f_n$ is defined to be the map from the $R$-algebra of quasi-symmetric functions to itself that sends every symmetric function $P(x_1, x_2, x_3, \ldots)$ to $P(x_1^n, x_2^n, x_3^n, \ldots)$. This operator $f_n$ is a Hopf algebra endomorphism, and satisfies

$$f_n M_{(i_1, i_2, i_3, \ldots)} = M_{(ni_1, ni_2, ni_3, \ldots)}$$

for every composition $(i_1, i_2, i_3, \ldots)$ (where $M$ means the monomial basis).

The n-th Frobenius operator is also called the n-th Frobenius endomorphism. It is not related to the Frobenius map which connects the ring of symmetric functions with the representation theory of the symmetric group.
The \( n \)-th Frobenius operator is also the \( n \)-th Adams operator of the \( \Lambda \)-ring of quasi-symmetric functions over the integers.

The restriction of the \( n \)-th Frobenius operator to the subring formed by all symmetric functions is, not unexpectedly, the \( n \)-th Frobenius operator of the ring of symmetric functions.

See also:

Symmetric functions plethysm

INPUT:
- \( n \) – a positive integer

OUTPUT:
The result of applying the \( n \)-th Frobenius operator (on the ring of quasi-symmetric functions) to self.

EXAMPLES:

```sage
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: F = QSym.F()
sage: M[3,2].frobenius(2)
M[6, 4]
sage: (M[2,1] - 2*M[3]).frobenius(4)
sage: M([]).frobenius(3)
M[]
sage: F[1,1].frobenius(2)
F[1, 1, 1, 1] - F[1, 1, 2] - F[2, 1, 1] + F[2, 2]
```

The Frobenius endomorphisms are multiplicative:

```sage
sage: all( all( M(I).frobenius(3) * M(J).frobenius(3) == (M(I) * M(J)).frobenius(3) for I in Compositions(3) ) for J in Compositions(2) )
True
```

Being Hopf algebra endomorphisms, the Frobenius operators commute with the antipode:

```sage
sage: all( M(I).frobenius(4).antipode() == M(I).antipode().frobenius(4) for I in Compositions(3) )
True
```

The restriction of the Frobenius operators to the subring of symmetric functions are the Frobenius operators of the latter:

```sage
sage: e = SymmetricFunctions(ZZ).e()
sage: all( M(e(lam)).frobenius(3) == M(e(lam).frobenius(3)) for lam in Partitions(3) )
True
```

```
internal_coproduct()
```

Return the inner coproduct of self in the basis of self.
The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the \(
\mathcal{R}\)-algebra of quasi-symmetric functions) is an \(
\mathcal{R}\)-algebra homomorphism \(\Delta^\times\) from the \(\mathcal{R}\)-algebra of quasi-symmetric functions to the tensor square (over \(\mathcal{R}\)) of quasi-symmetric functions.

It can be defined in the following two ways:

1. If \(I\) is a composition, then a \((0, I)\)-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the non-zero entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is \(I\). If \(A\) is a \((0, I)\)-matrix, then \(\text{row}(A)\) will denote the vector of row sums of \(A\) (regarded as a composition), and \(\text{column}(A)\) will denote the vector of column sums of \(A\) (regarded as a composition).

For every composition \(I\), the internal coproduct \(\Delta^\times(M_I)\) of the \(I\)-th monomial quasisymmetric function \(M_I\) is the sum

\[
\sum_{A \text{ a } (0, I)\text{-matrix}} M_{\text{row}(A)} \otimes M_{\text{column}(A)}.
\]

See Section 11.39 of [HazWitt1].

2. For every permutation \(w\), let \(C(w)\) denote the descent composition of \(w\). Then, for any composition \(I\) of size \(n\), the internal coproduct \(\Delta^\times(F_I)\) of the \(I\)-th fundamental quasisymmetric function \(F_I\) is the sum

\[
\sum_{\sigma \in S_n, \tau \in S_n, \tau \sigma = \pi} F_{C(\sigma)} \otimes F_{C(\tau)},
\]

where \(\pi\) is any permutation in \(S_n\) having descent composition \(I\) and where permutations act from the left and multiply accordingly, so \(\tau \sigma\) means first applying \(\sigma\) and then \(\tau\). See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1].

The restriction of the internal coproduct to the \(\mathcal{R}\)-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.

The method \texttt{kroncker_coproduct()} is a synonym of this one.

**EXAMPLES:**

Let us compute the internal coproduct of \(M_{21}\) (which is short for \(M_{[2,1]}\)). The \((0, [2, 1])\)-matrices are

\[
\begin{bmatrix} 2 & 1 \\ 1 & 0 \end{bmatrix}, \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}, \text{ and } \begin{bmatrix} 0 & 2 \\ 1 & 0 \end{bmatrix}
\]

so

\[
\Delta^\times(M_{21}) = M_3 \otimes M_{21} + M_{21} \otimes M_3 + M_{21} \otimes M_{21} + M_{21} \otimes M_{12}.
\]

This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```sage
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
```

Further examples:
The definition of $\Delta^\times(M_I)$ in terms of $(0, I)$-matrices is not suitable for computation in cases where the length of $I$ is large, but we can use it as a doctest. Here is a naive implementation:

```python
sage: def naive_internal_coproduct_on_M(I):
    ....: # INPUT: composition I
    ....: # (not quasi-symmetric function)
    ....: # OUTPUT: interior coproduct of M_I
    ....: M = QuasiSymmetricFunctions(ZZ).M()
    ....: M2 = M.tensor(M)
    ....: res = M2.zero()
    ....: l = len(I)
    ....: n = I.size()
    ....: for S in Subsets(range(l**2), l):
    ....:     M_list = sorted(S)
    ....:     row_M = [sum([I[M_list.index(l * i + j)]
    ....:                     for j in range(l) if
    ....:                     l * i + j in S])
    ....:              for i in range(l)]
    ....:     col_M = [sum([I[M_list.index(l * i + j)]
    ....:                     for i in range(l) if
    ....:                     l * i + j in S])
    ....:              for j in range(l)]
    ....:     if 0 in row_M:
    ....:         first_zero = row_M.index(0)
    ....:         row_M = row_M[:first_zero]
    ....:         if sum(row_M) != n:
    ....:             continue
    ....:     if 0 in col_M:
    ....:         first_zero = col_M.index(0)
    ....:         col_M = col_M[:first_zero]
    ....:         if sum(col_M) != n:
    ....:             continue
    ....:     res += tensor([M(Compositions(n)(row_M)),
                      M(Compositions(n)(col_M))])
    ....: return res
```

```
sage: all( naive_internal_coproduct_on_M(I)
        ....: == M(I).internal_coproduct()
        ....: for I in Compositions(3) )
True
```

Todo: Implement this directly on the monomial basis maybe? The $(0, I)$-matrices are a pain to generate from their definition, but maybe there is a good algorithm. If so, the above “further examples” should be moved to the M-method.

is_symmetric()
Return True if self is an element of the symmetric functions.

This is being tested by looking at the expansion in the Monomial basis and checking if the coefficients are the same if the indexing compositions are permutations of each other.

OUTPUT:
• True if self is symmetric. False if self is not symmetric.

EXAMPLES:
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: F = QSym.Fundamental()
sage: (F[3,2] + F[2,3]).is_symmetric()
False
sage: (F[1, 1, 2] + F[1, 1, 3] + F[1, 3, 1] + F[2, 1, 1, 1] + F[3, 1, \ldots 1]).is_symmetric()
True
sage: F([]).is_symmetric()
True

kronecker_coproduct()

Return the inner coproduct of self in the basis of self.

The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the \(R\)-algebra of quasi-symmetric functions) is an \(R\)-algebra homomorphism \(\Delta^\times\) from the \(R\)-algebra of quasi-symmetric functions to the tensor square (over \(R\)) of quasi-symmetric functions.

It can be defined in the following two ways:
1. If \(I\) is a composition, then a \((0, I)\)-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the non-zero entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is \(I\). If \(A\) is a \((0, I)\)-matrix, then \(\text{row}(A)\) will denote the vector of row sums of \(A\) (regarded as a composition), and \(\text{column}(A)\) will denote the vector of column sums of \(A\) (regarded as a composition).

For every composition \(I\), the internal coproduct \(\Delta^\times(M_I)\) of the \(I\)-th monomial quasisymmetric function \(M_I\) is the sum

\[
\sum_{A \text{ is a } (0, I)\text{-matrix}} M_{\text{row}(A)} \otimes M_{\text{column}(A)}.
\]

See Section 11.39 of [HazWitt1].

2. For every permutation \(w\), let \(C(w)\) denote the descent composition of \(w\). Then, for any composition \(I\) of size \(n\), the internal coproduct \(\Delta^\times(F_I)\) of the \(I\)-th fundamental quasisymmetric function \(F_I\) is the sum

\[
\sum_{\sigma \in S_n, \tau \in S_n, \tau \pi = \pi} F_{C(\sigma)} \otimes F_{C(\tau)},
\]

where \(\pi\) is any permutation in \(S_n\) having descent composition \(I\) and where permutations act from the left and multiply accordingly, so \(\tau \sigma\) means first applying \(\sigma\) and then \(\tau\). See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1].

The restriction of the internal coproduct to the \(R\)-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.

The method kronecker_coproduct() is a synonym of this one.

EXAMPLES:
Let us compute the internal coproduct of $M_{21}$ (which is short for $M_{[2,1]}$). The $(0,[2,1])$-matrices are

\[
\begin{bmatrix} 2 & 1 \\ 1 & 0 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}, \text{ and } \begin{bmatrix} 0 & 2 \\ 1 & 0 \end{bmatrix}
\]

so

\[
\Delta^\times(M_{21}) = M_5 \otimes M_{21} + M_{21} \otimes M_5 + M_{21} \otimes M_{21} + M_{21} \otimes M_{12}.
\]

This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```python
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
```

Further examples:

```python
sage: all( M([i]).internal_coproduct() == tensor([M([i]), M([i])])
....:     for i in range(1, 4) )
True
sage: M([1, 2]).internal_coproduct()
```

The definition of $\Delta^\times(M_I)$ in terms of $(0,I)$-matrices is not suitable for computation in cases where the length of $I$ is large, but we can use it as a doctest. Here is a naive implementation:

```python
sage: def naive_internal_coproduct_on_M(I):
....:     # INPUT: composition I
....:     # (not quasi-symmetric function)
....:     # OUTPUT: interior coproduct of M_I
....:     M = QuasiSymmetricFunctions(ZZ).M()
....:     M2 = M.tensor(M)
....:     res = M2.zero()
....:     l = len(I)
....:     n = I.size()
....:     for S in Subsets(range(l**2), l):
....:         M_list = sorted(S)
....:         row_M = [sum([I[M_list.index(l * i + j)]
....:                        for j in range(l) if
....:                        l * i + j in S])
....:                  for i in range(l)]
....:         col_M = [sum([I[M_list.index(l * i + j)]
....:                        for i in range(l) if
....:                        l * i + j in S])
....:                  for j in range(l)]
....:         if 0 in row_M:
....:             first_zero = row_M.index(0)
....:             row_M = row_M[:first_zero]
....:             if sum(row_M) != n:
....:                 continue
....:         if 0 in col_M:
```
..:\first_zero = col_M.index(0)
..:\col_M = col_M[:first_zero]
..:\if sum(col_M) != n:
..:\    continue
..:\res += tensor([M(Compositions(n)(row_M)),
..:\    M(Compositions(n)(col_M))])
..:\return res

..: all( naive_internal_coproduct_on_M(I) == M(I).internal_coproduct() for I in Compositions(3) )
..: True

Todo: Implement this directly on the monomial basis maybe? The \((0, I)\)-matrices are a pain to generate from their definition, but maybe there is a good algorithm. If so, the above “further examples” should be moved to the M-method.

omega_involution()

Return the image of the quasisymmetric function \self under the omega involution.

The omega involution is defined as the linear map \(QS\) \(\rightarrow QSym\) which, for every composition \(I\), sends the fundamental quasisymmetric function \(F_I\) to \(F_{I^t}\), where \(I^t\) denotes the conjugate \([\text{conjugate()}]\) of the composition \(I\). This map is commonly denoted by \(\omega\). It is an algebra homomorphism and a coalgebra antihomomorphism; it also is an involution and an automorphism of the graded vector space \(QSym\). Also, every composition \(I\) satisfies

\[
\omega(M_I) = (-1)^{l(I)-l(I^t)} \sum M_J,
\]

where the sum ranges over all compositions \(J\) of \(|I|\) which are coarser than the reversed composition \(I^r\) of \(I\). Here, \(l(I)\) denotes the length of the composition \(I\) (that is, the number of parts of \(I\)).

If \(f\) is a homogeneous element of \(NCSF\) of degree \(n\), then

\[
\omega(f) = (-1)^n S(f),
\]

where \(S\) denotes the antipode of \(QSym\).

The restriction of \(\omega\) to the ring of symmetric functions (which is a subring of \(QSym\)) is precisely the omega involution \(\omega()\) of said ring.

The omega involution on \(QSym\) is adjoint to the omega involution on \(NCSF\) by the standard adjunction between \(NCSF\) and \(QSym\).

The omega involution has been denoted by \(\omega\) in [LMvW13], section 3.6.

See also:

omega involution on NCSF, psi involution on QSym, star involution on QSym.

EXAMPLES:

sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F()
sage: F[3,2].omega_involution() F[1, 2, 1, 1]
This page contains a continuation of the previous page discussing the involution of quasi-symmetric functions. The involution is defined as a linear map from $QSym$ to $QSym$ that sends the fundamental quasisymmetric function $F_I$ to $F_{I^c}$, where $I^c$ denotes the complement of the composition $I$. The involution is an involution and a graded Hopf algebra automorphism of $QSym$. Its restriction to the ring of symmetric functions coincides with the omega automorphism of the latter ring.

Testing the fact that the restriction of $\omega$ to $Sym$ is the omega automorphism of $Sym$:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: all( F(e[lam]).omega_involution() == F(e[lam].omega()) 
       ....: for lam in Partitions(4) )
True
```

```
 psi_involution()

Return the image of the quasisymmetric function self under the involution $\psi$.

The involution $\psi$ is defined as the linear map $QSym \rightarrow QSym$ which, for every composition $I$, sends the fundamental quasisymmetric function $F_I$ to $F_{I^c}$, where $I^c$ denotes the complement of the composition $I$. The map $\psi$ is an involution and a graded Hopf algebra automorphism of $QSym$. Its restriction to the ring of symmetric functions coincides with the omega automorphism of the latter ring.

The involution $\psi$ of $QSym$ is adjoint to the involution $\psi$ of $NCSF$ by the standard adjunction between $NCSF$ and $QSym$.

The involution $\psi$ has been denoted by $\psi$ in [LMvW13], section 3.6.

See also:

psi involution on NCSF, star involution on QSym.

EXAMPLES:
```
```
The involution $\psi$ commutes with the antipode:

```
sage: all( F(I).psi_involution().antipode() == F(I).antipode().psi_involution() for I in Compositions(4) )
True
```

Testing the fact that the restriction of $\psi$ to $Sym$ is the omega automorphism of $Sym$:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: all( F(e[lam]).psi_involution() == F(e[lam].omega()) for lam in Partitions(4) )
True
```

star_involution() 

Return the image of the quasisymmetric function self under the star involution.

The star involution is defined as the linear map $QSym \rightarrow QSym$ which, for every composition $I$, sends the monomial quasisymmetric function $M_I$ to $M_{I'}$. Here, if $I$ is a composition, we denote by $I'$ the reversed composition of $I$. Denoting by $f^*$ the image of an element $f \in QSym$ under the star involution, it can be shown that every composition $I$ satisfies

$$(M_I)^* = M_{I'}, \quad (F_I)^* = F_{I'},$$

where $F_I$ denotes the fundamental quasisymmetric function corresponding to the composition $I$. The star involution is an involution, an algebra automorphism and a coalgebra anti-automorphism of $QSym$. It also is an automorphism of the graded vector space $QSym$, and is the identity on the subspace $Sym$ of $QSym$. It is adjoint to the star involution on $NCSF$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by $\rho$ in [LMvW13], section 3.6.

See also:

star involution on NCSF.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: M[3,2].star_involution()
M[2, 3]
sage: M[6,3].star_involution()
M[3, 6]
sage: (M[3,3] - 2*M[2]).star_involution()
```

(continues on next page)
The star involution commutes with the antipode:

```python
sage: all( M(I).star_involution().antipode() == M(I).antipode().star_involution() for I in Compositions(4) )
True
```

The star involution is the identity on $\text{Sym}$:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: all( M(e(lam)).star_involution() == M(e(lam)) for lam in Partitions(4) )
True
```

### to_symmetric_function()

Convert a quasi-symmetric function to a symmetric function.

**OUTPUT:**

- If `self` is a symmetric function, then return the expansion in the monomial basis. Otherwise raise an error.

**EXAMPLES:**

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: F = QSym.Fundamental()
sage: (F[3,2] + F[2,3]).to_symmetric_function()
Traceback (most recent call last):
...
ValueError: F[2, 3] + F[3, 2] is not a symmetric function
```

```python
sage: m = SymmetricFunctions(QQ).m()
sage: s = SymmetricFunctions(QQ).s()
sage: F(s[3,1,1]).to_symmetric_function()
6*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + m[2, 2, 1] + m[3, 1, 1]
sage: m(s[3,1,1])
6*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + m[2, 2, 1] + m[3, 1, 1]
```

class ParentMethods

Bases: object

Methods common to all bases of QuasiSymmetricFunctions.

**Eulerian**($n, j, k=None$)

Return the Eulerian (quasi)symmetric function $Q_{n,j}$ in terms of `self`.

**INPUT:**

- `n` – the value $n$ or a partition

```python
sage: M([4,2]).star_involution()
M[2, 4]
sage: dI = QSym.dI()
sage: dI([1,2]).star_involution()
-dI[1, 2] + dI[2, 1]
sage: dI.zero().star_involution()
0
```

```python
sage: all( M(I).star_involution().antipode() == M(I).antipode().star_involution() for I in Compositions(4) )
True
```

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: all( M(e(lam)).star_involution() == M(e(lam)) for lam in Partitions(4) )
True
```

```python
to_symmetric_function()
Convert a quasi-symmetric function to a symmetric function.

**OUTPUT:**

- If `self` is a symmetric function, then return the expansion in the monomial basis. Otherwise raise an error.

**EXAMPLES:**

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: F = QSym.Fundamental()
sage: (F[3,2] + F[2,3]).to_symmetric_function()
Traceback (most recent call last):
...
ValueError: F[2, 3] + F[3, 2] is not a symmetric function
```

```python
sage: m = SymmetricFunctions(QQ).m()
sage: s = SymmetricFunctions(QQ).s()
sage: F(s[3,1,1]).to_symmetric_function()
6*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + m[2, 2, 1] + m[3, 1, 1]
sage: m(s[3,1,1])
6*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + m[2, 2, 1] + m[3, 1, 1]
```

class ParentMethods

Bases: object

Methods common to all bases of QuasiSymmetricFunctions.

**Eulerian**($n, j, k=None$)

Return the Eulerian (quasi)symmetric function $Q_{n,j}$ in terms of `self`.

**INPUT:**

- `n` – the value $n$ or a partition

```python
sage: M([4,2]).star_involution()
M[2, 4]
sage: dI = QSym.dI()
sage: dI([1,2]).star_involution()
-dI[1, 2] + dI[2, 1]
sage: dI.zero().star_involution()
0
```

The star involution commutes with the antipode:

```python
sage: all( M(I).star_involution().antipode() == M(I).antipode().star_involution() for I in Compositions(4) )
True
```

The star involution is the identity on $\text{Sym}$:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: all( M(e(lam)).star_involution() == M(e(lam)) for lam in Partitions(4) )
True
```
Combinatorics, Release 10.0

• \( j \) – the number of excedances
• \( k \) – (optional) if specified, determines the number of fixed points of the permutation

**EXAMPLES:**

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: M.Eulerian(3, 1)
sage: M.Eulerian(4, 1, 2)
sage: QS = QSym.QS()
sage: QS.Eulerian(4, 2)
sage: QS.Eulerian([2, 2, 1], 2)
sage: dI = QSym.dI()
sage: dI.Eulerian(5, 2)
```

**from_polynomial**(*f*, *check=True*)

The quasi-symmetric function expanded in this basis corresponding to the quasi-symmetric polynomial \( f \).

This is a default implementation that computes the expansion in the Monomial basis and converts to this basis.

**INPUT:**
• \( f \) – a polynomial in finitely many variables over the same base ring as \( \text{self} \). It is assumed that this polynomial is quasi-symmetric.
• \( \text{check} \) – boolean (default: True), checks whether the polynomial is indeed quasi-symmetric.

**OUTPUT:**
• quasi-symmetric function

**EXAMPLES:**

```python
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: M.from_polynomial(f)
M[1]
sage: F.from_polynomial(f)
F[1]
sage: f = x[0]**2+x[1]**2+x[2]**2
sage: M.from_polynomial(f)
M[2]
sage: F.from_polynomial(f)
-F[1, 1] + F[2]
```

If the polynomial is not quasi-symmetric, an error is raised:
```
sage: f = x[0]^2+x[1]
sage: M.from_polynomial(f)
Traceback (most recent call last):
...
ValueError: x0^2 + x1 is not a quasi-symmetric polynomial
sage: F.from_polynomial(f)
Traceback (most recent call last):
...
ValueError: x0^2 + x1 is not a quasi-symmetric polynomial
```

**super_categories()**

Return the super categories of bases of the Quasi-symmetric functions.

OUTPUT:
- a list of categories

**E**

alias of `Essential`

**class Essential(QSym)**

**Bases:** `CombinatorialFreeModule, BindableClass`

The Hopf algebra of quasi-symmetric functions in the Essential basis.

The Essential quasi-symmetric functions are defined by

\[
E_I = \sum_{J \geq I} M_J = \sum_{i_1 \leq \cdots \leq i_k} x_{i_1}^{I_1} \cdots x_{i_k}^{I_k},
\]

where \( I = (I_1, \ldots, I_k) \).

**Note:** Our convention of \( \leq \) and \( \geq \) of compositions is opposite that of [Hoff2015].

**EXAMPLES:**

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: E = QSym.E()
sage: M = QSym.M()
sage: E(M[2,2])
sage: s = SymmetricFunctions(QQ).s()
sage: E(s[3,2])
5*E[1, 1, 1, 1] - 2*E[1, 1, 1, 2] - 2*E[1, 1, 2, 1] - 2*E[2, 1, 2, 1] + E[2, 1, 2] + E[2, 2, 1]
sage: (1 + E[1])^3
sage: E[1,2,1].coproduct()
```

The following is an alias for this basis:

```
sage: QSym.Essential()
Quasisymmetric functions over the Rational Field in the Essential basis
```
**antipode_on_basis**(compo)
Return the result of the antipode applied to a quasi-symmetric Essential basis element.

**INPUT:**
- compo – composition

**OUTPUT:**
- The result of the antipode applied to the composition compo, expressed in the Essential basis.

**EXAMPLES:**
```
sage: E = QuasiSymmetricFunctions(QQ).E()
sage: E.antipode_on_basis(Composition([2,1]))
E[1, 2] - E[3]
sage: E.antipode_on_basis(Composition([]))
E[]
```

**coproduct_on_basis**(compo)
Return the coproduct of a Essential basis element.

Combinatorial rule: deconcatenation.

**INPUT:**
- compo – composition

**OUTPUT:**
- The coproduct applied to the Essential quasi-symmetric function indexed by compo, expressed in the Essential basis.

**EXAMPLES:**
```
sage: E = QuasiSymmetricFunctions(QQ).Essential()
sage: E[4,2,3].coproduct()
sage: E.coproduct_on_basis(Composition([]))
E[] # E[]
```

**product_on_basis**(I, J)
The product on Essential basis elements.

The product of the basis elements indexed by two compositions I and J is the sum of the basis elements indexed by compositions K in the stuffle product (also called the overlapping shuffle product) of I and J with a coefficient of $(-1)^{\ell(I)+\ell(J)-\ell(K)}$, where $\ell(C)$ is the length of the composition C.

**INPUT:**
- I, J – compositions

**OUTPUT:**
- The product of the Essential quasi-symmetric functions indexed by I and J, expressed in the Essential basis.

**EXAMPLES:**
```
sage: E = QuasiSymmetricFunctions(QQ).E()
sage: c1 = Composition([2])
sage: c2 = Composition([1,3])
sage: E.product_on_basis(c1, c2)
sage: E.product_on_basis(c1, Composition([]))
E[2]
sage: E.product_on_basis(c1, Composition([3]))
```
Combinatorics, Release 10.0

\( F \)

alias of \textit{Fundamental}

\textbf{class Fundamental}(\textit{QSym})

Bases: \texttt{CombinatorialFreeModule}, \texttt{BindableClass}

The Hopf algebra of quasi-symmetric functions in the Fundamental basis.

\textbf{EXCEPTIONS:}

\begin{verbatim}
    sage: QSym = QuasiSymmetricFunctions(QQ)
    sage: F = QSym.F()
    sage: M = QSym.M()
    sage: F(M[2,2])
    F[1, 1, 1, 1] - F[1, 1, 2] - F[2, 1, 1] + F[2, 2]
    sage: s = SymmetricFunctions(QQ).s()
    sage: F(s[3,2])
    sage: (1+F[1])^3
    sage: F[1,2,1].coproduct()
\end{verbatim}

The following is an alias for this basis:

\begin{verbatim}
    sage: QSym.Fundamental()
    Quasisymmetric functions over the Rational Field in the Fundamental basis
\end{verbatim}

\textbf{class Element}

Bases: \texttt{IndexedFreeModuleElement}

\begin{verbatim}
    internal_coproduct()
        Return the inner coproduct of \texttt{self} in the Fundamental basis.
        
        The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the \( R \)-algebra of quasi-symmetric functions) is an \( R \)-algebra homomorphism \( \Delta^\times \) from the \( R \)-algebra of quasi-symmetric functions to the tensor square (over \( R \)) of quasi-symmetric functions. It can be defined in the following two ways:
        1. If \( I \) is a composition, then a \((0, I)\)-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the non-zero entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is \( I \). If \( A \) is a \((0, I)\)-matrix, then \( \text{row}(A) \) will denote the vector of row sums of \( A \) (regarded as a composition), and \( \text{column}(A) \) will denote the vector of column sums of \( A \) (regarded as a composition).
        2. For every permutation \( w \), let \( C(w) \) denote the descent composition of \( w \). Then, for any composition \( I \) of size \( n \), the internal coproduct \( \Delta^\times(F_I) \) of the \( I \)-th fundamental quasisymmetric function \( M_I \) is the sum

        \[ \sum_{A \text{ is a } (0, I)\text{-matrix}} M_{\text{row}(A)} \otimes M_{\text{column}(A)}. \]

        See Section 11.39 of [HazWitt1].
\end{verbatim}
function $F_I$ is the sum

$$\sum_{\sigma \in S_n, \tau \in S_n, \tau \sigma = \pi} F_{\mathcal{C}(\sigma)} \otimes F_{\mathcal{C}(\tau)},$$

where $\pi$ is any permutation in $S_n$ having descent composition $I$ and where permutations act from the left and multiply accordingly, so $\tau \sigma$ means first applying $\sigma$ and then $\tau$. See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1].

The restriction of the internal coproduct to the $R$-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.

The method `kronecker_coproduct()` is a synonym of this one.

**EXAMPLES:**

Let us compute the internal coproduct of $M_{21}$ (which is short for $M_{\{2,1\}}$). The $(0, [2,1])$-matrices are

$$\begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix}, \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix}, \text{ and } \begin{pmatrix} 0 & 2 \\ 1 & 0 \end{pmatrix},$$

so

$$\Delta^\times(M_{21}) = M_3 \otimes M_{21} + M_{21} \otimes M_3 + M_{21} \otimes M_{21} + M_{21} \otimes M_{12}.$$ 

This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```sage
M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
```

Some examples on the Fundamental basis:

```sage
F = QuasiSymmetricFunctions(ZZ).F()
sage: F([1,1]).internal_coproduct()
F[1, 1] # F[1, 1] + F[1, 2] # F[1, 1]
sage: F([2]).internal_coproduct()
sage: F([3]).internal_coproduct()
sage: F([1,2]).internal_coproduct()
```

`kronecker_coproduct()`

Return the inner coproduct of `self` in the Fundamental basis.

The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the $R$-algebra of quasi-symmetric functions) is an $R$-algebra homomorphism $\Delta^\times$ from the $R$-algebra of quasi-symmetric functions to the tensor square (over $R$) of quasi-symmetric functions. It can be defined in the following two ways:

1. If $I$ is a composition, then a $(0, I)$-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the non-zero
entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is $I$. If $A$ is a $(0,I)$-matrix, then $\text{row}(A)$ will denote the vector of row sums of $A$ (regarded as a composition), and $\text{column}(A)$ will denote the vector of column sums of $A$ (regarded as a composition).

For every composition $I$, the internal coproduct $\Delta^\times(M_I)$ of the $I$-th monomial quasisymmetric function $M_I$ is the sum

$$\sum_{A \text{ is a } (0,I)-\text{matrix}} M_{\text{row}(A)} \otimes M_{\text{column}(A)}.$$  

See Section 11.39 of [HazWitt1].

2. For every permutation $w$, let $C(w)$ denote the descent composition of $w$. Then, for any composition $I$ of size $n$, the internal coproduct $\Delta^\times(F_I)$ of the $I$-th fundamental quasisymmetric function $F_I$ is the sum

$$\sum_{\sigma \in S_n, \tau \sigma = \pi} F_{C(\sigma)} \otimes F_{C(\tau)},$$

where $\pi$ is any permutation in $S_n$ having descent composition $I$ and where permutations act from the left and multiply accordingly, so $\tau \sigma$ means first applying $\sigma$ and then $\tau$. See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1].

The restriction of the internal coproduct to the $R$-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.

The method $\text{kronecker_coproduct()}$ is a synonym of this one.

EXAMPLES:

Let us compute the internal coproduct of $M_{21}$ (which is short for $M_{[2,1]}$). The $(0,[2,1])$-matrices are

$$\begin{bmatrix} 2 & 1 \\ 1 & 0 \end{bmatrix}, \begin{bmatrix} 2 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 & 2 \\ 1 & 0 \end{bmatrix},$$

so

$$\Delta^\times(M_{21}) = M_3 \otimes M_{21} + M_{21} \otimes M_5 + M_{21} \otimes M_{21} + M_{21} \otimes M_{12}.$$  

This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```sage
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
```

Some examples on the Fundamental basis:

```sage
sage: F = QuasiSymmetricFunctions(ZZ).F()
sage: F([1,1]).internal_coproduct()
sage: F([2]).internal_coproduct()
sage: F([3]).internal_coproduct()
F[1, 1, 1] # F[1, 1, 1] + F[1, 2] # F[1, 2] + F[1, 2] # F[2, 1]
```

(continues on next page)
star_involution()

Return the image of the quasisymmetric function self under the star involution.

The star involution is defined as the linear map \( QSym \rightarrow QSym \) which, for every composition \( I \), sends the monomial quasisymmetric function \( M_I \) to \( M_{I'} \). Here, if \( I \) is a composition, we denote by \( I' \) the reversed composition of \( I \). Denoting by \( f^* \) the image of an element \( f \in QSym \) under the star involution, it can be shown that every composition \( I \) satisfies

\[
(M_I)^* = M_{I'}, \quad (F_I)^* = F_{I'},
\]

where \( F_I \) denotes the fundamental quasisymmetric function corresponding to the composition \( I \).

The star involution is an involution, an algebra automorphism and a coalgebra anti-automorphism of \( QSym \). It also is an automorphism of the graded vector space \( QSym \), and is the identity on the subspace \( Sym \) of \( QSym \). It is adjoint to the star involution on \( NCSF \) by the standard adjunction between \( NCSF \) and \( QSym \).

The star involution has been denoted by \( \rho \) in [LMvW13], section 3.6.

See also:

star involution on \( QSym \), star involution on \( NCSF \).

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F()
sage: F[3,1].star_involution()
F[1, 3]
sage: F[5,3].star_involution()
F[3, 5]
sage: (F[3,3] - 2*F[2]).star_involution()
sage: F([4,2]).star_involution()
F[2, 4]
sage: dI = QSym.dI()
sage: dI([1,2]).star_involution()
-dI[1, 2] + dI[2, 1]
sage: dI.zero().star_involution()
0
```

Eulerian\((n, j, k=None)\)

Return the Eulerian (quasi)symmetric function \( Q_{n,j} \) (with \( n \) either an integer or a partition) defined in [SW2010] in terms of the fundamental quasisymmetric functions. Or, if the optional argument \( k \) is specified, return the function \( Q_{n,j,k} \) defined ibidem.

If \( n \) and \( j \) are nonnegative integers, then the Eulerian quasisymmetric function \( Q_{n,j} \) is defined as

\[
Q_{n,j} := \sum_{\sigma} F_{Dex(\sigma)},
\]
where we sum over all permutations $\sigma \in S_n$ such that the number of excedances of $\sigma$ is $j$, and where $Dex(\sigma)$ is a composition of $n$ defined as follows: Let $S$ be the set of all $i \in \{1, 2, \ldots, n-1\}$ such that either $\sigma_i > \sigma_{i+1} > i + 1$ or $i \geq \sigma_i > \sigma_{i+1}$ or $\sigma_{i+1} > i + 1 > \sigma_i$. Then, $Dex(\sigma)$ is set to be the composition of $n$ whose descent set is $S$.

Here, an excedance of a permutation $\sigma \in S_n$ means an element $i \in \{1, 2, \ldots, n-1\}$ satisfying $\sigma_i > i$.

Similarly we can define a quasisymmetric function $Q_{\lambda, j}$ for every partition $\lambda$ and every nonnegative integer $j$. This differs from $Q_{n,j}$ only in that the sum is restricted to all permutations $\sigma \in S_n$ whose cycle type is $\lambda$ (where $n = |\lambda|$, and where we still require the number of excedances to be $j$). The method at hand allows computing these functions by passing $\lambda$ as the $n$ parameter.

Analogously we can define a quasisymmetric function $Q_{n,j,k}$ for any nonnegative integers $n$, $j$ and $k$ by restricting the sum to all permutations $\sigma \in S_n$ that have exactly $k$ fixed points (and $j$ excedances). This can be obtained by specifying the optional $k$ argument in this method.

All three versions of Eulerian quasisymmetric functions ($Q_{n,j}$, $Q_{\lambda,j}$ and $Q_{n,j,k}$) are actually symmetric functions. See `Eulerian()`.

**INPUT:**

- $n$ – the nonnegative integer $n$ or a partition
- $j$ – the number of excedances
- $k$ – (optional) if specified, determines the number of fixed points of the permutations which are being summed over

**EXAMPLES:**

```python
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F.Eulerian(3, 1)

sage: F.Eulerian(4, 2)

sage: F.Eulerian(5, 2)

sage: F.Eulerian(4, 0)
F[4]

sage: F.Eulerian(4, 3)
F[4]

sage: F.Eulerian(4, 1, 2)

sage: F.Eulerian(Partition([2, 2, 1]), 2)

sage: F.Eulerian(0, 0)
F[]

sage: F.Eulerian(0, 1)
[]

sage: F.Eulerian(1, 0)
F[1]

sage: F.Eulerian(1, 1)
[]
```

**antipode_on_basis**(compo)

Return the antipode to a Fundamental quasi-symmetric basis element.
INPUT:
• compo – composition

OUTPUT:
• The result of the antipode applied to the quasi-symmetric Fundamental basis element indexed by compo.

EXAMPLES:

```
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F.antipode_on_basis(Composition([2,1]))
-F[2, 1]
```

coproduct_on_basis(compo)

Return the coproduct to a Fundamental quasi-symmetric basis element.

Combinatorial rule: quasi-deconcatenation.

INPUT:
• compo – composition

OUTPUT:
• The application of the coproduct to the Fundamental quasi-symmetric function indexed by the composition compo.

EXAMPLES:

```
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: F[4].coproduct()
sage: F[2,1,3].coproduct()
```

dual()

Return the dual basis to the Fundamental basis. This is the ribbon basis of the non-commutative symmetric functions.

OUTPUT:
• The ribbon basis of the non-commutative symmetric functions.

EXAMPLES:

```
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F.dual()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon
˓→ basis
```

class HazewinkelLambda(QSym)

Bases: CombinatorialFreeModule, BindableClass

The Hazewinkel lambda basis of the quasi-symmetric functions.

This basis goes back to [Haz2004], albeit it is indexed in a different way here. It is a multiplicative basis in a weak sense of this word (the product of any two basis elements is a basis element, but of course not the one obtained by concatenating the indexing compositions).

In [Haz2004], Hazewinkel showed that the k-algebra QSym is a polynomial algebra. (The proof is correct but rests upon an unproven claim that the lexicographically largest term of the n-th shuffle power of a Lyndon word is the n-fold concatenation of this Lyndon word with itself, occurring n! times in that shuffle power. But this can be deduced from Section 2 of [Rad1979]. See also Chapter 6 of [GriRei18], specifically Theorem 6.5.13, for a complete proof.) More precisely, he showed that QSym is generated, as a free
combinatorial k-algebra, by the elements $\lambda^n(M_I)$, where $n$ ranges over the positive integers, and $I$ ranges over all compositions which are Lyndon words and whose entries have gcd 1. Here, $\lambda^n$ denotes the $n$-th lambda operation as explained in \texttt{lambda_of_monomial()}.

Thus, products of these generators form a k-module basis of $\text{QSym}$. We index this basis by compositions here. More precisely, we define the Hazewinkel lambda basis $(\text{HWL}_I)_I$ (with $I$ ranging over all compositions) as follows:

Let $I$ be a composition. Let $I = I_1I_2\ldots I_k$ be the Chen-Fox-Lyndon factorization of $I$ (see \texttt{lyndon_factorization()}). For every $j \in \{1, 2, \ldots, k\}$, let $g_j$ be the gcd of the entries of the Lyndon word $I_j$, and let $J_j$ be the result of dividing the entries of $I_j$ by this gcd. Then, $\text{HWL}_I$ is defined to be $\prod_{j=1}^k \lambda^{g_j}(M_{J_j})$.

**Todo:** The conversion from the M basis to the HWL basis is currently implemented in the naive way (inverting the base-change matrix in the other direction). This matrix is not triangular (not even after any permutations of the bases), and there could very well be a faster method (the one given by Hazewinkel?).

**EXAMPLES:**

```python
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: HWL = QSym.HazewinkelLambda()
sage: M = QSym.M()
sage: M(HWL([2]))
M[1, 1]
sage: M(HWL([1,2]))
M[1, 2]
sage: 3*M[1, 1, 1] + M[1, 2] + M[2, 1]
sage: M(HWL(Composition([])))
M[]
sage: HWL(M([1,1]))
HWL[1, 1]
sage: HWL(M(Composition([2])))
HWL[1, 1] - 2*HWL[2]
sage: HWL(M([1]))
HWL[1]
```

**product_on_basis(I, J)**

The product on Hazewinkel Lambda basis elements.

The product of the basis elements indexed by two compositions $I$ and $J$ is the basis element obtained by concatenating the Lyndon factorizations of the words $I$ and $J$, then reordering the Lyndon factors in nonincreasing order, and finally concatenating them in this order (giving a new composition).

**INPUT:**

- $I, J$ – compositions

**OUTPUT:**

- The product of the Hazewinkel Lambda quasi-symmetric functions indexed by $I$ and $J$, expressed in the Hazewinkel Lambda basis.

**EXAMPLES:**
sage: HWL = QuasiSymmetricFunctions(QQ).HazewinkelLambda()
sage: c1 = Composition([1, 2, 1])
sage: c2 = Composition([2, 1, 3, 2])
sage: HWL.product_on_basis(c1, c2)
HWL[2, 1, 3, 2, 1, 2, 1]
sage: HWL.product_on_basis(c1, Composition([]))
HWL[1, 2, 1]
sage: HWL.product_on_basis(Composition([]), Composition([]))
HWL[]

M
alias of Monomial
class Monomial(QSym)
Bases: CombinatorialFreeModule, BindableClass
The Hopf algebra of quasi-symmetric function in the Monomial basis.
EXAMPLES:

sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: F = QSym.F()
sage: M(F[2,2])
sage: m = SymmetricFunctions(QQ).m()
sage: M(m[3,1,1])
M[1, 1, 3] + M[1, 3, 1] + M[3, 1, 1]
sage: (1+M[1])^3

The following is an alias for this basis:

sage: QSym.Monomial()
Quasisymmetric functions over the Rational Field in the Monomial basis
class Element
Bases: IndexedFreeModuleElement
Element methods of the Monomial basis of QuasiSymmetricFunctions.
expand(n, alphabet='x')
Expand the quasi-symmetric function written in the monomial basis in \( n \) variables.

INPUT:
- \( n \) – an integer
- alphabet – (default: 'x') a string

OUTPUT:
- The quasi-symmetric function self expressed in the \( n \) variables described by alphabet.

Todo: accept an alphabet as input

EXAMPLES:
One can use a different set of variables by using the optional argument alphabet:

```python
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: M[2,1,1].expand(4, alphabet='y')
y0^2*y1*y2 + y0^2*y1*y3 + y0^2*y2*y3 + y1^2*y2*y3
```

is_symmetric()

Determine if a quasi-symmetric function, written in the Monomial basis, is symmetric.

This is being tested by looking at the expansion in the Monomial basis and checking if the coefficients are the same if the indexing compositions are permutations of each other.

OUTPUT:

- True if self is an element of the symmetric functions and False otherwise.

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.Monomial()
sage: (M[3,2] + M[2,3] + M[4,1]).is_symmetric()
False
sage: (M[3,2] + M[2,3]).is_symmetric()
True
sage: (M[1,2,1] + M[1,1,2]).is_symmetric()
False
sage: (M[1,2,1] + M[1,1,2] + M[2,1,1]).is_symmetric()
True
```

psi_involution()

Return the image of the quasisymmetric function self under the involution $\psi$.

The involution $\psi$ is defined as the linear map $QSym \to QSym$ which, for every composition $I$, sends the fundamental quasisymmetric function $F_I$ to $F_{I^c}$, where $I^c$ denotes the complement of the composition $I$. The map $\psi$ is an involution and a graded Hopf algebra automorphism of $QSym$. Its restriction to the ring of symmetric functions coincides with the omega automorphism of the latter ring.

The involution $\psi$ of $QSym$ is adjoint to the involution $\psi$ of $NCSF$ by the standard adjunction between $NCSF$ and $QSym$.

The involution $\psi$ has been denoted by $\chi$ in [LMvW13], section 3.6.

See also:

- psi involution on QSym
- psi involution on NCSF
- star involution on QSym

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: M[3,2].psi_involution()
sage: M[3,1].psi_involution()
```

(continues on next page)
This particular implementation is tailored to the monomial basis. It is semantically equivalent to the generic implementation it overshadows:

```
sage: F = QSym.F()
sage: all( F(M[I].psi_involution()) == F(M[I]).psi_involution()
    ....:     for I in Compositions(3) )
True
sage: F = QSym.F()
sage: all( F(M[I].psi_involution()) == F(M[I]).psi_involution()
    ....:     for I in Compositions(4) )
True
```

```
to_symmetric_function()
```

Take a quasi-symmetric function, expressed in the monomial basis, and return its symmetric realization, when possible, expressed in the monomial basis of symmetric functions.

**OUTPUT:**
- If self is a symmetric function, then the expansion in the monomial basis of the symmetric functions is returned. Otherwise an error is raised.

**EXAMPLES:**

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.Monomial()
sage: (M[3, 2] + M[2, 3] + M[4, 1]).to_symmetric_function()
Traceback (most recent call last):
...  
m[3, 2] + 2*m[4, 1]
sage: m = SymmetricFunctions(QQ).m()
sage: M(m[3, 1, 1]).to_symmetric_function()
m[3, 1, 1]
sage: (M(m[2, 1])^2*m([2, 1])).to_symmetric_function()-m[2, 1]^2*m[2, 1]
0
```

```
antipode_on_basis(compo)
```

Return the result of the antipode applied to a quasi-symmetric Monomial basis element.

**INPUT:**
- compo – composition

**OUTPUT:**
- The result of the antipode applied to the composition compo, expressed in the Monomial basis.
EXAMPLES:
```
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.antipode_on_basis(Composition([2,1]))
M[1, 2] + M[3]
sage: M.antipode_on_basis(Composition([]))
M[]
```

coproduct_on_basis(compo)

Return the coproduct of a Monomial basis element.

Combinatorial rule: deconcatenation.

INPUT:
- compo – composition

OUTPUT:
- The coproduct applied to the Monomial quasi-symmetric function indexed by compo, expressed in the Monomial basis.

EXAMPLES:
```
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M[coproduct_on_basis(Composition([]))]
M[]
```
dual()

Return the dual basis to the Monomial basis. This is the complete basis of the non-commutative symmetric functions.

OUTPUT:
- The complete basis of the non-commutative symmetric functions.

EXAMPLES:
```
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.dual()
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
```

lambda_of_monomial(I, n)

Return the image of the monomial quasi-symmetric function $M_I$ under the lambda-map $\lambda^n$, expanded in the monomial basis.

The ring of quasi-symmetric functions over the integers, $\text{QSym}_\mathbb{Z}$ (and more generally, the ring of quasi-symmetric functions over any binomial ring) becomes a $\lambda$-ring (with the $\lambda$-structure inherited from the ring of formal power series, so that $\lambda^i(x_j)$ is $x_j$ if $i = 1$ and $0$ if $i > 1$).

The Adams operations of this $\lambda$-ring are the Frobenius endomorphisms $f_n$ (see `frobenius()` for their definition). Using these endomorphisms, the $\lambda$-operations can be explicitly computed via the formula

$$\exp\left(-\sum_{n=1}^{\infty} \frac{1}{n} f_n(x) t^n\right) = \sum_{j=0}^{\infty} (-1)^j \lambda^j(x) t^j$$

in the ring of formal power series in a variable $t$ over the ring of quasi-symmetric functions. In partic-
ular, every composition \( I = (I_1, I_2, \cdots, I_\ell) \) satisfies
\[
\exp \left( - \sum_{n=1}^{\infty} \frac{1}{n} M(nI_1, nI_2, \cdots, nI_\ell) t^n \right) = \sum_{j=0}^{\infty} (-1)^j \lambda^j(M_I) t^j
\]
(corrected version of Remark 2.4 in [Haz2004]).

The quasi-symmetric functions \( \lambda^j(M_I) \) with \( n \) ranging over the positive integers and \( I \) ranging over the reduced Lyndon compositions (i.e., compositions which are Lyndon words and have the gcd of their entries equal to 1) form a set of free polynomial generators for \( \text{QSym} \). See [GriRei18], Chapter 6, for the proof, and [Haz2004] for a major part of it.

**INPUT:**
- \( I \) – composition
- \( n \) – nonnegative integer

**OUTPUT:**

The quasi-symmetric function \( \lambda^n(M_I) \), expanded in the monomial basis over the ground ring of \( \text{self} \).

**EXAMPLES:**

```python
sage: M = QuasiSymmetricFunctions(CyclotomicField()).Monomial()
sage: M.lambda_of_monomial([1, 2], 2)
sage: M = QuasiSymmetricFunctions(Integers(19)).Monomial()
sage: all( M.lambda_of_monomial(I, 1) == M(I) for I in Compositions(3) )
True
```

The map \( \lambda^0 \) sends everything to 1:

```python
sage: M = QuasiSymmetricFunctions(ZZ).Monomial()
sage: all( M.lambda_of_monomial(I, 0) == M.one() for I in Compositions(3) )
True
```

The map \( \lambda^1 \) is the identity map:

```python
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: all( M.lambda_of_monomial(I, 1) == M(I) for I in Compositions(3) )
True
```

(continues on next page)
sage: M = QuasiSymmetricFunctions(ZZ).Monomial()
sage: all( M.lambda_of_monomial(I, 1) == M(I) 
    ....:     for I in Compositions(3) )
True

product_on_basis(I, J)

The product on Monomial basis elements.

The product of the basis elements indexed by two compositions I and J is the sum of the basis elements indexed by compositions in the shuffle product (also called the overlapping shuffle product) of I and J.

INPUT:
• I, J – compositions

OUTPUT:
• The product of the Monomial quasi-symmetric functions indexed by I and J, expressed in the Monomial basis.

EXAMPLES:

sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: c1 = Composition([2])
sage: c2 = Composition([1,3])
sage: M.product_on_basis(c1, c2)
sage: M.product_on_basis(c1, Composition([]))
M[2]

QS

alias of Quasisymmetric_Schur

class Quasisymmetric_Schur(QSym)

    Bases: CombinatorialFreeModule, BindableClass

    The Hopf algebra of quasi-symmetric function in the Quasisymmetric Schur basis.

    The basis of Quasisymmetric Schur functions is defined in [QSCHUR] and in Definition 5.1.1 of [LMvW13]. Don’t mistake them for the completely unrelated quasi-Schur functions of [NCSF1]!

    EXAMPLES:

sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QS = QSym.QS()
sage: F = QSym.F()
sage: M = QSym.M()
sage: F(QS[1,2])
F[1, 2]
sage: M(QS[1,2])
M[1, 1, 1] + M[1, 2]
sage: s = SymmetricFunctions(QQ).s()
sage: QS(s[2,1,1])
QS[1, 1, 1] + QS[1, 2, 1] + QS[2, 1, 1]

dual()

    The dual basis to the Quasisymmetric Schur basis.

    The dual basis to the Quasisymmetric Schur basis is implemented as dual.
OUTPUT:
  • the dual Quasisymmetric Schur basis of the non-commutative symmetric functions

EXAMPLES:

```
sage: QS = QuasiSymmetricFunctions(QQ).Quasisymmetric_Schur()
sage: QS.dual()
Non-Commutative Symmetric Functions over the Rational Field
in the dual Quasisymmetric-Schur basis
```

**YQS**
alias of *Young_Quasisymmetric_Schur*

class *Young_Quasisymmetric_Schur* (*QSym*)

Bases: `CombinatorialFreeModule`, `BindableClass`

The Hopf algebra of quasi-symmetric functions in the Young Quasisymmetric Schur basis.

The basis of Young Quasisymmetric Schur functions is from Definition 5.2.1 of [LMvW13].

This basis is related to the Quasisymmetric Schur basis *QS* by

\[ QS(\alpha.reversed()) == YQS(\alpha).star_involution() \]

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: YQS = QSym.YQS()
sage: F = QSym.F()
sage: QS = QSym.QS()
sage: F(YQS[1,2])
F[1, 2]
sage: all(QS(al.reversed()) == YQS(al).star_involution() for al in Compositions(5))
True
sage: s = SymmetricFunctions(QQ).s()
sage: YQS(s[2,1,1])
YQS[1, 1, 2] + YQS[1, 2, 1] + YQS[2, 1, 1]
```

**a_realization()**

Return the realization of the Monomial basis of the ring of quasi-symmetric functions.

**OUTPUT:**
  • The Monomial basis of quasi-symmetric functions.

**EXAMPLES:**

```
sage: QuasiSymmetricFunctions(QQ).a_realization()
Quasisymmetric functions over the Rational Field in the Monomial basis
```

**dI**
alias of *dualImmaculate*

dual()

Return the dual Hopf algebra of the quasi-symmetric functions, which is the non-commutative symmetric functions.

**OUTPUT:**
  • The non-commutative symmetric functions.
EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.dual()
Non-Commutative Symmetric Functions over the Rational Field
```

```python
class dualImmaculate(QSym)
    Bases: CombinatorialFreeModule, BindableClass

The dual immaculate basis of the quasi-symmetric functions.

This basis first appears in [BBSSZ2012].
```

```python
sage: dI = QSym.dI()
sage: dI([1,3,2])*dI([1])  # long time (6s on sage.math, 2013)
dI[1, 1, 3, 2] + dI[2, 3, 2]
sage: dI([1,3])*dI([1,1])  # long time (7s on sage.math, 2013)
sage: F = QSym.F()
sage: F(dI(F([2,1,3])))
F[2, 1, 3]
```

```python
from_polynomial(f, check=True)

Return the quasi-symmetric function in the Monomial basis corresponding to the quasi-symmetric polynomial f.

INPUT:

- f – a polynomial in finitely many variables over the same base ring as self. It is assumed that this polynomial is quasi-symmetric.
- check – boolean (default: True), checks whether the polynomial is indeed quasi-symmetric.

OUTPUT:

- quasi-symmetric function in the Monomial basis
```

```python
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.from_polynomial(f)
M[1]
```

Beware of setting check=False:
To expand the quasi-symmetric function in a basis other than the Monomial basis, the following shorthands are provided:

```
sage: M = QSym.Monomial()
sage: f = x[0]**2+x[1]**2+x[2]**2
sage: g = M.from_polynomial(f); g
M[2]
sage: F = QSym.Fundamental()
sage: F(g)
-F[1, 1] + F[2]
sage: F.from_polynomial(f)
-F[1, 1] + F[2]
```

class phi(QSym)
Bases: CombinatorialFreeModule, BindableClass

The Hopf algebra of quasi-symmetric functions in the \( \phi \) basis.

The \( \phi \) basis is defined as a rescaled Hopf dual of the \( \Phi \) basis of the non-commutative symmetric functions (see Section 3.1 of [BDHM2017]), where the pairing is

\[
(\phi_I, \Phi_J) = z_I \delta_{I,J},
\]

where \( z_I = \frac{1^{m_1} m_1! 2^{m_2} m_2! \cdots} {sp_{I,J} M_J} \)

where \( sp_{I,J} \) is as defined in [NCSF].

The \( \phi \)-basis is well-defined only when the base ring is a \( \mathbb{Q} \)-algebra.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: phi = QSym.phi(); phi
Quasisymmetric functions over the Rational Field in the phi basis
sage: phi.an_element()
2*phi[] + 2*phi[1] + 3*phi[1, 1]
sage: p = SymmetricFunctions(QQ).p()
sage: phi(p[2,2,1])
phi[1, 2, 2] + phi[2, 1, 2] + phi[2, 2, 1]
sage: all(sum(phi(list(al)) for al in Permutations(la))==phi(p(la)) for la in Partitions(6))
True
```

(continues on next page)
Checking the equivalent definition of $\phi_n$:

```python
sage: def test_phi(n):
    phi = QuasiSymmetricFunctions(QQ).phi()
    Phi = NonCommutativeSymmetricFunctions(QQ).Phi()
    M = matrix([[phi[I].duality_pairing(Phi[J])
                 for J in Compositions(n)]
                 for I in Compositions(n)])
    def z(J):
        return J.to_partition().centralizer_size()
    return M == matrix.diagonal([z(I) for I in Compositions(n)])
sage: all(test_phi(k) for k in range(1,5))
True
```

class psi(QSym)

    Bases: CombinatorialFreeModule, BindableClass

The Hopf algebra of quasi-symmetric functions in the $\psi$ basis.

The $\psi$ basis is defined as a rescaled Hopf dual of the $\Psi$ basis of the non-commutative symmetric functions (see Section 3.1 of [BDHMN2017]), where the pairing is

$$(\psi_I, \Psi_J) = z_I \delta_{I,J}$$

where $z_I = 1^{m_1} m_1! 2^{m_2} m_2! \cdots$ with $m_i$ being the multiplicity of $i$ in the composition $I$. Therefore, we call these the quasi-symmetric power sums of the first kind.

Using the duality, we can directly define the $\psi$ basis by

$$\psi_I = \sum_{J \succ I} z_J / \pi_{I,J} M_J,$$

where $\pi_{I,J}$ is as defined in [NCSF].

The $\psi$-basis is well-defined only when the base ring is a $\mathbb{Q}$-algebra.

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
```

```python
sage: psi = QSym.psi(); psi
Quasisymmetric functions over the Rational Field in the psi basis
```

```python
sage: psi.an_element()
2*psi[] + 2*psi[1] + 3*psi[1, 1]
```

```python
sage: p = SymmetricFunctions(QQ).p()
```

```python
sage: psi(p[2, 2, 1])
psi[1, 2, 2] + psi[2, 1, 2] + psi[2, 2, 1]
```

```python
sage: all(sum(psi(list(al)) for al in Permutations(la))==psi(p(la)) for la in Partitions(6))
True
```

```python
sage: p = SymmetricFunctions(QQ).p()
```

```python
sage: psi(p[3, 2, 2])
psi[2, 2, 3] + psi[2, 3, 2] + psi[3, 2, 2]
```
Checking the equivalent definition of $\psi_n$:

```python
sage: def test_psi(n):
    psi = QuasiSymmetricFunctions(QQ).psi()
    Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
    M = matrix([[psi[I].duality_pairing(Psi[J])
                 for I in Compositions(n)]
                for J in Compositions(n)])
    def z(J):
        return J.to_partition().centralizer_size()
    return M == matrix.diagonal([z(I) for I in Compositions(n)])

sage: all(test_psi(k) for k in range(1,5))
True
```

5.1.146 Introduction to Quasisymmetric Functions

In this document we briefly explain the quasisymmetric function bases and related functionality in Sage. We assume the reader is familiar with the package `SymmetricFunctions`.

Quasisymmetric functions, denoted $QSym$, form a subring of the power series ring in countably many variables. $QSym$ contains the symmetric functions. These functions first arose in the theory of $P$-partitions. The initial ideas in this field are attributed to MacMahon, Knuth, Kremer, Glänfridw Thomas, Stanley. In 1984, Gessel formalized the study of quasisymmetric functions and introduced the basis of fundamental quasisymmetric functions [Ges]. In 1995, Gelfand, Krob, Lascoux, Leclerc, Retakh, and Thibon showed that the ring of quasisymmetric functions is Hopf dual to the noncommutative symmetric functions [NCSF]. Many results have built on these.

One advantage of working in $QSym$ is that many interesting families of symmetric functions have explicit expansions in fundamental quasisymmetric functions such as Schur functions [Ges], Macdonald polynomials [HHL05], and plethysm of Schur functions [LW12].

For more background see Wikipedia article Quasisymmetric_function.

To begin, initialize the ring. Below we chose to use the rational numbers $\mathbb{Q}$. Other options include the integers $\mathbb{Z}$ and $\mathbb{C}$:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym
Quasisymmetric functions over the Rational Field

sage: QSym = QuasiSymmetricFunctions(CC); QSym
Quasisymmetric functions over the Complex Field with 53 bits of precision

sage: QSym = QuasiSymmetricFunctions(ZZ); QSym
Quasisymmetric functions over the Integer Ring
```

All bases of $QSym$ are indexed by compositions e.g. $[3,1,1,4]$. The convention is to use capital letters for bases of $QSym$ and lowercase letters for bases of the symmetric functions $Sym$. Next set up names for the known bases by running `inject_shorthands()`. As with symmetric functions, you do not need to run this command and you could assign these bases other names.

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.inject_shorthands()
Defining M as shorthand for Quasisymmetric functions over the Rational Field in the
    Monomial basis
Defining F as shorthand for Quasisymmetric functions over the Rational Field in the
    Fundamental basis
(continues on next page)
```
Now one can start constructing quasisymmetric functions.

**Note:** It is best to use variables other than \( M \) and \( F \).

```sage
sage: x = M[2,1] + M[1,2]
sage: x
M[1, 2] + M[2, 1]
sage: y = 3*M[1,2] + M[3]^2; y
sage: F[3,1,3] + 7*F[2,1]
7*F[2, 1] + F[3, 1, 3]
F[1, 2, 2, 1] + F[1, 2, 3] + 2*F[1, 3, 2] + F[1, 4, 1] + F[1, 5] + 3*F[2, 1, 2]
```

To convert from one basis to another is easy:

```sage
sage: z = M[1,2,1]
sage: z
M[1, 2, 1]
sage: F(z)
-F[1, 1, 1, 1] + F[1, 2, 1]
sage: M(F(z))
M[1, 2, 1]
```

To expand in variables, one can specify a finite size alphabet \( x_1, x_2, \ldots, x_m \):

```sage
sage: y = M[1,2,1]
sage: y.expand(4)
x0*x1^2*x2 + x0*x1^2*x3 + x0*x2^2*x3 + x1*x2^2*x3
```

The usual methods on free modules are available such as coefficients, degrees, and the support:
sage: z = 3*M[1,2]+M[3]^2; z
sage: z.coefficient([1,2])
3
sage: z.degree()
6
sage: sorted(z.coefficients())
[[1, 2], [3, 3], [6]]
sage: sorted(z.monomials(), key=lambda x: tuple(x.support()))
[[M[1, 2], M[3, 3], M[6]]]
sage: z.monomial_coefficients()
{[1, 2]: 3, [3, 3]: 2, [6]: 1}

As with the symmetric functions package, the quasisymmetric function 1 has several instantiations. However, the most obvious way to write 1 leads to an error (this is due to the semantics of python):
sage: M[]
M[]
sage: M.one()
M[]
sage: M(1)
M[]
sage: M[] == 1
True
sage: M[]
Traceback (most recent call last):
  ...
  SyntaxError: invalid ...

Working with symmetric functions

The quasisymmetric functions are a ring which contains the symmetric functions as a subring. The Monomial quasisymmetric functions are related to the monomial symmetric functions by \( m_\lambda = \sum_\text{sort}(c) = \lambda M_c \), where sort(c) means the partition obtained by sorting the composition c:

sage: SymmetricFunctions(QQ).inject_shorthands()
Defining e as shorthand for Symmetric Functions over Rational Field in the elementary basis
Defining f as shorthand for Symmetric Functions over Rational Field in the forgotten basis
Defining h as shorthand for Symmetric Functions over Rational Field in the homogeneous basis
Defining m as shorthand for Symmetric Functions over Rational Field in the monomial basis
Defining p as shorthand for Symmetric Functions over Rational Field in the powersum basis
Defining s as shorthand for Symmetric Functions over Rational Field in the Schur basis
sage: m[2,1]
There are methods to test if an expression \( f \) in the quasisymmetric functions is a symmetric function:

\[
\begin{align*}
\text{sage: } & f = M[1,1,2] + M[1,2,1] \\
\text{sage: } & f\text{.is_symmetric()} \\
& \text{False} \\
\text{sage: } & f = M[3,1] + M[1,3] \\
\text{sage: } & f\text{.is_symmetric()} \\
& \text{True}
\end{align*}
\]

If \( f \) is symmetric, there are methods to convert \( f \) to an expression in the symmetric functions:

\[
\begin{align*}
\text{sage: } & f\text{.to_symmetric_function()} \\
& m[3, 1]
\end{align*}
\]

The expansion of the Schur function in terms of the Fundamental quasisymmetric functions is due to [Ges]. There is one term in the expansion for each standard tableau of shape equal to the partition indexing the Schur function.

\[
\begin{align*}
\text{sage: } & f\text{.is_symmetric()} \\
& \text{True} \\
\text{sage: } & f\text{.to_symmetric_function()} \\
& 5*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + 2*m[2, 2, 1] + m[3, 1, 1] + m[3, 2] \\
\text{sage: } & s(f\text{.to_symmetric_function()}()) \\
& s[3, 2]
\end{align*}
\]

It is also possible to convert any symmetric function to the quasisymmetric function expansion in any known basis. The converse is not true:

\[
\begin{align*}
\text{sage: } & M( m[3,1,1] ) \\
\text{sage: } & F( s[2,2,1] ) \\
& F[1, 1, 2, 1] + F[1, 2, 1, 1] + F[1, 2, 2] + F[2, 1, 2] + F[2, 2, 1] \\
\text{sage: } & s(M[2,1]) \\
& \text{Traceback (most recent call last):} \\
& \text{...} \\
& \text{TypeError: do not know how to make } x (= M[2, 1]) \text{ an element of self}
\end{align*}
\]

It is possible to experiment with the quasisymmetric function expansion of other bases, but it is important that the base ring be the same for both algebras.

\[
\begin{align*}
\text{sage: } & R = QQ[\{'t\'}] \\
\text{sage: } & Qp = SymmetricFunctions(R).hall_littlewood().Qp() \\
\text{sage: } & QSymt = QuasiSymmetricFunctions(R) \\
\text{sage: } & Ft = QSymt.F() \\
\text{sage: } & Ft( Qp[2,2] ) \\
\end{align*}
\]
K = QQ['q','t'].fraction_field()
sage: Ht = SymmetricFunctions(K).macdonald().Ht()
sage: Fqt = QuasiSymmetricFunctions(Ht.base_ring()).F()
sage: Fqt(Ht[2,1])
q*t*F[1, 1, 1] + (q+t)*F[1, 2] + (q+t)*F[2, 1] + F[3]

The following will raise an error because the base ring of F is not equal to the base ring of Ht:

F(Ht[2,1])

Traceback (most recent call last):
...
TypeError: do not know how to make x (= McdHt[2, 1]) an element of self (=Quasisymmetric_functions over the Rational Field in the Fundamental basis)

QSym is a Hopf algebra

The product on QSym is commutative and is inherited from the product by the realization within the polynomial ring:

M[3]*M[1,1] == M[1,1]*M[3]
True

There is a coproduct on this ring as well, which in the Monomial basis acts by cutting the composition into a left half and a right half. The co-product is non-co-commutative:

M[1,3,1].coproduct()

The Duality Pairing with Non-Commutative Symmetric Functions

These two operations endow QSym with the structure of a Hopf algebra. It is the dual Hopf algebra of the non-commutative symmetric functions NCSF. Under this duality, the Monomial basis of QSym is dual to the Complete basis of NCSF, and the Fundamental basis of QSym is dual to the Ribbon basis of NCSF (see [MR]):
Let $H$ and $G$ be elements of $QS\! ym$ and $h$ an element of $NCSF$. Then if we represent the duality pairing with the mathematical notation $[\cdot,\cdot]$, we have:

$$[H \cdot G, h] = [H \otimes G, \Delta(h)].$$

For example, the coefficient of $\mathbb{M}[2,1,4,1]$ in $\mathbb{M}[1,3]^* \mathbb{M}[2,1,1]$ may be computed with the duality pairing:

```sage
sage: I, J = Composition([1,3]), Composition([2,1,1])
sage: (M[I]*M[J]).duality_pairing(S[2,1,4,1])
1
```

And the coefficient of $S[1,3] \# S[2,1,1]$ in $S[2,1,4,1].\text{coproduct}()$ is equal to this result:

```sage
sage: S[2,1,4,1].coproduct()
S[] # S[2, 1, 4, 1] + ... + S[1, 3] # S[2, 1, 1] + ... + S[4, 1] # S[2, 1]
```

The duality pairing on the tensor space is another way of getting this coefficient, but currently the method
Combinatorics, Release 10.0

The operation \texttt{skew_by()} is not defined on the tensor squared space. However, we can extend this functionality by applying a linear morphism to the terms in the coproduct, as follows:

```sage
sage: X = S[2,1,4,1].coproduct()
sage: def linear_morphism(x, y):
    ....:    return x.duality_pairing(M[1,3]) * y.duality_pairing(M[2,1,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

Similarly, if \( H \) is an element of \( QSym \) and \( g \) and \( h \) are elements of \( NCSF \), then

\[
[H, g \cdot h] = [\Delta(H), g \otimes h].
\]

For example, the coefficient of \( R[2,3,1] \) in \( R[2,1]^*R[2,1] \) is computed with the duality pairing by the following command:

```sage
sage: (R[2,1]^*R[2,1]).duality_pairing(F[2,3,1])
1
sage: R[2,1]^*R[2,1]
R[2, 1, 2, 1] + R[2, 3, 1]
```

This coefficient should then be equal to the coefficient of \( F[2,1] \ # F[2,1] \) in \( F[2,3,1].coproduct() \):

```sage
sage: F[2,3,1].coproduct()
F[] # F[2, 3, 1] + ... + F[2, 1] # F[2, 1] + ... + F[2, 3, 1] # F[]
```

This can also be computed by the duality pairing on the tensor space, as above:

```sage
sage: X = F[2,3,1].coproduct()
sage: def linear_morphism(x, y):
    ....:    return x.duality_pairing(R[2,1]) * y.duality_pairing(R[2,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

### The Operation Adjoint to Multiplication by a Non-Commutative Symmetric Function

Let \( g \in NCSF \) and consider the linear endomorphism of \( NCSF \) defined by left (respectively, right) multiplication by \( g \). Since there is a duality between \( QSym \) and \( NCSF \), this linear transformation induces an operator \( g^\perp \) on \( QSym \) satisfying

\[
[g^\perp(H), h] = [H, g \cdot h].
\]

for any non-commutative symmetric function \( h \).

This is implemented by the method \texttt{skew_by()}. Explicitly, if \( H \) is a quasisymmetric function and \( g \) a non-commutative symmetric function, then \( H.skew_by(g) \) and \( H.skew_by(g, \text{side}='right') \) are expressions that satisfy, for any non-commutative symmetric function \( h \), the following identities:

\[
H.skew_by(g).duality_pairing(h) = H.duality_pairing(g*h)
H.skew_by(g, \text{side}='right').duality_pairing(h) = H.duality_pairing(h*g)
\]

For example, \( M[J].skew_by(S[I]) \) is 0 unless the composition \( J \) begins with \( I \) and \( M(J).skew_by(S(I), \text{side}='right') \) is 0 unless the composition \( J \) ends with \( I \):
The antipode

The antipode sends the Fundamental basis element indexed by the composition \( I \) to \(-1\) to the size of \( I \) times the Fundamental basis element indexed by the conjugate composition to \( I \):

```python
sage: F[3,2,2].antipode()
-F[1, 2, 2, 1, 1]
sage: Composition([3,2,2]).conjugate()
[1, 2, 2, 1, 1]
sage: M[3,2,2].antipode()
```

We demonstrate here the defining relation of the antipode:

```python
sage: X = F[3,2,2].coproduct()
sage: X.apply_multilinear_morphism(lambda x,y: x*y.antipode())
0
sage: X.apply_multilinear_morphism(lambda x,y: x.antipode()*y)
0
```

5.1.148 Bases for $\textit{NCSym}$

AUTHORS:

- Travis Scrimshaw (08-04-2013): Initial version

```python
class sage.combinat.ncsym.bases.MultiplicativeNCSymBases(parent_with_realization):
    Bases: Category_realization_of_parent

    Category of multiplicative bases of symmetric functions in non-commuting variables.

    A multiplicative basis is one for which $b_A b_B = b_{A|B}$ where $A|B$ is the pipe() operation on set partitions.

    EXAMPLES:

    sage: from sage.combinat.ncsym.bases import MultiplicativeNCSymBases
    sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
    sage: MultiplicativeNCSymBases(NCSym)
    Category of multiplicative bases of symmetric functions in non-commuting variables over the Rational Field

class ElementMethods
    Bases: object

class ParentMethods
    Bases: object

    product_on_basis(A, B)

    The product on basis elements.

    The product on a multiplicative basis is given by $b_A \cdot b_B = b_{A|B}$.

    The bases $\{e, h, x, cp, p, chi, rho\}$ are all multiplicative.

    INPUT:
    - $A, B$ – set partitions

    OUTPUT:
    - an element in the basis self

    EXAMPLES:

    sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
    sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
    sage: x = SymmetricFunctionsNonCommutingVariables(QQ).x()
    sage: cp = SymmetricFunctionsNonCommutingVariables(QQ).cp()
    sage: p = SymmetricFunctionsNonCommutingVariables(QQ).p()
    sage: chi = SymmetricFunctionsNonCommutingVariables(QQ).chi()
    sage: rho = SymmetricFunctionsNonCommutingVariables(QQ).rho()
    sage: A = SetPartition([[1], [2, 3]])
    sage: B = SetPartition([[1], [3], [2, 4]])
    sage: e.product_on_basis(A, B)
    e{{1}, {2, 3}, {4}, {5, 7}, {6}}
    sage: h.product_on_basis(A, B)
    h{{1}, {2, 3}, {4}, {5, 7}, {6}}
    sage: x.product_on_basis(A, B)
    x{{1}, {2, 3}, {4}, {5, 7}, {6}}
    sage: cp.product_on_basis(A, B)
    cp{{1}, {2, 3}, {4}, {5, 7}, {6}}
    sage: p.product_on_basis(A, B)
```

(continues on next page)
Combinatorics, Release 10.0

\texttt{True}

\texttt{super_categories()}

Return the super categories of bases of the Hopf dual of the symmetric functions in non-commuting variables.

\textbf{OUTPUT:}

\begin{itemize}
  \item a list of categories
\end{itemize}

\textbf{class} \texttt{sage.combinat.ncsym.bases.NCSymBases}(\texttt{parent_with_realization})

Bases: \texttt{Category\_realization\_of\_parent}

Category of bases of symmetric functions in non-commuting variables.

\textbf{EXAMPLES:}

\begin{verbatim}
\texttt{sage: from sage.combinat.ncsym.bases import NCSymBases}
\texttt{sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)}
\texttt{sage: NCSymBases(NCSym)}
\texttt{Category of bases of symmetric functions in non-commuting variables over the Rational Field}
\end{verbatim}

\textbf{class} \texttt{ElementMethods}

Bases: \texttt{object}

\texttt{expand}(\texttt{n, alphabet='x'})

Expand the symmetric function into \texttt{n} non-commuting variables in an alphabet, which by default is 'x'.

This computation is completed by coercing the element \texttt{self} into the monomial basis and computing the expansion in the alphabet there.

\textbf{INPUT:}

\begin{itemize}
  \item \texttt{n} – the number of variables in the expansion
  \item \texttt{alphabet} – (default: 'x') the alphabet in which \texttt{self} is to be expanded
\end{itemize}

\textbf{OUTPUT:}

\begin{itemize}
  \item an expansion of \texttt{self} into the \texttt{n} non-commuting variables specified by \texttt{alphabet}
\end{itemize}

\textbf{EXAMPLES:}

\end{verbatim}
\end{verbatim}
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: h[[1,3],[2]].expand(3)
2*x0^3 + x0^2*x1 + x0^2*x2 + 2*x0*x1*x0 + x0*x1^2 + x0*x1*x2 + 2*x0*x2*x0 +
  x0*x2*x1 + x0*x2*x2 + x1*x0^2 + 2*x1*x0*x1 + x1*x0*x2 + x1^2*x0 + 2*x1^2 +
  x1^2*x2 + x1*x2*x0 + 2*x1*x2*x1 + x1*x2*x2 + x2*x0^2 + x2*x0*x1 + x2*x0*x2 +
  x2*x1*x0 + x2*x1*x2 + 2*x2*x1*x0 + x2*x1^2 + 2*x2*x1*x2 + x2*x1^2 + x2*x2*x0 +
  x2*x2*x1 + x2*x2*x2 + x2*x2*x1 + 2*x2*x2
sage: x = SymmetricFunctionsNonCommutingVariables(QQ).x()
sage: x[[1,3],[2]].expand(3)
-x0^2*x1 - x0^2*x2 - x0*x1^2 - x0*x1*x2 - x0*x2*x1 - x0*x2^2 - x1*x0^2 -
  x1*x0*x2 - x1*x0^2*x0 - x1*x2*x2 - x1*x2*x0 - x1*x2*x1 - x1*x2^2 - x2*x0^2 -
  x2*x0*x1 - x2*x1*x0 - x2*x1^2 - x2*x1*x2 - x2*x1^2 - x2*x2*x0 - x2*x2*x1 +
  x2*x2*x2

internal_coproduct()

Return the internal coproduct of self.

The internal coproduct is defined on the power sum basis as

\[ P_A \mapsto P_A \otimes P_A \]

and the map is extended linearly.

OUTPUT:

• an element of the tensor square of the basis of self

EXAMPLES:

sage: x = SymmetricFunctionsNonCommutingVariables(QQ).x()
sage: x[[1,3],[2]].internal_coproduct()
x{{{1}, {2}, {3}}} \# x{{{1}, {3}, {2}}} + x{{{1}, {3}, {2}}} \# x{{{1}, {2}, {3}}} +
  x{{{1}, {3}, {2}}} \# x{{{1}, {3}, {2}}}

omega()

Return the involution \( \omega \) applied to self.

The involution \( \omega \) is defined by

\[ e_A \mapsto h_A \]

and the result is extended linearly.

OUTPUT:

• an element in the same basis as self

EXAMPLES:

sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: m[[1,3],[2]].omega()
-2*m{{{1}, {2}, {3}}} - m{{{1}, {3}, {2}}}
sage: p = NCSym.p()
sage: p[[1,3],[2]].omega()
-p{{{1}, {3}, {2}}}
sage: cp = NCSym.cp()
sage: cp[[1,3],[2]].omega()
-2*cp{{{1}, {2}, {3}}} - cp{{{1}, {3}, {2}}}
sage: x = NCSym.x()

(continues on next page)
Combinatorics, Release 10.0

sage: x[[1,3],[2]].omega()
\[-2*x\{1\}, \{2\}, \{3\} - x\{1\}, \{3\}, \{2\}\]

to_symmetric_function()

Compute the projection of an element of symmetric function in non-commuting variables to the symmetric functions.

The projection of a monomial symmetric function in non-commuting variables indexed by the set partition \(A\) is defined as

\[
m_A \mapsto m_{\lambda(A)} \prod_i n_i(\lambda(A))!
\]

where \(\lambda(A)\) is the partition associated with \(A\) by taking the sizes of the parts and \(n_i(\mu)\) is the multiplicity of \(i\) in \(\mu\). For other bases this map is extended linearly.

OUTPUT:

• an element of the symmetric functions in the monomial basis

EXAMPLES:

sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: p = NCSym.p()
sage: cp = NCSym.cp()
sage: x = NCSym.x()
sage: cp[[1,3],[2]].to_symmetric_function()
m[2, 1]
sage: x[[1,3],[2]].to_symmetric_function()
-6*m[1, 1, 1] - 2*m[2, 1]
sage: e[[1,3],[2]].to_symmetric_function()
2*e[2, 1]
sage: h[[1,3],[2]].to_symmetric_function()
2*h[2, 1]
sage: p[[1,3],[2]].to_symmetric_function()
p[2, 1]

to_wqsym()

Return the image of self under the canonical inclusion map \(NCSym \to WQSym\).

The canonical inclusion map \(NCSym \to WQSym\) is an injective homomorphism of algebras. It sends a basis element \(m_A\) of \(NCSym\) to the sum of basis elements \(M_P\) of \(WQSym\), where \(P\) ranges over all ordered set partitions that become \(A\) when the ordering is forgotten. This map is denoted by \(\theta\) in \([BZ05]\) (17).

See also:

WordQuasiSymmetricFunctions for a definition of \(WQSym\).

EXAMPLES:

sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: p = NCSym.p()
Combinatorics, Release 10.0

```
sage: cp = NCSym.cp()
sage: x = NCSym.x()
sage: m = NCSym.m()
sage: m[[1,3],[2]].to_wqsym()
M[[1, 3], {2}] + M[{2}, {1, 3}]
sage: x[[1,3],[2]].to_wqsym()
-M[{1}, {2}, {3}] - M[{1}, {2, 3}] - M[{1}, {3}, {2}]
- M[{1, 2}, {3}] - M[{2}, {1}, {3}] - M[{2}, {3}, {1}]
- M[{2, 3}, {1}] - M[{3}, {1}, {2}] - M[{3}, {1, 2}]
- M[{3}, {2}, {1}]
sage: (4*p[[1,3],[2]]-p[[1]]).to_wqsym()
-M[{1}] + 4*M[{1, 2, 3}] + 4*M[{1, 3}, {2}] + 4*M[{2}, {1, 3}]
```

class ParentMethods
Bases: object

```
from_symmetric_function() /
```

Return the image of the symmetric function \( f \) in \( self \).

This is performed by converting to the monomial basis and extending the method
\texttt{sum_of_partitions()} linearly. This is a linear map from the symmetric functions to the
symmetric functions in non-commuting variables that does not preserve the product or coproduct
structure of the Hopf algebra.

See also:

\texttt{to_symmetric_function()}

INPUT:
- \( f \) – a symmetric function

OUTPUT:
- an element of \( self \)

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: Sym = SymmetricFunctions(QQ)
sage: e = NCSym.e()
sage: elem = Sym.e()
sage: elt = e.from_symmetric_function(elem[[2,1,1]]); elt
1/12*e{{1}, {2}, {3, 4}} + 1/12*e{{1}, {2, 3}, {4}} + 1/12*e{{1}, {2, 4},
\rightarrow{3}}
+ 1/12*e{{1, 2}, {3}, {4}} + 1/12*e{{1, 3}, {2}, {4}} + 1/12*e{{1, 4}, {2},
\rightarrow{3}}
sage: elem(elt.to_symmetric_function())
e[2, 1, 1]
sage: e.from_symmetric_function(elem[[4]])
1/24*e{{1, 2, 3, 4}}
sage: p = NCSym.p()
sage: pow = Sym.p()
sage: elt = p.from_symmetric_function(pow[[2,1,1]]); elt
1/6*p{{1}, {2}, {3, 4}} + 1/6*p{{1}, {2, 3}, {4}} + 1/6*p{{1}, {2, 4}, {3}}
+ 1/6*p{{1, 2}, {3}, {4}} + 1/6*p{{1, 3}, {2}, {4}} + 1/6*p{{1, 4}, {2},
\rightarrow{3}}
sage: pow(elt.to_symmetric_function())
```

(continues on next page)
p[2, 1, 1]

sage: p.from_symmetric_function(pow[4])
p{{1, 2, 3, 4}}
)
sage: h = NCSym.h()sage: comp = Sym.complete()sage: elt = h.from_symmetric_function(comp[2, 1, 1]); elt1/12*h{{1}, {2}, {3, 4}} + 1/12*h{{1}, {2, 3}, {4}} + 1/12*h{{1}, {2, 4}, →{3}} + 1/12*h{{1, 2}, {3}, {4}} + 1/12*h{{1, 3}, {2}, {4}} + 1/12*h{{1, 4}, {2}, → {3}}sage: comp(elt.to_symmetric_function())h[2, 1, 1]sage: h.from_symmetric_function(comp[4])1/24*h{{1, 2, 3, 4}}

internal_coproduct()

Compute the internal coproduct of self.

If internal_coproduct_on_basis() is available, construct the internal coproduct morphism from self to self⊗self by extending it by linearity. Otherwise, this uses internal_coproduct_by_coercion(), if available.

OUTPUT:

• an element of the tensor squared of self

EXAMPLES:

sage: cp = SymmetricFunctionsNonCommutingVariables(QQ).cp()sage: cp.internal_coproduct(cp[[1,3],[2]] - 2*cp[[1]])-2*cp{{1}} # cp{{1}} + cp{{1, 2, 3}} # cp{{1, 3}, {2}} + cp{{1, 3}, {2}} #␣ → cp{{1, 2, 3}}+ cp{{1, 3}, {2}} # cp{{1, 3}, {2}}

internal_coproduct_by_coercion(x)

Return the internal coproduct by coercing the element to the powersum basis.

INPUT:

• x – an element of self

OUTPUT:

• an element of the tensor squared of self

EXAMPLES:

sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()sage: h[[1,3],[2]].internal_coproduct() # indirect doctest2*h{{1}, {2}, {3}} # h{{1}, {2}, {3}} - h{{1}, {2}, {3}} # h{{1, 3}, {2}}- h{{1, 3}, {2}} # h{{1}, {2}, {3}} + h{{1, 3}, {2}} # h{{1, 3}, {2}}

internal_coproduct_on_basis(i)

The internal coproduct of the algebra on the basis (optional).

INPUT:

• i – the indices of an element of the basis of self

OUTPUT:

• an element of the tensor squared of self

EXAMPLES:
```python
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.internal_coproduct_on_basis(SetPartition([[1,2]]))
```

**primitive**(A, \(i=1\))

Return the primitive associated to \(A\) in \(self\).

**See also:**

primitive()

**INPUT:**

- \(A\) – a set partition
- \(i\) – a positive integer

**OUTPUT:**

- an element of \(self\)

**EXAMPLES:**

```python
sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
sage: elt = e.primitive(SetPartition([[1,3],[2]])); elt
ek{{1, 2}, {3}} - e{{1, 3}, {2}}
sage: elt.coproduct()
e{} # e{{1, 2}, {3}} - e{} # e{{1, 3}, {2}} + e{{1, 2}, {3}} # e{} - e{{1, \rightarrow 3}, {2}} # e{}
```

**super_categories**()

Return the super categories of bases of the Hopf dual of the symmetric functions in non-commuting variables.

**OUTPUT:**

- a list of categories

```python
class sage.combinat.ncsym.bases.NCSymBasis_abstract(R, basis_keys=None, element_class=None, category=None, prefix=None, names=None, **kwds)

Bases: CombinatorialFreeModule, BindableClass

Abstract base class for a basis of \(NCSym\) or its dual.

class sage.combinat.ncsym.bases.NCSymDualBases(parent_with_realization)

Bases: Category_realization_of_parent

Category of bases of dual symmetric functions in non-commuting variables.

**EXAMPLES:**

```python
sage: from sage.combinat.ncsym.bases import NCSymDualBases
sage: DNCSym = SymmetricFunctionsNonCommutingVariables(QQ).dual()
sage: NCSymDualBases(DNCSym)
Category of bases of dual symmetric functions in non-commuting variables over the Rational Field
```

**super_categories**()

Return the super categories of bases of the Hopf dual of the symmetric functions in non-commuting variables.

**OUTPUT:**

- a list of categories
• a list of categories

class sage.combinat.ncsym.bases.NCSymOrNCSymDualBases(parent_with_realization)

Bases: Category_realization_of_parent

Base category for the category of bases of symmetric functions in non-commuting variables or its Hopf dual for the common code.

class ElementMethods

Bases: object
duality_pairing(other)

Compute the pairing between self and an element other of the dual.

EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: w = m.dual_basis()
sage: elt = m[[1,3],[2]] - 3*m[[1,2],[3]]
sage: elt.duality_pairing(w[[1,3],[2]])
1
sage: elt.duality_pairing(w[[1,2],[3]])
-3
sage: elt.duality_pairing(w[[1,2]])
0
sage: e = NCSym.e()
sage: w[[1,3],[2]].duality_pairing(e[[1,3],[2]])
0
```

class ParentMethods

Bases: object
counit_on_basis(A)

The counit is defined by sending all elements of positive degree to zero.

INPUT:
• A -- a set partition

OUTPUT:
• either the 0 or the 1 of the base ring of self

EXAMPLES:

```python
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.counit_on_basis(SetPartition([[1,3], [2]]))
0
sage: m.counit_on_basis(SetPartition([[]))
1
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.counit_on_basis(SetPartition([[1,3], [2]]))
0
sage: w.counit_on_basis(SetPartition([[]))
1
```

duality_pairing(x, y)

Compute the pairing between an element of self and an element of the dual.

Carry out this computation by converting x to the m basis and y to the w basis.
INPUT:
• x – an element of symmetric functions in non-commuting variables
• y – an element of the dual of symmetric functions in non-commuting variables

OUTPUT:
• an element of the base ring of self

EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: h = NCSym.h()
sage: w = NCSym.m().dual_basis()
sage: matrix([[h(A).duality_pairing(w(B)) for A in SetPartitions(3)] for B in SetPartitions(3)])
\begin{bmatrix}
6 & 2 & 2 & 2 & 1 \\
2 & 2 & 1 & 1 & 1 \\
2 & 1 & 2 & 1 & 1 \\
2 & 1 & 1 & 2 & 1 \\
1 & 1 & 1 & 1 & 1 \\
\end{bmatrix}
sage: (h[[1,2],[3]] + 3*h[[1,3],[2]]).duality_pairing(2*w[[1,3],[2]] + w[[1,2,3]] + 2*w[[1,2],[3]])
32
```

duality_pairing_matrix(basis, degree)
The matrix of scalar products between elements of NCSym and elements of NCSym*.

INPUT:
• basis – a basis of the dual Hopf algebra
• degree – a non-negative integer

OUTPUT:
• the matrix of scalar products between the basis self and the basis basis in the dual Hopf algebra of degree degree

EXAMPLES:
The matrix between the m basis and the w basis:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: w = NCSym.dual().w()
sage: m.duality_pairing_matrix(w, 3)
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1 \\
\end{bmatrix}
sage: e = NCSym.e()
sage: e.duality_pairing_matrix(w, 3)
\begin{bmatrix}
0 & 0 & 0 & 0 & 1 \\
0 & 0 & 1 & 1 & 1 \\
0 & 1 & 0 & 1 & 1 \\
0 & 1 & 1 & 0 & 1 \\
1 & 1 & 1 & 1 & 1 \\
\end{bmatrix}
sage: p = NCSym.p()
sage: p.duality_pairing_matrix(w, 3)
```

(continues on next page)
A base case test:

```
sage: m.duality_pairing_matrix(w, 0)
[1]
```

**one_basis()**

Return the index of the basis element containing 1.

**OUTPUT:**

• The empty set partition

**EXAMPLES:**

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.one_basis()
{}
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.one_basis()
{}
```

**super_categories()**

Return the super categories of bases of (the Hopf dual of) the symmetric functions in non-commuting variables.

**OUTPUT:**

• a list of categories
5.1.149 Dual Symmetric Functions in Non-Commuting Variables

AUTHORS:

- Travis Scrimshaw (08-04-2013): Initial version

```python
class sage.combinat.ncsym.dual.SymmetricFunctionsNonCommutingVariablesDual(R):
    Bases: UniqueRepresentation, Parent

    The Hopf dual to the symmetric functions in non-commuting variables.
    See Section 2.3 of [BZ05] for a study.

    a_realization()
    Return the realization of the w basis of self.

    EXAMPLES:

    sage: SymmetricFunctionsNonCommutingVariables(QQ).dual().a_realization()
    Dual symmetric functions in non-commuting variables over the Rational Field in the w basis

    dual()
    Return the dual Hopf algebra of the dual symmetric functions in non-commuting variables.

    EXAMPLES:

    sage: NCSymD = SymmetricFunctionsNonCommutingVariables(QQ).dual()
sage: NCSymD.dual()
    Symmetric functions in non-commuting variables over the Rational Field

```

class w(NCSymD)
Bases: NCSymBasis_abstract

The Hopf algebra of symmetric functions in non-commuting variables in the w basis.

EXAMPLES:

```python
sage: NCSymD = SymmetricFunctionsNonCommutingVariables(QQ).dual()
sage: w = NCSymD.w()

We have the embedding \( \chi^* \) of Sym into \( NCSym^* \) available as a coercion:

```python
sage: h = SymmetricFunctions(QQ).h()
sage: w(h[[2,1]])
\[ w\{\{1\}, \{2, 3\}\} + w\{\{1, 2\}, \{3\}\} + w\{\{1, 3\}, \{2\}\} \]
```

Similarly we can pull back when we are in the image of \( \chi^* \):

```python
sage: elt = 3*(w[[1],[2,3]] + w[[1,2],[3]] + w[[1,3],[2]])
sage: h(elt)
3*h[2, 1]
```

class Element
    Bases: IndexedFreeModuleElement

An element in the w basis.
expand($n$, letter='x')

Expand self written in the w basis in $n^2$ commuting variables which satisfy the relation $x_{ij}x_{ik} = 0$ for all $i, j,$ and $k$.

The expansion of an element of the w basis is given by equations (26) and (55) in [HNT06].

INPUT:
• $n$ – an integer
• letter – (default: 'x') a string

OUTPUT:
• The symmetric function of self expressed in the $n \times n$ non-commuting variables described by letter.

REFERENCES:

EXAMPLES:

sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w[[1,3],[2]].expand(4)
x02*x11*x20 + x03*x11*x30 + x03*x22*x30 + x13*x22*x31

One can use a different set of variable by using the optional argument letter:

sage: w[[1,3],[2]].expand(3, letter='y')
y02*y11*y20

is_symmetric()

Determine if a $NCsym^*$ function, expressed in the w basis, is symmetric.

A function $f$ in the w basis is a symmetric function if it is in the image of $\chi^*$. That is to say we have

$$f = \sum_{\lambda} c_\lambda \prod_i m_i(\lambda)! \sum_{\lambda(A) = \lambda} w_A$$

where the second sum is over all set partitions $A$ whose shape $\lambda(A)$ is equal to $\lambda$ and $m_i(\mu)$ is the multiplicity of $i$ in the partition $\mu$.

OUTPUT:
• True if $\lambda(A) = \lambda(B)$ implies the coefficients of $w_A$ and $w_B$ are equal, False otherwise

EXAMPLES:

sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: elt = w.sum_of_partitions([2,1,1])
sage: elt.is_symmetric()
True
sage: elt -= 3*w.sum_of_partitions([1,1])
sage: elt.is_symmetric()
True
sage: w = SymmetricFunctionsNonCommutingVariables(ZZ).dual().w()
sage: elt = w.sum_of_partitions([2,1,1]) / 2
sage: elt.is_symmetric()
False
sage: elt = w[[1,3],[2]]
sage: elt.is_symmetric()
False
sage: elt = w[[1,2],[3]] + w[[1,2],[3]] + 2*w[[1,3],[2]]

(continues on next page)
to_symmetric_function()

Take a function in the \( w \) basis, and return its symmetric realization, when possible, expressed in the homogeneous basis of symmetric functions.

OUTPUT:
• If \( \text{self} \) is a symmetric function, then the expansion in the homogeneous basis of the symmetric functions is returned. Otherwise an error is raised.

EXAMPLES:

```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: elt = w[[1],[2,3]] + w[[1,2],[3]] + w[[1,3],[2]]
sage: elt.to_symmetric_function()
h[2, 1]
sage: elt = w.sum_of_partitions([2,1,1]) / 2
sage: elt.to_symmetric_function()
1/2*h[2, 1, 1]
```

antipode_on_basis(A)

Return the antipode applied to the basis element indexed by \( A \).

INPUT:
• \( A \) – a set partition

OUTPUT:
• an element in the basis \( \text{self} \)

EXAMPLES:

```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.antipode_on_basis(SetPartition([[1],[2,3]]))
-3*w{{1}, {2}, {3}} + w{{1}} # w{{1, 2}} + w{{1}, {2}} # w{{1}} + w{{1}, {2, 3}} # w{}
```

coproduct_on_basis(A)

Return the coproduct of a \( w \) basis element.

The coproduct on the basis element \( w_A \) is the sum over tensor product terms \( w_B \otimes w_C \) where \( B \) is the restriction of \( A \) to \( \{1, 2, \ldots, k\} \) and \( C \) is the restriction of \( A \) to \( \{k + 1, k + 2, \ldots, n\} \).

INPUT:
• \( A \) – a set partition

OUTPUT:
• The coproduct applied to the \( w \) dual symmetric function in non-commuting variables indexed by \( A \) expressed in the \( w \) basis.

EXAMPLES:

```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w[[1, [2,3]]].coproduct()
w{} # w{{1}, {2, 3}} + w{{1}} # w{{1, 2}}
+ w{{1}, {2}} # w{{1}} + w{{1}, {2, 3}} # w{}
```

(continues on next page)
dual_basis()

Return the dual basis to the w basis.

The dual basis to the w basis is the monomial basis of the symmetric functions in non-commuting variables.

OUTPUT:

• the monomial basis of the symmetric functions in non-commuting variables

EXAMPLES:

```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.dual_basis()
Symmetric functions in non-commuting variables over the Rational Field in
  the monomial basis
```

duality_pairing(x, y)

Compute the pairing between an element of self and an element of the dual.

INPUT:

• x – an element of the dual of symmetric functions in non-commuting variables
• y – an element of the symmetric functions in non-commuting variables

OUTPUT:

• an element of the base ring of self

EXAMPLES:

```python
sage: DNCSym = SymmetricFunctionsNonCommutingVariablesDual(QQ)
sage: w = DNCSym.w()
sage: m = w.dual_basis()
sage: matrix([[w(A).duality_pairing(m(B)) for A in SetPartitions(3)] for B in SetPartitions(3))
[[1 0 0 0 0]
 [0 1 0 0 0]
 [0 0 1 0 0]
 [0 0 0 1 0]
 [0 0 0 0 1]]
sage: (w[[1,2],[3]] + 3*w[[1,3],[2]]).duality_pairing(2*m[[1,3],[2]] + m[[1,2,3]] + 2*m[[1,2],[3]])
8
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: matrix([[w(A).duality_pairing(h(B)) for A in SetPartitions(3)] for B in SetPartitions(3))
[[6 2 2 2 1]
 [2 2 1 1 1]
 [2 1 2 1 1]
 [2 1 1 2 1]
 [1 1 1 1 1]]
sage: (2*w[[1,3],[2]] + w[[1,2,3]] + 2*w[[1,2],[3]]).duality_pairing(h[[1,2,3]] + 3*h[[1,3],[2]])
32
```

product_on_basis(A, B)
The product on \( w \) basis elements.

The product on the \( w \) is the dual to the coproduct on the \( m \) basis. On the basis \( w \) it is defined as

\[
    w_A w_B = \sum_{S \subseteq [n]} w_{A \uparrow_S \cup B \uparrow_S^c}
\]

where the sum is over all possible subsets \( S \) of \([n]\) such that \(|S| = |A|\) with a term indexed the union of \( A \uparrow_S \) and \( B \uparrow_{S^c} \). The notation \( A \uparrow_S \) represents the unique set partition of the set \( S \) such that the standardization is \( A \). This product is commutative.

**INPUT:**
- \( A, B \) – set partitions

**OUTPUT:**
- an element of the \( w \) basis

**EXAMPLES:**

```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: A = SetPartition([[1], [2,3]])
sage: B = SetPartition([[1, 2, 3]])
sage: w.product_on_basis(A, B)

w{{1}, {2, 3}, {4, 5, 6}} + w{{1}, {2, 3, 4}, {5, 6}}
+ w{{1}, {2, 3, 5}, {4, 6}} + w{{1}, {2, 3, 6}, {4, 5}}
+ w{{1}, {2, 4}, {3, 5, 6}} + w{{1}, {2, 4, 5}, {3, 6}}
+ w{{1}, {2, 4, 6}, {3, 5}} + w{{1}, {2, 5}, {3, 4, 6}}
+ w{{1}, {2, 5, 6}, {3, 4}} + w{{1}, {2, 6}, {3, 4, 5}}
+ w{{1, 2, 3}, {4}, {5, 6}} + w{{1, 2, 4}, {3}, {5, 6}}
+ w{{1, 2, 5}, {3}, {4, 6}} + w{{1, 2, 6}, {3}, {4, 5}}
+ w{{1, 3, 4}, {2}, {5, 6}} + w{{1, 3, 5}, {2}, {4, 6}}
+ w{{1, 3, 6}, {2}, {4, 5}} + w{{1, 4, 5}, {2}, {3, 6}}
+ w{{1, 4, 6}, {2}, {3, 5}} + w{{1, 5, 6}, {2}, {3, 4}}

sage: B = SetPartition([[1], [2]])
sage: w.product_on_basis(A, B)

3*w{{1}, {2}, {3}, {4, 5}} + 2*w{{1}, {2}, {3, 4}, {5}}
+ 2*w{{1}, {2}, {3, 5}, {4}} + w{{1}, {2}, {3, 6}}
+ w{{1}, {2, 4}, {3}, {5}} + w{{1}, {2, 3}, {4}, {5}}

sage: w.product_on_basis(A, SetPartition([]))

w{{1}, {2, 3}}
```

**sum_of_partitions(la)**

Return the sum over all set partitions whose shape is \( la \), scaled by \( \prod_i m_i! \) where \( m_i \) is the multiplicity of \( i \) in \( la \).

**INPUT:**
- \( la \) – an integer partition

**OUTPUT:**
- an element of self

**EXAMPLES:**

```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.sum_of_partitions([2,1,1])

2*w{{1}, {2}, {3, 4}} + 2*w{{1}, {2, 3}, {4}} + 2*w{{1}, {2, 4}, {3}}
+ 2*w{{1, 2}, {3}, {4}} + 2*w{{1, 3}, {2}, {4}} + 2*w{{1, 4}, {2}, {3}}
```

5.1. Comprehensive Module List 1573
to_symmetric_function()

The preimage of \( \chi^* \) in the w basis.

EXAMPLES:

```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.to_symmetric_function
Generic morphism:
  From: Dual symmetric functions in non-commuting variables over the
    Rational Field in the w basis
  To:  Symmetric Functions over Rational Field in the homogeneous basis
```

5.1.150 Symmetric Functions in Non-Commuting Variables

AUTHORS:

- Travis Scrimshaw (08-04-2013): Initial version

class sage.combinat.ncsym.ncsym.SymmetricFunctionsNonCommutingVariables(R)

    Bases: UniqueRepresentation, Parent

Symmetric functions in non-commutative variables.

The ring of symmetric functions in non-commutative variables, which is not to be confused with the non-commutative symmetric functions, is the ring of all bounded-degree noncommutative power series in countably many indeterminates (i.e., elements in \( R((x_1, x_2, x_3, \ldots)) \) of bounded degree) which are invariant with respect to the action of the symmetric group \( S_\infty \) on the indices of the indeterminates. It can be regarded as a direct limit over all \( n \to \infty \) of rings of \( S_n \)-invariant polynomials in \( n \) non-commuting variables (that is, \( S_n \)-invariant elements of \( R(x_1, x_2, \ldots, x_n) \)).

This ring is implemented as a Hopf algebra whose basis elements are indexed by set partitions.

Let \( A = \{A_1, A_2, \ldots, A_r\} \) be a set partition of the integers \( [k] := \{1, 2, \ldots, k\} \). This partition \( A \) determines an equivalence relation \( \sim_A \) on \( [k] \), which has \( c \sim_A d \) if and only if \( c \) and \( d \) are in the same part \( A_j \) of \( A \). The monomial basis element \( m_A \) indexed by \( A \) is the sum of monomials \( x_{i_1} x_{i_2} \cdots x_{i_k} \) such that \( i_c = i_d \) if and only if \( c \sim_A d \).

The \( k \)-th graded component of the ring of symmetric functions in non-commutative variables has its dimension equal to the number of set partitions of \( [k] \). (If we work, instead, with finitely many – say, \( n \) – variables, then its dimension is equal to the number of set partitions of \( [k] \) where the number of parts is at most \( n \).)

Note: All set partitions are considered standard (i.e., set partitions of \( [n] \) for some \( n \)) unless otherwise stated.

REFERENCES:

EXAMPLES:

We begin by first creating the ring of \( NCSym \) and the bases that are analogues of the usual symmetric functions:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: p = NCSym.p()
sage: m
```
Symmetric functions in non-commuting variables over the Rational Field in the monomial basis

The basis is indexed by set partitions, so we create a few elements and convert them between these bases:

```
sage: elt = m(SetPartition([[1,3],[2]])) - 2*m(SetPartition([[1],[2]])); elt
-2*m({1}, {2}) + m({1, 3}, {2})
sage: e(elt)
1/2*e({1, {2, 3}}) - 2*e({1, 2}) + 1/2*e({1, 2, {3}}) - 1/2*e({1, 2, 3}) - 1/2*e({1, 3}, {2})
sage: h(elt)
-4*h({1}, {2}) - 2*h({1, 2}) + 1/2*h({1, 2, 3}) + 3/2*h({1, 3}, {2})
sage: p(elt)
-2*p({1}, {2}) + 2*p({1, 2}) + p({1, 3}, {2})
sage: m(p(elt))
-2*m({1}, {2}) + m({1, 3}, {2})
sage: elt = p(SetPartition([[1,3],[2]])) - 4*p(SetPartition([[1],[2]])) + 2; elt
2*p() - 4*p({1}, {2}) + p({1, 3}, {2})
sage: e(elt)
2*e({1, 2}) - 4*e({1}, {2}) + e({1}, {2, 3}) - e({1, 3}, {2})
sage: m(elt)
2*m() - 4*m({1}, {2}) - 4*m({1, 2}) + m({1, 2, 3}) + m({1, 3}, {2})
sage: h(elt)
2*h() - 4*h({1, 2}) + 1/2*h({1, 2, 3}) + 3/2*h({1, 3}, {2})
sage: p(m(elt))
2*p() - 4*p({1}, {2}) + p({1, 3}, {2})
```

There is also a shorthand for creating elements. Note that we must use `p([])` to create the empty set partition due to python’s syntax.

```
sage: eltm = m([[1,3],[2]]) - 3*m([[1],[2]]); eltm
-3*m({1}, {2}) + m({1, 3}, {2})
sage: elte = e([[1,3],[2]]); elte
e(1, 3}, {2})
sage: elth = h([[1,3],[2,4]]); elth
h(1, 3}, {2, 4})
sage: eltp = p([[1,3],[2,4]] + 2*p([[1]]) - 4*p([]); eltp
-4*p() + 2*p({1}) + p({1, 3}, {2, 4})
```

There is also a natural projection to the usual symmetric functions by letting the variables commute. This projection map preserves the product and coproduct structure. We check that Theorem 2.1 of [RS06] holds:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Sm = Sym.m()
sage: Se = Sym.e()
sage: Sh = Sym.h()
sage: Sp = Sym.p()
sage: eltm.to_symmetric_function()
-6*m[1, 1] + m[2, 1]
sage: Sm(p(eltm).to_symmetric_function())
-6*m[1, 1] + m[2, 1]
```
```python
sage: elte.to_symmetric_function()
2*e[2, 1]
sage: Se(h(elte).to_symmetric_function())
2*e[2, 1]
sage: elth.to_symmetric_function()
4*h[2, 2]
sage: Sh(m(elth).to_symmetric_function())
4*h[2, 2]
sage: eltp.to_symmetric_function()
-4*p[] + 2*p[1] + p[2, 2]
sage: Sp(e(eltp).to_symmetric_function())
-4*p[] + 2*p[1] + p[2, 2]
```

### a_realization()

Return the realization of the powersum basis of `self`.

**OUTPUT:**

- The powersum basis of symmetric functions in non-commuting variables.

**EXAMPLES:**

```python
sage: SymmetricFunctionsNonCommutingVariables(QQ).a_realization()
Symmetric functions in non-commuting variables over the Rational Field in the
powersum basis
```

### chi

alias of `supercharacter`

### class coarse_powersum(NCSym)

Bases: `NCSymBasis_abstract`

The Hopf algebra of symmetric functions in non-commuting variables in the `cp` basis.

This basis was defined in [BZ05] as

\[
\text{cp}_A = \sum_{A \leq B} m_B,
\]

where we sum over all strict coarsenings of the set partition $A$. An alternative description of this basis was given in [BT13] as

\[
\text{cp}_A = \sum_{A \subseteq B} m_B,
\]

where we sum over all set partitions whose arcs are a subset of the arcs of the set partition $A$.

**Note:** In [BZ05], this basis was denoted by $q$. In [BT13], this basis was called the powersum basis and denoted by $p$. However, it is a coarser basis than the usual powersum basis in the sense that it does not yield the usual powersum basis of the symmetric function under the natural map of letting the variables commute.

**EXAMPLES:**
Combinatorics, Release 10.0

sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: cp = NCSym.cp()
sage: cp[[1,3],[2,4]]*cp[[1,2,3]]
cp\{\{1, 2\}, \{3\}\} # cp\{\{1, 2\}, \{3\}\}
sage: ps = SymmetricFunctions(NCSym.base_ring()).p()
sage: ps(cp[[1,3],[2]].to_symmetric_function())
p\{1, 2\} - p\{3\}

\(\text{cp}\) (alias of \text{coarse_powersum})

class \text{deformed_coarse_powersum}(NCSym, q=2)

Bases: \text{NCSymBasis_abstract}

The Hopf algebra of symmetric functions in non-commuting variables in the \(\rho\) basis.

This basis was defined in [BT13] as a \(q\)-deformation of the \(cp\) basis:

\[
\rho_A = \sum_{A \subseteq B} \frac{1}{q^{n_{B-A}}} m_B,
\]

where we sum over all set partitions whose arcs are a subset of the arcs of the set partition \(A\).

INPUT:

- \(q\) – (default: 2) the parameter \(q\)

EXAMPLES:

sage: R = QQ['q'].fraction_field()
sage: q = R.gen()
sage: NCSym = SymmetricFunctionsNonCommutingVariables(R)
sage: rho = NCSym.rho(q)

We construct Example 3.1 in [BT13]:

sage: rnode = lambda A: sorted([a[1] for a in A.arcs()], reverse=True)
sage: dimv = lambda A: sorted([a[1]-a[0] for a in A.arcs()], reverse=True)
sage: lst = list(SetPartitions(4))
sage: S = sorted(lst, key=lambda A: (dimv(A), rnode(A)))
sage: m = NCSym.m()
sage: matrix([[m(rho[A])[B] for B in S] for A in S])

(continues on next page)
Return the deformation parameter $q$ of self.

**EXAMPLES:**

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: rho = NCSym.rho(5)
sage: rho.q()
5
sage: R = QQ['q'].fraction_field()
sage: q = R.gen()
sage: NCSym = SymmetricFunctionsNonCommutingVariables(R)
sage: rho = NCSym.rho(q)
sage: rho.q() == q
True
```

dual()

Return the dual Hopf algebra of the symmetric functions in non-commuting variables.

**EXAMPLES:**

```
sage: SymmetricFunctionsNonCommutingVariables(QQ).dual()
Dual symmetric functions in non-commuting variables over the Rational Field
```

e

**alias of** `elementary`

class `elementary`(NCSym)

**Bases:** `NCSymBasis_abstract`

The Hopf algebra of symmetric functions in non-commuting variables in the elementary basis.

**EXAMPLES:**

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
```

class `Element`

**Bases:** `IndexedFreeModuleElement`

An element in the elementary basis of `NCSym`.

**omega()**

Return the involution $\omega$ applied to `self`.

The involution $\omega$ on $NCSym$ is defined by $\omega(e_A) = h_A$.

**OUTPUT:**

- an element in the basis `self`
EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: elt = e[[1,3],[2]].omega(); elt
2*e{{1}, {2}, {3}} - e{{1, 3}, {2}}
sage: elt.omega()
e{{1, 3}, {2}}
sage: h(elt)
h{{1, 3}, {2}}
```

to_symmetric_function()

The projection of self to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the \( \text{e} \) basis, and return the projection of expressed in the elementary basis of symmetric functions.

The map \( \chi: NCSym \to Sym \) is given by

\[
e_A \mapsto e_{\lambda(A)} \prod_i \lambda(A)_i!
\]

where \( \lambda(A) \) is the partition associated with \( A \) by taking the sizes of the parts.

OUTPUT:

• An element of the symmetric functions in the elementary basis

EXAMPLES:

```python
sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
sage: e[[1,3],[2]].to_symmetric_function()
2*e[2, 1]
sage: e[[1],[3],[2]].to_symmetric_function()
e[1, 1, 1]
```

h

alias of homogeneous

class homogeneous(NCSym)

Bases: NCSymBasis_abstract

The Hopf algebra of symmetric functions in non-commuting variables in the homogeneous basis.

EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: h = NCSym.h()
sage: h[[1,3],[2,4]]*h[[1,2,3]]
h{{1, 3}, {2, 4}, {5, 6, 7}}
sage: h[[1,2]].coproduct()
h{} # h{{1, 2}} + 2*h{{1}} # h{{1}} + h{{1, 2}} # h{}
```

class Element

Bases: IndexedFreeModuleElement

An element in the homogeneous basis of \( NCSym \).
**omega()**

Return the involution \( \omega \) applied to self.

The involution \( \omega \) on \( NCSym \) is defined by \( \omega(h_A) = e_A \).

**OUTPUT:**

- an element in the basis self

**EXAMPLES:**

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: h = NCSym.h()
sage: e = NCSym.e()
sage: elt = h[[1,3],[2]].omega(); elt
2*h{{1}, {2}, {3}} - h{{1, 3}, {2}}
sage: elt.omega()
h{{1, 3}, {2}}
sage: e(elt)
e{{1, 3}, {2}}
```

**to_symmetric_function()**

The projection of self to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the \( h \) basis, and return the projection of expressed in the complete basis of symmetric functions.

The map \( \chi : NCSym \to Sym \) is given by

\[
h_A \mapsto h_{\lambda(A)} \prod_i \lambda(A)_i!
\]

where \( \lambda(A) \) is the partition associated with \( A \) by taking the sizes of the parts.

**OUTPUT:**

- An element of the symmetric functions in the complete basis

**EXAMPLES:**

```
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: h[[1,3],[2]].to_symmetric_function()
2*h[2, 1]
sage: h[[1],[3],[2]].to_symmetric_function()
h[1, 1, 1]
```

**m**

alias of *monomial*

**class monomial(NCSym)**

**Bases:** *NCSymBasis_abstract*

The Hopf algebra of symmetric functions in non-commuting variables in the monomial basis.

**EXAMPLES:**

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: m[[1,3],[2]]*m[[1,2]]
m{{1, 3}, {2}} + m{{1, 3}, {2, 4, 5}} + m{{1, 3, 4, 5}, {2}}
sage: m[[1,3],[2]].coproduct()
```

(continues on next page)
class Element

Bases: IndexedFreeModuleElement

An element in the monomial basis of $NCSym$.

expand($n$, alphabet='x')

Expand self written in the monomial basis in $n$ non-commuting variables.

INPUT:
• $n$ – an integer
• alphabet – (default: 'x') a string

OUTPUT:
• The symmetric function of self expressed in the $n$ non-commuting variables described by alphabet.

EXAMPLES:

sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()

sage: m[[1,3],[2]].expand(4)

x0*x1*x0 + x0*x2*x0 + x0*x3*x0 + x1*x0*x1 + x1*x2*x1 + x1*x3*x1
+ x2*x0*x2 + x2*x1*x2 + x2*x3*x2 + x3*x0*x3 + x3*x1*x3 + x3*x2*x3

One can use a different set of variables by using the optional argument alphabet:

sage: m[[1],[2,3]].expand(3,alphabet='y')
y0*y1^2 + y0*y2^2 + y1*y0^2 + y1*y2^2 + y2*y0^2 + y2*y1^2

to_symmetric_function()

The projection of self to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the m basis, and return the projection of expressed in the monomial basis of symmetric functions.

The map $\chi: NCSym \to Sym$ is defined by

$$m_A \mapsto m_{\lambda(A)} \prod_i n_i(\lambda(A))!$$

where $\lambda(A)$ is the partition associated with $A$ by taking the sizes of the parts and $n_i(\mu)$ is the multiplicity of $i$ in $\mu$.

OUTPUT:
• an element of the symmetric functions in the monomial basis

EXAMPLES:

sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()

sage: m[[1,3],[2]].to_symmetric_function()
m[1, 1]

sage: m[[1],[3],[2]].to_symmetric_function()
6*m[1, 1, 1]

coproduct_on_basis($A$)

Return the coproduct of a monomial basis element.

INPUT:
• A – a set partition

OUTPUT:
• The coproduct applied to the monomial symmetric function in non-commuting variables indexed by A expressed in the monomial basis.

EXAMPLES:

```python
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: m[[1, 3], [2]].coproduct()
m{} # m{{1, 3}, {2}} + m{{1}} # m{{1, 2}} + m{{1, 2}} # m{{1}} + m{{1, 3}, ˓→{2}} # m{}
sage: m.coproduct_on_basis(SetPartition([]))
m{} # m{}
sage: m.coproduct_on_basis(SetPartition([[1,2,3]]))
m{} # m{{1, 2, 3}} + m{{1, 2, 3}} # m{}
sage: m[[1,5],[2,4],[3,7],[6]].coproduct()
m{} # m{{1, 5}, {2, 4}, {3, 7}, {6}} + m{{1}} # m{{1, 5}, {2, 4}, {3, 6}} ˓→ 2*m{{1, 2}} # m{{1, 3}, {2, 5}, {4}} + m{{1, 2}} # m{{1, 4}, {2, 3}, {5}} ˓→ 2*m{{1, 2}, {3}} # m{{1, 3}, {2, 4}} + m{{1, 3}} # m{{1, 4}, {2}} + m{{1, 4}, {2, 3}} ˓→ 2*m{{1, 3}, {2, 4}} # m{{1, 2}, {3}} + 2*m{{1, 3}, {2, 4}} # m{{1, 3}, {2}} + 2*m{{1, 3}, {2, 4}, {5}} # m{{1, 3}, {2, 4}} + m{{1, 5}, {2, 4}, {3, 6}} # m{{1,} ˓→ 2}} + m{{1, 5}, {2, 4}, {3, 7}} # m{{1, 5}, {2, 4}, {3, 6}} + m{{1, 5}, {2, 4}, {3, 7}, {6}} # m{}
```

dual_basis()

Return the dual basis to the monomial basis.

OUTPUT:
• the \( w \) basis of the dual Hopf algebra

EXAMPLES:

```python
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.dual_basis()
Dual symmetric functions in non-commuting variables over the Rational Field in the \( w \) basis
duality_pairing(x, y)

Compute the pairing between an element of self and an element of the dual.

INPUT:
• \( x \) – an element of symmetric functions in non-commuting variables
• \( y \) – an element of the dual of symmetric functions in non-commuting variables

OUTPUT:
• an element of the base ring of self

EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: w = m.dual_basis()
sage: matrix([[m(A).duality_pairing(w(B)) for A in SetPartitions(3)] for B in SetPartitions(3))]
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```
from_symmetric_function(f)

Return the image of the symmetric function f in self.

This is performed by converting to the monomial basis and extending the method sum_of_partitions() linearly. This is a linear map from the symmetric functions to the symmetric functions in non-commuting variables that does not preserve the product or coproduct structure of the Hopf algebra.

See also:

to_symmetric_function()

INPUT:

• f – an element of the symmetric functions

OUTPUT:

• An element of the m basis

EXAMPLES:

sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: mon = SymmetricFunctions(QQ).m()
sage: elt = m.from_symmetric_function(mon[2,1,1]); elt
1/12*m{{1}, {2}, {3, 4}} + 1/12*m{{1}, {2, 3}, {4}} + 1/12*m{{1}, {2, 4}, \rightarrow {3}}
+ 1/12*m{{1, 2}, {3}, {4}} + 1/12*m{{1, 3}, {2}, {4}} + 1/12*m{{1, 4}, {2}, \rightarrow {3}}
sage: elt.to_symmetric_function()
m[2, 1, 1]
sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
sage: elm = SymmetricFunctions(QQ).e()
sage: e(m.from_symmetric_function(elm[4]))
1/24*e{{1, 2, 3, 4}}
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: hom = SymmetricFunctions(QQ).h()
sage: h(m.from_symmetric_function(hom[4]))
1/24*h{{1, 2, 3, 4}}
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).p()
sage: pow = SymmetricFunctions(QQ).p()
sage: p(m.from_symmetric_function(pow[4]))
p{{1, 2, 3, 4}}
sage: p(m.from_symmetric_function(pow[2,1]))
1/3*p{{1}, {2, 3}} + 1/3*p{{1, 2}, {3}} + 1/3*p{{1, 3}, {2}}
sage: p([[1,2]])*p([[1]])
p{{1, 2}, {3}}

Check that χ ∘ ⃗χ is the identity on Sym:

sage: all((m.from_symmetric_function(pow(la)).to_symmetric_function() ==\n\npow(la))\n....: \n\nfor la in Partitions(4))

(continues on next page)
internal_coproduct_on_basis(A)

Return the internal coproduct of a monomial basis element.

The internal coproduct is defined by

\[ \Delta^\square(m_A) = \sum_{B \triangleleft C = A} m_B \otimes m_C \]

where we sum over all pairs of set partitions \( B \) and \( C \) whose infimum is \( A \).

INPUT:
• \( A \) – a set partition

OUTPUT:
• an element of the tensor square of the \( m \) basis

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: m.internal_coproduct_on_basis(SetPartition([[1,3],[2]]))
m{{1, 2, 3}} # m{{1, 3}, {2}} + m{{1, 3}, {2}} # m{{1, 2, 3}} + m{{1, 3}, \rightarrow{2}} # m{{1, 3}, {2}}
```

product_on_basis(A, B)

The product on monomial basis elements.

The product of the basis elements indexed by two set partitions \( A \) and \( B \) is the sum of the basis elements indexed by set partitions \( C \) such that \( C \land ([n][k]) = A|B \) where \( n = |A| \) and \( k = |B| \). Here \( A \land B \) is the infimum of \( A \) and \( B \) and \( A|B \) is the SetPartition.pipe() operation. Equivalently we can describe all \( C \) as matchings between the parts of \( A \) and \( B \) where if \( a \in A \) is matched with \( b \in B \), we take \( a \cup b \) instead of \( a \) and \( b \) in \( C \).

INPUT:
• \( A, B \) – set partitions

OUTPUT:
• an element of the \( m \) basis

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: A = SetPartition([[1],[2,3]])
sage: B = SetPartition([[1],[3],[2,4]])
sage: m.product_on_basis(A, B)
m{{1}, {2, 3}, {4}, {5}, {6}} + m{{1}, {2, 3, 4}, {5}} + m{{1}, {2, 3, 5}, {4}, {6}} + m{{1}, {2, 3, 6}, {4}, {5}} + m{{1}, {2, 3, 4, 5}, {6}} + m{{1}, {2, 3, 5, 6}, {4}} + m{{1}, {2, 3, 6, 5}, {4}} + m{{1}, {2, 3, 4, 6}, {5}} + m{{1}, {2, 3, 5, 6}, {4}} + m{{1}, {2, 3, 6, 5}, {4}} + m{{1}, {2, 3, 4, 6}, {5}} + m{{1}, {2, 3, 5, 6}, {4}} + m{{1}, {2, 3, 6, 5}, {4}} + m{{1}, {2, 3, 4, 6}, {5}}
sage: B = SetPartition([[1],[2]])
sage: m.product_on_basis(A, B)
m{{1}, {2, 3}, {4}, {5}} + m{{1}, {2, 3, 4}, {5}} + m{{1}, {2, 3, 5}, {4}} + m{{1}, {2, 3, 6}, {5}} + m{{1}, {2, 3, 4, 5}, {6}} + m{{1}, {2, 3, 5, 6}, {4}} + m{{1}, {2, 3, 6, 5}, {4}} + m{{1}, {2, 3, 4, 6}, {5}} + m{{1}, {2, 3, 5, 6}, {4}} + m{{1}, {2, 3, 6, 5}, {4}} + m{{1}, {2, 3, 4, 6}, {5}} + m{{1}, {2, 3, 5, 6}, {4}} + m{{1}, {2, 3, 6, 5}, {4}} + m{{1}, {2, 3, 4, 6}, {5}}
```
Combinatorics, Release 10.0

sage: m.product_on_basis(A, SetPartition([]))
m{{1}, {2, 3}}

**sum_of_partitions**\( (\lambda) \)

Return the sum over all set partitions whose shape is \( \lambda \) with a fixed coefficient \( C \) defined below.

Fix a partition \( \lambda \), we define \( \lambda! := \prod_i \lambda_i! \) and \( \lambda^! := \prod_i m_i! \). Recall that \( |\lambda| = \sum_i \lambda_i \) and \( m_i \) is the number of parts of length \( i \) of \( \lambda \). Thus we defined the coefficient as

\[
C := \frac{\lambda! \lambda^!}{|\lambda|!}.
\]

Hence we can define a lift \( \bar{\chi} \) from \( Sym \) to \( NCSym \) by

\[
m_\lambda \mapsto C \sum_A m_A
\]

where the sum is over all set partitions whose shape is \( \lambda \).

**INPUT:**

- \( \lambda \) – an integer partition

**OUTPUT:**

- an element of the \( m \) basis

**EXAMPLES:**

```python
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.sum_of_partitions(Partition([2, 1, 1]))
1/12*m{{1}, {2}, {3, 4}} + 1/12*m{{1}, {2, 3}, {4}} + 1/12*m{{1}, {2, 4}, ->{3}}
+ 1/12*m{{1, 2}, {3}, {4}} + 1/12*m{{1, 3}, {2}, {4}} + 1/12*m{{1, 4}, {2}, ->{3}}
```

\( p \)

alias of powersum

**class powersum**\( (NCSym) \)

Bases: \( NCSymBasis_abstract \)

The Hopf algebra of symmetric functions in non-commuting variables in the powersum basis.

The powersum basis is given by

\[
p_A = \sum_{A \leq B} m_B,
\]

where we sum over all coarsenings of the set partition \( A \). If we allow our variables to commute, then \( p_A \) goes to the usual powersum symmetric function \( p_\lambda \) whose (integer) partition \( \lambda \) is the shape of \( A \).

**EXAMPLES:**

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: p = NCSym.p()
sage: x = p.an_element()**2; x
4*p[] + 8*p{1} + 4*p{1, 1} + 12*p{2} + 12*p{2, 1} + 9*p{2, 2}
```
class Element
Bases: IndexedFreeModuleElement

An element in the powersum basis of NCSym.

to_symmetric_function()

The projection of self to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the \( p \) basis, and return the projection of expressed in the powersum basis of symmetric functions.

The map \( \chi: NCSym \to Sym \) is given by

\[
P_A \mapsto p_{\lambda(A)}
\]

where \( \lambda(A) \) is the partition associated with \( A \) by taking the sizes of the parts.

OUTPUT:
• an element of symmetric functions in the power sum basis

EXAMPLES:

sage: p = SymmetricFunctionsNonCommutingVariables(QQ).p()
sage: p[[1,3],[2]].to_symmetric_function()
p[2, 1]
sage: p[[1],[3],[2]].to_symmetric_function()
p[1, 1, 1]

antipode_on_basis(A)

Return the result of the antipode applied to a powersum basis element.

Let \( A \) be a set partition. The antipode given in [LM2011] is

\[
S(p_A) = \sum_{\gamma} (-1)^{\ell(\gamma)} p_{\gamma[A]}
\]

where we sum over all ordered set partitions (i.e. set compositions) of \( [\ell(A)] \) and

\[
\gamma[A] = A_1^{\ell(A)} | \cdots | A_{\ell(A)}^{\ell(A)}
\]

is the action of \( \gamma \) on \( A \) defined in SetPartition.ordered_set_partition_action().

INPUT:
• \( A \) – a set partition

OUTPUT:
• an element in the basis self

EXAMPLES:

sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: p.antipode_on_basis(SetPartition([[1], [2,3]]))
p{{1, 2}, {3}}
sage: p.antipode_on_basis(SetPartition([]))
p{}
sage: F = p[[1,3],[5],[2,4]].coproduct()
sage: F.apply_multilinear_morphism(lambda x,y: x.antipode() * y)
0
**coproduct_on_basis**(A)

Return the coproduct of a monomial basis element.

**INPUT:**
- A – a set partition

**OUTPUT:**
- The coproduct applied to the monomial symmetric function in non-commuting variables indexed by A expressed in the monomial basis.

**EXAMPLES:**

```python
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: p[SetPartition([[1,3],[2]])].coproduct()
sage: p[SetPartition([])].coproduct()
sage: p.coproduct_on_basis(SetPartition([[1],[2]]))
```

**internal_coproduct_on_basis**(A)

Return the internal coproduct of a powersum basis element.

The internal coproduct is defined by

\[ \Delta^\otimes(p_A) = p_A \otimes p_A \]

**INPUT:**
- A – a set partition

**OUTPUT:**
- an element of the tensor square of self

**EXAMPLES:**

```python
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: p[SetPartition([[1,3],[2]])].internal_coproduct_on_basis()
```

**primitive**(A, i=1)

Return the primitive associated to A in self.

Fix some \(i \in S\). Let \(A\) be an atomic set partition of \(S\), then the primitive \(p(A)\) given in [LM2011] is

\[ p(A) = \sum_\gamma (-1)^{\ell(\gamma)} p_{\gamma[A]} \]

where we sum over all ordered set partitions of \([\ell(A)]\) such that \(i \in \gamma_1\) and \(\gamma[A]\) is the action of \(\gamma\) on \(A\) defined in \(SetPartition.ordered_set_partition_action()\). If \(A\) is not atomic, then \(p(A) = 0\).

**See also:**

\(SetPartition.is_atomic()\)

**INPUT:**
- A – a set partition
- i – (default: 1) index in the base set for A specifying which set of primitives this belongs to

**OUTPUT:**
- an element in the basis self
EXAMPLES:

```
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: elt = p.primitive(SetPartition([[1,3], [2]])); elt
-p{{1, 2}, {3}} + p{{1, 3}, {2}}
sage: elt.coproduct()
-p{} # p{{1, 2}, {3}} + p{} # p{{1, 3}, {2}} - p{{1, 2}, {3}} # p{} + p{{1, ω → 3}, {2}} # p{}
sage: p.primitive(SetPartition([[1], [2,3]]))
0
sage: p.primitive(SetPartition([]))
p{}
```

**rho**

alias of `deformed_coarse_powersum`

**class supercharacter(NCSym, q=2)**

Bases: `NCSymBasis_abstract`

The Hopf algebra of symmetric functions in non-commuting variables in the supercharacter \( \chi \) basis.

This basis was defined in [BT13] as a \( q \)-deformation of the supercharacter basis.

\[
\chi_A = \sum_B \chi_A(B) m_B,
\]

where we sum over all set partitions \( A \) and \( \chi_A(B) \) is the evaluation of the supercharacter \( \chi_A \) on the superclass \( \mu_B \).

**Note:** The supercharacters considered in [BT13] are coarser than those considered by Aguiar et. al.

**INPUT:**

- \( q \) – (default: 2) the parameter \( q \)

**EXAMPLES:**

```
sage: R = QQ['q'].fraction_field()
sage: q = R.gen()
sage: NCSym = SymmetricFunctionsNonCommutingVariables(R)
sage: chi = NCSym.chi(q)
sage: chi[[1,3],[2]]*chi[[1,2]]
chi{{1, 3}, {2}, {4, 5}}
sage: chi[[1,3],[2]].coproduct()
chi{} # chi{{1, 3}, {2}} + (2*q-2)*chi{{1}} # chi{{1}, {2}} +
(3*q-2)*chi{{1}} # chi{{1}, {2}} + (2*q-2)*chi{{1}} # chi{{1}} +
(3*q-2)*chi{{1, 2}} # chi{{1}} + chi{{1, 3}, {2}} # chi{}
sage: chi2 = NCSym.chi()
sage: chi(chi2[[1,2],[3]])
((-q+2)/q)*chi{{1, 2}, {3}} + 2/q*chi{{1, 2}, {3}}
sage: chi2
Symmetric functions in non-commuting variables over the Fraction Field
of Univariate Polynomial Ring in q over Rational Field in the
supercharacter basis with parameter q=2
```

1588 Chapter 5. Comprehensive Module List
Return the deformation parameter \( q \) of \( \texttt{self} \).

**EXAMPLES:**

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: chi = NCSym.chi(5)
sage: chi.q()
5

sage: R = QQ['q'].fraction_field()
sage: q = R.gen()
sage: NCSym = SymmetricFunctionsNonCommutingVariables(R)
sage: chi = NCSym.chi(q)
sage: chi.q() == q
True
```

\( x \)

alias of \( \texttt{x\_basis} \)

**class** \( \texttt{x\_basis}(\texttt{NCSym}) \)

**Bases:** \( \texttt{NCSymBasis\_abstract} \)

The Hopf algebra of symmetric functions in non-commuting variables in the \( x \) basis.

This basis is defined in \cite{BHRZ06} by the formula:

\[
x_A = \sum_{B \subseteq A} \mu(B, A)p_B
\]

and has the following properties:

\[
x_Ax_B = x_{A|B}, \quad \Delta(x_C) = \sum_{AB=C} x_A \otimes x_B.
\]

**EXAMPLES:**

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: x = NCSym.x()
sage: x[[1,3],[2,4]]*x[[1,2,3]]
x{{1, 3}, {2, 4}, {5, 6, 7}}

sage: x[[1,2],[3]].internal_coproduct()
x{{1}, {2}, {3}} # x{{1, 2}, {3}} + x{{1, 2}, {3}} # x{{1}, {2}, {3}} +
x{{1, 2}, {3}} # x{{1, 2}, {3}}
```

sage.combinat.ncsym.ncsym.matchings\((A, B)\)

Iterate through all matchings of the sets \( A \) and \( B \).

**EXAMPLES:**

```python
sage: from sage.combinat.ncsym.ncsym import matchings
sage: list(matchings([1, 2, 3], [-1, -2]))
[[[1], [2], [3], [-1], [-2]],
 [[1], [2], [3, -1], [-2]],
 [[1], [2], [3, -2], [-1]],
 [[1], [2, -1], [3], [-2]],
(continues on next page)
```

5.1. Comprehensive Module List 1589
sage.combinat.ncsym.ncsym.nesting(la, nu)

Return the nesting number of la inside of nu.

If we consider a set partition \( A \) as a set of arcs \( i - j \) where \( i \) and \( j \) are in the same part of \( A \). Define

\[
\text{nst}_\lambda^\nu = \#\{ i < j < k < l \mid i - l \in \nu, j - k \in \lambda \},
\]

and this corresponds to the number of arcs of \( \lambda \) strictly contained inside of \( \nu \).

EXAMPLES:

```
sage: from sage.combinat.ncsym.ncsym import nesting
sage: nu = SetPartition([[1, 4], [2], [3]])
sage: mu = SetPartition([[1, 4], [2, 3]])
sage: nesting(set(mu).difference(nu), nu)
1
```

```
sage: lst = list(SetPartitions(4))
sage: d = {}
sage: for i, nu in enumerate(lst):
    ....:     for mu in nu.coarsenings():
    ....:         if set(nu.arcs()).issubset(mu.arcs()):
    ....:             d[i, lst.index(mu)] = nesting(set(mu).difference(nu), nu)

sage: matrix(d)

```

```
\[
\begin{bmatrix}

\end{bmatrix}
\]
5.1.151 Necklaces

The algorithm used in this file comes from

`sage.combinat.necklace.Necklaces(content)`

Return the set of necklaces with evaluation `content`.

A necklace is a list of integers that such that the list is the smallest lexicographic representative of all the cyclic shifts of the list.

See also:

*LyndonWords*

INPUT:

- `content` – a list or tuple of non-negative integers

EXAMPLES:

```
sage: Necklaces([2,1,1])
Necklaces with evaluation [2, 1, 1]
sage: Necklaces([2,1,1]).cardinality()
3
sage: Necklaces([2,1,1]).first()
[1, 1, 2, 3]
sage: Necklaces([2,1,1]).last()
[1, 2, 1, 3]
sage: Necklaces([2,1,1]).list()
[[1, 1, 2, 3], [1, 1, 3, 2], [1, 2, 1, 3]]
sage: Necklaces([0,2,1,1]).list()
[[2, 2, 3, 4], [2, 2, 4, 3], [2, 3, 2, 4]]
sage: Necklaces([2,0,1,1]).list()
[[1, 1, 3, 4], [1, 1, 4, 3], [1, 3, 1, 4]]
```

class `sage.combinat.necklace.Necklaces_evaluation(content)`

Bases: `UniqueRepresentation`, `Parent`

Necklaces with a fixed evaluation (content).

INPUT:

- `content` – a list or tuple of non-negative integers

`cardinality()`

Return the number of integer necklaces with the evaluation `content`.

The formula for the number of necklaces of content `α` a composition of `n` is:

\[
\sum_{d \mid \gcd(\alpha)} \phi(d) \left( \frac{n/d}{\alpha_1/d, \ldots, \alpha_k/d} \right),
\]

where \(\phi(d)\) is the Euler \(\phi\) function.

EXAMPLES:
sage: Necklaces([]).cardinality()
0
sage: Necklaces([2,2]).cardinality()
2
sage: Necklaces([2,3,2]).cardinality()
30
sage: Necklaces([0,3,2]).cardinality()
2

Check to make sure that the count matches up with the number of necklace words generated.

sage: comps = [[],[2,2],[3,2,7],[4,2],[0,4,2],[2,0,4]]+Compositions(4).list()
sage: ns = [Necklaces(comp) for comp in comps]
sage: all(n.cardinality() == len(n.list()) for n in ns)
True

content()

Return the content (or evaluation) of the necklaces.

EXAMPLES:

sage: N = Necklaces([2,2,2])
sage: N.content()
[2, 2, 2]

5.1.152 Non-Decreasing Parking Functions

A non-decreasing parking function of size $n$ is a non-decreasing function $f$ from $\{1, \ldots, n\}$ to itself such that for all $i$, one has $f(i) \leq i$.

The number of non-decreasing parking functions of size $n$ is the $n$-th Catalan number.

The set of non-decreasing parking functions of size $n$ is in bijection with the set of Dyck words of size $n$.

AUTHORS:

- Florent Hivert (2009-04)
- Christian Stump (2012-11) added pretty printing

class sage.combinat.non_decreasing_parking_function.NonDecreasingParkingFunction(lst)

Bases: Element

A non decreasing parking function of size $n$ is a non-decreasing function $f$ from $\{1, \ldots, n\}$ to itself such that for all $i$, one has $f(i) \leq i$.

EXAMPLES:

sage: NonDecreasingParkingFunction([])
[]
sage: NonDecreasingParkingFunction([1])
[1]
sage: NonDecreasingParkingFunction([2])
Traceback (most recent call last):
...
ValueError: [2] is not a non-decreasing parking function

(continues on next page)
sage: NonDecreasingParkingFunction([1,2])
[1, 2]
sage: NonDecreasingParkingFunction([1,1,2])
[1, 1, 2]
sage: NonDecreasingParkingFunction([1,1,4])
Traceback (most recent call last):
  ... ValueError: [1, 1, 4] is not a non-decreasing parking function

classmethod from_dyck_word(dw)

Bijection from Dyck words. It is the inverse of the bijection to_dyck_word(). You can find there the mathematical definition.

EXAMPLES:

sage: NonDecreasingParkingFunction.from_dyck_word([])
[]
sage: NonDecreasingParkingFunction.from_dyck_word([1,0])
[1]
sage: NonDecreasingParkingFunction.from_dyck_word([1,1,0,0])
[1, 1]
sage: NonDecreasingParkingFunction.from_dyck_word([1,0,1,0])
[1, 2]
sage: NonDecreasingParkingFunction.from_dyck_word([1,0,1,1,0,1,0,1,0,1,0,1,0])
[1, 2, 2, 3, 5]

grade()

Return the length of self.

EXAMPLES:

sage: ndpf = NonDecreasingParkingFunctions(5)
sage: len(ndpf.random_element())
5

to_dyck_word()

Implement the bijection to Dyck words, which is defined as follows. Take a non decreasing parking function, say [1,1,2,4,5,5], and draw its graph:

```
  ___
 /  | . 5
/   | . 5
 ___| . . 4
|  | . . . 2
|  | . . . . 1
|  | . . . . 1
```

The corresponding Dyck word [1,1,0,1,0,1,0,1,1,0,0] is then read off from the sequence of horizontal and vertical steps. The converse bijection is from_dyck_word().

EXAMPLES:

sage: NonDecreasingParkingFunction([1,1,2,4,5,5]).to_dyck_word()
[1, 1, 0, 1, 0, 1, 0, 1, 1, 0, 0]
sage: NonDecreasingParkingFunction([]).to_dyck_word()
[]
sage: NonDecreasingParkingFunction([1,1,1]).to_dyck_word()
[1, 1, 1, 0, 0, 0]
sage: NonDecreasingParkingFunction([1,2,3]).to_dyck_word()
[1, 0, 1, 0, 1, 0]
sage: NonDecreasingParkingFunction([1,1,3,3,4,6,6]).to_dyck_word()
[1, 1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 0]

Return the set of Non-Decreasing Parking Functions.

A non-decreasing parking function of size $n$ is a non-decreasing function $f$ from \{1, ..., $n$\} to itself such that for all $i$, one has $f(i) \leq i$.

EXAMPLES:

Here are all the non-decreasing parking functions of size 5:

sage: NonDecreasingParkingFunctions(3).list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]

If no size is specified, then NonDecreasingParkingFunctions returns the set of all non-decreasing parking functions.

sage: PF = NonDecreasingParkingFunctions(); PF
Non-decreasing parking functions
sage: [] in PF
True
sage: [1] in PF
True
sage: [2] in PF
False
sage: [1,1,3] in PF
True
sage: [1,1,4] in PF
False

If the size $n$ is specified, then NonDecreasingParkingFunctions returns the set of all non-decreasing parking functions of size $n$.

sage: PF = NonDecreasingParkingFunctions(0)
sage: PF.list()
[]
sage: PF = NonDecreasingParkingFunctions(1)
sage: PF.list()
[[1]]
sage: PF = NonDecreasingParkingFunctions(3)
sage: PF.list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]

sage: PF3 = NonDecreasingParkingFunctions(3); PF3
Non-decreasing parking functions of size 3
sage: [] in PF3
False

(continues on next page)
False
sage: [1] in PF3
False
sage: [1,1,3] in PF3
True
sage: [1,1,4] in PF3
False

class sage.combinat.non_decreasing_parking_function.NonDecreasingParkingFunctions_all
Bases: UniqueRepresentation, Parent

graded_component(n)
   Return the graded component.

   EXAMPLES:

   sage: P = NonDecreasingParkingFunctions()
sage: P.graded_component(4) == NonDecreasingParkingFunctions(4)
True

class sage.combinat.non_decreasing_parking_function.NonDecreasingParkingFunctions_n(n)
Bases: UniqueRepresentation, Parent

The combinatorial class of non-decreasing parking functions of size $n$.

A non-decreasing parking function of size $n$ is a non-decreasing function $f$ from \{1,\ldots,n\} to itself such that for all $i$, one has $f(i) \leq i$.

The number of non-decreasing parking functions of size $n$ is the $n$-th Catalan number.

EXAMPLES:

sage: PF = NonDecreasingParkingFunctions(3)
sage: PF.list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]
sage: PF = NonDecreasingParkingFunctions(4)
sage: PF.list()
[[1, 1, 1, 1], [1, 1, 1, 2], [1, 1, 1, 3], [1, 1, 1, 4], [1, 1, 2, 2], [1, 1, 2, 3], [1, 1, 2, 4], [1, 1, 3, 3], [1, 1, 3, 4], [1, 1, 4, 4], [1, 2, 2, 2], [1, 2, 2, 3], [1, 2, 2, 4], [1, 2, 3, 3], [1, 2, 3, 4], [1, 2, 4, 4], [1, 3, 3, 3], [1, 3, 3, 4], [1, 3, 4, 4], [1, 4, 4, 4], [2, 2, 2, 2], [2, 2, 2, 3], [2, 2, 2, 4], [2, 2, 3, 3], [2, 2, 3, 4], [2, 2, 4, 4], [2, 3, 3, 3], [2, 3, 3, 4], [2, 3, 4, 4], [2, 4, 4, 4], [3, 3, 3, 3], [3, 3, 3, 4], [3, 3, 4, 4], [3, 4, 4, 4], [4, 4, 4, 4]]

Warning: The precise order in which the parking function are generated or listed is not fixed, and may change in the future.

AUTHORS:
- Florent Hivert

Element
   alias of NonDecreasingParkingFunction
**cardinality()**

Return the number of non-decreasing parking functions of size $n$.

This number is the $n$-th **Catalan number**.

**EXAMPLES:**

```python
sage: PF = NonDecreasingParkingFunctions(0)
sage: PF.cardinality()
sage: PF = NonDecreasingParkingFunctions(1)
sage: PF.cardinality()
sage: PF = NonDecreasingParkingFunctions(3)
sage: PF.cardinality()
sage: PF = NonDecreasingParkingFunctions(5)
sage: PF.cardinality()
```

**one()**

Return the unit of this monoid.

This is the non-decreasing parking function $[1, 2, \ldots, n]$.

**EXAMPLES:**

```python
sage: ndpf = NonDecreasingParkingFunctions(5)
sage: x = ndpf.random_element(); x  # random
sage: e = ndpf.one()
sage: x == e*e == x*e
True
```

**random_element()**

Return a random parking function of the given size.

**EXAMPLES:**

```python
sage: ndpf = NonDecreasingParkingFunctions(5)
sage: x = ndpf.random_element(); x  # random
sage: in ndpf
```

**sage.combinat.non_decreasing_parking_function.is_a(x, n=None)**

Check whether a list is a non-decreasing parking function.

If a size $n$ is specified, checks if a list is a non-decreasing parking function of size $n$. 

5.1.153 $\nu$-Dyck Words

A class of the $\nu$-Dyck word, see [PRV2017] for details.

AUTHORS:

- Aram Dermenjian (2020-09-26)

This file is based off the class DyckWords written by Mike Hansen, Dan Drake, Florent Hivert, Christian Stump, Mike Zabrocki, Jean–Baptiste Priez and Travis Scrimshaw

```python
class sage.combinat.nu_dyck_word.NuDyckWord(parent, dw, latex_options=None)
    Bases: CombinatorialElement

    $\nu$-Dyck word.

    Given a lattice path $\nu$ in the $\mathbb{Z}^2$ grid starting at the origin $(0,0)$ consisting of North $N = (0,1)$ and East $E = (1,0)$ steps, a $\nu$-Dyck path is a lattice path in the $\mathbb{Z}^2$ grid starting at the origin $(0,0)$ and ending at the same coordinate as $\nu$ such that it is weakly above $\nu$. A $\nu$-Dyck word is the representation of a $\nu$-Dyck path where a North step is represented by a 1 and an East step is represented by a 0.

    INPUT:

    - k1 – A path for the $\nu$-Dyck word
    - k2 – A path for $\nu$

    EXAMPLES:
```
sage: dw = NuDyckWord([1,0,1,0],[1,0,0,1]); dw
[1, 0, 1, 0]
sage: print(dw)
NENE
sage: dw.height()
2
sage: dw = NuDyckWord('1010',[1,0,0,1]); dw
[1, 0, 1, 0]
sage: dw = NuDyckWord('NENE',[1,0,0,1]); dw
[1, 0, 1, 0]
sage: NuDyckWord([1,0,1,0],[1,0,0,1]).pretty_print()

__
|\ |
|  .|

sage: from sage.combinat.nu_dyck_word import update_ndw_symbols
sage: update_ndw_symbols(0,1)
sage: dw = NuDyckWord('0101001','0110010'); dw
[0, 1, 0, 1, 0, 0, 1]
sage: dw.pp()

__
|\ |
|  .|

sage: update_ndw_symbols(1,0)
```

5.1. Comprehensive Module List
**can_mutate(i)**

Return True/False based on if mutable at height $i$.

Can only mutate if an east step is followed by a north step at height $i$.

**OUTPUT:**

Whether we can mutate at height of $i$.

**EXAMPLES:**

```
sage: NDW = NuDyckWord('10010100','00000111')
sage: NDW.can_mutate(1)
False
sage: NDW.can_mutate(3)
5
```

**height()**

Return the height of self.

The height is the number of north steps.

**EXAMPLES:**

```
sage: NuDyckWord('1101110011010010011011000110000',
......: '1010101010101010101010101010101010').height()
17
```

**heights()**

Return the heights of each point on self.

We view the Dyck word as a Dyck path from $(0, 0)$ to $(x, y)$ in the first quadrant by letting 1’s represent steps in the direction $(0, 1)$ and 0’s represent steps in the direction $(1, 0)$.

The heights is the sequence of the $y$-coordinates of all $x + y$ lattice points along the path.

**EXAMPLES:**

```
sage: NuDyckWord('010','010').heights()
[0, 0, 1, 1]
sage: NuDyckWord('110100','101010').heights()
[0, 1, 2, 2, 3, 3, 3]
```

**horizontal_distance()**

Return a list of how far each point is from $\nu$.

**EXAMPLES:**

```
sage: NDW = NuDyckWord('10010100','00000111')
sage: NDW.horizontal_distance()
[5, 5, 4, 3, 3, 2, 2, 1, 0]
sage: NDW = NuDyckWord('10010100','00001011')
sage: NDW.horizontal_distance()
[4, 5, 4, 3, 3, 2, 2, 1, 0]
sage: NDW = NuDyckWord('10010001000','00100101001')
sage: NDW.horizontal_distance()
[2, 4, 3, 2, 3, 5, 4, 3, 3, 2, 1, 0]
```
latex_options()

Return the latex options for use in the \_latex\_ function as a dictionary.

The default values are set using the options.

- **color** – (default: black) the line color.
- **line width** – (default: \(2^{\text{'tikz_scale'}}\)) value representing the line width.
- **nu_options** – (default: 'rounded corners=1, color=red, line width=1') str to indicate what the tikz options should be for path of \(\nu\).
- **points_color** – (default: 'black') str to indicate color points should be drawn with.
- **show_grid** – (default: True) boolean value to indicate if grid should be shown.
- **show_nu** – (default: True) boolean value to indicate if \(\nu\) should be shown.
- **show_points** – (default: False) boolean value to indicate if points should be shown on path.
- **tikz_scale** – (default: 1) scale for use with the tikz package.

EXAMPLES:

```sage
sage: NDW = NuDyckWord('010', '010')
sage: NDW.latex_options()
{'color': black,
 'line width': 2,
 'nu_options': 'rounded corners=1, color=red, line width=1,
 'points_color': black,
 'show_grid': True,
 'show_nu': True,
 'show_points': False,
 'tikz_scale': 1}
```

Todo: This should probably be merged into NuDyckWord.options.

length()

Return the length of self.

The length is the total number of steps.

EXAMPLES:

```sage
sage: NDW = NuDyckWord('10011001000', '00100101001')
sage: NDW.length()
11
```

mutate(i)

Return a new \(\nu\)-Dyck Word if possible.

If at height \(i\) we have an east step E meeting a north step N then we calculate all horizontal distances from this point until we find the first point that has the same horizontal distance to \(\nu\). We let

- **d** is everything up until EN (not including EN)
- **f** be everything between N and the point with the same horizontal distance (including N)
- **g** is everything after \(f\)
See also:

`can_mutate()`

EXAMPLES:

```
sage: NDW = NuDyckWord('10010100','00000111')
sage: NDW.mutate(1)
sage: NDW.mutate(3)
[1, 0, 0, 1, 1, 0, 0, 0]
```

`path()`

Return the underlying path object.

EXAMPLES:

```
sage: NDW = NuDyckWord('10011001000','00100101001')
sage: NDW.path()
Path: 10011001000
```

`plot(**kwds)`

Plot a ν-Dyck word as a continuous path.

EXAMPLES:

```
sage: NDW = NuDyckWord('010','010')
sage: NDW.plot()
Graphics object consisting of 1 graphics primitive
```

`points()`

Return an iterator for the points on the ν-Dyck path.

EXAMPLES:

```
sage: list(NuDyckWord('110110011101001000110111100011000',
                      ....: '101010101010101010101010101010101')._path.points())

 (9, 9),
 (9, 10),
```

(continues on next page)
Display a NuDyckWord as a lattice path in the $\mathbb{Z}^2$ grid.

If the style is “N-E”, then a cell below the diagonal is indicated by a period, whereas a cell below the path but above the diagonal is indicated by an x. If a list of labels is included, they are displayed along the vertical edges of the Dyck path.

INPUT:

- **style** – (default: None) can either be:
  - None to use the option default
  - “N-E” to show self as a path of north and east steps, or
- **labelling** – (if style is “N-E”) a list of labels assigned to the up steps in self.
- **underpath** – (if style is “N-E”, default: True) If True, an x to show the boxes between $\nu$ and the $\nu$-Dyck Path.

EXAMPLES:

```python
sage: for ND in NuDyckWords('101010'): ND.pretty_print()
```
sage: nu = [1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0]

|x  .  4
|x  .  3
|x  .  2
| .  1

sage: NuDyckWord().pretty_print()

pretty_print(style=None, labelling=None)

Display a NuDyckWord as a lattice path in the $\mathbb{Z}^2$ grid.

If the style is “N-E”, then a cell below the diagonal is indicated by a period, whereas a cell below the path but above the diagonal is indicated by an x. If a list of labels is included, they are displayed along the vertical edges of the Dyck path.
INPUT:

- **style** – (default: None) can either be:
  - None to use the option default
  - “N-E” to show `self` as a path of north and east steps, or
- **labelling** – (if style is “N-E”) a list of labels assigned to the up steps in `self`.
- **underpath** – (if style is “N-E”, default: True) If True, an x to show the boxes between $\nu$ and the $\nu$-Dyck Path.

EXAMPLES:

```python
sage: for ND in NuDyckWords('101010'): ND.pretty_print()

__
| .  
| .

|x      3
|x      2
|       1

sage: NuDyckWord().pretty_print()
```

```python
set_latex_options(D)

Set the latex options for use in the _latex_ function.

The default values are set in the __init__ function.

- **color** – (default: black) the line color.
- **line width** – (default: 2 \times \text{tikz_scale}) value representing the line width.
- **nu_options** – (default: 'rounded corners=1, color=red, line width=1') str to indicate what the tikz options should be for path of \( \nu \).
- **points_color** – (default: 'black') str to indicate color points should be drawn with.
- **show_grid** – (default: True) boolean value to indicate if grid should be shown.
- **show_nu** – (default: True) boolean value to indicate if \( \nu \) should be shown.
- **show_points** – (default: False) boolean value to indicate if points should be shown on path.
- **tikz_scale** – (default: 1) scale for use with the tikz package.

**INPUT:**

- **D** – a dictionary with a list of latex parameters to change

**EXAMPLES:**

```sage
sage: NDW = NuDyckWord('010','010')
sage: NDW.set_latex_options({'tikz_scale':2})
sage: NDW.set_latex_options({'color':'blue', 'show_points':True})
```

1604 Chapter 5. Comprehensive Module List
Todo: This should probably be merged into NuDyckWord.options.

**width()**

Return the width of self.

The width is the number of east steps.

EXAMPLES:

```
sage: NuDyckWord('110111001101001000110111100011000',
       ....: '101010101010101010101010101010101').width()
16
```

**widths()**

Return the widths of each point on self.

We view the Dyck word as a Dyck path from $(0,0)$ to $(x,y)$ in the first quadrant by letting 1’s represent steps in the direction $(0,1)$ and 0’s represent steps in the direction $(1,0)$.

The widths is the sequence of the $x$-coordinates of all $x+y$ lattice points along the path.

EXAMPLES:

```
sage: NuDyckWord('010', '010').widths()
[0, 1, 1, 2]
sage: NuDyckWord('110100', '101010').widths()
[0, 0, 0, 1, 1, 2, 3]
```

```
class sage.combinat.nu_dyck_word.NuDyckWords(nu=())
Bases: Parent
ν-Dyck words.

Given a lattice path $\nu$ in the $\mathbb{Z}^2$ grid starting at the origin $(0,0)$ consisting of North $N = (0,1)$ and East $E = (1,0)$ steps, a $\nu$-Dyck path is a lattice path in the $\mathbb{Z}^2$ grid starting at the origin $(0,0)$ and ending at the same coordinate as $\nu$ such that it is weakly above $\nu$. A $\nu$-Dyck word is the representation of a $\nu$-Dyck path where a North step is represented by a 1 and an East step is represented by a 0.

INPUT:

- nu – the base lattice path.

EXAMPLES:

```
sage: NDW = NuDyckWords('1010'); NDW
[1, 0, 1, 0] Dyck words
sage: [1, 0, 1, 0] in NDW
True
sage: [1, 1, 0, 0] in NDW
True
sage: [1, 0, 0, 1] in NDW
False
sage: [0, 1, 0, 1] in NDW
False
sage: NDW.cardinality()
2
```
Element

alias of \texttt{NuDyckWord}

cardinality()

Return the number of $\nu$-Dyck words.

EXAMPLES:

```sage
NDW = NuDyckWords('1010'); NDW.cardinality()
5
NDW = NuDyckWords('101010'); NDW.cardinality()
7
NDW = NuDyckWords('10010100'); NDW.cardinality()
12
```

```python
options = Current options for NuDyckWords - ascii_art: pretty_output -
diagram_style: grid - display: list - latex_color: black -
latex_line_width_scalar: 2 - latex_nu_options: rounded corners=1, color=red, line
width=1 - latex_points_color: black - latex_show_grid: True - latex_show_nu: True -
latex_show_points: False - latex_tikz_scale: 1
```

```sage
sage.combinat.nu_dyck_word.path_weakly_above_other(path, other)
```

Test if \emph{path} is weakly above \emph{other}.

A \emph{path} $P$ is weakly above another path $Q$ if $P$ and $Q$ are the same length and if any prefix of length $n$ of $Q$ contains more North steps than the prefix of length $n$ of $P$.

INPUT:

- \texttt{path} – The path to verify is weakly above the other path.
- \texttt{other} – The other path to verify is weakly below the path.

OUTPUT:

\texttt{bool}

EXAMPLES:

```sage
from sage.combinat.nu_dyck_word import path_weakly_above_other
path_weakly_above_other('1001','0110')
False
path_weakly_above_other('1001','0101')
True
path_weakly_above_other('1111','0101')
False
path_weakly_above_other('111100','0101')
False
```

```python
sage.combinat.nu_dyck_word.replace_dyck_char(x)
```

A map sending an opening character ('1', 'N', and '(') to \texttt{ndw_open_symbol}, a closing character ('0', 'E', and ')') to \texttt{ndw_close_symbol}, and raising an error on any input other than one of the opening or closing characters.

This is the inverse map of \texttt{replace_dyck_symbol}.

INPUT:

- \texttt{x = str} - A '1', '0', 'N', 'E', '(' or ')'
OUTPUT:

- If $x$ is an opening character, replace $x$ with the constant \texttt{ndw_open_symbol}.
- If $x$ is a closing character, replace $x$ with the constant \texttt{ndw_close_symbol}.
- Raise a \texttt{ValueError} if $x$ is neither an opening nor a closing character.

See also:

\texttt{replace_dyck_symbol()}

EXAMPLES:

```
sage: from sage.combinat.nu_dyck_word import replace_dyck_char
sage: replace_dyck_char('(')
1
sage: replace_dyck_char(')')
0
sage: replace_dyck_char(1)
Traceback (most recent call last):
  ... ValueError
```

\texttt{sage.combinat.nu_dyck_word.replace_dyck_symbol(x, open_char='N', close_char='E')}

A map sending \texttt{ndw_open_symbol} to \texttt{open_char} and \texttt{ndw_close_symbol} to \texttt{close_char}, and raising an error on any input other than \texttt{ndw_open_symbol} and \texttt{ndw_close_symbol}. The values of the constants \texttt{ndw_open_symbol} and \texttt{ndw_close_symbol} are subject to change.

This is the inverse map of \texttt{replace_dyck_char()}.  

INPUT:

- $x$ – either \texttt{ndw_open_symbol} or \texttt{ndw_close_symbol}.
- \texttt{open_char} – str (optional) default 'N'
- \texttt{close_char} – str (optional) default 'E'

OUTPUT:

- If $x$ is \texttt{ndw_open_symbol}, replace $x$ with \texttt{open_char}.
- If $x$ is \texttt{ndw_close_symbol}, replace $x$ with \texttt{close_char}.
- If $x$ is neither \texttt{ndw_open_symbol} nor \texttt{ndw_close_symbol}, a \texttt{ValueError} is raised.

See also:

\texttt{replace_dyck_char()}

EXAMPLES:

```
sage: from sage.combinat.nu_dyck_word import replace_dyck_symbol
sage: replace_dyck_symbol(1)
'N'
sage: replace_dyck_symbol(0)
'E'
sage: replace_dyck_symbol(3)
Traceback (most recent call last):
  ... ValueError
```
sage.combinat.nu_dyck_word.to_word_path(word)
Convert input into a word path over an appropriate alphabet.
Helper function.

INPUT:
• word – word to convert to wordpath

OUTPUT:
• A FiniteWordPath_north_east object.

EXAMPLES:

```
sage: from sage.combinat.nu_dyck_word import to_word_path
sage: wp = to_word_path('NEENENEN'); wp
Path: 10010101
sage: from sage.combinat.words.paths import FiniteWordPath_north_east
sage: isinstance(wp,FiniteWordPath_north_east)
True
sage: to_word_path('1001')
Path: 1001
sage: to_word_path([0,1,0,0,1,0])
Path: 010010
```

sage.combinat.nu_dyck_word.update_ndw_symbols(os, cs)
A way to alter the open and close symbols from sage.

INPUT:
• os – the open symbol
• cs – the close symbol

EXAMPLES:

```
sage: from sage.combinat.nu_dyck_word import update_ndw_symbols
sage: update_ndw_symbols(0,1)
sage: dw = NuDyckWord('0101001','0110010'); dw
[0, 1, 0, 1, 0, 0, 1]
sage: dw = NuDyckWord('1010110','1001101'); dw
Traceback (most recent call last):
  ... ValueError: invalid nu-Dyck word
sage: update_ndw_symbols(1,0)
```

5.1.154 $\nu$-Tamari lattice
A class of the $\nu$-Tamari lattice, see [PRV2017] for details.
These lattices depend on one parameter $\nu$ where $\nu$ is a path of North and East steps.
The elements are $nu$-Dyck paths which are weakly above $\nu$.
To use the provided functionality, you should import $\nu$-Tamari lattices by typing:
sage: from sage.combinat.nu_tamari_lattice import NuTamariLattice

Then,

sage: NuTamariLattice([1,1,1,0,0,1,1,0])
Finite lattice containing 6 elements
sage: NuTamariLattice([0,0,0,1,1,0,0,1])
Finite lattice containing 40 elements

The classical Tamari lattices and the Generalized Tamari lattices are special cases of this construction and are also available with this poset:

sage: NuTamariLattice([1,0,1,0,1,0])
Finite lattice containing 5 elements
sage: NuTamariLattice([1,0,0,1,0,0,1,0,0])
Finite lattice containing 12 elements

See also:

For more detailed information see NuTamariLattice(). For more information on the standard Tamari lattice see sage.combinat.tamari_lattices.TamariLattice(), sage.combinat.tamari_lattices.GeneralizedTamariLattice()
sage.combinat.nu_tamari_lattice.NuTamariLattice(nu)

Return the ν-Tamari lattice.

INPUT:

• ν – a list of 0s and 1s or a string of 0s and 1s.

OUTPUT:

a finite lattice

The elements of the lattice are nu-Dyck paths weakly above ν.

The usual Tamari lattice is the special case where ν = (NE)^h where h is the height.

Other special cases give the m-Tamari lattices studied in [BMFPR].

EXAMPLES:

sage: from sage.combinat.nu_tamari_lattice import NuTamariLattice
sage: NuTamariLattice([1,0,1,0,1,0])
Finite lattice containing 7 elements
sage: NuTamariLattice([1,0,1,0,1,0])
Finite lattice containing 5 elements
sage: NuTamariLattice([1,0,1,0,1,0,1,0])
Finite lattice containing 14 elements
sage: NuTamariLattice([1,0,1,0,1,0,0,0,1])
Finite lattice containing 24 elements
5.1.155 Ordered Rooted Trees

AUTHORS:
• Florent Hivert (2010-2011): initial revision
• Frédéric Chapoton (2010): contributed some methods

class sage.combinat.ordered_tree.LabelledOrderedTree(parent, children, label=None, check=True)
Bases: AbstractLabelledClonableTree, OrderedTree

Labelled ordered trees.

A labelled ordered tree is an ordered tree with a label attached at each node.

INPUT:
• children – a list or tuple or more generally any iterable of trees or object convertible to trees
• label – any Sage object (default: None)

EXAMPLES:

```
sage: x = LabelledOrderedTree([], label = 3); x
3[

sage: LabelledOrderedTree([x, x, x], label = 2)
2[3[], 3[], 3[]]

sage: LabelledOrderedTree((x, x, x), label = 2)
2[3[], 3[], 3[]]

sage: LabelledOrderedTree([], [[], []], label = 3)
3[None[], None[None[], None[]]]
```

left_right_symmetry()

Return the symmetric tree of self.

The symmetric tree $s(T)$ of a labelled ordered tree $T$ is defined as follows: If $T$ is a labelled ordered tree with children $C_1, C_2, \ldots, C_k$ (listed from left to right), then the symmetric tree $s(T)$ of $T$ is a labelled ordered tree with children $s(C_k), s(C_{k-1}), \ldots, s(C_1)$ (from left to right), and with the same root label as $T$.

**Note:** If you have a subclass of LabelledOrderedTree() which also inherits from another subclass of OrderedTree() which does not come with a labelling, then (depending on the method resolution order) it might happen that this method gets overridden by an implementation from that other subclass, and thus forgets about the labels. In this case you need to manually override this method on your subclass.

EXAMPLES:

```
sage: L2 = LabelledOrderedTree([], label=2)
sage: L3 = LabelledOrderedTree([], label=3)
sage: T23 = LabelledOrderedTree([L2, L3], label=4)
sage: T23.left_right_symmetry()
4[3[], 2[]]

sage: T223 = LabelledOrderedTree([L2, T23], label=17)
sage: T223.left_right_symmetry()
17[4[3[], 2[]], 2[]]

sage: T223.left_right_symmetry().left_right_symmetry() == T223
True
```
sort_key()

Return a tuple of nonnegative integers encoding the labelled tree self.

The first entry of the tuple is a pair consisting of the number of children of the root and the label of the root. Then the rest of the tuple is the concatenation of the tuples associated to these children (we view the children of a tree as trees themselves) from left to right.

This tuple characterizes the labelled tree uniquely, and can be used to sort the labelled ordered trees provided that the labels belong to a type which is totally ordered.

Warning: This method overrides OrderedTree.sort_key() and returns a result different from what the latter would return, as it wants to encode the whole labelled tree including its labelling rather than just the unlabelled tree. Therefore, be careful with using this method on subclasses of LabelledOrderedTree; under some circumstances they could inherit it from another superclass instead of from OrderedTree, which would cause the method to forget the labelling. See the docstring of OrderedTree.sort_key().

EXAMPLES:

```python
sage: L2 = LabelledOrderedTree([], label=2)
sage: L3 = LabelledOrderedTree([], label=3)
sage: T23 = LabelledOrderedTree([L2, L3], label=4)
sage: T23.sort_key()
((2, 4), (0, 2), (0, 3))
sage: T32 = LabelledOrderedTree([L3, L2], label=5)
sage: T32.sort_key()
((2, 5), (0, 3), (0, 2))
sage: T23322 = LabelledOrderedTree([T23, T32, L2], label=14)
sage: T23322.sort_key()
((3, 14), (2, 4), (0, 2), (0, 3), (2, 5), (0, 3), (0, 2), (0, 2))
```

class sage.combinat.ordered_tree.LabelledOrderedTrees(category=None)

Bases: UniqueRepresentation, Parent

This is a parent stub to serve as a factory class for trees with various label constraints.

EXAMPLES:

```python
sage: LOT = LabelledOrderedTrees(); LOT
Labelled ordered trees
sage: x = LOT([], label = 3); x
3[]
sage: x.parent() is LOT
True
sage: y = LOT([x, x, x], label = 2); y
2[3[], 3[], 3[]]
sage: y.parent() is LOT
True
```

Element

alias of LabelledOrderedTree

cardinality()

Return the cardinality of self.
EXAMPLES:

```python
sage: LabelledOrderedTrees().cardinality()
+Infinity
```

**labelled_trees()**

Return the set of labelled trees associated to `self`.

This is precisely `self`, because `self` already is the set of labelled ordered trees.

**EXAMPLES:**

```python
sage: LabelledOrderedTrees().labelled_trees()
Labelled ordered trees
sage: LOT = LabelledOrderedTrees()
```

```python
sage: x = LOT([], label = 3)
sage: y = LOT([x, x, x], label = 2)
sage: y.canonical_labelling()
[2, 3, 4]
```

**unlabelled_trees()**

Return the set of unlabelled trees associated to `self`.

This is the set of ordered trees, since `self` is the set of labelled ordered trees.

**EXAMPLES:**

```python
sage: LabelledOrderedTrees().unlabelled_trees()
Ordered trees
```

**class** `sage.combinat.ordered_tree.OrderedTree(parent=None, children=None, check=True)`

Bases: `AbstractClonableTree`, `ClonableList`

The class of (ordered rooted) trees.

An ordered tree is constructed from a node, called the root, on which one has grafted a possibly empty list of trees. There is a total order on the children of a node which is given by the order of the elements in the list. Note that there is no empty ordered tree (so the smallest ordered tree consists of just one node).

**INPUT:**

One can create a tree from any list (or more generally iterable) of trees or objects convertible to a tree. Alternatively a string is also accepted. The syntax is the same as for printing: children are grouped by square brackets.

**EXAMPLES:**

```python
sage: x = OrderedTree([])
sage: x1 = OrderedTree([x,x])
sage: x2 = OrderedTree([[],[]])
sage: x1 == x2
True
sage: tt1 = OrderedTree([x,x1,x2])
sage: tt2 = OrderedTree([[], [[]], [[]], x2])
sage: tt1 == tt2
True
sage: OrderedTree([]) == OrderedTree()
True
```
is_empty()  
Return if self is the empty tree.  
For ordered trees, this always returns False.  

Note: this is different from bool(t) which returns whether t has some child or not.

EXAMPLES:

```python  
sage: t = OrderedTrees(4)([[],[[]])  
sage: t.is_empty()  
False  
sage: bool(t)  
True  
```

left_right_symmetry()  
Return the symmetric tree of self.  
The symmetric tree \( s(T) \) of an ordered tree \( T \) is defined as follows: If \( T \) is an ordered tree with children \( C_1, C_2, \ldots, C_k \) (listed from left to right), then the symmetric tree \( s(T) \) of \( T \) is the ordered tree with children \( s(C_k), s(C_{k-1}), \ldots, s(C_1) \) (from left to right).

EXAMPLES:

```python  
sage: T = OrderedTree([[],[]])  
sage: T.left_right_symmetry()  
[[[]], []]  
sage: T = OrderedTree([[], [[]], [], [][]])  
sage: T.left_right_symmetry()  
[[[[]]], [[]], [], [[]]]  
```

normalize(inplace=False)  
Return the normalized tree of self.  
INPUT:

* inplace – boolean, (default False) if True, then self is modified and nothing returned. Otherwise the normalized tree is returned.

The normalization of an ordered tree \( t \) is an ordered tree \( s \) which has the property that \( t \) and \( s \) are isomorphic as unordered rooted trees, and that if two ordered trees \( t \) and \( t' \) are isomorphic as unordered rooted trees, then the normalizations of \( t \) and \( t' \) are identical. In other words, normalization is a map from the set of ordered trees to itself which picks a representative from every equivalence class with respect to the relation of “being isomorphic as unordered trees”, and maps every ordered tree to the representative chosen from its class.

This map proceeds recursively by first normalizing every subtree, and then sorting the subtrees according to the value of the sort_key() method.

Consider the quotient map \( \pi \) that sends a planar rooted tree to the associated unordered rooted tree. Normalization is the composite \( s \circ \pi \), where \( s \) is a section of \( \pi \).

EXAMPLES:

```python  
sage: OT = OrderedTree  
sage: ta = OT([],[[]])  
sage: tb = OT([[]],[])  ```
An example with inplace normalization:

```python
sage: OT = OrderedTree
sage: ta = OT([[], [[]]])
sage: tb = OT([[[]], []])
sage: ta.normalize(inplace=True); ta
[[[], [[]]]]
sage: tb.normalize(inplace=True); tb
[[[], [[]]]]
```

`plot()`

Plot the tree `self`.

**Warning:** For a labelled tree, this will fail unless all labels are distinct. For unlabelled trees, some arbitrary labels are chosen. Use `_latex_`, `view`, `_ascii_art_` or `pretty_print` for more faithful representations of the data of the tree.

**EXAMPLES:**

```python
sage: p = OrderedTree([[[], [], []]])
sage: ascii_art(p)
  _o__
 / / /
 o o o
 | |
 o
sage: p.plot()
Graphics object consisting of 10 graphics primitives
```

Now a labelled example:

```python
sage: g = OrderedTree([[[], [[]], []]]).canonical_labelling()
sage: ascii_art(g)
  _1__
 / / /
2 3 5
 | |
4
sage: g.plot()
Graphics object consisting of 10 graphics primitives
```

`sort_key()`

Return a tuple of nonnegative integers encoding the ordered tree `self`.

The first entry of the tuple is the number of children of the root. Then the rest of the tuple is the concatenation of the tuples associated to these children (we view the children of a tree as trees themselves) from left to right.
5.1. Comprehensive Module List
This tuple characterizes the tree uniquely, and can be used to sort the ordered trees.

**Note:** By default, this method does not encode any extra structure that `self` might have – e.g., if you were to define a class `EdgeColoredOrderedTree` which implements edge-colored trees and which inherits from `OrderedTree`, then the `sort_key()` method it would inherit would forget about the colors of the edges (and thus would not characterize edge-colored trees uniquely). If you want to preserve extra data, you need to override this method or use a new method. For instance, on the `LabelledOrderedTree` subclass, this method is overridden by a slightly different method, which encodes not only the numbers of children of the nodes of `self`, but also their labels. Be careful with using overridden methods, however: If you have (say) a class `BalancedTree` which inherits from `OrderedTree` and which encodes balanced trees, and if you have another class `BalancedLabelledOrderedTree` which inherits both from `BalancedOrderedTree` and from `LabelledOrderedTree`, then (depending on the MRO) the default `sort_key()` method on `BalancedLabelledOrderedTree` (unless manually overridden) will be taken either from `BalancedTree` or from `LabelledOrderedTree`, and in the former case will ignore the labelling!

**EXAMPLES:**

```python
sage: RT = OrderedTree
dsage: RT([[],[[]]]).sort_key()
(2, 0, 1, 0)
sage: RT([[[],[]],[]]).sort_key()
(2, 1, 0, 0)
```

`to_binary_tree_left_branch()`

Return a binary tree of size $n - 1$ (where $n$ is the size of $t$, and where $t$ is `self`) obtained from $t$ by the following recursive rule:

- if $x$ is the left brother of $y$ in $t$, then $x$ becomes the left child of $y$;
- if $x$ is the last child of $y$ in $t$, then $x$ becomes the right child of $y$,

and removing the root of $t$.

**EXAMPLES:**

```python
sage: T = OrderedTree([[],[[]]])
sage: T.to_binary_tree_left_branch()
[[., .], .]
sage: T = OrderedTree([[], [[], []], [], [[], [[]]]])
sage: T.to_binary_tree_left_branch()
[[[., .], [[., .], .]], [[., .], [., .]]]
```

`to_binary_tree_right_branch()`

Return a binary tree of size $n - 1$ (where $n$ is the size of $t$, and where $t$ is `self`) obtained from $t$ by the following recursive rule:

- if $x$ is the right brother of $y$ in $t$, then $x$ becomes the right child of $y$;
- if $x$ is the first child of $y$ in $t$, then $x$ becomes the left child of $y$,

and removing the root of $t$.

**EXAMPLES:**

```python
sage: T = OrderedTree([[],[[]]])
sage: T.to_binary_tree_right_branch()
```

(continues on next page)
```
[., [. . .]]
sage: T = OrderedTree([[[], [[], []], [], [[], [], []]]])
sage: T.to_binary_tree_right_branch()
[., [[., [., .]], [[., [., .]], .]]]
```

### to_dyck_word()

Return the Dyck path corresponding to self where the maximal height of the Dyck path is the depth of self.

**EXAMPLES:**

```
sage: T = OrderedTree([[[]], []])
sage: T.to_dyck_word()
[1, 0, 1, 0]
sage: T = OrderedTree([[[]], [[]]])
sage: T.to_dyck_word()
[1, 0, 1, 1, 0, 0]
sage: T = OrderedTree([[[]], [], [[], []], [], [[], [], []]])
sage: T.to_dyck_word()
[1, 0, 1, 1, 0, 1, 1, 0, 0, 1, 1, 0, 1, 1, 0, 1, 0, 0]
```

### to_parallelogram_polyomino(bijection=None)

Return a polyomino parallelogram.

**INPUT:**

- **bijection** – (default: 'Boussicault-Socci') is the name of the bijection to use. Possible values are 'Boussicault-Socci', 'via dyck and Delest-Viennot'.

**EXAMPLES:**

```
sage: T = OrderedTree([[[]], [], [[], []], [], [[], [], []]])
sage: T.to_parallelogram_polyomino( bijection='Boussicault-Socci' )
[[0, 0, 0, 1, 1, 0, 1, 1, 1, 1, 0, 1, 1, 1], [1, 1, 1, 1, 1, 0, 0, 1, 1, 0, 1, 0, 0, 0, 0]]
sage: T = OrderedTree([])
sage: T.to_parallelogram_polyomino()
[[1]], [[1]]
sage: T = OrderedTree([])
sage: T.to_parallelogram_polyomino()
[[0, 1], [1, 0]]
sage: T = OrderedTree([])
sage: T.to_parallelogram_polyomino()
[[0, 1], [1, 0]]
sage: T = OrderedTree([])
sage: T.to_parallelogram_polyomino()
[[0, 0, 1], [1, 0, 0]]
```

### to_poset(root_to_leaf=False)

Return the poset obtained by interpreting the tree as a Hasse diagram. The default orientation is from leaves to root but you can pass root_to_leaf=True to obtain the inverse orientation.

**INPUT:**

- **root_to_leaf** – boolean, true if the poset orientation should be from root to leaves. It is false by default.
EXAMPLES:

```python
sage: t = OrderedTree([])
sage: t.to_poset()
Finite poset containing 1 elements
sage: p = OrderedTree([[[]],[[],[]]]).to_poset()
sage: p.height(), p.width()
(3, 3)
```

If the tree is labelled, we use its labelling to label the poset. Otherwise, we use the poset canonical labelling:

```python
sage: t = OrderedTree([[[]],[[],[]]]).canonical_labelling().to_poset()
sage: t.height(), t.width()
(3, 3)
```

to_undirected_graph()

Return the undirected graph obtained from the tree nodes and edges. The graph is endowed with an embedding, so that it will be displayed correctly.

EXAMPLES:

```python
sage: t = OrderedTree([])
sage: t.to_undirected_graph()
Graph on 1 vertex
sage: t = OrderedTree([[[]],[[],[]]])
sage: t.to_undirected_graph()
Graph on 5 vertices
```

If the tree is labelled, we use its labelling to label the graph. This will fail if the labels are not all distinct. Otherwise, we use the graph canonical labelling which means that two different trees can have the same graph.

EXAMPLES:

```python
sage: t = OrderedTree([[[]],[[],[]]])
sage: t.canonical_labelling().to_undirected_graph()
Graph on 5 vertices
```

```python
class sage.combinat.ordered_tree.OrderedTrees
Bases: UniqueRepresentation, Parent
Factory for ordered trees
INPUT:
• size – (optional) an integer
OUTPUT:
• the set of all ordered trees (of the given size if specified)
EXAMPLES:

sage: OrderedTrees()
Ordered trees
sage: OrderedTrees(2)
Ordered trees of size 2
```
Combinatorics, Release 10.0

Note: this is a factory class whose constructor returns instances of subclasses.

Note: the fact that OrderedTrees is a class instead of a simple callable is an implementation detail. It could be changed in the future and one should not rely on it.

leaf()

Return a leaf tree with self as parent

EXAMPLES:

```
sage: OrderedTrees().leaf()
[]
```

class sage.combinat.ordered_tree.OrderedTrees_all

Bases: DisjointUnionEnumeratedSets, OrderedTrees

The set of all ordered trees.

EXAMPLES:

```
sage: OT = OrderedTrees(); OT
Ordered trees
sage: OT.cardinality()
+Infinity
```

Element

alias of OrderedTree

labelled_trees()

Return the set of labelled trees associated to self

EXAMPLES:

```
sage: OrderedTrees().labelled_trees()
Labelled ordered trees
```

unlabelled_trees()

Return the set of unlabelled trees associated to self

EXAMPLES:

```
sage: OrderedTrees().unlabelled_trees()
Ordered trees
```

class sage.combinat.ordered_tree.OrderedTrees_size(size)

Bases: OrderedTrees

The enumerated sets of binary trees of a given size

EXAMPLES:

```
sage: S = OrderedTrees(3); S
Ordered trees of size 3
sage: S.cardinality()
```

(continues on next page)
sage: S.list()
[[[], []], []]

cardinality()

The cardinality of self

This is a Catalan number.

element_class()

The class of the element of self

EXAMPLES:

sage: from sage.combinat.ordered_tree import OrderedTrees_size, OrderedTrees_all
sage: S = OrderedTrees_size(3)
sage: S.element_class is OrderedTrees().element_class
True
sage: S.first().__class__ == OrderedTrees_all().first().__class__
True

random_element()

Return a random OrderedTree with uniform probability.

This method generates a random DyckWord and then uses a bijection between Dyck words and ordered trees.

EXAMPLES:

sage: OrderedTrees(5).random_element()  # random
[[[], []], []]
sage: OrderedTrees(0).random_element()
Traceback (most recent call last):
...
EmptySetError: there are no ordered trees of size 0
sage: OrderedTrees(1).random_element()
[]

5.1.156 Output functions

These are the output functions for latexing and ascii/unicode art versions of partitions and tableaux.

AUTHORS:

• Mike Hansen (?): initial version

• Andrew Mathas (2013-02-14): Added support for displaying conventions and lines, and tableaux of skew partition, composition, and skew/composition/partition/tableaux tuple shape.

• Travis Scrimshaw (2020-08): Added support for ascii/unicode art

sage.combinat.output.ascii_art_table(data, use_unicode=False, convention='English')

Return an ascii art table of data.

EXAMPLES:
sage: from sage.combinat.output import ascii_art_table

sage: data = [[None, None, 1], [2, 2], [3, 4, 5], [None, None, 10], [], [6]]

sage: print(ascii_art_table(data))

+----+
| 1 |
+---+---+----+
| 2 | 2 |
+---+---+----+
| 3 | 4 | 5 |
+---+---+----+
| 10 |
+----+

+---+
| 6 |
++-

sage: print(ascii_art_table(data, use_unicode=True))

+—-+
| 1 |
+—+—+—-+
| 2 | 2 |
+—+—+—-+
| 3 | 4 | 5 |
+—+—+—-+
| 10 |

+—+
| 6 |
++

sage: data = [[1, None, 2], [None, 2]]

sage: print(ascii_art_table(data))

+---+ +---+
| 1 | | 2 |
+---+---+---+
| 2 |
++-

sage: print(ascii_art_table(data, use_unicode=True))

+—+ +—+
| 1 | | 2 |
+—+—+—+
| 2 |
++

sage.combinat.output.tex_from_array(array, with_lines=True)

Return a latex string for a two dimensional array of partition, composition or skew composition shape

INPUT:

• array – a list of list

• with_lines – a boolean (default: True)

    Whether to draw a line to separate the entries in the array.
Empty rows are allowed; however, such rows should be given as [None] rather than [].

The array is drawn using either the English or French convention following \texttt{Tableaux.options}.

See also:
\texttt{tex_from_array_tuple()}

EXAMPLES:

```python
sage: from sage.combinat.output import tex_from_array
sage: print(tex_from_array(([1,2,3],[4,5])))
\begin{array}{*{3}c}
\cline{1-3}
\multicolumn{1}{|c|}{1} & \multicolumn{1}{|c|}{2} & \multicolumn{1}{|c|}{3} \\
\cline{1-3}
\multicolumn{1}{|c|}{4} & \multicolumn{1}{|c|}{5} \\
\cline{1-2}
\end{array}

sage: print(tex_from_array(([1,2,3],[4,5]), with_lines=False))
\begin{array}{*{3}c}
\multicolumn{1}{|c|}{1} & \multicolumn{1}{|c|}{2} & \multicolumn{1}{|c|}{3} \\
\multicolumn{1}{|c|}{4} & \multicolumn{1}{|c|}{5} \\
\end{array}

sage: print(tex_from_array(([1,2,3],[4,5,6,7],[8])))
\begin{array}{*{4}c}
\cline{1-3}
\multicolumn{1}{|c|}{1} & \multicolumn{1}{|c|}{2} & \multicolumn{1}{|c|}{3} \\
\cline{1-4}
\multicolumn{1}{|c|}{4} & \multicolumn{1}{|c|}{5} & \multicolumn{1}{|c|}{6} & \multicolumn{1}{|c|}{7} \\
\cline{1-4}
\multicolumn{1}{|c|}{8} \\
\cline{1-1}
\end{array}

sage: print(tex_from_array([[None,None,3],[None,5,6,7],[8]]))
\begin{array}{*{4}c}
\cline{3-3}
\multicolumn{2}{|c|}{3} \\
\cline{2-4}
\multicolumn{3}{|c|}{5} & \multicolumn{1}{|c|}{6} & \multicolumn{1}{|c|}{7} \\
\cline{1-4}
\multicolumn{1}{|c|}{8} \\
\cline{1-1}
\end{array}

sage: print(tex_from_array([[None,None,3],[None,5,6,7],[None,8]]))
(continues on next page)
sage: print(tex_from_array([[None,None,3],[None,5,6,7],[8]], with_lines=False))
\begin{array}{*{3}c}
\cline{1-1}
1
\cline{1-3}
2
\cline{1-3}
3
\end{array}

sage: print(tex_from_array([[None,None,3],[None,5,6,7],[None,8]], with_lines=False))
\begin{array}{*{3}c}
\cline{1-1}
1
\cline{1-3}
2
\cline{1-3}
3
\end{array}

sage: Tableaux.options.convention="french"

sage: print(tex_from_array([[1,2,3],[4,5]]))
\begin{array}{*{2}c}
\cline{1-2}
1
\cline{1-2}
2
\cline{1-2}
3
\end{array}

sage: print(tex_from_array([[1,2,3],[4,5]], with_lines=False))
\begin{array}{*{2}c}
\cline{1-1}
1
\cline{1-1}
2
\cline{1-1}
3
\end{array}

sage: print(tex_from_array([[1,2,3],[4,5,6,7],[8]]))
\begin{array}{*{4}c}
\cline{1-1}
1
\cline{1-4}
2
\cline{1-4}
3
\end{array}
sage: print(tex_from_array([[1,2,3],[4,5,6,7],[8]], with_lines=False))
\begin{array}\lr{8}\
\lr{4}&\lr{5}&\lr{6}&\lr{7}\n\lr{1}&\lr{2}&\lr{3}\n\end{array}

sage: print(tex_from_array([[None,None,3],[None,5,6,7],[8]]))
\begin{array}\lr{8}\
\lr{5}&\lr{6}&\lr{7}\
\lr{3}\n\end{array}

sage: print(tex_from_array([[None,None,3],[None,5,6,7],[None,8]], with_lines=False))
\begin{array}\lr{8}\
\lr{5}&\lr{6}&\lr{7}\
\lr{3}\n\end{array}

sage: print(tex_from_array([[None,None,3],[None,5,6,7],[None,8]], with_lines=True))
\begin{array}\lr{8}\
\lr{5}&\lr{6}&\lr{7}\
\lr{3}\n\end{array}

sage: Tableaux.options._reset()

sage.combinat.output.tex_from_array_tuple(a_tuple, with_lines=True)

Return a latex string for a tuple of two dimensional array of partition, composition or skew composition shape.

INPUT:
- a_tuple – a tuple of lists of lists
Combinatorics, Release 10.0

- **with_lines** – a boolean (default: True) Whether to draw lines to separate the entries in the components of `a_tuple`.

See also:

tex_from_array() for the description of each array

EXAMPLES:

sage: from sage.combinat.output import tex_from_array_tuple
sage: print(tex_from_array_tuple([[1,2,3],[4,5]], [[None, 6, 7], [None, 8], [9]]))
\begin{array}{*{3}c}
\cline{1-3}
\begin{array}{*{3}c}
\cline{1-3}
\end{array}
\end{array}, \emptyset, \begin{array}{*{3}c}
\cline{1-3}
\end{array}

sage: print(tex_from_array_tuple([[1,2,3],[4,5]], [[None, 6, 7], [None, 8], [9]], with_lines=False))
\begin{array}{*{3}c}
\cline{1-3}
\end{array}, \emptyset, \begin{array}{*{3}c}
\cline{1-3}
\end{array}

sage: Tableaux.options.convention="french"
sage: print(tex_from_array_tuple([[1,2,3],[4,5]], [[None, 6, 7], [None, 8], [9]]))
\begin{array}{*{3}c}
\cline{1-3}
\end{array}, \emptyset, \begin{array}{*{3}c}
\cline{1-3}
\end{array}

sage: print(tex_from_array_tuple([[1,2,3],[4,5]], [[None, 6, 7], [None, 8], [9]], with_lines=False))
\begin{array}{*{3}c}
\cline{1-3}
\end{array}, \emptyset, \begin{array}{*{3}c}
\cline{1-3}
\end{array}

(continues on next page)
This function creates LaTeX code for a “skew composition” array. That is, for a two-dimensional array in which each row can begin with an arbitrary number of None’s and the remaining entries could, in principle, be anything but probably should be strings or integers of similar width. A row consisting completely of None’s is allowed.

**INPUT:**
- array – The array
- with_lines – (Default: False) If True lines are drawn, if False they are not
- align – (Default: 'b') Determines the alignment on the LaTeX array environments

**EXAMPLES:**

```python
sage: array=[[None, 2, 3, 4], [None, None], [5, 6, 7, 8]]
sage: print(sage.combinat.output.tex_from_skew_array(array))
\begin{array}{cccc}
&2 &3 &4\\
&\phantom{2} &\phantom{3} &\phantom{4}\\
5 &6 &7 &8
\end{array}
```

### 5.1.157 Parallelogram Polyominoes

The goal of this module is to give some tools to manipulate the parallelogram polyominoes.

```python
class sage.combinat.parallelogram_polyomino.LocalOptions(name='', **options):
    Bases: object
    This class allows to add local options to an object. LocalOptions is like a dictionary, it has keys and values that represent options and the values associated to the option. This is useful to decorate an object with some optional informations.

    **LocalOptions** should be used as follow.

**INPUT:**
- name – The name of the LocalOptions
- <options>=dict(...) – dictionary specifying an option

The options are specified by keyword arguments with their values being a dictionary which describes the option. The allowed/expected keys in the dictionary are:
- checker – a function for checking whether a particular value for the option is valid
- default – the default value of the option
```
values – a dictionary of the legal values for this option (this automatically defines the corresponding checker); this dictionary gives the possible options, as keys, together with a brief description of them.

```python
sage: from sage.combinatparallelogram_polyomino import LocalOptions
sage: o = LocalOptions(
    'Name Example',
    delim=dict(
        default='b',
        values=dict('b': 'the option b', 'p': 'the option p'))
)

sage: class Ex:
    options = o
    def _repr_b(self):
        return 'b'
    def _repr_p(self):
        return 'p'
    def __repr__(self):
        return self.options._dispatch(self, '_repr_', 'delim')

sage: e = Ex(); e
b
sage: e.options(delim='p'); e
p
```

This class is temporary, in the future, this class should be integrated in sage.structure.global_options.py. We should split global_option in two classes LocalOptions and GlobalOptions.

**keys()**

Return the list of the options in self.

**EXAMPLES:**

```python
sage: from sage.combinatparallelogram_polyomino import (LocalOptions)

sage: o = LocalOptions(
    "Name Example",
    tikz_options=dict(
        default="toto",
        values=dict(  
            toto="name",
            x="3"
        ))
    ),
    display=dict(  
        default="list",
        values=dict(  
            list="list representation",
            diagram="diagram representation"
        )
    )
)

sage: keys = o.keys()
sage: keys.sort()
sage: keys
['display', 'tikz_options']
```
class sage.combinat.parallelgram_polyomino.ParallelogramPolyomino(parent, value, check=True)

    Bases: ClonableList

    Parallelogram Polyominoes.

    A parallelogram polyomino is a finite connected union of cells whose boundary can be decomposed in two paths, the upper and the lower paths, which are comprised of north and east unit steps and meet only at their starting and final points.

    Parallelogram Polyominoes can be defined with those two paths.

    EXAMPLES:

    sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
    sage: pp
    [[0, 1], [1, 0]]

    area()

    Return the area of the parallelogram polyomino. The area of a parallelogram polyomino is the number of cells of the parallelogram polyomino.

    EXAMPLES:

    sage: pp = ParallelogramPolyomino(
    ....:     [0, 0, 1, 0, 1, 1, 1, 0, 0, 1, 1],
    ....:     [1, 1, 0, 1, 0, 1, 1, 0, 1, 0, 0]
    ....:     )
    sage: pp.area()
    13

    sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
    sage: pp.area()
    1

    sage: pp = ParallelogramPolyomino([[1], [1]])
    sage: pp.area()
    0

    bounce(direction=1)

    Return the bounce of the parallelogram polyomino.

    Let \( p \) be the bounce path of the parallelogram polyomino (\texttt{bounce_path()}). The bounce is defined by:

    \[
    \sum \left( (1 + \text{floor}(i/2)) \cdot p[i] \right) \quad \text{for } i \in \text{range} \left( \text{len}(p) \right)
    \]

    INPUT:

    \* direction – the initial direction of the bounce path (see \texttt{bounce_path()} for the definition).

    EXAMPLES:

    sage: PP = ParallelogramPolyomino(  
    ....:     [[0, 0, 1, 0, 1, 1], [1, 1, 0, 0, 1, 0]]  
    ....:     )
    sage: PP.bounce(direction=1)
    6

    (continues on next page)
sage: PP.bounce(direction=0)
7
sage: PP = ParallelogramPolyomino(
    ....: [0, 0, 1, 1, 0, 1, 1, 0, 1],
    ....: [1, 1, 1, 0, 1, 1, 0, 0, 1])
    ....:
    ....:
    ....:
    ....: )
    ....:
sage: PP.bounce(direction=1)
12
sage: PP.bounce(direction=0)
10
sage: PP = ParallelogramPolyomino([[0, 1], [1, 0]])
    ....:
    ....:
sage: PP.bounce(direction=1)
1
sage: PP.bounce(direction=0)
1
sage: PP = ParallelogramPolyomino([[1], [1]])
    ....:
    ....:
sage: PP.bounce(direction=1)
0
sage: PP.bounce(direction=0)
0

**bounce_path**(direction=1)

Return the bounce path of the parallelogram polyomino.

The bounce path is a path with two steps (1, 0) and (0, 1).

If `direction` is 1 (resp. 0), the bounce path is the path starting at position (h=1, w=0) (resp. (h=0, w=1)) with initial direction, the vector (0, 1) (resp. (1, 0)), and turning each time the path crosses the perimeter of the parallelogram polyomino.

The path is coded by a list of integers. Each integer represents the size of the path between two turnings.

You can visualize the two bounce paths by using the following commands.

**INPUT:**

- `direction` – the initial direction of the bounce path (see above for the definition).

**EXAMPLES:**

```python
sage: PP = ParallelogramPolyomino(
    ....: [[0, 0, 1, 1, 0, 1, 1], [1, 1, 1, 0, 1, 1, 0]]
    ....: )
sage: PP.bounce_path(direction=1)
[2, 2, 1]
sage: PP.bounce_path(direction=0)
[2, 1, 1, 1]
```
Combinatorics, Release 10.0

(continued from previous page)

```python
....:     [0, 0, 1, 1, 0, 0, 1, 1],
....:     [1, 1, 1, 0, 1, 1, 0, 0]
....: )
sage: PP.bounce_path(direction=1)
[3, 1, 2, 2]
sage: PP.bounce_path(direction=0)
[2, 4, 2]
sage: PP = ParallelogramPolyomino(
....:     [[0, 0, 1, 0, 1, 1], [1, 1, 0, 0, 1, 0]]
....: )
sage: PP.set_options(
....:     drawing_components=dict(
....:         diagram = True
....:     , bounce_0 = True
....:     , bounce_1 = True
....:     )
....: )
sage: view(PP) # not tested
sage: PP = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: PP.bounce_path(direction=1)
[1]
sage: PP.bounce_path(direction=0)
[1]
sage: PP = ParallelogramPolyomino([[1], [1]])
sage: PP.bounce_path(direction=1)
[]
sage: PP.bounce_path(direction=0)
[]
```

`box_is_node(pos)`

Return True if the box contains a node in the context of the Aval-Boussicault bijection between parallelogram polyomino and binary tree.

A box is a node if there is no cell on the top of the box in the same column or on the left of the box in the same row.

INPUT:

- `pos` – the [x,y] coordinate of the box.

OUTPUT:

A boolean

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino(
....:     [[0, 0, 1, 0, 1, 1, 1, 1], [1, 1, 0, 0, 1, 1, 0, 0]]
....: )
sage: pp.set_options(display='drawing')
sage: pp
```

(continues on next page)
box_is_root(box)

Return True if the box contains the root of the tree: it is the top-left box of the parallelogram polyomino.

INPUT:

• box – the x,y coordinate of the cell.

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino([0, 0, 1, 0, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0])
sage: pp.box_is_root([0, 0])
True
sage: pp.box_is_root([0, 1])
False
```

cell_is_inside(w, h)

Determine whether the cell at a given position is inside the parallelogram polyomino.

INPUT:

• w – The x coordinate of the box position.
• h – The y coordinate of the box position.

OUTPUT:

Return 0 if there is no cell at the given position, return 1 if there is a cell.

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino([0, 1, 0, 0, 1, 1, 0, 1, 1, 1], [1, 1, 0, 1, 0, 0, 1, 1, 0])
sage: pp.cell_is_inside(0, 0)
1
sage: pp.cell_is_inside(1, 0)
1
sage: pp.cell_is_inside(0, 1)
0
```
sage: pp.cell_is_inside(3, 0)
0
sage: pp.cell_is_inside(pp.width()-1,pp.height()-1)
1
sage: pp.cell_is_inside(pp.width(),pp.height()-1)
0
sage: pp.cell_is_inside(pp.width()-1,pp.height())
0

check()
This method raises an error if the internal data of the class does not represent a parallelogram polyomino.

EXAMPLES:

sage: pp = ParallelogramPolyomino([...
      [0, 0, 0, 1, 0, 1, 0, 1, 1],
      [1, 0, 1, 1, 0, 0, 1, 0, 0]
    ])
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp = ParallelogramPolyomino([[1], [1]])

degree_convexity()

Return the degree convexity of a parallelogram polyomino.

A convex polyomino is said to be k-convex if every pair of its cells can be connected by a monotone path (path with south and east steps) with at most k changes of direction. The degree of convexity of a convex polyomino P is the smallest integer k such that P is k-convex.

If the parallelogram polyomino is empty, the function return -1.

EXAMPLES:

sage: pp = ParallelogramPolyomino(
....: [0, 0, 0, 1, 0, 1, 0, 1, 1],
....: [1, 0, 1, 1, 0, 0, 1, 0, 0]
....: )
sage: pp.degree_convexity()
3

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.degree_convexity()
0

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.degree_convexity()
-1

static from_dyck_word(dyck, bijection=None)

Convert a Dyck word to parallelogram polyomino.

INPUT:

• dyck – a Dyck word

• bijection – string or None (default:None) the bijection to use. See to_dyck_word() for more details.

OUTPUT:

A parallelogram polyomino.

EXAMPLES:
Combinatorics, Release 10.0

```
sage: dyck = DyckWord([1, 1, 0, 1, 1, 0, 1, 0, 0, 0])
sage: ParallelogramPolyomino.from_dyck_word(dyck)
[[0, 1, 0, 1, 1, 0, 1, 0, 0, 0]]
sage: ParallelogramPolyomino.from_dyck_word(dyck, bijection='Delest-Viennot')
[[0, 1, 0, 1, 1, 0, 1, 0, 0, 0]]
sage: ParallelogramPolyomino.from_dyck_word(dyck, bijection='Delest-Viennot-beta')
[[0, 0, 1, 0, 1, 1, 1, 0, 0, 0]]
```

**geometry()**

Return a pair \([h, w]\) containing the height and the width of the parallelogram polyomino.

**EXAMPLES:**

```
sage: pp = ParallelogramPolyomino(
    ....:     [[0, 1, 1, 1, 1], [1, 1, 1, 1, 0]])
sage: pp.geometry()
[1, 4]
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.geometry()
[1, 1]
sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.geometry()
[0, 1]
```

**get_BS_nodes()**

Return the list of cells containing node of the left and right planar tree in the Boussicault-Socci bijection.

**EXAMPLES:**

```
sage: pp = ParallelogramPolyomino(
    ....:     [[0, 0, 1, 0, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0]])
sage: pp.set_options(display='drawing')
sage: pp
[[1 1 0]
 [1 1 1]
 [0 1 1]
 [0 1 1]
 [0 1 1]]
sage: sorted(pp.get_BS_nodes())
[[0, 1], [1, 0], [1, 2], [2, 1], [3, 1], [4, 1]]
```

You can draw the point inside the parallelogram polyomino by typing (the left nodes are in blue, and the right node are in red)

```
sage: pp.set_options(drawing_components=dict(tree=True))
sage: view(pp) # not tested
```

**get_array()**

Return an array of 0s and 1s such that the 1s represent the boxes of the parallelogram polyomino.

---

5.1. Comprehensive Module List 1635
EXAMPLES:

```python
sage: pp = ParallelogramPolyomino(
    ....:     [0, 0, 0, 0, 1, 0, 1, 0, 1],
    ....:     [1, 0, 0, 0, 1, 1, 0, 0, 0]
    ....:     )
sage: matrix(pp.get_array())
[[1 0 0]
 [1 0 0]
 [1 0 0]
 [1 1 1]
 [0 1 1]
 [0 0 1]]

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])

sage: pp.get_array()
[[1]]

sage: pp = ParallelogramPolyomino([[1], [1]])

sage: pp.get_array()
[]
```

`get_left_BS_nodes()`

Return the list of cells containing node of the left planar tree in the Boussicault-Socci bijection between parallelogram polyominoes and pair of ordered trees.

OUTPUT:

A list of [row,column] position of cells.

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino(
    ....:     [[0, 0, 1, 0, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0]]
    ....:     )

sage: pp.set_options(display='drawing')

sage: pp
[1 0 0]
[1 1 1]
[0 1 1]
[0 1 1]

sage: sorted(pp.get_left_BS_nodes())
[[0, 1], [2, 1], [3, 1], [4, 1]]

sage: pp = ParallelogramPolyomino(
    ....:     [[0, 0, 1, 0, 0, 0, 1, 1], [1, 0, 1, 1, 0, 0, 0, 0]]
    ....:     )

sage: pp.set_options(display='drawing')

sage: pp
[1 0 0]
[1 1 1]
[0 1 1]
```

(continues on next page)
You can draw the point inside the parallelogram polyomino by typing (the left nodes are in blue, and the right node are in red)

```python
sage: pp.set_options(drawing_components=dict(tree=True))
sage: view(pp)  # not tested
```

**get_node_position_from_box** *(box_position, direction, nb_crossed_nodes=None)*

This function starts from a cell inside a parallelogram polyomino and a direction.

If **direction** is equal to 0, the function selects the column associated with the y-coordinate of **box_position** and then returns the topmost cell of the column that is on the top of **box_position** (the cell of **box_position** is included).

If **direction** is equal to 1, the function selects the row associated with the x-coordinate of **box_position** and then returns the leftmost cell of the row that is on the left of **box_position**. (the cell of **box_position** is included).

This function updates the entry of **nb_crossed_nodes**. The function increases the entry of **nb_crossed_nodes** by the number of boxes that is a node (see **box_is_node**) located on the top if **direction** is 0 (resp. on the left if **direction** is 1) of **box_position** (cell at **box_position** is excluded).

**INPUT:**

- **box_position** – the position of the starting cell.
- **direction** – the direction (0 or 1).
- **nb_crossed_nodes** – [0] (default) a list containing just one integer.

**OUTPUT:**

A [row, column] position of the cell.

**EXAMPLES:**

```python
sage: pp = ParallelogramPolyomino(
    ....:     [[0, 0, 1, 0, 0, 0, 1, 1],
    ....:      [1, 0, 1, 1, 0, 0, 0, 0]]
    ....: )
sage: matrix(pp.get_array())
[1 0 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
sage: l = [0]
sage: pp.get_node_position_from_box([3, 2], 0, l)
[1, 2]
sage: l
[1]
sage: l = [0]
sage: pp.get_node_position_from_box([3, 2], 1, l)
```

(continues on next page)

```
[3, 1]
sage: l
[1]
sage: l = [0]
sage: pp.get_node_position_from_box([1, 2], 0, l)
[1, 2]
sage: l
[0]
sage: l = [0]
sage: pp.get_node_position_from_box([1, 2], 1, l)
[1, 0]
sage: l
[2]
sage: l = [0]
sage: pp.get_node_position_from_box([3, 1], 0, l)
[1, 1]
sage: l
[2]
sage: l = [0]
sage: pp.get_node_position_from_box([3, 1], 1, l)
[3, 1]
sage: l
[0]
```

**get_options()**

Return all the options of the object.

**EXAMPLES:**

```
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.get_options()
Current options for ParallelogramPolyominoes_size
- display: 'list'
- drawing_components: {'bounce_0': False, 'bounce_1': False, 'bounce_values': False, 'diagram': True, 'tree': False}
- latex: 'drawing'
- tikz_options: {'color_bounce_0': 'red', 'color_bounce_1': 'blue', 'color_line': 'black', 'color_point': 'black', 'line_size': 1, 'mirror': None, 'point_size': 3.5, 'rotation': 0, 'scale': 1, 'translation': [0, 0]}
```

**get_right_BS_nodes()**

Return the list of cells containing node of the right planar tree in the Boussicault-Socci bijection between parallelogram polyominoes and pair of ordered trees.
EXAMPLES:

```python
sage: pp = ParallelogramPolyomino(
    ....:     [[0, 0, 1, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0]],
    ....: )
sage: pp.set_options(display='drawing')
sage: pp

[[1 1 0]
 [1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]]
sage: sorted(pp.get_right_BS_nodes())
[[1, 0], [1, 2]]

sage: pp = ParallelogramPolyomino(
    ....:     [[0, 0, 1, 0, 0, 1, 1], [1, 0, 1, 1, 0, 0, 0, 0]],
    ....: )
sage: pp.set_options(display='drawing')
sage: pp

[[1 0 0]
 [1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]]
sage: sorted(pp.get_right_BS_nodes())
[[1, 0], [1, 1], [1, 2], [2, 1], [3, 1], [4, 1]]
```

You can draw the point inside the parallelogram polyomino by typing, (the left nodes are in blue, and the right node are in red)

```python
sage: pp.set_options(drawing_components=dict(tree=True))
sage: view(pp) # not tested
```

**get_tikz_options()**

Return all the tikz options permitting to draw the parallelogram polyomino.

See `LocalOption` to have more informations about the modification of those options.

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.get_tikz_options()
{'color_bounce_0': 'red',
 'color_bounce_1': 'blue',
 'color_line': 'black',
 'color_point': 'black',
 'line_size': 1,
 'mirror': None,
 'point_size': 3.5,
 'rotation': 0,
 'scale': 1,
 'translation': [0, 0]}
```

**height()**
Return the height of the parallelogram polyomino.

EXAMPLES:

```sage
sage: pp = ParallelogramPolyomino(
    ....:     
    ....:         [0, 1, 0, 0, 1, 1, 0, 1, 1, 1],
    ....:         [1, 1, 1, 0, 1, 0, 0, 1, 1, 0]
    ....:     )
sage: pp.height()
    4
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.height()
    1
sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.height()
    0
```

heights()

Return a list of heights of the parallelogram polyomino.

Namely, the parallelogram polyomino is split column by column and the method returns the list containing the sizes of the columns.

EXAMPLES:

```sage
sage: pp = ParallelogramPolyomino(
    ....:     
    ....:         [0, 0, 0, 1, 0, 1, 0, 1, 1],
    ....:         [1, 0, 1, 1, 0, 0, 1, 0, 0]
    ....:     )
sage: pp.heights()
    [3, 3, 4, 2]
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.heights()
    [1]
sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.heights()
    [0]
```

is_flat()

Return whether the two bounce paths join together in the rightmost cell of the bottom row of P.

EXAMPLES:

```sage
sage: pp = ParallelogramPolyomino(
    ....:     
    ....:         [0, 0, 0, 1, 0, 1, 0, 1, 1],
    ....:         [0, 0, 0, 1, 0, 1, 0, 1, 1]
    ....:     )
```

(continues on next page)
is_k_directed($k$)
Return whether the Polyomino Parallelogram is $k$-directed.

A convex polyomino is said to be $k$-convex if every pair of its cells can be connected by a monotone path (path with south and east steps) with at most $k$ changes of direction.

The degree of convexity of a convex polyomino $P$ is the smallest integer $k$ such that $P$ is $k$-convex.

INPUT:

- $k$ – An non negative integer.

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino([ [0, 1, 0, 1, 0, 1, 0, 1, 1],
                                 [0, 0, 0, 1, 0, 0, 1, 0, 0]]
sage: pp.is_k_directed(3)
True
sage: pp.is_k_directed(4)
True
sage: pp.is_k_directed(5)
True
sage: pp.is_k_directed(0)
False
sage: pp.is_k_directed(1)
False
sage: pp.is_k_directed(2)
False
sage: pp = ParallelogramPolyomino([ [0, 1], [1, 0]])
```

(continues on next page)
sage: pp.is_k_directed(0)
True
sage: pp.is_k_directed(1)
True

lower_heights()

Return the list of heights associated to each vertical step of the parallelogram polyomino’s lower path.

OUTPUT:
A list of integers.

EXAMPLES:

sage: ParallelogramPolyomino([[0, 1], [1, 0]]).lower_heights()
[1]
sage: ParallelogramPolyomino(
    ....:   [[0, 0, 1, 1, 0, 1, 1, 1], [1, 0, 1, 1, 0, 1, 1, 0]]
    ....: ).lower_heights()
[2, 2, 3, 3, 3]

lower_path()

Get the lower path of the parallelogram polyomino.

EXAMPLES:

sage: lower_path = [0, 0, 1, 0, 1, 1]
sage: upper_path = [1, 1, 0, 1, 0, 0]
sage: pp = ParallelogramPolyomino([lower_path, upper_path])
sage: pp.lower_path()
[0, 0, 1, 0, 1, 1]

lower_widths()

Return the list of widths associated to each horizontal step of the parallelogram polyomino’s lower path.

OUTPUT:
A list of integers.

EXAMPLES:

sage: ParallelogramPolyomino([[0, 1], [1, 0]]).lower_widths()
[0]
sage: ParallelogramPolyomino(
    ....:   [[0, 0, 1, 1, 0, 1, 1, 1], [1, 0, 1, 1, 0, 1, 1, 0]]
    ....: ).lower_widths()
[0, 0, 2]

plot()

Return a plot of self.

EXAMPLES:

sage: pp = ParallelogramPolyomino([[0,1],[1,0]])
sage: pp.plot()
Graphics object consisting of 4 graphics primitives
\begin{verbatim}
sage: pp.set_options(drawing_components=dict(diagram=True, bounce_0=True, bounce_1=True, bounce_values=0))
sage: pp.plot()
Graphics object consisting of 7 graphics primitives

\textbf{reflect()}

Return the parallelogram polyomino obtained by switching rows and columns.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: pp = ParallelogramPolyomino([[0,0,0,0,1,1,0,1,0,1], [1,0,1,0,0,1,1,0,0,0]])
sage: pp.heights(), pp.upper_heights()
([4, 3, 2, 3], [0, 1, 3, 3])
sage: pp = pp.reflect()
sage: pp.widths(), pp.lower_widths()
([4, 3, 2, 3], [0, 1, 3, 3])
\end{verbatim}

\begin{verbatim}
sage: pp = ParallelogramPolyomino([[0,0,0,1,1], [1,0,0,1,0]])
sage: ascii_art(pp)
*
*
**
sage: ascii_art(pp.reflect())
***
**
*
\end{verbatim}

\textbf{rotate()}

Return the parallelogram polyomino obtained by rotation of 180 degrees.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: pp = ParallelogramPolyomino([[0,0,0,1,1], [1,0,0,1,0]])
sage: ascii_art(pp)
*
*
**
sage: ascii_art(pp.rotate())
**
*
*
\end{verbatim}

\textbf{set_options(*get_value, **set_value)}

Set new options to the object. See \textit{LocalOptions} for more info.

\textbf{EXAMPLES:}
\end{verbatim}
.. code-block:: python

    sage: pp = ParallelogramPolyomino(
    ....:     [0, 0, 0, 0, 1, 0, 1, 0],
    ....:     [1, 0, 0, 0, 1, 1, 0, 0]
    ....: )
    sage: pp
    [[0, 0, 0, 0, 1, 0, 1, 0], [1, 0, 0, 0, 1, 1, 0, 0]]
    sage: pp.set_options(display='drawing')
    sage: pp
    [1 0 0]
    [1 0 0]
    [1 1 1]
    [0 1 1]
    [0 0 1]

    sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
    sage: view(pp)  # not tested
    sage: pp.set_options(
    ....:     drawing_components=dict(
    ....:         diagram = True,
    ....:         bounce_0 = True,
    ....:         bounce_1 = True,
    ....:     )
    ....: )
    sage: view(pp)  # not tested

**size()**

Return the size of the parallelogram polyomino.

The size of a parallelogram polyomino is its half-perimeter.

**EXAMPLES:**

    sage: pp = ParallelogramPolyomino(
    ....:     [[0, 0, 0, 0, 1, 0, 1, 1],
    ....:      [1, 0, 0, 0, 1, 1, 0, 0]]
    ....: )
    sage: pp.size()
    8
    sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
    sage: pp.size()
    2
    sage: pp = ParallelogramPolyomino([[1], [1]])
    sage: pp.size()
    1

**to_binary_tree(bijection=None)**

Convert to a binary tree.

**INPUT:**

* bijectio – string or None (default=None) The name of bijection to use for the conversion.
The possible values are None or 'Aval-Boussicault'. The None value is equivalent to 'Aval-Boussicault'.

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino(
    ....: [0, 0, 1, 0, 1, 0, 1, 0, 1, 1],
    ....: [1, 1, 0, 1, 1, 0, 0, 0, 1, 0]
    ....: )

sage: pp.to_binary_tree()
[[., .], [[., .], .]]

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])

sage: pp.to_binary_tree()
[., .]

sage: pp = ParallelogramPolyomino([[1], [1]])

sage: pp.to_binary_tree()
.
```

to_dyck_word(bijection=None)

Convert to a Dyck word.

INPUT:

- bijection - string or None (default: None) The name of the bijection. If it is set to None then the 'Delest-Viennot' bijection is used. Expected values are None, 'Delest-Viennot', or 'Delest-Viennot-beta'.

OUTPUT:

a Dyck word

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino([[0, 1, 0, 0, 1, 1], [1, 1, 1, 0, 0, 0]])

sage: pp.to_dyck_word()
[1, 1, 0, 1, 1, 0, 1, 0, 0, 0]

sage: pp.to_dyck_word(bijection='Delest-Viennot')
[1, 1, 0, 1, 1, 0, 1, 0, 0, 0]

sage: pp.to_dyck_word(bijection='Delest-Viennot-beta')
[1, 0, 1, 1, 1, 0, 1, 0, 0, 0]
```

to_ordered_tree(bijection=None)

Return an ordered tree from the parallelogram polyomino.

Different bijections can be specified.

The bijection 'via dyck and Delest-Viennot' is the composition of _to_dyck_delest_viennot() and the classical bijection between dyck paths and ordered trees.

The bijection between Dyck Word and ordered trees is described in [DerZak1980] (See page 12 and 13 and Figure 3.1).

The bijection 'Boussicault-Socci' is described in [BRS2015].

INPUT:
• **bijection** — string or None (default: None) The name of bijection to use for the conversion. The possible value are None, 'Boussicault-Socci' or 'via dyck and Delest-Viennot'. The None value is equivalent to the 'Boussicault-Socci' value.

EXAMPLES:

```python
to_tikz()
Return the tikz code of the parallelogram polyomino.
This code is the code present inside a tikz latex environment.
We can modify the output with the options.
EXAMPLES:

```
(continued from previous page)

\draw[color=black, line width=1] (2.000000, 6.000000) -- (2.000000, 2.000000);
\draw[color=black, line width=1] (3.000000, 6.000000) -- (3.000000, 0.000000);
\draw[color=black, line width=1] (4.000000, 4.000000) -- (4.000000, 0.000000);
\draw[color=black, line width=1] (5.000000, 4.000000) -- (5.000000, 0.000000);
\draw[color=black, line width=1] (0.000000, 5.000000) -- (3.000000, 5.000000);
\draw[color=black, line width=1] (0.000000, 4.000000) -- (5.000000, 4.000000);
\draw[color=black, line width=1] (0.000000, 3.000000) -- (5.000000, 3.000000);
\draw[color=black, line width=1] (2.000000, 2.000000) -- (6.000000, 2.000000);
\draw[color=black, line width=1] (3.000000, 1.000000) -- (6.000000, 1.000000);
sage: pp.set_options(
    drawing_components=dict(
        diagram=True,
        tree=True,
        bounce_0=True,
        bounce_1=True
    )
)
sage: print(pp.to_tikz())

\draw[color=black, line width=1] (0.000000, 6.000000) -- (0.000000, 3.000000);

\draw[color=black, line width=1] (3.000000, 1.000000) -- (6.000000, 1.000000);

(continues on next page)

5.1. Comprehensive Module List 1647
upper_heights()  
Return the list of heights associated to each vertical step of the parallelogram polyomino’s upper path.

OUTPUT:
A list of integers.

EXAMPLES:

```
sage: ParallelogramPolyomino([[0, 1], [1, 0]]).upper_heights()
[0]
sage: ParallelogramPolyomino(
       ....: [[0, 0, 1, 1, 0, 1, 1, 0],
       ....:  [1, 0, 1, 1, 0, 1, 1, 0]]
       ....: ).upper_heights()
[0, 1, 1, 2, 2]
```

upper_path()  
Get the upper path of the parallelogram polyomino.

EXAMPLES:
Combinatorics, Release 10.0

```python
sage: lower_path = [0, 0, 1, 0, 1, 1]
sage: upper_path = [1, 1, 0, 1, 0, 0]
sage: pp = ParallelogramPolyomino([lower_path, upper_path])
sage: pp.upper_path()
[1, 1, 0, 1, 0, 0]
```

**upper_widths()**

Return the list of widths associated to each horizontal step of the parallelogram polyomino's upper path.

OUTPUT:

A list of integers.

EXAMPLES:

```python
sage: ParallelogramPolyomino([[0, 1], [1, 0]]).upper_widths()
[1]
sage: ParallelogramPolyomino(
    ....:     [[0, 0, 1, 1, 0, 1, 1, 1], [1, 0, 1, 1, 0, 1, 1, 0]]
    ....: ).upper_widths()
[1, 3, 5]
```

**width()**

Return the width of the parallelogram polyomino.

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino(
    ....:     [0, 0, 0, 1, 0, 1, 0, 1, 1],
    ....:     [1, 1, 1, 0, 1, 0, 0, 1, 1, 0]
    ....: )
sage: pp.width()
6
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.width()
1
sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.width()
1
```

**widths()**

Return a list of the widths of the parallelogram polyomino.

Namely, the parallelogram polyomino is split row by row and the method returns the list containing the sizes of the rows.

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino(
    ....:     [
    ....:         [0, 0, 0, 1, 0, 1, 0, 1, 1],
    ....:         [1, 1, 1, 0, 1, 0, 0, 1, 1, 0]
    ....:     ]
    ....: )
```

(continues on next page)
sage.combinat.parallelgram_polyomino.ParallelogramPolyominoes(size=None, policy=None)

Return a family of parallelogram polyominoes enumerated with the parameter constraints.

INPUT:

• size – integer (default: None), the size of the parallelogram
  polyominoes contained in the family. If set to None, the family returned contains all the parallelogram
  polyominoes.

EXAMPLES:

sage: PPS = ParallelogramPolyominoes(size=4)
sage: PPS
Parallelogram polyominoes of size 4
sage: sorted(PPS)
[[[0, 0, 0, 1], [1, 0, 0, 0]],
 [0, 0, 1, 1], [1, 0, 1, 0]],
 [[0, 0, 1, 1], [1, 1, 0, 0]],
 [[0, 1, 0, 1], [1, 1, 0, 0]],
 [[0, 1, 1, 1], [1, 1, 1, 0]]]

sage: PPS = ParallelogramPolyominoes()
sage: PPS
Parallelogram polyominoes
sage: PPS.cardinality()+Infinity

sage: PPS = ParallelogramPolyominoes(size=None)
sage: PPS
Parallelogram polyominoes
sage: PPS.cardinality()+Infinity

class sage.combinat.parallelgram_polyomino.ParallelogramPolyominoesFactory

Bases: SetFactory

The parallelogram polyominoes factory.

EXAMPLES:
Combinatorics, Release 10.0

sage: PPS = ParallelogramPolyominoes(size=4)
sage: PPS
Parallelogram polyominoes of size 4
sage: sorted(PPS)
[[[0, 0, 0, 1], [1, 0, 0, 0]],
 [[[0, 0, 1, 1], [1, 0, 1, 0]],
 [[[0, 0, 1, 1], [1, 1, 0, 0]],
 [[[0, 1, 1, 1], [1, 1, 1, 0]]]

sage: PPS = ParallelogramPolyominoes()
sage: PPS
Parallelogram polyominoes
sage: PPS.cardinality()
+Infinity

sage.combinat.parallelogram_polyomino.ParallelogramPolyominoesOptions = Current options for ParallelogramPolyominoes size - display: 'list' - drawing_components: {'bounce_0': False, 'bounce_1': False, 'bounce_values': False, 'diagram': True, 'tree': False} - latex: 'drawing' - tikz_options: {'color_bounce_0': 'red', 'color_bounce_1': 'blue', 'color_line': 'black', 'color_point': 'black', 'line_size': 1, 'mirror': None, 'point_size': 3.5, 'rotation': 0, 'scale': 1, 'translation': [0, 0]}

This global option contains all the data needed by the Parallelogram classes to draw, display in ASCII, compile in latex a parallelogram polyomino.
The available options are:

- tikz_options: this option configure all the information useful to generate TIKZ code. For example, color, line size, etc ...

- drawing_components: this option is used to explain to the system which component of the drawing you want to draw. For example, you can ask to draw some elements of the following list: - the diagram, - the tree inside the parallelogram polyomino, - the bounce paths inside the parallelogram polyomino, - the value of the bounce on each square of a bounce path.

- display: this option is used to configure the ASCII display. The available options are: - list: (this is the default value) is used to represent PP as a list containing the upper and lower path. - drawing: this value is used to explain we want to display an array with the PP drawn inside (with connected 1).

- latex: Same as display. The default is “drawing”.

See ParallelogramPolyomino.get_options() for more details and for an user use of options.

EXAMPLES:

sage: from sage.combinat.parallelogram_polyomino import (.....: ParallelogramPolyominoesOptions.....:)sage: opt = ParallelogramPolyominoesOptions['tikz_options']sage: opt
{'color_bounce_0': 'red',
 'color_bounce_1': 'blue',
 'color_line': 'black',
 'color_point': 'black',
 'line_size': 1,
Combinatorics, Release 10.0

(continued from previous page)

```python
'mirror': None,
'point_size': 3.5,
'rotation': 0,
'scale': 1,
'translation': [0, 0]}
```

class sage.combinat.parallelogram_polyomino.ParallelogramPolyominoes_all(policy)

Bases: ParentWithSetFactory, DisjointUnionEnumeratedSets

This class enumerates all the parallelogram polyominoes.

EXAMPLES:

```python
sage: PPS = ParallelogramPolyominoes()
sage: PPS
Parallelogram polyominoes
```

def check_element(el, check)

Check is a given element `el` is in the set of parallelogram polyominoes.

EXAMPLES:

```python
sage: PPS = ParallelogramPolyominoes()
sage: ParallelogramPolyomino(  # indirect doctest
    [[0, 1, 1], [1, 1, 0]])
in PPS
True
```

def get_options()

Return all the options associated with the set of parallelogram polyominoes.

EXAMPLES:

```python
sage: PPS = ParallelogramPolyominoes()
sage: options = PPS.get_options()
sage: options
Current options for ParallelogramPolyominoes_size - display: 'list' -
drawing_components: {'bounce_0': False, 'bounce_1': False, 'bounce_values': False, 'diagram': True, 'tree': False} - latex: 'drawing' - tikz_options: {'color_bounce_0': 'red', 'color_bounce_1': 'blue', 'color_line': 'black', 'color_point': 'black', 'line_size': 1, 'mirror': None, 'point_size': 3.5, 'rotation': 0, 'scale': 1, 'translation': [0, 0]}
```

set_options(*get_value, **set_value)

Set new options to the object.

EXAMPLES:
sage: PPS = ParallelogramPolyominoes()
sage: PPS.set_options(
    drawing_components=dict(  
        diagram = True,
        bounce_0 = True,
        bounce_1 = True,
    )
)
sage: pp = next(iter(PPS))
sage: view(pp)  # not tested

class sage.combinat.parallelogram_polyomino.ParallelogramPolyominoes_size(size, policy)
Bases: ParentWithSetFactory, UniqueRepresentation

The parallelogram polyominoes of size $n$.

EXAMPLES:

sage: PPS = ParallelogramPolyominoes(4)
sage: PPS
Parallelogram polyominoes of size 4
sage: sorted(PPS)
[[[0, 0, 0, 1], [1, 0, 0, 0]],
 [[0, 0, 1, 1], [1, 0, 1, 0]],
 [[0, 0, 1, 1], [1, 1, 0, 0]],
 [[0, 1, 0, 1], [1, 1, 0, 0]],
 [[0, 1, 1, 1], [1, 1, 1, 0]]]

an_element()
Return an element of a parallelogram polyomino of a given size.

EXAMPLES:

sage: PPS = ParallelogramPolyominoes(4)
sage: PPS.an_element() in PPS
True

cardinality()
Return the number of parallelogram polyominoes.

The number of parallelogram polyominoes of size $n$ is given by the Catalan number $c_{n-1}$.

EXAMPLES:

sage: ParallelogramPolyominoes(1).cardinality()
1
sage: ParallelogramPolyominoes(2).cardinality()
1
sage: ParallelogramPolyominoes(3).cardinality()
2
sage: ParallelogramPolyominoes(4).cardinality()
5
sage: all(  
    ....:     ParallelogramPolyominoes(i).cardinality()  
    ....:     for i in range(1, 5)  
)  
True
Combinatorics, Release 10.0

(continued from previous page)

```python
....:   == len(list(ParallelogramPolyominoes(i)))
....:   for i in range(1,7)
....:
True
```

**check_element**(el, check)

Check is a given element `el` is in the set of parallelogram polyominoes of a fixed size.

**EXAMPLES:**

```python
sage: PPS = ParallelogramPolyominoes(3)
sage: ParallelogramPolyomino([0, 1, 1], [1, 1, 0]) in PPS
True
```

**get_options()**

Return all the options associated with all the elements of the set of parallelogram polyominoes with a fixed size.

**EXAMPLES:**

```python
sage: pps = ParallelogramPolyominoes(5)
sage: pps.get_options()
Current options for ParallelogramPolyominoes_size - display: 'list'
- drawing_components: {'bounce_0': False, 'bounce_1': False, 'bounce_values': False, 'diagram': True, 'tree': False} - latex: 'drawing' - tikz_options: {'color_bounce_0': 'red', 'color_bounce_1': 'blue', 'color_line': 'black', 'color_point': 'black', 'line_size': 1, 'mirror': None, 'point_size': 3.5, 'rotation': 0, 'scale': 1, 'translation': [0, 0]}
```

The options for ParallelogramPolyominoes.

**set_options(** *get_value*, **set_value**)**

Set new options to the object.

**EXAMPLES:**

```python
sage: PPS = ParallelogramPolyominoes(3)
sage: PPS.set_options(
....:   drawing_components=dict(
....:       diagram = True,
....:       bounce_0 = True,
....:       bounce_1 = True,
....:   )
....: )
sage: pp = PPS[0]
sage: view(pp) # not tested
```

**size()**

Return the size of the parallelogram polyominoes generated by this parent.
**EXAMPLES:**

```
sage: ParallelogramPolyominoes(0).size()
sage: ParallelogramPolyominoes(1).size()
sage: ParallelogramPolyominoes(5).size()
```

```
sage.combinat.parallelogram_polyomino.default_tikz_options = {'color_bounce_0': 'red',
'color_bounce_1': 'blue', 'color_line': 'black', 'color_point': 'black', 'line_size':
1, 'mirror': None, 'point_size': 3.5, 'rotation': 0, 'scale': 1, 'translation': [0, 0]}
```

This is the default TIKZ options.

This option is used to configure element of a drawing to allow TIKZ code generation.

**5.1.158 Parking Functions**

INFORMALLY (reference [Beck]):

Imagine a one-way cul-de-sac with $n$ parking spots. We will give the first parking spot the number 1, the next one number 2, etc., down to the last one, number $n$. Initially they are all free, but there are $n$ cars approaching the street, and they would all like to park there. To make life interesting, every car has a parking preference, and we record the preferences in a sequence; For example, if $n = 3$, the sequence $(2, 1, 1)$ means that the first car would like to park at spot number 2, the second car prefers parking spot number 1, and the last car would also like to part at number 1. The street is very narrow, so there is no way to back up. Now each car enters the street and approaches its preferred parking spot; if it is free, it parks there, and if not, it moves down the street to the first available spot. We call a sequence a parking function (of length $n$) if all cars end up finding a parking spot. For example, the sequence $(2, 1, 1)$ is a parking sequence (of length 3), whereas the sequence $(2, 3, 2)$ is not.

FORMALLY:

A parking function of size $n$ is a sequence $(a_1, \ldots, a_n)$ of positive integers such that if $b_1 \leq b_2 \leq \cdots \leq b_n$ is the increasing rearrangement of $a_1, \ldots, a_n$, then $b_i \leq i$.

A parking function of size $n$ is a pair $(L, D)$ of two sequences $L$ and $D$ where $L$ is a permutation and $D$ is an area sequence of a Dyck path of size $n$ such that $D[i] \geq 0$, $D[i+1] \leq D[i] + 1$ and if $D[i+1] = D[i] + 1$ then $L[i+1] > L[i]$. The number of parking functions of size $n$ is equal to the number of rooted forests on $n$ vertices and is equal to $(n+1)^{n-1}$.

```

alias of ParkingFunction

```
class sage.combinat.parking_functions.ParkingFunction(parent, lst)
```

Bases: ClonableArray

A Parking Function.

A parking function of size $n$ is a sequence $(a_1, \ldots, a_n)$ of positive integers such that if $b_1 \leq b_2 \leq \cdots \leq b_n$ is the increasing rearrangement of $a_1, \ldots, a_n$, then $b_i \leq i$.  

5.1. Comprehensive Module List 1655
A parking function of size $n$ is a pair $(L, D)$ of two sequences $L$ and $D$ where $L$ is a permutation and $D$ is an area sequence of a Dyck Path of size $n$ such that $D[i] \geq 0$, $D[i + 1] \leq D[i] + 1$ and if $D[i + 1] = D[i] + 1$ then $L[i + 1] > L[i]$.

The number of parking functions of size $n$ is equal to the number of rooted forests on $n$ vertices and is equal to $(n + 1)^{n-1}$.

**INPUT:**
- `pf` – (default: None) a list whose increasing rearrangement satisfies $b_i \leq i$
- `labelling` – (default: None) a labelling of the Dyck path
- `area_sequence` – (default: None) an area sequence of a Dyck path
- `labelled_dyck_word` – (default: None) a Dyck word with 1’s replaced by labelling

**OUTPUT:**
A parking function

**EXAMPLES:**

```python
sage: ParkingFunction([])
[]
sage: ParkingFunction([1])
[1]
sage: ParkingFunction([2])
Traceback (most recent call last):
  ... ValueError: [2] is not a parking function	sage: ParkingFunction([1,2])
[1, 2]
sage: ParkingFunction([1,1,2])
[1, 1, 2]
sage: ParkingFunction([1,4,1])
Traceback (most recent call last):
  ... ValueError: [1, 4, 1] is not a parking function	sage: ParkingFunction(labelling=[3,1,2], area_sequence=[0,0,1])
[2, 2, 1]
sage: ParkingFunction([2,2,1]).to_labelled_dyck_word()
[3, 0, 1, 2, 0, 0]
sage: ParkingFunction(labelled_dyck_word=[3,0,1,2,0,0])
[2, 2, 1]
sage: ParkingFunction(labelling=[3,1,2], area_sequence=[0,1,1])
Traceback (most recent call last):
  ... ValueError: [3, 1, 2] is not a valid labeling of area sequence [0, 1, 1]
```

def area()

Return the area of the labelled Dyck path corresponding to the parking function.

**OUTPUT:**
- the sum of squares under and over the main diagonal the Dyck Path, corresponding to the parking function

**EXAMPLES:**
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.area()
6

sage: ParkingFunction([3,1,1,4]).area()
1
sage: ParkingFunction([4,1,1,1]).area()
3
sage: ParkingFunction([2,1,4,1]).area()
2

cars_permutation()

Return the sequence of cars that take parking spots 1 through \( n \) and corresponding to the parking function.

For example, cars_permutation(PF) = [2, 4, 5, 6, 3, 1, 7] means that car 2 takes spots 1, car 4 takes spot 2, ..., car 1 takes spot 6 and car 7 takes spot 7.

OUTPUT:

- the permutation of cars corresponding to the parking function and which is the same size as parking function

EXAMPLES:

sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.cars_permutation()
[2, 4, 5, 6, 3, 1, 7]

sage: ParkingFunction([3,1,1,4]).cars_permutation()
[2, 3, 1, 4]

sage: ParkingFunction([4,1,1,1]).cars_permutation()
[2, 3, 4, 1]

sage: ParkingFunction([2,1,4,1]).cars_permutation()
[2, 1, 4, 3]

characteristic_quasisymmetric_function(q=None, R=Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field)

Return the characteristic quasisymmetric function of self.

The characteristic function of the Parking Function is the sum over all permutation labellings of the Dyck path \( q^{\text{inv}(PF)} F_{\text{ides}(PF)} \), where \( \text{ides}(PF) \) is the descent composition of the diagonal reading word of the parking function.

INPUT:

- \( q \) – (default: \( q = R('q') \)) a parameter for the generating function power
- \( R \) – (default: \( R = QQ['q','t'].fraction_field() \)) the base ring to do the calculations over

OUTPUT:

- an element of the quasisymmetric functions over the ring \( R \)

EXAMPLES:

sage: R = QQ['q','t'].fraction_field()
sage: (q,t) = R.gens()
sage: cqf = sum(t**PF.area()*PF.characteristic_quasisymmetric_function() for PF in ParkingFunctions(3)); cqf
(q^3+q^2*t+q*t^2+t^3+q*t)*F[1, 1, 1] + (q^2+q^2*t+t^2+q+t)*F[1, 2] + (q^2+q^2+q^2+t^2+q+t)*F[2, 1] + F[3]

sage: s = SymmetricFunctions(R).s()
sage: s(cqf.to_symmetric_function())
(q^3+q^2*t+q*t^2+t^3+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q+t)*s[2, 1] + s[3]

sage: s(cqf.to_symmetric_function()).nabla(power = -1)
s[1, 1, 1]

sage: p = ParkingFunction([3, 1, 2])
sage: p.characteristic_quasisymmetric_function()
q^2*F[1, 1, 2, 1, 3]

check()
Check that self is a valid parking function.

EXAMPLES:

sage: PF = ParkingFunction([1, 1, 2, 2, 5, 6])
sage: PF.check()

diagonal_composition()
Return the composition of the labelled Dyck path corresponding to the parking function.

For example, touch_composition(PF) = [4, 3] means that the first touch is four diagonal units from the starting point, and the second is three units further (see [GXZ] p. 2).

OUTPUT:

• the length between the corresponding touch points which of the labelled Dyck path that corresponds to self

EXAMPLES:

sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.touch_composition()
[4, 3]

sage: ParkingFunction([3,1,1,4]).touch_composition() [2, 1, 1]
sage: ParkingFunction([4,1,1,1]).touch_composition() [3, 1]
sage: ParkingFunction([2,1,4,1]).touch_composition() [3, 1]

diagonal_reading_word()
Return a diagonal word of the labelled Dyck path corresponding to parking function (see [Hag08] p. 75).

OUTPUT:

• returns a word, read diagonally from NE to SW of the pretty print of the labelled Dyck path that corresponds to self and the same size as self
diagonal_word()  
Return a diagonal word of the labelled Dyck path corresponding to parking function (see [Hag08] p. 75).

OUTPUT:
• returns a word, read diagonally from NE to SW of the pretty print of the labelled Dyck path that corresponds to self and the same size as self

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.diagonal_reading_word()
[5, 1, 7, 4, 6, 3, 2]
sage: ParkingFunction([1, 1, 1]).diagonal_reading_word()
[3, 2, 1]
sage: ParkingFunction([1, 2, 3]).diagonal_reading_word()
[3, 2, 1]
sage: ParkingFunction([1, 1, 3, 4]).diagonal_reading_word()
[2, 4, 3, 1]
sage: ParkingFunction([1, 1, 1]).diagonal_word()
[3, 2, 1]
sage: ParkingFunction([1, 2, 3]).diagonal_word()
[3, 2, 1]
sage: ParkingFunction([1, 4, 3, 1]).diagonal_word()
[4, 2, 3, 1]
```
• the number of dinversion pairs

EXAMPLES:

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.dinv()
6
```

```python
sage: ParkingFunction([3,1,1,4]).dinv()
sage: ParkingFunction([4,1,1,1]).dinv()
sage: ParkingFunction([2,1,4,1]).dinv()
3
1
2
```

dinversion_pairs()

Return the descent inversion pairs of a labelled Dyck path corresponding to the parking function.

OUTPUT:

• the primary and secondary diversion pairs

EXAMPLES:

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.dinversion_pairs()
[(0, 4), (1, 5), (2, 5), (1, 4), (2, 4), (3, 6)]
sage: ParkingFunction([3,1,1,4]).dinversion_pairs()
[(0, 3), (2, 3), (1, 2)]
sage: ParkingFunction([4,1,1,1]).dinversion_pairs()
[(1, 3)]
sage: ParkingFunction([2,1,4,1]).dinversion_pairs()
[(0, 3), (1, 3)]
```

grade()

Return the length of the parking function.

EXAMPLES:

```python
sage: PF = ParkingFunction([1, 1, 2, 2, 5, 6])
sage: PF.grade()
6
```

ides()

Return the \texttt{descents()} sequence of the inverse of the \texttt{diagonal_reading_word()} of \texttt{self}.

\textbf{Warning}: Here we use the standard convention that descent labels start at 1. This behaviour has been changed in \texttt{github issue #20555}.

For example, \texttt{ides(PF) = [2, 3, 4, 6]} means that descents are at the 2nd, 3rd, 4th and 6th positions in the inverse of the \texttt{diagonal_reading_word()} of the parking function (see [GXZ] p. 2).

OUTPUT:

• the descents sequence of the inverse of the \texttt{diagonal_reading_word()} of the parking function
EXAMPLES:

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.ides() [2, 3, 4, 6]
```

```python
sage: ParkingFunction([3,1,1,4]).ides() [2]
sage: ParkingFunction([4,1,1,1]).ides() [2, 3]
sage: ParkingFunction([4,3,1,1]).ides() [3]
```

`ides_composition()`

Return the `descents_composition()` of the inverse of the `diagonal_reading_word()` of corresponding parking function.

For example, `ides_composition(PF) = [4, 2, 1]` means that the descents of the inverse of the permutation `diagonal_reading_word()` of the parking function with word `PF` are at the 4th and 6th positions.

OUTPUT:

- the descents composition of the inverse of the `diagonal_reading_word()` of the parking function

EXAMPLES:

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.ides_composition() [2, 1, 1, 2, 1]
```

```python
sage: ParkingFunction([3,1,1,4]).ides_composition() [2, 2]
sage: ParkingFunction([4,1,1,1]).ides_composition() [2, 1, 1]
sage: ParkingFunction([4,3,1,1]).ides_composition() [3, 1]
```

`jump()`

Return the sum of the differences between the parked and preferred parking spots.

See [Shin] p. 18.

OUTPUT:

- the sum of the differences between the parked and preferred parking spots

EXAMPLES:

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.jump() 6
```

```python
sage: ParkingFunction([3,1,1,4]).jump() 1
sage: ParkingFunction([4,1,1,1]).jump()
```

(continues on next page)
jump_list()

Return the displacements of cars that corresponds to the parking function.

For example, `jump_list(PF) = [0, 0, 0, 0, 1, 3, 2]` means that car 1 through 4 parked in their preferred spots, car 5 had to park one spot farther (jumped or was displaced by one spot), car 6 had to jump 3 spots, and car 7 had to jump two spots.

OUTPUT:

- the displacements sequence of parked cars which corresponds to the parking function and which is the same size as parking function

EXAMPLES:

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.jump_list()
[0, 0, 0, 0, 1, 3, 2]
```

```python
sage: ParkingFunction([3,1,1,4]).jump_list()
[0, 0, 1, 0]
sage: ParkingFunction([4,1,1,1]).jump_list()
[0, 0, 1, 2]
sage: ParkingFunction([2,1,4,1]).jump_list()
[0, 0, 0, 2]
```

luck()

Return the number of cars that parked in their preferred parking spots (see [Shin] p. 33).

OUTPUT:

- the number of cars that parked in their preferred parking spots

EXAMPLES:

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.luck()
4
```

```python
sage: ParkingFunction([3,1,1,4]).luck()
3
sage: ParkingFunction([4,1,1,1]).luck()
2
sage: ParkingFunction([2,1,4,1]).luck()
3
```

lucky_cars()

Return the cars that can park in their preferred spots. For example, `lucky_cars(PF) = [1, 2, 7]` means that cars 1, 2 and 7 parked in their preferred spots and all the other cars did not.

OUTPUT:

- the cars that can park in their preferred spots
EXAMPLES:

```sage
PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
P.F.lucky_cars()
[1, 2, 3, 4]
```

```sage
PF = ParkingFunction([3,1,1,4]).lucky_cars()
[1, 2, 4]
P.F = ParkingFunction([4,1,1,1]).lucky_cars()
[1, 2]
P.F = ParkingFunction([2,1,4,1]).lucky_cars()
[1, 2, 3]
```

```sage
PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
P.F.parking_permutation()
[6, 1, 5, 2, 3, 4, 7]
P.F = ParkingFunction([3,1,1,4]).parking_permutation()
[3, 1, 2, 4]
P.F = ParkingFunction([4,1,1,1]).parking_permutation()
[4, 1, 2, 3]
P.F = ParkingFunction([2,1,4,1]).parking_permutation()
[2, 1, 4, 3]
```

```sage
PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
P.F.pretty_print()
```

```
___
 |\1x
 |7x
_____\3
```

(continues on next page)
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.pretty_print(underpath = false)

sage: pf = ParkingFunction([1,2,3,7,3,2,1,2,3,2,1])
sage: pf.pretty_print()
The diagram shows a labelled Dyck path with the corresponding parking function.

**primary_dinversion_pairs()**

Return the primary descent inversion pairs of a labelled Dyck path corresponding to the parking function.

**OUTPUT:**
- the pairs \((i, j)\) such that \(i < j\), and \(i^{th}\) area = \(j^{th}\) area, and \(i^{th}\) label < \(j^{th}\) label

**EXAMPLES:**
```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.primary_dinversion_pairs()
[(0, 4), (1, 5), (2, 5)]
sage: ParkingFunction([3,1,1,4]).primary_dinversion_pairs()
[(0, 3)]
sage: ParkingFunction([4,1,1,1]).primary_dinversion_pairs()
[]
sage: ParkingFunction([2,1,4,1]).primary_dinversion_pairs()
[(0, 3)]
```

**secondary_dinversion_pairs()**

Return the secondary descent inversion pairs of a labelled Dyck path corresponding to the parking function.

**OUTPUT:**
- the pairs \((i, j)\) such that \(i < j\), and \(i^{th}\) area = \(j^{th}\) area + 1, and \(i^{th}\) label > \(j^{th}\) label

**EXAMPLES:**
```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.secondary_dinversion_pairs()
[(1, 4), (2, 4), (3, 6)]
sage: ParkingFunction([3,1,1,4]).secondary_dinversion_pairs()
[(1, 2)]
sage: ParkingFunction([4,1,1,1]).secondary_dinversion_pairs()
[(1, 3)]
sage: ParkingFunction([2,1,4,1]).secondary_dinversion_pairs()
[(1, 3)]
```

**to_NonDecreasingParkingFunction()**

Return the non-decreasing parking function which underlies the parking function.
OUTPUT:

- a sorted parking function

See also:

NonDecreasingParkingFunction()

EXAMPLES:

```sage
PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
PF.to_NonDecreasingParkingFunction()
[1, 1, 2, 2, 5, 5, 6]
```

```sage
ParkingFunction([3,1,1,4]).to_NonDecreasingParkingFunction()
[1, 1, 3, 4]
```

```sage
ParkingFunction([4,1,1,1]).to_NonDecreasingParkingFunction()
[1, 1, 1, 4]
```

```sage
ParkingFunction([2,1,4,1]).to_NonDecreasingParkingFunction()
[1, 1, 2, 4]
```

```sage
ParkingFunction([4,1,2,1]).to_NonDecreasingParkingFunction()
[1, 1, 2, 4]
```

to_area_sequence()

Return the area sequence of the support Dyck path of the parking function.

OUTPUT:

- the area sequence of the Dyck path

EXAMPLES:

```sage
PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
PF.to_area_sequence()
[0, 1, 1, 2, 0, 1, 1]
```

```sage
ParkingFunction([3,1,1,4]).to_area_sequence()
[0, 1, 0, 0]
```

```sage
ParkingFunction([4,1,1,1]).to_area_sequence()
[0, 1, 2, 0]
```

```sage
ParkingFunction([2,1,4,1]).to_area_sequence()
[0, 1, 1, 0]
```

to_dyck_word()

Return the support Dyck word of the parking function.

OUTPUT:

- the Dyck word of the corresponding parking function

See also:

DyckWord()

EXAMPLES:

```sage
PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
PF.to_dyck_word()
[1, 1, 0, 1, 1, 0, 0, 1, 1, 0, 1, 0, 0]
```
to_labelled_dyck_word()

Return the labelled Dyck word corresponding to the parking function.

This is a representation of the parking function as a list where the entries of 1 in the Dyck word are replaced with the corresponding label.

OUTPUT:

• the labelled Dyck word of the corresponding parking function which is twice the size of parking function word

EXAMPLES:

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelled_dyck_word()
[2, 6, 0, 4, 5, 0, 0, 0, 3, 7, 0, 1, 0, 0]
```

```python
sage: ParkingFunction([3,1,1,4]).to_labelled_dyck_word()
[2, 3, 0, 0, 1, 0, 4, 0]
```

```python
sage: ParkingFunction([4,1,1,1]).to_labelled_dyck_word()
[2, 3, 4, 0, 0, 0, 1, 0]
```

```python
sage: ParkingFunction([2,1,4,1]).to_labelled_dyck_word()
[2, 4, 0, 1, 0, 0, 3, 0]
```

to_labelling_area_sequence_pair()

Return a pair consisting of a labelling and an area sequence of a Dyck path which corresponds to the given parking function.

OUTPUT:

• returns a pair (L, D) where L is a labelling and D is the area sequence of the underlying Dyck path

EXAMPLES:

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelling_area_sequence_pair()
([2, 6, 4, 5, 3, 7, 1], [0, 1, 1, 2, 0, 1, 1])
```

```python
sage: ParkingFunction([1, 1, 1]).to_labelling_area_sequence_pair()
([1, 2, 3], [0, 1, 2])
```

```python
sage: ParkingFunction([1, 2, 3]).to_labelling_area_sequence_pair()
([1, 2, 3], [0, 0, 0])
```

```python
sage: ParkingFunction([1, 1, 2]).to_labelling_area_sequence_pair()
([1, 2, 3], [0, 1, 1])
```

```python
sage: ParkingFunction([1, 1, 3, 1]).to_labelling_area_sequence_pair()
([1, 2, 4, 3], [0, 1, 2, 1])
```

to_labelling_dyck_word_pair()

Return the pair (L, D) where L is a labelling and D is the Dyck word of the parking function.
• the pair \((L, D)\), where \(L\) is the labelling and \(D\) is the Dyck word of the parking function

See also:
\(\text{DyckWord()}\)

EXAMPLES:

\[
\begin{align*}
\text{sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])} \\
\text{sage: PF.to_labelling_dyck_word_pair()}
&= ([2, 6, 4, 5, 3, 7, 1], [1, 1, 0, 1, 1, 0, 0, 1, 1, 0, 1, 0, 0]) \\
\text{sage: ParkingFunction([3,1,1,4]).to_labelling_dyck_word_pair()}
&= ([2, 3, 1, 4], [1, 1, 0, 0, 1, 0, 1, 0]) \\
\text{sage: ParkingFunction([4,1,1,1]).to_labelling_dyck_word_pair()}
&= ([2, 4, 1, 3], [1, 1, 0, 1, 0, 0, 1, 0]) \\
\text{sage: ParkingFunction([2,1,4,1]).to_labelling_dyck_word_pair()}
&= ([2, 4, 1, 3], [1, 1, 0, 1, 0, 1, 0])
\end{align*}
\]

\(\text{to_labelling_permutation()}\)

Return the labelling of the support Dyck path of the parking function.

OUTPUT:
• the labelling of the Dyck path

EXAMPLES:

\[
\begin{align*}
\text{sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])} \\
\text{sage: PF.to_labelling_permutation()}
&= [2, 6, 4, 5, 3, 7, 1] \\
\text{sage: ParkingFunction([3,1,1,4]).to_labelling_permutation()}
&= [2, 3, 1, 4] \\
\text{sage: ParkingFunction([4,1,1,1]).to_labelling_permutation()}
&= [2, 3, 4, 1] \\
\text{sage: ParkingFunction([2,1,4,1]).to_labelling_permutation()}
&= [2, 4, 1, 3]
\end{align*}
\]

\(\text{touch_composition()}\)

Return the composition of the labelled Dyck path corresponding to the parking function.

For example, \(\text{touch_composition(PF)} = [4, 3]\) means that the first touch is four diagonal units from the starting point, and the second is three units further (see [GXZ] p. 2).

OUTPUT:
• the length between the corresponding touch points which of the labelled Dyck path that corresponds to the parking function

EXAMPLES:

\[
\begin{align*}
\text{sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])} \\
\text{sage: PF.touch_composition()}
&= [4, 3]
\end{align*}
\]
sage: ParkingFunction([3,1,1,4]).touch_composition()
[2, 1, 1]
sage: ParkingFunction([4,1,1,1]).touch_composition()
[3, 1]
sage: ParkingFunction([2,1,4,1]).touch_composition()
[3, 1]

touch_points()

Return the sequence of touch points which corresponds to the labelled Dyck path after initial step.

For example, touch_points(PF) = [4, 7] means that after the initial step, the path touches the main diagonal at points (4, 4) and (7, 7).

OUTPUT:

• the sequence of touch points after the initial step of the labelled Dyck path that corresponds to the parking function

EXAMPLES:

sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.touch_points()
[4, 7]
sage: ParkingFunction([3,1,1,4]).touch_points()
[2, 3, 4]
sage: ParkingFunction([4,1,1,1]).touch_points()
[3, 4]
sage: ParkingFunction([2,1,4,1]).touch_points()
[3, 4]

class sage.combinat.parking_functions.ParkingFunctions

Bases: UniqueRepresentation, Parent

Return the combinatorial class of Parking Functions.

A parking function of size \( n \) is a sequence \((a_1, \ldots, a_n)\) of positive integers such that if \( b_1 \leq b_2 \leq \cdots \leq b_n \) is the increasing rearrangement of \( a_1, \ldots, a_n \), then \( b_i \leq i \).

A parking function of size \( n \) is a pair \((L, D)\) of two sequences \( L \) and \( D \) where \( L \) is a permutation and \( D \) is an area sequence of a Dyck Path of size \( n \) such that \( D[i] \geq 0 \), \( D[i+1] \leq D[i]+1 \) and if \( D[i+1] = D[i]+1 \) then \( L[i+1] > L[i] \).

The number of parking functions of size \( n \) is equal to the number of rooted forests on \( n \) vertices and is equal to \( (n+1)^{n-1} \).

EXAMPLES:

Here are all parking functions of size 3:

sage: from sage.combinat.parking_functions import ParkingFunctions
sage: ParkingFunctions(3).list()
[[1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [1, 1, 3], [1, 3, 1],
 [3, 1, 1], [1, 2, 2], [2, 1, 2], [2, 2, 1], [1, 2, 3], [1, 3, 2],
 [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]

If no size is specified, then ParkingFunctions returns the combinatorial class of all parking functions.
If the size $n$ is specified, then ParkingFunctions returns the combinatorial class of all parking functions of size $n$.

```sage
PF = ParkingFunctions(0)
sage: PF.list()
[[]]
sage: PF = ParkingFunctions(1)
sage: PF.list()
[[1]]
sage: PF = ParkingFunctions(3)
sage: PF.list()
[[[1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [1, 1, 3],
  [1, 3, 1], [3, 1, 1], [1, 2, 2], [2, 1, 2], [2, 2, 1],
  [1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]]
```

```sage
PF3 = ParkingFunctions(3); PF3
Parking functions of size 3
sage: [] in PF3
False
sage: [1] in PF3
False
sage: [1,3,1] in PF3
True
sage: [1,4,1] in PF3
False
```

class sage.combinat.parking_functions.ParkingFunctions_all

Bases: ParkingFunctions

Element

alias of ParkingFunction

graded_component($n$)

Return the graded component.

EXAMPLES:

```sage
PF = ParkingFunctions()
sage: PF.graded_component(4) == ParkingFunctions(4)
True
sage: it = iter(ParkingFunctions()) # indirect doctest
```
class sage.combinat.parking_functions.ParkingFunctions_n(n)

The combinatorial class of parking functions of size $n$.

A parking function of size $n$ is a sequence $(a_1, \ldots, a_n)$ of positive integers such that if $b_1 \leq b_2 \leq \cdots \leq b_n$ is the increasing rearrangement of $a_1, \ldots, a_n$, then $b_i \leq i$.

A parking function of size $n$ is a pair $(L, D)$ of two sequences $L$ and $D$ where $L$ is a permutation and $D$ is an area sequence of a Dyck Path of size $n$ such that $D[i] \geq 0$, $D[i+1] \leq D[i] + 1$ and if $D[i+1] = D[i] + 1$ then $L[i+1] > L[i]$.

The number of parking functions of size $n$ is equal to the number of rooted forests on $n$ vertices and is equal to $(n + 1)^{n-1}$.

EXAMPLES:

```
sage: PF = ParkingFunctions(3)
sage: PF.list()
[[1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [1, 1, 3], [1, 3, 1], [3, 1, 1], [1, 2, 2], [2, 1, 2], [2, 2, 1], [1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
sage: [ParkingFunctions(i).cardinality() for i in range(6)]
[1, 1, 3, 16, 125, 1296]
```

Warning: The precise order in which the parking function are generated or listed is not fixed, and may change in the future.

Element

alias of ParkingFunction

cardinality()  

Return the number of parking functions of size $n$.

The cardinality is equal to $(n + 1)^{n-1}$.

EXAMPLES:

```
sage: [ParkingFunctions(i).cardinality() for i in range(6)]
[1, 1, 3, 16, 125, 1296]
```

random_element()  

Return a random parking function of size $n$.

The algorithm uses a circular parking space with $n + 1$ spots. Then all $n$ cars can park and there remains one empty spot. Spots are then renumbered so that the empty spot is 0.

The probability distribution is uniform on the set of $(n + 1)^{n-1}$ parking functions of size $n$.

EXAMPLES:
sage: pf = ParkingFunctions(8)
sage: a = pf.random_element(); a  # random
[5, 7, 2, 4, 2, 5, 1, 3]
sage: a in pf
True

sage.combinat.parking_functions.from_labelled_dyck_word(LDW)

Return the parking function corresponding to the labelled Dyck word.

INPUT:

• LDW – labelled Dyck word

OUTPUT:

• the parking function corresponding to the labelled Dyck word that is half the size of LDW

EXAMPLES:

sage: from sage.combinat.parking_functions import from_labelled_dyck_word
sage: LDW = [2, 6, 0, 4, 5, 0, 0, 3, 7, 0, 1, 0, 0]
sage: from_labelled_dyck_word(LDW)
[6, 1, 5, 2, 2, 1, 5]
sage: from_labelled_dyck_word([2, 3, 0, 0, 1, 0, 4, 0])
[3, 1, 1, 1]
sage: from_labelled_dyck_word([2, 4, 0, 1, 0, 0, 3, 0])
[2, 1, 4, 1]

sage.combinat.parking_functions.from_labelling_and_area_sequence(L, D)

Return the parking function corresponding to the labelling area sequence pair.

INPUT:

• L – a labelling permutation
  
• D – an area sequence for a Dyck word

OUTPUT:

• the parking function corresponding the labelling permutation L and D an area sequence of the corresponding Dyck path

EXAMPLES:

sage: from sage.combinat.parking_functions import from_labelling_and_area_sequence
sage: from_labelling_and_area_sequence([2, 6, 4, 5, 3, 7, 1], [0, 1, 1, 2, 0, 1, 1])
[6, 1, 5, 2, 2, 1, 5]
sage: from_labelling_and_area_sequence([1, 2, 3], [0, 1, 2])
[1, 1, 1]
sage: from_labelling_and_area_sequence([1, 2, 3], [0, 0, 0])
[1, 2, 3]
sage: from_labelling_and_area_sequence([1, 2, 3], [0, 1, 1])
[1, 1, 2]
sage: from_labelling_and_area_sequence([1, 2, 4, 3], [0, 1, 2, 1])
[1, 1, 3, 1]

sage.combinat.parking_functions.is_a(x, n=None)
  Check whether a list is a parking function.
  If a size $n$ is specified, checks if a list is a parking function of size $n$.

5.1.159 Catalog of Path Tableaux

The path_tableaux object may be used to access examples of various path tableau objects currently implemented in Sage. Using tab-completion on this object is an easy way to discover and quickly create the path tableaux that are available (as listed here).

Let <tab> indicate pressing the Tab key. So begin by typing path_tableaux.<tab> to see the currently implemented path tableaux.

- SemistandardPathTableaux

5.1.160 Dyck Paths

This is an implementation of the abstract base class sage.combinat.path_tableaux.path_tableau.PathTableau. This is the simplest implementation of a path tableau and is included to provide a convenient test case and for pedagogical purposes.

In this implementation we have sequences of nonnegative integers. These are required to be the heights Dyck words (except that we do not require the sequence to start or end at height zero). These are in bijection with skew standard tableaux with at most two rows. Sequences which start and end at height zero are in bijection with noncrossing perfect matchings.

AUTHORS:
- Bruce Westbury (2018): initial version

class sage.combinat.path_tableaux.dyck_path.DyckPath(parent, ot, check=True)
  Bases: PathTableau

  An instance is the sequence of nonnegative integers given by the heights of a Dyck word.

  INPUT:
  - a sequence of nonnegative integers
  - a two row standard skew tableau
  - a Dyck word
  - a noncrossing perfect matching

5.1. Comprehensive Module List
EXAMPLES:

```python
sage: path_tableaux.DyckPath([0,1,2,1,0])
[0, 1, 2, 1, 0]
sage: w = DyckWord([1,1,0,0])
sage: path_tableaux.DyckPath(w)
[0, 1, 2, 1, 0]
sage: p = PerfectMatching([(1,2), (3,4)])
sage: path_tableaux.DyckPath(p)
[0, 1, 0, 1, 0]
sage: t = Tableau([[1,2,4],[3,5,6]])
sage: path_tableaux.DyckPath(t)
[0, 1, 2, 1, 2, 1, 0]
sage: st = SkewTableau([[None, 1,4],[2,3]])
sage: path_tableaux.DyckPath(st)
[1, 2, 1, 0, 1]
```

Here we illustrate the slogan that promotion = rotation:

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.to_perfect_matching()
[(0, 5), (1, 4), (2, 3)]
sage: t = t.promotion()
sage: t.to_perfect_matching()
[(0, 3), (1, 2), (4, 5)]
sage: t = t.promotion()
sage: t.to_perfect_matching()
[(0, 1), (2, 5), (3, 4)]
sage: t = t.promotion()
sage: t.to_perfect_matching()
[(0, 5), (1, 4), (2, 3)]
```

**check()**

Check that `self` is a valid path.

EXAMPLES:

```python
sage: path_tableaux.DyckPath([0,1,0,-1,0]) # indirect doctest
Traceback (most recent call last):
... ValueError: [0, 1, 0, -1, 0] has a negative entry
sage: path_tableaux.DyckPath([0,1,3,1,0]) # indirect doctest
Traceback (most recent call last):
... ValueError: [0, 1, 3, 1, 0] is not a Dyck path
```

**descents()**
Return the descent set of self.

EXAMPLES:

```python
sage: path_tableaux.DyckPath([0,1,2,1,0,1,0]).descents()
{3, 6}
```

`is_skew()`

Return True if self is skew and False if not.

EXAMPLES:

```python
sage: path_tableaux.DyckPath([0,1,2,1]).is_skew()
False
sage: path_tableaux.DyckPath([1,0,1,2,1]).is_skew()
True
```

`local_rule(i)`

This has input a list of objects. This method first takes the list of objects of length three consisting of the

\( (i-1) \)-st, \( i \)-th and \( (i+1) \)-term and applies the rule. It then replaces the \( i \)-th object by the object returned

by the rule.

EXAMPLES:

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.local_rule(3)
[0, 1, 2, 1, 2, 1, 0]
```

`to_DyckWord()`

Converts self to a Dyck word.

EXAMPLES:

```python
sage: c = path_tableaux.DyckPath([0,1,2,1,0])
sage: c.to_DyckWord()
[1, 1, 0, 0]
```

`to_perfect_matching()`

Return the perfect matching associated to self.

EXAMPLES:

```python
sage: path_tableaux.DyckPath([0,1,2,1,0,1,0]).to_perfect_matching()
[(0, 5), (1, 2), (3, 4), (6, 7)]
```

`to_tableau()`

Return the skew tableau associated to self.

EXAMPLES:

```python
sage: T = path_tableaux.DyckPath([0,1,2,3,2,3])
sage: T.to_tableau()
[[1, 2, 3, 5], [4]]
```

(continues on next page)
sage: U = path_tableaux.DyckPath([2,3,2,3])
sage: U.to_tableau()
[[None, None, 1, 3], [2]]

to_word()
Return the word in the alphabet \{0,1\} associated to self.

EXAMPLES:
sage: path_tableaux.DyckPath([1,0,1,2,1]).to_word()
[0, 1, 1, 0]

class sage.combinat.path_tableaux.dyck_path.DyckPaths

Bases: PathTableaux

The parent class for DyckPath.

Element

alias of DyckPath

5.1.161 Frieze Patterns

This implements the original frieze patterns due to Conway and Coxeter. Such a frieze pattern is considered as a sequence of nonnegative integers following [CoCo1] and [CoCo2] using sage.combinat.path_tableaux.

path_tableau.

AUTHORS:

• Bruce Westbury (2019): initial version

class sage.combinat.path_tableaux.frieze.FriezePattern

Bases: PathTableau

A frieze pattern.

We encode a frieze pattern as a sequence in a fixed ground field.

INPUT:

• fp – a sequence of elements of field
• field – (default: QQ) the ground field

EXAMPLES:
sage: t = path_tableaux.FriezePattern([1,2,1,2,3,1])
sage: path_tableaux.CylindricalDiagram(t)
[0, 1, 2, 1, 2, 3, 1, 0]
[0, 1, 1, 3, 5, 2, 1, 0]
[0, 1, 4, 7, 3, 2, 1, 0]
[0, 1, 2, 1, 1, 1, 1, 0]
[0, 1, 1, 2, 3, 4, 1, 0]
[0, 1, 3, 5, 7, 2, 1, 0]
[0, 1, 2, 1, 2, 3, 1, 0]
[0, 1, 2, 1, 2, 3, 1, 0]
sage: TestSuite(t).run()

sage: t = path_tableaux.FriezePattern([1,2,7,5,3,7,4,1])

sage: path_tableaux.CylindricalDiagram(t)
[0, 1, 2, 7, 5, 3, 7, 4, 1, 0]
[0, 1, 4, 3, 2, 5, 3, 1, 1, 0]
[0, 1, 2, 7, 5, 3, 7, 4, 1, 0]
[0, 1, 4, 3, 2, 5, 3, 1, 1, 0]
[0, 1, 2, 7, 5, 3, 7, 4, 1, 0]
[0, 1, 4, 3, 2, 5, 3, 1, 1, 0]
[0, 1, 2, 7, 5, 3, 7, 4, 1, 0]
[0, 1, 4, 3, 2, 5, 3, 1, 1, 0]

sage: TestSuite(t).run()

sage: t = path_tableaux.FriezePattern([1,3,4,5,1])

sage: path_tableaux.CylindricalDiagram(t)
[0, 1, 3, 4, 5, 1, 0]
[0, 1, 5/3, 7/3, 2/3, 1, 0]
[0, 1, 2, 1, 3, 1, 0]
[0, 1, 1, 4, 5/3, 1, 0]
[0, 1, 5, 7/3, 2, 1, 0]
[0, 1, 2/3, 1, 1, 1, 0]
[0, 1, 3, 4, 5, 1, 0]
[0, 1, 4, 3, 2, 5, 3, 1, 1, 0]

sage: TestSuite(t).run()

This constructs the examples from [HJ18]:

sage: K.<sqrt3> = NumberField(x^2-3)

sage: t = path_tableaux.FriezePattern([1,sqrt3,2,sqrt3,1,1], field=K)

sage: path_tableaux.CylindricalDiagram(t)
[0, 1, sqrt3, 2, sqrt3, 1, 1, ⨲ 0]
[0, 1, sqrt3, 2, sqrt3, sqrt3 + 1, ⨲ 1, 0]
[0, 1, sqrt3, 2, sqrt3 + 2, ⨲ sqrt3, 1, 0]
[0, 1, sqrt3 + 1, sqrt3 + 2, ⨲ sqrt3, 2, 1, 0]
[0, 1, sqrt3 + 2, sqrt3 + 2, ⨲ sqrt3 + 1, sqrt3 + 1, 0]
[0, 1, sqrt3 + 1, sqrt3 + 2, ⨲ sqrt3 + 2, sqrt3 + 1, 0]

sage: TestSuite(t).run()
```plaintext
sage: K.<sqrt2> = NumberField(x^2-2)
sage: t = path_tableaux.FriezePattern([1,sqrt2,1,sqrt2,3,2*sqrt2,5,3*sqrt2,1],
→   field=K)
sage: path_tableaux.CylindricalDiagram(t)
[ [ 0, 1, sqrt2, 1, sqrt2, 3, 2*sqrt2, 5, 3*sqrt2, 1],
→   1, 0]
[ [ 0, 1, sqrt2, 3, 5*sqrt2, 7, 9*sqrt2, 11, 3*sqrt2, 1],
→   2*sqrt2, 1, 0]
[ [ 0, 1, 2*sqrt2, 7, 5*sqrt2, 13, 8*sqrt2, 5, 3*sqrt2, 1],
→   sqrt2, 1, 0]
[ [ 1, sqrt2, 3, 2*sqrt2, 1, 0],
→   sqrt2, 1, sqrt2, 1, 0]
[ [ 1, 2*sqrt2, 7, 5*sqrt2, 3, sqrt2, 1, 0],
→   sqrt2, 3, 5*sqrt2, 7, 2*sqrt2, 1, 0]
[ [ 0, 1, 2*sqrt2, 3, 2*sqrt2, 1, 0],
→   1, 0]
[ [ 1, 3*sqrt2, 11, 8*sqrt2, 5, 2*sqrt2, 3, sqrt2, 1],
→   0]
[ [ 0, 1, 2*sqrt2, 3, sqrt2, 1, sqrt2, 1, sqrt2, 1],
→   1, 0]
[ [ 0, 1, sqrt2, 1, sqrt2, 3, 2*sqrt2, 5, 3*sqrt2, 1],
→   1, 0]
```

```plaintext
change_ring(R)

Return self as a frieze pattern with coefficients in R assuming there is a canonical coerce map from the base ring of self to R.

EXAMPLES:

```plaintext
sage: path_tableaux.FriezePattern([1,2,7,5,3,7,4,1]).change_ring(RealField())
[0.000000000000000, 1.00000000000000, ... 4.00000000000000, 1.00000000000000, 0.
→   0.000000000000000]
```

```plaintext
sage: path_tableaux.FriezePattern([1,2,7,5,3,7,4,1]).change_ring(GF(7))
Traceback (most recent call last):
...
TypeError: no base extension defined
```

```plaintext
check()

Check that self is a valid frieze pattern.
```

```plaintext
is_integral()

Return True if all entries of the frieze pattern are positive integers.
```
EXAMPLES:

```python
sage: path_tableaux.FriezePattern([1,2,7,5,3,7,4,1]).is_integral()
True
sage: path_tableaux.FriezePattern([1,3,4,5,1]).is_integral()
False
```

**is_positive()**
Return True if all elements of self are positive.
This implies that all entries of CylindricalDiagram(self) are positive.

**Warning:** There are orders on all fields. These may not be ordered fields as they may not be compatible with the field operations. This method is intended to be used with ordered fields only.

EXAMPLES:

```python
sage: path_tableaux.FriezePattern([1,2,7,5,3,7,4,1]).is_positive()
True
sage: path_tableaux.FriezePattern([1,-3,4,5,1]).is_positive()
False
sage: K.<sqrt3> = NumberField(x^2-3)
sage: path_tableaux.FriezePattern([1,sqrt3,1],K).is_positive()
True
```

**is_skew()**
Return True if self is skew and False if not.

EXAMPLES:

```
sage: path_tableaux.FriezePattern([1,2,1,2,3,1]).is_skew()
False
sage: path_tableaux.FriezePattern([2,2,1,2,3,1]).is_skew()
True
```

**local_rule(i)**
Return the $i$-th local rule on self.
This interprets self as a list of objects. This method first takes the list of objects of length three consisting of the $(i-1)$-st, $i$-th and $(i+1)$-term and applies the rule. It then replaces the $i$-th object by the object returned by the rule.

EXAMPLES:

```
sage: t = path_tableaux.FriezePattern([1,2,1,2,3,1])
sage: t.local_rule(3)
[1, 2, 5, 2, 3, 1]
sage: t = path_tableaux.FriezePattern([1,2,1,2,3,1])
sage: t.local_rule(0)
```

(continues on next page)
Traceback (most recent call last):
...
ValueError: 0 is not a valid integer

plot(model='UHP')
Plot the frieze as an ideal hyperbolic polygon.
This is only defined up to isometry of the hyperbolic plane.
We are identifying the boundary of the hyperbolic plane with the real projective line.
The option model must be one of
  • 'UHP' - (default) for the upper half plane model
  • 'PD' - for the Poincare disk model
  • 'KM' - for the Klein model
The hyperboloid model is not an option as this does not implement boundary points.

EXAMPLES:

```
sage: t = path_tableaux.FriezePattern([1,2,7,5,3,7,4,1])
sage: t.plot()
Graphics object consisting of 18 graphics primitives
sage: t.plot(model='UHP')
Graphics object consisting of 18 graphics primitives
sage: t.plot(model='PD')
Traceback (most recent call last):
...
TypeError: '>' not supported between instances of 'NotANumber' and 'Pi'
sage: t.plot(model='KM')
Graphics object consisting of 18 graphics primitives
```
**triangulation()**

Plot a regular polygon with some diagonals.

If `self` is positive and integral then this will be a triangulation.

```
sage: path_tableaux.FriezePattern([1,2,7,5,3,7,4,1]).triangulation()
Graphics object consisting of 25 graphics primitives

sage: path_tableaux.FriezePattern([1,2,1/7,5,3]).triangulation()
Graphics object consisting of 12 graphics primitives

sage: K.<sqrt2> = NumberField(x^2-2)
sage: path_tableaux.FriezePattern([1,sqrt2,1,sqrt2,3,2*sqrt2,5,3*sqrt2,1],field=K).triangulation()
Graphics object consisting of 24 graphics primitives
```

**width()**

Return the width of `self`.

If the first and last terms of `self` are 1 then this is the length of `self` plus two and otherwise is undefined.

**EXAMPLES:**

```
sage: path_tableaux.FriezePattern([1,2,1,2,3,1]).width()
8

sage: path_tableaux.FriezePattern([1,2,1,2,3,4]).width() is None
True
```

class `sage.combinat.path_tableaux.frieze.FriezePatterns(field)`

Bases: `PathTableaux`

The set of all frieze patterns.

**EXAMPLES:**
5.1.162 Path Tableaux

This is an abstract base class for using local rules to construct rectification and the action of the cactus group [Wes2017]. This is a construction of the Henriques-Kamnitzer construction of the action of the cactus group on tensor powers of a crystal. This is also a generalisation of the Fomin growth rules, which are a version of the operations on standard tableaux which were previously constructed using jeu de taquin.

The basic operations are rectification, evacuation and promotion. Rectification of standard skew tableaux agrees with the rectification by jeu de taquin as does evacuation. Promotion agrees with promotion by jeu de taquin on rectangular tableaux but in general they are different.

REFERENCES:
- [Wes2017]

AUTHORS:
- Bruce Westbury (2018): initial version

**class** `sage.combinat.path_tableaux.path_tableau.CylindricalDiagram(T)`

Bases: `SageObject`

Cylindrical growth diagrams.

**EXAMPLES:**

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: path_tableaux.CylindricalDiagram(t)
[0, 1, 2, 3, 2, 1, 0]
[ , 0, 1, 2, 1, 0, 1, 0]
[ , , 0, 1, 0, 1, 2, 1, 0]
[ , , , 0, 1, 2, 3, 2, 1, 0]
[ , , , , 0, 1, 2, 1, 0, 1, 0]
[ , , , , , 0, 1, 0, 1, 2, 1, 0]
[ , , , , , , 0, 1, 2, 3, 2, 1, 0]
```

**pp()**

A pretty print utility method.

**EXAMPLES:**

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: path_tableaux.CylindricalDiagram(t).pp()
```

(continues on next page)
0 1 2 3 2 1 0
0 1 2 1 0 1 0
0 1 0 2 1 0
0 1 2 3 2 1 0
0 1 2 1 0 1 0
0 1 0 1 2 1 0
0 1 2 3 2 1 0

sage: t = path_tableaux.FriezePattern([1,3,4,5,1])
sage: path_tableaux.CylindricalDiagram(t).pp()
0 1 3 4 5 1 0
0 1 5/3 7/3 2/3 1 0
0 1 2 1 3 1 0
0 1 1 4 5/3 1 0
0 1 5 7/3 2 1 0
0 1 2/3 1 1 1 0
0 1 3 4 5 1 0

class sage.combinat.path_tableaux.path_tableau.PathTableau
Bases: ClonableArray

This is the abstract base class for a path tableau.

cactus(i, j)

Return the action of the generator \( s_{i,j} \) of the cactus group on \( \text{self} \).

INPUT:

i – a positive integer
j – a positive integer weakly greater than i

EXAMPLES:

sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.cactus(1,5)
[0, 1, 2, 1, 0]
sage: t.cactus(1,6)
[0, 1, 2, 3, 2, 1, 0]
sage: t.cactus(1,7) == t.evacuation()
True
sage: t.cactus(1,7).cactus(1,6) == t.promotion()
True

commutor(other, verbose=False)

Return the commutor of \( \text{self} \) with \( \text{other} \).

If verbose=True then the function will print the rectangle.

EXAMPLES:

sage: t1 = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t2 = path_tableaux.DyckPath([0,1,2,1,0])
sage: t1.commutor(t2)
([0, 1, 2, 1, 0], [0, 1, 2, 3, 2, 1, 0])
sage: t1.commutor(t2, verbose=True)
[[0, 1, 2, 1, 0],
 [1, 2, 3, 2, 1],
 [2, 3, 4, 3, 2],
 [3, 4, 5, 4, 3],
 [2, 3, 4, 3, 2],
 [1, 2, 3, 2, 1],
 [0, 1, 2, 1, 0]]

dual_equivalence_graph()

Return the graph with vertices the orbit of `self` and edges given by the action of the cactus group generators.

In most implementations the generators $s_{i,i+1}$ will act as the identity operators. The usual dual equivalence graphs are given by replacing the label $i, i + 2$ by $i$ and removing edges with other labels.

EXAMPLES:

sage: s = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: s.dual_equivalence_graph().edges(sort=True)

[(0, 1, 0, 1, 0, 1, 0), (0, 1, 2, 1, 0, 1, 0), '2,6'],
 [(0, 1, 0, 1, 2, 1, 0), (0, 1, 2, 3, 2, 1, 0), '3,7'],
 [(0, 1, 2, 1, 2, 1, 0), (0, 1, 2, 3, 2, 1, 0), '3,6']
]

evacuation()

Return the evacuation operator applied to `self`.

EXAMPLES:

sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.evacuation()
[0, 1, 2, 3, 2, 1, 0]
**final_shape()**

Return the final shape of self.

**EXAMPLES:**

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.final_shape()
[]
```

**initial_shape()**

Return the initial shape of self.

**EXAMPLES:**

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.initial_shape()
[]
```

**local_rule(i)**

This is the abstract local rule defined in any coboundary category.

This has input a list of objects. This method first takes the list of objects of length three consisting of the
\((i - 1)\)-st, \(i\)-th and \((i + 1)\)-term and applies the rule. It then replaces the \(i\)-th object by the object returned
by the rule.

**EXAMPLES:**

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.local_rule(3)
[0, 1, 2, 1, 2, 1, 0]
```

**orbit()**

Return the orbit of self under the action of the cactus group.

**EXAMPLES:**

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.orbit()
{[0, 1, 0, 1, 0, 1, 0],
 [0, 1, 0, 1, 2, 1, 0],
 [0, 1, 2, 1, 0, 1, 0],
 [0, 1, 2, 1, 2, 1, 0],
 [0, 1, 2, 3, 2, 1, 0]}
```

**promotion()**

Return the promotion operator applied to self.

**EXAMPLES:**

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.promotion()
[0, 1, 2, 1, 0, 1, 0]
```

**size()**

Return the size or length of self.

**EXAMPLES:**
class sage.combinat.path_tableaux.path_tableau.PathTableaux
    Bases: UniqueRepresentation, Parent

    The abstract parent class for PathTableau.

5.1.163 Semistandard Tableaux

This is an implementation of the abstract base class sage.combinat.path_tableaux.path_tableau.PathTableau.

This implementation is for semistandard tableaux, represented as a chain of partitions (essentially, the Gelfand-Tsetlin pattern). This generalises the jeu de taquin operations of rectification, promotion, evacuation from standard tableaux to semistandard tableaux. The local rule is the Bender-Knuth involution.

EXAMPLES:

```python
sage: pt = path_tableaux.SemistandardPathTableau([[],[3],[3,2],[3,3,1],[3,3,2,1],[4,3,3,1,0]])
sage: pt.promotion()
[(), (2,), (3, 1), (3, 2, 1), (4, 3, 1, 0), (4, 3, 3, 1, 0)]

sage: pt.evacuation()
[(), (2,), (4, 0), (4, 2, 0), (4, 3, 1, 0), (4, 3, 3, 1, 0)]

sage: pt = path_tableaux.SemistandardPathTableau([[],[3],[3,2],[3,3,1],[3,3,2,1],[9/2,3,3,1,0]])
sage: pt.promotion()
[(), (2,), (3, 1), (3, 2, 1), (9/2, 3, 1, 0), (9/2, 3, 3, 1, 0)]

sage: pt.evacuation()
[(), (5/2,), (9/2, 0), (9/2, 2, 0), (9/2, 3, 1, 0), (9/2, 3, 3, 1, 0)]

sage: pt = path_tableaux.SemistandardPathTableau([[],[3],[4,2],[5,4,1]])
sage: path_tableaux.CylindricalDiagram(pt)
[ (), (3,), (4, 2), (5, 4, 1)]
[ , (), (3,), (5, 2), (5, 4, 1)]
[ , , (), (4,), (4, 3), (5, 4, 1)]
[ , , , (), (3,), (5, 1), (5, 4, 1)]

sage: pt2 = path_tableaux.SemistandardPathTableau([[],[3],[3,2],[3,3,1],[3,3,2,1],[4,3,3,1,0]])
sage: pt1 = path_tableaux.SemistandardPathTableau([[],[3],[3,2]])
sage: pt1.commutor(pt2)
(((), (2,), (2, 2), (4, 2, 0)), [(4, 2, 0), (4, 3, 2, 0), (4, 3, 3, 1, 0)])

sage: pt1.commutor(pt2,verbose=True)
((3, 2), (3, 3, 1), (3, 3, 2, 1), (4, 3, 3, 1, 0)]
[[3,3), (3, 2), (3, 3, 2), (4, 3, 2, 0)]
[[(), (2,), (2, 2), (4, 2, 0)]
[[(), (2,), (2, 2), (4, 2, 0)], [(4, 2, 0), (4, 3, 2, 0), (4, 3, 3, 1, 0)])
```

(continues on next page)
sage: st = SkewTableau([[None, None, None, 4, 4, 5, 6, 7], [None, 2, 4, 6, 7, 7], [None, 4, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]])

sage: pt = path_tableaux.SemistandardPathTableau(st)

sage: bk = [SkewTableau(st.bender_knuth_involution(i+1)) for i in range(10)]

sage: lr = [pt.local_rule(i+1) for i in range(10)]

sage: [r.to_tableau() for r in lr] == bk
True

AUTHORS:

• Bruce Westbury (2020): initial version

class sage.combinat.path_tableaux.semistandard.SemistandardPathTableau(parent, st, check=True)

Bases: PathTableau

An instance is a sequence of lists. Usually the entries will be non-negative integers in which case this is the chain of partitions of a (skew) semistandard tableau. In general the entries are elements of an ordered abelian group; each list is weakly decreasing and successive lists are interleaved.

INPUT:

Can be any of the following

• a sequence of partitions

• a sequence of lists/tuples

• a semistandard tableau

• a semistandard skew tableau

• a Gelfand-Tsetlin pattern

EXAMPLES:

sage: path_tableaux.SemistandardPathTableau([[], [2], [2, 1]])
[(), (2,), (2, 1)]

sage: gt = GelfandTsetlinPattern([[2, 1], [2]])

sage: path_tableaux.SemistandardPathTableau(gt)
[(), (2,), (2, 1)]

sage: st = SemistandardTableau([[1, 1], [2]])

sage: path_tableaux.SemistandardPathTableau(st)
[(), (2,), (2, 1)]

sage: st = SkewTableau([[1, 1], [2]])

sage: path_tableaux.SemistandardPathTableau(st)
[(), (2,), (2, 1)]

sage: st = SkewTableau([[None, 1, 1], [2]])

sage: path_tableaux.SemistandardPathTableau(st)
[(), (3, 0), (3, 1, 0)]

sage: path_tableaux.SemistandardPathTableau([[], [5/2], [7/2, 2]])
[(), (5/2,), (7/2, 2)]
Combinatorics, Release 10.0

\begin{verbatim}
 sage: path_tableaux.SemistandardPathTableau([[],[2.5],[3.5,2]])
[(), (2.50000000000000,), (3.50000000000000, 2)]
\end{verbatim}

check()
Check that self is a valid path.

EXAMPLES:
\begin{verbatim}
 sage: path_tableaux.SemistandardPathTableau([[],[3],[2,2]])
# indirect test
Traceback (most recent call last):
... ValueError: [(), (3,), (2, 2)] does not satisfy the required inequalities in row 1
 sage: path_tableaux.SemistandardPathTableau([[],[3/2],[2,5/2]])
# indirect test
Traceback (most recent call last):
... ValueError: [(), (3/2,), (2, 5/2)] does not satisfy the required inequalities in row 1
\end{verbatim}

is_integral()
Return True if all entries are non-negative integers.

EXAMPLES:
\begin{verbatim}
 sage: path_tableaux.SemistandardPathTableau([[],[3],[3,2]]).is_integral()
True
 sage: path_tableaux.SemistandardPathTableau([[],[5/2],[7/2,2]]).is_integral()
False
 sage: path_tableaux.SemistandardPathTableau([[],[3],[3,-2]]).is_integral()
False
\end{verbatim}

is_skew()
Return True if self is skew.

EXAMPLES:
\begin{verbatim}
 sage: path_tableaux.SemistandardPathTableau([[],[2]]).is_skew()
False
 sage: path_tableaux.SemistandardPathTableau([[],[3],[3,1]]).is_skew()
True
\end{verbatim}

local_rule(i)
This is the Bender-Knuth involution.

This is implemented by toggling the entries of the i-th list. The allowed range for i is 0 < i < len(self)-1 so any row except the first and last can be changed.

EXAMPLES:
\begin{verbatim}
 sage: pt = path_tableaux.SemistandardPathTableau([[],[3],[3,2],[3,3,1],[3,3,2,1]])
 sage: pt.local_rule(1)
[(), (2,), (3, 2), (3, 3, 1), (3, 3, 2, 1)]
\end{verbatim}

\end{verbatim}
sage: pt.local_rule(2)
[(0, 0), (3,), (3, 2), (3, 3, 1), (3, 3, 2, 1)]
sage: pt.local_rule(3)
[(0, 0), (3, 2), (3, 2, 2), (3, 3, 2, 1)]

rectify(inner=None, verbose=False)
Rectify self.

This gives the usual rectification of a skew standard tableau and gives a generalisation to skew semistandard tableaux. The usual construction uses jeu de taquin but here we use the Bender-Knuth involutions.

EXAMPLES:

sage: st = SkewTableau([[None, None, None, 4], [None, None, 1, 6], [None, None, 5], [2, 3, 1]])
sage: path_tableaux.SemistandardPathTableau(st).rectify()
[(0, 0), (1,), (1, 1), (2, 1, 0), (3, 1, 0, 0), (3, 2, 0, 0, 0), (4, 2, 0, 0, 0, 0)]
sage: path_tableaux.SemistandardPathTableau(st).rectify(verbos=True)
[(3, 2, 2), (3, 3, 2, 0), (3, 3, 2, 1, 0), (3, 3, 2, 2, 0, 0), (4, 3, 2, 2, 0, 0, 0, 0),
 (4, 3, 3, 2, 0, 0, 0, 0, 0), (4, 4, 3, 2, 0, 0, 0, 0, 0, 0),
 (3, 2, 1, 0), (3, 3, 1, 0), (3, 3, 2, 0, 0), (4, 3, 2, 0, 0, 0), (4, 3, 3, 2, 0, 0, 0, 0, 0),
 (4, 3, 3, 3, 2, 0, 0, 0, 0, 0, 0), (4, 4, 3, 3, 2, 0, 0, 0, 0, 0, 0, 0)]

size()
Return the size or length of self.

EXAMPLES:

sage: path_tableaux.SemistandardPathTableau([[None, None, None, 4], [None, None, 1, 6], [None, None, 5], [2, 3, 1]]).size()
5

to_pattern()
Convert self to a Gelfand-Tsetlin pattern.

EXAMPLES:

sage: pt = path_tableaux.SemistandardPathTableau([[None, None, None, 4], [None, None, 1, 6], [None, None, 5], [2, 3, 1]])
sage: pt.to_pattern()
[[4, 3, 3, 1, 0], [3, 3, 2, 1], [3, 3, 1], [3, 2], [3]]

to_tableau()
Convert self to a SemistandardTableau.

The SemistandardSkewTableau is not implemented so this returns a SkewTableau

EXAMPLES:

sage: pt = path_tableaux.SemistandardPathTableau([[None, None, None, 4], [None, None, 1, 6], [None, None, 5], [2, 3, 1]])
(continues on next page)
Combinatorics, Release 10.0

    sage: pt.to_tableau()
[[1, 1, 1, 5], [2, 2, 3], [3, 4, 5], [4]]

class sage.combinat.path_tableaux.semistandard.SemistandardPathTableaux
    Bases: PathTableaux
    The parent class for SemistandardPathTableau.

Element
    alias of SemistandardPathTableau

5.1.164 Plane Partitions

AUTHORS:

• Jang Soo Kim (2016): Initial implementation
• Jessica Striker (2016): Added additional methods
• Kevin Dilks (2021): Added symmetry classes

class sage.combinat.plane_partition.PlanePartition(parent, pp, check=True)
    Bases: ClonableArray
    A plane partition.
    
A plane partition is a stack of cubes in the positive orthant.

INPUT:

• PP – a list of lists which represents a tableau
• box_size – (optional) a list [A, B, C] of 3 positive integers, where A, B, C are the lengths of the box in the x-axis, y-axis, z-axis, respectively; if this is not given, it is determined by the smallest box bounding PP

OUTPUT:

The plane partition whose tableau representation is PP.

EXAMPLES:

    sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
    sage: PP
    Plane partition [[4, 3, 3, 1], [2, 1, 1], [1, 1]]

bounding_box()

    Return the smallest box (a, b, c) that self is contained in.

    EXAMPLES:

    sage: PP = PlanePartition([[5,2,1,1], [2,2], [2]])
    sage: PP.bounding_box()
    (3, 4, 5)

cells()

    Return the list of cells inside self.

    EXAMPLES:
sage: PP = PlanePartition([[3,1],[2]])
sage: PP.cells()
[[0, 0, 0], [0, 0, 1], [0, 1, 0], [1, 0, 1]]

check()
Check to see that self is a valid plane partition.

EXAMPLES:
sage: a = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: a.check()
sage: b = PlanePartition([[1,2],[1]])
Traceback (most recent call last):
... ValueError: not weakly decreasing along rows
sage: c = PlanePartition([[1,1],[2]])
Traceback (most recent call last):
... ValueError: not weakly decreasing along columns
sage: d = PlanePartition([[2,-1],[-2]])
Traceback (most recent call last):
... ValueError: entries not all nonnegative
sage: e = PlanePartition([[3/2,1],[.5]])
Traceback (most recent call last):
... ValueError: entries not all integers

complement(tableau_only=False)
Return the complement of self.

If the parent of self consists only of partitions inside a given box, then the complement is taken in this
box. Otherwise, the complement is taken in the smallest box containing the plane partition. The empty
plane partition with no box specified is its own complement.

If tableau_only is set to True, then only the tableau consisting of the projection of boxes size onto the xy-
plane is returned instead of a PlanePartition. This output will not have empty trailing rows or trailing
zeros removed.

EXAMPLES:
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.complement()
Plane partition [[4, 3, 3, 3], [4, 3, 3, 2], [3, 1, 1]]
sage: PP.complement(True)
[[4, 4, 3, 3], [4, 3, 3, 2], [3, 1, 1, 0]]

contains(PP)
Return True if PP is a plane partition that fits inside self.

Specifically, self contains PP if, for all i, j, the height of PP at ij is less than or equal to the height of
self at ij.

EXAMPLES:
sage: P1 = PlanePartition([[5,4,3], [3,2,2], [1]])
sage: P2 = PlanePartition([[3,2], [1,1], [0,0], [0,0]])
sage: P3 = PlanePartition([[5,5,5], [2,1,0]])
sage: P1.contains(P2)  # True
sage: P2.contains(P1)  # False
sage: P1.contains(P3)  # False
sage: P3.contains(P2)  # True

cyclically_rotate(preserve_parent=False)

Return the cyclic rotation of self.

By default, if the parent of self consists of plane partitions inside an $a \times b \times c$ box, the result will have a parent consisting of partitions inside a $c \times a \times b$ box, unless the optional parameter preserve_parent is set to True. Enabling this setting may give an element that is not an element of its parent.

EXAMPLES:

```python
sage: PlanePartition([[3,2,1],[2,2],[2]]).cyclically_rotate()
Plane partition [[3, 3, 1], [2, 2], [1]]
sage: PP = PlanePartition([[4,1],[1],[1]])
```

```python
sage: PP.cyclically_rotate()
Plane partition [[3, 1, 1, 1], [1]]
sage: PP == PP.cyclically_rotate().cyclically_rotate().cyclically_rotate()
True
sage: PP = PlanePartitions([4,3,2]).random_element()
```

```python
sage: PP.cyclically_rotate().parent()
```

```python
sage: PP_rotated = PP.cyclically_rotate(preserve_parent=True)
sage: PP_rotated in PP_rotated.parent()
False
```

is_CSPP()

Return whether self is a cyclically symmetric plane partition.

A plane partition is cyclically symmetric if its $x$, $y$, and $z$ tableaux are all equal.

EXAMPLES:

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
```

```python
sage: PP.is_CSPP()
False
sage: PP = PlanePartition([[3,2,2],[3,1,0],[1,1,0]])
```

```python
sage: PP.is_CSPP()
True
```

is_CSSCPP()

Return whether self is a cyclically symmetric and self-complementary plane partition.

EXAMPLES:
is_CSTCPP()

Return whether self is a cyclically symmetric and transpose-complementary plane partition.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_CSTCPP()
False
sage: PP = PlanePartition([[4,4,4,1],[3,3,2,1],[3,2,1,1],[3,0,0,0]])
sage: PP.is_CSTCPP()
True
```

is_SCPP()

Return whether self is a self-complementary plane partition.

Note that the complement of a plane partition (and thus the property of being self-complementary) is dependent on the choice of a box that it is contained in. If no parent/bounding box is specified, the box is taken to be the smallest box that contains the plane partition.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_SCPP()
False
sage: PP = PlanePartition([[4,4,4,4],[4,4,2,0],[4,2,0,0],[0,0,0,0]])
sage: PP.is_SCPP()
False
sage: PP = PlanePartitions([4,4])([[4,4,4,4],[4,4,2,0],[4,2,0,0],[0,0,0,0]])
sage: PP.is_SCPP()
True
```

is_SPP()

Return whether self is a symmetric plane partition.

A plane partition is symmetric if the corresponding tableau is symmetric about the diagonal.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_SPP()
False
sage: PP = PlanePartition([[3,3,2],[3,3,2],[2,2,2]])
sage: PP.is_SPP()
True
sage: PP = PlanePartition([[3,2,1],[2,0,0]])
sage: PP.is_SPP()
False
sage: PP = PlanePartition([[3,2,0],[2,0,0]])
```

(continues on next page)
sage: PP.is_SPP()
True
sage: PP = PlanePartition([[3,2],[2,0],[1,0]])
sage: PP.is_SPP()
False
sage: PP = PlanePartition([[3,2],[2,0],[0,0]])
sage: PP.is_SPP()
True

is_SSCPP()
Return whether self is a symmetric, self-complementary plane partition.

EXAMPLES:

sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_SSCPP()
False
sage: PP = PlanePartition([[4,3,3,2],[3,2,2,1],[3,2,2,1],[2,1,1,0]])
sage: PP.is_SSCPP()
True
sage: PP = PlanePartition([[2,1],[1,0]])
sage: PP.is_SSCPP()
True
sage: PP = PlanePartition([[4,3,2],[3,2,1],[2,1,0]])
sage: PP.is_SSCPP()
True
sage: PP = PlanePartition([[4,2,2,2],[2,2,2,2],[2,2,2,2],[2,2,2,0]])
sage: PP.is_SSCPP()
True

is_TCPP()
Return whether self is a transpose-complementary plane partition.

EXAMPLES:

sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_TCPP()
False
sage: PP = PlanePartition([[4,4,3,2],[4,4,2,1],[4,2,0,0],[2,0,0,0]])
sage: PP.is_TCPP()
True

is_TSPP()
Return whether self is a totally symmetric plane partition.

A plane partition is totally symmetric if it is both symmetric and cyclically symmetric.

EXAMPLES:

sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_TSPP()
False
sage: PP = PlanePartition([[3,3,3],[3,3,2],[3,2,1]])
(continues on next page)
sage: PP.is_TSSPP()
True

is_TSSCPP()
Return whether self is a totally symmetric self-complementary plane partition.

EXAMPLES:

sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_TSSCPP()
False
sage: PP = PlanePartition([[4,4,3,2],[4,3,2,1],[3,2,1,0],[2,1,0,0]])
sage: PP.is_TSSCPP()
True

maximal_boxes()
Return the coordinates of the maximal boxes of self.
The maximal boxes of a plane partitions are the boxes that can be removed from a plane partition and still
yield a valid plane partition.

EXAMPLES:

sage: sorted(PlanePartition([[3,2,1],[2,2],[2]]).maximal_boxes())
[[0, 0, 2], [0, 2, 0], [1, 1, 1], [2, 0, 1]]
sage: sorted(PlanePartition([[2,1],[1],[1]]).maximal_boxes())
[[0, 0, 1], [0, 1, 0], [2, 0, 0]]

number_of_boxes()
Return the number of boxes in the plane partition.

EXAMPLES:

sage: PP = PlanePartition([[3,1],[2]])
sage: PP.number_of_boxes()
6

plot(show_box=False, colors=None)
Return a plot of self.

INPUT:

• show_box – boolean (default: False); if True, also shows the visible tiles on the xy-, yz-, zx-planes
• colors – (default: ["white", "lightgray", "darkgray"] list [A, B, C] of 3 strings repre-
   senting colors

EXAMPLES:

sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.plot()
Graphics object consisting of 27 graphics primitives

plot3d(colors=None)
Return a 3D-plot of self.

INPUT:
• colors – (default: ["white", "lightgray", "darkgray"]) list [A, B, C] of 3 strings representing colors

EXAMPLES:

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.plot3d()
Graphics3d Object
```

```
pp(show_box=False)
```

Return a pretty print of the plane partition.

**INPUT:**

• show_box – boolean (default: False); if True, also shows the visible tiles on the \(xy\), \(yz\), \(zx\)-planes

**OUTPUT:**

A pretty print of the plane partition.

**EXAMPLES:**

```python
sage: PlanePartition([[4,3,3,1],[2,1,1],[1,1]]).pp()
```

```
* * *
  _/\_ 
 _/ /\_/ 
_/ /_/ /_/ 
_/ /_/ /_/ 
_/ /_/ /_/ 
_/ /_/ /_/ 
```

```python
sage: PlanePartition([[4,3,3,1],[2,1,1],[1,1]]).pp(True)
```

```
* * *
  _/\_ 
 _/ /\_/ 
_/ /_/ /_/ 
_/ /_/ /_/ 
_/ /_/ /_/ 
_/ /_/ /_/ 
```

```
to_order_ideal()
```

Return the order ideal corresponding to \(self\).

**Todo:** As many families of symmetric plane partitions are in bijection with order ideals in an associated poset, this function could feasibly have options to send symmetric plane partitions to the associated order ideal in that poset, instead.

**EXAMPLES:**

```python
sage: PlanePartition([[3,2,1],[2,2],[2]]).to_order_ideal()
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (0, 1, 1), (0, 2, 0), (1, 0, 0), (1, 0, 1), (1, 1, 0), (1, 1, 1), (2, 0, 0), (2, 0, 1)]
```

(continues on next page)
```python
sage: PlanePartition([[2,1],[1],[1]]).to_order_ideal()
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (1, 0, 0), (2, 0, 0)]
```

**to_tableau()**

Return the tableau class of self.

EXAMLPES:

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.to_tableau()
[[4, 3, 3, 1], [2, 1, 1], [1, 1]]
```

**transpose(tableau_only=False)**

Return the transpose of self.

If `tableau_only` is set to True, then only the tableau consisting of the projection of boxes size onto the $xy$-plane is returned instead of a `PlanePartition`. This will not necessarily have trailing rows or trailing zeros removed.

EXAMPLES:

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.transpose()
Plane partition [[4, 2, 1], [3, 1, 1], [3, 1], [1]]
sage: PP.transpose(True)
[[4, 2, 1], [3, 1, 1], [3, 1, 0], [1, 0, 0]]
sage: PPP = PlanePartitions([1, 2, 3])
sage: PP = PPP([[1, 1]])
sage: PT = PP.transpose(); PT
Plane partition [[1], [1]]
sage: PT.parent()
Plane partitions inside a 2 x 1 x 3 box
```

**x_tableau(tableau=True)**

Return the projection of self in the $x$ direction.

If `tableau` is set to False, then only the list of lists consisting of the projection of boxes size onto the $yz$-plane is returned instead of a `Tableau` object. This output will not have empty trailing rows or trailing zeros removed.

EXAMPLES:

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.x_tableau()
[[3, 2, 1, 1], [3, 1, 1, 0], [2, 1, 1, 0], [1, 0, 0, 0]]
```

**y_tableau(tableau=True)**

Return the projection of self in the $y$ direction.

If `tableau` is set to False, then only the list of lists consisting of the projection of boxes size onto the $xz$-plane is returned instead of a `Tableau` object. This output will not have empty trailing rows or trailing zeros removed.

EXAMPLES:
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.y_tableau()
[[4, 3, 2], [3, 1, 0], [3, 0, 0], [1, 0, 0]]

z_tableau(tableau=True)

Return the projection of self in the z direction.

If tableau is set to False, then only the list of lists consisting of the projection of boxes size onto the xy-plane is returned instead of a Tableau object. This output will not have empty trailing rows or trailing zeros removed.

EXAMPLES:

sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.z_tableau()
[[4, 3, 3, 1], [2, 1, 1, 0], [1, 1, 0, 0]]

class sage.combinat.plane_partition.PlanePartitions(box_size=None, symmetry=None, category=None)

Bases: UniqueRepresentation, Parent

Plane partitions.

PlanePartitions() returns the class of all plane partitions.

PlanePartitions(n) return the class of all plane partitions with precisely n boxes.

PlanePartitions([a, b, c]) returns the class of plane partitions that fit inside an a x b x c box.

PlanePartitions([a, b, c]) has the optional keyword symmetry, which restricts the plane partitions inside a box of the specified size satisfying certain symmetry conditions.

• symmetry='SPP' gives the class of symmetric plane partitions. which is all plane partitions fixed under reflection across the diagonal. Requires that a = b.

• symmetry='CSPP' gives the class of cyclic plane partitions, which is all plane partitions fixed under cyclic rotation of coordinates. Requires that a = b = c.

• symmetry='TSPP' gives the class of totally symmetric plane partitions, which is all plane partitions fixed under any interchanging of coordinates. Requires that a = b = c.

• symmetry='SCPP' gives the class of self-complementary plane partitions. which is all plane partitions that are equal to their own complement in the specified box. Requires at least one of a, b, c be even.

• symmetry='TCPP' gives the class of transpose complement plane partitions, which is all plane partitions whose complement in the box of the specified size is equal to their transpose. Requires a = b and at least one of a, b, c be even.

• symmetry='SSCPP' gives the class of symmetric self-complementary plane partitions, which is all plane partitions that are both symmetric and self-complementary. Requires a = b and at least one of a, b, c be even.

• symmetry='CSTCPP' gives the class of cyclically symmetric transpose complement plane partitions, which is all plane partitions that are both symmetric and equal to the transpose of their complement. Requires a = b = c.

• symmetry='CSSCPP' gives the class of cyclically symmetric self-complementary plane partitions, which is all plane partitions that are both cyclically symmetric and self-complementary. Requires a = b = c and all a, b, c be even.
• symmetry='TSSCPP' gives the class of totally symmetric self-complementary plane partitions, which is all plane partitions that are totally symmetric and also self-complementary. Requires $a = b = c$ and all $a, b, c$ be even.

EXAMPLES:
If no arguments are passed, then the class of all plane partitions is returned:

```
sage: PlanePartitions()
Plane partitions
sage: [[2,1],[1]] in PlanePartitions()
True
```
If an integer $n$ is passed, then the class of plane partitions of $n$ is returned:

```
sage: PlanePartitions(3)
Plane partitions of size 3
sage: PlanePartitions(3).list()
[Plane partition [[3]],
 Plane partition [[2, 1]],
 Plane partition [[1, 1, 1]],
 Plane partition [[2], [1]],
 Plane partition [[1, 1], [1]],
 Plane partition [[1], [1], [1]]]
```
If a three-element tuple or list $[a, b, c]$ is passed, then the class of all plane partitions that fit inside and $a \times b \times c$ box is returned:

```
sage: PlanePartitions([2,2,2])
Plane partitions inside a 2 x 2 x 2 box
sage: [[2,1],[1]] in PlanePartitions([2,2,2])
True
```
If an additional keyword `symmetry` is pass along with a three-element tuple or list $[a, b, c]$, then the class of all plane partitions that fit inside an $a \times b \times c$ box with the specified symmetry is returned:

```
sage: PlanePartitions([2,2,2], symmetry='CSPP')
Cyclically symmetric plane partitions inside a 2 x 2 x 2 box
sage: [[2,1],[1]] in PlanePartitions([2,2,2], symmetry='CSPP')
True
```

**Element**
alias of `PlanePartition`

**box()**
Return the size of the box of the plane partition of `self` is contained in.

**EXAMPLES:**
```
sage: P = PlanePartitions([4,3,5])
sage: P.box()  
(4, 3, 5)
sage: PP = PlanePartitions()  
sage: PP.box() is None  
True
```

**symmetry()**
Return the symmetry class of `self`.

**EXAMPLES:**
```
sage: PP = PlanePartitions([3,3,2], symmetry='SPP')  
sage: PP.symmetry()  
'SPP'
sage: PP = PlanePartitions()  
sage: PP.symmetry() is None  
True
```

class `sage.combinat.plane_partition.PlanePartitions_CSPP(box_size)`

Bases: `PlanePartitions`

Plane partitions that fit inside a box of a specified size that are cyclically symmetric.

**cardinality()**
Return the cardinality of `self`.

The number of cyclically symmetric plane partitions inside an \( a \times a \times a \) box is equal to

\[
\left(\prod_{i=1}^{a}\frac{3i-1}{3i-2}\right) \left(\prod_{1 \leq i < j \leq a}\frac{i+j+a-1}{2i+j-1}\right).
\]

**EXAMPLES:**
```
sage: P = PlanePartitions([4,4,4], symmetry='CSPP')  
sage: P.cardinality()  
132
```
from_antichain(acl)

Return the cyclically symmetric plane partition corresponding to an antichain in the poset given in to_poset().

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,3], symmetry='CSPP')
sage: A = [(∅, 2, 2), (1, 1, 1)]
sage: PP.from_antichain(A)
Plane partition [[3, 3, 3], [3, 2, 1], [3, 1, 1]]
```

from_order_ideal(I)

Return the cyclically symmetric plane partition corresponding to an order ideal in the poset given in to_poset().

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,3], symmetry='CSPP')
sage: I = [(∅, 0, 0), (0, 0, 1), (0, 0, 2), (0, 1, 1), (0, 1, 2),
      ....: (1, 0, 2), (0, 2, 2), (1, 1, 1), (1, 1, 2), (1, 2, 2)]
sage: PP.from_order_ideal(I)
Plane partition [[3, 3, 3], [3, 3, 3], [3, 3, 2]]
```

random_element()

Return a uniformly random element of self.

ALGORITHM:

This uses the random_order_ideal() method and the natural bijection between cyclically symmetric plane partitions and order ideals in an associated poset.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,3], symmetry='CSPP')
sage: PP.random_element() # random
Plane partition [[3, 2, 2], [3, 1], [1, 1]]
```

to_poset()

Return a partially ordered set whose order ideals are in bijection with cyclically symmetric plane partitions.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,3], symmetry='CSPP')
sage: PP.to_poset()
Finite poset containing 11 elements
sage: PP.to_poset().order_ideals_lattice().cardinality() == PP.cardinality()
True
```

class sage.combinat.plane_partition.PlanePartitions_CSSCPP(box_size)

Bases: PlanePartitions

Plane partitions that fit inside a box of a specified size that are cyclically symmetric self-complementary.

cardinality()

Return the cardinality of self.
The number of cyclically symmetric self-complementary plane partitions inside a $2a \times 2a \times 2a$ box is equal to

\[
\left( \prod_{i=0}^{a-1} \frac{(3i+1)!}{(a+i)!} \right)^2.
\]

**EXAMPLES:**

```python
sage: P = PlanePartitions([6,6,6], symmetry='CSSCPP')
sage: P.cardinality()
sage: 49
```

```python
class sage.combinat.plane_partition.PlanePartitions_CSTCPP(box_size)

Bases: PlanePartitions

Plane partitions that fit inside a box of a specified size that are cyclically symmetric and transpose-complement.

cardinality()

Return the cardinality of self.

The number of cyclically symmetric transpose complement plane partitions inside a $2a \times 2a \times 2a$ box is equal to

\[
\left( \prod_{i=0}^{a-1} \frac{(3i+1)(6i)!}{(4i)!} \right)^2.
\]

**EXAMPLES:**

```python
sage: P = PlanePartitions([6,6,6], symmetry='CSTCPP')
sage: P.cardinality()
sage: 11
```

```python
class sage.combinat.plane_partition.PlanePartitions_SCPP(box_size)

Bases: PlanePartitions

Plane partitions that fit inside a box of a specified size that are self-complementary.

cardinality()

Return the cardinality of self.

The number of self complementary plane partitions inside a $2a \times 2b \times 2c$ box is equal to

\[
\left( \prod_{i=1}^{a} \prod_{j=1}^{b} \frac{i+j+c-1}{i+j-1} \right)^2.
\]

The number of self complementary plane partitions inside an $(2a+1) \times 2b \times 2c$ box is equal to

\[
\left( \prod_{i=1}^{a} \prod_{j=1}^{b} \frac{i+j+c-1}{i+j-1} \right) \left( \prod_{i=1}^{a+1} \prod_{j=1}^{b} \frac{i+j+c-1}{i+j-1} \right).
\]

The number of self complementary plane partitions inside an $(2a+1) \times (2b+1) \times 2c$ box is equal to

\[
\left( \prod_{i=1}^{a+1} \prod_{j=1}^{b} \frac{i+j+c-1}{i+j-1} \right) \left( \prod_{i=1}^{a} \prod_{j=1}^{b+1} \frac{i+j+c-1}{i+j-1} \right).
\]

**EXAMPLES:**
Combinatorics, Release 10.0

```python
sage: P = PlanePartitions([4,4,4], symmetry='SCPP')
sage: P.cardinality()
400
sage: P = PlanePartitions([5,4,4], symmetry='SCPP')
sage: P.cardinality()
1000
sage: P = PlanePartitions([4,5,4], symmetry='SCPP')
sage: P.cardinality()
1000
sage: P = PlanePartitions([4,4,5], symmetry='SCPP')
sage: P.cardinality()
1000
sage: P = PlanePartitions([5,5,4], symmetry='SCPP')
sage: P.cardinality()
2500
sage: P = PlanePartitions([5,4,5], symmetry='SCPP')
sage: P.cardinality()
2500
sage: P = PlanePartitions([4,5,5], symmetry='SCPP')
sage: P.cardinality()
2500
```

class `sage.combinat.plane_partition.PlanePartitions_SPP(box_size)`

Bases: `PlanePartitions`

Plane partitions that fit inside a box of a specified size that are symmetric.

**cardinality()**

Return the cardinality of `self`.

The number of symmetric plane partitions inside an $a \times a \times b$ box is equal to

$$\left( \prod_{i=1}^{a} \frac{2i+b-1}{2i-1} \right) \left( \prod_{1 \leq i < j \leq a} \frac{i+j+b-1}{i+j-1} \right).$$

**EXAMPLES:**

```python
sage: P = PlanePartitions([3,3,2], symmetry='SPP')
sage: P.cardinality()
35
```

**from_antichain(A)**

Return the symmetric plane partition corresponding to an antichain in the poset given in `to_poset()`.

**EXAMPLES:**

```python
sage: PP = PlanePartitions([3,3,2], symmetry='SPP')
sage: A = [(2, 2, 0), (1, 0, 1), (1, 1, 0)]
sage: PP.from_antichain(A)
Plane partition [[2, 2, 1], [2, 1, 1], [1, 1, 1]]
```
from_order_ideal(I)
Return the symmetric plane partition corresponding to an order ideal in the poset given in `to_poset()`.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,2], symmetry='SPP')
sage: I = [(0, 0, 0), (1, 0, 0), (1, 1, 0), (2, 0, 0)]
sage: PP.from_order_ideal(I)
Plane partition [[1, 1, 1], [1, 1], [1]]
```

random_element()
Return a uniformly random element of `self`.

ALGORITHM:
This uses the `random_order_ideal()` method and the natural bijection between symmetric plane partitions and order ideals in an associated poset.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,2], symmetry='SPP')
sage: PP.random_element() # random
Plane partition [[2, 2, 2], [2, 2], [2]]
```

to_poset()
Return a poset whose order ideals are in bijection with symmetric plane partitions.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,2], symmetry='SPP')
sage: PP.to_poset()
Finite poset containing 12 elements
sage: PP.to_poset().order_ideals_lattice().cardinality() == PP.cardinality()
True
```

class sage.combinat.plane_partition.PlanePartitions_SSCPP(box_size)
Bases: `PlanePartitions`

Plane partitions that fit inside a box of a specified size that are symmetric self-complementary.

cardinality()
Return the cardinality of `self`.

The number of symmetric self-complementary plane partitions inside a $2a \times 2a \times 2b$ box is equal to

$$\prod_{i=1}^{a} \prod_{j=1}^{a} \frac{i + j + b - 1}{i + j - 1}.$$ 

The number of symmetric self-complementary plane partitions inside a $(2a + 1) \times (2a + 1) \times 2b$ box is equal to

$$\prod_{i=1}^{a} \prod_{j=1}^{a+1} \frac{i + j + b - 1}{i + j - 1}.$$ 

EXAMPLES:
```python
sage: P = PlanePartitions([4,4,2], symmetry='SSCPP')
sage: P.cardinality()
6
sage: Q = PlanePartitions([3,3,2], symmetry='SSCPP')
sage: Q.cardinality()
3
```

```python
class sage.combinat.plane_partition.PlanePartitions_TCPP(box_size)
    Bases: PlanePartitions
    Plane partitions that fit inside a box of a specified size that are transpose-complement.
    
cardinality()
    Return the cardinality of self.

    The number of transpose complement plane partitions inside an \(a \times a \times 2b\) box is equal to
    \[
    \binom{b + 1 - 1}{a - 1} \prod_{1 \leq i, j \leq a - 2} \frac{i + j + 2b - 1}{i + j - 1}.
    \]

    EXAMPLES:
    ```
    sage: P = PlanePartitions([3,3,2], symmetry='TCPP')
sage: P.cardinality()
5
```

```python
class sage.combinat.plane_partition.PlanePartitions_TSPP(box_size)
    Bases: PlanePartitions
    Plane partitions that fit inside a box of a specified size that are totally symmetric.
    
cardinality()
    Return the cardinality of self.

    The number of totally symmetric plane partitions inside an \(a \times a \times a\) box is equal to
    \[
    \prod_{1 \leq i, j \leq a} \frac{i + j + a - 1}{i + 2j - 2}.
    \]

    EXAMPLES:
    ```
    sage: P = PlanePartitions([4,4,4], symmetry='TSPP')
sage: P.cardinality()
66
```

```python
from_antichain(acl)
    Return the totally symmetric plane partition corresponding to an antichain in the poset given in to_poset().

    EXAMPLES:
    ```
    sage: PP = PlanePartitions([3,3,3], symmetry='TSPP')
sage: A = [(0, 0, 2), (0, 1, 1)]
sage: PP.from_antichain(A)
Plane partition [[3, 2, 1], [2, 1], [1]]
```
```
from_order_ideal(I)
Return the totally symmetric plane partition corresponding to an order ideal in the poset given in to_poset().
EXAMPLES:

```python
sage: PP = PlanePartitions([3,3,3], symmetry='TSPP')
sage: I = [(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 1, 1)]
sage: PP.from_order_ideal(I)
Plane partition [[3, 2, 1], [2, 1], [1]]
```

to_poset()
Return a poset whose order ideals are in bijection with totally symmetric plane partitions.
EXAMPLES:

```python
sage: PP = PlanePartitions([3,3,3], symmetry='TSPP')
sage: PP.to_poset()
Finite poset containing 10 elements
sage: PP.to_poset().order_ideals_lattice().cardinality() == PP.cardinality()
True
```

class sage.combinat.plane_partition.PlanePartitions_TSSCPP(box_size)
Bases: PlanePartitions
Plane partitions that fit inside a box of a specified size that are totally symmetric self-complementary.
cardinality()
Return the cardinality of self.
The number of totally symmetric self-complementary plane partitions inside a $2a \times 2a \times 2a$ box is equal to

$$
\prod_{i=0}^{a-1} \frac{(3i + 1)!}{(a + i)!}.
$$

EXAMPLES:

```python
sage: P = PlanePartitions([6,6,6], symmetry='TSSCPP')
sage: P.cardinality()
7
```

from_antichain(acl)
Return the totally symmetric self-complementary plane partition corresponding to an antichain in the poset given in to_poset().
EXAMPLES:

```python
sage: PP = PlanePartitions([6,6,6], symmetry='TSSCPP')
sage: A = [(0, 0, 1), (1, 1, 0)]
sage: PP.from_antichain(A)
Plane partition [[6, 6, 6, 5, 5, 3], [6, 5, 5, 4, 3, 1], [6, 5, 4, 3, 2, 1], [5, 4, 3, 2, 1], [5, 3, 2, 1, 1], [3, 1, 1]]
```

from_order_ideal(I)
Return the totally symmetric self-complementary plane partition corresponding to an order ideal in the poset given in to_poset().
EXAMPLES:

```
sage: PP = PlanePartitions([6,6,6], symmetry='TSSCPP')
sage: I = [(0, 0, 0), (0, 1, 0), (1, 1, 0)]
sage: PP.from_order_ideal(I)

Plane partition [[6, 6, 6, 5, 5, 3], [6, 5, 5, 3, 3, 1], [6, 5, 5, 3, 3, 1], [5, 3, 3, 1, 1], [5, 3, 3, 1, 1], [3, 1, 1]]
```

to_poset()

Return a poset whose order ideals are in bijection with totally symmetric self-complementary plane partitions.

EXAMPLES:

```
sage: PP = PlanePartitions([6,6,6], symmetry='TSSCPP')
sage: PP.to_poset()
Finite poset containing 4 elements
sage: PP.to_poset().order_ideals_lattice().cardinality() == PP.cardinality()
True
```

class sage.combinat.plane_partition.PlanePartitions_all

Bases: `PlanePartitions`, `DisjointUnionEnumeratedSets`

All plane partitions.

an_element()

Return a particular element of the class.

class sage.combinat.plane_partition.PlanePartitions_box(box_size)

Bases: `PlanePartitions`

All plane partitions that fit inside a box of a specified size.

By convention, a plane partition in an $a \times b \times c$ box will have at most $a$ rows, of lengths at most $b$, with entries at most $c$.

cardinality()

Return the cardinality of self.

The number of plane partitions inside an $a \times b \times c$ box is equal to

$$\prod_{i=1}^{a} \prod_{j=1}^{b} \prod_{k=1}^{c} \frac{i+j+k-1}{i+j+k-2}. $$

EXAMPLES:

```
sage: P = PlanePartitions([4,3,5])
sage: P.cardinality()
116424
```

from_antichain(A)

Return the plane partition corresponding to an antichain in the poset given in `to_poset()`.

EXAMPLES:

```
sage: A = [(1,0,1), (0,1,1), (1,1,0)]
sage: PlanePartitions([2,2,2]).from_antichain(A)
Plane partition [[2, 2], [2, 1]]
```
from_order_ideal(I)
Return the plane partition corresponding to an order ideal in the poset given in to_poset().

EXAMPLES:

sage: I = [(1, 0, 0), (1, 0, 1), (1, 1, 0), (0, 1, 0), (0, 0, 0), (0, 0, 1), (0, 1, 1)]

sage: PlanePartitions([2,2,2]).from_order_ideal(I)
Plane partition [[2, 2], [2, 1]]

random_element()
Return a uniformly random plane partition inside a box.

ALGORITHM:
This uses the random_order_ideal() method and the natural bijection with plane partitions.

EXAMPLES:

sage: P = PlanePartitions([4,3,5])

sage: P.random_element() # random
Plane partition [[4, 3, 3], [4], [2]]

to_poset()
Return the product of three chains poset, whose order ideals are naturally in bijection with plane partitions inside a box.

EXAMPLES:

sage: PlanePartitions([2,2,2]).to_poset()
Finite lattice containing 8 elements

class sage.combinat.plane_partition.PlanePartitions_n(n)
Bases: PlanePartitions

Plane partitions with a fixed number of boxes.

cardinality()
Return the number of plane partitions with n boxes.

Calculated using the recurrence relation

\[ PL(n) = \sum_{k=1}^{n} PL(n - k)\sigma_2(k), \]

where \( \sigma_k(n) \) is the sum of the k-th powers of divisors of n.

EXAMPLES:

sage: P = PlanePartitions(17)

sage: P.cardinality()
18334
5.1.165 Integer partitions

A partition $p$ of a nonnegative integer $n$ is a non-increasing list of positive integers (the *parts* of the partition) with total sum $n$.

A partition can be depicted by a diagram made of rows of cells, where the number of cells in the $i^{th}$ row starting from the top is the $i^{th}$ part of the partition.

The coordinate system related to a partition applies from the top to the bottom and from left to right. So, the corners of the partition $[5, 3, 1]$ are $[[0, 4], [1, 2], [2, 0]]$.

For display options, see `Partitions.options`.

**Note:**
- Boxes is a synonym for cells. All methods will use ‘cell’ and ‘cells’ instead of ‘box’ and ‘boxes’.
- Partitions are 0 based with coordinates in the form of (row-index, column-index).
- If given coordinates of the form $(r, c)$, then use Python’s *-operator.
- Throughout this documentation, for a partition $\lambda$ we will denote its conjugate partition by $\lambda'$. For more on conjugate partitions, see `Partition.conjugate()`.
- The comparisons on partitions use lexicographic order.

**Note:** We use the convention that lexicographic ordering is read from left-to-right. That is to say $[1, 3, 7]$ is smaller than $[2, 3, 4]$.

**AUTHORS:**
- Mike Hansen (2007): initial version
- Dan Drake (2009-03-28): deprecate RestrictedPartitions and implement Partitions_parts_in
- Travis Scrimshaw (2012-01-12): Implemented latex function to Partition_class
- Travis Scrimshaw (2012-05-09): Fixed Partitions(-1).list() infinite recursion loop by saying Partitions_n is the empty set.
- Travis Scrimshaw (2012-05-11): Fixed bug in inner where if the length was longer than the length of the inner partition, it would include 0’s.
- Andrew Mathas (2012-06-01): Removed deprecated functions and added compatibility with the PartitionTuple classes. See [github issue #13072](https://github.com/sagemath/sage/issues/13072)
- Travis Scrimshaw (2012-10-12): Added options. Made `Partition_class` to the element `Partition`. `Partitions*` are now all in the category framework except `PartitionsRestricted` (which will eventually be removed). Cleaned up documentation.
- Matthew Lancellotti (2018-09-14): Added a bunch of “k” methods to `Partition`.

**EXAMPLES:**

There are 5 partitions of the integer 4:

```python
sage: Partitions(4).cardinality()
sage: Partitions(4).list()
```

```
5
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```
We can use the method \texttt{.first()} to get the ‘first’ partition of a number:

\begin{verbatim}
sage: Partitions(4).first()
[4]
\end{verbatim}

Using the method \texttt{.next(p)}, we can calculate the ‘next’ partition after \( p \). When we are at the last partition, \texttt{None} will be returned:

\begin{verbatim}
sage: Partitions(4).next([4])
[3, 1]
sage: Partitions(4).next([1,1,1,1]) is None
True
\end{verbatim}

We can use \texttt{iter} to get an object which iterates over the partitions one by one to save memory. Note that when we do something like \texttt{for part in Partitions(4)} this iterator is used in the background:

\begin{verbatim}
sage: g = iter(Partitions(4))
sage: next(g)
[4]
sage: next(g)
[3, 1]
sage: next(g)
[2, 2]
sage: for p in Partitions(4): print(p)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
\end{verbatim}

We can add constraints to the type of partitions we want. For example, to get all of the partitions of 4 of length 2, we'd do the following:

\begin{verbatim}
sage: Partitions(4, length=2).list()
[[3, 1], [2, 2]]
\end{verbatim}

Here is the list of partitions of length at least 2 and the list of ones with length at most 2:

\begin{verbatim}
sage: Partitions(4, min_length=2).list()
[[3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: Partitions(4, max_length=2).list()
[[4], [3, 1], [2, 2]]
\end{verbatim}

The options \texttt{min_part} and \texttt{max_part} can be used to set constraints on the sizes of all parts. Using \texttt{max_part}, we can select partitions having only ‘small’ entries. The following is the list of the partitions of 4 with parts at most 2:

\begin{verbatim}
sage: Partitions(4, max_part=2).list()
[[2, 2], [2, 1, 1], [1, 1, 1, 1]]
\end{verbatim}

The \texttt{min_part} options is complementary to \texttt{max_part} and selects partitions having only ‘large’ parts. Here is the list of all partitions of 4 with each part at least 2:

\begin{verbatim}
sage: Partitions(4, min_part=2).list()
[[4], [2, 2]]
\end{verbatim}
The options `inner` and `outer` can be used to set part-by-part constraints. This is the list of partitions of 4 with [3, 1, 1] as an outer bound (that is, partitions of 4 contained in the partition [3, 1, 1]):

```
sage: Partitions(4, outer=[3,1,1]).list()
[[3, 1], [2, 1, 1]]
```

`outer` sets `max_length` to the length of its argument. Moreover, the parts of `outer` may be infinite to clear constraints on specific parts. Here is the list of the partitions of 4 of length at most 3 such that the second and third part are 1 when they exist:

```
sage: Partitions(4, outer=[oo,1,1]).list()
[[4], [3, 1], [2, 1, 1]]
```

Finally, here are the partitions of 4 with [1,1,1] as an inner bound (i.e., the partitions of 4 containing the partition [1,1,1]). Note that `inner` sets `min_length` to the length of its argument:

```
sage: Partitions(4, inner=[1,1,1]).list()
[[2, 1, 1], [1, 1, 1, 1]]
```

The options `min_slope` and `max_slope` can be used to set constraints on the slope, that is on the difference $p_{i+1} - p_{i}$ of two consecutive parts. Here is the list of the strictly decreasing partitions of 4:

```
sage: Partitions(4, max_slope=-1).list()
[[4], [3, 1]]
```

The constraints can be combined together in all reasonable ways. Here are all the partitions of 11 of length between 2 and 4 such that the difference between two consecutive parts is between $-3$ and $-1$:

```
sage: Partitions(11,min_slope=-3,max_slope=-1,min_length=2,max_length=4).list()
[[7, 4], [6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2], [5, 3, 2, 1]]
```

Partition objects can also be created individually with `Partition`:

```
sage: Partition([2,1])
[2, 1]
```

Once we have a partition object, then there are a variety of methods that we can use. For example, we can get the conjugate of a partition. Geometrically, the conjugate of a partition is the reflection of that partition through its main diagonal. Of course, this operation is an involution:

```
sage: Partition([4,1]).conjugate()
[2, 1, 1, 1]
sage: Partition([4,1]).conjugate().conjugate()
[4, 1]
```

If we create a partition with extra zeros at the end, they will be dropped:

```
sage: Partition([4,1,0,0])
[4, 1]
sage: Partition([0])
[]
sage: Partition([0,0])
[]
```

The idea of a partition being followed by infinitely many parts of size 0 is consistent with the `get_part` method:
We can go back and forth between the standard and the exponential notations of a partition. The exponential notation can be padded with extra zeros:

```
sage: Partition([6,4,4,2,1]).to_exp()
[1, 1, 0, 2, 0, 1]
sage: Partition(exp=[1,1,0,2,0,1])
[6, 4, 4, 2, 1]
sage: Partition([6,4,4,2,1]).to_exp(5)
[1, 1, 0, 2, 0, 1, 0]
sage: Partition([6,4,4,2,1]).to_exp(10)
[1, 1, 0, 2, 0, 1, 0, 0, 0, 0]
```

We can get the (zero-based!) coordinates of the corners of a partition:

```
sage: Partition([4,3,1]).corners()
[(0, 3), (1, 2), (2, 0)]
```

We can compute the core and quotient of a partition and build the partition back up from them:

```
sage: Partition([6,3,2,2]).core(3)
[2, 1, 1]
sage: Partition([7,7,5,3,3,3,1]).quotient(3)
([2], [1], [2, 2, 2])
sage: p = Partition([11,5,5,3,2,2,2])
sage: p.core(3)
[]
sage: p.quotient(3)
([2, 1], [4], [1, 1, 1])
sage: Partition(core=[],quotient=(2, 1), [4], [1, 1, 1]))
[11, 5, 5, 3, 2, 2, 2]
```

We can compute the \(0 - 1\) sequence and go back and forth:

```
sage: Partitions().from_zero_one([1, 1, 1, 1, 0, 1, 0])
[5, 4]
sage: all(Partitions().from_zero_one(mu.zero_one_sequence())
....:    == mu for n in range(5) for mu in Partitions(n))
True
```

We can compute the Frobenius coordinates and go back and forth:

```
sage: Partition([7,3,1]).frobenius_coordinates()
([6, 1, [2, 0]])
sage: Partition(frobenius_coordinates=(6,1,2,0))
[7, 3, 1]
sage: all(mu == Partition(frobenius_coordinates=mu.frobenius_coordinates())
```
for n in range(12) for mu in Partitions(n))

We use the lexicographic ordering:

```python
sage: pl = Partition([4,1,1])
sage: ql = Partitions()([3,3])
sage: pl > ql
True
sage: PL = Partitions()
sage: pl = PL([4,1,1])
sage: ql = PL([3,3])
sage: pl > ql
True
```

```python
class sage.combinat.partition.OrderedPartitions(n, k)

Bases: Partitions

The class of ordered partitions of n. If k is specified, then this contains only the ordered partitions of length k.

An ordered partition of a nonnegative integer n means a list of positive integers whose sum is n. This is the same as a composition of n.

Note: It is recommended that you use Compositions() instead as OrderedPartitions() wraps GAP.

EXAMPLES:

```python
sage: OrderedPartitions(3)
Ordered partitions of 3
sage: OrderedPartitions(3).list()
[[3], [2, 1], [1, 2], [1, 1, 1]]
sage: OrderedPartitions(3,2)
Ordered partitions of 3 of length 2
sage: OrderedPartitions(3,2).list()
[[2, 1], [1, 2]]
sage: OrderedPartitions(10,k=2).list()
[[9, 1], [8, 2], [7, 3], [6, 4], [5, 5], [4, 6], [3, 7], [2, 8], [1, 9]]
sage: OrderedPartitions(4).list()
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

cardinality()

Return the cardinality of self.

EXAMPLES:

```python
sage: OrderedPartitions(3).cardinality()
4
sage: OrderedPartitions(3,2).cardinality()
2
sage: OrderedPartitions(10,2).cardinality()
9
```
Combinatorics, Release 10.0

sage: OrderedPartitions(15).cardinality()
16384

list()

Return a list of partitions in self.

EXAMPLES:

sage: OrderedPartitions(3).list()
[[3], [2, 1], [1, 2], [1, 1, 1]]
sage: OrderedPartitions(3,2).list()
[[2, 1], [1, 2]]

class sage.combinat.partition.Particlen(parent, mu)

Bases: CombinatorialElement

A partition $\mu$ of a nonnegative integer $n$ is a non-increasing list of positive integers (the parts of the partition) with total sum $n$.

A partition is often represented as a diagram consisting of cells, or boxes, placed in rows on top of each other such that the number of cells in the $i^{th}$ row, reading from top to bottom, is the $i^{th}$ part of the partition. The rows are left-justified (and become shorter and shorter the farther down one goes). This diagram is called the Young diagram of the partition, or more precisely its Young diagram in English notation. (French and Russian notations are variations on this representation.)

The coordinate system related to a partition applies from the top to the bottom and from left to right. So, the corners of the partition $[5, 3, 1]$ are $[[0,4], [1,2], [2,0]]$.

For display options, see Partitions.options().

Note: Partitions are 0 based with coordinates in the form of (row-index, column-index). For example consider the partition $\mu=\text{Partition}([4,3,2,2])$, the first part is $\mu[0]$ (which is 4), the second is $\mu[1]$, and so on, and the upper-left cell in English convention is $(0, 0)$.

A partition can be specified in one of the following ways:

- a list (the default)
- using exponential notation
- by Frobenius coordinates
- specifying its 0 – 1 sequence
- specifying the core and the quotient

See the examples below.

EXAMPLES:

Creating partitions though parents:

sage: mu = Partitions(8)([3,2,1,1,1]); mu
[3, 2, 1, 1, 1]
sage: nu = Partition([3,2,1,1,1]); nu
[3, 2, 1, 1, 1]
sage: mu == nu
True
sage: mu is nu
False
sage: mu in Partitions()
True
sage: mu.parent()
Partitions of the integer 8
sage: mu.size()
8
sage: mu.category()
Category of elements of Partitions of the integer 8
sage: nu.parent()
Partitions
sage: nu.category()
Category of elements of Partitions
sage: mu[0]
3
sage: mu[1]
2
sage: mu[2]
1
sage: mu.pp()
***
**
*
*
sage: mu.removable_cells()
[(0, 2), (1, 1), (4, 0)]
sage: mu.down_list()
[[2, 2, 1, 1, 1], [3, 1, 1, 1, 1], [3, 2, 1, 1]]
sage: mu.addable_cells()
[(0, 3), (1, 2), (2, 1), (5, 0)]
sage: mu.up_list()
[[4, 2, 1, 1, 1], [3, 3, 1, 1, 1], [3, 2, 2, 1, 1], [3, 2, 1, 1, 1, 1]]
sage: mu.conjugate()
[5, 2, 1]
sage: mu.dominates(nu)
True
sage: nu.dominates(mu)
True

Creating partitions using Partition:

sage: Partition([3, 2, 1])
[3, 2, 1]
sage: Partition(exp=[2, 1, 1])
[3, 2, 1, 1]
sage: Partition(core=[2, 1], quotient=[[2, 1], [3], [1, 1, 1]])
[11, 5, 5, 3, 2, 2, 2]
sage: Partition(frobenius_coordinates=[[3, 2], [4, 0]])
[4, 4, 1, 1, 1]
Sage ignores trailing zeros at the end of partitions:

```
sage: Partition([3, 2, 1, 0])
[3, 2, 1]
sage: Partitions()([3, 2, 1])
[3, 2, 1]
sage: Partitions(6)([3, 2, 1])
[3, 2, 1]
```

```
add_cell(i, j=None)
Return a partition corresponding to self with a cell added in row i. (This does not change self.)

EXAMPLES:
```
sage: Partition([3, 2, 1, 1]).add_cell(0)
[4, 2, 1, 1]
sage: cell = [4, 0]; Partition([3, 2, 1, 1]).add_cell(*cell)
[3, 2, 1, 1, 1]
```

```
add_horizontal_border_strip(k)
Return a list of all the partitions that can be obtained by adding a horizontal border strip of length k to self.

EXAMPLES:
```
sage: Partition([]).add_horizontal_border_strip(0)
[]
sage: Partition([3,2,1]).add_horizontal_border_strip(0)
[[3, 2, 1]]
sage: Partition([2,2]).add_horizontal_border_strip(2)
[[4, 2], [3, 2, 1], [2, 2, 2]]
sage: Partition([3,2,2]).add_horizontal_border_strip(2)
[[5, 2, 2], [4, 3, 2], [4, 2, 2, 1], [3, 3, 2, 1], [3, 2, 2, 2]]
```

```
add_vertical_border_strip(k)
Return a list of all the partitions that can be obtained by adding a vertical border strip of length k to self.

EXAMPLES:
```
sage: Partition([]).add_vertical_border_strip(0)
[]
```
```
addable_cells()

Return a list of the outside corners of the partition self.

An outside corner (also called a cocorner) of a partition \( \lambda \) is a cell on \( \mathbb{Z}^2 \) which does not belong to the Young diagram of \( \lambda \) but can be added to this Young diagram to still form a straight-shape Young diagram.

The entries of the list returned are pairs of the form \((i, j)\), where \( i \) and \( j \) are the coordinates of the respective corner. The coordinates are counted from 0.

Note: These are called “outer corners” in [Sag2001].

EXAMPLES:

```python
sage: Partition([2,2,1]).outside_corners()
[(0, 2), (2, 1), (3, 0)]

sage: Partition([2,2]).outside_corners()
[(0, 2), (2, 0)]

sage: Partition([6,3,3,1,1,1]).outside_corners()
[(0, 6), (1, 3), (3, 1), (6, 0)]

sage: Partition([]).outside_corners()
[(0, 0)]
```

addable_cells_residue\((i, l)\)

Return a list of the outside corners of the partition self having \( l \)-residue \( i \).

An outside corner (also called a cocorner) of a partition \( \lambda \) is a cell on \( \mathbb{Z}^2 \) which does not belong to the Young diagram of \( \lambda \) but can be added to this Young diagram to still form a straight-shape Young diagram. See residue() for the definition of the \( l \)-residue.

The entries of the list returned are pairs of the form \((i, j)\), where \( i \) and \( j \) are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```python
sage: Partition([2,2,1]).outside_corners_residue(0, 3)
[(0, 3), (3, 0)]

sage: Partition([2,2]).outside_corners_residue(1, 3)
[(1, 2)]

sage: Partition([3,2,1]).outside_corners_residue(2, 3)
[(2, 1)]
```

arm_cells\((i, j)\)

Return the list of the cells of the arm of cell \((i, j)\) in self.

The arm of cell \( c = (i, j) \) is the boxes that appear to the right of \( c \).
The cell coordinates are zero-based, i.e., the northwesternmost cell is (0, 0).

INPUT:
• i, j – two integers

OUTPUT:
A list of pairs of integers

EXAMPLES:

```
sage: Partition([4,4,3,1]).arm_cells(1,1)
[(1, 2), (1, 3)]
sage: Partition([]).arm_cells(0,0)
Traceback (most recent call last):
...
ValueError: the cell is not in the diagram
```

`arm_length(i, j)`

Return the length of the arm of cell (i, j) in self.

The arm of cell (i, j) is the cells that appear to the right of cell (i, j).

The cell coordinates are zero-based, i.e., the northwesternmost cell is (0, 0).

INPUT:
• i, j – two integers

OUTPUT:
An integer or a ValueError

EXAMPLES:

```
sage: p = Partition([2,2,1])
sage: p.arm_length(0, 0)
1
sage: p.arm_length(0, 1)
0
sage: p.arm_length(2, 0)
0
sage: Partition([3,3]).arm_length(0, 0)
2
sage: Partition([3,3]).arm_length(*[0,0])
2
```

`arm_lengths(flat=False)`

Return a tableau of shape self where each cell is filled with its arm length.

The optional boolean parameter flat provides the option of returning a flat list.

EXAMPLES:

```
sage: Partition([2,2,1]).arm_lengths()
[[[1, 0], [1, 0], [0]]]
sage: Partition([2,2,1]).arm_lengths(flat=True)
[[1, 0, 1, 0, 0]]
```

Combinatorics, Release 10.0

sage: Partition([3,3]).arm_lengths()
[[2, 1, 0], [2, 1, 0]]
sage: Partition([3,3]).arm_lengths(flat=True)
[2, 1, 0, 2, 1, 0]

arms_legs_coeff(i, j)
This is a statistic on a cell \( c = (i, j) \) in the diagram of partition \( p \) given by
\[
\frac{1 - q^a \cdot t^{\ell + 1}}{1 - q^{a + 1} \cdot t^\ell}
\]
where \( a \) is the arm length of \( c \) and \( \ell \) is the leg length of \( c \).

The coordinates \( i \) and \( j \) of the cell are understood to be 0-based, so that \((0, 0)\) is the northwesternmost cell (in English notation).

EXAMPLES:

sage: Partition([3,2,1]).arms_legs_coeff(1,1)
(-t + 1)/(-q + 1)
sage: Partition([3,2,1]).arms_legs_coeff(0,0)
(-q^2*t^3 + 1)/(-q^3*t^2 + 1)
sage: Partition([3,2,1]).arms_legs_coeff(*[0,0])
(-q^2*t^3 + 1)/(-q^3*t^2 + 1)

atom()
Return a list of the standard tableaux of size self.size() whose atom is equal to self.

EXAMPLES:

sage: Partition([2,1]).atom()
[[[1, 2], [3]]]
sage: Partition([3,2,1]).atom()
[[[1, 2, 3, 6], [4, 5]], [[1, 2, 3], [4, 5], [6]]]

attacking_pairs()
Return a list of the attacking pairs of the Young diagram of self.

A pair of cells \((c, d)\) of a Young diagram (in English notation) is said to be attacking if one of the following conditions holds:
1. \( c \) and \( d \) lie in the same row with \( c \) strictly to the west of \( d \).
2. \( c \) is in the row immediately to the south of \( d \), and \( c \) lies strictly east of \( d \).

This particular method returns each pair \((c, d)\) as a tuple, where each of \( c \) and \( d \) is given as a tuple \((i, j)\) with \( i \) and \( j \) zero-based (so \( i = 0 \) means that the cell lies in the topmost row).

EXAMPLES:

sage: p = Partition([3, 2])
sage: p.attacking_pairs()
[((0, 0), (0, 1)), ((0, 0), (0, 2)), ((0, 1), (0, 2)), ((1, 0), (1, 1)),
  ((1, 0), (1, 2)), ((1, 1), (1, 2)), ((1, 1), (1, 3)), ((1, 2), (1, 3)),
  ((2, 0), (2, 1)), ((2, 0), (2, 2)), ((2, 1), (2, 2))]

(continues on next page)
aut\((r=0, q=0)\)

Return the size of the centralizer of any permutation of cycle type \(\text{self}\).

If \(m_i\) is the multiplicity of \(i\) as a part of \(p\), this is given by

\[
\prod_i m_i! m_i^2.
\]

Including the optional parameters \(t\) and \(q\) gives the \(q, t\) analog, which is the former product times

\[
\prod_{i=1}^{\text{length}(p)} \frac{1 - q^{p_i}}{1 - t^{p_i}}.
\]

See Section 1.3, p. 24, in [Ke1991].

EXAMPLES:

\[
\begin{align*}
sage: & \text{Partition([2,2,1]).centralizer_size()} \\
& 8 \\
sage: & \text{Partition([2,2,2]).centralizer_size()} \\
& 48 \\
sage: & \text{Partition([2,2,1]).centralizer_size(q=2, t=3)} \\
& 9/16 \\
sage: & \text{Partition([[]].centralizer_size()} \\
& 1 \\
sage: & \text{Partition([[]].centralizer_size(q=2, t=4)} \\
& 1
\end{align*}
\]

beta_numbers\((\text{length=\text{None}})\)

Return the set of beta numbers corresponding to \(\text{self}\).

The optional argument \(\text{length}\) specifies the length of the beta set (which must be at least the length of \(\text{self}\)).

For more on beta numbers, see \texttt{frobenius_coordinates()}.

EXAMPLES:

\[
\begin{align*}
sage: & \text{Partition([4,3,2]).beta_numbers()} \\
& [6, 4, 2] \\
sage: & \text{Partition([4,3,2]).beta_numbers(5)} \\
& [8, 6, 4, 1, 0] \\
sage: & \text{Partition([[]].beta_numbers()} \\
& [] \\
sage: & \text{Partition([[]].beta_numbers(3)} \\
& [2, 1, 0] \\
sage: & \text{Partition([6,4,1,1]).beta_numbers()} \\
& [9, 6, 2, 1] \\
sage: & \text{Partition([6,4,1,1]).beta_numbers(6)} \\
& [11, 8, 4, 3, 1, 0] \\
sage: & \text{Partition([1,1,1].beta_numbers()} \\
& []
\end{align*}
\]
block\((e, \text{multicharge}=(0,))\)

Return a dictionary \(\beta\) that determines the block associated to the partition \(\text{self}\) and the quantum_characteristic() \(e\).

**INPUT:**

- \(e\) – the quantum characteristic
- \(\text{multicharge}\) – the multicharge (default \((0,))\)

**OUTPUT:**

- A dictionary giving the multiplicities of the residues in the partition tuple \(\text{self}\)

In more detail, the value \(\text{beta}[i]\) is equal to the number of nodes of residue \(i\). This corresponds to the positive root

\[
\sum_{i \in I} \beta_i \alpha_i \in Q^+,
\]

a element of the positive root lattice of the corresponding Kac-Moody algebra. See [DJM1998] and [BK2009] for more details.

This is a useful statistics because two Specht modules for a Hecke algebra of type \(A\) belong to the same block if and only if they correspond to same element \(\beta\) of the root lattice, given above.

We return a dictionary because when the quantum characteristic is 0, the Cartan type is \(A_\infty\), in which case the simple roots are indexed by the integers.

**EXAMPLES:**

```python
sage: Partition([4,3,2]).block(0)
{0: 4, 1: 5}
```

```python
sage: Partition([4,3,2]).block(2)
{0: 5, 1: 4}
```

```python
sage: Partition([4,3,2]).block(2, multicharge=(1,))
{0: 5, 1: 4}
```

```python
sage: Partition([4,3,2]).block(3)
{0: 1, 3: 2, 2: 3}
```

```python
sage: Partition([4,3,2]).block(4)
{0: 2, 1: 2, 2: 2, 3: 3}
```

boundary()

Return the integer coordinates of points on the boundary of \(\text{self}\).

For the following description, picture the Ferrer’s diagram of \(\text{self}\) using the French convention. Recall that the French convention puts the longest row on the bottom and the shortest row on the top. In addition, interpret the Ferrer’s diagram as 1 x 1 cells in the Euclidean plane. So if \(\text{self}\) was the partition \([3, 1]\), the lower-left vertices of the 1 x 1 cells in the Ferrer’s diagram would be \((0, 0), (1, 0), (2, 0), \) and \((0, 1)\).

The boundary of a partition is the set \(\{\text{NE}(d) \mid \forall d \text{ diagonal}\}\). That is, for every diagonal line \(y = x + b\) where \(b \in \mathbb{Z}\), we find the northeasternmost (NE) point on that diagonal which is also in the Ferrer’s diagram.

The boundary will go from bottom-right to top-left.

**EXAMPLES:**

5.1. Comprehensive Module List 1721
Consider the partition (1) depicted as a square on a cartesian plane with vertices (0, 0), (1, 0), (1, 1), and (0, 1). Three of those vertices in the appropriate order form the boundary:

```
sage: Partition([1]).boundary()
[(1, 0), (1, 1), (0, 1)]
```

The partition (3, 1) can be visualized as three squares on a cartesian plane. The coordinates of the appropriate vertices form the boundary:

```
sage: Partition([3, 1]).boundary()
[(3, 0), (3, 1), (2, 1), (1, 1), (1, 2), (0, 2)]
```

See also:

`k_rim()`. You might have been looking for `k_boundary()` instead.

`cell_poset(orientation='SE')`

Return the Young diagram of `self` as a poset. The optional keyword variable `orientation` determines the order relation of the poset.

The poset always uses the set of cells of the Young diagram of `self` as its ground set. The order relation of the poset depends on the `orientation` variable (which defaults to "SE"). Concretely, `orientation` has to be specified to one of the strings "NW", "NE", "SW", and "SE", standing for “northwest”, “northeast”, “southwest” and “southeast”, respectively. If `orientation` is "SE", then the order relation of the poset is such that a cell `𝑢` is greater or equal to a cell `𝑣` in the poset if and only if `𝑢` lies weakly southeast of `𝑣` (this means that `𝑢` can be reached from `𝑣` by a sequence of south and east steps; the sequence is allowed to consist of south steps only, or of east steps only, or even be empty). Similarly the order relation is defined for the other three orientations. The Young diagram is supposed to be drawn in English notation.

The elements of the poset are the cells of the Young diagram of `self`, written as tuples of zero-based coordinates (so that (3, 7) stands for the 8-th cell of the 4-th row, etc.).

EXAMPLES:

```
sage: p = Partition([3,3,1])
sage: Q = p.cell_poset(); Q
Finite poset containing 7 elements

sage: sorted(Q)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]

sage: sorted(Q.maximal_elements())
[(1, 2), (2, 0)]

sage: Q.minimal_elements()
[(0, 0)]

sage: sorted(Q.upper_covers((1, 0)))
[(1, 1), (2, 0)]

sage: P = p.cell_poset(orientation="NW"); P
Finite poset containing 7 elements

sage: sorted(P)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]

sage: sorted(P.minimal_elements())
[(1, 2), (2, 0)]

sage: P.maximal_elements()
[(0, 0)]
```

(continues on next page)
sage: P.upper_covers((2, 0))
[(1, 0)]
sage: sorted(P.upper_covers((1, 2)))
[(0, 2), (1, 1)]
sage: sorted(P.upper_covers((1, 1)))
[(0, 1), (1, 0)]
sage: sorted([len(P.upper_covers(v)) for v in P])
[0, 1, 1, 1, 1, 2, 2]
sage: R = p.cell_poset(orientation="NE"); R
Finite poset containing 7 elements
sage: sorted(R)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: R.maximal_elements()
[(0, 2)]
sage: R.minimal_elements()
[(2, 0)]
sage: sorted([len(R.upper_covers(v)) for v in R])
[0, 1, 1, 1, 1, 2, 2]
sage: R.is_isomorphic(P)
False
sage: R.is_isomorphic(P.dual())
False

Linear extensions of \( p.cell\_poset() \) are in 1-to-1 correspondence with standard Young tableaux of shape \( p \):

sage: all( len(p.cell_poset().linear_extensions()) ==
...... len(p.standard_tableaux())
...... for n in range(8) for p in Partitions(n) )
True

This is not the case for northeast orientation:

sage: q = Partition([3, 1])
sage: q.cell_poset(orientation="NE").is_chain()
True
cells()  
Return the coordinates of the cells of self.

EXAMPLES:

sage: Partition([2,2]).cells()
[[0, 0], (0, 1), (1, 0), (1, 1)]
sage: Partition([3,2]).cells()
[[0, 0], (0, 1), (0, 2), (1, 0), (1, 1)]

centralizer_size\((t=0, q=0)\)  
Return the size of the centralizer of any permutation of cycle type self.

If \( m_i \) is the multiplicity of \( i \) as a part of \( p \), this is given by

\[
\prod_i m_i!^{m_i}.
\]
Including the optional parameters $t$ and $q$ gives the $q,t$ analog, which is the former product times

$$\prod_{i=1}^{\text{length}(p)} \frac{1 - q^{p_i}}{1 - t^{p_i}}.$$ 

See Section 1.3, p. 24, in [Ke1991].

EXAMPLES:

```python
sage: Partition([2,2,1]).centralizer_size()
8
sage: Partition([2,2,2]).centralizer_size()
48
sage: Partition([2,2,1]).centralizer_size(q=2, t=3)
9/16
sage: Partition([]).centralizer_size()
1
sage: Partition([]).centralizer_size(q=2, t=4)
1
```

**character_polynomial()**

Return the character polynomial associated to the partition `self`.

The character polynomial $q_\mu$ associated to a partition $\mu$ is defined by

$$q_\mu(x_1, x_2, \ldots, x_k) = \downarrow \sum_{\alpha \vdash k} \chi^\mu_\alpha 1^{a_1} 2^{a_2} \cdots k^{a_k} a_1! a_2! \cdots a_k! \prod_{i=1}^{k} (ix_i - 1)^{a_i}$$

where $k$ is the size of $\mu$, and $a_i$ is the multiplicity of $i$ in $\alpha$.

It is computed in the following manner:

1. Expand the Schur function $s_\mu$ in the power-sum basis,
2. Replace each $p_i$ with $ix_i - 1$,
3. Apply the umbral operator $\downarrow$ to the resulting polynomial.

EXAMPLES:

```python
sage: Partition([1]).character_polynomial()
x - 1
sage: Partition([1,1]).character_polynomial()
1/2*x0^2 - 3/2*x0 - x1 + 1
sage: Partition([2,1]).character_polynomial()
1/3*x0^3 - 2*x0^2 - 8/3*x0 - x2
```

**components()**

Return a list containing the shape of `self`.

This method exists only for compatibility with `PartitionTuples`.

EXAMPLES:

```python
sage: Partition([3,2]).components()
[[3, 2]]
```
**conjugacy_class_size()**

Return the size of the conjugacy class of the symmetric group indexed by `self`.

**EXAMPLES:**

```
sage: Partition([2,2,2]).conjugacy_class_size()
15
sage: Partition([2,2,1]).conjugacy_class_size()
15
sage: Partition([2,1,1]).conjugacy_class_size()
6
```

**conjugate()**

Return the conjugate partition of the partition `self`. This is also called the associated partition or the transpose in the literature.

**EXAMPLES:**

```
sage: Partition([2,2]).conjugate()
[2, 2]
sage: Partition([6,3,1]).conjugate()
[3, 2, 1, 1, 1, 1]
```

The conjugate partition is obtained by transposing the Ferrers diagram of the partition (see `ferrers_diagram()`):

```
sage: print(Partition([6,3,1]).ferrers_diagram())
******
***
*
sage: print(Partition([6,3,1]).conjugate().ferrers_diagram())
***
**
**
*
*
```

**contains(x)**

Return `True` if `x` is a partition whose Ferrers diagram is contained in the Ferrers diagram of `self`.

**EXAMPLES:**

```
sage: p = Partition([3,2,1])
sage: p.contains([2,1])
True
sage: all(p.contains(mu) for mu in Partitions(3))
True
sage: all(p.contains(mu) for mu in Partitions(4))
False
```

**content(r, c, multicharge=(0,))**

Return the content of the cell at row `r` and column `c`.

The content of a cell is `c - r`. 

5.1. Comprehensive Module List 1725
For consistency with partition tuples there is also an optional `multicharge` argument which is an offset to the usual content. By setting the `multicharge` equal to the 0-element of the ring \( \mathbb{Z}/e\mathbb{Z} \), the corresponding \( e \)-residue will be returned. This is the content modulo \( e \).

The content (and residue) do not strictly depend on the partition, however, this method is included because it is often useful in the context of partitions.

**EXAMPLES:**

```sage
sage: Partition([2,1]).content(1,0)
-1
sage: p = Partition([3,2])
sage: sum([p.content(*c) for c in p.cells()])
2
```

and now we return the 3-residue of a cell:

```sage
sage: Partition([2,1]).content(1,0, multicharge=IntegerModRing(3)(0))
2
```

### `contents_tableau(multicharge=(0,))`

Return the tableau which has \((k,r,c)\)-th cell equal to the content \(multicharge[k] - r + c\) of the cell.

**EXAMPLES:**

```sage
sage: Partition([2,1]).contents_tableau()
[[0, 1], [-1]]
sage: Partition([3,2,1,1]).contents_tableau().pp()
   0 1 2
  -1 0
  -2
-3
sage: Partition([3,2,1,1]).contents_tableau([ IntegerModRing(3)(0) ] ).pp()
   0 1 2
  2 0
  1
-0
```

### `core(length)`

Return the `length`-core of the partition – in the literature the core is commonly referred to as the \( k \)-core, \( p \)-core, \( r \)-core, ... .

The \( r \)-core of a partition \( \lambda \) can be obtained by repeatedly removing rim hooks of size \( r \) from (the Young diagram of) \( \lambda \) until this is no longer possible. The remaining partition is the core.

**EXAMPLES:**

```sage
sage: Partition([6,3,2,2]).core(3)
[2, 1, 1]
sage: Partition([]).core(3)
[]
sage: Partition([8,7,7,4,1,1,1,1,1]).core(3)
[2, 1, 1]
```

### `corners()`

Return a list of the corners of the partition `self`.
A corner of a partition \( \lambda \) is a cell of the Young diagram of \( \lambda \) which can be removed from the Young diagram while still leaving a straight shape behind.

The entries of the list returned are pairs of the form \((i, j)\), where \(i\) and \(j\) are the coordinates of the respective corner. The coordinates are counted from 0.

**Note:** This is referred to as an “inner corner” in [Sag2001].

**EXAMPLES:**

```
sage: Partition([3,2,1]).corners()
[(0, 2), (1, 1), (2, 0)]
sage: Partition([3,3,1]).corners()
[(1, 2), (2, 0)]
sage: Partition([]).corners()
[]
```

corners_residue\((i, l)\)

Return a list of the corners of the partition \( \text{self} \) having \(l\)-residue \(i\).

A corner of a partition \( \lambda \) is a cell of the Young diagram of \( \lambda \) which can be removed from the Young diagram while still leaving a straight shape behind. See residue() for the definition of the \(l\)-residue.

The entries of the list returned are pairs of the form \((i, j)\), where \(i\) and \(j\) are the coordinates of the respective corner. The coordinates are counted from 0.

**EXAMPLES:**

```
sage: Partition([3,2,1]).corners_residue(0, 3)
[(1, 1)]
sage: Partition([3,2,1]).corners_residue(1, 3)
[(2, 0)]
sage: Partition([3,2,1]).corners_residue(2, 3)
[(0, 2)]
```

crank()

Return the Dyson crank of \( \text{self} \).

The Dyson crank of a partition \( \lambda \) is defined as follows: If \( \lambda \) contains at least one 1, then the crank is \( \mu(\lambda) - \omega(\lambda) \), where \( \omega(\lambda) \) is the number of 1’s in \( \lambda \), and \( \mu(\lambda) \) is the number of parts of \( \lambda \) larger than \( \omega(\lambda) \). If \( \lambda \) contains no 1, then the crank is simply the largest part of \( \lambda \).

**REFERENCES:**

- [AG1988]

**EXAMPLES:**

```
sage: Partition([]).crank()
0
sage: Partition([3,2,2]).crank()
3
sage: Partition([5,4,2,1,1]).crank()
0
sage: Partition([1,1,1]).crank()
-3
```

(continues on next page)
sage: Partition([6,4,4,3]).crank()
6
sage: Partition([6,3,3,1,1]).crank()
1
sage: Partition([6]).crank()
6
sage: Partition([5,1]).crank()
0
sage: Partition([4,2]).crank()
4
sage: Partition([4,1,1]).crank()
-1
sage: Partition([3,3]).crank()
3
sage: Partition([3,2,1]).crank()
1
sage: Partition([3,1,1,1]).crank()
-3
sage: Partition([2,2,2]).crank()
2
sage: Partition([2,2,1,1]).crank()
-2
sage: Partition([2,1,1,1,1]).crank()
-4
sage: Partition([1,1,1,1,1,1]).crank()
-6

defect(e, multicharge=(0,))

Return the e-defect or the e-weight of self.

The e-defect is the number of (connected) e-rim hooks that can be removed from the partition.

The defect of a partition is given by

\[
\text{defect}(\beta) = (\Lambda, \beta) - \frac{1}{2} (\beta, \beta),
\]

where \( \Lambda = \sum_{r} A_{\kappa_{r}} \) for the multicharge \( (\kappa_{1}, \ldots, \kappa_{t}) \) and \( \beta = \sum_{(r,c)} a_{(c-r) \mod e} \), with the sum being over the cells in the partition.

INPUT:

- e – the quantum characteristic
- multicharge – the multicharge (default (0,))

OUTPUT:

- a non-negative integer, which is the defect of the block containing the partition self

EXAMPLES:

sage: Partition([4,3,2]).defect(2)
3
sage: Partition([0]).defect(2)
0
sage: Partition([3]).defect(2)
degree($e$)

Return the $e$-th degree of self.

The $e$-th degree of a partition $\lambda$ is the sum of the $e$-th degrees of the standard tableaux of shape $\lambda$. The $e$-th degree is the exponent of $\Phi_e(q)$ in the Gram determinant of the Specht module for a semisimple Iwahori-Hecke algebra of type $A$ with parameter $q$.

INPUT:

• $e$ – an integer $e > 1$

OUTPUT:

A non-negative integer.

EXAMPLES:

```python
sage: Partition([4,3]).degree(2)
28
sage: Partition([4,3]).degree(3)
15
sage: Partition([4,3]).degree(4)
8
sage: Partition([4,3]).degree(5)
13
sage: Partition([4,3]).degree(6)
0
sage: Partition([4,3]).degree(7)
0
```

Therefore, the Gram determinant of $S(5,3)$ when the Hecke parameter $q$ is “generic” is

$$q^N \Phi_2(q)^{28} \Phi_3(q)^{15} \Phi_4(q)^8 \Phi_5(q)^{13}$$

for some integer $N$. Compare with `prime_degree()`.
**dimension**(smaller=None, k=1)

Return the number of paths from the smaller partition to the partition self, where each step consists of adding a k-ribbon while keeping a partition.

Note that a 1-ribbon is just a single cell, so this counts paths in the Young graph when \( k = 1 \).

Note also that the default case (\( k = 1 \) and smaller = []) gives the dimension of the irreducible representation of the symmetric group corresponding to self.

**INPUT:**

- smaller – a partition (default: an empty list [])
- k – a positive integer (default: 1)

**OUTPUT:**

The number of such paths

**EXAMPLES:**

Looks at the number of ways of getting from [5, 4] to the empty partition, removing one cell at a time:

```
sage: mu = Partition([5,4])
sage: mu.dimension()
42
```

Same, but removing one 3-ribbon at a time. Note that the 3-core of mu is empty:

```
sage: mu.dimension(k=3)
3
```

The 2-core of mu is not the empty partition:

```
sage: mu.dimension(k=2)
0
```

Indeed, the 2-core of mu is [1]:

```
sage: mu.dimension(Partition([1]),k=2)
2
```

**ALGORITHM:**

Depending on the parameters given, different simplifications occur. When \( k = 1 \) and smaller is empty, this function uses the hook formula. When \( k = 1 \) and smaller is not empty, it uses a formula from [ORV].

When \( k \neq 1 \), we first check that both self and smaller have the same k-core, then use the k-quotients and the same algorithm on each of the k-quotients.

**AUTHORS:**

- Paul-Olivier Dehaye (2011-06-07)

**dominated_partitions**(rows=None)

Return a list of the partitions dominated by \( n \). If rows is specified, then it only returns the ones whose number of rows is at most rows.

**EXAMPLES:**
sage: Partition([3,2,1]).dominated_partitions()
[[[3, 2, 1], [3, 1, 1, 1], [2, 2, 2], [2, 2, 1, 1], [2, 1, 1, 1, 1], [1, 1, 1, 1, 1], [1, 1, 1, 1, 1], [1, 1, 1, 1, 1], [1, 1, 1, 1, 1]],
   [3, 2, 1], [2, 2, 2], [2, 2, 1, 1], [2, 1, 1, 1, 1], [1, 1, 1, 1, 1], [1, 1, 1, 1, 1], [1, 1, 1, 1, 1], [1, 1, 1, 1, 1]]

sage: Partition([3,2,1]).dominated_partitions(rows=3)
[[[3, 2, 1], [2, 2, 2]]

dominates(p2)

Return True if self dominates the partition p2. Otherwise it returns False.

EXAMPLES:

sage: p = Partition([3,2])
sage: p.dominates([3,1])
True
sage: p.dominates([2,2])
True
sage: p.dominates([2,1,1])
True
sage: p.dominates([3,3])
False
sage: p.dominates([4])
False
sage: Partition([4]).dominates(p)
False
sage: Partition([]).dominates([1])
False
sage: Partition([]).dominates([])
True
sage: Partition([1]).dominates([])
True
down()

Return a generator for partitions that can be obtained from self by removing a cell.

EXAMPLES:

sage: [p for p in Partition([2,1,1]).down()]
[[1, 1, 1], [2, 1]]
sage: [p for p in Partition([3,2]).down()]
[[2, 2], [3, 1]]
sage: [p for p in Partition([3,2,1]).down()]
[[2, 2, 1], [3, 1, 1], [3, 2]]
down_list()

Return a list of the partitions that can be obtained from self by removing a cell.

EXAMPLES:

sage: Partition([2,1,1]).down_list()
[[1, 1, 1], [2, 1]]
sage: Partition([3,2]).down_list()
[[2, 2], [3, 1]]
sage: Partition([3,2,1]).down_list()
[[2, 2, 1], [3, 1, 1], [3, 2]]
dual_equivalence_graph(directed=False, coloring=None)

Return the dual equivalence graph of self.

Two permutations $p$ and $q$ in the symmetric group $S_n$ differ by an $i$-elementary dual equivalence (or dual Knuth) relation (where $i$ is an integer with $1 < i < n$) when the following two conditions are satisfied:

- In the one-line notation of the permutation $p$, the letter $i$ does not appear inbetween $i - 1$ and $i + 1$.
- The permutation $q$ is obtained from $p$ by switching two of the three letters $i - 1, i, i + 1$ (in its one-line notation) – namely, the leftmost and the rightmost one in order of their appearance in $p$.

Notice that this is equivalent to the statement that the permutations $p^{-1}$ and $q^{-1}$ differ by an elementary Knuth equivalence at positions $i - 1, i, i + 1$.

Two standard Young tableaux of shape $\lambda$ differ by an $i$-elementary dual equivalence relation (of color $i$), if their reading words differ by an $i$-elementary dual equivalence relation.

The dual equivalence graph of the partition $\lambda$ is the edge-colored graph whose vertices are the standard Young tableaux of shape $\lambda$, and whose edges colored by $i$ are given by the $i$-elementary dual equivalences.

INPUT:

- directed – (default: False) whether to have the dual equivalence graph be directed (where we have a directed edge $S \to T$ if $i$ appears to the left of $i + 1$ in the reading word of $T$; otherwise we have the directed edge $T \to S$)
- coloring – (optional) a function which sends each integer $i > 1$ to a color (as a string, e.g., 'red' or 'black') to be used when visually representing the resulting graph using dot2tex; the default choice is $2 \to 'red', 3 \to 'blue', 4 \to 'green', 5 \to 'purple', 6 \to 'brown', 7 \to 'orange', 8 \to 'yellow', anything greater than 8 \to 'black'.

REFERENCES:

- [As2008b]

EXAMPLES:

```python
sage: P = Partition([3,1,1])
sage: G = P.dual_equivalence_graph()
sage: G = P.dual_equivalence_graph(directed=True)
```
evaluation()

Return the evaluation of self.

The **commutative evaluation**, often shortened to **evaluation**, of a word (we think of a partition as a word in \([1, 2, 3, \ldots]\)) is its image in the free commutative monoid. In other words, this counts how many occurrences there are of each letter.

This is also known as **Parikh vector** and **abelianization** and has the same output as **to_exp()**.

**EXAMPLES:**

```python
sage: Partition([4,3,1,1]).evaluation()
[2, 0, 1, 1]
```

ferrers_diagram()

Return the Ferrers diagram of self.

**EXAMPLES:**

```python
sage: mu = Partition([5,5,2,1])
sage: Partitions.options(diagram_str='*', convention="english")
sage: print(mu.ferrers_diagram())
*****
*****
**
*
```

```python
sage: Partitions.options(diagram_str='#', convention="english")
sage: print(mu.ferrers_diagram())
#####
#####
##
#
```

```python
sage: Partitions.options.convention="french"
sage: print(mu.ferrers_diagram())
#
##
#####
#####
```

```python
sage: print(Partition([]).ferrers_diagram())
-
```

```python
sage: Partitions.options(diagram_str='\-')
sage: print(Partition([]).ferrers_diagram())
(\-)
```

```python
sage: Partitions.options._reset()
```

frobenius_coordinates()

Return a pair of sequences of Frobenius coordinates aka beta numbers of the partition.

These are two strictly decreasing sequences of nonnegative integers of the same length.

**EXAMPLES:**

```python
sage: Partition([]).frobenius_coordinates()
([], [])
```

```python
sage: Partition([1]).frobenius_coordinates()
([0], [0])
```
sage: Partition([3,3,3]).frobenius_coordinates()
([2, 1, 0], [2, 1, 0])
sage: Partition([9,1,1,1,1,1,1]).frobenius_coordinates()
([8], [6])

frobenius_rank()

Return the Frobenius rank of the partition self.

The Frobenius rank of a partition $\lambda = (\lambda_1, \lambda_2, \lambda_3, \cdots)$ is defined to be the largest $i$ such that $\lambda_i \geq i$. In other words, it is the number of cells on the main diagonal of $\lambda$. In yet other words, it is the size of the largest square fitting into the Young diagram of $\lambda$.

EXAMPLES:
sage: Partition([]).frobenius_rank()
0
sage: Partition([1]).frobenius_rank()
1
sage: Partition([3,3,3]).frobenius_rank()
3
sage: Partition([9,1,1,1,1,1,1]).frobenius_rank()
1
sage: Partition([2,1,1,1,1,1]).frobenius_rank()
1
sage: Partition([2,2,1,1,1,1]).frobenius_rank()
2
sage: Partition([3,2]).frobenius_rank()
2
sage: Partition([3,2,2]).frobenius_rank()
2
sage: Partition([8,4,4,4,4]).frobenius_rank()
4
sage: Partition([8,4,1]).frobenius_rank()
2
sage: Partition([3,3,1]).frobenius_rank()
2

from_kbounded_to_grassmannian(k)

Maps a $k$-bounded partition to a Grassmannian element in the affine Weyl group of type $A_k^{(1)}$.

For details, see the documentation of the method from_kbounded_to_reduced_word() .

EXAMPLES:
sage: p = Partition([2,1,1])
sage: p.from_kbounded_to_grassmannian(2)
[-1  1  1]
[-2  2  1]
[-2  1  2]
sage: p = Partition([])
sage: p.from_kbounded_to_grassmannian(2)
[1 0 0]
[0 1 0]
[0 0 1]
**from_kbounded_to_reduced_word**(\(k\))

Maps a \(k\)-bounded partition to a reduced word for an element in the affine permutation group.

This uses the fact that there is a bijection between \(k\)-bounded partitions and \((k + 1)\)-cores and an action of the affine nilCoxeter algebra of type \(A^{(1)}_k\) on \((k + 1)\)-cores as described in [LM2006b].

**EXAMPLES:**

```python
sage: p = Partition([2,1,1])
sage: p.from_kbounded_to_reduced_word(2)
[2, 1, 2, 0]
sage: p = Partition([3,1])
sage: p.from_kbounded_to_reduced_word(3)
[3, 2, 1, 0]
sage: p.from_kbounded_to_reduced_word(2)
Traceback (most recent call last):
...
ValueError: the partition must be 2-bounded
sage: p = Partition([])
sage: p.from_kbounded_to_reduced_word(2)
[]
```

**garnir_tableau**(\(*\text{cell}\*))

Return the Garnir tableau of shape \texttt{self} corresponding to the cell \texttt{cell}. If \texttt{cell} = \((a, c)\) then \((a + 1, c)\) must belong to the diagram of \texttt{self}.

The Garnir tableaux play an important role in integral and non-semisimple representation theory because they determine the “straightening” rules for the Specht modules over an arbitrary ring.

The Garnir tableaux are the “first” non-standard tableaux which arise when you act by simple transpositions. If \((a, c)\) is a cell in the Young diagram of a partition, which is not at the bottom of its column, then the corresponding Garnir tableau has the integers \(1, 2, \ldots, n\) entered in order from left to right along the rows of the diagram up to the cell \((a, c - 1)\), then along the cells \((a + 1, 1)\) to \((a + 1, c)\), then \((a, c)\) until the end of row \(a\) and then continuing from left to right in the remaining positions. The examples below probably make this clearer!

**Note:** The function also sets \texttt{g._garnir_cell}, where \texttt{g} is the resulting Garnir tableau, equal to \texttt{cell} which is used by some other functions.

**EXAMPLES:**

```python
sage: g = Partition([5,3,3,2]).garnir_tableau((0,2)); g.pp()
  1  2  6  7  8
  3  4  5
  9 10 11
 12 13
sage: g.is_row_strict(); g.is_column_strict()
True
False
sage: Partition([5,3,3,2]).garnir_tableau(0,2).pp()
  1  2  6  7  8
  3  4  5
  9 10 11
```
12 13
sage: Partition([5,3,3,2]).garnir_tableau(2,1).pp()
 1 2 3 4 5
 6 7 8
 9 12 13
10 11
sage: Partition([5,3,3,2]).garnir_tableau(2,2).pp()
Traceback (most recent call last):
  ...
ValueError: (row+1, col) must be inside the diagram

See also:

• top_garnir_tableau()

generalized_pochhammer_symbol(a, alpha)

Return the generalized Pochhammer symbol \( (a)_{\alpha} \). This is the product over all cells \((i, j)\) in \(self\) of \(a - (i - 1)/\alpha + j - 1\).

EXAMPLES:

sage: Partition([2,2]).generalized_pochhammer_symbol(2,1)
12

get_part(i, default=0)

Return the \(i\)th part of \(self\), or \(default\) if it does not exist.

EXAMPLES:

sage: p = Partition([2,1])
sage: p.get_part(0), p.get_part(1), p.get_part(2)
(2, 1, 0)
sage: p.get_part(10,-1)
-1
sage: Partition([]).get_part(0)
0

has_k_rectangle(k)

Return True if the Ferrer's diagram of \(self\) contains \(k - i + 1\) rows (or more) of length \(i\) (exactly) for any \(i\) in \([1, k]\).

This is mainly a helper function for is_k_reducible() and is_k_irreducible(), the only difference between this function and is_k_reducible() being that this function allows any partition as input while is_k_reducible() requires the input to be \(k\)-bounded.

EXAMPLES:

The partition \([1, 1, 1]\) has at least 2 rows of length 1:

sage: Partition([1, 1, 1]).has_k_rectangle(2)
True

The partition \([1, 1, 1]\) does not have 4 rows of length 1, 3 rows of length 2, 2 rows of length 3, nor 1 row of length 4:
Combinatorics, Release 10.0

```python
sage: Partition([1, 1, 1]).has_k_rectangle(4)
False
```

See also:

`is_k_irreducible(), is_k_reducible(), has_rectangle()`

**has_rectangle** *(h, w)*

Return True if the Ferrer’s diagram of `self` has *h* (or more) rows of length *w* (exactly).

**INPUT:**
- *h* – An integer \( h \geq 1 \). The (minimum) height of the rectangle.
- *w* – An integer \( w \geq 1 \). The width of the rectangle.

**EXAMPLES:**

```python
sage: Partition([3, 3, 3, 3]).has_rectangle(2, 3)
True
sage: Partition([3, 3]).has_rectangle(2, 3)
True
sage: Partition([4, 3]).has_rectangle(2, 3)
False
sage: Partition([3]).has_rectangle(2, 3)
False
```

See also:

`has_k_rectangle()`

**hook_length** *(i, j)*

Return the length of the hook of cell \((i, j)\) in `self`.

The (length of the) hook of cell \((i, j)\) of a partition \( \lambda \) is

\[
\lambda_i + \lambda_j' - i - j + 1
\]

where \( \lambda' \) is the conjugate partition. In English convention, the hook length is the number of cells horizontally to the right and vertically below the cell \((i, j)\) (including that cell).

**EXAMPLES:**

```python
sage: p = Partition([2,2,1])
sage: p.hook_length(0, 0)
4
sage: p.hook_length(0, 1)
2
sage: p.hook_length(2, 0)
1
sage: Partition([3,3]).hook_length(0, 0)
4
sage: cell = [0,0]; Partition([3,3]).hook_length(*cell)
4
```

**hook_lengths()**

Return a tableau of shape `self` with the cells filled in with the hook lengths.
In each cell, put the sum of one plus the number of cells horizontally to the right and vertically below the cell (the hook length).

For example, consider the partition \([3, 2, 1]\) of 6 with Ferrers diagram:

```
# # #
# #
#
```

When we fill in the cells with the hook lengths, we obtain:

```
5 3 1
3 1
1
```

**EXAMPLES:**

```python
sage: Partition([2,2,1]).hook_lengths()
[[4, 2], [3, 1], [1]]
sage: Partition([3,3]).hook_lengths()
[[4, 3, 2], [3, 2, 1]]
sage: Partition([3,2,1]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
sage: Partition([2,2]).hook_lengths()
[[3, 2], [2, 1]]
sage: Partition([5]).hook_lengths()
[[5, 4, 3, 2, 1]]
```

**REFERENCES:**

### hook_polynomial \((q, t)\)

Return the two-variable hook polynomial.

**EXAMPLES:**

```python
sage: R.<q,t> = PolynomialRing(QQ)
sage: a = Partition([2,2]).hook_polynomial(q,t)
sage: a == (1 - t)*(1 - q*t)*(1 - t^2)*(1 - q*t^2)
True
sage: a = Partition([3,2,1]).hook_polynomial(q,t)
sage: a == (1 - t)^3*(1 - q*t^2)^2*(1 - q^2*t^3)
True
```

### hook_product \((a)\)

Return the Jack hook-product.

**EXAMPLES:**

```python
sage: Partition([3,2,1]).hook_product(x)
(2*x + 3)*(x + 2)^2
sage: Partition([2,2]).hook_product(x)
2*(x + 2)*(x + 1)
```

### hooks()

Return a sorted list of the hook lengths in `self`. 

---

1738 Chapter 5. Comprehensive Module List
EXAMPLES:

```python
sage: Partition([3,2,1]).hooks()
[5, 3, 3, 1, 1, 1]
```

**horizontal_border_strip_cells**

Return a list of all the horizontal border strips of length \( k \) which can be added to \( \text{self} \), where each horizontal border strip is a generator of cells.

EXAMPLES:

```python
sage: list(Partition([]).horizontal_border_strip_cells(0))
[]
sage: list(Partition([3,2,1]).horizontal_border_strip_cells(0))
[]
sage: list(Partition([]).horizontal_border_strip_cells(2))
[[[0, 0], (0, 1)]]
sage: list(Partition([2,2]).horizontal_border_strip_cells(2))
[[[0, 2], (0, 3)], [[0, 2], (2, 0)], [[2, 0], (2, 1)]]
sage: list(Partition([3,2,2]).horizontal_border_strip_cells(2))
[[[0, 3], (0, 4)],
 [[0, 3], (1, 2)],
 [[0, 3], (3, 0)],
 [[1, 2], (3, 0)],
 [[3, 0], (3, 1)]]
```

**initial_column_tableau**

Return the initial column tableau of shape \( \text{self} \).

The initial column tableau of shape \( \text{self} \) is the standard tableau that has the numbers 1 to \( n \), where \( n \) is the \texttt{size()} of \( \text{self} \), entered in order from top to bottom and then left to right down the columns of \( \text{self} \).

EXAMPLES:

```python
sage: Partition([3,2]).initial_column_tableau()
[[1, 3, 5], [2, 4]]
```

**initial_tableau**

Return the standard tableau which has the numbers 1, 2, ..., \( n \) where \( n \) is the \texttt{size()} of \( \text{self} \) entered in order from left to right along the rows of each component, where the components are ordered from left to right.

EXAMPLES:

```python
sage: Partition([3,2,2]).initial_tableau()
[[1, 2, 3], [4, 5], [6, 7]]
```

**inside_corners**

Return a list of the corners of the partition \( \text{self} \).

A corner of a partition \( \lambda \) is a cell of the Young diagram of \( \lambda \) which can be removed from the Young diagram while still leaving a straight shape behind.

The entries of the list returned are pairs of the form \((i, j)\), where \( i \) and \( j \) are the coordinates of the respective corner. The coordinates are counted from 0.
Note: This is referred to as an “inner corner” in [Sag2001].

EXAMPLES:

```
sage: Partition([3,2,1]).corners()
[(0, 2), (1, 1), (2, 0)]
sage: Partition([3,3,1]).corners()
[(1, 2), (2, 0)]
sage: Partition([]).corners()
[]
```

inside_corners_residue(i, l)

Return a list of the corners of the partition self having l-residue $i$.

A corner of a partition $\lambda$ is a cell of the Young diagram of $\lambda$ which can be removed from the Young diagram while still leaving a straight shape behind. See residue() for the definition of the l-residue.

The entries of the list returned are pairs of the form $(i, j)$, where $i$ and $j$ are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([3,2,1]).corners_residue(0, 3)
[(1, 1)]
sage: Partition([3,2,1]).corners_residue(1, 3)
[(2, 0)]
sage: Partition([3,2,1]).corners_residue(2, 3)
[(0, 2)]
```

is_core(k)

Return True if the Partition self is a k-core.

A partition is said to be a `$k`-core if it has no hooks of length $k$. Equivalently, a partition is said to be a $k$-core if it is its own $k$-core (where the latter is defined as in core()).

Visually, this can be checked by trying to remove border strips of size $k$ from self. If this is not possible, then self is a $k$-core.

EXAMPLES:

In the partition (2, 1), a hook length of 2 does not occur, but a hook length of 3 does:

```
sage: p = Partition([2, 1])
sage: p.is_core(2)
True
sage: p.is_core(3)
False
sage: q = Partition([12, 8, 5, 5, 2, 2, 1])
sage: q.is_core(4)
False
sage: q.is_core(5)
True
sage: q.is_core(0)
True
```
See also:

- `core()`, `Core`

**is_empty()**

Return True if `self` is the empty partition.

**EXAMPLES:**

```python
sage: Partition([]).is_empty()
True
sage: Partition([2,1,1]).is_empty()
False
```

**is_k_bounded**

Return True if the partition `self` is bounded by `k`.

**EXAMPLES:**

```python
sage: Partition([4, 3, 1]).is_k_bounded(4)
True
sage: Partition([4, 3, 1]).is_k_bounded(7)
True
sage: Partition([4, 3, 1]).is_k_bounded(3)
False
```

**is_k_irreducible**

Return True if the partition `self` is k-irreducible.

A k-bounded partition is **k-irreducible** if its Ferrer’s diagram does not contain \( k - i + 1 \) rows (or more) of length \( i \) (exactly) for every \( i \in [1, k] \).

(Also, a \( k \)-bounded partition is \( k \)-irreducible if and only if it is not \( k \)-reducible.)

**EXAMPLES:**

The partition \([1, 1, 1]\) has at least 2 rows of length 1:

```python
sage: Partition([1, 1, 1]).is_k_irreducible(2)
False
```

The partition \([1, 1, 1]\) does not have 4 rows of length 1, 3 rows of length 2, 2 rows of length 3, nor 1 row of length 4:

```python
sage: Partition([1, 1, 1]).is_k_irreducible(4)
True
```

See also:

- `is_k_reducible()`, `has_k_rectangle()`

**is_k_reducible**

Return True if the partition `self` is k-reducible.

A k-bounded partition is **k-reducible** if its Ferrer’s diagram contains \( k - i + 1 \) rows (or more) of length \( i \) (exactly) for some \( i \in [1, k] \).

(Also, a \( k \)-bounded partition is \( k \)-reducible if and only if it is not \( k \)-irreducible.)

**EXAMPLES:**
The partition \([1, 1, 1]\) has at least 2 rows of length 1:

```
sage: Partition([1, 1, 1]).is_k_reducible(2)
True
```

The partition \([1, 1, 1]\) does not have 4 rows of length 1, 3 rows of length 2, 2 rows of length 3, nor 1 row of length 4:

```
sage: Partition([1, 1, 1]).is_k_reducible(4)
False
```

See also:

\(\text{is\_k\_irreducible()}, \text{has\_k\_rectangle()}\)

\(\text{is\_regular}(e, \text{multicharge}=(0,))\)

Return True if this is an \(e\)-regular partition.

A partition is \(e\)-regular if it does not have \(e\) equal non-zero parts.

EXAMPLES:

```
sage: Partition([4,3,3,3]).is_regular(2)
False
sage: Partition([4,3,3,3]).is_regular(3)
False
sage: Partition([4,3,3,3]).is_regular(4)
True
```

\(\text{is\_restricted}(e, \text{multicharge}=(0,))\)

Return True if this is an \(e\)-restricted partition.

An \(e\)-restricted partition is a partition such that the difference of consecutive parts is always strictly less than \(e\), where partitions are considered to have an infinite number of 0 parts. I.e., the last part must be strictly less than \(e\).

EXAMPLES:

```
sage: Partition([4,3,3,2]).is_restricted(2)
False
sage: Partition([4,3,3,2]).is_restricted(3)
True
sage: Partition([4,3,3,2]).is_restricted(4)
True
sage: Partition([4]).is_restricted(4)
False
```

\(\text{is\_symmetric()}\)

Return True if the partition self equals its own transpose.

EXAMPLES:

```
sage: Partition([2, 1]).is_symmetric()
True
sage: Partition([3, 1]).is_symmetric()
False
```
jacobi_trudi()

Return the Jacobi-Trudi matrix of self thought of as a skew partition. See SkewPartition. jacobi_trudi().

EXAMPLES:

```
sage: part = Partition([3,2,1])
sage: jt = part.jacobi_trudi(); jt
sage: s = SymmetricFunctions(QQ).schur()
sage: h = SymmetricFunctions(QQ).homogeneous()
sage: h( s(part) )
sage: jt.det()
```

k_atom(k)

Return a list of the standard tableaux of size self.size() whose k-atom is equal to self.

EXAMPLES:

```
sage: p = Partition([3,2,1])
sage: p.k_atom(1)
[]
sage: p.k_atom(3)
[[[1, 1, 1, 2, 3], [2]],
 [[[1, 1, 1, 2], [2, 2]],
 [[[1, 1, 1, 2], [2]], [3]],
 [[[1, 1, 1], [2, 2], [3]]]
sage: Partition([3,2,1]).k_atom(4)
[[[1, 1, 1, 3], [2, 2]], [[1, 1, 1], [2], [3]]]
```

k_boundary(k)

Return the skew partition formed by removing the cells of the k-interior, see k_interior().

EXAMPLES:

```
sage: p = Partition([3,2,1])
sage: p.k_boundary(2)
[3, 2, 1] / [2, 1]
sage: p.k_boundary(3)
[3, 2, 1] / [1]
sage: p = Partition([12,8,5,5,2,2,1])
sage: p.k_boundary(4)
[12, 8, 5, 5, 2, 2, 1] / [8, 5, 2, 2]
```

k_column_lengths(k)

Return the k-column-shape of the partition self.

This is the 'column' analog of k_row_lengths().

EXAMPLES:
**k_conjugate**(k)

Return the k-conjugate of self.

The k-conjugate is the partition that is given by the columns of the k-skew diagram of the partition.

We can also define the k-conjugate in the following way. Let P denote the bijection from (k + 1)-cores to k-bounded partitions. The k-conjugate of a (k + 1)-core \( \lambda \) is

\[
\lambda^{(k)} = P^{-1}((P(\lambda))^\prime).
\]

**EXAMPLES:**

```python
sage: p = Partition([4,3,2,2,1,1])
sage: p.k_conjugate(4)
[3, 2, 2, 1, 1, 1, 1, 1, 1]
```

**k_interior**(k)

Return the partition consisting of the cells of self whose hook lengths are greater than k.

**EXAMPLES:**

```python
sage: p = Partition([3,2,1])
sage: p.hook_lengths()  
[[5, 3, 1], [3, 1], [1]]
sage: p.k_interior(2)
[2, 1]
sage: p.k_interior(3)
[1]
```

**k_irreducible**(k)

Return the partition with all \( r \times (k + 1 - r) \) rectangles removed.

If self is a k-bounded partition, then this method will return the partition where all rectangles of dimension \( r \times (k + 1 - r) \) for \( 1 \leq r \leq k \) have been deleted.

If self is not a k-bounded partition then the method will raise an error.

**INPUT:**

- k – a non-negative integer

**OUTPUT:**

- a partition
EXAMPLES:

```
sage: Partition([3,2,2,1,1,1]).k_irreducible(4)
[3, 2, 2, 1, 1, 1]
sage: Partition([3,2,2,1,1,1]).k_irreducible(3)
[]
sage: Partition([3,3,3,2,2,2,2,2,1,1,1,1]).k_irreducible(3)
[2, 1]
```

**k_rim**$(k)$

Return the k-rim of self as a list of integer coordinates.

The $k$-rim of a partition is the “line between” (or “intersection of”) the $k$-boundary and the $k$-interior. (Section 2.3 of [HM2011])

It will be output as an ordered list of integer coordinates, where the origin is $(0, 0)$. It will start at the top-left of the $k$-rim (using French convention) and end at the bottom-right.

**EXAMPLES:**

Consider the partition $(3, 1)$ split up into its $1$-interior and $1$-boundary:

![Diagram showing 1-rim and 1-boundary]

The line shown in bold is the 1-rim, and that information is equivalent to the integer coordinates of the points that occur along that line:

```
sage: Partition([3, 1]).k_rim(1)
[(3, 0), (2, 0), (2, 1), (1, 1), (0, 1), (0, 2)]
```

See also:

$k\_interior()$, $k\_boundary()$, $boundary()$

**k_row_lengths**$(k)$

Return the $k$-row-shape of the partition self.

This is equivalent to taking the $k$-boundary of the partition and then returning the row-shape of that. We do not discard rows of length 0. (Section 2.2 of [LLMS2013])

**EXAMPLES:**

```
sage: Partition([6, 1]).k_row_lengths(2)
[2, 1]
sage: Partition([4, 4, 4, 3, 2]).k_row_lengths(2)
[0, 1, 1, 1, 2]
```
See also:

\texttt{k\_column\_lengths()}, \texttt{k\_boundary()}, \texttt{SkewPartition.row\_lengths()}, \texttt{SkewPartition.column\_lengths()}

\textbf{\texttt{k\_size}(k)}

Given a partition \texttt{self} and a \texttt{k}, return the size of the \texttt{k}-boundary.

This is the same as the length method \texttt{sage.combinat.core.Core.length()} of the \texttt{sage.combinat.core.Core} object, with the exception that here we don’t require \texttt{self} to be a \texttt{k + 1-core}.

EXAMPLES:

\begin{verbatim}
sage: Partition([2, 1, 1]).k_size(1) 2
sage: Partition([2, 1, 1]).k_size(2) 3
sage: Partition([2, 1, 1]).k_size(3) 3
sage: Partition([2, 1, 1]).k_size(4) 4
\end{verbatim}

See also:

\texttt{k\_boundary()}, \texttt{SkewPartition.size()}

\textbf{\texttt{k\_skew}(k)}

Return the \texttt{k}\dash skew partition.

The \texttt{k}\dash skew diagram of a \texttt{k}-bounded partition is the skew diagram denoted \texttt{\lambda/k} satisfying the conditions:

1. row \texttt{i} of \texttt{\lambda/k} has length \texttt{\lambda_i},
2. no cell in \texttt{\lambda/k} has hook-length exceeding \texttt{k},
3. every square above the diagram of \texttt{\lambda/k} has hook length exceeding \texttt{k}.

REFERENCES:

- [LM2004]

EXAMPLES:

\begin{verbatim}
sage: p = Partition([4,3,2,2,1,1])
sage: p.k_skew(4) [[9, 5, 3, 2, 1, 1] / [5, 2, 1]]
\end{verbatim}

\textbf{\texttt{k\_split}(k)}

Return the \texttt{k}\dash split of \texttt{self}.

EXAMPLES:

\begin{verbatim}
sage: Partition([4,3,2,1]).k_split(3) []
sage: Partition([4,3,2,1]).k_split(4) [[4], [3, 2], [1]]
sage: Partition([4,3,2,1]).k_split(5) [[4, 3], [2, 1]]
sage: Partition([4,3,2,1]).k_split(6) [[4, 3, 2], [1]]
\end{verbatim}
\begin{verbatim}
sage: Partition([4,3,2,1]).k_split(7)
[[4, 3, 2, 1]]
sage: Partition([4,3,2,1]).k_split(8)
[[4, 3, 2, 1]]
\end{verbatim}

larger_lex(rhs)

Return True if \texttt{self} is larger than \texttt{rhs} in lexicographic order. Otherwise return False.

EXAMPLES:

\begin{verbatim}
sage: p = Partition([3,2])
sage: p.larger_lex([3,1])
True
sage: p.larger_lex([1,4])
True
sage: p.larger_lex([3,2,1])
False
sage: p.larger_lex([3])
True
sage: p.larger_lex([5])
False
sage: p.larger_lex([3,1,1,1,1,1,1,1])
True
\end{verbatim}

leg_cells(i, j)

Return the list of the cells of the leg of cell \((i, j)\) in \texttt{self}.

The leg of cell \(c = (i, j)\) is defined to be the cells below \(c\) (in English convention).

The cell coordinates are zero-based, i. e., the northwesternmost cell is \((0,0)\).

INPUT:

• \(i, j\) – two integers

OUTPUT:

A list of pairs of integers

EXAMPLES:

\begin{verbatim}
sage: Partition([4,4,3,1]).leg_cells(1,1)
[(2, 1)]
sage: Partition([4,4,3,1]).leg_cells(0,1)
[(1, 1), (2, 1)]
sage: Partition([]).leg_cells(0,0)
Traceback (most recent call last):
...
ValueError: the cell is not in the diagram
\end{verbatim}

leg_length(i, j)

Return the length of the leg of cell \((i, j)\) in \texttt{self}.

The leg of cell \(c = (i, j)\) is defined to be the cells below \(c\) (in English convention).

The cell coordinates are zero-based, i. e., the northwesternmost cell is \((0,0)\).
INPUT:

• i, j – two integers

OUTPUT:

An integer or a ValueError

EXAMPLES:

```
sage: p = Partition([2,2,1])
sage: p.leg_length(0, 0)
2
sage: p.leg_length(0,1)
1
sage: p.leg_length(2,0)
0
sage: Partition([3,3]).leg_length(0, 0)
1
sage: cell = [0,0]; Partition([3,3]).leg_length(*cell)
```

leg_lengths (flat=False)

Return a tableau of shape self with each cell filled in with its leg length. The optional boolean parameter flat provides the option of returning a flat list.

EXAMPLES:

```
sage: Partition([2,2,1]).leg_lengths()
[[2, 1], [1, 0], [0]]
sage: Partition([2,2,1]).leg_lengths(flat=True)
[2, 1, 1, 0, 0]
sage: Partition([3,3]).leg_lengths()
[[1, 1, 1], [0, 0, 0]]
sage: Partition([3,3]).leg_lengths(flat=True)
[1, 1, 1, 0, 0, 0]
```

length()

Return the number of parts in self.

EXAMPLES:

```
sage: Partition([3,2]).length()
2
sage: Partition([2,2,1]).length()
3
sage: Partition([]).length()
0
```

level()

Return the level of self, which is always 1.

This method exists only for compatibility with PartitionTuples.

EXAMPLES:

```
sage: Partition([4,3,2]).level()
1
```
**lower_hook** *(i, j, alpha)*

Return the lower hook length of the cell *(i, j)* in *self*. When *alpha* = 1, this is just the normal hook length.

The lower hook length of a cell *(i, j)* in a partition *κ* is defined by

\[ h^κ_*(i, j) = κ'_j - i + 1 + α(κ_i - j). \]

**EXAMPLES:**

```python
sage: p = Partition([2, 1])
sage: p.lower_hook(0, 0, 1)
3
sage: p.hook_length(0, 0)
3
sage: [p.lower_hook(i, j, x) for i, j in p.cells()]
x + 2, 1, 1
```

**lower_hook_lengths** *(alpha)*

Return a tableau of shape *self* with the cells filled in with the lower hook lengths. When *alpha* = 1, these are just the normal hook lengths.

The lower hook length of a cell *(i, j)* in a partition *κ* is defined by

\[ h^κ_*(i, j) = κ'_j - i + 1 + α(κ_i - j). \]

**EXAMPLES:**

```python
sage: Partition([3, 2, 1]).lower_hook_lengths(x)
[[2*x + 3, x + 2, 1], [x + 2, 1], [1]]
sage: Partition([3, 2, 1]).lower_hook_lengths(1)
[[3, 1], [3, 1], [1]]
sage: Partition([3, 2, 1]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
```

**next()**

Return the partition that lexicographically follows *self*, of the same size. If *self* is the last partition, then return False.

**EXAMPLES:**

```python
sage: next(Partition([4]))
[3, 1]
sage: next(Partition([1, 1, 1, 1]))
False
```

**next_within_bounds** *(min=[], max=None, partition_type=None)*

Get the next partition lexicographically that contains *min* and is contained in *max*.

**INPUT:**

- *min* – (default []) The ‘minimum partition’ that *next_within_bounds*(*self*) must contain.
- *max* – (default None) The ‘maximum partition’ that *next_within_bounds*(*self*) must be contained in. If set to None, then there is no restriction.
• partition_type – (default None) The type of partitions allowed. For example, ‘strict’ for strictly decreasing partitions, or None to allow any valid partition.

EXAMPLES:

```
sage: m = [1, 1]
sage: M = [3, 2, 1]
sage: Partition([1, 1]).next_within_bounds(min=m, max=M)
[1, 1, 1]
sage: Partition([1, 1, 1]).next_within_bounds(min=m, max=M)
[2, 1]
sage: Partition([2, 1]).next_within_bounds(min=m, max=M)
[2, 1, 1]
sage: Partition([2, 1, 1]).next_within_bounds(min=m, max=M)
[2, 2]
sage: Partition([2, 2]).next_within_bounds(min=m, max=M)
[2, 2, 1]
sage: Partition([2, 2, 1]).next_within_bounds(min=m, max=M)
[3, 1]
sage: Partition([3, 1]).next_within_bounds(min=m, max=M)
[3, 1, 1]
sage: Partition([3, 1, 1]).next_within_bounds(min=m, max=M)
[3, 2]
sage: Partition([3, 2]).next_within_bounds(min=m, max=M)
[3, 2, 1]
sage: Partition([3, 2, 1]).next_within_bounds(min=m, max=M) == None
True
```

See also:

next()

outer_rim()

Return the outer rim of self.

The outer rim of a partition \( \lambda \) is defined as the cells which do not belong to \( \lambda \) and which are adjacent to cells in \( \lambda \).

EXAMPLES:

The outer rim of the partition \([4, 1]\) consists of the cells marked with \# below:

```
****#
*####
##
```

```
sage: Partition([4,1]).outer_rim()
[(2, 0), (2, 1), (1, 1), (1, 2), (1, 3), (1, 4), (0, 4)]
sage: Partition([2,2,1]).outer_rim()
[(2, 0), (2, 1), (2, 1), (2, 2), (1, 2), (0, 2)]
sage: Partition([2,2]).outer_rim()
[(2, 0), (2, 1), (2, 2), (1, 2), (0, 2)]
sage: Partition([6,3,3,1,1]).outer_rim()
[(5, 0), (5, 1), (4, 1), (3, 1), (3, 2), (3, 3), (2, 3), (1, 3), (1, 4), (1, 5),
  (1, 6), (0, 6)]
```
**sage:** Partition([ ]). outer_rim()

```
[(0, 0)]
```

**outline**(variable=None)

Return the outline of the partition `self`.

This is a piecewise linear function, normalized so that the area under the partition `[1]` is 2.

**INPUT:**

- variable – a variable (default: 'x' in the symbolic ring)

**EXAMPLES:**

```
sage: [Partition([5,4]).outline()(x=i) for i in range(-10,11)]
[10, 9, 8, 7, 6, 5, 6, 5, 6, 5, 4, 3, 2, 3, 4, 5, 6, 7, 8, 9, 10]
sage: Partition([ ]). outline()
abs(x)
sage: Partition([1]).outline()
abs(x + 1) + abs(x - 1) - abs(x)
sage: y = SR.var("y")
sage: Partition([6,5,1]).outline(variable=y)
abs(y + 6) - abs(y + 5) + abs(y + 4) - abs(y + 3) + abs(y - 1) - abs(y - 2) +
˓→abs(y - 3)
```

**outside_corners()**

Return a list of the outside corners of the partition `self`.

An outside corner (also called a cocorner) of a partition `\lambda` is a cell on $\mathbb{Z}^2$ which does not belong to the Young diagram of `\lambda` but can be added to this Young diagram to still form a straight-shape Young diagram.

The entries of the list returned are pairs of the form `(i, j)`, where `i` and `j` are the coordinates of the respective corner. The coordinates are counted from 0.

**Note:** These are called “outer corners” in [Sag2001].

**EXAMPLES:**

```
sage: Partition([2,2,1]).outside_corners()
[(0, 2), (2, 1), (3, 0)]
sage: Partition([2,2]).outside_corners()
[(0, 2), (2, 0)]
sage: Partition([6,3,3,1,1,1]).outside_corners()
[(0, 6), (1, 3), (3, 1), (6, 0)]
sage: Partition([ ]).outside_corners()
[(0, 0)]
```

**outside_corners_residue**(i, l)

Return a list of the outside corners of the partition `self` having `l`-residue `i`.

An outside corner (also called a cocorner) of a partition `\lambda` is a cell on $\mathbb{Z}^2$ which does not belong to the Young diagram of `\lambda` but can be added to this Young diagram to still form a straight-shape Young diagram.
See \textit{residue()} for the definition of the $1$-residue.

The entries of the list returned are pairs of the form $(i, j)$, where $i$ and $j$ are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

\begin{verbatim}
sage: Partition([3,2,1]).outside_corners_residue(0, 3)
[(0, 3), (3, 0)]
sage: Partition([3,2,1]).outside_corners_residue(1, 3)
[(1, 2)]
sage: Partition([3,2,1]).outside_corners_residue(2, 3)
[(2, 1)]
\end{verbatim}

\textbf{plancherel_measure()}

Return the probability of \texttt{self} under the Plancherel probability measure on partitions of the same size.

This probability distribution comes from the uniform distribution on permutations via the Robinson-Schensted correspondence.

See \textit{Wikipedia article Plancherel_measure} and \textit{Partitions.n.random_element_plancherel()}. 

EXAMPLES:

\begin{verbatim}
sage: Partition([]).plancherel_measure()
1
sage: Partition([1]).plancherel_measure()
1
sage: Partition([2]).plancherel_measure()
1/2
sage: [mu.plancherel_measure() for mu in Partitions(3)]
[1/6, 2/3, 1/6]
sage: Partition([5,4]).plancherel_measure()
7/1440
\end{verbatim}

\textbf{power}(k)

Return the cycle type of the $k$-th power of any permutation with cycle type \texttt{self} (thus describes the power map of symmetric groups).

Equivalent to GAP's \texttt{PowerPartition}.

EXAMPLES:

\begin{verbatim}
sage: p = Partition([5,3])
sage: p.power(1)
[5, 3]
sage: p.power(2)
[5, 3]
sage: p.power(3)
[5, 1, 1, 1]
sage: p.power(4)
[5, 3]
\end{verbatim}

Now let us compare this to the power map on $S_8$:

\begin{verbatim}
sage: G = SymmetricGroup(8)
sage: g = G([(1,2,3,4,5),(6,7,8)])
\end{verbatim}

(continues on next page)
sage: \( g \)
\((1,2,3,4,5)(6,7,8)\)
sage: \( g^2 \)
\((1,3,5,2,4)(6,8,7)\)
sage: \( g^3 \)
\((1,4,2,5,3)\)
sage: \( g^4 \)
\((1,5,4,3,2)(6,7,8)\)

\[
\text{sage: Partition([3,2,1]).power(3)}
\]
\[
\begin{pmatrix}
2 \\
1 \\
1 \\
1 \\
1
\end{pmatrix}
\]

\text{pp()}
Print the Ferrers diagram.

See \texttt{ferrers_diagram()} for more on the Ferrers diagram.

\textbf{EXAMPLES:}

\[
\text{sage: Partition([5,5,2,1]).pp()}
\]
\[
\begin{array}{cccc}
**** & **** & & \\
 & **** & * & \\
\end{array}
\]
\[
\text{sage: Partitions.options.convention='French'}
\]
\[
\text{sage: Partition([5,5,2,1]).pp()}
\]
\[
* \\
** \\
***** \\
*****
\]
\[
\text{sage: Partitions.options._reset()}
\]

\textbf{prime_degree}(p)
Return the prime degree for the prime integer \( p \) for \texttt{self}.

\textbf{INPUT:}

\begin{itemize}
\item \( p \) – a prime integer
\end{itemize}

\textbf{OUTPUT:}

A non-negative integer

The degree of a partition \( \lambda \) is the sum of the \texttt{e-degree()} of the standard tableaux of shape \( \lambda \), for \( e \) a power of the prime \( p \). The prime degree gives the exponent of \( p \) in the Gram determinant of the integral Specht module of the symmetric group.

\textbf{EXAMPLES:}

\[
\text{sage: Partition([4,3]).prime_degree(2)}
\]
36
\[
\text{sage: Partition([4,3]).prime_degree(3)}
\]
15
\[
\text{sage: Partition([4,3]).prime_degree(5)}
\]
13
Therefore, the Gram determinant of $S(5, 3)$ when $q = 1$ is $2^{36} 3^{15} 5^{13}$. Compare with `degree()`.

**quotient(length)**

Return the quotient of the partition – in the literature the quotient is commonly referred to as the $k$-quotient, $p$-quotient, $r$-quotient, ... .

The $r$-quotient of a partition $\lambda$ is a list of $r$ partitions (labelled from 0 to $r-1$), constructed in the following way. Label each cell in the Young diagram of $\lambda$ with its content modulo $r$. Let $R_i$ be the set of rows ending in a cell labelled $i$, and $C_j$ be the set of columns ending in a cell labelled $i$. Then the $j$-th component of the quotient of $\lambda$ is the partition defined by intersecting $R_j$ with $C_{j+1}$. (See Theorem 2.7.37 in [JK1981].)

**EXAMPLES:**

```python
sage: Partition([7,7,5,3,3,3,1]).quotient(3)
([[2], [1], [2, 2, 2]])
```

**reading_tableau()**

Return the RSK recording tableau of the reading word of the (standard) tableau $T$ labeled down (in English convention) each column to the shape of `self`.

For an example of the tableau $T$, consider the partition $\lambda = (3, 2, 1)$, then we have:

```
  1 4 6
  2 5
  3
```

For more, see `RSK()`.

**EXAMPLES:**

```python
sage: Partition([3,2,1]).reading_tableau()
[[1, 3, 6], [2, 5], [4]]
```

**removable_cells()**

Return a list of the corners of the partition `self`.

A corner of a partition $\lambda$ is a cell of the Young diagram of $\lambda$ which can be removed from the Young diagram while still leaving a straight shape behind.

The entries of the list returned are pairs of the form $(i, j)$, where $i$ and $j$ are the coordinates of the respective corner. The coordinates are counted from 0.

**Note:** This is referred to as an “inner corner” in [Sag2001].

**EXAMPLES:**

```python
sage: Partition([3,2,1]).corners()
[(0, 2), (1, 1), (2, 0)]
sage: Partition([3,3,1]).corners()
[(1, 2), (2, 0)]
sage: Partition([]).corners()
[]
```
**removable_cells_residue**(i, l)

Return a list of the corners of the partition self having 1-residue i.

A corner of a partition \( \lambda \) is a cell of the Young diagram of \( \lambda \) which can be removed from the Young diagram while still leaving a straight shape behind. See \( \text{residue()} \) for the definition of the 1-residue.

The entries of the list returned are pairs of the form \((i, j)\), where \(i\) and \(j\) are the coordinates of the respective corner. The coordinates are counted from 0.

**EXAMPLES:**

```python
sage: Partition([3,2,1]).corners_residue(0, 3)
[(1, 1)]
sage: Partition([3,2,1]).corners_residue(1, 3)
[(2, 0)]
sage: Partition([3,2,1]).corners_residue(2, 3)
[(0, 2)]
```

**remove_cell**(i, j=None)

Return the partition obtained by removing a cell at the end of row \(i\) of self.

**EXAMPLES:**

```python
sage: Partition([2,2]).remove_cell(1)
[2, 1]
sage: Partition([2,2,1]).remove_cell(2)
[2, 2]
sage: Partition([2,2,1]).remove_cell(1,1)
[2, 1]
sage: Partition([2,2]).remove_cell(1,0)
```

**remove_horizontal_border_strip**(k)

Return the partitions obtained from self by removing an horizontal border strip of length \(k\).

**EXAMPLES:**

```python
sage: Partition([5,3,1]).remove_horizontal_border_strip(0).list()
[[5, 3, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(1).list()
[[5, 3], [5, 2, 1], [4, 3, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(2).list()
[[5, 2], [5, 1, 1], [4, 3], [4, 2, 1], [3, 3, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(3).list()
[[5, 1], [4, 2], [4, 1, 1], [3, 3], [3, 2, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(4).list()
[[4, 1], [3, 2], [3, 1, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(5).list()
[[3, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(6).list()
[]
```

The result is returned as an instance of \(\text{Partitions_with_constraints}\):
**Combinatorics, Release 10.0**

---

```python
def remove_horizontal_border_strip(partition, length):
    subpartitions = []
    for subpartition in partition:
        new_subpartition = subpartition[1:]
        subpartitions.append(new_subpartition)
    return subpartitions
```

**residue(r, c, l)**

Return the 1-residue of the cell at row $r$ and column $c$.

The $\ell$-residue of a cell is $c - r$ modulo $\ell$.

This does not strictly depend upon the partition, however, this method is included because it is often useful in the context of partitions.

**EXAMPLES:**

```python
def residue(partition, row, column, residue):
    return partition.residue(row, column, residue)
```

**rim()**

Return the rim of self.

The rim of a partition $\lambda$ is defined as the cells which belong to $\lambda$ and which are adjacent to cells not in $\lambda$.

**EXAMPLES:**

The rim of the partition $[5, 5, 2, 1]$ consists of the cells marked with # below:

```python
# # #
# # #
# # #
# # #
```

```python
def rim(partition):
    return partition.rim()
```

```
**row_standard_tableaux()**

Return the row standard tableaux of shape self.

**EXAMPLES:**

```python
def row_standard_tableaux(partition):
    return partition.row_standard_tableaux()
```

```
**sign()**

Return the sign of any permutation with cycle type self.

This function corresponds to a homomorphism from the symmetric group $S_n$ into the cyclic group of order 2, whose kernel is exactly the alternating group $A_n$. Partitions of sign 1 are called even partitions while partitions of sign $-1$ are called odd.

```python
def sign(partition):
    return partition.sign()
```
Zolotarev’s lemma states that the Legendre symbol \( \left( \frac{a}{p} \right) \) for an integer \( a \pmod{p} \) (\( p \) a prime number), can be computed as \( \text{sign}(\text{p}_a) \), where \( \text{sign} \) denotes the sign of a permutation and \( \text{p}_a \) the permutation of the residue classes \( \pmod{p} \) induced by modular multiplication by \( a \), provided \( p \) does not divide \( a \).

We verify this in some examples.

```python
sage: F = GF(11)
sage: a = F.multiplicative_generator(); a
2
sage: plist = [int(a*F(x)) for x in range(1,11)]; plist
[2, 4, 6, 8, 10, 1, 3, 5, 7, 9]
This corresponds to the permutation (1, 2, 4, 8, 5, 10, 9, 7, 3, 6) (acting the set \( \{1, 2, \ldots, 10\} \)) and to the partition \([10]\).

sage: p = PermutationGroupElement('(1, 2, 4, 8, 5, 10, 9, 7, 3, 6)')
sage: p.sign()
-1
sage: Partition([10]).sign()
-1
sage: kronecker_symbol(11,2)
-1

Now replace 2 by 3:

```python
sage: plist = [int(F(3*x)) for x in range(1,11)]; plist
[3, 6, 9, 1, 4, 7, 10, 2, 5, 8]
sage: list(range(1, 11))
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
sage: p = PermutationGroupElement('(3,4,8,7,9)')
sage: p.sign()
1
sage: kronecker_symbol(3,11)
1
sage: Partition([5,1,1,1,1,1]).sign()
1
```

In both cases, Zolotarev holds.

REFERENCES:

- Wikipedia article Zolotarev’s lemma
Combinatorics, Release 10.0

```
sage: Partition([2,2]).size()
sage: Partition([3,2,1]).size()
4
6
```

**specht_module** *(base_ring=None)*

Return the Specht module corresponding to self.

**EXAMPLES:**

```
sage: SM = Partition([2,2,1]).specht_module(QQ)
sage: SM
Specht module of [(0, 0), (0, 1), (1, 0), (1, 1), (2, 0)] over Rational Field
sage: s = SymmetricFunctions(QQ).s()
sage: s(SM.frobenius_image())
s[2, 2, 1]
```

**specht_module_dimension** *(base_ring=None)*

Return the dimension of the Specht module corresponding to self.

This is equal to the number of standard tableaux of shape self when over a field of characteristic 0.

**INPUT:**

• BR – (default: Q) the base ring

**EXAMPLES:**

```
sage: Partition([2,2,1]).specht_module_dimension()
sage: Partition([2,2,1]).specht_module_dimension(GF(2))
5
5
```

**standard_tableaux** *

Return the standard tableaux of shape self.

**EXAMPLES:**

```
sage: Partition([3,2,2,1]).standard_tableaux()
Standard tableaux of shape [3, 2, 2, 1]
```

**stretch** *(k)*

Return the partition obtained by multiplying each part with the given number.

**EXAMPLES:**

```
sage: p = Partition([4,2,2,1,1])
sage: p.stretch(3)
[12, 6, 6, 3, 3]
```

**suter_diagonal_slide** *(n, exp=1)*

Return the image of self in $Y_n$ under Suter’s diagonal slide $\sigma_n$, where the notations used are those defined in [Sut2002].

The set $Y_n$ is defined as the set of all partitions $\lambda$ such that the hook length of the $(0,0)$-cell (i.e. the northwestern most cell in English notation) of $\lambda$ is less than $n$, including the empty partition.
The map $\sigma_n$ sends a partition (with non-zero entries) $(\lambda_1, \lambda_2, \ldots, \lambda_m) \in Y_n$ to the partition $(\lambda_2 + 1, \lambda_3 + 1, \ldots, \lambda_m + 1, 1, 1, \ldots, 1)$. In other words, it pads the partition with trailing zeroes until it has length $n - \lambda_1$, then removes its first part, and finally adds 1 to each part.

By Theorem 2.1 of [Sut2002], the dihedral group $D_n$ with $2n$ elements acts on $Y_n$ by letting the primitive rotation act as $\sigma_n$ and the reflection act as conjugation of partitions ($\text{conjugate()}$). This action is faithful if $n \geq 3$.

**INPUT:**

- $n$ – nonnegative integer
- $\exp$ – (default: 1) how many times $\sigma_n$ should be applied

**OUTPUT:**

The result of applying Suter’s diagonal slide $\sigma_n$ to self, assuming that self lies in $Y_n$. If the optional argument $\exp$ is set, then the slide $\sigma_n$ is applied not just once, but $\exp$ times (note that $\exp$ is allowed to be negative, since the slide has finite order).

**EXAMPLES:**

```sage
sage: Partition([5,4,1]).suter_diagonal_slide(8)
[5, 2]
sage: Partition([5,4,1]).suter_diagonal_slide(9)
[5, 2, 1]
sage: Partition([]).suter_diagonal_slide(7)
[1, 1, 1, 1, 1, 1]
sage: Partition([]).suter_diagonal_slide(1)
[]
sage: Partition([]).suter_diagonal_slide(7, exp=-1)
[6]
sage: Partition([]).suter_diagonal_slide(1, exp=-1)
[]
sage: P7 = Partitions(7)
sage: all( p == p.suter_diagonal_slide(9, exp=-1).suter_diagonal_slide(9)  
... for p in P7 )
True
sage: all( p == p.suter_diagonal_slide(9, exp=3)  
... .suter_diagonal_slide(9, exp=3) 
... .suter_diagonal_slide(9, exp=3)  
... for p in P7 )
True
sage: all( p == p.suter_diagonal_slide(9, exp=6)  
... .suter_diagonal_slide(9, exp=6) 
... .suter_diagonal_slide(9, exp=6)  
... for p in P7 )
True
sage: all( p == p.suter_diagonal_slide(9, exp=-1)  
... .suter_diagonal_slide(9, exp=1) 
... .suter_diagonal_slide(9, exp=1)  
... for p in P7 )
True
```

Check of the assertion in [Sut2002] that $\sigma_n(\sigma_n(\lambda')) = \lambda$: 5.1. Comprehensive Module List 1759
Check of Claim 1 in [Sut2002]:

```python
sage: P5 = Partitions(5)
sage: all( all( (p.suter_diagonal_slide(6) in q.suter_diagonal_slide(6).down()) or (q.suter_diagonal_slide(6) in p.suter_diagonal_slide(6).down()) for p in q.down() ) for q in P5 )
True
```

### t_completion(t)

Return the t-completion of the partition self.

If \( \lambda = (\lambda_1, \lambda_2, \lambda_3, \ldots) \) is a partition and \( t \) is an integer greater or equal to \( |\lambda| + \lambda_1 \), then the \( t \)-completion of \( \lambda \) is defined as the partition \( (t - |\lambda|, \lambda_1, \lambda_2, \lambda_3, \ldots) \) of \( t \). This partition is denoted by \( \lambda[t] \) in [BOR2009], by \( \lambda_{[t]} \) in [BdVO2012], and by \( \lambda(t) \) in [CO2010].

**EXAMPLES:**

```python
sage: Partition([]).t_completion(0)
[]
sage: Partition([]).t_completion(1)
[1]
sage: Partition([]).t_completion(2)
[2]
sage: Partition([]).t_completion(3)
[3]
sage: Partition([2, 1]).t_completion(5)
[2, 2, 1]
sage: Partition([2, 1]).t_completion(6)
[3, 2, 1]
sage: Partition([4, 2, 1]).t_completion(13)
[4, 4, 2, 2, 1]
sage: Partition([4, 2, 1]).t_completion(19)
[10, 4, 2, 2, 1]
sage: Partition([4, 2, 1]).t_completion(10)
Traceback (most recent call last):
... ValueError: 10-completion is not defined
sage: Partition([4, 2, 1]).t_completion(5)
Traceback (most recent call last):
... ValueError: 5-completion is not defined
```

### to_core(k)

Maps the \( k \)-bounded partition self to its corresponding \( k + 1 \)-core.

See also \( k\_skew() \).

**EXAMPLES:**
sage: p = Partition([4,3,2,2,1,1])
sage: c = p.to_core(4); c
[9, 5, 3, 2, 1, 1]
sage: type(c)
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: c.to_bounded_partition() == p
True

to_dyck_word(n=\text{None})

Return the n-Dyck word whose corresponding partition is self (or, if n is not specified, the n-Dyck word with smallest n to satisfy this property).

If w is an n-Dyck word (that is, a Dyck word with n open symbols and n close symbols), then the Dyck path corresponding to w can be regarded as a lattice path in the northeastern half of an n \times n-square. The region to the northeast of this Dyck path can be regarded as a partition. It is called the partition corresponding to the Dyck word w. (See to_partition().)

For every partition \lambda and every nonnegative integer n, there exists at most one n-Dyck word w such that the partition corresponding to w is \lambda (in fact, such w exists if and only if \lambda_i + i \leq n for every i, where \lambda is written in the form (\lambda_1, \lambda_2, \ldots, \lambda_k) with \lambda_k \geq 0). This method computes this w for a given \lambda and n. If n is not specified, this method computes the w for the smallest possible n for which such an w exists. (The minimality of n means that the partition demarcated by the Dyck path touches the diagonal.)

EXAMPLES:

sage: Partition([2,2]).to_dyck_word()
[1, 1, 0, 0, 1, 1, 0, 0]
sage: Partition([2,2]).to_dyck_word(4)
[1, 1, 0, 0, 1, 1, 0, 0]
sage: Partition([2,2]).to_dyck_word(5)
[1, 1, 1, 0, 0, 1, 1, 0, 0]
sage: Partition([6,3,1]).to_dyck_word()
[1, 1, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 1, 0]
sage: Partition([]).to_dyck_word()
[]
sage: Partition([]).to_dyck_word(3)
[1, 1, 1, 0, 0, 0]

The partition corresponding to self.dyck_word() is self indeed:

sage: all( p.to_dyck_word().to_partition() == p
.....:    for p in Partitions(5) )
True

to_exp(k=0)

Return a list of the multiplicities of the parts of a partition. Use the optional parameter k to get a return list of length at least k.

EXAMPLES:

sage: Partition([3,2,2,1]).to_exp()
[1, 2, 1]
sage: Partition([3,2,2,1]).to_exp(5)
[1, 2, 1, 0, 0]
to_exp_dict()

Return a dictionary containing the multiplicities of the parts of self.

EXAMPLES:

```python
sage: p = Partition([4,2,2,1])
sage: d = p.to_exp_dict()
sage: d[4]
1
sage: d[2]
2
sage: d[1]
1
sage: 5 in d
False
```

to_list()

Return self as a list.

EXAMPLES:

```python
sage: p = Partition([2,1]).to_list(); p
[2, 1]
sage: type(p)
<class 'list'>
```

top_garnir_tableau(e, cell)

Return the most dominant standard tableau which dominates the corresponding Garnir tableau and has the same e-residue.

The Garnir tableau play an important role in integral and non-semisimple representation theory because they determine the “straightening” rules for the Specht modules. The top Garnir tableaux arise in the graded representation theory of the symmetric groups and higher level Hecke algebras. They were introduced in [KMR2012].

If the Garnir node is cell=(r,c) and m and M are the entries in the cells (r,c) and (r+1,c), respectively, in the initial tableau then the top e-Garnir tableau is obtained by inserting the numbers m, m+1,...,M in order from left to right first in the cells in row r+1 which are not in the e-Garnir belt, then in the cell in rows r and r+1 which are in the Garnir belt and then, finally, in the remaining cells in row r which are not in the Garnir belt. All other entries in the tableau remain unchanged.

If e = 0, or if there are no e-bricks in either row r or r+1, then the top Garnir tableau is the corresponding Garnir tableau.

EXAMPLES:

```python
sage: Partition([5,4,3,2]).top_garnir_tableau(2,(0,2)).pp()
  1 2 4 5 8
  3 6 7 9
 10 11 12
 13 14
sage: Partition([5,4,3,2]).top_garnir_tableau(3,(0,2)).pp()
  1 2 3 4 5
  6 7 8 9
 10 11 12
 13 14
```

(continues on next page)
sage: Partition([5,4,3,2]).top_garnir_tableau(4,(0,2)).pp()
1 2 6 7 8
3 4 5 9
10 11 12
13 14
sage: Partition([5,4,3,2]).top_garnir_tableau(0,(0,2)).pp()
1 2 6 7 8
3 4 5 9
10 11 12
13 14

REFERENCES:
• [KMR2012]

up()
Return a generator for partitions that can be obtained from self by adding a cell.

EXAMPLES:

sage: list(Partition([2,1,1]).up())
[[3, 1, 1], [2, 2, 1], [2, 1, 1, 1]]
sage: list(Partition([3,2]).up())
[[4, 2], [3, 3], [3, 2, 1]]
sage: [p for p in Partition([]).up()]
[[1]]

up_list()
Return a list of the partitions that can be formed from self by adding a cell.

EXAMPLES:

sage: Partition([2,1,1]).up_list()
[[3, 1, 1], [2, 2, 1], [2, 1, 1, 1]]
sage: Partition([3,2]).up_list()
[[4, 2], [3, 3], [3, 2, 1]]
sage: Partition([]).up_list()
[[1]]

upper_hook(i, j, alpha)

Return the upper hook length of the cell (i, j) in self. When alpha = 1, this is just the normal hook length.

The upper hook length of a cell (i, j) in a partition $\kappa$ is defined by

$$h^*_\kappa(i, j) = \kappa'_j - i + \alpha(\kappa_i - j + 1).$$

EXAMPLES:

sage: p = Partition([2,1])
sage: p.upper_hook(0,0,1)
3
sage: p.hook_length(0,0)
3
sage: [p.upper_hook(i,j,x) for i,j in p.cells()]
[2*x + 1, x, x]
upper_hook_lengths(alpha)

Return a tableau of shape self with the cells filled in with the upper hook lengths. When alpha = 1, these are just the normal hook lengths.

The upper hook length of a cell (i, j) in a partition κ is defined by

\[ h^*_κ(i, j) = κ'_j - i + α(κ_i - j + 1). \]

EXAMPLES:

```python
sage: Partition([3, 2, 1]).upper_hook_lengths(x)
[[3*x + 2, 2*x + 1, x], [2*x + 1, x], [x]]

sage: Partition([3, 2, 1]).upper_hook_lengths(1)
[[5, 3, 1], [3, 1], [1]]

sage: Partition([3, 2, 1]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
```

vertical_border_strip_cells(k)

Return a list of all the vertical border strips of length k which can be added to self, where each horizontal border strip is a generator of cells.

EXAMPLES:

```python
sage: list(Partition([]).vertical_border_strip_cells(0))
[]

sage: list(Partition([3, 2, 1]).vertical_border_strip_cells(0))
[]

sage: list(Partition([]).vertical_border_strip_cells(2))
[(0, 0), (1, 0)]

sage: list(Partition([2, 2]).vertical_border_strip_cells(2))
[(0, 2), (1, 2), (2, 0), (3, 0)]

sage: list(Partition([2, 2]).vertical_border_strip_cells(2))
[(0, 3), (3, 0)]
```

weighted_size()

Return the weighted size of self.

The weighted size of a partition \( \lambda \) is

\[
\sum_i i \cdot \lambda_i,
\]

where \( \lambda = (\lambda_0, \lambda_1, \lambda_2, \cdots) \).

This also the sum of the leg length of every cell in \( \lambda \), or

\[
\sum_i \left( \frac{\lambda'_i}{2} \right)
\]

where \( \lambda' \) is the conjugate partition of \( \lambda \).

EXAMPLES:
Combinatorics, Release 10.0

```
sage: Partition([2,2]).weighted_size()
2
sage: Partition([3,3,3]).weighted_size()
9
sage: Partition([5,2]).weighted_size()
2
sage: Partition([]).weighted_size()
0
```

**young_subgroup()**

Return the corresponding Young, or parabolic, subgroup of the symmetric group.

The Young subgroup of a partition \( \lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell) \) of \( n \) is the group:

\[
S_{\lambda_1} \times S_{\lambda_2} \times \cdots \times S_{\lambda_\ell}
\]

embedded into \( S_n \) in the standard way (i.e., the \( S_{\lambda_i} \) factor acts on the numbers from \( \lambda_1 + \lambda_2 + \cdots + \lambda_{i-1} + 1 \) to \( \lambda_1 + \lambda_2 + \cdots + \lambda_i \)).

**EXAMPLES:**

```
sage: Partition([4,2]).young_subgroup()
Permutation Group with generators [((), (5,6), (3,4), (2,3), (1,2))]
```

**young_subgroup_generators()**

Return an indexing set for the generators of the corresponding Young subgroup. Here the generators correspond to the simple adjacent transpositions \( s_i = (i \ i+1) \).

**EXAMPLES:**

```
sage: Partition([4,2]).young_subgroup_generators()
[1, 2, 3, 5]
sage: Partition([1,1,1]).young_subgroup_generators()
[]
sage: Partition([2,2]).young_subgroup_generators()
[1, 3]
```

See also:

*young_subgroup()*

**zero_one_sequence()**

Compute the finite \( 0 \rightarrow 1 \) sequence of the partition.

The full \( 0 \rightarrow 1 \) sequence is the sequence (infinite in both directions) indicating the steps taken when following the outer rim of the diagram of the partition. We use the convention that in English convention, a 1 corresponds to an East step, and a 0 corresponds to a North step.

Note that every full \( 0 \rightarrow 1 \) sequence starts with infinitely many 0’s and ends with infinitely many 1’s.

One place where these arise is in the affine symmetric group where one takes an affine permutation \( w \) and every \( i \) such that \( w(i) \leq 0 \) corresponds to a 1 and \( w(i) > 0 \) corresponds to a 0. See pages 24-25 of [LLMSSZ2013] for connections to affine Grassmannian elements (note there they use the French convention for their partitions).

These are also known as **path sequences, Maya diagrams, plus-minus diagrams, Comet code** [Sta-EC2], among others.
The finite 0−1 sequence is obtained from the full 0−1 sequence by omitting all heading 0’s and trailing 1’s. The output sequence is finite, starts with a 1 and ends with a 0 (unless it is empty, for the empty partition). Its length is the sum of the first part of the partition with the length of the partition.

EXAMPLES:

```python
sage: Partition([5, 4]).zero_one_sequence()
[1, 1, 1, 1, 0, 1, 0]
sage: Partition([]).zero_one_sequence()
[]
sage: Partition([2]).zero_one_sequence()
[1, 1, 0]
```

class sage.combinat.partition.Partitions(is_infinite=False)

Bases: UniqueRepresentation, Parent

Partitions(n, **kwargs) returns the combinatorial class of integer partitions of \(n\) subject to the constraints given by the keywords. Valid keywords are: starting, ending, min_part, max_part, max_length, min_length, length, max_slope, min_slope, inner, outer, parts_in, regular, and restricted. They have the following meanings:

* starting=p specifies that the partitions should all be less than or equal to \(p\) in lex order. This argument cannot be combined with any other (see github issue #15467).
* ending=p specifies that the partitions should all be greater than or equal to \(p\) in lex order. This argument cannot be combined with any other (see github issue #15467).
* length=k specifies that the partitions have exactly \(k\) parts.
* min_length=k specifies that the partitions have at least \(k\) parts.
* min_part=k specifies that all parts of the partitions are at least \(k\).
* inner=p specifies that the partitions must contain the partition \(p\).
* outer=p specifies that the partitions be contained inside the partition \(p\).
* min_slope=k specifies that the partitions have slope at least \(k\); the slope at position \(i\) is the difference between the \((i+1)\)-th part and the \(i\)-th part.
* parts_in=S specifies that the partitions have parts in the set \(S\), which can be any sequence of pairwise distinct positive integers. This argument cannot be combined with any other (see github issue #15467).
* regular=ell specifies that the partitions are \(\ell\)-regular, and can only be combined with the max_length or max_part, but not both, keywords if \(n\) is not specified
* restricted=ell specifies that the partitions are \(\ell\)-restricted, and cannot be combined with any other keywords

The max_* versions, along with inner and ending, work analogously.

Right now, the parts_in, starting, ending, regular, and restricted keyword arguments are mutually exclusive, both of each other and of other keyword arguments. If you specify, say, parts_in, all other keyword arguments will be ignored; starting, ending, regular, and restricted work the same way.

EXAMPLES:

If no arguments are passed, then the combinatorial class of all integer partitions is returned:
If an integer \( n \) is passed, then the combinatorial class of integer partitions of \( n \) is returned:

```sage
Partitions(3)
Partitions of the integer 3
Partitions(3).list()
[[3], [2, 1], [1, 1, 1]]
```

If `starting=p` is passed, then the combinatorial class of partitions greater than or equal to \( p \) in lexicographic order is returned:

```sage
Partitions(3, starting=[2,1])
Partitions of the integer 3 starting with [2, 1]
Partitions(3, starting=[2,1]).list()
[[2, 1], [1, 1, 1]]
```

If `ending=p` is passed, then the combinatorial class of partitions at most \( p \) in lexicographic order is returned:

```sage
Partitions(3, ending=[2,1])
Partitions of the integer 3 ending with [2, 1]
Partitions(3, ending=[2,1]).list()
[[3], [2, 1]]
```

Using `max_slope=-1` yields partitions into distinct parts – each part differs from the next by at least 1. Use a different `max_slope` to get parts that differ by, say, 2:

```sage
Partitions(7, max_slope=-1).list()
[[7], [6, 1], [5, 2], [4, 3], [4, 2, 1]]
Partitions(15, max_slope=-1).cardinality()
27
```

The number of partitions of \( n \) into odd parts equals the number of partitions into distinct parts. Let’s test that for \( n \) from 10 to 20:

```sage
test = lambda n: Partitions(n, max_slope=-1).cardinality() == Partitions(n, parts_in=[1,3..n]).cardinality()
test: all(test(n) for n in [10..20])
True
```

The number of partitions of \( n \) into distinct parts that differ by at least 2 equals the number of partitions into parts that equal 1 or 4 modulo 5; this is one of the Rogers-Ramanujan identities:

```sage
test = lambda n: Partitions(n, max_slope=-2).cardinality() == Partitions(n, parts_in=[1,6..n] + [4,9..n]).cardinality()
test: all(test(n) for n in [10..20])
True
```

Here are some more examples illustrating `min_part`, `max_part`, and `length`:
Partitions of the integer 5 satisfying constraints min_part=2
[[5], [3, 2]]

Partitions of the integer 3 with max_length=2
[[3], [2, 1]]

Partitions of 10 with min_part=2, length=3
[[6, 2, 2], [5, 3, 2], [4, 4, 2], [4, 3, 3]]

Some examples using the regular keyword:

4-Regular Partitions

4-Regular Partitions with max length 3

4-Regular 3-Bounded Partitions

4-Regular Partitions of the integer 3

Some examples using the restricted keyword:

4-Restricted Partitions

4-Restricted Partitions of the integer 3

Here are some further examples using various constraints:

4, 1, 1, 1]]
[[4], [3, 1]]

4, 1, 1, 1]]
[[4], [3, 1]]

4, 1, 1, 1]]
[[4], [3, 1]]

(continues on next page)
Note that if you specify min_part=0, then it will treat the minimum part as being 1 (see github issue #13605):

```
sage: [x for x in Partitions(4, length=3, min_part=0)]
[[2, 1, 1]]
sage: [x for x in Partitions(4, min_length=3, min_part=0)]
[[2, 1, 1], [1, 1, 1, 1]]
```

Except for very special cases, counting is done by brute force iteration through all the partitions. However the iteration itself has a reasonable complexity (see `IntegerListsLex`), which allows for manipulating large partitions:

```
sage: Partitions(1000, max_length=1).list()
[[1000]]
```

In particular, getting the first element is also constant time:

```
sage: Partitions(30, max_part=29).first()
[29, 1]
```

### Element

alias of `Partition`

```
options = Current options for Partitions - convention: English - diagram_str: * - display: list - latex: young_diagram - latex_diagram_str: \ast
```

```
sage: subset(*args, **kwargs)
Return self if no arguments are given, otherwise raises a ValueError.
```

### Examples:

```
sage: P = Partitions(5, starting=[3,1]); P
Partitions of the integer 5 starting with [3, 1]
sage: P.subset()
Partitions of the integer 5 starting with [3, 1]
sage: P.subset(ending=[3,1])
Traceback (most recent call last):
  ... ValueError: invalid combination of arguments
```

## 5.1. Comprehensive Module List
Combinatorics, Release 10.0

sage: PartitionsGreatestEQ(10, 2)
Partitions of 10 having greatest part equal to 2
sage: PartitionsGreatestEQ(10, 2).list()
[[2, 2, 2, 2, 2],
 [2, 2, 2, 1, 1],
 [2, 2, 1, 1, 1, 1],
 [2, 1, 1, 1, 1, 1, 1],
 [1, 1, 1, 1, 1, 1, 1, 1]]

sage: [4,3,2,1] in PartitionsGreatestEQ(10, 2)
False
sage: [2,2,2,2,2] in PartitionsGreatestEQ(10, 2)
True

The empty partition has no maximal part, but it is contained in the set of partitions with any specified maximal part:

sage: PartitionsGreatestEQ(0, 2).list()
[[[]]]

Element

alias of Partition
cardinality()
Return the cardinality of self.

EXAMPLES:

sage: PartitionsGreatestEQ(10, 2).cardinality()
5

options = Current options for Partitions - convention: English - diagram_str: * - display: list - latex: young_diagram - latex_diagram_str: \ast

class sage.combinat.partition.PartitionsGreatestLE(n,k)

Bases: UniqueRepresentation, IntegerListsLex

The class of all (unordered) “restricted” partitions of the integer $n$ having parts less than or equal to the integer $k$.

EXAMPLES:

sage: PartitionsGreatestLE(10, 2)
Partitions of 10 having parts less than or equal to 2
sage: PartitionsGreatestLE(10, 2).list()
[[2, 2, 2, 2],
 [2, 2, 2, 1, 1],
 [2, 2, 1, 1, 1, 1],
 [2, 1, 1, 1, 1, 1, 1],
 [1, 1, 1, 1, 1, 1, 1, 1]]

sage: [4,3,2,1] in PartitionsGreatestLE(10, 2)
False
sage: [2,2,2,2,2] in PartitionsGreatestLE(10, 2)

(continues on next page)
True

```
sage: PartitionsGreatestLE(10, 2).first().parent()
Partitions...
```

**Element**

alias of *Partition*

**cardinality()**

Return the cardinality of *self*.

**EXAMPLES:**

```
sage: PartitionsGreatestLE(9, 5).cardinality()
23
```

```
options = Current options for Partitions - convention: English - diagram_str: * - display: list - latex: young_diagram - latex_diagram_str: \ast
```

class sage.combinat.partition.PartitionsInBox(h, w)

```
Bases: Partitions
```

All partitions which fit in an \( h \times w \) box.

**EXAMPLES:**

```
sage: PartitionsInBox(2,2)
Integer partitions which fit in a 2 x 2 box
sage: PartitionsInBox(2,2).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2]]
```

```
cardinality()
```

Return the cardinality of *self*.

**EXAMPLES:**

```
sage: PartitionsInBox(2, 3).cardinality()
10
```

```
list()
```

Return a list of all the partitions inside a box of height \( h \) and width \( w \).

**EXAMPLES:**

```
sage: PartitionsInBox(2,2).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2]]
sage: PartitionsInBox(2,3).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2], [3], [3, 1], [3, 2], [3, 3]]
```

class sage.combinat.partition.Partitions_all

```
Bases: Partitions
```

Class of all partitions.

```
from_beta_numbers(beta)
```

Return a partition corresponding to a sequence of beta numbers.
A sequence of beta numbers is a strictly increasing sequence \(0 \leq b_1 < \cdots < b_k\) of non-negative integers. The corresponding partition \(\mu = (\mu_k, \ldots, \mu_1)\) is given by \(\mu_i = [1,i) \setminus \{b_1, \ldots, b_i\}\). This gives a bijection from the set of partitions with at most \(k\) non-zero parts to the set of strictly increasing sequences of non-negative integers of length \(k\).

**EXAMPLES:**

```python
sage: Partitions().from_beta_numbers([0,1,2,4,5,8])
[3, 1, 1]
sage: Partitions().from_beta_numbers([0,2,3,6])
[3, 1, 1]
```

**from_core_and_quotient**(core, quotient)

Return a partition from its core and quotient.

Algorithm from mupad-combinat.

**EXAMPLES:**

```python
sage: Partitions().from_core_and_quotient([2,1], [[2,1],[3],[1,1,1]])
[11, 5, 5, 3, 2, 2, 2]
```

**from_exp**(exp)

Return a partition from its list of multiplicities.

**EXAMPLES:**

```python
sage: Partitions().from_exp([2,2,1])
[3, 2, 2, 1, 1]
```

**from_frobenius_coordinates**(frobenius_coordinates)

Return a partition from a pair of sequences of Frobenius coordinates.

**EXAMPLES:**

```python
sage: Partitions().from_frobenius_coordinates([],[]) [[]]
sage: Partitions().from_frobenius_coordinates([0],[0])
[1]
sage: Partitions().from_frobenius_coordinates([1],[1])
[2, 1]
sage: Partitions().from_frobenius_coordinates([6,3,2],[4,1,0])
[7, 5, 5, 1, 1]
```

**from_zero_one**(seq)

Return a partition from its \(0-1\) sequence.

The full \(0-1\) sequence is the sequence (infinite in both directions) indicating the steps taken when following the outer rim of the diagram of the partition. We use the convention that in English convention, a \(1\) corresponds to an East step, and a \(0\) corresponds to a North step.

Note that every full \(0-1\) sequence starts with infinitely many \(0\)'s and ends with infinitely many \(1\)'s.

See also:

Partition.zero_one_sequence()

**INPUT:**
The input should be a finite sequence of 0’s and 1’s. The heading 0’s and trailing 1’s will be discarded.

**EXAMPLES:**

```
sage: Partitions().from_zero_one([])
[]
sage: Partitions().from_zero_one([1,0])
[1]
sage: Partitions().from_zero_one([1,1,1,1,0,1,0])
[5, 4]
```

Heading 0’s and trailing 1’s are correctly handled:

```
sage: Partitions().from_zero_one([0,0,1,1,1,1,0,1,0,1,1,1])
[5, 4]
```

**subset(size=None, **kwargs)**

Return the subset of partitions of a given size and additional keyword arguments.

**EXAMPLES:**

```
sage: P = Partitions()
sage: P.subset(4)
Partitions of the integer 4
```

---

**5.1. Comprehensive Module List**

---
class sage.combinat.partition.Partitions_n(n)

Bases: Partitions

Partitions of the integer n.

cardinality(algorithm='flint')

Return the number of partitions of the specified size.

INPUT:

• algorithm - (default: 'flint')
  - 'flint' – use FLINT (currently the fastest)
  - 'gap' – use GAP (VERY slow)
  - 'pari' – use PARI. Speed seems the same as GAP until n is in the thousands, in which case PARI is faster.

It is possible to associate with every partition of the integer n a conjugacy class of permutations in the symmetric group on n points and vice versa. Therefore the number of partitions \( p_n \) is the number of conjugacy classes of the symmetric group on n points.

EXAMPLES:

```sage
v = Partitions(5).list(); v
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
len(v)
7
Partitions(5).cardinality(algorithm='gap')
7
Partitions(5).cardinality(algorithm='pari')
7
number_of_partitions(5, algorithm='flint')
7
```

```sage
Partitions(10).cardinality()
42
Partitions(3).cardinality()
3
Partitions(10).cardinality()
42
Partitions(3).cardinality(algorithm='pari')
3
Partitions(10).cardinality(algorithm='pari')
42
Partitions(40).cardinality()
37338
Partitions(100).cardinality()
190569292
```

A generating function for \( p_n \) is given by the reciprocal of Euler’s function:

\[
\sum_{n=0}^{\infty} p_n x^n = \prod_{k=1}^{\infty} \frac{1}{1 - x^k}.
\]

We use Sage to verify that the first several coefficients do indeed agree:
```python
sage: q = PowerSeriesRing(QQ, 'q', default_prec=9).gen()
sage: prod([(1-q^k)^(-1) for k in range(1,9)])  # partial product of
1 + q + 2*q^2 + 3*q^3 + 5*q^4 + 7*q^5 + 11*q^6 + 15*q^7 + 22*q^8 + O(q^9)
sage: [Partitions(k).cardinality() for k in range(2,10)]
[2, 3, 5, 7, 11, 15, 22, 30]
```

Another consistency test for \( n \) up to 500:

```python
sage: len([n for n in [1..500] if Partitions(n).cardinality() != Partitions(n).cardinality(algorithm='pari')])
0
```

For negative inputs, the result is zero (the algorithm is ignored):

```python
sage: Partitions(-5).cardinality()
0
```

REFERENCES:
- Wikipedia article Partition_(number_theory)

**first()**
Return the lexicographically first partition of a positive integer \( n \). This is the partition \([n]\).

EXAMPLES:

```python
sage: Partitions(4).first()
[4]
```

**last()**
Return the lexicographically last partition of the positive integer \( n \). This is the all-ones partition.

EXAMPLES:

```python
sage: Partitions(4).last()
[1, 1, 1, 1]
```

**next(p)**
Return the lexicographically next partition after the partition \( p \).

EXAMPLES:

```python
sage: Partitions(4).next([4])
[3, 1]
sage: Partitions(4).next([1,1,1,1]) is None
True
```

**random_element**(\( measure='uniform' \))
Return a random partitions of \( n \) for the specified measure.

INPUT:
- \( measure \) – 'uniform' or 'Plancherel' (default: 'uniform')

See also:
- \( random_element_uniform() \)
- `random_element_plancherel()`

**Examples:**

```python
sage: Partitions(5).random_element()  # random
[2, 1, 1, 1]
sage: Partitions(5).random_element(measure='Plancherel')  # random
[2, 1, 1, 1]
```

`random_element_plancherel()`

Return a random partition of \( n \) (for the Plancherel measure).

This probability distribution comes from the uniform distribution on permutations via the Robinson-Schensted correspondence.

See Wikipedia article Plancherel_measure and `Partition.plancherel_measure()`.

**Examples:**

```python
sage: Partitions(5).random_element_plancherel()  # random
[2, 1, 1, 1]
sage: Partitions(20).random_element_plancherel()  # random
[9, 3, 3, 2, 2, 1]
```

**Algorithm:**

- insert by Robinson-Schensted a uniform random permutation of \( n \) and returns the shape of the resulting tableau. The complexity is \( O(n \log(n)) \) which is likely optimal. However, the implementation could be optimized.

**Author:**

- Florent Hivert (2009-11-23)

---

`random_element_uniform()`

Return a random partition of \( n \) with uniform probability.

**Examples:**

```python
sage: Partitions(5).random_element_uniform()  # random
[2, 1, 1, 1]
sage: Partitions(20).random_element_uniform()  # random
[9, 3, 3, 2, 2, 1]
```

**Algorithm:**

- It is a python Implementation of RANDPAR, see [NW1978]. The complexity is unknown, there may be better algorithms.

**Todo:** Check in Knuth AOCP4.

- There is also certainly a lot of room for optimizations, see comments in the code.

**Author:**

- Florent Hivert (2009-11-23)
**subset(**kwargs)**

Return a subset of self with the additional optional arguments.

EXAMPLES:

```
sage: P = Partitions(5); P
Partitions of the integer 5
sage: P.subset(starting=[3,1])
Partitions of the integer 5 starting with [3, 1]
```

class sage.combinat.partition.Particles_nk(n, k)

Bases: Partitions

Partitions of the integer n of length equal to k.

cardinality(algorithm='hybrid')

Return the number of partitions of the specified size with the specified length.

INPUT:

- algorithm – (default: 'hybrid') the algorithm to compute the cardinality and can be one of the following:
  - 'hybrid' - use a hybrid algorithm which uses heuristics to reduce the complexity
  - 'gap' - use GAP

EXAMPLES:

```
sage: v = Partitions(5, length=2).list(); v
[[4, 1], [3, 2]]
sage: len(v)
2
sage: Partitions(5, length=2).cardinality()
2
```

More generally, the number of partitions of $n$ of length 2 is $\left\lfloor \frac{n}{2} \right\rfloor$:

```
sage: all( Partitions(n, length=2).cardinality() == n // 2 for n in range(10) )
True
```

The number of partitions of $n$ of length 1 is 1 for $n$ positive:

```
sage: all( Partitions(n, length=1).cardinality() == 1 for n in range(1, 10) )
True
```

Further examples:

```
sage: Partitions(5, length=3).cardinality()
2
sage: Partitions(6, length=3).cardinality()
3
sage: Partitions(8, length=4).cardinality()
5
sage: Partitions(8, length=5).cardinality()
```

(continues on next page)
```
3
sage: Partitions(15, length=6).cardinality()
26
sage: Partitions(0, length=0).cardinality()
1
sage: Partitions(0, length=1).cardinality()
0
sage: Partitions(1, length=0).cardinality()
0
sage: Partitions(1, length=4).cardinality()
0
```

**subset(****kwargs**)**

Return a subset of self with the additional optional arguments.

**EXAMPLES:**

```
sage: P = Partitions(5, length=2); P
Partitions of the integer 5 of length 2
sage: P.subset(max_part=3)
Partitions of the integer 5 satisfying constraints length=2, max_part=3
```

**class** **sage.combinat.partition.Partitions_parts_in(n, parts)**

**Bases:** **Partitions**

Partitions of \( n \) with parts in a given set \( S \).

This is invoked indirectly when calling \texttt{Partitions(n, parts=parts)}, where \texttt{parts} is a list of pairwise distinct integers.

**cardinality()**

Return the number of partitions with parts in self. Wraps GAP's \texttt{NrRestrictedPartitions}.

**EXAMPLES:**

```
sage: Partitions(15, parts_in=[2,3,7]).cardinality()
5
```

If you can use all parts 1 through \( n \), we'd better get \( p(n) \):

```
sage: Partitions(20, parts_in=[1..20]).cardinality() == Partitions(20).˓→cardinality()
True
```

**first()**

Return the lexicographically first partition of a positive integer \( n \) with the specified parts, or \texttt{None} if no such partition exists.

**EXAMPLES:**

```
sage: Partitions(9, parts_in=[3,4]).first()
[3, 3, 3]
sage: Partitions(6, parts_in=[1..6]).first()
[6]
```
sage: Partitions(30, parts_in=[4,7,8,10,11]).first()
[11, 11, 8]

last()
Return the lexicographically last partition of the positive integer \( n \) with the specified parts, or \( \text{None} \) if no such partition exists.

EXAMPLES:

\[
\begin{align*}
sage: \text{Partitions}(15, \text{parts_in}=[2,3]).\text{last()} & \quad [3, 2, 2, 2, 2, 2, 2] \\
sage: \text{Partitions}(30, \text{parts_in}=[4,7,8,10,11]).\text{last()} & \quad [7, 7, 4, 4, 4, 4] \\
sage: \text{Partitions}(10, \text{parts_in}=[3,6]).\text{last()} \quad \text{is None} \\
\text{True} \\
sage: \text{Partitions}(50, \text{parts_in}=[11,12,13]).\text{last()} & \quad [13, 13, 12, 12] \\
sage: \text{Partitions}(30, \text{parts_in}=[4,7,8,10,11]).\text{last()} & \quad [7, 7, 4, 4, 4, 4]
\end{align*}
\]

class sage.combinat.partition.Partitions_starting(n, starting_partition)
Bases: Partitions
All partitions with a given start.

first()
Return the first partition in self.

EXAMPLES:

\[
\begin{align*}
sage: \text{Partitions}(3, \text{starting}=[2,1]).\text{first()} & \quad [2, 1]
\end{align*}
\]

next(part)
Return the next partition after part in self.

EXAMPLES:

\[
\begin{align*}
sage: \text{Partitions}(3, \text{starting}=[2,1]).\text{next}(\text{Partition([2,1])}) & \quad [1, 1, 1]
\end{align*}
\]

class sage.combinat.partition.Partitions_with_constraints(*args, **kwds)
Bases: IntegerListsLex
Partitions which satisfy a set of constraints.

EXAMPLES:

\[
\begin{align*}
sage: P = \text{Partitions}(6, \text{inner}=[1,1], \text{max_slope}=-1) \\
sage: \text{list}(P) & \quad [[5, 1], [4, 2], [3, 2, 1]]
\end{align*}
\]

options = Current options for Partitions - convention: English - diagram_str: * - display: list - latex: young_diagram - latex_diagram_str: \ast

class sage.combinat.partition.RegularPartitions(ell, is_infinite=False)
Bases: Partitions
Base class for \(\ell\)-regular partitions.
Let \(\ell\) be a positive integer. A partition \(\lambda\) is \(\ell\)-regular if \(m_i < \ell\) for all \(i\), where \(m_i\) is the multiplicity of \(i\) in \(\lambda\).

**Note:** This is conjugate to the notion of \(\ell\)-restricted partitions, where the difference between any two consecutive parts is \(< \ell\).

**INPUT:**
- \(\text{ell}\) – the positive integer \(\ell\)
- \(\text{is\_infinite}\) – boolean; if the subset of \(\ell\)-regular partitions is infinite

**ell()**
Return the value \(\ell\).

**EXAMPLES:**

```python
sage: P = Partitions(regular=2)
sage: P.ell()
2
```

class sage.combinat.partition.RegularPartitions_all(ell)
Bases: RegularPartitions
The class of all \(\ell\)-regular partitions.

**INPUT:**
- \(\text{ell}\) – the positive integer \(\ell\)

**See also:**
- RegularPartitions

class sage.combinat.partition.RegularPartitions_bounded(ell, k)
Bases: RegularPartitions
The class of \(\ell\)-regular \(k\)-bounded partitions.

**INPUT:**
- \(\text{ell}\) – the integer \(\ell\)
- \(k\) – integer; the value \(k\)

**See also:**
- RegularPartitions

class sage.combinat.partition.RegularPartitions_n(n, ell)
Bases: RegularPartitions, Partitions_n
The class of \(\ell\)-regular partitions of \(n\).

**INPUT:**
• n – the integer n to partition
• ell – the integer ℓ

See also:
RegularPartitions

`cardinality()`
Return the cardinality of self.

EXAMPLES:
```
sage: P = Partitions(5, regular=3)
sage: P.cardinality()
5
sage: P = Partitions(5, regular=6)
sage: P.cardinality()
7
sage: P.cardinality() == Partitions(5).cardinality()
True
```

class sage.combinat.partition.RegularPartitions_truncated(ell, max_len)
Bases: RegularPartitions
The class of ℓ-regular partitions with max length k.

INPUT:
• ell – the integer ℓ
• max_len – integer; the maximum length

See also:
RegularPartitions

`max_length()`
Return the maximum length of the partitions of self.

EXAMPLES:
```
sage: P = Partitions(regular=4, max_length=3)
sage: P.max_length()
3
```

class sage.combinat.partition.RestrictedPartitions_all(ell)
Bases: RestrictedPartitions_generic
The class of all ℓ-restricted partitions.

INPUT:
• ell – the positive integer ℓ

See also:
RestrictedPartitions_generic

class sage.combinat.partition.RestrictedPartitions_generic(ell, is_infinite=False)
Bases: Partitions
Base class for ℓ-restricted partitions.
Let $\ell$ be a positive integer. A partition $\lambda$ is $\ell$-restricted if $\lambda_i - \lambda_{i+1} < \ell$ for all $i$, including rows of length 0.

**Note:** This is conjugate to the notion of $\ell$-regular partitions, where the multiplicity of any parts is at most $\ell$.

**INPUT:**
- $\text{ell}$ – the positive integer $\ell$
- $\text{is_infinite}$ – boolean; if the subset of $\ell$-restricted partitions is infinite

**ell()**

Return the value $\ell$.

**EXAMPLES:**

```
sage: P = Partitions(restricted=2)
sage: P.ell()
2
```

**class** `sage.combinat.partition.RestrictedPartitions_n(n, ell)`

Bases: `RestrictedPartitions_generic, Partitions_n`

The class of $\ell$-restricted partitions of $n$.

**INPUT:**
- $n$ – the integer $n$ to partition
- $\text{ell}$ – the integer $\ell$

**See also:**
- `RestrictedPartitions_generic`

**cardinality()**

Return the cardinality of $\text{self}$.

**EXAMPLES:**

```
sage: P = Partitions(5, restricted=3)
sage: P.cardinality()
5
sage: P = Partitions(5, restricted=6)
sage: P.cardinality()
7
sage: P.cardinality() == Partitions(5).cardinality()
True
```

`sage.combinat.partition.number_of_partitions(n, algorithm='default')`

Return the number of partitions of $n$ with, optionally, at most $k$ parts.

The options of `number_of_partitions()` are being deprecated github issue #13072 in favour of `Partitions_n.cardinality()` so that `number_of_partitions()` can become a stripped down version of the fastest algorithm available (currently this is using FLINT).

**INPUT:**
- $n$ – an integer
- $\text{algorithm}$ – (default: ‘default’) [Will be deprecated except in Partition().cardinality() ]
Combinatorics, Release 10.0

- 'default' – If k is not None, then use Gap (very slow). If k is None, use FLINT.
- 'flint' – use FLINT

**EXAMPLES:**

```python
sage: v = Partitions(5).list(); v
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: len(v)
7
```

The input must be a nonnegative integer or a `ValueError` is raised.

```python
sage: number_of_partitions(-5)
Traceback (most recent call last):
  ... ValueError: n (=5) must be a nonnegative integer
```

```python
sage: number_of_partitions(10)
42
sage: number_of_partitions(3)
3
sage: number_of_partitions(10)
42
sage: number_of_partitions(40)
37338
sage: number_of_partitions(100)
190569292
sage: number_of_partitions(100000)
274935105697756965126775163209863526881734293159800547582031259843021473281149641730590507416607366215901578447742962489406986911617458360719769746337355030059187485153988550896191483754930457533405400066252160797545505832299180021799268102963791042549029300331774472454151195452658394075319228632255923668968688389603065565227322735938091073458759520043356746020549826534855239638448134659869258350063706848917382361484119579600472088093904714349409898308319511968037352475479794332591745275479224440044590473045315695055840750790912287573700135396407280254821295760565553047541638715447943233537232581232320731309079848802765033095923333661770418548720201070389095003209648415026700868626433668570125820451520132918690137295495784757990064753311068521816607941650810670267940657228254361994058495585657609097148773385782043350749015715729443202141882111743343865925342703838220592694093331975859087617645158149433970645358782784756526549373432785831335457958473321512048740447048984276642852279374055991890429776437637779287459510167287189313389936026888411937172894535551322285863490061526522828945881765548196140020785865045503985300933640740670556208719947424797335918801602177720206651942528088313464129888287521318150861447200527880367118342857782971080717244283654699458467012891288212370294831053854588710567088708798201145886198724738980691179414296947184279018367929316670577774825716722407383116988076)
```

A generating function for the number of partitions $p_n$ is given by the reciprocal of Euler’s function:

$$
\sum_{n=0}^{\infty} p_n x^n = \prod_{k=1}^{\infty} \left( \frac{1}{1-x^k} \right).
$$

We use Sage to verify that the first several coefficients do indeed agree:

```python
sage: q = PowerSeriesRing(QQ, 'q', default_prec=9).gen()
sage: prod([(1-q^k)^(-1) for k in range(1,9)])
# partial product of
1 + q + 2*q^2 + 3*q^3 + 5*q^4 + 7*q^5 + 11*q^6 + 15*q^7 + 22*q^8 + O(q^9)
sage: [number_of_partitions(k) for k in range(2,11)]
[2, 3, 5, 7, 11, 15, 22, 30]
```

**REFERENCES:**

- Wikipedia article Partition_(number_theory)

`sage.combinat.partition.number_of_partitions_length(n, k, algorithm='hybrid')`

Return the number of partitions of $n$ with length $k$.

This is a wrapper for GAP’s NrPartitions function.

**EXAMPLES:**

```

sage.combinat.partition_algebra.SetPartitionsAk(k)

Return the combinatorial class of set partitions of type $A_k$.

EXAMPLES:

```
sage: A3 = SetPartitionsAk(3); A3
Set partitions of {1, ..., 3, -1, ..., -3}
sage: A3.first()  #random
{{1, 2, 3, -1, -3, -2}}
sage: A3.last()  #random
{{-1}, {-2}, {3}, {1}, {-3}, {2}}
sage: A3.random_element()  #random
{{1, 3, -3, -1}, {2, -2}}
sage: A3.cardinality()
203
```

```
sage: A2p5 = SetPartitionsAk(2.5); A2p5
```

(continues on next page)
Set partitions of \{1, \ldots, 3, -1, \ldots, -3\} with 3 and -3 in the same block

\texttt{sage: A2p5.cardinality()}
52

\texttt{sage: A2p5.first() \#random}
\{\{1, 2, 3, -1, -3, -2\}\}

\texttt{sage: A2p5.last() \#random}
\{\{-1\}, \{-2\}, \{2\}, \{3, -3\}, \{1\}\}

\texttt{sage: A2p5.random_element() \#random}
\{\{-1\}, \{-2\}, \{3, -3\}, \{1, 2\}\}

\begin{verbatim}

    Bases: SetPartitions_set
    Element
        alias of SetPartitionsXkElement
sage.combinat.partition_algebra.SetPartitionsBk(k)
    Return the combinatorial class of set partitions of type \(B_k\).
    These are the set partitions where every block has size 2.

    EXAMPLES:
\end{verbatim}

\texttt{sage: B3 = SetPartitionsBk(3); B3}
Set partitions of \{1, \ldots, 3, -1, \ldots, -3\} with block size 2

\texttt{sage: B3.first() \#random}
\{\{2, -2\}, \{1, -3\}, \{3, -1\}\}

\{\{2, -2\}, \{3, -3\}, \{1, -1\}\}

(continues on next page)
class sage.combinat.partition_algebra.SetPartitionsBk_k(k)
Bases: SetPartitionsAk_k
cardinality()

Return the number of set partitions in $B_k$ where $k$ is an integer.

This is given by $(2k)!! = (2k-1)*(2k-3)*...*3*1$.

EXAMPLES:

```python
sage: SetPartitionsBk(3).cardinality()
15
sage: SetPartitionsBk(2).cardinality()
3
sage: SetPartitionsBk(1).cardinality()
1
sage: SetPartitionsBk(4).cardinality()
105
sage: SetPartitionsBk(5).cardinality()
945
```

class sage.combinat.partition_algebra.SetPartitionsBkhalf_k(k)
Bases: SetPartitionsAkhalf_k
cardinality()

sage.combinat.partition_algebra.SetPartitionsIk(k)

Return the combinatorial class of set partitions of type $I_k$.

These are set partitions with a propagating number of less than $k$. Note that the identity set partition $\{\{1, -1\}, \ldots, \{k, -k\}\}$ is not in $I_k$.

EXAMPLES:

```python
sage: I3 = SetPartitionsIk(3); I3
Set partitions of {1, ..., 3, -1, ..., -3} with propagating number < 3
sage: I3.cardinality()
197

sage: I3.first()  #random
\{\{1, 2, 3, -1, -3, -2\}\}

sage: I3.last()  #random
\{\{-1\}, \{-2\}, \{3\}, \{1\}, \{-3\}, \{2\}\}

sage: I3.random_element()  #random
\{\{-1\}, \{-3\}, \{-2\}, \{2, 3\}, \{1\}\}

sage: I2p5 = SetPartitionsIk(2.5); I2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and propagating number < 3
sage: I2p5.cardinality()
50
```
class sage.combinat.partition_algebra.SetPartitionsIk_k(k)

Bases: SetPartitionsAk_k
cardinality()

class sage.combinat.partition_algebra.SetPartitionsIkhalf_k(k)

Bases: SetPartitionsAkhalf_k
cardinality()

sage.combinat.partition_algebra.SetPartitionsPRk(k)

Return the combinatorial class of set partitions of type $P_{R_k}$.

EXAMPLES:

sage: SetPartitionsPRk(3)
Set partitions of {1, ..., 3, -1, ..., -3} with at most 1 positive and negative entry in each block and that are planar

class sage.combinat.partition_algebra.SetPartitionsPRk_k(k)

Bases: SetPartitionsRk_k
cardinality()

class sage.combinat.partition_algebra.SetPartitionsPRkhalf_k(k)

Bases: SetPartitionsRkhalf_k
cardinality()

sage.combinat.partition_algebra.SetPartitionsPk(k)

Return the combinatorial class of set partitions of type $P_k$.

These are the planar set partitions.

EXAMPLES:

sage: P3 = SetPartitionsPk(3); P3
Set partitions of {1, ..., 3, -1, ..., -3} that are planar
sage: P3.cardinality()
132

sage: P3.first() #random
{{1, 2, 3, -1, -3, -2}}
sage: P3.last() #random
{{-1}, {-2}, {3}, {1}, {-3}, {2}}
sage: P3.random_element() #random
{{1, 2, -1}, {-3}, {3, -2}}
sage: P2p5 = SetPartitionsPk(2.5); P2p5
Set partitions of \{1, \ldots, 3, -1, \ldots, -3\} with 3 and -3 in the same block and that are planar
sage: P2p5.cardinality()
42

sage: P2p5.first() #random
\{\{1, 2, 3, -1, -3, -2\}\}
sage: P2p5.last() #random
\{\{-1\}, \{-2\}, \{2\}, \{3, -3\}, \{1\}\}
sage: P2p5.random_element() #random
\{\{1, 2, 3, -3\}, \{-1, -2\}\}

class sage.combinat.partition_algebra.SetPartitionsPkp_k(k)
Bases: SetPartitionsAk_k
cardinality()

class sage.combinat.partition_algebra.SetPartitionsPkp_half_k(k)
Bases: SetPartitionsAkp_half_k
cardinality()

class sage.combinat.partition_algebra.SetPartitionsRk(k)
Return the combinatorial class of set partitions of type \(R_k\).

EXAMPLES:

sage: SetPartitionsRk(3)
Set partitions of \{1, \ldots, 3, -1, \ldots, -3\} with at most 1 positive and negative entry in each block

class sage.combinat.partition_algebra.SetPartitionsRkp_k(k)
Bases: SetPartitionsAk_k
cardinality()

class sage.combinat.partition_algebra.SetPartitionsRkp_half_k(k)
Bases: SetPartitionsAkp_half_k
cardinality()

sage.combinat.partition_algebra.SetPartitionsSk(k)
Return the combinatorial class of set partitions of type \(S_k\).

There is a bijection between these set partitions and the permutations of \(1, \ldots, k\).

EXAMPLES:

sage: S3 = SetPartitionsSk(3); S3
Set partitions of \{1, \ldots, 3, -1, \ldots, -3\} with propagating number 3
sage: S3.cardinality()
6

sage: S3.list() #random
sage: S3p5 = SetPartitionsSk(3.5); S3p5
Set partitions of \{1, ..., 4, -1, ..., -4\} with 4 and -4 in the same block and
→ propagating number 4
sage: S3p5.cardinality()
6

sage: S3p5.list() #random

class sage.combinat.partition_algebra.SetPartitionsSk_k(k)

Bases: SetPartitionsAk_k

cardinality()

Return k!.

class sage.combinat.partition_algebra.SetPartitionsSkhalf_k(k)

Bases: SetPartitionsAkhalf_k
cardinality()

sage.combinat.partition_algebra.SetPartitionsTk(k)

Return the combinatorial class of set partitions of type \(T_k\).

These are planar set partitions where every block is of size 2.

EXAMPLES:

sage: T3 = SetPartitionsTk(3); T3
Set partitions of \{1, ..., 3, -1, ..., -3\} with block size 2 and that are planar
sage: T3.cardinality()
sage: T3.first()  #random
{{1, -3}, {2, 3}, {-1, -2}}
sage: T3.last()  #random
{{1, 2}, {3, -1}, {-3, -2}}
sage: T3.random_element()  #random
{{1, -3}, {2, 3}, {-1, -2}}

sage: T2p5 = SetPartitionsTk(2.5); T2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and with
→block size 2 and that are planar
sage: T2p5.cardinality()
2

sage: T2p5.first()  #random
{{2, -2}, {3, -3}, {1, -1}}
sage: T2p5.last()  #random
{{1, 2}, {3, -3}, {-1, -2}}

class sage.combinat.partition_algebra.SetPartitionsTk_k(k)
    Bases: SetPartitionsBk_k
cardinality()

class sage.combinat.partition_algebra.SetPartitionsTkhalf_k(k)
    Bases: SetPartitionsBkhalf_k
cardinality()

class sage.combinat.partition_algebra.SetPartitionsXkElement(parent, s, check=True)
    Bases: SetPartition
    An element for the classes of SetPartitionXk where X is some letter.
    check()
        Check to make sure this is a set partition.
        EXAMPLES:

        sage: A2p5 = SetPartitionsAk(2.5)
        sage: x = A2p5.first(); x
        {{-3, -2, -1, 1, 2, 3}}
        sage: x.check()
        sage: y = A2p5.next(x); y
        {{-3, 3}, {-2, -1, 1, 2}}
        sage: y.check()

sage.combinat.partition_algebra.identity(k)
    Return the identity set partition 1, -1, ..., k, -k
    EXAMPLES:
sage: import sage.combinat.partition_algebra as pa
sage: pa.identity(2)
{{2, -2}, {1, -1}}

sage.combinat.partition_algebra.is_planar(sp)

Return True if the diagram corresponding to the set partition is planar; otherwise, it returns False.

EXAMPLES:

sage: import sage.combinat.partition_algebra as pa
sage: pa.is_planar( pa.to_set_partition([[1,-2],[2,-1]]))
False
sage: pa.is_planar( pa.to_set_partition([[1,-1],[2,-2]]))
True

sage.combinat.partition_algebra.pair_to_graph(sp1, sp2)

Return a graph consisting of the disjoint union of the graphs of set partitions sp1 and sp2 along with edges joining the bottom row (negative numbers) of sp1 to the top row (positive numbers) of sp2.

The vertices of the graph sp1 appear in the result as pairs (k, 1), whereas the vertices of the graph sp2 appear as pairs (k, 2).

EXAMPLES:

sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = pa.to_set_partition([[1,-2],[2,-1]])
sage: g = pa.pair_to_graph( sp1, sp2 ); g
Graph on 8 vertices
sage: g.vertices(sort=False)  # random
[(-2, 1), (-2, 2), (-1, 1), (-1, 2), (1, 1), (1, 2), (2, 1), (2, 2)]
sage: g.edges(sort=False)  # random
[((-2, 1), (2, 2), None), ((-1, 1), (1, 1), None),
((-1, 1), (1, 2), None)]

Another example which used to be wrong until github issue #15958:

sage: sp3 = pa.to_set_partition([[1, -1], [2], [-2]])
sage: sp4 = pa.to_set_partition([[1], [-1], [2], [-2]])
sage: g = pa.pair_to_graph( sp3, sp4 ); g
Graph on 8 vertices
sage: g.vertices(sort=True)
[(-2, 1), (-2, 2), (-1, 1), (-1, 2), (1, 1), (1, 2), (2, 1), (2, 2)]
sage: g.edges(sort=True)
[((-2, 1), (2, 2), None), ((-1, 1), (1, 1), None),
((-1, 1), (1, 2), None)]

sage.combinat.partition_algebra.propagating_number(sp)

Return the propagating number of the set partition sp.
The propagating number is the number of blocks with both a positive and negative number.

**EXAMPLES:**

```python
sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = pa.to_set_partition([[1,2],[-2,-1]])
sage: pa.propagating_number(sp1)
2
sage: pa.propagating_number(sp2)
0
```

`sage.combinat.partition_algebra.set_partition_composition(sp1, sp2)`

Return a tuple consisting of the composition of the set partitions sp1 and sp2 and the number of components removed from the middle rows of the graph.

**EXAMPLES:**

```python
sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = pa.to_set_partition([[1,-2],[2,-1]])
sage: pa.set_partition_composition(sp1, sp2) == (pa.identity(2), 0)
True
```

`sage.combinat.partition_algebra.to_graph(sp)`

Return a graph representing the set partition sp.

**EXAMPLES:**

```python
sage: import sage.combinat.partition_algebra as pa
sage: g = pa.to_graph( pa.to_set_partition([[1,-1],[2,-2]]))
Graph on 4 vertices
sage: g.vertices(sort=False)  #random
[1, 2, -2, -1]
sage: g.edges(sort=False)  #random
[(1, -2, None), (2, -1, None)]
```

`sage.combinat.partition_algebra.to_set_partition(l, k=None)`

Convert a list of a list of numbers to a set partitions.

Each list of numbers in the outer list specifies the numbers contained in one of the blocks in the set partition.

If k is specified, then the set partition will be a set partition of 1, ..., k, -1, ..., -k. Otherwise, k will default to the minimum number needed to contain all of the specified numbers.

**EXAMPLES:**

```python
sage: import sage.combinat.partition_algebra as pa
sage: pa.to_set_partition([[1,-1],[2,-2]]) == pa.identity(2)
True
```
A partition (tuple) \(\mu\) is Kleshchev if it can be recursively obtained by adding a sequence of good nodes to the empty \texttt{PartitionTuple} of the same \texttt{level()} and \texttt{multicharge}. In this way, the set of Kleshchev multipartitions becomes a realization of a Kashiwara crystal \texttt{sage.combinat.crystals.crystals} for an irreducible integral highest weight representation of \(U_q(\widehat{\mathfrak{sl}}_n)\).

The Kleshchev multipartitions first appeared in the work of Ariki and Mathas [AM2000] where it was shown that they index the irreducible representations of the cyclotomic Hecke algebras of type \(A\) [AK1994]. Soon afterwards Ariki [Ariki2001] showed that the set of Kleshchev multipartitions naturally label the irreducible representations of these algebras. As a far reaching generalization of these ideas the Ariki-Brundan-Kleshchev categorification theorem [Ariki1996] [BK2009] says that these algebras categorify the irreducible integral highest weight representations of the quantum group \(U_q(\widehat{\mathfrak{sl}}_n)\) of the affine special linear group. Under this categorification, \(q\) corresponds to the grading shift on the cyclotomic Hecke algebras, where the grading from the Brundan-Kleshchev graded isomorphism theorem to the \(KLR\) algebras of type \(A\) [BK2009].

The group algebras of the symmetric group in characteristic \(p\) are an important special case of the cyclotomic Hecke algebras of type \(A\). In this case, depending on your prefer convention, the set of Kleshchev partitions is the set of \('p\'-\text{regular} or \('p\'-\text{restricted Partitions}. In this case, Kleshchev [Kle1995] proved that the \textit{modular branching rules} were given by adding and removing \textit{good nodes}; see \texttt{good_cells()}. Lascoux, Leclerc and Thibon [LLT1996] noticed that Kleshchev’s branching rules coincided with Kashiwara’s crystal operators for the fundamental representation of \(L(\Lambda_0)\) of \(U_q(\widehat{\mathfrak{sl}}_p)\) and their celebrated \textit{LLT conjecture} said that decomposition matrices of the \texttt{sage.algebras.iwahori_hecke_algebra.IwahoriHeckeAlgebra} of the symmetric group should be computable using the canonical basis of \(L(\Lambda_0)\). This was proved and generalized to all cyclotomic Hecke algebras of type \(A\) by Ariki [Ariki1996] and then further generalized to the graded setting by Brundan and Kleshchev [BK2009].

The main class for accessing Kleshchev partition (tuples) is \texttt{KleshchevPartitions}. Unfortunately, just as with the symmetric group, different authors use different conventions when defining Kleshchev partitions, which depends on whether you read components from left to right, or right to left, and whether you read the nodes in the partition in each component from top to bottom or bottom to top. The \texttt{KleshchevPartitions} class supports these four different conventions:

\begin{verbatim}
sage: KPlg = KleshchevPartitions(2, [0,0], size=2, convention='left regular')[::]
[([1], [1]), ([2], [])]
sage: KPls = KleshchevPartitions(2, [0,0], size=2, convention='left restricted')[::]
[([1], [1]), ([], [1, 1])]
sage: KPlrg = KleshchevPartitions(2, [0,0], size=2, convention='right regular')[::]
[([1], [1]), ([], [2])]
sage: KPlrs = KleshchevPartitions(2, [0,0], size=2, convention='right restricted')[::]
[([1], [1]), ([1, 1], [])]
\end{verbatim}

By default, the \textit{left restricted} convention is used. As a shorthand, LG, LS, RG and RS, respectively, can be used to specify the convention. With the \textit{left} convention the partition tuples should be ordered with the most dominant partitions in the partition tuple on the left and with the \textit{right} convention the most dominant partition is on the right.

The \texttt{KleshchevPartitions} class can automatically convert between these four different conventions:

\begin{verbatim}
sage: KPlg = KleshchevPartitions(2, [0,0], size=2, convention='left regular')
sage: KPls = KleshchevPartitions(2, [0,0], size=2, convention='left restricted')
sage: [KPlg(mu) for mu in KPls] # indirect doc test
[([1], [1]), ([2], [])]
\end{verbatim}

\section*{AUTHORS:}

- Andrew Mathas and Travis Scrimshaw (2018-05-1): Initial version

\section*{5.1. Comprehensive Module List}

1795
class sage.combinat.partition_kleshchev.KleshchevCrystalMixin
Bases: object

Mixin class for the crystal structure of a Kleshchev partition.

Epsilon()
    Return $\varepsilon$ of self.
    EXAMPLES:
    sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
    sage: x = C([[5,4,1],[3,2,1,1]])
    sage: x.Epsilon()
    3*Lambda[1]

Phi()
    Return $\phi$ of self.
    EXAMPLES:
    sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
    sage: x = C([[5,4,1],[3,2,1,1]])
    sage: x.Phi()
    3*Lambda[0] + 2*Lambda[1]

epsilon(i)
    Return the Kashiwara crystal operator $\varepsilon_i$ applied to self.
    INPUT:
    • i – an element of the index set
    EXAMPLES:
    sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
    sage: x = C([[5,4,1],[3,2,1,1]])
    sage: [x.epsilon(i) for i in C.index_set()]
    [0, 3, 0]

phi(i)
    Return the Kashiwara crystal operator $\varphi_i$ applied to self.
    INPUT:
    • i – an element of the index set
    EXAMPLES:
    sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
    sage: x = C([[5,4,1],[3,2,1,1]])
    sage: [x.phi(i) for i in C.index_set()]
    [3, 2, 0]

weight()
    Return the weight of self.
    EXAMPLES:
```python
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([5,4,1], [3,2,1,1])
sage: x.weight()
3*Lambda[0] - Lambda[1] - 5*delta
sage: x.Phi() - x.Epsilon()
3*Lambda[0] - Lambda[1]
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="right regular")
sage: y = C([5,1,1], [4,2,2,1,1])
sage: y.weight()
6*Lambda[0] - 4*Lambda[1] - 4*delta
sage: y.Phi() - y.Epsilon()
6*Lambda[0] - 4*Lambda[1]
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: y = C([5,1,1], [4,2,2,1,1])
sage: y.weight()
6*Lambda[0] - 4*Lambda[1] - 4*delta
sage: y.Phi() - y.Epsilon()
6*Lambda[0] - 4*Lambda[1]
```

**class** `sage.combinat.partition_kleshchev.KleshchevPartition(parent, mu)`

Bases: `Partition`

Abstract base class for Kleshchev partitions. See `KleshchevPartitions`.

**cogood_cells**(i=None)

Return a list of the cells of self that are cogood.

The cogood 𝑖-cell is the ‘last’ conormal 𝑖-cell. As with the conormal cells we can choose to read either up or down the partition as specified by convention().

**INPUT:**

- i – (optional) a residue

**OUTPUT:**

If no residue i is specified then a dictionary of cogood cells is returned, which gives the cogood cells for 0 <= i < e.

**EXAMPLES:**

```python
sage: KP = KleshchevPartitions(3, convention="regular")
sage: KP([5,4,4,3,2]).cogood_cells()
{0: (1, 4), 1: (4, 2)}
sage: KP([5,4,4,3,2]).cogood_cells(0)
(1, 4)
sage: KP([5,4,4,3,2]).cogood_cells(1)
(4, 2)
sage: KP = KleshchevPartitions(4, convention='restricted')
sage: KP([5,4,4,3,2]).cogood_cells()
{1: (0, 5), 2: (4, 2), 3: (1, 4)}
sage: KP([5,4,4,3,2]).cogood_cells(0)
sage: KP([5,4,4,3,2]).cogood_cells(2)
(4, 2)
```
**conormal_cells**(i=None)

Return a dictionary of the cells of **self** which are conormal.

Following [Kle1995], the conormal cells are computed by reading up (or down) the rows of the partition and marking all of the addable and removable cells of c-residue i and then recursively removing all adjacent pairs of removable and addable cells (in that order) from this list. The addable i-cells that remain at the end of the this process are the conormal i-cells.

When computing conormal cells you can either read the cells in order from top to bottom (this corresponds to labeling the simple modules of the symmetric group by regular partitions) or from bottom to top (corresponding to labeling the simples by restricted partitions). By default we read down the partition but this can be changed by setting convention = 'RS'.

**INPUT:**

- i – (optional) a residue

**OUTPUT:**

If no residue i is specified then a dictionary of conormal cells is returned, which gives the conormal cells for 0 <= i < e.

**EXAMPLES:**

```python
sage: KP = KleshchevPartitions(3, convention="regular")
sage: KP([5,4,4,3,2]).conormal_cells()
{0: [{1, 4}], 1: [[5, 0], (4, 2)]}
sage: KP([5,4,4,3,2]).conormal_cells(0)
[(1, 4)]
sage: KP([5,4,4,3,2]).conormal_cells(1)
[(5, 0), (4, 2)]
sage: KP = KleshchevPartitions(3, convention="restricted")
sage: KP([5,4,4,3,2]).conormal_cells()
{0: [{1, 4}, (3, 3)], 2: [[0, 5]]}
```

**good_cell_sequence()**

Return a sequence of good nodes from the empty partition to **self**, or None if no such sequence exists.

**EXAMPLES:**

```python
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).good_cell_sequence()
[(0, 0), (1, 0), (0, 1), (2, 0), (1, 1), (0, 2),
 (3, 0), (2, 1), (1, 2), (3, 1), (0, 3), (1, 3),
 (2, 2), (3, 2), (4, 0), (4, 1), (0, 4), (2, 3)]
sage: KP = KleshchevPartitions(3, convention='restricted')
sage: KP([5,4,4,3,2]).good_cell_sequence()
[(0, 0), (0, 1), (1, 0), (0, 2), (1, 1), (2, 0),
 (0, 3), (2, 1), (1, 2), (3, 1), (3, 0), (3, 1),
 (2, 2), (4, 0), (2, 3), (3, 2), (0, 4), (4, 1)]
```

**good_cells**(i=None)

Return a list of the cells of **self** that are good.

The good i-cell is the ‘first’ normal i-cell. As with the normal cells we can choose to read either up or down the partition as specified by **convention()**.

**INPUT:**
• i – (optional) a residue

OUTPUT:

If no residue $i$ is specified then a dictionary of good cells is returned, which gives the good cells for $0 \leq i < e$.

EXAMPLES:

```python
sage: KP3 = KleshchevPartitions(3, convention='regular')
sage: KP3([5,4,4,3,2]).good_cells()
{1: (2, 3)}
sage: KP3([5,4,4,3,2]).good_cells(1)
(2, 3)
sage: KP4 = KleshchevPartitions(4, convention='restricted')
sage: KP4([5,4,4,3,2]).good_cells()
{1: (2, 3)}
sage: KP4([5,4,4,3,2]).good_cells(0)
sage: KP4([5,4,4,3,2]).good_cells(1)
(2, 3)
```

good_residue_sequence()

Return a sequence of good nodes from the empty partition to self, or None if no such sequence exists.

EXAMPLES:

```python
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).good_residue_sequence()
[0, 2, 1, 1, 0, 2, 0, 2, 1, 1, 0, 2, 0, 2, 2, 0, 1, 1]
sage: KP = KleshchevPartitions(3, convention='restricted')
sage: KP([5,4,4,3,2]).good_residue_sequence()
[0, 1, 2, 2, 0, 1, 0, 2, 1, 2, 0, 1, 0, 2, 1, 2, 1, 0]
```

is_regular()

Return True if self is a $e$-regular partition tuple.

A partition tuple is $e$-regular if we can get to the empty partition tuple by successively removing a sequence of good cells in the down direction. Equivalently, all partitions are 0-regular and if $e > 0$ then a partition is $e$-regular if no $e$ non-zero parts of self are equal.

EXAMPLES:

```python
sage: KP = KleshchevPartitions(2)
sage: KP([2,1,1]).is_regular()  
False
sage: KP = KleshchevPartitions(3)
sage: KP([2,1,1]).is_regular()  
True
sage: KP([]).is_regular()  
True
```

is_restricted()

Return True if self is an $e$-restricted partition tuple.

A partition tuple is $e$-restricted if we can get to the empty partition tuple by successively removing a sequence of good cells in the up direction. Equivalently, all partitions are 0-restricted and if $e > 0$ then a partition is $e$-restricted if the difference of successive parts of self are always strictly less than $e$. 

5.1. Comprehensive Module List
EXAMPLES:

```python
sage: KP = KleshchevPartitions(2, convention='regular')
sage: KP([3,1]).is_restricted()
False
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([3,1]).is_restricted()
True
sage: KP([]).is_restricted()
True
```

```
mullineux_conjugate()

Return the partition tuple that is the Mullineux conjugate of self.

It follows from results in [BK2009], [Mat2015] that if $\nu$ is the Mullineux conjugate of the Kleshchev partition tuple $\mu$ then the simple module $D^\nu = (D^\mu)^{sgn}$ is obtained from $D^\mu$ by twisting by the sgn-automorphism with is the Iwahori-Hecke algebra analogue of tensoring with the one dimensional sign representation.

EXAMPLES:

```python
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).mullineux_conjugate()
[9, 7, 1, 1]
sage: KP = KleshchevPartitions(3, convention='restricted')
sage: KP([5,4,4,3,2]).mullineux_conjugate()
[3, 2, 2, 2, 2, 2, 1, 1, 1]
sage: KP = KleshchevPartitions(3, [2], convention='regular')
sage: mc = KP([5,4,4,3,2]).mullineux_conjugate(); mc
[9, 7, 1, 1]
sage: mc.parent().multicharge()
(1,)
sage: KP = KleshchevPartitions(3, [2], convention='restricted')
sage: mc = KP([5,4,4,3,2]).mullineux_conjugate(); mc
[3, 2, 2, 2, 2, 2, 1, 1, 1]
sage: mc.parent().multicharge()
(1,)
```

```
normal_cells(i=None)

Return a dictionary of the cells of the partition that are normal.

Following [Kle1995], the normal cells are computed by reading up (or down) the rows of the partition and marking all of the addable and removable cells of $e$-residue $i$ and then recursively removing all adjacent pairs of removable and addable cells (in that order) from this list. The removable $i$-cells that remain at the end of the this process are the normal $i$-cells.

When computing normal cells you can either read the cells in order from top to bottom (this corresponds to labeling the simple modules of the symmetric group by regular partitions) or from bottom to top (corresponding to labeling the simples by restricted partitions). By default we read down the partition but this can be changed by setting convention = 'RS'.

INPUT:

- $i$ – (optional) a residue

OUTPUT:
If no residue $i$ is specified then a dictionary of normal cells is returned, which gives the normal cells for $0 \leq i < e$.

EXAMPLES:

```python
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).normal_cells()
{1: [(2, 3), (0, 4)]}
sage: KP([5,4,4,3,2]).normal_cells(1)
[(2, 3), (0, 4)]
sage: KP = KleshchevPartitions(3, convention='restricted')
sage: KP([5,4,4,3,2]).normal_cells()
{0: [(4, 1)], 2: [(3, 2)]}
sage: KP([5,4,4,3,2]).normal_cells(2)
[(3, 2)]
```

```python
class sage.combinat.partition_kleshchev.KleshchevPartitionCrystal(
    parent, mu)
Bases: KleshchevPartition, KleshchevCrystalMixin
Kleshchev partition with the crystal structure.

\( e(i) \)

Return the action of \( e_i \) on self.

INPUT:

- \( i \) – an element of the index set

EXAMPLES:

```python
sage: C = crystals.KleshchevPartitions(3, convention="left regular")
sage: x = C([5,4,1])
sage: x.e(0)
[5, 4]
sage: x.e(1)
[5, 5, 1]
sage: x.e(2)
[5, 4, 2]
```

\( f(i) \)

Return the action of \( f_i \) on self.

INPUT:

- \( i \) – an element of the index set

EXAMPLES:

```python
sage: C = crystals.KleshchevPartitions(3, convention="left regular")
sage: x = C([5,4,1])
sage: x.f(0)
[5, 5, 1]
sage: x.f(1)
[5, 4, 2]
sage: x.f(2)
[5, 4, 2]
```

```python
class sage.combinat.partition_kleshchev.KleshchevPartitionTuple(
    parent, mu)
Bases: PartitionTuple
Abstract base class for Kleshchev partition tuples. See KleshchevPartitions.
```
**cogood_cells**\( (i=\text{None}) \)

Return a list of the cells of the partition that are cogood.

The cogood \( i \)-cell is the ‘last’ conormal \( i \)-cell. As with the conormal cells we can choose to read either up or down the partition as specified by \texttt{convention()}.  

**INPUT:**

- \( i \) – (optional) a residue

**OUTPUT:**

If no residue \( i \) is specified then a dictionary of cogood cells is returned, which gives the cogood cells for \( 0 \leq i < e \).

**EXAMPLES:**

```
sage: KP = KleshchevPartitions(3, [0,1])
sage: pt = KP([[4, 2], [5, 3, 1]])
sage: pt.cogood_cells()
{0: (1, 2, 1), 1: (1, 3, 0)}
sage: pt.cogood_cells(0)
(1, 2, 1)
sage: KP = KleshchevPartitions(4, [0,1], convention="left regular")
sage: pt = KP([[5, 2, 2], [6, 1, 1]])
sage: pt.cogood_cells()
{1: (0, 0, 5), 2: (1, 3, 0)
```

**conormal_cells**\( (i=\text{None}) \)

Return a dictionary of the cells of the partition that are conormal.

Following [Kle1995], the conormal cells are computed by reading up (or down) the rows of the partition and marking all of the addable and removable cells of \( e \)-residue \( i \) and then recursively removing all adjacent pairs of removable and addable cells (in that order) from this list. The addable \( i \)-cells that remain at the end of the this process are the conormal \( i \)-cells.

When computing conormal cells you can either read the cells in order from top to bottom (this corresponds to labeling the simple modules of the symmetric group by regular partitions) or from bottom to top (corresponding to labeling the simples by restricted partitions). By default we read down the partition but this can be changed by setting \texttt{convention = 'RS'}.  

**INPUT:**

- \( i \) – (optional) a residue

**OUTPUT:**

If no residue \( i \) is specified then a dictionary of conormal cells is returned, which gives the conormal cells for \( 0 \leq i < e \).

**EXAMPLES:**

```
sage: KP = KleshchevPartitions(3, [0,1])
sage: pt = KP([[4, 2], [5, 3, 1]])
sage: pt.conormal_cells()
{0: [(1, 2, 1), (1, 1, 3), (1, 0, 5)],
1: [(1, 3, 0), (0, 2, 0), (0, 1, 2), (0, 0, 4)]
```
sage: KP([[4, 2], [5, 3, 1]]).conormal_cells(1)
[(1, 3, 0), (0, 2, 0), (0, 1, 2), (0, 0, 4)]
sage: KP([[4, 2], [5, 3, 1]]).conormal_cells(2)
[]
sage: KP = KleshchevPartitions(3, [0,1], convention="right restricted")
sage: KP([[4, 2], [5, 3, 1]]).conormal_cells(0)
[(1, 0, 5), (1, 1, 3), (1, 2, 1)]

good_cell_sequence()

Return a sequence of good nodes from the empty partition to self.

EXAMPLES:

sage: KP = KleshchevPartitions(3,[0,1])
sage: pt = KP([[4, 2], [5, 3, 1]])
sage: pt.good_cells()
{2: (1, 0, 4)}
sage: pt.good_cells(2)
(1, 0, 4)
sage: KP = KleshchevPartitions(4, [0,1], convention="left regular")
sage: pt = KP([[5, 2, 2], [6, 2, 1]])
sage: pt.good_cells()
{0: (0, 0, 4), 2: (1, 0, 5), 3: (0, 2, 1)}
sage: pt.good_cells(1) is None
True

good_cells(i=None)

Return a list of the cells of the partition tuple which are good.

The good i-cell is the ‘first’ normal i-cell. As with the normal cells we can choose to read either up or down the partition as specified by convention().

INPUT:

• i – (optional) a residue

OUTPUT:

If no residue i is specified then a dictionary of good cells is returned, which gives the good cells for 0 <= i < e.

EXAMPLES:

sage: KP = KleshchevPartitions(3,[0,1])
sage: pt = KP([[4, 2], [5, 3, 1]])
sage: pt.good_cells()
{2: (1, 0, 4)}
sage: pt.good_cells(2)
(1, 0, 4)
sage: KP = KleshchevPartitions(4, [0,1], convention="left regular")
sage: pt = KP([[5, 2, 2], [6, 2, 1]])
sage: pt.good_cells()
{0: (0, 0, 4), 2: (1, 0, 5), 3: (0, 2, 1)}
sage: pt.good_cells(1) is None
True

good_residue_sequence()

Return a sequence of good nodes from the empty partition to self.

EXAMPLES:
is_regular()

Return True if self is a $e$-regular partition tuple.

A partition tuple is $e$-regular if we can get to the empty partition tuple by successively removing a sequence of good cells in the down direction.

EXAMPLES:

```python
sage: KP = KleshchevPartitions(2, [0,2], convention="right restricted")
sage: KP([[3,2,1], [2,1,1]]).is_regular()
False
sage: KP([[3,2,1], [2,1,1]]).is_regular()
True
sage: KP([[], []]).is_regular()
True
```

is_restricted()

Return True if self is an $e$-restricted partition tuple.

A partition tuple is $e$-restricted if we can get to the empty partition tuple by successively removing a sequence of good cells in the up direction.

EXAMPLES:

```python
sage: KP = KleshchevPartitions(2, [0,2], convention="left regular")
sage: KP([[3,2,1], [3,1]]).is_restricted()
False
sage: KP = KleshchevPartitions(3, [0,2], convention="left regular")
sage: KP([[3,2,1], [3,1]]).is_restricted()
True
sage: KP([[], []]).is_restricted()
True
```

mullineux_conjugate()

Return the partition that is the Mullineux conjugate of self.

It follows from results in [Kle1996] [Bru1998] that if $\nu$ is the Mullineux conjugate of the Kleshchev partition tuple $\mu$ then the simple module $D^{\nu} = (D^{\mu})^{sgn}$ is obtained from $D^{\mu}$ by twisting by the $sgn$-automorphism with is the Hecke algebra analogue of tensoring with the one dimensional sign representation.

EXAMPLES:

```python
sage: KP = KleshchevPartitions(3, [0,1])
sage: mc = KP([[4, 2], [5, 3, 1]]).mullineux_conjugate(); mc
([2, 2, 1, 1], [3, 2, 2, 1, 1])
sage: mc.parent()
Kleshchev partitions with e=3 and multicharge=(0,2)
```

normal_cells(i=None)

Return a dictionary of the removable cells of the partition that are normal.
Following [Kle1995], the normal cells are computed by reading up (or down) the rows of the partition and marking all of the addable and removable cells of $e$-residue $i$ and then recursively removing all adjacent pairs of removable and addable cells (in that order) from this list. The removable $i$-cells that remain at the end of this process are the normal $i$-cells.

When computing normal cells you can either read the cells in order from top to bottom (this corresponds to labeling the simple modules of the symmetric group by regular partitions) or from bottom to top (corresponding to labeling the simples by restricted partitions). By default we read down the partition but this can be changed by setting convention = 'RS'.

INPUT:

- $i$ – (optional) a residue

OUTPUT:

If no residue $i$ is specified then a dictionary of normal cells is returned, which gives the normal cells for $0 \leq i < e$.

EXAMPLES:

```python
sage: KP = KleshchevPartitions(3, [0,1], convention="left restricted")
sage: KP([[[4, 2], [5, 3, 1]]]).normal_cells()
{2: [[(1, 0, 4), (1, 1, 2), (1, 2, 0)]},
 sage: KP([[[4, 2], [5, 3, 1]]]).normal_cells(1)
{2: [[(1, 0, 4), (1, 1, 2), (1, 2, 0)]},
 sage: KP = KleshchevPartitions(3, [0,1], convention="left regular")
 sage: KP([[4, 2], [5, 3, 1]]).normal_cells()
{0: [[[0, 1, 1), (0, 0, 3)], 2: [(1, 2, 0), (1, 1, 2), (1, 0, 4)]},
 sage: KP = KleshchevPartitions(3, [0,1], convention="right regular")
 sage: KP([[4, 2], [5, 3, 1]]).normal_cells()
{2: [[(1, 2, 0), (1, 1, 2), (1, 0, 4)]},
 sage: KP = KleshchevPartitions(3, [0,1], convention="right restricted")
 sage: KP([[4, 2], [5, 3, 1]]).normal_cells()
{0: [[[0, 0, 3), (0, 1, 1)], 2: [(1, 0, 4), (1, 1, 2), (1, 2, 0)]},
```

class sage.combinat.partition_kleshchev.KleshchevPartitionTupleCrystal(parent, mu)

Bases: KleshchevPartitionTuple, KleshchevCrystalMixin

Kleshchev partition tuple with the crystal structure.

e()

Return the action of $e_i$ on self.

INPUT:

- $i$ – an element of the index set

EXAMPLES:

```python
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C((5,4,1],[3,2,1,1]))
sage: x.e(0)
([5, 4, 1], [2, 2, 1, 1])
sage: x.e(1)
```

f()

Return the action of $f_i$ on self.

INPUT:
Combinatorics, Release 10.0

- $i$ – an element of the index set

**EXAMPLES:**

```
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([[5,4,1],[3,2,1,1]])
sage: x.f(0)
([5, 5, 1], [3, 2, 1, 1])
sage: x.f(1)
([5, 4, 1], [3, 2, 2, 1])
sage: x.f(2)
```

**class** sage.combinat.partition_kleshchev.KleshchevPartitions

**Bases:** PartitionTuples

Kleshchev partitions

A partition (tuple) $\mu$ is Kleshchev if it can be recursively obtained by adding a sequence of good nodes to the empty PartitionTuple of the same level() and multicharge.

There are four different conventions that are used in the literature for Kleshchev partitions, depending on whether we read partitions from top to bottom (regular) or bottom to top (restricted) and whether we read partition tuples from left to right or right to left. All of these conventions are supported:

```
sage: KleshchevPartitions(2, [0,0], size=2, convention='left regular')[:]
[[[1], [1]], [[2], []]]
sage: KleshchevPartitions(2, [0,0], size=2, convention='left restricted')[:]
[[[1], [1]], [[1], [1, 1]]]
sage: KleshchevPartitions(2, [0,0], size=2, convention='right regular')[:]
[[[1], [1]], [[1, 1], [2]]]
sage: KleshchevPartitions(2, [0,0], size=2, convention='right restricted')[:]
[[[1], [1]], [[1, 1], []]]
```

By default, the left restricted convention is used. As a shorthand, LG, LS, RG and RS, respectively, can be used to specify the convention. With the left convention the partition tuples should be ordered with the most dominant partitions in the partition tuple on the left and with the right convention the most dominant partition is on the right.

The KleshchevPartitions class will automatically convert between these four different conventions:

```
sage: KPlg = KleshchevPartitions(2, [0,0], size=2, convention='left regular')
sage: KPls = KleshchevPartitions(2, [0,0], size=2, convention='left restricted')
sage: [KPlg(mu) for mu in KPls]
[[[1], [1]], [[2], []]]
```

**EXAMPLES:**

```
sage: sorted(KleshchevPartitions(5, [3,2,1], 1, convention='RS'))
[[[], [], [1]], [[1], [1], []], [[1], [], []]]
sage: sorted(KleshchevPartitions(5, [3,2,1], 1, convention='LS'))
[[[], [], [1]], [[1], [1], []], [[1], [], []]]
sage: sorted(KleshchevPartitions(5, [3,2,1], 3))
[[[], [], [1, 1, 1]], [[1], [], [2, 1]],
 [[1], [1], [3]], [[1], [1], []]]
```

- [Kle2009]

\textbf{convention()}

Return the convention of \texttt{self}.

\textbf{EXAMPLES:}

\textbf{sage: } \texttt{KP = KleshchevPartitions(4)}
\textbf{sage: } \texttt{KP.convention()}
'restricted'
\textbf{sage: } \texttt{KP = KleshchevPartitions(6, [4], 3, convention="right regular")}
\textbf{sage: } \texttt{KP.convention()}
'regular'
\textbf{sage: } \texttt{KP = KleshchevPartitions(5, [3,0,1], 1)}
\textbf{sage: } \texttt{KP.convention()}
'left restricted'
\textbf{sage: } \texttt{KP = KleshchevPartitions(5, [3,0,1], 1, convention='right regular')}
Combinatorics, Release 10.0

(continued from previous page)

```python
sage: KP.convention()
'right regular'
```

**multicharge()**

Return the multicharge of self.

EXAMPLES:

```python
sage: KP = KleshchevPartitions(6, [2])
sage: KP.multicharge()
(2,)
sage: KP = KleshchevPartitions(5, [3,0,1], 1, convention='LS')
sage: KP.multicharge()
(3, 0, 1)
```

class sage.combinat.partition_kleshchev.KleshchevPartitions_all(e, multicharge, convention)

Bases: KleshchevPartitions

Class of all Kleshchev partitions.

**Crystal structure**

We consider type $A_{e-1}^{(1)}$ crystals, and let $r = (r_i | r_i \in \mathbb{Z}/e\mathbb{Z})$ be a finite sequence of length $k$, which is the level, and $\lambda = \sum_i \lambda_i r_i$. We will model the highest weight $U_q(g)$-crystal $B(\lambda)$ by a particular subset of partition tuples of level $k$.

Consider a partition tuple $\mu$ with multicharge $r$. We define $e_i(\mu)$ as the partition tuple obtained after the deletion of the $i$-good cell to $\mu$ and $0$ if there is no $i$-good cell. We define $f_i(\mu)$ as the partition tuple obtained by the addition of the $i$-cogood cell to $\mu$ and $0$ if there is no $i$-good cell.

The crystal $B(\lambda)$ is the crystal generated by the empty partition tuple. We can compute the weight of an element $\mu$ by taking $\lambda - \sum_{i=0}^{n} c_i \alpha_i$ where $c_i$ is the number of cells of $n$-residue $i$ in $\mu$. Partition tuples in the crystal are known as Kleshchev partitions.

**Note:** We can describe normal (not restricted) Kleshchev partition tuples in $B(\lambda)$ as partition tuples $\mu$ such that $\mu_{r_t-r_{t+1}+x}^{(t)} < \mu_{x}^{(t+1)}$ for all $x \geq 1$ and $1 \leq t \leq k-1$.

**INPUT:**

- $e$ – for type $A_{e-1}^{(1)}$ or $0$
- multicharge – the multicharge sequence $r$
- convention – (default: 'LS') the reading convention

**EXAMPLES:**

We first do an example of a level 1 crystal:

```python
sage: C = crystals.KleshchevPartitions(3, [0], convention="left restricted")
sage: C
Kleshchev partitions with e=3
sage: mg = C.highest_weight_vector()
sage: mg
```

(continues on next page)
Combinatorics, Release 10.0

Now a higher level crystal:

```python
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="right restricted")
sage: mg = C.highest_weight_vector()
sage: mg
([], [])
sage: mg.f(0)
([1], [])
sage: mg.f(2)
([], [1])
sage: mg.f_string([0,1,2,0])
([2, 2], [])
sage: mg.f_string([0,2,1,0])
([1, 1, 1], [1])
sage: mg.f_string([2,0,1,0])
([2, 1], [1])
sage: GC = C.subcrystal(max_depth=5).digraph()
sage: GB = B.subcrystal(max_depth=5).digraph()
sage: GC.is_isomorphic(GB, edge_labels=True)
True
```

The ordering of the residues gives a different representation of the higher level crystals (but it is still isomorphic):

```python
sage: C2 = crystals.KleshchevPartitions(3, [2,0], convention="right restricted")
sage: mg2 = C2.highest_weight_vector()
sage: mg2.f_string([0,1,2,0])
([2], [2])
sage: mg2.f_string([0,2,1,0])
([1, 1, 1], [1])
sage: mg2.f_string([2,0,1,0])
([2, 1], [1])
sage: GC2 = C2.subcrystal(max_depth=5).digraph()
sage: GC.is_isomorphic(GC2, edge_labels=True)
True
```

REFERENCES:

class sage.combinat.partition_kleshchev.KleshchevPartitions_size(e, multicharge=(0,), size=0, convention='RS')

Bases: KleshchevPartitions

Kleshchev partitions of a fixed size.

Element

alias of KleshchevPartitionTuple

5.1.168 Partition Shifting Algebras

This module contains families of operators that act on partitions or, more generally, integer sequences. In particular, this includes Young’s raising operators $R_{ij}$, which act on integer sequences by adding 1 to the $i$-th entry and subtracting 1 to the $j$-th entry. A special case is acting on partitions.

AUTHORS:

• Matthew Lancellotti, George H. Seelinger (2018): Initial version

class sage.combinat.partition_shifting_algebras.ShiftingOperatorAlgebra(base_ring=Univariate Polynomial Ring in t over Rational Field, prefix='S')

Bases: CombinatorialFreeModule

An algebra of shifting operators.

Let $R$ be a commutative ring. The algebra of shifting operators is isomorphic as an $R$-algebra to the Laurent polynomial ring $R[x_1^\pm, x_2^\pm, x_3^\pm, \ldots]$. Moreover, the monomials of the shifting operator algebra act on any integer sequence $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell)$ as follows. Let $S$ be our algebra of shifting operators. Then, for any monomial $s = x_1^{a_1}x_2^{a_2}\cdots x_r^{a_r} \in S$ where $a_i \in \mathbb{Z}$ and $r \geq \ell$, we get that $s \cdot \lambda = (\lambda_1 + a_1, \lambda_2 + a_2, \ldots, \lambda_r + a_r)$ where we pad $\lambda$ with $r - \ell$ zeros. In particular, we can recover Young’s raising operator, $R_{ij}$, for $i < j$, acting on partitions by having $x_i^{-1}$ act on a partition $\lambda$.

One can extend the action of these shifting operators to a basis of symmetric functions, but at the expense of no longer actually having a well-defined operator. Formally, to extend the action of the shifting operators on a symmetric function basis $B = \{ b_\lambda \}_\lambda$, we define an $R$-module homomorphism $\phi : R[x_1^\pm, x_2^\pm, \ldots] \to B$. Then we compute $x_1^{a_1}\cdots x_r^{a_r}.b_\lambda$ by first computing $(x_1^{a_1}\cdots x_r^{a_r})x_1^{\lambda_1}\cdots x_\ell^{\lambda_\ell}$ and then applying $\phi$ to the result. For examples of what this looks like with specific bases, see below.

This implementation is consistent with how many references work formally with raising operators. For instance, see exposition surrounding [BMPS2018] Equation (4.1).

We follow the following convention for creating elements: $S(1, 0, -1, 2)$ is the shifting operator that raises the first part by 1, lowers the third part by 1, and raises the fourth part by 2.

In addition to acting on partitions (or any integer sequence), the shifting operators can also act on symmetric functions in a basis $B$ when a conversion to $B$ has been registered, preferably using build_and_register_conversion().

For a definition of raising operators, see [BMPS2018] Definition 2.1. See $ij()$ to create operators using the notation in [BMPS2018].
INPUT:

- base_ring – (default: \(\mathbb{Q}[t]\)) the base ring
- prefix – (default: "S") the label for the shifting operators

EXAMPLES:

```python
sage: S = ShiftingOperatorAlgebra()
sage: elm = S[1, -1, 2]; elm
S(1, -1, 2)
sage: elm([5, 4])
[[[6, 3, 2], 1]]
```

The shifting operator monomials can act on a complete homogeneous symmetric function or a Schur function:

```python
sage: s = SymmetricFunctions(QQ['t']).s()
sage: h = SymmetricFunctions(QQ['t']).h()
sage: elm(s[5, 4])
s[6, 3, 2]
sage: elm(h[5, 4])
h[6, 3, 2]
sage: S[1, -1](s[5, 4])
s[6, 3]
sage: S[1, -1](h[5, 4])
h[6]
```

In fact, we can extend this action by linearity:

```python
sage: elm = (1 - S[1,-1]) * (1 - S[4])
sage: elm == S([]) - S([1, -1]) - S([4]) + S([5, -1])
True
sage: elm(s[2, 2, 1])
s[2, 2, 1] - s[3, 1, 1] - s[6, 2, 1] + s[7, 1, 1]
sage: elm = (1 - S[1,-1]) * (1 - S[0,1,-1])
sage: elm == 1 - S[0,1,-1] - S[1,-1] + S[1,0,-1]
True
sage: elm(s[2, 2, 1])
s[2, 2, 1] - s[3, 1, 1] + s[3, 2]
```

The algebra also comes equipped with homomorphisms to various symmetric function bases; these homomorphisms are how the action of \(S\) on the specific symmetric function bases is implemented:

```python
sage: elm = S([3,1,2]); elm
S(3, 1, 2)
sage: h(elm)
h[3, 2, 1]
sage: s(elm)
0
```

However, not all homomorphisms are equivalent, so the action is basis dependent:
We can also use raising operators to implement the Jacobi-Trudi identity:

```
sage: op = (1-S[(1,-1)]) * (1-S[(1,0,-1)]) * (1-S[(0,1,-1)])
sage: s(op(h[3,2,1]))
s[3, 2, 1]
```

class Element

Bases: IndexedFreeModuleElement

An element of a ShiftingOperatorAlgebra.

**build_and_register_conversion**(*support_map, codomain*)

Build a module homomorphism from a map sending integer sequences to codomain and registers the result into Sage’s conversion model.

The intended use is to define a morphism from self to a basis $B$ of symmetric functions that will be used by ShiftingOperatorAlgebra to define the action of the operators on $B$.

**Note:** The actions on the complete homogeneous symmetric functions and on the Schur functions by morphisms are already registered.

**Warning:** Because ShiftingOperatorAlgebra inherits from UniqueRepresentation, once you register a conversion, this will apply to all instances of ShiftingOperatorAlgebra over the same base ring with the same prefix.

**INPUT:**

- support_map – a map from integer sequences to codomain
- codomain – the codomain of support_map, usually a basis of symmetric functions

**EXAMPLES:**

```
sage: S = ShiftingOperatorAlgebra(QQ)
sage: sym = SymmetricFunctions(QQ)
sage: p = sym.p()
sage: zero_map = lambda part: p.zero()
sage: S.build_and_register_conversion(zero_map, p)
sage: p(2*S([1,0,-1]) + S([2,1,0]) - 3*S([0,1,3]))
0
sage: op = S((1, -1))
True
```
For a more illustrative example, we can implement a simple (but not mathematically justified!) conversion on the monomial basis:

```python
sage: S = ShiftingOperatorAlgebra(QQ)
sage: sym = SymmetricFunctions(QQ)
sage: m = sym.m()
sage: def supp_map(gamma):
    ...:     gsort = sorted(gamma, reverse=True)
    ...:     return m(gsort) if gsort in Partitions() else m.zero()
sage: S.build_and_register_conversion(supp_map, m)
sage: op = S.ij(0, 1)
sage: op(2*m[4,3] + 5*m[2,2] + 7*m[2]) == 2*m[5, 2] + 5*m[3, 1]
True
```

**ij**(i, j)

Return the raising operator $R_{ij}$ as notated in [BMPS2018] Definition 2.1.

Shorthand element constructor that allows you to create raising operators using the familiar $R_{ij}$ notation found in [BMPS2018] Definition 2.1, with the exception that indices here are 0-based, not 1-based.

**EXAMPLES:**

Create the raising operator which raises part 0 and lowers part 2 (indices are 0-based):

```python
sage: R = ShiftingOperatorAlgebra()
sage: R.ij(0, 2)
S(1, 0, -1)
```

**one_basis()**

Return the index of the basis element for 1.

**EXAMPLES:**

```python
sage: S = ShiftingOperatorAlgebra()
sage: S.one_basis()
()  # Identity
```

**product_on_basis**(x, y)

Return the product of basis elements indexed by x and y.

**EXAMPLES:**

```python
sage: S = ShiftingOperatorAlgebra()
sage: S.product_on_basis((0, 5, 2), (3, 2, -2, 5))
S(3, 7, 0, 5)
sage: S.product_on_basis((1, -2, 0, 3, -6), (-1, 2, 2))
S(0, 0, 2, 3, -6)
sage: S.product_on_basis((1, -2, -2), (-1, 2, 2))
S()
```

**class** sage.combinat.partition_shifting_algebras.ShiftingSequenceSpace

Bases: Singleton, Parent

A helper for ShiftingOperatorAlgebra that contains all tuples with entries in $\mathbb{Z}$ of finite support with no trailing 0's.

**EXAMPLES:**
```python
sage: from sage.combinat.partition_shifting_algebras import ShiftingSequenceSpace
sage: S = ShiftingSequenceSpace()
sage: (1, -1) in S
True
sage: (1, -1, 0, 9) in S
True
sage: [1, -1] in S
False
sage: (0.5, 1) in S
False
```

```python
check(seq)
```

Verify that `seq` is a valid shifting sequence.

If it is not, raise a `ValueError`.

**EXAMPLES:**

```python
sage: from sage.combinat.partition_shifting_algebras import ShiftingSequenceSpace
sage: S = ShiftingSequenceSpace()
sage: S.check((1, -1))
sage: S.check((1, -1, 0, 9))
sage: S.check([1, -1])
Traceback (most recent call last):
  ... ValueError: invalid index [1, -1]
sage: S.check((0.5, 1))
Traceback (most recent call last):
  ... ValueError: invalid index (0.500000000000000, 1)
```

## 5.1.169 Partition tuples

A *PartitionTuple* is a tuple of partitions. That is, an ordered \(k\)-tuple of partitions \(\mu = (\mu^{(1)}, \mu^{(2)}, \ldots, \mu^{(k)})\). If

\[
 n = |\mu| = |\mu^{(1)}| + |\mu^{(2)}| + \cdots + |\mu^{(k)}|
\]

then we say that \(\mu\) is a \(k\)-partition of \(n\).

In representation theory partition tuples arise as the natural indexing set for the ordinary irreducible representations of:

- the wreath products of cyclic groups with symmetric groups,
- the Ariki-Koike algebras, or the cyclotomic Hecke algebras of the complex reflection groups of type \(G(r, 1, n)\),
- the degenerate cyclotomic Hecke algebras of type \(G(r, 1, n)\).

When these algebras are not semisimple, partition tuples index an important class of modules for the algebras, which are generalisations of the Specht modules of the symmetric groups.

Tuples of partitions also index the standard basis of the higher level combinatorial Fock spaces. As a consequence, the combinatorics of partition tuples encapsulates the canonical bases of crystal graphs for the irreducible integrable highest weight modules of the (quantized) affine special linear groups and the (quantized) affine general linear groups. By the categorification theorems of Ariki, Varagnolo-Vasserot, Stroppel-Webster and others, in characteristic zero the
degenerate and non-degenerate cyclotomic Hecke algebras, via their Khovanov-Lauda-Rouquier grading, categorify the canonical bases of the quantum affine special and general linear groups.

Partitions are naturally in bijection with 1-tuples of partitions. Most of the combinatorial operations defined on partitions extend to partition tuples in a meaningful way. For example, the semisimple branching rules for the Specht modules are described by adding and removing cells from partition tuples and the modular branching rules correspond to adding and removing good and cogood nodes, which is the underlying combinatorics for the associated crystal graphs.

A `PartitionTuple` belongs to `PartitionTuples` and its derived classes. `PartitionTuples` is the parent class for all partitions tuples. Four different classes of tuples of partitions are currently supported:

- `PartitionTuples(level=k,size=n)` are $k$-tuple of partitions of $n$.
- `PartitionTuples(level=k)` are $k$-tuple of partitions.
- `PartitionTuples(size=n)` are tuples of partitions of $n$.
- `PartitionTuples()` are tuples of partitions.

**Note:** As with `Partitions`, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is $[0,0,0]$.

**EXAMPLES:**

```python
sage: PartitionTuple([[2,2],[1,1],[2]]).cells()
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (0, 1, 1), (1, 0, 0), (1, 1, 0), (2, 0, 0), (2, 0, 1)]
```

**Note:** Many `PartitionTuple` methods take the individual coordinates $(k,r,c)$ as their arguments, here $k$ is the component, $r$ is the row index and $c$ is the column index. If your coordinates are in the form $(k,r,c)$ then use Python’s *-operator.

**EXAMPLES:**

```python
sage: mu=PartitionTuple([[1,1],[2],[2,1]])
sage: [ mu.arm_length(*c) for c in mu.cells()]
[0, 0, 1, 0, 1, 0, 0]
```

**Warning:** In sage, if mu is a partition tuple then mu[k] most naturally refers to the $k$-th component of mu, so we use the convention of the $(k,r,c)$-th cell in a partition tuple refers to the cell in component $k$, row $r$, and column $c$. In the literature, the cells of a partition tuple are usually written in the form $(r,c,k)$, where $r$ is the row index, $c$ is the column index, and $k$ is the component index.

**REFERENCES:**

- [DJM1998]
- [BK2009]

**AUTHORS:**

**EXAMPLES:**

First is a finite enumerated set and the remaining classes are infinite enumerated sets:
One tuples of partitions are naturally in bijection with partitions and, as far as possible, partition tuples attempts to identify one tuples with partitions:

```
sage: Partition([4,3]) == PartitionTuple([[4,3]])
True
sage: Partition([4,3]) == PartitionTuple([4,3])
True
sage: PartitionTuple([4,3])
[4, 3]
sage: Partition([4,3]) in PartitionTuples()
True
```

Partition tuples come equipped with many of the corresponding methods for partitions. For example, it is possible to add and remove cells, to conjugate partition tuples, to work with their diagrams, compare partition tuples in dominance and so:

```
sage: PartitionTuple([[4,1],[[],[2,2,1],[3]]]).pp()
    **** _ ** ***
    *  **
    *
sage: PartitionTuple([[4,1],[[],[2,2,1],[3]]]).conjugate()
([1, 1, 1], [3, 2], [], [2, 1, 1, 1])
sage: PartitionTuple([[4,1],[[],[2,2,1],[3]]]).conjugate().pp()
```

(2, 1, 1), (2, 2, 0), (3, 0, 0), (3, 0, 1), (3, 0, 2)]
sage: mu.addable_cells()
[(0, 0, 4), (0, 1, 1), (0, 2, 0), (1, 0, 0), (2, 0, 2), (2, 2, 1), (2, 3, 0), (3, 0, 3),
(3, 1, 0)]
sage: mu.removable_cells()
[(0, 0, 3), (0, 1, 0), (2, 1, 1), (2, 2, 0), (3, 0, 2)]

Attached to a partition tuple is the corresponding Young, or parabolic, subgroup:

sage: mu.young_subgroup()
Permutation Group with generators [((), (12,13), (11,12), (8,9), (6,7), (3,4), (2,3), (1,
(2)],
sage: mu.young_subgroup_generators()
[1, 2, 3, 6, 8, 11, 12]

class sage.combinat.partition_tuple.PartitionTuple(parent, mu)

Bases: CombinatorialElement

A tuple of Partition.

A tuple of partition comes equipped with many of methods available to partitions. The level of the Partition-
Tuple is the length of the tuple.

This is an ordered k-tuple of partitions μ = (μ(1), μ(2), ..., μ(k)). If

\[ n = |μ| = |μ(1)| + |μ(2)| + \cdots + |μ(k)| \]

then μ is a k-partition of n.
In representation theory PartitionTuples arise as the natural indexing set for the ordinary irreducible representations of:

- the wreath products of cyclic groups with symmetric groups
- the Ariki-Koike algebras, or the cyclotomic Hecke algebras of the complex reflection groups of type $G(r, 1, n)$
- the degenerate cyclotomic Hecke algebras of type $G(r, 1, n)$

When these algebras are not semisimple, partition tuples index an important class of modules for the algebras which are generalisations of the Specht modules of the symmetric groups.

Tuples of partitions also index the standard basis of the higher level combinatorial Fock spaces. As a consequence, the combinatorics of partition tuples encapsulates the canonical bases of crystal graphs for the irreducible integrable highest weight modules of the (quantized) affine special linear groups and the (quantized) affine general linear groups. By the categorification theorems of Ariki, Varagnolo-Vasserot, Stroppel-Webster and others, in characteristic zero the degenerate and non-degenerate cyclotomic Hecke algebras, via their Khovanov-Lauda-Rouquier grading, categorify the canonical bases of the quantum affine special and general linear groups.

Partitions are naturally in bijection with 1-tuples of partitions. Most of the combinatorial operations defined on partitions extend to PartitionTuples in a meaningful way. For example, the semisimple branching rules for the Specht modules are described by adding and removing cells from partition tuples and the modular branching rules correspond to adding and removing good and cogood nodes, which is the underlying combinatorics for the associated crystal graphs.

**Warning:** In the literature, the cells of a partition tuple are usually written in the form $(r, c, k)$, where $r$ is the row index, $c$ is the column index, and $k$ is the component index. In sage, if $\mu$ is a partition tuple then $\mu[k]$ most naturally refers to the $k$-th component of $\mu$, so we use the convention of the $(k, r, c)$-th cell in a partition tuple refers to the cell in component $k$, row $r$, and column $c$.

**INPUT:**

Anything which can reasonably be interpreted as a tuple of partitions. That is, a list or tuple of partitions or valid input to `Partition`.

**EXAMPLES:**

```python
sage: mu=PartitionTuple( [[3,2],[2,1],[],[1,1,1,1]] ); mu
([3, 2], [2, 1], [], [1, 1, 1, 1])
sage: nu=PartitionTuple( ([3,2],[2,1],[],[1,1,1,1]) ); nu
([3, 2], [2, 1], [], [1, 1, 1, 1])
sage: mu == nu
True
sage: mu is nu
False
sage: mu in PartitionTuples()
True
sage: mu.parent()

See also:

• PartitionTuples
• Partitions

Element

alias of Partition

add_cell(k, r, c)

Return the partition tuple obtained by adding a cell in row r, column c, and component k.

This does not change self.

EXAMPLES:

sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).add_cell(0,0,1)
([2, 1], [4, 3], [2, 1, 1])

addable_cells()

Return a list of the removable cells of this partition tuple.
All indices are of the form \((k, r, c)\), where \(r\) is the row-index, \(c\) is the column index and \(k\) is the component.

**EXAMPLES:**

```sage
PartitionTuple([[1,1],[2],[2,1]]).addable_cells()
```

\[
(0, 0, 1), (0, 2, 0), (1, 0, 2), (1, 1, 0), (2, 0, 2), (2, 1, 1), (2, 2, 0)
\]

```sage
PartitionTuple([[1,1],[4,3],[2,1,1]]).addable_cells()
```

\[
(0, 0, 1), (0, 2, 0), (1, 0, 4), (1, 1, 3), (1, 2, 0), (2, 0, 2), (2, 1, 1), (2, 3, 0)
\]

**arm_length**\((k, r, c)\)

Return the length of the arm of cell \((k, r, c)\) in self.

**INPUT:**

- \(k\) – The component
- \(r\) – The row
- \(c\) – The cell

**OUTPUT:**

- The arm length as an integer

The arm of cell \((k, r, c)\) is the number of cells in the \(k\)-th component which are to the right of the cell in row \(r\) and column \(c\).

**EXAMPLES:**

```sage
PartitionTuple([[],[2,1],[2,2,1],[3]]).arm_length(2,0,0)
```

1

```sage
PartitionTuple([[],[2,1],[2,2,1],[3]]).arm_length(2,0,1)
```

0

```sage
PartitionTuple([[],[2,1],[2,2,1],[3]]).arm_length(2,2,0)
```

0

**block**\((e, multicharge)\)

Return a dictionary \(\beta\) that determines the block associated to the partition self and the quantum_characteristic() \(e\).

**INPUT:**

- \(e\) – the quantum characteristic
- \(multicharge\) – the multicharge (default \((0, )\))

**OUTPUT:**

- a dictionary giving the multiplicities of the residues in the partition tuple self

In more detail, the value \(\beta[i]\) is equal to the number of nodes of residue \(i\). This corresponds to the positive root

\[
\sum_{i \in I} \beta_i \alpha_i \in Q^+,
\]

a element of the positive root lattice of the corresponding Kac-Moody algebra. See [DJM1998] and [BK2009] for more details.

This is a useful statistics because two Specht modules for a cyclotomic Hecke algebra of type \(A\) belong to the same block if and only if they correspond to same element \(\beta\) of the root lattice, given above.
We return a dictionary because when the quantum characteristic is 0, the Cartan type is $A_\infty$, in which case the simple roots are indexed by the integers.

**EXAMPLES:**

```python
sage: PartitionTuple([[2,2],[2,2]]).block(0,(0,0))
{-1: 2, 0: 4, 1: 2}
sage: PartitionTuple([[2,2],[2,2]]).block(2,(0,0))
{0: 4, 1: 4}
sage: PartitionTuple([[2,2],[2,2]]).block(2,(0,1))
{0: 4, 1: 4}
sage: PartitionTuple([[2,2],[2,2]]).block(3,(0,2))
{0: 3, 1: 2, 2: 3}
sage: PartitionTuple([[2,2],[2,2]]).block(3,(0,2))
{0: 3, 1: 2, 2: 3}
sage: PartitionTuple([[2,2],[2,2]]).block(3,(3,2))
{0: 3, 1: 2, 2: 3}
sage: PartitionTuple([[2,2],[2,2]]).block(4,(0,0))
{0: 4, 1: 2, 3: 2}
```

cells()

Return the coordinates of the cells of self. Coordinates are given as (component index, row index, column index) and are 0 based.

**EXAMPLES:**

```python
sage: PartitionTuple([[2,1],[1],[1,1,1]]).cells()
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (1, 0, 0), (2, 0, 0), (2, 1, 0), (2, 2, 0)]
```

components()

Return a list containing the shape of this partition.

This function exists in order to give a uniform way of iterating over the "components" of partition tuples of level 1 (partitions) and for higher levels.

**EXAMPLES:**

```python
sage: for t in PartitionTuple([[2,1],[3,2],[3]]).components():
....:    print('%s
' % t.ferrers_diagram())
**
*
***
**
***
sage: for t in PartitionTuple([3,2]).components():
....:    print('%s
' % t.ferrers_diagram())
***
**
```

conjugate()

Return the conjugate partition tuple of self.

The conjugate partition tuple is obtained by reversing the order of the components and then swapping the rows and columns in each component.
EXAMPLES:

```python
sage: PartitionTuple([[2,1],[1],[1,1,1]]).conjugate()
([3], [1], [2, 1])
```

`contains(mu)`

Return `True` if this partition tuple contains $\mu$.

If $\lambda = (\lambda^{(1)}, \ldots, \lambda^{(l)})$ and $\mu = (\mu^{(1)}, \ldots, \mu^{(m)})$ are two partition tuples then $\lambda$ contains $\mu$ if $m \leq l$ and $\mu^{(i)}_r \leq \lambda^{(i)}_r$ for $1 \leq i \leq m$ and $r \geq 0$.

EXAMPLES:

```python
sage: PartitionTuple([[1,1],[2],[2,1]]).contains(PartitionTuple([[1,1],[2],[2,1]]))
True
```

`content(k, r, c, multicharge)`

Return the content of the cell.

Let $m_k = \text{multicharge}[k]$, then the content of a cell is $m_k + c - r$.

If the `multicharge` is a list of integers then it simply offsets the values of the contents in each component. On the other hand, if the `multicharge` belongs to $\mathbb{Z}/e\mathbb{Z}$ then the corresponding $e$-residue is returned (that is, the content mod $e$).

As with the `content` method for partitions, the content of a cell does not technically depend on the partition tuple, but this method is included because it is often useful.

EXAMPLES:

```python
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(0,1,0, [0,0,0])
-1
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(0,1,0, [1,0,0])
0
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(2,1,0, [0,0,0])
-1
```

and now we return the 3-residue of a cell:

```python
sage: multicharge = [IntegerModRing(3)(c) for c in [0,0,0]]
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(0,1,0, multicharge)
2
```

`content_tableau(multicharge)`

Return the tableau which has $(k,r,c)$th entry equal to the content $\text{multicharge}[k] - r + c$ of this cell.

As with the `content` function, by setting the `multicharge` appropriately the tableau containing the residues is returned.

EXAMPLES:

```python
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content_tableau([0,0,0])
([[0, 1], [-1]], [[0, 1]], [[0], [-1], [-2]])
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content_tableau([0,0,1]).pp()
  0  1  0  1  1
 -1  0
   -1
```
as with the content function the multicharge can be used to return the tableau containing the residues of the cells:

```sage
sage: multicharge=[ IntegerModRing(3)(c) for c in [0,0,1] ]
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content_tableau(multicharge).pp()
0 1 0 1 1
2 0
2
```

**corners()**

Return a list of the removable cells of this partition tuple.

All indices are of the form \((k, r, c)\), where \(r\) is the row-index, \(c\) is the column index and \(k\) is the component.

**EXAMPLES:**

```sage
sage: PartitionTuple([[1,1],[2],[2,1]]).removable_cells()
[(0, 1, 0), (1, 0, 1), (2, 0, 1), (2, 1, 0)]
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).removable_cells()
[(0, 1, 0), (1, 0, 3), (1, 1, 2), (2, 0, 1), (2, 2, 0)]
```

**defect\((e, multicharge)\)**

Return the \(e\)-defect or the \(e\)-weight of the block containing the partition tuple \(self\).

The \(e\)-defect is the number of (connected) \(e\)-rim hooks that can be removed from the partition.

The defect of a partition tuple is given by

\[
\text{defect}(\beta) = (\Lambda, \beta) - \frac{1}{2}(\beta, \beta),
\]

where \(\Lambda = \sum_r \Lambda_{r, e}\) for the multicharge \((\kappa_1, \ldots, \kappa_e)\) and \(\beta = \sum_{(r,c)} \alpha_{(c-r)} \mod e\), with the sum being over the cells in the partition.

**INPUT:**

- \(e\) – the quantum characteristic
- \(multicharge\) – the multicharge (default \((0, )\))

**OUTPUT:**

- a non-negative integer, which is the defect of the block containing the partition tuple \(self\)

**EXAMPLES:**

```sage
sage: PartitionTuple([[2,2],[2,2]]).defect(0,(0,0))
0
sage: PartitionTuple([[2,2],[2,2]]).defect(2,(0,0))
8
sage: PartitionTuple([[2,2],[2,2]]).defect(2,(0,1))
8
sage: PartitionTuple([[2,2],[2,2]]).defect(2,(0,1))
8
sage: PartitionTuple([[2,2],[2,2]]).defect(3,(0,2))
5
sage: PartitionTuple([[2,2],[2,2]]).defect(3,(0,2))
5
sage: PartitionTuple([[2,2],[2,2]]).defect(3,(3,2))
2
sage: PartitionTuple([[2,2],[2,2]]).defect(4,(0,0))
0
```
\textbf{degree}(\(e\))

Return the \(e\)-th degree of \texttt{self}.

The \(e\)-th degree is the sum of the degrees of the standard tableaux of shape \(\lambda\). The \(e\)-th degree is the exponent of \(\Phi_e(q)\) in the Gram determinant of the Specht module for a semisimple cyclotomic Hecke algebra of type \(A\) with parameter \(q\).

For this calculation the multicharge \((\kappa_1, \ldots, \kappa_l)\) is chosen so that \(\kappa_{r+1} - \kappa_r > n\), where \(n\) is the \texttt{size()} of \(\lambda\) as this ensures that the Hecke algebra is semisimple.

**INPUT:**

- \(e\) – an integer \(e > 1\)

**OUTPUT:**

A non-negative integer.

**EXAMPLES:**

\begin{verbatim}
sage: PartitionTuple([[2,1],[2,2]]).degree(2)
532
sage: PartitionTuple([[2,1],[2,2]]).degree(3)
259
sage: PartitionTuple([[2,1],[2,2]]).degree(4)
196
sage: PartitionTuple([[2,1],[2,2]]).degree(5)
105
sage: PartitionTuple([[2,1],[2,2]]).degree(6)
105
sage: PartitionTuple([[2,1],[2,2]]).degree(7)
0
\end{verbatim}

Therefore, the Gram determinant of \(S(2,1|2,2)\) when the Hecke parameter \(q\) is “generic” is

\[ q^N \Phi_2(q)^{532} \Phi_3(q)^{259} \Phi_4(q)^{196} \Phi_5(q)^{105} \Phi_6(q)^{105} \]

for some integer \(N\). Compare with \texttt{prime_degree()}.

\textbf{diagram()}

Return a string for the Ferrers diagram of \texttt{self}.

**EXAMPLES:**

\begin{verbatim}
sage: print(PartitionTuple([[2,1],[3,2],[1,1,1]]).diagram())
**** *
*** *
* *
sage: print(PartitionTuple([[3,2],[2,1],[1,1,1,1]]).diagram())
*** ** *** *
** * ** *
* *
sage: PartitionTuples.options(convention="french")
sage: print(PartitionTuple([[3,2],[2,1],[1,1,1,1]]).diagram())
* *
** *
* *
* *
\end{verbatim}

(continues on next page)
dominates($\mu$)

Return True if the PartitionTuple dominates or equals $\mu$ and False otherwise.

Given partition tuples $\mu = (\mu^{(1)}, \ldots, \mu^{(m)})$ and $\nu = (\nu^{(1)}, \ldots, \nu^{(n)})$ then $\mu$ dominates $\nu$ if

$$
\sum_{k=1}^{l-1} |\mu^{(k)}| + \sum_{r \geq 1} \mu^{(l)} \geq \sum_{k=1}^{l-1} |\nu^{(k)}| + \sum_{r \geq 1} \nu^{(l)}
$$

EXAMPLES:

```
sage: mu=PartitionTuple([[1,1],[2],[2,1]])
sage: nu=PartitionTuple([[1,1],[1,1],[2,1]])
sage: mu.dominates(mu)
True
sage: mu.dominates(nu)
True
sage: nu.dominates(mu)
False
sage: tau=PartitionTuple([[],[2,1],[]])
sage: tau.dominates([[],[2,1],[]])
False
sage: tau.dominates([[],[],[2,1]])
True
```

down()

Generator (iterator) for the partition tuples that are obtained from $\texttt{self}$ by removing a cell.

EXAMPLES:

```
sage: [mu for mu in PartitionTuple([[],[3,1],[1,1]]).down()]
[[[], [2, 1], [1, 1]], ([]), [3], [1, 1]], ([]), [3, 1], [1]]
sage: [mu for mu in PartitionTuple([[],[],[]]).down()]
[]
```

down_list()

Return a list of the partition tuples that can be formed from $\texttt{self}$ by removing a cell.

EXAMPLES:

```
sage: PartitionTuple([[],[3,1],[1,1]]).down_list()
[[[], [2, 1], [1, 1]], ([]), [3], [1, 1]], ([]), [3, 1], [1]]
sage: PartitionTuple([[],[],[]]).down_list()
[]
```

ferrers_diagram()

Return a string for the Ferrers diagram of $\texttt{self}$.

EXAMPLES:
sage: print(PartitionTuple([[2,1],[3,2],[1,1,1]]).diagram())
 ** *** *
 ** ** *

sage: print(PartitionTuple([[3,2],[2,1],[[],[1,1,1,1]]]).diagram())
 *** ** - *
 ** * *

sage: PartitionTuples.options(convention="french")

sage: print(PartitionTuple([[3,2],[2,1],[[],[1,1,1,1]]]).diagram())
 *
 ** *

sage: PartitionTuples.options._reset()

garnir_tableau(*cell)

Return the Garnir tableau of shape self corresponding to the cell cell.

If cell = (k, a, c) then (k, a + 1, c) must belong to the diagram of the PartitionTuple. If this is not the case then we return False.

Note: The function also sets g._garnir_cell equal to cell which is used by some other functions.

The Garnir tableaux play an important role in integral and non-semisimple representation theory because they determine the “straightening” rules for the Specht modules over an arbitrary ring.

The Garnir tableau are the “first” non-standard tableaux which arise when you act by simple transpositions. If (k, a, c) is a cell in the Young diagram of a partition, which is not at the bottom of its column, then the corresponding Garnir tableau has the integers 1, 2, ..., n entered in order from left to right along the rows of the diagram up to the cell (k, a, c − 1), then along the cells (k, a + 1, 1) to (k, a + 1, c), then (k, a, c) until the end of row a and then continuing from left to right in the remaining positions. The examples below probably make this clearer!

EXAMPLES:

sage: PartitionTuple([[5,3],[2,2],[4,3]]).garnir_tableau((0,0,2)).pp()

1 2 6 7 8 9 10 13 14 15 16
3 4 5

sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((0,0,2)).pp()

1 2 6 7 8 12 13 16 17 18 19
3 4 5 14 15 20 21 22
9 10 11

sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((0,1,2)).pp()

1 2 3 4 5 12 13 16 17 18 19
6 7 11 14 15 20 21 22
8 9 10

sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((1,0,0)).pp()

1 2 3 4 5 13 14 16 17 18 19
6 7 8 12 15 20 21 22
9 10 11

sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((1,0,1)).pp()

(continues on next page)
sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((2,0,1)).pp()
1 2 3 4 5 12 13 16 19 20 21
6 7 8 14 15 17 18 22
9 10 11

sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((2,1,1)).pp()
Traceback (most recent call last):
...  
ValueError: (comp, row+1, col) must be inside the diagram

See also:

- top_garnir_tableau()

**hook_length**(*k*, *r*, *c*)

Return the length of the hook of cell (k, r, c) in the partition.

The hook of cell (k, r, c) is defined as the cells to the right or below (in the English convention). If your coordinates are in the form (k, r, c), use Python’s *-operator.

**EXAMPLES:**

```python
sage: mu=PartitionTuple([[1,1],[2],[2,1]])
sage: [ mu.hook_length(*c) for c in mu.cells()]
[2, 1, 2, 1, 3, 1, 1]
```

**initial_column_tableau()**

Return the initial column tableau of shape self.

The initial column tableau of shape \( \lambda \) is the standard tableau that has the numbers 1 to \( n \), where \( n \) is the size() of \( \lambda \), entered in order from top to bottom, and then left to right, down the columns of each component, starting from the rightmost component and working to the left.

**EXAMPLES:**

```python
sage: PartitionTuple([ [3,1],[3,2] ]).initial_column_tableau()
([[6, 8, 9], [7]], [[1, 3, 5], [2, 4]])
```

**initial_tableau()**

Return the **StandardTableauTuple** which has the numbers 1, 2, ..., \( n \), where \( n \) is the size() of self, entered in order from left to right along the rows of each component, where the components are ordered from left to right.

**EXAMPLES:**

```python
sage: PartitionTuple([ [2,1],[3,2] ]).initial_tableau()
([[1, 2], [3]], [[4, 5, 6], [7, 8]])
```

**leg_length**(*k*, *r*, *c*)

Return the length of the leg of cell (k, r, c) in self.

**INPUT:**

- k – The component
• r – The row
• c – The cell

OUTPUT:
• The leg length as an integer

The leg of cell \((k, r, c)\) is the number of cells in the \(k\)-th component which are below the node in row \(r\) and column \(c\).

EXAMPLES:

```sage
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).leg_length(2,0,0)
2
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).leg_length(2,0,1)
1
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).leg_length(2,2,0)
0
```

level()

Return the level of this partition tuple.

The level is the length of the tuple.

EXAMPLES:

```sage
sage: PartitionTuple([[],[2,1,0],[2,1]]).level()
2
sage: PartitionTuple([[],[],[2,1,1]]).level()
3
```

outside_corners()

Return a list of the removable cells of this partition tuple.

All indices are of the form \((k, r, c)\), where \(r\) is the row-index, \(c\) is the column index and \(k\) is the component.

EXAMPLES:

```sage
sage: PartitionTuple([[],[1,1],[2,1,1]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 2), (1, 1, 0), (2, 0, 2), (2, 1, 1), (2, 2, 0)]
sage: PartitionTuple([[],[1,1],[4,3],[2,1,1]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 4), (1, 1, 3), (1, 2, 0), (2, 0, 2), (2, 1, 1), (2, 3, 0)]
```

pp()

Pretty prints this partition tuple. See `diagram()`.

EXAMPLES:

```sage
sage: PartitionTuple([[5,5,2,1],[3,2]]).pp()
*****  ***
*****  **
**
*```
prime_degree($p$)

Return the $p$-th prime degree of self.

The degree of a partition $\lambda$ is the sum of the $e$-degrees of the standard tableaux of shape $\lambda$ (see degree()), for $e$ a power of the prime $p$. The prime degree gives the exponent of $p$ in the Gram determinant of the integral Specht module of the symmetric group.

The $p$-th degree is the sum of the degrees of the standard tableaux of shape $\lambda$. The $p$-th degree is the exponent of $p$ in the Gram determinant of a semisimple cyclotomic Hecke algebra of type $A$ with parameter $q = 1$.

As with degree(), for this calculation the multicharge $(\kappa_1, \ldots, \kappa_l)$ is chosen so that $\kappa_{r+1} - \kappa_r > n$, where $n$ is the size() of $\lambda$ as this ensures that the Hecke algebra is semisimple.

INPUT:
- $e$ – an integer $e > 1$
- multicharge – an $l$-tuple of integers, where $l$ is the level() of self

OUTPUT:
A non-negative integer

EXAMPLES:

```
sage: PartitionTuple([[2,1],[2,2]]).prime_degree(2)
sage: PartitionTuple([[2,1],[2,2]]).prime_degree(3)
sage: PartitionTuple([[2,1],[2,2]]).prime_degree(5)
sage: PartitionTuple([[2,1],[2,2]]).prime_degree(7)
```

Therefore, the Gram determinant of $S(2, 1|2; 2)$ when $q = 1$ is $2^{728}3^{259}5^{105}$. Compare with degree().

removable_cells()

Return a list of the removable cells of this partition tuple.

All indices are of the form ($k$, $r$, $c$), where $r$ is the row-index, $c$ is the column index and $k$ is the component.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[2],[2,1]]).removable_cells()
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).removable_cells()
```

remove_cell($k$, $r$, $c$)

Return the partition tuple obtained by removing a cell in row $r$, column $c$, and component $k$.

This does not change self.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).remove_cell(0,1,0)
```
**row_standard_tableaux()**

Return the *row standard tableau tuples* of shape self.

**EXAMPLES:**

```python
sage: PartitionTuple([[],[3,2,2,1],[2,2,1],[3]]).row_standard_tableaux()
Row standard tableau tuples of shape ([], [3, 2, 2, 1], [2, 2, 1], [3])
```

**size()**

Return the size of a partition tuple.

**EXAMPLES:**

```python
sage: PartitionTuple([[2,1],[[],[2,2]]]).size()
7
sage: PartitionTuple([[],[[1],[3,2,1]]]).size()
7
```

**standard_tableaux()**

Return the *standard tableau tuples* of shape self.

**EXAMPLES:**

```python
sage: PartitionTuple([[3,2,2,1],[2,2,1],[3]]).standard_tableaux()
Standard tableau tuples of shape ([3, 2, 2, 1], [2, 2, 1], [3])
```

**to_exp(\(k=0\))**

Return a tuple of the multiplicities of the parts of a partition.

Use the optional parameter \(k\) to get a return list of length at least \(k\).

**EXAMPLES:**

```python
sage: PartitionTuple([[1,1],[2],[2,1]]).to_exp()
([2], [0, 1], [1, 1])
sage: PartitionTuple([[1,1],[2,2,2],[2,1]]).to_exp()
([2], [0, 4], [1, 1])
```

**to_list()**

Return self as a list of lists.

**EXAMPLES:**

```python
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).to_list()
[[1, 1], [4, 3], [2, 1, 1]]
```

**top_garnir_tableau(\(e, cell\))**

Return the most dominant *standard* tableau which dominates the corresponding Garnir tableau and has the same residue that has shape self and is determined by \(e\) and \(cell\).

The Garnir tableau play an important role in integral and non-semisimple representation theory because they determine the “straightening” rules for the Specht modules over an arbitrary ring. The *top Garnir tableaux* arise in the graded representation theory of the symmetric groups and higher level Hecke algebras. They were introduced in [KMR2012].

If the Garnir node is \(cell=(k,r,c)\) and \(m\) and \(M\) are the entries in the cells \((k,r,c)\) and \((k,r+1, c)\), respectively, in the initial tableau then the top \(e\)-Garnir tableau is obtained by inserting the numbers \(m, m+1, \ldots, M\) in order from left to right first in the cells in row \(r+1\) which are not in the \(e\)-Garnir belt,
then in the cell in rows \( r \) and \( r+1 \) which are in the Garnir belt and then, finally, in the remaining cells in row \( r \) which are not in the Garnir belt. All other entries in the tableau remain unchanged.

If \( e = 0 \), or if there are no \( e \)-bricks in either row \( r \) or \( r+1 \), then the top Garnir tableau is the corresponding Garnir tableau.

**EXAMPLES:**

```python
sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(2,(1,0,2)).pp()
1 2 3 9 10 12 13 16
4 5 6 11 14 15 17
7 8 18 19 20
21 22

sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(2,(1,0,1)).pp()
1 2 3 9 10 11 12 13
4 5 6 14 15 16 17
7 8 18 19 20
21 22

sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(3,(1,0,1)).pp()
1 2 3 9 12 13 14 15
4 5 6 10 11 16 17
7 8 18 19 20
21 22

sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(3,(3,0,1)).pp()
Traceback (most recent call last):
... ValueError: (comp, row+1, col) must be inside the diagram
```

See also:

- garnir_tableau()

**GENERATOR FUNCTION**

```python
up()
```

Generator (iterator) for the partition tuples that are obtained from `self` by adding a cell.

**EXAMPLES:**

```python
sage: [mu for mu in PartitionTuple([[],[3,1],[1,1]]).up()]
[([], [3, 1], [1, 1]), ([], [4, 1], [1, 1]), ([], [3, 2], [1, 1]), ([], [3, 1, 1], [1, 1]), ([], [3, 1], [2, 1]), ([], [3, 1], [1, 1, 1])]

sage: [mu for mu in PartitionTuple([[],[],[],[]]).up()]
[([], [], [], []), ([], [1], [], []), ([], [], [1], []), ([], [], [], [1])]
```

**RETURN VALUE**

```python
up_list()
```

Return a list of the partition tuples that can be formed from `self` by adding a cell.

**EXAMPLES:**

```python
sage: PartitionTuple([[],[3,1],[1,1]]).up_list()
[([], [3, 1], [1, 1]), ([], [4, 1], [1, 1]), ([], [3, 2], [1, 1]), ([], [3, 1, 1], [1, 1]), ([], [3, 1], [2, 1]), ([], [3, 1], [1, 1, 1])]

sage: PartitionTuple([[],[],[],[]]).up_list()
[([], [], [], []), ([], [1], [], []), ([], [], [1], []), ([], [], [], [1])]
```
young_subgroup()
Return the corresponding Young, or parabolic, subgroup of the symmetric group.

EXAMPLES:

```python
sage: PartitionTuple([[2,1],[4,2],[1]]).young_subgroup()
Permutation Group with generators [(1,2), (4,5), (5,6), (6,7), (8,9)]
```

young_subgroup_generators()
Return an indexing set for the generators of the corresponding Young subgroup.

EXAMPLES:

```python
sage: PartitionTuple([[2,1],[4,2],[1]]).young_subgroup_generators()
[1, 4, 5, 6, 8]
```

class sage.combinat.partition_tuple.PartitionTuples
Bases: UniqueRepresentation, Parent
Class of all partition tuples.
For more information about partition tuples, see PartitionTuple.
This is a factory class which returns the appropriate parent based on the values of level, size, and regular
INPUT:
• level – the length of the tuple
• size – the total number of cells
• regular – a positive integer or a tuple of non-negative integers; if an integer, the highest multiplicity an
  entry may have in a component plus 1

If a level $k$ is specified and regular is a tuple of integers $\ell_1, \ldots, \ell_k$, then this specifies partition tuples $\mu$ such
that $\mu_i$ is $\ell_i$-regular, where 0 here represents $\infty$-regular partitions (equivalently, partitions without restrictions).
If regular is an integer $\ell$, then we set $\ell_i = \ell$ for all $i$.

Element
alias of PartitionTuple

level()
Return the level or None if it is not defined.

EXAMPLES:

```python
sage: PartitionTuples().level() is None
True
sage: PartitionTuples(7).level()
7
```

options = Current options for Partitions - convention: English - diagram_str: * - display: list - latex: young_diagram - latex_diagram_str: \ast

size()
Return the size or None if it is not defined.

EXAMPLES:
class sage.combinat.partition_tuple.PartitionTuples_all
    Bases: PartitionTuples
    
    Class of partition tuples of an arbitrary level and arbitrary sum.

class sage.combinat.partition_tuple.PartitionTuples_level
    (level, category=None)
    Bases: PartitionTuples
    
    Class of partition tuples of a fixed level, but summing to an arbitrary integer.

class sage.combinat.partition_tuple.PartitionTuples_level_size
    (level, size)
    Bases: PartitionTuples
    
    Class of partition tuples with a fixed level and a fixed size.

cardinality()
    Return the number of level-tuples of partitions of size n.
    Wraps a pari function call using pari:eta.

    EXAMPLES:
    
    sage: PartitionTuples(2,3).cardinality()
    10
    sage: PartitionTuples(2,8).cardinality()
    185

class sage.combinat.partition_tuple.PartitionTuples_size
    (size)
    Bases: PartitionTuples
    
    Class of partition tuples of a fixed size, but arbitrary level.

class sage.combinat.partition_tuple.RegularPartitionTuples
    (regular, **kwds)
    Bases: PartitionTuples
    
    Abstract base class for \ell-regular partition tuples.

class sage.combinat.partition_tuple.RegularPartitionTuples_all
    (regular)
    Bases: RegularPartitionTuples
    
    Class of \ell-regular partition tuples.

class sage.combinat.partition_tuple.RegularPartitionTuples_level
    (level, regular)
    Bases: PartitionTuples_level
    
    Regular Partition tuples of a fixed level.

    INPUT:

    * level – a non-negative Integer; the level
    * regular – a positive integer or a tuple of non-negative integers; if an integer, the highest multiplicity
      an entry may have in a component plus 1 with 0 representing \infty-regular (equivalently, partitions without
      restrictions)
regular is a tuple of integers \((\ell_1, \ldots, \ell_k)\) that specifies partition tuples \(\mu\) such that \(\mu_i\) is \(\ell_i\)-regular. If regular is an integer \(\ell\), then we set \(\ell_i = \ell\) for all \(i\).

EXAMPLES:

```
sage: RPT = PartitionTuples(level=4, regular=(2,3,0,2))
sage: RPT[:24]
[([], [], [], []),
 (1, [], [], []),
 (2, [], [], []),
 (1, [], [1], []),
 (2, [], [2], []),
 (1, [1], [], []),
 (2, [2], [], []),
 (1, [1], [1], []),
 (2, [2], [2], []),
 (1, [1], [1], [1]),
 (2, [2], [2], [2]),
 (1, [1], [1], [1]),
 (2, [2], [2], [2]),
 (1, [1], [1], [], []),
 (1, [1, 1], [1], []),
 (1, [1], [1, 1], []),
 (2, [2], [2, 2], []),
 (1, [1, 1], [1, 1], []),
 (2, [2], [2, 2], [2]),
 (1, [1, 1], [1, 1], [1]),
 (2, [2], [2, 2], [2]),
 (1, [1, 1], [1, 1], [], []),
 (1, [1, 1], [1, 1, 1], []),
 (1, [1, 1], [1, 1, 1], [], []),
 (1, [1, 1], [1, 1, 1], [], []),
 (1, [1, 1], [1, 1, 1], [], []),
 (1, [1, 1], [1, 1, 1], [], []),
 (1, [1, 1], [1, 1, 1], [], []),
 (1, [1, 1], [1, 1, 1], [], []),
 (1, [1, 1], [1, 1, 1], [], []),
 (1, [1, 1], [1, 1, 1], [], [])]
sage: [[1,1],[3],[5,5,5],[7,2]] in RPT
False
sage: [[1,1],[3],[5,5,5],[7,2]] in RPT
True
sage: [[3,1],[3],[5,5,5]] in RPT
False
```

class sage.combinat.partition_tuple.RegularPartitionTuples_level_size(level, size, regular)

Bases: PartitionTuples_level_size

Class of \(\ell\)-regular partition tuples with a fixed level and a fixed size.

INPUT:

- level – a non-negative Integer; the level
- size – a non-negative Integer; the size
- regular – a positive integer or a tuple of non-negative integers; if an integer, the highest multiplicity an entry may have in a component plus 1 with 0 representing \(\infty\)-regular (equivalently, partitions without restrictions)

regular is a tuple of integers \((\ell_1, \ldots, \ell_k)\) that specifies partition tuples \(\mu\) such that \(\mu_i\) is \(\ell_i\)-regular. If regular is an integer \(\ell\), then we set \(\ell_i = \ell\) for all \(i\).

EXAMPLES:
class sage.combinat.partition_tuple.RegularPartitionTuples_size(size, regular)

Bases: RegularPartitionTuples

Class of $\ell$-regular partition tuples with a fixed size.

5.1.170 Iterators over the partitions of an integer

AUTHOR:

- Jonathan Bober (2007-07-28): wrote the program partitions_c.cc that does all the actual heavy lifting.

sage.combinat.partitions.ZS1_iterator(n)

A fast iterator for the partitions of $n$ (in the decreasing lexicographic order) which returns lists and not objects of type Partition.

This is an implementation of the ZS1 algorithm found in [ZS98].

REFERENCES:

EXAMPLES:

```
sage: from sage.combinat.partitions import ZS1_iterator
sage: it = ZS1_iterator(4)
sage: next(it)
[4]
sage: type(_)
<class 'list'>
```
sage.combinat.partitions.ZS1_iterator_nk(n, k)
An iterator for the partitions of \( n \) of length at most \( k \) (in the decreasing lexicographic order) which returns lists and not objects of type Partition.

The algorithm is a mild variation on \texttt{ZS1_iterator}(); I would not vow for its speed.

EXAMPLES:

```python
sage: from sage.combinat.partitions import ZS1_iterator_nk
sage: it = ZS1_iterator_nk(4, 3)
sage: next(it)
[4]
sage: type(_)
<class 'list'>
```

5.1.171 Perfect matchings

A perfect matching of a set \( S \) is a partition into 2-element sets. If \( S \) is the set \{1, ..., \( n \)\}, it is equivalent to fixpoint-free involutions. These simple combinatorial objects appear in different domains such as combinatorics of orthogonal polynomials and of the hyperoctaedral groups (see [MV], [McD] and also [CM]):

AUTHOR:

• Valentin Feray, 2010: initial version

• Martin Rubey, 2017: inherit from SetPartition, move crossings and nestings to SetPartition

EXAMPLES:

Create a perfect matching:

```python
sage: m = PerfectMatching([('a', 'e'), ('b', 'c'), ('d', 'f')]); m
[('a', 'e'), ('b', 'c'), ('d', 'f')]
```

Count its crossings, if the ground set is totally ordered:

```python
sage: n = PerfectMatching([3, 8, 1, 7, 6, 5, 4, 2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.number_of_crossings()
1
```

List the perfect matchings of a given ground set:

```python
sage: PerfectMatchings(4).list()
[[[1, 2], [3, 4]], [[1, 3], [2, 4]], [[1, 4], [2, 3]]
```

REFERENCES:

class sage.combinat.perfect_matching.PerfectMatching(parent, s, check=True, sort=True)

Bases: SetPartition

A perfect matching.

A perfect matching of a set \( X \) is a set partition of \( X \) where all parts have size 2.

A perfect matching can be created from a list of pairs or from a fixed point-free involution as follows:
**Combinatorics, Release 10.0**

```python
sage: m = PerfectMatching([('a', 'e'), ('b', 'c'), ('d', 'f')]); m
[('a', 'e'), ('b', 'c'), ('d', 'f')]
sage: n = PerfectMatching([3, 8, 1, 7, 6, 5, 4, 2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: isinstance(m, PerfectMatching)
True
```

The parent, which is the set of perfect matchings of the ground set, is automatically created:

```python
sage: n.parent()
Perfect matchings of {1, 2, 3, 4, 5, 6, 7, 8}
```

If the ground set is ordered, one can, for example, ask if the matching is non crossing:

```python
sage: PerfectMatching([(1, 4), (2, 3), (5, 6)]).is_noncrossing()
True
```

**Weingarten_function**($d$, other=None)

Return the Weingarten function of two pairings.

This function is the value of some integrals over the orthogonal groups $O_N$. With the convention of [CM], the method returns $W_{O(d)}^d$(other, self).

**EXAMPLES:**

```python
sage: var('N')
N
sage: m = PerfectMatching([(1,3),(2,4)])
```

```python
sage: n = PerfectMatching([(1,2),(3,4)])
```

```python
sage: factor(m.Weingarten_function(N,n))
-1/((N + 2)*(N - 1)*N)
```

**loop_type**($other=None$)

Return the loop type of self.

**INPUT:**

- other – a perfect matching of the same set of self. (if the second argument is empty, the method an_element() is called on the parent of the first)

**OUTPUT:**

If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union of cycles of even lengths. The function returns the ordered list of the semi-length of these cycles (considered as a partition)

**EXAMPLES:**

```python
sage: m = PerfectMatching([('a', 'e'), ('b', 'c'), ('d', 'f')])
```

```python
sage: n = PerfectMatching([('a', 'b'), ('d', 'f'), ('e', 'c')])
```

```python
sage: m.loop_type(n)
[2, 1]
```

**loops**($other=None$)

Return the loops of self.

**INPUT:**
• other – a perfect matching of the same set of self. (if the second argument is empty, the method
an_element() is called on the parent of the first)

OUTPUT:

If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union
of cycles of even lengths. The function returns the list of these cycles (each cycle is given as a list).

EXAMPLES:

```
sage: m = PerfectMatching([('a', 'e'), ('b', 'c'), ('d', 'f')])
sage: n = PerfectMatching([('a', 'b'), ('d', 'f'), ('e', 'c')])
sage: loops = m.loops(n)
sage: loops
# random
[['a', 'e', 'c', 'b'], ['d', 'f']]
```

```
sage: o = PerfectMatching([(1, 7), (2, 4), (3, 8), (5, 6)])
sage: p = PerfectMatching([(1, 6), (2, 7), (3, 4), (5, 8)])
sage: o.loops(p)
[[1, 7, 2, 4, 3, 8, 5, 6]]
```

loops_iterator(\textit{other}=None)
Iterate through the loops of self.

INPUT:

• other – a perfect matching of the same set of self. (if the second argument is empty, the method
an_element() is called on the parent of the first)

OUTPUT:

If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union
of cycles of even lengths. The function returns an iterator for these cycles (each cycle is given as a list).

EXAMPLES:

```
sage: o = PerfectMatching([(1, 7), (2, 4), (3, 8), (5, 6)])
sage: p = PerfectMatching([(1, 6), (2, 7), (3, 4), (5, 8)])
sage: it = o.loops_iterator(p)
sage: next(it)
[1, 7, 2, 4, 3, 8, 5, 6]
sage: next(it)
Traceback (most recent call last):
... StopIteration
```

number_of_loops(\textit{other}=None)
Return the number of loops of self.

INPUT:

• other – a perfect matching of the same set of self. (if the second argument is empty, the method
an_element() is called on the parent of the first)

OUTPUT:

If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union
of cycles of even lengths. The function returns their numbers.

EXAMPLES:
sage: m = PerfectMatching([('a', 'e'), ('b', 'c'), ('d', 'f')])
sage: n = PerfectMatching([('a', 'b'), ('d', 'f'), ('e', 'c')])
sage: m.number_of_loops(n)
2

partner(x)

Return the element in the same pair than x in the matching self.

EXAMPLES:

sage: m = PerfectMatching([(-3, 1), (2, 4), (-2, 7)])
sage: m.partner(4)
2
sage: n = PerfectMatching([('c', 'b'), ('d', 'f'), ('e', 'a')])
sage: n.partner('c')
'b'

standardization()

Return the standardization of self.

See SetPartition.standardization() for details.

EXAMPLES:

sage: n = PerfectMatching([('c', 'b'), ('d', 'f'), ('e', 'a')])
sage: n.standardization()
[(1, 5), (2, 3), (4, 6)]

to_graph()

Return the graph corresponding to the perfect matching.

OUTPUT:

The realization of self as a graph.

EXAMPLES:

sage: PerfectMatching([[1,3], [4,2]]).to_graph().edges(sort=True, labels=False)
[(1, 3), (2, 4)]
sage: PerfectMatching([[1,4], [3,2]]).to_graph().edges(sort=True, labels=False)
[(1, 4), (2, 3)]
sage: PerfectMatching([]).to_graph().edges(sort=True, labels=False)
[]

to_noncrossing_set_partition()

Return the noncrossing set partition (on half as many elements) corresponding to the perfect matching if the perfect matching is noncrossing, and otherwise gives an error.

OUTPUT:

The realization of self as a noncrossing set partition.

EXAMPLES:

sage: PerfectMatching([[1,3], [4,2]]).to_noncrossing_set_partition()
Traceback (most recent call last):
...
ValueError: matching must be non-crossing

sage: PerfectMatching([[1,4], [3,2]]).to_noncrossing_set_partition()
{{1, 2}}
sage: PerfectMatching([]).to_noncrossing_set_partition()
{{}}

class sage.combinat PerfectMatchings(s)

Bases: SetPartitions_set

Perfect matchings of a ground set.

INPUT:

• s – an iterable of hashable objects or an integer

EXAMPLES:

If the argument s is an integer n, it will be transformed into the set {1, ..., n}:

sage: M = PerfectMatchings(6); M
Perfect matchings of {1, 2, 3, 4, 5, 6}
sage: PerfectMatchings([-1, -3, 1, 2])
Perfect matchings of {1, 2, -3, -1}

One can ask for the list, the cardinality or an element of a set of perfect matching:

sage: PerfectMatchings(4).list()
[[[1, 2], [3, 4]], [[1, 3], [2, 4]], [[1, 4], [2, 3]]]
sage: PerfectMatchings(8).cardinality()
105
sage: M = PerfectMatchings(('a', 'e', 'b', 'f', 'c', 'd'))
sage: x = M.an_element()
sage: x # random
[('a', 'c'), ('b', 'e'), ('d', 'f')]
sage: all(PerfectMatchings(i).an_element() in PerfectMatchings(i)......: for i in range(2,11,2))
True

Element

alias of PerfectMatching

Weingarten_matrix(N)

Return the Weingarten matrix corresponding to the set of PerfectMatchings self.

It is a useful theoretical tool to compute polynomial integrals over the orthogonal group $O_N$ (see [CM]).

EXAMPLES:

sage: M = PerfectMatchings(4).Weingarten_matrix(var('N'))
sage: N*(N-1)*(N+2)*M.apply_map(factor)
[N + 1 -1 -1]
[ -1 N + 1 -1]
[ -1 -1 N + 1]

base_set()

Return the base set of self.
EXAMPLES:

```
sage: PerfectMatchings(3).base_set()
{1, 2, 3}
```

**base_set_cardinality()**

- Return the cardinality of the base set of *self*.

EXAMPLES:

```
sage: PerfectMatchings(3).base_set_cardinality()
3
```

**cardinality()**

- Return the cardinality of the set of perfect matchings *self*.
  - This is \(1 \times 3 \times 5 \times \ldots \times (2n - 1)\), where \(2n\) is the size of the ground set.

EXAMPLES:

```
sage: PerfectMatchings(8).cardinality()
105
sage: PerfectMatchings([1,2,3,4]).cardinality()
3
sage: PerfectMatchings(3).cardinality()
0
sage: PerfectMatchings([]).cardinality()
1
```

**random_element()**

- Return a random element of *self*.

EXAMPLES:

```
sage: M = PerfectMatchings(('a', 'e', 'b', 'f', 'c', 'd'))
sage: x = M.random_element()
sage: x # random
[(\'a\', \'b\'), (\'c\', \'d\'), (\'e\', \'f\')]
```

## 5.1.172 Permutations

The Permutations module. Use `Permutation?` to get information about the Permutation class, and `Permutations?` to get information about the combinatorial class of permutations.

**Warning:** This file defined `Permutation` which depends upon `CombinatorialElement` despite it being deprecated (see [github issue #13742](https://github.com/sagemath/sage/issues/13742)). This is dangerous. In particular, the `Permutation._left_to_right_multiply_on_right()` method (which can be called through multiplication) disables the input checks (see `Permutation()`). This should not happen. Do not trust the results.
What does this file define?

The main part of this file consists in the definition of permutation objects, i.e. the `Permutation()` method and the `Permutation` class. Global options for elements of the permutation class can be set through the `Permutations.options()` object.

Below are listed all methods and classes defined in this file.

### Methods of Permutations objects

<table>
<thead>
<tr>
<th>Method Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>left_action_product()</code></td>
<td>Returns the product of <code>self</code> with another permutation, in which the other permutation is applied first.</td>
</tr>
<tr>
<td><code>right_action_product()</code></td>
<td>Returns the product of <code>self</code> with another permutation, in which <code>self</code> is applied first.</td>
</tr>
<tr>
<td><code>size()</code></td>
<td>Returns the size of the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>cycle_string()</code></td>
<td>Returns the disjoint-cycles representation of <code>self</code> as string.</td>
</tr>
<tr>
<td><code>next()</code></td>
<td>Returns the permutation that follows <code>self</code> in lexicographic order (in the same symmetric group as <code>self</code>).</td>
</tr>
<tr>
<td><code>prev()</code></td>
<td>Returns the permutation that comes directly before <code>self</code> in lexicographic order (in the same symmetric group as <code>self</code>).</td>
</tr>
<tr>
<td><code>to_tableau_by_shape()</code></td>
<td>Returns a tableau of shape <code>shape</code> with the entries in <code>self</code>.</td>
</tr>
<tr>
<td><code>to_cycles()</code></td>
<td>Returns the permutation <code>self</code> as a list of disjoint cycles.</td>
</tr>
<tr>
<td><code>forget_cycles()</code></td>
<td>Return <code>self</code> under the forget cycle map.</td>
</tr>
<tr>
<td><code>to_permutation_group_element()</code></td>
<td>Returns a <code>PermutationGroupElement</code> equal to <code>self</code>.</td>
</tr>
<tr>
<td><code>signature()</code></td>
<td>Returns the signature of the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>is_even()</code></td>
<td>Returns <code>True</code> if the permutation <code>self</code> is even, and <code>False</code> otherwise.</td>
</tr>
<tr>
<td><code>to_matrix()</code></td>
<td>Returns a matrix representing the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>rank()</code></td>
<td>Returns the rank of <code>self</code> in lexicographic ordering (on the symmetric group containing <code>self</code>).</td>
</tr>
<tr>
<td><code>to_inversion_vector()</code></td>
<td>Returns the inversion vector of a permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>inversions()</code></td>
<td>Returns a list of the inversions of permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>stack_sort()</code></td>
<td>Returns the permutation obtained by sorting <code>self</code> through one stack.</td>
</tr>
<tr>
<td><code>to_digraph()</code></td>
<td>Return a digraph representation of <code>self</code>.</td>
</tr>
<tr>
<td><code>show()</code></td>
<td>Displays the permutation as a drawing.</td>
</tr>
<tr>
<td><code>number_of_inversions()</code></td>
<td>Returns the number of inversions in the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>noninversions()</code></td>
<td>Returns the k-noninversions in the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>number_of_noninversions()</code></td>
<td>Returns the number of k-noninversions in the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>length()</code></td>
<td>Returns the Coxeter length of a permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>inverse()</code></td>
<td>Returns the inverse of a permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>ishift()</code></td>
<td>Returns the i-shift of <code>self</code>.</td>
</tr>
<tr>
<td><code>iswitch()</code></td>
<td>Returns the i-switch of <code>self</code>.</td>
</tr>
<tr>
<td><code>runs()</code></td>
<td>Returns a list of the runs in the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>longest_increasing_subsequence_length()</code></td>
<td>Returns the length of the longest increasing subsequences of <code>self</code>.</td>
</tr>
<tr>
<td><code>longest_increasing_subsequence()</code></td>
<td>The list of the longest increasing subsequences of <code>self</code>.</td>
</tr>
<tr>
<td><code>longest_increasing_subsequence_number()</code></td>
<td>Returns the number of longest increasing subsequences</td>
</tr>
<tr>
<td><code>cycle_type()</code></td>
<td>Returns the cycle type of <code>self</code> as a partition of <code>len(self)</code>.</td>
</tr>
<tr>
<td><code>foata_bijection()</code></td>
<td>Returns the image of the permutation <code>self</code> under the Foata bijection $\phi$.</td>
</tr>
<tr>
<td><code>foata_bijection_inverse()</code></td>
<td>Returns the image of the permutation <code>self</code> under the inverse of the Foata bijection $\phi$.</td>
</tr>
<tr>
<td><code>fundamental_transformation</code></td>
<td>Returns the image of the permutation <code>self</code> under the Renyi-Foata-Schuetzenberger fundamental transformation.</td>
</tr>
<tr>
<td>Function Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>fundamental_transformation_inverse()</td>
<td>Returns the image of the permutation self under the inverse of the Renyi-Foata-Schuetzenberger fundamental transformation.</td>
</tr>
<tr>
<td>destandardize()</td>
<td>Returns the destandardization of self with respect to weight and ordered alphabet.</td>
</tr>
<tr>
<td>to_lehmer_code()</td>
<td>Returns the Lehmer code of the permutation self.</td>
</tr>
<tr>
<td>to_lehmer_cocode()</td>
<td>Returns the Lehmer code of self.</td>
</tr>
<tr>
<td>reduced_word()</td>
<td>Returns the reduced word of the permutation self.</td>
</tr>
<tr>
<td>reduced_words()</td>
<td>Returns a list of the reduced words of the permutation self.</td>
</tr>
<tr>
<td>reduced_words_iterator()</td>
<td>An iterator for the reduced words of the permutation self.</td>
</tr>
<tr>
<td>fixed_points()</td>
<td>Returns a list of the fixed points of the permutation self.</td>
</tr>
<tr>
<td>is_derangement()</td>
<td>Returns True if the permutation self is a derangement, and False otherwise.</td>
</tr>
<tr>
<td>is_simple()</td>
<td>Returns True if the permutation self is simple, and False otherwise.</td>
</tr>
<tr>
<td>number_of_fixed_points()</td>
<td>Returns the number of fixed points of the permutation self.</td>
</tr>
<tr>
<td>recoils()</td>
<td>Returns the list of the positions of the recoils of the permutation self.</td>
</tr>
<tr>
<td>number_of_recoils()</td>
<td>Returns the number of recoils of the permutation self.</td>
</tr>
<tr>
<td>recoils_composition()</td>
<td>Returns the composition corresponding to the recoils of self.</td>
</tr>
<tr>
<td>descents()</td>
<td>Returns the list of the descents of the permutation self.</td>
</tr>
<tr>
<td>idescents()</td>
<td>Returns a list of the idescents of self.</td>
</tr>
<tr>
<td>idescents_signature()</td>
<td>Returns the list obtained by mapping each position in self to −1 if it is an idescent and 1 if it is not an idescent.</td>
</tr>
<tr>
<td>number_of_descents()</td>
<td>Returns the number of descents of the permutation self.</td>
</tr>
<tr>
<td>number_of_idescents()</td>
<td>Returns the number of idescents of the permutation self.</td>
</tr>
<tr>
<td>descents_composition()</td>
<td>Returns the composition corresponding to the descents of self.</td>
</tr>
<tr>
<td>descent_polynomial()</td>
<td>Returns the descent polynomial of the permutation self.</td>
</tr>
<tr>
<td>major_index()</td>
<td>Returns the major index of the permutation self.</td>
</tr>
<tr>
<td>imajor_index()</td>
<td>Returns the inverse major index of the permutation self.</td>
</tr>
<tr>
<td>to_major_code()</td>
<td>Returns the major code of the permutation self.</td>
</tr>
<tr>
<td>peaks()</td>
<td>Returns a list of the peaks of the permutation self.</td>
</tr>
<tr>
<td>number_of_peaks()</td>
<td>Returns the number of peaks of the permutation self.</td>
</tr>
<tr>
<td>saliances()</td>
<td>Returns a list of the saliances of the permutation self.</td>
</tr>
<tr>
<td>number_of_saliences()</td>
<td>Returns the number of saliances of the permutation self.</td>
</tr>
<tr>
<td>bruhat_lequal()</td>
<td>Returns True if self is less or equal to p2 in the Bruhat order.</td>
</tr>
<tr>
<td>weak_excedences()</td>
<td>Returns all the numbers self[i] such that self[i] &gt;= i+1.</td>
</tr>
<tr>
<td>bruhat_inversions()</td>
<td>Returns the list of inversions of self such that the application of this inversion to self decrements its number of inversions.</td>
</tr>
<tr>
<td>bruhat_inversions_iterator()</td>
<td>Returns an iterator over Bruhat inversions of self.</td>
</tr>
<tr>
<td>bruhat_succ()</td>
<td>Returns a list of the permutations covering self in the Bruhat order.</td>
</tr>
<tr>
<td>bruhat_succ_iterator()</td>
<td>An iterator for the permutations covering self in the Bruhat order.</td>
</tr>
<tr>
<td>bruhat_pred()</td>
<td>Returns a list of the permutations covered by self in the Bruhat order.</td>
</tr>
<tr>
<td>bruhat_pred_iterator()</td>
<td>An iterator for the permutations covered by self in the Bruhat order.</td>
</tr>
<tr>
<td>bruhat_smaller()</td>
<td>Returns the combinatorial class of permutations smaller than or equal to self in the Bruhat order.</td>
</tr>
<tr>
<td>bruhat_greater()</td>
<td>Returns the combinatorial class of permutations greater than or equal to self in the Bruhat order.</td>
</tr>
<tr>
<td>permutohedron_lequal()</td>
<td>Returns True if self is less or equal to p2 in the permutohedron order.</td>
</tr>
<tr>
<td>permutohedron_succ()</td>
<td>Returns a list of the permutations covering self in the permutohedron order.</td>
</tr>
<tr>
<td>permutohedron_pred()</td>
<td>Returns a list of the permutations covered by self in the permutohedron order.</td>
</tr>
<tr>
<td>permutohedron_smaller()</td>
<td>Returns a list of permutations smaller than or equal to self in the permutohedron order.</td>
</tr>
<tr>
<td>Method</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>---------------------------------------------------------------------------</td>
</tr>
<tr>
<td>permutohedron_greater()</td>
<td>Returns a list of permutations greater than or equal to <code>self</code> in the permutohedron order.</td>
</tr>
<tr>
<td>right_permutohedron_iterator()</td>
<td>Returns an iterator over permutations in an interval of the permutohedron order.</td>
</tr>
<tr>
<td>has_pattern()</td>
<td>Tests whether the permutation <code>self</code> matches the pattern.</td>
</tr>
<tr>
<td>avoids()</td>
<td>Tests whether the permutation <code>self</code> avoids the pattern.</td>
</tr>
<tr>
<td>pattern_positions()</td>
<td>Returns the list of positions where the pattern <code>patt</code> appears in <code>self</code>.</td>
</tr>
<tr>
<td>reverse()</td>
<td>Returns the permutation obtained by reversing the 1-line notation of <code>self</code>.</td>
</tr>
<tr>
<td>complement()</td>
<td>Returns the complement of the permutation which is obtained by replacing each value <code>x</code> in the 1-line notation of <code>self</code> with <code>n - x + 1</code>.</td>
</tr>
<tr>
<td>permutation_poset()</td>
<td>Returns the permutation poset of <code>self</code>.</td>
</tr>
<tr>
<td>dict()</td>
<td>Returns a dictionary corresponding to the permutation <code>self</code>.</td>
</tr>
<tr>
<td>robinson_schensted()</td>
<td>Returns the pair of standard tableaux obtained by running the Robinson-Schensted Algorithm on <code>self</code>.</td>
</tr>
<tr>
<td>left_tableau()</td>
<td>Returns the left standard tableau after performing the RSK algorithm.</td>
</tr>
<tr>
<td>right_tableau()</td>
<td>Returns the right standard tableau after performing the RSK algorithm.</td>
</tr>
<tr>
<td>increasing_tree()</td>
<td>Returns the increasing tree of <code>self</code>.</td>
</tr>
<tr>
<td>increasing_tree_shape()</td>
<td>Returns the shape of the increasing tree of <code>self</code>.</td>
</tr>
<tr>
<td>binary_search_tree()</td>
<td>Returns the binary search tree of <code>self</code>.</td>
</tr>
<tr>
<td>sylvester_class()</td>
<td>Iterates over the equivalence class of <code>self</code> under sylvester congruence.</td>
</tr>
<tr>
<td>RS_partition()</td>
<td>Returns the shape of the tableaux obtained by the RSK algorithm.</td>
</tr>
<tr>
<td>remove_extra_fixed_points()</td>
<td>Returns the permutation obtained by removing any fixed points at the end of <code>self</code>.</td>
</tr>
<tr>
<td>retract_plain()</td>
<td>Returns the plain retract of <code>self</code> to a smaller symmetric group $S_m$.</td>
</tr>
<tr>
<td>retract_direct_product()</td>
<td>Returns the direct-product retract of <code>self</code> to a smaller symmetric group $S_m$.</td>
</tr>
<tr>
<td>retract_okounkov_vershik()</td>
<td>Returns the Okounkov-Vershik retract of <code>self</code> to a smaller symmetric group $S_m$.</td>
</tr>
<tr>
<td>hyperoctahedral_double_coset_type()</td>
<td>Returns the coset-type of <code>self</code> as a partition.</td>
</tr>
<tr>
<td>binary_search_tree_shape()</td>
<td>Returns the shape of the binary search tree of <code>self</code> (a non labelled binary tree).</td>
</tr>
<tr>
<td>shifted_concatenation()</td>
<td>Returns the right (or left) shifted concatenation of <code>self</code> with a permutation <code>other</code>.</td>
</tr>
<tr>
<td>shifted_shuffle()</td>
<td>Returns the shifted shuffle of <code>self</code> with a permutation <code>other</code>.</td>
</tr>
</tbody>

AUTHORS:

- Mike Hansen
- Dan Drake (2008-04-07): allow Permutation() to take lists of tuples
- Sébastien Labbé (2009-03-17): added robinson_schensted_inverse
- Travis Scrimshaw:
  - (2012-08-16): to_standard() no longer modifies input
- Travis Scrimshaw (2014-02-05): Made StandardPermutations_n a finite Weyl group to make it more uniform with SymmetricGroup. Added ability to compute the conjugacy classes.
- Trevor K. Karn (2022-08-05): Add Permutation.n_reduced_words()

Classes and methods

class sage.combinat.permutation.Arrangements

Bases: Permutations

An arrangement of a multiset mset is an ordered selection without repetitions. It is represented by a list that contains only elements from mset, but maybe in a different order.

Arrangements returns the combinatorial class of arrangements of the multiset mset that contain k elements.

EXAMPLES:

```
sage: mset = [1,1,2,3,4,4,5]
sage: Arrangements(mset,2).list()
[[1, 1],
 [1, 2],
 [1, 3],
 [1, 4],
 [1, 5],
 [2, 1],
 [2, 3],
 [2, 4],
 [2, 5],
 [3, 1],
 [3, 2],
 [3, 4],
 [3, 5],
 [4, 1],
 [4, 2],
 [4, 3],
 [4, 4],
 [4, 5],
 [5, 1],
```

(continues on next page)
sage: Arrangements(mset,2).cardinality()
sage: Arrangements(["c","a","t"], 2 ).list()
[["c", 'a'], ["c", 't'], ["a", 'c'], ["a", 't'], ["t", 'c'], ["t", 'a']]
sage: Arrangements(["c","a","t"], 3 ).list()
[['c', 'a', 't'], ['c', 't', 'a'], ['a', 'c', 't'], ['a', 't', 'c'], ['t', 'c', 'a'], ['t', 'a', 'c']]

\texttt{cardinality()}

Return the cardinality of \texttt{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: A = Arrangements([1,1,2,3,4,4,5], 2)
sage: A.cardinality()
sage: A = Arrangements([1,1,2,3,4,4,5], 3)
sage: A.cardinality()
sage: A = Arrangements([1,1,2,3,4,4,5], 4)
sage: A.cardinality()
22
\end{verbatim}

\textbf{class} \texttt{sage.combinat.permutation.Arrangements\_msetk}(\texttt{mset}, \texttt{k})

\textbf{Bases:} \texttt{Arrangements, Permutations\_msetk}

Arrangements of length \texttt{k} of a multiset \texttt{M}.

\textbf{class} \texttt{sage.combinat.permutation.Arrangements\_setk}(\texttt{s}, \texttt{k})

\textbf{Bases:} \texttt{Arrangements, Permutations\_setk}

Arrangements of length \texttt{k} of a set \texttt{S}.

\textbf{class} \texttt{sage.combinat.permutation.CyclicPermutations}(\texttt{mset})

\textbf{Bases:} \texttt{Permutations\_mset}

Return the class of all cyclic permutations of \texttt{mset} in cycle notation. These are the same as necklaces.

\textbf{INPUT:}

- \texttt{mset} -- A multiset

\textbf{EXAMPLES:}

\begin{verbatim}
sage: CyclicPermutations(range(4)).list()
sage: CyclicPermutations([1,1,1]).list()
[[0, 1, 2, 3], [0, 1, 3, 2], [0, 2, 1, 3], [0, 2, 3, 1], [0, 3, 1, 2], [0, 3, 2, 1]]
[[1, 1, 1]]
\end{verbatim}
**iterator** *(distinct=False)*

EXAMPLES:

```python
sage: CyclicPermutations(range(4)).list() # indirect doctest
[[0, 1, 2, 3],
 [0, 1, 3, 2],
 [0, 2, 1, 3],
 [0, 2, 3, 1],
 [0, 3, 1, 2],
 [0, 3, 2, 1]]
sage: CyclicPermutations([1,1,1]).list()
[[1, 1, 1]]
sage: CyclicPermutations([1,1,1]).list(distinct=True)
[[1, 1, 1], [1, 1, 1]]
```

**list** *(distinct=False)*

EXAMPLES:

```python
sage: CyclicPermutations(range(4)).list()
[[0, 1, 2, 3],
 [0, 1, 3, 2],
 [0, 2, 1, 3],
 [0, 2, 3, 1],
 [0, 3, 1, 2],
 [0, 3, 2, 1]]
```

**class** `sage.combinat.permutation.CyclicPermutationsOfPartition(partition)`

Bases: `Permutations`

Combinations of cyclic permutations of each cell of a given partition.

This is the same as a Cartesian product of necklaces.

EXAMPLES:

```python
sage: CyclicPermutationsOfPartition([[1,2,3,4],[5,6,7]]).list()
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
sage: CyclicPermutationsOfPartition([[1,2,3,4],[4,4,4]]).list()
[[[1, 2, 3, 4], [4, 4, 4]],
 [[1, 2, 4, 3], [4, 4, 4]],
 [[1, 3, 2, 4], [4, 4, 4]],
 [[1, 3, 4, 2], [4, 4, 4]],
 [[1, 4, 2, 3], [4, 4, 4]],
 [[1, 4, 3, 2], [4, 4, 4]],

(continues on next page)
\[
[ [1, 4, 2, 3], [4, 4, 4]],
[ [1, 4, 3, 2], [4, 4, 4]]
\]

\[\text{sage: CyclicPermutationsOfPartition([[1,2,3],[4,4,4]]).list()}
[ [ [1, 2, 3], [4, 4, 4]], [ [1, 3, 2], [4, 4, 4]]]
\]

\[\text{sage: CyclicPermutationsOfPartition([[1,2,3],[4,4,4]]).list(distinct=True)}
[ [ [1, 2, 3], [4, 4, 4]],
[ [1, 3, 2], [4, 4, 4]],
[ [1, 2, 3], [4, 4, 4]],
[ [1, 3, 2], [4, 4, 4]]
\]

class Element
    
    Bases: ClonableArray

    A cyclic permutation of a partition.

    \text{check()}
    
    Check that \text{self} is a valid element.

    EXAMPLES:

    \[\text{sage: CP = CyclicPermutationsOfPartition([[1,2,3,4],[5,6,7]])}
    \text{sage: elt = CP[0]}
    \text{sage: elt.check()}
\]

    \text{iterator}(distinct=False)

    AUTHORS:

    \item Robert Miller

    EXAMPLES:

    \[\text{sage: CyclicPermutationsOfPartition([[1,2,3,4],[5,6,7]]).list()} \text{ # indirect doctest}
    \]

\[\text{[[[1, 2, 3, 4], [5, 6, 7]],}
[ [1, 2, 4, 3], [5, 6, 7]],
[ [1, 3, 2, 4], [5, 6, 7]],
[ [1, 3, 4, 2], [5, 6, 7]],
[ [1, 4, 2, 3], [5, 6, 7]],
[ [1, 4, 3, 2], [5, 6, 7]],
[ [1, 2, 3, 4], [5, 7, 6]],
[ [1, 2, 4, 3], [5, 7, 6]],
[ [1, 3, 2, 4], [5, 7, 6]],
[ [1, 3, 4, 2], [5, 7, 6]],
[ [1, 4, 2, 3], [5, 7, 6]],
[ [1, 4, 3, 2], [5, 7, 6]]
\]

\[\text{sage: CyclicPermutationsOfPartition([[1,2,3,4],[4,4,4]]).list()}
[ [ [1, 2, 3, 4], [4, 4, 4]],
[ [1, 2, 4, 3], [4, 4, 4]],
[ [1, 3, 2, 4], [4, 4, 4]],
[ [1, 3, 4, 2], [4, 4, 4]],

[[[1, 2, 3], [4, 4, 4]], [[1, 3, 2], [4, 4, 4]]]
sage: CyclicPermutationsOfPartition([[1,2,3],[4,4,4]]).list(distinct=True)
[[[1, 2, 3], [4, 4, 4]],
 [[1, 3, 2], [4, 4, 4]],
 [[1, 2, 3], [4, 4, 4]],
 [[1, 3, 2], [4, 4, 4]]]
\end{verbatim}

class sage.combinat.permutation.PatternAvoider(parent, patterns)

Bases: GenericBacktracker

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.permutation import PatternAvoider
sage: P = Permutations(4)
sage: p = PatternAvoider(P, [[1,2,3]])
sage: loads(dumps(p))
<sage.combinat.permutation.PatternAvoider object at 0x...>
\end{verbatim}

class sage.combinat.permutation.Permutation(parent, l, check=True)

A permutation.

Converts \( l \) to a permutation on \( \{1, 2, \ldots, n\} \).

INPUT:

- \( l \) – Can be any one of the following:
  - an instance of \texttt{Permutation},
  - list of integers, viewed as one-line permutation notation. The construction checks that you give an acceptable entry. To avoid the check, use the check option.
  - string, expressing the permutation in cycle notation.
  - list of tuples of integers, expressing the permutation in cycle notation.
  - a \texttt{PermutationGroupElement}
  - a pair of two standard tableaux of the same shape. This yields the permutation obtained from the pair using the inverse of the Robinson-Schensted algorithm.
• **check** (boolean) – whether to check that input is correct. Slows
  the function down, but ensures that nothing bad happens. This is set to True by default.

**Warning:** Since github issue #13742 the input is checked for correctness: it is not accepted unless it
actually is a permutation on \{1, \ldots, n\}. It means that some `Permutation()` objects cannot be created
anymore without setting `check=False`, as there is no certainty that its functions can handle them, and this
should be fixed in a much better way ASAP (the functions should be rewritten to handle those cases, and new
tests be added).

**Warning:** There are two possible conventions for multiplying permutations, and the one currently enabled
in Sage by default is the one which has \((pq)(i) = q(p(i))\) for any permutations \(p \in S_n\) and \(q \in S_n\) and any
\(1 \leq i \leq n\). (This equation looks less strange when the action of permutations on numbers is written from the
right: then it takes the form \(i^{pq} = (ip)^q\), which is an associativity law). There is an alternative convention,
which has \((pq)(i) = p(q(i))\) instead. The conventions can be switched at runtime using `sage.combinat.
permutation.Permutations.options()`. It is best for code not to rely on this setting being set to a
particular standard, but rather use the methods `left_action_product()` and `right_action_product()`
for multiplying permutations (these methods don’t depend on the setting). See github issue #14885 for more
details.

**Note:** The bruhat* methods refer to the strong Bruhat order. To use the weak Bruhat order, look under
permutohedron*.

**EXAMPLES:**

```
sage: Permutation([2,1])
[2, 1]
sage: Permutation([2, 1, 4, 5, 3])
[2, 1, 4, 5, 3]
sage: Permutation('(1,2)')
[2, 1]
sage: Permutation('(1,2)(3,4,5)')
[2, 1, 4, 5, 3]
sage: Permutation( ((1,2),(3,4,5)) )
[2, 1, 4, 5, 3]
sage: Permutation( [(1,2),(3,4,5)] )
[2, 1, 4, 5, 3]
sage: Permutation( ((1,2)) )
[2, 1]
sage: Permutation( (1,2) )
[2, 1]
sage: Permutation( ((1,2),) )
[2, 1]
sage: Permutation( ((1,),) )
[1]
sage: Permutation( (1,) )
[1]
sage: Permutation( () )
[]
sage: Permutation( (), )
```

(continues on next page)
Construction from a string in cycle notation:

\[ \begin{array}{l}
\text{sage: } p = \text{Permutation('(4,5)'); } p \\
\text{[1, 2, 3, 5, 4]} \\
\text{sage: } \text{len}(p); \text{len}(p2) \\
5 \hspace{1cm} 10
\end{array} \]

The size of the permutation is the maximum integer appearing; add a 1-cycle to increase this:

\[ \begin{array}{l}
\text{sage: } p2 = \text{Permutation('(4,5)(10)'); } p2 \\
\text{[1, 2, 3, 5, 4, 6, 7, 8, 9, 10]} \\
\text{sage: } \text{len}(p); \text{len}(p2) \\
5 \hspace{1cm} 10
\end{array} \]

We construct a \texttt{Permutation} from a \texttt{PermutationGroupElement}:

\[ \begin{array}{l}
\text{sage: } g = \text{PermutationGroupElement([2,1,3])} \\
\text{sage: } \text{Permutation}(g) \\
\text{[2, 1, 3]}
\end{array} \]

From a pair of tableaux of the same shape. This uses the inverse of the Robinson-Schensted algorithm:

\[ \begin{array}{l}
\text{sage: } p = [[1, 4, 7], [2, 5], [3], [6]] \\
\text{sage: } q = [[1, 2, 5], [3, 6], [4], [7]] \\
\text{sage: } P = \text{Tableau}(p) \\
\text{sage: } Q = \text{Tableau}(q) \\
\text{sage: } \text{Permutation( (p, q) )} \\
\text{[3, 6, 5, 2, 7, 4, 1]} \\
\text{sage: } \text{Permutation( [p, q] )} \\
\text{[3, 6, 5, 2, 7, 4, 1]} \\
\text{sage: } \text{Permutation( (P, Q) )} \\
\text{[3, 6, 5, 2, 7, 4, 1]} \\
\text{sage: } \text{Permutation( [P, Q] )} \\
\text{[3, 6, 5, 2, 7, 4, 1]}
\end{array} \]

\textbf{RS\_partition()}

Return the shape of the tableaux obtained by applying the RSK algorithm to \texttt{self}.

\textbf{EXAMPLES:}

\[ \begin{array}{l}
\text{sage: } \text{Permutation([1,4,3,2]).RS\_partition()} \\
\text{[2, 1, 1]}
\end{array} \]

\textbf{absolute\_length()}

Return the absolute length of \texttt{self}

The absolute length is the length of the shortest expression of the element as a product of reflections.
For permutations in the symmetric groups, the absolute length is the size minus the number of its disjoint cycles.

EXAMPLES:

```python
sage: Permutation([4,2,3,1]).absolute_length()
1
```

**action(a)**

Return the action of the permutation `self` on a list `a`.

The action of a permutation $p \in S_n$ on an $n$-element list $(a_1, a_2, \ldots, a_n)$ is defined to be $(a_{p(1)}, a_{p(2)}, \ldots, a_{p(n)})$.

EXAMPLES:

```python
sage: p = Permutation([2,1,3])
sage: a = list(range(3))
sage: p.action(a)
[1, 0, 2]
sage: b = [1,2,3,4]
sage: p.action(b)
Traceback (most recent call last):
  ... ValueError: len(a) must equal len(self)
sage: q = Permutation([2,3,1])
sage: a = list(range(3))
sage: q.action(a)
[1, 2, 0]
```

**avoids(patt)**

Test whether the permutation `self` avoids the pattern `patt`.

EXAMPLES:

```python
sage: Permutation([6,2,5,4,3,1]).avoids([4,2,3,1])
False
sage: Permutation([6,1,2,5,4,3]).avoids([4,2,3,1])
True
sage: Permutation([6,1,2,5,4,3]).avoids([3,4,1,2])
True
```

**binary_search_tree(left_to_right=True)**

Return the binary search tree associated to `self`.

If $w$ is a word, then the binary search tree associated to $w$ is defined as the result of starting with an empty binary tree, and then inserting the letters of $w$ one by one into this tree. Here, the insertion is being done according to the method `binary_search_insert()`, and the word $w$ is being traversed from left to right.

A permutation is regarded as a word (using one-line notation), and thus a binary search tree associated to a permutation is defined.

If the optional keyword variable `left_to_right` is set to False, the word $w$ is being traversed from right to left instead.

EXAMPLES:
Combinatorics, Release 10.0

```sage
sage: Permutation([1,4,3,2]).binary_search_tree()
[1[., 4[3[2[., .], .], .]], .]

sage: Permutation([1,4,3,2]).binary_search_tree()
[1[., 4[3[2[., .], .], .]], .]

By passing the option `left_to_right=False` one can have the insertion going from right to left:

```sage
sage: Permutation([1,4,3,2]).binary_search_tree(False)
[2[1[., .], 3[., 4[., .]]], .]

sage: Permutation([1,4,3,2]).binary_search_tree(False)
[2[1[., .], 3[., 4[., .]]], .]
```

`binary_search_tree_shape(left_to_right=True)`

Return the shape of the binary search tree of the permutation (a non labelled binary tree).

EXAMPLES:

```sage
sage: Permutation([1,4,3,2]).binary_search_tree_shape()
[., [[[., .], .], .]]

sage: Permutation([4,1,3,2]).binary_search_tree_shape()
[[[., .], .], .]]
```

By passing the option `left_to_right=False` one can have the insertion going from right to left:

```sage
sage: Permutation([1,4,3,2]).binary_search_tree_shape(False)
[[[., .], .], [., [., .]]]

sage: Permutation([4,1,3,2]).binary_search_tree_shape(False)
[[[., .], .], [., [., .]]]
```

`bruhat_greater()`

Return the combinatorial class of permutations greater than or equal to `self` in the Bruhat order (on the symmetric group containing `self`).

See `bruhat_lequal()` for the definition of the Bruhat order.

EXAMPLES:

```sage
sage: Permutation([4,1,2,3]).bruhat_greater().list()
[[4, 1, 2, 3],
 [4, 1, 3, 2],
 [4, 2, 1, 3],
 [4, 2, 3, 1],
 [4, 3, 1, 2],
 [4, 3, 2, 1]]
```

`bruhat_inversions()`

Return the list of inversions of `self` such that the application of this inversion to `self` decreases its number of inversions by exactly 1.

Equivalently, it returns the list of pairs `(i, j)` such that `i < j`, such that `p(i) > p(j)` and such that there exists no `k` (strictly) between `i` and `j` satisfying `p(i) > p(k) > p(j)`.

EXAMPLES:
bruhat_inversions_iterator()

Return the iterator for the inversions of self such that the application of this inversion to self decreases its number of inversions by exactly 1.

EXAMPLES:

```python
sage: list(Permutation([5,2,3,4,1]).bruhat_inversions_iterator())
[[0, 1], [0, 2], [0, 3], [1, 4], [2, 4], [3, 4]]
sage: list(Permutation([6,1,4,5,2,3]).bruhat_inversions_iterator())
[[0, 1], [0, 2], [0, 3], [2, 4], [2, 5], [3, 4], [3, 5]]
```

bruhat_lequal(p2)

Return True if self is less or equal to p2 in the Bruhat order.

The Bruhat order (also called strong Bruhat order or Chevalley order) on the symmetric group \( S_n \) is the partial order on \( S_n \) determined by the following condition: If \( p \) is a permutation, and \( i \) and \( j \) are two indices satisfying \( p(i) > p(j) \) and \( i < j \) (that is, \( (i, j) \) is an inversion of \( p \) with \( i < j \)), then \( p \circ (i, j) \) (the permutation obtained by first switching \( i \) with \( j \) and then applying \( p \)) is smaller than \( p \) in the Bruhat order.

One can show that a permutation \( p \in S_n \) is less or equal to a permutation \( q \in S_n \) in the Bruhat order if and only if for every \( i \in \{0, 1, \ldots, n\} \) and \( j \in \{1, 2, \ldots, n\} \), the number of the elements among \( p(1), p(2), \ldots, p(j) \) that are greater than \( i \) is \( \leq \) to the number of the elements among \( q(1), q(2), \ldots, q(j) \) that are greater than \( i \).

This method assumes that self and p2 are permutations of the same integer \( n \).

EXAMPLES:

```python
sage: Permutation([2,4,3,1]).bruhat_lequal(Permutation([3,4,2,1]))
True
sage: Permutation([2,1,3]).bruhat_lequal(Permutation([2,3,1]))
True
sage: Permutation([2,1,3]).bruhat_lequal(Permutation([3,1,2]))
True
sage: Permutation([2,1,3]).bruhat_lequal(Permutation([1,2,3]))
False
sage: Permutation([1,3,2]).bruhat_lequal(Permutation([2,1,3]))
False
sage: Permutation([1,3,2]).bruhat_lequal(Permutation([2,3,1]))
True
sage: Permutation([2,3,1]).bruhat_lequal(Permutation([1,3,2]))
False
sage: sorted([len([b for b in Permutations(3) if a.bruhat_lequal(b)])
            for a in Permutations(3)])
[1, 2, 2, 4, 4, 6]
sage: Permutation([]).bruhat_lequal(Permutation([]))
True
```
bruhat_pred()

Return a list of the permutations strictly smaller than self in the Bruhat order (on the symmetric group containing self) such that there is no permutation between one of those and self.

See bruhat_lequal() for the definition of the Bruhat order.

EXAMPLES:

```
sage: Permutation([6,1,4,5,2,3]).bruhat_pred()
[[1, 6, 4, 5, 2, 3],
 [4, 1, 6, 5, 2, 3],
 [5, 1, 4, 6, 2, 3],
 [6, 1, 2, 5, 4, 3],
 [6, 1, 3, 5, 2, 4],
 [6, 1, 4, 2, 5, 3],
 [6, 1, 4, 3, 2, 5]]
```

bruhat_pred_iterator()

An iterator for the permutations strictly smaller than self in the Bruhat order (on the symmetric group containing self) such that there is no permutation between one of those and self.

See bruhat_lequal() for the definition of the Bruhat order.

EXAMPLES:

```
sage: [x for x in Permutation([6,1,4,5,2,3]).bruhat_pred_iterator()]
[[1, 6, 4, 5, 2, 3],
 [4, 1, 6, 5, 2, 3],
 [5, 1, 4, 6, 2, 3],
 [6, 1, 2, 5, 4, 3],
 [6, 1, 3, 5, 2, 4],
 [6, 1, 4, 2, 5, 3],
 [6, 1, 4, 3, 2, 5]]
```

bruhat_smaller()

Return the combinatorial class of permutations smaller than or equal to self in the Bruhat order (on the symmetric group containing self).

See bruhat_lequal() for the definition of the Bruhat order.

EXAMPLES:

```
sage: Permutation([4,1,2,3]).bruhat_smaller().list()
[[1, 2, 3, 4],
 [1, 2, 4, 3],
 [1, 3, 2, 4],
 [1, 4, 2, 3],
 [2, 1, 3, 4],
 [2, 1, 4, 3],
 [3, 1, 2, 4],
 [4, 1, 2, 3]]
```

bruhat_succ()

Return a list of the permutations strictly greater than self in the Bruhat order (on the symmetric group containing self) such that there is no permutation between one of those and self.

See bruhat_lequal() for the definition of the Bruhat order.
EXAMPLES:

```python
sage: Permutation([6,1,4,5,2,3]).bruhat_succ()
[[6, 4, 1, 5, 2, 3],
 [6, 2, 4, 5, 1, 3],
 [6, 1, 5, 4, 2, 3],
 [6, 1, 4, 5, 3, 2]]
```

**bruhat_succ_iterator()**

An iterator for the permutations that are strictly greater than `self` in the Bruhat order (on the symmetric group containing `self`) such that there is no permutation between one of those and `self`.

See **bruhat_lequal()** for the definition of the Bruhat order.

EXAMPLES:

```python
sage: [x for x in Permutation([6,1,4,5,2,3]).bruhat_succ_iterator()]
[[6, 4, 1, 5, 2, 3],
 [6, 2, 4, 5, 1, 3],
 [6, 1, 5, 4, 2, 3],
 [6, 1, 4, 5, 3, 2]]
```

**complement()**

Return the complement of the permutation `self`.

The complement of a permutation $w \in S_n$ is defined as the permutation in $S_n$ sending each $i$ to $n + 1 - w(i)$.

EXAMPLES:

```python
sage: Permutation([1,2,3]).complement()
[3, 2, 1]
```

```python
sage: Permutation([1, 3, 2]).complement()
[3, 1, 2]
```

**cycle_string**(singletons=False)

Return a string of the permutation in cycle notation.

If `singletons=True`, it includes 1-cycles in the string.

EXAMPLES:

```python
sage: Permutation([1,2,3]).cycle_string()
'()'
```

```python
sage: Permutation([2,1,3]).cycle_string()
'(1,2)'
```

```python
sage: Permutation([2,3,1]).cycle_string()
'(1,2,3)'
```

```python
sage: Permutation([2,1,3]).cycle_string(singletons=True)
'(1,2)(3)'
```

**cycle_tuples**(singletons=True, use_min=True)

Return the permutation `self` as a list of disjoint cycles.

The cycles are returned in the order of increasing smallest elements, and each cycle is returned as a tuple which starts with its smallest element.

If `singletons=False` is given, the list does not contain the singleton cycles.
If `use_min=False` is given, the cycles are returned in the order of increasing largest (not smallest) elements, and each cycle starts with its largest element.

**EXAMPLES:**

\[
\begin{align*}
\text{sage: } & \text{Permutation([2,1,3,4]).to_cycles()} \\
& [(1, 2), (3,), (4,)] \\
\text{sage: } & \text{Permutation([2,1,3,4]).to_cycles(singletons=False)} \\
& [(1, 2)] \\
\text{sage: } & \text{Permutation([2,1,3,4]).to_cycles(\text{use_min=True})} \\
& [(1, 2), (3,), (4,)] \\
\text{sage: } & \text{Permutation([2,1,3,4]).to_cycles(\text{use_min=False})} \\
& [(4,), (3,), (2, 1)] \\
\text{sage: } & \text{Permutation([2,1,3,4]).to_cycles(singletons=False, use_min=False)} \\
& [(2, 1)] \\
\text{sage: } & \text{Permutation([4,1,5,2,6,3]).to_cycles()} \\
& [(1, 4, 2), (3, 5, 6)] \\
\text{sage: } & \text{Permutation([4,1,5,2,6,3]).to_cycles(\text{use_min=False})} \\
& [(6, 3, 5), (4, 2, 1)] \\
\text{sage: } & \text{Permutation([6,4,5,2,3,1]).to_cycles()} \\
& [(1, 6), (2, 4), (3, 5)] \\
\text{sage: } & \text{Permutation([6,4,5,2,3,1]).to_cycles(\text{use_min=False})} \\
& [(6, 1), (5, 3), (4, 2)]
\end{align*}
\]

The algorithm is of complexity $O(n)$ where $n$ is the size of the given permutation.

**cycle_type()**

Return a partition of `len(self)` corresponding to the cycle type of `self`.

This is a non-increasing sequence of the cycle lengths of `self`.

**EXAMPLES:**

\[
\text{sage: } \text{Permutation([3,1,2,4]).cycle_type()} \\
[3, 1]
\]

**decreasing_runs(as_tuple=False)**

Decreasing runs of the permutation.

**INPUT:**

- `as_tuple` – boolean (default: `False`) choice of output format

**OUTPUT:**

a list of lists or a tuple of tuples

**See also:**

**runs()**

**EXAMPLES:**

\[
\begin{align*}
\text{sage: } & \text{s = Permutation([2,8,3,9,6,4,5,1,7])} \\
\text{sage: } & \text{s.decreasing_runs()} \\
& [[2], [8, 3], [9, 6, 4], [5, 1], [7]]
\end{align*}
\]
Combinatorics, Release 10.0

sage: s.decreasing_runs(as_tuple=True)
((2,), (8, 3), (9, 6, 4), (5, 1), (7,))

descent_polynomial()

Return the descent polynomial of the permutation self.

The descent polynomial of a permutation \( p \) is the product of all the \( z[p(i)] \) where \( i \) ranges over the descents of \( p \).

A descent of a permutation \( p \) is an integer \( i \) such that \( p(i) > p(i+1) \).

REFERENCES:
  • [GS1984]

EXAMPLES:

sage: Permutation([2,1,3]).descent_polynomial()
z1
sage: Permutation([4,3,2,1]).descent_polynomial()
z1*z2^2*z3^3

Todo: This docstring needs to be fixed. First, the definition does not match the implementation (or the examples). Second, this doesn't seem to be defined in [GS1984] (the descent monomial in their (7.23) is different).

descents(final_descent=False, side='right', positive=False, from_zero=False, index_set=None)

Return the list of the descents of self.

A descent of a permutation \( p \) is an integer \( i \) such that \( p(i) > p(i+1) \).

Warning: By default, the descents are returned as elements in the index set, i.e., starting at 1. If you want them to start at 0, set the keyword from_zero to True.

INPUT:
  • final_descent – boolean (default False); if True, the last position of a non-empty permutation is also considered as a descent
  • side – 'right' (default) or 'left'; if 'left', return the descents of the inverse permutation
  • positive – boolean (default False); if True, return the positions that are not descents
  • from_zero – boolean (default False); if True, return the positions starting from 0
  • index_set – list (default: \([1, \ldots, n-1]\) where self is a permutation of \( n \)); the index set to check for descents

EXAMPLES:

sage: Permutation([3,1,2]).descents()
[1]
sage: Permutation([1,4,3,2]).descents()
[2, 3]
sage: Permutation([1,4,3,2]).descents(final_descent=True)
(continues on next page)
Combinatorics, Release 10.0

[2, 3, 4]
sage: Permutation([1,4,3,2]).descents(index_set=[1,2])
[2]
sage: Permutation([1,4,3,2]).descents(from_zero=True)
[1, 2]

descents_composition()

Return the descent composition of self.

The descent composition of a permutation \( p \in S_n \) is defined as the composition of \( n \) whose descent set equals the descent set of \( p \). Here, the descent set of \( p \) is defined as the set of all \( i \in \{1, 2, \ldots, n - 1\} \) satisfying \( p(i) > p(i + 1) \). The descent set of a composition \( c = (i_1, i_2, \ldots, i_k) \) is defined as the set \( \{i_1, i_1 + i_2, i_1 + i_2 + i_3, \ldots, i_1 + i_2 + \cdots + i_{k-1}\} \).

EXAMPLES:

sage: Permutation([1,3,2,4]).descents_composition()
[2, 2]
sage: Permutation([4,1,6,7,2,3,8,5]).descents_composition()
[1, 3, 3, 1]
sage: Permutation([]).descents_composition()
[]

destandardize(weight, ordered_alphabet=None)

Return destandardization of self with respect to weight and ordered_alphabet.

INPUT:

- weight – list or tuple of nonnegative integers that sum to \( n \) if self is a permutation in \( S_n \).
- ordered_alphabet – (default: None) a list or tuple specifying the ordered alphabet the destandardized word is over

OUTPUT: word over the ordered_alphabet which standardizes to self.

Let \( \text{weight} = (w_1, w_2, \ldots, w_\ell) \). Then this methods looks for an increasing sequence of \( 1, 2, \ldots, w_1 \) and labels all letters in it by 1, then an increasing sequence of \( w_1 + 1, w_1 + 2, \ldots, w_1 + w_2 \) and labels all these letters by 2, etc.. If an increasing sequence for the specified weight does not exist, an error is returned. The output is a word \( w \) over the specified ordered alphabet with evaluation weight such that \( w.\text{standard_permutation}() \) is self.

EXAMPLES:

sage: p = Permutation([1,2,5,3,6,4])
sage: p.destandardize([3,1,2])
word: 113132
sage: p = Permutation([2,1,3])
sage: p.destandardize([2,1])
Traceback (most recent call last):
... ValueError: Standardization with weight [2, 1] is not possible!

dict()

Return a dictionary corresponding to the permutation.

EXAMPLES:
sage: p = Permutation([2,1,3])
sage: d = p.dict()
sage: d[1]
2
sage: d[2]
1
sage: d[3]
3

**fixed_points()**

Return a list of the fixed points of `self`.

**EXAMPLES:**
sage: Permutation([1,3,2,4]).fixed_points() [1, 4]
sage: Permutation([1,2,3,4]).fixed_points() [1, 2, 3, 4]

**foata_bijection()**

Return the image of the permutation `self` under the Foata bijection $\phi$.

The bijection shows that $\text{maj}$ (the major index) and $\text{inv}$ (the number of inversions) are equidistributed: if $\phi(P) = Q$, then $\text{maj}(P) = \text{inv}(Q)$.

The Foata bijection $\phi$ is a bijection on the set of words with no two equal letters. It can be defined by induction on the size of the word: Given a word $w_1 w_2 \cdots w_n$, start with $\phi(w_1) = w_1$. At the $i$-th step, if $\phi(w_1 w_2 \cdots w_i) = v_1 v_2 \cdots v_i$, we define $\phi(w_1 w_2 \cdots w_i w_{i+1})$ by placing $w_{i+1}$ on the end of the word $v_1 v_2 \cdots v_i$ and breaking the word up into blocks as follows. If $w_{i+1} > v_i$, place a vertical line to the right of each $v_k$ for which $w_{i+1} > v_k$. Otherwise, if $w_{i+1} < v_i$, place a vertical line to the right of each $v_k$ for which $w_{i+1} < v_k$. In either case, place a vertical line at the start of the word as well. Now, within each block between vertical lines, cyclically shift the entries one place to the right.

For instance, to compute $\phi([1,4,2,5,3])$, the sequence of words is

- 1,
- |1|4 → 14,
- |14|2 → 412,
- |41|2|5 → 4125,
- |4125|3 → 45123.

So $\phi([1,4,2,5,3]) = [4,5,1,2,3]$.

See section 2 of [FS1978], and the proof of Proposition 1.4.6 in [EnumComb1].

See also:

**foata_bijection_inverse()** for the inverse map.

**EXAMPLES:**
sage: Permutation([1,2,4,3]).foata_bijection() [4, 1, 2, 3]
sage: Permutation([2,5,1,3,4]).foata_bijection() [2, 1, 3, 5, 4]
 sage: P = Permutation([2,5,1,3,4])
sage: P.major_index() == P.foata_bijection().number_of_inversions()
True
 sage: all( P.major_index() == P.foata_bijection().number_of_inversions()
     ....:     for P in Permutations(4) )
True

The example from [FS1978]:

 sage: Permutation([7,4,9,2,6,1,5,8,3]).foata_bijection()
[4, 7, 2, 6, 1, 9, 5, 8, 3]

Border cases:

 sage: Permutation([]).foata_bijection()
[]
sage: Permutation([1]).foata_bijection()
[1]

\textbf{foata\_bijection\_inverse()} 

Return the image of the permutation \texttt{self} under the inverse of the Foata bijection $\phi$.

See \texttt{foata\_bijection()} for the definition of the Foata bijection.

EXAMPLES:

 sage: Permutation([4, 1, 2, 3]).foata_bijection()
[1, 2, 4, 3]

\textbf{forget\_cycles()} 

Return the image of \texttt{self} under the map which forgets cycles.

Consider a permutation $\sigma$ written in standard cyclic form:

$$
\sigma = (a_{1,1}, \ldots, a_{1,k_1})(a_{2,1}, \ldots, a_{2,k_2})\cdots(a_{m,1}, \ldots, a_{m,k_m}),
$$

where $a_{1,1} < a_{2,1} < \cdots < a_{m,1}$ and $a_{j,1} < a_{j,i}$ for all $1 \leq j \leq m$ and $2 \leq i \leq k_j$ where we include cycles of length 1 as well. The image of the forget cycle map $\phi$ is given by

$$
\phi(\sigma) = [a_{1,1}, \ldots, a_{1,k_1}, a_{2,1}, \ldots, a_{2,k_2}, \ldots, a_{m,1}, \ldots, a_{m,k_m}],
$$

considered as a permutation in 1-line notation.

See also:

\texttt{fundamental\_transformation()}, which is a similar map that is defined by instead taking $a_{j,1} > a_{j,i}$ and is bijective.

EXAMPLES:

 sage: P = Permutations(5)
sage: x = P([1, 5, 3, 4, 2])
sage: x.forget_cycles()
[1, 2, 5, 3, 4]
We select all permutations with a cycle composition of $[2, 3, 1]$ in $S_6$:

```
sage: P = Permutations(6)
sage: l = [p for p in P if [len(t) for t in p.to_cycles()] == [1, 3, 2]]
```

Next we apply $\phi$ and then take the inverse, and then view the results as a poset under the Bruhat order:

```
sage: l = [p.forget_cycles().inverse() for p in l]
sage: B = Poset([l, lambda x,y: x.bruhat_lequal(y)])
sage: R.<q> = QQ[]
sage: sum(q^B.rank_function()(x) for x in B)
q^5 + 2*q^4 + 3*q^3 + 3*q^2 + 2*q + 1
```

We check the statement in [CC2013] that the posets $C_{[1,3,1,1]}$ and $C_{[1,3,2]}$ are isomorphic:

```
sage: l2 = [p for p in P if [len(t) for t in p.to_cycles()] == [1, 3, 1, 1]]
sage: l2 = [p.forget_cycles().inverse() for p in l2]
sage: B2 = Poset([l2, lambda x,y: x.bruhat_lequal(y)])
sage: B.is_isomorphic(B2)
True
```

See also:

`fundamental_transformation()`.

`fundamental_transformation()`

Return the image of the permutation `self` under the Renyi-Foata-Schuetzenberger fundamental transformation.

The fundamental transformation is a bijection from the set of all permutations of $\{1, 2, \ldots, n\}$ to itself, which transforms any such permutation $w$ as follows: Write $w$ in cycle form, with each cycle starting with its highest element, and the cycles being sorted in increasing order of their highest elements. Drop the parentheses in the resulting expression, thus reading it as a one-line notation of a new permutation $u$. Then, $u$ is the image of $w$ under the fundamental transformation.

See [EnumComb1], Proposition 1.3.1.

See also:

`fundamental_transformation_inverse()` for the inverse map.

`forget_cycles()` for a similar (but non-bijective) map where each cycle is starting from its lowest element.

**EXAMPLES:**

```
sage: Permutation([5, 1, 3, 4, 2]).fundamental_transformation()
[3, 4, 5, 2, 1]
sage: Permutations(5)([1, 5, 3, 4, 2]).fundamental_transformation()
[1, 3, 4, 5, 2]
sage: Permutation([8, 4, 7, 2, 9, 6, 5, 1, 3]).fundamental_transformation()
[4, 2, 6, 8, 1, 9, 3, 7, 5]
```

Comparison with `forget_cycles()`:

```
sage: P = Permutation(([1,3,4),(2,5]))
sage: P
[3, 5, 4, 1, 2]
```

(continues on next page)
sage: P.forget_cycles()
[1, 3, 4, 2, 5]
sage: P.fundamental_transformation()
[4, 1, 3, 5, 2]

fundamental_transformation_inverse()

Return the image of the permutation self under the inverse of the Renyi-Foata-Schuetzenberger fundamental transformation.

The inverse of the fundamental transformation is a bijection from the set of all permutations of \{1, 2, \ldots, n\} to itself, which transforms any such permutation \(w\) as follows: Let \(I = \{i_1 < i_2 < \cdots < i_k\}\) be the set of all left-to-right maxima of \(w\) (that is, of all indices \(j\) such that \(w(j)\) is bigger than each of \(w(1), w(2), \ldots, w(j-1)\)). The image of \(w\) under the inverse of the fundamental transformation is the permutation \(u\) that sends \(w(i-1)\) to \(w(i)\) for all \(i \notin I\) (notice that this makes sense, since \(1 \in I\) whenever \(n > 0\), while sending each \(w(i_p - 1)\) (with \(p \geq 2\)) to \(w(i_{p-1})\). Here, we set \(i_{k+1} = n + 1\).

See [EnumComb1], Proposition 1.3.1.

See also:

fundamental_transformation() for the inverse map.

EXAMPLES:

sage: Permutation([3, 4, 5, 2, 1]).fundamental_transformation_inverse()
[5, 1, 3, 4, 2]
sage: Permutation([4, 2, 6, 8, 1, 9, 3, 7, 5]).fundamental_transformation_inverse()
[8, 4, 7, 2, 9, 6, 5, 1, 3]

grade()

Return the size of self.

EXAMPLES:

sage: Permutation([3, 4, 1, 2, 5]).size()
5

has_pattern(patt)

Test whether the permutation self contains the pattern patt.

EXAMPLES:

sage: Permutation([3, 5, 1, 4, 6, 2]).has_pattern([1, 3, 2])
True

hyperoctahedral_double_coset_type()

Return the coset-type of self as a partition.

self must be a permutation of even size 2n. The coset-type determines the double class of the permutation, that is its image in \(H_n \backslash S_{2n}/H_n\), where \(H_n\) is the \(n\)-th hyperoctahedral group.

The coset-type is determined as follows. Consider the perfect matching \(\{(1, 2), (3, 4), \ldots, (2n - 1, 2n)\}\) and its image by self, and draw them simultaneously as edges of a graph whose vertices are labeled by 1, 2, \ldots, 2n. The coset-type is the ordered sequence of the semi-lengths of the cycles of this graph (see Chapter VII of [Mac1995] for more details, particularly Section VII.2).

EXAMPLES:
sage: Permutation([3, 4, 6, 1, 5, 7, 2, 8]).hyperoctahedral_double_coset_type()
[3, 1]
sage: all(p.hyperoctahedral_double_coset_type() ==
....:   p.inverse().hyperoctahedral_double_coset_type()
....:   for p in Permutations(4))
True
sage: Permutation([]).hyperoctahedral_double_coset_type()
[]
sage: Permutation([3,1,2]).hyperoctahedral_double_coset_type()
Traceback (most recent call last):
...
ValueError: [3, 1, 2] is a permutation of odd size and has no coset-type

idescents(final_descent=False, from_zero=False)

Return a list of the idescents of self, that is the list of the descents of self’s inverse.

A descent of a permutation p is an integer i such that p(i) > p(i+1).

Warning: By default, the descents are returned as elements in the index set, i.e., starting at 1. If you want them to start at 0, set the keyword from_zero to True.

INPUT:

• final_descent – boolean (default False); if True, the last position of a non-empty permutation is also considered as a descent

• from_zero – optional boolean (default False); if False, return the positions starting from 1

EXAMPLES:

sage: Permutation([2,3,1]).idescents()
[1]
sage: Permutation([1,4,3,2]).idescents()
[2, 3]
sage: Permutation([1,4,3,2]).idescents(final_descent=True)
[2, 3, 4]
sage: Permutation([1,4,3,2]).idescents(from_zero=True)
[1, 2]

idescents_signature(final_descent=False)

Return the list obtained as follows: Each position in self is mapped to -1 if it is an idescent and 1 if it is not an idescent.

See idescents() for a definition of idescents.

With the final_descent option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:

sage: Permutation([1,4,3,2]).idescents()
[2, 3]
sage: Permutation([1,4,3,2]).idescents_signature()
[1, -1, -1, 1]
**imajor_index**(*final_descent=False*)

Return the inverse major index of the permutation `self`, which is the major index of the inverse of `self`.

The major index of a permutation $p$ is the sum of the descents of $p$. Since our permutation indices are 0-based, we need to add the number of descents.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

**EXAMPLES:**

```python
sage: Permutation([2,1,3]).imajor_index()
1
sage: Permutation([3,4,1,2]).imajor_index()
2
sage: Permutation([4,3,2,1]).imajor_index()
6
```

**increasing_tree**(*compare=<built-in function min>*)

Return the increasing tree associated to `self`.

**EXAMPLES:**

```python
sage: Permutation([1,4,3,2]).increasing_tree()
1[., 2[3[4[., .], .], .]]
sage: Permutation([4,1,3,2]).increasing_tree()
1[4[., .], 2[3[., .], .]]
```

By passing the option `compare=max` one can have the decreasing tree instead:

```python
sage: Permutation([2,3,4,1]).increasing_tree(max)
4[3[2[., .], .], 1[., .]]
sage: Permutation([2,3,1,4]).increasing_tree(max)
4[3[2[., .], 1[., .]], .]
```

**increasing_tree_shape**(*compare=<built-in function min>*)

Return the shape of the increasing tree associated with the permutation.

**EXAMPLES:**

```python
sage: Permutation([1,4,3,2]).increasing_tree_shape()
[., [[., .], .], .]
sage: Permutation([4,1,3,2]).increasing_tree_shape()
[[., .], [[., .], .]]
```

By passing the option `compare=max` one can have the decreasing tree instead:

```python
sage: Permutation([2,3,4,1]).increasing_tree_shape(max)
[[[., .], .], [[., .]]]
sage: Permutation([2,3,1,4]).increasing_tree_shape(max)
[[[., .], [[., .]], .]
```

**inverse**()

Return the inverse of `self`.

**EXAMPLES:**
```python
sage: Permutation([3,8,5,10,9,4,6,1,7,2]).inverse()
[8, 10, 1, 6, 3, 7, 9, 2, 5, 4]
sage: Permutation([2, 4, 1, 5, 3]).inverse()
[3, 1, 5, 2, 4]
sage: ~Permutation([2, 4, 1, 5, 3])
[3, 1, 5, 2, 4]
```

**inversions()**

Return a list of the inversions of self.

An inversion of a permutation \( p \) is a pair \((i, j)\) such that \( i < j \) and \( p(i) > p(j) \).

**EXAMPLES:**

```python
sage: Permutation([3,2,4,1,5]).inversions()
[(1, 2), (1, 4), (2, 4), (3, 4)]
```

**is_derangement()**

Return whether self is a derangement.

A permutation \( \sigma \) is a derangement if \( \sigma \) has no fixed points.

**EXAMPLES:**

```python
sage: P = Permutation([1,4,2,3])
sage: P.is_derangement()
False
sage: P = Permutation([2,3,1])
sage: P.is_derangement()
True
```

**is_even()**

Return True if the permutation self is even and False otherwise.

**EXAMPLES:**

```python
sage: Permutation([1,2,3]).is_even()
True
sage: Permutation([2,1,3]).is_even()
False
```

**is_simple()**

Return whether self is simple.

A permutation is simple if it does not send any proper sub-interval to a sub-interval.

For instance, \([6,1,3,5,2,4]\) is not simple because it maps the interval \([3,4,5,6]\) to \([2,3,4,5]\), whereas \([2,6,3,5,1,4]\) is simple.

See OEIS sequence A111111

**EXAMPLES:**

```python
sage: g = Permutation([4,2,3,1])
sage: g.is_simple()
False
```

(continues on next page)
sage: g = Permutation([6,1,3,5,2,4])
sage: g.is_simple()
False

sage: g = Permutation([2,6,3,5,1,4])
sage: g.is_simple()
True

```python
sage: [len([pi for pi in Permutations(n) if pi.is_simple()])
    for n in range(6)]
[1, 1, 2, 0, 2, 6]
```

### ishift(i)

Return the i-shift of self. If an i-shift of self can't be performed, then self is returned.

An i-shift can be applied when i is not inbetween i − 1 and i + 1. The i-shift moves i to the other side, and leaves the relative positions of i − 1 and i + 1 in place. All other entries of the permutations are also left in place.

**EXAMPLES:**

Here, 2 is to the left of both 1 and 3. A 2-shift can be applied which moves the 2 to the right and leaves 1 and 3 in their same relative order:

```python
sage: Permutation([2,1,3]).ishift(2)
[1, 3, 2]
```

All entries other than i, i − 1 and i + 1 are unchanged:

```python
sage: Permutation([2,4,1,3]).ishift(2)
[1, 4, 3, 2]
```

Since 2 is between 1 and 3 in [1,2,3], a 2-shift cannot be applied to [1,2,3]

```python
sage: Permutation([1,2,3]).ishift(2)
[1, 2, 3]
```

### iswitch(i)

Return the i-switch of self. If an i-switch of self can't be performed, then self is returned.

An i-switch can be applied when the subsequence of self formed by the entries i − 1, i and i + 1 is neither increasing nor decreasing. In this case, this subsequence is reversed (i.e., its leftmost element and its rightmost element switch places), while all other letters of self are kept in place.

**EXAMPLES:**

Here, 2 is to the left of both 1 and 3. A 2-switch can be applied which moves the 2 to the right and switches the relative order between 1 and 3:

```python
sage: Permutation([2,1,3]).iswitch(2)
[3, 1, 2]
```

All entries other than i − 1, i and i + 1 are unchanged:

```python
sage: Permutation([2,4,1,3]).iswitch(2)
[3, 4, 1, 2]
```
Since 2 is between 1 and 3 in \([1, 2, 3]\), a 2-switch cannot be applied to \([1, 2, 3]\)

```python
sage: Permutation([1,2,3]).iswitch(2)
[1, 2, 3]
```

**left_action_product**(*lp*)

Return the permutation obtained by composing *self* with *lp* in such an order that *lp* is applied first and *self* is applied afterwards.

This is usually denoted by either *self* * * * * 1p or 1p * * * * self depending on the conventions used by the author. If the value of a permutation \(p \in S_n\) on an integer \(i \in \{1, 2, \ldots, n\}\) is denoted by \(p(i)\), then this should be denoted by *self* * * * 1p in order to have associativity (i.e., in order to have \((p \cdot q)(i) = p(q(i))\) for all \(p, q\) and \(i\)). If, on the other hand, the value of a permutation \(p \in S_n\) on an integer \(i \in \{1, 2, \ldots, n\}\) is denoted by \(i^p\), then this should be denoted by 1p * * * * self in order to have associativity (i.e., in order to have \(i^{pq} = (i^p)^q\) for all \(p, q\) and \(i\)).

**EXAMPLES:**

```python
sage: p = Permutation([2,1,3])
sage: q = Permutation([3,1,2])
sage: p.left_action_product(q)
[3, 2, 1]
sage: q.left_action_product(p)
[1, 3, 2]
```

**left_tableau**()

Return the left standard tableau after performing the RSK algorithm on *self*.

**EXAMPLES:**

```python
sage: Permutation([1,4,3,2]).left_tableau()
[[1, 2], [3], [4]]
```

**length**()

Return the Coxeter length of *self*.

The length of a permutation \(p\) is given by the number of inversions of \(p\).

**EXAMPLES:**

```python
sage: Permutation([5, 1, 3, 4, 2]).length()
6
```

**longest_increasing_subsequence_length**()

Return the length of the longest increasing subsequences of *self*.

**EXAMPLES:**

```python
sage: Permutation([2,3,1,4]).longest_increasing_subsequence_length()
3
sage: all(i.longest_increasing_subsequence_length() == len(RSK(i)[0][0]) for i → in Permutations(5))
True
sage: Permutation([]).longest_increasing_subsequence_length()
0
```
**longest_increasing_subsequences()**

Return the list of the longest increasing subsequences of `self`.

A theorem of Schensted ([Sch1961]) states that an increasing subsequence of length \(i\) ends with the value entered in the \(i\)-th column of the p-tableau. The algorithm records which column of the p-tableau each value of the permutation is entered into, creates a digraph to record all increasing subsequences, and reads the paths from a source to a sink; these are the longest increasing subsequences.

**EXAMPLES:**

```
sage: Permutation([2,3,4,1]).longest_increasing_subsequences()
[[2, 3, 4]]
sage: Permutation([5, 7, 1, 2, 6, 4, 3]).longest_increasing_subsequences()
[[1, 2, 6], [1, 2, 4], [1, 2, 3]]
```

**Note:** This algorithm could be made faster using a balanced search tree for each column instead of sorted lists. See discussion on github issue #31451.

**longest_increasing_subsequences_number()**

Return the number of increasing subsequences of maximal length in `self`.

The list of longest increasing subsequences of a permutation is given by `longest_increasing_subsequences()`, and the length of these subsequences is given by `longest_increasing_subsequence_length()`.

The algorithm is similar to `longest_increasing_subsequences()`. Namely, the longest increasing subsequences are encoded as increasing sequences in a ranked poset from a smallest to a largest element. Their number can be obtained via dynamic programming: for each \(v\) in the poset we compute the number of paths from a smallest element to \(v\).

**EXAMPLES:**

```
sage: sum(p.longest_increasing_subsequences_number() for p in Permutations(8))
120770
sage: p = Permutations(50).random_element()
sage: (len(p.longest_increasing_subsequences()) == ....: p.longest_increasing_subsequences_number())
True
```

**major_index(final_descent=False)**

Return the major index of `self`.

The major index of a permutation \(p\) is the sum of the descents of \(p\). Since our permutation indices are 0-based, we need to add the number of descents.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

**EXAMPLES:**

```
sage: Permutation([2,1,3]).major_index()
1
sage: Permutation([3,4,1,2]).major_index()
2
```

(continues on next page)
sage: Permutation([4,3,2,1]).major_index()
6

**multi_major_index** *(composition)*

Return the multimajor index of this permutation with respect to *composition*.

INPUT:

- *composition* – a composition of the *size()* of this permutation

EXAMPLES:

```python
sage: p = Permutation([5, 6, 2, 1, 3, 7, 4])
sage: p.multi_major_index([3, 2, 2])
[2, 0, 1]
sage: p.multi_major_index([7]) == [p.major_index()]
True
sage: p.multi_major_index([1]*7)
[0, 0, 0, 0, 0, 0, 0]
sage: Permutation([]).multi_major_index([])
[]
```

REFERENCES:

- [JS2000]

**next()**

Return the permutation that follows *self* in lexicographic order on the symmetric group containing *self*. If *self* is the last permutation, then *next* returns False.

EXAMPLES:

```python
sage: p = Permutation([1, 3, 2])
sage: next(p)
[2, 1, 3]
sage: p = Permutation([4,3,2,1])
sage: next(p)
False
```

**noninversions** *(k)*

Return the list of all *k*-noninversions in *self*.

If *k* is an integer and *p* ∈ *S*ₙ is a permutation, then a *k*-nonversion in *p* is defined as a strictly increasing sequence *(i₁,i₂,...,iₖ)* of elements of *{1,2,...,n}* satisfying *p*(i₁) < *p*(i₂) < ⋯ < *p*(iₖ). (In other words, a *k*-nonversion in *p* can be regarded as a *k*-element subset of *{1,2,...,n}* on which *p* restricts to an increasing map.)

EXAMPLES:

```python
sage: p = Permutation([3, 2, 4, 1, 5])
sage: p.noninversions(1)
[[3], [2], [4], [1], [5]]
sage: p.noninversions(2)
[[3, 4], [3, 5], [2, 4], [2, 5], [4, 5], [1, 5]]
sage: p.noninversions(3)
[[3, 4, 5], [2, 4, 5]]
```
sage: p.noninversions(4)
[]
sage: p.noninversions(5)
[]

**number_of_descents***(final_descent=False)***
Return the number of descents of **self**.

With the final_descent option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).number_of_descents()
2
sage: Permutation([1,4,3,2]).number_of_descents(final_descent=True)
3
```

**number_of_fixed_points**()
Return the number of fixed points of **self**.

EXAMPLES:

```
sage: Permutation([1,3,2,4]).number_of_fixed_points()
2
sage: Permutation([1,2,3,4]).number_of_fixed_points()
4
```

**number_of_idescents***(final_descent=False)***
Return the number of idescents of **self**.

See idescents() for a definition of idescents.

With the final_descent option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).number_of_idescents()
2
sage: Permutation([1,4,3,2]).number_of_idescents(final_descent=True)
3
```

**number_of_inversions**()
Return the number of inversions in **self**.

An inversion of a permutation is a pair of elements \((i, j)\) with \(i < j\) and \(p(i) > p(j)\).

REFERENCES:

- [http://mathworld.wolfram.com/PermutationInversion.html](http://mathworld.wolfram.com/PermutationInversion.html)

EXAMPLES:

```
sage: Permutation([3, 2, 4, 1, 5]).number_of_inversions()
4
```

(continues on next page)
Combinatorics, Release 10.0

number_of_noninversions($k$)

Return the number of $k$-noninversions in self.

If $k$ is an integer and $p \in S_n$ is a permutation, then a $k$-noninversion in $p$ is defined as a strictly increasing sequence $(i_1, i_2, \ldots, i_k)$ of elements of $\{1, 2, \ldots, n\}$ satisfying $p(i_1) < p(i_2) < \cdots < p(i_k)$. (In other words, a $k$-noninversion in $p$ can be regarded as a $k$-element subset of $\{1, 2, \ldots, n\}$ on which $p$ restricts to an increasing map.)

The number of $k$-noninversions in $p$ has been denoted by $\text{noninv}_k(p)$ in [RSW2011], where conjectures and results regarding this number have been stated.

EXAMPLES:

```
sage: p = Permutation([3, 2, 4, 1, 5])
sage: p.number_of_noninversions(1)
  5
sage: p.number_of_noninversions(2)
  6
sage: p.number_of_noninversions(3)
  2
sage: p.number_of_noninversions(4)
  0
sage: p.number_of_noninversions(5)
  0
```

The number of 2-noninversions of a permutation $p \in S_n$ is $\binom{n}{2}$ minus its number of inversions:

```
sage: b = binomial(5, 2)
sage: all( x.number_of_noninversions(2) == b - x.number_of_inversions() 
.....: for x in Permutations(5) )
True
```

We also check some corner cases:

```
sage: all( x.number_of_noninversions(1) == 5 for x in Permutations(5) )
True
sage: all( x.number_of_noninversions(0) == 1 for x in Permutations(5) )
True
sage: Permutation([]).number_of_noninversions(1)
  0
sage: Permutation([]).number_of_noninversions(0)
  1
sage: Permutation([2, 1]).number_of_noninversions(3)
  0
```

number_of_peaks()

Return the number of peaks of the permutation self.

A peak of a permutation $p$ is an integer $i$ such that $p(i - 1) < p(i)$ and $p(i) > p(i + 1)$.

EXAMPLES:
number_of_recoils()
Return the number of recoils of the permutation self.

EXAMPLES:

```python
sage: Permutation([1,4,3,2]).number_of_recoils()
2
```

number_of_reduced_words()
Return the number of reduced words of self without explicitly computing them all.

EXAMPLES:

```python
sage: p = Permutation([6,4,2,5,1,8,3,7])
sage: len(p.reduced_words()) == p.number_of_reduced_words()
True
```

number_of_saliances()
Return the number of saliances of self.
A saliance of a permutation \( p \) is an integer \( i \) such that \( p(i) > p(j) \) for all \( j > i \).

EXAMPLES:

```python
sage: Permutation([2,3,1,5,4]).number_of_saliances()
2
sage: Permutation([5,4,3,2,1]).number_of_saliances()
5
```

pattern_positions(patt)
Return the list of positions where the pattern \( patt \) appears in the permutation self.

EXAMPLES:

```python
sage: Permutation([3,5,1,4,6,2]).pattern_positions([1,3,2])
[[0, 1, 3], [2, 3, 5], [2, 4, 5]]
```

peaks()
Return a list of the peaks of the permutation self.
A peak of a permutation \( p \) is an integer \( i \) such that \( p(i - 1) < p(i) \) and \( p(i) > p(i + 1) \).

EXAMPLES:

```python
sage: Permutation([1,3,2,4,5]).peaks()
[1]
sage: Permutation([4,1,3,2,6,5]).peaks()
[2, 4]
sage: Permutation([]).peaks()
[]
```
permutation_poset()

Return the permutation poset of self.

The permutation poset of a permutation \( p \) is the poset with vertices \((i, p(i))\) for \( i = 1, 2, \ldots, n \) (where \( n \) is the size of \( p \)) and order inherited from \( \mathbb{Z} \times \mathbb{Z} \).

EXAMPLES:

```python
sage: Permutation([3,1,5,4,2]).permutation_poset().cover_relations()
[(2, 1), (5, 2)],
[(2, 1), (3, 5)],
[(2, 1), (4, 4)],
[(1, 3), (3, 5)],
[(1, 3), (4, 4)]
```

```
sage: Permutation([]).permutation_poset().cover_relations()
[]
```

```
sage: Permutation([1,3,2]).permutation_poset().cover_relations()
[[1, 1], [2, 3]]
```

```
sage: Permutation([1,2]).permutation_poset().cover_relations()
[[1, 1], [2, 2]]
```

```
P = Permutation([1,5,2,4,3])
sage: P.RS_partition() == P.RS_partition() # This should hold for any P.
True
```

permutohedron_greater(side='right')

Return a list of permutations greater than or equal to self in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option side='left', then they will be done in the left permutohedron.

See permutohedron_lequal() for the definition of the permutohedron orders.

EXAMPLES:

```
sage: Permutation([4,2,1,3]).permutohedron_greater()
[[4, 2, 1, 3], [4, 2, 3, 1], [4, 3, 2, 1]]
```

```
sage: Permutation([4,2,1,3]).permutohedron_greater(side='left')
[[4, 2, 1, 3], [4, 3, 1, 2], [4, 3, 2, 1]]
```

permutohedron_join(other, side='right')

Return the join of the permutations self and other in the right permutohedron order (or, if side is set to 'left', in the left permutohedron order).

The permutohedron orders (see permutohedron_lequal()) are lattices; the join operation refers to this lattice structure. In more elementary terms, the join of two permutations \( \pi \) and \( \psi \) in the symmetric group \( S_n \) is the permutation in \( S_n \) whose set of inversion is the transitive closure of the union of the set of inversions of \( \pi \) with the set of inversions of \( \psi \).

See also:

permutohedron_lequal(), permutohedron_meet.

ALGORITHM:

It is enough to construct the join of any two permutations \( \pi \) and \( \psi \) in \( S_n \) with respect to the right weak order. (The join of \( \pi \) and \( \psi \) with respect to the left weak order is the inverse of the join of \( \pi^{-1} \) and \( \psi^{-1} \) with respect to the right weak order.) Start with an empty list \( l \) (denoted \( xs \) in the actual code). For \( i = 1, 2, \ldots, n \) (in this order), we insert \( i \) into this list in the rightmost possible position such that any letter in \( \{1, 2, \ldots, i-1\} \)
which appears further right than \(i\) in either \(\pi\) or \(\psi\) (or both) must appear further right than \(i\) in the resulting list. After all numbers are inserted, we are left with a list which is precisely the join of \(\pi\) and \(\psi\) (in one-line notation). This algorithm is due to Markowsky, [Mar1994] (Theorem 1 (a)).

AUTHORS:

Viviane Pons and Darij Grinberg, 18 June 2014.

EXAMPLES:

```python
sage: p = Permutation([3,1,2])
sage: q = Permutation([1,3,2])
sage: p.permutohedron_join(q)
[3, 1, 2]
sage: r = Permutation([2,1,3])
sage: r.permutohedron_join(p)
[3, 2, 1]

sage: p = Permutation([3,2,4,1])
sage: q = Permutation([4,2,1,3])
sage: p.permutohedron_join(q)
[4, 3, 2, 1]
sage: r = Permutation([3,1,2,4])
sage: p.permutohedron_join(r)
[3, 2, 4, 1]
sage: q.permutohedron_join(r)
[4, 3, 2, 1]
sage: s = Permutation([1,4,2,3])
sage: s.permutohedron_join(r)
[4, 3, 1, 2]
```

The universal property of the join operation is satisfied:

```python
sage: def test_uni_join(p, q):
    ...:     j = p.permutohedron_join(q)
    ...:     if not p.permutohedron_lequal(j):
    ...:         return False
    ...:     if not q.permutohedron_lequal(j):
    ...:         return False
    ...:     for r in p.permutohedron_greater():
    ...:         if q.permutohedron_lequal(r) and not j.permutohedron_lequal(r):
    ...:             return False
    ...:     return True
sage: all( test_uni_join(p, q) for p in Permutations(3) for q in Permutations(3) )
True
sage: test_uni_join(Permutation([6, 4, 7, 3, 2, 5, 8, 1]), Permutation([7, 3, 1, 2, 5, 4, 6, 8]))
True
```

Border cases:

```python
sage: p = Permutation([])
sage: p.permutohedron_join(p)
[]
```

(continues on next page)
sage: p = Permutation([1])
sage: p.permutohedron_join(p)
[1]

The left permutohedron:

sage: p = Permutation([3,1,2])
sage: q = Permutation([1,3,2])
sage: p.permutohedron_join(q, side="left")
[3, 2, 1]
sage: r = Permutation([2,1,3])
sage: r.permutohedron_join(p, side="left")
[3, 1, 2]

permutohedron_lequal(p2, side='right')

Return True if self is less or equal to p2 in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option side='left', then they will be done in the left permutohedron.

For every nonnegative integer \( n \), the right (resp. left) permutohedron order (also called the right (resp. left) weak order, or the right (resp. left) weak Bruhat order) is a partial order on the symmetric group \( S_n \). It can be defined in various ways, including the following ones:

- Two permutations \( u \) and \( v \) in \( S_n \) satisfy \( u \leq v \) in the right (resp. left) permutohedron order if and only if the (Coxeter) length of the permutation \( v^{-1} \circ u \) (resp. of the permutation \( u \circ v^{-1} \)) equals the length of \( v \) minus the length of \( u \). Here, \( p \circ q \) means the permutation obtained by applying \( q \) first and then \( p \). (Recall that the Coxeter length of a permutation is its number of inversions.)

- Two permutations \( u \) and \( v \) in \( S_n \) satisfy \( u \leq v \) in the right (resp. left) permutohedron order if and only if every pair \((i,j)\) of elements of \( \{1,2,\ldots,n\} \) such that \( i < j \) and \( u^{-1}(i) > u^{-1}(j) \) (resp. \( u(i) > u(j) \)) also satisfies \( v^{-1}(i) > v^{-1}(j) \) (resp. \( v(i) > v(j) \)).

- A permutation \( v \) covers a permutation \( u \) in \( S_n \) in the right (resp. left) permutohedron order if and only if we have \( v = u \circ (i,i+1) \) (resp. \( v = (i,i+1) \circ u \)) for some \( i \in \{1,2,\ldots,n-1\} \) satisfying \( u(i) < u(i+1) \) (resp. \( u^{-1}(i) < u^{-1}(i+1) \)). Here, again, \( p \circ q \) means the permutation obtained by applying \( q \) first and then \( p \).

The right and the left permutohedron order are mutually isomorphic, with the isomorphism being the map sending every permutation to its inverse. Each of these orders endows the symmetric group \( S_n \) with the structure of a graded poset (the rank function being the Coxeter length).

Warning: The permutohedron order is not to be mistaken for the strong Bruhat order \( (bruhat_lequal()) \), despite both orders being occasionally referred to as the Bruhat order.

EXAMPLES:

sage: p = Permutation([3,2,1,4])
sage: p.permutohedron_lequal(Permutation([4,2,1,3]))
False
sage: p.permutohedron_lequal(Permutation([4,2,1,3]), side='left')
True
sage: p.permutohedron_lequal(p)
True
Combinatorics, Release 10.0

(continued from previous page)

```
sage: Permutation([2,1,3]).permutohedron_lequal(Permutation([2,3,1]))
True
sage: Permutation([2,1,3]).permutohedron_lequal(Permutation([3,1,2]))
False
sage: Permutation([2,1,3]).permutohedron_lequal(Permutation([1,2,3]))
False
sage: Permutation([1,3,2]).permutohedron_lequal(Permutation([2,3,1]))
False
sage: Permutation([1,3,2]).permutohedron_lequal(Permutation([2,1,3]))
False
sage: Permutation([2,3,1]).permutohedron_lequal(Permutation([1,3,2]), side='left')
False
sage: sorted([len([b for b in Permutations(3) if a.permutohedron_lequal(b)])
          for a in Permutations(3)])
[1, 2, 2, 3, 3, 6]
sage: sorted([len([b for b in Permutations(3) if a.permutohedron_lequal(b,side="left")])
          for a in Permutations(3)])
[1, 2, 2, 3, 3, 6]
sage: Permutation([]).permutohedron_lequal(Permutation([]))
True
```

**permutohedron_meet**(other, side='right')

Return the meet of the permutations `self` and `other` in the right permutohedron order (or, if `side` is set to 'left', in the left permutohedron order).

The permutohedron orders (see `permutohedron_lequal()`) are lattices; the meet operation refers to this lattice structure. It is connected to the join operation by the following simple symmetry property: If \( \pi \) and \( \psi \) are two permutations \( \pi \) and \( \psi \) in the symmetric group \( S_n \), and if \( w_0 \) denotes the permutation \( (n, n - 1, \ldots, 1) \in S_n \), then

\[
\pi \land \psi = w_0 \circ ((w_0 \circ \pi) \lor (w_0 \circ \psi)) = ((\pi \circ w_0) \lor (\psi \circ w_0)) \circ w_0
\]

and

\[
\pi \lor \psi = w_0 \circ ((w_0 \circ \pi) \land (w_0 \circ \psi)) = ((\pi \circ w_0) \land (\psi \circ w_0)) \circ w_0,
\]

where \( \land \) means meet and \( \lor \) means join.

See also:

`permutohedron_lequal()`, `permutohedron_join()`.

AUTHORS:

Viviane Pons and Darij Grinberg, 18 June 2014.

EXAMPLES:
sage: p = Permutation([3,1,2])
sage: q = Permutation([1,3,2])
sage: p.permutohedron_meet(q)
[1, 3, 2]
sage: r = Permutation([2,1,3])
sage: r.permutohedron_meet(p)
[1, 2, 3]

sage: p = Permutation([3,2,4,1])
sage: q = Permutation([4,2,1,3])
sage: p.permutohedron_meet(q)
[2, 1, 3, 4]
sage: r = Permutation([3,1,2,4])
sage: p.permutohedron_meet(r)
[3, 1, 2, 4]
sage: q.permutohedron_meet(r)
[1, 2, 3, 4]
sage: s = Permutation([1,4,2,3])
sage: s.permutohedron_meet(r)
[1, 2, 3, 4]

The universal property of the meet operation is satisfied:

```python
sage: def test_uni_meet(p, q):
    ....:     m = p.permutohedron_meet(q)
    ....:     if not m.permutohedron_lequal(p):
    ....:         return False
    ....:     if not m.permutohedron_lequal(q):
    ....:         return False
    ....:     for r in p.permutohedron_smaller():
    ....:         if r.permutohedron_lequal(q) and not r.permutohedron_lequal(m):
    ....:             return False
    ....:     return True

sage: all( test_uni_meet(p, q) for p in Permutations(3) for q in Permutations(3) )
True
```

Border cases:

```python
sage: p = Permutation([])
sage: p.permutohedron_meet(p)
[]
sage: p = Permutation([1])
sage: p.permutohedron_meet(p)
[1]
```

The left permutohedron:

```python
sage: p = Permutation([3,1,2])
sage: q = Permutation([1,3,2])
```
Combinatorics, Release 10.0

sage: p.permutohedron_meet(q, side="left")
[1, 2, 3]
sage: r = Permutation([2,1,3])
sage: r.permutohedron_meet(p, side="left")
[2, 1, 3]

**permutohedron_pred**(side='right')

Return a list of the permutations strictly smaller than self in the permutohedron order such that there is no permutation between any of those and self.

By default, the computations are done in the right permutohedron. If you pass the option side='left', then they will be done in the left permutohedron.

See **permutohedron_lequal()** for the definition of the permutohedron orders.

**EXAMPLES:**

```python
sage: p = Permutation([4,2,1,3])
sage: p.permutohedron_pred()
[[2, 4, 1, 3], [4, 1, 2, 3]]
sage: p.permutohedron_pred(side='left')
[[4, 1, 2, 3], [3, 2, 1, 4]]
```

**permutohedron_smaller**(side='right')

Return a list of permutations smaller than or equal to self in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option side='left', then they will be done in the left permutohedron.

See **permutohedron_lequal()** for the definition of the permutohedron orders.

**EXAMPLES:**

```python
sage: Permutation([4,2,1,3]).permutohedron_smaller()
[[1, 2, 3, 4],
 [1, 2, 4, 3],
 [1, 4, 2, 3],
 [2, 1, 3, 4],
 [2, 1, 4, 3],
 [2, 4, 1, 3],
 [4, 1, 2, 3],
 [4, 2, 1, 3]]
sage: Permutation([4,2,1,3]).permutohedron_smaller(side='left')
[[1, 2, 3, 4],
 [1, 3, 2, 4],
 [2, 1, 3, 4],
 [2, 3, 1, 4],
 [3, 1, 2, 4],
 [3, 2, 1, 4],
 [4, 1, 2, 3],
 [4, 2, 1, 3]]
```

**permutohedron_succ**(side='right')

5.1. Comprehensive Module List 1881
Return a list of the permutations strictly greater than \texttt{self} in the permutohedron order such that there is no permutation between any of those and \texttt{self}.

By default, the computations are done in the right permutohedron. If you pass the option \texttt{side='left'}, then they will be done in the left permutohedron.

See \texttt{permutohedron_lequal()} for the definition of the permutohedron orders.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: p = Permutation([4,2,1,3])
sage: p.permutohedron_succ()
[[4, 2, 3, 1]]
sage: p.permutohedron_succ(side='left')
[[4, 3, 1, 2]]
\end{verbatim}

\textbf{prev()}

Return the permutation that comes directly before \texttt{self} in lexicographic order on the symmetric group containing \texttt{self}. If \texttt{self} is the first permutation, then it returns \texttt{False}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: p = Permutation([1,2,3])
sage: p.prev()
False
sage: p = Permutation([1,3,2])
sage: p.prev()
[1, 2, 3]
\end{verbatim}

\textbf{rank()}

Return the rank of \texttt{self} in the lexicographic ordering on the symmetric group to which \texttt{self} belongs.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Permutation([1,2,3]).rank()
0
sage: Permutation([1, 2, 4, 6, 3, 5]).rank()
10
sage: perms = Permutations(6).list()
sage: [p.rank() for p in perms] == list(range(factorial(6)))
True
\end{verbatim}

\textbf{recoils()}

Return the list of the positions of the recoils of \texttt{self}.

A recoil of a permutation \(p\) is an integer \(i\) such that \(i+1\) appears to the left of \(i\) in \(p\). Here, the positions are being counted starting at 0. (Note that it is the positions, not the recoils themselves, which are being listed.)

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Permutation([1,4,3,2]).recoils()
[2, 3]
sage: Permutation([]).recoils()
[]
\end{verbatim}
recoils_composition()

Return the recoils composition of self.

The recoils composition of a permutation \( p \in S_n \) is the composition of \( n \) whose descent set is the set of the recoils of \( p \) (not their positions). In other words, this is the descents composition of \( p^{-1} \).

EXAMPLES:

```python
sage: Permutation([1,3,2,4]).recoils_composition()
[2, 2]
sage: Permutation([]).recoils_composition()
[]
```

reduced_word()

Return a reduced word of the permutation self.

See reduced_words() for the definition of reduced words and a way to compute them all.

**Warning:** This does not respect the multiplication convention.

EXAMPLES:

```python
sage: Permutation([3,5,4,6,2,1]).reduced_word()
[2, 1, 4, 3, 2, 4, 3, 5, 4, 5]
```

reduced_word_lexmin()

Return a lexicographically minimal reduced word of the permutation self.

See reduced_words() for the definition of reduced words and a way to compute them all.

EXAMPLES:

```python
sage: Permutation([3,4,2,1]).reduced_word_lexmin()
[1, 2, 1, 3, 2]
```

reduced_words()

Return a list of the reduced words of self.

The notion of a reduced word is based on the well-known fact that every permutation can be written as a product of adjacent transpositions. In more detail: If \( n \) is a nonnegative integer, we can define the transpositions \( s_i = (i, i+1) \in S_n \) for all \( i \in \{1, 2, \ldots, n-1\} \), and every \( p \in S_n \) can then be written as a product \( s_{i_1} s_{i_2} \cdots s_{i_k} \) for some sequence \( (i_1, i_2, \ldots, i_k) \) of elements of \( \{1, 2, \ldots, n-1\} \) (here \( \{1, 2, \ldots, n-1\} \) denotes the empty set when \( n \leq 1 \)). Fixing a \( p \), the sequences \( (i_1, i_2, \ldots, i_k) \) of smallest length satisfying \( p = s_{i_1} s_{i_2} \cdots s_{i_k} \) are called the reduced words of \( p \). (Their length is the Coxeter length of \( p \), and can be computed using length().)
Note that the product of permutations is defined here in such a way that \((pq)(i) = p(q(i))\) for all permutations \(p\) and \(q\) and each \(i \in \{1, 2, \ldots, n\}\) (this is the same convention as in \texttt{left_action_product()}, but not the default semantics of the \(\ast\) operator on permutations in Sage). Thus, for instance, \(s_2s_1\) is the permutation obtained by first transposing 1 with 2 and then transposing 2 with 3.

See also:
\texttt{reduced_word()}, \texttt{reduced_word_lexmin()}

\textbf{EXAMPLES:}

```
sage: Permutation([2,1,3]).reduced_words()
[[1]]
sage: Permutation([3,1,2]).reduced_words()
[[2, 1]]
sage: Permutation([3,2,1]).reduced_words()
[[1, 2, 1], [2, 1, 2]]
sage: Permutation([3,2,4,1]).reduced_words()
[[1, 2, 3, 1], [1, 2, 1, 3], [2, 1, 2, 3]]
```

\texttt{reduced_words_iterator()}

Return an iterator for the reduced words of \texttt{self}.

\textbf{EXAMPLES:}

```
sage: next(Permutation([5,2,3,4,1]).reduced_words_iterator())
[1, 2, 3, 4, 3, 2, 1]
```

\texttt{remove_extra_fixed_points()}

Return the permutation obtained by removing any fixed points at the end of \texttt{self}.

However, return [1] rather than [] if \texttt{self} is the identity permutation.

This is mostly a helper method for \texttt{sage.combinat.schubert_polynomial}, where it is used to normalize finitary permutations of \(\{1, 2, 3, \ldots\}\).

\textbf{EXAMPLES:}

```
sage: Permutation([2,1,3]).remove_extra_fixed_points()
[2, 1]
sage: Permutation([1,2,3,4]).remove_extra_fixed_points()
[1]
sage: Permutation([2,1,2]).remove_extra_fixed_points()
[2, 1]
sage: Permutation([]).remove_extra_fixed_points()
[1]
```

See also:
\texttt{retract_plain()}
\texttt{retract_direct_product}(\(m\))

Return the direct-product retract of the permutation \texttt{self} \(\in S_n\) to \(S_m\), where \(m \leq n\). If this retract is undefined, then \texttt{None} is returned.
If \( p \in S_n \) is a permutation, and \( m \) is a nonnegative integer less or equal to \( n \), then the direct-product retract of \( p \) to \( S_m \) is defined only if \( p([m]) = [m] \), where \([m]\) denotes the interval \( \{1, 2, \ldots, m\} \). In this case, it is defined as the permutation written \((p(1), p(2), \ldots, p(m))\) in one-line notation.

**EXAMPLES:**

```python
sage: Permutation([4,1,2,3,5]).retract_direct_product(4)
[4, 1, 2, 3]
sage: Permutation([4,1,2,3,5]).retract_direct_product(3)

sage: Permutation([1,4,2,3,6,5]).retract_direct_product(5)
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(4)
[1, 4, 2, 3]
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(3)

sage: all( p.retract_direct_product(3) == p for p in Permutations(3) )
True
```

See also:

- `retract_plain()`, `retract_okounkov_vershik()`

**retract_okounkov_vershik**

Return the Okounkov-Vershik retract of the permutation \( s \in S_n \) to \( S_m \), where \( m \leq n \).

If \( p \in S_n \) is a permutation, and \( m \) is a nonnegative integer less or equal to \( n \), then the Okounkov-Vershik retract of \( p \) to \( S_m \) is defined as the permutation in \( S_m \) which sends every \( i \in \{1, 2, \ldots, m\} \) to \( p^{k_i}(i) \), where \( k_i \) is the smallest positive integer \( k \) satisfying \( p^k(i) \leq m \).

In other words, the Okounkov-Vershik retract of \( p \) is the permutation whose disjoint cycle decomposition is obtained by removing all letters strictly greater than \( m \) from the decomposition of \( p \) into disjoint cycles (and removing all cycles which are emptied in the process).

When \( m = n - 1 \), the Okounkov-Vershik retract (as a map \( S_n \to S_{n-1} \)) is the map \( \tilde{p}_n \) introduced in Section 7 of [VO2005], and appears as (3.20) in [CST2010]. In the general case, the Okounkov-Vershik retract of a permutation in \( S_n \) to \( S_m \) can be obtained by first taking its Okounkov-Vershik retract to \( S_{n-1} \), then that of the resulting permutation to \( S_{n-2} \), etc. until arriving in \( S_m \).

**EXAMPLES:**

```python
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(4)
[4, 1, 2, 3]
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(3)
[3, 1, 2]
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(2)
[2, 1]
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(1)
[1]
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(0)
[]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(5)

(continues on next page)
```
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(4)
[1, 4, 2, 3, 5]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(3)
[1, 4, 2, 3]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(2)
[1, 4, 2, 3]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(1)
[1]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(0)
[]
sage: Permutation([6,5,4,3,2,1]).retract_okounkov_vershik(5)
[1, 5, 4, 3, 2]
sage: Permutation([6,5,4,3,2,1]).retract_okounkov_vershik(4)
[1, 2, 4, 3]
sage: Permutation([1,5,2,6,3,7,4,8]).retract_okounkov_vershik(4)
[1, 3, 2, 4]
sage: all( p.retract_direct_product(3) == p for p in Permutations(3) )
True

See also:
retract_plain(), retract_direct_product()

retract_plain(m)
Return the plain retract of the permutation self in $S_n$ to $S_m$, where $m \leq n$. If this retract is undefined, then None is returned.

If $p \in S_n$ is a permutation, and $m$ is a nonnegative integer less or equal to $n$, then the plain retract of $p$ to $S_m$ is defined only if every $i > m$ satisfies $p(i) = i$. In this case, it is defined as the permutation written $(p(1), p(2), \ldots, p(m))$ in one-line notation.

EXAMPLES:

sage: Permutation([4,1,2,3,5]).retract_plain(4)
[4, 1, 2, 3, 5]
sage: Permutation([4,1,2,3,5]).retract_plain(3)
[4, 1, 2, 3]

sage: Permutation([1,3,2,4,5,6]).retract_plain(3)
[1, 3, 2]

sage: all( p.retract_plain(3) == p for p in Permutations(3) )
True
See also:

retract_direct_product(), retract_okounkov_vershik(), remove_extra_fixed_points()

reverse()

Return the permutation obtained by reversing the list.

EXAMPLES:

```plaintext
sage: Permutation([3,4,1,2]).reverse()
[2, 1, 4, 3]
sage: Permutation([1,2,3,4,5]).reverse()
[5, 4, 3, 2, 1]
```

right_action_product(rp)

Return the permutation obtained by composing self with rp in such an order that self is applied first and rp is applied afterwards.

This is usually denoted by either self * rp or rp * self depending on the conventions used by the author. If the value of a permutation \( p \in S_n \) on an integer \( i \in \{1, 2, \ldots, n\} \) is denoted by \( p(i) \), then this should be denoted by \( rp \cdot self \) in order to have associativity (i.e., in order to have \( (p \cdot q)(i) = p(q(i)) \) for all \( p, q \) and \( i \)). If, on the other hand, the value of a permutation \( p \in S_n \) on an integer \( i \in \{1, 2, \ldots, n\} \) is denoted by \( i^p \), then this should be denoted by \( self \cdot rp \) in order to have associativity (i.e., in order to have \( i^{p \cdot q} = (i^p)^q \) for all \( p, q \) and \( i \)).

EXAMPLES:

```plaintext
sage: p = Permutation([2,1,3])
sage: q = Permutation([3,1,2])
sage: p.right_action_product(q)
[1, 3, 2]
sage: q.right_action_product(p)
[3, 2, 1]
```

right_permutohedron_interval(other)

Return the list of the permutations belonging to the right permutohedron interval where self is the minimal element and other the maximal element.

See permutohedron_lequal() for the definition of the permutohedron orders.

EXAMPLES:

```plaintext
sage: Permutation([2, 1, 4, 5, 3]).right_permutohedron_interval(Permutation([2, ˓→5, 4, 1, 3]))
[[2, 4, 5, 1, 3], [2, 4, 1, 5, 3], [2, 1, 4, 5, 3], [2, 1, 5, 4, 3], [2, 5, 1, ˓→4, 3], [2, 5, 4, 1, 3]]
```

right_permutohedron_interval_iterator(other)

Return an iterator on the permutations (represented as integer lists) belonging to the right permutohedron interval where self is the minimal element and other the maximal element.

See permutohedron_lequal() for the definition of the permutohedron orders.

EXAMPLES:

```plaintext
sage: Permutation([2, 1, 4, 5, 3]).right_permutohedron_interval_iterator(Permutation([2, ˓→5, 4, 1, 3])) # indirect doctest
```

(continues on next page)
right_tableau()
Return the right standard tableau after performing the RSK algorithm on self.

EXAMPLES:
```
sage: Permutation([1,4,3,2]).right_tableau()
[[1, 2], [3], [4]]
```

robinson_schensted()
Return the pair of standard tableaux obtained by running the Robinson-Schensted algorithm on self.
This can also be done by running RSK() on self (with the optional argument check_standard=True to return standard Young tableaux).

EXAMPLES:
```
sage: Permutation([6,2,3,1,7,5,4]).robinson_schensted()
[[[1, 3, 4], [2, 5], [6, 7]], [[1, 3, 5], [2, 6], [4, 7]]]
```

rothe_diagram()
Return the Rothe diagram of self.

EXAMPLES:
```
sage: p = Permutation([4,2,1,3])
sage: D = p.rothe_diagram(); D
[(0, 0), (0, 1), (0, 2), (1, 0)]
sage: D.pp()
 . . .
 . . .
 . . .
```

runs(as_tuple=False)
Return a list of the runs in the nonempty permutation self.
A run in a permutation is defined to be a maximal (with respect to inclusion) nonempty increasing substring (i.e., contiguous subsequence). For instance, the runs in the permutation [6,1,7,3,4,5,2] are [6], [1, 7], [3,4,5] and [2].
Runs in an empty permutation are not defined.

INPUT:
• as_tuple – boolean (default: False) choice of output format

OUTPUT:
a list of lists or a tuple of tuples

REFERENCES:
• http://mathworld.wolfram.com/PermutationRun.html

EXAMPLES:
The example from above:

```python
sage: Permutation([6,1,7,3,4,5,2]).runs()
[[6], [1, 7], [3, 4, 5], [2]]
sage: Permutation([6,1,7,3,4,5,2]).runs(as_tuple=True)
((6,), (1, 7), (3, 4, 5), (2,))
```

The number of runs in a nonempty permutation equals its number of descents plus 1:

```python
sage: all(len(p.runs()) == p.number_of_descents() + 1
.....: for p in Permutations(6) )
True
```

```
sage: Permutation([2,3,1,5,4]).saliances()
[3, 4]
sage: Permutation([5,4,3,2,1]).saliances()
[0, 1, 2, 3, 4]
```

```
sage: Permutation([]).shifted_concatenation(Permutation([]), "right")
[]
```

(continues on next page)
Combinatorics, Release 10.0

(continued from previous page)

```python
sage: Permutation([]).shifted_concatenation(Permutation([]), "left")
[]
sage: Permutation([2, 4, 1, 3]).shifted_concatenation(Permutation([3, 1, 2]),
            "right")
[2, 4, 1, 3, 7, 5, 6]
sage: Permutation([2, 4, 1, 3]).shifted_concatenation(Permutation([3, 1, 2]),
            "left")
[7, 5, 6, 2, 4, 1, 3]
```

**shifted_shuffle**(other)

Return the shifted shuffle of two permutations self and other.

**INPUT:**

- other – a permutation, a list, a tuple, or any iterable representing a permutation.

**OUTPUT:**

The list of the permutations appearing in the shifted shuffle of the permutations self and other.

**EXAMPLES:**

```python
sage: Permutation([]).shifted_shuffle(Permutation([]))
[]
sage: Permutation([1, 2, 3]).shifted_shuffle(Permutation([1]))
[[4, 1, 2, 3], [1, 2, 3, 4], [1, 2, 4, 3], [1, 4, 2, 3]]
sage: Permutation([1, 2]).shifted_shuffle(Permutation([2, 1]))
[[4, 1, 3, 2], [4, 3, 1, 2], [1, 4, 3, 2], [1, 4, 2, 3], [1, 2, 4, 3], [4, 1, 2, 3]]
sage: Permutation([1]).shifted_shuffle([1])
[[2, 1], [1, 2]]
sage: len(Permutation([3, 1, 5, 4, 2]).shifted_shuffle(Permutation([2, 1, 4])))
126
```

The shifted shuffle product is associative. We can test this on an admittedly toy example:

```python
sage: all( all( all( sorted(flatten([abs.shifted_shuffle(c)
                               ....:         for abs in a.shifted_shuffle(b)]))
                               ....:           == sorted(flatten([a.shifted_shuffle(bcs)
                               ....:               for bcs in b.shifted_shuffle(c)]))
                               ....:                   for c in Permutations(2) )
                               ....:               for b in Permutations(2) )
                               ....:           for a in Permutations(2) )
                           True
```

The shifted_shuffle method on permutations gives the same permutations as the shifted_shuffle method on words (but is faster):

```python
sage: all( all( sorted(p1.shifted_shuffle(p2))
                        ....:           == sorted([Permutation(p) for p in
                        ....:                       Word(p1).shifted_shuffle(Word(p2))])
                        ....:               for p2 in Permutations(3) )
                        ....:         for p1 in Permutations(2) )
                           True
```
show(\text{representation}='cycles', \text{orientation}='landscape', **\text{args})

Display the permutation as a drawing.

INPUT:

\begin{itemize}
  \item \text{representation} – different kinds of drawings are available
  \hspace{10pt} - "cycles" (default) – the permutation is displayed as a collection of directed cycles
  \hspace{10pt} - "braid" – the permutation is displayed as segments linking each element 1, ..., \(n\) to its image on a parallel line.
  \hspace{10pt} - When using this drawing, it is also possible to display the permutation horizontally (\text{orientation} = "landscape", default option) or vertically (\text{orientation} = "portrait").
  \hspace{10pt} - "chord-diagram" – the permutation is displayed as a directed graph, all of its vertices being located on a circle.
\end{itemize}

All additional arguments are forwarded to the show subcalls.

EXAMPLES:

\begin{verbatim}
sage: Permutations(20).random_element().show(\text{representation} = "cycles")
sage: Permutations(20).random_element().show(\text{representation} = "chord-diagram")
sage: Permutations(20).random_element().show(\text{representation} = "braid", \text{orientation} = "portrait")
\end{verbatim}

\textbf{sign()}

Return the signature of the permutation \texttt{self}. This is \((-1)^{\ell}\), where \(\ell\) is the number of inversions of \texttt{self}.

\textbf{Note:} \texttt{sign()} can be used as an alias for \texttt{signature().}

EXAMPLES:

\begin{verbatim}
sage: Permutation([4, 2, 3, 1, 5]).signature()
sage: Permutation([1,3,2,5,4]).sign()
sage: Permutation([]).sign()
\end{verbatim}

\textbf{signature()}

Return the signature of the permutation \texttt{self}. This is \((-1)^{\ell}\), where \(\ell\) is the number of inversions of \texttt{self}.

\textbf{Note:} \texttt{sign()} can be used as an alias for \texttt{signature().}

EXAMPLES:

\begin{verbatim}
sage: Permutation([4, 2, 3, 1, 5]).signature()
sage: Permutation([1,3,2,5,4]).sign()
sage: Permutation([]).sign()
\end{verbatim}
**simion_schmidt(avoid=[1, 2, 3])**

Implements the Simion-Schmidt map which sends an arbitrary permutation to a pattern avoiding permutation, where the permutation pattern is one of four length-three patterns. This method also implements the bijection between (for example) [1,2,3]- and [1,3,2]-avoiding permutations.

**INPUT:**

- `avoid` – one of the patterns [1,2,3], [1,3,2], [3,1,2], [3,2,1].

**EXAMPLES:**

```python
sage: P = Permutations(6)
sage: p = P([4,5,1,6,3,2])
sage: pl = [ [1,2,3], [1,3,2], [3,1,2], [3,2,1] ]
sage: for q in pl:
....:     s = p.simion_schmidt(q)
....:     print("{} {}\n&s, s.has_pattern(q)))
[4, 6, 1, 5, 3, 2] False
[4, 2, 1, 3, 5, 6] False
[4, 5, 3, 6, 2, 1] False
[4, 5, 1, 6, 2, 3] False
```

**size()**

Return the size of `self`.

**EXAMPLES:**

```python
sage: Permutation([3,4,1,2,5]).size()
5
```

**stack_sort()**

Return the stack sort of a permutation.

This is another permutation obtained through the process of sorting using one stack. If the result is the identity permutation, the original permutation is stack-sortable.

See [Wikipedia article Stack-sortable_permutation](https://en.wikipedia.org/wiki/Stack-sortable_permutation)

**EXAMPLES:**

```python
sage: p = Permutation([2,1,5,3,4,9,7,8,6])
sage: p.stack_sort()
[1, 2, 3, 4, 5, 7, 6, 8, 9]
sage: S5 = Permutations(5)
sage: len([1 for s in S5 if s.stack_sort() == S5.one()])
42
```

**sylvester_class(left_to_right=False)**

Iterate over the equivalence class of the permutation `self` under sylvester congruence.

Sylvester congruence is an equivalence relation on the set $S_n$ of all permutations of $n$. It is defined as the smallest equivalence relation such that every permutation of the form $uacbvw$ with $u$, $v$ and $w$ being words and $a$, $b$ and $c$ being letters satisfying $a \leq b < c$ is equivalent to the permutation $ucbavw$. (Here, permutations are regarded as words by way of one-line notation.) This definition comes from [HNT2005], Definition 8, where it is more generally applied to arbitrary words.
The equivalence class of a permutation \( p \in S_n \) under sylvester congruence is called the **sylvester class** of \( p \). It is an interval in the right permutohedron order (see `permutohedron_lequal()`) on \( S_n \).

This is related to the `sylvester_class()` method in that the equivalence class of a permutation \( \pi \) under sylvester congruence is the sylvester class of the right-to-left binary search tree of \( \pi \). However, the present method yields permutations, while the method on labelled binary trees yields plain lists.

If the variable `left_to_right` is set to `True`, the method instead iterates over the equivalence class of `self` with respect to the left sylvester congruence. The left sylvester congruence is easiest to define by saying that two permutations are equivalent under it if and only if their reverses (`reverse()`) are equivalent under (standard) sylvester congruence.

**EXAMPLES:**

The sylvester class of a permutation in \( S_5 \):

```python
sage: p = Permutation([3, 5, 1, 2, 4])
sage: sorted(p.sylvester_class())
[[1, 3, 2, 5, 4],
 [1, 3, 5, 2, 4],
 [1, 5, 3, 2, 4],
 [3, 1, 2, 5, 4],
 [3, 1, 5, 2, 4],
 [3, 5, 1, 2, 4],
 [5, 1, 3, 2, 4],
 [5, 3, 1, 2, 4]]
```

The sylvester class of a permutation \( p \) contains \( p \):

```python
sage: all( p in p.sylvester_class() for p in Permutations(4) )
True
```

Small cases:

```python
sage: list(Permutation([]).sylvester_class())
[[[]]]
sage: list(Permutation([1]).sylvester_class())
[[[1]]]
```

The sylvester classes in \( S_3 \):

```python
sage: [sorted(p.sylvester_class()) for p in Permutations(3)]
[[[1, 2, 3]],
 [[1, 3, 2], [3, 1, 2]],
 [[2, 1, 3]],
 [[2, 3, 1]],
 [[1, 3, 2], [3, 1, 2]],
 [[3, 2, 1]]]
```

The left sylvester classes in \( S_3 \):

```python
sage: [sorted(p.sylvester_class(left_to_right=True)) for p in Permutations(3)]
[[[1, 2, 3]],
 [[1, 3, 2]],
 [[2, 1, 3], [2, 3, 1]],
 (continues on next page)
A left sylvester class in $S_5$:

```
sage: p = Permutation([4, 2, 1, 5, 3])
sage: sorted(p.sylvester_class(left_to_right=True))
[[4, 2, 1, 3, 5],
 [4, 2, 1, 5, 3],
 [4, 2, 3, 1, 5],
 [4, 2, 3, 5, 1],
 [4, 2, 5, 1, 3],
 [4, 2, 5, 3, 1],
 [4, 5, 2, 1, 3],
 [4, 5, 2, 3, 1]]
```

to_alternating_sign_matrix()

Return a matrix representing the permutation in the AlternatingSignMatrix class.

EXAMPLES:

```
sage: m = Permutation([1,2,3]).to_alternating_sign_matrix(); m
[1 0 0]
[0 1 0]
[0 0 1]
sage: parent(m)
Alternating sign matrices of size 3
```

to_cycles(singletons=True, use_min=True)

Return the permutation self as a list of disjoint cycles.

The cycles are returned in the order of increasing smallest elements, and each cycle is returned as a tuple which starts with its smallest element.

If singletons=False is given, the list does not contain the singleton cycles.

If use_min=False is given, the cycles are returned in the order of increasing largest (not smallest) elements, and each cycle starts with its largest element.

EXAMPLES:

```
sage: Permutation([2,1,3,4]).to_cycles()
[(1, 2), (3,), (4,)]
sage: Permutation([2,1,3,4]).to_cycles(singletons=False)
[(1, 2)]
sage: Permutation([2,1,3,4]).to_cycles(use_min=True)
[(1, 2), (3,), (4,)]
sage: Permutation([2,1,3,4]).to_cycles(use_min=False)
[(4,), (3,), (2, 1)]
sage: Permutation([2,1,3,4]).to_cycles(singletons=False, use_min=False)
[(2, 1)]
sage: Permutation([4,1,5,2,6,3]).to_cycles()
[(1, 4, 2), (3, 5, 6)]
```
sage: Permutation([4,1,5,2,6,3]).to_cycles(use_min=False)
[(6, 3, 5), (4, 2, 1)]

sage: Permutation([6, 4, 5, 2, 3, 1]).to_cycles()
[(1, 6), (2, 4), (3, 5)]

sage: Permutation([6, 4, 5, 2, 3, 1]).to_cycles(use_min=False)
[(6, 1), (5, 3), (4, 2)]

The algorithm is of complexity $O(n)$ where $n$ is the size of the given permutation.

**to_digraph()**

Return a digraph representation of self.

**EXAMPLES:**

```python
sage: d = Permutation([3, 1, 2]).to_digraph()
sage: d.edges(sort=True, labels=False)
[(1, 3), (2, 1), (3, 2)]
sage: P = Permutations(range(1, 10))
sage: d = Permutation(P.random_element()).to_digraph()
sage: all(c.is_cycle() for c in d.strongly_connected_components_subgraphs())
True
```

**to_inversion_vector()**

Return the inversion vector of self.

The inversion vector of a permutation $p \in S_n$ is defined as the vector $(v_1, v_2, \ldots, v_n)$, where $v_i$ is the number of elements larger than $i$ that appear to the left of $i$ in the permutation $p$.

The algorithm is of complexity $O(n \log(n))$ where $n$ is the size of the given permutation.

**EXAMPLES:**

```python
sage: Permutation([5,9,1,8,2,6,4,7,3]).to_inversion_vector()
[2, 3, 6, 4, 0, 2, 2, 1, 0]
sage: Permutation([8,7,2,1,9,4,6,5,10,3]).to_inversion_vector()
[3, 2, 7, 3, 4, 3, 1, 0, 0, 0]
sage: Permutation([3,2,4,1,5]).to_inversion_vector()
[3, 1, 0, 0, 0]
```

**to_lehmer_cocode()**

Return the Lehmer cocode of the permutation self.

The Lehmer cocode of a permutation $p$ is defined as the list $(c_1, c_2, \ldots, c_n)$, where $c_i$ is the number of $j < i$ such that $p(j) > p(i)$.

**EXAMPLES:**

```python
sage: p = Permutation([2,1,3])
sage: p.to_lehmer_cocode()
[0, 1, 0]
sage: q = Permutation([3,1,2])
sage: q.to_lehmer_cocode()
[0, 1, 1]
```
to_lehmer_code()

Return the Lehmer code of the permutation self.

The Lehmer code of a permutation \( p \) is defined as the list \([c[1], c[2], ..., c[n]]\), where \( c[i] \) is the number of \( j > i \) such that \( p(j) < p(i) \).

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: p.to_lehmer_code()
[1, 0, 0]
sage: q = Permutation([3,1,2])
sage: q.to_lehmer_code()
[2, 0, 0]
sage: Permutation([1]).to_lehmer_code()
[0]
sage: Permutation([]).to_lehmer_code()
[]
```

to_major_code(final_descent=False)

Return the major code of the permutation self.

The major code of a permutation \( p \) is defined as the sequence \((m_1 - m_2, m_2 - m_3, \ldots, m_n)\), where \( m_i \) is the major index of the permutation obtained by erasing all letters smaller than \( i \) from \( p \).

With the final_descent option, the last position of a non-empty permutation is also considered as a descent. This has an effect on the computation of major indices.

REFERENCES:

EXAMPLES:

```
sage: Permutation([9,3,5,7,2,1,4,6,8]).to_major_code()
[5, 0, 1, 0, 1, 2, 0, 1, 0]
sage: Permutation([2,8,4,3,6,7,9,5,1]).to_major_code()
[8, 3, 3, 1, 4, 0, 1, 0, 0]
```

to_matrix()

Return a matrix representing the permutation.

EXAMPLES:

```
sage: Permutation([1,2,3]).to_matrix()
[1 0 0]
[0 1 0]
[0 0 1]
```

Alternatively:

```
sage: matrix(Permutation([1,3,2]))
[1 0 0]
```

(continues on next page)
Notice that matrix multiplication corresponds to permutation multiplication only when the permutation option mult='r2l'.

```sage
sage: Permutations.options.mult='r2l'
sage: p = Permutation([2,1,3])
sage: q = Permutation([3,1,2])
sage: (p*q).to_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
sage: p.to_matrix()*q.to_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
sage: Permutations.options.mult='l2r'
sage: (p*q).to_matrix()
[1 0 0]
[0 0 1]
[0 1 0]
```

**to_permutation_group_element()**

Return a PermutationGroupElement equal to self.

EXAMPLES:

```sage
sage: Permutation([2,1,4,3]).to_permutation_group_element()
(1,2)(3,4)
sage: Permutation([1,2,3]).to_permutation_group_element()
()""
```

**to_tableau_by_shape**(shape)

Return a tableau of shape shape with the entries in self. The tableau is such that the reading word (i.e., the word obtained by reading the tableau row by row, starting from the top row in English notation, with each row being read from left to right) is self.

EXAMPLES:

```sage
sage: Permutation([3,4,1,2,5]).to_tableau_by_shape([3,2])
[[1, 2, 5], [3, 4]]
sage: Permutation([3,4,1,2,5]).to_tableau_by_shape([3,2]).reading_word_
˓→permutation()
[3, 4, 1, 2, 5]
```

**weak_excedences()**

Return all the numbers self[i] such that self[i] >= i+1.

EXAMPLES:

```sage
sage: Permutation([1,4,3,2,5]).weak_excedences()
[1, 4, 3, 5]
```
class sage.combinat.permutation.Permutations

Bases: UniqueRepresentation, Parent

Permutations.

Permutations(n) returns the class of permutations of n, if n is an integer, list, set, or string.

Permutations(n, k) returns the class of length-k partial permutations of n (where n is any of the above things); k must be a nonnegative integer. A length-\(k\) partial permutation of \(n\) is defined as a \(k\)-tuple of pairwise distinct elements of \(\{1, 2, \ldots, n\}\).

Permutations(descents=(list, n)) returns the class of permutations of \(n\) with descents in the positions specified by list. This uses the slightly nonstandard convention that the images of \(1, 2, \ldots, n\) under the permutation are regarded as positions \(0, 1, \ldots, n - 1\), so for example the presence of \(1\) in list signifies that the permutations \(\pi\) should satisfy \(\pi(2) > \pi(3)\). Note that list is supposed to be a list of positions of the descents, not the descents composition. It does not return the class of permutations with descents composition list.

Permutations(bruhat_smaller=p) and Permutations(bruhat_greater=p) return the class of permutations smaller-or-equal or greater-or-equal, respectively, than the given permutation \(p\) in the Bruhat order. (The Bruhat order is defined in \(\text{bruhat_lequal()}\). It is also referred to as the strong Bruhat order.)

Permutations(recoils=p) returns the class of permutations whose recoils composition is \(p\). Unlike the descents=(list, n) syntax, this actually takes a composition as input.

Permutations(recoils_fatter=p) and Permutations(recoils_finer=p) return the class of permutations whose recoils composition is fatter or finer, respectively, than the given composition \(p\).

Permutations(n, avoiding=P) returns the class of permutations of \(n\) avoiding \(P\). Here \(P\) may be a single permutation or a list of permutations; the returned class will avoid all patterns in \(P\).

EXAMPLES:

```
sage: p = Permutations(3); p
Standard permutations of 3
sage: p.list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]

sage: p = Permutations(3, 2); p
Permutations of {1,...,3} of length 2
sage: p.list()
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]

sage: p = Permutations(['c', 'a', 't']); p
Permutations of the set ['c', 'a', 't']
sage: p.list()
[['c', 'a', 't'], ['c', 't', 'a'], ['a', 'c', 't'], ['a', 't', 'c'], ['t', 'c', 'a'], ['t', 'a', 'c']]

sage: p = Permutations(['c', 'a', 't'], 2); p
Permutations of the set ['c', 'a', 't'] of length 2
```

(continues on next page)
sage: p.list()
[['c', 'a'], ['c', 't'], ['a', 'c'], ['a', 't'], ['t', 'c'], ['t', 'a']]

sage: p = Permutations([1,1,2]); p
Permutations of the multi-set [1, 1, 2]
sage: p.list()
[[1, 1, 2], [1, 2, 1], [2, 1, 1]]

sage: p = Permutations([1,1,2], 2); p
Permutations of the multi-set [1, 1, 2] of length 2
sage: p.list()
[[1, 1], [1, 2], [2, 1]]

sage: p = Permutations(descents=((1), 4)); p
Standard permutations of 4 with descents [1]
sage: p.list()
[[2, 4, 1, 3], [3, 4, 1, 2], [1, 4, 2, 3], [1, 3, 2, 4], [2, 3, 1, 4]]

sage: p = Permutations(bruhat_smaller=[1,3,2,4]); p
Standard permutations that are less than or equal to [1, 3, 2, 4] in the Bruhat order
sage: p.list()
[[1, 2, 3, 4], [1, 3, 2, 4]]

sage: p = Permutations(bruhat_greater=[4,2,3,1]); p
Standard permutations that are greater than or equal to [4, 2, 3, 1] in the Bruhat order
sage: p.list()
[[4, 2, 3, 1], [4, 3, 2, 1]]

sage: p = Permutations(recoils_finer=[2,1]); p
Standard permutations whose recoils composition is finer than [2, 1]
sage: p.list()
[[3, 1, 2], [1, 3, 2]]

sage: p = Permutations(recoils_fatter=[2,1]); p
Standard permutations whose recoils composition is fatter than [2, 1]
sage: p.list()
[[3, 1, 2], [3, 2, 1], [1, 3, 2]]

sage: p = Permutations(recoils=[2,1]); p
Standard permutations whose recoils composition is [2, 1]
sage: p.list()
[[3, 1, 2], [1, 3, 2]]

sage: p = Permutations(4, avoiding=[1,3,2]); p
Standard permutations of 4 avoiding [[1, 3, 2]]
\[ [4, 2, 1, 3], \\
[4, 2, 3, 1], \\

**Element**

alias of **Permutation**

```python
options = Current options for Permutations - display: list - generator_name: s - latex: list - latex_empty_str: 1 - mult: l2r
```

class **sage.combinat.permutation.PermutationsNK**(s, k)

Bases: **Permutations_setk**

This exists solely for unpickling **PermutationsNK** objects created with Sage <= 6.3.

class **sage.combinat.permutation.Permutations_mset**(mset)

Bases: **Permutations**

Permutations of a multiset \( M \).

A permutation of a multiset \( M \) is represented by a list that contains exactly the same elements as \( M \) (with the same multiplicities), but possibly in different order. If \( M \) is a proper set there are \(|M|!\) such permutations. Otherwise, if the first element appears \( k_1 \) times, the second element appears \( k_2 \) times and so on, the number of permutations is \(|M|!/(k_1!k_2!...))\), which is sometimes called a multinomial coefficient.

**EXAMPLES:**

```python
sage: mset = [1,1,2,2,2]
```

```python
sage: from sage.combinat.permutation import Permutations_mset
sage: P = Permutations_mset(mset); P \\
Permutations of the multi-set [1, 1, 2, 2, 2]
```

```python
sage: sorted(P) \\
[[1, 1, 2, 2, 2], \\
 [1, 2, 1, 2, 2], \\
 [1, 2, 2, 1, 2], \\
 [1, 2, 2, 2, 1], \\
 [2, 1, 2, 2, 2], \\
 [2, 2, 1, 2, 2], 
```
[2, 1, 2, 1, 2],
[2, 1, 2, 2, 1],
[2, 2, 1, 1, 2],
[2, 2, 1, 2, 1],
[2, 2, 2, 1, 1]]
sage: MS = MatrixSpace(GF(2),2,2)
sage: A = MS([1,0,1,1])
sage: rows = A.rows()
sage: rows[0].set_immutable()
sage: rows[1].set_immutable()
sage: P = Permutations_mset(rows); P
Permutations of the multi-set [(1, 0), (1, 1)]
sage: sorted(P)
[[((1, 0), (1, 1)), ((1, 1), (1, 0))]

class Element
   Bases: ClonableArray
   A permutation of an arbitrary multiset.
   check()
      Verify that self is a valid permutation of the underlying multiset.
      EXAMPLES:
      sage: S = Permutations(['c','a','c'])
      sage: elt = S(['c','c','a'])
      sage: elt.check()

cardinality()
   Return the cardinality of the set.
   EXAMPLES:
   sage: Permutations([1,2,2]).cardinality()
   3
   sage: Permutations([1,1,2,2,2]).cardinality()
   10

rank(p)
   Return the rank of p in lexicographic order.
   INPUT:
      * p – a permutation of M
   ALGORITHM:
The algorithm uses the recurrence from the solution to exercise 4 in [Knu2011], Section 7.2.1.2:

$$\text{rank}(p_1 \ldots p_n) = \text{rank}(p_2 \ldots p_n) + \frac{1}{n} \binom{n}{n_1, \ldots, n_t} \sum_{j=1}^{t} n_j \left[x_j < p_1\right],$$

where $x_j, n_j$ are the distinct elements of $p$ with their multiplicities, $n$ is the sum of $n_1, \ldots, n_t$, $\binom{n}{n_1, \ldots, n_t}$ is the multinomial coefficient $\frac{n!}{n_1! \cdots n_t!}$, and $\sum_{j=1}^{t} n_j \left[x_j < p_1\right]$ means “the number of elements to the right of the first element that are less than the first element”.

5.1. Comprehensive Module List 1901
EXAMPLES:

```python
sage: mset = [1, 1, 2, 3, 4, 5, 5, 6, 9]
sage: p = Permutations(mset)
sage: p.rank(list(sorted(mset)))
0
sage: p.rank(list(reversed(sorted(mset)))) == p.cardinality() - 1
True
sage: p.rank([3, 1, 4, 1, 5, 9, 2, 6, 5])
30991
```

unrank($r$)

Return the permutation of $M$ having lexicographic rank $r$.

**INPUT:**

- $r$ – an integer between 0 and self.cardinality()-1 inclusive

**ALGORITHM:**

The algorithm is adapted from the solution to exercise 4 in [Knu2011], Section 7.2.1.2.

EXAMPLES:

```python
sage: mset = [1, 1, 2, 3, 4, 5, 5, 6, 9]
sage: p = Permutations(mset)
sage: p.unrank(30991)
[3, 1, 4, 1, 5, 9, 2, 6, 5]
sage: p.rank(p.unrank(10))
10
sage: p.unrank(0) == list(sorted(mset))
True
sage: p.unrank(p.cardinality()-1) == list(reversed(sorted(mset)))
True
```

class sage.combinat.permutation.Permutations_msetk(mset, k)

Bases: Permutations_mset

Length-$k$ partial permutations of a multiset.

A length-$k$ partial permutation of a multiset $M$ is represented by a list of length $k$ whose entries are elements of $M$, appearing in the list with a multiplicity not higher than their respective multiplicity in $M$.

**cardinality()**

Return the cardinality of the set.

**EXAMPLES:**

```python
sage: Permutations([1,2,2],2).cardinality()
3
```

class sage.combinat.permutation.Permutations_nk(n, k)

Bases: Permutations

Length-$k$ partial permutations of $\{1, 2, \ldots, n\}$.

**class Element**

Bases: ClonableArray

A length-$k$ partial permutation of $[n]$. 

1902 Chapter 5. Comprehensive Module List
check()
Verify that \texttt{self} is a valid length-$k$ partial permutation of $[n]$.

\textbf{EXAMPLES:}
\begin{verbatim}
sage: S = Permutations(4, 2)
sage: elt = S([3, 1])
sage: elt.check()
\end{verbatim}

cardinality()
\textbf{EXAMPLES:}
\begin{verbatim}
sage: Permutations(3,0).cardinality()
1
sage: Permutations(3,1).cardinality()
3
sage: Permutations(3,2).cardinality()
6
sage: Permutations(3,3).cardinality()
6
sage: Permutations(3,4).cardinality()
0
\end{verbatim}

random_element()
\textbf{EXAMPLES:}
\begin{verbatim}
sage: s = Permutations(3,2).random_element()
sage: s in Permutations(3,2)
True
\end{verbatim}

class \texttt{sage.combinat.permutation.Permutations\_set}(s)
Bases: \texttt{Permutations}
Permutations of an arbitrary given finite set.
Here, a “permutation of a finite set $S$” means a list of the elements of $S$ in which every element of $S$ occurs exactly once. This is not to be confused with bijections from $S$ to $S$, which are also often called permutations in literature.

class \texttt{Element}
Bases: \texttt{ClonableArray}
A permutation of an arbitrary set.
check()
Verify that \texttt{self} is a valid permutation of the underlying set.

\textbf{EXAMPLES:}
\begin{verbatim}
sage: S = Permutations(['c','a','t'])
sage: elt = S(['t','c','a'])
sage: elt.check()
\end{verbatim}

cardinality()
Return the cardinality of the set.

\textbf{EXAMPLES:}
sage: Permutations([1,2,3]).cardinality()
6

random_element()
EXAMPLES:

sage: s = Permutations([1,2,3]).random_element()
sage: s.parent() is Permutations([1,2,3])
True

class sage.combinat.permutation.Permutations_setk(s, k)
Bases: Permutations_set

Length-\(k\) partial permutations of an arbitrary given finite set.

Here, a “length-\(k\) partial permutation of a finite set \(S\)” means a list of length \(k\) whose entries are pairwise distinct and all belong to \(S\).

random_element()
EXAMPLES:

sage: s = Permutations([1,2,4], 2).random_element()
sage: s in Permutations([1,2,4], 2)
True

class sage.combinat.permutation.StandardPermutations_all
Bases: Permutations

All standard permutations.

graded_component(n)
Return the graded component.

EXAMPLES:

sage: P = Permutations()
sage: P.graded_component(4) == Permutations(4)
True

class sage.combinat.permutation.StandardPermutations_all_avoiding(a)
Bases: StandardPermutations_all

All standard permutations avoiding a set of patterns.

patterns()
Return the patterns avoided by this class of permutations.

EXAMPLES:

sage: P = Permutations(avoiding=[[2,1,3],[1,2,3]])
sage: P.patterns()
([2, 1, 3], [1, 2, 3])

class sage.combinat.permutation.StandardPermutations_avoiding_12(n)
Bases: StandardPermutations_avoiding_generic
cardinality()

Return the cardinality of self.

EXAMPLES:

```python
sage: P = Permutations(3, avoiding=[1, 2])
sage: P.cardinality()
1
```

class sage.combinat.permutation.StandardPermutations_avoiding_123(n)

Bases: StandardPermutations_avoiding_generic
cardinality()

EXAMPLES:

```python
sage: Permutations(5, avoiding=[1, 2, 3]).cardinality()
42
sage: len( Permutations(5, avoiding=[1, 2, 3]).list() )
42
```

class sage.combinat.permutation.StandardPermutations_avoiding_132(n)

Bases: StandardPermutations_avoiding_generic
cardinality()

EXAMPLES:

```python
sage: Permutations(5, avoiding=[1, 3, 2]).cardinality()
42
sage: len( Permutations(5, avoiding=[1, 3, 2]).list() )
42
```

class sage.combinat.permutation.StandardPermutations_avoiding_21(n)

Bases: StandardPermutations_avoiding_generic
cardinality()

Return the cardinality of self.

EXAMPLES:

```python
sage: P = Permutations(3, avoiding=[2, 1])
sage: P.cardinality()
1
```

class sage.combinat.permutation.StandardPermutations_avoiding_213(n)

Bases: StandardPermutations_avoiding_generic
cardinality()

EXAMPLES:

```python
sage: Permutations(5, avoiding=[2, 1, 3]).cardinality()
42
sage: len( Permutations(5, avoiding=[2, 1, 3]).list() )
42
```
class sage.combinat.permutation.StandardPermutations_avoiding_231(n)
    Bases: StandardPermutations_avoiding_generic

    cardinality()
    EXAMPLES:

    sage: Permutations(5, avoiding=[2, 3, 1]).cardinality()
    42
    sage: len( Permutations(5, avoiding=[2, 3, 1]).list() )
    42

class sage.combinat.permutation.StandardPermutations_avoiding_312(n)
    Bases: StandardPermutations_avoiding_generic

    cardinality()
    EXAMPLES:

    sage: Permutations(5, avoiding=[3, 1, 2]).cardinality()
    42
    sage: len( Permutations(5, avoiding=[3, 1, 2]).list() )
    42

class sage.combinat.permutation.StandardPermutations_avoiding_321(n)
    Bases: StandardPermutations_avoiding_generic

    cardinality()
    EXAMPLES:

    sage: Permutations(5, avoiding=[3, 2, 1]).cardinality()
    42
    sage: len( Permutations(5, avoiding=[3, 2, 1]).list() )
    42

class sage.combinat.permutation.StandardPermutations_avoiding_generic(n, a)
    Bases: StandardPermutations_n_abstract

    Generic class for subset of permutations avoiding a set of patterns.

    property a
        self.a is deprecated; use patterns() instead.

    cardinality()
        Return the cardinality of self.
        EXAMPLES:

        sage: P = Permutations(3, avoiding=[[2, 1, 3],[1,2,3]])
        sage: P.cardinality()
        4

    patterns()
        Return the patterns avoided by this class of permutations.
        EXAMPLES:
```python
sage: P = Permutations(3, avoiding=[[2,1,3],[1,2,3]])
sage: P.patterns()
([2, 1, 3], [1, 2, 3])
```

class sage.combinat.permutation.StandardPermutations_bruhat_greater(p)

Bases: Permutations

Permutations of \(\{1, \ldots, n\}\) that are greater than or equal to a permutation \(p\) in the Bruhat order.

class sage.combinat.permutation.StandardPermutations_bruhat_smaller(p)

Bases: Permutations

Permutations of \(\{1, \ldots, n\}\) that are less than or equal to a permutation \(p\) in the Bruhat order.

class sage.combinat.permutation.StandardPermutations_descents(d, n)

Bases: StandardPermutations_n_abstract

Permutations of \(\{1, \ldots, n\}\) with a fixed set of descents.

cardinality()

Return the cardinality of self.

ALGORITHM:

The algorithm described in [Vie1979] is implemented naively.

EXAMPLES:

```python
sage: P = Permutations(descents=(\[1,0,2\], 5))
sage: P.cardinality()
4
```

first()

Return the first permutation with descents \(d\).

EXAMPLES:

```python
sage: Permutations(descents=(\[1,0,4,8\],12)).first()
[3, 2, 1, 4, 6, 5, 7, 8, 10, 9, 11, 12]
```

last()

Return the last permutation with descents \(d\).

EXAMPLES:

```python
sage: Permutations(descents=(\[1,0,4,8\],12)).last()
[12, 11, 8, 9, 10, 4, 5, 6, 7, 1, 2, 3]
```

class sage.combinat.permutation.StandardPermutations_n(n)

Bases: StandardPermutations_n_abstract

Permutations of the set \(\{1,2,\ldots,n\}\).

These are also called permutations of size \(n\), or the elements of the \(n\)-th symmetric group.

Todo: Have a reduced_word() which works in both multiplication conventions.

5.1. Comprehensive Module List
class `Element`(*parent, l, check=True*)

**Bases:** `Permutation`

- `apply_simple_reflection_left(i)`
  - Return `self` multiplied by the simple reflection `s[i]` on the left.
  - This acts by switching the entries in positions `i` and `i + 1`.

**Warning:** This ignores the multiplication convention in order to be consistent with other Coxeter operations in permutations (e.g., computing `reduced_word()`).

**EXAMPLES:**

```
sage: W = Permutations(3)
sage: w = W([2,3,1])
sage: w.apply_simple_reflection_left(1)
[1, 3, 2]
sage: w.apply_simple_reflection_left(2)
[3, 2, 1]
```

- `apply_simple_reflection_right(i)`
  - Return `self` multiplied by the simple reflection `s[i]` on the right.
  - This acts by switching the entries `i` and `i + 1`.

**Warning:** This ignores the multiplication convention in order to be consistent with other Coxeter operations in permutations (e.g., computing `reduced_word()`).

**EXAMPLES:**

```
sage: W = Permutations(3)
sage: w = W([2,3,1])
sage: w.apply_simple_reflection_right(1)
[3, 2, 1]
sage: w.apply_simple_reflection_right(2)
[2, 1, 3]
```

- `has_left_descent(i, multi=None)`
  - Check if `i` is a left descent of `self`.
  - A left descent of a permutation `π ∈ Sn` means an index `i ∈ {1, 2, ..., n−1}` such that `s_i π` has smaller length than `π`. Thus, a left descent of `π` is an index `i ∈ {1, 2, ..., n−1}` satisfying `π−1(i) > π−1(i+1)`.

**Warning:** The methods `descents()` and `idescents()` behave differently than their Weyl group counterparts. In particular, the indexing is 0-based. This could lead to errors. Instead, construct the descent set as in the example.

**Warning:** This ignores the multiplication convention in order to be consistent with other Coxeter operations in permutations (e.g., computing `reduced_word()`).
EXAMPLES:

```python
sage: P = Permutations(4)
sage: x = P([3, 2, 4, 1])
sage: (~x).descents()
[1, 2]
sage: [i for i in P.index_set() if x.has_left_descent(i)]
[1, 2]
```

`has_right_descent(i, mult=None)`

Check if \( i \) is a right descent of \( self \).

A right descent of a permutation \( \pi \in S_n \) means an index \( i \in \{1, 2, \ldots, n - 1\} \) such that \( \pi \circ s_i \) has smaller length than \( \pi \). Thus, a right descent of \( \pi \) is an index \( i \in \{1, 2, \ldots, n - 1\} \) satisfying \( \pi(i) > \pi(i + 1) \).

**Warning:** The methods `descents()` and `idescents()` behave differently than their Weyl group counterparts. In particular, the indexing is 0-based. This could lead to errors. Instead, construct the descent set as in the example.

**Warning:** This ignores the multiplication convention in order to be consistent with other Coxeter operations in permutations (e.g., computing `reduced_word()`).

EXAMPLES:

```python
sage: P = Permutations(4)
sage: x = P([3, 2, 4, 1])
sage: x.descents()
[1, 3]
sage: [i for i in P.index_set() if x.has_right_descent(i)]
[1, 3]
```

`inverse()`

Return the inverse of `self`.

EXAMPLES:

```python
sage: P = Permutations(4)
sage: w0 = P([4, 3, 2, 1])
sage: w0.inverse() == w0
True
sage: w0.inverse().parent() is P
True
sage: P([3, 2, 4, 1]).inverse()
[4, 2, 1, 3]
```

`algebra(base_ring, category=None)`

Return the symmetric group algebra associated to `self`.

**INPUT:**

- `base_ring` -- a ring
• **category** – a category (default: the category of *self*)

**EXAMPLES:**

```python
sage: P = Permutations(4)
sage: A = P.algebra(QQ); A
Symmetric group algebra of order 4 over Rational Field

sage: A.category()
Join of Category of coxeter group algebras over Rational Field
    and Category of finite group algebras over Rational Field
    and Category of finite dimensional cellular algebras with basis over Rational Field

sage: A = P.algebra(QQ, category=Monoids())
sage: A.category()
Category of finite dimensional cellular monoid algebras over Rational Field
```

**as_permutation_group()**

Return *self* as a permutation group.

**EXAMPLES:**

```python
sage: P = Permutations(4)
sage: PG = P.as_permutation_group()
sage: PG
Symmetric group of order 4! as a permutation group

sage: G = SymmetricGroup(4)
sage: PG is G
True
```

**cardinality()**

Return the number of permutations of size *n*, which is *n*!.

**EXAMPLES:**

```python
sage: Permutations(0).cardinality()
1
sage: Permutations(3).cardinality()
6
sage: Permutations(4).cardinality()
24
```

**cartan_type()**

Return the Cartan type of *self*.

The symmetric group *S*ₙ is a Coxeter group of type *A*ₙ₋₁.

**EXAMPLES:**

```python
sage: A = SymmetricGroup([2,3,7]); A.cartan_type()
['A', 2]
sage: A = SymmetricGroup([]); A.cartan_type()
['A', 0]
```
codegrees()

Return the codegrees of self.

EXAMPLES:

```
sage: Permutations(3).codegrees()
(0, 1)
sage: Permutations(7).codegrees()
(0, 1, 2, 3, 4, 5)
```

conjugacy_class(g)

Return the conjugacy class of g in self.

INPUT:

- g – a partition or an element of self

EXAMPLES:

```
sage: G = Permutations(5)
sage: g = G([2,3,4,1,5])
sage: G.conjugacy_class(g)
Conjugacy class of cycle type [4, 1] in Standard permutations of 5
sage: G.conjugacy_class(Partition([2, 1, 1, 1]))
Conjugacy class of cycle type [2, 1, 1, 1] in Standard permutations of 5
```

conjugacy_classes()

Return a list of the conjugacy classes of self.

EXAMPLES:

```
sage: G = Permutations(4)
sage: G.conjugacy_classes()
[Conjugacy class of cycle type [1, 1, 1, 1] in Standard permutations of 4,
 Conjugacy class of cycle type [2, 1, 1] in Standard permutations of 4,
 Conjugacy class of cycle type [2, 2] in Standard permutations of 4,
 Conjugacy class of cycle type [3, 1] in Standard permutations of 4,
```

conjugacy_classes_iterator()

Iterate over the conjugacy classes of self.

EXAMPLES:

```
sage: G = Permutations(4)
sage: list(G.conjugacy_classes_iterator()) == G.conjugacy_classes()
True
```

conjugacy_classes_representatives()

Return a complete list of representatives of conjugacy classes in self.

Let \( S_n \) be the symmetric group on \( n \) letters. The conjugacy classes are indexed by partitions \( \lambda \) of \( n \). The ordering of the conjugacy classes is reverse lexicographic order of the partitions.

EXAMPLES:
sage: G = Permutations(5)
sage: G.conjugacy_classes_representatives()
[[1, 2, 3, 4, 5],
 [2, 1, 3, 4, 5],
 [2, 1, 4, 3, 5],
 [2, 3, 1, 4, 5],
 [2, 3, 1, 5, 4],
 [2, 3, 4, 1, 5],
 [2, 3, 4, 5, 1]]

degree()
Return the degree of self.
This is the cardinality \( n \) of the set self acts on.
EXAMPLES:

```
sage: Permutations(0).degree()
0
sage: Permutations(1).degree()
1
sage: Permutations(5).degree()
5
```
degrees()
Return the degrees of self.
These are the degrees of the fundamental invariants of the ring of polynomial invariants.
EXAMPLES:

```
sage: Permutations(3).degrees()
(2, 3)
sage: Permutations(7).degrees()
(2, 3, 4, 5, 6, 7)
```
element_in_conjugacy_classes(\( \nu \))
Return a permutation with cycle type \( \nu \).
If the size of \( \nu \) is smaller than the size of permutations in self, then some fixed points are added.
EXAMPLES:

```
sage: PP = Permutations(5)
sage: PP.element_in_conjugacy_classes([2,2])
[2, 1, 4, 3, 5]
```

identity()
Return the identity permutation of size \( n \).
EXAMPLES:

```
sage: Permutations(4).identity()
[1, 2, 3, 4]
sage: Permutations(0).identity()
[]
```
index_set()
Return the index set for the descents of the symmetric group self.
This is \{1, 2, \ldots, n - 1\}, where self is \(S_n\).
EXAMPLES:

```
    sage: P = Permutations(8)
    sage: P.index_set()
    (1, 2, 3, 4, 5, 6, 7)
```

one()
Return the identity permutation of size \(n\).
EXAMPLES:

```
    sage: Permutations(4).identity()
    [1, 2, 3, 4]
    sage: Permutations(0).identity()
    []
```

random_element()
EXAMPLES:

```
    sage: s = Permutations(4).random_element(); s  # random
    [1, 2, 4, 3]
    sage: s in Permutations(4)
    True
```

class

rank(p=None)
Return the rank of self or p depending on input.
If a permutation p is given, return the rank of p in self. Otherwise return the dimension of the underlying vector space spanned by the (simple) roots.
EXAMPLES:

```
    sage: P = Permutations(5)
    sage: P.rank()
    4
    sage: SP3 = Permutations(3)
    sage: list(map(SP3.rank, SP3))
    [0, 1, 2, 3, 4, 5]
    sage: SP0 = Permutations(0)
    sage: list(map(SP0.rank, SP0))
    [0]
```

simple_reflection(i)
For \(i\) in the index set of self (that is, for \(i\) in \(\{1, 2, \ldots, n - 1\}\), where self is \(S_n\)), this returns the elementary transposition \(s_i = (i, i + 1)\).
EXAMPLES:

```
    sage: P = Permutations(4)
    sage: P.simple_reflection(2)
```
Combinatorics, Release 10.0

[1, 3, 2, 4]

sage: P.simple_reflections()
Finite family {1: [2, 1, 3, 4], 2: [1, 3, 2, 4], 3: [1, 2, 4, 3]}

unrank(r)

EXAMPLES:

sage: SP3 = Permutations(3)
sage: l = list(map(SP3.unrank, range(6)))
sage: l == SP3.list()
True

sage: SP0 = Permutations(0)
sage: l = list(map(SP0.unrank, range(1)))
sage: l == SP0.list()
True

class sage.combinat.permutation.StandardPermutations_n_abstract(n, category=None)

Bases: Permutations

Abstract base class for subsets of permutations of the set \{1, 2, \ldots, n\}.

Warning: Anything inheriting from this class should override the \_\_contains\_\_ method.

class sage.combinat.permutation.StandardPermutations_recoils(recoils)

Bases: Permutations

Permutations of \{1, \ldots, n\} with a fixed recoils composition.

class sage.combinat.permutation.StandardPermutations_recoilsfatter(recoils)

Bases: Permutations

class sage.combinat.permutation.StandardPermutations_recoilsfiner(recoils)

Bases: Permutations

sage.combinat.permutation.bistochastic_as_sum_of_permutations(M, check=True)

Return the positive sum of permutations corresponding to the bistochastic matrix \( M \).

A stochastic matrix is a matrix with nonnegative real entries such that the sum of the elements of any row is equal to 1. A bistochastic matrix is a stochastic matrix whose transpose matrix is also stochastic (there are conditions both on the rows and on the columns).

According to the Birkhoff-von Neumann Theorem, any bistochastic matrix can be written as a convex combination of permutation matrices, which also means that the polytope of bistochastic matrices is integer.

As a non-bistochastic matrix can obviously not be written as a convex combination of permutations, this theorem is an equivalence.

This function, given a bistochastic matrix, returns the corresponding decomposition.

INPUT:

- \( M \) – A bistochastic matrix
- \( \text{check} \) (boolean) – set to True (default) to check that the matrix is indeed bistochastic

OUTPUT:
• An element of `CombinatorialFreeModule`, which is a free $F$-module (where $F$ is the ground ring of the given matrix) whose basis is indexed by the permutations.

**Note:**

• In this function, we just assume $1$ to be any constant: for us a matrix $M$ is bistochastic if there exists $c > 0$ such that $M/c$ is bistochastic.

• You can obtain a sequence of pairs `(permutation, coeff)`, where `permutation` is a Sage `Permutation` instance, and `coeff` its corresponding coefficient from the result of this function by applying the `list` function.

• If you are interested in the matrix corresponding to a `Permutation` you will be glad to learn about the `Permutation.to_matrix()` method.

• The base ring of the matrix can be anything that can be coerced to `RR`.

**See also:**

• `as_sum_of_permutations()` to use this method through the `Matrix` class.

**EXAMPLES:**

We create a bistochastic matrix from a convex sum of permutations, then try to deduce the decomposition from the matrix:

```python
sage: from sage.combinat.permutation import bistochastic_as_sum_of_permutations
sage: L = []
sage: L.append((9, Permutation([4, 1, 3, 5, 2])))
sage: L.append((6, Permutation([5, 3, 4, 1, 2])))
sage: L.append((3, Permutation([3, 1, 4, 2, 5])))
sage: L.append((2, Permutation([1, 4, 2, 3, 5])))
sage: M = sum([c * p.to_matrix() for (c, p) in L])
sage: decomp = bistochastic_as_sum_of_permutations(M)
sage: print(decomp)
2*B[[1, 4, 2, 3, 5]] + 3*B[[3, 1, 4, 2, 5]] + 9*B[[4, 1, 3, 5, 2]] + 6*B[[5, 3, 4, ˓→1, 2]]
```

An exception is raised when the matrix is not positive and bistochastic:

```python
sage: M = Matrix([[2,3],[2,2]])
sage: decom = bistochastic_as_sum_of_permutations(M)
Traceback (most recent call last):
  ... ValueError: The matrix is not bistochastic
```

```python
sage: bistochastic_as_sum_of_permutations(Matrix(GF(7), 2, [2,1,1,2]))
Traceback (most recent call last):
  ... ValueError: The base ring of the matrix must have a coercion map to RR
```

```python
sage: bistochastic_as_sum_of_permutations(Matrix(ZZ, 2, [2,-1,-1,2]))
Traceback (most recent call last):
  ... ValueError: The matrix should have nonnegative entries
```
sage.combinat.permutation.bounded_affine_permutation(A)

Return the bounded affine permutation of a matrix.

The *bounded affine permutation* of a matrix \(A\) with entries in \(R\) is a partial permutation of length \(n\), where \(n\) is the number of columns of \(A\). The entry in position \(i\) is the smallest value \(j\) such that column \(i\) is in the span of columns \(i+1, \ldots, j\) over \(R\), where column indices are taken modulo \(n\). If column \(i\) is the zero vector, then the permutation has a fixed point at \(i\).

**INPUT:**

- \(A\) – matrix with entries in a ring \(R\)

**EXAMPLES:**

```python
sage: from sage.combinat.permutation import bounded_affine_permutation
sage: A = Matrix(ZZ, [[[1,0,0,0], [0,1,0,0]]])
[5, 6, 3, 4]
sage: A = Matrix(ZZ, [[[0,1,0,1,0], [0,0,1,1,0]]])
[1, 4, 7, 8, 5]
```

**REFERENCES:**

- [KLS2013]

sage.combinat.permutation.bruhat_lequal(p1, p2)

Return True if \(p1\) is less than \(p2\) in the Bruhat order.

Algorithm from mupad-combinat.

**EXAMPLES:**

```python
sage: import sage.combinat.permutation as permutation
deprecated::
sage: import sage.combinat.permutation as permutation
```

sage.combinat.permutation.descents_composition_first(dc)

Compute the smallest element of a descent class having a descent composition \(dc\).

**EXAMPLES:**

```python
sage: import sage.combinat.permutation as permutation
deprecated::
sage: import sage.combinat.permutation as permutation
```

sage.combinat.permutation.descents_composition_last(dc)

Return the largest element of a descent class having a descent composition \(dc\).

**EXAMPLES:**

```python
sage: import sage.combinat.permutation as permutation
deprecated::
sage: import sage.combinat.permutation as permutation
```

sage.combinat.permutation.descents_composition_list(dc)

Return a list of all the permutations that have the descent composition \(dc\).
Combinatorics, Release 10.0

EXAMPLES:

```python
sage: import sage.combinat.permutation as permutation
sage: permutation.descents_composition_list([1,2,2])
[[5, 2, 4, 1, 3],
 [5, 3, 4, 1, 2],
 [4, 3, 5, 1, 2],
 [4, 2, 5, 1, 3],
 [3, 2, 5, 1, 4],
 [2, 1, 5, 3, 4],
 [3, 1, 5, 2, 4],
 [4, 1, 5, 2, 3],
 [5, 1, 4, 2, 3],
 [5, 1, 3, 2, 4],
 [4, 1, 3, 2, 5],
 [3, 1, 4, 2, 5],
 [2, 1, 4, 3, 5],
 [3, 2, 4, 1, 5],
 [4, 2, 3, 1, 5],
 [5, 2, 3, 1, 4]]
```

`sage.combinat.permutation.from_cycles(n, cycles, parent=None)`

Return the permutation in the \( n \)-th symmetric group whose decomposition into disjoint cycles is `cycles`.

This function checks that its input is correct (i.e. that the cycles are disjoint and their elements integers among 1...\( n \)). It raises an exception otherwise.

**Warning:** It assumes that the elements are of `int` type.

EXAMPLES:

```python
sage: import sage.combinat.permutation as permutation
sage: permutation.from_cycles(4, [[1,2]])
[2, 1, 3, 4]
sage: permutation.from_cycles(4, [[1,2,4]])
[2, 4, 3, 1]
sage: permutation.from_cycles(10, [[3,1],[4,5],[6,8,9]])
[3, 2, 1, 5, 4, 8, 7, 9, 6, 10]
sage: permutation.from_cycles(10, ((2, 5), (6, 1, 3)))
[3, 5, 6, 4, 2, 1, 7, 8, 9, 10]
sage: permutation.from_cycles(4, [])
[1, 2, 3, 4]
sage: permutation.from_cycles(4, [[]])
[1, 2, 3, 4]
sage: permutation.from_cycles(0, [])
[]
```

Bad input (see github issue #13742):

```python
sage: Permutation("(-12,2)(3,4)")
Traceback (most recent call last):
...
ValueError: all elements should be strictly positive integers, but I found -12
```

(continues on next page)
sage.combinat.permutation.from_inversion_vector(iv, parent=None)

Return the permutation corresponding to inversion vector iv.

See `sage.combinat.permutation.Permutation.to_inversion_vector` for a definition of the inversion vector of a permutation.

EXAMPLES:

```python
sage: import sage.combinat.permutation as permutation
sage: permutation.from_inversion_vector([3,1,0,0,0])
[3, 2, 4, 1, 5]
sage: permutation.from_inversion_vector([2,3,6,4,0,2,2,1,0])
[5, 9, 1, 8, 2, 6, 4, 7, 3]
sage: permutation.from_inversion_vector([0])
[1]
sage: permutation.from_inversion_vector([])
[]
```

sage.combinat.permutation.from_lehmer_cocode(lehmer, parent=Standard permutations)

Return the permutation with Lehmer cocode lehmer.

The Lehmer cocode of a permutation \( p \) is defined as the list \((c_1, c_2, \ldots, c_n)\), where \( c_i \) is the number of \( j < i \) such that \( p(j) > p(i) \).

EXAMPLES:

```python
sage: import sage.combinat.permutation as permutation
sage: lcc = Permutation([2,1,5,4,3]).to_lehmer_cocode(); lcc
[0, 1, 0, 1, 2]
sage: permutation.from_lehmer_cocode(lcc)
[2, 1, 5, 4, 3]
```

sage.combinat.permutation.from_lehmer_code(lehmer, parent=None)

Return the permutation with Lehmer code lehmer.

EXAMPLES:

```python
sage: import sage.combinat.permutation as permutation
sage: lc = Permutation([2,1,5,4,3]).to_lehmer_code(); lc
[1, 0, 2, 1, 0]
sage: permutation.from_lehmer_code(lc)
[2, 1, 5, 4, 3]
```

sage.combinat.permutation.from_major_code(mc, final_descent=False)

Return the permutation with major code mc.

The major code of a permutation is defined in `to_major_code()`.
**Warning:** This function creates illegal permutations (i.e. `Permutation([9])`), and this is dangerous as the `Permutation()` class is only designed to handle permutations on $1,...,n$. This will have to be changed when Sage permutations will be able to handle anything, but right now this should be fixed. Be careful with the results.

**Warning:** If mc is not a major index of a permutation, then the return value of this method can be anything. Garbage in, garbage out!

REFERENCES:

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.from_major_code([5, 0, 1, 0, 1, 2, 0, 1, 0])
[9, 3, 5, 7, 2, 1, 4, 6, 8]
sage: permutation.from_major_code([8, 3, 3, 1, 4, 0, 1, 0, 0])
[2, 8, 4, 3, 6, 7, 9, 5, 1]
sage: Permutation([2,1,6,4,7,3,5]).to_major_code()
[3, 2, 0, 2, 2, 0, 0]
sage: permutation.from_major_code([3, 2, 0, 2, 2, 0, 0])
[2, 1, 6, 4, 7, 3, 5]
```

```
sage.combinat.permutation.from_permutation_group_element(pge, parent=None)
```

Return a `Permutation` given a `PermutationGroupElement` pge.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: pge = PermutationGroupElement([(1,2),(3,4)])
sage: permutation.from_permutation_group_element(pge)
[2, 1, 4, 3]
```

```
sage.combinat.permutation.from_rank(n, rank)
```

Return the permutation of the set $\{1, ..., n\}$ with lexicographic rank `rank`. This is the permutation whose Lehmer code is the factoradic representation of `rank`. In particular, the permutation with rank 0 is the identity permutation.

The permutation is computed without iterating through all of the permutations with lower rank. This makes it efficient for large permutations.

**Note:** The variable `rank` is not checked for being in the interval from 0 to $n! - 1$. When outside this interval, it acts as its residue modulo $n!$.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: Permutation([3, 6, 5, 4, 2, 1]).rank()
359
sage: [permutation.from_rank(3, i) for i in range(6)]
```

(continues on next page)
sage.combinat.permutation.from_reduced_word(rw, parent=None)

Return the permutation corresponding to the reduced word rw.

See reduced_words() for a definition of reduced words and the convention on the order of multiplication used.

EXAMPLES:

sage: import sage.combinat.permutation as permutation
sage: permutation.from_reduced_word([3, 2, 3, 1, 2, 3, 1])
[3, 4, 2, 1]
sage: permutation.from_reduced_word([])
[]

sage.combinat.permutation.permutohedron_lequal(p1, p2, side='right')

Return True if p1 is less than or equal to p2 in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option side='left', then they will be done in the left permutohedron.

EXAMPLES:

sage: import sage.combinat.permutation as permutation
sage: permutation.permutohedron_lequal(Permutation([3, 2, 1, 4]), Permutation([4, 2, 1, 3]))
False
sage: permutation.permutohedron_lequal(Permutation([3, 2, 1, 4]), Permutation([4, 2, 1, 3]), side='left')
True

sage.combinat.permutation.to_standard(p, key=None)

Return a standard permutation corresponding to the iterable p.

INPUT:

- p – an iterable
- key – (optional) a comparison key for the element x of p

EXAMPLES:

sage: import sage.combinat.permutation as permutation
sage: permutation.to_standard([4, 2, 7])
[2, 1, 3]
sage: permutation.to_standard([1, 2, 3])
[1, 2, 3]
sage: permutation.to_standard([])
[]
sage: permutation.to_standard([1, 2, 3], key=lambda x: -x)
[3, 2, 1]
5.1.173 Permutations (Cython file)

This is a nearly-straightforward implementation of what Knuth calls “Algorithm P” in TAOCP 7.2.1.2. The intent is to be able to enumerate permutation by “plain changes”, or multiplication by adjacent transpositions, as a generator. This is useful when a class of objects is inherently enumerated by permutations, but it is faster to swap items in a permutation than construct the next object directly from the next permutation in a list. The backtracking algorithm in sage/graphs/genus.pyx is an example of this.

The lowest level is implemented as a struct with auxiliary methods. This is because Cython does not allow pointers to class instances, so a list of these objects is inherently slower than a list of structs. The author prefers ugly code to slow code.

For those willing to sacrifice a (very small) amount of speed, we provide a class that wraps our struct.

sage.combinat.permutation_cython.left_action_product(S, lp)

Return the permutation obtained by composing a permutation S with a permutation lp in such an order that lp is applied first and S is applied afterwards.

See also:

sage.combinat.permutation.Permutation.left_action_product()

EXAMPLES:

```
sage: p = [2,1,3,4]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import left_action_product
sage: left_action_product(p, q)
[3, 2, 1, 4]
sage: left_action_product(q, p)
[1, 3, 2, 4]
sage: q
[3, 1, 2]
```

sage.combinat.permutation_cython.left_action_same_n(S, lp)

Return the permutation obtained by composing a permutation S with a permutation lp in such an order that lp is applied first and S is applied afterwards and S and lp are of the same length.

See also:

sage.combinat.permutation.Permutation.left_action_product()

EXAMPLES:

```
sage: p = [2,1,3]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import left_action_same_n
sage: left_action_same_n(p, q)
[3, 2, 1]
sage: left_action_same_n(q, p)
[1, 3, 2]
```
sage.combinat.permutation_cython.map_to_list(l, values, n)

Build a list by mapping the array l using values.

**Warning:** There is no check of the input data at any point. Using wrong types or values with wrong length is likely to result in a Sage crash.

**INPUT:**

- l – array of unsigned int (i.e., type ‘I’)
- values – tuple; the values of the permutation
- n – int; the length of the array l

**OUTPUT:**

A list representing the permutation.

**EXAMPLES:**

```python
sage: from array import array
sage: from sage.combinat.permutation_cython import map_to_list
sage: l = array('I', [0, 1, 0, 3, 3, 0, 1])
sage: map_to_list(l, ('a', 'b', 'c', 'd'), 7)
['a', 'b', 'a', 'd', 'd', 'a', 'b']
```

sage.combinat.permutation_cython.next_perm(l)

Obtain the next permutation under lex order of l by mutating l.

Algorithm based on: [http://marknelson.us/2002/03/01/next-permutation/](http://marknelson.us/2002/03/01/next-permutation/)

**INPUT:**

- l – array of unsigned int (i.e., type ‘I’)

**Warning:** This method mutates the array l.

**OUTPUT:**

boolean; whether another permutation was obtained

**EXAMPLES:**

```python
sage: from sage.combinat.permutation_cython import next_perm
sage: from array import array
sage: L = array('I', [1, 1, 2, 3])
sage: while next_perm(L):
    ....:     print(L)
array('I', [1, 1, 3, 2])
array('I', [1, 2, 1, 3])
array('I', [1, 2, 3, 1])
array('I', [1, 3, 1, 2])
array('I', [1, 3, 2, 1])
array('I', [2, 1, 1, 3])
array('I', [2, 1, 3, 1])
array('I', [2, 3, 1, 1])
```
array('I', [3, 1, 1, 2])
array('I', [3, 1, 2, 1])
array('I', [3, 2, 1, 1])

sage.combinat.permutation_cython.permutation_iterator_transposition_list(n)

Returns a list of transposition indices to enumerate the permutations on \( n \) letters by adjacent transpositions. Assumes zero-based lists. We artificially limit the argument to \( n < 12 \) to avoid overflowing 32-bit pointers. While the algorithm works for larger \( n \), the user is encouraged to avoid filling anything more than 4GB of memory with the output of this function.

EXAMPLES:

```python
sage: import sage.combinat.permutation_cython
sage: from sage.combinat.permutation_cython import permutation_iterator_transposition_list
sage: permutation_iterator_transposition_list(4)
[2, 1, 0, 2, 0, 1, 2, 0, 2, 1, 0, 2, 0, 1, 2, 0, 2, 1, 0, 2, 0, 1, 2]
sage: permutation_iterator_transposition_list(200)
Traceback (most recent call last):
  ... ValueError: Cowardly refusing to enumerate the permutations on more than 12 letters.
sage: permutation_iterator_transposition_list(1)
[]
```

sage.combinat.permutation_cython.right_action_product(S, rp)

Return the permutation obtained by composing a permutation \( S \) with a permutation \( rp \) in such an order that \( S \) is applied first and \( rp \) is applied afterwards.

See also:

sage.combinat.permutation.Permutation.right_action_product()

EXAMPLES:

```python
sage: p = [2,1,3,4]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import right_action_product
sage: right_action_product(p, q)
[1, 3, 2, 4]
sage: right_action_product(q, p)
[3, 2, 1, 4]
sage: q
[3, 1, 2]
```

sage.combinat.permutation_cython.right_action_same_n(S, rp)

5.1. Comprehensive Module List
Return the permutation obtained by composing a permutation \( S \) with a permutation \( rp \) in such an order that \( S \) is applied first and \( rp \) is applied afterwards and \( S \) and \( rp \) are of the same length.

**See also:**

sage.combinat.permutation.Permutation.right_action_product()

**EXAMPLES:**

```python
sage: p = [2,1,3]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import right_action_same_n
sage: right_action_same_n(p, q)
[1, 3, 2]
sage: right_action_same_n(q, p)
[3, 2, 1]
```

**5.1.174 Posets**

Common posets can be accessed through posets.<tab> and are listed in the posets catalog:

- Catalog of posets and lattices

Poset-related classes:

- Finite posets
- Finite lattices and semilattices
- Linear Extensions of Posets
- D-Complete Posets
- Forest Posets
- Mobile posets
- Incidence Algebras
- Cartesian products of Posets
- Möbius Algebras
- Generalized Tamari lattices
- Tamari Interval-posets
- Shard intersection order

If you are looking for Poset-related categories, see Posets, FinitePosets, LatticePosets and FiniteLatticePosets.
5.1.175 Cartesian products of Posets

AUTHORS:

• Daniel Krenn (2015)

class sage.combinat.posets.cartesian_product.CartesianProductPoset(sets, category, order=None, **kwargs)

Bases: CartesianProduct

A class implementing Cartesian products of posets (and elements thereof). Compared to CartesianProduct you are able to specify an order for comparison of the elements.

INPUT:

• sets – a tuple of parents.

• category – a subcategory of Sets().CartesianProducts() & Posets().

• order – a string or function specifying an order less or equal. It can be one of the following:
  – 'native' – elements are ordered by their native ordering, i.e., the order the wrapped elements (tuples) provide.
  – 'lex' – elements are ordered lexicographically.
  – 'product' – an element is less or equal to another element, if less or equal is true for all its components (Cartesian projections).
  – A function which performs the comparison \( \leq \). It takes two input arguments and outputs a boolean.

Other keyword arguments (kwargs) are passed to the constructor of CartesianProduct.

EXAMPLES:

```sage
sage: P = Poset((srange(3), lambda left, right: left <= right))
sage: Cl = cartesian_product((P, P), order='lex')
sage: Cl((1, 1)) <= Cl((2, 0))
True
sage: Cp = cartesian_product((P, P), order='product')
sage: Cp((1, 1)) <= Cp((2, 0))
False
sage: def le_sum(left, right):
    ....:     return (sum(left) < sum(right) or
    ....:         sum(left) == sum(right) and left[0] <= right[0])
sage: Cs = cartesian_product((P, P), order=le_sum)
sage: Cs((1, 1)) <= Cs((2, 0))
True
```

See also:

CartesianProduct

class Element

Bases: Element

le(left, right)

Test whether left is less than or equal to right.

INPUT:

• left – an element.
• right – an element.

OUTPUT:
A boolean.

Note: This method uses the order defined on creation of this Cartesian product. See CartesianProductPoset.

EXAMPLES:

```python
sage: P = posets.ChainPoset(10)
sage: def le_sum(left, right):
....:     return (sum(left) < sum(right) or
....:             sum(left) == sum(right) and left[0] <= right[0])
sage: C = cartesian_product((P, P), order=le_sum)
sage: C.le(C((1, 6)), C((6, 1)))
True
sage: C.le(C((6, 1)), C((1, 6)))
False
sage: C.le(C((1, 6)), C((6, 6)))
True
sage: C.le(C((6, 6)), C((1, 6)))
False
```

le_lex(left, right)
Test whether left is lexicographically smaller or equal to right.

INPUT:

• left – an element.
• right – an element.

OUTPUT:
A boolean.

EXAMPLES:

```python
sage: P = Poset((srange(2), lambda left, right: left <= right))
sage: Q = cartesian_product((P, P), order='lex')
sage: T = [Q((0, 0)), Q((1, 1)), Q((0, 1)), Q((1, 0))]
sage: for a in T:
....:     for b in T:
....:         assert Q.le(a, b) == (a <= b)
....:         print("%s <= %s = %s" % (a, b, a <= b))
(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 1) <= (0, 0) = False
(0, 1) <= (0, 1) = False
(0, 1) <= (1, 0) = False
(0, 1) <= (1, 1) = False
```

(continues on next page)
(0, 1) <= (1, 1) = True
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = True
(1, 0) <= (0, 0) = False
(1, 0) <= (1, 1) = True
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True

le_native(left, right)

Test whether left is smaller or equal to right in the order provided by the elements themselves.

INPUT:

• left – an element.
• right – an element.

OUTPUT:

A boolean.

EXAMPLES:

sage: P = Poset((srange(2), lambda left, right: left <= right))
sage: Q = cartesian_product((P, P), order='native')
sage: T = [Q((0, 0)), Q((1, 1)), Q((0, 1)), Q((1, 0))]
sage: for a in T:
    for b in T:
        assert Q.le(a, b) == (a <= b)
        print('%s <= %s = %s' % (a, b, a <= b))

(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 1) <= (0, 0) = False
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = True
(0, 1) <= (1, 1) = True
(1, 0) <= (0, 0) = False
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True

le_product(left, right)

Test whether left is component-wise smaller or equal to right.

INPUT:

• left – an element.
• right – an element.

OUTPUT:
A boolean.

The comparison is True if the result of the comparison in each component is True.

EXAMPLES:

```
sage: P = Poset((srange(2), lambda left, right: left <= right))
sage: Q = cartesian_product((P, P), order='product')
sage: T = [Q((0, 0)), Q((1, 1)), Q((0, 1)), Q((1, 0))]
sage: for a in T:
    ....:    for b in T:
    ....:        assert (Q.le(a, b) == (a <= b))
    ....:        print('%%s <= %%s = %s' % (a, b, a <= b))

(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 0) <= (0, 0) = False
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(0, 1) <= (0, 0) = False
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = False
(1, 0) <= (0, 0) = False
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True
```

5.1.176 D-Complete Posets

AUTHORS:

- Stefan Grosser (06-2020): initial implementation

```
class sage.combinat.posets.d_complete.DCompletePoset(hasse_diagram, elements, category, facade, key):
    Bases: FiniteJoinSemilattice

A d-complete poset.

D-complete posets are a class of posets introduced by Proctor in [Proc1999]. It includes common families such as shapes, shifted shapes, and rooted forests. Proctor showed in [PDynk1999] that d-complete posets have decompositions in irreducible posets, and showed in [Proc2014] that d-complete posets admit a hook-length formula (see Wikipedia article Hook_length_formula). A complete proof of the hook-length formula can be found in [KY2019].

EXAMPLES:

```
sage: from sage.combinat.posets.poset_examples import Posets
sage: P = Posets.DoubleTailedDiamond(2)
sage: TestSuite(P).run()

def get_hook(self):
    Return the hook length of the element elmt.
```
EXAMPLES:
```
sage: from sage.combinat.posets.d_complete import DCompletePoset
da_complete = DCompletePoset(DiGraph({0: [1], 1: [2]}))
sage: P = DCompletePoset(DiGraph({0: [1, 2], 1: [3], 2: [3], 3: []}))
sage: P.get_hooks()
{0: 1, 1: 2, 2: 2, 3: 3}
sage: P = DCompletePoset(Posets.YoungDiagramPoset(Partition([3, 2, 1]))._hasse_diagram.reverse())
sage: P.get_hooks()
{0: 5, 1: 3, 2: 1, 3: 3, 4: 1, 5: 1}
```

`get_hooks()`

Return all the hook lengths as a dictionary.

EXAMPLES:
```
sage: from sage.combinat.posets.d_complete import DCompletePoset
da_complete = DCompletePoset(DiGraph({0: [1, 2], 1: [3], 2: [3], 3: []}))
sage: P = DCompletePoset(P.posets.YoungDiagramPoset(Partition([3, 2, 1]))._hasse_diagram.reverse())
sage: P.get_hooks()
{0: 5, 1: 3, 2: 1, 3: 3, 4: 1, 5: 1}
```

`hook_product()`

Return the hook product for the poset.

### 5.1.177 Mobile posets

**class** `sage.combinat.posets.mobile.MobilePoset(hasse_diagram, elements, category, facade, key, ribbon=None, check=True)`

Bases: `FinitePoset`

A mobile poset.

Mobile posets are an extension of d-complete posets which permit a determinant formula for counting linear extensions. They are formed by having a ribbon poset with d-complete posets ‘hanging’ below it and at most one d-complete poset above it, known as the anchor. See [GGMM2020] for the definition.

EXAMPLES:
```
sage: P = posets.MobilePoset(posets.RibbonPoset(7, [1,3]),
.....: {1: [posets.YoungDiagramPoset([3, 2], dual=True)],
.....: 3: [posets.DoubleTailedDiamond(6)]},
.....: anchor=(4, 2, posets.ChainPoset(6)))
sage: len(P._ribbon)
8
sage: P._anchor
(4, 5)
```

This example is Example 5.9 in [GGMM2020]:
```
sage: P1 = posets.MobilePoset(posets.RibbonPoset(8, [2,3,4]),
.....: {4: [posets.ChainPoset(1)]},
.....: anchor=(3, 0, posets.ChainPoset(1)))
sage: sorted([P1._element_to_vertex(i) for i in P1._ribbon])
```

[0, 1, 2, 6, 7, 9]
sage: P1._anchor
(3, 2)

sage: P2 = posets.MobilePoset(posets.RibbonPoset(15, [1,3,5,7,9,11,13]),
....:   {}, anchor=(8, 0, posets.ChainPoset(1)))
sage: sorted(P2._ribbon)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13]
sage: P2._anchor
(8, (8, 0))
sage: P2.linear_extensions().cardinality()
21399440939

sage: EP = posets.MobilePoset(posets.ChainPoset(0), {})
Traceback (most recent call last):
...
ValueError: the empty poset is not a mobile poset

anchor()
Return the anchor of the mobile poset.

EXAMPLES:

sage: from sage.combinat.posets.mobile import MobilePoset
sage: M2 = MobilePoset(Poset([[0,1,2,3,4,5,6,7,8],
....:   [(1,0),(3,0),(2,1),(2,3),(4,3),(5,4),(7,4),(7,8)]])
sage: M2.anchor()
(4, 3)
sage: M3 = MobilePoset(Posets.RibbonPoset(5, [1,2]))
sage: M3.anchor() is None
True

ribbon()
Return the ribbon of the mobile poset.

EXAMPLES:

sage: from sage.combinat.posets.mobile import MobilePoset
sage: M3 = MobilePoset(Posets.RibbonPoset(5, [1,2]))
sage: sorted(M3.ribbon())
[1, 2, 3, 4]

5.1.178 Elements of posets, lattices, semilattices, etc.

class sage.combinat.posets.elements.JoinSemilatticeElement(poset, element, vertex)
Bases: PosetElement

class sage.combinat.posets.elements.LatticePosetElement(poset, element, vertex)
Bases: MeetSemilatticeElement, JoinSemilatticeElement

class sage.combinat.posets.elements.MeetSemilatticeElement(poset, element, vertex)
Bases: PosetElement
class sage.combinat.posets.elements.PosetElement(poset, element, vertex)
Bases: Element

Establish the parent-child relationship between poset and element, where element is associated to the vertex of the Hasse diagram of the poset.

INPUT:
• poset – a poset object
• element – any object
• vertex – a vertex of the Hasse diagram of the poset

5.1.179 Forest Posets

AUTHORS:
• Stefan Grosser (06-2020): initial implementation

class sage.combinat.posets.forest.ForestPoset(hasse_diagram, elements, category, facade, key)
Bases: FinitePoset

A forest poset is a poset where the underlying Hasse diagram and is directed acyclic graph.

5.1.180 Hasse diagrams of posets

<table>
<thead>
<tr>

class sage.combinat.posets.hasse_diagram.HasseDiagram(
    data=None, pos=None, loops=None, format=None, weighted=None,
    data_structure='sparse', vertex_labels=True, name=None, multiedges=None,
    convert_empty_dict_labels_to_None=False, sparse=True, immutable=False,
    hash_labels=None)

Bases: DiGraph

The Hasse diagram of a poset. This is just a transitively-reduced, directed, acyclic graph without loops or multiple edges.

Note: We assume that range(n) is a linear extension of the poset. That is, range(n) is the vertex set and a topological sort of the digraph.

This should not be called directly, use Poset instead; all type checking happens there.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]}); H
Hasse diagram of a poset containing 4 elements
sage: TestSuite(H).run()

sage: H.antichains(element_class=list)
```

Return all antichains of self, organized as a prefix tree

INPUT:

- element_class – (default:list) an iterable type

EXAMPLES:

```python
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: A = H.antichains()
sage: list(A)
[[[]], [0], [1], [1, 2], [1, 3], [2], [3], [4]]
sage: A.cardinality()
8
sage: [1,3] in A
True
sage: [1,4] in A
False
```
antichains_iterator()

Return an iterator over the antichains of the poset.

Note: The algorithm is based on Freese-Jezek-Nation p. 226. It does a depth first search through the set of all antichains organized in a prefix tree.

EXAMPLES:

```python
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: H.antichains_iterator()
<generator object ...antichains_iterator at ...>
sage: list(H.antichains_iterator())
[[], [4], [3], [2], [1], [1, 3], [1, 2], [0]]
```

are_comparable(i, j)

Return whether i and j are comparable in the poset

INPUT:

• i, j – vertices of this Hasse diagram

EXAMPLES:

```python
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: H.are_comparable(1,2)
False
```

are_incomparable(i, j)

Return whether i and j are incomparable in the poset

INPUT:

• i, j – vertices of this Hasse diagram

EXAMPLES:
```python
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: H.are_incomparable(1,2)
True
sage: V = H.vertices(sort=True)
[sage: [ (i,j) for i in V for j in V if H.are_incomparable(i,j)]
[(1, 2), (1, 3), (2, 1), (3, 1)]
```

**atoms_of_congruence_lattice()**

Return atoms of the congruence lattice.

In other words, return “minimal non-trivial” congruences: A congruence is minimal if the only finer (as a partition of set of elements) congruence is the trivial congruence where every block contains only one element.

**See also:**

`congruence()`

**OUTPUT:**

List of congruences, every congruence as `sage.combinat.set_partition.SetPartition`

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: N5 = HasseDiagram({0: [1, 2], 1: [4], 2: [3], 3:[4]})
```

```python
sage: N5.atoms_of_congruence_lattice()
[[{0}, {1}, {2, 3}, {4}]]
```

```python
sage: Hex = HasseDiagram({0: [1, 2], 1: [3], 2: [4], 3: [5], 4: [5]})
```

```python
sage: Hex.atoms_of_congruence_lattice()
[{{0}, {1, 3}, {2}, {4}, {5}}, {{0}, {1, 3}, {2}, {4}, {5}}]
```

**ALGORITHM:**

Every atom is a join-irreducible. Every join-irreducible of \(\text{Con}(L)\) is a principal congruence generated by a meet-irreducible element and the only element covering it (and also by a join-irreducible element and the only element covered by it). Hence we check those principal congruences to find the minimal ones.

**bottom()**

Return the bottom element of the poset, if it exists.

**EXAMPLES:**

```python
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
```

```python
sage: P.bottom() is None
True
```

```python
sage: Q = Poset({0:[1],1:[]})
```

```python
sage: Q.bottom()
0
```

**bottom_moebius_function()**

Return the value of the Möbius function of the poset on the elements `zero` and `j`, where `zero` is `self.bottom()`, the unique minimal element of the poset.

**EXAMPLES:**

```python
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
```

```python
sage: P.bottom() is None
True
```

```python
sage: Q = Poset({0:[1],1:[]})
```

```python
sage: Q.bottom()
0
```
sage: P = Poset({0: [1,2]})
sage: hasse = P._hasse_diagram
sage: hasse.bottom_moebius_function(1)
-1
sage: hasse.bottom_moebius_function(2)
-1
sage: P = Poset({0: [1,3], 1:[2], 2:[4], 3:[4]})
sage: hasse = P._hasse_diagram
sage: for i in range(5):
    ....: print(hasse.bottom_moebius_function(i))
1
-1
0
-1
1

**cardinality()**

Return the number of elements in the poset.

**EXAMPLES:**

```
sage: Poset([[1,2,3],[4],[4],[4],[[]]).cardinality()
5
```

**chains**(element_class=<class 'list'>, exclude=None, conversion=None)

Return all chains of self, organized as a prefix tree.

**INPUT:**

- element_class – (optional, default: list) an iterable type
- exclude – elements of the poset to be excluded (optional, default: None)
- conversion – (optional, default: None) used to pass the list of elements of the poset in their fixed order

**OUTPUT:**

The enumerated set (with a forest structure given by prefix ordering) consisting of all chains of self, each of which is given as an element_class.

If conversion is given, then the chains are converted to chain of elements of this list.

**EXAMPLES:**

```
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: A = H.chains()
sage: list(A)
[[], [0], [0, 1], [0, 1, 4], [0, 2], [0, 2, 3], [0, 2, 3, 4], [0, 2, 4], [0, 3], ...
→ [0, 3, 4], [0, 4], [1], [1, 4], [2], [2, 3], [2, 3, 4], [2, 4], [3], [3, 4],...
→[4]]
sage: A.cardinality()
20
sage: [1,3] in A
False
```

(continues on next page)
sage: True

One can exclude some vertices:

```sage
c: = P = Poset({1: [2, 3], 2: [4]})
c: list(P.hasse_diagram.chains(element_class=tuple))
```

The `element_class` keyword determines how the chains are being returned:

```sage
c: = P = Poset({1: [2, 3], 2: [4]})
c: list(P.hasse_diagram.chains(exclude=[0]))
```

(See also): `antichains()`

**closed_interval(x, y)**

Return a list of the elements \( z \) of self such that \( x \leq z \leq y \).

The order is that induced by the ordering in self.linear_extension.

**INPUT:**

- \( x \) – any element of the poset
- \( y \) – any element of the poset

**Note:** The method `_precompute_intervals()` creates a cache which is used if available, making the function very fast.

(See also): `interval_iterator()`

**common_lower_covers(vertices)**

Return the list of all common lower covers of vertices.

**EXAMPLES:**
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1,2], 1: [3], 2: [3], 3: []})

sage: H.common_lower_covers([1, 2])
[0]

sage: from sage.combinat.posets.poset_examples import Posets
sage: H = Posets.YoungDiagramPoset(Partition([3, 2, 2]))._hasse_diagram
sage: H.common_lower_covers([4, 5])
[3]

common_upper_covers(vertices)

Return the list of all common upper covers of vertices.

EXAMPLES:

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1,2], 1: [3], 2: [3], 3: []})

sage: H.common_upper_covers([1, 2])
[3]

sage: from sage.combinat.posets.poset_examples import Posets
sage: H = Posets.YoungDiagramPoset(Partition([3, 2, 2]))._hasse_diagram

sage: H.common_upper_covers([4, 5])
[6]

congruence(parts, start=None, stop_pairs=[])  

Return the congruence start “extended” by parts.

start is assumed to be a valid congruence of the lattice, and this is not checked.

INPUT:

• parts – a list of lists; congruences to add
• start – a disjoint set; already computed congruence (or None)
• stop_pairs – a list of pairs; list of pairs for stopping computation

OUTPUT:

None, if the congruence generated by start and parts together contains a block that has elements \(a, b\) so that \((a, b)\) is in the list stop_pairs. Otherwise the least congruence that contains a block whose subset is \(p\) for every \(p\) in parts or start, given as sage.sets.disjoint_set.DisjointSet_class.

ALGORITHM:

Use the quadrilateral argument from page 120 of [Dav1997].

Basically we take one block from todo-list, search quadrilateral blocks up and down against the block, and then complete them to closed intervals and add to todo-list.

EXAMPLES:

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1,2], 1: [3], 2: [4], 3: [4]})

sage: cong = H.congruence([[0, 1]]); cong
{{0, 1, 3}, {2, 4}}

sage: H.congruence([[0, 2]], start=cong)
Combinatorics, Release 10.0

{{0, 1, 2, 3, 4}}

sage: H.congruence([[0, 1]], stop_pairs=[(1, 3)]) is None
True

congruences_iterator()

Return an iterator over all congruences of the lattice.

EXAMPLES:

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(‘GY@OQ?OW@?O?’)
congruences_iterator()  # it
<generator object ...>

sage: sorted([cong.number_of_subsets() for cong in it])
[1, 2, 2, 4, 4, 4, 8]

cover_relations()

Return the list of cover relations.

EXAMPLES:

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]})

sage: H.cover_relations()
[(0, 2), (0, 3), (1, 3), (1, 4), (2, 5), (3, 5), (4, 5)]

cover_relations_iterator()

Iterate over cover relations.

EXAMPLES:

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]})

sage: list(H.cover_relations_iterator())
[(0, 2), (0, 3), (1, 3), (1, 4), (2, 5), (3, 5), (4, 5)]

covers(x, y)

Return True if y covers x and False otherwise.

EXAMPLES:

sage: Q = Poset([[1,5],[2,6],[3],[4],[],[]])

sage: Q.covers(Q(1),Q(6))
True

sage: Q.covers(Q(1),Q(4))
False

coxeter_transformation(algorithm=’cython’)

Return the matrix of the Auslander-Reiten translation acting on the Grothendieck group of the derived category of modules on the poset, in the basis of simple modules.

INPUT:

• algorithm – optional, 'cython' (default) or 'matrix'

5.1. Comprehensive Module List
This uses either a specific matrix code in Cython, or generic matrices.

See also:

lequal_matrix(), moebius_function_matrix()

EXAMPLES:

```
sage: P = posets.PentagonPoset()._hasse_diagram
sage: M = P.coxeter_transformation(); M
[ 0 0 0 0 -1]
[ 0 0 0 1 -1]
[ 0 1 0 0 -1]
[-1 1 1 0 -1]
[-1 1 0 1 -1]
sage: P.__dict__['coxeter_transformation'].clear_cache()
sage: P.coxeter_transformation(algorithm="matrix") == M
True
```

**diamonds()**

Return the list of diamonds of self.

A diamond is the following subgraph of the Hasse diagram:

```
z
/ \
x  y
\ /  \
 w
```

Thus each edge represents a cover relation in the Hasse diagram. We represent his as the tuple $(w, x, y, z)$.

OUTPUT:

A tuple with

• a list of all diamonds in the Hasse Diagram,

• a boolean checking that every $w, x, y$ that form a $V$, there is a unique element $z$, which completes the diamond.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1,2], 1: [3], 2: [3], 3: []})
sage: H.diamonds()
(((0, 1, 2, 3), True))

sage: P = posets.YoungDiagramPoset(Partition([3, 2, 2]))
sage: H = P._hasse_diagram
sage: H.diamonds()
(((0, 1, 3, 4), (3, 4, 5, 6), False))
```

**dual()**

Return a poset that is dual to the given poset.

This means that it has the same elements but opposite order. The elements are renumbered to ensure that range(n) is a linear extension.

EXAMPLES:

```python
sage: P = posets.IntegerPartitions(4)
sage: H = P._hasse_diagram; H
Hasse diagram of a poset containing 5 elements
sage: H.dual()
Hasse diagram of a poset containing 5 elements
```

**find_nonsemidistributive_elements**(*meet_or_join*)

Check if the lattice is semidistributive or not.

**INPUT:**

- *meet_or_join* – string 'meet' or 'join' to decide if to check for join-semidistributivity or meet-semidistributivity

**OUTPUT:**

- None if the lattice is semidistributive OR
- tuple (u, e, x, y) such that \( u = e \lor x = e \lor y \) but \( u \neq e \lor (x \land y) \) if *meet_or_join*=='join'
  and \( u = e \land x = e \land y \) but \( u \neq e \land (x \lor y) \) if *meet_or_join*=='meet'

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1, 2], 1:[3, 4], 2:[4, 5], 3:[6], 4:[6], 5:[6]})
sage: H.find_nonsemidistributive_elements('join') is None
False
sage: H.find_nonsemidistributive_elements('meet') is None
True
```

**find_nonsemimodular_pair**(*upper*)

Return pair of elements showing the lattice is not modular.

**INPUT:**

- *upper*, a Boolean – if True, test whether the lattice is upper semimodular; otherwise test whether the lattice is lower semimodular.

**OUTPUT:**

None, if the lattice is semimodular. Pair \((a, b)\) violating semimodularity otherwise.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1, 2], 1:[3, 4], 2:[4, 5], 3:[6], 4:[6], 5:[6]})
sage: H.find_nonsemimodular_pair(upper=True) is None
True
sage: H.find_nonsemimodular_pair(upper=False)
(5, 3)
sage: H_ = HasseDiagram(H.reverse().relabel(lambda x: 6-x, inplace=False))
sage: H_.find_nonsemimodular_pair(upper=True)
(3, 1)
sage: H_.find_nonsemimodular_pair(upper=False) is None
True
```
**find_nontrivial_congruence**

Return a pair that generates non-trivial congruence or None if there is not any.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [5], 2: [3, 4], 3: [5], 4: [5]})
sage: H.find_nontrivial_congruence()
{{0, 1}, {2, 3, 4, 5}}
sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})
sage: H.find_nontrivial_congruence() is None
True
```

**ALGORITHM:**

See [https://www.math.hawaii.edu/~ralph/Preprints/conlat.pdf](https://www.math.hawaii.edu/~ralph/Preprints/conlat.pdf):

If $\Theta$ is a join irreducible element of a $\text{Con}(L)$, then there is at least one join-irreducible $j$ and one meet-irreducible $m$ such that $\Theta$ is both the principal congruence generated by $(j^*, j)$, where $j^*$ is the unique lower cover of $j$, and the principal congruence generated by $(m, m^*)$, where $m^*$ is the unique upper cover of $m$.

So, we only check join irreducibles or meet irreducibles, whichever is a smaller set. To optimize more we stop computation whenever it finds a pair that we know to generate one-element congruence.

**frattini_sublattice**

Return the list of elements of the Frattini sublattice of the lattice.

**EXAMPLES:**

```python
sage: H = posets.PentagonPoset()._hasse_diagram
sage: H.frattini_sublattice()
[0, 4]
```

**greedy_linear_extensions_iterator**

Return an iterator over greedy linear extensions of the Hasse diagram.

A linear extension $[e_1, e_2, \ldots, e_n]$ is greedy if for every $i$ either $e_{i+1}$ covers $e_i$ or all upper covers of $e_i$ have at least one lower cover that is not in $[e_1, e_2, \ldots, e_i]$.

Informally said a linear extension is greedy if it “always goes up when possible” and so has no unnecessary jumps.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: N5 = HasseDiagram({0: [1, 2], 2: [3], 1: [4], 3: [4]})
sage: for l in N5.greedy_linear_extensions_iterator():
    print(l)
[0, 1, 2, 3, 4]
[0, 2, 3, 1, 4]
```

**has_bottom**

Return True if the poset has a unique minimal element.

**EXAMPLES:**

```python
```
```python
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.has_bottom()
False
sage: Q = Poset({0:[1],1:[]})
sage: Q.has_bottom()
True
```

**has_top()**

Return True if the poset contains a unique maximal element, and False otherwise.

**EXAMPLES:**

```python
sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.has_top()
False
sage: Q = Poset({0:[1],1:[]})
sage: Q.has_top()
True
```

**interval(x, y)**

Return a list of the elements $z$ of self such that $x \leq z \leq y$.

The order is that induced by the ordering in self.linear_extension.

**INPUT:**

- $x$ – any element of the poset
- $y$ – any element of the poset

**Note:** The method `_precompute_intervals()` creates a cache which is used if available, making the function very fast.

See also:

**interval_iterator()**

**EXAMPLES:**

```python
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(dag)
sage: I = set([2,5,6,4,7])
sage: I == set(H.interval(2,7))
True
```

**interval_iterator(x, y)**

Return an iterator of the elements $z$ of self such that $x \leq z \leq y$.

**INPUT:**

- $x$ – any element of the poset
- $y$ – any element of the poset
Combinatorics, Release 10.0

See also:

interval()

Note: This becomes much faster when first calling _leq_storage(), which precomputes the principal upper ideals.

EXAMPLES:

```sage
uc = [[1, 3, 2], [4], [4, 5, 6], [6], [7], [7], [7], []

sage: dag = DiGraph(dict(zip(range(len(uc)), uc)))

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram

sage: H = HasseDiagram(dag)

sage: I = set([2, 5, 6, 4, 7])

sage: I == set(H.interval_iterator(2, 7))

True
```

is_antichain_of_poset(elms)

Return True if elms is an antichain of the Hasse diagram and False otherwise.

EXAMPLES:

```sage
from sage.combinat.posets.hasse_diagram import HasseDiagram

H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})

H.is_antichain_of_poset([1, 2, 3])

True

H.is_antichain_of_poset([0, 2, 3])

False
```

is_bounded()

Return True if the poset contains a unique maximal element and a unique minimal element, and False otherwise.

EXAMPLES:

```sage
P = Poset({0: [3], 1: [3], 2: [3], 3: [4, 5], 4: [], 5: []})

P.is_bounded()

False

Q = Poset({0: [1], 1: []})

Q.is_bounded()

True
```

is_chain()

Return True if the poset is totally ordered, and False otherwise.

EXAMPLES:

```sage
L = Poset({0: [1], 1: [2], 2: [3], 3: [4]})

L.is_chain()

True

V = Poset({0: [1, 2]})

V.is_chain()

False
```
is_complemented()

Return an element of the lattice that has no complement.
If the lattice is complemented, return None.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1, 2], 1:[3], 2:[3], 3:[4]})
sage: H.is_complemented()
1
sage: H = HasseDiagram({0:[1, 2, 3], 1:[4], 2:[4], 3:[4]})
sage: H.is_complemented() is None
True
```

is_congruence_normal()

Return True if the lattice can be constructed from the one-element lattice with Day doubling constructions of convex subsets.
Subsets to double does not need to be lower nor upper pseudo-intervals. On the other hand they must be convex, i.e. doubling a non-convex but municipal subset will give a lattice that returns False from this function.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram('IXQ@AG?Q@?AG?QW?Q@?@

sage: H.is_congruence_normal() True

```
The 5-element diamond is the smallest non-example:

```python
sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})
sage: H.is_congruence_normal() False

```
This is done by doubling a non-convex subset:

```python

sage: H.is_congruence_normal() False

```

ALGORITHM:

See http://www.math.hawaii.edu/~jb/inflation.pdf

is_convex_subset(S)

Return True if S is a convex subset of the poset, and False otherwise.
A subset S is convex in the poset if b \in S whenever a, c \in S and a \leq b \leq c.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: B3 = HasseDiagram({0: [1, 2, 4], 1: [3, 5], 2: [3, 6],
```
Combinatorics, Release 10.0

continuing from previous page

\[
\begin{array}{l}
\text{sage: B3.is_convex_subset([1, 3, 5, 4])} \quad \# \text{Also connected} \\
\text{True} \\
\text{sage: B3.is_convex_subset([1, 3, 4])} \quad \# \text{Not connected} \\
\text{True} \\
\text{sage: B3.is_convex_subset([0, 1, 2, 3, 6])} \quad \# \text{No, } 0 < 4 < 6 \\
\text{False} \\
\text{sage: B3.is_convex_subset([0, 1, 2, 7])} \quad \# \text{No, } 1 < 3 < 7. \\
\text{False}
\end{array}
\]

\text{is_gequal}(x, y)

Return True if \(x\) is greater than or equal to \(y\), and False otherwise.

\text{EXAMPLES:}

\[
\begin{array}{l}
\text{sage: from sage.combinat.posets.hasse_diagram import HasseDiagram} \\
\text{sage: Q = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})} \\
\text{sage: x,y,z = 0,1,4} \\
\text{sage: Q.is_gequal(x,y)} \\
\text{False} \\
\text{sage: Q.is_gequal(y,x)} \\
\text{False} \\
\text{sage: Q.is_gequal(x,z)} \\
\text{False} \\
\text{sage: Q.is_gequal(z,x)} \\
\text{True} \\
\text{sage: Q.is_gequal(z,y)} \\
\text{True} \\
\text{sage: Q.is_gequal(z,z)} \\
\text{True}
\end{array}
\]

\text{is_greater_than}(x, y)

Return True if \(x\) is greater than but not equal to \(y\), and False otherwise.

\text{EXAMPLES:}

\[
\begin{array}{l}
\text{sage: from sage.combinat.posets.hasse_diagram import HasseDiagram} \\
\text{sage: Q = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})} \\
\text{sage: x,y,z = 0,1,4} \\
\text{sage: Q.is_greater_than(x,y)} \\
\text{False} \\
\text{sage: Q.is_greater_than(y,x)} \\
\text{False} \\
\text{sage: Q.is_greater_than(x,z)} \\
\text{False} \\
\text{sage: Q.is_greater_than(z,x)} \\
\text{True} \\
\text{sage: Q.is_greater_than(z,y)} \\
\text{True} \\
\text{sage: Q.is_greater_than(z,z)} \\
\text{False}
\end{array}
\]
is_join_semilattice()
Return True if self has a join operation, and False otherwise.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2], 1:[4], 2:[4,5,6], 3:[6], 4:[7], 5:[7], 6:[7], 7:[[]])
sage: H.is_join_semilattice()
True
sage: H = HasseDiagram({0:[2,3], 1:[2,3]})
sage: H.is_join_semilattice()
False
sage: H = HasseDiagram({0:[2,3], 1:[2,3], 2:[4], 3:[4]})
sage: H.is_join_semilattice()
False
```

is_lequal(i, j)
Return True if i is less than or equal to j in the poset, and False otherwise.

Note: If the lequal_matrix() has been computed, then this method is redefined to use the cached data (see alternate_is_lequal()).

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[[]])
sage: x,y,z = 0, 1, 4
sage: H.is_lequal(x,y)
False
sage: H.is_lequal(y,x)
False
sage: H.is_lequal(x,z)
True
sage: H.is_lequal(y,z)
True
sage: H.is_lequal(z,z)
True
```

is_less_than(x, y)
Return True if x is less than but not equal to y in the poset, and False otherwise.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[[]])
sage: x,y,z = 0, 1, 4
sage: H.is_less_than(x,y)
False
sage: H.is_less_than(y,x)
False
sage: H.is_less_than(x,z)
True
sage: H.is_less_than(y,z)
True
```

(continues on next page)
Combinatorics, Release 10.0

True

sage: H.is_less_than(z, z)
False

**is_linear_extension** *(lin_ext=None)*

Test if an ordering is a linear extension.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: H.is_linear_extension(list(range(4)))
True
sage: H.is_linear_extension([3,2,1,0])
False
```

**is_linear_interval** *(t_min, t_max)*

Return whether the interval \([t_min, t_max]\) is linear.

This means that this interval is a total order.

**EXAMPLES:**

```python
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: H.is_linear_interval(0, 4)
False
sage: H.is_linear_interval(0, 3)
True
sage: H.is_linear_interval(1, 3)
False
sage: H.is_linear_interval(1, 1)
True
```

**is_meet_semilattice** *

Return True if self has a meet operation, and False otherwise.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.is_meet_semilattice()
True
```

(continues on next page)
Combinatorics, Release 10.0

(continued from previous page)

```sage
sage: H.is_meet_semilattice()
False
```

**is_ranked()**

Return True if the poset is ranked, and False otherwise.

A poset is ranked if it admits a rank function. For more information about the rank function, see `rank_function()` and `is_graded()`.

**EXAMPLES:**

```sage
sage: P = Poset([[1],[2],[3],[4],[5]])
sage: P.is_ranked()
True
sage: Q = Poset([[1],[2],[3],[4],[5],[6],[7]])
sage: Q.is_ranked()
False
```

**join_matrix()**

Return the matrix of joins of self, when self is a join-semilattice; raise an error otherwise.

The \((x,y)\)-entry of this matrix is the join of \(x\) and \(y\) in self.

This algorithm is modelled after the algorithm of Freese-Jezek-Nation (p217). It can also be found on page 140 of [Gec81].

**Note:** If self is a join-semilattice, then the return of this method is the same as `_join()`. Once the matrix has been computed, it is stored in `_join()`. Delete this attribute if you want to recompute the matrix.

**EXAMPLES:**

```sage
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2,3,4,5,6,7], 1:[4,5,6,7], 2:[4,5,6,7], 3:[6,7], 4:[7], 5:[7], 6:[7], 7:[7]})
sage: H.join_matrix()
[[0 1 2 3 4 5 6 7]
 [1 1 4 7 4 7 7 7]
 [2 4 2 6 4 5 6 7]
 [3 7 6 3 7 6 7 7]
 [4 4 4 7 4 7 7 7]
 [5 7 5 7 5 7 7 7]
 [6 7 6 6 7 7 6 7]
 [7 7 7 7 7 7 7 7]]
```

**kappa(a)**

Return the maximum element greater than the element covered by \(a\) but not greater than \(a\).

Define \(\kappa(a)\) as the maximum element of \((\uparrow a_+) \setminus (\uparrow a)\), where \(a_+\) is the element covered by \(a\). It is always a meet-irreducible element, if it exists.

**Note:** Element \(a\) is expected to be join-irreducible, and this is not checked.

**INPUT:**

5.1. Comprehensive Module List 1949
• a – a join-irreducible element of the lattice

OUTPUT:
The element \( \kappa(a) \) or None if there is not a unique greatest element with given constraints.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4, 5], 3: [5], 4: [6], 5: [6]}
˓→)

sage: H.kappa(1)
5
sage: H.kappa(2) is None
True
```

**kappa_dual\( (a) \)**

Return the minimum element smaller than the element covering \( a \) but not smaller than \( a \).

Define \( \kappa^*(a) \) as the minimum element of \( (\downarrow a^*) \setminus (\downarrow a) \), where \( a^* \) is the element covering \( a \). It is always a join-irreducible element, if it exists.

**Note:** Element \( a \) is expected to be meet-irreducible, and this is not checked.

INPUT:
• a – a join-irreducible element of the lattice

OUTPUT:
The element \( \kappa^*(a) \) or None if there is not a unique smallest element with given constraints.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3, 4], 2: [4, 5], 3: [6], 4: [6], 5: [6]}
˓→)

sage: H.kappa_dual(3)
2
sage: H.kappa_dual(4) is None
True
```

**lequal_matrix\( (boolean=False) \)**

Return a matrix whose \((i,j)\) entry is 1 if \( i \) is less than \( j \) in the poset, and 0 otherwise; and redefines \( __lt__ \) to use the boolean version of this matrix.

INPUT:
• boolean – optional flag (default False) telling whether to return a matrix with coefficients in \( \mathbb{F}_2 \) or in \( \mathbb{Z} \)

See also:
moebius_function_matrix(), coxeter_transformation()

EXAMPLES:
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: H = P._hasse_diagram
sage: M = H.lequal_matrix(); M
\begin{pmatrix}
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
0 & 1 & 0 & 1 & 0 & 0 & 0 & 1 \\
0 & 0 & 1 & 1 & 1 & 0 & 1 & 1 \\
0 & 0 & 0 & 1 & 0 & 0 & 1 & 1 \\
0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
\end{pmatrix}
sage: M.base_ring()
Integer Ring

sage: P = posets.DiamondPoset(6)
sage: H = P._hasse_diagram
sage: M = H.lequal_matrix(boolean=True)
sage: M.base_ring()
Finite Field of size 2

**linear_extension()**

Return a linear extension

**linear_extensions()**

Return an iterator over all linear extensions.

**lower_covers_iterator(element)**

Return the list of elements that are covered by element.

**maximal_elements()**

Return a list of the maximal elements of the poset.
EXAMPLES:

```python
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.maximal_elements()
[4]
```

**maximal_sublattices()**

Return maximal sublattices of the lattice.

EXAMPLES:

```python
sage: L = posets.PentagonPoset()
sage: ms = L._hasse_diagram.maximal_sublattices()
sage: sorted(ms, key=sorted)
[{
0, 1, 2, 4},
{0, 1, 3, 4},
{0, 2, 3, 4}
]
```

**meet_matrix()**

Return the matrix of meets of `self`, when `self` is a meet-semilattice; raise an error otherwise.

The \((x,y)\)-entry of this matrix is the meet of \(x\) and \(y\) in `self`.

This algorithm is modelled after the algorithm of Freese-Jezek-Nation (p217). It can also be found on page 140 of [Gec81].

**Note:** If `self` is a meet-semilattice, then the return of this method is the same as `_meet()`. Once the matrix has been computed, it is stored in `_meet()`. Delete this attribute if you want to recompute the matrix.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.meet_matrix()
[0 0 0 0 0 0 0 0]
[0 1 0 1 0 0 1]
[0 0 2 2 2 2]
[0 0 0 3 0 3 3]
[0 1 2 4 2 4]
[0 0 2 5 2 5]
[0 0 2 3 2 6 6]
[0 1 2 3 4 5 6 7]
```

**REFERENCE:**

**minimal_elements()**

Return a list of the minimal elements of the poset.

EXAMPLES:

```python
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P(0) in P.minimal_elements()
True
sage: P(1) in P.minimal_elements()
True
```

(continues on next page)
moebius_function(i, j)
Return the value of the Möbius function of the poset on the elements \(i\) and \(j\).

EXAMPLES:

```python
sage: P = Poset([[1,2,3],[4],[4],[4],[[]])
sage: H = P._hasse_diagram
sage: H.moebius_function(0,4)
2
sage: for u,v in P.cover_relations_iterator():
    ....:   if P.moebius_function(u,v) != -1:
    ....:     print("Bug in moebius_function!")
```

moebius_function_matrix(algorithm=’cython’)
Return the matrix of the Möbius function of this poset.
This returns the matrix over \(\mathbb{Z}\) whose entries are the value of the Möbius function of self evaluated on \(x\) and \(y\), and redefines moebius_function() to use it.

INPUT:

- algorithm – optional, 'recursive', 'matrix' or 'cython' (default)

This uses either the recursive formula, a generic matrix inversion or a specific matrix inversion coded in Cython.

OUTPUT:

- a dense matrix for the algorithm cython, a sparse matrix otherwise

Note: The result is cached in _moebius_function_matrix().

See also:
lequal_matrix(), coxeter_transformation()

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[[]])
sage: H.moebius_function_matrix()
```

neutral_elements()
Return the list of neutral elements of the lattice.
An element \(a\) in a lattice is neutral if the sublattice generated by \(a, x\) and \(y\) is distributive for every \(x, y\) in the lattice.

**EXAMPLES:**

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
code升值: H = HasseDiagram({0: [1, 2], 1: [4], 2: [3], 3: [4, 5],
....: 4: [6], 5:[6]})
sage: sorted(H.neutral_elements())
[0, 4, 6]
```

**ALGORITHM:**

Basically we just check the distributivity against all element pairs \(x, y\) to see if element \(a\) is neutral or not.

If we found that \(a, x, y\) is not a distributive triple, we add all three to list of non-neutral elements. If we found \(a\) to be neutral, we add it to list of neutral elements. When testing we skip already found neutral elements, as they can’t be our \(x\) or \(y\).

We skip \(a, x, y\) as trivial if it is a chain. We do that by letting \(x\) to be a non-comparable to \(a\); \(y\) can be any element.

We first try to found \(x\) and \(y\) from elements not yet tested, so that we could get three birds with one stone.

And last, the top and bottom elements are always neutral and need not be tested.

**open_interval**(\(x, y\))

Return a list of the elements \(z\) of \(self\) such that \(x < z < y\).

The order is that induced by the ordering in \(self.linear_extension\).

**EXAMPLES:**

```
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[7]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
code升值: H = HasseDiagram(dag)
sage: set([5,6,4]) == set(H.open_interval(2,7))
True
sage: H.open_interval(7,2)
[]
```

**order_filter**(\(elements\))

Return the order filter generated by a list of elements.

\(I\) is an order filter if, for any \(x\) in \(I\) and \(y\) such that \(y\geq x\), then \(y\) is in \(I\).

**EXAMPLES:**

```
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.order_filter([3,8])
[3, 7, 8, 9, 10, 11, 12, 13, 14, 15]
```

**order_ideal**(\(elements\))

Return the order ideal generated by a list of elements.

\(I\) is an order ideal if, for any \(x\) in \(I\) and \(y\) such that \(y\leq x\), then \(y\) is in \(I\).

**EXAMPLES:**

```
order_ideal_cardinality(elements)

Return the cardinality of the order ideal generated by elements.

$I$ is an order ideal if, for any $x$ in $I$ and $y$ such that $y \leq x$, then $y$ is in $I$.

EXAMPLES:

```sage
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.order_ideal_cardinality([7,10])
10
```

orthocomplementations_iterator()

Return an iterator over orthocomplementations of the lattice.

OUTPUT:

An iterator that gives plain list of integers.

EXAMPLES:

```sage
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3], 2: [4], 3: [4]})

sage: list(H.orthocomplementations_iterator())
[[9, 8, 5, 6, 7, 2, 3, 4, 1, 0], [9, 8, 5, 7, 6, 2, 4, 3, 1, 0]]
```

ALGORITHM:

As DiamondPoset($2n+2$) has $(2n)!/(n!2^n)$ different orthocomplementations, the complexity of listing all of them is necessarily $O(n!)$.

An orthocomplemented lattice is self-dual, so that for example orthocomplement of an atom is a coatom. This function basically just computes list of possible orthocomplementations for every element (i.e. they must be complements and “duals”), and then tries to fit them all.

prime_elements()

Return the join-prime and meet-prime elements of the bounded poset.

An element $x$ of a poset $P$ is join-prime if the subposet induced by $\{y \in P \mid y \not\geq x\}$ has a top element. Meet-prime is defined dually.

Note: The poset is expected to be bounded, and this is not checked.

OUTPUT:

A pair $(j, m)$ where $j$ is a list of join-prime elements and $m$ is a list of meet-prime elements.

EXAMPLES:

```sage
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3], 2: [4], 3: [4]})

sage: H.prime_elements()
([1, 2], [2, 3])
```
**principal_congruences_poset()**

Return the poset of join-irreducibles of the congruence lattice.

**OUTPUT:**

A pair \((P, D)\) where \(P\) is a poset and \(D\) is a dictionary.

Elements of \(P\) are pairs \((x, y)\) such that \(x\) is an element of the lattice and \(y\) is an element covering it. In the poset \((a, b)\) is less than \((c, d)\) iff the principal congruence generated by \((a, b)\) is refinement of the principal congruence generated by \((c, d)\).

\(D\) is a dictionary from pairs \((x, y)\) to the congruence (given as DisjointSet) generated by the pair.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: N5 = HasseDiagram({0: [1, 2], 1: [4], 2: [3], 3: [4]})
sage: P, D = N5.principal_congruences_poset()
sage: P
Finite poset containing 3 elements
sage: P.bottom()
(2, 3)
sage: D[(2, 3)]
{{0}, {1}, {2, 3}, {4}}
```

**principal_order_filter(i)**

Return the order filter generated by \(i\).

**EXAMPLES:**

```python
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.principal_order_filter(2)
[2, 3, 6, 7, 10, 11, 14, 15]
```

**principal_order_ideal(i)**

Return the order ideal generated by \(i\).

**EXAMPLES:**

```python
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.principal_order_ideal(6)
[0, 2, 4, 6]
```

**pseudocomplement(element)**

Return the pseudocomplement of \(element\), if it exists.

The pseudocomplement is the greatest element whose meet with given element is the bottom element. It may not exist, and then the function returns \(None\).

**INPUT:**

- \(element\) – an element of the lattice.

**OUTPUT:**

An element of the Hasse diagram, i.e. an integer, or \(None\) if the pseudocomplement does not exist.

**EXAMPLES:**
Combinatorics, Release 10.0

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3], 2: [4], 3: [4]})
sage: H.pseudocomplement(2)
3
sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})
sage: H.pseudocomplement(2) is None
True
```

**rank**(element=None)

Return the rank of `element`, or the rank of the poset if `element` is `None`. (The rank of a poset is the length of the longest chain of elements of the poset.)

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[[]])
sage: H.rank(5)
2
sage: H.rank()
3
sage: Q = HasseDiagram({0:[1,2],1:[3],2:[[]],3:[[]]})
sage: Q.rank()
2
sage: Q.rank(1)
1
```

**rank_function()**

Return the (normalized) rank function of the poset, if it exists.

A rank function of a poset `P` is a function `r` that maps elements of `P` to integers and satisfies: `r(x) = r(y)+1` if `x` covers `y`. The function `r` is normalized such that its minimum value on every connected component of the Hasse diagram of `P` is `0`. This determines the function `r` uniquely (when it exists).

**OUTPUT:**

- a lambda function, if the poset admits a rank function
- `None`, if the poset does not admit a rank function

**EXAMPLES:**

```python
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[[]])
sage: P.rank_function() is not None
True
sage: P = Poset([[1,2,3,4],[1,4],[2,3],[3,4]], facade = True)
sage: P.rank_function() is not None
True
sage: P = Poset([[1,2,3,4,5],[1,2],[2,3],[3,4],[1,5],[5,4]], facade = True)
sage: P.rank_function() is not None
False
sage: P = Poset([[1,2,3,4,5,6,7,8],[1,4],[2,3],[3,4],[5,7],[6,7]], facade = True)
False
sage: f = P.rank_function(); f is not None
True
sage: f(5)
```

(continues on next page)
skeleton()

Return the skeleton of the lattice.

The lattice is expected to be pseudocomplemented and non-empty.

The skeleton of the lattice is the subposet induced by those elements that are the pseudocomplement to at least one element.

OUTPUT:

List of elements such that the subposet induced by them is the skeleton of the lattice.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3, 4], 2: [4],
                   3: [5], 4: [5]})
sage: H.skeleton()
[5, 2, 0, 3]
```

sublattices_iterator(elms, min_e)

Return an iterator over sublattices of the Hasse diagram.

INPUT:

- `elms` – elements already in sublattice; use set() at start
- `min_e` – smallest new element to add for new sublattices

OUTPUT:

List of sublattices as sets of integers.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3], 2: [3]})
sage: it = H.sublattices_iterator(set(), 0); it
<generator object ...sublattices_iterator at ...>
sage: next(it)
set()
sage: next(it)
{0}
```

supergreedy_linear_extensions_iterator()

Return an iterator over supergreedy linear extensions of the Hasse diagram.

A linear extension \([e_1, e_2, \ldots, e_n]\) is supergreedy if, for every \(i\) and \(j\) where \(i > j\), \(e_i\) covers \(e_j\) if for every \(i > k > j\) at least one lower cover of \(e_k\) is not in \([e_1, e_2, \ldots, e_k]\).

Informally said a linear extension is supergreedy if it “always goes as high possible, and withdraw so less as possible”. These are also called depth-first linear extensions.

EXAMPLES:

We show the difference between “only greedy” and supergreedy extensions:
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 2: [3, 4]})
sage: G_ext = list(H.greedy_linear_extensions_iterator())
sage: SG_ext = list(H.supergreedy_linear_extensions_iterator())
sage: [0, 2, 3, 1, 4] in G_ext
True
sage: [0, 2, 3, 1, 4] in SG_ext
False
sage: len(SG_ext)
4

**top()**

Return the top element of the poset, if it exists.

**EXAMPLES:**

sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.top() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.top()
1

**upper_covers_iterator**(element)

Return the list of elements that cover element.

**EXAMPLES:**

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: list(H.upper_covers_iterator(0))
[1, 2, 3]
sage: list(H.upper_covers_iterator(7))
[]

**vertical_decomposition**(return_list=False)

Return vertical decomposition of the lattice.

This is the backend function for vertical decomposition functions of lattices.

The property of being vertically decomposable is defined for lattices. This is not checked, and the function works with any bounded poset.

**INPUT:**

• return_list, a boolean. If False (the default), return an element that is not the top neither the bottom element of the lattice, but is comparable to all elements of the lattice, if the lattice is vertically decomposable and None otherwise. If True, return list of decomposition elements.

**EXAMPLES:**

sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.vertical_decomposition()
is None
True
sage: P = Poset( ([1,2,3,6,12,18,36], attrcall("divides")) )

(continues on next page)
sage: P._hasse_diagram.vertical_decomposition()
3
sage: P._hasse_diagram.vertical_decomposition(return_list=True)
[3]

exception sage.combinat.posets.hasse_diagram.LatticeError(fail, x, y)
Bases: ValueError

Helper exception class to forward elements without meet or join to upper level, so that the user will see “No meet for a and b” instead of “No meet for 1 and 2”.

5.1.181 Incidence Algebras

class sage.combinat.posets.incidence_algebras.IncidenceAlgebra(R, P, prefix='I')
Bases: CombinatorialFreeModule

The incidence algebra of a poset.

Let $P$ be a poset and $R$ be a commutative unital associative ring. The *incidence algebra* $I_P$ is the algebra of functions $\alpha : P \times P \to R$ such that $\alpha(x, y) = 0$ if $x \not\leq y$ where multiplication is given by convolution:

$$(\alpha * \beta)(x, y) = \sum_{x \leq k \leq y} \alpha(x, k)\beta(k, y).$$

This has a natural basis given by indicator functions for the interval $[a, b]$, i.e. $X_{a,b}(x, y) = \delta_{ax}\delta_{by}$. The incidence algebra is a unital algebra with the identity given by the Kronecker delta $\delta(x, y) = \delta_{xy}$. The Möbius function of $P$ is another element of $I_P$ whose inverse is the $\zeta$ function of the poset (so $\zeta(x, y) = 1$ for every interval $[x, y]$).

Todo: Implement the incidence coalgebra.

REFERENCES:
- Wikipedia article Incidence_algebra

class Element
Bases: IndexedFreeModuleElement

An element of an incidence algebra.

is_unit()
return if self is a unit.

EXAMPLES:

sage: P = posets.BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: mu = I.moebius()
sage: mu.is_unit()
True
sage: zeta = I.zeta()
sage: zeta.is_unit()
True
sage: x = mu - I.zeta() + I[2,2]
sage: x.is_unit()
False

delta()
Return the element 1 in self (which is the Kronecker delta $\delta(x, y)$).

EXAMPLES:

\begin{verbatim}
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.one()
\end{verbatim}

moebius()
Return the Möbius function of self.

EXAMPLES:

\begin{verbatim}
sage: P = posets.BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: I.moebius()
\end{verbatim}

(continues on next page)
I[0, 0] - I[0, 1] - I[0, 2] + I[0, 3] + I[1, 1] - I[1, 3] + I[2, 2] - I[2, 3] + I[3, 3]

one()

Return the element 1 in self (which is the Kronecker delta $\delta(x, y)$).

EXAMPLES:

```python
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.one()
```

poset()

Return the defining poset of self.

EXAMPLES:

```python
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.poset()
Finite lattice containing 16 elements
```

product_on_basis(A, B)

Return the product of basis elements indexed by $A$ and $B$.

EXAMPLES:

```python
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.product_on_basis((1, 3), (3, 11))
I[1, 11]
sage: I.product_on_basis((1, 3), (2, 2))
0
```

reduced_subalgebra(prefix='R')

Return the reduced incidence subalgebra.

EXAMPLES:

```python
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.reduced_subalgebra()
Reduced incidence algebra of Finite lattice containing 16 elements over Rational Field
```

some_elements()

Return a list of elements of self.

EXAMPLES:
```sage
sage: P = posets.BooleanLattice(1)
sage: I = P.incidence_algebra(QQ)
sage: Ielts = I.some_elements(); Ielts # random
[2*I[0, 0] + 2*I[0, 1] + 3*I[1, 1],
 I[0, 0] - I[0, 1] + I[1, 1],
 I[0, 0] + I[0, 1] + I[1, 1]]
sage: [a in I for a in Ielts]
[True, True, True]
```

**zeta()**

Return the $\zeta$ function in self.

The $\zeta$ function on a poset $P$ is given by

$$\zeta(x, y) = \begin{cases} 1 & x \leq y, \\ 0 & x \not\leq y. \end{cases}$$

**EXAMPLES:**

```sage
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.zeta() * I.moebius() == I.one()
True
```

**class** `sage.combinat.posets.incidence_algebras.ReducedIncidenceAlgebra(I, prefix='R')`

Bases: `CombinatorialFreeModule`

The reduced incidence algebra of a poset.

The reduced incidence algebra $R_P$ is a subalgebra of the incidence algebra $I_P$ where $\alpha(x, y) = \alpha(x', y')$ when $[x, y]$ is isomorphic to $[x', y']$ as posets. Thus the delta, Möbius, and zeta functions are all elements of $R_P$.

**class** `Element`

Bases: `IndexedFreeModuleElement`

An element of a reduced incidence algebra.

**is_unit()**

Return if self is a unit.

**EXAMPLES:**

```sage
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: x = R.an_element()
sage: x.is_unit()
True
```

**lift()**

Return the lift of self to the ambient space.

**EXAMPLES:**

```sage
sage: P = posets.BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: R = I.reduced_subalgebra()
```
sage: x = R.an_element(); x
2*R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)]
sage: x.lift()

**to_matrix()**

Return self as a matrix.

EXAMPLES:

```python
sage: P = posets.BooleanLattice(2)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: mu = R.moebius()
sage: mu.to_matrix()
[ 1 -1 -1 1]
[ 0 1 0 -1]
[ 0 0 1 -1]
[ 0 0 0 1]
```

**delta()**

Return the Kronecker delta function in self.

EXAMPLES:

```python
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.delta()
R[(0, 0)]
```

**lift()**

Return the lift morphism from self to the ambient space.

EXAMPLES:

```python
sage: P = posets.BooleanLattice(2)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.lift
Generic morphism:
  From: Reduced incidence algebra of Finite lattice containing 4 elements over Rational Field
  To:  Incidence algebra of Finite lattice containing 4 elements over Rational Field
sage: R.an_element() - R.one()
R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)]
sage: R.lift(R.an_element() - R.one())
```

**moebius()**

Return the Möbius function of self.

EXAMPLES:
```python
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.moebius()
R[(0, 0)] - R[(0, 1)] + R[(0, 3)] - R[(0, 7)] + R[(0, 15)]
```

**one_basis()**

Return the index of the element 1 in self.

**EXAMPLES:**

```python
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.one_basis()
(0, 0)
```

**poset()**

Return the defining poset of self.

**EXAMPLES:**

```python
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.poset()
Finite lattice containing 16 elements
sage: R.poset() == P
True
```

**some_elements()**

Return a list of elements of self.

**EXAMPLES:**

```python
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.some_elements()
[2*R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)],
 R[(0, 0)] - R[(0, 1)] + R[(0, 3)] - R[(0, 7)] + R[(0, 15)],
 R[(0, 0)] + R[(0, 1)] + R[(0, 3)] + R[(0, 7)] + R[(0, 15)]]
```

**zeta()**

Return the function in self.

The function on a poset $P$ is given by

\[
\zeta(x, y) = \begin{cases} 
1 & x \leq y, \\
0 & x \not\leq y.
\end{cases}
\]

**EXAMPLES:**

```python
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.zeta()
R[(0, 0)] + R[(0, 1)] + R[(0, 3)] + R[(0, 7)] + R[(0, 15)]
```
5.1.182 Finite lattices and semilattices

This module implements finite (semi)lattices. It defines:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LatticePoset()</td>
<td>Construct a lattice.</td>
</tr>
<tr>
<td>MeetSemilattice()</td>
<td>Construct a meet semi-lattice.</td>

<tr>
<td>frattini_sublattice()</td>
<td>Return the intersection of maximal sublattices of the lattice.</td>
</tr>
<tr>
<td>skeleton()</td>
<td>Return the skeleton of the lattice.</td>
</tr>
<tr>
<td>center()</td>
<td>Return the sublattice of complemented neutral elements.</td>
</tr>
<tr>
<td>vertical_decomposition()</td>
<td>Return the vertical decomposition of the lattice.</td>
</tr>
</tbody>
</table>

### Miscellaneous

5.1. Comprehensive Module List
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>moebius_algebra()</code></td>
<td>Return the Möbius algebra of the lattice.</td>
</tr>
<tr>
<td><code>quantum_moebius_algebra()</code></td>
<td>Return the quantum Möbius algebra of the lattice.</td>
</tr>
<tr>
<td><code>vertical_composition()</code></td>
<td>Return ordinal sum of lattices with top/bottom element unified.</td>

</table>

```python
class sage.combinat.posets.lattices.FiniteJoinSemilattice(hasse_diagram, elements, category, facade, key):
    Bases: FinitePoset
    We assume that the argument passed to FiniteJoinSemilattice is the poset of a join-semilattice (i.e. a poset with least upper bound for each pair of elements).

    Element
    alias of JoinSemilatticeElement

    coatoms()
    Return the list of co-atoms of this (semi)lattice.
    A co-atom of a lattice is an element covered by the top element.
    EXAMPLES:
    sage: L = posets.DivisorLattice(60)
    sage: sorted(L.coatoms())
    [12, 20, 30]

    See also:
    • Dual function: atoms()

    join(x, y=None)
    Return the join of given elements in the lattice.
    INPUT:
    • x, y – two elements of the (semi)lattice OR
    • x – a list or tuple of elements
    EXAMPLES:
    sage: D = posets.DiamondPoset(5)
    sage: D.join(1, 2)
    4
    sage: D.join(1, 1)
    1
    sage: D.join(1, 4)
    4
    sage: D.join(1, 0)
    1

    Using list of elements as an argument. Join of empty list is the bottom element:
```
```
sage: B4=posets.BooleanLattice(4)
sage: B4.join([2,4,8])
14
sage: B4.join([])
0
```

For non-facade lattices operator + works for join:

```
sage: L = posets.PentagonPoset(facade=False)
sage: L(1)+L(2)
4
```

See also:

- Dual function: `meet()`

`join_matrix()`

Return a matrix whose \((i,j)\) entry is \(k\), where `self.linear_extension()[k]` is the join (least upper bound) of `self.linear_extension()[i]` and `self.linear_extension()[j]`.

**EXAMPLES:**

```
sage: P = LatticePoset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]], facade=False)
sage: J = P.join_matrix(); J
[0 1 2 3 4 5 6 7]
[1 1 3 7 7 7 7 7]
[2 3 2 3 4 6 6 7]
[3 3 3 7 7 7 7 7]
[4 7 4 7 4 7 7 7]
[5 7 6 7 5 6 7 7]
[6 7 6 7 6 7 7 7]
[7 7 7 7 7 7 7 7]
True
True
False
```

class `sage.combinat.posets.lattices.FiniteLatticePoset`

Bases: `FiniteMeetSemilattice`, `FiniteJoinSemilattice`

We assume that the argument passed to `FiniteLatticePoset` is the poset of a lattice (i.e. a poset with greatest lower bound and least upper bound for each pair of elements).

**Element**

- alias of `LatticePosetElement`

**adjunct**(other, a, b)

Return the adjunct of the lattice by other on the pair \((a, b)\).

It is assumed that \(a < b\) but \(b\) does not cover \(a\).

The adjunct of a lattice \(K\) to \(L\) with respect to pair \((a, b)\) of \(L\) is defined such that \(x < y\) if
• \( x, y \in K \) and \( x < y \) in \( K \),
• \( x, y \in L \) and \( x < y \) in \( L \),
• \( x \in L, y \in K \) and \( x \leq a \) in \( L \), or
• \( x \in K, y \in L \) and \( b \leq y \) in \( L \).

Informally this can be seen as attaching the lattice \( K \) to \( L \) as a new block between \( a \) and \( b \). Dismantlable lattices are exactly those that can be created from chains with this function.

Mathematically, it is only defined when \( L \) and \( K \) have no common element; here we force that by giving them different names in the resulting lattice.

**EXAMPLES:**

```sage
definitions:
    Pnum = posets.PentagonPoset()
    Palp = Pnum.relabel(lambda x: chr(ord('a') + x))
    PP = Pnum.adjunct(Palp, 0, 3)
    PP.atoms()
    [[(0, 1), (0, 2), (1, 'a')]
    sage: PP.coatoms()
    [[(0, 3), (0, 1)]
```

**breadth** *(certificate=False)*

Return the breadth of the lattice.

The breadth of a lattice is the largest integer \( n \) such that any join of elements \( x_1, x_2, \ldots, x_{n+1} \) is join of a proper subset of \( x_i \).

This can be also characterized by subposets: a lattice of breadth at least \( n \) contains a subposet isomorphic to the Boolean lattice of \( 2^n \) elements.

**INPUT:**
• certificate – (default: False) whether to return a certificate

**OUTPUT:**
• If certificate=True return the pair \((b, a)\) where \( b \) is the breadth and \( a \) is an antichain such that the join of \( a \) differs from the join of any proper subset of \( a \). If certificate=False return just the breadth.

**EXAMPLES:**

```sage
definitions:
    D10 = posets.DiamondPoset(10)
    D10.breadth()
    2
    sage: B3 = posets.BooleanLattice(3)
    B3.breadth()
    3
    sage: B3.breadth(certificate=True)
    (3, [1, 2, 4])
```

**ALGORITHM:**

For a lattice to have breadth at least \( n \), it must have an \( n \)-element antichain \( A \) with join \( j \). Element \( j \) must cover at least \( n \) elements. There must also be \( n - 2 \) levels of elements between \( A \) and \( j \). So we start by searching elements that could be our \( j \) and then just check possible antichains \( A \).
**Note:** Prior to version 8.1 this function returned just an antichain with `certificate=True`.

**canonical_joinands(e)**

Return the canonical joinands of `e`.

The canonical joinands of an element `e` in the lattice `L` is the subset `S ⊆ L` such that 1) the join of `S` is `e`, and 2) if the join of some other subset `S'` of is also `e`, then for every element `s ∈ S` there is an element `s' ∈ S'` such that `s ≤ s'`.

Informally said this is the set of lowest possible elements with given join. It exists for every element if and only if the lattice is join-semidistributive. Canonical joinands are always join-irreducibles.

**INPUT:**

- `e` – an element of the lattice

**OUTPUT:**

- canonical joinands as a list, if it exists; if not, `None`

**EXAMPLES:**

```python
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [5], 4: [6],
                      ....: 5: [7], 6: [7]})
sage: L.canonical_joinands(7)
[3, 4]
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [6], 4: [6],
                      ....: 5: [6]})
sage: L.canonical_joinands(6) is None
True
```

See also:

**canonical_meetands()**

**canonical_meetands(e)**

Return the canonical meetands of `e`.

The canonical meetands of an element `e` in the lattice `L` is the subset `S ⊆ L` such that 1) the meet of `S` is `e`, and 2) if the meet of some other subset `S'` of is also `e`, then for every element `s ∈ S` there is an element `s' ∈ S'` such that `s ≥ s'`.

Informally said this is the set of greatest possible elements with given meet. It exists for every element if and only if the lattice is meet-semidistributive. Canonical meetands are always meet-irreducibles.

**INPUT:**

- `e` – an element of the lattice

**OUTPUT:**

- canonical meetands as a list, if it exists; if not, `None`

**EXAMPLES:**

```python
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [5, 6], 4: [6],
                      ....: 5: [7], 6: [7]})
sage: L.canonical_meetands(1)
[5, 4]
```

(continues on next page)
Combinatorics, Release 10.0

(continued from previous page)

```python
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [6], 4: [6],
.....: 5: [6]})
sage: L.canonical_meetands(1) is None
True
```

See also:

* canonical_joinands()

center()

Return the center of the lattice.

An element of a lattice is central if it is neutral and has a complement. The subposet induced by central elements is a center of the lattice. Actually it is a Boolean lattice.

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [6, 7], 3: [8, 9, 7],
.....: 4: [5, 6], 5: [8, 10], 6: [10], 7: [13, 11],
.....: 8: [13, 12], 9: [11, 12], 10: [13],
.....: 11: [14], 12: [14], 13: [14]})
sage: C = L.center(); C
Finite lattice containing 4 elements
```

```python
sage: C = L.center(); C
Finite lattice containing 4 elements
```

```python
sage: C = L.center(); C
Finite lattice containing 4 elements
```

EXAMPLES:

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [6, 7], 3: [8, 9, 7],
.....: 4: [5, 6], 5: [8, 10], 6: [10], 7: [13, 11],
.....: 8: [13, 12], 9: [11, 12], 10: [13],
.....: 11: [14], 12: [14], 13: [14]})
sage: C = L.center(); C
Finite lattice containing 4 elements
```

See also:

* neutral_elements(), complements()

complements(element=None)

Return the list of complements of an element in the lattice, or the dictionary of complements for all elements.

Elements \(x\) and \(y\) are complements if their meet and join are respectively the bottom and the top element of the lattice.

INPUT:

* `element` – an element of the lattice whose complement is returned. If `None` (default) then dictionary of complements for all elements having at least one complement is returned.

EXAMPLES:

```python
sage: L = LatticePoset({0:['a','b','c'],'a':[1],'b':[1],'c':[1]})
sage: C = L.complements()
```

Let us check that ‘a’ and ‘b’ are complements of each other:

```python
sage: 'a' in C['b']
True
sage: 'b' in C['a']
True
```
Full list of complements:

```python
sage: L.complements()  # random order
{0: [1], 1: [0], 'a': ['b', 'c'], 'b': ['c', 'a'], 'c': ['b', 'a']}
```

```python
sage: L = LatticePoset({0:[1,2], 1:[3], 2:[3], 3:[4]})
sage: L.complements()  # random order
{0: [4], 4: [0]}
```

See also:

`is_complemented()`

congruence($S$)

Return the congruence generated by set of sets $S$.

A congruence of a lattice is an equivalence relation $\cong$ that is compatible with meet and join; i.e. if $a_1 \cong a_2$ and $b_1 \cong b_2$, then $(a_1 \vee b_1) \cong (a_2 \vee b_2)$ and $(a_1 \wedge b_1) \cong (a_2 \wedge b_2)$.

By the congruence generated by set of sets $\{S_1, \ldots, S_n\}$ we mean the least congruence $\cong$ such that for every $x, y \in S_i$ for some $i$ we have $x \cong y$.

INPUT:

* $S$ – a list of lists; list of element blocks that the congruence will contain

OUTPUT:

Congruence of the lattice as a `sage.combinat.set_partition.SetPartition`.

EXAMPLES:

```python
sage: L = posets.DivisorLattice(12)
sage: cong = L.congruence([[1, 3]])
sage: sorted(sorted(c) for c in cong)
[[1, 3], [2, 6], [4, 12]]
```

```python
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [4], 4: [5], ....: 6: [8], 3: [9], 7: [10], 8: [10], 9:[10]})
sage: cong = L.congruence([[1, 2]])
sage: cong[0]
frozenset({1, 2, 3, 4, 5, 6, 7, 8, 9, 10})
```

See also:

`quotient()`

congruences_lattice($labels$=’congruence’)

Return the lattice of congruences.
A congruence of a lattice is a partition of elements to classes compatible with both meet- and join-operation; see `congruence()`. Elements of the congruence lattice are congruences ordered by refinement; i.e. if every class of a congruence \( \Theta \) is contained in some class of \( \Phi \), then \( \Theta \leq \Phi \) in the congruence lattice.

INPUT:
- labels – a string; the type of elements in the resulting lattice

OUTPUT:
A distributive lattice.
- If `labels='congruence'`, then elements of the result will be congruences given as `sage.combinat.set_partition.SetPartition`.
- If `labels='integers'`, result is a lattice on integers isomorphic to the congruence lattice.

EXAMPLES:

```python
sage: N5 = posets.PentagonPoset()
sage: CL = N5.congruences_lattice(); CL
Finite lattice containing 5 elements
sage: CL.atoms()
[{{0}, {1}, {2, 3}, {4}}]
sage: CL.coatoms()
[{{0, 1}, {2, 3, 4}}, {{0, 2, 3}, {1, 4}}]
```

```
sage: C4 = posets.ChainPoset(4)
sage: CL = C4.congruences_lattice(labels='integer')
sage: CL.is_isomorphic(posets.BooleanLattice(3))
True
```

day_doubling\((S)\)

Return the lattice with Alan Day’s doubling construction of subset \( S \).

The subset \( S \) is assumed to be convex (i.e. if \( a, c \in S \) and \( a < b < c \) in the lattice, then \( b \in S \)) and connected (i.e. if \( a, b \in S \) then there is a chain \( a = e_1, e_2, \ldots, e_n = b \) such that \( e_i \) either covers or is covered by \( e_{i+1} \)).
Alan Day’s doubling construction is a specific extension of the lattice. Here we formulate it in a format more suitable for computation.

Let $L$ be a lattice and $S$ a convex subset of it. The resulting lattice $L[S]$ has elements $(e, 0)$ for each $e \in L$ and $(e, 1)$ for each $e \in S$. If $x \leq y$ in $L$, then in the new lattice we have:

- $(x, 0), (x, 1) \leq (y, 0), (y, 1)$
- $(x, 0) \leq (x, 1)$

**INPUT:**
- $S$ – a subset of the lattice

**EXAMPLES:**

```sage
define L = LatticePoset({1: ['a', 'b', 2], 'a': ['c'], 'b': ['c', 'd'],
                            ....: 2: [3], 'c': [4], 'd': [4], 3: [4])
define L2 = L.day_doubling([['a', 'b', 'c', 'd']]); L2
Finite lattice containing 12 elements
```

```sage
define set(L2.upper_covers((1, 0))) == set(((2, 0), ('a', 0), ('b', 0)))
True
```

```sage
define set(L2.upper_covers(('b', 0))) == set(((4, 0), ('b', 1), ('c', 0)))
True
```

See also:
- `is_constructible_by_doublings()`
- `double_irreducibles()`

**double_irreducibles()**

Return the list of double irreducible elements of this lattice.

A double irreducible element of a lattice is an element covering and covered by exactly one element. In other words it is neither a meet nor a join of any elements.

**EXAMPLES:**
Combinatorics, Release 10.0

```python
sage: L = posets.DivisorLattice(12)
sage: sorted(L.double_irreducibles())
[3, 4]
sage: L = posets.BooleanLattice(3)
sage: L.double_irreducibles()
[]
```

See also: `meet_irreducibles()`, `join_irreducibles()`

`feichtner_yuzvinsky_ring(G, use_defining=False, base_ring=None)`

Return the Feichtner-Yuzvinsky ring of `self` and `G`.

Let $R$ be a commutative ring, $L$ a lattice, and $G \subseteq L$. The Feichtner-Yuzvinsky ring is the quotient of the polynomial ring $R[h_g \mid g \in G]$ by the ideal generated by

- $h_a$ for every atom $a \in L \cap G$ and
- for every antichain $A$ of the subposet $G$ such that $g := \bigvee A \in G$ (with the join taken in $L$)

$$\prod_{a \in A} (h_g - h_a).$$

This was originally described for $G$ such that $(L, G)$ is a built lattice in the sense of [FY2004] (which has a geometric motivation), but this has been extended to $G$ being an arbitrary subset.

This is not the original definition, which uses the nested subsets of $G$ (see [FY2004] for the definition). However, the original construction, which we call the defining presentation and use the variables $\{x_g \mid g \in G\}$, can be recovered by setting $h_g = \sum_{g' \geq g} x_{g'}$ (where $g' \in G$).

**INPUT:**

- `G` – a subset of elements of `self`
- `use_defining` – (default: False) whether or not to use the defining presentation in $x_g$
- `base_ring` – (default: $\mathbb{Q}$) the base ring

The order on the variables is equal to the ordering of the elements in $G$.

**EXAMPLES:**

```python
sage: B2 = posets.BooleanLattice(2)
sage: FY = B2.feichtner_yuzvinsky_ring(B2[1:])
sage: FY
Quotient of Multivariate Polynomial Ring in h0, h1, h2 over Rational Field
by the ideal (h0, h1, h0*h1 - h0*h2 - h1*h2 + h2^2)
sage: FY = B2.feichtner_yuzvinsky_ring(B2[1:], use_defining=True)
sage: FY
Quotient of Multivariate Polynomial Ring in x0, x1, x2 over Rational Field
by the ideal (x0 + x2, x1 + x2, x0*x1)
```

We reproduce the example from Section 5 of [Coron2023]:

1976 Chapter 5. Comprehensive Module List
sage: H.<a,b,c,d> = HyperplaneArrangements(QQ)
sage: Arr = H(a-b, b-c, c-d, d-a)
sage: P = LatticePoset(Arr.intersection_poset())
sage: FY = P.feichtner_yuzvinsky_ring([P.top(),5,1,2,3,4])
sage: FY.defining_ideal().groebner_basis()
[h0^2 - h0*h1, h1^2, h2, h3, h4, h5]

frattini_sublattice()

Return the Frattini sublattice of the lattice.

The Frattini sublattice $\Phi(L)$ is the intersection of all proper maximal sublattices of $L$. It is also the set of "non-generators" - if the sublattice generated by set $S$ of elements is whole lattice, then also $S \setminus \Phi(L)$ generates whole lattice.

EXAMPLES:

sage: L = LatticePoset(( [], [[1,2],[1,17],[1,8],[2,3],[2,22],
....: [2,5],[2,7],[17,22],[17,13],[8,7],
....: [8,13],[3,16],[3,9],[22,16],[22,18],
....: [22,10],[5,18],[5,14],[7,9],[7,14],
....: [7,10],[13,10],[16,6],[16,19],[9,19],
....: [18,6],[18,33],[14,33],[10,19],
....: [10,33],[6,4],[19,4],[33,4] ))
sage: sorted(L.frattini_sublattice().list())
[1, 2, 4, 10, 19, 22, 33]

is_atomic(certificate=False)

Return True if the lattice is atomic, and False otherwise.

A lattice is atomic if every element can be written as a join of atoms.

INPUT:

• certificate – (default: False) whether to return a certificate

OUTPUT:

• If certificate=True return either (True, None) or (False, e), where $e$ is a join-irreducible element that is not an atom. If certificate=False return True or False.

EXAMPLES:

sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3:[5], 4:[6], 5:[6]})
sage: L.is_atomic()
True
sage: L = LatticePoset({0: [1, 2], 1: [3], 2: [3], 3:[4]})
sage: L.is_atomic()
False
sage: L.is_atomic(certificate=True)
(False, 4)

Note: See [EnumComb1], Section 3.3 for a discussion of atomic lattices.

See also:
• Dual property: `is_coatomic()`

• Stronger properties: `is_sectionally_complemented()`

• Mutually exclusive properties: `is_vertically_decomposable()`

**`is_coatomic(certificate=\text{False})`**

Return True if the lattice is coatomic, and False otherwise.

A lattice is coatomic if every element can be written as a meet of coatoms; i.e. if the dual of the lattice is atomic.

**INPUT:**

• `certificate` – (default: False) whether to return a certificate

**OUTPUT:**

• If `certificate=True` return either (True, None) or (False, e), where e is a meet-irreducible element that is not a coatom. If `certificate=False` return True or False.

**EXAMPLES:**

```
sage: L = posets.BooleanLattice(3)
sage: L.is_coatomic()
True

sage: L = LatticePoset({1: [2], 2: [3, 4], 3: [5], 4: [5]})
sage: L.is_coatomic()
False
sage: L.is_coatomic(certificate=True)
(False, 1)
```

See also:

• Dual property: `is_atomic()`

• Stronger properties: `is_cosectionally_complemented()`

• Mutually exclusive properties: `is_vertically_decomposable()`

**`is_complemented(certificate=\text{False})`**

Return True if the lattice is complemented, and False otherwise.

A lattice is complemented if every element has at least one complement.

**INPUT:**

• `certificate` – (default: False) whether to return a certificate

**OUTPUT:**

• If `certificate=True` return either (True, None) or (False, e), where e is an element without a complement. If `certificate=False` return True or False.

**EXAMPLES:**

```
sage: L = LatticePoset({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})
sage: L.is_complemented()
True
```

(continues on next page)
Combinatorics, Release 10.0

sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [5], 4: [6],
.....: 5: [7], 6: [7]})
sage: L.is_complemented()
False
sage: L.is_complemented(certificate=True)
(False, 2)

See also:

• Stronger properties: is_sectionally_complemented(), is_cosectionally_complemented(),
is_orthocomplemented()

• Other: complements()

is_constructible_by_doublings(type)

Return True if the lattice is constructible by doublings, and False otherwise.

We call a lattice doubling constructible if it can be constructed from the one element lattice by a sequence of Alan Day's doubling constructions.

Lattices constructible by interval doubling are also called bounded. Lattices constructible by lower and upper pseudo-interval are called lower bounded and upper bounded. Lattices constructible by any convex set doubling are called congruence normal.

INPUT:

• type – a string; can be one of the following:
  – 'interval' - allow only doublings of an interval
  – 'lower' - allow doublings of lower pseudo-interval; that is, a subset of the lattice with a unique minimal element
  – 'upper' - allow doublings of upper pseudo-interval; that is, a subset of the lattice with a unique maximal element
  – 'convex' - allow doubling of any convex set
  – 'any' - allow doubling of any set

EXAMPLES:

The pentagon can be constructed by doubling intervals; the 5-element diamond can not be constructed by any doublings:

sage: posets.PentagonPoset().is_constructible_by_doublings('interval')
True
sage: posets.DiamondPoset(5).is_constructible_by_doublings('any')
False

After doubling both upper and lower pseudo-interval a lattice is constructible by convex subset doubling:

sage: L = posets.BooleanLattice(2)
sage: L = L.day_doubling([0, 1, 2])  # A lower pseudo-interval
sage: L.is_constructible_by_doublings('interval')
False
sage: L.is_constructible_by_doublings('lower')
(continues on next page)

5.1. Comprehensive Module List
Combinatorics, Release 10.0

True
sage: L = L.day_doubling([(3,0), (1,1), (2,1)])  # An upper pseudo-interval
sage: L.is_constructible_by_doublings('upper')
False
sage: L.is_constructible_by_doublings('convex')
True

An example of a lattice that can be constructed by doublings of a non-convex subsets:

sage: L = LatticePoset(DiGraph('OQC?a?@CO?G_C@?GA?O??_??@?BO?A_?G??C??_@???'))
sage: L.is_constructible_by_doublings('convex')
False
sage: L.is_constructible_by_doublings('any')
True

See also:

- Stronger properties: is_distributive() (doubling by interval), is_join_semidistributive() (doubling by lower pseudo-intervals), is_meet_semidistributive() (doubling by upper pseudo-intervals)
- Mutually exclusive properties: is_simple() (doubling by any set)
- Other: day_doubling()

ALGORITHM:

According to [HOLM2016] a lattice \( L \) is lower bounded if and only if \(|\text{Ji}(L)| = |\text{Ji}(\text{Con} L)|\), and so dually \(|\text{Mi}(L)| = |\text{Mi}(\text{Con} L)|\) in upper bounded lattices. The same reference gives a test for being constructible by convex or by any subset.

is_cosectionally_complemented(certificate=False)

Return True if the lattice is cosectionally complemented, and False otherwise.

A lattice is cosectionally complemented if all intervals to the top element interpreted as sublattices are complemented lattices.

INPUT:

- certificate – (default: False) Whether to return a certificate if the lattice is not cosectionally complemented.

OUTPUT:

- If certificate=False return True or False. If certificate=True return either (True, None) or (False, (b, e)), where \( b \) is an element so that in the sublattice from \( b \) to the top element has no complement for element \( e \).

EXAMPLES:

The smallest sectionally but not cosectionally complemented lattice:

sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3: [5], 4: [6], 5: [6]})
sage: L.is_sectionally_complemented(), L.is_cosectionally_complemented()
(True, False)

A sectionally and cosectionally but not relatively complemented lattice:
Combinatorics, Release 10.0

```python
sage: L = LatticePoset(DiGraph('MYi@O?P??D?OG?O?_?C?Q??O?W?O????

sage: L.is_sectionally_complemented() and L.is_cosectionally_complemented()
True

sage: L.is_relatively_complemented()
False

Getting a certificate:

sage: L = LatticePoset(DiGraph('HW?@D?Q?GE?G@??

sage: L.is_cosectionally_complemented(certificate=True)
(False, (2, 7))
```

See also:

- Dual property: `is_sectionally_complemented`
- Weaker properties: `is_complemented`, `is_coatomic`, `is_regular`
- Stronger properties: `is_relatively_complemented`

**is_dismantlable** *(certificate=False)*

Return True if the lattice is dismantlable, and False otherwise.

An \(n\)-element lattice \(L_n\) is dismantlable if there is a sublattice chain \(L_{n-1} \supset L_{n-2} \supset \cdots \supset L_0\) so that every \(L_i\) is a sublattice of \(L_{i+1}\) with one element less, and \(L_0\) is the empty lattice. In other words, a dismantlable lattice can be reduced to empty lattice removing doubly irreducible element one by one.

**INPUT:**

- **certificate** *(boolean)* – Whether to return a certificate.
  - If `certificate = False` (default), returns True or False accordingly.
  - If `certificate = True`, returns:
    * (True, elms) when the lattice is dismantlable, where elms is elements listed in a possible removing order.
    * (False, crown) when the lattice is not dismantlable, where crown is a subposet of \(2k\) elements \(a_1, \ldots, a_k, b_1, \ldots, b_k\) with covering relations \(a_i \lessdot b_i\) and \(a_i \lessdot b_{i+1}\) for \(i \in [1, \ldots, k-1]\), and \(a_k \lessdot b_1\).

**EXAMPLES:**

```python
sage: DL12 = LatticePoset((divisors(12), attrcall("divides")))

sage: DL12.is_dismantlable(True)
(True, [4, 2, 1, 3, 6, 12])

sage: B3 = posets.BooleanLattice(3)

sage: B3.is_dismantlable(False)
False

sage: B3.is_dismantlable(certificate=True)
(False, Finite poset containing 6 elements)
```

Every planar lattice is dismantlable. Converse is not true:
sage: L = LatticePoset( ([], [[0, 1], [0, 2], [0, 3], [0, 4],
....: [1, 7], [2, 6], [3, 5], [4, 5],
....: [4, 6], [4, 7], [5, 8], [6, 8],
....: [7, 8]] )

sage: L.is_dismantlable()
True
sage: L.is_planar()
False

See also:

• Stronger properties: is_planar()
• Weaker properties: is_sublattice_dismantlable()

is_distributive(certificate=False)

Return True if the lattice is distributive, and False otherwise.

A lattice \((L, \vee, \wedge)\) is distributive if meet distributes over join: \(x \wedge (y \vee z) = (x \wedge y) \vee (x \wedge z)\) for every \(x, y, z \in L\) just like \(x \cdot (y + z) = x \cdot y + x \cdot z\) in normal arithmetic. For duality in lattices it follows that then also join distributes over meet.

• certificate – (default: False) whether to return a certificate

OUTPUT:

• If certificate=True return either (True, None) or (False, (x, y, z)), where x, y and z are elements of the lattice such that \(x \wedge (y \vee z) \neq (x \wedge y) \vee (x \wedge z)\). If certificate=False return True or False.

EXAMPLES:

sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [4], 4: [5]})
sage: L.is_distributive()
True
sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3: [6], 4: [6], 5: [6]})
sage: L.is_distributive()
False
sage: L.is_distributive(certificate=True)
(False, (5, 3, 2))

See also:

• Weaker properties: is_modular(), is_semidistributive(), is_join_distributive(), is_meet_distributive(), is_subdirectly_reducible(), is_trim(), is_constructible_by_doublings() (by interval doubling), is_extremal()
• Stronger properties: is_stone()

is_extremal()

Return True if the lattice is extremal, and False otherwise.

A lattice is extremal if the number of join-irreducibles is equal to the number of meet-irreducibles and to the number of cover relations in the longest chains.

EXAMPLES:
sage: posets.PentagonPoset().is_extremal()
True

sage: P = LatticePoset(posets.SymmetricGroupWeakOrderPoset(3))
sage: P.is_extremal()
False

See also:

• Stronger properties: is_distributive(), is_trim()

REFERENCES:

• [Mark1992]

is_geometric()

Return True if the lattice is geometric, and False otherwise.

A lattice is geometric if it is both atomic and upper semimodular.

EXAMPLES:

Canonical example is the lattice of partitions of finite set ordered by refinement:

sage: L = posets.SetPartitions(4)
sage: L.is_geometric()
True

Smallest example of geometric lattice that is not modular:

sage: L = LatticePoset(DiGraph('K???g@S?q?M?@??@??@??@??'))
sage: L.is_geometric()
True
sage: L.is_modular()
False

Two non-examples:

sage: L = LatticePoset({1:[2, 3, 4], 2:[5, 6], 3:[5], 4:[6], 5:[7], 6:[7]})
sage: L.is_geometric()  # Graded, but not upper semimodular
False
sage: L = posets.ChainPoset(3)
sage: L.is_geometric()  # Modular, but not atomic
False

See also:

• Weaker properties: is_upper_semimodular(), is_relatively_complemented()

is_interval_dismantlable(\text{\texttt{certificate=\texttt{False}}})

Return True if the lattice is interval dismantlable, and False otherwise.

An interval dismantling is a subdivision of a lattice to a principal upper set and a principal lower set. A lattice is \textit{interval dismantlable} if it can be decomposed into 1-element lattices by consecutive interval dismantlings.
A lattice is minimally interval non-dismantlable if it is not interval dismantlable, but all of its sublattices are interval dismantlable.

INPUT:
- certificate – (default: False) whether to return a certificate

OUTPUT:
- if certificate=False, return only True or False
- if certificate=True, return either
  - (True, list) where list is a nested list showing the decomposition; for example list[1][0]
    is a lower part of upper part of the lattice when decomposed twice.
  - (False, M) where M is a minimally interval non-dismantlable sublattice of the lattice.

EXAMPLES:

```python
sage: L1 = LatticePoset({1: [2, 3], 3: [4, 5], 2: [6], 4: [6], 5: [6]})
sage: L1.is_interval_dismantlable()
True
sage: L2 = LatticePoset({1: [2, 3, 4, 5], 2: [6], 3: [6], 4: [6],
...: 5: [6, 7], 6: [8], 7: [9, 10], 8:[10], 9:[10]})
sage: L2.is_interval_dismantlable()
False
```

To get certificates:

```python
sage: L1.is_interval_dismantlable(certificate=True)
(True, [[[1], [2]], [[[3], [5]], [[4], [6]]]])
sage: L2.is_interval_dismantlable(certificate=True)
(False, Finite lattice containing 5 elements)
```

See also:

- Stronger properties: `is_join_semidistributive()`, `is_meet_semidistributive()`
- Weaker properties: `is_sublattice_dismantlable()`

**is_isoform(certificate=False)**

Return True if the lattice is isoform and False otherwise.

A congruence is isoform (or isotype) if all blocks are isomorphic sublattices. A lattice is isoform if it has only isoform congruences.

INPUT:
- certificate – (default: False) whether to return a certificate if the lattice is not isoform

OUTPUT:
- If certificate=True return either (True, None) or (False, C), where C is a non-isoform con-
  gruence as a `sage.combinat.set_partition.SetPartition`. If certificate=False return
  True or False.

EXAMPLES:
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [6, 7], 4: [7], 5: [8], 6: \[8], 7: [8]})
sage: L.is_isoform()
True

Every isoform lattice is (trivially) uniform, but the converse is not true:

sage: L = LatticePoset({1: [2, 3, 6], 2: [4, 5], 3: [5], 4: [9, 8], 5: [7, 8], 6: [9], 7: [10], 8: [10], 9: [10]})
sage: L.is_isoform(), L.is_uniform()
(False, True)
sage: L.is_isoform(certificate=True)
(False, {{1, 2, 4, 6, 9}, {3, 5, 7, 8, 10}})

See also:
- Weaker properties: is_uniform()
- Stronger properties: is_simple(), is_relatively_complemented()
- Other: congruence()

**is_join_distributive** (certificate=False)

Return True if the lattice is join-distributive and False otherwise.

A lattice is join-distributive if every interval from an element to the join of the element’s upper covers is a distributive lattice. Actually this distributive sublattice is then a Boolean lattice.

They are also called as Dilworth’s lattices and upper locally distributive lattices. They can be characterized in many other ways, see [Dil1940].

**INPUT:**
- certificate – (default: False) whether to return a certificate

**OUTPUT:**
- If certificate=True return either (True, None) or (False, e), where e is an element such that the interval from e to the meet of upper covers of e is not distributive. If certificate=False return True or False.

**EXAMPLES:**

sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [5, 7],
....: 4: [6, 7], 5: [8, 9], 6: [9], 7: [9, 10],
....: 8: [11], 9: [11], 10: [11]})
sage: L.is_join_distributive()
True
sage: L = LatticePoset({1: [2], 2: [3, 4], 3: [5], 4: [6],
....: 5: [7], 6: [7]})
sage: L.is_join_distributive()
False
sage: L.is_join_distributive(certificate=True)
(False, 2)

See also:
**is_join_pseudocomplemented** *(certificate=False)*

Return True if the lattice is join-pseudocomplemented, and False otherwise.

A lattice is join-pseudocomplemented if every element \( e \) has a join-pseudocomplement \( e' \), i.e. the least element such that the join of \( e \) and \( e' \) is the top element.

**INPUT:**
- certificate – (default: False) whether to return a certificate

**OUTPUT:**
- If certificate=True return either (True, None) or (False, \( e \)), where \( e \) is an element without a join-pseudocomplement. If certificate=False return True or False.

**EXAMPLES:**

```python
sage: L = LatticePoset({1: [2, 5], 2: [3, 6], 3: [4], 4: [7],
                    ....: 5: [6], 6: [7]})
sage: L.is_join_pseudocomplemented()
True

sage: L = LatticePoset({1: [2, 3], 2: [4, 5, 6], 3: [6], 4: [7],
                    ....: 5: [7], 6: [7]})
sage: L.is_join_pseudocomplemented()
False

sage: L.is_join_pseudocomplemented(certificate=True)
(False, 4)
```

**See also:**
- Dual property: *is_pseudocomplemented()*
- Stronger properties: *is_join_semidistributive()*

**is_join_semidistributive** *(certificate=False)*

Return True if the lattice is join-semidistributive, and False otherwise.

A lattice is join-semidistributive if for all elements \( e, x, y \) in the lattice we have

\[
e \lor x = e \lor y \implies e \lor x = e \lor (x \land y)
\]

**INPUT:**
- certificate – (default: False) whether to return a certificate

**OUTPUT:**
- If certificate=True return either (True, None) or (False, \( (e, x, y) \)) such that \( e \lor x = e \lor y \) but \( e \lor x \neq e \lor (x \land y) \). If certificate=False return True or False.

**EXAMPLES:**
sage: T4 = posets.TamariLattice(4)
sage: T4.is_join_semidistributive()
True
sage: L = LatticePoset({1:[2, 3], 2:[4, 5], 3:[5, 6],
    ....:             4:[7], 5:[7], 6:[7]})
sage: L.is_join_semidistributive()
False
sage: L.is_join_semidistributive(certificate=True)
(False, (5, 4, 6))

See also:

• Dual property: is_meet_semidistributive()
• Weaker properties: is_join_pseudocomplemented(), is_interval_dismantlable()
• Stronger properties: is_semidistributive(), is_meet_distributive(),
  is_constructible_by_doublings() (by lower pseudo-intervals)

is_left_modular_element(x)

Return True if x is a left modular element and False otherwise.

INPUT:

• x – an element of the lattice

An element x in a lattice L is left modular if

\[(y \lor x) \land z = y \lor (x \land z)\]

for every \(y \leq z \in L\).

It is enough to check this condition on all cover relations \(y < z\).

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: [i for i in P if P.is_left_modular_element(i)]
[0, 2, 3, 4]
```

See also:

• Stronger properties: is_modular_element()

is_lower_semimodular(certificate=False)

Return True if the lattice is lower semimodular and False otherwise.

A lattice is lower semimodular if any pair of elements with a common upper cover have also a common
lower cover.

INPUT:

• certificate – (default: False) Whether to return a certificate if the lattice is not lower semimodular.

OUTPUT:

• If certificate=False return True or False. If certificate=True return either (True, None)
  or (False, (a, b)), where a and b are covered by their join but do no cover their meet.

5.1. Comprehensive Module List 1987
Combinatorics, Release 10.0

See Wikipedia article Semimodular_lattice

EXAMPLES:

```sage
sage: L = posets.DiamondPoset(5)
sage: L.is_lower_semimodular()
True

sage: L = posets.PentagonPoset()
sage: L.is_lower_semimodular()
False

sage: L = posets.ChainPoset(6)
sage: L.is_lower_semimodular()
True

sage: L = LatticePoset(DiGraph('IS?`?AAOE_@?C?_@??'))
sage: L.is_lower_semimodular(certificate=True)
(False, (4, 2))
```

See also:

• Dual property: `is_upper_semimodular()`
• Weaker properties: `is_graded()`
• Stronger properties: `is_modular()`, `is_meet_distributive()`

`is_meet_distributive(certificate=False)`

Return True if the lattice is meet-distributive and False otherwise.

A lattice is *meet-distributive* if every interval to an element from the meet of the element’s lower covers is a distributive lattice. Actually this distributive sublattice is then a Boolean lattice.

They are also called as *lower locally distributive lattices*. They can be characterized in many other ways, see [Dil1940].

INPUT:

• certificate – (default: False) whether to return a certificate

OUTPUT:

• If certificate=True return either (True, None) or (False, e), where e is an element such that the interval to e from the meet of lower covers of e is not distributive. If certificate=False return True or False.

EXAMPLES:

```sage
sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3: [5, 6, 7],
....: 4: [7], 5: [9, 8], 6: [10, 8], 7:
....: [9, 10], 8: [11], 9: [11], 10: [11]})
sage: L.is_meet_distributive()
True

sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [5], 4: [6],
....: 5: [6], 6: [7]})
sage: L.is_meet_distributive()
(continues on next page)```
False

\texttt{sage: L.is_meet_distributive(certificate=True)}

(False, 6)

See also:

- Dual property: \texttt{is_join_distributive()}
- Weaker properties: \texttt{is_join_semidistributive()}, \texttt{is_lower_semidistributive()}
- Stronger properties: \texttt{is_distributive()}

\texttt{is_meet_semidistributive(certificate=False)}

Return True if the lattice is meet-semidistributive, and False otherwise.

A lattice is meet-semidistributive if for all elements \(e, x, y\) in the lattice we have

\[
e \land x = e \land y \Rightarrow e \land x = e \land (x \lor y)
\]

INPUT:

- \texttt{certificate} – (default: False) whether to return a certificate

OUTPUT:

- If \texttt{certificate=True} return either \texttt{(True, None)} or \texttt{(False, (e, x, y))} such that \(e \land x = e \land y\) but \(e \land x \neq e \land (x \lor y)\). If \texttt{certificate=False} return True or False.

EXAMPLES:

\texttt{sage: L = LatticePoset({1:[2, 3, 4], 2:[4, 5], 3:[5, 6], ....: 4:[7], 5:[7], 6:[7]})}
\texttt{sage: L.is_meet_semidistributive()}
True
\texttt{sage: L_ = L.dual()}
\texttt{sage: L_.is_meet_semidistributive()}
False
\texttt{sage: L_.is_meet_semidistributive(certificate=True)}

(True, (5, 4, 6))

See also:

- Dual property: \texttt{is_join_semidistributive()}
- Weaker properties: \texttt{is_pseudocomplemented()}, \texttt{is_interval_dismantlable()}
- Stronger properties: \texttt{is_semidistributive()}, \texttt{is_join_distributive()}

\texttt{is_constructible_by_doublings()} (by upper pseudo-intervals)

\texttt{is_modular(L=None, certificate=False)}

Return True if the lattice is modular and False otherwise.

An element \(b\) of a lattice is modular if

\[
x \lor (a \land b) = (x \lor a) \land b
\]

for every element \(x \leq b\) and \(a\). A lattice is modular if every element is modular. There are other equivalent definitions, see Wikipedia article Modular_lattice.
With the parameter \( L \) this can be used to check that some subset of elements are all modular.

**INPUT:**

- \( L \) – (default: None) a list of elements to check being modular, if \( L \) is None, then this checks the entire lattice
- `certificate` – (default: False) whether to return a certificate

**OUTPUT:**

- If `certificate=True` return either \((True, None)\) or \((False, (x, a, b))\), where \(a, b\) and \(x\) are elements of the lattice such that \(x < b\) but \(x \lor (a \land b) \neq (x \lor a) \land b\). If also \( L \) is given then \(b\) in the certificate will be an element of \( L \). If `certificate=False` return \(True\) or \(False\).

**EXAMPLES:**

```python
sage: L = posets.DiamondPoset(5)
sage: L.is_modular()
True
sage: L = posets.PentagonPoset()
sage: L.is_modular()
False
sage: L = LatticePoset({1:[2,3],2:[4,5],3:[5,6],4:[7],5:[7],6:[7]})
sage: L.is_modular(certificate=True)
(False, (2, 6, 4))
sage: [L.is_modular_element(x) for x in L]
[True, True, False, True, True, False, True]
```

**See also:**

- Weaker properties: `is_upper_semimodular()`, `is_lower_semimodular()`, `is_supersolvable()`
- Stronger properties: `is_distributive()`
- Other: `is_modular_element()`

**is_modular_element(x)**

Return \(True\) if \(x\) is a modular element and \(False\) otherwise.

**INPUT:**

- \(x\) – an element of the lattice

An element \(x\) in a lattice \(L\) is **modular** if \(x \leq b\) implies

\[
x \lor (a \land b) = (x \lor a) \land b
\]

for every \(a, b \in L\).

**EXAMPLES:**

```python
sage: L = LatticePoset({1:[2,3],2:[4,5],3:[5,6],4:[7],5:[7],6:[7]})
sage: L.is_modular()
False
sage: [L.is_modular_element(x) for x in L]
[True, True, False, True, True, False, True]
```
See also:

- Weaker properties: `is_left_modular_element()`
- Other: `is_modular()` to check modularity for the full lattice or some set of elements

**is_orthocomplemented**(unique=False)

Return `True` if the lattice admits an orthocomplementation, and `False` otherwise.

An orthocomplementation of a lattice is a function defined for every element \(e\) and marked as \(e^\perp\) such that

1) they are complements, i.e. \(e \lor e^\perp\) is the top element and \(e \land e^\perp\) is the bottom element,
2) it is involution, i.e. \((e^\perp)^\perp = e\), and
3) it is order-reversing, i.e. if \(a < b\) then \(b^\perp < a^\perp\).

**INPUT:**

- `unique`, a Boolean – If True, return `True` only if the lattice has exactly one orthocomplementation. If False (the default), return `True` when the lattice has at least one orthocomplementation.

**EXAMPLES:**

```python
sage: D5 = posets.DiamondPoset(5)
sage: D5.is_orthocomplemented()
False

sage: D6 = posets.DiamondPoset(6)
sage: D6.is_orthocomplemented()
True

sage: D6.is_orthocomplemented(unique=True)
False

sage: hexagon = LatticePoset({0:[1, 2], 1:[3], 2:[4], 3:[5], 4:[5]})
sage: hexagon.is_orthocomplemented(unique=True)
True
```

See also:

- Weaker properties: `is_complemented()`, `is_self_dual()`

**is_planar()**

Return `True` if the lattice is upward planar, and `False` otherwise.

A lattice is upward planar if its Hasse diagram has a planar drawing in the \(\mathbb{R}^2\) plane, in such a way that \(x\) is strictly below \(y\) (on the vertical axis) whenever \(x < y\) in the lattice.

Note that the scientific literature on posets often omits “upward” and shortens it to “planar lattice” (e.g. [GW2014]), which can cause confusion with the notion of graph planarity in graph theory.

**Note:** Not all lattices which are planar – in the sense of graph planarity – admit such a planar drawing (see example below).

**ALGORITHM:**

Using the result from [Platt1976], this method returns its result by testing that the Hasse diagram of the lattice is planar (in the sense of graph theory) when an edge is added between the top and bottom elements.

**EXAMPLES:**

The Boolean lattice of \(2^3\) elements is not upward planar, even if its covering relations graph is planar:
Combinatorics, Release 10.0

sage: B3 = posets.BooleanLattice(3)
sage: B3.is_planar()
False
sage: G = B3.cover_relations_graph()
sage: G.is_planar()
True

Ordinal product of planar lattices is obviously planar. Same does not apply to Cartesian products:

sage: P = posets.PentagonPoset()
sage: Pc = P.product(P)
sage: Po = P.ordinal_product(P)
sage: Pc.is_planar()
False
sage: Po.is_planar()
True

See also:

• Weaker properties: is_dismantlable()

is_pseudocomplemented(certificate=False)

Return True if the lattice is pseudocomplemented, and False otherwise.

A lattice is (meet-)pseudocomplemented if every element \( e \) has a pseudocomplement \( e^* \), i.e. the greatest element such that the meet of \( e \) and \( e^* \) is the bottom element.

See Wikipedia article Pseudocomplement.

INPUT:

• certificate – (default: False) whether to return a certificate

OUTPUT:

• If certificate=True return either (True, None) or (False, e), where e is an element without a pseudocomplement. If certificate=False return True or False.

EXAMPLES:

sage: L = LatticePoset({1: [2, 5], 2: [3, 6], 3: [4], 4: [7],
.....: 5: [6], 6: [7]})
sage: L.is_pseudocomplemented()
True
sage: L = LatticePoset({1: [2, 3], 2: [4, 5, 6], 3: [6], 4: [7],
.....: 5: [7], 6: [7]})
sage: L.is_pseudocomplemented()
False
sage: L.is_pseudocomplemented(certificate=True)
(False, 3)

See also:

• Dual property: is_join_pseudocomplemented()

• Stronger properties: is_meet_semidistributive()
• Other: pseudocomplement().

ALGORITHM:
According to [Cha92] a lattice is pseudocomplemented if and only if every atom has a pseudocomplement. So we only check those.

\texttt{is\_regular}(\texttt{certificate=False})

Return True if the lattice is regular and False otherwise.

A congruence of a lattice is regular if it is generated by any of its parts. A lattice is regular if it has only regular congruences.

INPUT:

• certificate – (default: False) whether to return a certificate if the lattice is not regular

OUTPUT:

• If certificate=True return either \((True, None)\) or \((False, (C, p))\), where \(C\) is a non-regular congruence as a \texttt{sage.combinat.set\_partition.SetPartition} and \(p\) is a congruence class of \(C\) such that the congruence generated by \(p\) is not \(C\). If certificate=False return True or False.

EXAMPLES:

\begin{verbatim}
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [8, 7], 4: [6, 7], 5: [8],
    6: [9], 7: [9], 8: [9]})
sage: L.is_regular()
True
sage: N5 = posets.PentagonPoset()
sage: N5.is_regular()
False
sage: N5.is_regular(certificate=True)
(False, ({{0}, {1}, {2, 3}, {4}}, [0]))
\end{verbatim}

See also:

• Stronger properties: \texttt{is\_uniform()}, \texttt{is\_sectionally\_complemented()}, \texttt{is\_cosectionally\_complemented()}

• Mutually exclusive properties: \texttt{is\_vertically\_decomposable()}

• Other: \texttt{congruence()}

\texttt{is\_relatively\_complemented}(\texttt{certificate=False})

Return True if the lattice is relatively complemented, and False otherwise.

A lattice is relatively complemented if every interval of it is a complemented lattice.

INPUT:

• certificate – (default: False) Whether to return a certificate if the lattice is not relatively complemented.

OUTPUT:

• If certificate=True return either \((True, None)\) or \((False, (a, b, c))\), where \(b\) is the only element that covers \(a\) and is covered by \(c\). If certificate=False return True or False.

EXAMPLES:
Relatively complemented lattice must be both atomic and coatomic. Implication to other direction does not hold:

```python
sage: L = LatticePoset({0: [1, 2, 3, 4, 5], 1: [6, 7], 2: [6, 8],
                   ....:
                   3: [7, 8, 9], 4: [9, 11], 5: [9, 10],
                   ....:
                   6: [10, 11], 7: [12], 8: [12], 9: [12],
                   ....:
                   10: [12], 11: [12]})
sage: L.is_atomic() and L.is_coatomic()
True
sage: L.is_relatively_complemented()
False
```

We can also get a non-complemented 3-element interval:

```python
sage: L.is_relatively_complemented(certificate=True)
(False, (1, 6, 11))
```

See also:

- Weaker properties: `is_sectionally_complemented()`, `is_cosectionally_complemented()`, `is_isoform()`
- Stronger properties: `is_geometric()`

### is_sectionally_complemented(certificate=False)

Return True if the lattice is sectionally complemented, and False otherwise.

A lattice is sectionally complemented if all intervals from the bottom element interpreted as sublattices are complemented lattices.

**INPUT:**

- `certificate` - (default: False) Whether to return a certificate if the lattice is not sectionally complemented.

**OUTPUT:**

- If `certificate=False` return either True or False. If `certificate=True` return either (True, None) or (False, (t, e)), where t is an element so that in the sublattice from the bottom element to t has no complement for element e.

**EXAMPLES:**

Smallest examples of a complemented but not sectionally complemented lattice and a sectionally complemented but not relatively complemented lattice:

```python
sage: L = posets.PentagonPoset()
sage: L.is_relatively_complemented()
False
```
True
\texttt{sage: L.is_sectionally_complemented()}
False

\texttt{sage: L = LatticePoset({0: \{1, 2, 3\}, 1: \{4\}, 2: \{4\}, 3: \{5\}, 4: \{5\}})}
\texttt{sage: L.is_sectionally_complemented()}
True
\texttt{sage: L.is_relatively_complemented()}
False

Getting a certificate:

\texttt{sage: L = LatticePoset(DiGraph('HYOgC?C@?C?G@??'))}
\texttt{sage: L.is_sectionally_complemented(certificate=True)}
(False, (6, 1))

\textbf{See also:}

- Dual property: \texttt{is_cosectionally_complemented()}
- Weaker properties: \texttt{is_complemented(), is_atomic(), is_regular()}
- Stronger properties: \texttt{is_relatively_complemented()}

\textbf{is_semidistributive()}

Return True if the lattice is both join- and meet-semidistributive, and False otherwise.

\textbf{EXAMPLES:}

Tamari lattices are typical examples of semidistributive but not distributive (and hence not modular) lattices:

\texttt{sage: T4 = posets.TamariLattice(4)}
\texttt{sage: T4.is_semidistributive(), T4.is_distributive()}
(True, False)

Smallest non-selfdual example:

\texttt{sage: L = LatticePoset({1: \{2, 3\}, 2: \{4, 5\}, 3: \{5\}, 4: \{6\}, 5: \{7\}, 6: \{7\}})}
\texttt{sage: L.is_semidistributive()}
True

The diamond is not semidistributive:

\texttt{sage: L = posets.DiamondPoset(5)}
\texttt{sage: L.is_semidistributive()}
False

\textbf{See also:}

- Weaker properties: \texttt{is_join_semidistributive(), is_meet_semidistributive()}
- Stronger properties: \texttt{is_distributive()}
**is_simple** *(certificate=False)*

Return **True** if the lattice is simple and **False** otherwise.

A lattice is *simple* if it has no nontrivial congruences; in other words, for every two distinct elements \(a\) and \(b\) the principal congruence generated by \((a, b)\) has only one component, i.e. the whole lattice.

**INPUT:**
- certificate – (default: **False**) whether to return a certificate if the lattice is not simple

**OUTPUT:**
- If certificate=**True** return either (**True**, **None**) or (**False**, \(c\)), where \(c\) is a nontrivial congruence as a `sage.combinat.set_partition.SetPartition`. If certificate=**False** return **True** or **False**.

**EXAMPLES:**

```python
sage: posets.DiamondPoset(5).is_simple()  # Smallest nontrivial example
True
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [6], 4: [6], 5: [6]})
sage: L.is_simple()
False
sage: L.is_simple(certificate=True)
(False, [{1, 3}, {2, 4, 5, 6}])
```

Two more examples. First is a non-simple lattice without any 2-element congruences:

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3: [5], 4: [6, 7], ...
.....: 5: [8], 6: [8], 7: [8]})
sage: L.is_simple()
False
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [6, 7], 4: [8], ...
.....: 5: [8], 6: [8], 7: [8]})
sage: L.is_simple()
True
```

See also:
- Weaker properties: `is_isoform()`
- Mutually exclusive properties: `is_constructible_by_doublings()` (by any set)
- Other: `congruence()`

**is_stone** *(certificate=False)*

Return **True** if the lattice is a Stone lattice, and **False** otherwise.

The lattice is expected to be distributive (and hence pseudocomplemented).

A pseudocomplemented lattice is a Stone lattice if

\[
e^* \lor e^{**} = \top
\]

for every element \(e\) of the lattice, where \(*\) is the pseudocomplement and \(\top\) is the top element of the lattice.

**INPUT:**
- certificate – (default: **False**) whether to return a certificate

**OUTPUT:**
• If certificate=True return either (True, None) or (False, e) such that $e^* \lor e^{**} \neq \top$. If certificate=False return True or False.

EXAMPLES:
Divisor lattices are canonical example:

```
sage: D72 = posets.DivisorLattice(72)
sage: D72.is_stone()
True
```

A non-example:

```
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [4], 4: [5]})
sage: L.is_stone()
False
```

See also:

• Weaker properties: \textit{is_distributive}()

\textbf{is_subdirectly_reducible}(certificate=False)

Return True if the lattice is subdirectly reducible.

A lattice $M$ is a \textit{subdirect product} of $K$ and $L$ if it is a sublattice of $K \times L$. Lattice $M$ is \textit{subdirectly reducible} if there exists such lattices $K$ and $L$ so that $M$ is not a sublattice of either.

INPUT:

• certificate – (default: False) whether to return a certificate

OUTPUT:

• if certificate=False, return only True or False
• if certificate=True, return either
  – (True, (K, L)) such that the lattice is isomorphic to a sublattice of $K \times L$.
  – (False, (a, b)), where $a$ and $b$ are elements that are in the same congruence class for every nontrivial congruence of the lattice. Special case: If the lattice has zero or one element, return (False, None).

EXAMPLES:

```
sage: N5 = posets.PentagonPoset()
sage: N5.is_subdirectly_reducible()
False
```

```
sage: hex = LatticePoset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
sage: hex.is_subdirectly_reducible()
True
```

```
sage: hex.is_subdirectly_reducible(certificate=True)
(True,
 (Finite lattice containing 5 elements, Finite lattice containing 5 elements))
```

```
sage: N5.is_subdirectly_reducible(certificate=True)
(False, (2, 3))
```

(continues on next page)
sage: res, cert = hex.is_subdirectly_reducible(certificate=True)
sage: cert[0].is_isomorphic(N5)
True

See also:

• Stronger properties: is_distributive(), is_vertically_decomposable()
• Other: subdirect_decomposition()

is_sublattice(other)

Return True if the lattice is a sublattice of other, and False otherwise.

Lattice \( K \) is a sublattice of \( L \) if \( K \) is an (induced) subposet of \( L \) and closed under meet and join of \( L \).

Note: This method does not check whether the lattice is a isomorphic (i.e., up to relabeling) sublattice of other, but only if other directly contains the lattice as an sublattice.

EXAMPLES:

A pentagon sublattice in a non-modular lattice:

sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [5, 6], 4: [7], 5: [7], 6: [7]}
˓→)
sage: N5 = LatticePoset({1: [2, 6], 2: [4], 4: [7], 6: [7]})
sage: N5.is_sublattice(L)
True

This pentagon is a subposet but not closed under join, hence not a sublattice:

sage: N5_ = LatticePoset({1: [2, 3], 2: [4], 3: [7], 4: [7]})
sage: N5_.is_induced_subposet(L)
True
sage: N5_.is_sublattice(L)
False

See also:

isomorphic_sublattices_iterator()

is_sublattice_dismantlable()

Return True if the lattice is sublattice dismantlable, and False otherwise.

A sublattice dismantling is a subdivision of a lattice into two non-empty sublattices. A lattice is sublattice dismantlable if it can be decomposed into 1-element lattices by consecutive sublattice dismantlings.

EXAMPLES:

The smallest non-example is this (and the dual):

sage: P = Poset({1: [11, 12, 13], 2: [11, 14, 15],
.....: 3: [12, 14, 16], 4: [13, 15, 16]})
sage: L = LatticePoset(P.with_bounds())
sage: L.is_sublattice_dismantlable()
False
Here we adjoin a (double-irreducible-)dismantlable lattice as a part to an interval-dismantlable lattice:

```python
sage: B3 = posets.BooleanLattice(3)
sage: N5 = posets.PentagonPoset()
sage: L = B3.adjunct(N5, 1, 7)
sage: L.is_dismantlable(), L.is_interval_dismantlable()
(False, False)
sage: L.is_sublattice_dismantlable()
True
```

See also:

- Stronger properties: `is_dismantlable()`, `is_interval_dismantlable()`

Todo: Add a certificate-option.

```python
is_supersolvable(certificate=False)
```

Return True if the lattice is supersolvable, and False otherwise.

A lattice \( L \) is supersolvable if there exists a maximal chain \( C \) such that every \( x \in C \) is a modular element in \( L \). Equivalent definition is that the sublattice generated by \( C \) and any other chain is distributive.

INPUT:

- `certificate` – (default: False) whether to return a certificate

OUTPUT:

- If `certificate=True` return either (False, None) or (True, \( C \)), where \( C \) is a maximal chain of modular elements. If `certificate=False` return True or False.

EXAMPLES:

```python
sage: L = posets.DiamondPoset(5)
sage: L.is_supersolvable()
True
sage: L = posets.PentagonPoset()
sage: L.is_supersolvable()
False
sage: L = LatticePoset({1:[2,3],2:[4,5],3:[5,6],4:[7],5:[7],6:[7]})
sage: L.is_supersolvable()
True
sage: L.is_supersolvable(certificate=True)
(True, [1, 2, 5, 7])
sage: L.is_modular()
False
sage: L = LatticePoset({0: [1, 2, 3, 4], 1: [5, 6, 7],
....: 2: [5, 8, 9], 3: [6, 8, 10], 4: [7, 9, 10],
....: 5: [11], 6: [11], 7: [11], 8: [11],
....: 9: [11], 10: [11]})

sage: L.is_supersolvable()
False
```

5.1. Comprehensive Module List 1999
See also:

- Weaker properties: `is_graded()`
- Stronger properties: `is_modular()`

**is_trim**(*certificate=False*)

Return whether a lattice is trim.

A lattice is trim if it is extremal and left modular.

This notion is defined in [Thom2006].

**INPUT:**

- `certificate` – boolean (default `False`) whether to return instead a maximum chain of left modular elements

**EXAMPLES:**

```python
sage: P = posets.PentagonPoset()
sage: P.is_trim()
True

sage: Q = LatticePoset(posets.SymmetricGroupWeakOrderPoset(3))
sage: Q.is_trim()
False
```

See also:

- Weaker properties: `is_extremal()`
- Stronger properties: `is_distributive()`

**REFERENCES:**

**is_uniform**(*certificate=False*)

Return `True` if the lattice is uniform and `False` otherwise.

A congruence is uniform if all blocks have equal number of elements. A lattice is uniform if it has only uniform congruences.

**INPUT:**

- `certificate` – (default: `False`) whether to return a certificate if the lattice is not uniform

**OUTPUT:**

- If `certificate=True` return either `(True, None)` or `(False, C)`, where `C` is a non-uniform congruence as a `sage.combinat.set_partition.SetPartition`. If `certificate=False` return `True` or `False`.

**EXAMPLES:**

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [6, 7], 3: [5], 4: [5], 5: [9, 8], 6: [9], 7: [10], 8: [10], 9: [10]})
sage: L.is_uniform()
True
```

Every uniform lattice is regular, but the converse is not true:
sage: N6 = LatticePoset({1: [2, 3, 5], 2: [4], 3: [4], 5: [6], 4: [6]})
sage: N6.is_uniform(), N6.is_regular()
(False, True)
sage: N6.is_uniform(certificate=True)
(False, {{1, 2, 3, 4}, {5, 6}})

See also:

- Weaker properties: \texttt{is\_regular()}
- Stronger properties: \texttt{is\_isoform()}
- Other: \texttt{congruence()}

\texttt{is\_upper\_semimodular(certificate=False)}

Return True if the lattice is upper semimodular and False otherwise.

A lattice is upper semimodular if any pair of elements with a common lower cover have also a common upper cover.

INPUT:

- \texttt{certificate} – (default: False) Whether to return a certificate if the lattice is not upper semimodular.

OUTPUT:

- If \texttt{certificate=False} return True or False. If \texttt{certificate=True} return either (True, None) or (False, (a, b)), where a and b covers their meet but are not covered by their join.

See \texttt{Wikipedia article Semimodular\_lattice}

EXAMPLES:

sage: L = posets.DiamondPoset(5)
sage: L.is_upper_semimodular()
True

sage: L = posets.PentagonPoset()
sage: L.is_upper_semimodular()
False

sage: L = LatticePoset(posets.IntegerPartitions(4))
sage: L.is_upper_semimodular()
True

sage: L = LatticePoset({1:[2, 3, 4], 2: [5], 3:[5, 6], 4:[6], 5:[7], 6:[7]})
sage: L.is_upper_semimodular(certificate=True)
(False, (4, 2))

See also:

- Dual property: \texttt{is\_lower\_semimodular()}
- Weaker properties: \texttt{is\_graded()}
- Stronger properties: \texttt{is\_modular(),\ is\_join\_distributive(),\ is\_geometric()}
**is_vertically_decomposable** *(certificate=False)*

Return *True* if the lattice is vertically decomposable, and *False* otherwise.

A lattice is vertically decomposable if it has an element that is comparable to all elements and is neither the bottom nor the top element.

Informally said, a lattice is vertically decomposable if it can be seen as two lattices “glued” by unifying the top element of first lattice to the bottom element of second one.

**INPUT:**

- **certificate** – *(default: False)* whether to return a certificate

**OUTPUT:**

- If *certificate=True* return either *(False, None)* or *(True, e)*, where *e* is an element that is comparable to all other elements and is neither the bottom nor the top element. If *certificate=False* return *True* or *False*.

**EXAMPLES:**

```python
sage: posets.TamariLattice(4).is_vertically_decomposable()
False
sage: L = LatticePoset( ([1, 2, 3, 6, 12, 18, 36],
                   ....: attrcall("divides") )
sage: L.is_vertically_decomposable()
True
sage: L.is_vertically_decomposable(certificate=True)
(True, 6)
```

See also:

- Weaker properties: *is_subdirectly_reducible()*
- Mutually exclusive properties: *is_atomic(), is_coatomic(), is_regular()*
- Other: *vertical_decomposition()*

**isomorphic_sublattices_iterator** *(other)*

Return an iterator over the sublattices of the lattice isomorphic to *other*.

**INPUT:**

- **other** – a finite lattice

**EXAMPLES:**

A non-modular lattice contains a pentagon sublattice:

```python
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [5, 6], 4: [7], 5: [7], 6: [7]})
sage: L.is_modular()
False
sage: N5 = posets.PentagonPoset()
sage: N5_in_L = next(L.isomorphic_sublattices_iterator(N5)); N5_in_L
Finite lattice containing 5 elements
sage: N5_in_L.list()
[1, 3, 6, 4, 7]
```
A divisor lattice is modular, hence does not contain the pentagon as sublattice, even if it has the pentagon subposet:

```python
sage: D12 = posets.DivisorLattice(12)
sage: D12.has_isomorphic_subposet(N5)
True
sage: list(D12.isomorphic_sublattices_iterator(N5))
[]
```

See also:

`sage.combinat.posets.posets.FinitePoset.isomorphic_subposets_iterator()`

**Warning:** This function will return same sublattice as many times as there are automorphism on it. This is due to `subgraph_search_iterator()` returning labelled subgraphs.

### join_primes()

Return the join-prime elements of the lattice.

An element $x$ of a lattice $L$ is *join-prime* if $x \leq a \lor b$ implies $x \leq a$ or $x \leq b$ for every $a, b \in L$.

These are also called *coprime* in some books. Every join-prime is join-irreducible; converse holds if and only if the lattice is distributive.

**EXAMPLES:**

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [5], ...
.....: 4: [6], 5: [7], 6: [7]})
sage: L.join_primes()
[3, 4]
sage: D12 = posets.DivisorLattice(12)  # Distributive lattice
sage: D12.join_irreducibles() == D12.join_primes()
True
```

See also:

- Dual function: `meet_primes()`
- Other: `join_irreducibles()`

### maximal_sublattices()

Return maximal (proper) sublattices of the lattice.

**EXAMPLES:**

```python
sage: L = LatticePoset(( [], [1,2],[1,17],[1,8],[2,3],[2,22],
.....:  [2,5],[2,7],[17,22],[17,13],[8,7],
.....:  [8,13],[3,16],[3,9],[22,16],[22,18],
.....:  [22,10],[5,18],[5,14],[7,9],[7,14],
.....:  [7,10],[13,10],[16,6],[16,19],[9,19],
.....:  [18,6],[18,33],[14,33],[10,19],
.....:  [10,33],[6,4],[19,4],[33,4] ))
sage: maxs = L.maximal_sublattices()
sage: len(maxs)
5
```

(continues on next page)
meet_primes()

Return the meet-prime elements of the lattice.

An element $x$ of a lattice $L$ is meet-prime if $x \geq a \land b$ implies $x \geq a$ or $x \geq b$ for every $a, b \in L$.

These are also called just prime in some books. Every meet-prime is meet-irreducible; converse holds if and only if the lattice is distributive.

EXAMPLES:

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [5],
                  ....: 4: [6], 5: [7], 6: [7]})
sage: L.meet_primes()
[6, 5]
sage: D12 = posets.DivisorLattice(12)
sage: sorted(D12.meet_primes())
[3, 4, 6]
```

See also:

- Dual function: join_primes()
- Other: meet_irreducibles()

moebius_algebra($R$)

Return the Möbius algebra of self over $R$.

OUTPUT:

EXAMPLES:

```python
sage: L = posets.BooleanLattice(4)
sage: L.moebius_algebra(QQ)
Moebius algebra of Finite lattice containing 16 elements over Rational Field
```

neutral_elements()

Return the list of neutral elements of the lattice.

An element $e$ of the lattice $L$ is neutral if the sublattice generated by $e, x$ and $y$ is distributive for all $x, y \in L$.

It can also be characterized as an element of intersection of maximal distributive sublattices.

EXAMPLES:

```python
sage: L = LatticePoset({1: [2, 3], 2: [6], 3: [4, 5, 6], 4: [8],
                  ....: 5: [7], 6: [7], 7: [8, 9], 8: [10], 9: [10]})
sage: L.neutral_elements()
[1, 3, 8, 10]
```
**quantum_moebius_algebra**(*q=None*)

Return the quantum Möbius algebra of self with parameter q.

**INPUT:**
- q – (optional) the deformation parameter q

**OUTPUT:**
An instance of `sage.combinat.posets.moebius_algebra.QuantumMoebiusAlgebra`.

**EXAMPLES:**
```python
sage: L = posets.BooleanLattice(4)
sage: L.quantum_moebius_algebra()
Quantum Moebius algebra of Finite lattice containing 16 elements with q=q over Univariate Laurent Polynomial Ring in q over Integer Ring
```

**quotient**(*congruence, labels='tuple'*)

Return the quotient lattice by congruence.

Let L be a lattice and Θ be a congruence of L with congruence classes Θ₁, Θ₂,.... The quotient lattice L/Θ is the lattice with elements {Θ₁, Θ₂,...} and meet and join given by the original lattice. Explicitly, if e₁ ∈ Θ₁ and e₂ ∈ Θ₂, such that e₁ ∨ e₂ ∈ Θ₃ then Θ₁ ∨ Θ₂ = Θ₃ in L/Θ and similarly for meets.

**INPUT:**
- congruence – list of lists; a congruence
- labels – string; the elements of the resulting lattice and can be one of the following:
  - 'tuple' - elements are tuples of elements of the original lattice
  - 'lattice' - elements are sublattices of the original lattice
  - 'integer' - elements are labeled by integers

**Warning:** congruence is expected to be a valid congruence of the lattice. This is not checked.

**EXAMPLES:**
```python
sage: L = posets.PentagonPoset()
sage: c = L.congruence([[0, 1]])
sage: I = L.quotient(c); I
Finite lattice containing 2 elements
sage: I.top()
(2, 3, 4)
sage: I = L.quotient(c, labels='lattice')
sage: I.top()
(2, 3, 4)
sage: B3 = posets.BooleanLattice(3)
sage: c = B3.congruence([[0, 1]])
sage: B2 = B3.quotient(c, labels='integer')
sage: B2.is_isomorphic(posets.BooleanLattice(2))
True
```
See also:

\textit{congruence()}\textnormal{\textregistered} \\
\textit{skeleton()} \\
Return the skeleton of the lattice.

The lattice is expected to be pseudocomplemented.

The \textit{skeleton} of a pseudocomplemented lattice \(L\), where \(\ast\) is the pseudocomplementation operation, is the subposet induced by \(\{e^\ast \mid e \in L\}\). Actually this poset is a Boolean lattice.

\textbf{EXAMPLES:}

```sage
d12 = posets.DivisorLattice(12)
s = d12.skeleton(); s
Finite lattice containing 4 elements
s.skeleton().cover_relations()
[[1, 3], [1, 4], [3, 12], [4, 12]]
t4 = posets.TamariLattice(4)
skeleton().is_isomorphic(posets.BooleanLattice(3))
True
```

See also:

\textit{sage.combinat.posets.lattices.FiniteMeetSemilattice.pseudocomplement()}.

\textit{subdirect\_decomposition()} \\
Return the subdirect decomposition of the lattice.

The subdirect decomposition of a lattice \(L\) is the list of smaller lattices \(L_1, \ldots, L_n\) such that \(L\) is a sublattice of \(L_1 \times \cdots \times L_n\), none of \(L_i\) can be decomposed further and \(L\) is not a sublattice of any \(L_i\). (Except when the list has only one element, i.e. when the lattice is subdirectly irreducible.)

\textbf{EXAMPLES:}

```sage
posets.ChainPoset(3).subdirect\_decomposition()
[ Finite lattice containing 2 elements, Finite lattice containing 2 elements ]
d = LatticePoset({1: [2, 4], 2: [3], 3: [6, 7], 4: [5, 7], 5: [9, 8], 6: [9], 7: [9], 8: [10], 9: [10]})
L = d.LatticePoset({1: [2, 4], 2: [3], 3: [6, 7], 4: [5, 7], 5: [9, 8], 6: [9], 7: [9], 8: [10], 9: [10]})
L.decomposition()  
[ fac.cardinality() for fac in L.decomposition() ]
[2, 5, 7]
L.decomposition[1].is_isomorphic(posets.PentagonPoset())
True
```

\textit{sublattice}(elms) \\
Return the smallest sublattice containing elements on the given list.

\textbf{INPUT:}

- \textit{elms} – a list of elements of the lattice.

\textbf{EXAMPLES:}

```sage
L = LatticePoset([[], [[1, 2], [1, 17], [1, 8], [2, 3], [2, 22], [2, 5], [2, 7], [17, 22], [17, 13], [8, 7], [8, 13], [3, 16], [3, 9], [22, 16], [22, 18], [22, 10], [5, 18], [5, 14]]
(continues on next page)```
sage: L = posets.BooleanLattice(3)
sage: L.sublattice([3, 5, 6, 7])
Finite lattice containing 8 elements

sublattices()
Return all sublattices of the lattice.

EXAMPLES:

sage: L = LatticePoset({1: [2, 3, 4], 2:[5], 3:[5, 6], 4:[6], ....:
5:[7], 6:[7]})
sage: sublats = L.sublattices(); len(sublats)
54
sage: sublats[3]
Finite lattice containing 4 elements
sage: sublats[3].list()
[1, 2, 3, 5]

sublattices_lattice(labels='lattice')
Return the lattice of sublattices.

Every element of the returned lattice is a sublattice and they are ordered by containment; that is, atoms are one-element lattices, coatoms are maximal sublattices of the original lattice and so on.

INPUT:

• labels – string; can be one of the following:
  – 'lattice' (default) elements of the lattice will be lattices that correspond to sublattices of the original lattice
  – 'tuple' - elements are tuples of elements of the sublattices of the original lattice
  – 'integer' - elements are plain integers

EXAMPLES:

sage: D4 = posets.DiamondPoset(4)
sage: sll = D4.sublattices_lattice(labels='tuple')
sage: sll.coatoms()  # = maximal sublattices of the original lattice
[(0, 1, 3), (0, 2, 3)]

sage: L = posets.DivisorLattice(12)
sage: sll = L.sublattices_lattice()
sage: L.is_dismantlable() == (len(sll.atoms()) == sll.rank())
True

vertical_composition(other, labels='pairs')
Return the vertical composition of the lattice with other.

Let $L$ and $K$ be lattices and $b_K$ the bottom element of $K$. The vertical composition of $L$ and $K$ is the ordinal sum of $L$ and $K \setminus \{b_K\}$. Informally said this is lattices “glued” together with a common element.
Mathematically, it is only defined when \( L \) and \( K \) have no common element; here we force that by giving them different names in the resulting poset.

INPUT:

- **other** – a lattice
- **labels** – a string (default `pairs`); can be one of the following:
  - `pairs` - each element \( v \) in this poset will be named \((0, v)\) and each element \( u \) in other will be named \((1, u)\) in the result
  - `integers` - the elements of the result will be relabeled with consecutive integers

EXAMPLES:

```
sage: L = LatticePoset({'a': ['b', 'c'], 'b': ['d'], 'c': ['d']})
sage: K = LatticePoset({'e': ['f', 'g'], 'f': ['h'], 'g': ['h']})
sage: M = L.vertical_composition(K)
sage: M.list()
[(0, 'a'), (0, 'b'), (0, 'c'), (0, 'd'), (1, 'f'), (1, 'g'), (1, 'h')]
sage: M.upper_covers((0, 'd'))
[(1, 'f'), (1, 'g')]
```

```
sage: C2 = posets.ChainPoset(2)
sage: M3 = posets.DiamondPoset(5)
sage: L = C2.vertical_composition(M3, labels='integers')
sage: L.cover_relations()
[[0, 1], [1, 2], [1, 3], [1, 4], [2, 5], [3, 5], [4, 5]]
```

See also:

vertical_decomposition(), sage.combinat.posets.posets.FinitePoset.ordinal_sum()
See also:

vertical_composition(), is_vertically_decomposable()

class sage.combinat.posets.lattices.FiniteMeetSemilattice(
    hasse_diagram, elements, category,
    facade, key)

Bases: FinitePoset

Note: We assume that the argument passed to MeetSemilattice is the poset of a meet-semilattice (i.e. a poset with greatest lower bound for each pair of elements).

Element

alias of MeetSemilatticeElement

atoms()

Return the list atoms of this (semi)lattice.

An atom of a lattice is an element covering the bottom element.

EXAMPLES:

```
sage: L = posets.DivisorLattice(60)
sage: sorted(L.atoms())
[2, 3, 5]
```

See also:

• Dual function: coatoms()

meet(x, y=None)

Return the meet of given elements in the lattice.

INPUT:

• x, y – two elements of the (semi)lattice OR
• x – a list or tuple of elements

EXAMPLES:

```
sage: D = posets.DiamondPoset(5)
sage: D.meet(1, 2)
0
sage: D.meet(1, 1)
1
sage: D.meet(1, 0)
0
sage: D.meet(1, 4)
1
```

Using list of elements as an argument. Meet of empty list is the bottom element:

```
sage: B4=posets.BooleanLattice(4)
sage: B4.meet([3,5,6])
0
sage: B4.meet([])
15
```
For non-facade lattices operator \* works for meet:

```
sage: L = posets.PentagonPoset(facade=False)
sage: L(1)*L(2)
0
```

See also:

- Dual function: `join()`

**meet_matrix()**

Return a matrix whose \((i,j)\) entry is \(k\), where `self.linear_extension()[k]` is the meet (greatest lower bound) of `self.linear_extension()[i]` and `self.linear_extension()[j]`.

**EXAMPLES:**

```
sage: P = LatticePoset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[7]], facade = False)
sage: M = P.meet_matrix(); M
[0 0 0 0 0 0 0 0]
[0 1 0 0 0 0 1]
[0 0 2 2 0 2 2]
[0 1 2 3 2 0 2 3]
[0 0 2 2 4 0 2 4]
[0 0 0 0 0 5 5 5]
[0 0 2 2 5 6 6]
[0 1 2 3 4 5 6 7]
True
True
False
```

**pseudocomplement(element)**

Return the pseudocomplement of `element`, if it exists.

The (meet-)pseudocomplement is the greatest element whose meet with given element is the bottom element. I.e. in a meet-semilattice with bottom element \(\hat{0}\) the pseudocomplement of an element \(e\) is the element \(e^*\) such that \(e \land e^* = \hat{0}\) and \(e' \leq e^*\) if \(e \land e' = \hat{0}\).

**INPUT:**

- `element` – an element of the lattice.

**OUTPUT:**

An element of the lattice or `None` if the pseudocomplement does not exist.

**EXAMPLES:**

The pseudocomplement’s pseudocomplement is not always the original element:

```
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
sage: L.pseudocomplement(2)
5
```

sage: L.pseudocomplement(5)
4

An element can have complements but no pseudocomplement, or vice versa:

sage: L = LatticePoset({0: [1, 2], 1: [3, 4, 5], 2: [5], 3: [6],
....: 4: [6], 5: [6]})
sage: L.complements(1), L.pseudocomplement(1)
([], 2)
sage: L.complements(2), L.pseudocomplement(2)
([3, 4], None)

See also:

is_pseudocomplemented()

subjoinsemilattice(elms)
Return the smallest join-subsemilattice containing elements on the given list.

INPUT:

• elms – a list of elements of the lattice.

EXAMPLES:

sage: L = posets.DivisorLattice(1000)
sage: L_ = L.subjoinsemilattice([2, 25, 125]); L_
Finite join-semilattice containing 5 elements
sage: sorted(L_.list())
[2, 25, 50, 125, 250]

See also:

• Dual function: submeetsemilattice()

submeetsemilattice(elms)
Return the smallest meet-subsemilattice containing elements on the given list.

INPUT:

• elms – a list of elements of the lattice.

EXAMPLES:

sage: L = posets.DivisorLattice(1000)
sage: L_ = L.submeetsemilattice([200, 250, 125]); L_
Finite meet-semilattice containing 5 elements
sage: L_.list()
[25, 50, 200, 125, 250]

See also:

• Dual function: subjoinsemilattice()
sage.combinat.posets.lattices.JoinSemilattice(data=None, *args, **options)

Construct a join semi-lattice from various forms of input data.

INPUT:

- data, *args, **options – data and options that will be passed down to Poset() to construct a poset that is also a join semilattice

See also:
Poset(), MeetSemilattice(), LatticePoset()

EXAMPLES:

Using data that defines a poset:

```
sage: JoinSemilattice([[1,2],[3],[3]])
Finite join-semilattice containing 3 elements
sage: JoinSemilattice([[1,2],[3],[3]], cover_relations = True)
Finite join-semilattice containing 3 elements
```

Using a previously constructed poset:

```
sage: P = Poset([[1,2],[3],[3]])
sage: J = JoinSemilattice(P); J
Finite join-semilattice containing 3 elements
sage: type(J)
<class 'sage.combinat.posets.lattices.FiniteJoinSemilattice_with_category'>
```

If the data is not a lattice, then an error is raised:

```
sage: JoinSemilattice({'a': ['b', 'c'], 'b': ['d', 'e'],
....:                    'c': ['d', 'e'], 'd': ['f'], 'e': ['f']})
Traceback (most recent call last):
...
LatticeError: no join for b and c
```

sage.combinat.posets.lattices.LatticePoset(data=None, *args, **options)

Construct a lattice from various forms of input data.

INPUT:

- data, *args, **options – data and options that will be passed down to Poset() to construct a poset that is also a lattice.

OUTPUT:

An instance of FiniteLatticePoset.

See also:
Posets, FiniteLatticePosets, JoinSemilattice(), MeetSemilattice()

EXAMPLES:

Using data that defines a poset:

```
sage: LatticePoset([[1,2],[3],[3]])
Finite lattice containing 3 elements
```

(continues on next page)
sage: LatticePoset([[1,2],[3],[3]], cover_relations = True)
Finite lattice containing 3 elements

Using a previously constructed poset:

sage: P = Poset([[1,2],[3],[3]])
sage: L = LatticePoset(P); L
Finite lattice containing 3 elements
sage: type(L)
<class 'sage.combinat.posets.lattices.FiniteLatticePoset_with_category'>

If the data is not a lattice, then an error is raised:

sage: elms = [1,2,3,4,5,6,7]
sage: rels = [[1,2],[3,4],[4,5],[2,5]]
sage: LatticePoset((elms, rels))
Traceback (most recent call last):
...  
ValueError: not a meet-semilattice: no bottom element

Creating a facade lattice:

sage: L = LatticePoset([[1,2],[3],[3]], facade = True)
sage: L.category()
Category of facade finite enumerated lattice posets
sage: parent(L[0])
Integer Ring
sage: TestSuite(L).run(skip = ['_test_an_element']) # is_parent_of is not yet implemented

sage.combinat.posets.lattices.MeetSemilattice(data=None, *args, **options)

Construct a meet semilattice from various forms of input data.

INPUT:

• data, *args, **options – data and options that will be passed down to Poset() to construct a poset that is also a meet semilattice.

See also:

Poset(), JoinSemilattice(), LatticePoset()

EXAMPLES:

Using data that defines a poset:

sage: MeetSemilattice([[1,2],[3],[3]])
Finite meet-semilattice containing 3 elements
sage: MeetSemilattice([[1,2],[3],[3]], cover_relations = True)
Finite meet-semilattice containing 3 elements

Using a previously constructed poset:
Combinatorics, Release 10.0

```
sage: P = Poset([[1,2],[3],[3]])
sage: L = MeetSemilattice(P); L
Finite meet-semilattice containing 3 elements
sage: type(L)
<class 'sage.combinat.posets.lattices.FiniteMeetSemilattice_with_category'>
```

If the data is not a lattice, then an error is raised:

```
sage: MeetSemilattice({'a': ['b', 'c'], 'b': ['d', 'e'],
....:     'c': ['d', 'e'], 'd': ['f'], 'e': ['f']})
Traceback (most recent call last):
...  
LatticeError: no meet for e and d
```}

### 5.1.183 Linear Extensions of Posets

This module defines two classes:

- `LinearExtensionOfPoset`
- `LinearExtensionsOfPoset`
- `LinearExtensionsOfPosetWithHooks`
- `LinearExtensionsOfForest`

**Classes and methods**

#### class `sage.combinat.posets.linear_extensions.LinearExtensionOfPoset`

**Bases:** `ClonableArray`

A linear extension of a finite poset $P$ of size $n$ is a total ordering $\pi := \pi_0 \pi_1 \ldots \pi_{n-1}$ of its elements such that $i < j$ whenever $\pi_i < \pi_j$ in the poset $P$.

When the elements of $P$ are indexed by $\{1, 2, \ldots, n\}$, $\pi$ denotes a permutation of the elements of $P$ in one-line notation.

**INPUT:**

- `linear_extension` – a list of the elements of $P$
- `poset` – the underlying poset $P$

**See also:**

`Poset`, `LinearExtensionsOfPoset`

**EXAMPLES:**

```
sage: P = Poset(((1,2,3,4), [[1,3],[1,4],[2,3]]), linear_extension=True, 
            facade=False)
sage: p = P.linear_extension([1,4,2,3]); p
[1, 4, 2, 3]
sage: p.parent()
The set of all linear extensions of Finite poset containing 4 elements with
    distinguished linear extension
```

(continues on next page)
Following Schützenberger and later Haiman and Malvenuto-Reutenauer, Stanley [Stan2009] defined a promotion and evacuation operator on any finite poset $P$ using operators $\tau_i$ on the linear extensions of $P$:

```python
sage: p.promotion()
[1, 2, 3, 4]
sage: Q = p.promotion().to_poset()
sage: Q.cover_relations()
[[1, 3], [1, 4], [2, 3]]
sage: Q == P
True
sage: p.promotion(3)
[1, 4, 2, 3]
sage: Q = p.promotion(3).to_poset()
sage: Q == P
False
sage: Q.cover_relations()
[[1, 2], [1, 4], [3, 4]]
```

**check()**

Checks whether `self` is indeed a linear extension of the underlying poset.

**evacuation()**

Compute evacuation on the linear extension of a poset.

Evacuation on a linear extension $\pi$ of length $n$ is defined as $\pi(\tau_1 \cdots \tau_{n-1})(\tau_1 \cdots \tau_{n-2}) \cdots (\tau_1)$. For more details see [Stan2009].

See also:

`tau()`, `promotion()`

**EXAMPLES:**

```python
sage: P = Poset((([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,6]]))
sage: p = P.linear_extension([1,2,3,4,5,6,7])
sage: p.evacuation()
[1, 4, 2, 3, 7, 5, 6]
sage: p.evacuation().evacuation() == p
True
```

**is_greedy()**

Return True if the linear extension is greedy.

A linear extension $[e_1, e_2, \ldots, e_n]$ is greedy if for every $i$ either $e_{i+1}$ covers $e_i$ or all upper covers of $e_i$ have at least one lower cover that is not in $[e_1, e_2, \ldots, e_i]$.

Informally said a linear extension is greedy if it “always goes up when possible” and so has no unnecessary jumps.

**EXAMPLES:**
is_supergreedy()

Return True if the linear extension is supergreedy.

A linear extension of a poset \( P \) with elements \( \{x_1, x_2, \ldots, x_t\} \) is super greedy, if it can be obtained using the following algorithm: choose \( x_1 \) to be a minimal element of \( P \); suppose \( X = \{x_1, \ldots, x_i\} \) have been chosen; let \( M \) be the set of minimal elements of \( P \ \setminus \ X \). If there is an element of \( M \) which covers an element \( x_j \) in \( X \), then let \( x_{i+1} \) be one of these such that \( j \) is maximal; otherwise, choose \( x_{i+1} \) to be any element of \( M \).

Informally, a linear extension is supergreedy if it “always goes up and recedes the least”; in other words, supergreedy linear extensions are depth-first linear extensions. For more details see [KTZ1987].

EXAMPLES:

```
sage: X = [0,1,2,3,4,5,6]
sage: Y = [[0,5],[1,4],[1,5],[3,6],[4,3],[5,6],[6,2]]
sage: P = Poset((X,Y), cover_relations = True, facade=False)
sage: for l in P.linear_extensions():
    ....:     if l.is_supergreedy():
    ....:         print(l)
[1, 4, 3, 0, 5, 6, 2]
[0, 1, 4, 3, 5, 6, 2]
[0, 1, 5, 4, 3, 6, 2]
```

jump_count()

Return the number of jumps in the linear extension.

A jump in a linear extension \([e_1, e_2, \ldots, e_n]\) is a pair \((e_i, e_{i+1})\) such that \( e_{i+1} \) does not cover \( e_i \).

See also:

- `sage.combinat.posets.posets.FinitePoset.jump_number()`

EXAMPLES:

```
sage: B3 = posets.BooleanLattice(3)
sage: l1 = B3.linear_extension((0, 1, 2, 3, 4, 5, 6, 7))
sage: l1.jump_count()
3
sage: l2 = B3.linear_extension((0, 1, 2, 4, 3, 5, 6, 7))
sage: l2.jump_count()
5
```
poset()

Return the underlying original poset.

EXAMPLES:

```
sage: P = Poset(((1,2,3,4), [[1,2],[2,3],[1,4]]))
sage: p = P.linear_extension([1,2,4,3])
sage: p.poset()
Finite poset containing 4 elements
```

promotion(i=1)

Compute the (generalized) promotion on the linear extension of a poset.

INPUT:

- `i` – (default: 1) an integer between 1 and \( n - 1 \), where \( n \) is the cardinality of the poset.

The \( i \)-th generalized promotion operator \( \partial_i \) on a linear extension \( \pi \) is defined as \( \pi \tau_i \tau_{i+1} \cdots \tau_{n-1} \), where \( n \) is the size of the linear extension (or size of the underlying poset).

For more details see [Stan2009].

See also:

`tau()`, `evacuation()`

EXAMPLES:

```
sage: P = Poset(((1,2,3,4,5,6,7), [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,6]]))
sage: p = P.linear_extension([1,2,3,4,5,6,7])
sage: q = p.promotion(4); q
[1, 2, 3, 5, 6, 4, 7]
sage: p.to_poset() == q.to_poset()
False
sage: p.to_poset().is_isomorphic(q.to_poset())
True
```

tau()

Return the operator \( \tau_i \) on linear extensions \( \text{self} \) of a poset.

INPUT:

- `i` – an integer between 1 and \( n - 1 \), where \( n \) is the cardinality of the poset.

The operator \( \tau_i \) on a linear extension \( \pi \) of a poset \( P \) interchanges positions \( i \) and \( i + 1 \) if the result is again a linear extension of \( P \), and otherwise acts trivially. For more details, see [Stan2009].

EXAMPLES:

```
sage: P = Poset(((1,2,3,4), [[1,3],[1,4],[2,3]]), linear_extension=True)
sage: L = P.linear_extensions()
sage: l = L.an_element(); l
[1, 2, 3, 4]
sage: l.tau(1)
[2, 1, 3, 4]
sage: for p in L:
....:     for i in range(1,4):
....:         print("{} {} {}".format(i, p, p.tau(i)))
1 [1, 2, 3, 4] [2, 1, 3, 4]
```
to_poset()

Return the poset associated to the linear extension self.

This method returns the poset obtained from the original poset $P$ by relabelling the $i$-th element of self to the $i$-th element of the original poset, while keeping the linear extension of the original poset.

For a poset with default linear extension $1, \ldots, n$, self can be interpreted as a permutation, and the relabelling is done according to the inverse of this permutation.

EXAMPLES:

```python
sage: P = Poset(((1,2,3,4), [(1,2), (1,3), (3,4)]), linear_extension=True, facade=False)
sage: p = P.linear_extension([1,3,4,2])
sage: Q = p.to_poset(); Q
Finite poset containing 4 elements with distinguished linear extension
sage: P == Q
False
```

The default linear extension remains the same:

```python
sage: list(P)
[1, 2, 3, 4]
sage: list(Q)
[1, 2, 3, 4]
```

But the relabelling can be seen on cover relations:

```python
sage: P.cover_relations()
[[1, 2], [1, 3], [3, 4]]
sage: Q.cover_relations()
[[1, 2], [1, 4], [2, 3]]
sage: p = P.linear_extension([1,2,3,4])
sage: Q = p.to_poset()
sage: P == Q
True
```
Linear extensions such that the poset is a forest.

\textbf{cardinality}()

Use Atkinson’s algorithm to compute the number of linear extensions.

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.posets.forest import ForestPoset
sage: from sage.combinat.posets.poset_examples import Posets
sage: P = Poset({0: [2], 1: [2], 2: [3, 4], 3: [], 4: []})
sage: P.linear_extensions().cardinality()
4

sage: Q = Poset({0: [1], 1: [2, 3], 2: [], 3: [], 4: [5, 6], 5: [], 6: []})
sage: Q.linear_extensions().cardinality()
140
\end{verbatim}

\textbf{class} \texttt{sage.combinat.posets.linear_extensions.LinearExtensionsOfMobile(poset, facade)}

Bases: \texttt{LinearExtensionsOfPoset}

Linear extensions for a mobile poset.

\textbf{cardinality}()

Return the number of linear extensions by using the determinant formula for counting linear extensions of mobiles.

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.posets.mobile import MobilePoset
sage: M = MobilePoset(DiGraph([[0,1,2,3,4,5,6,7,8], [(1,0),(3,0),(2,1),(2,3),(4,....: 3), (5,4),(5,6),(7,4),(7,8)]]))
sage: M.linear_extensions().cardinality()
1098

sage: M1 = posets.RibbonPoset(6, [1,3])
sage: M1.linear_extensions().cardinality()
61

 DoubledTailedDiamond(6)]},
....: anchor=(4, 2, posets.ChainPoset(6))
}sage: P.linear_extensions().cardinality()
361628701868606400
\end{verbatim}

\textbf{class} \texttt{sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset(poset, facade)}

Bases: \texttt{UniqueRepresentation, Parent}

The set of all linear extensions of a finite poset

\textbf{INPUT:}

- \texttt{poset} – a poset \(P\) of size \(n\)
- \texttt{facade} – a boolean (default: False)

\textbf{See also:}

- \texttt{sage.combinat.posets.posets.FinitePoset.linear_extensions()}

\section{5.1. Comprehensive Module List}

\textbf{2019}
EXAMPLES:

```python
sage: elms = [1,2,3,4]
sage: rels = [[1,3],[1,4],[2,3]]
sage: P = Poset((elms, rels), linear_extension=True)
sage: L = P.linear_extensions(); L
The set of all linear extensions of Finite poset containing 4 elements with
→ distinguished linear extension
sage: L.cardinality()
5
sage: L.list()
[[1, 2, 3, 4], [2, 1, 3, 4], [2, 1, 4, 3], [1, 4, 2, 3], [1, 2, 4, 3]]
sage: L.an_element()
[1, 2, 3, 4]
sage: L.poset()
Finite poset containing 4 elements with distinguished linear extension
```

**Element**

alias of *LinearExtensionOfPoset*

**cardinality()**

Return the number of linear extensions.

EXAMPLES:

```python
sage: N = Poset({0: [2, 3], 1: [3]})
sage: N.linear_extensions().cardinality()
5
```

**markov_chain_digraph** *(action='promotion', labeling='identity')*

Return the digraph of the action of generalized promotion or tau on **self**

**INPUT:**

- `action` – ‘promotion’ or ‘tau’ (default: ‘promotion’)
- `labeling` – ‘identity’ or ‘source’ (default: ‘identity’)

**Todo:**

- generalize this feature by accepting a family of operators as input
- move up in some appropriate category

This method creates a graph with vertices being the linear extensions of a given finite poset and an edge from \( \pi \) to \( \pi' \) if \( \pi' = \pi \varphi_i \) where \( \varphi_i \) is the promotion operator (see *promotion()* ) if action is set to *promotion* and \( \tau_i \) (see *tau()* ) if action is set to *tau*. The label of the edge is \( i \) (resp. \( \pi_i \)) if labeling is set to *identity* (resp. *source*).

**EXAMPLES:**

```python
sage: P = Poset(((1,2,3,4), [[1,3],[1,4],[2,3]]), linear_extension=True)
sage: L = P.linear_extensions()
sage: G = L.markov_chain_digraph(); G
Looped multi-digraph on 5 vertices
sage: G.vertices(sort=True, key=repr)
(continues on next page)
```
The edges of the graph are by default colored using blue for edge 1, red for edge 2, green for edge 3, and yellow for edge 4:

```
sage: view(G) # optional - dot2tex graphviz, not tested (opens external window)
```

Alternatively, one may get the graph of the action of the $\tau$ operator:

```
sage: G = L.markov_chain_digraph(action='tau'); G
Looped multi-digraph on 5 vertices
```

sage: view(G)  # optional - dot2tex graphviz, not tested (opens external window)

See also:

markov_chain_transition_matrix(), promotion(), tau()

markov_chain_transition_matrix(action='promotion', labeling='identity')

Return the transition matrix of the Markov chain for the action of generalized promotion or tau on self

INPUT:

• action – ‘promotion’ or ‘tau’ (default: ‘promotion’)

• labeling – ‘identity’ or ‘source’ (default: ‘identity’)

This method yields the transition matrix of the Markov chain defined by the action of the generalized
promotion operator \( \partial_i \) (resp. \( \tau_i \)) on the set of linear extensions of a finite poset. Here the transition from
the linear extension \( \pi \) to \( \pi' \), where \( \pi' = \pi \partial_i \) (resp. \( \pi' = \pi \tau_i \)) is counted with weight \( x_i \) (resp. \( x_{\pi_i} \) if
labeling is set to source).

EXAMPLES:

sage: P = Poset(((1, 2, 3, 4), [[1, 3], [1, 4], [2, 3]]), linear_extension = True)
sage: L = P.linear_extensions()
sage: L.markov_chain_transition_matrix()

\[
\begin{pmatrix}
-x_0 & -x_1 & -x_2 & x_2 & x_0 & +x_1 & 0 & 0 \\
x_1 & +x_2 & -x_0 & -x_1 & -x_2 & 0 & x_0 & 0 \\
0 & x_1 & -x_0 & -x_1 & 0 & x_0 & 0 \\
0 & x_0 & 0 & -x_0 & -x_1 & -x_2 & x_1 & +x_2 \\
x_0 & 0 & 0 & x_1 & +x_2 & -x_0 & -x_1 & -x_2
\end{pmatrix}
\]

sage: L.markov_chain_transition_matrix(labeling = 'source')

\[
\begin{pmatrix}
-x_0 & -x_1 & -x_2 & x_3 & x_0 & +x_3 & 0 & 0 \\
x_1 & +x_2 & -x_0 & -x_1 & -x_3 & 0 & x_1 & 0 \\
0 & x_1 & -x_0 & -x_3 & 0 & x_1 & 0 \\
0 & x_0 & 0 & -x_0 & -x_1 & -x_2 & x_0 & +x_3 \\
x_0 & 0 & 0 & x_0 & +x_2 & -x_0 & -x_1 & -x_3
\end{pmatrix}
\]

sage: L.markov_chain_transition_matrix(action = 'tau')

\[
\begin{pmatrix}
-x_0 & -x_2 & x_2 & 0 & x_0 & 0 \\
x_2 & -x_0 & -x_1 & -x_2 & x_1 & 0 & x_0 \\
0 & x_1 & -x_1 & 0 & 0 & 0 \\
x_0 & 0 & 0 & -x_0 & -x_2 & x_2 & 0 \\
0 & x_0 & 0 & x_2 & -x_0 & -x_2 & 0
\end{pmatrix}
\]

sage: L.markov_chain_transition_matrix(action = 'tau', labeling = 'source')

\[
\begin{pmatrix}
-x_0 & -x_2 & x_3 & 0 & x_1 & 0 \\
x_2 & -x_0 & -x_1 & -x_3 & x_3 & 0 & x_1 \\
0 & x_1 & -x_3 & 0 & 0 & 0 \\
x_0 & 0 & 0 & -x_1 & -x_2 & x_3 & 0 \\
0 & x_0 & 0 & x_2 & -x_1 & -x_3 & 0
\end{pmatrix}
\]

2022 Chapter 5. Comprehensive Module List
See also:

`markov_chain_digraph()`, `promotion()`, `tau()`

**poset()**

Return the underlying original poset.

**EXAMPLES:**

```
sage: P = Poset(((1,2,3,4), [(1,2), (2,3), (1,4)]))
sage: L = P.linear_extensions()
sage: L.poset()
Finite poset containing 4 elements
```

---

**class** `sage.combinat.posets.linear_extensions.LinearExtensionsOfPosetWithHooks(poset, facade)`

**Bases:** `LinearExtensionsOfPoset`

Linear extensions such that the poset has well-defined hook lengths (i.e., d-complete).

**cardinality()**

Count the number of linear extensions using a hook-length formula.

**EXAMPLES:**

```
sage: from sage.combinat.posets.poset_examples import Posets
sage: P = Posets.YoungDiagramPoset(Partition([3,2]), dual=True)
sage: P.linear_extensions().cardinality()
5
```

### 5.1.184 Möbius Algebras

**class** `sage.combinat.posets.moebius_algebra.BasisAbstract(R, basis_keys=None, element_class=None, category=None, prefix=None, names=None, **kwds)`

**Bases:** `CombinatorialFreeModule`, `BindableClass`

Abstract base class for a basis.

**class** `sage.combinat.posets.moebius_algebra.MoebiusAlgebra(R, L)`

**Bases:** `Parent`, `UniqueRepresentation`

The Möbius algebra of a lattice.

Let $L$ be a lattice. The Möbius algebra $M_L$ was originally constructed by Solomon [Solomon67] and has a natural basis $\{E_x \mid x \in L\}$ with multiplication given by $E_x \cdot E_y = E_{x \lor y}$. Moreover this has a basis given by orthogonal idempotents $\{I_x \mid x \in L\}$ (so $I_x I_y = \delta_{xy} I_x$ where $\delta$ is the Kronecker delta) related to the natural basis by

$$I_x = \sum_{x \leq y} \mu_L(x, y) E_y,$$

where $\mu_L$ is the Möbius function of $L$.

**Note:** We use the join $\lor$ for our multiplication, whereas [Greene73] and [Etienne98] define the Möbius algebra using the meet $\land$. This is done for compatibility with `QuantumMoebiusAlgebra`.

**REFERENCES:**

---

5.1. Comprehensive Module List
class E(M, prefix='E')
Bases: BasisAbstract

The natural basis of a Möbius algebra.

Let $E_x$ and $E_y$ be basis elements of $M_L$ for some lattice $L$. Multiplication is given by $E_x E_y = E_{x \lor y}$.

one()

Return the element 1 of self.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: E = L.moebius_algebra(QQ).E()
sage: E.one()
E[0]
```

product_on_basis(x, y)

Return the product of basis elements indexed by x and y.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: E = L.moebius_algebra(QQ).E()
sage: E.product_on_basis(5, 14)
E[15]
sage: E.product_on_basis(2, 8)
E[10]
```

class I(M, prefix='I')
Bases: BasisAbstract

The (orthogonal) idempotent basis of a Möbius algebra.

Let $I_x$ and $I_y$ be basis elements of $M_L$ for some lattice $L$. Multiplication is given by $I_x I_y = \delta_{xy} I_x$ where $\delta_{xy}$ is the Kronecker delta.

one()

Return the element 1 of self.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: I = L.moebius_algebra(QQ).I()
sage: I.one()
```

product_on_basis(x, y)

Return the product of basis elements indexed by x and y.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: I = L.moebius_algebra(QQ).I()
sage: I.product_on_basis(5, 14)
0
```

(continues on next page)
a_realization()

Return a particular realization of self (the $B$-basis).

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: M = L.moebius_algebra(QQ)
sage: M.a_realization()
Moebius algebra of Finite lattice containing 16 elements
over Rational Field in the natural basis
```

idempotent

alias of $I$

lattice()

Return the defining lattice of self.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: M = L.moebius_algebra(QQ)
sage: M.lattice()
Finite lattice containing 16 elements
sage: M.lattice() == L
True
```

natural

alias of $E$

class sage.combinat.posets.moebius_algebra.MoebiusAlgebraBases

Bases: Category_realization_of_parent

The category of bases of a Möbius algebra.

INPUT:

- base – a Möbius algebra

class ElementMethods

Bases: object

class ParentMethods

Bases: object

one()

Return the element 1 of self.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: C = L.quantum_moebius_algebra().C()
sage: all(C.one() * b == b for b in C.basis())
True
```
**product_on_basis**(x, y)

Return the product of basis elements indexed by x and y.

**EXAMPLES:**

```python
sage: L = posets.BooleanLattice(4)
sage: C = L.quantum_moebius_algebra().C()
sage: C.product_on_basis(5, 14)
q^3*C[15]
sage: C.product_on_basis(2, 8)
q^4*C[10]
```

**super_categories()**

The super categories of `self`.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.moebius_algebra import MoebiusAlgebraBases
c sage: N = posets.BooleanLattice(4).moebius_algebra(QQ)
sage: bases = MoebiusAlgebraBases(N)
sage: bases.super_categories()
[Category of finite dimensional commutative algebras with basis over `Rational Field`,
Category of realizations of Moebius algebra of Finite lattice containing 16 elements over Rational Field]
```

class sage.combinat.posets.moebius_algebra.QuantumMoebiusAlgebra(L, q=None)

Bases: `Parent`, `UniqueRepresentation`

The quantum Möbius algebra of a lattice.

Let `L` be a lattice, and we define the *quantum Möbius algebra* `M_L(q)` as the algebra with basis `{E_x | x ∈ L}` with multiplication given by

\[ E_x E_y = \sum_{a \geq x \lor y} \mu_L(a, z) q^{\text{crk} a} E_z, \]

where `\mu_L` is the Möbius function of `L` and `\text{crk}` is the corank function (i.e., `\text{crk} a = \text{rank} L - \text{rank} a`). At `q = 1`, this reduces to the multiplication formula originally given by Solomon.

class C(M, prefix='C')

Bases: `BasisAbstract`

The characteristic basis of a quantum Möbius algebra.

The characteristic basis `{C_x | x ∈ L}` of `M_L` for some lattice `L` is defined by

\[ C_x = \sum_{a \geq x} P(F^x; q) E_a, \]

where `F^x = \{y ∈ L | y \geq x\}` is the principal order filter of `x` and `P(F^x; q)` is the characteristic polynomial of the (sub)poset `F^x`.

class E(M, prefix='E')

Bases: `BasisAbstract`

The natural basis of a quantum Möbius algebra.
Let $E_x$ and $E_y$ be basis elements of $M_L$ for some lattice $L$. Multiplication is given by

$$E_x E_y = \sum_{z \geq a \geq x \wedge y} \mu_L(a, z) q^{\text{crk} a} E_z,$$

where $\mu_L$ is the Möbius function of $L$ and $\text{crk}$ is the corank function (i.e., $\text{crk} a = \text{rank} L - \text{rank} a$).

**one()**

Return the element $1$ of self.

**EXAMPLES:**

```python
sage: L = posets.BooleanLattice(4)
sage: E = L.quantum_moebius_algebra().E()
sage: all(E.one() * b == b for b in E.basis())
True
```

**product_on_basis(x, y)**

Return the product of basis elements indexed by $x$ and $y$.

**EXAMPLES:**

```python
sage: L = posets.BooleanLattice(4)
sage: E = L.quantum_moebius_algebra().E()
sage: E.product_on_basis(5, 14)
E[15]
sage: E.product_on_basis(2, 8)
```

**class KL(M, prefix='KL')**

Bases: `BasisAbstract`

The Kazhdan-Lusztig basis of a quantum Möbius algebra.

The Kazhdan-Lusztig basis $\{B_x | x \in L\}$ of $M_L$ for some lattice $L$ is defined by

$$B_x = \sum_{y \geq x} P_{x, y}(q) E_y,$$

where $P_{x, y}(q)$ is the Kazhdan-Lusztig polynomial of $L$, following the definition given in [EPW14].

**EXAMPLES:**

We construct some examples of Proposition 4.5 of [EPW14]:

```python
sage: N = posets.BooleanLattice(4).quantum_moebius_algebra()
sage: KL = N.KL()
(q^2+q^3)*KL[5] + (q+2*q^2+q^3)*KL[7] + (q+2*q^2+q^3)*KL[13] + (1+3*q+3*q^2+q^3)*KL[15]
(1+3*q+3*q^2+q^3)*KL[15]
(q+3*q^2+3*q^3+q^4)*KL[14] + (1+4*q+6*q^2+4*q^3+q^4)*KL[15]
```

**a_realization()**

Return a particular realization of self (the $B$-basis).

**EXAMPLES:**

5.1. Comprehensive Module List
sage: L = posets.BooleanLattice(4)
sage: M = L.quantum_moebius_algebra()
sage: M.a_realization()
Quantum Moebius algebra of Finite lattice containing 16 elements with q=q over Univariate Laurent Polynomial Ring in q over Integer Ring in the natural basis

**characteristic_basis**
alias of C

**kazhdan_lusztig**
alias of KL

**lattice()**
Return the defining lattice of self.

**EXAMPLES:**

sage: L = posets.BooleanLattice(4)
sage: M = L.quantum_moebius_algebra()
sage: M.lattice()
Finite lattice containing 16 elements
sage: M.lattice() == L
True

**natural**
alias of E

### 5.1.185 Catalog of posets and lattices

Some common posets can be accessed through the `posets.<tab>` object:

```
sage: posets.PentagonPoset()
Finite lattice containing 5 elements
```

Moreover, the set of all posets of order $n$ is represented by `Posets(n)`:  

```
sage: Posets(5)
Posets containing 5 elements
```

The infinite set of all posets can be used to find minimal examples:

```
sage: for P in Posets():
    ....:     if not P.is_series_parallel():
    ....:         break
sage: P
Finite poset containing 4 elements
```

**Catalog of common posets:**

- **AntichainPoset()**
  - Return an antichain on $n$ elements.

- **BooleanLattice()**
  - Return the Boolean lattice on $2^n$ elements.
Table 6 – continued from previous page

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ChainPoset()</td>
<td>Return a chain on $n$ elements.</td>
</tr>
<tr>

</table>
Constructions

class sage.combinat.posets.poset_examples.Posets
    Bases: object

    A collection of posets and lattices.

    EXAMPLES:

    sage: posets.BooleanLattice(3)
    Finite lattice containing 8 elements
    sage: posets.ChainPoset(3)
    Finite lattice containing 3 elements
    sage: posets.RandomPoset(17,.15)
    Finite poset containing 17 elements

    The category of all posets:

    sage: Posets()
    Category of posets

    The enumerated set of all posets on 3 elements, up to an isomorphism:

    sage: Posets(3)
    Posets containing 3 elements

    See also:
    Posets, FinitePosets, Poset()

    static AntichainPoset(n, facade=None)
    Return an antichain (a poset with no comparable elements) containing \(n\) elements.

    INPUT:

    • \(n\) (an integer) – number of elements
    • \(facade\) (boolean) – whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the Poset() constructor

    EXAMPLES:

    sage: A = posets.AntichainPoset(6); A
    Finite poset containing 6 elements

    static BooleanLattice(n, facade=None, use_subsets=False)
    Return the Boolean lattice containing \(2^n\) elements.

    • \(n\) – integer; number of elements will be \(2^n\)
    • \(facade\) – boolean; whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the Poset() constructor
    • \(use\_subsets\) – boolean (default: False); if True, then label the elements by subsets of \(\{1, 2, \ldots, n\}\); otherwise label the elements by \(0, 1, 2, \ldots, 2^n - 1\)

    EXAMPLES:
sage: posets.BooleanLattice(5)
Finite lattice containing 32 elements
sage: sorted(posets.BooleanLattice(2))
[0, 1, 2, 3]
sage: sorted(posets.BooleanLattice(2, use_subsets=True), key=list)
[{}, {1}, {1, 2}, {2}]

static ChainPoset(n, facade=None)
Return a chain (a totally ordered poset) containing n elements.

- n (an integer) – number of elements.
- facade (boolean) – whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the Poset() constructor.

EXAMPLES:

sage: C = posets.ChainPoset(6); C
Finite lattice containing 6 elements
sage: C.linear_extension()
[0, 1, 2, 3, 4, 5]

static CoxeterGroupAbsoluteOrderPoset(W, use_reduced_words=True)
Return the poset of elements of a Coxeter group with respect to absolute order.

INPUT:

- W – a Coxeter group
- use_reduced_words – boolean (default: True); if True, then the elements are labeled by their lexicographically minimal reduced word

EXAMPLES:

sage: W = CoxeterGroup(['B', 3])
sage: posets.CoxeterGroupAbsoluteOrderPoset(W)
Finite poset containing 48 elements
sage: W = WeylGroup(['B', 2], prefix='s')
sage: posets.CoxeterGroupAbsoluteOrderPoset(W, False)
Finite poset containing 8 elements

static Crown(n, facade=None)
Return the crown poset of 2n elements.

In this poset every element i for 0 ≤ i ≤ n − 1 is covered by elements i + n and i + n + 1, except that n − 1 is covered by n and n + 1.

INPUT:

- n – number of elements, an integer at least 2
- facade (boolean) – whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the Poset() constructor

EXAMPLES:
sage: posets.Crown(3)
Finite poset containing 6 elements

static DexterSemilattice(n)
Return the $n$-th Dexter meet-semilattice.

INPUT:
• $n$ – a nonnegative integer (the index)

OUTPUT:
a finite meet-semilattice

The elements of the semilattice are Dyck paths in the $(n + 1 \times n)$-rectangle.

EXAMPLES:

```
sage: posets.DexterSemilattice(3)
Finite meet-semilattice containing 5 elements

sage: P = posets.DexterSemilattice(4); P
Finite meet-semilattice containing 14 elements
sage: len(P.maximal_chains())
15
sage: len(P.maximal_elements())
4
sage: P.chain_polynomial()
q^5 + 19*q^4 + 47*q^3 + 42*q^2 + 14*q + 1
```

REFERENCES:
• [Cha18]

static DiamondPoset(n, facade=None)
Return the lattice of rank two containing $n$ elements.

INPUT:
• $n$ – number of elements, an integer at least 3
• facade (boolean) – whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the Poset() constructor

EXAMPLES:

```
sage: posets.DiamondPoset(7)
Finite lattice containing 7 elements
```

static DivisorLattice(n, facade=None)
Return the divisor lattice of an integer.

Elements of the lattice are divisors of $n$ and $x < y$ in the lattice if $x$ divides $y$.

INPUT:
• $n$ – an integer
• facade (boolean) – whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the Poset() constructor

EXAMPLES:
Combinatorics, Release 10.0

static DoubleTailedDiamond(n)
Return a double-tailed diamond of \(2n + 2\) elements.

INPUT:

• \(n\) – a positive integer

EXAMPLES:

```python
sage: P = posets.DoubleTailedDiamond(2); P
Finite d-complete poset containing 6 elements
sage: P.cover_relations()
[[1, 2], [2, 3], [2, 4], [3, 5], [4, 5], [5, 6]]
```

static IntegerCompositions(n)
Return the poset of integer compositions of the integer \(n\).

A composition of a positive integer \(n\) is a list of positive integers that sum to \(n\). The order is reverse refinement: \([p_1, p_2, ..., p_l] < [q_1, q_2, ..., q_m]\) if \(q\) consists of an integer composition of \(p_1\), followed by an integer composition of \(p_2\), and so on.

EXAMPLES:

```python
sage: P = posets.IntegerCompositions(7); P
Finite poset containing 64 elements
sage: len(P.cover_relations())
192
```

static IntegerPartitions(n)
Return the poset of integer partitions on the integer \(n\).

A partition of a positive integer \(n\) is a non-increasing list of positive integers that sum to \(n\). If \(p\) and \(q\) are integer partitions of \(n\), then \(p\) covers \(q\) if and only if \(q\) is obtained from \(p\) by joining two parts of \(p\) (and sorting, if necessary).

EXAMPLES:

```python
sage: P = posets.IntegerPartitions(7); P
Finite poset containing 15 elements
sage: len(P.cover_relations())
28
```

static IntegerPartitionsDominanceOrder(n)
Return the lattice of integer partitions on the integer \(n\) ordered by dominance.

That is, if \(p = (p_1, ..., p_l)\) and \(q = (q_1, ..., q_m)\) are integer partitions of \(n\), then \(p\) is greater than \(q\) if and only if \(p_1 + \cdots + p_k > q_1 + \cdots + q_k\) for all \(k\).

INPUT:
• n – a positive integer

EXAMPLES:

```python
sage: P = posets.IntegerPartitionsDominanceOrder(6); P
Finite lattice containing 11 elements
sage: P.cover_relations()
[[[1, 1, 1, 1, 1, 1], [2, 1, 1, 1, 1, 1]],
[[2, 1, 1, 1, 1, 1], [2, 2, 1, 1, 1, 1]],
[[2, 2, 1, 1, 1], [2, 2, 2]],
[[2, 2, 1, 1], [3, 1, 1, 1]],
[[2, 2, 2], [3, 2, 1]],
[[3, 1, 1, 1], [3, 2, 1]],
[[3, 2, 1], [3, 3]],
[[3, 2, 1], [4, 1, 1]],
[[3, 3], [4, 2]],
[[4, 1, 1], [4, 2]],
[[4, 2], [5, 1]],
[[5, 1], [6]]]
```

**static MobilePoset(ribbon, hangers, anchor=None)**

Return a mobile poset with the ribbon `ribbon` and with hanging d-complete posets specified in `hangers` and a d-complete poset attached above, specified in `anchor`.

**INPUT:**

- `ribbon` – a finite poset that is a ribbon
- `hangers` – a dictionary mapping an element on the ribbon to a list of d-complete posets that it covers
- `anchor` – (optional) a tuple `(ribbon_elmt, anchor_elmt, anchor_poset)`, where `anchor_elmt` covers `ribbon_elmt`, and `anchor_elmt` is an acyclic element of `anchor_poset`

**EXAMPLES:**

```python
sage: R = Posets.RibbonPoset(5, [1,2])
sage: H = Poset([[5, 6, 7], [(5, 6), (6,7)]])
sage: M = Posets.MobilePoset(R, {3: [H]})
sage: len(M.cover_relations())
7

sage: P = posets.MobilePoset(posets.RibbonPoset(7, [1,3]),
....:                      {1: [posets.YoungDiagramPoset([3, 2], dual=True)],
....:                       3: [posets.DoubleTailedDiamond(6)]},
....:                      anchor=(4, 2, posets.ChainPoset(6)))
sage: len(P.cover_relations())
33
```

**static NoncrossingPartitions(W)**

Return the lattice of noncrossing partitions.

**INPUT:**

- `W` – a finite Coxeter group or a Weyl group

**EXAMPLES:**

```python

```
```python
sage: W = CoxeterGroup(['A', 3])
sage: posets.NoncrossingPartitions(W)
Finite lattice containing 14 elements
sage: W = WeylGroup(['B', 2], prefix='s')
sage: posets.NoncrossingPartitions(W)
Finite lattice containing 6 elements
```

**static PentagonPoset**(facade=None)

Return the Pentagon poset.

**INPUT:**

- facade (boolean) – whether to make the returned poset a facade poset (see `sage.categories.facade_sets`); the default behaviour is the same as the default behaviour of the `Poset()` constructor

**EXAMPLES:**

```python
sage: P = posets.PentagonPoset(); P
Finite lattice containing 5 elements
sage: P.cover_relations()
[[0, 1], [0, 2], [1, 4], [2, 3], [3, 4]]
```

**static PermutationPattern**(n)

Return the poset of permutations under pattern containment up to rank n.

**INPUT:**

- n – a positive integer

A permutation \( u = u_1 \cdots u_n \) contains the pattern \( v = v_1 \cdots v_m \) if there is a (not necessarily consecutive) subsequence of \( u \) of length \( m \) whose entries have the same relative order as \( v \).

See Wikipedia article Permutation_pattern.

**EXAMPLES:**

```python
sage: P4 = posets.PermutationPattern(4); P4
Finite poset containing 33 elements
sage: sorted(P4.lower_covers(Permutation([2, 4, 1, 3])))
[[1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2]]
```

See also:

- `has_pattern()`

**static PermutationPatternInterval**(bottom, top)

Return the poset consisting of an interval in the poset of permutations under pattern containment between bottom and top.

**INPUT:**

- bottom, top – permutations where top contains bottom as a pattern

A permutation \( u = u_1 \cdots u_n \) contains the pattern \( v = v_1 \cdots v_m \) if there is a (not necessarily consecutive) subsequence of \( u \) of length \( m \) whose entries have the same relative order as \( v \).

See Wikipedia article Permutation_pattern.

**EXAMPLES:**
sage: t = Permutation([2,3,1])
sage: b = Permutation([4,6,2,3,5,1])
sage: R = posets.PermutationPatternInterval(t, b); R
Finite poset containing 14 elements
sage: R.moebius_function(R.bottom(),R.top())
-4

See also:
has_pattern(), PermutationPattern()

static PermutationPatternOccurrenceInterval(bottom, top, pos)
Return the poset consisting of an interval in the poset of permutations under pattern containment between bottom and top, where a specified instance of bottom in top must be maintained.

INPUT:
- bottom, top – permutations where top contains bottom as a pattern
- pos – a list of indices indicating a distinguished copy of bottom inside top (indexed starting at 0)

For further information (and picture illustrating included example), see [ST2010].

See Wikipedia article Permutation_pattern.

EXAMPLES:

sage: t = Permutation([3,2,1])
sage: b = Permutation([6,3,4,5,2,1])
sage: A = posets.PermutationPatternOccurrenceInterval(t, b, (0,2,4)); A
Finite poset containing 8 elements

See also:
has_pattern(), PermutationPattern(), PermutationPatternInterval()

static PowerPoset(n)
Return the power poset on n element posets.

Elements of the power poset are all posets on the set \{0, \ldots, n - 1\} ordered by extension. That is, the antichain of n elements is the bottom and \(P_a \leq P_b\) in the power poset if \(P_b\) is an extension of \(P_a\).

These were studied in [Bru1994].

EXAMPLES:

sage: P3 = posets.PowerPoset(3); P3
Finite meet-semilattice containing 19 elements
sage: all(P.is_chain() for P in P3.maximal_elements())
True

static ProductOfChains(chain_lengths, facade=None)
Return a product of chains.

- chain_lengths – A list of nonnegative integers; number of elements in each chain.
- facade – boolean; whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the Poset() constructor
EXAMPLES:

```
sage: P = posets.ProductOfChains([2, 2]); P
Finite lattice containing 4 elements
sage: P.linear_extension()
[(0, 0), (0, 1), (1, 0), (1, 1)]
sage: P.upper_covers((0,0))
[(0, 1), (1, 0)]
sage: P.lower_covers((1,1))
[(0, 1), (1, 0)]
```

**static RandomLattice**(n, p, properties=None)

Return a random lattice on n elements.

**INPUT:**
- n – number of elements, a non-negative integer
- p – a probability, a positive real number less than one
- properties – a list of properties for the lattice. Currently implemented:
  - None, no restrictions for lattices to create
  - 'planar', the lattice has an upward planar drawing
  - 'dismantlable' (implicated by 'planar')
  - 'distributive' (implicated by 'stone')
  - 'stone'

**OUTPUT:**
A lattice on n elements. When properties is None, the probability p roughly measures number of covering relations of the lattice. To create interesting examples, make the probability a little below one, for example 0.9.

Currently parameter p has no effect only when properties is not None.

**Note:** Results are reproducible in same Sage version only. Underlying algorithm may change in future versions.

EXAMPLES:

```
sage: set_random_seed(0)  # Results are reproducible
sage: L = posets.RandomLattice(8, 0.995); L
Finite lattice containing 8 elements
sage: L.cover_relations()
[[7, 6], [7, 3], [7, 1], ... , [5, 4], [2, 4], [1, 4], [0, 4]]
sage: L = posets.RandomLattice(10, 0, properties=['dismantlable'])
sage: L.is_dismantlable()
True
```

See also:

*RandomPoset()*
**static RandomPoset**(n, p)

Generate a random poset on n elements according to a probability p.

**INPUT:**

- n - number of elements, a non-negative integer
- p - a probability, a real number between 0 and 1 (inclusive)

**OUTPUT:**

A poset on n elements. The probability p roughly measures width/height of the output: p = 0 always generates an antichain, p = 1 will return a chain. To create interesting examples, keep the probability small, perhaps on the order of 1/n.

**EXAMPLES:**

```sage
sage: set_random_seed(0) # Results are reproducible
sage: P = posets.RandomPoset(5, 0.3)
sage: P.cover_relations()
[[[5, 4], [4, 2], [1, 2]]
```

See also:

*RandomLattice()*

**static RestrictedIntegerPartitions**(n)

Return the poset of integer partitions on the integer n ordered by restricted refinement.

That is, if p and q are integer partitions of n, then p covers q if and only if q is obtained from p by joining two distinct parts of p (and sorting, if necessary).

**EXAMPLES:**

```sage
sage: P = posets.RestrictedIntegerPartitions(7); P
Finite poset containing 15 elements
sage: len(P.cover_relations())
17
```

**static RibbonPoset**(n, descents)

Return a ribbon poset on n vertices with descents at descents.

**INPUT:**

- n – the number of vertices
- descents – an iterable; the indices on the ribbon where \( y > x \)

**EXAMPLES:**

```sage
sage: R = Posets.RibbonPoset(5, [1,2])
sage: sorted(R.cover_relations())
[[[0, 1], [2, 1], [3, 2], [3, 4]]
```

**static SSTPoset**(s, f=None)

The lattice poset on semistandard tableaux of shape s and largest entry f that is ordered by componentwise comparison of the entries.

**INPUT:**

- s - shape of the tableaux

---

*Combinatorics, Release 10.0*

---
• $f$ - maximum fill number. This is an optional argument. If no maximal number is given, it will use the number of cells in the shape.

Note: This is a basic implementation and most certainly not the most efficient.

EXAMPLES:

```
sage: posets.SSTPoset([2,1])
Finite lattice containing 8 elements
sage: posets.SSTPoset([2,1],4)
Finite lattice containing 20 elements
sage: posets.SSTPoset([2,1],2).cover_relations()  
[[[1, 1], [2]], [[1, 2], [2]]]
sage: posets.SSTPoset([3,2]).bottom()  # long time (6s on sage.math, 2012)  
[[1, 1, 1], [2, 2]]
sage: posets.SSTPoset([3,2],4).maximal_elements()  
[[[3, 3, 4], [4, 4]]]
```

static SetPartitions$(n)$  
Return the lattice of set partitions of the set $\{1, \ldots, n\}$ ordered by refinement.

INPUT:

• $n$ – a positive integer

EXAMPLES:

```
sage: posets.SetPartitions(4)  
Finite lattice containing 15 elements
```

static ShardPoset$(n)$  
Return the shard intersection order on permutations of size $n$.

This is defined on the set of permutations. To every permutation, one can attach a pre-order, using the descending runs and their relative positions.

The shard intersection order is given by the implication (or refinement) order on the set of pre-orders defined from all permutations.

This can also be seen in a geometrical way. Every pre-order defines a cone in a vector space of dimension $n$. The shard poset is given by the inclusion of these cones.

See also:  
shard_preorder_graph()  

EXAMPLES:

```
sage: P = posets.ShardPoset(4); P  # indirect doctest  
Finite poset containing 24 elements
sage: P.chain_polynomial()  
34*q^4 + 90*q^3 + 79*q^2 + 24*q + 1
sage: P.characteristic_polynomial()  
```

(continues on next page)
\[ q^3 - 11q^2 + 23q - 13 \]
\[
\text{sage: } P.zeta_polynomial()
\]
\[ 17/3q^3 - 6q^2 + 4/3q \]
\[
\text{sage: } P.is_self_dual()
\]
\[ \text{False} \]

**static StandardExample** \((n, \text{facade}=\text{None})\)

Return the partially ordered set on \(2n\) elements with dimension \(n\).

Let \(P\) be the poset on \(\{0, 1, 2, \ldots, 2n - 1\}\) whose defining relations are that \(i < j\) for every \(0 \leq i < n \leq j < 2n\) except when \(i + n = j\). The poset \(P\) is the so-called standard example of a poset with dimension \(n\).

**INPUT:**

- \(n\) – an integer \(\geq 2\), dimension of the constructed poset
- \(\text{facade}\) (boolean) – whether to make the returned poset a facade poset (see `sage.categories.facade_sets`; the default behaviour is the same as the default behaviour of the `Poset()` constructor)

**OUTPUT:**

The standard example of a poset of dimension \(n\).

**EXAMPLES:**

\[
\text{sage: } A = \text{posets.StandardExample}(3); A \\
\text{Finite poset containing 6 elements} \\
\text{sage: } A.dimension() \\
3
\]

**REFERENCES:**

- [Gar2015]
- [Ros1999]

**static SymmetricGroupAbsoluteOrderPoset** \((n, \text{labels}=\text{'}\text{permutations}\text{'})\)

Return the poset of permutations with respect to absolute order.

**INPUT:**

- \(n\) – a positive integer
- \(\text{label}\) – (default: 'permutations') a label for the elements of the poset returned by the function; the options are
  - 'permutations' - labels the elements are given by their one-line notation
  - 'reduced_words' - labels the elements by the lexicographically minimal reduced word
  - 'cycles' - labels the elements by their expression as a product of cycles

**EXAMPLES:**

\[
\text{sage: } \text{posets.SymmetricGroupAbsoluteOrderPoset}(4) \\
\text{Finite poset containing 24 elements} \\
\text{sage: } \text{posets.SymmetricGroupAbsoluteOrderPoset}(3, \text{labels=\text{'}cycles\text{'})} \\
\text{Finite poset containing 6 elements} \\
\text{sage: } \text{posets.SymmetricGroupAbsoluteOrderPoset}(3, \text{labels=\text{'}reduced_words\text{'})} \\
\text{Finite poset containing 6 elements}
\]
static SymmetricGroupBruhatIntervalPoset\( (start, end) \)
The poset of permutations with respect to Bruhat order.

**INPUT:**

- \( start \) - list permutation
- \( end \) - list permutation (same \( n \), of course)

**Note:** Must have \( start \leq end \).

**EXAMPLES:**
Any interval is rank symmetric if and only if it avoids these permutations:

```python
sage: P1 = posets.SymmetricGroupBruhatIntervalPoset([1,2,3,4], [3,4,1,2])
sage: P2 = posets.SymmetricGroupBruhatIntervalPoset([1,2,3,4], [4,2,3,1])
sage: ranks1 = [P1.rank(v) for v in P1]
sage: ranks2 = [P2.rank(v) for v in P2]
sage: [ranks1.count(i) for i in sorted(set(ranks1))]
[1, 3, 5, 4, 1]
sage: [ranks2.count(i) for i in sorted(set(ranks2))]
[1, 3, 5, 6, 4, 1]
```

static SymmetricGroupBruhatOrderPoset\( (n) \)
The poset of permutations with respect to Bruhat order.

**EXAMPLES:**

```python
sage: posets.SymmetricGroupBruhatOrderPoset(4)
Finite poset containing 24 elements
```

static SymmetricGroupWeakOrderPoset\( (n, labels='permutations', side='right') \)
The poset of permutations of \( \{1, 2, \ldots, n\} \) with respect to the weak order (also known as the permutohedron order, cf. \texttt{permutohedron\_lequal()}).

The optional variable labels (default: "permutations") determines the labelling of the elements if \( n < 10 \). The optional variable side (default: "right") determines whether the right or the left permutohedron order is to be used.

**EXAMPLES:**

```python
sage: posets.SymmetricGroupWeakOrderPoset(4)
Finite poset containing 24 elements
```

static TamariLattice\( (n, m=1) \)
Return the \( n \)-th Tamari lattice.

Using the slope parameter \( m \), one can also get the \( m \)-Tamari lattices.

**INPUT:**

- \( n \) – a nonnegative integer (the index)
- \( m \) – an optional nonnegative integer (the slope, default to 1)

**OUTPUT:**
a finite lattice

5.1. Comprehensive Module List
In the usual case, the elements of the lattice are Dyck paths in the \((n + 1 \times n)\)-rectangle. For a general slope \(m\), the elements are Dyck paths in the \((mn + 1 \times n)\)-rectangle.

See Tamari lattice for mathematical background.

**EXAMPLES:**

```python
sage: posets.TamariLattice(3)
Finite lattice containing 5 elements
sage: posets.TamariLattice(3, 2)
Finite lattice containing 12 elements
```

**REFERENCES:**

- [BMFPR]

**static TetrahedralPoset\((n, \ast colors, \ast \ast labels)\)**

Return the tetrahedral poset based on the input colors.

This method will return the tetrahedral poset with \(n\)-1 layers and covering relations based on the input colors of ‘green’, ‘red’, ‘orange’, ‘silver’, ‘yellow’ and ‘blue’ as defined in [Striker2011]. For particular color choices, the order ideals of the resulting tetrahedral poset will be isomorphic to known combinatorial objects.

For example, for the colors ‘blue’, ‘yellow’, ‘orange’, and ‘green’, the order ideals will be in bijection with alternating sign matrices. For the colors ‘yellow’, ‘orange’, and ‘green’, the order ideals will be in bijection with semistandard Young tableaux of staircase shape. For the colors ‘red’, ‘orange’, ‘green’, and optionally ‘yellow’, the order ideals will be in bijection with totally symmetric self-complementary plane partitions in a \(2n \times 2n \times 2n\) box.

**INPUT:**

- \(n\) - Defines the number (\(n\)-1) of layers in the poset.
- \(\ast colors\) - The colors that define the covering relations of the poset. Colors used are ‘green’, ‘red’, ‘yellow’, ‘orange’, ‘silver’, and ‘blue’.
- \(\ast \ast labels\) - Keyword variable used to determine whether the poset is labeled with integers or tuples. To label with integers, the method should be called with \(\ast labels\)='integers'. Otherwise, the labeling will default to tuples.

**EXAMPLES:**

```python
sage: posets.TetrahedralPoset(4, 'green', 'red', 'yellow', 'silver', 'blue', 'orange')
Finite poset containing 10 elements
sage: posets.TetrahedralPoset(4, 'green', 'red', 'yellow', 'silver', 'blue', 'orange',
                           \ast labels='integers')
Finite poset containing 10 elements
sage: A = AlternatingSignMatrices(3)
sage: p = A.lattice()
sage: ji = p.join_irreducibles_poset()
sage: tet = posets.TetrahedralPoset(3, 'green', 'yellow', 'blue', 'orange')
sage: ji.is_isomorphic(tet)
True
```
**static UpDownPoset**\((n, m=1)\)

Return the up-down poset on \(n\) elements where every \((m + 1)\) step is down and the rest are up.

The case where \(m = 1\) is sometimes referred to as the zig-zag poset or the fence.

**INPUT:**
- \(n\) - nonnegative integer, number of elements in the poset
- \(m\) - nonnegative integer (default 1), how frequently down steps occur

**OUTPUT:**

The partially ordered set on \(\{0, 1, \ldots, n - 1\}\) where \(i\) covers \(i + 1\) if \(m\) divides \(i + 1\), and \(i + 1\) covers \(i\) otherwise.

**EXAMPLES:**

```python
sage: P = posets.UpDownPoset(7, 2); P
Finite poset containing 7 elements
sage: sorted(P.cover_relations())
[[[0, 1], [1, 2], [3, 2], [3, 4], [4, 5], [6, 5]]
```

Fibonacci numbers as the number of antichains of a poset:

```python
sage: [len(posets.UpDownPoset(n).antichains().list()) for n in range(6)]
[1, 2, 3, 5, 8, 13]
```

**static YoungDiagramPoset**\((\lambda, dual=False)\)

Return the poset of cells in the Young diagram of a partition.

**INPUT:**
- \(\lambda\) – a partition
- dual – (default: False) determines the orientation of the poset; if True, then it is a join semilattice, otherwise it is a meet semilattice

**EXAMPLES:**

```python
sage: P = posets.YoungDiagramPoset(Partition([2, 2])); P
Finite meet-semilattice containing 4 elements
sage: sorted(P.cover_relations())
[[[0, 0), (0, 1)], [(0, 0), (1, 0)], [(0, 1), (1, 1)], [(1, 0), (1, 1)]]
```

```python
sage: P = posets.YoungDiagramPoset([3, 2], dual=True)
Finite join-semilattice containing 5 elements
```

**static YoungFibonacci**\((n)\)

Return the Young-Fibonacci lattice up to rank \(n\).

Elements of the (infinite) lattice are words with letters ‘1’ and ‘2’. The covers of a word are the words with another ‘1’ added somewhere not after the first occurrence of an existing ‘1’ and, additionally, the words where the first ‘1’ is replaced by a ‘2’. The lattice is truncated to have rank \(n\).

See Wikipedia article Young-Fibonacci lattice.

**EXAMPLES:**

```python
sage: Y5 = posets.YoungFibonacci(5); Y5
Finite meet-semilattice containing 20 elements
sage: sorted(Y5.upper_covers(Word('211')))
[word: 1211, word: 2111, word: 221]
```

**static YoungsLattice(n)**

Return Young’s Lattice up to rank \( n \).

In other words, the poset of partitions of size less than or equal to \( n \) ordered by inclusion.

**INPUT:**

- \( n \) – a positive integer

**EXAMPLES:**

```python
sage: P = posets.YoungsLattice(3); P
Finite meet-semilattice containing 7 elements
sage: P.cover_relations()
[[[]], [1]],
[[1], [1, 1]],
[[1], [2]],
[[1, 1], [2, 1]],
[[2], [2, 1]],
[[2], [3]]]
```

**static YoungsLatticePrincipalOrderIdeal(lam)**

Return the principal order ideal of the partition \( lam \) in Young’s Lattice.

**INPUT:**

- \( lam \) – a partition

**EXAMPLES:**

```python
sage: P = posets.YoungsLatticePrincipalOrderIdeal(Partition([2,2])); P
Finite lattice containing 6 elements
sage: P.cover_relations()
[[[]], [1]],
[[1], [1, 1]],
[[1], [2]],
[[1, 1], [2, 1]],
[[2], [2, 1]],
[[2], [3]]]
```

sage = <module 'sage' ("_frozen_importlib_external._NamespaceLoader object")>

sage.combinat.posets.set_examples.check_int(n, minimum=0)

Check that \( n \) is an integer at least equal to \( minimum \).

This is a boilerplate function ensuring input safety.

**INPUT:**

- \( n \) – anything
- \( minimum \) – an optional integer (default: 0)
EXAMPLES:

```python
sage: from sage.combinat.posets.poset_examples import check_int
sage: check_int(6, 3)
6
sage: check_int(6)
6

sage: check_int(-1)
Traceback (most recent call last):
...  
ValueError: number of elements must be a non-negative integer, not -1

sage: check_int(1, 3)
Traceback (most recent call last):
...  
ValueError: number of elements must be an integer at least 3, not 1

sage: check_int('junk')
Traceback (most recent call last):
...  
ValueError: number of elements must be a non-negative integer, not junk
```

sage.combinat.posets.poset_examples.posets
alias of Posets

5.1.186 Finite posets

This module implements finite partially ordered sets. It defines:

<table>
<thead>
<tr>
<th>FinitePoset</th>
<th>A class for finite posets</th>
</tr>
</thead>
<tbody>
<tr>
<td>FinitePosets_n</td>
<td>A class for finite posets up to isomorphism (i.e. unlabeled posets)</td>
</tr>
<tr>
<td>Poset()</td>
<td>Construct a finite poset from various forms of input data.</td>
</tr>
<tr>
<td>is_poset()</td>
<td>Return True if a directed graph is acyclic and transitively reduced.</td>
</tr>
</tbody>
</table>

List of Poset methods

Comparing, intervals and relations

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>

<tr>
<td><code>minimal_elements()</code></td>
<td>Return the list of the minimal elements of the poset.</td>
</tr>
</tbody>
</table>

New posets from old ones
disjoint_union()  Return the disjoint union of the poset with other poset.
ordinal_sum()  Return the ordinal sum of the poset with other poset.
product()  Return the Cartesian product of the poset with other poset.
ordinal_product()  Return the ordinal product of the poset with other poset.
rees_product()  Return the Rees product of the poset with other poset.
lexicographic_sum()  Return the lexicographic sum of posets.
star_product()  Return the star product of the poset with other poset.
with_bounds()  Return the poset with bottom and top element adjoined.
without_bounds()  Return the poset with bottom and top element removed.
dual()  Return the dual of the poset.
completion_by_cuts()  Return the Dedekind-MacNeille completion of the poset.
intervals_poset()  Return the poset of intervals of the poset.
connected_components()  Return the connected components of the poset as subposets.
factor()  Return the decomposition of the poset as a Cartesian product.
ordinal_summands()  Return the ordinal summands of the poset.
subposet()  Return the subposet containing elements with partial order induced by this poset.
random_subposet()  Return a random subposet that contains each element with given probability.
relabel()  Return a copy of this poset with its elements relabelled.
canonical_label()  Return copy of the poset canonically (re)labelled to integers.
slant_sum()  Return the slant sum poset of two posets.

Chains, antichains & linear intervals

is_chain_of_poset()  Return True if elements in the given list are comparable.
is_antichain_of_poset()  Return True if elements in the given list are incomparable.
is_linear_interval()  Return whether the given interval is a total order.
chains()  Return the chains of the poset.
antichains()  Return the antichains of the poset.
maximal_chains()  Return the maximal chains of the poset.
maximal_antichains()  Return the maximal antichains of the poset.
maximal_chains_iterator()  Return an iterator over the maximal chains of the poset.
maximal_chain_length()  Return the maximum length of maximal chains of the poset.
antichains_iterator()  Return an iterator over the antichains of the poset.
random_maximal_chain()  Return a random maximal chain.
random_maximal_antichain()  Return a random maximal antichain.
linear_intervals_count()  Return the enumeration of linear intervals in the poset.

Drawing

show()  Display the Hasse diagram of the poset.
plot()  Return a Graphic object corresponding the Hasse diagram of the poset.
graphviz_string()  Return a representation in the DOT language, ready to render in graphviz.

Comparing posets

is_isomorphic()  Return True if both posets are isomorphic.
is_induced_subposet()  Return True if given poset is an induced subposet of this poset.

Polynomials

Miscellaneous

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sorted()</code></td>
<td>Return given list sorted by the poset.</td>
</tr>
<tr>
<td><code>isomorphic_subposets()</code></td>
<td>Return all subposets isomorphic to another poset.</td>
</tr>
<tr>
<td><code>isomorphic_subposets_iterator()</code></td>
<td>Return an iterator over the subposets isomorphic to another poset.</td>
</tr>
<tr>
<td><code>has_isomorphic_subposet()</code></td>
<td>Return <code>True</code> if the poset contains a subposet isomorphic to another poset.</td>
</tr>
<tr>
<td><code>list()</code></td>
<td>List the elements of the poset.</td>
</tr>
<tr>
<td><code>cuts()</code></td>
<td>Return the cuts of the given poset.</td>
</tr>
<tr>
<td><code>dilworth_decomposition()</code></td>
<td>Return a partition of the points into the minimal number of chains.</td>
</tr>
<tr>
<td><code>greene_shape()</code></td>
<td>Computes the Greene-Kleitman partition aka Greene shape of the poset <code>self</code></td>
</tr>
<tr>
<td><code>incidence_algebra()</code></td>
<td>Return the incidence algebra of <code>self</code>.</td>
</tr>
<tr>
<td><code>is_EL_labelling()</code></td>
<td>Return whether <code>f</code> is an EL labelling of the poset.</td>
</tr>
<tr>
<td><code>isomorphic_subposets_iterator()</code></td>
<td>Return an iterator over the subposets isomorphic to another poset.</td>
</tr>
<tr>
<td><code>isomorphic_subposets()</code></td>
<td>Return all subposets isomorphic to another poset.</td>
</tr>
<tr>
<td><code>level_sets()</code></td>
<td>Return elements grouped by maximal number of cover relations from a minimal element.</td>
</tr>
<tr>
<td><code>order_complex()</code></td>
<td>Return the order complex associated to this poset.</td>
</tr>
<tr>
<td><code>random_order_ideal()</code></td>
<td>Return a random order ideal of <code>self</code> with uniform probability.</td>
</tr>
<tr>
<td><code>rank()</code></td>
<td>Return the rank of an element, or the rank of the poset.</td>
</tr>
<tr>
<td><code>rank_function()</code></td>
<td>Return a rank function of the poset, if it exists.</td>
</tr>
<tr>
<td><code>unwrap()</code></td>
<td>Unwraps an element of this poset.</td>
</tr>
<tr>
<td><code>atkinson()</code></td>
<td>Return the $a$-spectrum of a poset whose undirected Hasse diagram is a forest.</td>
</tr>
<tr>
<td><code>spectrum()</code></td>
<td>Return the $a$-spectrum of this poset.</td>
</tr>
</tbody>
</table>

Classes and functions

class sage.combinat.posets.posets.FinitePoset(hasse_diagram, elements, category, facade, key)

Bases: UniqueRepresentation, Parent

A (finite) $n$-element poset constructed from a directed acyclic graph.

INPUT:

- `hasse_diagram` – an instance of `FinitePoset`, or a `DiGraph` that is transitively-reduced, acyclic, loop-free, and multiedge-free.

- `elements` – an optional list of elements, with `element[i]` corresponding to vertex $i$. If `elements` is `None`, then it is set to be the vertex set of the digraph. Note that if this option is set, then `elements` is considered as a specified linear extension of the poset and the `linear_extension` attribute is set.

- `category` – `FinitePosets`, or a subcategory thereof.

- `facade` – a boolean or `None` (default); whether the `FinitePoset`'s elements should be wrapped to make them aware of the Poset they belong to.
  
  - If `facade = True`, the `FinitePoset`'s elements are exactly those given as input.
  
  - If `facade = False`, the `FinitePoset`'s elements will become `PosetElement` objects.
  
  - If `facade = None` (default) the expected behaviour is the behaviour of `facade = True`, unless the opposite can be deduced from the context (i.e. for instance if a `FinitePoset` is built from another `FinitePoset`, itself built with `facade = False`)

- `key` – any hashable value (default: `None`).

EXAKLPLAJESE:
Combinatorics, Release 10.0

sage: uc = [[2,3], [], [1], [1], [1], [3,4]]
sage: from sage.combinat.posets.posets import FinitePoset
sage: P = FinitePoset(DiGraph(dict([(i,uc[i]) for i in range(len(uc))])), facade=False); P
Finite poset containing 6 elements
sage: P.cover_relations()
[[5, 4], [5, 3], [4, 1], [0, 2], [0, 3], [2, 1], [3, 1]]
sage: TestSuite(P).run()
sage: P.category()
Category of finite enumerated posets
sage: P.__class__
<class 'sage.combinat.posets.posets.FinitePoset_with_category'>
sage: Q = sage.combinat.posets.posets.FinitePoset(P, facade=False); Q
Finite poset containing 6 elements
sage: Q is P
True

We keep the same underlying Hasse diagram, but change the elements:

sage: Q = sage.combinat.posets.posets.FinitePoset(P, elements=[1,2,3,4,5,6], facade=False); Q
Finite poset containing 6 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 5], [2, 6], [3, 4], [3, 5], [4, 6], [5, 6]]

We test the facade argument:

sage: P = Poset(DiGraph({'a':'b','b':'c','c':'d'}), facade=False)
sage: P.category()
Category of finite enumerated posets
sage: parent(P[0]) is P
True
sage: Q = Poset(DiGraph({'a':'b','b':'c','c':'d'}), facade=True)
sage: Q.category()
Category of facade finite enumerated posets
sage: parent(Q[0]) is str
True
sage: TestSuite(Q).run(skip = ['_test_an_element']) # is_parent_of is not yet implemented

Changing a non facade poset to a facade poset:

sage: PQ = Poset(P, facade=True)
sage: PQ.category()
Category of facade finite enumerated posets
sage: parent(PQ[0]) is str
True
sage: PQ is Q
True

Changing a facade poset to a non facade poset:
Conversion to some other software is possible:

```python
sage: P = posets.TamariLattice(3)
sage: libgap(P)  # optional - gap_packages
<A poset on 5 points>
```

```python
sage: P = Poset({1:[2],2:[]})
sage: macaulay2('needsPackage "Posets"')  # optional - macaulay2
Posets
sage: macaulay2(P)  # optional - macaulay2
Relation Matrix: | 1 1 |
| 0 1 |
```

**Note:** A class that inherits from this class needs to define `Element`. This is the class of the elements that the inheriting class contains. For example, for this class, `FinitePoset.Element` is `PosetElement`. It can also define `_dual_class` which is the class of dual posets of this class. E.g. `FiniteMeetSemilattice._dual_class` is `FiniteJoinSemilattice`.

**Element**

alias of `PosetElement`

**M_triangle()**

Return the M-triangle of the poset.

The poset is expected to be graded.

**OUTPUT:**

an `M_triangle`

The M-triangle is the generating polynomial of the Möbius numbers

\[ M(x, y) = \sum_{a \leq b} \mu(a, b) x^{\lfloor a \rfloor} y^{\lfloor b \rfloor}. \]

**EXAMPLES:**

```python
sage: P = posets.DiamondPoset(5)
sage: P.M_triangle()
M: x^2*y^2 - 3*x*y^2 + 3*x*y + 2*y^2 - 3*y + 1
```

**antichains(element_constructor=<class 'list'>)**

Return the antichains of the poset.

An *antichain* of a poset is a set of elements of the poset that are pairwise incomparable.

**INPUT:**

- `element_constructor` – a function taking an iterable as argument (default: list)
OUTPUT:

The enumerated set (of type `PairwiseCompatibleSubsets`) of all antichains of the poset, each of which is given as an `element_constructor`.

EXAMPLES:

```sage
sage: A = posets.PentagonPoset().antichains(); A
Set of antichains of Finite lattice containing 5 elements
sage: list(A)
[[], [0], [1], [1, 2], [1, 3], [2], [3], [4]]
sage: A.cardinality()
8
sage: A[3]
[1, 2]
```

To get the antichains as, say, sets, one may use the `element_constructor` option:

```sage
sage: list(posets.ChainPoset(3).antichains(element_constructor=set))
[set(), {0}, {1}, {2}]
```

To get the antichains of a given size one can currently use:

```sage
sage: list(A.elements_of_depth_iterator(2))
[[[1, 2], [1, 3]]
```

Eventually the following syntax will be accepted:

```sage
sage: A.subset(size = 2) # todo: not implemented
```

**Note:** Internally, this uses `sage.combinat.subsets_pairwise.PairwiseCompatibleSubsets` and `RecursivelyEnumeratedSet_forest`. At this point, iterating through this set is about twice slower than using `antichains_iterator()` (tested on `posets.AntichainPoset(15)`). The algorithm is the same (depth first search through the tree), but `antichains_iterator()` manually inlines things which apparently avoids some infrastructure overhead.

On the other hand, this returns a full featured enumerated set, with containment testing, etc.

---

**See also:**

- `maximal_antichains()`, `chains()`
- `antichains_iterator()`

`antichains_iterator()`

Return an iterator over the antichains of the poset.

**EXAMPLES:**

```sage
sage: it = posets.PentagonPoset().antichains_iterator(); it
<generator object ...antichains_iterator at ...>
sage: next(it), next(it)
([], [4])
```

**See also:**

- `antichains()`
atkinson($a$)

Return the $a$-spectrum of a poset whose Hasse diagram is cycle-free as an undirected graph.

Given an element $a$ in a poset $P$, the $a$-spectrum is the list of integers whose $i$-th term contains the number of linear extensions of $P$ with element $a$ located in the $i$-th position.

**INPUT:**

- `self` – a poset whose Hasse diagram is a forest
- `a` – an element of the poset

**OUTPUT:**

The $a$-spectrum of this poset, returned as a list.

**EXAMPLES:**

```python
sage: P = Poset({0: [2], 1: [2], 2: [3, 4], 3: [], 4: []})
sage: P.atkinson(0)
[2, 0, 0, 0]
sage: P = Poset({0: [1], 1: [2, 3], 2: [], 3: [], 4: [5, 6], 5: [], 6: []})
sage: P.atkinson(5)
[0, 10, 18, 24, 28, 30, 30]
sage: P = posets.AntichainPoset(10)
sage: P.atkinson(0)
[362880, 362880, 362880, 362880, 362880, 362880, 362880, 362880, 362880, 362880]
```

**Note:** This function is the implementation of the algorithm from [At1990].

bottom()

Return the unique minimal element of the poset, if it exists.

**EXAMPLES:**

```python
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.bottom() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.bottom()
0
```

See also:

`has_bottom()`, `top()`

canonical_label(algorithm=None)

Return the unique poset on the labels $\{0, \ldots, n - 1\}$ (where $n$ is the number of elements in the poset) that is isomorphic to this poset and invariant in the isomorphism class.

**INPUT:**

- `algorithm` – string (optional); a parameter forwarded to underlying graph function to select the algorithm to use

**EXAMPLES:**

```python
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: Q = P.canonical_label()
sage: sorted(Q.list())
[0, 1, 2, 3, 4, 5]
sage: Q.is_isomorphic(P)
True

Canonical labeling of (semi)lattice returns (semi)lattice:

sage: D = DiGraph({'a': ['b', 'c']})
sage: P = Poset(D)
sage: ML = MeetSemilattice(D)
sage: P.canonical_label()
Finite poset containing 3 elements
sage: ML.canonical_label()
Finite meet-semilattice containing 3 elements

See also:
• Canonical labeling of directed graphs: canonical_label()

**cardinality()**
Return the number of elements in the poset.

EXAMPLES:

sage: P = Poset([[1,2,3],[4],[4],[4],[]])
sage: P.cardinality()
5

See also:
• degree_polynomial() for a more refined invariant

**chain_polynomial()**
Return the chain polynomial of the poset.

The coefficient of \(q^k\) is the number of chains of \(k\) elements in the poset. List of coefficients of this polynomial is also called a *f*-vector of the poset.

**Note:** This is not what has been called the chain polynomial in [St1986]. The latter is identical with the order polynomial in SageMath (order_polynomial()).

See also:
• f_polynomial(), order_polynomial()
sage: P = posets.BooleanLattice(3)
sage: P.chain_polynomial()
6\,q^4 + 18\,q^3 + 19\,q^2 + 8\,q + 1

sage: P = posets.AntichainPoset(5)
sage: P.chain_polynomial()
5\,q + 1

chain_polytope()

Return the chain polytope of the poset self.

The chain polytope of a finite poset \( P \) is defined as the subset of \( \mathbb{R}^P \) consisting of all maps \( x : P \to \mathbb{R} \) satisfying

\[
x(p) \geq 0 \text{ for all } p \in P,
\]

and

\[
x(p_1) + x(p_2) + \ldots + x(p_k) \leq 1 \text{ for all chains } p_1 < p_2 < \ldots < p_k \text{ in } P.
\]

This polytope was defined and studied in [St1986].

EXAMPLES:

sage: P = posets.AntichainPoset(3)
sage: Q = P.chain_polytope(); Q
A 3-dimensional polyhedron in ZZ^3 defined as the convex hull of 8 vertices
sage: P = posets.PentagonPoset()
sage: Q = P.chain_polytope(); Q
A 5-dimensional polyhedron in ZZ^5 defined as the convex hull of 8 vertices

chains(element_constructor=<class 'list'>, exclude=None)

Return the chains of the poset.

A chain of a poset is an increasing sequence of distinct elements of the poset.

INPUT:

• element_constructor – a function taking an iterable as argument (optional, default: list)

• exclude – elements of the poset to be excluded (optional, default: None)

OUTPUT:

The enumerated set (of type PairwiseCompatibleSubsets) of all chains of the poset, each of which is given as an element_constructor.

EXAMPLES:

sage: C = posets.PentagonPoset().chains(); C
Set of chains of Finite lattice containing 5 elements
sage: list(C)
\[
[\], [0], [0, 1], [0, 1, 4], [0, 2], [0, 2, 3], [0, 2, 3, 4], [0, 2, 4], [0, 3], [0, 3, 4], [0, 4], [1], [1, 4], [2], [2, 3], [2, 3, 4], [2, 4], [3], [3, 4], ...
\]
sage: P = Poset({1: [2, 3], 2: [4], 3: [4, 5]})
sage: list(P.chains(element_constructor=tuple, exclude=[3]))
[(), (1,), (1, 2), (1, 2, 4), (1, 4), (1, 5), (2,), (2, 4), (4,), (5,)]

To get the chains of a given size one can currently use:

sage: list(C.elements_of_depth_iterator(2))
[[0, 1], [0, 2], [0, 3], [0, 4], [1, 4], [2, 3], [2, 4], [3, 4]]

Eventually the following syntax will be accepted:

sage: C.subset(size = 2) # todo: not implemented

See also:
maximal_chains(), antichains()

characteristic_polynomial()
Return the characteristic polynomial of the poset.

The poset is expected to be graded and have a bottom element.

If $P$ is a graded poset with rank $n$ and a unique minimal element $\hat{0}$, then the characteristic polynomial of $P$ is defined to be

$$\sum_{x \in P} \mu(\hat{0}, x) q^{n - \rho(x)} \in \mathbb{Z}[q],$$

where $\rho$ is the rank function, and $\mu$ is the Möbius function of $P$.

See section 3.10 of [EnumComb1].

EXAMPLES:

sage: P = posets.DiamondPoset(5)
sage: P.characteristic_polynomial()
q^2 - 3*q + 2
sage: P = Poset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6], 6: [7]})
sage: P.characteristic_polynomial()
q^4 - 2*q^3 + q

closed_interval(x, y)
Return the list of elements $z$ such that $x \leq z \leq y$ in the poset.

EXAMPLES:

sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.closed_interval(2, 100)
[2, 4, 10, 20, 50, 100]

See also:
open_interval()

common_lower_covers(elmts)
Return all of the common lower covers of the elements elmts.

EXAMPLES:
sage: P = Poset({0: [1,2], 1: [3], 2: [3], 3: []})
sage: P.common_lower_covers([1, 2])
[0]

common_upper_covers(elmts)
Return all of the common upper covers of the elements elmts.

EXAMPLES:

sage: P = Poset({0: [1,2], 1: [3], 2: [3], 3: []})
sage: P.common_upper_covers([1, 2])
[3]

comparability_graph()
Return the comparability graph of the poset.

The comparability graph is an undirected graph where vertices are the elements of the poset and there is an edge between two vertices if they are comparable in the poset.

See Wikipedia article Comparability_graph

EXAMPLES:

sage: Y = Poset({1: [2], 2: [3, 4]})
sage: g = Y.comparability_graph(); g
Comparability graph on 4 vertices
sage: Y.compare_elements(1, 3) is not None
True
sage: g.has_edge(1, 3)
True

See also:
incomparability_graph(), sage.graphs.comparability

compare_elements(x, y)
Compare x and y in the poset.

• If \( x < y \), return -1.
• If \( x = y \), return 0.
• If \( x > y \), return 1.
• If x and y are not comparable, return None.

EXAMPLES:

sage: P = Poset([[1, 2], [4], [3], [4], []])
sage: P.compare_elements(0, 0)
0
sage: P.compare_elements(0, 4)
-1
sage: P.compare_elements(4, 0)
1
sage: P.compare_elements(1, 2) is None
True
**completion_by_cuts()**

Return the completion by cuts of \texttt{self}.

This is the smallest lattice containing the poset. This is also called the Dedekind-MacNeille completion.

See the Wikipedia article Dedekind-MacNeille completion.

**OUTPUT:**

- a finite lattice

**EXAMPLES:**

```
sage: P = posets.PentagonPoset()
sage: P.completion_by_cuts().is_isomorphic(P)
True

sage: Y = Poset({1: [2], 2: [3, 4]})
sage: trafficsign = LatticePoset({1: [2], 2: [3, 4], 3: [5], 4: [5]})
sage: L = Y.completion_by_cuts()
sage: L.is_isomorphic(trafficsign)
True

sage: P = posets.SymmetricGroupBruhatOrderPoset(3)
sage: Q = P.completion_by_cuts(); Q
Finite lattice containing 7 elements
```

See also:

- \texttt{cuts()}, \texttt{irreducibles_poset()}

**connected_components()**

Return the connected components of the poset as subposets.

**EXAMPLES:**

```
sage: P = Poset({1: [2, 3], 3: [4, 5], 6: [7, 8]})
sage: parts = sorted(P.connected_components(), key=len); parts
[Finite poset containing 3 elements,
 Finite poset containing 5 elements]
sage: parts[0].cover_relations()
[[6, 7], [6, 8]]
```

See also:

- \texttt{disjoint_union()}, \texttt{is_connected()}

**cover_relations()**

Return the list of pairs [\texttt{x, y}] of elements of the poset such that \texttt{y} covers \texttt{x}.

**EXAMPLES:**

```
sage: P = Poset({0: [2], 1: [2], 2: [3], 3: [4], 4: []})
sage: P.cover_relations()
[[1, 2], [0, 2], [2, 3], [3, 4]]
```

**cover_relations_graph()**

Return the (undirected) graph of cover relations.

**EXAMPLES:**
sage: P = Poset({0: [1, 2], 1: [3], 2: [3]})
sage: G = P.cover_relations_graph(); G
Graph on 4 vertices
sage: G.has_edge(3, 1), G.has_edge(3, 0)
(True, False)

See also:

cover_relations_iterator()

Return an iterator over the cover relations of the poset.

EXAMPLES:

sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: type(P.cover_relations_iterator())
<class 'generator'>
sage: [z for z in P.cover_relations_iterator()]
[[1, 2], [0, 2], [2, 3], [3, 4]]

covers(x, y)

Return True if y covers x and False otherwise.

Element y covers x if x < y and there is no z such that x < z < y.

EXAMPLES:

sage: P = Poset(([1,5], [2,6], [3], [4], [], [6,3], [4]))
sage: P.covers(1, 6)
True
sage: P.covers(1, 4)
False
sage: P.covers(1, 5)
False

coxeter_polynomial()

Return the Coxeter polynomial of the poset.

OUTPUT:

a polynomial in one variable

The output is the characteristic polynomial of the Coxeter transformation. This polynomial only depends on the derived category of modules on the poset.

EXAMPLES:

sage: P = posets.PentagonPoset()
sage: P.coxeter_polynomial()
x^5 + x^4 + x + 1
sage: p = posets.SymmetricGroupWeakOrderPoset(3)
sage: p.coxeter_polynomial()
x^6 + x^5 - x^3 + x + 1

See also:

coxeter_transformation(), coxeter_smith_form()
The Smith normal form of \( x \) minus the Coxeter transformation matrix.

INPUT:

- `algorithm` – optional (default 'singular'), possible values are 'singular', 'sage', 'gap', 'pari', 'maple', 'magma', 'fricas'

Beware that speed depends very much on the choice of algorithm. Sage is rather slow, Singular is faster and Pari is fast at least for small sizes.

OUTPUT:

- list of polynomials in one variable, each one dividing the next one

The output list is a refinement of the characteristic polynomial of the Coxeter transformation, which is its product. This list of polynomials only depends on the derived category of modules on the poset.

EXAMPLES:

```python
sage: P = posets.PentagonPoset()
sage: P.coxeter_smith_form()
[1, 1, 1, 1, x^5 + x^4 + x + 1]
sage: P = posets.DiamondPoset(7)
sage: prod(P.coxeter_smith_form()) == P.coxeter_polynomial()
True
```

See also:

- `coxeter_transformation()`, `coxeter_matrix()`

Return the Coxeter transformation of the poset.

OUTPUT:

a square matrix with integer coefficients

The output is the matrix of the Auslander-Reiten translation acting on the Grothendieck group of the derived category of modules on the poset, in the basis of simple modules. This matrix is usually called the Coxeter transformation.

EXAMPLES:

```python
sage: posets.PentagonPoset().coxeter_transformation()
[ 0 0 0 0 -1]
[ 0 0 0 1 -1]
[ 0 1 0 0 -1]
[-1 1 1 0 -1]
[-1 1 0 1 -1]
```

See also:

- `coxeter_polynomial()`, `coxeter_smith_form()`

Return the list of cuts of the poset `self`.

A cut is a subset \( A \) of `self` such that the set of lower bounds of the set of upper bounds of \( A \) is exactly \( A \).
The cuts are computed here using the maximal independent sets in the auxiliary graph defined as $P \times [0,1]$ with an edge from $(x,0)$ to $(y,1)$ if and only if $x \not\geq_P y$. See the end of section 4 in [JRJ94].

**EXAMPLES:**

```python
sage: P = posets.AntichainPoset(3)
sage: Pc = P.cuts()
sage: Pc  # random
[frozenset({0}),
 frozenset(),
 frozenset({0, 1, 2}),
 frozenset({2}),
 frozenset({1})]
sage: sorted(list(c) for c in Pc)
[[], [0], [0, 1, 2], [1], [2]]
```

See also:

`completion_by_cuts()`

**degree_polynomial()**

Return the generating polynomial of degrees of vertices in `self`. This is the sum

$$\sum_{v \in P} x^{in(v)} y^{out(v)},$$

where `in(v)` and `out(v)` are the number of incoming and outgoing edges at vertex `v` in the Hasse diagram of `P`.

Because this polynomial is multiplicative for Cartesian product of posets, it is useful to help see if the poset can be isomorphic to a Cartesian product.

**EXAMPLES:**

```python
sage: P = posets.PentagonPoset()
sage: P.degree_polynomial()
x^2 + 3*x*y + y^2
sage: P = posets.BooleanLattice(4)
sage: P.degree_polynomial().factor()
(x + y)^4
```

See also:

`cardinality()` for the value at $(x, y) = (1, 1)$

**diamonds()**

Return the list of diamonds of `self`.

A diamond is the following subgraph of the Hasse diagram:

```
z
/ \
x y
\ / \\
w
```
Thus each edge represents a cover relation in the Hasse diagram. We represent this as the tuple \((w, x, y, z)\).

**OUTPUT:**

A tuple with

- a list of all diamonds in the Hasse Diagram,
- a boolean checking that every \(w, x, y\) that form a \(V\), there is a unique element \(z\), which completes the diamond.

**EXAMPLES:**

```python
sage: P = Poset({0: [1, 2], 1: [3], 2: [3], 3: []})
sage: P.diamonds()
(([]), True)
```

```python
sage: P = posets.YoungDiagramPoset(Partition([3, 2, 2]))
sage: P.diamonds()
((((0, 0), (0, 1), (1, 0), (1, 1)), ((1, 0), (1, 1), (2, 0), (2, 1))), False)
```

dilworth_decomposition()

Return a partition of the points into the minimal number of chains.

According to Dilworth’s theorem, the points of a poset can be partitioned into \(\alpha\) chains, where \(\alpha\) is the cardinality of its largest antichain. This method returns such a partition.

See Wikipedia article Dilworth’s theorem.

**ALGORITHM:**

We build a bipartite graph in which a vertex \(v\) of the poset is represented by two vertices \(v^-\), \(v^+\). For any two \(u, v\) such that \(u < v\) in the poset we add an edge \(v^+u^-\).

A matching in this graph is equivalent to a partition of the poset into chains: indeed, a chain \(v_1...v_k\) gives rise to the matching \(v_1^-v_2^+, v_2^-v_3^+, ...\), and from a matching one can build the union of chains.

According to Dilworth’s theorem, the number of chains is equal to \(\alpha\) (the posets’ width).

**EXAMPLES:**

```python
sage: p = posets.BooleanLattice(4)
sage: p.width()
6
sage: p.dilworth_decomposition()  # random
[[7, 6, 4], [11, 3], [12, 8, 0], [13, 9, 1], [14, 10, 2], [15, 5]]
```

See also:

level_sets() to return elements grouped to antichains.

dimension(certificate, solver, integrality_tolerance=False)

Return the dimension of the Poset.

The (Dushnik-Miller) dimension of a poset is the minimal number of total orders so that the poset is their “intersection”. More precisely, the dimension of a poset defined on a set \(X\) of points is the smallest integer \(n\) such that there exist linear extensions \(P_1, ..., P_n\) of \(P\) satisfying:

\[ u \leq_P v \text{ if and only if } \forall i, u \leq_{P_i} v \]

For more information, see the Wikipedia article Order_dimension.

**INPUT:**
Combinatorics, Release 10.0

- **certificate** (boolean; default: False) – whether to return an integer (the dimension) or a certificate, i.e. a smallest set of linear extensions.
- **solver** – (default: None) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to None, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- **integrality_tolerance** – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

**Note:** The speed of this function greatly improves when more efficient MILP solvers (e.g. Gurobi, CPLEX) are installed. See `MixedIntegerLinearProgram` for more information.

**Note:** Prior to version 8.3 this returned only realizer with `certificate=True`. Now it returns a pair having a realizer as the second element. See github issue #25588 for details.

**ALGORITHM:**

As explained [FT00], the dimension of a poset is equal to the (weak) chromatic number of a hypergraph. More precisely:

Let \( \text{inc}(P) \) be the set of (ordered) pairs of incomparable elements of \( P \), i.e. all \( uv \) and \( vu \) such that \( u \not\leq_P v \) and \( v \not\leq_P u \). Any linear extension of \( P \) is a total order on \( X \) that can be seen as the union of relations from \( P \) along with some relations from \( \text{inc}(P) \). Thus, the dimension of \( P \) is the smallest number of linear extensions of \( P \) which cover all points of \( \text{inc}(P) \).

Consequently, \( \text{dim}(P) \) is equal to the chromatic number of the hypergraph \( H_{\text{inc}} \), where \( H_{\text{inc}} \) is the hypergraph defined on \( \text{inc}(P) \) whose sets are all \( S \subseteq \text{inc}(P) \) such that \( P \cup S \) is not acyclic.

We solve this problem through a Mixed Integer Linear Program.

The problem is known to be NP-complete.

**EXAMPLES:**

We create a poset, compute a set of linear extensions and check that we get back the poset from them:

```python
sage: P = Poset([[1,4], [3], [4,5,3], [6], [], [6], []])
sage: P.dimension() 3
sage: dim, L = P.dimension(certificate=True)
sage: L # random -- architecture-dependent
[[0, 2, 4, 5, 1, 3, 6], [2, 5, 0, 1, 3, 4, 6], [0, 1, 2, 3, 5, 6, 4]]
sage: Poset( (L[0], lambda x, y: all(l.index(x) < l.index(y) for l in L)) ) == P True
```

According to Schnyder’s theorem, the incidence poset (of height 2) of a graph has dimension \( \leq 3 \) if and only if the graph is planar:

```python
sage: G = graphs.CompleteGraph(4)
sage: P = Poset(DiGraph({(u,v):[u,v] for u,v,_ in G.edges(sort=True)}))
sage: P.dimension() 3
sage: G = graphs.CompleteBipartiteGraph(3,3)
```

(continues on next page)
disjoint_union(other, labels='pairs')

Return a poset isomorphic to disjoint union (also called direct sum) of the poset with other.

The disjoint union of \( P \) and \( Q \) is a poset that contains every element and relation from both \( P \) and \( Q \), and where every element of \( P \) is incomparable to every element of \( Q \).

Mathematically, it is only defined when \( P \) and \( Q \) have no common element; here we force that by giving them different names in the resulting poset.

**INPUT:**

• other, a poset.

• labels - (defaults to ‘pairs’) If set to ‘pairs’, each element \( v \) in this poset will be named \((0, v)\) and each element \( u \) in other will be named \((1, u)\) in the result. If set to ‘integers’, the elements of the result will be relabeled with consecutive integers.

**EXAMPLES:**

```python
sage: P1 = Poset({'a': 'b'})
sage: P2 = Poset({'c': 'd'})
sage: P = P1.disjoint_union(P2); P
Finite poset containing 4 elements
sage: sorted(P.cover_relations())
[[0, 'a'], [0, 'b'], [1, 'c'], [1, 'd']]
sage: P = P1.disjoint_union(P2, labels='integers')
sage: P.cover_relations()
[[0, 1], [2, 3]]
sage: N5 = posets.PentagonPoset(); N5
Finite lattice containing 5 elements
sage: N5.disjoint_union(N5) # Union of lattices is not a lattice
Finite poset containing 10 elements
```

We show how to get literally direct sum with elements untouched:

```python
sage: P = P1.disjoint_union(P2).relabel(lambda x: x[1])
sage: sorted(P.cover_relations())
[['a', 'b'], ['c', 'd']]
```

See also:

[connected_components()](#)

dual()

Return the dual poset of the given poset.

In the dual of a poset \( P \) we have \( x \leq y \) iff \( y \leq x \) in \( P \).

**EXAMPLES:**

```python
sage: P = Poset({1: [2, 3], 3: [4]})
sage: P.cover_relations()
```
Dual of a lattice is a lattice; dual of a meet-semilattice is join-semilattice and vice versa. Also the dual of a (non-)facade poset is again (non-)facade:

```python
sage: V = MeetSemilattice({1: [2, 3]}, facade=False)
sage: A = V.dual(); A
Finite join-semilattice containing 3 elements
sage: A(2) < A(1)
True
```

See also:

`is_self_dual()`

`evacuation()`

Compute evacuation on the linear extension associated to the poset `self`.

**OUTPUT:**

- an isomorphic poset, with the same default linear extension

Evacuation is defined on a poset `self` of size `n` by applying the evacuation operator \((\tau_1 \cdots \tau_{n-1}) (\tau_1 \cdots \tau_{n-2}) \cdots (\tau_1)\), to the default linear extension \(\pi\) of `self` (see `evacuation()`), and relabeling `self` accordingly. For more details see [Stan2009].

**EXAMPLES:**

```python
sage: P = Poset(((1,2), [[1,2]]), linear_extension=True, facade=False)
sage: P.evacuation()
Finite poset containing 2 elements with distinguished linear extension
sage: P.evacuation() == P
True
sage: P = Poset(((1,2,3,4,5,6,7), [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,6]]),
             linear_extension=True, facade=False)
sage: P.list()
[1, 2, 3, 4, 5, 6, 7]
sage: Q = P.evacuation(); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 3], [2, 5], [3, 4], [3, 6], [4, 7], [6, 7]]
```

Note that the results depend on the linear extension associated to the poset:

```python
sage: P = Poset(((1,2,3,4,5,6,7), [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,6]]))
sage: P.list()
[1, 2, 3, 5, 6, 4, 7]
sage: Q = P.evacuation(); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 5], [2, 3], [5, 6], [5, 4], [6, 7], [4, 7]]
```
Here is an example of a poset where the elements are not labelled by \{1, 2, \ldots, n\}:

```sage
P = Poset((divisors(15), attrcall("divides")), linear_extension = True)
P.list()
[1, 3, 5, 15]
P = P.evacuation(); Q
Finite poset containing 4 elements with distinguished linear extension
Q.cover_relations()
[[[1, 3], [1, 5], [3, 15], [5, 15]]
```

See also:

- `linear_extension()`
- `with_linear_extension()` and the `linear_extension` option of `Poset()`
- `evacuation()`
- `promotion()`

AUTHOR:

- Anne Schilling (2012-02-18)

**f_polynomial()**

Return the \(f\)-polynomial of the poset.

The poset is expected to be bounded.

This is the \(f\)-polynomial of the order complex of the poset minus its bounds.

The coefficient of \(q^i\) is the number of chains of \(i + 1\) elements containing both bounds of the poset.

**Note:** This is slightly different from the \(fPolynomial\) method in Macaulay2.

**EXAMPLES:**

```sage
P = posets.DiamondPoset(5)
P.f_polynomial()
3*q^2 + q
P = Poset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [7], 6: [7]})
P.f_polynomial()
q^4 + 4*q^3 + 5*q^2 + q
```

See also:

- `is_bounded()`, `h_polynomial()`, `order_complex()`, `sage.topology.cell_complex.GenericCellComplex.f_vector()`

**factor()**

Factor the poset as a Cartesian product of smaller posets.

This only works for connected posets for the moment.

The decomposition of a connected poset as a Cartesian product of posets (prime in the sense that they cannot be written as Cartesian products) is unique up to reordering and isomorphism.

**OUTPUT:**
EXAMPLES:

```python
sage: P = posets.PentagonPoset()
sage: Q = P*P
sage: Q.factor()
[Finite poset containing 5 elements,  
 Finite poset containing 5 elements]

sage: P1 = posets.ChainPoset(3)
sage: P2 = posets.ChainPoset(7)
sage: P1.factor()
[Finite lattice containing 3 elements]

sage: (P1 * P2).factor()
[Finite poset containing 7 elements,  
 Finite poset containing 3 elements]

sage: P = posets.TamariLattice(4)
sage: (P*P).factor()
[Finite poset containing 14 elements,  
 Finite poset containing 14 elements]
```

See also:

- `product()`

REFERENCES:

**flag_f_polynomial()**

Return the flag $f$-polynomial of the poset.

The poset is expected to be bounded and ranked.

This is the sum, over all chains containing both bounds, of a monomial encoding the ranks of the elements of the chain.

More precisely, if $P$ is a bounded ranked poset, then the flag $f$-polynomial of $P$ is defined as the polynomial

$$
\sum_{\min P < p_1 < p_2 < \ldots < p_k, \ p_0 = \min P, \ p_k = \max P} x_{\rho(p_1)} x_{\rho(p_2)} \cdots x_{\rho(p_k)} \in \mathbb{Z}[x_1, x_2, \ldots, x_n],
$$

where $\min P$ and $\max P$ are (respectively) the minimum and the maximum of $P$, where $\rho$ is the rank function of $P$ (normalized to satisfy $\rho(\min P) = 0$), and where $n$ is the rank of $\max P$. (Note that the indeterminate $x_0$ does not actually appear in the polynomial.)

For technical reasons, the polynomial is returned in the slightly larger ring $\mathbb{Z}[x_0, x_1, x_2, \ldots, x_{n+1}]$ by this method.

EXAMPLES:

```python
sage: P = posets.DiamondPoset(5)
sage: P.flag_f_polynomial()
3*x1*x2 + x2

sage: P = Poset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
```
fl = P.flag_f_polynomial(); fl
2*x1*x2*x3 + 2*x1*x3 + 2*x2*x3 + x3

q = polygen(ZZ, 'q')
fl(q,q,q,q) == P.f_polynomial()
True

P = Poset({1: [2, 3, 4], 2: [5], 3: [5], 4: [5], 5: [6]})
P.flag_f_polynomial()
3*x1*x2*x3 + 3*x1*x3 + x2*x3 + x3

See also:

is_bounded(), flag_h_polynomial()

flag_h_polynomial()

Return the flag ℎ--polynomial of the poset.

The poset is expected to be bounded and ranked.

If $P$ is a bounded ranked poset whose maximal element has rank $n$ (where the minimal element is set to have rank 0), then the flag $h$-polynomial of $P$ is defined as the polynomial

$$
\prod_{k=1}^{n} (1 - x_k) \cdot f\left(\frac{x_1}{1 - x_1}, \frac{x_2}{1 - x_2}, \cdots, \frac{x_n}{1 - x_n}\right) \in \mathbb{Z}[x_1, x_2, \cdots, x_n],
$$

where $f$ is the flag $f$-polynomial of $P$ (see flag_f_polynomial()).

For technical reasons, the polynomial is returned in the slightly larger ring $\mathbb{Q}[x_0, x_1, x_2, \cdots, x_{n+1}]$ by this method.

See Wikipedia article h-vector.

EXAMPLES:

sage: P = posets.DiamondPoset(5)
sage: P.flag_h_polynomial()
2*x1*x2 + x2

sage: P = Poset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
sage: fl = P.flag_h_polynomial(); fl
-x1*x2*x3 + x1*x3 + x2*x3 + x3
sage: q = polygen(ZZ, 'q')
sage: fl(q,q,q,q) == P.h_polynomial()
True

sage: P = Poset({1: [2, 3, 4], 2: [5], 3: [5], 4: [5], 5: [6]})
sage: P.flag_h_polynomial()
2*x1*x3 + x3

sage: P = posets.ChainPoset(4)
sage: P.flag_h_polynomial()
x3

See also:

is_bounded(), flag_f_polynomial()
frank_network()  
Return Frank’s network of the poset.  
This is defined in Section 8 of [BF1999].  

OUTPUT: 
A pair \((G, e)\), where \(G\) is Frank’s network of \(P\) encoded as a DiGraph, and \(e\) is the cost function on its edges encoded as a dictionary (indexed by these edges, which in turn are encoded as tuples of 2 vertices).

**Note:** Frank’s network of \(P\) is a certain directed graph with \(2|P| + 2\) vertices, defined in Section 8 of [BF1999]. Its set of vertices consists of two vertices \((-1, 0)\) and \((1, p)\) for each element \(p\) of \(P\), as well as two vertices \((-1, 0)\) and \((2, 0)\). (These notations are not the ones used in [BF1999]; see the table below for their relation.) The edges are:

- for each \(p\) in \(P\), an edge from \((-1, 0)\) to \((0, p)\);
- for each \(p\) in \(P\), an edge from \((1, p)\) to \((2, 0)\);
- for each \(p\) and \(q\) in \(P\) such that \(p \geq q\), an edge from \((0, p)\) to \((1, q)\).

We make this digraph into a network in the sense of flow theory as follows: The vertex \((-1, 0)\) is considered as the source of this network, and the vertex \((2, 0)\) as the sink. The cost function is defined to be 1 on the edge from \((0, p)\) to \((1, p)\) for each \(p \in P\), and to be 0 on every other edge. The capacity is 1 on each edge. Here is how to translate this notations into that used in [BF1999]:

<table>
<thead>
<tr>
<th>our notations</th>
<th>[BF1999]</th>
</tr>
</thead>
<tbody>
<tr>
<td>(-1, 0)</td>
<td>s</td>
</tr>
<tr>
<td>(0, p)</td>
<td>x_p</td>

</tbody>
</table>

**EXAMPLES:**

```python
sage: ps = [[16, 12, 14, -13], [12, 14], [14, -13], [12, 16], [16, -13]]
sage: G, e = Poset(ps).frank_network()
sage: G.edges(sort=True)
[((-1, 0), (0, -13), None), ((-1, 0), (0, 12), None), ((-1, 0), (0, 14), None),
((-1, 0), (0, 16), None), ((0, -13), (1, -13), None), ((0, -13), (1, 12), None),
((0, -13), (1, 14), None), ((0, -13), (1, 16), None), ((0, 12), (1, -13), None),
((0, 12), (1, 14), None), ((0, 12), (1, 16), None), ((0, 14), (1, 12), None),
((0, 14), (1, 14), None), ((0, 14), (1, 16), None), ((0, 16), (1, -13), None),
((0, 16), (1, 12), None), ((0, 16), (1, 14), None), ((0, 16), (1, 16), None),
((1, -13), (2, 0), None), ((1, 12), (2, -13), None), ((1, 12), (2, 14), None),
((1, 12), (2, 16), None), ((1, 14), (2, 0), None), ((1, 14), (2, 12), None),
((1, 14), (2, 14), None), ((1, 14), (2, 16), None), ((1, 16), (2, 0), None),
((1, 16), (2, 12), None), ((1, 16), (2, 14), None), ((1, 16), (2, 16), None)]
sage: e
{((-1, 0), (0, -13)): 0,
((-1, 0), (0, 12)): 0,
((-1, 0), (0, 14)): 0,
((-1, 0), (0, 16)): 0,
((0, -13), (1, 12)): 1,
((0, -13), (1, 14)): 0,
((0, -13), (1, 16)): 0,

((1, 16), (2, 16)): 0}
```
Author:

• Darij Grinberg (2013-05-09)

ge(x, y)

Return True if x is greater than or equal to y in the poset, and False otherwise.

Examples:
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4[:]}).

sage: P.is_gequal(3, 1)
True
sage: P.is_gequal(2, 2)
True
sage: P.is_gequal(0, 1)
False

See also:
is_greater_than(), is_lequal().

graphviz_string(graph_string='graph', edge_string='--')

Return a representation in the DOT language, ready to render in graphviz.

EXAMPLES:
sage: P = Poset({'a':['b','d'], 'c':['d'], 'd':['f'], 'e':['f'], 'f':[]})

sage: print(P.graphviz_string())
graph {
  "f"="d";"b"="a";"c"="e";
  "f"--"e";"d"--"c";"b"--"a";"d"--"b";"f"--"d";
}

greene_shape()

Return the Greene-Kleitman partition of self.

The Greene-Kleitman partition of a finite poset $P$ is the partition $(c_1 - c_0, c_2 - c_1, c_3 - c_2, \ldots)$, where $c_k$ is the maximum cardinality of a union of $k$ chains of $P$. Equivalently, this is the conjugate of the partition $(a_1 - a_0, a_2 - a_1, a_3 - a_2, \ldots)$, where $a_k$ is the maximum cardinality of a union of $k$ antichains of $P$.

See many sources, e. g., [BF1999], for proofs of this equivalence.

EXAMPLES:
sage: P = Poset([[3,2,1],[[3,1],[2,1]]])

sage: P.greene_shape()
[2, 1]

sage: P = Poset([[1,2,3,4],[[1,4],[2,4],[4,3]]])

sage: P.greene_shape()
[3, 1]

sage: P = Poset([[1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22],[[1, 2, 3, 4],[2,4],[4,3]]])

sage: P.greene_shape()
[3, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]

sage: P = Poset([[],[[]]])

sage: P.greene_shape()
[]

AUTHOR:
  • Darij Grinberg (2013-05-09)

gt(x, y)

Return True if $x$ is greater than but not equal to $y$ in the poset, and False otherwise.
EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_greater_than(3, 1)
True
sage: P.is_greater_than(1, 2)
False
sage: P.is_greater_than(3, 3)
False
sage: P.is_greater_than(0, 1)
False
```

For non-facade posets also > works:

```
sage: P = Poset({3: [1, 2]}, facade=False)
sage: P(2) > P(3)
True
```

See also:

`is_gequal()`, `is_less_than()`.

**h_polynomial()**

Return the $h$-polynomial of a bounded poset `self`.

This is the $h$-polynomial of the order complex of the poset minus its bounds.

This is related to the $f$-polynomial by a simple change of variables:

$$h(q) = (1 - q)^{\deg f} f \left( \frac{q}{1 - q} \right),$$

where $f$ and $h$ denote the $f$-polynomial and the $h$-polynomial, respectively.

See Wikipedia article h-vector.

**Warning:** This is slightly different from the `hPolynomial` method in Macaulay2.

EXAMPLES:

```
sage: P = posets.AntichainPoset(3).order_ideals_lattice()
sage: P.h_polynomial()
q^3 + 4*q^2 + q
sage: P = posets.DiamondPoset(5)
sage: P.h_polynomial()
2*q^2 + q
sage: P = Poset({1: []})
sage: P.h_polynomial()
1
```

See also:

`is_bounded()`, `f_polynomial()`, `order_complex()`, `sage.topology.simplicial_complex.SimplicialComplex.h_vector()`
has_bottom()  
Return True if the poset has a unique minimal element, and False otherwise.

EXAMPLES:

```python
sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4], 4:[]})
sage: P.has_bottom()
False
sage: Q = Poset({0:[1], 1:[]})
sage: Q.has_bottom()
True
```

See also:

- Dual Property: has_top()
- Stronger properties: is_bounded()
- Other: bottom()

has_isomorphic_subposet(other)

Return True if the poset contains a subposet isomorphic to other.

By subposet we mean that there exist a set X of elements such that self.subposet(X) is isomorphic to other.

INPUT:

- other – a finite poset

EXAMPLES:

```python
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
sage: T = Poset({1:[2,3], 2:[4,5], 3:[6,7]})
sage: N5 = posets.PentagonPoset()

sage: N5.has_isomorphic_subposet(T)
False
sage: N5.has_isomorphic_subposet(D)
True

sage: len([P for P in Posets(5) if P.has_isomorphic_subposet(D)])
11
```

has_top()  
Return True if the poset has a unique maximal element, and False otherwise.

EXAMPLES:

```python
sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4, 5], 4:[]})
sage: P.has_top()
False
sage: Q = Poset({0:[3], 1:[3], 2:[3], 3:[4], 4:[]})
sage: Q.has_top()
True
```

See also:
• Dual Property: `has_bottom()`
• Stronger properties: `is_bounded()`
• Other: `top()`

`hasse_diagram()`

Return the Hasse diagram of the poset as a Sage `DiGraph`.

The Hasse diagram is a directed graph where vertices are the elements of the poset and there is an edge from `u` to `v` whenever `v` covers `u` in the poset.

If `dot2tex` is installed, then this sets the Hasse diagram’s latex options to use the `dot2tex` formatting.

**EXAMPLES:**

```python
sage: P = posets.DivisorLattice(12)
sage: H = P.hasse_diagram(); H
Digraph on 6 vertices
sage: P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: H.edges(sort=True, labels=False)
[(1, 2), (1, 3), (2, 4), (2, 6), (3, 6), (4, 12), (6, 12)]
```

`height(certificate=False)`

Return the height (number of elements in a longest chain) of the poset.

**INPUT:**

• `certificate` – (default: `False`) whether to return a certificate

**OUTPUT:**

• If `certificate=True` return `(h, c)`, where `h` is the height and `c` is a chain of maximum cardinality.
  If `certificate=False` return only the height.

**EXAMPLES:**

```python
sage: P = Poset({0: [1], 2: [3, 4], 4: [5, 6]})
sage: P.height()
3
sage: posets.PentagonPoset().height(certificate=True)
(4, [0, 2, 3, 4])
```

`incidence_algebra(R, prefix='I')`

Return the incidence algebra of `self` over `R`.

**OUTPUT:**

**EXAMPLES:**

```python
sage: P = posets.BooleanLattice(4)
sage: P.incidence_algebra(QQ)
Incidence algebra of Finite lattice containing 16 elements over Rational Field
```
incomparability_graph()

Return the incomparability graph of the poset.

This is the complement of the comparability graph, i.e. an undirected graph where vertices are the elements of the poset and there is an edge between vertices if they are not comparable in the poset.

EXAMPLES:

```python
sage: Y = Poset({1: [2], 2: [3, 4]})
sage: g = Y.incomparability_graph(); g
Incomparability graph on 4 vertices
sage: Y.compare_elements(1, 3) is not None
True
sage: g.has_edge(1, 3)
False
```

See also:

comparability_graph()

interval(x, y)

Return a list of the elements \(z\) such that \(x \leq z \leq y\).

INPUT:

- \(x\) – any element of the poset
- \(y\) – any element of the poset

EXAMPLES:

```python
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: P = Poset(dag)
sage: I = set(map(P,[2,5,6,4,7]))
sage: I == set(P.interval(2,7))
True
sage: dg = DiGraph({"a":["b","c"], "b":["d"], "c":["d"]})
sage: P = Poset(dg, facade = False)
sage: P.interval("a","d")
[a, b, c, d]
```

intervals_number()

Return the number of relations in the poset.

A relation is a pair of elements \(x\) and \(y\) such that \(x \leq y\) in the poset.

Relations are also often called intervals. The number of intervals is the dimension of the incidence algebra.

EXAMPLES:

```python
sage: P = posets.PentagonPoset()
sage: P.relations_number()
13
```

```python
sage: posets.TamariLattice(4).relations_number()
68
```
See also:

relations_iterator(), relations()

intervals_poset()

Return the natural partial order on the set of intervals of the poset.

OUTPUT:

a finite poset

The poset of intervals of a poset \( P \) has the set of intervals \([x, y] \) in \( P \) as elements, endowed with the order relation defined by \([x_1, y_1] \leq [x_2, y_2] \) if and only if \( x_1 \leq x_2 \) and \( y_1 \leq y_2 \).

This is also called \( P \) to the power 2, meaning the poset of poset-morphisms from the 2-chain to \( P \).

If \( P \) is a lattice, the result is also a lattice.

EXAMPLES:

```
sage: P = Poset({0:[1]})
sage: P.intervals_poset()
Finite poset containing 3 elements
```

```
sage: P = posets.PentagonPoset()
sage: P.intervals_poset()
Finite lattice containing 13 elements
```

is_EL_labelling(\( f \), return_raising_chains=False)

Return True if \( f \) is an EL labelling of self.

A labelling \( f \) of the edges of the Hasse diagram of a poset is called an EL labelling (edge lexicographic labelling) if for any two elements \( u \) and \( v \) with \( u \leq v \),

- there is a unique \( f \)-raising chain from \( u \) to \( v \) in the Hasse diagram, and this chain is lexicographically first among all chains from \( u \) to \( v \).

For more details, see [Bj1980].

INPUT:

- \( f \) – a function taking two elements \( a \) and \( b \) in self such that \( b \) covers \( a \) and returning elements in a totally ordered set.
- return_raising_chains (optional; default:False) if True, returns the set of all raising chains in self, if possible.

EXAMPLES:

Let us consider a Boolean poset:

```
sage: P = Poset([[0,0],[0,1],[1,0],[1,1]],facade=True)
sage: label = lambda a,b: min( i for i in [0,1] if a[i] != b[i] )
sage: P.is_EL_labelling(label)
True
```

```
sage: P.is_EL_labelling(label,return_raising_chains=True)
{((0, 0), (0, 1)): [1],
 ((0, 0), (1, 0)): [0],
 ((0, 0), (1, 1)): [0, 1],
 ((0, 1), (1, 0)): [0],
 ((0, 1), (1, 1)): [1]}
```
**is_antichain_of_poset**(*elms*)

Return True if *elms* is an antichain of the poset and False otherwise.

Set of elements are an antichain of a poset if they are pairwise incomparable.

**EXAMPLES:**
```
sage: P = posets.BooleanLattice(5)
sage: P.is_antichain_of_poset([3, 5, 7])
False
sage: P.is_antichain_of_poset([3, 5, 14])
True
```

**is_bounded()**

Return True if the poset is bounded, and False otherwise.

A poset is bounded if it contains both a unique maximal element and a unique minimal element.

**EXAMPLES:**
```
sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4, 5], 4:[], 5:[]})
sage: P.is_bounded()
False
sage: Q = posets.DiamondPoset(5)
sage: Q.is_bounded()
True
```

See also:

- Weaker properties: `has_bottom()`, `has_top()`
- Other: `with_bounds()`, `without_bounds()`

**is_chain()**

Return True if the poset is totally ordered (“chain”), and False otherwise.

**EXAMPLES:**
```
sage: I = Poset({0:[1], 1:[2], 2:[3], 3:[4]})
sage: I.is_chain()
True
sage: II = Poset({0:[1], 2:[3]})
sage: II.is_chain()
False
sage: V = Poset({0:[1, 2]})
sage: V.is_chain()
False
```

**is_chain_of_poset**(*elms, ordered=False*)

Return True if *elms* is a chain of the poset, and False otherwise.

Set of elements are a chain of a poset if they are comparable to each other.

**INPUT:**
- *elms* – a list or other iterable containing some elements of the poset
• ordered – a Boolean. If True, then return True only if elements in elms are strictly increasing in the poset; this makes no sense if elms is a set. If False (the default), then elements can be repeated and be in any order.

EXAMPLES:

```
sage: P = Poset((divisors(12), attrcall("divides")))
sage: sorted(P.list())
[1, 2, 3, 4, 6, 12]
sage: P.is_chain_of_poset([12, 3])
True
sage: P.is_chain_of_poset([3, 4, 12])
False
sage: P.is_chain_of_poset([12, 3], ordered=True)
False
sage: P.is_chain_of_poset((1, 1, 3))
True
sage: P.is_chain_of_poset((1, 1, 3), ordered=True)
False
sage: P.is_chain_of_poset((1, 3), ordered=True)
True
```

is_connected()
Return True if the poset is connected, and False otherwise.

A poset is connected if its Hasse diagram is connected.

If a poset is not connected, then it can be divided to parts \( S_1 \) and \( S_2 \) so that every element of \( S_1 \) is incomparable to every element of \( S_2 \).

EXAMPLES:

```
sage: P = Poset({1:[2, 3], 3:[4, 5]})
sage: P.is_connected()
True
sage: P = Poset({1:[2, 3], 3:[4, 5], 6:[7, 8]})
sage: P.is_connected()
False
```

See also:

connected_components()

is_d_complete()
Return True if a poset is d-complete and False otherwise.

See also:

• d_complete

EXAMPLES:

```
sage: from sage.combinat.posets.posets import FinitePoset
sage: A = Poset({0: [1,2]})
sage: A.is_d_complete()
False
```
sage: from sage.combinat.posets.poset_examples import Posets
sage: B = Posets.DoubleTailedDiamond(3)

sage: B.is_d_complete()
True

sage: C = Poset({0: [2], 1: [2], 2: [3, 4], 3: [5], 4: [5], 5: [6]})

sage: C.is_d_complete()
False

sage: D = Poset({0: [1, 2], 1: [4], 2: [4], 3: [4]})

sage: D.is_d_complete()
False

sage: P = Posets.YoungDiagramPoset(Partition([3, 2, 2]), dual=True)

sage: P.is_d_complete()
True

is_eulerian($k=$None, $certificate=$False)

Return True if the poset is Eulerian, and False otherwise.

The poset is expected to be graded and bounded.

A poset is Eulerian if every non-trivial interval has the same number of elements of even rank as of odd rank. A poset is $k$-eulerian if every non-trivial interval up to rank $k$ is Eulerian.

See Wikipedia article Eulerian_poset.

INPUT:

• $k$, an integer – only check if the poset is $k$-eulerian. If None (the default), check if the poset is Eulerian.

• $certificate$, a Boolean – (default: False) whether to return a certificate

OUTPUT:

• If $certificate=True$ return either True, None or False, $(a, b)$, where the interval $(a, b)$ is not Eulerian. If $certificate=False$ return True or False.

EXAMPLES:

sage: P = Poset({0: [1, 2, 3], 1: [4, 5, 6], 2: [4, 6], 3: [5, 6],
.....: 4: [7, 8], 5: [7, 8], 6: [7, 8], 7: [9], 8: [9]})

sage: P.is_eulerian()
True

sage: P = Poset({0: [1, 2, 3], 1: [4, 5, 6], 2: [4, 6], 3: [5, 6],
.....: 4: [7], 5:[7], 6:[7]})

sage: P.is_eulerian()
False

Canonical examples of Eulerian posets are the face lattices of convex polytopes:

sage: P = polytopes.cube().face_lattice()

sage: P.is_eulerian()
True

A poset that is 3- but not 4-eulerian:
Combinatorics, Release 10.0

```python
sage: P = Poset(DiGraph('MWW@_?W?@_?W??@O@_?W?@_?W?@??O??')); P
Finite poset containing 14 elements
sage: P.is_eulerian(k=3)
True
sage: P.is_eulerian(k=4)
False
```

Getting an interval that is not Eulerian:

```python
sage: P = posets.DivisorLattice(12)
sage: P.is_eulerian(certificate=True)
(False, (1, 4))
```

**is_gequal(x, y)**

Return True if \( x \) is greater than or equal to \( y \) in the poset, and False otherwise.

**EXAMPLES:**

```python
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_gequal(3, 1)
True
sage: P.is_gequal(2, 2)
True
sage: P.is_gequal(0, 1)
False
```

See also:

`is_greater_than()`, `is_lequal()`.

**is_graded()**

Return True if the poset is graded, and False otherwise.

A poset is graded if all its maximal chains have the same length.

There are various competing definitions for graded posets (see Wikipedia article Graded_poset). This definition is from section 3.1 of Richard Stanley’s *Enumerative Combinatorics, Vol. 1* [EnumComb1]. Some sources call these posets tiered.

Every graded poset is ranked. The converse is true for bounded posets, including lattices.

**EXAMPLES:**

```python
sage: P = posets.PentagonPoset()  # Not even ranked
sage: P.is_graded()
False
sage: P = Poset({1:[2, 3], 3:[4]})  # Ranked, but not graded
sage: P.is_graded()
False
sage: P = Poset({1:[3, 4], 2:[3, 4], 5:[6]})
```

(continues on next page)
is_greater_than\(x, y\)

Return True if \(x\) is greater than but not equal to \(y\) in the poset, and False otherwise.

EXAMPLES:

```python
sage: P = Poset({0: [2], 1: [2], 2: [3], 3: [4], 4: []})
sage: P.is_greater_than(3, 1)
True
sage: P.is_greater_than(1, 2)
False
sage: P.is_greater_than(3, 3)
False
sage: P.is_greater_than(0, 1)
False
```

For non-facade posets also \(>\) works:

```python
sage: P = Poset({3: [1, 2]}, facade=False)
sage: P(2) > P(3)
True
```

See also:

is_gequal(), is_less_than().

is_greedy\(certificate=False\)

Return True if the poset is greedy, and False otherwise.

A poset is greedy if every greedy linear extension has the same number of jumps.

INPUT:

- certificate – (default: False) whether to return a certificate

OUTPUT:

- If certificate=True return either (True, None) or (False, (A, B)) where \(A\) and \(B\) are greedy linear extension so that \(B\) has more jumps. If certificate=False return True or False.

EXAMPLES:

This is not a self-dual property:

```python
sage: W = Poset({1: [3, 4], 2: [4, 5]})
sage: M = W.dual()
sage: W.is_greedy()
True
sage: M.is_greedy()
False
```

Getting a certificate:
sage: N = Poset({1: [3], 2: [3, 4]})
sage: N.is_greedy(certificate=True)
(False, ([1, 2, 4, 3], [2, 4, 1, 3]))

is_incomparable_chain_free\((m, n=None)\)
Return True if the poset is \((m + n)\)-free, and False otherwise.
A poset is \((m + n)\)-free if there is no incomparable chains of lengths \(m\) and \(n\). Three cases have special name (see [EnumComb1], exercise 3.15):

• “interval order” is \((2 + 2)\)-free
• “semiorder” (or “unit interval order”) is \((1 + 3)\)-free and \((2 + 2)\)-free
• “weak order” is \((1 + 2)\)-free.

INPUT:
• \(m, n\) - positive integers

It is also possible to give a list of integer pairs as argument. See below for an example.

EXAMPLES:

sage: B3 = posets.BooleanLattice(3)
sage: B3.is_incomparable_chain_free(1, 3)
True
sage: B3.is_incomparable_chain_free(2, 2)
False
sage: IP6 = posets.IntegerPartitions(6)
sage: IP6.is_incomparable_chain_free(1, 3)
False
sage: IP6.is_incomparable_chain_free(2, 2)
True

A list of pairs as an argument:

sage: B3.is_incomparable_chain_free([[1, 3], [2, 2]])
False

We show how to get an incomparable chain pair:

sage: P = posets.PentagonPoset()
sage: chains_1_2 = Poset({0: [], 1: [2]})
sage: incomps = P.isomorphic_subposets(chains_1_2)[0]
sage: sorted(incomps.list()), incomps.cover_relations()
([1, 2, 3], [[2, 3]])

AUTHOR:
• Eric Rowland (2013-05-28)

is_induced_subposet\((other)\)
Return True if the poset is an induced subposet of \(other\), and False otherwise.
A poset \(P\) is an induced subposet of \(Q\) if every element of \(P\) is an element of \(Q\), and \(x \leq_P y\) iff \(x \leq_Q y\).
Note that “induced” here has somewhat different meaning compared to that of graphs.

INPUT:
• other, a poset.

**Note:** This method does not check whether the poset is a isomorphic (i.e., up to relabeling) subposet of other, but only if other directly contains the poset as an induced subposet. For isomorphic subposets see has_isomorphic_subposet().

**EXAMPLES:**

```python
sage: P = Poset({1:[2, 3]})
sage: Q = Poset({1:[2, 4], 2:[3]})
sage: P.is_induced_subposet(Q)
False
sage: R = Poset({0:[1], 1:[3, 4], 3:[5], 4:[2]})
sage: P.is_induced_subposet(R)
True
```

**is_isomorphic(other, **kwds)**

Return True if both posets are isomorphic.

**EXAMPLES:**

```python
sage: P = Poset(([1,2,3],[[1,3],[2,3]]))
sage: Q = Poset(([4,5,6],[[4,6],[5,6]]))
sage: P.is_isomorphic(Q)
True
```

**is_join_semilattice(certificate=False)**

Return True if the poset has a join operation, and False otherwise.

A join is the least upper bound for given elements, if it exists.

**INPUT:**

• certificate – (default: False) whether to return a certificate

**OUTPUT:**

• If certificate=True return either (True, None) or (False, (a, b)) where elements a and b have no least upper bound. If certificate=False return True or False.

**EXAMPLES:**

```python
sage: P = Poset(([1,3,2], [4], [4,5,6], [6], [7], [7], [7], []))
sage: P.is_join_semilattice()
True
sage: P = Poset({1:[3, 4], 2:[3, 4], 3:[5], 4:[5]})
sage: P.is_join_semilattice()
False
sage: P.is_join_semilattice(certificate=True)
(False, (2, 1))
```

See also:

• Dual property: **is_meet_semilattice()**

• Stronger properties: **is_lattice()**
\textbf{is_jump_critical}(\textit{certificate=False})

Return True if the poset is jump-critical, and False otherwise.

A poset $P$ is \textit{jump-critical} if every proper subposet has smaller jump number.

INPUT:

\begin{itemize}
\item \textit{certificate} – (default: False) whether to return a certificate
\end{itemize}

OUTPUT:

\begin{itemize}
\item If \textit{certificate=True} return either (True, None) or (False, e) so that removing element $e$ from the poset does not decrease the jump number. If \textit{certificate=False} return True or False.
\end{itemize}

EXAMPLES:

\begin{verbatim}
sage: P = Poset({1: [3, 6], 2: [3, 4, 5], 4: [6, 7], 5: [7]})
sage: P.is_jump_critical()
True
sage: P = posets.PentagonPoset()
sage: P.is_jump_critical()
False
sage: P.is_jump_critical(certificate=True)
(False, 3)
\end{verbatim}

See also: 
\textit{jump_number()}

\textbf{is_lequal}(x, y)

Return True if $x$ is less than or equal to $y$ in the poset, and False otherwise.

EXAMPLES:

\begin{verbatim}
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_lequal(2, 4)
True
sage: P.is_lequal(2, 2)
True
sage: P.is_lequal(0, 1)
False
sage: P.is_lequal(3, 2)
False
\end{verbatim}

See also:
\textit{is_less_than(), is_gequal().}

\textbf{is_less_than}(x, y)

Return True if $x$ is less than but not equal to $y$ in the poset, and False otherwise.

EXAMPLES:

\begin{verbatim}
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_less_than(1, 3)
True
sage: P.is_less_than(0, 1)
False
\end{verbatim}
sage: P.is_less_than(2, 2)
False

For non-facade posets also < works:

sage: P = Poset({3: [1, 2]}, facade=False)
sage: P(1) < P(2)
False

See also:

\texttt{is\_lequal()}, \texttt{is\_greater\_than()}.

\textbf{is\_linear\_extension()}(l)

Return whether \texttt{l} is a linear extension of \texttt{self}.

INPUT:

\begin{itemize}
  \item \texttt{l} – a list (or iterable) containing all of the elements of \texttt{self} exactly once
\end{itemize}

EXAMPLES:

sage: P = Poset((divisors(12), attrcall("divides")), facade=True, linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: P.is_linear_extension([1, 2, 4, 3, 6, 12])
True
sage: P.is_linear_extension([1, 2, 4, 6, 3, 12])
False

sage: [p for p in Permutations(list(P)) if P.is_linear_extension(p)]
[[1, 2, 3, 4, 6, 12],
 [1, 2, 3, 6, 4, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 2, 4, 6, 3, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12]]
sage: list(P.linear_extensions())
[[1, 2, 3, 4, 6, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 2, 4, 6, 3, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12],
 [1, 2, 3, 6, 4, 12]]

\textbf{Note:} This is used and systematically tested in LinearExtensionsOfPosets

See also:

\texttt{linear\_extension()}, \texttt{linear\_extensions()}

\textbf{is\_linear\_interval}(x, y)

Return whether the interval \([x, y]\) is linear.

This means that this interval is a total order.

EXAMPLES:
sage: P = posets.PentagonPoset()
sage: P.is_linear_interval(0, 4)
False
sage: P.is_linear_interval(0, 3)
True
sage: P.is_linear_interval(1, 3)
False

is_meet_semilattice(certificate=False)
Return True if the poset has a meet operation, and False otherwise.
A meet is the greatest lower bound for given elements, if it exists.

INPUT:
• certificate = (default: False) whether to return a certificate

OUTPUT:
• If certificate=True return either (True, None) or (False, (a, b)) where elements a and b have no greatest lower bound. If certificate=False return True or False.

EXAMPLES:

sage: P = Poset({1:[2, 3, 4], 2:[5, 6], 3:[6], 4:[6, 7]})
sage: P.is_meet_semilattice()
True
sage: Q = P.dual()
sage: Q.is_meet_semilattice()
False
sage: V = posets.IntegerPartitions(5)
sage: V.is_meet_semilattice(certificate=True)
(False, ((2, 2, 1), (3, 1, 1)))

See also:
• Dual property: is_join_semilattice()
• Stronger properties: is_lattice()

is_parent_of(x)
Return True if x is an element of the poset.

is_rank_symmetric()
Return True if the poset is rank symmetric, and False otherwise.
The poset is expected to be graded and connected.
A poset of rank h (maximal chains have h + 1 elements) is rank symmetric if the number of elements are equal in ranks i and h − i for every i in 0, 1, . . . , h.

EXAMPLES:

sage: P = Poset({1:[3, 4, 5], 2:[3, 4, 5], 3:[5], 4:[7], 5:[7]})
sage: P.is_rank_symmetric()
True
is_ranked()  
Return True if the poset is ranked, and False otherwise.

A poset is ranked if there is a function \( r \) from poset elements to integers so that \( r(x) = r(y) + 1 \) when \( x \) covers \( y \).

Informally said a ranked poset can be “levelized”: every element is on a “level”, and every cover relation goes only one level up.

EXAMPLES:

```sage
 sage: P = Poset(([1, 2, 3, 4], [[1, 2], [2, 4], [3, 4]]))
 sage: P.is_ranked()
 True
 sage: P = Poset(([1, 5], [2, 6], [3], [4], [], [6, 3], [4]))
 sage: P.is_ranked()
 False
```

See also:

`rank_function()`, `rank()`, `is_graded()`

is_series_parallel()  
Return True if the poset is series-parallel, and False otherwise.

A poset is series-parallel if it can be built up from one-element posets using the operations of disjoint union and ordinal sum. This is also called \( N \)-free property: every poset that is not series-parallel contains a subposet isomorphic to the 4-element N-shaped poset where \( a > c, d \) and \( b > d \).

Note: Some papers use the term N-free for posets having no N-shaped poset as a cover-preserving subposet. This definition is not used here.

See Wikipedia article Series-parallel partial order.

EXAMPLES:

```sage
 sage: VA = Poset({1: [2, 3], 4: [5], 6: [5]})
 sage: VA.is_series_parallel()
 True
 sage: big_N = Poset({1: [2, 4], 2: [3], 4:[7], 5:[6], 6:[7]})
 sage: big_N.is_series_parallel()
 False
```

is_slender (certificate=False)  
Return True if the poset is slender, and False otherwise.

A finite graded poset is slender if every rank 2 interval contains three or four elements, as defined in [Stan2009]. (This notion of “slender” is unrelated to the eponymous notion defined by Graetzer and Kelly in “The Free \( m \)-Lattice on the Poset \( H \)”, Order 1 (1984), 47–65.)
This function does not check if the poset is graded or not. Instead, it just returns True if the poset does not contain 5 distinct elements \(x, y, a, b\) and \(c\) such that \(x \prec a, b, c \prec y\) where \(\prec\) is the covering relation.

**INPUT:**
- certificate – (default: False) whether to return a certificate

**OUTPUT:**
- If certificate=True return either (True, None) or (False, (a, b)) so that the interval \([a, b]\) has at least five elements. If certificate=False return True or False.

**EXAMPLES:**

```python
sage: P = Poset(([1, 2, 3, 4], [[1, 2], [1, 3], [2, 4], [3, 4]]))
sage: P.is_slender()
True
sage: P = Poset(([1, 2, 3, 4, 5], [[1, 2], [1, 3], [1, 4], [2, 5], [3, 5], [4, 5]]))
sage: P.is_slender()
False
sage: W = WeylGroup(['A', 2])
sage: G = W.bruhat_poset()
sage: G.is_slender()
True
sage: W = WeylGroup(['A', 3])
sage: G = W.bruhat_poset()
sage: G.is_slender()
True
sage: P = posets.IntegerPartitions(6)
sage: P.is_slender(certificate=True)
(False, ((6,), (3, 2, 1)))
```

**is_sperner()**

Return True if the poset is Sperner, and False otherwise.

The poset is expected to be ranked.

A poset is Sperner, if no antichain is larger than the largest rank level (one of the sets of elements of the same rank) in the poset.

See Wikipedia article Sperner_property_of_a_partially_ordered_set

See also:
- width()
- dilworth_decomposition()

**EXAMPLES:**

```python
sage: posets.SetPartitions(3).is_sperner()
True
sage: P = Poset({0:[3, 4, 5], 1:[5], 2:[5]})
sage: P.is_sperner()
False
```

**isomorphic_subposets(other)**

Return a list of subposets of self isomorphic to other.
By subposet we mean self.subposet(X) which is isomorphic to other and where X is a subset of elements of self.

INPUT:

• other – a finite poset

EXAMPLES:

```
sage: C2 = Poset({0:[1]})
sage: C3 = Poset({"a": ["b"], "b": ["c"]})
sage: L = sorted(x.cover_relations() for x in C3.isomorphic_subposets(C2))
sage: for x in L: print(x)
[['a', 'b']]
[['a', 'c']]
[['b', 'c']]
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
sage: N5 = posets.PentagonPoset()
sage: len(N5.isomorphic_subposets(D))
2
```

**Note:** If this function takes too much time, try using isomorphic_subposets_iterator().

isomorphic_subposets_iterator(other)

Return an iterator over the subposets of self isomorphic to other.

By subposet we mean self.subposet(X) which is isomorphic to other and where X is a subset of elements of self.

INPUT:

• other – a finite poset

EXAMPLES:

```
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
sage: N5 = posets.PentagonPoset()
sage: for P in N5.isomorphic_subposets_iterator(D):
....:     print(P.cover_relations())
[[0, 1], [0, 2], [1, 4], [2, 4]]
[[0, 1], [0, 3], [1, 4], [3, 4]]
[[0, 1], [0, 2], [1, 4], [2, 4]]
[[0, 1], [0, 3], [1, 4], [3, 4]]
```

**Warning:** This function will return same subposet as many times as there are automorphism on it. This is due to subgraph_search_iterator() returning labelled subgraphs. On the other hand, this function does not eat memory like isomorphic_subposets() does.

See also:

sage.combinat.posets.lattices.FiniteLatticePoset.isomorphic_sublattices_iterator().

join(x, y)

Return the join of two elements x, y in the poset if the join exists; and None otherwise.
EXAMPLES:

```
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
sage: D.join(2, 3)
4
sage: P = Poset({'e': ['b'], 'f': ['b', 'c', 'd'], 'g': ['c', 'd'],
              'b': ['a'], 'c': ['a']})
sage: P.join('a', 'b')
'a'
sage: P.join('e', 'a')
'a'
sage: P.join('c', 'b')
'a'
sage: P.join('e', 'f')
'b'
sage: P.join('e', 'g')
'a'
sage: P.join('c', 'd')
is None
True
sage: P.join('g', 'f')
is None
True
```

`jump_number(certificate=False)`

Return the jump number of the poset.

A jump in a linear extension \([e_1, \ldots, e_n]\) of a poset \(P\) is a pair \((e_i, e_{i+1})\) so that \(e_{i+1}\) does not cover \(e_i\) in \(P\). The jump number of a poset is the minimal number of jumps in linear extensions of a poset.

**INPUT:**
- `certificate` – (default: `False`) Whether to return a certificate

**OUTPUT:**
- If `certificate=True` return a pair \((n, l)\) where \(n\) is the jump number and \(l\) is a linear extension with \(n\) jumps. If `certificate=False` return only the jump number.

**EXAMPLES:**

```
sage: B3 = posets.BooleanLattice(3)
sage: B3.jump_number()
3
sage: N = Poset({1: [3, 4], 2: [3]})
sage: N.jump_number(certificate=True)
(1, [1, 4, 2, 3])
```

**ALGORITHM:**

It is known that every poset has a greedy linear extension — an extension \([e_1, e_2, \ldots, e_n]\) where every \(e_{i+1}\) is an upper cover of \(e_i\) if that is possible — with the smallest possible number of jumps; see [Sys1987].

Hence it suffices to test only those. We do that by backtracking.

The problem is proven to be NP-complete.

**See also:**

`is_jump_critical()`
The Kazhdan-Lusztig polynomial $P_{x,y}(q)$ of the poset.

The poset is expected to be ranked.

We follow the definition given in [EPW14]. Let $G$ denote a graded poset with unique minimal and maximal elements and $\chi_G$ denote the characteristic polynomial of $G$. Let $I_x$ and $F_x$ denote the principal order ideal and filter of $x$ respectively. Define the Kazhdan-Lusztig polynomial of $G$ as the unique polynomial $P_G(q)$ satisfying the following:

1. If $\text{rank } G = 0$, then $P_G(q) = 1$.
2. If $\text{rank } G > 0$, then $\deg P_G(q) < \frac{1}{2} \text{rank } G$.
3. We have
   
   $$q^{\text{rank } G} P_G(q^{-1}) = \sum_{x \in G} \chi_{I_x}(q) P_{F_x}(q).$$

We then extend this to $P_{x,y}(q)$ by considering the subposet corresponding to the (closed) interval $[x, y]$. We also define $P_0(q) = 0$ (so if $x \not\leq y$, then $P_{x,y}(q) = 0$).

INPUT:

- $q$ – (default: $q \in \mathbb{Z}[q]$) the indeterminate $q$
- $x$ – (default: the minimal element) the element $x$
- $y$ – (default: the maximal element) the element $y$
- $\text{canonical_labels}$ – (optional) for subposets, use the canonical labeling (this can limit recursive calls for posets with large amounts of symmetry, but producing the labeling takes time); if not specified, this is $\text{True}$ if $x$ and $y$ are both not specified and $\text{False}$ otherwise

EXAMPLES:

```python
sage: L = posets.BooleanLattice(3)
sage: L.kazhdan_lusztig_polynomial()
1

sage: L = posets.SymmetricGroupWeakOrderPoset(4)
sage: L.kazhdan_lusztig_polynomial()
1
sage: x = '2314'
sage: y = '3421'
sage: L.kazhdan_lusztig_polynomial(x, y)
-t + 1
sage: L.kazhdan_lusztig_polynomial(x, y, var('t'))
-t + 1
```

AUTHORS:

- Travis Scrimshaw (27-12-2014)

le($x, y$)

Return True if $x$ is less than or equal to $y$ in the poset, and False otherwise.

EXAMPLES:
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4[:]});

sage: P.is_lequal(2, 4)
True
sage: P.is_lequal(2, 2)
True
sage: P.is_lequal(0, 1)
False
sage: P.is_lequal(3, 2)
False

See also:

* is_less_than(), is_gequal().

**lequal_matrix(ring=Integer Ring, sparse=False)**

Compute the matrix whose (i,j) entry is 1 if self.linear_extension()[i] < self.linear_extension()[j] and 0 otherwise.

INPUT:

* ring – the ring of coefficients (default: ZZ)
* sparse – whether the returned matrix is sparse or not (default: True)

EXAMPLES:

sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]], facade = False)
sage: LEQM = P.lequal_matrix(); LEQM

\[
\begin{bmatrix}
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 1 & 1 & 0 & 1 & 1 & 1 \\
0 & 0 & 0 & 1 & 0 & 0 & 1 & 1 \\
0 & 0 & 0 & 0 & 1 & 0 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
\end{bmatrix}
\]

sage: LEQM[1,3] 1
sage: P.linear_extension()[1] < P.linear_extension()[3]
True
sage: LEQM[2,5] 0
False

We now demonstrate the usage of the optional parameters:

sage: P.lequal_matrix(ring=QQ, sparse=False).parent()

Full MatrixSpace of 8 by 8 dense matrices over Rational Field

**level_sets()**

Return elements grouped by maximal number of cover relations from a minimal element.

This returns a list of lists l such that l[i] is the set of minimal elements of the poset obtained by removing the elements in l[0], l[1], ..., l[i-1]. (In particular, l[0] is the set of minimal elements of self.)

Every level is an antichain of the poset.
EXAMPLES:

```python
sage: P = Poset({0:[1,2],1:[3],2:[3],3:[]})
sage: P.level_sets()
[[0], [1, 2], [3]]
```

```python
sage: Q = Poset({0:[1,2], 1:[3], 2:[4], 3:[4]})
sage: Q.level_sets()
[[0], [1, 2], [3], [4]]
```

See also:

`dilworth_decomposition()` to return elements grouped to chains.

**lexicographic_sum**

Return the lexicographic sum using this poset as index.

In the lexicographic sum of posets $P_t$ by index poset $T$ we have $x \leq y$ if either $x \leq y$ in $P_t$ for some $t \in T$, or $x \in P_i$, $y \in P_j$ and $i \leq j$ in $T$.

Informally said we substitute every element of $T$ by corresponding poset $P_t$.

Mathematically, it is only defined when all $P_t$ have no common element; here we force that by giving them different names in the resulting poset.

`disjoint_union()` and `ordinal_sum()` are special cases of lexicographic sum where the index poset is an (anti)chain. `ordinal_product()` is a special case where every $P_t$ is same poset.

**INPUT:**

- $P$ – dictionary whose keys are elements of this poset, values are posets

**EXAMPLES:**

```python
sage: N = Poset({1: [3, 4], 2: [4]})
sage: NP = N.lexicographic_sum(P); NP
Finite poset containing 16 elements
sage: sorted(NP.minimal_elements())
[(1, 0), (2, 1), (2, 2)]
```

**linear_extension** *(linear_extension=None, check=True)*

Return a linear extension of this poset.

A linear extension of a finite poset $P$ of size $n$ is a total ordering $\pi := \pi_0 \pi_1 \ldots \pi_{n-1}$ of its elements such that $i < j$ whenever $\pi_i < \pi_j$ in the poset $P$.

**INPUT:**

- linear_extension – (default: None) a list of the elements of self
- check – a boolean (default: True); whether to check that linear_extension is indeed a linear extension of self.

**EXAMPLES:**

```python
sage: P = Poset((divisors(15), attrcall("divides")), facade=True)
```

Without optional argument, the default linear extension of the poset is returned, as a plain list:
Otherwise, a full-featured linear extension is constructed as an element of `P.linear_extensions()`:

```sage
sage: l = P.linear_extension([1,5,3,15]); l
[1, 5, 3, 15]
sage: type(l)
<class 'sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset_with_category.element_class'>
sage: l.parent()
The set of all linear extensions of Finite poset containing 4 elements
```

By default, the linear extension is checked for correctness:

```sage
sage: l = P.linear_extension([1,3,15,5])
Traceback (most recent call last):
  ... ValueError: [1, 3, 15, 5] is not a linear extension of Finite poset containing 4 elements
```

This can be disabled (at your own risks!) with:

```sage
sage: P.linear_extension([1,3,15,5], check=False)
[1, 3, 15, 5]
```

See also:

- `is_linear_extension()`, `linear_extensions()`

Todo:

- Is it acceptable to have those two features for a single method?
- In particular, we miss a short idiom to get the default linear extension

**linear_extensions**(facade=False)

Return the enumerated set of all the linear extensions of this poset.

**INPUT:**

- `facade` – a boolean (default: False); whether to return the linear extensions as plain lists

**Warning:** The facade option is not yet fully functional:

```sage
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: L = P.linear_extensions(facade=True); L
The set of all linear extensions of Finite poset containing 6 elements
with distinguished linear extension
sage: L([1, 2, 3, 4, 6, 12])
Traceback (most recent call last):
  ... TypeError: Cannot convert list to sage.structure.element.Element
```
EXAMPLES:

```python
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: L = P.linear_extensions(); L
The set of all linear extensions of Finite poset containing 6 elements with...
distinguished linear extension
sage: l = L.an_element(); l
[1, 2, 3, 4, 6, 12]
```

Each element is aware that it is a linear extension of $P$:

```python
sage: type(l.parent())
<class 'sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset_with...
category'>
```

With `facade=True`, the elements of $L$ are plain lists instead:

```python
sage: L = P.linear_extensions(facade=True)
sage: l = L.an_element()
sage: type(l)
<class 'list'>
```

**Warning:** In Sage <= 4.8, this function used to return a plain list of lists. To recover the previous functionality, please use:

```python
sage: L = list(P.linear_extensions(facade=True)); L
[[1, 2, 3, 4, 6, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12],
 [1, 2, 3, 6, 4, 12]]
sage: type(L[0])
<class 'list'>
```

See also:

- `linear_extension()`, `is_linear_extension()`
- `linear_extensions_graph()`

*linear_extensions_graph()*

Return the linear extensions graph of the poset.

Vertices of the graph are linear extensions of the poset. Two vertices are connected by an edge if the linear extensions differ by only one adjacent transposition.

EXAMPLES:
Combinatorics, Release 10.0

```python
sage: N = Poset({1: [3, 4], 2: [4]})
sage: G = N.linear_extensions_graph(); G
Graph on 5 vertices
sage: G.neighbors(N.linear_extension([1,2,3,4]))
[[2, 1, 3, 4], [1, 3, 2, 4], [1, 2, 4, 3]]

sage: chevron = Poset({1: [2, 6], 2: [3], 4: [3, 5], 6: [5]})
sage: G = chevron.linear_extensions_graph(); G
Graph on 22 vertices
sage: G.size()
36
```

**linear_intervals_count()**

Return the enumeration of linear intervals w.r.t. their cardinality.

An interval is linear if it is a total order.

OUTPUT: list of integers

See also:

* is_linear_interval()

EXAMPLES:

```python
sage: P = posets.PentagonPoset()
sage: P.linear_intervals_count()
[5, 5, 2]
sage: P = posets.TamariLattice(4)
sage: P.linear_intervals_count()
[14, 21, 12, 2]
```

**list()**

List the elements of the poset. This just returns the result of `linear_extension()`.

EXAMPLES:

```python
sage: D = Poset({0:[1,2], 1:[3], 2:[3,4]}, facade = False)
sage: D.list()
[0, 1, 2, 3, 4]
sage: type(D.list()[0])
<class 'sage.combinat.posets.posets.FinitePoset_with_category.element_class'>
```

**lower_covers(x)**

Return the list of lower covers of the element x.

A lower cover of x is an element y such that y < x and there is no element z so that y < z < x.

EXAMPLES:

```python
sage: P = Poset([[1, 5], [2, 6], [3], [4], [], [6, 3], [4]])
sage: P.lower_covers(3)
[2, 5]
sage: P.lower_covers(0)
[]
```
See also:

upper_covers()

lower_covers_iterator(x)

Return an iterator over the lower covers of the element x.

EXAMPLES:

    sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[]})
    sage: l0 = P.lower_covers_iterator(3)
    sage: type(l0)
    <class 'generator'>
    sage: next(l0)
    2

ltr(x, y)

Return True if x is less than but not equal to y in the poset, and False otherwise.

EXAMPLES:

    sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
    sage: P.is_less_than(1, 3)
    True
    sage: P.is_less_than(0, 1)
    False
    sage: P.is_less_than(2, 2)
    False

For non-facade posets also < works:

    sage: P = Poset({3: [1, 2]}, facade=False)
    sage: P(1) < P(2)
    False

See also:

is_lequal(), is_greater_than().

magnitude()

Return the magnitude of self.

The magnitude is an integer defined as the sum of all Möbius numbers, and can be seen as some kind of Euler characteristic of the poset. It is additive under disjoint union and multiplicative under Cartesian product.

REFERENCES:

- https://golem.ph.utexas.edu/category/2011/06/the_magnitude_of_an_enriched_c.html

EXAMPLES:

    sage: P = posets.PentagonPoset()
    sage: P.magnitude()
    1

(continues on next page)
sage: W = SymmetricGroup(4)
sage: P = W.noncrossing_partition_lattice().without_bounds()
sage: P.magnitude()
-4

sage: P = posets.TamariLattice(4).without_bounds()
sage: P.magnitude()
0

See also:

order_complex()

maximal_antichains()
Return the maximal antichains of the poset.
An antichain \( a \) of poset \( P \) is maximal if there is no element \( e \in P \setminus a \) such that \( a \cup \{e\} \) is an antichain.

EXAMPLES:

```
sage: P = Poset({'a': ['b', 'c'], 'b': ['d', 'e']})
sage: [sorted(anti) for anti in P.maximal_antichains()]
[["a"], ["b", "c"], ["c", "d", "e"]]
sage: posets.PentagonPoset().maximal_antichains()
[[0], [1, 2], [1, 3], [4]]
```

See also:

antichains(), maximal_chains()

maximal_chain_length()
Return the maximum length of a maximal chain in the poset.
The length here is the number of vertices.

EXAMPLES:

```
sage: P = posets.TamariLattice(5)
sage: P.maximal_chain_length()
11
```

See also:

maximal_chains(), maximal_chains_iterator()

maximal_chains(partial=None)
Return all maximal chains of this poset.
Each chain is listed in increasing order.

INPUT:

- partial – list (optional); if given, the list partial is assumed to be the start of a maximal chain, and the function will find all maximal chains starting with the elements in partial

This is used in constructing the order complex for the poset.

EXAMPLES:
```python
sage: P = posets.BooleanLattice(3)
sage: P.maximal_chains()
[[0, 1, 3, 7], [0, 1, 5, 7], [0, 2, 3, 7], [0, 2, 6, 7], [0, 4, 5, 7], [0, 4, 6, 7]]
sage: P.maximal_chains(partial=[0,2])
[[0, 2, 3, 7], [0, 2, 6, 7]]
sage: Q = posets.ChainPoset(6)
sage: Q.maximal_chains()
[[0, 1, 2, 3, 4, 5]]
```

See also:

- `maximal_antichains()`, `chains()`

**maximal_chains_iterator**(partial=None)

Return an iterator over maximal chains.

Each chain is listed in increasing order.

**INPUT:**

- **partial** – list (optional); if given, the list `partial` is assumed to be the start of a maximal chain, and the function will yield all maximal chains starting with the elements in `partial`.

**EXAMPLES:**

```python
sage: P = posets.BooleanLattice(3)
sage: it = P.maximal_chains_iterator()
sage: next(it)
[0, 1, 3, 7]
```

See also:

- antichains_iterator()

**maximal_elements()**

Return the list of the maximal elements of the poset.

**EXAMPLES:**

```python
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.maximal_elements()
[4]
```

See also:

- minimal_elements()

**meet**(x, y)

Return the meet of two elements `x, y` in the poset if the meet exists; and `None` otherwise.

**EXAMPLES:**

```python
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
sage: D.meet(2, 3)
1
sage: P = Poset({'a':['b', 'c'], 'b':['e', 'f'], 'c':['f', 'g'],
.....: 'd':['f', 'g']})
```

(continues on next page)
\begin{verbatim}
mutable_elements()
Return the list of the minimal elements of the poset.

EXAMPLES:

sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[4]})
sage: P(0) in P.mutable_elements()
True
sage: P(1) in P.mutable_elements()
True
sage: P(2) in P.mutable_elements()
True

See also:
\emph{maximal_elements()}.

moebius_function(x, y)
Return the value of the Möbius function of the poset on the elements x and y.

EXAMPLES:

sage: P = Poset([[1,2,3],[4],[4],[4],[4]])
sage: P.moebius_function(0,4)
2
sage: sum(P.moebius_function(u,v) for v in P)
0
sage: sum(abs(P.moebius_function(u,v)) for v in P)
6
sage: for u,v in P.cover_relations_iterator:
....:   if P.moebius_function(u,v) != -1:
....:       print("Bug in moebius_function!")

sage: Q = Poset([[1,2,3],[4],[4,5,6],[6],[7],[7],[7],[7],[7],[7]])
sage: Q.moebius_function(0,4)
0
sage: Q.moebius_function(0,5)
0
\end{verbatim}
\begin{verbatim}
sage: Q.moebius_function(Q(2),Q(7))
2
sage: Q.moebius_function(Q(3),Q(3))
1
sage: sum([Q.moebius_function(Q(0),v) for v in Q])
0
\end{verbatim}

\textbf{moebius_function_matrix}(\texttt{ring=\textit{Integer Ring}, \texttt{sparse=False}})

Return a matrix whose \((i,j)\) entry is the value of the Möbius function evaluated at \texttt{self.linear_extension()[i]} and \texttt{self.linear_extension()[j]}.

INPUT:

- \texttt{ring} – the ring of coefficients (default: \texttt{ZZ})
- \texttt{sparse} – whether the returned matrix is sparse or not (default: \texttt{True})

EXAMPLES:

\begin{verbatim}
sage: P = Poset([[4,2,3],[],[1],[1],[1]])
sage: x,y = (P.linear_extension()[0],P.linear_extension()[1])
sage: P.moebius_function(x,y)
-1
sage: M = P.moebius_function_matrix(); M
\[
\begin{bmatrix}
1 & -1 & -1 & -1 & 2 \\
0 & 1 & 0 & 0 & -1 \\
0 & 0 & 1 & 0 & -1 \\
0 & 0 & 0 & 1 & -1 \\
0 & 0 & 0 & 0 & 1
\end{bmatrix}
\]
sage: M[0,4]
2
sage: M[0,1]
-1
\end{verbatim}

We now demonstrate the usage of the optional parameters:

\begin{verbatim}
sage: P.moebius_function_matrix(ring=QQ, sparse=False).parent()
Full MatrixSpace of 5 by 5 dense matrices over Rational Field
\end{verbatim}

\textbf{open_interval}(x,y)

Return the list of elements \(z\) such that \(x < z < y\) in the poset.

EXAMPLES:

\begin{verbatim}
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.open_interval(2, 100)
[4, 10, 20, 50]
\end{verbatim}

See also:

\textit{closed_interval()}

\textbf{order_complex}(\texttt{on_ints=False})

Return the order complex associated to this poset.

The order complex is the simplicial complex with vertices equal to the elements of the poset, and faces given by the chains.
INPUT:

- on_ints – a boolean (default: False)

OUTPUT:
an order complex of type SimplicialComplex

EXAMPLES:

```python
sage: P = posets.BooleanLattice(3)
sage: S = P.order_complex(); S
Simplicial complex with vertex set (0, 1, 2, 3, 4, 5, 6, 7) and 6 facets
sage: S.f_vector()
[1, 8, 19, 18, 6]
sage: S.homology()
{0: 0, 1: 0, 2: 0, 3: 0}
sage: Q = P.subposet([1,2,3,4,5,6])
sage: Q.order_complex().homology()
{0: 0, 1: \mathbb{Z}}
```

If on_ints, then the elements of the poset are labelled 0, 1,… in the chain complex:

```python
sage: P.order_complex(on_ints=True)
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(0, 1, 3), (0, 2, 3)}
```

**order_filter(elements)**

Return the order filter generated by the elements of an iterable elements.

$I$ is an order filter if, for any $x$ in $I$ and $y$ such that $y \geq x$, then $y$ is in $I$. This is also called upper set or upset.

EXAMPLES:

```python
sage: P = Poset((divisors(15), attrcall("divides")), facade = True)
sage: P.order_complex()
Simplicial complex with vertex set (1, 3, 5, 15) and facets {{(1, 3, 15), (1, 5, 15)}}
```

**order_ideal(elements)**

Return the order ideal generated by the elements of an iterable elements.

$I$ is an order ideal if, for any $x$ in $I$ and $y$ such that $y \leq x$, then $y$ is in $I$. This is also called lower set or downset.

EXAMPLES:

```python
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.order_ideal([20, 25])
[1, 2, 4, 5, 10, 20, 25]
```

See also:

`order_ideal()`, `principal_order_filter()`.

**order_ideal(elements)**

Return the order ideal generated by the elements of an iterable elements.

$I$ is an order ideal if, for any $x$ in $I$ and $y$ such that $y \leq x$, then $y$ is in $I$. This is also called lower set or downset.

EXAMPLES:

```python
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.order_ideal([20, 25])
[1, 2, 4, 5, 10, 20, 25]
```
See also:

`order_filter()`, `principal_order_ideal()`.

**order_ideal_cardinality(elements)**

Return the cardinality of the order ideal generated by elements.

The elements \( I \) is an order ideal if, for any \( x \in I \) and \( y \) such that \( y \leq x \), then \( y \in I \).

**EXAMPLES:**

```python
sage: P = posets.BooleanLattice(4)
sage: P.order_ideal_cardinality([7,10])
10
```

**order_ideal_plot(elements)**

Return a plot of the order ideal generated by the elements of an iterable elements.

\( I \) is an order ideal if, for any \( x \) in \( I \) and \( y \) such that \( y \leq x \), then \( y \) is in \( I \). This is also called lower set or downset.

**EXAMPLES:**

```python
sage: P = Poset((divisors(1000), attrcall("divides"))
sage: P.order_ideal_plot([20, 25])
```

Graphics object consisting of 41 graphics primitives

**order_polynomial()**

Return the order polynomial of the poset.

The order polynomial \( \Omega_P(q) \) of a poset \( P \) is defined as the unique polynomial \( S \) such that for each integer \( m \geq 1 \), \( S(m) \) is the number of order-preserving maps from \( P \) to \( \{1, \ldots, m\} \).

See sections 3.12 and 3.15 of [EnumComb1], and also [St1986].

**EXAMPLES:**

```python
sage: P = posets.AntichainPoset(3)
sage: P.order_polynomial()
q^3
sage: P = posets.ChainPoset(3)
sage: f = P.order_polynomial(); f
1/6*q^3 + 1/2*q^2 + 1/3*q
sage: [f(i) for i in range(4)]
[0, 1, 4, 10]
```

See also:

`order_polytope()`

**order_polytope()**

Return the order polytope of the poset self.

The order polytope of a finite poset \( P \) is defined as the subset of \( \mathbb{R}^P \) consisting of all maps \( x : P \to \mathbb{R} \) satisfying

\[
0 \leq x(p) \leq 1 \text{ for all } p \in P,
\]
and

\[ x(p) \leq x(q) \text{ for all } p, q \in P \text{ satisfying } p < q. \]

This polytope was defined and studied in [St1986].

EXAMPLES:

```
sage: P = posets.AntichainPoset(3)
sage: Q = P.order_polytope();Q
A 3-dimensional polyhedron in ZZ^3 defined as the convex hull of 8 vertices
sage: P = posets.PentagonPoset()
sage: Q = P.order_polytope();Q
A 5-dimensional polyhedron in ZZ^5 defined as the convex hull of 8 vertices
sage: P = Poset([[1,2,3],[[1,2],[1,3]]])
sage: Q = P.order_polytope()
sage: Q.contains((1,0,0))
False
sage: Q.contains((0,1,1))
True
```

**ordinal_product**(other, labels='pairs')

Return the ordinal product of self and other.

The ordinal product of two posets \( P \) and \( Q \) is a partial order on the Cartesian product of the underlying sets of \( P \) and \( Q \), defined as follows (see [EnumComb1], p. 284).

In the ordinal product, \((p, q) \leq (p', q')\) if either \( p \leq p' \) or \( p = p' \) and \( q \leq q' \).

This construction is not symmetric in \( P \) and \( Q \). Informally said we put a copy of \( Q \) in place of every element of \( P \).

INPUT:

- **other** – a poset
- **labels** – either 'integers' or 'pairs' (default); how the resulting poset will be labeled

EXAMPLES:

```
sage: P1 = Poset((['a', 'b'], [['a', 'b']]))
sage: P2 = Poset((['c', 'd'], [['c', 'd']]))
sage: P = P1.ordinal_product(P2); P
Finite poset containing 4 elements
sage: sorted(P.cover_relations())
[[('a', 'c'), ('a', 'd'), ('b', 'c')],
 [('b', 'c'), ('b', 'd')]]
```

See also:

- `product()`, `ordinal_sum()`

**ordinal_sum**(other, labels='pairs')

Return a poset or (semi)lattice isomorphic to ordinal sum of the poset with other.

The ordinal sum of \( P \) and \( Q \) is a poset that contains every element and relation from both \( P \) and \( Q \), and where every element of \( P \) is smaller than any element of \( Q \).

Mathematically, it is only defined when \( P \) and \( Q \) have no common element; here we force that by giving them different names in the resulting poset.
The ordinal sum on lattices is a lattice; resp. for meet- and join-semilattices.

INPUT:
- `other`, a poset.
- `labels` - (defaults to `pairs`) If set to `pairs`, each element v in this poset will be named (0,v) and each element u in `other` will be named (1,u) in the result. If set to `integers`, the elements of the result will be relabeled with consecutive integers.

EXAMPLES:

```python
sage: P1 = Poset( ([1, 2, 3, 4], [[1, 2], [1, 3], [1, 4]])
sage: P2 = Poset( ([1, 2, 3, ], [[2,1], [3,1]])
sage: P3 = P1.ordinal_sum(P2); P3
Finite poset containing 7 elements
sage: len(P1.maximal_elements())*len(P2.minimal_elements())
6
sage: len(P1.cover_relations()+P2.cover_relations())
5
sage: len(P3.cover_relations()) # Every element of P2 is greater than elements
11
  of P1.
sage: P3.list() # random
[(0, 1), (0, 2), (0, 4), (0, 3), (1, 2), (1, 3), (1, 1)]
sage: P4 = P1.ordinal_sum(P2, labels='integers')
sage: P4.list() # random
[0, 1, 2, 3, 5, 6, 4]
```

Return type depends on input types:

```python
sage: P = Poset({1:[2]}); P
Finite poset containing 2 elements
sage: JL = JoinSemilattice({1:[2]}); JL
Finite join-semilattice containing 2 elements
sage: L = LatticePoset({1:[2]}); L
Finite lattice containing 2 elements
sage: P.ordinal_sum(L)
Finite poset containing 4 elements
sage: L.ordinal_sum(JL)
Finite join-semilattice containing 4 elements
sage: L.ordinal_sum(L)
Finite lattice containing 4 elements
```

See also:

`ordinal_summands()`, `disjoint_union()`, `sage.combinat.posets.lattices.FiniteLatticePoset.vertical_composition()`

`ordinal_summands()`

Return the ordinal summands of the poset as subposets.

The ordinal summands of a poset $P$ is the longest list of non-empty subposets $P_1, \ldots, P_n$ whose ordinal sum is $P$. This decomposition is unique.

EXAMPLES:
Combinatorics, Release 10.0

```python
sage: P = Poset({'a': ['c', 'd'], 'b': ['d'], 'c': ['x', 'y'],
             'd': ['x', 'y']})
sage: parts = P.ordinal_summands(); parts
[Finite poset containing 4 elements, Finite poset containing 2 elements]
sage: sorted(parts[0])
['a', 'b', 'c', 'd']
sage: Q = parts[0].ordinal_sum(parts[1])
sage: Q.is_isomorphic(P)
True
```

See also:

`ordinal_sum()`

**ALGORITHM:**

Suppose that a poset $P$ is the ordinal sum of posets $L$ and $U$. Then $P$ contains maximal antichains $l$ and $u$ such that every element of $u$ covers every element of $l$; they correspond to maximal elements of $L$ and minimal elements of $U$.

We consider a linear extension $x_1, \ldots, x_n$ of the poset’s elements.

We keep track of the maximal elements of subposet induced by elements $0, \ldots, x_i$ and minimal elements of subposet induced by elements $x_{i+1}, \ldots, x_n$, incrementing $i$ one by one. We then check if $l$ and $u$ fit the previous description.

**p_partition Enumerator**(tup, R, weights=None, check=False)

Return a $P$-partition enumerator of self.

Given a total order $\prec$ on the elements of a finite poset $P$ (the order of $P$ and the total order $\prec$ can be unrelated; in particular, the latter does not have to extend the former), a $P$-partition enumerator is the quasisymmetric function $\sum_f \prod_{p \in P} x_{f(p)}$, where the first sum is taken over all $P$-partitions $f$.

A $P$-partition is a function $f: P \to \{1, 2, 3, \ldots\}$ satisfying the following properties for any two elements $i$ and $j$ of $P$ satisfying $i \prec_P j$:

- if $i \prec j$ then $f(i) \leq f(j)$,
- if $j \prec i$ then $f(i) < f(j)$.

The optional argument `weights` allows constructing a generalized (“weighted”) version of the $P$-partition enumerator. Namely, `weights` should be a dictionary whose keys are the elements of $P$. Then, the generalized $P$-partition enumerator corresponding to weights `weights` is $\sum_f \prod_{p \in P} x_{w(p)}$, where the sum is again over all $P$-partitions $f$. Here, $w(p)$ is `weights[p]`. The classical $P$-partition enumerator is the particular case obtained when all $p$ satisfy $w(p) = 1$.

In the language of [Grinb2016a], the generalized $P$-partition enumerator is the quasisymmetric function $\Gamma(E, w)$, where $E$ is the special double poset $(P, <_P, \prec)$, and where $w$ is the dictionary `weights` (regarded as a function from $P$ to the positive integers).

**INPUT:**

- `tup` – the tuple containing all elements of $P$ (each of them exactly once), in the order dictated by the total order $\prec$
- `R` – a commutative ring
- `weights` – (optional) a dictionary of positive integers, indexed by elements of $P$; any missing item will be understood as 1
OUTPUT:

The $P$-partition enumerator of `self` according to `tup` in the algebra $QSym$ of quasisymmetric functions over the base ring $R$.

EXAMPLES:

```python
sage: P = Poset([[1,2,3,4],[[1,4],[2,4],[4,3]]])
sage: FP = P.p_partition_enumerator((3,1,2,4), QQ, check=True); FP
sage: expansion = FP.expand(5)
sage: xs = expansion.parent().gens()
sage: expansion == sum([xs[a]*xs[b]*xs[c]*xs[d] for a in range(5) for b in range(5) for c in range(5) for d in range(5) if a <= b and c <= b and b < d])
True
sage: P = Poset([[],[]])
sage: FP = P.p_partition_enumerator((), QQ, check=True); FP
M[]
```

With the `weights` parameter:

```python
sage: P = Poset([[1,2,3,4],[[1,4],[2,4],[4,3]]])
sage: FP = P.p_partition_enumerator((3,1,2,4), QQ, weights={1: 1, 2: 2, 3: 1, 4: 1}, check=True); FP
sage: FP = P.p_partition_enumerator((3,1,2,4), QQ, weights={2: 2}, check=True); FP
sage: P = Poset([['a','b','c'], [['a','b'], ['a','c']]])
sage: FP = P.p_partition_enumerator(('b','c','a'), QQ, weights={'a': 3, 'b': 5, 'c': 7}, check=True); FP
sage: P = Poset([['a','b','c'], [['a','c'], ['b','c']]])
sage: FP = P.p_partition_enumerator(('b','c','a'), QQ, weights={'a': 3, 'b': 5, 'c': 7}, check=True); FP
sage: FP = P.p_partition_enumerator(('a','b','c'), QQ, weights={'a': 3, 'b': 5, 'c': 7}, check=True); FP
```

```python
plot(label_elements=True, element_labels=None, layout='acyclic', cover_labels=None, **kwds)
```

Return a Graphic object for the Hasse diagram of the poset.

If the poset is ranked, the plot uses the rank function for the heights of the elements.

INPUT:

- Options to change element look:
  - `element_colors` - a dictionary where keys are colors and values are lists of elements
  - `element_color` - a color for elements not set in `element_colors`
- **element_shape** - the shape of elements, like 's' for square; see https://matplotlib.org/api/markers_api.html for the list
- **element_size** (default: 200) - the size of elements
- **label_elements** (default: True) - whether to display element labels
- **element_labels** (default: None) - a dictionary where keys are elements and values are labels to show

**Options to change cover relation look:**
- **cover_colors** - a dictionary where keys are colors and values are lists of cover relations given as pairs of elements
- **cover_color** - a color for elements not set in **cover_colors**
- **cover_style** - style for cover relations: 'solid', 'dashed', 'dotted' or 'dashdot'
- **cover_labels** - a dictionary, list or function representing labels of the covers of the poset. When set to None (default) no label is displayed on the edges of the Hasse Diagram.
- **cover_labels_background** - a background color for cover relations. The default is “white”. To achieve a transparent background use “transparent”.

**Options to change overall look:**
- **figsize** (default: 8) - size of the whole plot
- **title** - a title for the plot
- **fontsize** - fontsize for the title
- **border** (default: False) - whether to draw a border over the plot

**Note:** All options of **GenericGraph.plot** are also available through this function.

**EXAMPLES:**

This function can be used without any parameters:

```
sage: D12 = posets.DivisorLattice(12)
sage: D12.plot()
Graphics object consisting of 14 graphics primitives
```

Just the abstract form of the poset; examples of relabeling:

```
sage: D12.plot(label_elements=False)
Graphics object consisting of 8 graphics primitives
sage: d = {1: 0, 2: 'a', 3: 'b', 4: 'c', 6: 'd', 12: 1}
sage: D12.plot(element_labels=d)
Graphics object consisting of 14 graphics primitives
sage: d = {i: str(factor(i)) for i in D12}
sage: D12.plot(element_labels=d)
Graphics object consisting of 14 graphics primitives
```

Some settings for coverings:

```
sage: d = {(a, b): b/a for a, b in D12.cover_relations()}
sage: D12.plot(cover_labels=d, cover_color='gray', cover_style='dotted')
Graphics object consisting of 21 graphics primitives
```
To emphasize some elements and show some options:

```python
sage: L = LatticePoset({0: [1, 2, 3, 4], 1: [12], 2: [6, 7], ....: 3: [5, 9], 4: [5, 6, 10, 11], 5: [13], ....: 6: [12], 7: [12, 8, 9], 8: [13], 9: [13], ....: 10: [12], 11: [12], 12: [13]})
sage: F = L.frattini_sublattice()
sage: F_internal = [c for c in F.cover_relations() if c in L.cover_relations()]
sage: L.plot(figsize=12, border=True, element_shape='s', ....: element_size=400, element_color='white', ....: element_colors={'blue': F, 'green': L.double_irreducibles()}, ....: cover_color='lightgray', cover_colors={'black': F_internal}, ....: title='The Frattini\nsublattice in blue', fontsize=10)
```

**product(\text{other})**

Return the Cartesian product of the poset with \text{other}.

The Cartesian (or ‘direct’) product of \(P\) and \(Q\) is defined by \((p, q) \leq (p', q')\) iff \(p \leq p'\) in \(P\) and \(q \leq q'\) in \(Q\).

Product of (semi)lattices are returned as a (semi)lattice.

**EXAMPLES:**

```python
sage: P = posets.ChainPoset(3)
sage: Q = posets.ChainPoset(4)
sage: PQ = P.product(Q) ; PQ
Finite lattice containing 12 elements
sage: len(PQ.cover_relations())
17
sage: Q.product(P).is_isomorphic(PQ)
True

sage: P = posets.BooleanLattice(2)
sage: Q = P.product(P)
sage: Q.is_isomorphic(posets.BooleanLattice(4))
True
```

One can also simply use *:

```python
sage: P = posets.ChainPoset(2)
sage: Q = posets.ChainPoset(3)
sage: P*Q
Finite lattice containing 6 elements
```

**See also:**

`CartesianProductPoset`, `factor()`

**promotion(\text{i=1})**

Compute the (extended) promotion on the linear extension of the poset \text{self}.

**INPUT:**

- \(i\) – an integer between 1 and \(n\) (default: 1)

**OUTPUT:**
• an isomorphic poset, with the same default linear extension

The extended promotion is defined on a poset self of size \( n \) by applying the promotion operator \( \tau_i \tau_{i+1} \cdots \tau_{n-1} \) to the default linear extension \( \pi \) of self (see \texttt{promotion()})\), and relabeling self accordingly. For more details see [Stan2009].

When the elements of the poset self are labelled by \( \{1, 2, \ldots, n\} \), the linear extension is the identity, and \( i = 1 \), the above algorithm corresponds to the promotion operator on posets defined by Schützenberger as follows. Remove 1 from self and replace it by the minimum \( j \) of all labels covering 1 in the poset. Then, remove \( j \) and replace it by the minimum of all labels covering \( j \), and so on. This process ends when a label is a local maximum. Place the label \( n + 1 \) at this vertex. Finally, decrease all labels by 1.

EXAMPLES:

```sage
sage: P = Poset(([1,2], [[1,2]]), linear_extension=True, facade=False)
sage: P.promotion()
Finite poset containing 2 elements with distinguished linear extension
sage: P == P.promotion()
True

sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,6]]))
sage: P.list()
[1, 2, 3, 5, 6, 4, 7]
sage: Q = P.promotion(4); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 6], [2, 3], [2, 5], [3, 7], [5, 7], [6, 4]]
```

Note that if one wants to obtain the promotion defined by Schützenberger’s algorithm directly on the poset, one needs to make sure the linear extension is the identity:

```sage
sage: P = P.with_linear_extension([1,2,3,4,5,6,7])
sage: P.list()
[1, 2, 3, 4, 5, 6, 7]
sage: Q = P.promotion(4); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 5], [3, 6], [4, 7], [5, 7]]
```

Here is an example for a poset not labelled by \( \{1, 2, \ldots, n\} \):

```sage
sage: P = Poset((divisors(30), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 5, 6, 10, 15, 30]
sage: P.cover_relations()
[[1, 2], [1, 3], [1, 5], [2, 6], [2, 10], [3, 6], [3, 15],
  [5, 10], [5, 15], [6, 30], [10, 30], [15, 30]]
sage: Q = P.promotion(4); Q
Finite poset containing 8 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 3], [1, 6], [2, 5], [2, 15], [3, 5], [3, 10],
  [5, 30], [6, 10], [6, 15], [10, 30], [15, 30]]
```
random_linear_extension()

Return a random linear extension of the poset.

The distribution is not uniform.

EXAMPLES:

```sage
sage: set_random_seed(0)  # results are reproduceable
sage: P = posets.BooleanLattice(4)
sage: P.random_linear_extension()
[0, 2, 8, 1, 9, 4, 5, 10, 6, 12, 14, 13, 3, 7, 11, 15]
```

random_maximal_antichain()

Return a random maximal antichain of the poset.

The distribution is not uniform.

EXAMPLES:

```sage
sage: set_random_seed(0)  # results are reproduceable
sage: P = posets.BooleanLattice(4)
sage: P.random_maximal_antichain()
[1, 8, 2, 4]
```

random_maximal_chain()

Return a random maximal chain of the poset.

The distribution is not uniform.

EXAMPLES:

```sage
sage: set_random_seed(0)  # results are reproduceable
sage: P = posets.BooleanLattice(4)
sage: P.random_maximal_chain()
[0, 2, 10, 11, 15]
```

random_order_ideal(direction='down')

Return a random order ideal with uniform probability.

INPUT:

- direction – 'up', 'down' or 'antichain' (default: 'down')

OUTPUT:

A randomly selected order ideal (or order filter if direction='up', or antichain if direction='antichain') where all order ideals have equal probability of occurring.
ALGORITHM:

Uses the coupling from the past algorithm described in [Propp1997].

EXAMPLES:

```python
sage: P = posets.BooleanLattice(3)
sage: P.random_order_ideal()  # random
[0, 1, 2, 3, 4, 5, 6]
sage: P.random_order_ideal(direction='up')  # random
[6, 7]
sage: P.random_order_ideal(direction='antichain')  # random
[1, 2]

sage: P = posets.TamariLattice(5)
sage: a = P.random_order_ideal('antichain')
sage: P.is_antichain_of_poset(a)
True
sage: a = P.random_order_ideal('up')
sage: P.is_order_filter(a)
True
sage: a = P.random_order_ideal('down')
sage: P.is_order_ideal(a)
True
```

random_subposet(p)

Return a random subposet that contains each element with probability \( p \).

EXAMPLES:

```python
sage: P = posets.BooleanLattice(3)
sage: set_random_seed(0)  # Results are reproducible
sage: Q = P.random_subposet(0.5)
sage: Q.cover_relations()
[[0, 2], [0, 5], [2, 3], [3, 7], [5, 7]]
```

rank(element=None)

Return the rank of an element \( element \) in the poset \( self \), or the rank of the poset if \( element \) is None.

(The rank of a poset is the length of the longest chain of elements of the poset. This is sometimes called the length of a poset.)

EXAMPLES:

```python
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]], facade=False)
sage: P.rank(5)
2
sage: P.rank()
3
sage: Q = Poset([[1,2],[3],[4]])
sage: P = posets.SymmetricGroupBruhatOrderPoset(4)
sage: [(v,P.rank(v)) for v in P]
[('1234', 0), ('1243', 1), ...
```

(continues on next page)
rank_function()
Return the (normalized) rank function of the poset, if it exists.

A rank function of a poset \( P \) is a function \( r \) that maps elements of \( P \) to integers and satisfies: \( r(x) = r(y) + 1 \) if \( x \) covers \( y \). The function \( r \) is normalized such that its minimum value on every connected component of the Hasse diagram of \( P \) is 0. This determines the function \( r \) uniquely (when it exists).

OUTPUT:
- a lambda function, if the poset admits a rank function
- None, if the poset does not admit a rank function

EXAMPLES:
```python
sage: P = Poset(((1,2,3,4),[[1,4],[2,3],[3,4]]), facade=True)
sage: P.rank_function() is not None
True
sage: P = Poset(((1,2,3,4,5),[[1,2],[2,3],[3,4],[1,5],[5,4]]), facade=True)
sage: P.rank_function() is not None
False
sage: P = Poset(((1,2,3,4,5,6,7,8),[[1,4],[2,3],[3,4],[5,7],[6,7]]), facade=True)
sage: f = P.rank_function(); f is not None
True
sage: f(5)
0
sage: f(2)
0
```

rees_product(other)
Return the Rees product of self and other.

This is only defined if both posets are graded.

The underlying set is the set of pairs \((p, q)\) in the Cartesian product such that \(\text{rk}(p) \geq \text{rk}(q)\).

This operation was defined by Björner and Welker in [BjWe2005]. Other references are [MBRe2011] and [LSW2012].

EXAMPLES:
```python
sage: B3 = posets.BooleanLattice(3)
sage: B3t = B3.subposet(list(range(1,8)))
sage: C3 = posets.ChainPoset(3)
sage: D = B3t.rees_product(C3); D
Finite poset containing 12 elements
sage: sorted(D.minimal_elements())
[(1, 0), (2, 0), (4, 0)]
sage: sorted(D.maximal_elements())
[(7, 0), (7, 1), (7, 2)]
sage: D.with_bounds().moebius_function('bottom','top')
2
```
See also:

*product*, *ordinal_product*, *star_product*

**relabel**(relabeling=None)

Return a copy of this poset with its elements relabeled.

**INPUT:**

- relabeling - a function, dictionary, list or tuple

The given function or dictionary must map each (non-wrapped) element of `self` to some distinct object.
The given list or tuple must be made of distinct objects.

When the input is a list or a tuple, the relabeling uses the total ordering of the elements of the poset given by `list(self)`.

If no relabeling is given, the poset is relabeled by integers from 0 to \(n - 1\) according to one of its linear extensions. This means that \(i < j\) as integers whenever \(i < j\) in the relabeled poset.

**EXAMPLES:**

Relabeling using a function:

```sage
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: P.cover_relations()
[[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: Q = P.relabel(lambda x: x+1)
sage: Q.list()
[2, 3, 4, 5, 7, 13]
sage: Q.cover_relations()
[[2, 3], [2, 4], [3, 5], [3, 7], [4, 7], [5, 13], [7, 13]]
```

Relabeling using a dictionary:

```sage
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True, facade=False)
sage: relabeling = {c.element:i for (i,c) in enumerate(P)}
sage: relabeling
{1: 0, 2: 1, 3: 2, 4: 3, 6: 4, 12: 5}
sage: Q = P.relabel(relabeling)
sage: Q.list()
[0, 1, 2, 3, 4]
sage: Q.cover_relations()
[[[0, 1], [0, 2], [1, 3], [1, 4], [2, 4], [3, 5], [4, 5]]
```

Mind the `c.element`; this is because the relabeling is applied to the elements of the poset without the wrapping. Thanks to this convention, the same relabeling function can be used both for facade or non-facade posets.

Relabeling using a list:

```sage
sage: P = posets.PentagonPoset()
sage: list(P)
[0, 1, 2, 3, 4]
sage: P.cover_relations()
```

(continues on next page)
\[
[[0, 1], [0, 2], [1, 4], [2, 3], [3, 4]]
\]

```
sage: Q = P.relabel(list('abcde'))
sage: Q.cover_relations()
[[['a', 'b'], ['a', 'c'], ['b', 'e'], ['c', 'd'], ['d', 'e']]]
```

Default behaviour is increasing relabeling:

```
sage: a2 = posets.ChainPoset(2)
sage: P = a2 * a2
sage: Q = P.relabel()
sage: Q.cover_relations()
[[0, 1], [0, 2], [1, 3], [2, 3]]
```

Relabeling a (semi)lattice gives a (semi)lattice:

```
sage: P = JoinSemilattice({0: [1]})
sage: P.relabel(lambda n: n+1)
Finite join-semilattice containing 2 elements
```

**Note:** As can be seen in the above examples, the default linear extension of \(Q\) is that of \(P\) after relabeling. In particular, \(P\) and \(Q\) share the same internal Hasse diagram.

**relations()**

Return the list of all relations of the poset.

A relation is a pair of elements \(x\) and \(y\) such that \(x \leq y\) in the poset.

The number of relations is the dimension of the incidence algebra.

**OUTPUT:**

A list of pairs (each pair is a list), where the first element of the pair is less than or equal to the second element.

**EXAMPLES:**

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4[:]})
sage: P.relations()
[[[1, 1], [1, 2], [1, 3], [1, 4], [0, 0], [0, 2], [0, 3], [0, 4], [2, 2], [2, 3], [2, 4], [3, 3], [3, 4], [4, 4]]]
```

**See also:**

- `relations_number()
- `relations_iterator()`

**AUTHOR:**

- Rob Beezer (2011-05-04)

**relations_iterator**(strict=False)

Return an iterator for all the relations of the poset.

A relation is a pair of elements \(x\) and \(y\) such that \(x \leq y\) in the poset.

**INPUT:**
• **strict** – a boolean (default False) if True, returns an iterator over relations \(x < y\), excluding all relations \(x \leq x\).

**OUTPUT:**
A generator that produces pairs (each pair is a list), where the first element of the pair is less than or equal to the second element.

**EXAMPLES:**

```python
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: it = P.relations_iterator()
sage: type(it)
<class 'generator'>
sage: next(it), next(it)
([1, 1], [1, 2])
sage: P = posets.PentagonPoset()
sage: list(P.relations_iterator(strict=True))
[[0, 1], [0, 2], [0, 4], [0, 3], [1, 4], [2, 3], [2, 4], [3, 4]]
```

See also:
`relations_number()`, `relations()`.

**AUTHOR:**
• Rob Beezer (2011-05-04)

### relations_number()
Return the number of relations in the poset.
A relation is a pair of elements \(x\) and \(y\) such that \(x \leq y\) in the poset.
Relations are also often called intervals. The number of intervals is the dimension of the incidence algebra.

**EXAMPLES:**

```python
sage: P = posets.PentagonPoset()
sage: P.relations_number()
13
sage: posets.TamariLattice(4).relations_number()
68
```

See also:
`relations_iterator()`, `relations()`

### show(label_elements=True, element_labels=None, cover_labels=None, **kwds)`
Displays the Hasse diagram of the poset.

**INPUT:**

• **label_elements** (default: True) - whether to display element labels
• **element_labels** (default: None) - a dictionary of element labels
• **cover_labels** - a dictionary, list or function representing labels of the covers of self. When set to None (default) no label is displayed on the edges of the Hasse Diagram.
Note: This method also accepts:

- All options of `GenericGraph.plot`
- All options of `Graphics.show`

EXAMPLES:

```python
sage: D = Poset({ 0:[1,2], 1:[3], 2:[3,4] })
sage: D.plot(label_elements=False)
Graphics object consisting of 6 graphics primitives
sage: D.show()
sage: elm_labs = {0:'a', 1:'b', 2:'c', 3:'d', 4:'e'}
sage: D.show(element_labels=elm_labs)
```

One more example with cover labels:

```python
sage: P = posets.PentagonPoset()
sage: P.show(cover_labels=lambda a, b: a - b)
```

\[ \text{slant\_sum}(p, \text{element}, p\_element) \]

Return the slant sum poset of posets `self` and `p` by connecting them with a cover relation \((p\_element, \text{element})\).

Note: The element names of `self` and `p` must be distinct.

INPUT:

- `p` – the poset used for the slant sum
- `element` – the element of `self` that is the top of the new cover relation
- `p_element` – the element of `p` that is the bottom of the new cover relation

EXAMPLES:

```python
sage: R = posets.RibbonPoset(5, [1,2])
sage: H = Poset([[5, 6, 7], [(5, 6), (6,7)]])
sage: SS = R.slant_sum(H, 3, 7)
sage: all(cr in SS.cover_relations() for cr in R.cover_relations())
True
sage: all(cr in SS.cover_relations() for cr in H.cover_relations())
True
sage: SS.covers(7, 3)
True
```

\[ \text{sorted}(l, allow\_incomparable=True, remove\_duplicates=False) \]

Return the list `l` sorted by the poset.

INPUT:

- `l` – a list of elements of the poset
- `allow_incomparable` – a Boolean. If `True` (the default), return incomparable elements in some order; if `False`, raise an error if `l` is not a chain of the poset.
- `remove_duplicates` - a Boolean. If `True`, remove duplicates from the output list.
EXAMPLES:

```python
sage: P = posets.DivisorLattice(36)
sage: P.sorted([1, 4, 1, 6, 2, 12])  # Random order for 4 and 6
[1, 1, 2, 4, 6, 12]
sage: P.sorted([1, 4, 1, 6, 2, 12], remove_duplicates=True)
[1, 2, 4, 6, 12]
sage: P.sorted([1, 4, 1, 6, 2, 12], allow_incomparable=False)
Traceback (most recent call last):
...
ValueError: the list contains incomparable elements
```

```python
sage: P = Poset({7:[1, 5], 1:[2, 6], 5:[3], 6:[3, 4]})
sage: P.sorted([4, 1, 4, 5, 7])  # Random order for 1 and 5
[7, 1, 5, 4, 4]
sage: P.sorted([1, 4, 4, 7], remove_duplicates=True)
[7, 1, 4]
sage: P.sorted([4, 1, 4, 5, 7], allow_incomparable=False)
Traceback (most recent call last):
...
ValueError: the list contains incomparable elements
```

`spectrum(a)`

Return the $a$-spectrum of this poset.

The $a$-spectrum in a poset $P$ is the list of integers whose $i$-th position contains the number of linear extensions of $P$ that have $a$ in the $i$-th location.

INPUT:

- $a$ – an element of this poset

OUTPUT:

The $a$-spectrum of this poset, returned as a list.

EXAMPLES:

```python
sage: P = posets.ChainPoset(5)
sage: P.spectrum(2)
[0, 0, 1, 0, 0]
sage: P = posets.BooleanLattice(3)
sage: P.spectrum(5)
[0, 0, 0, 4, 12, 16, 16, 0]
sage: P = posets.YoungDiagramPoset(Partition([3,2,1]))
sage: P.spectrum((0,1))
[0, 8, 6, 2, 0, 0]
sage: P = posets.AntichainPoset(4)
sage: P.spectrum(3)
[6, 6, 6, 6]
```

`star_product(other, labels='pairs')`

Return a poset isomorphic to the star product of the poset with other.
Both this poset and other are expected to be bounded and have at least two elements.

Let $P$ be a poset with top element $\top_P$ and $Q$ be a poset with bottom element $\bot_Q$. The star product of $P$ and $Q$ is the ordinal sum of $P \setminus \top_P$ and $Q \setminus \bot_Q$.

Mathematically, it is only defined when $P$ and $Q$ have no common elements; here we force that by giving them different names in the resulting poset.

INPUT:

* other – a poset.

* labels – (defaults to ‘pairs’) If set to ‘pairs’, each element $v$ in this poset will be named $(0, v)$ and each element $u$ in other will be named $(1, u)$ in the result. If set to ‘integers’, the elements of the result will be relabeled with consecutive integers.

EXAMPLES:

This is mostly used to combine two Eulerian posets to third one, and makes sense for graded posets only:

```
sage: B2 = posets.BooleanLattice(2)
sage: B3 = posets.BooleanLattice(3)
sage: P = B2.star_product(B3); P
Finite poset containing 10 elements
sage: P.is_eulerian()
True
```

We can get elements as pairs or as integers:

```
sage: ABC = Poset({'a': ['b'], 'b': ['c']})
sage: XYZ = Poset({'x': ['y'], 'y': ['z']})
sage: ABC.star_product(XYZ).list()
[(0, 'a'), (0, 'b'), (1, 'y'), (1, 'z')]
sage: sorted(ABC.star_product(XYZ, labels='integers'))
[0, 1, 2, 3]
```

The `subposet(elements)`

Return the poset containing given elements with partial order induced by this poset.

EXAMPLES:

```
sage: P = Poset({'
'    'a': ['c', 'd'], 'b': ['d', 'e'], 'c': ['f'],
'    ....:
'    'd': ['f'], 'e': ['f']})
sage: Q = P.subposet(['a', 'b', 'f']); Q
Finite poset containing 3 elements
sage: Q.cover_relations()
[['b', 'f'], ['a', 'f']]
```

A subposet of a non-facade poset is again a non-facade poset:

```
sage: P = posets.PentagonPoset(facade=False)
sage: Q = P.subposet([0, 1, 2, 4])
sage: Q(1) < Q(2)
False
```

The `top()`

Return the unique maximal element of the poset, if it exists.

EXAMPLES:
sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4,5], 4:[], 5:[]})
sage: P.top() is None
True
sage: Q = Poset({0:[1], 1:[]})
sage: Q.top()
1

See also:
has_top(), bottom()

unwrap(element)

Return the element element of the poset self in unwrapped form.

INPUT:

• element – an element of self

EXAMPLES:

sage: P = Poset((divisors(15), attrcall("divides")), facade = False)
sage: x = P.an_element(); x
1
sage: x.parent()
Finite poset containing 4 elements
sage: P.unwrap(x)
1
sage: P.unwrap(x).parent()
Integer Ring

For a non facade poset, this is equivalent to using the .element attribute:

sage: P.unwrap(x) is x.element
True

For a facade poset, this does nothing:

sage: P = Poset((divisors(15), attrcall("divides")), facade=True)
sage: x = P.an_element()
sage: P.unwrap(x) is x
True

This method is useful in code where we do not know if P is a facade poset or not.

upper_covers(x)

Return the list of upper covers of the element x.

An upper cover of x is an element y such that x < y and there is no element z so that x < z < y.

EXAMPLES:

sage: P = Poset([[1,5], [2,6], [3], [4], [], [6,3], [4]])
sage: P.upper_covers(1)
[2, 6]

See also:
lower_covers()
upper_covers_iterator(x)

Return an iterator over the upper covers of the element x.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[]})
sage: type(P.upper_covers_iterator(0))
<class 'generator'>
```

width(certificate=False)

Return the width of the poset (the size of its longest antichain).

It is computed through a matching in a bipartite graph; see Wikipedia article Dilworth's_theorem for more information. The width is also called Dilworth number.

INPUT:

- certificate – (default: False) whether to return a certificate

OUTPUT:

- If certificate=True return (w, a), where w is the width of a poset and a is an antichain of maximum cardinality. If certificate=False return only width of the poset.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: P.width()
6
sage: w, max_achain = P.width(certificate=True)
sage: sorted(max_achain)
[3, 5, 6, 9, 10, 12]
```

with_bounds(labels=('bottom', 'top'))

Return the poset with bottom and top elements adjoined.

This function adds top and bottom elements to the poset. It will always add elements, it does not check if the poset already has a bottom or a top element.

For lattices and semilattices this function returns a lattice.

INPUT:

- labels – A pair of elements to use as a bottom and top element of the poset. Default is strings 'bottom' and 'top'. Either of them can be None, and then a new bottom or top element will not be added.

EXAMPLES:

```
sage: V = Poset({0: [1, 2]})
sage: trafficsign = V.with_bounds(); trafficsign
Finite poset containing 5 elements
sage: trafficsign.list()
['bottom', 0, 1, 2, 'top']
sage: trafficsign = V.with_bounds(labels=(-1, -2))
sage: trafficsign.cover_relations()
[[-1, 0], [0, 1], [0, 2], [1, -2], [2, -2]]
```
sage: Y = V.with_bounds(labels=(-1, None))
sage: Y.cover_relations()
\[-1, 0], [0, 1], [0, 2]\]

sage: P = posets.PentagonPoset()  # A lattice
sage: P.with_bounds()
Finite lattice containing 7 elements

sage: P = posets.PentagonPoset(facade=False)
sage: P.with_bounds()
Finite lattice containing 7 elements

See also:
without_bounds() for the reverse operation

with_linear_extension(linear_extension)
Return a copy of self with a different default linear extension.

EXAMPLES:

sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: list(P)
[1, 2, 3, 4, 6, 12]
sage: Q = P.with_linear_extension([1,3,2,6,4,12])
sage: list(Q)
[1, 3, 2, 6, 4, 12]
sage: Q.cover_relations()
[[1, 3], [1, 2], [3, 6], [2, 6], [2, 4], [6, 12], [4, 12]]

Note: With the current implementation, this requires relabeling the internal DiGraph which is $O(n + m)$, where $n$ is the number of elements and $m$ the number of cover relations.

without_bounds()
Return the poset without its top and bottom elements.
This is useful as an input for the method order_complex().
If there is either no top or no bottom element, this raises a TypeError.

EXAMPLES:

sage: P = posets.PentagonPoset()
sage: Q = P.without_bounds(); Q
Finite poset containing 3 elements

sage: P = posets.DiamondPoset(5)
sage: Q = P.without_bounds(); Q
Finite poset containing 3 elements
sage: Q.cover_relations()
[]

See also:

\texttt{with\_bounds()} for the reverse operation

\textbf{zeta\_polynomial()}

Return the zeta polynomial of the poset.

The zeta polynomial of a poset is the unique polynomial \( Z(q) \) such that for every integer \( m > 1 \), \( Z(m) \) is the number of weakly increasing sequences \( x_1 \leq x_2 \leq \cdots \leq x_{m-1} \) of elements of the poset.

The polynomial \( Z(q) \) is integral-valued, but generally does not have integer coefficients. It can be computed as

\[
Z(q) = \sum_{k \geq 1} \binom{q-2}{k-1} c_k,
\]

where \( c_k \) is the number of all chains of length \( k \) in the poset.

For more information, see section 3.12 of [EnumComb1].

In particular, \( Z(2) \) is the number of vertices and \( Z(3) \) is the number of intervals.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: posets.ChainPoset(2).zeta_polynomial() q
sage: posets.ChainPoset(3).zeta_polynomial()
1/2*q^2 + 1/2*q
sage: P = posets.PentagonPoset()
sage: P.zeta_polynomial()
1/6*q^3 + q^2 - 1/6*q
sage: P = posets.DiamondPoset(5)
sage: P.zeta_polynomial()
3/2*q^2 - 1/2*q
\end{verbatim}

\textbf{class} \texttt{sage.combinat.posets.posets.FinitePosets\_n(n)}

\textbf{Bases:} \texttt{UniqueRepresentation, Parent}

The finite enumerated set of all posets on \( n \) elements, up to an isomorphism.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: P = Posets(3)
sage: P.cardinality()
5
sage: for p in P: print(p.cover_relations())
    []
    [[0, 1], [0, 2]]
    [[0, 1], [1, 2]]
    [[1, 2], [0, 2]]
\end{verbatim}
cardinality(from_iterator=False)

Return the cardinality of this object.

**Note:** By default, this returns pre-computed values obtained from the On-Line Encyclopedia of Integer Sequences (OEIS sequence A000112). To override this, pass the argument `from_iterator=True`.

**EXAMPLES:**

```python
sage: P = Posets(3)
sage: P.cardinality()
5
sage: P.cardinality(from_iterator=True)
5
```

```python
sage.combinat.posets.posets.Poset(data=None, element_labels=None, cover_relations=False, linear_extension=False, category=None, facade=None, key=None)
```

Construct a finite poset from various forms of input data.

**INPUT:**

- **data** — different input are accepted by this constructor:
  1. A two-element list or tuple \((E, R)\), where \(E\) is a collection of elements of the poset and \(R\) is a collection of relations \(x \leq y\), each represented as a two-element list/tuple/iterable such as \([x, y]\). The poset is then the transitive closure of the provided relations. If `cover_relations=True`, then \(R\) is assumed to contain exactly the cover relations of the poset. If \(E\) is empty, then \(E\) is taken to be the set of elements appearing in the relations \(R\).
  2. A two-element list or tuple \((E, f)\), where \(E\) is the set of elements of the poset and \(f\) is a function such that, for any pair \(x, y\) of elements of \(E\), \(f(x, y)\) returns whether \(x \leq y\). If `cover_relations=True`, then \(f(x, y)\) should instead return whether \(x\) is covered by \(y\).
  3. A dictionary of upper covers: \(\text{data}[x]\) is a list of the elements that cover the element \(x\) in the poset.
  4. A list or tuple of upper covers: \(\text{data}[x]\) is a list of the elements that cover the element \(x\) in the poset.
     If the set of elements is not a set of consecutive integers starting from zero, then:
     - every element must appear in the data, for example in its own entry.
     - data must be ordered in the same way as sorted elements.

  **Warning:** If data is a list or tuple of length 2, then it is handled by the case 2 above.

  5. An acyclic, loop-free and multi-edge free DiGraph. If `cover_relations` is `True`, then the edges of the digraph are assumed to correspond to the cover relations of the poset. Otherwise, the cover relations are computed.

  6. A previously constructed poset (the poset itself is returned).

- **element_labels** — (default: `None`); an optional list or dictionary of objects that label the poset elements.
- **cover_relations** — a boolean (default: `False`); whether the data can be assumed to describe a directed acyclic graph whose arrows are cover relations; otherwise, the cover relations are first computed.
- **linear_extension** — a boolean (default: `False`); whether to use the provided list of elements as default linear extension for the poset; otherwise a linear extension is computed. If the data is given as the pair \((E, f)\), then \(E\) is taken to be the linear extension.
• facade – a boolean or None (default); whether the Poset()’s elements should be wrapped to make them aware of the Poset they belong to.
  – If facade = True, the Poset()’s elements are exactly those given as input.
  – If facade = False, the Poset()’s elements will become PosetElement objects.
  – If facade = None (default) the expected behaviour is the behaviour of facade = True, unless the opposite can be deduced from the context (i.e. for instance if a Poset() is built from another Poset(), itself built with facade = False)

OUTPUT:
FinitePoset – an instance of the FinitePoset class.
If category is specified, then the poset is created in this category instead of FinitePosets.

See also:
Posets, Posets, FinitePosets

EXAMPLES:
1. Elements and cover relations:

```
sage: elms = [1,2,3,4,5,6,7]
sage: rels = [[1,2],[3,4],[4,5],[2,5]]
sage: Poset((elms, rels), cover_relations = True, facade = False)
Finite poset containing 7 elements
```

Elements and non-cover relations:

```
sage: elms = [1,2,3,4]
sage: rels = [[1,2],[1,3],[1,4],[2,3],[2,4],[3,4]]
sage: P = Poset((elms,rels),cover_relations=False); P
Finite poset containing 4 elements
sage: P.cover_relations()
[[1, 2], [2, 3], [3, 4]]
```

2. Elements and function: the standard permutations of [1, 2, 3, 4] with the Bruhat order:

```
sage: elms = Permutations(4)
sage: fcn = lambda p,q : p.bruhat_lequal(q)
sage: Poset((elms, fcn))
Finite poset containing 24 elements
```

With a function that identifies the cover relations: the set partitions of \{1, 2, 3\} ordered by refinement:

```
sage: elms = SetPartitions(3)
sage: def fcn(A, B):
.....:     if len(A) != len(B)+1:
.....:         return False
.....:     for a in A:
.....:         if not any(set(a).issubset(b) for b in B):
.....:             return False
.....:     return True
sage: Poset((elms, fcn), cover_relations=True)
Finite poset containing 5 elements
```

3. A dictionary of upper covers:
4. A list of upper covers, with range(5) as set of vertices:

```python
sage: Poset([[1,2],[4],[3],[4],[]])
Finite poset containing 5 elements
```

A list of upper covers, with letters as vertices:

```python
sage: Poset([['a','b'],['b','c'],['c']])
Finite poset containing 3 elements
```

A list of upper covers and a dictionary of labels:

```python
sage: elm_labs = {0:'a', 1:'b', 2:'c', 3:'d', 4:'e'}
sage: P = Poset([[1,2],[4],[3],[4],[]], elm_labs, facade=False)
sage: P.list()
[a, b, c, d, e]
```

**Warning:** The special case where the argument data is a list or tuple of length 2 is handled by the case 2. So you cannot use this method to input a 2-element poset.

5. An acyclic DiGraph.

```python
sage: dag = DiGraph({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]})
sage: Poset(dag)
Finite poset containing 6 elements
```

Any directed acyclic graph without loops or multiple edges, as long as `cover_relations=False`:

```python
sage: dig = DiGraph({0:[2,3], 1:[3,4,5], 2:[5], 3:[5], 4:[5]})
sage: dig.allows_multiple_edges()
False
sage: dig.allows_loops()
False
sage: dig.transitive_reduction() == dig
False
sage: Poset(dig, cover_relations=False)
Finite poset containing 6 elements
sage: Poset(dig, cover_relations=True)
Traceback (most recent call last):
  ... ValueError: Hasse diagram is not transitive reduced
```
**Default Linear extension**

Every poset $P$ obtained with `Poset` comes equipped with a default linear extension, which is also used for enumerating its elements. By default, this linear extension is computed, and has no particular significance:

```
sage: P = Poset((divisors(12), attrcall("divides")))
sage: P.list()
[1, 2, 4, 3, 6, 12]
sage: P.linear_extension()
[1, 2, 4, 3, 6, 12]
```

You may enforce a specific linear extension using the `linear_extension` option:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: P.linear_extension()
[1, 2, 3, 4, 6, 12]
```

Depending on popular request, `Poset` might eventually get modified to always use the provided list of elements as default linear extension, when it is one.

**See also:**

- `FinitePoset.linear_extensions()`

**Facade posets**

When `facade = False`, the elements of a poset are wrapped so as to make them aware that they belong to that poset:

```
sage: P = Poset(DiGraph({'d': ['c', 'b'], 'c': ['a'], 'b': ['a']}), facade = False)
sage: d,c,b,a = list(P)
sage: a.parent() is P
True
```

This allows for comparing elements according to $P$:

```
sage: c < a
True
```

However, this may have surprising effects:

```
sage: my_elements = ['a', 'b', 'c', 'd']
sage: any(x in my_elements for x in P)
False
```

and can be annoying when one wants to manipulate the elements of the poset:

```
sage: a + b
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for +: 'Finite poset containing 4 elements' and 'Finite poset containing 4 elements'
```
By default, facade posets are constructed instead:

```
sage: P = Poset(DiGraph({'d': ['c', 'b'], 'c': ['a'], 'b': ['a']}))
```

In this example, the elements of the poset remain plain strings:

```
sage: d, c, b, a = list(P)
sage: type(a)
<class 'str'>
```

Of course, those strings are not aware of $P$. So to compare two such strings, one needs to query $P$:

```
sage: a < b
True
sage: P.lt(a, b)
False
```

which models the usual mathematical notation $a <_P b$.

Most operations seem to still work, but at this point there is no guarantee whatsoever:

```
sage: P.list()
['d', 'c', 'b', 'a']
sage: P.principal_order_ideal('a')
['d', 'c', 'b', 'a']
sage: P.principal_order_ideal('b')
['d', 'b']
sage: P.principal_order_ideal('d')
['d']
sage: TestSuite(P).run()
```

**Warning:** `DiGraph` is used to construct the poset, and the vertices of a `DiGraph` are converted to plain Python int's if they are `Integer`'s:

```
sage: G = DiGraph({0: [2, 3], 1: [3, 4], 2: [5], 3: [5], 4: [5]})
sage: type(G.vertices(sort=True)[0])
<class 'int'>
```

This is worked around by systematically converting back the vertices of a poset to `Integer`'s if they are int's:

```
sage: P = Poset((divisors(15), attrcall("divides")), facade = False)
sage: type(P.an_element().element)
<class 'sage.rings.integer.Integer'>
sage: P = Poset((divisors(15), attrcall("divides")), facade=True)
sage: type(P.an_element())
<class 'sage.rings.integer.Integer'>
```

This may be abusive:
**Unique representation**

As most parents, `Poset` have unique representation (see `UniqueRepresentation`). Namely if two posets are created from two equal data, then they are not only equal but actually identical:

```
sage: data1 = [[1,2],[3],[3]]
sage: data2 = [[1,2],[3],[3]]
sage: P1 = Poset(data1)
sage: P2 = Poset(data2)
sage: P1 == P2
True
sage: P1 is P2
True
```

In situations where this behaviour is not desired, one can use the `key` option:

```
sage: P1 = Poset(data1, key = "foo")
sage: P2 = Poset(data2, key = "bar")
sage: P1 is P2
False
sage: P1 == P2
False
```

`key` can be any hashable value and is passed down to `UniqueRepresentation`. It is otherwise ignored by the poset constructor.

```
sage.combinat.posets.posets.is_poset(dig)
```

Return True if a directed graph is acyclic and transitively reduced, and False otherwise.

**EXAMPLES:**

```
sage: from sage.combinat.posets.posets import is_poset
sage: dig = DiGraph({0:[2, 3], 1:[3, 4, 5], 2:[5], 3:[5], 4:[5]})
sage: is_poset(dig)
False
sage: is_poset(dig.transitive_reduction())
True
```
5.1.187  $q$-Analogues

`sage.combinat.q_analogues.gaussian_binomial(n, k, q=None, algorithm='auto')`

This is an alias of `q_binomial()`.

See `q_binomial()` for the full documentation.

EXAMPLES:

```
sage: gaussian_binomial(4,2)
q^4 + q^3 + 2*q^2 + q + 1
```

`sage.combinat.q_analogues.gaussian_multinomial(seq, q=None, binomial_algorithm='auto')`

Return the $q$-multinomial coefficient.

This is also known as the Gaussian multinomial coefficient, and is defined by

$$
\binom{n}{k_1, k_2, \ldots, k_m}_q = \frac{[n]_q!}{[k_1]_q! [k_2]_q! \cdots [k_m]_q!}
$$

where $n = k_1 + k_2 + \cdots + k_m$.

If $q$ is unspecified, then the variable is the generator $q$ for a univariate polynomial ring over the integers.

INPUT:

- `seq` – an iterable of the values $k_1$ to $k_m$ defined above
- `q` – (default: None) the variable $q$; if None, then use a default variable in $\mathbb{Z}[q]$
- `binomial_algorithm` – (default: 'auto') the algorithm to use in `q_binomial()`; see possible values there

ALGORITHM:

We use the equivalent formula

$$
\binom{k_1 + \cdots + k_m}{k_1, \ldots, k_m}_q = \prod_{i=1}^{m} \binom{\sum_{j=1}^{i} k_j}{k_i}_q.
$$

EXAMPLES:

```
sage: from sage.combinat.q_analogues import q_multinomial
sage: q_multinomial([1,2,1])
q^5 + 2*q^4 + 3*q^3 + 3*q^2 + 2*q + 1
sage: q_multinomial([1,2,1], q=1) == multinomial([1,2,1])
True
sage: q_multinomial((3,2)) == q_binomial(5,3)
True
sage: q_multinomial([])
1
```

`sage.combinat.q_analogues.q_binomial(n, k, q=None, algorithm='auto')`

Return the $q$-binomial coefficient.

This is also known as the Gaussian binomial coefficient, and is defined by

$$
\binom{n}{k}_q = \frac{(1 - q^n)(1 - q^{n-1}) \cdots (1 - q^{n-k+1})}{(1-q)(1-q^2) \cdots (1-q^k)}.
$$
Combinatorics, Release 10.0

See Wikipedia article Gaussian_binomial_coefficient.

If \( q \) is unspecified, then the variable is the generator \( q \) for a univariate polynomial ring over the integers.

**INPUT:**
- \( n, k \) – the values \( n \) and \( k \) defined above
- \( q \) – (default: None) the variable \( q \); if None, then use a default variable in \( \mathbb{Z}[q] \)
- **algorithm** – (default: 'auto') the algorithm to use and can be one of the following:
  - 'auto' – automatically choose the algorithm; see the algorithm section below
  - 'naive' – use the naive algorithm
  - 'cyclotomic' – use cyclotomic algorithm

**ALGORITHM:**
The naive algorithm uses the product formula. The cyclotomic algorithm uses a product of cyclotomic polynomials (cf. [CH2006]).

When the algorithm is set to 'auto', we choose according to the following rules:
- If \( q \) is a polynomial:
  - When \( n \) is small or \( k \) is small with respect to \( n \), one uses the naive algorithm. When both \( n \) and \( k \) are big, one uses the cyclotomic algorithm.
- If \( q \) is in the symbolic ring (or a symbolic subring), one uses the cyclotomic algorithm.
- Otherwise one uses the naive algorithm, unless \( q \) is a root of unity, then one uses the cyclotomic algorithm.

**EXAMPLES:**
By default, the variable is the generator of \( \mathbb{Z}[q] \):

```python
sage: from sage.combinat.q_analogues import q_binomial
sage: g = q_binomial(5,1) ; g
q^4 + q^3 + q^2 + q + 1
sage: g.parent()
Univariate Polynomial Ring in q over Integer Ring
```

The \( q \)-binomial coefficient vanishes unless \( 0 \leq k \leq n \):

```python
sage: q_binomial(4,5)
0
sage: q_binomial(5,-1)
0
```

Other variables can be used, given as third parameter:

```python
sage: p = ZZ['p'].gen()
sage: q_binomial(4,2,p)
p^4 + p^3 + 2*p^2 + p + 1
```

The third parameter can also be arbitrary values:

```python
sage: q_binomial(5,1,2) == g.subs(q=2)
True
sage: q_binomial(5,1,1)
```

(continues on next page)
We can also do this for more complicated objects such as matrices or symmetric functions:

\[
\text{sage: } \text{q\_binomial}(4, 2, \text{matrix}([[2, 1], [-1, 3]])) \\
\begin{bmatrix}
-6 & 84 \\
-84 & 78
\end{bmatrix}
\]

\[
\text{sage: } \text{Sym} = \text{SymmetricFunctions}(\mathbb{Q}) \\
\text{sage: } s = \text{Sym}.\text{schur}() \\
\text{sage: } \text{q\_binomial}(4, 1, s[2]+s[1])
\]

\[
\]

- Frédéric Chapoton, David Joyner and William Stein

sage.combinat.q_analogues.q_catalan_number\((n, q=None)\)

Return the \(q\)-Catalan number of index \(n\).

If \(q\) is unspecified, then it defaults to using the generator \(q\) for a univariate polynomial ring over the integers.

There are several \(q\)-Catalan numbers. This procedure returns the one which can be written using the \(q\)-binomial coefficients.

EXAMPLES:

\[
\text{sage: } \text{from sage.combinat.q_analogues import q\_catalan\_number} \\
\text{sage: } q\_catalan\_number(4) \\
q^12 + q^10 + q^9 + 2*q^8 + q^7 + 2*q^6 + q^5 + 2*q^4 + q^3 + q^2 + 1 \\
\text{sage: } p = \mathbb{Z}['p'].0 \\
\text{sage: } q\_catalan\_number(4, p) \\
p^12 + p^10 + p^9 + 2*p^8 + p^7 + 2*p^6 + p^5 + 2*p^4 + p^3 + p^2 + 1
\]

The \(q\)-Catalan number of index \(n\) is only defined for \(n\) a nonnegative integer (github issue #11411):

\[
\text{sage: } q\_catalan\_number(-2) \\
\text{ValueError: argument (-2) must be a nonnegative integer}
\]

sage.combinat.q_analogues.q_factorial\((n, q=None)\)

Return the \(q\)-analogue of the factorial \(n\)!.
This is the product
\[ [1]_q [2]_q \cdots [n]_q = 1 \cdot (1 + q) \cdot (1 + q + q^2) \cdots (1 + q + q^2 + \cdots + q^{n-1}). \]

If \( q \) is unspecified, then this function defaults to using the generator \( q \) for a univariate polynomial ring over the integers.

**EXAMPLES:**

```
sage: from sage.combinat.q_analogues import q_factorial
sage: q_factorial(3)
q^3 + 2*q^2 + 2*q + 1
sage: p = ZZ['p'].0
sage: q_factorial(3, p)
p^3 + 2*p^2 + 2*p + 1
```

The \( q \)-analogue of \( n! \) is only defined for \( n \) a non-negative integer (github issue #11411):

```
sage: q_factorial(-2)
Traceback (most recent call last):
  ... ValueError: argument (-2) must be a nonnegative integer
```

```
sage.combinat.q_analogues.q_int(n, q=None)
Return the \( q \)-analogue of the integer \( n \).

The \( q \)-analogue of the integer \( n \) is given by
\[
[n]_q = \begin{cases} 
1 + q + \cdots + q^{n-1}, & \text{if } n \geq 0, \\
-q^{-n}[-n]_q, & \text{if } n \leq 0.
\end{cases}
\]

Consequently, if \( q = 1 \) then \([n]_1 = n\) and if \( q \neq 1 \) then \([n]_q = (q^n - 1)/(q - 1)\).

If the argument \( q \) is not specified then it defaults to the generator \( q \) of the univariate polynomial ring over the integers.

**EXAMPLES:**

```
sage: from sage.combinat.q_analogues import q_int
sage: q_int(3)
q^2 + q + 1
sage: q_int(-3)
(-q^2 - q - 1)/q^3
sage: p = ZZ['p'].0
sage: q_int(3,p)
p^2 + p + 1
sage: q_int(3/2)
Traceback (most recent call last):
  ... ValueError: 3/2 must be an integer
```

```
sage.combinat.q_analogues.q_jordan(q=None)
Return the \( q \)-Jordan number of \( t \).

If \( q \) is the power of a prime number, the output is the number of complete flags in \( F_q^N \) (where \( N \) is the size of \( t \)) stable under a linear nilpotent endomorphism \( f_t \) whose Jordan type is given by \( t \), i.e. such that for all \( i \):
\[
\dim(\ker f_t^i) = t[0] + \cdots + t[i-1]
\]

```

---

5.1. Comprehensive Module List 2133
If \( q \) is unspecified, then it defaults to using the generator \( q \) for a univariate polynomial ring over the integers. The result is cached.

**INPUT:**
- \( t \) – an integer partition, or an argument accepted by `Partition`
- \( q \) – (default: `None`) the variable \( q \); if `None`, then use a default variable in \( \mathbb{Z}[q] \)

**EXAMPLES:**

```python
sage: from sage.combinat.q_analogues import q_jordan
sage: [q_jordan(mu, 2) for mu in Partitions(5)]
[9765, 1029, 213, 93, 29, 9, 1]
sage: [q_jordan(mu, 2) for mu in Partitions(6)]
[615195, 40635, 5643, 2331, 1491, 515, 147, 87, 47, 11, 1]
sage: q_jordan([3,2,1])
16*q^4 + 24*q^3 + 14*q^2 + 5*q + 1
sage: q_jordan([2,1], x)
2*x + 1
```

If the partition is trivial (i.e., has only one part), we get the \( q \)-factorial (in this case, the nilpotent endomorphism is necessarily 0):

```python
sage: from sage.combinat.q_analogues import q_factorial
sage: q_jordan([5]) == q_factorial(5)
True
sage: q_jordan([11], 5) == q_factorial(11, 5)
True
```

**AUTHOR:**
- Xavier Caruso (2012-06-29)

sage.combinat.q_analogues.q_multinomial(seq, q=None, binomial_algorithm='auto')

Return the \( q \)-multinomial coefficient.

This is also known as the Gaussian multinomial coefficient, and is defined by

\[
\binom{n}{k_1, k_2, \ldots, k_m}_q = \frac{[n]_q!}{[k_1]_q! [k_2]_q! \cdots [k_m]_q!}
\]

where \( n = k_1 + k_2 + \cdots + k_m \).

If \( q \) is unspecified, then the variable is the generator \( q \) for a univariate polynomial ring over the integers.

**INPUT:**
- `seq` – an iterable of the values \( k_1 \) to \( k_m \) defined above
- `q` – (default: `None`) the variable \( q \); if `None`, then use a default variable in \( \mathbb{Z}[q] \)
- `binomial_algorithm` – (default: 'auto') the algorithm to use in `q_binomial()`; see possible values there

**ALGORITHM:**

We use the equivalent formula

\[
\binom{k_1 + \cdots + k_m}{k_1, \ldots, k_m}_q = \prod_{i=1}^m \binom{\sum_{j=1}^i k_j}{k_i}_q.
\]
EXAMPLES:

```python
sage: from sage.combinat.q_analogues import q_multinomial
dsage: q_multinomial([1,2,1])
q^5 + 2*q^4 + 3*q^3 + 3*q^2 + 2*q + 1
dsage: q_multinomial([1,2,1], q=1) == multinomial([1,2,1])
True
dsage: q_multinomial((3,2)) == q_binomial(5,3)
True
dsage: q_multinomial([])
1
```

```python
sage.combinat.q_analogues.
q_pochhammer(n, a, q=None)
```

Return the $q$-Pochhammer $(a; q)_n$.

The $q$-Pochhammer symbol is defined by

$$(a; q)_n = \prod_{k=0}^{n-1} (1 - aq^k)$$

with $(a; q)_0 = 1$ for all $a$, $q$ and $n \in \mathbb{N}$. By using the identity

$$(a; q)_n = \frac{(a; q)_\infty}{(aq^n; q)_\infty},$$

we can extend the definition to $n < 0$ by

$$(a; q)_n = \frac{1}{(aq^n; q)_{-n}} = \prod_{k=1}^{-n} \frac{1}{1 - a/q^k}.$$`

EXAMPLES:

```python
sage: from sage.combinat.q_analogues import q_pochhammer
sage: q_pochhammer(3, 1/7)
6/343*q^3 - 6/49*q^2 - 6/49*q + 6/7
sage: q_pochhammer(3, 3)
-18*q^3 + 6*q^2 + 6*q - 2
sage: q_pochhammer(3, 1)
0
sage: R.<q> = ZZ[]
sage: q_pochhammer(4, q)
q^10 - q^9 - q^8 + 2*q^5 - q^2 - q + 1
sage: q_pochhammer(4, q^2)
q^14 - q^12 - q^11 - q^10 + q^8 + 2*q^7 + q^6 - q^4 - q^3 - q^2 + 1
sage: q_pochhammer(-3, q)
1/(-q^9 + q^7 + q^6 + q^5 - q^4 - q^3 - q^2 + 1)
```

REFERENCES:

- Wikipedia article Q-Pochhammer_symbol

```python
sage.combinat.q_analogues.
q_stirling_number1(k, q=None)
```

Return the (unsigned) $q$-Stirling number of the first kind.

This is a $q$-analogue of `sage.combinat.combinat.stirling_number1()`.

INPUT:
• $n, k$ – integers with $1 \leq k \leq n$
• $q$ – optional variable (default $q$)

OUTPut: a polynomial in the variable $q$

These polynomials satisfy the recurrence

$$s_{n,k} = s_{n-1,k-1} + [n-1]q s_{n-1,k}.$$  

EXAMPLES:

```python
sage: from sage.combinat.q_analogues import q_stirling_number1
sage: q_stirling_number1(4,2)
q^3 + 3*q^2 + 4*q + 3
sage: all(stirling_number1(6,k) == q_stirling_number1(6,k)(1)
....: for k in range(1,7))
True
```

REFERENCES:

• [Ca1948]
• [Ca1954]
Return the \(q\)-number of subgroups of type \(\mu\) in a finite abelian group of type \(\lambda\).

**INPUT:**

- \(\lambda\) – type of the ambient group as a *Partition*
- \(\mu\) – type of the subgroup as a *Partition*
- \(q\) – (default: None) an indeterminate or a prime number; if None, this defaults to \(q \in \mathbb{Z}[q]\)
- \(algorithm\) – (default: 'birkhoff') the algorithm to use can be one of the following:
  - 'birkhoff' – use the Birkhoff formula from [Bu87]
  - 'delsarte' – use the formula from [Delsarte48]

**OUTPUT:**

The number of subgroups of type \(\mu\) in a group of type \(\lambda\) as a polynomial in \(q\).

**ALGORITHM:**

Let \(q\) be a prime number and \(\lambda = (\lambda_1, \ldots, \lambda_l)\) be a partition. A finite abelian \(q\)-group is of type \(\lambda\) if it is isomorphic to

\[
\mathbb{Z}/q^{\lambda_1}\mathbb{Z} \times \cdots \times \mathbb{Z}/q^{\lambda_l}\mathbb{Z}.
\]

The formula from [Bu87] works as follows: Let \(\lambda\) and \(\mu\) be partitions. Let \(\lambda'\) and \(\mu'\) denote the conjugate partitions to \(\lambda\) and \(\mu\), respectively. The number of subgroups of type \(\mu\) in a group of type \(\lambda\) is given by

\[
\prod_{i=1}^{\mu_1} q^{(\lambda_i' - \mu_i') + 1} \frac{\lambda_i' - \mu_i'}{\mu_i' + 1} q
\]

The formula from [Delsarte48] works as follows: Let \(\lambda\) and \(\mu\) be partitions. Let \((s_1, s_2, \ldots, s_l)\) and \((r_1, r_2, \ldots, r_k)\) denote the parts of the partitions conjugate to \(\lambda\) and \(\mu\) respectively. Let

\[
\mathfrak{F}(\xi_1, \ldots, \xi_k) = \xi_1^{r_1} \xi_2^{r_2} \cdots \xi_k^{r_k} \prod_{i_1=r_2}^{r_1-1} (\xi_1 - q^{i_1}) \prod_{i_2=r_3}^{r_2-1} (\xi_2 - q^{i_2}) \cdots \prod_{i_k=0}^{r_k-1} (\xi_k - q^{-i_k}).
\]

Then the number of subgroups of type \(\mu\) in a group of type \(\lambda\) is given by

\[
\frac{\mathfrak{F}(q^{s_1}, q^{s_2}, \ldots, q^{s_l})}{\mathfrak{F}(q^{r_1}, q^{r_2}, \ldots, q^{r_k})}.
\]

**EXAMPLES:**

```python
sage: from sage.combinat.q_analogues import q_subgroups_of_abelian_group
sage: q_subgroups_of_abelian_group([1,1], [1])
q + 1
sage: q_subgroups_of_abelian_group([3,3,2,1], [2,1])
qu^6 + 2qu^5 + 3qu^4 + 2qu^3 + q^2
sage: R.<t> = QQ[]
sage: q_subgroups_of_abelian_group([5,3,1], [3,1], t)
t^4 + 2t^3 + t^2
sage: q_subgroups_of_abelian_group([5,3,1], [3,1], 3)
144
sage: q_subgroups_of_abelian_group([1,1,1], [1]) == q_subgroups_of_abelian_group([1,1,1], [1,1,1])
True
```

• Tomer Bauer (2013, 2018): Implemented the Birkhoff algorithm and refactoring

sage.combinat.q_analogues.qt_catalan_number(n)

Return the $q,t$-Catalan number of index $n$.

EXAMPLES:

sage: from sage.combinat.q_analogues import qt_catalan_number
sage: qt_catalan_number(1)
1
sage: qt_catalan_number(2)
q + t
sage: qt_catalan_number(3)
q^3 + q^2*t + q*t^2 + t^3 + q*t
sage: qt_catalan_number(4)
q^6 + q^5*t + q^4*t^2 + q^3*t^3 + q^2*t^4 + q*t^5 + t^6 + q^4*t + q^3*t^2 + q^2*t^3 + q*t^4 + q^3*t + q^2*t^2 + q*t^3

The $q,t$-Catalan number of index $n$ is only defined for $n$ a nonnegative integer (github issue #11411):

sage: qt_catalan_number(-2)
Traceback (most recent call last):
... ValueError: argument (-2) must be a nonnegative integer

5.1.188 $q$-Bernoulli Numbers and Polynomials

sage.combinat.q_bernoulli.q_bernoulli(p=None)

Compute Carlitz’s $q$-analogue of the Bernoulli numbers.

For every nonnegative integer $m$, the $q$-Bernoulli number $\beta_m$ is a rational function of the indeterminate $q$ whose value at $q = 1$ is the usual Bernoulli number $B_m$.

INPUT:

• $m$ – a nonnegative integer
• $p$ (default: None) – an optional value for $q$

OUTPUT:

A rational function of the indeterminate $q$ (if $p$ is None)
Otherwise, the rational function is evaluated at \( p \).

**EXAMPLES:**

```python
sage: from sage.combinat.q_bernoulli import q_bernoulli
sage: q_bernoulli(0)
1
sage: q_bernoulli(1)
-1/(q + 1)
sage: q_bernoulli(2)
q/(q^3 + 2*q^2 + 2*q + 1)
sage: all(q_bernoulli(i)(q=1) == bernoulli(i) for i in range(12))
True
```

One can evaluate the rational function by giving a second argument:

```python
sage: x = PolynomialRing(GF(2), 'x').gen()
sage: q_bernoulli(5,x)
x/(x^6 + x^5 + x + 1)
```

The function does not accept negative arguments:

```python
sage: q_bernoulli(-1)
Traceback (most recent call last):
  ...
ValueError: the argument must be a nonnegative integer
```

**REFERENCES:**

sage.combinat.q_bernoulli.q_bernoulli_polynomial()

Compute Carlitz’s \( q \)-analogue of the Bernoulli polynomials.

For every nonnegative integer \( m \), the \( q \)-Bernoulli polynomial is a polynomial in one variable \( x \) with coefficients in \( \mathbb{Q}(q) \) whose value at \( q = 1 \) is the usual Bernoulli polynomial \( B_m(x) \).

The original \( q \)-Bernoulli polynomials introduced by Carlitz were polynomials in \( q^y \) with coefficients in \( \mathbb{Q}(q) \). This function returns these polynomials but expressed in the variable \( x = (q^y - 1)/(q - 1) \). This allows to let \( q = 1 \) to recover the classical Bernoulli polynomials.

**INPUT:**

- \( m \) – a nonnegative integer

**OUTPUT:**

A polynomial in one variable \( x \).

**EXAMPLES:**

```python
sage: from sage.combinat.q_bernoulli import q_bernoulli_polynomial, q_bernoulli
sage: q_bernoulli_polynomial(0)
1
sage: q_bernoulli_polynomial(1)
(2/(q + 1))*x - 1/(q + 1)
sage: x = q_bernoulli_polynomial(1).parent().gen()
sage: all(q_bernoulli_polynomial(i)(q=1)==bernoulli_polynomial(x,i) for i in range(12))
True
```
The function does not accept negative arguments:

```
sage: q_bernoulli_polynomial(-1)
Traceback (most recent call last):
  ...<ValueError: the argument must be a nonnegative integer>
```
Combinatorics, Release 10.0

(continued from previous page)

```python
sage: Word('aabacabaa').is_palindrome()
True
sage: WordMorphism('a->ab,b->a').fixed_point('a')
word: ababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababa...```

Polytopes:

```python
sage: points = random_matrix(ZZ, 6, 3, x=7).rows()
sage: L = LatticePolytope(points)
sage: L.npoints(); L.plot3d()  # random
```

Root systems, Coxeter and Weyl groups:

```python
sage: WeylGroup(['B',3]).bruhat_poset()
Finite poset containing 48 elements
sage: RootSystem(['A',2,1]).weight_lattice().plot()  # not tested
```

Crystals:

```python
sage: CrystalOfTableaux(['A',3], shape = [3,2]).some_flashy_feature()  # not tested
```

Symmetric functions and combinatorial Hopf algebras:

```python
sage: Sym = SymmetricFunctions(QQ); Sym.inject_shorthands(VERBOSE=False)
sage: m( ( h[2,1] * (1 + 3 * p[2,1]) ) + s[2](s[3]) )
3*m[1, 1, 1] + ... + 10*m[5, 1] + 4*m[6]
```

Discrete groups, Permutation groups:

```python
sage: S = SymmetricGroup(4)
sage: M = PolynomialRing(QQ, 'x0,x1,x2,x3')
sage: M.an_element() * S.an_element()
x0
```

Graph theory, posets, lattices (Graph Theory, Posets):

```python
sage: Poset({1: [2,3], 2: [4], 3: [4]}).linear_extensions().cardinality()
2
```

5.1.190 Rankers

sage.combinat.ranker.from_list(lst)

Returns a ranker from the list l.

**INPUT:**

- l - a list

**OUTPUT:**

- [rank, unrank] - functions

**EXAMPLES:**

5.1. Comprehensive Module List
sage.combinat.ranker.on_fly()

Returns a pair of enumeration functions rank / unrank.

rank assigns on the fly an integer, starting from 0, to any object passed as argument. The object should be hashable. unrank is the inverse function; it returns None for indices that have not yet been assigned.

EXAMPLES:

sage: [rank, unrank] = sage.combinat.ranker.on_fly()
sage: rank('a')
0
sage: rank('b')
1
sage: rank('c')
2
sage: rank('a')
0
sage: unrank(2)
'c'
sage: unrank(3)

sage.combinat.ranker.rank_from_list(l)

Return a rank function for the elements of l.

INPUT:

- l – a duplicate free list (or iterable) of hashable objects

OUTPUT:

- a function from the elements of l to 0,...,len(l)

EXAMPLES:
For non elements a ValueError is raised, as with the usual index method of lists:

```python
sage: r('blah')
Traceback (most recent call last):
  ... ValueError: 'blah' is not in dict
```

Currently, the rank function is a CallableDict; but this is an implementation detail:

```python
sage: type(r)
<class 'sage.misc.callable_dict.CallableDict'>
sage: r
{'a': 0, 'b': 1, 'c': 2}
```

With the current implementation, no error is issued in case of duplicate value in `l`. Instead, the rank function returns the position of some of the duplicates:

```python
sage: r = ranker.rank_from_list(['a', 'b', 'a', 'c'])
sage: r('a')
2
```

Constructing the rank function itself is of complexity $O(|l|)$. Then, each call to the rank function consists of an essentially constant time dictionary lookup.

**sage.combinat.ranker.unrank**

Return the $i$-th element of $L$.

**INPUT:**

- $L$ – a list, tuple, finite enumerated set, ...
- $i$ – an int or Integer

The purpose of this utility is to give a uniform idiom to recover the $i$-th element of an object $L$, whether $L$ is a list, tuple (or more generally a `collections.abc.Sequence`), an enumerated set, some old parent of Sage still implementing unranking in the method `__getitem__`, or an iterable (see `collections.abc.Iterable`). See github issue #15919.

**EXAMPLES:**

Lists, tuples, and other sequences:

```python
sage: from sage.combinat.ranker import unrank
sage: unrank(['a', 'b', 'c'], 2)
'c'
sage: unrank(['a', 'b', 'c'], 1)
'b'
sage: unrank(range(3,13,2), 1)
5
```

Enumerated sets:
sage: unrank(GF(7), 2)
2
sage: unrank(IntegerModRing(29), 10)
10

An iterable:

sage: unrank(NN, 4)
4

An iterator:

sage: unrank(('a{}'.format(i) for i in range(20)), 0)
'a0'
sage: unrank(('a{}'.format(i) for i in range(20)), 2)
'a2'

Warning: When unranking an iterator, it returns the i-th element beyond where it is currently at:

sage: from sage.combinat.ranker import unrank
sage: it = iter(range(20))
sage: unrank(it, 2)
2
sage: unrank(it, 2)
5

sage.combinat.ranker.unrank_from_list(l)
Returns an unrank function from a list.

EXAMPLES:

sage: import sage.combinat.ranker as ranker
sage: l = [1,2,3]
sage: u = ranker.unrank_from_list(l)
sage: u(2)
3
sage: u(0)
1

5.1.191 Recognizable Series

Let \(A\) be an alphabet and \(K\) a semiring. Then a formal series \(S\) with coefficients in \(K\) and indices in the words \(A^*\) is called recognizable if it has a linear representation, i.e., there exists

- a nonnegative integer \(n\)

and there exist

- two vectors \(\text{left}\) and \(\text{right}\) of dimension \(n\) and
- a morphism of monoids \(\mu\) from \(A^*\) to \(n \times n\) matrices over \(K\)
such that the coefficient corresponding to a word \( w \in A^* \) equals

\[
\left\{ \begin{array}{l}
\mu(w) \\
right.
\end{array} \right.
\]

**Note:** Whenever a minimization \( \text{minimized}() \) of a series needs to be computed, it is required that \( K \) is a field. In particular, minimization is called before checking if a series is nonzero.

**Warning:** As this code is experimental, warnings are thrown when a recognizable series space is created for the first time in a session (see \texttt{sage.misc.superseded.experimental}).

**Various**

**See also:**

\textit{k-regular sequence, sage.rings.cfinite_sequence, sage.combinat.binary_recurrence_sequences}.

**AUTHORS:**

- Daniel Krenn (2016, 2021)

**ACKNOWLEDGEMENT:**

**Classes and Methods**

\texttt{class sage.combinat.recognizable_series.PrefixClosedSet(words)}

Bases: \texttt{object}

A prefix-closed set.

Creation of this prefix-closed set is interactive iteratively.

**INPUT:**

- \texttt{words} – a class of words (instance of \texttt{Words})

**EXAMPLES:**

\begin{verbatim}
sage: from sage.combinat.recognizable_series import PrefixClosedSetsage: P = PrefixClosedSet(Words([0, 1], infinite=False)); P
[word: ]
sage: P = PrefixClosedSet.create_by_alphabet([0, 1]); P
[word: ]
\end{verbatim}

See \texttt{iterate_possible_additions()} for further examples.

\texttt{add(w, check=True)}

Add a word to this prefix-closed set.

**INPUT:**

- \texttt{w} – a word

5.1. Comprehensive Module List
• check – boolean (default: True). If set, then it is verified whether all proper prefixes of \( w \) are already in this prefix-closed set.

OUTPUT:
Nothing, but a RuntimeError is raised if the check fails.

EXAMPLES:

```python
sage: from sage.combinat.recognizable_series import PrefixClosedSet
sage: P = PrefixClosedSet.create_by_alphabet([0, 1])
sage: W = P.words
sage: P.add(W([0])); P
[word: , word: 0]
sage: P.add(W([0, 1])); P
[word: , word: 0, word: 01]
sage: P.add(W([1, 1]))
Traceback (most recent call last):
... ValueError: cannot add as not all prefixes of 11 are included yet
```

classmethod create_by_alphabet(alphabet)
A prefix-closed set
This is a convenience method for the creation of prefix-closed sets by specifying an alphabet.

INPUT:
• alphabet – finite words over this alphabet will used

EXAMPLES:

```python
sage: from sage.combinat.recognizable_series import PrefixClosedSet
sage: P = PrefixClosedSet.create_by_alphabet([0, 1]); P
[word: ]
```

iterate_possible_additions()
Return an iterator over all elements including possible new elements.

OUTPUT:
An iterator

EXAMPLES:

```python
sage: from sage.combinat.recognizable_series import PrefixClosedSet
sage: P = PrefixClosedSet.create_by_alphabet([0, 1]); P
[word: ]
sage: for n, p in enumerate(P.iterate_possible_additions()):
    ....:     print('{}?'.format(p))
    ....:     if n in (0, 2, 3, 5):
    ....:         P.add(p)
    ....:         print('...added')
0?
...added
1?
00?
...added
```

(continues on next page)
Calling the iterator once more, returns all elements:

```
sage: list(P.iterate_possible_additions())
[word: 0, word: 1, word: 00, word: 01, word: 000, word: 001, word: 010, word: 011, word: 0010, word: 0011]
```

The method `iterate_possible_additions()` is roughly equivalent to

```
sage: list(p + a
....: for p in P.elements
....: for a in P.words.iterate_by_length(1))
[word: 0, word: 1, word: 00, word: 01, word: 000, word: 001, word: 010, word: 011, word: 0010, word: 0011]
```

However, the above does not allow to add elements during iteration, whereas `iterate_possible_additions()` does.

**prefix_set()**

Return the set of minimal (with respect to prefix ordering) elements of the complement of this prefix closed set.

See also Proposition 2.3.1 of [BR2010a].

OUTPUT:

A list
class sage.combinat.recognizable_series.RecognizableSeries(parent, mu, left, right)

A recognizable series.

- **parent** – an instance of RecognizableSeriesSpace
- **mu** – a family of square matrices, all of which have the same dimension. The indices of this family are the elements of the alphabet. mu may be a list or tuple of the same cardinality as the alphabet as well. See also mu.
- **left** – a vector. When evaluating a coefficient, this vector is multiplied from the left to the matrix obtained from mu applying on a word. See also left.
- **right** – a vector. When evaluating a coefficient, this vector is multiplied from the right to the matrix obtained from mu applying on a word. See also right.

When created via the parent RecognizableSeriesSpace, then the following option is available.

EXAMPLES:

```python
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: S = Rec((Matrix([[3, 6], [0, 1]]), Matrix([[0, -6], [1, 5]])),
.....:   vector([0, 1]), vector([1, 0])).transposed(); S
[1] + 3*[01] + [10] + 5*[11] + 9*[001] + 3*[010] + ...
```

We can access coefficients by

```python
sage: W = Rec.indices()
sage: S[W([0, 0, 1])]
9
```

See also:

- recognizable series, RecognizableSeriesSpace.
- coefficient_of_word(w, multiply_left=True, multiply_right=True)

Return the coefficient to word w of this series.

INPUT:

- **w** – a word over the parent’s alphabet()
- **multiply_left** – (default: True) a boolean. If False, then multiplication by left is skipped.
- **multiply_right** – (default: True) a boolean. If False, then multiplication by right is skipped.
OUTPUT:
An element in the parent's coefficient_ring()

EXAMPLES:

```sage
Rec = RecognizableSeriesSpace(ZZ, [0, 1])
W = Rec.indices()
S = Rec((Matrix([[1, 0], [0, 1]]), Matrix([[0, -1], [1, 2]])),
.....: left=vector([0, 1]), right=vector([1, 0]))
S[W(7.digits(2))]  # indirect doctest
```

`dimension()`
Return the dimension of this recognizable series.

EXAMPLES:

```sage
Rec = RecognizableSeriesSpace(ZZ, [0, 1])
Rec((Matrix([[1, 0], [0, 1]]), Matrix([[1, 0], [0, 1]])),
.....: left=vector([0, 1]), right=vector([1, 0])).dimension()
```

`hadamard_product(*args, **kwds)`
Return the Hadamard product of this recognizable series and the other recognizable series, i.e., multiply the two series coefficient-wise.

INPUT:
- `other` – a RecognizableSeries with the same parent as this recognizable series
- `minimize` – (default: None) a boolean or None. If True, then minimized() is called after the operation, if False, then not. If this argument is None, then the default specified by the parent's minimize_results is used.

OUTPUT:
A RecognizableSeries

EXAMPLES:

```sage
Seq2 = kRegularSequenceSpace(2, ZZ)
E = Seq2((Matrix([[0, 1], [0, 1]]), Matrix([[0, 0], [0, 1]])),
.....: vector([1, 0]), vector([1, 1]))
E
2-regular sequence 1, 0, 1, 0, 1, 0, 1, 0, ...

O = Seq2((Matrix([[0, 0], [0, 1]]), Matrix([[0, 1], [0, 1]])),
.....: vector([1, 0]), vector([0, 1]))
O
2-regular sequence 0, 1, 0, 1, 0, 1, 0, 1, 0, ...

C = Seq2((Matrix([[2, 0], [2, 1]]), Matrix([[0, 1], [-2, 3]])),
.....: vector([1, 0]), vector([0, 1]))
C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
```
sage: CE = C.hadamard_product(E)
sage: CE
2-regular sequence 0, 0, 2, 0, 4, 0, 6, 0, 8, 0, ...
sage: CE.linear_representation()
((1, 0, 0),
 Finite family {0: [0 1 0]
              [0 2 0]
              [0 2 1],
           1: [ 0 0 0]
              [ 0 0 1]
              [ 0 -2 3]},
(0, 0, 2))

sage: Z = E.hadamard_product(O)
sage: Z
2-regular sequence 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, ...
sage: Z.linear_representation()
(()
 Finite family {0: [],
           1: []},
())

is_trivial_zero()
Return whether this recognizable series is trivially equal to zero (without any minimization).

EXAMPLES:

sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])

sage: Rec((Matrix([[1, 0], [0, 1]]), Matrix([[1, 0], [0, 1]])),
       left=vector([0, 1]), right=vector([1, 0])).is_trivial_zero()
False

sage: Rec((Matrix([[1, 0], [0, 1]]), Matrix([[1, 0], [0, 1]])),
       left=vector([0, 0]), right=vector([1, 0])).is_trivial_zero()
True

sage: Rec((Matrix([[1, 0], [0, 1]]), Matrix([[1, 0], [0, 1]])),
       left=vector([0, 1]), right=vector([0, 0])).is_trivial_zero()
True

The following two differ in the coefficient of the empty word:

sage: Rec((Matrix([[0, 0], [0, 0]]), Matrix([[0, 0], [0, 0]])),
       left=vector([0, 1]), right=vector([1, 0])).is_trivial_zero()
True

sage: Rec((Matrix([[0, 0], [0, 0]]), Matrix([[0, 0], [0, 0]])),
       left=vector([1, 1]), right=vector([1, 1])).is_trivial_zero()
False

property left
When evaluating a coefficient, this vector is multiplied from the left to the matrix obtained from mu applied on a word.

linear_representation()
Return the linear representation of this series.

OUTPUT:
A triple \((\text{left}, \mu, \text{right})\) containing the vectors \(\text{left}\) and \(\text{right}\), and the family of matrices \(\mu\).

**EXAMPLES:**

```python
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: Rec((Matrix([[3, 6], [0, 1]]), Matrix([[0, -6], [1, 5]])),
.....:   vector([0, 1]), vector([1, 0])
.....: ).transposed().linear_representation()
((1, 0),
 Finite family {0: [3 0]
    [6 1],
    1: [ 0 1]
    [-6 5]},
(0, 1))
```

**minimized()**

Return a recognizable series equivalent to this series, but with a minimized linear representation.

The coefficients of the involved matrices need be in a field. If this is not the case, then the coefficients are automatically coerced to their fraction field.

**OUTPUT:**

A \(\text{RecognizableSeries}\)

**ALGORITHM:**

This method implements the minimization algorithm presented in Chapter 2 of [BR2010a].

**Note:** Due to the algorithm, the left vector of the result is always \((1, 0, \ldots, 0)\), i.e., the first vector of the standard basis.

**EXAMPLES:**

```python
sage: from itertools import islice
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: S = Rec((Matrix([[3, 6], [0, 1]]), Matrix([[0, -6], [1, 5]])),
.....:   vector([0, 1]), vector([1, 0])).transposed()
sage: S
 + 15*[011] + [100] + 11*[101] + 5*[110] + ...
sage: M = S.minimized()
sage: M.mu[0], M.mu[1], M.left, M.right
([3 0] [ 0 1]
[6 1], [-6 5], (1, 0), (0, 1))
sage: M.left == vector([1, 0])
True
sage: all(c == d and v == w
.....:   for (c, v), (d, w) in islice(zip(iter(S), iter(M)), 20))
True
sage: S = Rec((Matrix([[2, 0], [1, 1]]), Matrix([[2, 0], [2, 1]])),
```

(continues on next page)
....:    vector([1, 0]), vector([1, 1]))
sage: S
    + 8*[000] + 8*[001] + 8*[010] + ...
sage: M = S.minimized()
sage: M.mu[0], M.mu[1], M.left, M.right
([2], [2], (1), (1))
sage: all(c == d and v == w
....:       for (c, v), (d, w)
in islice(zip(iter(S), iter(M)), 20))
True

property mu
When evaluating a coefficient, this is applied on each letter of a word; the result is a matrix. This extends
mu to words over the parent's alphabet().

property right
When evaluating a coefficient, this vector is multiplied from the right to the matrix obtained from mu applied
on a word.

transposed()    
Return the transposed series.

OUTPUT:
A RecognizableSeries

Each of the matrices in mu is transposed. Additionally the vectors left and right are switched.

EXAMPLES:

sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: S = Rec((Matrix([[3, 6], [0, 1]]), Matrix([[0, -6], [1, 5]])),
....:    vector([0, 1]), vector([1, 0])).transposed()
sage: S
    + 15*[011] + [100] + 11*[101] + 5*[110] + ...
sage: S.mu[0], S.mu[1], S.left, S.right
([3 0]
[6 1], [-6 5], (1, 0), (0, 1))
sage: T = S.transposed()
sage: T
[1] + [01] + 3*[10] + 5*[11] + [001] + 3*[010]
    + 5*[011] + 9*[100] + 11*[101] + 15*[110] + ...
sage: T.mu[0], T.mu[1], T.left, T.right
([3 6]
[0 1], [1 5], (0, 1), (1, 0))

class sage.combinat.recognizable_series.RecognizableSeriesSpace(coefficient_ring, indices,
category, minimize_results)

Bases: UniqueRepresentation, Parent

The space of recognizable series on the given alphabet and with the given coefficients.
INPUT:

- **coefficient_ring** – a (semi-)ring
- **alphabet** – a tuple, list or `TotallyOrderedFiniteSet`. If specified, then the **indices** are the finite words over this **alphabet**. **alphabet** and **indices** cannot be specified at the same time.
- **indices** – a SageMath-parent of finite words over an **alphabet**. **alphabet** and **indices** cannot be specified at the same time.
- **category** – (default: None) the category of this space

EXAMPLES:

We create a recognizable series that counts the number of ones in each word:

```python
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: Rec
Space of recognizable series on {0, 1} with coefficients in Integer Ring
sage: Rec((Matrix([[1, 0], [0, 1]]), Matrix([[1, 1], [0, 1]]),
.....:
    vector([1, 0]), vector([0, 1]))
[1] + [01] + [10] + 2*[11] + [001] + [010] + 2*[011] + [100] + 2*[101] + 2*[110] + ...
```

All of the following examples create the same space:

```python
sage: Rec1 = RecognizableSeriesSpace(ZZ, [0, 1])
sage: Rec1
Space of recognizable series on {0, 1} with coefficients in Integer Ring
sage: Rec2 = RecognizableSeriesSpace(coefficient_ring=ZZ, alphabet=[0, 1])
sage: Rec2
Space of recognizable series on {0, 1} with coefficients in Integer Ring
sage: Rec3 = RecognizableSeriesSpace(ZZ, indices=Words([0, 1], infinite=False))
sage: Rec3
Space of recognizable series on {0, 1} with coefficients in Integer Ring
```

See also:

`recognizable series`, `RecognizableSeries`.

**Element**

**alphabet()**

Return the alphabet of this recognizable series space.

**OUTPUT:**

A totally ordered set

**EXAMPLES:**

```python
sage: RecognizableSeriesSpace(ZZ, [0, 1]).alphabet()
{0, 1}
```

**coefficient_ring()**

Return the coefficients of this recognizable series space.

**OUTPUT:**

A (semi-)ring

5.1. Comprehensive Module List
EXAMPLES:

```python
sage: RecognizableSeriesSpace(ZZ, [0, 1]).coefficient_ring()
Integer Ring
```

**indices()**

Return the indices of the recognizable series.

**OUTPUT:**

The set of finite words over the alphabet

**EXAMPLES:**

```python
sage: RecognizableSeriesSpace(ZZ, [0, 1]).indices()
Finite words over {0, 1}
```

**property minimize_results**

A boolean indicating whether `RecognizableSeries.minimized()` is automatically called after performing operations.

**one_hadamard()**

Return the identity with respect to the `hadamard_product()`, i.e. the coefficient-wise multiplication.

**OUTPUT:**

A `RecognizableSeries`

**EXAMPLES:**

```python
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: Rec.one_hadamard()
[0] + [0] + [0] + [00] + [01] + [10]
  + [11] + [000] + [001] + [010] + ...
```

**some_elements()**

Return some elements of this recognizable series space.

See `TestSuite` for a typical use case.

**OUTPUT:**

An iterator

**EXAMPLES:**

```python
sage: tuple(RecognizableSeriesSpace(ZZ, [0, 1]).some_elements())
([1] + [0] + [1] + [00] + [01] + [10]
  + 2*[11] + [100] + 2*[101] + 2*[110] + ...,
 [1] + [1] + [1] + [111] + [111] + [1111] + [11111] + [111111] + ...,
 [0] + [0] + [1] + [00] + [10] + [11]
  + [000] - 1*[000] + [100] + [110] + ...,
2*[1] - 1*[1] + 2*[10] - 1*[101]
  + 2*[1010] - 1*[10101] + 2*[101010] + ...,
  + 288*[0000] - 33*[0001] + ...,
-5*[1] + ...,
...
```

(continues on next page)
Combinatorics, Release 10.0

sage.combinat.recognizable_series.minimize_result(operation)

A decorator for operations that enables control of automatic minimization on the result.

INPUT:
• operation – a method

OUTPUT:
A method with the following additional argument:
• minimize – (default: None) a boolean or None. If True, then minimized() is called after the operation, if False, then not. If this argument is None, then the default specified by the parent’s minimize_results is used.

5.1.192 Restricted growth arrays

These combinatorial objects are in bijection with set partitions.

class sage.combinat.restricted_growth.RestrictedGrowthArrays(n)

Bases: UniqueRepresentation, Parent

EXAMPLES:

sage: from sage.combinat.restricted_growth import RestrictedGrowthArrays
sage: R = RestrictedGrowthArrays(3)

sage: R == loads(dumps(R))
True
sage: TestSuite(R).run(skip=['_test_an_element',
              ....:   '_test_enumerated_set_contains',
              ....:   '_test_some_elements'])

cardinality()

EXAMPLES:

sage: from sage.combinat.restricted_growth import RestrictedGrowthArrays
sage: R = RestrictedGrowthArrays(6)
sage: R.cardinality()
203

5.1.193 Ribbons

5.1.194 Ribbon Shaped Tableaux

class sage.combinat.ribbon_shaped_tableau.RibbonShapedTableau(parent, t)

Bases: SkewTableau

A ribbon shaped tableau.

For the purposes of this class, a ribbon shaped tableau is a skew tableau whose shape is a skew partition which:
• has at least one cell in row 1;
Combinatorics, Release 10.0

- has at least one cell in column 1;
- has exactly one cell in each of \( q \) consecutive diagonals, for some nonnegative integer \( q \).

A ribbon is given by a list of the rows from top to bottom.

EXAMPLES:

```python
sage: x = RibbonShapedTableau([[None, None, None, 2, 3], [None, 1, 4, 5], [3, 2]]);
˓→ x
[[None, None, None, 2, 3], [None, 1, 4, 5], [3, 2]]
sage: x.pp()
. . . 2 3
. 1 4 5
3 2
sage: x.shape()
[5, 4, 2] / [3, 1]
```

The entries labeled by \texttt{None} correspond to the inner partition. Using \texttt{None} is optional; the entries will be shifted accordingly.

```python
sage: x = RibbonShapedTableau([[2,3], [1,4,5], [3,2]]); x.pp()
. . . 2 3
. 1 4 5
3 2
```

**height()**

Return the height of \texttt{self}.

The height is given by the number of rows in the outer partition.

EXAMPLES:

```python
sage: RibbonShapedTableau([[2,3],[1,4,5]]).height()
2
```

**spin()**

Return the spin of \texttt{self}.

EXAMPLES:

```python
sage: RibbonShapedTableau([[2,3],[1,4,5]]).spin()
1/2
```

**width()**

Return the width of the ribbon.

This is given by the length of the longest row in the outer partition.

EXAMPLES:

```python
sage: RibbonShapedTableau([[2,3],[1,4,5]]).width()
4
sage: RibbonShapedTableau([]).width()
0
```
class sage.combinat.ribbon_shaped_tableau.RibbonShapedTableaux(category=None)
    Bases: SkewTableaux
    The set of all ribbon shaped tableaux.

    Element
    alias of RibbonShapedTableau

    from_shape_and_word(shape, word)
    Return the ribbon corresponding to the given ribbon shape and word.

    EXAMPLES:

    sage: RibbonShapedTableaux().from_shape_and_word([1,3],[1,3,3,7])
    [[None, None, 1], [3, 3, 7]]

    options = Current options for Tableaux - ascii_art: repr - convention: English -
display: list - latex: diagram

class sage.combinat.ribbon_shaped_tableau.Ribbon_class(parent, t)
    Bases: RibbonShapedTableau
    This exists solely for unpickling Ribbon_class objects.

class sage.combinat.ribbon_shaped_tableau.StandardRibbonShapedTableaux(category=None)
    Bases: StandardSkewTableaux
    The set of all standard ribbon shaped tableaux.

    INPUT:
    - shape - (optional) the composition shape of the rows

    Element
    alias of RibbonShapedTableau

    from_permutation(p)
    Return a standard ribbon of size len(p) from a permutation p. The lengths of each row are given by the
distance between the descents of the permutation p.

    EXAMPLES:

    sage: import sage.combinat.ribbon_shaped_tableau as rst
    sage: [StandardRibbonShapedTableaux().from_permutation(p) for p in Permutations(3)]
    [[[1, 2, 3]],
     [[None, 2], [1, 3]],
     [[1, 3], [2]],
     [[None, 1], [2, 3]],
     [[1, 2], [3]],
     [[1], [2], [3]]]

    from_shape_and_word(shape, word)
    Return the ribbon corresponding to the given ribbon shape and word.

    EXAMPLES:

    sage: StandardRibbonShapedTableaux().from_shape_and_word([2,3],[1,2,3,4,5])
    [[None, None, 1, 2], [3, 4, 5]]
options = Current options for Tableaux - ascii_art: repr - convention: English - display: list - latex: diagram

class sage.combinat.ribbon_shaped_tableau.StandardRibbonShapedTableaux(shape)
    Bases: StandardRibbonShapedTableaux

    Class of standard ribbon shaped tableaux of ribbon shape shape.

    EXAMPLES:

    sage: StandardRibbonShapedTableaux([2,2])
    Standard ribbon shaped tableaux of shape [2, 2]
    sage: StandardRibbonShapedTableaux([2,2]).first()
    [[None, 2, 4], [1, 3]]
    sage: StandardRibbonShapedTableaux([2,2]).last()
    [[None, 1, 2], [3, 4]]
    sage: StandardRibbonShapedTableaux([2,2]).cardinality()
    5
    sage: StandardRibbonShapedTableaux([2,2]).list()
    [[[None, 1, 3], [2, 4]],
     [[None, 1, 2], [3, 4]],
     [[None, 2, 3], [1, 4]],
     [[None, 2, 4], [1, 3]],
     [[None, 1, 4], [2, 3]]]
    sage: StandardRibbonShapedTableaux([3,2,2]).cardinality()
    155

    first()
        Return the first standard ribbon of self.

        EXAMPLES:

        sage: StandardRibbonShapedTableaux([2,2]).first()
        [[None, 2, 4], [1, 3]]

    last()
        Return the last standard ribbon of self.

        EXAMPLES:

        sage: StandardRibbonShapedTableaux([2,2]).last()
        [[None, 1, 2], [3, 4]]

5.1.195 Ribbon Tableaux

class sage.combinat.ribbon_tableau.MultiSkewTableau(parent, *args, **kwds)
    Bases: CombinatorialElement

    A multi skew tableau which is a tuple of skew tableaux.

    EXAMPLES:

    sage: s = MultiSkewTableau([ [[None,1],[2,3]], [[1,2],[2]] ])  
sage: s.size()
    6
inversion_pairs()
Return a list of the inversion pairs of self.

EXAMPLES:

```python
sage: s = MultiSkewTableau([[[2,3],[5,5]], [[1,1],[3,3]], [[2],[6]]])
sage: s.inversion_pairs()
[((0, (0)), (1, (0))),
 ((0, (1)), (1, (0))),
 ((0, (1)), (1, (1))),
 ((0, (1)), (2, (0))),
 ((1, (0)), (2, (0))),
 ((1, (1)), (2, (0)))]
```

inversions()
Return the number of inversion pairs of self.

EXAMPLES:

```python
sage: t1 = SkewTableau([[1]])
sage: t2 = SkewTableau([[2]])
sage: MultiSkewTableau([t1,t1]).inversions() 0
sage: MultiSkewTableau([t1,t2]).inversions() 0
sage: MultiSkewTableau([t2,t2]).inversions() 0
sage: MultiSkewTableau([t2,t1]).inversions() 1
sage: s = MultiSkewTableau([[[2,3],[5,5]], [[1,1],[3,3]], [[2],[6]]])
sage: s.inversions() 7
```

shape()
Return the shape of self.

EXAMPLES:

```python
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
sage: a.shape()
[[2, 2] / [1], [2, 2] / [1], [2, 2] / [1]]
```

size()
Return the size of self.

This is the sum of the sizes of the skew tableaux in self.

EXAMPLES:
Combinatorics, Release 10.0

```
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
sage: a.size()
9
```

### weight()

Return the weight of `self`.

**EXAMPLES:**

```
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
sage: a.weight()
[5, 3, 1]
```

```python
class sage.combinat.ribbon_tableau.MultiSkewTableaux(category=None)
    Bases: UniqueRepresentation, Parent

    Multiskew tableaux.

    **Element**
    
    alias of `MultiSkewTableau`

class sage.combinat.ribbon_tableau.RibbonTableau(parent, st)
    Bases: SkewTableau

    A ribbon tableau.

    A ribbon is a connected skew shape which does not contain any $2 \times 2$ boxes. A ribbon tableau is a skew tableau whose shape is partitioned into ribbons, each of which is filled with identical entries.

    **EXAMPLES:**

    ```python
    sage: rt = RibbonTableau([[None, 1],[2,3]]); rt
    [[None, 1], [2, 3]]
    sage: rt.inner_shape()
    [1]
    sage: rt.outer_shape()
    [2, 2]
    sage: rt = RibbonTableau([[None, None, 0, 0, 0], [None, 0, 0, 2], [1, 0, 1]]); rt.pp()
    . . 0 0 0
    . 0 0 2
    1 0 1
    ```

    In the previous example, each ribbon is uniquely determined by a non-zero entry. The 0 entries are used to fill in the rest of the skew shape.

    **Note:** Sanity checks are not performed; lists can contain any object.
```

```
sage: RibbonTableau(expr=[[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```
length()

Return the length of the ribbons into a ribbon tableau.

EXAMPLES:

```python
sage: RibbonTableau([[None, 1], [2, 3]]).length()
1
sage: RibbonTableau([[1, 0], [2, 0]]).length()
2
```

to_word()

Return a word obtained from a row reading of self.

WARNING: Unlike the to_word method on skew tableaux (which are a superclass of this), this method does not filter out None entries.

EXAMPLES:

```python
sage: R = RibbonTableau([[0, 0, 3, 0], [1, 1, 0], [2, 0, 4]])
sage: R.to_word()
word: 2041100030
```

class sage.combinat.ribbon_tableau.RibbonTableau_class(parent, st)

Bases: RibbonTableau

This exists solely for unpickling RibbonTableau_class objects.

class sage.combinat.ribbon_tableau.RibbonTableaux

Bases: UniqueRepresentation, Parent

Ribbon tableaux.

A ribbon tableau is a skew tableau whose skew shape is tiled by ribbons of length length. The weight is calculated from the labels on the ribbons.

Note: Here we impose the condition that the ribbon tableaux are semistandard.

INPUT(Optional):

- shape – skew shape as a list of lists or an object of type SkewPartition
- length – integer, shape is partitioned into ribbons of length length
- weight – list of integers, computed from the values of non-zero entries labeling the ribbons

EXAMPLES:

```python
sage: RibbonTableaux([[2, 1], []], [1, 1, 1], 1)
Ribbon tableaux of shape [2, 1] / [] and weight [1, 1, 1] with 1-ribbons
sage: R = RibbonTableaux([[5, 4, 3], [2, 1]], [2, 1], 3)
sage: for i in R: i.pp(); print('
')
  . 0 0 0
  . 0 0 2
  1 0 1
```
REFERENCES:

Element
alias of RibbonTableau

from_expr(l)
Return a RibbonTableau from a MuPAD-Combinat expr for a skew tableau. The first list in expr is the
inner shape of the skew tableau. The second list are the entries in the rows of the skew tableau from bottom
to top.
Provided primarily for compatibility with MuPAD-Combinat.
EXAMPLES:

```
sage: RibbonTableaux().from_expr([[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

options = Current options for Tableaux - ascii_art: repr - convention: English-
display: list - latex: diagram

class sage.combinat.ribbon_tableau.RibbonTableaux_shape_weight_length(shape, weight, length)
Bases: RibbonTableaux
Ribbon tableaux of a given shape, weight, and length.
cardinality()
Return the cardinality of self.
EXAMPLES:

```
sage: RibbonTableaux([[2,1],[[]],[1,1,1],[1]]).cardinality()
2
sage: RibbonTableaux([[2,2],[[]],[1,1,2]]).cardinality()
2
sage: RibbonTableaux([[4,3],[[]],[2,1,1,1,2]]).cardinality()
5
```

class sage.combinat.ribbon_tableau.SemistandardMultiSkewTableaux(shape, weight)
Bases: MultiSkewTableaux
Semistandard multi skew tableaux.
A multi skew tableau is a k-tuple of skew tableaux of given shape with a specified total weight.
EXAMPLES:
```sage
S = SemistandardMultiSkewTableaux([[[2,1],[[]]], [[2,2],[[1]]],[[2,2,2]]]; S
Semistandard multi skew tableaux of shape [[2, 1] / [], [2, 2] / [1]] and weight [2, → 2, 2]
sage: S.list()
[[[None, 2], [3, 3]],
[[None, 2], [3, 3]],
[[None, 2], [2, 3]],
[[None, 2], [2, 3]],
[[None, 2], [2, 3]],
[[None, 2], [1, 3]],
[[None, 2], [1, 3]],
[[None, 2], [1, 3]],
[[None, 1], [2, 3]],
[[None, 1], [2, 3]],
[[None, 1], [1, 3]],
[[None, 1], [1, 2]],
[[None, 1], [1, 2]]]
sage.combinat.ribbon_tableau.cospin_polynomial(part, weight, length)
Return the cospin polynomial associated to part, weight, and length.
EXAMPLES:
```
```sage
sage: from sage.combinat.ribbon_tableau import cospin_polynomial
sage: cospin_polynomial([6,6,6],[4,2],3)
t^4 + t^3 + 2*t^2 + t + 1
sage: cospin_polynomial([3,3,3,2,1], [3,1], 3)
t + 1
sage: cospin_polynomial([3,3,3,2,1], [2,2], 3)
t + 2
sage: cospin_polynomial([3,3,3,2,1], [2,1,1], 3)
t^2 + 2*t^2 + 3
sage: cospin_polynomial([3,3,3,2,1], [1,1,1,1], 3)
t^3 + 3*t^2 + 5*t + 3
sage: cospin_polynomial([5,4,3,2,1,1,1], [2,2,1], 3)
2*t^2 + 6*t + 2
sage: cospin_polynomial([[6]*6, [3,3]], [4,4,2], 3)
3*t^4 + 6*t^3 + 9*t^2 + 5*t + 3
```
```sage
cospin_polynomial(part, weight, length)
```
```sage
sage.combinat.ribbon_tableau.count_rec(nexts, current, part, weight, length)
INPUT:
• nexts, current, part – skew partitions
• weight – non-negative integer list
• length – integer
```
```sage
count_rec(nexts, current, part, weight, length)
```
```sage
sage.combinat.ribbon_tableau.graph_implementation_rec(skp, weight, length, function)
sage.combinat.ribbon_tableau.insertion_tableau(skp, perm, evaluation, tableau, length)
INPUT:
• skp – skew partitions
• perm, evaluation – non-negative integers
• tableau – skew tableau
• length – integer
```
```sage
```
5.1. Comprehensive Module List
2163
sage.combinat.ribbon_tableau.list_rec(nexts, current, part, weight, length)

INPUT:
- nexts, current, part – skew partitions
- weight – non-negative integer list
- length – integer

sage.combinat.ribbon_tableau.spin_polynomial(part, weight, length)

Returns the spin polynomial associated to part, weight, and length.

EXAMPLES:

```
sage: from sage.combinat.ribbon_tableau import spin_polynomial
sage: spin_polynomial([6,6,6],[4,2],3)
t^6 + t^5 + 2*t^4 + t^3 + t^2
sage: spin_polynomial([6,6,6],[4,1,1],3)
t^6 + 2*t^5 + 3*t^4 + 2*t^3 + t^2
sage: spin_polynomial([3,3,3,2,1], [2,2], 3)
t^(7/2) + t^(5/2)
sage: spin_polynomial([3,3,3,2,1], [2,1,1], 3)
2*t^7 + 2*t^5 + t^3
sage: spin_polynomial([3,3,3,2,1], [1,1,1,1], 3)
3*t^7 + 5*t^5 + 3*t^3 + sqrt(t)
sage: spin_polynomial([5,4,3,2,1,1,1], [2,2,1], 3)
2*t^9 + 6*t^7 + 2*t^5
sage: spin_polynomial([3,3,3,2,1,1], [2,2,1], 3)
3*t^9 + 5*t^8 + 9*t^7 + 6*t^6 + 3*t^5
```

sage.combinat.ribbon_tableau.spin_polynomial_square(part, weight, length)

Returns the spin polynomial associated with part, weight, and length, with the substitution \( t \rightarrow t^2 \) made.

EXAMPLES:

```
sage: from sage.combinat.ribbon_tableau import spin_polynomial_square
sage: spin_polynomial_square([6,6,6],[4,2],3)
t^12 + t^10 + 2*t^8 + t^6 + t^4
sage: spin_polynomial_square([6,6,6],[4,1,1],3)
t^12 + 2*t^10 + 3*t^8 + 2*t^6 + t^4
sage: spin_polynomial_square([3,3,3,2,1], [2,2], 3)
t^7 + t^5
sage: spin_polynomial_square([3,3,3,2,1], [2,1,1], 3)
2*t^7 + 2*t^5 + t^3
sage: spin_polynomial_square([3,3,3,2,1], [1,1,1,1], 3)
3*t^7 + 5*t^5 + 3*t^3 + t
sage: spin_polynomial_square([5,4,3,2,1,1,1], [2,2,1], 3)
2*t^9 + 6*t^7 + 2*t^5
sage: spin_polynomial_square([3,3,3,2,1,1], [2,2,1], 3)
3*t^9 + 5*t^8 + 9*t^7 + 6*t^6 + 3*t^5
```

sage.combinat.ribbon_tableau.spin_rec(t, nexts, current, part, weight, length)

Routine used for constructing the spin polynomial.

INPUT:
- weight – list of non-negative integers
- length – the length of the ribbons we're tiling with
- t – the variable

EXAMPLES:

```python
sage: from sage.combinat.ribbon_tableau import spin_rec
sage: sp = SkewPartition
sage: t = ZZ['t'].gen()

sage: spin_rec(t, [[]], [[[[]], [3, 3]]], sp([[2, 2, 2], []]), [2], 3)
[t^4]

sage: spin_rec(t, [[0]], [[2, 1, 1, 1, 1], [0, 3]], [[2, 2, 2], [3, 0]], sp([[2, 2, 2, 1], []]), [2, 1], 3)
[t^5]

sage: spin_rec(t, [[]], [[[[]], [3, 3, 0]]], sp([[3, 3], []]), [2], 3)
[t^2]

sage: spin_rec(t, [[t^4], [t^3], [t^2]], [[2, 2, 2, 0, 0, 3]], [[3, 2, 2, 1, 0, 0, 3]], sp([[3, 3, 3], []]), [2, 1], 3)
[t^6 + t^4 + t^2]

sage: spin_rec(t, [[t^5], [t^4], [t^6 + t^4 + t^2]], [[2, 2, 2, 1, 0, 0, 3]], [[3, 3, 1, 1, 1, 0, 0, 0]], sp([[3, 3, 3, 2, 1], []]), [2, 1, 1], 3)
[2*t^7 + 2*t^5 + t^3]
```

### 5.1.196 Rigged configurations

**Todo:** Proofread / point to the main classes rather than the modules?

- Crystal of Rigged Configurations
- Rigged Configurations of \(B(\infty)\)
- Rigged Configurations
- Rigged Configuration Elements
- Tensor Product of Kirillov-Reshetikhin Tableaux

Bijections

- **Bijection between rigged configurations and KR tableaux**
- **Abstract classes for the rigged configuration bijections**
  - **Bijection classes for type $A_n^{(1)}$**
  - **Bijection classes for type $B_n^{(1)}$**
  - **Bijection classes for type $C_n^{(1)}$**
  - **Bijection classes for type $D_n^{(1)}$**
  - **Bijection classes for type $A_{2n-1}^{(2)}$.**
  - **Bijection classes for type $A_{2n}^{(2)}$.**
  - **Bijection classes for type $A_{2n}^{(2)\dagger}$**
  - **Bijection classes for type $D_{n+1}^{(2)}$.**
  - **Bijection classes for type $D_4^{(3)}$.**
- **Bijection between rigged configurations for $B(\infty)$ and marginally large tableaux**

### 5.1.197 Abstract classes for the rigged configuration bijections

This file contains two sets of classes, one for the bijection from KR tableaux to rigged configurations and the other for the reverse bijection. We do this for two reasons, one is because we can store a state in the bijection locally, so we do not have to constantly pass it around between functions. The other is because it makes the code easier to read in the *_element.py files.

These classes are not meant to be used by the user and are only supposed to be used internally to perform the bijections between `TensorProductOfKirillovReshetikhinTableaux` and `RiggedConfigurations`.

**AUTHORS:**

```python
class sage.combinat.rigged_configurations.bij_abstract_class.KRTToRCBijectionAbstract(tp_krt):
    Bases: object
    Root abstract class for the bijection from KR tableaux to rigged configurations.

    This class holds the state of the bijection and generates the next state. This class should never be created directly.

    next_state(val)
        Build the next state in the bijection.

        INPUT:
        - val – The value we are adding

    run(overwrite=False)
        Run the bijection from a tensor product of KR tableaux to a rigged configuration.

        INPUT:
        - tp_krt – A tensor product of KR tableaux
        - overwrite – (Default: False) Display each step in the bijection
```

**EXAMPLES:**
```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 4, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_A import RKTToRCBijectionTypeA
sage: RKTToRCBijectionTypeA(KRT(pathlist=[[5,2]])).run()
-1[-1]
1[ ]1
0[ ]0
-1[-1]
```

class sage.combinat.rigged_configurations.bij_abstract_class.RCToKRTBijectionAbstract(RC_element)
    Bases: object

    Root abstract class for the bijection from rigged configurations to tensor product of Kirillov-Reshetikhin tableaux. This class holds the state of the bijection and generates the next state. This class should never be created directly.

    next_state(height)
        Build the next state in the bijection.

    run(verbos=True, build_graph=False)
        Run the bijection from rigged configurations to tensor product of KR tableaux.

        INPUT:

        • verbose – (default: False) display each step in the bijection
        • build_graph – (default: False) build the graph of each step of the bijection

        EXAMPLES:
```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 1]])
sage: x = RC(partition_list=[[1],[1],[1],[1]])
sage: from sage.combinat.rigged_configurations.bij_type_A import RCToKRTBijectionTypeA
    RCToKRTBijectionTypeA(x).run()
    [[2], [5]]
sage: bij = RCToKRTBijectionTypeA(x)
sage: bij.run(build_graph=True)
    [[2], [5]]
sage: bij._graph
    Digraph on 3 vertices
```
5.1.198 Bijection between rigged configurations for $B(\infty)$ and marginally large tableaux

AUTHORS:
- Travis Scrimshaw (2015-07-01): Initial version

REFERENCES:

class sage.combinat.rigged_configurations.bij_infinity.FromRCIsomorphism
   Bases: Morphism
   Crystal isomorphism of $B(\infty)$ in the rigged configuration model to the tableau model.

class sage.combinat.rigged_configurations.bij_infinity.FromTableauIsomorphism
   Bases: Morphism
   Crystal isomorphism of $B(\infty)$ in the tableau model to the rigged configuration model.

class sage.combinat.rigged_configurations.bij_infinity.MLTToRCBijectionTypeB(tp_krt)
   Bases: KRTToRCBijectionTypeB
   run()
   Run the bijection from a marginally large tableaux to a rigged configuration.

   EXAMPLES:

   sage: vct = CartanType(['B',4]).as_folding()
   sage: RC = crystals.infinity.RiggedConfigurations(vct)
   sage: T = crystals.infinity.Tableaux(['B',4])
   sage: Psi = T.crystal_morphism({T.module_generators[0]: RC.module_generators[0]})
   sage: TS = [x.value for x in T.subcrystal(max_depth=4)]
   sage: all(Psi(b) == RC(b) for b in TS) # long time # indirect doctest
   True

   class sage.combinat.rigged_configurations.bij_infinity.MLTToRCBijectionTypeD(tp_krt)
   Bases: KRTToRCBijectionTypeD
   run()
   Run the bijection from a marginally large tableaux to a rigged configuration.

   EXAMPLES:

   sage: RC = crystals.infinity.RiggedConfigurations(['D',4])
   sage: T = crystals.infinity.Tableaux(['D',4])
   sage: Psi = T.crystal_morphism({T.module_generators[0]: RC.module_generators[0]})
   sage: TS = [x.value for x in T.subcrystal(max_depth=4)]
   sage: all(Psi(b) == RC(b) for b in TS) # long time # indirect doctest
   True

   class sage.combinat.rigged_configurations.bij_infinity.RCToMLTBijectionTypeB(RC_element)
   Bases: RCToKRTBijectionTypeB
   run()
   Run the bijection from rigged configurations to a marginally large tableau.

   EXAMPLES:
class sage.combinat.rigged_configurations.bij_infinity.RCToMLTBijectionTypeD(RC_element)
    Bases: RCToKRTBijectionTypeD

    run()
    Run the bijection from rigged configurations to a marginally large tableau.
    EXAMPLES:

    sage: RC = crystals.infinity.RiggedConfigurations(['D',4])
    sage: T = crystals.infinity.Tableaux(['D',4])
    sage: Psi = RC.crystal_morphism({RC.module_generators[0]: T.module_generators[0]})
    sage: RCS = [x.value for x in RC.subcrystal(max_depth=4)]
    sage: all(Psi(nu) == T(nu) for nu in RCS) # long time # indirect doctest
    True

5.1.199 Bijection classes for type $A_n^{(1)}$

Part of the (internal) classes which run the bijection between rigged configurations and tensor products of Kirillov-Reshetikhin tableaux of type $A_n^{(1)}$.

AUTHORS:

class sage.combinat.rigged_configurations.bij_type_A.KRTToRCBijectionTypeA(tp_krt)
    Bases: KRTToRCBijectionAbstract

    next_state(val)
    Build the next state for type $A_n^{(1)}$.
    EXAMPLES:

    sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 4, 1], [[2,1]])
    sage: from sage.combinat.rigged_configurations.bij_type_A import KRTToRCBijectionTypeA
    sage: bijection = KRTToRCBijectionTypeA(KRT(pathlist=[[4,3]]))
    sage: bijection.cur_path.insert(0, [])
    sage: bijection.cur_dims.insert(0, [0, 1])
    sage: bijection.cur_path[0].insert(0, [3])
    sage: bijection.next_state(3)
class sage.combinat.rigged_configurations.bij_type_A.RCToKRTBijectionTypeA(RC_element)
    Bases: RCToKRTBijectionAbstract
    Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $A_n(1)$.

    next_state(height)
    Build the next state for type $A_n(1)$.

EXAMPLES:

    sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 1]])
    sage: from sage.combinat.rigged_configurations.bij_type_A import RCToKRTBijectionTypeA
    sage: bijection = RCToKRTBijectionTypeA(RC(partition_list=[[1], [1], [1], [1]]))
    sage: bijection.next_state(1)
    5

5.1.200 Bijection classes for type $A_{2n}^{(2)\dagger}$

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $A_{2n}^{(2)\dagger}$.

AUTHORS:

- Travis Scrimshaw (2012-12-21): Initial version

class sage.combinat.rigged_configurations.bij_type_A2_dual.KRTToRCBijectionTypeA2Dual(tp_krt)
    Bases: KRTToRCBijectionTypeC
    Specific implementation of the bijection from KR tableaux to rigged configurations for type $A_{2n}^{(2)\dagger}$.

This inherits from type $C_n(1)$ because we use the same methods in some places.

    next_state(val)
    Build the next state for type $A_{2n}^{(2)\dagger}$.

class sage.combinat.rigged_configurations.bij_type_A2_dual.RCToKRTBijectionTypeA2Dual(RC_element)
    Bases: RCToKRTBijectionTypeC
    Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $A_{2n}^{(2)\dagger}$.

    next_state(height)
    Build the next state for type $A_{2n}^{(2)\dagger}$.

5.1.201 Bijection classes for type $A_{2n}^{(2)}$

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $A_{2n}^{(2)}$.

AUTHORS:

- Travis Scrimshaw (2012-12-21): Initial version
class sage.combinat.rigged_configurations.bij_type_A2_even.KRTToRCBijectionTypeA2Even(tp_krt)
    Bases: KRTToRCBijectionTypeC
    Specific implementation of the bijection from KR tableaux to rigged configurations for type $A_{2n}^{(2)}$.
    This inherits from type $C_n^{(1)}$ because we use the same methods in some places.
    next_state(val)
        Build the next state for type $A_{2n}^{(2)}$.

class sage.combinat.rigged_configurations.bij_type_A2_even.RCToKRTBijectionTypeA2Even(RC_element)
    Bases: RCToKRTBijectionTypeC
    Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $A_{2n}^{(2)}$.
    next_state(height)
        Build the next state for type $A_{2n}^{(2)}$.

5.1.202 Bijection classes for type $A_{2n-1}^{(2)}$.

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $A_{2n-1}^{(2)}$.

AUTHORS:
• Travis Scrimshaw (2012-12-21): Initial version

class sage.combinat.rigged_configurations.bij_type_A2_odd.KRTToRCBijectionTypeA2Odd(tp_krt)
    Bases: KRTToRCBijectionTypeA
    Specific implementation of the bijection from KR tableaux to rigged configurations for type $A_{2n-1}^{(2)}$.
    This inherits from type $A_n^{(1)}$ because we use the same methods in some places.
    next_state(val)
        Build the next state for type $A_{2n-1}^{(2)}$.

class sage.combinat.rigged_configurations.bij_type_A2_odd.RCToKRTBijectionTypeA2Odd(RC_element)
    Bases: RCToKRTBijectionTypeA
    Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $A_{2n-1}^{(2)}$.
    next_state(height)
        Build the next state for type $A_{2n-1}^{(2)}$.

5.1.203 Bijection classes for type $B_n^{(1)}$.

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $B_n^{(1)}$.

AUTHORS:
• Travis Scrimshaw (2012-12-21): Initial version
class sage.combinat.rigged_configurations.bij_type_B.KRTToRCBijectionTypeB(tp_krt)

Bases: KRTToRCBijectionTypeC

Specific implementation of the bijection from KR tableaux to rigged configurations for type $B_{n}^{(1)}$.

next_state(val)

Build the next state for type $B_{n}^{(1)}$.

other_outcome(rc, pos_val, width_n)

Do the other case $(QS)$ possibility.

This arises from the ambiguity when we found a singular string at the max width in $\nu^{(n)}$. We had first attempted case $(S)$, and if that resulted in an invalid rigged configuration, we now finish the bijection using case $(QS)$.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['B',3,1], [[2,1],[1,2]])
sage: rc = RC(partition_list=[[2,1], [2,1,1], [5,1]])
sage: t = rc.to_tensor_product_of_kirillov_reshetikhin_tableaux()
sage: t.to_rigged_configuration() == rc
# indirect doctest
True
```

run(verbos=False)

Run the bijection from a tensor product of KR tableaux to a rigged configuration.

INPUT:

- `tp_krt` – A tensor product of KR tableaux
- `verbose` – (Default: False) Display each step in the bijection

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.bij_type_B import KRTToRCBijectionTypeB
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['B', 3, 1],-
->[2, 1])
sage: KRTToRCBijectionTypeB(KRT(pathlist=[[0,3]])).run()
0 0
-1 -1
-1 -1
0 0

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['B', 3, 1],-
->[3, 1])
sage: KRTToRCBijectionTypeB(KRT(pathlist=[[-2,3,1]])).run()
(1/)
-1 -1
0 0
```

2172 Chapter 5. Comprehensive Module List
class sage.combinat.rigged_configurations.bij_type_B.RCToKRTBijectionTypeB(RC_element)
Bases: RCToKRTBijectionTypeC

Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $B_n^{(1)}$.

**next_state(height)**
Build the next state for type $B_n^{(1)}$.

**run(verbose=False, build_graph=False)**
Run the bijection from rigged configurations to tensor product of KR tableaux for type $B_n^{(1)}$.

**INPUT:**
- verbose – (default: False) display each step in the bijection
- build_graph – (default: False) build the graph of each step of the bijection

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['B', 3, 1], [[2, 1]])
\rightarrow RCToKRTBijectionTypeB
sage: RCToKRTBijectionTypeB(RC(partition_list=[[1],[1],[1]])).run()
[[3], [0]]

sage: RC = RiggedConfigurations(['B', 3, 1], [[3, 1]])

sage: x = RC(partition_list=[[1],[1],[1]])

sage: RCToKRTBijectionTypeB(x).run()
[[1], [3], [-2]]

sage: bij = RCToKRTBijectionTypeB(x)

sage: bij.run(build_graph=True)
[[1], [3], [-2]]

sage: bij._graph
Digraph on 6 vertices
```

### 5.1.204 Bijection classes for type $C_n^{(1)}$

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $C_n^{(1)}$.

**AUTHORS:**
- Travis Scrimshaw (2012-12-21): Initial version

class sage.combinat.rigged_configurations.bij_type_C.KRTToRCBijectionTypeC(tp_krt)
Bases: KRTToRCBijectionTypeA

Specific implementation of the bijection from KR tableaux to rigged configurations for type $C_n^{(1)}$.

This inherits from type $A_n^{(1)}$ because we use the same methods in some places.

**next_state(val)**
Build the next state for type $C_n^{(1)}$.  

5.1. Comprehensive Module List 2173
class sage.combinat.rigged_configurations.bij_type_C.RCToKRTBijectionTypeC(RC_element)
    Bases: RCToKRTBijectionTypeA

    Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $C_n^{(1)}$.

    next_state(height)
        Build the next state for type $C_n^{(1)}$.

5.1.205 Bijection classes for type $D_n^{(1)}$

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $D_n^{(1)}$.

AUTHORS:

class sage.combinat.rigged_configurations.bij_type_D.KRTToRCBijectionTypeD(tp_krt)
    Bases: KRTToRCBijectionTypeA

    Specific implementation of the bijection from KR tableaux to rigged configurations for type $D_n^{(1)}$.
    This inherits from type $A_n^{(1)}$ because we use the same methods in some places.

doubling_map()
    Perform the doubling map of the rigged configuration at the current state of the bijection.
    This is the map $B(\Lambda) \mapsto B(2\Lambda)$ which doubles each of the rigged partitions and updates the vacancy numbers accordingly.

halving_map()
    Perform the halving map of the rigged configuration at the current state of the bijection.
    This is the inverse map to $B(\Lambda) \mapsto B(2\Lambda)$ which halves each of the rigged partitions and updates the vacancy numbers accordingly.

next_state(val)
    Build the next state for type $D_n^{(1)}$.

run(verbose=False)
    Run the bijection from a tensor product of KR tableaux to a rigged configuration for type $D_n^{(1)}$.

    INPUT:
    * tp_krt -- A tensor product of KR tableaux
    * verbose -- (Default: False) Display each step in the bijection

    EXAMPLES:

    sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[2,1]])
    sage: from sage.combinat.rigged_configurations.bij_type_D import KRTToRCBijectionTypeD
    sage: KRTToRCBijectionTypeD(KRT(pathlist=[[[-3,2]]])).run()
    -1[ ]-1
class sage.combinat.rigged_configurations.bij_type_D.RCToKRTBijectionTypeD(RC_element)

Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $D_n^{(1)}$.

doubling_map()

Perform the doubling map of the rigged configuration at the current state of the bijection.

This is the map $B(\Lambda) \mapsto B(2\Lambda)$ which doubles each of the rigged partitions and updates the vacancy numbers accordingly.

halving_map()

Perform the halving map of the rigged configuration at the current state of the bijection.

This is the inverse map to $B(\Lambda) \mapsto B(2\Lambda)$ which halves each of the rigged partitions and updates the vacancy numbers accordingly.

next_state(height)

Build the next state for type $D_n^{(1)}$.

run(verbos=False, build_graph=False)

Run the bijection from rigged configurations to tensor product of KR tableaux for type $D_n^{(1)}$.

INPUT:

• verbose – (default: False) display each step in the bijection

• build_graph – (default: False) build the graph of each step of the bijection

EXAMPLES:

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 1]])
sage: x = RC(partition_list=[[1], [1], [1], [1]])
sage: from sage.combinat.rigged_configurations.bij_type_D import RCToKRTBijectionTypeD
sage: RCToKRTBijectionTypeD(x).run()
[[2], [-3]]
sage: bij = RCToKRTBijectionTypeD(x)
sage: bij.run(build_graph=True)
[[2], [-3]]
sage: bij._graph
Digraph on 3 vertices
```
5.1.206 Bijection classes for type $D_{n+1}^{(2)}$

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $D_{n+1}^{(2)}$.

AUTHORS:

    next_state(height)
        Build the next state for type $D_4^{(3)}$.
```

5.1.208 Bijection between rigged configurations and KR tableaux

Functions which are big switch statements to create the bijection class of the correct type.

AUTHORS:

- Travis Scrimshaw (2012-12-21): Added all non-exceptional bijection types
- Travis Scrimshaw (2014-09-10): Added type $D_4^{(3)}$

```python
sage.combinat.rigged_configurations.bijection.KRTToRCBijection(tp_krt)
    Return the correct KR tableaux to rigged configuration bijection helper class.

class sage.combinat.rigged_configurations.bijection.RCToKRTBijection(rc_elt):
    Return the correct rigged configuration to KR tableaux bijection helper class.
```

5.1. Comprehensive Module List 2177
5.1.209 Kleber Trees

A Kleber tree is a tree of weights generated by Kleber’s algorithm [Kleber1]. The nodes correspond to the weights in the positive Weyl chamber obtained by subtracting a (non-zero) positive root. The edges are labeled by the coefficients of the roots of the difference.

AUTHORS:
- Travis Scrimshaw (2011-05-03): Initial version
- Travis Scrimshaw (2013-02-13): Added support for virtual trees and improved LaTeX output

EXAMPLES:

```sage
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KleberTree(['A', 3, 1], [[3,2], [2,1], [1,1], [1,1]])
Kleber tree of Cartan type ['A', 3, 1] and B = ((3, 2), (2, 1), (1, 1), (1, 1))
sage: KleberTree(['D', 4, 1], [[2,2]])
Kleber tree of Cartan type ['D', 4, 1] and B = ((2, 2),)
```

class `sage.combinat.rigged_configurations.kleber_tree.KleberTree`(cartan_type, B, classical_ct)

Bases: `UniqueRepresentation`, `Parent`

The tree that is generated by Kleber’s algorithm.

A Kleber tree is a tree of weights generated by Kleber’s algorithm [Kleber1]. It is used to generate the set of all admissible rigged configurations for the simply-laced affine types $A_{1}^{(1)}, D_{n}^{(1)}, E_{6}^{(1)}, E_{7}^{(1)},$ and $E_{8}^{(1)}$.

See also:
There is a modified version for non-simply-laced affine types at `VirtualKleberTree`.

The nodes correspond to the weights in the positive Weyl chamber obtained by subtracting a (non-zero) positive root. The edges are labeled by the coefficients of the roots, and $X$ is a child of $Y$ if $Y$ is the root else if the edge label of $Y$ to its parent $Z$ is greater (in every component) than the label from $X$ to $Y$.

For a Kleber tree, one needs to specify an affine (simply-laced) Cartan type and a sequence of pairs $(r, s)$, where $s$ is any positive integer and $r$ is a node in the Dynkin diagram. Each $(r, s)$ can be viewed as a rectangle of width $s$ and height $r$.

INPUT:

- `cartan_type` – an affine simply-laced Cartan type
- `B` – a list of dimensions of rectangles by $[r, c]$ where $r$ is the number of rows and $c$ is the number of columns

REFERENCES:

EXAMPLES:

Simply-laced example:

```sage
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A', 3, 1], [[3,2], [1,1]])
sage: KT.list()
[Kleber tree node with weight [1, 0, 2] and upwards edge root [0, 0, 0],
 Kleber tree node with weight [0, 0, 1] and upwards edge root [1, 1, 1]]
sage: KT = KleberTree(['A', 3, 1], [[3,2], [2,1], [1,1], [1,1]])
sage: KT.cardinality()
10
sage: KT = KleberTree(['D', 4, 1], [[2,2]])
```

(continues on next page)
sage: KT.cardinality()
3
sage: KT = KleberTree(['D', 4, 1], [[4,5]])

sage: KT.cardinality()
1

From [Kleber2]:

sage: KT = KleberTree(['E', 6, 1], [[4, 2]])  # long time (9s on sage.math, 2012)

sage: KT.cardinality()  # long time
12

We check that relabelled types work (github issue #16876):

sage: ct = CartanType(['A',3,1]).relabel(lambda x: x+2)
sage: kt = KleberTree(ct, [[3,1],[5,1]])

sage: list(kt)
[Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 0, 0],
 Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 1, 1]]

sage: kt = KleberTree(['A',3,1], [[1,1],[3,1]])

sage: list(kt)
[Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 0, 0],
 Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 1, 1]]

Element
alias of KleberTreeNode

breadth_first_iter()
Iterate over all nodes in the tree following a breadth-first traversal.

EXAMPLES:

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A', 3, 1], [[2, 2], [2, 3]])
sage: for x in KT.breadth_first_iter(): x
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 0, 0],
Kleber tree node with weight [1, 3, 1] and upwards edge root [0, 1, 0],
Kleber tree node with weight [2, 1, 2] and upwards edge root [0, 1, 0],
Kleber tree node with weight [1, 1, 1] and upwards edge root [1, 2, 1]
```

cartan_type()
Return the Cartan type of this Kleber tree.

EXAMPLES:

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
da
```

depth_first_iter()
Iterate (recursively) over the nodes in the tree following a depth-first traversal.
**EXAMPLES:**

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A', 3, 1], [[2, 2], [2, 3]])
sage: for x in KT.depth_first_iter(): x
Kleber tree node with weight [0, 5, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 3, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [2, 1, 2] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 3, 0] and upwards edge root [1, 2, 1]
Kleber tree node with weight [1, 1, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 1, 0] and upwards edge root [1, 2, 1]
```

**digraph()**

Return a DiGraph representation of this Kleber tree.

**EXAMPLES:**

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['D', 4, 1], [[2, 2]])
sage: KT.digraph()
Digraph on 3 vertices
```

**latex_options(** options **)**

Return the current latex options if no arguments are passed, otherwise set the corresponding latex option.

**OPTIONS:**

- `hspace` – (default: 2.5) the horizontal spacing of the tree nodes
- `vspace` – (default: $x$) the vertical spacing of the tree nodes, here $x$ is the minimum of $\frac{2.5}{n}$ or $\frac{7.5}{n}$ where $n$ is the rank of the classical type
- `edge_labels` – (default: True) display edge labels
- `use_vector_notation` – (default: False) display edge labels using vector notation instead of a linear combination

**EXAMPLES:**

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['D', 3, 1], [[2, 1], [2, 1]])
sage: KT.latex_options(vspace=-4, use_vector_notation=True)
sage: sorted(KT.latex_options().items())
[('edge_labels', True), ('hspace', 2.5), ('use_vector_notation', True), ('vspace →', -4)]
```

**plot(** options **)**

Return the plot of self as a directed graph.

**EXAMPLES:**

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['D', 4, 1], [[2, 2]])
sage: print(KT.plot())
Graphics object consisting of 8 graphics primitives
```

**class** `sage.combinat.rigged_configurations.kleber_tree.KleberTreeNode(parent_obj, node_weight, dominant_root, parent_node=None)`
Bases: Element
A node in the Kleber tree.
This class is meant to be used internally by the Kleber tree class and should not be created directly by the user.
For more on the Kleber tree and the nodes, see KleberTree.
The dominating root is the up_root which is the difference between the parent node’s weight and this node’s weight.

INPUT:
• parent_obj – The parent object of this element
• node_weight – The weight of this node
• dominant_root – The dominating root
• parent_node – (default:None) The parent node of this node

depth()
Return the depth of this node in the tree.

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: RS = RootSystem(['A', 2])
sage: WS = RS.weight_lattice()
sage: R = RS.root_lattice()
sage: KT = KleberTree(['A', 2, 1], [[1,1]])
sage: n = KT(WS.sum_of_terms([[1,5], [2,2]]), R.zero())
sage: n.depth
0
sage: n2 = KT(WS.sum_of_terms([[1,5], [2,2]]), R.zero(), n)
sage: n2.depth
1
```

multiplicity()
Return the multiplicity of self.
The multiplicity of a node $x$ of depth $d$ weight $\lambda$ in a simply-laced Kleber tree is equal to:

$$
\prod_{i>0} \prod_{a \in T} \left( \frac{p_i^{(a)} + m_i^{(a)}}{p_i^{(a)}} \right)
$$

Recall that

$$
m_i^{(a)} = \left( \lambda^{(i-1)} - 2\lambda^{(i)} + \lambda^{(i+1)} \mid \alpha_a \right),
\quad p_i^{(a)} = \left( \alpha_a \mid \lambda^{(i)} \right) - \sum_{j>i} (j-i)L_j^{(a)},
$$

where $\lambda^{(i)}$ is the weight node at depth $i$ in the path to $x$ from the root and we set $\lambda^{(j)} = \lambda$ for all $j \geq d$.

Note that $m_i^{(a)} = 0$ for all $i > d$.  

EXAMPLES:
```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A', 3, 1], [[3,2],[2,1],[1,1],[1,1]])
```
```
sage: for x in KT: x, x.multiplicity()
(Kleber tree node with weight [2, 1, 2] and upwards edge root [0, 0, 0], 1)
(Kleber tree node with weight [3, 0, 1] and upwards edge root [0, 1, 1], 1)
(Kleber tree node with weight [0, 2, 2] and upwards edge root [1, 1, 0], 2)
(Kleber tree node with weight [1, 0, 3] and upwards edge root [1, 1, 0], 2)
(Kleber tree node with weight [1, 1, 1] and upwards edge root [1, 1, 1], 4)
(Kleber tree node with weight [0, 0, 2] and upwards edge root [2, 2, 1], 2)
```
```
class sage.combinat.rigged_configurations.kleber_tree.KleberTreeTypeA2Even(cartan_type, B)
    Bases: VirtualKleberTree
    
    Kleber tree for types $A^{(2)}_{2n}$ and $A^{(2)}_{2n}$.  
    
    Note that here for $A^{(2)}_{2n}$ we use $\tilde{\gamma}_a$ in place of $\gamma_a$  
    in constructing the virtual Kleber tree, and so we end up selecting  
    all nodes since $\tilde{\gamma}_a = 1$ for all $a \in \mathcal{I}$.  
    For type $A^{(2)}_{2n}^\dagger$, we have $\gamma_a = 1$ for all $a \in \mathcal{I}$.  
    
    See also:
    
    VirtualKleberTree

    breadth_first_iter(all_nodes=False)
    
    Iterate over all nodes in the tree following a breadth-first traversal.
    
    INPUT:
    
    • all_nodes – (default: False) if True, output all nodes in the tree
    
    EXAMPLES:

    ```python
    sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
    sage: KT = VirtualKleberTree(['A', 4, 2], [[2,1]])
    sage: for x in KT.breadth_first_iter(): x
    Kleber tree node with weight [0, 2, 0] and upwards edge root [0, 0, 0]
    Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
    Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 2, 1]
    sage: for x in KT.breadth_first_iter(True): x
    Kleber tree node with weight [0, 2, 0] and upwards edge root [0, 0, 0]
    Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
    Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 2, 1]
    ```
```
```
    depth_first_iter(all_nodes=False)
    
    Iterate (recursively) over the nodes in the tree following a depth-first traversal.
    
    INPUT:
    
    • all_nodes – (default: False) if True, output all nodes in the tree
    
    EXAMPLES:
```
```
sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree

sage: KT = VirtualKleberTree(['A', 4, 2], [[2,1]])
sage: for x in KT.depth_first_iter(): x
Kleber tree node with weight [0, 2, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 2, 1]
sage: for x in KT.depth_first_iter(True): x
Kleber tree node with weight [0, 2, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 2, 1]

class sage.combinat.rigged_configurations.kleber_tree.VirtualKleberTree(cartan_type, B)

    Bases: KleberTree

    A virtual Kleber tree.

    We can use a modified version of the Kleber algorithm called the virtual Kleber algorithm [OSS03] to compute all admissible rigged configurations for non-simply-laced types. This uses the following embeddings into the simply-laced types:

    \[
    \begin{align*}
    C_n^{(1)} &\rightarrow A_{2n}^{(2)}; \\
    A_{2n}^{(2)} &\rightarrow A_{2n-1}^{(1)}; \\
    D_{n+1}^{(2)} &\rightarrow A_{2n-1}^{(1)}; \\
    B_n^{(1)} &\rightarrow D_{n+1}^{(1)}; \\
    E_6^{(2)} &\rightarrow E_6^{(1)}; \\
    F_4^{(1)} &\rightarrow D_4^{(1)}; \\
    D_4^{(3)} &\rightarrow G_2^{(1)}.
    \end{align*}
    \]

    One then selects the subset of admissible nodes which are translates of the virtual requirements. In the graph, the selected nodes are indicated by brackets [ ].

    Note: Because these are virtual nodes, all information is given in the corresponding simply-laced type.

    See also:

    For more on the Kleber algorithm, see `KleberTree`.

    REFERENCES:

    INPUT:

    • cartan_type – an affine non-simply-laced Cartan type
    • B – a list of dimensions of rectangles by \([r, c]\) where \(r\) is the number of rows and \(c\) is the number of columns

    EXAMPLES:

    sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
    sage: KT = VirtualKleberTree(['C', 4, 1], [[2,2]])
    sage: KT.cardinality()
    3
    sage: KT.base_tree().cardinality()
    6
    sage: KT = VirtualKleberTree(['C', 4, 1], [[4,5]])
    sage: KT.cardinality()
    1
sage: KT = VirtualKleberTree(['D', 5, 2], [[2,1], [1,1]])
sage: KT.cardinality()
8
sage: KT = VirtualKleberTree(CartanType(['A', 4, 2]).dual(), [[1,1], [2,2]])
sage: KT.cardinality()
15

base_tree()

Return the underlying virtual Kleber tree associated to self.

EXAMPLES:

sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
sage: KT = VirtualKleberTree(['C', 2, 1], [[1,1], [2,1]])
sage: KT.base_tree()
Kleber tree of Cartan type ['A', 7, 1] and B = ((2, 2), (6, 2))

breadth_first_iter(all_nodes=False)

Iterate over all nodes in the tree following a breadth-first traversal.

INPUT:

• all_nodes – (default: False) if True, output all nodes in the tree

EXAMPLES:

sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
sage: KT = VirtualKleberTree(['C', 2, 1], [[1,1], [2,1]])
sage: for x in KT.breadth_first_iter(): x
Kleber tree node with weight [1, 2, 1] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
sage: for x in KT.breadth_first_iter(True): x
Kleber tree node with weight [1, 2, 1] and upwards edge root [0, 0, 0]
Kleber tree node with weight [0, 2, 0] and upwards edge root [1, 1, 1]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]

depth_first_iter(all_nodes=False)

Iterate (recursively) over the nodes in the tree following a depth-first traversal.

INPUT:

• all_nodes – (default: False) if True, output all nodes in the tree

EXAMPLES:

sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
sage: KT = VirtualKleberTree(['C', 2, 1], [[1,1], [2,1]])
sage: for x in KT.depth_first_iter(): x
Kleber tree node with weight [1, 2, 1] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
sage: for x in KT.depth_first_iter(True): x
Kleber tree node with weight [1, 2, 1] and upwards edge root [0, 0, 0]
5.1.210 Kirillov-Reshetikhin Tableaux

Kirillov-Reshetikhin tableaux are rectangular tableaux with \( r \) rows and \( s \) columns that naturally arise under the bijection between rigged configurations and tableaux \([\text{RigConBijection}]\). They are in bijection with the elements of the Kirillov-Reshetikhin crystal \( B^{r,s} \) under the (inverse) filling map \([\text{OSS13}]\) \([\text{SS2015}]\). They do not have to satisfy the semistandard row or column restrictions. These tensor products are the result from the bijection from rigged configurations \([\text{RigConBijection}]\).

For more information, see \texttt{KirillovReshetikhinTableaux} and \texttt{TensorProductOfKirillovReshetikhinTableaux}.

\begin{Verbatim}
\text{5.1. Comprehensive Module List} 2185
\end{Verbatim}
Element

alias of KRTableauxSpinElement
class sage.combinat.rigged_configurations.kr_tableaux.KRTableauxRectangle(cartan_type, r, s)
Bases: KirillovReshetikhinTableaux

Kirillov-Reshetikhin tableaux $B_{r,s}$ whose module generator is a single $r \times s$ rectangle.

These are Kirillov-Reshetikhin tableaux $B_{r,s}$ of type:

• $A^{(1)}_n$ for all $1 \leq r \leq n$,
• $C^{(1)}_n$ when $r = n$.

from_kirillov_reshetikhin_crystal(krc)

Construct a KirillovReshetikhinTableauxElement.

EXAMPLES:

sage: KRT = crystals.KirillovReshetikhin(["A", 4, 1], 2, 1, model='KR')
sage: C = crystals.KirillovReshetikhin(["A",4,1], 2, 1, model='KN')
sage: krc = C(4,3); krc
[[3], [4]]
sage: KRT.from_kirillov_reshetikhin_crystal(krc)
[[3], [4]]

class sage.combinat.rigged_configurations.kr_tableaux.KRTableauxSpin(cartan_type, r, s)
Bases: KRTableauxRectangle

Kirillov-Reshetikhin tableaux $B_{r,s}$ of type $D^{(1)}_n$ with $r = n, n-1$.

Element

alias of KRTableauxSpinElement
class sage.combinat.rigged_configurations.kr_tableaux.KRTableauxSpinElement(parent, list, **options)
Bases: KirillovReshetikhinTableauxElement

Kirillov-Reshetikhin tableau for spinors.

Here we are in the embedding $B(\Lambda_n) \hookrightarrow B(2\Lambda_n)$, so $e_i$ and $f_i$ act by $e_i^2$ and $f_i^2$ respectively for all $i \neq 0$. We do this so our columns are full width (as opposed to half width and/or uses a $\pm$ representation).

classical_weight()

Return the classical weight of self.

EXAMPLES:

sage: KRT = crystals.KirillovReshetikhin(["D", 4, 1], 4, 1, model='KR')
sage: KRT.module_generators[0].classical_weight()
(1/2, 1/2, 1/2, 1/2)

e(i)

Calculate the action of $e_i$ on self.

EXAMPLES:
Combinatorics, Release 10.0

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 4, 1, model='KR')
sage: KRT(-1, -4, 3, 2).e(1)
[[1], [3], [-4], [-2]]
sage: KRT(-1, -4, 3, 2).e(3)
[]
```

**epsilon**

Compute $\varepsilon_i$ of self.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 4, 1, model='KR')
sage: KRT(-1, -4, 3, 2).epsilon(1)
1
sage: KRT(-1, -4, 3, 2).epsilon(3)
0
```

**f(i)**

Calculate the action of $f_i$ on self.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 4, 1, model='KR')
sage: KRT(-1, -4, 3, 2).f(1)
[[2], [4], [-3], [-1]]
```

**left_split()**

Return the image of self under the left column splitting map.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 4, 3, model='KR')
sage: elt = KRT(-3,-4,2,1,-3,-4,2,1,-2,-4,3,1); elt.pp()
  1  1  1
  2  2  3
-4 -4 -4
-3 -3 -2
sage: elt.left_split().pp()
  1 (X) 1 1
  2  2  3
-4 -4 -4
-3 -3 -2
```

**phi()**

Compute $\varphi_i$ of self.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 4, 1, model='KR')
sage: KRT(-1, -4, 3, 2).phi(1)
0
sage: KRT(-1, -4, 3, 2).phi(3)
1
```
to_array\(\texttt{(rows=True)}\)

Return a 2-dimensional array representation of this Kirillov-Reshetikhin element.

If the output is in rows, then it outputs the top row first (in the English convention) from left to right.

For example: if the reading word is \([2, 1, 4, 3]\), so as a \(2 \times 2\) tableau:

\[
\begin{array}{cc}
1 & 3 \\
2 & 4
\end{array}
\]

we output \([\begin{array}{c}1, 3 \end{array}, \begin{array}{c}2, 4 \end{array}]\).

If the output is in columns, then it outputs the leftmost column first with the bottom element first. In other words this parses the reading word into its columns.

Continuing with the previous example, the output would be \([\begin{array}{c}2, 1 \end{array}, \begin{array}{c}4, 3 \end{array}]\).

INPUT:

* \texttt{rows} – (Default: \texttt{True}) Set to \texttt{True} if the resulting array is by row, otherwise it is by column.

EXAMPLES:

\[
\begin{align*}
\text{sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 4, 3, model='KR')}\\
\text{sage: elt = KRT(-3,-4,2,1,-3,-4,2,1,-2,-4,3,1)}\\
\text{sage: elt.to_array()}
\end{align*}
\]

\[
\begin{array}{c}
[1, 1, 1] \\
[2, 2, 3] \\
[-4, -4, -4] \\
[-3, -3, -2]
\end{array}
\]

\[
\begin{align*}
\text{sage: elt.to_array(False)}\\
\text{sage: elt.to_array(False)}
\end{align*}
\]

\[
\begin{array}{c}
[-3, -4, 2, 1] \\
[-3, -4, 2, 1] \\
[-2, -4, 3, 1]
\end{array}
\]

class \texttt{sage.combinat.rigged_configurations.kr_tableaux.KRTableauxTypeBox(cartan_type, r, s)}

Bases: \texttt{KRTableauxTypeVertical}

Kirillov-Reshetikhin tableaux \(B^{r,s}\) of type:

- \(A_{2n}^{(2)}\) for all \(r \leq n\),
- \(D_{n+1}^{(2)}\) for all \(r < n\),
- \(D_{4}^{(3)}\) for \(r = 1\).

class \texttt{sage.combinat.rigged_configurations.kr_tableaux.KRTableauxTypeFromRC(cartan_type, r, s)}

Bases: \texttt{KirillovReshetikhinTableaux}

Kirillov-Reshetikhin tableaux \(B^{r,s}\) constructed from rigged configurations under the bijection \(\Phi\).

\textbf{Warning:} The Kashiwara-Nakashima version is not implemented due to the non-trivial multiplicities of classical components, so \texttt{classical_decomposition() does not work.}

Element

alias of \texttt{KRTableauxTypeFromRCElement}

module\_generators()

The module generators of \texttt{self}.

EXAMPLES:
```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 3], 2, 1, model='KR')
sage: KRT.module_generators
([[1], [2]], [[1], [0]], [[1], [E]], [[E], [E]])
```

```python
class sage.combinat.rigged_configurations.kr_tableaux.KRTableauxTypeFromRCElement(parent, list, **options)
```

Bases: `KirillovReshetikhinTableauxElement`

A Kirillov-Reshetikhin tableau constructed from rigged configurations under the bijection $\Phi$.

**e(i)**

Perform the action of $e_i$ on `self`.

**Todo**: Implement a direct action of $e_0$ without moving to rigged configurations.

**Examples**:

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 3], 2, 1, model='KR')
sage: KRT.module_generators[0].e(0)
[[2], [E]]
```

**epsilon(i)**

Compute $\epsilon_i$ of `self`.

**Todo**: Implement a direct action of $\epsilon_0$ without moving to KR crystals.

**Examples**:

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 3], 2, 1, model='KR')
sage: KRT.module_generators[0].epsilon(0)
6
```

**f(i)**

Perform the action of $f_i$ on `self`.

**Todo**: Implement a direct action of $f_0$ without moving to rigged configurations.

**Examples**:

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 3], 2, 1, model='KR')
sage: KRT.module_generators[0].f(0)
sage: KRT.module_generators[3].f(0)
[[1], [0]]
```

**phi(i)**

Compute $\phi_i$ of `self`.

**Todo**: Compute $\phi_0$ without moving to KR crystals.
EXAMPLES:

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,3], 2, 2, model='KR')
sage: KRT.module_generators[0].phi(0)
0
```

class sage.combinat.rigged_configurations.kr_tableaux.KRTableauxTypeHorizontal(cartan_type, r, s):

Bases: `KirillovReshetikhinTableaux`

Kirillov-Reshetikhin tableaux $B^{r,s}$ of type:

- $C_n^{(1)}$ for $1 \leq r < n$,
- $A_{2n-1}^{(2)}$ for $1 \leq r \leq n$.

`from_kirillov_reshetikhin_crystal(krc)`

Construct an element of self from the Kirillov-Reshetikhin crystal element krc.

EXAMPLES:

```python
sage: KRT = crystals.KirillovReshetikhin(['C',4,1], 2, 3, model='KR')
sage: C = crystals.KirillovReshetikhin(['C',4,1], 2, 3, model='KN')
sage: krc = C(4,3); krc
[[3], [4]]
sage: KRT.from_kirillov_reshetikhin_crystal(krc)
[[3, -2, 1], [4, -1, 2]]
```

class sage.combinat.rigged_configurations.kr_tableaux.KRTableauxTypeVertical(cartan_type, r, s):

Bases: `KirillovReshetikhinTableaux`

Kirillov-Reshetikhin tableaux $B^{r,s}$ of type:

- $D_n^{(1)}$ for all $1 \leq r < n - 1$,
- $B_n^{(1)}$ for all $1 \leq r < n$,
- $A_{2n-1}^{(2)}$ for all $1 \leq r \leq n$.

`from_kirillov_reshetikhin_crystal(krc)`

Construct an element of self from the Kirillov-Reshetikhin crystal element krc.

EXAMPLES:

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 3, model='KR')
sage: C = crystals.KirillovReshetikhin(['D',4,1], 2, 3, model='KN')
sage: krc = C(4,3); krc
[[3], [4]]
sage: KRT.from_kirillov_reshetikhin_crystal(krc)
[[3, -2, 1], [4, -1, 2]]
```

class sage.combinat.rigged_configurations.kr_tableaux.KirillovReshetikhinTableaux(cartan_type, r, s):

Bases: `CrystalOfWords`

Kirillov-Reshetikhin tableaux.
Kirillov-Reshetikhin tableaux are rectangular tableaux with \( r \) rows and \( s \) columns that naturally arise under the bijection between rigged configurations and tableaux \([\text{RigConBijection}]\). They are in bijection with the elements of the Kirillov-Reshetikhin crystal \( B^{r,s} \) under the (inverse) filling map.

Whenever \( B^{r,s} \cong B(s\Lambda_r) \) as a classical crystal (which is the case for \( B^{r,s} \) in type \( A_n^{(1)} \), \( B_{n,s} \) in type \( C_{n}^{(1)} \) and \( D_{n+1}^{(2)} \), \( B_{n,s} \) and \( B_{n-1,s} \) in type \( D_{n}^{(1)} \)) then the filling map is trivial.

For \( B^{r,s} \) in:
- \( \text{type } D_{n}^{(1)} \) when \( r \leq n - 2 \),
- \( \text{type } B_{n}^{(1)} \) when \( r < n \),
- \( \text{type } A_{2n-1}^{(2)} \) for all \( r \),
the filling map is defined in \([\text{OSS2011}]\).

For the spinor cases in type \( D_{n}^{(1)} \), the crystal \( B_{k,s} \) where \( k = n - 1 \), \( n \), is isomorphic as a classical crystal to \( B(s\Lambda_k) \), and here we consider the Kirillov-Reshetikhin tableaux as living in \( B(2s\Lambda_k) \) under the natural doubling map. In this case, the crystal operators \( e_i \) and \( f_i \) act as \( e_i^2 \) and \( f_i^2 \) respectively. See \([\text{BijectionDn}]\).

For the spinor case in type \( B_{n}^{(1)} \), the crystal \( B_{n,s} \), we consider the images under the natural doubling map into \( B_{n,2s} \). The classical components of this crystal are now given by removing \( 2 \times 2 \) boxes. The filling map is the same as below (see the non-spin type \( C_{n}^{(1)} \)).

For \( B^{r,s} \) in:
- \( \text{type } C_{n}^{(1)} \) when \( r < n \),
- \( \text{type } A_{2n}^{(2)} \) for all \( r \),
the filling map is given as follows. Suppose we are considering the (classically) highest weight element in the classical component \( B(\lambda) \). Then we fill it in with the horizontal dominoes \([i, i] \) in the \( i \)-th row from the top (in English notation) and reordering the columns so that they are increasing. Recall from above that \( B^{n,s} \cong B(s\Lambda_n) \) in type \( C_{n}^{(1)} \).

For \( B^{r,s} \) in:
- \( \text{type } A_{2n}^{(2)} \) for all \( r \),
- \( \text{type } D_{n+1}^{(2)} \) when \( r < n \),
- \( \text{type } D_{4}^{(3)} \) when \( r = 1 \),
the filling map is the same as given in \([\text{OSS2011}]\) except for the rightmost column which is given by the column \([1, 2, \ldots, k, \emptyset, \ldots, \emptyset] \) where \( k = (r + x - 1)/2 \) in Step 3 of \([\text{OSS2011}]\).

For the spinor case in type \( D_{n+1}^{(2)} \), the crystal \( B_{n,s} \), we define the filling map in the same way as in type \( D_{n}^{(1)} \).

\[ \text{Note: } \] The filling map and classical decompositions in non-spinor cases can be classified by how the special node \( 0 \) connects with the corresponding classical diagram.

The classical crystal structure is given by the usual Kashiwara-Nakashima tableaux rules. That is to embed this into \( B(\Lambda_1)^{\otimes n} \) by using the reading word and then applying the classical crystal operator. The affine crystal structure is given by converting to the corresponding KR crystal element, performing the affine crystal operator, and pulling back to a KR tableau.

For more information about the bijection between rigged configurations and tensor products of Kirillov-Reshetikhin tableaux, see \( \text{TensorProductOfKirillovReshetikhinTableaux} \).
Note: The tableaux for all non-simply-laced types are provably correct if the bijection with rigged configurations holds. Therefore this is currently only proven for $B_{r}^{\gamma}$ or $B_{r}^{1\gamma}$ and in general for types $A_{n}^{(1)}$ and $D_{n}^{(1)}$.

INPUT:

- cartan_type – the Cartan type
- r – the Dynkin diagram index (typically the number of rows)
- s – the number of columns

EXAMPLES:

```python
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR')
sage: elt = KRT(4, 3); elt
[[3], [4]]
```

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 1, model='KR')
sage: elt = KRT(-1, 1); elt
[[1], [-1]]
```

We can create highest weight crystals from a given shape or weight:

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
sage: KRT.module_generator(shape=[1,1])
[[1, 1], [2, -1]]
sage: KRT.module_generator(column_shape=[2])
[[1, 1], [2, -1]]
sage: WS = RootSystem(['D',4,1]).weight_space()
sage: KRT.module_generator(weight=WS.sum_of_terms([[0,-2],[2,1]]))
[[1, 1], [2, -1]]
sage: WSC = RootSystem(['D',4]).weight_space()
sage: KRT.module_generator(classical_weight=WSC.fundamental_weight(2))
[[1, 1], [2, -1]]
```

We can go between `KashiwaraNakashimaTableaux()` and `KirillovReshetikhinTableaux` elements:

```python
sage: KRCrys = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KN')
sage: KRTab = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
sage: elt = KRCrys(3, 2); elt
[[2], [3]]
sage: k = KRTab(elt); k
[[2, 1], [3, -1]]
sage: KRCrys(k)
[[2], [3]]
```

We check that the classical weights in the classical decompositions agree in a few different type:

```python
sage: KRCrys = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KN')
sage: KRTab = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
sage: all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)
True
sage: KRCrys = crystals.KirillovReshetikhin(['B', 3, 1], 2, 2, model='KN')
```

(continues on next page)
sage: KRTab = crystals.KirillovReshetikhin(['B', 3, 1], 2, 2, model='KR')
sage: all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)
True
sage: KCRys = crystals.KirillovReshetikhin(['C', 3, 1], 2, 2, model='KN')
sage: KRTab = crystals.KirillovReshetikhin(['C', 3, 1], 2, 2, model='KR')
sage: all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)
True
sage: KCRys = crystals.KirillovReshetikhin(['D', 4, 2], 2, 2, model='KN')
sage: KRTab = crystals.KirillovReshetikhin(['D', 4, 2], 2, 2, model='KR')
sage: all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)
True
sage: KCRys = crystals.KirillovReshetikhin(['A', 4, 2], 2, 2, model='KN')
sage: KRTab = crystals.KirillovReshetikhin(['A', 4, 2], 2, 2, model='KR')
sage: all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)
True

Element

alias of KirillovReshetikhinTableauxElement
classical_decomposition()
Return the classical crystal decomposition of self.
EXAMPLES:

sage: crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR').classical_decomposition()
The crystal of tableaux of type ['D', 4] and shape(s) [[], [1, 1], [2, 2]]

from_kirillov_reshetikhin_crystal(krc)
Construct an element of self from the Kirillov-Reshetikhin crystal element krc.
EXAMPLES:

sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR')
sage: C = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KN')
sage: krc = C(4,3); krc
[[3], [4]]
sage: KRT.from_kirillov_reshetikhin_crystal(krc)
[[3], [4]]

kirillov_reshetikhin_crystal()
Return the corresponding KR crystal in the Kashiwara-Nakashima model.
EXAMPLES:

sage: crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR').kirillov_reshetikhin_crystal()
Kirillov-Reshetikhin crystal of type ['A', 4] with (r,s)=(2,1)

module_generator(i=None, **options)
Return the specified module generator.
INPUT:

• i – the index of the module generator
We can also get a module generator by using one of the following optional arguments:

- `shape` – the associated shape
- `column_shape` – the shape given as columns (a column of length $k$ correspond to a classical weight $\omega_k$)
- `weight` – the weight
- `classical_weight` – the classical weight

If no arguments are specified, then return the unique module generator of classical weight $s\Lambda_r$.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
sage: KRT.module_generator(1)
[[1, 1], [2, -1]]
sage: KRT.module_generator(shape=[1,1])
[[1, 1], [2, -1]]
sage: KRT.module_generator(column_shape=[2])
[[1, 1], [2, -1]]
sage: WS = RootSystem(['D',4]).weight_space()
sage: KRT.module_generator(weight=WS.sum_of_terms([[0,-2],[2,1]]))
[[1, 1], [2, -1]]
sage: WSC = RootSystem(['D',4]).weight_space()
sage: KRT.module_generator(classical_weight=WSC.fundamental_weight(2))
[[1, 1], [2, -1]]
sage: KRT.module_generator()
[[1, 1], [2, 2]]
```

$r()$
Return the value $r$ for this tableaux class which corresponds to the number of rows.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2, model='KR')
sage: KRT.r()
2
```

$s()$
Return the value $s$ for this tableaux class which corresponds to the number of columns.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR')
sage: KRT.s()
1
```

`tensor(*crystals, **options)`
Return the tensor product of `self` with `crystals`.

If `crystals` is a list of (a tensor product of) KR tableaux, this returns a `TensorProductOfKirillovReshetikhinTableaux`. 

2194 Chapter 5. Comprehensive Module List
EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2, model='KR')
sage: TP = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1], [[1, \rightarrow 3],[3,1]])
sage: K.tensor(TP, K)
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1]
and factor(s) ((2, 2), (1, 3), (3, 1), (2, 2))

sage: C = crystals.KirillovReshetikhin(['A', 3, 1], 3, 1, model='KN')
sage: K.tensor(K, C)
Full tensor product of the crystals
Kirillov-Reshetikhin tableau of type ['A', 3, 1] and shape (2, 2),
Kirillov-Reshetikhin tableau of type ['A', 3, 1] and shape (2, 2),
Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(3,1)
```

```python
class sage.combinat.rigged_configurations.kr_tableaux.KirillovReshetikhinTableauxElement(parent, list, **options)

Bases: TensorProductOfRegularCrystalsElement

A Kirillov-Reshetikhin tableau.

For more information, see KirillovReshetikhinTableaux and TensorProductOfKirillovReshetikhinTableaux.

classical_weight()

Return the classical weight of self.

EXAMPLES:

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
sage: elt = KRT(3,2,-1,1); elt
[[2, 1], [3, -1]]
sage: elt.classical_weight()
(0, 1, 1, 0)
```

e()

Perform the action of $e_i$ on self.

**Todo:** Implement a direct action of $e_0$ without moving to KR crystals.

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
sage: KRT.module_generators[0].e(0)
[[[-2, 1], [-1, -1]]
```

epsilon()

Compute $\varepsilon_i$ of self.

**Todo:** Implement a direct action of $\varepsilon_0$ without moving to KR crystals.
EXAMPLES:

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
sage: KRT.module_generators[0].epsilon(0)
2
```

**f(i)**

Perform the action of $f_i$ on `self`.

**Todo:** Implement a direct action of $f_0$ without moving to KR crystals.

EXAMPLES:

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
sage: KRT.module_generators[0].f(0)
[[1, 1], [2, -1]]
```

**left_split()**

Return the image of `self` under the left column splitting map.

EXAMPLES:

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 3, model='KR')
sage: mg = KRT.module_generators[1]; mg.pp()
1 -2 1
2 -1 2
sage: ls = mg.left_split(); ls.pp()
1 (X) -2 1
2 -1 2
sage: ls.parent()
Tensor product of Kirillov-Reshetikhin tableaux of type ['D', 4, 1] and␣
˓factor(s) ((2, 1), (2, 2))
```

**phi(i)**

Compute $\varphi_i$ of `self`.

**Todo:** Compute $\varphi_0$ without moving to KR crystals.

EXAMPLES: Compute $\varphi_0$ without moving to KR crystals.

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
sage: KRT.module_generators[0].phi(0)
2
```

**pp()**

Pretty print `self`.

EXAMPLES:

```python
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 2, model='KR')
sage: elt = KRT(2, 1, 4, 3); elt
[[1, 3], [2, 4]]
```
right_split()
Return the image of self under the right column splitting map.

Let * denote the Lusztig involution, and ls as the left splitting map. The right splitting map is defined as
\[ rs := * \circ ls \circ * . \]

EXAMPLES:
```
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 3, model='KR')
sage: mg = KRT.module_generators[1]; mg.pp()
   1  2
   2  1
sage: ls = mg.right_split(); ls.pp()
  -2  1   (X)  1
   -1  2      2
sage: ls.parent()
Tensor product of Kirillov-Reshetikhin tableaux of type ['D', 4, 1] and
˓→factor(s) ((2, 2), (2, 1))
```

to_array(rows=True)
Return a 2-dimensional array representation of this Kirillov-Reshetikhin element.

If the output is in rows, then it outputs the top row first (in the English convention) from left to right.

For example: if the reading word is [2, 1, 4, 3], so as a 2 × 2 tableau:
```
   1  3
   2  4
```
we output [[1, 3], [2, 4]].

If the output is in columns, then it outputs the leftmost column first with the bottom element first. In other words this parses the reading word into its columns.

Continuing with the previous example, the output would be [[2, 1], [4, 3]].

INPUT:
• rows – (Default: True) Set to True if the resulting array is by row, otherwise it is by column.

EXAMPLES:
```
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 2, model='KR')
sage: elt = KRT(2, 1, 4, 3)
sage: elt.to_array()
[[1, 3], [2, 4]]
sage: elt.to_array(False)
[[2, 1], [4, 3]]
```

to_classical_highest_weight(index_set=None)
Return the classical highest weight element corresponding to self.

INPUT:
• **index_set** – (Default: None) Return the highest weight with respect to the index set. If None is passed in, then this uses the classical index set.

OUTPUT:
A pair \([H, f_{str}]\) where \(H\) is the highest weight element and \(f_{str}\) is a list of \(a_i\) of \(f_{a_i}\) needed to reach \(H\).

EXAMPLES:

```python
sage: KRTab = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: elt = KRTab(3,2,-1,1); elt
[[2, 1], [3, -1]]
sage: elt.to_classical_highest_weight()
[[[1, 1], [2, -1]], [1, 2]]
```

### to_kirillov_reshetikhin_crystal()

Construct a KashiwaraNakashimaTableaux() element from self.

We construct the Kirillov-Reshetikhin crystal element as follows:

1. Determine the shape \(\lambda\) of the KR crystal from the weight.
2. Determine a path \(e_{i_1} e_{i_2} \cdots e_{i_k}\) to the highest weight.
3. Apply \(f_{i_k} \cdots f_{i_2} f_{i_1}\) to a highest weight KR crystal of shape \(\lambda\).

EXAMPLES:

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: elt = KRT(3,2,-1,1); elt
[[2, 1], [3, -1]]
sage: elt.to_kirillov_reshetikhin_crystal()
[[2], [3]]
```

### to_tableau()

Return a Tableau object of self.

EXAMPLES:

```python
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 2, model='KR')
sage: elt = KRT(2,1,4,3); elt
[[1, 3], [2, 4]]
sage: t = elt.to_tableau(); t
[[1, 3], [2, 4]]
sage: type(t)
<class 'sage.combinat.tableau.Tableaux_all_with_category.element_class'>
```

### weight()

Return the weight of self.

EXAMPLES:

```python
sage: KR = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: KR.module_generators[1].weight()
-2*Lambda[0] + Lambda[2]
```
5.1.211 Crystal of Rigged Configurations

AUTHORS:

• Travis Scrimshaw (2010-09-26): Initial version

We only consider the highest weight crystal structure, not the Kirillov-Reshetikhin structure, and we extend this to symmetrizable types.

```python
class sage.combinat.rigged_configurations.rc_crystal.CrystalOfNonSimplyLacedRC(vct, wt, WLR):
    Bases: CrystalOfRiggedConfigurations

    Highest weight crystal of rigged configurations in non-simply-laced type.

    Element
    alias of RCHWNonSimplyLacedElement

    from_virtual(vrc)
    Convert vrc in the virtual crystal into a rigged configuration of the original Cartan type.
    INPUT:
    • vrc – a virtual rigged configuration
    EXAMPLES:

    sage: La = RootSystem(['C', 3]).weight_lattice().fundamental_weights()
sage: vct = CartanType(['C', 3]).as_folding()
sage: RC = crystals.RiggedConfigurations(vct, La[2])
sage: elt = RC(partition_list=[[0], [1], [1]])
sage: elt == RC.from_virtual(RC.to_virtual(elt))
    True

to_virtual(rc)
    Convert rc into a rigged configuration in the virtual crystal.
    INPUT:
    • rc – a rigged configuration element
    EXAMPLES:

    sage: La = RootSystem(['C', 3]).weight_lattice().fundamental_weights()
sage: vct = CartanType(['C', 3]).as_folding()
sage: RC = crystals.RiggedConfigurations(vct, La[2])
sage: elt = RC(partition_list=[[], [1], [1]]); elt

    (continues on next page)```
virtual()

Return the corresponding virtual crystal.

EXAMPLES:

```python
sage: La = RootSystem(['C', 2, 1]).weight_lattice().fundamental_weights()
sage: vct = CartanType(['C', 2, 1]).as_folding()
sage: RC = crystals.RiggedConfigurations(vct, La[0])
sage: RC
Crystal of rigged configurations of type ['C', 2, 1] and weight Lambda[0]
sage: RC.virtual
Crystal of rigged configurations of type ['A', 3, 1] and weight 2*Lambda[0]
```

class sage.combinat.rigged_configurations.rc_crystal.CrystalOfRiggedConfigurations(wt, WLR)

Bases: UniqueRepresentation, Parent

A highest weight crystal of rigged configurations.

The crystal structure for finite simply-laced types is given in [CrysStructSchilling06]. These were then shown to be the crystal operators in all finite types in [SS2015], all simply-laced and a large class of foldings of simply-laced types in [SS2015III], and all symmetrizable types (uniformly) in [SS2017].

INPUT:

- `cartan_type` – (optional) a Cartan type or a Cartan type given as a folding
- `wt` – the highest weight vector in the weight lattice

EXAMPLES:

For simplicity, we display the rigged configurations horizontally:

```python
sage: RiggedConfigurations.options.display='horizontal'
```

We start with a simply-laced finite type:

```python
sage: La = RootSystem(['A', 2]).weight_lattice().fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[1] + La[2])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([1,2])
0[ ]0 0[ ]-1
sage: mg.f_string([1,2,2])
0[ ]0 -2[ ][ ]-2
sage: mg.f_string([1,2,2,2])
-1[ ][ ]-1 -1[ ][ ]-1
sage: RC.cardinality()
```

(continues on next page)
We construct a non-simply-laced affine type:

```python
sage: La = RootSystem(['C', 3]).weight_lattice().fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[2])
sage: mg = RC.highest_weight_vector()
(\) 1[ ]1 -1[ ]-1
sage: T = crystals.Tableaux(['C', 3], shape=[1,1])
sage: RC.digraph().is_isomorphic(T.digraph(), edge_labels=True)
True
```

We can construct rigged configurations using a diagram folding of a simply-laced type. This yields an equivalent but distinct crystal:

```python
sage: vct = CartanType(['C', 3]).as_folding()
sage: RC = crystals.RiggedConfigurations(vct, La[2])
sage: mg = RC.highest_weight_vector()
(\) 0[ ]0 -1[ ]-1
sage: T = crystals.Tableaux(['C', 3], shape=[1,1])
sage: RC.digraph().is_isomorphic(T.digraph(), edge_labels=True)
True
```

We reset the global options:

```python
sage: RiggedConfigurations.options._reset()
```

REFERENCES:

- [SS2015]
- [SS2015II]
- [SS2017]

Element

alias of `RCHighestWeightElement`

```python
options = Current options for RiggedConfigurations - convention:  English - display:
vertical - element_ascii_art: True - half_width_boxes_type_B: True

weight_lattice_realization()

Return the weight lattice realization used to express the weights of elements in self.
```

EXAMPLES:

```python
sage: La = RootSystem(['A', 2, 1]).weight_lattice(extended=True).fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[0])
sage: RC.weight_lattice_realization()
Extended weight lattice of the Root system of type ['A', 2, 1]
```
5.1.212 Rigged Configurations of \( B(\infty) \)

**AUTHORS:**

- Travis Scrimshaw (2013-04-16): Initial version

```python
class sage.combinat.rigged_configurations.rc_infinity.InfinityCrystalOfNonSimplyLacedRC(vct):
    Bases: InfinityCrystalOfRiggedConfigurations

    Rigged configurations for \( B(\infty) \) in non-simply-laced types.

class Element(parent, rigged_partitions=[], **options):
    Bases: RCNonSimplyLacedElement

    A rigged configuration in \( B(\infty) \) in non-simply-laced types.

    weight()
    Return the weight of self.

    EXAMPLES:

    sage: vct = CartanType(['C', 3]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: elt = RC(partition_list=[[1],[1,1],[1]], rigging_list=[[0],[-1,-1], [-[0]])
sage: elt.weight()
(-1, -1, 0)

    sage: vct = CartanType(['F', 4, 1]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: mg = RC.highest_weight_vector()
sage: elt = mg.f_string([1,0,3,4,2,2]); ascii_art(elt)
-1[ ] [-1 0[ ] 1 -2[ ] -2 0[ ] 1 -1[ ] -1
sage: wt = elt.weight(); wt

    sage: al = RC.weight_lattice_realization().simple_roots()
True
```

**from_virtual**(vrc)

Convert vrc in the virtual crystal into a rigged configuration of the original Cartan type.

**INPUT:**

- vrc – a virtual rigged configuration

**EXAMPLES:**

```python
sage: vct = CartanType(['C', 2]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: elt = RC(partition_list=[[3],[2]], rigging_list=[[2],[0]])
sage: vrc_elt = RC.to_virtual(elt)
sage: ret = RC.from_virtual(vrc_elt); ret
-3[ ][ ][ ]
-1[ ][ ]
```

(continues on next page)
Combinatorics, Release 10.0

sage: ret == elt
True

to_virtual(rc)
Convert rc into a rigged configuration in the virtual crystal.

INPUT:
• rc – a rigged configuration element

EXAMPLES:

```python
sage: vct = CartanType(['C', 2]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: mg = RC.highest_weight_vector()
sage: elt = mg.f_string([1,2,2,1,1]); elt
-3[ ][ ][ ]-2
-1[ ][ ]0
sage: velt = RC.to_virtual(elt); velt
-3[ ][ ][ ]-2
-2[ ][ ][ ]0
-3[ ][ ][ ]-2
```

```python
sage: velt.parent()
The infinity crystal of rigged configurations of type ['A', 3]
```

virtual()
Return the corresponding virtual crystal.

EXAMPLES:

```python
sage: vct = CartanType(['C', 3]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: RC
The infinity crystal of rigged configurations of type ['C', 3]
sage: RC.virtual
The infinity crystal of rigged configurations of type ['A', 5]
```

class sage.combinat.rigged_configurations.rc_infinity.InfinityCrystalOfRiggedConfigurations(cartan_type)
Bases: UniqueRepresentation, Parent

Rigged configuration model for $B(\infty)$.

The crystal is generated by the empty rigged configuration with the same crystal structure given by the highest weight model except we remove the condition that the resulting rigged configuration needs to be valid when applying $f_a$.

INPUT:
• cartan_type – a Cartan type
EXAMPLES:

For simplicity, we display all of the rigged configurations horizontally:

```
sage: RiggedConfigurations.options(display='horizontal')
```

We begin with a simply-laced finite type:

```
sage: RC = crystals.infinity.RiggedConfigurations(['A', 3]); RC
The infinity crystal of rigged configurations of type ['A', 3]
sage: RC.options(display='horizontal')
sage: mg = RC.highest_weight_vector(); mg
</> </> </>
```

```
sage: elt = mg.f_string([2,1,3,2]); elt
0[ ]0 -2[ ]-1 0[ ]0
-2[ ]-1
```

```
sage: elt.e(1)
sage: elt.e(3)
sage: mg.f_string([2,1,3,2]).e(2)
-1[ ]-1 0[ ]1 -1[ ]-1
```

```
sage: mg.f_string([2,3,2,1,3,2])
0[ ]0 -3[ ][ ]-1 -1[ ][ ]-1
-2[ ]-1
```

Next we consider a non-simply-laced finite type:

```
sage: RC = crystals.infinity.RiggedConfigurations(['C', 3])
sage: mg = RC.highest_weight_vector(); mg
<>/ </> (/
```

```
sage: elt = mg.f_string([2,1,3,2]); elt
0[ ]0 -1[ ]0 0[ ]0
-1[ ]-1
```

```
sage: mg.f_string([2,3,2,1,3,2])
0[ ]-1 -1[ ][ ]-1 -1[ ][ ]0
-1[ ]0
```

We can construct rigged configurations using a diagram folding of a simply-laced type. This yields an equivalent but distinct crystal:

```
sage: vct = CartanType(['C', 3]).as_folding()
sage: VRC = crystals.infinity.RiggedConfigurations(vct)
sage: mg = VRC.highest_weight_vector(); mg
```

```
sage: mg.f_string([2,1,3,2])
0[ ]0 -2[ ]-1 0[ ]0
-2[ ]-1
```

```
sage: mg.f_string([2,3,2,1,3,2])
-1[ ]-1 -2[ ][ ][ ]-1 -1[ ][ ]0
```

```
sage: G = RC.subcrystal(max_depth=5).digraph()
sage: VG = VRC.subcrystal(max_depth=5).digraph()
sage: G.is_isomorphic(VG, edge_labels=True)
True
```

We can also construct $B(\infty)$ using rigged configurations in affine types:
sage: RC = crystals.infinity.RiggedConfigurations(['A', 3, 1])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([0,1,2,3,0,1,3])
-1[ ]0  -1[ ]-1  1[ ]1  -1[ ] [ ]-1
-1[ ]0  -1[ ]-1

sage: RC = crystals.infinity.RiggedConfigurations(['C', 3, 1])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([1,2,3,0,1,2,3,3,0])
-2[ ][ ]-1  0[ ]1  0[ ]0  -4[ ][ ][ ]-2
  0[ ]0  0[ ]-1

sage: RC = crystals.infinity.RiggedConfigurations(['A', 6, 2])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([1,2,3,0,1,2,3,3,0])
0[ ][ ]-1  0[ ]1  0[ ]0  -4[ ][ ][ ]-2
  0[ ][ ]-1  0[ ]1  0[ ][ ]-1

We reset the global options:

sage: RiggedConfigurations.options._reset()

class Element(parent, rigged_partitions=[], **options)

   Bases: RiggedConfigurationElement

   A rigged configuration in $\mathcal{B}(\infty)$ in simply-laced types.

   weight()

   Return the weight of self.

   EXAMPLES:

   sage: RC = crystals.infinity.RiggedConfigurations(['A', 3, 1])
   sage: elt = RC(partition_list=[[1,1]]*4, rigging_list=[[1,1], [0,0], [0,0], [-1,-1]])
   sage: elt.weight()
   -2*delta

   options = Current options for RiggedConfigurations - convention: English - display: vertical - element_ascii_art: True - half_width_boxes_type_B: True

   weight_lattice_realization()

   Return the weight lattice realization used to express the weights of elements in self.

   EXAMPLES:

   sage: RC = crystals.infinity.RiggedConfigurations(['A', 2, 1])
   sage: RC.weight_lattice_realization()
   Extended weight lattice of the Root system of type ['A', 2, 1]
5.1.213 Rigged Configuration Elements

A rigged configuration element is a sequence of RiggedPartition objects.

AUTHORS:

- Travis Scrimshaw (2010-09-26): Initial version
- Travis Scrimshaw (2012-10-25): Added virtual rigged configurations

```python
class sage.combinat.rigged_configurations.rigged_configuration_element.KRRiggedConfigurationElement(RCRiggedConfigurationElement, **options):
    pass
```

**U**′_q(g) rigged configurations in non-simply-laced types.

```python
cc()
```

Compute the cocharge statistic.

Computes the cocharge statistic [OSS03] on this rigged configuration (ν, J) by computing the cocharge as a virtual rigged configuration (ν̂, Ĵ) and then using the identity \( cc(\nu, J) = \gamma_0 cc(\nu, J) \).

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['C', 3, 1], [[2,1], [1,1]])
sage: RC(partition_list=[[1,1],[2,1],[1,1]]).cocharge()
1
```

```python
cocharge()
```

Compute the cocharge statistic.

Computes the cocharge statistic [OSS03] on this rigged configuration (ν, J) by computing the cocharge as a virtual rigged configuration (ν̂, Ĵ) and then using the identity \( cc(\nu, J) = \gamma_0 cc(\nu, J) \).

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['C', 3, 1], [[2,1], [1,1]])
sage: RC(partition_list=[[1,1],[2,1],[1,1]]).cocharge()
1
```

```python
e(a)
```

Return the action of \( e_a \) on self.

This works by lifting into the virtual configuration, then applying

\[
e_a^\nu = \prod_{j \in \nu} e_j^{\gamma_j}
\]

and pulling back.

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A', 6, 2], [[1,1]]*7)
sage: elt = RC(partition_list=[[1]*5,[2,1,1],[3,2]])
sage: elt.e(3)
0[ ]0
```

(continues on next page)
Return the action of $f_a$ on self.

This works by lifting into the virtual configuration, then applying

$$f'_a = \prod_{j \in \{a\}} f_j^\gamma$$

and pulling back.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A',6,2], [[1,1]]^7)
sage: elt = RC(partition_list=[[1]*5,[2,1,1],[2,1]], rigging_list=[[0]*5,[0,1,-1],[1,0]])
sage: elt.f(3)
```

```
0[ ]0
0[ ]0
0[ ]0
0[ ]0
0[ ][ ]0
1[ ]1
1[ ]1
1[ ][ ]1
1[ ]0
```

```
class sage.combinat.rigged_configurations.rigged_configuration_element.KRRCSimplyLacedElement
    
    Bases: KRRiggedConfigurationElement

    \(U_q'(g)\) rigged configurations in simply-laced types.

    \(cc()\)

    Compute the cocharge statistic of self.

    Computes the cocharge statistic [CryStructSchilling06] on this rigged configuration \((\nu, J)\). The cocharge
```
Combinatorics, Release 10.0

statistic is defined as:
\[
cc(\nu, J) = \frac{1}{2} \sum_{a,b \in I_0} \sum_{j,k > 0} (\alpha_a \mid \alpha_b) \min(j, k) m_j^{(a)} m_k^{(b)} + \sum_{a \in I} \sum_{i > 0} |J^{(a,i)}|.
\]

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [2, 1], [1,1]])
sage: RC(partition_list=[[1], [1], []]).cocharge()
1
```

charge()
Compute the charge statistic of self.

Let \( B \) denote a set of rigged configurations. The charge \( c \) of a rigged configuration \( b \) is computed as
\[
c(b) = \max(\{cc(b) \mid b \in B\}) - cc(b).
\]

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [2, 1], [1,1]])
sage: RC(partition_list=[[1], [1], []]).charge()
2
sage: RC(partition_list=[[1], [1], []]).charge()
1
```

cocharge()
Compute the cocharge statistic of self.

Computes the cocharge statistic \([\text{CrysStructSchilling06}]\) on this rigged configuration \((\nu, J)\). The cocharge statistic is defined as:
\[
cc(\nu, J) = \frac{1}{2} \sum_{a \in I_0} \sum_{i > 0} \left( \sum_{j > 0} \min(i, j) L_j^{(a)} - p_i^{(a)} \right) + \sum_{a \in I} \sum_{i > 0} |J^{(a,i)}|.
\]

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [2, 1], [1,1]])
sage: RC(partition_list=[[1], [1], []]).cocharge()
1
```

class sage.combinat.rigged_configurations.rigged_configuration_element.KRRCTypeA2DualElement (parent, rigged_partitions=\[
\]
Bases: KRRCNonSimplyLacedElement
\(U_q'(g)\) rigged configurations in type \(A_{2n}^{(2)\dagger}\). 

ccc()
Compute the cocharge statistic.

Computes the cocharge statistic \([\text{RigConBijection}]\) on this rigged configuration \((\nu, J)\). The cocharge statistic is computed as:
\[
cc(\nu, J) = \frac{1}{2} \sum_{a \in I_0} \sum_{i > 0} \left( \sum_{j > 0} \min(i, j) L_j^{(a)} - p_i^{(a)} \right) + \sum_{a \in I} \sum_{i > 0} |J^{(a,i)}|.
\]

EXAMPLES:
cocharge()

Compute the cocharge statistic.

Computes the cocharge statistic [RigConBijection] on this rigged configuration \((\nu, J)\). The cocharge statistic is computed as:

\[
cc(\nu, J) = \frac{1}{2} \sum_{a \in I_0} \sum_{i > 0} t_a^\vee m_i^{(a)} \left( \sum_{j > 0} \min(i, j) I_j^{(a)} - p_i^{(a)} \right) + \sum_{a \in I} t_a^\vee \sum_{i > 0} |J^{(a,i)}|.
\]

EXAMPLES:

```python
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,1],[2,2]])
sage: sc = RC.cartan_type().as_folding().scaling_factors()
sage: all(mg.cocharge() * sc[0] == mg.to_virtual_configuration().cocharge()
    ....:     for mg in RC.module_generators)
True
```

epsilon(a)

Return the value of \(\varepsilon_a\) of self.

Here we need to modify the usual definition by \(\varepsilon'_n := 2\varepsilon_n\).

EXAMPLES:

```python
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,1],[2,2]])
sage: def epsilon(x, i):
    ....:     x = x.e(i)
    ....:     eps = 0
    ....:     while x is not None:
    ....:         x = x.e(i)
    ....:         eps = eps + 1
    ....:     return eps
sage: all(epsilon(rc, 2) == rc.epsilon(2) for rc in RC)
True
```

phi(a)

Return the value of \(\phi_a\) of self.

Here we need to modify the usual definition by \(\phi'_n := 2\phi_n\).

EXAMPLES:

```python
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,1],[2,2]])
sage: def phi(x, i):
    ....:     x = x.f(i)
    ....:     ph = 0
    ....:     while x is not None:
    ....:         x = x.f(i)
    ....:         ph = ph + 1
```
....:     return ph
sage: all(phi(rc, 2) == rc.phi(2) for rc in RC)
True

class sage.combinat.rigged_configurations.rigged_configuration_element.KRRiggedConfigurationElement(parent, rigged_partitions=[], **options)

Bases: RiggedConfigurationElement

$U_q'(g)$ rigged configurations.

EXAMPLES:

We can go between rigged configurations and tensor products of tensor products of KR tableaux:

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[1,1], [2,1]])
sage: rc_elt = RC(partition_list=[[1], [1,1], [1], [1]])
sage: tp_krtab = rc_elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); tp_krtab
[[[-2]], [[1], [2]]]
sage: tp_krcrys = rc_elt.to_tensor_product_of_kirillov_reshetikhin_crystals(); tp_krcrys
[[[-2]], [[1], [2]]]
sage: tp_krcrys == tp_krtab.to_tensor_product_of_kirillov_reshetikhin_crystals()
True
sage: RC(tp_krcrys) == rc_elt
True
sage: RC(tp_krtab) == rc_elt
True
sage: tp_krtab.to_rigged_configuration() == rc_elt
True
```

check()

Make sure all of the riggings are less than or equal to the vacancy number.

classical_weight()

Return the classical weight of self.

The classical weight $\Lambda$ of a rigged configuration is

$$
\Lambda = \sum_{a \in \mathcal{R}} \sum_{i > 0} iL_i^{(a)} \Lambda_a - \sum_{a \in \mathcal{R}} \sum_{i > 0} im_i^{(a)} \alpha_a.
$$

EXAMPLES:

```
sage: RC = RiggedConfigurations(['D',4,1], [[2,2]])
sage: elt = RC(partition_list=[[2],[2,1],[1],[1]])
sage: elt.classical_weight()
(0, 1, 1, 0)
```

This agrees with the corresponding classical weight as KR tableaux:

```
sage: krt = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); krt
[[[2, 1], [3, -1]]]
```
Combinatorics, Release 10.0

(continued from previous page)

```
sage: krt.classical_weight() == elt.classical_weight()
True
```

**complement_rigging**(reverse_factors=False)

Apply the complement rigging morphism $\theta$ to self.

Consider a highest weight rigged configuration $(\nu, J)$, the complement rigging morphism $\theta: RC(L) \rightarrow RC(L)$ is given by sending $(\nu, J) \mapsto (\nu, J')$, where $J'$ is obtained by taking the coriggings $x'_i = p_i^{(a)} - x_i$ and then extending as a crystal morphism. (The name comes from taking the complement partition for the riggings in a $m_1^{(a)} \times p_i^{(a)}$ box.)

INPUT:

- reverse_factors – (default: False) if True, then this returns an element in $RC(B')$ where $B'$ is the tensor factors of self in reverse order

EXAMPLES:

```
sage: RC = RiggedConfigurations(["D",4,1], [[1,1],[2,2]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
[ ] [ ] 1 [ ] [ ] 0 [ ] [ ] 0 [ ] [ ] 0 [ ] [ ] 0
sage: ascii_art(mg.complement_rigging())
[ ] [ ] 0 [ ] [ ] 0 [ ] [ ] 0 [ ] [ ] 0 [ ] [ ] 0

sage: lw = mg.to_lowest_weight([1,2,3,4])[0]
sage: ascii_art(lw)
-1 [ ] [ ]-1 0 [ ] [ ] 0 [ ] [ ] 0 [ ] [ ] 0 [ ] [ ] 0
-1 [ ]-1 0 [ ] [ ] 0 [ ] [ ] 0 [ ] 0 [ ] 0
-1 [ ]-1 0 [ ] 0 [ ] 0 [ ]

sage: lw.complement_rigging() == mg.complement_rigging().to_lowest_weight([1,2,3,4])[0]
True
```

We check that the Lusztig involution (under the modification of also mapping to the highest weight element) intertwines with the complement map $\theta$ (that reverses the tensor factors) under the bijection $\Phi$:

```
sage: RC = RiggedConfigurations(["D", 4, 1], [[2, 2], [2, 1], [1, 2]])
sage: for mg in RC.module_generators: # long time
    y = mg.to_tensor_product_of_kirillov_reshetikhin_tableaux()
    hw = y.lusztig_involution().to_highest_weight([1,2,3,4])[0]
    c = mg.complement_rigging(True)
    hwc = c.to_tensor_product_of_kirillov_reshetikhin_tableaux()
    ... assert hw == hwc
```

5.1. Comprehensive Module List 2211
delta\((\text{return\_b}=False)\)

Return the image of self under the left box removal map \(\delta\).

The map \(\delta : RC(B^r_1 \otimes B) \rightarrow RC(B^{\delta r-1,1}_r \otimes B)\) (if \(r = 1\), then we remove the left-most factor) is the basic map in the bijection \(\Phi\) between rigged configurations and tensor products of Kirillov-Reshetikhin tableaux. For more information, see \text{to\_tensor\_product\_of\_kirillov\_reshetikhin\_tableaux()}. We can extend \(\delta\) when the left-most factor is not a single column by precomposing with a \text{left\_split()}.

**Note:** Due to the special nature of the bijection for the spinor cases in types \(D_n^{(1)}, B_n^{(1)}\), and \(A_{2n-1}^{(2)}\), this map is not defined in these cases.

**INPUT:**
- \text{\textbullet return\_b \text{\textunderscore} (default: False) whether to return the resulting letter from \(\delta\) \text{\textunderscore}**

**OUTPUT:**
The resulting rigged configuration or if \text{return\_b} is \text{True}, then a tuple of the resulting rigged configuration and the letter.

**EXAMPLES:**

```
sage: RC = RiggedConfigurations(['C', 4, 1], [[3,2]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
     0[ ][ ]0 0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
     0[ ][ ]0 0[ ][ ]0

sage: ascii_art(mg.left_box())
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
     0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
     0[ ][ ]0 0[ ][ ]0

sage: x,b = mg.left_box(True)
sage: b
-1
sage: b.parent()
The crystal of letters for type ['C', 4]
```

e\((a)\)

Return the action of the crystal operator \(e_a\) on self.

For the classical operators, this implements the method defined in [CrysStructSchilling06]. For \(e_0\), this converts the class to a tensor product of KR tableaux and does the corresponding \(e_0\) and pulls back.

**Todo:** Implement \(e_0\) without appealing to tensor product of KR tableaux.

**INPUT:**
- \text{\textbullet a \text{\textunderscore} the index of the partition to remove a box \text{\textunderscore}**

**OUTPUT:**
The resulting rigged configuration element.

**EXAMPLES:**
Combinatorics, Release 10.0

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 1]])
sage: elt = RC(partition_list=[[1], [1], [1], [1]])
sage: elt.e(3)
sage: elt.e(1)
```

```
0[ ]0
0[ ]0
| -1[ ]-1
```

\textbf{epsilon}(\alpha)

Return \( \varepsilon_\alpha \) of \textit{self}.

\textbf{EXAMPLES:}

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2]])
sage: I = RC.index_set()
sage: matrix([[mg.epsilon(i) for i in I] for mg in RC.module_generators])
```

```
[4 0 0 0 0]
[3 0 0 0 0]
[2 0 0 0 0]
```

\textbf{f}(\alpha)

Return the action of the crystal operator \( f_\alpha \) on \textit{self}.

For the classical operators, this implements the method defined in \cite{CrysStructSchilling06}. For \( f_0 \), this converts the class to a tensor product of KR tableaux and does the corresponding \( f_0 \) and pulls back.

\textbf{Todo:} Implement \( f_0 \) without appealing to tensor product of KR tableaux.

\textbf{INPUT:}

- \( \alpha \) – the index of the partition to add a box

\textbf{OUTPUT:}

The resulting rigged configuration element.

\textbf{EXAMPLES:}

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 1]])
sage: elt = RC(partition_list=[[1], [1], [1], [1]])
sage: elt.f(1)
sage: elt.f(2)
```

```
0[ ]0
| -1[ ]-1
| -1[ ]-1
| 1[ ]1
```

(continues on next page)
left_box(return_b=False)

Return the image of self under the left box removal map $\delta$.

The map $\delta : RC(B^{r,1} \otimes B) \to RC(B^{r-1,1} \otimes B)$ (if $r = 1$, then we remove the left-most factor) is the basic map in the bijection $\Phi$ between rigged configurations and tensor products of Kirillov-Reshetikhin tableaux. For more information, see to_tensor_product_of_kirillov_reshetikhin_tableaux().

We can extend $\delta$ when the left-most factor is not a single column by precomposing with a left_split().

Note: Due to the special nature of the bijection for the spinor cases in types $D_n^{(1)}$, $B_n^{(1)}$, and $A_{2n-1}^{(2)}$, this map is not defined in these cases.

INPUT:

* return_b – (default: False) whether to return the resulting letter from $\delta$

OUTPUT:

The resulting rigged configuration or if return_b is True, then a tuple of the resulting rigged configuration and the letter.

EXAMPLES:

```sage
sage: RC = RiggedConfigurations(['C',4,1], [[3,2]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
0[ ]0 0[ ][ ]0 0[ ][ ]0
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
sage: ascii_art(mg.left_box())
0[ ]0 0[ ][ ]0 0[ ][ ]0
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
sage: x,b = mg.left_box(True)
sage: b
-1
sage: b.parent()
The crystal of letters for type ['C', 4]
```

left_column_box()

Return the image of self under the left column box splitting map $\gamma$.

Consider the map $\gamma : RC(B^{r,1} \otimes B) \to RC(B^{1,1} \otimes B^{r-1,1} \otimes B)$ for $r > 1$, which is a natural strict classical crystal injection. On rigged configurations, the map $\gamma$ adds a singular string of length 1 to $\nu^{(a)}$.

We can extend $\gamma$ when the left-most factor is not a single column by precomposing with a left_split().

EXAMPLES:

```sage
sage: RC = RiggedConfigurations(['C',3,1], [[3,1], [2,1]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
0[ ]0 0[ ][ ]0 0[ ][ ]0
0[ ][ ]0 0[ ][ ]0
0[ ][ ]0 0[ ][ ]0
```

(continues on next page)
sage: ascii_art(mg.left_column_box())
0[ ]0 0[ ]0 0[ ]0
0[ ]0 0[ ]0 0[ ]0
0[ ]0

sage: RC = RiggedConfigurations(['C',3,1], [[2,1], [1,1], [3,1]])
sage: mg = RC.module_generators[7]
sage: ascii_art(mg)
1[ ]0 0[ ]0 0[ ]0
1[ ]1 0[ ]0 0[ ]0
1[ ]0 0[ ]0 0[ ]0

left_split()

Return the image of self under the left column splitting map $\beta$.

Consider the map $\beta : RC(B^s \otimes B) \rightarrow RC(B^{r,1} \otimes B^{r,s-1} \otimes B)$ for $s > 1$ which is a natural classical crystal injection. On rigged configurations, the map $\beta$ does nothing (except possibly changing the vacancy numbers).

EXAMPLES:

sage: RC = RiggedConfigurations(['C',4,1], [[3,3]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
0[ ]0 0[ ]0 0[ ]0
0[ ]0 0[ ]0
0[ ]0

sage: ascii_art(mg.left_split())
0[ ]0 0[ ]0 1[ ]0 0[ ]0
0[ ]0 1[ ]0 0[ ]0
1[ ]0 0[ ]0 0[ ]0

phi(a)

Return $\varphi_a$ of self.

EXAMPLES:

sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2]])
sage: I = RC.index_set()
sage: matrix([[mg.phi(i) for i in I] for mg in RC.module_generators])
[0 0 2 0 0]
[1 0 1 0 0]
[2 0 0 0 0]

right_column_box()

Return the image of self under the right column box splitting map $\gamma^*$.

Consider the map $\gamma^* : RC(B \otimes B^{r,1}) \rightarrow RC(B \otimes B^{r-1,1} \otimes B^{1,1})$ for $r > 1$, which is a natural strict classical crystal injection. On rigged configurations, the map $\gamma$ adds a string of length 1 with rigging 0 to $\nu(a)$ for all $a < r$ to a classically highest weight element and extended as a classical crystal morphism.

We can extend $\gamma^*$ when the right-most factor is not a single column by precomposing with a $\text{right_split()}$. 

5.1. Comprehensive Module List
Combinatorics, Release 10.0

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['C', 3, 1], [[2, 1], [1, 1], [3, 1]])
sage: mg = RC.module_generators[7]
sage: ascii_art(mg)
1[ ] 0 0[ ] 0[ ] 0[ ] 0 [ ] 0 0[ ]
0[ ] 0 [ ] 0[ ]
sage: ascii_art(mg.right_column_box())
1[ ] 0 0[ ] 0[ ] 0[ ] 0 [ ] 0 0[ ]
1[ ] 0 0[ ] 0 [ ] 0[ ]
0[ ] 0 [ ]
```

```python
def right_split():
    Return the image of self under the right column splitting map β*. Let θ denote the complement rigging map which reverses the tensor factors and β denote the left splitting map, we define the right splitting map by β*: = θ ∘ β ∘ θ.

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['C', 4, 1], [[3, 3]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
0[ ] 0[ ] 0[ ] 0[ ] 0[ ] 0[ ] 0[ ]
0[ ] 0[ ] 0[ ] 0[ ]
sage: ascii_art(mg.right_split())
0[ ] 0[ ] 0[ ] 0[ ] 1[ ] 1 0[ ]
0[ ] 0[ ] 1[ ] 1 0[ ]
1[ ] 1 0[ ]
```

We check that the bijection commutes with the right splitting map:

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[1, 1], [2, 2]])
sage: all(rc.right_split().to_tensor_product_of_kirillov_reshetikhin_tableaux() ==
      rc.to_tensor_product_of_kirillov_reshetikhin_tableaux().right_split() for rc in RC)
True
```

```python
def to_tensor_product_of_kirillov_reshetikhin_crystals(display_steps=False, build_graph=False):
    Return the corresponding tensor product of Kirillov-Reshetikhin crystals.

    This is a composition of the map to a tensor product of KR tableaux, and then to a tensor product of KR crystals.
```

2216 Chapter 5. Comprehensive Module List
INPUT:

- `display_steps` – (default: False) boolean which indicates if we want to print each step in the algorithm
- `build_graph` – (default: False) boolean which indicates if we want to construct and return a graph of the bijection whose vertices are rigged configurations obtained at each step and edges are labeled by either the return value of $\delta$ or the doubling/halving map

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2]])
sage: elt = RC(partition_list=[[2], [2, 2], [1], [1]])
sage: krc = elt.to_tensor_product_of_kirillov_reshetikhin_crystals(); krc
[[[2, 3], [3, -2]]]
```

We can recover the rigged configuration:

```python
sage: ret = RC(krc); ret
```

```python
0
-2
-2
0
0
```

```python
sage: elt == ret
True
```

We can also construct and display a graph of the bijection as follows:

```python
sage: ret, G = elt.to_tensor_product_of_kirillov_reshetikhin_crystals(build_graph=True)
sage: view(G) # not tested
```

`to_tensor_product_of_kirillov_reshetikhin_tableaux(display_steps=False, build_graph=False)`

Perform the bijection from this rigged configuration to a tensor product of Kirillov-Reshetikhin tableaux given in [RigConBijection] for single boxes and with [BijectionLRT] and [BijectionDn] for multiple columns and rows.

**Note:** This is only proven to be a bijection in types $A_n^{(1)}$ and $D_n^{(1)}$, as well as $\otimes \mathbb{B}^{1,1}$ and $\otimes \mathbb{B}^{1,s_i}$ for general affine types.

INPUT:

- `display_steps` – (default: False) boolean which indicates if we want to print each step in the algorithm
- `build_graph` – (default: False) boolean which indicates if we want to construct and return a graph of the bijection whose vertices are rigged configurations obtained at each step and edges are labeled by either the return value of $\delta$ or the doubling/halving map
• The tensor product of KR tableaux element corresponding to this rigged configuration.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RC(partition_list=[[2], [2,2], [2], [2]]).to_tensor_product_of_kirillov_reshetikhin_tableaux()
[[3], [5, 5]]
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2]])
sage: elt = RC(partition_list=[[2], [2,2], [1], [1]])
sage: tp_krt = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); tp_krt
[[2, 3], [3, -2]]
```

This is invertible by calling `to_rigged_configuration()`:

```
sage: ret = tp_krt.to_rigged_configuration(); ret
0[ ]0
-2[ ]0-2
-2[ ]0-2
0[ ]0
0[ ]0
0[ ]0
0[ ]0
sage: elt == ret
True
```

To view the steps of the bijection in the output, run with the `display_steps=True` option:

```
sage: elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(True)
```

```
0[ ]0
-2[ ]0-2
-2[ ]0-2
0[ ]0
0[ ]0
0[ ]0
0[ ]0
-------------------------------
[[3, 2]]
-------------------------------
...
[[2, 3], [3, -2]]
```

We can also construct and display a graph of the bijection as follows:

```
sage: ret, G = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(build_graph=True)
```

(continues on next page)
weight()

Return the weight of self.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['E', 6, 1], [[2,2]])
sage: [x.weight() for x in RC.module_generators]
[-4*Lambda[0] + 2*Lambda[2], -2*Lambda[0] + Lambda[2], 0]
sage: KR = crystals.KirillovReshetikhin(['E',6,1], 2,2)
sage: [x.weight() for x in KR.module_generators]  # long time
[0, -2*Lambda[0] + Lambda[2], -4*Lambda[0] + 2*Lambda[2]]
sage: RC = RiggedConfigurations(['D', 6, 1], [[4,2]])
sage: [x.weight() for x in RC.module_generators]
[-4*Lambda[0] + 2*Lambda[4], -4*Lambda[0] + Lambda[2] + Lambda[4],
 -2*Lambda[0] + Lambda[4], -4*Lambda[0] + 2*Lambda[2],
 -2*Lambda[0] + Lambda[2], 0]
```

class sage.combinat.rigged_configurations.rigged_configuration_element.RCHWNonSimplyLacedElement (parent, rigged_partitions=[], **options)

Bases: RCNonSimplyLacedElement

Rigged configurations in highest weight crystals.

check()

Make sure all of the riggings are less than or equal to the vacancy number.

f(a)

Return the action of $f_a$ on self.

This works by lifting into the virtual configuration, then applying

$$f_a' = \prod_{j \in \iota(a)} \hat{f}_j^{\gamma_j}$$

and pulling back.

EXAMPLES:

```
sage: La = RootSystem(['C',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: vct = CartanType(['C',2,1]).as_folding()
sage: RC = crystals.RiggedConfigurations(vct, La[0])
sage: elt = RC(partition_list=[[1,1],[2],[2]])
sage: elt.f(0)
sage: ascii_art(elt.f(1))
0[ ]0 0[ ]0 0[ ]0 -1[ ]-1
0[ ]0 -1[ ]-1
sage: elt.f(2)
```
weight()

Return the weight of self.

EXAMPLES:

```python
sage: La = RootSystem(['C',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: vct = CartanType(['C',2,1]).as_folding()
sage: B = crystals.RiggedConfigurations(vct, La[0])
sage: mg = B.module_generators[0]
sage: mg.f_string([0,1,2]).weight()
```

class sage.combinat.rigged_configurations.rigged_configuration_element.RCHighestWeightElement(parent, rigged_partitions=[], **options)

Bases: RiggedConfigurationElement

Rigged configurations in highest weight crystals.

check()

Make sure all of the riggings are less than or equal to the vacancy number.

f(a)

Return the action of the crystal operator $f_a$ on self.

This implements the method defined in [CrysStructSchilling06] which finds the value $k$ which is the length of the string with the smallest nonpositive rigging of largest length. Then it adds a box from a string of length $k$ in the $a$-th rigged partition, keeping all colabels fixed and decreasing the new label by one. If no such string exists, then it adds a new string of length 1 with label $-1$. If any of the resulting vacancy numbers are larger than the labels (i.e. it is an invalid rigged configuration), then $f_a$ is undefined.

INPUT:

• a – the index of the partition to add a box

OUTPUT:

The resulting rigged configuration element.

EXAMPLES:

```python
sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: RC = crystals.RiggedConfigurations(['A',2,1], La[0])
sage: elt = RC(partition_list=[[1,1],[1],[2]])
sage: elt.f(0)
-2[- ][-2]
-1[-1]
 1[ 1]
0[ ][]
sage: elt.f(1)
(continues on next page)
```
weight()

Return the weight of self.

EXAMPLES:

```python
sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: B = crystals.RiggedConfigurations(['A',2,1], La[0])
sage: mg = B.module_generators[0]
sage: mg.f_string([0,1,2,0]).weight()
```

class sage.combinat.rigged_configurations.rigged_configuration_element.RCNonSimplyLacedElement(parent, rigged_partitions=[], **options)

Bases: RiggedConfigurationElement

Rigged configuration elements for non-simply-laced types.

e(a)

Return the action of $e_a$ on self.

This works by lifting into the virtual configuration, then applying

$$e_a^\nu = \prod_{j \in \iota(a)} \hat{e}_j^{\gamma_j}$$

and pulling back.

EXAMPLES:

```python
sage: vct = CartanType(['C',2,1]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: elt = RC(partition_list=[[2],[1,1],[2]], rigging_list=[[1],[1,-1],[1]])
sage: ascii_art(elt.e(0))
0[ ][ ]
0[ ][ ]
-2[ ][ ]-1
-2[ ][ ]-1
sage: ascii_art(elt.e(1))
-2[ ][ ]-1
-3[ ][ ]-2
0[ ][ ]-3[ ][ ]-2
sage: ascii_art(elt.e(2))
-2[ ][ ]-1
-2[ ][ ]-1
0[ ][ ]
-2[ ][ ]-1
```
Return the action of \( f_\alpha \) on \( \text{self} \).

This works by lifting into the virtual configuration, then applying

\[
f'_\alpha = \prod_{j \in \{\alpha\}} f'_{\gamma_j}
\]

and pulling back.

**EXAMPLES:**

```python
sage: vct = CartanType(['C',2,1]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: elt = RC(partition_list=[[2],[1,1],[2]], rigging_list=[[-1],[-1,-1],[-1]])
sage: ascii_art(elt.f(0))
-4[ ][ ][ ]-2
-2[ ][ ]-1
-2[ ][ ]-1
sage: ascii_art(elt.f(1))
-1[ ][ ]0
-2[ ][ ]-2
-1[ ][ ]0
-2[ ][ ]-1
sage: ascii_art(elt.f(2))
-2[ ][ ]-1
-2[ ][ ]-1
-4[ ][ ][ ]-2
-2[ ][ ]-1
```

to_virtual_configuration()

Return the corresponding rigged configuration in the virtual crystal.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['C',2,1], [[1,2],[1,1],[2,1]])
sage: elt = RC(partition_list=[[3],[2]]); elt
0[ ][ ][ ][ ]
0[ ][ ]
sage: elt.to_virtual_configuration()
0[ ][ ][ ][ ]
0[ ][ ]
0[ ][ ][ ][ ]
0[ ][ ][ ]
```

class sage.combinat.rigged_configurations.rigged_configuration_element.RiggedConfigurationElement(parent, rigged_partitions=[], **options)

Bases: ClonableArray

A rigged configuration for simply-laced types.

For more information on rigged configurations, see `RiggedConfigurations`. For rigged configurations for non-simply-laced types, use `RCNonSimplyLacedElement`.

Typically to create a specific rigged configuration, the user will pass in the optional argument `partition_list` and if the user wants to specify the rigging values, give the optional argument `rigging_list` as well. If `rigging_list` is not passed, the rigging values are set to the corresponding vacancy numbers.
INPUT:

- **parent** – the parent of this element
- **rigged_partitions** – a list of rigged partitions

There are two optional arguments to explicitly construct a rigged configuration. The first is **partition_list** which gives a list of partitions, and the second is **rigging_list** which is a list of corresponding lists of riggings. If only **partition_list** is specified, then it sets the rigging equal to the calculated vacancy numbers.

If we are constructing a rigged configuration from a rigged configuration (say of another type) and we don’t want to recompute the vacancy numbers, we can use the **use_vacancy_numbers** to avoid the recomputation.

EXAMPLES:

Type $A_n^{(1)}$ examples:

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RC(partition_list=[[2], [2, 2], [2], [2]])
```

```
0

   0[ ]0

check()

Check the rigged configuration is properly defined.

There is nothing to check here.

EXAMPLES:

sage: RC = crystals.infinity.RiggedConfigurations(['A', 4])

sage: b = RC.module_generators[0].f_string([1,2,1,1,2,4,2,3,3,2])

sage: b.check()

e(a)

Return the action of the crystal operator $e_a$ on self.

This implements the method defined in [CrysStructSchilling06] which finds the value $k$ which is the length of the string with the smallest negative rigging of smallest length. Then it removes a box from a string of length $k$ in the $a$-th rigged partition, keeping all colabels fixed and increasing the new label by one. If no such string exists, then $e_a$ is undefined.
This method can also be used when the underlying Cartan matrix is a Borcherds-Cartan matrix. In this case, then method of [SS2018] is used, where the new label is increased by half of the \(a\)-th diagonal entry of the underlying Borcherds-Cartan matrix. This method will also return \(\text{None}\) if \(a\) is imaginary and the smallest rigging in the \(a\)-th rigged partition is not exactly half of the \(a\)-th diagonal entry of the Borcherds-Cartan matrix.

**INPUT:**

- \(a\) – the index of the partition to remove a box

**OUTPUT:**

The resulting rigged configuration element.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2,1]])
sage: elt = RC(partition_list=[[1], [1], [1], [1]])
sage: elt.e(3)
sage: elt.e(1)
```

\(0[\ ]0\)

\(0[\ ]0\)

\(-1[\ ]-1\)

```python
sage: A = CartanMatrix([[-2,-1],[-1,-2]], borcherds=True)
sage: RC = crystals.infinity.RiggedConfigurations(A)
sage: nu0 = RC(partition_list=[[],[]])
sage: nu = nu0.f_string([1,0,0,0])
sage: ascii_art(nu.e(0))
```

5[ ]3 4[ ]3

5[ ]1

\(\epsilon(a)\)

Return \(\epsilon(a)\) of self.

Let \(x_i\) be the smallest string of \(\nu^{(a)}\) or 0 if \(\nu^{(a)} = \emptyset\), then we have \(\epsilon(a) = -\min(0, x_i)\).

**EXAMPLES:**

```python
sage: La = RootSystem(['B',2]).weight_lattice().fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[1]+La[2])
sage: I = RC.index_set()
sage: matrix([[rc.epsilon(i) for i in I] for rc in RC[:4]])
```

\[
\begin{bmatrix}
0 & 0 \\
1 & 0 \\
0 & 1 \\
0 & 2
\end{bmatrix}
\]

\(f(a)\)

Return the action of the crystal operator \(f_a\) on self.
This implements the method defined in [CrysStructSchilling06] which finds the value $k$ which is the length of the string with the smallest nonpositive rigging of largest length. Then it adds a box from a string of length $k$ in the $a$-th rigged partition, keeping all colabels fixed and decreasing the new label by one. If no such string exists, then it adds a new string of length 1 with label $-1$. However we need to modify the definition to work for $B(\infty)$ by removing the condition that the resulting rigged configuration is valid.

This method can also be used when the underlying Cartan matrix is a Borcherds-Cartan matrix. In this case, then method of [SS2018] is used, where the new label is decreased by half of the $a$-th diagonal entry of the underlying Borcherds-Cartan matrix.

**INPUT:**

- $a$ – the index of the partition to add a box

**OUTPUT:**

The resulting rigged configuration element.

**EXAMPLES:**

```python
sage: RC = crystals.infinity.RiggedConfigurations(['A', 3])
sage: nu0 = RC.module_generators[0]
sage: nu0.f(2)
\(-2[ ]\)
\(-1\)

sage: A = CartanMatrix([[-2,-1],[-1,-2]], borcherds=True)
sage: RC = crystals.infinity.RiggedConfigurations(A)
sage: nu0 = RC(partition_list=[[[],[]]])
sage: nu = nu0.f_string([1,0,0,0])
sage: ascii_art(nu.f(0))

\begin{align*}
9[ ] & 7 \quad 6[ ] 5 \\
9[ ] & 5 \\
9[ ] & 3 \\
9[ ] & 1
\end{align*}
```

**nu()**

Return the list $\nu$ of rigged partitions of this rigged configuration element.

**OUTPUT:**

The $\nu$ array as a list.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RC(partition_list=[[2], [2,2], [2], [2]]).nu()

\begin{align*}
[0[ ][ ]0
, -2[ ][ ]-2 \\
-2[ ][ ]-2 \\
2[ ][ ]2 \\
-2[ ][ ]-2
\]
```

**partition_rigging_lists()**

Return the list of partitions and the associated list of riggings of `self`.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A',3,1], [[1,2],[2,2]])
sage: rc = RC(partition_list=[[2],[1],[1]], rigging_list=[[-1],[0],[-1]]); rc
-1[ ][ ]-1
1[ ][ ]0
-1[ ][ ]-1
sage: rc.partition_rigging_lists()
[[[2], [1], [1]], [[-1], [0], [-1]]]
```

**phi(\(\alpha\))**

Return \(\varphi_\alpha\) of `self`.

Let \(x_\ell\) be the smallest string of \(\nu^{(\alpha)}\) or 0 if \(\nu^{(\alpha)} = \emptyset\), then we have \(e_\alpha = p^{(\alpha)} - \min(0, x_\ell)\).

**EXAMPLES:**

```python
sage: La = RootSystem(['B',2]).weight_lattice().fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[1]+La[2])
sage: I = RC.index_set()
sage: matrix([[rc.phi(i) for i in I] for rc in RC[:4]])
[1 1]
[0 3]
[0 2]
[1 1]
```

**vacancy_number(\(a, i\))**

Return the vacancy number \(p^{(\alpha)}_i\).

**INPUT:**

- `a` – the index of the rigged partition
- `i` – the row of the rigged partition

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A',4,1], [[2, 2]])
sage: elt = RC(partition_list=[[1], [2,1], [1], [1]])
sage: elt.vacancy_number(2, 3)
-2
sage: elt.vacancy_number(2, 2)
-2
sage: elt.vacancy_number(2, 1)
-1
sage: RC = RiggedConfigurations(['D',4,1], [[2,1], [2,1]])
sage: x = RC(partition_list=[[3], [3,1,1], [2], [3,1]]); ascii_art(x)
-1[ ][ ]-1 1[ ][ ]1 0[ ][ ]0 -3[ ][ ]-3
```

(continues on next page)
5.1.214 Rigged Configurations

AUTHORS:

• Travis Scrimshaw (2010-09-26): Initial version

sage.combinat.rigged_configurations.rigged_configurations.KirillovReshetikhinCrystal(cartan_type, r, s)

Return the KR crystal $B_{r,s}$ using rigged configurations.

This is the rigged configuration $RC(B_{r,s})$ or $RC(L)$ with $L = (L^{(a)}_i)$ and $L^{(a)}_i = \delta_{a,r} \delta_{i,s}$.

EXAMPLES:

sage: K1 = crystals.kirillov_reshetikhin.RiggedConfigurations(['A',6,2], 2, 1)
sage: K2 = crystals.kirillov_reshetikhin.LSPaths(['A',6,2], 2, 1)
sage: K1.digraph().is_isomorphic(K2.digraph(), edge_labels=True)
True

class sage.combinat.rigged_configurations.rigged_configurations.RCNonSimplyLaced(cartan_type, dims)

Bases: RiggedConfigurations

Rigged configurations in non-simply-laced types.

These are rigged configurations which lift to virtual rigged configurations in a simply-laced type.

For more on rigged configurations, see RiggedConfigurations.

Element

alias of KRRNonSimplyLacedElement

from_virtual(vrc)

Convert vrc in the virtual crystal into a rigged configuration of the original Cartan type.

INPUT:

• vrc – a virtual rigged configuration

EXAMPLES:

sage: RC = RiggedConfigurations(['C',2,1], [[1,2],[1,1],[2,1]])
sage: elt = RC(partition_list=[[3],[2]])
sage: vrc_elt = RC.to_virtual(elt)
sage: ret = RC.from_virtual(vrc_elt); ret

0[ ]0
0[ ]0
sage: ret == elt
True
kleber_tree()
Return the underlying (virtual) Kleber tree used to generate all highest weight rigged configurations.

EXAMPLES:

```sage
class RC(RiggedConfigurations):
    def kleber_tree(self):
        pass
```

module_generators()
Module generators for this set of rigged configurations.
Iterate over the highest weight rigged configurations by moving through the KleberTree and then setting appropriate values of the partitions.

EXAMPLES:

```sage
class RC(RiggedConfigurations):
    def module_generators(self):
        pass
```

to_virtual(rc)
Convert rc into a rigged configuration in the virtual crystal.

INPUT:

* rc – a rigged configuration element

EXAMPLES:

```sage
class RC(RiggedConfigurations):
    def to_virtual(self, rc):
        pass
```

(continues on next page)
virtual()

Return the corresponding virtual crystal.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C',2,1], [[1,2],[1,1],[2,1]])
sage: RC
Rigged configurations of type ['C', 2, 1] and factor(s) ((1, 2), (1, 1), (2, 1))
sage: RC.virtual
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 2), (3, 2), (1, 1), (3, 1), (2, 2))
```

class sage.combinat.rigged_configurations.rigged_configurations.RCTypeA2Dual(cartan_type, dims)

Bases: RCTypeA2Even

Rigged configurations of type $A^{(2)}_{2n}$.

For more on rigged configurations, see RiggedConfigurations.

EXAMPLES:

```
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,2],[1,1],[2,1]])
sage: RC
Rigged configurations of type ['BC', 2, 2] and factor(s) ((1, 2), (1, 1), (2, 1))
sage: RC.cardinality()
750
sage: RC = RiggedConfigurations(CartanType(['A',2,2]).dual(), [[1,1]])
```

Element
alias of \texttt{KRRCTypeA2DualElement}

\textbf{\texttt{from\_virtual}(vrc)}

Convert vrc in the virtual crystal into a rigged configuration of the original Cartan type.

\textbf{INPUT:}

\begin{itemize}
  \item vrc – a virtual rigged configuration element
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[2,2]])
sage: elt = RC(partition_list=[[1],[1]])
sage: velt = RC.to_virtual(elt)
sage: ret = RC.from_virtual(velt); ret
-1[-]1
1[ ]1
sage: ret == elt
True
\end{verbatim}

\textbf{\texttt{module\_generators}()}\textbf{\hspace{1em}}

Module generators for rigged configurations of type $A_{2n}^{(2)}$.

Iterate over the highest weight rigged configurations by moving through the \texttt{KleberTree} and then setting appropriate values of the partitions. This also skips rigged configurations where $P_i^{(n)} < 1$ when $i$ is odd.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,1]])
sage: for x in RC.module_generators: x

(\(/\))

(\(/\))
\end{verbatim}

\textbf{\texttt{to\_virtual}(rc)}

Convert rc into a rigged configuration in the virtual crystal.

\textbf{INPUT:}

\begin{itemize}
  \item rc – a rigged configuration element
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[2,2]])
sage: elt = RC(partition_list=[[1],[1]]); elt
-1[-]1
1[ ]1
sage: velt = RC.to_virtual(elt); velt

(continues on next page)
Rigged configurations for type $\alpha_2$.
For more on rigged configurations, see `RiggedConfigurations`.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A',4,2], [[2,1], [1,2]])
sage: RC.cardinality()
150
sage: RC = RiggedConfigurations(['A',2,2], [[1,1]])
sage: RC.cardinality()
3
sage: RC = RiggedConfigurations(['A',2,2], [[1,2],[1,1]])
sage: TestSuite(RC).run() # long time
sage: RC = RiggedConfigurations(['A',4,2], [[2,1]])
sage: TestSuite(RC).run() # long time
```

**cardinality()**

Return the cardinality of self.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A',4,2], [[1,1], [2,2]])
sage: RC.cardinality()
250
```

**from_virtual(vrc)**

Convert vrc in the virtual crystal into a rigged configuration of the original Cartan type.

**INPUT:**

* vrc – a virtual rigged configuration element

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A',4,2], [[2,2]])
sage: elt = RC(partition_list=[[1],[1]])
sage: velt = RC.to_virtual(elt)
sage: ret = RC.from_virtual(velt); ret
-1[ ]-1
```
to_virtual(rc)

Convert rc into a rigged configuration in the virtual crystal.

INPUT:

• rc – a rigged configuration element

EXAMPLES:

```
sage: RC = RiggedConfigurations(["A", 4, 2], [[2, 2]])
sage: elt = RC(partition_list=[[1], [1]]); elt

sage: velt = RC.to_virtual(elt); velt

sage: velt.parent()
```

virtual()

Return the corresponding virtual crystal.

EXAMPLES:

```
sage: RC = RiggedConfigurations(["A", 4, 2], [[1, 2], [1, 1], [2, 1]])
sage: RC.virtua
```

5.1. Comprehensive Module List
that

\[ \sum_{T \times \mathbb{Z}_{\geq 0}} i m_i^{(a)} \alpha_a = \sum_{T \times \mathbb{Z}_{\geq 0}} i L_i^{(a)} \Lambda_a - \Lambda \]

where \( \alpha_a \) is a simple root, \( \Lambda_a \) is a fundamental weight, and \( m_i^{(a)} \) is the number of rows of length \( i \) in the partition \( \nu^{(a)} \).

Each partition \( \nu^{(a)} \), in the sequence also comes with a sequence of statistics \( p_i^{(a)} \) called vacancy numbers and a weakly decreasing sequence \( J_i^{(a)} \) of length \( m_i^{(a)} \) called riggings. Vacancy numbers are computed based upon the partitions and \( L_i^{(a)} \), and the riggings must satisfy \( \max J_i^{(a)} \leq p_i^{(a)} \). We call such a partition a rigged partition. For more, see [RigConBijection] [CrysStructSchilling06] [BijectionLRT].

Rigged configurations form combinatorial objects first introduced by Kerov, Kirillov and Reshetikhin that arose from studies of statistical mechanical models using the Bethe Ansatz. They are sequences of rigged partitions. A rigged partition is a partition together with a label associated to each part that satisfy certain constraints. The labels are also called riggings.

Rigged configurations exist for all affine Kac-Moody Lie algebras. See for example [HKOTT2002]. In Sage they are specified by providing a Cartan type and a list of rectangular shapes \( B \). The list of all (highest weight) rigged configurations for given \( B \) is computed via the (virtual) Kleber algorithm (see also KleberTree and VirtualKleberTree).

Rigged configurations in simply-laced types all admit a classical crystal structure [CrysStructSchilling06]. For non-simply-laced types, the crystal is given by using virtual rigged configurations [OSS03]. The highest weight rigged configurations are those where all riggings are nonnegative. The list of all rigged configurations is computed from the highest weight ones using the crystal operators.

Rigged configurations are conjecturally in bijection with TensorProductOfKirillovReshetikhinTableaux of non-exceptional affine types where the list \( B \) corresponds to the tensor factors \( B'^{r,s} \). The bijection has been proven in types \( A_n^{(1)} \) and \( D_n^{(1)} \) and when the only non-zero entries of \( L_i^{(a)} \) are either only \( L_i^{(a)} \) or only \( J_i^{(1)} \) (corresponding to single columns or rows respectively) [RigConBijection], [BijectionLRT], [BijectionDn].

KR crystals are implemented in Sage, see KirillovReshetikhinCrystal(), however, in the bijection with rigged configurations a different realization of the elements in the crystal are obtained, which are coined KR tableaux, see KirillovReshetikhinTableaux. For more details see [OSS2011].

**Note:** All non-simply-laced rigged configurations have not been proven to give rise to aligned virtual crystals (i.e. have the correct crystal structure or isomorphic as affine crystals to the tensor product of KR tableaux).

**INPUT:**

- `cartan_type` – a Cartan type
- \( B \) – a list of positive integer tuples \((r, s)\) corresponding to the tensor factors in the bijection with tensor product of Kirillov-Reshetikhin tableaux or equivalently the sequence of width \( s \) and height \( r \) rectangles

**REFERENCES:**

**EXAMPLES:**

```
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [1, 2], [1, 1]])
sage: RC
Rigged configurations of type ['A', 3, 1] and factor(s) ((3, 2), (1, 2), (1, 1))
sage: RC = RiggedConfigurations(['A', 3, 1], [[2, 1]]);
RC
Rigged configurations of type ['A', 3, 1] and factor(s) ((2, 1),)
```
A rigged configuration element with all riggings equal to the vacancy numbers can be created as follows:

```
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [2, 1], [1, 1], [1, 1]]); RC
Rigged configurations of type ['A', 3, 1] and factor(s) ((3, 2), (2, 1), (1, 1), (1, 1))
sage: elt = RC(partition_list=[[1],[],[]]); elt
0[ ]0
( )
( )
```

If on the other hand we also want to specify the riggings, this can be achieved as follows:

```
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [1, 2], [1, 1]])
sage: RC(partition_list=[[2],[2],[2]])
1[ ]0
0[ ]0
0[ ]0
sage: RC(partition_list=[[2],[2],[2]], rigging_list=[[0],[0],[0]])
1[ ]0
0[ ]0
0[ ]0
```

A larger example:

```
sage: RC = RiggedConfigurations(['D', 7, 1], [[3,3],[5,2],[4,3],[2,3],[4,4],[3,1],
                      [1,4],[2,2]]);
sage: elt = RC(partition_list=[[2],[3,2,1],[2,2,1,1],[2,2,1,1,1],[3,2,1,1,1,1],[2,1,1,1,1,1],
                      [2,1,1,1,1,1]],
```

(continues on next page)
To obtain the KR tableau under the bijection between rigged configurations and KR tableaux, we can type the following. This example was checked against Reiho Sakamoto’s Mathematica program on rigged configurations:

```
sage: output = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); output
[[1, 1, 1], [2, 3, 3], [3, 4, -5]] (X) [[1, 1], [2, 2], [3, 3], [5, -6], [6, -5]] →
[[1, 1, 2], [2, 2, 3], [3, 3, 7], [4, 4, -7]] (X) [[1, 1, 1], [2, 2, 2]] (X)
[[1, 1, 1, 3], [2, 2, 3, 4], [3, 3, 4, 5], [4, 4, 5, 6]] (X) [[1, 2], [3]] (X) →
[[1, 1, 1, 1]] (X) [[1, 1, 2]] (X)
```

```
sage: elt.to_tensor_product_of_kirillov_reshetikhin_tableaux().to_rigged_configuration() == elt
True
sage: output.to_rigged_configuration().to_tensor_product_of_kirillov_reshetikhin_tableaux() == output
True
```

We can also convert between rigged configurations and tensor products of KR crystals:

```
sage: output = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); output
[[1, 1, 1], [2, 3, 3], [3, 4, -5]] (X) [[1, 1], [2, 2], [3, 3], [5, -6], [6, -5]] →
[[1, 1, 2], [2, 2, 3], [3, 3, 7], [4, 4, -7]] (X) [[1, 1, 1], [2, 2, 2]] (X)
[[1, 1, 1, 3], [2, 2, 3, 4], [3, 3, 4, 5], [4, 4, 5, 6]] (X) [[1, 2], [3]] (X) →
[[1, 1, 1, 1]] (X) [[1, 1, 2]] (X)
```

```
sage: output.to_rigged_configuration().to_tensor_product_of_kirillov_reshetikhin_tableaux() == output
True
```

We can also convert between rigged configurations and tensor products of KR crystals:
```python
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 1]])
sage: elt = RC(partition_list=[[1],[1,1],[1],[1]])
sage: tp_krc = elt.to_tensor_product_of_kirillov_reshetikhin_crystals(); tp_krc
[]
sage: ret = RC(tp_krc)
sage: ret == elt
True
sage: RC = RiggedConfigurations(['D', 4, 1], [[4,1], [3,3]])
sage: KR1 = crystals.KirillovReshetikhin(['D', 4, 1], 4, 1)
sage: KR2 = crystals.KirillovReshetikhin(['D', 4, 1], 3, 3)
sage: T = crystals.TensorProduct(KR1, KR2)
sage: t = T[1]; t
[[++++, []], [++++-, [[1], [2], [4], [-4]]]]
sage: ret = RC(t)
sage: ret.to_tensor_product_of_kirillov_reshetikhin_crystals()
[[++++, []], [++++-, [[1], [2], [4], [-4]]]]
```

Element

alias of `KRRCSimplyLacedElement`

```python
classically_highest_weight_vectors()
```

Return the classically highest weight elements of `self`.

```python
fermionic_formula(q=None, only_highest_weight=False, weight=None)
```

Return the fermionic formula associated to `self`. Given a set of rigged configurations $RC(\lambda, L)$, the fermionic formula is defined as:

$$M(\lambda, L; q) = \sum_{(\nu,J)} q^{cc(\nu,J)}$$

where we sum over all (classically highest weight) rigged configurations of weight $\lambda$ where $cc$ is the cocharge statistic. This is known to reduce to

$$M(\lambda, L; q) = \sum_{\nu} q^{cc(\nu)} \prod_{(a,i) \in I \times \mathbb{Z}} \left[ \frac{p_i^{(a)} + m_i^{(a)}}{m_i^{(a)}} \right]_q.$$

The generating function of $M(\lambda, L; q)$ in the weight algebra subsumes all fermionic formulas:

$$M(L; q) = \sum_{\lambda \in P} M(\lambda, L; q) \lambda.$$  

This is conjecturally equal to the one dimensional configuration sum of the corresponding tensor product of Kirillov-Reshetikhin crystals, see [HKOTT2002]. This has been proven in general for type $A_n^{(1)}$ [BijectionLRT], single factors $B_r^{e,s}$ in type $D_n^{(1)}$ [OSS2011] with the result from [Sakamoto13], as well as for a tensor product of single columns [OSS2003], [BijectionDn] or a tensor product of single rows [OSS03] for all non-exceptional types.

**INPUT:**

- `q` – the variable $q$
- `only_highest_weight` – use only the classically highest weight rigged configurations
- `weight` – return the fermionic formula $M(\lambda, L; q)$ where $\lambda$ is the classical weight weight
REFERENCES:
EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A', 2, 1], [[1, 1], [1, 1]])
sage: RC.fermionic_formula()
B[-2*Lambda[1] + 2*Lambda[2]] + (q+1)*B[-Lambda[1]]
 + B[-2*Lambda[2]] + (q+1)*B[Lambda[2]]
sage: t = QQ['t'].gen(0)
sage: RC.fermionic_formula(t)
B[-2*Lambda[1] + 2*Lambda[2]] + (t+1)*B[-Lambda[1]]
 + B[-2*Lambda[2]] + (t+1)*B[Lambda[2]]
sage: La = RC.weight_lattice_realization().classical().fundamental_weights()
sage: RC.fermionic_formula(weight=La[2])
q + 1
sage: RC.fermionic_formula(only_highest_weight=True, weight=La[2])
q
```

Only using the highest weight elements on other types:

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 1], [2, 2]])
sage: RC.fermionic_formula(only_highest_weight=True)
 + (q^4+q^3+q^2)*B[Lambda[3]]
sage: RC = RiggedConfigurations(['D', 4, 2], [[3, 1], [2, 2]])
sage: RC.fermionic_formula(only_highest_weight=True) # long time
(q^2+q)*B[Lambda[1] + Lambda[2] + Lambda[3]] + (q^5+2*q^4+q^3)*B[Lambda[1]]
 + (q^6+q^5+q^4)*B[Lambda[3]]
sage: RC = RiggedConfigurations(CartanType(['A', 4, 2]).dual(), [[1, 1], [2, 2]])
sage: RC.fermionic_formula(only_highest_weight=True)
```

kleber_tree()

Return the underlying Kleber tree used to generate all highest weight rigged configurations.
EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[1, 1], [2, 1]])
sage: RC.kleber_tree()
Kleber tree of Cartan type ['A', 3, 1] and B = ((1, 1), (2, 1))
```

**module_generators()**

Module generators for this set of rigged configurations.

Iterate over the highest weight rigged configurations by moving through the `KleberTree` and then setting appropriate values of the partitions.

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 1]])
sage: for x in RC.module_generators: x

(//)
(//)
(//)
(//)
0[ ]0
0[ ]0
0[ ]0
0[ ]0
0[ ]0

options = Current options for RiggedConfigurations - convention: English - display: vertical - element_ascii_art: True - half_width_boxes_type_B: True

**tensor(*crystals, **options)**

Return the tensor product of self with crystals.

If crystals is a list of rigged configurations of the same Cartan type, then this returns a new `RiggedConfigurations`.

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[2, 1], [1, 3]])
sage: RC2 = RiggedConfigurations(['A', 3, 1], [[1, 1], [3, 3]])
sage: RC.tensor(RC2, RC2)
Rigged configurations of type ['A', 3, 1] and factor(s) ((2, 1), (1, 3), (1, 1), (3, 3), (1, 1), (3, 3))
sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2, model='KR')
sage: RC.tensor(K)
Full tensor product of the crystals
```

(continues on next page)
tensor_product_of_kirillov_reshetikhin_crystals()

Return the corresponding tensor product of Kirillov-Reshetikhin crystals.

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[3,1],[2,2]])
sage: RC.tensor_product_of_kirillov_reshetikhin_crystals()
Full tensor product of the crystals
Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(3,1),
Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(2,2)
```

tensor_product_of_kirillov_reshetikhin_tableaux()

Return the corresponding tensor product of Kirillov-Reshetikhin tableaux.

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [1, 2]])
sage: RC.tensor_product_of_kirillov_reshetikhin_tableaux()
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and
˓→factor(s) ((3, 2), (1, 2))
```

5.1.215 Rigged Partitions

Class and methods of the rigged partition which are used by the rigged configuration class. This is an internal class used by the rigged configurations and KR tableaux during the bijection, and is not to be used by the end-user.

We hold the partitions as an 1-dim array of positive integers where each value corresponds to the length of the row. This is the shape of the partition which can be accessed by the regular index.

The data for the vacancy number is also stored in a 1-dim array which each entry corresponds to the row of the tableau, and similarly for the partition values.

AUTHORS:

- Travis Scrimshaw (2010-09-26): Initial version

Todo: Convert this to using multiplicities \( m_i \) (perhaps with a dictionary)?

class sage.combinat.rigged_configurations.rigged_partition.RiggedPartition

Bases: SageObject

The RiggedPartition class which is the data structure of a rigged (i.e. marked or decorated) Young diagram of a partition.

Note that this class as a stand-alone object does not make sense since the vacancy numbers are calculated using the entire rigged configuration. For more, see RiggedConfigurations.

EXAMPLES:
### get_num_cells_to_column(*end_column, t=1*)

Get the number of cells in all columns before the *end_column*.

**INPUT:**

- *end_column* – The index of the column to end at
- *t* – The scaling factor

**OUTPUT:**

- The number of cells

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations([['A', 4, 1], [[2, 2]]])
sage: RP = RC(partition_list=[[2],[2,2],[2,1],[2]])[2]
sage: RP.get_num_cells_to_column(1)
2
sage: RP.get_num_cells_to_column(2)
3
sage: RP.get_num_cells_to_column(3)
3
sage: RP.get_num_cells_to_column(3, 2)
5
```

### insert_cell(*max_width*)

Insert a cell given at a singular value as long as its less than the specified width.

Note that `insert_cell()` does not update riggings or vacancy numbers, but it does prepare the space for them. Returns the width of the row we inserted at.

**INPUT:**

- *max_width* – The maximum width (i.e. row length) that we can insert the cell at

**OUTPUT:**

- The width of the row we inserted at.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations([['A', 4, 1], [[2, 2]]])
sage: RP = RC(partition_list=[[2],[2,2],[2,1],[2]])[2]
sage: RP.insert_cell(2)
2
sage: RP
0[ ][ ]None
-1[ ][ ]
```

### remove_cell(*row, num_cells=1*)

Removes a cell at the specified *row*.
Combinatorics, Release 10.0

Note that \texttt{remove\_cell()} does not set/update the vacancy numbers or the riggings, but guarantees that the location has been allocated in the returned index.

**INPUT:**
- \texttt{\_row} – the row to remove the cell from
- \texttt{\_num\_cells} – (default: 1) the number of cells to remove

**OUTPUT:**
- The location of the newly constructed row or \texttt{None} if unable to remove row or if deleted a row.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RP = RC(partition_list=[[2],[2,2],[2,1],[2]])[2]
sage: RP.remove_cell(0)

0
sage: RP
None

-rigging
-vacancy\_numbers
```

**class** \texttt{sage.combinat.rigged\_configurations.rigged\_partition.RiggedPartitionTypeB}

Bases: \texttt{RiggedPartition}

Rigged partitions for type $B_{(1)}^{(1)}$ which has special printing rules which comes from the fact that the $n$-th partition can have columns of width $\frac{1}{2}$.

### 5.1.216 Tensor Product of Kirillov-Reshetikhin Tableaux

A tensor product of \texttt{KirillovReshetikhinTableaux} which are tableaux of $r$ rows and $s$ columns which naturally arise in the bijection between rigged configurations and tableaux and which are in bijection with the elements of the Kirillov-Reshetikhin crystal $B^{r,s}$, see \texttt{KirillovReshetikhinCrystal()}.

**AUTHORS:**
- Travis Scrimshaw (2010-09-26): Initial version

**EXAMPLES:**

Type $A_{(1)}^{(1)}$ examples:

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[3,1], [2, 1]])
sage: KRT
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and factor(s) ((3,0), (2, 1))
sage: KRT.cardinality()
24
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[1,1], [2,1], [3,1]])
sage: KRT
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and factor(s) ((1,0), (1, 0))
```

(continues on next page)
−1), (2, 1), (3, 1))
sage: len(KRT.module_generators)
5
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[1,1], [2,1], [3,1]])
sage: KRT.cardinality()
96

Type $D_n^{(1)}$ examples:

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[1, 1], [2, 1], [3, 1]])
sage: KRT.cardinality()
96

---

Warning: This class is for internal use only!

class sage.combinat.rigged_configurations.tensor_product_kr_tableaux.HighestWeightTensorKRT(tp_krt)

Bases: UniqueRepresentation

Class so we do not have to build the module generators for $\text{TensorProductOfKirillovReshetikhinTableaux}$ at initialization.

cardinality()

Return the cardinality of self, which is the number of highest weight elements.

EXAMPLES:

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[2, 1], [3, 1]])
sage: from sage.combinat.rigged_configurations.tensor_product_kr_tableaux import HighestWeightTensorKRT
sage: HW = HighestWeightTensorKRT(KRT)
sage: HW.cardinality()
3

---

class sage.combinat.rigged_configurations.tensor_product_kr_tableaux.TensorProductOfKirillovReshetikhinTableaux

Bases: FullTensorProductOfRegularCrystals

5.1. Comprehensive Module List 2243
A tensor product of *KirillovReshetikhinTableaux*.

Through the bijection with rigged configurations, the tableaux that are produced in all nonexceptional types are all of rectangular shapes and do not necessarily obey the usual strict increase in columns and weak increase in rows. The relation between the elements of the Kirillov-Reshetikhin crystal, given by the Kashiwara-Nakashima tableaux, and the Kirillov-Reshetikhin tableaux is given by a filling map.

**Note:** The tableaux for all non-simply-laced types are provably correct if the bijection with *rigged configurations* holds. Therefore this is currently only proven for $B^{r,1}$ or $B^{1,s}$ and in general for types $A_n^{(1)}$ and $D_n^{(1)}$.

For more information see [OSS2011] and *KirillovReshetikhinTableaux*.

For more information on KR crystals, see `sage.combinat.crystals.kirillov_reshetikhin`.

**INPUT:**

- `cartan_type` – a Cartan type
- `B` – an (ordered) list of pairs $(r, s)$ which give the dimension of a rectangle with $r$ rows and $s$ columns and corresponds to a Kirillov-Reshetikhin tableaux factor of $B^{r,s}$.

**REFERENCES:**

**EXAMPLES:**

We can go between tensor products of KR crystals and rigged configurations:

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[3,1], [2,2]])
sage: tp_krt = KRT(pathlist=[[3,2,1],[3,2,3,2]]); tp_krt
[[1], [2], [3]]

sage: RC = RiggedConfigurations(['A',3,1], [[3,1],[2,2]]);
sage: rc_elt = tp_krt.to_rigged_configuration(); rc_elt
-2[ ]

sage: tp_krc = tp_krt.to_tensor_product_of_kirillov_reshetikhin_crystals(); tp_krc
[[[1], [2], [3]], [[2, 2], [3, 3]]]
sage: KRT(tp_krc) == tp_krt
True
sage: rc_elt == tp_krt.to_rigged_configuration()
True

sage: KR1 = crystals.KirillovReshetikhin(['A',3,1], 3,1)
sage: KR2 = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: T = crystals.TensorProduct(KR1, KR2)
sage: t = T(KR1(3,2,1), KR2(3,2,3,2))
sage: KRT(t) == tp_krt
True
sage: t == tp_krc
True
```

We can get the highest weight elements by using the attribute `module_generators`:
Combinatorics, Release 10.0

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[3,1], [2,1]])
sage: list(KRT.module_generators)
[[[1], [2], [3]], [[1], [2]], [[1], [3], [4]], [[1], [2]], [[1], [3], [4]], [[1], [2]]]
```

To create elements directly (i.e. not passing in KR tableau elements), there is the `pathlist` option will receive a list of lists which contain the reversed far-eastern reading word of the tableau. That is to say, in English notation, the word obtain from reading bottom-to-top, left-to-right.

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[3,2], [1,2], [2,1]])
sage: elt = KRT(pathlist=[[3, 2, 1, 4, 2, 1], [1, 3], [3, 1]])
sage: elt.pp()
  1 1 (X) 1 3 (X) 1
  2 2 3
  3 4
```

One can still create elements in the same way as tensor product of crystals:

```python
sage: K1 = crystals.KirillovReshetikhin(['A',3,1], 3, 2, model='KR')
sage: K2 = crystals.KirillovReshetikhin(['A',3,1], 1, 2, model='KR')
sage: K3 = crystals.KirillovReshetikhin(['A',3,1], 2, 1, model='KR')
sage: eltlonl = KRT(K1(3, 2, 1, 4, 2, 1), K2(1, 3), K3(3, 1))
sage: eltlonl == elt
True
```

**Element**

alias of `TensorProductOfKirillovReshetikhinTableauxElement`

**rigged_configurations()**

Return the corresponding set of rigged configurations.

**EXAMPLES:**

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[1, 3], [2,1]])
sage: KRT.rigged_configurations()
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 3), (2, 1))
```

**tensor(**crystals, **options)**

Return the tensor product of self with crystals.

If `crystals` is a list of (a tensor product of) KR tableaux, this returns a `TensorProductOfKirillovReshetikhinTableaux`.

**EXAMPLES:**

```python
sage: TP = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1], [[1, 3],[2,1]])
sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2, model='KR')
sage: TP.tensor(K, TP)
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1]
and factor(s) ((1, 3), (3, 1), (2, 2), (1, 3), (3, 1))
sage: C = crystals.KirillovReshetikhin(['A',3,1], 3, 1, model='KN')
```

(continues on next page)
sage: TP.tensor(K, C)
Full tensor product of the crystals
  [Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (1, 3),
  Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (3, 1),
  Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (2, 2),
  Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(3,1)]

\texttt{tensor\_product\_of\_kirillov\_reshetikhin\_crystals()}  

Return the corresponding tensor product of Kirillov-Reshetikhin crystals.

EXAMPLES:

\begin{verbatim}sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1], [[3, 1], [2, 2]]) sage: KRT.tensor_product_of_kirillov_reshetikhin_crystals() Full tensor product of the crystals 
  [Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(3,1),
  Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(2,2)]\end{verbatim}

5.1.217 Tensor Product of Kirillov-Reshetikhin Tableaux Elements

A tensor product of \textit{KirillovReshetikhinTableauxElement}.

AUTHORS:

- Travis Scrimshaw (2010-09-26): Initial version

\texttt{class sage.combinat.rigged_configurations.tensor_product_kr_tableaux_element.TensorProductOfKirillovReshetikhinTableauxElement(parent, list=[], **options)}

Bases: \texttt{TensorProductOfRegularCrystalsElement}

An element in a tensor product of Kirillov-Reshetikhin tableaux.

For more on tensor product of Kirillov-Reshetikhin tableaux, see \texttt{TensorProductOfKirillovReshetikhinTableaux}.

The most common way to construct an element is to specify the option \texttt{pathlist} which is a list of lists which will be used to generate the individual factors of \textit{KirillovReshetikhinTableauxElement}.

EXAMPLES:

Type $A_n^{(1)}$ examples:

\begin{verbatim}sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1], [[1,1], [2,1], [1,1], [2,1], [2,1]]) sage: T = KRT(pathlist=[[2], [4,1], [3], [4,2], [3,1], [2,1]]) sage: T [[2]] (X) [[1], [4]] (X) [[3]] (X) [[2], [4]] (X) [[1], [3]] (X) [[1], [2]] sage: T.to_rigged_configuration()
0 [ ] [ ] 0 1 [ ] 1 1 [ ] [ ] 0\end{verbatim}
sage: T = KRT(pathlist=[[1], [2,1], [1], [4,1], [3,1], [2,1]])
```
1[ ]0
1[ ]0
0[ ][ ]0
```
sage: T
```
[1] (X) [1], [2] (X) [1], [4] (X) [1], [3] (X) [1], [2]
```
```python
sage: T.to_rigged_configuration()
```
```
1[ ]0
1[ ]0
0[ ]0
0[ ]0
```

Type $D_n^{(1)}$ examples:
```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[1,1], [1,1], [1,1], [1]])
sage: T = KRT(pathlist=[[-1], [-1], [1], [1]])
sage: T
```
```
[-1] (X) [-1] (X) [1] (X) [1]
```
```python
sage: T.to_rigged_configuration()
```
```
0[ ][ ]0
0[ ][ ]0
0[ ][ ]0
0[ ][ ]0
0[ ][ ]0
0[ ][ ]0
```
```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[2,1], [1,1], [1,1], [1]])
sage: T = KRT(pathlist=[[3,2], [1], [-1], [1]])
sage: T
```
```
[2] (X) [3] (X) [1] (X) [-1] (X) [1]
```
```python
sage: T.to_rigged_configuration()
```
```
0[ ]0
0[ ]0
0[ ]0
0[ ]0
0[ ]0
1[ ]0
```
```
1[ ]0

sage: T.to_rigged_configuration().to_tensor_product_of_kirillov_reshetikhin_tableaux()
[[2], [3]] (X) [[1]] (X) [[-1]] (X) [[1]]

classical_weight()
Return the classical weight of self.

EXAMPLES:

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D',4,1], [[2, 2]])
sage: elt = KRT(pathlist=[[3,2,-1,1]]); elt
[[2, 1], [3, -1]]
sage: elt.classical_weight()
(0, 1, 1, 0)
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[2, 2],[1,3]])
sage: elt = KRT(pathlist=[[2,1,3,2],[1,4,4]]); elt
[[1, 2], [2, 3]] (X) [[1, 4, 4]]
sage: elt.classical_weight()
(2, 2, 1, 2)

left_split()
Return the image of self under the left column splitting map.

EXAMPLES:

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[2, 2],[1,3]])
sage: elt = KRT(pathlist=[[2,1,3,2],[1,4,4]]); elt.pp()
  1 2 (X) 1 4 4
  2 3
sage: elt.left_split().pp()
  1 (X) 2 (X) 1 4 4
  2 3

lusztig_involution()
Return the result of the classical Lusztig involution on self.

EXAMPLES:

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[2, 2],[1,3]])
sage: elt = KRT(pathlist=[[2,1,3,2],[1,4,4]])
sage: li = elt.lusztig_involution(); li
[[1, 1, 4]] (X) [[2, 3], [3, 4]]
sage: li.parent()
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and factor(s) ((1, 3), (2, 2))
pp() Pretty print self.

EXAMPLES:

```
sage: TPKRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',4,1],
                      [[2,2],[3,1],[3,3]])
sage: TPKRT.module_generators[0].pp()
  1 1  (X) 1  1  1
  2 2  (X) 2  2  2
  3 3  3  3  3
```

right_split() Return the image of self under the right column splitting map.

EXAMPLES:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1],
                      [[2,2],[1,3]])
sage: elt = KRT(pathlist=[[2,1,3,2],[1,4,4]]); elt.pp()
  1 2  (X) 1  4  4
  2 3
sage: elt.right_split().pp()
  1 2  (X) 1  4 (X) 4
  2 3
```

Let * denote the Lusztig involution, we check that * ∘ ls ∘ * = rs:

```
sage: all(x.lusztig_involution().left_split().lusztig_involution() == x.right_split() for x in KRT)
True
```

to_rigged_configuration(display_steps=False)

Perform the bijection from self to a rigged configuration which is described in [RigConBijection], [BijectionLRT], and [BijectionDn].

**Note:** This is only proven to be a bijection in types $A^{(1)}_n$ and $D^{(1)}_n$, as well as $\bigotimes B^{1,s_i}$ and $\bigotimes B^{1,s_i}$ for general affine types.

INPUT:

- `display_steps` – (default: False) Boolean which indicates if we want to output each step in the algorithm.

OUTPUT:

The rigged configuration corresponding to self.

EXAMPLES:

Type $A^{(1)}_n$ example:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1],
                      [[2,1],[2,1],[2,1]])
sage: T = KRT(pathlist=[[4, 2], [3, 1], [2, 1]])
sage: T
(continues on next page)```
This is invertible by calling `to_tensor_product_of_kirillov_reshetikhin_tableaux()`:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[2, 2]])
```

(continues on next page)
sage: T = KRT(pathlist=[[2,1,4,3]])
sage: rc = T.to_rigged_configuration()
sage: ret = rc.to_tensor_product_of_kirillov_reshetikhin_tableaux(); ret
[[1, 3], [2, 4]]
sage: ret == T
True

to_tensor_product_of_kirillov_reshetikhin_crystals()
Return a tensor product of Kirillov-Reshetikhin crystals corresponding to self.
This works by performing the filling map on each individual factor. For more on the filling map, see KirillovReshetikhinTableaux.

EXAMPLES:

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D',4,1], [[1, 1], [2,2]])
sage: elt = KRT(pathlist=[[1,-1],[-1,2,-1,1]]); elt
[[1], [2, 1], [-1, -1]]
sage: tp_krc = elt.to_tensor_product_of_kirillov_reshetikhin_crystals(); tp_krc
[[[1], [2]], [[-1]]]

We can recover the original tensor product of KR tableaux:

sage: ret = KRT(tp_krc); ret
[[1], [2, 1], [-1, -1]]
sage: ret == elt
True

5.1.218 Root Systems

Quickref

- T = CartanType(['A', 3]), T.is_finite() – Cartan types
- T.dynkin_diagram(), DynkinDiagram(['G',2]) – Dynkin diagrams
- T.cartan_matrix(), CartanMatrix(['F',4]) – Cartan matrices

5.1.219 Ambient lattices and ambient spaces

class `sage.combinat.root_system.ambient_space.AmbientSpace`(root_system, base_ring, index_set=None)

Bases: `CombinatorialFreeModule`

Abstract class for ambient spaces

All subclasses should implement a class method `smallest_base_ring` taking a Cartan type as input, and a method `dimension` working on a partially initialized instance with just `root_system` as attribute. There is no safe default implementation for the later, so none is provided.

EXAMPLES:

```
sage: AL = RootSystem(['A',2]).ambient_lattice()
```

Note: This is only used so far for finite root systems.

Caveat: Most of the ambient spaces currently have a basis indexed by 0,...,n, unlike the usual mathematical convention:

```
sage: e = AL.basis()
sage: e[0], e[1], e[2]
((1, 0, 0), (0, 1, 0), (0, 0, 1))
```

This will be cleaned up!

See also:

- `sage.combinat.root_system.type_G.AmbientSpace`
• `sage.combinat.root_system.type_dual.AmbientSpace`
• `sage.combinat.root_system.type_affine.AmbientSpace`

**Element**

alias of `AmbientSpaceElement`

**coroot_lattice()**

EXAMPLES:

```python
sage: e = RootSystem("A", 3).ambient_lattice()
sage: e.coroot_lattice()
Ambient lattice of the Root system of type ['A', 3]
```

**dimension()**

Return the dimension of this ambient space.

EXAMPLES:

```python
sage: from sage.combinat.root_system.ambient_space import AmbientSpace
def: e = RootSystem(['F', 4]).ambient_space()
sage: AmbientSpace.dimension(e)
Traceback (most recent call last):
  ...NotImplementedError
```

**from_vector_notation**(weight, style='lattice')

INPUT:

* weight - a vector or tuple representing a weight

Returns an element of self. If the weight lattice is not of full rank, it coerces it into the weight lattice, or its ambient space by orthogonal projection. This arises in two cases: for $SL(r+1)$, the weight lattice is contained in a hyperplane of codimension one in the ambient space, and for types $E6$ and $E7$, the weight lattice is contained in a subspace of codimensions 2 or 3, respectively.

If style="coroots" and the data is a tuple of integers, it is assumed that the data represent a linear combination of fundamental weights. If style="coroots", and the root lattice is not of full rank in the ambient space, it is projected into the subspace corresponding to the semisimple derived group. This arises with Cartan type $A$, $E6$ and $E7$.

EXAMPLES:

```python
sage: RootSystem("A2").ambient_space().from_vector_notation((1,0,0))
(1, 0, 0)
sage: RootSystem("A2").ambient_space().from_vector_notation([1,0,0])
(1, 0, 0)
sage: RootSystem("A2").ambient_space().from_vector_notation((1,0),style="coroots \rightarrow")
(2/3, -1/3, -1/3)
```

**fundamental_weight(i)**

Returns the fundamental weight $\Lambda_i$ in self.

In several of the ambient spaces, it is more convenient to construct all fundamental weights at once. To support this, we provide this default implementation of `fundamental_weight` using the method `fundamental_weights`. Beware that this will cause a loop if neither `fundamental_weight` nor `fundamental_weights` is implemented.
EXAMPLES:

```python
sage: e = RootSystem(['F',4]).ambient_space()
sage: e.fundamental_weight(3)
(3/2, 1/2, 1/2, 1/2)

sage: e = RootSystem(['G',2]).ambient_space()
sage: e.fundamental_weight(1)
(1, 0, -1)

sage: e = RootSystem(['E',6]).ambient_space()
sage: e.fundamental_weight(3)
(-1/2, 1/2, 1/2, 1/2, 1/2, -5/6, -5/6, 5/6)
```

`reflection(root, coroot=None)`

EXAMPLES:

```python
sage: e = RootSystem(['A', 3]).ambient_lattice()
sage: a = e.simple_root(0); a
(-1, 0, 0, 0)

sage: b = e.simple_root(1); b
(1, -1, 0, 0)

sage: s_a = e.reflection(a)
sage: s_a(b)
(0, -1, 0, 0)
```

`simple_coroot(i)`

Returns the i-th simple coroot, as an element of this space

EXAMPLES:

```python
sage: R = RootSystem(['A',3])
sage: L = R.ambient_lattice()
sage: L.simple_coroot(1)
(1, -1, 0, 0)

sage: L.simple_coroot(2)
(0, 1, -1, 0)

sage: L.simple_coroot(3)
(0, 0, 1, -1)
```

`classmethod smallest_base_ring(cartan_type=None)`

Return the smallest ground ring over which the ambient space can be realized.

This class method will get called with the Cartan type as input. This default implementation returns \( \mathbb{Q} \); subclasses should override it as appropriate.

EXAMPLES:

```python
sage: e = RootSystem(['F',4]).ambient_space()
sage: e.smallest_base_ring()
Rational Field
```

`to_ambient_space_morphism()`

Return the identity map on `self`. 

This is present for uniformity of use: the corresponding method for abstract root and weight lattices/spaces, is not trivial.

EXAMPLES:

```python
sage: P = RootSystem(['A',2]).ambient_space()
sage: f = P.to_ambient_space_morphism()
sage: p = P.an_element()
sage: p
(2, 2, 3)
sage: f(p)
(2, 2, 3)
sage: f(p)==p
True
```

```python
class sage.combinat.root_system.ambient_space.AmbientSpaceElement
Bases: IndexedFreeModuleElement

associated_coroot()

EXAMPLES:

```python
sage: e = RootSystem(['F',4]).ambient_space()
sage: a = e.simple_root(0); a
(1/2, -1/2, -1/2, -1/2)
sage: a.associated_coroot()
(1, -1, -1, -1)
```

coerce_to_e6()

For type E7 or E8, orthogonally projects an element of the root lattice into the E6 root lattice. This operation on weights corresponds to intersection with the semisimple subgroup E6.

EXAMPLES:

```python
sage: [b.coerce_to_e6() for b in RootSystem("E8").ambient_space().basis()]
[(1, 0, 0, 0, 0, 0, 0, 0), (0, 1, 0, 0, 0, 0, 0, 0), (0, 0, 1, 0, 0, 0, 0, 0), (0, 0, 0, 1, 0, 0, 0, 0), (0, 0, 0, 0, 1, 0, 0, 0), (0, 0, 0, 0, 0, 1/3, 1/3, -1/3), (0, 0, 0, 0, 0, -1/3, -1/3, 1/3)]
```

coerce_to_e7()

For type E8, this orthogonally projects the given element of the E8 root lattice into the E7 root lattice. This operation on weights corresponds to intersection with the semisimple subgroup E7.

EXAMPLES:

```python
sage: [b.coerce_to_e7() for b in RootSystem("E8").ambient_space().basis()]
[(1, 0, 0, 0, 0, 0, 0, 0), (0, 1, 0, 0, 0, 0, 0, 0), (0, 0, 1, 0, 0, 0, 0, 0), (0, 0, 0, 1, 0, 0, 0, 0), (0, 0, 0, 0, 1, 0, 0, 0), (0, 0, 0, 0, 0, 1/2, -1/2), (0, 0, 0, 0, 0, -1/2, 1/2)]
```

coerce_to_sl()

For type ['A',r], this coerces the element of the ambient space into the root space by orthogonal projection. The root space has codimension one and corresponds to the Lie algebra of SL(r+1,CC), whereas the full weight space corresponds to the Lie algebra of GL(r+1,CC). So this operation corresponds to multiplication by a (possibly fractional) power of the determinant to give a weight determinant one.
EXAMPLES:

```python
sage: [fw.coerce_to_sl() for fw in RootSystem("A2").ambient_space().fundamental_weights()]
[(2/3, -1/3, -1/3), (1/3, 1/3, -2/3)]
```

```python
sage: L = RootSystem("A2xA3").ambient_space()
sage: L([1,2,3,4,5,0,0]).coerce_to_sl()
(-1, 0, 1, 7/4, 11/4, -9/4, -9/4)
```

**dot_product**(lambdacheck)

The scalar product with elements of the coroot lattice embedded in the ambient space.

```python
sage: e = RootSystem(['A',2]).ambient_space()
sage: a = e.simple_root(0); a
(-1, 0, 0)
sage: a.inner_product(a)
2
```

**inner_product**(lambdacheck)

The scalar product with elements of the coroot lattice embedded in the ambient space.

```python
sage: e = RootSystem(['A',2]).ambient_space()
sage: a = e.simple_root(0); a
(-1, 0, 0)
sage: a.inner_product(a)
2
```

**is_positive_root**( )

```python
sage: R = RootSystem(['A',3]).ambient_space()
sage: r=R.simple_root(1)+R.simple_root(2)
sage: r.is_positive_root()
True
```

```python
sage: r=R.simple_root(1)-R.simple_root(2)
sage: r.is_positive_root()
False
```

**scalar**(lambdacheck)

The scalar product with elements of the coroot lattice embedded in the ambient space.

```python
sage: e = RootSystem(['A',2]).ambient_space()
sage: a = e.simple_root(0); a
(-1, 0, 0)
sage: a.inner_product(a)
2
```

**to_ambient**( )

Map self to the ambient space.
This exists for uniformity. Its analogue for root and weight lattice realizations, is not trivial.

EXAMPLES:

```
sage: v = CartanType(['C',3]).root_system().ambient_space().an_element(); v
(2, 2, 3)
sage: v.to_ambient()
(2, 2, 3)
```

### 5.1.220 Associahedron

**Todo:**
- fix adjacency matrix
- edit graph method to get proper vertex labellings
- UniqueRepresentation?

**AUTHORS:**
- Christian Stump

`sage.combinat.root_system.associahedron.Associahedra(base_ring, ambient_dim, backend='ppl')`

Construct a parent class of Associahedra according to `backend`.

**See also:**
`Associahedra_base`

**class** `sage.combinat.root_system.associahedron.Associahedra_base`

Bases: `object`

Base class of parent of Associahedra of specified dimension

**EXAMPLES:**

```
sage: from sage.combinat.root_system.associahedron import Associahedra
sage: parent = Associahedra(QQ,2,'ppl'); parent
Polyhedra in QQ^2
sage: type(parent)
<class 'sage.combinat.root_system.associahedron.Associahedra_ppl_with_category'>
sage: parent(['A',2])
Generalized associahedron of type ['A', 2] with 5 vertices
```

Importantly, the parent knows the dimension of the ambient space. If you try to construct an associahedron of a different dimension, a `ValueError` is raised:

```
sage: parent(['A',3])
Traceback (most recent call last):
  ...
ValueError: V-representation data requires a list of length ambient_dim
```

**class** `sage.combinat.root_system.associahedron.Associahedra_cdd(base_ring, ambient_dim, backend)`

Bases: `Associahedra_base, Polyhedra_QQ_cdd`
Construct an associahedron.

The generalized associahedron is a polytopal complex with vertices in one-to-one correspondence with clusters in the cluster complex, and with edges between two vertices if and only if the associated two clusters intersect in codimension 1.

The associahedron of type $A_n$ is one way to realize the classical associahedron as defined in the Wikipedia article on Associahedron.

A polytopal realization of the associahedron can be found in [CFZ2002]. The implementation is based on [CFZ2002], Theorem 1.5, Remark 1.6, and Corollary 1.9.

INPUT:

- cartan_type – a cartan type according to sage.combinat.root_system.cartan_type.CartanTypeFactory
- backend – string ('ppl'); the backend to use; see sage.geometry.polyhedron.constructor.Polyhedron()

EXAMPLES:

```
sage: Asso = polytopes.associahedron(['A',2]); Asso
Generalized associahedron of type ['A', 2] with 5 vertices

sage: sorted(Asso.Hrepresentation(), key=repr)
[An inequality (-1, 0) x + 1 >= 0,
 (continues on next page)
An inequality \((0, -1) x + 1 \geq 0\),
An inequality \((0, 1) x + 1 \geq 0\),
An inequality \((1, 0) x + 1 \geq 0\),
An inequality \((1, 1) x + 1 \geq 0\)

\texttt{sage: Asso.Vrepresentation()}
(A vertex at \((1, -1)\), A vertex at \((1, 1)\), A vertex at \((-1, 1)\),
A vertex at \((-1, 0)\), A vertex at \((0, -1)\))

\texttt{sage: polytopes.associahedron(['B',2])}
Generalized associahedron of type ['B', 2] with 6 vertices

The two pictures of [CFZ2002] can be recovered with:

\texttt{sage: Asso = polytopes.associahedron(['A',3]); Asso}
Generalized associahedron of type ['A', 3] with 14 vertices
\texttt{sage: Asso.plot()}  # long time
Graphics3d Object

\texttt{sage: Asso = polytopes.associahedron(['B',3]); Asso}
Generalized associahedron of type ['B', 3] with 20 vertices
\texttt{sage: Asso.plot()}  # long time
Graphics3d Object

\texttt{class sage.combinat.root_system.associahedron.Associahedron_class_base(parent=None,}
\texttt{Vrep=None, Hrep=None, cartan_type=None, **kwds)}

Bases: object

The base class of the Python class of an associahedron

You should use the \texttt{Associahedron()} convenience function to construct associahedra from the Cartan type.

\texttt{cartan_type()}
Return the Cartan type of self.

\texttt{EXAMPLES:}

\texttt{sage: polytopes.associahedron(['A',3]).cartan_type()}
['A', 3]

\texttt{vertices_in_root_space()}
Return the vertices of self as elements in the root space.

\texttt{EXAMPLES:}

\texttt{sage: Asso = polytopes.associahedron(['A',2])}
\texttt{sage: Asso.vertices()}
(A vertex at \((1, -1)\), A vertex at \((1, 1)\),
A vertex at \((-1, 1)\), A vertex at \((-1, 0)\),
A vertex at \((0, -1)\)
Combinatorics, Release 10.0

sage: Asso.vertices_in_root_space()
-alph[1], -alph[2])

class sage.combinat.root_system.associahedron.Associahedron_class_cdd(parent=None,
Vrep=None, Hrep=None,
cartan_type=None,
**kwds)

Bases: Associahedron_class_base, Polyhedron_QQ_cdd

class sage.combinat.root_system.associahedron.Associahedron_class_field(parent=None,
Vrep=None, Hrep=None,
cartan_type=None,
**kwds)

Bases: Associahedron_class_base, Polyhedron_field

class sage.combinat.root_system.associahedron.Associahedron_class_normaliz(parent=None,
Vrep=None, Hrep=None,
cartan_type=None,
**kwds)

Bases: Associahedron_class_base, Polyhedron_QQ_normaliz

class sage.combinat.root_system.associahedron.Associahedron_class_polymake(parent=None,
Vrep=None, Hrep=None,
cartan_type=None,
**kwds)

Bases: Associahedron_class_base, Polyhedron_polymake

class sage.combinat.root_system.associahedron.Associahedron_class_ppl(parent=None,
Vrep=None, Hrep=None,
cartan_type=None,
**kwds)

Bases: Associahedron_class_base, Polyhedron_QQ_ppl

5.1.221 Braid Move Calculator

AUTHORS:

• Dinakar Muthiah (2014-06-03): initial version

class sage.combinat.root_system.braid_move_calculator.BraidMoveCalculator(coxeter_group)

Bases: object

Helper class to compute braid moves.

chain_of_reduced_words(start_word, end_word)

Compute the chain of reduced words from start_word to end_word.

INPUT:

• start_word, end_word – two reduced expressions for the long word
EXAMPLES:

```python
sage: from sage.combinat.root_system.braid_move_calculator import BraidMoveCalculator
sage: W = CoxeterGroup(['A',5])
sage: B = BraidMoveCalculator(W)
sage: B.chain_of_reduced_words((1,2,1,3,2,1,4,3,2,1,5,4,3,2,1), # not tested
....: (5,4,5,3,4,5,2,3,4,5,1,2,3,4,5))
```

`put_in_front(k, input_word)`

Return a list of reduced words starting with `input_word` and ending with a reduced word whose first letter is `k`.

There still remains an issue with 0 indices.

EXAMPLES:

```python
sage: from sage.combinat.root_system.braid_move_calculator import BraidMoveCalculator
sage: W = CoxeterGroup(['C',3])
sage: B = BraidMoveCalculator(W)
sage: B.put_in_front(2, (3, 2, 3, 1, 2, 3, 1, 2, 1))
((3, 2, 3, 1, 2, 3, 1, 2, 1),
 (3, 2, 3, 1, 2, 1, 3, 2, 1),
 (3, 2, 3, 2, 1, 2, 3, 2, 1),
 (2, 3, 2, 3, 1, 2, 3, 2, 1))
sage: B.put_in_front(1, (3, 2, 3, 1, 2, 3, 1, 2, 1))
((3, 2, 3, 1, 2, 3, 1, 2, 1),
 (3, 2, 1, 3, 2, 3, 1, 2, 1),
 (3, 2, 1, 3, 2, 3, 2, 1, 2),
 (3, 1, 2, 1, 3, 2, 3, 2, 1),
 (3, 1, 2, 1, 3, 2, 3, 1, 2),
 (1, 3, 2, 1, 3, 2, 3, 1, 2))
sage: B.put_in_front(1, (1, 3, 2, 3, 2, 1, 2, 3, 2))
((1, 3, 2, 3, 2, 1, 2, 3, 2),)
```

### 5.1.222 Braid Orbit

Cython function to compute the orbit of the braid moves on a reduced word.

```python
sage.combinat.root_system.braid_orbit.BraidOrbit(word, rels)
```

Return the orbit of `word` by all replacements given by `rels`.

**INPUT:**

- `word` – list of integers
- `rels` – list of pairs (A, B), where A and B are lists of integers the same length

**EXAMPLES:**

```python
sage: from sage.combinat.root_system.braid_orbit import BraidOrbit
sage: word = [1,2,1,3,2,1]
sage: rels = [[[2, 1, 2], [1, 2, 1]], [[3, 1], [1, 3]], [[3, 2, 3], [2, 3, 2]]]
sage: sorted(BraidOrbit(word, rels))
```
[(1, 2, 1, 3, 2, 1),
(1, 2, 3, 1, 2, 1),
(1, 2, 3, 2, 1, 2),
(1, 3, 2, 1, 3, 2),
(1, 3, 2, 3, 1, 2),
(2, 1, 2, 3, 2, 1),
(2, 1, 3, 2, 1, 3),
(2, 1, 3, 2, 3, 1),
(2, 3, 1, 2, 1, 3),
(2, 3, 1, 2, 1, 3),
(2, 3, 1, 2, 3, 1),
(2, 3, 2, 1, 2, 3),
(3, 1, 2, 1, 3, 2),
(3, 1, 2, 3, 1, 2),
(3, 2, 1, 2, 3, 2),
(3, 2, 1, 3, 2, 3),
(3, 2, 3, 1, 2, 3)]

sage: len(_)
16

5.1.223 Branching Rules

class sage.combinat.root_system.branching_rules.BranchingRule(R, S, f, name='default',
    intermediate_types=[],
    intermediate_names=[])

Bases: SageObject

A class for branching rules.

\textbf{Rtype()}

In a branching rule R \rightarrow S, returns the Cartan Type of the ambient group R.

\textbf{EXAMPLES:}

sage: branching_rule("A3","A2","levi").Rtype()
['A', 3]

\textbf{Stype()}

In a branching rule R \rightarrow S, returns the Cartan Type of the subgroup S.

\textbf{EXAMPLES:}

sage: branching_rule("A3","A2","levi").Stype()
['A', 2]

\textbf{branch(chi, style=None)}

\textbf{INPUT:}

\begin{itemize}
    \item \texttt{chi} – A character of the WeylCharacterRing with Cartan type self.Rtype().
\end{itemize}

Returns the branched character.

\textbf{EXAMPLES:}
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: chi=G2(1,1); chi.degree()
64
sage: b=G2.maximal_subgroup("A2"); b
extended branching rule G2 => A2
sage: b.branch(chi)
A2(0,1) + A2(1,0) + 2*A2(1,1) + A2(2,0) + A2(1,2) + A2(2,1)
sage: A2=WeylCharacterRing("A2",style="coroots"); A2
The Weyl Character Ring of Type A2 with Integer Ring coefficients
sage: chi.branch(A2,rule=b)
A2(0,1) + A2(1,0) + 2*A2(1,1) + A2(2,0) + A2(1,2) + A2(2,1)

describe(verbose=False, debug=False, no_r=False)

Describes how extended roots restrict under self.

EXAMPLES:

```
sage: branching_rule("G2","A2","extended").describe()
3
0<=0---0
1  2  0
G2~

root restrictions G2 => A2:

0---0
1  2
A2

0 => 2
2 => 1

For more detailed information use verbose=True
```

In this example, 0 is the affine root, that is, the negative of the highest root, for "G2". If i => j is printed, this means that the i-th simple (or affine) root of the ambient group restricts to the j-th simple root of the subgroup. For reference the Dynkin diagrams are also printed. The extended Dynkin diagram of the ambient group is printed if the affine root restricts to a simple root. More information is printed if the parameter verbose is true.

```
sage.combinat.root_system.branching_rules.branch_weyl_character(chi, R, S, rule='default')
```

**INPUT:**

- `chi` – a character of $G$
- `R` – the Weyl Character Ring of $G$
• S – the Weyl Character Ring of $H$

• rule – an element of the BranchingRule class or one (most usually) a keyword such as:
  - "levi"
  - "automorphic"
  - "symmetric"
  - "extended"
  - "orthogonal_sum"
  - "tensor"
  - "triality"
  - "miscellaneous"

The BranchingRule class is a wrapper for functions from the weight lattice of $G$ to the weight lattice of $H$. An instance of this class encodes an embedding of $H$ into $G$. The usual way to specify an embedding is to supply a keyword, which tells Sage to use one of the built-in rules. We will discuss these first.

To explain the predefined rules, we survey the most important branching rules. These may be classified into several cases, and once this is understood, the detailed classification can be read off from the Dynkin diagrams. Dynkin classified the maximal subgroups of Lie groups in Mat. Sbornik N.S. 30(72):349-462 (1952).

We will list give predefined rules that cover most cases where the branching rule is to a maximal subgroup. For convenience, we also give some branching rules to subgroups that are not maximal. For example, a Levi subgroup may or may not be maximal.

For example, there is a “levi” branching rule defined from $SL(5)$ (with Cartan type $A_4$) to $SL(4)$ (with Cartan type $A_3$), so we may compute the branching rule as follows:

**EXAMPLES:**

```sage
A3=WeylCharacterRing("A3",style="coroots")
A2=WeylCharacterRing("A2",style="coroots")
[A3(fw).branch(A2,rule="levi") for fw in A3.fundamental_weights()]
```

In this case the Levi branching rule is the default branching rule so we may omit the specification rule="levi".

If a subgroup is not maximal, you may specify a branching rule by finding a chain of intermediate subgroups. For this purpose, branching rules may be multiplied as in the following example.

**EXAMPLES:**

```sage
A4=WeylCharacterRing("A4",style="coroots")
A2=WeylCharacterRing("A2",style="coroots")
br=branching_rule("A4","A3")*branching_rule("A3","A2")
A4(1,0,0,0).branch(A2,rule=br)
```

You may try omitting the rule if it is “obvious”. Default rules are provided for the following cases:

$A_{2s} \Rightarrow B_s,$
$A_{2s-1} \Rightarrow C_s,$
$A_{2s-1} \Rightarrow D_s.$
The above default rules correspond to embedding the group $SO(2s + 1)$, $Sp(2s)$ or $SO(2s)$ into the corresponding general or special linear group by the standard representation. Default rules are also specified for the following cases:

$$B_{s+1} \Rightarrow D_s,$$
$$D_s \Rightarrow B_s.$$

These correspond to the embedding of $O(n)$ into $O(n + 1)$ where $n = 2s$ or $2s + 1$. Finally, the branching rule for the embedding of a Levi subgroup is also implemented as a default rule.

EXCEPTIONS:

```python
sage: A1 = WeylCharacterRing("A1", style="coroots")
sage: A2 = WeylCharacterRing("A2", style="coroots")
sage: D4 = WeylCharacterRing("D4", style="coroots")
sage: B3 = WeylCharacterRing("B3", style="coroots")
sage: B4 = WeylCharacterRing("B4", style="coroots")
sage: A6 = WeylCharacterRing("A6", style="coroots")
sage: A7 = WeylCharacterRing("A7", style="coroots")
sage: def try_default_rule(R,S):
    return [R(f).branch(S) for f in R.fundamental_weights()]
sage: try_default_rule(A2,A1)
[A1(0) + A1(1), A1(0) + A1(1)]
sage: try_default_rule(D4,B3)
[B3(0,0,0) + B3(1,0,0), B3(1,0,0) + B3(0,1,0), B3(0,0,1), B3(0,0,1)]
sage: try_default_rule(D4,B4)
[D4(0,0,0) + D4(1,0,0), D4(1,0,0) + D4(0,1,0),
 D4(0,1,0) + D4(0,0,1), D4(0,0,1) + D4(0,0,1)]
sage: try_default_rule(A7,D4)
[D4(1,0,0,0), D4(0,1,0,0), D4(0,0,1,1), D4(0,0,2,0) + D4(0,0,0,2),
 D4(0,0,1,1),
 D4(0,1,0,0),
 D4(1,0,0,0)]
sage: try_default_rule(A6,B3)
[B3(1,0,0), B3(0,1,0), B3(0,0,2), B3(0,0,2), B3(0,1,0), B3(1,0,0)]
```

If a default rule is not known, you may cue Sage as to what the Lie group embedding is by supplying a rule from the list of predefined rules. We will treat these next.

**Levi Type**

These can be read off from the Dynkin diagram. If removing a node from the Dynkin diagram produces another Dynkin diagram, there is a branching rule. A Levi subgroup may or may not be maximal. If it is maximal, there may or may not be a built-in branching rule for but you may obtain the Levi branching rule by first branching to
a suitable maximal subgroup. For these rules use the option rule="levi":

\[ A_r \Rightarrow A_{r-1} \]
\[ B_r \Rightarrow A_{r-1} \]
\[ B_r \Rightarrow B_{r-1} \]
\[ C_r \Rightarrow A_{r-1} \]
\[ C_r \Rightarrow C_{r-1} \]
\[ D_r \Rightarrow A_{r-1} \]
\[ D_r \Rightarrow D_{r-1} \]
\[ E_r \Rightarrow A_{r-1} \quad r = 7, 8 \]
\[ E_r \Rightarrow D_{r-1} \quad r = 6, 7, 8 \]
\[ E_r \Rightarrow E_{r-1} \]
\[ F_4 \Rightarrow B_3 \]
\[ F_4 \Rightarrow C_4 \]
\[ G_2 \Rightarrow A_1 \text{ (short root)} \]

Not all Levi subgroups are maximal subgroups. If the Levi is not maximal there may or may not be a preprogrammed rule="levi" for it. If there is not, the branching rule may still be obtained by going through an intermediate subgroup that is maximal using rule="extended". Thus the other Levi branching rule from \( G_2 \Rightarrow A_1 \) corresponding to the long root is available by first branching \( G_2 \Rightarrow A_2 \) then \( A_2 \Rightarrow A_1 \). Similarly the branching rules to the Levi subgroup:

\[ E_r \Rightarrow A_{r-1} \quad r = 6, 7, 8 \]

may be obtained by first branching \( E_6 \Rightarrow A_5 \times A_1, E_7 \Rightarrow A_7 \) or \( E_8 \Rightarrow A_8 \).

EXAMPLES:

```
sage: A1 = WeylCharacterRing("A1")
sage: A2 = WeylCharacterRing("A2")
sage: A3 = WeylCharacterRing("A3")
sage: A4 = WeylCharacterRing("A4")
sage: A5 = WeylCharacterRing("A5")
sage: B2 = WeylCharacterRing("B2")
sage: B3 = WeylCharacterRing("B3")
sage: B4 = WeylCharacterRing("B4")
sage: C2 = WeylCharacterRing("C2")
sage: C3 = WeylCharacterRing("C3")
sage: D3 = WeylCharacterRing("D3")
sage: D4 = WeylCharacterRing("D4")
sage: G2 = WeylCharacterRing("G2")
sage: F4 = WeylCharacterRing("F4", style="coroots")
sage: E6=WeylCharacterRing("E6",style="coroots")
sage: E7=WeylCharacterRing("E7",style="coroots")
sage: D5=WeylCharacterRing("D5",style="coroots")
sage: D6=WeylCharacterRing("D6",style="coroots")
sage: [B3(w).branch(A2,rule="levi") for w in B3.fundamental_weights()]
```

The last example must be understood as follows. The representation of \( B_3 \) being branched is spin, which is not a representation of \( SO(7) \) but of its double cover \( spin(7) \). The group \( A_2 \) is really \( GL(3) \) and the double cover of...
SO(7) induces a cover of GL(3) that is trivial over SL(3) but not over the center of GL(3). The weight lattice for this GL(3) consists of triples \((a, b, c)\) of half integers such that \(a - b\) and \(b - c\) are in \(\mathbb{Z}\), and this is reflected in the last decomposition.

```python
sage: [C3(w).branch(A2,rule="levi") for w in C3.fundamental_weights()]
[A2(1,0,0) + A2(0,0,-1),
 A2(1,1,0) + A2(1,0,-1) + A2(0,-1,-1),
 A2(-1,-1,-1) + A2(-1,-1,-1) + A2(1,1,-1) + A2(1,1,1)]
```

```python
sage: [D4(w).branch(A3,rule="levi") for w in D4.fundamental_weights()]
[A3(1,0,0,0) + A3(0,0,0,-1),
 A3(1,1,0,0) + A3(1,0,0,-1) + A3(0,0,-1,-1),
 A3(1/2,-1/2,1/2,-1/2) + A3(1/2,1/2,1/2,-1/2),
 A3(-1/2,-1/2,-1/2,-1/2) + A3(1/2,1/2,-1/2,-1/2) + A3(1/2,1/2,1/2,1/2)]
```

```python
sage: [B3(w).branch(B2,rule="levi") for w in B3.fundamental_weights()]
[2*B2(0,0) + B2(1,0), B2(0,0) + 2*B2(1,0) + B2(1,1), 2*B2(1,1,1)]
```

```python
sage: [D7=WeylCharacterRing("D7",style="coroots")
  E8=WeylCharacterRing("E8",style="coroots")
  D7=WeylCharacterRing("D7",style="coroots")
  E8(1,0,0,0,0,0,0,0).branch(D7,rule="levi") # long time (7s)
  3*D7(0,0,0,0,0,0) + 2*D7(0,0,0,0,0,1) + 2*D7(0,0,0,0,0,0,0) + 2*D7(1,0,0,0,0,0,0,0)
  + D7(0,0,0,0,0,0,0,0) + 2*D7(0,0,0,0,0,0,0,0) + D7(0,0,0,0,0,0,0,0) + D7(1,0,0,0,0,0,0,0)
  + D7(1,0,0,0,0,0,0,0) + D7(2,0,0,0,0,0,0,0)
```

(continues on next page)
Automorphic Type

If the Dynkin diagram has a symmetry, then there is an automorphism that is a special case of a branching rule. There is also an exotic “triality” automorphism of $D_4$ having order 3. Use rule="automorphic" (or for $D_4$ rule="triality"):  

\[ A_r \Rightarrow A_r \]
\[ D_r \Rightarrow D_r \]
\[ E_6 \Rightarrow E_6 \]

EXAMPLES:

```
sage: [A3(chi).branch(A3,rule="automorphic") for chi in A3.fundamental_weights()]
[A3(0,0,0,-1), A3(0,0,-1,-1), A3(0,-1,-1,-1)]
sage: [D4(chi).branch(D4,rule="automorphic") for chi in D4.fundamental_weights()]
[D4(1,0,0,0), D4(1,1,0,0), D4(1/2,1/2,1/2,1/2), D4(1/2,1/2,1/2,-1/2), D4(1/2,1/2,-1/2,-1/2)]
```

Here is an example with $D_4$ triality:

```
sage: [D4(chi).branch(D4,rule="triality") for chi in D4.fundamental_weights()]
[D4(1/2,1/2,1/2,-1/2), D4(1,1,0,0), D4(1/2,1/2,1/2,1/2), D4(1/2,1/2,1/2,-1/2), D4(1,0,0,0)]
```
**Symmetric Type**

Related to the automorphic type, when $G$ admits an outer automorphism (usually of degree 2) we may consider the branching rule to the isotropy subgroup $H$. Outer automorphisms correspond to symmetries of the Dynkin diagram. For such isotropy subgroups use rule="symmetric". We may thus obtain the following branching rules.

\[
\begin{align*}
A_{2r} & \Rightarrow B_r \\
A_{2r-1} & \Rightarrow C_r \\
A_{2r-1} & \Rightarrow D_r \\
D_r & \Rightarrow B_{r-1} \\
E_6 & \Rightarrow F_4 \\
E_6 & \Rightarrow C_4 \\
D_4 & \Rightarrow G_2
\end{align*}
\]

The last branching rule, $D_4 \Rightarrow G_2$ is not to a maximal subgroup since $D_4 \Rightarrow B_3 \Rightarrow G_2$, but it is included for convenience.

In some cases, two outer automorphisms that differ by an inner automorphism may have different fixed subgroups. Thus, while the Dynkin diagram of $E_6$ has a single involutory automorphism, there are two involutions of the group (differing by an inner automorphism) with fixed subgroups $F_4$ and $C_4$. Similarly $SL(2r)$, of Cartan type $A_{2r-1}$, has subgroups $SO(2r)$ and $Sp(2r)$, both fixed subgroups of outer automorphisms that differ from each other by an inner automorphism.

In many cases the Dynkin diagram of $H$ can be obtained by folding the Dynkin diagram of $G$.

**EXAMPLES:**

```
sage: [w.branch(B2,rule="symmetric") for w in [A4(1,0,0,0,0),A4(1,1,0,0,0),A4(1,1,1,˓→0,0),A4(2,0,0,0,0)]]
[B2(1,0), B2(1,1), B2(1,1), B2(0,0) + B2(2,0)]
sage: [A5(w).branch(C3,rule="symmetric") for w in A5.fundamental_weights()]
[C3(1,0,0), C3(0,0,0) + C3(1,1,0), C3(1,0,0) + C3(1,1,1), C3(0,0,0) + C3(1,1,0), C3(1,0,0) + C3(1,0,0), C3(1,0,0)]
sage: [A5(w).branch(D3,rule="symmetric") for w in A5.fundamental_weights()]
[D3(1,0,0), D3(1,1,0), D3(1,1,-1) + D3(1,1,1), D3(1,0,0), D3(1,0,0)]
sage: [D4(x).branch(B3,rule="symmetric") for x in D4.fundamental_weights()]
[B3(0,0,0) + B3(1,0,0), B3(1,0,0) + B3(1,1,0), B3(1/2,1/2,1/2), B3(1/2,1/2,1/2)]
sage: [D4(x).branch(G2,rule="symmetric") for x in D4.fundamental_weights()]
[G2(0,0,0) + G2(1,0,-1), 2*G2(1,0,-1) + G2(2,-1,-1), G2(0,0,0) + G2(1,0,-1), G2(0,0,0) + G2(1,0,-1)]
sage: [E6(fw).branch(F4,rule="symmetric") for fw in E6.fundamental_weights()] #␣˓→long time (4s)
[F4(0,0,0,0) + F4(0,0,0,1), F4(0,0,0,1) + F4(1,0,0,0), F4(0,0,0,1) + F4(1,0,0,0) + F4(0,0,1,0), F4(1,0,0,0) + F4(0,0,0,1)+ F4(0,0,0,0), F4(1,0,0,0) + F4(0,0,0,1) + F4(0,0,0,0) + F4(0,1,0,0), F4(0,0,0,0) + F4(0,0,0,1) + F4(0,0,0,0) + F4(0,0,0,1)]
sage: E6=WeylCharacterRing("E6",style=coroots)
sage: C4=WeylCharacterRing("C4",style=coroots)
sage: chi = E6(1,0,0,0,0,0); chi.degree() 27
sage: chi.branch(C4,rule="symmetric")
C4(0,1,0,0)
```
Extended Type

If removing a node from the extended Dynkin diagram results in a Dynkin diagram, then there is a branching
rule. Use rule="extended" for these. We will also use this classification for some rules that are not of this
type, mainly involving type $B$, such as $D_6 \Rightarrow B_3 \times B_3$.

Here is the extended Dynkin diagram for $D_6$:

```
0 6
0 0
| |  \\
| |  \\
0---0---0---0---0
1 2 3 4 6
```

Removing the node 3 results in an embedding $D_3 \times D_3 \Rightarrow D_6$. This corresponds to the embedding $SO(6) \times SO(6) \Rightarrow SO(12)$, and is of extended type. On the other hand the embedding $SO(5) \times SO(7) \Rightarrow SO(12)$ (e.g. $B_2 \times B_3 \Rightarrow D_6$) cannot be explained this way but for uniformity is implemented under rule="extended".

The following rules are implemented as special cases of rule="extended":

- $E_6 \Rightarrow A_5 \times A_1, A_2 \times A_2 \times A_2$
- $E_7 \Rightarrow A_7, D_6 \times A_1, A_3 \times A_3 \times A_1$
- $E_8 \Rightarrow A_8, D_8, E_7 \times A_1, A_4 \times A_4, D_5 \times A_3, E_6 \times A_2$
- $F_4 \Rightarrow B_4, C_3 \times A_1, A_2 \times A_2, A_3 \times A_1$
- $G_2 \Rightarrow A_1 \times A_1$

Note that $E_8$ has only a limited number of representations of reasonably low degree.

EXAMPLES:

```sage
sage: [B3(x).branch(D3,rule="extended") for x in B3.fundamental_weights()]
[0, 0, 0] + D3(1, 0, 0),
D3(1, 0, 0) + D3(1, 1, 0),
D3(1/2, 1/2, 1/2) + D3(1/2, 1/2, 1/2)
```

```
sage: [G2(w).branch(A2, rule="extended") for w in G2.fundamental_weights()]
A2(0, 0, 0) + A2(1/3, 1/3, -2/3) + A2(2/3, -1/3, -1/3),
A2(1/3, 1/3, -2/3) + A2(2/3, -1/3, -1/3) + A2(1, 0, -1)
```

```
sage: [F4(fw).branch(B4,rule="extended") for fw in F4.fundamental_weights()] # long...
B4(1/2, 1/2, 1/2, 1/2) + B4(1, 0, 0),
B4(1, 0, 0) + B4(1, 1, 0) + B4(3/2, 1/2, 1/2, 1/2) + B4(3/2, 3/2, 1/2, 1/2) + B4(2, 1, 1,
B4(1/2, 1/2, 1/2, 1/2) + B4(1, 0, 0, 0) + B4(1, 1, 0, 0) + B4(1, 1, 1, 0) + B4(3/2, 1/2, 1/2, 1/2,
B4(0, 0, 0, 0) + B4(1/2, 1/2, 1/2, 1/2) + B4(1, 0, 0, 0)
```

```
sage: E6 = WeylCharacterRing("E6", style="coroots")
sage: A2xA2xA2 = WeylCharacterRing("A2xA2xA2",style="coroots")
sage: A5xA1 = WeylCharacterRing("A5xA1",style="coroots")
sage: G2 = WeylCharacterRing("G2", style="coroots")
sage: A1xA1 = WeylCharacterRing("A1xA1", style="coroots")
sage: F4 = WeylCharacterRing("F4",style="coroots")

[sage: F4(1,0,0,0).branch(A1xC3,rule="extended") # (0.05s)
D4(fw).branch(D2xD2, rule="extended") for fw in D4.fundamental_weights()]
[D2xD2(1,0,0,1) + D2xD2(0,0,1,1),
D2xD2(2,0,0,0) + D2xD2(0,2,0,0) + D2xD2(1,1,1,1) + D2xD2(0,0,2,0) + D2xD2(0,0,0,2),
D2xD2(0,0,1,1) + D2xD2(0,1,1,0),
D2xD2(0,1,0,1) + D2xD2(0,1,1,1)]

Orthogonal Sum

Using rule="orthogonal_sum", for \( n = a + b + c + \cdots \), you can get any branching rule

\[
SO(n) \Rightarrow SO(a) \times SO(b) \times SO(c) \times \cdots, \\
Sp(2n) \Rightarrow Sp(2a) \times Sp(2b) \times Sp(2c) \times \cdots,
\]

where \( O(a) \) is type \( D_r \) for \( a = 2r \) or \( B_r \) for \( a = 2r + 1 \) and \( Sp(2r) \) is type \( C_r \). In some cases these are also of extended type, as in the case \( D_3 \times D_3 \Rightarrow D_6 \) discussed above. But in other cases, for example \( B_3 \times B_3 \Rightarrow D_7 \), they are not of extended type.
Tensor

There are branching rules:

\[ A_{rs-1} \Rightarrow A_{r-1} \times A_{s-1}, \]
\[ B_{2rs+r+s} \Rightarrow B_r \times B_s, \]
\[ D_{2rs+s} \Rightarrow B_r \times D_s, \]
\[ D_{2rs} \Rightarrow D_r \times D_s, \]
\[ C_{2rs+s} \Rightarrow B_r \times C_s, \]
\[ C_{2rs} \Rightarrow D_r \times C_s. \]

corresponding to the tensor product homomorphism. For type \( A \), the homomorphism is \( GL(r) \times GL(s) \Rightarrow GL(rs) \). For the classical types, the relevant fact is that if \( V, W \) are orthogonal or symplectic spaces, that is, spaces endowed with symmetric or skew-symmetric bilinear forms, then \( V \otimes W \) is also an orthogonal space (if \( V \) and \( W \) are both orthogonal or both symplectic) or symplectic (if one of \( V \) and \( W \) is orthogonal and the other symplectic).

The corresponding branching rules are obtained using \texttt{rule="tensor"}. 

**EXAMPLES:**

```python
sage: A5=WeylCharacterRing("A5", style="coroots")
sage: A2xA1=WeylCharacterRing("A2xA1", style="coroots")
sage: [A5(hwv).branch(A2xA1, rule="tensor") for hwv in A5.fundamental_weights()]
[A2xA1(1,0,1),
 A2xA1(0,1,2) + A2xA1(2,0,0),
 A2xA1(1,1,1) + A2xA1(0,0,3),
 A2xA1(1,0,2) + A2xA1(0,2,0),
 A2xA1(0,1,1)]
```

```python
sage: B4=WeylCharacterRing("B4",style="coroots")
sage: B1xB1=WeylCharacterRing("B1xB1",style="coroots")
sage: [B4(f).branch(B1xB1,rule="tensor") for f in B4.fundamental_weights()]
[B1xB1(2,2),
 B1xB1(2,0) + B1xB1(2,4) + B1xB1(4,2) + B1xB1(0,2),
 B1xB1(2,0) + B1xB1(2,2) + B1xB1(2,4) + B1xB1(4,2) + B1xB1(4,4) + B1xB1(6,0) +
 B1xB1(0,2) + B1xB1(0,6),
 B1xB1(1,3) + B1xB1(3,1)]
```

```python
sage: D4=WeylCharacterRing("D4",style="coroots")
sage: C2xC1=WeylCharacterRing("C2xC1",style="coroots")
sage: [D4(f).branch(C2xC1,rule="tensor") for f in D4.fundamental_weights()]
[C2xC1(1,0,1),
 C2xC1(0,1,2) + C2xC1(2,0,0) + C2xC1(0,0,2),
 C2xC1(1,0,1),
 C2xC1(0,1,0) + C2xC1(0,0,2)]
```

```python
sage: C3=WeylCharacterRing("C3",style="coroots")
sage: B1xC1=WeylCharacterRing("B1xC1",style="coroots")
sage: [C3(f).branch(B1xC1,rule="tensor") for f in C3.fundamental_weights()]
[B1xC1(2,1), B1xC1(2,2) + B1xC1(4,0), B1xC1(4,1) + B1xC1(0,3)]
```
Symmetric Power

The $k$-th symmetric and exterior power homomorphisms map

$$GL(n) \Rightarrow GL\left(\binom{n + k - 1}{k}\right) \times GL\left(\binom{n}{k}\right).$$

The corresponding branching rules are not implemented but a special case is. The $k$-th symmetric power homomorphism $SL(2) \Rightarrow GL(k+1)$ has its image inside of $SO(2r+1)$ if $k = 2r$ and inside of $Sp(2r)$ if $k = 2r - 1$. Hence there are branching rules:

$$B_r \Rightarrow A_1$$
$$C_r \Rightarrow A_1$$

and these may be obtained using the rule “symmetric_power”.

EXAMPLES:

```
sage: A1=WeylCharacterRing("A1",style="coroots")
sage: B3=WeylCharacterRing("B3",style="coroots")
sage: C3=WeylCharacterRing("C3",style="coroots")
sage: [B3(fw).branch(A1,rule="symmetric_power") for fw in B3.fundamental_weights()]
[A1(6), A1(2) + A1(6) + A1(10), A1(0) + A1(6)]
sage: [C3(fw).branch(A1,rule="symmetric_power") for fw in C3.fundamental_weights()]
```

Miscellaneous

Use rule="miscellaneous" for the following embeddings of maximal subgroups, all involving exceptional groups.

$$B_3 \Rightarrow G_2,$$
$$E_6 \Rightarrow G_2,$$
$$E_6 \Rightarrow A_2,$$
$$F_4 \Rightarrow G_2 \times A_1,$$
$$E_6 \Rightarrow G_2 \times A_2,$$
$$E_7 \Rightarrow G_2 \times C_3,$$
$$E_7 \Rightarrow F_4 \times A_1,$$
$$E_7 \Rightarrow A_1 \times A_1,$$
$$E_7 \Rightarrow G_2 \times A_1,$$
$$E_8 \Rightarrow G_2 \times F_4,$$
$$E_8 \Rightarrow A_2 \times A_1,$$
$$E_8 \Rightarrow B_2.$$

Except for those embeddings available by rule="extended", these are the only embeddings of these groups as maximal subgroups. There may be other embeddings besides these. For example, there are other more obvious embeddings of $A_2$ and $G_2$ into $E_6$. However the embeddings in this table are characterized as embeddings as maximal subgroups. Regarding the embeddings of $A_2$ and $G_2$ in $E_6$, the embeddings in question may be characterized by the condition that the 27-dimensional representations of $E_6$ restrict irreducibly to $A_2$ or $G_2$. Since $G_2$ has a subgroup isomorphic to $A_2$, it is worth mentioning that the composite branching rules:
branching_rule("E6","G2","miscellaneous") * branching_rule("G2","A2","extended")
branching_rule("E6","A2","miscellaneous")

are distinct.

These embeddings are described more completely (with references to the literature) in the thematic tutorial at:

EXAMPLES:

```
sage: G2 = WeylCharacterRing("G2")
sage: [fw1, fw2, fw3] = B3.fundamental_weights()
sage: B3(fw1+fw3).branch(G2, rule="miscellaneous")
G2(1,0,-1) + G2(2,-1,-1) + G2(2,0,-2)
sage: E6 = WeylCharacterRing("E6",style="coroots")
sage: G2 = WeylCharacterRing("G2",style="coroots")
sage: E6(1,0,0,0,0,0).branch(G2,"miscellaneous")
G2(2,0)
sage: A2 = WeylCharacterRing("A2",style="coroots")
sage: E6(1,0,0,0,0,0).branch(A2,rule="miscellaneous")
A2(1,1) + A2(1,4) + A2(4,1)
sage: E6(0,1,0,0,0,0).branch(A2,rule="miscellaneous")
A2(2,2)
sage: E6(0,1,0,0,0,0).branch(A2,rule="miscellaneous")
A2(1,1) + A2(1,4) + A2(4,1)
sage: E6(0,0,0,0,0,2).branch(G2,"miscellaneous") # long time (0.59s)
G2(0,0) + G2(2,0) + G2(1,1) + G2(0,2) + G2(4,0)
sage: F4 = WeylCharacterRing("F4",style="coroots")
sage: G2xA1=WeylCharacterRing("G2xA1",style="coroots")
sage: F4(0,0,1,0).branch(G2xA1,rule="miscellaneous")
G2xA1(1,0,0) + G2xA1(1,0,2) + G2xA1(1,0,4) + G2xA1(1,0,6) + G2xA1(0,1,4) + G2xA1(2,0,2) + G2xA1(0,0,2) + G2xA1(0,0,6)
sage: E7=WeylCharacterRing("E7",style="coroots")
sage: G2xC3=WeylCharacterRing("G2xC3",style="coroots")
sage: E7(0,0,0,0,0,0,1).branch(G2xC3,rule="miscellaneous") # long time (1.84s)
G2xC3(1,0,1,0) + G2xC3(1,0,1,1) + G2xC3(0,1,0,1) + G2xC3(2,0,1,0,0) + G2xC3(0,0,1,1,0)
sage: F4xA1=WeylCharacterRing("F4xA1",style="coroots")
sage: E7(0,0,0,0,0,0,1).branch(F4xA1,"miscellaneous")
F4xA1(0,0,0,0,0,1,0,0,1) + F4xA1(0,0,0,0,0,0,3)
sage: A1xA1=WeylCharacterRing("A1xA1",style="coroots")
sage: E7(0,0,0,0,0,0,1).branch(A1xA1,rule="miscellaneous")
A1xA1(2,5) + A1xA1(4,1) + A1xA1(6,3)
sage: A2=WeylCharacterRing("A2",style="coroots")
sage: E7(0,0,0,0,0,0,1).branch(A2,rule="miscellaneous")
A2(0,6) + A2(6,0)
sage: G2xA1=WeylCharacterRing("G2xA1",style="coroots")
sage: E7(1,0,0,0,0,0,0).branch(G2xA1,rule="miscellaneous")
G2xA1(1,0,4) + G2xA1(0,1,0) + G2xA1(2,0,2) + G2xA1(0,0,2)
sage: E8 = WeylCharacterRing("E8",style="coroots")
sage: G2xF4 = WeylCharacterRing("G2xF4",style="coroots")
```
A1 maximal subgroups of exceptional groups

There are seven cases where the exceptional group \( G_2, F_4, E_7 \) or \( E_8 \) contains a maximal subgroup of type \( A_1 \). These are tabulated in Theorem 1 of Testerman, The construction of the maximal A1’s in the exceptional algebraic groups, Proc. Amer. Math. Soc. 116 (1992), no. 3, 635-644. The names of these branching rules are roman numerals referring to the seven cases of her Theorem 1. Use these branching rules as in the following examples.

EXAMPLES:

\[
sage: A1=WeylCharacterRing("A1",style="coroots")
\]
\[
sage: G2=WeylCharacterRing("G2",style="coroots")
\]
\[
sage: F4=WeylCharacterRing("F4",style="coroots")
\]
\[
sage: E7=WeylCharacterRing("E7",style="coroots")
\]
\[
sage: E8=WeylCharacterRing("E8",style="coroots")
\]
\[
[sage: G2(f).branch(A1,rule="i") for f in G2.fundamental_weights()]
\]
\[
[A1(6), A1(2) + A1(10)]
\]
\[
sage: F4(1,0,0,0).branch(A1,rule="ii")
\]
\[
A1(2) + A1(10) + A1(14) + A1(22)
\]
\[
sage: E7(0,0,0,0,0,1).branch(A1,rule="iii")
\]
\[
A1(9) + A1(17) + A1(27)
\]
\[
sage: E7(0,0,0,0,0,1).branch(A1,rule="iv")
\]
\[
\]
\[
sage: E8(0,0,0,0,0,1).branch(A1,rule="v") # long time (0.6s)
\]
\[
\]
\[
sage: E8(0,0,0,0,0,1).branch(A1,rule="vi") # long time (0.6s)
\]
\[
\]
\[
sage: E8(0,0,0,0,0,1).branch(A1,rule="vii") # long time (0.6s)
\]
\[
\]
Branching Rules From Plethysms

Nearly all branching rules $G \Rightarrow H$ where $G$ is of type $A$, $B$, $C$ or $D$ are covered by the preceding rules. The function `branching_rule_from_plethysm()` covers the remaining cases.

This is a general rule that includes any branching rule from types $A$, $B$, $C$, or $D$ as a special case. Thus it could be used in place of the above rules and would give the same results. However it is most useful when branching from $G$ to a maximal subgroup $H$ such that $\text{rank}(H) < \text{rank}(G) - 1$.

We consider a homomorphism $H \Rightarrow G$ where $G$ is one of $SL(r+1)$, $SO(2r+1)$, $Sp(2r)$ or $SO(2r)$. The function `branching_rule_from_plethysm()` produces the corresponding branching rule. The main ingredient is the character $\chi$ of the representation of $H$ that is the homomorphism to $GL(r+1)$, $GL(2r + 1)$ or $GL(2r)$.

This rule is so powerful that it contains the other rules implemented above as special cases. First let us consider the symmetric fifth power representation of $SL(2)$.

```
sage: A1=WeylCharacterRing("A1",style="coroots")
sage: chi=A1([5])
sage: chi.degree()
6
sage: chi.frobenius_schur_indicator()
-1
```

This confirms that the character has degree 6 and is symplectic, so it corresponds to a homomorphism $SL(2) \Rightarrow Sp(6)$, and there is a corresponding branching rule $C_3 \Rightarrow A_1$.

```
sage: C3 = WeylCharacterRing("C3",style="coroots")
sage: sym5rule = branching_rule_from_plethysm(chi,"C3")
sage: [C3(hwv).branch(A1,rule=sym5rule) for hwv in C3.fundamental_weights()]
```

This is identical to the results we would obtain using `rule="symmetric_power"`. The next example gives a branching not available by other standard rules.

```
sage: G2 = WeylCharacterRing("G2",style="coroots")
sage: D7 = WeylCharacterRing("D7",style="coroots")
sage: ad=G2(0,1); ad.degree(); ad.frobenius_schur_indicator()
14
1
sage: spin = D7(0,0,0,0,0,1,0); spin.degree()
64
sage: spin.branch(G2, rule=branching_rule_from_plethysm(ad, "D7"))
G2(1,1)
```

We have confirmed that the adjoint representation of $G_2$ gives a homomorphism into $SO(14)$, and that the pullback of the one of the two 64 dimensional spin representations to $SO(14)$ is an irreducible representation of $G_2$.

We do not actually have to create the character or its parent WeylCharacterRing to create the branching rule:

```
sage: b = branching_rule("C7","C3(0,0,1)","plethysm"); b
plethysm (along C3(0,0,1)) branching rule C7 => C3
```
Isomorphic Type

Although not usually referred to as a branching rule, the effects of the accidental isomorphisms may be handled using rule="isomorphic":

\[
\begin{align*}
B_2 & \Rightarrow C_2 \\
C_2 & \Rightarrow B_2 \\
A_3 & \Rightarrow D_3 \\
D_3 & \Rightarrow A_3 \\
D_2 & \Rightarrow A_1 \Rightarrow A_1 \\
B_1 & \Rightarrow A_1 \\
C_1 & \Rightarrow A_1
\end{align*}
\]

**EXAMPLES:**

```python
sage: B2 = WeylCharacterRing("B2")
sage: C2 = WeylCharacterRing("C2")
sage: [B2(x).branch(C2, rule="isomorphic") for x in B2.fundamental_weights()]
[[C2(1,1), C2(1,0)]]
sage: [C2(x).branch(B2, rule="isomorphic") for x in C2.fundamental_weights()]
[[B2(1,1/2), B2(1,0)]]
sage: D3 = WeylCharacterRing("D3")
sage: A3 = WeylCharacterRing("A3")
sage: [D3(fw).branch(A3,rule="isomorphic") for fw in D3.fundamental_weights()]
[[A3(1,0,0), A3(0,1,0), A3(0,0,1)]]
sage: [D3(fw).branch(A3,rule="isomorphic") for fw in D3.fundamental_weights()]
[[A3(1,1,1,0), A3(1,1,1,0), A3(0,0,1)]]
sage: D2 = WeylCharacterRing("D2", style="coroots")
sage: A1xA1 = WeylCharacterRing("A1xA1", style="coroots")
sage: [D2(fw).branch(A1xA1,rule="isomorphic") for fw in D2.fundamental_weights()]
[[A1xA1(1,0), A1xA1(0,1)]]
```

Here $A_3(x,y,z,w)$ can be understood as a representation of $SL(4)$. The weights $x, y, z, w$ and $x + t, y + t, z + t, w + t$ represent the same representation of $SL(4)$ - though not of $GL(4)$ - since $A_3(x + t, y + t, z + t, w + t)$ is the same as $A_3(x, y, z, w)$ tensored with $det^t$. So as a representation of $SL(4)$, $A_3(1/4,1/4,1/4,-3/4)$ is the same as $A_3(1,1,1,0)$. The exterior square representation $SL(4) \Rightarrow GL(6)$ admits an invariant symmetric bilinear form, so is a representation $SL(4) \Rightarrow SO(6)$ that lifts to an isomorphism $SL(4) \Rightarrow Spin(6)$. Conversely, there are two isomorphisms $SO(6) \Rightarrow SL(4)$, of which we've selected one.

In cases like this you might prefer style="coroots":

```python
sage: A3 = WeylCharacterRing("A3",style="coroots")
sage: D3 = WeylCharacterRing("D3",style="coroots")
sage: [D3(fw) for fw in D3.fundamental_weights()]
[[D3(1,0,0), D3(0,1,0), D3(0,0,1)]]
sage: [D3(fw).branch(A3,rule="isomorphic") for fw in D3.fundamental_weights()]
[[A3(0,1,0), A3(0,0,1), A3(1,0,0)]]
sage: D2 = WeylCharacterRing("D2", style="coroots")
sage: A1xA1 = WeylCharacterRing("A1xA1", style="coroots")
sage: [D2(fw).branch(A1xA1,rule="isomorphic") for fw in D2.fundamental_weights()]
[[A1xA1(1,0), A1xA1(0,1)]]
```
**Branching From a Reducible WeylCharacterRing**

If the Cartan Type of R is reducible, we may project a character onto any of the components, or any combination of components. The rule to project on the first component is specified by the string "proj1", the rule to project on the second component is "proj2". To project on the first and third components, use "proj13" and so on.

**EXAMPLES:**

```sage
A2xG2=WeylCharacterRing("A2xG2",style="coroots")
A2=WeylCharacterRing("A2",style="coroots")
G2=WeylCharacterRing("G2",style="coroots")
A2xG2(1,0,1,0).branch(A2,rule="proj1")
7*A2(1,0)
A2xG2(1,0,1,0).branch(G2,rule="proj2")
3*G2(1,0)
A2xA2xG2=WeylCharacterRing("A2xA2xG2",style="coroots")
A2xA2xG2(0,1,1,1,0,1).branch(A2xG2,rule="proj13")
8*A2xG2(0,1,0,1)
```

A more general way of specifying a branching rule from a reducible type is to supply a list of rules, one **component rule** for each component type in the root system. In the following example, we branch the fundamental representations of $D_4$ down to $A_1 \times A_1 \times A_1 \times A_1$ through the intermediate group $D_2 \times D_2$. We use multiplicative notation to compose the branching rules. There is no need to construct the intermediate WeylCharacterRing with type $D_2 \times D_2$.

**EXAMPLES:**

```sage
D4 = WeylCharacterRing("D4",style="coroots")
A1xA1xA1xA1 = WeylCharacterRing("A1xA1xA1xA1",style="coroots")
b = branching_rule("D2","A1xA1","isomorphic")
br = branching_rule("D4","D2xD2","extended")*branching_rule("D2xD2","A1xA1xA1",[b,b])
[D4(fw).branch(A1xA1xA1xA1,rule=br) for fw in D4.fundamental_weights()]

[1,1,0,0] + [1,0,1,1],
[1,1,1,1] + [2,0,0,0] + [0,2,0,0] + [0,0,2,0] + [0,0,0,2],
[1,1,1,1] + [1,0,1,0],
[1,1,1,1] + [0,1,0,1] + [0,1,1,0] + [1,0,1,0]
```

In the list of rules to be supplied in branching from a reducible root system, we may use two key words "omit" and "identity". The term "omit" means that we omit one factor, projecting onto the remaining factors. The term "identity" is supplied when the irreducible factor Cartan Types of both the target and the source are the same, and the component branching rule is to be the identity map. For example, we have projection maps from $A_3 \times A_2$ to $A_3$ and $A_2$, and the corresponding branching may be accomplished as follows. In this example the same could be accomplished using rule="proj2".

**EXAMPLES:**

```sage
A3xA2=WeylCharacterRing("A3xA2",style="coroots")
A3=WeylCharacterRing("A3",style="coroots")
chi = A3xA2(0,1,0,1,0)
chi.branch(A3,rule=["identity","omit"])
3*A3(0,1,0)
A2=WeylCharacterRing("A2",style="coroots")
```
Yet another way of branching from a reducible root system with repeated Cartan types is to embed along the diagonal. The branching rule is equivalent to the tensor product, as the example shows:

```python
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: G2=WeylCharacterRing("G2xG2",style="coroots")
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: G2=WeylCharacterRing("G2xG2",style="coroots")
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: G2=WeylCharacterRing("G2xG2",style="coroots")
sage: G2=WeylCharacterRing("G2",style="coroots")
```

Writing Your Own (Branching) Rules

Suppose you want to branch from a group \(G\) to a subgroup \(H\). Arrange the embedding so that a Cartan subalgebra \(U\) of \(H\) is contained in a Cartan subalgebra \(T\) of \(G\). There is thus a mapping from the weight spaces \(\text{Lie}(T)^* \rightarrow \text{Lie}(U)^*\). Two embeddings will produce identical branching rules if they differ by an element of the Weyl group of \(H\).

The rule is this map \(\text{Lie}(T)^*\), which is \(G.\text{space}()\), to \(\text{Lie}(U)^*\), which is \(H.\text{space}()\), which you may implement as a function. As an example, let us consider how to implement the branching rule \(A_3 \Rightarrow C_2\). Here \(H = C_2 = Sp(4)\) embedded as a subgroup in \(A_3 = GL(4)\). The Cartan subalgebra \(U\) consists of diagonal matrices with eigenvalues \(u_1, u_2, -u_2, -u_1\). The \(C_2.\text{space}()\) is the two dimensional vector spaces consisting of the linear functionals \(u_1\) and \(u_2\) on \(U\). On the other hand \(\text{Lie}(T)\) is \(\mathbb{R}^4\). A convenient way to see the restriction is to think of it as the adjoint of the map \((u_1, u_2) \mapsto (u_1, u_2, -u_2, -u_1)\), that is, \((x_0, x_1, x_2, x_3) \Rightarrow (x_0 - x_3, x_1 - x_2)\). Hence we may encode the rule as follows:

```python
def rule(x):
    return [x[0]-x[3],x[1]-x[2]]
```

or simply:

```python
rule = lambda x: [x[0]-x[3],x[1]-x[2]]
```

We may now make and use the branching rule as follows.

```python
EXAMPLES:
sage: br = BranchingRule("A3", "C2", lambda x: [x[0]-x[3],x[1]-x[2]], "homemade");
```

```python
sage: br
homemade branching rule A3 => C2
```

```python
sage: A3(0,1,0).branch(C2,rule=br)
C2(0,0) + C2(0,1)
```

```python
sage.combinat.root_system.branching_rules.branching_rule(Rtype, Stype, rule='default')
```

Creates a branching rule.

**INPUT:**

- \(R\) – the Weyl Character Ring of \(G\)
- \(S\) – the Weyl Character Ring of \(H\)
Combinatorics, Release 10.0

• rule – a string describing the branching rule as a map from the weight space of $S$ to the weight space of $R$.

If the rule parameter is omitted, in some cases, a default rule is supplied. See `branch_weyl_character()`.

EXAMPLES:

```python
sage: rule = branching_rule(CartanType("A3"), CartanType("C2"), "symmetric")
sage: [rule(x) for x in WeylCharacterRing("A3").fundamental_weights()]
[[1, 0], [1, 1], [1, 0]]
```

`sage.combinat.root_system.branching_rules.branching_rule_from_plethysm(chi, cartan_type, return_matrix=False)`

Create the branching rule of a plethysm.

**INPUT:**

• `chi` – the character of an irreducible representation $\pi$ of a group $G$
• `cartan_type` – a classical Cartan type ($A$, $B$, $C$, or $D$).

It is assumed that the image of the irreducible representation $\pi$ naturally has its image in the group $G$.

Returns a branching rule for this plethysm.

**EXAMPLES:**

The adjoint representation $\text{SL}(3) \to \text{GL}(8)$ factors through $\text{SO}(8)$. The branching rule in question will describe how representations of $\text{SO}(8)$ composed with this homomorphism decompose into irreducible characters of $\text{SL}(3)$:

```python
sage: A2 = WeylCharacterRing("A2")
sage: A2 = WeylCharacterRing("A2", style="coroots")
sage: ad = A2.adjoint_representation(); ad
A2(1,1)
sage: ad.degree()
8
sage: ad.frobenius_schur_indicator()
1
```

This confirms that $ad$ has degree 8 and is orthogonal, hence factors through $\text{SO}(8)$ which is type $D_4$:

```python
sage: br = branching_rule_from_plethysm(ad, "D4")
sage: D4 = WeylCharacterRing("D4")
sage: [D4(f).branch(A2, rule = br) for f in D4.fundamental_weights()]
[A2(1,1), A2(0,3) + A2(1,1) + A2(3,0), A2(1,1), A2(1,1)]
```

`sage.combinat.root_system.branching_rules.get_branching_rule(Rtype, Stype, rule='default')`

Creates a branching rule.

**INPUT:**

• `R` – the Weyl Character Ring of $G$
• `S` – the Weyl Character Ring of $H$
• `rule` – a string describing the branching rule as a map from the weight space of $S$ to the weight space of $R$.

If the rule parameter is omitted, in some cases, a default rule is supplied. See `branch_weyl_character()`.

**EXAMPLES:**
sage: rule = branching_rule(CartanType("A3"),CartanType("C2"),"symmetric")
sage: [rule(x) for x in WeylCharacterRing("A3").fundamental_weights()]
[[1, 0], [1, 1], [1, 0]]

sage.combinat.root_system.branching_rules.maximal_subgroups(ct, mode='print_rules')

Given a classical Cartan type (of rank less than or equal to 8) this prints the Cartan types of maximal subgroups, with a method of obtaining the branching rule. The string to the right of the colon in the output is a command to create a branching rule.

INPUT:

• ct – a classical irreducible Cartan type

Returns a list of maximal subgroups of ct.

EXAMPLES:

sage: from sage.combinat.root_system.branching_rules import maximal_subgroups
sage: maximal_subgroups("D4")
B3:branching_rule("D4","B3","symmetric")
A2:branching_rule("D4","A2(1,1)","plethysm")
A1xC2:branching_rule("D4","ClxC2","tensor")*branching_rule("ClxC2","A1xC2",
cluirbranching_rule("Cl","A1","isomorphic"),"identity")

5.1.224 Cartan matrices

AUTHORS:

• Travis Scrimshaw (2012-04-22): Nicolas M. Thiery moved matrix creation to CartanType to prepare cartan_matrix() for deprecation.
• Ben Salisbury (2018-08-07): Added Borcherds-Cartan matrices.

class sage.combinat.root_system.cartan_matrix.CartanMatrix

Bases: Matrix_integer_sparse, CartanType_abstract

A (generalized) Cartan matrix.

A matrix $A = (a_{ij})_{i,j \in I}$ for some index set $I$ is a generalized Cartan matrix if it satisfies the following properties:

• $a_{ii} = 2$ for all $i$,
• $a_{ij} \leq 0$ for all $i \neq j$,
• $a_{ij} = 0$ if and only if $a_{ji} = 0$ for all $i \neq j$.

Additionally some reference assume that a Cartan matrix is symmetrizable (see is_symmetrizable()). However following Kac, we do not make that assumption here.

An even, integral Borcherds–Cartan matrix is an integral matrix $A = (a_{ij})_{i,j \in I}$ for some countable index set $I$ which satisfies the following properties:
• $a_{ii} \in \{2\} \cup 2\mathbb{Z}_{<0}$ for all $i$,
• $a_{ij} \leq 0$ for all $i \neq j$,
• $a_{ij} = 0$ if and only if $a_{ji} = 0$ for all $i \neq j$.

INPUT:

Can be anything which is accepted by CartanType or a matrix.

If given a matrix, one can also use the keyword cartan_type when giving a matrix to explicitly state the type. Otherwise this will try to check the input matrix against possible standard types of Cartan matrices. To disable this check, use the keyword cartan_type_check = False.

If one wants to initialize a Borcherds-Cartan matrix using matrix data, use the keyword borcherds=True. To specify the diagonal entries of corresponding to a Cartan type (a Cartan matrix is treated as matrix data), use borcherds with a list of the diagonal entries.

EXAMPLES:

```python
sage: CartanMatrix(['A', 4])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -1]
[ 0  0 -1  2]
sage: CartanMatrix(['B', 6])
[ 2 -1  0  0  0  0]
[-1  2 -1  0  0  0]
[ 0 -1  2 -1  0  0]
[ 0  0 -1  2 -1  0]
[ 0  0  0 -1  2 -2]
[ 0  0  0  0 -2  2]
sage: CartanMatrix(['C', 4])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -2]
[ 0  0 -1  2]
sage: CartanMatrix(['D', 6])
[ 2 -1  0  0  0  0]
[-1  2 -1  0  0  0]
[ 0 -1  2 -1  0  0]
[ 0  0 -1  2 -1 -1]
[ 0  0  0 -1  2  0]
[ 0  0  0  0  2]
sage: CartanMatrix(['E', 6])
[ 2  0 -1  0  0  0]
[ 0  2  0 -1  0  0]
[-1  0  2 -1  0  0]
[ 0 -1  0  2 -1  0]
[ 0  0 -1  2 -1  0]
[ 0  0  0 -1  2]
sage: CartanMatrix(['E', 7])
[ 2  0 -1  0  0  0  0]
[ 0  2  0 -1  0  0  0]
[-1  0  2 -1  0  0  0]
[ 0 -1  0  2 -1  0  0]
[ 0  0 -1  2 -1  0  0]
[ 0  0  0 -1  2 -1  0]
```
Continued from previous page:

\[
\begin{bmatrix}
0 & 0 & 0 & 0 & -1 & 2 & -1 \\
0 & 0 & 0 & 0 & 0 & -1 & 2 \\
\end{bmatrix}
\]

```
sage: CartanMatrix(['E', 8])
\[
\begin{bmatrix}
2 & 0 & -1 & 0 & 0 & 0 & 0 \\
0 & 2 & 0 & -1 & 0 & 0 & 0 \\

0 & -1 & 0 & 2 & -1 & 0 \\
0 & 0 & -1 & -1 & 2 & -1 \\
\end{bmatrix}
```

(continues on next page)
Examples of Borcherds-Cartan matrices:

```python
sage: CartanMatrix([[2,-1],[-1,-2]], borcherds=True)
[ 2 -1]
[-1 -2]
sage: CartanMatrix('B3', borcherds=[-4,-6,2])
[-4 -1 0]
[-1 -6 -1]
[ 0 -2 2]
```

**Note:** Since this is a matrix, `row()` and `column()` will return the standard row and column respectively. To get the row with the indices as in Dynkin diagrams/Cartan types, use `row_with_indices()` and `column_with_indices()` respectively.

```python
cartan_matrix()

Return the Cartan matrix of `self`.

EXAMPLES:
```
CartanMatrix(
['C', 3]).cartan_matrix()
[ 2 -1  0]
[-1  2 -2]
[ 0 -1  2]

cartan_type()
Return the Cartan type of self or self if unknown.

EXAMPLES:

sage: C = CartanMatrix(['A', 4, 1])
sage: C.cartan_type()
['A', 4, 1]

If the Cartan type is unknown:

sage: C = CartanMatrix([[2, -1, -2], [-1, 2, -1], [-2, -1, 2]])
sage: C.cartan_type()
[ 2 -1 -2]
[-1  2 -1]
[-2 -1  2]

column_with_indices(j)
Return the j\text{th} column \(a_{i,j}\) of self as a container (or iterator) of tuples \((i, a_{i,j})\)

EXAMPLES:

sage: M = CartanMatrix(['B', 4])
sage: [ (i,a) for (i,a) in M.column_with_indices(3) ]
[(3, 2), (2, -1), (4, -2)]

coxeter_diagram()
Construct the Coxeter diagram of self.

See also:

CartanType_abstract.coxeter_diagram()

EXAMPLES:

sage: cm = CartanMatrix([[2,-5,0],[-2,2,-1],[0,-1,2]])
sage: G = cm.coxeter_diagram(); G
Graph on 3 vertices
sage: G.edges(sort=True)
[(0, 1, +Infinity), (1, 2, 3)]
sage: ct = CartanType([[ 'A', 2, 2], ['B', 3]])
sage: ct.coxeter_diagram()
Graph on 5 vertices
sage: ct.cartan_matrix().coxeter_diagram() == ct.coxeter_diagram()
True

coxeter_matrix()
Return the Coxeter matrix for self.

See also:

CartanType_abstract.coxeter_matrix()
EXEMPLARY:

```python
sage: cm = CartanMatrix([[2,-5,0],[-2,2,-1],[0,-1,2]])
sage: cm.coxeter_matrix()
[ 1 -1  2]
[-1  1  3]
[ 2  3  1]
sage: ct = CartanType(['A',2,2], ['B',3])
sage: ct.coxeter_matrix()
[ 1 -1  2  2  2]
[-1  1  2  2  2]
[ 2  2  1  3  2]
[ 2  2  3  1  4]
[ 2  2  2  4  1]
sage: ct.cartan_matrix().coxeter_matrix() == ct.coxeter_matrix()
True
```

dual()  
Return the dual Cartan matrix of self, which is obtained by taking the transpose.

EXEMPLARY:

```python
sage: ct = CartanType(['C',3])
sage: M = CartanMatrix(ct); M
[ 2 -1  0]
[-1  2 -2]
[ 0 -1  2]
sage: M.dual()
[ 2 -1  0]
[-1  2 -1]
[ 0 -2  2]
sage: M.dual() == CartanMatrix(ct.dual())
True
sage: M.dual().cartan_type() == ct.dual()
True
```

An example with arbitrary Cartan matrices:

```python
sage: cm = CartanMatrix([[2,-5, -2, 2]]); cm
[ 2 -5]
[-2  2]
sage: cm.dual()
[ 2 -2]
[-5  2]
sage: cm.dual() == CartanMatrix(cm.transpose())
True
sage: cm.dual().dual() == cm
True
```

dynkin_diagram()  
Return the Dynkin diagram corresponding to self.

EXEMPLARY:
sage: C = CartanMatrix(['A',2])
sage: C.dynkin_diagram()
O---O
1 2
A2
sage: C = CartanMatrix(['F',4,1])
sage: C.dynkin_diagram()
O---O---O=>=O---O
0 1 2 3 4
F4~
sage: C = CartanMatrix([[2,-4],[-4,2]])
sage: C.dynkin_diagram()
Dynkin diagram of rank 2

indecoplusable_blocks()
Return a tuple of all indecomposable blocks of self.

EXAMPLES:

sage: M = CartanMatrix(['A',2])
sage: M.indecomposable_blocks()
([ 2 -1]
 [-1 2])
sage: M = CartanMatrix([[['A',2,1],['A',3,1]]]
sage: M.indecomposable_blocks()
([ 2 -1 0 -1]
 [-1 2 -1 0] [ 2 -1 -1]
 [ 0 -1 2 -1] [-1 2 -1]
 [-1 0 -1 2], [-1 -1 2])

index_set()
Return the index set of self.

EXAMPLES:

sage: C = CartanMatrix(['A',1,1])
sage: C.index_set()
(0, 1)
sage: C = CartanMatrix(['E',6])
sage: C.index_set()
(1, 2, 3, 4, 5, 6)

is_affine()
Return True if self is an affine type or False otherwise.

A generalized Cartan matrix is affine if all of its indecomposable blocks are either finite (see is_finite()) or have zero determinant with all proper principal minors positive.

EXAMPLES:
sage: M = CartanMatrix(['C',4])
sage: M.is_affine()
False
sage: M = CartanMatrix(['D',4,1])
sage: M.is_affine()
True
sage: M = CartanMatrix([[2, -4], [-3, 2]])
sage: M.is_affine()
False

is_crystallographic()

Implements CartanType_abstract.is_crystallographic().

A Cartan matrix is crystallographic if it is symmetrizable.

EXAMPLES:

sage: CartanMatrix(['F',4]).is_crystallographic()
True

is_finite()

Return True if self is a finite type or False otherwise.

A generalized Cartan matrix is finite if the determinant of all its principal submatrices (see principal_submatrices()) is positive. Such matrices have a positive definite symmetrized matrix. Note that a finite matrix may consist of multiple blocks of Cartan matrices each having finite Cartan type.

EXAMPLES:

sage: M = CartanMatrix(['C',4])
sage: M.is_finite()
True
sage: M = CartanMatrix(['D',4,1])
sage: M.is_finite()
False
sage: M = CartanMatrix([[2, -4], [-3, 2]])
sage: M.is_finite()
False

is_hyperbolic(compact=False)

Return if True if self is a (compact) hyperbolic type or False otherwise.

An indecomposable generalized Cartan matrix is hyperbolic if it has negative determinant and if any proper connected subdiagram of its Dynkin diagram is of finite or affine type. It is compact hyperbolic if any proper connected subdiagram has finite type.

INPUT:

• compact – if True, check if matrix is compact hyperbolic

EXAMPLES:

sage: M = CartanMatrix([[2,-2,0],[-2,2,-1],[0,-1,2]])
sage: M.is_hyperbolic()
True
sage: M.is_hyperbolic(compact=True)
False
sage: M = CartanMatrix([[-3,2],[-3,2]])
sage: M.is_hyperbolic()
True
sage: M = CartanMatrix(['C',4])
sage: M.is_hyperbolic()
False

is_indecomposable()
Return if self is an indecomposable matrix or False otherwise.
EXAMPLES:

sage: M = CartanMatrix(['A',5])
sage: M.is_indecomposable()
True
sage: M = CartanMatrix([[2,-1,0],[-1,2,0],[0,0,2]])
sage: M.is_indecomposable()
False

is_indefinite()
Return if self is an indefinite type or False otherwise.
EXAMPLES:

sage: M = CartanMatrix([[-3,2],[-3,2]])
sage: M.is_indefinite()
True
sage: M = CartanMatrix('A2')
sage: M.is_indefinite()
False

is_lorentzian()
Return True if self is a Lorentzian type or False otherwise.
A generalized Cartan matrix is Lorentzian if it has negative determinant and exactly one negative eigenvalue.
EXAMPLES:

sage: M = CartanMatrix([[-3,2],[-3,2]])
sage: M.is_lorentzian()
True
sage: M = CartanMatrix([[2,-1],[-1,2]])
sage: M.is_lorentzian()
False

is_simply_laced()
Implements CartanType_abstract.is_simply_laced().
A Cartan matrix is simply-laced if all non diagonal entries are 0 or -1.
EXAMPLES:
Combinatorics, Release 10.0

```
sage: cm = CartanMatrix([[2, -1, -1, -1], [-1, 2, -1, -1], [-1, -1, 2, -1], [-1, -1, -1, 2]])
sage: cm.is_simply_laced()
True
```

**matrix_space(nrows=None, ncols=None, sparse=None)**

Return a matrix space over the integers.

**INPUT:**

- `nrows` - number of rows
- `ncols` - number of columns
- `sparse` - (boolean) sparseness

**EXAMPLES:**

```
sage: cm = CartanMatrix(['A', 3])
sage: cm.matrix_space()
Full MatrixSpace of 3 by 3 sparse matrices over Integer Ring
sage: cm.matrix_space(2, 2)
Full MatrixSpace of 2 by 2 sparse matrices over Integer Ring
sage: cm[:,2,1:]  # indirect doctest
[-1 0]
[ 2 -1]
```

**principal_submatrices(proper=False)**

Return a list of all principal submatrices of `self`.

**INPUT:**

- `proper` - if True, return only proper submatrices

**EXAMPLES:**

```
sage: M = CartanMatrix(['A',2])
sage: M.principal_submatrices()
[[]
 [ 2 -1]
 [2, [2], [2], [-1 2]]
]
sage: M.principal_submatrices(proper=True)
[[], [2], [2]]
```

**rank()**

Return the rank of `self`.

**EXAMPLES:**

```
sage: CartanMatrix(['C',3]).rank()
3
sage: CartanMatrix(['A2','B2','F4']).rank()
8
```

**reflection_group(type='matrix')**

Return the reflection group corresponding to `self`.

```
EXAMPLES:

```python
sage: C = CartanMatrix(['A',3])
sage: C.reflection_group()
Weyl Group of type ['A', 3] (as a matrix group acting on the root space)
```

```python
relabel (relabelling)

Return the relabelled Cartan matrix.

EXAMPLES:

```python
sage: CM = CartanMatrix(['C',3])
sage: R = CM.relabel({1:0, 2:4, 3:1}); R

```

```python
root_space()

Return the root space corresponding to self.

EXAMPLES:

```python
sage: C = CartanMatrix(['A',3])
sage: C.root_space()
Root space over the Rational Field of the Root system of type ['A', 3]
```

```python
root_system()

Return the root system corresponding to self.

EXAMPLES:

```python
sage: C = CartanMatrix(['A',3])
sage: C.root_system()
Root system of type ['A', 3]
```

```python
row_with_indices(i)

Return the $i^{th}$ row $(a_{i,j})$ of self as a container (or iterator) of tuples $(j, a_{i,j})$

EXAMPLES:

```python
sage: M = CartanMatrix(['C',4])
sage: [(i,a) for (i,a) in M.row_with_indices(3) ]
[(3, 2), (2, -1), (4, -2)]
```

```python
subtype (index_set)

Return a subtype of self given by index_set.

A subtype can be considered the Dynkin diagram induced from the Dynkin diagram of self by index_set.

EXAMPLES:

```
```
 sage: C = CartanMatrix(['F',4])
sage: S = C.subtype([1,2,3])
 sage: S
 [ 2 -1  0]
[-1  2 -1]
 [ 0 -2  2]
sage: S.index_set()
(1, 2, 3)

**symmetrized_matrix()**

Return the symmetrized matrix of self if symmetrizable.

EXAMPLES:

 sage: cm = CartanMatrix(['B',4,1])
sage: cm.symmetrized_matrix()
 [ 4  0 -2  0  0]
 [ 0  4 -2  0  0]
[-2 -2  4 -2  0]
 [ 0  0 -2  4 -2]
 [ 0  0  0 -2  2]

**symmetrizer()**

Return the symmetrizer of self.

EXAMPLES:

 sage: cm = CartanMatrix([[2,-5],[-2,2]])
sage: cm.symmetrizer()
Finite family {0: 2, 1: 5}

sage.combinat.root_system.cartan_matrix.find_cartan_type_from_matrix(CM)

Find a Cartan type by direct comparison of Dynkin diagrams given from the generalized Cartan matrix CM and return None if not found.

INPUT:

• CM – a generalized Cartan matrix

EXAMPLES:

 sage: from sage.combinat.root_system.cartan_matrix import find_cartan_type_from_matrix
 sage: CM = CartanMatrix([[2,-1,-1], [-1,2,-1], [-1,-1,2]])
sage: find_cartan_type_from_matrix(CM)
['A', 2, 1]
sage: CM = CartanMatrix([[2,-1,0], [-1,2,-2], [0,-1,2]])
sage: find_cartan_type_from_matrix(CM)
['C', 3] relabelled by {1: 0, 2: 1, 3: 2}
sage: CM = CartanMatrix([[2,-1,-2], [-1,2,-1], [-2,-1,2]])
sage: find_cartan_type_from_matrix(CM)

sage.combinat.root_system.cartan_matrix.is_borcherds_cartan_matrix(M)

Return True if M is an even, integral Borcherds-Cartan matrix. For a definition of such a matrix, see CartanMatrix.
EXAMPLES:

```python
sage: from sage.combinat.root_system.cartan_matrix import is_borcherds_cartan_matrix
sage: M = Matrix([[2,-1], [-1,2]])
sage: is_borcherds_cartan_matrix(M)
True
sage: N = Matrix([[2,-1], [-1,0]])
sage: is_borcherds_cartan_matrix(N)
False
sage: O = Matrix([[2,-1], [-1,-2]])
sage: is_borcherds_cartan_matrix(O)
True
sage: O = Matrix([[2,-1], [-1,-3]])
sage: is_borcherds_cartan_matrix(O)
False
```

```
sage.combinat.root_system.cartan_matrix.is_generalized_cartan_matrix(M)
```

Return True if \( M \) is a generalized Cartan matrix. For a definition of a generalized Cartan matrix, see `CartanMatrix`.

EXAMPLES:

```python
sage: from sage.combinat.root_system.cartan_matrix import is_generalized_cartan_matrix
sage: M = matrix([[2,-1,-2], [-1,2,-1], [-2,-1,2]])
sage: is_generalized_cartan_matrix(M)
True
sage: M = matrix([[2,-1,-2], [-1,2,-1], [0,-1,2]])
sage: is_generalized_cartan_matrix(M)
False
sage: M = matrix([[1,-1,-2], [-1,2,-1], [-2,-1,2]])
sage: is_generalized_cartan_matrix(M)
False
```

A non-symmetrizable example:

```python
sage: M = matrix([[2,-1,-2], [-1,2,-1], [-1,-1,2]])
sage: is_generalized_cartan_matrix(M)
True
```

### 5.1.225 Cartan types

**Todo:** Why does sphinx complain if I use sections here?

Introduction

Loosely speaking, Dynkin diagrams (or equivalently Cartan matrices) are graphs which are used to classify root systems, Coxeter and Weyl groups, Lie algebras, Lie groups, crystals, etc. up to an isomorphism. Cartan types are a standard set of names for those Dynkin diagrams (see Wikipedia article Dynkin_diagram).

Let us consider, for example, the Cartan type \( A_4 \):
sage: T = CartanType(['A', 4])

sage: T
['A', 4]

It is the name of the following Dynkin diagram:

```
sage: DynkinDiagram(T)
0---0---0---0
 1  2  3  4
```

A4

**Note:** For convenience, the following shortcuts are available:

```
sage: DynkinDiagram(['A', 4])
0---0---0---0
 1  2  3  4
```

A4

```
sage: DynkinDiagram('A4')
0---0---0---0
 1  2  3  4
```

A4

```
sage: T.dynkin_diagram()
0---0---0---0
 1  2  3  4
```

A4

See *DynkinDiagram* for how to further manipulate Dynkin diagrams.

From this data (the *Cartan datum*), one can construct the associated root system:

```
sage: RootSystem(T)
Root system of type ['A', 4]
```

The associated Weyl group of $A_n$ is the symmetric group $S_{n+1}$:

```
sage: W = WeylGroup(T)
sage: W
Weyl Group of type ['A', 4] (as a matrix group acting on the ambient space)
sage: W.cardinality()
120
```

while the Lie algebra is $sl_{n+1}$, and the Lie group $SL_{n+1}$ (TODO: illustrate this once this is implemented).

One may also construct crystals associated to various Dynkin diagrams. For example:

```
sage: C = crystals.Letters(T)
sage: C
The crystal of letters for type ['A', 4]
sage: C.list()
[1, 2, 3, 4, 5]
```

```
sage: C = crystals.Tableaux(T, shape=[2])
sage: C
```

(continues on next page)
The crystal of tableaux of type ['A', 4] and shape(s) [[2]]
sage: C.cardinality()
15

Here is a sample of all the finite irreducible crystallographic Cartan types:
sage: CartanType.samples(finite = True, crystallographic = True)
[['A', 1], ['A', 5], ['B', 1], ['B', 5], ['C', 1], ['C', 5], ['D', 2], ['D', 3], ['D', 5], ['E', 6], ['E', 7], ['E', 8], ['F', 4], ['G', 2]]

One can also get latex representations of the crystallographic Cartan types and their corresponding Dynkin diagrams:
sage: [latex(ct) for ct in CartanType.samples(crystallographic=True)]
[A_1, A_5, B_1, B_5, C_1, C_5, D_2, D_3, D_5, E_6, E_7, E_8, F_4, G_2, A_1^{(1)}, A_5^{(1)}, B_1^{(1)}, B_5^{(1)}, C_1^{(1)}, C_5^{(1)}, D_3^{(1)}, D_5^{(1)}, E_6^{(1)}, E_7^{(1)}, E_8^{(1)}, F_4^{(1)}, G_2^{(1)}, B_5^{(1)\vee}, C_4^{(1)\vee}, F_4^{(1)\vee}, G_2^{(1)\vee}, B_5^{(2)\vee}, C_4^{(2)\vee}, F_4^{(2)\vee}, G_2^{(2)\vee}]
sage: view([DynkinDiagram(ct) for ct in CartanType.samples(crystallographic=True)]) # not tested

Non-crystallographic Cartan types are also partially supported:
sage: CartanType.samples(finite = True, crystallographic = False)
[['I', 5], ['H', 3], ['H', 4]]

In Sage, a Cartan type is used as a database of type-specific information and algorithms (see e.g. sage.combinat.root_system.type_A). This database includes how to construct the Dynkin diagram, the ambient space for the root system (see Wikipedia article Root_system), and further mathematical properties:
sage: T.is_finite(), T.is_simply_laced(), T.is_affine(), T.is_crystallographic()
(True, True, False, True)

In particular, a Sage Cartan type is endowed with a fixed choice of labels for the nodes of the Dynkin diagram. This choice follows the conventions of Nicolas Bourbaki, Lie Groups and Lie Algebras: Chapter 4-6, Elements of Mathematics, Springer (2002). ISBN 978-3540426509. For example:
sage: T = CartanType(['D', 4])
sage: DynkinDiagram(T)

\[
\begin{array}{c}
  O \\
  \mid \\
  O---O---O \\
  1 2 3 \\
\end{array}
\]

sage: E6 = CartanType(['E', 6])
sage: DynkinDiagram(E6)

\[
\begin{array}{c}
  0 \\
  \mid \\
  0---0---0 \\
  1 2 3 \\
\end{array}
\]

5.1. Comprehensive Module List
Note: The direction of the arrows is the opposite (i.e. the transpose) of Bourbaki’s convention, but agrees with Kac’s. For example, in type $C_2$, we have:

```
sage: C2 = DynkinDiagram(['C',2]); C2
0<=<0
1  2
C2
sage: C2.cartan_matrix()
[[ 2 -2]
 [−1  2]]
```

However Bourbaki would have the Cartan matrix as:

\[
\begin{bmatrix}
2 & -1 \\
-2 & 2
\end{bmatrix}
\]

If desired, other node labelling conventions can be achieved. For example the Kac labelling for type $E_6$ can be obtained via:

```
sage: E6.relabel({1:1,2:6,3:2,4:3,5:4,6:5}).dynkin_diagram()
0---0---0---0---0---0
1  2  3  4  5
E6 relabelled by {1: 1, 2: 6, 3: 2, 4: 3, 5: 4, 6: 5}
```

Contributions implementing other conventions are very welcome.

Another option is to build from scratch a new Dynkin diagram. The architecture has been designed to make it fairly easy to add other labelling conventions. In particular, we strived at choosing type free algorithms whenever possible, so in principle most features should remain available even with custom Cartan types. This has not been used much yet, so some rough corners certainly remain.

Here, we construct the hyperbolic example of Exercise 4.9 p. 57 of Kac, Infinite Dimensional Lie Algebras. We start with an empty Dynkin diagram, and add a couple nodes:

```
sage: g = DynkinDiagram()
sage: g.add_vertices([1,2,3])
```

Note that the diagonal of the Cartan matrix is already initialized:

```
sage: g.cartan_matrix()
[ 2  0  0]
[ 0  2  0]
[ 0  0  2]
```
Then we add a couple edges:

```
sage: g.add_edge(1,2,2)
sage: g.add_edge(1,3)
sage: g.add_edge(2,3)
```

and we get the desired Cartan matrix:

```
sage: g.cartan_matrix()
[2 0 0]
[0 2 0]
[0 0 2]
```

Oops, the Cartan matrix did not change! This is because it is cached for efficiency (see cached_method). In general, a Dynkin diagram should not be modified after having been used.

**Warning:** this is not checked currently

**Todo:** add a method set_mutable() as, say, for matrices

Here, we can work around this by clearing the cache:

```
sage: delattr(g, 'cartan_matrix')
```

Now we get the desired Cartan matrix:

```
sage: g.cartan_matrix()
[ 2 -1 -1]
[-2 2 -1]
[-1 -1  2]
```

Note that backward edges have been automatically added:

```
sage: g.edges(sort=True)
[(1, 2, 2), (1, 3, 1), (2, 1, 1), (2, 3, 1), (3, 1, 1), (3, 2, 1)]
```

**Reducible Cartan types**

Reducible Cartan types can be specified by passing a sequence or list of irreducible Cartan types:

```
sage: CartanType(['A',2],['B',2])
A2xB2
sage: CartanType([['A',2],['B',2]])
A2xB2
sage: CartanType(['A',2],['B',2]).is_reducible()
True
```

or using the following short hand notation:
Degenerate cases

When possible, type $I_n$ is automatically converted to the isomorphic crystallographic Cartan types (any reason not to do so?):

```python
sage: CartanType("I",1)
A1xA1
sage: CartanType("I",3)
['A', 2]
sage: CartanType("I",4)
['C', 2]
sage: CartanType("I",6)
['G', 2]
```

The Dynkin diagrams for types $B_1$, $C_1$, $D_2$, and $D_3$ are isomorphic to that for $A_1$, $A_1$, $A_1 \times A_1$, and $A_3$, respectively. However their natural ambient space realizations (stemming from the corresponding infinite families of Lie groups) are different. Therefore, the Cartan types are considered as distinct:

```python
sage: CartanType(['B',1])
['B', 1]
sage: CartanType(['C',1])
['C', 1]
sage: CartanType(['D',2])
['D', 2]
sage: CartanType(['D',3])
['D', 3]
```

Affine Cartan types

For affine types, we use the usual conventions for affine Coxeter groups: each affine type is either untwisted (that is, arise from the natural affinisation of a finite Cartan type):

```python
sage: CartanType(['A', 4, 1]).dynkin_diagram()
\[\begin{array}{cccc}
\text{0} & \text{1} & \text{2} & \text{3} \\
\end{array}\]
\text{A}_4^~
```

```python
sage: CartanType(['B', 4, 1]).dynkin_diagram()
\[\begin{array}{cccc}
\text{0} & \text{1} & \text{2} & \text{3} \\
\end{array}\]
\text{B}_4^~
```

(continues on next page)
or dual thereof:

```
sage: CartanType(['B', 4, 1]).dual().dynkin_diagram()
O 0
| |
O---O---O=<=O
1 2 3 4
B4~*
```

or is of type $\tilde{BC}_n$ (which yields an irreducible, but nonreduced root system):

```
sage: CartanType(['BC', 4, 2]).dynkin_diagram()
O=<=O---O---O=<=O
0 1 2 3 4
BC4~
```

This includes the two degenerate cases:

```
sage: CartanType(['A', 1, 1]).dynkin_diagram()
O<=>O
0 1
A1~
sage: CartanType(['BC', 1, 2]).dynkin_diagram()
4
O=<=O
0 1
BC1~
```

For the user convenience, Kac's notations for twisted affine types are automatically translated into the previous ones:

```
sage: CartanType(['A', 9, 2])
['B', 5, 1]^*
```

```
sage: CartanType(['A', 9, 2]).dynkin_diagram()
O 0
| |
O---O---O---O=<=O
1 2 3 4 5
B5~*
```

```
sage: CartanType(['A', 10, 2]).dynkin_diagram()
O=<=O---O---O---O=<=O
0 1 2 3 4 5
BC5~
```

```
sage: CartanType(['D', 5, 2]).dynkin_diagram()
O=<=O---O---O=>=O
0 1 2 3 4
C4~*
```

```
sage: CartanType(['D', 4, 3]).dynkin_diagram()
3
```

(continues on next page)
Additionally one can set the notation option to use Kac's notation:

```
sage: CartanType.options['notation'] = 'Kac'
sage: CartanType(['A', 9, 2])
['A', 9, 2]
sage: CartanType(['A', 9, 2]).dynkin_diagram()
 0 0
  |
0---0-----0<=0<=0
1 2 3 4 5
A9^2
sage: CartanType(['A', 10, 2]).dynkin_diagram()
0<=0-----0-----0<=0
0 1 2 3 4 5
A10^2
sage: CartanType(['D', 5, 2]).dynkin_diagram()
3
0=>=0-----0
2 1 0
D5^2
sage: CartanType(['E', 6, 2]).dynkin_diagram()
0---0-----0<=0<=0
0 1 2 3 4 5
E6^2
```

**Infinite Cartan types**

There are minimal implementations of the Cartan types $A_\infty$ and $A_{+\infty}$. In sage $oo$ is the same as $+Infinity$, so $NN$ and $ZZ$ are used to differentiate between the $A_{+\infty}$ and $A_\infty$ root systems:

```
sage: CartanType(['A', 'NN'])
['A', 'NN']
sage: print(CartanType(['A', 'NN']).ascii_art())
0 1 2 3 4 5 6
sage: CartanType(['A', 'ZZ'])
['A', 'ZZ']
```
There are also the following shorthands:

```
sage: CartanType("Aoo")
['A', ZZ]
sage: CartanType("A+oo")
['A', NN]
```

**Abstract classes for Cartan types**

Cartan types

Todo: Why does sphinx complain if I use sections here?

Introduction

Loosely speaking, Dynkin diagrams (or equivalently Cartan matrices) are graphs which are used to classify root systems, Coxeter and Weyl groups, Lie algebras, Lie groups, crystals, etc. up to an isomorphism. Cartan types are a standard set of names for those Dynkin diagrams (see Wikipedia article Dynkin_diagram).

Let us consider, for example, the Cartan type $A_4$:

```
sage: T = CartanType(["A", 4])
sage: T
["A", 4]
```

It is the name of the following Dynkin diagram:

```
sage: DynkinDiagram(T)
0---0---0---0
1 2 3 4
A4
```

Note: For convenience, the following shortcuts are available:

```
sage: DynkinDiagram(['A',4])
0---0---0---0
1 2 3 4
A4
sage: DynkinDiagram('A4')
```

(continues on next page)
See `DynkinDiagram` for how to further manipulate Dynkin diagrams.

From this data (the *Cartan datum*), one can construct the associated root system:

```
sage: RootSystem(T)
Root system of type ['A', 4]
```

The associated Weyl group of $A_n$ is the symmetric group $S_{n+1}$:

```
sage: W = WeylGroup(T)
sage: W
Weyl Group of type ['A', 4] (as a matrix group acting on the ambient space)
sage: W.cardinality()
120
```

while the Lie algebra is $sl_{n+1}$, and the Lie group $SL_{n+1}$ (TODO: illustrate this once this is implemented).

One may also construct crystals associated to various Dynkin diagrams. For example:

```
sage: C = crystals.Letters(T)
sage: C
The crystal of letters for type ['A', 4]
sage: C.list()
[1, 2, 3, 4, 5]
sage: C = crystals.Tableaux(T, shape=[2])
sage: C
The crystal of tableaux of type ['A', 4] and shape(s) [[2]]
sage: C.cardinality()
15
```

Here is a sample of all the finite irreducible crystallographic Cartan types:

```
sage: CartanType.samples(finite = True, crystallographic = True)
[[['A', 1], ['A', 5], ['B', 1], ['B', 5], ['C', 1], ['C', 5], ['D', 2], ['D', 3], ['D ~', 5], ['E', 6], ['E', 7], ['E', 8], ['F', 4], ['G', 2]]
```

One can also get latex representations of the crystallographic Cartan types and their corresponding Dynkin diagrams:

```
sage: [latex(ct) for ct in CartanType.samples(crystallographic=True)]
[A_{1}, A_{5}, B_{1}, B_{5}, C_{1}, C_{5}, D_{2}, D_{3}, D_{5}, E_{6}, E_{7}, E_{8}, F_{4}, G_{2}, A_{1}^{(1)}, A_{5}^{(1)}, B_{1}^{(1)}, B_{5}^{(1)}, C_{1}^{(1)}, C_{5}^{(1)}, D_{3}]
```

(continues on next page)
Non-crystallographic Cartan types are also partially supported:

```python
sage: CartanType.samples(finite = True, crystallographic = False)
[['I', 5], ['H', 3], ['H', 4]]
```

In Sage, a Cartan type is used as a database of type-specific information and algorithms (see e.g. `sage.combinat.root_system.type_A`). This database includes how to construct the Dynkin diagram, the ambient space for the root system (see Wikipedia article Root system), and further mathematical properties:

```python
sage: T.is_finite(), T.is_simply_laced(), T.is_affine(), T.is_crystallographic()
(True, True, False, True)
```

In particular, a Sage Cartan type is endowed with a fixed choice of labels for the nodes of the Dynkin diagram. This choice follows the conventions of Nicolas Bourbaki, Lie Groups and Lie Algebras: Chapter 4-6, Elements of Mathematics, Springer (2002). ISBN 978-3-540426509. For example:

```python
sage: T = CartanType(['D', 4])
sage: DynkinDiagram(T)  
 0 4  
/    
|     
0---0---0 1 2 3  D4
sage: E6 = CartanType(['E', 6])
sage: DynkinDiagram(E6)
 0 2  
/    
|     
0---0---0---0---0---0 1 3 4 5 6  E6
```

**Note:** The direction of the arrows is the **opposite** (i.e. the transpose) of Bourbaki’s convention, but agrees with Kac’s.

For example, in type $C_2$, we have:

```python
sage: C2 = DynkinDiagram(['C',2]); C2
O<=<O  
1 2  C2
sage: C2.cartan_matrix()
```

(continues on next page)
However Bourbaki would have the Cartan matrix as:

\[
\begin{bmatrix}
2 & -1 \\
-2 & 2
\end{bmatrix}.
\]

If desired, other node labelling conventions can be achieved. For example the Kac labelling for type $E_6$ can be obtained via:

```
sage: E6.relabel({1:1,2:6,3:2,4:3,5:4,6:5}).dynkin_diagram()
O 6
|   |
O---O---O---O---O
1 2 3 4 5
```

```
E6 relabelled by {1: 1, 2: 6, 3: 2, 4: 3, 5: 4, 6: 5}
```

Contributions implementing other conventions are very welcome.

Another option is to build from scratch a new Dynkin diagram. The architecture has been designed to make it fairly easy to add other labelling conventions. In particular, we strived at choosing type free algorithms whenever possible, so in principle most features should remain available even with custom Cartan types. This has not been used much yet, so some rough corners certainly remain.

Here, we construct the hyperbolic example of Exercise 4.9 p. 57 of Kac, Infinite Dimensional Lie Algebras. We start with an empty Dynkin diagram, and add a couple nodes:

```
sage: g = DynkinDiagram()
sage: g.add_vertices([1,2,3])
```

Note that the diagonal of the Cartan matrix is already initialized:

```
sage: g.cartan_matrix()
[2 0 0]
[0 2 0]
[0 0 2]
```

Then we add a couple edges:

```
sage: g.add_edge(1,2,2)
sage: g.add_edge(1,3)
sage: g.add_edge(2,3)
```

```
and we get the desired Cartan matrix:
```
```
sage: g.cartan_matrix()
[2 0 0]
[0 2 0]
[0 0 2]
```

Oops, the Cartan matrix did not change! This is because it is cached for efficiency (see `cached_method`). In general, a Dynkin diagram should not be modified after having been used.
Warning: this is not checked currently

Todo: add a method \texttt{set\_mutable()} as, say, for matrices

Here, we can work around this by clearing the cache:

\begin{Verbatim}
sage: delattr(g, 'cartan\_matrix')
\end{Verbatim}

Now we get the desired Cartan matrix:

\begin{Verbatim}
sage: g.cartan\_matrix()
\begin{pmatrix}
  2 & -1 & -1 \\
  -2 & 2 & -1 \\
  -1 & -1 & 2
\end{pmatrix}
\end{Verbatim}

Note that backward edges have been automatically added:

\begin{Verbatim}
sage: g.edges(sort=True)
[(1, 2, 2), (1, 3, 1), (2, 1, 1), (2, 3, 1), (3, 1, 1), (3, 2, 1)]
\end{Verbatim}

Reducible Cartan types

Reducible Cartan types can be specified by passing a sequence or list of irreducible Cartan types:

\begin{Verbatim}
sage: CartanType(['A',2],['B',2])
A2xB2
sage: CartanType([['A',2],['B',2]])
A2xB2
sage: CartanType(['A',2],['B',2]).is\_reducible()
True
\end{Verbatim}

or using the following short hand notation:

\begin{Verbatim}
sage: CartanType("A2xB2")
A2xB2
sage: CartanType("A2","B2") == CartanType("A2xB2")
True
\end{Verbatim}

Degenerate cases

When possible, type \( I_n \) is automatically converted to the isomorphic crystallographic Cartan types (any reason not to do so?):

\begin{Verbatim}
sage: CartanType(['I',1])
A1xA1
sage: CartanType(['I',3])
['A', 2]
sage: CartanType(['I',4])
['C', 2]
\end{Verbatim}

(continues on next page)
Combinatorics, Release 10.0

sage: CartanType(['I', 6])
['G', 2]

The Dynkin diagrams for types $B_1$, $C_1$, $D_2$, and $D_3$ are isomorphic to that for $A_1$, $A_1$, $A_1 \times A_1$, and $A_3$, respectively. However their natural ambient space realizations (stemming from the corresponding infinite families of Lie groups) are different. Therefore, the Cartan types are considered as distinct:

sage: CartanType(['B', 1])
['B', 1]
sage: CartanType(['C', 1])
['C', 1]
sage: CartanType(['D', 2])
['D', 2]
sage: CartanType(['D', 3])
['D', 3]

Affine Cartan types

For affine types, we use the usual conventions for affine Coxeter groups: each affine type is either untwisted (that is arise from the natural affinisation of a finite Cartan type):

sage: CartanType(['A', 4, 1]).dynkin_diagram()
0
O=<=O---O---O=<=O
1 2 3 4
A4~
sage: CartanType(['B', 4, 1]).dynkin_diagram()
0
O=<=O---O=>=O
1 2 3 4
B4~

or dual thereof:

sage: CartanType(['B', 4, 1]).dual().dynkin_diagram()
0
O=<=O---O=>=O
1 2 3 4
B4~*

or is of type $\tilde{BC}_n$ (which yields an irreducible, but nonreduced root system):

sage: CartanType(['BC', 4, 2]).dynkin_diagram()
0=<=O---O---O=<=O
(continues on next page)
This includes the two degenerate cases:

```python
sage: CartanType(['A', 1, 1]).dynkin_diagram()
O<=>O
0 1
A1~
sage: CartanType(['BC', 1, 2]).dynkin_diagram()
4
O=<=O
0 1
BC1~
```

For the user convenience, Kac’s notations for twisted affine types are automatically translated into the previous ones:

```python
sage: CartanType(['A', 9, 2])
['B', 5, 1]^*
sage: CartanType(['A', 9, 2]).dynkin_diagram()
O 0
| |
O---O---O---O=<=O
1 2 3 4 5
B5~*
sage: CartanType(['A', 10, 2]).dynkin_diagram()
O=<=O---O---O=<=O
0 1 2 3 4 5
BC5~
sage: CartanType(['D', 5, 2]).dynkin_diagram()
O=<=O---O=>=O
0 1 2 3 4
C4~*
sage: CartanType(['D', 4, 3]).dynkin_diagram()
3
O=>=O---O
2 1 0
G2~* relabelled by {0: 0, 1: 2, 2: 1}
sage: CartanType(['E', 6, 2]).dynkin_diagram()
O---O---O=<=O---O
0 1 2 3 4
F4~*
```

Additionally one can set the notation option to use Kac’s notation:

```python
sage: CartanType.options['notation'] = 'Kac'
sage: CartanType(['A', 9, 2])
['A', 9, 2]
sage: CartanType(['A', 9, 2]).dynkin_diagram()
O 0
| |
2310 Chapter 5. Comprehensive Module List
Infinite Cartan types

There are minimal implementations of the Cartan types $A_\infty$ and $A_{+\infty}$. In `sage` $oo$ is the same as $+Infinity$, so `NN` and `ZZ` are used to differentiate between the $A_{+\infty}$ and $A_\infty$ root systems:

```python
sage: CartanType(["A", NN])
["A", NN]
sage: print(CartanType(["A", NN]).ascii_art())
0---0---0---0==0==0
 0 1 2 3 4 5
sage: CartanType(["A", ZZ])
["A", ZZ]
sage: print(CartanType(["A", ZZ]).ascii_art())
---0---0---0==0==0==0==0==0==0==0
 -3 -2 -1 0 1 2 3
```

There are also the following shorthands:

```python
sage: CartanType("Aoo")
["A", ZZ]
sage: CartanType("A+oo")
["A", NN]
```
Abstract classes for Cartan types

- CartanType_abstract
- CartanType_crystallographic
- CartanType_simply_laced
- CartanType_simple
- CartanType_finite
- CartanType_affine (see also Root system data for affine Cartan types)
- sage.combinat.root_system.cartan_type.CartanType
- Root system data for dual Cartan types
- Root system data for reducible Cartan types
- Root system data for relabelled Cartan types

Concrete classes for Cartan types

- CartanType_standard
- CartanType_standard_finite
- CartanType_standard_affine
- CartanType_standard_untwisted_affine

Type specific data

The data essentially consists of a description of the Dynkin/Coxeter diagram and, when relevant, of the natural embedding of the root system in an Euclidean space. Everything else is reconstructed from this data.

- Root system data for type A
- Root system data for type B
- Root system data for type C
- Root system data for type D
- Root system data for type E
- Root system data for type F
- Root system data for type G
- Root system data for type H
- Root system data for type I
- Root system data for super type A
- Root system data for type Q
- Root system data for (untwisted) type A affine
- Root system data for (untwisted) type B affine
- Root system data for (untwisted) type C affine
- Root system data for (untwisted) type D affine
- Root system data for (untwisted) type E affine
- Root system data for (untwisted) type F affine
Todo: Should those indexes come before the introduction?

class sage.combinat.root_system.cartan_type.CartanTypeFactory
Bases: SageObject

classmethod color(i)
Default color scheme for the vertices of a Dynkin diagram (and associated objects)

EXAMPLES:

```
sage: CartanType.color(1)
'blue'
sage: CartanType.color(2)
'red'
sage: CartanType.color(3)
'green'
```

The default color is black:

```
sage: CartanType.color(0)
'black'
```

Negative indices get the same color as their positive counterparts:

```
sage: CartanType.color(-1)
'blue'
sage: CartanType.color(-2)
'red'
sage: CartanType.color(-3)
'green'
```

\[
\text{options} = \text{Current options for CartanType} - \text{dual latex}: \ \backslash \text{vee} - \text{dual str}: \ \ast - \\
\text{latex marked}: \text{True} - \text{latex relabel}: \text{True} - \text{mark special node}: \text{none} - \\
\text{marked node str}: \text{X} - \text{notation}: \text{Stembridge} - \text{special node str}: \ @
\]

\[
\text{samples(}\text{finite}=\text{None}, \text{affine}=\text{None}, \text{crystallographic}=\text{None})
\]
Return a sample of the available Cartan types.

INPUT:

\[
\begin{itemize}
  \item finite – a boolean or None (default: None)
  \item affine – a boolean or None (default: None)
  \item crystallographic – a boolean or None (default: None)
\end{itemize}
\]

The sample contains all the exceptional finite and affine Cartan types, as well as typical representatives of the infinite families.

EXAMPLES:
class sage.combinat.root_system.cartan_type.CartanType_abstract
Bases: object

Abstract class for Cartan types

Subclasses should implement:

- dynkin_diagram()
- cartan_matrix()

Todo: add some reducible Cartan types (suggestions?)
- `is_finite()`
- `is_affine()`
- `is_irreducible()`

`as_folding(folding_of=None, sigma=None)`

Return `self` realized as a folded Cartan type.

For finite and affine types, this is realized by the Dynkin diagram foldings:

\[
C_n^{(1)}, A_{2n}^{(2)}, C_{n+1}^{(2)} \leftrightarrow A_{2n-1}^{(1)},
\]
\[
A_{2n-1}^{(1)}, B_n^{(1)} \leftrightarrow D_n^{(1)},
\]
\[
E_6^{(1)}, F_4^{(1)} \leftrightarrow E_6^{(1)},
\]
\[
D_4^{(1)}, G_2^{(1)} \leftrightarrow D_4^{(1)},
\]
\[
C_n \leftrightarrow A_{2n-1},
\]
\[
B_n \leftrightarrow D_{n+1},
\]
\[
F_4 \leftrightarrow E_6,
\]
\[
G_2 \leftrightarrow D_4.
\]

For general types, this returns `self` as a folded type of `self` with \(\sigma\) as the identity map.

For more information on these foldings and folded Cartan types, see `sage.combinat.root_system.type_folded.CartanTypeFolded`.

If the optional inputs `folding_of` and `sigma` are specified, then this returns the folded Cartan type of `self` in `folding_of` given by the automorphism `sigma`.

EXAMPLES:

```python
sage: CartanType(['B', 3, 1]).as_folding()
['B', 3, 1] as a folding of ['D', 4, 1]
sage: CartanType(['F', 4]).as_folding()
['F', 4] as a folding of ['E', 6]
sage: CartanType(['BC', 3, 2]).as_folding()
['BC', 3, 2] as a folding of ['A', 5, 1]
sage: CartanType(['D', 4, 3]).as_folding()
['G', 2, 1]^* relabelled by {0: 0, 1: 2, 2: 1} as a folding of ['D', 4, 1]
```

`coxeter_diagram()`

Return the Coxeter diagram for `self`.

EXAMPLES:

```python
sage: CartanType(['B', 3]).coxeter_diagram()
Graph on 3 vertices
sage: CartanType(['A', 3]).coxeter_diagram().edges(sort=True)
[(1, 2, 3), (2, 3, 3)]
sage: CartanType(['B', 3]).coxeter_diagram().edges(sort=True)
[(1, 2, 3), (2, 3, 4)]
sage: CartanType(['G', 2]).coxeter_diagram().edges(sort=True)
[(1, 2, 6)]
sage: CartanType(['F', 4]).coxeter_diagram().edges(sort=True)
[(1, 2, 3), (2, 3, 4), (3, 4, 3)]
```

`coxeter_matrix()`

Return the Coxeter matrix for `self`.

EXAMPLES:
```
sage: CartanType(['A', 4]).coxeter_matrix()
[1 3 2 2]
[3 1 3 2]
[2 3 1 3]
[2 2 3 1]
coxeter_type()
Return the Coxeter type for self.
EXAMPLES:
sage: CartanType(['A', 4]).coxeter_type()
Coxeter type of ['A', 4]
dual()
Return the dual Cartan type, possibly just as a formal dual.
EXAMPLES:
sage: CartanType(['A',3]).dual()
['A', 3]
sage: CartanType(['B', 3]).dual()
['C', 3]
sage: CartanType(['C',2]).dual()
['B', 2]
sage: CartanType(['D',4]).dual()
['D', 4]
sage: CartanType(['E',8]).dual()
['E', 8]
sage: CartanType(['F',4]).dual()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
index_set()
Return the index set for self.
This is the list of the nodes of the associated Coxeter or Dynkin diagram.
EXAMPLES:
sage: CartanType(['A', 3, 1]).index_set()
(0, 1, 2, 3)
sage: CartanType(['D', 4]).index_set()
(1, 2, 3, 4)
sage: CartanType(['A', 7, 2]).index_set()
(0, 1, 2, 3, 4)
sage: CartanType(['A', 7, 2]).index_set()
(0, 1, 2, 3, 4)
sage: CartanType(['A', 6, 2]).index_set()
(0, 1, 2, 3)
sage: CartanType(['D', 6, 2]).index_set()
(0, 1, 2, 3, 4, 5)
sage: CartanType(['E', 6, 1]).index_set()
(0, 1, 2, 3, 4, 5, 6)
sage: CartanType(['E', 6, 2]).index_set()
(0, 1, 2, 3, 4)
```
sage: CartanType(['A', 2, 2]).index_set()
(0, 1)
sage: CartanType(['G', 2, 1]).index_set()
(0, 1, 2)
sage: CartanType(['F', 4, 1]).index_set()
(0, 1, 2, 3, 4)

is_affine()

Return whether self is affine.

EXAMPLES:

sage: CartanType(['A', 3]).is_affine()
False
sage: CartanType(['A', 3, 1]).is_affine()
True

is_atomic()

This method is usually equivalent to is_reducible(), except for the Cartan type $D_2$.

$D_2$ is not a standard Cartan type. It is equivalent to type $A_1 \times A_1$ which is reducible; however the isomorphism from its ambient space (for the orthogonal group of degree 4) to that of $A_1 \times A_1$ is non trivial, and it is useful to have it.

From a programming point of view its implementation is more similar to the irreducible types, and so the method is_atomic() is supplied.

EXAMPLES:

sage: CartanType("D2").is_atomic()
True
sage: CartanType("D2").is_irreducible()
False

is_compound()

A short hand for not is_atomic().

is_crystallographic()

Return whether this Cartan type is crystallographic.

This returns False by default. Derived class should override this appropriately.

EXAMPLES:

sage: [ [t, t.is_crystallographic()] for t in CartanType.samples(finite=True) ]
[[['A', 1], True], [['A', 5], True], [['B', 1], True], [['B', 5], True], [['C', 1], True], [['C', 5], True], [['D', 2], True], [['D', 3], True], [['D', 5], True], [['E', 6], True], [['E', 7], True], [['E', 8], True], [['F', 4], True], [['G', 2], True], [['I', 5], False], [['H', 3], False], [['H', 4], False]]

is_finite()

Return whether this Cartan type is finite.
EXAMPLES:

```
sage: from sage.combinat.root_system.cartan_type import CartanType_abstract
sage: C = CartanType_abstract()
sage: C.is_finite()
Traceback (most recent call last):
  ...  
NotImplementedError: <abstract method is_finite at ...>
```

```
sage: CartanType(["A",4]).is_finite()
True
sage: CartanType(["A",4,1]).is_finite()
False
```

`isImplemented()`
Check whether the Cartan datum for self is actually implemented.

EXAMPLES:

```
sage: CartanType(["A",4,1]).is_implemented()
True
sage: CartanType(["H",3]).is_implemented()
True
```

`isIrreducible()`
Report whether this Cartan type is irreducible (i.e. simple). This should be overridden in any subclass.

This returns False by default. Derived class should override this appropriately.

EXAMPLES:

```
sage: from sage.combinat.root_system.cartan_type import CartanType_abstract
sage: C = CartanType_abstract()
sage: C.is_irreducible()
False
```

`isReducible()`
Report whether the root system is reducible (i.e. not simple), that is whether it can be factored as a product of root systems.

EXAMPLES:

```
sage: CartanType("A2xB3").is_reducible()
True
sage: CartanType(["A",2]).is_reducible()
False
```

`isSimplyLaced()`
Return whether this Cartan type is simply laced.

This returns False by default. Derived class should override this appropriately.

EXAMPLES:

```
sage: [ [t, t.is_simply_laced()] for t in CartanType.samples() ]
[[["A", 1], True], [["A", 5], True],
```

(continues on next page)
Combinatorics, Release 10.0

marked_nodes(marked_nodes)

Return a Cartan type with the nodes marked_nodes marked.

INPUT:
  • marked_nodes – a list of nodes to mark

EXAMPLES:

sage: CartanType(['F', 4]).marked_nodes([1, 3]).dynkin_diagram()
X---O=>=X---O
1 2 3 4
F4 with nodes (1, 3) marked

options = Current options for CartanType - dual_latex: \vee - dual_str: * - latex_marked: True - latex_relabel: True - mark_special_node: none - marked_node_str: X - notation: Stembridge - special_node_str: @

rank()

Return the rank of self.

This is the number of nodes of the associated Coxeter or Dynkin diagram.

EXAMPLES:

sage: CartanType(['A', 4]).rank()
4
sage: CartanType(['A', 7, 2]).rank()
5
sage: CartanType(['I', 8]).rank()
2

relabel(relabelling)

Return a relabelled copy of this Cartan type.

INPUT:
  • relabelling – a function (or a list or dictionary)
an isomorphic Cartan type obtained by relabelling the nodes of the Dynkin diagram. Namely, the node with label $i$ is relabelled $f(i)$ (or, by $f[i]$ if $f$ is a list or dictionary).

**EXAMPLES:**

```python
sage: CartanType(['F',4]).relabel({ 1:4, 2:3, 3:2, 4:1 }).dynkin_diagram()
O---O=>=O---O
4 3 2 1
F4 relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

**root_system()**
Return the root system associated to `self`.

**EXAMPLES:**

```python
sage: CartanType(['A',4]).root_system()
Root system of type ['A', 4]
```

**subtype(index_set)**
Return a subtype of `self` given by `index_set`.

A subtype can be considered the Dynkin diagram induced from the Dynkin diagram of `self` by `index_set`.

**EXAMPLES:**

```python
sage: ct = CartanType(['A',6,2])
sage: ct.dynkin_diagram()
O=<=O---O=<=O
0 1 2 3
BC3~
sage: ct.subtype([1,2,3])
['C', 3]
```

**type()**
Return the type of `self`, or `None` if unknown.

This method should be overridden in any subclass.

**EXAMPLES:**

```python
sage: from sage.combinat.root_system.cartan_type import CartanType_abstract
sage: C = CartanType_abstract()
sage: C.type() is None
True
```

**class** `sage.combinat.root_system.cartan_type.CartanType_affine`
Bases: `CartanType_simple, CartanType_crystallographic`

An abstract class for simple affine Cartan types

**AmbientSpace**
alias of `AmbientSpace`

**a()**
Return the unique minimal non trivial annihilating linear combination of $\alpha^\vee_0, \alpha^\vee, \ldots, \alpha^\vee$ with nonnegative coefficients (or alternatively, the unique minimal non trivial annihilating linear combination of the columns of the Cartan matrix with non-negative coefficients).
Throw an error if the existence or uniqueness does not hold

FIXME: the current implementation assumes that the Cartan matrix is indexed by \([0, 1, ...]\), in the same order as the index set.

EXAMPLES:

```
sage: RootSystem(['C',2,1]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 1}
sage: RootSystem(['D',4,1]).cartan_type().a()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
sage: RootSystem(['F',4,1]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 3, 3: 4, 4: 2}
sage: RootSystem(['BC',4,2]).cartan_type().a()
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}
```

\(a\) is a shortcut for \texttt{col\_annihilator}:

```
sage: RootSystem(['BC',4,2]).cartan_type().col\_annihilator()
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}
```

\texttt{acheck}(\(m=None\))

Return the unique minimal non trivial annihilating linear combination of \(\alpha_0, \alpha_1, \ldots, \alpha_n\) with nonnegative coefficients (or alternatively, the unique minimal non trivial annihilating linear combination of the rows of the Cartan matrix with non-negative coefficients).

Throw an error if the existence of uniqueness does not hold

The optional argument \(m\) is for internal use only.

EXAMPLES:

```
sage: RootSystem(['C',2,1]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 1}
sage: RootSystem(['D',4,1]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
sage: RootSystem(['F',4,1]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 3, 3: 4, 4: 1}
sage: RootSystem(['BC',4,2]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

\texttt{acheck} is a shortcut for \texttt{row\_annihilator}:

```
sage: RootSystem(['BC',4,2]).cartan_type().row\_annihilator()
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

FIXME:

- The current implementation assumes that the Cartan matrix is indexed by \([0, 1, ...]\), in the same order as the index set.
- This really should be a method of \texttt{CartanMatrix}.

\texttt{basic\_untwisted}()

Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type \(X_n^{(r)}\), the basic untwisted type is \(X_n\). In other words, it is the classical Cartan type that is twisted to obtain \texttt{self}.
EXAMPLES:

- `sage: CartanType(['A', 1, 1]).basic_untwisted() ['A', 1]
- `sage: CartanType(['A', 3, 1]).basic_untwisted() ['A', 3]
- `sage: CartanType(['B', 3, 1]).basic_untwisted() ['B', 3]
- `sage: CartanType(['E', 6, 1]).basic_untwisted() ['E', 6]
- `sage: CartanType(['G', 2, 1]).basic_untwisted() ['G', 2]
- `sage: CartanType(['A', 2, 2]).basic_untwisted() ['A', 2]
- `sage: CartanType(['A', 4, 2]).basic_untwisted() ['A', 4]
- `sage: CartanType(['A', 11, 2]).basic_untwisted() ['A', 11]
- `sage: CartanType(['D', 5, 2]).basic_untwisted() ['D', 5]
- `sage: CartanType(['E', 6, 2]).basic_untwisted() ['E', 6]
- `sage: CartanType(['D', 4, 3]).basic_untwisted() ['D', 4]

\[c()\]

Returns the family \((c_i)_i\) of integer coefficients defined by \(c_i = \max(1, a_i/a^n e_i)\) (see e.g. [FSS07] p. 3)

FIXME: the current implementation assumes that the Cartan matrix is indexed by \([0, 1, \ldots]\), in the same order as the index set.

EXAMPLES:

- `sage: RootSystem(['C',2,1]).cartan_type().c()
  Finite family {0: 1, 1: 2, 2: 1}
- `sage: RootSystem(['D',4,1]).cartan_type().c()
  Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 1}
- `sage: RootSystem(['F',4,1]).cartan_type().c()
  Finite family {0: 1, 1: 1, 2: 1, 3: 2, 4: 2}
- `sage: RootSystem(['BC',4,2]).cartan_type().c()
  Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 1}

REFERENCES:

- `classical()\n  Return the classical Cartan type associated with this affine Cartan type.

EXAMPLES:

- `sage: CartanType(['A', 1, 1]).classical() ['A', 1]
- `sage: CartanType(['A', 3, 1]).classical() ['A', 3]
- `sage: CartanType(['B', 3, 1]).classical()
Combinatorics, Release 10.0

[continued from previous page]

['B', 3]
sage: CartanType(['A', 2, 2]).classical()
['C', 1]
sage: CartanType(['BC', 1, 2]).classical()
['C', 1]
sage: CartanType(['A', 4, 2]).classical()
['C', 2]
sage: CartanType(['BC', 2, 2]).classical()
['C', 2]
sage: CartanType(['A', 10, 2]).classical()
['C', 5]
sage: CartanType(['BC', 5, 2]).classical()
['C', 5]
sage: CartanType(['D', 5, 2]).classical()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: CartanType(['D', 4, 3]).classical()
['G', 2]

We check that `classical()`, `sage.combinat.root_system.cartan_type.
CartanType_crystallographic.dynkin_diagram()`, and `special_node()` are consistent:

```
sage: for ct in CartanType.samples(affine = True):
    ....:     g1 = ct.classical().dynkin_diagram()
    ....:     g2 = ct.dynkin_diagram()
    ....:     g2.delete_vertex(ct.special_node())
    ....:     assert g1.vertices(sort=True) == g2.vertices(sort=True)
    ....:     assert g1.edges(sort=True) == g2.edges(sort=True)
```

**col annihilator()**

Return the unique minimal non trivial annihilating linear combination of \(\alpha_0^\vee, \alpha_1^\vee, \ldots, \alpha_r^\vee\) with nonnegative coefficients (or alternatively, the unique minimal non trivial annihilating linear combination of the columns of the Cartan matrix with non-negative coefficients).

Throw an error if the existence or uniqueness does not hold

FIXME: the current implementation assumes that the Cartan matrix is indexed by \([0, 1, \ldots]\), in the same order as the index set.

**EXAMPLES:**

```
sage: RootSystem(['C',2,1]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 1}
sage: RootSystem(['D',4,1]).cartan_type().a()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
sage: RootSystem(['F',4,1]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 3, 3: 4, 4: 2}
```

(continues on next page)
sage: RootSystem(['BC',4,2]).cartan_type().a()
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}

a is a shortcut for col_annihilator:
sage: RootSystem(['BC',4,2]).cartan_type().col_annihilator()
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}

is_affine()
EXAMPLES:
sage: CartanType(['A', 3, 1]).is_affine()
True

is_finite()
EXAMPLES:
sage: CartanType(['A', 3, 1]).is_finite()
False

is_untwisted_affine()
Return whether self is untwisted affine

A Cartan type is untwisted affine if it is the canonical affine extension of some finite type. Every affine type is either untwisted affine, dual thereof, or of type BC.

EXAMPLES:
sage: CartanType(['A', 3, 1]).is_untwisted_affine()
True
sage: CartanType(['A', 3, 1]).dual().is_untwisted_affine()  # this one is self...
True
sage: CartanType(['B', 3, 1]).dual().is_untwisted_affine()
False
sage: CartanType(['BC', 3, 2]).is_untwisted_affine()
False

other_affinization()
Return the other affinization of the same classical type.

EXAMPLES:
sage: CartanType(['A', 3, 1]).other_affinization()
['A', 3, 1]
sage: CartanType(['B', 3, 1]).other_affinization()
['C', 3, 1]**
sage: CartanType(['C', 3, 1]).dual().other_affinization()
['B', 3, 1]

Is this what we want?:
sage: CartanType(['BC', 3, 2]).dual().other_affinization()
['B', 3, 1]
row_annihilator($m=None$)

Return the unique minimal non trivial annihilating linear combination of $\alpha_0, \alpha_1, \ldots, \alpha_n$ with nonnegative coefficients (or alternatively, the unique minimal non trivial annihilating linear combination of the rows of the Cartan matrix with non-negative coefficients).

Throw an error if the existence of uniqueness does not hold

The optional argument $m$ is for internal use only.

EXAMPLES:

```python
sage: RootSystem(['C',2,1]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 1}
sage: RootSystem(['D',4,1]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
sage: RootSystem(['F',4,1]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 3, 3: 2, 4: 1}
sage: RootSystem(['BC',4,2]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

acheck is a shortcut for row_annihilator:

```python
sage: RootSystem(['BC',4,2]).cartan_type().row_annihilator()
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

FIXME:

- The current implementation assumes that the Cartan matrix is indexed by $[0, 1, ...]$, in the same order as the index set.
- This really should be a method of CartanMatrix.

special_node()

Return a special node of the Dynkin diagram.

A special node is a node of the Dynkin diagram such that pruning it yields a Dynkin diagram for the associated classical type (see classical()).

This method returns the label of some special node. This is usually 0 in the standard conventions.

EXAMPLES:

```python
sage: CartanType(['A', 3, 1]).special_node()
0
```

The choice is guaranteed to be consistent with the indexing of the nodes of the classical Dynkin diagram:

```python
sage: CartanType(['A', 3, 1]).index_set()
(0, 1, 2, 3)
sage: CartanType(['A', 3, 1]).classical().index_set()
(1, 2, 3)
```

special_nodes()

Return the set of special nodes of the affine Dynkin diagram.

EXAMPLES:
translation_factors()

Return the translation factors for self.

Those are the smallest factors $t_i$ such that the translation by $t_i\alpha_i$ maps the fundamental polygon to another polygon in the alcove picture.

OUTPUT:

a dictionary from self.index_set() to $\mathbb{Z}$ (or $\mathbb{Q}$ for affine type $BC$)

Those coefficients are all 1 for dual untwisted, and in particular for simply laced. They coincide with the usual $c_i$ coefficients (see c()) for untwisted and dual thereof. See the discussion below for affine type $BC$.

**Note:** One usually realizes the alcove picture in the coweight lattice, with translations by coroots; in that case, one will use the translation factors for the dual Cartan type.

FIXME: the current implementation assumes that the Cartan matrix is indexed by $[0, 1, ...]$, in the same order as the index set.

EXAMPLES:

```python
sage: CartanType(['C',2,1]).translation_factors()
Finite family {0: 1, 1: 2, 2: 1}
sage: CartanType(['C',2,1]).dual().translation_factors()
Finite family {0: 1, 1: 1, 2: 1}
sage: CartanType(['D',4,1]).translation_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 1}
sage: CartanType(['F',4,1]).translation_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 2, 4: 2}
sage: CartanType(['BC',4,2]).translation_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 1/2}
```

We proceed with systematic tests taken from MuPAD-Combinat’s testsuite:

```python
sage: list(CartanType(['A', 1, 1]).translation_factors())
[1, 1]
sage: list(CartanType(['A', 5, 1]).translation_factors())
[1, 1, 1, 1, 1]
sage: list(CartanType(['B', 5, 1]).translation_factors())
[1, 1, 1, 1, 1]
sage: list(CartanType(['C', 5, 1]).translation_factors())
(continues on next page)
```
We conclude with a discussion of the appropriate value for affine type $BC$. Let us consider the alcove picture realized in the weight lattice. It is obtained by taking the level-1 affine hyperplane in the weight lattice, and projecting it along $\Lambda_0$:

```
sage: R = RootSystem("BC",2,2)
sage: alpha = R.weight_space().simple_roots()
sage: alphacheck = R.coroot_space().simple_roots()
sage: Lambda = R.weight_space().fundamental_weights()
```

Here are the levels of the fundamental weights:

```
sage: Lambda[0].level(), Lambda[1].level(), Lambda[2].level()
(1, 2, 2)
```

So the “center” of the fundamental polygon at level 1 is:

```
sage: 0 = Lambda[0]
sage: 0.level()
1
```

We take the projection $\omega_1$ at level 0 of $\Lambda_1$ as unit vector on the $x$-axis, and the projection $\omega_2$ at level 0 of $\Lambda_2$ as unit vector of the $y$-axis:
The projections of the simple roots can be read off:

sage: alpha[0]
2*Lambda[0] - Lambda[1]
sage: alpha[1]
sage: alpha[2]

Namely $\alpha_0 = -\omega_1$, $\alpha_1 = 2\omega_1 - \omega_2$ and $\alpha_2 = -2\omega_1 + 2\omega_2$.

The reflection hyperplane defined by $\alpha_0^\vee$ goes through the points $O + 1/2\omega_1$ and $O + 1/2\omega_2$:

sage: (O+(1/2)*omega1).scalar(alphacheck[0])
0
sage: (O+(1/2)*omega2).scalar(alphacheck[0])
0

Hence, the fundamental alcove is the triangle $(O, O + 1/2\omega_1, O + 1/2\omega_2)$. By successive reflections, one can tile the full plane. This induces a tiling of the full plane by translates of the fundamental polygon.

Todo: Add the picture here, once root system plots in the weight lattice will be implemented. In the mean time, the reader may look up the dual picture on Figure 2 of [HST09] which was produced by MuPAD-Combinat.

From this picture, one can read that translations by $\alpha_0$, $\alpha_1$, and $1/2\alpha_2$ map the fundamental polygon to translates of it in the alcove picture, and are smallest with this property. Hence, the translation factors for affine type $BC$ are $t_0 = 1, t_1 = 1, t_2 = 1/2$:

sage: CartanType(['BC',2,2]).translation_factors()
Finite family {0: 1, 1: 1, 2: 1/2}

REFERENCES:

class sage.combinat.root_system.cartan_type.CartanType_crystallographic

Bases: CartanType_abstract

An abstract class for crystallographic Cartan types.

ascii_art(label=lambda x: x, node=None)

Return an ascii art representation of the Dynkin diagram.

INPUT:

- label – (default: the identity) a relabeling function for the nodes
- node – (optional) a function which returns the character for a node

EXAMPLES:
```python
sage: cartan_type = CartanType(['B', 5, 1])
sage: print(cartan_type.ascii_art())
O 0
| |
0---0---0---0=>=0
1 2 3 4 5
```

The label option is useful to visualize various statistics on the nodes of the Dynkin diagram:

```python
sage: a = cartan_type.col_annihilator(); a
Finite family {0: 1, 1: 1, 2: 2, 3: 2, 4: 2, 5: 2}
sage: print(CartanType(['B', 5, 1]).ascii_art(label=a.__getitem__))
O 1
| |
0---0---0---0=>=0
1 2 2 2 2
```

cartan_matrix()

Return the Cartan matrix associated with self.

EXAMPLES:

```python
sage: CartanType(['A', 4]).cartan_matrix()
[ 2 -1 0 0]
[-1 2 -1 0]
[ 0 -1 2 -1]
[ 0 0 -1 2]
```

coxeter_diagram()

Return the Coxeter diagram for self.

This implementation constructs it from the Dynkin diagram.

See also:

CartanType_abstract.coxeter_diagram()

EXAMPLES:

```python
sage: CartanType(['A', 3]).coxeter_diagram()
Graph on 3 vertices
sage: CartanType(['A', 3]).coxeter_diagram().edges(sort=True)
[(1, 2, 3), (2, 3, 3)]
sage: CartanType(['B', 3]).coxeter_diagram().edges(sort=True)
[(1, 2, 3), (2, 3, 4)]
sage: CartanType(['G', 2]).coxeter_diagram().edges(sort=True)
[(1, 2, 6)]
sage: CartanType(['F', 4]).coxeter_diagram().edges(sort=True)
[(1, 2, 3), (2, 3, 4), (3, 4, 3)]
sage: CartanType(['A', 2, 2]).coxeter_diagram().edges(sort=True)
[(0, 1, +Infinity)]
```

dynkin_diagram()

Return the Dynkin diagram associated with self.

5.1. Comprehensive Module List 2329
EXAMPLES:

```
sage: CartanType(['A',4]).dynkin_diagram()
O---O---O---O
1 2 3 4
A4
```

**Note:** Derived subclasses should typically implement this as a cached method.

---

**index_set_bipartition()**

Return a bipartition \( \{ L, R \} \) of the vertices of the Dynkin diagram.

For \( i \) and \( j \) both in \( L \) (or both in \( R \)), the simple reflections \( s_i \) and \( s_j \) commute.

Of course, the Dynkin diagram should be bipartite. This is always the case for all finite types.

**EXAMPLES:**

```
sage: CartanType(['A',5]).index_set_bipartition()
({1, 3, 5}, {2, 4})
sage: CartanType(['A',2,1]).index_set_bipartition()
Traceback (most recent call last):
...
ValueError: the Dynkin diagram must be bipartite
```

---

**is_crystallographic()**

Implements `CartanType_abstract.is_crystallographic()` by returning `True`.

**EXAMPLES:**

```
sage: CartanType(['A', 3, 1]).is_crystallographic()
True
```

---

**symmetrizer()**

Return the symmetrizer of the Cartan matrix of `self`.

A Cartan matrix \( M \) is symmetrizable if there exists a non trivial diagonal matrix \( D \) such that \( DM = M^T D \). In that case, \( D \) is unique, up to a scalar factor for each connected component of the Dynkin diagram.

This method computes the unique minimal such \( D \) with positive integral coefficients. If \( D \) exists, it is returned as a family. Otherwise `None` is returned.

The coefficients are coerced to `base_ring`.

**EXAMPLES:**

```
sage: CartanType(['B',5]).symmetrizer()
Finite family {1: 2, 2: 2, 3: 2, 4: 2, 5: 1}
```

Here is a neat trick to visualize it better:

```
sage: T = CartanType(['B',5])
sage: print(T.ascii_art(T.symmetrizer().__getitem__))
```

(continues on next page)
Here is the symmetrizer of some reducible Cartan types:

```python
sage: T = CartanType(['BC', 5, 2])
sage: print(T.ascii_art(T.symmetrizer()._getitem_))
O=<=O---O---O---O=<=O
1 2 2 2 2 4
```

Property: up to an overall scalar factor, this gives the norm of the simple roots in the ambient space:

```python
sage: T = CartanType(['C', 5])
sage: print(T.ascii_art(T.symmetrizer()._getitem_))
O---O---O---O=<=O
1 1 1 1 2
```

```
sage: alpha = RootSystem(T).ambient_space().simple_roots()
sage: print(T.ascii_art(lambda i: alpha[i].scalar(alpha[i])))
O---O---O---O=<=O
2 2 2 2 4
```

**class** `sage.combinat.root_system.cartan_type.CartanType_decorator(ct)`

**Bases:** `UniqueRepresentation`, `SageObject`, `CartanType_abstract`

Concrete base class for Cartan types that decorate another Cartan type.

**index_set()**

**EXAMPLES:**

```python
sage: ct = CartanType(['F', 4, 1]).dual()
sage: ct.index_set()
(0, 1, 2, 3, 4)
```

**is_affine()**

**EXAMPLES:**

```python
sage: ct = CartanType(['G', 2]).relabel({1:2, 2:1})
sage: ct.is_affine()
False
```
is_crystallographic()  
EXAMPLES:
```python
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.is_crystallographic()
True
```

is_finite()  
EXAMPLES:
```python
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.is_finite()
True
```

is_irreducible()  
EXAMPLES:
```python
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.is_irreducible()
True
```

rank()  
EXAMPLES:
```python
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.rank()
2
```

class sage.combinat.root_system.cartan_type.CartanType_finite  

Bases: CartanType_abstract  
An abstract class for simple affine Cartan types.

is_affine()  
EXAMPLES:
```python
sage: CartanType(['A', 3]).is_affine()
False
```

is_finite()  
EXAMPLES:
```python
sage: CartanType(['A', 3]).is_finite()
True
```

class sage.combinat.root_system.cartan_type.CartanType_simple  

Bases: CartanType_abstract  
An abstract class for simple Cartan types.

is_irreducible()  
Return whether self is irreducible, which is True.

EXAMPLES:
```python
sage: CartanType(['A', 3]).is_irreducible()
True
```

class sage.combinat.root_system.cartan_type.CartanType_simple_finite

Bases: object

class sage.combinat.root_system.cartan_type.CartanType_simply_laced

Bases: CartanType_crystallographic

An abstract class for simply laced Cartan types.

dual()

Simply laced Cartan types are self-dual, so return self.

EXAMPLES:

```python
sage: CartanType(['A', 3]).dual()
['A', 3]
sage: CartanType(['A', 3, 1]).dual()
['A', 3, 1]
sage: CartanType(['D', 3]).dual()
['D', 3]
sage: CartanType(['D', 4, 1]).dual()
['D', 4, 1]
sage: CartanType(['E', 6]).dual()
['E', 6]
sage: CartanType(['E', 6, 1]).dual()
['E', 6, 1]
```

is_simply_laced()

Return whether self is simply laced, which is True.

EXAMPLES:

```python
sage: CartanType(['A',3,1]).is_simply_laced()
True
sage: CartanType(['A',2]).is_simply_laced()
True
```

class sage.combinat.root_system.cartan_type.CartanType_standard

Bases: UniqueRepresentation, SageObject

class sage.combinat.root_system.cartan_type.CartanType_standard_affine(letter, n, affine=1)

Bases: CartanType_standard, CartanType_affine

A concrete class for affine simple Cartan types.

index_set()

Implements CartanType_abstract.index_set().

The index set for all standard affine Cartan types is of the form \(\{0, \ldots, n\}\).

EXAMPLES:

```python
sage: CartanType(['A', 5, 1]).index_set()
(0, 1, 2, 3, 4, 5)
```
rank()

Return the rank of self which for type \(X^{(1)}_n\) is \(n + 1\).

EXAMPLES:

```python
sage: CartanType(['A', 4, 1]).rank()
5
sage: CartanType(['B', 4, 1]).rank()
5
sage: CartanType(['C', 3, 1]).rank()
4
sage: CartanType(['D', 4, 1]).rank()
5
sage: CartanType(['E', 6, 1]).rank()
7
sage: CartanType(['E', 7, 1]).rank()
8
sage: CartanType(['F', 4, 1]).rank()
5
sage: CartanType(['G', 2, 1]).rank()
3
sage: CartanType(['A', 2, 2]).rank()
2
sage: CartanType(['A', 6, 2]).rank()
4
sage: CartanType(['A', 7, 2]).rank()
5
sage: CartanType(['D', 5, 2]).rank()
5
sage: CartanType(['E', 6, 2]).rank()
5
sage: CartanType(['D', 4, 3]).rank()
3
```

special_node()

Implement `CartanType_abstract.special_node()`.

With the standard labelling conventions, 0 is always a special node.

EXAMPLES:

```python
sage: CartanType(['A', 3, 1]).special_node()
0
```

type()

Return the type of self.

EXAMPLES:

```python
sage: CartanType(['A', 4, 1]).type()
'A'
```

class sage.combinat.root_system.cartan_type.CartanType_standard_finite(letter, n)

Bases: `CartanType_standard`, `CartanType_finite`

A concrete base class for the finite standard Cartan types.
This includes for example $A_3$, $D_4$, or $E_8$.

**affine()**

Return the corresponding untwisted affine Cartan type.

**EXAMPLES:**

```
sage: CartanType(['A',3]).affine()
['A', 3, 1]
```

**coxeter_number()**

Return the Coxeter number associated with self.

The Coxeter number is the order of a Coxeter element of the corresponding Weyl group.

See Bourbaki, Lie Groups and Lie Algebras V.6.1 or *Wikipedia article Coxeter_element* for more information.

**EXAMPLES:**

```
sage: CartanType(['A',4]).coxeter_number()
5
sage: CartanType(['B',4]).coxeter_number()
8
sage: CartanType(['C',4]).coxeter_number()
8
```

**dual_coxeter_number()**

Return the Coxeter number associated with self.

**EXAMPLES:**

```
sage: CartanType(['A',4]).dual_coxeter_number()
5
sage: CartanType(['B',4]).dual_coxeter_number()
7
sage: CartanType(['C',4]).dual_coxeter_number()
5
```

**index_set()**

Implements *CartanType_abstract.index_set()*.

The index set for all standard finite Cartan types is of the form \{1,\ldots,n\}. (See *type_I* for a slight abuse of this).

**EXAMPLES:**

```
sage: CartanType(['A', 5]).index_set()
(1, 2, 3, 4, 5)
```

**opposition_automorphism()**

Returns the opposition automorphism

The *opposition automorphism* is the automorphism $i \mapsto i^*$ of the vertices Dynkin diagram such that, for $w_0$ the longest element of the Weyl group, and any simple root $\alpha_i$, one has $\alpha_i^* = -w_0(\alpha_i)$.

The automorphism is returned as a Family.

**EXAMPLES:**

```
```
```python
sage: ct = CartanType(['A', 5])
sage: ct.opposition_automorphism()
Finite family {1: 5, 2: 4, 3: 3, 4: 2, 5: 1}

sage: ct = CartanType(['D', 4])
sage: ct.opposition_automorphism()
Finite family {1: 1, 2: 2, 3: 3, 4: 4}

sage: ct = CartanType(['D', 5])
sage: ct.opposition_automorphism()
Finite family {1: 1, 2: 2, 3: 3, 4: 5, 5: 4}

sage: ct = CartanType(['C', 4])
sage: ct.opposition_automorphism()
Finite family {1: 1, 2: 2, 3: 3, 4: 4}
```

**rank()**

Return the rank of self which for type $X_n$ is $n$.

EXAMPLES:

```python
sage: CartanType(['A', 3]).rank()
3
sage: CartanType(['B', 3]).rank()
3
sage: CartanType(['C', 3]).rank()
3
sage: CartanType(['D', 4]).rank()
4
sage: CartanType(['E', 6]).rank()
6
```

**type()**

Returns the type of self.

EXAMPLES:

```python
sage: CartanType(['A', 4]).type()
'A'
sage: CartanType(['A', 4, 1]).type()
'A'
```

**class** `sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine(letter, n, affine=1)`

Bases: `CartanType_standard_affine`

A concrete class for the standard untwisted affine Cartan types.

**basic_untwisted()**

Return the basic_untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic_untwisted type is $X_n$. In other words, it is the classical Cartan type that is twisted to obtain self.

EXAMPLES:
```python
sage: CartanType(['A', 1, 1]).basic_untwisted()
['A', 1]
sage: CartanType(['A', 3, 1]).basic_untwisted()
['A', 3]
sage: CartanType(['B', 3, 1]).basic_untwisted()
['B', 3]
sage: CartanType(['E', 6, 1]).basic_untwisted()
['E', 6]
sage: CartanType(['G', 2, 1]).basic_untwisted()
['G', 2]
```

classical()

Return the classical Cartan type associated with `self`.

EXAMPLES:

```python
sage: CartanType(['A', 3, 1]).classical()
['A', 3]
sage: CartanType(['B', 3, 1]).classical()
['B', 3]
sage: CartanType(['C', 3, 1]).classical()
['C', 3]
sage: CartanType(['D', 4, 1]).classical()
['D', 4]
sage: CartanType(['E', 6, 1]).classical()
['E', 6]
sage: CartanType(['F', 4, 1]).classical()
['F', 4]
sage: CartanType(['G', 2, 1]).classical()
['G', 2]
```

is_untwisted_affine()

Implement `CartanType_affine.is_untwisted_affine()` by returning `True`.

EXAMPLES:

```python
sage: CartanType(['B', 3, 1]).is_untwisted_affine()
True
```

class `sage.combinat.root_system.cartan_type.SuperCartanType_standard`

Bases: `UniqueRepresentation`, `SageObject`

```python
options = Current options for CartanType - dual_latex: \vee - dual_str: * - latex_marked: True - latex_relabel: True - mark_special_node: none - marked_node_str: X - notation: Stembridge - special_node_str: @
```
5.1.226 Coxeter Groups

sage.combinat.root_system.coxeter_group.CoxeterGroup(data, implementation='reflection', base_ring=None, index_set=None)

Return an implementation of the Coxeter group given by data.

INPUT:

- data – a Cartan type (or coercible into; see CartanType) or a Coxeter matrix or graph
- implementation – (default: 'reflection') can be one of the following:
  - 'permutation' - as a permutation representation
  - 'matrix' - as a Weyl group (as a matrix group acting on the root space); if this is not implemented, this uses the “reflection” implementation
  - 'coxeter3' - using the coxeter3 package
  - 'reflection' - as elements in the reflection representation; see CoxeterMatrixGroup
- base_ring – (optional) the base ring for the 'reflection' implementation
- index_set – (optional) the index set for the 'reflection' implementation

EXAMPLES:

Now assume that data represents a Cartan type. If implementation is not specified, the reflection representation is returned:

```
sage: W = CoxeterGroup(['A',2])
sage: W
Finite Coxeter group over Integer Ring with Coxeter matrix:
[1 3]
[3 1]

sage: W = CoxeterGroup(['A',3,1]); W
Coxeter group over Integer Ring with Coxeter matrix:
[1 3 2 3]
[3 1 3 2]
[2 3 1 3]
[3 2 3 1]

sage: W = CoxeterGroup(['H',3]); W
Finite Coxeter group over Number Field in a with defining polynomial x^2 - 5 with a approximately 2.236067977499790? with Coxeter matrix:
[1 3 2]
[3 1 5]
[2 5 1]
```

We now use the implementation option:

```
sage: W = CoxeterGroup(['A',2], implementation = "permutation") # optional - gap3
sage: W
Permutation Group with generators [(1,4)(2,3)(5,6), (1,3)(2,5)(4,6)]

sage: W.category()
# optional - gap3
Join of Category of finite enumerated permutation groups
    and Category of finite weyl groups
    and Category of well generated finite irreducible complex reflection groups
```

(continues on next page)
sage: W = CoxeterGroup(['A',2], implementation="matrix")
sage: W
Weyl Group of type ['A', 2] (as a matrix group acting on the ambient space)

sage: W = CoxeterGroup(['H',3], implementation="matrix")
sage: W
Finite Coxeter group over Number Field in a with defining polynomial x^2 - 5 with a → 2.236067977499790? with Coxeter matrix:
[1 3 2]
[3 1 5]
[2 5 1]

sage: W = CoxeterGroup(['H',3], implementation="reflection")
sage: W
Finite Coxeter group over Number Field in a with defining polynomial x^2 - 5 with a → 2.236067977499790? with Coxeter matrix:
[1 3 2]
[3 1 5]
[2 5 1]

sage: W = CoxeterGroup(['A',4,1], implementation="permutation")
Traceback (most recent call last):
...
ValueError: the type must be finite

sage: W = CoxeterGroup(['A',4], implementation="chevie"); W
# optional - gap3
Irreducible real reflection group of rank 4 and type A4

We use the different options for the "reflection" implementation:

sage: W = CoxeterGroup(['H',3], implementation="reflection", base_ring=RR)
sage: W
Finite Coxeter group over Real Field with 53 bits of precision with Coxeter matrix:
[1 3 2]
[3 1 5]
[2 5 1]

sage: W = CoxeterGroup([[1,10],[10,1]], implementation="reflection", index_set=['a', → 'b'], base_ring=SR)
sage: W
Finite Coxeter group over Symbolic Ring with Coxeter matrix:
[ 1 10]
[10  1]
5.1.227 Coxeter Matrices

**class** `sage.combinat.root_system.coxeter_matrix.CoxeterMatrix(parent, data, coxeter_type, index_set)`

**Bases:** `CoxeterType`

A Coxeter matrix.

A Coxeter matrix $M = (m_{ij})_{i,j \in I}$ is a matrix encoding a Coxeter system $(W, S)$, where the relations are given by $(s_i s_j)^{m_{ij}}$. Thus $M$ is symmetric and has entries in $\{1, 2, 3, \ldots, \infty\}$ with $m_{ij} = 1$ if and only if $i = j$.

We represent $m_{ij} = \infty$ by any number $m_{ij} \leq -1$. In particular, we can construct a bilinear form $B = (b_{ij})_{i,j \in I}$ from $M$ by

$$b_{ij} = \begin{cases} m_{ij} & m_{ij} < 0 \text{ (i.e., } m_{ij} = \infty) \\ -\cos \left( \frac{\pi}{m_{ij}} \right) & \text{otherwise} \end{cases}$$

**EXAMPLES:**

```python
sage: CoxeterMatrix(['A', 4])
[1 3 2 2]
[3 1 3 2]
[2 3 1 3]
[2 2 3 1]
sage: CoxeterMatrix(['B', 4])
[1 3 2 2]
[3 1 3 2]
[2 3 1 4]
[2 2 4 1]
sage: CoxeterMatrix(['C', 4])
[1 3 2 2]
[3 1 3 2]
[2 3 1 4]
[2 2 4 1]
sage: CoxeterMatrix(['D', 4])
[1 3 2 2]
[3 1 3 3]
[2 3 1 2]
[2 3 2 1]
sage: CoxeterMatrix(['E', 6])
[1 2 3 2 2 2]
[2 1 2 3 2 2]
[3 2 1 3 2 2]
[2 3 3 1 3 2]
[2 2 2 3 1 3]
[2 2 2 2 3 1]
sage: CoxeterMatrix(['F', 4])
[1 3 2 2]
[3 1 4 2]
[2 4 1 3]
[2 2 3 1]
```

(continues on next page)
sage: CoxeterMatrix(['G', 2])
[1 6]
[6 1]

By default, entries representing $\infty$ are given by $-1$ in the Coxeter matrix:

sage: G = Graph([(0,1,None), (1,2,4), (0,2,oo)])
sage: CoxeterMatrix(G)
[ 1  3 -1]
[ 3  1  4]
[-1 -4  1]

It is possible to give a number $\leq -1$ to represent an infinite label:

sage: CoxeterMatrix([[1,-1],[-1,1]])
[ 1 -1]
[-1  1]
sage: CoxeterMatrix([[1,-3/2],[-3/2,1]])
[ 1 -3/2]
[-3/2  1]

*bilinear_form*(R=None)

Return the bilinear form of self.

EXAMPLES:

sage: CoxeterType(['A', 2, 1]).bilinear_form()
[ 1 -1/2 -1/2]
[-1/2  1 -1/2]
[-1/2 -1/2  1]
sage: CoxeterType(['H', 3]).bilinear_form()
[ 1 -1/2 0]
[-1/2  1 1/2*E(5)^2 + 1/2*E(5)^3]
[-1/2 1/2*E(5)^2 + 1/2*E(5)^3 1]
sage: C = CoxeterMatrix([[1,-1,-1],[-1,1,-1],[-1,-1,1]])
sage: C.bilinear_form()
[ 1 -1 -1]
[-1  1 -1]
[-1 -1  1]

*coxeter_graph*( )

Return the Coxeter graph of self.

EXAMPLES:

sage: C = CoxeterMatrix(['A',3])
sage: C.coxeter_graph()
Graph on 3 vertices

sage: C = CoxeterMatrix(['A',3],['A',1])
sage: C.coxeter_graph()
Graph on 4 vertices
**coxeter_matrix()**

Return the Coxeter matrix of self.

**EXAMPLES:**

```python
sage: C = CoxeterMatrix(['C',3]).coxeter_matrix()
[1 3 2]
[3 1 4]
[2 4 1]
```

**coxeter_type()**

Return the Coxeter type of self or self if unknown.

**EXAMPLES:**

```python
sage: C = CoxeterMatrix(['A',4,1])
sage: C.coxeter_type()
Coxeter type of ['A', 4, 1]
If the Coxeter type is unknown:

```python
sage: C = CoxeterMatrix([[1,3,4], [3,1,-1], [4,-1,1]])
sage: C.coxeter_type()
[ 1 3 4]
[ 3 1 -1]
[ 4 -1 1]
```

**index_set()**

Return the index set of self.

**EXAMPLES:**

```python
sage: C = CoxeterMatrix(['A',1,1])
sage: C.index_set()
(0, 1)
sage: C = CoxeterMatrix(['E',6])
sage: C.index_set()
(1, 2, 3, 4, 5, 6)
```

**is_affine()**

Return if self is an affine type or False if unknown.

**EXAMPLES:**

```python
sage: M = CoxeterMatrix(['C',4])
sage: M.is_affine()
False
sage: M = CoxeterMatrix(['D',4,1])
sage: M.is_affine()
True
sage: M = CoxeterMatrix([[1, 3],[3,1]])
sage: M.is_affine()
False
sage: M = CoxeterMatrix([[1, -1, 7], [-1, 1, 3], [7, 3, 1]])
sage: M.is_affine()
False
```
is_crystallographic()
Return whether self is crystallographic.
A Coxeter matrix is crystallographic if all non-diagonal entries are either 2, 3, 4, or 6.

EXAMPLES:

```
sage: C = CoxeterMatrix(['F',4]).is_crystallographic()
True
sage: C = CoxeterMatrix(['H',3]).is_crystallographic()
False
```

is_finite()
Return if self is a finite type or False if unknown.

EXAMPLES:

```
sage: M = CoxeterMatrix(['C',4])
sage: M.is_finite()
True
sage: M = CoxeterMatrix(['D',4,1])
sage: M.is_finite()
False
sage: M = CoxeterMatrix([[1, -1], [-1, 1]])
sage: M.is_finite()
False
```

is_irreducible()
Return whether self is irreducible.
A Coxeter matrix is irreducible if the Coxeter graph is connected.

EXAMPLES:

```
sage: C = CoxeterMatrix([[F',4],[A',1]]).is_irreducible()
False
sage: C = CoxeterMatrix(['H',3]).is_irreducible()
True
```

is_simply_laced()
Return if self is simply-laced.
A Coxeter matrix is simply-laced if all non-diagonal entries are either 2 or 3.

EXAMPLES:

```
sage: cm = CoxeterMatrix([[1,3,3,3], [3,1,3,3], [3,3,1,3], [3,3,3,1]])
sage: cm.is_simply_laced()
True
```

rank()
Return the rank of self.

EXAMPLES:

```
sage: C = CoxeterMatrix(['C',3]).rank()
3
```
(continues on next page)
sage: CoxeterMatrix(["A2","B2","F4"]).rank()
8

relabel

Return a relabelled copy of this Coxeter matrix.

INPUT:

- relabelling – a function (or dictionary)

OUTPUT:

an isomorphic Coxeter type obtained by relabelling the nodes of the Coxeter graph. Namely, the node with label i is relabelled f(i) (or, by f[i] if f is a dictionary).

EXAMPLES:

sage: CoxeterMatrix(['F',4]).relabel({ 1:2, 2:3, 3:4, 4:1})

\[
\begin{pmatrix}
1 & 4 & 2 & 3 \\
4 & 1 & 3 & 2 \\
2 & 3 & 1 & 2 \\
3 & 2 & 2 & 1 \\
\end{pmatrix}
\]

sage: CoxeterMatrix(['F',4]).relabel(lambda x: x+1 if x<4 else 1)

\[
\begin{pmatrix}
1 & 4 & 2 & 3 \\
4 & 1 & 3 & 2 \\
2 & 3 & 1 & 2 \\
3 & 2 & 2 & 1 \\
\end{pmatrix}
\]

classmethod samples

Return a sample of the available Coxeter types.

INPUT:

- finite – (default: None) a boolean or None
- affine – (default: None) a boolean or None
- crystallographic – (default: None) a boolean or None
- higher_rank – (default: None) a boolean or None

The sample contains all the exceptional finite and affine Coxeter types, as well as typical representatives of the infinite families. Here the higher_rank term denotes non-finite, non-affine, Coxeter groups (including hyperbolic types).

Todo: Implement the hyperbolic and compact hyperbolic in the samples.

EXAMPLES:

sage: [CM.coxeter_type() for CM in CoxeterMatrix.samples()]

[Cogxeter type of ['A', 1], Coxeter type of ['A', 5],
Coxeter type of ['B', 5], Coxeter type of ['D', 4],
Coxeter type of ['D', 5], Coxeter type of ['E', 6],
]
Coxeter type of ['E', 7], Coxeter type of ['E', 8],
Coxeter type of ['F', 4], Coxeter type of ['H', 3],
Coxeter type of ['H', 4], Coxeter type of ['I', 10],
Coxeter type of ['A', 2, 1], Coxeter type of ['B', 5, 1],
Coxeter type of ['C', 5, 1], Coxeter type of ['D', 5, 1],
Coxeter type of ['E', 6, 1], Coxeter type of ['E', 7],
Coxeter type of ['F', 4, 1], Coxeter type of ['H', 3],
Coxeter type of ['H', 4], Coxeter type of ['I', 10],

\[
\begin{bmatrix}
1 & -1 & -1 \\
-1 & 1 & -1 \\
\end{bmatrix}
\]

The finite, affine and crystallographic options allow respectively for restricting to (non) finite, (non) affine, and (non) crystallographic Cartan types:

```python
sage: [CM.coxeter_type() for CM in CoxeterMatrix.samples(finite=True)]
[Cogxeter type of ['A', 1], Coxeter type of ['A', 5],
 Coxeter type of ['B', 5], Coxeter type of ['D', 4],
 Coxeter type of ['E', 5], Coxeter type of ['E', 6],
 Coxeter type of ['E', 7], Coxeter type of ['E', 8],
 Coxeter type of ['F', 4], Coxeter type of ['H', 3],
 Coxeter type of ['H', 4], Coxeter type of ['I', 10]]
```

```python
sage: [CM.coxeter_type() for CM in CoxeterMatrix.samples(affine=True)]
[Cogxeter type of ['A', 2, 1], Coxeter type of ['B', 5, 1],
 Coxeter type of ['C', 5, 1], Coxeter type of ['D', 5, 1],
 Coxeter type of ['E', 6, 1], Coxeter type of ['E', 7, 1],
 Coxeter type of ['E', 8, 1], Coxeter type of ['F', 4, 1],
 Coxeter type of ['G', 2, 1], Coxeter type of ['A', 1, 1]]
```

```python
sage: [CM.coxeter_type() for CM in CoxeterMatrix.samples(crystallographic=True)]
[Cogxeter type of ['A', 1], Coxeter type of ['A', 5],
 Coxeter type of ['B', 5], Coxeter type of ['D', 4],
 Coxeter type of ['E', 5], Coxeter type of ['E', 6],
 Coxeter type of ['E', 7], Coxeter type of ['E', 8],
 Coxeter type of ['F', 4], Coxeter type of ['G', 2, 1],
 Coxeter type of ['H', 3], Coxeter type of ['H', 4],
 Coxeter type of ['I', 10]]
```
Coxeter type of ['F', 4, 1], Coxeter type of ['G', 2, 1] ]

sage: CoxeterMatrix.samples(crystallographic=False)
[
[1 3 2 2],
[1 3 2] [3 1 3 2]
[3 1 5] [2 3 1 5] [1 10] [1 -1] [1 -1 1] [2 1 7]
[2 5 1], [2 2 5 1], [10 1], [-1 1], [-1 -1], [3 7 1],
[ 1 -2 3 2],
[ -2 1 2 3]
[ 3 2 1 -8]
[2 3 -8 1]
]

Todo: add some reducible Coxeter types (suggestions?)

sage.combinat.root_system.coxeter_matrix.check_coxeter_matrix(m)
Check if m represents a generalized Coxeter matrix and raise and error if not.

EXAMPLES:

sage: from sage.combinat.root_system.coxeter_matrix import check_coxeter_matrix
sage: m = matrix([[1,3,2],[3,1,-1],[2,-1,1]])
sage: check_coxeter_matrix(m)

sage: m = matrix([[1,3],[3,1],[2,-1]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
... ValueError: not a square matrix

sage: m = matrix([[1,3,2],[3,1,-1],[2,-1,2]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
... ValueError: the matrix diagonal is not all 1

sage: m = matrix([[1,3,3],[3,1,-1],[1/2,-1,1]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
... ValueError: the matrix is not symmetric

sage: m = matrix([[1,3,1/2],[3,1,-1],[1/2,-1,1]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
... ValueError: invalid Coxeter label 1/2

sage: m = matrix([[1,3,1],[3,1,-1],[1,-1,1]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
...
ValueError: invalid Coxeter label 1

sage.combinat.root_system.coxeter_matrix.coxeter_matrix_as_function(t)
Return the Coxeter matrix, as a function.

INPUT:
• t – a Cartan type

EXAMPLES:

sage: from sage.combinat.root_system.coxeter_matrix import coxeter_matrix_as_function
sage: f = coxeter_matrix_as_function(['A',4])
sage: matrix([[f(i,j) for j in range(1,5)] for i in range(1,5)])
[1 3 2 2]
[3 1 3 2]
[2 3 1 3]
[2 2 3 1]

sage.combinat.root_system.coxeter_matrix.recognize_coxeter_type_from_matrix(coxeter_matrix, index_set)
Return the Coxeter type of coxeter_matrix if known, otherwise return None.

EXAMPLES:
Some infinite ones:

sage: C = CoxeterMatrix([[1,3,2],[3,1,-1],[2,-1,1]])
sage: C.is_finite()  # indirect doctest
False
sage: C = CoxeterMatrix([[1,-1,-1],[-1,1,-1],[-1,-1,1]])
sage: C.is_finite()  # indirect doctest
False

Some finite ones:

sage: m = matrix(CoxeterMatrix(['D', 4]))

sage: CoxeterMatrix(m).is_finite()  # indirect doctest
True
sage: m = matrix(CoxeterMatrix(['H', 4]))

sage: CoxeterMatrix(m).is_finite()  # indirect doctest
True

sage: CoxeterMatrix(CoxeterType(['A',10]).coxeter_graph()).coxeter_type()
Coxeter type of ['A', 10]
sage: CoxeterMatrix(CoxeterType(['B',10]).coxeter_graph()).coxeter_type()
Coxeter type of ['B', 10]
sage: CoxeterMatrix(CoxeterType(['C',10]).coxeter_graph()).coxeter_type()
Coxeter type of ['C', 10]
sage: CoxeterMatrix(CoxeterType(['D',10]).coxeter_graph()).coxeter_type()
Coxeter type of ['D', 10]
sage: CoxeterMatrix(CoxeterType(['E',6]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 6]
sage: CoxeterMatrix(CoxeterType(['E',7]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 7]
sage: CoxeterMatrix(CoxeterType(['E',8]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 8]
sage: CoxeterMatrix(CoxeterType(['F',4]).coxeter_graph()).coxeter_type()
Coxeter type of ['F', 4]
sage: CoxeterMatrix(CoxeterType(['G',2]).coxeter_graph()).coxeter_type()
Coxeter type of ['G', 2]
sage: CoxeterMatrix(CoxeterType(['H',3]).coxeter_graph()).coxeter_type()
Coxeter type of ['H', 3]
sage: CoxeterMatrix(CoxeterType(['H',4]).coxeter_graph()).coxeter_type()
Coxeter type of ['H', 4]
sage: CoxeterMatrix(CoxeterType(['I',100]).coxeter_graph()).coxeter_type()
Coxeter type of ['I', 100]

Some affine graphs:

sage: CoxeterMatrix(CoxeterType(['A',1,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['A', 1, 1]
sage: CoxeterMatrix(CoxeterType(['A',10,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['A', 10, 1]
sage: CoxeterMatrix(CoxeterType(['B',10,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['B', 10, 1]
sage: CoxeterMatrix(CoxeterType(['C',10,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['C', 10, 1]
sage: CoxeterMatrix(CoxeterType(['D',10,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['D', 10, 1]
sage: CoxeterMatrix(CoxeterType(['E',6,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 6, 1]
sage: CoxeterMatrix(CoxeterType(['E',7,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 7, 1]
sage: CoxeterMatrix(CoxeterType(['E',8,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 8, 1]
sage: CoxeterMatrix(CoxeterType(['F',4,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['F', 4, 1]
sage: CoxeterMatrix(CoxeterType(['G',2,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['G', 2, 1]

### 5.1.228 Coxeter Types

**class** sage.combinat.root_system.coxeter_type.CoxeterType

**Bases:** SageObject

Abstract class for Coxeter types.

**bilinear_form**(*R=None*)

Return the bilinear form over *R* associated to self.

**INPUT:**
• \( R \) – (default: universal cyclotomic field) a ring used to compute the bilinear form

**EXAMPLES:**

```python
sage: CoxeterType(['A', 2]).bilinear_form()
[ 1 -1/2 -1/2]
[-1/2 1 -1/2]
[-1/2 -1/2 1]
sage: CoxeterType(['H', 3]).bilinear_form()
[ 1 -1/2 0]
[-1/2 1 1/2*E(5)^2 + 1/2*E(5)^3]
[ 0 1/2*E(5)^2 + 1/2*E(5)^3 1]
sage: C = CoxeterMatrix([[1,-1,-1],[-1,1,-1],[-1,-1,1]])
sage: C.bilinear_form()
[ 1 -1 -1]
[-1 1 -1]
[-1 -1 1]
```

coxeter_graph()

Return the Coxeter graph associated to \texttt{self}.

**EXAMPLES:**

```python
sage: CoxeterType(['A', 3]).coxeter_graph()
Graph on 3 vertices
sage: CoxeterType(['A', 3, 1]).coxeter_graph()
Graph on 4 vertices
```

coxeter_matrix()

Return the Coxeter matrix associated to \texttt{self}.

**EXAMPLES:**

```python
sage: CoxeterType(['A', 3]).coxeter_matrix()
[1 3 2]
[3 1 3]
[2 3 1]
sage: CoxeterType(['A', 3, 1]).coxeter_matrix()
[1 3 2 3]
[3 1 3 2]
[2 3 1 3]
[3 2 3 1]
```

index_set()

Return the index set for \texttt{self}.

This is the list of the nodes of the associated Coxeter graph.

**EXAMPLES:**

```python
sage: CoxeterType(['A', 3]).index_set()
(0, 1, 2, 3)
sage: CoxeterType(['D', 4]).index_set()
(1, 2, 3, 4)
sage: CoxeterType(['A', 7, 2]).index_set()
(0, 1, 2, 3, 4)
```

(continues on next page)
sage: CoxeterType(['A', 7, 2]).index_set()
(0, 1, 2, 3, 4)
sage: CoxeterType(['A', 6, 2]).index_set()
(0, 1, 2, 3)
sage: CoxeterType(['D', 6, 2]).index_set()
(0, 1, 2, 3, 4, 5)
sage: CoxeterType(['E', 6, 1]).index_set()
(0, 1, 2, 3, 4, 5, 6)
sage: CoxeterType(['E', 6, 2]).index_set()
(0, 1, 2, 3, 4)
sage: CoxeterType(['A', 2, 2]).index_set()
(0, 1)
sage: CoxeterType(['G', 2, 1]).index_set()
(0, 1, 2)
sage: CoxeterType(['F', 4, 1]).index_set()
(0, 1, 2, 3, 4)

is_affine()
Return whether self is affine.

EXAMPLES:

sage: CoxeterType(['A', 3]).is_affine()
False
sage: CoxeterType(['A', 3, 1]).is_affine()
True

is_crystallographic()
Return whether self is crystallographic.

This returns False by default. Derived class should override this appropriately.

EXAMPLES:

sage: [ [t, t.is_crystallographic()] for t in CartanType.samples(finite=True) ]
[['A', 1], True], [['A', 5], True],
[['B', 1], True], [['B', 5], True],
[['C', 1], True], [['C', 5], True],
[['D', 2], True], [['D', 3], True], [['D', 5], True],
[['E', 6], True], [['E', 7], True], [['E', 8], True],
[['F', 4], True], [['G', 2], True],
[['I', 5], False], [['H', 3], False], [['H', 4], False]]

is_finite()
Return whether self is finite.

EXAMPLES:

sage: CoxeterType(['A',4]).is_finite()
True
sage: CoxeterType(['A',4, 1]).is_finite()
False
is_simply_laced()
Return whether self is simply laced.
This returns False by default. Derived class should override this appropriately.

EXAMPLES:

```sage
sage: CartanType.sample() [t, t.is_simply_laced()] for t in CartanType.samples() ]
[[['A', 1], True], [['A', 5], True], [['B', 1], True], [['B', 5], False], [['C', 1], True], [['C', 5], False], [['D', 2], True], [['D', 3], True], [['D', 5], True], [['E', 6], True], [['E', 7], True], [['E', 8], True], [['F', 4], False], [['G', 2], False], [['H', 3], False], [['H', 4], False], [['A', 1, 1], False], [['A', 5, 1], True], [['B', 1, 1], False], [['B', 5, 1], False], [['C', 1, 1], False], [['C', 5, 1], False], [['D', 3, 1], True], [['D', 5, 1], True], [['E', 6, 1], True], [['E', 7, 1], True], [['E', 8, 1], True], [['F', 4, 1], False], [['G', 2, 1], False], [['BC', 1, 2], False], [['BC', 5, 2], False], [['BC', 5, 1]^*, False], [['BC', 4, 1]^*, False], [['F', 4, 1]^*, False], [['G', 2, 1]^*, False], [['BC', 1, 2]^*, False], [['BC', 5, 2]^*, False]]
```

rank()
Return the rank of self.
This is the number of nodes of the associated Coxeter graph.

EXAMPLES:

```sage
sage: [ t.rank() for t in CartanType.samples() ]
4
sage: [ t.rank() for t in CartanType.samples() ]
5
sage: [ t.rank() for t in CartanType.samples() ]
2
```

classmethod samples(finite=None, affine=None, crystallographic=None)
Return a sample of the available Coxeter types.

INPUT:

- `finite` – a boolean or None (default: None)
- `affine` – a boolean or None (default: None)
- `crystallographic` – a boolean or None (default: None)

The sample contains all the exceptional finite and affine Coxeter types, as well as typical representatives of the infinite families.

EXAMPLES:

```sage
sage: CartanType.samples()
[Cartan type of ['A', 1], Cartan type of ['A', 5], ...]
```
The finite, affine and crystallographic options allow respectively for restricting to (non) finite, (non) affine, and (non) crystallographic Cartan types:

sage: CoxeterType.samples(finite=True)
[[Coxeter type of ['A', 1], Coxeter type of ['A', 5],
  Coxeter type of ['B', 1], Coxeter type of ['B', 5],
  Coxeter type of ['C', 1], Coxeter type of ['C', 5],
  Coxeter type of ['D', 4], Coxeter type of ['D', 5],
  Coxeter type of ['E', 6], Coxeter type of ['E', 7],
  Coxeter type of ['E', 8], Coxeter type of ['F', 4],
  Coxeter type of ['H', 3], Coxeter type of ['H', 4],
  Coxeter type of ['I', 10]]

sage: CoxeterType.samples(affine=True)
[[Coxeter type of ['A', 2, 1], Coxeter type of ['B', 5, 1],
  Coxeter type of ['C', 5, 1], Coxeter type of ['D', 5, 1],
  Coxeter type of ['E', 6, 1], Coxeter type of ['E', 7, 1],
  Coxeter type of ['E', 8, 1], Coxeter type of ['F', 4, 1],
  Coxeter type of ['G', 2, 1], Coxeter type of ['A', 1, 1]]

sage: CoxeterType.samples(crystallographic=True)
[[Coxeter type of ['A', 1], Coxeter type of ['A', 5],
  Coxeter type of ['B', 1], Coxeter type of ['B', 5],
  Coxeter type of ['C', 1], Coxeter type of ['C', 5],
  Coxeter type of ['D', 4], Coxeter type of ['D', 5],
  Coxeter type of ['E', 6], Coxeter type of ['E', 7],
  Coxeter type of ['E', 8], Coxeter type of ['F', 4],
  Coxeter type of ['A', 2, 1], Coxeter type of ['B', 5, 1],
  Coxeter type of ['C', 5, 1], Coxeter type of ['D', 5, 1],
  Coxeter type of ['E', 6, 1], Coxeter type of ['E', 7, 1],
  Coxeter type of ['E', 8, 1], Coxeter type of ['F', 4, 1],
  Coxeter type of ['G', 2, 1], Coxeter type of ['A', 1, 1]]

sage: CoxeterType.samples(crystallographic=False)
[[Coxeter type of ['H', 3],
  Coxeter type of ['I', 10]]]
Todo: add some reducible Coxeter types (suggestions?)

```python
class sage.combinat.root_system.coxeter_type.CoxeterTypeFromCartanType(cartan_type):
    Bases: UniqueRepresentation, CoxeterType

    A Coxeter type associated to a Cartan type.

cartan_type()  
    Return the Cartan type used to construct self.

    EXAMPLES:
    sage: C = CoxeterType(['C',3])
    sage: C.cartan_type()
    ['C', 3]

component_types()  
    A list of Coxeter types making up the reducible type.

    EXAMPLES:
    sage: CoxeterType(['A',2],['B',2]).component_types()  
    [Coxeter type of ['A', 2], Coxeter type of ['B', 2]]
    sage: CoxeterType('A4xB3').component_types()  
    [Coxeter type of ['A', 4], Coxeter type of ['B', 3]]
    sage: CoxeterType(['A', 2]).component_types()  
    Traceback (most recent call last):
    ...  
    ValueError: component types only defined for reducible types

coxeter_graph()  
    Return the Coxeter graph of self.

    EXAMPLES:
    sage: C = CoxeterType(['H',3])
    sage: C.coxeter_graph().edges(sort=True)
    [(1, 2, 3), (2, 3, 5)]

coxeter_matrix()  
    Return the Coxeter matrix associated to self.

    EXAMPLES:
    sage: C = CoxeterType(['H',3])
    sage: C.coxeter_matrix()
    [1 3 2]
    [3 1 5]
    [2 5 1]

index_set()  
    Return the index set of self.

    EXAMPLES:
sage: C = CoxeterType(['A', 4])
sage: C.index_set()
(1, 2, 3, 4)

is_affine()
Return if self is an affine type.

EXAMPLES:

sage: C = CoxeterType(['F', 4, 1])
sage: C.is_affine()
True

is_crystallographic()
Return if self is crystallographic.

EXAMPLES:

sage: C = CoxeterType(['C', 3])
sage: C.is_crystallographic()
True
sage: C = CoxeterType(['H', 3])
sage: C.is_crystallographic()
False

is_finite()
Return if self is a finite type.

EXAMPLES:

sage: C = CoxeterType(['E', 6])
sage: C.is_finite()
True

is_irreducible()
Return if self is irreducible.

EXAMPLES:

sage: C = CoxeterType(['A', 5])
sage: C.is_irreducible()
True
sage: C = CoxeterType('B3xB3')
sage: C.is_irreducible()
False

is_reducible()
Return if self is reducible.

EXAMPLES:

sage: C = CoxeterType(['A', 5])
sage: C.is_reducible()
False

```python
sage: C = CoxeterType('A2xA2')
sage: C.is_reducible()
True
```

**is_simply_laced()**

Return if self is simply-laced.

**EXAMPLES:**

```python
sage: C = CoxeterType(['A', 5])
sage: C.is_simply_laced()
True
sage: C = CoxeterType(['B', 3])
sage: C.is_simply_laced()
False
```

**rank()**

Return the rank of self.

**EXAMPLES:**

```python
sage: C = CoxeterType(['I', 16])
sage: C.rank()
2
```

**relabel**(relabelling)

Return a relabelled copy of self.

**EXAMPLES:**

```python
sage: ct = CoxeterType(['A',2])
sage: ct.relabel({1:-1, 2:-2})
Coxeter type of ['A', 2] relabelled by {1: -1, 2: -2}
```

**type()**

Return the type of self.

**EXAMPLES:**

```python
sage: C = CoxeterType(['A', 4])
sage: C.type()
'A'
```
5.1.229 Dynkin diagrams

AUTHORS:

• Travis Scrimshaw (2012-04-22): Nicolas M. Thiery moved Cartan matrix creation to here and I cached results for speed.

• Travis Scrimshaw (2013-06-11): Changed inputs of Dynkin diagrams to handle other Dynkin diagrams and graphs. Implemented remaining Cartan type methods.

sage.combinat.root_system.dynkin_diagram.DynkinDiagram(*args, **kwds)

Return the Dynkin diagram corresponding to the input.

INPUT:

The input can be one of the following:

• empty to obtain an empty Dynkin diagram
• a Cartan type
• a Cartan matrix
• a Cartan matrix and an indexing set

One can also input an indexing set by passing a tuple using the optional argument index_set.

The edge multiplicities are encoded as edge labels. For the corresponding Cartan matrices, this uses the convention in Hong and Kang, Kac, Fulton and Harris, and crystals. This is the opposite convention in Bourbaki and Wikipedia’s Dynkin diagram (Wikipedia article Dynkin_diagram). That is for $i \neq j$:

\[
i \leftrightarrow k \iff a_{ij} = -k
\]
\[
\iff -\text{scalar(coroot}[i], \text{root}[j]) = k
\]
\[
\iff \text{multiple arrows point from the longer root to the shorter one}
\]

For example, in type $C_2$, we have:

```
sage: C2 = DynkinDiagram(['C',2]); C2
0 O--O--O--O
  1 2 3 4
C2
sage: C2.cartan_matrix()
[ 2 -2]
[-1  2]
```

However Bourbaki would have the Cartan matrix as:

\[
\begin{pmatrix}
2 & -1 \\
-2 & 2
\end{pmatrix}
\]

EXAMPLES:

```
sage: DynkinDiagram(['A', 4])
O---O---O---O---O
  1 2 3 4
A4
```

(continues on next page)
sage: DynkinDiagram(['A',1],['A',1])
A1xA1

sage: R = RootSystem("A2xB2xF4")
sage: DynkinDiagram(R)
O---O
1 2
O=>=O
3 4
O---O=>=O---O
5 6 7 8
A2xB2xF4

sage: R = RootSystem("A2xB2xF4")
sage: CM = R.cartan_matrix(); CM
\[
\begin{bmatrix}
  2 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\
-1 & 2 & 0 & 0 & 0 & 0 & 0 & 0 \\
  0 & 0 & 2 & -1 & 0 & 0 & 0 & 0 \\
  0 & 0 & -2 & 2 & 0 & 0 & 0 & 0 \\
  0 & 0 & 0 & 0 & 2 & -1 & 0 & 0 \\
  0 & 0 & 0 & 0 & -1 & 2 & -1 & 0 \\
  0 & 0 & 0 & 0 & 0 & -2 & 2 & -1 \\
  0 & 0 & 0 & 0 & 0 & 0 & -1 & 2 \\
\end{bmatrix}
\]
sage: DD = DynkinDiagram(CM); DD
O---O
1 2
O=>=O
3 4
O---O=>=O---O
5 6 7 8
A2xB2xF4

sage: DD.cartan_matrix()
\[
\begin{bmatrix}
  2 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\
  0 & 0 & 2 & -1 & 0 & 0 & 0 & 0 \\
  0 & 0 & -2 & 2 & 0 & 0 & 0 & 0 \\
  0 & 0 & 0 & 0 & 2 & -1 & 0 & 0 \\
  0 & 0 & 0 & 0 & -1 & 2 & -1 & 0 \\
  0 & 0 & 0 & 0 & 0 & -2 & 2 & -1 \\
  0 & 0 & 0 & 0 & 0 & 0 & -1 & 2 \\
\end{bmatrix}
\]

We can also create Dynkin diagrams from arbitrary Cartan matrices:

sage: C = CartanMatrix([[2, -3], [-4, 2]])
sage: DynkinDiagram(C)
Dynkin diagram of rank 2
sage: CI = CartanMatrix([[2, -3], [-4, 2]], [3, 5])
sage: DI = DynkinDiagram(CI)
sage: DI.index_set()
(3, 5)
sage: CII = CartanMatrix([[2, -3], [-4, 2]])
sage: DII = DynkinDiagram(CII, ('y', 'x'))
sage: DII.index_set()
('x', 'y')

See also:

CartanType() for a general discussion on Cartan types and in particular node labeling conventions.

class sage.combinat.root_system.dynkin_diagram.DynkinDiagram_class(t=None, index_set=None, odd_isotropic_roots=[], **options)

Bases: DiGraph, CartanType_abstract

A Dynkin diagram.

See also:

DynkinDiagram()

INPUT:

• t – a Cartan type, Cartan matrix, or None

EXAMPLES:

sage: DynkinDiagram(['A', 3])
\[0\rightarrow0\rightarrow0\]
1 2 3
A3
sage: C = CartanMatrix([[2, -3], [-4, 2]])
sage: DynkinDiagram(C)
Dynkin diagram of rank 2
sage: C.dynkin_diagram().cartan_matrix() == C
True

add_edge(i, j, label=1)

EXAMPLES:

sage: from sage.combinat.root_system.dynkin_diagram import DynkinDiagram_class
sage: d = DynkinDiagram_class(CartanType(['A', 3]))
sage: sorted(d.edges(sort=True))
[]
sage: d.add_edge(2, 3)
sage: sorted(d.edges(sort=True))
[(2, 3), (3, 2), (1, 2), (2, 1)]

static an_instance()

Returns an example of Dynkin diagram

EXAMPLES:
sage: from sage.combinat.root_system.dynkin_diagram import DynkinDiagram_class
sage: g = DynkinDiagram_class.an_instance()
sage: g
Dynkin diagram of rank 3
sage: g.cartan_matrix()
[ 2 -1 -1]
[-2 2 -1]
[-1 -1 2]

**cartan_matrix()**

Returns the Cartan matrix for this Dynkin diagram

**EXAMPLES:**

```
sage: DynkinDiagram(['C',3]).cartan_matrix()
[ 2 -1 0]
[-1 2 -2]
[ 0 -1 2]
```

**cartan_type()**

**EXAMPLES:**

```
sage: DynkinDiagram("A2","B2","F4").cartan_type()
A2xB2xF4
```

**column(j)**

Returns the \( j \)th column \( (a_{i,j}) \) of the Cartan matrix corresponding to this Dynkin diagram, as a container (or iterator) of tuples \((i, a_{i,j})\)

**EXAMPLES:**

```
sage: g = DynkinDiagram(['B',4])
sage: [ (i,a) for (i,a) in g.column(3) ]
[(3, 2), (2, -1), (4, -2)]
```

**coxeter_diagram()**

Construct the Coxeter diagram of self.

See also:

```
CartanType_abstract.coxeter_diagram()
```

**EXAMPLES:**

```
sage: cm = CartanMatrix([[2,-5,0],[-2,2,-1],[0,-1,2]])
sage: D = cm.dynkin_diagram()
sage: G = D.coxeter_diagram(); G
Graph on 3 vertices
sage: G.edges(sort=True)
[(0, 1, +Infinity), (1, 2, 3)]
```

(continues on next page)
sage: ct.dynkin_diagram().coxeter_diagram() == ct.coxeter_diagram()
True

dual()

Returns the dual Dynkin diagram, obtained by reversing all edges.

EXAMPLES:

sage: D = DynkinDiagram(['C', 3])
sage: D.edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]
sage: D.dual()
O---O=<=O
1 2 3
B3
sage: D.dual().edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1)]
sage: D.dual() == DynkinDiagram(['B', 3])
True

dynkin_diagram()

EXAMPLES:

sage: DynkinDiagram(['C', 3]).dynkin_diagram()
O---O=<=O
1 2 3
C3

index_set()

EXAMPLES:

sage: DynkinDiagram(['C', 3]).index_set()
(1, 2, 3)
sage: DynkinDiagram("A2","B2","F4").index_set()
(1, 2, 3, 4, 5, 6, 7, 8)

is_affine()

Check if self corresponds to an affine root system.

EXAMPLES:

sage: CartanType(['F', 4]).dynkin_diagram().is_affine()
False
sage: D = DynkinDiagram(CartanMatrix([[2, -4], [-3, 2]]))
sage: D.is_affine()
False

is_crystallographic()

Implements CartanType_abstract.is_crystallographic()

A Dynkin diagram always corresponds to a crystallographic root system.

EXAMPLES:
```python
sage: CartanType(['F',4]).dynkin_diagram().is_crystallographic()
True
```

**is_finite()**

Check if self corresponds to a finite root system.

**EXAMPLES:**

```python
sage: CartanType(['F',4]).dynkin_diagram().is_finite()
True
sage: D = DynkinDiagram(CartanMatrix([[2, -4], [-3, 2]]))
sage: D.is_finite()
False
```

**is_irreducible()**

Check if self corresponds to an irreducible root system.

**EXAMPLES:**

```python
sage: CartanType(['F',4]).dynkin_diagram().is_irreducible()
True
sage: CM = CartanMatrix([[2,-6],[[-4,2]])
sage: CM.dynkin_diagram().is_irreducible()
True
sage: CartanType("A2xB3").dynkin_diagram().is_irreducible()
False
sage: CM = CartanMatrix([[2,-6,0],[-4,2,0],[0,0,2]])
sage: CM.dynkin_diagram().is_irreducible()
False
```

**odd_isotropic_roots()**

Return the odd isotropic roots of self.

**EXAMPLES:**

```python
sage: g = DynkinDiagram(['A',4])
sage: g.odd_isotropic_roots()
()  
sage: g = DynkinDiagram(['A',4,3])
sage: g.odd_isotropic_roots()
(0,)
```

**rank()**

Returns the index set for this Dynkin diagram

**EXAMPLES:**

```python
sage: DynkinDiagram(['C',3]).rank()
3
sage: DynkinDiagram("A2","B2","F4").rank()
8
```

**relabel(*args, **kwds)**

Return the relabelled Dynkin diagram of self.

**INPUT:** see **relabel()**
There is one difference: the default value for inplace is False instead of True.

EXAMPLES:

```python
sage: D = DynkinDiagram(['C', 3])
sage: D.relabel({1:0, 2:4, 3:1})
O---O<=<=O
 0 4 1
C3 relabelled by {1: 0, 2: 4, 3: 1}
sage: D
O---O<=<=O
 1 2 3
C3
sage: _ = D.relabel({1:0, 2:4, 3:1}, inplace=True)
sage: D
O---O<=<=O
 0 4 1
C3 relabelled by {1: 0, 2: 4, 3: 1}
sage: D = DynkinDiagram(['A', [1,2]])
sage: Dp = D.relabel({-1:4, 0:-3, 1:3, 2:2})
sage: Dp
O---X---O---O
 4 -3 3 2
A1|2 relabelled by {-1: 4, 0: -3, 1: 3, 2: 2}
sage: Dp.odd_isotropic_roots()
(-3,)
sage: D = DynkinDiagram(['D', 5])
sage: G, perm = D.relabel(range(5), return_map=True)
sage: G
 0 4
| |
O---O---O---O
 0 1 2 3
D5 relabelled by {1: 0, 2: 1, 3: 2, 4: 3, 5: 4}
sage: perm
{1: 0, 2: 1, 3: 2, 4: 3, 5: 4}
sage: perm = D.relabel(range(5), return_map=True, inplace=True)
sage: D
 0 4
| |
O---O---O---O
 0 1 2 3
D5 relabelled by {1: 0, 2: 1, 3: 2, 4: 3, 5: 4}
sage: perm
{1: 0, 2: 1, 3: 2, 4: 3, 5: 4}
```

**row(i)**

Returns the \(i^{th}\) row \((a_{i,j})_j\) of the Cartan matrix corresponding to this Dynkin diagram, as a container (or
iterator) of tuples \((j, a_{i,j})\)

**EXAMPLES:**

```python
sage: g = DynkinDiagram(['C',4])
sage: [(i,a) for (i,a) in g.row(3)]
[(3, 2), (2, -1), (4, -2)]
```

**subtype(index_set)**

Return a subtype of self given by index_set.

A subtype can be considered the Dynkin diagram induced from the Dynkin diagram of self by index_set.

**EXAMPLES:**

```python
sage: D = DynkinDiagram(['A',6,2]); D
O=<=O---O=<=O
0 1 2 3
BC3~
sage: D.subtype([1,2,3])
Dynkin diagram of rank 3
```

**symmetrizer()**

Return the symmetrizer of the corresponding Cartan matrix.

**EXAMPLES:**

```python
sage: d = DynkinDiagram()
sage: d.add_edge(1,2,3)
sage: d.add_edge(2,3)
sage: d.add_edge(3,4,3)
sage: d.symmetrizer()
Finite family {1: 9, 2: 3, 3: 3, 4: 1}
```

```python
sage.combinat.root_system.dynkin_diagram.precheck(t, letter=None, length=None, affine=None, n_ge=None, n=None)
```

**EXAMPLES:**

```python
sage: from sage.combinat.root_system.dynkin_diagram import precheck
sage: ct = CartanType(['A',4])
sage: precheck(ct, letter='C')
Traceback (most recent call last):
  ... ValueError: t[0] must be = 'C'
sage: precheck(ct, affine=1)
Traceback (most recent call last):
  ... ValueError: t[2] must be = 1
sage: precheck(ct, length=3)
Traceback (most recent call last):
  ... ValueError: len(t) must be = 3
sage: precheck(ct, n=3)
Traceback (most recent call last):
  ...
```

(continues on next page)
ValueError: t[1] must be = 3

sage: precheck(ct, n_ge=5)
Traceback (most recent call last):
  ...  
ValueError: t[1] must be >= 5

5.1.230 Hecke algebra representations

class sage.combinat.root_system.hecke_algebra_representation.CherednikOperatorsEigenvectors(T, T_Y=None, normalized=True)

Bases: UniqueRepresentation, SageObject

A class for the family of eigenvectors of the \( Y \) Cherednik operators for a module over a (Double) Affine Hecke algebra

INPUT:

- \( T \) – a family \((T_i)_{i \in I}\) implementing the action of the generators of an affine Hecke algebra on self. The intertwiner operators are built from these.
- \( T_Y \) – a family \((T^Y_i)_{i \in I}\) implementing the action of the generators of an affine Hecke algebra on self. By default, this is \( T \). But this can be used to get the action of the full Double Affine Hecke Algebra. The \( Y \) operators are built from the \( T_Y \).

This returns a function \( \mu \mapsto E_\mu \) which uses intertwining operators to calculate recursively eigenvectors \( E_\mu \) for the action of the torus of the affine Hecke algebra with eigenvalue given by \( f \). Namely:

\[ E_\mu.Y^\lambda^\vee = f(\lambda^\vee, \mu)E_\mu \]

Assumptions:

- \( \text{seed}(\mu) \) initializes the recurrence by returning an appropriate eigenvector \( E_\mu \) for \( \mu \) trivial enough. For example, for nonsymmetric Macdonald polynomials \( \text{seed}(\mu) \) returns the monomial \( X^\mu \) for a minuscule weight \( \mu \).
- \( f \) is almost equivariant. Namely, \( f(\lambda^\vee, \mu) = f(\lambda^\vee s_i, \text{twist}(\mu, i)) \) whenever \( i \) is a descent of \( \mu \).
- \( \text{twist}(\mu, i) \) maps \( \mu \) closer to the dominant chamber whenever \( i \) is a descent of \( \mu \).

Todo: Add tests for the above assumptions, and also that the classical operators \( T_1, \ldots, T_n \) from \( T \) and \( T_Y \) coincide.

\( \text{Y()} \)

Return the Cherednik operators.

EXAMPLES:

sage: W = WeylGroup(["B",2])
sage: K = QQ["q1,q2"].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = \hat{W}.algebra(K)
affine_lift($\mu$)
Lift the index $\mu$ to a space admitting an action of the affine Weyl group.

INPUT:

- $\mu$ – an element $\mu$ of the indexing set

In this space, one should have first_descent and apply_simple_reflection act properly.

EXAMPLES:

```python
sage: W = WeylGroup(['A',3])
sage: W.element_class._repr_ = lambda x: ''.join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w = W.an_element(); w
123
sage: E.affine_lift(w)
121
```

affine_retract($\mu$)
Retract $\mu$ from a space admitting an action of the affine Weyl group.

EXAMPLES:

```python
sage: W = WeylGroup(['A',3])
sage: W.element_class._repr_ = lambda x: ''.join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w = W.an_element(); w
123
sage: E.affine_lift(w)
121
sage: E.affine_retract(E.affine_lift(w)) == w
True
```

cartan_type()
Return Cartan type of self.

EXAMPLES:

```python
sage: W = WeylGroup(['B',3])
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: E.cartan_type()
['B', 3, 1]
```

(continues on next page)
sage: NonSymmetricMacdonaldPolynomials(["B", 2, 1]).cartan_type()
['B', 2, 1]

domain()

The module on which the affine Hecke algebra acts.

EXAMPLES:

sage: W = WeylGroup(['B',3])
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: E.domain()
Algebra of Weyl Group of type ['B', 3] (as a matrix group acting on the ambient space) over Multivariate Polynomial Ring in q1, q2 over Rational Field

eigenvalue(mu, l)

Return the eigenvalue of $Y_{\lambda^\vee}$ on $E_{\mu}$ computed by applying $Y_{\lambda^\vee}$ on $E_{\mu}$.

INPUT:

* mu – the index $\mu$ of an eigenvector, or a tentative eigenvector
* l – the index $\lambda^\vee$ of a Cherednik operator in self.Y_index_set()

This default implementation applies explicitly $Y_{\mu}$ to $E_{\lambda}$.

EXAMPLES:

sage: W = WeylGroup(['B',2])
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w0 = W.long_element()
sage: Y = E.Y()
sage: alphacheck = Y.keys().simple_roots()
sage: E.eigenvalue(w0, alphacheck[1])
q1/(-q2)
sage: E.eigenvalue(w0, alphacheck[2])
q1/(-q2)
sage: E.eigenvalue(w0, alphacheck[0])
q2^2/q1^2

The following checks that all $E_{w}$ are eigenvectors, with eigenvalue given by Lemma 7.5 of [HST2008] (checked for $A_2, A_3$):

sage: Pcheck = Y.keys()  
sage: Wcheck = Pcheck.weyl_group()  
sage: P0check = Pcheck.classical()  
sage: def height(root):      
.....:      return sum(P0check(root).coefficients())  
sage: def eigenvalue(w, mu):  
.....:      return (-q2/q1)^height(Wcheck.from_reduced_word(w.reduced_word)).
→ action(μ))
sage: all(E.eigenvalue(w, a) == eigenvalue(w, a) for w in E.keys() for a in Y.
˓→ keys().simple_roots()) # long time (2.5s)
True

**eigenvalues(μ)**
Return the eigenvalues of \( Y_{α_0}, \ldots, Y_{α_n} \) on \( E_μ \).

**INPUT:**

- `μ` – the index \( μ \) of an eigenvector or a tentative eigenvector

**EXAMPLES:**

```python
sage: W = WeylGroup(["B",2])
```

```python
sage: K = QQ['q1,q2'].fraction_field()
```

```python
sage: q1, q2 = K.gens()
```

```python
sage: KW = W.algebra(K)
```

```python
sage: T = KW.demazure_lusztig_operators(q1, q2)
```

```python
sage: E = T.Y_eigenvectors()
```

```python
sage: E.eigenvalues(q1)
```

```python
sage: E.eigenvalues(q2)
```

```python
sage: E.hecke_parameters(1)
```

```python
sage: E.hecke_parameters(2)
```

```python
sage: E.hecke_parameters(0)
```

**hecke_parameters(𝑖)**
Return the Hecke parameters for index \( i \).

**EXAMPLES:**

```python
sage: W = WeylGroup(["A",3])
```

```python
sage: K = QQ['q1,q2']
```

```python
sage: q1, q2 = K.gens()
```

```python
sage: KW = W.algebra(K)
```

```python
sage: T = KW.demazure_lusztig_operators(q1, q2, affine=True)
```

```python
sage: E = T.Y_eigenvectors()
```

```python
sage: E.hecke_parameters(0)
```

```python
sage: E.hecke_parameters(1)
```

```python
sage: E.hecke_parameters(2)
```

**keys()**
The index set for the eigenvectors.

By default, this assumes that the eigenvectors span the full affine Hecke algebra module and that the eigenvectors have the same indexing as the basis of this module.

**EXAMPLES:**

```python
sage: W = WeylGroup(["A",3])
```

```python
sage: K = QQ['q1,q2']
```

```python
sage: q1, q2 = K.gens()
```
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: E.keys()
Weyl Group of type ['A', 3] (as a matrix group acting on the ambient space)

**recursion**(\(\mu\))

Return the indices used in the recursion.

**INPUT:**

- \(\mu\) – the index \(\mu\) of an eigenvector

**EXAMPLES:**

```python
sage: W = WeylGroup(['A',3])
sage: W.element_class._repr_=lambda x: ''.join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w0 = W.long_element()
sage: E.recursion(w0)
[]
sage: w = W.an_element(); w
123
sage: E.recursion(w)
[1, 2, 1]
```

**seed**(\(\mu\))

Return the eigenvector for \(\mu\) minusculc.

**INPUT:**

- \(\mu\) – an element \(\mu\) of the indexing set

**OUTPUT:** an element of \(T\).domain()

This default implementation returns the monomial indexed by \(\mu\).

**EXAMPLES:**

```python
sage: W = WeylGroup(['A',3])
sage: W.element_class._repr_=lambda x: ''.join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: E.seed(W.long_element())
123121
```

**twist**(\(\mu, i\))

Act by \(s_i\) on \(\mu\).

By default, this calls the method apply_simple_reflection.

**EXAMPLES:**
sage: W = WeylGroup(['B',3])
sage: W.element_class._repr_=lambda x: ''.join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: T = KW.demazure_lusztig_operators(q1, q2, affine=True)
sage: E = T.Y_eigenvectors()
sage: w = W.an_element(); w
123
sage: E.twist(w,1)
1231

class sage.combinat.root_system.hecke_algebra_representation.HeckeAlgebraRepresentation(domain, on_basis, cartan_type, q1, q2, q=1, side='right')

Bases: WithEqualityById, SageObject

A representation of an (affine) Hecke algebra given by the action of the $T$ generators

Let $F_i$ be a family of operators implementing an action of the operators $(T_i)_{i \in I}$ of the Hecke algebra on some vector space $\text{domain}$, given by their action on the basis of $\text{domain}$. This constructs the family of operators $(F_w)_{w \in W}$ describing the action of all elements of the basis $(T_w)_{w \in W}$ of the Hecke algebra. This is achieved by linearity on the first argument, and applying recursively the $F_i$ along a reduced word for $w = s_i \cdots s_k$:

$$F_w(x) = F_{s_k} \circ \cdots \circ F_{s_1}(x).$$

INPUT:

• $\text{domain}$ – a vector space
• $\text{f}$ – a function $f(l,i)$ taking a basis element $l$ of $\text{domain}$ and an index $i$, and returning $F_i$
• $\text{cartan_type}$ – The Cartan type of the Hecke algebra
• $q1,q2$ – The eigenvalues of the generators $T$ of the Hecke algebra
• $\text{side}$ – “left” or “right” (default: “right”) whether this is a left or right representation

EXAMPLES:

sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = WeylGroup(['A',3]).algebra(QQ)
sage: H = KW.demazure_lusztig_operators(q1,q2); H
A representation of the (q1, q2)-Hecke algebra of type ['A', 3, 1] on Algebra of Weyl Group of type ['A', 3] (as a matrix group acting on the ambient space) over Rational Field

Among other things, it implements the $T_w$ operators, their inverses and compositions thereof:
and the Cherednik operators $Y^{\lambda}$:

```python
sage: H.Y()
Lazy family (...)_{i in Coroot lattice of the Root system of type ['A', 3, 1]}
```

REFERENCES:

• [HST2008]

**Ti_inverse_on_basis**($x, i$)

The $T_i^{-1}$ operators, on basis elements

**INPUT:**

- $x$ – the index of a basis element
- $i$ – the index of a generator

**EXAMPLES:**

```python
sage: W = WeylGroup("A3")
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1,q2)
sage: w = W.an_element()
sage: rho.Ti_inverse_on_basis(w, 1)
-1/q2*1231 + ((q1+q2)/(q1*q2))*123
```

**Ti_on_basis**($x, i$)

The $T_i$ operators, on basis elements.

**INPUT:**

- $x$ – the index of a basis element
- $i$ – the index of a generator

**EXAMPLES:**

```python
sage: W = WeylGroup("A3")
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1,q2)
sage: w = W.an_element()
sage: rho.Ti_on_basis(w, 1)
q1*1231
```

**Tw**($word, signs=None, scalar=None$)

Return $T_w$.

**INPUT:**

```python
sage: H.Tw((1,2))
Generic endomorphism of Algebra of Weyl Group of type ['A', 3] (as a matrix group acting on the ambient space) over Rational Field
```
• **word** – a word $i_1, \ldots, i_k$ for some element $w$ of the Weyl group. See `straighten_word()` for how this word can be specified.

• **signs** – a list $\varepsilon_1, \ldots, \varepsilon_k$ of the same length as `word` with $\varepsilon_i = \pm 1$ or `None` for $1, \ldots, 1$ (default: `None`)

• **scalar** – an element $c$ of the base ring or `None` for $1$ (default: `None`)

**OUTPUT:**

a module morphism implementing

$$T_w = T_{i_k} \circ \cdots \circ T_{i_1}$$

in left action notation; that is $T_{i_1}$ is applied first, then $T_{i_2}$, etc.

More generally, if scalar or signs is specified, the morphism implements

$$cT_{i_k}^\varepsilon \circ \cdots \circ T_{i_1}^\varepsilon.$$

**EXAMPLES:**

```
sage: W = WeylGroup("A3")

sage: W.element_class._repr_ = lambda x: ('e' if not x.reduced_word() ....: else ''.join(str(i) for i in x.reduced_word()))

sage: K = QQ['q1,q2'].fraction_field()

sage: q1, q2 = K.gens()

sage: KW = W.algebra(K)

sage: x = KW.an_element(); x
123 + 3*2312 + 2*31 + e

sage: T = KW.demazure_lusztig_operators(q1,q2)

sage: T12 = T.Tw( (1,2) )

sage: T12(KW.one())
q1^2*12

sage: T[2](T[1](KW.one()))
q1^2*12

sage: T[1](T[2](KW.one()))
q1^2*21

sage: T12(x) == T[2](T[1](x))
True
```

This is $T_2 \circ T_1$:

```
sage: T[2](T[1](KW.one()))
q1^2*12

sage: T[1](T[2](KW.one()))
q1^2*21

sage: T12(x) == T[2](T[1](x))
True
```

Now with signs and scalar coefficient we construct $3T_2 \circ T_1^{-1}$:

```
sage: phi = T.Tw((1,2), (-1,1), 3)

sage: phi(KW.one())
((-3*q1)/q2)*12 + ((3*q1+3*q2)/q2)*2

sage: phi(T[1](x)) == 3*T[2](x)
True
```

For debugging purposes, one can recover the input data:

```
sage: phi.word
(1, 2)

sage: phi.signs
```

(continues on next page)
(-1, 1)
sage: phi.scalar
3

Tw_inverse(word)

Return $T_w^{-1}$.

This is essentially a shorthand for $Tw()$ with all minus signs.

Todo: Add an example where $T_i \neq T_i^{-1}$

EXAMPLES:

```sage
W = WeylGroup(['A',3])
sage: W.element_class._repr_ = lambda x: ''.join(str(i) for i in x.reduced_word())
sage: KW = W.algebra(QQ)
sage: rho = KW.demazure_lusztig_operators(1, -1)
sage: x = KW.monomial(W.an_element()); x
123
sage: word = [1,2]
sage: rho.Tw(word)(x)
12312
sage: rho.Tw_inverse(word)(x)
12321
```

$Y(base\_ring=Integer\_Ring)$

Return the Cherednik operators $Y$ for this representation of an affine Hecke algebra.

INPUT:

- `self` – a representation of an affine Hecke algebra
- `base_ring` – the base ring of the coroot lattice

This is a family of operators indexed by the coroot lattice for this Cartan type. In practice this is currently indexed instead by the affine coroot lattice, even if this indexing is not one to one, in order to allow for $Y[\alpha_0^\vee]$.

EXAMPLES:
sage: W = WeylGroup(["A",3])
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q2, q1)
sage: Y = rho.Y(); Y
Lazy family (...(i))_{i in Coroot lattice of the Root system of type ['A', 3, →1]}
\[
\begin{align*}
& (-q_2^2)/(q_1^2+q_1q_2-q_2^2))_{21}^{12} + \frac{q_2^2}{q_1^2+q_1q_2-q_2^2})_{21}^{12} + 21 - 21 + 1, \\
& (-q_2^2)/(q_1^2+q_1q_2-q_2^2))_{21}^{12} + \frac{q_2^2}{q_1^2+q_1q_2-q_2^2})_{21}^{12} + 21 - 21 + 1, \\
& (q_2^2)/(q_1^2+q_1q_2-q_2^2))_{21}^{12} + (-q_2^2)/(q_1^2+q_1q_2-q_2^2))_{21}^{12} - 21 + 1, \\
& (q_2^2)/(q_1^2+q_1q_2-q_2^2))_{21}^{12} + (-q_2^2)/(q_1^2+q_1q_2-q_2^2))_{21}^{12} - 21 + 1.
\end{align*}
\]

The \( Y \) operators commute:
\[
\begin{align*}
& \text{sage: Y0(Y1(x)) - Y1(Y0(x))} \quad 0 \\
& \text{sage: Y2(Y1(x)) - Y1(Y2(x))} \quad 0
\end{align*}
\]

In the classical root lattice, \( \alpha_0 + \alpha_1 + \alpha_2 = 0 \):
Lemma 7.2 of [HST2008]:

\[
\begin{align*}
\text{sage: } & w_0 = KW.monomial(W\text{.long_element()}) \\
\text{sage: } & \rho(Tw(0))(w_0) = q^2 \\
\text{sage: } & \rho(Tw_inverse(1))(w_0) = \frac{1}{q^2} q^2 121 \\
\text{sage: } & \rho(Tw_inverse(2))(w_0) = \frac{1}{q^2} q^2 121
\end{align*}
\]

Lemma 7.5 of [HST2008]:

\[
\begin{align*}
\text{sage: } & Y_0(w_0) = q_1^2/q_2^2 q^2 121 \\
\text{sage: } & Y_1(w_0) = (q_2/(-q_1)) q^2 121 \\
\text{sage: } & Y_2(w_0) = (q_2/(-q_1)) q^2 121
\end{align*}
\]

Todo: Add more tests
Add tests in type BC affine where the null coroot $\delta^\vee$ can have non trivial coefficient in term of $\alpha_0$

See also:

- [HST2008] for the formula in terms of $q_1, q_2$

cartan_type()

Return the Cartan type of self.

EXAMPLES:

\[
\begin{align*}
\text{sage: } & \text{from sage.combinat.root_system.hecke_algebra_representation import HeckeAlgebraRepresentation} \\
\text{sage: } & KW = SymmetricGroup(3).algebra(QQ) \\
\text{sage: } & \text{action = lambda x,i: KW.monomial(x.apply_simple_reflection(i, side="right"))} \\
\text{sage: } & H = HeckeAlgebraRepresentation(KW, action, CartanType(['A',2]), 1, -1) \\
\text{sage: } & H.cartan_type() \\
& ['A', 2] \\
\text{sage: } & H = WeylGroup(['A',3]).algebra(QQ).demazure_lusztig_operators(-1,1) \\
\text{sage: } & H.cartan_type() \\
& ['A', 3, 1]
\end{align*}
\]

domain()

Return the domain of self.

EXAMPLES:
Combinatorics, Release 10.0

```
sage: H = WeylGroup(["A",3]).algebra(QQ).demazure_lusztig_operators(-1,1)
sage: H.domain()
Algebra of Weyl Group of type ['A', 3] (as a matrix group acting on the ambient → space) over Rational Field
```

**on_basis**(*x, word, signs=None, scalar=None*)

Action of product of $T_i$ and $T_i^{-1}$ on $x$.

**INPUT:**

- $x$ – the index of a basis element
- $word$ – word of indices of generators
- $signs$ – (default: None) sequence of signs of same length as $word$; determines which operators are supposed to be taken as inverses.
- $scalar$ – (default: None) scalar to multiply the answer by

**EXAMPLES:**

```
sage: from sage.combinat.root_system.hecke_algebra_representation import HeckeAlgebraRepresentation
sage: W = SymmetricGroup(3)
sage: domain = W.algebra(QQ)
sage: action = lambda x,i: domain.monomial(x.apply_simple_reflection(i, side="right"))
sage: rho = HeckeAlgebraRepresentation(domain, action, CartanType(["A",2]), 1, -1)
sage: rho.on_basis(W.one(), (1,2,1))
(1,3)
sage: word = (1,2)
sage: u = W.from_reduced_word(word)
sage: for w in W: assert rho.on_basis(w, word) == domain.monomial(w*u)
```

The next example tests the signs:

```
sage: W = WeylGroup("A3")
sage: W.element_class._repr_ = lambda x: ''.join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1,q2)
sage: w = W.an_element(); w
123
sage: rho.on_basis(w, (1,), signs=(-1,))
-1/q2*1231 + ((q1+q2)/(q1*q2))*123
sage: rho.on_basis(w, (1,), signs=(1,))
q1*1231
sage: rho.on_basis(w, (1,1), signs=(1,-1))
123
sage: rho.on_basis(w, (1,1), signs=(-1,1))
123
```
parameters(i)
Return $q_1, q_2$ such that $(T_i - q_1)(T_i - q_2) = 0$.

EXAMPLES:

```
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = WeylGroup(['A',3]).algebra(QQ)
sage: H = KW.demazure_lusztig_operators(q1,q2)
sage: H.parameters(1)
(q1, q2)
sage: H = KW.demazure_lusztig_operators(1,-1)
sage: H.parameters(1)
(1, -1)
```

Todo: At this point, this method is constant. It’s meant as a starting point for implementing parameters depending on the node $i$ of the Dynkin diagram.

straighten_word(word)
Return a tuple of indices of generators after some straightening.

INPUT:

- **word** – a list/tuple of indices of generators, the index of a generator, or an object with a reduced word method

OUTPUT: a tuple of indices of generators

EXAMPLES:

```
sage: W = WeylGroup(['A',3])
sage: H = W.algebra(QQ).demazure_lusztig_operators(-1,1)
sage: H.straighten_word(1)
(1,)
sage: H.straighten_word((2,1))
(2, 1)
sage: H.straighten_word([2,1])
(2, 1)
sage: H.straighten_word(W.an_element())
(1, 2, 3)
```

5.1.231 Integrable Representations of Affine Lie Algebras

class sage.combinat.root_system.integrable_representations.IntegrableRepresentation(Lam)
Bases: UniqueRepresentation, CategoryObject
An irreducible integrable highest weight representation of an affine Lie algebra.

INPUT:

- **Lam** – a dominant weight in an extended weight lattice of affine type

REFERENCES:

- [Ka1990]
If \( \Lambda \) is a dominant integral weight for an affine root system, there exists a unique integrable representation \( V = V_\Lambda \) of highest weight \( \Lambda \). If \( \mu \) is another weight, let \( m(\mu) \) denote the multiplicity of the weight \( \mu \) in this representation. The set \( \text{supp}(V) \) of \( \mu \) such that \( m(\mu) > 0 \) is contained in the paraboloid

\[
(\Lambda + \rho | \Lambda + \rho) - (\mu + \rho | \mu + \rho) \geq 0
\]

where \(| \cdot |\) is the invariant inner product on the weight lattice and \( \rho \) is the Weyl vector. Moreover if \( m(\mu) > 0 \) then \( \mu \in \text{supp}(V) \) differs from \( \Lambda \) by an element of the root lattice ([Ka1990], Propositions 11.3 and 11.4).

Let \( \delta \) be the nullroot, which is the lowest positive imaginary root. Then by [Ka1990], Proposition 11.3 or Corollary 11.9, for fixed \( \mu \) the function \( m(\mu - k\delta) \) is a monotone increasing function of \( k \). It is useful to take \( \mu \) to be such that this function is nonzero if and only if \( k \geq 0 \). Therefore we make the following definition. If \( \mu \) is such that \( m(\mu) \neq 0 \) but \( m(\mu + \delta) = 0 \) then \( \mu \) is called maximal.

Since \( \delta \) is fixed under the action of the affine Weyl group, and since the weight multiplicities are Weyl group invariant, the function \( k \mapsto m(\mu - k\delta) \) is unchanged if \( \mu \) is replaced by an equivalent weight. Therefore in tabulating these functions, we may assume that \( \mu \) is dominant. There are only a finite number of dominant maximal weights.

Since every nonzero weight multiplicity appears in the string \( \mu - k\delta \) for one of the finite number of dominant maximal weights \( \mu \), it is important to be able to compute these. We may do this as follows.

**EXAMPLES:**

```python
sage: Lambda = RootSystem(['A',3,1]).weight_lattice(extended=True).fundamental_weights()
2*Lambda[0] + Lambda[2]: 4 31 161 665 2380 7658 22721 63120 166085 417295 1007601
  \rightarrow 2349655
Lambda[0] + 2*Lambda[1]: 2 18 99 430 1593 5274 16005 45324 121200 308829 754884
  \rightarrow 1779570
Lambda[0] + 2*Lambda[3]: 2 18 99 430 1593 5274 16005 45324 121200 308829 754884
  \rightarrow 1779570
  \rightarrow 1799620
3*Lambda[2] - delta: 3 21 107 450 1638 5367 16194 45687 121876 310056 757056 1783324
sage: Lambda = RootSystem(['D',4,1]).weight_lattice(extended=True).fundamental_weights()
sage: IntegrableRepresentation(Lambda[0]+Lambda[1]).print_strings()
# long time
Lambda[0] + Lambda[1]: 1 10 62 293 1165 4097 13120 38997 109036 289575
  \rightarrow 563390 1343178
3*Lambda[2] - delta: 3 21 107 450 1638 5367 16194 45687 121876 310056 757056 1783324
sage: Lambda = RootSystem(['D',4,1]).weight_lattice(extended=True).fundamental_weights()
sage: IntegrableRepresentation(Lambda[0]+Lambda[1]).print_strings()
# long time
Lambda[0] + Lambda[1]: 1 10 62 293 1165 4097 13120 38997 109036 289575
  \rightarrow 563390 1343178
3*Lambda[2] - delta: 3 21 107 450 1638 5367 16194 45687 121876 310056 757056 1783324
```

In this example, we construct the extended weight lattice of Cartan type \( A_3^{(1)} \), then define \( \Lambda \) to be the fundamental weights \( (\Lambda_i)_{i \in I} \). We find there are 5 maximal dominant weights in irreducible representation of highest weight \( \Lambda_1 + \Lambda_2 + \Lambda_3 \), and we determine their strings.

It was shown in [KacPeterson] that each string is the set of Fourier coefficients of a modular form.

Every weight \( \mu \) such that the weight multiplicity \( m(\mu) \) is nonzero has the form

\[
\Lambda - n_0\alpha_0 - n_1\alpha_1 - \cdots,
\]

where the \( n_i \) are nonnegative integers. This is represented internally as a tuple \((n_0, n_1, n_2, \ldots)\). If you want an individual multiplicity you use the method \( m() \) and supply it with this tuple:
The `IntegrableRepresentation` class has methods `to_weight()` and `from_weight()` to convert between this internal representation and the weight lattice:

```python
sage: delta = V.weight_lattice().null_root()
sage: V.to_weight((4,3,2))
(4, 3, 2)
```

To get more values, use the depth parameter:

```python
sage: L0 = RootSystem(['A',1,1]).weight_lattice(extended=true).fundamental_weights(); L0
Lambda[0]
sage: IntegrableRepresentation(4*L0).print_strings(depth=20)
4*Lambda[0]: 1 1 3 6 13 24 44 75 131 215 354 561 889 1368 2097 3153 4712 6936 10151
2850 4256 6303 9222 13396 19262
6936 10121 14677 21055
```

An example in type $C_2^{(1)}$:

```python
sage: Lambda = RootSystem(['C',2,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: V.print_strings()  # long time
2*Lambda[0]: 1 2 9 26 77 194 477 1084 2387 5010 10227 20198
Lambda[0] + Lambda[2] - delta: 1 5 18 55 149 372 872 1941 4141 8523 17005 33019
2*Lambda[1] - delta: 1 4 15 44 122 304 721 1612 3469 7176 14414 28124
```

Examples for twisted affine types:

```python
sage: Lambda = RootSystem(['A',2,2]).weight_lattice(extended=True).fundamental_weights()
sage: IntegrableRepresentation(Lambda[0]).strings()
{Lambda[0]: [1, 1, 2, 3, 5, 7, 11, 15, 22, 30, 42, 56]}
sage: Lambda = RootSystem(['G',2,1]).dual.weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0]+Lambda[1]+Lambda[2])
sage: V.print_strings()  # long time
6*Lambdacheck[0]: 4 28 100 320 944 2460 6664 14300 31968 69020 144676 293916
3*Lambdacheck[0] + Lambdacheck[1]: 2 16 58 192 588 1568 3952 9520 21644 47456
109906 207536
```

(continues on next page)
\[4\text{Lambdacheck}[0] + \text{Lambdacheck}[2]: 4 \ 22 \ 84 \ 276 \ 800 \ 2124 \ 5288 \ 12470 \ 28116 \ 61056\]
\[\rightarrow 128304 \ 261972\]

\[\rightarrow 15625727 \ 48938396 \ 146190544\]
\[\text{Lambda}[0] + 2\text{Lambda}[3] - 4\text{delta}: 15 \ 195 \ 1539 \ 9186 \ 45804 \ 200073 \ 789201 \ 2866560\]
\[\rightarrow 9723582 \ 31120281 \ 94724550 \ 275919741\]

\text{branch}(i=None, weyl_character_ring=None, sequence=None, depth=5)

Return the branching rule on \textit{self}.

Removing any node from the extended Dynkin diagram of the affine Lie algebra results in the Dynkin diagram of a classical Lie algebra, which is therefore a Lie subalgebra. For example removing the 0 node from the Dynkin diagram of type [X, r, 1] produces the classical Dynkin diagram of [X, r].

Thus for each \(i\) in the index set, we may restrict \textit{self} to the corresponding classical subalgebra. Of course \textit{self} is an infinite dimensional representation, but each weight \(\mu\) is assigned a grading by the number of times the simple root \(\alpha_i\) appears in \(\Lambda - \mu\). Thus the branched representation is graded and we get sequence of finite-dimensional representations which this method is able to compute.

OPTIONAL:

\begin{itemize}
  \item \textit{i} – (default: 0) an element of the index set
  \item \texttt{weyl\_character\_ring} – a WeylCharacterRing
  \item \texttt{sequence} – a dictionary
  \item \texttt{depth} – (default: 5) an upper bound for \(k\) determining how many terms to give
\end{itemize}

In the default case where \(i = 0\), you do not need to specify anything else, though you may want to increase the depth if you need more terms.

EXAMPLES:

\text{sage:} \quad \text{Lambda} = \text{RootSystem}(['A',2,1]).weight_lattice(extended=true).fundamental_weights()
\text{sage:} \quad V = \text{IntegrableRepresentation}(2\text{Lambda}[0])
sage: b = V.branch(); b
[A2(0, 0),
 A2(1, 1),
 A2(0, 0) + 2*A2(1, 1) + A2(2, 2),
 2*A2(0, 0) + 2*A2(0, 3) + 4*A2(1, 1) + 2*A2(3, 0) + 2*A2(2, 2),
 4*A2(0, 0) + 3*A2(0, 3) + 10*A2(1, 1) + 3*A2(3, 0) + A2(1, 4) + 6*A2(2, 2) + A2(4, 1),
 6*A2(0, 0) + 9*A2(0, 3) + 20*A2(1, 1) + 9*A2(3, 0) + 3*A2(1, 4) + 12*A2(2, 2) +
 → 3*A2(4, 1) + A2(3, 3)]

If the parameter `weyl_character_ring` is omitted, the ring may be recovered as the parent of one of the branched coefficients:

sage: A2 = b[0].parent(); A2
The Weyl Character Ring of Type A2 with Integer Ring coefficients

If \( i \) is not zero then you should specify the `WeylCharacterRing` that you are branching to. This is determined by the Dynkin diagram:

sage: Lambda = RootSystem(['B',3,1]).weight_lattice(extended=true).fundamental_weights()

sage: V = IntegrableRepresentation(Lambda[0])

sage: V.cartan_type().dynkin_diagram()

O 0
| |
O---O=>=O
1 2 3

B3~

In this example, we observe that removing the \( i = 2 \) node from the Dynkin diagram produces a reducible diagram of type \( A1xA1xA1 \). Thus we have a branching to \( \mathfrak{sl}(2) \times \mathfrak{sl}(2) \times \mathfrak{sl}(2) \):

sage: A1xA1xA1 = WeylCharacterRing("A1xA1xA1",style="coroots")

sage: V.branch(i=2,weyl_character_ring=A1xA1xA1)
[A1xA1xA1(1,0,0),
 A1xA1xA1(0,1,2),
 A1xA1xA1(1,0,0) + A1xA1xA1(1,2,0) + A1xA1xA1(1,0,2),
 A1xA1xA1(2,1,2) + A1xA1xA1(0,1,0) + 2*A1xA1xA1(0,1,2),
 3*A1xA1xA1(1,0,0) + 2*A1xA1xA1(1,2,0) + A1xA1xA1(1,2,2) + 2*A1xA1xA1(1,0,2) +
 → A1xA1xA1(1,0,4) + A1xA1xA1(3,0,0),
 A1xA1xA1(2,1,0) + 3*A1xA1xA1(2,1,2) + 2*A1xA1xA1(0,1,0) + 5*A1xA1xA1(0,1,2) +
 → A1xA1xA1(0,1,4) + A1xA1xA1(0,3,2)]

If the nodes of the two Dynkin diagrams are not in the same order, you must specify an additional parameter, `sequence` which gives a dictionary to the affine Dynkin diagram to the classical one.

EXAMPLES:
Observe that removing the \( i = 1 \) node from the \( \mathcal{F}_4 \) Dynkin diagram gives the \( A_1 \times C_3 \) diagram, but the roots are in a different order. The nodes 0, 2, 3, 4 of \( \mathcal{F}_4 \) correspond to 1, 4, 3, 2 of \( A_1 \times C_3 \) and so we encode this in a dictionary:

```
sage: V.branch(i=1,weyl_character_ring=A1xC3,sequence={0:1,2:4,3:3,4:2})
```

The branch method gives a way of computing the graded dimension of the integrable representation:

```
sage: Lambda = RootSystem("A1~").weight_lattice(extended=true).fundamental_weights()
sage: V=IntegrableRepresentation(Lambda[0])
sage: r = [x.degree() for x in V.branch(depth=15)]; r
[1, 3, 4, 7, 13, 19, 29, 43, 62, 90, 126, 174, 239, 325, 435, 580]
sage: oeis(r)  # optional
```

```
0: A029552: Expansion of \( \phi(x) / f(-x) \) in powers of \( x \) where \( \phi(), f() \) are Ramanujan theta functions.
```

```
cartan_type()
```
Return the Cartan type of \( \text{self} \).

EXAMPLES:

```
sage: Lambda = RootSystem(["F",4,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.cartan_type()
['F', 4, 1]
```

```
coxeter_number()
```
Return the Coxeter number of the Cartan type of \( \text{self} \).

The Coxeter number is defined in [Ka1990] Chapter 6, and commonly denoted \( h \).

EXAMPLES:
sage: Lambda = RootSystem(['F',4,1]).weight_lattice(extended=True).fundamental_weights()  
sage: V = IntegrableRepresentation(Lambda[0])  
sage: V.coxeter_number()  
12

dominant_maximal_weights()

Return the dominant maximal weights of self.

A weight \( \mu \) is maximal if it has nonzero multiplicity but \( \mu + \delta \) has multiplicity zero. There are a finite number of dominant maximal weights. Indeed, [Ka1990] Proposition 12.6 shows that the dominant maximal weights are in bijection with the classical weights in \( k \cdot F \) where \( F \) is the fundamental alcove and \( k \) is the level. The construction used in this method is based on that Proposition.

EXAMPLES:

sage: Lambda = RootSystem(['C',3,1]).weight_lattice(extended=True).fundamental_weights()  
sage: IntegrableRepresentation(2*Lambda[0]).dominant_maximal_weights()  
((2*Lambda[0], Lambda[0] + Lambda[2] - delta,  
  2*Lambda[1] - delta,  
  Lambda[1] + Lambda[3] - 2*delta,  
  2*Lambda[2] - 2*delta,  
  2*Lambda[3] - 3*delta))

dual_coxeter_number()

Return the dual Coxeter number of the Cartan type of self.

The dual Coxeter number is defined in [Ka1990] Chapter 6, and commonly denoted \( h^\vee \).

EXAMPLES:

sage: Lambda = RootSystem(['F',4,1]).weight_lattice(extended=True).fundamental_weights()  
sage: V = IntegrableRepresentation(Lambda[0])  
sage: V.dual_coxeter_number()  
9

from_weight(mu)

Return the tuple \((n_0, n_1, ...)\) such that \( \mu \) equals \( \Lambda - \sum_{i \in I} n_i \alpha_i \) in self, where \( \Lambda \) is the highest weight of self.

EXAMPLES:

sage: Lambda = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()  
sage: V = IntegrableRepresentation(2*Lambda[2])  
sage: V.to_weight((1,0,0))  
sage: delta = V.weight_lattice().null_root()  
(1, 0, 0)

highest_weight()

Returns the highest weight of self.
EXAMPLES:

```python
sage: Lambda = RootSystem(['D',4,1]).weight_lattice(extended=true).fundamental_weights()
sage: IntegrableRepresentation(Lambda[0]+2*Lambda[2]).highest_weight()
Lambda[0] + 2*Lambda[2]
```

`level()`

Return the level of `self`.

The level of a highest weight representation $V_\Lambda$ is defined as $(\Lambda|\delta)$ See [Ka1990] section 12.4.

EXAMPLES:

```python
sage: Lambda = RootSystem(['G',2,1]).weight_lattice(extended=true).fundamental_weights()
sage: [IntegrableRepresentation(Lambda[i]).level() for i in [0,1,2]]
[1, 1, 2]
```

$m(n)$

Return the multiplicity of the weight $\mu$ in `self`, where $\mu = \Lambda - \sum n_i \alpha_i$.

INPUT:

* `n` – a tuple representing a weight $\mu$.

EXAMPLES:

```python
sage: Lambda = RootSystem(['E',6,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: u = V.highest_weight() - V.weight_lattice().null_root()
sage: V.from_weight(u)
(1, 1, 2, 2, 3, 2, 1)
sage: V.m(V.from_weight(u))
6
```

`modular_characteristic(mu=None)`

Return the modular characteristic of `self`.

The modular characteristic is a rational number introduced by Kac and Peterson [KacPeterson], required to interpret the string functions as Fourier coefficients of modular forms. See [Ka1990] Section 12.7. Let $k$ be the level, and let $h^\vee$ be the dual Coxeter number. Then

$$
m_\Lambda = \frac{|\Lambda + \rho|^2}{2(k + h^\vee)} - \frac{|ho|^2}{2h^\vee}
$$

If $\mu$ is a weight, then

$$
m_{\Lambda,\mu} = m_\Lambda - \frac{|\mu|^2}{2k}.
$$

OPTIONAL:

* `mu` – a weight; or alternatively:
* `n` – a tuple representing a weight $\mu$. 

2384 Chapter 5. Comprehensive Module List
If no optional parameter is specified, this returns $m_\Lambda$. If $\mu$ is specified, it returns $m_{\Lambda,\mu}$. You may use the tuple $n$ to specify $\mu$. If you do this, $\mu = \Lambda - \sum_i n_i \alpha_i$.

EXAMPLES:

```python
sage: Lambda = RootSystem(['A',1,1]).weight_lattice(extended=True).fundamental_weights()
sage: V = IntegrableRepresentation(3*Lambda[0]+2*Lambda[1])
sage: [V.modular_characteristic(x) for x in V.dominant_maximal_weights()]
[11/56, -1/280, 111/280]
```

`mult(\mu)`

Return the weight multiplicity of $\mu$.

INPUT:

- $\mu$ – an element of the weight lattice

EXAMPLES:

```python
sage: L = RootSystem("B3~").weight_lattice(extended=True)
sage: Lambda = L.fundamental_weights()
sage: delta = L.null_root()
sage: W = L.weyl_group(prefix="s")
sage: [s0,s1,s2,s3] = W.simple_reflections()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.mult(Lambda[2]-2*delta)
3
sage: V.mult(Lambda[2]-Lambda[1])
0
sage: weights = [w.action(Lambda[1]-4*delta) for w in [s1,s2,s0*s1*s2*s3]]
sage: weights
sage: [V.mult(mu) for mu in weights]
[35, 35, 35]
```

`print_strings(depth=12)`

Print the strings of self.

See also:

`strings()`

EXAMPLES:

```python
sage: Lambda = RootSystem(['A',1,1]).weight_lattice(extended=True).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: V.print_strings(depth=25)
2*Lambda[0]: 1 1 3 5 10 16 28 43 70 105 161 236 350 501 722 1016 1431 1981 2741 ...
                3740 5096 6868 9233 12306 16357
2*Lambda[1] - delta: 1 2 4 7 13 21 35 55 86 130 196 287 420 602 858 1206 1687 ...
                2331 3206 4368 5922 7967 10670 14193 18803
```

5.1. Comprehensive Module List 2385
\textbf{root_lattice(\textit{self})}

Return the root lattice associated to \textit{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: V = IntegrableRepresentation(RootSystem(['F',4,1]).weight_lattice(extended=true).fundamental_weight(0))
sage: V.root_lattice()
Root lattice of the Root system of type ['F', 4, 1]
\end{verbatim}

\textbf{s(\textit{n}, \textit{i})}

Return the action of the \textit{i}-th simple reflection on the internal representation of weights by tuples \textit{n} in \textit{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: V = IntegrableRepresentation(RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weight(0))
sage: [V.s((0,0,0),i) for i in V._index_set]
[(1, 0, 0), (0, 0, 0), (0, 0, 0)]
\end{verbatim}

\textbf{string(\textit{max_weight}, \textit{depth}=12)}

Return the list of multiplicities \(m(\Lambda - k\delta)\) in \textit{self}, where \(\Lambda\) is \textit{max_weight} and \(k\) runs from 0 to \textit{depth}.

\textbf{INPUT:}

- \textit{max_weight} – a dominant maximal weight
- \textit{depth} – (default: 12) the maximum value of \(k\)

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Lambda = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: V.string(2*Lambda[0])
[1, 2, 8, 20, 52, 116, 256, 522, 1045, 1996, 3736, 6780]
sage: V.string(Lambda[1] + Lambda[2])
[0, 1, 4, 12, 32, 77, 172, 365, 740, 1445, 2736, 5041]
\end{verbatim}

\textbf{strings(\textit{depth}=12)}

Return the set of dominant maximal weights of \textit{self}, together with the string coefficients for each.

\textbf{OPTIONAL:}

- \textit{depth} – (default: 12) a parameter indicating how far to push computations

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Lambda = RootSystem(['A',1,1]).weight_lattice(extended=True).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: S = V.strings(depth=25)
sage: for k in S:
    ...:     print("{}: {}\".format(k, ' '.join(str(x) for x in S[k])))
2*Lambda[0]: 1 1 1 3 5 10 16 28 43 70 105 161 236 350 501 722 1016 1431 1981 2741
   -> 3740 5096 6868 9233 12306 16357
2*Lambda[1] - delta: 1 2 4 7 13 21 35 55 86 130 196 287 420 602 858 1206 1687
   -> 2331 3206 4368 5922 7967 10670 14193 18803
\end{verbatim}
to_dominant($n$)
Return the dominant weight in self equivalent to $n$ under the affine Weyl group.

EXAMPLES:

```python
sage: Lambda = RootSystem(['A',2,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(3*Lambda[0])
sage: n = V.to_dominant((13,11,7)); n
(4, 3, 3)
sage: V.to_weight(n)
```

to_weight($n$)
Return the weight associated to the tuple $n$ in self.

If $n$ is the tuple $(n_1, n_2, \ldots)$, then the associated weight is $\Lambda - \sum_i n_i \alpha_i$, where $\Lambda$ is the weight of the representation.

INPUT:
- $n$ – a tuple representing a weight

EXAMPLES:

```python
sage: Lambda = RootSystem(['A',2,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[2])
sage: V.to_weight((1,0,0))
```

weight_lattice()
Return the weight lattice associated to self.

EXAMPLES:

```python
sage: V=IntegrableRepresentation(RootSystem(['E',6,1]).weight_lattice(extended=true).fundamental_weight(0))
sage: V.weight_lattice()
Extended weight lattice of the Root system of type ['E', 6, 1]
```

5.1.232 Nonsymmetric Macdonald polynomials

AUTHORS:
- Anne Schilling and Nicolas M. Thiéry (2013): initial version

ACKNOWLEDGEMENTS:
The initial version of this code (together with root_lattice_realization_algebras.Algebras and hecke_algebra_representation.HeckeAlgebraRepresentation) was written by Anne Schilling and Nicolas M. Thiéry during the ICERM Semester Program on “Automorphic Forms, Combinatorial Representation Theory and Multiple Dirichlet Series” (January 28, 2013 - May 3, 2013) with the help of Dan Bump, Ben Brubaker, Bogdan Ion, Dan Orr, Arun Ram, Siddhartha Sahi, and Mark Shimozono. Special thanks go to Bogdan Ion and Mark Shimozono for their patient explanations and hand computations to check the code.
class sage.combinat.root_system.non_symmetric_macdonald_polynomials.NonSymmetricMacdonaldPolynomials(KL, q, q1, q2, normalized):

Bases: CherednikOperatorsEigenvectors

Nonsymmetric Macdonald polynomials

INPUT:

• KL – an affine Cartan type or the group algebra of a realization of the affine weight lattice
• q, q1, q2 – parameters in the base ring of the group algebra (default: q, q1, q2)
• normalized – a boolean (default: True) whether to normalize the result to have leading coefficient 1

This implementation covers all reduced affine root systems. The polynomials are constructed recursively by the
application of intertwining operators.

Todo:

• Non-reduced case (Koornwinder polynomials).
• Non-equal parameters for the affine Hecke algebra.
• Choice of convention (dominant/anti-dominant, ...).
• More uniform implementation of the $T_0^\vee$ operator.
• Optimizations, in particular in the calculation of the eigenvalues for the recursion.

EXAMPLES:

We construct the family of nonsymmetric Macdonald polynomials in three variables in type $A$:

```
sage: E = NonSymmetricMacdonaldPolynomials(['A',2,1])
```

They are constructed as elements of the group algebra of the classical weight lattice $L_0$ (or one of its
realizations, such as the ambient space, which is used here) and indexed by elements of $L_0$:

```
sage: L0 = E.keys(); L0
Ambient space of the Root system of type ['A', 2]
```

Here is the nonsymmetric Macdonald polynomial with leading term $[2,0,1]$:

```
sage: E[L0([2,0,1])]
((-q*q1-q*q2)/(-q*q1-q2))*B[(1, 1, 1)] + ((-q1-q2)/(-q*q1-q2))*B[(2, 1, 0)] + B[(2, -\rightarrow0, 1)]
```

It can be seen as a polynomial (or in general a Laurent polynomial) by interpreting each term as an
exponent vector. The parameter $q$ is the exponential of the null (co)root, whereas $q_1$ and $q_2$ are the two eigenvalues of each
generator $T_i$ of the affine Hecke algebra (see the background section for details).

By setting $q_1 = t$, $q_2 = -1$ and using the root_lattice_realization_algebras.Algebras. ElementMethods.expand() method, we recover the nonsymmetric Macdonald polynomial as computed by [HHL06]'s combinatorial formula:
Here is a type $G^{(1)}_2$ nonsymmetric Macdonald polynomial:

\[
(\frac{t - 1}{q^* t - 1})^* x_0^2 x_1 + x_0^2 x_2 + \frac{(q^* t - q)}{(q^* t - 1)} x_0 x_1 x_2
\]

Many more examples are given after the background section.

- `SymmetricFunctions.macdonald()`

**Background**

The polynomial module

The nonsymmetric Macdonald polynomials are a distinguished basis of the “polynomial” module of the affine Hecke algebra. Given:

- a ground ring `K`, which contains the input parameters `q, q_1, q_2`
- an affine root system, specified by a Cartan type `C`
- a realization `L` of the weight lattice of type `C`

the polynomial module is the group algebra $K[L_0]$ of the classical weight lattice $L_0$ with coefficients in $K$. It is isomorphic to the Laurent polynomial ring over $K$ generated by the formal exponentials of any basis of $L_0$.

In our running example $L$ is the ambient space of type $C^{(1)}_2$.

```python
sage: K = QQ['q,q1,q2'].fraction_field()
sage: q, q1, q2 = K.gens()
sage: C = CartanType(['C',2,1])
sage: L = RootSystem(C).ambient_space(); L
Ambient space of the Root system of type ['C', 2, 1]
sage: L.simple_roots()
Finite family {0: -2*e[0] + e['delta'], 1: e[0] - e[1], 2: 2*e[1]}
sage: omega = L.fundamental_weights(); omega
Finite family {0: e['deltacheck'], 1: e[0] + e['deltacheck'], 2: e[0] + e[1] + e[...]
```
Affine Hecke algebra

The affine Hecke algebra is generated by elements $T_i$ for $i$ in the set of affine Dynkin nodes. They satisfy the same braid relations as the simple reflections $s_i$ of the affine Weyl group. The $T_i$ satisfy the quadratic relation

$$(T_i - q_1) \circ (T_i - q_2) = 0,$$

where $q_1$ and $q_2$ are the input parameters. Some of the representation theory requires that $q_1$ and $q_2$ satisfy additional relations; typically one uses the specializations $q_1 = u$ and $q_2 = -1/u$ or $q_1 = t$ and $q_2 = -1$. This can be achieved by constructing an appropriate field and passing $q_1$ and $q_2$ appropriately; see the examples. In principle, the parameter(s) could further depend on $i$; this is not yet implemented but the code has been designed in such a way that this feature is easy to add.

Demazure-Lusztig operators

The $i$-th Demazure-Lusztig operator is an operator on $K[L]$ which interpolates between the reflection $s_i$ and the Demazure operator $\pi_i$ (see root_lattice_realization.RootLatticeRealization.Algebras.ParentMethods.demazure_lusztig_operators()).

The affine Hecke algebra acts on $K[L]$ by letting the generators $T_i$ act by the Demazure-Lusztig operators. The class sage.combinat.root_system.hecke_algebra_representation.HeckeAlgebraRepresentation implements some simple generic features for representations of affine Hecke algebras defined by the action of their $T$-generators.
Here we construct the operator \( q_1 T_2^{-1} \circ T_1^{-1} T_0 \) from a signed reduced word:

```
sage: T.Tw([0,1,2],[1,-1,-1], q1^2)
Generic endomorphism of Algebra of the Ambient space of the Root system of type ['C', 2, 1]
over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational Field
```

(note the reversal of the word). Inverses are computed using the quadratic relation.

### Cherednik operators

The affine Hecke algebra contains elements \( Y_\lambda \) indexed by the coroot lattice. Their action on \( K[L] \) is implemented in Sage:

```
sage: Y = T.Y(); Y
Lazy family (...)_{i in Coroot lattice of the Root system of type ['C', 2, 1]}
sage: alphacheck = Y.keys().simple_roots()
sage: Y1 = Y[alphacheck[1]]
sage: Y1(x)
((q1^2+2*q1*q2+q2^2)/(-q1*q2))*B[e[0] + e[deltacheck]]
+ ((-q1^2-q1*q2)/(-q2^2))*B[2*e[0] - e[1] - e[delta]]
+ e['deltacheck'] + ((q1^3+2*q1^2*q2+q1*q2^2)/(-q2^3))*B[-e[0] - e[delta] + e['deltacheck']]
+ ((q1^3+q1^2*q2)/(-q2^3))*B[-e[0] - 2*e[1] - e[delta] + e['deltacheck']]
+ ((q1^3+q1^2*q2)/(-q2^3))*B[3*e[0] - 3*e[delta] + e['deltacheck']]
+ ((q1^3+q1^2*q2)/(-q2^3))*B[-e[0] - 2*e[1] - e[delta] + e['deltacheck']]
```

The Cherednik operators span a Laurent polynomial ring inside the affine Hecke algebra; namely \( \lambda \mapsto Y_\lambda \) is a group isomorphism from the classical root lattice (viewed additively) to the affine Hecke algebra (viewed multiplicatively). In practice, \( Y_\lambda \) is constructed by computing combinatorially its signed reduced word (and an overall scalar factor) using the periodic orientation of the alcove model in the coweight lattice (see `hecke_algebra_representation.HeckeAlgebraRepresentation.Y_lambdacheck()`):

```
sage: lcheck = L.root_system.coweight_lattice()
sage: w = lcheck.reduced_word_of_translation(lcheck(alphacheck[1])); w
[0, 2, 1, 0, 2, 1]
sage: lcheck.signs_of_alcovewalk(w)
[1, -1, 1, -1, 1, 1]
```
Level zero representation of the affine Hecke algebra

The action of the affine Hecke algebra on $K[L]$ induces an action on $K[L_0]$: the action of $T_i$ on $X^\lambda$ for $\lambda$ a classical weight in $L_0$ is obtained by embedding the weight at level zero in the affine weight lattice (see `weight_lattice_realizations.WeightLatticeRealizations.ParentMethods.embed_at_level()`) applying the Demazure-Lusztig operator there, and projecting from $K[L] \to K[L_0]$ mapping the exponential of $\delta$ to $q$ (see `root_lattice_realization_algebras.Algebras.ParentMethods.q_project()`). This is implemented in `root_lattice_realization_algebras.Algebras.ParentMethods.demazure_lusztig_operators_on_classical()`:

```python
sage: T = KL.demazure_lusztig_operators_on_classical(q, q1,q2)
sage: omega = L0.fundamental_weights()
sage: x = KL0.monomial(omega[1])
sage: T[0](x)
(-q*q2)*B[(-1, 0)]
```

For classical nodes these are the usual Demazure-Lusztig operators:

```python
sage: T[1](x)
(q1+q2)*B[(1, 0)] + q1*B[(0, 1)]
```

Nonsymmetric Macdonald polynomials

We can now finally define the nonsymmetric Macdonald polynomials. Because the Cherednik operators commute (and there is no radical), they can be simultaneously diagonalized; namely, $K[L_0]$ admits a $K$-basis of joint eigenvectors for the $Y_\lambda$. For $\mu \in L_0$, the nonsymmetric Macdonald polynomial $E_\mu$ is the unique eigenvector of the family of Cherednik operators $Y_\lambda$ having $\mu$ as leading term:

```python
sage: E = NonSymmetricMacdonaldPolynomials(KL, q, q1, q2); E
The family of the Macdonald polynomials of type ['C', 2, 1] with parameters q, q1,\omega \to q2
```

Or for short:

```python
sage: E = NonSymmetricMacdonaldPolynomials(C)
```

Recursive construction of the nonsymmetric Macdonald polynomials

The generators $T_i$ of the affine Hecke algebra almost skew commute with the Cherednik operators. More precisely, one can deform them into the so-called intertwining operators:

$$\tau_i = T_i - (q_1 + q_2) \frac{Y_i^{a-1}}{1 - Y_i^a}.$$  

(where $a = 1$ except for $i = 0$ in type $BC$ where $a = a_0 = 2$) which satisfy the following skew commutation relations:

$$\tau_i Y_\lambda = \tau_i Y_{s_i \lambda}.$$  

If $s_i \mu \neq \mu$, applying $\tau_i$ on an eigenvector $E_\mu$ produces a new eigenvector (essentially $E_{s_i \mu}$) with a distinct eigenvalue. It follows that the eigenvectors indexed by an affine Weyl orbit of weights, may be recursively computed from a single weight in the orbit.
In the case at hand, there is a little complication: namely, the simple reflections $s_i$ acting at level 0 do not act transitively on classical weights; in fact the orbits for the classical Weyl group and for the affine Weyl group are the same. Thus, one can construct the nonsymmetric Macdonald polynomials for all weights from those for the classical dominant weights, but one is lacking a creation operator to construct the nonsymmetric Macdonald polynomials for dominant weights.

**Twisted Demazure-Lusztig operators**

To compensate for this, one needs to consider another affinization of the action of the classical Demazure-Lusztig operators $T_1, \ldots, T_n$, which gives rise to the double affine Hecke algebra. Following Cherednik, one adds another operator $T_0^\lor$ implemented in: `root_lattice_realization_algebras.Algebras.ParentMethods.T0_check_on_basis()`. See also: `root_lattice_realization_algebras.Algebras.ParentMethods.twisted_demazure_lusztig_operators()`.

Depending on the type (untwisted or not), this is a representation of the affine Hecke algebra for another affinization of the classical Cartan type. The corresponding action of the affine Weyl group – which is used to compute the recursion on $\mu$ – occurs in the corresponding weight lattice realization:

```python
sage: E.L()
Ambient space of the Root system of type ['C', 2, 1]
sage: E.L_prime()
Coambient space of the Root system of type ['B', 2, 1]
sage: E.L_prime().classical()
Ambient space of the Root system of type ['C', 2]
```

See `L_prime()` and `cartan_type.CartanType_affine.other_affinization()`.

**More examples**

We show how to create the nonsymmetric Macdonald polynomials in two different ways and check that they are the same:

```python
sage: K = QQ['q,u'].fraction_field()
sage: q, u = K.gens()
sage: E = NonSymmetricMacdonaldPolynomials(['D',3,1], q, u, -1/u)
sage: omega = E.keys().fundamental_weights()
((-q*u^2+q)/(-q*u^4+1))*B[(1/2, -1/2, 1/2)] + ((-q*u^2+q)/(-q*u^4+1))*B[(1/2, 1/2, -1/2)] + B[(3/2, 1/2, 1/2)]
sage: KL = RootSystem(['D',3,1]).ambient_space().algebra(K)
sage: P = NonSymmetricMacdonaldPolynomials(KL, q, u, -1/u)
True
sage: E[E.keys()((0,1,-1))]
((-q*u^2+q)/(-q*u^2+1))*B[(0, 0, 0)] + ((-u^2+1)/(-q*u^2+1))*B[(1, 1, 0)] + ((-u^2+1)/(-q*u^2+1))*B[(1, 0, -1)] + B[(0, 1, -1)]
```

In type $A$, there is also a combinatorial implementation of the nonsymmetric Macdonald polynomials in terms of augmented diagram fillings as in [HHL06]. See `sage.combinat.sf.ns_macdonald.E()`. First we check that these polynomials are indeed eigenvectors of the Cherednik operators:
sage: K = QQ['q,t'].fraction_field()
sage: q,t = K.gens()
sage: q1 = t; q2 = -1
sage: KL = RootSystem(['A',2,1]).ambient_space().algebra(K)
sage: KL0 = KL.classical()
sage: E = NonSymmetricMacdonaldPolynomials(KL, q, q1, q2)
sage: omega = E.keys().fundamental_weights()
sage: w = omega[1]
sage: import sage.combinat.sf.ns_macdonald as NS
sage: p = NS.E([1,0,0]); p

Next we check explicitly that they agree with the current implementation:
The same, directly in the ambient lattice with several shifts:

```python
sage: E[L0([2,0])]
((-q*t+q)/(-q*t+1))*B[(1,1)] + B[(2,0)]
sage: E[L0([1,-1])]
((-q*t+q)/(-q*t+1))*B[(0,0)] + B[(1,-1)]
sage: E[L0([0,-2])]
((-q*t+q)/(-q*t+1))*B[(-1,-1)] + B[(0,-2)]
```

Systematic checks with Sage's implementation of [HHL06]:

```python
sage: assert all(EE([x,y]) == NS.E([x,y]) for d in range(5) for x,y in IntegerVectors(d,2))
```

With the current implementation, we can compute nonsymmetric Macdonald polynomials for any type, for example for type $E_6^{(1)}$:

```python
sage: K=QQ['q,u'].fraction_field()
sage: q, u = K.gens()
sage: KL = RootSystem(["E",6,1]).weight_space(extended=True).algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q,u,-1/u)
sage: L0 = E.keys()
sage: E[L0.fundamental_weight(1).weyl_action([2,4,3,2,1])]
((-u^2+1)/(-q*u^16+1))*B[-Lambda[3] + Lambda[4]]
sage: E[L0.fundamental_weight(2).weyl_action([2,5,3,4,2])]
# long time (6s)
```

5.1. Comprehensive Module List
We test various other types:

```
sage: K=QQ['q,u'].fraction_field()
sage: q, u = K.gens()
sage: KL = RootSystem(['A',5,2]).ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL, q, u, -1/u)
sage: L0 = E.keys()
sage: E[L0.fundamental_weight(2)]
((-q*u^2+q)/(-q*u^8+1))*B[(0, 0, 0)] + B[(1, 1, 0)]
sage: E[L0((0,-1,1))]
((-q^2*u^10+q^2*u^8-q*u^6+q*u^4+q*u^2+u^2-q-1)/(-q^3*u^12+q^2*u^8+q*u^4-1))*B[(0, 0, -1, 1)]
```

```
sage: K=QQ['q,u'].fraction_field()
sage: q, u = K.gens()
sage: KL = RootSystem(['E',6,2]).ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q,u,-1/u)
sage: L0 = E.keys()
sage: E[L0.fundamental_weight(4)]
((-q^3*u^20+q^3*u^18+q*u^4-q^2*u^2-2*q*u^2+q^2+q)/(q^3*u^18-q^2*u^12-q*u^6+1))*B[(0, 0, 0, 0)]
```

(continues on next page)
Next we test a twisted type (checked against Maple computation by Bogdan Ion for \(q_1 = t^2\) and \(q_2 = -1\)):

\[
\text{sage: } E = \text{NonSymmetricMacdonaldPolynomials(\"A\",5,2)}
\]

\[
\text{sage: } \omega = E.\text{keys()}
\]

\[
\text{sage: } E[\omega[1]]
\]

\[
\text{sage: } E[-\omega[1]]
\]

\[
\text{sage: } E[\omega[2]]
\]

\[
\text{sage: } E[-\omega[2]]
\]

\[
\text{sage: } E[-\omega[1]-\omega[2]]
\]

\[
\text{sage: } E[\omega[1]-\omega[2]]
\]

\[
\begin{align*}
+ \frac{(-q u^4 + 2 q u^2 - q)}{(-q^3 u^18 + q^2 u^12 + q u^6 - 1)} B[(0, 1, 0, 0)] \\
+ \frac{(-q u^4 + 2 q u^2 - q)}{(-q^3 u^18 + q^2 u^12 + q u^6 - 1)} B[(0, 0, -1, 0)] \\
+ \frac{(-q u^4 + 2 q u^2 - q)}{(-q^3 u^18 + q^2 u^12 + q u^6 - 1)} B[(0, 0, 1, 0)] \\
+ \frac{(-q u^4 + 2 q u^2 - q)}{(-q^3 u^18 + q^2 u^12 + q u^6 - 1)} B[(0, 0, 0, -1)] \\
+ \frac{(-q u^4 + 2 q u^2 - q)}{(-q^3 u^18 + q^2 u^12 + q u^6 - 1)} B[(0, 0, 0, 1)]
\end{align*}
\]
(continued from previous page)

\[7))*B[(1, 1, 0)] + ((-q1*q2-q2^2)/(q*q1^2-q2^2))*B[(1, 0, -1)] + ((q1*q2+q2^2)/(-q*q1^2+q2^2))*B[(1, 0, 1)]

\[sage: E[\omega[3]]((q*q1^4*q2+q*q1^3*q2^2-q1*q2^4-q2^5)/(-q^2*q1^5-q2^5))*B[(1, 0, 0)] + ((q*q1^4-q2^4-q2^5)/(-q^2*q1^5-q2^5))*B[(0, 0, 0)] + B[(-1, 0, -1)] + B[(1, 0, 0)] + B[(-1, 0, 0)] + B[(1, 0, 0)] + B[(0, -1, 0)] + B[(0, -1, 0)] + B[(0, 0, -1)] + B[(0, 0, 1)]

\[\text{Comparison with the energy function of crystals}\]

Next we test that the nonsymmetric Macdonald polynomials at \(t = 0\) match with the one-dimensional configuration sums involving Kirillov-Reshetikhin crystals for various types. See [LNSSS12]:

\[\text{sage: } K = \text{QQ['q','t'].fraction_field()}\]
\[\text{sage: } q,t = K.gens()\]
\[\text{sage: } KL = \text{RootSystem('A',5,2).ambient_space().algebra(K)}\]
\[\text{sage: } E = \text{NonSymmetricMacdonaldPolynomials(KL, q, t, -1)}\]
\[\text{sage: } \omega = E.keys().fundamental_weights()\]
\[\text{sage: } E[-\omega[1]].map_coefficients(\lambda x:x.subs(t=0)) == B[(-1, 0, 0)] + B[(1, 0, 0)] + B[(-1, 0, 1)] + B[(1, 0, 1)] + B[(0, -1, 0)] + B[(0, 1, 0)] + B[(0, 0, 0)] + B[(-1, 0, -1)] + B[(1, 0, -1)] + B[(1, 1, 0)] + B[(1, 1, 1)] + B[(0, -1, -1)] + B[(0, -1, 1)] + B[(0, 1, -1)] + B[(0, 1, 1)]\]

\[\text{sage: } KL = \text{RootSystem('C',3,1).ambient_space().algebra(K)}\]
\[\text{sage: } E = \text{NonSymmetricMacdonaldPolynomials(KL,q, t,-1)}\]
\[\text{sage: } \omega = E.keys().fundamental_weights()\]
\[\text{sage: } E[-\omega[2]].map_coefficients(\lambda x:x.subs(t=0)) == 2*B[(0, 0, 0)] + B[(-1, 0, 0)] + B[(1, 0, 0)] + B[(-1, 1, 0)] + B[(1, 1, 0)] + B[(0, 0, -1)] + B[(0, 0, 1)] + B[(0, -1, 0)] + B[(0, 1, 0)] + B[(1, 0, -1)] + B[(1, 0, 1)] + B[(0, 0, 0)] + B[(-1, 0, 0)] + B[(1, 0, 0)] + B[(-1, 1, 0)] + B[(1, 1, 0)] + B[(0, 0, -1)] + B[(0, 0, 1)] + B[(0, -1, 0)] + B[(0, 1, 0)] + B[(1, 0, -1)] + B[(1, 0, 1)]\]

\[\text{sage: } R = \text{RootSystem('C',3,1)}\]
