Return the content of the cell of the head in the highest row of all ribbons labeled by \(v\) of the underlying standard tableau. If there is no cell with entry \(v\) then the value returned is the length of the first row.

**INPUT:**
- \(v\) – an integer representing the label in the standard tableau

**OUTPUT:**
- an integer representing the content of the head of the highest ribbon with label \(v\)

**EXAMPLES:**
```python
sage: [StrongTableau([[-1, 2, -3], [-2, 3], [3]], 1).content_of_highest_head(v)
    for v in range(1, 5)]
[0, -1, -2, 3]
```

**content_of_marked_head(v)**

Return the diagonal of the marked label v in the standard part of self.

Return the content (the \( j - i \) coordinate of the cell) of the v-th marked cell in the strong standard tableau self. If there is no mark, then the value returned is the size of first row.

**INPUT:**
- v – an integer representing the label in the standard tableau

**OUTPUT:**
- an integer representing the residue of the location of the mark

**EXAMPLES:**

```python
sage: [ StrongTableau([[1, 3, -4], [2]], 3).content_of_marked_head(i)
    for i in range(1, 7)]
[0, -1, 1, -2, 3, 4]
```

```python
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
                        [-3], [3], [3], [3]], 4)
```

```python
sage: [ T.content_of_marked_head(i) for i in range(1, 7)]
[-2, 2, -1, 3, -4, 4]
```

**contents_of_heads(v)**

A list of contents of the cells which are heads of the ribbons with label v.

If there is no cell labelled by v then return the empty list.

**INPUT:**
- v – an integer label

**OUTPUT:**
- a list of integers of the content of the heads of the ribbons with label v

**EXAMPLES:**

```python
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
                        [-3], [3], [3], [3]], 4)
```

```python
sage: T.contents_of_heads(1)
[-2]
```

```python
sage: T.contents_of_heads(2)
[-3, 2]
```

```python
sage: T.contents_of_heads(3)
[-1]
```

```python
sage: T.contents_of_heads(4)
[-2, 3]
```

```python
sage: T.contents_of_heads(5)
[-4]
```

```python
sage: T.contents_of_heads(6)
[]
```

**entries_by_content(diag)**

Return the entries on the diagonal of self.
Return the entries in the tableau that are in the cells \((i, j)\) with \(j - i\) equal to \(\text{diag}\) (that is, with content equal to \(\text{diag}\)).

**INPUT:**
- \(\text{diag}\) – an integer indicating the diagonal

**OUTPUT:**
- a list (perhaps empty) of labels on the diagonal \(\text{diag}\)

**EXAMPLES:**

```
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], --> [-3], [3], [3], [3]], 4)
sage: T.entries_by_content(0)
[]
sage: T.entries_by_content(1)
[]
sage: T.entries_by_content(2)
[-1]
sage: T.entries_by_content(-2)
[-1, 2]
```

---

**entries_by_content_standard\((\text{diag})\)**

Return the entries on the diagonal of the standard part of \(\text{self}\).

Return the entries in the tableau that are in the cells \((i, j)\) with \(j - i\) equal to \(\text{diag}\) (that is, with content equal to \(\text{diag}\)) in the standard tableau.

**INPUT:**
- \(\text{diag}\) – an integer indicating the diagonal

**OUTPUT:**
- a list (perhaps empty) of labels on the diagonal \(\text{diag}\)

**EXAMPLES:**

```
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], --> [-3], [3], [3], [3]], 4)
sage: T.entries_by_content_standard(0)
[]
sage: T.entries_by_content_standard(1)
[]
sage: T.entries_by_content_standard(2)
[-1]
sage: T.entries_by_content_standard(-2)
[-1, 4]
```

---

**follows_tableau\()**

Return a list of strong marked tableaux with length one longer than \(\text{self}\).

Return list of all strong tableaux obtained from \(\text{self}\) by extending to a core which follows the shape of \(\text{self}\) in the strong order.

**OUTPUT:**
- a list of strong tableaux which follow \(\text{self}\) in strong order

**EXAMPLES:**
sage: T = StrongTableau([[-1, -2, -4, -7], [-3, 6, -6, 8], [4, 7], [-5, -8]], 3, [2, 2, 3, -1])
sage: T.follows_tableau()

[[[-1, -1, -2, -3, 5, 5, -5], [-2, 3, -3, 4], [2, 3], [-3, -4]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [5]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5, -3, -4], [5]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5, -3, -4, 5]],

sage: StrongTableau([[None, None, -1, -2], [None, None, -3, 4, -5], [-1, 3], [-4, 5]], 3).follows_tableau()

[[[None, None, 1, -2], [None, None, -3, 4, -5], [-1, 3], [-4, 5]],
 [[-1, -2, 5, 5, -5], [-3, -4]], [2, 3, 5], [-3, -4], [5]],
 [[-1, -2, 5, 5, -5], [-3, -4, 5]], [2, 3, -5], [-3, -4], [5]]

height_of_ribbon(v)
The number of rows occupied by one of the ribbons with label \(v\).
The number of rows occupied by the marked ribbon with label \(v\) (and by consequence the number of rows occupied by any ribbon with the same label) in the standard part of \(self\).

INPUT:

- \(v\) – the label of the standard marked tableau

OUTPUT:

- a non-negative integer representing the number of rows occupied by the ribbon which is marked

EXAMPLES:

sage: T = StrongTableau([[-1, -1, -2, -2, 3], [2, -3], [-3]], 3)
sage: T.to_standard_list()

[[-1, -2, -3, -4, 6], [4, -6], [-5]]
sage: T.height_of_ribbon(1)
1
sage: T.height_of_ribbon(4)
1
sage: T = StrongTableau([[None, None, 1, -2], [None, None, -3, 4, -5], [-1, 3], [-4, 5]], 3)
sage: T.height_of_ribbon(3)
2
sage: T.height_of_ribbon(6)
0

inner_shape()
Return the inner shape of \(self\).

If \(self\) is a strong skew tableau, then this method returns the inner shape (the shape of the cells labelled with \(None\)). If \(self\) is not skew, then the inner shape is empty.

OUTPUT:

- a \((k+1)\)-core

EXAMPLES:

sage: StrongTableau([[None, None, 1, -2], [None, None, -3, 4, -5], [-1, 3], [-4, 5]], 3).inner_shape()
[2, 2]
sage: StrongTableau([[-1, -2, -4, -7], [-3, 6, -6, 8], [4, 7], [-5, -8]], 3, [2, 2, 3, 1]).inner_shape()
[1]
intermediate_shapes()  
Return the intermediate shapes of self.

A (skew) tableau with letters $1, 2, \ldots, \ell$ can be viewed as a sequence of shapes, where the $i$-th shape is given by the shape of the subtableau on letters $1, 2, \ldots, i$.

The output is the list of these shapes. The marked cells are ignored so to recover the strong tableau one would need the intermediate shapes and the content_of_marked_head() for each pair of adjacent shapes in the list.

OUTPUT:
• a list of lists of integers representing $k + 1$-cores

EXAMPLES:

```
sage: T = StrongTableau([[[-1, -2, -4, -7], [-3, 6, -6, 8], [4, 7], [-5, -8]], 3, [2, 2, 3, -1]])
sage: T.intermediate_shapes()  
[[], [2], [3, 1, 1], [4, 3, 2, 1], [4, 4, 2, 2]]
```

is_column_strict_with_weight(mu)  
Test if self is a column strict tableau with respect to the weight $mu$.

INPUT:
• $mu$ – a vector of weights

OUTPUT:
• a boolean, True means the underlying column strict strong marked tableau is valid

EXAMPLES:

```
sage: StrongTableau([[[-1, -2, -3], [3]], 2]).is_column_strict_with_weight([3])  
True
sage: StrongTableau([[[-1, -2, 3], [-3]], 2]).is_column_strict_with_weight([3])  
False
```

left_action(tij)  
Action of transposition $tij$ on self by adding marked ribbons.

Computes the left action of the transposition $tij$ on the tableau. If $tij$ acting on the element of the affine Grassmannian raises the length by 1, then this function will add a cell to the standard tableau.

INPUT:
• $tij$ – a transposition represented as a pair $(i, j)$.

OUTPUT:
• self after it has been modified by the action of the transposition $tij$

EXAMPLES:

```
sage: StrongTableau([[None, -1, -2, -3], [3], [-4]], 3, weight=[1,1,1,1]).left_action([0,1])  
[[None, -1, -2, -3, 5], [3, -5, [-4]]]
sage: StrongTableau([[None, -1, -2, -3], [3], [-4]], 3, weight=[1,1,1,1]).left_action([4,5])
(continues on next page)
```
number_of_connected_components(v)

Number of connected components of ribbons with label $v$ in the standard part.

The number of connected components is calculated by finding the number of cells with label $v$ in the standard part of the tableau and dividing by the number of cells in the ribbon.

**INPUT:**
- $v$ – the label of the standard marked tableau

**OUTPUT:**
- a non-negative integer representing the number of connected components

**EXAMPLES:**

```python
sage: T = StrongTableau([[None, None, -1, -2, -3, -5], [3, 5], [-4]], 3, weight=[1,1,1,1])
sage: T.left_action([-3,-2])
[[None, -1, -2, -3, -5], [3, 5], [-4], [-5]]
sage: T = StrongTableau([[None, -1, -2, -3], [3], [-4], [-5]], 3, weight=[3,1])
sage: T.left_action([-3,-2])
[[None, -1, -1, -1], [1], [-2], [-3]]
sage: T
[[None, -1, -1, -1], [1], [-2]]
sage: T.check()
sage: T.weight()
(3, 1)
```

outer_shape()

Return the outer shape of self.

This method returns the outer shape of self as viewed as a Core. The outer shape of a strong tableau is always a $(k + 1)$-core.

**OUTPUT:**
- a $(k + 1)$-core

**EXAMPLES:**

```python
sage: T = StrongTableau([[None, None, -1, -2, -3], [2, -3], [-3, 3, 3], [-3, -3], [3], [3], [3]], 3)
sage: T.to_standard_list()
[[None, -1, -2, -3, -4, 6], [4, -6], [3, 3, 3]]
sage: T.number_of_connected_components(1)
1
sage: T = StrongTableau([[None, -1, -2, -3, -4, -5], [3, 6, -6, 8], [4, 7, -5, -8]], 3)
sage: T.number_of_connected_components(6)
1
sage: T = StrongTableau([[None, None, -1, -2, -3], [None, None], [3], [3], [3]], 4).outer_shape()
[4, 2, 2, 2, 1, 1, 1, 1]
```
sage: StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,1]).
   \rightarrow \text{outer\_shape()}
[4, 4, 2, 2]

PP()
Print the strong tableau self in pretty print format.

EXAMPLES:

sage: T = StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,1])
sage: T.pp()
-1 -1 -2 -3
-2 3 3 4
  2
  3
  3

sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -3], [-2, 2],
   \rightarrow [-3], [3], [3], [3]], 4)
sage: T.pp()
. . -1 -2
. . -1 -2
  1 2
  3
  3
  3

sage: Tableaux.options(convention="French")
sage: T.pp()
3
3
3
. . -1 -2

sage: Tableaux.options(convention="English")

restrict(r)
Restrict the standard part of the tableau to the labels 1, 2, . . . , r.

Return the tableau consisting of the labels of the standard part of self restricted to the labels of 1 through r. The result is another StrongTableau object.

INPUT:

• r – an integer

OUTPUT:

• A strong tableau

EXAMPLES:

sage: T = StrongTableau([[None, None, -4, 5, -5], [None, None], [-1, -3], [-2, 2], [2], [2], [3]], 4, weight=[1,1,1,1,1])
sage: T.restrict(3)
[[None, None], [None, None], [-1, -3], [-2], [2], [2], [3]]
sage: TT = T.restrict(0)
sage: TT
[[None, None], [None, None]]
sage: TT == StrongTableau( [[None, None], [None, None]], 4 )
True
sage: T.restrict(5) == T
True

ribbons_above_marked(v)

Number of ribbons of label v higher than the marked ribbon in the standard part.

Return the number of copies of the ribbon with label v in the standard part of self which are in a higher row than the marked ribbon. Note that the result is independent of the weight of the tableau.

INPUT:

• v – the entry of the standard tableau

OUTPUT:

• an integer representing the number of copies of the ribbon above the marked ribbon

EXAMPLES:

sage: T = StrongTableau([[-1,-2,-4,-7], [-3,6,-6,8], [4,7], [-5,-8]], 3)
sage: T.ribbons_above_marked(4)
1
sage: T.ribbons_above_marked(6)
0
sage: T.ribbons_above_marked(9)
0
sage: StrongTableau([[-1,-2,-3,-4], [2,3,4], [3,4], [4]], 1).ribbons_above_marked(4)
3

set_weight(mu)

Sets a new weight mu for self.

This method first tests if the underlying standard tableau is column-strict with respect to the weight mu. If it is, then it changes the weight and returns the tableau; otherwise it raises an error.

INPUT:

• mu – a list of non-negative integers representing the new weight

EXAMPLES:

sage: StrongTableau( [[-1, -2, -3], [3]], 2 ).set_weight( [3] )
[[[-1, -1, -1], [1]]]
sage: StrongTableau( [[-1, -2, -3], [3]], 2 ).set_weight( [0,3] )
[[[-2, -2, -2], [2]]]
sage: StrongTableau( [[-1, -2, 3], [-3]], 2 ).set_weight( [2, 0, 1] )
[[[-1, -1, 3], [-3]]]
sage: StrongTableau( [[-1, -2, 3], [-3]], 2 ).set_weight( [3] )
Traceback (most recent call last):
  ...
ValueError: [[-1, -2, 3], [-3]] is not a semistandard strong tableau with respect to the partition [3]
shape()
Return the shape of self.
If self is a skew tableau then return a pair of $k + 1$-cores consisting of the outer and the inner shape. If self is strong tableau with no inner shape then return a $k + 1$-core.

INPUT:
• form - optional argument to indicate ‘inner’, ‘outer’ or ‘skew’ (default : ‘outer’)

OUTPUT:
• a $k + 1$-core or a pair of $k + 1$-cores if form is not ‘inner’ or ‘outer’

EXAMPLES:

```python
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], 
\[-3], [3], [3], [3]], 4)
sage: T.shape()
([4, 2, 2, 2, 1, 1, 1, 1], [2, 2])
sage: StrongTableau([[-1, -2, 3], [-3]], 2).shape()
[3, 1]
sage: type(StrongTableau([[-1, -2, 3], [-3]], 2).shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
```

size()
Return the size of the strong tableau.

The size of the strong tableau is the sum of the entries in the weight(). It will also be equal to the length of the outer shape (as a $k + 1$-core) minus the length of the inner shape.

See also:
sage.combinat.core.Core.length()

OUTPUT:
• a non-negative integer

EXAMPLES:

```python
sage: StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3).size()
5
sage: StrongTableau([[None, None, -1, 2], [-2], [-3]], 3).size()
3
```

spin()
Return the spin statistic of the tableau self.

The spin is an integer statistic on a strong marked tableau. It is the sum of $(h - 1)r$ plus the number of connected components above the marked one where $h$ is the height of the marked ribbon and $r$ is the number of connected components.

See also:
height_of_ribbon(), number_of_connected_components(), ribbons_above_marked()

The $k$-Schur functions with a parameter $t$ can be defined as

$$s^{(k)}_{\lambda}[X; t] = \sum_{T} t^{\text{spin}(T)} m_{\text{weight}(T)}[X]$$

where the sum is over all column strict marked strong $k$-tableaux of shape $\lambda$ and partition content.
OUTPUT:

- an integer value representing the spin.

EXAMPLES:

```python
sage: StrongTableau([[-1,-2,5,6],[-3,-4,-7,8],[-5,-6],[7,-8]], 3, [2,2,3,1]).spin()
1
sage: StrongTableau([[1,-2,4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,1]).spin()
2
sage: StrongTableau([[None,None,-1,-3],[-2,3,-3,4],[2,3],[-3,-4]], 3).spin()
2
sage: ks3 = SymmetricFunctions(QQ['t'].fraction_field()).kschur(3)
sage: t = ks3.realization_of().t
sage: m = ks3.ambient().realization_of().m()
sage: myks221 = sum(sum(t**T.spin() for T in StrongTableaux(3, [3,2,1], weight=mu))*m(mu) for mu in Partitions(5, max_part=3))
sage: myks221 == m(ks3[2,2,1])
True
sage: h = ks3.ambient().realization_of().h()
sage: Core([4,4,2,2],4).to_bounded_partition([2,2,2,2])
[2, 2, 2, 2]
sage: ks3[2,2,2,2].lift().scalar(h[3,3,2]) == sum( t**T.spin() for T in StrongTableaux(3, [4,4,2,2], weight=[3,3,2]) )
True
```

spin_of_ribbon(v)

Return the spin of the ribbon with label v in the standard part of self.

The spin of a ribbon is an integer statistic. It is the sum of \((h - 1)r\) plus the number of connected components above the marked one where \(h\) is the height of the marked ribbon and \(r\) is the number of connected components.

See also:

- height_of_ribbon()
- number_of_connected_components()
- ribbons_above_marked()

INPUT:

- \(v\) – a label of the standard part of the tableau

OUTPUT:

- an integer value representing the spin of the ribbon with label \(v\).

EXAMPLES:

```python
sage: T = StrongTableau([[-1,-2,5,6],[-3,-4,-7,8],[-5,-6],[7,-8]], 3)
sage: [T.spin_of_ribbon(v) for v in range(1,9)]
[0, 0, 0, 0, 0, 1, 0]
sage: T = StrongTableau([[None,None,-1,-3],[-2,3,-3,4],[2,3],[-3,-4]], 3)
sage: [T.spin_of_ribbon(v) for v in range(1,7)]
[0, 1, 0, 0, 1, 0]
```

to_list()

Return the marked column strict (possibly skew) tableau as a list of lists.

OUTPUT:

- a list of lists of integers or None
EXAMPLES:

```python
sage: StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3).set_weight([2,1,1,1]).
        to_list()
[[[-1, -1, -2, 3], [-3], [-4]]
```

```python
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
        3], [3], [3], [3]], 4).to_list()
[[[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], [3]]
```

```python
sage: StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1]).to_list()
[[[-1, -1, -1, 2], [-2], [-3]]
```

`to_standard_list()`

Return the underlying standard strong tableau as a list of lists.

Internally, for a strong tableau the standard strong tableau and its weight is stored separately. This method returns the underlying standard part.

OUTPUT:

- a list of lists of integers or None

EXAMPLES:

```python
sage: StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1]).to_standard_
        list()
[[[-1, -2, -3, 4], [-4], [-5]]
```

```python
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
        3], [3], [3], [3]], 4).to_standard_list()
[[[None, None, -2, -4], [None, None], [-1, -3], [2, 4], [-5], [5], [5], [5]]
```

`to_standard_tableau()`

Return the underlying standard strong tableau as a `StrongTableau` object.

Internally, for a strong tableau the standard strong tableau and its weight is stored separately. This method returns the underlying standard part as a `StrongTableau`.

OUTPUT:

- a strong tableau with standard weight

EXAMPLES:

```python
sage: T = StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1])
sage: T.to_standard_tableau()
[[[-1, -2, -3, 4], [-4], [-5]]
```

```python
sage: T.to_standard_tableau() == T.to_standard_list()
False
```

```python
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
        3], [3], [3], [3]], 4).to_standard_tableau()
[[[None, None, -2, -4], [None, None], [-1, -3], [2, 4], [-5], [5], [5], [5]]
```

`to_transposition_sequence()`

Return a list of transpositions corresponding to `self`.

Given a strong column strict tableau `self` returns the list of transpositions which when applied to the left of an empty tableau gives the corresponding strong standard tableau.

OUTPUT:

- a list of pairs of values \([i, j]\) representing the transpositions \(t_{ij}\)

EXAMPLES:
```
sage: T = StrongTableau([[-1, -1, -1], [1]], 2)
sage: T.to_transposition_sequence()
[[2, 3], [1, 2], [0, 1]]
sage: T = StrongTableau([[-1, -1, 2], [-2]], 2)
sage: T.to_transposition_sequence()
[[-1, 0], [1, 2], [0, 1]]
sage: T = StrongTableau([[None, -1, 2, -3], [-2, 3]], 2)
sage: T.to_transposition_sequence()
[[3, 4], [-1, 0], [1, 2]]
```

**to_unmarked_list()**

Return the tableau as a list of lists with markings removed.

Return the list of lists of the rows of the tableau where the markings have been removed.

**OUTPUT:**

- a list of lists of integers or None

**EXAMPLES:**

```
sage: T = StrongTableau( [[-1, -2, -3, 4], [-4], [-5]], 3, [3, 1, 1])
sage: T.to_unmarked_list()
[[1, 1, 1, 2], [2], [3]]
sage: TT = T.set_weight([2, 1, 1, 1])
sage: TT.to_unmarked_list()
[[1, 1, 2, 3], [3], [4]]
sage: StrongTableau( [[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
˓→3], [3], [3], [3]], 4).to_unmarked_list()
[[None, None, 1, 2], [None, None], [1, 3], [2, 4], [5], [5], [5], [5]]
```

**to_unmarked_standard_list()**

Return the standard part of the tableau as a list of lists with markings removed.

Return the list of lists of the rows of the tableau where the markings have been removed.

**OUTPUT:**

- a list of lists of integers or None

**EXAMPLES:**

```
sage: StrongTableau( [[-1, -2, -3, 4], [-4], [-5]], 3, [3, 1, 1]).to_unmarked_˓→standard_list()
[[1, 2, 3, 4], [4], [5]]
sage: StrongTableau( [[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
˓→3], [3], [3], [3]], 4).to_unmarked_standard_list()
[[None, None, 2, 4], [None, None], [1, 3], [2, 4], [5], [5], [5], [5]]
```

**weight()**

Return the weight of the tableau.

The weight is a list of non-negative integers indicating the number of 1s, number of 2s, number of 3s, etc.

**OUTPUT:**

- a list of non-negative integers

**EXAMPLES:**
sage: T = StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3); T.weight()
(1, 1, 1, 1, 1)
sage: T.set_weight([3,1,1]).weight()
(3, 1, 1)
sage: StrongTableau([[-1,-1,-2,-3],[2,3],[-3,-4]], 3).weight()
(2, 2, 3, 1)

class sage.combinat.k_tableau.StrongTableaux(k, shape, weight)
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Element
alias of StrongTableau
classmethod add_marking(unmarkedT, marking, k, weight)
Add markings to a partially marked strong tableau.

Given an partially marked standard tableau and a list of cells where the marks should be placed along with a weight, return the semi-standard marked strong tableau. The marking should complete the marking so that the result is a strong standard marked tableau.

INPUT:
• unmarkedT - a list of lists which is a partially marked strong $k$-tableau
• marking - a list of pairs of coordinates where cells are to be marked
• k - a positive integer
• weight - a tuple of the weight of the output tableau

OUTPUT:
• a StrongTableau object

EXAMPLES:

sage: StrongTableaux.add_marking([[[None,1,2],[2]], [[0,1], (1,0)], 2, [1,1])
[[None, -1, 2], [-2]]
sage: StrongTableaux.add_marking([[[None,1,2],[2]], [[0,1], (1,0)], 2, [2])
Traceback (most recent call last):
...
ValueError: The weight=(2,) and the markings on the standard tableau=[[None, -1, 2], [-2]) do not agree.
sage: StrongTableaux.add_marking([[[None,1,2],[2]], [[0,1], (0,2)], 2, [2])
[[None, -1, -1], [1]]

an_element()
Return the first generated element of the class of StrongTableaux.

EXAMPLES:

sage: ST = StrongTableaux(3, [3], weight=[3])
sage: ST.an_element()
[[-1, -1, -1]]

classmethod cells_head_dictionary(T)
Return a dictionary with the locations of the heads of all markings.

Return a dictionary of values and lists of cells where the heads with the values are located in a strong standard unmarked tableau T.
INPUT:

- \( T \) – a strong standard unmarked tableau as a list of lists

OUTPUT:

- a dictionary with keys the entries in the tableau and values are the coordinates of the heads with those entries

EXAMPLES:

```python
sage: StrongTableaux.cells_head_dictionary([[1, 2, 4, 7], [3, 6, 6, 8], [4, 7], [5, 8]])
{1: [(0, 0)],
2: [(0, 1)],
3: [(1, 0)],
4: [(2, 0), (0, 2)],
5: [(3, 0)],
6: [(1, 2)],
7: [(2, 1), (0, 3)],
8: [(3, 1), (1, 3)]}
```

```python
sage: StrongTableaux.cells_head_dictionary([[None, 2, 2, 4, 5, 6, 6, 6], [None, 3, 6, 6, 6], [1, 4]])
{1: [(2, 0)],
2: [(0, 2)],
3: [(1, 1)],
4: [(2, 1), (0, 3)],
5: [(0, 4)],
6: [(1, 4), (0, 7)]}
```

.. classmethod:: follows_tableau_unsigned_standard(Tlist, k)

   Return a list of strong tableaux one longer in length than \( Tlist \).

   Return list of all standard strong tableaux obtained from \( Tlist \) by extending to a core which follows the shape of \( Tlist \) in the strong order. It does not put the markings on the last entry that it adds but it does keep the markings on all entries smaller. The objects returned are not StrongTableau objects (and cannot be) because the last entry will not properly marked.

   INPUT:

   - \( Tlist \) – a filling of a \( k + 1 \)-core as a list of lists
   - \( k \) - an integer

   OUTPUT:

   - a list of strong tableaux which follow \( Tlist \) in strong order

   EXAMPLES:

```python
sage: StrongTableaux.follows_tableau_unsigned_standard([[-1, -1, -2, -3], [-2, -3, 4], [2, 3, [-3, -4]], 3])
[[[-1, -1, -2, -3, 5, 5, 5], [-2, 3, -3, 4], [2, 3], [-3, -4]],
[[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [5]],
[[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4], [5], [5], [5]]
```

```python
sage: StrongTableaux.follows_tableau_unsigned_standard([[None, -1, -2, -3], 3])
[[[None, -1, 4, 4, 4], [-2, -3]], [[None, -1, 4, [-2, -3], [4]],
[[None, -1], [-2, -3], [4], [4], [4]]]
```

.. method:: inner_shape()

   Return the inner shape of the class of strong tableaux.

   OUTPUT:
• a $k + 1$-core

EXAMPLES:

```python
sage: StrongTableaux( 2, [3,1] ).inner_shape()
[]
sage: type(StrongTableaux( 2, [3,1] ).inner_shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: StrongTableaux( 4, [[2,1], [1]] ).inner_shape()
[1]
```

classmethod marked_CST_to_transposition_sequence($T$, $k$)

Return a list of transpositions corresponding to $T$.

Given a strong column strict tableau $T$ returns the list of transpositions which when applied to the left of an empty tableau gives the corresponding strong standard tableau.

INPUT:

• $T$ – a non-empty column strict tableau as a list of lists
• $k$ – a positive integer

OUTPUT:

• a list of pairs of values $[i, j]$ representing the transpositions $t_{ij}$

EXAMPLES:

```python
sage: CST_to_trans = StrongTableaux.marked_CST_to_transposition_sequence
sage: CST_to_trans([[-1, -1, -1], [1]], 2)
[[2, 3], [1, 2], [0, 1]]
sage: CST_to_trans([], 2)
[]
sage: CST_to_trans([[-2, -2, -2], [2]], 2)
[[2, 3], [1, 2], [0, 1]]
sage: CST_to_trans([[-1, -2, -2, -2, -2], [-2, 2], [2]], 3)
[[4, 5], [3, 4], [2, 3], [1, 2], [-1, 0], [0, 1]]
sage: CST_to_trans([[-1, -2, -5, 5, -5, 5, -5], [-3, -4, 5, 5], [5]],3)
[[5, 7], [3, 5], [2, 3], [0, 1], [-1, 0], [1, 2], [0, 1]]
sage: CST_to_trans([[-1, -2, -3, 4, -7], [-4, -6], [-5, 6]],3)
[[4, 5], [-1, 1], [-2, -1], [-1, 0], [2, 3], [1, 2], [0, 1]]
```

classmethod marked_given_unmarked_and_weight_iterator($unmarkedT$, $k$, $weight$)

An iterator generating strong marked tableaux from an unmarked strong tableau.

Iterator which lists all marked tableaux of weight $weight$ such that the standard unmarked part of the tableau is equal to $unmarkedT$.

INPUT:

• $unmarkedT$ - a list of lists representing a strong unmarked tableau
• $k$ - a positive integer
• $weight$ - a list of non-negative integers indicating the weight

OUTPUT:

• an iterator that returns $StrongTableau$ objects

EXAMPLES:
```python
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[1,2,3], ˓→[3]], 2, [3])
sage: list(ST)
[[[-1, -1, -1], [1]]]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[1,2,3], ˓→[3]], 2, [0,3])
sage: list(ST)
[[[-2, -2, -2], [2]]]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[1,2,3], ˓→[3]], 2, [1,2])
sage: list(ST)
[[[-1, -2, -2], [2]]]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[1,2,3], ˓→[3]], 2, [2,1])
sage: list(ST)
[[[-1, -1, 2], [-2]], [[-1, -1, -2], [2]]]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[None, None, 1, 2, 4], [2, 4], [3]], 3, [3,1])
sage: list(ST)
[]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[None, None, 1, 2, 4], [2, 4], [3]], 3, [2,2])
sage: list(ST)
[[[None, None, -1, -1, 2], [1, -2], [-2]], [[None, None, -1, -1, -2], [1, 2], [-2]]]
```

**options(*get_value, **set_value*)**

Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:

- **ascii_art** – (default: repr) Controls the ascii art output for tableaux
  - compact – minimal length ascii art
  - repr – display using the diagram string representation
  - table – display as a table
- **convention** – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention
- **display** – (default: list) Controls the way in which tableaux are printed
  - array – alias for diagram
  - compact – minimal length string representation
  - diagram – display as Young diagram (similar to `pp()`)
  - ferrers_diagram – alias for diagram
  - list – print tableaux as lists
  - young_diagram – alias for diagram
- **latex** – (default: diagram) Controls the way in which tableaux are latexed
  - array – alias for diagram
- diagram – as a Young diagram
- ferrers_diagram – alias for diagram
- list – as a list
- young_diagram – alias for diagram
- notation – alternative name for convention

**Note:** Changing the convention for tableaux also changes the convention for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

**EXAMPLES:**

```sage
sage: T = Tableau([[1,2,3],[4,5]])
sage: T
[[1, 2, 3], [4, 5]]
sage: Tableaux.options.display="array"
sage: T
1 2 3
4 5
sage: Tableaux.options.convention="french"
sage: T
4 5
1 2 3
```

Changing the convention for tableaux also changes the convention for partitions and vice versa:

```sage
sage: P = Partition([3,3,1])
sage: print(P.ferrers_diagram())
*
***
***
sage: Partitions.options.convention="english"
sage: print(P.ferrers_diagram())
***
***
*
sage: T
1 2 3
4 5
```

The ASCII art can also be changed:

```sage
sage: t = Tableau([[1,2,3],[4,5]])
sage: ascii_art(t)
  1 2 3
  4 5
sage: Tableaux.options.ascii_art = "table"
sage: ascii_art(t)
+---+---+---+
| 1 | 2 | 3 |
+---+---+---+
| 4 | 5 |
+---+
sage: Tableaux.options.ascii_art = "compact"
```

(continues on next page)
outer_shape()

Return the outer shape of the class of strong tableaux.

OUTPUT:

• a $k+1$-core

EXAMPLES:

```sage
sage: StrongTableaux(2, [3,1]).outer_shape()
[3, 1]
sage: type(StrongTableaux(2, [3,1]).outer_shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: StrongTableaux(4, [[2,1], [1]]).outer_shape()
[2, 1]
```

shape()

Return the shape of self.

If the self has an inner shape return a pair consisting of an inner and an outer shape. If the inner shape is empty then return only the outer shape.

OUTPUT:

• a $k+1$-core or a pair of $k+1$-cores

EXAMPLES:

```sage
sage: StrongTableaux(2, [3,1]).shape()
[3, 1]
sage: type(StrongTableaux(2, [3,1]).shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: StrongTableaux(4, [[2,1], [1]]).shape()
([[2, 1], [1]])
```

classmethod standard_marked_iterator(k, size, outer_shape=None, inner_shape=[]) An iterator for generating standard strong marked tableaux.

An iterator which generates all standard marked $k$-tableaux of a given size which are contained in outer_shape and contain the inner_shape. If outer_shape is None then there is no restriction on the shape of the tableaux which are created.

INPUT:

• k - a positive integer

• size - a positive integer

• outer_shape - a list which is a $k+1$-core (default: None)

• inner_shape - a list which is a $k+1$-core (default: [])

OUTPUT:
• an iterator which returns the standard marked tableaux with size cells and that are contained in outer_shape and contain inner_shape

EXAMPLES:

 sage: list(StrongTableaux.standard_marked_iterator(2, 3))
 [[[-1, -2, 3], [-3]], [[-1, -2, -3], [3]], [[-1, -2], [-3], [3]], [[-1, 3, -3], [-2]], [[-1, 3], [-2], [-3]], [[-1, -3], [-2], [-3]]
 sage: list(StrongTableaux.standard_marked_iterator(2, 1, inner_shape=[1,1]))
 [[[None, 1, -1], [None]], [[None, 1], [None], [-1]], [[None, -1], [None], [-1]]]
 sage: len(list(StrongTableaux.standard_marked_iterator(4,4)))
 10
 sage: len(list(StrongTableaux.standard_marked_iterator(4,6)))
 98
 sage: len(list(StrongTableaux.standard_marked_iterator(4,4, inner_shape=[2,2])))
 92
 sage: len(list(StrongTableaux.standard_marked_iterator(4,4, outer_shape=[5,2,2,1], inner_shape=[2,2])))
 10

classmethod standard_unmarked_iterator(k, size, outer_shape=None, inner_shape=[])  
An iterator for standard unmarked strong tableaux.

An iterator which generates all unmarked tableaux of a given size which are contained in outer_shape and which contain the inner_shape.

These are built recursively by building all standard marked strong tableaux of size size – 1 and adding all possible covers.

If outer_shape is None then there is no restriction on the shape of the tableaux which are created.

INPUT:

• k, size - a positive integers
• outer_shape - a list representing a k + 1-core (default: None)
• inner_shape - a list representing a k + 1-core (default: [])

OUTPUT:

• an iterator which lists all standard strong unmarked tableaux with size cells and which are contained in outer_shape and contain inner_shape

EXAMPLES:

 sage: list(StrongTableaux.standard_unmarked_iterator(2, 3))
 [[[1, 2, 3], [3]], [[1, 2], [3], [3]], [[1, 3, 3], [2]], [[1, 3], [2], [3]]
 sage: list(StrongTableaux.standard_unmarked_iterator(2, 1, inner_shape=[1,1]))
 [[[None, 1, 1], [None]], [[None, 1], [None], [1]]]
 sage: len(list(StrongTableaux.standard_unmarked_iterator(4,4)))
 10
 sage: len(list(StrongTableaux.standard_unmarked_iterator(4,6)))
 98
 sage: len(list(StrongTableaux.standard_unmarked_iterator(4,4, inner_shape=[2,2])))
 92
 sage: len(list(StrongTableaux.standard_unmarked_iterator(4,4, outer_shape=[5,2,2,1], inner_shape=[2,2])))
 10
classmethod transpositions_to_standard_strong(transeq, k, emptyTableau=[])  
Return a strong tableau corresponding to a sequence of transpositions.

This method returns the action by left multiplication on the empty strong tableau by transpositions specified by transeq.

INPUT:

- transeq – a sequence of transpositions $t_{ij}$ (a list of pairs).
- emptyTableau – (default: []) an empty list or a skew strong tableau possibly consisting of None entries

OUTPUT:

- a StrongTableau object

EXAMPLES:

```python
sage: StrongTableaux.transpositions_to_standard_strong([[0,1]], 2)  
[[[-1]]]
```

```python
sage: StrongTableaux.transpositions_to_standard_strong([[-2,-1], [2,3]], 2,  
    innerTableau=[[None, None]])  
[[[None, None], [1], [-2]]]
```

```python
sage: StrongTableaux.transpositions_to_standard_strong([[2, 3], [1, 2], [0,  
    0]], 2)  
[[[-1, -2, -3], [3]]]
```

```python
sage: StrongTableaux.transpositions_to_standard_strong([[1, 2], [0,  
    0]], 2)  
[[[-1, -2, 3], [3]]]
```

```python
sage: StrongTableaux.transpositions_to_standard_strong([[3, 4], [-1, 0], [1,  
    0]], 2,  
    innerTableau=[[None]])  
[[None, -1, 2, -3], [-2, 3]]
```

This is the dispatcher method for the element class of weak $k$-tableaux.

Standard weak $k$-tableaux correspond to saturated chains in the weak order. There are three formulations of weak tableaux, one in terms of cores, one in terms of $k$-bounded partitions, and one in terms of factorizations of affine Grassmannian elements. For semistandard weak $k$-tableaux, all letters of the same value have to satisfy the conditions of a horizontal strip. In the affine Grassmannian formulation this means that all factors are cyclically decreasing elements. For more information, see for example [LLMSSZ2013].

INPUT:

- $t$ – a weak $k$-tableau in the specified representation:
  - for the ‘core’ representation $t$ is a list of lists where each subtableaux should have a $k+1$-core shape; None is allowed as an entry for skew weak $k$-tableaux
  - for the ‘bounded’ representation $t$ is a list of lists where each subtableaux should have a $k$-bounded shape; None is allowed as an entry for skew weak $k$-tableaux
  - for the ‘factorized_permutation’ representation $t$ is either a list of cyclically decreasing Weyl group elements or a list of reduced words of cyclically decreasing Weyl group elements; to indicate a skew tableau in this representation, inner_shape should be the inner shape as a $(k+1)$-core

- $k$ – positive integer

- inner_shape – this entry is only relevant for the ‘factorized_permutation’ representation and specifies the inner shape in case the tableau is skew (default: [])

- representation – ‘core’, ‘bounded’, or ‘factorized_permutation’ (default: ‘core’)
**EXAMPLES:**

Here is an example of a weak 3-tableau in core representation:

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.shape()
[5, 2, 1]
sage: t.weight()
(2, 2, 2)
sage: type(t)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
```

And now we give a skew weak 3-tableau in core representation:

```python
sage: ts = WeakTableau([[None, 1, 1, 2, 2], [None, 2], [1]], 3)
sage: ts.shape()
([5, 2, 1], [1, 1])
sage: ts.weight()
(2, 2)
sage: type(ts)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
```

Next we create the analogue of the first example in bounded representation:

```python
sage: tb = WeakTableau([[1,1,2], [2,3], [3]], 3, representation="bounded")
sage: tb.shape()
[3, 2, 1]
sage: tb.weight()
(2, 2, 2)
sage: type(tb)
<class 'sage.combinat.k_tableau.WeakTableaux_bounded_with_category.element_class'>
sage: tb.to_core_tableau()
[[1, 1, 2, 2, 3], [2, 3], [3]]
sage: t == tb.to_core_tableau()  # Note: This should be False, but the check is not completed
True
```

And the analogue of the skew example in bounded representation:

```python
sage: tbs = WeakTableau([[None, 1, 2], [None, 2], [1]], 3, representation = "bounded")
sage: tbs.shape()
([3, 2, 1], [1, 1])
sage: tbs.weight()
(2, 2)
sage: type(tbs)
<class 'sage.combinat.k_tableau.WeakTableaux_bounded_with_category.element_class'>
sage: tbs.to_core_tableau()
[[None, 1, 1, 2, 2], [None, 2], [1]]
sage: ts.to_bounded_tableau() == tbs  # Note: This should be True, but the check is not completed
True
```

Finally we do the same examples for the factorized permutation representation:

```python
sage: tf = WeakTableau([[2,0],[3,2],[1,0]], 3, representation = "factorized_permutation")
sage: tf.shape()
[5, 2, 1]
sage: tf.weight()
(2, 2, 2)
sage: type(tf)
(continues on next page)
Another way to pass from one representation to another is as follows:

```
sage: ts
[[None, 1, 1, 2, 2], [None, 2], [1]]
sage: ts.parent()._representation
'core'
sage: ts.representation('bounded')
[[None, 1, 2], [None, 2], [1]]
```

To test whether a given semistandard tableau is a weak $k$-tableau in the bounded representation, one can ask:

```
sage: t = Tableau([[1,1,2],[2,3],[3]])
sage: t.is_k_tableau(3)
True
sage: t = SkewTableau([[None, 1, 2], [None, 2], [1]])
sage: t.is_k_tableau(3)
True
sage: t = SkewTableau([[None, 1, 1], [None, 2], [2]])
sage: t.is_k_tableau(3)
False
```

### class sage.combinat.k_tableau.WeakTableau_abstract

Bases: sage.structure.list_clone.ClonoableList

Abstract class for the various element classes of WeakTableau.

**intermediate_shapes()**

Return the intermediate shapes of self.

A (skew) tableau with letters $1, 2, \ldots, \ell$ can be viewed as a sequence of shapes, where the $i$-th shape is given by the shape of the subtableau on letters $1, 2, \ldots, i$. The output is the list of these shapes.

**EXAMPLES:**

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.intermediate_shapes()
[[[1], [2], [4, 1], [5, 2, 1]]]
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.intermediate_shapes()
[[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]]
```
sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.intermediate_shapes()
[[], [3], [3, 2], [3, 2, 1]]

sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation = 'bounded')
sage: t.intermediate_shapes()
[[2], [3], [3, 1], [3, 1, 1], [3, 2, 1]]

sage: t = WeakTableau([[0],[3],[2],[3]], 3, inner_shape = [2], representation = 'factorized_permutation')
sage: t.intermediate_shapes()
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]

PP()  
Return a pretty print string of the tableau.

EXAMPLES:

sage: t = WeakTableau([[None, None, 1, 2, 2], [2], [1]], 3)
sage: t.pp()
    1 1 2
    2 1

sage: t = WeakTableau([[None, 1, 2], [None, 2], [1]], 3, representation = 'core')
sage: t.representation('bounded')
[[1, 1, 2], [2, 3], [3, 4], [5, 6], [6], [7]]

representation(representation=’core’)  
Return the analogue of self in the specified representation.

INPUT:

• representation – ‘core’, ‘bounded’, or ‘factorized_permutation’ (default: ‘core’)

EXAMPLES:

sage: t = WeakTableau([[1,1,2,3,4,4,5,5,6], [2,3,5,5,6], [3,4,7], [5,6], [6], [7]], 4)
sage: t.parent()._representation = 'core'
sage: t.representation('bounded')
[[1, 1, 2, 4], [2, 3, 5], [3, 4], [5, 6], [6], [7]]

sage: t.representation('factorized_permutation')
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]

sage: tb = WeakTableau([[1,1,2,4], [2,3,5], [3,4], [5,6], [6], [7]], 4,
representation = 'bounded')
sage: tb.parent()._representation = 'core'
sage: tb.representation('bounded') == t
True

sage: tb.representation('factorized_permutation')
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]

sage: tp = WeakTableau([[0],[3],[2],[0,4],[3,0],[4,2],[1,0]], 4,
representation = 'factorized_permutation')

(continues on next page)
shape()

Return the shape of self.

When the tableau is straight, the outer shape is returned. When the tableau is skew, the tuple of the outer and inner shape is returned.

EXAMPLES:

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.shape()
[5, 2, 1]
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.shape()
([5, 2, 1], [2])
sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation = 'bounded')
sage: t.shape()
([3, 2, 1], [2])
sage: t = WeakTableau([[2, 0], [3, 2]], 3, representation = 'factorized_permutation')
sage: t.shape()
([5, 2, 1], [2])
```

size()

Return the size of the shape of self.

In the bounded representation, the size of the shape is the number of boxes in the outer shape minus the number of boxes in the inner shape. For the core and factorized permutation representation, the size is the length of the outer shape minus the length of the inner shape.

See also:

`sage.combinat.core.Core.length()`

EXAMPLES:

```python
sage: t = WeakTableau([[None, 1, 1, 2, 2], [None, 2], [1]], 3)
sage: t.shape()
([5, 2, 1], [1, 1])
sage: t.size()
4
sage: t = WeakTableau([[1,1,2],[2,3],[3]], 3, representation="bounded")
```
weight()

Return the weight of self.

The weight is a tuple whose $i$-th entry is the number of labels $i$ in the bounded representation of self.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.weight()
(2, 2, 2)
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.weight()
(1, 1, 1, 1)
sage: t = WeakTableau([[None,2,3],[3]],2)
sage: t.weight()
(0, 1, 1)
sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.weight()
(3, 2, 1)
sage: t = WeakTableau([[1,1,2],[2,3],[3]], 3, representation = 'bounded')
sage: t.weight()
(2, 2, 2)
sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation = 'bounded')
sage: t.weight()
(1, 1, 1, 1)
sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_permutation')
sage: t.weight()
(3, 2, 1)
sage: t = WeakTableau([[2,0],[3,2],[1,0]], 3, representation = 'factorized_permutation')
sage: t.weight()
(2, 2, 2)
sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation = 'factorized_permutation')
sage: t.weight()
(2, 2)
```

class sage.combinat.k_tableau.WeakTableau_bounded(parent, t)

A (skew) weak $k$-tableau represented in terms of $k$-bounded partitions.

check()

Check that self is a valid weak $k$-tableau.

EXAMPLES:

```
sage: t = WeakTableau([[1,1],[2]], 2, representation = 'bounded')
sage: t.check()
```
sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation = 'bounded')
sage: t.check()

classmethod from_core_tableau(t, k)
Construct weak k-bounded tableau from in k-core tableau.

EXAMPLES:

sage: from sage.combinat.k_tableau import WeakTableau_bounded
sage: WeakTableau_bounded.from_core_tableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
[[1, 1, 2], [2, 3], [3]]
sage: WeakTableau_bounded.from_core_tableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
[[None, None, 3], [1, 4], [2]]
sage: WeakTableau_bounded.from_core_tableau([[None, 2, 3], [3]], 2)
[[None, 2], [3]]

k_charge(algorithm='I')
Return the k-charge of self.

INPUT:
• algorithm – (default: ‘I’) if “I”, computes k-charge using the I algorithm, otherwise uses the J-algorithm

OUTPUT:
• a nonnegative integer

For the definition of k-charge and the various algorithms to compute it see Section 3.3 of [LLMSSZ2013].

EXAMPLES:

sage: t = WeakTableau([[1, 1, 2], [2, 3], [3]], 3, representation = 'bounded')
sage: t.k_charge()
2
sage: t = WeakTableau([[1, 3, 5], [2, 6], [4]], 3, representation = 'bounded')
sage: t.k_charge()
8
sage: t = WeakTableau([[1, 1, 2, 4], [2, 3, 5], [3, 4], [5, 6], [6], [7]], 4,
representation = 'bounded')
sage: t.k_charge()
12

shape_bounded()
Return the shape of self as k-bounded partition.

When the tableau is straight, the outer shape is returned as a k-bounded partition. When the tableau is skew, the tuple of the outer and inner shape is returned as k-bounded partitions.

EXAMPLES:

sage: t = WeakTableau([[1,1,1], [2,2], [3]], 3, representation = 'bounded')
sage: t.shape_bounded()
[3, 2, 1]
\begin{verbatim}
sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation = 'bounded')
sage: t.shape_bounded()
([3, 2, 1], [2])

shape_core()
Return the shape of self as \((k+1)\)-core.

When the tableau is straight, the outer shape is returned as a \((k+1)\)-core. When the tableau is skew, the tuple of the outer and inner shape is returned as \((k+1)\)-cores.

EXAMPLES:

sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.shape_core()
[5, 2, 1]

sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation = 'bounded')
sage: t.shape_core()
([5, 2, 1], [2])

to_core_tableau()
Return the weak \(k\)-tableau self where the shape of each restricted tableau is a \((k+1)\)-core.

EXAMPLES:

sage: t = WeakTableau([[1,1,2,4],[2,3,5],[3,4],[5,6],[6],[7]], 4,
representation = 'bounded')
sage: c = t.to_core_tableau(); c
[[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]]
sage: type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
sage: t = WeakTableau([], 4, representation = 'bounded')
sage: t.to_core_tableau()
[]

sage: from sage.combinat.k_tableau import WeakTableau_bounded
sage: t = WeakTableau([[1,1,2],[2,3],[3]], 3, representation = 'bounded')
sage: WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),3)
[[1, 1, 2], [2, 3], [3]]

sage: t == WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),3)
True

sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation = 'bounded')
sage: t.to_core_tableau()
[[None, None, 1, 2, 4], [2, 4], [3]]
sage: t == WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),3)
True
\end{verbatim}

\textbf{class} \texttt{sage.combinat.k_tableau.WeakTableau_core}(parent, t)
\textbf{Bases:} \texttt{sage.combinat.k_tableau.WeakTableau_abstract}

A (skew) weak \(k\)-tableau represented in terms of \((k+1)\)-cores.
check()  
Check that self is a valid weak \( k \)-tableau.

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2], [2]], 2)
sage: t.check()
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.check()
```

dictionary_of_coordinates_at_residues(v)  
Return a dictionary assigning to all residues of self with label \( v \) a list of cells with the given residue.

**INPUT:**

- \( v \) – a label of a cell in self

**OUTPUT:**

- dictionary assigning coordinates in self to residues

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.dictionary_of_coordinates_at_residues(3)
{0: [(0, 4), (1, 1)], 2: [(2, 0)]}
sage: t = WeakTableau([[None, None, 1, 1, 4], [1, 4], [3]], 3)
sage: t.dictionary_of_coordinates_at_residues(1)
{2: [(0, 2)], 3: [(0, 3), (1, 0)]}
sage: t = WeakTableau([], 3)
sage: t.dictionary_of_coordinates_at_residues(1)
{}```

k_charge(algorithm='I')  
Return the \( k \)-charge of self.

**INPUT:**

- algorithm – (default: ‘I’) if “I”, computes \( k \)-charge using the \( I \) algorithm, otherwise uses the \( J \)-algorithm

**OUTPUT:**

- a nonnegative integer

For the definition of \( k \)-charge and the various algorithms to compute it see Section 3.3 of [LLMSSZ2013].

**See also:**  
k_charge_I() and k_charge_J()

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.k_charge()
2
sage: t = WeakTableau([[1, 3, 4, 5, 6], [2, 6], [4]], 3)
sage: t.k_charge()
8
sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, →7], [5, 6], [6], [7]], 4)
```
sage: t.k_charge()  
12

\textbf{k\_charge\_I()}  
Return the $k$-charge of \texttt{self} using the $I$-algorithm.  
For the definition of $k$-charge and the $I$-algorithm see Section 3.3 of [LLMSSZ2013].  
\textbf{OUTPUT:}  
\begin{itemize}  
\item a nonnegative integer  
\end{itemize}  
\textbf{See also:}  
\texttt{k\_charge()} and \texttt{k\_charge\_J()}  
\textbf{EXAMPLES:}

\begin{verbatim}sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3) sage: t.k_charge_I() 2 sage: t = WeakTableau([[1, 3, 4, 5, 6], [2, 6], [4]], 3) sage: t.k_charge_I() 8 sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, \rightarrow 7], [5, 6], [6], [7]], 4) sage: t.k_charge_I() 12
\end{verbatim}

\textbf{k\_charge\_J()}  
Return the $k$-charge of \texttt{self} using the $J$-algorithm.  
For the definition of $k$-charge and the $J$-algorithm see Section 3.3 of [LLMSSZ2013].  
\textbf{OUTPUT:}  
\begin{itemize}  
\item a nonnegative integer  
\end{itemize}  
\textbf{See also:}  
\texttt{k\_charge()} and \texttt{k\_charge\_I()}  
\textbf{EXAMPLES:}

\begin{verbatim}sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3) sage: t.k_charge_J() 2 sage: t = WeakTableau([[1, 3, 4, 5, 6], [2, 6], [4]], 3) sage: t.k_charge_J() 8 sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, \rightarrow 7], [5, 6], [6], [7]], 4) sage: t.k_charge_J() 12
\end{verbatim}

\textbf{list\_of\_standard\_cells()}  
Return a list of lists of the coordinates of the standard cells of \texttt{self}.  
\textbf{INPUT:}  
\begin{itemize}  
\item \texttt{self} -- a weak $k$-tableau in core representation with partition weight
OUTPUT:

- a list of lists of coordinates

**Warning:** This method currently only works for straight weak tableaux with partition weight.

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.list_of_standard_cells()
[[[0, 1], (1, 0), (2, 0)], [(0, 0), (0, 2), (1, 1)]

sage: t = WeakTableau([[1, 1, 1, 2], [2, 2, 3]], 5)
sage: t.list_of_standard_cells()
[[[0, 2], (1, 1), (1, 2)], [(0, 1), (1, 0)], [(0, 0), (0, 3)]

sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]], 4)
sage: t.list_of_standard_cells()
[[[0, 1], (1, 0), (2, 0), (0, 5), (3, 0), (4, 0), (5, 0)], [(0, 0), (0, 2), (1, 1), (2, 1), (1, 2), (3, 1)]
```

**residues_of_entries**(v)

Return a list of residues of cells of weak k-tableau self labeled by v.

INPUT:

- v – a label of a cell in self

OUTPUT:

- a list of residues

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]],3)
sage: t.residues_of_entries(1)
[0, 1]

sage: t = WeakTableau([[None, None, 1, 1, 4], [1, 4], [2]], 3)
sage: t.residues_of_entries(1)
[2, 3]
```

**shape_bounded**( )

Return the shape of self as a k-bounded partition.

When the tableau is straight, the outer shape is returned as a k-bounded partition. When the tableau is skew, the tuple of the outer and inner shape is returned as k-bounded partitions.

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]],3)
sage: t.shape_bounded()
[3, 2, 1]

sage: t = WeakTableau([[None, None, 1, 1, 4], [1, 4], [2]], 3)
sage: t.shape_bounded()
([3, 2, 1], [2])
```

**shape_core**( )

Return the shape of self as a (k + 1)-core.
When the tableau is straight, the outer shape is returned as a core. When the tableau is skew, the tuple of the outer and inner shape is returned as cores.

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.shape_core()
[5, 2, 1]
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.shape_core()
([5, 2, 1], [2])
```

to_bounded_tableau()

Return the bounded representation of the weak $k$-tableau self.

Each restricted subtableau of the output is a $k$-bounded partition.

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: c = t.to_bounded_tableau(); c
[[1, 1, 2], [2, 3], [3]]
sage: type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_bounded_with_category.element_' -> class'>
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.to_bounded_tableau()
[[None, None, 3], [1, 4], [2]]
sage: t.to_bounded_tableau().to_core_tableau() == t
True
```

to_factorized_permutation_tableau()

Return the factorized permutation representation of the weak $k$-tableau self.

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: c = t.to_factorized_permutation_tableau(); c
[s2*s0, s3*s2, s1*s0]
sage: type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_ -> category.element_class'>
sage: c.to_core_tableau() == t
True
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: c = t.to_factorized_permutation_tableau(); c
[s0, s3, s2, s3]
sage: c._inner_shape
[2]
sage: c.to_core_tableau() == t
True
```

class sage.combinat.k_tableau.WeakTableau_factorized_permutation (parent, t)

Bases: sage.combinat.k_tableau.WeakTableau_abstract

A weak (skew) $k$-tableau represented in terms of factorizations of affine permutations into cyclically decreasing elements.
check()
Check that self is a valid weak k-tableau.

EXAMPLES:

```
sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_˓→permutation')
sage: t.check()
```

classmethod from_core_tableau(t, k)
Construct weak factorized affine permutation tableau from a k-core tableau.

EXAMPLES:

```
sage: from sage.combinat.k_tableau import WeakTableau_factorized_permutation
sage: WeakTableau_factorized_permutation.from_core_tableau([[1, 1, 2, 2, 3], ˓→[2, 3], [3]], 3)
[\textit{s2} \times \textit{s0}, \textit{s3} \times \textit{s2}, \textit{s1} \times \textit{s0}]
sage: WeakTableau_factorized_permutation.from_core_tableau([[1, 1, 2, 3, 4, 4, ˓→5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]], 4)
[\textit{s0}, \textit{s3} \times \textit{s1}, \textit{s2} \times \textit{s1}, \textit{s0} \times \textit{s4}, \textit{s3} \times \textit{s0}, \textit{s4} \times \textit{s2}, \textit{s1} \times \textit{s0}]
sage: WeakTableau_factorized_permutation.from_core_tableau([[None, 1, 1, 2, ˓→3], [None, 2], [1]], 3)
[\textit{s0} \times \textit{s3}, \textit{s2} \times \textit{s1}]
```

k_charge(algorithm=’I’)
Return the k-charge of self.

OUTPUT:

• a nonnegative integer

EXAMPLES:

```
sage: t = WeakTableau([[2,0],[3,2],[1,0]], 3, representation = 'factorized_˓→permutation')
sage: t.k_charge()
2
sage: t = WeakTableau([[0],[3],[2],[1],[3],[0]], 3, representation = 'factorized_permutation')
sage: t.k_charge()
8
sage: t = WeakTableau([[0],[3,1],[2,1],[0,4],[3,0],[4,2],[1,0]], 4, ˓→representation = 'factorized_permutation')
sage: t.k_charge()
12
```

shape_bounded()
Return the shape of self as a k-bounded partition.

When the tableau is straight, the outer shape is returned as a k-bounded partition. When the tableau is skew, the tuple of the outer and inner shape is returned as k-bounded partitions.

EXAMPLES:

```
sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_˓→permutation')
sage: t.shape_bounded()
[3, 2, 1]
```
shape_core()

Return the shape of self as a \((k + 1)\)-core.

When the tableau is straight, the outer shape is returned as a core. When the tableau is skew, the tuple of the outer and inner shape is returned as cores.

EXAMPLES:

```python
sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation = 'factorized_permutation')
sage: t.shape_bounded()
([3, 2, 1], [2])
sage: t.shape_core()
[5, 2, 1]
sage: t = WeakTableau([[2,0],[3,2]], 3, representation = 'factorized_permutation')
sage: t.shape()([5, 2, 1], [2])
```

static straighten_input(t, k)

Straightens input.

INPUT:

- \(t\) – a list of reduced words or a list of elements in the Weyl group of type \(A_k^{(1)}\)
- \(k\) – a positive integer

EXAMPLES:

```python
sage: from sage.combinat.k_tableau import WeakTableau_factorized_permutation
sage: WeakTableau_factorized_permutation.straighten_input([[2,0],[3,2],[1,0]], 3)
(s2*s0, s3*s2, s1*s0)
sage: W = WeylGroup(['A',4,1])
sage: WeakTableau_factorized_permutation.straighten_input([W.an_element(),W.an_element()], 4)
(s0*s1*s2*s3*s4, s0*s1*s2*s3*s4)
```

to_core_tableau()

Return the weak \(k\)-tableau self where the shape of each restricted tableau is a \((k + 1)\)-core.

EXAMPLES:

```python
sage: t = WeakTableau([], 4, representation = 'factorized_permutation'); t
[1]
sage: t.to_core_tableau()
```

(continues on next page)
sage: from sage.combinat.k_tableau import WeakTableau_factorized_permutation
sage: t = WeakTableau([[2,0],[3,2],[1,0]], 3, representation = 'factorized_permutation')

sage: WeakTableau_factorized_permutation.from_core_tableau(t.to_core_tableau(), 3)
[s2*s0, s3*s2, s1*s0]

sage: t == WeakTableau_factorized_permutation.from_core_tableau(t.to_core_tableau(), 3)
True

sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation = 'factorized_permutation')

sage: t.to_core_tableau()
[[None, None, 1, 1, 2], [1, 2], [2]]

sage: t == WeakTableau_factorized_permutation.from_core_tableau(t.to_core_tableau(), 3)
True

sage.combinat.k_tableau.WeakTableaux(k, shape, weight, representation='core')

This is the dispatcher method for the parent class of weak \(k\)-tableaux.

INPUT:

- \(k\) – positive integer
- \(shape\) – shape of the weak \(k\)-tableaux; for the ‘core’ and ‘factorized_permutation’ representation, the shape is inputted as a \((k+1)\)-core; for the ‘bounded’ representation, the shape is inputted as a \(k\)-bounded partition; for skew tableaux, the shape is inputted as a tuple of the outer and inner shape
- \(weight\) – the weight of the weak \(k\)-tableaux as a list or tuple
- \(representation\) – ‘core’, ‘bounded’, or ‘factorized_permutation’ (default: ‘core’)

EXAMPLES:

sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1,1])

sage: T.list()
[[[1, 3, 5], [2, 6], [4]],
 [[1, 2, 5], [3, 6], [4]],
 [[1, 2, 3], [4, 6], [5]],
 [[1, 2, 3], [4, 5], [6]]]

sage: T.cardinality()
4

sage: T = WeakTableaux(3, [[5,2,1], [2]], [1,1,1,1])

sage: T.list()
[[[None, None, 2, 3, 4], [1, 4], [2]],
 [[None, None, 1, 2, 4], [3, 4], [2]],
 [[None, None, 1, 2, 3], [2, 3], [4]]]

sage: T = WeakTableaux(3, [3,2,1], [1,1,1,1,1,1], representation = 'bounded')

sage: T.list()
[[[1, 3, 5], [2, 6], [4]],
 [[1, 2, 5], [3, 6], [4]],
 [[1, 2, 3], [4, 6], [5]],
 [[1, 2, 3], [4, 5], [6]]]
sage: T = WeakTableaux(3, [[3,2,1], [2]], [1,1,1,1], representation = 'bounded')
sage: T.list()
[[[None, None, 3], [1, 4], [2]],
 [[None, None, 1], [2, 4], [3]],
 [[None, None, 1], [2, 3], [4]]]

sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1,1], representation = 'factorized_permutation')
sage: T.list()
[[s0, s3, s2, s1, s3, s0],
 [s0, s3, s2, s3, s1, s0],
 [s0, s2, s3, s2, s1, s0],
 [s2, s0, s3, s2, s1, s0]]

sage: T = WeakTableaux(3, [[5,2,1], [2]], [1,1,1,1], representation = 'factorized_permutation')
sage: T.list()
[[s0, s3, s2, s3],
 [s0, s2, s3, s2],
 [s2, s0, s3, s2]]

class sage.combinat.k_tableau.WeakTableaux_abstract
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Abstract class for the various parent classes of WeakTableaux.

**representation** *(representation='core')*

Return the analogue of *self* in the specified representation.

INPUT:

* representation – ‘core’, ‘bounded’, or ‘factorized_permutation’ (default: ‘core’)

EXAMPLES:

sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1,1])
sage: T._representation
'core'
sage: T.representation('bounded')
Bounded weak 3-Tableaux of (skew) 3-bounded shape [3, 2, 1] and weight (1, 1, 1)

sage: T.representation('factorized_permutation')
Factorized permutation (skew) weak 3-Tableaux of shape [5, 2, 1] and weight
(1, 1, 1, 1, 1)

sage: T = WeakTableaux(3, [3,2,1], [1,1,1,1,1,1], representation = 'bounded')
sage: T._representation
'bounded'
sage: T.representation('core')
Core weak 3-Tableaux of (skew) core shape [5, 2, 1] and weight (1, 1, 1, 1, 1)

sage: T.representation('bounded')
Bounded weak 3-Tableaux of (skew) 3-bounded shape [3, 2, 1] and weight (1, 1, 1, 1)

sage: T.representation('factorized_permutation')
Factorized permutation (skew) weak 3-Tableaux of shape [5, 2, 1] and weight
(1, 1, 1, 1, 1, 1)

sage: T.representation('bounded') == T
True
sage: T.representation('factorized_permutation')
Factorized permutation (skew) weak 3-Tableaux of shape [5, 2, 1] and weight
(1, 1, 1, 1, 1, 1)
sage: T.representation('factorized_permutation') == T
False

sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1], representation = 'factorized_permutation')
sage: T._representation
'factorized_permutation'
sage: T.representation('core')
Core weak 3-Tableaux of (skew) core shape [5, 2, 1] and weight (1, 1, 1, 1, 1)

sage: T.representation('bounded')
Bounded weak 3-Tableaux of (skew) 3-bounded shape [3, 2, 1] and weight (1, 1, 1, 1, 1)

sage: T.representation('factorized_permutation')
Factorized permutation (skew) weak 3-Tableaux of shape [5, 2, 1] and weight (1, 1, 1, 1, 1)

\section{shape()}

Return the shape of the tableaux of \texttt{self}.

When \texttt{self} is the class of straight tableaux, the outer shape is returned. When \texttt{self} is the class of skew tableaux, the tuple of the outer and inner shape is returned.

Note that in the `core` and `factorized_permutation` representation, the shapes are \((k + 1)\)-cores. In the `bounded` representation, the shapes are \(k\)-bounded partitions.

If the user wants to access the skew shape (even if the inner shape is empty), please use \texttt{self._shape}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: T = WeakTableaux(3, [5,2,2], [2,2,2,1])
sage: T.shape()
[5, 2, 2]
sage: T._shape
([5, 2, 2], [])
sage: T = WeakTableaux(3, [[5,2,2], [1]], [2,1,2,1])
sage: T.shape()
([5, 2, 2], [1])

sage: T = WeakTableaux(3, [3,2,2], [2,2,2,1], representation = 'bounded')
sage: T.shape()
[3, 2, 2]
sage: T._shape
([3, 2, 2], [])
sage: T = WeakTableaux(3, [[3,2,2], [1]], [2,1,2,1], representation = 'bounded')
sage: T.shape()
([3, 2, 2], [1])

sage: T = WeakTableaux(3, [4,1], [2,2], representation = 'factorized_permutation')
sage: T.shape()
[4, 1]
sage: T._shape
([4, 1], [])
sage: T = WeakTableaux(4, [[6,2,1], [2]], [2,1,1,1], representation = 'factorized_permutation')
sage: T.shape()

\end{verbatim}

(continues on next page)
size()  
Return the size of the shape.

In the bounded representation, the size of the shape is the number of boxes in the outer shape minus the number of boxes in the inner shape. For the core and factorized permutation representation, the size is the length of the outer shape minus the length of the inner shape.

EXAMPLES:

```python
sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1,1])
sage: T.size()
6
sage: T = WeakTableaux(3, [3,2,1], [1,1,1,1,1,1], representation = 'bounded')
sage: T.size()
6
sage: T = WeakTableaux(4, [[6,2,1], [2]], [2,1,1,1], 'factorized_permutation')
sage: T.size()
5
```

class sage.combinat.k_tableau.WeakTableaux_bounded(k, shape, weight)

Bases: sage.combinat.k_tableau.WeakTableaux_abstract

The class of (skew) weak \(k\)-tableaux in the bounded representation of shape `shape` (as \(k\)-bounded partition or tuple of \(k\)-bounded partitions in the skew case) and weight `weight`.

INPUT:
- `k` – positive integer
- `shape` – the shape of the \(k\)-tableaux represented as a \(k\)-bounded partition; if the tableaux are skew, the shape is a tuple of the outer and inner shape each represented as a \(k\)-bounded partition
- `weight` – the weight of the \(k\)-tableaux

EXAMPLES:

```python
sage: T = WeakTableaux(3, [3,1], [2,2], representation = 'bounded')
sage: T.list()
[[[1, 1, 2], [2]]]

sage: T = WeakTableaux(3, [[3,2,1], [2]], [1,1,1,1], representation = 'bounded')
sage: T.list()
[[[None, None, 3], [1, 4], [2]],
 [[None, None, 1], [2, 4], [3]],
 [[None, None, 1], [2, 3], [4]]]
```

Element alias of WeakTableau_bounded

class sage.combinat.k_tableau.WeakTableaux_core(k, shape, weight)

Bases: sage.combinat.k_tableau.WeakTableaux_abstract

The class of (skew) weak \(k\)-tableaux in the core representation of shape `shape` (as \(k+1\)-core) and weight `weight`.

INPUT:
- `k` – positive integer
• **shape** – the shape of the \( k \)-tableaux represented as a \((k + 1)\)-core; if the tableaux are skew, the shape is a tuple of the outer and inner shape (both as \((k + 1)\)-cores)

• **weight** – the weight of the \( k \)-tableaux

**EXAMPLES:**

```python
sage: T = WeakTableaux(3, [4,1], [2,2])
sage: T.list()
[[[1, 1, 2, 2], [2]]]

sage: T = WeakTableaux(3, [[5,2,1], [2]], [1,1,1])
sage: T.list()
[[[None, None, 2, 3, 4], [1, 4], [2]],
 [[None, None, 1, 2, 4], [2, 4], [3]],
 [[None, None, 1, 2, 3], [2, 3], [4]]]
```

**Element**

**alias of** `WeakTableau_core`

**circular_distance** \((cr, r)\)

Return the shortest counterclockwise distance between \( cr \) and \( r \) modulo \( k + 1 \).

**INPUT:**

- \( cr, r \) – nonnegative integers between 0 and \( k \)

**OUTPUT:**

- a positive integer

**EXAMPLES:**

```python
sage: T = WeakTableaux(10, [], [])
sage: T.circular_distance(8, 6)
2
sage: T.circular_distance(8, 8)
0
sage: T.circular_distance(8, 9)
10
```

**diag** \((c, ha)\)

Return the number of diagonals strictly between cells \( c \) and \( ha \) of the same residue as \( c \).

**INPUT:**

- \( c \) – a cell in the lattice
- \( ha \) – another cell in the lattice with bigger row and smaller column than \( c \)

**OUTPUT:**

- a nonnegative integer

**EXAMPLES:**

```python
sage: T = WeakTableaux(4, [5,2,2], [2,2,2,1])
sage: T.diag((1,2),(4,0))
0
```

**class** `sage.combinat.k_tableau.WeakTableaux_factorized_permutation` \((k, \text{shape}, \text{weight})\)

**Bases:** `sage.combinat.k_tableau.WeakTableaux_abstract`
The class of (skew) weak $k$-tableaux in the factorized permutation representation of shape \texttt{shape} (as $k+1$-core or tuple of $(k+1)$-cores in the skew case) and \texttt{weight}.

\textbf{INPUT:}

- $k$ – positive integer
- \texttt{shape} – the shape of the $k$-tableaux represented as a $(k+1)$-core; in the skew case the shape is a tuple of the outer and inner shape both as $(k+1)$-cores
- \texttt{weight} – the weight of the $k$-tableaux

\textbf{EXAMPLES:}

\begin{verbatim}
  sage: T = WeakTableaux(3, [4,1], [2,2], representation = 'factorized_permutation')
  sage: T.list()
  [[s3*s2, s1*s0]]

  sage: T = WeakTableaux(4, [[6,2,1], [2]], [2,1,1,1], representation = 'factorized_permutation')
  sage: T.list()
  [[s0, s4, s3, s4*s2], [s0, s3, s4, s3*s2], [s3, s0, s4, s3*s2]]
\end{verbatim}

\textbf{Element} alias of \texttt{WeakTableau_factorized_permutation}

**sage.combinat.k_tableau.intermediate_shapes(t)**

Return the intermediate shapes of tableau \texttt{t}.

A (skew) tableau with letters $1, 2, \ldots, \ell$ can be viewed as a sequence of shapes, where the $i$-th shape is given by the shape of the subtableau on letters $1, 2, \ldots, i$. The output is the list of these shapes.

\textbf{OUTPUT:}

- a list of lists representing partitions

\textbf{EXAMPLES:}

\begin{verbatim}
  sage: from sage.combinat.k_tableau import intermediate_shapes
  sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
  sage: intermediate_shapes(t)
  [[], [2], [4, 1], [5, 2, 1]]

  sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
  sage: intermediate_shapes(t)
  [[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]
\end{verbatim}

**sage.combinat.k_tableau.nabs(v)**

Return the absolute value of \texttt{v} or \texttt{None}.

\textbf{INPUT:}

- \texttt{v} – either an integer or \texttt{None}

\textbf{OUTPUT:}

- either a non-negative integer or \texttt{None}

\textbf{EXAMPLES:}

\begin{verbatim}
  sage: from sage.combinat.k_tableau import nabs
  sage: nabs(None)
  None
  sage: nabs(-3)
  3
\end{verbatim}

(continues on next page)
5.1.133 Kazhdan-Lusztig Polynomials

AUTHORS:

- Daniel Bump (2008): initial version

```python
class sage.combinat.kazhdan_lusztig.KazhdanLusztigPolynomial(W, q, trace=False):
    Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.sage_object.SageObject

A Kazhdan-Lusztig polynomial.

INPUT:

- $W$ – a Weyl Group
- $q$ – an indeterminate

OPTIONAL:

- trace – if True, then this displays the trace: the intermediate results. This is instructive and fun.

The parent of $q$ may be a PolynomialRing or a LaurentPolynomialRing.

EXAMPLES:

```python
sage: W = WeylGroup("B3",prefix="s")
sage: [s1,s2,s3] = W.simple_reflections()
sage: R.<q> = LaurentPolynomialRing(QQ)
sage: KL = KazhdanLusztigPolynomial(W,q)
sage: KL.P(s2,s3*s2*s3*s1*s2)
1 + q
```

A faster implementation (using the optional package Coxeter 3) is given by:

```python
sage: W = CoxeterGroup(['B', 3], implementation='coxeter3')  # optional - coxeter3
sage: W.kazhdan_lusztig_polynomial([2], [3,2,3,1,2])  # optional - coxeter3
q + 1
```

$P(x, y)$

Return the Kazhdan-Lusztig $P$ polynomial.

If the rank is large, this runs slowly at first but speeds up as you do repeated calculations due to the caching.

INPUT:

- $x, y$ – elements of the underlying Coxeter group

See also:

kazhdan_lusztig_polynomial for a faster implementation using Fokko Ducloux’s Coxeter3 C++ library.

EXAMPLES:
```
sage: R.<q> = QQ[]
sage: W = WeylGroup("A3", prefix="s")
sage: [s1,s2,s3] = W.simple_reflections()
sage: KL = KazhdanLusztigPolynomial(W, q)
sage: KL.P(s2,s2*s1*s3*s2)
q + 1
```

\[ R(x, y) \]

Return the Kazhdan-Lusztig \( R \) polynomial.

**INPUT:**

- \( x, y \) – elements of the underlying Coxeter group

**EXAMPLES:**

```
sage: R.<q>=QQ[]
sage: W = WeylGroup("A2", prefix="s")
sage: [s1,s2]=W.simple_reflections()
sage: KL = KazhdanLusztigPolynomial(W, q)
sage: [KL.R(x,s2*s1) for x in [1,s1,s2,s1*s2]]
[q^2 - 2*q + 1, q - 1, q - 1, 0]
```

\[ \tilde{R}(x, y) \]

Return the Kazhdan-Lusztig \( \tilde{R} \) polynomial.

Information about the \( \tilde{R} \) polynomials can be found in [Dy1993] and [BB2005].

**INPUT:**

- \( x, y \) – elements of the underlying Coxeter group

**EXAMPLES:**

```
sage: R.<q> = QQ[]
sage: W = WeylGroup("A2", prefix="s")
sage: [s1,s2] = W.simple_reflections()
sage: KL = KazhdanLusztigPolynomial(W, q)
sage: [KL.R_tilde(x,s2*s1) for x in [1,s1,s2,s1*s2]]
[q^2, q, q, 0]
```
5.1.134 Knutson-Tao Puzzles

This module implements a generic algorithm to solve Knutson-Tao puzzles. An instance of this class will be callable: the arguments are the labels of north-east and north-west sides of the puzzle boundary; the output is the list of the fillings of the puzzle with the specified pieces.

Acknowledgements

This code was written during Sage Days 45 at ICERM with Franco Saliola, Anne Schilling, and Avinash Dalal in discussions with Allen Knutson. The code was tested afterwards by Liz Beazley and Ed Richmond.

Todo:

Functionality to add:

• plotter will not plot edge labels higher than 2; e.g. in BK puzzles, the labels are 1, . . . , n and so in 3-step examples, none of the edge labels with 3 appear

• we should also have a 3-step puzzle pieces constructor, taken from p22 of arXiv math/0610538

• implement the bijection from puzzles to tableaux; see for example R. Vakil, A geometric Littlewood-Richardson rule, arXiv math/0302294 or K. Purbhoo, Puzzles, Tableaux and Mosaics, arXiv 0705.1184.

sage.combinat.knutson_tao_puzzles.BK_pieces(max_letter)

The puzzle pieces used in computing the Belkale-Kumar coefficients for any partial flag variety in type A.

There are two types of puzzle pieces:

• a triangle, with each edge labeled with the same letter;

• a rhombus, with edges labeled $i, j, i, j$ in clockwise order with $i > j$.

Each of these is rotated by 60 degrees, but not reflected.

We model the rhombus pieces as two triangles: a delta piece north-west label $i$, north-east label $j$ and south label $i(j)$; and a nabla piece with south-east label $i$, south-west label $j$ and north label $i(j)$.

INPUT:

• max_letter – positive integer specifying the number of steps in the partial flag variety, equivalently, the number of elements in the alphabet for the edge labels. The smallest label is 1.

REFERENCES:

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import BK_pieces
sage: BK_pieces(3)
Nablas : ['1\1/1', '1\2(1)/2', '1\3(1)/3', '2(1)\2/1', '2\1/2(1)', '2\2/2', '2\3(2)/3', '3(1)\3/1', '3(2)\3/2', '3\1/3(1)', '3\2/3(2)', '3\3/3']
Deltas : ['1/1\1', '1/2\2(1)', '1\3(1)/3', '2(1)/1\2', '2/1\2(1)', '2/2\2', '2/3\3(2)', '3(1)/1\3', '3(2)/2\3', '3\3(1)/1', '3\3(2)/2', '3\3/3']
```

class sage.combinat.knutson_tao_puzzles.DeltaPiece(south, north_west, north_east)

Bases: sage.combinat.knutson_tao_puzzles.PuzzlePiece

Delta Piece takes as input three labels, inputted as strings. They label the South, Northwest and Northeast edges, respectively.

EXAMPLES:
```python
from sage.combinat.knutson_tao_puzzles import DeltaPiece
DeltaPiece('a','b','c')
```

**clockwise_rotation()**
Rotates the Delta piece by 120 degree clockwise.

**OUTPUT:**
- Delta piece

**EXAMPLES:**
```python
from sage.combinat.knutson_tao_puzzles import DeltaPiece
delta = DeltaPiece('1','2','3')
delta.clockwise_rotation()
```

```text
b/a\c
```

**edges()**
Return the tuple of edge names.

**EXAMPLES:**
```python
from sage.combinat.knutson_tao_puzzles import DeltaPiece
delta = DeltaPiece('1','2','3')
delta.edges()
```

```text
('south', 'north_west', 'north_east')
```

**half_turn_rotation()**
Rotates the Delta piece by 180 degree.

**OUTPUT:**
- Nabla piece

**EXAMPLES:**
```python
from sage.combinat.knutson_tao_puzzles import DeltaPiece
delta = DeltaPiece('1','2','3')
delta.half_turn_rotation()
```

```text
1/3\2
```

```python
sage.combinat.knutson_tao_puzzles.HT_grassmannian_pieces()
```
Defines the puzzle pieces used in computing the torus-equivariant cohomology of the Grassmannian.

**REFERENCES:**

**EXAMPLES:**
```python
from sage.combinat.knutson_tao_puzzles import HT_grassmannian_pieces
HT_grassmannian_pieces()
```

```text
Nablas : [0\0/0, 0/1\0, 1\0/0, 1\1/0, 1\1/1, 1\T0|1/0]
Deltas : [0/0\0, 0/1\10, 0/T0|1\1, 1/10\0, 1/1\1, 10/0\1]
```

```python
sage.combinat.knutson_tao_puzzles.HT_two_step_pieces()
```
Defines the puzzle pieces used in computing the equivariant two step puzzle pieces.

**REFERENCES:**

**EXAMPLES:**
```python
from sage.combinat.knutson_tao_puzzles import HT_two_step_pieces
HT_two_step_pieces()
```

```text
For the puzzle pieces, see Figure 26 on page 22 of [CoskunVakil06].
```
sage: from sage.combinat.knutson_tao_puzzles import HT_two_step_pieces
sage: HT_two_step_pieces()

Nablas : [(21)0\21/0, 0\(21)0/21, 0\0/0, 0\10/1, 0\20/2, 10\1/0, 10\2(10)/2, 1\0/10, 1\1/1, 1\21/2, 1\T0|1/0, 2(10)\2/20, 20\2/0, 21\0/(21)0, 21\2/1, 21\T0|21/0, 21\T10|21/10, 2\0/20, 2\1/21, 2\10/2(10), 2\2/2, 2\T0|2/0, 2\T10|2/10, 2\T1|2/1] 

Deltas : [(21)0\0/21, 0/0\0, 0/1\10, 0/21\21/0, 0/2\20, 0/T0|1\1, 0/T0|21/2, 0/\T0|2/2, 10/0\1, 10/2\21, 10/\0\1, 10/2\10, 10/T0|21/21, 10/T0|2\2, 2(10)/10\2, 2(10)/10\10, 2\20, 2/21, 2/2\2, 20/0\2, 21/(21)0\0, 21/1\2]

sage.combinat.knutson_tao_puzzles.H_grassmannian_pieces()

Defines the puzzle pieces used in computing the cohomology of the Grassmannian.

REFERENCES:

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import H_grassmannian_pieces
sage: H_grassmannian_pieces()

Nablas : [0\0/0, 0\10/1, 10\\1/0, 10/10, 11/1]

sage: K_grassmannian_pieces()

Nablas : [0\0/0, 0\10/1, 0\K/1, 10\\1/0, 10/10, 1\0\K, 1\1/1, K/1/0]

Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0/1, K/K/1]

class sage.combinat.knutson_tao_puzzles.KnutsonTaoPuzzleSolver (puzzle_pieces)
Bases: sage.structure.unique_representation.UniqueRepresentation

Returns puzzle solver function used to create all puzzles with given boundary conditions.

This class implements a generic algorithm to solve Knutson-Tao puzzles. An instance of this class will be callable: the arguments are the labels of north-east and north-west sides of the puzzle boundary; the output is
the list of the fillings of the puzzle with the specified pieces.

INPUT:

- `puzzle_pieces` – takes either a collection of puzzle pieces or a string indicating a pre-programmed collection of puzzle pieces:
  - `H` – cohomology of the Grassmannian
  - `HT` – equivariant cohomology of the Grassmannian
  - `K` – K-theory
  - `H2step` – cohomology of the 2-step Grassmannian
  - `HT2step` – equivariant cohomology of the 2-step Grassmannian
  - `BK` – Belkale-Kumar puzzle pieces

- `max_letter` – (default: None) None or a positive integer. This is only required only for Belkale-Kumar puzzles.

EXAMPLES:

Each puzzle piece is an edge-labelled triangle oriented in such a way that it has a south edge (called a *delta* piece) or a north edge (called a *nabla* piece). For example, the puzzle pieces corresponding to the cohomology of the Grassmannian are the following:

```
sage: from sage.combinat.knutson_tao_puzzles import H_grassmannian_pieces
sage: H_grassmannian_pieces()
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

In the string representation, the nabla pieces are depicted as \(c\backslash a/b\), where \(a\) is the label of the north edge, \(b\) is the label of the south-east edge, and \(c\) is the label of the south-west edge. A similar string representation exists for the delta pieces.

To create a puzzle solver, one specifies a collection of puzzle pieces:

```
sage: KnutsonTaoPuzzleSolver(H_grassmannian_pieces())
Knutson-Tao puzzle solver with pieces:
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

The following shorthand to create the above puzzle solver is also supported:

```
sage: KnutsonTaoPuzzleSolver('H')
Knutson-Tao puzzle solver with pieces:
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

The solver will compute all fillings of the puzzle with the given puzzle pieces. The user specifies the labels of north-east and north-west sides of the puzzle boundary and the output is a list of the fillings of the puzzle with the specified pieces. For example, there is one solution to the puzzle whose north-west and north-east edges are both labeled ‘0’:

```
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: ps('0', '0')
[{{(1, 1): 0/0\0}}]
```

There are two solutions to the puzzle whose north-west and north-east edges are both labeled ‘0101’:

```
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: ps('0', '0')
[{{(1, 1): 0/0\0}}, {{(1, 1): 0/0\1}}]
```
The pieces in a puzzle filling are indexed by pairs of non-negative integers \((i, j)\) with \(1 \leq i \leq j \leq n\), where \(n\) is the length of the word labelling the triangle edge. The pieces indexed by \((i, i)\) are the triangles along the south edge of the puzzle.

The pieces indexed by \((i, j)\) for \(j > i\) are a pair consisting of a delta piece and nabla piece glued together along the south edge and north edge, respectively (these pairs are called rhombi).

There are various methods and options to display puzzle solutions. A single puzzle can be displayed using the plot method of the puzzle:

To plot several puzzle solutions, use the plot method of the puzzle solver:

The code can also generate a PDF of a puzzle (using LaTeX and \texttt{tikz}):
Below are examples of using each of the currently supported puzzles.

Cohomology of the Grassmannian:

```
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: solns = ps('0101', '0101')
sage: sorted(solns, key=str)

[(1, 1): 0/0\0,
 (1, 2): 1/\1 0/\1,
 (1, 3): 0/\0 0/\0,
 (1, 4): 1/\0 0/\1,
 (2, 2): 1/1\1,
 (2, 3): 0/\10 1/\1,
 (2, 4): 1/\1 10/\0,
 (3, 3): 1/1\1,
 (3, 4): 0/\0 1/\10,
 (4, 4): 10/0\1}, {(1, 1): 0/1\10,
 (1, 2): 1/\1 10/\0,
 (1, 3): 0/\0 1/\10,
 (1, 4): 1/\0 0/\1,

Belkale-Kumar puzzles (the following example is Figure 2 of [KnutsonPurbhoo10]):

```
sage: ps = KnutsonTaoPuzzleSolver('BK', 3)
sage: solns = ps('12132', '23112')
sage: len(solns)
1
sage: solns[0].south_labels()
('3', '2', '1', '2', '1')
sage: solns
({(1, 1): 1/3\3(1),
  (1, 2): 2/3\2 3(1)\1,
  (1, 3): 1/3\3(1) 3(2)\2,
  (1, 4): 3/3\3 3(1)\1,
  (1, 5): 2/2\2 3(3)\2(1),
  (2, 2): 1/2\2(1),
  (2, 3): 2/2\2 2(1)\1,
  (2, 4): 1/\2 2\2/2,
  (2, 5): 3/3(2)/\3 2(1)\1,
  (3, 3): 1/1\1,
  (3, 4): 2/1 1/2,
  (3, 5): 1/1 1/1,
  (4, 4): 2/2\2,
  (4, 5): 1/\1 2/2(1),
  (5, 5): 2(2)/1\2})
```

```
plot (puzzles)
    Return plot of puzzles.

INPUT:
    • puzzles – list of puzzles

EXAMPLES:
```
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver('K')
sage: solns = ps('0101', '0101')
sage: ps.plot(solns)  # not tested
```

```
puzzle_pieces()
    The puzzle pieces used for filling in the puzzles.

EXAMPLES:
```
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: ps.puzzle_pieces()
```
Nablas: \[
[0\/0/0, 0/10/1, 10/1/0, 1/0/10, 1\/1/1] \\
\]
Deltas: \[
[0/0\/0, 0/1\/10, 1/10/0, 1/1\/1, 10/0/1] \\
\]

**solutions** *(\(\lambda, \mu, \text{algorithm}='\text{strips}'\))*

**structure\_constants** *(\(\lambda, \mu, \nu=None\))*

Compute cohomology structure coefficients from puzzles.

**INPUT:**

- pieces – puzzle pieces to be used
- \(\lambda, \mu\) – edge labels of puzzle for northwest and north east side
- \(\nu\) – (default: None) If \(\nu\) is not specified a dictionary is returned with the structure coefficients corresponding to all south labels; if \(\nu\) is given, only the coefficients with the specified label is returned.

**OUTPUT:** dictionary

**EXAMPLES:**

Note: In order to standardize the output of the following examples, we output a sorted list of items from the dictionary instead of the dictionary itself.

**Grassmannian cohomology:**

```sage
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: cp = ps.structure_constants('0101', '0101')
sage: sorted(cp.items(), key=str)
[(('0', '1', '1', '0'), 1), (('1', '0', '0', '1'), 1)]
sage: ps.structure_constants('001001', '001010', '010100')
1
```

**Equivariant cohomology:**

```sage
sage: ps = KnutsonTaoPuzzleSolver('HT')
sage: cp = ps.structure_constants('0101', '0101')
sage: sorted(cp.items(), key=str)
[(('0', '1', '0', '1'), y2 - y3),
 (('0', '1', '1', '0'), 1),
 (('1', '0', '0', '1'), 1),
 (('1', '0', '0', '1'), 1))
```

**K-theory:**

```sage
sage: ps = KnutsonTaoPuzzleSolver('K')
sage: cp = ps.structure_constants('0101', '0101')
sage: sorted(cp.items(), key=str)
[(('0', '1', '1', '0'), 1), (('1', '0', '0', '1'), 1), (('1', '0', '1', '0'), -1),
 ('-1'))
```

**Two-step:**

```sage
sage: ps = KnutsonTaoPuzzleSolver('H2step')
sage: cp = ps.structure_constants('01122', '01122')
sage: sorted(cp.items(), key=str)
[(('0', '1', '1', '2', '2'), 1)]
sage: cp = ps.structure_constants('01201', '01021')
sage: sorted(cp.items(), key=str)
```

(continues on next page)
Two-step equivariant:

```python
sage: ps = KnutsonTaoPuzzleSolver('HT2step')
sage: cp = ps.structure_constants('10212', '12012')
sage: sorted(cp.items(), key=str)
```

```python
[(('1', '2', '0', '1', '2'), y1*y2 - y2*y3 - y1*y4 + y3*y4),
(('1', '2', '0', '2', '1'), y1 - y3),
(('1', '2', '1', '0', '2'), y2 - y4),
(('1', '2', '1', '2', '0'), 1),
(('1', '2', '2', '0', '1'), 1),
(('2', '1', '0', '1', '2'), y1 - y3),
(('2', '1', '1', '0', '2'), 1))
```

```python
class sage.combinat.knutson_tao_puzzles.NablaPiece(north, south_east, south_west)
Bases: sage.combinat.knutson_tao_puzzles.PuzzlePiece

Nabla Piece takes as input three labels, inputted as strings. They label the North, Southeast and Southwest edges, respectively.

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: NablaPiece('a','b','c')
c\a/b
```

```python
clockwise_rotation()
Rotates the Nabla piece by 120 degree clockwise.

OUTPUT:

• Nabla piece

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: nabla = NablaPiece('1','2','3')
sage: nabla.clockwise_rotation()
2\3/1
```

```python
depth()
Return the tuple of edge names.

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: nabla = NablaPiece('1','2','3')
sage: nabla.depth()
('north', 'south_east', 'south_west')
```

```python
half_turn_rotation()
Rotates the Nabla piece by 180 degree.

OUTPUT:

• Delta piece

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: nabla = NablaPiece('1','2','3')
sage: nabla.half_turn_rotation()
```
EXAMPLES:

```
from sage.combinat.knutson_tao_puzzles import NablaPiece
nabla = NablaPiece('1','2','3')
nabla.half_turn_rotation()
```

```python
class sage.combinat.knutson_tao_puzzles.PuzzleFilling(north_west_labels, north_east_labels)
Bases: object

Create partial puzzles and provides methods to build puzzles from them.

**add_piece** *(piece)*

Adds piece to partial puzzle.

EXAMPLES:

```
from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
piece = DeltaPiece('0','1','0')
P = PuzzleFilling('0101','0101'); P
P.add_piece(piece); P
```

**add_pieces** *(pieces)*

Adds piece to partial puzzle.

INPUT:

- **pieces** – tuple of pieces

EXAMPLES:

```
from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
P = PuzzleFilling('0101','0101'); P
piece = DeltaPiece('0','1','0')
pieces = [piece, piece]
P.add_pieces(pieces)
P
```

**contribution** *

Return equivariant contributions from self in polynomial ring.

EXAMPLES:

```
from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
ps = KnutsonTaoPuzzleSolver("HT")
puzzles = ps('0101','1001')
sorted([p.contribution() for p in puzzles], key=str)
```

**copy** *

Return copy of self.

EXAMPLES:
is_completed()
Whether partial puzzle is complete (completely filled) or not.

is_in_south_edge()
Checks whether kink coordinates of partial puzzle is in south corner.

kink_coordinates()
Provides the coordinates of the kinks.

north_east_label_of_kink()
Return north east label of kink.
sage: P.north_east_label_of_kink()
'0'

north_west_label_of_kink()
Return north-west label of kink.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101', '0101')
sage: P.north_west_label_of_kink()
'1'
```

plot (labels=True, style='fill')
Plots completed puzzle.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: puzzle = ps('0101', '1001')[0]
sage: puzzle.plot()  #not tested
sage: puzzle.plot(style='fill')  #not tested
sage: puzzle.plot(style='edges')  #not tested
```

south_labels()
Return south labels for completed puzzle.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: ps('0101', '1001')[0].south_labels()
('1', '0', '1', '0')
```

class sage.combinat.knutson_tao_puzzles.PuzzlePiece
Abstract class for puzzle pieces.

This abstract class contains information on how to test equality of puzzle pieces, and sets color and plotting options.

border()
Returns the border of self.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('a', 'b', 'c')
sage: delta.border()
('a', 'b', 'c')
```

color()
Returns the color of self.

EXAMPLES:
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('a','b','c')
sage: delta.color()
'white'
sage: delta = DeltaPiece('0','0','0')
sage: delta.color()
'red'
sage: delta = DeltaPiece('1','1','1')
sage: delta.color()
'blue'
sage: delta = DeltaPiece('2','2','2')
sage: delta.color()
'green'
sage: delta = DeltaPiece('2','K','2')
sage: delta.color()
'orange'
sage: delta = DeltaPiece('2','T1/2','2')
sage: delta.color()
'yellow'

edge_color(edge)
Color of the specified edge of self (to be used when plotting the piece).

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('1','0','10')
edge:  sage: delta.edge_color('south')
       'blue'
edge:  sage: delta.edge_color('north_west')
       'red'
edge:  sage: delta.edge_color('north_east')
       'white'

edge_label(edge)
Return the edge label of edge.

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('2','K','2')
edge:  sage: delta.edge_label('south')
       '2'
edge:  sage: delta.edge_label('north_west')
       'K'

class sage.combinat.knutson_tao_puzzles.PuzzlePieces(forbidden_border_labels=None)
Bases: object

Construct a valid set of puzzle pieces.

This class constructs the set of valid puzzle pieces. It can take a list of forbidden border labels as input. These labels are forbidden from appearing on the south edge of a puzzle filling. The user can add valid nabla or delta pieces and specify which rotations of these pieces are legal. For example, rotations=0 does not add any additional pieces (only the piece itself), rotations=60 adds six pieces (the pieces and its rotations by 60, 120, 180, 240, 300), etc.
EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, NablaPiece
sage: forbidden_border_labels = ['10']
sage: pieces = PuzzlePieces(forbidden_border_labels)
sage: pieces.add_piece(NablaPiece('0','0','0'), rotations=60)
sage: pieces.add_piece(NablaPiece('1','1','1'), rotations=60)
sage: pieces.add_piece(NablaPiece('1','0','10'), rotations=60)
sage: pieces
```

```
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

The user can obtain the list of valid rhombi pieces as follows:

```python
sage: sorted([p for p in pieces.rhombus_pieces()], key=str)
[0/\0 0\0/0, 0\0/0 1/\10, 0/\10 10/\0, 0/\10 1/\1, 1/\0 0\\1, 1/\1 10/\0, 1\1/1 1\1/1, 10/\1 0/\0, 10/\1 1\1/10]
```

`add_T_piece(label1, label2)`

Adds a nabla and delta piece with `label1` and `label2`.

This method adds a nabla piece with edges `label2`T``label1``|``label2`` / `label1`. and a delta piece with edges `label1`/ T``label1``\``label2`` label2`. It also adds T``label1``\``label2`` to the forbidden list.

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces
sage: pieces = PuzzlePieces()
sage: pieces.add_T_piece('1','3')
sage: pieces
```

```
Nablas : [3\T1|3/1]
Deltas : [1/T1\3/3]
```

`add_forbidden_label(label)`

Adds forbidden border labels.

**INPUT:**

- `label` – string specifying a new forbidden label

**EXAMPLES:**

```python
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces
sage: pieces = PuzzlePieces()
sage: pieces.add_forbidden_label('1')
sage: pieces._forbidden_border_labels
['1']
sage: pieces.add_forbidden_label('2')
sage: pieces._forbidden_border_labels
['1', '2']
```

`add_piece(piece, rotations=120)`

Adds `piece` to the list of pieces.

**INPUT:**

- `piece` – a nabla piece or a delta piece
The user can add valid nabla or delta pieces and specify which rotations of these pieces are legal. For example, \texttt{rotations=0} does not add any additional pieces (only the piece itself), \texttt{rotations=60} adds six pieces (namely three delta and three nabla pieces), while \texttt{rotations=120} adds only delta or nabla (depending on which piece \texttt{self} is). \texttt{rotations=180} adds the piece and its 180 degree rotation, i.e. one delta and one nabla piece.

\begin{Verbatim}
\texttt{sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece}
\texttt{sage: delta = DeltaPiece('a','b','c')}
\texttt{sage: pieces = PuzzlePieces()}
\texttt{sage: pieces.add_piece(delta)}
\texttt{sage: pieces}
\texttt{Nablas : [ ]}
\texttt{Deltas : [a/c\b, b/a\c, c/b\a]}
\texttt{sage: pieces = PuzzlePieces()}\texttt{\  (rotations=0)}
\texttt{sage: pieces.add_piece(delta)}
\texttt{sage: pieces}
\texttt{Nablas : [ ]}
\texttt{Deltas : [b/a\c]}
\end{Verbatim}

\begin{Verbatim}
\texttt{sage: pieces = PuzzlePieces()}
\texttt{sage: pieces.add_piece(delta, rotations=60)}
\texttt{sage: pieces}
\texttt{Nablas : [a/b/c, b\c/a, c\a/b]}
\texttt{Deltas : [a/c\b, b/a\c, c/b\a]}
\end{Verbatim}

\texttt{boundary_deltas()}

Returns deltas with south edges not in the forbidden list.

\begin{Verbatim}
\texttt{sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece}
\texttt{sage: pieces = PuzzlePieces(['a'])}
\texttt{sage: delta = DeltaPiece('a','b','c')}
\texttt{sage: pieces.add_piece(delta, rotations=60)}
\texttt{sage: sorted([p for p in pieces.boundary_deltas()], key=str)}
\texttt{[a/c\b, c/b\a]}
\end{Verbatim}

\texttt{delta_pieces()}

Returns the delta pieces as a set.

\begin{Verbatim}
\texttt{sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece}
\texttt{sage: pieces = PuzzlePieces()}
\texttt{sage: delta = DeltaPiece('a','b','c')}
\texttt{sage: pieces.add_piece(delta, rotations=60)}
\texttt{sage: sorted([p for p in pieces.delta_pieces()], key=str)}
\texttt{[a/c\b, b/a\c, c/b\a]}
\end{Verbatim}

\texttt{nabla_pieces()}

Returns the nabla pieces as a set.
EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
doctest: ran 2.
sage: pieces = PuzzlePieces()
sage: delta = DeltaPiece('a','b','c')
sage: pieces.add_piece(delta, rotations=60)
sage: sorted([p for p in pieces.nabla_pieces()], key=str)
[a\b/c, b\c/a, c\a/b]
```

```
rhombus_pieces()
Returns a list of all allowable rhombus pieces.
Allowable rhombus pieces are those where the south edge of the delta piece equals the north edge of the
nabla piece.
EXAMPLES:
```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
doctest: ran 2.
sage: pieces = PuzzlePieces()
sage: delta = DeltaPiece('a','b','c')
sage: pieces.add_piece(delta, rotations=60)
sage: sorted([p for p in pieces.rhombus_pieces()], key=str)
[a/b\a b/c\a, b/c\b, c/a\b]
```

```
class sage.combinat.knutson_tao_puzzles.RhombusPiece(north_piece, south_piece)
Bases: sage.combinat.knutson_tao_puzzles.PuzzlePiece
Class of rhombi pieces.
To construct a rhombus piece we input a delta and a nabla piece. The delta and nabla pieces are joined along the
south and north edge, respectively.
EXAMPLES:
```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,
doctest: ran 2.
    →RhombusPiece
sage: delta = DeltaPiece('1','2','3')
sage: nabla = NablaPiece('4','5','6')
sage: RhombusPiece(delta, nabla)
2/\3 6/\5
```

```
edges()
Return the tuple of edge names.
EXAMPLES:
```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,
doctest: ran 2.
    →RhombusPiece
sage: delta = DeltaPiece('1','2','3')
sage: nabla = NablaPiece('4','5','6')
sage: RhombusPiece(delta, nabla).edges()
('north_west', 'north_east', 'south_east', 'south_west')
```

```
north_piece()
Return the north piece.
EXAMPLES:
```
```
```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,
     RhombusPiece

sage: delta = DeltaPiece('1','2','3')
sage: nabla = NablaPiece('4','5','6')
sage: r = RhombusPiece(delta, nabla)
sage: r.north_piece()
2/1\3

sage: r.south_piece()
6\4/5
```

**south_piece()**

Return the south piece.

**EXAMPLES:**

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,
     RhombusPiece

sage: delta = DeltaPiece('1','2','3')
sage: nabla = NablaPiece('4','5','6')
sage: r = RhombusPiece(delta, nabla)
sage: r.south_piece()
```

---

5.1.135 Combinatorics on matrices

- Dancing Links internal pyx code
- Dancing links C++ wrapper
- Hadamard matrices
- Latin Squares

5.1.136 Combinatorics on matrix features that are imported by default in the interpreter namespace

5.1.137 Dancing Links internal pyx code

**EXAMPLES:**

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver

sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: x = dlx_solver(rows)
sage: x
Dancing links solver for 6 columns and 6 rows

sage: x.number_of_solutions()
3

sage: sorted(map(sorted, x.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

The number of solutions:

```
sage: x.number_of_solutions()
3
```

Iterate over the solutions:

```
sage: sorted(map(sorted, x.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```
All solutions (computed in parallel):

```
sage: sorted(map(sorted, x.all_solutions()))
[[0, 1], [2, 3], [4, 5]]
```

Return the first solution found when the computation is done in parallel:

```
sage: sorted(x.one_solution(ncpus=2)) # random
[0, 1]
```

Find all solutions using some specific rows:

```
sage: x_using_row_2 = x.restrict([2])
sage: x_using_row_2
Dancing links solver for 7 columns and 6 rows
sage: sorted(map(sorted, x_using_row_2.solutions_iterator()))
[[2, 3]]
```

The two basic methods that are wrapped in this class are `search` which returns 1 if a solution is found or 0 otherwise and `get_solution` which return the current solution:

```
sage: x = dlx_solver(rows)
sage: x.search()
1
sage: x.get_solution()
[0, 1]
sage: x.search()
1
sage: x.get_solution()
[2, 3]
sage: x.search()
1
sage: x.get_solution()
[4, 5]
sage: x.search()
0
```

There is also a method `reinitialize` to reinitialize the algorithm:

```
sage: x.reinitialize()
sage: x.search()
1
sage: x.get_solution()
[0, 1]
```

```class sage.combinat.matrices.dancing_links.dancing_linksWrapper
   Bases: object
   A simple class that implements dancing links.
   The main methods to list the solutions are `search()` and `get_solution()`. You can also use `number_of_solutions()` to count them.
   This class simply wraps a C++ implementation of Carlo Hamalainen.
   `all_solutions (ncpus=None, column=None)`
   Return all solutions found after splitting the problem to allow parallel computation.
   ```
• ncpus – integer (default: None), maximal number of subprocesses to use at the same time. If None, it detects the number of effective CPUs in the system using `sage.parallel.ncpus.ncpus()`.

• column – integer (default: None), the column used to split the problem, if None a random column is chosen.

OUTPUT:

list of solutions

EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: S = d.all_solutions()
sage: sorted(sorted(s) for s in S)
[[0, 1], [2, 3], [4, 5]]
```

The number of CPUs can be specified as input:

```python
sage: S = Subsets(range(4))
sage: rows = map(list, S)
sage: dlx = dlx_solver(rows)
sage: dlx
Dancing links solver for 4 columns and 16 rows
sage: dlx.number_of_solutions()
15
sage: sorted(sorted(s) for s in dlx.all_solutions(ncpus=2))
[[1, 2, 3, 4],
 [1, 2, 10],
 [1, 3, 9],
 [1, 4, 8],
 [1, 14],
 [2, 3, 7],
 [2, 4, 6],
 [2, 13],
 [3, 4, 5],
 [3, 12],
 [4, 11],
 [5, 10],
 [6, 9],
 [7, 8],
 [15]]
```

If ncpus=1, the computation is not done in parallel:

```python
sage: sorted(sorted(s) for s in dlx.all_solutions(ncpus=1))
[[1, 2, 3, 4],
 [1, 2, 10],
 [1, 3, 9],
 [1, 4, 8],
 [1, 14],
 [2, 3, 7],
 [2, 4, 6],
 [2, 13],
 [3, 4, 5],
 [3, 12],
 [4, 11],
 [5, 10],
 [6, 9],
 [7, 8],
 [15]]
```

(continues on next page)
get_solution()

Return the current solution.

After a new solution is found using the method search() this method return the rows that make up the current solution.

cols()

Return the number of columns.

EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [1,2], [0], [3,4,5]]
sage: dlx = dlx_solver(rows)
sage: dlx.ncols()
6
```
	nrows()

Return the number of rows.

EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [1,2], [0], [3,4,5]]
sage: dlx = dlx_solver(rows)
sage: dlx.nrows()
4
```

number_of_solutions(ncpus=None, column=None)

Return the number of distinct solutions.

INPUT:

- `ncpus` -- integer (default: None), maximal number of subprocesses to use at the same time. If `ncpus > 1` the dancing links problem is split into independent subproblems to allow parallel computation. If None, it detects the number of effective CPUs in the system using `sage.parallel.ncpus()`.

- `column` -- integer (default: None), the column used to split the problem, if None a random column is chosen (this argument is ignored if ncpu is 1)

OUTPUT:

integer

EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2]]
sage: rows += [[0,2]]
sage: rows += [[1]]
sage: rows += [[3]]
sage: x = dlx_solver(rows)
sage: x.number_of_solutions()
2
```
The number of CPUs can be specified as input:

```python
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: x = dlx_solver(rows)
sage: x.number_of_solutions(ncpus=2, column=3)
3
```

```python
sage: S = Subsets(range(5))
sage: rows = map(list, S)
sage: d = dlx_solver(rows)
sage: d.number_of_solutions()
52
```

### one_solution(ncpus=None, column=None)

Return the first solution found.

This method allows parallel computations which might be useful for some kind of problems when it is very hard just to find one solution.

**INPUT:**

- `ncpus` – integer (default: None), maximal number of subprocesses to use at the same time. If None, it detects the number of effective CPUs in the system using `sage.parallel.ncpus.ncpus()`. If ncpus=1, the first solution is searched serially.

- `column` – integer (default: None), the column used to split the problem (see `restrict()`). If None, a random column is chosen. This argument is ignored if ncpus=1.

**OUTPUT:**

list of rows or None if no solution is found

**Note:** For some case, increasing the number of cpus makes it faster. For other instances, ncpus=1 is faster. It all depends on problem which is considered.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: solutions = [[0,1], [2,3], [4,5]]
sage: sorted(d.one_solution()) in solutions
True
```

The number of CPUs can be specified as input:

```python
sage: sorted(d.one_solution(ncpus=2)) in solutions
True
```

The column used to split the problem for parallel computations can be given:

```python
sage: sorted(d.one_solution(ncpus=2, column=4)) in solutions
True
```

When no solution is found:
sage: rows = [[0,1,2], [2,3,4,5], [0,1,2,3]]
sage: d = dlx_solver(rows)
sage: d.one_solution() is None
True

one_solution_using_milp_solver(solver=None)

Return a solution found using a MILP solver.

INPUT:

• solver – string or None (default: None), possible values include 'GLPK', 'GLPK/exact', 'Coin', 'CPLEX', 'Gurobi', 'CVXOPT', 'PPL', 'InteractiveLP'.

OUTPUT:

list of rows or None if no solution is found

Note: When comparing the time taken by method one_solution, have in mind that one_solution_using_milp_solver first creates (and caches) the MILP solver instance from the dancing links solver. This copy of data may take many seconds depending on the size of the problem.

EXAMPLES:

Using optional solvers:

sage: s = d.one_solution_using_milp_solver('gurobi') # optional - gurobi sage_numerical_backends_gurobi
sage: s in solutions # optional - gurobi sage_numerical_backends_gurobi
True

When no solution is found:

sage: rows = [[0,1,2], [2,3,4,5], [0,1,2,3]]
sage: d = dlx_solver(rows)
sage: d.one_solution_using_milp_solver() is None
True

one_solution_using_sat_solver(solver=None)

Return a solution found using a SAT solver.

INPUT:

• solver – string or None (default: None), possible values include 'picosat', 'cryptominisat', 'LP', 'glucose', 'glucose-syrup'.

OUTPUT:

list of rows or None if no solution is found
Note: When comparing the time taken by method one_solution, have in mind that one_solution, sing,at,olver first creates the SAT solver instance from the dancing links solver. This copy of data may take many seconds depending on the size of the problem.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
dsage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
dsage: d = dlx_solver(rows)
dsage: solutions = [[0,1], [2,3], [4,5]]
dsage: d.one_solution_using_sat_solver() in solutions
True
```

Using optional solvers:

```
sage: s = d.one_solution_using_sat_solver('glucose') # optional - glucose
sage: s in solutions # optional - glucose
True
```

When no solution is found:

```
sage: rows = [[0,1,2], [2,3,4,5], [0,1,2,3]]
dsage: d = dlx_solver(rows)
dsage: d.one_solution_using_sat_solver() is None
True
```

reinitialize()

Reinitialization of the search algorithm

This recreates an empty dancing links object and adds the rows to the instance of dancing links.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
dsage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
dsage: x = dlx_solver(rows)
dsage: x.get_solution() if x.search() else None
[0, 1]
dsage: x.get_solution() if x.search() else None
[2, 3]
```

Reinitialization of the algorithm:

```
sage: x.reinitialize()
sage: x.get_solution() if x.search() else None
[0, 1]
sage: x.get_solution() if x.search() else None
[2, 3]
sage: x.get_solution() if x.search() else None
[4, 5]
sage: x.get_solution() if x.search() else None
```

Reinitialization works after solutions are exhausted:

```
sage: x.reinitialize()
sage: x.get_solution() if x.search() else None
```

(continues on next page)
**restrict (indices)**

Return a dancing links solver solving the subcase which uses some given rows.

For every row that is wanted in the solution, we add a new column to the row to make sure it is in the solution.

**INPUT:**

- `indices` – list, row indices to be found in the solution

**OUTPUT:**

dancing links solver

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: d
Dancing links solver for 6 columns and 6 rows
sage: sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

To impose that the 0th row is part of the solution, the rows of the new problem are:

```python
sage: d_using_0 = d.restrict([0])
sage: d_using_0
Dancing links solver for 7 columns and 6 rows
sage: d_using_0.rows()
[[0, 1, 2, 6], [3, 4, 5], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
```

After restriction the subproblem has one more columns and the same number of rows as the original one:

```python
sage: d.restrict([1]).rows()
[[0, 1, 2], [3, 4, 5, 6], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
sage: d.restrict([2]).rows()
[[0, 1, 2], [3, 4, 5], [0, 1, 6], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
```

This method allows to find solutions where the 0th row is part of a solution:

```python
sage: sorted(map(sorted, d.restrict([0]).solutions_iterator()))
[[0, 1]]
```

Some other examples:

```python
sage: sorted(map(sorted, d.restrict([1]).solutions_iterator()))
[[0, 1]]
sage: sorted(map(sorted, d.restrict([2]).solutions_iterator()))
[[2, 3]]
sage: sorted(map(sorted, d.restrict([3]).solutions_iterator()))
[[2, 3]]
```
Here there are no solution using both 0th and 3rd row:

```
sage: list(d.restrict([0,3]).solutions_iterator())
[]
```

**rows()**

Return the list of rows.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [1,2], [0]]
sage: x = dlx_solver(rows)
sage: x.rows()
[[0, 1, 2], [1, 2], [0]]
```

**search()**

Search for a new solution.

Return 1 if a new solution is found and 0 otherwise. To recover the solution, use the method `get_solution()`.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2]]
sage: rows+= [[0,2]]
sage: rows+= [[1]]
sage: rows+= [[3]]
sage: x = dlx_solver(rows)
sage: print(x.search())
1
sage: print(x.get_solution())
[3, 0]
```

**solutions_iterator()**

Return an iterator of the solutions.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

**split(column)**

Return a dict of independent solvers.

For each i-th row containing a 1 in the column, the dict associates the solver giving all solution using the i-th row.

This is used for parallel computations.

INPUT:

- column – integer, the column used to split the problem into independent subproblems

OUTPUT:

dict where keys are row numbers and values are dlx solvers
EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: d
Dancing links solver for 6 columns and 6 rows
sage: sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

After the split each subproblem has one more column and the same number of rows as the original problem:

```python
sage: D = d.split(0)
sage: D
{0: Dancing links solver for 7 columns and 6 rows,
2: Dancing links solver for 7 columns and 6 rows,
4: Dancing links solver for 7 columns and 6 rows}
```

The (disjoint) union of the solutions of the subproblems is equal to the set of solutions shown above:

```python
sage: for x in D.values(): sorted(map(sorted, x.solutions_iterator()))
[[0, 1]]
[[2, 3]]
[[4, 5]]
```

**to_milp**(solver=None)

Return the mixed integer linear program (MILP) representing an equivalent problem.

See also sage.numerical.mip.MixedIntegerLinearProgram.

**INPUT:**

- solver - string or None (default: None), possible values include 'GLPK', 'GLPK/exact', 'Coin', 'CPLEX', 'Gurobi', 'CVXOPT', 'PPL', 'InteractiveLP'.

**OUTPUT:**

- MixedIntegerLinearProgram instance
- MIPVariable of dimension 1

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [0,2], [1], [3]]
sage: d = dlx_solver(rows)
sage: p,x = d.to_milp()
sage: p
Boolean Program (no objective, 4 variables, 4 constraints)
```

In the reduction, the boolean variable \( x_i \) is True if and only if the \( i \)-th row is in the solution:

```python
sage: p.show()
Maximization:
Constraints:
  one 1 in 0-th column: 1.0 <= x_0 + x_1 <= 1.0
```
one 1 in 1-th column: 1.0 <= x_0 + x_2 <= 1.0
one 1 in 2-th column: 1.0 <= x_0 + x_1 <= 1.0
one 1 in 3-th column: 1.0 <= x_3 <= 1.0

Variables:
\( x_0 \) is a boolean variable (min=0.0, max=1.0)
\( x_1 \) is a boolean variable (min=0.0, max=1.0)
\( x_2 \) is a boolean variable (min=0.0, max=1.0)
\( x_3 \) is a boolean variable (min=0.0, max=1.0)

Using some optional MILP solvers:

```python
sage: d.to_milp('gurobi')  # optional - gurobi sage_numerical_backends_gurobi
(Boolean Program (no objective, 4 variables, 4 constraints),
MIPVariable of dimension 1)
```

`to_sat_solver` *(solver=None)*

Return the SAT solver solving an equivalent problem.

Note that row index \( i \) in the dancing links solver corresponds to the boolean variable index \( i + 1 \) for the SAT solver to avoid the variable index 0.

See also `sage.sat.solvers.satsolver`.

**INPUT:**

* solver – string or None (default: None), possible values include 'picosat', 'cryptominisat', 'LP', 'glucose', 'glucose-syrup'.

**OUTPUT:**

SAT solver instance

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [0,2], [1], [3]]
sage: x = dlx_solver(rows)
sage: s = x.to_sat_solver()
```

Using some optional SAT solvers:

```python
sage: x.to_sat_solver('cryptominisat')  # optional - cryptominisat
CryptoMiniSat solver: 4 variables, 7 clauses.
```

`sage.combinat.matrices.dancing_links.dlx_solver(rows)`

Internal-use wrapper for the dancing links C++ code.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2]]
sage: rows+= [[0,2]]
sage: rows+= [[1]]
sage: rows+= [[3]]
sage: x = dlx_solver(rows)
sage: print(x.search())
1
sage: print(x.get_solution())
[3, 0]
```
sage: print(x.search())
1
sage: print(x.get_solution())
[3, 1, 2]
sage: print(x.search())
0

sage.combinat.matrices.dancing_links.make_dlxwrapper(s)
Create a dlx wrapper from a Python string s.
This was historically used in unpickling and is kept for backwards compatibility. We expect s to be
dumps(rows) where rows is the list of rows used to instantiate the object.

5.1.138 Dancing links C++ wrapper

sage.combinat.matrices.dlxcpp.AllExactCovers(M)
Solves the exact cover problem on the matrix M (treated as a dense binary matrix).

EXAMPLES: No exact covers:

sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]])
sage: [cover for cover in AllExactCovers(M)]
[]

Two exact covers:

sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]])
sage: [cover for cover in AllExactCovers(M)]
[[[1, 1, 0), (0, 0, 1)], [(1, 0, 1), (0, 1, 0)]]

sage.combinat.matrices.dlxcpp.DLXCPP(rows)
Solves the Exact Cover problem by using the Dancing Links algorithm described by Knuth.

Consider a matrix M with entries of 0 and 1, and compute a subset of the rows of this matrix which sum to the
vector of all 1’s.

The dancing links algorithm works particularly well for sparse matrices, so the input is a list of lists of the form:

```python
[
  [i_11,i_12,...,i_1r]
  ...
  [i_m1,i_m2,...,i_ms]
]
```

where M[j][i_jk] = 1.

The first example below corresponds to the matrix:

```
1110
1010
0100
0001
```

which is exactly covered by:

```
1110
0001
```
If soln is a solution given by DLXCPP(rows) then
\[ \text{[ rows[soln[0]], rows[soln[1]], \ldots \ rows[soln[len(soln)-1]] ]} \]
is an exact cover.

Solutions are given as a list.

EXAMPLES:

```
sage: rows = [[0,1,2]]
sage: rows+= [[0,2]]
sage: rows+= [[1]]
sage: rows+= [[3]]
sage: [x for x in DLXCPP(rows)]
[[3, 0], [3, 1, 2]]
```

```
sage.combinat.matrices.dlxcpp.OneExactCover(M)
Solves the exact cover problem on the matrix M (treated as a dense binary matrix).

EXAMPLES:

```
sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]]) #no exact covers
sage: print(OneExactCover(M))
None
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]]) #two exact covers
sage: OneExactCover(M)
[(1, 1, 0), (0, 0, 1)]
```

### 5.1.139 Hadamard matrices

A Hadamard matrix is an \( n \times n \) matrix \( H \) whose entries are either +1 or -1 and whose rows are mutually orthogonal. For example, the matrix \( H_2 \) defined by

\[
\begin{pmatrix}
1 & 1 \\
1 & -1
\end{pmatrix}
\]

is a Hadamard matrix. An \( n \times n \) matrix \( H \) whose entries are either +1 or -1 is a Hadamard matrix if and only if:

(a) \(|\text{det}(H)| = n^{n/2}\) or

(b) \(H \ast H^t = n \cdot I_n\), where \(I_n\) is the identity matrix.

In general, the tensor product of an \( m \times m \) Hadamard matrix and an \( n \times n \) Hadamard matrix is an \((mn) \times (mn)\) matrix. In particular, if there is an \( n \times n \) Hadamard matrix then there is a \((2n) \times (2n)\) Hadamard matrix (since one may tensor with \(H_2\)). This particular case is sometimes called the Sylvester construction.

The Hadamard conjecture (possibly due to Paley) states that a Hadamard matrix of order \( n \) exists if and only if \( n = 1, 2 \) or \( n \) is a multiple of 4.

The module below implements the Paley constructions (see for example \([\text{Hora}]\)) and the Sylvester construction. It also allows you to pull a Hadamard matrix from the database at \([\text{HadaSloa}]\).

AUTHORS:
REFERENCES:
sage.combinat.matrices.hadamard_matrix.GS_skew_hadamard_smallcases(n, existence=False, check=True)

Data for Williamson-Goethals-Seidel construction of skew Hadamard matrices

Here we keep the data for this construction. Namely, it needs 4 circulant matrices with extra properties, as described in sage.combinat.matrices.hadamard_matrix.williamson_goethals_seidel_skew_hadamard_matrix() Matrices for \( n = 36 \) and 52 are given in [GS70s]. Matrices for \( n = 92 \) are given in [Wall71].

INPUT:
- \( n \) – the order of the matrix
- existence – if true (default), only check that we can do the construction
- check – if true (default), check the result.

sage.combinat.matrices.hadamard_matrix.RSHCD_324(\( e \))

Return a size 324x324 Regular Symmetric Hadamard Matrix with Constant Diagonal.

We build the matrix \( M \) for the case \( n = 324, \epsilon = 1 \) directly from JankoKharaghaniTonchevGraph and for the case \( \epsilon = -1 \) from the “twist” \( M' \) of \( M \), using Lemma 11 in [HX10]. Namely, it turns out that the matrix

\[
M' = \begin{pmatrix}
   M_{12} & M_{11} \\
   M_{11}^T & M_{21}
\end{pmatrix}, \quad \text{where} \quad M = \begin{pmatrix}
   M_{11} & M_{12} \\
   M_{21} & M_{22}
\end{pmatrix},
\]

and the \( M_{ij} \) are 162x162-blocks, also RSHCD, its diagonal blocks having zero row sums, as needed by [loc.cit.]. Interestingly, the corresponding \((324, 152, 70, 72)\)-strongly regular graph has a vertex-transitive automorphism group of order 2592, twice the order of the (intransitive) automorphism group of the graph corresponding to \( M \). Cf. [CP16].

INPUT:
- \( e \) – one of \(-1\) or \(+1\), equal to the value of \( \epsilon \)

REFERENCE:
sage.combinat.matrices.hadamard_matrix.hadamard_matrix(n, existence=False, check=True)

This function is available as hadamard_matrix(...) and matrix.hadamard(...).

Tries to construct a Hadamard matrix using a combination of Paley and Sylvester constructions.

INPUT:
- \( n \) (integer) – dimension of the matrix
- existence (boolean) – whether to build the matrix or merely query if a construction is available in Sage. When set to True, the function returns:
  - True – meaning that Sage knows how to build the matrix
  - Unknown – meaning that Sage does not know how to build the matrix, although the matrix may exist (see sage.misc.unknown).
  - False – meaning that the matrix does not exist.
- check (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.
EXAMPLES:

```python
sage: hadamard_matrix(12).det()
2985984
sage: 12^6
2985984
sage: hadamard_matrix(1)
[1]
sage: hadamard_matrix(2)
[ 1 1]
[ 1 -1]
sage: hadamard_matrix(8) # random
[ 1 1 1 1 1 1 1 1]
[ 1 -1 -1 -1 -1 -1 -1 -1]
[ 1 -1 1 1 -1 -1 1 1]
[ 1 1 -1 1 -1 1 -1 1]
[ 1 -1 1 1 1 1 -1 -1]
[ 1 1 -1 -1 1 -1 1 1]
[ 1 1 1 -1 -1 1 1 1]
[ 1 -1 -1 1 1 1 -1 -1]
sage: hadamard_matrix(8).det() == 8^4
True
```

We note that `hadamard_matrix()` returns a normalised Hadamard matrix (the entries in the first row and column are all +1)

```python
sage: hadamard_matrix(12) # random
[ 1 1 1 1 1 1 1 1]
[ 1 -1 1 -1 1 -1 1 -1]
[ 1 -1 -1 1 1 -1 1 -1]
[ 1 1 1 1 -1 -1 -1 -1]
[ 1 -1 1 -1 1 1 -1 1]
[ 1 1 -1 1 -1 1 1 1]
[ 1 -1 -1 -1 1 1 1 1]
[ 1 -1 -1 -1 -1 -1 -1 -1]
[ 1 1 1 1 -1 -1 -1 -1]
[ 1 -1 1 1 1 1 -1 -1]
[ 1 1 1 -1 -1 1 1 1]
[ 1 -1 -1 1 1 1 -1 -1]
```

We note that `hadamard_matrix()` returns a normalised Hadamard matrix (the entries in the first row and column are all +1)

```python
sage: hadamard_matrix(12) # random
[ 1 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1]
[ 1 -1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1]
[-----------------------------------------------]
[ 1 -1| 1 -1| 1 | 1 -1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1]
[ 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1]
[-----------------------------------------------]
[ 1 | 1 | 1 -1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1| 1 -1]
[-----------------------------------------------]
[ 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1]
[-----------------------------------------------]
[ 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1]
[-----------------------------------------------]
[ 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1]
[-----------------------------------------------]
[ 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1]
```

sage.combinat.matrices.hadamard_matrix.hadamard_matrix_paleyI(n, normalize=True)

Implement the Paley type I construction.

The Paley type I case corresponds to the case $p \equiv 3 \mod 4$ for a prime $p$ (see [Hora]).

INPUT:

- $n$ – the matrix size
- `normalize` (boolean) – whether to normalize the result.

EXAMPLES:

We note that this method by default returns a normalised Hadamard matrix
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_paleyI
sage: hadamard_matrix_paleyI(4)
[ 1 1 1 1]
[ 1 -1 1 -1]
[ 1 -1 -1 1]
[ 1 1 -1 -1]

Otherwise, it returns a skew Hadamard matrix $H$, i.e. $H = S + I$, with $S = -S^T$

sage: M=hadamard_matrix_paleyI(4, normalize=False); M
[ 1 1 1 1]
[-1 1 1 -1]
[-1 -1 1 1]
[-1 1 -1 1]

sage: S=M-identity_matrix(4); -S==S.T
True

sage.combinat.matrices.hadamard_matrix.hadamard_matrix_paleyII($n$)
Implement the Paley type II construction.

The Paley type II case corresponds to the case $p \equiv 1 \mod 4$ for a prime $p$ (see [Hora]).

EXAMPLES:

sage: sage.combinat.matrices.hadamard_matrix.hadamard_matrix_paleyII(12).det()
2985984

sage: 12^6
2985984

We note that the method returns a normalised Hadamard matrix

sage: sage.combinat.matrices.hadamard_matrix.hadamard_matrix_paleyII(12)

sage.combinat.matrices.hadamard_matrix.hadamard_matrix_www($url_file$, comments=False)
Pull file from Sloane’s database and return the corresponding Hadamard matrix as a Sage matrix.

You must input a filename of the form “had.n.xxx.txt” as described on the webpage http://neilsloane.com/hadamard/, where “xxx” could be empty or a number of some characters.

If comments=True then the “Automorphism…” line of the had.n.xxx.txt file is printed if it exists. Otherwise nothing is done.
EXAMPLES:

```python
sage: hadamard_matrix_www("had.4.txt")  # optional - internet
[ 1  1  1  1
 [ 1 -1  1 -1
 [ 1  1 -1 -1
 [ 1 -1 -1  1

sage: hadamard_matrix_www("had.16.2.txt", comments=True)  # optional - internet
Automorphism group has order = 49152 = 2^14 * 3

[ 1  1  1  1  1  1  1  1  1  1  1  1  1  1  1  1
 [ 1 -1  1 -1  1 -1  1 -1  1 -1  1 -1  1 -1  1 -1
 [ 1  1  1 -1 -1 -1  1  1  1  1 -1 -1 -1 -1 -1 -1
 [ 1 -1 -1 -1  1 -1  1 -1  1 -1  1 -1  1 -1  1 -1
 [ 1  1 -1 -1  1 -1  1 -1  1 -1  1 -1  1 -1  1 -1
 [ 1 -1  1 -1  1 -1  1 -1  1 -1  1 -1  1 -1  1 -1
 [ 1  1  1  1 -1 -1 -1 -1  1  1 -1 -1 -1 -1 -1 -1
 [ 1  1 -1  1 -1  1 -1  1 -1  1 -1  1 -1  1 -1  1
 [ 1  1 -1  1 -1  1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1
 [ 1  1  1  1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1
 [ 1  1  1  1  1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1
 [ 1 -1 -1  1 -1  1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1
 [ 1 -1 -1  1 -1  1 -1  1 -1  1 -1  1 -1  1 -1  1
 [ 1 -1 -1  1 -1  1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1
 [ 1  1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1

sage.combinat.matrices.hadamard_matrix.is_hadamard_matrix(M, normalized=False, skew=False, verbose=False)

Test if $M$ is a hadamard matrix.

INPUT:

- $M$ – a matrix
- normalized (boolean) – whether to test if $M$ is a normalized Hadamard matrix, i.e. has its first row/column filled with +1.
- skew (boolean) – whether to test if $M$ is a skew Hadamard matrix, i.e. $M = S + I$ for $-S = S^T$, and $I$ the identity matrix.
- verbose (boolean) – whether to be verbose when the matrix is not Hadamard.

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import is_hadamard_matrix
sage: h = matrix.hadamard(12)
True
sage: h = skew_hadamard_matrix(12)
True
sage: h = matrix.hadamard(12, skew=True)
True
sage: h[0,0] = 2

The matrix does not only contain +1 and -1 entries, e.g. 2

False
sage: h = matrix.hadamard(12)
```
....:  h[i, 2] = -h[i, 2]
sage: is_hadamard_matrix(h, verbose=True, normalized=True)
The matrix is not normalized
False

sage.combinat.matrices.hadamard_matrix.normalise_hadamard(H)
Return the normalised Hadamard matrix corresponding to H.

The normalised Hadamard matrix corresponding to a Hadamard matrix $H$ is a matrix whose every entry in the first row and column is +1.

EXAMPLES:

sage: from sage.combinat.matrices.hadamard_matrix import normalise_hadamard
sage: H = normalise_hadamard(hadamard_matrix(4))
sage: H == hadamard_matrix(4)
True

sage.combinat.matrices.hadamard_matrix.regular_symmetric_hadamard_matrix_with_constant_diagonal(n, e, existence=False)
Return a Regular Symmetric Hadamard Matrix with Constant Diagonal.

A Hadamard matrix is said to be regular if its rows all sum to the same value.

For $\epsilon \in \{-1, +1\}$, we say that $M$ is a $(n, \epsilon) - RSHCD$ if $M$ is a regular symmetric Hadamard matrix with constant diagonal $\delta \in \{-1, +1\}$ and row sums all equal to $\delta \epsilon \sqrt{n}$. For more information, see [HX10] or 10.5.1 in [BH12]. For the case $n = 324$, see $RSHCD_{324}$ and [CP16].

INPUT:

- $n$ (integer) – side of the matrix
- $e$ – one of $-1$ or $+1$, equal to the value of $\epsilon$

EXAMPLES:

sage: from sage.combinat.matrices.hadamard_matrix import regular_symmetric_hadamard_matrix_with_constant_diagonal
sage: regular_symmetric_hadamard_matrix_with_constant_diagonal(4, 1)
[ 1 1 1 -1]
[ 1 1 -1 1]
[ 1 -1 1 1]
[-1 1 1 -1]
sage: regular_symmetric_hadamard_matrix_with_constant_diagonal(4, -1)
[ 1 -1 -1 -1]
[-1 1 -1 -1]
[-1 -1 1 -1]
[-1 -1 -1 1]

Other hardcoded values:

sage: for n, e in [(36,1), (36,-1), (100,1), (100,-1), (196,1)]:
    # long time
    ....:  print(repr(regular_symmetric_hadamard_matrix_with_constant_diagonal(n, e)))
36 x 36 dense matrix over Integer Ring
36 x 36 dense matrix over Integer Ring
36 x 36 dense matrix over Integer Ring
36 x 36 dense matrix over Integer Ring
36 x 36 dense matrix over Integer Ring
(continues on next page)
100 x 100 dense matrix over Integer Ring
100 x 100 dense matrix over Integer Ring
196 x 196 dense matrix over Integer Ring

```sage```
for n, e in [(324, 1), (324, -1)]: # not tested - long time, tested in RSHCD_324
    print(repr(regular_symmetric_hadamard_matrix_with_constant_diagonal(n, e)))
```

324 x 324 dense matrix over Integer Ring
324 x 324 dense matrix over Integer Ring

From two close prime powers:

```sage```
regular_symmetric_hadamard_matrix_with_constant_diagonal(64, -1)
```
64 x 64 dense matrix over Integer Ring (use the '.str()' method to see the entries)

From a prime power and a conference matrix:

```sage```
regular_symmetric_hadamard_matrix_with_constant_diagonal(676, 1)  # long time
```
676 x 676 dense matrix over Integer Ring (use the '.str()' method to see the entries)

Recursive construction:

```sage```
regular_symmetric_hadamard_matrix_with_constant_diagonal(144, -1)
```
144 x 144 dense matrix over Integer Ring (use the '.str()' method to see the entries)

REFERENCE:

sage.combinat.matrices.hadamard_matrix.rshcd_from_close_prime_powers(n)
Return a \((n^2, 1)\)-RSHCD when \(n - 1\) and \(n + 1\) are odd prime powers and \(n \equiv 0 \pmod{4}\).

The construction implemented here appears in Theorem 4.3 from [GS1970].

Note that the authors of [SWW72] claim in Corollary 5.12 (page 342) to have proved the same result without the \(n \equiv 0 \pmod{4}\) restriction with a very similar construction. So far, however, I (Nathann Cohen) have not been able to make it work.

INPUT:

- n – an integer congruent to 0 (mod 4)

See also:

regular_symmetric_hadamard_matrix_with_constant_diagonal()

EXAMPLES:

```sage```
from sage.combinat.matrices.hadamard_matrix import rshcd_from_close_prime_powers
```
```
([-1 -1 1 -1 1 -1 -1 1 -1 1 -1 1 -1 1 -1 1 -1]
 [-1 -1 -1 1 1 -1 -1 1 -1 -1 1 -1 -1 1 1 -1]
 [ 1 1 1 -1 1 -1 -1 -1 1 -1 -1 1 -1 -1 -1 1]
 [ 1 1 1 -1 -1 1 -1 -1 -1 1 -1 -1 1 -1 -1 -1]
 [-1 -1 1 1 -1 -1 1 -1 -1 1 -1 -1 1 -1 -1 -1]
 [-1 -1 -1 1 -1 -1 1 -1 -1 1 -1 -1 1 -1 -1 -1]
 [ 1 1 1 -1 -1 1 -1 -1 -1 1 -1 -1 1 -1 -1 -1]
 [-1 -1 1 1 -1 -1 1 -1 -1 1 -1 -1 1 -1 -1 -1]
 [-1 -1 1 -1 -1 1 -1 -1 1 -1 -1 1 -1 -1 -1 -1]
 [-1 -1 1 -1 -1 1 -1 -1 1 -1 -1 1 -1 -1 -1 -1])
```

(continues on next page)

(continued from previous page)

\[
\begin{bmatrix}
 1 & 1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 & 1 & -1 & -1 & -1 & 1 & 1 & 1 \\
-1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 & 1 & -1 & -1 & -1 & 1 & 1 & 1 \\
1 & -1 & -1 & -1 & -1 & 1 & -1 & 1 -1 & -1 & 1 & 1 & 1 -1 & 1 & 1 & 1 \\
-1 & 1 & -1 & -1 & 1 & -1 & 1 -1 & 1 -1 & 1 & 1 & -1 & -1 & 1 & 1 & 1 \\
-1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & 1 & 1 & -1 & 1 & 1 & 1 & 1 \\
1 & -1 & 1 & -1 & 1 & 1 & -1 & 1 -1 & -1 & 1 & -1 & -1 & -1 & -1 & -1 & -1 \\
-1 & 1 & -1 & 1 & -1 & 1 & 1 & -1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 & -1 & -1 \\
1 & -1 & 1 & -1 & 1 & 1 & -1 & 1 -1 & -1 & 1 & -1 & -1 & -1 & -1 & -1 & -1 \\
-1 & 1 & -1 & 1 & 1 & 1 & -1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 \\
-1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 \\
\end{bmatrix}
\]

REFERENCE:
sage.combinat.matrices.hadamard_matrix.rshcd_from_prime_power_and_conference_matrix(n)

Return a \((n - 1)^2, 1)\)-RSHCD if \(n\) is prime power, and symmetric \((n - 1)\)-conference matrix exists

The construction implemented here is Theorem 16 (and Corollary 17) from [WW72].

In [SWW72] this construction (Theorem 5.15 and Corollary 5.16) is reproduced with a typo. Note that [WW72] refers to [Sz69] for the construction, provided by `szekeres_difference_set_pair()`, of complementary difference sets, and the latter has a typo.

From a `symmetric_conference_matrix()`, we only need the Seidel adjacency matrix of the underlying strongly regular conference (i.e. Paley type) graph, which we construct directly.

INPUT:

\* \(n\) – an integer

See also:

`regular_symmetric_hadamard_matrix_with_constant_diagonal()`

EXAMPLES:

A 36x36 example

```python
sage: from sage.combinat.matrices.hadamard_matrix import rshcd_from_prime_power_and_conference_matrix
sage: from sage.combinat.matrices.hadamard_matrix import is_hadamard_matrix
sage: H = rshcd_from_prime_power_and_conference_matrix(7); H
36 x 36 dense matrix over Integer Ring (use the '.str()' method to see the entries)
sage: H == H.T and is_hadamard_matrix(H) and H.diagonal()==[1]*36 and list(sum(H))==[6]*36
True
```

Bigger examples, only provided by this construction

```python
sage: H = rshcd_from_prime_power_and_conference_matrix(27)  # long time
sage: H == H.T and is_hadamard_matrix(H)  # long time
True
sage: H.diagonal()==[1]*676 and list(sum(H))==[26]*676  # long time
True
```

In this example the conference matrix is not Paley, as 45 is not a prime power

```python
sage: H = rshcd_from_prime_power_and_conference_matrix(47)  # not tested (long time)
```

REFERENCE:

5.1. Comprehensive Module list 1241
sage.combinat.matrices.hadamard_matrix.skew_hadamard_matrix(n, existence=False, skew_normalize=True, check=True)

Tries to construct a skew Hadamard matrix

A Hadamard matrix $H$ is called skew if $H = S - I$, for $I$ the identity matrix and $-S = S^T$. Currently constructions from Section 14.1 of [Ha83] and few more exotic ones are implemented.

INPUT:

- $n$ (integer) – dimension of the matrix
- existence (boolean) – whether to build the matrix or merely query if a construction is available in Sage. When set to True, the function returns:
  - True – meaning that Sage knows how to build the matrix
  - Unknown – meaning that Sage does not know how to build the matrix, but that the design may exist (see sage.misc.unknown).
  - False – meaning that the matrix does not exist.
- skew_normalize (boolean) – whether to make the 1st row all-one, and adjust the 1st column accordingly. Set to True by default.
- check (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix
sage: skew_hadamard_matrix(12).det()
2985984
sage: 12^6
2985984
sage: skew_hadamard_matrix(1)
[1]
sage: skew_hadamard_matrix(2)
[ 1  1]
[-1  1]
```

REFERENCES:

sage.combinat.matrices.hadamard_matrix.symmetric_conference_matrix(n, check=True)

Tries to construct a symmetric conference matrix

A conference matrix is an $n \times n$ matrix $C$ with 0s on the main diagonal and 1s and -1s elsewhere, satisfying $CC^T = (n-1)I$. If $C = C^T$ then $n \equiv 2 \mod 4$ and $C$ is Seidel adjacency matrix of a graph, whose descendent graphs are strongly regular graphs with parameters $(n-1, (n-2)/2, (n-6)/4, (n-2)/4)$, see Sec.10.4 of [BH12]. Thus we build $C$ from the Seidel adjacency matrix of the latter by adding row and column of 1s.

INPUT:

- $n$ (integer) – dimension of the matrix
- check (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

EXAMPLES:
sage: from sage.combinat.matrices.hadamard_matrix import symmetric_conference_matrix
sage: C=symmetric_conference_matrix(10); C
[ 0 1 1 1 1 1 1 1 1 1]
[ 1 0 -1 -1 1 -1 1 1 1 -1]
[ 1 -1 0 -1 1 1 -1 -1 1 1]
[ 1 -1 0 -1 1 1 -1 -1 1 1]
[ 1 1 1 -1 0 -1 1 1 1 -1]
[ 1 -1 1 1 -1 0 -1 1 1 -1]
[ 1 1 -1 -1 0 -1 1 1 1 -1]
[ 1 1 -1 -1 0 -1 1 1 1 -1]
[ 1 1 1 -1 0 -1 1 1 1 -1]
[ 1 -1 1 1 -1 0 -1 1 1 -1]
sage: C^2==9*identity_matrix(10) and C==C.T
True

sage.combinat.matrices.hadamard_matrix.szekeres_difference_set_pair(m, check=True)

Construct Szekeres \((2m + 1, m, 1)\)-cyclic difference family

Let \(4m + 3\) be a prime power. Theorem 3 in \([Sz69]\) contains a construction of a pair of complementary difference sets \(A, B\) in the subgroup \(G\) of the quadratic residues in \(F_{4m+3}^\times\). Namely \(|A| = |B| = m, a \in A\) whenever \(a - 1 \in G, b \in B\) whenever \(b + 1 \in G\). See also Theorem 2.6 in \([SWW72]\) (there the formula for \(B\) is correct, as opposed to (4.2) in \([Sz69]\), where the sign before 1 is wrong.

In modern terminology, for \(m > 1\) the sets \(A\) and \(B\) form a difference family with parameters \((2m + 1, m, 1)\). I.e. each non-identity \(g \in G\) can be expressed uniquely as \(xy^{-1}\) for \(x, y \in A\) or \(x, y \in B\). Other, specific to this construction, properties of \(A\) and \(B\) are: for \(a \in A\) one has \(a^{-1}\) not in \(A\), whereas for \(b \in B\) one has \(b^{-1}\) in \(B\).

INPUT:

- \(m\) (integer) – dimension of the matrix
- \(check\) (default: True) – whether to check \(A\) and \(B\) for correctness

EXAMPLES:

```sage
def szekeres_difference_set_pair(m, check=True):
    from sage.combinat.matrices.hadamard_matrix import symmetric_conference_matrix
    C = symmetric_conference_matrix(10)
    G, A, B = szekeres_difference_set_pair(6)
    typeI_matrix_difference_set(G, A)
```

REFERENCE:

sage.combinat.matrices.hadamard_matrix.typeI_matrix_difference_set(G, A)

\((1, -1)\)-incidence type I matrix of a difference set \(A\) in \(G\)

Let \(A\) be a difference set in a group \(G\) of order \(n\). Return \(n \times n\) matrix \(M\) with \(M_{ij} = 1\) if \(A_iA_j^{-1} \in A\), and \(M_{ij} = -1\) otherwise.

EXAMPLES:

```sage
def typeI_matrix_difference_set(G, A):
    return A * A^(-1) - I
```

(continues on next page)
Williamson-Goethals-Seidel construction of a skew Hadamard matrix

Given \( n \times n \) (anti)circulant matrices \( A, B, C, D \) with 1,-1 entries, and satisfying \( A + A^\top = 2I \), \( AA^\top + BB^\top + CC^\top + DD^\top = 4nI \), one can construct a skew Hadamard matrix of order \( 4n \), cf. [GS70s].

INPUT:
- \( a \) – 1,-1 list specifying the 1st row of \( A \)
- \( b \) – 1,-1 list specifying the 1st row of \( B \)
- \( c \) – 1,-1 list specifying the 1st row of \( C \)
- \( d \) – 1,-1 list specifying the 1st row of \( D \)

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import williamson_goethals_seidel_skew_hadamard_matrix as WGS
sage: a=[ 1, 1, 1, -1, 1, -1, 1, -1, -1]
sage: b=[ 1, -1, 1, 1, -1, -1, 1, 1, -1]
sage: c=[-1, -1]+[1]*6+[1]
sage: d=[ 1, 1, 1, -1, 1, 1, -1, 1, 1]
sage: M=WGS(a,b,c,d,check=True)
```

REFERENCES:

5.1.140 Latin Squares

A latin square of order \( n \) is an \( n \times n \) array such that each symbol \( s \in \{0, 1, \ldots, n-1\} \) appears precisely once in each row, and precisely once in each column. A partial latin square of order \( n \) is an \( n \times n \) array such that each symbol \( s \in \{0, 1, \ldots, n-1\} \) appears at most once in each row, and at most once in each column. Empty cells are denoted by \(-1\). A latin square \( L \) is a completion of a partial latin square \( P \) if \( P \subseteq L \). If \( P \) completes to just \( L \) then \( P \) has unique completion.

A latin bitrade \( (T_1, T_2) \) is a pair of partial latin squares such that:

1. \( \{(i, j) \mid (i, j, k) \in T_1 \text{ for some symbol } k\} = \{(i, j) \mid (i, j, k') \in T_2 \text{ for some symbol } k'\} \);
2. for each \( (i, j, k) \in T_1 \) and \( (i, j, k') \in T_2 \), \( k \neq k' \);
3. the symbols appearing in row \( i \) of \( T_1 \) are the same as those of row \( i \) of \( T_2 \); the symbols appearing in column \( j \) of \( T_1 \) are the same as those of column \( j \) of \( T_2 \).

Intuitively speaking, a bitrade gives the difference between two latin squares, so if \( (T_1, T_2) \) is a bitrade for the pair of latin squares \( (L_1, L_2) \), then \( L_1 = (L_2 \setminus T_1) \cup T_2 \) and \( L_2 = (L_1 \setminus T_2) \cup T_1 \).

This file contains

1. LatinSquare class definition;
2. some named latin squares (back circulant, forward circulant, abelian 2-group);
3. functions is_partial_latin_square and is_latin_square to test if a LatinSquare object satisfies the definition of a latin square or partial latin square, respectively;
4. tests for completion and unique completion (these use the C++ implementation of Knuth’s dancing links algorithm to solve the problem as a instance of 0 − 1 matrix exact cover);
5. functions for calculating the \( \tau_i \) representation of a bitrade and the genus of the associated hypermap embedding;
6. Markov chain of Jacobson and Matthews (1996) for generating latin squares uniformly at random (provides a generator interface);
7. a few examples of \( \tau_i \) representations of bitrades constructed from the action of a group on itself by right multiplication, functions for converting to a pair of LatinSquare objects.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(5)
sage: B
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
sage: B.is_latin_square()  # True
sage: B[0, 1] = 0
sage: B.is_latin_square()  # False

sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[ 0 -1 3 1]
[-1 1 0 2]
[ 1 3 2 -1]
[ 2 0 -1 3]
sage: T1.nr_filled_cells()  # 12
sage: genus(T1, T2)
1
```

Todo:

1. Latin squares with symbols from a ring instead of the integers \( \{0, 1, \ldots, n-1\} \).
2. Isotopism testing of latin squares and bitrades via graph isomorphism (nauty?).
3. Combinatorial constructions for bitrades.

AUTHORS:

- Carlo Hamalainen (2008-03-23): initial version
class sage.combinat.matrices.latin.LatinSquare(*args)
    Bases: object

Latin squares.

This class implements a latin square of order n with rows and columns indexed by the set 0, 1, ..., n-1 and symbols from the same set. The underlying latin square is a matrix(ZZ, n, n). If L is a latin square, then the cell at row r, column c is empty if and only if L[r, c] < 0. In this way we allow partial latin squares and can speak of completions to latin squares, etc.

There are two ways to declare a latin square:

Empty latin square of order n:

```
sage: n = 3
sage: L = LatinSquare(n)
sage: L
[-1 -1 -1]
[-1 -1 -1]
[-1 -1 -1]
```

Latin square from a matrix:

```
sage: M = matrix(ZZ, [[0, 1], [2, 3]])
sage: LatinSquare(M)
[0 1]
[2 3]
```

`actual_row_col_sym_sizes()`  
Bitrades sometimes end up in partial latin squares with unused rows, columns, or symbols. This function works out the actual number of used rows, columns, and symbols.

**Warning:** We assume that the unused rows/columns occur in the lower right of self, and that the used symbols are in the range \{0, 1, ..., m\} (no holes in that list).

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(3)
sage: B[0,0] = B[2,1] = -1
sage: B
[-1  1 -1]
[ 1  2 -1]
[ 2 -1 -1]
sage: B.actual_row_col_sym_sizes()
(3, 2, 2)
```

`apply_isotopism(row_perm, col_perm, sym_perm)`  
An isotopism is a permutation of the rows, columns, and symbols of a partial latin square self. Use isotopism() to convert a tuple (indexed from 0) to a Permutation object.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(5)
```

(continues on next page)
\begin{verbatim}
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
sage: alpha = isotopism((0,1,2,3,4))
sage: beta = isotopism((1,0,2,3,4))
sage: gamma = isotopism((2,1,0,3,4))
sage: B.apply_isotopism(alpha, beta, gamma)
[3 4 2 0 1]
[0 2 3 1 4]
[1 3 0 4 2]
[4 0 1 2 3]
[2 1 4 3 0]
\end{verbatim}

\section{clear_cells()}
Mark every cell in self as being empty.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: A = LatinSquare(matrix(ZZ, [[0, 1], [2, 3]]))
sage: A.clear_cells()
sage: A
[-1 -1]
[-1 -1]
\end{verbatim}

\section{column(x)}
Return column $x$ of the latin square.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(3).column(0)
(0, 1, 2)
\end{verbatim}

\section{contained_in(Q)}
Return True if self is a subset of Q?

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.combinat.matrices.latin import *
sage: P = elementary_abelian_2group(2)
sage: P[0, 0] = -1
sage: P.contained_in(elementary_abelian_2group(2))
True
sage: back_circulant(4).contained_in(elementary_abelian_2group(2))
False
\end{verbatim}

\section{disjoint_mate_dlxcpp_rows_and_map(allow_subtrade)}
Internal function for find_disjoint_mates.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(4)
sage: B.disjoint_mate_dlxcpp_rows_and_map(allow_subtrade = True)
([[0, 16, 32],
  [16, 32, 0],
  [32, 0, 16]])

&(11, 31, 46): (3, 2, 3), \\
&(12, 16, 35): (0, 3, 0), \\
&(12, 20, 39): (1, 3, 0), \\
&(12, 24, 43): (2, 3, 0), \\
\end{align*}
\]
dlxcpp_has_unique_completion()
Check if the partial latin square self of order n can be embedded in precisely one latin square of order n.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(2).dlxcpp_has_unique_completion()
True
sage: P = LatinSquare(2)
sage: P.dlxcpp_has_unique_completion()
False
sage: P[0, 0] = 0
sage: P.dlxcpp_has_unique_completion()
True
```

dumps()
Since the latin square class does not hold any other private variables we just call dumps on self.square:

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(2) == loads(dumps(back_circulant(2)))
True
```

filled_cells_map()
Number the filled cells of self with integers from \{1, 2, 3, \ldots \}

INPUT:

- self - Partial latin square self (empty cells have negative values)

OUTPUT: A dictionary cells_map where cells_map[(i,j)] = m means that (i,j) is the m-th filled cell in P, while cells_map[m] = (i,j).

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
(a, b, c, G) = alternating_group_bitrade_generators(1)
(T1, T2) = bitrade_from_group(a, b, c, G)
D = T1.filled_cells_map()
sage: {i: v for i, v in D.items() if i in ZZ}
{1: (0, 0), 2: (0, 2), 3: (0, 3),}
```
find_disjoint_mates \( (nr\_to\_find=None, allow\_subtrade=False) \)

**Warning:** If allow_subtrade is True then we may return a partial latin square that is not disjoint to self. In that case, use bitrade(P, Q) to get an actual bitrade.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(4)
sage: g = B.find_disjoint_mates(allow_subtrade = True)
sage: B1 = next(g)
sage: B0, B1 = bitrade(B, B1)
sage: assert is_bitrade(B0, B1)
sage: print (B0)
[-1  1  2 -1]
[-1  2 -1  0]
[-1 -1 -1  1]
[-1  0  1  2]
sage: print (B1)
[-1  2  1 -1]
[-1  0 -1  2]
[-1 -1 -1 -1]
[-1  1  2  0]
```

gcs ()
A greedy critical set of a latin square self is found by successively removing elements in a row-wise (bottom-up) manner, checking for unique completion at each step.

**EXAMPLES:**
```
sage: from sage.combinat.matrices.latin import *
sage: A = elementary_abelian_2group(3)
sage: G = A.gcs()
sage: A

    [0 1 2 3 4 5 6 7]
    [1 0 3 2 5 4 7 6]
    [2 3 0 1 6 7 4 5]
    [3 2 1 0 7 6 5 4]
    [4 5 6 7 0 1 2 3]
    [5 4 7 6 1 0 3 2]
    [6 7 4 5 2 3 0 1]
    [7 6 5 4 3 2 1 0]

sage: G

    [ 0 1 2 3 4 5 6 -1]
    [ 1 0 3 2 5 4 -1 -1]
    [ 2 3 0 1 6 -1 4 -1]
    [ 3 2 1 0 -1 -1 -1 -1]
    [ 4 5 6 -1 0 1 2 -1]
    [ 5 4 -1 -1 1 0 -1 -1]
    [ 6 -1 4 -1 2 -1 0 -1]
    [-1 -1 -1 -1 -1 -1 -1 -1]

is_completable()

Return True if the partial latin square can be completed to a latin square.

EXAMPLES:
The following partial latin square has no completion because there is nowhere that we can place the symbol
0 in the third row:

```
sage: B = LatinSquare(3)
sage: B[0, 0] = 0
sage: B[1, 1] = 0
sage: B[2, 2] = 1
sage: B

    [ 0 -1 -1]
    [-1 0 -1]
    [-1 -1 1]

sage: B.is_completable()
False

sage: B[2, 2] = 0
sage: B.is_completable()
True
```

is_empty_column(c)

Check if column c of the partial latin square self is empty.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(4)
sage: L.is_empty_column(0)
```
is_empty_row(r)
Check if row r of the partial latin square self is empty.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(4)
sage: L.is_empty_row(0)
False
sage: L[0,0] = L[0,1] = L[0,2] = L[0,3] = -1
sage: L.is_empty_row(0)
True
```

is_latin_square()
self is a latin square if it is an n by n matrix, and each symbol in [0, 1, ..., n-1] appears exactly once in each row, and exactly once in each column.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: elementary_abelian_2group(4).is_latin_square()
True
sage: forward_circulant(7).is_latin_square()
True
```

is_partial_latin_square()
self is a partial latin square if it is an n by n matrix, and each symbol in [0, 1, ..., n-1] appears at most once in each row, and at most once in each column.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: LatinSquare(4).is_partial_latin_square()
True
sage: back_circulant(3).gcs().is_partial_latin_square()
True
sage: back_circulant(6).is_partial_latin_square()
True
```

is_uniquely_completable()
Return True if the partial latin square self has exactly one completion to a latin square. This is just a wrapper for the current best-known algorithm, Dancing Links by Knuth. See dancing_links.spyx

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(4).gcs().is_uniquely_completable()
True
```

```python
sage: G = elementary_abelian_2group(3).gcs()
sage: G.is_uniquely_completable()
True

sage: G[0, 0] = -1
sage: G.is_uniquely_completable()
False
```

latex()

Return LaTeX code for the latin square.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: print(back_circulant(3).latex())
\begin{array}{|c|c|c|}
\hline
0 & 1 & 2 \\
\hline
1 & 2 & 0 \\
\hline
2 & 0 & 1 \\
\hline
\end{array}
```

list()

Convert the latin square into a list, in a row-wise manner.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(3).list()
[0, 1, 2, 1, 2, 0, 2, 0, 1]
```

ncols()

Number of columns in the latin square.

EXAMPLES:

```python
sage: LatinSquare(3).ncols()
3
```

nr_distinct_symbols()

Return the number of distinct symbols in the partial latin square self.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(5).nr_distinct_symbols()
5
sage: L = LatinSquare(10)
sage: L.nr_distinct_symbols()
0
sage: L[0, 0] = 0
sage: L[0, 1] = 1
sage: L.nr_distinct_symbols()
2
```

nr_filled_cells()

Return the number of filled cells (i.e. cells with a positive value) in the partial latin square self.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: LatinSquare(matrix([[0, -1], [-1, 0]])).nr_filled_cells()
2
```
nrows()  
Number of rows in the latin square.

EXAMPLES:

```
sage: LatinSquare(3).nrows()
3
```

permissable_values(r, c)  
Find all values that do not appear in row r and column c of the latin square self. If self[r, c] is filled then we return the empty list.

INPUT:

- self - LatinSquare
- r - int; row of the latin square
- c - int; column of the latin square

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(5)
sage: L[0, 0] = -1
sage: L.permissable_values(0, 0)
[0]
```

random_empty_cell()  
Find an empty cell of self, uniformly at random.

INPUT:

- self - LatinSquare

OUTPUT:

- [r, c] - cell such that self[r, c] is empty, or returns None if self is a (full) latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: P = back_circulant(2)
sage: P[1,1] = -1
sage: P.random_empty_cell()
[1, 1]
```

row(x)  
Return row x of the latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(3).row(0)
(0, 1, 2)
```

set_immutable()  
A latin square is immutable if the underlying matrix is immutable.

EXAMPLES:
sage: L = LatinSquare(matrix(ZZ, [[0, 1], [2, 3]]))
sage: L.set Immutable()
sage: {L : 0}  # this would fail without set Immutable()
{{0 1}
  {2 3}: 0}

top_left_empty_cell()  
Return the least [r, c] such that self[r, c] is an empty cell. If all cells are filled then we return None.  

INPUT:  
• self - LatinSquare

EXAMPLES:

vals_in_col(c)  
Return a dictionary with key e if and only if column c of self has the symbol e.  

EXAMPLES:

vals_in_row(r)  
Return a dictionary with key e if and only if row r of self has the symbol e.  

EXAMPLES:

sage.combinat.matrices.latin.LatinSquare_generator(L_start, check assertions=False)  
Generator for a sequence of uniformly distributed latin squares, given L_start as the initial latin square.  

This code implements the Markov chain algorithm of Jacobson and Matthews (1996), see below for the BibTex entry. This generator will never throw the StopIteration exception, so it provides an infinite sequence of latin squares.  

EXAMPLES:

Use the back circulant latin square of order 4 as the initial square and print the next two latin squares given by the Markov chain:

sage: from sage.combinat.matrices.latin import *  
sage: B = back_circulant(5)  
sage: B[3, 4] = -1  
sage: B.top_left_empty_cell()  
[3, 4]

vals_in_col(3)  
Return a dictionary with key e if and only if column c of self has the symbol e.  

EXAMPLES:

sage: from sage.combinat.matrices.latin import *  
sage: B = back_circulant(3)  
sage: B[0, 0] = -1  
sage: B.top_left_empty_cell()  
[3, 4]

vals_in_row(0)  
Return a dictionary with key e if and only if row r of self has the symbol e.  

EXAMPLES:

sage: from sage.combinat.matrices.latin import *  
sage: B = back_circulant(3)  
sage: B[0, 0] = -1  
sage: B.top_left_empty_cell()  
[3, 4]
REFERENCES:

sage.combinat.matrices.latin.alternating_group_bitrade_generators(m)
Construct generators a, b, c for the alternating group on 3m+1 points, such that a*b*c = 1.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = alternating_group_bitrade_generators(1)
sage: (a, b, c, G)
((1,2,3), (1,4,2), (2,4,3), Permutation Group with generators [(1,2,3), (1,4,2)])
sage: a*b*c
()```

```python
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[ 0 -1  3  1]
[-1  1  0  2]
[ 1  3  2 -1]
[ 2  0 -1  3]
sage: T2
[ 1 -1  0  3]
[-1  0  2  1]
[ 2  1  3 -1]
[ 0  3 -1  2]
```

sage.combinat.matrices.latin.back_circulant(n)
The back-circulant latin square of order n is the Cayley table for (Z_n, +), the integers under addition modulo n.

INPUT:
• n – int; order of the latin square.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(5)
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
```

sage.combinat.matrices.latin.beta1(rce, T1, T2)
Find the unique (x, c, e) in T2 such that (r, c, e) is in T1.

INPUT:
• rce - tuple (or list) (r, c, e) in T1
• T1, T2 - latin bitrade

OUTPUT: (x, c, e) in T2.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
```
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: beta1([0, 0, 0], T1, T2)
(1, 0, 0)

sage.combinat.matrices.latin.beta2(rce, T1, T2)
Find the unique \((r, x, e)\) in \(T2\) such that \((r, c, e)\) is in \(T1\).

**INPUT:**

- \(rce\) - tuple (or list) \((r, c, e)\) in \(T1\)
- \(T1, T2\) - latin bitrade

**OUTPUT:**

- \((r, x, e)\) in \(T2\).

**EXAMPLES:**

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: beta2([0, 0, 0], T1, T2)
(0, 1, 0)
```

sage.combinat.matrices.latin.beta3(rce, T1, T2)
Find the unique \((r, c, x)\) in \(T2\) such that \((r, c, e)\) is in \(T1\).

**INPUT:**

- \(rce\) - tuple (or list) \((r, c, e)\) in \(T1\)
- \(T1, T2\) - latin bitrade

**OUTPUT:**

- \((r, c, x)\) in \(T2\).

**EXAMPLES:**

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: beta3([0, 0, 0], T1, T2)
(0, 0, 4)
```

sage.combinat.matrices.latin.bitrade(T1, T2)
Form the bitrade \((Q1, Q2)\) from \((T1, T2)\) by setting empty the cells \((r, c)\) such that \(T1[r, c] == T2[r, c]\).

**EXAMPLES:**
sage: from sage.combinat.matrices.latin import *
sage: B1 = back_circulant(5)
sage: alpha = isotopism((0,1,2,3,4))
sage: beta = isotopism((1,0,2,3,4))
sage: gamma = isotopism((2,1,0,3,4))
sage: B2 = B1.apply_isotopism(alpha, beta, gamma)
sage: T1, T2 = bitrade(B1, B2)
sage: T1
[[ 0  1 -1  3  4]
 [ 1 -1  1  4  0]
 [ 2 -1  4  0  1]
 [ 3  4  0  1  2]
 [ 4  0  1  2  3]]
sage: T2
[[ 3  4 -1  0  1]
 [ 0 -1 -1  1  4]
 [ 1 -1  1  4  2]
 [ 4  0  1  2  3]
 [ 2  1  4  3  0]]

\sage{.combinat.matrices.latin.bitrade_from_group}\(a, b, c, G\)

Given group elements a, b, c in G such that abc = 1 and the subgroups a, b, c intersect (pairwise) only in the identity, construct a bitrade (T1, T2) where rows, columns, and symbols correspond to cosets of a, b, and c, respectively.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[[ 0 -1  3  1]
 [-1  1  0  2]
 [ 1  3  2 -1]
 [ 2  0 -1  3]]
sage: T2
[[ 1 -1  0  3]
 [-1  0  2  1]
 [ 2  1  3  1]
 [ 0  3 -1  2]]

\sage{.combinat.matrices.latin.cells_map_as_square}\(\text{cells\_map}, n\)

Return a LatinSquare with cells numbered from 1, 2, … to given the dictionary \text{cells\_map}.

\textbf{Note:} The value n should be the maximum of the number of rows and columns of the original partial latin square.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[[ 0 -1  3  1]
 [-1  1  0  2]]
(continues on next page)
There are 12 filled cells in T:

```
[ 1 3 2 -1]
[ 2 0 -1 3]
```

```
sage: cells_map_as_square(T1.filled_cells_map(), max(T1.nrows(), T1.ncols()))
[ 1 -1 2 3]
[-1 4 5 6]
[ 7 8 9 -1]
[10 11 -1 12]
```

```
sage.combinat.matrices.latin.check_bitrade_generators(a, b, c)
```

Three group elements a, b, c will generate a bitrade if \(a^*b^*c = 1\) and the subgroups \(a, b, c\) intersect (pairwise) in just the identity.

**EXAMPLES:**

```
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = p3_group_bitrade_generators(3)
sage: check_bitrade_generators(a, b, c)
True
sage: check_bitrade_generators(a, b, gap('()'))
False
```

```
sage.combinat.matrices.latin.coin()
```

Simulate a fair coin (returns True or False) using ZZ.random_element(2).

**EXAMPLES:**

```
sage: from sage.combinat.matrices.latin import coin
sage: x = coin()
sage: x == 0 or x == 1
True
```

```
sage.combinat.matrices.latin.column_containing_sym(L, r, x)
```

Given an improper latin square \(L\) with \(L[r, c1] = L[r, c2] = x\), return \(c1\) or \(c2\) with equal probability. This is an internal function and should only be used in LatinSquare_generator().

**EXAMPLES:**

```
sage: from sage.combinat.matrices.latin import *
sage: L = matrix([[1, 0, 2, 3], [0, 2, 3, 0], [2, 3, 0, 1], [3, 0, 1, 2]])
sage: L
[1 0 2 3]
[0 2 3 0]
[2 3 0 1]
[3 0 1 2]
sage: c = column_containing_sym(L, 1, 0)
sage: c == 0 or c == 3
True
```

```
sage.combinat.matrices.latin.direct_product(L1, L2, L3, L4)
```

The ‘direct product’ of four latin squares \(L1, L2, L3, L4\) of order \(n\) is the latin square of order \(2n\) consisting of

```
| L1 | L2 |
--------------
```

(continues on next page)
where the subsquares L2 and L3 have entries offset by n.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: direct_product(back_circulant(4), back_circulant(4), elementary_abelian_2group(2), elementary_abelian_2group(2))
[[0 1 2 3 4 5 6 7]
 [1 2 3 0 5 6 7 4]
 [2 3 0 1 6 7 4 5]
 [3 0 1 2 7 4 5 6]
 [4 5 6 7 0 1 2 3]
 [5 4 7 6 1 0 3 2]
 [6 7 4 5 2 3 0 1]
 [7 6 5 4 3 2 1 0]]
```

sage.combinat.matrices.latin.dlxcpp_find_completions(P, nr_to_find=None)

Return a list of all latin squares L of the same order as P such that P is contained in L. The optional parameter nr_to_find limits the number of latin squares that are found.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: dlxcpp_find_completions(LatinSquare(2))
[[0 1]
 [1 0], [1 0]
 [0 1]]
sage: dlxcpp_find_completions(LatinSquare(2), 1)
[[0 1]
 [1 0]]
```

sage.combinat.matrices.latin.dlxcpp_rows_and_map(P)

Internal function for dlxcpp_find_completions. Given a partial latin square P we construct a list of rows of a 0-1 matrix M such that an exact cover of M corresponds to a completion of P to a latin square.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: dlxcpp_rows_and_map(LatinSquare(2))
([[[0, 4, 8],
   [1, 5, 8],
   [2, 4, 9],
   [3, 5, 9],
   [0, 6, 10],
   [1, 7, 10],
   [2, 6, 11],
   [3, 7, 11]],
  [(0, 4, 8): (0, 0, 0),
   (0, 6, 10): (1, 0, 0),
   (1, 5, 8): (0, 0, 1),
   (1, 7, 10): (1, 0, 1),
   (2, 4, 9): (0, 1, 0),
   (2, 6, 11): (1, 1, 0),
])
```
sage.combinat.matrices.latin.elementary_abelian_2group(s)

Return the latin square based on the Cayley table for the elementary abelian 2-group of order 2s.

**INPUT:**

- s – int; order of the latin square will be 2s.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: elementary_abelian_2group(3)
[0 1 2 3 4 5 6 7]
[1 0 3 2 5 4 7 6]
[2 3 0 1 6 7 4 5]
[3 2 1 0 7 6 5 4]
[4 5 6 7 0 1 2 3]
[5 4 7 6 1 0 3 2]
[6 7 4 5 2 3 0 1]
[7 6 5 4 3 2 1 0]
```

sage.combinat.matrices.latin.forward_circulant(n)

The forward-circulant latin square of order n is the Cayley table for the operation r + c = (n-c+r) mod n.

**INPUT:**

- n – int; order of the latin square.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: forward_circulant(5)
[0 4 3 2 1]
[1 0 4 3 2]
[2 1 0 4 3]
[3 2 1 0 4]
[4 3 2 1 0]
```

sage.combinat.matrices.latin.genus(T1, T2)

Return the genus of hypermap embedding associated with the bitrade (T1, T2).

Informally, we compute the [tau_1, tau_2, tau_3] permutation representation of the bitrade. Each cycle of tau_1, tau_2, and tau_3 gives a rotation scheme for a black, white, and star vertex (respectively). The genus then comes from Euler’s formula.

For more details see Carlo Hamalainen: *Partitioning 3-homogeneous latin bitrades*. To appear in Geometriae Dedicata, available at arXiv 0710.0938

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: genus(T1, T2)
1
sage: (a, b, c, G) = pq_group_bitrade_generators(3, 7)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
```
sage: genus(T1, T2)
3

sage.combinat.matrices.latin.group_to_LatinSquare(G)
Construct a latin square on the symbols [0, 1, ..., n-1] for a group with an n by n Cayley table.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import group_to_LatinSquare
sage: group_to_LatinSquare(DihedralGroup(2))
[0 1 2 3]
[1 0 3 2]
[2 3 0 1]
[3 2 1 0]
```

```
sage: G = gap.Group(PermutationGroupElement((1,2,3)))
sage: group_to_LatinSquare(G)
[0 1 2]
[1 2 0]
[2 0 1]
```

sage.combinat.matrices.latin.is_bitrade(T1, T2)
Combinatorially, a pair (T1, T2) of partial latin squares is a bitrade if they are disjoint, have the same shape, and have row and column balance. For definitions of each of these terms see the relevant function in this file.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism((0,1,2,3,4))
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
```

sage.combinat.matrices.latin.is_disjoint(T1, T2)
The partial latin squares T1 and T2 are disjoint if T1[r, c] != T2[r, c] or T1[r, c] == T2[r, c] == -1 for each cell [r, c].

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import is_disjoint, back_circulant,
    isotopism
sage: is_disjoint(back_circulant(2), back_circulant(2))
False
```

```
sage: T1 = back_circulant(5)
sage: x = isotopism((0,1,2,3,4))
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_disjoint(T1, T2)
True
```
sage.combinat.matrices.latin\texttt{.is_primary_bitrade}(a, b, c, G)

A bitrade generated from elements $a$, $b$, $c$ is primary if $a, b, c = G$.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = p3_group_bitrade_generators(5)
sage: is_primary_bitrade(a, b, c, G)
True
```

sage.combinat.matrices.latin\texttt{.is_row_and_col_balanced}(T1, T2)

Partial latin squares $T1$ and $T2$ are balanced if the symbols appearing in row $r$ of $T1$ are the same as the symbols appearing in row $r$ of $T2$, for each $r$, and if the same condition holds on columns.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: T1 = matrix([[0,1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
sage: T2 = matrix([[0,1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
sage: is_row_and_col_balanced(T1, T2)
True
sage: T2 = matrix([[0,3,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
sage: is_row_and_col_balanced(T1, T2)
False
```

sage.combinat.matrices.latin\texttt{.is_same_shape}(T1, T2)

Two partial latin squares $T1$, $T2$ have the same shape if $T1[r, c] = 0$ if and only if $T2[r, c] = 0$.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: is_same_shape(elementary_abelian_2group(2), back_circulant(4))
True
sage: is_same_shape(LatinSquare(5), LatinSquare(5))
True
sage: is_same_shape(forward_circulant(5), LatinSquare(5))
False
```

sage.combinat.matrices.latin\texttt{.isotopism}(p)

Return a \texttt{Permutation} object that represents an isotopism (for rows, columns or symbols of a partial latin square).

Technically, all this function does is take as input a representation of a permutation of $0, \ldots, n - 1$ and return a \texttt{Permutation} object defined on $1, \ldots, n$.

For a definition of isotopism, see the wikipedia section on isotopism.

INPUT:

According to the type of input (see examples below):

- an integer $n$ – the function returns the identity on $1, \ldots, n$.
- a string representing a permutation in disjoint cycles notation, e.g. (0, 1, 2)(3, 4, 5) – the corresponding permutation is returned, shifted by 1 to act on $1, \ldots, n$.
- list/tuple of tuples – assumes disjoint cycle notation, see previous entry.
- a list of integers – the function adds 1 to each member of the list, and returns the corresponding permutation.
- a \texttt{PermutationGroupElement} $p$ – returns a permutation describing $p$ \textbf{without} any shift.

EXAMPLES:
```python
sage: from sage.combinat.matrices.latin import *
sage: isotopism(5) # identity on 5 points
[1, 2, 3, 4, 5]

sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: g = G.gen(0)
sage: isotopism(g)
[2, 3, 1, 5, 4]

sage: isotopism([0,3,2,1]) # 0 goes to 0, 1 goes to 3, etc.
[1, 4, 3, 2]

sage: isotopism((0,1,2)) # single cycle, presented as a tuple
[2, 3, 1]

sage: x = isotopism(((0,1,2), (3,4))) # tuple of cycles
sage: x
[2, 3, 1, 5, 4]

sage: x.to_cycles()
[(1, 2, 3), (4, 5)]
```

`sage.combinat.matrices.latin.next_conjugate(L)`

Permute \( L[r, c] = e \) to the conjugate \( L[c, e] = r \).

We assume that \( L \) is an \( n \) by \( n \) matrix and has values in the range 0, 1, \ldots, n-1.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(6)
sage: L
[0 1 2 3 4 5]
[1 2 3 4 5 0]
[2 3 4 5 0 1]
[3 4 5 0 1 2]
[4 5 0 1 2 3]
[5 0 1 2 3 4]
sage: next_conjugate(L)
[0 1 2 3 4 5]
[5 0 1 2 3 4]
[4 5 0 1 2 3]
[3 4 5 0 1 2]
[2 3 4 5 0 1]
[1 2 3 4 5 0]
sage: L == next_conjugate(next_conjugate(next_conjugate(L)))
True
```

`sage.combinat.matrices.latin.p3_group_bitrade_generators(p)`

Generators for a group of order \( p^3 \) where \( p \) is a prime.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: p3_group_bitrade_generators(3)
((2,6,7)(3,8,9), (1,2,3)(4,7,8)(5,6,9), (1,9,2)(3,7,4)(5,8,6), Permutation Group with generators [(2,6,7)(3,8,9), (1,2,3)(4,7,8)(5,6,9)])
```
sage.combinat.matrices.latin.pq_group_bitrade_generators(p, q)
Generators for a group of order pq where p and q are primes such that (q % p) == 1.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: pq_group_bitrade_generators(3,7)
((2,3,5)(4,7,6), (1,2,3,4,5,6,7), (1,4,2)(3,5,6), Permutation Group with generators [(2,3,5)(4,7,6), (1,2,3,4,5,6,7)])
```

sage.combinat.matrices.latin.row_containing_sym(L, c, x)
Given an improper latin square L with L[r1, c] = L[r2, c] = x, return r1 or r2 with equal probability. This is an internal function and should only be used in LatinSquare_generator().

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = matrix([[0, 1, 0, 3], [3, 0, 2, 1], [1, 0, 3, 2], [2, 3, 1, 0]])
sage: L
[0 1 0 3]
[3 0 2 1]
[1 0 3 2]
[2 3 1 0]
sage: c = row_containing_sym(L, 1, 0)
sage: c == 1 or c == 2
True
```

sage.combinat.matrices.latin.tau1(T1, T2, cells_map)
The definition of $\tau_1$ is

$\tau_1 : T1 \rightarrow T1$

$\tau_1 = \beta_2^{-1} \beta_3$

where the composition is left to right and $\beta_i : T2 \rightarrow T1$ changes just the $i^{th}$ coordinate of a triple.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism((0,1,2,3,4))
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: (cells_map, t1, t2, t3) = tau123(T1, T2)
sage: t1 = tau1(T1, T2, cells_map)
sage: t1
[2, 3, 4, 5, 1, 7, 8, 9, 10, 11, 17, 18, 19, 20, 16, 22, 23, 24, 25, 21]
sage: t1.to_cycles()
[(1, 2, 3, 4, 5), (6, 7, 8, 9, 10), (11, 12, 13, 14, 15), (16, 17, 18, 19, 20), (21, 22, 23, 24, 25)]
```

sage.combinat.matrices.latin.tau123(T1, T2)
Compute the tau_i representation for a bitrade (T1, T2).

See the functions tau1, tau2, and tau3 for the mathematical definitions.

OUTPUT:
• \((\text{cells\_map, t1, t2, t3})\)

where \(\text{cells\_map}\) is a map to/from the filled cells of \(\text{T1}\), and \(t1, t2, t3\) are the \(\tau1,\ \tau2,\ \tau3\) permutations.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = pq_group_bitrade_generators(3, 7)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
\[

\end{bmatrix}
\]

sage: t1

\[3, 1, 2, 6, 4, 5, 9, 7, 8, 12, 10, 11, 15, 13, 14, 18, 16, 17, 21, 19, 20\]

sage: t2

\[4, 8, 15, 7, 11, 18, 10, 14, 21, 13, 17, 3, 16, 20, 6, 19, 2, 9, 1, 5, 12\]

sage: t3

\[20, 18, 10, 2, 21, 13, 5, 3, 16, 8, 6, 19, 11, 9, 1, 14, 12, 4, 17, 15, 7\]

sage: t1.to_cycles()

\[(1, 3, 2), (4, 6, 5), (7, 9, 8), (10, 12, 11), (13, 15, 14), (16, 18, 17), (19, 21, 20)\]

sage: t2.to_cycles()

\[(1, 4, 7, 10, 13, 16, 19), (2, 8, 14, 20, 5, 11, 17), (3, 15, 6, 18, 9, 21, 12)\]

sage: t3.to_cycles()

\[(1, 20, 15), (2, 18, 4), (3, 10, 8), (5, 21, 7), (6, 13, 11), (9, 16, 14), (12, 19, 17)\]

The product \(t_1 \ast t_2 \ast t_3\) is the identity, i.e. it fixes every point:

sage: len((t1*t2*t3).fixed_points()) == T1.nr_filled_cells()

True

sage.combinat.matrices.latin.tau2(T1, T2, cells_map)

The definition of \(\tau_2\) is

\[
\tau_2 : T1 \rightarrow T1 \\
\tau_2 = \beta_3^{-1} \beta_1
\]

where the composition is left to right and \(\beta_i : T2 \rightarrow T1\) changes just the \(i^{th}\) coordinate of a triple.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *

sage: T1 = back_circulant(5)

sage: x = isotopism( (0,1,2,3,4) )

sage: y = isotopism(5) # identity

sage: z = isotopism(5) # identity

(continues on next page)
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: (cells_map, t1, t2, t3) = tau123(T1, T2)
sage: t2 = tau2(T1, T2, cells_map)
sage: t2
[21, 22, 23, 24, 25, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20]
sage: t2.to_cycles()
[(1, 21, 16, 11, 6), (2, 22, 17, 12, 7), (3, 23, 18, 13, 8), (4, 24, 19, 14, 9), (5, 25, 20, 15, 10)]

sage.combinat.matrices.latin.tau3(T1, T2, cells_map)
The definition of $\tau_3$ is

$$\tau_3 : T1 \to T1$$

$$\tau_3 = \beta_1^{-1} \beta_2$$

where the composition is left to right and $\beta_i : T2 \to T1$ changes just the $i^{th}$ coordinate of a triple.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: (cells_map, t1, t2, t3) = tau123(T1, T2)
sage: t3 = tau3(T1, T2, cells_map)
sage: t3
[10, 6, 7, 8, 9, 15, 11, 12, 13, 14, 20, 16, 17, 18, 19, 25, 21, 22, 23, 24, 5, 1, 2, 3, 4]
sage: t3.to_cycles()
[(1, 10, 14, 18, 22), (2, 6, 15, 19, 23), (3, 7, 11, 20, 24), (4, 8, 12, 16, 25), (5, 9, 13, 17, 21)]

sage.combinat.matrices.latin.tau_to_bitrade(t1, t2, t3)
Given permutations t1, t2, t3 that represent a latin bitrade, convert them to an explicit latin bitrade (T1, T2). The result is unique up to isotopism.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: _, t1, t2, t3 = tau123(T1, T2)
sage: U1, U2 = tau_to_bitrade(t1, t2, t3)
sage: assert is_bitrade(U1, U2)
sage: U1
[0 1 2 3 4]
[1 2 3 4 0]
5.1.141 Miscellaneous

class sage.combinat.misc.DoublyLinkedList(l)
   Bases: object

A doubly linked list class that provides constant time hiding and unhiding of entries.

Note that this list's indexing is 1-based.

EXAMPLES:

```python
sage: dll = sage.combinat.misc.DoublyLinkedList([1, 2, 3]); dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
sage: dll.hide(1); dll
Doubly linked list of [1, 2, 3]: [2, 3]
sage: dll.unhide(1); dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
sage: dll.hide(2); dll
Doubly linked list of [1, 2, 3]: [1, 3]
sage: dll.unhide(2); dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
```

head()
hide(i)
next(j)
prev(j)
unhide(i)

class sage.combinat.misc.IterableFunctionCall(f, *args, **kwargs)
   Bases: object

This class wraps functions with a yield statement (generators) by an object that can be iterated over. For example,

EXAMPLES:

```python
sage: def f(): yield 'a'; yield 'b'
sage: def f(): yield 'a'; yield 'b'
This does not work:
sage: for z in f: print(z)
Traceback (most recent call last):
  ...  
TypeError: 'function' object is not iterable
```

Use IterableFunctionCall if you want something like the above to work:
sage: from sage.combinat.misc import IterableFunctionCall
sage: g = IterableFunctionCall(f)
sage: for z in g: print(z)
  a
  b

If your function takes arguments, just put them after the function name. You needn’t enclose them in a tuple or anything, just put them there:

sage: def f(n, m):
    yield 'a' * n;
    yield 'b' * m;
    yield 'foo'
sage: g = IterableFunctionCall(f, 2, 3)
sage: for z in g: print(z)
  aa
  bbb
  foo

sage.combinat.misc.check_integer_list_constraints(l, **kwargs)

EXAMPLES:

sage: from sage.combinat.misc import check_integer_list_constraints
sage: cilc = check_integer_list_constraints
sage: l = [[[2,1,3],[1,2],[3,3],[4,1,1]]
  [[3, 3]]
sage: cilc(l, min_part=2)    
  [[3, 3]]
sage: cilc(l, max_part=2)    
  [[1, 2]]
sage: cilc(l, length=2)    
  [[1, 2], [3, 3]]
sage: cilc(l, max_length=2)    
  [[1, 2], [3, 3]]
sage: cilc(l, min_length=3)    
  [[2, 1, 3], [4, 1, 1]]
sage: cilc(l, max_slope=0)    
  [[3, 3], [4, 1, 1]]
sage: cilc(l, min_slope=1)    
  [[1, 2]]
sage: cilc(l, outer=[2,2])    
  [[1, 2]]
sage: cilc(l, inner=[2,2])    
  [[3, 3]]

sage: cilc([1,2,3], length=3, singleton=True)
  [1, 2, 3]
sage: cilc([1,2,3], length=2, singleton=True) is None
  True

sage.combinat.misc.umbral_operation(poly)

Returns the umbral operation ↓ applied to poly.

The umbral operation replaces each instance of $x_i^{a_i}$ with $x_i*(x_i-1)\cdots*(x_i-a_i+1)$.

EXAMPLES:

sage: P = PolynomialRing(QQ, 2, 'x')
sage: x = P.gens()
sage: from sage.combinat.misc import umbral_operation
sage: umbral_operation(x[0]^3) == x[0]*(x[0]-1)*(x[0]-2)
5.1.142 Ordered Multiset Partitions into Sets and the Minimaj Crystal

This module provides element and parent classes for ordered multiset partitions. It also implements the minimaj crystal of Benkart et al. [BCHOPSY2017]. (See MinimajCrystal.)

AUTHORS:

• Aaron Lauve (2018): initial implementation. First draft of minimaj crystal code provided by Anne Schilling.

REFERENCES:

• [BCHOPSY2017]
• [HRW2015]
• [HRS2016]
• [LM2018]

EXAMPLES:

An ordered multiset partition into sets of the multiset \{\{1, 3, 3, 5\}\}:

```sage
sage: OrderedMultisetPartitionIntoSets([\[5, 3\], \[1, 3\]])
\[\{3, 5\}, \{1, 3\}\]
```

Ordered multiset partitions into sets of the multiset \{\{1, 3, 3\}\}:

```sage
sage: OrderedMultisetPartitionsIntoSets([1,1,3]).list()
\[\{1\}, \{1\}, \{1, 3\}\]
```

Ordered multiset partitions into sets of the integer 4:

```sage
sage: OrderedMultisetPartitionsIntoSets(4).list()
\[\{4\}, \{1, 4\}, \{1\}, \{1\}, \{1\}, \{1, 4\}\]
```

Ordered multiset partitions into sets on the alphabet \{1, 4\} of order 3:

```sage
sage: OrderedMultisetPartitionsIntoSets([1,4], 3).list()
\[\{1, 4\}, \{1\}, \{1\}, \{1, 4\}, \{1\}, \{1\}, \{1\}\]
```

Crystal of ordered multiset partitions into sets on the alphabet \{1, 2, 3\} with 4 letters divided into 2 blocks:

```sage
sage: crystals.Minimaj(3, 4, 2).list()
\[\{(2, 3), (1, 2), (2, 3), (1, 3)\}, \{(2, 1), (1, 2)\}, \{(2, 3), (1, 2), (2, 3), (1, 3)\}\]
```
class sage.combinat.multiset_partition_into_sets_ordered.MinimajCrystal(n, ell, k)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Crystal of ordered multiset partitions into sets with $ell$ letters from alphabet $\{1, 2, \ldots, n\}$ divided into $k$ blocks.

Elements are represented in the minimaj ordering of blocks as in Benkart et al. [BCHOPSY2017].

Note: Elements are not stored internally as ordered multiset partitions into sets, but as certain (pairs of) words stemming from the minimaj bijection $\phi$ of [BCHOPSY2017]. See sage.combinat.multiset_partition_into_sets_ordered.MinimajCrystal.Element for further details.

AUTHORS:

• Anne Schilling (2018): initial draft
• Aaron Lauve (2018): changed to use Letters crystal for elements

EXAMPLES:

sage: list(crystals.Minimaj(2,3,2))
[(2, 1), (1, )], ((2,), (1, 2, 3)), ((3,), (1, 2, 3)), ((1,),(1, 2, 3)), ((1, 2), (2, 3)), ((1, 2, 3), (3,))

class Element

Bases: sage.structure.element_wrapper.ElementWrapper

An element of a Minimaj crystal.

Note: Minimaj elements $b$ are stored internally as pairs $(w, \text{breaks})$, where:

• $w$ is a word of length self.parent().ell over the letters 1 up to self.parent().n;

• breaks is a list of de-concatenation points to turn $w$ into a list of row words of (skew-)tableaux that represent $b$ under the minimaj bijection $\phi$ of [BCHOPSY2017].

The pair $(w, \text{breaks})$ may be recovered via b.value.
sage: [b.e(i) for i in range(1,4)]
[((1, 3), (3,)), ((2,), (2, 3)), None]

f(i)
Return f_i on self.

EXAMPLES:

sage: B = crystals.Minimaj(4,3,2)
sage: b = B([[2,3], [3]]); b
((2, 3), (3,))
sage: [b.f(i) for i in range(1,4)]
[None, None, ((2, 3), (4,))]

to_tableaux_words()
Return the image of the ordered multiset partition into sets self under the minimaj bijection \( \phi \) of [BCHOPSY2017].

EXAMPLES:

sage: B = crystals.Minimaj(4,5,3)
sage: b = B.an_element(); b
((2, 3, 1), (1,), (1,))
sage: b.to_tableaux_words()
[[1], [3], [2, 1, 1]]
sage: b = B([[1,3,4], [3], [3]]); b
((4, 1, 3), (3,), (3,))
sage: b.to_tableaux_words()
[[3, 1], [], [4, 3, 3]]

from_tableau(t)
Return the bijection \( \phi^{-1} \) of [BCHOPSY2017] applied to t.

INPUT:

• t – a sequence of column tableaux and a ribbon tableau

EXAMPLES:

sage: B = crystals.Minimaj(3,6,3)
sage: b = B.an_element(); b
((3, 1, 2), (2, 1), (1,))
sage: t = b.to_tableaux_words(); t
[[[1], [2, 1], []], [3, 2, 1]]
sage: B.from_tableau(t)
((3, 1, 2), (2, 1), (1,))
sage: B.from_tableau(t) == b
True

val(q='q')
Return the \( Val \) polynomial corresponding to self.

EXAMPLES:

Verifying Example 4.5 from [BCHOPSY2017]:
```python
sage: B = crystals.Minimaj(3, 4, 2) # for `Val_{4,1}^{(3)}`
sage: B.val()
(q^2+q+1)*s[2, 1, 1] + q*s[2, 2]
```

```python
class sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionIntoSets(parent, data)

Bases: sage.structure.list_clone.ClonableArray

Ordered Multiset Partition into sets

An ordered multiset partition into sets $c$ of a multiset $X$ is a list $[c_1, \ldots, c_r]$ of nonempty subsets of $X$ (note: not sub-multisets), called the blocks of $c$, whose multi-union is $X$.

EXAMPLES:
The simplest way to create an ordered multiset partition into sets is by specifying its blocks as a list or tuple:

```python
sage: OrderedMultisetPartitionIntoSets([[3], [2, 1]])
[[3], [1, 2]]

sage: OrderedMultisetPartitionIntoSets(((3,), (1, 2)))
[(3), (1, 2)]

sage: OrderedMultisetPartitionIntoSets([set([i]) for i in range(2, 5)])
[(2), (3), (4)]
```

REFERENCES:

• [HRW2015]
• [HRS2016]
• [LM2018]

```python
def check()
    Check that we are a valid ordered multiset partition into sets.
    EXAMPLES:

sage: c = OrderedMultisetPartitionsIntoSets(4)([[1], [1, 2]])
sage: c.check()

sage: OMPs = OrderedMultisetPartitionsIntoSets()
sage: c = OMPs([[1], [1], ['a']])
sage: c.check()
```

```python
deconcatenate(k=2)
    Return the list of $k$-deconcatenations of self.
    A $k$-tuple $(C_1, \ldots, C_k)$ of ordered multiset partitions into sets represents a $k$-deconcatenation of an ordered multiset partition into sets $C$ if $C_1 + \cdots + C_k = C$.

    Note: This is not to be confused with self.split_blocks(), which splits each block of self before making $k$-tuples of ordered multiset partitions into sets.
    EXAMPLES:

sage: OrderedMultisetPartitionIntoSets([[7, 1], [3, 4, 5]]).deconcatenate()
[([[1, 7], [3, 4, 5]], []), ([[1, 7]], [3, 4, 5]), ([[1, 7]], [3, 4, 5]), [[1, 7], [3, 4, 5]])]

sage: OrderedMultisetPartitionIntoSets([['b', 'c'], ['a']]).deconcatenate()
[([['b', 'c'], ['a']]), [], [(['b', 'c'], ['a'])]]
```
```
... (continued from previous page)

```python
sage: OrderedMultisetPartitionIntoSets([['a','b','c']]).deconcatenate(3)
[[['a','b','c']]], [[]], [[]]
([[['a','b','c']]], [[]], [[]])
```

**fatten** *(grouping)*

Return the ordered multiset partition into sets fatter than `self`, obtained by grouping together consecutive parts according to `grouping` (whenever this does not violate the strictness condition).

**INPUT:**

- `grouping` – a composition (or list) whose sum is the length of `self`

**EXAMPLES:**

Let us start with the composition:

```python
sage: C = OrderedMultisetPartitionIntoSets([[4,1,5], [2], [7,1]]); C
{1,4,5}, {2}, {1,7}
```

With `grouping` equal to `(1,1,1), C` is left unchanged:

```python
sage: C.fatten([1,1,1])
{1,4,5}, {2}, {1,7}
```

With `grouping` equal to `(2,1)` or `(1,2), a union of consecutive parts is achieved:

```python
sage: C.fatten([2,1])
{1,2,4,5}, {1,7}
```

```python
sage: C.fatten([1,2])
{1,4,5}, {1,2,7}
```

However, the `grouping` `(3)` will throw an error, as `1` cannot appear twice in any block of `C`:

```python
sage: C.fatten(Composition([3]))
Traceback (most recent call last):
  ... ValueError: {{1,4,5,2,1,7}} is not a valid ordered multiset partition into sets
```

**fatter()**

Return the set of ordered multiset partitions into sets which are fatter than `self`.

An ordered multiset partition into sets `A` is fatter than another `B` if, reading left-to-right, every block of `A` is the union of some consecutive blocks of `B`.

**EXAMPLES:**

```python
sage: C = OrderedMultisetPartitionIntoSets([[1,4,5], [2], [1,7]]).fatter()
sage: len(C)
3
```

```python
sage: sorted(C)
[[[1,4,5], [2], [1,7]], [[1,4,5], [1,2,7]], [[1,2,4,5], [1,7]]]
```

```python
sage: sorted(OrderedMultisetPartitionIntoSets([['a','b'],['c'],['a']].fatter())
```

Some extreme cases:
**finer** *(strong=False)*

Return the set of ordered multiset partitions into sets that are finer than `self`.

An ordered multiset partition into sets `A` is finer than another `B` if, reading left-to-right, every block of `B` is the union of some consecutive blocks of `A`.

If optional argument `strong` is set to `True`, then return only those `A` whose blocks are deconcatenations of blocks of `B`. (Here, we view blocks of `B` as sorted lists instead of sets.)

**EXAMPLES:**

```python
sage: C = OrderedMultisetPartitionIntoSets([[3,2]]).finer()
sage: len(C)
3
sage: sorted(C, key=str)
[[[2,3]], [[2], [3]], [[3], [2]]]
sage: OrderedMultisetPartitionIntoSets([]).finer()
[]
sage: O = OrderedMultisetPartitionsIntoSets([1, 1, 'a', 'b'])
sage: o = O([{'1'}, {'a','b'}, {'1'})
sage: sorted(o.finer(), key=str)
[[{'1'}, {'a','b'}, {'1'}], [{'1'}, {'a'}, {'b'}, {'1'}], [{'1'}, {'b'}, {'a'}, {'1'}]]
sage: o.finer() & o.fatter() == set([o])
True
```

**is_finer** *(co)*

Return `True` if the ordered multiset partition into sets `self` is finer than the composition `co`; otherwise, return `False`.

**EXAMPLES:**

```python
sage: OrderedMultisetPartitionIntoSets([[4],[1],[2]]).is_finer([[1,4],[2]])
True
sage: OrderedMultisetPartitionIntoSets([[1],[4],[2]]).is_finer([[1,4],[2]])
True
sage: OrderedMultisetPartitionIntoSets([[1,4],[1],[1]]).is_finer([[1,4],[2]])
False
```

**length**

Return the number of blocks of `self`.

**EXAMPLES:**

```python
sage: OrderedMultisetPartitionIntoSets([[7,1],[3]]).length()
2
```

**letters**

Return the set of distinct elements occurring within the blocks of `self`.

**EXAMPLES:**
The major index is a statistic on ordered multiset partitions into sets, which we define here via an example.

1. Sort each block in the list `self` in descending order to create a word $w$, keeping track of the original separation into blocks:

   ```
   in:    [[3,4,5], [2,3,4], [1], [4,5]]
   out:   [5,4,3 / 4,3,2 / 1 / 5,4]
   ```

2. Create a sequence $v = (v_0, v_1, v_2, \ldots)$ of length `self.order()+1`, built recursively by:
   1. $v_0 = 0$
   2. $v_j = v_{j-1} + \delta(j)$, where $\delta(j) = 1$ if $j$ is the index of an end of a block, and zero otherwise.

   ```
   in:    [5,4,3 / 4,3,2 / 1 / 5,4]
   out:   (0, 0,0,1, 1,1,2, 3, 3,4)
   ```

3. Compute $\sum_j v_j$, restricted to descent positions in $w$, i.e., sum over those $j$ with $w_j > w_{j+1}$:

   ```
   in:  w:   [5, 4, 3, 4, 3, 2, 1, 5, 4]
        v:   (0 0, 0, 1, 1, 1, 2, 3, 3, 4)
   maj := 0 +0 +0 +1 +1 +2 +3 = 7
   ```

REFERENCES:

• [HRW2015]

EXAMPLES:

```python
sage: C = OrderedMultisetPartitionIntoSets([[1,5,7], [2,4], [5,6], [4,6,8], [1,3], [1,2,3]])
sage: C.major_index()
27
sage: C = OrderedMultisetPartitionIntoSets([[3,4,5], [2,3,4], [1], [4,5]])
sage: C.major_index()
7
```

`max_letter()`

Return the maximum letter appearing in `self.letters()` of `self`.

EXAMPLES:

```python
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]])
sage: C.max_letter()
7
sage: D = OrderedMultisetPartitionIntoSets([['a','b','c'],['a','b'],['a'],['b','c','f'],['c','d']])
sage: D.max_letter()
'f'
sage: C = OrderedMultisetPartitionIntoSets([])
sage: C.max_letter()
```
minimaj()  
Return the minimaj statistic on ordered multiset partitions into sets.

We define \textit{minimaj} via an example:

1. Sort the block in \texttt{self} as prescribed by \texttt{self.minimaj_word()}, keeping track of the original separation into blocks:

   \begin{verbatim}
in:  [(1,5,7), (2,4), (5,6), (4,6,8), (1,3), (1,2,3)]
out:  (5,7,1 / 2,4 / 5,6 / 4,6,8 / 3,1 / 1,2,3 )
\end{verbatim}

2. Record the indices where descents in this word occur:

   \begin{verbatim}
word:  (5, 7, 1 / 2, 4 / 5, 6 / 4, 6, 8 / 3, 1 / 1, 2, 3)
indices:  1 2 3 4 5 6 7 8 9 10 11 12 13 14 15
descents:  { 2, 7, 10, 11 }
\end{verbatim}

3. Compute the sum of the descents:

   \begin{verbatim}
minimaj = 2 + 7 + 10 + 11 = 30
\end{verbatim}

REFERENCES:

- [HRW2015]

EXAMPLES:

\begin{verbatim}
sage: C = OrderedMultisetPartitionIntoSets([(1,5,7), (2,4), (5,6), (4,6,8), (1,3), (1,2,3)])
sage: C.minimaj_word()
([(1,5,7), (2,4), (5,6), (4,6,8), (1,3), (1,2,3)],
 (5, 7, 1 / 2, 4 / 5, 6 / 4, 6, 8 / 3, 1 / 1, 2, 3))
sage: C.minimaj()
30
sage: C = OrderedMultisetPartitionIntoSets([(2,4), (1,2,3), (1,6,8), (2,3)])
sage: C.minimaj_word()
([(2,4), (1,2,3), (1,6,8), (2,3)], (2, 4, 1, 2, 3, 6, 8, 1, 2, 3))
sage: C.minimaj()
9
sage: OrderedMultisetPartitionIntoSets([]).minimaj()
0
sage: C = OrderedMultisetPartitionIntoSets([['b','d'],['a','b','c'],['b']])
sage: C.minimaj_word()
([['b','d'],['a','b','c'],['b']], ['d', 'b', 'c', 'a', 'b', 'b'])
sage: C.minimaj()
4
\end{verbatim}

minimaj_blocks()  
Return the minimaj ordering on blocks of \texttt{self}.

We define the ordering via the example below.

Sort the blocks \([B_1, ..., B_k]\) of \texttt{self} from right to left via:

1. Sort the last block \(B_k\) in increasing order, call it the word \(W_k\)

2. If blocks \(B_{i+1}, ..., B_k\) have been converted to words \(W_{i+1}, ..., W_k\), use the letters in \(B_i\) to make the unique word \(W_i\) that has a factorization \(W_i = (u, v)\) satisfying:

   - letters of \(u\) and \(v\) appear in increasing order, with \(v\) possibly empty;
   - letters in \(uv\) appear in increasing order;
• \(v[-1]\) is the largest letter \(a \in B_i\) satisfying \(a \leq W_{i+1}[0]\).

**EXAMPLES:**

```python
sage: OrderedMultisetPartitionIntoSets([[1,5,7], [2,4], [5,6], [4,6,8], [1,3], → [1,2,3]])
([[1,5,7], [2,4], [5,6], [4,6,8], [1,3], [1,2,3])
sage: _.minimaj_blocks()
((5, 7, 1), (2, 4), (5, 6), (4, 6, 8), (3, 1), (1, 2, 3))
sage: OrderedMultisetPartitionIntoSets([]).minimaj_blocks()
()
```

**minimaj_word()**

Return an ordering of `self._multiset` derived from the minimaj ordering on blocks of `self`.

See also: `OrderedMultisetPartitionIntoSets.minimaj_blocks()`.

**EXAMPLES:**

```python
sage: C = OrderedMultisetPartitionIntoSets([[2,1], [1,2,3], [1,2], [3], [1]]);
 → C
([[1,2], [1,2,3], [1,2], [3], [1])
sage: C.minimaj_blocks()
((1, 2), (2, 3, 1), (1, 2), (3,), (1,))
sage: C.minimaj_word()
(1, 2, 2, 3, 1, 1, 2, 3, 1)
```

**multiset (as_dict=False)**

Return the multiset corresponding to `self`.

**INPUT:**

• `as_dict=(default: False)` whether to return the multiset as a tuple of a dict of multiplicities

**EXAMPLES:**

```python
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]]); C
([[3,4], [2], [1,2,3,7])
sage: C.multiset()
(1, 2, 2, 3, 3, 4, 7)
sage: C.multiset(as_dict=True)
{1: 2, 2: 2, 3: 2, 4: 1, 7: 1}
sage: OrderedMultisetPartitionIntoSets([]).multiset() == ()
True
```

**order()**

Return the total number of elements in all blocks of `self`.

**EXAMPLES:**

```python
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]]); C
([[3,4], [2], [1,2,3,7])
sage: C.order()
8
sage: C.order() == sum(C.weight().values())
True
sage: C.order() == sum(k for k in C.shape_from_cardinality())
True
```

(continues on next page)
sage: OrderedMultisetPartitionIntoSets([[7,1],[3]]).order()
3

reversal()

Return the reverse ordered multiset partition into sets of self.

Given an ordered multiset partition into sets \((B_1, B_2, \ldots, B_k)\), its reversal is defined to be the ordered multiset partition into sets \((B_k, \ldots, B_2, B_1)\).

EXAMPLES:

sage: C = OrderedMultisetPartitionIntoSets([[1], [1,3], [2,3,4]]); C
[[1], [1,3], [2,3,4]]
sage: C.reversal()

sage: C = OrderedMultisetPartitionIntoSets([[1,3,4], [2], [1,3,7]]); C
[[1,3,4], [2], [1,3,7]]
sage: C.shape_from_cardinality()

shape_from_cardinality()

Return a composition that records the cardinality of each block of self.

EXAMPLES:

sage: C = OrderedMultisetPartitionIntoSets([[3,4,1], [2], [1,2,3,7]]); C
[[3,4,1], [2], [1,2,3,7]]
sage: C.shape_from_cardinality()

shape_from_size()

Return a composition that records the sum of entries of each block of self.

EXAMPLES:

sage: C = OrderedMultisetPartitionIntoSets([[3,4,1], [2], [1,2,3,7]]); C
[[3,4,1], [2], [1,2,3,7]]
sage: C.shape_from_size()

shuffle_product (other, overlap=False)

Return the shuffles (with multiplicity) of blocks of self with blocks of other.

In case optional argument overlap is True, instead return the allowable overlapping shuffles. An overlapping shuffle \(C\) is allowable if, whenever one of its blocks \(c\) comes from the union \(c = a \cup b\) of a block of self and a block of other, then this union is disjoint.

See also:

Composition.shuffle_product()

EXAMPLES:

sage: A = OrderedMultisetPartitionIntoSets([[2,1,3], [1,2]]); A
[[2,1,3], [1,2]]
sage: B = OrderedMultisetPartitionIntoSets([[3,4]]); B
[[3,4]]
sage: C = OrderedMultisetPartitionIntoSets([[4,5]]); C
[[4,5]]
sage: list(A.shuffle_product(B))
size()

Return the size of self (that is, the sum of all integers in all blocks) if self is a list of subsets of positive integers.

Else, return None.

EXAMPLES:

```python
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]]); C
[[3, 4, 1], [2], [1, 2, 3, 7]]
sage: C.size()
23
sage: C.size() == sum(k for k in C.shape_from_size())
True
sage: OrderedMultisetPartitionIntoSets([[7,1],[3]]).size()
11
```

split_blocks(k=2)

Return a dictionary representing the k-splittings of self.

A k-tuple \((A^1, \ldots, A^k)\) of ordered multiset partitions into sets represents a k-splitting of an ordered multiset partition into sets \(A = [b_1, \ldots, b_r]\) if one can express each block \(b_i\) as an (ordered) disjoint union of sets \(b_i = b_1^i \sqcup \cdots \sqcup b_k^i\) (some possibly empty) so that each \(A^j\) is the ordered multiset partition into sets corresponding to the list \([b_1^j, b_2^j, \ldots, b_k^j]\), excising empty sets appearing therein.

This operation represents the coproduct in Hopf algebra of ordered multiset partitions into sets in its natural basis [LM2018].

EXAMPLES:

```python
sage: sorted(OrderedMultisetPartitionIntoSets([[1,2],[3,4]]).split_blocks(), key=str)

[((), [[1,2], [3,4]]),
 ((), [[1,2], [3,4]], []),
 ((), [[1,2], [3]], [[4]]),
 ((), [[1,2], [4]], [[3]]),
 ((), [[1,2]], [[3,4]]),
 ((), ([1], [3,4], [[2]]),
 ((), ([1], [3], [[2], [4]]),
 ((), ([1], [4], [[2], [3]]),
 ((), ([2], [3,4], [[1]]),
 ((), ([2], [3], [[1], [4]]),
 ((), ([2], [4], [[1], [3]]),
 ((), ([2], [1], [[3,4]]),
 ((), ([1], [3,4], [[2]]),
 ((), ([1], [3], [[2], [4]]),
 ((), ([1], [4], [[2], [3]]),
 ((), ([4], [[1,2], [3]]))

sage: sorted(OrderedMultisetPartitionIntoSets([[1,2]]).split_blocks(3), key=str)
```
to_tableaux_words()

Return a sequence of lists corresponding to row words of (skew-)tableaux.

OUTPUT:

The minimaj bijection $\phi$ of [BCHOPSY2017] applied to self.

Todo: Implement option for mapping to sequence of (skew-)tableaux?

EXAMPLES:

sage: co = ((1,2,4),(4,5),(3,), (4,6,1),(2,3,1),(1,), (2,5))
sage: OrderedMultisetPartitionIntoSets(co).to_tableaux_words()

\[
[[5, 1], [3, 1], [6], [5, 4, 2], [1, 4, 3, 4, 2, 1, 2]]
\]

weight (as_weak_comp=False)

Return a dictionary, with keys being the letters in self.letters() and values being their (positive) frequency.

Alternatively, if as_weak_comp is True, count the number of instances $n_i$ for each distinct positive integer $i$ across all blocks of self. Return as a list $[n_1, n_2, ..., n_k]$, where $k$ is the max letter appearing in self.letters().

EXAMPLES:

sage: c = OrderedMultisetPartitionIntoSets([[6,1],[1,3],[1,3,6]])
sage: c.weight()

\[1: 3, 3: 2, 6: 2\]
sage: c.weight(as_weak_comp=True)

\[3, 0, 2, 0, 0, 2\]

class sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Ordered Multiset Partitions into Sets.

An ordered multiset partition into sets $c$ of a multiset $X$ is a list of nonempty subsets (not multisets), called the blocks of $c$, whose multi-union is $X$.

The number of blocks of $c$ is called its length. The order of $c$ is the cardinality of the multiset $X$. If, additionally, $X$ is a multiset of positive integers, then the size of $c$ is the sum of all elements of $X$.

The user may wish to focus on ordered multiset partitions into sets of a given size, or over a given alphabet. Hence, this class allows a variety of arguments as input.

INPUT:

Expects one or two arguments, with different behaviors resulting:

- One Argument:
• $X$ – a dictionary or list or tuple (representing a multiset for $c$), or an integer (representing the size of $c$)

• Two Arguments:
  – $A$ – a list (representing allowable letters within blocks of $c$), or a positive integer (representing the maximal allowable letter)
  – $n$ – a nonnegative integer (the total number of letters within $c$)

Optional keyword arguments are as follows: (See corresponding methods in see \texttt{OrderedMultisetPartitionIntoSets} for more details.)

• \texttt{weight=}$X$ (list or dictionary $X$) specifies the multiset for $c$
• \texttt{size=}$n$ (integer $n$) specifies the size of $c$
• \texttt{alphabet=}$A$ (iterable $A$) specifies allowable elements for the blocks of $c$
• \texttt{length=}$k$ (integer $k$) specifies the number of blocks in the partition
• \texttt{min\_length=}$k$ (integer $k$) specifies minimum number of blocks in the partition
• \texttt{max\_length=}$k$ (integer $k$) specifies maximum number of blocks in the partition
• \texttt{order=}$n$ (integer $n$) specifies the cardinality of the multiset that $c$ partitions
• \texttt{min\_order=}$n$ (integer $n$) specifies minimum number of elements in the partition
• \texttt{max\_order=}$n$ (integer $n$) specifies maximum number of elements in the partition

\textbf{EXAMPLES:}

Passing one argument to \texttt{OrderedMultisetPartitionsIntoSets}:  
There are 5 ordered multiset partitions into sets of the multiset $\{1,1,4\}$:

\begin{verbatim}
sage: OrderedMultisetPartitionsIntoSets([1,1,4]).cardinality()
5
\end{verbatim}

Here is the list of them:

\begin{verbatim}
sage: OrderedMultisetPartitionsIntoSets([1,1,4]).list()
[[[1], [1], [4]], [[1], [1,4]], [[1], [4], [1]], [[1,4], [1]], [[4], [1], [1]]]
\end{verbatim}

By chance, there are also 5 ordered multiset partitions into sets of the integer 3:

\begin{verbatim}
sage: OrderedMultisetPartitionsIntoSets(3).cardinality()
5
\end{verbatim}

Here is the list of them:

\begin{verbatim}
sage: OrderedMultisetPartitionsIntoSets(3).list()
[[[3]], [[1,2]], [[2], [1]], [[1], [2]], [[1], [1], [1]]]
\end{verbatim}

Passing two arguments to \texttt{OrderedMultisetPartitionsIntoSets}:  
There are also 5 ordered multiset partitions into sets of order 2 over the alphabet $\{1, 4\}$:

\begin{verbatim}
sage: OrderedMultisetPartitionsIntoSets([1, 4], 2)
Ordered Multiset Partitions into Sets of order 2 over alphabet {1, 4}
sage: OrderedMultisetPartitionsIntoSets([1, 4], 2).cardinality()
5
\end{verbatim}
Here is the list of them:

```
sage: OrderedMultisetPartitionsIntoSets([1, 4], 2).list()
[[[1, 4]], [[1], [4]], [[4], [1]], [[4], [4]]]
```

If no arguments are passed to `OrderedMultisetPartitionsIntoSets`, then the code returns all ordered multiset partitions into sets:

```
sage: OrderedMultisetPartitionsIntoSets()
Ordered Multiset Partitions into Sets
sage: [] in OrderedMultisetPartitionsIntoSets()
True
sage: [[2, 3], [1]] in OrderedMultisetPartitionsIntoSets()
True
sage: [['a', 'b'], ['a']] in OrderedMultisetPartitionsIntoSets()
True
sage: [[-2, 3], [3]] in OrderedMultisetPartitionsIntoSets()
True
sage: [[2], [3, 3]] in OrderedMultisetPartitionsIntoSets()
False
```

The following examples show how to test whether or not an object is an ordered multiset partition into sets:

```
sage: [[3, 2], [2]] in OrderedMultisetPartitionsIntoSets()
True
sage: [[3, 2], [2]] in OrderedMultisetPartitionsIntoSets(7)
True
sage: [[3, 2], [2]] in OrderedMultisetPartitionsIntoSets([2, 2, 3])
True
sage: [[3, 2], [2]] in OrderedMultisetPartitionsIntoSets(5)
False
```

**Optional keyword arguments**

Passing keyword arguments that are incompatible with required requirements results in an error; otherwise, the collection of ordered multiset partitions into sets is restricted accordingly:

The `weight` keyword:

This is used to specify which multiset \( X \) is to be considered, if this multiset was not passed as one of the required arguments for `OrderedMultisetPartitionsIntoSets`. In principle, it is a dictionary, but weak compositions are also allowed. For example, the ordered multiset partitions into sets of integer 4 are listed by weight below:

```
sage: OrderedMultisetPartitionsIntoSets(4, weight=[0, 0, 0, 1])
Ordered Multiset Partitions into Sets of integer 4 with constraint: weight={4: 1}
sage: OrderedMultisetPartitionsIntoSets(4, weight=[0, 0, 0, 1]).list()
[[[4]]]
sage: OrderedMultisetPartitionsIntoSets(4, weight=[1, 0, 1]).list()
[[[1], [3]], [[1, 3]], [[3], [1]]]
sage: OrderedMultisetPartitionsIntoSets(4, weight=[0, 2]).list()
[[[2], [2]]]
sage: OrderedMultisetPartitionsIntoSets(4, weight=[0, 1, 1]).list()
[]
sage: OrderedMultisetPartitionsIntoSets(4, weight=[2, 1]).list()
[[[1], [1, 2]], [[1], [1, 2]], [[1], (2), [1]], [[1, 2], [1]], [[2], [1, 1]]]
sage: O1 = OrderedMultisetPartitionsIntoSets(weight=[2, 0, 1])
```

(continues on next page)
sage: O2 = OrderedMultisetPartitionsIntoSets(weight={1:2, 3:1})
sage: O1 == O2
True
sage: OrderedMultisetPartitionsIntoSets(4, weight=[4]).list()

[[[1], [1], [1], [1]]]

The size keyword:

This is used to constrain the sum of entries across all blocks of the ordered multiset partition into sets. (This size is not pre-determined when alphabet \(A\) and order \(d\) are passed as required arguments.) For example, the ordered multiset partitions into sets of order 3 over the alphabet \([1, 2, 4]\) that have size equal to 5 are as follows:

sage: OMPs = OrderedMultisetPartitionsIntoSets
sage: OMPs([1,2,4], 3, size=5).list()

[[[1,2], [2]], [[2], [1,2]], [[2], [2], [1]],
[[2], [1], [2]], [[1], [2], [2]]]

The alphabet option:

This is used to constrain which integers appear across all blocks of the ordered multiset partition into sets. For example, the ordered multiset partitions into sets of integer 4 are listed for different choices of alphabet below. Note that alphabet is allowed to be an integer or an iterable:

sage: OMPs = OrderedMultisetPartitionsIntoSets
sage: OMPs(4, alphabet=3).list()

[[[1,3]], [[3], [1]],
[[1,2], [1]], [[2], [2]],
[[2], [1], [1]], [[1], [3]],
[[1], [1,2]], [[1], [2], [1]],
[[1], [1], [2]], [[1], [1], [1]]

sage: OMPs(4, alphabet=[1,2,3]) == OMPs(4, alphabet=[1,2,3])
True
sage: OMPs(4, alphabet=[1,3]).list()

[]
sage: OMPs(4, alphabet=[1,3]).list()

[[[1,3]], [[3], [1]], [[1], [3]], [[1], [1,1]], [[1], [1], [1]]]

sage: OMPs(4, alphabet=[2]).list()

[[[1,2], [1]], [[2], [1]],
[[1], [2], [1]], [[1], [1], [2]], [[1], [1], [1]]

sage: OMPs(4, alphabet=4).list() == OMPs(4).list()
True

The length, min_length, and max_length options:

These are used to constrain the number of blocks within the ordered multiset partitions into sets. For example, the ordered multiset partitions into sets of integer 4 of length exactly 2, at least 2, and at most 2 are given by:

sage: OrderedMultisetPartitionsIntoSets(4, length=2).list()

[[[3], [1]], [[1,2], [1]], [[2], [2]], [[1], [3]], [[1], [1,2]]]

sage: OrderedMultisetPartitionsIntoSets(4, min_length=3).list()

[[[2], [1], [1]], [[1], [2], [1]], [[1], [1], [2]], [[1], [1], [1]]

sage: OrderedMultisetPartitionsIntoSets(4, max_length=2).list()

[[[4], [[1,3]], [[3], [1]], [[1,2], [1]], [[2], [2]], [[1], [3]],
[[1], [1,2]]]

The order, min_order, and max_order options:
These are used to constrain the number of elements across all blocks of the ordered multiset partitions into sets. For example, the ordered multiset partitions into sets of integer 4 are listed by order below:

```
sage: OrderedMultisetPartitionsIntoSets(4, order=1).list()
[[[4]]]
sage: OrderedMultisetPartitionsIntoSets(4, order=2).list()
[[[1,3]], [[3], [1]], [[2], [2]], [[1], [3]]]
sage: OrderedMultisetPartitionsIntoSets(4, order=3).list()
[[[1,2], [1]], [[2], [1]], [[1], [1]], [[1], [2]], [[1], [1], [2]]]
sage: OrderedMultisetPartitionsIntoSets(4, order=4).list()
[[[1], [1], [1], [1]]]
```

Also, here is a use of `max_order`, giving the ordered multiset partitions into sets of integer 4 with order 1 or 2:

```
sage: OrderedMultisetPartitionsIntoSets(4, max_order=2).list()
[[[4]], [[1,3]], [[3], [1]], [[2], [2]], [[1], [3]]]
```

Element alias of `OrderedMultisetPartitionIntoSets` subset(size)

Return a subset of all ordered multiset partitions into sets.

INPUT:

- size – an integer representing a slice of all ordered multiset partitions into sets

The slice alluded to above is taken with respect to length, or to order, or to size, depending on the constraints of self.

EXAMPLES:

```
sage: C = OrderedMultisetPartitionsIntoSets(weight={2:2, 3:1, 5:1})
sage: C.subset(3)
Ordered Multiset Partitions into Sets of multiset {{2, 2, 3, 5}} with constraint: length=3
sage: C = OrderedMultisetPartitionsIntoSets(weight={2:2, 3:1, 5:1}, min_length=2)
Ordered Multiset Partitions into Sets of multiset {{2, 2, 3, 5}} with constraint: length=2
sage: C = OrderedMultisetPartitionsIntoSets(alphabet=[2,3,5])
Ordered Multiset Partitions into Sets of order 3 over alphabet {2, 3, 5}
sage: C = OrderedMultisetPartitionsIntoSets(order=5)
Ordered Multiset Partitions into Sets of integer 3 with constraint: order=5
sage: C = OrderedMultisetPartitionsIntoSets(alphabet=[2,3,5], order=5, min_length=3)
Ordered Multiset Partitions into Sets of order 3 over alphabet {2, 3, 5} with constraint: length=3
sage: C = OrderedMultisetPartitionsIntoSets(alphabet=[2,3,5])
Ordered Multiset Partitions into Sets of order 3 over alphabet {2, 3, 5}
```

```
sage: C = OrderedMultisetPartitionsIntoSets()  
Ordered Multiset Partitions into Sets of integer 3
sage: C.subset(3) == OrderedMultisetPartitionsIntoSets(3)
True
```

class `sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets`
Bases: `sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets`

Class of ordered multiset partitions into sets of a fixed multiset $X$.

`cardinality()`

Return the number of ordered partitions of multiset $X$.

`random_element()`

Return a random element of `self`.

This method does not return elements of `self` with uniform probability, but it does cover all elements. The scheme is as follows:

- produce a random permutation $p$ of the multiset;
- create blocks of an OMP fat by breaking $p$ after non-ascents;
- take a random element of fat.finer().

EXAMPLES:

```python
sage: OrderedMultisetPartitionsIntoSets([1,1,3]).random_element()  # random
[[1], [1, 3]]
```

```python
sage: OMP = OrderedMultisetPartitionsIntoSets([1,1,3,3])
sage: d = {}
sage: for _ in range(1000):
    x = OMP.random_element()
    d[x] = d.get(x, 0) + 1
sage: d.values()  # random
[102, 25, 76, 24, 66, 88, 327, 27, 83, 83, 239, 72, 88]
```

class `sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets_X_constraints` (**constraints**)

Bases: `sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets`

Class of ordered multiset partitions into sets of a fixed multiset $X$ satisfying constraints.

class `sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets_all_constraints` (**constrains**)

Bases: `sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets`

All ordered multiset partitions into sets (with or without constraints).

EXAMPLES:

```python
sage: C = OrderedMultisetPartitionsIntoSets(); C
Ordered Multiset Partitions into Sets
sage: [[1], [1, 'a']] in C
True
```

```python
sage: OrderedMultisetPartitionsIntoSets(weight=[2,0,1], length=2)
Ordered Multiset Partitions into Sets of multiset \{1, 1, 3\} with constraint:
  \[*\]length=2
```
class sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets_alph_d_constraints
Bases: sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets

Class of ordered multiset partitions into sets of specified order $d$ over a fixed alphabet $A$ satisfying constraints.

cardinality()
Return the number of elements in self.

random_element()
Return a random element of self.

This method does not return elements of self with uniform probability, but it does cover all elements. The scheme is as follows:

• produce a random composition $C$;
• choose a random partition of $c$ into distinct parts for each $c$ in $C$.

EXAMPLES:
sage: OrderedMultisetPartitionsIntoSets(5).random_element()  # random
[(1, 2), (1), (1)]
sage: OrderedMultisetPartitionsIntoSets(5).random_element()  # random
[(2), (1, 2)]

sage: OMP = OrderedMultisetPartitionsIntoSets(5)
sage: d = {}
sage: for _ in range(1100):
    x = OMP.random_element()
    d[x] = d.get(x, 0) + 1
sage: d.values()  # random
[72, 73, 162, 78, 135, 75, 109, 65, 135, 134, 62]

class sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets

Bases: sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets

Class of ordered multiset partitions into sets of a fixed integer $n$ satisfying constraints.

5.1.143 Non-Commutative Symmetric Functions and Quasi-Symmetric Functions

• Introduction to Quasisymmetric Functions
• Non-Commutative Symmetric Functions (NCSF)
• Quasi-Symmetric Functions (QSym)
• Generic code for bases

5.1.144 Features that are imported by default in the interpreter namespace

5.1.145 Common combinatorial tools

REFERENCES:
sage.combinat.ncsf_qsym.combinatorics.coeff_dab(I, J)

Return the number of standard composition tableaux of shape $I$ with descent composition $J$.

INPUT:
• $I$, $J$ – compositions

OUTPUT:
• An integer

EXAMPLES:
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_dab
sage: coeff_dab(Composition([2,1]),Composition([2,1]))
1
sage: coeff_dab(Composition([1,1,2]),Composition([1,2,1]))
0
sage.combinat.ncsf_qsym.combinatorics.coeff_ell(J, I)
Returns the coefficient $\ell_{J,I}$ as defined in [NCSF].

INPUT:
• J – a composition
• I – a composition refining J

OUTPUT:
• integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_ell
sage: coeff_ell(Composition([1,1,1]), Composition([2,1]))
2
sage: coeff_ell(Composition([2,1]), Composition([3]))
2
```

sage.combinat.ncsf_qsym.combinatorics.coeff_lp(J, I)
Returns the coefficient $lp_{J,I}$ as defined in [NCSF].

INPUT:
• J – a composition
• I – a composition refining J

OUTPUT:
• integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_lp
sage: coeff_lp(Composition([1,1,1]), Composition([2,1]))
1
sage: coeff_lp(Composition([2,1]), Composition([3]))
1
```

sage.combinat.ncsf_qsym.combinatorics.coeff_pi(J, I)
Returns the coefficient $\pi_{J,I}$ as defined in [NCSF].

INPUT:
• J – a composition
• I – a composition refining J

OUTPUT:
• integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_pi
sage: coeff_pi(Composition([1,1,1]), Composition([2,1]))
2
sage: coeff_pi(Composition([2,1]), Composition([3]))
6
```
sage.combinat.ncsf_qsym.combinatorics.coeff_sp(J, I)
Returns the coefficient \( s_p_{J, I} \) as defined in [NCSF].

**INPUT:**
- \( J \) – a composition
- \( I \) – a composition refining \( J \)

**OUTPUT:**
- integer

**EXAMPLES:**

```python
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_sp
sage: coeff_sp(Composition([1,1,1]), Composition([2,1]))
2
sage: coeff_sp(Composition([2,1]), Composition([3]))
4
```

sage.combinat.ncsf_qsym.combinatorics.compositions_order(n)
Return the compositions of \( n \) ordered as defined in [QSCHUR].

Let \( S(\gamma) \) return the composition \( \gamma \) after sorting. For compositions \( \alpha \) and \( \beta \), we order \( \alpha \triangleright \beta \) if

1. \( S(\alpha) > S(\beta) \) lexicographically, or
2. \( S(\alpha) = S(\beta) \) and \( \alpha > \beta \) lexicographically.

**INPUT:**
- \( n \) – a positive integer

**OUTPUT:**
- A list of the compositions of \( n \) sorted into decreasing order by \( \triangleright \)

**EXAMPLES:**

```python
sage: from sage.combinat.ncsf_qsym.combinatorics import compositions_order
sage: compositions_order(3)
[[3], [2, 1], [1, 2], [1, 1, 1]]
sage: compositions_order(4)
[[4], [3, 1], [2, 3], [2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

sage.combinat.ncsf_qsym.combinatorics.m_to_s_stat(R, I, K)
Return the coefficient of the complete non-commutative symmetric function \( S^K \) in the expansion of the monomial non-commutative symmetric function \( M^I \) with respect to the complete basis over the ring \( R \). This is the coefficient in formula (36) of Tevlin’s paper [Tev2007].

**INPUT:**
- \( R \) – A ring, supposed to be a \( \mathbb{Q} \)-algebra
- \( I, K \) – compositions

**OUTPUT:**
- The coefficient of \( S^K \) in the expansion of \( M^I \) in the complete basis of the non-commutative symmetric functions over \( R \).

**EXAMPLES:**
sage: from sage.combinat.ncsf_qsym.combinatorics import m_to_s_stat
sage: m_to_s_stat(QQ, Composition([2,1]), Composition([1,1,1]))
-1
sage: m_to_s_stat(QQ, Composition([3]), Composition([1,2]))
-2
sage: m_to_s_stat(QQ, Composition([2,1,2]), Composition([2,1,2]))
8/3

sage.combinat.ncsf_qsym.combinatorics.number_of_SSRCT(content_comp, shape_comp)
The number of semi-standard reverse composition tableaux.

The dual quasisymmetric-Schur functions satisfy a left Pieri rule where \( S_n dQ_S \gamma \) is a sum over dual quasisymmetric-Schur functions indexed by compositions which contain the composition \( \gamma \). The definition of an SSRCT comes from this rule. The number of SSRCT of content \( \beta \) and shape \( \alpha \) is equal to the number of SSRCT of content \((\beta_2, \ldots, \beta_t)\) and shape \( \gamma \) where \( dQ_S \alpha \) appears in the expansion of \( S_\beta dQ_S \gamma \).

In sage the recording tableau for these objects are called CompositionTableaux.

INPUT:

- content_comp, shape_comp – compositions

OUTPUT:

- An integer

EXAMPLES:

sage: from sage.combinat.ncsf_qsym.combinatorics import number_of_SSRCT
sage: number_of_SSRCT(Composition([3,1]), Composition([1,3]))
0
sage: number_of_SSRCT(Composition([1,2,1]), Composition([1,3]))
1
sage: number_of_SSRCT(Composition([1,1,2,2]), Composition([3,3]))
2
sage: all(CompositionTableaux(be).cardinality() == sum(number_of_SSRCT(al,be)*binomial(4,len(al)) for al in Compositions(4)) for be in Compositions(4))
True

sage.combinat.ncsf_qsym.combinatorics.number_of_fCT(content_comp, shape_comp)
Return the number of immaculate tableaux of shape shape_comp and content content_comp.

See [BBSSZ2012], Definition 3.9, for the notion of an immaculate tableau.

INPUT:

- content_comp, shape_comp – compositions

OUTPUT:

- An integer

EXAMPLES:

sage: from sage.combinat.ncsf_qsym.combinatorics import number_of_fCT
sage: number_of_fCT(Composition([3,1]), Composition([1,3]))
0
sage: number_of_fCT(Composition([1,2,1]), Composition([1,3]))
1

(continues on next page)
5.1.146 Generic code for bases

This is a collection of code that is shared by bases of noncommutative symmetric functions and quasisymmetric functions.

AUTHORS:

• Jason Bandlow
• Franco Saliola
• Chris Berg

class sage.combinat.ncsf_qsym.generic_basis_code.AlgebraMorphism(domain, on_generators, position=0, codomain=None, category=None, anti=False)

Bases: sage.modules.with_basis.morphism.ModuleMorphismByLinearity

A class for algebra morphism defined on a free algebra from the image of the generators

class sage.combinat.ncsf_qsym.generic_basis_code.BasesOfQSymOrNCSF(parent_with_realization)

Bases: sage.categories.realizations.Category_realization_of_parent

class ElementMethods

Bases: object

degree()

The maximum of the degrees of the homogeneous summands.

See also:

homogeneous_degree()

EXAMPLES:

sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: (x, y) = (S[2], S[3])
sage: x.degree()
2
sage: (x^3 + 4*y^2).degree()
6
sage: ((1 + x)^3).degree()
6

sage: F = QuasiSymmetricFunctions(QQ).F()
sage: (x, y) = (F[2], F[3])
sage: x.degree()
2
sage: (x^3 + 4*y^2).degree()
6
sage: ((1 + x)^3).degree()
6
degree_negation()

Return the image of self under the degree negation automorphism of the parent of self.

The degree negation is the automorphism which scales every homogeneous element of degree $k$ by $(-1)^k$ (for all $k$).

Calling degree_negation(self) is equivalent to calling self.parent().degree_negation(self).

EXAMPLES:

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: f = 2*S[2,1] + 4*S[1,1] - 5*S[1,2] - 3*S[]
sage: f.degree_negation()
-3*S[] + 4*S[1, 1] + 5*S[1, 2] - 2*S[2, 1]

sage: QSym = QuasiSymmetricFunctions(QQ)
sage: dI = QSym.dualImmaculate()
sage: f.degree_negation()
```

Todo: Generalize this to all graded vector spaces?

duality_pairing(y)

The duality pairing between elements of $NSym$ and elements of $QSym$.

The complete basis is dual to the monomial basis with respect to this pairing.

INPUT:

- y – an element of the dual Hopf algebra of self

OUTPUT:

- The result of pairing self with y.

EXAMPLES:

```python
sage: R = NonCommutativeSymmetricFunctions(QQ).Ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R[1,1,2].duality_pairing(F[1,1,2])
1
sage: R[1,2,1].duality_pairing(F[1,1,2])
0
sage: L = NonCommutativeSymmetricFunctions(QQ).Elementary()
sage: L[1,2].duality_pairing(F[1,2])
0
sage: L[1,1,1].duality_pairing(F[1,2])
1
```

skew_by (y, side='left')

The operation which is dual to multiplication by $y$, where $y$ is an element of the dual space of self.

This is calculated through the coproduct of self and the expansion of $y$ in the dual basis.

INPUT:

- y – an element of the dual Hopf algebra of self
- side – (Default='left') Either 'left' or 'right'
• The result of skewing \( \text{self} \) by \( y \), on the side \( \text{side} \)

**EXAMPLES:**

Skewing an element of NCSF by an element of QSym:

```python
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R([2,2,2]).skew_by(F[1,1])
sage: R([2,2,2]).skew_by(F[2])
```

Skewing an element of QSym by an element of NCSF:

```python
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F[3,2].skew_by(R[1,1])
0
sage: F[3,2].skew_by(R[1,1], side='right')
0
sage: F[3,2].skew_by(S[1,1,1], side='right')
F[2]
sage: F[3,2].skew_by(S[1,2], side='right')
F[2]
sage: F[3,2].skew_by(S[2,1], side='right')
0
sage: F[3,2].skew_by(S[1,1,1])
F[2]
sage: F[3,2].skew_by(S[1,1])
F[1, 2]
sage: F[3,2].skew_by(S[1,1,1])
F[2, 2]
```

```python
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M[3,2].skew_by(S[2])
0
sage: M[3,2].skew_by(S[2], side='right')
M[3]
sage: M[3,2].skew_by(S[3])
M[2]
sage: M[3,2].skew_by(S[3], side='right')
0
```

```python

class ParentMethods
    Bases: object

    alternating_sum_of_compositions(n)
    Alternating sum over compositions of \( n \).

    Note that this differs from the method \( \text{alternating\_sum\_of\_finer\_compositions()} \) because the coefficient of the composition \( 1^n \) is positive. This method is used in the expansion of the elementary generators into the complete generators and vice versa.
```
INPUT:
• \( n \) – a positive integer

OUTPUT:
• The expansion of the complete generator indexed by \( n \) into the elementary basis.

EXAMPLES:

```python
sage: L=NonCommutativeSymmetricFunctions(QQ).L()
sage: L.alternating_sum_of_compositions(0)
L[]
sage: L.alternating_sum_of_compositions(1)
L[1]
sage: L.alternating_sum_of_compositions(2)
L[1, 1] - L[2]
```

alternating_sum_of_fatter_compositions (composition)

Return the alternating sum of fatter compositions in a basis of the non-commutative symmetric functions.

INPUT:
• composition – a composition

OUTPUT:
• The alternating sum of the compositions fatter than composition, in the basis self. The alternation is upon the length of the compositions, and is normalized so that composition has coefficient 1.

EXAMPLES:

```python
sage: NCSF=NonCommutativeSymmetricFunctions(QQ)
sage: elementary = NCSF.elementary()
sage: elementary.alternating_sum_of_fatter_compositions(Composition([2,2,1]))
sage: elementary.alternating_sum_of_fatter_compositions(Composition([1,2]))
L[1, 2] - L[3]
```

alternating_sum_of_finer_compositions (composition, conjugate=False)

Return the alternating sum of finer compositions in a basis of the non-commutative symmetric functions.

INPUT:
• composition – a composition
• conjugate – (default: False) a boolean

OUTPUT:
• The alternating sum of the compositions finer than composition, in the basis self. The alternation is upon the length of the compositions, and is normalized so that composition has coefficient 1. If the variable conjugate is set to True, then the conjugate of composition is used instead of composition.

EXAMPLES:

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: elementary = NCSF.elementary()
sage: elementary.alternating_sum_of_finer_compositions(Composition([2,2,-1]))
(continues on next page)
```
\begin{verbatim}
L[1, 1, 1, 1, 1] - L[1, 1, 2, 1] - L[2, 1, 1, 1] + L[2, 2, 1] + L[1, 1, 1] - L[1, 2]
sage: elementary.alternating_sum_of_finer_compositions(Composition([1, 2]))
-L[1, 1, 1] + L[1, 2]
\end{verbatim}

c\text{counit\_on\_basis}(I)

The counit is defined by sending all elements of positive degree to zero.

\text{EXAMPLES:}

\begin{verbatim}
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.counit_on_basis([1, 3])
0
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.counit_on_basis([1, 3])
0
\end{verbatim}

d\text{degree\_negation}(element)

Return the image of \text{element} under the degree negation automorphism of \text{self}.

The degree negation is the automorphism which scales every homogeneous element of degree \( k \) by \((-1)^k\) (for all \( k \)).

\text{INPUT:}

• \text{element} – element of \text{self}

\text{EXAMPLES:}

\begin{verbatim}
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: S.degree_negation(f)
-3*F[[]] + 4*F[1, 1] + 5*F[1, 2] - 2*F[2, 1]
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: dI = QSym.dualImmaculate()
sage: dI.degree_negation(f)
\end{verbatim}

\text{Todo:} Generalize this to all graded vector spaces?

d\text{degree\_on\_basis}(I)

Return the degree of the basis element indexed by \( I \).

\text{INPUT:}

• \( I \) – a composition

\text{OUTPUT:}

• The degree of the non-commutative symmetric function basis element of \text{self} indexed by \( I \). By definition, this is the size of the composition \( I \).

\text{EXAMPLES:}

\begin{verbatim}
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R.decomposition_on_basis(Composition([2, 3]))
5
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: M.decomposition_on_basis(Composition([3, 2]))
\end{verbatim}
The duality pairing between elements of $NSym$ and elements of $QSym$.

This is a default implementation that uses `self.realizations_of().a_realization()` and its dual basis.

**INPUT:**
- $x$ – an element of `self`
- $y$ – an element in the dual basis of `self`

**OUTPUT:**
- The result of pairing the function $x$ from `self` with the function $y$ from the dual basis of `self`

**EXAMPLES:**

```python
sage: R = NonCommutativeSymmetricFunctions(QQ).Ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R.duality_pairing(R[1,1,2], F[1,1,2])
1
sage: R.duality_pairing(R[1,2,1], F[1,1,2])
0
sage: F.duality_pairing(F[1,2,1], R[1,1,2])
0
sage: S = NonCommutativeSymmetricFunctions(QQ).Complete()
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: S.duality_pairing(S[1,1,2], M[1,1,2])
1
sage: S.duality_pairing(S[1,2,1], M[1,1,2])
0
sage: M.duality_pairing(M[1,1,2], S[1,1,2])
1
sage: M.duality_pairing(M[1,2,1], S[1,1,2])
0
sage: S = NonCommutativeSymmetricFunctions(QQ).Complete()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: S.duality_pairing(S[1,2], F[1,1,1])
0
sage: S.duality_pairing(S[1,1,1,1], F[4])
1
```

duality_pairing_by_coercion$(x,y)$

The duality pairing between elements of $NSym$ and elements of $QSym$.

This is a default implementation that uses `self.realizations_of().a_realization()` and its dual basis.

**INPUT:**
- $x$ – an element of `self`
- $y$ – an element in the dual basis of `self`

**OUTPUT:**
- The result of pairing the function $x$ from `self` with the function $y$ from the dual basis of `self`

**EXAMPLES:**

```python
```
sage: L = NonCommutativeSymmetricFunctions(QQ).Elementary()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: L.duality_pairing_by_coercion(L[1,2], F[1,2])
0
sage: F.duality_pairing_by_coercion(F[1,2], L[1,2])
0
sage: L.duality_pairing_by_coercion(L[1,1,1], F[1,2])
1
sage: F.duality_pairing_by_coercion(F[1,2], L[1,1,1])
1

duality_pairing_matrix(basis, degree)
The matrix of scalar products between elements of NSym and elements of QSym.

INPUT:
• basis – A basis of the dual Hopf algebra
• degree – a non-negative integer

OUTPUT:
• The matrix of scalar products between the basis self and the basis basis in the dual Hopf algebra in degree degree.

EXAMPLES:
The ribbon basis of NCSF is dual to the fundamental basis of QSym:

sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R.duality_pairing_matrix(F, 3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: F.duality_pairing_matrix(R, 3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]

The complete basis of NCSF is dual to the monomial basis of QSym:

sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: S.duality_pairing_matrix(M, 3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: M.duality_pairing_matrix(S, 3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]

The matrix between the ribbon basis of NCSF and the monomial basis of QSym:

sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: R.duality_pairing_matrix(M, 3)
(continues on next page)
The matrix between the complete basis of NCSF and the fundamental basis of QSym:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: S.duality_pairing_matrix(F, 3)
[ 1 1 1 1]
[ 0 1 0 1]
[ 0 0 1 1]
[ 0 0 0 1]
```

A base case test:

```
sage: R.duality_pairing_matrix(M, 0)
[1]
```

**one_basis()**

Return the empty composition.

**OUTPUT:**

* The empty composition.

**EXAMPLES:**

```
sage: L = NonCommutativeSymmetricFunctions(QQ).L()
sage: parent(L)
<class 'sage.combinat.ncsf_qsym.ncsf.NonCommutativeSymmetricFunctions.
˓Elementary_with_category'>
sage: parent(L).one_basis()
[]
```

**skew** *(x, y, side='left')*

Return a function \( x \) in \( \text{self} \) skewed by a function \( y \) in the Hopf dual of \( \text{self} \).

**INPUT:**

* \( x \) – a non-commutative or quasi-symmetric function; it is an element of \( \text{self} \)
* \( y \) – a quasi-symmetric or non-commutative symmetric function; it is an element of the dual algebra of \( \text{self} \)
* \( \text{side} \) – (default: 'left') either 'left' or 'right'

**OUTPUT:**

* The result of skewing the element \( x \) by the Hopf algebra element \( y \) (either from the left or from the right, as determined by \( \text{side} \)), written in the basis \( \text{self} \).

**EXAMPLES:**

```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: S.skew(S[2, 2, 2], F[1, 1])
S[1, 1, 2] + S[1, 2, 1] + S[2, 1, 1]
```
sage: S.skew(S[2,2,2], F[2])
S[1, 1, 2] + S[1, 2, 1] + S[2, 1, 1] + 3*S[2, 2]

sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R.skew(R[2,2,2], F[1,1])

sage: R.skew(R[2,2,2], F[2])

sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.skew(M[3,2], S[2])

sum_of_fatter_compositions (composition)
Return the sum of all fatter compositions.

INPUT:
• composition – a composition

OUTPUT:
• the sum of all basis elements which are indexed by compositions fatter (coarser?) than
  composition.

EXAMPLES:

sage: L=NonCommutativeSymmetricFunctions(QQ).L()
sage: L.sum_of_fatter_compositions(Composition([2,1]))
L[2, 1] + L[3]

sage: R=NonCommutativeSymmetricFunctions(QQ).R()
sage: R.sum_of_fatter_compositions(Composition([1,3]))
R[1, 3] + R[4]

sum_of_finer_compositions (composition)
Return the sum of all finer compositions.

INPUT:
• composition – a composition

OUTPUT:
• The sum of all basis self elements which are indexed by compositions finer than
  composition.

EXAMPLES:

sage: L=NonCommutativeSymmetricFunctions(QQ).L()
sage: L.sum_of_finer_compositions(Composition([2,1]))
L[1, 1, 1] + L[2, 1]

sage: R=NonCommutativeSymmetricFunctions(QQ).R()
sum_of_partition_rearrangements (par)

Return the sum of all basis elements indexed by compositions which can be sorted to obtain a given partition.

INPUT:
• par – a partition

OUTPUT:
• The sum of all self basis elements indexed by compositions which are permutations of par (without multiplicity).

EXAMPLES:

```
sage: NCSF=NonCommutativeSymmetricFunctions(QQ)
sage: elementary = NCSF.elementary()
sage: elementary.sum_of_partition_rearrangements(Partition([2,2,1]))
L[1, 2, 2] + L[2, 1, 2] + L[2, 2, 1]
sage: elementary.sum_of_partition_rearrangements(Partition([3,2,1]))
L[1, 2, 3] + L[1, 3, 2] + L[2, 1, 3] + L[2, 3, 1] + L[3, 1, 2] + L[3, 2, 1]
sage: elementary.sum_of_partition_rearrangements(Partition([]))
L[]
```

super_categories ()

class sage.combinat.ncsf_qsym.generic_basis_code.GradedModulesWithInternalProduct (base, name=None):

Bases: sage.categories.category_types.Category_over_base_ring

Constructs the class of modules with internal product. This is used to give an internal product structure to the non-commutative symmetric functions.

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.generic_basis_code import GradedModulesWithInternalProduct
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: R in GradedModulesWithInternalProduct(QQ)
True
```

class ElementMethods

Bases: object

internal_product (other)

Return the internal product of two non-commutative symmetric functions.

The internal product on the algebra of non-commutative symmetric functions is adjoint to the internal coproduct on the algebra of quasisymmetric functions with respect to the duality pairing between these two algebras. This means, explicitly, that any two non-commutative symmetric functions \( f \) and \( g \) and any quasi-symmetric function \( h \) satisfy

\[
\langle f \ast g, h \rangle = \sum_i \langle f, h'_i \rangle \langle g, h''_i \rangle ,
\]

where we write \( \Delta^X(h) \) as \( \sum_i h'_i \otimes h''_i \). Here, \( f \ast g \) denotes the internal product of the non-commutative symmetric functions \( f \) and \( g \).
If \( f \) and \( g \) are two homogeneous elements of \( NSym \) having distinct degrees, then the internal product \( f \ast g \) is zero.

Explicit formulas can be given for internal products of elements of the complete and the Psi bases. First, the formula for the Complete basis ([NCSF1] Proposition 5.1): If \( I \) and \( J \) are two compositions of lengths \( p \) and \( q \), respectively, then the corresponding Complete homogeneous non-commutative symmetric functions \( S^I \) and \( S^J \) have internal product

\[
S^I \ast S^J = \sum S^{\text{comp } M},
\]

where the sum ranges over all \( p \times q \)-matrices \( M \in \mathbb{N}^{p\times q} \) (with nonnegative integers as entries) whose row sum vector is \( I \) (that is, the sum of the entries of the \( r \)-th row is the \( r \)-th part of \( I \) for all \( r \)) and whose column sum vector is \( J \) (that is, the sum of all entries of the \( s \)-th row is the \( s \)-th part of \( J \) for all \( s \)). Here, for any \( M \in \mathbb{N}^{p\times q} \), we denote by \( \text{comp } M \) the composition obtained by reading the entries of the matrix \( M \) in the usual order (row by row, proceeding left to right in each row, traversing the rows from top to bottom).

The formula on the Psi basis ([NCSF2] Lemma 3.10) is more complicated. Let \( I \) and \( J \) be two compositions of lengths \( p \) and \( q \), respectively, having the same size \( |I| = |J| \). We denote by \( \Psi^K \) the element of the Psi basis corresponding to any composition \( K \).

- If \( p > q \), then \( \Psi^I \ast \Psi^J \) is plainly 0.
- Assume that \( p = q \). Let \( \delta_{I,J} \) denote the integer 1 if the compositions \( I \) and \( J \) are permutations of each other, and the integer 0 otherwise. For every positive integer \( i \), let \( m_i \) denote the number of parts of \( I \) equal to \( i \). Then, \( \Psi^I \ast \Psi^J \) equals \( \delta_{I,J} \prod_{i>0} i^{m_i} \Psi^I \).
- Now assume that \( p < q \). Write the composition \( I \) as \( I = (i_1, i_2, \ldots, i_p) \). For every nonempty composition \( K = (k_1, k_2, \ldots, k_q) \), denote by \( \Gamma_K \) the non-commutative symmetric function \( k_1[[[\Psi_{k_1}, \Psi_{k_2}], \Psi_{k_3}]] \). For any subset \( A \) of \( \{1, 2, \ldots, q\} \), let \( J_A \) be the composition obtained from \( J \) by removing the \( r \)-th parts for all \( r \notin A \) (while keeping the \( r \)-th parts for all \( r \in A \) in order). Then, \( \Psi^I \ast \Psi^J \) equals the sum of \( \Gamma_{J_{K_1}} \Gamma_{J_{K_2}} \cdots \Gamma_{J_{K_p}} \) over all ordered set partitions \( (K_1, K_2, \ldots, K_p) \) of \( \{1, 2, \ldots, q\} \) into \( p \) parts such that each \( 1 \leq k \leq p \) satisfies \( |J_{K_k}| = i_k \). (See \text{OrderedSetPartition} for the meaning of “ordered set partition”.)

Aliases for \text{internal_product()} are \text{itensor()} and \text{kronecker_product()}. 

**INPUT:**
- **other** – another non-commutative symmetric function 

**OUTPUT:**
- The result of taking the internal product of \text{self} with \text{other}.

**EXAMPLES:**

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: x = S.an_element(); x
2*S[] + 2*S[1] + 3*S[1, 1]
sage: x.internal_product(S[2])
3*S[1, 1]
sage: x.internal_product(S[1])
2*S[1]
sage: S[1,2].internal_product(S[1,2])
S[1, 1, 1] + S[1, 2]
```

Let us check the duality between the inner product and the inner coproduct in degree 4:

```python
sage: M = QuasiSymmetricFunctions(FiniteField(29)).M()
sage: S = NonCommutativeSymmetricFunctions(FiniteField(29)).S()
sage: def tensor_incorp(f, g, h): # computes \sum_i \left< f, h'_i \right> \langle g, h''_i \rangle
    result = h.base_ring().zero()
    ....
```

(continues on next page)
The internal product on the algebra of non-commutative symmetric functions commutes with the canonical commutative projection on the symmetric functions:

\[
\langle f \ast g, h \rangle = \sum_{i} \langle f, h_i' \rangle \langle g, h_i'' \rangle,
\]

where we write \( \Delta^X(h) \) as \( \sum_i h_i' \otimes h_i'' \). Here, \( f \ast g \) denotes the internal product of the non-commutative symmetric functions \( f \) and \( g \).

If \( f \) and \( g \) are two homogeneous elements of \( NSym \) having distinct degrees, then the internal product \( f \ast g \) is zero.

Explicit formulas can be given for internal products of elements of the complete and the Psi bases. First, the formula for the Complete basis ([NCSF1] Proposition 5.1): If \( I \) and \( J \) are two compositions of lengths \( p \) and \( q \), respectively, then the corresponding Complete homogeneous non-commutative symmetric functions \( S_I \) and \( S_J \) have internal product

\[
S_I \ast S_J = \sum S^{\text{comp } M},
\]

where the sum ranges over all \( p \times q \)-matrices \( M \in \mathbb{N}^{p \times q} \) (with nonnegative integers as entries) whose row sum vector is \( I \) (that is, the sum of the entries of the \( r \)-th row is the \( r \)-th part of \( I \) for all \( r \)) and
whose column sum vector is $J$ (that is, the sum of all entries of the $s$-th row is the $s$-th part of $J$ for all $s$). Here, for any $M \in \mathbb{N}^{n \times q}$, we denote by $\text{comp} M$ the composition obtained by reading the entries of the matrix $M$ in the usual order (row by row, proceeding left to right in each row, traversing the rows from top to bottom).

The formula on the Psi basis ([NCSF2] Lemma 3.10) is more complicated. Let $I$ and $J$ be two compositions of lengths $p$ and $q$, respectively, having the same size $|I| = |J|$. We denote by $\Psi^K$ the element of the Psi basis corresponding to any composition $K$.

- If $p > q$, then $\Psi^I \ast \Psi^J$ is plainly 0.
- Assume that $p = q$. Let $\delta_{I,J}$ denote the integer 1 if the compositions $I$ and $J$ are permutations of each other, and the integer 0 otherwise. For every positive integer $i$, let $m_i$ denote the number of parts of $I$ equal to $i$. Then, $\Psi^I \ast \Psi^J = \delta_{I,J} \prod_{i \geq 0} i^{m_i} \Psi^I$.

- Now assume that $p < q$. Write the composition $I$ as $I = (i_1, i_2, \ldots, i_p)$. For every nonempty composition $K = (k_1, k_2, \ldots, k_s)$, denote by $\Gamma_K$ the non-commutative symmetric function $k_1 [\Psi_{k_1}, \Psi_{k_2}, \ldots, \Psi_{k_s}]$. For any subset $A$ of $\{1, 2, \ldots, q\}$, let $J_A$ be the composition obtained from $J$ by removing the $r$-th parts for all $r \notin A$ (while keeping the $r$-th parts for all $r \in A$ in order). Then, $\Psi^I \ast \Psi^J$ equals the sum of $\Gamma_{J_{k_1}} \Gamma_{J_{k_2}} \cdots \Gamma_{J_{k_p}}$ over all ordered set partitions $(K_1, K_2, \ldots, K_p)$ of $\{1, 2, \ldots, q\}$ into $p$ parts such that each $1 \leq k \leq p$ satisfies $|J_{k_i}| = i_k$. (See OrderedSetPartition() for the meaning of “ordered set partition.”)

Aliases for internal_product() are itensor() and kronecker_product().

**INPUT:**

- other – another non-commutative symmetric function

**OUTPUT:**

The result of taking the internal product of self with other.

**EXAMPLES:**

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: x = S.an_element(); x
2*S[] + 2*S[1] + 3*S[1, 1]
sage: x.internal_product(S[2])
3*S[1, 1]
sage: x.internal_product(S[1])
2*S[1]
sage: S[1,2].internal_product(S[1,2])
S[1, 1, 1] + S[1, 2]
```

Let us check the duality between the inner product and the inner coproduct in degree 4:

```
sage: M = QuasiSymmetricFunctions(FiniteField(29)).M()
sage: S = NonCommutativeSymmetricFunctions(FiniteField(29)).S()
sage: def tensor_incorp(f, g, h):
    # computes \sum_i \left< f, h'_i \right> \left< g, h''_i \right>
    result = h.base_ring().zero()
    h_parent = h.parent()
    for partition_pair, coeff in h.internal_coproduct().monomial_coefficients().items():
        result += coeff * f.duality_pairing(h_parent[partition_pair[0]]) * g.duality_pairing(h_parent[partition_pair[1]])
    return result
sage: def testall(n):
    return all( all( tensor_incorp(S[u], S[v], M[w]) == (S[u].itensor(S[v])).duality_pairing(M[w])
                 for w in Compositions(n) )
                for v in Compositions(n) )
```

(continues on next page)
The internal product on the algebra of non-commutative symmetric functions commutes with the canonical commutative projection on the symmetric functions:

```
sage: S = NonCommutativeSymmetricFunctions(ZZ).S()
sage: e = SymmetricFunctions(ZZ).e()
sage: def int_pr_of_S_in_e(I, J):
    ....:     return (S[I].internal_product(S[J])).to_symmetric_function()
sage: all( all( int_pr_of_S_in_e(I, J)
    ....:                 == S[I].to_symmetric_function().internal_product(S[J].to_symmetric_function())
    ....:               for I in Compositions(3) )
    ....:             for J in Compositions(3) )
True
```

**kronecker_product** *(other)*

Return the internal product of two non-commutative symmetric functions.

The internal product on the algebra of non-commutative symmetric functions is adjoint to the internal coproduct on the algebra of quasisymmetric functions with respect to the duality pairing between these two algebras. This means, explicitly, that any two non-commutative symmetric functions $f$ and $g$ and any quasi-symmetric function $h$ satisfy

$$\langle f \ast g, h \rangle = \sum_i \langle f, h'_i \rangle \langle g, h''_i \rangle,$$

where we write $\Delta^\times(h)$ as $\sum_i h'_i \otimes h''_i$. Here, $f \ast g$ denotes the internal product of the non-commutative symmetric functions $f$ and $g$.

If $f$ and $g$ are two homogeneous elements of $NSym$ having distinct degrees, then the internal product $f \ast g$ is zero.

Explicit formulas can be given for internal products of elements of the complete and the Psi bases. First, the formula for the Complete basis ([NCSF1] Proposition 5.1): If $I$ and $J$ are two compositions of lengths $p$ and $q$, respectively, then the corresponding Complete homogeneous non-commutative symmetric functions $S^I$ and $S^J$ have internal product

$$S^I \ast S^J = \sum S^{\text{comp } M},$$

where the sum ranges over all $p \times q$-matrices $M \in \mathbb{N}^{p \times q}$ (with nonnegative integers as entries) whose row sum vector is $I$ (that is, the sum of the entries of the $r$-th row is the $r$-th part of $I$ for all $r$) and whose column sum vector is $J$ (that is, the sum of all entries of the $s$-th row is the $s$-th part of $J$ for all $s$). Here, for any $M \in \mathbb{N}^{p \times q}$, we denote by $\text{comp } M$ the composition obtained by reading the entries of the matrix $M$ in the usual order (row by row, proceeding left to right in each row, traversing the rows from top to bottom).

The formula on the Psi basis ([NCSF2] Lemma 3.10) is more complicated. Let $I$ and $J$ be two compositions of lengths $p$ and $q$, respectively, having the same size $|I| = |J|$. We denote by $\Psi^K$ the element of the Psi basis corresponding to any composition $K$.

- If $p > q$, then $\Psi^I \ast \Psi^J$ is plainly 0.
• Assume that $p = q$. Let $\delta_{I,J}$ denote the integer 1 if the compositions $I$ and $J$ are permutations of each other, and the integer 0 otherwise. For every positive integer $i$, let $m_i$ denote the number of parts of $I$ equal to $i$. Then, $\Psi^I \Psi^J$ equals $\delta_{I,J} \prod_{i>0} i^{m_i} m_i! \Psi^I$.

• Now assume that $p < q$. Write the composition $I$ as $I = (i_1, i_2, \ldots, i_p)$. For every nonempty composition $K = (k_1, k_2, \ldots, k_s)$, denote by $\Gamma_K$ the non-commutative symmetric function $k_1[\Psi_{k_1}, \Psi_{k_2}, \ldots, \Psi_{k_s}]$. For any subset $A$ of $\{1,2,\ldots,q\}$, let $J_A$ be the composition obtained from $J$ by removing the $r$-th parts for all $r \notin A$ (while keeping the $r$-th parts for all $r \in A$ in order). Then, $\Psi^I \Psi^J$ equals the sum of $\Gamma_{J_A} \Gamma_{J_A'}$ over all ordered set partitions $(K_1, K_2, \ldots, K_p)$ of $\{1,2,\ldots,q\}$ into $p$ parts such that each $1 \leq k \leq p$ satisfies $|J_{K_k}| = i_k$. (See OrderedSetPartition() for the meaning of “ordered set partition”.)

Aliases for internal_product() are itensor() and kronecker_product().

INPUT:
• other – another non-commutative symmetric function
OUTPUT:
• The result of taking the internal product of self with other.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: x = S.an_element(); x
2*S[] + 2*S[1] + 3*S[1, 1]
sage: x.internal_product(S[2])
3*S[1, 1]
sage: x.internal_product(S[1])
2*S[1]
sage: S[1,2].internal_product(S[1,2])
S[1, 1, 1] + S[1, 2]
```

Let us check the duality between the inner product and the inner coproduct in degree 4:

sage: all( all( int_pr_of_S_in_e(I, J)
    ...:             == S[I].to_symmetric_function().internal_product(S[J].to_symmetric_function())
    ...:             for I in Compositions(3) )
    ...:             for J in Compositions(3) )
True
```

```python
class ParentMethods
    Bases: object

    internal_product()
        The bilinear product inherited from the isomorphism with the descent algebra.

        This is constructed by extending the method `internal_product_on_basis()` bilinearly, if available, or using the method `internal_product_by_coercion()`.

        OUTPUT:
        • The internal product map of the algebra the non-commutative symmetric functions.

        EXAMPLES:
```
```
sage: S.internal_product_on_basis([2, 2], [2, 1])
0

itensor()
The bilinear product inherited from the isomorphism with the descent algebra.
This is constructed by extending the method `internal_product_on_basis()` bilinearly, if available, or using the method `internal_product_by_coercion()`.

OUTPUT:
• The internal product map of the algebra the non-commutative symmetric functions.

EXAMPLES:
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product(S[2,2], S[1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product(S[2,2], S[1,2])
0

kronecker_product()
The bilinear product inherited from the isomorphism with the descent algebra.
This is constructed by extending the method `internal_product_on_basis()` bilinearly, if available, or using the method `internal_product_by_coercion()`.

OUTPUT:
• The internal product map of the algebra the non-commutative symmetric functions.

EXAMPLES:
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product(S[2,2], S[1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product(S[2,2], S[1,2])
0

sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: R.internal_product(R[1, 1], R[1,1])
R[2]
sage: R.internal_product(R[2,2], R[1,2])
0

(continues on next page)
class Realizations (category, *args)
Bases: sage.categories.realizations.RealizationsCategory

class ParentMethods
Bases: object

internal_product_by_coercion (left, right)
Internal product of left and right.

This is a default implementation that computes the internal product in the realization specified by self.realization_of().a_realization().

INPUT:
• left – an element of the non-commutative symmetric functions
• right – an element of the non-commutative symmetric functions

OUTPUT:
• The internal product of left and right.

EXAMPLES:

sage: S=NonCommutativeSymmetricFunctions(QQ).S()
sage: S.internal_product_by_coercion(S[2,1], S[3])
S[2, 1]
sage: S.internal_product_by_coercion(S[2,1], S[4])
0

super_categories()  
EXAMPLES:

sage: from sage.combinat.ncsf_qsym.generic_basis_code import ...
˓→GradedModulesWithInternalProduct
sage: GradedModulesWithInternalProduct(ZZ).super_categories()[Category of graded modules over Integer Ring]

5.1.147 Non-Commutative Symmetric Functions

class sage.combinat.ncsf_qsym.ncsf.NonCommutativeSymmetricFunctions (R)
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent Parent

The abstract algebra of non-commutative symmetric functions.

We construct the abstract algebra of non-commutative symmetric functions over the rational numbers:

sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: NCSF
Non-Commutative Symmetric Functions over the Rational Field
sage: S = NCSF.complete()
sage: R = NCSF.ribbon()
sage: S[2,1]*R[1,2]
S[2, 1, 1, 2] - S[2, 1, 3]

NCSF is the unique free (non-commutative!) graded connected algebra with one generator in each degree:

```python
sage: NCSF.category()
Join of Category of hopf algebras over Rational Field
    and Category of graded algebras over Rational Field
    and Category of monoids with realizations
    and Category of graded coalgebras over Rational Field
    and Category of coalgebras over Rational Field with realizations

sage: [S[i].degree() for i in range(10)]
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

We use the Sage standard renaming idiom to get shorter outputs:

```python
sage: NCSF.rename("NCSF")
sage: NCSF
NCSF
```

NCSF has many representations as a concrete algebra. Each of them has a distinguished basis, and its elements are expanded in this basis. Here is the $\Psi (\Psi)$ representation:

```python
sage: Psi = NCSF.Psi()
sage: Psi
NCSF in the Psi basis
```

Elements of $\Psi$ are linear combinations of basis elements indexed by compositions:

```python
sage: Psi.an_element()
2*Psi[] + 2*Psi[1] + 3*Psi[1, 1]
```

The basis itself is accessible through:

```python
sage: Psi.basis()
Lazy family (Term map from Compositions of non-negative integers...
```

To construct an element one can therefore do:

```python
sage: Psi.basis()[Composition([2, 1, 3])]
Psi[2, 1, 3]
```

As this is rather cumbersome, the following abuses of notation are allowed:

```python
sage: Psi[Composition([2, 1, 3])]
Psi[2, 1, 3]
```

or even:

```python
sage: Psi[(i for i in [2, 1, 3])]
Psi[2, 1, 3]
```

Unfortunately, due to a limitation in Python syntax, one cannot use:
Instead, you can use:

```
sage: Psi[]
Psi[]
```

Now, we can construct linear combinations of basis elements:

```
```

**Algebra structure**

To start with, Psi is a graded algebra, the grading being induced by the size of compositions. The one is the basis element indexed by the empty composition:

```
sage: Psi.one()
Psi[]
sage: S.one()
S[]
sage: R.one()
R[]
```

As we have seen above, the Psi basis is multiplicative; that is multiplication is induced by linearity from the concatenation of compositions:

```
sage: Psi[1,3] * Psi[2,1]
Psi[1, 3, 2, 1]
sage: (Psi.one() + 2 * Psi[1,3]) * Psi[2, 4]
2*Psi[1, 3, 2, 4] + Psi[2, 4]
```

**Hopf algebra structure**

Psi is further endowed with a coalgebra structure. The coproduct is an algebra morphism, and therefore determined by its values on the generators; those are primitive:

```
sage: Psi[1].coproduct()
Psi[] # Psi[1] + Psi[1] # Psi[]
sage: Psi[2].coproduct()
```

The coproduct, being cocommutative on the generators, is cocommutative everywhere:

```
sage: Psi[1,2].coproduct()
```

The algebra and coalgebra structures on Psi combine to form a bialgebra structure, which cooperates with the grading to form a connected graded bialgebra. Thus, as any connected graded bialgebra, Psi is a Hopf algebra. Over \(\mathbb{Q}\) (or any other \(\mathbb{Q}\)-algebra), this Hopf algebra \(\Psi\) is isomorphic to the tensor algebra of its space of primitive elements.

The antipode is an anti-algebra morphism; in the Psi basis, it sends the generators to their opposites and changes their sign if they are of odd degree:
The counit is defined by sending all elements of positive degree to zero:

```python
sage: S[3].degree(), S[3,1,2].degree(), S.one().degree()
(3, 6, 0)
sage: S[3].counit()
0
sage: S[3,1,2].counit()
0
sage: S.one().counit()
1
7
7
```

It is possible to change the prefix used to display the basis elements using the method `print_options()`. Say that for instance one wanted to display the `Complete` basis as having a prefix `H` instead of the default `S`:

```python
sage: H = NCSF.complete()
sage: H.an_element()
2*S[] + 2*S[1] + 3*S[1, 1]
sage: H.print_options(prefix='H')
sage: H.an_element()
2*H[] + 2*H[1] + 3*H[1, 1]
sage: H.print_options(prefix='S')  # restore to 'S'
```

### Concrete representations

NCSF admits the concrete realizations defined in [NCSF1]:

```python
sage: Phi = NCSF.Phi()
sage: Psi = NCSF.Psi()
sage: ribbon = NCSF.ribbon()
sage: complete = NCSF.complete()
sage: elementary = NCSF.elementary()
```

To change from one basis to another, one simply does:

```python
sage: Phi(Psi[1])
Phi[1]
sage: Phi(Psi[3])
-1/4*Phi[1, 2] + 1/4*Phi[2, 1] + Phi[3]
```

In general, one can mix up different bases in computations:

```python
sage: Phi[1] * Psi[1]
Phi[1, 1]
```
Some of the changes of basis are easy to guess:

\[
\text{\texttt{sage: ribbon(complete([1,3,2])})}
\]
\[
\]

This is the sum of all fatter compositions. Using the usual Möbius function for the boolean lattice, the inverse change of basis is given by the alternating sum of all fatter compositions:

\[
\text{\texttt{sage: complete(ribbon([1,3,2])})}
\]
\[
\]

The analogue of the elementary basis is the sum over all finer compositions than the ‘complement’ of the composition in the ribbon basis:

\[
\text{\texttt{sage: Composition([1,3,2]).complement()}}
\]
\[
[2, 1, 2, 1]
\]
\[
\text{\texttt{sage: ribbon(elementary([1,3,2]))}}
\]
\[
R[1, 1, 1, 1, 1, 1] + R[1, 1, 1, 2, 1] + R[2, 1, 1, 1, 1, 1] + R[2, 1, 2, 1]
\]

By Möbius inversion on the composition poset, the ribbon basis element corresponding to a composition \(I\) is then the alternating sum over all compositions fatter than the complement composition of \(I\) in the elementary basis:

\[
\text{\texttt{sage: elementary(ribbon([2,1,2,1]))}}
\]
\[
\]

The \(\Phi\) (\(\Phi\)) and \(\Psi\) bases are computed by changing to and from the \texttt{Complete} basis. The expansion of \(\Psi\) basis is given in Proposition 4.5 of [NCSF1] by the formulae

\[
S^J = \sum_{J \geq I} \frac{1}{\pi_u(J, I)} \Psi^J
\]

and

\[
\Psi^J = \sum_{J \geq I} (-1)^{\ell(J) - \ell(I)} \ell(J, I) S^J
\]

where the coefficients \(\pi_u(J, I)\) and \(\ell(J, I)\) are coefficients in the methods \texttt{coeff_pi()} and \texttt{coeff_lp()} respectively. For example:

\[
\text{\texttt{sage: Psi(complete([3])})}
\]
\[
1/6*Psi[1, 1, 1] + 1/3*Psi[1, 2] + 1/6*Psi[2, 1] + 1/3*Psi[3]
\]
\[
\text{\texttt{sage: complete(Psi([3])})}
\]
\[
\]

The \(\Phi\) basis is another analogue of the power sum basis from the algebra of symmetric functions and the expansion in the \texttt{Complete} basis is given in Proposition 4.9 of [NCSF1] by the formulae

\[
S^J = \sum_{J \geq I} \frac{1}{sp(J, I)} \Phi^J
\]

and

\[
\Phi^J = \sum_{J \geq I} (-1)^{\ell(J) - \ell(I)} \ell(J, I) S^J
\]

where the coefficients \(sp(J, I)\) and \(\ell(J, I)\) are coefficients in the methods \texttt{coeff_sp()} and \texttt{coeff_ell()} respectively. For example:
Here is how to fetch the conversion morphisms:

```python
sage: f = complete.coerce_map_from(elementary); f
Generic morphism:
  From: NCSF in the Elementary basis
  To:   NCSF in the Complete basis
sage: g = elementary.coerce_map_from(complete); g
Generic morphism:
  From: NCSF in the Complete basis
  To:   NCSF in the Elementary basis
sage: f.category()
Category of homsets of unital magmas and right modules over Rational Field and
  left modules over Rational Field
sage: f(elementary[1,2,2])
S[1, 1, 1, 1, 1] - S[1, 1, 1, 2] - S[1, 2, 1, 1] + S[1, 2, 2]
sage: g(complete[1,2,2])
L[1, 1, 1, 1, 1] - L[1, 1, 1, 2] - L[1, 2, 1, 1] + L[1, 2, 2]
sage: h = f*g; h
Composite map:
  From: NCSF in the Complete basis
  To:   NCSF in the Complete basis
    Defn: Generic morphism:
      From: NCSF in the Complete basis
      To: NCSF in the Elementary basis
      then
        Generic morphism:
          From: NCSF in the Elementary basis
          To: NCSF in the Complete basis
sage: h(complete[1,3,2])
S[1, 3, 2]
```

**Additional concrete representations**

NCSF has some additional bases which appear in the literature:

```python
sage: Monomial = NCSF.Monomial()
sage: Immaculate = NCSF.Immaculate()
sage: dualQuasisymmetric_Schur = NCSF.dualQuasisymmetric_Schur()
```

The `Monomial` basis was introduced in [Tev2007] and the `Immaculate` basis was introduced in [BBSSZ2012]. The `Quasisymmetric_Schur` were defined in [QSCHUR] and the dual basis is implemented here as `dualQuasisymmetric_Schur`. Refer to the documentation for the use and definition of these bases.

**Todo:**

- implement fundamental, forgotten, and simple (coming from the simple modules of HS_n) bases.

We revert back to the original name from our custom short name NCSF:
class Bases(parent_with_realization)
Bases: sage.categories.realizations.Category_realization_of_parent

Category of bases of non-commutative symmetric functions.

EXAMPLES:

sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.Bases()
Category of bases of Non-Commutative Symmetric Functions over the Rational Field
sage: R = N.Ribbon()
sage: R in N.Bases()
True

class ElementMethods
Bases: object

bernstein_creation_operator(n)
Return the image of self under the n-th Bernstein creation operator.

Let n be an integer. The n-th Bernstein creation operator \( \mathbb{B}_n \) is defined as the endomorphism of the space \( NSym \) of noncommutative symmetric functions which sends every \( f \) to

\[
\sum_{i \geq 0} (-1)^i H_{n+i} F^\perp_{1^i},
\]

where usual notations are in place (the letter \( H \) stands for the complete basis of \( NSym \), the letter \( F \) stands for the fundamental basis of the algebra \( QSym \) of quasisymmetric functions, and \( F^\perp_{1^i} \) means skewing (\( \text{skew}_1 \)) by \( F_{1^i} \)). Notice that \( F_{1^i} \) is nothing other than the elementary symmetric function \( e_i \).

This has been introduced in \[BBSSZ2012\], section 3.1, in analogy to the Bernstein creation operators on the symmetric functions (\( \text{bernstein_creation_operator()} \)), and studied further in \[BBSSZ2012\], mainly in the context of immaculate functions (\( \text{Immaculate} \)). In fact, if \( (\alpha_1, \alpha_2, \ldots, \alpha_m) \) is an \( m \)-tuple of integers, then

\[
\mathbb{B}_n I_{(\alpha_1, \alpha_2, \ldots, \alpha_m)} = I_{(n, \alpha_1, \alpha_2, \ldots, \alpha_m)},
\]

where \( I_{(\alpha_1, \alpha_2, \ldots, \alpha_m)} \) is the immaculate function associated to the \( m \)-tuple \( (\alpha_1, \alpha_2, \ldots, \alpha_m) \) (see \( \text{immaculate_function()} \)).

EXAMPLES:
We get the immaculate functions by repeated application of Bernstein creation operators:

sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: I = NSym.I()
sage: S = NSym.S()
sage: def immaculate_by_bernstein(xs):
....:     # immaculate function corresponding to integer
....:     # tuple \`\`xs\`\`, computed by iterated application
....:     # of Bernstein creation operators.

(continues on next page)
....:    res = S.one()
....:    for i in reversed(xs):
....:        res = res.bernstein_creation_operator(i)
....:    return res
sage: import itertools
sage: all( immaculate_by_bernstein(p) == I.immaculate_function(p)
....:     for p in itertools.product(range(-1, 3), repeat=3))
True

Some examples:

```
sage: S[3,2].bernstein_creation_operator(-2)
S[2, 1]
sage: S[3,2].bernstein_creation_operator(-1)
S[1, 2, 1] - S[2, 2] - S[3, 1]
sage: S[3,2].bernstein_creation_operator(0)
-S[1, 2, 2] - S[1, 3, 1] + S[2, 2, 1] + S[3, 2]
sage: S[3,2].bernstein_creation_operator(1)
sage: S[3,2].bernstein_creation_operator(2)
```

chi ()

Return the commutative image of a non-commutative symmetric function.

OUTPUT:

• The commutative image of self. This will be a symmetric function.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
sage: x.to_symmetric_function()
2*s[] + 2*s[1] + 3*s[1, 1]
sage: y = N.Phi()[1,3]
sage: y.to_symmetric_function()
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
```

expand (n, alphabet='x')

Expand the noncommutative symmetric function into an element of a free algebra in \( n \) indeterminates of an alphabet, which by default is ‘x’.

INPUT:

• \( n \) – a nonnegative integer; the number of variables in the expansion
• \( \text{alphabet} \) – (default: ‘x’); the alphabet in which self is to be expanded

OUTPUT:

• An expansion of self into the \( n \) variables specified by alphabet.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: S[3].expand(3)
x0^3 + x0^2*x1 + x0^2*x2 + x0*x1^2 + x0*x1*x2
+ x0*x2^2 + x1^3 + x1^2*x2 + x1*x2^2 + x2^3
sage: L = NSym.L()
```
sage: L[3].expand(3)
x2*x1*x0
sage: L[2].expand(3)
x1*x0 + x2*x0 + x2*x1
sage: L[3].expand(4)
x2*x1*x0 + x3*x1*x0 + x3*x2*x0 + x3*x2*x1
sage: Psi = NSym.Psi()
sage: Psi[2, 1].expand(3)
x0^3 + x0^2*x1 + x0^2*x2 + x0*x1*x0 + x0*x1^2 + x0*x1*x2 + x0*x2*x0 + x0*x2*x1 + x0*x2^2 - x1*x0^2 - x1*x0*x1 - x1*x0*x2 + x1^2*x0 + x1^3 + x1^2*x2 + x1*x2*x0 + x1*x2*x1 + x1*x2^2 - x2*x0^2 - x2*x0*x1 - x2*x0*x2 - x2*x1*x0 - x2*x1^2 - x2*x1*x2 + x2^2*x0 + x2^2*x1 + x2^3

One can use a different set of variables by adding an optional argument `alphabet=...`

sage: L[3].expand(4, alphabet="y")
y2*y1*y0 + y3*y1*y0 + y3*y2*y0 + y3*y2*y1

Todo: So far this is only implemented on the elementary basis, and everything else goes through coercion. Maybe it is worth shortcutting some of the other bases?

left_padded_kronecker_product (x)

Return the left-padded Kronecker product of `self` and `x` in the basis of `self`.

The left-padded Kronecker product is a bilinear map mapping two non-commutative symmetric functions to another, not necessarily preserving degree. It can be defined as follows: Let $*$ denote the internal product (`internal_product()`) on the space of non-commutative symmetric functions. For any composition $I$, let $S^I$ denote the complete homogeneous symmetric function indexed by $I$. For any compositions $\alpha, \beta, \gamma$, let $g_{\alpha, \beta}^{\gamma}$ denote the coefficient of $S^\gamma$ in the internal product $S^\alpha * S^\beta$. For every composition $I = (i_1, i_2, \ldots, i_k)$ and every integer $n > |I|$, define the \textit{n}-completion of $I$ to be the composition $(n - |I|, i_1, i_2, \ldots, i_k)$; this $n$-completion is denoted by $I[n]$. Then, for any compositions $\alpha$ and $\beta$ and every integer $n > |\alpha| + |\beta|$, we can write the internal product $S^\alpha[n] * S^\beta[n]$ in the form

$$S^\alpha[n] * S^\beta[n] = \sum_{\gamma} g_{\alpha[n], \beta[n]}^{\gamma} S^\gamma[n]$$

with $\gamma$ ranging over all compositions. The coefficients $g_{\alpha[n], \beta[n]}^{\gamma}$ are independent on $n$. These coefficients $g_{\alpha[n], \beta[n]}^{\gamma}$ are denoted by $\tilde{g}_{\alpha, \beta}^{\gamma}$, and the non-commutative symmetric function

$$\sum_{\gamma} \tilde{g}_{\alpha, \beta}^{\gamma} S^\gamma$$

is said to be the \textit{left-padded Kronecker product} of $S^\alpha$ and $S^\beta$. By bilinearity, this extends to a definition of a left-padded Kronecker product of any two non-commutative symmetric functions.

The left-padded Kronecker product on the non-commutative symmetric functions lifts the left-padded Kronecker product on the symmetric functions. More precisely: Let $\pi$ denote the canonical projection (`to_symmetric_function()`) from the non-commutative symmetric functions to the symmetric functions. Then, any two non-commutative symmetric functions $f$ and $g$ satisfy

$$\pi(f \pi g) = \pi(f) \pi \pi(g),$$

5.1. Comprehensive Module list

1319
where the \(\boxtimes\) on the left-hand side denotes the left-padded Kronecker product on the non-commutative symmetric functions, and the \(\boxplus\) on the right-hand side denotes the left-padded Kronecker product on the symmetric functions.

**INPUT:**
- \(x\) – element of the ring of non-commutative symmetric functions over the same base ring as \(\text{self}\)

**OUTPUT:**
- the left-padded Kronecker product of \(\text{self}\) with \(x\) (an element of the ring of non-commutative symmetric functions in the same basis as \(\text{self}\))

**AUTHORS:**
- Darij Grinberg (15 Mar 2014)

**EXAMPLES:**

```python
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: S[2,1].left_padded_kronecker_product(S[3])
sage: S[2,1].left_padded_kronecker_product(S[1])
S[1, 1, 1] + S[1, 2, 1] + S[2, 1]
sage: S[1].left_padded_kronecker_product(S[2,1])
S[1, 1, 1] + S[2, 1] + S[2, 1, 1]
sage: S[1,1].left_padded_kronecker_product(S[2])
S[1, 1] + 2*S[1, 1, 1] + S[2, 1, 1]
sage: S[1].left_padded_kronecker_product(S[1,2,1])
S[1, 1, 1, 1] + S[1, 2, 1] + S[1, 2, 1, 1] + S[2, 1, 1]
sage: S[2].left_padded_kronecker_product(S[3])
S[1, 2] + S[2, 1, 1] + S[3, 2]
```

Taking the left-padded Kronecker product with \(1 = S\) is the identity map on the ring of non-commutative symmetric functions:

```python
sage: all( S[Composition([])].left_padded_kronecker_product(S[lam])
    == S[lam].left_padded_kronecker_product(S[Composition([])])
    for lam in Compositions(4) )
True
```

Here is a rule for the left-padded Kronecker product of \(S_1\) (this is the same as \(S^{(1)}\)) with any complete homogeneous function: Let \(I\) be a composition. Then, the left-padded Kronecker product of \(S_1\) and \(S^I\) is \(\sum_K a_K S^K\), where the sum runs over all compositions \(K\), and the coefficient \(a_K\) is defined as the number of ways to obtain \(K\) from \(I\) by one of the following two operations:
- Insert a \(1\) at the end of \(I\).
- Subtract \(1\) from one of the entries of \(I\) (and remove the entry if it thus becomes \(0\)), and insert a \(1\) at the end of \(I\).

We check this for compositions of size \(\leq 4\):

```python
sage: def multis1(I):
    # Left left-padded Kronecker multiplication by S[1].
    res = S[I[:]] + [1]
    for k in range(len(I)):
        I2 = I[:]
        if I2[k] == 1:
            I2 = I2[:k] + I2[k+1:]
        else:
            I2[k] -= 1
    return res
```
A similar rule can be made for the left-padded Kronecker product of any complete homogeneous function with $S_1$: Let $I$ be a composition. Then, the left-padded Kronecker product of $S^I$ and $S_1$ is $\sum_K b_K S^K$, where the sum runs over all compositions $K$, and the coefficient $b_K$ is defined as the number of ways to obtain $K$ from $I$ by one of the following two operations:
- Insert a 1 at the front of $I$.
- Subtract 1 from one of the entries of $I$ (and remove the entry if it thus becomes 0), and insert a 1 right after this entry.

We check this for compositions of size $\leq 4$:

Checking the $\pi(fg) = \pi(f)\pi(g)$ equality:

omega_involusion()  
Return the image of the noncommutative symmetric function self under the omega involution.  
The omega involution is defined as the algebra antihomomorphism $NCSF \to NCSF$ which, for every positive integer $n$, sends the $n$-th complete non-commutative symmetric function $S_n$ to the $n$-th elementary non-commutative symmetric function $\Lambda_n$. This omega involution is denoted by $\omega$. It can be shown that every composition $I$ satisfies

$$\omega(S^I) = \Lambda^I, \quad \omega(\Lambda^I) = S^I, \quad \omega(R_I) = R_I, \quad \omega(\Phi^I) = (-1)^{|I|-\ell(I)}\Phi^I, \omega(\Psi^I) = (-1)^{|I|-\ell(I)}\Psi^I,$$
where $I_r$ denotes the reversed composition of $I$, and $I_t$ denotes the conjugate composition of $I$, and $\ell(I)$ denotes the length of the composition $I$, and standard notations for classical bases of $NCSF$ are being used ($S$ for the complete basis, $\Lambda$ for the elementary basis, $R$ for the ribbon basis, $\Phi$ for that of the power-sums of the second kind, and $\Psi$ for that of the power-sums of the first kind). More generally, if $f$ is a homogeneous element of $NCSF$ of degree $n$, then

$$\omega(f) = (-1)^n S(f),$$

where $S$ denotes the antipode of $NCSF$.

The omega involution $\omega$ is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. If $\pi$ denotes the projection from $NCSF$ to the ring of symmetric functions ($\text{to_symmetric_function()}$), then $\pi(\omega(f)) = \omega(\pi(f))$ for every $f \in NCSF$, where the $\omega$ on the right hand side denotes the omega automorphism of $Sym$.

The omega involution on $NCSF$ is adjoint to the omega involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The omega involution has been denoted by $\omega$ in [LMvW13], section 3.6. See [NCSF1], section 3.1 for the properties of this map.

See also:

omega involution of $QSym$, psi involution of $NCSF$, star involution of $NCSF$.

**EXAMPLES:**

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: L = NSym.L()
sage: L(S[3,2].omega_involution())
L[2, 3]
sage: L(S[6,3].omega_involution())
L[3, 6]
sage: L(S[1,3].omega_involution())
L[3, 1]
sage: L(S([4,2]).omega_involution())
L[2, 4]
sage: R = NSym.R()
sage: R([4,2]).omega_involution()
R[1, 2, 1, 1, 1]
sage: R.zero().omega_involution()
0
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NSym.Phi()
sage: Phi([2,1]).omega_involution()
-Phi[1, 2]
sage: Psi = NSym.Psi()
sage: Psi([2,1]).omega_involution()
-Psi[1, 2]
sage: Psi([3,1]).omega_involution()
Psi[1, 3]
```
Testing the $\pi(\omega(f)) = \omega(\pi(f))$ relation noticed above:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: R = NSym.R()
sage: all( R(I).omega_involution().to_symmetric_function()
....:   == R(I).to_symmetric_function().omega_involution()
....:   for I in Compositions(4) )
True
```

The omega involution on $QSym$ is adjoint to the omega involution on $NSym$ with respect to the duality pairing:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: all( all( M(I).omega_involution().duality_pairing(S(J))
....:       == M(I).duality_pairing(S(J).omega_involution())
....:       for I in Compositions(2) )
....:       for J in Compositions(3) )
True
```

### psi_involution()

Return the image of the noncommutative symmetric function $\text{self}$ under the involution $\psi$.

The involution $\psi$ is defined as the linear map $NCSF \to NCSF$ which, for every composition $I$, sends the complete noncommutative symmetric function $S^I$ to the elementary noncommutative symmetric function $\Lambda^I$. It can be shown that every composition $I$ satisfies

$$
\psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I| - \ell(I)} \Phi^I
$$

where $I^c$ denotes the complement of the composition $I$, and $\ell(I)$ denotes the length of $I$, and where standard notations for classical bases of $NCSF$ are being used ($S$ for the complete basis, $\Lambda$ for the elementary basis, $\Phi$ for the basis of the power sums of the second kind, and $R$ for the ribbon basis). The map $\psi$ is an involution and a graded Hopf algebra automorphism of $NCSF$. If $\pi$ denotes the projection from $NCSF$ to the ring of symmetric functions, then $\pi(\psi(f)) = \omega(\pi(f))$ for every $f \in NCSF$, where the $\omega$ on the right hand side denotes the omega automorphism of $Sym$.

The involution $\psi$ of $NCSF$ is adjoint to the involution $\psi$ of $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The involution $\psi$ has been denoted by $\psi$ in [LMvW13], section 3.6.

**See also:**

*psi involution of QSym*, *star involution of NCSF*.

**EXAMPLES:**

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: R = NSym.R()
sage: R[3,2].psi_involution()
R[1, 1, 2, 1]
sage: R[6,3].psi_involution()
R[1, 1, 1, 1, 1, 2, 1, 1]
4*R[] - 3*R[1, 1, 1] + R[1, 1, 1, 1, 1, 1, 1, 1, 2] - R[1, 1, 1, 1, 1, 1, 1, 1, 1, 2, 1] + 2*R[1, 2, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
```

(continues on next page)
The Psi basis doesn’t behave as nicely:

```
sage: Psi = NSym.Psi()
sage: Psi([2,1]).psi_involution()
-Psi[2, 1]
sage: Psi([3,1]).psi_involution()
1/2*Psi[1, 2, 1] - 1/2*Psi[2, 1, 1] + Psi[3, 1]
```

The involution \( \psi \) commutes with the antipode:

```
sage: all( R(I).psi_involution().antipode() == R(I).antipode().psi_involution() for I in Compositions(4) )
True
```

Testing the \( \pi(\psi(f)) = \omega(\pi(f)) \) relation noticed above:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: R = NSym.R()
sage: all( R(I).psi_involution().to_symmetric_function().omega() == R(I).to_symmetric_function().omega() for I in Compositions(4) )
True
```

The involution \( \psi \) of \( QSym \) is adjoint to the involution \( \psi \) of \( NSym \) with respect to the duality pairing:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: all( all( M(I).psi_involution().duality_pairing(S(J)) == M(I).duality_pairing(S(J).psi_involution()) for I in Compositions(2) ) for J in Compositions(3) )
True
```

**star_involution()**

Return the image of the noncommutative symmetric function `self` under the star involution.

The star involution is defined as the algebra antihomomorphism \( NCSF \to NCSF \) which, for
every positive integer \( n \), sends the \( n \)-th complete non-commutative symmetric function \( S_n \) to \( S_n \). Denoting by \( f^* \) the image of an element \( f \in NCSF \) under this star involution, it can be shown that every composition \( I \) satisfies

\[
(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R_I^* = R_{I^r}, \quad (\Phi^I)^* = \Phi^{I^r},
\]

where \( I^r \) denotes the reversed composition of \( I \), and standard notations for classical bases of \( NCSF \) are being used (\( S \) for the complete basis, \( \Lambda \) for the elementary basis, \( R \) for the ribbon basis, and \( \Phi \) for that of the power-sums of the second kind). The star involution is an involution and a coalgebra automorphism of \( NCSF \). It is an automorphism of the graded vector space \( NCSF \). Under the canonical isomorphism between the \( n \)-th graded component of \( NCSF \) and the descent algebra of the symmetric group \( S_n \) (see \texttt{to_descent_algebra()}), the star involution (restricted to the \( n \)-th graded component) corresponds to the automorphism of the descent algebra given by \( x \mapsto \omega_n x \omega_n \), where \( \omega_n \) is the permutation \((n, n-1, \ldots, 1) \in S_n \) (written here in one-line notation). If \( \pi \) denotes the projection from \( NCSF \) to the ring of symmetric functions (\texttt{to_symmetric_function()}), then \( \pi(f^*) = \pi(f) \) for every \( f \in NCSF \).

The star involution on \( NCSF \) is adjoint to the star involution on \( QSym \) by the standard adjunction between \( NCSF \) and \( QSym \).

The star involution has been denoted by \( \rho \) in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

See also:

\textit{star involution of QSym}, \textit{psi involution of NCSF}.

EXAMPLES:

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: S[3,2].star_involution()
S[2, 3]
sage: S[6,3].star_involution()
S[3, 6]
sage: (S[3,3] - 2*S[2]).star_involution()
sage: S([4,2]).star_involution()
S[2, 4]
sage: R = NSym.R()
sage: R([4,2]).star_involution()
R[2, 4]
sage: R.zero().star_involution()
0
sage: Phi = NSym.Phi()
sage: Phi([2,1]).star_involution()
Phi[1, 2]
```

The \( \Phi \) basis doesn’t behave as nicely:

```python
sage: Phi = NSym.Phi()
sage: Phi([2,1]).star_involution()
Phi[1, 2]
```

The star involution commutes with the antipode:

```python
sage: S[3,1].star_involution() - 1/2*Psi[1, 2, 1] + 1/2*Psi[1, 1, 2] + Psi[1, 3]
```

The Psi basis doesn’t behave as nicely:

```python
sage: Psi = NSym.Psi()
sage: Psi([2,1]).star_involution()
Psi[1, 2]
sage: Psi([3,1]).star_involution()
1/2*Psi[1, 1, 2] - 1/2*Psi[1, 2, 1] + Psi[1, 3]
```
Checking the relation with the descent algebra described above:

```
sage: def descent_test(n):
    DA = DescentAlgebra(QQ, n)
    NSym = NonCommutativeSymmetricFunctions(QQ)
    S = NSym.S()
    DAD = DA.D()
    w_n = DAD(set(range(1, n)))
    for I in Compositions(n):
        if not (S[I].star_involution() == w_n * S[I].to_descent_algebra(n) * w_n):
            return False
    return True
sage: all( descent_test(i) for i in range(4) )
True
sage: all( descent_test(i) for i in range(6) )
# long time
True
```

Testing the $\pi(f^*) = \pi(f)$ relation noticed above:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: R = NSym.R()
sage: all( R(I).star_involution().to_symmetric_function() == R(I).to_symmetric_function() for I in Compositions(4) )
True
```

The star involution on $QSym$ is adjoint to the star involution on $NSym$ with respect to the duality pairing:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: all( all( M(I).star_involution().duality_pairing(S(J)) == M(I).duality_pairing(S(J).star_involution()) for I in Compositions(2) ) for J in Compositions(3) )
True
```

**to_descent_algebra** *(n=None)*

Return the image of the n-th degree homogeneous component of self in the descent algebra of $S_n$ over the same base ring as self.

This is based upon the canonical isomorphism from the n-th degree homogeneous component of the algebra of noncommutative symmetric functions to the descent algebra of $S_n$. This isomorphism maps the inner product of noncommutative symmetric functions either to the product in the descent algebra of $S_n$ or to its opposite (depending on how the latter is defined).

If n is not specified, it will be taken to be the highest homogeneous component of self.

**OUTPUT:**
• The image of the $n$-th homogeneous component of $\text{self}$ under the isomorphism into the descent algebra of $S_n$ over the same base ring as $\text{self}$.

EXAMPLES:

```python
sage: S = NonCommutativeSymmetricFunctions(ZZ).S()
sage: S[2,1].to_descent_algebra(3)
B[2, 1]
sage: (S[1,2,1] - 3 * S[1,1,2]).to_descent_algebra(4)
-3*B[1, 1, 2] + B[1, 2, 1]
sage: S[2,1].to_descent_algebra(2)
0
sage: S.zero().to_descent_algebra().parent()
Descent algebra of 0 over Integer Ring in the subset basis
sage: (S[1,2,1] - 3 * S[1,1,2]).to_descent_algebra(1)
0
```

to_fqsym()

Return the image of the non-commutative symmetric function $\text{self}$ under the morphism $\iota : \NSym \to \FQSym$.

This morphism is the injective algebra homomorphism $\NSym \to \FQSym$ that sends each Complete generator $S_n$ to $F_{[1,2,...,n]}$. It is the inclusion map, if we regard both $\NSym$ and $\FQSym$ as rings of noncommutative power series.

See also:

`FreeQuasisymmetricFunctions` for a definition of $\FQSym$.

EXAMPLES:

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x.to_fqsym()
sage: R[2,1].to_fqsym()
F[1, 3, 2] + F[3, 1, 2]
sage: x = R.an_element(); x
2*R[[]] + 2*R[1] + 3*R[1, 1]
sage: x.to_fqsym()
```

```python
sage: y = N.Phi()[1,2]
sage: y.to_fqsym()
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S[2].to_fqsym()
F[1, 2]
sage: S[1,2].to_fqsym()
F[1, 2, 3] + F[2, 1, 3] + F[2, 3, 1]
sage: S[2,1].to_fqsym()
F[1, 2, 3] + F[1, 3, 2] + F[3, 1, 2]
sage: S[1,2,1].to_fqsym()
```

(continues on next page)

```
to_fsym()
Return the image of self under the natural map to FSym.

There is an injective Hopf algebra morphism from \( NSym \) to \( FSym \) (see FreeSymmetricFunctions), which maps the ribbon \( R_\alpha \) indexed by a composition \( \alpha \) to the sum of all tableaux whose descent composition is \( \alpha \). If we regard \( NSym \) as a Hopf subalgebra of \( FQSym \) via the morphism \( \iota : NSym \to FQSym \) (implemented as to_fqsym()), then this injective morphism is just the inclusion map.

EXAMPLES:
```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x.to_fsym()
sage: R[2,1].to_fsym()
G[12|3]
sage: R[1,2].to_fsym()
G[13|2]
sage: R[2,1,2].to_fsym()
sage: x = R.an_element(); x
2*R[[]] + 2*R[1] + 3*R[1, 1]
sage: x.to_fsym()
2*G[[]] + 2*G[1] + 3*G[1|2]
sage: y = N.Phi()[1,2]
sage: y.to_fsym()
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S[2].to_fsym()
G[12]
sage: S[2,1].to_fsym()
G[12|3] + G[123]
```

```
to_ncsym()
Return the image of self under the injective algebra homomorphism \( \kappa : NSym \to NCSym \) that fixes the symmetric functions.

As usual, \( NCSym \) denotes the ring of symmetric functions in non-commuting variables. Let \( S_n \) denote a generator of the complete basis. The algebra homomorphism \( \kappa : NSym \to NCSym \) is defined by

\[
S_n \mapsto \sum_{A \vdash [n]} \frac{\lambda(A)! \lambda(A)_1!}{n!} m_A.
\]

It has the property that the canonical maps \( \chi : NCSym \to Sym \) and \( \rho : NSym \to Sym \) satisfy \( \chi \circ \kappa = \rho \).

**Note:** A remark in [BRRZ08] makes it clear that the embedding of \( NSym \) into \( NCSym \) that preserves the projection into the symmetric functions is not unique. While this seems to be a
natural embedding, any free set of algebraic generators of $NSym$ can be sent to a set of free elements in $NCSym$ to form another embedding.

See also:

NonCommutativeSymmetricFunctions for a definition of $NCSym$.

EXAMPLES:

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S[2].to_ncsym()
1/2*m{{1}, {2}} + m{{1, 2}}
sage: S[1,2,1].to_ncsym()
1/2*m{{1}, {2}, {3}, {4}} + 1/2*m{{1, 2}, {3}, {4}} + m{{1, {2, 3}, {4}}}
```
to_symmetric_group_algebra()  
Return the image of a non-commutative symmetric function into the symmetric group algebra  
where the ribbon basis element indexed by a composition is associated with the sum of all  
permutations which have descent set equal to said composition. In compliance with the anti-iso-  
morphism between the descent algebra and the non-commutative symmetric functions, we index  
descent positions by the reversed composition.  

OUTPUT:  
• The image of self under the embedding of the $n$-th degree homogeneous component of the  
  non-commutative symmetric functions in the symmetric group algebra of $S_n$. This can behave  
  unexpectedly when self is not homogeneous.  

EXAMPLES:  

```
sage: R=NonCommutativeSymmetricFunctions(QQ).R()
sage: R[2,1].to_symmetric_group_algebra()
[1, 3, 2] + [2, 3, 1]
sage: R([]).to_symmetric_group_algebra()
[]
```

verschiebung($n$)  
Return the image of the noncommutative symmetric function self under the $n$-th Verschiebung  
operator.  

The $n$-th Verschiebung operator $V_n$ is defined to be the map from the $k$-algebra of noncommutative  
symmetric functions to itself that sends the complete function $S^I$ indexed by a composition $I = (i_1, i_2, \ldots, i_k)$ to $S^{(i_1/n, i_2/n, \ldots, i_k/n)}$ if all of the numbers $i_1, i_2, \ldots, i_k$ are divisible by $n$,  
and to $0$ otherwise. This operator $V_n$ is a Hopf algebra endomorphism. For every positive integer  
r with $n \mid r$, it satisfies  

$$V_n(S_r) = S_{r/n}, \quad V_n(\Lambda_r) = (-1)^{r-n/n} \Lambda_{r/n}, \quad V_n(\Psi_r) = n \Psi_{r/n}, \quad V_n(\Phi_r) = n \Phi_{r/n}$$  

(where $S_r$ denotes the $r$-th complete non-commutative symmetric function, $\Lambda_r$ denotes the  
r-th elementary non-commutative symmetric function, $\Psi_r$ denotes the $r$-th power-sum non-  
commutative symmetric function of the first kind, and $\Phi_r$ denotes the $r$-th power-sum non-  
commutative symmetric function of the second kind). For every positive integer $r$ with $n \nmid r$,  
it satisfies  

$$V_n(S_r) = V_n(\Lambda_r) = V_n(\Psi_r) = V_n(\Phi_r) = 0.$$  
The $n$-th Verschiebung operator is also called the $n$-th Verschiebung endomorphism.  
It is a lift of the $n$-th Verschiebung operator on the ring of symmetric functions (verschiebung()) to the ring of noncommutative symmetric functions.  
The action of the $n$-th Verschiebung operator can also be described on the ribbon Schur functions.  
Namely, every composition $I$ of size $n\ell$ satisfies  

$$V_n(R_I) = (-1)^{\ell(I)-\ell(J)} \cdot R_{J/n},$$  

where $J$ denotes the meet of the compositions $I$ and $\underbrace{(n, n, \ldots, n)}_{|I|/n \text{ times}}$, where $\ell(I)$ is the length of
and where \( J/n \) denotes the composition obtained by dividing every entry of \( J \) by \( n \). For a composition \( I \) of size not divisible by \( n \), we have \( V_n(R_I) = 0 \).

See also:

* frobenius method of QSym
* verschiebung method of Sym

INPUT:
- \( n \) – a positive integer

OUTPUT:

The result of applying the \( n \)-th Verschiebung operator (on the ring of noncommutative symmetric functions) to self.

EXAMPLES:

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: S[3,2].verschiebung(2)
0
sage: S[6,4].verschiebung(2)
S[3, 2]
sage: (S[3,3] - 2*S[2]).verschiebung(3)
S[1, 1]
sage: S([4,2]).verschiebung(1)
S[4, 2]
sage: R = NSym.R()
sage: R([4,2]).verschiebung(2)
R[2, 1]
```

Being Hopf algebra endomorphisms, the Verschiebung operators commute with the antipode:

```python
sage: all( R(I).verschiebung(2).antipode()
....:     == R(I).antipode().verschiebung(2)
....:     for I in Compositions(4) )
True
```

They lift the Verschiebung operators of the ring of symmetric functions:

```python
sage: all( S(I).verschiebung(2).to_symmetric_function()
....:     == S(I).to_symmetric_function().verschiebung(2)
....:     for I in Compositions(4) )
True
```

The Frobenius operators on \( QSym \) are adjoint to the Verschiebung operators on \( NSym \) with respect to the duality pairing:

```python
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: all( all( M(I).frobenius(3).duality_pairing(S(J))
....:          == M(I).duality_pairing(S(J).verschiebung(3))
....:          for I in Compositions(2) )
....:     for J in Compositions(3) )
True
```

```python
class ParentMethods
    Bases: object
```
immaculate_function(xs)

Return the immaculate function corresponding to the integer vector xs, written in the basis self.

If \( \alpha \) is any integer vector – i.e., an element of \( \mathbb{Z}^m \) for some \( m \in \mathbb{N} \) –, the immaculate function corresponding to \( \alpha \) is a non-commutative symmetric function denoted by \( S_\alpha \). One way to define this function is by setting

\[
S_\alpha = \sum_{\sigma \in S_m} (-1)^{\sigma(1)} S_{\sigma_1} S_{\sigma_2} + \cdots + (-1)^{\sigma(m)} S_{\sigma_m}.
\]

where \( \alpha \) is written in the form \( (\alpha_1, \alpha_2, \ldots, \alpha_m) \), and where \( S \) stands for the complete basis (Complete).

The immaculate function \( S_\alpha \) first appeared in [BBSSZ2012] (where it was defined differently, but the definition we gave above appeared as Theorem 3.27).

The immaculate functions \( S_\alpha \) for \( \alpha \) running over all compositions (i.e., finite sequences of positive integers) form a basis of \( NCSF \). This is the immaculate basis (Immaculate).

INPUT:

• xs – list (or tuple or any iterable – possibly a composition) of integers

OUTPUT:

The immaculate function \( S_{xs} \) written in the basis self.

EXAMPLES:

Let us first check that, for xs a composition, we get the same as the result of \( \text{self}.\text{realization_of().I()}[\text{xs}] \):

```python
sage: def test_comp(xs):
    ....:     NSym = NonCommutativeSymmetricFunctions(QQ)
    ....:     I = NSym.I()
    ....:     return I[xs] == I.immaculate_function(xs)
sage: def test_allcomp(n):
    ....:     return all( test_comp(c) for c in Compositions(n) )
sage: test_allcomp(1)
True
sage: test_allcomp(2)
True
sage: test_allcomp(3)
True
```

Now some examples of non-composition immaculate functions:

```python
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: I = NSym.I()
sage: I.immaculate_function([0, 1])
0
sage: I.immaculate_function([0, 2])
-I[1, 1]
sage: I.immaculate_function([-1, 1])
-I[1]
sage: I.immaculate_function([2, -1])
0
sage: I.immaculate_function([2, 0])
I[2]
sage: I.immaculate_function([2, 0, 1])
0
sage: I.immaculate_function([1, 0, 2])
```

(continues on next page)
to_symmetric_function()
Morphism to the algebra of symmetric functions.
This is constructed by extending the computation on the basis or by coercion to the complete basis.

OUTPUT:
- The module morphism from the basis self to the symmetric functions which corresponds to taking a commutative image.

EXAMPLES:

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x = R.an_element(); x
sage: R.to_symmetric_function(x)
sage: nM = N.Monomial()
sage: nM.to_symmetric_function(nM[3,1])
```

to_symmetric_function_on_basis(I)
The image of the basis element indexed by I under the map to the symmetric functions.
This default implementation does a change of basis and computes the image in the complete basis.

INPUT:
- I - a composition

OUTPUT:
- The image of the non-commutative basis element of self indexed by the composition I under the map from non-commutative symmetric functions to the symmetric functions. This will be a symmetric function.

EXAMPLES:

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: I = N.Immaculate()
sage: I.to_symmetric_function(I[1,3])
-h[2, 2] + h[3, 1]
sage: I.to_symmetric_function(I[1,2])
0
sage: Phi = N.Phi()
sage: Phi.to_symmetric_function_on_basis([3,1,2])==Phi.to_symmetric_function(Phi[3,1,2])
True
sage: Phi.to_symmetric_function_on_basis([[]])
h[]
```

super_categories()  
Return the super categories of the category of bases of the non-commutative symmetric functions.
class Complete(NCSF)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_classBindableClass

The Hopf algebra of non-commutative symmetric functions in the Complete basis.

The Complete basis is defined in Definition 3.4 of \cite{NCSF1}, where it is denoted by \((S^I)_I\). It is a multiplicative basis, and is connected to the elementary generators \(\Lambda_i\) of the ring of non-commutative symmetric functions by the following relation: Define a non-commutative symmetric function \(S_n\) for every nonnegative integer \(n\) by the power series identity

\[
\sum_{k \geq 0} t^k S_k = \left(\sum_{k \geq 0} (-t)^k \Lambda_k\right)^{-1},
\]

with \(\Lambda_0\) denoting 1. For every composition \((i_1, i_2, \ldots, i_k)\), we have \(S^{(i_1, i_2, \ldots, i_k)} = S_{i_1} S_{i_2} \cdots S_{i_k}\).

EXAMPLES:

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: S = NCSF.Complete(); S
Non-Commutative Symmetric Functions over the Rational Field in the Complete →basis
sage: S.an_element()
```

The following are aliases for this basis:

```python
sage: NCSF.complete()
Non-Commutative Symmetric Functions over the Rational Field in the Complete →basis
sage: NCSF.S()
Non-Commutative Symmetric Functions over the Rational Field in the Complete →basis
```

class Element

Bases: sage.modules.with_basis.indexed_element.

An element in the Complete basis.

psi_involution()

Return the image of the noncommutative symmetric function self under the involution \(\psi\).

The involution \(\psi\) is defined as the linear map \(NCSF \rightarrow NCSF\) which, for every composition \(I\), sends the complete noncommutative symmetric function \(S^I\) to the elementary noncommutative symmetric function \(\Lambda^I\). It can be shown that every composition \(I\) satisfies

\[
\psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I| - \ell(I)} \Phi^I
\]

where \(I^c\) denotes the complement of the composition \(I\), and \(\ell(I)\) denotes the length of \(I\), and where standard notations for classical bases of \(NCSF\) are being used (\(S\) for the complete basis, \(\Lambda\) for the elementary basis, \(\Phi\) for the basis of the power sums of the second kind, and \(R\) for the ribbon basis). The map \(\psi\) is an involution and a graded Hopf algebra automorphism of \(NCSF\). If \(\pi\) denotes the projection from \(NCSF\) to the ring of symmetric functions \((to_symmetric_function())\), then \(\pi(\psi(f)) = \omega(\pi(f))\) for every \(f \in NCSF\), where the \(\omega\) on the right hand side denotes the omega automorphism of \(Sym\).
The involution $\psi$ of $NCSF$ is adjoint to the involution $\psi$ of $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The involution $\psi$ has been denoted by $\psi$ in [LMvW13], section 3.6.

See also:

- psi involution of $NCSF$
- psi involution of $QSym$
- star involution of $NCSF$

EXAMPLES:

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: L = NSym.L()
sage: S[3,1].psi_involution()
S[1, 1, 1, 1] - S[1, 2, 1] - S[2, 1, 1] + S[3, 1]
sage: L(S[3,1].psi_involution())
L[3, 1]
sage: S[[]].psi_involution()
S[]
sage: S[1,1].psi_involution()
S[1, 1]
sage: (S[2,1] - 2*S[2]).psi_involution()
```

The implementation at hand is tailored to the complete basis. It is equivalent to the generic implementation via the ribbon basis:

```python
sage: R = NSym.R()
sage: all( R(S[I].psi_involution()) == R(S[I]).psi_involution() ....: for I in Compositions(4) )
True
```

dual()

Return the dual basis to the complete basis of non-commutative symmetric functions. This is the Monomial basis of quasi-symmetric functions.

OUTPUT:

- The Monomial basis of quasi-symmetric functions.

EXAMPLES:

```python
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.dual()
Quasisymmetric functions over the Rational Field in the Monomial basis
```

internal_product_on_basis($I, J$)

The internal product of two non-commutative symmetric complete functions.

See internal_product() for a thorough documentation of this operation.

INPUT:

- $I, J$ – compositions

OUTPUT:

- The internal product of the complete non-commutative symmetric function basis elements indexed by $I$ and $J$, expressed in the complete basis.

EXAMPLES:
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product_on_basis([2,2],[1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product_on_basis([2,2],[1,2])
0

to_symmetric_function()
Morphism to the algebra of symmetric functions.
This is constructed by extending the computation on the complete basis.
OUTPUT:
• The module morphism from the basis self to the symmetric functions which corresponds to
taking a commutative image.
EXAMPLES:
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.to_symmetric_function(S[3,1,2])
h[3, 2, 1]
sage: S.to_symmetric_function(S[[]])
h[

to_symmetric_function_on_basis(I)
The commutative image of a complete element
The commutative image of a basis element is obtained by sorting the indexing composition of the
basis element and the output is in the complete basis of the symmetric functions.
INPUT:
• I - a composition
OUTPUT:
• The commutative image of the complete basis element indexed by I. The result is the complete
symmetric function indexed by the partition obtained by sorting I.
EXAMPLES:
sage: S=NonCommutativeSymmetricFunctions(QQ).complete()
sage: S.to_symmetric_function_on_basis([2,1,3])
h[3, 2, 1]
sage: S.to_symmetric_function_on_basis([])
h[

class Elementary(NCSF)
bindable_classBindableClass

The Hopf algebra of non-commutative symmetric functions in the Elementary basis.
The Elementary basis is defined in Definition 3.4 of [NCSF1], where it is denoted by \((\Lambda^I)_I\). It is a mul-
tiplicative basis, and is obtained from the elementary generators \(\Lambda_i\) of the ring of non-commutative sym-
metric functions through the formula \(\Lambda^{(i_1, i_2, \ldots, i_k)} = \Lambda_{i_1} \Lambda_{i_2} \cdots \Lambda_{i_k}\) for every composition \((i_1, i_2, \ldots, i_k)\).
EXAMPLES:
The following are aliases for this basis:

```
sage: NCSF.elementary()
Non-Commutative Symmetric Functions over the Rational Field in the Elementary basis
sage: NCSF.L()
Non-Commutative Symmetric Functions over the Rational Field in the Elementary basis
```

```python
class Element
Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

psi_involution()

Return the image of the noncommutative symmetric function `self` under the involution \( \psi \).

The involution \( \psi \) is defined as the linear map \( NCSF \rightarrow NCSF \) which, for every composition \( I \), sends the complete noncommutative symmetric function \( S^I \) to the elementary noncommutative symmetric function \( \Lambda^I \). It can be shown that every composition \( I \) satisfies

\[
\psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I| - \ell(I)} \Phi^I
\]

where \( I^c \) denotes the complement of the composition \( I \), and \( \ell(I) \) denotes the length of \( I \), and where standard notations for classical bases of \( NCSF \) are being used (\( S \) for the complete basis, \( \Lambda \) for the elementary basis, \( \Phi \) for the basis of the power sums of the second kind, and \( R \) for the ribbon basis). The map \( \psi \) is an involution and a graded Hopf algebra automorphism of \( NCSF \). If \( \pi \) denotes the projection from \( NCSF \) to the ring of symmetric functions \( \text{to_symmetric_function()} \), then \( \pi(\psi(f)) = \omega(\pi(f)) \) for every \( f \in NCSF \), where the \( \omega \) on the right hand side denotes the omega automorphism of \( \text{Sym} \).

The involution \( \psi \) of \( NCSF \) is adjoint to the involution \( \psi \) of \( QSym \) by the standard adjunction between \( NCSF \) and \( QSym \).

The involution \( \psi \) has been denoted by \( \psi \) in [LMvW13], section 3.6.

See also:

\( psi \) involution of \( NCSF \), \( psi \) involution of \( QSym \), star involution of \( NCSF \).

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: L = NSym.L()
sage: L[3,1].psi_involution()
L[1, 1, 1, 1] - L[1, 2, 1] - L[2, 1, 1] + L[3, 1]
sage: S(L[3,1].psi_involution())
S[3, 1]
sage: L[].psi_involution()
L[]
sage: L[1,1].psi_involution()
L[1, 1]
sage: (L[2,1] - 2*L[2]).psi_involution()
```
The implementation at hand is tailored to the elementary basis. It is equivalent to the generic implementation via the ribbon basis:

```python
sage: R = NSym.R()
sage: all( R(L[I].psi_involution()) == R(L[I]).psi_involution() for I in Compositions(3) )
True
sage: all( R(L[I].psi_involution()) == R(L[I]).psi_involution() for I in Compositions(4) )
True
```

`star_involution()`

Return the image of the noncommutative symmetric function `self` under the star involution.

The star involution is defined as the algebra antihomomorphism $NCSF \to NCSF$ which, for every positive integer $n$, sends the $n$-th complete non-commutative symmetric function $S_n$ to $S_n$. Denoting by $f^*$ the image of an element $f \in NCSF$ under this star involution, it can be shown that every composition $I$ satisfies

$$(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R^I_1 = R_{I^r}, \quad (\Phi^I)^* = \Phi^{I^r},$$

where $I^r$ denotes the reversed composition of $I$, and standard notations for classical bases of $NCSF$ are being used ($S$ for the complete basis, $\Lambda$ for the elementary basis, $R$ for the ribbon basis, and $\Phi$ for that of the power-sums of the second kind). The star involution is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. Under the canonical isomorphism between the $n$-th graded component of $NCSF$ and the descent algebra of the symmetric group $S_n$ (see `to_descent_algebra()`), the star involution (restricted to the $n$-th graded component) corresponds to the automorphism of the descent algebra given by $x \mapsto \omega_n x^t \omega_n$, where $\omega_n$ is the permutation $(n, n-1, \ldots, 1) \in S_n$ (written here in one-line notation). If $\pi$ denotes the projection from $NCSF$ to the ring of symmetric functions (`.to_symmetric_function()`), then $\pi(f^*) = \pi(f)$ for every $f \in NCSF$.

The star involution on $NCSF$ is adjoint to the star involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by $\rho$ in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

See also:

- `star_involution of NCSF`
- `psi_involution of NCSF`
- `star_involution of QSym`

EXAMPLES:

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: L = NSym.L()
sage: L[3,3,2,3].star_involution()
L[3, 2, 3, 3]
sage: L[6,3,3].star_involution()
L[3, 3, 6]
sage: L[[4,1]].star_involution()
L[1, 4]
```
The implementation at hand is tailored to the elementary basis. It is equivalent to the generic implementation via the complete basis:

```
sage: S = NSym.S()
sage: all( S(L[I].star_involution()) == S(L[I]).star_involution() 
....:    for I in Compositions(4) )
True
```

### `verschiebung(n)`

Return the image of the noncommutative symmetric function `self` under the `n`-th Verschiebung operator.

The `n`-th Verschiebung operator $V_n$ is defined to be the map from the $k$-algebra of noncommutative symmetric functions to itself that sends the complete function $S^I$ indexed by a composition $I = (i_1, i_2, \ldots, i_k)$ to $S^{(i_1/n, i_2/n, \ldots, i_k/n)}$ if all of the numbers $i_1, i_2, \ldots, i_k$ are divisible by $n$, and to 0 otherwise. This operator $V_n$ is a Hopf algebra endomorphism. For every positive integer $r$ with $n \mid r$, it satisfies

$$V_n(S_r) = S_{r/n}, \quad V_n(\Lambda_r) = (-1)^{r-n/\lambda} \Lambda_{r/n}, \quad V_n(\Psi_r) = n \Psi_{r/n}, \quad V_n(\Phi_r) = n \Phi_{r/n}$$

(where $S_r$ denotes the $r$-th complete non-commutative symmetric function, $\Lambda_r$ denotes the $r$-th elementary non-commutative symmetric function, $\Psi_r$ denotes the $r$-th power-sum non-commutative symmetric function of the first kind, and $\Phi_r$ denotes the $r$-th power-sum non-commutative symmetric function of the second kind). For every positive integer $r$ with $n \nmid r$, it satisfies

$$V_n(S_r) = V_n(\Lambda_r) = V_n(\Psi_r) = V_n(\Phi_r) = 0.$$

The `n`-th Verschiebung operator is also called the `n`-th Verschiebung endomorphism.

It is a lift of the `n`-th Verschiebung operator on the ring of symmetric functions (`verschiebung()`) to the ring of noncommutative symmetric functions.

The action of the `n`-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition $I$ of size $n \ell$ satisfies

$$V_n(R_I) = (-1)^{\ell(I) - \ell(J)} \cdot R_{J/n},$$

where $J$ denotes the meet of the compositions $I$ and $(n, n, \ldots, n)$, where $\ell(I)$ is the length of $I$, and where $J/n$ denotes the composition obtained by dividing every entry of $J$ by $n$. For a composition $I$ of size not divisible by $n$, we have $V_n(R_I) = 0$.

See also:

- `verschiebung method of NCSF`
- `frobenius method of QSym`
- `verschiebung method of Sym`

**INPUT:**

- $n$ – a positive integer

**OUTPUT:**

The result of applying the `n`-th Verschiebung operator (on the ring of noncommutative symmetric functions) to `self`.

**EXAMPLES:**
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: L = NSym.L()
sage: L([4,2]).verschiebung(2)
-L[2, 1]
sage: L([2,4]).verschiebung(2)
-L[1, 2]
sage: L([6]).verschiebung(2)
-L[3]
sage: L([2,1]).verschiebung(3)
0
sage: L([3]).verschiebung(2)
0
sage: L([1]).verschiebung(2)
L[]
sage: L([5, 1]).verschiebung(3)
0
sage: L([5, 1]).verschiebung(6)
0
sage: L([5, 1]).verschiebung(2)
0
sage: L([1, 2, 3, 1]).verschiebung(7)
0
sage: L([7]).verschiebung(7)
L[1]
sage: L([1, 2, 3, 1]).verschiebung(5)
0

I

alias of NonCommutativeSymmetricFunctions.Immaculate
class Immaculate (NCSF)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_classBindableClass

The immaculate basis of the non-commutative symmetric functions.

The immaculate basis first appears in Berg, Bergeron, Saliola, Serrano and Zabrocki’s [BBSSZ2012]. It
can be described as the family \( \{S_\alpha\} \), where \( \alpha \) runs over all compositions, and \( S_\alpha \) denotes the immaculate
function corresponding to \( \alpha \) (see immaculate_function()).

If \( \alpha \) is a composition \( (\alpha_1, \alpha_2, \ldots, \alpha_m) \), then
\[
S_\alpha = \sum_{\sigma \in S_m} (-1)^\sigma S_{\alpha_1+\sigma(1)-1}S_{\alpha_2+\sigma(2)-2} \cdots S_{\alpha_m+\sigma(m)-m}.
\]

Warning: This basis contains only the immaculate functions indexed by compositions (i.e., finite
sequences of positive integers). To obtain the remaining immaculate functions (sensu lato), use the
immaculate_function() method. Calling the immaculate basis with a list which is not a com-
position will currently return garbage!

EXAMPLES:

sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: I = NCSF.I()
(continued from previous page)

```
sage: I([1,3,2])*I([1])
I[1, 3, 2, 1] + I[1, 3, 3] + I[1, 4, 2] + I[2, 3, 2]
sage: I([1])*I([1,3,2])
sage: I([3,1])*I([2,1])
sage: R = NCSF.ribbon()
sage: R(I(R([2,1,3])))
I[2, 1, 3]
```

```
class Element
    Bases: sage.modules.with_basis.indexed_element.
           IndexedFreeModuleElement

    An element in the Immaculate basis.

    bernstein_creation_operator(n)

    Return the image of self under the n-th Bernstein creation operator.

    Let n be an integer. The n-th Bernstein creation operator \( \mathbb{B}_n \) is defined as the endomorphism of the space \( NSym \) of noncommutative symmetric functions given by

    \[
    \mathbb{B}_n I_{(\alpha_1, \alpha_2, \ldots, \alpha_m)} = I_{(n, \alpha_1, \alpha_2, \ldots, \alpha_m)},
    \]

    where \( I_{(\alpha_1, \alpha_2, \ldots, \alpha_m)} \) is the immaculate function associated to the \( m \)-tuple \( (\alpha_1, \alpha_2, \ldots, \alpha_m) \in \mathbb{Z}^m \).

    This has been introduced in [BBSSZ2012], section 3.1, in analogy to the Bernstein creation operators on the symmetric functions.

    For more information on the n-th Bernstein creation operator, see bernstein_creation_operator().

    EXAMPLES:

    ```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: I = NSym.I()
sage: b = I[1,3,2,1]
sage: b.bernstein_creation_operator(3)
I[3, 1, 3, 2, 1]
sage: b.bernstein_creation_operator(5)
I[5, 1, 3, 2, 1]
sage: elt = b + 3*I[4,1,2]
sage: elt.bernstein_creation_operator(1)
I[1, 1, 3, 2, 1] + 3*I[1, 4, 1, 2]
```

We check that this agrees with the definition on the Complete basis:

```
sage: S = NSym.S()
sage: S(elt).bernstein_creation_operator(1) == S(elt.bernstein_creation_operator(1))
True
```

Check on non-positive values of n:

```
```
**dual()**

Return the dual basis to the Immaculate basis of NCSF.

The basis returned is the dualImmaculate basis of QSym.

**OUTPUT:**
- The dualImmaculate basis of the quasi-symmetric functions.

**EXAMPLES:**

```python
sage: I=NonCommutativeSymmetricFunctions(QQ).Immaculate()
sage: I.dual()
Quasisymmetric functions over the Rational Field in the dualImmaculate basis
```

**L**

alias of `NonCommutativeSymmetricFunctions.Elementary`

**class** **Monomial** *(NCSF)*

**Bases:** `sage.combinat.free_module.CombinatorialFreeModule`, `sage.misc.bindable_classBindableClass`

The monomial basis defined in Tevlin’s paper [Tev2007].

The monomial basis is well-defined only when the base ring is a $\mathbb{Q}$-algebra. It is the basis denoted by $(M^I)_I$ in [Tev2007].

**class** **MultiplicativeBases** *(parent_with_realization)*

**Bases:** `sage.categories.realizations.Category_realization_of_parent`

Category of multiplicative bases of non-commutative symmetric functions.

**EXAMPLES:**

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.MultiplicativeBases()
Category of multiplicative bases of Non-Commutative Symmetric Functions over \(\mathbb{Q}\)
```

The complete basis is a multiplicative basis, but the ribbon basis is not:

```python
sage: N.Complete() in N.MultiplicativeBases()
True
sage: N.Ribbon() in N.MultiplicativeBases()
False
```

**class** **ParentMethods**

**Bases:** `object`

**algebra generators()**

Return the algebra generators of a given multiplicative basis of non-commutative symmetric functions.

**OUTPUT:**
- The family of generators of the multiplicative basis `self`.

**EXAMPLES:**

```python
```
algebra_morphism \text{on}_{\text{generators}} \text{,**keywords)}

Given a map defined on the generators of the multiplicative basis self, return the algebra morphism that extends this map to the whole algebra of non-commutative symmetric functions.

INPUT:
- \text{on}_{\text{generators}} – a function defined on the index set of the generators (that is, on the positive integers)
- \text{anti} – a boolean; defaults to False
- \text{category} – a category; defaults to None

OUTPUT:
- The algebra morphism of self which is defined by on\_generators in the basis self.
  When anti is set to True, an algebra anti-morphism is computed instead of an algebra morphism.

EXAMPLES:

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: Psi = NCSF.Psi()
sage: double = lambda i: Psi[i,i]
sage: f = Psi.algebra_morphism(double, codomain = Psi)
sage: f
Generic endomorphism of Non-Commutative Symmetric Functions over the
\rightarrow\text{Rational Field in the Psi basis}
sage: f(2*Psi[[]] + 3 * Psi[1,3,2] + Psi[2,4] )
2*Psi[[]] + 3*Psi[1, 3, 2] + Psi[2, 4]
sage: f.category()
Category of endsets of unital magmas and right modules over Rational Field
```

When extra properties about the morphism are known, one can specify the category of which it is a morphism:

```python
sage: negate = lambda i: -Psi[i]
sage: f = Psi.algebra_morphism(negate, codomain = Psi, category =)
\rightarrow\text{GradedHopfAlgebrasWithBasis(QQ))}
sage: f
Generic endomorphism of Non-Commutative Symmetric Functions over the
\rightarrow\text{Rational Field in the Psi basis}
sage: f(2*Psi[[]] + 3 * Psi[1,3,2] + Psi[2,4] )
2*Psi[[]] - 3*Psi[1, 3, 2] + Psi[2, 4]
sage: f.category()
Category of endsets of hopf algebras over Rational Field and graded
\rightarrow\text{modules over Rational Field}
```

If anti is true, this returns an anti-algebra morphism:

```python
sage: f = Psi.algebra_morphism(double, codomain = Psi, anti=True)
sage: f
Generic endomorphism of Non-Commutative Symmetric Functions over the
\rightarrow\text{Rational Field in the Psi basis}
sage: f(2*Psi[[]] + 3 * Psi[1,3,2] + Psi[2,4] )
```

(continues on next page)
2*\Psi[] + 3*\Psi[2, 2, 3, 3, 1, 1] + \Psi[4, 4, 2, 2] 

**antipode()**

Return the antipode morphism on the basis `self`.

The antipode of `NSym` is closely related to the omega involution; see `omega_involution()` for the latter.

**OUTPUT:**

• The antipode module map from non-commutative symmetric functions on basis `self`.

**EXAMPLES:**

```python
sage: S=NonCommutativeSymmetricFunctions(QQ).S()
sage: S.antipode
Generic endomorphism of Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
```

**coproduct()**

Return the coproduct morphism in the basis `self`.

**OUTPUT:**

• The coproduct module map from non-commutative symmetric functions on basis `self`.

**EXAMPLES:**

```python
sage: S=NonCommutativeSymmetricFunctions(QQ).S()
sage: S.coproduct
Generic morphism:
  From: Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
  To: Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
```

**product_on_basis**(composition1, composition2)

Return the product of two basis elements from the multiplicative basis. Multiplication is just concatenation on compositions.

**INPUT:**

• `composition1, composition2` – integer compositions

**OUTPUT:**

• The product of the two non-commutative symmetric functions indexed by `composition1` and `composition2` in the multiplicative basis `self`. This will be again a non-commutative symmetric function.

**EXAMPLES:**

```python
sage: Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
sage: Psi[3,1,2] * Psi[4,2] == Psi[3,1,2,4,2]
True
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.product_on_basis(Composition([1,2,1]), Composition([2,1]))
S[2, 1, 1, 1]
```

**to_symmetric_function()**

Morphism to the algebra of symmetric functions.

This is constructed by extending the algebra morphism by the image of the generators.
• The module morphism from the basis self to the symmetric functions which corresponds to taking a commutative image.

EXAMPLES:

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.to_symmetric_function(S[1,3])
h[3, 1]
sage: Phi = N.Phi()
sage: Phi.to_symmetric_function(Phi[1,3])
h[1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
sage: Psi = N.Psi()
sage: Psi.to_symmetric_function(Psi[1,3])
h[1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
```

to_symmetric_function_on_generators(i)
Morphism of the generators to symmetric functions.
This is constructed by coercion to the complete basis and applying the morphism.

OUTPUT:
• The module morphism from the basis self to the symmetric functions which corresponds to taking a commutative image.

EXAMPLES:

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = N.Phi()
sage: Phi.to_symmetric_function_on_generators(3)
h[1, 1, 1] - 3*h[2, 1] + 3*h[3]
sage: Phi.to_symmetric_function_on_generators(0)
h[1, 1, 1] - 3*h[2, 1] + 3*h[3]
sage: L = N.elementary()
sage: L.to_symmetric_function_on_generators(3)
h[1, 1, 1] - 2*h[2, 1] + h[3]
```

super_categories()
Return the super categories of the category of multiplicative bases of the non-commutative symmetric functions.

OUTPUT:
• list

class MultiplicativeBasesOnGroupLikeElements(parent_with_realization)
Bases: sage.categories.realizations.Category_realization_of_parent

Category of multiplicative bases on grouplike elements of non-commutative symmetric functions.

Here, a “multiplicative basis on grouplike elements” means a multiplicative basis whose generators \((f_1, f_2, f_3, \ldots)\) satisfy

\[
\Delta(f_i) = \sum_{j=0}^{i} f_j \otimes f_{i-j}
\]

with \(f_0 = 1\). (In other words, the generators are to form a divided power sequence in the sense of a coalgebra.) This does not mean that the generators are grouplike, but means that the element \(1 + f_1 + f_2 + \)
\( f_3 + \cdots \) in the completion of the ring of non-commutative symmetric functions with respect to the grading is grouplike.

**EXAMPLES:**

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.MultiplicativeBasesOnGroupLikeElements()
Category of multiplicative bases on group like elements of Non-Commutative

\[ \text{The complete basis is a multiplicative basis, but the ribbon basis is not:} \]

```python
sage: N.Complete() in N.MultiplicativeBasesOnGroupLikeElements()
True
sage: N.Ribbon() in N.MultiplicativeBasesOnGroupLikeElements()
False
```

```python
class ParentMethods
Bases: object

\textbf{antipode_on_basis}(\textit{composition})

Return the application of the antipode to a basis element.

\textbf{INPUT:}
- \textit{composition} – a composition

\textbf{OUTPUT:}
- The image of the basis element indexed by \textit{composition} under the antipode map.

\textbf{EXAMPLES:}

```python
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: S.antipode_on_basis(Composition([2,1]))
-S[1, 1, 1] + S[1, 2]
sage: S[1].antipode()  # indirect doctest
-S[1]
sage: S[2].antipode()  # indirect doctest
S[1, 1] - S[2]
sage: S[3].antipode()  # indirect doctest
-S[1, 1, 1] + S[1, 2] + S[2, 1] - S[3]
sage: S[2, 3].coproduct().apply_multilinear_morphism(lambda be,ga:
\rightarrow S(be)*S(ga).antipode())
0
sage: S[2, 3].coproduct().apply_multilinear_morphism(lambda be,ga:
\rightarrow S(be).antipode() + S(ga))
0
```

\textbf{coproduct_on_generators}(\textit{i})

Return the image of the \textit{i}th generator of the algebra under the coproduct.

\textbf{INPUT:}
- \textit{i} – a positive integer

\textbf{OUTPUT:}
- The result of applying the coproduct to the \textit{i}th generator of \textit{self}.

\textbf{EXAMPLES:}

```python
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: S.coproduct_on_generators(3)
```
super_categories()

Return the super categories of the category of multiplicative bases of group-like elements of the non-commutative symmetric functions.

OUTPUT:

• list

class MultiplicativeBasesOnPrimitiveElements (parent_with_realization)

Bases: sage.categories.realizations.Category_realization_of_parent

Category of multiplicative bases of the non-commutative symmetric functions whose generators are primitive elements.

An element $x$ of a bialgebra is primitive if $\Delta(x) = x \otimes 1 + 1 \otimes x$, where $\Delta$ is the coproduct of the bialgebra.

Given a multiplicative basis and knowing the coproducts and antipodes of its generators, one can compute the coproduct and the antipode of any element, since they are respectively algebra morphisms and antihomomorphisms. See antipode_on_generators() and coproduct_on_generators().

Todo: this could be generalized to any free algebra.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.MultiplicativeBasesOnPrimitiveElements()
Category of multiplicative bases on primitive elements of Non-Commutative
˓→Symmetric Functions over the Rational Field
```

The Phi and Psi bases are multiplicative bases whose generators are primitive elements, but the complete and ribbon bases are not:

```
sage: N.Phi() in N.MultiplicativeBasesOnPrimitiveElements()
True
sage: N.Psi() in N.MultiplicativeBasesOnPrimitiveElements()
True
sage: N.Complete() in N.MultiplicativeBasesOnPrimitiveElements()
False
sage: N.Ribbon() in N.MultiplicativeBasesOnPrimitiveElements()
False
```

class ParentMethods

Bases: object

antipode_on_generators (i)

Return the image of a generator of a primitive basis of the non-commutative symmetric functions under the antipode map.

INPUT:

• i – a positive integer

OUTPUT:

• The image of the $i$-th generator of the multiplicative basis self under the antipode of the algebra of non-commutative symmetric functions.

EXAMPLES:

```
sage: Psi=NonCommutativeSymmetricFunctions(QQ).Psi()
sage: Psi.antipode_on_generators(2)
-Psi[2]
```
coproduct_on_generators($i$)

Return the image of the $i^{th}$ generator of the multiplicative basis `self` under the coproduct.

**INPUT:**
- $i$ – a positive integer

**OUTPUT:**
- The result of applying the coproduct to the $i^{th}$ generator of `self`.

**EXAMPLES:**

```python
sage: Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
sage: Psi.coproduct_on_generators(3)
```

super_categories()

Return the super categories of the category of multiplicative bases of primitive elements of the noncommutative symmetric functions.

**OUTPUT:**
- list

```python
class Phi(NCSF)
    Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_class.BindableClass

The Hopf algebra of non-commutative symmetric functions in the Phi basis.

The Phi basis is defined in Definition 3.4 of [NCSF1], where it is denoted by ($\Phi^I$). It is a multiplicative basis, and is connected to the elementary generators $\Lambda_i$ of the ring of non-commutative symmetric functions by the following relation: Define a non-commutative symmetric function $\Phi_n$ for every positive integer $n$ by the power series identity

$$
\sum_{k \geq 1} \frac{t^k}{k} \Phi_k = -\log \left( \sum_{k \geq 0} (-t)^k \Lambda_k \right),
$$

with $\Lambda_0$ denoting 1. For every composition $(i_1, i_2, \ldots, i_k)$, we have $\Phi^{(i_1, i_2, \ldots, i_k)} = \Phi_{i_1} \Phi_{i_2} \cdots \Phi_{i_k}$.

The $\Phi$-basis is well-defined only when the base ring is a $\mathbb{Q}$-algebra. The elements of the $\Phi$-basis are known as the “power-sum non-commutative symmetric functions of the second kind”.

The generators $\Phi_n$ are related to the (first) Eulerian idempotents in the descent algebras of the symmetric groups (see [NCSF1], 5.4 for details).

**EXAMPLES:**

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NCSF.Phi(); Phi
Non-Commutative Symmetric Functions over the Rational Field in the Phi basis
sage: Phi.an_element()
2*Phi[] + 2*Phi[1] + 3*Phi[1, 1]
```

class Element

```python
class Element
    Bases: sage.modules.with_basis.indexed_element.
        IndexedFreeModuleElement

psi_involution()

Return the image of the noncommutative symmetric function `self` under the involution $\psi$.

The involution $\psi$ is defined as the linear map $NCSF \to NCSF$ which, for every composition $I$, sends the complete noncommutative symmetric function $S^I$ to the elementary noncommutative
symmetric function $\Lambda^I$. It can be shown that every composition $I$ satisfies

$$\psi(R_I) = R_{I^c}, \quad \psi(S_I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I| - \ell(I)} \Phi^I$$

where $I^c$ denotes the complement of the composition $I$, and $\ell(I)$ denotes the length of $I$, and where standard notations for classical bases of $NCSF$ are being used ($S$ for the complete basis, $\Lambda$ for the elementary basis, $\Phi$ for the basis of the power sums of the second kind, and $R$ for the ribbon basis). The map $\psi$ is an involution and a graded Hopf algebra automorphism of $NCSF$. If $\pi$ denotes the projection from $NCSF$ to the ring of symmetric functions ($\text{to_symmetric_function()}$), then $\pi(\psi(f)) = \omega(\pi(f))$ for every $f \in NCSF$, where the $\omega$ on the right hand side denotes the omega automorphism of $\text{Sym}$.

The involution $\psi$ of $NCSF$ is adjoint to the involution $\psi$ of $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The involution $\psi$ has been denoted by $\psi$ in [LMvW13], section 3.6.

See also:

psi involution of NCSF, psi involution of QSym, star involution of NCSF.

EXAMPLES:

```python
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NSym.Phi()
sage: Phi[3,2].psi_involution()
-Phi[3, 2]
sage: Phi[2,2].psi_involution()
Phi[2, 2]
sage: Phi[[1]].psi_involution()
Phi[]
sage: (Phi[2,1] - 2*Phi[2]).psi_involution()
2*Phi[2] - Phi[2, 1]
sage: Phi(0).psi_involution()
0
```

The implementation at hand is tailored to the Phi basis. It is equivalent to the generic implementation via the ribbon basis:

```python
sage: R = NSym.R()
sage: all( R(Phi[I].psi_involution()) == R(Phi[I]).psi_involution() 
.......: for I in Compositions(4) )
True
```

**star_involution()**

Return the image of the noncommutative symmetric function self under the star involution.

The star involution is defined as the algebra antihomomorphism $\text{NCSF} \rightarrow \text{NCSF}$ which, for every positive integer $n$, sends the $n$-th complete non-commutative symmetric function $S_n$ to $S_n$. Denoting by $f^*$ the image of an element $f \in NCSF$ under this star involution, it can be shown that every composition $I$ satisfies

$$(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R_I^* = R_{I^r}, \quad (\Phi^I)^* = \Phi^{I^r},$$

where $I^r$ denotes the reversed composition of $I$, and standard notations for classical bases of $NCSF$ are being used ($S$ for the complete basis, $\Lambda$ for the elementary basis, $R$ for the ribbon basis, and $\Phi$ for that of the power-sums of the second kind). The star involution is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space
\(\text{NC SF}\). Under the canonical isomorphism between the \(n\)-th graded component of \(\text{NC SF}\) and the descent algebra of the symmetric group \(S_n\) (see \text{to\_descent\_algebra()}\), the star involution (restricted to the \(n\)-th graded component) corresponds to the automorphism of the descent algebra given by \(x \mapsto \omega_n x \omega_n\), where \(\omega_n\) is the permutation \((n, n-1, \ldots, 1)\) in \(S_n\) (written here in one-line notation). If \(\pi\) denotes the projection from \(\text{NC SF}\) to the ring of symmetric functions \(\text{to\_symmetric\_function()}\), then \(\pi(f^*) = \pi(f)\) for every \(f \in \text{NC SF}\).

The star involution on \(\text{NC SF}\) is adjoint to the star involution on \(Q Sym\) by the standard adjunction between \(\text{NC SF}\) and \(Q Sym\).

The star involution has been denoted by \(\rho\) in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

See also:

\text{star involution of NC SF}, \text{psi involution of NC SF}, \text{star involution of QSym}.

**EXAMPLES:**

```python
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NSym.Phi()
sage: Phi[3,1,1,4].star_involution()
Phi[4, 1, 1, 3]
sage: Phi[4,2,1].star_involution()
Phi[1, 2, 4]
sage: (Phi[3,3] + 3*Phi[1]).star_involution()
3*Phi[1] + Phi[3, 3]
sage: Phi([2,1]).star_involution()
Phi[1, 2]
```

The implementation at hand is tailored to the Phi basis. It is equivalent to the generic implementation via the complete basis:

```python
sage: S = NSym.S()
sage: all( S(Phi[I].star_involution()) == S(Phi[I]).star_involution() for I in Compositions(4) )
True
```

\text{verschiebung} \((n)\)

Return the image of the noncommutative symmetric function \(\text{self}\) under the \(n\)-th Verschiebung operator.

The \(n\)-th Verschiebung operator \(V_n\) is defined to be the map from the \(k\)-algebra of noncommutative symmetric functions to itself that sends the complete function \(S_I\) indexed by a composition \(I = (i_1, i_2, \ldots, i_k)\) to \(S_{(i_1/n, i_2/n, \ldots, i_k/n)}\) if all of the numbers \(i_1, i_2, \ldots, i_k\) are divisible by \(n\), and to 0 otherwise. This operator \(V_n\) is a Hopf algebra endomorphism. For every positive integer \(r\) with \(n \mid r\), it satisfies

\[
V_n(S_r) = S_{r/n}, \quad V_n(\Lambda_r) = (-1)^{r/n} \Lambda_{r/n}, \quad V_n(\Psi_r) = n\Psi_{r/n}, \quad V_n(\Phi_r) = n\Phi_{r/n}
\]

(where \(S_r\) denotes the \(r\)-th complete non-commutative symmetric function, \(\Lambda_r\) denotes the \(r\)-th elementary non-commutative symmetric function, \(\Psi_r\) denotes the \(r\)-th power-sum non-commutative symmetric function of the first kind, and \(\Phi_r\) denotes the \(r\)-th power-sum non-commutative symmetric function of the second kind). For every positive integer \(r\) with \(n \nmid r\),
it satisfies

\[ V_n(S_r) = V_n(\Lambda_r) = V_n(\Psi_r) = V_n(\Phi_r) = 0. \]

The \( n \)-th Verschiebung operator is also called the \( n \)-th Verschiebung endomorphism. It is a lift of the \( n \)-th Verschiebung operator on the ring of symmetric functions \((\text{verschiebung}())\) to the ring of noncommutative symmetric functions.

The action of the \( n \)-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition \( I \) of size \( n\ell \) satisfies

\[ V_n(R_I) = (-1)^{\ell(I) - \ell(J)} \cdot R_{J/n}, \]

where \( J \) denotes the meet of the compositions \( I \) and \((n, n, \ldots, n)\), where \( \ell(I) \) is the length of \( I \), and where \( J/n \) denotes the composition obtained by dividing every entry of \( J \) by \( n \). For a composition \( I \) of size not divisible by \( n \), we have \( V_n(R_I) = 0 \).

See also:

\textit{verschiebung method of NCSF}, \quad \textit{frobenius method of QSym}, \quad \textit{verschiebung method of Sym}

INPUT:

\begin{itemize}
  \item \texttt{n} – a positive integer
\end{itemize}

OUTPUT:

The result of applying the \( n \)-th Verschiebung operator (on the ring of noncommutative symmetric functions) to \texttt{self}.

EXAMPLES:

\begin{verbatim}
    sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
    sage: Phi = NSym.Phi()
    sage: Phi([4,2]).verschiebung(2)
    4*Phi[2, 1]
    sage: Phi([2,4]).verschiebung(2)
    4*Phi[1, 2]
    sage: Phi([6]).verschiebung(2)
    2*Phi[3]
    sage: Phi([2,1]).verschiebung(3)
    0
    sage: Phi([3]).verschiebung(2)
    0
    sage: Phi([]).verschiebung(2)
    Phi[]
    sage: Phi([5, 1]).verschiebung(3)
    0
    sage: Phi([5, 1]).verschiebung(6)
    0
    sage: Phi([5, 1]).verschiebung(2)
    0
    sage: Phi([1, 2, 3, 1]).verschiebung(7)
    0
    sage: Phi([7]).verschiebung(7)
    7*Phi[1]
    sage: Phi([1, 2, 3, 1]).verschiebung(5)
    0
    sage: (Phi[1] - Phi[2] + 2*Phi[3]).verschiebung(1)
\end{verbatim}
class Psi(NCSF)
Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_class.BindableClass

The Hopf algebra of non-commutative symmetric functions in the Psi basis.

The Psi basis is defined in Definition 3.4 of [NCSF1], where it is denoted by \((\Psi_I)_I\). It is a multiplicative basis, and is connected to the elementary generators \(\Lambda_i\) of the ring of non-commutative symmetric functions by the following relation: Define a non-commutative symmetric function \(\Psi_n\) for every positive integer \(n\) by the power series identity

\[
\frac{d}{dt} \sigma(t) = \sigma(t) \cdot \left( \sum_{k \geq 1} t^{k-1} \Psi_k \right),
\]

where

\[
\sigma(t) = \left( \sum_{k \geq 0} (-t)^k \Lambda_k \right)^{-1}
\]

and where \(\Lambda_0\) denotes 1. For every composition \((i_1, i_2, \ldots, i_k)\), we have \(\Psi^{(i_1, i_2, \ldots, i_k)} = \Psi_{i_1} \Psi_{i_2} \cdots \Psi_{i_k}\).

The \(\Psi\)-basis is a basis only when the base ring is a \(\mathbb{Q}\)-algebra (although the \(\Psi_I\) can be defined over any base ring). The elements of the \(\Psi\)-basis are known as the "power-sum non-commutative symmetric functions of the first kind". The generators \(\Psi_n\) correspond to the Dynkin (quasi-)idempotents in the descent algebras of the symmetric groups (see [NCSF1], 5.2 for details).

Another (equivalent) definition of \(\Psi_n\) is

\[
\Psi_n = \sum_{i=0}^{n-1} (-1)^i R_{1^i, n-i},
\]

where \(R\) denotes the ribbon basis of \(NCSF\), and where \(1^i\) stands for \(i\) repetitions of the integer 1.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: Psi = NCSF.Psi(); Psi
Non-Commutative Symmetric Functions over the Rational Field in the Psi basis
sage: Psi.an_element()
2*Psi[] + 2*Psi[1] + 3*Psi[1, 1]
```

Checking the equivalent definition of \(\Psi_n\):

```
sage: def test_psi(n):
....:     NCSF = NonCommutativeSymmetricFunctions(ZZ)
....:     R = NCSF.R()
....:     Psi = NCSF.Psi()
....:     a = R.sum([[(-1) ** i * R[[1]*i + [n-i]]
....:                for i in range(n)])
....:     return a == R(Psi[n])
sage: test_psi(2)
True
sage: test_psi(3)
True
sage: test_psi(4)
True
```
class Element
   Bases: sage.modules.with_basis.indexed_element.
      IndexedFreeModuleElement
verschiebung(n)
   Return the image of the noncommutative symmetric function self under the n-th Verschiebung operator.

   The n-th Verschiebung operator \( V_n \) is defined to be the map from the \( k \)-algebra of noncommutative symmetric functions to itself that sends the complete function \( S_I \) indexed by a composition \( I = (i_1, i_2, \ldots, i_k) \) to \( S_{(i_1/n, i_2/n, \ldots, i_k/n)} \) if all of the numbers \( i_1, i_2, \ldots, i_k \) are divisible by \( n \), and to 0 otherwise. This operator \( V_n \) is a Hopf algebra endomorphism. For every positive integer \( r \) with \( n \mid r \), it satisfies

   \[
   V_n(S_r) = S_{r/n}, \quad V_n(\Lambda_r) = (-1)^{r-r/n} \Lambda_{r/n}, \quad V_n(\Psi_r) = n \Psi_{r/n}, \quad V_n(\Phi_r) = n \Phi_{r/n}
   \]

   (where \( S_r \) denotes the \( r \)-th complete non-commutative symmetric function, \( \Lambda_r \) denotes the \( r \)-th elementary non-commutative symmetric function, \( \Psi_r \) denotes the \( r \)-th power-sum non-commutative symmetric function of the first kind, and \( \Phi_r \) denotes the \( r \)-th power-sum non-commutative symmetric function of the second kind). For every positive integer \( r \) with \( n \nmid r \), it satisfies

   \[
   V_n(S_r) = V_n(\Lambda_r) = V_n(\Psi_r) = V_n(\Phi_r) = 0.
   \]

   The \( n \)-th Verschiebung operator is also called the \( n \)-th Verschiebung endomorphism.

   It is a lift of the \( n \)-th Verschiebung operator on the ring of symmetric functions \( \text{verschiebung}(\cdot) \) to the ring of noncommutative symmetric functions.

   The action of the \( n \)-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition \( I \) of size \( n \ell \) satisfies

   \[
   V_n(R_I) = (-1)^{\ell(I) - \ell(J)} \cdot R_{J/n},
   \]

   where \( J \) denotes the meet of the compositions \( I \) and \( (n, n, \ldots, n) \), where \( \ell(I) \) is the length of \( I \) divided \( n \) times \( |I|/n \) times \( J \), and where \( J/n \) denotes the composition obtained by dividing every entry of \( J \) by \( n \). For a composition \( I \) of size not divisible by \( n \), we have \( V_n(R_I) = 0 \).

See also:
verschiebung method of NCSF, frobenius method of QSym, verschiebung method of Sym

INPUT:
• \( n \) – a positive integer

OUTPUT:
The result of applying the \( n \)-th Verschiebung operator (on the ring of noncommutative symmetric functions) to self.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: Psi = NSym.Psi()
sage: Psi([4,2]).verschiebung(2)
4*Psi[2, 1]
sage: Psi([2,4]).verschiebung(2)
4*Psi[1, 2]
```
internal_product_on_basis_by_bracketing(I, J)

The internal product of two elements of the Psi basis.

See internal_product() for a thorough documentation of this operation.

This is an implementation using [NCSF2] Lemma 3.10. It is fast when the length of \( I \) is small, but can get very slow otherwise. Therefore it is not being used by default for internally multiplying Psi functions.

INPUT:
• \( I, J \) – compositions

OUTPUT:
• The internal product of the elements of the Psi basis of \( N Sym \) indexed by \( I \) and \( J \), expressed in the Psi basis.

AUTHORS:
• Travis Scrimshaw, 29 Mar 2014

EXAMPLES:

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: Psi = N.Psi()
sage: Psi.internal_product_on_basis_by_bracketing([2,2],[1,2,1])
0
sage: Psi.internal_product_on_basis_by_bracketing([1,2,1],[2,1,1])
4*Psi[1, 2, 1]
sage: Psi.internal_product_on_basis_by_bracketing([2,1,1],[1,2,1])
4*Psi[2, 1, 1]
sage: Psi.internal_product_on_basis_by_bracketing([1,2,1], [1,1,1,1])
0
sage: Psi.internal_product_on_basis_by_bracketing([3,1], [1,2,1])
-Psi[1, 2, 1] + Psi[2, 1, 1]
sage: Psi.internal_product_on_basis_by_bracketing([1,2,1], [3,1])
0
sage: Psi.internal_product_on_basis_by_bracketing([2,2],[1,2])
0
```

(continues on next page)
sage: Psi.internal_product_on_basis_by_bracketing([4], [1,2,1])
-Psi[1, 1, 2] + 2*Psi[1, 2, 1] - Psi[2, 1, 1]

R
alias of NonCommutativeSymmetricFunctions.Ribbon
class Ribbon(NCSF)
Bases:
  sage.combinat.free_module.CombinatorialFreeModule, sage.misc.
  bindable_classBindableClass

The Hopf algebra of non-commutative symmetric functions in the Ribbon basis.

The Ribbon basis is defined in Definition 3.12 of [NCSF1], where it is denoted by \( R_I \). It is connected to the complete basis of the ring of non-commutative symmetric functions by the following relation: For every composition \( I \), we have

\[
R_I = \sum_J (-1)^{\ell(I) - \ell(J)} S_J,
\]

where the sum is over all compositions \( J \) which are coarser than \( I \) and \( \ell(I) \) denotes the length of \( I \). (See the proof of Proposition 4.13 in [NCSF1].)

The elements of the Ribbon basis are commonly referred to as the ribbon Schur functions.

EXAMPLES:

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: R = NCSF.Ribbon(); R
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon
˓→basis
sage: R.an_element()
2*R[] + 2*R[1] + 3*R[1, 1]
```

The following are aliases for this basis:

```python
sage: NCSF.ribbon()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon
˓→basis
sage: NCSF.R()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon
˓→basis
```

class Element

```
Bases: sage.modules.with_basis.indexed_element.
  IndexedFreeModuleElement

star_involution()

Return the image of the noncommutative symmetric function self under the star involution.

The star involution is defined as the algebra antihomomorphism \( NCSF \rightarrow NCSF \) which, for every positive integer \( n \), sends the \( n \)-th complete non-commutative symmetric function \( S_n \) to \( S_n \). Denoting by \( f^* \) the image of an element \( f \in NCSF \) under this star involution, it can be shown that every composition \( I \) satisfies

\[
(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R_I^* = R_{I^r}, \quad (\Phi^I)^* = \Phi^{I^r},
\]

where \( I^r \) denotes the reversed composition of \( I \), and standard notations for classical bases of \( NCSF \) are being used (\( S \) for the complete basis, \( \Lambda \) for the elementary basis, \( R \) for the ribbon basis, and \( \Phi \) for that of the power sums of the second kind). The star involution is an involution

5.1. Comprehensive Module list
and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. Under the canonical isomorphism between the $n$-th graded component of $NCSF$ and the descent algebra of the symmetric group $S_n$ (see to_descent_algebra()), the star involution (restricted to the $n$-th graded component) corresponds to the automorphism of the descent algebra given by $x \mapsto \omega_n x \omega_n$, where $\omega_n$ is the permutation $(n, n-1, \ldots, 1) \in S_n$ (written here in one-line notation). If $\pi$ denotes the projection from $NCSF$ to the ring of symmetric functions (to_symmetric_function()), then $\pi(f^*) = \pi(f)$ for every $f \in NCSF$.

The star involution on $NCSF$ is adjoint to the star involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by $\rho$ in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

See also:

* star involution of $NCSF$, star involution of $QSym$, psi involution of $NCSF$.

**EXAMPLES:**

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: R = NSym.R()
sage: R[3,1,4,2].star_involution()
R[2, 4, 1, 3]
sage: R[4,1,2].star_involution()
R[2, 1, 4]
sage: (R[3,3] - 21*R[1]).star_involution()
-21*R[1] + R[3, 3]
sage: R([14,1]).star_involution()
R[1, 14]
```

The implementation at hand is tailored to the ribbon basis. It is equivalent to the generic implementation via the complete basis:

```python
sage: S = NSym.S()
sage: all( S(R[I].star_involution()) == S(R[I]).star_involution() 
......: for I in Compositions(4) )
True
```

**verschiebung** ($n$)

Return the image of the noncommutative symmetric function self under the $n$-th Verschiebung operator.

The $n$-th Verschiebung operator $V_n$ is defined to be the map from the $k$-algebra of noncommutative symmetric functions to itself that sends the complete function $S_I$ indexed by a composition $I = (i_1, i_2, \ldots, i_k)$ to $S_{(i_1/n,i_2/n,\ldots,i_k/n)}$ if all of the numbers $i_1, i_2, \ldots, i_k$ are divisible by $n$, and to 0 otherwise. This operator $V_n$ is a Hopf algebra endomorphism. For every positive integer $r$ with $n \mid r$, it satisfies

$$V_n(S_r) = S_{r/n}, \quad V_n(\Lambda_r) = (-1)^{r-n} \Lambda_{r/n}, \quad V_n(\Psi_r) = n \Psi_{r/n}, \quad V_n(\Phi_r) = n \Phi_{r/n}$$

(where $S_r$ denotes the $r$-th complete non-commutative symmetric function, $\Lambda_r$ denotes the $r$-th elementary non-commutative symmetric function, $\Psi_r$ denotes the $r$-th power-sum non-commutative symmetric function of the first kind, and $\Phi_r$ denotes the $r$-th power-sum non-commutative symmetric function of the second kind). For every positive integer $r$ with $n \nmid r$,
it satisfies
\[ V_n(S_r) = V_n(\Lambda_r) = V_n(\Psi_r) = V_n(\Phi_r) = 0. \]

The \( n \)-th Verschiebung operator is also called the \( n \)-th Verschiebung endomorphism.

It is a lift of the \( n \)-th Verschiebung operator on the ring of symmetric functions \((\text{verschiebung}(J))\) to the ring of noncommutative symmetric functions.

The action of the \( n \)-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition \( I \) of size \( n \ell \) satisfies
\[ V_n(R_I) = (-1)^{\ell(I) - \ell(J)} \cdot R_{J/n}, \]
where \( J \) denotes the meet of the compositions \( I \) and \((n, n, \ldots, n)\), where \( \ell(I) \) is the length of \( I \), and where \( J/n \) denotes the composition obtained by dividing every entry of \( J \) by \( n \). For a composition \( I \) of size not divisible by \( n \), we have \( V_n(R_I) = 0 \).

See also:

\textit{verschiebung method of NCSF}, \hspace{1cm} \textit{frobenius method of QSym}, \hspace{1cm} \textit{verschiebung method of Sym}

INPUT:

\begin{itemize}
  \item \( n \) – a positive integer
\end{itemize}

OUTPUT:

The result of applying the \( n \)-th Verschiebung operator (on the ring of noncommutative symmetric functions) to \texttt{self}.

EXAMPLES:

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: R = NSym.R()
sage: R([4,2]).verschiebung(2)
R[2, 1]
sage: R([2,1]).verschiebung(3)
-R[1]
sage: R([3]).verschiebung(2)
0
sage: R([[]]).verschiebung(2)
R[]
sage: R([5, 1]).verschiebung(3)
-R[2]
sage: R([5, 1]).verschiebung(6)
-R[1]
sage: R([5, 1]).verschiebung(2)
-R[3]
sage: R([1, 2, 3, 1]).verschiebung(7)
-R[1]
sage: R([1, 2, 3, 1]).verschiebung(5)
0
```

\texttt{antipode_on_basis}(\texttt{composition})

Return the application of the antipode to a basis element of the ribbon basis \texttt{self}.

INPUT:
• composition – a composition

OUTPUT:
• The image of the basis element indexed by composition under the antipode map.

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R.antipode_on_basis(Composition([2,1]))
-R[2, 1]
sage: R[3,1].antipode() # indirect doctest
R[2, 1, 1]
sage: R[].antipode() # indirect doctest
R[]
```

We check that the implementation of the antipode at hand does not contradict the generic one:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: all( S(R[I].antipode()) == S(R[I]).antipode() 
      ....:     for I in Compositions(4) )
True
```

dual()

Return the dual basis to the ribbon basis of the non-commutative symmetric functions. This is the Fundamental basis of the quasi-symmetric functions.

OUTPUT:
• The fundamental basis of the quasi-symmetric functions.

EXAMPLES:

```
sage: R=NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R.dual()
Quasisymmetric functions over the Rational Field in the Fundamental basis
```

product_on_basis(I, J)

Return the product of two ribbon basis elements of the non-commutative symmetric functions.

INPUT:
• I, J – compositions

OUTPUT:
• The product of the ribbon functions indexed by I and J.

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R[1,2,1] * R[3,1]
R[1, 2, 1, 3, 1] + R[1, 2, 4, 1]
sage: ( R[1,2,1] + R[3,1] ) * ( R[3,1] + R[1,2,1] )
```

to_symmetric_function_on_basis(I)

Return the commutative image of a ribbon basis element of the non-commutative symmetric functions.

INPUT:
• I – a composition

OUTPUT:
• The commutative image of the ribbon basis element indexed by I. This will be expressed as a symmetric function in the Schur basis.

EXAMPLES:
S
alias of NonCommutativeSymmetricFunctions.Complete

ZL
alias of NonCommutativeSymmetricFunctions.Zassenhaus_left

ZR
alias of NonCommutativeSymmetricFunctions.Zassenhaus_right

class Zassenhaus_left(NCSF)
Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_class.BindableClass

The Hopf algebra of non-commutative symmetric functions in the left Zassenhaus basis.
This basis is the left-version of the basis defined in Section 2.5.1 of [HLNT09]. It is multiplicative, with $Z_n$ defined as the element of $NCSF_n$ satisfying the equation

$$\sigma_1 = \cdots \exp(Z_n) \cdots \exp(Z_2) \exp(Z_1),$$

where

$$\sigma_1 = \sum_{n \geq 0} S_n.$$

It can be recursively computed by the formula

$$S_n = \sum_{\lambda \vdash n} \frac{1}{m_1(\lambda)! m_2(\lambda)! m_3(\lambda)! \cdots} Z_{\lambda_1} Z_{\lambda_2} Z_{\lambda_3} \cdots$$

for all $n \geq 0$.

class Zassenhaus_right(NCSF)
Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_class.BindableClass

The Hopf algebra of non-commutative symmetric functions in the right Zassenhaus basis.
This basis is defined in Section 2.5.1 of [HLNT09]. It is multiplicative, with $Z_n$ defined as the element of $NCSF_n$ satisfying the equation

$$\sigma_1 = \exp(Z_1) \exp(Z_2) \exp(Z_3) \cdots \exp(Z_n) \cdots$$

where

$$\sigma_1 = \sum_{n \geq 0} S_n.$$

It can be recursively computed by the formula

$$S_n = \sum_{\lambda \vdash n} \frac{1}{m_1(\lambda)! m_2(\lambda)! m_3(\lambda)! \cdots} Z_{\lambda_1} Z_{\lambda_2} Z_{\lambda_3} \cdots$$
for all $n \geq 0$.

Note that there is a variant (called the “noncommutative power sum symmetric functions of the third kind”) in Definition 5.26 of [NCSF2] that satisfies:

$$\sigma_1 = \exp(Z_1)\exp(Z_2/2)\exp(Z_3/3)\cdots\exp(Z_n/n)\cdots.$$  

**a_realization()**

Gives a realization of the algebra of non-commutative symmetric functions. This particular realization is the complete basis of non-commutative symmetric functions.

**OUTPUT:**

- The realization of the non-commutative symmetric functions in the complete basis.

**EXAMPLES:**

```python
sage: NonCommutativeSymmetricFunctions(ZZ).a_realization()
Non-Commutative Symmetric Functions over the Integer Ring in the Complete
˓→basis
```

**complete**

alias of `NonCommutativeSymmetricFunctions.Complete`

**dQS**

alias of `NonCommutativeSymmetricFunctions.dualQuasisymmetric_Schur`

**dYQS**

alias of `NonCommutativeSymmetricFunctions.dualYoungQuasisymmetric_Schur`

**dual()**

Return the dual to the non-commutative symmetric functions.

**OUTPUT:**

- The dual of the non-commutative symmetric functions over a ring. This is the algebra of quasi-symmetric functions over the ring.

**EXAMPLES:**

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: NCSF.dual()
Quasisymmetric functions over the Rational Field
```

**class dualQuasisymmetric_Schur(NCSF)**

Bases: `sage.combinat.free_module.CombinatorialFreeModule`, `sage.misc.bindable_classBindableClass`

The basis of NCSF dual to the Quasisymmetric-Schur basis of QSym.

The Quasisymmetric_Schur functions are defined in [QSCHUR] (see also Definition 5.1.1 of [LMvW13]). The dual basis in the algebra of non-commutative symmetric functions is defined by the following formula:

$$R_\alpha = \sum_T dQS_{\text{shape}(T)},$$

where the sum is over all standard composition tableaux with descent composition equal to $\alpha$. The Quasisymmetric_Schur basis $QS_\alpha$ has the property that

$$s_\lambda = \sum_{\text{sort}(\alpha) = \lambda} QS_\alpha.$$
As a consequence the commutative image of a dual Quasisymmetric-Schur element in the algebra of symmetric functions (the map defined in the method `to_symmetric_function()`) is equal to the Schur function indexed by the decreasing sort of the indexing composition.

See also:

`CompositionTableaux`, `CompositionTableau`.

**EXAMPLES:**

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: dQS = NCSF.dQS()
sage: dQS([1,3,2])*dQS([1])
dQS[1, 2, 4] + dQS[1, 3, 2, 1] + dQS[1, 3, 3] + dQS[3, 2, 2]
sage: dQS([1,3,2])*dQS([1,3,2])
dQS[1, 3, 3] + dQS[1, 4, 2] + dQS[2, 3, 2]
sage: dQS([1,3,2])*dQS([1,3,1])
sage: dQS([3,1])*dQS([2,1])
sage: dQS([1,1]).coproduct()
sage: dQS([3,3]).coproduct().monomial_coefficients()[{Composition([1,2]), --Composition([1,2])}]
-1
sage: S = NCSF.complete()
sage: S(dQS([2,1,3]).to_symmetric_function())
s[2, 1, 3]
```

**dual()**

The dual basis to the dual Quasisymmetric-Schur basis of NCSF.

The basis returned is the `Quasisymmetric_Schur` basis of QSym.

**OUTPUT:**

- the Quasisymmetric-Schur basis of the quasi-symmetric functions

**EXAMPLES:**

```python
sage: dQS=NonCommutativeSymmetricFunctions(QQ).dualQuasisymmetric_Schur()
sage: dQS.dual()
Quasisymmetric functions over the Rational Field in the Quasisymmetric Schur basis
sage: dQS.duality_pairing_matrix(dQS.dual(),3)
[[1 0 0 0]
 [0 1 0 0]
 [0 0 1 0]
 [0 0 0 1]]
```

**to_symmetric_function_on_basis()**

The commutative image of a dual quasi-symmetric Schur element

The commutative image of a basis element is obtained by sorting the indexing composition of the basis element.

**INPUT:**
• \( I \) – a composition

**OUTPUT:**

• The commutative image of the dual quasi-Schur basis element indexed by \( I \). The result is the Schur symmetric function indexed by the partition obtained by sorting \( I \).

**EXAMPLES:**

```python
sage: dQS = NonCommutativeSymmetricFunctions(QQ).dQS()
sage: dQS.to_symmetric_function_on_basis([2, 1, 3])
s[3, 2, 1]
sage: dQS.to_symmetric_function_on_basis([1, 3, 2])
s[1, 3, 2]
sage: dQS.to_symmetric_function_on_basis([])
s[]
```

class `dualYoungQuasisymmetric_Schur` (NCSF)

**Bases:** `sage.combinat.free_module.CombinatorialFreeModule`, `sage.misc.bindable_classBindableClass`

The basis of NCSF dual to the Young Quasisymmetric-Schur basis of QSym.

The `YoungQuasisymmetric_Schur` functions are given in Definition 5.2.1 of [LMvW13]. The dual basis in the algebra of non-commutative symmetric functions are related by an involution reversing the indexing composition of the complete expansion of a quasi-Schur basis element. This basis has many of the same properties as the Quasisymmetric Schur basis and is related to that basis by an algebraic transformation.

**EXAMPLES:**

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: dYQS = NCSF.dYQS()
sage: dYQS([1, 3, 2])*dYQS([1])
sage: dYQS([1, 1, 3, 2])*dYQS([1, 1])
sage: dYQS([1, 1, 3, 1])*dYQS([1, 1])
sage: dYQS([3, 1, 2, 1])*dYQS([2, 1])
sage: dYQS([1, 1, 1, 1]).coproduct()
dYQS[] # dYQS[1, 1] # dYQS[1] # dYQS[1] # dYQS[]
sage: dYQS([3, 3, 3]).coproduct().monomial_coefficients()[(Composition([1, 2]), --Composition([2, 1]))]
1
sage: S = NCSF.complete()
sage: dYQS(S([1, 3, 1]))
sage: S(dYQS([1, 3, 1]))
sage: s = SymmetricFunctions(QQ).s()
sage: s(S(dYQS([2, 1, 3])).to_symmetric_function())
s[3, 2, 1]
```

dual()

The dual basis to the dual Quasisymmetric-Schur basis of NCSF.

The basis returned is the `Quasisymmetric_Schur` basis of QSym.

**OUTPUT:**

• the Young Quasisymmetric-Schur basis of quasi-symmetric functions
EXAMPLES:

```python
sage: dYQS=NonCommutativeSymmetricFunctions(QQ).dualYoungQuasisymmetric_.Schur()
sage: dYQS.dual()
Quasisymmetric functions over the Rational Field in the Young Quasisymmetric Schur basis
sage: dYQS.duality_pairing_matrix(dYQS.dual(),3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

`to_symmetric_function_on_basis(I)`

The commutative image of a dual Young quasi-symmetric Schur element.

The commutative image of a basis element is obtained by sorting the indexing composition of the basis element.

INPUT:
- I – a composition

OUTPUT:
- The commutative image of the dual Young quasi-Schur basis element indexed by I. The result is the Schur symmetric function indexed by the partition obtained by sorting I.

EXAMPLES:

```python
sage: dYQS=NonCommutativeSymmetricFunctions(QQ).dYQS()
sage: dYQS.to_symmetric_function_on_basis([2,1,3])
s[3, 2, 1]
sage: dYQS.to_symmetric_function_on_basis([])
s[]

### 5.1.148 Quasisymmetric functions

REFERENCES:

AUTHOR:
- Jason Bandlow
- Franco Saliola
- Chris Berg
- Darij Grinberg
class sage.combinat.ncsf_qsym.qsym.QuasiSymmetricFunctions(R)
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The Hopf algebra of quasisymmetric functions.

Let $R$ be a commutative ring with unity. The $R$-algebra of quasi-symmetric functions may be realized as an $R$-subalgebra of the ring of power series in countably many variables $R[[x_1, x_2, x_3, \ldots]]$. It consists of those formal power series $p$ which are degree-bounded (i.e., the degrees of all monomials occurring with nonzero coefficient in $p$ are bounded from above, although the bound can depend on $p$) and satisfy the following condition: For every tuple $(a_1, a_2, \ldots, a_m)$ of positive integers, the coefficient of the monomial $x_1^{a_1} x_2^{a_2} \cdots x_m^{a_m}$ in $p$ is the same for all strictly increasing sequences $(i_1 < i_2 < \cdots < i_m)$ of positive integers. (In other words, the coefficient of a monomial in $p$ depends only on the sequence of nonzero exponents in the monomial. If “sequence” were to be replaced by “multiset” here, we would obtain the definition of a symmetric function.)

The $R$-algebra of quasi-symmetric functions is commonly called $QSym_R$ or occasionally just $QSym$ (when $R$ is clear from the context or $\mathbb{Z}$ or $\mathbb{Q}$). It is graded by the total degree of the power series. Its homogeneous elements of degree $k$ form a free $R$-submodule of rank equal to the number of compositions of $k$ (that is, $2^{k-1}$ if $k \geq 1$, else 1).

The two classical bases of $QSym$, the monomial basis $(M_I)_I$ and the fundamental basis $(F_I)_I$, are indexed by compositions $I = (I_1, I_2, \cdots, I_\ell)$ and defined by the formulas:

$$M_I = \sum_{1 \leq i_1 < i_2 < \cdots < i_\ell} x_1^{I_1} x_2^{I_2} \cdots x_\ell^{I_\ell}$$

and

$$F_I = \sum_{(j_1, j_2, \ldots, j_n)} x_{j_1} x_{j_2} \cdots x_{j_n}$$

where in the second equation the sum runs over all weakly increasing $n$-tuples $(j_1, j_2, \ldots, j_n)$ of positive integers (where $n$ is the size of $I$) which increase strictly from $j_r$ to $j_{r+1}$ if $r$ is a descent of the composition $I$.

These bases are related by the formula

$$F_I = \sum_{J \leq I} M_J$$

where the inequality $J \leq I$ indicates that $J$ is finer than $I$.

The $R$-algebra of quasi-symmetric functions is a Hopf algebra, with the coproduct satisfying

$$\Delta M_I = \sum_{k=0}^{\ell} M_{(I_1, I_2, \cdots, I_k)} \otimes M_{(I_{k+1}, I_{k+2}, \cdots, I_\ell)}$$

for every composition $I = (I_1, I_2, \cdots, I_\ell)$.

It is possible to define an $R$-algebra of quasi-symmetric functions in a finite number of variables as well (but it is not a bialgebra). These quasi-symmetric functions are actual polynomials then, not just power series.

Chapter 5 of [GriRei18] and Section 11 of [HazWitt1] are devoted to quasi-symmetric functions, as are Malvenuto’s thesis [Mal1993] and part of Chapter 7 of [Sta-EC2].
The implementation of the quasi-symmetric function Hopf algebra

We realize the \( R \)-algebra of quasi-symmetric functions in Sage as a graded Hopf algebra with basis elements indexed by compositions:

\[
\text{sage: } \text{QSym} = \text{QuasiSymmetricFunctions}(\mathbb{Q})
\]

\[
\text{sage: } \text{QSym}.\text{category()}
\]

Join of Category of hopf algebras over Rational Field
and Category of graded algebras over Rational Field
and Category of commutative algebras over Rational Field
and Category of monoids with realizations
and Category of graded coalgebras over Rational Field
and Category of coalgebras over Rational Field with realizations

The most standard two bases for this \( R \)-algebra are the monomial and fundamental bases, and are accessible by the \( M() \) and \( F() \) methods:

\[
\text{sage: } \text{M} = \text{QSym}.\text{M()}
\]

\[
\text{sage: } \text{F} = \text{QSym}.\text{F()}
\]

\[
\text{sage: } \text{M}(\text{F}[2,1,2])
\]

\[
\text{M}[1, 1, 1, 1] + \text{M}[1, 1, 1, 2] + \text{M}[2, 1, 1, 1] + \text{M}[2, 1, 2]
\]

\[
\text{sage: } \text{F}(\text{M}[2,1,2])
\]

\[
\text{F}[1, 1, 1, 1, 1] - \text{F}[1, 1, 1, 2] - \text{F}[2, 1, 1, 1] + \text{F}[2, 1, 2]
\]

The product on this space is commutative and is inherited from the product on the realization within the ring of power series:

\[
\text{sage: } \text{M}[3]*\text{M}[1,1] == \text{M}[1,1]*\text{M}[3]
\]

\[
\text{True}
\]

\[
\text{sage: } \text{M}[3]*\text{M}[1,1]
\]

\[
\text{M}[1, 1, 3] + \text{M}[1, 3, 1] + \text{M}[1, 4] + \text{M}[3, 1, 1] + \text{M}[4, 1]
\]

\[
\text{sage: } \text{F}[3]*\text{F}[1,1]
\]

\[
\text{F}[1, 1, 3] + \text{F}[1, 2, 2] + \text{F}[1, 3, 1] + \text{F}[1, 4] + \text{F}[2, 1, 2]
\]

\[
\text{+ F}[2, 2, 1] + \text{F}[3, 1, 1] + \text{F}[3, 2] + \text{F}[4, 1]
\]

\[
\text{sage: } \text{M}[3]*\text{F}[2]
\]

\[
\text{M}[1, 1, 3] + \text{M}[1, 3, 1] + \text{M}[1, 4] + \text{M}[2, 3] + \text{M}[3, 1, 1] + \text{M}[3, 2]
\]

\[
\text{+ M}[4, 1] + \text{M}[5]
\]

\[
\text{sage: } \text{F}[2]*\text{M}[3]
\]

\[
\text{F}[1, 1, 1, 2] - \text{F}[1, 2, 2] + \text{F}[2, 1, 1, 1] - \text{F}[2, 1, 2] - \text{F}[2, 2, 1]
\]

\[
\text{+ F}[5]
\]

There is a coproduct on \( \text{QSym} \) as well, which in the Monomial basis acts by cutting the composition into a left half and a right half. The coproduct is not co-commutative:

\[
\text{sage: } \text{M}[1,3,1].\text{coproduct()}
\]

\[

\[
\text{sage: } \text{F}[1,3,1].\text{coproduct()}
\]

\[
\text{F[1, 3, 1] \# F[1, 3, 1] + F[1, 3] \# F[1, 1] + F[1, 1] \# F[2, 1]}
\]

\[
\]
The duality pairing with non-commutative symmetric functions

These two operations endow the quasi-symmetric functions $\text{QSym}$ with the structure of a Hopf algebra. It is the graded dual Hopf algebra of the non-commutative symmetric functions $\text{NCSF}$. Under this duality, the Monomial basis of $\text{QSym}$ is dual to the Complete basis of $\text{NCSF}$, and the Fundamental basis of $\text{QSym}$ is dual to the Ribbon basis of $\text{NCSF}$ (see [MR]).

```
sage: S = M.dual(); S
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
sage: M[1,3,1].duality_pairing( S[1,3,1] )
1

[0 0 0 0 1 0 0 0]
[0 0 0 0 0 1 0 0]
[0 0 0 0 0 0 1 0]
[0 0 0 0 0 0 0 1]
sage: NCSF = M.realization_of().dual()
sage: R = NCSF.Ribbon()
sage: F.duality_pairing_matrix( R, degree=4 )
[1 0 0 0 0 0 0 0]
[0 1 0 0 0 0 0 0]
[0 0 1 0 0 0 0 0]
[0 0 0 1 0 0 0 0]
[0 0 0 0 1 0 0 0]
[0 0 0 0 0 1 0 0]
[0 0 0 0 0 0 1 0]
[0 0 0 0 0 0 0 1]
sage: M.duality_pairing_matrix( R, degree=4 )
[ 1 0 0 0 0 0 0 0]
[-1 1 0 0 0 0 0 0]
[-1 0 1 0 0 0 0 0]
[ 1 -1 -1 1 0 0 0 0]
[-1 0 0 0 1 0 0 0]
[ 1 -1 0 0 -1 1 0 0]
[ 1 0 -1 0 -1 0 1 0]
[-1 1 1 -1 1 -1 -1 1]
```

Let $H$ and $G$ be elements of $\text{QSym}$, and $h$ an element of $\text{NCSF}$. Then, if we represent the duality pairing with the mathematical notation $\langle \cdot, \cdot \rangle$,

$$[HG, h] = [H \otimes G, \Delta(h)].$$

For example, the coefficient of $M[2,1,4,1]$ in $M[1,3] \ast M[2,1,1]$ may be computed with the duality pairing:
And the coefficient of $S[1, 3] \ # S[2, 1, 1]$ in $S[2, 1, 4, 1].coproduct()$ is equal to this result:

```
sage: S[2, 1, 4, 1].coproduct()
S[] \ # S[2, 1, 4, 1] + \ldots + S[1, 3] \ # S[2, 1, 1] + \ldots + S[4, 1] \ # S[2, 1]
```

The duality pairing on the tensor space is another way of getting this coefficient, but currently the method `duality_pairing` is not defined on the tensor squared space. However, we can extend this functionality by applying a linear morphism to the terms in the coproduct, as follows:

```
sage: X = S[2,1,4,1].coproduct()
sage: def linear_morphism(x, y):
    return x.duality_pairing(M[1,3]) * y.duality_pairing(M[2,1,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

Similarly, if $H$ is an element of $QSym$ and $g$ and $h$ are elements of $NCSF$, then

$$[H, gh] = [\Delta(H), g \otimes h].$$

For example, the coefficient of $R[2, 3, 1]$ in $R[2, 1] \ast R[2, 1]$ is computed with the duality pairing by the following command:

```
sage: (R[2,1] \ast R[2,1]).duality_pairing(F[2,3,1])
1
```

This coefficient should then be equal to the coefficient of $F[2,1] \ # F[2,1]$ in $F[2,3,1].coproduct()$:

```
sage: F[2,3,1].coproduct()
F[] \ # F[2, 3, 1] + \ldots + F[2, 1] \ # F[2, 1] + \ldots + F[2, 3, 1] \ # F[]
```

This can also be computed by the duality pairing on the tensor space, as above:

```
sage: X = F[2,3,1].coproduct()
sage: def linear_morphism(x, y):
    return x.duality_pairing(R[2,1]) * y.duality_pairing(R[2,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

**The operation dual to multiplication by a non-commutative symmetric function**

Let $g \in NCSF$ and consider the linear endomorphism of $NCSF$ defined by left (respectively, right) multiplication by $g$. Since there is a duality between $QSym$ and $NCSF$, this linear transformation induces an operator $g^\perp$ on $QSym$ satisfying

$$[g^\perp(H), h] = [H, gh].$$

for any non-commutative symmetric function $h$. 
This is implemented by the method `skew_by()`. Explicitly, if $H$ is a quasi-symmetric function and $g$ a non-commutative symmetric function, then $H.skew_by(g)$ and $H.skew_by(g, side='right')$ are expressions that satisfy, for any non-commutative symmetric function $h$, the following equalities:

$$
H.skew_by(g).duality_pairing(h) == H.duality_pairing(g*h)
$$
$$
H.skew_by(g, side='right').duality_pairing(h) == H.duality_pairing(h*g)
$$

For example, $M[J].skew_by(S[I])$ is 0 unless the composition $J$ begins with $I$ and $M(J).skew_by(S(I), side='right')$ is 0 unless the composition $J$ ends with $I$. For example:

```python
sage: M[3,2,2].skew_by(S[3])
M[2, 2]
sage: M[3,2,2].skew_by(S[2])
0
sage: M[3,2,2].coproduct().apply_multilinear_morphism(lambda x,y: x.duality_pairing(S[3])*y)
M[2, 2]
sage: M[3,2,2].skew_by(S[3], side='right')
0
sage: M[3,2,2].skew_by(S[2], side='right')
M[3, 2]
```

**The counit**

The counit is defined by sending all elements of positive degree to zero:

```python
sage: M[3].degree(), M[3,1,2].degree(), M.one().degree()
(3, 6, 0)
sage: M[3].counit()
0
sage: M[3,1,2].counit()
0
sage: M.one().counit()
1
7
7
```

**The antipode**

The antipode sends the Fundamental basis element indexed by the composition $I$ to $(-1)^{|I|}$ times the Fundamental basis element indexed by the conjugate composition to $I$ (where $|I|$ stands for the size of $I$, that is, the sum of all entries of $I$).

```python
sage: F[3,2,2].antipode()
-F[1, 2, 2, 1, 1]
sage: Composition([3,2,2]).conjugate()
[1, 2, 2, 1, 1]
```

The antipodes of the Monomial quasisymmetric functions can also be computed easily: Every composition $I$ satisfies

$$
\omega(M_I) = (-1)^{|I|} \sum M_J,
$$
where the sum ranges over all compositions \( J \) of \(| I | \) which are coarser than the reversed composition \( I^r \) of \( I \). Here, \( \ell(I) \) denotes the length of the composition \( I \) (that is, the number of its parts).

\[
\text{sage: } M[3,2,1].antipode()
\]

\[
\text{sage: } M[3,2,2].antipode()
\]

We demonstrate here the defining relation of the antipode:

\[
\text{sage: } X = F[3,2,2].coproduct()
\text{sage: } X.apply_multilinear_morphism(\lambda x,y: x*y.antipode())
0
\]

\[
\text{sage: } X.apply_multilinear_morphism(\lambda x,y: x.antipode()*y)
0
\]

### The relation with symmetric functions

The quasi-symmetric functions are a ring which contain the symmetric functions as a subring. The Monomial quasi-symmetric functions are related to the monomial symmetric functions by

\[
m_\lambda = \sum_{\text{sort}(I) = \lambda} M_I
\]

(\text{where sort}(I) denotes the result of sorting the entries of } I \text{ in decreasing order}).

There are methods to test if an expression in the quasi-symmetric functions is a symmetric function and, if it is, send it to an expression in the symmetric functions:

\[
\text{sage: } f = M[1,1,2] + M[1,2,1]
\text{sage: } f.is_symmetric()
False
\]

\[
\text{sage: } g = M[3,1] + M[1,3]
\text{sage: } g.is_symmetric()
True
\]

\[
\text{sage: } g.to_symmetric_function()
m[3, 1]
\]

The expansion of the Schur function in terms of the Fundamental quasi-symmetric functions is due to [Ges]. There is one term in the expansion for each standard tableau of shape equal to the partition indexing the Schur function.

\[
\text{sage: } f.is_symmetric()
True
\]

\[
\text{sage: } f.to_symmetric_function()
5*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + 2*m[2, 2, 1] + m[3, 1, 1] + m[3, 2]
\]

\[
\text{sage: } s = SymmetricFunctions(QQ).s()
\text{sage: } s(f.to_symmetric_function())
s[3, 2]
\]

It is also possible to convert a symmetric function to a quasi-symmetric function:

\[
\text{sage: } m = SymmetricFunctions(QQ).m()
\text{sage: } M( m[3,1,1] )
M[1, 1, 3] + M[1, 3, 1] + M[3, 1, 1]
\]
It is possible to experiment with the quasi-symmetric function expansion of other bases, but it is important that the base ring be the same for both algebras.

The following will raise an error because the base ring of \( F \) is not equal to the base ring of \( Ht \):

```python
sage: F(Ht[2,1])
Traceback (most recent call last):
  ...  
TypeError: do not know how to make x (= McdHt[2, 1]) an element of self_
˓
  (=Quasisymmetric functions over the Rational Field in the Fundamental basis)
```

### The map to the ring of polynomials

The quasi-symmetric functions can be seen as an inverse limit of a subring of a polynomial ring as the number of variables increases. Indeed, there exists a projection from the quasi-symmetric functions onto the polynomial ring \( \mathbb{R}[x_1, x_2, \ldots, x_n] \). This projection is defined by sending the variables \( x_{n+1}, x_{n+2}, \ldots \) to 0, while the remaining \( n \) variables remain fixed. Note that this projection sends \( M_I \) to 0 if the length of the composition \( I \) is higher than \( n \).

```python
sage: M[1,3,1].expand(4)
0
sage: F[1,3,1].expand(4)
x0*x1^3*x3 + x0*x1*x2^2*x3 + x0*x1^2*x3 + x0*x1*x2^3*x3
```

#### class Bases (parent_with_realization)

Bases: `sage.categories.realizations.Category_realization_of_parent`

Category of bases of quasi-symmetric functions.

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.Bases()
Category of bases of Quasisymmetric functions over the Rational Field
```

#### class ElementMethods

Bases: `object`
Methods common to all elements of QuasiSymmetricFunctions.

dendriform_leq(other)
Return the result of applying the dendriform smaller-or-equal operation to the two quasi-
symmetric functions self and other.

The dendriform smaller-or-equal operation is a binary operation, denoted by \( \preceq \) and written infix, on the ring of quasi-symmetric functions. It can be defined as a restriction of a binary operation (denoted by \( \preceq \) and written infix as well) on the ring of formal power series \( R[[x_1, x_2, x_3, \ldots]] \), which is defined as follows: If \( m \) and \( n \) are two monomials in \( x_1, x_2, x_3, \ldots \), then we let \( m \preceq n \) be the product \( mn \) if the smallest positive integer \( i \) for which \( x_i \) occurs in \( m \) is smaller or equal to the smallest positive integer \( j \) for which \( x_j \) occurs in \( n \) (this is understood to be false when \( m = 1 \) and \( n \neq 1 \), and true when \( n = 1 \)), and we let \( m \preceq n \) be 0 otherwise. Having thus defined \( \preceq \) on monomials, we extend \( \preceq \) to a binary operation on \( R[[x_1, x_2, x_3, \ldots]] \) by requiring it to be continuous (in both inputs) and \( R \)-bilinear. It is easily seen that \( QSym \preceq QSym \subseteq QSym \), so that \( \preceq \) restricts to a binary operation on \( QSym \).

This operation \( \preceq \) is related to the dendriform smaller relation \( \prec \) (dendriform_less()). Namely, if we define a binary operation \( \succ \) on \( QSym \) by \( a \succ b = b \prec a \), then \( (QSym, \preceq, \succ) \) is a dendriform \( R \)-algebra. Thus, any \( a, b \in QSym \) satisfy \( a \preceq b = ab - b \prec a \).

See also:
dendriform_less()

INPUT:
• other – a quasi-symmetric function over the same base ring as self

OUTPUT:

The quasi-symmetric function \( self \preceq other \), written in the basis of \( self \).

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: M[2, 1].dendriform_leq(M[1, 2])
sage: F = QSym.F()
sage: F[2, 1].dendriform_leq(F[1, 2])
```

dendriform_less(other)
Return the result of applying the dendriform smaller operation to the two quasi-symmetric functions self and other.

The dendriform smaller operation is a binary operation, denoted by \( \prec \) and written infix, on the ring of quasi-symmetric functions. It can be defined as a restriction of a binary operation (denoted by \( \prec \) and written infix as well) on the ring of formal power series \( R[[x_1, x_2, x_3, \ldots]] \), which is defined as follows: If \( m \) and \( n \) are two monomials in \( x_1, x_2, x_3, \ldots \), then we let \( m \prec n \) be the product \( mn \) if the smallest positive integer \( i \) for which \( x_i \) occurs in \( m \) is smaller than the smallest positive integer \( j \) for which \( x_j \) occurs in \( n \) (this is understood to be false when \( m = 1 \), and true when \( m \neq 1 \) and \( n = 1 \)), and we let \( m \prec n \) be 0 otherwise. Having thus defined \( \prec \) on monomials, we extend \( \prec \) to a binary operation on \( R[[x_1, x_2, x_3, \ldots]] \) by requiring it to be continuous (in both inputs) and \( R \)-bilinear. It is easily seen that \( QSym \prec QSym \subseteq QSym \), so that \( \prec \) restricts to a binary operation on \( QSym \).

See also:
dendriform_leq()

INPUT:
• other - a quasi-symmetric function over the same base ring as self

OUTPUT:
The quasi-symmetric function self \prec other, written in the basis of self.

EXAMPLES:

```sage
definitions:
QSym = QuasiSymmetricFunctions(QQ)
M = QSym.M()
M[2, 1].dendriform_less(M[1, 2])
F = QSym.F()
F[2, 1].dendriform_less(F[1, 2])
The operation \prec can be used to recursively construct the dual immaculate basis: For every positive integer m and every composition I, the dual immaculate function dI[m, I] of the composition [m, I] (this composition is I with m prepended to it) is F[m] \prec dI.

definitions:
dI = QSym.dI()
dI(F[2]).dendriform_less(dI[1, 2])
dI[2, 1, 2]
We check with the identity element:

```sage
definitions:
M.one().dendriform_less(M[1,2])
0
M[1,2].dendriform_less(M.one())
M[1, 2]
The operation \prec is not symmetric, nor if a \prec b \neq 0, then b \prec a = 0 (as it would be for a single monomial):

```sage
definitions:
M[1,2,1].dendriform_less(M[1,2])

expand(n, alphabet='x')
Expand the quasi-symmetric function into n variables in an alphabet, which by default is 'x'.

INPUT:
• n - A nonnegative integer; the number of variables in the expansion
• alphabet - (default: 'x'); the alphabet in which self is to be expanded

OUTPUT:
• An expansion of self into the n variables specified by alphabet.

EXAMPLES:
One can use a different set of variable by adding an optional argument \texttt{alphabet=...}.

\begin{verbatim}
sage: F=QuasiSymmetricFunctions(QQ).Fundamental()
sage: F[3].expand(2,alphabet='y')
y0^3 + y0^2*y1 + y0*y1^2 + y1^3
\end{verbatim}

\begin{verbatim}
sage: Frobenius\((n)\)
Return the image of the quasi-symmetric function \texttt{self} under the \(n\)-th Frobenius operator.

The \(n\)-th Frobenius operator \(f_n\) is defined to be the map from the \(R\)-algebra of quasi-symmetric functions to itself that sends every symmetric function \(P(x_1,x_2,x_3,\ldots)\) to \(P(x_1^n,x_2^n,x_3^n,\ldots)\). This operator \(f_n\) is a Hopf algebra endomorphism, and satisfies

\[ f_n M_{(i_1,i_2,i_3,\ldots)} = M_{(ni_1,ni_2,ni_3,\ldots)} \]

for every composition \((i_1,i_2,i_3,\ldots)\) (where \(M\) means the monomial basis).

The \(n\)-th Frobenius operator is also called the \(n\)-th Frobenius endomorphism. It is not related to the Frobenius map which connects the ring of symmetric functions with the representation theory of the symmetric group.

The \(n\)-th Frobenius operator is also the \(n\)-th Adams operator of the \(\Lambda\)-ring of quasi-symmetric functions over the integers.

The restriction of the \(n\)-th Frobenius operator to the subring formed by all symmetric functions is, not unexpectedly, the \(n\)-th Frobenius operator of the ring of symmetric functions.

See also:

\texttt{Symmetric functions plethysm}

INPUT:

\begin{itemize}
  \item \texttt{n} – a positive integer
\end{itemize}

OUTPUT:

The result of applying the \(n\)-th Frobenius operator (on the ring of quasi-symmetric functions) to \texttt{self}.

EXAMPLES:

\begin{verbatim}
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: F = QSym.F()
sage: M[3,2].frobenius(2)
M[6, 4]
sage: (M[2,1] - 2*M[3]).frobenius(4)
sage: M([]).frobenius(3)
M[]
sage: F[1,1].frobenius(2)
F[1, 1, 1, 1] - F[1, 1, 2] - F[2, 1, 1] + F[2, 2]
\end{verbatim}

The Frobenius endomorphisms are multiplicative:
Being Hopf algebra endomorphisms, the Frobenius operators commute with the antipode:

```python
sage: all( M(I).frobenius(4).antipode() == M(I).antipode().frobenius(4) for I in Compositions(3) )
True
```

The restriction of the Frobenius operators to the subring of symmetric functions are the Frobenius operators of the latter:

```python
sage: e = SymmetricFunctions(ZZ).e()
sage: all( M(e(lam)).frobenius(3) == M(e(lam).frobenius(3)) for lam in Partitions(3) )
True
```

### internal_coproduct()

Return the inner coproduct of `self` in the basis of `self`.

The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the $R$-algebra of quasi-symmetric functions) is an $R$-algebra homomorphism $\Delta^\times$ from the $R$-algebra of quasi-symmetric functions to the tensor square (over $R$) of quasi-symmetric functions. It can be defined in the following two ways:

1. If $I$ is a composition, then a $(0,I)$-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the non-zero entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is $I$. If $A$ is a $(0,I)$-matrix, then `row(A)` will denote the vector of row sums of $A$ (regarded as a composition), and `column(A)` will denote the vector of column sums of $A$ (regarded as a composition).

   For every composition $I$, the internal coproduct $\Delta^\times(M_I)$ of the $I$-th monomial quasisymmetric function $M_I$ is the sum

   $$\sum_{A \text{ is a } (0,I)-\text{matrix}} M_{\text{row}(A)} \otimes M_{\text{column}(A)}.$$ 

   See Section 11.39 of [HazWitt1].

2. For every permutation $w$, let $C(w)$ denote the descent composition of $w$. Then, for any composition $I$ of size $n$, the internal coproduct $\Delta^\times(F_I)$ of the $I$-th fundamental quasisymmetric function $F_I$ is the sum

   $$\sum_{\sigma \in S_n, \tau \in S_n, \tau \sigma = \pi} F_{C(\sigma)} \otimes F_{C(\tau)},$$

   where $\pi$ is any permutation in $S_n$ having descent composition $I$ and where permutations act from the left and multiply accordingly, so $\tau \sigma$ means first applying $\sigma$ and then $\tau$. See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1].

The restriction of the internal coproduct to the $R$-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.
The method \texttt{kronecker_coproduct()} is a synonym of this one.

**EXAMPLES:**

Let us compute the internal coproduct of \(M_{21}\) (which is short for \(M_{[2,1]}\)). The \((0, [2, 1])\)-matrices are

\[
\begin{bmatrix} 2 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}, \text{and} \begin{bmatrix} 0 & 2 \\ 1 & 0 \end{bmatrix}
\]

so

\[
\Delta^N(M_{21}) = M_3 \otimes M_{21} + M_{21} \otimes M_3 + M_{21} \otimes M_{21} + M_{21} \otimes M_{12}.
\]

This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```sage
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
```

Further examples:

```sage
sage: all( M([i]).internal_coproduct() == tensor([M([i]), M([i])])
.....:     for i in range(1, 4) )
True
sage: M([1, 2]).internal_coproduct()
```

The definition of \(\Delta^N(M_I)\) in terms of \((0, I)\)-matrices is not suitable for computation in cases where the length of \(I\) is large, but we can use it as a doctest. Here is a naive implementation:

```sage
def naive_internal_coproduct_on_M(I):
    M = QuasiSymmetricFunctions(ZZ).M()
    M2 = M.tensor(M)
    res = M2.zero()
    l = len(I)
    n = I.size()
    for S in Subsets(range(l**2), l):
        M_list = sorted(S)
        row_M = [sum([I[M_list.index(l * i + j)]
                      for j in range(l) if 
                      l * i + j in S])
                 for i in range(l)]
        col_M = [sum([I[M_list.index(l * i + j)]
                      for i in range(l) if 
                      l * i + j in S])
                 for j in range(l)]
        if 0 in row_M:
            first_zero = row_M.index(0)
            row_M = row_M[:first_zero]
        if sum(row_M) != n:
            continue
        if 0 in col_M:
```

(continues on next page)
\begin{verbatim}
.....:   first_zero = col_M.index(0)
.....:   col_M = col_M[:first_zero]
.....:   if sum(col_M) != n:
.....:     continue
.....:   res += tensor([M(Compositions(n)(row_M)),
.....:                    M(Compositions(n)(col_M))])
.....: return res
sage: all( naive_internal_coproduct_on_M(I)
.....:    == M(I).internal_coproduct()  
.....:    for I in Compositions(3) )
True
\end{verbatim}

**Todo**: Implement this directly on the monomial basis maybe? The (0, I)-matrices are a pain to generate from their definition, but maybe there is a good algorithm. If so, the above “further examples” should be moved to the M-method.

### is_symmetric()

Return True if self is an element of the symmetric functions.

This is being tested by looking at the expansion in the Monomial basis and checking if the coefficients are the same if the indexing compositions are permutations of each other.

**OUTPUT:**

- True if self is symmetric. False if self is not symmetric.

**EXAMPLES:**

\begin{verbatim}
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: F = QSym.Fundamental()
sage: (F[3,2] + F[2,3]).is_symmetric()  
False
sage: (F[1, 1, 1, 2] + F[1, 1, 3] + F[1, 3, 1] + F[2, 1, 1, 1] + F[3, 1]) .is_symmetric()  
True
sage: F([]).is_symmetric()  
True
\end{verbatim}

### kronecker_coproduct()

Return the inner coproduct of self in the basis of self.

The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the \(R\)-algebra of quasi-symmetric functions) is an \(R\)-algebra homomorphism \(\Delta^\times\) from the \(R\)-algebra of quasi-symmetric functions to the tensor square (over \(R\)) of quasi-symmetric functions.

It can be defined in the following two ways:

1. If I is a composition, then a \((0, I)\)-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the non-zero entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is \(I\). If \(A\) is a \((0, I)\)-matrix, then \(\text{row}(A)\) will denote the vector of row sums of \(A\) (regarded as a composition), and \(\text{column}(A)\) will denote the vector of column sums of \(A\) (regarded as a composition).

For every composition \(I\), the internal coproduct \(\Delta^\times(M_I)\) of the \(I\)-th monomial quasisymmetric function \(M_I\) is the sum

\[
\sum_{A \text{ is a } (0, I)-\text{matrix}} M_{\text{row}(A)} \otimes M_{\text{column}(A)}.
\]

\end{verbatim}
See Section 11.39 of [HazWitt1].

2. For every permutation \( w \), let \( C(w) \) denote the descent composition of \( w \). Then, for any composition \( I \) of size \( n \), the internal coproduct \( \Delta^\times(F_I) \) of the \( I \)-th fundamental quasisymmetric function \( F_I \) is the sum

\[
\sum_{\sigma \in S_n} F_{C(\sigma)} \otimes F_{C(\tau)},
\]

where \( \pi \) is any permutation in \( S_n \) having descent composition \( I \) and where permutations act from the left and multiply accordingly, so \( \tau \sigma \) means first applying \( \sigma \) and then \( \tau \). See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1].

The restriction of the internal coproduct to the \( R \)-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.

The method \texttt{kronecker_coproduct()} is a synonym of this one.

**EXAMPLES:**

Let us compute the internal coproduct of \( M_{21} \) (which is short for \( M_{[2,1]} \)). The \((0, I)\)-matrices are

\[
\begin{pmatrix}
2 & 1 \\
1 & 0 \\
0 & 1
\end{pmatrix}
\]

so

\[
\Delta^\times(M_{21}) = M_3 \otimes M_{21} + M_{21} \otimes M_3 + M_{21} \otimes M_{21} + M_{21} \otimes M_{21}.
\]

This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
```

Further examples:

```
sage: all( M([i]).internal_coproduct() == tensor([M([i]), M([i])]) for i in range(1, 4) )
True
sage: M([1, 2]).internal_coproduct()
```

The definition of \( \Delta^\times(M_I) \) in terms of \((0, I)\)-matrices is not suitable for computation in cases where the length of \( I \) is large, but we can use it as a doctest. Here is a naive implementation:

```
sage: def naive_internal_coproduct_on_M(I):
......:     # INPUT: composition I
......:     # (not quasi-symmetric function)
......:     # OUTPUT: interior coproduct of M_I
......:     M = QuasiSymmetricFunctions(ZZ).M()
......:     M2 = M.tensor(M)
......:     res = M2.zero()
......:     l = len(I)
......:     n = I.size()
```

(continues on next page)
for S in Subsets(range(l**2), l):
    M_list = sorted(S)
    row_M = [sum([I[M_list.index(l * i + j)]
                  for j in range(l) if l * i + j in S])
              for i in range(l)]
    col_M = [sum([I[M_list.index(l * i + j)]
                  for i in range(l) if l * i + j in S])
              for j in range(l)]
    if 0 in row_M:
        first_zero = row_M.index(0)
        row_M = row_M[:first_zero]
        if sum(row_M) != n:
            continue
    if 0 in col_M:
        first_zero = col_M.index(0)
        col_M = col_M[:first_zero]
        if sum(col_M) != n:
            continue
    res += tensor([M(Compositions(n)(row_M)),
                    M(Compositions(n)(col_M))])
return res

sage: all( naive_internal_coproduct_on_M(I)
       == M(I).internal_coproduct()
       for I in Compositions(3) )
True

Todo: Implement this directly on the monomial basis maybe? The \((0, I)\)-matrices are a pain to generate from their definition, but maybe there is a good algorithm. If so, the above “further examples” should be moved to the M-method.

omega_involution()
Return the image of the quasisymmetric function self under the omega involution.

The omega involution is defined as the linear map \(\text{QSym} \to \text{QSym} \) which, for every composition \(I\), sends the fundamental quasisymmetric function \(F_I\) to \(F_{I^t}\), where \(I^t\) denotes the conjugate (\(\text{conjugate}()\)) of the composition \(I\). This map is commonly denoted by \(\omega\). It is an algebra homomorphism and a coalgebra antihomomorphism; it also is an involution and an automorphism of the graded vector space \(\text{QSym}\). Also, every composition \(I\) satisfies

\[
\omega(M_I) = (-1)^{|I|-\ell(I)} \sum M_J,
\]

where the sum ranges over all compositions \(J\) of \(|I|\) which are coarser than the reversed composition \(I^r\) of \(I\). Here, \(\ell(I)\) denotes the length of the composition \(I\) (that is, the number of parts of \(I\)).

If \(f\) is a homogeneous element of \(NCSF\) of degree \(n\), then

\[
\omega(f) = (-1)^n S(f),
\]

where \(S\) denotes the antipode of \(\text{QSym}\).

The restriction of \(\omega\) to the ring of symmetric functions (which is a subring of \(\text{QSym}\)) is precisely the omega involution (\(\text{omega}()\)) of said ring.
The omega involution on \( QSym \) is adjoint to the omega involution on \( NCSF \) by the standard adjunction between \( NCSF \) and \( QSym \).

The omega involution has been denoted by \( \omega \) in [LMvW13], section 3.6.

**See also:**

omega involution on NCSF, psi involution on QSym, star involution on QSym.

**EXAMPLES:**

```python
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F()
sage: F[3,2].omega_involution()
F[1, 2, 1, 1]
sage: F[6,3].omega_involution()
F[1, 1, 2, 1, 1, 1, 1]
4*F[1] - 3*F[1, 1, 1] + 2*F[1, 1, 1, 1, 1] - F[1, 2, 1, 1, 1, 1, 1, 1, 1] + F[2, 1, 1, 1, 1, 1, 1, 1, 1]
sage: (F[3,3] - 2*F[2]).omega_involution()
-2*F[1, 1] + F[1, 2, 1, 1]
sage: F([2,1,1]).omega_involution()
F[3, 1]
sage: M = QSym.M()
sage: M([2,1]).omega_involution()
-M[1, 2] - M[3]
sage: M.zero().omega_involution()
0
```

Testing the fact that the restriction of \( \omega \) to \( Sym \) is the omega automorphism of \( Sym \):

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: all( F(e[lam]).omega_involution() == F(e[lam].omega()) ....: for lam in Partitions(4) )
True
```

**psi_involution()**

Return the image of the quasisymmetric function \( self \) under the involution \( \psi \).

The involution \( \psi \) is defined as the linear map \( QSym \to QSym \) which, for every composition \( I \), sends the fundamental quasisymmetric function \( F_I \) to \( F_{I^c} \), where \( I^c \) denotes the complement of the composition \( I \). The map \( \psi \) is an involution and a graded Hopf algebra automorphism of \( QSym \). Its restriction to the ring of symmetric functions coincides with the omega automorphism of the latter ring.

The involution \( \psi \) of \( QSym \) is adjoint to the involution \( \psi \) of \( NCSF \) by the standard adjunction between \( NCSF \) and \( QSym \).

The involution \( \psi \) has been denoted by \( \psi \) in [LMvW13], section 3.6.

**See also:**

psi involution on NCSF, star involution on QSym.

**EXAMPLES:**
```python
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F()
sage: F[3,2].psi_involution()
F[1, 2, 2]
sage: F[6,3].psi_involution()
F[1, 1, 1, 1, 2, 1, 1, 1]
4*F[[]] - 3*F[1, 1, 1, 1, 1, 1, 1, 1, 2] + F[1, 1, 1, 1, 2, 1, 1, 1, 1, 1, 1]
sage: (F[3,3] - 2*F[2]).psi_involution()
-2*F[1, 1] + F[1, 1, 2, 1, 1]
sage: F([2,1,1]).psi_involution()
F[1, 3]
sage: M = QSym.M()
sage: M([2,1]).psi_involution()
sage: M.zero().psi_involution()
0
```

The involution \( \psi \) commutes with the antipode:

```python
sage: all( F(I).psi_involution().antipode() == F(I).antipode().psi_involution() for I in Compositions(4) )
True
```

Testing the fact that the restriction of \( \psi \) to \( Sym \) is the omega automorphism of \( Sym \):

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: all( F(e[lam]).psi_involution() == F(e[lam].omega()) for lam in Partitions(4) )
True
```

**star_involution()**

Return the image of the quasisymmetric function `self` under the star involution.

The star involution is defined as the linear map \( QSym \to QSym \) which, for every composition \( I \), sends the monomial quasisymmetric function \( M_I \) to \( M_{I^r} \). Here, if \( I \) is a composition, we denote by \( I^r \) the reversed composition of \( I \). Denoting by \( f^* \) the image of an element \( f \in QSym \) under the star involution, it can be shown that every composition \( I \) satisfies

\[
(M_I)^* = M_{I^r}, \quad (F_I)^* = F_{I^r},
\]

where \( F_I \) denotes the fundamental quasisymmetric function corresponding to the composition \( I \). The star involution is an involution, an algebra automorphism and a coalgebra anti-automorphism of \( QSym \). It also is an automorphism of the graded vector space \( QSym \), and is the identity on the subspace \( Sym \) of \( QSym \). It is adjoint to the star involution on \( NCSF \) by the standard adjunction between \( NCSF \) and \( QSym \).

The star involution has been denoted by \( \rho \) in [LMvW13], section 3.6.

**See also:**

*star involution on NCSF.*

**EXAMPLES:**
### to_symmetric_function()

Convert a quasi-symmetric function to a symmetric function.

**OUTPUT:**
- If `self` is a symmetric function, then return the expansion in the monomial basis. Otherwise raise an error.

**EXAMPLES:**

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: F = QSym.Fundamental()
sage: (F[3,2] + F[2,3]).to_symmetric_function()
Traceback (most recent call last):
...
ValueError: F[2, 3] + F[3, 2] is not a symmetric function
```

```python
sage: m = SymmetricFunctions(QQ).m()
sage: s = SymmetricFunctions(QQ).s()
sage: F(s[3,1,1]).to_symmetric_function()
6*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + m[2, 2, 1] + m[3, 1, 1]
sage: m(s[3,1,1])
6*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + m[2, 2, 1] + m[3, 1, 1]
```

```python
class ParentMethods
    Bases: object

    Methods common to all bases of QuasiSymmetricFunctions.
```
**Eulerian** \((n, j, k=None)\)

Return the Eulerian (quasi)symmetric function \(Q_{n,j}\) in terms of self.

**INPUT:**
- \(n\) – the value \(n\) or a partition
- \(j\) – the number of excedances
- \(k\) – (optional) if specified, determines the number of fixed points of the permutation

**EXAMPLES:**

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: M.Eulerian(3, 1)
sage: M.Eulerian(4, 1, 2)
sage: QS = QSym.QS()
sage: QS.Eulerian(4, 2)
sage: QS.Eulerian([2, 2, 1], 2)
sage: dI = QSym.dI()
sage: dI.Eulerian(5, 2)
```

**from_polynomial** \((f, check=True)\)

The quasi-symmetric function expanded in this basis corresponding to the quasi-symmetric polynomial \(f\).

This is a default implementation that computes the expansion in the Monomial basis and converts to this basis.

**INPUT:**
- \(f\) – a polynomial in finitely many variables over the same base ring as self. It is assumed that this polynomial is quasi-symmetric.
- \(check\) – boolean (default: True), checks whether the polynomial is indeed quasi-symmetric.

**OUTPUT:**
- quasi-symmetric function

**EXAMPLES:**

```python
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: M.from_polynomial(f)
M[1]
sage: F.from_polynomial(f)
F[1]
sage: f = x[0]**2 + x[1]**2 + x[2]**2
sage: M.from_polynomial(f)
M[2]
sage: F.from_polynomial(f)
-F[1, 1] + F[2]
```

If the polynomial is not quasi-symmetric, an error is raised:
super_categories()

Return the super categories of bases of the Quasi-symmetric functions.

OUTPUT:

• a list of categories

E

alias of QuasiSymmetricFunctions.Essential

class Essential(QSym)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_classBindableClass

The Hopf algebra of quasi-symmetric functions in the Essential basis.

The Essential quasi-symmetric functions are defined by

\[ E_I = \sum_{J \geq I} M_J = \sum_{i_1 \leq \cdots \leq i_k} x_{i_1}^{I_1} \cdots x_{i_k}^{I_k}, \]

where \( I = (I_1, \ldots, I_k) \).

Note: Our convention of \( \leq \) and \( \geq \) of compositions is opposite that of [Hoff2015].

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: E = QSym.E()
sage: M = QSym.M()
sage: E(M[2,2])
sage: s = SymmetricFunctions(QQ).s()
sage: E(s[3,2])
S*x[1, 1, 1, 1, 1] - 2*x[1, 1, 1, 2] - 2*x[1, 1, 2, 1] - 2*x[2, 1, 1, 1] - 2*x[2, 1, 2] + E[2, 1, 1, 1] + E[2, 1, 2] + E[3, 2, 1] + E[3]
sage: (1 + E[1])^3
sage: E[1,2,1].coproduct()
```

The following is an alias for this basis:

```
sage: QSym.Essential()
Quasisymmetric functions over the Rational Field in the Essential basis
```
antipode_on_basis(compo)

Return the result of the antipode applied to a quasi-symmetric Essential basis element.

INPUT:
• compo – composition

OUTPUT:
• The result of the antipode applied to the composition compo, expressed in the Essential basis.

EXAMPLES:

```
sage: E = QuasiSymmetricFunctions(QQ).E()
sage: E.antipode_on_basis(Composition([2,1]))
E[1, 2] - E[3]
sage: E.antipode_on_basis(Composition([]))
E[]
```

coproduct_on_basis(compo)

Return the coproduct of a Essential basis element.

Combinatorial rule: deconcatenation.

INPUT:
• compo – composition

OUTPUT:
• The coproduct applied to the Essential quasi-symmetric function indexed by compo, expressed in the Essential basis.

EXAMPLES:

```
sage: E = QuasiSymmetricFunctions(QQ).Essential()
sage: E[4,2,3].coproduct()
sage: E.coproduct_on_basis(Composition([]))
E[] # E[]
```

product_on_basis(I, J)

The product on Essential basis elements.

The product of the basis elements indexed by two compositions I and J is the sum of the basis elements indexed by compositions K in the stuffle product (also called the overlapping shuffle product) of I and J with a coefficient of \((-1)^{\ell(I)+\ell(J)-\ell(K)}\), where \(\ell(C)\) is the length of the composition C.

INPUT:
• I, J – compositions

OUTPUT:
• The product of the Essential quasi-symmetric functions indexed by I and J, expressed in the Essential basis.

EXAMPLES:

```
sage: E = QuasiSymmetricFunctions(QQ).E()
sage: c1 = Composition([2])
sage: c2 = Composition([1,3])
sage: E.product_on_basis(c1, c2)
sage: E.product_on_basis(c1, Composition([]))
E[2]
sage: E.product_on_basis(c1, Composition([3]))
```

F

alias of QuasiSymmetricFunctions.Fundamental
class Fundamental(QSym)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_classBindableClass

The Hopf algebra of quasi-symmetric functions in the Fundamental basis.

EXAMPLES:

sage: QSym = QuasiSymmetricFunctions(QQ)
sage: F = QSym.F()
sage: M = QSym.M()
sage: F(M[2,2])
F[1, 1, 1, 1] - F[1, 1, 2] - F[2, 1, 1] + F[2, 2]
sage: s = SymmetricFunctions(QQ).s()
sage: F(s[3,2])
sage: (1+F[1])^3
sage: F[1,2,1].coproduct()

The following is an alias for this basis:

sage: QSym.Fundamental()
Quasisymmetric functions over the Rational Field in the Fundamental basis

class Element

Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

internal_coproduct()

Return the inner coproduct of self in the Fundamental basis.

The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the R-algebra of quasi-symmetric functions) is an R-algebra homomorphism \( \Delta^\times \) from the R-algebra of quasi-symmetric functions to the tensor square (over R) of quasi-symmetric functions. It can be defined in the following two ways:

1. If \( I \) is a composition, then a \((0, I)\)-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the non-zero entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is \( I \). If \( A \) is a \((0, I)\)-matrix, then \( \text{row}(A) \) will denote the vector of row sums of \( A \) (regarded as a composition), and \( \text{column}(A) \) will denote the vector of column sums of \( A \) (regarded as a composition).

For every composition \( I \), the internal coproduct \( \Delta^\times(M_I) \) of the \( I \)-th monomial quasi-symmetric function \( M_I \) is the sum

\[
\sum_{A \text{ is a (0,I)-matrix}} M_{\text{row}(A)} \otimes M_{\text{column}(A)}.
\]

See Section 11.39 of [HazWitt1].

2. For every permutation \( w \), let \( C(w) \) denote the descent composition of \( w \). Then, for any composition \( I \) of size \( n \), the internal coproduct \( \Delta^\times(F_I) \) of the \( I \)-th fundamental quasi-symmetric function \( F_I \) is the sum

\[
\sum_{\sigma \in S_n, \tau \sigma = \pi, \sigma C(\tau),}
\]

5.1. Comprehensive Module list
where $\pi$ is any permutation in $S_n$ having descent composition $I$ and where permutations act from the left and multiply accordingly, so $\tau \sigma$ means first applying $\sigma$ and then $\tau$. See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1].

The restriction of the internal coproduct to the $R$-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.

The method `kronecker_coproduct()` is a synonym of this one.

**EXAMPLES:**

Let us compute the internal coproduct of $M_{21}$ (which is short for $M_{[2,1]}$). The $(0,[2,1])$-matrices are

\[
\begin{bmatrix} 2 & 1 \\ 1 \\ 0 & 1 \end{bmatrix}, \quad \begin{bmatrix} 2 & 0 \\ 1 \\ 0 \end{bmatrix}, \quad \text{and} \quad \begin{bmatrix} 0 & 2 \\ 1 \end{bmatrix}
\]

so

\[
\Delta^\times(M_{21}) = M_3 \otimes M_{21} + M_{21} \otimes M_3 + M_{21} \otimes M_{21} + M_{21} \otimes M_{12}.
\]

This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```python
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
```

Some examples on the Fundamental basis:

```python
sage: F = QuasiSymmetricFunctions(ZZ).F()
sage: F([1,1]).internal_coproduct()
F[1, 1] # F[1, 2] + F[1, 1] # F[2, 1]
sage: F([2]).internal_coproduct()
sage: F([3]).internal_coproduct()
F[1, 1, 1] # F[1, 1, 1] + F[1, 1, 2] # F[1, 2] + F[1, 2] # F[2, 1]
```

`kronecker_coproduct()`

Return the inner coproduct of self in the Fundamental basis.

The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the $R$-algebra of quasi-symmetric functions) is an $R$-algebra homomorphism $\Delta^\times$ from the $R$-algebra of quasi-symmetric functions to the tensor square (over $R$) of quasi-symmetric functions. It can be defined in the following two ways:

1. If $I$ is a composition, then a $(0, I)$-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the non-zero entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is $I$. If $A$ is a $(0, I)$-matrix, then $\text{row}(A)$ will denote the vector of row sums of $A$ (regarded as a composition), and $\text{column}(A)$ will denote the vector of column sums of $A$ (regarded as a composition).

For every composition $I$, the internal coproduct $\Delta^\times(M_I)$ of the $I$-th monomial quasisymmetric
function $M_I$ is the sum

$$
\sum_{A \text{ is a } (0,1)-\text{matrix}} M_{\text{row}(A)} \otimes M_{\text{column}(A)}.
$$

See Section 11.39 of [HazWitt1].

2. For every permutation $w$, let $C(w)$ denote the descent composition of $w$. Then, for any composition $I$ of size $n$, the internal coproduct $\Delta^\times(F_I)$ of the $I$-th fundamental quasisymmetric function $F_I$ is the sum

$$
\sum_{\sigma \in S_n, \tau \in S_n, \tau \sigma = \pi} F_C(\sigma) \otimes F_C(\tau),
$$

where $\pi$ is any permutation in $S_n$ having descent composition $I$ and where permutations act from the left and multiply accordingly, so $\tau \sigma$ means first applying $\sigma$ and then $\tau$. See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1].

The restriction of the internal coproduct to the $R$-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.

The method $\text{kronecker_coproduct()}$ is a synonym of this one.

**EXAMPLES:**

Let us compute the internal coproduct of $M_{21}$ (which is short for $M_{[2,1]}$). The $(0, [2, 1])$-matrices are

$$
\begin{bmatrix} 2 & 1 \\ 1 & \end{bmatrix}, \begin{bmatrix} 2 & 0 \\ 0 & 1 \\ \end{bmatrix}, \text{ and } \begin{bmatrix} 0 & 2 \\ 1 & 0 \\ \end{bmatrix}
$$

so

$$
\Delta^\times(M_{21}) = M_3 \otimes M_{21} + M_{21} \otimes M_3 + M_{21} \otimes M_{21} + M_{21} \otimes M_{12}.
$$

This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
```

Some examples on the Fundamental basis:

```
sage: F = QuasiSymmetricFunctions(ZZ).F()
sage: F([1,1]).internal_coproduct()
sage: F([2]).internal_coproduct()
sage: F([3]).internal_coproduct()
sage: F([1,2]).internal_coproduct()
```

$\text{star_involution()}$

Return the image of the quasisymmetric function $\text{self}$ under the star involution.

5.1. Comprehensive Module list
The star involution is defined as the linear map $\mathcal{QSym} \to \mathcal{QSym}$ which, for every composition $I$, sends the monomial quasisymmetric function $M_I$ to $M_{I^r}$. Here, if $I$ is a composition, we denote by $I^r$ the reversed composition of $I$. Denoting by $f^*$ the image of an element $f \in \mathcal{QSym}$ under the star involution, it can be shown that every composition $I$ satisfies

$$(M_I)^* = M_{I^r}, \quad (F_I)^* = F_{I^r},$$

where $F_I$ denotes the fundamental quasisymmetric function corresponding to the composition $I$.

The star involution is an involution, an algebra automorphism and a coalgebra anti-automorphism of $\mathcal{QSym}$. It also is an automorphism of the graded vector space $\mathcal{QSym}$, and is the identity on the subspace $\text{Sym}$ of $\mathcal{QSym}$. It is adjoint to the star involution on $\text{NCSF}$ by the standard adjunction between $\text{NCSF}$ and $\mathcal{QSym}$.

The star involution has been denoted by $\rho$ in [LMvW13], section 3.6.

See also:

* star involution on $\mathcal{QSym}$
* star involution on $\text{NCSF}$.

**EXAMPLES:**

```python
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F()
sage: F[3,1].star_involution()
F[1, 3]
sage: F[5,3].star_involution()
F[3, 5]
sage: (F[3,3] - 2*F[2]).star_involution()
sage: F([4,2]).star_involution()
F[2, 4]
sage: dI = QSym.dI()
sage: dI([1,2]).star_involution()
-dI[1, 2] + dI[2, 1]
sage: dI.zero().star_involution()
0
```

**Eulerian** $(n, j, k=\text{None})$

Return the Eulerian (quasi)symmetric function $Q_{n,j}$ (with $n$ either an integer or a partition) defined in [SW2010] in terms of the fundamental quasisymmetric functions. Or, if the optional argument $k$ is specified, return the function $Q_{n,j,k}$ defined ibidem.

If $n$ and $j$ are nonnegative integers, then the Eulerian quasisymmetric function $Q_{n,j}$ is defined as

$$Q_{n,j} := \sum_{\sigma} F_{\text{Dex}(\sigma)},$$

where we sum over all permutations $\sigma \in S_n$ such that the number of excedances of $\sigma$ is $j$, and where $\text{Dex}(\sigma)$ is a composition of $n$ defined as follows: Let $S$ be the set of all $i \in \{1, 2, \ldots, n-1\}$ such that either $\sigma_i > \sigma_{i+1} > i + 1$ or $i \geq \sigma_i > \sigma_{i+1}$ or $\sigma_{i+1} > i + 1 > \sigma_i$. Then, $\text{Dex}(\sigma)$ is set to be the composition of $n$ whose descent set is $S$.

Here, an excedance of a permutation $\sigma \in S_n$ means an element $i \in \{1, 2, \ldots, n-1\}$ satisfying $\sigma_i > i$.

Similarly we can define a quasisymmetric function $Q_{\lambda,j}$ for every partition $\lambda$ and every nonnegative integer $j$. This differs from $Q_{n,j}$ only in that the sum is restricted to all permutations $\sigma \in S_n$ whose
cycle type is $\lambda$ (where $n = |\lambda|$, and where we still require the number of excedances to be $j$). The method at hand allows computing these functions by passing $\lambda$ as the $n$ parameter.

Analogously we can define a quasisymmetric function $Q_{n,j,k}$ for any nonnegative integers $n$, $j$ and $k$ by restricting the sum to all permutations $\sigma \in S_n$ that have exactly $k$ fixed points (and $j$ excedances). This can be obtained by specifying the optional $k$ argument in this method.

All three versions of Eulerian quasisymmetric functions ($Q_{n,j}$, $Q_{\lambda,j}$ and $Q_{n,j,k}$) are actually symmetric functions. See Eulerian().

**INPUT:**
- $n$ – the nonnegative integer $n$ or a partition
- $j$ – the number of excedances
- $k$ – (optional) if specified, determines the number of fixed points of the permutations which are being summed over

**EXAMPLES:**

```python
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F.Eulerian(3, 1)
sage: F.Eulerian(4, 2)
sage: F.Eulerian(5, 2)
sage: F.Eulerian(4, 0)
F[4]
sage: F.Eulerian(4, 3)
F[4]
sage: F.Eulerian(4, 1, 2)
sage: F.Eulerian(Partition([2, 2, 1]), 2)
sage: F.Eulerian(0, 0)
F[]
sage: F.Eulerian(0, 1)
0
sage: F.Eulerian(1, 0)
F[1]
sage: F.Eulerian(1, 1)
0
```

**antipode_on_basis**(compo)
Return the antipode to a Fundamental quasi-symmetric basis element.

**INPUT:**
- compo – composition

**OUTPUT:**
- The result of the antipode applied to the quasi-symmetric Fundamental basis element indexed by compo.

**EXAMPLES:**

```python
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F.antipode_on_basis(Composition([2,1]))
-F[2, 1]
```
coproduct_on_basis\((\text{compo})\)

Return the coproduct to a Fundamental quasi-symmetric basis element.

Combinatorial rule: quasi-deconcatenation.

INPUT:
• \text{compo} – composition

OUTPUT:
• The application of the coproduct to the Fundamental quasi-symmetric function indexed by the composition \text{compo}.

EXAMPLES:

```python
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: F[4].coproduct()
sage: F[2,1,3].coproduct()
```

dual\()

Return the dual basis to the Fundamental basis. This is the ribbon basis of the non-commutative symmetric functions.

OUTPUT:
• The ribbon basis of the non-commutative symmetric functions.

EXAMPLES:

```python
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F.dual()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon\)
```

class HazewinkelLambda\((QSym)\)

Bases: \text{sage.combinat.free_module.CombinatorialFreeModule}, \text{sage.misc.bindable_classBindableClass}

The Hazewinkel lambda basis of the quasi-symmetric functions.

This basis goes back to [Haz2004], albeit it is indexed in a different way here. It is a multiplicative basis in a weak sense of this word (the product of any two basis elements is a basis element, but of course not the one obtained by concatenating the indexing compositions).

In [Haz2004], Hazewinkel showed that the \(k\)-algebra \(QSym\) is a polynomial algebra. (The proof is correct but rests upon an unproven claim that the lexicographically largest term of the \(n\)-th shuffle power of a Lyndon word is the \(n\)-fold concatenation of this Lyndon word with itself, occurring \(n!\) times in that shuffle power. But this can be deduced from Section 2 of [Rad1979]. See also Chapter 6 of [GriRei18], specifically Theorem 6.5.13, for a complete proof.) More precisely, he showed that \(QSym\) is generated, as a free commutative \(k\)-algebra, by the elements \(\lambda^n(M_I)\), where \(n\) ranges over the positive integers, and \(I\) ranges over all compositions which are Lyndon words and whose entries have gcd 1. Here, \(\lambda^n\) denotes the \(n\)-th lambda operation as explained in \text{lambda_of_monomial}().

Thus, products of these generators form a \(k\)-module basis of \(QSym\). We index this basis by compositions here. More precisely, we define the Hazewinkel lambda basis \((\text{HWL}_I)_I\) (with \(I\) ranging over all compositions) as follows:

Let \(I\) be a composition. Let \(I = I_1I_2\ldots I_k\) be the Chen-Fox-Lyndon factorization of \(I\) (see \text{lyndon_factorization}()). For every \(j \in \{1, 2, \ldots, k\}\), let \(g_j\) be the gcd of the entries of the Lyndon word \(I_j\), and let \(J_j\) be the result of dividing the entries of \(I_j\) by this gcd. Then, \(\text{HWL}_I\) is defined to be \(\prod_{j=1}^{k} \lambda^{g_j}(M_{J_j})\).
Todo: The conversion from the M basis to the HWL basis is currently implemented in the naive way (inverting the base-change matrix in the other direction). This matrix is not triangular (not even after any permutations of the bases), and there could very well be a faster method (the one given by Hazewinkel?).

EXAMPLES:

```sage
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: HWL = QSym.HazewinkelLambda()
sage: M = QSym.M()
sage: M(HWL([2]))
M[1, 1]
sage: M(HWL([1,1]))
sage: M(HWL([1,2]))
M[1, 2]
sage: M(HWL([2,1]))
3*M[1, 1, 1] + M[1, 2] + M[2, 1]
sage: M(HWL(Composition([])))
M[]
sage: HWL(M([1,1]))
HWL[2]
sage: HWL(M(Composition([2])))
HWL[1, 1] - 2*HWL[2]
sage: HWL(M([1]))
HWL[1]
```

**product_on_basis**(I, J)

The product on Hazewinkel Lambda basis elements.

The product of the basis elements indexed by two compositions I and J is the basis element obtained by concatenating the Lyndon factorizations of the words I and J, then reordering the Lyndon factors in nonincreasing order, and finally concatenating them in this order (giving a new composition).

**INPUT:**
- I, J – compositions

**OUTPUT:**
- The product of the Hazewinkel Lambda quasi-symmetric functions indexed by I and J, expressed in the Hazewinkel Lambda basis.

**EXAMPLES:**

```sage
sage: HWL = QuasiSymmetricFunctions(QQ).HazewinkelLambda()
sage: c1 = Composition([1, 2, 1])
sage: c2 = Composition([2, 1, 3, 2])
sage: HWL.product_on_basis(c1, c2)
HWL[2, 1, 3, 2, 1, 2, 1]
sage: HWL.product_on_basis(c1, Composition([]))
HWL[1, 2, 1]
sage: HWL.product_on_basis(Composition([]), Composition([]))
HWL[]
```

M

alias of `QuasiSymmetricFunctions.Monomial`

class Monomial(QSym)

Bases: `sage.combinat.free_module.CombinatorialFreeModule`, `sage.misc.bindable_class.BindableClass`
The Hopf algebra of quasi-symmetric function in the Monomial basis.

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: F = QSym.F()
sage: M(F[2,2])
sage: m = SymmetricFunctions(QQ).m()
sage: M(m[3,1,1])
M[1, 1, 3] + M[1, 3, 1] + M[3, 1, 1]
sage: (1+M[1])^3
sage: M[1,2,1].coproduct()
```

The following is an alias for this basis:

```python
sage: QSym.Monomial()
Quasisymmetric functions over the Rational Field in the Monomial basis
```

class Element

Bases:

```
sage.modules.with_basis.indexed_element.IndexedFreeModuleElement
```

Element methods of the Monomial basis of `QuasiSymmetricFunctions`.

**expand** \((n, \text{alphabet}='x')\)

Expand the quasi-symmetric function written in the monomial basis in \(n\) variables.

**INPUT:**

- \(n\) – an integer
- \(\text{alphabet}\) – (default: 'x') a string

**OUTPUT:**

- The quasi-symmetric function `self` expressed in the \(n\) variables described by `alphabet`.

**Todo:** accept an `alphabet` as input

**EXAMPLES:**

```python
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: M[4,2].expand(3)
x0^4*x1^2 + x0^4*x2^2 + x1^4*x2^2
```

One can use a different set of variables by using the optional argument `alphabet`:

```python
sage: M=QuasiSymmetricFunctions(QQ).Monomial()
sage: M[2,1,1].expand(4,alphabet='y')
y0^2*y1*y2 + y0^2*y1*y3 + y0^2*y2*y3 + y1^2*y2*y3
```

**is_symmetric**

Determine if a quasi-symmetric function, written in the Monomial basis, is symmetric.

This is being tested by looking at the expansion in the Monomial basis and checking if the coefficients are the same if the indexing compositions are permutations of each other.

**OUTPUT:**
• True if self is an element of the symmetric functions and False otherwise.

Examples:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.Monomial()
sage: (M[3,2] + M[2,3] + M[4,1]).is_symmetric()
False
sage: (M[3,2] + M[2,3]).is_symmetric()
True
sage: (M[1,2,1] + M[1,1,2]).is_symmetric()
False
sage: (M[1,2,1] + M[1,1,2] + M[2,1,1]).is_symmetric()
True
```

 psi_involution()  

Return the image of the quasisymmetric function self under the involution $\psi$.

The involution $\psi$ is defined as the linear map $QSym \to QSym$ which, for every composition $I$, sends the fundamental quasisymmetric function $F_I$ to $F_{I^c}$, where $I^c$ denotes the complement of the composition $I$. The map $\psi$ is an involution and a graded Hopf algebra automorphism of $QSym$. Its restriction to the ring of symmetric functions coincides with the omega automorphism of the latter ring.

The involution $\psi$ of $QSym$ is adjoint to the involution $\psi$ of $NCSF$ by the standard adjunction between $NCSF$ and $QSym$.

The involution $\psi$ has been denoted by $\psi$ in [LMvW13], section 3.6.

See also:

psi involution on QSym, psi involution on NCSF, star involution on QSym.

Examples:

```python
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: M[3,2].psi_involution()
sage: M[3,1].psi_involution()
sage: M[3,1,1].psi_involution()
sage: M[1,1,1].psi_involution()
sage: M([]).psi_involution()
M[]
sage: M(0).psi_involution()
0
```

This particular implementation is tailored to the monomial basis. It is semantically equivalent to the generic implementation it overshadows:

```python
sage: F = QSym.F()
sage: all( F(M[I].psi_involution()) == F(M[I]).psi_involution() 
.....: for I in Compositions(3) )
True
```
to\_symmetric\_function()\

Take a quasi-symmetric function, expressed in the monomial basis, and return its symmetric realization, when possible, expressed in the monomial basis of symmetric functions.

OUTPUT:

- If self is a symmetric function, then the expansion in the monomial basis of the symmetric functions is returned. Otherwise an error is raised.

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.Monomial()
sage: (M[3,2] + M[2,3] + M[4,1]).to_symmetric_function()
Traceback (most recent call last):
m[3, 2] + 2*m[4, 1]
sage: m = SymmetricFunctions(QQ).m()
sage: M(m[3,1,1]).to_symmetric_function()
m[3, 1, 1]
sage: (M(m[2,1])*M(m[2,1])).to_symmetric_function() - m[2,1]*m[2,1]
0
```

antipode\_on\_basis(compo)

Return the result of the antipode applied to a quasi-symmetric Monomial basis element.

INPUT:

- compo – composition

OUTPUT:

- The result of the antipode applied to the composition compo, expressed in the Monomial basis.

EXAMPLES:

```python
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.antipode_on_basis(Composition([2,1]))
M[1, 2] + M[3]
sage: M.antipode_on_basis(Composition([]))
M[]
```

coproduct\_on\_basis(compo)

Return the coproduct of a Monomial basis element.

Combinatorial rule: deconcatenation.

INPUT:

- compo – composition

OUTPUT:

- The coproduct applied to the Monomial quasi-symmetric function indexed by compo, expressed in the Monomial basis.

EXAMPLES:
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: M[4,2,3].coproduct()
sage: M.coproduct_on_basis(Composition([]))
M[] # M[]

\textbf{dual()}

Return the dual basis to the Monomial basis. This is the complete basis of the non-commutative symmetric functions.

\textbf{OUTPUT:}
- The complete basis of the non-commutative symmetric functions.

\textbf{EXAMPLES:}

sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.dual()
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis

\textbf{lambda_of_monomial}(I, n)

Return the image of the monomial quasi-symmetric function $M_I$ under the lambda-map $\lambda^n$, expanded in the monomial basis.

The ring of quasi-symmetric functions over the integers, $QSym_\mathbb{Z}$ (and more generally, the ring of quasi-symmetric functions over any binomial ring) becomes a $\lambda$-ring (with the $\lambda$-structure inherited from the ring of formal power series, so that $\lambda^i(x_j)$ is $x_j$ if $i = 1$ and 0 if $i > 1$).

The Adams operations of this $\lambda$-ring are the Frobenius endomorphisms $f_n$ (see \texttt{frobenius()} for their definition). Using these endomorphisms, the $\lambda$-operations can be explicitly computed via the formula

$$
\exp \left( - \sum_{n=1}^{\infty} \frac{1}{n} f_n(x) t^n \right) = \sum_{j=0}^{\infty} (-1)^j \lambda^j(x) t^j
$$

in the ring of formal power series in a variable $t$ over the ring of quasi-symmetric functions. In particular, every composition $I = (I_1, I_2, \cdots, I_\ell)$ satisfies

$$
\exp \left( - \sum_{n=1}^{\infty} \frac{1}{n} M_{(n_1, n_2, \cdots, n_\ell)} t^n \right) = \sum_{j=0}^{\infty} (-1)^j \lambda^j(M_I) t^j
$$

(corrected version of Remark 2.4 in [Haz2004]).

The quasi-symmetric functions $\lambda^j(M_I)$ with $n$ ranging over the positive integers and $I$ ranging over the reduced Lyndon compositions (i.e., compositions which are Lyndon words and have the gcd of their entries equal to 1) form a set of free polynomial generators for $QSym$. See [GriRei18], Chapter 6, for the proof, and [Haz2004] for a major part of it.

\textbf{INPUT:}
- $I$ -- composition
- $n$ -- nonnegative integer

\textbf{OUTPUT:}

The quasi-symmetric function $\lambda^n(M_I)$, expanded in the monomial basis over the ground ring of self.

\textbf{EXAMPLES:}
sage: M = QuasiSymmetricFunctions(CyclotomicField()).Monomial()
sage: M.lambda_of_monomial([1, 1], 2)
3*M[1, 1, 1, 1] + M[1, 1, 2] + M[1, 2, 1] + M[2, 1, 1]
sage: M = QuasiSymmetricFunctions(Integers(19)).Monomial()
sage: M.lambda_of_monomial([1, 2], 3)

The map \(\lambda^0\) sends everything to 1:

sage: M = QuasiSymmetricFunctions(ZZ).Monomial()
sage: all( M.lambda_of_monomial(I, 0) == M.one() for I in Compositions(3) )
True

The map \(\lambda^1\) is the identity map:

sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: all( M.lambda_of_monomial(I, 1) == M(I) for I in Compositions(3) )
True

sage: M = QuasiSymmetricFunctions(Integers(5)).Monomial()
sage: all( M.lambda_of_monomial(I, 1) == M(I) for I in Compositions(3) )
True

sage: M = QuasiSymmetricFunctions(ZZ).Monomial()
sage: all( M.lambda_of_monomial(I, 1) == M(I) for I in Compositions(3) )
True

product_on_basis\((I, J)\)

The product on Monomial basis elements.

The product of the basis elements indexed by two compositions \(I\) and \(J\) is the sum of the basis elements indexed by compositions in the stuffle product (also called the overlapping shuffle product) of \(I\) and \(J\).

INPUT:
• \(I, J\) – compositions

OUTPUT:
• The product of the Monomial quasi-symmetric functions indexed by \(I\) and \(J\), expressed in the Monomial basis.

EXAMPLES:

sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: c1 = Composition([2])
sage: c2 = Composition([1, 3])
QS

alias of QuasiSymmetricFunctions.Quasisymmetric_Schur

class Quasisymmetric_Schur(QSym)

- Bases:  
  sage.combinat.free_module.CombinatorialFreeModule,  
  sage.misc.bindable_classBindableClass

  The Hopf algebra of quasi-symmetric function in the Quasisymmetric Schur basis.

  The basis of Quasisymmetric Schur functions is defined in [QSCHUR] and in Definition 5.1.1 of [LMvW13].  
  Don’t mistake them for the completely unrelated quasi-Schur functions of [NCSF1]!

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QS = QSym.QS()
sage: F = QSym.F()
sage: M = QSym.M()
sage: F(QS[1,2])
F[1, 2]
sage: M(QS[1,2])
M[1, 1, 1] + M[1, 2]
sage: s = SymmetricFunctions(QQ).s()
sage: QS(s[2,1,1])
QS[1, 1, 2] + QS[1, 2, 1] + QS[2, 1, 1]
```

dual()

- The dual basis to the Quasisymmetric Schur basis.

  The dual basis to the Quasisymmetric Schur basis is implemented as dual.

OUTPUT:

- the dual Quasisymmetric Schur basis of the non-commutative symmetric functions

EXAMPLES:

```python
sage: QS = QuasiSymmetricFunctions(QQ).Quasisymmetric_Schur()
sage: QS.dual()
Non-Commutative Symmetric Functions over the Rational Field
in the dual Quasisymmetric-Schur basis
```

YQS

alias of QuasiSymmetricFunctions.Young_Quasisymmetric_Schur

class Young_Quasisymmetric_Schur(QSym)

- Bases:  
  sage.combinat.free_module.CombinatorialFreeModule,  
  sage.misc.bindable_classBindableClass

  The Hopf algebra of quasi-symmetric functions in the Young Quasisymmetric Schur basis.

  The basis of Young Quasisymmetric Schur functions is from Definition 5.2.1 of [LMvW13].

  This basis is related to the Quasisymmetric Schur basis QS by \( QS(\alpha).\text{star involution}() = YQS(\alpha).\text{star involution}() \).

EXAMPLES:
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: YQS = QSym.YQS()
sage: F = QSym.F()
sage: QS = QSym.QS()
sage: F(YQS[1,2])
\[ F[1, 2] \]
sage: all(QS(al.reversed())==YQS(al).star_involution() for al in Compositions(5))
True
sage: s = SymmetricFunctions(QQ).s()
sage: YQS(s[2,1,1])
\[ YQS[1, 1, 2] + YQS[1, 2, 1] + YQS[2, 1, 1] \]

\textbf{a\_realization()}

Return the realization of the Monomial basis of the ring of quasi-symmetric functions.

\textbf{OUTPUT:}

- The Monomial basis of quasi-symmetric functions.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: QuasiSymmetricFunctions(QQ).a\_realization()
\text{Quasisymmetric functions over the Rational Field in the Monomial basis}
\end{verbatim}

\textbf{dI}

alias of \texttt{QuasiSymmetricFunctions.dualImmaculate}

\textbf{dual()}

Return the dual Hopf algebra of the quasi-symmetric functions, which is the non-commutative symmetric functions.

\textbf{OUTPUT:}

- The non-commutative symmetric functions.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.dual()
\text{Non-Commutative Symmetric Functions over the Rational Field}
\end{verbatim}

\textbf{class dualImmaculate(QSym)}

\textbf{Bases:} \texttt{sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable\_class.BindableClass}

The dual immaculate basis of the quasi-symmetric functions.

This basis first appears in [BBSSZ2012].

\textbf{EXAMPLES:}

\begin{verbatim}
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: dI = QSym.dI()
sage: dI([1,3,2])*dI([1])  # long time (6s on sage.math, 2013)
dI[1, 1, 3, 2] + dI[2, 3, 2]
sage: dI([1,3])*dI([1,1])
sage: dI([3,1])*dI([2,1])  # long time (7s on sage.math, 2013)
\end{verbatim}
from_polynomial (f, check=True)
Return the quasi-symmetric function in the Monomial basis corresponding to the quasi-symmetric polynomial f.

INPUT:
• f – a polynomial in finitely many variables over the same base ring as self. It is assumed that this polynomial is quasi-symmetric.
• check – boolean (default: True), checks whether the polynomial is indeed quasi-symmetric.

OUTPUT:
• quasi-symmetric function in the Monomial basis

EXAMPLES:

```python
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.from_polynomial(f)
M[1]
```

Beware of setting check=False:

```python
sage: f = x[0] + 2*x[1] + x[2]
sage: QSym.from_polynomial(f, check=True)
Traceback (most recent call last):
  ...
ValueError: x0 + 2*x1 + x2 is not a quasi-symmetric polynomial
```

To expand the quasi-symmetric function in a basis other than the Monomial basis, the following shorthands are provided:

```python
sage: M = QSym.Monomial()
sage: f = x[0]**2 + x[1]**2 + x[2]**2
sage: g = M.from_polynomial(f); g
M[2]
sage: F = QSym.Fundamental()
sage: F(g)
-F[2] + F[1, 1]
```

class phi (QSym)
Bases: `sage.combinat.free_module.CombinatorialFreeModule`, `sage.misc.bindable_classBindableClass`
The Hopf algebra of quasi-symmetric functions in the $\phi$ basis.

The $\phi$ basis is defined as a rescaled Hopf dual of the $\Phi$ basis of the non-commutative symmetric functions (see Section 3.1 of [BDHMN2017]), where the pairing is

$$(\phi_I, \Phi_J) = z_I \delta_{I,J},$$

where $z_I = 1^{m_1} m_1! 2^{m_2} m_2! \cdots$ with $m_i$ being the multiplicity of $i$ in the composition $I$. Therefore, we call these the quasi-symmetric power sums of the second kind.

Using the duality, we can directly define the $\phi$ basis by

$$\phi_I = \sum_{J \succ I} z_I / sp_{I,J} M_J,$$

where $sp_{I,J}$ is as defined in [NCSF].

The $\phi$-basis is well-defined only when the base ring is a $\mathbb{Q}$-algebra.

EXAMPLES:

```sage
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: phi = QSym.phi(); phi
Quasisymmetric functions over the Rational Field in the phi basis
sage: phi.an_element()
2*phi[] + 2*phi[1] + 3*phi[1, 1]
sage: p = SymmetricFunctions(QQ).p()
sage: phi(p[2,2,1])
phi[1, 2, 2] + phi[2, 1, 2] + phi[2, 2, 1]
sage: all(sum(phi(list(al)) for al in Permutations(la))==phi(p(la)) for la in Partitions(6))
True
sage: p = SymmetricFunctions(QQ).p()
sage: phi(p[3,2,2])
phi[2, 2, 3] + phi[2, 3, 2] + phi[3, 2, 2]
```

Checking the equivalent definition of $\phi_n$:

```sage
def test_phi(n):
    phi = QuasiSymmetricFunctions(QQ).phi()
    Phi = NonCommutativeSymmetricFunctions(QQ).Phi()
    M = matrix([[phi[I].duality_pairing(Phi[J])
                 for J in Compositions(n)]
                for I in Compositions(n)])
    def z(J):
        return J.to_partition().centralizer_size()
    return M == matrix.diagonal([z(I) for I in Compositions(n)])
sage: all(test_phi(k) for k in range(1,5))
True
```

class psi (QSym)

Bases: `sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_classBindableClass`

The Hopf algebra of quasi-symmetric functions in the $\psi$ basis.

The $\psi$ basis is defined as a rescaled Hopf dual of the $\Psi$ basis of the non-commutative symmetric functions (see Section 3.1 of [BDHMN2017]), where the pairing is

$$(\psi_I, \Psi_J) = z_I \delta_{I,J},$$
where \( z_I = 1^{m_1} m_1! ^2 m_2! \cdots \) with \( m_i \) being the multiplicity of \( i \) in the composition \( I \). Therefore, we call these the \textit{quasi-symmetric power sums of the first kind}.

Using the duality, we can directly define the \( \psi \) basis by

\[
\psi_I = \sum_{J \succ I} z_I / \pi_{I,J} M_J,
\]

where \( \pi_{I,J} \) is as defined in \([\text{NCSF}]\).

The \( \psi \)-basis is well-defined only when the base ring is a \( \mathbb{Q} \)-algebra.

EXEMPLARY:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: psi = QSym.psi(); psi
Quasisymmetric functions over the Rational Field in the psi basis
sage: psi.an_element()
2*psi[0] + 2*psi[1] + 3*psi[1, 1]
sage: p = SymmetricFunctions(QQ).p()
sage: psi(p[2,2,1])
psi[1, 2, 2] + psi[2, 1, 2] + psi[2, 2, 1]
sage: all(sum(psi(list(al))) == psi(p(la)) for la in Partitions(6))
True

Checking the equivalent definition of \( \psi_n \):

```python
sage: def test_psi(n):
....:     psi = QuasiSymmetricFunctions(QQ).psi()
....:     Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
....:     M = matrix([[psi[I].duality_pairing(Psi[J])
....:                  for I in Compositions(n)]
....:                  for J in Compositions(n)])
....:     for I in Compositions(n)]
....:     def z(J):
....:        return J.to_partition().centralizer_size()
....:     return M == matrix.diagonal([z(I) for I in Compositions(n)])

sage: all(test_psi(k) for k in range(1,5))
True
```

5.1.149 Introduction to Quasisymmetric Functions

In this document we briefly explain the quasisymmetric function bases and related functionality in Sage. We assume the reader is familiar with the package \texttt{SymmetricFunctions}.

Quasisymmetric functions, denoted \( QSym \), form a subring of the power series ring in countably many variables. \( QSym \) contains the symmetric functions. These functions first arose in the theory of \( P \)-partitions. The initial ideas in this field are attributed to MacMahon, Knuth, Kreweras, Glânfrwd Thomas, Stanley. In 1984, Gessel formalized the study of quasisymmetric functions and introduced the basis of fundamental quasisymmetric functions \([\text{Ges}]\). In 1995, Gelfand, Krob, Lascoux, Leclerc, Retakh, and Thibon showed that the ring of quasisymmetric functions is Hopf dual to the noncommutative symmetric functions \([\text{NCSF}]\). Many results have built on these.

One advantage of working in \( QSym \) is that many interesting families of symmetric functions have explicit expansions in fundamental quasisymmetric functions such as Schur functions \([\text{Ges}]\), Macdonald polynomials \([\text{HHL05}]\), and plethysm of Schur functions \([\text{LW12}]\).

For more background see Wikipedia article Quasisymmetric_function.
To begin, initialize the ring. Below we chose to use the rational numbers $\mathbb{Q}$. Other options include the integers $\mathbb{Z}$ and $\mathbb{C}$:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym
Quasisymmetric functions over the Rational Field
sage: QSym = QuasiSymmetricFunctions(CC); QSym
Quasisymmetric functions over the Complex Field with 53 bits of precision
sage: QSym = QuasiSymmetricFunctions(ZZ); QSym
Quasisymmetric functions over the Integer Ring
```

All bases of $\mathcal{QSym}$ are indexed by compositions e.g. $[3, 1, 1, 4]$. The convention is to use capital letters for bases of $\mathcal{QSym}$ and lowercase letters for bases of the symmetric functions $\mathcal{Sym}$. Next set up names for the known bases by running `inject_shorthands()`. As with symmetric functions, you do not need to run this command and you could assign these bases other names.

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.inject_shorthands()
Defining M as shorthand for Quasisymmetric functions over the Rational Field in the Monomial basis
Defining F as shorthand for Quasisymmetric functions over the Rational Field in the Fundamental basis
Defining E as shorthand for Quasisymmetric functions over the Rational Field in the Essential basis
Defining dI as shorthand for Quasisymmetric functions over the Rational Field in the dualImmaculate basis
Defining QS as shorthand for Quasisymmetric functions over the Rational Field in the Quasisymmetric Schur basis
Defining QYS as shorthand for Quasisymmetric functions over the Rational Field in the Young Quasisymmetric Schur basis
Defining phi as shorthand for Quasisymmetric functions over the Rational Field in the phi basis
Defining psi as shorthand for Quasisymmetric functions over the Rational Field in the psi basis
```

Now one can start constructing quasisymmetric functions.

**Note:** It is best to use variables other than $M$ and $F$.

```
sage: x = M[2,1] + M[1,2]
sage: x
M[1, 2] + M[2, 1]
sage: y = 3*M[1,2] + M[3]^2; y
sage: F[3,1,3] + 7*F[2,1]
7*F[2, 1] + F[3, 1, 3]
```

To convert from one basis to another is easy:
To expand in variables, one can specify a finite size alphabet $x_1, x_2, \ldots, x_m$:

sage: y = M[1,2,1]
sage: y.expand(4)
$x_0x_1^2x_2 + x_0x_1^2x_3 + x_0x_2^2x_3 + x_1x_2^2x_3$

The usual methods on free modules are available such as coefficients, degrees, and the support:

sage: z=3*M[1,2]+M[3]^2; z
sage: z.coefficient([1,2])
3
sage: z.degree()
6
sage: sorted(z.coefficients())
[[1, 2], [3, 3], [6]]
sage: sorted(z.monomials(), key=lambda x: x.support())
[[M[1, 2], M[3, 3], M[6]]]
sage: z.monomial_coefficients()
{[1, 2]: 3, [3, 3]: 2, [6]: 1}

As with the symmetric functions package, the quasisymmetric function 1 has several instantiations. However, the most obvious way to write 1 leads to an error (this is due to the semantics of python):

sage: M[]
M[]
sage: M.one()
M[]
sage: M(1)
M[]
sage: M[[[]] == 1
True
sage: M[]
Traceback (most recent call last):
  ... SyntaxError: invalid syntax
Working with symmetric functions

The quasisymmetric functions are a ring which contains the symmetric functions as a subring. The Monomial quasisymmetric functions are related to the monomial symmetric functions by
\[ m_\lambda = \sum_{\text{sort}(c) = \lambda} M_c, \]
where \( \text{sort}(c) \) means the partition obtained by sorting the composition \( c \):

```
sage: SymmetricFunctions(QQ).inject_shorthands()
Defining e as shorthand for Symmetric Functions over Rational Field in the elementary basis
Defining f as shorthand for Symmetric Functions over Rational Field in the forgotten basis
Defining h as shorthand for Symmetric Functions over Rational Field in the homogeneous basis
Defining m as shorthand for Symmetric Functions over Rational Field in the monomial basis
Defining p as shorthand for Symmetric Functions over Rational Field in the powersum basis
Defining s as shorthand for Symmetric Functions over Rational Field in the Schur basis

sage: m[2,1]
\[ m[2, 1] \]
sage: M(m[2,1])
\[ M[1, 2] + M[2, 1] \]
sage: M(s[2,1])
\[ 2*M[1, 1, 1] + M[1, 2] + M[2, 1] \]
```

There are methods to test if an expression \( f \) in the quasisymmetric functions is a symmetric function:

```
sage: f = M[1,1,2] + M[1,2,1]
sage: f.is_symmetric()
False
sage: f = M[3,1] + M[1,3]
sage: f.is_symmetric()
True
```

If \( f \) is symmetric, there are methods to convert \( f \) to an expression in the symmetric functions:

```
sage: f.to_symmetric_function()
m[3, 1]
```

The expansion of the Schur function in terms of the Fundamental quasisymmetric functions is due to [Ges]. There is one term in the expansion for each standard tableau of shape equal to the partition indexing the Schur function.

```
sage: f.is_symmetric()
True
sage: f.to_symmetric_function()
s[3, 2]
```

It is also possible to convert any symmetric function to the quasisymmetric function expansion in any known basis. The converse is not true:

```
sage: M( m[3,1,1] )
M[1, 1, 3] + M[1, 3, 1] + M[3, 1, 1]
sage: F( s[2,2,1] )
```

(continues on next page)
F[1, 1, 2, 1] + F[1, 2, 1, 1] + F[1, 2, 2] + F[2, 1, 2] + F[2, 2, 1]

sage: s(M[2,1])
Traceback (most recent call last):
  ...
TypeError: do not know how to make x (= M[2, 1]) an element of self

It is possible to experiment with the quasisymmetric function expansion of other bases, but it is important that the base ring be the same for both algebras.

sage: R = QQ['t']
sage: Qp = SymmetricFunctions(R).hall_littlewood().Qp()
sage: QSymt = QuasiSymmetricFunctions(R)
sage: Ft = QSymt.F()
sage: Ft( Qp[2,2] )

sage: K = QQ['q','t'].fraction_field()
sage: Ht = SymmetricFunctions(K).macdonald().Ht()
sage: Fqt = QuasiSymmetricFunctions(Ht.base_ring()).F()
sage: Fqt(Ht[2,1])
q*t*F[1, 1, 1] + (q+t)*F[1, 2] + (q+t)*F[2, 1] + F[3]

The following will raise an error because the base ring of F is not equal to the base ring of Ht:

sage: F(Ht[2,1])
Traceback (most recent call last):
  ...
TypeError: do not know how to make x (= McdHt[2, 1]) an element of self

QSym is a Hopf algebra

The product on QSym is commutative and is inherited from the product by the realization within the polynomial ring:

sage: M[3]*M[1,1] == M[1,1]*M[3]
True
sage: M[3]*M[1,1]
sage: F[3]*F[1,1]
sage: M[3]*F[2]
sage: F[2]*M[3]

There is a coproduct on this ring as well, which in the Monomial basis acts by cutting the composition into a left half and a right half. The co-product is non-co-commutative:

sage: M[1,3,1].coproduct()
sage: F[1,3,1].coproduct()
The Duality Pairing with Non-Commutative Symmetric Functions

These two operations endow $QSym$ with the structure of a Hopf algebra. It is the dual Hopf algebra of the non-commutative symmetric functions $NCSF$. Under this duality, the Monomial basis of $QSym$ is dual to the Complete basis of $NCSF$, and the Fundamental basis of $QSym$ is dual to the Ribbon basis of $NCSF$ (see [MR]):

```
sage: S = M.dual(); S
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
sage: M[1,3,1].duality_pairing( S[1,3,1] )
1
sage: M.duality_pairing_matrix( S, degree=4 )
[1 0 0 0 0 0 0 0]
[0 1 0 0 0 0 0 0]
[0 0 1 0 0 0 0 0]
[0 0 0 1 0 0 0 0]
[0 0 0 0 1 0 0 0]
[0 0 0 0 0 1 0 0]
[0 0 0 0 0 0 1 0]
[0 0 0 0 0 0 0 1]
sage: F.duality_pairing_matrix( S, degree=4 )
[1 0 0 0 0 0 0 0]
[0 1 0 0 0 0 0 0]
[0 0 1 0 0 0 0 0]
[0 0 0 1 0 0 0 0]
[0 0 0 0 1 0 0 0]
[0 0 0 0 0 1 0 0]
[0 0 0 0 0 0 1 0]
[0 0 0 0 0 0 0 1]
sage: NCSF = M.realization_of().dual()
sage: R = NCSF.Ribbon()
sage: F.duality_pairing_matrix( R, degree=4 )
[1 0 0 0 0 0 0 0]
[0 1 0 0 0 0 0 0]
[0 0 1 0 0 0 0 0]
[0 0 0 1 0 0 0 0]
[0 0 0 0 1 0 0 0]
[0 0 0 0 0 1 0 0]
[0 0 0 0 0 0 1 0]
[0 0 0 0 0 0 0 1]
sage: M.duality_pairing_matrix( R, degree=4 )
[ 1 0 0 0 0 0 0 0]
[-1 1 0 0 0 0 0 0]
[-1 0 1 0 0 0 0 0]
[ 1 -1 -1 1 0 0 0 0]
[-1 0 0 0 1 0 0 0]
[-1 0 -1 0 -1 1 0 0]
[ 1 0 -1 0 -1 0 1 0]
[-1 1 1 -1 1 -1 -1 1]
```

Let $H$ and $G$ be elements of $QSym$ and $h$ an element of $NCSF$. Then if we represent the duality pairing with the mathematical notation $[\cdot, \cdot]$, we have:

$[H \cdot G, h] = [H \otimes G, \Delta(h)]$.

For example, the coefficient of $M[2,1,4,1]$ in $M[1,3] \otimes M[2,1,1]$ may be computed with the duality pairing:

```
sage: I, J = Composition([1,3]), Composition([2,1,1])
sage: (M[I] * M[J]).duality_pairing(S[2,1,4,1])
```
And the coefficient of $S[1, 3] \otimes S[2, 1, 1]$ in $S[2, 1, 4, 1].\text{coproduct}()$ is equal to this result:

```sage
sage: S[2,1,4,1].coproduct()
S[] \otimes S[2, 1, 4, 1] + ... + S[1, 3] \otimes S[2, 1, 1] + ... + S[4, 1] \otimes S[2, 1]
```

The duality pairing on the tensor space is another way of getting this coefficient, but currently the method `duality_pairing()` is not defined on the tensor squared space. However, we can extend this functionality by applying a linear morphism to the terms in the coproduct, as follows:

```sage
sage: X = S[2,1,4,1].coproduct()
sage: def linear_morphism(x, y):
    ....:     return x.duality_pairing(M[1,3]) * y.duality_pairing(M[2,1,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
```

Similarly, if $H$ is an element of $\mathcal{QSym}$ and $g$ and $h$ are elements of $\mathcal{NCSF}$, then

$$\left[H, g \cdot h\right] = \left[\Delta(H), g \otimes h\right].$$

For example, the coefficient of $R[2, 3, 1]$ in $R[2, 1] \otimes R[2, 1]$ is computed with the duality pairing by the following command:

```sage
sage: (R[2,1] \otimes R[2,1]).duality_pairing(F[2,3,1])
1
sage: R[2,1] \otimes R[2,1]
R[2, 1, 2, 1] + R[2, 3, 1]
```

This coefficient should then be equal to the coefficient of $F[2, 1] \otimes F[2, 1]$ in $F[2, 3, 1].\text{coproduct}()$:

```sage
sage: F[2,3,1].coproduct()
F[] \otimes F[2, 3, 1] + ... + F[2, 1] \otimes F[2, 1] + ... + F[2, 3, 1] \otimes F[]
```

This can also be computed by the duality pairing on the tensor space, as above:

```sage
sage: X = F[2,3,1].coproduct()
sage: def linear_morphism(x, y):
    ....:     return x.duality_pairing(R[2,1]) * y.duality_pairing(R[2,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
```

### The Operation Adjoint to Multiplication by a Non-Commutative Symmetric Function

Let $g \in \mathcal{NCSF}$ and consider the linear endomorphism of $\mathcal{NCSF}$ defined by left (respectively, right) multiplication by $g$. Since there is a duality between $\mathcal{QSym}$ and $\mathcal{NCSF}$, this linear transformation induces an operator $g^\perp$ on $\mathcal{QSym}$ satisfying

$$[g^\perp(H), h] = [H, g \cdot h].$$

for any non-commutative symmetric function $h$.

This is implemented by the method `skew_by()`. Explicitly, if $H$ is a quasisymmetric function and $g$ a non-commutative symmetric function, then $H\text{.skew_by}(g)$ and $H\text{.skew_by}(g, \text{side}='\text{right}')$ are expressions that satisfy, for any non-commutative symmetric function $h$, the following identities:
H.skew_by(g).duality_pairing(h) == H.duality_pairing(g*h)
H.skew_by(g, side='right').duality_pairing(h) == H.duality_pairing(h*g)

For example, M[J].skew_by(S[I]) is 0 unless the composition \( J \) begins with \( I \) and \( M(J).skew_by(S(I), side='right') \) is 0 unless the composition \( J \) ends with \( I \):

```python
sage: M[3,2,2].skew_by(S[3])
M[2, 2]
sage: M[3,2,2].skew_by(S[2])
0
sage: M[3,2,2].coproduct().apply_multilinear_morphism(lamb
da x,y: x.duality_˓→pairing(S[3])*y )
M[2, 2]
sage: M[3,2,2].skew_by(S[3], side='right')
0
sage: M[3,2,2].skew_by(S[2], side='right')
M[3, 2]
```

### The antipode

The antipode sends the Fundamental basis element indexed by the composition \( I \) to \(-1\) to the size of \( I \) times the Fundamental basis element indexed by the conjugate composition to \( I \):

```python
sage: F[3,2,2].antipode()
-F[1, 2, 2, 1, 1]
sage: Composition([3,2,2]).conjugate()
[1, 2, 2, 1, 1]
sage: M[3,2,2].antipode()
```

We demonstrate here the defining relation of the antipode:

```python
sage: X = F[3,2,2].coproduct()
sage: X.apply_multilinear_morphism(lamb
da x,y: x*y.antipode())
0
sage: X.apply_multilinear_morphism(lamb
da x,y: x.antipode()*y)
0
```

5.1.152 Bases for \( NCSym \)

AUTHORS:

- Travis Scrimshaw (08-04-2013): Initial version

```python
class sage.combinat.ncsym.bases.MultiplicativeNCSymBases(parent_with_realization):
    Bases: sage.categories.realizations.Category_realization_of_parent

Category of multiplicative bases of symmetric functions in non-commuting variables.

A multiplicative basis is one for which \( b_A b_B = b_{A\upharpoonright B} \) where \( A\upharpoonright B \) is the \( \text{pipe}() \) operation on set partitions.

EXAMPLES:
```

```
sage: from sage.combinat.ncsym.bases import MultiplicativeNCSymBases
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: MultiplicativeNCSymBases(NCSym)
Category of multiplicative bases of symmetric functions in non-commuting variables over the Rational Field
```

```python
class ElementMethods:
    Bases: object

class ParentMethods:
    Bases: object

    product_on_basis(A, B)

    The product on basis elements.

    The product on a multiplicative basis is given by \( b_A \cdot b_B = b_{A\upharpoonright B} \).

    The bases \( \{e, h, x, cp, p, chi, rho\} \) are all multiplicative.

    INPUT:
    - A, B – set partitions

    OUTPUT:
    - an element in the basis self

    EXAMPLES:
```

```
sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: x = SymmetricFunctionsNonCommutingVariables(QQ).x()
sage: cp = SymmetricFunctionsNonCommutingVariables(QQ).cp()
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).p()
sage: chi = SymmetricFunctionsNonCommutingVariables(QQ).chi()
sage: rho = SymmetricFunctionsNonCommutingVariables(QQ).rho()
sage: A = SetPartition([[1], [2, 3]])
sage: B = SetPartition([[1], [3], [2, 4]])
sage: e.product_on_basis(A, B)
  e({1}, {2, 3}, {4}, {5, 7}, {6})
sage: h.product_on_basis(A, B)
  h({1}, {2, 3}, {4}, {5, 7}, {6})
sage: x.product_on_basis(A, B)
  x({1}, {2, 3}, {4}, {5, 7}, {6})
sage: cp.product_on_basis(A, B)
  cp({1}, {2, 3}, {4}, {5, 7}, {6})
sage: p.product_on_basis(A, B)
```

(continues on next page)
super_categories()

Return the super categories of bases of the Hopf dual of the symmetric functions in non-commuting variables.

OUTPUT:
• a list of categories

class sage.combinat.ncsym.bases.NCSymBases(parent_with_realization)

Bases: sage.categories.realizations.Category_realization_of_parent

Category of bases of symmetric functions in non-commuting variables.

EXAMPLES:

sage: from sage.combinat.ncsym.bases import NCSymBases
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: NCSymBases(NCSym)
Category of bases of symmetric functions in non-commuting variables over the Rational Field

class ElementMethods

Bases: object

expand(n, alphabet='x')

Expand the symmetric function into \( n \) non-commuting variables in an alphabet, which by default is 'x'.

This computation is completed by coercing the element self into the monomial basis and computing the expansion in the alphabet there.

INPUT:
• \( n \) – the number of variables in the expansion
• alphabet – (default: 'x') the alphabet in which self is to be expanded

OUTPUT:
• an expansion of self into the \( n \) non-commuting variables specified by alphabet

EXAMPLES:

sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: h[[1,3],[2]].expand(3)
2*x0^3 + x0^2*x1 + x0*x1^2 + x0*x1*x2 + x0*x0*x1*x0 + x0^2*x0 + x0*x1 + x0*x2 + x1^2 + x1*x0 + x1*x2 + x1*x0^2 + x1*x0*x1 + x1*x0*x2 + x1^2*x0 + 2*x1^3

(continued from previous page)
internal_coproduct()

Return the internal coproduct of self.

The internal coproduct is defined on the power sum basis as

\[ P_A \mapsto P_A \otimes P_A \]

and the map is extended linearly.

OUTPUT:

• an element of the tensor square of the basis of self

EXAMPLES:

```sage
sage: x = SymmetricFunctionsNonCommutingVariables(QQ).x()
sage: x[[1,3],[2]].internal_coproduct()
x{{1}, {2}, {3}} # x{{1, 3}, {2}} + x{{1, 3}, {2}} # x{{1}, {2}, {3}}
+ x{{1, 3}, {2}} # x{{1, 3}, {2}}
```

omega()

Return the involution \( \omega \) applied to self.

The involution \( \omega \) is defined by

\[ e_A \mapsto h_A \]

and the result is extended linearly.

OUTPUT:

• an element in the same basis as self

EXAMPLES:

```sage
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: m[[1,3],[2]].omega()
-2*m{{1, 2, 3}} - m{{1, 3}, {2}}
sage: p = NCSym.p()
sage: p[[1,3],[2]].omega()
-p{{1, 3}, {2}}
sage: cp = NCSym.cp()
sage: cp[[1,3],[2]].omega()
-2*cp{{1, 2, 3}} - cp{{1, 3}, {2}}
sage: x = NCSym.x()
sage: x[[1,3],[2]].omega()
-2*x{{1}, {2}, {3}} - x{{1, 3}, {2}}
```

to_symmetric_function()

Compute the projection of an element of symmetric function in non-commuting variables to the symmetric functions.
The projection of a monomial symmetric function in non-commuting variables indexed by the set partition $A$ is defined as

$$m_A \mapsto m_{\lambda(A)} \prod_i n_i(\lambda(A))!$$

where $\lambda(A)$ is the partition associated with $A$ by taking the sizes of the parts and $n_i(\mu)$ is the multiplicity of $i$ in $\mu$. For other bases this map is extended linearly.

**OUTPUT:**
- an element of the symmetric functions in the monomial basis

**EXAMPLES:**

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: p = NCSym.p()
sage: cp = NCSym.cp()
sage: x = NCSym.x()
sage: m = NCSym.m()

sage: m[[1,3],[2]].to_symmetric_function()
m[2, 1]
sage: x[[1,3],[2]].to_symmetric_function()
-6*m[1, 1, 1] - 2*m[2, 1]

sage: e[[1,3],[2]].to_symmetric_function()
2*e[2, 1]

sage: h[[1,3],[2]].to_symmetric_function()
2*h[2, 1]

sage: p[[1,3],[2]].to_symmetric_function()
p[2, 1]
```

**to_wqsym()**
Return the image of `self` under the canonical inclusion map $NCSym \to WQSym$.

The canonical inclusion map $NCSym \to WQSym$ is an injective homomorphism of algebras. It sends a basis element $m_A$ of $NCSym$ to the sum of basis elements $M_P$ of $WQSym$, where $P$ ranges over all ordered set partitions that become $A$ when the ordering is forgotten. This map is denoted by $\theta$ in [BZ05] (17).

See also:
- `WordQuasiSymmetricFunctions` for a definition of $WQSym$.

**EXAMPLES:**

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: p = NCSym.p()
sage: cp = NCSym.cp()
sage: x = NCSym.x()
sage: m = NCSym.m()

sage: m[[1,3],[2]].to_wqsym()
M[{1, 3}, {2}] + M[{2}, {1, 3}]
sage: x[[1,3],[2]].to_wqsym()
-M[{1}, {2}, {3}] - M[{1}, {2, 3}] - M[{1}, {3}, {2}]
- M[{1, 2}, {3}] - M[{2}, {1}, {3}] - M[{2}, {3}, {1}]
- M[{2, 3}, {1}] - M[{3}, {1}, {2}] - M[{3}, {1, 2}]
- M[{3}, {2}, {1}]
sage: (4*p[[1,3],[2]]-p[[1]]).to_wqsym()
-M[{1}] + 4*M[{1, 2, 3}] + 4*M[{1, 3}, {2}] + 4*M[{2}, {1, 3}]```
class ParentMethods
    Bases: object

from_symmetric_function(f)
    Return the image of the symmetric function f in self.

    This is performed by converting to the monomial basis and extending the method sum_of_partitions() linearly. This is a linear map from the symmetric functions to the symmetric functions in non-commuting variables that does not preserve the product or coproduct structure of the Hopf algebra.

See also:

    to_symmetric_function()

INPUT:
    • f – a symmetric function

OUTPUT:
    • an element of self

EXAMPLES:

    sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
    sage: Sym = SymmetricFunctions(QQ)
    sage: e = NCSym.e()
    sage: elem = Sym.e()
    sage: elt = e.from_symmetric_function(elem[2,1,1]); elt
    1/12*e{{1}, {2}, {3, 4}} + 1/12*e{{1}, {2, 3}, {4}} + 1/12*e{{1}, {2, 4}, →{3}}
    + 1/12*e{{1, 2}, {3}, {4}} + 1/12*e{{1, 3}, {2}, {4}} + 1/12*e{{1, 4}, →{2}, {3}}
    sage: elem(elt.to_symmetric_function())
    e[2, 1, 1]

    sage: e.from_symmetric_function(elem[4])
    1/24*e((1, 2, 3, 4))

    sage: p = NCSym.p()
    sage: pow = Sym.p()
    sage: elt = p.from_symmetric_function(pow[2,1,1]); elt
    1/6*p((1), (2), (3, 4)) + 1/6*p((1), (2, 3), (4)) + 1/6*p((1), (2, 4), (3) →)
    + 1/6*p((1, 2), (3), (4)) + 1/6*p((1, 3), (2), (4)) + 1/6*p((1, 4), (2), →{3})
    sage: pow(elt.to_symmetric_function())
    p[2, 1, 1]

    sage: p.from_symmetric_function(pow[4])
    p((1, 2, 3, 4))

    sage: h = NCSym.h()
    sage: comp = Sym.complete()
    sage: elt = h.from_symmetric_function(comp[2,1,1]); elt
    1/12*h((1), (2), (3, 4)) + 1/12*h((1), (2, 3), (4)) + 1/12*h((1), (2, 4), →{3})
    + 1/12*h((1, 2), (3), (4)) + 1/12*h((1, 3), (2), (4)) + 1/12*h((1, 4), →{2}, {3})
    sage: comp(elt.to_symmetric_function())
    h[2, 1, 1]

    sage: h.from_symmetric_function(comp[4])
    1/24*h((1, 2, 3, 4))

internal_coproduct()
    Compute the internal coproduct of self.
If `internal_coproduct_on_basis()` is available, construct the internal coproduct morphism from `self` to `self ⊗ self` by extending it by linearity. Otherwise, this uses `internal_coproduct_by_coercion()`, if available.

**OUTPUT:**
- an element of the tensor squared of `self`

**EXAMPLES:**

```python
sage: cp = SymmetricFunctionsNonCommutingVariables(QQ).cp()
sage: cp.internal_coproduct(cp[[1,3],[2]] - 2*cp[[1]])
-2*cp{{1}} # cp{{1}} + cp{{1, 2, 3}} # cp{{1, 3}, {2}} + cp{{1, 3}, {2}}
-# cp{{1, 2, 3}} + cp{{1, 3}, {2}} # cp{{1, 3}, {2}}
```

`internal_coproduct_by_coercion(x)`

Return the internal coproduct by coercing the element to the powersum basis.

**INPUT:**
- `x` – an element of `self`

**OUTPUT:**
- an element of the tensor squared of `self`

**EXAMPLES:**

```python
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: h[[1,3],[2]].internal_coproduct()
# indirect doctest
2*h{{1}, {2}, {3}} # h{{1}, {2}, {3}} - h{{1}, {2}, {3}} # h{{1, 3}, {2}}
- h{{1, 3}, {2}} # h{{1}, {2}, {3}} + h{{1, 3}, {2}} # h{{1, 3}, {2}}
```

`internal_coproduct_on_basis(i)`

The internal coproduct of the algebra on the basis (optional).

**INPUT:**
- `i` – the indices of an element of the basis of `self`

**OUTPUT:**
- an element of the tensor squared of `self`

**EXAMPLES:**

```python
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.internal_coproduct_on_basis(SetPartition([[1,2]]))
m{{1, 2}} # m{{1, 2}}
```

`primitive(A, i=1)`

Return the primitive associated to `A` in `self`.

**See also:**

`primitive()`

**INPUT:**
- `A` – a set partition
- `i` – a positive integer

**OUTPUT:**
- an element of `self`

**EXAMPLES:**

```python
sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
sage: elt = e.primitive(SetPartition([[1,3],[2]])); elt
e{{1, 2}, {3}} - e{{1, 3}, {2}}
```

(continues on next page)
sage: elt.coproduct()
e() # e({1, 2}, {3}) - e() # e({1, 3}, {2}) + e({1, 2}, {3}) # e() - e({1, 3}, {2}) # e()

super_categories()

Return the super categories of bases of the Hopf dual of the symmetric functions in non-commuting variables.

OUTPUT:

* a list of categories

class sage.combinat.ncsym.bases.NCSymBasis_abstract (R, basis_keys=None, element_class=None, category=None, prefix=None, names=None, **kwds)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_classBindableClass

Abstract base class for a basis of NCSym or its dual.

class sage.combinat.ncsym.bases.NCSymDualBases (parent_with_realization)

Bases: sage.categories.realizations.Category_realization_of_parent

Category of bases of dual symmetric functions in non-commuting variables.

EXAMPLES:

sage: from sage.combinat.ncsym.bases import NCSymDualBases
sage: DNCSym = SymmetricFunctionsNonCommutingVariables(QQ).dual()
sage: NCSymDualBases(DNCSym)
Category of bases of dual symmetric functions in non-commuting variables over the Rational Field

super_categories()

Return the super categories of bases of the Hopf dual of the symmetric functions in non-commuting variables.

OUTPUT:

* a list of categories

class sage.combinat.ncsym.bases.NCSymOrNCSymDualBases (parent_with_realization)

Bases: sage.categories.realizations.Category_realization_of_parent

Base category for the category of bases of symmetric functions in non-commuting variables or its Hopf dual for the common code.

class ElementMethods

Bases: object

duality_pairing (other)

Compute the pairing between self and an element other of the dual.

EXAMPLES:

sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: w = m.dual_basis()
sage: elt = m[[1,3],[2]] - 3*m([[1,2],[3]])
sage: elt.duality_pairing(w[[1,3],[2]])

(continues on next page)
class ParentMethods
Bases: object

counit_on_basis(A)
The counit is defined by sending all elements of positive degree to zero.

INPUT:
• A – a set partition

OUTPUT:
• either the 0 or the 1 of the base ring of self

EXAMPLES:

```python
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.counit_on_basis(SetPartition([[1,3], [2]]))
0
sage: m.counit_on_basis(SetPartition([]))
1
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.counit_on_basis(SetPartition([[1,3], [2]]))
0
sage: w.counit_on_basis(SetPartition([]))
1
```

duality_pairing(x, y)
Compute the pairing between an element of self and an element of the dual.

Carry out this computation by converting x to the m basis and y to the w basis.

INPUT:
• x – an element of symmetric functions in non-commuting variables
• y – an element of the dual of symmetric functions in non-commuting variables

OUTPUT:
• an element of the base ring of self

EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: h = NCSym.h()
sage: w = NCSym.m().dual_basis()
sage: matrix([[h(A).duality_pairing(w(B)) for A in SetPartitions(3)] for B in SetPartitions(3)])
[6 2 2 2 1]
[2 2 1 1 1]
[2 1 2 1 1]
[2 1 1 2 1]
[1 1 1 1 1]
sage: (h([[1,2],[3]]) + 3*h([[1,3],[2]])).duality_pairing(2*w([[1,3],[2]]) + w([[1,2,3]] + 2*w([[1,2],[3]]))
32
```
**duality_pairing_matrix**(basis, degree)

The matrix of scalar products between elements of \(NCSym\) and elements of \(NCSym^*\).

**INPUT:**
- basis – a basis of the dual Hopf algebra
- degree – a non-negative integer

**OUTPUT:**
- the matrix of scalar products between the basis self and the basis basis in the dual Hopf algebra of degree degree

**EXAMPLES:**
The matrix between the \(m\) basis and the \(w\) basis:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: w = NCSym.dual().w()
sage: m.duality_pairing_matrix(w, 3)
[[0 0 0 0]
 [1 0 0 0]
 [0 1 0 0]
 [0 0 1 0]
 [0 0 0 1]]
```

Similarly for some of the other basis of \(NCSym\) and the \(w\) basis:

```
sage: e = NCSym.e()
sage: e.duality_pairing_matrix(w, 3)
[[0 0 0 1]
 [0 0 1 1]
 [0 1 0 1]
 [0 1 1 0]
 [1 1 0 1]]
sage: p = NCSym.p()
sage: p.duality_pairing_matrix(w, 3)
[[0 0 0 0]
 [1 0 0 0]
 [1 0 1 0]
 [0 0 1 0]
 [0 1 1 1]]
sage: cp = NCSym.cp()
sage: cp.duality_pairing_matrix(w, 3)
[[0 0 0 0]
 [1 1 0 0]
 [0 0 1 0]
 [1 1 1 1]
 [1 1 1 1]]
sage: x = NCSym.x()
sage: w.duality_pairing_matrix(x, 3)
[[0 0 0 1]
 [1 0 -1 -1]
 [1 -1 0 -1]
 [1 -1 -1 0]
 [2 -1 -1 -1]]
```

A base case test:

```
sage: m.duality_pairing_matrix(w, 0)
[[1]]
```
one_basis()
Return the index of the basis element containing 1.

OUTPUT:
• The empty set partition

EXAMPLES:

Super_categories()
Return the super categories of bases of (the Hopf dual of) the symmetric functions in non-commuting variables.

OUTPUT:
• a list of categories

5.1.153 Dual Symmetric Functions in Non-Commuting Variables

AUTHORS:
• Travis Scrimshaw (08-04-2013): Initial version

class sage.combinat.ncsym.dual.SymmetricFunctionsNonCommutingVariablesDual(R)
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The Hopf dual to the symmetric functions in non-commuting variables.
See Section 2.3 of [BZ05] for a study.

a_realization()
Return the realization of the \( w \) basis of \( \text{self} \).

EXAMPLES:

Dual()
Return the dual Hopf algebra of the dual symmetric functions in non-commuting variables.

EXAMPLES:

class w(NCSymD)
Bases: sage.combinat.ncsym.bases.NCSymBasis_abstract

The Hopf algebra of symmetric functions in non-commuting variables in the \( w \) basis.

EXAMPLES:
We have the embedding $\chi^*$ of $Sym$ into $NCSym^*$ available as a coercion:

```python
sage: h = SymmetricFunctions(QQ).h()
sage: w(h[[2,1]])
w({1}, {2, 3}) + w({1, 2}, {3}) + w({1, 3}, {2})
```

Similarly we can pull back when we are in the image of $\chi^*$:

```python
sage: elt = 3*(w[[1],[2,3]] + w[[1,2],[3]] + w[[1,3],[2]])
sage: h(elt)
3*h[[2, 1]]
```

class Element

Bases: `sage.modules.with_basis.indexed_element.IndexedFreeModuleElement`

An element in the $w$ basis.

```python
expand(n, letter='x')
```

Expand self written in the $w$ basis in $n^2$ commuting variables which satisfy the relation $x_{ij}x_{ik} = 0$ for all $i, j, k$.

The expansion of an element of the $w$ basis is given by equations (26) and (55) in [HNT06].

The expansion is symmetric if it is in the image of $\chi^*$. That is to say we have:

$$f = \sum_{\lambda} c_{\lambda} \prod_i m_i(\lambda)! \sum_{\lambda(A) = \lambda} w_A$$

where the second sum is over all set partitions $A$ whose shape $\lambda(A)$ is equal to $\lambda$ and $m_i(\mu)$ is the multiplicity of $i$ in the partition $\mu$.
• True if \( \lambda(A) = \lambda(B) \) implies the coefficients of \( w_A \) and \( w_B \) are equal, False otherwise.

**EXAMPLES:**

```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: elt = w.sum_of_partitions([2,1,1])
sage: elt.is_symmetric()
True
sage: elt -= 3*w.sum_of_partitions([1,1])
sage: elt.is_symmetric()
True
```

**to_symmetric_function()**

Take a function in the \( w \) basis, and return its symmetric realization, when possible, expressed in the homogeneous basis of symmetric functions.

**OUTPUT:**

• If \( self \) is a symmetric function, then the expansion in the homogeneous basis of the symmetric functions is returned. Otherwise an error is raised.

**EXAMPLES:**

```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: elt = w[[1], [2,3]] + w[[1,2], [3]] + w[[1,3], [2]]
sage: elt.to_symmetric_function()
h[2, 1]
sage: elt = w.sum_of_partitions([2,1,1]) / 2
sage: elt.to_symmetric_function()
1/2*h[2, 1, 1]
```

**antipode_on_basis\( (A) \)**

Return the antipode applied to the basis element indexed by \( A \).

**INPUT:**

• \( A \) – a set partition

**OUTPUT:**

• an element in the basis \( self \)

**EXAMPLES:**

```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: elt = w[[1], [2,3]] + w[[1,2], [3]] + w[[1,3], [2]]
sage: elt.antipode()
-3*w[[1], [2], [3]] + w[[1, 2], [3]] + w[[1, 3], [2]]
sage: F = w[[1,3],[5],[2,4]].coproduct()
sage: F.apply_multilinear_morphism(lambda x,y: x.antipode()*y)
0
```

**coproduct_on_basis\( (A) \)**

Return the coproduct of a \( w \) basis element.

The coproduct on the basis element \( w_A \) is the sum over tensor product terms \( w_B \otimes w_C \) where \( B \) is the restriction of \( A \) to \{1, 2, \ldots, k\} and \( C \) is the restriction of \( A \) to \{k + 1, k + 2, \ldots, n\}. 

1420 Chapter 5. Comprehensive Module List
INPUT:
• A – a set partition

OUTPUT:
• The coproduct applied to the w dual symmetric function in non-commuting variables indexed by
  A expressed in the w basis.

EXAMPLES:
```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w[[1], [2,3]].coproduct()
w() # w([[1], [2, 3]]) + w({1}) # w({1, 2})
  + w({1}, [2]) # w({1}) + w({1}, [2, 3]) # w()
sage: w.coproduct_on_basis(SetPartition([]))
w{} # w({})
```

dual_basis()
Return the dual basis to the w basis.

The dual basis to the w basis is the monomial basis of the symmetric functions in non-commuting
variables.

OUTPUT:
• the monomial basis of the symmetric functions in non-commuting variables

EXAMPLES:
```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.dual_basis()
Symmetric functions in non-commuting variables over the Rational Field in
  the monomial basis
```
duality_pairing(x, y)
Compute the pairing between an element of self and an element of the dual.

INPUT:
• x – an element of the dual of symmetric functions in non-commuting variables
• y – an element of the symmetric functions in non-commuting variables

OUTPUT:
• an element of the base ring of self

EXAMPLES:
```
sage: DNCSym = SymmetricFunctionsNonCommutingVariablesDual(QQ)
sage: w = DNCSym.w()
sage: m = w.dual_basis()
sage: matrix([[w(A).duality_pairing(m(B)) for A in SetPartitions(3)] for
  B in SetPartitions(3)])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
sage: (w([[1,2],[3]]) + 3*w([[1,3],[2]])).duality_pairing(2*m([[1,3],[2]]) +
  m([[1,2,3]]) + 2*m([[1,2],[3]])
8
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: matrix([[w(A).duality_pairing(h(B)) for A in SetPartitions(3)] for
  B in SetPartitions(3)])
[6 2 2 2 1]
[2 2 1 1 1]
[2 1 2 1 1]
```

(continues on next page)
The product on \(w\) basis elements.

The product on the \(w\) is the dual to the coproduct on the \(m\) basis. On the basis \(w\) it is defined as

\[
\left( w_A w_B \right)_S = \sum_{S \subseteq \{1, \ldots, n\}} w_{A^S B^c} S
\]

where the sum is over all possible subsets \(S\) of \([n]\) such that \(|S| = |A|\) with a term indexed the union of \(A^S\) and \(B^c\). The notation \(A^S\) represents the unique set partition of the set \(S\) such that the standardization is \(A\). This product is commutative.

INPUT:
• \(A, B\) – set partitions

OUTPUT:
• an element of the \(w\) basis

EXAMPLES:

```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: A = SetPartition([[1], [2, 3]])
sage: B = SetPartition([[1, 2, 3]])
sage: w.product_on_basis(A, B)
3*w{{1}, {2}, {3}, {4}, {5, 6}} + 2*w{{1}, {2}, {3, 4}, {5}}
+ 2*w{{1}, {2}, {3, 5}, {4}} + w{{1}, {2, 3}, {4}, {5}}
+ w{{1}, {2, 4}, {3}, {5, 6}} + w{{1}, {2, 5}, {3}, {4, 6}}
+ w{{1}, {2, 6}, {3}, {4, 5}} + w{{1}, {3}, {2}, {4, 5}}
+ w{{1}, {3, 4}, {2}, {5, 6}} + w{{1}, {3, 5}, {2}, {4}}
+ w{{1}, {3, 6}, {2}, {4, 5}} + w{{1}, {5, 6}, {2}, {3}}
+ w{{1}, {4, 6}, {2}, {3, 5}} + w{{1}, {5, 6}, {2}, {3, 4}}
```

\( \text{sum_of_partitions}(la) \)

Return the sum over all sets partitions whose shape is \(la\), scaled by \(\prod_i m_i!\) where \(m_i\) is the multiplicity of \(i\) in \(la\).

INPUT:
• \(la\) – an integer partition

OUTPUT:
• an element of \(self\)

EXAMPLES:

```python
sage: sum_of_partitions([1, 1, 2, 1, 1, 1])
```

```python
sage: sum_of_partitions([1, 1, 2, 1])
```

```python
sage: sum_of_partitions([2, 1, 1, 2, 1])
```
```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.sum_of_partitions([2,1,1])
2*w{1} + 2*w{2, 3} + 2*w{2, 4} + 2*w{1, 2} + 2*w{1, 3} + 2*w{1, 4}
```

\textbf{to\_symmetric\_function()}

The preimage of $\chi^*$ in the $w$ basis.

\textbf{EXAMPLES:}

```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.to_symmetric_function
Generic morphism:
  From: Dual symmetric functions in non-commuting variables over the Rational Field in the w basis
  To: Symmetric Functions over Rational Field in the homogeneous basis
```

5.1.154 \textbf{Symmetric Functions in Non-Commuting Variables}

\textbf{AUTHORS:}

- Travis Scrimshaw (08-04-2013): Initial version

\textbf{class} \texttt{sage.combinat.ncsym.ncsym.SymmetricFunctionsNonCommutingVariables}(R)

\textbf{Bases:} \texttt{sage.structure.unique_representation.UniqueRepresentation}, \texttt{sage.structure.parent.Parent}

Symmetric functions in non-commutative variables.

The ring of symmetric functions in non-commutative variables, which is not to be confused with the \textit{non-commutative symmetric functions}, is the ring of all bounded-degree noncommutative power series in countably many indeterminates (i.e., elements in $R\langle\langle x_1, x_2, x_3, \ldots \rangle\rangle$ of bounded degree) which are invariant with respect to the action of the symmetric group $S_\infty$ on the indices of the indeterminates. It can be regarded as a direct limit over all $n \to \infty$ of rings of $S_n$-invariant polynomials in $n$ non-commuting variables (that is, $S_n$-invariant elements of $R\langle x_1, x_2, \ldots, x_n \rangle$).

This ring is implemented as a Hopf algebra whose basis elements are indexed by set partitions.

Let $A = \{A_1, A_2, \ldots, A_r\}$ be a set partition of the integers $[k] := \{1, 2, \ldots, k\}$. This partition $A$ determines an equivalence relation $\sim_A$ on $[k]$, which has $c \sim_A d$ if and only if $c$ and $d$ are in the same part $A_j$ of $A$. The monomial basis element $m_A$ indexed by $A$ is the sum of monomials $x_{i_1} x_{i_2} \cdots x_{i_k}$ such that $i_c = i_d$ if and only if $c \sim_A d$.

The $k$-th graded component of the ring of symmetric functions in non-commutative variables has its dimension equal to the number of set partitions of $[k]$. (If we work, instead, with finitely many -- say, $n$ -- variables, then its dimension is equal to the number of set partitions of $[k]$ where the number of parts is at most $n$.)

\textbf{Note:} All set partitions are considered standard (i.e., set partitions of $[n]$ for some $n$) unless otherwise stated.

\textbf{REFERENCES:}

\textbf{EXAMPLES:}

We begin by first creating the ring of \textit{NCSym} and the bases that are analogues of the usual symmetric functions:
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: p = NCSym.p()
sage: m
Symmetric functions in non-commuting variables over the Rational Field in the monomial basis

The basis is indexed by set partitions, so we create a few elements and convert them between these bases:

sage: elt = m(SetPartition([[1,3],[2]])) - 2*m(SetPartition([[1],[2]])); elt
-2*m{1, 2} + m{1, 3} + m{2}

sage: e(elt)
1/2*e{1, 3} - 2*e{1, 2} + 1/2*e{2} + 1/2*e{1, 2, 3} - 1/2*e{1, 3, 2}

sage: h(elt)
-4*h{1, 2} - 2*h{1} + 1/2*h{1, 2, 3} + 2*h{1, 3} - 1/2*h{2} + 3/2*h{1, 3, 2}

sage: p(elt)
-2*p{1, 2} + 2*p{1} + p{1, 3} - 4*p{1, 2, 3} + p{2} + p{1, 2, 3}

There is also a shorthand for creating elements. We note that we must use p[[]] to create the empty set partition due to python’s syntax.

sage: eltm = m[[1,3],[2]] - 3*m[[1],[2]]; eltm
-3*m{1, 2} + m{1, 3} + m{2}

sage: elte = e[[1,3],[2]]; elte
e{1, 3} + e{1, 2} + e{1, 2, 3} + e{2}

sage: elth = h[[1,3],[2]]; elth
h{1, 2} + h{1} + h{1, 2, 3} + h{2} + h{1, 3}

There is also a natural projection to the usual symmetric functions by letting the variables commute. This projection map preserves the product and coproduct structure. We check that Theorem 2.1 of [RS06] holds:

sage: Sym = SymmetricFunctions(QQ)
sage: Sm = Sym.m()
sage: Se = Sym.e()
sage: Sh = Sym.h()
sage: Sp = Sym.p()

sage: eltm.to_symmetric_function()
-6*m{1, 2} + m{1, 3} + m{2} + m{2, 1}
<table>
<thead>
<tr>
<th>sage:</th>
<th>Sm(p(eltm).to_symmetric_function())</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

**a_realization()**

Return the realization of the powersum basis of `self`.

**OUTPUT:**

- The powersum basis of symmetric functions in non-commuting variables.

**EXAMPLES:**

```python
sage: SymmetricFunctionsNonCommutingVariables(QQ).a_realization()
Symmetric functions in non-commuting variables over the Rational Field in the powersum basis
```

**chi**

alias of `SymmetricFunctionsNonCommutingVariables.supercharacter`

**class coarse_powersum (NCSym)**

Bases: `sage.combinat.ncsym.bases.NCSymBasis_abstract`

The Hopf algebra of symmetric functions in non-commuting variables in the `cp` basis.

This basis was defined in [BZ05] as

\[ cp_A = \sum_{A \leq B} m_B, \]

where we sum over all strict coarsenings of the set partition `A`. An alternative description of this basis was given in [BT13] as

\[ cp_A = \sum_{A \subseteq B} m_B, \]

where we sum over all set partitions whose arcs are a subset of the arcs of the set partition `A`.

**Note:** In [BZ05], this basis was denoted by `q`. In [BT13], this basis was called the powersum basis and denoted by `p`. However it is a coarser basis than the usual powersum basis in the sense that it does not yield the usual powersum basis of the symmetric function under the natural map of letting the variables commute.

**EXAMPLES:**
```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: cp = NCSym.cp()
sage: cp[[1,3],[2,4]]*cp[[1,2,3]]
cp{{1, 3}, {2, 4}} # cp{{1, 2}, {3}}
sage: cp = SymmetricFunctions(NCSym.base_ring()).cp()
```

```python
sage: cp[[1,2],[3]] . internal_coproduct()
cp{{1, 2}, {3}} # cp{{1, 2}, {3}}
sage: ps = SymmetricFunctions(NCSym.base_ring()).p()
sage: ps(cp[[1,3],[2]].to_symmetric_function())
sage: ps(cp[[1,2],[3]].to_symmetric_function())
p[2, 1]
```

### cp

alias of `SymmetricFunctionsNonCommutingVariables.coarse_powersum`

```python
class deformed_coarse_powersum (NCSym, q=2)
Bases: sage.combinat.ncsym.bases.NCSymBasis_abstract
```

The Hopf algebra of symmetric functions in non-commuting variables in the \( \rho \) basis.

This basis was defined in [BT13] as a \( q \)-deformation of the \( \text{cp} \) basis:

\[
\rho_A = \sum_{A \subseteq B} \frac{1}{q^{n_A n_B}} m_B,
\]

where we sum over all set partitions whose arcs are a subset of the arcs of the set partition \( A \).

**INPUT:**

- \( q \) – (default: 2) the parameter \( q \)

**EXAMPLES:**

```python
sage: R = QQ['q'].fraction_field()
sage: q = R.gen()
sage: NCSym = SymmetricFunctionsNonCommutingVariables(R)
sage: rho = NCSym.rho(q)
```

We construct Example 3.1 in [BT13]:

```python
sage: rnode = lambda A: sorted([a[1] for a in A.arcs()], reverse=True)
sage: dimv = lambda A: sorted([-a[0] for a in A.arcs()], reverse=True)
sage: lst = list(SetPartitions(4))
sage: S = sorted(lst, key=lambda A: (dimv(A), rnode(A)))
sage: m = NCSym.m()
sage: matrix([[m(rho[A])[B] for B in S] for A in S])
```

(continues on next page)
Return the deformation parameter $q$ of self.

EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: rho = NCSym.rho(5)
sage: rho.q()
5
sage: R = QQ['q'].fraction_field()
sage: q = R.gen()
sage: NCSym = SymmetricFunctionsNonCommutingVariables(R)
sage: rho = NCSym.rho(q)
sage: rho.q() == q
True
```

dual()  
Return the dual Hopf algebra of the symmetric functions in non-commuting variables.

EXAMPLES:

```python
sage: SymmetricFunctionsNonCommutingVariables(QQ).dual()
Dual symmetric functions in non-commuting variables over the Rational Field
```

e
alias of `SymmetricFunctionsNonCommutingVariables.elementary`

class elementary(NCSym)

Bases: `sage.combinat.ncsym.bases.NCSymBasis_abstract`

The Hopf algebra of symmetric functions in non-commuting variables in the elementary basis.

EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
```

class Element

Bases: `sage.modules.with_basis.indexed_element.IndexedFreeModuleElement`

An element in the elementary basis of `NCSym`.

omega()  
Return the involution $\omega$ applied to self.

The involution $\omega$ on `NCSym` is defined by $\omega(e_A) = h_A$.

OUTPUT:
• an element in the basis self

EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
sage: h = NCSym.h()
```
```python
sage: elt = e[[1,3],[2]].omega(); elt
2*e{{1}, {2}, {3}} - e{{1, 3}, {2}}
sage: elt.omega()
e{{1, 3}, {2}}
sage: h(elt)
h({{1, 3}, {2}})
```

to_symmetric_function()

The projection of self to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the e basis, and return the projection of expressed in the elementary basis of symmetric functions.

The map \( \chi: NCSym \rightarrow Sym \) is given by

\[
\text{e}_A \mapsto e_{\lambda(A)} \prod_i \lambda(A)_i!
\]

where \( \lambda(A) \) is the partition associated with \( A \) by taking the sizes of the parts.

**OUTPUT:**
- An element of the symmetric functions in the elementary basis

**EXAMPLES:**

```python
sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
sage: e[[1,3],[2]].to_symmetric_function()
2*e[2, 1]
sage: e[[1],[3],[2]].to_symmetric_function()
e[1, 1, 1]
```

```
h
```

alias of SymmetricFunctionsNonCommutingVariables.homogeneous

class homogeneous (NCSym)

The Hopf algebra of symmetric functions in non-commuting variables in the homogeneous basis.

**EXAMPLES:**

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: h = NCSym.h()
sage: h[[1,3],[2,4]]*h[[1,2,3]]
h{{1, 3}, {2, 4}, {5, 6, 7}}
sage: h[[1,2]].coproduct()
h() # h({1, 2}) + 2*h({1}) # h({1}) + h({1, 2}) # h()
```

class Element

Bases: sage.modules.with_basis.indexed_element.

An element in the homogeneous basis of NCSym.

**omega()**

Return the involution \( \omega \) applied to self.

The involution \( \omega \) on NCSym is defined by \( \omega(h_A) = e_A \).

**OUTPUT:**
- an element in the basis self
EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: h = NCSym.h()
sage: e = NCSym.e()
sage: elt = h[[1,3],[2]].omega(); elt
2*h{{1}, {2}, {3}} - h{{1, 3}, {2}}
sage: elt.omega()
h{{1, 3}, {2}}
sage: e(elt)
e{{1, 3}, {2}}
```

```
to_symmetric_function()
```

The projection of `self` to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the `h` basis, and return the projection of expressed in the complete basis of symmetric functions.

The map \( \chi : NCSym \rightarrow Sym \) is given by

\[
h_A \mapsto h_{\lambda(A)} \prod_i \lambda(A)_i!
\]

where \( \lambda(A) \) is the partition associated with \( A \) by taking the sizes of the parts.

OUTPUT:
• An element of the symmetric functions in the complete basis

EXAMPLES:

```python
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: h[[1,3],[2]].to_symmetric_function()
2*h[2, 1]
sage: h[[1],[3],[2]].to_symmetric_function()
h[1, 1, 1]
```

```
m
d alias of SymmetricFunctionsNonCommutingVariables.monomial
```

class monomial(NCSym)

Bases: sage.combinat.ncsym.bases.NCSymBasis_abstract

The Hopf algebra of symmetric functions in non-commuting variables in the monomial basis.

EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: m[[1,3],[2]]*m[[1,2]]
m{{1, 3}, {2}, {4, 5}} + m{{1, 3}, {2}, {4, 5}, {2}}
sage: m[[1,3],[2]].coproduct()
m{} # m{{1, 3}, {2}} + m{{1}} # m{{1, 2}} + m{{1, 2}} # m{{1}} + m{{1, 3}, {2}} # m{}
```

class Element

Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

An element in the monomial basis of `NCSym`.

```
expand(n, alphabet='x')
```

Expand `self` written in the monomial basis in `n` non-commuting variables.
INPUT:
- n – an integer
- alphabet – (default: 'x') a string

OUTPUT:
- The symmetric function of self expressed in the n non-commuting variables described by alphabet.

EXAMPLES:

```sage
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: m[[1,3],[2]].expand(4)
x0*x1*x0 + x0*x2*x0 + x0*x3*x0 + x1*x0*x1 + x1*x2*x1 + x1*x3*x1 + x2*x0*x2 + x2*x1*x2 + x2*x3*x2 + x3*x0*x3 + x3*x1*x3 + x3*x2*x3
```

One can use a different set of variables by using the optional argument alphabet:

```sage
sage: m[[1],[2,3]].expand(3, alphabet='y')
y0*y1^2 + y0*y2^2 + y1*y0^2 + y1*y2^2 + y2*y0^2 + y2*y1^2
```

to_symmetric_function()
The projection of self to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the m basis, and return the projection of expressed in the monomial basis of symmetric functions.

The map $\chi: \text{NCSym} \rightarrow \text{Sym}$ is defined by

$$m_A \mapsto m_{\lambda(A)} \prod_i n_i(\lambda(A))!$$

where $\lambda(A)$ is the partition associated with $A$ by taking the sizes of the parts and $n_i(\mu)$ is the multiplicity of $i$ in $\mu$.

OUTPUT:
- an element of the symmetric functions in the monomial basis

EXAMPLES:

```sage
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: m[[1,3],[2]].to_symmetric_function()
m[2, 1]
sage: m[[1],[3],[2]].to_symmetric_function()
6*m[1, 1, 1]
```

coproduct_on_basis(A)
Return the coproduct of a monomial basis element.

INPUT:
- A – a set partition

OUTPUT:
- The coproduct applied to the monomial symmetric function in non-commuting variables indexed by A expressed in the monomial basis.

EXAMPLES:

```sage
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: m[[1, 3], [2]].coproduct()
m() # m((1, 3), (2)) + m((1)) # m((1, 2)) + m((1, 2)) # m((1)) + m((1, 3), (2)) # m()
sage: m.coproduct_on_basis(SetPartition([]))
m() # m()
```
sage: m.coproduct_on_basis(SetPartition([[1, 2, 3]]))
m() # m({1, 2, 3}) + m({1, 2, 3}) # m()
sage: m[[1, 5], [2, 4], [3, 7], [6]].coproduct()
m() # m({1, 5}, {2, 4}, {3, 7}, {6}) + m({1, 5}) # m({1, 5}, {2, 4}, {3, 6})
    + 2*m({1, 2}) # m({1, 3}, {2, 5}, {4}) + m({1, 2}) # m({1, 4}, {2, 3},
    →{5})
    + 2*m({1, 2}, {3}) # m({1, 3}, {2, 4}) + m({1, 3}, {2}) # m({1, 4}, {2, 3},
    →{3})
    + 2*m({1, 3}, {2, 4}) # m({1, 2}, {3}) + 2*m({1, 3}, {2, 5}, {4}) # m({1, 2},
    →{2})
    + m({1, 4}, {2, 3}) # m({1, 3}, {2}) + m({1, 4}, {2, 3}, {5}) # m({1, 2})
    + m({1, 5}, {2, 4}, {3, 6}) # m({1, 3}) + m({1, 5}, {2, 4}, {3, 7}, {6}) # m
    →{2})

\textbf{dual\_basis()}

Return the dual basis to the monomial basis.

\textbf{OUTPUT:}

• the \textit{w} basis of the dual Hopf algebra

\textbf{EXAMPLES:}

\begin{verbatim}
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.dual_basis()
Dual symmetric functions in non-commuting variables over the Rational
  Field in the \textit{w} basis
\end{verbatim}

\textbf{duality\_pairing}(x, y)

Compute the pairing between an element of self and an element of the dual.

\textbf{INPUT:}

• \textit{x} – an element of symmetric functions in non-commuting variables
• \textit{y} – an element of the dual of symmetric functions in non-commuting variables

\textbf{OUTPUT:}

• an element of the base ring of self

\textbf{EXAMPLES:}

\begin{verbatim}
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: w = m.dual_basis()
sage: matrix([[m(A).duality_pairing(w(B)) for A in SetPartitions(3)] for
\  \ B in SetPartitions(3))]
\end{verbatim}

\begin{verbatim}
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
sage: (m[[1, 2], [3]] + 3*m[[1, 3], [2]]).duality_pairing(2*w[[1, 3], [2]] +
\  \ 2*w[[1, 2, 3]] + 2*w[[1, 2], [3]])
\end{verbatim}

\textbf{from\_symmetric\_function}(f)

Return the image of the symmetric function \textit{f} in self.

This is performed by converting to the monomial basis and extending the method
\textit{sum\_of\_partitions()} linearly. This is a linear map from the symmetric functions to the
symmetric functions in non-commuting variables that does not preserve the product or coproduct
structure of the Hopf algebra.

\section{5.1. Comprehensive Module list}
See also:

\texttt{to_symmetric_function()}

INPUT:
• \(f\) – an element of the symmetric functions

OUTPUT:
• An element of the \(m\) basis

EXAMPLES:

```python
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: mon = SymmetricFunctions(QQ).m()
sage: elt = m.from_symmetric_function(mon[[2,1,1]]); elt
1/12*m{{1}, {2}, {3, 4}} + 1/12*m{{1}, {2, 3}, {4}} + 1/12*m{{1}, {2, 4}, →{3}}
+ 1/12*m{{1, 2}, {3}, {4}} + 1/12*m{{1, 3}, {2}, {4}} + 1/12*m{{1, 4}, →{2}, {3}}
sage: elt.to_symmetric_function()
```

```python
m[[2, 1, 1]]
```

```python
e = SymmetricFunctionsNonCommutingVariables(QQ).e()
e = e(m.from_symmetric_function(elm[[4]]))
e = 1/24*e({1, 2, 3, 4})
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
```

```python
h = h(m.from_symmetric_function(hom[[4]]))
```

```python
h = h({1, 2, 3, 4})
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).p()
sage: pow = SymmetricFunctions(QQ).p()
sage: p = p(m.from_symmetric_function(pow[[4]]))
p({1, 2, 3, 4})
```

```python
p = p(m.from_symmetric_function(pow[[2,1]]))
p = p({1, 2, 3, 4}) + 1/3*p({1, 2}, {3}) + 1/3*p({1, 3}, {2})
sage: p([[1,2]]*p([[1]])
```

Check that \(\chi \circ \overline{\chi}\) is the identity on \(Sym\):

```python
sage: all(m.from_symmetric_function(pow(la)).to_symmetric_function() ==
....: pow(la)
True
```

internal\texttt{coproduct_on_basis}(A)

Return the internal coproduct of a monomial basis element.

The internal coproduct is defined by

\[
\Delta^\otimes(m_A) = \sum_{B \cap C = A} m_B \otimes m_C
\]

where we sum over all pairs of set partitions \(B\) and \(C\) whose infimum is \(A\).

INPUT:
• \(A\) – a set partition

OUTPUT:
• an element of the tensor square of the \(m\) basis

EXAMPLES:
```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: m.internal_coproduct_on_basis(SetPartition([[1,3],[2]]))
m{{{1, 2, 3}} # m{{1, 3}, {2}} + m{{1, 3}, {2}} # m{{1, 2, 3}} + m{{1, 3}, {2}} # m{{1, 3}, {2}}}
```

**product_on_basis** \((A, B)\)

The product on monomial basis elements.

The product of the basis elements indexed by two set partitions \(A\) and \(B\) is the sum of the basis elements indexed by set partitions \(C\) such that \(C \wedge (\{n\} \mid \{k\}) = A \mid B\) where \(n = |A|\) and \(k = |B|\). Here \(A \wedge B\) is the infimum of \(A\) and \(B\) and \(A \mid B\) is the \texttt{SetPartition.pipe()} operation. Equivalently we can describe all \(C\) as matchings between the parts of \(A\) and \(B\) where if \(a \in A\) is matched with \(b \in B\), we take \(a \cup b\) instead of \(a\) and \(b\) in \(C\).

**INPUT:**
- \(A, B\) – set partitions

**OUTPUT:**
- an element of the \(m\) basis

**EXAMPLES:**
```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: A = SetPartition([[1], [2,3]])
sage: B = SetPartition([[1], [3], [2,4]])
sage: m.product_on_basis(A, B)
m{{1}, {2, 3}, {4}, {5}, {6}} + m{{1}, {2, 3, 4}, {5}, {6}} + m{{1}, {2, 3, 5}, {4}, {6}} + m{{1}, {2, 3, 6}, {4}, {5}} + m{{1}, {2, 3, 4}, {5}, {6}} + m{{1}, {2, 3, 5}, {4}, {6}} + m{{1}, {2, 3, 6}, {4}, {5}} + m{{1}, {2, 3, 4}, {5}, {6}}
sage: B = SetPartition([[1], [2]])
sage: m.product_on_basis(A, B)
m{{1}, {2, 3}, {4}, {5}} + m{{1}, {2, 3, 4}, {5}} + m{{1}, {2, 3, 5}, {4}} + m{{1}, {2, 3, 6}, {4}}
sage: m.product_on_basis(A, SetPartition([]))
m{{1}, {2, 3}}
```

**sum_of_partitions** \((\lambda)\)

Return the sum over all set partitions whose shape is \(\lambda\) with a fixed coefficient \(C\) defined below.

Fix a partition \(\lambda\), we define \(\lambda! := \prod_i \lambda_i!\) and \(\lambda^! := \prod_i m_i!\). Recall that \(|\lambda| = \sum_i \lambda_i\) and \(m_i\) is the number of parts of length \(i\) of \(\lambda\). Thus we defined the coefficient as

\[
C := \frac{\lambda! \lambda^!}{|\lambda|!}
\]

Hence we can define a lift \(\bar{\chi}\) from \(\text{Sym}\) to \(\text{NCSym}\) by

\[
m_\lambda \mapsto C \sum_A m_A
\]

where the sum is over all set partitions whose shape is \(\lambda\).

**INPUT:**
- \(\lambda\) – an integer partition

**OUTPUT:**
- an element of the \(m\) basis
EXAMPLES:

```python
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.sum_of_partitions(Partition([2,1,1]))
1/12*m{{1}, {2}, {3, 4}} + 1/12*m{{1}, {2, 3}, {4}} + 1/12*m{{1}, {2, 4}, {3}}
+ 1/12*m{{1, 2}, {3}, {4}} + 1/12*m{{1, 3}, {2}, {4}} + 1/12*m{{1, 4}, {2}, {3}}
```

\[ p \]

alias of `SymmetricFunctionsNonCommutingVariables.powersum`

class powersum(NCSym)

Bases: `sage.combinat.ncsym.bases.NCSymBasis_abstract`

The Hopf algebra of symmetric functions in non-commuting variables in the powersum basis.

The powersum basis is given by

\[ p_A = \sum_{A \leq B} m_B, \]

where we sum over all coarsenings of the set partition \( A \). If we allow our variables to commute, then \( p_A \) goes to the usual powersum symmetric function \( p_\lambda \) whose (integer) partition \( \lambda \) is the shape of \( A \).

EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: p = NCSym.p()
sage: x = p.an_element()**2; x
4*p{} + 8*p{{1}} + 4*p{{1}, {2}} + 6*p{{1}, {2, 3}}
+ 12*p{{1, 2}} + 6*p{{1, 2}, {3}} + 9*p{{1, 2}, {3, 4}}
```

class Element

Bases: `sage.modules.with_basis.indexed_element.IndexedFreeModuleElement`

An element in the powersum basis of `NCSym`.

to_symmetric_function()

The projection of `self` to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the \( p \) basis, and return the projection of expressed in the powersum basis of symmetric functions.

The map \( \chi: NCSym \rightarrow Sym \) is given by

\[ p_A \mapsto p_{\lambda(A)} \]

where \( \lambda(A) \) is the partition associated with \( A \) by taking the sizes of the parts.

OUTPUT:

- an element of symmetric functions in the power sum basis

EXAMPLES:

```python
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).p()
sage: p[[1,3],[2]].to_symmetric_function()
```

(continues on next page)
antipode_on_basis($A$)
Return the result of the antipode applied to a powersum basis element.

Let $A$ be a set partition. The antipode given in [LM2011] is

$$S(p_A) = \sum_{\gamma} (-1)^{\ell(\gamma)} p_{\gamma[A]}$$

where we sum over all ordered set partitions (i.e. set compositions) of $[\ell(A)]$ and

$$\gamma[A] = A^\dagger_1 \cdots A^\dagger_{\ell(A)}$$

is the action of $\gamma$ on $A$ defined in $SetPartition.ordered_set_partition_action()$.

INPUT:
• $A$ – a set partition

OUTPUT:
• an element in the basis self

EXAMPLES:

```python
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: p.antipode_on_basis(SetPartition([[1], [2,3]]))
p{{1, 2}, {3}}
sage: p.antipode_on_basis(SetPartition([]))
p{}
```

coproduct_on_basis($A$)
Return the coproduct of a monomial basis element.

INPUT:
• $A$ – a set partition

OUTPUT:
• The coproduct applied to the monomial symmetric function in non-commuting variables indexed by $A$ expressed in the monomial basis.

EXAMPLES:

```python
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: p[1, 3].coproduct()
p{} # p{{1, 3}} + p{{1}} # p{{1, 2}} + p{{1, 2}} # p{{1}} + p{{1, 3}, –(2)} # p{}
sage: p.coproduct_on_basis(SetPartition([[]]))
p{} # p{{1}} + p{{1}} # p{}
sage: p.coproduct_on_basis(SetPartition([]))
p{} # p{}
```

internal_coproduct_on_basis($A$)
Return the internal coproduct of a powersum basis element.

The internal coproduct is defined by

$$\Delta^\circ(p_A) = p_A \otimes p_A$$
INPUT:
• A – a set partition
OUTPUT:
• an element of the tensor square of self
EXAMPLES:

```python
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: p.internal_coproduct_on_basis(SetPartition([[[1, 3], [2]]]))
p({{1, 3}, {2}}) # p({{1, 3}, {2}})
```

**primitive** *(A, i=1)*
Return the primitive associated to *A* in *self*.

Fix some *i* ∈ *S*. Let *A* be an atomic set partition of *S*, then the primitive *p(A)* given in [LM2011] is

\[ p(A) = \sum_{\gamma} (-1)^{f(\gamma)-1} p_{\gamma[A]} \]

where we sum over all ordered set partitions of \([f(A)]\) such that *i* ∈ \(\gamma_1\) and \(\gamma[A]\) is the action of \(\gamma\) on *A* defined in `SetPartition.ordered_set_partition_action()`. If *A* is not atomic, then *p(A) = 0*.

See also:
`SetPartition.is_atomic()`

**rho**
alias of `SymmetricFunctionsNonCommutingVariables.deformed_coarse_powersum`

**class supercharacter**(NCSym, q=2)
Bases: `sage.combinat.ncsym.bases.NCSymBasis_abstract`

The Hopf algebra of symmetric functions in non-commuting variables in the supercharacter \(\chi\) basis.

This basis was defined in [BT13] as a \(q\)-deformation of the supercharacter basis.

\[ \chi_A = \sum_B \chi_A(B) m_B, \]

where we sum over all set partitions *A* and \(\chi_A(B)\) is the evaluation of the supercharacter \(\chi_A\) on the superclass \(\mu_B\).
Note: The supercharacters considered in [BT13] are coarser than those considered by Aguiar et. al.

INPUT:

• \( q \) – (default: 2) the parameter \( q \)

EXAMPLES:

```python
sage: R = QQ['q'].fraction_field()
sage: q = R.gen()
sage: NCSym = SymmetricFunctionsNonCommutingVariables(R)
sage: chi = NCSym.chi(q)
sage: chi[[1,3],[2]]*chi[[[1,2]]]

```

```
chi({1, 3}, {2}, {4, 5})
```

```python
sage: chi2 = NCSym.chi()
sage: chi(chi2[[1,2],[3]])
```

```
((-q+2)/q)*chi{{1}, {2}, {3}} + 2/q*chi{{1, 2}, {3}}
```

```python
sage: x = NCSym.chi()
sage: x.q() == q
```

```
True
```

\( x \)

alias of SymmetricFunctionsNonCommutingVariables.x_basis

class x_basis(NCSym)

Bases: sage.combinat.ncsym.bases.NSymBasis_abstract

The Hopf algebra of symmetric functions in non-commuting variables in the \( x \) basis.

This basis is defined in [BHRZ06] by the formula:

\[
 x_A = \sum_{B \subseteq A} \mu(B, A)p_B
\]

and has the following properties:

\[
x_A x_B = x_{A|B}, \quad \Delta^\otimes(x_C) = \sum_{A \vee B = C} x_A \otimes x_B.
\]
EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: x = NCSym.x()
sage: x[[1,3],[2,4]]*x[[1,2,3]]
x{{1, 3}, {2, 4}, {5, 6, 7}}
sage: x[[1,2],[3]].internal_coproduct()
x{{1}, {2}, {3}} # x{{1, 2}, {3}} + x{{1, 2}, {3}} # x{{1}, {2}, {3}} +
x{{1, 2}, {3}} # x{{1, 2}, {3}}
```

```
sage.combinat.ncsym.ncsym.matchings(A, B)
Iterate through all matchings of the sets A and B.
```

```python
sage: from sage.combinat.ncsym.ncsym import matchings
go: list(matchings([1, 2, 3], [-1, -2]))
[[[1], [2], [3], [-1], [-2]],
 [[1], [2], [3], [-1], [-2]],
 [[1], [2], [3, -2], [-1]],
 [[1], [2, -1], [3], [-2]],
 [[1], [2, -1], [3, -2]],
 [[1], [2, -2], [3], [-1]],
 [[1], [2, -2], [3, -1]],
 [[1, -1], [2], [3], [-2]],
 [[1, -1], [2], [3, -2]],
 [[1, -1], [2, -2], [3]],
 [[1, -2], [2], [3], [-1]],
 [[1, -2], [2], [-1], [3]]]
```

```
sage.combinat.ncsym.ncsym.nesting(la, nu)
Return the nesting number of la inside of nu.
If we consider a set partition A as a set of arcs i − j where i and j are in the same part of A. Define

\[
nst_\lambda^\nu = \# \{ i < j < k < l \mid i - l \in \nu, j - k \in \lambda \},
\]

and this corresponds to the number of arcs of \( \lambda \) strictly contained inside of \( \nu \).
```

```python
sage: from sage.combinat.ncsym.ncsym import nesting
go: nu = SetPartition([[1,4], [2], [3]])
go: mu = SetPartition([[1,4], [2,3]])
go: nesting(set(mu).difference(nu), nu)
1
```

```python
sage: lst = list(SetPartitions(4))
sage: d = {}  
  ....:   for i, nu in enumerate(lst):
  ....:     for mu in nu.coarsenings():
  ....:       if set(nu.arcs()).issubset(mu.arcs()):
  ....:         d[i, lst.index(mu)] = nesting(set(mu).difference(nu), nu)

sage: matrix(d)
```

```
<table>
<thead>
<tr>
<th></th>
<th>0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0</td>
</tr>
<tr>
<td>0</td>
<td>0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0</td>
</tr>
<tr>

</tr>
</tbody>
</table>
```
(continues on next page)
5.1.155 Necklaces

The algorithm used in this file comes from

- Sawada, Joe. “A fast algorithm to generate necklaces with fixed content”, Source Theoretical Computer Science archive Volume 301, Issue 1-3 (May 2003)

sage.combinat.necklace.Necklaces\(\text{(content)}\)

Return the set of necklaces with evaluation \(\text{content}\).

A necklace is a list of integers that such that the list is the smallest lexicographic representative of all the cyclic shifts of the list.

See also:

LyndonWords

INPUT:

- \(\text{content}\) – a list or tuple of non-negative integers

EXAMPLES:

```python
sage: Necklaces([2,1,1])
Necklaces with evaluation [2, 1, 1]
sage: Necklaces([2,1,1]).cardinality()
3
sage: Necklaces([2,1,1]).first()
[1, 1, 2, 3]
sage: Necklaces([2,1,1]).last()
[1, 2, 1, 3]
sage: Necklaces([2,1,1]).list()
[[1, 1, 2, 3], [1, 1, 3, 2], [1, 2, 1, 3]]
sage: Necklaces([0,2,1,1]).list()
[[2, 2, 3, 4], [2, 2, 4, 3], [2, 3, 2, 4]]
sage: Necklaces([2,0,1,1]).list()
[[1, 1, 3, 4], [1, 1, 4, 3], [1, 3, 1, 4]]
```

class sage.combinat.necklace.Necklaces_evaluation\(\text{(content)}\)

Bases: \text{sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent}

Necklaces with a fixed evaluation \(\text{content}\).

INPUT:
• content — a list or tuple of non-negative integers

**cardinality()**

Return the number of integer necklaces with the evaluation content.

The formula for the number of necklaces of content \( \alpha \) a composition of \( n \) is:

\[
\sum_{d \mid \gcd(\alpha)} \phi(d)^{n/d}
\]

where \( \phi(d) \) is the Euler \( \phi \) function.

**EXAMPLES:**

```python
sage: Necklaces([]).cardinality()
0
sage: Necklaces([2,2]).cardinality()
2
sage: Necklaces([2,3,2]).cardinality()
30
sage: Necklaces([0,3,2]).cardinality()
2
```

Check to make sure that the count matches up with the number of necklace words generated.

```python
sage: comps = [[], [2,2], [3,2,7], [4,2], [0,4,2], [2,0,4]]+Compositions(4).list()
sage: ns = [Necklaces(comp) for comp in comps]
sage: all(n.cardinality() == len(n.list()) for n in ns)
True
```

**content()**

Return the content (or evaluation) of the necklaces.

### 5.1.156 Non-Decreasing Parking Functions

A *non-decreasing parking function* of size \( n \) is a non-decreasing function \( f \) from \( \{1, \ldots, n\} \) to itself such that for all \( i \), one has \( f(i) \leq i \).

The number of non-decreasing parking functions of size \( n \) is the \( n \)-th Catalan number.

The set of non-decreasing parking functions of size \( n \) is in bijection with the set of Dyck words of size \( n \).

**AUTHORS:**

• Florent Hivert (2009-04)
• Christian Stump (2012-11) added pretty printing

```python
class sage.combinat.non_decreasing_parking_function.NonDecreasingParkingFunction(lst)
    Bases: sage.structure.element.Element

A non decreasing parking function of size \( n \) is a non-decreasing function \( f \) from \( \{1, \ldots, n\} \) to itself such that for all \( i \), one has \( f(i) \leq i \).

**EXAMPLES:**

```python
sage: NonDecreasingParkingFunction([])
[]
sage: NonDecreasingParkingFunction([1])
[1]
```
```python
sage: NonDecreasingParkingFunction([2])
Traceback (most recent call last):
...  
ValueError: [2] is not a non-decreasing parking function
sage: NonDecreasingParkingFunction([1,2])
[1, 2]
sage: NonDecreasingParkingFunction([1,1,2])
[1, 1, 2]
sage: NonDecreasingParkingFunction([1,1,4])
Traceback (most recent call last):
...  
ValueError: [1, 1, 4] is not a non-decreasing parking function
```

**classmethod from_dyck_word(dw)**

Bijection from Dyck words. It is the inverse of the bijection to_dyck_word(). You can find there the mathematical definition.

**EXAMPLES:**

```python
sage: NonDecreasingParkingFunction.from_dyck_word([])
[]
sage: NonDecreasingParkingFunction.from_dyck_word([1,0])
[1]
sage: NonDecreasingParkingFunction.from_dyck_word([1,1,0,0])
[1, 1]
sage: NonDecreasingParkingFunction.from_dyck_word([1,0,1,0])
[1, 2]
sage: NonDecreasingParkingFunction.from_dyck_word([1,0,1,0,1,0,0,1,0,1,0,0,1,0])
[1, 2, 2, 3, 5]
```

**to_dyck_word()**

Implement the bijection to Dyck words, which is defined as follows. Take a non decreasing parking function, say [1,1,2,4,5,5], and draw its graph:

```
___
| . 5
| . 5
___| .. 4
| ... 2
| ... 1
| ... 1
```

The corresponding Dyck word [1,1,0,1,0,0,1,0,1,1,0,0] is then read off from the sequence of horizontal and vertical steps. The converse bijection is from_dyck_word().

**EXAMPLES:**

```python
sage: NonDecreasingParkingFunction([1,1,2,4,5,5]).to_dyck_word()
[1, 1, 0, 1, 0, 0, 1, 0, 1, 1, 0, 0]
sage: NonDecreasingParkingFunction([]).to_dyck_word()
[]
sage: NonDecreasingParkingFunction([1,1]).to_dyck_word()
[1, 1, 0, 0, 0]
sage: NonDecreasingParkingFunction([1,2,3]).to_dyck_word()
[1, 0, 1, 0, 1, 0]
sage: NonDecreasingParkingFunction([1,1,3,3,4,6,6]).to_dyck_word()
[1, 1, 0, 0, 1, 0, 1, 0, 0, 1, 1, 0, 0]
```
A non-decreasing parking function of size \( n \) is a non-decreasing function \( f \) from \( \{1, \ldots, n\} \) to itself such that for all \( i \), one has \( f(i) \leq i \).

**EXAMPLES:**

Here are all the non-decreasing parking functions of size 5:

```
sage: NonDecreasingParkingFunctions(3).list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]
```

If no size is specified, then NonDecreasingParkingFunctions returns the set of all non-decreasing parking functions.

```
sage: PF = NonDecreasingParkingFunctions(); PF
Non-decreasing parking functions
sage: [] in PF
True
sage: [1] in PF
True
sage: [2] in PF
False
sage: [1,1,3] in PF
True
sage: [1,1,4] in PF
False
```

If the size \( n \) is specified, then NonDecreasingParkingFunctions returns the set of all non-decreasing parking functions of size \( n \).

```
sage: PF = NonDecreasingParkingFunctions(0)
sage: PF.list()
[]
sage: PF = NonDecreasingParkingFunctions(1)
sage: PF.list()
[[1]]
sage: PF = NonDecreasingParkingFunctions(3)
sage: PF.list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]
sage: PF3 = NonDecreasingParkingFunctions(3); PF3
Non-decreasing parking functions of size 3
sage: [] in PF3
False
sage: [1] in PF3
False
sage: [1,1,3] in PF3
True
sage: [1,1,4] in PF3
False
```
The combinatorial class of non-decreasing parking functions of size $n$.

A *non-decreasing parking function* of size $n$ is a non-decreasing function $f$ from $\{1, \ldots, n\}$ to itself such that for all $i$, one has $f(i) \leq i$.

The number of non-decreasing parking functions of size $n$ is the $n$-th Catalan number.

**EXAMPLES:**

```python
sage: PF = NonDecreasingParkingFunctions(3)
sage: PF.list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]
sage: PF = NonDecreasingParkingFunctions(4)
sage: PF.list()
[[1, 1, 1, 1], [1, 1, 1, 2], [1, 1, 1, 3], [1, 1, 1, 4], [1, 1, 2, 2], [1, 1, 2, 3], [1, 1, 2, 4], [1, 1, 3, 3], [1, 1, 3, 4], [1, 2, 2, 2], [1, 2, 2, 3], [1, 2, 2, 4], [1, 2, 3, 3], [1, 2, 3, 4]]
sage: [NonDecreasingParkingFunctions(i).cardinality() for i in range(10)]
[1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
```

**Warning:** The precise order in which the parking function are generated or listed is not fixed, and may change in the future.

**AUTHORS:**

- Florent Hivert

**Element**

alias of `NonDecreasingParkingFunction`

**cardinality()**

Return the number of non-decreasing parking functions of size $n$.

This number is the $n$-th *Catalan number*.

**EXAMPLES:**

```python
sage: PF = NonDecreasingParkingFunctions(0)
sage: PF.cardinality()
1
sage: PF = NonDecreasingParkingFunctions(1)
sage: PF.cardinality()
1
sage: PF = NonDecreasingParkingFunctions(3)
sage: PF.cardinality()
5
sage: PF = NonDecreasingParkingFunctions(5)
sage: PF.cardinality()
42
```

**one()**

Return the unit of this monoid.

This is the non-decreasing parking function $[1, 2, \ldots, n]$.

**EXAMPLES:**

```python
sage: ndpf = NonDecreasingParkingFunctions(5)
sage: x = ndpf.random_element(); x  # random
```
random_element()

Return a random parking function of the given size.

EXAMPLES:

```
sage: ndpf = NonDecreasingParkingFunctions(5)
sage: x = ndpf.random_element(); x  # random
[1, 2, 2, 4, 5]
sage: x in ndpf
True
```

sage.combinat.non_decreasing_parking_function.is_a(x, n=None)

Check whether a list is a non-decreasing parking function.

If a size n is specified, checks if a list is a non-decreasing parking function of size n.

### 5.1.157 Ordered Rooted Trees

**AUTHORS:**

- Florent Hivert (2010-2011): initial revision
- Frédéric Chapoton (2010): contributed some methods

**class** sage.combinat.ordered_tree.LabelledOrderedTree(parent, children, label=None, check=True)

Bases: sage.combinat.abstract_tree.AbstractLabelledClonableTree, sage.combinat.ordered_tree.OrderedTree

Labelled ordered trees.

A labelled ordered tree is an ordered tree with a label attached at each node.

**INPUT:**

- children – a list or tuple or more generally any iterable of trees or object convertible to trees
- label – any Sage object (default: None)

**EXAMPLES:**

```
sage: x = LabelledOrderedTree([], label = 3); x
3[]
sage: LabelledOrderedTree([x, x, x], label = 2)
2[3[], 3[], 3[]]
sage: LabelledOrderedTree((x, x, x), label = 2)
2[3[], 3[], 3[]]
sage: LabelledOrderedTree([[],[[]], []], label = 3)
3[None[], None[None[], None[]]]
```

**left_right_symmetry()**

Return the symmetric tree of self.

The symmetric tree \( s(T) \) of a labelled ordered tree \( T \) is defined as follows: If \( T \) is a labelled ordered tree with children \( C_1, C_2, \ldots, C_k \) (listed from left to right), then the symmetric tree \( s(T) \) of \( T \) is a labelled...
ordered tree with children \( s(C_k), s(C_{k-1}), \ldots, s(C_1) \) (from left to right), and with the same root label as \( T \).

**Note:** If you have a subclass of `LabelledOrderedTree()` which also inherits from another subclass of `OrderedTree()` which does not come with a labelling, then (depending on the method resolution order) it might happen that this method gets overridden by an implementation from that other subclass, and thus forgets about the labels. In this case you need to manually override this method on your subclass.

**EXAMPLES:**

```python
sage: L2 = LabelledOrderedTree([], label=2)
sage: L3 = LabelledOrderedTree([], label=3)
sage: T23 = LabelledOrderedTree([L2, L3], label=4)
sage: T23.left_right_symmetry()
sage: L23 = LabelledOrderedTree([L2, T23], label=17)
sage: T223.left_right_symmetry()
sage: T223.left_right_symmetry().left_right_symmetry() == T223
True
```

**sort_key()**

Return a tuple of nonnegative integers encoding the labelled tree self.

The first entry of the tuple is a pair consisting of the number of children of the root and the label of the root. Then the rest of the tuple is the concatenation of the tuples associated to these children (we view the children of a tree as trees themselves) from left to right.

This tuple characterizes the labelled tree uniquely, and can be used to sort the labelled ordered trees provided that the labels belong to a type which is totally ordered.

**Warning:** This method overrides `OrderedTree.sort_key()` and returns a result different from what the latter would return, as it wants to encode the whole labelled tree including its labelling rather than just the unlabelled tree. Therefore, be careful with using this method on subclasses of `LabelledOrderedTree`; under some circumstances they could inherit it from another superclass instead of from `OrderedTree`, which would cause the method to forget the labelling. See the docstring of `OrderedTree.sort_key()`.

**EXAMPLES:**

```python
sage: L2 = LabelledOrderedTree([], label=2)
sage: L3 = LabelledOrderedTree([], label=3)
sage: T23 = LabelledOrderedTree([L2, L3], label=4)
sage: T23.sort_key()
((2, 4), (0, 2), (0, 3))
sage: T32 = LabelledOrderedTree([L3, L2], label=5)
sage: T32.sort_key()
((2, 5), (0, 3), (0, 2))
sage: T23322 = LabelledOrderedTree([T23, T32, L2], label=14)
sage: T23322.sort_key()
((3, 14), (2, 4), (0, 2), (0, 3), (2, 5), (0, 3), (0, 2), (0, 2))
```

**class** `sage.combinat.ordered_tree.LabelledOrderedTrees(category=None)`

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`
This is a parent stub to serve as a factory class for trees with various label constraints.

**EXAMPLES:**

```python
sage: LOT = LabelledOrderedTrees(); LOT
Labelled ordered trees
sage: x = LOT([], label = 3); x
3[
```

```python
sage: x.parent() is LOT
True
sage: y = LOT([x, x, x], label = 2); y
2[3[[], 3[[], 3[]]]
```

```python
sage: y.parent() is LOT
True
```

**Element**

alias of :class:`LabelledOrderedTree`

**cardinality()**

Return the cardinality of self.

**EXAMPLES:**

```python
sage: LabelledOrderedTrees().cardinality()
+Infinity
```

**labelled_trees()**

Return the set of labelled trees associated to self.

This is precisely self, because self already is the set of labelled ordered trees.

**EXAMPLES:**

```python
sage: LabelledOrderedTrees().labelled_trees()
Labelled ordered trees
sage: LOT = LabelledOrderedTrees()
sage: x = LOT([], label = 3)
sage: y = LOT([x, x, x], label = 2)
sage: y.canonical_labelling()
1[2[[], 3[[], 4[]]]]
```

**unlabelled_trees()**

Return the set of unlabelled trees associated to self.

This is the set of ordered trees, since self is the set of labelled ordered trees.

**EXAMPLES:**

```python
sage: LabelledOrderedTrees().unlabelled_trees()
Ordered trees
```

**class** :class:`sage.combinat.ordered_tree.OrderedTree`

The class of (ordered rooted) trees.

An ordered tree is constructed from a node, called the root, on which one has grafted a possibly empty list of trees. There is a total order on the children of a node which is given by the order of the elements in the list. Note that there is no empty ordered tree (so the smallest ordered tree consists of just one node).

**INPUT:**
One can create a tree from any list (or more generally iterable) of trees or objects convertible to a tree. Alternatively a string is also accepted. The syntax is the same as for printing: children are grouped by square brackets.

**EXAMPLES:**

```python
sage: x = OrderedTree([])
sage: x1 = OrderedTree([x,x])
sage: x2 = OrderedTree([[],[[]]])
sage: x1 == x2
True
sage: tt1 = OrderedTree([x,x1,x2])
sage: tt2 = OrderedTree([[], [[], []], x2])
sage: tt1 == tt2
True
sage: OrderedTree([]) == OrderedTree()
True
```

**is_empty()**

Return if `self` is the empty tree.

For ordered trees, this always returns `False`.

**Note:** this is different from `bool(t)` which returns whether `t` has some child or not.

**EXAMPLES:**

```python
sage: t = OrderedTrees(4)([[],[[]])
sage: t.is_empty()
False
sage: bool(t)
True
```

**left_right_symmetry()**

Return the symmetric tree of `self`.

The symmetric tree $s(T)$ of an ordered tree $T$ is defined as follows: If $T$ is an ordered tree with children $C_1, C_2, \ldots, C_k$ (listed from left to right), then the symmetric tree $s(T)$ of $T$ is the ordered tree with children $s(C_k), s(C_{k-1}), \ldots, s(C_1)$ (from left to right).

**EXAMPLES:**

```python
sage: T = OrderedTree([[[]],[]])
sage: T.left_right_symmetry()
[[[]],[[]]]
sage: T = OrderedTree([[[]],[], [[]], [[]]])
sage: T.left_right_symmetry()
[[[[]],[]], [[[]],[]]]
```

**normalize**(inplace=False)

Return the normalized tree of `self`.

**INPUT:**

- `inplace` - boolean, (default False) if True, then `self` is modified and nothing returned. Otherwise the normalized tree is returned.
The normalization of an ordered tree $t$ is an ordered tree $s$ which has the property that $t$ and $s$ are isomorphic as unordered rooted trees, and that if two ordered trees $t$ and $t'$ are isomorphic as unordered rooted trees, then the normalizations of $t$ and $t'$ are identical. In other words, normalization is a map from the set of ordered trees to itself which picks a representative from every equivalence class with respect to the relation of “being isomorphic as unordered trees”, and maps every ordered tree to the representative chosen from its class.

This map proceeds recursively by first normalizing every subtree, and then sorting the subtrees according to the value of the \texttt{sort_key()} method.

Consider the quotient map $\pi$ that sends a planar rooted tree to the associated unordered rooted tree. Normalization is the composite $s \circ \pi$, where $s$ is a section of $\pi$.

**EXAMPLES:**

```python
sage: OT = OrderedTree
sage: ta = OT([[],[[]])
sage: tb = OT([[[]],]])
sage: ta.normalize() == tb.normalize()
True
sage: ta == tb
False
```

An example with inplace normalization:

```python
sage: OT = OrderedTree
sage: ta = OT([[],[[]])
sage: tb = OT([[[]],]])
sage: ta.normalize(inplace=True); ta
[[], [[]]]
sage: tb.normalize(inplace=True); tb
[[], [[]]]
```

**plot()**

Plot the tree \texttt{self}.

**Warning:** For a labelled tree, this will fail unless all labels are distinct. For unlabelled trees, some arbitrary labels are chosen. Use \_latex\_(), \texttt{view}, \_ascii\_\_() or \texttt{pretty_print} for more faithful representations of the data of the tree.

**EXAMPLES:**

```python
sage: p = OrderedTree([[],[[]],[]])
sage: ascii_art(p)

___
/ / /
\circ \circ \
| \\
\circ

sage: p.plot()
Graphics object consisting of 10 graphics primitives
```

Now a labelled example:

```python
sage: g = OrderedTree([[],[[]],[]]).canonical_labelling()
sage: ascii_art(g)
```

(continues on next page)
sort_key()

Return a tuple of nonnegative integers encoding the ordered tree self.

The first entry of the tuple is the number of children of the root. Then the rest of the tuple is the concatenation of the tuples associated to these children (we view the children of a tree as trees themselves) from left to right.

This tuple characterizes the tree uniquely, and can be used to sort the ordered trees.

Note: By default, this method does not encode any extra structure that self might have – e.g., if you were to define a class EdgeColoredOrderedTree which implements edge-colored trees and which inherits from OrderedTree, then the sort_key() method it would inherit would forget about the colors of the edges (and thus would not characterize edge-colored trees uniquely). If you want to preserve extra data, you need to override this method or use a new method. For instance, on the LabelledOrderedTree subclass, this method is overridden by a slightly different method, which encodes not only the numbers of children of the nodes of self, but also their labels. Be careful with using overridden methods, however: If
you have (say) a class `BalancedTree` which inherits from `OrderedTree` and which encodes balanced trees, and if you have another class `BalancedLabelledOrderedTree` which inherits both from `BalancedOrderedTree` and from `LabelledOrderedTree`, then (depending on the MRO) the default `sort_key()` method on `BalancedLabelledOrderedTree` (unless manually overridden) will be taken either from `BalancedTree` or from `LabelledOrderedTree`, and in the former case will ignore the labelling!

**EXAMPLES:**

```python
sage: RT = OrderedTree
sage: RT([[[],[]]]).sort_key()
(2, 0, 1, 0)
sage: RT([[[]],[[]]]).sort_key()
(2, 1, 0, 0)
```

### `to_binary_tree_left_branch()`

Return a binary tree of size \(n - 1\) (where \(n\) is the size of \(t\), and where \(t\) is `self`) obtained from \(t\) by the following recursive rule:

- if \(x\) is the left brother of \(y\) in \(t\), then \(x\) becomes the left child of \(y\);
- if \(x\) is the last child of \(y\) in \(t\), then \(x\) becomes the right child of \(y\),

and removing the root of \(t\).

**EXAMPLES:**

```python
sage: T = OrderedTree([[[]]])
sage: T.to_binary_tree_left_branch()
[[., .], .]
sage: T = OrderedTree([[[], []], [], []])
sage: T.to_binary_tree_left_branch()
[[[., .], [[., .], .]], [[., .], [[., .], .]]]
```

### `to_binary_tree_right_branch()`

Return a binary tree of size \(n - 1\) (where \(n\) is the size of \(t\), and where \(t\) is `self`) obtained from \(t\) by the following recursive rule:

- if \(x\) is the right brother of \(y\) in \(t\), then \(x\) becomes the right child of \(y\);
- if \(x\) is the first child of \(y\) in \(t\), then \(x\) becomes the left child of \(y\),

and removing the root of \(t\).

**EXAMPLES:**

```python
sage: T = OrderedTree([[[]]])
sage: T.to_binary_tree_right_branch()
[., [., .]]
sage: T = OrderedTree([[[], []], [], []])
sage: T.to_binary_tree_right_branch()
[., [[., [., .]], [[., [., .]], .]]]
```

### `to_dyck_word()`

Return the Dyck path corresponding to `self` where the maximal height of the Dyck path is the depth of `self`.

**EXAMPLES:**
sage: T = OrderedTree([[],[]])
sage: T.to_dyck_word()
[1, 0, 1, 0]
sage: T = OrderedTree([[],[[]]])
sage: T.to_dyck_word()
[1, 0, 1, 0, 0]
sage: T = OrderedTree([[], [], [[]], [], []])
sage: T.to_dyck_word()
[1, 0, 1, 0, 0, 1, 0, 1, 0, 1, 0, 0, 0]

to_parallelogram_polyomino(bijection=None)
Return a polyomino parallelogram.

INPUT:

• bijection – (default: 'Boussicault-Socci') is the name of the bijection to use. Possible values are 'Boussicault-Socci', 'via dyck and Delest-Viennot'.

EXAMPLES:

sage: T = OrderedTree([[[], [[]]], [], [[],[]]], [1, 1, 1, 1, 1, 1, 0, 0, 1, 1, 0, 1, 1, 0, 0, 0])
sage: T.to_parallelogram_polyomino(bijection='Boussicault-Socci')
[[0, 0, 0, 1, 1, 0, 1, 1, 1, 1, 0, 1, 1, 1], [1, 1, 1, 1, 1, 0, 0, 1, 1, 0, 1, → 1, 0, 0]]
sage: T = OrderedTree([])
sage: T.to_parallelogram_polyomino()
[[1], [1]]
sage: T = OrderedTree([[]])
sage: T.to_parallelogram_polyomino()
[[0, 1], [1, 0]]
sage: T = OrderedTree([[[]]])
sage: T.to_parallelogram_polyomino()
[[0, 1, 1], [1, 1, 0]]
sage: T = OrderedTree([[]])
sage: T.to_parallelogram_polyomino()
[[0, 0, 1], [1, 0, 0]]

to_poset(root_to_leaf=False)
Return the poset obtained by interpreting the tree as a Hasse diagram. The default orientation is from leaves to root but you can pass root_to_leaf=True to obtain the inverse orientation.

INPUT:

• root_to_leaf – boolean, true if the poset orientation should be from root to leaves. It is false by default.

EXAMPLES:

sage: t = OrderedTree([])
sage: t.to_poset()
Finite poset containing 1 elements
sage: p = OrderedTree([[[]],[[],[]]]).to_poset()
sage: p.height(), p.width()
(3, 3)

If the tree is labelled, we use its labelling to label the poset. Otherwise, we use the poset canonical labelling:
\begin{Verbatim}[commandchars=\[\]]
sage: t = OrderedTree([[[]],[[]],[[]]]).canonical_labelling().to_poset()
sage: t.height(), t.width()
(3, 3)
\end{Verbatim}

to\_undirected\_graph()
Return the undirected graph obtained from the tree nodes and edges.
The graph is endowed with an embedding, so that it will be displayed correctly.

EXAMPLES:

\begin{Verbatim}[commandchars=\[\]]
sage: t = OrderedTree([])
sage: t.to\_undirected\_graph()
Graph on 1 vertex
sage: t = OrderedTree([[[]],[[]],[[]]])
sage: t.to\_undirected\_graph()
Graph on 5 vertices
\end{Verbatim}

If the tree is labelled, we use its labelling to label the graph. This will fail if the labels are not all distinct. Otherwise, we use the graph canonical labelling which means that two different trees can have the same graph.

EXAMPLES:

\begin{Verbatim}[commandchars=\[\]]
sage: t = OrderedTree([[[]],[[]],[[]]])
sage: t.canonical\_labelling().to\_undirected\_graph()
Graph on 5 vertices
\end{Verbatim}

class sage.combinat.ordered_tree.OrderedTrees
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent
Factory for ordered trees

INPUT:

• size – (optional) an integer

OUTPUT:

• the set of all ordered trees (of the given size if specified)

EXAMPLES:

\begin{Verbatim}[commandchars=\[\]]
sage: OrderedTrees()
Ordered trees
sage: OrderedTrees(2)
Ordered trees of size 2
\end{Verbatim}

Note: this is a factory class whose constructor returns instances of subclasses.

Note: the fact that OrderedTrees is a class instead of a simple callable is an implementation detail. It could be changed in the future and one should not rely on it.

leaf()
Return a leaf tree with \texttt{self} as parent
class sage.combinat.ordered_tree.OrderedTrees_all

Bases: sage.sets.disjoint_unionEnumeratedSets, sage.combinat.ordered_tree.OrderedTrees

The set of all ordered trees.

EXAMPLES:

```
sage: OT = OrderedTrees(); OT
Ordered trees
sage: OT.cardinality()
+Infinity
```

Element

alias of OrderedTree

labelled_trees()

Return the set of labelled trees associated to self

EXAMPLES:

```
sage: OrderedTrees().labelled_trees()
Labelled ordered trees
```

unlabelled_trees()

Return the set of unlabelled trees associated to self

EXAMPLES:

```
sage: OrderedTrees().unlabelled_trees()
Ordered trees
```

class sage.combinat.ordered_tree.OrderedTrees_size(size)

Bases: sage.combinat.ordered_tree.OrderedTrees

The enumerated sets of binary trees of a given size

EXAMPLES:

```
sage: S = OrderedTrees(3); S
Ordered trees of size 3
sage: S.cardinality()
2
sage: S.list()
[[[[], []], [[]]]]
```

cardinality()

The cardinality of self

This is a Catalan number.

element_class()

The class of the element of self

EXAMPLES:
random_element()

Return a random OrderedTree with uniform probability.

This method generates a random DyckWord and then uses a bijection between Dyck words and ordered trees.

EXAMPLES:

```sage
sage: OrderedTrees(5).random_element() # random
[[[], [], []]]
```

5.1.158 Output functions

These are the output functions for latexing and ascii/unicode art versions of partitions and tableaux.

AUTHORS:

- Mike Hansen (?): initial version
- Travis Scrimshaw (2020-08): Added support for ascii/unicode art

```sage
sage.combinat.output.ascii_art_table(data, use_unicode=False, convention='English')
```

Return an ascii art table of data.

EXAMPLES:

```sage
sage: from sage.combinat.output import ascii_art_table
sage: data = [[None, None, 1], [2, 2], [3,4,5], [None, None, 10], [], [6]]
sage: print(ascii_art_table(data))
+----+
| 1 |
+---+---+----+
| 2 | 2 |
+---+---+----+
| 3 | 4 | 5 |
+---+---+----+
| 10 |
| 6 |
```

(continues on next page)
sage.combinat.output.tex_from_array(array, with_lines=True)

Return a latex string for a two dimensional array of partition, composition or skew composition shape

INPUT:

- array – a list of list
- with_lines – a boolean (default: True) Whether to draw a line to separate the entries in the array.

Empty rows are allowed; however, such rows should be given as [None] rather than [].

The array is drawn using either the English or French convention following Tableaux.options().

See also:

tex_from_array_tuple()

EXAMPLES:

```python
sage: from sage.combinat.output import tex_from_array
sage: print(tex_from_array([[1,2,3],[4,5]]))
\begin{array}{ccc}
\hline \hline
1 & 2 & 3 \\
\hline \hline
4 & 5 \\
\hline
\hline
\end{array}
```
sage: print(tex_from_array([[1,2,3],[4,5]], with_lines=False))
\begin{array}{|c|c|}
\hline
1 & 2 \\
\hline
4 & 5 \\
\hline
\end{array}

sage: print(tex_from_array([[1,2,3],[4,5,6,7],[8]], with_lines=False))
\begin{array}{|c|c|c|}
\hline
1 & 2 & 3 \\
\hline
4 & 5 & 6 & 7 \\
\hline
8 \\
\hline
\end{array}

sage: print(tex_from_array([[None,None,3],[None,5,6,7],[None,8]], with_lines=False))
\begin{array}{|c|c|c|}
\hline
\multicolumn{3}{|c|}{3} \\
\hline
& 5 & 6 & 7 \\
\hline
& 8 \\
\hline
\end{array}

sage: print(tex_from_array([[None,None,3],[None,5,6,7],[None,8]], with_lines=False))
\begin{array}{|c|c|c|}
\hline
\multicolumn{3}{|c|}{3} \\
\hline
& 5 & 6 & 7 \\
\hline
& 8 \\
\hline
\end{array}

1\end{array}
\end{array}\}
\end{array}$}

sage: print(tex_from_array_tuple([[None, None, 3], [None, 5, 6, 7], [None, 8]], with_lines=False))
{\def\lr#1{\multicolumn{1}{@{\hspace{.6ex}}c@{\hspace{.6ex}}}\{\raisebox{-.3ex}{$#1$}}}
\begin{array}{c}
\begin{array}{c}
1\end{array}
\end{array}\}
\end{array}$}

sage: Tableaux.options._reset()

sage.combinat.output.tex_from_array_tuple(a_tuple, with_lines=True)

Return a latex string for a tuple of two dimensional array of partition, composition or skew composition shape.

INPUT:

- a_tuple – a tuple of lists of lists
- with_lines – a boolean (default: True) Whether to draw lines to separate the entries in the components of a_tuple.

See also:
tex_from_array() for the description of each array

EXAMPLES:

sage: from sage.combinat.output import tex_from_array_tuple
sage: print(tex_from_array_tuple([[1, 2, 3], [4, 5]], [[None, 6, 7], [None, 8], [9]]))
\begin{array}{c}
\begin{array}{c}
1\end{array}
\end{array}\}
\end{array}$

(continues on next page)
sage: Tableaux.options.convention=“french"

sage: print(tex_from_array_tuple([[1,2,3],[4,5]],[],[[None,6,7],[None,8],[9]]))
\begin{array}{*{3}c}
| 0 & 0 & 0 \\
\end{array}
\begin{array}{*{3}c}
| 1 & 2 & 3 \\
\end{array}
\begin{array}{*{3}c}
| 6 & 7 & 8 \\
\end{array}

sage: print(tex_from_array_tuple([[1,2,3],[4,5]],[],[[None,6,7],[None,8],[9]],with_lines=False))
\begin{array}{*{3}c}
| 0 & 0 & 0 \\
| 1 & 2 & 3 \\
\end{array}
\begin{array}{*{3}c}
| 6 & 7 & 8 \\
\end{array}

sage: Tableaux.options._reset()

sage.combinat.output.tex_from_skew_array(array, with_lines=False, align='b')

This function creates latex code for a “skew composition” array. That is, for a two dimensional array in which each row can begin with an arbitrary number None’s and the remaining entries could, in principle, be anything but probably should be strings or integers of similar width. A row consisting completely of None’s is allowed.

**INPUT:**

- **array** – The array
- **with_lines** – (Default: False) If True lines are drawn, if False they are not
- **align** – (Default: ‘b’) Determines the alignment on the latex array environments

**EXAMPLES:**

```python
sage: array=[[None, 2,3,4],[None,None],[5,6,7,8]]
sage: print(sage.combinat.output.tex_from_skew_array(array))
\begin{array}{*{4}c}
| 2 & 3 & 4 & 0 \\
\end{array}
\begin{array}{*{3}c}
| 5 & 6 & 7 \\
\end{array}
\begin{array}{*{3}c}
| 8 & | 0 & 0 \\
\end{array}
```
5.1.159 Parallelogram Polyominoes

The goal of this module is to give some tools to manipulate the parallelogram polyominoes.

```python
from sage.combinat.parallelgram_polyomino import LocalOptions
sage: o = LocalOptions(
    'Name Example',
    delim=dict(d=
        default='b',
        values={'b':'the option b', 'p':'the option p'}
    )
)
```

This class allows to add local options to an object. LocalOptions is like a dictionary, it has keys and values that represent options and the values associated to the option. This is useful to decorate an object with some optional informations.

`LocalOptions` should be used as follow.

**INPUT:**

- `name` – The name of the LocalOptions
- `<options>=dict(...)` – dictionary specifying an option

The options are specified by keyword arguments with their values being a dictionary which describes the option. The allowed/expected keys in the dictionary are:

- `checker` – a function for checking whether a particular value for the option is valid
- `default` – the default value of the option
- `values` – a dictionary of the legal values for this option (this automatically defines the corresponding checker); this dictionary gives the possible options, as keys, together with a brief description of them.

```python
sage: from sage.combinat.parallelgram_polyomino import LocalOptions
sage: class Ex:
    options=o
    def _repr_b(self):
        return "b"
    def _repr_p(self):
        return "p"
    def __repr__(self):
        self.options._dispatch(
            self, '_repr_', 'delim'
        )

sage: e = Ex(); e
b
sage: e.options(delim='p'); e
p
```

This class is temporary, in the future, this class should be integrated in `sage.structure.global_options.py`. We should split `global_option` in two classes `LocalOptions` and `GlobalOptions`.

**keys()**

Return the list of the options in `self`.

**EXAMPLES:**

```python
from sage.combinat.parallelgram_polyomino import LocalOptions
```

(continued from previous page)

....: )
sage: o = LocalOptions(
....:
"Name Example",
....:
tikz_options=dict(
....:
default="toto",
....:
values=dict(
....:
toto="name",
....:
x="3"
....:
)
....:
),
....:
display=dict(
....:
default="list",
....:
values=dict(
....:
list="list representation",
....:
diagram="diagram representation"
....:
)
....:
)
....: )
sage: keys=o.keys()
sage: keys.sort()
sage: keys
['display', 'tikz_options']

class sage.combinat.parallelogram_polyomino.ParallelogramPolyomino(parent,
value,
check=True)
Bases: sage.structure.list_clone.ClonableList
Parallelogram Polyominoes.
A parallelogram polyomino is a finite connected union of cells whose boundary can be decomposed in two
paths, the upper and the lower paths, which are comprised of north and east unit steps and meet only at their
starting and final points.
Parallelogram Polyominoes can be defined with those two paths.
EXAMPLES:
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp
[[0, 1], [1, 0]]

area()
Return the area of the parallelogram polyomino. The area of a parallelogram polyomino is the number of
cells of the parallelogram polyomino.
EXAMPLES:
sage: pp = ParallelogramPolyomino(
....:
[
....:
[0, 0, 1, 0, 1, 1, 1, 0, 0, 1, 1],
....:
[1, 1, 0, 1, 0, 1, 1, 0, 1, 0, 0]
....:
]
....: )
sage: pp.area()
13
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
(continues on next page)

1462

Chapter 5. Comprehensive Module List


\begin{verbatim}
sage: pp.area()
1
sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.area()
0
\end{verbatim}

\textbf{bounce} (\textit{direction}=1)

Return the bounce of the parallelogram polyomino.

Let \(p\) be the bounce path of the parallelogram polyomino (\textit{bounce_path()}). The bounce is defined by:

\[
\text{sum}([\lfloor \frac{i}{2} \rfloor \times p[i] \text{ for } i \text{ in range(len(p))}])
\]

\textbf{INPUT:}

- \textbf{direction} – the initial direction of the bounce path (see \textit{bounce_path()} for the definition).

\textbf{EXAMPLES:}

\begin{verbatim}
sage: PP = ParallelogramPolyomino(
....:     [[0, 0, 1, 0, 1, 1], [1, 1, 0, 0, 1, 0]])
sage: PP.bounce(direction=1)
6
sage: PP.bounce(direction=0)
7

sage: PP = ParallelogramPolyomino(
....:     [[0, 0, 1, 1, 1, 0, 0, 1, 1],
....:      [1, 1, 1, 0, 1, 1, 0, 0, 0]])

sage: PP.bounce(direction=1)
12
sage: PP.bounce(direction=0)
10

sage: PP = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: PP.bounce(direction=1)
1
sage: PP.bounce(direction=0)
1

sage: PP = ParallelogramPolyomino([[1], [1]])
sage: PP.bounce(direction=1)
0
sage: PP.bounce(direction=0)
0
\end{verbatim}

\textbf{bounce_path} (\textit{direction}=1)

Return the bounce path of the parallelogram polyomino.

The bounce path is a path with two steps \((1, 0)\) and \((0, 1)\).

If `direction` is 1 (resp. 0), the bounce path is the path starting at position \((h=1, w=0)\) (resp. \((h=0, w=1)\)) with initial direction, the vector \((0, 1)\) (resp. \((1, 0)\)), and turning each time the path crosses the perimeter of the parallelogram polyomino.
The path is coded by a list of integers. Each integer represents the size of the path between two turnings. You can visualize the two bounce paths by using the following commands.

**INPUT:**

- `direction` – the initial direction of the bounce path (see above for the definition).

**EXAMPLES:**

```python
sage: PP = ParallelogramPolyomino(
    [[0, 0, 1, 0, 1, 1], [1, 1, 0, 0, 1, 0]]
)  # not tested
sage: PP.bounce_path(direction=1)
[2, 2, 1]
sage: PP.bounce_path(direction=0)
[2, 1, 1, 1]
sage: PP = ParallelogramPolyomino(
    [[0, 0, 1, 1, 1, 0, 0, 1, 1],
     [1, 1, 1, 0, 1, 1, 0, 0, 0]]
)  # not tested
sage: PP.bounce_path(direction=1)
[3, 1, 2, 2]
sage: PP.bounce_path(direction=0)
[2, 4, 2]
sage: PP = ParallelogramPolyomino(
    [[0, 0, 1, 0, 1, 1], [1, 1, 0, 0, 1, 0]]
)  # not tested
sage: PP.set_options(
    drawing_components=dict(
        diagram = True,
        bounce_0 = True,
        bounce_1 = True,
    )
)  # not tested
sage: view(PP)  # not tested
sage: PP = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: PP.bounce_path(direction=1)
[1]
sage: PP.bounce_path(direction=0)
[1]
sage: PP = ParallelogramPolyomino([[1], [1]])
sage: PP.bounce_path(direction=1)
[]
sage: PP.bounce_path(direction=0)
[]
```

**box_is_node(pos)**

Return True if the box contains a node in the context of the Aval-Boussicault bijection between parallelogram polyomino and binary tree. A box is a node if there is no cell on the top of the box in the same column or on the left of the box in the same row.

**INPUT:**

- `pos` – the [x,y] coordinate of the box.
OUTPUT:
A boolean

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
    ....:     [[0, 0, 1, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0]]
    ....: )
sage: pp.set_options(display='drawing')
sage: pp
[1 1 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
sage: pp.box_is_node([2,1])
True
sage: pp.box_is_node([2,0])
False
sage: pp.box_is_node([1,1])
False
```

**box_is_root**(box)
Return True if the box contains the root of the tree: it is the top-left box of the parallelogram polyomino.

INPUT:
* box – the x,y coordinate of the cell.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
    ....:     [[0, 0, 1, 0, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0]]
    ....: )
sage: pp.box_is_root([2,1])
True
sage: pp.box_is_root([2,0])
False
```

**cell_is_inside**(w,h)
Determine whether the cell at a given position is inside the parallelogram polyomino.

INPUT:
* w – The x coordinate of the box position.
* h – The y coordinate of the box position.

OUTPUT:
Return 0 if there is no cell at the given position, return 1 if there is a cell.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
    ....:     [ ]
    ....:     [0, 1, 0, 1, 0, 1, 0, 1, 1, 1],
    ....:     [1, 1, 0, 1, 0, 0, 1, 1, 0]
    ....: )
sage: pp.cell_is_inside(0, 0)
(continues on next page)
```
sage: pp.cell_is_inside(1, 0)
sage: pp.cell_is_inside(0, 1)
sage: pp.cell_is_inside(3, 0)
sage: pp.cell_is_inside(pp.width()-1,pp.height()-1)
sage: pp.cell_is_inside(pp.width(),pp.height()-1)
sage: pp.cell_is_inside(pp.width()-1,pp.height())

check()

This method raises an error if the internal data of the class does not represent a parallelogram polyomino.

EXAMPLES:

sage: pp = ParallelogramPolyomino([  
....:     [0, 0, 0, 1, 0, 1, 0, 1, 1],
....:     [1, 0, 1, 1, 0, 0, 1, 0, 0]  
....: ])
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp = ParallelogramPolyomino([  
....:     [[1, 0], [0, 1]]  
....: ])
# indirect doctest
Traceback (most recent call last):
...  
ValueError: the lower and upper paths are crossing

sage: pp = ParallelogramPolyomino([[1], [0, 1]])  # indirect doctest
Traceback (most recent call last):
...  
ValueError: the lower and upper paths have different sizes (2 != 1)

sage: pp = ParallelogramPolyomino([[1], [0]])  # indirect doctest
Traceback (most recent call last):
...  
ValueError: the two paths have distinct ends

sage: pp = ParallelogramPolyomino([[0], [1]])  # indirect doctest
Traceback (most recent call last):
...  
ValueError: the two paths have distinct ends

sage: pp = ParallelogramPolyomino([[0], [0]])  # indirect doctest
Traceback (most recent call last):
...  
ValueError: the lower or the upper path can...t be equal to [0]

sage: pp = ParallelogramPolyomino([[], [0]])  # indirect doctest
Traceback (most recent call last):
ValueError: the lower or the upper path can't be equal to []

```python
sage: pp = ParallelogramPolyomino([[0], []])  # indirect doctest
Traceback (most recent call last):
  ... 
ValueError: the lower or the upper path can't be equal to []
```

**degree_convexity()**

Return the degree convexity of a parallelogram polyomino.

A convex polyomino is said to be k-convex if every pair of its cells can be connected by a monotone path (path with south and east steps) with at most k changes of direction. The degree of convexity of a convex polyomino P is the smallest integer k such that P is k-convex.

If the parallelogram polyomino is empty, the function return -1.

**EXAMPLES:**

```python
sage: pp = ParallelogramPolyomino(
    ....:
    ....:   [0, 0, 0, 1, 0, 1, 0, 1, 1],
    ....:   [1, 0, 1, 1, 0, 0, 1, 0, 0]
    ....:)
sage: pp.degree_convexity()
3
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.degree_convexity()
0
sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.degree_convexity()
-1
```

**static from_dyck_word(dyck, bijection=None)**

Convert a Dyck word to parallelogram polyomino.

**INPUT:**

- dyck – a Dyck word
- bijection – string or None (default:None) the bijection to use. See `to_dyck_word()` for more details.

**OUTPUT:**

A parallelogram polyomino.

**EXAMPLES:**

```python
sage: dyck = DyckWord([1, 1, 0, 1, 0, 1, 0, 1, 0, 0])
sage: pp = ParallelogramPolyomino.from_dyck_word(dyck)
```
```
sage: pp
[[0, 1, 0, 0, 1, 1], [1, 1, 0, 0, 0, 0]]
sage: pp = ParallelogramPolyomino.from_dyck_word(
    ....:     dyck, bijection='Delest-Viennot'
    ....: )
sage: pp
[[0, 1, 0, 0, 1, 1], [1, 1, 0, 0, 0, 0]]
```

**geometry()**
Return a pair \([h, w]\) containing the height and the width of the parallelogram polyomino.

**EXAMPLES:**
```
sage: pp = ParallelogramPolyomino(
    ....:     [[0, 1, 1, 1, 1], [1, 1, 1, 1, 0]]
    ....: )
sage: pp.geometry()
[1, 4]
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.geometry()
[1, 1]
sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.geometry()
[0, 1]
```

**get_BS_nodes()**
Return the list of cells containing node of the left and right planar tree in the Boussicault-Socci bijection.

**EXAMPLES:**
```
sage: pp = ParallelogramPolyomino(
    ....:     [[0, 0, 1, 0, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0]]
    ....: )
sage: pp.set_options(display='drawing')
sage: pp
[1, 1, 0]
[1, 1, 1]
[0, 1, 1]
[0, 1, 1]
sage: sorted(pp.get_BS_nodes())
[[0, 1], [1, 0], [1, 2], [2, 1], [3, 1], [4, 1]]
```

You can draw the point inside the parallelogram polyomino by typing (the left nodes are in blue, and the right node are in red)
```
sage: pp.set_options(drawing_components=dict(tree=True))
sage: view(pp)  # not tested
```

**get_array()**
Return an array of 0s and 1s such that the 1s represent the boxes of the parallelogram polyomino.

**EXAMPLES:**
```python
sage: pp = ParallelogramPolyomino(
    ....:     [0, 0, 0, 0, 1, 0, 1, 0, 1],
    ....:     [1, 0, 0, 0, 1, 1, 0, 0, 0]
    ....: )
```

```python
sage: matrix(pp.get_array())
```

```
[1 0 0]
[1 0 0]
[1 0 0]
[1 1 1]
[0 1 1]
[0 1 1]
```

```python
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
```

```python
sage: pp.get_array()
```

```
[[1]]
```

```python
sage: pp = ParallelogramPolyomino([[1], [1]])
```

```python
sage: pp.get_array()
```

```
[]
```

### get_left_BS_nodes()

Return the list of cells containing node of the left planar tree in the Boussicault-Socci bijection between parallelogram polyominoes and pair of ordered trees.

**OUTPUT:**

A list of [row,colum] position of cells.

**EXAMPLES:**

```python
sage: pp = ParallelogramPolyomino(
    ....:     [[0, 0, 1, 0, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0]]
    ....: )
```

```python
sage: pp.set_options(display='drawing')
sage: pp
```

```
[1 0 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
```

```python
sage: sorted(pp.get_left_BS_nodes())
```

```
[[0, 1], [2, 1], [3, 1], [4, 1]]
```

```python
sage: pp = ParallelogramPolyomino(
    ....:     [[0, 0, 1, 0, 0, 0, 1, 1], [1, 0, 1, 1, 0, 0, 0, 0]]
    ....: )
```

```python
sage: pp.set_options(display='drawing')
sage: pp
```

```
[1 0 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
```

```python
sage: sorted(pp.get_left_BS_nodes())
```

```
[]
```

You can draw the point inside the parallelogram polyomino by typing (the left nodes are in blue, and the
right node are in red)

```python
sage: pp.set_options(drawing_components=dict(tree=True))
sage: view(pp) # not tested
```

**get_node_position_from_box** *(box_position, direction, nb_crossed_nodes=[0])*

This function starts from a cell inside a parallelogram polyomino and a direction.

If `direction` is equal to 0, the function selects the column associated with the y-coordinate of `box_position` and then returns the topmost cell of the column that is on the top of `box_position` (the cell of `box_position` is included).

If `direction` is equal to 1, the function selects the row associated with the x-coordinate of `box_position` and then returns the leftmost cell of the row that is on the left of `box_position`. (the cell of `box_position` is included).

This function updates the entry of `nb_crossed_nodes`. The function increases the entry of `nb_crossed_nodes` by the number of boxes that is a node (see `box_is_node`) located on the top if `direction` is 0 (resp. on the left if `direction` is 1) of `box_position` (cell at `box_position` is excluded).

**INPUT:**

- `box_position` – the position of the starting cell.
- `direction` – the direction (0 or 1).
- `nb_crossed_nodes` – [0] (default) a list containing just one integer.

**OUTPUT:**

A [row, column] position of the cell.

**EXAMPLES:**

```python
sage: pp = ParallelogramPolyomino(
   ....:     [[0, 0, 1, 0, 0, 0, 1, 1],
   ....:      [1, 0, 1, 1, 0, 0, 0, 0]]
   ....: )
sage: matrix(pp.get_array())
[[1 0 0]
 [1 1 1]
 [0 1 1]
 [0 1 1]
 [0 1 1]]
sage: l = [0]
sage: pp.get_node_position_from_box([3, 2], 0, l)
[1, 2]
```

(continues on next page)
[1, 0]
sage: l
[2]
sage: l = [0]
sage: pp.get_node_position_from_box([3, 1], 0, l)
[1, 1]
sage: l
[2]
sage: l = [0]
sage: pp.get_node_position_from_box([3, 1], 1, l)
[3, 1]
sage: l
[0]

get_options()

Return all the options of the object.

EXAMPLES:

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.get_options()
Current options for ParallelogramPolyominoes_size
- display: u'list'
- drawing_components: {'bounce_0': False, 'bounce_1': False, 'bounce_values': False, 'diagram': True, 'tree': False}
- latex: u'drawing'
- tikz_options: {'color_bounce_0': u'red', 'color_bounce_1': u'blue', 'color_line': u'black', 'color_point': u'black', 'line_size': 1, 'mirror': None, 'point_size': 3.5, 'rotation': 0, 'scale': 1, 'translation': [0, 0]}

get_right_BS_nodes()

Return the list of cells containing node of the right planar tree in the Boussicault-Socci bijection between parallelogram polyominoes and pair of ordered trees.

EXAMPLES:

sage: pp = ParallelogramPolyomino([...: [[0, 0, 1, 0, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0]]
....: ])
sage: pp.set_options(display='drawing')
sage: pp
[1 1 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
sage: sorted(pp.get_right_BS_nodes())
You can draw the point inside the parallelogram polyomino by typing, (the left nodes are in blue, and the right node are in red)

```sage
pp.set_options(drawing_components=dict(tree=True))
view(pp)  # not tested
```

**get_tikz_options()**

Return all the tikz options permitting to draw the parallelogram polyomino.

See `LocalOption` to have more informations about the modification of those options.

**EXAMPLES:**

```sage
pp = ParallelogramPolyomino([[0, 1], [1, 0]])
pp.get_tikz_options()
{'color_bounce_0': u'red',
 'color_bounce_1': u'blue',
 'color_line': u'black',
 'color_point': u'black',
 'line_size': 1,
 'mirror': None,
 'point_size': 3.5,
 'rotation': 0,
 'scale': 1,
 'translation': [0, 0]}
```

**height()**

Return the height of the parallelogram polyomino.

**EXAMPLES:**

```sage
pp = ParallelogramPolyomino([[0, 1], [1, 0]])
pp.height()
4
```

(continues on next page)
sage: pp = ParallelogramPolyomino([[1, 1]])
sage: pp.height() 0

**heights()**

Return a list of heights of the parallelogram polyomino.

Namely, the parallelogram polyomino is split column by column and the method returns the list containing the sizes of the columns.

**EXAMPLES:**

```python
sage: pp = ParallelogramPolyomino(
    ....: [0, 0, 0, 1, 0, 1, 0, 1, 1],
    ....: [1, 0, 1, 1, 0, 0, 1, 0, 0]
    ....: )
sage: pp.heights()
[3, 3, 4, 2]
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.heights()
[1]
sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.heights()
[0]
```

**is_flat()**

Return whether the two bounce paths join together in the rightmost cell of the bottom row of P.

**EXAMPLES:**

```python
sage: pp = ParallelogramPolyomino(
    ....: [0, 0, 0, 1, 0, 1, 0, 1, 1],
    ....: [1, 0, 1, 1, 0, 0, 1, 0, 0]
    ....: )
sage: pp.is_flat() False
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.is_flat() True
sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.is_flat() True
```

**is_k_directed(k)**

Return whether the Polyomino Parallelogram is k-directed.

A convex polyomino is said to be k-convex if every pair of its cells can be connected by a monotone path (path with south and east steps) with at most k changes of direction.

5.1. Comprehensive Module list
The degree of convexity of a convex polyomino $P$ is the smallest integer $k$ such that $P$ is $k$-convex.

**INPUT:**

- $k$ – An non negative integer.

**EXAMPLES:**

```python
sage: pp = ParallelogramPolyomino([ [0, 0, 0, 1, 0, 1, 0, 1, 1], [1, 0, 1, 1, 0, 0, 1, 0, 0] ])
sage: pp.is_k_directed(3)
True
sage: pp.is_k_directed(4)
True
sage: pp.is_k_directed(5)
True
sage: pp.is_k_directed(0)
False
sage: pp.is_k_directed(1)
False
sage: pp.is_k_directed(2)
False
```

```python
sage: pp = ParallelogramPolyomino([ [0, 1], [1, 0] ])
sage: pp.is_k_directed(0)
True
sage: pp.is_k_directed(1)
True
sage: pp = ParallelogramPolyomino([ [1], [1] ])
sage: pp.is_k_directed(0)
True
sage: pp.is_k_directed(1)
True
```

**lower_heights()**

Return the list of heights associated to each vertical step of the parallelogram polyomino’s lower path.

**OUTPUT:**

A list of integers.

**EXAMPLES:**

```python
sage: ParallelogramPolyomino([ [0, 1], [1, 0] ]).lower_heights()
[1]
```

```python
sage: ParallelogramPolyomino([ [0, 0, 1, 1, 0, 1, 1, 1], [1, 0, 1, 1, 0, 1, 1, 0] ]).lower_heights()
[2, 2, 3, 3, 3]
```

**lower_path()**

Get the lower path of the parallelogram polyomino.

**EXAMPLES:**
sage: lower_path = [0, 0, 1, 0, 1, 1]
sage: upper_path = [1, 1, 0, 1, 0, 0]
sage: pp = ParallelogramPolyomino([lower_path, upper_path])
sage: pp.lower_path()
[0, 0, 1, 0, 1, 1]

lower_widths()  
Return the list of widths associated to each horizontal step of the parallelogram polyomino’s lower path.  

OUTPUT:  
A list of integers.

EXAMPLES:

sage: ParallelogramPolyomino([[0, 1], [1, 0]]).lower_widths()  
[0]
sage: ParallelogramPolyomino(
    ....:   [[0, 0, 1, 1, 0, 1, 1, 1], [1, 0, 1, 1, 0, 1, 1, 0]]
    ....: ).lower_widths()  
[0, 0, 2]

plot()  
Return a plot of self.

EXAMPLES:

sage: pp = ParallelogramPolyomino([[0,1], [1,0]])
sage: pp.plot()
Graphics object consisting of 4 graphics primitives
sage: pp.set_options(
    ....:     drawing_components=dict(
    ....:         diagram = True
    ....:     , bounce_0 = True
    ....:     , bounce_1 = True
    ....:     , bounce_values = 0
    ....:     )
    ....: )
sage: pp.plot()
Graphics object consisting of 7 graphics primitives

set_options(*get_value, **set_value)  
Set new options to the object. See LocalOptions for more info.

EXAMPLES:

sage: pp = ParallelogramPolyomino(
    ....:   [
    ....:     [0, 0, 0, 0, 1, 0, 1, 0, 1],
    ....:     [1, 0, 0, 0, 1, 1, 0, 0, 0]
    ....:   ]
    ....: )
sage: pp
[[0, 0, 0, 0, 1, 0, 1, 0, 1], [1, 0, 0, 0, 1, 1, 0, 0, 0]]
sage: pp.set_options(display='drawing')
sage: pp
[1 0 0]
[1 0 0]
[1 0 0]  
(continues on next page)
size()

Return the size of the parallelogram polyomino.

The size of a parallelogram polyomino is its half-perimeter.

EXAMPLES:

    sage: pp = ParallelogramPolyomino(
    ....:   [[0, 0, 0, 0, 1, 0, 1, 1], [1, 0, 0, 0, 1, 1, 0, 0]]
    ....: )
    sage: pp.size()
    8
    sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
    sage: pp.size()
    2
    sage: pp = ParallelogramPolyomino([[1], [1]])
    sage: pp.size()
    1

to_binary_tree(bijection=None)

Convert to a binary tree

INPUT:

- bijection – string or None (default:None) The name of bijection to use for the conversion.
  The possible values are None or 'Aval-Boussicault'. The None value is equivalent to
  'Aval-Boussicault'.

EXAMPLES:

    sage: pp = ParallelogramPolyomino(
    ....:   [[0, 0, 1, 0, 1, 0, 1, 0, 1, 1], [1, 0, 0, 1, 1, 0, 0], [0, 0, 1, 0, 1, 0, 1, 0, 1, 0]]
    ....: )
    sage: pp.to_binary_tree()
    [[., [[., .], [[., .], .]]], [[., .], .]]
    sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
    sage: pp.to_binary_tree()

\begin{verbatim}
[., .]
sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.to_binary_tree()
.
\end{verbatim}

\textbf{to\_dyck\_word (bijection=None)}

Convert to a Dyck word.

This bijection is described page 179 and page 180 Figure 6 in the article [DeVi1984].

\textbf{INPUT:}

\begin{itemize}
  \item bijection -- string or None (default:None) The name of the bijection. If it is set to None then the 'Delest-Viennot' bijection is used. Expected values are None or 'Delest-Viennot'.
\end{itemize}

\textbf{OUTPUT:}

a Dyck word

\textbf{EXAMPLES:}

\begin{verbatim}
sage: pp = ParallelogramPolyomino(
  ....:   [[0, 1, 0, 0, 1, 1], [1, 1, 1, 0, 0, 0]]
  ....: )
sage: pp.to_dyck_word()
[1, 1, 0, 1, 1, 0, 1, 0, 0, 0]
sage: pp.to_dyck_word(bijection='Delest-Viennot')
[1, 1, 0, 1, 1, 0, 1, 0, 0, 0]
\end{verbatim}

\textbf{to\_ordered\_tree (bijection=None)}

Return an ordered tree from the parallelogram polyomino.

Different bijections can be specified.

The bijection 'via dyck and Delest-Viennot' is the composition of \_to\_dyck\_delest\_viennot() and the classical bijection between dyck paths and ordered trees.

The bijection between Dyck Word and ordered trees is described in [DerZak1980] (See page 12 and 13 and Figure 3.1).

The bijection 'Boussicault-Socci' is described in [BRS2015].

\textbf{INPUT:}

\begin{itemize}
  \item bijection -- string or None (default:None) The name of bijection to use for the conversion. The possible value are None, 'Boussicault-Socci' or 'via dyck and Delest-Viennot'. The None value is equivalent to the 'Boussicault-Socci' value.
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: pp = ParallelogramPolyomino(
  ....:   [...
  ....:     [0, 0, 1, 0, 1, 0, 1, 0, 1, 1],
  ....:     [1, 1, 0, 1, 1, 0, 0, 0, 1, 0]
  ....: ]
  ....: )
sage: pp.to_ordered_tree()
[[[[[[]], [[]]]], [[]]]]
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
\end{verbatim}
sage: pp.to_ordered_tree()
[[[]]]

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.to_ordered_tree()
[]

sage: pp = ParallelogramPolyomino(
    ....:     [0, 0, 1, 0, 1, 0, 1, 0, 1, 1],
    ....:     [1, 1, 0, 1, 0, 0, 0, 1, 0, 1, 0]
    ....: )
sage: pp.to_ordered_tree('via dyck and Delest-Viennot')
[[[[]], [[]]], [[]]]

to_tikz()
Return the tikz code of the parallelogram polyomino.

This code is the code present inside a tikz latex environment.

We can modify the output with the options.

EXAMPLES:

sage: pp = ParallelogramPolyomino(
    ....:     [[0,0,0,1,1,0,1,0,0,1,1,1],
    ....:      [1,1,1,0,0,1,1,0,0,1,0,0]])
sage: print pp.to_tikz()
\draw[color=black, line width=1] (0.000000, 6.000000) -- (0.000000, 3.000000);
\draw[color=black, line width=1] (6.000000, 2.000000) -- (6.000000, 0.000000);
\draw[color=black, line width=1] (0.000000, 6.000000) -- (3.000000, 6.000000);
\draw[color=black, line width=1] (3.000000, 0.000000) -- (6.000000, 0.000000);
\draw[color=black, line width=1] (1.000000, 6.000000) -- (1.000000, 3.000000);
\draw[color=black, line width=1] (2.000000, 6.000000) -- (2.000000, 2.000000);
\draw[color=black, line width=1] (3.000000, 6.000000) -- (3.000000, 0.000000);
\draw[color=black, line width=1] (4.000000, 4.000000) -- (4.000000, 0.000000);
\draw[color=black, line width=1] (5.000000, 4.000000) -- (5.000000, 0.000000);
\draw[color=black, line width=1] (0.000000, 5.000000) -- (3.000000, 5.000000);
\draw[color=black, line width=1] (0.000000, 4.000000) -- (5.000000, 4.000000);
\draw[color=black, line width=1] (0.000000, 3.000000) -- (5.000000, 3.000000);
\draw[color=black, line width=1] (2.000000, 2.000000) -- (6.000000, 2.000000);
\draw[color=black, line width=1] (3.000000, 1.000000) -- (6.000000, 1.000000);
sage: pp.set_options(...:
....:   drawing_components=dict(...:
....:       diagram=True,
....:       tree=True,
....:       bounce_0=True,
....:       bounce_1=True)
....: }

sage: print (pp.to_tikz())
\draw[color=black, line width=1] (0.000000, 6.000000) -- (0.000000, 3.000000);
\draw[color=black, line width=1] (6.000000, 2.000000) -- (6.000000, 0.000000);
\draw[color=black, line width=1] (0.000000, 6.000000) -- (3.000000, 6.000000);
\draw[color=black, line width=1] (3.000000, 6.000000) -- (6.000000, 0.000000);
\draw[color=black, line width=1] (0.000000, 6.000000) -- (1.000000, 6.000000);
\draw[color=black, line width=1] (2.000000, 6.000000) -- (2.000000, 2.000000);
\draw[color=black, line width=1] (3.000000, 6.000000) -- (3.000000, 0.000000);
\draw[color=black, line width=1] (4.000000, 4.000000) -- (4.000000, 0.000000);
\draw[color=black, line width=1] (5.000000, 4.000000) -- (5.000000, 0.000000);
\draw[color=black, line width=1] (0.000000, 5.000000) -- (3.000000, 5.000000);
\draw[color=black, line width=1] (0.000000, 4.000000) -- (5.000000, 4.000000);
\draw[color=black, line width=1] (0.000000, 3.000000) -- (5.000000, 3.000000);
\draw[color=black, line width=1] (2.000000, 2.000000) -- (6.000000, 2.000000);
\draw[color=black, line width=1] (3.000000, 1.000000) -- (6.000000, 1.000000);
\draw[color=blue, line width=3] (0.000000, 5.000000) -- (3.000000, 5.000000);
\draw[color=blue, line width=3] (3.000000, 5.000000) -- (3.000000, 2.000000);
\draw[color=blue, line width=3] (3.000000, 2.000000) -- (5.000000, 2.000000);
\draw[color=blue, line width=3] (5.000000, 2.000000) -- (5.000000, 0.000000);
\draw[color=blue, line width=3] (5.000000, 0.000000) -- (6.000000, 0.000000);
\draw[color=red, line width=2] (1.000000, 6.000000) -- (0.000000, 3.000000);
\draw[color=red, line width=2] (1.000000, 3.000000) -- (5.000000, 3.000000);
\draw[color=red, line width=2] (5.000000, 3.000000) -- (5.000000, 0.000000);
\draw[color=red, line width=2] (5.000000, 0.000000) -- (6.000000, 0.000000);
\filldraw[color=black] (0.500000, 4.500000) circle (3.5pt);
upper_heights()
Return the list of heights associated to each vertical step of the parallelogram polyomino’s upper path.

OUTPUT:
A list of integers.

EXAMPLES:

```python
sage: upper_heights = ParallelogramPolyomino([[0, 1], [1, 0]]).upper_heights()
sage: upper_heights
```

upper_path()
Get the upper path of the parallelogram polyomino.

EXAMPLES:

```python
sage: lower_path = [0, 0, 1, 0, 1, 1]
sage: upper_path = [1, 1, 0, 1, 0, 0]
sage: pp = ParallelogramPolyomino([lower_path, upper_path])
sage: pp.upper_path()
```

upper_widths()
Return the list of widths associated to each horizontal step of the parallelogram polyomino’s upper path.

OUTPUT:
A list of integers.

EXAMPLES:

```python
sage: upper_widths = ParallelogramPolyomino([[0, 1], [1, 0]]).upper_widths()
sage: upper_widths
```

width()
Return the width of the parallelogram polyomino.

EXAMPLES:
sage: pp = ParallelogramPolyomino(
    ....:     [0, 1, 0, 1, 0, 1, 0, 1, 1, 1],
    ....:     [1, 1, 0, 1, 0, 0, 1, 0, 1, 0]
    ....: )
sage: pp.width()
6

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.width()
1

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.width()
1

widths()  
Return a list of the widths of the parallelogram polyomino.

Namely, the parallelogram polyomino is split row by row and the method returns the list containing the
sizes of the rows.

EXAMPLES:

sage: pp = ParallelogramPolyomino(
    ....:     [0, 0, 0, 1, 0, 1, 0, 1, 1],
    ....:     [1, 0, 1, 1, 0, 0, 1, 0, 0]
    ....: )
sage: pp.widths()
[1, 3, 3, 3, 2]

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.widths()
[1]

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.widths()
[]

sage.combinat.parallelogram_polyomino.ParallelogramPolyominoes = Factory for parallelogram polyominoes

class sage.combinat.parallelogram_polyomino.ParallelogramPolyominoesFactory
    Bases: sage.structure.set_factories.SetFactory

The parallelogram polyominoes factory.

EXAMPLES:

sage: PPS = ParallelogramPolyominoes(size=4)
sage: PPS
Parallelogram polyominoes of size 4

sage: sorted(PPS)

(continues on next page)
sage.combinat.parallelogram_polyomino.ParallelogramPolyominoesOptions = Current options for ParallelogramPolyominoes

This global option contains all the data needed by the Parallelogram classes to draw, display in ASCII, compile in latex a parallelogram polyomino.

The available options are:

- **tikz_options**: this option configure all the information useful to generate TIKZ code. For example, color, line size, etc …
- **drawing_components**: this option is used to explain to the system which component of the drawing you want to draw. For example, you can ask to draw some elements of the following list: - the diagram, - the tree inside the parallelogram polyomino, - the bounce paths inside the parallelogram polyomino, - the value of the bounce on each square of a bounce path.
- **display**: this option is used to configure the ASCII display. The available options are: - list: (this is the default value) is used to represent PP as a list containing the upper and lower path. - drawing : this value is used to explain we want to display an array with the PP drawn inside (with connected 1).
- **latex**: Same as display. The default is “drawing”.

See `ParallelogramPolyomino.get_options()` for more details and for an user use of options.

**EXAMPLES:**

```python
sage: from sage.combinat.parallelogram_polyomino import (....:   ParallelogramPolyominoesOptions
....: )
```
```python
sage: opt = ParallelogramPolyominoesOptions['tikz_options']
```
```python
sage: opt
{'color_bounce_0': u'red',
 'color_bounce_1': u'blue',
 'color_line': u'black',
 'color_point': u'black',
 'line_size': 1,
 'mirror': None,
 'point_size': 3.5,
 'rotation': 0,
 'scale': 1,
 'translation': [0, 0]}
```

class sage.combinat.parallelogram_polyomino.ParallelogramPolyominoes_all(policy)

Bases: sage.structure.set_factories.ParentWithSetFactory, sage.sets.disjoint_union EnumeratedSets.Disjoint Union Enumerated Sets

This class enumerates all the parallelogram polyominoes.

**EXAMPLES:**
Parallelogram polyominoes

check_element (el, check)

Check is a given element el is in the set of parallelogram polyominoes.

EXAMPLES:

```
sage: PPS = ParallelogramPolyominoes()
sage: PPS
ParallelogramPolyominoes()

sage: PPS
ParallelogramPolyominoes()

sage: [[0, 1, 1], [1, 1, 0]] in PPS
True
```

get_options ()

Return all the options associated with the set of parallelogram polyominoes.

EXAMPLES:

```
sage: PPS = ParallelogramPolyominoes()
sage: options = PPS.get_options()
sage: options
Current options for ParallelogramPolyominoes_size
  - display: u'list'
  ...
```

options = Current options for ParallelogramPolyominoes_size - display: 'list' - drawing

The options for ParallelogramPolyominoes.

set_options (*get_value, **set_value)

Set new options to the object.

EXAMPLES:

```
sage: PPS = ParallelogramPolyominoes()
sage: PPS.set_options(
  ....:     drawing_components=dict(
  ....:         diagram=True,
  ....:         bounce_0=True,
  ....:         bounce_1=True,
  ....:     )
  ....:)
sage: pp = next(iter(PPS))
sage: view(pp) # not tested
```

class sage.combinatparallelogramPolyomino.ParallelogramPolyominoes_size (size, policy)

Bases: sage.structure.set_factories.ParentWithSetFactory, sage.structure.unique_representation.UniqueRepresentation

The parallelogram polyominoes of size n.

EXAMPLES:

```
sage: PPS = ParallelogramPolyominoes(4)
sage: PPS
Parallelogram polyominoes of size 4
```

(continues on next page)
an_element()

Return an element of a parallelogram polyomino of a given size.

EXAMPLES:

```python
sage: PPS = ParallelogramPolyominoes(4)
sage: PPS.an_element() in PPS
True
```

cardinality()

Return the number of parallelogram polyominoes.

The number of parallelogram polyominoes of size $n$ is given by the Catalan number $c_n$.  

EXAMPLES:

```python
sage: ParallelogramPolyominoes(1).cardinality()
1
sage: ParallelogramPolyominoes(2).cardinality()
1
sage: ParallelogramPolyominoes(3).cardinality()
2
sage: ParallelogramPolyominoes(4).cardinality()
5
```

check_element(el, check)

Check is a given element $el$ is in the set of parallelogram polyominoes of a fixed size.

EXAMPLES:

```python
sage: PPS = ParallelogramPolyominoes(3)
sage: ParallelogramPolyomino(
....:   [[0, 1, 1], [1, 1, 0]]
....: ) in PPS # indirect doctest
True
```

get_options()

Return all the options associated with all the elements of the set of parallelogram polyominoes with a fixed size.

EXAMPLES:

```python
sage: pps = ParallelogramPolyominoes(5)
sage: pps.get_options()
```
options = Current options for ParallelogramPolyominoes_size - display: 'list' - drawing
The options for ParallelogramPolyominoes.

set_options(*get_value, **set_value)
Set new options to the object.

EXAMPLES:

```
sage: PPS = ParallelogramPolyominoes(3)
sage: PPS.set_options(
    ....:     drawing_components=dict(
    ....:         diagram = True,
    ....:         bounce_0 = True,
    ....:         bounce_1 = True,
    ....:     )
    ....:)
sage: pp = PPS[0]
sage: view(pp) # not tested
```

size()
Return the size of the parallelogram polyominoes generated by this parent.

EXAMPLES:

```
sage: ParallelogramPolyominoes(0).size() 0
sage: ParallelogramPolyominoes(1).size() 1
sage: ParallelogramPolyominoes(5).size() 5
```

This is the default TIKZ options.
This option is used to configure element of a drawing to allow TIKZ code generation.

5.1.160 Parking Functions

INFORMALLY (reference [Beck]):

Imagine a one-way cul-de-sac with \( n \) parking spots. We will give the first parking spot the number 1, the next one number 2, etc., down to the last one, number \( n \). Initially they are all free, but there are \( n \) cars approaching the street, and they would all like to park there. To make life interesting, every car has a parking preference, and we record the preferences in a sequence; For example, if \( n = 3 \), the sequence (2, 1, 1) means that the first car would like to park at spot number 2, the second car prefers parking spot number 1, and the last car would also like to part at number 1. The street is very narrow, so there is no way to back up. Now each car enters the street and approaches its preferred parking spot; if it is free, it parks there, and if not, it moves down the street to the first available spot. We call a sequence a parking function (of length \( n \)) if all cars end up finding a parking spot. For example, the sequence (2, 1, 1) is a parking sequence (of length 3), whereas the sequence (2, 3, 2) is not.

FORMALLY:
A parking function of size $n$ is a sequence $(a_1, \ldots, a_n)$ of positive integers such that if $b_1 \leq b_2 \leq \cdots \leq b_n$ is the increasing rearrangement of $a_1, \ldots, a_n$, then $b_i \leq i$.

A parking function of size $n$ is a pair $(L, D)$ of two sequences $L$ and $D$ where $L$ is a permutation and $D$ is an area sequence of a Dyck path of size $n$ such that $D[i] \geq 0$, $D[i+1] \leq D[i] + 1$ and if $D[i+1] = D[i] + 1$ then $L[i+1] > L[i]$.

The number of parking functions of size $n$ is equal to the number of rooted forests on $n$ vertices and is equal to $(n+1)^{n-1}$.

REFERENCES:

AUTHORS:

• used non-decreasing_parking_functions code by Florent Hivert (2009 - 04)
• Dorota Mazur (2012 - 09)

```
sage.combinat.parking_functions.ParkingFunction (pf=None, labelling=None, area_sequence=None, labelled_dyck_word=None)
```

Return the combinatorial class of Parking Functions.

A parking function of size $n$ is a sequence $(a_1, \ldots, a_n)$ of positive integers such that if $b_1 \leq b_2 \leq \cdots \leq b_n$ is the increasing rearrangement of $a_1, \ldots, a_n$, then $b_i \leq i$.

A parking function of size $n$ is a pair $(L, D)$ of two sequences $L$ and $D$ where $L$ is a permutation and $D$ is an area sequence of a Dyck Path of size $n$ such that $D[i] \geq 0$, $D[i+1] \leq D[i] + 1$ and if $D[i+1] = D[i] + 1$ then $L[i+1] > L[i]$.

The number of parking functions of size $n$ is equal to the number of rooted forests on $n$ vertices and is equal to $(n+1)^{n-1}$.

INPUT:

• $pf$ – (default: None) a list whose increasing rearrangement satisfies $b_i \leq i$
• $labelling$ – (default: None) a labelling of the Dyck path
• $area_sequence$ – (default: None) an area sequence of a Dyck path
• $labelled_dyck_word$ – (default: None) a Dyck word with 1’s replaced by labelling

OUTPUT:

• A parking function

EXAMPLES:

```
sage: ParkingFunction([])
[]
sage: ParkingFunction([1])
[1]
sage: ParkingFunction([2])
Traceback (most recent call last):
  ...
ValueError: [2] is not a parking function.
sage: ParkingFunction([1,2])
[1, 2]
sage: ParkingFunction([1,1,2])
[1, 1, 2]
sage: ParkingFunction([1,4,1])
Traceback (most recent call last):
  ...
```

(continues on next page)
ValueError: [1, 4, 1] is not a parking function.
sage: ParkingFunction(labelling=[3,1,2], area_sequence=[0,0,1])
[2, 2, 1]
sage: ParkingFunction([2,2,1]).to_labelled_dyck_word()
[3, 0, 1, 2, 0, 0]
sage: ParkingFunction(labelling=[3,1,2], area_sequence=[0,1,1])
[2, 2, 1]
Traceback (most recent call last):
  ... ValueError: [3, 1, 2] is not a valid labeling of area sequence [0, 1, 1]

class sage.combinat.parking_functions.ParkingFunction_class(lst)
    Bases: sage.combinat.combinat.CombinatorialObject

area()
    Return the area of the labelled Dyck path corresponding to the parking function.
    INPUT:
    • self – parking function word
    OUTPUT:
    • the sum of squares under and over the main diagonal the Dyck Path, corresponding to the parking function
    EXAMPLES:

    sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.area()
6
    sage: ParkingFunction([3,1,1,4]).area()
1
    sage: ParkingFunction([4,1,1,1]).area()
3
    sage: ParkingFunction([2,1,4,1]).area()
2
cars_permutation()
    Return the sequence of cars that take parking spots 1 through \( n \) and corresponding to the parking function.
    For example, cars_permutation(PF) = [2, 4, 5, 6, 3, 1, 7] means that car 2 takes spots 1, car 4 takes spot 2, ..., car 1 takes spot 6 and car 7 takes spot 7.
    INPUT:
    • self – parking function word
    OUTPUT:
    • the permutation of cars corresponding to the parking function and which is the same size as parking function
    EXAMPLES:

    sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.cars_permutation()
[2, 4, 5, 6, 3, 1, 7]
sage: ParkingFunction([3,1,1,4]).cars_permutation()
[2, 3, 1, 4]
sage: ParkingFunction([4,1,1,1]).cars_permutation()
[2, 3, 4, 1]
sage: ParkingFunction([2,1,4,1]).cars_permutation()
[2, 1, 4, 3]

characteristic_quasisymmetric_function(q=None, R=Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field)

Return the characteristic quasisymmetric function of self.

The characteristic function of the Parking Function is the sum over all permutation labellings of the Dyck path \( q^{\text{area}(PF)} F_{\text{ides}(PF)} \) where \( \text{ides}(PF) \) is the descent composition of the diagonal reading word of the parking function.

INPUT:

- \( q \) – (default: \( q = R('q') \)) a parameter for the generating function power
- \( R \) – (default: \( R = \mathbb{Q}[\text{\textquoteleft}q\text{\textquoteleft}, \text{\textquoteleft}t\text{\textquoteleft}].fraction_field() \)) the base ring to do the calculations over

OUTPUT:

- an element of the quasisymmetric functions over the ring \( R \)

EXAMPLES:

```
sage: R = QQ['q','t'].fraction_field()
sage: (q,t) = R.gens()
sage: cqf = sum(t**PF.area()*PF.characteristic_quasisymmetric_function() for \rightarrow PF in ParkingFunctions(3)); cqf
(q^3+q^2*t+q*t^2+t^3+q*t)*F[1, 1, 1] + (q^2+q*t+t^2+q+t)*F[1, 2] + (q^2+q*t+t^2+q+t)*F[2, 1] + F[3]
sage: s = SymmetricFunctions(R).s()
sage: s(cqf.to_symmetric_function())
(q^3+q^2*t+q*t^2+t^3+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q+t)*s[2, 1] + s[3]
sage: s(cqf.to_symmetric_function()).nabla(power = -1)
s[1, 1, 1]
```

diagonal_composition()

Return the composition of the labelled Dyck path corresponding to the parking function.

For example, \( \text{touch_composition}(PF) = [4, 3] \) means that the first touch is four diagonal units from the starting point, and the second is three units further (see [GXZ] p. 2).

INPUT:

- \( \text{self} \) – parking function word

OUTPUT:

- the length between the corresponding touch points which of the labelled Dyck path that corresponds to the parking function

EXAMPLES:

```
sage: p = ParkingFunction([3, 1, 2])
sage: p.characteristic_quasisymmetric_function()
q*F[2, 1]
sage: pf = ParkingFunction([1,2,7,2,1,2,3,2,1])
sage: pf.characteristic_quasisymmetric_function()
q^2*F[1, 1, 1, 2, 1, 2, 1, 3]
```

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.touch_composition()
[4, 3]
```

```
sage: ParkingFunction([3,1,1,4]).touch_composition()
[2, 1, 1]
sage: ParkingFunction([4,1,1,1]).touch_composition()
[3, 1]
sage: ParkingFunction([2,1,4,1]).touch_composition()
[3, 1]
```

diagonal_reading_word()
Return a diagonal word of the labelled Dyck path corresponding to parking function (see [Hag08] p. 75).

INPUT:

• self – parking function word

OUTPUT:

• returns a word, read diagonally from NE to SW of the pretty print of the labelled Dyck path that corresponds to self and the same size as self

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.diagonal_reading_word()
[5, 1, 7, 4, 6, 3, 2]
```

```
sage: ParkingFunction([1, 1, 1]).diagonal_reading_word()
[3, 2, 1]
sage: ParkingFunction([1, 2, 3]).diagonal_reading_word()
[3, 2, 1]
sage: ParkingFunction([1, 1, 3, 4]).diagonal_reading_word()
[2, 4, 3, 1]
```

diagonal_word()
Return a diagonal word of the labelled Dyck path corresponding to parking function (see [Hag08] p. 75).

INPUT:

• self – parking function word

OUTPUT:

• returns a word, read diagonally from NE to SW of the pretty print of the labelled Dyck path that corresponds to self and the same size as self

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.diagonal_word()
[5, 1, 7, 4, 6, 3, 2]
```

5.1. Comprehensive Module list 1489
\[
\text{sage: ParkingFunction([1, 1, 1]).diagonal_reading_word()}
\] [3, 2, 1]
\[
\text{sage: ParkingFunction([1, 2, 3]).diagonal_reading_word()}
\] [3, 2, 1]
\[
\text{sage: ParkingFunction([1, 1, 3, 4]).diagonal_reading_word()}
\] [2, 4, 3, 1]
\[
\text{sage: ParkingFunction([1, 1, 1]).diagonal_word()}
\] [3, 2, 1]
\[
\text{sage: ParkingFunction([1, 2, 3]).diagonal_word()}
\] [3, 2, 1]
\[
\text{sage: ParkingFunction([1, 4, 3, 1]).diagonal_word()}
\] [4, 2, 3, 1]

```
dinv()
```

Return the number of inversions of a labelled Dyck path corresponding to the parking function (see [Hag08] p. 74).

Same as the cardinality of `dinversion_pairs()`.

**INPUT:**

- `self` - parking function word

**OUTPUT:**

- the number of dinversion pairs

**EXAMPLES:**

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.dinv()
6
```

```
sage: ParkingFunction([3,1,1,4]).dinv()
3
sage: ParkingFunction([4,1,1,1]).dinv()
1
sage: ParkingFunction([2,1,4,1]).dinv()
2
```

```
dinversion_pairs()
```

Return the descent inversion pairs of a labelled Dyck path corresponding to the parking function.

**INPUT:**

- `self` - parking function word

**OUTPUT:**

- the primary and secondary diversion pairs

**EXAMPLES:**

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.dinversion_pairs()
[(0, 4), (1, 5), (2, 5), (1, 4), (2, 4), (3, 6)]
```
ides()  
Return the descents() sequence of the inverse of the diagonal_reading_word() of self.

**Warning:** Here we use the standard convention that descent labels start at 1. This behaviour has been changed in trac ticket #20555.

For example, \( \text{ides}(PF) = [2, 3, 4, 6] \) means that descents are at the 2nd, 3rd, 4th and 6th positions in the inverse of the \( \text{diagonal_reading_word()} \) of the parking function (see [GXZ] p. 2).

**INPUT:**
- `self` – parking function word

**OUTPUT:**
- the descents sequence of the inverse of the \( \text{diagonal_reading_word()} \) of the parking function

**EXAMPLES:**

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.ides()
[2, 3, 4, 6]
```

```
sage: ParkingFunction([3,1,1,4]).ides()
[2]
sage: ParkingFunction([4,1,1,1]).ides()
[2, 3]
sage: ParkingFunction([4,3,1,1]).ides()
[3]
```

ides_composition()  
Return the descents_composition() of the inverse of the \( \text{diagonal_reading_word()} \) of corresponding parking function.

For example, \( \text{ides_composition}(PF) = [4, 2, 1] \) means that the descents of the inverse of the permutation \( \text{diagonal_reading_word()} \) of the parking function with word \( PF \) are at the 4th and 6th positions.

**INPUT:**
- `self` – parking function word

**OUTPUT:**
- the descents composition of the inverse of the \( \text{diagonal_reading_word()} \) of the parking function

**EXAMPLES:**

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.ides_composition()
[2, 1, 1, 2, 1]
```

5.1. Comprehensive Module list 1491
jump()

Return the sum of the differences between the parked and preferred parking spots.

See [Shin] p. 18.

INPUT:

• self – a parking function word

OUTPUT:

• the sum of the differences between the parked and preferred parking spots

EXAMPLES:

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.jump()
6
```

```python
sage: ParkingFunction([3,1,4]).jump()
1
sage: ParkingFunction([4,1,1]).jump()
3
sage: ParkingFunction([2,1,4,1]).jump()
2
```

jump_list()

Return the displacements of cars that corresponds to the parking function.

For example, jump_list(PF) = [0, 0, 0, 0, 1, 3, 2] means that car 1 through 4 parked in their preferred spots, car 5 had to park one spot farther (jumped or was displaced by one spot), car 6 had to jump 3 spots, and car 7 had to jump two spots.

INPUT:

• self – parking function word

OUTPUT:

• the displacements sequence of parked cars which corresponds to the parking function and which is the same size as parking function

EXAMPLES:

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.jump_list()
[0, 0, 0, 0, 1, 3, 2]
```

```python
sage: ParkingFunction([3,1,4]).jump_list()
[0, 0, 1, 0]
sage: ParkingFunction([4,1,1,1]).jump_list()
[0, 0, 1, 2]
sage: ParkingFunction([2,1,4,1]).jump_list()
[0, 0, 0, 2]
```
luck()  
Return the number of cars that parked in their preferred parking spots (see [Shin] p. 33).

INPUT:
• self – parking function word

OUTPUT:
• the number of cars that parked in their preferred parking spots

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.luck()
4
```
```
sage: ParkingFunction([3,1,1,4]).luck()
sage: ParkingFunction([4,1,1,1]).luck()
sage: ParkingFunction([2,1,4,1]).luck()
```

lucky_cars()  
Return the cars that can park in their preferred spots. For example, `lucky_cars(PF) = [1, 2, 7]` means that cars 1, 2 and 7 parked in their preferred spots and all the other cars did not.

INPUT:
• self – parking function word

OUTPUT:
• the cars that can park in their preferred spots

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.lucky_cars()
[1, 2, 3, 4]
```
```
sage: ParkingFunction([3,1,1,4]).lucky_cars()
[1, 2, 4]
```
```
sage: ParkingFunction([4,1,1,1]).lucky_cars()
[1, 2]
```
```
sage: ParkingFunction([2,1,4,1]).lucky_cars()
[1, 2, 3]
```

parking_permutation()  
Return the sequence of parking spots that are taken by cars 1 through n and corresponding to the parking function.

For example, `parking_permutation(PF) = [6, 1, 5, 2, 3, 4, 7]` means that spot 6 is taken by car 1, spot 1 by car 2, spot 5 by car 3, spot 2 is taken by car 4, spot 3 is taken by car 5, spot 4 is taken by car 6 and spot 7 is taken by car 7.

INPUT:
• self – parking function word

OUTPUT:
• the permutation of parking spots that corresponds to the parking function and which is the same size as parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.parking_permutation()
[6, 1, 5, 2, 3, 4, 7]
```

```
sage: ParkingFunction([3,1,1,4]).parking_permutation()
[3, 1, 2, 4]
sage: ParkingFunction([4,1,1,1]).parking_permutation()
[4, 1, 2, 3]
sage: ParkingFunction([2,1,4,1]).parking_permutation()
[2, 1, 4, 3]
```

**pretty_print** *(underpath=True)*

Displays a parking function as a lattice path consisting of a Dyck path and a labelling with the labels displayed along the edges of the Dyck path.

**INPUT:**

• `underpath` – if the length of the parking function is less than or equal to 9 then display the labels under the path if `underpath` is True otherwise display them to the right of the path (default: True)

**EXAMPLES:**

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.pretty_print()
___
|1x
|7x .
|3 x ...
|5 x ... 
|4 x .... 
|6 x .... .
|2 .......

sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.pretty_print(underpath = false)
___
| x 1
| . 7
| . 3
| x ... 5
| x .... 4
| x .... 6
| .... 2
```

```
sage: ParkingFunction([3, 1, 1, 4]).pretty_print()
_  
| 4
|1 .
|3x .
|2 .

sage: ParkingFunction([1,1,1]).pretty_print()
____
(continues on next page)
primary_dinversion_pairs()

Return the primary descent inversion pairs of a labelled Dyck path corresponding to the parking function.

INPUT:

• self – parking function word

OUTPUT:

• the pairs $(i, j)$ such that $i < j$, and $i^{th}$ area = $j^{th}$ area, and $i^{th}$ label < $j^{th}$ label

EXAMPLES:

```sage
PF = ParkingFunction([6, 1, 5, 2, 2, 1])
sage: PF.primary_dinversion_pairs()
[(0, 4), (1, 5), (2, 5)]
```
secondary_dinversion_pairs()
Return the secondary descent inversion pairs of a labelled Dyck path corresponding to the parking function.

INPUT:
• self – parking function word

OUTPUT:
• the pairs \((i, j)\) such that \(i < j\), and \(i^{th}\) area = \(j^{th}\) area + 1, and \(i^{th}\) label > \(j^{th}\) label

EXAMPLES:

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.secondary_dinversion_pairs()
[(1, 4), (2, 4), (3, 6)]
sage: ParkingFunction([3,1,1,4]).secondary_dinversion_pairs()
[(1, 2)]
sage: ParkingFunction([4,1,1,1]).secondary_dinversion_pairs()
[(1, 3)]
sage: ParkingFunction([2,1,4,1]).secondary_dinversion_pairs()
[(1, 3)]
```

to_NonDecreasingParkingFunction()
Return the non-decreasing parking function which underlies the parking function.

INPUT:
• self – parking function word

OUTPUT:
• a sorted parking function

See also:
NonDecreasingParkingFunction()

EXAMPLES:

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_NonDecreasingParkingFunction()
[1, 1, 2, 2, 5, 5, 6]
sage: ParkingFunction([3,1,1,4]).to_NonDecreasingParkingFunction()
[1, 1, 3, 4]
sage: ParkingFunction([4,1,1,1]).to_NonDecreasingParkingFunction()
[1, 1, 4]
sage: ParkingFunction([2,1,4,1]).to_NonDecreasingParkingFunction()
[1, 1, 2, 4]
sage: ParkingFunction([4,1,2,1]).to_NonDecreasingParkingFunction()
[1, 1, 2, 4]
```
to_area_sequence()

Return the area sequence of the support Dyck path of the parking function.

INPUT:

• self – parking function word

OUTPUT:

• the area sequence of the Dyck path

EXAMPLES:

sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
[sage: PF.to_area_sequence()]
[0, 1, 1, 2, 0, 1, 1]

sage: ParkingFunction([3,1,1,4]).to_area_sequence()
[0, 1, 0, 0]

sage: ParkingFunction([4,1,1,1]).to_area_sequence()
[0, 1, 2, 0]

sage: ParkingFunction([2,1,4,1]).to_area_sequence()
[0, 1, 1, 0]

to_dyck_word()

Return the support Dyck word of the parking function.

INPUT:

• self – parking function word

OUTPUT:

• the Dyck word of the corresponding parking function

See also:

DyckWord()

EXAMPLES:

sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
[sage: PF.to_dyck_word()]
[1, 1, 0, 1, 1, 0, 0, 0, 1, 1, 0, 1, 0, 0]

sage: ParkingFunction([3,1,1,4]).to_dyck_word()
[1, 1, 0, 0, 1, 0, 1, 0]

sage: ParkingFunction([4,1,1,1]).to_dyck_word()
[1, 1, 1, 0, 0, 0, 1, 0]

sage: ParkingFunction([2,1,4,1]).to_dyck_word()
[1, 1, 0, 1, 0, 0, 1, 0]

to_labelled_dyck_word()

Return the labelled Dyck word corresponding to the parking function.

This is a representation of the parking function as a list where the entries of 1 in the Dyck word are replaced with the corresponding label.

INPUT:

• self – parking function word

OUTPUT:
• the labelled Dyck word of the corresponding parking function which is twice the size of parking function word

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelled_dyck_word()
[2, 6, 0, 4, 5, 0, 0, 3, 7, 0, 1, 0, 0]
```

```
sage: ParkingFunction([3,1,1,4]).to_labelled_dyck_word()
[2, 3, 0, 0, 1, 0, 4, 0]
```

```
sage: ParkingFunction([4,1,1,1]).to_labelled_dyck_word()
[2, 3, 4, 0, 0, 0, 1, 0]
```

```
sage: ParkingFunction([2,1,4,1]).to_labelled_dyck_word()
[2, 4, 0, 1, 0, 0, 3, 0]
```

to_labelling_area_sequence_pair()
Return a pair consisting of a labelling and an area sequence of a Dyck path which corresponds to the given parking function.

INPUT:
• self – the parking function word

OUTPUT:
• returns a pair (L, D) where L is a labelling and D is the area sequence of the underlying Dyck path

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelling_area_sequence_pair()
([2, 6, 4, 5, 3, 7, 1], [0, 1, 1, 2, 0, 1, 1])
```

```
sage: ParkingFunction([1, 1, 1]).to_labelling_area_sequence_pair()
([1, 2, 3], [0, 1, 2])
```

```
sage: ParkingFunction([1, 2, 3]).to_labelling_area_sequence_pair()
([1, 2, 3], [0, 0, 0])
```

```
sage: ParkingFunction([1, 1, 2]).to_labelling_area_sequence_pair()
([1, 2, 3], [0, 1, 1])
```

```
sage: ParkingFunction([1, 1, 3, 1]).to_labelling_area_sequence_pair()
([1, 2, 4, 3], [0, 1, 2, 1])
```

to_labelling_dyck_word_pair()
Return the pair (L, D) where L is a labelling and D is the Dyck word of the parking function.

INPUT:
• self – parking function word

OUTPUT:
• the pair (L, D), where L is the labelling and D is the Dyck word of the parking function

See also:
DyckWord()

EXAMPLES:

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelling_dyck_word_pair()
([2, 6, 4, 5, 3, 7, 1], [1, 1, 0, 1, 0, 0, 0, 1, 1, 0, 0, 0, 1, 0, 0])
```

```python
sage: ParkingFunction([3,1,1,4]).to_labelling_dyck_word_pair()
([2, 3, 1, 4], [1, 1, 0, 0, 1, 0, 1, 0])
sage: ParkingFunction([4,1,1,1]).to_labelling_dyck_word_pair()
([2, 3, 4, 1], [1, 1, 1, 0, 0, 0, 1, 0])
sage: ParkingFunction([2,1,4,1]).to_labelling_dyck_word_pair()
([2, 4, 1, 3], [1, 1, 0, 1, 0, 0, 1, 0])
```

**to_labelling_permutation()**

Return the labelling of the support Dyck path of the parking function.

**INPUT:**

- `self` – parking function word

**OUTPUT:**

- the labelling of the Dyck path

**EXAMPLES:**

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelling_permutation()
[2, 6, 4, 5, 3, 7, 1]
sage: ParkingFunction([3,1,1,4]).to_labelling_permutation()
[2, 3, 1, 4]
sage: ParkingFunction([4,1,1,1]).to_labelling_permutation()
[2, 3, 4, 1]
sage: ParkingFunction([2,1,4,1]).to_labelling_permutation()
[2, 4, 1, 3]
```

**touch_composition()**

Return the composition of the labelled Dyck path corresponding to the parking function.

For example, `touch_composition(PF) = [4, 3]` means that the first touch is four diagonal units from the starting point, and the second is three units further (see [GXZ] p. 2).

**INPUT:**

- `self` – parking function word

**OUTPUT:**

- the length between the corresponding touch points which of the labelled Dyck path that corresponds to the parking function

**EXAMPLES:**

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.touch_composition()
[4, 3]
sage: ParkingFunction([3,1,1,4]).touch_composition()
[2, 1, 1]
sage: ParkingFunction([4,1,1,1]).touch_composition()
[3, 1]
```

(continues on next page)
touch_points()

Return the sequence of touch points which corresponds to the labelled Dyck path after initial step.

For example, touch_points(PF) = [4, 7] means that after the initial step, the path touches the main diagonal at points (4, 4) and (7, 7).

INPUT:

• self – parking function word

OUTPUT:

• the sequence of touch points after the initial step of the labelled Dyck path that corresponds to the parking function

EXAMPRLS:

sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.touch_points()
[4, 7]
sage: ParkingFunction([3,1,1,4]).touch_points()
[2, 3, 4]
sage: ParkingFunction([4,1,1,1]).touch_points()
[3, 4]
sage: ParkingFunction([2,1,4,1]).touch_points()
[3, 4]

sage.combinat.parking_functions.ParkingFunctions(n=None)

Return the combinatorial class of Parking Functions.

A parking function of size $n$ is a sequence $(a_1, \ldots, a_n)$ of positive integers such that if $b_1 \leq b_2 \leq \cdots \leq b_n$ is the increasing rearrangement of $a_1, \ldots, a_n$, then $b_i \leq i$.

A parking function of size $n$ is a pair $(L, D)$ of two sequences $L$ and $D$ where $L$ is a permutation and $D$ is an area sequence of a Dyck Path of size $n$ such that $D[i] \geq 0$, $D[i + 1] \leq D[i] + 1$ and if $D[i + 1] = D[i] + 1$ then $L[i + 1] > L[i]$.

The number of parking functions of size $n$ is equal to the number of rooted forests on $n$ vertices and is equal to $(n + 1)^{n-1}$.

EXAMPLES:

Here are all parking functions of size 3:

sage: from sage.combinat.parking_functions import ParkingFunctions
sage: ParkingFunctions(3).list()
[[1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [1, 1, 3], [1, 3, 1], [3, 1, 1], [1, 2, 2], [2, 1, 2], [2, 2, 1], [1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]

If no size is specified, then ParkingFunctions returns the combinatorial class of all parking functions.

sage: PF = ParkingFunctions(); PF
Parking functions
sage: [] in PF
(continues on next page)
If the size $n$ is specified, then ParkingFunctions returns the combinatorial class of all parking functions of size $n$.

```python
sage: PF = ParkingFunctions(0)
sage: PF.list()
[[]]
sage: PF = ParkingFunctions(1)
sage: PF.list()
[[1]]
sage: PF = ParkingFunctions(3)
sage: PF.list()
[[1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [1, 1, 3],
 [1, 3, 1], [3, 1, 1], [1, 2, 2], [2, 1, 2], [2, 2, 1],
 [1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

```python
sage: PF3 = ParkingFunctions(3); PF3
Parking functions of size 3
sage: [] in PF3
False
sage: [1] in PF3
False
sage: [1,3,1] in PF3
True
sage: [1,4,1] in PF3
False
```

**class** `sage.combinat.parking_functions.ParkingFunctions_all`

Bases: `sage.combinat.combinat.InfiniteAbstractCombinatorialClass`

**class** `sage.combinat.parking_functions.ParkingFunctions_n(n)`

Bases: `sage.combinat.combinat.CombinatorialClass`

The combinatorial class of parking functions of size $n$.

A parking function of size $n$ is a sequence $(a_1, \ldots, a_n)$ of positive integers such that if $b_1 \leq b_2 \leq \cdots \leq b_n$ is the increasing rearrangement of $a_1, \ldots, a_n$, then $b_i \leq i$.

A parking function of size $n$ is a pair $(L, D)$ of two sequences $L$ and $D$ where $L$ is a permutation and $D$ is an area sequence of a Dyck Path of size $n$ such that $D[i] \geq 0$, $D[i+1] \leq D[i]+1$ and if $D[i+1] = D[i]+1$ then $L[i+1] > L[i]$.

The number of parking functions of size $n$ is equal to the number of rooted forests on $n$ vertices and is equal to $(n+1)^{n-1}$.

**EXAMPLES:**

```python
sage: PF = ParkingFunctions(3)
sage: PF.list()
```

(continues on next page)
\[
[[1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [1, 1, 3],
[1, 3, 1], [3, 1, 1], [1, 2, 2], [2, 1, 2], [2, 2, 1],
[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
\]

sage: [ParkingFunctions(i).cardinality() for i in range(6)]
[1, 1, 3, 16, 125, 1296]

**Warning:** The precise order in which the parking function are generated or listed is not fixed, and may change in the future.

**cardinality()**

Return the number of parking functions of size \(n\).

The cardinality is equal to \((n+1)^{n-1}\).

**EXAMPLES:**

sage: [ParkingFunctions(i).cardinality() for i in range(6)]
[1, 1, 3, 16, 125, 1296]

**random_element()**

Return a random parking function of size \(n\).

The algorithm uses a circular parking space with \(n+1\) spots. Then all \(n\) cars can park and there remains one empty spot. Spots are then renumbered so that the empty spot is 0.

The probability distribution is uniform on the set of \((n+1)^{n-1}\) parking functions of size \(n\).

**EXAMPLES:**

sage: pf = ParkingFunctions(8)
sage: a = pf.random_element(); a  # random
[5, 7, 2, 4, 2, 5, 1, 3]
sage: a in pf
True

sage.combinat.parking_functions.from_labelled_dyck_word(LDW)

Return the parking function corresponding to the labelled Dyck word.

**INPUT:**

- \(LDW\) – labelled Dyck word

**OUTPUT:**

- the parking function corresponding to the labelled Dyck word that is half the size of \(LDW\)

**EXAMPLES:**

sage: from sage.combinat.parking_functions import from_labelled_dyck_word
sage: LDW = [2, 6, 0, 4, 5, 0, 0, 3, 7, 0, 1, 0, 0]
sage: from_labelled_dyck_word(LDW)
[6, 1, 5, 2, 2, 1, 5]

sage: from_labelled_dyck_word([2, 3, 0, 0, 1, 0, 4, 0])
[3, 1, 1, 4]
sage: from_labelled_dyck_word([2, 3, 4, 0, 0, 0, 1, 0])
sage: from labelled_dyck_word([2, 4, 0, 1, 0, 0, 3, 0])
[2, 1, 4, 1]

sage.combinat.parking_functions.from_labelling_and_area_sequence(L, D)
Return the parking function corresponding to the labelling area sequence pair.

INPUT:
• L – a labelling permutation
• D – an area sequence for a Dyck word

OUTPUT:
• the parking function corresponding the labelling permutation L and D an area sequence of the corresponding Dyck path

EXAMPLES:

sage: from sage.combinat.parking_functions import from_labelling_and_area_sequence
sage: from_labelling_and_area_sequence([2, 6, 4, 5, 3, 7, 1], [0, 1, 1, 2, 0, 1, 1])
[6, 1, 5, 2, 2, 1, 5]
sage: from_labelling_and_area_sequence([1, 2, 3], [0, 1, 2])
[1, 1, 1]
sage: from_labelling_and_area_sequence([1, 2, 3], [0, 0, 0])
[1, 2, 3]
sage: from_labelling_and_area_sequence([1, 2, 3], [0, 1, 1])
[1, 1, 2]
sage: from_labelling_and_area_sequence([1, 2, 4, 3], [0, 1, 2, 1])
[1, 1, 3, 1]

sage.combinat.parking_functions.is_a(x, n=None)
Check whether a list is a parking function.
If a size n is specified, checks if a list is a parking function of size n.

5.1.161 Catalog of Path Tableaux

The path_tableaux object may be used to access examples of various path tableau objects currently implemented in Sage. Using tab-completion on this object is an easy way to discover and quickly create the path tableaux that are available (as listed here).

Let <tab> indicate pressing the tab key. So begin by typing path_tableaux.<tab> to the see the currently implemented path tableaux.

- CylindricalDiagram
- DyckPath
- DyckPaths
- FriezePattern
- FriezePatterns
5.1.162 Dyck Paths

This is an implementation of the abstract base class `sage.combinat.path_tableaux.path_tableau.PathTableau`. This is the simplest implementation of a path tableau and is included to provide a convenient test case and for pedagogical purposes.

In this implementation we have sequences of nonnegative integers. These are required to be the heights Dyck words (except that we do not require the sequence to start or end at height zero). These are in bijection with skew standard tableaux with at most two rows. Sequences which start and end at height zero are in bijection with noncrossing perfect matchings.

AUTHORS:

- Bruce Westbury (2018): initial version

```python
class sage.combinat.path_tableaux.dyck_path.DyckPath(parent, ot, check=True)
    Bases: sage.combinat.path_tableaux.path_tableau.PathTableau

An instance is the sequence of nonnegative integers given by the heights of a Dyck word.

INPUT:

- a sequence of nonnegative integers
- a two row standard skew tableau
- a Dyck word
- a noncrossing perfect matching

EXAMPLES:

```sage
path_tableaux.DyckPath([0,1,2,1,0])
[0, 1, 2, 1, 0]
sage: w = DyckWord([1,1,0,0])
sage: path_tableaux.DyckPath(w)
[0, 1, 2, 1, 0]
sage: p = PerfectMatching([(1,2), (3,4)])
sage: path_tableaux.DyckPath(p)
[0, 1, 0, 1, 0]
sage: t = Tableau([[1,2,4],[3,5,6]])
sage: path_tableaux.DyckPath(t)
[0, 1, 2, 1, 2, 1, 0]
sage: st = SkewTableau([[None, 1,4],[2,3]])
sage: path_tableaux.DyckPath(st)
[1, 2, 1, 0, 1]
```

Here we illustrate the slogan that promotion = rotation:

```sage
t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.to_perfect_matching()
[(0, 5), (1, 4), (2, 3)]
sage: t = t.promotion()
sage: t.to_perfect_matching()
[(0, 3), (1, 2), (4, 5)]
```

(continues on next page)
sage: t = t.promotion()
sage: t.to_perfect_matching()
[[0, 1), (2, 5), (3, 4)]

sage: t = t.promotion()
sage: t.to_perfect_matching()
[[0, 5), (1, 4), (2, 3)]

check()
Checks that self is a valid path.

descents()
Return the descent set of self.

EXAMPLES:

sage: path_tableaux.DyckPath([0,1,2,1,2,1,0,1,0]).descents()
{3, 6}

is_skew()
Return True if self is skew and False if not.

EXAMPLES:

sage: path_tableaux.DyckPath([0,1,2,1]).is_skew()
False
sage: path_tableaux.DyckPath([1,0,1,2,1]).is_skew()
True

local_rule(i)
This has input a list of objects. This method first takes the list of objects of length three consisting of the
(i−1)-st, i-th and (i+1)-term and applies the rule. It then replaces the i-th object by the object returned
by the rule.

EXAMPLES:

sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.local_rule(3)
[0, 1, 2, 1, 2, 1, 0]

to_DyckWord()
Converts self to a Dyck word.

EXAMPLES:

sage: c = path_tableaux.DyckPath([0,1,2,1,0])
sage: c.to_DyckWord()
[1, 1, 0, 0]

to_perfect_matching()
Return the perfect matching associated to self.

EXAMPLES:

sage: path_tableaux.DyckPath([0,1,2,2,1,0,1,0]).to_perfect_matching()
[(0, 5), (1, 2), (3, 4), (6, 7)]
**to_tableau()**

Return the skew tableau associated to `self`.

**EXAMPLES:**

```python
sage: T = path_tableaux.DyckPath([0,1,2,3,2,3])
sage: T.to_tableau()
[[1, 2, 3, 5], [4]]
sage: U = path_tableaux.DyckPath([2,3,2,3])
sage: U.to_tableau()
[[None, None, 1, 3], [2]]
```

**to_word()**

Return the word in the alphabet \{0, 1\} associated to `self`.

**EXAMPLES:**

```python
sage: path_tableaux.DyckPath([1,0,1,2,1]).to_word()
[0, 1, 1, 0]
```

---

**class** `sage.combinat.path_tableaux.dyck_path.DyckPaths`

**Bases:** `sage.combinat.path_tableaux.path_tableau.PathTableaux`

The parent class for DyckPath.

**Element**

alias of `DyckPath`

---

### 5.1.163 Path Tableaux

This is an abstract base class for using local rules to construct rectification and the action of the cactus group [Wes2017].

This is a construction of the Henriques-Kamnitzer construction of the action of the cactus group on tensor powers of a crystal. This is also a generalisation of the Fomin growth rules, which are a version of the operations on standard tableaux which were previously constructed using jeu-de-taquin.

The basic operations are rectification, evacuation and promotion. Rectification of standard skew tableaux agrees with the rectification by jeu-de-taquin as does evacuation. Promotion agrees with promotion by jeu-de-taquin on rectangular tableaux but in general they are different.

**REFERENCES:**

- [Wes2017]

**AUTHORS:**

- Bruce Westbury (2018): initial version

**class** `sage.combinat.path_tableaux.path_tableau.CylindricalDiagram(T)`

**Bases:** `sage.structure.sage_object.SageObject`

Cylindrical growth diagrams.

**EXAMPLES:**

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: path_tableaux.CylindricalDiagram(t)
[0, 1, 2, 3, 2, 1, 0]
```
pp()  
A pretty print utility method.

EXAMPLES:

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: path_tableaux.CylindricalDiagram(t).pp()

0 1 2 3 2 1 0
0 1 2 1 0 1 0
0 1 0 1 2 1 0
0 1 2 1 0 1 0
0 1 2 3 2 1 0
0 1 2 3 2 1 0
0 1 2 3 2 1 0

sage: t = path_tableaux.FriezePattern([1,3,4,5,1])
sage: path_tableaux.CylindricalDiagram(t).pp()

0 1 3 4 5 1 0
0 1 3 4 5 1 0
0 1 2 1 3 1 0
0 1 1 4 5/3 1 0
0 1 5 7/3 2 1 0
0 1 2/3 1 1 1 0
0 1 3 4 5 1 0
```

```python
class_path_tableaux = sage.combinat.path_tableaux.path_tableau.PathTableau
Bases: sage.structure.list_clone.ClonableArray
```

This is the abstract base class for a path tableau.

```python
cactus(i,j)  
Return the action of the generator s_{i,j} of the cactus group on self.

INPUT:

i – a positive integer
j – a positive integer weakly greater than i

EXAMPLES:

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.cactus(1,5)
[0, 1, 0, 1, 2, 1, 0]
sage: t.cactus(1,6) == t.evacuation()
True
sage: t.cactus(1,7).cactus(1,6) == t.promotion()
True
```
**commutor** *(other, verbose=False)*

Return the commutor of self with other.

If verbose=True then the function will print the rectangle.

**EXAMPLES:**

```
sage: t1 = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t2 = path_tableaux.DyckPath([0,1,2,1,0])
sage: t1.commutor(t2)
([0, 1, 2, 1, 0], [0, 1, 2, 3, 2, 1, 0])
sage: t1.commutor(t2,verbose=True)
[0, 1, 2, 1, 0]
[1, 2, 3, 2, 1]
[2, 3, 4, 3, 2]
[3, 4, 5, 4, 3]
[2, 3, 4, 3, 2]
[1, 2, 3, 2, 1]
[0, 1, 2, 1, 0]
([0, 1, 2, 1, 0], [0, 1, 2, 3, 2, 1, 0])
```

**dual_equivalence_graph()**

Return the graph with vertices the orbit of self and edges given by the action of the cactus group generators.

In most implementations the generators $s_i, i+1$ will act as the identity operators. The usual dual equivalence graphs are given by replacing the label $i, i+2$ by $i$ and removing edges with other labels.

**EXAMPLES:**

```
sage: s = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: sorted(s.dual_equivalence_graph().edges())
[(\[0, 1, 0, 1, 0, 1, 0\], \[0, 1, 0, 1, 2, 1, 0\], '4,7'),
 (\[0, 1, 0, 1, 0, 1, 0\], \[0, 1, 2, 1, 0, 1, 0\], '2,5'),
 (\[0, 1, 0, 1, 0, 1, 0\], \[0, 1, 2, 1, 2, 1, 0\], '2,7'),
 (\[0, 1, 0, 1, 0, 1, 0\], \[0, 1, 2, 3, 2, 1, 0\], '2,6'),
 (\[0, 1, 0, 1, 0, 1, 0\], \[0, 1, 2, 1, 2, 1, 0\], '1,4'),
 (\[0, 1, 0, 1, 0, 1, 0\], \[0, 1, 2, 3, 2, 1, 0\], '2,7'),
 (\[0, 1, 2, 1, 0, 1, 0\], \[0, 1, 2, 3, 2, 1, 0\], '4,7'),
 (\[0, 1, 2, 1, 0, 1, 0\], \[0, 1, 2, 3, 2, 1, 0\], '3,7'),
 (\[0, 1, 2, 1, 0, 1, 0\], \[0, 1, 2, 3, 2, 1, 0\], '3,6')]```

**evacuation()**

Return the evacuation operator applied to self.
EXAMPLES:

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.evacuation()
[0, 1, 2, 3, 2, 1, 0]
```

**final_shape()**

Return the final shape of `self`.

EXAMPLES:

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.final_shape()
0
```

**initial_shape()**

Return the initial shape of `self`.

EXAMPLES:

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.initial_shape()
0
```

**local_rule(i)**

This is the abstract local rule defined in any coboundary category.

This has input a list of objects. This method first takes the list of objects of length three consisting of the \((i - 1)\)-st, \(i\)-th and \((i + 1)\)-term and applies the rule. It then replaces the \(i\)-th object by the object returned by the rule.

EXAMPLES:

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.local_rule(3)
[0, 1, 2, 1, 2, 1, 0]
```

**orbit()**

Return the orbit of `self` under the action of the cactus group.

EXAMPLES:

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.orbit()
{[0, 1, 0, 1, 0, 1, 0],
 [0, 1, 0, 1, 2, 1, 0],
 [0, 1, 2, 1, 0, 1, 0],
 [0, 1, 2, 1, 2, 1, 0],
 [0, 1, 2, 3, 2, 1, 0]}
```

**promotion()**

Return the promotion operator applied to `self`.

EXAMPLES:

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.promotion()
[0, 1, 2, 1, 0, 1, 0]
```
size()

Return the size or length of self.

EXAMPLES:

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.size()
7
```

class sage.combinat.path_tableaux.path_tableau.PathTableaux

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The abstract parent class for PathTableau.

5.1.164 Plane Partitions

AUTHORS:

• Jang Soo Kim (2016): Initial implementation

• Jessica Striker (2016): Added additional methods

class sage.combinat.plane_partition.PlanePartition(parent, PP, check=True)

Bases: sage.structure.list_clone.ClonableArray

A plane partition.

A `plane partition` is a stack of cubes in the positive orthant.

INPUT:

• PP – a list of lists which represents a tableau

• box_size – (optional) a list `[A, B, C]` of 3 positive integers, where A, B, C are the lengths of the box in the x-axis, y-axis, z-axis, respectively; if this is not given, it is determined by the smallest box bounding PP

OUTPUT:

The plane partition whose tableau representation is PP.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP
Plane partition [[4, 3, 3, 1], [2, 1, 1], [1, 1]]
```

cells()

Return the list of cells inside self.

EXAMPLES:

```
sage: PP = PlanePartition([[3,1],[2]])
sage: PP.cells()
[[0, 0, 0], [0, 0, 1], [0, 0, 2], [0, 1, 0], [1, 0, 0], [1, 0, 1]]
```

check()

Check to see that self is a valid plane partition.

EXAMPLES:
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.check()

complement (tableau_only=False)
Return the complement of self.

EXAMPLES:

sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.complement()
Plane partition [[4, 4, 3, 3], [4, 3, 3, 2], [3, 1, 1, 0]]
sage: PP.complement(True)
[[4, 4, 3, 3], [4, 3, 3, 2], [3, 1, 1, 0]]

is_CSPP ()
Return whether self is a cyclically symmetric plane partition.
A plane partition is cyclically symmetric if its x, y, and z tableaux are all equal.

EXAMPLES:

sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_CSPP()
False
sage: PP = PlanePartition([[3,2,2],[3,1,0],[1,1,0]])
sage: PP.is_CSPP()
True

is_CSSCPP ()
Return whether self is a cyclically symmetric and self-complementary plane partition.

EXAMPLES:

sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_CSSCPP()
False
sage: PP = PlanePartition([[4,4,4,1],[3,3,2,1],[3,2,1,1],[3,0,0,0]])
sage: PP.is_CSSCPP()
True

is_CSTCPP ()
Return whether self is a cyclically symmetric and transpose-complementary plane partition.

EXAMPLES:

sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_CSTCPP()
False
sage: PP = PlanePartition([[4,4,3,2],[4,3,2,1],[3,2,1,0],[2,1,0,0]])
sage: PP.is_CSTCPP()
True

is_SCPP ()
Return whether self is a self-complementary plane partition.

EXAMPLES:

sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_SCPP()
False
sage: PP = PlanePartition([[4,4,4,4],[4,4,2,0],[4,2,0,0],[0,0,0,0]])
sage: PP.is_SCPP()
True

is_SPP()

Return whether self is a symmetric plane partition.

A plane partition is symmetric if the corresponding tableau is symmetric about the diagonal.

EXAMPLES:

sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_SPP()
False
sage: PP = PlanePartition([[3,3,2],[3,3,2],[2,2,2]])
sage: PP.is_SPP()
True
sage: PP = PlanePartition([[3,2,1],[2,0,0]])
sage: PP.is_SPP()
False
sage: PP = PlanePartition([[3,2,0],[2,0,0]])
sage: PP.is_SPP()
True
sage: PP = PlanePartition([[3,2],[2,0],[1,0]])
sage: PP.is_SPP()
False
sage: PP = PlanePartition([[3,2],[2,0],[0,0]])
sage: PP.is_SPP()
True

is_SSCPP()

Return whether self is a symmetric, self-complementary plane partition.

EXAMPLES:

sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_SSCPP()
False
sage: PP = PlanePartition([[4,3,3,2],[3,2,2,1],[3,2,2,1],[2,1,1,0]])
sage: PP.is_SSCPP()
True
sage: PP = PlanePartition([[2,1],[1,0]])
sage: PP.is_SSCPP()
True
sage: PP = PlanePartition([[4,3,2],[3,2,1],[2,1,0]])
sage: PP.is_SSCPP()
True
sage: PP = PlanePartition([[4,2,2,2],[2,2,2,2],[2,2,2,2],[2,2,2,0]])
sage: PP.is_SSCPP()
True

is_TCPP()

Return whether self is a transpose-complementary plane partition.

EXAMPLES:

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_TCPP()
False
sage: PP = PlanePartition([[4,4,3,2],[4,4,2,1],[4,2,0,0],[2,0,0,0]])
sage: PP.is_TCPP()
True
```

is_TCPP() 

Return whether self is a totally cyclically symmetric plane partition.

A plane partition is totally cyclically symmetric if it is both symmetric and cyclically symmetric.

EXAMPLES:

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_TCPP()
False
sage: PP = PlanePartition([[3,3,3],[3,3,2],[3,2,1]])
sage: PP.is_TCPP()
True
```

is_TSSCPP() 

Return whether self is a totally symmetric self-complementary plane partition.

EXAMPLES:

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_TSSCPP()
False
sage: PP = PlanePartition([[4,4,3,2],[4,3,2,1],[3,2,1,0],[2,1,0,0]])
sage: PP.is_TSSCPP()
True
```

plot(show_box=False, colors=["white", "lightgray", "darkgray"])

Return a plot of self.

INPUT:

• show_box – boolean (default: False); if True, also shows the visible tiles on the \(xy\), \(yz\), \(zx\)-planes

• colors – (default: ["white", "lightgray", "darkgray"] list \([A, B, C]\) of 3 strings representing colors

EXAMPLES:

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.plot()
Graphics object consisting of 27 graphics primitives
```

pp(show_box=False)

Return a pretty print of the plane partition.

INPUT:

• show_box – boolean (default: False); if True, also shows the visible tiles on the \(xy\), \(yz\), \(zx\)-planes

OUTPUT:

A pretty print of the plane partition.
EXAMPLES:

```python
sage: PP = PlanePartition([[4, 3, 3, 1], [2, 1, 1], [1, 1]])
sage: PP.to_tableau()
[[3, 2, 1, 1], [3, 1, 1, 0], [2, 1, 1, 0], [1, 0, 0, 0]]
sage: PP.transpose()
Plane partition [[4, 2, 1], [3, 1, 1], [3, 1, 0], [1, 0, 0]]
sage: PP.transpose(True)
[[4, 2, 1], [3, 1, 1], [3, 1, 0], [1, 0, 0]]
sage: PP.x_tableau()
[[3, 2, 1, 1], [3, 1, 1, 0], [2, 1, 1, 0], [1, 0, 0, 0]]
sage: PP.y_tableau()
```

to_tableau()

Return the tableau class of self.

EXAMPLES:

```python
sage: PP = PlanePartition([[4, 3, 3, 1], [2, 1, 1], [1, 1]])
sage: PP.to_tableau()
[[4, 3, 3, 1], [2, 1, 1], [1, 1]]
```

transpose(tableau_only=False)

Return the transpose of self.

EXAMPLES:

```python
sage: PP = PlanePartition([[4, 3, 3, 1], [2, 1, 1], [1, 1]])
sage: PP.transpose()
[[4, 2, 1], [3, 1, 1], [3, 1, 0], [1, 0, 0]]
sage: PP.transpose(True)
[[4, 3, 3, 1], [2, 1, 1], [1, 1]]
```

x_tableau()

Return the projection of self in the x direction.

EXAMPLES:

```python
sage: PP = PlanePartition([[4, 3, 3, 1], [2, 1, 1], [1, 1]])
sage: PP.x_tableau()
[[3, 2, 1, 1], [3, 1, 1, 0], [2, 1, 1, 0], [1, 0, 0, 0]]
```

y_tableau()

Return the projection of self in the y direction.

EXAMPLES:
sage: PP = PlanePartition([[4, 3, 3, 1], [2, 1, 1], [1, 1]])
sage: PP.y_tableau()
[[4, 3, 2], [3, 1, 0], [3, 0, 0], [1, 0, 0]]

z_tableau()
Return the projection of self in the z direction.

EXAMPLES:

sage: PP = PlanePartition([[4, 3, 3, 1], [2, 1, 1], [1, 1]])
sage: PP.z_tableau()
[[4, 3, 3, 1], [2, 1, 1, 0], [1, 1, 0, 0]]

class sage.combinat.plane_partition.PlanePartitions(box_size)
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.
structure.parent.Parent

All plane partitions inside a rectangular box of given side lengths.

INPUT:

• box_size – a triple of positive integers indicating the size of the box containing the plane partition

EXAMPLES:

This will create an instance to manipulate the plane partitions in a $4 \times 3 \times 2$ box:

sage: P = PlanePartitions((4, 3, 2))
sage: P
Plane partitions inside a 4 x 3 x 2 box
sage: P.cardinality()
490

See also:

PlanePartition

Element
alias of PlanePartition

box()
Return the sizes of the box of the plane partitions of self are contained in.

EXAMPLES:

sage: P = PlanePartitions((4, 3, 5))
sage: P.box()
(4, 3, 5)

cardinality()
Return the cardinality of self.

The number of plane partitions inside an $a \times b \times c$ box is equal to

$$\prod_{i=1}^{a} \prod_{j=1}^{b} \prod_{k=1}^{c} \frac{i+j+k-1}{i+j+k-2}$$

EXAMPLES:
sage: P = PlanePartitions((4,3,5))
sage: P.cardinality()
116424

random_element()

Return a uniformly random element of self.

ALGORITHM:

This uses the random_order_ideal() method and the natural bijection with plane partitions.

EXAMPLES:

sage: P = PlanePartitions((4,3,5))
sage: p = P.random_element()
sage: p.parent() is P
True

5.1.165 Integer partitions

A partition $p$ of a nonnegative integer $n$ is a non-increasing list of positive integers (the parts of the partition) with total sum $n$.

A partition can be depicted by a diagram made of rows of cells, where the number of cells in the $i^{th}$ row starting from the top is the $i^{th}$ part of the partition.

The coordinate system related to a partition applies from the top to the bottom and from left to right. So, the corners of the partition $[5, 3, 1]$ are $[[0, 4], [1, 2], [2, 0]]$.

For display options, see Partitions.options.

Note:

- Boxes is a synonym for cells. All methods will use ‘cell’ and ‘cells’ instead of ‘box’ and ‘boxes’.
- Partitions are 0 based with coordinates in the form of (row-index, column-index).
- If given coordinates of the form $(r, c)$, then use Python’s *-operator.
- Throughout this documentation, for a partition $\lambda$ we will denote its conjugate partition by $\lambda'$. For more on conjugate partitions, see Partition.conjugate().
- The comparisons on partitions use lexicographic order.

Note: We use the convention that lexicographic ordering is read from left-to-right. That is to say $[1, 3, 7]$ is smaller than $[2, 3, 4]$.

AUTHORS:

- Mike Hansen (2007): initial version
- Dan Drake (2009-03-28): deprecate RestrictedPartitions and implement Partitions_parts_in
- Travis Scrimshaw (2012-01-12): Implemented latex function to Partition_class
- Travis Scrimshaw (2012-05-09): Fixed Partitions(-1).list() infinite recursion loop by saying Partitions_n is the empty set.

• Travis Scrimshaw (2012-05-11): Fixed bug in inner where if the length was longer than the length of the inner partition, it would include 0's.

• Andrew Mathas (2012-06-01): Removed deprecated functions and added compatibility with the PartitionTuple classes. See trac ticket #13072

• Travis Scrimshaw (2012-10-12): Added options. Made \texttt{Partition\_class} to the element \texttt{Partition}. \texttt{Partitions*} are now all in the category framework except \texttt{PartitionsRestricted} (which will eventually be removed). Cleaned up documentation.

• Matthew Lancellotti (2018-09-14): Added a bunch of “k” methods to \texttt{Partition}.

EXAMPLES:

There are 5 partitions of the integer 4:

\begin{verbatim}
sage: Partitions(4).cardinality()
5
sage: Partitions(4).list()
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
\end{verbatim}

We can use the method \texttt{.first()} to get the ‘first’ partition of a number:

\begin{verbatim}
sage: Partitions(4).first()
[4]
\end{verbatim}

Using the method \texttt{.next(p)}, we can calculate the ‘next’ partition after \textit{p}. When we are at the last partition, None will be returned:

\begin{verbatim}
sage: Partitions(4).next([4])
[3, 1]
sage: Partitions(4).next([1,1,1,1]) \texttt{is None}
True
\end{verbatim}

We can use \texttt{iter} to get an object which iterates over the partitions one by one to save memory. Note that when we do something like \texttt{for part in Partitions(4)} this iterator is used in the background:

\begin{verbatim}
sage: g = iter(Partitions(4))
sage: next(g)
[4]
sage: next(g)
[3, 1]
sage: next(g)
[2, 2]
sage: for p in Partitions(4): print(p)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
\end{verbatim}

We can add constraints to the type of partitions we want. For example, to get all of the partitions of 4 of length 2, we’d do the following:

\begin{verbatim}
sage: Partitions(4, length=2).list()
[[3, 1], [2, 2]]
\end{verbatim}

Here is the list of partitions of length at least 2 and the list of ones with length at most 2:

5.1. Comprehensive Module list
The options \texttt{min_part} and \texttt{max_part} can be used to set constraints on the sizes of all parts. Using \texttt{max_part}, we can select partitions having only ‘small’ entries. The following is the list of the partitions of 4 with parts at most 2:

\begin{verbatim}
sage: Partitions(4, max_part=2).list()
[[2, 2], [2, 1, 1], [1, 1, 1, 1]]
\end{verbatim}

The \texttt{min_part} options is complementary to \texttt{max_part} and selects partitions having only ‘large’ parts. Here is the list of all partitions of 4 with each part at least 2:

\begin{verbatim}
sage: Partitions(4, min_part=2).list()
[[4], [2, 2]]
\end{verbatim}

The options \texttt{inner} and \texttt{outer} can be used to set part-by-part constraints. This is the list of partitions of 4 with \([3, 1, 1]\) as an outer bound (that is, partitions of 4 contained in the partition \([3, 1, 1]\)):

\begin{verbatim}
sage: Partitions(4, outer=[3,1,1]).list()
[[3, 1], [2, 1, 1]]
\end{verbatim}

\texttt{outer} sets \texttt{max_length} to the length of its argument. Moreover, the parts of \texttt{outer} may be infinite to clear constraints on specific parts. Here is the list of the partitions of 4 of length at most 3 such that the second and third part are 1 when they exist:

\begin{verbatim}
sage: Partitions(4, outer=[oo,1,1]).list()
[[4], [3, 1], [2, 1, 1]]
\end{verbatim}

Finally, here are the partitions of 4 with \([1,1,1]\) as an inner bound (i. e., the partitions of 4 containing the partition \([1,1,1]\)). Note that \texttt{inner} sets \texttt{min_length} to the length of its argument:

\begin{verbatim}
sage: Partitions(4, inner=[1,1,1]).list()
[[2, 1, 1], [1, 1, 1, 1]]
\end{verbatim}

The options \texttt{min_slope} and \texttt{max_slope} can be used to set constraints on the slope, that is on the difference \(p[i+1]-p[i]\) of two consecutive parts. Here is the list of the strictly decreasing partitions of 4:

\begin{verbatim}
sage: Partitions(4, max_slope=-1).list()
[[4], [3, 1]]
\end{verbatim}

The constraints can be combined together in all reasonable ways. Here are all the partitions of 11 of length between 2 and 4 such that the difference between two consecutive parts is between \(-3\) and \(-1\):

\begin{verbatim}
sage: Partitions(11,min_slope=-3,max_slope=-1,min_length=2,max_length=4).list()
[[7, 4], [6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2], [5, 3, 2, 1]]
\end{verbatim}

Partition objects can also be created individually with \texttt{Partition}:

\begin{verbatim}
sage: Partition([2,1])
[2, 1]
\end{verbatim}

Once we have a partition object, then there are a variety of methods that we can use. For example, we can get the conjugate of a partition. Geometrically, the conjugate of a partition is the reflection of that partition through its main diagonal. Of course, this operation is an involution:
If we create a partition with extra zeros at the end, they will be dropped:

```python
sage: Partition([4,1,0,0])
[4, 1]
sage: Partition([0])
[]
sage: Partition([0,0])
[]
```

The idea of a partition being followed by infinitely many parts of size 0 is consistent with the `get_part` method:

```python
sage: p = Partition([5, 2])
sage: p.get_part(0)
5
sage: p.get_part(10)
0
```

We can go back and forth between the standard and the exponential notations of a partition. The exponential notation can be padded with extra zeros:

```python
sage: Partition([6,4,4,2,1]).to_exp()
[1, 1, 0, 2, 0, 1]
sage: Partition(exp=[1,1,0,2,0,1])
[6, 4, 4, 2, 1]
sage: Partition([6,4,4,2,1]).to_exp(5)
[1, 1, 0, 2, 0, 1, 0]
sage: Partition([6,4,4,2,1]).to_exp(7)
[1, 1, 0, 2, 0, 1, 0, 0]
```

We can get the (zero-based!) coordinates of the corners of a partition:

```python
sage: Partition([4,3,1]).corners()
[(0, 3), (1, 2), (2, 0)]
```

We can compute the core and quotient of a partition and build the partition back up from them:

```python
sage: Partition([6,3,2,2]).core(3)
[2, 1, 1]
sage: Partition([7,7,5,3,3,3,1]).quotient(3)
([2], [1], [2, 2, 2])
sage: p = Partition([11,5,5,3,2,2,2])
sage: p.core(3)
[]
sage: p.quotient(3)
([], [4], [1, 1, 1])
sage: Partition(core=[],quotient=[[2, 1], [4], [1, 1, 1]])
[11, 5, 5, 3, 2, 2, 2]
```

We can compute the $0 - 1$ sequence and go back and forth:
We can compute the Frobenius coordinates and go back and forth:

```
sage: Partition([7,3,1]).frobenius_coordinates()
((6, 1), (2, 0))
sage: Partition(frobenius_coordinates=([6,1],[2,0]))
[7, 3, 1]
sage: all(mu == Partition(frobenius_coordinates=mu.frobenius_coordinates())
    ....:     for n in range(12) for mu in Partitions(n))
True
```

We use the lexicographic ordering:

```
sage: pl = Partition([4,1,1])
sage: ql = Partitions([3,3])
sage: pl > ql
True
sage: PL = Partitions()
sage: pl = PL([4,1,1])
sage: ql = PL([3,3])
sage: pl > ql
True
```

class `sage.combinat.partition.OrderedPartitions(n,k)`

Bases: `sage.combinat.partition.Partitions`

The class of ordered partitions of \(n\). If \(k\) is specified, then this contains only the ordered partitions of length \(k\).

An ordered partition of a nonnegative integer \(n\) means a list of positive integers whose sum is \(n\). This is the same as a composition of \(n\).

**Note:** It is recommended that you use `Compositions()` instead as `OrderedPartitions()` wraps GAP.

**EXAMPLES:**

```
sage: OrderedPartitions(3)
Ordered partitions of 3
sage: OrderedPartitions(3).list()
[[3], [2, 1], [1, 2], [1, 1, 1]]
sage: OrderedPartitions(3,2)
Ordered partitions of 3 of length 2
sage: OrderedPartitions(3,2).list()
[[2, 1], [1, 2]]
sage: OrderedPartitions(10,k=2).list()
[[9, 1], [8, 2], [7, 3], [6, 4], [5, 5], [4, 6], [3, 7], [2, 8], [1, 9]]
sage: OrderedPartitions(4).list()
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

`cardinality()`

Return the cardinality of `self`.
EXAMPLES:

```
sage: OrderedPartitions(3).cardinality()
sage: OrderedPartitions(3,2).cardinality()
sage: OrderedPartitions(10,2).cardinality()
sage: OrderedPartitions(15).cardinality()
4
2
9
16384
```

```
list()

Return a list of partitions in self.

EXAMPLES:

```
sage: OrderedPartitions(3).list()
sage: OrderedPartitions(3,2).list()
[[3], [2, 1], [1, 2], [1, 1, 1]]
[[2, 1], [1, 2]]
```

```
class sage.combinat.partition.Partition(parent, mu)

Bases: sage.combinat.combinat.CombinatorialElement

A partition \( p \) of a nonnegative integer \( n \) is a non-increasing list of positive integers (the parts of the partition) with total sum \( n \).

A partition is often represented as a diagram consisting of cells, or boxes, placed in rows on top of each other such that the number of cells in the \( i \)\textsuperscript{th} row, reading from top to bottom, is the \( i \)\textsuperscript{th} part of the partition. The rows are left-justified (and become shorter and shorter the farther down one goes). This diagram is called the Young diagram of the partition, or more precisely its Young diagram in English notation. (French and Russian notations are variations on this representation.)

The coordinate system related to a partition applies from the top to the bottom and from left to right. So, the corners of the partition \([5, 3, 1]\) are \([(0, 4), (1, 2), (2, 0)]\).

For display options, see `Partitions.options()`.

Note: Partitions are 0 based with coordinates in the form of (row-index, column-index). For example consider the partition \( \mu=\text{Partition}([4, 3, 2, 2]) \), the first part is \( \mu[0] \) (which is 4), the second is \( \mu[1] \), and so on, and the upper-left cell in English convention is \((0, 0)\).

A partition can be specified in one of the following ways:

- a list (the default)
- using exponential notation
- by Frobenius coordinates
- specifying its 0 − 1 sequence
- specifying the core and the quotient

See the examples below.

EXAMPLES:

Creating partitions though parents:
sage: mu = Partitions(8)([3, 2, 1, 1, 1]); mu
[3, 2, 1, 1, 1]
sage: nu = Partition([3, 2, 1, 1, 1]); nu
[3, 2, 1, 1, 1]
sage: mu == nu
True
sage: mu is nu
False
sage: mu in Partitions()
True
sage: mu.parent()
Partitions of the integer 8
sage: mu.size()
8
sage: mu.category()
Category of elements of Partitions of the integer 8
sage: nu.parent()
Partitions
sage: nu.category()
Category of elements of Partitions
sage: mu[0]
3
sage: mu[1]
2
sage: mu[2]
1
sage: mu.pp()
***
** *
*
*
sage: mu.removable_cells()
[(0, 2), (1, 1), (4, 0)]
sage: mu.down_list()
[[2, 2, 1, 1, 1], [3, 1, 1, 1, 1], [3, 2, 1, 1]]
sage: mu.addable_cells()
[(0, 3), (1, 2), (2, 1), (5, 0)]
sage: mu.up_list()
[[4, 2, 1, 1, 1], [3, 3, 1, 1, 1], [3, 2, 2, 1, 1], [3, 2, 1, 1, 1], [3, 2, 1, 1, 1]]
sage: mu.conjugate()
[5, 2, 1]
sage: mu.dominates(nu)
True
sage: nu.dominates(mu)
True

Creating partitions using Partition:

sage: Partition([3, 2, 1])
[3, 2, 1]
sage: Partition(exp=[2, 1, 1])
[3, 2, 1]
sage: Partition(core=[2, 1], quotient=[[2, 1], [3], [1, 1, 1]])
[11, 5, 5, 3, 2, 2, 2]
sage: Partition(frobenius_coordinates=((3, 2), (4, 0)))
[4, 4, 1, 1, 1]
Sage ignores trailing zeros at the end of partitions:

```python
sage: Partitions([3, 2, 1, 0])
[3, 2, 1]
```

```python
sage: Partitions([3, 2, 1])
[3, 2, 1]
```

```python
sage: Partitions(6)([3, 2, 1, 0])
[3, 2, 1]
```

### add_cell

#### (i, j=None)

Return a partition corresponding to `self` with a cell added in row `i`. (This does not change `self`.)

**EXAMPLES:**

```python
sage: Partition([3, 2, 1, 1]).add_cell(0)
[4, 2, 1, 1]
```

```python
sage: cell = [4, 0]; Partition([3, 2, 1, 1]).add_cell(*cell)
[3, 2, 1, 1, 1]
```

### add_horizontal_border_strip

#### (k)

Return a list of all the partitions that can be obtained by adding a horizontal border strip of length `k` to `self`.

**EXAMPLES:**

```python
sage: Partition([]).add_horizontal_border_strip(0)
[[[]]]
```

```python
sage: Partition([]).add_horizontal_border_strip(2)
[[[2]]]
```

```python
sage: Partition([2, 2]).add_horizontal_border_strip(2)
[[[2, 2], [3, 2, 1], [4, 2]]]
```

```python
sage: Partition([3, 2, 2]).add_horizontal_border_strip(2)
[[[3, 2, 2], [3, 3, 2, 1], [4, 2, 2, 1], [4, 3, 2], [5, 2, 2]]]
```

**Todo:** Reimplement like `remove_horizontal_border_strip` using `IntegerListsLex`

### add_vertical_border_strip

#### (k)

Return a list of all the partitions that can be obtained by adding a vertical border strip of length `k` to `self`.

**EXAMPLES:**

```python
sage: Partition([]).add_vertical_border_strip(0)
[[[]]]
```

```python
sage: Partition([]).add_vertical_border_strip(2)
[[[2]]]
```

```python
sage: Partition([2, 2]).add_vertical_border_strip(2)
[[[2, 2], [3, 2, 1], [4, 2]]]
```

```python
sage: Partition([3, 2, 2]).add_vertical_border_strip(2)
[[[3, 2, 2], [3, 3, 2, 1], [4, 2, 2, 1], [4, 3, 2], [5, 2, 2]]]
```

(continues on next page)
addable_cells()

Return a list of the outside corners of the partition self.

An outside corner (also called a cocorner) of a partition \( \lambda \) is a cell on \( \mathbb{Z}^2 \) which does not belong to the Young diagram of \( \lambda \) but can be added to this Young diagram to still form a straight-shape Young diagram.

The entries of the list returned are pairs of the form \((i, j)\), where \(i\) and \(j\) are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([2,2,1]).outside_corners()
[(0, 2), (2, 1), (3, 0)]
sage: Partition([2,2]).outside_corners()
[(0, 2), (2, 0)]
sage: Partition([6,3,3,1,1,1]).outside_corners()
[(0, 6), (1, 3), (3, 1), (6, 0)]
sage: Partition([]).outside_corners()
[(0, 0)]
```

addable_cells_residue\((i, l)\)

Return a list of the outside corners of the partition self having \(l\)-residue \(i\).

An outside corner (also called a cocorner) of a partition \( \lambda \) is a cell on \( \mathbb{Z}^2 \) which does not belong to the Young diagram of \( \lambda \) but can be added to this Young diagram to still form a straight-shape Young diagram. See residue() for the definition of the \(l\)-residue.

The entries of the list returned are pairs of the form \((i, j)\), where \(i\) and \(j\) are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([3,2,1]).outside_corners_residue(0, 3)
[(0, 3), (3, 0)]
sage: Partition([3,2,1]).outside_corners_residue(1, 3)
[(1, 2)]
sage: Partition([3,2,1]).outside_corners_residue(2, 3)
[(2, 1)]
```

arm_cells\((i, j)\)

Return the list of the cells of the arm of cell \((i, j)\) in self.

The arm of cell \(c = (i, j)\) is the boxes that appear to the right of \(c\).

The cell coordinates are zero-based, i.e., the northwesternmost cell is \((0, 0)\).

INPUT:

- \(i, j\) – two integers

OUTPUT:

A list of pairs of integers

EXAMPLES:
**arm_length** \((i, j)\)

Return the length of the arm of cell \((i, j)\) in self.

The arm of cell \((i, j)\) is the cells that appear to the right of cell \((i, j)\). The cell coordinates are zero-based, i.e., the northwesternmost cell is \((0, 0)\).

**INPUT:**
- \(i, j\) – two integers

**OUTPUT:**
An integer or a `ValueError`

**EXAMPLES:**

```python
sage: p = Partition([2, 2, 1])
sage: p.arm_length(0, 0)
1
sage: p.arm_length(0, 1)
0
sage: p.arm_length(2, 0)
0
sage: Partition([3, 3]).arm_length(0, 0)
2
sage: Partition([3, 3]).arm_length(*[0, 0])
2
```

**arm_lengths** *(flat=False)*

Return a tableau of shape self where each cell is filled with its arm length. The optional boolean parameter `flat` provides the option of returning a flat list.

**EXAMPLES:**

```python
sage: Partition([2, 2, 1]).arm_lengths()
[[1, 0], [1, 0], [0]]
sage: Partition([2, 2, 1]).arm_lengths(flat=True)
[1, 0, 1, 0, 0]
sage: Partition([3, 3]).arm_lengths()
[[2, 1, 0], [2, 1, 0]]
sage: Partition([3, 3]).arm_lengths(flat=True)
[2, 1, 0, 2, 1, 0]
```

**arms_legs_coeff** \((i, j)\)

This is a statistic on a cell \(c = (i, j)\) in the diagram of partition \(p\) given by

\[
1 - q^a \cdot t^{\ell+1} \\
1 - q^{a+1} \cdot t^\ell
\]

where \(a\) is the arm length of \(c\) and \(\ell\) is the leg length of \(c\).
The coordinates \( i \) and \( j \) of the cell are understood to be 0-based, so that \( (0, 0) \) is the northwesternmost cell (in English notation).

**EXAMPLES:**

```python
sage: Partition([3,2,1]).arms_legs_coeff(1,1)
(-t + 1)/(-q + 1)
sage: Partition([3,2,1]).arms_legs_coeff(0,0)
(-q^2*t^3 + 1)/(-q^3*t^2 + 1)
sage: Partition([3,2,1]).arms_legs_coeff(*[0,0])
(-q^2*t^3 + 1)/(-q^3*t^2 + 1)
```

**atom()**

Return a list of the standard tableaux of size `self.size()` whose atom is equal to `self`.

**EXAMPLES:**

```python
sage: Partition([2,1]).atom()

[[[1, 2]], [[3]]]
sage: Partition([3,2,1]).atom()

[[[1, 2, 3, 6], [4, 5]], [[1, 2, 3], [4, 5], [6]]]
```

**attacking_pairs()**

Return a list of the attacking pairs of the Young diagram of `self`.

A pair of cells \((c, d)\) of a Young diagram (in English notation) is said to be attacking if one of the following conditions holds:

1. \( c \) and \( d \) lie in the same row with \( c \) strictly to the west of \( d \).
2. \( c \) is in the row immediately to the south of \( d \), and \( c \) lies strictly east of \( d \).

This particular method returns each pair \((c, d)\) as a tuple, where each of \( c \) and \( d \) is given as a tuple \((i, j)\) with \( i \) and \( j \) zero-based (so \( i = 0 \) means that the cell lies in the topmost row).

**EXAMPLES:**

```python
sage: p = Partition([3, 2])
sage: p.attacking_pairs()

[((0, 0), (0, 1)),
 (0, 0), (0, 2)),
 (0, 1), (0, 2)),
 (1, 0), (1, 1)),
 (1, 1), (0, 0))]
sage: Partition([[]).attacking_pairs()
[]
```

**aut \((t=0, q=0)\)**

Return the size of the centralizer of any permutation of cycle type `self`. If \( m_i \) is the multiplicity of \( i \) as a part of \( p \), this is given by

\[
\prod_i m_i! i^{m_i}.
\]

Including the optional parameters \( t \) and \( q \) gives the \( q, t \) analog, which is the former product times

\[
\prod_{i=1}^{\text{length}(p)} \frac{1 - q^{p_i}}{1 - t^{p_i}}.
\]

See Section 1.3, p. 24, in [Ke1991].
EXAMPLES:

```
sage: Partition([2,2,1]).centralizer_size()
8
sage: Partition([2,2,2]).centralizer_size()
48
sage: Partition([2,2,1]).centralizer_size(q=2, t=3)
9/16
sage: Partition([]).centralizer_size()
1
sage: Partition([]).centralizer_size(q=2, t=4)
1
```

**beta_numbers**(length=None)

Return the set of beta numbers corresponding to `self`.

The optional argument `length` specifies the length of the beta set (which must be at least the length of `self`).

For more on beta numbers, see `frobenius_coordinates()`.

EXAMPLES:

```
sage: Partition([4,3,2]).beta_numbers()
[6, 4, 2]
sage: Partition([4,3,2]).beta_numbers(5)
[8, 6, 4, 1, 0]
sage: Partition([]).beta_numbers()
[]
sage: Partition([]).beta_numbers(3)
[2, 1, 0]
sage: Partition([6,4,1,1]).beta_numbers()
[9, 6, 2, 1]
sage: Partition([6,4,1,1]).beta_numbers(6)
[11, 8, 4, 3, 1, 0]
sage: Partition([1,1,1]).beta_numbers()
[3, 2, 1]
sage: Partition([1,1,1]).beta_numbers(4)
[4, 3, 2, 0]
```

**block**(e, multicharge=0)

Return a dictionary $\beta$ that determines the block associated to the partition `self` and the `quantum_characteristic()` `e`.

**INPUT:**

- `e` – the quantum characteristic
- `multicharge` – the multicharge (default (0,))

**OUTPUT:**

- A dictionary giving the multiplicities of the residues in the partition tuple `self`

In more detail, the value `beta[i]` is equal to the number of nodes of residue $i$. This corresponds to the positive root

$$\sum_{i \in I} \beta_i \alpha_i \in Q^+,$$

a element of the positive root lattice of the corresponding Kac-Moody algebra. See [DJM1998] and [BK2009] for more details.
This is a useful statistics because two Specht modules for a Hecke algebra of type $A$ belong to the same block if and only if they correspond to same element $\beta$ of the root lattice, given above.

We return a dictionary because when the quantum characteristic is 0, the Cartan type is $A_\infty$, in which case the simple roots are indexed by the integers.

**EXAMPLES:**

```python
sage: Partition([4,3,2]).block(0)
{-2: 1, -1: 2, 0: 2, 1: 2, 2: 1, 3: 1}
sage: Partition([4,3,2]).block(2)
{0: 4, 1: 5}
sage: Partition([4,3,2]).block(2, multicharge=(1,))
{0: 5, 1: 4}
sage: Partition([4,3,2]).block(3)
{0: 3, 1: 3, 2: 3}
sage: Partition([4,3,2]).block(4)
{0: 2, 1: 2, 2: 2, 3: 3}
```

**boundary()**

Return the integer coordinates of points on the boundary of `self`.

For the following description, picture the Ferrer’s diagram of `self` using the French convention. Recall that the French convention puts the longest row on the bottom and the shortest row on the top. In addition, interpret the Ferrer’s diagram as 1 x 1 cells in the Euclidean plane. So if `self` was the partition [3, 1], the lower-left vertices of the 1 x 1 cells in the Ferrer’s diagram would be (0, 0), (1, 0), (2, 0), and (0, 1).

The boundary of a partition is the set $\{\text{NE}(d) \mid \forall d \text{ diagonal}\}$. That is, for every diagonal line $y = x + b$ where $b \in \mathbb{Z}$, we find the northeasternmost (NE) point on that diagonal which is also in the Ferrer’s diagram.

The boundary will go from bottom-right to top-left.

**EXAMPLES:**

Consider the partition (1) depicted as a square on a cartesian plane with vertices (0, 0), (1, 0), (1, 1), and (0, 1). Three of those vertices in the appropriate order form the boundary:

```python
sage: Partition([1]).boundary()
[(1, 0), (1, 1), (0, 1)]
```

The partition (3, 1) can be visualized as three squares on a cartesian plane. The coordinates of the appropriate vertices form the boundary:

```python
sage: Partition([3, 1]).boundary()
[(3, 0), (3, 1), (2, 1), (1, 1), (1, 2), (0, 2)]
```

**See also:**

`k_rim()`. You might have been looking for `k_boundary()` instead.

**cell_poset**(orientation='SE')

Return the Young diagram of `self` as a poset. The optional keyword variable `orientation` determines the order relation of the poset.

The poset always uses the set of cells of the Young diagram of `self` as its ground set. The order relation of the poset depends on the `orientation` variable (which defaults to "SE"). Concretely, `orientation` has to be specified to one of the strings "NW", "NE", "SW", and "SE", standing for “northwest”, “northeast”, “southwest” and “southeast”, respectively. If `orientation` is "SE", then the order relation of the poset is such that a cell $u$ is greater or equal to a cell $v$ in the poset if and only if $u$ lies weakly southeast of $v$ (this means that $u$ can be reached from $v$ by a sequence of south and east steps; the sequence is allowed to
consist of south steps only, or of east steps only, or even be empty). Similarly the order relation is defined for the other three orientations. The Young diagram is supposed to be drawn in English notation.

The elements of the poset are the cells of the Young diagram of self, written as tuples of zero-based coordinates (so that (3, 7) stands for the 8-th cell of the 4-th row, etc.).

EXAMPLES:

```python
sage: p = Partition([3,3,1])
sage: Q = p.cell_poset(); Q
Finite poset containing 7 elements
sage: sorted(Q)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: sorted(Q.maximal_elements())
[(1, 2), (2, 0)]
sage: Q.minimal_elements()
[(0, 0)]
sage: sorted(Q.upper_covers((1, 0)))
[(1, 1), (2, 0)]
sage: Q.upper_covers((1, 1))
[(1, 2)]

sage: P = p.cell_poset(orientation="NW"); P
Finite poset containing 7 elements
sage: sorted(P)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: sorted(P.minimal_elements())
[(1, 2), (2, 0)]
sage: P.maximal_elements()
[(0, 0)]
sage: P.upper_covers((2, 0))
[(1, 0)]
sage: sorted(P.upper_covers((1, 2)))
[(0, 2), (1, 1)]
sage: sorted(P.upper_covers((1, 1)))
[(0, 1), (1, 0)]
sage: sorted([len(P.upper_covers(v)) for v in P])
[0, 1, 1, 1, 1, 2, 2]

sage: R = p.cell_poset(orientation="NE"); R
Finite poset containing 7 elements
sage: sorted(R)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: R.maximal_elements()
[(0, 2)]
sage: R.minimal_elements()
[(2, 0)]
sage: sorted([len(R.upper_covers(v)) for v in R])
[0, 1, 1, 1, 1, 2, 2]
sage: R.is_isomorphic(P)
False
sage: R.is_isomorphic(P.dual())
False
```

Linear extensions of p.cell_poset() are in 1-to-1 correspondence with standard Young tableaux of shape p:

```python
sage: all( len(p.cell_poset().linear_extensions())
```

(continues on next page)
This is not the case for northeast orientation:

```python
sage: q = Partition([3, 1])
sage: q.cell_poset(orientation="NE").is_chain()
True
```

### cells()

Return the coordinates of the cells of `self`.

**EXAMPLES:**

```python
sage: Partition([2,2]).cells()
[(0, 0), (0, 1), (1, 0), (1, 1)]
sage: Partition([3,2]).cells()
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1)]
```

### centralizer_size (t=0, q=0)

Return the size of the centralizer of any permutation of cycle type `self`.

If $m_i$ is the multiplicity of $i$ as a part of $p$, this is given by

$$\prod_i m_i!^{m_i}.$$  

Including the optional parameters $t$ and $q$ gives the $q, t$ analog, which is the former product times

$$\frac{\text{length}(p)}{\prod_{i=1}^{\text{length}(p)} \frac{1 - q^{p_i}}{1 - t^{p_i}}}.$$  

See Section 1.3, p. 24, in [Ke1991].

**EXAMPLES:**

```python
sage: Partition([2,2,1]).centralizer_size()
8
sage: Partition([2,2,2]).centralizer_size()
48
sage: Partition([2,2,1]).centralizer_size(q=2, t=3)
9/16
sage: Partition([]).centralizer_size()
1
sage: Partition([]).centralizer_size(q=2, t=4)
1
```

### character_polynomial()

Return the character polynomial associated to the partition `self`.

The character polynomial $q_\mu$ associated to a partition $\mu$ is defined by

$$q_\mu(x_1, x_2, \ldots, x_k) = \sum_{\alpha \vdash k} \frac{x_\alpha^\mu}{1^{a_1}2^{a_2}\ldots k^{a_k}a_1!a_2!\ldots a_k!} \prod_{i=1}^k (ix_i - 1)^{a_i},$$

where $k$ is the size of $\mu$, and $a_i$ is the multiplicity of $i$ in $\alpha$.

It is computed in the following manner:
1. Expand the Schur function $s_\mu$ in the power-sum basis,
2. Replace each $p_i$ with $ix_i - 1$,
3. Apply the umbral operator $\downarrow$ to the resulting polynomial.

**EXAMPLES:**

```python
sage: Partition([1]).character_polynomial()
x - 1
sage: Partition([1,1]).character_polynomial()
1/2*x0^2 - 3/2*x0 - x1 + 1
sage: Partition([2,1]).character_polynomial()
1/3*x0^3 - 2*x0^2 + 8/3*x0 - x2
```

**components()**

Return a list containing the shape of self.

This method exists only for compatibility with `PartitionTuples`.

**EXAMPLES:**

```python
sage: Partition([3,2]).components()
[[3, 2]]
```

**conjugacy_class_size()**

Return the size of the conjugacy class of the symmetric group indexed by self.

**EXAMPLES:**

```python
sage: Partition([2,2,2]).conjugacy_class_size()
15
sage: Partition([2,2,1]).conjugacy_class_size()
15
sage: Partition([2,1,1]).conjugacy_class_size()
6
```

**conjugate()**

Return the conjugate partition of the partition self. This is also called the associated partition or the transpose in the literature.

**EXAMPLES:**

```python
sage: Partition([2,2]).conjugate()
[2, 2]
sage: Partition([6,3,1]).conjugate()
[3, 2, 2, 1, 1, 1]
```

The conjugate partition is obtained by transposing the Ferrers diagram of the partition (see `ferrers_diagram()`):

```python
sage: print(Partition([6,3,1]).ferrers_diagram())
******
***
*
sage: print(Partition([6,3,1]).conjugate().ferrers_diagram())
***
**
*```
contains \( (x) \)
Return True if \( x \) is a partition whose Ferrers diagram is contained in the Ferrers diagram of self.

EXAMPLES:

```
sage: p = Partition([3,2,1])
sage: p.contains([2,1])
True
sage: all(p.contains(mu) for mu in Partitions(3))
True
sage: all(p.contains(mu) for mu in Partitions(4))
False
```

content \( (r, c, \text{multicharge}=0) \)
Return the content of the cell at row \( r \) and column \( c \).

The content of a cell is \( c - r \).

For consistency with partition tuples there is also an optional \text{multicharge} argument which is an offset to the usual content. By setting the \text{multicharge} equal to the 0-element of the ring \( \mathbb{Z}/e\mathbb{Z} \), the corresponding \( e \)-residue will be returned. This is the content modulo \( e \).

The content (and residue) do not strictly depend on the partition, however, this method is included because it is often useful in the context of partitions.

EXAMPLES:

```
sage: Partition([2,1]).content(1,0)
-1
sage: p = Partition([3,2])
sage: sum([p.content(*c) for c in p.cells()]),
2
and now we return the 3-residue of a cell:
```

```
sage: Partition([2,1]).content(1,0, multicharge=[IntegerModRing(3)(0)])
2
```

contents_tableau \( (\text{multicharge}=0) \)
Return the tableau which has \( (k,r,c) \)-th cell equal to the content \( \text{multicharge}[k] - r + c \) of the cell.

EXAMPLES:

```
sage: Partition([2,1]).contents_tableau()
[[0, 1], [-1]]
sage: Partition([3,2,1,1]).contents_tableau().pp()
 0 1 2
-1 0
-2
-3
sage: Partition([3,2,1,1]).contents_tableau([ IntegerModRing(3)(0)] ).pp()
 0 1 2
 2 0
```
core (length)
Return the length-core of the partition – in the literature the core is commonly referred to as the \( k \)-core, \( p \)-core, \( r \)-core, . . . .

The \( r \)-core of a partition \( \lambda \) can be obtained by repeatedly removing rim hooks of size \( r \) from (the Young diagram of) \( \lambda \) until this is no longer possible. The remaining partition is the core.

EXAMPLES:

```
sage: Partition([6,3,2,2]).core(3)
[2, 1, 1]
sage: Partition([]).core(3)
[]
sage: Partition([8,7,7,4,1,1,1,1,1]).core(3)
[2, 1, 1]
```

corners ()
Return a list of the corners of the partition \( \text{self} \).

A corner of a partition \( \lambda \) is a cell of the Young diagram of \( \lambda \) which can be removed from the Young diagram while still leaving a straight shape behind.

The entries of the list returned are pairs of the form \((i, j)\), where \( i \) and \( j \) are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([3,2,1]).corners()
[(0, 2), (1, 1), (2, 0)]
sage: Partition([3,3,1]).corners()
[(1, 2), (2, 0)]
sage: Partition([]).corners()
[]
```

corners_residue (i, l)
Return a list of the corners of the partition \( \text{self} \) having \( l \)-residue \( i \).

A corner of a partition \( \lambda \) is a cell of the Young diagram of \( \lambda \) which can be removed from the Young diagram while still leaving a straight shape behind. See \( \text{residue()} \) for the definition of the \( l \)-residue.

The entries of the list returned are pairs of the form \((i, j)\), where \( i \) and \( j \) are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([3,2,1]).corners_residue(0, 3)
[(1, 1)]
sage: Partition([3,2,1]).corners_residue(1, 3)
[(2, 0)]
sage: Partition([3,2,1]).corners_residue(2, 3)
[(0, 2)]
```

crank ()
Return the Dyson crank of \( \text{self} \).
The Dyson crank of a partition $\lambda$ is defined as follows: If $\lambda$ contains at least one 1, then the crank is $\mu(\lambda) - \omega(\lambda)$, where $\omega(\lambda)$ is the number of 1, and $\mu(\lambda)$ is the number of parts of $\lambda$ larger than $\omega(\lambda)$. If $\lambda$ contains no 1, then the crank is simply the largest part of $\lambda$.

REFERENCES:

• [AG1988]

EXAMPLES:

```python
sage: Partition([]).crank()
0
sage: Partition([3,2,2]).crank()
3
sage: Partition([5,4,2,1,1]).crank()
0
sage: Partition([1,1,1]).crank()
-3
sage: Partition([6,4,4,3]).crank()
6
sage: Partition([6,3,3,1,1]).crank()
1
sage: Partition([6]).crank()
6
sage: Partition([5,1]).crank()
0
sage: Partition([4,2]).crank()
4
sage: Partition([4,1,1]).crank()
-1
sage: Partition([3,3]).crank()
3
sage: Partition([3,2,1]).crank()
1
sage: Partition([3,1,1,1]).crank()
-3
sage: Partition([2,2,2]).crank()
2
sage: Partition([2,2,1,1]).crank()
-2
sage: Partition([2,1,1,1,1]).crank()
-4
sage: Partition([1,1,1,1,1,1]).crank()
-6
```

defect ($e$, multicharge=0)

Return the $e$-defect or the $e$-weight of self.

The $e$-defect is the number of (connected) $e$-rim hooks that can be removed from the partition.

The defect of a partition is given by

$$
defect(\beta) = (\Lambda, \beta) - \frac{1}{2}(\beta, \beta),$$

where $\Lambda = \sum_{r} A_{\kappa_r}$ for the multicharge $(\kappa_1, \ldots, \kappa_\ell)$ and $\beta = \sum_{(r,c)} \alpha_{(c-r)} \mod e$, with the sum being over the cells in the partition.

INPUT:

• $e$ – the quantum characteristic
• `multicharge` – the multicharge (default (0,))

OUTPUT:

• a non-negative integer, which is the defect of the block containing the partition `self`

EXAMPLES:

```
sage: Partition([4,3,2]).defect(2)
3
sage: Partition([0]).defect(2)
0
sage: Partition([3]).defect(2)
1
sage: Partition([6]).defect(2)
3
sage: Partition([9]).defect(2)
4
sage: Partition([12]).defect(2)
6
sage: Partition([4,3,2]).defect(3)
3
sage: Partition([0]).defect(3)
0
sage: Partition([3]).defect(3)
1
sage: Partition([6]).defect(3)
2
sage: Partition([9]).defect(3)
3
sage: Partition([12]).defect(3)
4
```

**degree** *(e)*

Return the $e$-th degree of `self`.

The $e$-th degree of a partition $\lambda$ is the sum of the $e$-th degrees of the standard tableaux of shape $\lambda$. The $e$-th degree is the exponent of $\Phi_e(q)$ in the Gram determinant of the Specht module for a semisimple Iwahori-Hecke algebra of type $A$ with parameter $q$.

INPUT:

• `e` – an integer $e > 1$

OUTPUT:

A non-negative integer.

EXAMPLES:

```
sage: Partition([4,3]).degree(2)
28
sage: Partition([4,3]).degree(3)
15
sage: Partition([4,3]).degree(4)
8
sage: Partition([4,3]).degree(5)
13
sage: Partition([4,3]).degree(6)
0
```

(continues on next page)
Therefore, the Gram determinant of $S(5, 3)$ when the Hecke parameter $q$ is “generic” is

$$q^N \Phi_2(q)^{28} \Phi_3(q)^{15} \Phi_4(q)^8 \Phi_5(q)^{13}$$

for some integer $N$. Compare with \texttt{prime_degree()}.

\begin{verbatim}
\texttt{sage: Partition([4,3]).degree(7)}
0
\end{verbatim}

\texttt{dimension} \texttt{(smaller=[], k=1)}

Return the number of paths from the \texttt{smaller} partition to the partition \texttt{self}, where each step consists of adding a $k$-ribbon while keeping a partition.

Note that a 1-ribbon is just a single cell, so this counts paths in the Young graph when $k = 1$.

Note also that the default case ($k = 1$ and \texttt{smaller} = []) gives the dimension of the irreducible representation of the symmetric group corresponding to \texttt{self}.

INPUT:

\begin{itemize}
  \item \texttt{smaller} – a partition (default: an empty list [ ])
  \item $k$ – a positive integer (default: 1)
\end{itemize}

OUTPUT:

The number of such paths

EXAMPLES:

Looks at the number of ways of getting from [5, 4] to the empty partition, removing one cell at a time:

\begin{verbatim}
\texttt{sage: mu = Partition([5,4])}
\texttt{sage: mu.dimension()}  
42
\end{verbatim}

Same, but removing one 3-ribbon at a time. Note that the 3-core of \texttt{mu} is empty:

\begin{verbatim}
\texttt{sage: mu.dimension(k=3)}  
3
\end{verbatim}

The 2-core of \texttt{mu} is not the empty partition:

\begin{verbatim}
\texttt{sage: mu.dimension(k=2)}  
0
\end{verbatim}

Indeed, the 2-core of \texttt{mu} is [1]:

\begin{verbatim}
\texttt{sage: mu.dimension(Partition([1]),k=2)}  
2
\end{verbatim}

ALGORITHM:

Depending on the parameters given, different simplifications occur. When $k = 1$ and \texttt{smaller} is empty, this function uses the hook formula. When $k = 1$ and \texttt{smaller} is not empty, it uses a formula from [ORV].

When $k \neq 1$, we first check that both \texttt{self} and \texttt{smaller} have the same $k$-core, then use the $k$-quotients and the same algorithm on each of the $k$-quotients.

AUTHORS:
**dominated_partitions** *(rows=None)*

Return a list of the partitions dominated by \( n \). If \( \text{rows} \) is specified, then it only returns the ones whose number of rows is at most \( \text{rows} \).

**EXAMPLES:**

```python
sage: Partition([3,2,1]).dominated_partitions()
[[3, 2, 1], [3, 1, 1, 1], [2, 2, 2], [2, 1, 1, 1, 1], [1, 1, 1, 1, 1, 1]]
sage: Partition([3,2,1]).dominated_partitions(rows=3)
[[3, 2, 1], [2, 2, 2]]
```

**dominates** *(p2)*

Return \( \text{True} \) if \( \text{self} \) dominates the partition \( p2 \). Otherwise it returns \( \text{False} \).

**EXAMPLES:**

```python
sage: p = Partition([3,2])
sage: p.dominates([3,1])
True
sage: p.dominates([2,2])
True
sage: p.dominates([2,1,1])
True
sage: p.dominates([3,3])
False
sage: p.dominates([4])
False
sage: Partition([4]).dominates(p)
False
sage: Partition([]).dominates([1])
False
sage: Partition([]).dominates([])
True
sage: Partition([1]).dominates([])
True
```

**down()**

Return a generator for partitions that can be obtained from \( \text{self} \) by removing a cell.

**EXAMPLES:**

```python
sage: [p for p in Partition([2,1,1]).down()]
[[1, 1, 1], [2, 1]]
sage: [p for p in Partition([3,2]).down()]
[[2, 2], [3, 1]]
sage: [p for p in Partition([3,2,1]).down()]
[[2, 2, 1], [3, 1, 1], [3, 2]]
```

**down_list()**

Return a list of the partitions that can be obtained from \( \text{self} \) by removing a cell.

**EXAMPLES:**

```python
sage: Partition([2,1,1]).down_list()
[[1, 1, 1], [2, 1]]
sage: Partition([3,2]).down_list()
```
dual_equivalence_graph (directed=False, coloring=None)

Return the dual equivalence graph of self.

Two permutations $p$ and $q$ in the symmetric group $S_n$ differ by an $i$-elementary dual equivalence (or dual Knuth) relation (where $i$ is an integer with $1 < i < n$) when the following two conditions are satisfied:

- In the one-line notation of the permutation $p$, the letter $i$ does not appear inbetween $i - 1$ and $i + 1$.
- The permutation $q$ is obtained from $p$ by switching two of the three letters $i-1$, $i$, $i+1$ (in its one-line notation) – namely, the leftmost and the rightmost one in order of their appearance in $p$.

Notice that this is equivalent to the statement that the permutations $p^{-1}$ and $q^{-1}$ differ by an elementary Knuth equivalence at positions $i - 1, i, i + 1$.

Two standard Young tableaux of shape $\lambda$ differ by an $i$-elementary dual equivalence relation (of color $i$), if their reading words differ by an $i$-elementary dual equivalence relation.

The dual equivalence graph of the partition $\lambda$ is the edge-colored graph whose vertices are the standard Young tableaux of shape $\lambda$, and whose edges colored by $i$ are given by the $i$-elementary dual equivalences.

INPUT:

- directed – (default: False) whether to have the dual equivalence graph be directed (where we have a directed edge $S \to T$ if $i$ appears to the left of $i + 1$ in the reading word of $T$; otherwise we have the directed edge $T \to S$)
- coloring – (optional) a function which sends each integer $i > 1$ to a color (as a string, e.g., 'red' or 'black') to be used when visually representing the resulting graph using dot2tex; the default choice is $2 \to 'red'$, $3 \to 'blue'$, $4 \to 'green'$, $5 \to 'purple'$, $6 \to 'brown'$, $7 \to 'orange'$, $8 \to 'yellow'$, anything greater than 8 $\to 'black'$.

REFERENCES:

- [As2008b]

EXAMPLES:

```
sage: P = Partition([3,1,1])
sage: G = P.dual_equivalence_graph()
sage: sorted(G.edges())
[([[1, 2, 3], [4], [5]], [[1, 2, 4], [3], [5]], 3),
 [[[1, 2, 4], [3], [5]], [[1, 2, 5], [3], [4]], 4),
 [[[1, 2, 4], [3], [5]], [[1, 3, 4], [2], [5]], 2),
 [[[1, 2, 5], [3], [4]], [[1, 3, 5], [2], [4]], 2),
 [[[1, 3, 4], [2], [5]], [[1, 3, 5], [2], [4]], 4),
 [[[1, 3, 5], [2], [4]], [[1, 4, 5], [2], [3]], 3)]
sage: G = P.dual_equivalence_graph(directed=True)
sage: sorted(G.edges())
[([[1, 2, 4], [3], [5]], [[1, 2, 3], [4], [5]], 3),
 [[[1, 2, 5], [3], [4]], [[1, 2, 4], [3], [5]], 4),
 [[[1, 3, 4], [2], [5]], [[1, 3, 5], [2], [4]], 2),
 [[[1, 3, 5], [2], [4]], [[1, 4, 5], [2], [3]], 3)]
```
evaluation()
Return the evaluation of self.

The commutative evaluation, often shortened to evaluation, of a word (we think of a partition as a word in \{1, 2, 3, \ldots\}) is its image in the free commutative monoid. In other words, this counts how many occurrences there are of each letter.

This is also is known as Parikh vector and abelianization and has the same output as to_exp().

EXAMPLES:

```
sage: Partition([4,3,1,1]).evaluation()
[2, 0, 1, 1]
```

ferrers_diagram()
Return the Ferrers diagram of self.

EXAMPLES:

```
sage: mu = Partition([5,5,2,1])
sage: Partitions.options(diagram_str='*', convention="english")
sage: print(mu.ferrers_diagram())
******
******
**
*
sage: Partitions.options(diagram_str='#')
sage: print(mu.ferrers_diagram())
#####
#####
##
#
sage: Partitions.options.convention="french"
sage: print(mu.ferrers_diagram())
#
#
####
####
sage: print(Partition([]).ferrers_diagram())
-
sage: Partitions.options(diagram_str='—')
sage: print(Partition([]).ferrers_diagram())
(/)
sage: Partitions.options._reset()
```

frobenius_coordinates()
Return a pair of sequences of Frobenius coordinates aka beta numbers of the partition.

These are two strictly decreasing sequences of nonnegative integers of the same length.

EXAMPLES:

```
sage: Partition([]).frobenius_coordinates()
([], [])
sage: Partition([1]).frobenius_coordinates()
([], [1])
```
\textbf{frobenius_rank()}

Return the Frobenius rank of the partition \texttt{self}.

The Frobenius rank of a partition \( \lambda = (\lambda_1, \lambda_2, \lambda_3, \cdots) \) is defined to be the largest \( i \) such that \( \lambda_i \geq i \). In other words, it is the number of cells on the main diagonal of \( \lambda \). In yet other words, it is the size of the largest square fitting into the Young diagram of \( \lambda \).

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Partition([]).frobenius_rank()
0
sage: Partition([1]).frobenius_rank()
1
sage: Partition([3,3,3]).frobenius_rank()
3
sage: Partition([9,1,1,1,1,1]).frobenius_rank()
1
sage: Partition([2,1,1,1,1]).frobenius_rank()
1
sage: Partition([2,2,1,1,1]).frobenius_rank()
2
sage: Partition([3,2]).frobenius_rank()
2
sage: Partition([3,2,2]).frobenius_rank()
2
sage: Partition([8,4,4,4,4]).frobenius_rank()
4
sage: Partition([8,4,1]).frobenius_rank()
2
sage: Partition([3,3,1]).frobenius_rank()
2
\end{verbatim}

\textbf{from_kbounded_to_grassmannian}(k)

Maps a \( k \)-bounded partition to a Grassmannian element in the affine Weyl group of type \( A_k^{(1)} \).

For details, see the documentation of the method \texttt{from_kbounded_to_reduced_word()}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: p=Partition([2,1,1])
sage: p.from_kbounded_to_grassmannian(2)
[-1 1 1]
[-2 2 1]
[-2 1 2]
sage: p=Partition([])
sage: p.from_kbounded_to_grassmannian(2)
[1 0 0]
[0 1 0]
[0 0 1]
\end{verbatim}

\textbf{from_kbounded_to_reduced_word}(k)

Maps a \( k \)-bounded partition to a reduced word for an element in the affine permutation group.
This uses the fact that there is a bijection between $k$-bounded partitions and $(k+1)$-cores and an action of the affine nilCoxeter algebra of type $A^{(1)}_k$ on $(k+1)$-cores as described in [LM2006b].

**EXAMPLES:**

```python
g = Partition([2,1,1]).garnir_tableau((0,2)); g.pp() 1 2 6 7 8 3 4 5 9 10 11 12 13
g.is_row_strict(); g.is_column_strict() True False
g = Partition([2,1,1]).garnir_tableau(0,2).pp() 1 2 6 7 8 3 4 5 9 10 11 12 13
```

The Garnir tableaux play an important role in integral and non-semisimple representation theory because they determine the “straightening” rules for the Specht modules over an arbitrary ring.

The Garnir tableaux are the “first” non-standard tableaux which arise when you act by simple transpositions. If $(a,c)$ is a cell in the Young diagram of a partition, which is not at the bottom of its column, then the corresponding Garnir tableau has the integers $1, 2, \ldots, n$ entered in order from left to right along the rows of the diagram up to the cell $(a,c-1)$, then along the cells $(a+1,1)$ to $(a+1,c)$, then $(a,c)$ until the end of row $a$ and then continuing from left to right in the remaining positions. The examples below probably make this clearer!

**Note:** The function also sets $g._garnir_cell$, where $g$ is the resulting Garnir tableau, equal to cell which is used by some other functions.

**EXAMPLES:**

```python
g = Partition([5,3,3,2]).garnir_tableau((0,2)); g.pp() 1 2 6 7 8 3 4 5 9 10 11 12 13
g.is_row_strict(); g.is_column_strict() True False
g = Partition([5,3,3,2]).garnir_tableau(0,2).pp() 1 2 6 7 8 3 4 5 9 10 11 12 13
g = Partition([5,3,3,2]).garnir_tableau(2,1).pp() 1 2 3 4 5 6 7 8 9 12 13 10 11
```
sage: Partition([5,3,3,2]).garnir_tableau(2,2).pp()
Traceback (most recent call last):
...
ValueError: (row+1, col) must be inside the diagram

See also:

- top_garnir_tableau()

**generalized_pochhammer_symbol** *(a, alpha)*

Return the generalized Pochhammer symbol \((a)_{\alpha}\). This is the product over all cells \((i, j)\) in \(\text{self}\) of 
\[ a - (i - 1)/\alpha + j - 1. \]

**EXAMPLES:**

sage: Partition([2,2]).generalized_pochhammer_symbol(2,1)
12

**get_part** *(i, default=0)*

Return the \(i^{th}\) part of \(\text{self}\), or \(\text{default}\) if it does not exist.

**EXAMPLES:**

sage: p = Partition([2,1])
sage: p.get_part(0), p.get_part(1), p.get_part(2)
(2, 1, 0)
sage: p.get_part(10,-1)
-1
sage: Partition([]).get_part(0)
0

**has_k_rectangle** *(k)*

Return True if the Ferrer’s diagram of \(\text{self}\) contains \(k - i + 1\) rows \(\text{or more}\) of length \(i\) \(\text{exactly}\) for any \(i\) in \([1, k]\).

This is mainly a helper function for is_k_reducible() and is_k_irreducible(), the only difference between this function and is_k_reducible() being that this function allows any partition as input while is_k_reducible() requires the input to be \(k\)-bounded.

**EXAMPLES:**

The partition \([1, 1, 1]\) has at least 2 rows of length 1:

sage: Partition([1, 1, 1]).has_k_rectangle(2)
True

The partition \([1, 1, 1]\) does not have 4 rows of length 1, 3 rows of length 2, 2 rows of length 3, nor 1 row of length 4:

sage: Partition([1, 1, 1]).has_k_rectangle(4)
False

See also:

- is_k_irreducible(), is_k_reducible(), has_rectangle()

**has_rectangle** *(h, w)*

Return True if the Ferrer’s diagram of \(\text{self}\) has \(h\) \(\text{or more}\) rows of length \(w\) \(\text{exactly}\).
INPUT:

- \( h \) – An integer \( h \geq 1 \). The (minimum) height of the rectangle.
- \( w \) – An integer \( w \geq 1 \). The width of the rectangle.

EXAMPLES:

```python
sage: Partition([3, 3, 3, 3]).has_rectangle(2, 3)
True
sage: Partition([3, 3]).has_rectangle(2, 3)
True
sage: Partition([4, 3]).has_rectangle(2, 3)
False
sage: Partition([3]).has_rectangle(2, 3)
False
```

See also:

`has_k_rectangle()`

`hook_length(i, j)`

Return the length of the hook of cell \((i, j)\) in `self`.

The (length of the) hook of cell \((i, j)\) of a partition \(\lambda\) is

\[
\lambda_i + \lambda'_j - i - j + 1
\]

where \(\lambda'\) is the conjugate partition. In English convention, the hook length is the number of cells horizontally to the right and vertically below the cell \((i, j)\) (including that cell).

EXAMPLES:

```python
sage: p = Partition([2,2,1])
sage: p.hook_length(0, 0)
4
sage: p.hook_length(0, 1)
2
sage: p.hook_length(2, 0)
1
sage: Partition([3,3]).hook_length(0, 0)
4
sage: cell = [0,0]; Partition([3,3]).hook_length(*cell)
4
```

`hook_lengths()`

Return a tableau of shape `self` with the cells filled in with the hook lengths.

In each cell, put the sum of one plus the number of cells horizontally to the right and vertically below the cell (the hook length).

For example, consider the partition \([3,2,1]\) of 6 with Ferrers diagram:

```
# # #
# #
#
```

When we fill in the cells with the hook lengths, we obtain:

```
5 3 1
3 1
1
```
EXAMPLES:

```python
sage: Partition([2,2,1]).hook_lengths()
[[4, 2], [3, 1], [1]]
sage: Partition([3,3]).hook_lengths()
[[4, 3, 2], [3, 2, 1]]
sage: Partition([3,2,1]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
sage: Partition([2,2]).hook_lengths()
[[3, 2], [2, 1]]
sage: Partition([5]).hook_lengths()
[[5, 4, 3, 2, 1]]
```

REFERENCES:

`hook_polynomial(q,t)`

Return the two-variable hook polynomial.

EXAMPLES:

```python
sage: R.<q,t> = PolynomialRing(QQ)
sage: a = Partition([2,2]).hook_polynomial(q,t)
sage: a == (1 - t)*(1 - q*t)*(1 - t^2)*(1 - q*t^2)
True
sage: a = Partition([3,2,1]).hook_polynomial(q,t)
sage: a == (1 - t)^3*(1 - q*t^2)^2*(1 - q^2*t^3)
True
```

`hook_product(a)`

Return the Jack hook-product.

EXAMPLES:

```python
sage: Partition([3,2,1]).hook_product(x)
(2*x + 3)*(x + 2)^2
sage: Partition([2,2]).hook_product(x)
2*(x + 2)*(x + 1)
```

`hooks()`

Return a sorted list of the hook lengths in `self`.

EXAMPLES:

```python
sage: Partition([3,2,1]).hooks()
[5, 3, 3, 1, 1, 1]
```

`initial_column_tableau()`

Return the initial column tableau of shape `self`.

The initial column tableau of shape `self` is the standard tableau that has the numbers 1 to `n`, where `n` is the `size()` of `self`, entered in order from top to bottom and then left to right down the columns of `self`.

EXAMPLES:

```python
sage: Partition([3,2]).initial_column_tableau()
[[1, 3, 5], [2, 4]]
```

`initial_tableau()`

Return the standard tableau which has the numbers 1, 2, ..., `n` where `n` is the `size()` of `self`
entered in order from left to right along the rows of each component, where the components are ordered from left to right.

EXAMPLES:

```python
sage: Partition([3,2,2]).initial_tableau()
[[1, 2, 3], [4, 5], [6, 7]]
```

**inside_corners()**

Return a list of the corners of the partition `self`.

A corner of a partition \( \lambda \) is a cell of the Young diagram of \( \lambda \) which can be removed from the Young diagram while still leaving a straight shape behind.

The entries of the list returned are pairs of the form \((i, j)\), where \(i\) and \(j\) are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```python
sage: Partition([3,2,1]).corners()
[(0, 2), (1, 1), (2, 0)]
sage: Partition([3,3,1]).corners()
[(1, 2), (2, 0)]
sage: Partition([[]]).corners()
[]
```

**inside_corners_residue\((i, l)\)**

Return a list of the corners of the partition `self` having \(l\)-residue \(i\).

A corner of a partition \( \lambda \) is a cell of the Young diagram of \( \lambda \) which can be removed from the Young diagram while still leaving a straight shape behind. See `residue()` for the definition of the \(l\)-residue.

The entries of the list returned are pairs of the form \((i, j)\), where \(i\) and \(j\) are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```python
sage: Partition([3,2,1]).corners_residue(0, 3)
[(1, 1)]
sage: Partition([3,2,1]).corners_residue(1, 3)
[(2, 0)]
sage: Partition([3,2,1]).corners_residue(2, 3)
[(0, 2)]
```

**is_core\((k)\)**

Return `True` if the Partition `self` is a \(k\)-core.

A partition is said to be a ‘\(k\)-core’ if it has no hooks of length \(k\). Equivalently, a partition is said to be a \(k\)-core if it is its own \(k\)-core (where the latter is defined as in `core()`).

Visually, this can be checked by trying to remove border strips of size \(k\) from `self`. If this is not possible, then `self` is a \(k\)-core.

EXAMPLES:

In the partition \((2, 1)\), a hook length of 2 does not occur, but a hook length of 3 does:

```python
sage: p = Partition([2, 1])
sage: p.is_core(2)
True
sage: p.is_core(3)
```

(continues on next page)
sage: q = Partition([12, 8, 5, 5, 2, 2, 1])
sage: q.is_core(4)
False
sage: q.is_core(5)
True
sage: q.is_core(0)
True

See also:

core(), Core

is_empty()
Return True if self is the empty partition.

EXAMPLES:

sage: Partition([]).is_empty()
True
sage: Partition([2,1,1]).is_empty()
False

is_k_bounded(k)
Return True if the partition self is bounded by k.

EXAMPLES:

sage: Partition([4, 3, 1]).is_k_bounded(4)
True
sage: Partition([4, 3, 1]).is_k_bounded(7)
True
sage: Partition([4, 3, 1]).is_k_bounded(3)
False

is_k_irreducible(k)
Return True if the partition self is k-irreducible.

A k-bounded partition is k-irreducible if its Ferrer’s diagram does not contain \(k - i + 1\) rows (or more) of length \(i\) (exactly) for every \(i \in [1, k]\).

(Also, a k-bounded partition is k-irreducible if and only if it is not k-reducible.)

EXAMPLES:
The partition [1, 1, 1] has at least 2 rows of length 1:

sage: Partition([1, 1, 1]).is_k_irreducible(2)
False

The partition [1, 1, 1] does not have 4 rows of length 1, 3 rows of length 2, 2 rows of length 3, nor 1 row of length 4:

sage: Partition([1, 1, 1]).is_k_irreducible(4)
True

See also:

is_k_reducible(), has_k_rectangle()
**is_k_reducible** *(k)*

Return True if the partition self is k-reducible.

A k-bounded partition is **k-reducible** if its Ferrer's diagram contains \(k - i + 1\) rows (or more) of length \(i\) (exactly) for some \(i \in [1, k]\).

(Also, a k-bounded partition is k-reducible if and only if it is not k-irreducible.)

**EXAMPLES:**

The partition [1, 1, 1] has at least 2 rows of length 1:

```
sage: Partition([1, 1, 1]).is_k_reducible(2)
True
```

The partition [1, 1, 1] does not have 4 rows of length 1, 3 rows of length 2, 2 rows of length 3, nor 1 row of length 4:

```
sage: Partition([1, 1, 1]).is_k_reducible(4)
False
```

**See also:**

`is_k_irreducible()`, `has_k_rectangle()`

**is_regular** *(e, multicharge=0)*

Return True is this is an e-regular partition.

A partition is e-regular if it does not have e equal non-zero parts.

**EXAMPLES:**

```
sage: Partition([4,3,3,3]).is_regular(2)
False
sage: Partition([4,3,3,3]).is_regular(3)
False
sage: Partition([4,3,3,3]).is_regular(4)
True
```

**is_restricted** *(e, multicharge=0)*

Return True is this is an e-restricted partition.

An e-restricted partition is a partition such that the difference of consecutive parts is always strictly less than e, where partitions are considered to have an infinite number of 0 parts. I.e., the last part must be strictly less than e.

**EXAMPLES:**

```
sage: Partition([4,3,3,2]).is_restricted(2)
False
sage: Partition([4,3,3,2]).is_restricted(3)
True
sage: Partition([4,3,3,2]).is_restricted(4)
True
sage: Partition([4]).is_restricted(4)
False
```

**is_symmetric()**

Return True if the partition self equals its own transpose.

**EXAMPLES:**
sage: Partition([2, 1]).is_symmetric()
True
sage: Partition([3, 1]).is_symmetric()
False

jacobi_trudi()
Return the Jacobi-Trudi matrix of self thought of as a skew partition. See SkewPartition.jacobi_trudi().

EXAMPLES:

sage: part = Partition([3,2,1])
sage: jt = part.jacobi_trudi(); jt
sage: s = SymmetricFunctions(QQ).schur()
sage: h = SymmetricFunctions(QQ).homogeneous()
sage: h( s(part) )
sage: jt.det()

k_atom(k)
Return a list of the standard tableaux of size self.size() whose k-atom is equal to self.

EXAMPLES:

sage: p = Partition([3,2,1])
sage: p.k_atom(1)
[]
sage: p.k_atom(3)
[[[1, 1, 1], [2, 2], [3]],
 [[1, 1, 1, 2], [2], [3]],
 [[1, 1, 1, 3], [2, 2]],
 [[1, 1, 1, 2, 3], [2]]]
sage: Partition([3,2,1]).k_atom(4)
[[[1, 1, 1], [2, 2], [3]], [[1, 1, 1, 3], [2, 2]]]

k_boundary(k)
Return the skew partition formed by removing the cells of the k-interior, see k_interior().

EXAMPLES:

sage: p = Partition([3,2,1])
sage: p.k_boundary(2)
[3, 2, 1] / [2, 1]
sage: p.k_boundary(3)
[3, 2, 1] / [1]
sage: p = Partition([12,8,5,5,2,2,1])
sage: p.k_boundary(4)
[12, 8, 5, 2, 2, 1] / [8, 5, 2]

k_column_lengths(k)
Return the k-column-shape of the partition self.

This is the ‘column’ analog of k_row_lengths().
EXAMPLES:

```
sage: Partition([6, 1]).k_column_lengths(2)
[1, 0, 0, 0, 1, 1]
sage: Partition([4, 4, 4, 3, 2]).k_column_lengths(2)
[1, 1, 1, 2]
```

See also:

- `k_row_lengths()`, `k_boundary()`, `SkewPartition.row_lengths()`, `SkewPartition.column_lengths()`

**k_conjugate**

Return the $k$-conjugate of `self`.

The $k$-conjugate is the partition that is given by the columns of the $k$-skew diagram of the partition.

We can also define the $k$-conjugate in the following way. Let $P$ denote the bijection from $(k+1)$-cores to $k$-bounded partitions. The $k$-conjugate of a $(k+1)$-core $\lambda$ is

$$
\lambda^{(k)} = P^{-1}((P(\lambda))').
$$

EXAMPLES:

```
sage: p = Partition([4,3,2,2,1,1])
sage: p.k_conjugate(4)
[3, 2, 2, 1, 1, 1, 1, 1, 1]
```

**k_interior**

Return the partition consisting of the cells of `self` whose hook lengths are greater than $k$.

EXAMPLES:

```
sage: p = Partition([3,2,1])
sage: p.hook_lengths()
[[5, 3, 1], [3, 1], [1]]
sage: p.k_interior(2)
[2, 1]
sage: p.k_interior(3)
[1]
sage: p = Partition([])
sage: p.k_interior(3)
[]
```

**k_irreducible**

Return the partition with all $r \times (k+1-r)$ rectangles removed.

If `self` is a $k$-bounded partition, then this method will return the partition where all rectangles of dimension $r \times (k+1-r)$ for $1 \leq r \leq k$ have been deleted.

If `self` is not a $k$-bounded partition then the method will raise an error.

**INPUT:**

- $k$ – a non-negative integer

**OUTPUT:**

- a partition
EXAMPLES:

```python
sage: Partition([3,2,2,1,1,1]).k_irreducible(4)
[3, 2, 2, 1, 1, 1]
sage: Partition([3,2,2,1,1,1]).k_irreducible(3)
[]
sage: Partition([3,3,3,2,2,2,2,2,1,1,1,1]).k_irreducible(3)
[2, 1]
```

**k_rim**($k$)

Return the $k$-rim of self as a list of integer coordinates.

The $k$-rim of a partition is the “line between” (or “intersection of”) the $k$-boundary and the $k$-interior. (Section 2.3 of [HM2011])

It will be output as an ordered list of integer coordinates, where the origin is $(0, 0)$. It will start at the top-left of the $k$-rim (using French convention) and end at the bottom-right.

**EXAMPLES:**

Consider the partition $(3, 1)$ split up into its 1-interior and 1-boundary:

![Diagram of 1-rim](image)

The line shown in bold is the 1-rim, and that information is equivalent to the integer coordinates of the points that occur along that line:

```python
sage: Partition([3, 1]).k_rim(1)
[(3, 0), (2, 0), (2, 1), (1, 1), (0, 1), (0, 2)]
```

**See also:**

```
k_interior(), k_boundary(), boundary()
```

**k_row_lengths**($k$)

Return the $k$-row-shape of the partition self.

This is equivalent to taking the $k$-boundary of the partition and then returning the row-shape of that. We do not discard rows of length 0. (Section 2.2 of [LLMS2013])

**EXAMPLES:**

```python
sage: Partition([6, 1]).k_row_lengths(2)
[2, 1]
sage: Partition([4, 4, 4, 3, 2]).k_row_lengths(2)
[0, 1, 1, 1, 2]
```

**See also:**
Given a partition $\text{self}$ and a $k$, return the size of the $k$-boundary.

This is the same as the length method $\text{sage.combinat.core.Core.length()}$ of the $\text{sage.combinat.core.Core}$ object, with the exception that here we don’t require $\text{self}$ to be a $k+1$-core.

**EXAMPLES:**

```python
sage: Partition([2, 1, 1]).k_size(1)
2
sage: Partition([2, 1, 1]).k_size(2)
3
sage: Partition([2, 1, 1]).k_size(3)
3
sage: Partition([2, 1, 1]).k_size(4)
4
```

**See also:**

$k\_boundary()$, $\text{SkewPartition.size()}$

**$k\_skew(k)$**

Return the $k$-skew partition.

The $k$-skew diagram of a $k$-bounded partition is the skew diagram denoted $\lambda/k$ satisfying the conditions:

1. row $i$ of $\lambda/k$ has length $\lambda_i$,
2. no cell in $\lambda/k$ has hook-length exceeding $k$,
3. every square above the diagram of $\lambda/k$ has hook length exceeding $k$.

**REFERENCES:**

- [LM2004]

**EXAMPLES:**

```python
sage: p = Partition([4,3,2,2,1,1])
sage: p.k_skew(4)
[9, 5, 3, 2, 1, 1] / [5, 2, 1]
```

**$k\_split(k)$**

Return the $k$-split of $\text{self}$.

**EXAMPLES:**

```python
sage: Partition([4,3,2,1]).k_split(3)
[]
sage: Partition([4,3,2,1]).k_split(4)
[[4], [3, 2], [1]]
sage: Partition([4,3,2,1]).k_split(5)
[[4, 3], [2, 1]]
sage: Partition([4,3,2,1]).k_split(6)
[[4, 3, 2], [1]]
sage: Partition([4,3,2,1]).k_split(7)
[[4, 3, 2, 1]]
sage: Partition([4,3,2,1]).k_split(8)
[[4, 3, 2, 1]]
```
larger_lex(rhs)
Return True if self is larger than rhs in lexicographic order. Otherwise return False.

EXAMPLES:

```python
sage: p = Partition([3,2])
sage: p.larger_lex([3,1])
True
sage: p.larger_lex([1,4])
True
sage: p.larger_lex([3,2,1])
False
sage: p.larger_lex([3])
True
sage: p.larger_lex([5])
False
sage: p.larger_lex([3,1,1,1,1,1,1,1])
True
```

leg_cells(i, j)
Return the list of the cells of the leg of cell (i, j) in self.

The leg of cell c = (i, j) is defined to be the cells below c (in English convention).
The cell coordinates are zero-based, i.e., the northwesternmost cell is (0, 0).

INPUT:
• i, j – two integers

OUTPUT:
A list of pairs of integers

EXAMPLES:

```python
sage: Partition([4,4,3,1]).leg_cells(1,1)
[(2, 1)]
sage: Partition([4,4,3,1]).leg_cells(0,1)
[(1, 1), (2, 1)]
sage: Partition([]).leg_cells(0,0)
Traceback (most recent call last):
  ...
ValueError: The cell is not in the diagram
```

leg_length(i, j)
Return the length of the leg of cell (i, j) in self.

The leg of cell c = (i, j) is defined to be the cells below c (in English convention).
The cell coordinates are zero-based, i.e., the northwesternmost cell is (0, 0).

INPUT:
• i, j – two integers

OUTPUT:
An integer or a ValueError

EXAMPLES:
```python
sage: p = Partition([2,2,1])
sage: p.leg_length(0, 0)
2
sage: p.leg_length(0, 1)
1
sage: p.leg_length(2, 0)
0
sage: Partition([3,3]).leg_length(0, 0)
1
sage: cell = [0,0]; Partition([3,3]).leg_length(*cell)
1
```

**leg_lengths** *(flat=False)*

Return a tableau of shape `self` with each cell filled in with its leg length. The optional boolean parameter `flat` provides the option of returning a flat list.

**EXAMPLES:**

```python
sage: Partition([2,2,1]).leg_lengths()
[[2, 1], [1, 0], [0]]
sage: Partition([2,2,1]).leg_lengths(flat=True)
[2, 1, 1, 0, 0]
sage: Partition([3,3]).leg_lengths()
[[1, 1, 1], [0, 0, 0]]
sage: Partition([3,3]).leg_lengths(flat=True)
[1, 1, 1, 0, 0, 0]
```

**length()**

Return the number of parts in `self`.

**EXAMPLES:**

```python
sage: Partition([3,2]).length()
2
sage: Partition([2,2,1]).length()
3
sage: Partition([]).length()
0
```

**level()**

Return the level of `self`, which is always 1.

This method exists only for compatibility with `PartitionTuples`.

**EXAMPLES:**

```python
sage: Partition([4,3,2]).level()
1
```

**lower_hook**(i, j, alpha)**

Return the lower hook length of the cell `(i, j)` in `self`. When `alpha = 1`, this is just the normal hook length.

The lower hook length of a cell `(i, j)` in a partition `κ` is defined by

\[ h^\alpha_\kappa(i, j) = \kappa_j' - i + 1 + \alpha(\kappa_i - j). \]

**EXAMPLES:**
The lower hook length of a cell \((i, j)\) in a partition \(\lambda\) is defined by

\[
h_\lambda^\kappa(i, j) = \lambda'_j - i + 1 + \alpha(\kappa_i - j).
\]

**EXAMPLES:**

```python
sage: Partition([3, 2, 1]).lower_hook_lengths(x)
[[2*x + 3, x + 2, 1], [x + 2, 1], [1]]
sage: Partition([3, 2, 1]).lower_hook_lengths(1)
[[5, 3, 1], [3, 1], [1]]
sage: Partition([3, 2, 1]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
```

The `next()` method returns the partition that lexicographically follows `self`, of the same size. If `self` is the last partition, then return `False`.

**EXAMPLES:**

```python
sage: next(Partition([4]))
[3, 1]
sage: next(Partition([1,1,1,1]))
False
```

The `next_within_bounds` method gets the next partition lexicographically that contains `min` and is contained in `max`.

**INPUT:**

- `min` – (default `[]`, the empty partition) The ‘minimum partition’ that `next_within_bounds(self)` must contain.
- `max` – (default `None`) The ‘maximum partition’ that `next_within_bounds(self)` must be contained in. If set to `None`, then there is no restriction.
- `partition_type` – (default `None`) The type of partitions allowed. For example, ‘strict’ for strictly decreasing partitions, or `None` to allow any valid partition.

**EXAMPLES:**

```python
sage: m = [1, 1]
sage: M = [3, 2, 1]
sage: Partition([1, 1]).next_within_bounds(min=m, max=M)
[1, 1, 1]
sage: Partition([1, 1, 1]).next_within_bounds(min=m, max=M)
[2, 1]
sage: Partition([2, 1]).next_within_bounds(min=m, max=M)
```

(continues on next page)
See also:

next()

outer_rim()

Return the outer rim of self.

The outer rim of a partition \( \lambda \) is defined as the cells which do not belong to \( \lambda \) and which are adjacent to cells in \( \lambda \).

EXAMPLES:

The outer rim of the partition [4, 1] consists of the cells marked with # below:

```
****#
*####
##
```

```
sage: Partition([4,1]).outer_rim()
[(2, 0), (2, 1), (1, 1), (1, 2), (1, 3), (1, 4), (0, 4)]
```

```
sage: Partition([2,2,1]).outer_rim()
[(3, 0), (3, 1), (2, 1), (2, 2), (1, 2), (0, 2)]
```

```
sage: Partition([2,2]).outer_rim()
[(2, 0), (2, 1), (2, 2), (1, 2), (0, 2)]
```

```
sage: Partition([6,3,3,1,1]).outer_rim()
[(5, 0), (5, 1), (4, 1), (3, 1), (3, 2), (3, 3), (2, 3), (1, 3), (1, 4), (1, 5), (1, 6), (0, 6)]
```

```
sage: Partition([]).outer_rim()
[(0, 0)]
```

```
outline(variable=None)
```

Return the outline of the partition self.

This is a piecewise linear function, normalized so that the area under the partition [1] is 2.

INPUT:

- variable – a variable (default: 'x' in the symbolic ring)

EXAMPLES:
sage: [Partition([5,4]).outline()(x=i) for i in range(-10,11)]
[10, 9, 8, 7, 6, 5, 6, 5, 6, 5, 4, 3, 2, 3, 4, 5, 6, 7, 8, 9, 10]
sage: Partition([]).outline()
abs(x)
sage: Partition([1]).outline()
abs(x + 1) + abs(x - 1) - abs(x)
sage: y=sage.symbolic.ring.var("y")
sage: Partition([6,5,1]).outline(variable=y)
abs(y + 6) - abs(y + 5) + abs(y + 4) - abs(y + 3) + abs(y - 1) - abs(y - 2) + \n→abs(y - 3)

outside_corners()  
Return a list of the outside corners of the partition self.  
An outside corner (also called a cocorner) of a partition \( \lambda \) is a cell on \( \mathbb{Z}^2 \) which does not belong to the Young diagram of \( \lambda \) but can be added to this Young diagram to still form a straight-shape Young diagram.  
The entries of the list returned are pairs of the form \((i,j)\), where \(i\) and \(j\) are the coordinates of the respective corner. The coordinates are counted from 0.  
EXAMPLES:

sage: Partition([2,2,1]).outside_corners()
[(0, 2), (2, 1), (3, 0)]
sage: Partition([2,2]).outside_corners()
[(0, 2), (2, 0)]
sage: Partition([6,3,3,1,1,1]).outside_corners()
[(0, 6), (1, 3), (3, 1), (6, 0)]
sage: Partition([]).outside_corners()
[(0, 0)]

outside_corners_residue(i, l)  
Return a list of the outside corners of the partition self having l-residue \(i\).  
An outside corner (also called a cocorner) of a partition \( \lambda \) is a cell on \( \mathbb{Z}^2 \) which does not belong to the Young diagram of \( \lambda \) but can be added to this Young diagram to still form a straight-shape Young diagram.  
See residue() for the definition of the l-residue.  
The entries of the list returned are pairs of the form \((i,j)\), where \(i\) and \(j\) are the coordinates of the respective corner. The coordinates are counted from 0.  
EXAMPLES:

sage: Partition([3,2,1]).outside_corners_residue(0, 3)
[(0, 3), (3, 0)]
sage: Partition([3,2,1]).outside_corners_residue(1, 3)
[(1, 2)]
sage: Partition([3,2,1]).outside_corners_residue(2, 3)
[(2, 1)]

plancherel_measure()  
Return the probability of self under the Plancherel probability measure on partitions of the same size.  
This probability distribution comes from the uniform distribution on permutations via the Robinson-Schensted correspondence.
See Wikipedia article Plancherel_measure and \texttt{Partitions.n.random_element_plancherel()}.  

**EXAMPLES:**

```python
sage: Partition([]).plancherel_measure()
1
sage: Partition([1]).plancherel_measure()
1
sage: Partition([2]).plancherel_measure()
1/2
sage: [mu.plancherel_measure() for mu in Partitions(3)]
[1/6, 2/3, 1/6]
sage: Partition([5,4]).plancherel_measure()
7/1440
```

**power** ($k$)

Return the cycle type of the $k$-th power of any permutation with cycle type \texttt{self} (thus describes the powermap of symmetric groups).

Equivalent to GAP’s \texttt{PowerPartition}.

**EXAMPLES:**

```python
sage: p = Partition([5,3])
sage: p.power(1)
[5, 3]
sage: p.power(2)
[5, 3]
sage: p.power(3)
[5, 1, 1, 1]
sage: p.power(4)
[5, 3]
```

Now let us compare this to the power map on $S_8$:

```python
sage: G = SymmetricGroup(8)
sage: g = G([(1,2,3,4,5),(6,7,8)])
sage: g
(1,2,3,4,5)(6,7,8)
sage: g^2
(1,3,5,2,4)(6,8,7)
sage: g^3
(1,4,2,5,3)
sage: g^4
(1,5,4,3,2)(6,7,8)
```

```python
sage: Partition([3,2,1]).power(3)
[2, 1, 1, 1, 1]
```

**PP()**

Print the Ferrers diagram.

See \texttt{ferrers_diagram()} for more on the Ferrers diagram.

**EXAMPLES:**

```python
sage: Partition([5,5,2,1]).pp()  
*****
```
prime_degree \( (p) \)
Return the prime degree for the prime integer \( `p` \) for \self.

**INPUT:**

\* \( p \) – a prime integer

**OUTPUT:**

A non-negative integer

The degree of a partition \( \lambda \) is the sum of the \( e\)-degree() of the standard tableaux of shape \( \lambda \), for \( e \) a power of the prime \( p \). The prime degree gives the exponent of \( p \) in the Gram determinant of the integral Specht module of the symmetric group.

**EXAMPLES:**

```python
sage: Partition([4, 3]).prime_degree(2)
36
sage: Partition([4, 3]).prime_degree(3)
15
sage: Partition([4, 3]).prime_degree(5)
13
sage: Partition([4, 3]).prime_degree(7)
0
```

Therefore, the Gram determinant of \( S(5, 3) \) when \( q = 1 \) is \( 2^{36} \cdot 3^{15} \cdot 5^{13} \). Compare with degree().

quotient \( (length) \)
Return the quotient of the partition – in the literature the quotient is commonly referred to as the \( k\)-quotient, \( p\)-quotient, \( r\)-quotient, \ldots .

The \( r\)-quotient of a partition \( \lambda \) is a list of \( r \) partitions (labelled from 0 to \( r - 1 \)), constructed in the following way. Label each cell in the Young diagram of \( \lambda \) with its content modulo \( r \). Let \( R_i \) be the set of rows ending in a cell labelled \( i \), and \( C_i \) be the set of columns ending in a cell labelled \( i \). Then the \( j \)-th component of the quotient of \( \lambda \) is the partition defined by intersecting \( R_j \) with \( C_{j+1} \). (See Theorem 2.7.37 in [JK1981].)

**EXAMPLES:**

```python
sage: Partition([7, 7, 5, 3, 3, 3, 1]).quotient(3)
([2], [1], [2, 2, 2])
```

reading_tableau()
Return the RSK recording tableau of the reading word of the (standard) tableau \( T \) labeled down (in English convention) each column to the shape of \self.

For an example of the tableau \( T \), consider the partition \( \lambda = (3, 2, 1) \), then we have:
For more, see \texttt{RSK()}.  

\textbf{EXAMPLES:}

```python
sage: Partition([3,2,1]).reading_tableau()
[[1, 3, 6], [2, 5], [4]]
```

\texttt{removable\_cells()}

Return a list of the corners of the partition \texttt{self}.

A corner of a partition $\lambda$ is a cell of the Young diagram of $\lambda$ which can be removed from the Young diagram while still leaving a straight shape behind.

The entries of the list returned are pairs of the form $(i, j)$, where $i$ and $j$ are the coordinates of the respective corner. The coordinates are counted from 0.

\textbf{EXAMPLES:}

```python
sage: Partition([3,2,1]).corners()
[(0, 2), (1, 1), (2, 0)]
```

\texttt{removable\_cells\_residue}(i, l)

Return a list of the corners of the partition \texttt{self} having $l$-residue $i$.

A corner of a partition $\lambda$ is a cell of the Young diagram of $\lambda$ which can be removed from the Young diagram while still leaving a straight shape behind. See \texttt{residue()} for the definition of the $l$-residue.

The entries of the list returned are pairs of the form $(i, j)$, where $i$ and $j$ are the coordinates of the respective corner. The coordinates are counted from 0.

\textbf{EXAMPLES:}

```python
sage: Partition([3,2,1]).corners_residue(0, 3)  
[(1, 1)]
```

\texttt{remove\_cell}(i, j=None)

Return the partition obtained by removing a cell at the end of row $i$ of \texttt{self}.

\textbf{EXAMPLES:}

```python
sage: Partition([2,2]).remove_cell(1)
[2, 1]  
sage: Partition([2,2,1]).remove_cell(2)
[2, 2]  
sage: #Partition([2,2]).remove_cell(0)
```
sage: Partition([2,2]).remove_cell(1,1)
[2, 1]
sage: #Partition([2,2]).remove_cell(1,0)

**remove_horizontal_border_strip(k)**

Return the partitions obtained from self by removing an horizontal border strip of length k.

**EXAMPLES:**

sage: Partition([5, 3, 1]).remove_horizontal_border_strip(0).list()
[[[5, 3, 1]]]
sage: Partition([5, 3, 1]).remove_horizontal_border_strip(1).list()
[[[5, 2], [5, 1, 1], [4, 3]], [[4, 2, 1], [3, 3, 1]]]
sage: Partition([5, 3, 1]).remove_horizontal_border_strip(2).list()
[[[5, 2], [5, 1, 1], [4, 3]], [[4, 2, 1], [3, 3, 1]]]
sage: Partition([5, 3, 1]).remove_horizontal_border_strip(3).list()
[[[5, 2], [5, 1, 1], [4, 3]], [[4, 2, 1], [3, 3, 1]]]
sage: Partition([5, 3, 1]).remove_horizontal_border_strip(4).list()
[[[4, 1], [3, 2], [3, 1, 1]]]
sage: Partition([5, 3, 1]).remove_horizontal_border_strip(5).list()
[[[3, 1]]]
sage: Partition([5, 3, 1]).remove_horizontal_border_strip(6).list()
[]

The result is returned as an instance of **Partitions_with_constraints:**

```
sage: Partition([5,3,1]).remove_horizontal_border_strip(5)
The subpartitions of [5, 3, 1] obtained by removing an horizontal border strip of length 5
```

**residue(r, c, ℓ)**

Return the ℓ-residue of the cell at row r and column c.

The ℓ-residue of a cell is \( c - r \mod ℓ \).

This does not strictly depend upon the partition, however, this method is included because it is often useful in the context of partitions.

**EXAMPLES:**

```
sage: Partition([2,1]).residue(1, 0, 3)
2
```

**rim()**

Return the rim of self.

The rim of a partition \( \lambda \) is defined as the cells which belong to \( \lambda \) and which are adjacent to cells not in \( \lambda \).

**EXAMPLES:**

The rim of the partition [5, 5, 2, 1] consists of the cells marked with # below:

```
****#
*###*
##

sage: Partition([5,5,2,1]).rim()
[(3, 0), (2, 0), (2, 1), (1, 1), (1, 2), (1, 3), (1, 4), (0, 4)]
```
row_standard_tableaux()  
Return the row standard tableaux of shape self.

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sage: Partition([3,2,2,1]).row_standard_tableaux()</td>
<td>Row standard tableaux of shape [3, 2, 2, 1]</td>
</tr>
</tbody>
</table>

sign()  
Return the sign of any permutation with cycle type self.

This function corresponds to a homomorphism from the symmetric group $S_n$ into the cyclic group of order 2, whose kernel is exactly the alternating group $A_n$. Partitions of sign 1 are called even partitions while partitions of sign −1 are called odd.

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sage: Partition([5,3]).sign()</td>
<td>1</td>
</tr>
<tr>
<td>sage: Partition([5,2]).sign()</td>
<td>-1</td>
</tr>
</tbody>
</table>

Zolotarev’s lemma states that the Legendre symbol $\left(\frac{a}{p}\right)$ for an integer $a$ (mod $p$) ($p$ a prime number), can be computed as sign(p_a), where sign denotes the sign of a permutation and p_a the permutation of the residue classes (mod $p$) induced by modular multiplication by $a$, provided $p$ does not divide $a$.

We verify this in some examples.

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sage: F = GF(11)</td>
<td></td>
</tr>
<tr>
<td>sage: a = F.multiplicative_generator();a</td>
<td>2</td>
</tr>
<tr>
<td>sage: plist = [int(a*F(x)) for x in range(1,11)]; plist</td>
<td>[2, 4, 6, 8, 10, 1, 3, 5, 7, 9]</td>
</tr>
</tbody>
</table>

This corresponds to the permutation $(1, 2, 4, 8, 5, 10, 9, 7, 3, 6)$ (acting the set {1, 2, ..., 10}) and to the partition [10].

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sage: p = PermutationGroupElement('[(1, 2, 4, 8, 5, 10, 9, 7, 3, 6)]')</td>
<td></td>
</tr>
<tr>
<td>sage: p.sign()</td>
<td>-1</td>
</tr>
<tr>
<td>sage: Partition([10]).sign()</td>
<td>-1</td>
</tr>
<tr>
<td>sage: kronecker_symbol(11,2)</td>
<td>-1</td>
</tr>
</tbody>
</table>

Now replace 2 by 3:
In both cases, Zolotarev holds.

REFERENCES:

- Wikipedia article Zolotarev’s lemma

\section*{size()}

Return the size of self.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Partition([2,2]).size() 4
sage: Partition([3,2,1]).size() 6
\end{verbatim}

\section*{standard_tableaux()}

Return the \textit{standard tableaux} of shape self.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Partition([3,2,2,1]).standard_tableaux()
Standard tableaux of shape [3, 2, 2, 1]
\end{verbatim}

\section*{suter_diagonal_slide(n, exp=1)}

Return the image of self in $Y_n$ under Suter’s diagonal slide $\sigma_n$, where the notations used are those defined in [Sut2002].

The set $Y_n$ is defined as the set of all partitions $\lambda$ such that the hook length of the $(0,0)$-cell (i.e. the northwestern most cell in English notation) of $\lambda$ is less than $n$, including the empty partition.

The map $\sigma_n$ sends a partition (with non-zero entries) $(\lambda_1, \lambda_2, \ldots, \lambda_m) \in Y_n$ to the partition $(\lambda_2 + 1, \lambda_3 + 1, \ldots, \lambda_m + 1, 1, 1, \ldots, 1)$. In other words, it pads the partition with trailing zeroes until it has length $n - \lambda_1$, then removes its first part, and finally adds 1 to each part.

By Theorem 2.1 of [Sut2002], the dihedral group $D_n$ with $2n$ elements acts on $Y_n$ by letting the primitive rotation act as $\sigma_n$ and the reflection act as conjugation of partitions (\texttt{conjugate()}). This action is faithful if $n \geq 3$.

\textbf{INPUT:}

- \texttt{n} – nonnegative integer
- \texttt{exp} – (default: 1) how many times $\sigma_n$ should be applied

\textbf{OUTPUT:}
The result of applying Suter’s diagonal slide $\sigma_n$ to self, assuming that self lies in $Y_n$. If the optional argument exp is set, then the slide $\sigma_n$ is applied not just once, but exp times (note that exp is allowed to be negative, since the slide has finite order).

**EXAMPLES:**

```
sage: Partition([5,4,1]).suter_diagonal_slide(8)
[5, 2]
sage: Partition([5,4,1]).suter_diagonal_slide(9)
[5, 2, 1]
sage: Partition([]).suter_diagonal_slide(7)
[1, 1, 1, 1, 1, 1]
sage: Partition([]).suter_diagonal_slide(1)
[]
sage: Partition([]).suter_diagonal_slide(7, exp=-1)
[6]
sage: Partition([]).suter_diagonal_slide(1, exp=-1)
[]
sage: P7 = Partitions(7)
sage: all( p == p.suter_diagonal_slide(9, exp=-1).suter_diagonal_slide(9)
....:     for p in P7 )
True
sage: all( p == p.suter_diagonal_slide(9, exp=3)
....:    .suter_diagonal_slide(9, exp=3)
....:    .suter_diagonal_slide(9, exp=3)
....:    for p in P7 )
True
sage: all( p == p.suter_diagonal_slide(9, exp=6)
....:    .suter_diagonal_slide(9, exp=6)
....:    .suter_diagonal_slide(9, exp=6)
....:    for p in P7 )
True
sage: all( p == p.suter_diagonal_slide(9, exp=-1)
....:    .suter_diagonal_slide(9, exp=1)
....:    for p in P7 )
True
```

Check of the assertion in [Sut2002] that $\sigma_n(\sigma_n(\lambda')) = \lambda$:

```
sage: all( p.suter_diagonal_slide(8).conjugate()
....:     == p.conjugate().suter_diagonal_slide(8, exp=-1)
....:     for p in P7 )
True
```

Check of Claim 1 in [Sut2002]:

```
sage: P5 = Partitions(5)
sage: all( all( p.suter_diagonal_slide(6) in q.suter_diagonal_slide(6).
....:                        down() )
....:     or (q.suter_diagonal_slide(6) in p.suter_diagonal_slide(6).
....:                        down() )
....:     for p in q.down() )
....:     for q in P5 )
True
```

```
t_completion(t)
Return the t-completion of the partition self.
```

If $\lambda = (\lambda_1, \lambda_2, \lambda_3, \ldots)$ is a partition and $t$ is an integer greater or equal to $|\lambda| + \lambda_1$, then the $t$-completion of
\( \lambda \) is defined as the partition \((t - |\lambda|, \lambda_1, \lambda_2, \lambda_3, \ldots)\) of \(t\). This partition is denoted by \(\lambda|t\) in [BOR2009], by \(\lambda|t\) in [BdVO2012], and by \(\lambda(t)\) in [CO2010].

EXAMPLES:

```python
sage: Partition([]).t_completion(0)
[]
sage: Partition([]).t_completion(1)
[1]
sage: Partition([]).t_completion(2)
[2]
sage: Partition([]).t_completion(3)
[3]
sage: Partition([2, 1]).t_completion(5)
[2, 2, 1]
sage: Partition([2, 1]).t_completion(6)
[3, 2, 1]
sage: Partition([4, 2, 2, 1]).t_completion(13)
[4, 4, 2, 2, 1]
sage: Partition([4, 2, 2, 1]).t_completion(19)
[10, 4, 2, 2, 1]
sage: Partition([4, 2, 2, 1]).t_completion(10)
Traceback (most recent call last):
  ... ValueError: 10-completion is not defined
sage: Partition([4, 2, 2, 1]).t_completion(5)
Traceback (most recent call last):
  ... ValueError: 5-completion is not defined
```

to_core\( (k) \)

Maps the \(k\)-bounded partition \(s\)elf to its corresponding \(k + 1\)-core.

See also \(k\text{-skew}()\).

EXAMPLES:

```python
sage: p = Partition([4, 3, 2, 2, 1, 1])
sage: c = p.to_core(4); c
[9, 5, 3, 2, 1, 1]
sage: type(c)
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: c.to_bounded_partition() == p
True
```

to_dyck_word\( (n=None) \)

Return the \(n\)-Dyck word whose corresponding partition is \(s\)elf (or, if \(n\) is not specified, the \(n\)-Dyck word with smallest \(n\) to satisfy this property).

If \(w\) is an \(n\)-Dyck word (that is, a Dyck word with \(n\) open symbols and \(n\) close symbols), then the Dyck path corresponding to \(w\) can be regarded as a lattice path in the northeastern half of an \(n \times n\)-square. The region to the northeast of this Dyck path can be regarded as a partition. It is called the partition corresponding to the Dyck word \(w\). (See to_partition().)

For every partition \(\lambda\) and every nonnegative integer \(n\), there exists at most one \(n\)-Dyck word \(w\) such that the partition corresponding to \(w\) is \(\lambda\) (in fact, such \(w\) exists if and only if \(\lambda_i + i \leq n\) for every \(i\), where \(\lambda\) is written in the form \((\lambda_1, \lambda_2, \ldots, \lambda_k)\) with \(\lambda_k > 0\)). This method computes this \(w\) for a given \(\lambda\) and \(n\). If \(n\) is not specified, this method computes the \(w\) for the smallest possible \(n\) for which such an \(w\) exists. (The minimality of \(n\) means that the partition demarcated by the Dyck path touches the diagonal.)
EXAMPLES:

```
sage: Partition([2,2]).to_dyck_word()
[1, 1, 0, 0, 1, 1, 0, 0]
sage: Partition([2,2]).to_dyck_word(4)
[1, 1, 0, 0, 1, 1, 0, 0]
sage: Partition([2,2]).to_dyck_word(5)
[1, 1, 1, 0, 0, 1, 1, 0, 0, 0]
sage: Partition([6,3,1]).to_dyck_word()
[1, 1, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 1, 0]
sage: Partition([]).to_dyck_word()
[]
sage: Partition([]).to_dyck_word(3)
[1, 1, 1, 0, 0, 0]
```

The partition corresponding to `self.dyck_word()` is `self` indeed:

```
sage: all( p.to_dyck_word().to_partition() == p
      ....:     for p in Partitions(5) )
True
```

to_exp (`k=0`)
Return a list of the multiplicities of the parts of a partition. Use the optional parameter `k` to get a return list of length at least `k`.

EXAMPLES:

```
sage: Partition([3,2,2,1]).to_exp()
[1, 2, 1]
sage: Partition([3,2,2,1]).to_exp(5)
[1, 2, 1, 0, 0]
```

to_exp_dict()
Return a dictionary containing the multiplicities of the parts of `self`.

EXAMPLES:

```
sage: p = Partition([4,2,2,1])
sage: d = p.to_exp_dict()
sage: d[4]
1
sage: d[2]
2
sage: d[1]
1
sage: 5 in d
False
```

to_list()
Return `self` as a list.

EXAMPLES:

```
sage: p = Partition([2,1]).to_list(); p
[2, 1]
sage: type(p)
<... 'list'>
```

top_garnir_tableau`(`e, cell`)
Return the most dominant standard tableau which dominates the corresponding Garnir tableau and has the same e-residue.

The Garnir tableau play an important role in integral and non-semisimple representation theory because they determine the “straightening” rules for the Specht modules. The top Garnir tableaux arise in the graded representation theory of the symmetric groups and higher level Hecke algebras. They were introduced in [KMR2012].

If the Garnir node is cell=(r, c) and m and M are the entries in the cells (r, c) and (r+1, c), respectively, in the initial tableau then the top e-Garnir tableau is obtained by inserting the numbers m, m+1, ..., M in order from left to right first in the cells in row r+1 which are not in the e-Garnir belt, then in the cell in rows r and r+1 which are in the Garnir belt and then, finally, in the remaining cells in row r which are not in the Garnir belt. All other entries in the tableau remain unchanged.

If e = 0, or if there are no e-bricks in either row r or r+1, then the top Garnir tableau is the corresponding Garnir tableau.

EXAMPLES:

```python
sage: Partition([5,4,3,2]).top_garnir_tableau(2,(0,2)).pp()
  1 2 4 5 8
  3 6 7 9
 10 11 12
 13 14
sage: Partition([5,4,3,2]).top_garnir_tableau(3,(0,2)).pp()
  1 2 3 4 5
  6 7 8 9
 10 11 12
 13 14
sage: Partition([5,4,3,2]).top_garnir_tableau(4,(0,2)).pp()
  1 2 6 7 8
  3 4 5 9
 10 11 12
 13 14
sage: Partition([5,4,3,2]).top_garnir_tableau(0,(0,2)).pp()
  1 2 6 7 8
  3 4 5 9
 10 11 12
 13 14
```

REFERENCES:

- [KMR2012]

up()  
Return a generator for partitions that can be obtained from self by adding a cell.

EXAMPLES:

```python
sage: list(Partition([2,1,1]).up())
[[3, 1, 1], [2, 2, 1], [2, 1, 1, 1]]

sage: list(Partition([3,2]).up())
[[4, 2], [3, 3], [3, 2, 1]]

sage: [p for p in Partition([]).up()]  # [[1]]
```

up_list()  
Return a list of the partitions that can be formed from self by adding a cell.

EXAMPLES:
sage: Partition([2,1,1]).up_list()
[[3, 1, 1], [2, 2, 1], [2, 1, 1, 1]]
sage: Partition([3,2]).up_list()
[[4, 2], [3, 3], [3, 2, 1]]
sage: Partition([]).up_list()
[[1]]

upper_hook \((i, j, \alpha)\)
Return the upper hook length of the cell \((i, j)\) in \(self\). When \(\alpha = 1\), this is just the normal hook length.

The upper hook length of a cell \((i, j)\) in a partition \(\kappa\) is defined by

\[ h^*_\kappa(i,j) = \kappa'_j - i + \alpha(\kappa_i - j + 1). \]

EXAMPLES:

```
sage: p = Partition([2,1])
sage: p.upper_hook(0,0,1)
3
sage: p.hook_length(0,0)
3
sage: [ p.upper_hook(i,j,x) for i,j in p.cells() ]
[2*x + 1, x, x]
```

upper_hook_lengths \((\alpha)\)
Return a tableau of shape \(self\) with the cells filled in with the upper hook lengths. When \(\alpha = 1\), these are just the normal hook lengths.

The upper hook length of a cell \((i, j)\) in a partition \(\kappa\) is defined by

\[ h^*_\kappa(i,j) = \kappa'_j - i + \alpha(\kappa_i - j + 1). \]

EXAMPLES:

```
sage: Partition([3,2,1]).upper_hook_lengths(x)
[[3*x + 2, 2*x + 1, x], [2*x + 1, x], [x]]
sage: Partition([3,2,1]).upper_hook_lengths(1)
[[5, 3, 1], [3, 1], [1]]
sage: Partition([3,2,1]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
```

weighted_size()
Return the weighted size of \(self\).

The weighted size of a partition \(\lambda\) is

\[ \sum_i i \cdot \lambda_i, \]

where \(\lambda = (\lambda_0, \lambda_1, \lambda_2, \cdots )\).

This also the sum of the leg length of every cell in \(\lambda\), or

\[ \sum_i \left( \frac{\lambda'_i}{2} \right) \]

where \(\lambda'\) is the conjugate partition of \(\lambda\).

EXAMPLES:
The Young subgroup of a partition \( \lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell) \) of \( n \) is the group:

\[
S_{\lambda_1} \times S_{\lambda_2} \times \cdots \times S_{\lambda_\ell}
\]

embedded into \( S_n \) in the standard way (i.e., the \( S_{\lambda_i} \) factor acts on the numbers from \( \lambda_1 + \lambda_2 + \cdots + \lambda_{i-1} + 1 \) to \( \lambda_1 + \lambda_2 + \cdots + \lambda_i \)).

EXAMPLES:

```
sage: Partition([4,2]).young_subgroup()
Permutation Group with generators [(1,2), (2,3), (3,4), (5,6)]
```

```
sage: Partition([1,1,1]).young_subgroup_generators()
[]
sage: Partition([2,2]).young_subgroup_generators()
[1, 3]
```

See also:

`young_subgroup()`

`zero_one_sequence()`

Compute the finite 0 − 1 sequence of the partition.

The full 0 − 1 sequence is the sequence (infinite in both directions) indicating the steps taken when following the outer rim of the diagram of the partition. We use the convention that in English convention, a 1 corresponds to an East step, and a 0 corresponds to a North step.

Note that every full 0 − 1 sequence starts with infinitely many 0’s and ends with infinitely many 1’s.

One place where these arise is in the affine symmetric group where one takes an affine permutation \( w \) and every \( i \) such that \( w(i) \leq 0 \) corresponds to a 1 and \( w(i) > 0 \) corresponds to a 0. See pages 24-25 of [LLMSSZ2013] for connections to affine Grassmannian elements (note there they use the French convention for their partitions).

These are also known as path sequences, Maya diagrams, plus-minus diagrams, Comet code [Sta-EC2], among others.

OUTPUT:
The finite \( 0 - 1 \) sequence is obtained from the full \( 0 - 1 \) sequence by omitting all heading \( 0 \)'s and trailing \( 1 \)'s. The output sequence is finite, starts with a \( 1 \) and ends with a \( 0 \) (unless it is empty, for the empty partition). Its length is the sum of the first part of the partition with the length of the partition.

**EXAMPLES:**

```python
sage: Partition([5,4]).zero_one_sequence()
[1, 1, 1, 1, 0, 1, 0]
sage: Partition([1]).zero_one_sequence()
[]
sage: Partition([2]).zero_one_sequence()
[1, 1, 0]
```

**class** `sage.combinat.partition.Partitions` *(is_infinite=False)*

**Bases:** `sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent`

`Partitions(n, **kwargs)` returns the combinatorial class of integer partitions of \( n \) subject to the constraints given by the keywords.

Valid keywords are: starting, ending, min_part, max_part, max_length, min_length, length, max_slope, min_slope, inner, outer, parts_in, regular, and restricted. They have the following meanings:

- **starting=p** specifies that the partitions should all be less than or equal to \( p \) in lex order. This argument cannot be combined with any other (see trac ticket #15467).
- **ending=p** specifies that the partitions should all be greater than or equal to \( p \) in lex order. This argument cannot be combined with any other (see trac ticket #15467).
- **length=k** specifies that the partitions have exactly \( k \) parts.
- **min_length=k** specifies that the partitions have at least \( k \) parts.
- **min_part=k** specifies that all parts of the partitions are at least \( k \).
- **inner=p** specifies that the partitions must contain the partition \( p \).
- **outer=p** specifies that the partitions be contained inside the partition \( p \).
- **min_slope=k** specifies that the partitions have slope at least \( k \); the slope at position \( i \) is the difference between the \((i + 1)\)-th part and the \( i \)-th part.
- **parts_in=S** specifies that the partitions have parts in the set \( S \), which can be any sequence of pairwise distinct positive integers. This argument cannot be combined with any other (see trac ticket #15467).
- **regular=ell** specifies that the partitions are \( \ell \)-regular, and can only be combined with the max_length or max_part, but not both, keywords if \( n \) is not specified
- **restricted=ell** specifies that the partitions are \( \ell \)-restricted, and cannot be combined with any other keywords

The max_* versions, along with inner and ending, work analogously.

Right now, the parts_in, starting, ending, regular, and restricted keyword arguments are mutually exclusive, both of each other and of other keyword arguments. If you specify, say, parts_in, all other keyword arguments will be ignored; starting, ending, regular, and restricted work the same way.

**EXAMPLES:**

If no arguments are passed, then the combinatorial class of all integer partitions is returned:
If an integer $n$ is passed, then the combinatorial class of integer partitions of $n$ is returned:

```
sage: Partitions(3)
Partitions of the integer 3
sage: Partitions(3).list()
[[3], [2, 1], [1, 1, 1]]
```

If `starting=p` is passed, then the combinatorial class of partitions greater than or equal to $p$ in lexicographic order is returned:

```
sage: Partitions(3, starting=[2,1])
Partitions of the integer 3 starting with [2, 1]
sage: Partitions(3, starting=[2,1]).list()
[[2, 1], [1, 1, 1]]
```

If `ending=p` is passed, then the combinatorial class of partitions at most $p$ in lexicographic order is returned:

```
sage: Partitions(3, ending=[2,1])
Partitions of the integer 3 ending with [2, 1]
sage: Partitions(3, ending=[2,1]).list()
[[3], [2, 1]]
```

Using `max_slope=-1` yields partitions into distinct parts – each part differs from the next by at least 1. Use a different `max_slope` to get parts that differ by, say, 2:

```
sage: Partitions(7, max_slope=-1).list()
[[7], [6, 1], [5, 2], [4, 3], [4, 2, 1]]
sage: Partitions(15, max_slope=-1).cardinality()
27
```

The number of partitions of $n$ into odd parts equals the number of partitions into distinct parts. Let’s test that for $n$ from 10 to 20:

```
sage: test = lambda n: Partitions(n, max_slope=-1).cardinality() == Partitions(n,
˓→parts_in=[1,3..n]).cardinality()
sage: all(test(n) for n in [10..20])
True
```

The number of partitions of $n$ into distinct parts that differ by at least 2 equals the number of partitions into parts that equal 1 or 4 modulo 5; this is one of the Rogers-Ramanujan identities:

```
sage: test = lambda n: Partitions(n, max_slope=-2).cardinality() == Partitions(n,
˓→parts_in=[1,6..n] + [4,9..n]).cardinality()
sage: all(test(n) for n in [10..20])
True
```

Here are some more examples illustrating `min_part`, `max_part`, and `length`:

```
sage: Partitions(5,min_part=2)
Partitions of the integer 5 satisfying constraints min_part=2
sage: Partitions(5,min_part=2).list()
[[5], [3, 2]]
```
Some examples using the **regular** keyword:

```sage
sage: Partitions(regular=4)
4-Regular Partitions
sage: Partitions(regular=4, max_length=3)
4-Regular Partitions with max length 3
sage: Partitions(regular=4, max_part=3)
4-Regular 3-Bounded Partitions
```

Some examples using the **restricted** keyword:

```sage
sage: Partitions(restricted=4)
4-Restricted Partitions
sage: Partitions(3, restricted=4)
4-Restricted Partitions of the integer 3
```

Here are some further examples using various constraints:

```sage
sage: [x for x in Partitions(4)]
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(4, length=2)]
[[3, 1], [2, 2]]
sage: [x for x in Partitions(4, min_length=2)]
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(4, max_part=2)]
[[4], [3, 1], [2, 2]]
sage: [x for x in Partitions(4, outer=[3,1,1])]
[[3, 1], [2, 1, 1]]
sage: [x for x in Partitions(4, max_slope=-1)]
[[4], [3, 1], [2, 1, 1]]
sage: [x for x in Partitions(4, min_slope=-1)]
[[4], [3, 1], [2, 1, 1]]
sage: [x for x in Partitions(11, max_slope=-1, min_slope=-3, min_length=2, max_length=4, outer=[6,5,2])]
[[6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2], [5, 3, 2, 1]]
sage: [x for x in Partitions(11, max_slope=-1, min_slope=-3, min_length=2, max_length=4)]
[[7, 4], [6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2], [5, 3, 2, 1]]
sage: [x for x in Partitions(11, max_slope=-1, min_slope=-3, min_length=2, max_length=4, outer=[6,5,2])]
[[6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2]]
```

Note that if you specify `min_part=0`, then it will treat the minimum part as being 1 (see trac ticket #13605):
Except for very special cases, counting is done by brute force iteration through all the partitions. However the iteration itself has a reasonable complexity (see IntegerListsLex), which allows for manipulating large partitions:

```
sage: Partitions(1000, max_length=1).list()
[[1000]]
```

In particular, getting the first element is also constant time:

```
sage: Partitions(30, max_part=29).first()
[29, 1]
```

**Element**

alias of `Partition`

**options(**`*get_value`, `**set_value`**)

Sets and displays the global options for elements of the partition, skew partition, and partition tuple classes. If no parameters are set, then the function returns a copy of the options dictionary.

The options to partitions can be accessed as the method `Partitions.options` of `Partitions` and related parent classes.

**OPTIONS:**

- `convention` – (default: `English`) Sets the convention used for displaying tableaux and partitions
  - `English` – use the English convention
  - `French` – use the French convention
- `diagram_str` – (default: `*`) The character used for the cells when printing Ferrers diagrams
- `display` – (default: `list`) Specifies how partitions should be printed
  - `array` – alias for `diagram`
  - `compact` – alias for `compact_low`
  - `compact_high` – compact form of `exp_high`
  - `compact_low` – compact form of `exp_low`
  - `diagram` – as a Ferrers diagram
  - `exp` – alias for `exp_low`
  - `exp_high` – in exponential form (highest first)
  - `exp_low` – in exponential form (lowest first)
  - `ferrers_diagram` – alias for `diagram`
  - `list` – displayed as a list
  - `young_diagram` – alias for `diagram`
- `latex` – (default: `young_diagram`) Specifies how partitions should be latexed
  - `array` – alias for `diagram`
- diagram – latex as a Ferrers diagram
- exp – alias for exp_low
- exp_high – latex as a list in exponential notation (highest first)
- exp_low – as a list latex in exponential notation (lowest first)
- ferrers_diagram – alias for diagram
- list – latex as a list
- young_diagram – latex as a Young diagram

- latex_diagram_str – (default: \ast) The character used for the cells when latexing Ferrers diagrams
- notation – alternative name for convention

EXAMPLES:

```python
sage: P = Partition([4,2,2,1])
sage: P
[4, 2, 2, 1]
sage: Partitions.options.display="exp"
sage: P
1, 2^2, 4
sage: Partitions.options.display="exp_high"
sage: P
4, 2^2, 1
```

It is also possible to use user defined functions for the display and latex options:

```python
sage: Partitions.options(display=lambda mu: '<%s> % ',
                           .join('%s'*m for m in mu._list)); P
<4,2,2,1>
sage: Partitions.options(latex=lambda mu: '\Diagram{\%s} % ',
                                 .join('%s'*m
                                 ___for m in mu._list)); latex(P)
\Diagram{4,2,2,1}
sage: Partitions.options(display="diagram", diagram_str="#")
sage: P
###
##
##
#
sage: Partitions.options(diagram_str="*", convention="french")
sage: print(P.ferrers_diagram())
*
**
***
****
```

Changing the convention for partitions also changes the convention option for tableaux and vice versa:

```python
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
  4 5
  1 2 3
sage: Tableaux.options.convention="english"
sage: print(P.ferrers_diagram())
```

(continues on next page)
sage: T.pp()
1 2 3
4 5
sage: Partitions.options._reset()

See :meth:`GlobalOptions` for more features of these options.

.. function:: subset(*args, **kwargs)

   Return :meth:`self` if no arguments are given, otherwise raises a :exc:`ValueError`.

   EXAMPLES:

   sage: P = Partitions(5, starting=[3,1]); P
   Partitions of the integer 5 starting with [3, 1]
   sage: P.subset()
   Partitions of the integer 5 starting with [3, 1]
   sage: P.subset(ending=[3,1])
   Traceback (most recent call last):
   ...
   ValueError: Invalid combination of arguments

.. class:: sage.combinat.partition.PartitionsGreatestEQ(n, k)

   The class of all (unordered) "restricted" partitions of the integer \(n\) having all its greatest parts equal to the integer \(k\).

   EXAMPLES:

   sage: PartitionsGreatestEQ(10, 2)
   Partitions of 10 having greatest part equal to 2
   sage: PartitionsGreatestEQ(10, 2).list()
   [[2, 2, 2, 2, 2],
    [2, 2, 2, 2, 1, 1],
    [2, 2, 2, 1, 1, 1, 1],
    [2, 2, 1, 1, 1, 1, 1, 1],
    [2, 1, 1, 1, 1, 1, 1, 1, 1]]

   sage: [4,3,2,1] in PartitionsGreatestEQ(10, 2)
   False
   sage: [2,2,2,2,2] in PartitionsGreatestEQ(10, 2)
   True

   The empty partition has no maximal part, but it is contained in the set of partitions with any specified maximal part:

   sage: PartitionsGreatestEQ(0, 2).list()
   [[[]]]

.. attribute:: Element

   alias of :class:`Partition`

.. attribute:: cardinality()

   Return the cardinality of :meth:`self`.
EXAM PLES:

```python
sage: PartitionsGreatestEQ(10, 2).cardinality()
5
```

`options(*get_value, **set_value)`

Sets and displays the global options for elements of the partition, skew partition, and partition tuple classes. If no parameters are set, then the function returns a copy of the options dictionary.

The options to partitions can be accessed as the method `Partitions.options` of `Partitions` and related parent classes.

OPTIONS:

- `convention` – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention
- `diagram_str` – (default: *) The character used for the cells when printing Ferrers diagrams
- `display` – (default: list) Specifies how partitions should be printed
  - array – alias for diagram
  - compact – alias for compact_low
  - compact_high – compact form of exp_high
  - compact_low – compact form of exp_low
  - diagram – as a Ferrers diagram
  - exp – alias for exp_low
  - exp_high – in exponential form (highest first)
  - exp_low – in exponential form (lowest first)
  - ferrers_diagram – alias for diagram
  - list – displayed as a list
  - young_diagram – alias for diagram
- `latex` – (default: young_diagram) Specifies how partitions should be latexed
  - array – alias for diagram
  - diagram – latex as a Ferrers diagram
  - exp – alias for exp_low
  - exp_high – latex as a list in exponential notation (highest first)
  - exp_low – as a list latex in exponential notation (lowest first)
  - ferrers_diagram – alias for diagram
  - list – latex as a list
  - young_diagram – latex as a Young diagram
- `latex_diagram_str` – (default: \ast) The character used for the cells when latexing Ferrers diagrams
- `notation` – alternative name for convention
EXAMPLES:

```
sage: P = Partition([4,2,2,1])
sage: P
[4, 2, 2, 1]
sage: Partitions.options.display="exp"
sage: P
1, 2^2, 4
sage: Partitions.options.display="exp_high"
sage: P
4, 2^2, 1
```

It is also possible to use user defined functions for the display and latex options:

```
sage: Partitions.options(display=lambda mu: '\<%s>' % ','.join('\$m$' for m in mu._list)); P
\<4,2,2,1>
sage: Partitions.options(latex=lambda mu: '\Diagram{\$s\}$' % ','.join('\$m\$ for m in mu._list)); latex(P)
\Diagram{4,2,2,1}
sage: Partitions.options(display="diagram", diagram_str="#")
sage: P
####
##
##
#
sage: Partitions.options(diagram_str="*", convention="french")
sage: print(P.ferrers_diagram())
*
**
***
****
```

Changing the convention for partitions also changes the convention option for tableaux and vice versa:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
4 5
1 2 3
sage: Tableaux.options.convention="english"
sage: print(T.ferrers_diagram())
****
**
**
*
sage: T.pp()
1 2 3
4 5
sage: Partitions.options._reset()
```

See GlobalOptions for more features of these options.

```python
class sage.combinat.partition.PartitionsGreatestLE(n, k)
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.combinat.integer_lists.invlex.IntegerListsLex

The class of all (unordered) “restricted” partitions of the integer \( n \) having parts less than or equal to the integer \( k \). ```
EXAMPLES:

```python
sage: PartitionsGreatestLE(10, 2)
Partitions of 10 having parts less than or equal to 2
sage: PartitionsGreatestLE(10, 2).list()
[[2, 2, 2, 2, 2],
 [2, 2, 2, 1, 1],
 [2, 2, 1, 1, 1, 1],
 [2, 1, 1, 1, 1, 1, 1],
 [1, 1, 1, 1, 1, 1, 1, 1]]

sage: [4,3,2,1] in PartitionsGreatestLE(10, 2)
False
sage: [2,2,2,2,2] in PartitionsGreatestLE(10, 2)
True
sage: PartitionsGreatestLE(10, 2).first().parent()
Partitions...
```

**Element**

alias of *Partition*

**cardinality()**

Return the cardinality of *self*.

EXAMPLES:

```python
sage: PartitionsGreatestLE(9, 5).cardinality()
23
```

**options(***get_value, **set_value*)**

Sets and displays the global options for elements of the partition, skew partition, and partition tuple classes. If no parameters are set, then the function returns a copy of the options dictionary.

The options to partitions can be accessed as the method *Partitions.options* of *Partitions* and related parent classes.

OPTIONS:

- **convention** – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention
- **diagram_str** – (default: *) The character used for the cells when printing Ferrers diagrams
- **display** – (default: list) Specifies how partitions should be printed
  - array – alias for diagram
  - compact – alias for compact_low
  - compact_high – compact form of exp_high
  - compact_low – compact form of exp_low
  - diagram – as a Ferrers diagram
  - exp – alias for exp_low
  - exp_high – in exponential form (highest first)
  - exp_low – in exponential form (lowest first)
\begin{itemize}
  \item \texttt{ferrers_diagram} – alias for \texttt{diagram}
  \item \texttt{list} – displayed as a list
  \item \texttt{young_diagram} – alias for \texttt{diagram}
  \item \texttt{latex} – (default: \texttt{young_diagram}) Specifies how partitions should be latexed
    \begin{itemize}
      \item \texttt{array} – alias for \texttt{diagram}
      \item \texttt{diagram} – latex as a Ferrers diagram
      \item \texttt{exp} – alias for \texttt{exp_low}
      \item \texttt{exp_high} – latex as a list in exponential notation (highest first)
      \item \texttt{exp_low} – as a list latex in exponential notation (lowest first)
      \item \texttt{ferrers_diagram} – alias for \texttt{diagram}
      \item \texttt{list} – latex as a list
      \item \texttt{young_diagram} – latex as a Young diagram
    \end{itemize}
  \item \texttt{latex_diagram_str} – (default: \texttt{	extbackslash{ast}}) The character used for the cells when latexing Ferrers diagrams
  \item \texttt{notation} – alternative name for \texttt{convention}
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: P = Partition([4,2,2,1])
sage: P
[4, 2, 2, 1]
sage: Partitions.options.display="exp"
sage: P
1, 2^2, 4
sage: Partitions.options.display="exp_high"
sage: P
4, 2^2, 1
\end{verbatim}

It is also possible to use user defined functions for the \texttt{display} and \texttt{latex} options:

\begin{verbatim}
sage: Partitions.options(display=lambda mu: "<\$s\'> \',\'.join('"$s"m for m in \mu._list)); P
<4,2,2,1>
sage: Partitions.options(latex=lambda mu: '\Diagram\$s\' \',\'.join('"$s"m \Diagram for m in mu._list)); latex(P)
\Diagram(4,2,2,1)
sage: Partitions.options(display="diagram", diagram_str="#")
sage: P
###
##
##
#
sage: Partitions.options(diagram_str="*", convention="french")
sage: print(P.ferrers_diagram())
*
**
**
****
\end{verbatim}

Changing the \texttt{convention} for partitions also changes the \texttt{convention} option for tableaux and vice versa:
```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
  4 5
  1 2 3
sage: Tableaux.options.convention="english"
sage: print(P.ferrers_diagram())
 ****
  **
  **
  *
sage: T.pp()
  1 2 3
  4 5
sage: Partitions.options._reset()
```

See :meth:`GlobalOptions` for more features of these options.

```python
class sage.combinat.partition.PartitionsInBox(h, w)
    Bases: sage.combinat.partition.Partitions

    All partitions which fit in an $h \times w$ box.

    EXAMPLES:

```
sage: PartitionsInBox(2,2)
    Integer partitions which fit in a 2 x 2 box
```

```
sage: PartitionsInBox(2,2).list()
    [[], [1], [1, 1], [2], [2, 1], [2, 2]]
```

```
cardinality()
    Return the cardinality of self.

    EXAMPLES:

```
sage: PartitionsInBox(2, 3).cardinality()
    10
```

```
list()
    Return a list of all the partitions inside a box of height $h$ and width $w$.

    EXAMPLES:

```
sage: PartitionsInBox(2,2).list()
    [[], [1], [1, 1], [2], [2, 1], [2, 2]]
```
```
sage: PartitionsInBox(2,3).list()
    [[], [1], [1, 1], [2], [2, 1], [2, 2], [3], [3, 1], [3, 2], [3, 3]]
```
```
class sage.combinat.partition.Partitions_all
    Bases: sage.combinat.partition.Partitions

    Class of all partitions.

    ..meth:`from_beta_numbers` (beta)
    
    Return a partition corresponding to a sequence of beta numbers.
    
    A sequence of beta numbers is a strictly increasing sequence $0 \leq b_1 < \cdots < b_k$ of non-negative integers. The corresponding partition $\mu = (\mu_k, \ldots, \mu_1)$ is given by $\mu_i = [1,i) \setminus \{b_1, \ldots, b_i\}$. This gives a bijection from the set of partitions with at most $k$ non-zero parts to the set of strictly increasing sequences of non-negative integers of length $k$.

    EXAMPLES:
```
```
**from_core_and_quotient** (*core, quotient*)

Returns a partition from its core and quotient.

Algorithm from mupad-combinat.

**EXAMPLES:**

```python
sage: Partitions().from_core_and_quotient([2,1], [[2,1],[3],[1,1,1]])
[11, 5, 5, 3, 2, 2, 2]
```

**from_exp** (*exp*)

Returns a partition from its list of multiplicities.

**EXAMPLES:**

```python
sage: Partitions().from_exp([2,2,1])
[3, 2, 2, 1, 1]
```

**from_frobenius_coordinates** (*frobenius_coordinates*)

Returns a partition from a pair of sequences of Frobenius coordinates.

**EXAMPLES:**

```python
sage: Partitions().from_frobenius_coordinates(([],[]))
[]
sage: Partitions().from_frobenius_coordinates(([0],[0]))
[1]
sage: Partitions().from_frobenius_coordinates(([1],[1]))
[2, 1]
sage: Partitions().from_frobenius_coordinates(([6,3,2],[4,1,0]))
[7, 5, 5, 1, 1]
```

**from_zero_one** (*seq*)

Return a partition from its 0 − 1 sequence.

The full 0 − 1 sequence is the sequence (infinite in both directions) indicating the steps taken when following the outer rim of the diagram of the partition. We use the convention that in English convention, a 1 corresponds to an East step, and a 0 corresponds to a North step.

Note that every full 0 − 1 sequence starts with infinitely many 0’s and ends with infinitely many 1’s.

**See also:**

`Partition.zero_one_sequence()`

**INPUT:**

The input should be a finite sequence of 0’s and 1’s. The heading 0’s and trailing 1’s will be discarded.

**EXAMPLES:**

```python
sage: Partitions().from_zero_one([])
[]
sage: Partitions().from_zero_one([1,0])
[1]
```
sage: Partitions().from_zero_one([1, 1, 1, 1, 0, 1, 0])
[5, 4]

Heading 0’s and trailing 1’s are correctly handled:

sage: Partitions().from_zero_one([0,0,1,1,1,1,0,1,0,1,1,1])
[5, 4]

subset (size=\text{None}, **\text{kwargs})

Returns the subset of partitions of a given size and additional keyword arguments.

EXAMPLES:

sage: P = Partitions()
sage: P.subset(4)
Partitions of the integer 4

\begin{verbatim}
class sage.combinat.partition.Partitions_all_bounded(k)
    Bases: sage.combinat.partition.Partitions
\end{verbatim}

\begin{verbatim}
class sage.combinat.partition.Partitions_constraints(*args, **kwargs)
    Bases: sage.combinat.integer_lists.invlex.IntegerListsLex

    For unpickling old constrained Partitions_constraints objects created with sage <= 3.4.1. See Partitions.
\end{verbatim}

\begin{verbatim}
class sage.combinat.partition.Partitions_ending(n, ending_partition)
    Bases: sage.combinat.partition.Partitions

    All partitions with a given ending.
\end{verbatim}

\begin{verbatim}
first()

    Return the first partition in self.

    EXAMPLES:

    sage: Partitions(4, ending=[1,1,1,1]).first()
    [4]
\end{verbatim}

\begin{verbatim}
next (part)

    Return the next partition after part in self.

    EXAMPLES:

    sage: Partitions(4, ending=[1,1,1,1]).next(Partition([4]))
    [3, 1]
    sage: Partitions(4, ending=[1,1,1,1]).next(Partition([1,1,1,1])) is None
    True
\end{verbatim}

\begin{verbatim}
class sage.combinat.partition.Partitions_n(n)
    Bases: sage.combinat.partition.Partitions

    Partitions of the integer n.
\end{verbatim}

cardinality (algorithm='\text{flint}')

Return the number of partitions of the specified size.

INPUT:

\begin{itemize}
    \item \text{algorithm} - (default: '\text{flint}')
\end{itemize}
– 'flint' – use FLINT (currently the fastest)
– 'gap' – use GAP (VERY slow)
– 'pari' – use PARI. Speed seems the same as GAP until \( n \) is in the thousands, in which case PARI is faster.

It is possible to associate with every partition of the integer \( n \) a conjugacy class of permutations in the symmetric group on \( n \) points and vice versa. Therefore the number of partitions \( p_n \) is the number of conjugacy classes of the symmetric group on \( n \) points.

EXAMPLES:

```python
sage: v = Partitions(5).list(); v
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: len(v)
7
sage: Partitions(5).cardinality(algorithm='gap')
7
sage: Partitions(5).cardinality(algorithm='pari')
7
sage: number_of_partitions(5, algorithm='flint')
7
```

The input must be a nonnegative integer or a ValueError is raised.

```python
sage: Partitions(10).cardinality()
42
sage: Partitions(3).cardinality()
3
sage: Partitions(10).cardinality()
42
sage: Partitions(3).cardinality(algorithm='pari')
3
sage: Partitions(10).cardinality(algorithm='pari')
42
sage: Partitions(40).cardinality()
37338
sage: Partitions(100).cardinality()
190569292
```

A generating function for \( p_n \) is given by the reciprocal of Euler’s function:

\[
\sum_{n=0}^{\infty} p_n x^n = \prod_{k=1}^{\infty} \frac{1}{1 - x^k}.
\]

We use Sage to verify that the first several coefficients do indeed agree:

```python
sage: q = PowerSeriesRing(QQ, 'q', default_prec=9).gen()
sage: prod([((1-q^k)^(-1) for k in range(1,9)])
## partial product of
1 + q + 2*q^2 + 3*q^3 + 5*q^4 + 7*q^5 + 11*q^6 + 15*q^7 + 22*q^8 + O(q^9)
sage: [Partitions(k).cardinality() for k in range(2,10)]
[2, 3, 5, 7, 11, 15, 22, 30]
```

Another consistency test for \( n \) up to 500:

```python
sage: len([n for n in 1..500 if Partitions(n).cardinality() != Partitions(n).cardinality(algorithm='pari')])
0
```
REFERENCES:

- Wikipedia article Partition_(number_theory)

**first()**

Returns the lexicographically first partition of a positive integer $n$. This is the partition $[n]$.

EXAMPLES:

```python
sage: Partitions(4).first()
[4]
```

**last()**

Return the lexicographically last partition of the positive integer $n$. This is the all-ones partition.

EXAMPLES:

```python
sage: Partitions(4).last()
[1, 1, 1, 1]
```

**next(p)**

Return the lexicographically next partition after the partition $p$.

EXAMPLES:

```python
sage: Partitions(4).next([4])
[3, 1]
sage: Partitions(4).next([1,1,1,1]) is None
True
```

**random_element(measure='uniform')**

Return a random partitions of $n$ for the specified measure.

INPUT:

- `measure='uniform'` or `Plancherel` (default: 'uniform')

See also:

- `random_element_uniform()`
- `random_element_plancherel()`

EXAMPLES:

```python
sage: Partitions(5).random_element() # random
[2, 1, 1, 1]
sage: Partitions(5).random_element(measure='Plancherel') # random
[2, 1, 1, 1]
```

**random_element_plancherel()**

Return a random partition of $n$ for the Plancherel measure.

This probability distribution comes from the uniform distribution on permutations via the Robinson-Schensted correspondence.

See Wikipedia article Plancherel_measure and `Partition.plancherel_measure()`.

EXAMPLES:
ALGORITHM:

• insert by Robinson-Schensted a uniform random permutations of \( n \) and returns the shape of the resulting tableau. The complexity is \( O(n \ln(n)) \) which is likely optimal. However, the implementation could be optimized.

AUTHOR:

• Florent Hivert (2009-11-23)

random_element_uniform()

Return a random partition of \( n \) with uniform probability.

EXAMPLES:

sage: Partitions(5).random_element_uniform()  # random
[2, 1, 1, 1]
sage: Partitions(20).random_element_uniform()  # random
[9, 3, 3, 2, 2, 1]

ALGORITHM:

• It is a python Implementation of RANDPAR, see [NW1978]. The complexity is unknown, there may be better algorithms.

Todo: Check in Knuth AOCP4.

• There is also certainly a lot of room for optimizations, see comments in the code.

AUTHOR:

• Florent Hivert (2009-11-23)

subset (**kwargs)

Return a subset of self with the additional optional arguments.

EXAMPLES:

sage: P = Partitions(5); P
Partitions of the integer 5
sage: P.subset(starting=[3,1])
Partitions of the integer 5 starting with [3, 1]

class sage.combinat.partition.Partitions_nk(n,k)

Bases: sage.combinat.partition.Partitions

Partitions of the integer \( n \) of length equal to \( k \).

cardinality(algorithm='hybrid')

Return the number of partitions of the specified size with the specified length.

INPUT:

• algorithm – (default: 'hybrid') the algorithm to compute the cardinality and can be one of the following:
'hybrid' - use a hybrid algorithm which uses heuristics to reduce the complexity

'gap' - use GAP

**EXAMPLES:**

```python
sage: v = Partitions(5, length=2).list(); v
[[4, 1], [3, 2]]
sage: len(v)
2
sage: Partitions(5, length=2).cardinality()
2
```

More generally, the number of partitions of $n$ of length 2 is $\left\lfloor \frac{n}{2} \right\rfloor$:

```python
sage: all( Partitions(n, length=2).cardinality() == n // 2 for n in range(10) )
True
```

The number of partitions of $n$ of length 1 is 1 for $n$ positive:

```python
sage: all( Partitions(n, length=1).cardinality() == 1 for n in range(1, 10) )
True
```

**Further examples:**

```python
sage: Partitions(5, length=3).cardinality()
2
sage: Partitions(6, length=3).cardinality()
3
sage: Partitions(8, length=4).cardinality()
5
sage: Partitions(8, length=5).cardinality()
3
sage: Partitions(15, length=6).cardinality()
26
sage: Partitions(0, length=0).cardinality()
1
sage: Partitions(0, length=1).cardinality()
0
sage: Partitions(1, length=0).cardinality()
0
sage: Partitions(1, length=4).cardinality()
0
```

**`subset(**kwargs)****

Return a subset of self with the additional optional arguments.

**EXAMPLES:**

```python
sage: P = Partitions(5, length=2); P
Partitions of the integer 5 of length 2
sage: P.subset(max_part=3)
Partitions of the integer 5 satisfying constraints length=2, max_part=3
```

**class** `sage.combinat.partition.Partitions_parts_in(n, parts)`

Bases: `sage.combinat.partition.Partitions`

Partitions of $n$ with parts in a given set $S$. 

5.1. Comprehensive Module list 1585
This is invoked indirectly when calling `Partitions(n, parts_in=parts)`, where `parts` is a list of pairwise distinct integers.

**cardinality()**
Return the number of partitions with parts in `self`. Wraps GAP’s `NrRestrictedPartitions`.

**EXAMPLES:**

```sage
sage: Partitions(15, parts_in=[2,3,7]).cardinality()
5
```

If you can use all parts 1 through `n`, we’d better get `p(n)`:  

```sage
sage: Partitions(20, parts_in=[1..20]).cardinality() == Partitions(20).cardinality()
True
```

**first()**
Return the lexicographically first partition of a positive integer `n` with the specified parts, or `None` if no such partition exists.

**EXAMPLES:**

```sage
sage: Partitions(9, parts_in=[3,4]).first()
[3, 3, 3]
sage: Partitions(6, parts_in=[1..6]).first()
[6]
sage: Partitions(30, parts_in=[4,7,8,10,11]).first()
[11, 11, 8]
```

**last()**
Return the lexicographically last partition of the positive integer `n` with the specified parts, or `None` if no such partition exists.

**EXAMPLES:**

```sage
sage: Partitions(15, parts_in=[2,3]).last()
[3, 2, 2, 2, 2, 2]
sage: Partitions(30, parts_in=[4,7,8,10,11]).last()
[7, 7, 4, 4, 4, 4]
sage: Partitions(10, parts_in=[3,6]).last() is None
True
sage: Partitions(50, parts_in=[11,12,13]).last()
[13, 13, 12, 12]
sage: Partitions(30, parts_in=[4,7,8,10,11]).last()
[7, 7, 4, 4, 4]
```

**class** `sage.combinat.partition.Partitions_starting(n, starting_partition)`

**Bases:** `sage.combinat.partition.Partitions`

All partitions with a given start.

**first()**
Return the first partition in `self`.

**EXAMPLES:**

```sage
sage: Partitions(3, starting=[2,1]).first()
[2, 1]
```
next \( (\text{part}) \)
Return the next partition after part in self.

EXAMPLES:

```
sage: Partitions(3, starting=[2,1]).next(Partition([2,1]))
[1, 1, 1]
```

class sage.combinat.partition.Partitions_with_constraints(*args, **kwds)

Bases: sage.combinat.integer_lists.invlex.IntegerListsLex

Partitions which satisfy a set of constraints.

EXAMPLES:

```
sage: P = Partitions(6, inner=[1,1], max_slope=-1)
sage: list(P)
[[5, 1], [4, 2], [3, 2, 1]]
```

Element
alias of Partition

options (*get_value, **set_value)
Sets and displays the global options for elements of the partition, skew partition, and partition tuple classes. If no parameters are set, then the function returns a copy of the options dictionary.

The options to partitions can be accessed as the method \texttt{Partitions.options} of \texttt{Partitions} and related parent classes.

OPTIONS:

- **convention** – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention
- **diagram_str** – (default: \ast) The character used for the cells when printing Ferrers diagrams
- **display** – (default: list) Specifies how partitions should be printed
  - array – alias for diagram
  - compact – alias for compact_low
  - compact_high – compact form of \texttt{exp_high}
  - compact_low – compact form of \texttt{exp_low}
  - diagram – as a Ferrers diagram
  - exp – alias for \texttt{exp_low}
  - exp_high – in exponential form (highest first)
  - exp_low – in exponential form (lowest first)
  - ferrers_diagram – alias for diagram
  - list – displayed as a list
  - young_diagram – alias for diagram
- **latex** – (default: young_diagram) Specifies how partitions should be latexed
  - array – alias for diagram
- diagram – latex as a Ferrers diagram
- exp – alias for exp_low
- exp_high – latex as a list in exponential notation (highest first)
- exp_low – as a list latex in exponential notation (lowest first)
- ferrers_diagram – alias for diagram
- list – latex as a list
- young_diagram – latex as a Young diagram

- latex_diagram_str – (default: \ast) The character used for the cells when latexing Ferrers diagrams
- notation – alternative name for convention

EXAMPLES:

```
sage: P = Partition([4,2,2,1])
sage: P
[4, 2, 2, 1]
sage: Partitions.options.display="exp"
sage: P
1, 2^2, 4
sage: Partitions.options.display="exp_high"
sage: P
4, 2^2, 1
```

It is also possible to use user defined functions for the display and latex options:

```
sage: Partitions.options(display=\lambda mu: '<'+'<%s>' % ',').join('%s'%'m for m in mu._list)); P
<sage: Partitions.options(latex=\lambda mu: '\\Diagram{%s}' % ',').join('%s'%'m
<sage: Partitions.options(display="diagram", diagram_str="#")
sage: P
####
##
###
```

Changing the convention for partitions also changes the convention option for tableaux and vice versa:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
  4 5
  1 2 3
sage: Tableaux.options.convention="english"
sage: print(P.ferrers_diagram())
  *
  **
  ***
  ****
```

(continues on next page)
class sage.combinat.partition.RegularPartitions(ell, is_infinite=False)

Bases: sage.combinat.partition.Partitions

Base class for $\ell$-regular partitions.

Let $\ell$ be a positive integer. A partition $\lambda$ is $\ell$-regular if $m_i < \ell$ for all $i$, where $m_i$ is the multiplicity of $i$ in $\lambda$.

**Note:** This is conjugate to the notion of $\ell$-restricted partitions, where the difference between any two consecutive parts is $< \ell$.

**INPUT:**

- `ell` – the positive integer $\ell$
- `is_infinite` – boolean; if the subset of $\ell$-regular partitions is infinite

`ell()`

Return the value $\ell$.

**EXAMPLES:**

```
sage: P = Partitions(regular=2)
sage: P.ell()
sage: Partitions.options._reset()
```

class sage.combinat.partition.RegularPartitions_all(ell)

Bases: sage.combinat.partition.RegularPartitions

The class of all $\ell$-regular partitions.

**INPUT:**

- `ell` – the integer $\ell$

See also:

RegularPartitions

class sage.combinat.partition.RegularPartitions_bounded(ell, k)

Bases: sage.combinat.partition.RegularPartitions

The class of $\ell$-regular $k$-bounded partitions.

**INPUT:**

- `ell` – the integer $\ell$
- `k` – integer; the value $k
See also:

RegularPartitions

class sage.combinat.partition.RegularPartitions_n(n, ell)
Bases: sage.combinat.partition.RegularPartitions, sage.combinat.partition.Partitions_n

The class of \(\ell\)-regular partitions of \(n\).

INPUT:

• \(n\) – the integer \(n\) to partition
• \(\ell\) – the integer \(\ell\)

See also:

RegularPartitions

cardinality()

Return the cardinality of self.

EXAMPLES:

sage: P = Partitions(5, regular=3)
sage: P.cardinality()
5
sage: P = Partitions(5, regular=6)
sage: P.cardinality()
7
sage: P.cardinality() == Partitions(5).cardinality()
True

class sage.combinat.partition.RegularPartitions_truncated(ell, max_len)
Bases: sage.combinat.partition.RegularPartitions

The class of \(\ell\)-regular partitions with max length \(k\).

INPUT:

• \(\ell\) – the integer \(\ell\)
• \(\text{max\_len}\) – integer; the maximum length

See also:

RegularPartitions

max_length()

Return the maximum length of the partitions of self.

EXAMPLES:

sage: P = Partitions(regular=4, max_length=3)
sage: P.max_length()
3

class sage.combinat.partition.RestrictedPartitions_all(ell)
Bases: sage.combinat.partition.RestrictedPartitions_generic

The class of all \(\ell\)-restricted partitions.

INPUT:

• \(\ell\) – the positive integer \(\ell\)
See also:

RestrictedPartitions_generic

class sage.combinat.partition.RestrictedPartitions_generic(ell, is_infinite=False)
Bases: sage.combinat.partition.Partitions

Base class for ℓ-restricted partitions.

Let ℓ be a positive integer. A partition λ is ℓ-restricted if λᵢ − λᵢ₊₁ < ℓ for all i, including rows of length 0.

Note: This is conjugate to the notion of ℓ-regular partitions, where the multiplicity of any parts is at most ℓ.

INPUT:

• ell – the positive integer ℓ
• is_infinite – boolean; if the subset of ℓ-restricted partitions is infinite

e ll()
Return the value ℓ.

EXAMPLES:

```
sage: P = Partitions(restricted=2)
sage: P.ell()
sage: P.ell()
2
```

class sage.combinat.partition.RestrictedPartitions_n(n, ell)
Bases: sage.combinat.partition.RestrictedPartitions_generic, sage.combinat.partition.Partitions_n

The class of ℓ-restricted partitions of n.

INPUT:

• n – the integer n to partition
• ell – the integer ℓ

See also:

RestrictedPartitions_generic
cardinality()
Return the cardinality of self.

EXAMPLES:

```
sage: P = Partitions(5, restricted=3)
sage: P.cardinality()
sage: P.cardinality()
sage: P = Partitions(5, restricted=6)
sage: P.cardinality()
sage: P.cardinality() == Partitions(5).cardinality()
```

sage.combinat.partition.number_of_partitions(n, algorithm='default')
Returns the number of partitions of n with, optionally, at most k parts.
The options of `number_of_partitions()` are being deprecated trac ticket #13072 in favour of `Partitions_n.cardinality()` so that `number_of_partitions()` can become a stripped down version of the fastest algorithm available (currently this is using FLINT).

**INPUT:**

- `n` – an integer
- `algorithm` – (default: ‘default’) [Will be deprecated except in Partition().cardinality() ]
  - "default" – If `k` is not `None`, then use Gap (very slow). If `k` is `None`, use FLINT.
  - "flint" – use FLINT

**EXAMPLES:**

```python
sage: v = Partitions(5).list(); v
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: len(v)
7
```

The input must be a nonnegative integer or a `ValueError` is raised.

```python
sage: number_of_partitions(-5)
Traceback (most recent call last):
  ...:
ValueError: n (-5) must be a nonnegative integer
```

```python
sage: number_of_partitions(10)
42
sage: number_of_partitions(3)
3
sage: number_of_partitions(10)
42
sage: number_of_partitions(40)
37338
sage: number_of_partitions(100)
190569292
sage: number_of_partitions(100000)
2749351056975696126775163209863526881734293159800547582031259843021473281149641730550507416607
```

A generating function for the number of partitions \( p_n \) is given by the reciprocal of Euler’s function:

\[
\sum_{n=0}^{\infty} p_n x^n = \prod_{k=1}^{\infty} \left( \frac{1}{1-x^k} \right).
\]

We use Sage to verify that the first several coefficients do instead agree:

```python
sage: q = PowerSeriesRing(QQ, 'q', default_prec=9).gen()
sage: prod([(1-q**k)**(-1) for k in range(1,9)])
# partial product of
1 + q + 2*q^2 + 3*q^3 + 5*q^4 + 7*q^5 + 11*q^6 + 15*q^7 + 22*q^8 + O(q^9)
sage: [number_of_partitions(k) for k in range(2,10)]
[2, 3, 5, 7, 11, 15, 22, 30]
```

**REFERENCES:**

- Wikipedia article Partition_(number_theory)

```python
sage.combinat.partition.number_of_partitions_length(n, k, algorithm='hybrid')
```

Return the number of partitions of \( n \) with length \( k \).
This is a wrapper for GAP's \texttt{NrPartitions} function.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.combinat.partition import number_of_partitions_length
sage: number_of_partitions_length(5, 2)
2
sage: number_of_partitions_length(10, 2)
5
sage: number_of_partitions_length(10, 4)
9
sage: number_of_partitions_length(10, 0)
0
sage: number_of_partitions_length(10, 1)
1
sage: number_of_partitions_length(0, 0)
1
sage: number_of_partitions_length(0, 1)
0
\end{verbatim}

5.1.166 Partition/Diagram Algebras

\begin{verbatim}
class sage.combinat.partition_algebra.PartitionAlgebraElement_ak
   Bases: sage.combinat.partition_algebra.PartitionAlgebraElement_generic

class sage.combinat.partition_algebra.PartitionAlgebraElement_bk
   Bases: sage.combinat.partition_algebra.PartitionAlgebraElement_generic

class sage.combinat.partition_algebra.PartitionAlgebraElement_generic
   Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

class sage.combinat.partition_algebra.PartitionAlgebraElement_pk
   Bases: sage.combinat.partition_algebra.PartitionAlgebraElement_generic

class sage.combinat.partition_algebra.PartitionAlgebraElement_prk
   Bases: sage.combinat.partition_algebra.PartitionAlgebraElement_generic

class sage.combinat.partition_algebra.PartitionAlgebraElement_rk
   Bases: sage.combinat.partition_algebra.PartitionAlgebraElement_generic

class sage.combinat.partition_algebra.PartitionAlgebraElement_sk

   Bases: sage.combinat.partition_algebra.PartitionAlgebraElement_generic

class sage.combinat.partition_algebra.PartitionAlgebraak(R, k, n, name=None)
   Bases: sage.combinat.partition_algebra.PartitionAlgebra_generic

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebraak(QQ, 3, 1)
sage: p == loads(dumps(p))
True
\end{verbatim}

\end{verbatim}

5.1. Comprehensive Module list
```
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_bk(QQ, 3, 1)
sage: p == loads(dumps(p))
True

class sage.combinat.partition_algebra.PartitionAlgebra_generic(R, cclass, n, k,
               name=None, prefix=None)

    Bases: sage.combinat.combinatorial_algebra.CombinatorialAlgebra

    EXAMPLES:

sage: from sage.combinat.partition_algebra import *
sage: s = PartitionAlgebra_sk(QQ, 3, 1)
sage: s == loads(dumps(s))
True

class sage.combinat.partition_algebra.PartitionAlgebra_pk(R, k, n, name=None)

    Bases: sage.combinat.partition_algebra.PartitionAlgebra_generic

    EXAMPLES:

sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_pk(QQ, 3, 1)
sage: p == loads(dumps(p))
True

class sage.combinat.partition_algebra.PartitionAlgebra_prk(R, k, n, name=None)

    Bases: sage.combinat.partition_algebra.PartitionAlgebra_generic

    EXAMPLES:

sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_prk(QQ, 3, 1)
sage: p == loads(dumps(p))
True

class sage.combinat.partition_algebra.PartitionAlgebra_rk(R, k, n, name=None)

    Bases: sage.combinat.partition_algebra.PartitionAlgebra_generic

    EXAMPLES:

sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_rk(QQ, 3, 1)
sage: p == loads(dumps(p))
True

class sage.combinat.partition_algebra.PartitionAlgebra_sk(R, k, n, name=None)

    Bases: sage.combinat.partition_algebra.PartitionAlgebra_generic

    EXAMPLES:

sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_sk(QQ, 3, 1)
sage: p == loads(dumps(p))
True

class sage.combinat.partition_algebra.PartitionAlgebra_tk(R, k, n, name=None)

    Bases: sage.combinat.partition_algebra.PartitionAlgebra_generic

    EXAMPLES:

sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_tk(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```
EXAMPLES:

```python
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_tk(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```

`sage.combinat.partition_algebra.SetPartitionsAk(k)`
Return the combinatorial class of set partitions of type $A_k$.

EXAMPLES:

```python
sage: A3 = SetPartitionsAk(3); A3
Set partitions of {1, ..., 3, -1, ..., -3}
sage: A3.first() #random
{{1, 2, 3, -1, -3, -2}}
sage: A3.last() #random
{{-1}, {-2}, {3}, {1}, {-3}, {2}}
sage: A3.random_element() #random
{{1, 3, -3, -1}, {2, -2}}
sage: A3.cardinality()
203
sage: A2p5 = SetPartitionsAk(2.5); A2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block
sage: A2p5.cardinality()
52
sage: A2p5.first() #random
{{1, 2, 3, -1, -3, -2}}
sage: A2p5.last() #random
{{-1}, {-2}, {2}, {3, -3}, {1}}
sage: A2p5.random_element() #random
{{-1}, {-2}, {3, -3}, {1, 2}}
```

class `sage.combinat.partition_algebra.SetPartitionsAk_k(k)`
Bases: `sage.combinat.set_partition.SetPartitions_set`  
Element  
alias of `SetPartitionsXkElement`

class `sage.combinat.partition_algebra.SetPartitionsAkhalf_k(k)`
Bases: `sage.combinat.set_partition.SetPartitions_set`  
Element  
alias of `SetPartitionsXkElement`

`sage.combinat.partition_algebra.SetPartitionsBk(k)`
Return the combinatorial class of set partitions of type $B_k$.

These are the set partitions where every block has size 2.

EXAMPLES:

```python
sage: B3 = SetPartitionsBk(3); B3
Set partitions of {1, ..., 3, -1, ..., -3} with block size 2
sage: B3.first() #random
```
{{{2, -2}, {1, -3}, {3, -1}}}
sage: B3.last() #random
{{1, 2}, {3, -2}, {-3, -1}}
sage: B3.random_element() #random
{{{2, -1}, {1, -3}, {3, -2}}}
sage: B3.cardinality()
15

sage: B2p5 = SetPartitionsBk(2.5); B2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and
→with block size 2

sage: B2p5.first() #random
{(2, -1), {3, -3}, {1, -2}}
sage: B2p5.last() #random
{(1, 2), {3, -3}, {-1, -2}}
sage: B2p5.random_element() #random
{(2, -2), {3, -3}, {1, -1}}
sage: B2p5.cardinality()
3

class sage.combinat.partition_algebra.SetPartitionsBk_k(k)
Bases: sage.combinat.partition_algebra.SetPartitionsAk_k
cardinality()

Return the number of set partitions in $B_k$ where $k$ is an integer.

This is given by $(2k)!! = (2k-1)*(2k-3)*...*5*3*1$.

EXAMPLES:

sage: SetPartitionsBk(3).cardinality()
15
sage: SetPartitionsBk(2).cardinality()
3
sage: SetPartitionsBk(1).cardinality()
1
sage: SetPartitionsBk(4).cardinality()
105
sage: SetPartitionsBk(5).cardinality()
945

class sage.combinat.partition_algebra.SetPartitionsBkhalf_k(k)
Bases: sage.combinat.partition_algebra.SetPartitionsAkhalf_k
cardinality()
sage.combinat.partition_algebra.SetPartitionsIk_k(k)

Return the combinatorial class of set partitions of type $I_k$.

These are set partitions with a propagating number of less than $k$. Note that the identity set partition
$\{\{1,-1\}, \ldots, \{k,-k\}\}$ is not in $I_k$.

EXAMPLES:

sage: I3 = SetPartitionsIk(3); I3
Set partitions of {1, ..., 3, -1, ..., -3} with propagating number < 3
sage: I3.cardinality()
197
sage: I3.first()  # random
{{1, 2, 3, -1, -3, -2}}

sage: I3.last()  # random
{{-1, {-2}, {3}, {1}, {-3}, {2}}}

sage: I3.random_element()  # random
{{-1}, {-3, -2}, {2, 3}, {1}}

sage: I2p5 = SetPartitionsIk(2.5); I2p5
# Set partitions of \{1, ..., 3, -1, ..., -3\} with 3 and -3 in the same block and

# propagating number < 3
sage: I2p5.cardinality()
50

sage: I2p5.first()  # random
{{1, 2, 3, -1, -3, -2}}

sage: I2p5.last()  # random
{{-1, {-2}, {2}, {3, -3}, {1}}}

sage: I2p5.random_element()  # random
{{-1}, {-2}, {1, 3, -3}, {2}}

class sage.combinat.partition_algebra.SetPartitionsIk_k(k)
   Bases: sage.combinat.partition_algebra.SetPartitionsAk_k
   cardinality()

class sage.combinat.partition_algebra.SetPartitionsIkhalf_k(k)
   Bases: sage.combinat.partition_algebra.SetPartitionsAkhalf_k
   cardinality()

sage.combinat.partition_algebra.SetPartitionsPRk(k)
Return the combinatorial class of set partitions of type \(PR_k\).

EXAMPLES:

sage: SetPartitionsPRk(3)
# Set partitions of \{1, ..., 3, -1, ..., -3\} with at most 1 positive
and negative entry in each block and that are planar

class sage.combinat.partition_algebra.SetPartitionsPRk_k(k)
   Bases: sage.combinat.partition_algebra.SetPartitionsRk_k
   cardinality()

class sage.combinat.partition_algebra.SetPartitionsPRkhalf_k(k)
   Bases: sage.combinat.partition_algebra.SetPartitionsRkhalf_k
   cardinality()

sage.combinat.partition_algebra.SetPartitionsPk(k)
Return the combinatorial class of set partitions of type \(P_k\).

These are the planar set partitions.

EXAMPLES:
```
sage: P3 = SetPartitionsPk(3); P3
Set partitions of {1, ..., 3, -1, ..., -3} that are planar
sage: P3.cardinality()
132
sage: P3.first()  #random
((1, 2, 3, -1, -3, -2))
sage: P3.last()  #random
((-1), (-2), (3), (1), (-3), (2))
sage: P3.random_element()  #random
((1, 2, -1), (-3), (3, -2))

sage: P2p5 = SetPartitionsPk(2.5); P2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and
that are planar
sage: P2p5.cardinality()
42
sage: P2p5.first()  #random
((1, 2, 3, -1, -3, -2))
sage: P2p5.last()  #random
((1, -1), (-2), (2), (3, -3), (1))
sage: P2p5.random_element()  #random
((1, 2, 3, -3), {-1, -2})
```

```python
class sage.combinat.partition_algebra.SetPartitionsPk_k(k):
    Bases: sage.combinat.partition_algebra.SetPartitionsAk_k
    
cardinality()

class sage.combinat.partition_algebra.SetPartitionsPkhalf_k(k):
    Bases: sage.combinat.partition_algebra.SetPartitionsAkhalf_k
    
cardinality()

sage.combinat.partition_algebra.SetPartitionsRk(k)
Return the combinatorial class of set partitions of type $R_k$.

EXAMPLES:
```
sage: SetPartitionsRk(3)
Set partitions of {1, ..., 3, -1, ..., -3} with at most 1 positive
and negative entry in each block
```

```python
class sage.combinat.partition_algebra.SetPartitionsRs_k(k):
    
cardinality()

class sage.combinat.partition_algebra.SetPartitionsRskhalf_k(k):
    
cardinality()

sage.combinat.partition_algebra.SetPartitionsSk(k)
Return the combinatorial class of set partitions of type $S_k$.

There is a bijection between these set partitions and the permutations of $1, \ldots, k$.

EXAMPLES:
sage: S3 = SetPartitionsSk(3); S3
Set partitions of \{1, ..., 3, -1, ..., -3\} with propagating number 3
sage: S3.cardinality()
6

sage: S3.list()  #random
[[[2, -2], [3, -3], [1, -1]],
 [[1, -1], [2, -3], [3, -2]],
 [[2, -1], [3, -3], [1, -2]],
 [[1, -2], [2, -3], [3, -1]],
 [[1, -3], [2, -1], [3, -2]],
 [[1, -3], [2, -2], [3, -1]]

sage: S3.first()  #random
([[2, -2], [3, -3], [1, -1]])

sage: S3.last()  #random
([[1, -3], [2, -2], [3, -1]])

sage: S3.random_element()  #random
([[1, -3], [2, -2], [3, -1]])

sage: S3p5 = SetPartitionsSk(3.5); S3p5
Set partitions of \{1, ..., 4, -1, ..., -4\} with 4 and -4 in the same block and
propagating number 4
sage: S3p5.cardinality()
6

sage: S3p5.list()  #random
[[[2, -2], [3, -3], [1, -1], [4, -4]],
 [[2, -3], [1, -1], [4, -4], [3, -2]],
 [[2, -1], [3, -3], [1, -2], [4, -4]],
 [[2, -3], [1, -2], [4, -4], [3, -1]],
 [[1, -3], [2, -1], [4, -4], [3, -2]],
 [[1, -3], [2, -2], [4, -4], [3, -1]]

sage: S3p5.first()  #random
([[2, -2], [3, -3], [1, -1], [4, -4]])

sage: S3p5.last()  #random
([[1, -3], [2, -2], [4, -4], [3, -1]])

sage: S3p5.random_element()  #random
([[1, -3], [2, -2], [4, -4], [3, -1]])

class sage.combinat.partition_algebra.SetPartitionsSk_k(k)
    Bases: sage.combinat.partition_algebra.SetPartitionsAk_k

cardinality()
    Returns k!.

class sage.combinat.partition_algebra.SetPartitionsSkhalf_k(k)
    Bases: sage.combinat.partition_algebra.SetPartitionsAkhalf_k

cardinality()

sage.combinat.partition_algebra.SetPartitionsTk(k)
    Return the combinatorial class of set partitions of type \(T_k\).

    These are planar set partitions where every block is of size 2.

    EXAMPLES:

    sage: T3 = SetPartitionsTk(3); T3
Set partitions of \{1, ..., 3, -1, ..., -3\} with block size 2 and that are planar
(continues on next page)
sage: T3.cardinality()
5

sage: T3.first() #random
{{1, -3}, {2, 3}, {-1, -2}}

sage: T3.last() #random
{{1, 2}, {3, -1}, {-3, -2}}

sage: T3.random_element() #random
{{1, -3}, {2, 3}, {-1, -2}}

sage: T2p5 = SetPartitionsTk(2.5); T2p5
Set partitions of \{1, \ldots, 3, -1, \ldots, -3\} with 3 and -3 in the same block and
→ with block size 2 and that are planar

sage: T2p5.cardinality()
2

sage: T2p5.first() #random
{{2, -2}, {3, -3}, {1, -1}}

sage: T2p5.last() #random
{{1, 2}, {3, -3}, {-1, -2}}

class sage.combinat.partition_algebra.SetPartitionsTk_k(k)
Bases: sage.combinat.partition_algebra.SetPartitionsBk_k
cardinality()

class sage.combinat.partition_algebra.SetPartitionsTkhalf_k(k)
Bases: sage.combinat.partition_algebra.SetPartitionsBkhalf_k
cardinality()

class sage.combinat.partition_algebra.SetPartitionsXkElement(parent, s, check=True)
Bases: sage.combinat.set_partition.SetPartition

An element for the classes of SetPartitionXk where X is some letter.

check()
Check to make sure this is a set partition.

EXAMPLES:

sage: A2p5 = SetPartitionsAk(2.5)
sage: x = A2p5.first(); x
{{-3, -2, -1, 1, 2, 3}}
sage: x.check()
sage: y = A2p5.next(x); y
{{-3, 3}, {-2, -1, 1, 2}}
sage: y.check()

sage.combinat.partition_algebra.identity(k)
Returns the identity set partition 1, -1, \ldots, k, -k

EXAMPLES:

sage: import sage.combinat.partition_algebra as pa
sage: pa.identity(2)
{{2, -2}, {1, -1}}
sage.combinat.partition_algebra.is_planar(sp)
Returns True if the diagram corresponding to the set partition is planar; otherwise, it returns False.

EXAMPLES:

```python
sage: import sage.combinat.partition_algebra as pa
sage: pa.is_planar( pa.to_set_partition([[1,-2],[2,-1]]))
False
sage: pa.is_planar( pa.to_set_partition([[1,-1],[2,-2]]))
True
```

sage.combinat.partition_algebra.pair_to_graph(sp1, sp2)
Return a graph consisting of the disjoint union of the graphs of set partitions sp1 and sp2 along with edges joining the bottom row (negative numbers) of sp1 to the top row (positive numbers) of sp2.

The vertices of the graph sp1 appear in the result as pairs (k, 1), whereas the vertices of the graph sp2 appear as pairs (k, 2).

EXAMPLES:

```python
sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sp2 = pa.to_set_partition([[1,-2],[2,-1]])
sage: g = pa.pair_to_graph( sp1, sp2 ); g
Graph on 8 vertices
sage: g.vertices()  #random
[(1, 2), (-1, 1), (-2, 2), (-1, 2), (-2, 1), (2, 1), (2, 2), (1, 1)]
sage: g.edges()  #random
[((1, 2), (-1, 1), None),
 ((1, 2), (-2, 2), None),
 ((-1, 1), (2, 1), None),
 ((-1, 2), (2, 2), None),
 ((-2, 1), (1, 1), None),
 ((-2, 1), (2, 2), None)]
```

Another example which used to be wrong until trac ticket #15958:

```python
sage: sp3 = pa.to_set_partition([[1, -1], [2], [-2]])
sage: sp4 = pa.to_set_partition([[1], [-1], [2], [-2]])
sage: g = pa.pair_to_graph( sp3, sp4 ); g
Graph on 8 vertices
sage: g.vertices()
[(-2, 1), (-2, 2), (-1, 1), (-1, 2), (1, 1), (1, 2), (2, 1), (2, 2)]
sage: g.edges()
[((-2, 1), (2, 2), None), ((-1, 1), (1, 1), None),
 ((-1, 1), (1, 2), None),
 ((-1, 1), (2, 2), None)]
```

sage.combinat.partition_algebra.propagating_number(sp)
Returns the propagating number of the set partition sp. The propagating number is the number of blocks with both a positive and negative number.

EXAMPLES:

```python
sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = pa.to_set_partition([[1,2],[-2,-1]])
```

(continues on next page)
sage: pa.propagating_number(sp1)
2
sage: pa.propagating_number(sp2)
0

sage.combinat.partition_algebra.set_partition_composition(sp1, sp2)

Returns a tuple consisting of the composition of the set partitions sp1 and sp2 and the number of components removed from the middle rows of the graph.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sp2 = pa.to_set_partition([[1,-2],[2,-1]])
sage: pa.set_partition_composition(sp1, sp2) == (pa.identity(2), 0)
True
```

sage.combinat.partition_algebra.to_graph(sp)

Returns a graph representing the set partition sp.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: g = pa.to_graph( pa.to_set_partition([[1,-2],[2,-1]])); g
Graph on 4 vertices
sage: g.vertices()  #random
[1, 2, -2, -1]
sage: g.edges()  #random
[(1, -2, None), (2, -1, None)]
```

sage.combinat.partition_algebra.to_set_partition(l, k=None)

Converts a list of a list of numbers to a set partitions. Each list of numbers in the outer list specifies the numbers contained in one of the blocks in the set partition.

If k is specified, then the set partition will be a set partition of 1, ..., k, -1, ..., -k. Otherwise, k will default to the minimum number needed to contain all of the specified numbers.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: pa.to_set_partition([[1,-1],[2,-2]]) == pa.identity(2)
True
```

5.1.167 Kleshchev partitions

A partition (tuple) $\mu$ is Kleshchev if it can be recursively obtained by adding a sequence of good nodes to the empty PartitionTuple of the same level() and multicharge. In this way, the set of Kleshchev multipartitions becomes a realization of a Kashiwara crystal sage.combinat.crystals.crystals for a irreducible integral highest weight representation of $U_q(\widehat{sl}_e)$.

The Kleshchev multipartitions first appeared in the work of Ariki and Mathas [AM2000] where it was shown that they index the irreducible representations of the cyclotomic Hecke algebras of type $A$ [AK1994]. Soon afterwards Ariki [Ariki2001] showed that the set of Kleshchev multipartitions naturally label the irreducible representations of
these algebras. As a far reaching generalization of these ideas the Ariki-Brundan-Kleshchev categorification theorem [Ariki1996] [BK2009] says that these algebras categorify the irreducible integral highest weight representations of the quantum group \( U_q(\hat{\mathfrak{sl}_e}) \) of the affine special linear group. Under this categorification, \( q \) corresponds to the grading shift on the cyclotomic Hecke algebras, where the grading from the Brundan-Kleshchev graded isomorphism theorem to the KLR algebras of type \( A \) [BK2009].

The group algebras of the symmetric group in characteristic \( p \) are an important special case of the cyclotomic Hecke algebras of type \( A \). In this case, depending on your prefer convention, the set of Kleshchev partitions is the set of \( 'p' \)-regular or \( 'p' \)-restricted Partitions. In this case, Kleshchev [Kle1995] proved that the modular branching rules were given by adding and removing good nodes; see good_cells(). Lascoux, Leclerc and Thibon [LLT1996] noticed that Kleshchev’s branching rules coincided with Kashiwara’s crystal operators for the fundamental representation of \( L(A_0) \) of \( U_q(\hat{\mathfrak{sl}_p}) \) and their celebrated LLT conjecture said that decomposition matrices of the sage.algebras.iwahori_hecke_algebra.IwahoriHeckeAlgebra of the symmetric group should be computable using the canonical basis of \( L(A_0) \). This was proved and generalised to all cyclotomic Hecke algebras of type \( A \) by Ariki [Ariki1996] and then further generalized to the graded setting by Brundan and Kleshchev [BK2009].

The main class for accessing Kleshchev partition (tuples) is KleshchevPartitions. Unfortunately, just as with the symmetric group, different authors use different conventions when defining Kleshchev partitions, which depends on whether you read components from left to right, or right to left, and whether you read the nodes in the partition in each component from top to bottom or bottom to top. The KleshchevPartitions class supports these four different conventions:

```python
sage: Kles = KleshchevPartitions(2, [0,0], size=2, convention='left regular')
sage: Kles
[([1], [1]), ([2], [])]
sage: Kles = KleshchevPartitions(2, [0,0], size=2, convention='left restricted')
sage: Kles
[([1], [1]), ([1], [1, 0])]
sage: Kles = KleshchevPartitions(2, [0,0], size=2, convention='right regular')
sage: Kles
[([1], [1]), ([1], [2])]
sage: Kles = KleshchevPartitions(2, [0,0], size=2, convention='right restricted')
sage: Kles
[([1], [1]), ([1], [1, 1])]
```

By default, the left restricted convention is used. As a shorthand, LG, LS, RG and RS, respectively, can be used to specify the convention. With the left convention the partition tuples should be ordered with the most dominant partitions in the partition tuple on the left and with the right convention the most dominant partition is on the right.

The KleshchevPartitions class can automatically convert between these four different conventions:

```python
sage: KPlg = KleshchevPartitions(2, [0,0], size=2, convention='left regular')
sage: KPls = KleshchevPartitions(2, [0,0], size=2, convention='left restricted')
sage: [KPlg(mu) for mu in KPls]  # indirect doctest
[([1], [1]), ([2], [])]
```

AUTHORS:

- Andrew Mathas and Travis Scrimshaw (2018-05-1): Initial version

class sage.combinat.partition_kleshchev.KleshchevCrystalMixin

Mixin class for the crystal structure of a Kleshchev partition.

Epsilon()

Return \( \epsilon \) of self.

EXAMPLES:

```python
sage: C = crystals.KleshchevPartitions3(3, [0,2], convention="left regular")
sage: x = C([[5,4,1],[3,2,1,1]])
```

(continues on next page)
sage: x.Epsilon()
3*Lambda[1]

\textbf{phi}()

Return $\phi$ of self.

\textbf{EXAMPLES:}

```
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([[5,4,1],[3,2,1,1]])
sage: x.phi()
3*Lambda[0] + 2*Lambda[1]
```

\textbf{epsilon}(i)

Return the Kashiwara crystal operator $\varepsilon_i$ applied to self.

\textbf{INPUT:}

- $i$ – an element of the index set

\textbf{EXAMPLES:}

```
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([[5,4,1],[3,2,1,1]])
sage: [x.epsilon(i) for i in C.index_set()]
[0, 3, 0]
```

\textbf{phi}(i)

Return the Kashiwara crystal operator $\varphi_i$ applied to self.

\textbf{INPUT:}

- $i$ – an element of the index set

\textbf{EXAMPLES:}

```
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([[5,4,1],[3,2,1,1]])
sage: [x.phi(i) for i in C.index_set()]
[3, 2, 0]
```

\textbf{weight}()

Return the weight of self.

\textbf{EXAMPLES:}

```
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([[5,4,1],[3,2,1,1]])
sage: x.weight()
3*Lambda[0] - Lambda[1] - 5*delta
sage: x.Phi() - x.Epsilon()
3*Lambda[0] - Lambda[1]
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="right regular")
sage: y = C([[5,1,1],[4,2,2,1,1]])
sage: y.weight()
6*Lambda[0] - 4*Lambda[1] - 4*delta
sage: y.Phi() - y.Epsilon()
6*Lambda[0] - 4*Lambda[1]
```

(continues on next page)

(continued from previous page)

```python
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: y = C([[5,1,1], [4,2,1,1]])
sage: y.weight()
6*Lambda[0] - 4*Lambda[1] - 4*delta
sage: y.Phi() - y.Epsilon()
6*Lambda[0] - 4*Lambda[1]
```

**class** sage.combinat.partition_kleshchev.KleshchevPartition(parent, mu)**

Abstract base class for Kleshchev partitions. See KleshchevPartitions.

**cogood_cells**(i=None)**

Return a list of the cells of self that are cogood.

The cogood \( i \)-cell is the ‘last’ conormal \( i \)-cell. As with the conormal cells we can choose to read either up or down the partition as specified by convention().

**INPUT:**

- **i** – (optional) a residue

**OUTPUT:**

If no residue \( i \) is specified then a dictionary of cogood cells is returned, which gives the cogood cells for \( 0 \leq i < e \).

**EXAMPLES:**

```python
sage: KP = KleshchevPartitions(3, convention="regular")
sage: KP([5,4,4,3,2]).cogood_cells()
{0: (1, 4), 1: (4, 2)}
sage: KP([5,4,4,3,2]).cogood_cells(0)
(1, 4)
sage: KP([5,4,4,3,2]).cogood_cells(1)
(4, 2)
sage: KP = KleshchevPartitions(4, convention='restricted')
sage: KP([5,4,4,3,2]).cogood_cells()
{1: (0, 5), 2: (4, 2), 3: (1, 4)}
sage: KP([5,4,4,3,2]).cogood_cells(0)
sage: KP([5,4,4,3,2]).cogood_cells(2)
```

**conormal_cells**(i=None)**

Return a dictionary of the cells of self which are conormal.

Following [Kle1995], the conormal cells are computed by reading up (or down) the rows of the partition and marking all of the addable and removable cells of \( e \)-residue \( i \) and then recursively removing all adjacent pairs of removable and addable cells (in that order) from this list. The addable \( i \)-cells that remain at the end of the this process are the conormal \( i \)-cells.

When computing conormal cells you can either read the cells in order from top to bottom (this corresponds to labeling the simple modules of the symmetric group by regular partitions) or from bottom to top (corresponding to labeling the simples by restricted partitions). By default we read down the partition but this can be changed by setting 

```
convention = 'RS'.
```

**INPUT:**

- **i** – (optional) a residue
If no residue $i$ is specified then a dictionary of conormal cells is returned, which gives the conormal cells for $0 \leq i < e$.

**EXAMPLES:**

```python
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).conormal_cells()
{0: [(1, 4)], 1: [(5, 0), (4, 2)]}
sage: KP([5,4,4,3,2]).conormal_cells(0)
[(1, 4)]
sage: KP([5,4,4,3,2]).conormal_cells(1)
[(5, 0), (4, 2)]
sage: KP = KleshchevPartitions(3, convention='restricted')
sage: KP([5,4,4,3,2]).conormal_cells()
{0: [(1, 4), (3, 3)], 2: [(0, 5)]}
```

**good_cell_sequence()**

Return a sequence of good nodes from the empty partition to `self`, or `None` if no such sequence exists.

**EXAMPLES:**

```python
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).good_cell_sequence()
[(0, 0), (1, 0), (0, 1), (2, 0), (1, 1), (0, 2),
(3, 0), (2, 1), (1, 2), (3, 1), (0, 3), (1, 3),
(2, 2), (3, 2), (4, 0), (4, 1), (0, 4), (2, 3)]
sage: KP = KleshchevPartitions(3, convention='restricted')
sage: KP([5,4,4,3,2]).good_cell_sequence()
[(0, 0), (0, 1), (1, 0), (0, 2), (1, 1), (2, 0),
(0, 3), (2, 1), (1, 2), (1, 3), (3, 0), (3, 1),
(2, 2), (4, 0), (2, 3), (3, 2), (0, 4), (4, 1)]
```

**good_cells($i=None$)**

Return a list of the cells of `self` that are good.

The good $i$-cell is the ‘first’ normal $i$-cell. As with the normal cells we can choose to read either up or down the partition as specified by `convention()`.

**INPUT:**

- $i$ – (optional) a residue

**OUTPUT:**

If no residue $i$ is specified then a dictionary of good cells is returned, which gives the good cells for $0 \leq i < e$.

**EXAMPLES:**

```python
sage: KP3 = KleshchevPartitions(3, convention='regular')
sage: KP3([5,4,4,3,2]).good_cells()
{1: (2, 3)}
sage: KP3([5,4,4,3,2]).good_cells(1)
(2, 3)
sage: KP4 = KleshchevPartitions(4, convention='restricted')
sage: KP4([5,4,4,3,2]).good_cells()
{1: (2, 3)}
sage: KP4([5,4,4,3,2]).good_cells(0)
```

(continues on next page)
good_residue_sequence()
Return a sequence of good nodes from the empty partition to self, or None if no such sequence exists.

EXAMPLES:

```
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).good_residue_sequence()
[0, 2, 1, 1, 0, 2, 0, 2, 2, 0, 1, 1]
sage: KP = KleshchevPartitions(3, convention='restricted')
sage: KP([5,4,4,3,2]).good_residue_sequence()
[0, 1, 2, 2, 0, 1, 0, 2, 1, 2, 0, 1, 0, 2, 1, 2, 2, 0, 1, 1]
```

is_regular()
Return True if self is a $\epsilon$-regular partition tuple.

A partition tuple is $\epsilon$-regular if we can get to the empty partition tuple by successively removing a sequence of good cells in the down direction. Equivalently, all partitions are 0-regular and if $\epsilon > 0$ then a partition is $\epsilon$-regular if no $\epsilon$ non-zero parts of self are equal.

EXAMPLES:

```
sage: KP = KleshchevPartitions(2)
sage: KP([2,1,1]).is_regular()
False
sage: KP = KleshchevPartitions(3)
sage: KP([2,1,1]).is_regular()
True
sage: KP([]).is_regular()
True
```

is_restricted()
Return True if self is an $\epsilon$-restricted partition tuple.

A partition tuple is $\epsilon$-restricted if we can get to the empty partition tuple by successively removing a sequence of good cells in the up direction. Equivalently, all partitions are 0-restricted and if $\epsilon > 0$ then a partition is $\epsilon$-restricted if the difference of successive parts of self are always strictly less than $\epsilon$.

EXAMPLES:

```
sage: KP = KleshchevPartitions(2, convention='regular')
sage: KP([3,1]).is_restricted()
False
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([3,1]).is_restricted()
True
sage: KP([]).is_restricted()
True
```

mullineux_conjugate()
Return the partition tuple that is the Mullineux conjugate of self.

It follows from results in [BK2009], [Mat2015] that if $\nu$ is the Mullineux conjugate of the Kleshchev partition tuple $\mu$ then the simple module $D^\nu = (D^\mu)^{sgn}$ is obtained from $D^\mu$ by twisting by the sgn-automorphism with is the Iwahori-Hecke algebra analogue of tensoring with the one dimensional sign representation.
EXAMPLES:

```python
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).mullineux_conjugate()  
[9, 7, 1, 1]
sage: KP = KleshchevPartitions(3, convention='restricted')
sage: KP([5,4,4,3,2]).mullineux_conjugate()  
[3, 2, 2, 2, 2, 2, 1, 1, 1]
sage: KP = KleshchevPartitions(3, [2], convention='regular')
sage: mc = KP([5,4,4,3,2]).mullineux_conjugate(); mc  
[9, 7, 1, 1]
sage: mc.parent().multicharge()  
(1,)
sage: KP = KleshchevPartitions(3, [2], convention='restricted')
sage: mc = KP([5,4,4,3,2]).mullineux_conjugate(); mc  
[3, 2, 2, 2, 2, 2, 1, 1, 1]
sage: mc.parent().multicharge()  
(1,)
```

normal_cells (i=None)

Return a dictionary of the cells of the partition that are normal.

Following [Kle1995], the normal cells are computed by reading up (or down) the rows of the partition and marking all of the addable and removable cells of $e$-residue $i$ and then recursively removing all adjacent pairs of removable and addable cells (in that order) from this list. The removable $i$-cells that remain at the end of the this process are the normal $i$-cells.

When computing normal cells you can either read the cells in order from top to bottom (this corresponds to labeling the simple modules of the symmetric group by regular partitions) or from bottom to top (corresponding to labeling the simples by restricted partitions). By default we read down the partition but this can be changed by setting convention = 'RS'.

INPUT:

- i – (optional) a residue

OUTPUT:

If no residue $i$ is specified then a dictionary of normal cells is returned, which gives the normal cells for $0 <= i < e$.

EXAMPLES:

```python
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).normal_cells()  
{1: [(2, 3), (0, 4)]}
sage: KP([5,4,4,3,2]).normal_cells(1)  
[(2, 3), (0, 4)]
sage: KP = KleshchevPartitions(3, [2], convention='restricted')
sage: KP([5,4,4,3,2]).normal_cells()  
{0: [(4, 1)], 2: [(3, 2)]}
sage: KP([5,4,4,3,2]).normal_cells(2)  
[(3, 2)]
```

class sage.combinat.partition_kleshchev.KleshchevPartitionCrystal (parent, mu)

Kleshchev partition with the crystal structure.
Return the action of \( e_i \) on \( self \).

**INPUT:**
- \( i \) – an element of the index set

**EXAMPLES:**

```python
sage: C = crystals.KleshchevPartitions(3, convention="left regular")
sage: x = C([5,4,1])
sage: x.e(0)
[5, 4]
sage: x.e(1)
[5, 4, 1]
sage: x.e(2)
[5, 4, 2]
```

Return the action of \( f_i \) on \( self \).

**INPUT:**
- \( i \) – an element of the index set

**EXAMPLES:**

```python
sage: C = crystals.KleshchevPartitions(3, convention="left regular")
sage: x = C([5,4,1])
sage: x.f(0)
[5, 5, 1]
sage: x.f(1)
[5, 4, 2]
sage: x.f(2)
[5, 4, 2]
```

**class** `sage.combinat.partition_kleshchev.KleshchevPartitionTuple` *(parent, mu)*

Abstract base class for Kleshchev partition tuples. See `KleshchevPartitions`.

**cogood_cells** *(i=None)*

Return a list of the cells of the partition that are cogood.

The cogood \( i \)-cell is the ‘last’ conormal \( i \)-cell. As with the conormal cells we can choose to read either up or down the partition as specified by `convention()`.

**INPUT:**
- \( i \) – (optional) a residue

**OUTPUT:**
If no residue \( i \) is specified then a dictionary of cogood cells is returned, which gives the cogood cells for \( 0 \leq i < e \).

**EXAMPLES:**

```python
sage: KP = KleshchevPartitions(3, [0,1])
sage: pt = KP([[4, 2], [5, 3, 1]])
sage: pt.cogood_cells()
{(0, 1, 2, 1), (1, 3, 0)}
sage: pt.cogood_cells(0)
(1, 2, 1)
sage: KP = KleshchevPartitions(4, [0,1], convention="left regular")
sage: pt = KP([[5, 2, 2], [6, 1, 1]])
```
conormal_cells \( (i=None) \)

Return a dictionary of the cells of the partition that are conormal.

Following [Kle1995], the \textit{conormal} cells are computed by reading up (or down) the rows of the partition and marking all of the addable and removable cells of \( e \)-residue \( i \) and then recursively removing all adjacent pairs of removable and addable cells (in that order) from this list. The addable \( i \)-cells that remain at the end of the this process are the conormal \( i \)-cells.

When computing conormal cells you can either read the cells in order from top to bottom (this corresponds to labeling the simple modules of the symmetric group by regular partitions) or from bottom to top (corresponding to labeling the simples by restricted partitions). By default we read down the partition but this can be changed by setting \texttt{convention = 'RS'}.  

INPUT:

- \( i \) – (optional) a residue

OUTPUT:

If no residue \( i \) is specified then a dictionary of conormal cells is returned, which gives the conormal cells for \( 0 \leq i < e \).

EXAMPLES:

```python
sage: KP = KleshchevPartitions(3, [0,1], convention="left regular")
sage: KP([[4,2], [5,3,1]]).conormal_cells()
{0: [(1, 2, 1), (1, 1, 3), (1, 0, 5)],
 1: [(1, 3, 0), (0, 2, 0), (0, 1, 2), (0, 0, 4)]}
sage: KP([[4,2], [5,3,1]]).conormal_cells(1)
[(1, 3, 0), (0, 2, 0), (0, 1, 2), (0, 0, 4)]
sage: KP([[4,2], [5,3,1]]).conormal_cells(2)
[]
sage: KP = KleshchevPartitions(3, [0,1], convention="right restricted")
sage: KP([[4,2], [5,3,1]]).conormal_cells(0)
[(1, 0, 5), (1, 1, 3), (1, 2, 1)]
```

good_cell_sequence()

Return a sequence of good nodes from the empty partition to self.

EXAMPLES:

```python
sage: KP = KleshchevPartitions(3, [0,1])
sage: KP([[4,2], [5,3,1]]).good_cell_sequence()
[(0, 0, 0), (1, 0, 0), (1, 0, 1), (0, 0, 1), (0, 1, 0),
  (1, 1, 0), (1, 1, 1), (1, 0, 2), (1, 2, 0), (0, 0, 2),
  (0, 1, 1), (1, 0, 3), (0, 0, 3), (1, 1, 2), (1, 0, 4)]
```

good_cells \( (i=None) \)

Return a list of the cells of the partition tuple which are good.

The good \( i \)-cell is the ‘first’ normal \( i \)-cell. As with the normal cells we can choose to read either up or down the partition as specified by \texttt{convention()}.  

```python
sage: pt = KleshchevPartitions(3, [0,1], convention="left regular")
sage: pt.cogood_cells()
{1: [(0, 0, 5), (1, 3, 0)], 2: [(1, 0, 5), (1, 1, 3), (1, 2, 1)]}
sage: pt.cogood_cells(0)
is None
True
sage: pt.cogood_cells(1)
is None
False
```
INPUT:

- \( i \) – (optional) a residue

OUTPUT:

If no residue \( i \) is specified then a dictionary of good cells is returned, which gives the good cells for \( 0 \leq i < e \).

EXAMPLES:

```
sage: KP = KleshchevPartitions(3, [0,1])
sage: pt = KP([[4, 2], [5, 3, 1]])
sage: pt.good_cells()
{2: (1, 0, 4)}
sage: pt.good_cells(2)
(1, 0, 4)
sage: KP = KleshchevPartitions(4, [0,1], convention="left regular")
sage: pt = KP([[5, 2, 2], [6, 2, 1]])
sage: pt.good_cells()
{0: (0, 0, 4), 2: (1, 0, 5), 3: (0, 2, 1)}
sage: pt.good_cells(1) is None
True
```

```
good_residue_sequence()  
Return a sequence of good nodes from the empty partition to self.

EXAMPLES:

```
sage: KP = KleshchevPartitions(3, [0,1])
sage: KP([[4, 2], [5, 3, 1]]).good_residue_sequence()
[0, 1, 2, 1, 2, 0, 1, 0, 2, 2, 0, 1, 0, 2, 2]
```

```
is_regular()  
Return True if self is a \( e \)-regular partition tuple.

A partition tuple is \( e \)-regular if we can get to the empty partition tuple by successively removing a sequence of good cells in the down direction.

EXAMPLES:

```
sage: KP = KleshchevPartitions(2, [0,2], convention="right restricted")
sage: KP([[3,2,1], [2,1,1]]).is_regular()
False
sage: KP = KleshchevPartitions(4, [0,2], convention="right restricted")
sage: KP([[3,2,1], [2,1,1]]).is_regular()
True
sage: KP([[], []]).is_regular()
True
```

```
is_restricted()  
Return True if self is an \( e \)-restricted partition tuple.

A partition tuple is \( e \)-restricted if we can get to the empty partition tuple by successively removing a sequence of good cells in the up direction.

EXAMPLES:

```
sage: KP = KleshchevPartitions(2, [0,2], convention="left regular")
sage: KP([[3,2,1], [3,1]]).is_restricted()
False
(continues on next page)
```
sage: KP = KleshchevPartitions(3, [0,2], convention="left regular")
sage: KP([[[3,2,1], [3,1]]]).is_restricted()
True
sage: KP([[[], []]]).is_restricted()
True

**mullineux_conjugate()**

Return the partition that is the Mullineux conjugate of `self`.

It follows from results in [Kle1996] [Bru1998] that if \( \nu \) is the Mullineux conjugate of the Kleshchev partition tuple \( \mu \) then the simple module \( D^\nu = (D^\mu)^{\text{sgn}} \) is obtained from \( D^\mu \) by twisting by the sgn-automorphism with is the Hecke algebra analogue of tensoring with the one dimensional sign representation.

**EXAMPLES:**

sage: KP = KleshchevPartitions(3, [0,1])
sage: mc = KP([[4, 2], [5, 3, 1]]).mullineux_conjugate(); mc
([2, 2, 1, 1], [3, 2, 2, 1, 1])
sage: mc.parent()
Kleshchev partitions with e=3 and multicharge=(0,2)

**normal_cells**(i=None)

Return a dictionary of the removable cells of the partition that are normal.

Following [Kle1995], the normal cells are computed by reading up (or down) the rows of the partition and marking all of the addable and removable cells of \( e \)-residue \( i \) and then recursively removing all adjacent pairs of removable and addable cells (in that order) from this list. The removable \( i \)-cells that remain at the end of this process are the normal \( i \)-cells.

When computing normal cells you can either read the cells in order from top to bottom (this corresponds to labeling the simple modules of the symmetric group by regular partitions) or from bottom to top (corresponding to labeling the simples by restricted partitions). By default we read down the partition but this can be changed by setting `convention = 'RS'`.

**INPUT:**

- `i` – (optional) a residue

**OUTPUT:**

If no residue \( i \) is specified then a dictionary of normal cells is returned, which gives the normal cells for 0 \( \leq i < e \).

**EXAMPLES:**

sage: KP = KleshchevPartitions(3, [0,1], convention="left restricted")
sage: KP([[4, 2], [5, 3, 1]]).normal_cells()
{0: [(0, 1, 1), (0, 0, 3)], 2: [(1, 2, 0), (1, 1, 2), (1, 2, 4)]}
sage: KP([[4, 2], [5, 3, 1]]).normal_cells(1)
[]
sage: KP = KleshchevPartitions(3, [0,1], convention="left regular")

(continues on next page)
class sage.combinat.partition_kleshchev.KleshchevPartitionTupleCrystal(parent, mu)

Kleshchev partition tuple with the crystal structure.

e(i)
Return the action of $e_i$ on self.

INPUT:
• $i$ – an element of the index set

EXAMPLES:

\[
\begin{align*}
\text{sage: } & C = \text{crystals.KleshchevPartitions}(3, [0,2], \text{convention="left regular"}) \\
\text{sage: } & x = C([[5,4,1],[3,2,1,1]]) \\
\text{sage: } & x.e(0) \\
\text{sage: } & x.e(1) \\
& ([5, 4, 1], [2, 2, 1, 1])
\end{align*}
\]

f(i)
Return the action of $f_i$ on self.

INPUT:
• $i$ – an element of the index set

EXAMPLES:

\[
\begin{align*}
\text{sage: } & C = \text{crystals.KleshchevPartitions}(3, [0,2], \text{convention="left regular"}) \\
\text{sage: } & x = C([[5,4,1],[3,2,1,1]]) \\
\text{sage: } & x.f(0) \\
& ([5, 5, 1], [3, 2, 1, 1]) \\
\text{sage: } & x.f(1) \\
& ([5, 4, 1], [3, 2, 2, 1]) \\
\text{sage: } & x.f(2)
\end{align*}
\]

class sage.combinat.partition_kleshchev.KleshchevPartitions

Kleshchev partitions

A partition (tuple) $\mu$ is Kleshchev if it can be recursively obtained by adding a sequence of good nodes to the empty PartitionTuple of the same level() and multicharge.

There are four different conventions that are used in the literature for Kleshchev partitions, depending on whether we read partitions from top to bottom (regular) or bottom to top (restricted) and whether we read partition tuples from left to right or right to left. All of these conventions are supported:

\[
\begin{align*}
\text{sage: } & \text{KleshchevPartitions}(2, [0,0], \text{size=2, convention='left regular'})[:]
& [[[1], [1]], [[2], [1]]] \\
\text{sage: } & \text{KleshchevPartitions}(2, [0,0], \text{size=2, convention='left restricted'})[:]
& [[[1], [1]], [([], [1, 1])]] \\
\text{sage: } & \text{KleshchevPartitions}(2, [0,0], \text{size=2, convention='right regular'})[:]
& [[[1], [1]], [([], [2])]]
\end{align*}
\]
sage: KleshchevPartitions(2, [0,0], size=2, convention='right restricted')[:]
  [([1], [1]), ([1, 1], [])]

By default, the left restricted convention is used. As a shorthand, LG, LS, RG and RS, respectively, can be used to specify the convention. With the left convention the partition tuples should be ordered with the most dominant partitions in the partition tuple on the left and with the right convention the most dominant partition is on the right.

The KleshchevPartitions class will automatically convert between these four different conventions:

```
sage: KP1g = KleshchevPartitions(2, [0,0], size=2, convention='left regular')
sage: KP1s = KleshchevPartitions(2, [0,0], size=2, convention='left restricted')
sage: [KP1g(mu) for mu in KP1s]
  [([1], [1]), ([2], [])]
```

EXAMPLES:

```
sage: sorted(KleshchevPartitions(5,[3,2,1],1, convention='RS'))
  [([], [], [1]), ([], [1], []), ([1], [], [])]
sage: sorted(KleshchevPartitions(5, [3,2,1], 1, convention='LS'))
  [([], [], [1]), ([], [1], []), ([1], [], [])]
sage: sorted(KleshchevPartitions(5, [3,2,1], 3))
  [([], [], [1, 1, 1]), ([], [1], [1, 1]), ([], [1], [2]), ([1, 1], [], []), ([1], [1], [1]), ([1], [2], []), ([1], [3], []), ([1], [1, 1], []), ([2], [], []), ([2], [1], []), ([3], [], [])]
sage: sorted(KleshchevPartitions(5, [3,2,1], 3, convention="left regular"))
  [([], [], [1, 1, 1]), ([], [1], [1, 1]), ([], [1], [2]), ([1, 1], [], []), ([1], [1], [1]), ([1], [2], []), ([1], [3], []), ([1], [1, 1], []), ([2], [], []), ([2], [1], []), ([3], [], []), ([3], [1], [])]
```

REFERENCES:
• [AM2000]
• [Ariki2001]
• [BK2009]
• [Kle2009]

**convention()**
Return the convention of self.

```python
sage: KP = KleshchevPartitions(4)
sage: KP.convention()
'restricted'
sage: KP = KleshchevPartitions(6, [4], 3, convention="right regular")
sage: KP.convention()
'regular'
sage: KP = KleshchevPartitions(5, [3,0,1], 1)
sage: KP.convention()
'left restricted'
sage: KP = KleshchevPartitions(5, [3,0,1], 1, convention='right regular')
sage: KP.convention()
'right regular'
```

**multicharge()**
Return the multicharge of self.

```python
sage: KP = KleshchevPartitions(6, [2])
sage: KP.multicharge()
(2,)
sage: KP = KleshchevPartitions(5, [3,0,1], 1, convention='LS')
sage: KP.multicharge()
(3, 0, 1)
```

**class** `sage.combinat.partition_kleshchev.KleshchevPartitions_all`(*e, multicharge, convention*)

Bases: `sage.combinat.partition_kleshchev.KleshchevPartitions`

Class of all Kleshchev partitions.

**Crystal structure**

We consider type $A_{e-1}^{(1)}$ crystals, and let $r = (r_i | r_i \in \mathbb{Z}/e\mathbb{Z})$ be a finite sequence of length $k$, which is the *level*, and $\lambda = \sum_1^k \lambda_i r_i$. We will model the highest weight $U_q(g)$-crystal $B(\lambda)$ by a particular subset of partition tuples of level $k$.

Consider a partition tuple $\mu$ with multicharge $r$. We define $e_i(\mu)$ as the partition tuple obtained after the deletion of the $i$-good cell to $\mu$ and 0 if there is no $i$-good cell. We define $f_i(\mu)$ as the partition tuple obtained by the addition of the $i$-cogood cell to $\mu$ and 0 if there is no $i$-good cell.

The crystal $B(\lambda)$ is the crystal generated by the empty partition tuple. We can compute the weight of an element $\mu$ by taking $\lambda - \sum_{i=0}^n c_i \alpha_i$ where $c_i$ is the number of cells of $n$-residue $i$ in $\mu$. Partition tuples in the crystal are known as *Kleshchev partitions*. 
Note: We can describe normal (not restricted) Kleshchev partition tuples in $B(\lambda)$ as partition tuples $\mu$ such that $\mu^{(t)}_{r_t-r_{t+1}+x} < \mu^{(t+1)}_{r_t}$ for all $x \geq 1$ and $1 \leq t \leq k - 1$.

INPUT:

- `e` – for type $A_{e-1}^{(1)}$ or 0
- `multicharge` – the multicharge sequence $r$
- `convention` – (default: 'LS') the reading convention

EXAMPLES:

We first do an example of a level 1 crystal:

```python
sage: C = crystals.KleshchevPartitions(3, [0], convention="left restricted")
sage: C
Kleshchev partitions with e=3
sage: mg = C.highest_weight_vector()
sage: mg
[]
sage: mg.f(0)
[1]
sage: mg.f(1)
sage: mg.f(2)
sage: mg.f_string([0,2,1,0])
[1, 1, 1, 1]
sage: mg.f_string([0,1,2,0])
[2, 2]
sage: GC = C.subcrystal(max_depth=5).digraph()
sage: B = crystals.LSPaths(['A',2,1], [1,0,0])
sage: GB = B.subcrystal(max_depth=5).digraph()
sage: GC.is_isomorphic(GB, edge_labels=True)
True
```

Now a higher level crystal:

```python
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="right restricted")
sage: mg = C.highest_weight_vector()
sage: mg
([], [])
sage: mg.f(0)
([], [])
sage: mg.f(1)
([], [])
sage: mg.f(2)
([], [])
sage: mg.f_string([0,1,2,0])
([2, 2], [])
sage: mg.f_string([0,2,1,0])
([], [], [], [], [])
sage: mg.f_string([2,0,1,0])
([2], [2])
sage: GC = C.subcrystal(max_depth=5).digraph()
sage: B = crystals.LSPaths(['A',2,1], [1,0,1])
sage: GB = B.subcrystal(max_depth=5).digraph()
sage: GC.is_isomorphic(GB, edge_labels=True)
True
```

The ordering of the residues gives a different representation of the higher level crystals (but it is still isomorphic):
```python
sage: C2 = crystals.KleshchevPartitions(3, [2,0], convention="right restricted")
sage: mg2 = C2.highest_weight_vector()
sage: mg2.f_string([0,1,2,0])
([2], [2])
sage: mg2.f_string([0,2,1,0])
([1, 1, 1], [1])
sage: mg2.f_string([2,0,1,0])
([2, 1], [1])
sage: GC2 = C2.subcrystal(max_depth=5).digraph()
sage: GC.is_isomorphic(GC2, edge_labels=True)
True
```

Kleshchev partitions of a fixed size.

Element
    alias of KleshchevPartitionTuple
```

### 5.1.168 Partition Shifting Algebras

This module contains families of operators that act on partitions or, more generally, integer sequences. In particular, this includes Young’s raising operators $R_{ij}$, which act on integer sequences by adding 1 to the $i$-th entry and subtracting 1 to the $j$-th entry. A special case is acting on partitions.

AUTHORS:

```python
class sage.combinat.partition_shifting_algebras.ShiftingOperatorAlgebra(base_ring=Univariate Polynomial Ring in t over Rational Field, prefix='S')
```
Bases: `sage.combinat.free_module.CombinatorialFreeModule`

An algebra of shifting operators.

Let $R$ be a commutative ring. The algebra of shifting operators is isomorphic as an $R$-algebra to the Laurent polynomial ring $R[x_1^\pm, x_2^\pm, x_3^\pm, \ldots]$. Moreover, the monomials of the shifting operator algebra act on any integer sequence $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell)$ as follows. Let $S$ be our algebra of shifting operators. Then, for any monomial $s = x_1^{a_1} \cdot x_2^{a_2} \cdot \ldots \cdot x_r^{a_r} \in S$ where $a_i \in \mathbb{Z}$ and $r \geq \ell$, we get that $s.\lambda = (\lambda_1 + a_1, \lambda_2 + a_2, \ldots, \lambda_r + a_r)$ where we pad $\lambda$ with $r - \ell$ zeros. In particular, we can recover Young’s raising operator, $R_{ij}$, for $i < j$, acting on partitions by having $\frac{\partial}{\partial x_j}$ act on a partition $\lambda$.

One can extend the action of these shifting operators to a basis of symmetric functions, but at the expense of no longer actually having a well-defined operator. Formally, to extend the action of the shifting operators on a symmetric function basis $B = \{b_\lambda\}_\lambda$, we define an $R$-module homomorphism $\phi : R[x_1^\pm, x_2^\pm, \ldots] \to B$. Then we compute $x_1^{a_1} \cdot x_2^{a_2} \cdot \ldots \cdot x_r^{a_r}.b_\lambda$ by first computing $(x_1^{a_1} \cdot \ldots \cdot x_r^{a_r}).x_1^{\lambda_1} \cdot \ldots \cdot x_\ell^{\lambda_\ell}$ and then applying $\phi$ to the result. For examples of what this looks like with specific bases, see below.

This implementation is consistent with how many references work formally with raising operators. For instance, see exposition surrounding [BMPS2018] Equation (4.1).

We follow the following convention for creating elements: $S(1, 0, -1, 2)$ is the shifting operator that raises the first part by 1, lowers the third part by 1, and raises the fourth part by 2.

In addition to acting on partitions (or any integer sequence), the shifting operators can also act on symmetric functions in a basis $B$ when a conversion to $B$ has been registered, preferably using `build_and_register_conversion()`.

For a definition of raising operators, see [BMPS2018] Definition 2.1. See `ij()` to create operators using the notation in [BMPS2018].

INPUT:

- `base_ring` (default: $\mathbb{Q}[t]$) the base ring
- `prefix` (default: "S") the label for the shifting operators

EXAMPLES:

```python
sage: S = ShiftingOperatorAlgebra()

sage: elm = S[1, -1, 2]; elm
S(1, -1, 2)
sage: elm([5, 4])
[[[6, 3, 2], 1]]
```

The shifting operator monomials can act on a complete homogeneous symmetric function or a Schur function:

```python
sage: s = SymmetricFunctions(QQ['t']).s()
sage: h = SymmetricFunctions(QQ['t']).h()

sage: elm(s[5, 4])
s[6, 3, 2]
sage: elm(h[5, 4])
h[6, 3, 2]

sage: S[1, -1](s[5, 4])
s[6, 3]
sage: S[1, -1](h[5, 4])
h[6, 3]
```

In fact, we can extend this action by linearity:
```
sage: elm = (1 - S[1,-1]) * (1 - S[4])
sage: elm == S([]) - S([1, -1]) - S([4]) + S([5, -1])
True
sage: elm(s[2, 2, 1])
s[2, 2, 1] - s[3, 1, 1] - s[6, 2, 1] + s[7, 1, 1]

sage: elm = (1 - S[1,-1]) * (1 - S[0,1,-1])
sage: elm == 1 - S[0,1,-1] - S[1,-1] + S[1,0,-1]
True
sage: elm(s[2, 2, 1])
s[2, 2, 1] - s[3, 1, 1] + s[3, 2]
```

The algebra also comes equipped with homomorphisms to various symmetric function bases; these homomorphisms are how the action of $S$ on the specific symmetric function bases is implemented:

```
sage: elm = S([3,1,2]); elm
S(3, 1, 2)
sage: h(elm)
h[3, 2, 1]
sage: s(elm)
0
```

However, not all homomorphisms are equivalent, so the action is basis dependent:

```
sage: elm = S([3,2,1]); elm
S(3, 2, 1)
sage: h(elm)
h[3, 2, 1]
sage: s(elm)
s[3, 2, 1]
sage: s(elm) == s(h(elm))
False
```

We can also use raising operators to implement the Jacobi-Trudi identity:

```
sage: op = (1-S[(1,-1)]) * (1-S[(1,0,-1)]) * (1-S[(0,1,-1)])
sage: s(op(h[3,2,1]))
s[3, 2, 1]
```

```
class Element
    Bases: sage.modules.with_basisindexed_element.IndexedFreeModuleElement
    An element of a ShiftingOperatorAlgebra.

    build_and_register_conversion(support_map, codomain)
    Build a module homomorphism from a map sending integer sequences to codomain and registers the result into Sage's conversion model.
    
The intended use is to define a morphism from self to a basis $B$ of symmetric functions that will be used by ShiftingOperatorAlgebra to define the action of the operators on $B$.

    Note: The actions on the complete homogeneous symmetric functions and on the Schur functions by morphisms are already registered.
```
Warning: Because ShiftingOperatorAlgebra inherits from UniqueRepresentation, once you register a conversion, this will apply to all instances of ShiftingOperatorAlgebra over the same base ring with the same prefix.

INPUT:

- support_map – a map from integer sequences to codomain
- codomain – the codomain of support_map, usually a basis of symmetric functions

EXAMPLES:

```python
sage: S = ShiftingOperatorAlgebra(QQ)
sage: sym = SymmetricFunctions(QQ)
sage: p = sym.p()
sage: zero_map = lambda part: p.zero()
sage: S.build_and_register_conversion(zero_map, p)
sage: p(2*S([1,0,-1]) + S([2,1,0]) - 3*S([0,1,3]))
0
sage: op = S.ij(0, 1)
True
```

For a more illustrative example, we can implement a simple (but not mathematically justified!) conversion on the monomial basis:

```python
sage: S = ShiftingOperatorAlgebra(QQ)
sage: sym = SymmetricFunctions(QQ)
sage: m = sym.m()
sage: def supp_map(gamma):
...:     gsort = sorted(gamma, reverse=True)
...:     return m(gsort) if gsort in Partitions() else m.zero()
sage: S.build_and_register_conversion(supp_map, m)
sage: op = S.ij(0, 1)
sage: op(2*m[4,3] + 5*m[2,2] + 7*m[2]) == 2*m[5, 2] + 5*m[3, 1]
True
```

\(i j(i, j)\)

Return the raising operator \(R_{ij}\) as notated in [BMPS2018] Definition 2.1.

Shorthand element constructor that allows you to create raising operators using the familiar \(R_{ij}\) notation found in [BMPS2018] Definition 2.1, with the exception that indices here are 0-based, not 1-based.

EXAMPLES:

Create the raising operator which raises part 0 and lowers part 2 (indices are 0-based):

```python
sage: R = ShiftingOperatorAlgebra()
sage: R.ij(0, 2)
```

\(one\_basis()\)

Return the index of the basis element for 1.

EXAMPLES:

```python
sage: S = ShiftingOperatorAlgebra()
sage: S.one_basis()
()`
**product_on_basis** (x, y)
Return the product of basis elements indexed by x and y.

**EXAMPLES:**

```python
sage: S = ShiftingOperatorAlgebra()
sage: S.product_on_basis((0, 5, 2), (3, 2, -2, 5))
S(3, 7, 0, 5)
sage: S.product_on_basis((1, -2, 0, 3, -6), (-1, 2, 2))
S(0, 0, 2, 3, -6)
sage: S.product_on_basis((1, -2, -2), (-1, 2, 2))
S()
```

**class** sage.combinat.partition_shifting_algebras.ShiftingSequenceSpace

**Bases:** sage.misc.fast_methods.Singleton, sage.structure.parent.Parent

A helper for ShiftingOperatorAlgebra that contains all tuples with entries in Z of finite support with no trailing 0's.

**EXAMPLES:**

```python
sage: from sage.combinat.partition_shifting_algebras import ShiftingSequenceSpace
sage: S = ShiftingSequenceSpace()
sage: (1, -1) in S
True
sage: (1, -1, 0, 9) in S
True
sage: [1, -1] in S
False
sage: (0.5, 1) in S
False
```

**check** (seq)
Verify that seq is a valid shifting sequence.
If it is not, raise a ValueError.

**EXAMPLES:**

```python
sage: from sage.combinat.partition_shifting_algebras import ShiftingSequenceSpace
sage: S = ShiftingSequenceSpace()
sage: S.check((1, -1))
sage: S.check((1, -1, 0, 9))
Traceback (most recent call last):
  ... ValueError: invalid index [1, -1]
sage: S.check((0.5, 1))
Traceback (most recent call last):
  ... ValueError: invalid index (0.500000000000000, 1)
```
5.1.169 Partition tuples

A **PartitionTuple** is a tuple of partitions. That is, an ordered \(k\)-tuple of partitions \(\mu = (\mu^{(1)}, \mu^{(2)}, \ldots, \mu^{(k)})\). If

\[ n = |\mu| = |\mu^{(1)}| + |\mu^{(2)}| + \cdots + |\mu^{(k)}| \]

then we say that \(\mu\) is a \(k\)-partition of \(n\).

In representation theory partition tuples arise as the natural indexing set for the ordinary irreducible representations of:

- the wreath products of cyclic groups with symmetric groups,
- the Ariki-Koike algebras, or the cyclotomic Hecke algebras of the complex reflection groups of type \(G(r, 1, n)\),
- the degenerate cyclotomic Hecke algebras of type \(G(r, 1, n)\).

When these algebras are not semisimple, partition tuples index an important class of modules for the algebras, which are generalisations of the Specht modules of the symmetric groups.

Tuples of partitions also index the standard basis of the higher level combinatorial Fock spaces. As a consequence, the combinatorics of partition tuples encapsulates the canonical bases of crystal graphs for the irreducible integrable highest weight modules of the (quantized) affine special linear groups and the (quantized) affine general linear groups. By the categorification theorems of Ariki, Varagnolo-Vasserot, Stroppel-Webster and others, in characteristic zero the degenerate and non-degenerate cyclotomic Hecke algebras, via their Khovanov-Lauda-Rouquier grading, categorify the canonical bases of the quantum affine special and general linear groups.

Partitions are naturally in bijection with 1-tuples of partitions. Most of the combinatorial operations defined on partitions extend to partition tuples in a meaningful way. For example, the semisimple branching rules for the Specht modules are described by adding and removing cells from partition tuples and the modular branching rules correspond to adding and removing good and cogood nodes, which is the underlying combinatorics for the associated crystal graphs.

A **PartitionTuple** belongs to **PartitionTuples** and its derived classes. **PartitionTuples** is the parent class for all partitions tuples. Four different classes of tuples of partitions are currently supported:

- **PartitionTuples**(level=k, size=n) are \(k\)-tuple of partitions of \(n\).
- **PartitionTuples**(level=k) are \(k\)-tuple of partitions.
- **PartitionTuples**(size=n) are tuples of partitions of \(n\).
- **PartitionTuples**() are tuples of partitions.

**Note:** As with **Partitions**, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is \([0, 0, 0]\).

**EXAMPLES:**

```python
sage: PartitionTuple([[2,2],[1,1],[2]]).cells()
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (0, 1, 1), (1, 0, 0), (1, 1, 0), (2, 0, 0), (2, 0, 1)]
```

**Note:** Many **PartitionTuple** methods take the individual coordinates \((k, r, c)\) as their arguments, here \(k\) is the component, \(r\) is the row index and \(c\) is the column index. If your coordinates are in the form \((k, r, c)\) then use Python’s *-operator.

**EXAMPLES:**
sage: mu=PartitionTuple([[1,1],[2],[2,1]])
sage: [ mu.arm_length(*c) for c in mu.cells()]
[0, 0, 1, 0, 1, 0, 0]

**Warning:** In Sage, if \( \mu \) is a partition tuple then \( \mu[k] \) most naturally refers to the \( k \)-th component of \( \mu \), so we use the convention of the \( (k, r, c) \)-th cell in a partition tuple refers to the cell in component \( k \), row \( r \), and column \( c \). In the literature, the cells of a partition tuple are usually written in the form \( (r, c, k) \), where \( r \) is the row index, \( c \) is the column index, and \( k \) is the component index.

**REFERENCES:**

- [DJM1998]
- [BK2009]

**AUTHORS:**

**EXAMPLES:**

First is a finite enumerated set and the remaining classes are infinite enumerated sets:

```python
sage: PartitionTuples().an_element()
([1, 1, 1, 1], [2, 1, 1], [3, 1], [4])
sage: PartitionTuples(4).an_element()
([], [1], [2], [3])
sage: PartitionTuples(size=5).an_element()
([1], [1], [1], [1], [1])
sage: PartitionTuples(4,5).an_element()
([1], [], [], [4])
sage: PartitionTuples(3,2)[:]
([(2), [], []],
 ([1], [1], []),
 ([1], [], []),
 ([1], [2], []),
 ([1], [1, 1], []),
 ([1], [1], [1]),
 ([1], [], [2]),
 ([1], [], [1, 1])),
([1], [], []))
sage: PartitionTuples(2,3).list()
([(3), []],
 ([2, 1], []),
 ([1, 1, 1], []),
 ([2], [1]),
 ([1, 1], [1]),
 ([1], [2]),
 ([1], [1, 1]),
 ([1], [3]),
 ([1], [2, 1]),
 ([1], [1, 1], []))
```

One tuples of partitions are naturally in bijection with partitions and, as far as possible, partition tuples attempts to identify one tuples with partitions:
Partition tuples come equipped with many of the corresponding methods for partitions. For example, it is possible to add and remove cells, to conjugate partition tuples, to work with their diagrams, compare partition tuples in dominance and so:

\[
\text{sage: } \text{PartitionTuple([4,1],[],[2,2,1],[3])}.pp()
\]

\[

\]
Every partition tuple behaves every much like a tuple of partitions:

```
sage: mu=PartitionTuple([[4,1],[2,2,1],[3]])
sage: [ nu for nu in mu ]

[4, 1, [2, 2, 1], [3]]
sage: Set(( type(nu) for nu in mu ))
set('sage.combinat.partition.Partitions_all_with_category.element_class')
sage: mu[2][2]
1
sage: mu[3]
[3]
sage: mu.components()

[[4, 1], [2, 2, 1], [3]]
sage: mu.components() == [ nu for nu in mu ]

True
sage: mu[0]
[4, 1]
sage: mu[1]
[]
sage: mu[2]
[2, 2, 1]
sage: mu[2][0]
2
sage: mu[2][1]
2
sage: mu.level()
4
sage: len(mu)
4
sage: mu.cells()

[(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 0, 3), (0, 1, 0), (2, 0, 0), (2, 0, 1), (2, 1, 0),
 (2, 1, 1), (2, 2, 0), (3, 0, 0), (3, 0, 1), (3, 0, 2)]
sage: mu.addable_cells()

[(0, 0, 4), (0, 1, 1), (0, 2, 0), (1, 0, 0), (2, 0, 2), (2, 2, 1), (2, 3, 0), (3, 0, 3),
 (3, 1, 0)]
sage: mu.removable_cells()

[(0, 0, 3), (0, 1, 0), (2, 1, 1), (2, 2, 0), (3, 0, 2)]
```

Attached to a partition tuple is the corresponding Young, or parabolic, subgroup:

```
sage: mu.young_subgroup()
Permutation Group with generators [(1,2), (11,12), (8,9), (6,7), (3,4), (2,3),
                                      (1,2)]
sage: mu.young_subgroup_generators()

[1, 2, 3, 6, 8, 11, 12]
```

The class `PartitionTuple` is defined as follows:

```
class sage.combinat.partition_tuple.PartitionTuple(parent, mu)
```
Bases: \texttt{sage.combinat.combinat.CombinatorialElement}

A tuple of \texttt{Partition}.

A tuple of partition comes equipped with many of methods available to partitions. The level of the PartitionTuple is the length of the tuple.

This is an ordered \(k\)-tuple of partitions \(\mu = (\mu^{(1)}, \mu^{(2)}, ..., \mu^{(k)})\). If

\[
n = |\mu| = |\mu^{(1)}| + |\mu^{(2)}| + \cdots + |\mu^{(k)}|
\]

then \(\mu\) is a \(k\)-partition of \(n\).

In representation theory PartitionTuples arise as the natural indexing set for the ordinary irreducible representations of:

- the wreath products of cyclic groups with symmetric groups
- the Ariki-Koike algebras, or the cyclotomic Hecke algebras of the complex reflection groups of type \(G(r, 1, n)\)
- the degenerate cyclotomic Hecke algebras of type \(G(r, 1, n)\)

When these algebras are not semisimple, partition tuples index an important class of modules for the algebras which are generalisations of the Specht modules of the symmetric groups.

Tuples of partitions also index the standard basis of the higher level combinatorial Fock spaces. As a consequence, the combinatorics of partition tuples encapsulates the canonical bases of crystal graphs for the irreducible integrable highest weight modules of the (quantized) affine special linear groups and the (quantized) affine general linear groups. By the categorification theorems of Ariki, Varagnolo-Vasserot, Stroppel-Webster and others, in characteristic zero the degenerate and non-degenerate cyclotomic Hecke algebras, via their Khovanov-Lauda-Rouquier grading, categorify the canonical bases of the quantum affine special and general linear groups.

Partitions are naturally in bijection with 1-tuples of partitions. Most of the combinatorial operations defined on partitions extend to PartitionTuples in a meaningful way. For example, the semisimple branching rules for the Specht modules are described by adding and removing cells from partition tuples and the modular branching rules correspond to adding and removing good and cogood nodes, which is the underlying combinatorics for the associated crystal graphs.

**Warning:** In the literature, the cells of a partition tuple are usually written in the form \((r, c, k)\), where \(r\) is the row index, \(c\) is the column index, and \(k\) is the component index. In sage, if \(\mu\) is a partition tuple then \(\mu[k]\) most naturally refers to the \(k\)-th component of \(\mu\), so we use the convention of the \((k, r, c)\)-th cell in a partition tuple refers to the cell in component \(k\), row \(r\), and column \(c\).

**INPUT:**

Anything which can reasonably be interpreted as a tuple of partitions. That is, a list or tuple of partitions or valid input to \texttt{Partition}.

**EXAMPLES:**

```python
sage: mu=PartitionTuple( [[[3,2],[2,1],[1,1,1,1]]]); mu
((3, 2), [2, 1], [1, 1, 1, 1])
sage: mu=PartitionTuple( [[[3,2],[2,1],[1,1,1,1]]]); nu
((3, 2), [2, 1], [1, 1, 1, 1])
sage: mu == nu
True
sage: mu is nu
```

(continues on next page)
False

```

sage: lam.addable_cells()
[(0, 0, 3), (0, 1, 2), (0, 2, 0), (1, 0, 0), (2, 0, 1), (2, 4, 0)]

sage: lam.up_list()
[((4, 2), [], [1, 1, 1, 1]), ([3, 3], [], [1, 1, 1, 1]), ([3, 2, 1], [], [1, 1, 1, 1, 1]), ([3, 2], [], [1, 1, 1, 1, 1]), ([3, 2], [], [1, 1, 1, 1, 1])]

sage: lam.conjugate()
([4], [], [2, 2, 1])

sage: lam.dominates( PartitionTuple([[3],[1],[1,1,1]]) )
False

sage: lam.dominates( PartitionTuple([[3],[2],[1,1]]) )
True
```

See also:

- `PartitionTuples`
- `Partitions`

**Element**

Alias of `sage.combinat.partition.Partition`

**add** _cell_ \((k, r, c)\)

Return the partition tuple obtained by adding a cell in row \(r\), column \(c\), and component \(k\).

This does not change \self.  

---

5.1. **Comprehensive Module list**

1627
EXAMPLES:

```
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).add_cell(0,0,1)
([2, 1], [4, 3], [2, 1, 1])
```

**addable_cells()**
Return a list of the removable cells of this partition tuple.

All indices are of the form \((k, r, c)\), where \(r\) is the row-index, \(c\) is the column index and \(k\) is the component.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[2],[2,1]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 2), (1, 1, 0), (2, 0, 2), (2, 1, 1), (2, 2, 0)]
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 4), (1, 1, 3), (1, 2, 0), (2, 0, 2), (2, 1, 1), ...
  \rightarrow (2, 3, 0)]
```

**arm_length\((k, r, c)\)**
Return the length of the arm of cell \((k, r, c)\) in self.

**INPUT:**

- \(k\) – The component
- \(r\) – The row
- \(c\) – The cell

**OUTPUT:**

- The arm length as an integer

The arm of cell \((k, r, c)\) is the number of cells in the \(k\)-th component which are to the right of the cell in row \(r\) and column \(c\).

EXAMPLES:

```
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).arm_length(2,0,0)
1
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).arm_length(2,0,1)
0
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).arm_length(2,2,0)
0
```

**block\((e, multicharge)\)**
Return a dictionary \(\beta\) that determines the block associated to the partition self and the `quantum_characteristic()` \(e\).

**INPUT:**

- \(e\) – the quantum characteristic
- `multicharge` – the multicharge (default \((0,))\)

**OUTPUT:**

- a dictionary giving the multiplicities of the residues in the partition tuple self
In more detail, the value $\beta[i]$ is equal to the number of nodes of residue $i$. This corresponds to the positive root

$$\sum_{i \in I} \beta_i \alpha_i \in \mathbb{Q}^+,$$

a element of the positive root lattice of the corresponding Kac-Moody algebra. See [DJM1998] and [BK2009] for more details.

This is a useful statistics because two Specht modules for a cyclotomic Hecke algebra of type $A$ belong to the same block if and only if they correspond to same element $\beta$ of the root lattice, given above.

We return a dictionary because when the quantum characteristic is 0, the Cartan type is $A_\infty$, in which case the simple roots are indexed by the integers.

**EXAMPLES:**

```python
sage: PartitionTuple([[2,2],[2,2]]).block(0,(0,0))
{0: 4, 1: 2}

sage: PartitionTuple([[2,2],[2,2]]).block(2,(0,0))
{0: 4, 1: 4}

sage: PartitionTuple([[2,2],[2,2]]).block(2,(0,1))
{0: 4, 1: 4}

sage: PartitionTuple([[2,2],[2,2]]).block(3,(0,2))
{0: 3, 1: 2, 2: 3}

sage: PartitionTuple([[2,2],[2,2]]).block(3,(3,2))
{0: 3, 1: 2, 2: 3}

sage: PartitionTuple([[2,2],[2,2]]).block(4,(0,0))
{0: 4, 1: 2, 3: 2}
```

cells()

Return the coordinates of the cells of self. Coordinates are given as (component index, row index, column index) and are 0 based.

**EXAMPLES:**

```python
sage: PartitionTuple([[2,1],[1],[1,1,1]]).cells()
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (1, 0, 0), (2, 0, 0), (2, 1, 0), (2, 2, 0)]
```

components()

Return a list containing the shape of this partition.

This function exists in order to give a uniform way of iterating over the “components” of partition tuples of level 1 (partitions) and for higher levels.

**EXAMPLES:**

```python
sage: for t in PartitionTuple([[2,1],[3,2],[3]]).components():
  ....:    print('**\n' % t.ferrers_diagram())
**
* 
***
**
```

```python
sage: for t in PartitionTuple([3,2]).components():
  ....:    print('**\n' % t.ferrers_diagram())
**
* 
***
**
```

(continues on next page)
conjugate()  
Return the conjugate partition tuple of self.

The conjugate partition tuple is obtained by reversing the order of the components and then swapping the rows and columns in each component.

EXAMPLES:

```python
sage: PartitionTuple([[2,1],[1],[1,1,1]]).conjugate()
((3), (1), (2, 1))
```

contains(\(\mu\))  
Return True if this partition tuple contains \(\mu\).

If \(\lambda = (\lambda^{(1)}, \ldots, \lambda^{(l)})\) and \(\mu = (\mu^{(1)}, \ldots, \mu^{(m)})\) are two partition tuples then \(\lambda\) contains \(\mu\) if \(m \leq l\) and \(\mu^{(i)}_r \leq \lambda^{(i)}_r\) for \(1 \leq i \leq m\) and \(r \geq 0\).

EXAMPLES:

```python
sage: PartitionTuple([[1,1],[2],[2,1]]).contains( PartitionTuple([[1,1],[2],[2,1]]) )
True
```

content(\(k, r, c, \text{multicharge}\))  
Return the content of the cell.

Let \(m_k = \text{multicharge}[k]\), then the content of a cell is \(m_k + c - r\).

If the multicharge is a list of integers then it simply offsets the values of the contents in each component. On the other hand, if the multicharge belongs to \(\mathbb{Z}/e\mathbb{Z}\) then the corresponding \(e\)-residue is returned (that is, the content mod \(e\)).

As with the content method for partitions, the content of a cell does not technically depend on the partition tuple, but this method is included because it is often useful.

EXAMPLES:

```python
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(0,1,0, [0,0,0])
-1
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(0,1,0, [1,0,0])
0
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(2,1,0, [0,0,0])
-1
```

and now we return the 3-residue of a cell:

```python
sage: multicharge = [IntegerModRing(3)(c) for c in [0,0,0]]
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(0,1,0, multicharge)
2
```

ccontent_tableau (multicharge)  
Return the tableau which has \((k,r,c)\)th entry equal to the content \(\text{multicharge}[k] - r + c\) of this cell.

As with the content function, by setting the multicharge appropriately the tableau containing the residues is returned.
EXAMPLES:

```python
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content_tableau([0,0,0])
([[0, 1], [-1]], [[0, 1]], [[0], [-1], [-2]])
```

as with the content function the multicharge can be used to return the tableau containing the residues of the cells:

```python
sage: multicharge=[ IntegerModRing(3)(c) for c in [0,0,1] ]
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content_tableau(multicharge).pp()
     0 1 0 1 1
    -1 0
     -1
```

corners()
Return a list of the removable cells of this partition tuple.
All indices are of the form (k, r, c), where r is the row-index, c is the column index and k is the component.

EXAMPLES:

```python
sage: PartitionTuple([[1,1],[2],[2,1]]).removable_cells()
[(0, 1, 0), (1, 0, 1), (2, 0, 1), (2, 1, 0)]
```

```python
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).removable_cells()
[(0, 1, 0), (1, 0, 3), (1, 1, 2), (2, 0, 1), (2, 2, 0)]
```

defect (e, multicharge)
Return the e-defect or the e-weight self.
The e-defect is the number of (connected) e-rim hooks that can be removed from the partition.
The defect of a partition tuple is given by
\[
\text{defect}(\beta) = (\Lambda, \beta) - \frac{1}{2}(\beta, \beta),
\]
where \( \Lambda = \sum_{r} \lambda_{r} \) for the multicharge \((\kappa_1, \ldots, \kappa_{\ell})\) and \( \beta = \sum_{(r,c)} \alpha_{(c-r) \ (\text{mod} \ e)} \), with the sum being over the cells in the partition.

INPUT:
• e – the quantum characteristic
• multicharge – the multicharge (default \((0,0)\))

OUTPUT:
• a non-negative integer, which is the defect of the block containing the partition tuple self

EXAMPLES:

```python
sage: PartitionTuple([[2,2],[2,2]]).defect(0,(0,0))
0
```

```python
sage: PartitionTuple([[2,2],[2,2]]).defect(2,(0,0))
8
```

```python
sage: PartitionTuple([[2,2],[2,2]]).defect(2,(0,1))
8
```
(continues on next page)
degree(e)
Return the e-th degree of self.

The e-th degree is the sum of the degrees of the standard tableaux of shape \( \lambda \). The e-th degree is the exponent of \( \Phi_e(q) \) in the Gram determinant of the Specht module for a semisimple cyclotomic Hecke algebra of type \( A \) with parameter \( q \).

For this calculation the multicharge \((\kappa_1, \ldots, \kappa_l)\) is chosen so that \( \kappa_{r+1} - \kappa_r > n \), where \( n \) is the size() of \( \lambda \) as this ensures that the Hecke algebra is semisimple.

INPUT:

- e – an integer \( e > 1 \)

OUTPUT:
A non-negative integer.

EXAMPLES:

```
sage: PartitionTuple([[2,1],[2,2]]).degree(2)
532
sage: PartitionTuple([[2,1],[2,2]]).degree(3)
259
sage: PartitionTuple([[2,1],[2,2]]).degree(4)
196
sage: PartitionTuple([[2,1],[2,2]]).degree(5)
105
sage: PartitionTuple([[2,1],[2,2]]).degree(6)
105
sage: PartitionTuple([[2,1],[2,2]]).degree(7)
0
```

Therefore, the Gram determinant of \( S(2,1|2,2) \) when the Hecke parameter \( q \) is “generic” is

\[
q^N \Phi_2(q)^{532} \Phi_3(q)^{259} \Phi_4(q)^{196} \Phi_5(q)^{105} \Phi_6(q)^{105}
\]

for some integer \( N \). Compare with \prime_degree()\.

diagram()
Return a string for the Ferrers diagram of self.

EXAMPLES:

```
sage: print(PartitionTuple([[2,1],[3,2],[1,1,1]]).diagram())
  ** *** *
  * ** * *
  *   *
sage: print(PartitionTuple([[3,2],[2,1],[1,1,1,1]]).diagram())
*** ** -- *
```
**dominates** *(mu)*

Return True if the PartitionTuple dominates or equals \(\mu\) and False otherwise.

Given partition tuples \(\mu = (\mu^{(1)}, \ldots, \mu^{(m)})\) and \(\nu = (\nu^{(1)}, \ldots, \nu^{(n)})\) then \(\mu\) dominates \(\nu\) if

\[
\sum_{k=1}^{l-1} |\mu^{(k)}| + \sum_{r \geq 1} \mu^{(l)} \geq \sum_{k=1}^{l-1} |\nu^{(k)}| + \sum_{r \geq 1} \nu^{(l)}
\]

**EXAMPLES:**

```
sage: mu=PartitionTuple([[1,1],[2],[2,1]])
sage: nu=PartitionTuple([[1,1],[1,1],[2,1]])
sage: mu.dominates(mu) True  
sage: mu.dominates(nu) True  
sage: nu.dominates(mu) False  
sage: tau=PartitionTuple([[],[2,1],[]])
sage: tau.dominates([[]],[2,1])  
sage: tau.dominates([[]],[2,1]) False  
sage: tau.dominates([[]],[2,1]) True
```

down ()

Generator (iterator) for the partition tuples that are obtained from self by removing a cell.

**EXAMPLES:**

```
sage: [mu for mu in PartitionTuple([[1],[3,1],[1,1]]).down()]
[([1], [2, 1], [1, 1]), ([1], [3], [1, 1]), ([1], [3, 1], [1])]
sage: [mu for mu in PartitionTuple([[1],[1],[1]]).down()]
[]
```

down_list ()

Return a list of the partition tuples that can be formed from self by removing a cell.

**EXAMPLES:**

```
sage: PartitionTuple([[1],[3,1],[1,1]]).down_list()
[([1], [2, 1], [1, 1]), ([1], [3], [1, 1]), ([1], [3, 1], [1])]
sage: PartitionTuple([[1],[1],[1]]).down_list()
[]
```

**ferrers_diagram ()**

Return a string for the Ferrers diagram of self.
EXAMPLES:

```
sage: print(PartitionTuple([[2,1],[3,2],[1,1,1]]).diagram())
** *** *
* ** *

sage: print(PartitionTuple([[3,2],[2,1],[],[1,1,1,1]]).diagram())
*** ** - *
** * *
*
*
sage: PartitionTuples.options(convention="french")
sage: print(PartitionTuple([[3,2],[2,1],[],[1,1,1,1]]).diagram())
*
*
** * *
*** ** - *
sage: PartitionTuples.options._reset()
```

garnir_tableau(*cell)

Return the Garnir tableau of shape self corresponding to the cell cell.

If cell = (k, a, c) then (k, a+1, c) must belong to the diagram of the PartitionTuple. If this is not the case then we return False.

Note: The function also sets g._garnir_cell equal to cell which is used by some other functions.

The Garnir tableaux play an important role in integral and non-semisimple representation theory because they determine the "straightening" rules for the Specht modules over an arbitrary ring.

The Garnir tableau are the “first” non-standard tableaux which arise when you act by simple transpositions. If (k, a, c) is a cell in the Young diagram of a partition, which is not at the bottom of its column, then the corresponding Garnir tableau has the integers 1, 2, ..., n entered in order from left to right along the rows of the diagram up to the cell (k, a, c − 1), then along the cells (k, a + 1, c) to (k, a + 1, c), then (k, a, c) until the end of row a and then continuing from left to right in the remaining positions. The examples below probably make this clearer!

EXAMPLES:

```
sage: PartitionTuple([[5,3],[2,2],[4,3]]).garnir_tableau((0,0,2)).pp()
1 2 6 7 8 9 10 13 14 15 16
3 4 5 11 12 17 18 19

sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((0,1,2)).pp()
1 2 3 4 5 12 13 16 17 18 19
6 7 11 14 15 20 21 22
8 9 10

sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((1,0,0)).pp()
1 2 3 4 5 13 14 16 17 18 19
6 7 8 12 15 20 21 22
9 10 11

sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((1,0,1)).pp()
1 2 3 4 5 12 13 16 17 18 19
6 7 8 13 14 20 21 22
9 10 11
```

(continues on next page)
sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((2,0,1)).pp()
  1 2 3 4 5  12 13  16 19 20  21
  6 7 8  14 15  17 18 22
  9 10 11

sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((2,1,1)).pp()
Traceback (most recent call last):
  ... ValueError: (comp, row+1, col) must be inside the diagram

See also:
  • top_garnir_tableau()

\textbf{hook\_length}(k, r, c)

Return the length of the hook of cell \((k, r, c)\) in the partition.

The hook of cell \((k, r, c)\) is defined as the cells to the right or below (in the English convention). If your coordinates are in the form \((k,r,c)\), use Python’s \* operator.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: mu=PartitionTuple([[1,1],[2],[2,1]])
sage: [ mu.hook_length(*c) for c in mu.cells() ]
[2, 1, 2, 1, 3, 1, 1]
\end{verbatim}

\textbf{initial\_column\_tableau()}

Return the initial column tableau of shape \(self\).

The initial column tableau of shape \(\lambda\) is the standard tableau that has the numbers 1 to \(n\), where \(n\) is the \textit{size()} of \(\lambda\), entered in order from top to bottom, and then left to right, down the columns of each component, starting from the rightmost component and working to the left.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: PartitionTuple([[3,1],[3,2]]).initial_column_tableau()
([[6, 8, 9], [7]], [[1, 3, 5], [2, 4]])
\end{verbatim}

\textbf{initial\_tableau()}

Return the \texttt{StandardTableauTuple} which has the numbers 1, 2, \ldots, \(n\), where \(n\) is the \textit{size()} of \(self\), entered in order from left to right along the rows of each component, where the components are ordered from left to right.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: PartitionTuple([[2,1],[3,2]]).initial_tableau()
([[1, 2], [3]], [[4, 5, 6], [7, 8]])
\end{verbatim}

\textbf{leg\_length}(k, r, c)

Return the length of the leg of cell \((k, r, c)\) in \(self\).

\textbf{INPUT:}
  \begin{itemize}
    \item k – The component
    \item r – The row
    \item c – The cell
  \end{itemize}

\textbf{OUTPUT:}
• The leg length as an integer

The leg of cell \((k, r, c)\) is the number of cells in the \(k\)-th component which are below the node in row \(r\) and column \(c\).

EXAMPLES:

```python
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).leg_length(2,0,0)
2
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).leg_length(2,0,1)
1
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).leg_length(2,2,0)
0
```

**level()**

Return the level of this partition tuple.

The level is the length of the tuple.

EXAMPLES:

```python
sage: PartitionTuple([[2,1,1,0],[2,1]]).level()
2
sage: PartitionTuple([[],[],[2,1,1]]).level()
3
```

**outside_corners()**

Return a list of the removable cells of this partition tuple.

All indices are of the form \((k, r, c)\), where \(r\) is the row-index, \(c\) is the column index and \(k\) is the component.

EXAMPLES:

```python
sage: PartitionTuple([[1,1],[2],[2,1]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 2), (1, 1, 0), (2, 0, 2), (2, 1, 1), (2, 2, 0)]
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 4), (1, 1, 3), (1, 2, 0), (2, 0, 2), (2, 1, 1), (2, 3, 0)]
```

**pp()**

Pretty prints this partition tuple. See `diagram()`.

EXAMPLES:

```python
sage: PartitionTuple([[5,5,2,1],[3,2]]).pp()
***** ***
***** **
** *
```

**prime_degree\(p\)**

Return the \(p\)-th prime degree of \(self\).

The degree of a partition \(\lambda\) is the sum of the \(e\)-degrees’ of the standard tableaux of shape \(\lambda\) (see `degree()`) for \(e\) a power of the prime \(p\). The prime degree gives the exponent of \(p\) in the Gram determinant of the integral Specht module of the symmetric group.

The \(p\)-th degree is the sum of the degrees of the standard tableaux of shape \(\lambda\). The \(p\)-th degree is the exponent of \(p\) in the Gram determinant of a semisimple cyclotomic Hecke algebra of type \(A\) with parameter \(q = 1\).
As with `degree()`, for this calculation the multicharge \((\kappa_1, \ldots, \kappa_l)\) is chosen so that \(\kappa_{r+1} - \kappa_r > n\), where \(n\) is the `size()` of \(\lambda\) as this ensures that the Hecke algebra is semisimple.

**INPUT:**
- \(e\) – an integer \(e > 1\)
- `multicharge` – an \(l\)-tuple of integers, where \(l\) is the `level()` of `self`

**OUTPUT:**
A non-negative integer

**EXAMPLES:**

```python
sage: PartitionTuple([[2,1],[2,2]]).prime_degree(2)
728
sage: PartitionTuple([[2,1],[2,2]]).prime_degree(3)
259
sage: PartitionTuple([[2,1],[2,2]]).prime_degree(5)
105
sage: PartitionTuple([[2,1],[2,2]]).prime_degree(7)
0
```

Therefore, the Gram determinant of \(S(2,1|2,2)\) when \(q = 1\) is \(2^{728} 3^{259} 5^{105}\). Compare with `degree()`.

**removable_cells()**
Return a list of the removable cells of this partition tuple.

All indices are of the form \((k, r, c)\), where \(r\) is the row-index, \(c\) is the column index and \(k\) is the component.

**EXAMPLES:**

```python
sage: PartitionTuple([[1,1],[2],[2,1]]).removable_cells()
[(0, 1, 0), (1, 0, 1), (2, 0, 1), (2, 1, 0)]
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).removable_cells()
[(0, 1, 0), (1, 0, 3), (1, 1, 2), (2, 0, 1), (2, 2, 0)]
```

**remove_cell\((k, r, c)\)**
Return the partition tuple obtained by removing a cell in row \(r\), column \(c\), and component \(k\).

This does not change `self`.

**EXAMPLES:**

```python
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).remove_cell(0,1,0)
([1], [4, 3], [2, 1, 1])
```

**row_standard_tableaux()**
Return the row standard tableau tuples of shape `self`.

**EXAMPLES:**

```python
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).row_standard_tableaux()
Row standard tableau tuples of shape ([1], [4, 3], [2, 1, 1])
```

**size()**
Return the size of a partition tuple.

**EXAMPLES:**
sage: PartitionTuple([[2,1],[1],[2,2]]).size()
7
sage: PartitionTuple([[],[1],[3,2,1]]).size()
7

**standard_tableaux()**

Return the standard tableau tuples of shape self.

**EXAMPLES:**

```python
sage: PartitionTuple([[],[3,2,2,1],[2,2,1],[2,2,1],[3]]).standard_tableaux()
Standard tableau tuples of shape ([], [3, 2, 2, 1], [2, 2, 1], [2, 2, 1], [3])
```

**to_exp (k=0)**

Return a tuple of the multiplicities of the parts of a partition.

Use the optional parameter k to get a return list of length at least k.

**EXAMPLES:**

```python
sage: PartitionTuple([[1,1],[2],[2,1]]).to_exp()
([2], [0, 1], [1, 1])
sage: PartitionTuple([[1,1],[2,2,2],[2,1]]).to_exp()
([2], [0, 4], [1, 1])
```

**to_list()**

Return self as a list of lists.

**EXAMPLES:**

```python
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).to_list()
[[1, 1], [4, 3], [2, 1, 1]]
```

**top_garnir_tableau (e, cell)**

Return the most dominant standard tableau which dominates the corresponding Garnir tableau and has the same residue that has shape self and is determined by e and cell.

The Garnir tableau play an important role in integral and non-semisimple representation theory because they determine the "straightening" rules for the Specht modules over an arbitrary ring. The top Garnir tableaux arise in the graded representation theory of the symmetric groups and higher level Hecke algebras. They were introduced in [KMR2012].

If the Garnir node is cell=(k, r, c) and m and M are the entries in the cells (k, r, c) and (k, r+1, c), respectively, in the initial tableau then the top e-Garnir tableau is obtained by inserting the numbers m, m+1, ..., M in order from left to right first in the cells in row r+1 which are not in the e-Garnir belt, then in the cell in rows r and r+1 which are in the Garnir belt and then, finally, in the remaining cells in row r which are not in the Garnir belt. All other entries in the tableau remain unchanged.

If e = 0, or if there are no e-bricks in either row r or r+1, then the top Garnir tableau is the corresponding Garnir tableau.

**EXAMPLES:**

```python
sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(2,(1,0,2)).pp()
  1  2  3  9 10 12 13 16
  4  5  6 11 14 15 17
  7  8  18 19 20
  21 22
sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(2,(1,0,1)).pp()
```

(continues on next page)
sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(3,(1,0,1)).pp()
1 2 3 9 10 11 12 13
4 5 6 14 15 16 17
7 8 18 19 20
21 22

sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(3,(3,0,1)).pp()
Traceback (most recent call last):
  ...:
ValueError: (comp, row+1, col) must be inside the diagram

See also:
• garnir_tableau()

up()

Generator (iterator) for the partition tuples that are obtained from self by adding a cell.

EXAMPLES:

sage: [mu for mu in PartitionTuple([[],[3,1],[1,1]]).up()]
[([1], [3, 1], [1, 1]), ([], [4, 1], [1, 1]), ([], [3, 2], [1, 1]), ([], [3, 1, 1], [1, 1])]

sage: [mu for mu in PartitionTuple([[],[1],[1]]).up()]
[([1], [1], [1]), ([], [1], [1]), ([], [1], [1]), ([], [1], [1])]
class sage.combinat.partition_tuple.PartitionTuples
    Bases: sage.structure.unique_representation.UniqueRepresentation, sage.
    structure.parent.Parent

    Class of all partition tuples.
    For more information about partition tuples, see PartitionTuple.
    This is a factory class which returns the appropriate parent based on the values of level, size, and regular
    INPUT:
    • level – the length of the tuple
    • size – the total number of cells
    • regular – a positive integer or a tuple of non-negative integers; if an integer, the highest multiplicity an
      entry may have in a component plus 1
    If a level \( k \) is specified and regular is a tuple of integers \( \ell_1, \ldots, \ell_k \), then this specifies partition tuples \( \mu \) such
    that \( \mu_i \) is \( \ell_i \)-regular, where 0 here represents \( \infty \)-regular partitions (equivalently, partitions without restrictions).
    If regular is an integer \( \ell \), then we set \( \ell_i = \ell \) for all \( i \).

Element
    alias of PartitionTuple

level()
    Return the level or None if it is not defined.

    EXAMPLES:

    sage: PartitionTuples().level() is None
    True
    sage: PartitionTuples(7).level()
    7

options(*get_value, **set_value)
    Sets and displays the global options for elements of the partition, skew partition, and partition tuple classes.
    If no parameters are set, then the function returns a copy of the options dictionary.
    The options to partitions can be accessed as the method Partitions.options of Partitions
    and related parent classes.

    OPTIONS:
    • convention – (default: English) Sets the convention used for displaying tableaux and partitions
      – English – use the English convention
      – French – use the French convention
    • diagram_str – (default: *) The character used for the cells when printing Ferrers diagrams
    • display – (default: list) Specifies how partitions should be printed
      – array – alias for diagram
      – compact – alias for compact_low
      – compact_high – compact form of exp_high
      – compact_low – compact form of exp_low
      – diagram – as a Ferrers diagram
      – exp – alias for exp_low
• exp_high – in exponential form (highest first)
• exp_low – in exponential form (lowest first)
• ferrers_diagram – alias for diagram
• list – displayed as a list
• young_diagram – alias for diagram

• latex – (default: young_diagram) Specifies how partitions should be latexed
  – array – alias for diagram
  – diagram – latex as a Ferrers diagram
  – exp – alias for exp_low
  – exp_high – latex as a list in exponential notation (highest first)
  – exp_low – as a list latex in exponential notation (lowest first)
  – ferrers_diagram – alias for diagram
  – list – latex as a list
  – young_diagram – latex as a Young diagram

• latex_diagram_str – (default: \ast) The character used for the cells when latexing Ferrers diagrams

• notation – alternative name for convention

EXAMPLES:

```
sage: P = Partition([4,2,2,1])
sage: P
[4, 2, 2, 1]
sage: Partitions.options.display="exp"
sage: P
1, 2^2, 4
sage: Partitions.options.display="exp_high"
sage: P
4, 2^2, 1
```

It is also possible to use user defined functions for the display and latex options:

```
sage: Partitions.options(display=lambda mu: '<s>' % ','.join('s%m for m in mu._list)); P
<4,2,2,1>
sage: Partitions.options(latex=lambda mu: '\Diagram%s' % ','.join('s%m
for m in mu._list)); latex(P)
\Diagram(4,2,2,1)
sage: Partitions.options(display="diagram", diagram_str="#")
sage: P
###
##
#
#
sage: Partitions.options(diagram_str=", convention="french")
sage: print(P.ferrers_diagram())
```

(continues on next page)
Changing the convention for partitions also changes the convention option for tableaux and vice versa:

```sage
t = Tableau([[1,2,3],[4,5]])
t.pp()
```

```sage:
T = Tableau([[(1,2,3),(4,5)]])
T.pp()
```

```sage:
Tableaux.options.convention = "english"
T.pp()
```

```sage:
Partitions.options._reset()
```

See `GlobalOptions` for more features of these options.

**size()**

Return the size or None if it is not defined.

**EXAMPLES:**

```sage:
PartitionTuples().size() is None
True
```

```sage:
PartitionTuples(size=7).size()
7
```

**class sage.combinat.partition_tuple.PartitionTuples_all**

Bases: `sage.combinat.partition_tuple.PartitionTuples`

Class of partition tuples of a arbitrary level and arbitrary sum.

**class sage.combinat.partition_tuple.PartitionTuples_level** (`level`, `category=None`)

Bases: `sage.combinat.partition_tuple.PartitionTuples`

Class of partition tuples of a fixed level, but summing to an arbitrary integer.

**class sage.combinat.partition_tuple.PartitionTuples_level_size** (`level`, `size`)

Bases: `sage.combinat.partition_tuple.PartitionTuples`

Class of partition tuples with a fixed level and a fixed size.

**cardinality()**

Return the number of level-tuples of partitions of size n.

Wraps a pari function call using `part.eTA`.

**EXAMPLES:**

```sage:
PartitionTuples(2,3).cardinality()
10
```

```sage:
PartitionTuples(2,8).cardinality()
185
```
class `sage.combinat.partition_tuple.PartitionTuples_size(size)`

    Bases: `sage.combinat.partition_tuple.PartitionTuples`

    Class of partition tuples of a fixed size, but arbitrary level.

class `sage.combinat.partition_tuple.RegularPartitionTuples(regular, **kwds)`

    Bases: `sage.combinat.partition_tuple.PartitionTuples`

    Abstract base class for $\ell$-regular partition tuples.

class `sage.combinat.partition_tuple.RegularPartitionTuples_all(regular)`

    Bases: `sage.combinat.partition_tuple.RegularPartitionTuples`

    Class of $\ell$-regular partition tuples.

class `sage.combinat.partition_tuple.RegularPartitionTuples_level(level, regular)`

    Bases: `sage.combinat.partition_tuple.PartitionTuples_level`

    Regular Partition tuples of a fixed level.

    INPUT:

    - `level` – a non-negative Integer; the level
    - `regular` – a positive integer or a tuple of non-negative integers; if an integer, the highest multiplicity an entry may have in a component plus 1 with 0 representing $\infty$-regular (equivalently, partitions without restrictions)

    `regular` is a tuple of integers $(\ell_1, \ldots, \ell_k)$ that specifies partition tuples $\mu$ such that $\mu_i$ is $\ell_i$-regular. If `regular` is an integer $\ell$, then we set $\ell_i = \ell$ for all $i$.

    EXAMPLES:

    ::

    sage: RPT = PartitionTuples(level=4, regular=(2,3,0,2))
    sage: RPT[:24]
    [([], [], [], []),
     ([1], [], [], []),
     ([], [1], [], []),
     ([], [], [1], []),
     ([], [], [], [1]),
     ([2], [], [], []),
     ([1], [1], [], []),
     ([1], [], [1], []),
     ([1], [], [], [1]),
     ([1], [], [], []),
     ([1], [], [], []),
     ([], [2], [], []),
     ([], [1, 1], [], []),
     ([], [1], [1], []),
     ([], [1], [], [1]),
     ([], [1], [], []),
     ([], [1, 1], [], []),
     ([], [1], [1], []),
     ([], [1], [], []),
     ([], [], [2], []),
     ([], [], [1, 1], []),
     ([], [], [], [1]),
     ([], [], [], []),
     ([], [], [], []),
     ([], [], [], []),
     ([], [], [], []),
     ([], [], [], []),
     ([], [], [], []),
     ([], [], [], []),
     ([], [], [], []),
     ([], [], [], []),
     ([], [], [], []),
     ([], [], [], []),
     ([], [], [], []),
     ([], [], [], [])]

    sage: [[1,1],[3],[5,5,5],[7,2]] in RPT
    False

(continues on next page)
sage: [[3,1],[3],[5,5],[7,2]] in RPT
True
sage: [[3,1],[3],[5,5]] in RPT
False

```
class sage.combinat.partition_tuple.RegularPartitionTuples_level_size(level, size, regular)

Bases: sage.combinat.partition_tuple.PartitionTuples_level_size

Class of ℓ-regular partition tuples with a fixed level and a fixed size.

INPUT:

• level – a non-negative Integer; the level

• size – a non-negative Integer; the size

• regular – a positive integer or a tuple of non-negative integers; if an integer, the highest multiplicity an entry may have in a component plus 1 with 0 representing ∞-regular (equivalently, partitions without restrictions)

regular is a tuple of integers (ℓ₁,...,ℓₖ) that specifies partition tuples μ such that μᵢ is ℓᵢ-regular. If regular is an integer ℓ, then we set ℓᵢ = ℓ for all i.

EXAMPLES:

sage: PartitionTuples(level=3, size=7, regular=(2,1,3))[0:24]

```

```
class sage.combinat.partition_tuple.RegularPartitionTuples_size(size, regular)

Bases: sage.combinat.partition_tuple.RegularPartitionTuples

Class of ℓ-regular partition tuples with a fixed size.

```
5.1.170 Iterators over the partitions of an integer

AUTHOR:

- Jonathan Bober (2007-07-28): wrote the program partitions_c.cc that does all the actual heavy lifting.

`sage.combinat.partitions.ZS1_iterator(n)`  
A fast iterator for the partitions of `n` (in the decreasing lexicographic order) which returns lists and not objects of type `Partition`.

This is an implementation of the ZS1 algorithm found in [ZS98].

REFERENCES:

EXAMPLES:

```python
sage: from sage.combinat.partitions import ZS1_iterator
sage: it = ZS1_iterator(4)
sage: next(it)
[4]
sage: type(_)
<... 'list'>
```

`sage.combinat.partitions.ZS1_iterator_nk(n, k)`  
An iterator for the partitions of `n` of length at most `k` (in the decreasing lexicographic order) which returns lists and not objects of type `Partition`.

The algorithm is a mild variation on `ZS1_iterator()`; I would not vow for its speed.

EXAMPLES:

```python
sage: from sage.combinat.partitions import ZS1_iterator_nk
sage: it = ZS1_iterator_nk(4, 3)
sage: next(it)
[4]
sage: type(_)
<... 'list'>
```

5.1.171 Perfect matchings

A perfect matching of a set `S` is a partition into 2-element sets. If `S` is the set `{1, ..., n}`, it is equivalent to fixpoint-free involutions. These simple combinatorial objects appear in different domains such as combinatorics of orthogonal polynomials and of the hyperoctaedral groups (see [MV], [McD] and also [CM]):

AUTHOR:

- Valentin Feray, 2010: initial version
- Martin Rubey, 2017: inherit from SetPartition, move crossings and nestings to SetPartition

EXAMPLES:

Create a perfect matching:

```python
sage: m = PerfectMatching([(('a', 'e'), ('b', 'c'), ('d', 'f'))]);m
[('a', 'e'), ('b', 'c'), ('d', 'f')]
```

Count its crossings, if the ground set is totally ordered:

```python
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.number_of_crossings()
1
```

List the perfect matchings of a given ground set:

```python
sage: PerfectMatchings(4).list()
[[(1, 2), (3, 4)], [(1, 3), (2, 4)], [(1, 4), (2, 3)]
```

REFERENCES:

```python
class sage.combinat.perfect_matching.PerfectMatching(s, check=True, sort=True)
```

A perfect matching.

A perfect matching of a set \(X\) is a set partition of \(X\) where all parts have size 2.

A perfect matching can be created from a list of pairs or from a fixed point-free involution as follows:

```python
sage: m = PerfectMatching([('a','e'),('b','c'),('d','f')]);m
[('a', 'e'), ('b', 'c'), ('d', 'f')]
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]);n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: isinstance(m,PerfectMatching)
True
```

The parent, which is the set of perfect matchings of the ground set, is automatically created:

```python
sage: n.parent()
Perfect matchings of {1, 2, 3, 4, 5, 6, 7, 8}
```

If the ground set is ordered, one can, for example, ask if the matching is non crossing:

```python
sage: PerfectMatching([(1, 4), (2, 3), (5, 6)]).is_noncrossing()
True
```

Weingarten_function \((d, other=None)\)

Return the Weingarten function of two pairings.

This function is the value of some integrals over the orthogonal groups \(O_N\). With the convention of [CM], the method returns \(W_g^{O(d)}(other, self)\).

EXAMPLES:

```python
sage: var('N')
N
sage: m = PerfectMatching([(1,3),(2,4)])
sage: n = PerfectMatching([(1,2),(3,4)])
sage: factor(m.Weingarten_function(N,n))
-1/((N + 2)*(N - 1)*N)
```

loop_type \((other=None)\)

Return the loop type of \(self\).

INPUT:

- \(other\) – a perfect matching of the same set of \(self\). (if the second argument is empty, the method \(an_element()\) is called on the parent of the first)
OUTPUT:
If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union of cycles of even lengths. The function returns the ordered list of the semi-length of these cycles (considered as a partition)

EXAMPLES:

```python
sage: m = PerfectMatching([('a','e'), ('b','c'), ('d','f')])
sage: n = PerfectMatching([('a','b'), ('d','f'), ('e','c')])
sage: m.loop_type(n)
[2, 1]
```

**loops** *(other=None)*
Return the loops of self.

INPUT:

- `other` – a perfect matching of the same set of self. (if the second argument is empty, the method `an_element()` is called on the parent of the first)

OUTPUT:
If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union of cycles of even lengths. The function returns the list of these cycles (each cycle is given as a list).

EXAMPLES:

```python
sage: m = PerfectMatching([('a','e'), ('b','c'), ('d','f')])
sage: n = PerfectMatching([('a','b'), ('d','f'), ('e','c')])
sage: loops = m.loops(n)
sage: loops
# random
[[a', e', c', b'], [d', f']]
sage: o = PerfectMatching([1, 7), (2, 4), (3, 8), (5, 6)])
sage: p = PerfectMatching([1, 6), (2, 7), (3, 4), (5, 8)])
sage: o.loops(p)
[[1, 7, 2, 4, 3, 8, 5, 6]]
```

**loops_iterator** *(other=None)*
Iterate through the loops of self.

INPUT:

- `other` – a perfect matching of the same set of self. (if the second argument is empty, the method `an_element()` is called on the parent of the first)

OUTPUT:
If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union of cycles of even lengths. The function returns an iterator for these cycles (each cycle is given as a list).

EXAMPLES:

```python
sage: o = PerfectMatching([1, 7), (2, 4), (3, 8), (5, 6)])
sage: p = PerfectMatching([1, 6), (2, 7), (3, 4), (5, 8)])
sage: it = o.loops_iterator(p)
sage: next(it)
[1, 7, 2, 4, 3, 8, 5, 6]
sage: next(it)
Traceback (most recent call last):
```

(continues on next page)
number_of_loops (other=None)

Return the number of loops of self.

INPUT:

- `other` – a perfect matching of the same set of `self`. (if the second argument is empty, the method `an_element()` is called on the parent of the first)

OUTPUT:

If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union of cycles of even lengths. The function returns their numbers.

EXAMPLES:

```
sage: m = PerfectMatching([('a','e'),('b','c'),('d','f')])
sage: n = PerfectMatching([('a','b'),('d','f'),('e','c')])
sage: m.number_of_loops(n)
2
```

partner (x)

Return the element in the same pair than x in the matching self.

EXAMPLES:

```
sage: m = PerfectMatching([(-3, 1), (2, 4), (-2, 7)])
sage: m.partner(4)
2
sage: n = PerfectMatching([('c','b'),('d','f'),('e','a')])
sage: n.partner('c')
'b'
```

standardization()

Return the standardization of self.

See `SetPartition.standardization()` for details.

EXAMPLES:

```
sage: n = PerfectMatching([('c','b'),('d','f'),('e','a')])
sage: n.standardization()
[(1, 5), (2, 3), (4, 6)]
```

to_graph()

Return the graph corresponding to the perfect matching.

OUTPUT:

The realization of self as a graph.

EXAMPLES:

```
sage: PerfectMatching([[1,3], [4,2]]).to_graph().edges(labels=False)
[(1, 3), (2, 4)]
sage: PerfectMatching([[1,4], [3,2]]).to_graph().edges(labels=False)
[(1, 4), (2, 3)]
```
to_noncrossing_set_partition()

Return the noncrossing set partition (on half as many elements) corresponding to the perfect matching if the perfect matching is noncrossing, and otherwise gives an error.

OUTPUT:

The realization of self as a noncrossing set partition.

EXAMPLES:

```
sage: PerfectMatching([[1,3], [4,2]]).to_noncrossing_set_partition()
Traceback (most recent call last):
  ... ValueError: matching must be non-crossing
sage: PerfectMatching([[1,4], [3,2]]).to_noncrossing_set_partition()
{{1, 2}}
sage: PerfectMatching([]).to_noncrossing_set_partition()
{}
```

class sage.combinat.perfect_matching.PerfectMatchings(s)

Bases: sage.combinat.set_partition.SetPartitions_set

Perfect matchings of a ground set.

INPUT:

- `s` – an iterable of hashable objects or an integer

EXAMPLES:

If the argument `s` is an integer `n`, it will be transformed into the set `{1, ..., n}`:

```
sage: M = PerfectMatchings(6); M
Perfect matchings of {1, 2, 3, 4, 5, 6}
sage: PerfectMatchings([-1, -3, 1, 2])
Perfect matchings of {1, 2, -3, -1}
```

One can ask for the list, the cardinality or an element of a set of perfect matching:

```
sage: PerfectMatchings(4).list()
[[[1, 2], (3, 4)], [[1, 3], (2, 4)], [[1, 4], (2, 3)]]
sage: PerfectMatchings(8).cardinality()
105
sage: M = PerfectMatchings(('a', 'e', 'b', 'f', 'c', 'd'))
sage: x = M.an_element()
sage: x
# random
[('a', 'c'), ('b', 'e'), ('d', 'f')]
sage: all(PerfectMatchings(i).an_element() in PerfectMatchings(i)
.... for i in range(2,11,2))
True
```

Element

alias of `PerfectMatching`

Weingarten_matrix(N)

Return the Weingarten matrix corresponding to the set of PerfectMatchings `self`. 

5.1. Comprehensive Module list 1649
It is a useful theoretical tool to compute polynomial integrals over the orthogonal group $O_N$ (see [CM]).

EXAMPLES:

```python
sage: M = PerfectMatchings(4).Weingarten_matrix(var('N'))
sage: N*(N-1)*(N+2)*M.apply_map(factor)
[N + 1 -1 -1]
[ -1 N + 1 -1]
[ -1 -1 N + 1]
```

**base_set()**

Return the base set of `self`.

EXAMPLES:

```python
sage: PerfectMatchings(3).base_set()
{1, 2, 3}
```

**base_set_cardinality()**

Return the cardinality of the base set of `self`.

EXAMPLES:

```python
sage: PerfectMatchings(3).base_set_cardinality()
3
```

**cardinality()**

Return the cardinality of the set of perfect matchings `self`.

This is $1 \times 3 \times 5 \times \ldots \times (2n - 1)$, where $2n$ is the size of the ground set.

EXAMPLES:

```python
sage: PerfectMatchings(8).cardinality()
105
sage: PerfectMatchings([1,2,3,4]).cardinality()
3
sage: PerfectMatchings(3).cardinality()
0
sage: PerfectMatchings([]).cardinality()
1
```

**random_element()**

Return a random element of `self`.

EXAMPLES:

```python
sage: M = PerfectMatchings(('a', 'e', 'b', 'f', 'c', 'd'))
sage: x = M.random_element()
sage: x # random
[('a', 'b'), ('c', 'd'), ('e', 'f')]
```
### 5.1.172 Permutations

The Permutations module. Use `Permutation?` to get information about the Permutation class, and `Permutations?` to get information about the combinatorial class of permutations.

**Warning:** This file defined `Permutation` which depends upon `CombinatorialElement` despite it being deprecated (see trac ticket #13742). This is dangerous. In particular, the `Permutation._left_to_right_multiply_on_right()` method (which can be called through multiplication) disables the input checks (see `Permutation()`). This should not happen. Do not trust the results.

What does this file define?

The main part of this file consists in the definition of permutation objects, i.e. the `Permutation()` method and the `Permutation` class. Global options for elements of the permutation class can be set through the `Permutations.options()` object.

Below are listed all methods and classes defined in this file.

**Methods of Permutations objects**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>left_action_product()</code></td>
<td>Returns the product of <code>self</code> with another permutation, in which the other permutation is applied first.</td>
</tr>
<tr>
<td><code>right_action_product()</code></td>
<td>Returns the product of <code>self</code> with another permutation, in which <code>self</code> is applied first.</td>
</tr>
<tr>
<td><code>size()</code></td>
<td>Returns the size of the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>cycle_string()</code></td>
<td>Returns the disjoint-cycles representation of <code>self</code> as string.</td>
</tr>
<tr>
<td><code>next()</code></td>
<td>Returns the permutation that follows <code>self</code> in lexicographic order (in the same symmetric group as <code>self</code>).</td>
</tr>
<tr>
<td><code>prev()</code></td>
<td>Returns the permutation that comes directly before <code>self</code> in lexicographic order (in the same symmetric group as <code>self</code>).</td>
</tr>
<tr>
<td><code>to_tableau_by_shape()</code></td>
<td>Returns a tableau of shape <code>shape</code> with the entries in <code>self</code>.</td>
</tr>
<tr>
<td><code>to_cycles()</code></td>
<td>Returns the permutation <code>self</code> as a list of disjoint cycles.</td>
</tr>
<tr>
<td><code>forget_cycles()</code></td>
<td>Return <code>self</code> under the forget cycle map.</td>
</tr>
<tr>
<td><code>to_permutation_group_element()</code></td>
<td>Returns a <code>PermutationGroupElement</code> equal to <code>self</code>.</td>
</tr>
<tr>
<td><code>signature()</code></td>
<td>Returns the signature of the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>is_even()</code></td>
<td>Returns <code>True</code> if the permutation <code>self</code> is even, and <code>False</code> otherwise.</td>
</tr>
<tr>
<td><code>to_matrix()</code></td>
<td>Returns a matrix representing the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>rank()</code></td>
<td>Returns the rank of <code>self</code> in lexicographic ordering (on the symmetric group containing <code>self</code>).</td>
</tr>
<tr>
<td><code>to_inversion_vector()</code></td>
<td>Returns the inversion vector of a permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>inversions()</code></td>
<td>Returns a list of the inversions of permutation <code>self</code>.</td>
</tr>
<tr>

AUTHORS:

- Mike Hansen
- Dan Drake (2008-04-07): allow Permutation() to take lists of tuples
- Sébastien Labbé (2009-03-17): added robinson_schensted_inverse
- Travis Scrimshaw:
  - (2012-08-16): to_standard() no longer modifies input
- Travis Scrimshaw (2014-02-05): Made StandardPermutations_n a finite Weyl group to make it more uniform with SymmetricGroup. Added ability to compute the conjugacy classes.

Classes and methods

class sage.combinat.permutation.Arrangements
Bases: sage.combinat.permutation.Permutations

An arrangement of a multiset mset is an ordered selection without repetitions. It is represented by a list that contains only elements from mset, but maybe in a different order.

Arrangements returns the combinatorial class of arrangements of the multiset mset that contain k elements.

EXAMPLES:

```python
sage: mset = [1,1,2,3,4,4,5]
sage: Arrangements(mset,2).list()
[[1, 1],
[1, 2],
[1, 3],
[1, 4],
[1, 5],
[2, 1],
[2, 3],
[2, 4],
[2, 5],
[3, 1],
[3, 2],
[3, 4],
[3, 5],
[4, 1],
[4, 2],
[4, 3],
[4, 4],
[4, 5],
[5, 1],
[5, 2],
[5, 3],
[5, 4]]
sage: Arrangements(mset,2).cardinality()
22
sage: Arrangements( ['c','a','t'], 2 ).list()
(continues on next page)
```
sage: Arrangements( ["c","a","t"], 3 ).list()
[['c', 'a', 't'], ['c', 't', 'a'], ['a', 'c', 't'], ['a', 't', 'c'], ['t', 'c', 'a'], ['t', 'a', 'c']]

sage: Arrangements( ["c","a","t"], 3 ).list()
[['c', 'a', 't'], ['c', 't', 'a'], ['a', 'c', 't'], ['a', 't', 'c'], ['t', 'c', 'a'], ['t', 'a', 'c']]

cardinality()
Return the cardinality of self.

EXAMPLES:

sage: A = Arrangements([1,1,2,3,4,4,5], 2)
sage: A.cardinality()
22

class sage.combinat.permutation.Arrangements_msetk(mset, k)

Arrangements of length k of a multiset M.
class sage.combinat.permutation.Arrangements_setk(s, k)

Arrangements of length k of a set S.
class sage.combinat.permutation.CyclicPermutations(mset)
Bases: sage.combinat.permutation.Permutations_mset

Return the class of all cyclic permutations of mset in cycle notation. These are the same as necklaces.

INPUT:

* mset – A multiset

EXAMPLES:

sage: CyclicPermutations(range(4)).list()
[[0, 1, 2, 3],
 [0, 1, 3, 2],
 [0, 2, 1, 3],
 [0, 2, 3, 1],
 [0, 3, 1, 2],
 [0, 3, 2, 1]]
sage: CyclicPermutations([1,1,1]).list()
[[1, 1, 1]]

iterator(distinct=False)
EXAMPLES:

sage: CyclicPermutations(range(4)).list() # indirect doctest
[[0, 1, 2, 3],
 [0, 1, 3, 2],
 [0, 2, 1, 3],
 [0, 2, 3, 1],
 [0, 3, 1, 2],
 [0, 3, 2, 1]]

(continued from previous page)

```python
[0, 3, 1, 2],
[0, 3, 2, 1]
sage: CyclicPermutations([1,1]).list()
[[1, 1]]
sage: CyclicPermutations([1,1]).list(distinct=True)
[[1, 1], [1, 1]]
```

**list** *(distinct=False)*

EXAMPLS:

```python
sage: CyclicPermutations(range(4)).list()
[[0, 1, 2, 3],
 [0, 1, 3, 2],
 [0, 2, 1, 3],
 [0, 2, 3, 1],
 [0, 3, 1, 2],
 [0, 3, 2, 1]]
```

```python
class sage.combinat.permutation.CyclicPermutationsOfPartition(partition)
Bases: sage.combinat.permutation.Permutations

Combinations of cyclic permutations of each cell of a given partition.

This is the same as a Cartesian product of necklaces.

EXAMPLS:

```python
sage: CyclicPermutationsOfPartition([[1,2,3,4],[5,6,7]]).list()

sage: CyclicPermutationsOfPartition([[1,2,3,4],[4,4,4]]).list()

sage: CyclicPermutationsOfPartition([[1,2,3],[4,4,4]]).list()
[[[1, 2, 3], [4, 4, 4]], [[1, 3, 2], [4, 4, 4]]]

sage: CyclicPermutationsOfPartition([[1,2,3],[4,4,4]]).list(distinct=True)
[[[1, 2, 3], [4, 4, 4]], [[1, 3, 2], [4, 4, 4]]]
```

5.1. Comprehensive Module list
class Element
Bases: sage.structure.list_clone.ClonableArray

A cyclic permutation of a partition.

check()
Check that self is a valid element.

EXAMPLES:

```
sage: CP = CyclicPermutationsOfPartition([[1,2,3,4],[5,6,7]])
sage: elt = CP[0]
sage: elt.check()
```

iterator (distinct=False)

AUTHORS:

• Robert Miller

EXAMPLES:

```
sage: CyclicPermutationsOfPartition([[1,2,3,4],[5,6,7]]).list()  # indirect doctest
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [7, 6, 5]],
 [[1, 2, 4, 3], [7, 6, 5]],
 [[1, 3, 2, 4], [7, 6, 5]],
 [[1, 3, 4, 2], [7, 6, 5]],
 [[1, 4, 2, 3], [7, 6, 5]],
 [[1, 4, 3, 2], [7, 6, 5]]]
```

```
sage: CyclicPermutationsOfPartition([[1,2,3],[5,6,6]]).list()
[[[1, 2, 3], [5, 6, 6]], [[1, 3, 2], [5, 6, 6]]]
```

```
sage: CyclicPermutationsOfPartition([[1,2,3],[5,6,6]]).list(distinct=True)
[[[1, 2, 3], [5, 6, 6]], [[1, 3, 2], [5, 6, 6]]]
```

list (distinct=False)

EXAMPLES:

```
sage: CyclicPermutationsOfPartition([[1,2,3],[5,6,6]]).list()
[[[1, 2, 3], [5, 6, 6]], [[1, 3, 2], [5, 6, 6]]]
```

(continues on next page)
class sage.combinat.permutation.PatternAvoider (parent, patterns)

Bases: sage.combinat.backtrack.GenericBacktracker

EXAMPLES:

sage: from sage.combinat.permutation import PatternAvoider
sage: P = Permutations(4)
sage: p = PatternAvoider(P, [[1,2,3]])
sage: loads(dumps(p))
<sage.combinat.permutation.PatternAvoider object at 0x...>

class sage.combinat.permutation.Permutation (parent, l, check_input=True)

Bases: sage.combinat.combinat.CombinatorialElement

A permutation.

Converts \( l \) to a permutation on \{1, 2, \ldots, n\}.

INPUT:

- \( l \) – Can be any one of the following:
  - an instance of \perm\( \),
  - list of integers, viewed as one-line permutation notation. The construction checks that you give an acceptable entry. To avoid the check, use the check_input option.
  - string, expressing the permutation in cycle notation.
  - list of tuples of integers, expressing the permutation in cycle notation.
  - a \perm\( \)
  - a pair of two standard tableaux of the same shape. This yields the permutation obtained from the pair using the inverse of the Robinson-Schensted algorithm.

- check_input (boolean) – whether to check that input is correct. Slows the function down, but ensures that nothing bad happens. This is set to True by default.

Warning: Since trac ticket #13742 the input is checked for correctness: it is not accepted unless it actually is a permutation on \{1, \ldots, n\}. It means that some \perm\( \) objects cannot be created anymore without setting check_input = False, as there is no certainty that its functions can handle them, and this should be fixed in a much better way ASAP (the functions should be rewritten to handle those cases, and new tests be added).

Warning: There are two possible conventions for multiplying permutations, and the one currently enabled in Sage by default is the one which has \((pq)(i) = q(p(i))\) for any permutations \(p \in S_n\) and \(q \in S_n\) and any \(1 \leq i \leq n\). (This equation looks less strange when the action of permutations on numbers is written from the right: then it takes the form \(i^q = (i^p)^q\), which is an associativity law). There is an alternative convention, which has \((pq)(i) = p(q(i))\) instead. The conventions can be switched at runtime using sage.combinat.permutation.Permutations.options(). It is best for code not to rely on
this setting being set to a particular standard, but rather use the methods `left_action_product()` and `right_action_product()` for multiplying permutations (these methods don’t depend on the setting).

See trac ticket #14885 for more details.

---

**Note:** The `bruhat*` methods refer to the *strong* Bruhat order. To use the *weak* Bruhat order, look under `permutohedron*`.

---

**EXAMPLES:**

```python
sage: Permutation([2,1])
[2, 1]

sage: Permutation([2, 1, 4, 5, 3])
[2, 1, 4, 5, 3]

sage: Permutation('(1,2)')
[2, 1]

sage: Permutation('(1,2)(3,4,5)')
[2, 1, 4, 5, 3]

sage: Permutation( ((1,2),(3,4,5)) )
[2, 1, 4, 5, 3]

sage: Permutation( '{{1,2}}' )
[2, 1]

sage: Permutation( (1,2) )
[2, 1]

sage: Permutation( ((1,2)) )
[2, 1]

sage: Permutation( (1,) )
[1]

sage: Permutation( () )
[]

sage: p = Permutation((1, 2, 5)); p
[2, 5, 3, 4, 1]

sage: type(p)
<class 'sage.combinat.permutation.StandardPermutations_n_with_category.element_class'>
```

Construction from a string in cycle notation:

```python
sage: p = Permutation( '(4,5)' ); p
[1, 2, 3, 5, 4]

sage: len(p); len(p2)
5
10
```

The size of the permutation is the maximum integer appearing; add a 1-cycle to increase this:

```python
sage: p2 = Permutation( '(4,5)(10)' ); p2
[1, 2, 3, 5, 4, 6, 7, 8, 9, 10]

sage: len(p); len(p2)
5
10
```

We construct a `Permutation` from a `PermutationGroupElement`: 
sage: g = PermutationGroupElement([2,1,3])
sage: Permutation(g)
[2, 1, 3]

From a pair of tableaux of the same shape. This uses the inverse of the Robinson-Schensted algorithm:

sage: p = [[1, 4, 7], [2, 5], [3], [6]]
sage: q = [[1, 2, 5], [3, 6], [4], [7]]
sage: P = Tableau(p)
sage: Q = Tableau(q)
sage: Permutation( (p, q) )
[3, 6, 5, 2, 7, 4, 1]
sage: Permutation( [p, q] )
[3, 6, 5, 2, 7, 4, 1]
sage: Permutation( (P, Q) )
[3, 6, 5, 2, 7, 4, 1]
sage: Permutation( [P, Q] )
[3, 6, 5, 2, 7, 4, 1]

RS_partition()
Return the shape of the tableaux obtained by applying the RSK algorithm to self.

EXAMPLES:

sage: Permutation([1,4,3,2]).RS_partition()
[2, 1, 1]

absolute_length()
Return the absolute length of self

The absolute length is the length of the shortest expression of the element as a product of reflections.

For permutations in the symmetric groups, the absolute length is the size minus the number of its disjoint cycles.

EXAMPLES:

sage: Permutation([4,2,3,1]).absolute_length()
1

action(a)
Return the action of the permutation self on a list a.

The action of a permutation $p \in S_n$ on an $n$-element list $(a_1, a_2, \ldots, a_n)$ is defined to be

$(a_p(1), a_p(2), \ldots, a_p(n))$.

EXAMPLES:

sage: p = Permutation([2,1,3])
sage: a = list(range(3))
sage: p.action(a)
[1, 0, 2]
sage: b = [1,2,3,4]
sage: p.action(b)
Traceback (most recent call last):
  ...
ValueError: len(a) must equal len(self)
sage: q = Permutation([2,3,1])

(continues on next page)
sage: a = list(range(3))
sage: q.action(a)
[1, 2, 0]

```

**avoid**s *(patt)*

Test whether the permutation *self* avoids the pattern *patt*.

**EXAMPLES:**

```
sage: Permutation([6,2,5,4,3,1]).avoids([4,2,3,1])
False
sage: Permutation([6,1,2,5,4,3]).avoids([4,2,3,1])
True
sage: Permutation([6,1,2,5,4,3]).avoids([3,4,1,2])
True
```

**binary_search_tree**(left_to_right=True)

Return the binary search tree associated to *self*.

If *w* is a word, then the binary search tree associated to *w* is defined as the result of starting with an empty binary tree, and then inserting the letters of *w* one by one into this tree. Here, the insertion is being done according to the method *binary_search_insert()* , and the word *w* is being traversed from left to right.

A permutation is regarded as a word (using one-line notation), and thus a binary search tree associated to a permutation is defined.

If the optional keyword variable *left_to_right* is set to *False*, the word *w* is being traversed from right to left instead.

**EXAMPLES:**

```
sage: Permutation([1,4,3,2]).binary_search_tree()
1[., 4[3[2[., .], .], .], .]
sage: Permutation([4,1,3,2]).binary_search_tree()
4[1[., 3[2[., .], .]], .]
```

By passing the option *left_to_right=False* one can have the insertion going from right to left:

```
sage: Permutation([1,4,3,2]).binary_search_tree(False)
2[1[., .], 3[., 4[., .]]]
sage: Permutation([4,1,3,2]).binary_search_tree(False)
2[1[., .], 3[., 4[., .]]]
```

**binary_search_tree_shape**(left_to_right=True)

Return the shape of the binary search tree of the permutation (a non labelled binary tree).

**EXAMPLES:**

```
sage: Permutation([1,4,3,2]).binary_search_tree_shape()
[., [[[., .], .], .]]
sage: Permutation([4,1,3,2]).binary_search_tree_shape()
[[., [[., .], .]], .]
```

By passing the option *left_to_right=False* one can have the insertion going from right to left:

```
sage: Permutation([1,4,3,2]).binary_search_tree_shape(False)
[[[., .], .], [[., .], .]]
```

(continues on next page)
bruhat_greater()  
Returns the combinatorial class of permutations greater than or equal to self in the Bruhat order (on the symmetric group containing self).

See bruhat_lequal() for the definition of the Bruhat order.

EXAMPLES:

```
sage: Permutation([4,1,2,3]).bruhat_greater().list()  
[[4, 1, 2, 3],  
 [4, 1, 3, 2],  
 [4, 2, 1, 3],  
 [4, 2, 3, 1],  
 [4, 3, 1, 2],  
 [4, 3, 2, 1]]
```

bruhat_inversions()  
Return the list of inversions of self such that the application of this inversion to self decreases its number of inversions by exactly 1.

Equivalently, it returns the list of pairs \((i, j)\) such that \(i < j\), such that \(p(i) > p(j)\) and such that there exists no \(k\) (strictly) between \(i\) and \(j\) satisfying \(p(i) > p(k) > p(j)\).

EXAMPLES:

```
sage: Permutation([5,2,3,4,1]).bruhat_inversions()  
[[0, 1], [0, 2], [0, 3], [1, 4], [2, 4], [3, 4]]

sage: Permutation([6,1,4,5,2,3]).bruhat_inversions()  
[[0, 1], [0, 2], [0, 3], [2, 4], [2, 5], [3, 4], [3, 5]]
```

bruhat_inversions_iterator()  
Return the iterator for the inversions of self such that the application of this inversion to self decreases its number of inversions by exactly 1.

EXAMPLES:

```
sage: list(Permutation([5,2,3,4,1]).bruhat_inversions_iterator())  
[[0, 1], [0, 2], [0, 3], [1, 4], [2, 4], [3, 4]]

sage: list(Permutation([6,1,4,5,2,3]).bruhat_inversions_iterator())  
[[0, 1], [0, 2], [0, 3], [2, 4], [2, 5], [3, 4], [3, 5]]
```

bruhat_lequal(p2)  
Return True if self is less or equal to p2 in theBruhat order.

The Bruhat order (also called strong Bruhat order or Chevalley order) on the symmetric group \(S_n\) is the partial order on \(S_n\) determined by the following condition: If \(p\) is a permutation, and \(i\) and \(j\) are two indices satisfying \(p(i) > p(j)\) and \(i < j\) (that is, \((i, j)\) is an inversion of \(p\) with \(i < j\)), then \(p \circ (i, j)\) (the permutation obtained by first switching \(i\) with \(j\) and then applying \(p\)) is smaller than \(p\) in the Bruhat order.

One can show that a permutation \(p \in S_n\) is less or equal to a permutation \(q \in S_n\) in the Bruhat order if and only if for every \(i \in \{0, 1, \ldots, n\}\) and \(j \in \{1, 2, \ldots, n\}\), the number of the elements among \(p(1), p(2), \ldots, p(j)\) that are greater than \(i\) is \(\leq\) to the number of the elements among \(q(1), q(2), \ldots, q(j)\) that are greater than \(i\).

This method assumes that self and p2 are permutations of the same integer \(n\).
EXAMPLES:

```python
sage: Permutation([2,4,3,1]).bruhat_lequal(Permutation([3,4,2,1]))
True
sage: Permutation([2,1,3]).bruhat_lequal(Permutation([2,3,1]))
True
sage: Permutation([2,1,3]).bruhat_lequal(Permutation([3,1,2]))
True
sage: Permutation([2,1,3]).bruhat_lequal(Permutation([1,2,3]))
False
sage: Permutation([1,3,2]).bruhat_lequal(Permutation([2,1,3]))
False
sage: Permutation([1,3,2]).bruhat_lequal(Permutation([2,3,1]))
True
sage: Permutation([2,3,1]).bruhat_lequal(Permutation([1,3,2]))
False
```

```python
sage: sorted([len([b for b in Permutations(3) if a.bruhat_lequal(b)])
          for a in Permutations(3)])
[1, 2, 2, 4, 4, 6]
```

```python
sage: Permutation([]).bruhat_lequal(Permutation([]))
True
```

**bruhat_pred()**

Return a list of the permutations strictly smaller than `self` in the Bruhat order (on the symmetric group containing `self`) such that there is no permutation between one of those and `self`.

See **bruhat_lequal()** for the definition of the Bruhat order.

**EXAMPLES:**

```python
sage: Permutation([6,1,4,5,2,3]).bruhat_pred()
[[1, 6, 4, 5, 2, 3],
 [4, 1, 6, 5, 2, 3],
 [5, 1, 4, 6, 2, 3],
 [6, 1, 2, 5, 4, 3],
 [6, 1, 3, 5, 2, 4],
 [6, 1, 4, 2, 5, 3],
 [6, 1, 4, 3, 2, 5]]
```

**bruhat_pred_iterator()**

An iterator for the permutations strictly smaller than `self` in the Bruhat order (on the symmetric group containing `self`) such that there is no permutation between one of those and `self`.

See **bruhat_lequal()** for the definition of the Bruhat order.

**EXAMPLES:**

```python
sage: [x for x in Permutation([6,1,4,5,2,3]).bruhat_pred_iterator()]
[[1, 6, 4, 5, 2, 3],
 [4, 1, 6, 5, 2, 3],
 [5, 1, 4, 6, 2, 3],
 [6, 1, 2, 5, 4, 3],
 [6, 1, 3, 5, 2, 4],
 [6, 1, 4, 2, 5, 3],
 [6, 1, 4, 3, 2, 5]]
```

**bruhat_smaller()**

Return the combinatorial class of permutations smaller than or equal to `self` in the Bruhat order (on the
symmetric group containing self).

See `bruhat_lequal()` for the definition of the Bruhat order.

EXAMPLES:

```
sage: Permutation([4,1,2,3]).bruhat_smaller().list()
[[1, 2, 3, 4],
 [1, 2, 4, 3],
 [1, 3, 2, 4],
 [1, 4, 2, 3],
 [2, 1, 3, 4],
 [2, 1, 4, 3],
 [3, 1, 2, 4],
 [4, 1, 2, 3]]
```

`bruhat_succ()`

Return a list of the permutations strictly greater than self in the Bruhat order (on the symmetric group containing self) such that there is no permutation between one of those and self.

See `bruhat_lequal()` for the definition of the Bruhat order.

EXAMPLES:

```
sage: Permutation([6,1,4,5,2,3]).bruhat_succ()
[[6, 4, 1, 5, 2, 3],
 [6, 2, 4, 5, 1, 3],
 [6, 1, 5, 4, 2, 3],
 [6, 1, 4, 5, 3, 2]]
```

`bruhat_succ_iterator()`

An iterator for the permutations that are strictly greater than self in the Bruhat order (on the symmetric group containing self) such that there is no permutation between one of those and self.

See `bruhat_lequal()` for the definition of the Bruhat order.

EXAMPLES:

```
sage: [x for x in Permutation([6,1,4,5,2,3]).bruhat_succ_iterator()]
[[6, 4, 1, 5, 2, 3],
 [6, 2, 4, 5, 1, 3],
 [6, 1, 5, 4, 2, 3],
 [6, 1, 4, 5, 3, 2]]
```

`complement()`

Return the complement of the permutation self.

The complement of a permutation $w \in S_n$ is defined as the permutation in $S_n$ sending each $i$ to $n+1-w(i)$.

EXAMPLES:

```
sage: Permutation([1,2,3]).complement()
[3, 2, 1]
sage: Permutation([1, 3, 2]).complement()
[3, 1, 2]
```

`cycle_string()`

Returns a string of the permutation in cycle notation.

If `singletons=True`, it includes 1-cycles in the string.

EXAMPLES:

```python
sage: Permutation([1,2,3]).cycle_string()
'(1)'
sage: Permutation([2,1,3]).cycle_string()
'(1,2)'
sage: Permutation([2,3,1]).cycle_string()
'(1,2,3)'
sage: Permutation([2,1,3]).cycle_string(singletons=True)
'(1,2)(3)'
```

cycle_tuples (singletons=True, use_min=True)

Return the permutation self as a list of disjoint cycles.

The cycles are returned in the order of increasing smallest elements, and each cycle is returned as a tuple which starts with its smallest element.

If singletons=False is given, the list does not contain the singleton cycles.

If use_min=False is given, the cycles are returned in the order of increasing largest (not smallest) elements, and each cycle starts with its largest element.

EXAMPLES:

```python
sage: Permutation([2,1,3,4]).to_cycles()
[(1, 2), (3,), (4,)]
sage: Permutation([2,1,3,4]).to_cycles(singletons=False)
[(1, 2)]
sage: Permutation([2,1,3,4]).to_cycles(use_min=True)
[(1, 2), (3,), (4,)]
sage: Permutation([2,1,3,4]).to_cycles(use_min=False)
[(4,), (3,), (2, 1)]
sage: Permutation([2,1,3,4]).to_cycles(singletons=False, use_min=False)
[(2, 1)]
sage: Permutation([4,1,5,2,6,3]).to_cycles()
[(1, 4, 2), (3, 5, 6)]
sage: Permutation([4,1,5,2,6,3]).to_cycles(use_min=False)
[(6, 3, 5), (4, 2, 1)]
sage: Permutation([6, 4, 5, 2, 3, 1]).to_cycles()
[(1, 6), (2, 4), (3, 5)]
sage: Permutation([6, 4, 5, 2, 3, 1]).to_cycles(use_min=False)
[(6, 1), (5, 3), (4, 2)]
```

The algorithm is of complexity $O(n)$ where $n$ is the size of the given permutation.

cycle_type()

Return a partition of len(self) corresponding to the cycle type of self. This is a non-increasing sequence of the cycle lengths of self.

EXAMPLES:

```python
sage: Permutation([3,1,2,4]).cycle_type()
[3, 1]
```

decreasing_runs (as_tuple=False)

Decreasing runs of the permutation.

INPUT:

- as_tuple – boolean (default: False) choice of output format
OUTPUT:

a list of lists or a tuple of tuples

See also:

runs()

EXAMPLES:

```python
sage: s = Permutation([2, 8, 3, 9, 6, 4, 5, 1, 7])
sage: s.decreasing_runs()
[[2], [8, 3], [9, 6, 4], [5, 1], [7]]
sage: s.decreasing_runs(as_tuple=True)
((2,), (8, 3), (9, 6, 4), (5, 1), (7,))
```

descent_polynomial()

Return the descent polynomial of the permutation self.

The descent polynomial of a permutation \( p \) is the product of all the \( z[p(i)] \) where \( i \) ranges over the descents of \( p \).

A descent of a permutation \( p \) is an integer \( i \) such that \( p(i) > p(i+1) \).

REFERENCES:

• [GS1984]

EXAMPLES:

```python
sage: Permutation([2,1,3]).descent_polynomial()
z1
sage: Permutation([4,3,2,1]).descent_polynomial()
z1+z2^2+z3^3
```

Todo: This docstring needs to be fixed. First, the definition does not match the implementation (or the examples). Second, this doesn’t seem to be defined in [GS1984] (the descent monomial in their (7.23) is different).

descents(final_descent=False, side='right', positive=False, from_zero=False, index_set=None)

Return the list of the descents of self.

A descent of a permutation \( p \) is an integer \( i \) such that \( p(i) > p(i+1) \).

**Warning:** By default, the descents are returned as elements in the index set, i.e., starting at 1. If you want them to start at 0, set the keyword from_zero to True.

INPUT:

- final_descent – boolean (default False); if True, the last position of a non-empty permutation is also considered as a descent
- side – 'right' (default) or 'left'; if 'left', return the descents of the inverse permutation
- positive – boolean (default False); if True, return the positions that are not descents
- from_zero – boolean (default False); if True, return the positions starting from 0
- index_set – list (default: [1, ..., n-1] where self is a permutation of n); the index set to check for descents
EXAMPLES:

```python
sage: Permutation([3,1,2]).descents()
[1]
sage: Permutation([1,4,3,2]).descents()
[2, 3]
sage: Permutation([1,4,3,2]).descents(final_descent=True)
[2, 3, 4]
sage: Permutation([1,4,3,2]).descents(index_set=[1,2])
[2]
sage: Permutation([1,4,3,2]).descents(from_zero=True)
[1, 2]
```

descents_composition()

Return the descent composition of self.

The descent composition of a permutation \( p \in S_n \) is defined as the composition of \( n \) whose descent set equals the descent set of \( p \). Here, the descent set of \( p \) is defined as the set of all \( i \in \{1, 2, \ldots, n-1\} \) satisfying \( p(i) > p(i+1) \). The descent set of a composition \( c = (i_1, i_2, \ldots, i_k) \) is defined as the set \( \{i_1, i_1 + i_2, i_1 + i_2 + i_3, \ldots, i_1 + i_2 + \cdots + i_{k-1}\} \).

EXAMPLES:

```python
sage: Permutation([1,3,2,4]).descents_composition()
[2, 2]
sage: Permutation([4,1,6,7,2,3,8,5]).descents_composition()
[1, 3, 3, 1]
sage: Permutation([]).descents_composition()
[]
```

destandardize(weight, ordered_alphabet=None)

Return destandardization of self with respect to weight and ordered_alphabet.

INPUT:

- weight – list or tuple of nonnegative integers that sum to \( n \) if self is a permutation in \( S_n \).
- ordered_alphabet – (default: None) a list or tuple specifying the ordered alphabet the destandardized word is over

OUTPUT: word over the ordered_alphabet which standardizes to self

Let \( weight = (w_1, w_2, \ldots, w_k) \). Then this methods looks for an increasing sequence of \( 1, 2, \ldots, w_1 \) and labels all letters in it by 1, then an increasing sequence of \( w_1 + 1, w_1 + 2, \ldots, w_1 + w_2 \) and labels all these letters by 2, etc.. If an increasing sequence for the specified weight does not exist, an error is returned. The output is a word \( w \) over the specified ordered alphabet with evaluation weight such that \( w.standard_permutation() \) is self.

EXAMPLES:

```python
sage: p = Permutation([1,2,5,3,6,4])
sage: p.destandardize([3,1,2])
word: 113132
sage: p.destandardize([2,1])
Traceback (most recent call last):
...
ValueError: Standardization with weight [2, 1] is not possible!
```

dict()

Returns a dictionary corresponding to the permutation.
EXAMPLES:

```python
sage: p = Permutation([2,1,3])
sage: d = p.dict()
sage: d[1]
2
sage: d[2]
1
sage: d[3]
3
```

**fixed_points()**

Return a list of the fixed points of `self`.

**EXAMPLES:**

```python
sage: Permutation([1,3,2,4]).fixed_points()
[1, 4]
sage: Permutation([1,2,3,4]).fixed_points()
[1, 2, 3, 4]
```

**foata_bijection()**

Return the image of the permutation `self` under the Foata bijection `\(\phi\)`.

The bijection shows that `maj` (the major index) and `inv` (the number of inversions) are equidistributed: if `\(\phi(P) = Q\)`, then `maj(P) = inv(Q)`.

The Foata bijection `\(\phi\)` is a bijection on the set of words with no two equal letters. It can be defined by induction on the size of the word: Given a word `\(w_1w_2\cdots w_n\)`, start with `\(\phi(w_1) = w_1\)`. At the `i`-th step, if `\(\phi(w_1w_2\cdots w_i) = v_1v_2\cdots v_i\)`, we define `\(\phi(w_1w_2\cdots w_iw_{i+1})\)` by placing `\(w_{i+1}\)` on the end of the word `\(v_1v_2\cdots v_i\)` and breaking the word up into blocks as follows. If `\(w_{i+1} > v_i\)`, place a vertical line to the right of each `\(v_k\)` for which `\(w_{i+1} > v_k\)`. Otherwise, if `\(w_{i+1} < v_i\)`, place a vertical line to the right of each `\(v_k\)` for which `\(w_{i+1} < v_k\)`. In either case, place a vertical line at the start of the word as well. Now, within each block between vertical lines, cyclically shift the entries one place to the right.

For instance, to compute `\(\phi([1, 4, 2, 5, 3])\)`, the sequence of words is

- `1`,
- `14` → `14`,
- `142` → `412`,
- `4125` → `4125`,
- `41253` → `41253`.

So `\(\phi([1, 4, 2, 5, 3]) = [4, 5, 1, 2, 3]\)`.

See section 2 of [FS1978], and the proof of Proposition 1.4.6 in [EnumComb1].

See also:

**foata_bijection_inverse()** for the inverse map.

**EXAMPLES:**

```python
sage: Permutation([1,2,4,3]).foata_bijection()
[4, 1, 2, 3]
sage: Permutation([2,5,1,3,4]).foata_bijection()
[2, 1, 3, 5, 4]
```

(continues on next page)
sage: P = Permutation([2,5,1,3,4])
sage: P.major_index() == P.foata_bijection().number_of_inversions()
True
sage: all( P.major_index() == P.foata_bijection().number_of_inversions()
....: for P in Permutations(4) )
True

The example from [FS1978]:

sage: Permutation([7,4,9,2,6,1,5,8,3]).foata_bijection()
[4, 7, 2, 6, 1, 9, 5, 8, 3]

Border cases:

sage: Permutation([]).foata_bijection()
[]
sage: Permutation([1]).foata_bijection()
[1]

foata_bijection_inverse()  
Return the image of the permutation self under the inverse of the Foata bijection φ.

See foata_bijection() for the definition of the Foata bijection.

EXAMPLES:

sage: Permutation([4,1,2,3]).foata_bijection_inverse()
[1, 2, 4, 3]

forget_cycles()  
Return the image of self under the map which forgets cycles.

Consider a permutation σ written in standard cyclic form:

$$
\sigma = (a_{1,1}, \ldots, a_{1,k_1})(a_{2,1}, \ldots, a_{2,k_2}) \cdots (a_{m,1}, \ldots, a_{m,k_m}),
$$

where $a_{1,1} < a_{2,1} < \cdots < a_{m,1}$ and $a_{j,1} < a_{j,i}$ for all $1 \leq j \leq m$ and $2 \leq i \leq k_j$ where we include cycles of length 1 as well. The image of the forget cycle map φ is given by

$$
\phi(\sigma) = [a_{1,1}, \ldots, a_{1,k_1}, a_{2,1}, \ldots, a_{2,k_2}, \ldots, a_{m,1}, \ldots, a_{m,k_m}],
$$

considered as a permutation in 1-line notation.

See also:  
fundamental_transformation(), which is a similar map that is defined by instead taking $a_{j,1} > a_{j,i}$ and is bijective.

EXAMPLES:

sage: P = Permutations(5)
sage: x = P([1, 5, 3, 4, 2])
sage: x.forget_cycles()
[1, 2, 5, 3, 4]

We select all permutations with a cycle composition of $[2, 3, 1]$ in $S_6$:  

sage: P = Permutations(6)
...: all( x.is_composition([2, 3, 1]) for x in P )
True
Next we apply \( \phi \) and then take the inverse, and then view the results as a poset under the Bruhat order:

Next we apply \( \phi \) and then take the inverse, and then view the results as a poset under the Bruhat order:

We check the statement in [CC2013] that the posets \( C_{[1,3,1,1]} \) and \( C_{[1,3,2]} \) are isomorphic:

See also:

\texttt{fundamental_transformation()} for the inverse map.

\texttt{forget_cycles()} for a similar (but non-bijective) map where each cycle is starting from its lowest element.

EXAMPLES:

Comparison with \texttt{forget_cycles()}:

5.1. Comprehensive Module list 1671
fundamental_transformation_inverse()

Return the image of the permutation self under the inverse of the Renyi-Foata-Schuetzenberger fundamental transformation.

The inverse of the fundamental transformation is a bijection from the set of all permutations of \(\{1, 2, \ldots, n\}\) to itself, which transforms any such permutation \(w\) as follows: Let \(I = \{i_1 < i_2 < \cdots < i_k\}\) be the set of all left-to-right maxima of \(w\) (that is, of all indices \(j\) such that \(w(j)\) is bigger than each of \(w(1), w(2), \ldots, w(j-1)\)). The image of \(w\) under the inverse of the fundamental transformation is the permutation \(u\) that sends \(w(i-1)\) to \(w(i)\) for all \(i \notin I\) (notice that this makes sense, since \(1 \notin I\) whenever \(n > 0\)), while sending each \(w(i_p - 1)\) (with \(p \geq 2\)) to \(w(i_{p-1})\). Here, we set \(i_{k+1} = n+1\).

See [EnumComb1], Proposition 1.3.1.

See also:

fundamental_transformation() for the inverse map.

EXAMPLES:

```
sage: Permutation([3, 4, 5, 2, 1]).fundamental_transformation_inverse()
[5, 1, 3, 4, 2]
sage: Permutation([4, 2, 6, 8, 1, 9, 3, 7, 5]).fundamental_transformation_inverse()
[8, 4, 7, 2, 9, 6, 5, 1, 3]
```

has_pattern(patt)

Test whether the permutation self contains the pattern patt.

EXAMPLES:

```
sage: Permutation([3,5,1,4,6,2]).has_pattern([1,3,2])
True
```

hyperoctahedral_double_coset_type()

Return the coset-type of self as a partition.

self must be a permutation of even size \(2n\). The coset-type determines the double class of the permutation, that is its image in \(H_n \backslash S_{2n}/H_n\), where \(H_n\) is the \(n\)-th hyperoctahedral group.

The coset-type is determined as follows. Consider the perfect matching \(\{(1, 2), (3, 4), \ldots, (2n-1, 2n)\}\) and its image by self, and draw them simultaneously as edges of a graph whose vertices are labeled by \(1, 2, \ldots, 2n\). The coset-type is the ordered sequence of the semi-lengths of the cycles of this graph (see Chapter VII of [Mac1995] for more details, particularly Section VII.2).

EXAMPLES:

```
sage: Permutation([3, 4, 6, 1, 5, 7, 2, 8]).hyperoctahedral_double_coset_type()
[3, 1]
sage: all(p.hyperoctahedral_double_coset_type() == ....: p.inverse().hyperoctahedral_double_coset_type() ....: for p in Permutations(4))
True
```

```
sage: Permutation([]).hyperoctahedral_double_coset_type()
[]
sage: Permutation([3,1,2]).hyperoctahedral_double_coset_type()
Traceback (most recent call last):
...
ValueError: [3, 1, 2] is a permutation of odd size and has no coset-type
```
idescents (final_descent=False, from_zero=False)
Return a list of the idescents of self, that is the list of the descents of self’s inverse.

A descent of a permutation \( p \) is an integer \( i \) such that \( p(i) > p(i+1) \).

**Warning:** By default, the descents are returned as elements in the index set, i.e., starting at 1. If you want them to start at 0, set the keyword from_zero to True.

**INPUT:**
- final_descent – boolean (default False); if True, the last position of a non-empty permutation is also considered as a descent
- from_zero – optional boolean (default False); if False, return the positions starting from 1

**EXAMPLES:**
- sage: Permutation([2,3,1]).idescents()
  [1]
- sage: Permutation([1,4,3,2]).idescents()
  [2, 3]
- sage: Permutation([1,4,3,2]).idescents(final_descent=True)
  [2, 3, 4]
- sage: Permutation([1,4,3,2]).idescents(from_zero=True)
  [1, 2]

idescents_signature (final_descent=False)
Return the list obtained as follows: Each position in self is mapped to \(-1\) if it is an idescent and \(1\) if it is not an idescent.

See idescents() for a definition of idescents.

With the final_descent option, the last position of a non-empty permutation is also considered as a descent.

**EXAMPLES:**
- sage: Permutation([1,4,3,2]).idescents()
  [2, 3]
- sage: Permutation([1,4,3,2]).idescents_signature()
  [1, -1, -1, 1]

imajor_index (final_descent=False)
Return the inverse major index of the permutation self, which is the major index of the inverse of self.

The major index of a permutation \( p \) is the sum of the descents of \( p \). Since our permutation indices are 0-based, we need to add the number of descents.

With the final_descent option, the last position of a non-empty permutation is also considered as a descent.

**EXAMPLES:**
- sage: Permutation([2,1,3]).imajor_index()
  1
- sage: Permutation([3,4,1,2]).imajor_index()
  2
- sage: Permutation([4,3,2,1]).imajor_index()
  6
**increasing_tree**(compare=<built-in function min>)

Return the increasing tree associated to *self*.

**EXAMPLES:**

```
sage: Permutation([1,4,3,2]).increasing_tree()
[1[., 2[3[., .], .], .]]
sage: Permutation([4,1,3,2]).increasing_tree()
[1[4[., .], 2[3[., .], .]]]
```

By passing the option compare=max one can have the decreasing tree instead:

```
sage: Permutation([2,3,4,1]).increasing_tree(max)
[4[3[2[., .], .], 1[., .]]]
sage: Permutation([2,3,1,4]).increasing_tree(max)
[4[3[2[., .], 1[., .]], .]]
```

**increasing_tree_shape**(compare=<built-in function min>)

Return the shape of the increasing tree associated with the permutation.

**EXAMPLES:**

```
sage: Permutation([1,4,3,2]).increasing_tree_shape()
[., [[., .], [., .]]]
sage: Permutation([4,1,3,2]).increasing_tree_shape()
[[., .], [[., .], [., .]]]
```

By passing the option compare=max one can have the decreasing tree instead:

```
sage: Permutation([2,3,4,1]).increasing_tree_shape(max)
[[[., .], [., .]], [., .]]
sage: Permutation([2,3,1,4]).increasing_tree_shape(max)
[[[., .], [., .]], [., .]]
```

**inverse()**

Return the inverse of *self*.

**EXAMPLES:**

```
sage: Permutation([3,8,5,10,9,4,6,1,7,2]).inverse()
[8, 10, 1, 6, 3, 7, 9, 2, 5, 4]
sage: Permutation([2, 4, 1, 5, 3]).inverse()
[3, 1, 5, 2, 4]
sage: ~Permutation([2, 4, 1, 5, 3])
[3, 1, 5, 2, 4]
```

**inversions()**

Return a list of the inversions of *self*.

An inversion of a permutation \( p \) is a pair \( (i, j) \) such that \( i < j \) and \( p(i) > p(j) \).

**EXAMPLES:**

```
sage: Permutation([3,2,4,1,5]).inversions()
[(1, 2), (1, 4), (2, 4), (3, 4)]
```

**is_derangement()**

Return if *self* is a derangement.

A permutation \( \sigma \) is a derangement if \( \sigma \) has no fixed points.
EXAMPLES:

```python
sage: P = Permutation([1,4,2,3])
sage: P.is_derangement()
False
sage: P = Permutation([2,3,1])
sage: P.is_derangement()
True
```

**is_even()**

Return True if the permutation self is even and False otherwise.

EXAMPLES:

```python
sage: Permutation([1,2,3]).is_even()
True
sage: Permutation([2,1,3]).is_even()
False
```

**ishift(i)**

Return the i-shift of self. If an i-shift of self can’t be performed, then self is returned.

An i-shift can be applied when i is not inbetween i − 1 and i + 1. The i-shift moves i to the other side, and leaves the relative positions of i − 1 and i + 1 in place. All other entries of the permutations are also left in place.

EXAMPLES:

Here, 2 is to the left of both 1 and 3. A 2-shift can be applied which moves the 2 to the right and leaves 1 and 3 in their same relative order:

```python
sage: Permutation([2,1,3]).ishift(2)
[1, 3, 2]
```

All entries other than i, i − 1 and i + 1 are unchanged:

```python
sage: Permutation([2,4,1,3]).ishift(2)
[1, 4, 3, 2]
```

Since 2 is between 1 and 3 in [1, 2, 3], a 2-shift cannot be applied to [1, 2, 3]

```python
sage: Permutation([1,2,3]).ishift(2)
[1, 2, 3]
```

**iswitch(i)**

Return the i-switch of self. If an i-switch of self can’t be performed, then self is returned.

An i-switch can be applied when the subsequence of self formed by the entries i − 1, i and i + 1 is neither increasing nor decreasing. In this case, this subsequence is reversed (i.e., its leftmost element and its rightmost element switch places), while all other letters of self are kept in place.

EXAMPLES:

Here, 2 is to the left of both 1 and 3. A 2-switch can be applied which moves the 2 to the right and switches the relative order between 1 and 3:

```python
sage: Permutation([2,1,3]).iswitch(2)
[3, 1, 2]
```

All entries other than i − 1, i and i + 1 are unchanged:
Since 2 is between 1 and 3 in \([1, 2, 3]\), a 2-switch cannot be applied to \([1, 2, 3]\).

```
sage: Permutation([1,2,3]).iswitch(2)
[1, 2, 3]
```

**left_action_product** \((lp)\)

Return the permutation obtained by composing \(self\) with \(lp\) in such an order that \(lp\) is applied first and \(self\) is applied afterwards.

This is usually denoted by either \(self \ast lp\) or \(lp \ast self\) depending on the conventions used by the author. If the value of a permutation \(p \in S_n\) on an integer \(i \in \{1, 2, \cdots, n\}\) is denoted by \(p(i)\), then this should be denoted by \(self \ast lp\) in order to have associativity (i.e., in order to have \((p \cdot q)(i) = p(q(i))\) for all \(p, q\) and \(i\)). If, on the other hand, the value of a permutation \(p \in S_n\) on an integer \(i \in \{1, 2, \cdots, n\}\) is denoted by \(i^p\), then this should be denoted by \(lp \ast self\) in order to have associativity (i.e., in order to have \(i^{p \cdot q} = (i^p)^q\) for all \(p, q\) and \(i\)).

**EXAMPLES:**

```sage
p = Permutation([2,1,3])
p = Permutation([3,1,2])
p.left_action_product(q)
[3, 2, 1]
p.q.left_action_product(p)
[1, 3, 2]
```

**left_tableau**

Return the left standard tableau after performing the RSK algorithm on \(self\).

**EXAMPLES:**

```sage
Permutation([1,4,3,2]).left_tableau()
[[1, 2], [3], [4]]
```

**length**

Return the Coxeter length of \(self\).

The length of a permutation \(p\) is given by the number of inversions of \(p\).

**EXAMPLES:**

```sage
Permutation([5, 1, 3, 4, 2]).length()
6
```

**longest_increasing_subsequence_length**

Return the length of the longest increasing subsequences of \(self\).

**EXAMPLES:**

```sage
Permutation([2,3,1,4]).longest_increasing_subsequence_length()
3
```

```sage
all(i.longest_increasing_subsequence_length() == len(RSK(i)[0][0]) for i in Permutations(5))
True
```

```sage
Permutation([]).longest_increasing_subsequence_length()
0
```
longest_increasing_subsequences()  
Return the list of the longest increasing subsequences of self.

Note: The algorithm is not optimal.

EXAMPLES:

```
sage: Permutation([2,3,4,1]).longest_increasing_subsequences()
[[2, 3, 4]]
sage: Permutation([5, 7, 1, 2, 6, 4, 3]).longest_increasing_subsequences()
[[1, 2, 6], [1, 2, 4], [1, 2, 3]]
```

major_index(final_descent=False)

Return the major index of self.

The major index of a permutation $p$ is the sum of the descents of $p$. Since our permutation indices are 0-based, we need to add the number of descents.

With the final_descent option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:

```
sage: Permutation([2,1,3]).major_index()
1
sage: Permutation([3,4,1,2]).major_index()
2
sage: Permutation([4,3,2,1]).major_index()
6
```

next()

Return the permutation that follows self in lexicographic order on the symmetric group containing self. If self is the last permutation, then next returns False.

EXAMPLES:

```
sage: p = Permutation([1, 3, 2])
sage: next(p)
[2, 1, 3]
sage: p = Permutation([4,3,2,1])
sage: next(p)
False
```

noninversions($k$)

Return the list of all $k$-noninversions in self.

If $k$ is an integer and $p \in S_n$ is a permutation, then a $k$-noninversion in $p$ is defined as a strictly increasing sequence $(i_1, i_2, \ldots, i_k)$ of elements of $\{1, 2, \ldots, n\}$ satisfying $p(i_1) < p(i_2) < \cdots < p(i_k)$. (In other words, a $k$-noninversion in $p$ can be regarded as a $k$-element subset of $\{1, 2, \ldots, n\}$ on which $p$ restricts to an increasing map.)

EXAMPLES:

```
sage: p = Permutation([3, 2, 4, 1, 5])
sage: p.noninversions(1)
[[3], [2], [4], [1], [5]]
sage: p.noninversions(2)
[[3, 4], [3, 5], [2, 4], [2, 5], [4, 5], [1, 5]]
```
sage: p.noninversions(3)
[[3, 4, 5], [2, 4, 5]]
sage: p.noninversions(4)
[]
sage: p.noninversions(5)
[]

**number_of_descents** (*final_descent=False*)

Return the number of descents of `self`.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

**EXAMPLES:**

```python
sage: Permutation([1,4,3,2]).number_of_descents()
2
sage: Permutation([1,4,3,2]).number_of_descents(final_descent=True)
3
```

**number_of_fixed_points**()

Return the number of fixed points of `self`.

**EXAMPLES:**

```python
sage: Permutation([1,3,2,4]).number_of_fixed_points()
2
sage: Permutation([1,2,3,4]).number_of_fixed_points()
4
```

**number_of_idescents** (*final_descent=False*)

Return the number of idescents of `self`.

See `idescents()` for a definition of idescents.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

**EXAMPLES:**

```python
sage: Permutation([1,4,3,2]).number_of_idescents()
2
sage: Permutation([1,4,3,2]).number_of_idescents(final_descent=True)
3
```

**number_of_inversions**()

Return the number of inversions in `self`.

An inversion of a permutation is a pair of elements \((i, j)\) with \(i < j\) and \(p(i) > p(j)\).

**REFERENCES:**

- http://mathworld.wolfram.com/PermutationInversion.html

**EXAMPLES:**

```python
sage: Permutation([3, 2, 4, 1, 5]).number_of_inversions()
4
sage: Permutation([1, 2, 6, 4, 7, 3, 5]).number_of_inversions()
6
```
**number_of_noninversions** ($k$)

Return the number of $k$-noninversions in `self`.

If $k$ is an integer and $p \in S_n$ is a permutation, then a $k$-noninversion in $p$ is defined as a strictly increasing sequence $(i_1, i_2, \ldots, i_k)$ of elements of $\{1, 2, \ldots, n\}$ satisfying $p(i_1) < p(i_2) < \cdots < p(i_k)$. (In other words, a $k$-noninversion in $p$ can be regarded as a $k$-element subset of $\{1, 2, \ldots, n\}$ on which $p$ restricts to an increasing map.)

The number of $k$-noninversions in $p$ has been denoted by $\text{noninv}_k(p)$ in [RSW2011], where conjectures and results regarding this number have been stated.

**EXAMPLES:**

```python
sage: p = Permutation([3, 2, 4, 1, 5])
sage: p.number_of_noninversions(1)
5
sage: p.number_of_noninversions(2)
6
sage: p.number_of_noninversions(3)
2
sage: p.number_of_noninversions(4)
0
sage: p.number_of_noninversions(5)
0
```

The number of 2-noninversions of a permutation $p \in S_n$ is $\binom{n}{2}$ minus its number of inversions:

```python
sage: b = binomial(5, 2)
sage: all( x.number_of_noninversions(2) == b - x.number_of_inversions() for x in Permutations(5) )
True
```

We also check some corner cases:

```python
sage: all( x.number_of_noninversions(1) == 5 for x in Permutations(5) )
True
sage: all( x.number_of_noninversions(0) == 1 for x in Permutations(5) )
True
sage: Permutation([]).number_of_noninversions(1)
0
sage: Permutation([]).number_of_noninversions(0)
1
sage: Permutation([2, 1]).number_of_noninversions(3)
0
```

**number_of_peaks**

Return the number of peaks of the permutation `self`.

A peak of a permutation $p$ is an integer $i$ such that $p(i - 1) < p(i)$ and $p(i) > p(i + 1)$.

**EXAMPLES:**

```python
sage: Permutation([1,3,2,4,5]).number_of_peaks()
1
sage: Permutation([4,1,3,2,6,5]).number_of_peaks()
2
```

**number_of_recoils**

Return the number of recoils of the permutation `self`.
EXAMPLES:

```
sage: Permutation([1, 4, 3, 2]).number_of_recoils()
2
```

**number_of_saliances()**

Return the number of saliances of `self`.

A saliance of a permutation \( p \) is an integer \( i \) such that \( p(i) > p(j) \) for all \( j > i \).

EXAMPLES:

```
sage: Permutation([2, 3, 1, 5, 4]).number_of_saliances()
2
sage: Permutation([5, 4, 3, 2, 1]).number_of_saliances()
5
```

**pattern_positions(patt)**

Return the list of positions where the pattern `patt` appears in the permutation `self`.

EXAMPLES:

```
sage: Permutation([3, 5, 1, 4, 6, 2]).pattern_positions([1, 3, 2])
[[0, 1, 3], [2, 3, 5], [2, 4, 5]]
```

**peaks()**

Return a list of the peaks of the permutation `self`.

A peak of a permutation \( p \) is an integer \( i \) such that \( p(i - 1) < p(i) \) and \( p(i) > p(i + 1) \).

EXAMPLES:

```
sage: Permutation([1, 3, 2, 4, 5]).peaks()
[1]
sage: Permutation([4, 1, 3, 2, 6, 5]).peaks()
[2, 4]
sage: Permutation([[]].peaks()
[]
```

**permutation_poset()**

Return the permutation poset of `self`.

The permutation poset of a permutation \( p \) is the poset with vertices \((i, p(i))\) for \( i = 1, 2, \ldots, n \) (where \( n \) is the size of \( p \)) and order inherited from \( \mathbb{Z} \times \mathbb{Z} \).

EXAMPLES:

```
sage: Permutation([3, 1, 5, 4, 2]).permutation_poset().cover_relations()
[[[2, 1], (5, 2)],
 [2, 1], (3, 5)],
 [2, 1], (4, 4)],
 [1, 3], (3, 5)],
 [1, 3], (4, 4)]
sage: Permutation([[]].permutation_poset().cover_relations()
[]
sage: Permutation([1, 3, 2]).permutation_poset().cover_relations()
[[[1, 1], (2, 3)], [[1, 1], (3, 2)]]
sage: Permutation([1, 2]).permutation_poset().cover_relations()
[[[1, 1], (2, 2)]]
sage: P = Permutation([1, 5, 2, 4, 3])
```

(continues on next page)
sage: P = Permutation([4,2,1,3])
sage: P.permutohedron_greater()
[[4, 2, 1, 3], [4, 2, 3, 1], [4, 3, 2, 1]]
sage: P = Permutation([4,2,1,3])
sage: P.permutohedron_greater(side='left')
[[4, 2, 1, 3], [4, 3, 1, 2], [4, 3, 2, 1]]

permutohedron_join(other, side='right')
Return the join of the permutations self and other in the right permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option side='left',
then they will be done in the left permutohedron.

See permutohedron_lequal() for the definition of the permutohedron orders.

EXAMPLES:

sage: p = Permutation([3,1,2])
sage: q = Permutation([1,3,2])
sage: p.permutohedron_join(q)
[3, 1, 2]
sage: r = Permutation([2,1,3])
sage: r.permutohedron_join(p)
[3, 2, 1]

permutohedron_meet() (side='right')
Return the meet of the permutations self and other in the right permutohedron order.

The permutohedron orders (see permutohedron_lequal()) are lattices; the meet operation refers to
this lattice structure. In more elementary terms, the meet of two permutations \( \pi \) and \( \psi \) in the symmetric

group \( S_n \) is the permutation in \( S_n \) whose set of inversion is the transitive closure of the union of the set of
inversions of \( \pi \) with the set of inversions of \( \psi \).

See also:
permutohedron_lequal(), permutohedron_meet().

AUTHORS:

Viviane Pons and Darij Grinberg, 18 June 2014.

EXAMPLES:

sage: p = Permutation([3,1,2])
sage: q = Permutation([1,3,2])
sage: p.permutohedron_meet(q)
[3, 1, 2]
The universal property of the join operation is satisfied:

```python
sage: def test_uni_join(p, q):
        j = p.permutohedron_join(q)
        if not p.permutohedron_lequal(j):
            return False
        if not q.permutohedron_lequal(j):
            return False
        for r in p.permutohedron_greater():
            if q.permutohedron_lequal(r) and not j.permutohedron_lequal(r):
                return False
        return True
sage: all( test_uni_join(p, q) for p in Permutations(3) for q in Permutations(3) )
True
sage: test_uni_join(Permutation([6, 4, 7, 3, 2, 5, 8, 1]), Permutation([7, 3, 1, 2, 5, 4, 6, 8]))
True
```

Border cases:

```python
sage: p = Permutation([])
```

```python
sage: p.permutohedron_join(p)
[]
sage: p = Permutation([1])
```

```python
sage: p.permutohedron_join(p)
[1]
```

The left permutohedron:

```python
sage: p = Permutation([3,1,2])
```

```python
sage: q = Permutation([1,3,2])
```

```python
sage: r = Permutation([2,1,3])
```

```python
sage: s = Permutation([1,4,2,3])
```

```python
sage: s.permutohedron_join(r)
[4, 3, 1, 2]
```

permutohedron_lequal(p2, side='right')

Return True if self is less or equal to p2 in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option side='left', then they will be done in the left permutohedron.

For every nonnegative integer \( n \), the right (resp. left) permutohedron order (also called the right (resp. left) weak order, or the right (resp. left) weak Bruhat order) is a partial order on the symmetric group \( S_n \). It can be defined in various ways, including the following ones:

- Two permutations \( u \) and \( v \) in \( S_n \) satisfy \( u \leq v \) in the right (resp. left) permutohedron order if and only if the (Coxeter) length of the permutation \( v^{-1} \circ u \) (resp. of the permutation \( u \circ v^{-1} \)) equals the length of \( v \) minus the length of \( u \). Here, \( p \circ q \) means the permutation obtained by applying \( q \) first and then \( p \). (Recall that the Coxeter length of a permutation is its number of inversions.)
• Two permutations $u$ and $v$ in $S_n$ satisfy $u \leq v$ in the right (resp. left) permutohedron order if and only if every pair $(i, j)$ of elements of $\{1, 2, \cdots, n\}$ such that $i < j$ and $u^{-1}(i) > u^{-1}(j)$ (resp. $u(i) > u(j)$) also satisfies $v^{-1}(i) > v^{-1}(j)$ (resp. $v(i) > v(j)$).

• A permutation $v \in S_n$ covers a permutation $u \in S_n$ in the right (resp. left) permutohedron order if and only if we have $v = u \circ (i, i+1)$ (resp. $v = (i, i+1) \circ u$) for some $i \in \{1, 2, \cdots, n-1\}$ satisfying $u(i) < u(i+1)$ (resp. $u^{-1}(i) < u^{-1}(i+1)$). Here, again, $p \circ q$ means the permutation obtained by applying $q$ first and then $p$.

The right and the left permutohedron order are mutually isomorphic, with the isomorphism being the map sending every permutation to its inverse. Each of these orders endows the symmetric group $S_n$ with the structure of a graded poset (the rank function being the Coxeter length).

Warning: The permutohedron order is not to be mistaken for the strong Bruhat order ($\text{bruhat_lequal()}$), despite both orders being occasionally referred to as the Bruhat order.

EXAMPLES:

```
sage: p = Permutation([3,2,1,4])
sage: p.permutohedron_lequal(Permutation([4,2,1,3]))
False
sage: p.permutohedron_lequal(Permutation([4,2,1,3]), side='left')
True
sage: p.permutohedron_lequal(p)
True
sage: Permutation([2,1,3]).permutohedron_lequal(Permutation([2,3,1]))
True
sage: Permutation([2,1,3]).permutohedron_lequal(Permutation([3,1,2]))
False
sage: Permutation([2,1,3]).permutohedron_lequal(Permutation([1,2,3]))
False
sage: Permutation([1,3,2]).permutohedron_lequal(Permutation([2,1,3]))
False
sage: Permutation([1,3,2]).permutohedron_lequal(Permutation([2,1,3]), side='left')
False
sage: Permutation([2,3,1]).permutohedron_lequal(Permutation([2,3,1]), side='left')
False
sage: sorted([len([b for b in Permutations(3) if a.permutohedron_lequal(b)])
          for a in Permutations(3)])
[1, 2, 2, 3, 3, 6]
sage: sorted([len([b for b in Permutations(3) if a.permutohedron_lequal(b, side='left')])
          for a in Permutations(3)])
[1, 2, 2, 3, 3, 6]
sage: Permutation([]).permutohedron_lequal(Permutation([]))
True
```

`permutohedron_meet` (other, side='right')

Return the meet of the permutations `self` and `other` in the right permutohedron order (or, if `side` is set to 'left', in the left permutohedron order).

The permutohedron orders (see `permutohedron_lequal()`) are lattices; the meet operation refers
to this lattice structure. It is connected to the join operation by the following simple symmetry property: If \( \pi \) and \( \psi \) are two permutations \( \pi \) and \( \psi \) in the symmetric group \( S_n \), and if \( w_0 \) denotes the permutation \( (n, n-1, \ldots, 1) \in S_n \), then
\[
\pi \land \psi = w_0 \circ ((w_0 \circ \pi) \lor (w_0 \circ \psi)) = ((\pi \circ w_0) \lor (\psi \circ w_0)) \circ w_0
\]
and
\[
\pi \lor \psi = w_0 \circ ((w_0 \circ \pi) \land (w_0 \circ \psi)) = ((\pi \circ w_0) \land (\psi \circ w_0)) \circ w_0,
\]
where \( \land \) means meet and \( \lor \) means join.

See also:
\( \text{permutohedron\_lequal()} \), \( \text{permutohedron\_join()} \).

AUTHORS:
Viviane Pons and Darij Grinberg, 18 June 2014.

EXAMPLES:

```python
sage: p = Permutation([3,1,2])
sage: q = Permutation([1,3,2])
sage: p.permutohedron_meet(q)
[1, 3, 2]
sage: r = Permutation([2,1,3])
sage: r.permutohedron_meet(p)
[1, 2, 3]
sage: p = Permutation([3,2,4,1])
sage: q = Permutation([4,2,1,3])
sage: p.permutohedron_meet(q)
[2, 1, 3, 4]
```

The universal property of the meet operation is satisfied:

```python
sage: def test_uni_meet(p, q):
    m = p.permutohedron_meet(q)
    if not m.permutohedron_lequal(p):
        return False
    if not m.permutohedron_lequal(q):
        return False
    for r in p.permutohedron_smaller():
        if r.permutohedron_lequal(q) and not r.permutohedron_lequal(m):
            return False
    return True
sage: all( test_uni_meet(p, q) for p in Permutations(3) for q in
   \rightarrow Permutations(3) )
True
sage: test_uni_meet(Permutation([6, 4, 7, 3, 2, 5, 8, 1]), Permutation([7, 3,
   \rightarrow 1, 2, 5, 4, 6, 8]))
True
```
Border cases:

```
sage: p = Permutation([])
sage: p.permutohedron_meet(p)
[]
sage: p = Permutation([1])
sage: p.permutohedron_meet(p)
[1]
```

The left permutohedron:

```
sage: p = Permutation([3,1,2])
sage: q = Permutation([1,3,2])
sage: p.permutohedron_meet(q, side="left")
[1, 2, 3]
sage: r = Permutation([2,1,3])
sage: r.permutohedron_meet(p, side="left")
[2, 1, 3]
```

`permutohedron_pred(side='right')`

Return a list of the permutations strictly smaller than `self` in the permutohedron order such that there is no permutation between any of those and `self`.

By default, the computations are done in the right permutohedron. If you pass the option `side='left'`, then they will be done in the left permutohedron.

See `permutohedron_lequal()` for the definition of the permutohedron orders.

**EXAMPLES:**

```
sage: p = Permutation([4,2,1,3])
sage: p.permutohedron_pred()
[[2, 4, 1, 3], [4, 1, 2, 3]]
sage: p.permutohedron_pred(side='left')
[[4, 1, 2, 3], [3, 2, 1, 4]]
```

`permutohedron_smaller(side='right')`

Return a list of permutations smaller than or equal to `self` in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option `side='left'`, then they will be done in the left permutohedron.

See `permutohedron_lequal()` for the definition of the permutohedron orders.

**EXAMPLES:**

```
sage: Permutation([4,2,1,3]).permutohedron_smaller()
[[1, 2, 3, 4],
 [1, 2, 4, 3],
 [1, 4, 2, 3],
 [2, 1, 3, 4],
 [2, 1, 4, 3],
 [2, 4, 1, 3],
 [4, 1, 2, 3],
 [4, 2, 1, 3]]
```

```
sage: Permutation([4,2,1,3]).permutohedron_smaller(side='left')
[[1, 2, 3, 4],
 [1, 3, 2, 4],
 [2, 1, 3, 4],
 [2, 3, 1, 4],
 [3, 1, 2, 4],
 [3, 2, 1, 4],
```

(continues on next page)
permutohedron_succ (side='right')
Return a list of the permutations strictly greater than self in the permutohedron order such that there is no permutation between any of those and self.

By default, the computations are done in the right permutohedron. If you pass the option side='left', then they will be done in the left permutohedron.

See permutohedron_lequal() for the definition of the permutohedron orders.

EXAMPLES:

```python
sage: p = Permutation([4,2,1,3])
sage: p.permutohedron_succ()
[[4, 2, 3, 1]]
sage: p.permutohedron_succ(side='left')
[[4, 3, 1, 2]]
```

prev()
Return the permutation that comes directly before self in lexicographic order on the symmetric group containing self. If self is the first permutation, then it returns False.

EXAMPLES:

```python
sage: p = Permutation([1,2,3])
sage: p.prev()
False
sage: p = Permutation([1,3,2])
sage: p.prev()
[1, 2, 3]
```

rank()
Return the rank of self in the lexicographic ordering on the symmetric group to which self belongs.

EXAMPLES:

```python
sage: Permutation([1,2,3]).rank()
0
sage: Permutation([1, 2, 4, 6, 3, 5]).rank()
10
sage: perms = Permutations(6).list()
sage: [p.rank() for p in perms] == list(range(factorial(6)))
True
```

recoils()
Return the list of the positions of the recoils of self.

A recoil of a permutation $p$ is an integer $i$ such that $i+1$ appears to the left of $i$ in $p$. Here, the positions are being counted starting at 0. (Note that it is the positions, not the recoils themselves, which are being listed.)

EXAMPLES:

```python
sage: Permutation([1,4,3,2]).recoils()
[2, 3]
sage: Permutation([]).recoils()
[]
```
**recoils_composition()**

Return the recoils composition of self.

The recoils composition of a permutation $p \in S_n$ is the composition of $n$ whose descent set is the set of the recoils of $p$ (not their positions). In other words, this is the descents composition of $p^{-1}$.

**EXAMPLES:**

```python
sage: Permutation([1,3,2,4]).recoils_composition()
[2, 2]
sage: Permutation([]).recoils_composition()
[]
```

**reduced_word()**

Return a reduced word of the permutation self.

See `reduced_words()` for the definition of reduced words and a way to compute them all.

**Warning:** This does not respect the multiplication convention.

**EXAMPLES:**

```python
sage: Permutation([3,5,4,6,2,1]).reduced_word()
[2, 1, 4, 3, 2, 4, 3, 5, 4, 5]
sage: Permutation([1]).reduced_word_lexmin()
[]
sage: Permutation([]).reduced_word_lexmin()
[]
```

**reduced_word_lexmin()**

Return a lexicographically minimal reduced word of the permutation self.

See `reduced_words()` for the definition of reduced words and a way to compute them all.

**EXAMPLES:**

```python
sage: Permutation([3,4,2,1]).reduced_word_lexmin()
[1, 2, 1, 3, 2]
sage: Permutation([1]).reduced_word_lexmin()
[]
sage: Permutation([]).reduced_word_lexmin()
[]
```

**reduced_words()**

Return a list of the reduced words of self.

The notion of a reduced word is based on the well-known fact that every permutation can be written as a product of adjacent transpositions. In more detail: If $n$ is a nonnegative integer, we can define the transpositions $s_i = (i, i + 1) \in S_n$ for all $i \in \{1, 2, \ldots, n-1\}$, and every $p \in S_n$ can then be written as a product $s_{i_1} s_{i_2} \cdots s_{i_k}$ for some sequence $(i_1, i_2, \ldots, i_k)$ of elements of $\{1, 2, \ldots, n-1\}$ (here $\{1, 2, \ldots, n-1\}$ denotes the empty set when $n \leq 1$). Fixing a $p$, the sequences $(i_1, i_2, \ldots, i_k)$ of smallest length satisfying $p = s_{i_1} s_{i_2} \cdots s_{i_k}$ are called the reduced words of $p$. (Their length is the Coxeter length of $p$, and can be computed using `length()`.)

Note that the product of permutations is defined here in such a way that $(pq)(i) = p(q(i))$ for all permutations $p$ and $q$ and each $i \in \{1, 2, \ldots, n\}$ (this is the same convention as in `left_action_product()`.)
but not the default semantics of the $*$ operator on permutations in Sage). Thus, for instance, $s_2s_1$ is the permutation obtained by first transposing 1 with 2 and then transposing 2 with 3.

See also:

* reduced_word() *, reduced_word_lexmin()

**EXAMPLES:**

```python
sage: Permutation([2,1,3]).reduced_words()
[[1]]
sage: Permutation([3,1,2]).reduced_words()
[[2, 1]]
sage: Permutation([3,2,1]).reduced_words()
[[1, 2, 1], [2, 1, 2]]
sage: Permutation([3,2,4,1]).reduced_words()
[[1, 2, 3, 1], [1, 2, 1, 3], [2, 1, 2, 3]]
```

**reduced_words_iterator()**

Return an iterator for the reduced words of self.

**EXAMPLES:**

```python
sage: next(Permutation([5,2,3,4,1]).reduced_words_iterator())
[1, 2, 3, 4, 3, 2, 1]
```

**remove_extra_fixed_points()**

Return the permutation obtained by removing any fixed points at the end of self.

**EXAMPLES:**

```python
sage: Permutation([2,1,3]).remove_extra_fixed_points()
[2, 1]
sage: Permutation([1,2,3,4]).remove_extra_fixed_points()
[1]
```

**See also:**

* retract_plain() *

**retract_direct_product**(m)

Return the direct-product retract of the permutation $s \in S_n$ to $S_m$, where $m \leq n$. If this retract is undefined, then None is returned.

If $p \in S_n$ is a permutation, and $m$ is a nonnegative integer less or equal to $n$, then the direct-product retract of $p$ to $S_m$ is defined only if $p([m]) = [m]$, where $[m]$ denotes the interval $\{1, 2, \ldots, m\}$. In this case, it is defined as the permutation written $(p(1), p(2), \ldots, p(m))$ in one-line notation.

**EXAMPLES:**

```python
sage: Permutation([4,1,2,3,5]).retract_direct_product(4)
[4, 1, 2, 3]
sage: Permutation([4,1,2,3,5]).retract_direct_product(3)

sage: Permutation([1,4,2,3,6,5]).retract_direct_product(5)
```

(continues on next page)
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(4)
[1, 4, 2, 3]
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(3)
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(2)
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(1)
[1]
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(0)
[]
sage: all( p.retract_direct_product(3) == p for p in Permutations(3) )
True

See also:
retract_plain(), retract_okounkov_vershik()

retract_okounkov_vershik(m)

Return the Okounkov-Vershik retract of the permutation self ∈ S_n to S_m, where m ≤ n.

If p ∈ S_n is a permutation, and m is a nonnegative integer less or equal to n, then the Okounkov-Vershik retract of p to S_m is defined as the permutation in S_m which sends every i ∈ {1, 2, ..., m} to p^{k_i}(i), where k_i is the smallest positive integer k satisfying p^k(i) ≤ m.

In other words, the Okounkov-Vershik retract of p is the permutation whose disjoint cycle decomposition is obtained by removing all letters strictly greater than m from the decomposition of p into disjoint cycles (and removing all cycles which are emptied in the process).

When m = n – 1, the Okounkov-Vershik retract (as a map S_n → S_{n-1}) is the map \( \tilde{p}_n \) introduced in Section 7 of [VO2005], and appears as (3.20) in [CST2010]. In the general case, the Okounkov-Vershik retract of a permutation in S_n to S_m can be obtained by first taking its Okounkov-Vershik retract to S_{n-1}, then that of the resulting permutation to S_{n-2}, etc. until arriving in S_m.

EXAMPLES:

sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(4)
[4, 1, 2, 3]
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(3)
[3, 1, 2]
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(2)
[2, 1]
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(1)
[1]
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(0)
[]

sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(5)
[1, 2, 3, 6]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(4)
[1, 4, 2, 3]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(3)
[1, 3, 2]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(2)
[1, 2]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(1)
[1]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(0)
[]
sage: Permutation([6,5,4,3,2,1]).retract_okounkov_vershik(5)
[1, 5, 4, 3, 2]
sage: Permutation([6,5,4,3,2,1]).retract_okounkov_vershik(4)
[1, 2, 4, 3]
sage: Permutation([1,5,2,6,3,7,4,8]).retract_okounkov_vershik(4)
[1, 3, 2, 4]
sage: all( p.retract_direct_product(3) == p for p in Permutations(3) )
True

See also:
retract_plain(), retract_direct_product()

retract_plain(m)
Return the plain retract of the permutation self in Sn to Sm, where m ≤ n. If this retract is undefined, then None is returned.

If p ∈ Sn is a permutation, and m is a nonnegative integer less or equal to n, then the plain retract of p to Sm is defined only if every i > m satisfies p(i) = i. In this case, it is defined as the permutation written (p(1), p(2),...,p(m)) in one-line notation.

EXAMPLES:

sage: Permutation([4,1,2,3,5]).retract_plain(4)
[4, 1, 2, 3]
sage: Permutation([4,1,2,3,5]).retract_plain(3)

sage: Permutation([1,3,2,4,5,6]).retract_plain(3)
[1, 3, 2]
sage: Permutation([1,3,2,4,5,6]).retract_plain(2)
sage: Permutation([1,2,3,4,5]).retract_plain(1)
[1]
sage: Permutation([1,2,3,4,5]).retract_plain(0)
[]
sage: all( p.retract_plain(3) == p for p in Permutations(3) )
True

See also:
retract_direct_product(), retract_okounkov_vershik(), remove_extra_fixed_points()

reverse()
Returns the permutation obtained by reversing the list.

EXAMPLES:

sage: Permutation([3,4,1,2]).reverse()
[2, 1, 4, 3]
sage: Permutation([1,2,3,4,5]).reverse()
[5, 4, 3, 2, 1]

right_action_product(rp)
Return the permutation obtained by composing self with rp in such an order that self is applied first and rp is applied afterwards.
This is usually denoted by either \texttt{self * rp} or \texttt{rp * self} depending on the conventions used by the author. If the value of a permutation \( p \in S_n \) on an integer \( i \in \{1,2,\ldots,n\} \) is denoted by \( p(i) \), then this should be denoted by \( rp * self \) in order to have associativity (i.e., in order to have \( (p \cdot q)(i) = p(q(i)) \) for all \( p, q \) and \( i \)). If, on the other hand, the value of a permutation \( p \in S_n \) on an integer \( i \in \{1,2,\ldots,n\} \) is denoted by \( ip \), then this should be denoted by \texttt{self * rp} in order to have associativity (i.e., in order to have \( i^{pq} = (ip)^q \) for all \( p, q \) and \( i \)).

\textbf{EXAMPLES:}

\begin{verbatim}
sage: p = Permutation([2,1,3])
sage: q = Permutation([3,1,2])
sage: p.right_action_product(q)
[1, 3, 2]
sage: q.right_action_product(p)
[3, 2, 1]
\end{verbatim}

\begin{verbatim}
\texttt{right_permutohedron_interval()} \texttt{(other)}
\end{verbatim}

Return the list of the permutations belonging to the right permutohedron interval where \texttt{self} is the minimal element and \texttt{other} the maximal element.

See \texttt{permutohedron_lequal()} for the definition of the permutohedron orders.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Permutation([2, 1, 4, 5, 3]).right_permutohedron_interval(Permutation([2, 5, 4, 1, 3]))
[[2, 4, 5, 1, 3], [2, 4, 1, 5, 3], [2, 1, 4, 5, 3], [2, 1, 5, 4, 3], [2, 5, 1, 4, 3], [2, 5, 4, 1, 3]]
\end{verbatim}

\begin{verbatim}
\texttt{right_permutohedron_interval_iterator()} \texttt{(other)}
\end{verbatim}

Return an iterator on the permutations (represented as integer lists) belonging to the right permutohedron interval where \texttt{self} is the minimal element and \texttt{other} the maximal element.

See \texttt{permutohedron_lequal()} for the definition of the permutohedron orders.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Permutation([2, 1, 4, 5, 3]).right_permutohedron_interval_iterator(Permutation([2, 5, 4, 1, 3]))
[[2, 4, 5, 1, 3], [2, 4, 1, 5, 3], [2, 1, 4, 5, 3], [2, 1, 5, 4, 3], [2, 5, 1, 4, 3], [2, 5, 4, 1, 3]]
\end{verbatim}

\begin{verbatim}
\texttt{right_tableau()}
\end{verbatim}

Return the right standard tableau after performing the RSK algorithm on \texttt{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Permutation([1,4,3,2]).right_tableau()
[[1, 2], [3], [4]]
\end{verbatim}

\begin{verbatim}
\texttt{robinson_schensted()}
\end{verbatim}

Return the pair of standard tableaux obtained by running the Robinson-Schensted algorithm on \texttt{self}.

This can also be done by running \texttt{RSK()} on \texttt{self} (with the optional argument check_standard=True to return standard Young tableaux).

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Permutation([6,2,3,1,7,5,4]).robinson_schensted()
[['[1, 3, 4], [2, 5], [6, 7]]
['[1, 3, 5], [2, 6], [4, 7]]
\end{verbatim}
runs (as_tuple=False)
Return a list of the runs in the nonempty permutation self.

A run in a permutation is defined to be a maximal (with respect to inclusion) nonempty increasing substring (i.e., contiguous subsequence). For instance, the runs in the permutation [6, 1, 7, 3, 4, 5, 2] are [6], [1, 7], [3, 4, 5] and [2].

Runs in an empty permutation are not defined.

INPUT:
• as_tuple – boolean (default: False) choice of output format

OUTPUT:
a list of lists or a tuple of tuples

REFERENCES:
• http://mathworld.wolfram.com/PermutationRun.html

EXAMPLES:

```
sage: Permutation([1,2,3,4]).runs()
[[1, 2, 3, 4]]
sage: Permutation([4,3,2,1]).runs()
[[4], [3], [2], [1]]
sage: Permutation([2,4,1,3]).runs()
[[2, 4], [1, 3]]
sage: Permutation([1]).runs()
[[1]]
```

The example from above:

```
sage: Permutation([6,1,7,3,4,5,2]).runs()  
[[6], [1, 7], [3, 4, 5], [2]]
sage: Permutation([6,1,7,3,4,5,2]).runs(as_tuple=True)  
((6,), (1, 7), (3, 4, 5), (2,))
```

The number of runs in a nonempty permutation equals its number of descents plus 1:

```
sage: all( len(p.runs()) == p.number_of_descents() + 1  
....:     for p in Permutations(6) )
True
```

saliences()
Return a list of the saliances of the permutation self.

A saliance of a permutation \( p \) is an integer \( i \) such that \( p(i) > p(j) \) for all \( j > i \).

EXAMPLES:

```
sage: Permutation([2,3,1,5,4]).saliences()
[3, 4]
sage: Permutation([5,4,3,2,1]).saliences()
[0, 1, 2, 3, 4]
```

shifted_concatenation (other, side='right')
Return the right (or left) shifted concatenation of self with a permutation other. These operations are also known as the Loday-Ronco over and under operations.

INPUT:
other – a permutation, a list, a tuple, or any iterable representing a permutation.

side – (default: "right") the string “left” or “right”.

OUTPUT:

If side is "right", the method returns the permutation obtained by concatenating self with the letters of other incremented by the size of self. This is what is called side / other in [LR0102066], and denoted as the “over” operation. Otherwise, i.e., when side is "left", the method returns the permutation obtained by concatenating the letters of other incremented by the size of self with self. This is what is called side \ other in [LR0102066] (which seems to use the \((\sigma \pi)(i) = \pi(\sigma(i))\) convention for the product of permutations).

EXAMPLES:

```
sage: Permutation([]).shifted_concatenation(Permutation([]), "right") []
sage: Permutation([]).shifted_concatenation(Permutation([]), "left") []
sage: Permutation([2, 4, 1, 3]).shifted_concatenation(Permutation([3, 1, 2]), "right") [2, 4, 1, 3, 7, 5, 6]
sage: Permutation([2, 4, 1, 3]).shifted_concatenation(Permutation([3, 1, 2]), "left") [7, 5, 6, 2, 4, 1, 3]
```

**shifted_shuffle**(other)

Return the shifted shuffle of two permutations self and other.

INPUT:

- other – a permutation, a list, a tuple, or any iterable representing a permutation.

OUTPUT:

The list of the permutations appearing in the shifted shuffle of the permutations self and other.

EXAMPLES:

```
sage: Permutation([]).shifted_shuffle(Permutation([])) [[]]
sage: Permutation([1, 2, 3]).shifted_shuffle(Permutation([1]))
[[4, 1, 2, 3], [1, 2, 3, 4], [1, 2, 4, 3], [1, 4, 2, 3]]
sage: Permutation([1, 2]).shifted_shuffle(Permutation([2, 1]))
[[4, 1, 3, 2], [4, 3, 1, 2], [1, 4, 3, 2], [1, 4, 2, 3], [1, 2, 4, 3], [4, 1, 2, 3]]
sage: Permutation([1]).shifted_shuffle([1])
[[2, 1], [1, 2]]
sage: len(Permutation([3, 1, 5, 4, 2]).shifted_shuffle(Permutation([2, 1, 4, 3])))
126
```

The shifted shuffle product is associative. We can test this on an admittedly toy example:

```
sage: all(all(sorted(flatten([abs.shifted_shuffle(c)
                           for abs in a.shifted_shuffle(b)]))
         for bcs in b.shifted_shuffle(c)))
```

(continues on next page)
The \texttt{shifted\_shuffle} method on permutations gives the same permutations as the \texttt{shifted\_shuffle} method on words (but is faster):

\begin{verbatim}
sage: all( all( sorted(p1.shifted_shuffle(p2)) == sorted([Permutation(p) for p in Word(p1).shifted_shuffle(Word(p2))]) for p2 in Permutations(3) ) for p1 in Permutations(2) )
True
\end{verbatim}

\texttt{show}(representation=’cycles’, orientation=’landscape’, **\texttt{args})

Display the permutation as a drawing.

\textbf{INPUT:}

\begin{itemize}
  \item \texttt{representation} – different kinds of drawings are available
    \begin{itemize}
    \item "cycles" (default) – the permutation is displayed as a collection of directed cycles
    \item "braid" – the permutation is displayed as segments linking each element 1, ..., \(n\) to its image on a parallel line.
    \end{itemize}
  \end{itemize}

When using this drawing, it is also possible to display the permutation horizontally (\texttt{orientation} = "landscape", default option) or vertically (\texttt{orientation} = "portrait").

\begin{itemize}
  \item "chord\_diagram" – the permutation is displayed as a directed graph, all of its vertices being located on a circle.
\end{itemize}

All additional arguments are forwarded to the \texttt{show} subcalls.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Permutations(20).random_element().show(representation = "cycles")
sage: Permutations(20).random_element().show(representation = "chord\_diagram")
sage: Permutations(20).random_element().show(representation = "braid")
sage: Permutations(20).random_element().show(representation = "braid", orientation='portrait')
\end{verbatim}

\texttt{sign}()

Return the signature of the permutation \texttt{self}. This is \((-1)^l\), where \(l\) is the number of inversions of \texttt{self}.

\textbf{Note:} \texttt{sign()} can be used as an alias for \texttt{signature}().

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Permutation([4, 2, 3, 1, 5]).signature()
-1
sage: Permutation([1,3,2,5,4]).sign()
1
sage: Permutation([]).sign()
1
\end{verbatim}

\texttt{signature}()

Return the signature of the permutation \texttt{self}. This is \((-1)^l\), where \(l\) is the number of inversions of \texttt{self}.
**Note:** `sign()` can be used as an alias for `signature()`.

**EXAMPLES:**

```
sage: Permutation([4, 2, 3, 1, 5]).signature()
sage: Permutation([1,3,2,5,4]).sign()
sage: Permutation([]).sign()
```

**simion_schmidt** *(avoid=[1, 2, 3])*

Implements the Simion-Schmidt map which sends an arbitrary permutation to a pattern avoiding permutation, where the permutation pattern is one of four length-three patterns. This method also implements the bijection between (for example) $[1, 2, 3]$- and $[1, 3, 2]$-avoiding permutations.

**INPUT:**

- avoid – one of the patterns $[1, 2, 3]$, $[1, 3, 2]$, $[3, 1, 2]$, $[3, 2, 1]$.

**EXAMPLES:**

```
sage: P = Permutations(6)
sage: p = P([4,5,1,6,3,2])
sage: pl = [ [1,2,3], [1,3,2], [3,1,2], [3,2,1] ]
sage: for q in pl:
....:     s = p.simion_schmidt(q)
....:     print("{} {}\n".format(s, s.has_pattern(q)))
[4, 6, 1, 5, 3, 2] False
[4, 2, 1, 3, 5, 6] False
[4, 5, 3, 6, 2, 1] False
[4, 5, 1, 6, 2, 3] False
```

**size()**

Return the size of `self`.

**EXAMPLES:**

```
sage: Permutation([3,4,1,2,5]).size()
```

**sylvester_class** *(left_to_right=False)*

Iterate over the equivalence class of the permutation `self` under sylvester congruence.

Sylvester congruence is an equivalence relation on the set $S_n$ of all permutations of $n$. It is defined as the smallest equivalence relation such that every permutation of the form $uacb$ with $u$, $v$ and $w$ being words and $a$, $b$ and $c$ being letters satisfying $a \leq b < c$ is equivalent to the permutation $ucabw$. (Here, permutations are regarded as words by way of one-line notation.) This definition comes from [HNT2005], Definition 8, where it is more generally applied to arbitrary words.

The equivalence class of a permutation $p \in S_n$ under sylvester congruence is called the *sylvester class* of $p$. It is an interval in the right permutahedron order (see `permutahedron_lequal()`) on $S_n$.

This is related to the `sylvester_class()` method in that the equivalence class of a permutation $\pi$ under sylvester congruence is the sylvester class of the right-to-left binary search tree of $\pi$. However, the present method yields permutations, while the method on labelled binary trees yields plain lists.

If the variable `left_to_right` is set to `True`, the method instead iterates over the equivalence class of `self` with respect to the *left* sylvester congruence. The left sylvester congruence is easiest to define.

5.1. Comprehensive Module list 1695
by saying that two permutations are equivalent under it if and only if their reverses (\texttt{reverse()}) are equivalent under (standard) sylvester congruence.

**EXAMPLES:**

The sylvester class of a permutation in $S_5$:

```python
sage: p = Permutation([3, 5, 1, 2, 4])
sage: sorted(p.sylvester_class())
[[1, 3, 2, 5, 4],
 [1, 3, 5, 2, 4],
 [1, 5, 3, 2, 4],
 [3, 1, 2, 5, 4],
 [3, 1, 5, 2, 4],
 [3, 5, 1, 2, 4],
 [5, 1, 3, 2, 4],
 [5, 3, 1, 2, 4]]
```

The sylvester class of a permutation $p$ contains $p$:

```python
sage: all( p in p.sylvester_class() for p in Permutations(4) )
True
```

Small cases:

```python
sage: list(Permutation([]).sylvester_class())
[[ ]]
sage: list(Permutation([1]).sylvester_class())
[[1]]
```

The sylvester classes in $S_3$:

```python
sage: [sorted(p.sylvester_class()) for p in Permutations(3)]
[[[1, 2, 3]],
 [[1, 3, 2], [3, 1, 2]],
 [[2, 1, 3]],
 [[2, 3, 1]],
 [[1, 3, 2], [3, 1, 2]],
 [[3, 2, 1]]]
```

The left sylvester classes in $S_3$:

```python
sage: [sorted(p.sylvester_class(left_to_right=True)) for p in Permutations(3)]
[[[1, 2, 3]],
 [[1, 3, 2]],
 [[2, 1, 3], [2, 3, 1]],
 [[2, 1, 3], [2, 3, 1]],
 [[3, 1, 2]],
 [[3, 2, 1]]]
```

A left sylvester class in $S_5$:

```python
sage: p = Permutation([4, 2, 1, 5, 3])
sage: sorted(p.sylvester_class(left_to_right=True))
[[4, 2, 1, 3, 5],
 [4, 2, 1, 5, 3],
 [4, 2, 3, 1, 5],
 [4, 2, 3, 1, 5],
 [4, 2, 3, 1, 5]]
```

(continues on next page)
to_alternating_sign_matrix()

Return a matrix representing the permutation in the AlternatingSignMatrix class.

EXAMPLES:

```
sage: m = Permutation([1,2,3]).to_alternating_sign_matrix(); m
[1 0 0]
[0 1 0]
[0 0 1]
sage: parent(m)
Alternating sign matrices of size 3
```

to_cycles (singletons=True, use_min=True)

Return the permutation self as a list of disjoint cycles.

The cycles are returned in the order of increasing smallest elements, and each cycle is returned as a tuple which starts with its smallest element.

If singletons=False is given, the list does not contain the singleton cycles.

If use_min=False is given, the cycles are returned in the order of increasing largest (not smallest) elements, and each cycle starts with its largest element.

EXAMPLES:

```
sage: Permutation([2,1,3,4]).to_cycles()
[(1, 2), (3,), (4,)]
sage: Permutation([2,1,3,4]).to_cycles(singletons=False)
[(1, 2)]
sage: Permutation([2,1,3,4]).to_cycles(use_min=True)
[(1, 2), (3,), (4,)]
sage: Permutation([2,1,3,4]).to_cycles(use_min=False)
[(4,), (3,), (2, 1)]
sage: Permutation([2,1,3,4]).to_cycles(singletons=False, use_min=False)
[(2, 1)]
sage: Permutation([4,1,5,2,6,3]).to_cycles()
[(1, 4, 2), (3, 5, 6)]
sage: Permutation([4,1,5,2,6,3]).to_cycles(use_min=False)
[(6, 3, 5), (4, 2, 1)]
sage: Permutation([6, 4, 5, 2, 3, 1]).to_cycles()
[(1, 6), (2, 4), (3, 5)]
sage: Permutation([6, 4, 5, 2, 3, 1]).to_cycles(use_min=False)
[(6, 1), (5, 3), (4, 2)]
```

The algorithm is of complexity $O(n)$ where $n$ is the size of the given permutation.

to_digraph()

Return a digraph representation of self.

EXAMPLES:
 sage: d = Permutation([3, 1, 2]).to_digraph()
sage: d.edges(labels=False)
[(1, 3), (2, 1), (3, 2)]
sage: P = Permutations(range(1, 10))
sage: d = Permutation(P.random_element()).to_digraph()
sage: all(c.is_cycle() for c in d.strongly_connected_components_subgraphs())
True

to_inversion_vector()
Return the inversion vector of self.

The inversion vector of a permutation \( p \in S_n \) is defined as the vector \((v_1, v_2, \ldots, v_n)\), where \( v_i \) is the number of elements larger than \( i \) that appear to the left of \( i \) in the permutation \( p \).

The algorithm is of complexity \( O(n \log(n)) \) where \( n \) is the size of the given permutation.

EXAMPLES:

 sage: Permutation([5,9,1,8,2,6,4,7,3]).to_inversion_vector()
[2, 3, 6, 4, 0, 2, 2, 1, 0]
sage: Permutation([8,7,2,1,9,4,6,5,10,3]).to_inversion_vector()
[3, 2, 7, 3, 4, 3, 1, 0, 0, 0]
sage: Permutation([3,2,4,1,5]).to_inversion_vector()
[3, 1, 0, 0, 0]

to_lehmer_cocode()
Return the Lehmer cocode of the permutation self.

The Lehmer cocode of a permutation \( p \) is defined as the list \((c_1, c_2, \ldots, c_n)\), where \( c_i \) is the number of \( j < i \) such that \( p(j) > p(i) \).

EXAMPLES:

 sage: p = Permutation([2,1,3])
sage: p.to_lehmer_cocode()
[0, 1, 0]
sage: q = Permutation([3,1,2])
sage: q.to_lehmer_cocode()
[0, 1, 1]

to_lehmer_code()
Return the Lehmer code of the permutation self.

The Lehmer code of a permutation \( p \) is defined as the list \([c[1], c[2], \ldots, c[n]]\), where \( c[i] \) is the number of \( j > i \) such that \( p(j) < p(i) \).

EXAMPLES:

 sage: p = Permutation([2,1,3])
sage: p.to_lehmer_code()
[1, 0, 0]
sage: q = Permutation([3,1,2])
sage: q.to_lehmer_code()
[2, 0, 0]
sage: Permutation([1]).to_lehmer_code()
[0]
sage: Permutation([]).to_lehmer_code()
[]
\textbf{to\_major\_code} (\texttt{final\_descent=False})

Return the major code of the permutation \texttt{self}.

The major code of a permutation $p$ is defined as the sequence $(m_1 - m_2, m_2 - m_3, \ldots, m_n)$, where $m_i$ is the major index of the permutation obtained by erasing all letters smaller than $i$ from $p$.

With the \texttt{final\_descent} option, the last position of a non-empty permutation is also considered as a descent. This has an effect on the computation of major indices.

\textbf{REFERENCES}:

\textbf{EXAMPLES}:

\begin{verbatim}
sage: Permutation([9,3,5,7,2,1,4,6,8]).to_major_code()
[5, 0, 1, 0, 1, 2, 0, 1, 0]
sage: Permutation([2,8,4,3,6,7,9,5,1]).to_major_code()
[8, 3, 3, 1, 4, 0, 1, 0, 0]
\end{verbatim}

\textbf{to\_matrix}()

Return a matrix representing the permutation.

\textbf{EXAMPLES}:

\begin{verbatim}
sage: Permutation([1,2,3]).to_matrix()
[1 0 0]
[0 1 0]
[0 0 1]
sage: matrix(Permutation([1,3,2]))
[1 0 0]
[0 0 1]
[0 1 0]
\end{verbatim}

Alternatively:

\begin{verbatim}
sage: Permutations.options.mult='r2l'
sage: q = Permutation([3,1,2])
sage: (p*q).to_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
sage: p.to_matrix()*q.to_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
\end{verbatim}

Notice that matrix multiplication corresponds to permutation multiplication only when the permutation option \texttt{mult='r2l'}
to_permutation_group_element()
Returns a PermutationGroupElement equal to self.

EXAMPLES:

```sage
sage: Permutation([2,1,4,3]).to_permutation_group_element()
(1,2)(3,4)
sage: Permutation([1,2,3]).to_permutation_group_element()
()
```

to_tableau_by_shape(shape)
Return a tableau of shape shape with the entries in self. The tableau is such that the reading word (i.e., the word obtained by reading the tableau row by row, starting from the top row in English notation, with each row being read from left to right) is self.

EXAMPLES:

```sage
sage: Permutation([3,4,1,2,5]).to_tableau_by_shape([3,2])
[[1, 2, 5], [3, 4]]
sage: Permutation([3,4,1,2,5]).to_tableau_by_shape([3,2]).reading_word_permutation()
[3, 4, 1, 2, 5]
```

weak_excedences()
Return all the numbers self[i] such that self[i] >= i+1.

EXAMPLES:

```sage
sage: Permutation([1,4,3,2,5]).weak_excedences()
[1, 4, 3, 5]
```

class sage.combinat.permutation.Permutations
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Permutations.
Permutations(n) returns the class of permutations of n, if n is an integer, list, set, or string.
Permutations(n, k) returns the class of length-k partial permutations of n (where n is any of the above things); k must be a nonnegative integer. A length-k partial permutation of n is defined as a k-tuple of pairwise distinct elements of \{1, 2, ..., n\}.

Permutations(descents=(list,n)) returns the class of permutations of n with descents in the positions specified by list. This uses the slightly nonstandard convention that the images of 1, 2, ..., n under the permutation are regarded as positions 0, 1, ..., n - 1, so for example the presence of 1 in list signifies that the permutations \pi should satisfy \pi(2) > \pi(3). Note that list is supposed to be a list of positions of the descents, not the descents composition. It does not return the class of permutations with descents composition list.

Permutations(bruhat_smaller=p) and Permutations(bruhat_greater=p) return the class of permutations smaller-or-equal or greater-or-equal, respectively, than the given permutation p in the Bruhat order. (The Bruhat order is defined in bruhat_lequal().) It is also referred to as the strong Bruhat order.

Permutations(recoils=p) returns the class of permutations whose recoils composition is p. Unlike the descents=(list, n) syntax, this actually takes a composition as input.

Permutations(recoils_fatter=p) and Permutations(recoils_finer=p) return the class of permutations whose recoils composition is fatter or finer, respectively, than the given composition p.
Permutations(n, avoiding=P) returns the class of permutations of \(n\) avoiding \(P\). Here \(P\) may be a single permutation or a list of permutations; the returned class will avoid all patterns in \(P\).

EXAMPLES:

```python
sage: p = Permutations(3); p
Standard permutations of 3
sage: p.list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

```python
sage: p = Permutations(3, 2); p
Permutations of {1,...,3} of length 2
sage: p.list()
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

```python
sage: p = Permutations(['c', 'a', 't']); p
Permutations of the set ['c', 'a', 't']
sage: p.list()
[['c', 'a', 't'], ['c', 't', 'a'], ['a', 'c', 't'], ['a', 't', 'c'], ['t', 'c', 'a'], ['t', 'a', 'c']]
```

```python
sage: p = Permutations(descents=(1, 4)); p
Standard permutations of 4 with descents [1]
sage: p.list()
[[2, 4, 1, 3], [3, 4, 1, 2], [1, 4, 2, 3], [1, 3, 2, 4], [2, 3, 1, 4]]
```

```python
sage: p = Permutations(bruhat_smaller=[1,3,2,4]); p
Standard permutations that are less than or equal to [1, 3, 2, 4] in the Bruhat order
sage: p.list()
[[1, 2, 3, 4], [1, 3, 2, 4]]
```

```python
sage: p = Permutations(bruhat_greater=[4,2,3,1]); p
Standard permutations that are greater than or equal to [4, 2, 3, 1] in the Bruhat order
sage: p.list()
[[4, 2, 3, 1], [4, 3, 2, 1]]
```
sage: p = Permutations(recoils_finer=[2,1]); p
Standard permutations whose recoils composition is finer than [2, 1]
sage: p.list()
[[3, 1, 2], [1, 2, 3], [1, 3, 2]]

sage: p = Permutations(recoils_fatter=[2,1]); p
Standard permutations whose recoils composition is fatter than [2, 1]
sage: p.list()
[[3, 1, 2], [3, 2, 1], [1, 3, 2]]

sage: p = Permutations(recoils=[2,1]); p
Standard permutations whose recoils composition is [2, 1]
sage: p.list()
[[3, 1, 2], [1, 3, 2]]

sage: p = Permutations(4, avoiding=[1,3,2]); p
Standard permutations of 4 avoiding [[1, 3, 2]]
sage: p.list()
[[4, 1, 2, 3],
 [4, 2, 1, 3],
 [4, 2, 3, 1],
 [4, 3, 1, 2],
 [4, 3, 2, 1],
 [3, 4, 1, 2],
 [3, 4, 2, 1],
 [2, 3, 4, 1],
 [3, 2, 4, 1],
 [1, 2, 3, 4],
 [2, 1, 3, 4],
 [2, 3, 1, 4],
 [3, 1, 2, 4],
 [3, 2, 1, 4]]

sage: p = Permutations(5, avoiding=[[3,4,1,2], [4,2,3,1]]); p
Standard permutations of 5 avoiding [[3, 4, 1, 2], [4, 2, 3, 1]]
sage: p.cardinality()
88
sage: p.random_element().parent() is p
True

Element
alias of Permutation

options(*get_value, **set_value)
Set the global options for elements of the permutation class. The defaults are for permutations to be
displayed in list notation and the multiplication done from left to right (like in GAP) – that is, \((\pi \psi)(i) = \psi(\pi(i))\) for all \(i\).

Note: These options have no effect on permutation group elements.

OPTIONS:

• display – (default: list) Specifies how the permutations should be printed
  – cycle – the permutations are displayed in cycle notation (i. e., as products of disjoint cycles)
- list – the permutations are displayed in list notation (aka 1-line notation)
- reduced_expression – alias for reduced_word
- reduced_word – the permutations are displayed as reduced words
- singleton – the permutations are displayed in cycle notation with singleton cycles shown as well
- word – alias for reduced_word

• generator_name – (default: s) the letter used in latexing the reduced word
• latex – (default: list) Specifies how the permutations should be latexed
  - cycle – latex in cycle notation
  - list – latex as a list in one-line notation
  - oneline – alias for list
  - reduced_expression – alias for reduced_word
  - reduced_word – latex as reduced words
  - singleton – latex in cycle notation with singleton cycles shown as well
  - twoline – latex in two-line notation
  - word – alias for reduced_word
• latex_empty_str – (default: 1) The \LaTeX{} representation of a reduced word when said word is empty
• mult – (default: l2r) The multiplication of permutations
  - l2r – left to right: \((p_1 \cdot p_2)(x) = p_2(p_1(x))\)
  - r2l – right to left: \((p_1 \cdot p_2)(x) = p_1(p_2(x))\)

EXAMPLES:

```sage
sage: p213 = Permutation([2,1,3])
sage: p312 = Permutation([3,1,2])
```
```sage
sage: Permutations.options(mult='l2r', display='list')
sage: Permutations.options.display
list
sage: p213
[2, 1, 3]
sage: Permutations.options.display='cycle'
sage: p213
(1,2)
sage: Permutations.options.display='singleton'
sage: p213
(1,2)(3)
sage: Permutations.options.display='list'
```
```sage
sage: Permutations.options.mult
l2r
sage: p213*p312
[1, 3, 2]
sage: Permutations.options.mult='r2l'
sage: p213*p312
[3, 2, 1]
sage: Permutations.options._reset()
```
See GlobalOptions for more features of these options.

class sage.combinat.permutation.PermutationsNK(s, k)
Bases: sage.combinat.permutation.Permutations_setk

This exists solely for unpickling PermutationsNK objects created with Sage <= 6.3.

class sage.combinat.permutation.Permutations_mset(mset)
Bases: sage.combinat.permutation.Permutations

Permutations of a multiset $M$.

A permutation of a multiset $M$ is represented by a list that contains exactly the same elements as $M$ (with the same multiplicities), but possibly in different order. If $M$ is a proper set there are $|M|!$ such permutations. Otherwise, if the first element appears $k_1$ times, the second element appears $k_2$ times and so on, the number of permutations is $|M|!/(k_1!k_2!\ldots)$, which is sometimes called a multinomial coefficient.

EXAMPLES:

```
sage: mset = [1,1,2,2,2]
sage: from sage.combinat.permutation import Permutations_mset
sage: P = Permutations_mset(mset); P
Permutations of the multi-set [1, 1, 2, 2, 2]
sage: sorted(P)
[[1, 1, 2, 2, 2],
 [1, 2, 1, 2, 2],
 [1, 2, 2, 1, 2],
 [2, 1, 1, 2, 2],
 [2, 1, 2, 1, 2],
 [2, 2, 1, 1, 2],
 [2, 2, 2, 1, 1],
 [2, 2, 2, 2, 1],
 [2, 2, 2, 1, 1]]
sage: MS = MatrixSpace(GF(2),2,2)
sage: A = MS([[1,0],[1,1]])
sage: rows = A.rows()
sage: rows[0].set_immutable()
sage: rows[1].set_immutable()
sage: P = Permutations_mset(rows); P
Permutations of the multi-set [(1, 0), (1, 1)]
sage: sorted(P)
[[[(1, 0), (1, 1)], [(1, 1), (1, 0)]]
```

class Element
Bases: sage.structure.list_clone.ClonableArray

A permutation of an arbitrary multiset.

check ()

Verify that self is a valid permutation of the underlying multiset.

EXAMPLES:

```
sage: S = Permutations(['c','a','c'])
sage: elt = S(['c','c','a'])
sage: elt.check()
```

cardinality ()

Return the cardinality of the set.

EXAMPLES:
rank \( p \)
Return the rank of \( p \) in lexicographic order.

INPUT:

- \( p \) – a permutation of \( M \)

ALGORITHM:
The algorithm uses the recurrence from the solution to exercise 4 in [Knu2011], Section 7.2.1.2:

\[
\text{rank}(p_1 \ldots p_n) = \text{rank}(p_2 \ldots p_n) + \frac{1}{n} \binom{n}{n_1, \ldots, n_t} \sum_{j=1}^{t} n_j [x_j < p_1],
\]

where \( x_j, n_j \) are the distinct elements of \( p \) with their multiplicities, \( n \) is the sum of \( n_1, \ldots, n_t \), \( \binom{n}{n_1, \ldots, n_t} \) is the multinomial coefficient \( \frac{n!}{n_1! \ldots n_t!} \), and \( \sum_{j=1}^{t} n_j [x_j < p_1] \) means “the number of elements to the right of the first element that are less than the first element”.

EXAMPLES:

```python
sage: mset = [1, 1, 2, 3, 4, 5, 5, 6, 9]
sage: p = Permutations(mset)
sage: p.rank(list(sorted(mset)))
0
sage: p.rank(list(reversed(sorted(mset)))) == p.cardinality() - 1
True
sage: p.rank([3, 1, 4, 1, 5, 9, 2, 6, 5])
30991
```

unrank \( r \)
Return the permutation of \( M \) having lexicographic rank \( r \).

INPUT:

- \( r \) – an integer between 0 and self.cardinality()-1 inclusive

ALGORITHM:
The algorithm is adapted from the solution to exercise 4 in [Knu2011], Section 7.2.1.2.

EXAMPLES:

```python
sage: mset = [1, 1, 2, 3, 4, 5, 5, 6, 9]
sage: p = Permutations(mset)
sage: p.unrank(30991)
[3, 1, 4, 1, 5, 9, 2, 6, 5]
sage: p.rank(p.unrank(10))
10
sage: p.unrank(0) == list(sorted(mset))
True
sage: p.unrank(p.cardinality()-1) == list(reversed(sorted(mset)))
True
```

Length-$k$ partial permutations of a multiset.

A length-$k$ partial permutation of a multiset $M$ is represented by a list of length $k$ whose entries are elements of $M$, appearing in the list with a multiplicity not higher than their respective multiplicity in $M$.

**cardinality()**

Return the cardinality of the set.

**EXAMPLES:**

```python
sage: Permutations([1,2,2],2).cardinality()
sage: Permutations([1,2,2],2).cardinality() 3
```

```python
class sage.combinat.permutation.Permutations_nk(n,k)
Bases: sage.combinat.permutation.Permutations

Length-$k$ partial permutations of $\{1, 2, \ldots, n\}$.

**class** Element

**check()**

Verify that self is a valid length-$k$ partial permutation of $[n]$.

**EXAMPLES:**

```python
sage: S = Permutations(4,2)
sage: elt = S([3,1])
sage: elt.check()
sage: S = Permutations(4,2)
sage: elt = S([3,1])
sage: elt.check()
```

```python
class sage.combinat.permutation.Permutations_set(s)
Bases: sage.combinat.permutation.Permutations

Permutations of an arbitrary given finite set.

Here, a “permutation of a finite set $S$” means a list of the elements of $S$ in which every element of $S$ occurs exactly once. This is not to be confused with bijections from $S$ to $S$, which are also often called permutations in literature.
class Element
Bases: sage.structure.list_clone.ClonableArray

A permutation of an arbitrary set.

check()
Verify that self is a valid permutation of the underlying set.

EXAMPLES:

```
sage: S = Permutations(['c', 'a', 't'])
sage: elt = S(['t', 'c', 'a'])
sage: elt.check()
```

cardinality()
Return the cardinality of the set.

EXAMPLES:

```
sage: Permutations([1,2,3]).cardinality()
6
```

random_element()

EXAMPLES:

```
sage: s = Permutations([1,2,3]).random_element()
sage: s.parent() == Permutations([1,2,3])
True
```

class sage.combinat.permutation.Permutations_setk(s, k)
Bases: sage.combinat.permutation.Permutations_set

Length-\(k\) partial permutations of an arbitrary given finite set.

Here, a “length-\(k\) partial permutation of a finite set \(S\)” means a list of length \(k\) whose entries are pairwise distinct and all belong to \(S\).

random_element()

EXAMPLES:

```
sage: s = Permutations([1,2,4], 2).random_element()
sage: s in Permutations([1,2,4], 2)
True
```

class sage.combinat.permutation.StandardPermutations_all
Bases: sage.combinat.permutation.Permutations

All standard permutations.

class sage.combinat.permutation.StandardPermutations_all_avoiding(a)
Bases: sage.combinat.permutation.StandardPermutations_all

All standard permutations avoiding a set of patterns.

patterns()
Return the patterns avoided by this class of permutations.

EXAMPLES:

```
sage: P = Permutations(avoiding=[[2,1,3],[1,2,3]])
sage: P.patterns()
([(2, 1, 3), [1, 2, 3])
```

5.1. Comprehensive Module list
class sage.combinat.permutation.StandardPermutations_avoiding_12(n)
    Bases: sage.combinat.permutation.StandardPermutations_avoiding_generic

cardinality()
    Return the cardinality of self.

    EXAMPLES:

        sage: P = Permutations(3, avoiding=[1, 2])
        sage: P.cardinality()
        1

class sage.combinat.permutation.StandardPermutations_avoiding_123(n)
    Bases: sage.combinat.permutation.StandardPermutations_avoiding_generic
cardinality()
    EXAMPLES:

        sage: P = Permutations(5, avoiding=[1, 2, 3])
        sage: len(P.list())
        42

class sage.combinat.permutation.StandardPermutations_avoiding_132(n)
    Bases: sage.combinat.permutation.StandardPermutations_avoiding_generic
cardinality()
    EXAMPLES:

        sage: P = Permutations(5, avoiding=[1, 3, 2])
        sage: len(P.list())
        42

class sage.combinat.permutation.StandardPermutations_avoiding_21(n)
    Bases: sage.combinat.permutation.StandardPermutations_avoiding_generic
cardinality()
    Return the cardinality of self.
    EXAMPLES:

        sage: P = Permutations(3, avoiding=[2, 1])
        sage: P.cardinality()
        1

class sage.combinat.permutation.StandardPermutations_avoiding_213(n)
    Bases: sage.combinat.permutation.StandardPermutations_avoiding_generic
cardinality()
    EXAMPLES:

        sage: P = Permutations(5, avoiding=[2, 1, 3])
        sage: len(P.list())
        42

class sage.combinat.permutation.StandardPermutations_avoiding_231(n)
    Bases: sage.combinat.permutation.StandardPermutations_avoiding_generic
**cardinality()**

EXAMPLES:

```
sage: Permutations(5, avoiding=[2, 3, 1]).cardinality()
sage: len( Permutations(5, avoiding=[2, 3, 1]).list() )
```

**class** `sage.combinat.permutation.StandardPermutations_avoiding_312(n)`

Bases: `sage.combinat.permutation.StandardPermutations_avoiding_generic`

**cardinality()**

EXAMPLES:

```
sage: Permutations(5, avoiding=[3, 1, 2]).cardinality()
sage: len( Permutations(5, avoiding=[3, 1, 2]).list() )
```

**class** `sage.combinat.permutation.StandardPermutations_avoiding_321(n)`

Bases: `sage.combinat.permutation.StandardPermutations_avoiding_generic`

**cardinality()**

EXAMPLES:

```
sage: Permutations(5, avoiding=[3, 2, 1]).cardinality()
sage: len( Permutations(5, avoiding=[3, 2, 1]).list() )
```

**class** `sage.combinat.permutation.StandardPermutations_avoiding_generic(n,a)`

Bases: `sage.combinat.permutation.StandardPermutations_n_abstract`

Generic class for subset of permutations avoiding a set of patterns.

```
a
```

`self.a` is deprecated; use `patterns()` instead.

**cardinality()**

Return the cardinality of `self`.

EXAMPLES:

```
sage: P = Permutations(3, avoiding=[[2, 1, 3],[1,2,3]])
sage: P.cardinality()
```

**patterns()**

Return the patterns avoided by this class of permutations.

EXAMPLES:

```
sage: P = Permutations(3, avoiding=[[2,1,3],[1,2,3]])
sage: P.patterns()
```

**class** `sage.combinat.permutation.StandardPermutations_bruhat_greater(p)`

Bases: `sage.combinat.permutation.Permutations`

Permutations of \( \{1, \ldots, n\} \) that are greater than or equal to a permutation \( p \) in the Bruhat order.
class sage.combinat.permutation.StandardPermutations_bruhat_smaller(p)
    Bases: sage.combinat.permutation.Permutations

Permutations of \{1, \ldots, n\} that are less than or equal to a permutation \(p\) in the Bruhat order.

class sage.combinat.permutation.StandardPermutations_descents(d, n)
    Bases: sage.combinat.permutation.StandardPermutations_n_abstract

Permutations of \{1, \ldots, n\} with a fixed set of descents.

cardinality()
    Return the cardinality of self.

    ALGORITHM:
    The algorithm described in [Vie1979] is implemented naively.

    EXAMPLES:

    sage: P = Permutations(descents=((1,0,2), 5))
    sage: P.cardinality()
    4

first()
    Return the first permutation with descents \(d\).

    EXAMPLES:

    sage: Permutations(descents=((1,0,4,8),12)).first()
    [3, 2, 1, 4, 6, 5, 7, 8, 10, 9, 11, 12]

last()
    Return the last permutation with descents \(d\).

    EXAMPLES:

    sage: Permutations(descents=((1,0,4,8),12)).last()
    [12, 11, 8, 9, 10, 4, 5, 6, 7, 1, 2, 3]

class sage.combinat.permutation.StandardPermutations_n(n)
    Bases: sage.combinat.permutation.StandardPermutations_n_abstract

Permutations of the set \{1, 2, \ldots, n\}.

These are also called permutations of size \(n\), or the elements of the \(n\)-th symmetric group.

Todo: Have a reduced_word() which works in both multiplication conventions.

class Element (parent, l, check_input=True)
    Bases: sage.combinat.permutation.Permutation

    apply_simple_reflection_left(\(i\))
        Return self multiplied by the simple reflection \(s[i]\) on the left.

        This acts by switching the entries in positions \(i\) and \(i + 1\).

    Warning: This ignores the multiplication convention in order to be consistent with other Coxeter operations in permutations (e.g., computing reduced_word()).
EXAMPLES:

```python
sage: W = Permutations(3)
sage: w = W([2,3,1])
sage: w.apply_simple_reflection_left(1)
[1, 3, 2]
sage: w.apply_simple_reflection_left(2)
[3, 2, 1]
```

`apply_simple_reflection_right(i)`
Return `self` multiplied by the simple reflection `s[i]` on the right.

This acts by switching the entries `i` and `i + 1`.

**Warning:** This ignores the multiplication convention in order to be consistent with other Coxeter operations in permutations (e.g., computing `reduced_word()`).

EXAMPLES:

```python
sage: W = Permutations(3)
sage: w = W([2,3,1])
sage: w.apply_simple_reflection_right(1)
[3, 2, 1]
sage: w.apply_simple_reflection_right(2)
[2, 1, 3]
```

`has_left_descent(i, mult=None)`
Check if `i` is a left descent of `self`.

A *left descent* of a permutation \( \pi \in S_n \) means an index \( i \in \{1, 2, \ldots, n-1\} \) such that \( s_i \circ \pi \) has smaller length than \( \pi \). Thus, a left descent of \( \pi \) is an index \( i \in \{1, 2, \ldots, n-1\} \) satisfying \( \pi^{-1}(i) > \pi^{-1}(i+1) \).

**Warning:** The methods `descents()` and `idescents()` behave differently than their Weyl group counterparts. In particular, the indexing is 0-based. This could lead to errors. Instead, construct the descent set as in the example.

**Warning:** This ignores the multiplication convention in order to be consistent with other Coxeter operations in permutations (e.g., computing `reduced_word()`).

EXAMPLES:

```python
sage: P = Permutations(4)
sage: x = P([3, 2, 4, 1])
sage: (~x).descents()
[1, 2]
sage: [i for i in P.index_set() if x.has_left_descent(i)]
[1, 2]
```

`has_right_descent(i, mult=None)`
Check if `i` is a right descent of `self`. 5.1. Comprehensive Module list
A right descent of a permutation $\pi \in S_n$ means an index $i \in \{1, 2, \ldots, n - 1\}$ such that $\pi \circ s_i$ has smaller length than $\pi$. Thus, a right descent of $\pi$ is an index $i \in \{1, 2, \ldots, n - 1\}$ satisfying $\pi(i) > \pi(i + 1)$.

**Warning:** The methods `descents()` and `idescents()` behave differently than their Weyl group counterparts. In particular, the indexing is 0-based. This could lead to errors. Instead, construct the descent set as in the example.

**Warning:** This ignores the multiplication convention in order to be consistent with other Coxeter operations in permutations (e.g., computing `reduced_word()`).

**EXAMPLES:**

```
sage: P = Permutations(4)
sage: x = P([3, 2, 4, 1])
sage: x.descents()
[1, 3]
sage: [i for i in P.index_set() if x.has_right_descent(i)]
[1, 3]
```

**inverse()**

Return the inverse of self.

**EXAMPLES:**

```
sage: P = Permutations(4)
sage: w0 = P([4,3,2,1])
sage: w0.inverse() == w0
True
sage: w0.inverse().parent() is P
True
sage: P([3,2,4,1]).inverse()
[4, 2, 1, 3]
```

**algebra(base_ring, category=None)**

Return the symmetric group algebra associated to self.

**INPUT:**

- `base_ring` – a ring
- `category` – a category (default: the category of self)

**EXAMPLES:**

```
sage: P = Permutations(4)
sage: A = P.algebra(QQ); A
Symmetric group algebra of order 4 over Rational Field
sage: A.category()
Join of Category of coxeter group algebras over Rational Field
    and Category of finite group algebras over Rational Field
    and Category of finite dimensional cellular algebras with basis over
    Rational Field
sage: A = P.algebra(QQ, category=Monoids())
```
sage: A.category()
Category of finite dimensional cellular monoid algebras over Rational Field

as_permutation_group()
Return self as a permutation group.

EXAMPLES:

sage: P = Permutations(4)
sage: PG = P.as_permutation_group()
sage: PG
Symmetric group of order 4! as a permutation group
sage: G = SymmetricGroup(4)
sage: PG == G
True

cardinality()
Return the number of permutations of size \( n \), which is \( n! \).

EXAMPLES:

sage: Permutations(0).cardinality()
1
sage: Permutations(3).cardinality()
6
sage: Permutations(4).cardinality()
24

cartan_type()
Return the Cartan type of self.

The symmetric group \( S_n \) is a Coxeter group of type \( A_{n-1} \).

EXAMPLES:

sage: A = SymmetricGroup([2,3,7]); A.cartan_type()
['A', 2]
sage: A = SymmetricGroup([]); A.cartan_type()
['A', 0]

codegrees()
Return the codegrees of self.

EXAMPLES:

sage: Permutations(3).codegrees()
(0, 1)
sage: Permutations(7).codegrees()
(0, 1, 2, 3, 4, 5)

conjugacy_class(g)
Return the conjugacy class of \( g \) in self.

INPUT:

- \( g \) – a partition or an element of self

EXAMPLES:
sage: G = Permutations(5)
sage: g = G([2,3,4,1,5])
sage: G.conjugacy_class(g)
Conjugacy class of cycle type [4, 1] in Standard permutations of 5
sage: G.conjugacy_class(Partition([2, 1, 1, 1]))
Conjugacy class of cycle type [2, 1, 1, 1] in Standard permutations of 5

conjugacy_classes()

Return a list of the conjugacy classes of self.

EXAMPLES:

sage: G = Permutations(4)
sage: G.conjugacy_classes()
[Conjugacy class of cycle type [1, 1, 1, 1] in Standard permutations of 4,
 Conjugacy class of cycle type [2, 1, 1] in Standard permutations of 4,
 Conjugacy class of cycle type [2, 2] in Standard permutations of 4,
 Conjugacy class of cycle type [3, 1] in Standard permutations of 4,

conjugacy_classes_iterator()

Iterate over the conjugacy classes of self.

EXAMPLES:

sage: G = Permutations(4)
sage: list(G.conjugacy_classes_iterator()) == G.conjugacy_classes()
True

conjugacy_classes_representatives()

Return a complete list of representatives of conjugacy classes in self.

Let $S_n$ be the symmetric group on $n$ letters. The conjugacy classes are indexed by partitions $\lambda$ of $n$. The ordering of the conjugacy classes is reverse lexicographic order of the partitions.

EXAMPLES:

sage: G = Permutations(5)
sage: G.conjugacy_classes_representatives()
[[1, 2, 3, 4, 5],
 [2, 1, 3, 4, 5],
 [2, 1, 4, 3, 5],
 [2, 3, 1, 4, 5],
 [2, 3, 1, 5, 4],
 [2, 3, 4, 1, 5],
 [2, 3, 4, 5, 1]]

degree()

Return the degree of self.

This is the cardinality $n$ of the set self acts on.

EXAMPLES:

sage: Permutations(0).degree()
0
sage: Permutations(1).degree()
1

(continues on next page)
degrees()

Return the degrees of self.

These are the degrees of the fundamental invariants of the ring of polynomial invariants.

EXAMPLES:

```
sage: Permutations(3).degrees()
(2, 3)
sage: Permutations(7).degrees()
(2, 3, 4, 5, 6, 7)
```

element_in_conjugacy_classes(nu)

Return a permutation with cycle type nu.

If the size of nu is smaller than the size of permutations in self, then some fixed points are added.

EXAMPLES:

```
sage: PP = Permutations(5)
sage: PP.element_in_conjugacy_classes([2,2])
[2, 1, 4, 3, 5]
```

identity()

Return the identity permutation of size n.

EXAMPLES:

```
sage: Permutations(4).identity()
[1, 2, 3, 4]
sage: Permutations(0).identity()
[]
```

index_set()

Return the index set for the descents of the symmetric group self.

This is \{1, 2, \ldots, n - 1\}, where self is \(S_n\).

EXAMPLES:

```
sage: P = Permutations(8)
sage: P.index_set()
(1, 2, 3, 4, 5, 6, 7)
```

one()

Return the identity permutation of size n.

EXAMPLES:

```
sage: Permutations(4).identity()
[1, 2, 3, 4]
sage: Permutations(0).identity()
[]
```

random_element()

EXAMPLES:
sage: s = Permutations(4).random_element(); s  # random
[1, 2, 4, 3]
sage: s in Permutations(4)
True

rank (p=None)
Return the rank of self or p depending on input.
If a permutation p is given, return the rank of p in self. Otherwise return the dimension of the underlying
vector space spanned by the (simple) roots.

EXAMPLES:

sage: P = Permutations(5)
sage: P.rank()
4
sage: SP3 = Permutations(3)
sage: list(map(SP3.rank, SP3))
[0, 1, 2, 3, 4, 5]
sage: SP0 = Permutations(0)
sage: list(map(SP0.rank, SP0))
[0]

simple_reflection(i)
For i in the index set of self (that is, for i in \{1, 2, ..., n – 1\}, where self is S_n), this returns the
elementary transposition s_i = (i, i + 1).

EXAMPLES:

sage: P = Permutations(4)
sage: P.simple_reflection(2)
[1, 3, 2, 4]
sage: P.simple_reflections()
Finite family {1: [2, 1, 3, 4], 2: [1, 3, 2, 4], 3: [1, 2, 4, 3]}

unrank (r)
EXAMPLES:

sage: SP3 = Permutations(3)
sage: 1 = list(map(SP3.unrank, range(6)))
sage: 1 == SP3.list()
True
sage: SP0 = Permutations(0)
sage: 1 = list(map(SP0.unrank, range(1)))
sage: 1 == SP0.list()
True

class sage.combinat.permutation.StandardPermutations_n_abstract(n,  
category=None)

Bases: sage.combinat.permutation.Permutations

Abstract base class for subsets of permutations of the set \{1,2,\ldots,n\}.

Warning: Anything inheriting from this class should override the __contains__ method.
class sage.combinat.permutation.StandardPermutations_recoils(recoils)
    Bases: sage.combinat.permutation.Permutations
    Permutations of \{1, \ldots, n\} with a fixed recoils composition.

class sage.combinat.permutation.StandardPermutations_recoilsfatter(recoils)
    Bases: sage.combinat.permutation.Permutations

class sage.combinat.permutation.StandardPermutations_recoilsfiner(recoils)
    Bases: sage.combinat.permutation.Permutations

sage.combinat.permutation.bistochastic_as_sum_of_permutations(M, check=True)
    Return the positive sum of permutations corresponding to the bistochastic matrix M.

    A stochastic matrix is a matrix with nonnegative real entries such that the sum of the elements of any row is
equal to 1. A bistochastic matrix is a stochastic matrix whose transpose matrix is also stochastic (there are
conditions both on the rows and on the columns).

    According to the Birkhoff-von Neumann Theorem, any bistochastic matrix can be written as a convex combi-
nation of permutation matrices, which also means that the polytope of bistochastic matrices is integer.

    As a non-bistochastic matrix can obviously not be written as a convex combination of permutations, this theorem
is an equivalence.

    This function, given a bistochastic matrix, returns the corresponding decomposition.

    INPUT:
    • M – A bistochastic matrix
    • check (boolean) – set to True (default) to check that the matrix is indeed bistochastic

    OUTPUT:
    • An element of CombinatorialFreeModule, which is a free \(F\)-module (where \(F\) is the ground ring
of the given matrix) whose basis is indexed by the permutations.

    Note:
    • In this function, we just assume 1 to be any constant: for us a matrix M is bistochastic if there exists \(c > 0\)
such that \(M/c\) is bistochastic.
    • You can obtain a sequence of pairs (permutation, coeff), where permutation is a Sage
Permutation instance, and coeff its corresponding coefficient from the result of this function by
applying the list function.
    • If you are interested in the matrix corresponding to a Permutation you will be glad to learn about the
Permutation.to_matrix() method.
    • The base ring of the matrix can be anything that can be coerced to RR.

    See also:
    • as_sum_of_permutations() to use this method through the Matrix class.

    EXAMPLES:
    We create a bistochastic matrix from a convex sum of permutations, then try to deduce the decomposition from
the matrix:
sage: from sage.combinat.permutation import bistochastic_as_sum_of_permutations
sage: L = []
sage: L.append((9,Permutation([4, 1, 3, 5, 2])))
sage: L.append((6,Permutation([5, 3, 4, 1, 2])))
sage: L.append((3,Permutation([3, 1, 4, 2, 5])))
sage: L.append((2,Permutation([1, 4, 2, 3, 5])))

sage: M = sum([c * p.to_matrix() for (c, p) in L])

sage: decomp = bistochastic_as_sum_of_permutations(M)
sage: print(decomp)
2*B[[1, 4, 2, 3, 5]] + 3*B[[3, 1, 4, 2, 5]] + 9*B[[4, 1, 3, 5, 2]] + 6*B[[5, 3, 4, 1, 2]]

An exception is raised when the matrix is not positive and bistochastic:

sage: M = Matrix([[2,3],[2,2]])

sage: decomp = bistochastic_as_sum_of_permutations(M)
Traceback (most recent call last):
... ValueError: The matrix is not bistochastic

sage: bistochastic_as_sum_of_permutations(Matrix(GF(7), 2, [2,1,1,2]))
Traceback (most recent call last):
... ValueError: The base ring of the matrix must have a coercion map to RR

sage: bistochastic_as_sum_of_permutations(Matrix(ZZ, 2, [2,-1,-1,2]))
Traceback (most recent call last):
... ValueError: The matrix should have nonnegative entries

sage.combinat.permutation.bounded_affine_permutation(A)

Return the bounded affine permutation of a matrix.

The bounded affine permutation of a matrix $A$ with entries in $R$ is a partial permutation of length $n$, where $n$ is the number of columns of $A$. The entry in position $i$ is the smallest value $j$ such that column $i$ is in the span of columns $i+1, \ldots, j$ over $R$, where column indices are taken modulo $n$. If column $i$ is the zero vector, then the permutation has a fixed point at $i$.

INPUT:

- $A$ – matrix with entries in a ring $R$

EXAMPLES:

sage: from sage.combinat.permutation import bounded_affine_permutation
sage: A = Matrix(ZZ, [[1,0,0,0], [0,1,0,0]])

sage: bounded_affine_permutation(A)
[5, 6, 3, 4]

sage: A = Matrix(ZZ, [[0,1,0,1,0], [0,0,1,1,0]])

sage: bounded_affine_permutation(A)
[1, 4, 7, 8, 5]

REFERENCES:

- [KLS2013]

sage.combinat.permutation.bruhat_lequal(pl, p2)

Return True if $p_1$ is less than $p_2$ in the Bruhat order.
Algorithm from mupad-combinat.

EXAMPLES:

```python
sage: import sage.combinat.permutation as permutation
sage: permutation.bruhat_lequal([2,4,3,1],[3,4,2,1])
True
```

`sage.combinat.permutation.descents_composition_first(dc)`
Compute the smallest element of a descent class having a descent composition `dc`.

EXAMPLES:

```python
sage: import sage.combinat.permutation as permutation
sage: permutation.descents_composition_first([1,1,3,4,3])
[3, 2, 1, 4, 6, 5, 7, 8, 10, 9, 11, 12]
```

`sage.combinat.permutation.descents_composition_last(dc)`
Return the largest element of a descent class having a descent composition `dc`.

EXAMPLES:

```python
sage: import sage.combinat.permutation as permutation
sage: permutation.descents_composition_last([1,1,3,4,3])
[12, 11, 8, 9, 10, 4, 5, 6, 7, 1, 2, 3]
```

`sage.combinat.permutation.descents_composition_list(dc)`
Return a list of all the permutations that have the descent composition `dc`.

EXAMPLES:

```python
sage: import sage.combinat.permutation as permutation
sage: permutation.descents_composition_list([1,2,2])
[[5, 2, 4, 1, 3],
 [5, 3, 4, 1, 2],
 [4, 3, 5, 1, 2],
 [4, 2, 5, 1, 3],
 [3, 2, 5, 1, 4],
 [2, 1, 5, 3, 4],
 [3, 1, 5, 2, 4],
 [4, 1, 5, 2, 3],
 [5, 1, 4, 2, 3],
 [5, 1, 3, 2, 4],
 [4, 1, 3, 2, 5],
 [3, 1, 4, 2, 5],
 [2, 1, 4, 3, 5],
 [3, 2, 4, 1, 5],
 [4, 2, 3, 1, 5],
 [5, 2, 3, 1, 4]]
```

`sage.combinat.permutation.from_cycles(n, cycles, parent=None)`
Return the permutation in the `n`-th symmetric group whose decomposition into disjoint cycles is `cycles`.

This function checks that its input is correct (i.e. that the cycles are disjoint and their elements integers among 1...n). It raises an exception otherwise.

**Warning:** It assumes that the elements are of `int` type.
EXAMPLES:

```python
sage: import sage.combinat.permutation as permutation
sage: permutation.from_cycles(4, [[1,2]])
[2, 1, 3, 4]
sage: permutation.from_cycles(4, [[1,2,4]])
[2, 4, 3, 1]
sage: permutation.from_cycles(10, [[3,1],[4,5],[6,8,9]])
[3, 2, 1, 5, 4, 8, 7, 9, 6, 10]
sage: permutation.from_cycles(10, ((2, 5), (6, 1, 3)))
[3, 5, 6, 4, 2, 1, 7, 8, 9, 10]
sage: permutation.from_cycles(4, [])
[1, 2, 3, 4]
sage: permutation.from_cycles(4, [[]])
[1, 2, 3, 4]
sage: permutation.from_cycles(0, [])
[]
```

Bad input (see trac ticket #13742):

```python
sage: Permutation("(-12,2)(3,4)"
Traceback (most recent call last):
... ValueError: All elements should be strictly positive integers, and I just found a non-positive one.
sage: Permutation("(1,2)(2,4)"
Traceback (most recent call last):
... ValueError: An element appears twice. It should not.
sage: permutation.from_cycles(4, [[1,18]])
Traceback (most recent call last):
... ValueError: You claimed that this was a permutation on 1...4 but it contains 18
```

```
sage.combinat.permutation.from_inversion_vector(iv, parent=None)
```

Return the permutation corresponding to inversion vector iv.

See `sage.combinat.permutation.Permutation.to_inversion_vector` for a definition of the inversion vector of a permutation.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.from_inversion_vector([3,1,0,0,0])
[3, 2, 4, 1, 5]
sage: permutation.from_inversion_vector([2,3,6,4,0,2,2,1,0])
[5, 9, 1, 8, 2, 6, 4, 7, 3]
sage: permutation.from_inversion_vector([0])
[1]
sage: permutation.from_inversion_vector([])
[]
```

```
sage.combinat.permutation.from_lehmer_code(lehmer, parent=None)
```

Return the permutation with Lehmer code lehmer.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: lc = Permutation([2,1,5,4,3]).to_lehmer_code(); lc
[4, 1, 2, 3, 5]
```

(continues on next page)
sage.combinat.permutation.from_major_code\((mc, final\_descent=False)\)

Return the permutation with major code \(mc\).

The major code of a permutation is defined in \(\text{to\_major\_code()}\).

**Warning:** This function creates illegal permutations (i.e. \(\text{Permutation([9])}\), and this is dangerous as the \(\text{Permutation()}\) class is only designed to handle permutations on 1...\(n\). This will have to be changed when Sage permutations will be able to handle anything, but right now this should be fixed. Be careful with the results.

**Warning:** If \(mc\) is not a major index of a permutation, then the return value of this method can be anything. Garbage in, garbage out!

REFERENCES:

EXAMPLES:

```python
sage: import sage.combinat.permutation as permutation
sage: permutation.from_major_code([5, 0, 1, 0, 1, 2, 0, 1, 0])
[9, 3, 5, 7, 2, 1, 4, 6, 8]
sage: permutation.from_major_code([8, 3, 3, 1, 4, 0, 1, 0, 0])
[2, 8, 4, 3, 6, 7, 9, 5, 1]
sage: Permutation([2,1,6,4,7,3,5]).to_major_code()
[3, 2, 0, 2, 2, 0, 0]
sage: permutation.from_major_code([3, 2, 0, 2, 2, 0, 0])
[2, 1, 6, 4, 7, 3, 5]
```

sage.combinat.permutation.from_permutation_group_element\((pge, parent=None)\)

Return a \(\text{Permutation}\) given a \(\text{PermutationGroupElement}\) \(pge\).

EXAMPLES:

```python
sage: import sage.combinat.permutation as permutation
sage: pge = PermutationGroupElement([(1,2),(3,4)])
[2, 1, 4, 3]
```

sage.combinat.permutation.from_rank\((n, rank)\)

Return the permutation of the set \(\{1,...,n\}\) with lexicographic rank \(rank\). This is the permutation whose Lehmer code is the factoradic representation of \(rank\). In particular, the permutation with rank 0 is the identity permutation.

The permutation is computed without iterating through all of the permutations with lower rank. This makes it efficient for large permutations.

**Note:** The variable \(rank\) is not checked for being in the interval from 0 to \(n! - 1\). When outside this interval,
it acts as its residue modulo $n!$.

**EXAMPLES:**

```python
sage: import sage.combinat.permutation as permutation
sage: Permutation([3, 6, 5, 4, 2, 1]).rank()
sage: 359
sage: [permutation.from_rank(3, i) for i in range(6)]
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
sage: Permutations(6)[10]
[1, 2, 4, 6, 3, 5]
sage: permutation.from_rank(6, 10)
[1, 2, 4, 6, 3, 5]
```

```python
sage.combinat.permutation.from_reduced_word(rw, parent=None)

Return the permutation corresponding to the reduced word $rw$.

See `reduced_words()` for a definition of reduced words and the convention on the order of multiplication used.

**EXAMPLES:**

```python
sage: import sage.combinat.permutation as permutation
sage: permutation.from_reduced_word([3, 2, 3, 1, 2, 3, 1])
[3, 4, 2, 1]
sage: permutation.from_reduced_word([])
[]
```

```python
sage.combinat.permutation.permutohedron_lequal(p1, p2, side='right')

Return True if $p1$ is less than or equal to $p2$ in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option `side='left'`, then they will be done in the left permutohedron.

**EXAMPLES:**

```python
sage: import sage.combinat.permutation as permutation
sage: permutation.permutohedron_lequal(Permutation([3, 2, 1, 4]), Permutation([4, 2, 1, 3]))
False
sage: permutation.permutohedron_lequal(Permutation([3, 2, 1, 4]), Permutation([4, 2, 1, 3]), side='left')
True
```

```python
sage.combinat.permutation.to_standard(p, key=None)

Return a standard permutation corresponding to the iterable $p$.

**INPUT:**

- $p$ – an iterable
- $key$ – (optional) a comparison key for the element $x$ of $p$

**EXAMPLES:**

```python
sage: import sage.combinat.permutation as permutation
sage: permutation.to_standard([4, 2, 7])
[2, 1, 3]
sage: permutation.to_standard([1, 2, 3])
[1, 2, 3]
```

(continues on next page)
sage: permutation.to_standard([])
[]
sage: permutation.to_standard([1,2,3], key=lambda x: -x)
[3, 2, 1]
sage: permutation.to_standard([5,8,2,5], key=lambda x: -x)
[2, 1, 4, 3]

5.1.173 Permutations (Cython file)

This is a nearly-straightforward implementation of what Knuth calls “Algorithm P” in TAOCP 7.2.1.2. The intent is
to be able to enumerate permutation by “plain changes”, or multiplication by adjacent transpositions, as a generator.
This is useful when a class of objects is inherently enumerated by permutations, but it is faster to swap items in a
permutation than construct the next object directly from the next permutation in a list. The backtracking algorithm in
sage/graphs/genus.pyx is an example of this.

The lowest level is implemented as a struct with auxiliary methods. This is because Cython does not allow pointers to
class instances, so a list of these objects is inherently slower than a list of structs. The author prefers ugly code to slow
code.

For those willing to sacrifice a (very small) amount of speed, we provide a class that wraps our struct.
sage.combinat.permutation_cython.

left_action_product

Return the permutation obtained by composing a permutation \( S \) with a permutation \( lp \) in such an order that \( lp \)
is applied first and \( S \) is applied afterwards.

See also:
sage.combinat.permutation.Permutation.left_action_product()  

EXAMPLES:

sage: p = [2,1,3,4]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import left_action_product
sage: left_action_product(p, q)
[3, 2, 1, 4]
sage: left_action_same_n(p, q)
[3, 1, 2]

sage.combinat.permutation_cython.

left_action_same_n

Return the permutation obtained by composing a permutation \( S \) with a permutation \( lp \) in such an order that \( lp \)
is applied first and \( S \) is applied afterwards and \( S \) and \( lp \) are of the same length.

See also:
sage.combinat.permutation.Permutation.left_action_same_n()

EXAMPLES:

sage: p = [2,1,3]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import left_action_same_n
sage: left_action_same_n(p, q)
[3, 2, 1]
sage: left_action_same_n(q, p)
[1, 3, 2]
sage.combinat.permutation_cython.map_to_list(l, values, n)
Build a list by mapping the array l using values.

**Warning:** There is no check of the input data at any point. Using wrong types or values with wrong length is likely to result in a Sage crash.

**INPUT:**
- l – array of unsigned int (i.e., type 'I')
- values – tuple; the values of the permutation
- n – int; the length of the array l

**OUTPUT:**
A list representing the permutation.

**EXAMPLES:**

```python
sage: from array import array
sage: from sage.combinat.permutation_cython import map_to_list
sage: l = array('I', [0, 1, 0, 3, 3, 0, 1])
sage: map_to_list(l, ('a', 'b', 'c', 'd'), 7)
['a', 'b', 'a', 'd', 'd', 'a', 'b']
```

sage.combinat.permutation_cython.next_perm(l)
Obtain the next permutation under lex order of l by mutating l.

**Algorithm based on:** [http://marknelson.us/2002/03/01/next-permutation/](http://marknelson.us/2002/03/01/next-permutation/)

**INPUT:**
- l – array of unsigned int (i.e., type 'I')

**Warning:** This method mutates the array l.

**OUTPUT:**
boolean; whether another permutation was obtained

**EXAMPLES:**

```python
sage: from sage.combinat.permutation_cython import next_perm
sage: from array import array
sage: L = array('I', [1, 1, 2, 3])
sage: while next_perm(L):
    print(L)
array('I', [1L, 1L, 3L, 2L])
array('I', [1L, 2L, 1L, 3L])
array('I', [1L, 2L, 3L, 1L])
array('I', [1L, 3L, 1L, 2L])
array('I', [1L, 3L, 2L, 1L])
array('I', [2L, 1L, 1L, 3L])
array('I', [2L, 1L, 3L, 1L])
array('I', [2L, 3L, 1L, 1L])
array('I', [3L, 1L, 1L, 2L])
```

(continues on next page)
sage.combinat.permutation_cython.permutation_iterator_transposition_list(n)

Returns a list of transposition indices to enumerate the permutations on \( n \) letters by adjacent transpositions. Assumes zero-based lists. We artificially limit the argument to \( n < 12 \) to avoid overflowing 32-bit pointers. While the algorithm works for larger \( n \), the user is encouraged to avoid filling anything more than 4GB of memory with the output of this function.

EXAMPLES:

```python
sage: import sage.combinat.permutation_cython
sage: from sage.combinat.permutation_cython import permutation_iterator_transposition_list
sage: permutation_iterator_transposition_list(4)
[2, 1, 0, 2, 0, 1, 2, 0, 2, 1, 0, 2, 0, 1, 2, 0, 2, 1, 0, 2, 0, 1, 2]

sage: permutation_iterator_transposition_list(200)
Traceback (most recent call last):
...
ValueError: Cowardly refusing to enumerate the permutations on more than 12 letters.

sage: permutation_iterator_transposition_list(1)
[]
```

sage.combinat.permutation_cython.right_action_product(S, rp)

Return the permutation obtained by composing a permutation \( S \) with a permutation \( rp \) in such an order that \( S \) is applied first and \( rp \) is applied afterwards.

See also:
sage.combinat.permutation.Permutation.right_action_product()

EXAMPLES:

```python
sage: p = [2,1,3,4]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import right_action_product
sage: right_action_product(p, q)
[1, 3, 2, 4]
sage: right_action_product(q, p)
[3, 2, 1, 4]
sage: q
[3, 1, 2]
```

sage.combinat.permutation_cython.right_action_same_n(S, rp)

Return the permutation obtained by composing a permutation \( S \) with a permutation \( rp \) in such an order that \( S \) is applied first and \( rp \) is applied afterwards and \( S \) and \( rp \) are of the same length.
See also:

`sage.combinat.permutation.Permutation.right_action_product()`

EXAMPLES:

```
sage: p = [2,1,3]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import right_action_same_n
sage: right_action_same_n(p, q)
[1, 3, 2]
sage: right_action_same_n(q, p)
[3, 2, 1]
```

5.1.174 Posets

Common posets can be accessed through `posets.<tab>` and are listed in the posets catalog:

- Catalog of posets and lattices

Poset-related classes:

- Finite posets
- Finite lattices and semilattices
- Linear Extensions of Posets
- D-Complete Posets
- Forest Posets
- MISSNG TITLE
- Incidence Algebras
- Cartesian products of Posets
- Möbius Algebras
- Generalized Tamari lattices
- Tamari Interval-posets
- Shard intersection order

If you are looking for Poset-related categories, see `Posets`, `FinitePosets`, `LatticePosets` and `FiniteLatticePosets`.

5.1.175 Poset features that are imported by default in the interpreter namespace

5.1.176 Cartesian products of Posets

AUTHORS:

- Daniel Krenn (2015)

```python
class sage.combinat.posets.cartesian_product.CartesianProductPoset
```

Bases: `sage.sets.cartesian_product.CartesianProduct`
A class implementing Cartesian products of posets (and elements thereof). Compared to \texttt{CartesianProduct} you are able to specify an order for comparison of the elements.

**INPUT:**

- \texttt{sets} – a tuple of parents.
- \texttt{category} – a subcategory of \texttt{Sets().CartesianProducts()} \& \texttt{Posets()}.
- \texttt{order} – a string or function specifying an order less or equal. It can be one of the following:
  - 'native' – elements are ordered by their native ordering, i.e., the order the wrapped elements (tuples) provide.
  - 'lex' – elements are ordered lexicographically.
  - 'product' – an element is less or equal to another element, if less or equal is true for all its components (Cartesian projections).
  - A function which performs the comparison $\leq$. It takes two input arguments and outputs a boolean.

Other keyword arguments (\texttt{kwargs}) are passed to the constructor of \texttt{CartesianProduct}.

**EXAMPLES:**

\begin{verbatim}
sage: P = Poset((srange(3), lambda left, right: left <= right))
sage: Cl = cartesian_product((P, P), order='lex')
sage: Cl((1, 1)) <= Cl((2, 0))
True
sage: Cp = cartesian_product((P, P), order='product')
sage: Cp((1, 1)) <= Cp((2, 0))
False
sage: def le_sum(left, right):
    ....: return (sum(left) < sum(right) or
    ....:          sum(left) == sum(right) and left[0] <= right[0])
sage: Cs = cartesian_product((P, P), order=le_sum)
sage: Cs((1, 1)) <= Cs((2, 0))
True
\end{verbatim}

See also:

\texttt{CartesianProduct}

\textbf{class} \texttt{Element}

\texttt{Bases: sage.sets.cartesian_product.CartesianProduct.Element}

\texttt{le(left, right)}

Test whether \texttt{left} is less than or equal to \texttt{right}.

**INPUT:**

- \texttt{left} – an element.
- \texttt{right} – an element.

**OUTPUT:**

A boolean.

---

**Note:** This method uses the order defined on creation of this Cartesian product. See \texttt{CartesianProductPoset}.

**EXAMPLES:**
sage: P = posets.ChainPoset(10)
sage: def le_sum(left, right):
....:     return (sum(left) < sum(right) or
....:     sum(left) == sum(right) and left[0] <= right[0])
sage: C = cartesian_product((P, P), order=le_sum)
sage: C.le(C((1, 6)), C((6, 1)))
True
sage: C.le(C((6, 1)), C((1, 6)))
False
sage: C.le(C((1, 6)), C((6, 6)))
True
sage: C.le(C((6, 6)), C((1, 6)))
False

le_lex(left, right)
Test whether left is lexicographically smaller or equal to right.

INPUT:

• left – an element.
• right – an element.

OUTPUT:
A boolean.

EXAMPLES:

sage: P = Poset((srange(2), lambda left, right: left <= right))
sage: Q = cartesian_product((P, P), order='lex')
sage: T = [Q((0, 0)), Q((1, 1)), Q((0, 1)), Q((1, 0))]
sage: for a in T:
....:     for b in T:
....:         assert Q.le(a, b) == (a <= b)
....:         print(' %s <= %s = %s' % (a, b, a <= b))
(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(1, 1) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 1) <= (0, 0) = False
(0, 1) <= (1, 1) = True
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = True
(1, 0) <= (0, 0) = False
(1, 0) <= (1, 1) = True
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True

le_native(left, right)
Test whether left is smaller or equal to right in the order provided by the elements themselves.

INPUT:

• left – an element.
• right – an element.
OUTPUT:

A boolean.

EXAMPLES:

```python
sage: P = Poset((srange(2), lambda left, right: left <= right))
sage: Q = cartesian_product((P, P), order='native')
sage: T = [Q((0, 0)), Q((1, 1)), Q((0, 1)), Q((1, 0))]
sage: for a in T:
    ....:     for b in T:
    ....:         assert Q.le(a, b) == (a <= b)
    ....:         print(' %s <= %s = %s' % (a, b, a <= b))
(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 1) <= (0, 0) = False
(0, 1) <= (1, 1) = True
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = True
(1, 0) <= (0, 0) = False
(1, 0) <= (1, 1) = True
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True
```

**le_product** *(left, right)*

Test whether left is component-wise smaller or equal to right.

**INPUT:**

- left – an element.
- right – an element.

**OUTPUT:**

A boolean.

The comparison is `True` if the result of the comparison in each component is `True`.

**EXAMPLES:**

```python
sage: P = Poset((srange(2), lambda left, right: left <= right))
sage: Q = cartesian_product((P, P), order='product')
sage: T = [Q((0, 0)), Q((1, 1)), Q((0, 1)), Q((1, 0))]
sage: for a in T:
    ....:     for b in T:
    ....:         assert Q.le(a, b) == (a <= b)
    ....:         print(' %s <= %s = %s' % (a, b, a <= b))
(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 1) <= (0, 0) = False
(0, 1) <= (1, 1) = True
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = True
(1, 0) <= (0, 0) = False
(1, 0) <= (1, 1) = True
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True
```

(continues on next page)
\[(1, 1) \leq (1, 0) = \text{False}\\ \(0, 1) \leq (0, 0) = \text{False}\\ (0, 1) \leq (1, 1) = \text{True}\\ (0, 1) \leq (0, 1) = \text{True}\\ (0, 1) \leq (1, 0) = \text{False}\\ (1, 0) \leq (0, 0) = \text{False}\\ (1, 0) \leq (1, 1) = \text{True}\\ (1, 0) \leq (0, 1) = \text{False}\\ (1, 0) \leq (1, 0) = \text{True}\\ \]

### 5.1.177 D-Complete Posets

**AUTHORS:**

- Stefan Grosser (06-2020): initial implementation

```python
class sage.combinat.posets.d_complete.DCompletePoset(hasse_diagram, elements, category, facade, key):
bases: sage.combinat.posets.lattices.FiniteJoinSemilattice
```

A d-complete poset.

D-complete posets are a class of posets introduced by Proctor in [Proc1999]. It includes common families such as shapes, shifted shapes, and rooted forests. Proctor showed in [PDynk1999] that d-complete posets have decompositions in irreducible posets, and showed in [Proc2014] that d-complete posets admit a hook-length formula (see Wikipedia article Hook_length_formula). A complete proof of the hook-length formula can be found in [KY2019].

**EXAMPLES:**

```python
sage: from sage.combinat.posets.poset_examples import Posets
sage: P = Posets.DoubleTailedDiamond(2)
sage: TestSuite(P).run()
```

#### get_hook (elmt)

Return the hook length of the element elmt.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.d_complete import DCompletePoset
sage: P = DCompletePoset(DiGraph({0: [1], 1: [2]}))
sage: P.get_hook(1)
2
```

#### gethooks ()

Return all the hook lengths as a dictionary.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.d_complete import DCompletePoset
sage: P = DCompletePoset(DiGraph({0: [1, 2], 1: [3], 2: [3], 3: []}))
sage: P.gethooks()
{0: 1, 1: 2, 2: 2, 3: 3}
sage: from sage.combinat.posets.poset_examples import Posets
sage: P = DCompletePoset(Posets.YoungDiagramPoset(Partition([3,2,1]))._hasse_diagram.reverse())
```
hook_product()  
Return the hook product for the poset.

5.1.178 MISSING TITLE

class sage.combinat.posets.mobile.MobilePoset  

(hasse_diagram, elements, category, facade, key, ribbon=\textit{None}, check=True)

Bases: sage.combinat.posets.posets.FinitePoset

A mobile poset.

Mobile posets are an extension of d-complete posets which permit a determinant formula for counting linear extensions. They are formed by having a ribbon poset with d-complete posets ‘hanging’ below it and at most one d-complete poset above it, known as the anchor. See [GGMM2020] for the definition.

EXAMPLES:

sage: P = posets.MobilePoset(posets.RibbonPoset(7, \[1,3\]),
......: \{1: \text{[posets.YoungDiagramPoset\([3, 2]\), dual=True]}\},
......: 3: \text{[posets.DoubleTailedDiamond(6)]},
......: anchor=(4, 2, posets.ChainPoset(6)))
sage: len(P._ribbon)
8
sage: P._anchor
(4, 5)

This example is Example 5.9 in [GGMM2020]:

sage: P1 = posets.MobilePoset(posets.RibbonPoset(8, \[2,3,4\]),
......: \{4: \text{[posets.ChainPoset\([1]\)]}\},
......: anchor=(3, 0, posets.ChainPoset(1)))
sage: sorted([P1._element_to_vertex(i) \text{ for } i \text{ in } P1._ribbon])
[0, 1, 2, 6, 7, 9]
sage: P1._anchor
(3, 2)
sage: P2 = posets.MobilePoset(posets.RibbonPoset(15, \[1,3,5,7,9,11,13\]),
......: \{\}, anchor=(8, 0, posets.ChainPoset(1)))
sage: P2._anchor
(8, (8, 0))
sage: P2.linear_extensions().cardinality()
2139940939

sage: EP = posets.MobilePoset(posets.ChainPoset(0), \{\})
Traceback (most recent call last):
...
ValueError: the empty poset is not a mobile poset

anchor()  
Return the anchor of the mobile poset.

EXAMPLES:
sage: from sage.combinat.posets.mobile import MobilePoset
sage: M2 = MobilePoset(Poset([[0,1,2,3,4,5,6,7,8],
...:[(1,0),(3,0),(2,1),(2,3),(4,3),(5,4),(7,4),(7,8)])))
sage: M2.anchor()
(4, 3)
sage: M3 = MobilePoset(Posets.RibbonPoset(5, [1,2]))
sage: M3.anchor()  # is None
True

ribbon()
Return the ribbon of the mobile poset.

EXAMPLES:

sage: from sage.combinat.posets.mobile import MobilePoset
sage: M3 = MobilePoset(Posets.RibbonPoset(5, [1,2]))
sage: sorted(M3.ribbon())
[1, 2, 3, 4]

5.1.179 Elements of posets, lattices, semilattices, etc.

class sage.combinat.posets.elements.JoinSemilatticeElement(poset, element, vertex)
Bases: sage.combinat.posets.elements.PosetElement

class sage.combinat.posets.elements.LatticePosetElement(poset, element, vertex)

class sage.combinat.posets.elements.MeetSemilatticeElement(poset, element, vertex)
Bases: sage.combinat.posets.elements.PosetElement

class sage.combinat.posets.elements.PosetElement(poset, element, vertex)
Bases: sage.structure.element.Element

Establish the parent-child relationship between poset and element, where element is associated to the vertex vertex of the Hasse diagram of the poset.

INPUT:

- poset – a poset object
- element – any object
- vertex – a vertex of the Hasse diagram of the poset

5.1.180 Forest Posets

AUTHORS:

- Stefan Grosser (06-2020): initial implementation

class sage.combinat.posets.forest.ForestPoset(hasse_diagram, elements, category, facade, key)
Bases: sage.combinat.posets.posetsFINITEPoset

A forest poset is a poset where the underlying Hasse diagram and is directed acyclic graph.
### 5.1.181 Hasse diagrams of posets

<td>Return an iterator over sublattices of the Hasse diagram.</td>
</tr>
<tr>
<td><code>supergreedy_linear_extensions()</code></td>
<td>Return an iterator over supergreedy linear extensions of the Hasse diagram.</td>
</tr>
<tr>
<td><code>top()</code></td>
<td>Return the top element of the poset, if it exists.</td>
</tr>
<tr>
<td><code>upper_covers_iterator()</code></td>
<td>Return the list of elements that cover <code>element</code>.</td>
</tr>
<tr>
<td><code>vertical_decomposition()</code></td>
<td>Return vertical decomposition of the lattice.</td>
</tr>
</tbody>
</table>

```python
class sage.combinat.posets.hasse_diagram.HasseDiagram(data=None, pos=None, loops=None, format=None, weighted=None, data_structure='sparse', vertex_labels=True, name=None, multiedges=None, convert_empty_dict_labels_to_None=None, sparse=True, immutable=False)
```

**Bases:** `sage.graphs.digraph.DiGraph`

The Hasse diagram of a poset. This is just a transitively-reduced, directed, acyclic graph without loops or multiple edges.

**Note:** We assume that `range(n)` is a linear extension of the poset. That is, `range(n)` is the vertex set and a topological sort of the digraph.

This should not be called directly, use `Poset` instead; all type checking happens there.
EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]}); H
Hasse diagram of a poset containing 4 elements
sage: TestSuite(H).run()
```

`antichains(element_class=<class 'list'>)`

Return all antichains of `self`, organized as a prefix tree

**INPUT:**

- `element_class` – (default: list) an iterable type

**EXAMPLES:**

```python
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: A = H.antichains()
sage: list(A)
[[''], [4], [3], [2], [1], [1, 3], [1, 2], [0]]
sage: A.cardinality()
8
sage: [1,3] in A
True
sage: [1,4] in A
False
```

`antichains_iterator()`

Return an iterator over the antichains of the poset.

**Note:** The algorithm is based on Freese-Jezek-Nation p. 226. It does a depth first search through the set of all antichains organized in a prefix tree.

**EXAMPLES:**

```python
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: list(H.antichains_iterator())
[[''], [4], [3], [2], [1], [1, 3], [1, 2], [0]]
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[4],2:[3],3:[4]})
sage: list(H.antichains_iterator())
[[''], [4], [3], [2], [1], [1, 3], [1, 2], [0]]
sage: H = HasseDiagram({0:[],1:[],2:[]})
sage: list(H.antichains_iterator())
[[''], [2], [1], [1, 2], [0], [0, 2], [0, 1], [0, 1, 2]]
sage: H = HasseDiagram({0:[1],1:[],2:[3]})
sage: list(H.antichains_iterator())
[[''], [4], [3], [2], [1], [0]]
```

`are_comparable(i,j)`

Return whether `i` and `j` are comparable in the poset
INPUT:

- \(i, j\) – vertices of this Hasse diagram

EXAMPLES:

```python
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: H.are_comparable(1, 2)
False
sage: [(i, j) for i in H.vertices() for j in H.vertices() if H.are_comparable(i, j)]
[(0, 0), (0, 1), (0, 2), (0, 3), (0, 4), (1, 0), (1, 1), (1, 4), (2, 0), (2, 3), (2, 4), (3, 0), (3, 2), (3, 3), (3, 4), (4, 0), (4, 1), (4, 2), (4, 3), (4, 4)]
```

### are_incomparable \((i, j)\)

Return whether \(i\) and \(j\) are incomparable in the poset

INPUT:

- \(i, j\) – vertices of this Hasse diagram

EXAMPLES:

```python
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: H.are_incomparable(1, 2)
True
sage: [(i, j) for i in H.vertices() for j in H.vertices() if H.are_incomparable(i, j)]
[(1, 2), (1, 3), (2, 1), (3, 1)]
```

### atoms_of_congruence_lattice()

Return atoms of the congruence lattice.

In other words, return “minimal non-trivial” congruences: A congruence is minimal if the only finer (as a partition of set of elements) congruence is the trivial congruence where every block contains only one element.

See also:

- `congruence()`

OUTPUT:

List of congruences, every congruence as `sage.combinat.set_partition.SetPartition`

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: N5 = HasseDiagram({0: [1, 2], 1: [4], 2: [3], 3:[4]})
sage: N5.atoms_of_congruence_lattice()
[[[0], [1], [2, 3], [4]]]
```

ALGORITHM:

Every atom is a join-irreducible. Every join-irreducible of \(\text{Con}(L)\) is a principal congruence generated by a meet-irreducible element and the only element covering it (and also by a join-irreducible element and the only element covered by it). Hence we check those principal congruences to find the minimal ones.
bottom()  
Return the bottom element of the poset, if it exists.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.bottom() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.bottom()
0
```

cardinality()  
Return the number of elements in the poset.

EXAMPLES:

```
sage: Poset([[],[1,2,3],[4],[4],[4],[[]]).cardinality()
5
```

chains(element_class=<class 'list'>, exclude=None)  
Return all chains of self, organized as a prefix tree.

INPUT:

• element_class - (default: list) an iterable type
• exclude - elements of the poset to be excluded (default: None)

OUTPUT:

The enumerated set (with a forest structure given by prefix ordering) consisting of all chains of self, each of which is given as an element_class.

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: A = H.chains()
sage: list(A)
[[], [0], [0, 1], [0, 1, 4], [0, 2], [0, 2, 3], [0, 2, 3, 4], [0, 2, 4], [0, 3, 4], [0, 4], [1], [1, 4], [2], [2, 3], [2, 3, 4], [2, 4], [3], [3, 4], [4]]
sage: A.cardinality()
20
sage: [1,3] in A
False
sage: [1,4] in A
True
```

One can exclude some vertices:

```
sage: list(H.chains(exclude=[4, 3]))
[[], [0], [0, 1], [0, 2], [1], [2]]
```

The element_class keyword determines how the chains are being returned:

```
sage: P = Poset({1: [2, 3], 2: [4]})
sage: list(P._hasse_diagram.chains(element_class=tuple))
[((), (0,), (0, 1), (0, 1, 2), (0, 2), (0, 3), (1,), (1, 2), (2,), (3,))]
```
sage: list(P._hasse_diagram.chains())
[[], [0], [0, 1], [0, 1, 2], [0, 2], [0, 3], [1], [1, 2], [2], [3]]

(Note that taking the Hasse diagram has renamed the vertices.)

sage: list(P._hasse_diagram.chains(element_class=tuple, exclude=[0]))
[(), (1,), (1, 2), (2,), (3,)]

See also:

antichains()

closed_interval (x, y)
Return a list of the elements \( z \) of self such that \( x \leq z \leq y \).
The order is that induced by the ordering in self.linear_extension.

INPUT:

- \( x \) – any element of the poset
- \( y \) – any element of the poset

EXAMPLES:

sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[7]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(dag)
sage: I = set([2,5,6,4,7])
sage: I == set(H.interval(2,7))
True

congruence (parts, start=None, stop_pairs=[]) Return the congruence\( \text{start} \) “extended” by parts.

start is assumed to be a valid congruence of the lattice, and this is not checked.

INPUT:

- parts – a list of lists; congruences to add
- start – a disjoint set; already computed congruence (or None)
- stop_pairs – a list of pairs; list of pairs for stopping computation
OUTPUT:

None, if the congruence generated by start and parts together contains a block that has elements \(a, b\) so that \((a, b)\) is in the list stop_pairs. Otherwise the least congruence that contains a block whose subset is \(p\) for every \(p\) in parts or start, given as `sage.sets.disjoint_set.DisjointSetClass`.

ALGORITHM:

Use the quadrilateral argument from page 120 of [Dav1997].

Basically we take one block from todo-list, search quadrilateral blocks up and down against the block, and then complete them to closed intervals and add to todo-list.

EXAMPLES:

```sage
def from sage.combinat.posets.hasse_diagram import HasseDiagram
H = HasseDiagram({'A': [2, 3], 'B': [3, 5], 'C': [4, 5], 'D': [1, 3, 4, 5]})
cong = H.congruence('A'); cong
H.congruence('A', start=cong)
H.congruence('A', start=cong, stop_pairs=[(3, 5)])
```

congruences_iterator()

Return an iterator over all congruences of the lattice.

EXAMPLES:

```sage
def from sage.combinat.posets.hasse_diagram import HasseDiagram
H = HasseDiagram('GYQ@OQ@OQ@OQ')
H.congruences_iterator()
H.congruences_iterator().number_of_subsets()
```

cover_relations()

Return the list of cover relations.

EXAMPLES:

```sage
def from sage.combinat.posets.hasse_diagram import HasseDiagram
H = HasseDiagram({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]})
H.cover_relations()
H.cover_relations_iterator()
```

covers(x, y)

Return True if y covers x and False otherwise.
EXAMPLES:

```python
sage: Q = Poset([[1,5],[2,6],[3],[4],[6,3],[4]])
sage: Q.covers(Q(1),Q(6))
True
sage: Q.covers(Q(1),Q(4))
False
```

`coxeter_transformation(algorithm='cython')`

Return the matrix of the Auslander-Reiten translation acting on the Grothendieck group of the derived category of modules on the poset, in the basis of simple modules.

**INPUT:**

- `algorithm` - optional, 'cython' (default) or 'matrix'

This uses either a specific matrix code in Cython, or generic matrices.

**See also:**

`lequal_matrix()`, `moebius_function_matrix()`

**EXAMPLES:**

```python
sage: P = posets.PentagonPoset()._hasse_diagram
sage: M = P.coxeter_transformation(); M
[ 0 0 0 0 -1]
[ 0 0 0 1 -1]
[ 0 1 0 0 -1]
[-1 1 1 0 -1]
[-1 1 0 1 -1]
sage: P.__dict__['coxeter_transformation'].clear_cache()
sage: P.coxeter_transformation(algorithm="matrix") == M
True
```

diamonds()

Return the list of diamonds of `self`.

A diamond is the following subgraph of the Hasse diagram:

```
    z
   / \
  x   y
 / \
w
```

Thus each edge represents a cover relation in the Hasse diagram. We represent his as the tuple \((w, x, y, z)\).

**OUTPUT:**

A tuple with

- a list of all diamonds in the Hasse Diagram,
- a boolean checking that every \(w, x, y\) that form a \(V\), there is a unique element \(z\), which completes the diamond.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1,2], 1: [3], 2: [3], 3: []})
sage: H.diamonds()
```
\[
\begin{align*}
([0, 1, 2, 3]), \text{True})
\end{align*}
\]

```
sage: P = posets.YoungDiagramPoset(Partition([3, 2, 2]))
sage: H = P._hasse_diagram
sage: H.diamonds()
((0, 1, 3, 4), (3, 4, 5, 6), False)
```

dual()  
Return a poset that is dual to the given poset.  
This means that it has the same elements but opposite order. The elements are renumbered to ensure that range(n) is a linear extension.

EXAMPLES:

```
sage: P = posets.IntegerPartitions(4)
sage: H = P._hasse_diagram; H
Hasse diagram of a poset containing 5 elements
sage: H.dual()
Hasse diagram of a poset containing 5 elements
```

\textbf{find\_nonsemidistributive\_elements}(\textit{meet\_or\_join})  
Check if the lattice is semidistributive or not.

INPUT:

\begin{itemize}
  \item \textit{meet\_or\_join} – string 'meet' or 'join' to decide if to check for join-semidistributivity or meet-semidistributivity
\end{itemize}

OUTPUT:

\begin{itemize}
  \item None if the lattice is semidistributive OR
  \item tuple \((u, e, x, y)\) such that \(u \lor x = e \land y\) but \(u \neq e \lor (x \land y)\) if \textit{meet\_or\_join=='join'}
  \item and \(u = e \land x = e \land y\) but \(u \neq e \land (x \lor y)\) if \textit{meet\_or\_join=='meet'}
\end{itemize}

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1, 2], 1:[3, 4], 2:[4, 5], 3:[6],
....: 4:[6], 5:[6]}))
sage: H.find_nonsemidistributive_elements('join') is None
False
sage: H.find_nonsemidistributive_elements('meet') is None
True
```

\textbf{find\_nonsemimodular\_pair}(\textit{upper})  
Return pair of elements showing the lattice is not modular.

INPUT:

\begin{itemize}
  \item \textit{upper}, a Boolean – if True, test whether the lattice is upper semimodular; otherwise test whether the lattice is lower semimodular.
\end{itemize}

OUTPUT:

None, if the lattice is semimodular. Pair \((a, b)\) violating semimodularity otherwise.

EXAMPLES:
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1, 2], 1:[3, 4], 2:[4, 5], 3:[6], 4:[6], 5:[6]})

sage: H.find_nonsemimodular_pair(upper=True) is None
True

sage: H.find_nonsemimodular_pair(upper=False)
(5, 3)

sage: H_ = HasseDiagram(H.reverse().relabel(lambda x: 6-x, inplace=False))

sage: H_.find_nonsemimodular_pair(upper=True)
(3, 1)

sage: H_.find_nonsemimodular_pair(upper=False) is None
True

find_nontrivial_congruence()
Return a pair that generates non-trivial congruence or None if there is not any.

EXAMPLES:

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [5], 2: [3, 4], 3: [5], 4: [5]})

sage: H.find_nontrivial_congruence()
{{0, 1}, {2, 3, 4, 5}}

sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})

sage: H.find_nontrivial_congruence() is None
True

ALGORITHM:
See https://www.math.hawaii.edu/~ralph/Preprints/conlat.pdf:

If \( \Theta \) is a join irreducible element of a \( \text{Con}(L) \), then there is at least one join-irreducible \( j \) and one meet-irreducible \( m \) such that \( \Theta \) is both the principal congruence generated by \( (j^*, j) \), where \( j^* \) is the unique lower cover of \( j \), and the principal congruence generated by \( (m, m^*) \), where \( m^* \) is the unique upper cover of \( m \).

So, we only check join irreducibles or meet irreducibles, whichever is a smaller set. To optimize more we stop computation whenever it finds a pair that we know to generate one-element congruence.

frattini_sublattice()
Return the list of elements of the Frattini sublattice of the lattice.

EXAMPLES:

sage: H = posets.PentagonPoset()._hasse_diagram

sage: H.frattini_sublattice()
[0, 4]

greedy_linear_extensions_iterator()
Return an iterator over greedy linear extensions of the Hasse diagram.

A linear extension \([e_1, e_2, \ldots, e_n]\) is greedy if for every \( i \) either \( e_{i+1} \) covers \( e_i \) or all upper covers of \( e_i \) have at least one lower cover that is not in \([e_1, e_2, \ldots, e_i]\).

Informally said a linear extension is greedy if it “always goes up when possible” and so has no unnecessary jumps.

EXAMPLES:
```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: N5 = HasseDiagram({0: [1, 2], 2: [3], 1: [4], 3: [4]})
sage: for l in N5.greedy_linear_extensions_iterator():
    ....: print(l)
    [0, 1, 2, 3, 4]
    [0, 2, 3, 1, 4]
```

**has_bottom()**

Return True if the poset has a unique minimal element.

**EXAMPLES:**

```python
sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.has_bottom()
False
```

```python
sage: Q = Poset({0:[1],1:[],2:[],3:[],4:[],5:[],6:[],7:[],8:[]})
sage: Q.has_bottom()
True
```

**has_top()**

Return True if the poset contains a unique maximal element, and False otherwise.

**EXAMPLES:**

```python
sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.has_top()
False
```

```python
sage: Q = Poset({0:[1],1:[],2:[],3:[],4:[],5:[],6:[],7:[],8:[]})
sage: Q.has_top()
True
```

**interval(x, y)**

Return a list of the elements $z$ of self such that $x \leq z \leq y$.

The order is that induced by the ordering in self.linear_extension.

**INPUT:**

- $x$ – any element of the poset
- $y$ – any element of the poset

**EXAMPLES:**

```python
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[7],[7]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(dag)
sage: I == set(H.interval(2,7))
True
```

**is_antichain_of_poset(elms)**

Return True if $elms$ is an antichain of the Hasse diagram and False otherwise.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})
sage: H.is_antichain_of_poset([1, 2, 3])
```
True

\verb+sage: H.is_antichain_of_poset([0, 2, 3])+
False

**is_bounded()**

Return True if the poset contains a unique maximal element and a unique minimal element, and False otherwise.

**EXAMPLES:**

\verb+sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4,5], 4:[], 5:[]})+
\verb+sage: P.is_bounded()+
False
\verb+sage: Q = Poset({0:[1], 1:[]})+
\verb+sage: Q.is_bounded()+
True

**is_chain()**

Return True if the poset is totally ordered, and False otherwise.

**EXAMPLES:**

\verb+sage: L = Poset({0:[1], 1:[2], 2:[3], 3:[4]})+
\verb+sage: L.is_chain()+
True
\verb+sage: V = Poset({0:[1,2]})+
\verb+sage: V.is_chain()+
False

**is_complemented()**

Return an element of the lattice that has no complement.

If the lattice is complemented, return None.

**EXAMPLES:**

\verb+sage: from sage.combinat.posets.hasse_diagram import HasseDiagram+
\verb+sage: H = HasseDiagram({0:[1, 2], 1:[3], 2:[3], 3:[4]})+
\verb+sage: H.is_complemented()+
1
\verb+sage: H = HasseDiagram({0:[1, 2, 3], 1:[4], 2:[4], 3:[4]})+
\verb+sage: H.is_complemented() is None+
True

**is_congruence_normal()**

Return True if the lattice can be constructed from the one-element lattice with Day doubling constructions of convex subsets.

Subsets to double does not need to be lower nor upper pseudo-intervals. On the other hand they must be convex, i.e. doubling a non-convex but municipal subset will give a lattice that returns False from this function.

**EXAMPLES:**

\verb+sage: from sage.combinat.posets.hasse_diagram import HasseDiagram+
\verb+sage: H = HasseDiagram('IXQAGWQ')+
\verb+sage: H.is_congruence_normal()+
(continues on next page)
The 5-element diamond is the smallest non-example:

```
sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})
sage: H.is_congruence_normal()
False
```

This is done by doubling a non-convex subset:

```
sage: H = HasseDiagram('OQC?a@CO?G_C@?GA?O??_??@?BO?A_?G??C??_?@???')
sage: H.is_congruence_normal()
False
```

ALGORITHM:
See http://www.math.hawaii.edu/~jb/inflation.pdf

**is_convex_subset** *(S)*
Return True if *S* is a convex subset of the poset, and False otherwise.

A subset *S* is **convex** in the poset if *b* ∈ *S* whenever *a*, *c* ∈ *S* and *a* ≤ *b* ≤ *c*.

**EXAMPLES:**

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: B3 = HasseDiagram({0: [1, 2, 4], 1: [3, 5], 2: [3, 6],
......: 3: [7], 4: [5, 6], 5: [7], 6: [7]})
sage: B3.is_convex_subset([1, 3, 5, 4])  # Also connected
True
sage: B3.is_convex_subset([1, 3, 4])     # Not connected
True
sage: B3.is_convex_subset([0, 1, 2, 3, 6])  # No, 0 < 4 < 6
False
sage: B3.is_convex_subset([0, 1, 2, 7])  # No, 1 < 3 < 7.
False
```

**is_gequal** *(x, y)*
Return True if *x* is greater than or equal to *y*, and False otherwise.

**EXAMPLES:**

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: Q = HasseDiagram({0: [2], 1: [2], 2: [3], 3: [4], 4: []})
sage: x, y, z = 0, 1, 4
sage: Q.is_gequal(x, y)
False
sage: Q.is_gequal(y, x)
False
sage: Q.is_gequal(x, z)
False
sage: Q.is_gequal(z, x)
True
sage: Q.is_gequal(z, y)
True
sage: Q.is_gequal(z, z)
True
```
is_greater_than\((x, y)\)
Return True if \(x\) is greater than but not equal to \(y\), and False otherwise.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: Q = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x,y,z = 0,1,4
sage: Q.is_greater_than(x,y)  # False
sage: Q.is_greater_than(y,x)  # False
sage: Q.is_greater_than(x,z)  # False
sage: Q.is_greater_than(z,x)  # True
sage: Q.is_greater_than(z,y)  # True
sage: Q.is_greater_than(z,z)  # False
```

is_join_semilattice()
Return True if self has a join operation, and False otherwise.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7], ˓→7:[]})
sage: H.is_join_semilattice()  # True
sage: H = HasseDiagram({0:[2,3],1:[2,3]})
```

is_lequal\((i, j)\)
Return True if \(i\) is less than or equal to \(j\) in the poset, and False otherwise.

Note: If the lequal_matrix() has been computed, then this method is redefined to use the cached data (see _alternate_is_lequal()).

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2,1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7], ˓→7:[]})
sage: x,y,z = 0, 1, 4
sage: H.is_lequal(x,y)  # True
sage: H.is_lequal(y,x)  # False
sage: H.is_lequal(x,z)  # True
sage: H.is_lequal(y,z)  # True
```

(continues on next page)
is_lequal(z, z)
True

is_less_than(x, y)
Return True if x is less than but not equal to y in the poset, and False otherwise.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2], 1:[2], 2:[4], 3:[4], 4:[[]})
```

```python
sage: x, y, z = 0, 1, 4
sage: H.is_less_than(x, y)
False
sage: H.is_less_than(y, x)
False
sage: H.is_less_than(x, z)
True
sage: H.is_less_than(y, z)
True
sage: H.is_less_than(z, z)
False
```

is_linear_extension(lin_ext=None)
Test if an ordering is a linear extension.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],[3],4:[7],5:[7],6:[7],7:[[]])
```

```python
sage: H.is_linear_extension(list(range(4)))
True
sage: H.is_linear_extension([3,2,1,0])
False
```

is_meet_semilattice()
Return True if self has a meet operation, and False otherwise.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2,3,2],1:[4],2:[4,5,6],3:[6],4:[7,5:7,6:[7],7:[[]])
```

```python
sage: H.is_meet_semilattice()
True
```

```python
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],[3],4:[7],5:[7],6:[7],7:[[]])
```

```python
sage: H.is_meet_semilattice()
True
```

```python
sage: H = HasseDiagram({0:[2,3],1:[2,3])
```

```python
sage: H.is_meet_semilattice()
False
```

is_ranked()
Return True if the poset is ranked, and False otherwise.

A poset is ranked if it admits a rank function. For more information about the rank function, see rank_function() and is_graded().
EXAMPLES:

```python
sage: P = Poset(([1],[2],[3],[4],[5]))
sage: P.is_ranked()
True
sage: Q = Poset(([1,5],[2,6],[3],[4],[6,3],[4]))
sage: Q.is_ranked()
False
```

**join_matrix()**

Return the matrix of joins of self. The \((x,y)\)-entry of this matrix is the join of \(x\) and \(y\) in self.

This algorithm is modelled after the algorithm of Freese-Jezek-Nation (p217). It can also be found on page 140 of [Gec81].

**Note:** Once the matrix has been computed, it is stored in `_join_matrix()`. Delete this attribute if you want to recompute the matrix.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4, 5], 3: [4, 5], 4: [6], 5: [6], 6: [7], 7: []})
sage: H.join_matrix()
[0 1 2 3 4 5 6 7]
[1 1 4 7 4 7 7 7]
[2 4 2 6 4 5 6 7]
[3 7 6 3 7 6 7 7]
[4 4 4 7 4 7 7 7]
[5 7 5 7 5 7 7 7]
[6 7 6 6 7 7 6 7]
[7 7 7 7 7 7 7 7]
```

**kappa(a)**

Return the maximum element greater than the element covered by \(a\) but not greater than \(a\).

Define \(\kappa(a)\) as the maximum element of \((\uparrow a_*) \setminus (\uparrow a)\), where \(a_*\) is the element covered by \(a\). It is always a meet-irreducible element, if it exists.

**Note:** Element \(a\) is expected to be join-irreducible, and this is not checked.

INPUT:

- \(a\) – a join-irreducible element of the lattice

OUTPUT:

The element \(\kappa(a)\) or None if there is not a unique greatest element with given constraints.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4, 5], 3: [5], 4: [6], 5: [6]})
sage: H.kappa(1)
5
```

(continues on next page)
kappa_dual(a)

Return the minimum element smaller than the element covering a but not smaller than a.

Define $\kappa^*(a)$ as the minimum element of $(\downarrow a_*) \setminus (\downarrow a)$, where $a_*$ is the element covering $a$. It is always a join-irreducible element, if it exists.

**Note:** Element $a$ is expected to be meet-irreducible, and this is *not* checked.

**INPUT:**

• $a$ – a join-irreducible element of the lattice

**OUTPUT:**

The element $\kappa^*(a)$ or `None` if there is not a unique smallest element with given constraints.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3, 4], 2: [4, 5], 3: [6], 4: [6], 5: [6]})
sage: H.kappa_dual(3)
2
sage: H.kappa_dual(4) is None
True
```

lequal_matrix(boolean=False)

Return a matrix whose $(i,j)$ entry is 1 if $i$ is less than $j$ in the poset, and 0 otherwise; and redefines `__lt__` to use the boolean version of this matrix.

**INPUT:**

• `boolean` – optional flag (default `False`) telling whether to return a matrix with coefficients in $\mathbb{F}_2$ or in $\mathbb{Z}$

**See also:**

`moebius_function_matrix()`, `coxeter_transformation()`

**EXAMPLES:**

```python
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7]])
sage: H = P._hasse_diagram
sage: M = H.lequal_matrix(); M
[1 1 1 1 1 1 1]
[0 1 0 1 0 0 0]
[0 0 1 1 0 1 1]
[0 0 0 1 0 0 0]
[0 0 0 0 1 0 0]
[0 0 0 0 0 1 1]
[0 0 0 0 0 0 1]
sage: M.base_ring()
Integer Ring
```
sage: P = posets.DiamondPoset(6)
sage: H = P._hasse_diagram
sage: M = H.lequal_matrix(boolean=True)
sage: M.base_ring()
Finite Field of size 2

**linear_extension()**

Return a linear extension

**EXAMPLES:**

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: H.linear_extension()
[0, 1, 2, 3]
```

**linear_extensions()**

Return an iterator over all linear extensions.

**EXAMPLES:**

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: list(H.linear_extensions())
[[0, 1, 2, 3], [0, 2, 1, 3]]
```

**lower_covers_iterator(element)**

Return the list of elements that are covered by `element`.

**EXAMPLES:**

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],
                      →7:[]})
sage: list(H.lower_covers_iterator(0))
[]
sage: list(H.lower_covers_iterator(4))
[1, 2]
```

**maximal_elements()**

Return a list of the maximal elements of the poset.

**EXAMPLES:**

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.maximal_elements()
[4]
```

**maximal_sublattices()**

Return maximal sublattices of the lattice.

**EXAMPLES:**

```
sage: L = posets.PentagonPoset()
sage: ms = L._hasse_diagram.maximal_sublattices()
sage: sorted(ms, key=sorted)
[{{0, 1, 2, 4}, {0, 1, 3, 4}, {0, 2, 3, 4}}]
```
meet_matrix()
Return the matrix of meets of self.

The \((x, y)\)-entry of this matrix is the meet of \(x\) and \(y\) in self.

This algorithm is modelled after the algorithm of Freese-Jezek-Nation (p217). It can also be found on page 140 of [Gec81].

**Note:** Once the matrix has been computed, it is stored in \_meet_matrix(). Delete this attribute if you want to recompute the matrix.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7], ˓→7:[]})
sage: H.meet_matrix()
[0 0 0 0 0 0 0 0]
[0 1 0 0 1 0 0 1]
[0 0 2 0 2 2 2 2]
[0 0 0 3 0 3 3 3]
[0 1 2 0 4 2 4 4]
[0 0 2 0 2 5 2 5]
[0 0 2 3 2 6 6 6]
[0 1 2 3 4 5 6 7]
```

**REFERENCE:**

minimal_elements()
Return a list of the minimal elements of the poset.

**EXAMPLES:**

```python
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P(0) in P.minimal_elements()
True
sage: P(1) in P.minimal_elements()
True
sage: P(2) in P.minimal_elements()
True
```

moebius_function\((i,j)\)
Return the value of the Möbius function of the poset on the elements \(i\) and \(j\).

**EXAMPLES:**

```python
sage: P = Poset(([1,2,3],[4],[4],[4],[4]))
sage: H = P._hasse_diagram
sage: H.moebius_function(0,4)
2
sage: for u,v in P.cover_relations_iterator():
    ....:     if P.moebius_function(u,v) != -1:
    ....:         print("Bug in moebius_function!")
```

**REFERENCE:**

moebius_function_matrix\((algorithm='cython')\)
Return the matrix of the Möbius function of this poset.

This returns the matrix over \(\mathbb{Z}\) whose \((x, y)\) entry is the value of the Möbius function of self evaluated on \(x\) and \(y\), and redefines moebius_function() to use it.
INPUT:

• algorithm—optional, 'recursive', 'matrix' or 'cython' (default)

This uses either the recursive formula, a generic matrix inversion or a specific matrix inversion coded in Cython.

OUTPUT:

a dense matrix for the algorithm cython, a sparse matrix otherwise

Note: The result is cached in _moebius_function_matrix().

See also:

lequal_matrix(), coxeter_transformation()

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2], 1:[4,], 2:[4,5,6], 3:[6], 4:[7], 5:[7], 6:[7], →7:[]})
sage: H.moebius_function_matrix()
[ 1 -1 -1 -1 1 0 1 0]
[ 0 1 0 0 -1 0 0 0]
[ 0 0 1 0 -1 -1 -1 2]
[ 0 0 0 1 0 0 -1 0]
[ 0 0 0 0 1 0 0 -1]
[ 0 0 0 0 0 0 1 -1]
[ 0 0 0 0 0 0 0 1]
```

neutral_elements()

Return the list of neutral elements of the lattice.

An element \(a\) in a lattice is neutral if the sublattice generated by \(a, x\) and \(y\) is distributive for every \(x, y\) in the lattice.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1,2], 1: [4], 2: [3], 3: [4,5], ....: 4: [6], 5:[6]})
```

```python
sage: sorted(H.neutral_elements())
[0, 4, 6]
```

ALGORITHM:

Basically we just check the distributivity against all element pairs \(x, y\) to see if element \(a\) is neutral or not.

If we found that \(a, x, y\) is not a distributive triple, we add all three to list of non-neutral elements. If we found \(a\) to be neutral, we add it to list of neutral elements. When testing we skip already found neutral elements, as they can’t be our \(x\) or \(y\).

We skip \(a, x, y\) as trivial if it is a chain. We do that by letting \(x\) to be a non-comparable to \(a; y\) can be any element.

We first try to found \(x\) and \(y\) from elements not yet tested, so that we could get three birds with one stone.

And last, the top and bottom elements are always neutral and need not be tested.
open_interval \( (x, y) \)
Return a list of the elements \( z \) of \( \text{self} \) such that \( x < z < y \).

The order is that induced by the ordering in \( \text{self.linear_extension} \).

**EXAMPLES:**

```python
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[7]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(dag)
sage: set([5,6,4]) == set(H.open_interval(2,7))
True
sage: H.open_interval(7,2)
[]
```

order_filter \( (\text{elements}) \)
Return the order filter generated by a list of elements.

\( I \) is an order filter if, for any \( x \) in \( I \) and \( y \) such that \( y \geq x \), then \( y \) is in \( I \).

**EXAMPLES:**

```python
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.order_filter([3,8])
[3, 7, 8, 9, 10, 11, 12, 13, 14, 15]
```

order_ideal \( (\text{elements}) \)
Return the order ideal generated by a list of elements.

\( I \) is an order ideal if, for any \( x \) in \( I \) and \( y \) such that \( y \leq x \), then \( y \) is in \( I \).

**EXAMPLES:**

```python
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.order_ideal([7,10])
[0, 1, 2, 3, 4, 5, 6, 7, 8, 10]
```

order_ideal_cardinality \( (\text{elements}) \)
Return the cardinality of the order ideal generated by \( \text{elements} \).

\( I \) is an order ideal if, for any \( x \) in \( I \) and \( y \) such that \( y \leq x \), then \( y \) is in \( I \).

**EXAMPLES:**

```python
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.order_ideal_cardinality([7,10])
10
```

orthocomplementations_iterator ()
Return an iterator over orthocomplementations of the lattice.

**OUTPUT:**

An iterator that gives plain list of integers.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2], 1:[3,4], 3:[5], 4:[5], 2:[6,7],
...: 6:[8], 7:[8], 5:[9], 8:[9]})
```
sage: list(H.orthocomplementations_iterator())
[[9, 8, 5, 6, 7, 2, 3, 4, 1, 0], [9, 8, 5, 7, 6, 2, 4, 3, 1, 0]]

ALGORITHM:
As \(\text{DiamondPoset}(2n+2)\) has \((2n)!/(n!2^n)\) different orthocomplementations, the complexity of listing all of them is necessarily \(O(n!)\).

An orthocomplemented lattice is self-dual, so that for example orthocomplement of an atom is a coatom. This function basically just computes list of possible orthocomplementations for every element (i.e. they must be complements and “duals”), and then tries to fit them all.

**prime_elements()**

Return the join-prime and meet-prime elements of the bounded poset.

An element \(x\) of a poset \(P\) is join-prime if the subposet induced by \(\{y \in P \mid y \not\geq x\}\) has a top element. Meet-prime is defined dually.

**Note:** The poset is expected to be bounded, and this is *not* checked.

**OUTPUT:**
A pair \((j, m)\) where \(j\) is a list of join-prime elements and \(m\) is a list of meet-prime elements.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3], 2: [4], 3: [4]})
sage: H.prime_elements()
([1, 2], [2, 3])
```

**principal_congruences_poset()**

Return the poset of join-irreducibles of the congruence lattice.

**OUTPUT:**
A pair \((P, D)\) where \(P\) is a poset and \(D\) is a dictionary.

Elements of \(P\) are pairs \((x, y)\) such that \(x\) is an element of the lattice and \(y\) is an element covering it. In the poset \((a, b)\) is less than \((c, d)\) iff the principal congruence generated by \((a, b)\) is refinement of the principal congruence generated by \((c, d)\).

\(D\) is a dictionary from pairs \((x, y)\) to the congruence (given as DisjointSet) generated by the pair.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: N5 = HasseDiagram({0: [1, 2], 1: [4], 2: [3], 3: [4]})
sage: P, D = N5.principal_congruences_poset()
sage: P
Finite poset containing 3 elements
sage: P.bottom()
(2, 3)
sage: D[(2, 3)]
{{0}, {1}, {2, 3}, {4}}
```

**principal_order_filter()**

Return the order filter generated by \(i\).
EXAMPLES:

```python
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.principal_order_filter(2)
[2, 3, 6, 7, 10, 11, 14, 15]
```

**principal_order_ideal(i)**

Return the order ideal generated by \(i\).

EXAMPLES:

```python
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.principal_order_ideal(6)
[0, 2, 4, 6]
```

**pseudocomplement (element)**

Return the pseudocomplement of \(element\), if it exists.

The pseudocomplement is the greatest element whose meet with given element is the bottom element. It may not exist, and then the function returns `None`.

INPUT:

- `element` – an element of the lattice.

OUTPUT:

An element of the Hasse diagram, i.e. an integer, or `None` if the pseudocomplement does not exist.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})
```

```python
sage: H.pseudocomplement(2)
is None
```

```python
sage: H.rank(5)
2
sage: H.rank()
3
```

```python
sage: Q = HasseDiagram({0: [1, 2], 1: [3], 2: [], 3: []})
```

```python
sage: Q.rank() 1
```

**rank (element=None)**

Return the rank of \(element\), or the rank of the poset if \(element\) is `None`. (The rank of a poset is the length of the longest chain of elements of the poset.)

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 3, 2], 1: [4], 2: [4, 5, 6], 3: [6], 4: [7], 5: [7], 6: [7], ...
```

```python
sage: H.rank(5)
2
sage: H.rank()
3
```

```python
sage: Q = HasseDiagram({0: [1, 2], 1: [3], 2: [], 3: []})
```

```python
sage: Q.rank()
2
sage: Q.rank(1)
1
```

**rank_function ()**

Return the (normalized) rank function of the poset, if it exists.
A rank function of a poset $P$ is a function $r$ that maps elements of $P$ to integers and satisfies: $r(x) = r(y) + 1$ if $x$ covers $y$. The function $r$ is normalized such that its minimum value on every connected component of the Hasse diagram of $P$ is 0. This determines the function $r$ uniquely (when it exists).

**OUTPUT:**
- a lambda function, if the poset admits a rank function
- None, if the poset does not admit a rank function

**EXAMPLES:**

```python
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: P.rank_function() is not None
True
sage: P = Poset(([1,2,3,4],[[1,4],[2,3],[3,4]]), facade = True)
sage: P.rank_function() is not None
True
sage: P = Poset(([1,2,3,4,5],[[1,2],[2,3],[3,4],[1,5],[5,4]]), facade = True)
sage: P.rank_function() is not None
False
sage: P = Poset(([1,2,3,4,5,6,7,8],[[1,4],[2,3],[3,4],[5,7],[6,7]]), facade = True)
sage: f = P.rank_function(); f is not None
True
sage: f(5)
0
sage: f(2)
0
```

**skeleton()**

Return the skeleton of the lattice.

The lattice is expected to be pseudocomplemented and non-empty.

The skeleton of the lattice is the subposet induced by those elements that are the pseudocomplement to at least one element.

**OUTPUT:**
List of elements such that the subposet induced by them is the skeleton of the lattice.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3, 4], 2: [4],
...: 3: [5], 4: [5]})
sage: H.skeleton()
[5, 2, 0, 3]
```

**sublattices_iterator (elms, min_e)**

Return an iterator over sublattices of the Hasse diagram.

**INPUT:**
- elms – elements already in sublattice; use set() at start
- min_e – smallest new element to add for new sublattices

**OUTPUT:**
List of sublattices as sets of integers.

**EXAMPLES:**
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3], 2: [3]})

sage: it = H.sublattices_iterator(set(), 0); it
<generator object ...sublattices_iterator at ...>
sage: next(it)
set()
sage: next(it)
{0}

supergreedy_linear_extensions_iterator()
Return an iterator over supergreedy linear extensions of the Hasse diagram.

A linear extension \([e_1, e_2, \ldots, e_n]\) is supergreedy if, for every \(i\) and \(j\) where \(i > j\), \(e_i\) covers \(e_j\) if for every \(i > k > j\) at least one lower cover of \(e_k\) is not in \([e_1, e_2, \ldots, e_k]\).

Informally said a linear extension is supergreedy if it “always goes as high possible, and withdraw so less as possible”. These are also called depth-first linear extensions.

EXAMPLES:

We show the difference between “only greedy” and supergreedy extensions:

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 2: [3, 4]})
sage: GExt = list(H.greedy_linear_extensions_iterator())
sage: SGExt = list(H.supergreedy_linear_extensions_iterator())

sage: [0, 2, 3, 1, 4] in GExt
True
sage: [0, 2, 3, 1, 4] in SGExt
False
sage: len(SGExt)
4

top()
Return the top element of the poset, if it exists.

EXAMPLES:

sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4,5], 4:[], 5:[]})
sage: P.top() is None
True
sage: Q = Poset({0:[1], 1:[]})
sage: Q.top()
1

upper_covers_iterator(element)
Return the list of elements that cover \(element\).

EXAMPLES:

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2], 1:[4], 2:[4,5,6], 3:[6], 4:[7], 5:[7], 6:[7], 7:[]})
sage: list(H.upper_covers_iterator(0))
[1, 2, 3]
sage: list(H.upper_covers_iterator(7))
[]
vertical_decomposition (return_list=False)

Return vertical decomposition of the lattice.

This is the backend function for vertical decomposition functions of lattices.

The property of being vertically decomposable is defined for lattices. This is not checked, and the function works with any bounded poset.

INPUT:

• return_list, a boolean. If False (the default), return an element that is not the top neither the bottom element of the lattice, but is comparable to all elements of the lattice, if the lattice is vertically decomposable and None otherwise. If True, return list of decomposition elements.

EXAMPLES:

```
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.vertical_decomposition()
  is None
  True
sage: P = Poset( ([1,2,3,6,12,18,36], attrcall("divides")) )
sage: P._hasse_diagram.vertical_decomposition()
  3
sage: P._hasse_diagram.vertical_decomposition(return_list=True)
  [3]
```

exception sage.combinat.posets.hasse_diagram.LatticeError (fail, x, y)

Bases: ValueError

Helper exception class to forward elements without meet or join to upper level, so that the user will see “No meet for a and b” instead of “No meet for 1 and 2”.

5.1.182 Incidence Algebras

class sage.combinat.posets.incidence_algebras.IncidenceAlgebra (R, P, prefix='I')

Bases: sage.combinat.free_module.CombinatorialFreeModule

The incidence algebra of a poset.

Let $P$ be a poset and $R$ be a commutative unital associative ring. The incidence algebra $I_P$ is the algebra of functions $\alpha: P \times P \to R$ such that $\alpha(x, y) = 0$ if $x \nleq y$ where multiplication is given by convolution:

$$(\alpha * \beta)(x, y) = \sum_{x \leq k \leq y} \alpha(x, k) \beta(k, y).$$

This has a natural basis given by indicator functions for the interval $[a, b]$, i.e. $X_{a,b}(x, y) = \delta_{ax} \delta_{by}$. The incidence algebra is a unital algebra with the identity given by the Kronecker delta $\delta(x, y) = \delta_{xy}$. The Möbius function of $P$ is another element of $I_P$, whose inverse is the $\zeta$ function of the poset (so $\zeta(x, y) = 1$ for every interval $[x, y]$).

Todo: Implement the incidence coalgebra.

REFERENCES:

• Wikipedia article Incidence_algebra

class Element

Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

An element of an incidence algebra.
**is_unit()**

Return if `self` is a unit.

**EXAMPLES:**

```python
sage: P = posets:BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: mu = I.moebius()
sage: mu.is_unit()
True
sage: zeta = I.zeta()
sage: zeta.is_unit()
True
sage: x = mu - I.zeta() + I[2,2]
sage: x.is_unit()
False
sage: y = I.moebius() + I.zeta()
sage: y.is_unit()
True
```

This depends on the base ring:

```python
sage: I = P.incidence_algebra(ZZ)
sage: y = I.moebius() + I.zeta()
sage: y.is_unit()
False
```

**to_matrix()**

Return `self` as a matrix.

We define a matrix $M_{xy} = \alpha(x, y)$ for some element $\alpha \in I_P$ in the incidence algebra $I_P$ and we order the elements $x, y \in P$ by some linear extension of $P$. This defines an algebra (iso)morphism; in particular, multiplication in the incidence algebra goes to matrix multiplication.

**EXAMPLES:**

```python
sage: P = posets:BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: I.moebius().to_matrix()
[ 1 -1 -1 1]
[ 0 1 0 -1]
[ 0 0 1 -1]
[ 0 0 0 1]
sage: I.zeta().to_matrix()
[1 1 1 1]
[0 1 0 1]
[0 0 1 1]
[0 0 0 1]
```

**delta()**

Return the element $1$ in `self` (which is the Kronecker delta $\delta(x, y)$).

**EXAMPLES:**

```python
sage: P = posets:BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.one()
```
moebius()

Return the Möbius function of \( \text{self} \).

EXAMPLES:

```
sage: P = posets.BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: I.moebius()
I[0, 0] - I[0, 1] - I[0, 2] + I[0, 3] + I[1, 1] - I[1, 3] + I[2, 2] - I[2, 3] + I[3, 3]
```

one()

Return the element 1 in \( \text{self} \) (which is the Kronecker delta \( \delta(x, y) \)).

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.one()
```

poset()

Return the defining poset of \( \text{self} \).

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.poset()
Finite lattice containing 16 elements
sage: I.poset() == P
True
```

product_on_basis \((A, B)\)

Return the product of basis elements indexed by \( A \) and \( B \).

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.product_on_basis((1, 3), (3, 11))
I[1, 11]
sage: I.product_on_basis((1, 3), (2, 2))
0
```

reduced_subalgebra \((\text{prefix} = 'R')\)

Return the reduced incidence subalgebra.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.reduced_subalgebra()
```
Reduced incidence algebra of Finite lattice containing 16 elements over Rational Field

**some_elements()**
Return a list of elements of self.

**EXAMPLES:**
```
sage: P = posets.BooleanLattice(1)
sage: I = P.incidence_algebra(QQ)
sage: Ielts = I.some_elements(); Ielts
# random
[2*I[0, 0] + 2*I[0, 1] + 3*I[1, 1],
I[0, 0] - I[0, 1] + I[1, 1],
I[0, 0] + I[0, 1] + I[1, 1]]
sage: [a in I for a in Ielts]
[True, True, True]
```

**zeta()**
Return the $\zeta$ function in self.

The $\zeta$ function on a poset $P$ is given by

\[
\zeta(x, y) = \begin{cases} 
1 & x \leq y, \\
0 & x \not\leq y.
\end{cases}
\]

**EXAMPLES:**
```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.zeta() * I.moebius() == I.one()
True
```

```
class sage.combinat.posets.incidence_algebras.ReducedIncidenceAlgebra(I, prefix='R')

Bases: sage.combinat.free_module.CombinatorialFreeModule

The reduced incidence algebra of a poset.

The reduced incidence algebra $R_P$ is a subalgebra of the incidence algebra $I_P$ where $\alpha(x, y) = \alpha(x', y')$ when $[x, y]$ is isomorphic to $[x', y']$ as posets. Thus the delta, Möbius, and zeta functions are all elements of $R_P$.

**Element**

An element of a reduced incidence algebra.

**is_unit()**
Return if self is a unit.

**EXAMPLES:**
```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: x = R.an_element()
sage: x.is_unit()
True
```

**lift()**
Return the lift of self to the ambient space.
EXAMPLES:

```python
sage: P = posets.BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: R = I.reduced_subalgebra()
sage: x = R.an_element(); x
2*R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)]
sage: x.lift()
```

**to_matrix()**

Return self as a matrix.

EXAMPLES:

```python
sage: P = posets.BooleanLattice(2)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: mu = R.moebius()
sage: mu.to_matrix()
[ 1 -1 -1 1]
[ 0 1 0 -1]
[ 0 0 1 -1]
[ 0 0 0 1]
```

**delta()**

Return the Kronecker delta function in self.

EXAMPLES:

```python
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.delta()
R[(0, 0)]
```

**lift()**

Return the lift morphism from self to the ambient space.

EXAMPLES:

```python
sage: P = posets.BooleanLattice(2)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.lift
Generic morphism:
  From: Reduced incidence algebra of Finite lattice containing 4 elements
  \[\rightarrow\] over Rational Field
  To:   Incidence algebra of Finite lattice containing 4 elements over
        \[\rightarrow\] Rational Field
sage: R.an_element() - R.one()
```

**moebius()**

Return the M"obius function of self.

EXAMPLES:
```python
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.moebius()
R[(0, 0)] - R[(0, 1)] + R[(0, 3)] - R[(0, 7)] + R[(0, 15)]
```

**one_basis()**

Return the index of the element 1 in self.

**EXAMPLES:**

```python
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.one_basis()
(0, 0)
```

**poset()**

Return the defining poset of self.

**EXAMPLES:**

```python
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.poset()
Finite lattice containing 16 elements
sage: R.poset() == P
True
```

**some_elements()**

Return a list of elements of self.

**EXAMPLES:**

```python
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.some_elements()
[2*R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)],
 R[(0, 0)] - R[(0, 1)] + R[(0, 3)] - R[(0, 7)] + R[(0, 15)],
 R[(0, 0)] + R[(0, 1)] + R[(0, 3)] + R[(0, 7)] + R[(0, 15)]]
```

**zeta()**

Return the $\zeta$ function in self.

The $\zeta$ function on a poset $P$ is given by

$$
\zeta(x, y) = \begin{cases} 
1 & x \leq y, \\
0 & x \nleq y.
\end{cases}
$$

**EXAMPLES:**

```python
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.zeta()
R[(0, 0)] + R[(0, 1)] + R[(0, 3)] + R[(0, 7)] + R[(0, 15)]
```
5.1.183 Finite lattices and semilattices

This module implements finite (semi)lattices. It defines:

<table>

| **is_trim()** | Return **True** if the lattice is a trim lattice. |
| **is_vertically_decomposable()** | Return **True** if the lattice is vertically decomposable. |
| **is_simple()** | Return **True** if the lattice has no nontrivial congruences. |
| **is_isomorphic()** | Return **True** if all congruences of the lattice consists of isoform blocks. |
| **is_uniform()** | Return **True** if all congruences of the lattice consists of equal-sized blocks. |
| **is_regular()** | Return **True** if all congruences of lattice are determined by any of the congruence blocks. |
| **is_subdirectly_reducible()** | Return **True** if the lattice is a sublattice of the product of smaller lattices. |
| **is_constructible_by_doublings()** | Return **True** if the lattice is constructible by doublings from the one-element lattice. |
| **breadth()** | Return the breadth of the lattice. |

**Specific elements**

| **atoms()** | Return elements covering the bottom element. |
| **coatoms()** | Return elements covered by the top element. |
| **double_irreducibles()** | Return double irreducible elements. |
| **join_primes()** | Return the join prime elements. |
| **meet_primes()** | Return the meet prime elements. |
| **complements()** | Return the list of complements of an element, or the dictionary of complements for all elements. |
| **pseudocomplement()** | Return the pseudocomplement of an element. |
| **is_modular_element()** | Return **True** if given element is modular in the lattice. |
| **is_left_modular_element()** | Return **True** if given element is left modular in the lattice. |
| **neutral_elements()** | Return neutral elements of the lattice. |
| **canonical_joinands()** | Return the canonical joinands of an element. |
| **canonical_meetands()** | Return the canonical meetands of an element. |

**Sublattices**

| **sublattice()** | Return sublattice generated by list of elements. |
| **submeetsemilattice()** | Return meet-subsemilattice generated by list of elements. |
| **subjoinsemilattice()** | Return join-subsemilattice generated by list of elements. |
| **is_sublattice()** | Return **True** if the lattice is a sublattice of given lattice. |
| **sublattices()** | Return all sublattices of the lattice. |
| **sublattices_lattice()** | Return the lattice of sublattices. |
| **isomorphic_sublattices()** | Return an iterator over the sublattices isomorphic to given lattice. |
| **maximal_sublattices()** | Return maximal sublattices of the lattice. |
| **frattini_sublattice()** | Return the intersection of maximal sublattices of the lattice. |
| **skeleton()** | Return the skeleton of the lattice. |
| **center()** | Return the sublattice of complemented neutral elements. |
| **vertical_decomposition()** | Return the vertical decomposition of the lattice. |

**Miscellaneous**
Return the Möbius algebra of the lattice.
Return the quantum Möbius algebra of the lattice.
Return ordinal sum of lattices with top/bottom element unified.
Return the lattice with Alan Day’s doubling construction of a subset.
Return the adjunct with other lattice.
Return the subdirect decomposition of the lattice.
Return the congruence generated by lists of elements.
Return the quotient lattice by a congruence.
Return the lattice of congruences.

class sage.combinat.posets.lattices.FiniteJoinSemilattice

Bases: sage.combinat.posets.posets.FinitePoset

We assume that the argument passed to FiniteJoinSemilattice is the poset of a join-semilattice (i.e. a poset with least upper bound for each pair of elements).

Element

alias of sage.combinat.posets.elements.JoinSemilatticeElement

coaoms()

Return the list of co-atoms of this (semi)lattice.

A co-atom of a lattice is an element covered by the top element.

EXAMPLES:

```python
sage: L = posets.DivisorLattice(60)
sage: sorted(L.coatoms())
[12, 20, 30]
```

See also:

• Dual function: atoms()

join (x, y=None)

Return the join of given elements in the lattice.

INPUT:

• x, y – two elements of the (semi)lattice OR
• x – a list or tuple of elements

EXAMPLES:

```python
sage: D = posets.DiamondPoset(5)
sage: D.join(1, 2)
4
sage: D.join(1, 1)
1
sage: D.join(1, 4)
4
sage: D.join(1, 0)
1
```

Using list of elements as an argument. Join of empty list is the bottom element:
sage: B4 = posets.BooleanLattice(4)
sage: B4.join([2, 4, 8])
14
sage: B4.join([])
0

For non-facade lattices operator + works for join:

```
sage: L = posets.PentagonPoset(facade=False)
sage: L(1) + L(2)
4
```

See also:

- Dual function: `meet()`

**join_matrix()**

Return a matrix whose \((i, j)\) entry is \(k\), where \(\text{self.linear_extension()[k]}\) is the join (least upper bound) of \(\text{self.linear_extension()[i]}\) and \(\text{self.linear_extension()[j]}\).

**EXAMPLES:**

```
sage: P = LatticePoset([[[1, 3, 2], [4], [4, 5, 6], [6], [7], [7], [7], []]], facade=False)
sage: J = P.join_matrix(); J
[0 1 2 3 4 5 6 7]
[1 1 3 7 7 7 7 7]
[2 3 2 3 4 6 7 7]
[3 3 3 3 7 7 7 7]
[4 7 4 7 4 7 7 7]
[5 7 6 7 5 6 7 7]
[6 7 6 7 6 6 7 7]
[7 7 7 7 7 7 7 7]
True
True
False
```

```
class sage.combinat.posets.lattices.FiniteLatticePoset (hasse_diagram, elements, category, facade, key)

We assume that the argument passed to FiniteLatticePoset is the poset of a lattice (i.e. a poset with greatest lower bound and least upper bound for each pair of elements).

**Element**

alias of sage.combinat.posets.elements.LatticePosetElement

**adjunct** (other, a, b)

Return the adjunct of the lattice by other on the pair \((a, b)\).

It is assumed that \(a < b\) but \(b\) does not cover \(a\).

The adjunct of a lattice \(K\) to \(L\) with respect to pair \((a, b)\) of \(L\) is defined such that \(x < y\) if

- \(x, y \in K\) and \(x < y\) in \(K\),
\[ x, y \in L \text{ and } x < y \text{ in } L, \]
\[ x \in L, y \in K \text{ and } x \leq a \text{ in } L, \text{ or} \]
\[ x \in K, y \in L \text{ and } b \leq y \text{ in } L. \]

Informally this can be seen as attaching the lattice \( K \) to \( L \) as a new block between \( a \) and \( b \). Dismantlable lattices are exactly those that can be created from chains with this function.

Mathematically, it is only defined when \( L \) and \( K \) have no common element; here we force that by giving them different names in the resulting lattice.

**EXAMPLES:**

```
sage: Pnum = posets.PentagonPoset()
sage: Palp = Pnum.relabel(lambda x: chr(ord('a')+x))
sage: PP = Pnum.adjunct(Palp, 0, 3)
sage: PP.atoms()  
[(0, 1), (0, 2), (1, 'a')]  
sage: PP.coatoms()  
[(0, 3), (0, 1)]  
```

**breadth** *(certificate=False)*  
Return the breadth of the lattice.

The breadth of a lattice is the largest integer \( n \) such that any join of elements \( x_1, x_2, \ldots, x_{n+1} \) is join of a proper subset of \( x_i \).

This can be also characterized by sublattices: a lattice of breadth at least \( n \) contains a sublattice isomorphic to the Boolean lattice of \( 2^n \) elements.

**INPUT:**

- `certificate` – (default: `False`) whether to return a certificate

**OUTPUT:**

- If `certificate=True` return the pair \((b, a)\) where \( b \) is the breadth and \( a \) is an antichain such that the join of \( a \) differs from the join of any proper subset of \( a \). If `certificate=False` return just the breadth.

**EXAMPLES:**

```
sage: D10 = posets.DiamondPoset(10)
sage: D10.breadth()  
2  
sage: B3 = posets.BooleanLattice(3)
sage: B3.breadth()  
3  
sage: B3.breadth(certificate=True)  
(3, [1, 2, 4])  
```

**ALGORITHM:**

For a lattice to have breadth at least \( n \), it must have an \( n \)-element antichain \( A \) with join \( j \). Element \( j \) must cover at least \( n \) elements. There must also be \( n - 2 \) levels of elements between \( A \) and \( j \). So we start by searching elements that could be our \( j \) and then just check possible antichains \( A \).

**Note:** Prior to version 8.1 this function returned just an antichain with `certificate=True`. 

canonical_joinands\((e)\)
Return the canonical joinands of \(e\).

The canonical joinands of an element \(e\) in the lattice \(L\) is the subset \(S \subseteq L\) such that 1) the join of \(S\) is \(e\), and 2) if the join of some other subset \(S'\) of is also \(e\), then for every element \(s \in S\) there is an element \(s' \in S'\) such that \(s \leq s'\).

Informally said this is the set of lowest possible elements with given join. It exists for every element if and only if the lattice is join-semidistributive. Canonical joinands are always join-irreducibles.

INPUT:
- \(e\) – an element of the lattice

OUTPUT:
- canonical joinands as a list, if it exists; if not, None

EXAMPLES:
```python
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [5], 4: [6],
.....: 5: [7], 6: [7]})
sage: L.canonical_joinands(7)
[3, 4]
```

See also:
canonical_meetands()

canonical_meetands\((e)\)
Return the canonical meetands of \(e\).

The canonical meetands of an element \(e\) in the lattice \(L\) is the subset \(S \subseteq L\) such that 1) the meet of \(S\) is \(e\), and 2) if the meet of some other subset \(S'\) of is also \(e\), then for every element \(s \in S\) there is an element \(s' \in S'\) such that \(s \geq s'\).

Informally said this is the set of greatest possible elements with given meet. It exists for every element if and only if the lattice is meet-semidistributive. Canonical meetands are always meet-irreducibles.

INPUT:
- \(e\) – an element of the lattice

OUTPUT:
- canonical meetands as a list, if it exists; if not, None

EXAMPLES:
```python
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [5, 6], 4: [6],
.....: 5: [6]})
sage: L.canonical_meetands(1)
is None
```

True
See also:

canonical_joinands()

center()
  Return the center of the lattice.

An element of a lattice is central if it is neutral and has a complement. The subposet induced by central
elements is a center of the lattice. Actually it is a Boolean lattice.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3, 4], 2: [6, 7], 3: [8, 9, 7], ....: 4: [5, 6], 5: [8, 10], 6: [10], 7: [13, 11], ....: 8: [13, 12], 9: [11, 12], 10: [13], ....: 11: [14], 12: [14], 13: [14])
sage: C = L.center(); C
Finite lattice containing 4 elements
sage: C.cover_relations()
[[1, 2], [1, 12], [2, 14], [12, 14]]
sage: L = posets.DivisorLattice(60)
sage: sorted(L.center().list())
[1, 3, 4, 5, 12, 15, 20, 60]
```

See also:

neutral_elements(), complements()

complements(element=None)
  Return the list of complements of an element in the lattice, or the dictionary of complements for all ele-
ments.

Elements $x$ and $y$ are complements if their meet and join are respectively the bottom and the top element
of the lattice.

INPUT:

• element – an element of the lattice whose complement is returned. If None (default) then dictionary
  of complements for all elements having at least one complement is returned.

EXAMPLES:

```
sage: L=LatticePoset({0:['a','b','c'], 'a':[1], 'b':[1], 'c':[1]})
sage: C = L.complements()

Let us check that ‘a’ and ‘b’ are complements of each other:

```
sage: 'a' in C['b']
True
sage: 'b' in C['a']
True
```

Full list of complements:

```
sage: L.complements() # random order
{0: [1], 1: [0], 'a': ['b', 'c'], 'b': ['c', 'a'], 'c': ['b', 'a']}
sage: L=LatticePoset({0:[1,2],1:[3],2:[3],3:[4]})
sage: L.complements() # random order
{0: [4], 4: [0]}
```
(continues on next page)
sage: L.complements(1)
[1]

See also:

is_complemented()

congruence (S)

Return the congruence generated by set of sets \( S \).

A congruence of a lattice is an equivalence relation \( \approx \) that is compatible with meet and join; i.e. if \( a_1 \approx a_2 \) and \( b_1 \approx b_2 \), then \( (a_1 \vee \neg b_1) \approx (a_2 \vee \neg b_2) \) and \( (a_1 \wedge \neg b_1) \approx (a_2 \wedge \neg b_2) \).

By the congruence generated by set of sets \( \{S_1, \ldots, S_n\} \) we mean the least congruence \( \approx \) such that for every \( x, y \in S_i \) for some \( i \) we have \( x \approx y \).

INPUT:

- \( S \) – a list of lists; list of element blocks that the congruence will contain

OUTPUT:

Congruence of the lattice as a \texttt{sage.combinat.set_partition.SetPartition}.

EXAMPLES:

```
sage: L = posets.DivisorLattice(12)
sage: cong = L.congruence([[1, 3]])
sage: sorted(sorted(c) for c in cong)
[[(1, 3)], [(2, 6), (4, 12)]]
sage: L.congruence([[1, 2], [6, 12]])
{{1, 2, 4}, {3, 6, 12}}
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [4], 4: [5],
....: 6: [8], 7: [9], 8: [10], 9: [10]})
sage: cong = L.congruence([[1, 2]])
sage: cong[0]
frozenset({1, 2, 3, 4, 5, 6, 7, 8, 9, 10})
```

See also:

quotient()

congruences_lattice (labels='congruence')

Return the lattice of congruences.

A congruence of a lattice is a partition of elements to classes compatible with both meet- and join-operation; see congruence(). Elements of the congruence lattice are congruences ordered by refinement; i.e. if every class of a congruence \( \Theta \) is contained in some class of \( \Phi \), then \( \Theta \leq \Phi \) in the congruence lattice.

INPUT:

- \( \text{labels} \) – a string; the type of elements in the resulting lattice
A distributive lattice.

- If `labels='congruence'`, then elements of the result will be congruences given as `sage.combinat.set_partition.SetPartition`.
- If `labels='integers'`, result is a lattice on integers isomorphic to the congruence lattice.

**EXAMPLES:**
```python
day_doubling(S)
Return the lattice with Alan Day's doubling construction of subset S.

The subset S is assumed to be convex (i.e. if a, c ∈ S and a < b < c in the lattice, then b ∈ S) and connected (i.e. if a, b ∈ S then there is a chain a = e₁, e₂, ..., eₙ = b such that eᵢ either covers or is covered by eᵢ₊₁).

Alan Day's doubling construction is a specific extension of the lattice. Here we formulate it in a format more suitable for computation.

Let L be a lattice and S a convex subset of it. The resulting lattice L[S] has elements (e, 0) for each e ∈ L and (e, 1) for each e ∈ S. If x ≤ y in L, then in the new lattice we have
\[ (x, 0), (x, 1) \leq (y, 0), (y, 1) \]
\[ (x, 0) \leq (x, 1) \]

**INPUT:**
- \( S \) – a subset of the lattice

**EXAMPLES:**

```python
sage: L = LatticePoset({1: ['a', 'b', 2], 'a': ['c'], 'b': ['c', 'd'], ....: 2: [3], 'c': [4], 'd': [4], 3: [4]})
sage: L2 = L.day_doubling(['a', 'b', 'c', 'd']); L2
Finite lattice containing 12 elements
sage: set(L2.upper_covers((1, 0))) == set([(2, 0), ('a', 0), ('b', 0)])
True
sage: set(L2.upper_covers(('b', 0))) == set([('d', 0), ('b', 1), ('c', 0)])
True
```

See also:

- `is_constructible_by_doublings()`

**double_irreducibles()**

Return the list of double irreducible elements of this lattice.

A double irreducible element of a lattice is an element covering and covered by exactly one element. In other words it is neither a meet nor a join of any elements.

**EXAMPLES:**

```python
sage: L = posets.DivisorLattice(12)
sage: sorted(L.double_irreducibles())
[3, 4]
sage: L = posets:BooleanLattice(3)
sage: L.double_irreducibles()
[]
```

See also:

- `meet_irreducibles()`, `join_irreducibles()`

**frattini_sublattice()**

Return the Frattini sublattice of the lattice.

The Frattini sublattice \( \Phi(L) \) is the intersection of all proper maximal sublattices of \( L \). It is also the set of “non-generators” - if the sublattice generated by set \( S \) of elements is whole lattice, then also \( S \setminus \Phi(L) \) generates whole lattice.

**EXAMPLES:**

```python
sage: L = LatticePoset(( [], [[1,2],[1,17],[1,8],[2,3],[2,22], ....: [2,5],[2,7],[17,22],[17,13],[8,7], ....: [8,13],[3,16],[3,9],[22,16],[22,18], ....: [22,10],[5,18],[5,14],[7,9],[7,14], ....: [7,10],[13,10],[16,6],[16,19],[9,19], ....: [18,6],[18,33],[14,33],[10,19], ....: [10,33],[6,4],[19,4],[33,4] ))
sage: sorted(L.frattini_sublattice().list())
[1, 2, 4, 10, 19, 22, 33]
```
is_atomic\( (\text{certificate}=\text{False}) \)
Return True if the lattice is atomic, and False otherwise.
A lattice is atomic if every element can be written as a join of atoms.

INPUT:
• certificate – (default: False) whether to return a certificate

OUTPUT:
• If certificate=True return either (True, None) or (False, e), where e is a join-irreducible element that is not an atom. If certificate=False return True or False.

EXAMPLES:

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3:[5], 4:[6], 5:[6]})
sage: L.is_atomic()
True
sage: L = LatticePoset({0: [1, 2], 1: [3], 2: [3], 3:[4]})
sage: L.is_atomic()
False
sage: L.is_atomic(certificate=True)
(False, 4)
```

Note: See [EnumComb1], Section 3.3 for a discussion of atomic lattices.

See also:
• Dual property: is_coatomic()
• Stronger properties: is_sectionally_complemented()
• Mutually exclusive properties: is_vertically_decomposable()

is_coatomic\( (\text{certificate}=\text{False}) \)
Return True if the lattice is coatomic, and False otherwise.
A lattice is coatomic if every element can be written as a meet of coatoms; i.e. if the dual of the lattice is atomic.

INPUT:
• certificate – (default: False) whether to return a certificate

OUTPUT:
• If certificate=True return either (True, None) or (False, e), where e is a meet-irreducible element that is not a coatom. If certificate=False return True or False.

EXAMPLES:

```python
sage: L = posets.BooleanLattice(3)
sage: L.is_coatomic()
True
sage: L = LatticePoset({1: [2], 2: [3, 4], 3: [5], 4:[5]})
sage: L.is_coatomic()
False
```

(continues on next page)

```python
sage: L.is_coatomic(certificate=True)
(False, 1)
```

See also:

- Dual property: `is_atomic()`
- Stronger properties: `is_cosectionally_complemented()`
- Mutually exclusive properties: `is_vertically_decomposable()`

```python
is_complemented(certificate=False)
```

Return `True` if the lattice is complemented, and `False` otherwise.

A lattice is complemented if every element has at least one complement.

**INPUT:**

- `certificate` – (default: `False`) whether to return a certificate

**OUTPUT:**

- If `certificate=True` return either `(True, None)` or `(False, e)`, where `e` is an element without a complement. If `certificate=False` return `True` or `False`.

**EXAMPLES:**

```python
sage: L = LatticePoset({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})
sage: L.is_complemented()
True
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [5], 4: [6], ...:
                     5: [7], 6: [7]})
sage: L.is_complemented()
False
sage: L.is_complemented(certificate=True)
(False, 2)
```

See also:

- Stronger properties: `is_sectionally_complemented()`, `is_cosectionally_complemented()`, `is_orthocomplemented()`
- Other: `complements()`

```python
is_constructible_by_doublings(type)
```

Return `True` if the lattice is constructible by doublings, and `False` otherwise.

We call a lattice doubling constructible if it can be constructed from the one element lattice by a sequence of Alan Day’s doubling constructions.

Lattices constructible by interval doubling are also called bounded. Lattices constructible by lower and upper pseudo-interval are called lower bounded and upper bounded. Lattices constructible by any convex set doubling are called congruence normal.

**INPUT:**

- `type` – a string; can be one of the following:
  - 'interval' - allow only doublings of an interval
- 'lower' - allow doublings of lower pseudo-interval; that is, a subset of the lattice with a unique minimal element
- 'upper' - allow doublings of upper pseudo-interval; that is, a subset of the lattice with a unique maximal element
- 'convex' - allow doubling of any convex set
- 'any' - allow doubling of any set

EXAMPLES:
The pentagon can be constructed by doubling intervals; the 5-element diamond cannot be constructed by any doublings:

```
sage: posets.PentagonPoset().is_constructible_by_doublings('interval')
True
sage: posets.DiamondPoset(5).is_constructible_by_doublings('any')
False
```

After doubling both upper and lower pseudo-interval a lattice is constructible by convex subset doubling:

```
sage: L = posets.BooleanLattice(2)
sage: L = L.day_doubling([0, 1, 2])  # A lower pseudo-interval
sage: L.is_constructible_by_doublings('interval')
False
sage: L.is_constructible_by_doublings('lower')
True
sage: L = L.day_doubling([(3,0), (1,1), (2,1)])  # An upper pseudo-interval
sage: L.is_constructible_by_doublings('upper')
False
sage: L.is_constructible_by_doublings('convex')
True
```

An example of a lattice that can be constructed by doublings of a non-convex subsets:

```
sage: L = LatticePoset(DiGraph('OQC?a?@CO?G_C@?GA?O??_??@?BO?A_?G??C??_?@??˓
˓→'))
sage: L.is_constructible_by_doublings('convex')
False
sage: L.is_constructible_by_doublings('any')
True
```

See also:

- Stronger properties: `is_distributive()` (doubling by interval), `is_join_semidistributive()` (doubling by lower pseudo-intervals), `is_meet_semidistributive()` (doubling by upper pseudo-intervals)
- Mutually exclusive properties: `is_simple()` (doubling by any set)
- Other: `day_doubling()`

ALGORITHM:

According to [HOLM2016] a lattice $L$ is lower bounded if and only if $|\text{Ji}(L)| = |\text{Ji}(\text{Con } L)|$, and so dually $|\text{Mi}(L)| = |\text{Mi}(\text{Con } L)|$ in upper bounded lattices. The same reference gives a test for being constructible by convex or by any subset.
**is_cosectionally_complemented** *(certificate=False)*

Return True if the lattice is cosectionally complemented, and False otherwise.

A lattice is *cosectionally complemented* if all intervals to the top element interpreted as sublattices are complemented lattices.

**INPUT:**

- **certificate** – (default: False) Whether to return a certificate if the lattice is not cosectionally complemented.

**OUTPUT:**

- If certificate=False return True or False. If certificate=True return either (True, None) or (False, (b, e)), where b is an element so that in the sublattice from b to the top element has no complement for element e.

**EXAMPLES:**

The smallest sectionally but not cosectionally complemented lattice:

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3: [5], 4: [6], 5: [6]})
sage: L.is_sectionally_complemented(), L.is_cosectionally_complemented()
(True, False)
```

A sectionally and cosectionally but not relatively complemented lattice:

```python
sage: L = LatticePoset(DiGraph('MYi@O?P??D?OG?@?O_?C?Q??O?W?@??O??'))
sage: L.is_sectionally_complemented() and L.is_cosectionally_complemented()
True
sage: L.is_relatively_complemented()
False
```

Getting a certificate:

```python
sage: L = LatticePoset(DiGraph('HW?@D?Q?GE?G@??'))
sage: L.is_cosectionally_complemented(certificate=True)
(False, (2, 7))
```

**See also:**

- Dual property: `is_sectionally_complemented()`
- Weaker properties: `is_complemented()`, `is_coatomic()`, `is_regular()`
- Stronger properties: `is_relatively_complemented()`

**is_dismantlable** *(certificate=False)*

Return True if the lattice is dismantlable, and False otherwise.

An n-element lattice $L_n$ is dismantlable if there is a sublattice chain $L_{n-1} \supset L_{n-2} \supset \cdots \supset L_0$ so that every $L_i$ is a sublattice of $L_{i+1}$ with one element less, and $L_0$ is the empty lattice. In other words, a dismantlable lattice can be reduced to empty lattice removing doubly irreducible element one by one.

**INPUT:**

- **certificate** (boolean) – Whether to return a certificate.
  - If certificate = False (default), returns True or False accordingly.
  - If certificate = True, returns:
* (True, elms) when the lattice is dismantlable, where elms is elements listed in a possible removing order.

* (False, crown) when the lattice is not dismantlable, where crown is a subposet of $2k$ elements $a_1, \ldots, a_k, b_1, \ldots, b_k$ with covering relations $a_i < b_i$ and $a_i < b_{i+1}$ for $i \in [1, \ldots, k-1]$, and $a_k < b_1$.

**EXAMPLES:**

```sage
dL12 = LatticePoset((divisors(12), attrcall("divides")))
sage: dL12.is_dismantlable()
True
sage: dL12.is_dismantlable(certificate=True)
(True, [4, 2, 1, 3, 6, 12])
```

```sage
B3 = posets.BooleanLattice(3)
sage: B3.is_dismantlable()
False
sage: B3.is_dismantlable(certificate=True)
(False, Finite poset containing 6 elements)
```

Every planar lattice is dismantlable. Converse is not true:

```sage
L = LatticePoset( [ [1], [1, 2], [2, 3], [3, 4], [4, 5], [5, 6], [6, 7], [7, 8] ] )
sage: L.is_dismantlable()
True
sage: L.is_planar()
False
```

See also:

- Stronger properties: `is_planar()`
- Weaker properties: `is_sublattice_dismantlable()`

**is_distributive** *(certificate=False)*

Return True if the lattice is distributive, and False otherwise.

A lattice $(L, \lor, \land)$ is distributive if meet distributes over join: $x \land (y \lor z) = (x \land y) \lor (x \land z)$ for every $x, y, z \in L$ just like $x \cdot (y + z) = x \cdot y + x \cdot z$ in normal arithmetic. For duality in lattices it follows that then also join distributes over meet.

- **certificate** – (default: False) whether to return a certificate

**OUTPUT:**

- If certificate=True return either (True, None) or (False, (x, y, z)), where x, y and z are elements of the lattice such that $x \land (y \lor z) \neq (x \land y) \lor (x \land z)$. If certificate=False return True or False.

**EXAMPLES:**

```sage
L = LatticePoset({1: [2, 3], 2: [4], 3: [4], 4: [5]})
sage: L.is_distributive()
True
```

(continues on next page)
False
sage: L.is_distributive(certificate=True)
(False, (5, 3, 2))

See also:

• Weaker properties: is_modular(), is_semidistributive(),
  is_join_distributive(), is_meet_distributive(),
  is_subdirectly_reducible(), is_trim(),
  is_constructible_by_doublings()
  (by interval doubling), is_extremal()

• Stronger properties: is_stone()

is_extremal()
Return True if the lattice is extremal, and False otherwise.
A lattice is extremal if the number of join-irreducibles is equal to the number of meet-irreducibles and to
the number of cover relations in the longest chains.

EXAMPLES:

sage: posets.PentagonPoset().is_extremal()
True
sage: P = LatticePoset(posets.SymmetricGroupWeakOrderPoset(3))
sage: P.is_extremal()
False

See also:

• Stronger properties: is_distributive(), is_trim()

REFERENCES:

• [Mark1992]

is_geometric()
Return True if the lattice is geometric, and False otherwise.
A lattice is geometric if it is both atomic and upper semimodular.

EXAMPLES:
Canonical example is the lattice of partitions of finite set ordered by refinement:

sage: L = posets.SetPartitions(4)
sage: L.is_geometric()
True

Smallest example of geometric lattice that is not modular:

sage: L = LatticePoset(DiGraph('K@?gS?q?M@?@?@?@?@??'))
sage: L.is_geometric()
True
sage: L.is_modular()
False

Two non-examples:

```python
sage: L = LatticePoset({1:[2, 3, 4], 2:[5, 6], 3:[5], 4:[6], 5:[7], 6:[7]})
sage: L.is_geometric()  # Graded, but not upper semimodular
False
sage: L = posets.ChainPoset(3)
sage: L.is_geometric()  # Modular, but not atomic
False
```

See also:

- Weaker properties: `is_upper_semimodular()`, `is_relatively_complemented()`

**is_interval_dismantlable** *(certificate=False)*

Return `True` if the lattice is interval dismantlable, and `False` otherwise.

An interval dismantling is a subdivision of a lattice to a principal upper set and a principal lower set. A lattice is *interval dismantlable* if it can be decomposed into 1-element lattices by consecutive interval dismantlings.

A lattice is *minimally interval non-dismantlable* if it is not interval dismantlable, but all of its sublattices are interval dismantlable.

**INPUT:**

- `certificate` – (default: `False`) whether to return a certificate

**OUTPUT:**

- if `certificate=False`, return only `True` or `False`
- if `certificate=True`, return either
  - `(True, list)` where `list` is a nested list showing the decomposition; for example `list[1][0]` is a lower part of upper part of the lattice when decomposed twice.
  - `(False, M)` where `M` is a minimally interval non-dismantlable sublattice of the lattice.

**EXAMPLES:**

```python
sage: L1 = LatticePoset({1: [2, 3], 3: [4, 5], 2: [6], 4: [6], 5: [6]})
sage: L1.is_interval_dismantlable()
True
sage: L2 = LatticePoset({1: [2, 3, 4, 5], 2: [6], 3: [6], 4: [6],
....:                     5: [6, 7], 6: [8], 7: [9, 10], 8:[10], 9:[10]})
sage: L2.is_interval_dismantlable()
False
```

To get certificates:

```python
sage: L1.is_interval_dismantlable(certificate=True)
(True, [[1], [2]], [[3], [5]], [[4], [6]])
sage: L2.is_interval_dismantlable(certificate=True)
(False, Finite lattice containing 5 elements)
```

See also:

- Stronger properties: `is_join_semidistributive()`, `is_meet_semidistributive()`
- Weaker properties: `is_sublattice_dismantlable()`
is_isoform (certificate=False)
Return True if the lattice is isoform and False otherwise.

A congruence is isoform (or isotype) if all blocks are isomorphic sublattices. A lattice is isoform if it has only isoform congruences.

INPUT:
- certificate – (default: False) whether to return a certificate if the lattice is not isoform

OUTPUT:
- If certificate=True return either (True, None) or (False, C), where C is a non-isoform congruence as a sage.combinat.set_partition.SetPartition. If certificate=False return True or False.

EXAMPLES:
```
sage: L = LatticePoset({1:[2, 3, 4], 2: [5, 6], 3: [6, 7], 4: [7], 5: [8], 6: [8], 7: [8]})
sage: L.is_isoform()
True
```

Every isoform lattice is (trivially) uniform, but the converse is not true:
```
sage: L = LatticePoset({1: [2, 3, 6], 2: [4, 5], 3: [5], 4: [9, 8], 5: [7, 8], 6: [9, 7, 10], 8: [10], 9: [10]})
sage: L.is_isoform(), L.is_uniform()
(False, True)
sage: L.is_isoform(certificate=True)
(False, {{1, 2, 4, 6, 9}, {3, 5, 7, 8, 10}})
```

See also:
- Weaker properties: is_uniform()
- Stronger properties: is_simple(), is_relatively_complemented()
- Other: congruence()

is_join_distributive (certificate=False)
Return True if the lattice is join-distributive and False otherwise.

A lattice is join-distributive if every interval from an element to the join of the element’s upper covers is a distributive lattice. Actually this distributive sublattice is then a Boolean lattice.

They are also called as Dilworth’s lattices and upper locally distributive lattices. They can be characterized in many other ways, see [Dil1940].

INPUT:
- certificate – (default: False) whether to return a certificate

OUTPUT:
- If certificate=True return either (True, None) or (False, e), where e is an element such that the interval from e to the meet of upper covers of e is not distributive. If certificate=False return True or False.

EXAMPLES:

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [5, 7],
                      4: [6, 7], 5: [8, 9], 6: [9], 7: [9, 10],
                      8: [11], 9: [11], 10: [11]})
```

```python
sage: L.is_join_distributive()
True
```

```python
sage: L = LatticePoset({1: [2], 2: [3, 4], 3: [5], 4: [6],
                      5: [7], 6: [7]})
```

```python
sage: L.is_join_distributive()
False
```

```python
sage: L.is_join_distributive(certificate=True)
(False, 2)
```

See also:

- Dual property: `is_meet_distributive()`
- Weaker properties: `is_meet_semidistributive(), is_upper_semidistributive()`
- Stronger properties: `is_distributive()`

### is_join_pseudocomplemented (certificate=False)

Return `True` if the lattice is join-pseudocomplemented, and `False` otherwise.

A lattice is join-pseudocomplemented if every element $e$ has a join-pseudocomplement $e'$, i.e. the least element such that the join of $e$ and $e'$ is the top element.

**INPUT:**

- `certificate` – (default: `False`) whether to return a certificate

**OUTPUT:**

- If `certificate=True` return either `(True, None)` or `(False, e)`, where $e$ is an element without a join-pseudocomplement. If `certificate=False` return `True` or `False`.

**EXAMPLES:**

```python
sage: L = LatticePoset({1: [2, 5], 2: [3, 6], 3: [4], 4: [7],
                      5: [6], 6: [7]})
```

```python
sage: L.is_join_pseudocomplemented()
True
```

```python
sage: L = LatticePoset({1: [2, 3], 2: [4, 5, 6], 3: [6], 4: [7],
                      5: [7], 6: [7]})
```

```python
sage: L.is_join_pseudocomplemented()
False
```

```python
sage: L.is_join_pseudocomplemented(certificate=True)
(False, 4)
```

See also:

- Dual property: `is_pseudocomplemented()`
- Stronger properties: `is_join_semidistributive()`

### is_join_semidistributive (certificate=False)

Return `True` if the lattice is join-semidistributive, and `False` otherwise.
A lattice is join-semidistributive if for all elements $e, x, y$ in the lattice we have

$$e \lor x = e \lor y \implies e \lor x = e \lor (x \land y)$$

**INPUT:**

- certificate – (default: False) whether to return a certificate

**OUTPUT:**

- If certificate=True return either (True, None) or (False, (e, x, y)) such that $e \lor x = e \lor y$ but $e \lor x \neq e \lor (x \land y)$. If certificate=False return True or False.

**EXAMPLES:**

```python
sage: T4 = posets.TamariLattice(4)
sage: T4.is_join_semidistributive()
True
sage: L = LatticePoset({1:[2, 3], 2:[4, 5], 3:[5, 6],
         ....: 4:[7], 5:[7], 6:[7]})
sage: L.is_join_semidistributive()
False
sage: L.is_join_semidistributive(certificate=True)
(False, (5, 4, 6))
```

See also:

- Dual property: `is_meet_semidistributive()`
- Weaker properties: `is_join_pseudocomplemented()`, `is_interval_dismantlable()`
- Stronger properties: `is_semidistributive()`, `is_meet_distributive()`, `is_constructible_by_doublings()` (by lower pseudo-intervals)

**is_left_modular_element($x$)**

Return True if $x$ is a left modular element and False otherwise.

**INPUT:**

- $x$ – an element of the lattice

An element $x$ in a lattice $L$ is **left modular** if

$$(y \lor x) \land z = y \lor (x \land z)$$

for every $y \leq z \in L$.

It is enough to check this condition on all cover relations $y < z$.

**EXAMPLES:**

```python
sage: P = posets.PentagonPoset()
sage: [i for i in P if P.is_left_modular_element(i)]
[0, 2, 3, 4]
```

See also:

- Stronger properties: `is_modular_element()`
**is_lower_semimodular** *(certificate=False)*

Return True if the lattice is lower semimodular and False otherwise.

A lattice is lower semimodular if any pair of elements with a common upper cover have also a common lower cover.

**INPUT:**

- **certificate** – (default: False) Whether to return a certificate if the lattice is not lower semimodular.

**OUTPUT:**

- If certificate=False return True or False. If certificate=True return either (True, None) or (False, (a, b)), where a and b are covered by their join but do no cover their meet.

See [Wikipedia article Semimodular lattice](https://en.wikipedia.org/wiki/Semimodular_lattice)

**EXAMPLES:**

```python
sage: L = posets.DiamondPoset(5)
sage: L.is_lower_semimodular()
True

sage: L = posets.PentagonPoset()
sage: L.is_lower_semimodular()
False

sage: L = posets.ChainPoset(6)
sage: L.is_lower_semimodular()
True

sage: L = LatticePoset(DiGraph('IS?`?AAOE_@?C?_@??'))
sage: L.is_lower_semimodular(certificate=True)
(False, (4, 2))
```

See also:

- Dual property: **is_upper_semimodular()**
- Weaker properties: **is_graded()**
- Stronger properties: **is_modular(), is_meet_distributive()**

**is_meet_distributive** *(certificate=False)*

Return True if the lattice is meet-distributive and False otherwise.

A lattice is meet-distributive if every interval to an element from the meet of the element’s lower covers is a distributive lattice. Actually this distributive sublattice is then a Boolean lattice.

They are also called as lower locally distributive lattices. They can be characterized in many other ways, see [Dil1940].

**INPUT:**

- **certificate** – (default: False) whether to return a certificate

**OUTPUT:**

- If certificate=True return either (True, None) or (False, e), where e is an element such that the interval to e from the meet of lower covers of e is not distributive. If certificate=False return True or False.
EXAMPLES:

```python
def is_meet_distributive(L, certificate=False):
    # Implement the logic for checking meet-distributivity
    #...)
    return True
```

See also:

- Dual property: `is_join_distributive()`
- Weaker properties: `is_join_semidistributive()`, `is_lower_semimodular()`
- Stronger properties: `is_distributive()`

**is_meet_semidistributive** (certificate=False)

Return `True` if the lattice is meet-semidistributive, and `False` otherwise.

A lattice is meet-semidistributive if for all elements `e, x, y` in the lattice we have

\[ e \land x = e \land y \implies e \land x = e \land (x \lor y) \]

**INPUT:**

- `certificate` – (default: `False`) whether to return a certificate

**OUTPUT:**

- If `certificate=True` return either `(True, None)` or `(False, (e, x, y))` such that `e \land x = e \land y` but `e \land x \neq e \land (x \lor y)`. If `certificate=False` return `True` or `False`.

EXAMPLES:

```python
def is_meet_semidistributive(L, certificate=False):
    # Implement the logic for checking meet-semidistributivity
    #...)
    return True
```

See also:

- Dual property: `is_join_semidistributive()`
- Weaker properties: `is_pseudocomplemented()`, `is_interval_dismantlable()`
- Stronger properties: `is_semidistributive()`, `is_join_distributive()`, `is_constructible_by_doublings()` (by upper pseudo-intervals)
**is_modular** \( (L=None, \text{certificate}=False) \)

Return True if the lattice is modular and False otherwise.

An element \( b \) of a lattice is modular if

\[
x \lor (a \land b) = (x \lor a) \land b
\]

for every element \( x \leq b \) and \( a \). A lattice is modular if every element is modular. There are other equivalent definitions, see Wikipedia article Modular_lattice.

With the parameter \( L \) this can be used to check that some subset of elements are all modular.

**INPUT:**

- \( L \) – (default: \( \text{None} \)) a list of elements to check being modular, if \( L \) is \( \text{None} \), then this checks the entire lattice
- \( \text{certificate} \) – (default: \( \text{False} \)) whether to return a certificate

**OUTPUT:**

- If \( \text{certificate}=\text{True} \) return either \((\text{True}, \text{None})\) or \((\text{False}, (x, a, b))\), where \( a, b \) and \( x \) are elements of the lattice such that \( x < b \) but \( x \lor (a \land b) \neq (x \lor a) \land b \). If also \( L \) is given then \( b \) in the certificate will be an element of \( L \). If \( \text{certificate}=\text{False} \) return True or False.

**EXAMPLES:**

```python
sage: L = posets.DiamondPoset(5)
sage: L.is_modular()
True
sage: L = posets.PentagonPoset()
sage: L.is_modular()
False
sage: L = LatticePoset({1:[2,3],2:[4,5],3:[5,6],4:[7],5:[7],6:[7]})
sage: L.is_modular(certificate=True)
(False, (2, 6, 4))
sage: [L.is_modular([x]) for x in L]
[True, True, False, True, True, False, True]
```

See also:

- Weaker properties: \( \text{is_upper_semimodular()} \), \( \text{is_lower_semimodular()} \), \( \text{is_supersolvable()} \)
- Stronger properties: \( \text{is_distributive()} \)
- Other: \( \text{is_modular_element()} \)

**is_modular_element** \( (x) \)

Return True if \( x \) is a modular element and False otherwise.

**INPUT:**

- \( x \) – an element of the lattice

An element \( x \) in a lattice \( L \) is modular if \( x \leq b \) implies

\[
x \lor (a \land b) = (x \lor a) \land b
\]

for every \( a, b \in L \).

**EXAMPLES:**
sage: L = LatticePoset({1:[2,3],2:[4,5],3:[5,6],4:[7],5:[7],6:[7]})
sage: L.is_modular()
False
sage: [L.is_modular_element(x) for x in L]
[True, True, False, True, True, False, True]

See also:

- Weaker properties: `is_left_modular_element()`
- Other: `is_modular()` to check modularity for the full lattice or some set of elements

**is_orthocomplemented**(unique=False)

Return `True` if the lattice admits an orthocomplementation, and `False` otherwise.

An orthocomplementation of a lattice is a function defined for every element \( e \) and marked as \( e \perp \) such that
1) they are complements, i.e. \( e \lor e \perp \) is the top element and \( e \land e \perp \) is the bottom element,
2) it is involution, i.e. \( (e \perp) \perp = e \), and
3) it is order-reversing, i.e. if \( a < b \) then \( b \perp < a \perp \).

**INPUT:**

- `unique`, a Boolean – If `True`, return `True` only if the lattice has exactly one orthocomplementation.
  If `False` (the default), return `True` when the lattice has at least one orthocomplementation.

**EXAMPLES:**

```
sage: D5 = posets.DiamondPoset(5)
sage: D5.is_orthocomplemented()
False
sage: D6 = posets.DiamondPoset(6)
sage: D6.is_orthocomplemented()
True
sage: D6.is_orthocomplemented(unique=True)
False
sage: hexagon = LatticePoset({0:[1, 2], 1:[3], 2:[4], 3:[5], 4:[5]})
sage: hexagon.is_orthocomplemented(unique=True)
True
```

See also:

- Weaker properties: `is_complemented()`, `is_self_dual()`

**is_planar()**

Return `True` if the lattice is *upward* planar, and `False` otherwise.

A lattice is upward planar if its Hasse diagram has a planar drawing in the \( \mathbb{R}^2 \) plane, in such a way that \( x \) is strictly below \( y \) (on the vertical axis) whenever \( x < y \) in the lattice.

Note that the scientific litterature on posets often omits “upward” and shortens it to “planar lattice” (e.g. [GW2014]), which can cause confusion with the notion of graph planarity in graph theory.

**Note:** Not all lattices which are planar – in the sense of graph planarity – admit such a planar drawing (see example below).

**ALGORITHM:**
Using the result from [Platt1976], this method returns its result by testing that the Hasse diagram of the lattice is planar (in the sense of graph theory) when an edge is added between the top and bottom elements.

EXAMPLES:
The Boolean lattice of $2^3$ elements is not upward planar, even if its covering relations graph is planar:

```sage
sage: B3 = posets.BooleanLattice(3)
sage: B3.is_planar()
False
sage: G = B3.cover_relations_graph()
sage: G.is_planar()
True
```

Ordinal product of planar lattices is obviously planar. Same does not apply to Cartesian products:

```sage
sage: P = posets.PentagonPoset()
sage: Pc = P.product(P)
sage: Po = P.ordinal_product(P)
sage: Pc.is_planar()
False
sage: Po.is_planar()
True
```

See also:

- Weaker properties: `is_dismantlable()`

### is_pseudocomplemented(certificate=False)

Return `True` if the lattice is pseudocomplemented, and `False` otherwise.

A lattice is (meet-)pseudocomplemented if every element $e$ has a pseudocomplement $e^*$, i.e. the greatest element such that the meet of $e$ and $e^*$ is the bottom element.

**INPUT:**

- `certificate` – (default: `False`) whether to return a certificate

**OUTPUT:**

- If `certificate=True` return either `(True, None)` or `(False, e)`, where $e$ is an element without a pseudocomplement. If `certificate=False` return `True` or `False`.

**EXAMPLES:**

```sage
sage: L = LatticePoset({1: [2, 5], 2: [3, 6], 3: [4], 4: [7],
....: 5: [6], 6: [7]})
sage: L.is_pseudocomplemented()
True
sage: L = LatticePoset({1: [2, 3], 2: [4, 5, 6], 3: [6], 4: [7],
....: 5: [7], 6: [7]})
sage: L.is_pseudocomplemented()
False
sage: L.is_pseudocomplemented(certificate=True)
(False, 3)
```

See also:
- Dual property: `is_join_pseudocomplemented()`
- Stronger properties: `is_meet_semidistributive()`
- Other: `pseudocomplement()`.

**ALGORITHM:**

According to [Cha92] a lattice is pseudocomplemented if and only if every atom has a pseudocomplement. So we only check those.

`is_regular` *(certificate=False)*

Return True if the lattice is regular and False otherwise.

A congruence of a lattice is regular if it is generated by any of its parts. A lattice is regular if it has only regular congruences.

**INPUT:**

- `certificate` – (default: False) whether to return a certificate if the lattice is not regular

**OUTPUT:**

- If `certificate=True` return either `(True, None)` or `(False, (C, p))`, where C is a non-regular congruence as a `sage.combinat.set_partition.SetPartition` and p is a congruence class of C such that the congruence generated by p is not C. If `certificate=False` return True or False.

**EXAMPLES:**

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [8, 7], 4: [6, 7], 5: [8],
  6: [9], 7: [9], 8: [9]})
sage: L.is_regular()
True
sage: N5 = posets.PentagonPoset()
sage: N5.is_regular()
False
sage: N5.is_regular(certificate=True)
(False, ({{0}, {1}, {2, 3}, {4}}, [0]))
```

See also:

- Stronger properties: `is_uniform()`, `is_sectionally_complemented()`, `is_cosectionally_complemented()`
- Mutually exclusive properties: `is_vertically_decomposable()`
- Other: `congruence()`

`is_relatively_complemented` *(certificate=False)*

Return True if the lattice is relatively complemented, and False otherwise.

A lattice is relatively complemented if every interval of it is a complemented lattice.

**INPUT:**

- `certificate` – (default: False) Whether to return a certificate if the lattice is not relatively complemented.

**OUTPUT:**
• If certificate=True return either \((True, None)\) or \((False, (a, b, c))\), where \(b\) is the only element that covers \(a\) and is covered by \(c\). If certificate=False return True or False.

**EXAMPLES:**

```
sage: L = LatticePoset({1: [2, 3, 4, 8], 2: [5, 6], 3: [5, 7],
                        ....: 4: [6, 7, 5: [9], 6: [9], 7: [9], 8: [9])})
sage: L.is_relatively_complemented()
True
sage: L = posets.PentagonPoset()
sage: L.is_relatively_complemented()
False
```

Relatively complemented lattice must be both atomic and coatomic. Implication to other direction does not hold:

```
sage: L = LatticePoset({0: [1, 2, 3, 4, 5], 1: [6, 7], 2: [6, 8],
                        ....: 3: [7, 8, 9], 4: [9, 11], 5: [9, 10],
                        ....: 6: [10, 11], 7: [12], 8: [12], 9: [12],
                        ....: 10: [12], 11: [12])}
sage: L.is_atomic() and L.is_coatomic()
True
sage: L.is_relatively_complemented()
False
```

We can also get a non-complemented 3-element interval:

```
sage: L.is_relatively_complemented(certificate=True)
(False, (1, 6, 11))
```

**See also:**

• Weaker properties: `is_sectionally_complemented()`, `is_cosectionally_complemented()`, `is_isoform()`

• Stronger properties: `is_geometric()`

**is_sectionally_complemented**(certificate=False)

Return True if the lattice is sectionally complemented, and False otherwise.

A lattice is sectionally complemented if all intervals from the bottom element interpreted as sublattices are complemented lattices.

**INPUT:**

• certificate – (default: False) Whether to return a certificate if the lattice is not sectionally complemented.

**OUTPUT:**

• If certificate=False return True or False. If certificate=True return either \((True, None)\) or \((False, (t, e))\), where \(t\) is an element so that in the sublattice from the bottom element to \(t\) has no complement for element \(e\).

**EXAMPLES:**

Smallest examples of a complemented but not sectionally complemented lattice and a sectionally complemented but not relatively complemented lattice:
sage: L = posets.PentagonPoset()
sage: L.is_complemented()
True
sage: L.is_sectionally_complemented()
False

sage: L = LatticePoset({0: [1, 2, 3], 1: [4], 2: [4], 3: [5], 4: [5]})
sage: L.is_sectionally_complemented()
True
sage: L.is_relatively_complemented()
False

Getting a certificate:

sage: L = LatticePoset(DiGraph('HYgCwC@?C?G@??'))
sage: L.is_sectionally_complemented(certificate=True)
(False, (6, 1))

See also:

• Dual property: is_cosectionally_complemented()
• Weaker properties: is_complemented(), is_atomic(), is_regular()
• Stronger properties: is_relatively_complemented()

is_semdistributive()
Return True if the lattice is both join- and meet-semidistributive, and False otherwise.

EXAMPLES:

Tamari lattices are typical examples of semidistributive but not distributive (and hence not modular) lattices:

sage: T4 = posets.TamariLattice(4)
sage: T4.is_semdistributive(), T4.is_distributive()
(True, False)

Smallest non-selfdual example:

sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [5], 4: [6], 5: [7], 6: [7]})
sage: L.is_semdistributive()
True

The diamond is not semidistributive:

sage: L = posets.DiamondPoset(5)
sage: L.is_semdistributive()
False

See also:

• Weaker properties: is_join_semdistributive(), is_meet_semdistributive()
• Stronger properties: is_distributive()

is_simple(certificate=False)
Return True if the lattice is simple and False otherwise.
A lattice is *simple* if it has no nontrivial congruences; in other words, for every two distinct elements \( a \) and \( b \) the principal congruence generated by \((a, b)\) has only one component, i.e. the whole lattice.

**INPUT:**

- `certificate` – (default: `False`) whether to return a certificate if the lattice is not simple

**OUTPUT:**

- If `certificate=True` return either `(True, None)` or `(False, c)`, where `c` is a nontrivial congruence as a `sage.combinat.set_partition.SetPartition`. If `certificate=False` return `True` or `False`.

**EXAMPLES:**

```python
sage: posets.DiamondPoset(5).is_simple()  # Smallest nontrivial example
True
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [6], 4: [6], 5: [6]})
sage: L.is_simple()
False
sage: L.is_simple(certificate=True)
(False, {{1, 3}, {2, 4, 5, 6}})
```

Two more examples. First is a non-simple lattice without any 2-element congruences:

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3: [5], 4: [6, 7],
          ....: 5: [8], 6: [8], 7: [8]})
sage: L.is_simple()
False
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [6, 7], 4: [8],
           ....: 5: [8], 6: [8], 7: [8]})
sage: L.is_simple()
True
```

**See also:**

- Weaker properties: `is_isoform()`
- Mutually exclusive properties: `is_constructible_by_doublings()` (by any set)
- Other: `congruence()`

**is_stone**  
`certificate=False`  
Return `True` if the lattice is a Stone lattice, and `False` otherwise.

The lattice is expected to be distributive (and hence pseudocomplemented).

A pseudocomplemented lattice is a Stone lattice if

\[ e^* \lor e^{**} = \top \]

for every element \( e \) of the lattice, where \( ^* \) is the pseudocomplement and \( \top \) is the top element of the lattice.

**INPUT:**

- `certificate` – (default: `False`) whether to return a certificate

**OUTPUT:**

- If `certificate=True` return either `(True, None)` or `(False, e)` such that \( e^* \lor e^{**} \neq \top \). If `certificate=False` return `True` or `False`. 
EXAMPLES:

Divisor lattices are canonical example:

```python
sage: D72 = posets.DivisorLattice(72)
sage: D72.is_stone()
True
```

A non-example:

```python
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [4], 4: [5]})
sage: L.is_stone()
False
```

See also:

- Weaker properties: `is_distributive()`

**is_subdirectly_reducible**(certificate=False)

Return `True` if the lattice is subdirectly reducible.

A lattice $M$ is a *subdirect product* of $K$ and $L$ if it is a sublattice of $K \times L$. Lattice $M$ is *subdirectly reducible* if there exists such lattices $K$ and $L$ so that $M$ is not a sublattice of either.

**INPUT:**

- certificate – (default: False) whether to return a certificate

**OUTPUT:**

- if certificate=False, return only `True` or `False`
- if certificate=True, return either:
  - `(True, (K, L))` such that the lattice is isomorphic to a sublattice of $K \times L$.
  - `(False, (a, b))`, where $a$ and $b$ are elements that are in the same congruence class for every nontrivial congruence of the lattice. Special case: If the lattice has zero or one element, return `(False, None)`.

**EXAMPLES:**

```python
sage: N5 = posets.PentagonPoset()
sage: N5.is_subdirectly_reducible()
False
sage: hex = LatticePoset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
sage: hex.is_subdirectly_reducible()
True
sage: hex.is_subdirectly_reducible(certificate=True)
(True, (Finite lattice containing 5 elements, Finite lattice containing 5 elements))
```

```python
sage: N5.is_subdirectly_reducible(certificate=True)
(False, (2, 3))
sage: res, cert = hex.is_subdirectly_reducible(certificate=True)
sage: cert[0].is_isomorphic(N5)
True
```

See also:
• Stronger properties: \( \texttt{is\_distributive()} \), \( \texttt{is\_vertically\_decomposable()} \)
• Other: \( \texttt{subdirect\_decomposition()} \)

**is\_sublattice\( (\text{other}) \)**

Return True if the lattice is a sublattice of other, and False otherwise.

Lattice \( K \) is a sublattice of \( L \) if \( K \) is an (induced) subposet of \( L \) and closed under meet and join of \( L \).

**Note:** This method does not check whether the lattice is a isomorphic (i.e., up to relabeling) sublattice of \( \text{other} \), but only if \( \text{other} \) directly contains the lattice as an sublattice.

**EXAMPLES:**

A pentagon sublattice in a non-modular lattice:

```python
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [5, 6], 4: [7], 5: [7], 6: \[7]})
sage: N5 = LatticePoset({1: [2, 6], 2: [4], 4: [7], 6: [7]})
sage: N5.is_sublattice(L)
True
```

This pentagon is a subposet but not closed under join, hence not a sublattice:

```python
sage: N5_ = LatticePoset({1: [2, 3], 2: [4], 3: [7], 4: [7]})
sage: N5_.is_induced_subposet(L)
True
sage: N5_.is_sublattice(L)
False
```

**See also:**

\( \texttt{isomorphic\_sublattices\_iterator()} \)

**is\_sublattice\_dismantlable\()**

Return True if the lattice is sublattice dismantlable, and False otherwise.

A sublattice dismantling is a subdivision of a lattice into two non-empty sublattices. A lattice is sublattice dismantlable if it can be decomposed into 1-element lattices by consecutive sublattice dismantlings.

**EXAMPLES:**

The smallest non-example is this (and the dual):

```python
sage: P = Poset({1: [11, 12, 13], 2: [11, 14, 15], 3: [11, 14, 16], 4: [13, 15, 16]})
sage: L = LatticePoset(P.with_bounds())
sage: L.is_sublattice_dismantlable()
False
```

Here we adjoin a (double-irreducible-)dismantlable lattice as a part to an interval-dismantlable lattice:

```python
sage: B3 = posets.BooleanLattice(3)
sage: N5 = posets.PentagonPoset()
sage: L = B3.adjunct(N5, 1, 7)
sage: L.is_dismantlable(), L.is_interval_dismantlable()
(False, False)
sage: L.is_sublattice_dismantlable()
True
```
See also:

- Stronger properties: `is_dismantlable(), is_interval_dismantlable()`

Todo: Add a certificate-option.

**is_supersolvable**(certificate=False)

Return True if the lattice is supersolvable, and False otherwise.

A lattice $L$ is *supersolvable* if there exists a maximal chain $C$ such that every $x \in C$ is a modular element in $L$. Equivalent definition is that the sublattice generated by $C$ and any other chain is distributive.

**INPUT:**

- certificate – (default: False) whether to return a certificate

**OUTPUT:**

- If certificate=True return either (False, None) or (True, C), where C is a maximal chain of modular elements. If certificate=False return True or False.

**EXAMPLES:**

```
sage: L = posets.DiamondPoset(5)
sage: L.is_supersolvable()
True

sage: L = posets.PentagonPoset()
sage: L.is_supersolvable()
False

sage: L = LatticePoset({1:[2,3],2:[4,5],3:[5,6],4:[7],5:[7],6:[7]})
sage: L.is_supersolvable()
True

sage: L.is_supersolvable(certificate=True)
(True, [1, 2, 5, 7])
sage: L.is_modular()
False

sage: L = LatticePoset({0: [1, 2, 3, 4], 1: [5, 6, 7],
   ....: 2: [5, 8, 9], 3: [6, 8, 10], 4: [7, 9, 10],
   ....: 5: [11], 6: [11], 7: [11], 8: [11],
   ....: 9: [11], 10: [11]})
sage: L.is_supersolvable()
False
```

See also:

- Weaker properties: `is_graded()`
- Stronger properties: `is_modular()`

**is_trim**(certificate=False)

Return whether a lattice is trim.

A lattice is trim if it is extremal and left modular.

This notion is defined in [Thom2006].
INPUT:

- certificate – boolean (default False) whether to return instead a maximum chain of left modular elements

EXAMPLES:

```python
sage: P = posets.PentagonPoset()
sage: P.is_trim()
True

sage: Q = LatticePoset(posets.SymmetricGroupWeakOrderPoset(3))
sage: Q.is_trim()
False
```

See also:

- Weaker properties: `is_extremal()`
- Stronger properties: `is_distributive()`

REFERENCES:

`is_uniform(certificate=False)`
Return `True` if the lattice is uniform and `False` otherwise.

A congruence is uniform if all blocks have equal number of elements. A lattice is uniform if it has only uniform congruences.

INPUT:

- certificate – (default: False) whether to return a certificate if the lattice is not uniform

OUTPUT:

- If certificate=True return either (True, None) or (False, C), where C is a non-uniform congruence as a `sage.combinat.set_partition.SetPartition`. If certificate=False return True or False.

EXAMPLES:

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [6, 7], 3: [5], 4: [5], 5: [9, 8], ...
                          6: [9], 7: [10], 8: [10], 9: [10]})
sage: L.is_uniform()
True
```

Every uniform lattice is regular, but the converse is not true:

```python
sage: N6 = LatticePoset({1: [2, 3, 5], 2: [4], 3: [4], 5: [6], 4: [6]})
sage: N6.is_uniform(), N6.is_regular()
(False, True)

sage: N6.is_uniform(certificate=True)
(False, {(1, 2, 3, 4), (5, 6)})
```

See also:

- Weaker properties: `is_regular()`
- Stronger properties: `is_skewform()`
- Other: `congruence()`
**is_upper_semimodular** *(certificate=False)*

Return `True` if the lattice is upper semimodular and `False` otherwise.

A lattice is upper semimodular if any pair of elements with a common lower cover have also a common upper cover.

**INPUT:**
- `certificate` – (default: `False`) Whether to return a certificate if the lattice is not upper semimodular.

**OUTPUT:**
- If `certificate=False` return `True` or `False`. If `certificate=True` return either `(True, None)` or `(False, (a, b))`, where `a` and `b` covers their meet but are not covered by their join.

See Wikipedia article Semimodular_lattice

**EXAMPLES:**

```python
sage: L = posets.DiamondPoset(5)
sage: L.is_upper_semimodular()
True

sage: L = posets.PentagonPoset()
sage: L.is_upper_semimodular()
False

sage: L = LatticePoset(posets.IntegerPartitions(4))
sage: L.is_upper_semimodular()
True

sage: L = LatticePoset({1:[2, 3, 4], 2: [5], 3:[5, 6], 4:[6], 5:[7], 6:[7]})
sage: L.is_upper_semimodular(certificate=True)
(False, (4, 2))
```

See also:
- Dual property: `is_lower_semimodular()`
- Weaker properties: `is_graded()`
- Stronger properties: `is_modular()`, `is_join_distributive()`, `is_geometric()`

**is_vertically_decomposable** *(certificate=False)*

Return `True` if the lattice is vertically decomposable, and `False` otherwise.

A lattice is vertically decomposable if it has an element that is comparable to all elements and is neither the bottom nor the top element.

Informally said, a lattice is vertically decomposable if it can be seen as two lattices “glued” by unifying the top element of first lattice to the bottom element of second one.

**INPUT:**
- `certificate` – (default: `False`) whether to return a certificate

**OUTPUT:**
- If `certificate=True` return either `(False, None)` or `(True, e)`, where `e` is an element that is comparable to all other elements and is neither the bottom nor the top element. If `certificate=False` return `True` or `False`. 

---

5.1. Comprehensive Module list 1797
EXAMPLES:

```python
sage: posets.TamariLattice(4).is_vertically_decomposable()
False
sage: L = LatticePoset(( [1, 2, 3, 6, 12, 18, 36],
                      attrcall("divides") ))
sage: L.is_vertically_decomposable()
True
sage: L.is_vertically_decomposable(certificate=True)
(True, 6)
```

See also:

- Weaker properties: `is_subdirectly_reducible()`
- Mutually exclusive properties: `is_atomic()`, `is_coatomic()`, `is_regular()`
- Other: `vertical_decomposition()`

`isomorphism_sublattices_iterator` *(other)*

Return an iterator over the sublattices of the lattice isomorphic to *other*.

INPUT:

- other – a finite lattice

EXAMPLES:

A non-modular lattice contains a pentagon sublattice:

```python
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [5, 6], 4: [7], 5: [7], 6: [7]})
sage: L.is_modular()
False
sage: N5 = posets.PentagonPoset()
sage: N5_in_L = next(L.isomorphic_sublattices_iterator(N5)); N5_in_L
Finite lattice containing 5 elements
```

A divisor lattice is modular, hence does not contain the pentagon as sublattice, even if it has the pentagon subposet:

```python
sage: D12 = posets.DivisorLattice(12)
sage: D12.has_isomorphic_subposet(N5)
True
sage: list(D12.isomorphic_sublattices_iterator(N5))
[]
```

See also:

`sage.combinat.posets.posets.FinitePoset.isomorphic_subposets_iterator()`

**Warning:** This function will return same sublattice as many times as there are automorphism on it. This is due to `subgraph_search_iterator()` returning labelled subgraphs.

`join_primes()`

Return the join-prime elements of the lattice.
An element \( x \) of a lattice \( L \) is **join-prime** if \( x \leq a \lor b \) implies \( x \leq a \) or \( x \leq b \) for every \( a, b \in L \).

These are also called **coprime** in some books. Every join-prime is join-irreducible; converse holds if and only if the lattice is distributive.

**EXAMPLES:**

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [5],
                       ....: 4: [6], 5: [7], 6: [7]})
```
```python
sage: L.join_primes()
[3, 4]
```
```python
sage: D12 = posets.DivisorLattice(12)  # Distributive lattice
sage: D12.join_irreducibles() == D12.join_primes()
True
```

See also:

- Dual function: `meet_primes()`
- Other: `join_irreducibles()`

### maximal_sublattices()

Return maximal (proper) sublattices of the lattice.

**EXAMPLES:**

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [5],
                       ....: 4: [6], 5: [7], 6: [7]})
```
```python
sage: L.meet_primes()
[6, 5]
```
```python
sage: len(maxs) 7
```
```python
sage: sorted(maxs[0].list())
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 14, 16, 18, 19, 22, 33]
```

```python
sage: D12 = posets.DivisorLattice(12)
```
```python
sage: sorted(D12.meet_primes())
[3, 4, 6]
```

### meet_primes()

Return the meet-prime elements of the lattice.

An element \( x \) of a lattice \( L \) is **meet-prime** if \( x \geq a \land b \) implies \( x \geq a \) or \( x \geq b \) for every \( a, b \in L \).

These are also called just **prime** in some books. Every meet-prime is meet-irreducible; converse holds if and only if the lattice is distributive.

**EXAMPLES:**

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [5],
                       ....: 4: [6], 5: [7], 6: [7]})
```
```python
sage: L.meet_primes()
[6, 5]
```
```python
sage: D12 = posets.DivisorLattice(12)
```
```python
sage: sorted(D12.meet_primes())
[3, 4, 6]
```

See also:
• Dual function: `join_primes()`
• Other: `meet_irreducibles()`

`moebius_algebra(R)`
Return the Möbius algebra of `self` over `R`.

OUTPUT:

EXAMPLES:
```
sage: L = posets.BooleanLattice(4)
sage: L.moebius_algebra(QQ)
Moebius algebra of Finite lattice containing 16 elements over Rational Field
```

`neutral_elements()`
Return the list of neutral elements of the lattice.

An element `e` of the lattice `L` is neutral if the sublattice generated by `e`, `x` and `y` is distributive for all `x, y ∈ L`. It can also be characterized as an element of intersection of maximal distributive sublattices.

EXAMPLES:
```
sage: L = LatticePoset({1: [2, 3], 2: [6], 3: [4, 5, 6], 4: [8],
                    ....: 5: [7], 6: [7], 7: [8, 9], 8: [10], 9: [10]})
sage: L.neutral_elements()
[1, 3, 8, 10]
```

`quantum_moebius_algebra(q=None)`
Return the quantum Möbius algebra of `self` with parameter `q`.

INPUT:
• `q` – (optional) the deformation parameter `q`

OUTPUT:
An instance of `sage.combinat.posets.moebius_algebra.QuantumMoebiusAlgebra`.

EXAMPLES:
```
sage: L = posets.BooleanLattice(4)
sage: L.quantum_moebius_algebra()
Quantum Moebius algebra of Finite lattice containing 16 elements with q=q over Univariate Laurent Polynomial Ring in q over Integer Ring
```

`quotient(congruence, labels='tuple')`
Return the quotient lattice by congruence.

Let `L` be a lattice and `Θ` be a congruence of `L` with congruence classes `Θ_1, Θ_2,...`. The quotient lattice `L/Θ` is the lattice with elements `{Θ_1, Θ_2,...}` and meet and join given by the original lattice. Explicitly, if `e_1 ∈ Θ_1` and `e_2 ∈ Θ_2`, such that `e_1 ∨ e_2 ∈ Θ_3` then `Θ_1 ∨ Θ_2 = Θ_3` in `L/Θ` and similarly for meets.

INPUT:
• `congruence` – list of lists; a congruence
• `labels` – string; the elements of the resulting lattice and can be one of the following:
  - 'tuple' - elements are tuples of elements of the original lattice
  - 'lattice' - elements are sublattices of the original lattice
- 'integer' - elements are labeled by integers

Warning: congruence is expected to be a valid congruence of the lattice. This is not checked.

EXAMPLES:

```python
sage: L = posets.PentagonPoset()
sage: c = L.congruence([[0, 1]])
sage: I = L.quotient(c); I
Finite lattice containing 2 elements
sage: I.top()
(2, 3, 4)
sage: I = L.quotient(c, labels='lattice')
sage: I.top()
Finite lattice containing 3 elements
sage: B3 = posets.BooleanLattice(3)
sage: c = B3.congruence([[0,1]])
sage: B2 = B3.quotient(c, labels='integer')
sage: B2.is_isomorphic(posets.BooleanLattice(2))
True
```

See also:

congruence()

skeleton()

Return the skeleton of the lattice.

The lattice is expected to be pseudocomplemented.

The skeleton of a pseudocomplemented lattice $L$, where $^*$ is the pseudocomplementation operation, is the subposet induced by $\{e^* \mid e \in L\}$. Actually this poset is a Boolean lattice.

EXAMPLES:

```python
sage: D12 = posets.DivisorLattice(12)
sage: S = D12.skeleton(); S
Finite lattice containing 4 elements
sage: S.cover_relations()
[[1, 3], [1, 4], [3, 12], [4, 12]]
sage: T4 = posets.TamariLattice(4)
sage: T4.skeleton().is_isomorphic(posets.BooleanLattice(3))
True
```

See also:

sage.combinat.posets.lattices.FiniteMeetSemilattice.pseudocomplement().

subdirect_decomposition()

Return the subdirect decomposition of the lattice.

The subdirect decomposition of a lattice $L$ is the list of smaller lattices $L_1, \ldots, L_n$ such that $L$ is a sublattice of $L_1 \times \ldots \times L_n$, none of $L_i$ can be decomposed further and $L$ is not a sublattice of any $L_i$. (Except when the list has only one element, i.e. when the lattice is subdirectly irreducible.)

EXAMPLES:
sage: posets.ChainPoset(3).subdirect_decomposition()
[Finite lattice containing 2 elements, Finite lattice containing 2 elements]

sage: L = LatticePoset({1: [2, 4], 2: [3], 3: [6, 7], 4: [5, 7],
....: 5: [9, 8], 6: [9], 7: [9], 8: [10], 9: [10]})

sage: Ldecomp = L.subdirect_decomposition()
sage: [fac.cardinality() for fac in Ldecomp]
[2, 5, 7]
sage: Ldecomp[1].is_isomorphic(posets.PentagonPoset())
True

sublattice (elms)
Return the smallest sublattice containing elements on the given list.

INPUT:

• elms – a list of elements of the lattice.

EXAMPLES:

sage: L=LatticePoset(([ [], [[1,2],[1,17],[1,8],[2,3],[2,22],[2,5],[2,7],[17,
-->22],[17,13],[8,7],[8,13],[3,16],[3,9],[22,16],[22,18],[22,10],[5,18],[5,14],
-->[7,9],[7,14],[7,10],[13,10],[16,6],[16,19],[9,19],[18,6],[18,33],[14,33],
-->[10,19],[10,33],[6,4],[19,4],[33,4]) ))

sage: L.sublattice([14, 13, 22]).list()
[1, 2, 8, 7, 14, 17, 13, 22, 10, 33]

sage: L = posets.BooleanLattice(3)

sage: L.sublattice([3,5,6,7])
Finite lattice containing 8 elements

sublattices ()
Return all sublattices of the lattice.

EXAMPLES:

sage: L = LatticePoset({1: [2, 3, 4], 2:[5], 3:[5, 6], 4:[6],
....: 5:[7], 6:[7]})

sage: sublats = L.sublattices(); len(sublats)
54

sage: sublats[3]
Finite lattice containing 4 elements

sage: sublats[3].list()
[1, 2, 3, 5]

sublattices_lattice (labels='lattice')
Return the lattice of sublattices.

Every element of the returned lattice is a sublattice and they are ordered by containment; that is, atoms are one-element lattices, coatoms are maximal sublattices of the original lattice and so on.

INPUT:

• labels – string: can be one of the following:
  – 'lattice' (default) elements of the lattice will be lattices that correspond to sublattices of the original lattice
  – 'tuple' - elements are tuples of elements of the sublattices of the original lattice
  – 'integer' - elements are plain integers
EXAMPLES:

```
sage: D4 = posets.DiamondPoset(4)
sage: sll = D4.sublattices_lattice(labels='tuple')
sage: sll.coatoms()  # = maximal sublattices of the original lattice
[(0, 1, 3), (0, 2, 3)]
```

```
sage: L = posets.DivisorLattice(12)
sage: sll = L.sublattices_lattice()
sage: L.is_dismantlable() == (len(sll.atoms()) == sll.rank())
True
```

vertical_composition(other, labels='pairs')

Return the vertical composition of the lattice with other.

Let $L$ and $K$ be lattices and $b_K$ the bottom element of $K$. The vertical composition of $L$ and $K$ is the ordinal sum of $L$ and $K \setminus \{b_K\}$. Informally said this is lattices “glued” together with a common element.

Mathematically, it is only defined when $L$ and $K$ have no common element; here we force that by giving them different names in the resulting poset.

INPUT:

- `other` – a lattice
- `labels` – a string (default `'pairs'`); can be one of the following:
  - `'pairs'` - each element $v$ in this poset will be named $(0, v)$ and each element $u$ in other will be named $(1, u)$ in the result
  - `'integers'` - the elements of the result will be relabeled with consecutive integers

EXAMPLES:

```
sage: L = LatticePoset({'a': ['b', 'c'], 'b': ['d'], 'c': ['d']})
sage: K = LatticePoset({'e': ['f', 'g'], 'f': ['h'], 'g': ['h']})
sage: M = L.vertical_composition(K)
sage: M.list()
[(0, 'a'), (0, 'b'), (0, 'c'), (0, 'd'), (1, 'f'), (1, 'g'), (1, 'h')]
sage: M.upper_covers((0, 'd'))
[(1, 'f'), (1, 'g')]
```

See also:
vertical_decomposition(), sage.combinat.posets.posets.FinitePoset.ordinal_sum()

vertical_decomposition(elements_only=False)

Return sublattices from the vertical decomposition of the lattice.

Let $d_1, \ldots, d_n$ be elements (excluding the top and bottom elements) comparable to every element of the lattice. Let $b$ be the bottom element and $t$ be the top element. This function returns either a list $d_1, \ldots, d_n$, or the list of intervals $[b, d_1], [d_1, d_2], \ldots, [d_{n-1}, d_n], [d_n, t]$ as lattices.

Informally said, this returns the lattice split into parts at every single-element “cutting point”.

INPUT:
• elements_only - if True, return the list of decomposing elements as defined above; if False (the default), return the list of sublattices so that the lattice is a vertical composition of them.

EXAMPLES:
Number 6 is divided by 1, 2, and 3, and it divides 12, 18 and 36:

```
sage: L = LatticePoset( ([1, 2, 3, 6, 12, 18, 36],
....: attrcall("divides")) )
sage: parts = L.vertical_decomposition()
sage: [lat.list() for lat in parts]
[[1, 2, 3, 6], [6, 12, 18, 36]]
sage: L.vertical_decomposition(elements_only=True)
[6]
```

See also:
vertical_composition(), is_vertically_decomposable()

```
class sage.combinat.posets.lattices.FiniteMeetSemilattice

Bases: sage.combinat.posets.posets.FinitePoset

Note: We assume that the argument passed to MeetSemilattice is the poset of a meet-semilattice (i.e. a poset with greatest lower bound for each pair of elements).

Element
alias of sage.combinat.posets.elements.MeetSemilatticeElement

atoms()
Return the list atoms of this (semi)lattice.

An atom of a lattice is an element covering the bottom element.

EXAMPLES:

```
sage: L = posets.DivisorLattice(60)
sage: sorted(L.atoms())
[2, 3, 5]
```

See also:
• Dual function: coatoms()

```
meet (x, y=None)
Return the meet of given elements in the lattice.

INPUT:
• x, y - two elements of the (semi)lattice OR
• x - a list or tuple of elements

EXAMPLES:

```
sage: D = posets.DiamondPoset(5)
sage: D.meet(1, 2)
0
sage: D.meet(1, 1)
1
```
(continues on next page)
Using list of elements as an argument. Meet of empty list is the bottom element:

```
sage: B4=posets.BooleanLattice(4)
sage: B4.meet([3,5,6])
0
sage: B4.meet([])
15
```

For non-facade lattices operator * works for meet:

```
sage: L = posets.PentagonPoset(facade=False)
sage: L(1)*L(2)
0
```

See also:

- Dual function: \texttt{join()}

\texttt{meet\_matrix()}

Return a matrix whose \((i,j)\) entry is \(k\), where \texttt{self.linear_extension()[k]} is the meet (greatest lower bound) of \texttt{self.linear_extension()[i]} and \texttt{self.linear_extension()[j]}.

\textbf{EXAMPLES:}

```
sage: P = LatticePoset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]], facade = False)
sage: M = P.meet_matrix(); M
[0 0 0 0 0 0 0 0]
[0 1 0 1 0 0 0 1]
[0 0 2 2 0 2 2]
[0 1 2 3 2 0 2 3]
[0 0 2 2 4 0 2 4]
[0 0 0 0 0 5 5 5]
[0 0 2 2 5 6 6]
[0 1 2 3 4 5 6 7]
True
True
False
```

\texttt{pseudocomplement(element)}

Return the pseudocomplement of \texttt{element}, if it exists.

The (meet-)pseudocomplement is the greatest element whose meet with given element is the bottom element. i.e. in a meet-semilattice with bottom element \(\hat{0}\) the pseudocomplement of an element \(e\) is the element \(e^*\) such that \(e \wedge e^* = \hat{0}\) and \(e' \leq e^*\) if \(e \wedge e' = \hat{0}\).

See Wikipedia article Pseudocomplement.

\textbf{INPUT:}
• element – an element of the lattice.

OUTPUT:
An element of the lattice or None if the pseudocomplement does not exist.

EXAMPLES:
The pseudocomplement’s pseudocomplement is not always the original element:

```python
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
sage: L.pseudocomplement(2)
5
sage: L.pseudocomplement(5)
4
```

An element can have complements but no pseudocomplement, or vice versa:

```python
sage: L = LatticePoset({0: [1, 2], 1: [3, 4, 5], 2: [5], 3: [6], ....:
4: [6], 5: [6]})
sage: L.complements(1), L.pseudocomplement(1)
([], 2)
sage: L.complements(2), L.pseudocomplement(2)
([3, 4], None)
```

See also:

`is_pseudocomplemented()`

`subjoinsemilattice(elms)`

Return the smallest join-subsemilattice containing elements on the given list.

INPUT:

• elms – a list of elements of the lattice.

EXAMPLES:

```python
sage: L = posets.DivisorLattice(1000)
sage: L_ = L.subjoinsemilattice([2, 25, 125]); L_
Finite join-semilattice containing 5 elements
sage: sorted(L_.list())
[2, 25, 50, 125, 250]
```

See also:

• Dual function: `submeetsemilattice()`

`submeetsemilattice(elms)`

Return the smallest meet-subsemilattice containing elements on the given list.

INPUT:

• elms – a list of elements of the lattice.

EXAMPLES:

```python
sage: L = posets.DivisorLattice(1000)
sage: L_ = L.submeetsemilattice([200, 250, 125]); L_
Finite meet-semilattice containing 5 elements
sage: L_.list()
[25, 50, 125, 250]
```
See also:

- Dual function: `subjoinsemilattice()`

`sage.combinat.posets.lattices.JoinSemilattice`(data=None, *args, **options)

Construct a join semi-lattice from various forms of input data.

INPUT:

- data, *args, **options – data and options that will be passed down to `Poset()` to construct a poset that is also a join semilattice

See also:

`Poset()`, `MeetSemilattice()`, `LatticePoset()`

EXAMPLES:

Using data that defines a poset:

```
sage: JoinSemilattice([[1,2],[3],[3]])
Finite join-semilattice containing 3 elements
```

```
sage: JoinSemilattice([[1,2],[3],[3]], cover_relations = True)
Finite join-semilattice containing 3 elements
```

Using a previously constructed poset:

```
sage: P = Poset([[1,2],[3],[3]])
sage: J = JoinSemilattice(P); J
Finite join-semilattice containing 3 elements
sage: type(J)
<class 'sage.combinat.posets.lattices.FiniteJoinSemilattice_with_category'>
```

If the data is not a lattice, then an error is raised:

```
sage: JoinSemilattice({'a': ['b', 'c'], 'b': ['d', 'e'],
....:   'c': ['d', 'e'], 'd': ['f'], 'e': ['f']})
Traceback (most recent call last):
  ...: LatticeError: no join for b and c
```

`sage.combinat.posets.lattices.LatticePoset`(data=None, *args, **options)

Construct a lattice from various forms of input data.

INPUT:

- data, *args, **options – data and options that will be passed down to `Poset()` to construct a poset that is also a lattice.

OUTPUT:

An instance of `FiniteLatticePoset`.

See also:

`Posets`, `FiniteLatticePosets`, `JoinSemilattice()`, `MeetSemilattice()`

EXAMPLES:

Using data that defines a poset:
Using a previously constructed poset:

```python
sage: P = Poset([[1,2],[3],[3]])
sage: L = LatticePoset(P); L
Finite lattice containing 3 elements
sage: type(L)
<class 'sage.combinat.posets.lattices.FiniteLatticePoset_with_category'>
```

If the data is not a lattice, then an error is raised:

```python
sage: elms = [1,2,3,4,5,6,7]
sage: rels = [[1,2],[3,4],[4,5],[2,5]]
sage: LatticePoset((elms, rels))
Traceback (most recent call last):
...
ValueError: not a meet-semilattice: no bottom element
```

Creating a facade lattice:

```python
sage: L = LatticePoset([[1,2],[3],[3]], facade = True)
sage: L.category()
Category of facade finite enumerated lattice posets
sage: parent(L[0])
Integer Ring
sage: TestSuite(L).run(skip = ['_test_an_element']) # is_parent_of is not yet implemented
```

`sage.combinat.posets.lattices.MeetSemilattice(data=None, *args, **options)`

Construct a meet semi-lattice from various forms of input data.

**INPUT:**

- `data,*args,**options` – data and options that will be passed down to `Poset()` to construct a poset that is also a meet semilattice.

**See also:**

`Poset()`, `JoinSemilattice()`, `LatticePoset()`

**EXAMPLES:**

Using data that defines a poset:

```python
sage: MeetSemilattice([[1,2],[3],[3]])
Finite meet-semilattice containing 3 elements
sage: MeetSemilattice([[1,2],[3],[3]], cover_relations = True)
Finite meet-semilattice containing 3 elements
```

Using a previously constructed poset:

```python
sage: P = Poset([[1,2],[3],[3]])
sage: L = MeetSemilattice(P); L
```
Finite meet-semilattice containing 3 elements

```
sage: type(L)
<class 'sage.combinat.posets.lattices.FiniteMeetSemilattice_with_category'>
```

If the data is not a lattice, then an error is raised:

```
sage: MeetSemilattice({'a': ['b', 'c'], 'b': ['d', 'e'], 'c': ['d', 'e'], 'd': ['f'], 'e': ['f']})
Traceback (most recent call last):
...  
LatticeError: no meet for e and d
```

### 5.1.184 Linear Extensions of Posets

This module defines two classes:

- `LinearExtensionOfPoset`
- `LinearExtensionsOfPoset`
- `LinearExtensionsOfPosetWithHooks`
- `LinearExtensionsOfForest`

#### Classes and methods

```python
class sage.combinat.posets.linear_extensions.LinearExtensionOfPoset
    Bases: sage.structure.list_clone.ClonableArray

A linear extension of a finite poset \( P \) of size \( n \) is a total ordering \( \pi := \pi_0 \pi_1 \ldots \pi_{n-1} \) of its elements such that \( i < j \) whenever \( \pi_i < \pi_j \) in the poset \( P \).

When the elements of \( P \) are indexed by \( \{1, 2, \ldots, n\} \), \( \pi \) denotes a permutation of the elements of \( P \) in one-line notation.

**INPUT:**

- `linear_extension` — a list of the elements of \( P \)
- `poset` — the underlying poset \( P \)

**See also:**
- `Poset`, `LinearExtensionsOfPoset`

**EXAMPLES:**

```
sage: P = Poset(((1,2,3,4), [(1,3),(1,4),(2,3)]), linear_extension=True, \n            facade=False)
sage: p = P.linear_extension([1,4,2,3]); p
[1, 4, 2, 3]
sage: p.parent()
The set of all linear extensions of Finite poset containing 4 elements with \n  distinguished linear extension
sage: p[0], p[1], p[2], p[3]
(1, 4, 2, 3)
```

Following Schützenberger and later Haiman and Malvenuto-Reutenauer, Stanley [Stan2009] defined a promotion and evacuation operator on any finite poset \( P \) using operators \( \tau_i \) on the linear extensions of \( P \):
**check()**
Checks whether *self* is indeed a linear extension of the underlying poset.

**evacuation()**
Compute evacuation on the linear extension of a poset.

Evacuation on a linear extension $\pi$ of length $n$ is defined as $\pi(\tau_1 \cdots \tau_{n-1})(\tau_1 \cdots \tau_{n-2}) \cdots (\tau_1)$. For more details see [Stan2009].

See also:
*tau*, *promotion*

**EXAMPLES:**

```
sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5, ˓→6]]))
sage: p = P.linear_extension([1,2,3,4,5,6,7])
sage: p.evacuation()
[1, 4, 2, 3, 7, 5, 6]
sage: p.evacuation().evacuation() == p
True
```

**is_greedy()**
Return True if the linear extension is greedy.

A linear extension $[e_1, e_2, \ldots, e_n]$ is greedy if for every $i$ either $e_{i+1}$ covers $e_i$ or all upper covers of $e_i$ have at least one lower cover that is not in $[e_1, e_2, \ldots, e_i]$.

Informally said a linear extension is greedy if it “always goes up when possible” and so has no unnecessary jumps.

**EXAMPLES:**

```
sage: P = posets.PentagonPoset()
sage: for l in P.linear_extensions():
    ....:     if not l.is_greedy():
        ....:         print(l)
[0, 2, 1, 3, 4]
```

**jump_count()**
Return the number of jumps in the linear extension.

A jump in a linear extension $[e_1, e_2, \ldots, e_n]$ is a pair $(e_i, e_{i+1})$ such that $e_{i+1}$ does not cover $e_i$.
See also:

- `sage.combinat.posets.posets.FinitePoset.jump_number()`

**Examples:****

```python
sage: B3 = posets.BooleanLattice(3)
sage: l1 = B3.linear_extension((0, 1, 2, 3, 4, 5, 6, 7))
sage: l1.jump_count()
3
sage: l2 = B3.linear_extension((0, 1, 2, 4, 3, 5, 6, 7))
sage: l2.jump_count()
5
```

**poset()**

Returns the underlying original poset.

**Examples:****

```python
sage: P = Poset(([1,2,3,4], [[1,2],[2,3],[1,4]]))
sage: p = P.linear_extension([1,2,4,3])
sage: p.poset()
Finite poset containing 4 elements
```

**promotion(i=1)**

Compute the (generalized) promotion on the linear extension of a poset.

**Input:**

- `i` – (default: 1) an integer between 1 and `n` − 1, where `n` is the cardinality of the poset

The `i`-th generalized promotion operator \( \partial_i \) on a linear extension \( \pi \) of a poset \( P \) is defined as \( \pi \tau_i \tau_{i+1} \cdots \tau_{n-1} \), where `n` is the size of the linear extension (or size of the underlying poset).

For more details see [Stan2009].

**See also:**

`tau()`, `evacuation()`

**Examples:****

```python
sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,6]]))
sage: p = P.linear_extension([1,2,3,4,5,6,7])
sage: q = p.promotion(4)
sage: q
[1, 2, 3, 5, 6, 4, 7]
sage: p.to_poset() == q.to_poset()
False
sage: p.to_poset().is_isomorphic(q.to_poset())
True
```

**tau(i)**

Returns the operator \( \tau_i \) on linear extensions `self` of a poset.

**Input:**

- `i` – an integer between 1 and `n` − 1, where `n` is the cardinality of the poset.

The operator \( \tau_i \) on a linear extension \( \pi \) of a poset \( P \) interchanges positions `i` and `i + 1` if the result is again a linear extension of \( P \), and otherwise acts trivially. For more details, see [Stan2009].
EXAMPLES:

```python
sage: P = Poset(([1,2,3,4], [[1,3],[1,4],[2,3]]), linear_extension=True)
sage: L = P.linear_extensions()
sage: l = L.an_element(); l
[1, 2, 3, 4]
sage: l.tau(1)
[2, 1, 3, 4]
sage: for p in L:
    ....:     for i in range(1,4):
    ....:         print("{} {} {}").format(i, p, p.tau(i))
1 [1, 2, 3, 4] [2, 1, 3, 4]
2 [1, 2, 3, 4] [1, 2, 3, 4]
3 [1, 2, 3, 4] [1, 2, 4, 3]
1 [2, 1, 3, 4] [1, 2, 3, 4]
3 [2, 1, 3, 4] [2, 1, 4, 3]
1 [2, 1, 4, 3] [1, 2, 4, 3]
2 [2, 1, 4, 3] [2, 1, 4, 3]
3 [2, 1, 4, 3] [2, 1, 3, 4]
1 [1, 2, 4, 3] [1, 2, 4, 3]
2 [1, 2, 4, 3] [1, 2, 4, 3]
3 [1, 2, 4, 3] [1, 4, 2, 3]
1 [1, 4, 2, 3] [1, 4, 2, 3]
2 [1, 4, 2, 3] [1, 2, 4, 3]
3 [1, 4, 2, 3] [1, 4, 2, 3]
1 [1, 4, 2, 3] [1, 2, 4, 3]
3 [1, 4, 2, 3] [1, 4, 2, 3]
```

to_poset()

Return the poset associated to the linear extension self.

This method returns the poset obtained from the original poset $P$ by relabelling the $i$-th element of self to the $i$-th element of the original poset, while keeping the linear extension of the original poset.

For a poset with default linear extension $1,\ldots,n$, self can be interpreted as a permutation, and the relabelling is done according to the inverse of this permutation.

EXAMPLES:

```python
to_poset = False)
sage: Q = p.to_poset(); Q
Finite poset containing 4 elements with distinguished linear extension
sage: P == Q
False
```

The default linear extension remains the same:

```python
sage: list(P)
[1, 2, 3, 4]
sage: list(Q)
[1, 2, 3, 4]
```

But the relabelling can be seen on cover relations:

```python
sage: P.cover_relations()
[[1, 2], [1, 3], [3, 4]]
sage: Q.cover_relations()
[[1, 2], [1, 4], [2, 3]]
```
class sage.combinat.posets.linear_extensions.LinearExtensionsOfForest(poset, facade)

Bases: sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset

Linear extensions such that the poset is a forest.

cardinality()

Use Atkinson’s algorithm to compute the number of linear extensions.

EXAMPLES:

```python
sage: from sage.combinat.posets.forest import ForestPoset
sage: P = Poset({0: [2], 1: [2], 2: [3, 4], 3: [], 4: []})
sage: P.linear_extensions().cardinality()
4

sage: Q = Poset({0: [1], 1: [2, 3], 2: [], 3: [], 4: [5, 6], 5: [], 6: []})
sage: Q.linear_extensions().cardinality()
140
```

class sage.combinat.posets.linear_extensions.LinearExtensionsOfMobile(poset, facade)

Bases: sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset

Linear extensions for a mobile poset.

cardinality()

Return the number of linear extensions by using the determinant formula for counting linear extensions of mobiles.

EXAMPLES:

```python
sage: from sage.combinat.posets.mobile import MobilePoset
sage: M = MobilePoset(DiGraph([([0,1,2,3,4,5,6,7,8], [(1,0),(3,0),(2,1),(2,3),
            (4,....: 3), (5,4),(5,6),(7,4),(7,8)])])

sage: M.linear_extensions().cardinality()
1098

sage: M1 = posets.RibbonPoset(6, [1,3])
sage: M1.linear_extensions().cardinality()
61

sage: P = posets.MobilePoset(posets.RibbonPoset(7, [1,3]), {1:
            ....: posets.YoungDiagramPoset([3, 2], dual=True)}, 3:
            [posets.
            ....: DoubleTailedDiamond(6)]},
            ....: anchor=(4, 2, posets.ChainPoset(6)))

sage: P.linear_extensions().cardinality()
361628701868606400
```
class sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset(poset, facade)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The set of all linear extensions of a finite poset

INPUT:

- poset – a poset $P$ of size $n$
- facade – a boolean (default: False)

See also:

- sage.combinat.posets.posets.FinitePoset.linear_extensions()

EXAMPLES:

```python
sage: elms = [1,2,3,4]
sage: rels = [[1,3],[1,4],[2,3]]
sage: P = Poset((elms, rels), linear_extension=True)
sage: L = P.linear_extensions(); L
The set of all linear extensions of Finite poset containing 4 elements with distinguished linear extension
sage: L.cardinality()
5
sage: L.list()
[[1, 2, 3, 4], [2, 1, 3, 4], [2, 1, 4, 3], [1, 4, 2, 3], [1, 2, 4, 3]]
sage: L.an_element()
[1, 2, 3, 4]
sage: L.poset()
Finite poset containing 4 elements with distinguished linear extension
```

Element

alias of LinearExtensionOfPoset

cardinality()

Return the number of linear extensions.

EXAMPLES:

```python
sage: N = Poset({0: [2, 3], 1: [3]})
sage: N.linear_extensions().cardinality()
5
```

markov_chain_digraph(action='promotion', labeling='identity')

Returns the digraph of the action of generalized promotion or tau on self

INPUT:

- action – ‘promotion’ or ‘tau’ (default: ‘promotion’)
- labeling – ‘identity’ or ‘source’ (default: ‘identity’)

Todo:

- generalize this feature by accepting a family of operators as input
- move up in some appropriate category
This method creates a graph with vertices being the linear extensions of a given finite poset and an edge from $\pi$ to $\pi'$ if $\pi' = \pi \cdot i$ where $i$ is the promotion operator (see promotion()) if action is set to promotion and $\tau_i$ (see tau()) if action is set to tau. The label of the edge is $i$ (resp. $\pi_i$) if labeling is set to identity (resp. source).

EXAMPLES:

```python
sage: P = Poset(([1,2,3,4], [[1,3],[1,4],[2,3]]), linear_extension = True)
sage: L = P.linear_extensions()
sage: G = L.markov_chain_digraph(); G
Looped multi-digraph on 5 vertices
sage: sorted(G.vertices(), key = repr)
[[1, 2, 3, 4], [1, 2, 4, 3], [1, 4, 2, 3], [2, 1, 3, 4], [2, 1, 4, 3]]
sage: sorted(G.edges(), key = repr)
[([1, 2, 3, 4], [1, 2, 3, 4], 4), ([1, 2, 3, 4], [1, 2, 4, 3], 2), ([1, 2, 4, 3], [1, 2, 3, 4], 3),
 ([1, 2, 4, 3], [1, 2, 4, 3], 4), ([1, 4, 2, 3], [2, 1, 3, 4], 1), ([1, 4, 2, 3], [2, 1, 3, 4], 3),
 ([1, 4, 2, 3], [1, 4, 2, 3], 3), ([2, 1, 3, 4], [2, 1, 3, 4], 1), ([2, 1, 3, 4], [2, 1, 3, 4], 3),
 ([2, 1, 3, 4], [1, 4, 2, 3], 2), ([2, 1, 3, 4], [1, 4, 2, 3], 4), ([2, 1, 3, 4], [2, 1, 3, 4], 2),
 ([2, 1, 3, 4], [2, 1, 3, 4], 4)]
```

sage: G = L.markov_chain_digraph(labeling = 'source')
sage: sorted(G.vertices(), key = repr)
[[1, 2, 3, 4], [1, 2, 4, 3], [1, 4, 2, 3], [2, 1, 3, 4], [2, 1, 4, 3]]

The edges of the graph are by default colored using blue for edge 1, red for edge 2, green for edge 3, and yellow for edge 4:

```python
sage: view(G) # optional - dot2tex graphviz, not tested (opens external window)
```

Alternatively, one may get the graph of the action of the tau operator:

```python
sage: G = L.markov_chain_digraph(action='tau'); G
Looped multi-digraph on 5 vertices
```
sage: sorted(G.vertices(), key = repr)
[[1, 2, 3, 4], [1, 2, 4, 3], [2, 1, 3, 4], [2, 1, 4, 3]]
sage: sorted(G.edges(), key = repr)

[(
[1, 2, 3, 4],
[1, 2, 3, 4], 2),

See also:

markov_chain_transition_matrix(), promotion(), tau()

markov_chain_transition_matrix(\texttt{action}='promotion', \texttt{labeling}='identity')

Returns the transition matrix of the Markov chain for the action of generalized promotion or tau on self

INPUT:

- \texttt{action} = ‘promotion’ or ‘tau’ (default: ‘promotion’)
- \texttt{labeling} = ‘identity’ or ‘source’ (default: ‘identity’)

This method yields the transition matrix of the Markov chain defined by the action of the generalized promotion operator $\partial_i$ (resp. $\tau_i$) on the set of linear extensions of a finite poset. Here the transition from the linear extension $\pi$ to $\pi'$, where $\pi' = \pi\partial_i$ (resp. $\pi' = \pi\tau_i$) is counted with weight $x_i$ (resp. $x_{\pi_i}$ if labeling is set to source).

EXAMPLES:

sage: P = Poset(((1,2,3,4), [[1,3],[1,4],[2,3]]), linear_extension = True)
sage: L = P.linear_extensions()
sage: L.markov_chain_transition_matrix()
[-x0 - x1 - x2 x2 x0 + x1 0 0]
[ x1 + x2 -x0 - x1 - x2 0 x0 0]
[ 0 x1 -x0 - x1 0 0 x0]
[ 0 x0 0 -x0 - x1 - x2 x1 + x2]
[ x0 0 0 x1 + x2 -x0 - x1 - x2]
sage: L.markov_chain_transition_matrix(labeling = 'source')
[-x0 - x1 - x2 x3 x0 + x3 0 0]
[ x1 + x2 -x0 - x1 - x3 0 x1 0]
[ 0 x1 -x0 - x3 0 x1]
[ 0 x0 0 -x0 - x1 - x2 x0 + x3]
[ x0 0 0 x0 + x2 -x0 - x1 - x3]
sage: L.markov_chain_transition_matrix(action = 'tau')
[ -x0 - x2 x2 0 x0 0]
[ x2 -x0 - x1 - x2 x1 0 x0]
[ 0 x1 -x1 0 0]
[ x0 0 0 -x0 - x2 x2]
[ 0 x0 0 0 x2 -x0 - x2]
sage: L.markov_chain_transition_matrix(action = 'tau', labeling = 'source')
[ -x0 - x2 x3 0 x1 0]
[ x2 -x0 - x1 - x3 x3 0 x1]
[ 0 x1 -x3 0 0]
[ x0 0 0 -x1 - x2 x3]
[ 0 x0 0 x2 -x1 - x3]

See also:
markov_chain_digraph(), promotion(), tau()

poset()
Returns the underlying original poset.

EXAMPLES:
sage: P = Poset(([1,2,3,4], [(1,2), (2,3), (1,4)]))
sage: L = P.linear_extensions()
sage: L.poset()
Finite poset containing 4 elements

class sage.combinat.posets.linear_extensions.LinearExtensionsOfPosetWithHooks (poset, facade)

Bases: sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset

Linear extensions such that the poset has well-defined hook lengths (i.e., d-complete).
cardinality()
Count the number of linear extensions using a hook-length formula.

EXAMPLES:
sage: from sage.combinat.posets.poset_examples import Posets
sage: P = Posets.YoungDiagramPoset(Partition([3,2]), dual=True)
sage: P.linear_extensions().cardinality()
5

5.1.185 Möbius Algebras
class sage.combinat.posets.moebius_algebra.BasisAbstract (R, basis_keys=None, element_class=None, category=None, prefix=None, names=None, **kwds)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_classBindableClass

Abstract base class for a basis.
class sage.combinat.posets.moebius_algebra.MoebiusAlgebra (R, L)
Bases: sage.structure.parent.Parent, sage.structure.unique_representation.UniqueRepresentation

The Möbius algebra of a lattice.
Let L be a lattice. The Möbius algebra $M_L$ was originally constructed by Solomon [Solomon67] and has a natural basis \( \{ E_x | x \in L \} \) with multiplication given by $E_x \cdot E_y = E_{x \vee y}$. Moreover this has a basis given by

5.1. Comprehensive Module list 1817
orthogonal idempotents \( \{ I_x \mid x \in L \} \) (so \( I_x I_y = \delta_{xy} I_x \) where \( \delta \) is the Kronecker delta) related to the natural basis by

\[
I_x = \sum_{x \leq y} \mu_L(x, y) E_y,
\]

where \( \mu_L \) is the Möbius function of \( L \).

**Note:** We use the join \( \vee \) for our multiplication, whereas [Greene73] and [Etienne98] define the Möbius algebra using the meet \( \wedge \). This is done for compatibility with QuantumMoebiusAlgebra.

**REFERENCES:**

```python
class E(M, prefix='E')
    Bases: sage.combinat.posets.moebius_algebra.BasisAbstract
    The natural basis of a Möbius algebra.
    Let \( E_x \) and \( E_y \) be basis elements of \( M_L \) for some lattice \( L \). Multiplication is given by \( E_x E_y = E_{x \vee y} \).
    one()
        Return the element 1 of self.
    EXAMPLES:
    sage: L = posets.BooleanLattice(4)
    sage: E = L.moebius_algebra(QQ).E()
    sage: E.one()

    product_on_basis(x, y)
        Return the product of basis elements indexed by \( x \) and \( y \).
    EXAMPLES:
    sage: L = posets.BooleanLattice(4)
    sage: E = L.moebius_algebra(QQ).E()
    sage: E.product_on_basis(5, 14)
    E[15]
    sage: E.product_on_basis(2, 8)
    E[10]
```

class I(M, prefix='I')
    Bases: sage.combinat.posets.moebius_algebra.BasisAbstract
    The (orthogonal) idempotent basis of a Möbius algebra.
    Let \( I_x \) and \( I_y \) be basis elements of \( M_L \) for some lattice \( L \). Multiplication is given by \( I_x I_y = \delta_{xy} I_x \) where \( \delta_{xy} \) is the Kronecker delta.
    one()
        Return the element 1 of self.
    EXAMPLES:
    sage: L = posets.BooleanLattice(4)
    sage: I = L.moebius_algebra(QQ).I()
    sage: I.one()
\texttt{product_on_basis}(x, y)

Return the product of basis elements indexed by \( x \) and \( y \).

EXAMPLES:

```python
sage: L = posets.BooleanLattice(4)
sage: I = L.moebius_algebra(QQ).I()
sage: I.product_on_basis(5, 14)
0
sage: I.product_on_basis(2, 2)
I[2]
```

\texttt{a_realization}()

Return a particular realization of \texttt{self} (the \( B \)-basis).

EXAMPLES:

```python
sage: L = posets.BooleanLattice(4)
sage: M = L.moebius_algebra(QQ)
sage: M.a_realization()
Moebius algebra of Finite lattice containing 16 elements over Rational Field in the natural basis
```

\texttt{idempotent}

alias of \texttt{MoebiusAlgebra.I}

\texttt{lattice}()

Return the defining lattice of \texttt{self}.

EXAMPLES:

```python
sage: L = posets.BooleanLattice(4)
sage: M = L.moebius_algebra(QQ)
sage: M.lattice()
Finite lattice containing 16 elements
sage: M.lattice() == L
True
```

\texttt{natural}

alias of \texttt{MoebiusAlgebra.E}

\texttt{class} sage.combinat.posets.moebius_algebra.MoebiusAlgebraBases\texttt{(parent_with_realization)}

Bases: sage.categories.realizations.Category_realization_of_parent

The category of bases of a Möbius algebra.

INPUT:

- base – a Möbius algebra

\texttt{class} ElementMethods

Bases: object

\texttt{class} ParentMethods

Bases: object

\texttt{one}()

Return the element 1 of \texttt{self}.

EXAMPLES:
sage: L = posets.BooleanLattice(4)
sage: C = L.quantum_moebius_algebra().C()
sage: all(C.one() * b == b for b in C.basis())
True

**product_on_basis**(x, y)

Return the product of basis elements indexed by x and y.

**EXAMPLES:**

```
sage: L = posets.BooleanLattice(4)
sage: C = L.quantum_moebius_algebra().C()
sage: C.product_on_basis(5, 14)
q^3*C[15]
sage: C.product_on_basis(2, 8)
q^4*C[10]
```

**super_categories**()

The super categories of self.

**EXAMPLES:**

```
sage: from sage.combinat.posets.moebius_algebra import MoebiusAlgebraBases
sage: M = posets.BooleanLattice(4).moebius_algebra(QQ)
sage: bases = MoebiusAlgebraBases(M)
sage: bases.super_categories()
[Category of finite dimensional commutative algebras with basis over Rational Field,
 Category of realizations of Moebius algebra of Finite lattice containing 16 elements over Rational Field]
```

**class** `sage.combinat.posets.moebius_algebra.QuantumMoebiusAlgebra**(L, q=None)**

**Bases:** `sage.structure.parent.Parent`, `sage.structure.unique_representation.UniqueRepresentation`

The quantum Möbius algebra of a lattice.

Let L be a lattice, and we define the *quantum Möbius algebra* $M_L(q)$ as the algebra with basis $\{E_x \mid x \in L\}$ with multiplication given by

$$E_x E_y = \sum_{z \geq a \geq x \vee y} \mu_L(a, z) q^{crk a} E_z,$$

where $\mu_L$ is the Möbius function of L and $crk a$ is the corank function (i.e., $crk a = \text{rank } L - \text{rank } a$). At $q = 1$, this reduces to the multiplication formula originally given by Solomon.

**class** `C(M, prefix='C')`

**Bases:** `sage.combinat.posets.moebius_algebra.BasisAbstract`

The characteristic basis of a quantum Möbius algebra.

The characteristic basis $\{C_x \mid x \in L\}$ of $M_L$ for some lattice L is defined by

$$C_x = \sum_{a \geq x} P(F^x; q) E_a,$$

where $F^x = \{y \in L \mid y \geq x\}$ is the principal order filter of x and $P(F^x; q)$ is the characteristic polynomial of the (sub)poset $F^x$. 
class E(M, prefix='E')

Bases: sage.combinat.posets.moebius_algebra.BasisAbstract

The natural basis of a quantum Möbius algebra.

Let \( E_x \) and \( E_y \) be basis elements of \( M_L \) for some lattice \( L \). Multiplication is given by

\[
E_x E_y = \sum_{z \geq a \geq x \lor y} \mu_L(a, z) q^{crk a} E_z,
\]

where \( \mu_L \) is the Möbius function of \( L \) and \( crk \) is the corank function (i.e., \( crk a = \text{rank} L - \text{rank} a \)).

one()

Return the element 1 of self.

EXAMPLES:

```python
sage: L = posets.BooleanLattice(4)
sage: E = L.quantum_moebius_algebra().E()
sage: all(E.one() * b == b for b in E.basis())
True
```

product_on_basis(x, y)

Return the product of basis elements indexed by \( x \) and \( y \).

EXAMPLES:

```python
sage: L = posets.BooleanLattice(4)
sage: E = L.quantum_moebius_algebra().E()
sage: E.product_on_basis(5, 14)
E[15]
sage: E.product_on_basis(2, 8)
```

class KL(M, prefix='KL')

Bases: sage.combinat.posets.moebius_algebra.BasisAbstract

The Kazhdan-Lusztig basis of a quantum Möbius algebra.

The Kazhdan-Lusztig basis \( \{ B_x \mid x \in L \} \) of \( M_L \) for some lattice \( L \) is defined by

\[
B_x = \sum_{y \geq x} P_{x,y}(q) E_a,
\]

where \( P_{x,y}(q) \) is the Kazhdan-Lusztig polynomial of \( L \), following the definition given in [EPW14].

EXAMPLES:

We construct some examples of Proposition 4.5 of [EPW14]:

```python
sage: M = posets.BooleanLattice(4).quantum_moebius_algebra()
sage: KL = M.KL()
(q^2+q^3)*KL[5] + (q+2*q^2+q^3)*KL[7] + (q+2*q^2+q^3)*KL[13] + (1+3*q+3*q^2+q^3)*KL[15]
(q+3*q^2+3*q^3+q^4)*KL[14] + (1+4*q+6*q^2+4*q^3+q^4)*KL[15]
(q+3*q^2+3*q^3+q^4)*KL[14] + (1+4*q+6*q^2+4*q^3+q^4)*KL[15]
```
a_realization()
Return a particular realization of self (the B-basis).

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: M = L.quantum_moebius_algebra()
sage: M.a_realization()
Quantum Moebius algebra of Finite lattice containing 16 elements
with q=q over Univariate Laurent Polynomial Ring in q
over Integer Ring in the natural basis
```

characteristic_basis
alias of QuantumMoebiusAlgebra.C

kazhdan_lusztig
alias of QuantumMoebiusAlgebra.KL

lattice()
Return the defining lattice of self.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: M = L.quantum_moebius_algebra()
sage: M.lattice()
Finite lattice containing 16 elements
sage: M.lattice() == L
True
```

natural
alias of QuantumMoebiusAlgebra.E

5.1.186 Catalog of posets and lattices

Some common posets can be accessed through the `posets.<tab>` object:

```
sage: posets.PentagonPoset()
Finite lattice containing 5 elements
```

Moreover, the set of all posets of order \( n \) is represented by `Posets(n)`:

```
sage: Posets(5)
Posets containing 5 elements
```

The infinite set of all posets can be used to find minimal examples:

```
sage: for P in Posets():
    ....:     if not P.is_series_parallel():
    ....:         break
sage: P
Finite poset containing 4 elements
```

Catalog of common posets:

| AntichainPoset() | Return an antichain on \( n \) elements. | continues on next page |
### Table 5 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>BooleanLattice()</code></td>
<td>Return the Boolean lattice on $2^n$ elements.</td>
</tr>
<tr>
<td><code>ChainPoset()</code></td>
<td>Return a chain on $n$ elements.</td>
</tr>
<tr>
<td><code>Crown()</code></td>
<td>Return the crown poset on $2n$ elements.</td>
</tr>
<tr>
<td><code>DexterSemilattice()</code></td>
<td>Return the Dexter semilattice.</td>

<td>Return the poset of integer partitions of $n$, ordered by restricted refinement.</td>
</tr>
<tr>
<td><code>SetPartitions()</code></td>
<td>Return the poset of set partitions of the set ${1, \ldots, n}$.</td>
</tr>
<tr>
<td><code>ShardPoset()</code></td>
<td>Return the shard intersection order.</td>
</tr>
<tr>
<td><code>SSTPoset()</code></td>
<td>Return the poset on semistandard tableaux of shape $s$ and largest entry $f$ that is ordered by componentwise comparison.</td>
</tr>
<tr>
<td><code>StandardExample()</code></td>
<td>Return the standard example of a poset with dimension $n$.</td>
</tr>
<tr>
<td><code>SymmetricGroupAbsoluteOrder()</code></td>
<td>The poset of permutations with respect to absolute order.</td>
</tr>
<tr>
<td><code>SymmetricGroupBruhatInterval()</code></td>
<td>The poset of permutations with respect to Bruhat order.</td>
</tr>
<tr>
<td><code>SymmetricGroupBruhatOrder()</code></td>
<td>The poset of permutations with respect to Bruhat order.</td>
</tr>
<tr>
<td><code>SymmetricGroupWeakOrder()</code></td>
<td>The poset of permutations of ${1, 2, \ldots, n}$ with respect to the weak order.</td>
</tr>
<tr>
<td><code>TamariLattice()</code></td>
<td>Return the Tamari lattice.</td>
</tr>
<tr>
<td><code>TetrahedralPoset()</code></td>
<td>Return the Tetrahedral poset with $n-1$ layers based on the input colors.</td>
</tr>
<tr>
<td><code>UpDownPoset()</code></td>
<td>Return the up-down poset on $n$ elements.</td>
</tr>
<tr>
<td><code>YoungDiagramPoset()</code></td>
<td>Return the poset of cells in the Young diagram of a partition.</td>
</tr>
<tr>
<td><code>YoungsLattice()</code></td>
<td>Return Young’s Lattice up to rank $n$.</td>
</tr>
<tr>
<td><code>YoungsLatticePrincipalOrderIdeal()</code></td>
<td>Return the principal order ideal of the partition $\lambda$ in Young’s Lattice.</td>
</tr>
<tr>
<td><code>YoungFibonacci()</code></td>
<td>Return the Young-Fibonacci lattice up to rank $n$.</td>
</tr>
</tbody>
</table>

### Constructions

```python
class sage.combinat.posets.poset_examples.Posets(Bases: object)
A collection of posets and lattices.

EXAMPLES:
```
The category of all posets:

```
sage: Posets()
Category of posets
```

The enumerated set of all posets on 3 elements, up to an isomorphism:

```
sage: Posets(3)
Posets containing 3 elements
```

See also:

`Posets, FinitePosets, Poset()`

**static AntichainPoset** \((n, \text{facade}=\text{None})\)

Return an antichain (a poset with no comparable elements) containing \(n\) elements.

**INPUT:**

- \(n\) (an integer) – number of elements
- \(\text{facade}\) (boolean) – whether to make the returned poset a facade poset (see `sage.categories.facade_sets`); the default behaviour is the same as the default behaviour of the `Poset()` constructor

**EXAMPLES:**

```
sage: A = posets.AntichainPoset(6); A
Finite poset containing 6 elements
```

**static BooleanLattice** \((n, \text{facade}=\text{None})\)

Return the Boolean lattice containing \(2^n\) elements.

**INPUT:**

- \(n\) (an integer) – number of elements will be \(2^n\)
- \(\text{facade}\) (boolean) – whether to make the returned poset a facade poset (see `sage.categories.facade_sets`); the default behaviour is the same as the default behaviour of the `Poset()` constructor

**EXAMPLES:**

```
sage: posets.BooleanLattice(5)
Finite lattice containing 32 elements
```

**static ChainPoset** \((n, \text{facade}=\text{None})\)

Return a chain (a totally ordered poset) containing \(n\) elements.

**INPUT:**

- \(n\) (an integer) – number of elements.
- \(\text{facade}\) (boolean) – whether to make the returned poset a facade poset (see `sage.categories.facade_sets`); the default behaviour is the same as the default behaviour of the `Poset()` constructor

**EXAMPLES:**

```
sage: posets.ChainPoset(3)
Finite lattice containing 3 elements
sage: posets.RandomPoset(17,.15)
Finite poset containing 17 elements
```

The category of all posets:
static CoxeterGroupAbsoluteOrderPoset \((W, \text{use\_reduced\_words=True})\)

Return the poset of elements of a Coxeter group with respect to absolute order.

INPUT:

- \(W\) – a Coxeter group
- \(\text{use\_reduced\_words}\) – boolean (default: True); if True, then the elements are labeled by their lexicographically minimal reduced word

EXAMPLES:

```python
sage: W = CoxeterGroup(['B', 3])
sage: posets.CoxeterGroupAbsoluteOrderPoset(W)
Finite poset containing 48 elements
sage: W = WeylGroup(['B', 2], prefix='s')
sage: posets.CoxeterGroupAbsoluteOrderPoset(W, False)
Finite poset containing 8 elements
```

static Crown \((n, \text{facade=None})\)

Return the crown poset of \(2n\) elements.

In this poset every element \(i\) for \(0 \leq i \leq n - 1\) is covered by elements \(i + n\) and \(i + n + 1\), except that \(n - 1\) is covered by \(n\) and \(n + 1\).

INPUT:

- \(n\) – number of elements, an integer at least 2
- \(\text{facade}\) (boolean) – whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the Poset() constructor

EXAMPLES:

```python
sage: posets.Crown(3)
Finite poset containing 6 elements
```

static DexterSemilattice \((n)\)

Return the \(n\)-th Dexter meet-semilattice.

INPUT:

- \(n\) – a nonnegative integer (the index)

OUTPUT:

a finite meet-semilattice

The elements of the semilattice are Dyck paths in the \((n + 1 \times n)\)-rectangle.

EXAMPLES:

```python
sage: posets.DexterSemilattice(3)
Finite meet-semilattice containing 5 elements
```
\begin{verbatim}
sage: P = posets.DexterSemilattice(4); P
Finite meet-semilattice containing 14 elements
sage: len(P.maximal_chains())
15
sage: len(P.maximal_elements())
4
sage: P.chain_polynomial()
q^5 + 19*q^4 + 47*q^3 + 42*q^2 + 14*q + 1
\end{verbatim}

REFERENCES:

• [Cha18]

\texttt{static DiamondPoset}(n, \texttt{facade=None})

Return the lattice of rank two containing \( n \) elements.

INPUT:

• \( n \) – number of elements, an integer at least 3
• \( \texttt{facade} \) (boolean) – whether to make the returned poset a facade poset (see \texttt{sage.categories.facade_sets}); the default behaviour is the same as the default behaviour of the \texttt{Poset()} constructor

EXAMPLES:

\begin{verbatim}
sage: posets.DiamondPoset(7)
Finite lattice containing 7 elements
\end{verbatim}

\texttt{static DivisorLattice}(n, \texttt{facade=None})

Return the divisor lattice of an integer.

Elements of the lattice are divisors of \( n \) and \( x < y \) in the lattice if \( x \) divides \( y \).

INPUT:

• \( n \) – an integer
• \( \texttt{facade} \) (boolean) – whether to make the returned poset a facade poset (see \texttt{sage.categories.facade_sets}); the default behaviour is the same as the default behaviour of the \texttt{Poset()} constructor

EXAMPLES:

\begin{verbatim}
sage: P = posets.DivisorLattice(12)
sage: sorted(P.cover_relations())
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: P = posets.DivisorLattice(10, facade=False)
sage: P(2) < P(5)
False
\end{verbatim}

\texttt{static DoubleTailedDiamond}(n)

Return a double-tailed diamond of \( 2n + 2 \) elements.

INPUT:

• \( n \) – a positive integer

EXAMPLES:
sage: P = posets.DoubleTailedDiamond(2); P
Finite d-complete poset containing 6 elements
sage: P.cover_relations()
[[1, 2], [2, 3], [2, 4], [3, 5], [4, 5], [5, 6]]

static IntegerCompositions(n)
Return the poset of integer compositions of the integer n.

A composition of a positive integer \(n\) is a list of positive integers that sum to \(n\). The order is reverse refinement: \([p_1, p_2, ..., p_l] < [q_1, q_2, ..., q_m]\) if \(q\) consists of an integer composition of \(p_1\), followed by an integer composition of \(p_2\), and so on.

EXAMPLES:

sage: P = posets.IntegerCompositions(7); P
Finite poset containing 64 elements
sage: len(P.cover_relations())
192

static IntegerPartitions(n)
Return the poset of integer partitions on the integer \(n\).

A partition of a positive integer \(n\) is a non-increasing list of positive integers that sum to \(n\). If \(p\) and \(q\) are integer partitions of \(n\), then \(p\) covers \(q\) if and only if \(q\) is obtained from \(p\) by joining two parts of \(p\) (and sorting, if necessary).

EXAMPLES:

sage: P = posets.IntegerPartitions(7); P
Finite poset containing 15 elements
sage: len(P.cover_relations())
28

static IntegerPartitionsDominanceOrder(n)
Return the lattice of integer partitions on the integer \(n\) ordered by dominance.

That is, if \(p = (p_1, \ldots, p_l)\) and \(q = (q_1, \ldots, q_j)\) are integer partitions of \(n\), then \(p\) is greater than \(q\) if and only if \(p_1 + \cdots + p_k > q_1 + \cdots + q_k\) for all \(k\).

INPUT:

• \(n\) – a positive integer

EXAMPLES:

sage: P = posets.IntegerPartitionsDominanceOrder(6); P
Finite lattice containing 11 elements
sage: P.cover_relations()
[[[1, 1, 1, 1, 1], [2, 1, 1, 1, 1]],
 [[2, 1, 1, 1, 1], [2, 2, 1, 1]],
 [[2, 2, 1, 1], [3, 1, 1, 1]],
 [[2, 2, 2], [3, 2, 1]],
 [[3, 1, 1, 1], [3, 2, 1]],
 [[3, 2, 1], [3, 3]],
 [[3, 2, 1], [4, 1, 1]],
 [[3, 3], [4, 2]],
 [[4, 1, 1], [4, 2]],
 [[4, 2], [5, 1]],
 [[5, 1], [6]]]
**static MobilePoset** *(ribbon, hangers, anchor=None)*

Return a mobile poset with the ribbon `ribbon` and with hanging d-complete posets specified in `hangers` and a d-complete poset attached above, specified in `anchor`.

**INPUT:**

- `ribbon` – a finite poset that is a ribbon
- `hangers` – a dictionary mapping an element on the ribbon to a list of d-complete posets that it covers
- `anchor` – (optional) a tuple `(ribbon_elmt, anchor_elmt, anchor_poset)`, where `anchor_elmt` covers `ribbon_elmt`, and `anchor_elmt` is an acyclic element of `anchor_poset`

**EXAMPLES:**

```sage
sage: R = Posets.RibbonPoset(5, [1,2])
sage: H = Poset(([5, 6, 7], [(5, 6), (6,7)]))
sage: M = Posets.MobilePoset(R, {3: [H]})
sage: len(M.cover_relations())
7
sage: P = posets.MobilePoset(posets.RibbonPoset(7, [1,3]),
....: {1: [posets.YoungDiagramPoset([3, 2], dual=True)],
....: 3: [posets.DoubleTailedDiamond(6)]},
....: anchor=(4, 2, posets.ChainPoset(6)))
sage: len(P.cover_relations())
33
```

**static NoncrossingPartitions** *(W)*

Return the lattice of noncrossing partitions.

**INPUT:**

- `W` – a finite Coxeter group or a Weyl group

**EXAMPLES:**

```sage
sage: W = CoxeterGroup(['A', 3])
sage: posets.NoncrossingPartitions(W)
Finite lattice containing 14 elements
sage: W = WeylGroup(['B', 2], prefix='s')
sage: posets.NoncrossingPartitions(W)
Finite lattice containing 6 elements
```

**static PentagonPoset** *(facade=None)*

Return the Pentagon poset.

**INPUT:**

- `facade` (boolean) – whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the `Poset()` constructor

**EXAMPLES:**

```sage
sage: P = posets.PentagonPoset(); P
Finite lattice containing 5 elements
sage: P.cover_relations()
[[0, 1], [0, 2], [1, 4], [2, 3], [3, 4]]
```
static PermutationPattern \((n)\)
Return the poset of permutations under pattern containment up to rank \(n\).

INPUT:

- \(n\) – a positive integer

A permutation \(u = u_1 \cdots u_n\) contains the pattern \(v = v_1 \cdots v_m\) if there is a (not necessarily consecutive) subsequence of \(u\) of length \(m\) whose entries have the same relative order as \(v\).

See Wikipedia article Permutation_pattern.

EXAMPLES:

```python
sage: P4 = posets.PermutationPattern(4); P4
Finite poset containing 33 elements
sage: sorted(P4.lower_covers(Permutation([2,4,1,3])))
[[1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2]]
```

See also:

has_pattern()

static PermutationPatternInterval \((bottom, top)\)
Return the poset consisting of an interval in the poset of permutations under pattern containment between \(bottom\) and \(top\).

INPUT:

- \(bottom, top\) – permutations where \(top\) contains \(bottom\) as a pattern

A permutation \(u = u_1 \cdots u_n\) contains the pattern \(v = v_1 \cdots v_m\) if there is a (not necessarily consecutive) subsequence of \(u\) of length \(m\) whose entries have the same relative order as \(v\).

See Wikipedia article Permutation_pattern.

EXAMPLES:

```python
sage: t = Permutation([2,3,1])
sage: b = Permutation([4,6,2,3,5,1])
sage: R = posets.PermutationPatternInterval(t, b); R
Finite poset containing 14 elements
sage: R.moebius_function(R.bottom(),R.top())
-4
```

See also:

has_pattern(), PermutationPattern()

static PermutationPatternOccurrenceInterval \((bottom, top, pos)\)
Return the poset consisting of an interval in the poset of permutations under pattern containment between \(bottom\) and \(top\), where a specified instance of \(bottom\) in \(top\) must be maintained.

INPUT:

- \(bottom, top\) – permutations where \(top\) contains \(bottom\) as a pattern
- \(pos\) – a list of indices indicating a distinguished copy of \(bottom\) inside \(top\) (indexed starting at 0)

For further information (and picture illustrating included example), see [ST2010].

See Wikipedia article Permutation_pattern.

EXAMPLES:
sage: t = Permutation([3,2,1])
sage: b = Permutation([6,3,4,5,2,1])
sage: A = posets.PermutationPatternOccurrenceInterval(t, b, (0,2,4)); A

Finite poset containing 8 elements

See also:

has_pattern(), PermutationPattern(), PermutationPatternInterval()

static PowerPoset(n)

Return the power poset on n element posets.

Elements of the power poset are all posets on the set \{0, 1, \ldots, n - 1\} ordered by extension. That is, the antichain of n elements is the bottom and \(P_a \leq P_b\) in the power poset if \(P_b\) is an extension of \(P_a\).

These were studied in [Bru1994].

EXAMPLES:

sage: P3 = posets.PowerPoset(3); P3
Finite meet-semilattice containing 19 elements
sage: all(P.is_chain() for P in P3.maximal_elements())
True

static ProductOfChains(chain_lengths, facade=None)

Return a product of chains.

- chain_lengths – A list of nonnegative integers; number of elements in each chain.
- facade – boolean; whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the Poset() constructor

EXAMPLES:

sage: P = posets.ProductOfChains([2, 2]); P
Finite lattice containing 4 elements
sage: P.linear_extension()
[(0, 0), (0, 1), (1, 0), (1, 1)]
sage: P.upper_covers((0,0))
[(0, 1), (1, 0)]
sage: P.lower_covers((1,1))
[(0, 1), (1, 0)]

static RandomLattice(n, p, properties=None)

Return a random lattice on n elements.

INPUT:

- n – number of elements, a non-negative integer
- p – a probability, a positive real number less than one
- properties – a list of properties for the lattice. Currently implemented:
  - None, no restrictions for lattices to create
  - 'planar', the lattice has an upward planar drawing
  - 'dismantlable' (implicated by 'planar')
  - 'distributive' (implicated by 'stone')
  - 'stone'
A lattice on \( n \) elements. When \texttt{properties} is \texttt{None}, the probability \( p \) roughly measures number of covering relations of the lattice. To create interesting examples, make the probability a little below one, for example 0.9.

Currently parameter \( p \) has no effect only when \texttt{properties} is not \texttt{None}.

\textbf{Note:} Results are reproducible in same Sage version only. Underlying algorithm may change in future versions.

\section*{Examples:}

\begin{verbatim}
sage: set_random_seed(0)  # Results are reproducible
sage: L = posets.RandomLattice(8, 0.995); L
Finite lattice containing 8 elements
sage: L.cover_relations()
[[7, 6], [7, 3], [7, 1], ..., [5, 4], [2, 4], [1, 4], [0, 4]]
sage: L = posets.RandomLattice(10, 0, properties=['dismantlable'])
sage: L.is_dismantlable()
True
\end{verbatim}

\textbf{See also:}

\texttt{RandomPoset()}

\texttt{static RandomPoset}(\( n, p \))

Generate a random poset on \( n \) elements according to a probability \( p \).

\textbf{Input:}

- \( n \) - number of elements, a non-negative integer
- \( p \) - a probability, a real number between 0 and 1 (inclusive)

\textbf{Output:}

A poset on \( n \) elements. The probability \( p \) roughly measures width/height of the output: \( p = 0 \) always generates an antichain, \( p = 1 \) will return a chain. To create interesting examples, keep the probability small, perhaps on the order of \( 1/n \).

\section*{Examples:}

\begin{verbatim}
sage: set_random_seed(0)  # Results are reproducible
sage: P = posets.RandomPoset(5, 0.3)
sage: P.cover_relations()
[[5, 4], [4, 2], [1, 2]]
\end{verbatim}

\textbf{See also:}

\texttt{RandomLattice()}

\texttt{static RestrictedIntegerPartitions}(\( n \))

Return the poset of integer partitions on the integer \( n \) ordered by restricted refinement.

That is, if \( p \) and \( q \) are integer partitions of \( n \), then \( p \) covers \( q \) if and only if \( q \) is obtained from \( p \) by joining two distinct parts of \( p \) (and sorting, if necessary).

\textbf{Examples:}
sage: P = posets.RestrictedIntegerPartitions(7); P
Finite poset containing 15 elements
sage: len(P.cover_relations())
17

static RibbonPoset \((n, \text{descents})\)
Return a ribbon poset on \(n\) vertices with descents at \(\text{descents}\).

INPUT:
- \(n\) – the number of vertices
- \(\text{descents}\) – an iterable; the indices on the ribbon where \(y > x\)

EXAMPLES:

sage: R = Posets.RibbonPoset(5, [1,2])
sage: sorted(R.cover_relations())
[[0, 1], [2, 1], [3, 2], [3, 4]]

static SSTPoset \((s, f=\text{None})\)
The lattice poset on semistandard tableaux of shape \(s\) and largest entry \(f\) that is ordered by componentwise comparison of the entries.

INPUT:
- \(s\) - shape of the tableaux
- \(f\) - maximum fill number. This is an optional argument. If no maximal number is given, it will use the number of cells in the shape.

Note: This is a basic implementation and most certainly not the most efficient.

EXAMPLES:

sage: posets.SSTPoset([2,1])
Finite lattice containing 8 elements
sage: posets.SSTPoset([2,1],4)
Finite lattice containing 20 elements
sage: posets.SSTPoset([2,1],2).cover_relations()
[[[1, 1], [2]], [[1, 2], [2]]]

sage: posets.SSTPoset([3,2]).bottom()  # long time (6s on sage.math, 2012)
[[1, 1, 1], [2, 2]]

sage: posets.SSTPoset([3,2],4).maximal_elements()
[[[3, 3, 4], [4, 4]]]

static SetPartitions \((n)\)
Return the lattice of set partitions of the set \(\{1, \ldots, n\}\) ordered by refinement.

INPUT:
- \(n\) – a positive integer

EXAMPLES:
static ShardPoset(n)

Return the shard intersection order on permutations of size n.

This is defined on the set of permutations. To every permutation, one can attach a pre-order, using the
descending runs and their relative positions.

The shard intersection order is given by the implication (or refinement) order on the set of pre-orders
defined from all permutations.

This can also be seen in a geometrical way. Every pre-order defines a cone in a vector space of dimension
n. The shard poset is given by the inclusion of these cones.

See also:

shard_preorder_graph()

EXAMPLES:

sage: P = posets.ShardPoset(4); P
Finite poset containing 24 elements
sage: P.chain_polynomial()
34*q^4 + 90*q^3 + 79*q^2 + 24*q + 1
sage: P.characteristic_polynomial()
q^3 - 11*q^2 + 23*q - 13
sage: P.zeta_polynomial()
17/3*q^3 - 6*q^2 + 4/3*q
sage: P.is_self_dual()
False

static StandardExample(n, facade=None)

Return the partially ordered set on 2n elements with dimension n.

Let P be the poset on \{0, 1, 2, \ldots, 2n - 1\} whose defining relations are that \(i < j\) for every \(0 \leq i < n \leq j < 2n\) except when \(i + n = j\). The poset P is the so-called standard example of a poset with dimension
n.

INPUT:

• n – an integer \(\geq 2\), dimension of the constructed poset
• facade (boolean) – whether to make the returned poset a facade poset (see sage.categories.
facade_sets); the default behaviour is the same as the default behaviour of the Poset() con-
structor

OUTPUT:

The standard example of a poset of dimension n.

EXAMPLES:

sage: A = posets.StandardExample(3); A
Finite poset containing 6 elements
sage: A.dimension()
3

REFERENCES:

• [Gar2015]
• [Ros1999]
**static SymmetricGroupAbsoluteOrderPoset** \((n, labels='permutations')\)

Return the poset of permutations with respect to absolute order.

**INPUT:**

- \(n\) – a positive integer
- \(label\) – (default: 'permutations') a label for the elements of the poset returned by the function; the options are
  - 'permutations' - labels the elements are given by their one-line notation
  - 'reduced_words' - labels the elements by the lexicographically minimal reduced word
  - 'cycles' - labels the elements by their expression as a product of cycles

**EXAMPLES:**

```python
sage: posets.SymmetricGroupAbsoluteOrderPoset(4)
Finite poset containing 24 elements
sage: posets.SymmetricGroupAbsoluteOrderPoset(3, labels="cycles")
Finite poset containing 6 elements
sage: posets.SymmetricGroupAbsoluteOrderPoset(3, labels="reduced_words")
Finite poset containing 6 elements
```

**static SymmetricGroupBruhatIntervalPoset** \((start, end)\)

The poset of permutations with respect to Bruhat order.

**INPUT:**

- \(start\) - list permutation
- \(end\) - list permutation (same \(n\), of course)

**Note:** Must have \(start \leq end\).

**EXAMPLES:**

Any interval is rank symmetric if and only if it avoids these permutations:

```python
sage: P1 = posets.SymmetricGroupBruhatIntervalPoset([1,2,3,4], [3,4,1,2])
sage: P2 = posets.SymmetricGroupBruhatIntervalPoset([1,2,3,4], [4,2,3,1])
sage: ranks1 = [P1.rank(v) for v in P1]
sage: ranks2 = [P2.rank(v) for v in P2]
sage: [ranks1.count(i) for i in sorted(set(ranks1))]
[1, 3, 5, 4, 1]
sage: [ranks2.count(i) for i in sorted(set(ranks2))]
[1, 3, 5, 6, 4, 1]
```

**static SymmetricGroupBruhatOrderPoset** \((n)\)

The poset of permutations with respect to Bruhat order.

**EXAMPLES:**

```python
sage: posets.SymmetricGroupBruhatOrderPoset(4)
Finite poset containing 24 elements
```

**static SymmetricGroupWeakOrderPoset** \((n, labels='permutations', side='right')\)

The poset of permutations of \(\{1,2,\ldots,n\}\) with respect to the weak order (also known as the permutohedron order, cf. permutohedron_lequal()).
The optional variable `labels` (default: "permutations") determines the labelling of the elements if \( n < 10 \). The optional variable `side` (default: "right") determines whether the right or the left permutohedron order is to be used.

**EXAMPLES:**

```python
sage: posets.SymmetricGroupWeakOrderPoset(4)
Finite poset containing 24 elements
```

**static TamariLattice** \((n, m=1)\)

Return the \(n\)-th Tamari lattice.

Using the slope parameter \(m\), one can also get the \(m\)-Tamari lattices.

**INPUT:**

- \(n\) – a nonnegative integer (the index)
- \(m\) – an optional nonnegative integer (the slope, default to 1)

**OUTPUT:**

a finite lattice

In the usual case, the elements of the lattice are **Dyck paths** in the \((n + 1 \times n)\)-rectangle. For a general slope \(m\), the elements are Dyck paths in the \((mn + 1 \times n)\)-rectangle.

See Tamari lattice for mathematical background.

**EXAMPLES:**

```python
sage: posets.TamariLattice(3)
Finite lattice containing 5 elements
sage: posets.TamariLattice(3, 2)
Finite lattice containing 12 elements
```

**REFERENCES:**

- [BMFPR]

**static TetrahedralPoset** \((n, \ast colors, \ast\ast labels)\)

Return the tetrahedral poset based on the input colors.

This method will return the tetrahedral poset with \(n\)-1 layers and covering relations based on the input colors of ‘green’, ‘red’, ‘orange’, ‘silver’, ‘yellow’ and ‘blue’ as defined in [Striker2011]. For particular color choices, the order ideals of the resulting tetrahedral poset will be isomorphic to known combinatorial objects.

For example, for the colors ‘blue’, ‘yellow’, ‘orange’, and ‘green’, the order ideals will be in bijection with alternating sign matrices. For the colors ‘yellow’, ‘orange’, and ‘green’, the order ideals will be in bijection with semistandard Young tableaux of staircase shape. For the colors ‘red’, ‘orange’, ‘green’, and optionally ‘yellow’, the order ideals will be in bijection with totally symmetric self-complementary plane partitions in a \(2n \times 2n \times 2n\) box.

**INPUT:**

- \(n\) - Defines the number (\(n\)-1) of layers in the poset.
- \(colors\) - The colors that define the covering relations of the poset. Colors used are ‘green’, ‘red’, ‘yellow’, ‘orange’, ‘silver’, and ‘blue’.
labels - Keyword variable used to determine whether the poset is labeled with integers or tuples. To label with integers, the method should be called with labels='integers'. Otherwise, the labeling will default to tuples.

EXAMPLES:

```python
sage: posets.TetrahedralPoset(4, 'green', 'red', 'yellow', 'silver', 'blue', 'orange')
Finite poset containing 10 elements
sage: posets.TetrahedralPoset(4, 'green', 'red', 'yellow', 'silver', 'blue', 'orange', labels='integers')
Finite poset containing 10 elements
sage: A = AlternatingSignMatrices(3)
sage: p = A.lattice()
sage: ji = p.join_irreducibles_poset()
sage: tet = posets.TetrahedralPoset(3, 'green', 'yellow', 'blue', 'orange')
sage: ji.is_isomorphic(tet)
True
```

static UpDownPoset(n, m=1)
Return the up-down poset on n elements where every \((m+1)\) step is down and the rest are up.

The case where \(m = 1\) is sometimes referred to as the zig-zag poset or the fence.

INPUT:
- \(n\) - nonnegative integer, number of elements in the poset
- \(m\) - nonnegative integer (default 1), how frequently down steps occur

OUTPUT:
The partially ordered set on \(\{0, 1, \ldots, n-1\}\) where \(i\) covers \(i+1\) if \(m\) divides \(i+1\), and \(i+1\) covers \(i\) otherwise.

EXAMPLES:

```python
sage: P = posets.UpDownPoset(7, 2); P
Finite poset containing 7 elements
sage: sorted(P.cover_relations())
[[0, 1], [1, 2], [3, 2], [3, 4], [4, 5], [6, 5]]
```

Fibonacci numbers as the number of antichains of a poset:

```python
sage: [len(posets.UpDownPoset(n).antichains().list()) for n in range(6)]
[1, 2, 3, 5, 8, 13]
```

static YoungDiagramPoset(lam, dual=False)
Return the poset of cells in the Young diagram of a partition.

INPUT:
- \(\lambda\) - a partition
- \(\text{dual} = \text{False}\) determines the orientation of the poset; if True, then it is a join semilattice, otherwise it is a meet semilattice

EXAMPLES:
```python
sage: P = posets.YoungDiagramPoset(Partition([2, 2])); P
Finite meet-semilattice containing 4 elements

sage: sorted(P.cover_relations())

[(0, 0), (0, 1), (0, 1), (1, 0), (1, 1), (1, 0), (1, 1)]

sage: posets.YoungDiagramPoset([3, 2], dual=True)
Finite join-semilattice containing 5 elements

static YoungFibonacci(n)
Return the Young-Fibonacci lattice up to rank \( n \).

Elements of the (infinite) lattice are words with letters ‘1’ and ‘2’. The covers of a word are the words with another ‘1’ added somewhere not after the first occurrence of an existing ‘1’ and, additionally, the words where the first ‘1’ is replaced by a ‘2’. The lattice is truncated to have rank \( n \).

See Wikipedia article Young-Fibonacci lattice.

EXAMPLES:

```python
sage: Y5 = posets.YoungFibonacci(5); Y5
Finite meet-semilattice containing 20 elements

sage: sorted(Y5.upper_covers(Word('211')))
[word: 1211, word: 2111, word: 221]
```

static YoungsLattice(n)
Return Young’s Lattice up to rank \( n \).

In other words, the poset of partitions of size less than or equal to \( n \) ordered by inclusion.

INPUT:

- \( n \) – a positive integer

EXAMPLES:

```python
sage: P = posets.YoungsLattice(3); P
Finite meet-semilattice containing 7 elements

sage: P.cover_relations()

[[[1], [1], [1]],
[[1], [1, 1]],
[[1], [2]],
[[1, 1], [1, 1, 1]],
[[1, 1], [2, 1]],
[[2], [2, 1]],
[[2], [3]]]
```

static YoungsLatticePrincipalOrderIdeal(lam)
Return the principal order ideal of the partition \( \lambda \) in Young’s Lattice.

INPUT:

- \( \lambda \) – a partition

EXAMPLES:

```python
sage: P = posets.YoungsLatticePrincipalOrderIdeal(Partition([2, 2]))
Finite lattice containing 6 elements

sage: P.cover_relations()
```
```
5.1.187 Finite posets

This module implements finite partially ordered sets. It defines:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>

</tbody>
</table>

### Properties of the poset
cardinality() | Return the number of elements in the poset.
height() | Return the number of elements in a longest chain of the poset.
width() | Return the number of elements in a longest antichain of the poset.
relations_number() | Return the number of relations in the poset.
dimension() | Return the dimension of the poset.
jump_number() | Return the jump number of the poset.
has_bottom() | Return True if the poset has a unique minimal element.
has_top() | Return True if the poset has a unique maximal element.
is_bounded() | Return True if the poset has both unique minimal and unique maximal element.
is_chain() | Return True if the poset is totally ordered.
is_connected() | Return True if the poset is connected.
is_graded() | Return True if all maximal chains of the poset has same length.
is_ranked() | Return True if the poset has a rank function.
is_rank_symmetric() | Return True if the poset is rank symmetric.
is_series_parallel() | Return True if the poset can be built by ordinal sums and disjoint unions.
is_greedy() | Return True if all greedy linear extensions have equal number of jumps.
is_jump_critical() | Return True if removal of any element reduces the jump number.
is_eulerian() | Return True if the poset is Eulerian.
is_incomparable_chain_free() | Return True if the poset is (m+n)-free.
is_slender() | Return True if the poset is slender.
is_sperner() | Return True if the poset is Sperner.
is_join_semilattice() | Return True if the poset has a join operation.
is_meet_semilattice() | Return True if the poset has a meet operation.

Minimal and maximal elements

bottom() | Return the bottom element of the poset, if it exists.
top() | Return the top element of the poset, if it exists.
maximal_elements() | Return the list of the maximal elements of the poset.
minimal_elements() | Return the list of the minimal elements of the poset.

New posets from old ones
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>disjoint_union()</td>
<td>Return the disjoint union of the poset with other poset.</td>
</tr>
<tr>
<td>ordinal_sum()</td>
<td>Return the ordinal sum of the poset with other poset.</td>
</tr>
<tr>
<td>product()</td>
<td>Return the Cartesian product of the poset with other poset.</td>
</tr>
<tr>
<td>ordinal_product()</td>
<td>Return the ordinal product of the poset with other poset.</td>
</tr>
<tr>
<td>rees_product()</td>
<td>Return the Rees product of the poset with other poset.</td>
</tr>
<tr>
<td>lexicographic_sum()</td>
<td>Return the lexicographic sum of posets.</td>
</tr>
<tr>
<td>star_product()</td>
<td>Return the star product of the poset with other poset.</td>
</tr>
<tr>
<td>with_bounds()</td>
<td>Return the poset with bottom and top element adjoined.</td>
</tr>
<tr>
<td>without_bounds()</td>
<td>Return the poset with bottom and top element removed.</td>
</tr>
<tr>
<td>dual()</td>
<td>Return the dual of the poset.</td>
</tr>
<tr>
<td>completion_by_cuts()</td>
<td>Return the Dedekind-MacNeille completion of the poset.</td>
</tr>
<tr>
<td>intervals_poset()</td>
<td>Return the poset of intervals of the poset.</td>
</tr>
<tr>
<td>connected_components()</td>
<td>Return the connected components of the poset as subposets.</td>
</tr>
<tr>
<td>factor()</td>
<td>Return the decomposition of the poset as a Cartesian product.</td>
</tr>
<tr>
<td>ordinal_summands()</td>
<td>Return the ordinal summands of the poset.</td>
</tr>
<tr>
<td>subposet()</td>
<td>Return the subposet containing elements with partial order induced by this poset.</td>
</tr>
<tr>
<td>random_subposet()</td>
<td>Return a random subposet that contains each element with given probability.</td>
</tr>
<tr>
<td>relabel()</td>
<td>Return a copy of this poset with its elements relabelled.</td>
</tr>
<tr>
<td>canonical_label()</td>
<td>Return copy of the poset canonically (re)labelled to integers.</td>
</tr>
<tr>
<td>slant_sum()</td>
<td>Return the slant sum poset of two posets.</td>
</tr>
</tbody>
</table>

**Chains & antichains**

<table>
<thead>

</tr>
<tr>
<td><code>moebius_function()</code></td>
<td>Return the value of Möbius function of given elements in the poset.</td>
</tr>
<tr>
<td><code>moebius_function_matrix()</code></td>
<td>Return a matrix whose $(i,j)$ entry is the value of the Möbius function evaluated at self.linear_extension()[$i$] and self.linear_extension()[$j$].</td>
</tr>
<tr>
<td><code>coxeter_transformation()</code></td>
<td>Return the matrix of the Auslander-Reiten translation acting on the Grothendieck group of the derived category of modules.</td>
</tr>
<tr>
<td><code>coxeter_smith_form()</code></td>
<td>Return the Smith form of the Coxeter transformation.</td>
</tr>
</tbody>
</table>

**Miscellaneous**

5.1. Comprehensive Module list
sorted() Return given list sorted by the poset.

isomorphic_subposets() Return all subposets isomorphic to another poset.

isomorphic_subposets_iterator() Return an iterator over the subposets isomorphic to another poset.

has_isomorphic_subposet() Return True if the poset contains a subposet isomorphic to another poset.

list() List the elements of the poset.

cuts() Return the cuts of the given poset.

dilworth_decomposition() Return a partition of the points into the minimal number of chains.

greene_shape() Computes the Greene-Kleitman partition aka Greene shape of the poset self.

incidence_algebra() Return the incidence algebra of self.

is_EL_labelling() Return whether f is an EL labelling of the poset.

isomorphic_subposets_iterator() Return an iterator over the subposets isomorphic to another poset.

isomorphic_subposets() Return all subposets isomorphic to another poset.

level_sets() Return elements grouped by maximal number of cover relations from a minimal element.

order_complex() Return the order complex associated to this poset.

random_order_ideal() Return a random order ideal of self with uniform probability.

rank() Return the rank of an element, or the rank of the poset.

rank_function() Return a rank function of the poset, if it exists.

unwrap() Unwraps an element of this poset.

atkinson() Return the 𝛼-spectrum of a poset whose undirected Hasse diagram is a forest.

spectrum() Return the 𝛼-spectrum of this poset.

### Classes and functions

**class** sage.combinat.posets.posets.FinitePoset (hasse_diagram, elements, category, facade, key)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

A (finite) n-element poset constructed from a directed acyclic graph.

**INPUT:**

- hasse_diagram – an instance of FinitePoset, or a DiGraph that is transitive-reduced, acyclic, loop-free, and multiedge-free.
- elements – an optional list of elements, with element[i] corresponding to vertex i. If elements is None, then it is set to be the vertex set of the digraph. Note that if this option is set, then elements is considered as a specified linear extension of the poset and the linear_extension attribute is set.
- category – FinitePosets, or a subcategory thereof.
- facade – a boolean or None (default); whether the FinitePoset’s elements should be wrapped to make them aware of the Poset they belong to.
  - If facade = True, the FinitePoset’s elements are exactly those given as input.
  - If facade = False, the FinitePoset’s elements will become PosetElement objects.
  - If facade = None (default) the expected behaviour is the behaviour of facade = True, unless the opposite can be deduced from the context (i.e. for instance if a FinitePoset is built from another FinitePoset, itself built with facade = False)
- key – any hashable value (default: None).

**EXAMPLES:**
We keep the same underlying Hasse diagram, but change the elements:

```python
sage: Q = sage.combinat.posets.posets.FinitePoset(P, elements=[1,2,3,4,5,6], facade=False); Q
Finite poset containing 6 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 5], [2, 6], [3, 4], [3, 5], [4, 6], [5, 6]]
```

We test the facade argument:

```python
sage: P = Poset(DiGraph({'a':['b'],'b':['c'],'c':['d']}), facade=False)
Category of finite enumerated posets
sage: parent(P[0]) is P
True
sage: Q = Poset(DiGraph({'a':['b'],'b':['c'],'c':['d']}), facade=True)
Category of facade finite enumerated posets
sage: parent(Q[0]) is str
True
sage: TestSuite(Q).run(skip = ['_test_an_element']) # is_parent_of is not yet implemented
```

Changing a non facade poset to a facade poset:

```python
sage: PQ = Poset(P, facade=True)
sage: PQ.category()
Category of facade finite enumerated posets
sage: parent(PQ[0]) is str
True
sage: PQ is Q
True
```

Changing a facade poset to a non facade poset:

```python
sage: QP = Poset(Q, facade=False)
sage: QP.category()
```

(continues on next page)
Category of finite enumerated posets

```
sage: parent(QP[0])
```

```
is QP
```

True

**Note:** A class that inherits from this class needs to define `Element`. This is the class of the elements that the inheriting class contains. For example, for this class, `FinitePoset.Element` is `PosetElement`. It can also define `_dual_class` which is the class of dual posets of this class. E.g. `FiniteMeetSemilattice._dual_class` is `FiniteJoinSemilattice`.

### `Element`

**alias of** `sage.combinat.posets.elements.PosetElement`

### `antichains`(*element_constructor*=<class 'list'>)

Return the antichains of the poset.

An antichain of a poset is a set of elements of the poset that are pairwise incomparable.

**INPUT:**

- `element_constructor` – a function taking an iterable as argument (default: `list`)

**OUTPUT:**

The enumerated set (of type `PairwiseCompatibleSubsets`) of all antichains of the poset, each of which is given as an `element_constructor`.

**EXAMPLES:**

```
sage: A = posets.PentagonPoset().antichains(); A
Set of antichains of Finite lattice containing 5 elements
```

```
sage: list(A)

[[], [0], [1], [1, 2], [1, 3], [2], [3], [4]]
```

```
sage: A.cardinality()
8
```

```
sage: A[3]

[1, 2]
```

To get the antichains as, say, sets, one may use the `element_constructor` option:

```
sage: list(posets.ChainPoset(3).antichains(element_constructor=set))

[set(), {0}, {1}, {2}]
```

To get the antichains of a given size one can currently use:

```
sage: list(A.elements_of_depth_iterator(2))

[[1, 2], [1, 3]]
```

Eventually the following syntax will be accepted:

```
sage: A.subset(size = 2)  # todo: not implemented
```

**Note:** Internally, this uses `sage.combinat.subsets_pairwise.PairwiseCompatibleSubsets` and `RecursivelyEnumeratedSet_forest`. At this point, iterating through this set is about twice slower than using `antichains_iterator()` (tested on `posets.AntichainPoset(15)`). The algorithm is the same (depth first search through the tree),
but \texttt{antichains\_iterator()} manually inlines things which apparently avoids some infrastructure overhead.

On the other hand, this returns a full featured enumerated set, with containment testing, etc.

\textbf{See also:}

\texttt{maximal\_antichains()}, \texttt{chains()}

\textbf{antichains\_iterator()}

Return an iterator over the antichains of the poset.

\texttt{sage: it = posets.PentagonPoset().antichains\_iterator(); it}
\begin{verbatim}
<generator object ...antichains_iterator at ...>
\end{verbatim}
\texttt{sage: next(it), next(it)}
\begin{verbatim}
([], [4])
\end{verbatim}

\textbf{See also:}

\texttt{antichains()}

\textbf{atkinson}(a)

Return the $a$-spectrum of a poset whose Hasse diagram is cycle-free as an undirected graph.

Given an element $a$ in a poset $P$, the $a$-spectrum is the list of integers whose $i$-th term contains the number of linear extensions of $P$ with element $a$ located in the $i$-th position.

\textbf{INPUT:}

\begin{itemize}
  \item \texttt{self} – a poset whose Hasse diagram is a forest
  \item \texttt{a} – an element of the poset
\end{itemize}

\textbf{OUTPUT:}

The $a$-spectrum of this poset, returned as a list.

\texttt{sage: P = Poset({0: [2], 1: [2], 2: [3, 4], 3: [], 4: []})}
\texttt{sage: P.atkinson(0)}
\begin{verbatim}
[2, 2, 0, 0, 0]
\end{verbatim}
\texttt{sage: P = Poset({0: [1], 1: [2, 3], 2: [], 3: [], 4: [5, 6], 5: [], 6: []})}
\texttt{sage: P.atkinson(5)}
\begin{verbatim}
[0, 10, 18, 24, 28, 30, 30]
\end{verbatim}
\texttt{sage: P = posets.AntichainPoset(10)}
\texttt{sage: P.atkinson(0)}
\begin{verbatim}
[362880, 362880, 362880, 362880, 362880, 362880, 362880, 362880, 362880, 362880]
\end{verbatim}

\textbf{Note:} This function is the implementation of the algorithm from [At1990].

\textbf{bottom()}

Return the unique minimal element of the poset, if it exists.

\texttt{sage: P = posets.PentagonPoset(); P}
\begin{verbatim}
Pentagon poset (with antisymmetric relation)
\end{verbatim}
\texttt{sage: P.bottom()}
\begin{verbatim}
0
\end{verbatim}

\textbf{EXAMPLES:}
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.bottom() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.bottom()
0

See also:

has_bottom(), top()
canonical_label(algorithm=None)
Return the unique poset on the labels \(\{0, \ldots, n - 1\}\) (where \(n\) is the number of elements in the poset) that is isomorphic to this poset and invariant in the isomorphism class.

INPUT:

- algorithm - string (optional): a parameter forwarded to underlying graph function to select the algorithm to use

EXAMPLES:

sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: Q = P.canonical_label()
sage: sorted(Q.list())
[0, 1, 2, 3, 4, 5]
sage: Q.is_isomorphic(P)
True

Canonical labeling of (semi)lattice returns (semi)lattice:

sage: D = DiGraph({'a':[b,c]})
sage: P = Poset(D)
sage: ML = MeetSemilattice(D)
sage: P.canonical_label()
Finite poset containing 3 elements
sage: ML.canonical_label()
Finite meet-semilattice containing 3 elements

See also:

- Canonical labeling of directed graphs: canonical_label()
cardinality()
Return the number of elements in the poset.

EXAMPLES:

sage: Poset([[1,2,3],[4],[4],[4],[[]]].cardinality()
5

See also:

degree_polynomial() for a more refined invariant
chain_polynomial()
Return the chain polynomial of the poset.
The coefficient of $q^k$ is the number of chains of $k$ elements in the poset. List of coefficients of this polynomial is also called a $f$-vector of the poset.

**Note:** This is not what has been called the chain polynomial in [St1986]. The latter is identical with the order polynomial in SageMath (order_polynomial()).

See also:

f_polynomial(), order_polynomial()

**EXAMPLES:**

```
sage: P = posets.ChainPoset(3)
sage: t = P.chain_polynomial(); t
q^3 + 3*q^2 + 3*q + 1
sage: t(1) == len(list(P.chains()))
True
sage: P = posets.BooleanLattice(3)
sage: P.chain_polynomial()
6*q^4 + 18*q^3 + 19*q^2 + 8*q + 1
sage: P = posets.AntichainPoset(5)
sage: P = P.chain_polynomial()
5*q + 1
```

**chain_polytope()**

Return the chain polytope of the poset self.

The chain polytope of a finite poset $P$ is defined as the subset of $\mathbb{R}^P$ consisting of all maps $x : P \rightarrow \mathbb{R}$ satisfying

$$x(p) \geq 0 \text{ for all } p \in P,$$

and

$$x(p_1) + x(p_2) + \ldots + x(p_k) \leq 1 \text{ for all chains } p_1 < p_2 < \ldots < p_k \text{ in } P.$$  

This polytope was defined and studied in [St1986].

**EXAMPLES:**

```
sage: P = posets.AntichainPoset(3)
sage: Q = P.chain_polytope();Q
A 3-dimensional polyhedron in ZZ^3 defined as the convex hull of 8 vertices
sage: P = posets.PentagonPoset()
sage: Q = P.chain_polytope();Q
A 5-dimensional polyhedron in ZZ^5 defined as the convex hull of 8 vertices
```

**chains (element_constructor=<class 'list'>, exclude=None)**

Return the chains of the poset.

A chain of a poset is a set of elements of the poset that are pairwise comparable.

**INPUT:**

- element_constructor – a function taking an iterable as argument (default: list)
- exclude – elements of the poset to be excluded (default: None)
OUTPUT:

The enumerated set (of type `PairwiseCompatibleSubsets`) of all chains of the poset, each of which is given as an `element_constructor`.

EXAMPLES:

```python
sage: C = posets.PentagonPoset().chains(); C
Set of chains of Finite lattice containing 5 elements
sage: list(C)
[[], [0], [0, 1], [0, 1, 4], [0, 2], [0, 2, 3], [0, 2, 3, 4], [0, 2, 4], [0, 3], [0, 3, 4], [0, 4], [1], [1, 4], [2], [2, 3], [2, 3, 4], [2, 4], [3], [3, 4], [4]]
```

Exclusion of elements, tuple (instead of list) as constructor:

```python
sage: P = Poset({1: [2, 3], 2: [4], 3: [4, 5]})
sage: list(P.chains(element_constructor=tuple, exclude=[3]))
[((), (1,), (1, 2), (1, 2, 4), (1, 4), (1, 5), (2,), (2, 4), (4,), (5,))]
```

To get the chains of a given size one can currently use:

```python
sage: list(C.elements_of_depth_iterator(2))
[[0, 1], [0, 2], [0, 3], [0, 4], [1, 4], [2, 3], [2, 4], [3, 4]]
```

Eventually the following syntax will be accepted:

```python
sage: C.subset(size = 2) # todo: not implemented
```

See also:

`maximal_chains()`, `antichains()`

`characteristic_polynomial()`

Return the characteristic polynomial of the poset.

The poset is expected to be graded and have a bottom element.

If $P$ is a graded poset with rank $n$ and a unique minimal element $\hat{0}$, then the characteristic polynomial of $P$ is defined to be

$$
\sum_{x \in P} \mu(\hat{0}, x)q^{n-\rho(x)} \in \mathbb{Z}[q],
$$

where $\rho$ is the rank function, and $\mu$ is the Möbius function of $P$.

See section 3.10 of [EnumComb1].

EXAMPLES:

```python
sage: P = posets.DiamondPoset(5)
sage: P.characteristic_polynomial()
q^2 - 3*q + 2
sage: P = Poset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
sage: P.characteristic_polynomial()
q^4 - 2*q^3 + q
```

`closed_interval(x, y)`

Return the list of elements $z$ such that $x \leq z \leq y$ in the poset.

EXAMPLES:
```python
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.closed_interval(2, 100)
[2, 4, 10, 20, 50, 100]
```

See also:

`open_interval()`

`common_upper_covers(elmts)`

Return all of the common upper covers of the elements `elmts`.

EXAMPLES:

```python
sage: P = Poset({0: [1, 2], 1: [3], 2: [3], 3: []})
sage: P.common_upper_covers([1, 2])
[3]
```

`comparability_graph()`

Return the comparability graph of the poset.

The comparability graph is an undirected graph where vertices are the elements of the poset and there is an edge between two vertices if they are comparable in the poset.

See Wikipedia article `Comparability_graph`

EXAMPLES:

```python
sage: Y = Poset({1: [2], 2: [3, 4]})
sage: g = Y.comparability_graph(); g
Comparability graph on 4 vertices
sage: Y.compare_elements(1, 3) is not None
True
sage: g.has_edge(1, 3)
True
```

See also:

`incomparability_graph()`, `sage.graphs.comparability`

`compare_elements(x, y)`

Compare `x` and `y` in the poset.

- If `x < y`, return `-1`.
- If `x = y`, return `0`.
- If `x > y`, return `1`.
- If `x` and `y` are not comparable, return `None`.

EXAMPLES:

```python
sage: P = Poset(([1, 2], [4], [3], [4], []))
sage: P.compare_elements(0, 0)
0
sage: P.compare_elements(0, 4)
-1
sage: P.compare_elements(4, 0)
1
sage: P.compare_elements(1, 2) is None
True
```
completion_by_cuts()
Return the completion by cuts of self.

This is the smallest lattice containing the poset. This is also called the Dedekind-MacNeille completion.
See the Wikipedia article Dedekind-MacNeille completion.

OUTPUT:
- a finite lattice

EXAMPLES:
```
sage: P = posets.PentagonPoset()
sage: P.completion_by_cuts().is_isomorphic(P)
True

sage: Y = Poset({1: [2], 2: [3, 4]})
sage: trafficsign = LatticePoset({1: [2], 2: [3, 4], 3: [5], 4: [5]})
sage: L = Y.completion_by_cuts()
sage: L.is_isomorphic(trafficsign)
True

sage: P = posets.SymmetricGroupBruhatOrderPoset(3)
sage: Q = P.completion_by_cuts(); Q
Finite lattice containing 7 elements
```

See also:
cuts(), irreducibles_poset()

connected_components()
Return the connected components of the poset as subposets.

EXAMPLES:
```
sage: P = Poset({1: [2, 3], 3: [4, 5], 6: [7, 8]})
sage: parts = sorted(P.connected_components(), key=len); parts
[Finite poset containing 3 elements,
 Finite poset containing 5 elements]
sage: parts[0].cover_relations()
[[6, 7], [6, 8]]
```

See also:
disjoint_union(), is_connected()

cover_relations()
Return the list of pairs \([x, y]\) of elements of the poset such that \(y\) covers \(x\).

EXAMPLES:
```
sage: P = Poset({0: [2], 1: [2], 2: [3], 3: [4, 5], 4: []})
sage: P.cover_relations()
[[1, 2], [0, 2], [2, 3], [3, 4]]
```

cover_relations_graph()
Return the (undirected) graph of cover relations.

EXAMPLES:
```sage
sage: P = Poset({0: [1, 2], 1: [3], 2: [3]})
sage: G = P.cover_relations_graph(); G
Graph on 4 vertices
sage: G.has_edge(3, 1), G.has_edge(3, 0)
(True, False)
```

See also:

`hasse_diagram()`

**cover_relations_iterator()**

Return an iterator over the cover relations of the poset.

**EXAMPLES:**

```sage
sage: P = Poset({0: [2], 1: [2], 2: [3], 3: [4], 4: [ ]})
sage: type(P.cover_relations_iterator())
<... 'generator'>
sage: [z for z in P.cover_relations_iterator()]
[[1, 2], [0, 2], [2, 3], [3, 4]]
```

**covers** *(x, y)*

Return True if y covers x and False otherwise.

Element y covers x if x < y and there is no z such that x < z < y.

**EXAMPLES:**

```sage
sage: P = Poset([[1,5], [2,6], [3], [4], [ ], [6,3], [4]])
sage: P.covers(1, 6)
True
sage: P.covers(1, 4)
False
sage: P.covers(1, 5)
False
```

**coxeter_polynomial()**

Return the Coxeter polynomial of the poset.

**OUTPUT:**

a polynomial in one variable

The output is the characteristic polynomial of the Coxeter transformation. This polynomial only depends on the derived category of modules on the poset.

**EXAMPLES:**

```sage
sage: P = posets.PentagonPoset()
sage: P.coxeter_polynomial()
x^5 + x^4 + x + 1
sage: p = posets.SymmetricGroupWeakOrderPoset(3)
sage: p.coxeter_polynomial()
x^6 + x^5 - x^3 + x + 1
```

See also:

`coxeter_transformation()`, `coxeter_smith_form()`
\texttt{coxeter_smith_form}(\texttt{algorithm='singular'})

Return the Smith normal form of $x$ minus the Coxeter transformation matrix.

INPUT:

- \texttt{algorithm} – optional (default 'singular'), possible values are 'singular', 'sage', 'gap', 'pari', 'maple', 'magma', 'fricas'

Beware that speed depends very much on the choice of algorithm. Sage is rather slow, Singular is faster and Pari is fast at least for small sizes.

OUTPUT:

- list of polynomials in one variable, each one dividing the next one

The output list is a refinement of the characteristic polynomial of the Coxeter transformation, which is its product. This list of polynomials only depends on the derived category of modules on the poset.

EXAMPLES:

\begin{verbatim}
sage: P = posets.PentagonPoset()
sage: P.coxeter_smith_form()
[1, 1, 1, 1, x^5 + x^4 + x + 1]
sage: P = posets.DiamondPoset(7)
sage: prod(P.coxeter_smith_form()) == P.coxeter_polynomial()
True
\end{verbatim}

See also:

\texttt{coxeter_transformation()}, \texttt{coxeter_matrix()}

\textbf{coxeter_transformation()}

Return the Coxeter transformation of the poset.

OUTPUT:

a square matrix with integer coefficients

The output is the matrix of the Auslander-Reiten translation acting on the Grothendieck group of the derived category of modules on the poset, in the basis of simple modules. This matrix is usually called the Coxeter transformation.

EXAMPLES:

\begin{verbatim}
sage: posets.PentagonPoset().coxeter_transformation()
[ 0 0 0 0 -1]
[ 0 0 0 1 -1]
[ 0 1 0 0 -1]
[-1 1 1 0 -1]
[-1 1 0 1 -1]
\end{verbatim}

See also:

\texttt{coxeter_polynomial()}, \texttt{coxeter_smith_form()}

\textbf{cuts()}

Return the list of cuts of the poset \texttt{self}.

A cut is a subset $A$ of \texttt{self} such that the set of lower bounds of the set of upper bounds of $A$ is exactly $A$.

The cuts are computed here using the maximal independent sets in the auxiliary graph defined as $P \times [0, 1]$ with an edge from $(x, 0)$ to $(y, 1)$ if and only if $x \not\geq_P y$. See the end of section 4 in [JRJ94].
EXAMPLES:

```python
sage: P = posets.AntichainPoset(3)
sage: Pc = P.cuts()
sage: Pc # random
[frozenset({0}),
 frozenset(),
 frozenset({0, 1, 2}),
 frozenset({2}),
 frozenset({1})]
sage: sorted(list(c for c in Pc))
[[], [0], [0, 1, 2], [1], [2]]
```

See also:
- `completion_by_cuts()`

`degree_polynomial()`
Return the generating polynomial of degrees of vertices in `self`.
This is the sum

\[
\sum_{v \in P} x^{in(v)} y^{out(v)},
\]

where \(in(v)\) and \(out(v)\) are the number of incoming and outgoing edges at vertex \(v\) in the Hasse diagram of \(P\).

Because this polynomial is multiplicative for Cartesian product of posets, it is useful to help see if the poset can be isomorphic to a Cartesian product.

EXAMPLES:

```python
sage: P = posets.PentagonPoset()
sage: P.degree_polynomial()
x^2 + 3*x*y + y^2
sage: P = posets.BooleanLattice(4)
sage: P.degree_polynomial().factor()
(x + y)^4
```

See also:
- `cardinality()` for the value at \((x, y) = (1, 1)\)

`diamonds()`
Return the list of diamonds of `self`.
A diamond is the following subgraph of the Hasse diagram:

```
z
/ \
\ x y
\ /\  
w
```

Thus each edge represents a cover relation in the Hasse diagram. We represent this as the tuple \((w, x, y, z)\).

OUTPUT:
A tuple with
- a list of all diamonds in the Hasse Diagram,
• a boolean checking that every \( w, x, y \) that form a \( V \), there is a unique element \( z \), which completes the diamond.

EXAMPLES:

```
sage: P = Poset({0: [1,2], 1: [3], 2: [3], 3: []})
sage: P.diamonds()
([(0, 1, 2, 3)], True)
```

```
sage: P = posets.YoungDiagramPoset(Partition([3, 2, 2]))
sage: P.diamonds()
([([(0, 0), (0, 1), (1, 0), (1, 1)], [(1, 0), (1, 1), (2, 0), (2, 1)])], False)
```

dilworth_decomposition()  
Return a partition of the points into the minimal number of chains.

According to Dilworth’s theorem, the points of a poset can be partitioned into \( \alpha \) chains, where \( \alpha \) is the cardinality of its largest antichain. This method returns such a partition.

See Wikipedia article Dilworth\'s theorem.

ALGORITHM:  
We build a bipartite graph in which a vertex \( v \) of the poset is represented by two vertices \( v^-, v^+ \). For any two \( u, v \) such that \( u < v \) in the poset we add an edge \( v^+ u^- \).

A matching in this graph is equivalent to a partition of the poset into chains: indeed, a chain \( v_1 \ldots v_k \) gives rise to the matching \( v_1^+ v_2^-, v_2^+ v_3^- \ldots \), and from a matching one can build the union of chains.

According to Dilworth\'s theorem, the number of chains is equal to \( \alpha \) (the posets' width).

EXAMPLES:

```
sage: p = posets.BooleanLattice(4)
sage: p.width()
6
```

```
sage: p.dilworth_decomposition()  # random
[[7, 6, 4], [11, 3], [12, 8, 0], [13, 9, 1], [14, 10, 2], [15, 5]]
```

See also:  
```
level_sets()  to return elements grouped to antichains.
```

dimension (certificate=False)  
Return the dimension of the Poset.

The (Dushnik-Miller) dimension of a poset is the minimal number of total orders so that the poset is their “intersection”. More precisely, the dimension of a poset defined on a set \( X \) of points is the smallest integer \( n \) such that there exist linear extensions \( P_1, \ldots, P_n \) of \( P \) satisfying:

\[
 u \leq_P v \text{ if and only if } \forall i, u \leq_{P_i} v
\]

For more information, see the Wikipedia article Order_dimension.

INPUT:

• certificate (boolean; default=False) – whether to return an integer (the dimension) or a certificate, i.e. a smallest set of linear extensions.

Note: The speed of this function greatly improves when more efficient MILP solvers (e.g. Gurobi, CPLEX) are installed. See MixedIntegerLinearProgram for more information.
Note: Prior to version 8.3 this returned only realizer with certificate=True. Now it returns a pair having a realizer as the second element. See trac ticket #25588 for details.

ALGORITHM:
As explained [FT00], the dimension of a poset is equal to the (weak) chromatic number of a hypergraph. More precisely:

Let $\text{inc}(P)$ be the set of (ordered) pairs of incomparable elements of $P$, i.e. all $uv$ and $vu$ such that $u \not\leq_P v$ and $v \not\leq_P u$. Any linear extension of $P$ is a total order on $X$ that can be seen as the union of relations from $P$ along with some relations from $\text{inc}(P)$. Thus, the dimension of $P$ is the smallest number of linear extensions of $P$ which cover all points of $\text{inc}(P)$.

Consequently, $\dim(P)$ is equal to the chromatic number of the hypergraph $\mathcal{H}_{\text{inc}}$, where $\mathcal{H}_{\text{inc}}$ is the hypergraph defined on $\text{inc}(P)$ whose sets are all $S \subseteq \text{inc}(P)$ such that $P \cup S$ is not acyclic.

We solve this problem through a Mixed Integer Linear Program.

The problem is known to be NP-complete.

EXAMPLES:
We create a poset, compute a set of linear extensions and check that we get back the poset from them:

```
sage: P = Poset([[1,4], [3], [4,5,3], [6], [], [6], []])
sage: P.dimension()
3
sage: dim, L = P.dimension(certificate=True)
sage: L
# random -- architecture-dependent
[[0, 2, 4, 5, 1, 3, 6], [2, 5, 0, 1, 3, 4, 6], [0, 1, 2, 3, 5, 6, 4]]
sage: Poset( (L[0], lambda x, y: all(l.index(x) < l.index(y) for l in L)) )
== P
True
```

According to Schnyder’s theorem, the incidence poset (of height 2) of a graph has dimension $\leq 3$ if and only if the graph is planar:

```
sage: G = graphs.CompleteGraph(4)
sage: P = Poset(DiGraph({(u,v):[u,v] for u,v,_ in G.edges()}))
sage: P.dimension()
3
sage: G = graphs.CompleteBipartiteGraph(3,3)
sage: P = Poset(DiGraph({(u,v):[u,v] for u,v,_ in G.edges()}))
sage: P.dimension()
# not tested - around 4s with CPLEX
4
```

disjoint_union (other, labels='pairs')
Return a poset isomorphic to disjoint union (also called direct sum) of the poset with other.

The disjoint union of $P$ and $Q$ is a poset that contains every element and relation from both $P$ and $Q$, and where every element of $P$ is incomparable to every element of $Q$.

Mathematically, it is only defined when $P$ and $Q$ have no common element; here we force that by giving them different names in the resulting poset.

INPUT:

- other, a poset.
• labels - (defaults to ‘pairs’) If set to ‘pairs’, each element \( v \) in this poset will be named \((0, v)\) and each element \( u \) in other will be named \((1, u)\) in the result. If set to ‘integers’, the elements of the result will be relabeled with consecutive integers.

EXAMPLES:

```python
sage: P1 = Poset({'a': 'b'})
sage: P2 = Poset({'c': 'd'})
sage: P = P1.disjoint_union(P2); P
Finite poset containing 4 elements
sage: sorted(P.cover_relations())
[[0, 'a'), (0, 'b')], [(1, 'c'), (1, 'd')]]
sage: P = P1.disjoint_union(P2, labels='integers')
sage: P.cover_relations()
[[2, 3], [0, 1]]
```

We show how to get literally direct sum with elements untouched:

```python
sage: P = P1.disjoint_union(P2).relabel(lambda x: x[1])
sage: sorted(P.cover_relations())
[('a', 'b'), ('c', 'd')]
```

See also:

- `connected_components()`
- `dual()`

`dual()`

Return the dual poset of the given poset.

In the dual of a poset \( P \) we have \( x \leq y \) iff \( y \leq x \) in \( P \).

EXAMPLES:

```python
sage: P = Poset({1: [2, 3], 3: [4]})
sage: P.cover_relations()
[[1, 2], [1, 3], [3, 4]]
sage: Q = P.dual()
sage: Q.cover_relations()
[[4, 3], [3, 1], [2, 1]]
```

Dual of a lattice is a lattice; dual of a meet-semilattice is join-semilattice and vice versa. Also the dual of a (non-)facade poset is again (non-)facade:

```python
sage: V = MeetSemilattice({1: [2, 3]}, facade=False)
sage: A = V.dual(); A
Finite join-semilattice containing 3 elements
sage: A(2) < A(1)
True
```

See also:

- `is_self_dual()`
- `evacuation()`

`evacuation()`

Compute evacuation on the linear extension associated to the poset `self`. 
OUTPUT:

- an isomorphic poset, with the same default linear extension

Evacuation is defined on a poset self of size \( n \) by applying the evacuation operator \((\tau_1 \cdots \tau_{n-1}) (\tau_1 \cdots \tau_{n-2}) \cdots (\tau_1)\), to the default linear extension \( \pi \) of self (see \texttt{evacuation()}), and relabeling self accordingly. For more details see [Stan2009].

EXAMPLES:

```python
sage: P = Poset(([1,2], [[1,2]]), linear_extension=True, facade=False)
sage: P.evacuation()
Finite poset containing 2 elements with distinguished linear extension
sage: P.evacuation() == P
True

sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,6]]), linear_extension=True, facade=False)
sage: P.evacuation()
Finite poset containing 7 elements with distinguished linear extension
sage: Q = P.evacuation(); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 3], [2, 5], [3, 4], [3, 6], [4, 7], [6, 7]]

Note that the results depend on the linear extension associated to the poset:

```python
sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,6]]))
sage: P.evacuation()
Finite poset containing 7 elements with distinguished linear extension
sage: Q = P.evacuation(); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 3], [2, 5], [3, 4], [3, 6], [4, 7], [4, 7]]

Here is an example of a poset where the elements are not labelled by \( \{1, 2, \ldots, n\} \):

```python
sage: P = Poset((divisors(15), attrcall("divides")), linear_extension = True)
sage: P.evacuation()
Finite poset containing 4 elements with distinguished linear extension
sage: Q = P.evacuation(); Q
Finite poset containing 4 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 3], [1, 5], [3, 15], [5, 15]]
```

- \texttt{with_linear_extension()} and the \texttt{linear_extension} option of \texttt{Poset()}
- \texttt{evacuation()}
- \texttt{promotion()}

AUTHOR:

- Anne Schilling (2012-02-18)
### f_polynomial()

Return the $f$-polynomial of the poset.

The poset is expected to be bounded.

This is the $f$-polynomial of the order complex of the poset minus its bounds.

The coefficient of $q^i$ is the number of chains of $i + 1$ elements containing both bounds of the poset.

**Note:** This is slightly different from the `fPolynomial` method in Macaulay2.

**EXAMPLES:**

```python
sage: P = posets.DiamondPoset(5)
sage: P.f_polynomial()
3*q^2 + q
sage: P = Poset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [7], 6: [7]})
sage: P.f_polynomial()
q^4 + 4*q^3 + 5*q^2 + q
```

**See also:**

`is_bounded()`, `h_polynomial()`, `order_complex()`, `sage.homology.cell_complex.GenericCellComplex.f_vector()`

### factor()

Factor the poset as a Cartesian product of smaller posets.

This only works for connected posets for the moment.

The decomposition of a connected poset as a Cartesian product of posets (prime in the sense that they cannot be written as Cartesian products) is unique up to reordering and isomorphism.

**OUTPUT:**

a list of posets

**EXAMPLES:**

```python
sage: P = posets.PentagonPoset()
sage: Q = P*P
sage: Q.factor()
[Finite poset containing 5 elements, Finite poset containing 5 elements]

sage: P1 = posets.ChainPoset(3)
sage: P2 = posets.ChainPoset(7)
sage: P1.factor()
[Finite lattice containing 3 elements]

sage: (P1 * P2).factor()
[Finite poset containing 7 elements, Finite poset containing 3 elements]

sage: P = posets.TamariLattice(4)
sage: (P*P).factor()
[Finite poset containing 14 elements, Finite poset containing 14 elements]
```

**See also:**

`is_bounded()`, `h_polynomial()`, `order_complex()`, `sage.homology.cell_complex.GenericCellComplex.f_vector()`
flag_f_polynomial()

Return the flag f-polynomial of the poset.

The poset is expected to be bounded and ranked.

This is the sum, over all chains containing both bounds, of a monomial encoding the ranks of the elements of the chain.

More precisely, if \( P \) is a bounded ranked poset, then the flag f-polynomial of \( P \) is defined as the polynomial

\[
\sum_{p_0 < p_1 < \ldots < p_k, \ p_0 = \min P, \ p_k = \max P} x_{\rho(p_1)} x_{\rho(p_2)} \cdots x_{\rho(p_k)} \in \mathbb{Z}[x_1, x_2, \ldots, x_n],
\]

where \( \min P \) and \( \max P \) are (respectively) the minimum and the maximum of \( P \), where \( \rho \) is the rank function of \( P \) (normalized to satisfy \( \rho(\min P) = 0 \)), and where \( n \) is the rank of \( \max P \). (Note that the indeterminate \( x_0 \) doesn’t actually appear in the polynomial.)

For technical reasons, the polynomial is returned in the slightly larger ring \( \mathbb{Z}[x_0, x_1, x_2, \ldots, x_{n+1}] \) by this method.

See Wikipedia article h-vector.

EXAMPLES:

```python
sage: P = posets.DiamondPoset(5)
sage: P.flag_f_polynomial()
3*x1*x2 + x2

sage: P = Poset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
sage: f1 = P.flag_f_polynomial(); f1
2*x1*x2*x3 + 2*x1*x3 + 2*x2*x3 + x3

sage: q = polygen(ZZ,'q')
sage: f1(q,q,q,q) == P.f_polynomial()
True

sage: P = Poset({1: [2, 3, 4], 2: [5], 3: [5], 4: [5], 5: [6]})
sage: P.flag_f_polynomial()
3*x1*x2*x3 + 3*x1*x3 + x2*x3 + x3
```

See also:

is_bounded(), flag_h_polynomial()

flag_h_polynomial()

Return the flag h-polynomial of the poset.

The poset is expected to be bounded and ranked.

If \( P \) is a bounded ranked poset whose maximal element has rank \( n \) (where the minimal element is set to have rank 0), then the flag h-polynomial of \( P \) is defined as the polynomial

\[
\prod_{k=1}^{n} (1 - x_k) \cdot f \left( \frac{x_1}{1 - x_1}, \frac{x_2}{1 - x_2}, \ldots, \frac{x_n}{1 - x_n} \right) \in \mathbb{Z}[x_1, x_2, \ldots, x_n],
\]

where \( f \) is the flag f-polynomial of \( P \) (see flag_f_polynomial()).

For technical reasons, the polynomial is returned in the slightly larger ring \( \mathbb{Q}[x_0, x_1, x_2, \ldots, x_{n+1}] \) by this method.
See Wikipedia article h-vector.

EXAMPLES:

```python
sage: P = posets.DiamondPoset(5)
sage: P.flag_h_polynomial()
2*x1*x2 + x2
sage: P = Poset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
sage: f1 = P.flag_h_polynomial(); f1
-x1*x2*x3 + x1*x3 + x2*x3 + x3
sage: q = polygen(ZZ, 'q')
sage: f1(q, q, q, q) == P.h_polynomial()
True
sage: P = Poset({1: [2, 3, 4], 2: [5], 3: [5], 4: [5], 5: [6]})
sage: P.flag_h_polynomial()
2*x1*x3 + x3
sage: P = posets.ChainPoset(4)
sage: P.flag_h_polynomial()
x3
```

See also:

`is_bounded()`, `flag_f_polynomial()`

`frank_network()`

Return Frank’s network of the poset.

This is defined in Section 8 of [BF1999].

OUTPUT:

A pair \((G, e)\), where \(G\) is Frank’s network of \(P\) encoded as a `DiGraph`, and \(e\) is the cost function on its edges encoded as a dictionary (indexed by these edges, which in turn are encoded as tuples of 2 vertices).

**Note:** Frank’s network of \(P\) is a certain directed graph with \(2|P| + 2\) vertices, defined in Section 8 of [BF1999]. Its set of vertices consists of two vertices \((0, p)\) and \((1, p)\) for each element \(p\) of \(P\), as well as two vertices \((-1, 0)\) and \((2, 0)\). (These notations are not the ones used in [BF1999]; see the table below for their relation.) The edges are:

- for each \(p\) in \(P\), an edge from \((-1, 0)\) to \((0, p)\);
- for each \(p\) in \(P\), an edge from \((1, p)\) to \((2, 0)\);
- for each \(p\) and \(q\) in \(P\) such that \(p \geq q\), an edge from \((0, p)\) to \((1, q)\).

We make this digraph into a network in the sense of flow theory as follows: The vertex \((-1, 0)\) is considered as the source of this network, and the vertex \((2, 0)\) as the sink. The cost function is defined to be 1 on the edge from \((0, p)\) to \((1, p)\) for each \(p \in P\), and to be 0 on every other edge. The capacity is 1 on each edge. Here is how to translate this notations into that used in [BF1999]:

<table>
<thead>
<tr>
<th>our notations</th>
<th>[BF1999]</th>
</tr>
</thead>
<tbody>
<tr>
<td>(-1, 0)</td>
<td>s</td>
</tr>
<tr>
<td>(0, p)</td>
<td>x_p</td>
</tr>
<tr>
<td>(1, p)</td>
<td>y_p</td>
</tr>
<tr>
<td>(2, 0)</td>
<td>t</td>
</tr>
<tr>
<td>a[e]</td>
<td>a(e)</td>
</tr>
</tbody>
</table>
EXAMPLES:

```python
sage: ps = [[16,12,14,-13],[12,14],[14,-13],[12,16],[16,-13]]
sage: G, e = Poset(ps).frank_network()
sage: G.edges(sort=True)
[((-1, 0), (0, -13), None), ((-1, 0), (0, 12), None), ((-1, 0), (0, 14), None), ((-1, 0), (0, 16), None), ((-1, 0), (1, -13), None), ((-1, 0), (1, 12), None), ((0, -13), (1, -13), None), ((0, -13), (1, 12), None), ((0, -13), (1, 14), None), ((0, -13), (1, 16), None), ((0, 12), (1, -13), None), ((0, 12), (1, 12), None), ((0, 12), (1, 14), None), ((0, 12), (1, 16), None), ((0, 14), (1, -13), None), ((0, 14), (1, 12), None), ((0, 14), (1, 14), None), ((0, 14), (1, 16), None), ((0, 16), (1, -13), None), ((0, 16), (1, 12), None), ((0, 16), (1, 14), None), ((0, 16), (1, 16), None), ((1, -13), (2, 0), None), ((1, 12), (2, 0), None), ((1, 14), (2, 0), None), ((1, 16), (2, 0), None)]

 (0, 9), (1, 2)): 0,
 (0, 9), (1, 3)): 0
(continues on next page)
```
ge(x, y)
Return True if x is greater than or equal to y in the poset, and False otherwise.

EXAMPLES:

```python
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_gequal(3, 1)
True
sage: P.is_gequal(2, 2)
True
sage: P.is_gequal(0, 1)
False
```

See also:

is_greater_than(), is_lequal()

graphviz_string(graph_string='graph', edge_string='--')
Return a representation in the DOT language, ready to render in graphviz.

EXAMPLES:

```python
sage: P = Poset({'a':['b'], 'b':['d'], 'c':['d'], 'd':['f'], 'e':['f'], 'f':[]})
sage: print(P.graphviz_string())
graph {
  "f" -- "e"; "d" -- "c"; "b" -- "a"; "d" -- "b"; "f" -- "d";
}
```

greene_shape()
Return the Greene-Kleitman partition of self.

The Greene-Kleitman partition of a finite poset $P$ is the partition $(c_1 - c_0, c_2 - c_1, ..., c_k - c_{k-1})$, where $c_k$ is the maximum cardinality of a union of $k$ chains of $P$. Equivalently, this is the conjugate of the partition $(a_1 - a_0, a_2 - a_1, ..., a_k - a_{k-1})$, where $a_k$ is the maximum cardinality of a union of $k$ antichains of $P$.

See many sources, e.g., [BF1999], for proofs of this equivalence.

EXAMPLES:

```python
sage: P = Poset([[3,2,1],[[3,1],[2,1]]])
sage: P.greene_shape()
[2, 1]
```
AUTHOR:
• Darij Grinberg (2013-05-09)

\texttt{gt}(x, y)

Return \texttt{True} if \(x\) is greater than but not equal to \(y\) in the poset, and \texttt{False} otherwise.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: P = Poset({0: [2], 1: [2], 2: [3], 3: [4], 4: []})
sage: P.is_greater_than(3, 1)
True
sage: P.is_greater_than(1, 2)
False
sage: P.is_greater_than(3, 3)
False
sage: P.is_greater_than(0, 1)
False
\end{verbatim}

For non-facade posets also \texttt{>} works:

\begin{verbatim}
sage: P = Poset({3: [1, 2]}, facade=False)
sage: P(2) > P(3)
True
\end{verbatim}

\textbf{See also:}

\texttt{is_gequal()}, \texttt{is_less_than()}.

\texttt{h_polynomial}()

Return the \(h\)-polynomial of a bounded poset \texttt{self}.

This is the \(h\)-polynomial of the order complex of the poset minus its bounds.

This is related to the \(f\)-polynomial by a simple change of variables:

\[
h(q) = (1 - q)^{\deg f} f \left( \frac{q}{1 - q} \right),
\]

where \(f\) and \(h\) denote the \(f\)-polynomial and the \(h\)-polynomial, respectively.

See Wikipedia article \(h\)-vector.

\textbf{Warning:}  This is slightly different from the \texttt{hPolynomial} method in Macaulay2.

\textbf{EXAMPLES:}
### sage

```python
sage: P = posets.AntichainPoset(3).order_ideals_lattice()
sage: P.h_polynomial()
q^3 + 4*q^2 + q
sage: P = posets.DiamondPoset(5)
sage: P.h_polynomial()
2*q^2 + q
sage: P = Poset({1: []})
sage: P.h_polynomial()
1
```

See also:

- `is_bounded()`, `f_polynomial()`, `order_complex()`, `sage.homology.simplicial_complex.SimplicialComplex.h_vector()`

### has_bottom()

Return True if the poset has a unique minimal element, and False otherwise.

**EXAMPLES:**

```python
sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4], 4:[]})
sage: P.has_bottom()
False
sage: Q = Poset({0:[1], 1:[]})
sage: Q.has_bottom()
True
```

See also:

- Dual Property: `has_top()`
- Stronger properties: `is_bounded()`
- Other: `bottom()`

### has_isomorphic_subposet(other)

Return True if the poset contains a subposet isomorphic to other.

By subposet we mean that there exist a set \( X \) of elements such that `self.subposet(X)` is isomorphic to other.

**INPUT:**

- `other` – a finite poset

**EXAMPLES:**

```python
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
sage: T = Poset({1:[2,3], 2:[4,5], 3:[6,7]})
sage: N5 = posets.PentagonPoset()

sage: N5.has_isomorphic_subposet(T)
False
sage: N5.has_isomorphic_subposet(D)
True

sage: len([P for P in Posets(5) if P.has_isomorphic_subposet(D)])
11
```
**has_top()**

Return `True` if the poset has a unique maximal element, and `False` otherwise.

**EXAMPLES:**

```
sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4, 5], 4:[], 5:[]})
sage: P.has_top()
False
sage: Q = Poset({0:[3], 1:[3], 2:[3], 3:[4], 4:[]})
sage: Q.has_top()
True
```

See also:

- Dual Property: `has_bottom()`
- Stronger properties: `is_bounded()`
- Other: `top()`

**hasse_diagram()**

Return the Hasse diagram of the poset as a Sage `DiGraph`.

The Hasse diagram is a directed graph where vertices are the elements of the poset and there is an edge from `u` to `v` whenever `v` covers `u` in the poset.

If `dot2tex` is installed, then this sets the Hasse diagram’s latex options to use the `dot2tex` formatting.

**EXAMPLES:**

```
sage: P = posets.DivisorLattice(12)
sage: H = P.hasse_diagram(); H
Digraph on 6 vertices
sage: P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: H.edges(labels=False)
[(1, 2), (1, 3), (2, 4), (2, 6), (3, 6), (4, 12), (6, 12)]
```

**height**

Return the height (number of elements in a longest chain) of the poset.

**INPUT:**

- `certificate` – (default: `False`) whether to return a certificate

**OUTPUT:**

- If `certificate=True` return `(h, c)`, where `h` is the height and `c` is a chain of maximum cardinality. If `certificate=False` return only the height.

**EXAMPLES:**

```
sage: P = Poset({0: [1], 2: [3, 4], 4: [5, 6]})
sage: P.height()
3
sage: posets.PentagonPoset().height(certificate=True)
(4, [0, 2, 3, 4])
```

**incidence_algebra**

Return the incidence algebra of `self` over `R`.

**OUTPUT:**

**EXAMPLES:**

```python
sage: P = posets.BooleanLattice(4)
sage: P.incidence_algebra(QQ)
Incidence algebra of Finite lattice containing 16 elements over Rational Field
```

### incomparability_graph()

Return the incomparability graph of the poset.

This is the complement of the comparability graph, i.e. an undirected graph where vertices are the elements of the poset and there is an edge between vertices if they are not comparable in the poset.

**EXAMPLES:**

```python
sage: Y = Poset({1: [2], 2: [3, 4]})
sage: g = Y.incomparability_graph(); g
Incomparability graph on 4 vertices
sage: Y.compare_elements(1, 3)
is not None
True
sage: g.has_edge(1, 3)
False
```

See also:

`comparability_graph()`

### interval(x, y)

Return a list of the elements \( z \) such that \( x \leq z \leq y \).

**INPUT:**

- \( x \) – any element of the poset
- \( y \) – any element of the poset

**EXAMPLES:**

```python
sage: uc = \[[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]\]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: P = Poset(dag)
sage: I = set(map(P,[2,5,6,4,7]))
sage: I == set(P.interval(2,7))
True
sage: dg = DiGraph({"a":["b","c"], "b":["d"], "c":["d"]})
sage: P = Poset(dg, facade = False)
sage: P.interval("a","d")
["a", "b", "c", "d"]
```

### intervals_number()

Return the number of relations in the poset.

A relation is a pair of elements \( x \) and \( y \) such that \( x \leq y \) in the poset.

Relations are also often called intervals. The number of intervals is the dimension of the incidence algebra.

**EXAMPLES:**
sage: P = posets.PentagonPoset()
sage: P.relations_number()
13
sage: posets.TamariLattice(4).relations_number()
68

See also:
relations_iterator(), relations()

intervals_poset()
Return the natural partial order on the set of intervals of the poset.

OUTPUT:

a finite poset

The poset of intervals of a poset $P$ has the set of intervals $[x, y]$ in $P$ as elements, endowed with the order relation defined by $[x_1, y_1] \leq [x_2, y_2]$ if and only if $x_1 \leq x_2$ and $y_1 \leq y_2$.

This is also called $P$ to the power 2, meaning the poset of poset-morphisms from the 2-chain to $P$.

If $P$ is a lattice, the result is also a lattice.

EXAMPLES:

sage: P = Poset({0: [1]})
sage: P.intervals_poset()
Finite poset containing 3 elements
sage: P = posets.PentagonPoset()
sage: P.intervals_poset()
Finite lattice containing 13 elements

is_EL_labelling(f, return_raising_chains=False)
Return True if $f$ is an EL labelling of self.

A labelling $f$ of the edges of the Hasse diagram of a poset is called an EL labelling (edge lexicographic labelling) if for any two elements $u$ and $v$ with $u \leq v$,

- there is a unique $f$-raising chain from $u$ to $v$ in the Hasse diagram, and this chain is lexicographically first among all chains from $u$ to $v$.

For more details, see [Bj1980].

INPUT:

- $f$ – a function taking two elements $a$ and $b$ in self such that $b$ covers $a$ and returning elements in a totally ordered set.

- return_raising_chains (optional; default:False) if True, returns the set of all raising chains in self, if possible.

EXAMPLES:

Let us consider a Boolean poset:

sage: P = Poset([[(0,0),(0,1),(1,0),(1,1)],
              [(0,0),(0,1)],
              [(0,0),(1,0)],
              [(0,1),(1,1)]], facade=True)
sage: label = lambda a,b: min( i for i in [0,1] if a[i] != b[i] )
sage: P.is_EL_labelling(label)
(continues on next page)
sage: P.is_EL_labelling(label, return_raising_chains=True)
{(0, 0), (0, 1)): [1],
((0, 0), (1, 0)): [0],
((0, 0), (1, 1)): [0, 1],
((0, 1), (1, 1)): [0],
((1, 0), (1, 1)): [1]}

is_antichain_of_poset (elms)

Return True if elms is an antichain of the poset and False otherwise.

Set of elements are an antichain of a poset if they are pairwise incomparable.

EXAMPLES:

sage: P = posets.BooleanLattice(5)
sage: P.is_antichain_of_poset([3, 5, 7])
False
sage: P.is_antichain_of_poset([3, 5, 14])
True

is_bounded ()

Return True if the poset is bounded, and False otherwise.

A poset is bounded if it contains both a unique maximal element and a unique minimal element.

EXAMPLES:

sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4, 5], 4:[], 5:[]})
sage: P.is_bounded()
False
sage: Q = posets.DiamondPoset(5)
sage: Q.is_bounded()
True

See also:

• Weaker properties: has_bottom(), has_top()

• Other: with_bounds(), without_bounds()

is_chain ()

Return True if the poset is totally ordered (“chain”), and False otherwise.

EXAMPLES:

sage: I = Poset({0:[1], 1:[2], 2:[3], 3:[4]})
sage: I.is_chain()
True
sage: II = Poset({0:[1], 2:[3]})
sage: II.is_chain()
False
sage: V = Poset({0:[1], 2})
sage: V.is_chain()
False
**is_chain_of_poset** *(elms, ordered=False)*

Return True if *elms* is a chain of the poset, and False otherwise.

Set of elements are a *chain* of a poset if they are comparable to each other.

**INPUT:**

- *elms* – a list or other iterable containing some elements of the poset
- *ordered* – a Boolean. If True, then return True only if elements in *elms* are strictly increasing in the poset; this makes no sense if *elms* is a set. If False (the default), then elements can be repeated and be in any order.

**EXAMPLES:**

```python
sage: P = Poset((divisors(12), attrcall("divides")))
sage: sorted(P.list())  
[1, 2, 3, 4, 6, 12]
sage: P.is_chain_of_poset([12, 3])
True
sage: P.is_chain_of_poset([3, 4, 12])
False
sage: P.is_chain_of_poset([12, 3], ordered=True)
False
sage: P.is_chain_of_poset((1, 1, 3))
True
sage: P.is_chain_of_poset((1, 1, 3), ordered=True)
False
sage: P.is_chain_of_poset((1, 3), ordered=True)
True
```

**is_connected()**

Return True if the poset is connected, and False otherwise.

A poset is connected if it’s Hasse diagram is connected.

If a poset is not connected, then it can be divided to parts $S_1$ and $S_2$ so that every element of $S_1$ is incomparable to every element of $S_2$.

**EXAMPLES:**

```python
sage: P = Poset({1:[2, 3], 3:[4, 5]})
sage: P.is_connected()
True
sage: P = Poset({1:[2, 3], 3:[4, 5], 6:[7, 8]})
sage: P.is_connected()
False
```

**See also:**

`connected_components()`

**is_d_complete()**

Return True if a poset is d-complete and False otherwise.

**See also:**

- `d_complete`

**EXAMPLES:**
is_eulerian \( \text{(k=None, certificate=False)} \)

Return \( \text{True} \) if the poset is Eulerian, and \( \text{False} \) otherwise.

The poset is expected to be graded and bounded.

A poset is Eulerian if every non-trivial interval has the same number of elements of even rank as of odd rank. A poset is \( k \)-eulerian if every non-trivial interval up to rank \( k \) is Eulerian.

See Wikipedia article Eulerian_poset.

INPUT:

- \( k \), an integer – only check if the poset is \( k \)-eulerian. If None (the default), check if the poset is Eulerian.
- \( \text{certificate} \), a Boolean – (default: False) whether to return a certificate

OUTPUT:

- If \( \text{certificate}=\text{True} \) return either \( \text{True} \), None or \( \text{False} \), \((a, b)\), where the interval \((a, b)\) is not Eulerian. If \( \text{certificate}=\text{False} \) return \( \text{True} \) or \( \text{False} \).

EXAMPLES:

```sage
sage: P = Poset({0: [1, 2, 3], 1: [4, 5], 2: [4, 6], 3: [5, 6],
              ....: 4: [7, 8], 5: [7, 8], 6: [7, 8], 7: [9], 8: [9]})
sage: P.is_eulerian()
True
sage: P = Poset({0: [1, 2, 3], 1: [4, 5, 6], 2: [4, 6], 3: [5, 6],
              ....: 4: [7], 5:[7], 6:[7]})
sage: P.is_eulerian()
False
```

Canonical examples of Eulerian posets are the face lattices of convex polytopes:

```sage
sage: P = polytopes.cube().face_lattice()
sage: P.is_eulerian()
True
```
A poset that is 3- but not 4-eulerian:

```
sage: P = Poset(DiGraph('MWW@_?W?@_?W?@_?W?@??O@_?W?@_?W?@??O???')); P
Finite poset containing 14 elements
sage: P.is_eulerian(k=3)
True
sage: P.is_eulerian(k=4)
False
```

Getting an interval that is not Eulerian:

```
sage: P = posets.DivisorLattice(12)
sage: P.is_eulerian(certificate=True)
(False, (1, 4))
```

`is_gequal(x, y)`

Return True if \( x \) is greater than or equal to \( y \) in the poset, and False otherwise.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_gequal(3, 1)
True
sage: P.is_gequal(2, 2)
True
sage: P.is_gequal(0, 1)
False
```

See also:

`is_greater_than()`, `is_lequal()`.

`is_graded()`

Return True if the poset is graded, and False otherwise.

A poset is graded if all its maximal chains have the same length.

There are various competing definitions for graded posets (see Wikipedia article Graded_poset). This definition is from section 3.1 of Richard Stanley’s *Enumerative Combinatorics, Vol. 1* [EnumComb1]. Some sources call these posets tiered.

Every graded poset is ranked. The converse is true for bounded posets, including lattices.

EXAMPLES:

```
sage: P = posets.PentagonPoset()  # Not even ranked
sage: P.is_graded()
False
sage: P = Poset({1:[2, 3], 3:[4]})  # Ranked, but not graded
sage: P.is_graded()
False
sage: P = Poset({1:[3, 4], 2:[3, 4], 5:[6]})
sage: P.is_graded()
True
sage: P = Poset([[1], [2], [3], [4], []])
sage: P.is_graded()
False
```
is_greater_than(x, y)

Return True if x is greater than but not equal to y in the poset, and False otherwise.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_greater_than(3, 1)
True
sage: P.is_greater_than(1, 2)
False
sage: P.is_greater_than(3, 3)
False
sage: P.is_greater_than(0, 1)
False
```

For non-facade posets also > works:

```
sage: P = Poset({3: [1, 2]}, facade=False)
sage: P(2) > P(3)
True
```

See also:

is_gequal(), is_less_than()

is_greedy(certificate=False)

Return True if the poset is greedy, and False otherwise.

A poset is greedy if every greedy linear extension has the same number of jumps.

INPUT:

• certificate – (default: False) whether to return a certificate

OUTPUT:

• If certificate=True return either (True, None) or (False, (A, B)) where A and B are greedy linear extension so that B has more jumps. If certificate=False return True or False.

EXAMPLES:

This is not a self-dual property:

```
sage: W = Poset({1: [3, 4], 2: [4, 5]})
sage: M = W.dual()
sage: W.is_greedy()
True
sage: M.is_greedy()
False
```

Getting a certificate:

```
sage: N = Poset({1: [3], 2: [3, 4]})
sage: N.is_greedy(certificate=True)
(False, ([1, 2, 4, 3], [2, 4, 1, 3]))
```
**is_incomparable_chain_free**\( (m, n=\text{None}) \)

Return *True* if the poset is \((m + n)\)-free, and *False* otherwise.

A poset is \((m + n)\)-free if there is no incomparable chains of lengths \(m\) and \(n\). Three cases have special name (see [EnumComb1], exercise 3.15):

- ‘‘interval order’’ is \((2 + 2)\)-free
- ‘‘semiorder’’ (or ‘‘unit interval order’’) is \((1 + 3)\)-free and \((2 + 2)\)-free
- ‘‘weak order’’ is \((1 + 2)\)-free.

**INPUT:**

- \(m, n\) - positive integers

It is also possible to give a list of integer pairs as argument. See below for an example.

**EXAMPLES:**

```python
sage: B3 = posets.BooleanLattice(3)
sage: B3.is_incomparable_chain_free(1, 3)
True
sage: B3.is_incomparable_chain_free(2, 2)
False
sage: IP6 = posets.IntegerPartitions(6)
sage: IP6.is_incomparable_chain_free(1, 3)
False
sage: IP6.is_incomparable_chain_free(2, 2)
True
```

A list of pairs as an argument:

```python
sage: B3.is_incomparable_chain_free([[1, 3], [2, 2]])
False
```

We show how to get an incomparable chain pair:

```python
sage: P = posets.PentagonPoset()
sage: chains_1_2 = Poset({0:[], 1:[2]})
sage: incomps = P.isomorphic_subposets(chains_1_2)[0]
sage: sorted(incomps.list()), incomps.cover_relations()
([1, 2, 3], [[2, 3]])
```

**AUTHOR:**

- Eric Rowland (2013-05-28)

**is_induced_subposet**\( (other) \)

Return *True* if the poset is an induced subposet of \(other\), and *False* otherwise.

A poset \(P\) is an induced subposet of \(Q\) if every element of \(P\) is an element of \(Q\), and \(x \leq_P y\) if \(x \leq_Q y\). Note that “induced” here has somewhat different meaning compared to that of graphs.

**INPUT:**

- \(other\), a poset.

**Note:** This method does not check whether the poset is a *isomorphic* (i.e., up to relabeling) subposet of \(other\), but only if \(other\) directly contains the poset as an induced subposet. For isomorphic subposets
see has_isomorphic_subposet().

EXAMPLES:

```
sage: P = Poset({1:[2, 3]})
sage: Q = Poset({1:[2, 4], 2:[3]})
sage: P.is_induced_subposet(Q)
False
sage: R = Poset({0:[1], 1:[3, 4], 3:[5], 4:[2]})
sage: P.is_induced_subposet(R)
True
```

**is_isomorphic** (*other, **kwds*)

Return True if both posets are isomorphic.

**EXAMPLES:**

```
sage: P = Poset(((1,2,3),[[1,3],[2,3]]))
sage: Q = Poset(((4,5,6),[[4,6],[5,6]]))
sage: P.is_isomorphic(Q)
True
```

**is_join_semilattice** (*certificate=False*)

Return True if the poset has a join operation, and False otherwise. A join is the least upper bound for given elements, if it exists.

**INPUT:**

- certificate – (default: False) whether to return a certificate

**OUTPUT:**

- If certificate=True return either (True, None) or (False, (a, b)) where elements a and b have no least upper bound. If certificate=False return True or False.

**EXAMPLES:**

```
sage: P = Poset(([[1,3,2], [4], [4,5,6], [6], [7], [7], [7], []]))
sage: P.is_join_semilattice()
True
sage: P = Poset(([[1,3,4], 2:[3, 4], 3:[5], 4:[5]]))
sage: P.is_join_semilattice()
False
sage: P.is_join_semilattice(certificate=True)
(False, (2, 1))
```

See also:

- Dual property: **is_meet_semilattice()**
- Stronger properties: **is_lattice()**

**is_jump_critical** (*certificate=False*)

Return True if the poset is jump-critical, and False otherwise. A poset $P$ is jump-critical if every proper subposet has smaller jump number.

**INPUT:**
• certificate – (default: False) whether to return a certificate

OUTPUT:

• If certificate=True return either (True, None) or (False, e) so that removing element e from the poset does not decrease the jump number. If certificate=False return True or False.

EXAMPLES:

```
sage: P = Poset({1: [3, 6], 2: [3, 4, 5], 4: [6, 7], 5: [7]})
sage: P.is_jump_critical()
True
sage: P = posets.PentagonPoset()
sage: P.is_jump_critical()
False
sage: P.is_jump_critical(certificate=True)
(False, 3)
```

See also:

`jump_number()`

`is_lequal(x, y)`

Return True if \( x \) is less than or equal to \( y \) in the poset, and False otherwise.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_lequal(2, 4)
True
sage: P.is_lequal(0, 1)
False
sage: P.is_lequal(2, 2)
False
```

See also:

`is_less_than()`, `is_gequal()`.

`is_less_than(x, y)`

Return True if \( x \) is less than but not equal to \( y \) in the poset, and False otherwise.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_less_than(1, 3)
True
sage: P.is_less_than(0, 1)
False
sage: P.is_less_than(2, 2)
False
```

For non-facade posets also < works:

```
sage: P = Poset({3: [1, 2]}, facade=False)
sage: P(1) < P(2)
False
```
See also:

is_lequal(), is_greater_than().

is_linear_extension(l)
Return whether l is a linear extension of self.

INPUT:

• l – a list (or iterable) containing all of the elements of self exactly once

EXAMPLES:

sage: P = Poset((divisors(12), attrcall("divides")), facade=True, linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: P.is_linear_extension([1, 2, 4, 3, 6, 12])
True
sage: P.is_linear_extension([1, 2, 4, 6, 3, 12])
False
sage: [p for p in Permutations(list(P)) if P.is_linear_extension(p)]
[[1, 2, 3, 4, 6, 12],
 [1, 2, 3, 6, 4, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12]]
sage: list(P.linear_extensions())
[[1, 2, 3, 4, 6, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12],
 [1, 2, 3, 6, 4, 12]]

Note: This is used and systematically tested in LinearExtensionsOfPosets

See also:

linear_extension(), linear_extensions()

is_meet_semilattice(certificate=False)
Return True if the poset has a meet operation, and False otherwise.
A meet is the greatest lower bound for given elements, if it exists.

INPUT:

• certificate – (default: False) whether to return a certificate

OUTPUT:

• If certificate=True return either (True, None) or (False, (a, b)) where elements a and b have no greatest lower bound. If certificate=False return True or False.

EXAMPLES:

sage: P = Poset({1:[2, 3, 4], 2:[5, 6], 3:[6], 4:[6, 7]})
sage: P.is_meet_semilattice()
True
sage: Q = P.dual()
sage: Q.is_meet_semilattice()
False

sage: V = posets.IntegerPartitions(5)
sage: V.is_meet_semilattice(certificate=True)
(False, ((2, 2, 1), (3, 1, 1)))

See also:

- Dual property: is_join_semilattice()
- Stronger properties: is_lattice()

is_parent_of(x)
Return True if x is an element of the poset.

is_rank_symmetric()
Return True if the poset is rank symmetric, and False otherwise.

The poset is expected to be graded and connected.

A poset of rank $h$ (maximal chains have $h + 1$ elements) is rank symmetric if the number of elements are equal in ranks $i$ and $h - i$ for every $i$ in $0, 1, \ldots, h$.

EXAMPLES:

sage: P = Poset({1:[3, 4, 5], 2:[3, 4, 5], 3:[6], 4:[7], 5:[7]})
sage: P.is_rank_symmetric()
True

sage: P = Poset({1:[2], 2:[3, 4], 3:[5], 4:[5]})
sage: P.is_rank_symmetric()
False

is_ranked()
Return True if the poset is ranked, and False otherwise.

A poset is ranked if there is a function $r$ from poset elements to integers so that $r(x) = r(y) + 1$ when $x$ covers $y$.

Informally said a ranked poset can be “levelized”: every element is on a “level”, and every cover relation goes only one level up.

EXAMPLES:

sage: P = Poset( ([1, 2, 3, 4], [[1, 2], [2, 4], [3, 4]] ) )
sage: P.is_ranked()
True

sage: P = Poset( ([1, 5], [2, 6], [3], [4], [6, 3], [4] ) )
sage: P.is_ranked()
False

See also:

rank_function(), rank(), is_graded()

is_series_parallel()
Return True if the poset is series-parallel, and False otherwise.
A poset is *series-parallel* if it can be built up from one-element posets using the operations of disjoint union and ordinal sum. This is also called *N-free* property: every poset that is not series-parallel contains a subposet isomorphic to the 4-element N-shaped poset where \( a > c, d \) and \( b > d \).

**Note:** Some papers use the term N-free for posets having no N-shaped poset as a *cover-preserving subposet*. This definition is not used here.

See Wikipedia article Series-parallel partial order.

**EXAMPLES:**

```python
sage: VA = Poset({1: [2, 3], 4: [5], 6: [5]})
sage: VA.is_series_parallel()
True
sage: big_N = Poset({1: [2, 4], 2: [3], 4:[7], 5:[6], 6:[7]})
sage: big_N.is_series_parallel()
False
```

### `is_slender(certificate=False)`

Return True if the poset is slender, and False otherwise.

A finite graded poset is *slender* if every rank 2 interval contains three or four elements, as defined in [Stan2009]. (This notion of “slender” is unrelated to the eponymous notion defined by Graetzer and Kelly in "The Free m-Lattice on the Poset \( H \)," Order 1 (1984), 47–65.)

This function does not check if the poset is graded or not. Instead it just returns True if the poset does not contain 5 distinct elements \( x, y, a, b, c \) such that \( x \ll a, b, c \ll y \) where \( \ll \) is the covering relation.

**INPUT:**

- `certificate` – (default: False) whether to return a certificate

**OUTPUT:**

- If `certificate=True` return either `(True, None)` or `(False, (a, b))` so that the interval \([a, b]\) has at least five elements. If `certificate=False` return True or False.

**EXAMPLES:**

```python
sage: P = Poset([([1, 2, 3, 4], [1, 2], [1, 3], [2, 4], [3, 4])])
sage: P.is_slender()
True
sage: P = Poset([([1,2,3,4,5],[1,2],[1,3],[1,4],[2,5],[3,5],[4,5])])
sage: P.is_slender()
False
sage: W = WeylGroup(['A', 2])
sage: G = W.bruhat_poset()
sage: G.is_slender()
True
sage: W = WeylGroup(['A', 3])
sage: G = W.bruhat_poset()
sage: G.is_slender()
True
sage: P = posets.IntegerPartitions(6)
sage: P.is_slender(certificate=True)
(False, ((6,), (3, 2, 1)))
```
is_sperner()  
Return True if the poset is Sperner, and False otherwise.

The poset is expected to be ranked.

A poset is Sperner, if no antichain is larger than the largest rank level (one of the sets of elements of the same rank) in the poset.

See Wikipedia article Sperner_property_of_a_partially_ordered_set

See also:
width(), dilworth_decomposition()

EXAMPLES:

```
sage: posets.SetPartitions(3).is_sperner()
True
sage: P = Poset({0:[3,4,5], 1:[5], 2:[5]})
sage: P.is_sperner()
False
```

isomorphic_subposets(other)  
Return a list of subposets of self isomorphic to other.

By subposet we mean self.subposet(X) which is isomorphic to other and where X is a subset of elements of self.

INPUT:

• other – a finite poset

EXAMPLES:

```
sage: C2 = Poset({0:[1]})
sage: C3 = Poset({'a':['b'], 'b':['c']})
sage: L = sorted(x.cover_relations() for x in C3.isomorphic_subposets(C2))
sage: for x in L: print(x)
[['a', 'b']]
[['a', 'c']]  
[['b', 'c']]
sage: D = Poset({1:[2,3], 2:[4, 3:[4]])
sage: N5 = posets.PentagonPoset()
sage: len(N5.isomorphic_subposets(D))
2
```

Note: If this function takes too much time, try using isomorphic_subposets_iterator().

isomorphic_subposets_iterator(other)  
Return an iterator over the subposets of self isomorphic to other.

By subposet we mean self.subposet(X) which is isomorphic to other and where X is a subset of elements of self.

INPUT:

• other – a finite poset

EXAMPLES:
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})

sage: N5 = posets.PentagonPoset()

sage: for P in N5.isomorphic_subposets_iterator(D):
....:   print(P.cover_relations())
[[0, 1], [0, 2], [1, 4], [2, 4]]
[[0, 1], [0, 3], [1, 4], [3, 4]]
[[0, 1], [0, 2], [1, 4], [2, 4]]
[[0, 1], [0, 3], [1, 4], [3, 4]]

**Warning:** This function will return same subposet as many times as there are automorphism on it. This is due to `subgraph_search_iterator()` returning labelled subgraphs. On the other hand, this function does not eat memory like `isomorphic_subposets()` does.

See also:

`sage.combinat.posets.lattices.FiniteLatticePoset.isomorphic_sublattices_iterator()`.

**jump_number** *(certificate=False)*

Return the jump number of the poset.

A *jump* in a linear extension \([e_1, \ldots, e_n]\) of a poset \(P\) is a pair \((e_i, e_{i+1})\) so that \(e_{i+1}\) does not cover \(e_i\) in \(P\). The jump number of a poset is the minimal number of jumps in linear extensions of a poset.

**INPUT:**

- `certificate` – (default: False) Whether to return a certificate

**OUTPUT:**

- If `certificate=True` return a pair \((n, l)\) where \(n\) is the jump number and \(l\) is a linear extension with \(n\) jumps. If `certificate=False` return only the jump number.

**EXAMPLES:**

```sage
sage: B3 = posets.BooleanLattice(3)
sage: B3.jump_number()
3

sage: N = Poset({1: [3, 4], 2: [3]})
sage: N.jump_number(certificate=True)
(1, [1, 4, 2, 3])
```

**ALGORITHM:**

It is known that every poset has a greedy linear extension – an extension \([e_1, e_2, \ldots, e_n]\) where every \(e_{i+1}\) is an upper cover of \(e_i\) if that is possible – with the smallest possible number of jumps; see [Sys1987].

Hence it suffices to test only those. We do that by backtracking.

The problem is proven to be NP-complete.

**See also:**

`is_jump_critical()`

**kazhdan_lusztig_polynomial** *(x=None, y=None, q=None, canonical_labels=None)*

Return the Kazhdan-Lusztig polynomial \(P_{x,y}(q)\) of the poset.

The poset is expected to be ranked.
We follow the definition given in [EPW14]. Let $G$ denote a graded poset with unique minimal and maximal elements and $\chi_G$ denote the characteristic polynomial of $G$. Let $I_x$ and $F_x$ denote the principal order ideal and filter of $x$ respectively. Define the Kazhdan-Lusztig polynomial of $G$ as the unique polynomial $P_G(q)$ satisfying the following:

1. If rank $G = 0$, then $P_G(q) = 1$.
2. If rank $G > 0$, then $\deg P_G(q) < \frac{1}{2} \text{rank } G$.
3. We have

$$q^{\text{rank } G} P_G(q^{-1}) = \sum_{x \in G} \chi_{I_x}(q) P_{F_x}(q).$$

We then extend this to $P_{x,y}(q)$ by considering the subposet corresponding to the (closed) interval $[x,y]$. We also define $P_0(q) = 0$ (so if $x \not\leq y$, then $P_{x,y}(q) = 0$).

INPUT:

- $q$ – (default: $q \in \mathbb{Z}[q]$) the indeterminate $q$
- $x$ – (default: the minimal element) the element $x$
- $y$ – (default: the maximal element) the element $y$
- canonical_labels – (optional) for subposets, use the canonical labeling (this can limit recursive calls for posets with large amounts of symmetry, but producing the labeling takes time); if not specified, this is True if $x$ and $y$ are both not specified and False otherwise

EXAMPLES:

```
sage: L = posets.BooleanLattice(3)
sage: L.kazhdan_lusztig_polynomial()
1
```

```
sage: L = posets.SymmetricGroupWeakOrderPoset(4)
sage: L.kazhdan_lusztig_polynomial()
1
sage: x = '2314'
sage: y = '3421'
sage: L.kazhdan_lusztig_polynomial(x, y)
-t + 1
```

AUTHORS:

- Travis Scrimshaw (27-12-2014)

le $(x,y)$

Return True if $x$ is less than or equal to $y$ in the poset, and False otherwise.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_lequal(2, 4)
True
sage: P.is_lequal(2, 2)
True
sage: P.is_lequal(0, 1)
False
```

(continues on next page)
sage: P.is_lequal(3, 2)
False

See also:

is_less_than(), is_gequal().

lequal_matrix (ring=Integer Ring, sparse=False)

Compute the matrix whose \((i, j)\) entry is 1 if \(\text{self.linear_extension()[i]} < \text{self.linear_extension()[j]}\) and 0 otherwise.

INPUT:

- ring – the ring of coefficients (default: \(\mathbb{Z}\))
- sparse – whether the returned matrix is sparse or not (default: True)

EXAMPLES:

sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]], facade = False)
sage: LEQM = P.lequal_matrix(); LEQM
\[
\begin{bmatrix}
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 \\
0 & 0 & 1 & 1 & 0 & 1 & 1 & 1 \\
0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1 & 1 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}
\]
sage: LEQM[1,3]
1
sage: P.linear_extension()[1] < P.linear_extension()[3]
True
sage: LEQM[2,5]
0
False

We now demonstrate the usage of the optional parameters:

sage: P.lequal_matrix(ring=QQ, sparse=False).parent()
Full MatrixSpace of 8 by 8 dense matrices over Rational Field

level_sets ()

Return elements grouped by maximal number of cover relations from a minimal element.

This returns a list of lists \(l\) such that \(l[i]\) is the set of minimal elements of the poset obtained by removing the elements in \(l[0], l[1], \ldots, l[i-1]\). (In particular, \(l[0]\) is the set of minimal elements of \(self\).)

Every level is an antichain of the poset.

EXAMPLES:

sage: P = Poset({0:[1,2],1:[3],2:[3],[3]})
sage: P.level_sets()
[[0], [1, 2], [3]]

sage: Q = Poset({0:[1,2], 1:[3], 2:[4], 3:[4]})

(continues on next page)
sage: Q.level_sets()
[[0], [1, 2], [3], [4]]

See also:
dilworth_decomposition() to return elements grouped to chains.

**lexicographic_sum**(*P*)

Return the lexicographic sum using this poset as index. In the lexicographic sum of posets $P_t$ by index poset $T$ we have $x \leq y$ if either $x \leq y$ in $P_t$ for some $t \in T$, or $x \in P_i, y \in P_j$ and $i \leq j$ in $T$.

Informally said we substitute every element of $T$ by corresponding poset $P_t$.

Mathematically, it is only defined when all $P_t$ have no common element; here we force that by giving them different names in the resulting poset.

`disjoint_union()` and `ordinal_sum()` are special cases of lexicographic sum where the index poset is an (anti)chain. `ordinal_product()` is a special case where every $P_t$ is same poset.

**INPUT:**

- *P* – dictionary whose keys are elements of this poset, values are posets

**EXAMPLES:**

```
sage: N = Poset({1: [3, 4], 2: [4]})
sage: NP = N.lexicographic_sum(P); NP
Finite poset containing 16 elements
sage: sorted(NP.minimal_elements())
[(1, 0), (2, 1), (2, 2)]
```

**linear_extension**(*linear_extension=None, check=True*)

Return a linear extension of this poset. A linear extension of a finite poset $P$ of size $n$ is a total ordering $\pi := \pi_0\pi_1...\pi_{n−1}$ of its elements such that $i < j$ whenever $\pi_i < \pi_j$ in the poset $P$.

**INPUT:**

- *linear_extension* – (default: None) a list of the elements of self
- *check* – a boolean (default: True); whether to check that linear_extension is indeed a linear extension of self.

**EXAMPLES:**

```
sage: P = Poset((divisors(15), attrcall("divides")), facade=True)
sage: P.linear_extension()
[1, 3, 5, 15]
```

Without optional argument, the default linear extension of the poset is returned, as a plain list:

```
sage: P.linear_extension()
[1, 3, 5, 15]
```

Otherwise, a full-featured linear extension is constructed as an element of `P.linear_extensions()`:
sage: l = P.linear_extension([1,5,3,15]); l
[1, 5, 3, 15]
sage: type(l)
<class 'sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset_with_category.element_class'>
sage: l.parent()
The set of all linear extensions of Finite poset containing 4 elements

By default, the linear extension is checked for correctness:

sage: l = P.linear_extension([1,3,15,5])
Traceback (most recent call last):
...  
ValueError: [1, 3, 15, 5] is not a linear extension of Finite poset containing 4 elements

This can be disabled (at your own risks!) with:

sage: P.linear_extension([1,3,15,5], check=False)
[1, 3, 15, 5]

See also:

is_linear_extension(), linear_extensions()

Todo:

• Is it acceptable to have those two features for a single method?
• In particular, we miss a short idiom to get the default linear extension

linear_extensions (facade=False)
Return the enumerated set of all the linear extensions of this poset.

INPUT:

• facade—a boolean (default: False); whether to return the linear extensions as plain lists

Warning: The facade option is not yet fully functional:

sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: L = P.linear_extensions(facade=True); L
The set of all linear extensions of Finite poset containing 6 elements
with distinguished linear extension
sage: L([1, 2, 3, 4, 6, 12])
Traceback (most recent call last):
...
TypeError: Cannot convert list to sage.structure.element.Element

EXAMPLES:

sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: L = P.linear_extensions(); L
The set of all linear extensions of Finite poset containing 6 elements with distinguished linear extension

```sage```
1 = L.an_element(); l
[1, 2, 3, 4, 6, 12]
sage: L.cardinality()
5
sage: L.list()
[[1, 2, 3, 4, 6, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12],
 [1, 2, 3, 6, 4, 12]]
```

Each element is aware that it is a linear extension of $P$:

```sage```
type(l.parent())
<class 'sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset_with_category'>
```

With `facade=True`, the elements of $L$ are plain lists instead:

```sage```
L = P.linear_extensions(facade=True)
sage: 1 = L.an_element()
sage: type(1)
<... 'list'>
```

**Warning:** In Sage <= 4.8, this function used to return a plain list of lists. To recover the previous functionality, please use:

```sage```
L = list(P.linear_extensions(facade=True)); L
[[1, 2, 3, 4, 6, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12],
 [1, 2, 3, 6, 4, 12]]
sage: type(L[0])
<... 'list'>
```

See also:

`linear_extension()`, `is_linear_extension()`

```sage```
linear_extensions_graph()
```

Return the linear extensions graph of the poset.

Vertices of the graph are linear extensions of the poset. Two vertices are connected by an edge if the linear extensions differ by only one adjacent transposition.

**EXAMPLES:**

```sage```
N = Poset({1: [3, 4], 2: [4]})
sage: G = N.linear_extensions_graph(); G
Graph on 5 vertices
sage: G.neighbors(N.linear_extension([1,2,3,4]))
[[2, 1, 3, 4], [1, 3, 2, 4], [1, 2, 4, 3]]
```

(continues on next page)
```python
sage: chevron = Poset({1: [2, 6], 2: [3], 4: [3, 5], 6: [5]})
sage: G = chevron.linear_extensions_graph(); G
Graph on 22 vertices
sage: G.size()
36
```

### list()

List the elements of the poset. This just returns the result of `linear_extension()`.

**EXAMPLES:**

```python
sage: D = Poset({ 0:[1,2], 1:[3], 2:[3,4] }, facade = False)
sage: D.list()
[0, 1, 2, 3, 4]
sage: type(D.list()[0])
<class 'sage.combinat.posets.posets.FinitePoset_with_category.element_class'>
```

### lower_covers(x)

Return the list of lower covers of the element x.

A lower cover of x is an element y such that y < x and there is no element z so that y < z < x.

**EXAMPLES:**

```python
sage: P = Poset([[1,5], [2,6], [3], [4], [], [6,3], [4]])
sage: P.lower_covers(3)
[2, 5]
sage: P.lower_covers(0)
[]
```

**See also:**

`upper_covers()`

### lower_covers_iterator(x)

Return an iterator over the lower covers of the element x.

**EXAMPLES:**

```python
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[]}))
sage: 10 = P.lower_covers_iterator(3)
sage: type(10)
<... 'generator'>
sage: next(10)
2
```

### lt(x, y)

Return `True` if x is less than but not equal to y in the poset, and `False` otherwise.

**EXAMPLES:**

```python
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_less_than(1, 3)
True
sage: P.is_less_than(0, 1)
False
sage: P.is_less_than(2, 2)
False
```
For non-facade posets also < works:

```python
sage: P = Poset({3: [1, 2]}, facade=False)
sage: P(1) < P(2)
False
```

See also:

`is_lequal().is_greater_than()`.

**maximal_antichains()**

Return the maximal antichains of the poset.

An antichain \( a \) of poset \( P \) is **maximal** if there is no element \( e \in P \setminus a \) such that \( a \cup \{e\} \) is an antichain.

**EXAMPLES**:

```python
sage: P=Poset({'a':['b', 'c'], 'b':['d','e']})
sage: [sorted(anti) for anti in P.maximal_antichains()]
[[a], [b, c], [c, d, e]]
sage: posets.PentagonPoset().maximal_antichains()
[[0], [1, 2], [1, 3], [4]]
```

See also:

`antichains().maximal_chains()`

**maximal_chains**(partial=None)

Return all maximal chains of this poset.

Each chain is listed in increasing order.

**INPUT:**

- **partial** – list (optional); if present, find all maximal chains starting with the elements in `partial`

This is used in constructing the order complex for the poset.

**EXAMPLES**:

```python
sage: P=posets.BooleanLattice(3)
sage: P.maximal_chains()
[[0, 1, 3, 7], [0, 1, 5, 7], [0, 2, 3, 7], [0, 2, 6, 7], [0, 4, 5, 7], [0, 4, 6, 7], [0, 4, 7]]
sage: P.maximal_chains(partial=[0,2])
[[0, 2, 3, 7], [0, 2, 6, 7]]
sage: Q = posets.ChainPoset(6)
sage: Q.maximal_chains()
[[0, 1, 2, 3, 4, 5]]
```

See also:

`maximal_antichains().chains()`

**maximal_elements()**

Return the list of the maximal elements of the poset.

**EXAMPLES**:

```python
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.maximal_elements()
[4]
```
See also:

minimal_elements().

**minimal_elements()**
Return the list of the minimal elements of the poset.

**EXAMPLES:**

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P(0) in P.minimal_elements()
True
sage: P(1) in P.minimal_elements()
True
sage: P(2) in P.minimal_elements()
True
```

See also:

maximal_elements().

**moebius_function** *(x, y)*
Return the value of the Möbius function of the poset on the elements x and y.

**EXAMPLES:**

```
sage: P = Poset([[1,2,3],[4],[4],[4],[7],[7],[7],[]])
sage: P.moebius_function(P(0),P(4))
2
sage: sum(P.moebius_function(P(0),v) for v in P)
0
sage: for u,v in P.cover_relations_iterator():
    if P.moebius_function(u,v) != -1:
        print("Bug in moebius_function!")
```

```
sage: Q = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: Q.moebius_function(Q(0),Q(7))
0
sage: Q.moebius_function(Q(0),Q(5))
0
sage: Q.moebius_function(Q(2),Q(7))
2
sage: Q.moebius_function(Q(3),Q(3))
1
sage: sum([Q.moebius_function(Q(0),v) for v in Q])
0
```

**moebius_function_matrix** *(ring=Integer Ring, sparse=False)*
Return a matrix whose *(i, j)* entry is the value of the Möbius function evaluated at `self.linear_extension()[i]` and `self.linear_extension()[j]`.

**INPUT:**

- `ring` – the ring of coefficients (default: ZZ)
- `sparse` – whether the returned matrix is sparse or not (default: True)

**EXAMPLES:**
```python
sage: P = Poset([[4,2,3],[1],[1],[1],[1]])
sage: x,y = (P.linear_extension()[0],P.linear_extension()[1])
sage: P.moebius_function(x,y)
-1
sage: M = P.moebius_function_matrix(); M
[ 1 -1 -1 -1 2]
[ 0 1 0 0 -1]
[ 0 0 1 0 -1]
[ 0 0 0 1 -1]
[ 0 0 0 0 1]
sage: M[0,4]
2
sage: M[0,1]
-1
```

We now demonstrate the usage of the optional parameters:

```python
sage: P.moebius_function_matrix(ring=QQ, sparse=False).parent()
Full MatrixSpace of 5 by 5 dense matrices over Rational Field
```

**open_interval** *(x, y)*

Return the list of elements *z* such that *x* < *z* < *y* in the poset.

**EXAMPLES:**

```python
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.open_interval(2, 100)
[4, 10, 20, 50]
```

See also:

`closed_interval`

**order_complex** *(on_ints=False)*

Return the order complex associated to this poset.

The order complex is the simplicial complex with vertices equal to the elements of the poset, and faces given by the chains.

**INPUT:**

- *on_ints* — a boolean (default: False)

**OUTPUT:**

an order complex of type `SimplicialComplex`

**EXAMPLES:**

```python
sage: P = posets.BooleanLattice(3)
sage: S = P.order_complex(); S
Simplicial complex with vertex set (0, 1, 2, 3, 4, 5, 6, 7) and 6 facets
sage: S.f_vector()
[1, 8, 19, 18, 6]
sage: S.homology()  # S is contractible
{0: 0, 1: 0, 2: 0, 3: 0}
sage: Q = P.subposet([1,2,3,4,5,6])
sage: Q.order_complex().homology()  # a circle
{0: 0, 1: Z}
```

(continues on next page)
sage: P = Poset((divisors(15), attrcall("divides")), facade = True)
sage: P.order_complex()
Simplicial complex with vertex set (1, 3, 5, 15) and facets {(1, 3, 15), (1, 5, 15)}

If on_ints, then the elements of the poset are labelled 0, 1, ... in the chain complex:
sage: P.order_complex(on_ints=True)
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(0, 1, 3), (0, 2, 3)}

**order_filter** *(elements)*
Return the order filter generated by the elements of an iterable elements.

$I$ is an order filter if, for any $x$ in $I$ and $y$ such that $y \geq x$, then $y$ is in $I$. This is also called upper set or upset.

**EXAMPLES:**
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.order_filter([20, 25])
[20, 40, 25, 50, 100, 200, 125, 250, 500, 1000]

See also:  
order_ideal(), principal_order_filter().

**order_ideal** *(elements)*
Return the order ideal generated by the elements of an iterable elements.

$I$ is an order ideal if, for any $x$ in $I$ and $y$ such that $y \leq x$, then $y$ is in $I$. This is also called lower set or downset.

**EXAMPLES:**
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.order_ideal([20, 25])
[1, 2, 4, 5, 10, 20, 25]

See also:  
order_filter(), principal_order_ideal().

**order_ideal_cardinality** *(elements)*
Return the cardinality of the order ideal generated by elements.

The elements $I$ is an order ideal if, for any $x \in I$ and $y$ such that $y \leq x$, then $y \in I$.

**EXAMPLES:**
sage: P = posets.BooleanLattice(4)
sage: P.order_ideal_cardinality([7,10])
10

**order_ideal_plot** *(elements)*
Return a plot of the order ideal generated by the elements of an iterable elements.

$I$ is an order ideal if, for any $x$ in $I$ and $y$ such that $y \leq x$, then $y$ is in $I$. This is also called lower set or downset.

**EXAMPLES:**
order_polynomial()  
Return the order polynomial of the poset.

The order polynomial $\Omega_P(q)$ of a poset $P$ is defined as the unique polynomial $S$ such that for each integer $m \geq 1$, $S(m)$ is the number of order-preserving maps from $P$ to $\{1, \ldots, m\}$.

See sections 3.12 and 3.15 of [EnumComb1], and also [St1986].

EXAMPLES:

```
sage: P = posets.AntichainPoset(3)
sage: P.order_polynomial()
s^3
sage: P = posets.ChainPoset(3)
sage: f = P.order_polynomial(); f
1/6*s^3 + 1/2*s^2 + 1/3*s
sage: [f(i) for i in range(4)]
[0, 1, 4, 10]
```

See also:

order_polytope()

order_polytope()  
Return the order polytope of the poset self.

The order polytope of a finite poset $P$ is defined as the subset of $\mathbb{R}^P$ consisting of all maps $x : P \to \mathbb{R}$ satisfying

$$0 \leq x(p) \leq 1 \text{ for all } p \in P,$$

and

$$x(p) \leq x(q) \text{ for all } p, q \in P \text{ satisfying } p < q.$$  

This polytope was defined and studied in [St1986].

EXAMPLES:

```
sage: P = posets.AntichainPoset(3)
sage: Q = P.order_polytope();Q
A 3-dimensional polyhedron in ZZ^3 defined as the convex hull of 8 vertices
sage: P = posets.PentagonPoset()
sage: Q = P.order_polytope();Q
A 5-dimensional polyhedron in ZZ^5 defined as the convex hull of 8 vertices
```

ordinal_product (other, labels='pairs')

Return the ordinal product of self and other.
The ordinal product of two posets $P$ and $Q$ is a partial order on the Cartesian product of the underlying sets of $P$ and $Q$, defined as follows (see [EnumComb1], p. 284).

In the ordinal product, $(p, q) \leq (p', q')$ if either $p \leq p'$ or $p = p'$ and $q \leq q'$.

This construction is not symmetric in $P$ and $Q$. Informally said we put a copy of $Q$ in place of every element of $P$.

**INPUT:**
- `other` – a poset
- `labels` – either 'integers' or 'pairs' (default); how the resulting poset will be labeled

**EXAMPLES:**

```python
sage: P1 = Poset((['a', 'b'], [['a', 'b']]))
sage: P2 = Poset(((c', 'd']), [['c', 'd']])
sage: P = P1.ordinal_product(P2); P
Finite poset containing 4 elements
sage: sorted(P.cover_relations())
[['(a', 'c'), ('a', 'd')], ['(a', 'd'), ('b', 'c')],
[['b', 'c'), ('b', 'd')]]
```

See also:
- `product()`, `ordinal_sum()`

**ordinal_sum** *(other, labels='pairs')*

Return a poset or (semi)lattice isomorphic to ordinal sum of the poset with `other`.

The ordinal sum of $P$ and $Q$ is a poset that contains every element and relation from both $P$ and $Q$, and where every element of $P$ is smaller than any element of $Q$.

Mathematically, it is only defined when $P$ and $Q$ have no common element; here we force that by giving them different names in the resulting poset.

The ordinal sum on lattices is a lattice; resp. for meet- and join-semilattices.

**INPUT:**
- `other`, a poset.
- `labels` - (defaults to 'pairs') If set to ‘pairs’, each element $v$ in this poset will be named $(0, v)$ and each element $u$ in `other` will be named $(1, u)$ in the result. If set to ‘integers’, the elements of the result will be relabeled with consecutive integers.

**EXAMPLES:**

```python
sage: P1 = Poset(([[1, 2, 3, 4], [[1, 2], [1, 3], [1, 4]])
sage: P2 = Poset(([[1, 2, 3], [[2,1], [3,1]])
sage: P3 = P1.ordinal_sum(P2); P3
Finite poset containing 7 elements
sage: len(P1.maximal_elements())*len(P2.minimal_elements())
6
sage: len(P1.cover_relations()+P2.cover_relations())
5
sage: len(P3.cover_relations())  # Every element of P2 is greater than
->elements of P1.
11
sage: P3.list()  # random
[(0, 1), (0, 2), (0, 4), (0, 3), (1, 2), (1, 3), (1, 1)]
sage: P4 = P1.ordinal_sum(P2, labels='integers')
```

(continues on next page)
Return type depends on input types:

```python
sage: P = Poset({1:[2]}); P
Finite poset containing 2 elements
sage: JL = JoinSemilattice({1:[2]}); JL
Finite join-semilattice containing 2 elements
sage: L = LatticePoset({1:[2]}); L
Finite lattice containing 2 elements
sage: P.ordinal_sum(L)
Finite poset containing 4 elements
sage: L.ordinal_sum(JL)
Finite join-semilattice containing 4 elements
sage: L.ordinal_sum(L)
Finite lattice containing 4 elements
```

See also:

- `ordinal_summands()`, `disjoint_union()`, `sage.combinat.posets.lattices.FiniteLatticePoset.vertical_composition()`

### `ordinal_summands()`

Return the ordinal summands of the poset as subposets.

The ordinal summands of a poset $P$ is the longest list of non-empty subposets $P_1, \ldots, P_n$ whose ordinal sum is $P$. This decomposition is unique.

**EXAMPLES:**

```python
sage: P = Poset({'a': ['c', 'd'], 'b': ['d'], 'c': ['x', 'y'],
             ....: 'd': ['x', 'y']})
[sage: parts = P.ordinal_summands(); parts
[Finite poset containing 4 elements, Finite poset containing 2 elements]
sage: sorted(parts[0])
['a', 'b', 'c', 'd']
sage: Q = parts[0].ordinal_sum(parts[1])
sage: Q.is_isomorphic(P)
True
```

See also:

- `ordinal_sum()`

**ALGORITHM:**

Suppose that a poset $P$ is the ordinal sum of posets $L$ and $U$. Then $P$ contains maximal antichains $l$ and $u$ such that every element of $u$ covers every element of $l$; they correspond to maximal elements of $L$ and minimal elements of $U$.

We consider a linear extension $x_1, \ldots, x_n$ of the poset’s elements.

We keep track of the maximal elements of subposet induced by elements $0, \ldots, x_i$ and minimal elements of subposet induced by elements $x_{i+1}, \ldots, x_n$, incrementing $i$ one by one. We then check if $l$ and $u$ fit the previous description.

### `p_partition_enumerator(tup, R, weights=None, check=False)`

Return a $P$-partition enumerator of `self`. 

5.1. Comprehensive Module list 1893
Given a total order $\prec$ on the elements of a finite poset $P$ (the order of $P$ and the total order $\prec$ can be unrelated; in particular, the latter does not have to extend the former), a $P$-partition enumerator is the quasisymmetric function $\sum_{f} \prod_{p \in P} x_{f(p)}$, where the first sum is taken over all $P$-partitions $f$.

A $P$-partition is a function $f : P \to \{1, 2, 3, \ldots\}$ satisfying the following properties for any two elements $i$ and $j$ of $P$ satisfying $i \prec P j$:

• if $i \prec j$ then $f(i) \leq f(j)$,
• if $j \prec i$ then $f(i) < f(j)$.

The optional argument weights allows constructing a generalized (“weighted”) version of the $P$-partition enumerator. Namely, weights should be a dictionary whose keys are the elements of $P$. Then, the generalized $P$-partition enumerator corresponding to weights weights is $\sum_{f} \prod_{p \in P} x_{w(p)}$, where the sum is again over all $P$-partitions $f$. Here, $w(p)$ is weights[p]. The classical $P$-partition enumerator is the particular case obtained when all $p$ satisfy $w(p) = 1$.

In the language of [Grinb2016a], the generalized $P$-partition enumerator is the quasisymmetric function $\Gamma(E, w)$, where $E$ is the special double poset $(P, <, \prec)$, and where $w$ is the dictionary weights (regarded as a function from $P$ to the positive integers).

INPUT:

• $tup$ – the tuple containing all elements of $P$ (each of them exactly once), in the order dictated by the total order $\prec$
• $R$ – a commutative ring
• weights – (optional) a dictionary of positive integers, indexed by elements of $P$; any missing item will be understood as 1

OUTPUT:

The $P$-partition enumerator of self according to $tup$ in the algebra $QSym$ of quasisymmetric functions over the base ring $R$.

EXAMPLES:

```
sage: P = Poset([[[1,2,3,4],[1,4],[2,4],[4,3]]])
sage: FP = P.p_partition Enumerator((3,1,2,4), QQ, check=True); FP

sage: expansion = FP.expand(5)
sage: xs = expansion.parent().gens()
sage: expansion == sum([xs[a]*xs[b]*xs[c]*xs[d] for a in range(5) for b in range(5) for c in range(5) for d in range(5) if a <= b and c <= b and b < d])
True

sage: P = Poset([[[],[]]])
sage: FP = P.p_partition Enumerator((), QQ, check=True); FP
M[]
```

With the weights parameter:

```
sage: P = Poset([[[1,2,3,4],[1,4],[2,4],[4,3]]])
sage: FP = P.p_partition Enumerator((3,1,2,4), QQ, weights={1: 1, 2: 2, 3: 1, 4: 1}, check=True); FP
sage: FP = P.p_partition Enumerator((3,1,2,4), QQ, weights={2: 2}, check=True); FP
```

(continues on next page)

sage: P = Poset([['a', 'b', 'c'], [['a', 'b'], ['a', 'c'], ['b', 'c']]])
sage: FP = P.p_partition_enumerator(('b', 'c', 'a'), QQ, weights={'a': 3, 'b': 5, 'c': 7}, check=True); FP

sage: P = Poset([['a', 'b', 'c'], [['a', 'c'], ['b', 'c']]])
sage: FP = P.p_partition_enumerator(('b', 'c', 'a'), QQ, weights={'a': 3, 'b': 5, 'c': 7}, check=True); FP

sage: FP = P.p_partition_enumerator(('a', 'b', 'c'), QQ, weights={'a': 3, 'b': 5, 'c': 7}, check=True); FP

plot (label_elements=True, element_labels=None, layout='acyclic', cover_labels=None, **kwds)

Return a Graphic object for the Hasse diagram of the poset.

If the poset is ranked, the plot uses the rank function for the heights of the elements.

INPUT:

- Options to change element look:
  - element_colors - a dictionary where keys are colors and values are lists of elements
  - element_color - a color for elements not set in element_colors
  - element_shape - the shape of elements, like 's' for square; see https://matplotlib.org/api/markers_api.html for the list
  - element_size (default: 200) - the size of elements
  - label_elements (default: True) - whether to display element labels
  - element_labels (default: None) - a dictionary where keys are elements and values are labels to show

- Options to change cover relation look:
  - cover_colors - a dictionary where keys are colors and values are lists of cover relations given as pairs of elements
  - cover_color - a color for elements not set in cover_colors
  - cover_style - style for cover relations: 'solid', 'dashed', 'dotted' or 'dashdot'
  - cover_labels - a dictionary, list or function representing labels of the covers of the poset.
  - When set to None (default) no label is displayed on the edges of the Hasse Diagram.
  - cover_labels_background - a background color for cover relations. The default is "white". To achieve a transparent background use "transparent".

- Options to change overall look:
  - figsize (default: 8) - size of the whole plot
  - title - a title for the plot
  - fontsize - fontsize for the title
  - border (default: False) - whether to draw a border over the plot

5.1. Comprehensive Module list
Note: All options of `GenericGraph.plot` are also available through this function.

EXAMPLES:

This function can be used without any parameters:

```sage
d12 = posets.DivisorLattice(12)
d12.plot()
```

Graphics object consisting of 14 graphics primitives

Just the abstract form of the poset; examples of relabeling:

```sage
d12.plot(label_elements=False)
d12.plot(element_labels=d)
d12.plot(element_labels=d)
d12.plot(element_labels=d)
d12.plot(element_labels=d)
d12.plot(element_labels=d)
```

Graphics object consisting of 8 graphics primitives

Some settings for coverings:

```sage
d = {(a, b): b/a for a, b in d12.cover_relations()}
d12.plot(cover_labels=d, cover_color='gray', cover_style='dotted')
```

Graphics object consisting of 21 graphics primitives

To emphasize some elements and show some options:

```sage
L = LatticePoset({0: [1, 2, 3, 4], 1: [2, 6, 7],
....: 3: [5, 9], 4: [5, 6, 10, 11], 5: [13],
....: 6: [12], 7: [12, 8, 9], 8: [13], 9: [13],
....: 10: [12], 11: [12], 12: [13]})
F = L.frattini_sublattice()
F_internal = [c for c in F.cover_relations() if c in L.cover_relations()]
L.plot(figsize=12, border=True, element_shape='s',
....: element_size=400, element_color='white',
....: element_colors={'blue': F, 'green': L.double_irreducibles()},
....: cover_color='lightgray', cover_colors={'black': F_internal},
....: title='The Frattini sublattice in blue', fontsize=10)
```

Graphics object consisting of 39 graphics primitives

**product**(other)

Return the Cartesian product of the poset with other.

The Cartesian (or 'direct') product of \( P \) and \( Q \) is defined by \((p, q) \leq (p', q') \) iff \( p \leq p' \) in \( P \) and \( q \leq q' \) in \( Q \).

Product of (semi)lattices are returned as a (semi)lattice.

EXAMPLES:

```sage
P = posets.ChainPoset(3)
Q = posets.ChainPoset(4)
PQ = P.product(Q) ; PQ
```

Finite lattice containing 12 elements

(continues on next page)
```python
sage: len(PQ.cover_relations())
17
sage: Q.product(P).is_isomorphic(PQ)
True

sage: P = posets.BooleanLattice(2)
sage: Q = P.product(P)
sage: Q.is_isomorphic(posets.BooleanLattice(4))
True

One can also simply use *:
```
```python
sage: P = posets.ChainPoset(2)
sage: Q = posets.ChainPoset(3)
sage: P*Q
Finite lattice containing 6 elements
```

See also:

* CartesianProductPoset, factor()

**promotion**(i=1)

Compute the (extended) promotion on the linear extension of the poset self.

INPUT:

* i – an integer between 1 and n (default: 1)

OUTPUT:

* an isomorphic poset, with the same default linear extension

The extended promotion is defined on a poset self of size n by applying the promotion operator \( \tau_1 \tau_2 \cdots \tau_{n-1} \) to the default linear extension \( \pi \) of self (see promotion()), and relabeling self accordingly. For more details see [Stan2009].

When the elements of the poset self are labelled by \{1, 2, \ldots, n\}, the linear extension is the identity, and \( i = 1 \), the above algorithm corresponds to the promotion operator on posets defined by Schützenberger as follows. Remove 1 from self and replace it by the minimum \( j \) of all labels covering 1 in the poset. Then, remove \( j \) and replace it by the minimum of all labels covering \( j \), and so on. This process ends when a label is a local maximum. Place the label \( n + 1 \) at this vertex. Finally, decrease all labels by 1.

EXAMPLES:

```python
sage: P = Poset(((1,2), [[1,2]]), linear_extension=True, facade=False)
sage: P.promotion()
Finite poset containing 2 elements with distinguished linear extension
sage: P == P.promotion()
True

sage: P = Poset(((1,2,3,4,5,6,7), [[1,2], [1,4], [2,3], [2,5], [3,6], [4,7], [5, 6]]))
sage: P.list()
[1, 2, 3, 5, 6, 4, 7]
sage: Q = P.promotion(4); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 6], [2, 3], [2, 5], [3, 7], [5, 7], [6, 4]]
```
Note that if one wants to obtain the promotion defined by Schützenberger’s algorithm directly on the poset, one needs to make sure the linear extension is the identity:

```python
sage: P = P.with_linear_extension([1, 2, 3, 4, 5, 6, 7])
sage: P.list()
[1, 2, 3, 4, 5, 6, 7]
sage: Q = P.promotion(4); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 6], [2, 3], [2, 4], [3, 5], [4, 5], [6, 7]]
sage: Q = P.promotion()
sage: Q.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 5], [3, 6], [4, 7], [5, 7]]
```

Here is an example for a poset not labelled by \{1, 2, \ldots, n\}:

```python
sage: P = Poset((divisors(30), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 5, 6, 10, 15, 30]
sage: P.cover_relations()
[[1, 2], [1, 3], [1, 5], [2, 6], [2, 10], [3, 6], [3, 15],
 [5, 10], [5, 15], [6, 30], [10, 30], [15, 30]]
sage: Q = P.promotion(4); Q
Finite poset containing 8 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 3], [1, 6], [2, 5], [2, 15], [3, 5], [3, 10],
 [5, 30], [6, 10], [6, 15], [10, 30], [15, 30]]
```

**AUTHOR:**

- Anne Schilling (2012-02-18)

**random_linear_extension()**

Return a random linear extension of the poset.

The distribution is not uniform.

**EXAMPLES:**

```python
sage: set_random_seed(0)  # results are reproducible
sage: P = posets.BooleanLattice(4)
sage: P.random_linear_extension()
[0, 2, 8, 1, 9, 4, 5, 10, 6, 12, 14, 13, 3, 7, 11, 15]
```

**random_maximal_antichain()**

Return a random maximal antichain of the poset.

The distribution is not uniform.

**EXAMPLES:**
**random_maximal_chain()**

Return a random maximal chain of the poset.

The distribution is not uniform.

EXAMPLES:

```
sage: set_random_seed(0)  # results are reproduceable
sage: P = posets.BooleanLattice(4)
sage: P.random_maximal_antichain()
[1, 8, 2, 4]
```

**random_order_ideal**(direction='down')

Return a random order ideal with uniform probability.

INPUT:

- direction – 'up', 'down' or 'antichain' (default: 'down')

OUTPUT:

A randomly selected order ideal (or order filter if direction='up', or antichain if direction='antichain') where all order ideals have equal probability of occurring.

ALGORITHM:

Uses the coupling from the past algorithm described in [Propp1997].

EXAMPLES:

```
sage: P = posets.BooleanLattice(3)
sage: P.random_order_ideal()  # random
[0, 1, 2, 3, 4, 5, 6]
sage: P.random_order_ideal(direction='up')  # random
[6, 7]
sage: P.random_order_ideal(direction='antichain')  # random
[1, 2]
sage: P = posets.TamariLattice(5)
sage: a = P.random_order_ideal('antichain')
sage: P.is_antichain_of_poset(a)  # random
True
sage: a = P.random_order_ideal('up')
sage: P.is_order_filter(a)  # random
True
sage: a = P.random_order_ideal('down')
sage: P.is_order_ideal(a)  # random
True
```

**random_subposet**(p)

Return a random subposet that contains each element with probability p.

EXAMPLES:
```
sage: P = posets.BooleanLattice(3)
sage: set_random_seed(0)  # Results are reproducible
sage: Q = P.random_subposet(0.5)
sage: Q.cover_relations()
[[0, 2], [0, 5], [2, 3], [3, 7], [5, 7]]
```

**rank (element=None)**

Return the rank of an element `element` in the poset `self`, or the rank of the poset if `element` is `None`.

(The rank of a poset is the length of the longest chain of elements of the poset. This is sometimes called the length of a poset.)

**EXAMPLES:**

```
sage: P = Poset(((1,3,2),[4],[4,5,6],[6],[7],[7],[7],[]), facade = False)
sage: P.rank(5)
2
sage: P.rank()
3
sage: Q = Poset(((1,2),[3],[],[]))
```

```
sage: P = posets.SymmetricGroupBruhatOrderPoset(4)
sage: [(v,P.rank(v)) for v in P]
[('1234', 0),
 ('1243', 1),
 ...,
 ('4312', 5),
 ('4321', 6)]
```

**rank_function()**

Return the (normalized) rank function of the poset, if it exists.

A rank function of a poset `P` is a function `r` that maps elements of `P` to integers and satisfies: `r(x) = r(y) + 1` if `x` covers `y`. The function `r` is normalized such that its minimum value on every connected component of the Hasse diagram of `P` is 0. This determines the function `r` uniquely (when it exists).

**OUTPUT:**

- a lambda function, if the poset admits a rank function
- `None`, if the poset does not admit a rank function

**EXAMPLES:**

```
sage: P = Poset(((1,2,3,4),[[1,4],[2,3],[3,4]], facade=True))
sage: P.rank_function() is not None
True
sage: P = Poset(((1,2,3,4,5),[[1,2],[2,3],[3,4],[1,5],[5,4]], facade=True))
sage: P.rank_function() is not None
False
sage: P = Poset(((1,2,3,4,5,6,7,8),[[1,4],[2,3],[3,4],[5,7],[6,7]]), facade=True)
sage: f = P.rank_function(); f is not None
True
sage: f(5)
0
sage: f(2)
0
```
**rees_product** *(other)*

Return the Rees product of *self* and *other*.

This is only defined if both posets are graded.

The underlying set is the set of pairs \((p, q)\) in the Cartesian product such that \(\text{rk}(p) \geq \text{rk}(q)\).

This operation was defined by Björner and Welker in [BjWe2005]. Other references are [MBRe2011] and [LSW2012].

**EXAMPLES:**

```
sage: B3 = posets.BooleanLattice(3)
sage: B3t = B3.subposet(list(range(1,8)))
sage: C3 = posets.ChainPoset(3)
sage: D = B3t.rees_product(C3); D
Finite poset containing 12 elements
sage: sorted(D.minimal_elements())
[(1, 0), (2, 0), (4, 0)]
sage: sorted(D.maximal_elements())
[(7, 0), (7, 1), (7, 2)]
sage: D.with_bounds().moebius_function('bottom','top')
2
```

See also:

*product*, *ordinal_product*, *star_product*

**relabel** *(relabeling=None)*

Return a copy of this poset with its elements relabeled.

**INPUT:**

- relabeling – a function, dictionary, list or tuple

The given function or dictionary must map each (non-wrapped) element of *self* to some distinct object.

The given list or tuple must be made of distinct objects.

When the input is a list or a tuple, the relabeling uses the total ordering of the elements of the poset given by `list(self)`.

If no relabeling is given, the poset is relabeled by integers from 0 to \(n - 1\) according to one of its linear extensions. This means that \(i < j\) as integers whenever \(i < j\) in the relabeled poset.

**EXAMPLES:**

Relabeling using a function:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: Q = P.relabel(lambdax: x+1)
sage: Q.list()
[2, 3, 4, 5, 7, 13]
sage: Q.cover_relations()
[[2, 3], [2, 4], [3, 5], [3, 7], [4, 7], [5, 13], [7, 13]]
```

Relabeling using a dictionary:
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True, facade=False)
sage: relabeling = {c.element:i for (i,c) in enumerate(P)}
sage: relabeling
{1: 0, 2: 1, 3: 2, 4: 3, 6: 4, 12: 5}
sage: Q = P.relabel(relabeling)
sage: Q.list()
[0, 1, 2, 3, 4, 5]
sage: Q.cover_relations()
[[0, 1], [0, 2], [1, 3], [1, 4], [2, 4], [3, 5], [4, 5]]

Mind the c.element; this is because the relabeling is applied to the elements of the poset without the wrapping. Thanks to this convention, the same relabeling function can be used both for facade or non facade posets.

Relabeling using a list:

sage: P = posets.PentagonPoset()
sage: list(P)
[0, 1, 2, 3, 4]
sage: P.cover_relations()
[[0, 1], [0, 2], [1, 4], [2, 3], [3, 4]]
sage: Q = P.relabel(list('abcde'))
sage: Q.cover_relations()
[['a', 'b'], ['a', 'c'], ['b', 'e'], ['c', 'd'], ['d', 'e']]

Default behaviour is increasing relabeling:

sage: a2 = posets.ChainPoset(2)
sage: P = a2 * a2
sage: Q = P.relabel()
sage: Q.cover_relations()
[[0, 1], [0, 2], [1, 3], [2, 3]]

Relabeling a (semi)lattice gives a (semi)lattice:

sage: P = JoinSemilattice({0: [1]})
sage: P.relabel(lambda n: n+1)
Finite join-semilattice containing 2 elements

Note: As can be seen in the above examples, the default linear extension of Q is that of P after relabeling. In particular, P and Q share the same internal Hasse diagram.

relations()
Return the list of all relations of the poset.
A relation is a pair of elements $x$ and $y$ such that $x \leq y$ in the poset.
The number of relations is the dimension of the incidence algebra.

OUTPUT:
A list of pairs (each pair is a list), where the first element of the pair is less than or equal to the second element.

EXAMPLES:
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[[]})
sage: P.relations()
[[[1, 1], [1, 2], [1, 3], [1, 4], [0, 0], [0, 2], [0, 3], [0, 4], [2, 2], [2, 3], [2, 4], [3, 3], [3, 4], [4, 4]]]

See also:
relations_number(), relations_iterator()

AUTHOR:
• Rob Beezer (2011-05-04)

relations_iterator(strict=False)
Return an iterator for all the relations of the poset.
A relation is a pair of elements \(x\) and \(y\) such that \(x \leq y\) in the poset.

INPUT:
• \texttt{strict} – a boolean (default False) if True, returns an iterator over relations \(x < y\), excluding all relations \(x \leq x\).

OUTPUT:
A generator that produces pairs (each pair is a list), where the first element of the pair is less than or equal to the second element.

EXAMPLES:
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[[]])
sage: it = P.relations_iterator()
sage: type(it)
<... 'generator'>
sage: next(it), next(it)
([1, 1], [1, 2])
sage: P = posets.PentagonPoset()
sage: list(P.relations_iterator(strict=True))
[[[0, 1], [0, 2], [0, 4], [0, 3], [1, 4], [2, 3], [2, 4], [3, 4]]]

See also:
relations_number(), relations().

AUTHOR:
• Rob Beezer (2011-05-04)

relations_number()
Return the number of relations in the poset.
A relation is a pair of elements \(x\) and \(y\) such that \(x \leq y\) in the poset.

Relations are also often called intervals. The number of intervals is the dimension of the incidence algebra.

EXAMPLES:
sage: P = posets.PentagonPoset()
sage: P.relations_number()
13

(continues on next page)
sage: posets.TamariLattice(4).relations_number()
68

See also:

relations_iterator(), relations()

show (label_elements=True, element_labels=None, cover_labels=None, **kwds)
Displays the Hasse diagram of the poset.

INPUT:

- label_elements (default: True) - whether to display element labels
- element_labels (default: None) - a dictionary of element labels
- cover_labels - a dictionary, list or function representing labels of the covers of self. When set to None (default) no label is displayed on the edges of the Hasse Diagram.

Note: This method also accepts:

- All options of GenericGraph.plot
- All options of Graphics.show

EXAMPLES:

sage: D = Poset({ 0:[1,2], 1:[3], 2:[3,4] })
sage: D.plot(label_elements=False)
Graphics object consisting of 6 graphics primitives
sage: D.show()
sage: elm_labs = {0:'a', 1:'b', 2:'c', 3:'d', 4:'e'}
sage: D.show(element_labels=elm_labs)

One more example with cover labels:

sage: P = posets.PentagonPoset()
sage: P.show(cover_labels=lambda a, b: a - b)

slant_sum(p, element, p_element)
Return the slant sum poset of posets self and p by connecting them with a cover relation (p_element, element).

Note: The element names of self and p must be distinct.

INPUT:

- p – the poset used for the slant sum
- element – the element of self that is the top of the new cover relation
- p_element – the element of p that is the bottom of the new cover relation

EXAMPLES:

sage: R = posets.RibbonPoset(5, [1,2])
sage: H = Poset([[5, 6, 7], [(5, 6), (6,7)]])
(continues on next page)
```python
sage: SS = R.slant_sum(H, 3, 7)
sage: all(cr in SS.cover_relations() for cr in R.cover_relations())
True
sage: all(cr in SS.cover_relations() for cr in H.cover_relations())
True
sage: SS.covers(7, 3)
True
```

```python
sorted(l, allow_incomparable=True, remove_duplicates=False)
```

Return the list \( l \) sorted by the poset.

**INPUT:**

- \( l \) – a list of elements of the poset
- allow_incomparable – a Boolean. If True (the default), return incomparable elements in some order; if False, raise an error if \( l \) is not a chain of the poset.
- remove_duplicates - a Boolean. If True, remove duplicates from the output list.

**EXAMPLES:**

```python
sage: P = posets.DivisorLattice(36)
sage: P.sorted([1, 4, 1, 6, 2, 12])  # Random order for 4 and 6
[1, 1, 2, 4, 6, 12]
sage: P.sorted([1, 4, 1, 6, 2, 12], remove_duplicates=True)
[1, 2, 4, 6, 12]
sage: P.sorted([1, 4, 1, 6, 2, 12], allow_incomparable=False)
Traceback (most recent call last):
  ...
ValueError: the list contains incomparable elements
```

```python
sage: P = Poset({7:[1, 5], 1:[2, 6], 5:[3], 6:[3, 4]})
sage: P.sorted([4, 1, 4, 5, 7])  # Random order for 1 and 5
[7, 1, 5, 4, 4]
sage: P.sorted([4, 1, 4, 7], remove_duplicates=True)
[7, 1, 4]
sage: P.sorted([4, 1, 4, 5, 7], allow_incomparable=False)
Traceback (most recent call last):
  ...
ValueError: the list contains incomparable elements
```

```python
spectrum(a)
```

Return the \( a \)-spectrum of this poset.

The \( a \)-spectrum in a poset \( P \) is the list of integers whose \( i \)-th position contains the number of linear extensions of \( P \) that have \( a \) in the \( i \)-th location.

**INPUT:**

- \( a \) – an element of this poset

**OUTPUT:**

The \( a \)-spectrum of this poset, returned as a list.

**EXAMPLES:**

```python
sage: P = posets.ChainPoset(5)
sage: P.spectrum(2)
```

(continues on next page)
sage: P = posets.BooleanLattice(3)
sage: P.spectrum(5)
[0, 0, 0, 4, 12, 16, 16, 0]
sage: P = posets.YoungDiagramPoset(Partition([3,2,1]))
sage: P.spectrum((0,1))
[0, 8, 6, 2, 0, 0]
sage: P = posets.AntichainPoset(4)
sage: P.spectrum(3)
[6, 6, 6, 6]

**star_product** *(other, labels='pairs')*

Return a poset isomorphic to the star product of the poset with `other`.

Both this poset and `other` are expected to be bounded and have at least two elements.

Let $P$ be a poset with top element $\top_P$ and $Q$ be a poset with bottom element $\bot_Q$. The star product of $P$ and $Q$ is the ordinal sum of $P \setminus \top_P$ and $Q \setminus \bot_Q$.

Mathematically, it is only defined when $P$ and $Q$ have no common elements; here we force that by giving them different names in the resulting poset.

**INPUT:**

- `other` – a poset.
- `labels` – (defaults to `pairs`) If set to `pairs`, each element $v$ in this poset will be named $(0, v)$ and each element $u$ in `other` will be named $(1, u)$ in the result. If set to `integers`, the elements of the result will be relabeled with consecutive integers.

**EXAMPLES:**

This is mostly used to combine two Eulerian posets to third one, and makes sense for graded posets only:

```
sage: B2 = posets.BooleanLattice(2)
sage: B3 = posets.BooleanLattice(3)
sage: P = B2.star_product(B3); P
Finite poset containing 10 elements
sage: P.is_eulerian()
True
```

We can get elements as pairs or as integers:

```
sage: ABC = Poset({'a': ['b'], 'b': ['c']})
sage: XYZ = Poset({'x': ['y'], 'y': ['z']})
sage: ABC.star_product(XYZ).list()
[(0, 'a'), (0, 'b'), (1, 'y'), (1, 'z')]
sage: sorted(ABC.star_product(XYZ, labels='integers'))
[0, 1, 2, 3]
```

**subposet** *(elements)*

Return the poset containing given elements with partial order induced by this poset.

**EXAMPLES:**
sage: P = Poset({"a": ["c", "d"], "b": ["d", "e"], "c": ["f"],
....: "d": ["f"], "e": ["f"]})
sage: Q = P.subposet(['a', 'b', 'f']); Q
Finite poset containing 3 elements
sage: Q.cover_relations()
[['b', 'f'], ['a', 'f']]

A subposet of a non-facade poset is again a non-facade poset:

sage: P = posets.PentagonPoset(facade=False)
sage: Q = P.subposet([0, 1, 2, 4])
sage: Q(1) < Q(2)
False

Return the unique maximal element of the poset, if it exists.

EXAMPLES:

sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.top() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.top()
1

See also:

has_top(), bottom()

unwrap (element)

Return the element element of the poset self in unwrapped form.

INPUT:

• element – an element of self

EXAMPLES:

sage: P = Poset((divisors(15), attrcall("divides")), facade = False)
sage: x = P.an_element(); x
1
sage: x.parent()
Finite poset containing 4 elements
sage: P.unwrap(x)
1
sage: P.unwrap(x).parent()
Integer Ring

For a non facade poset, this is equivalent to using the .element attribute:

sage: P.unwrap(x) is x.element
True

For a facade poset, this does nothing:

sage: P = Poset((divisors(15), attrcall("divides")), facade=True)
sage: x = P.an_element()
sage: P.unwrap(x) is x
True
This method is useful in code where we don’t know if $P$ is a facade poset or not.

**upper_covers** ($x$)
Return the list of upper covers of the element $x$.

An upper cover of $x$ is an element $y$ such that $x < y$ and there is no element $z$ so that $x < z < y$.

**EXAMPLES:**

```python
sage: P = Poset([[1,5], [2,6], [3], [4], [], [6,3], [4]])
sage: P.upper_covers(1)
[2, 6]
```

**See also:**
- **lower_covers()**
- **upper_covers_iterator** ($x$)

**width** (**certificate=False**)
Return the width of the poset (the size of its longest antichain).

It is computed through a matching in a bipartite graph; see Wikipedia article Dilworth%27s_theorem for more information. The width is also called Dilworth number.

**INPUT:**
- **certificate** – (default: False) whether to return a certificate

**OUTPUT:**
- If certificate=True return ($w$, $a$), where $w$ is the width of a poset and $a$ is an antichain of maximum cardinality. If certificate=False return only width of the poset.

**EXAMPLES:**

```python
sage: P = posets.BooleanLattice(4)
sage: P.width()
6
sage: w, max_achain = P.width(certificate=True)
sage: sorted(max_achain)
[3, 5, 6, 9, 10, 12]
```

**with_bounds** (**labels='bottom', 'top'**)
Return the poset with bottom and top elements adjoined.

This function adds top and bottom elements to the poset. It will always add elements, it does not check if the poset already has a bottom or a top element.

For lattices and semilattices this function returns a lattice.

**INPUT:**
- **labels** – A pair of elements to use as a bottom and top element of the poset. Default is strings 'bottom' and 'top'. Either of them can be None, and then a new bottom or top element will not be added.
EXAMPLES:

```python
sage: V = Poset({0: [1, 2]})
sage: trafficsign = V.with_bounds(); trafficsign
Finite poset containing 5 elements
sage: trafficsign.list()
['bottom', 0, 1, 2, 'top']
sage: trafficsign = V.with_bounds(labels=(-1, -2))
sage: trafficsign.cover_relations()
[[-1, 0], [0, 1], [0, 2], [1, -2], [2, -2]]
sage: Y = V.with_bounds(labels=(-1, None))
sage: Y.cover_relations()
[[-1, 0], [0, 1], [0, 2]]
sage: P = posets.PentagonPoset()  # A lattice
sage: P.with_bounds()
Finite lattice containing 7 elements
sage: P = posets.PentagonPoset(facade=False)
sage: P.with_bounds()
Finite lattice containing 7 elements
```

See also:

`without_bounds()` for the reverse operation

`with_linear_extension(linear_extension)`

Return a copy of `self` with a different default linear extension.

EXAMPLES:

```python
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: list(P)
[1, 2, 3, 4, 6, 12]
sage: Q = P.with_linear_extension([1,3,2,6,4,12])
sage: list(Q)
[1, 3, 2, 6, 4, 12]
sage: Q.cover_relations()
[[1, 3], [1, 2], [3, 6], [2, 6], [2, 4], [6, 12], [4, 12]]
```

Note: With the current implementation, this requires relabeling the internal DiGraph which is \(O(n+m)\), where \(n\) is the number of elements and \(m\) the number of cover relations.

`without_bounds()`

Return the poset without its top and bottom elements.

This is useful as an input for the method `order_complex()`.

If there is either no top or no bottom element, this raises a `TypeError`.

EXAMPLES:

```python
sage: P = posets.PentagonPoset()
sage: Q = P.without_bounds(); Q
Finite poset containing 3 elements
```
sage: Q.cover_relations()
[[2, 3]]

sage: P = posets.DiamondPoset(5)
sage: Q = P.without_bounds(); Q
Finite poset containing 3 elements
sage: Q.cover_relations()
[]

See also:

with_bounds() for the reverse operation

zeta_polynomial()

Return the zeta polynomial of the poset.

The zeta polynomial of a poset is the unique polynomial \( Z(q) \) such that for every integer \( m > 1 \), \( Z(m) \) is the number of weakly increasing sequences \( x_1 \leq x_2 \leq \cdots \leq x_{m-1} \) of elements of the poset.

The polynomial \( Z(q) \) is integral-valued, but generally does not have integer coefficients. It can be computed as

\[
Z(q) = \sum_{k \geq 1} \binom{q-2}{k-1} c_k,
\]

where \( c_k \) is the number of all chains of length \( k \) in the poset.

For more information, see section 3.12 of [EnumComb1].

In particular, \( Z(2) \) is the number of vertices and \( Z(3) \) is the number of intervals.

EXAMPLES:

sage: posets.ChainPoset(2).zeta_polynomial()
q
sage: posets.ChainPoset(3).zeta_polynomial()
1/2*q^2 + 1/2*q

sage: P = posets.PentagonPoset()
sage: P.zeta_polynomial()
1/6*q^3 + q^2 - 1/6*q

sage: P = posets.DiamondPoset(5)
sage: P.zeta_polynomial()
3/2*q^2 - 1/2*q

class sage.combinat.posets.posets.FinitePosets_n(n)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The finite enumerated set of all posets on \( n \) elements, up to an isomorphism.

EXAMPLES:

sage: P = Posets(3)
sage: P.cardinality()
5
sage: for p in P: print(p.cover_relations())
[]

(continued on next page)
cardinality (from_iterator=False)

Return the cardinality of this object.

**Note:** By default, this returns pre-computed values obtained from the On-Line Encyclopedia of Integer Sequences (OEIS sequence A000112). To override this, pass the argument from_iterator=True.

**EXAMPLES:**

```python
sage: P = Posets(3)
sage: P.cardinality()
5
sage: P.cardinality(from_iterator=True)
5
```

`sage.combinat.posets.posets.Poset` (data=None, element_labels=None, cover_relations=False, linear_extension=False, category=None, facade=None, key=None)

Construct a finite poset from various forms of input data.

**INPUT:**

- **data** – different input are accepted by this constructor:
  1. A two-element list or tuple (E, R), where E is a collection of elements of the poset and R is a collection of relations \( x \leq y \), each represented as a two-element list/tuple/iterable such as \([x, y]\). The poset is then the transitive closure of the provided relations. If `cover_relations=True`, then R is assumed to contain exactly the cover relations of the poset. If E is empty, then E is taken to be the set of elements appearing in the relations R.
  2. A two-element list or tuple (E, f), where E is the set of elements of the poset and f is a function such that, for any pair \( x, y \) of elements of E, \( f(x, y) \) returns whether \( x \leq y \). If `cover_relations=True`, then \( f(x, y) \) should instead return whether \( x \) is covered by \( y \).
  3. A dictionary of upper covers: data[x] is a list of the elements that cover the element \( x \) in the poset.
  4. A list or tuple of upper covers: data[x] is a list of the elements that cover the element \( x \) in the poset.

  If the set of elements is not a set of consecutive integers starting from zero, then:
  - every element must appear in the data, for example in its own entry.
  - data must be ordered in the same way as sorted elements.

  **Warning:** If data is a list or tuple of length 2, then it is handled by the case 2 above.

  5. An acyclic, loop-free and multi-edge free DiGraph. If `cover_relations` is True, then the edges of the digraph are assumed to correspond to the cover relations of the poset. Otherwise, the cover relations are computed.
  6. A previously constructed poset (the poset itself is returned).
• *element_labels* — (default: None); an optional list or dictionary of objects that label the poset elements.

• *cover_relations* — a boolean (default: False); whether the data can be assumed to describe a directed acyclic graph whose arrows are cover relations; otherwise, the cover relations are first computed.

• *linear_extension* — a boolean (default: False); whether to use the provided list of elements as default linear extension for the poset; otherwise a linear extension is computed. If the data is given as the pair \((E, f)\), then \(E\) is taken to be the linear extension.

• *facade* — a boolean or None (default); whether the \(\texttt{Poset()}\)’s elements should be wrapped to make them aware of the Poset they belong to.
  
  – If \(\text{facade} = \text{True}\), the \(\texttt{Poset()}\)’s elements are exactly those given as input.
  
  – If \(\text{facade} = \text{False}\), the \(\texttt{Poset()}\)’s elements will become \texttt{PosetElement} objects.
  
  – If \(\text{facade} = \text{None}\) (default) the expected behaviour is the behaviour of \(\text{facade} = \text{True}\), unless the opposite can be deduced from the context (i.e. for instance if a \(\texttt{Poset()}\) is built from another \(\texttt{Poset()}\), itself built with \(\text{facade} = \text{False}\)).

**OUTPUT:**

\(\text{FinitePoset}\) — an instance of the \texttt{FinitePoset} class.

If \texttt{category} is specified, then the poset is created in this category instead of \texttt{FinitePosets}.

**See also:**

\texttt{Posets,Posets,FinitePosets}

**EXAMPLES:**

1. Elements and cover relations:

```sage
sage: elms = [1,2,3,4,5,6,7]
sage: rels = [[1,2],[3,4],[4,5],[2,5]]
sage: Poset((elms, rels), cover_relations = True, facade = False)
Finite poset containing 7 elements
```

Elements and non-cover relations:

```sage
sage: elms = [1,2,3,4]
sage: rels = [[1,2],[1,3],[1,4],[2,3],[2,4],[3,4]]
sage: P = Poset([elms,rels],cover_relations=False); P
Finite poset containing 4 elements
sage: P.cover_relations()
[[1, 2], [2, 3], [3, 4]]
```

2. Elements and function: the standard permutations of \([1, 2, 3, 4]\) with the Bruhat order:

```sage
sage: elms = Permutations(4)
sage: fcn = lambda p,q : p.bruhat_lequal(q)
sage: Poset((elms, fcn))
Finite poset containing 24 elements
```

With a function that identifies the cover relations: the set partitions of \(\{1, 2, 3\}\) ordered by refinement:

```sage
sage: elms = SetPartitions(3)
sage: def fcn(A, B):
....:     if len(A) != len(B)+1:
....:         return False
```
....:    for a in A:
....:        if not any(set(a).issubset(b) for b in B):
....:            return False
....:    return True

sage: Poset((elms, fcn), cover_relations=True)
Finite poset containing 5 elements

3. A dictionary of upper covers:

sage: Poset({"a":["b","c"], "b":["d"], "c":["d"], "d":[]})
Finite poset containing 4 elements

4. A list of upper covers, with range(5) as set of vertices:

sage: Poset([[1,2],[4],[3],[4],[[]]])
Finite poset containing 5 elements

A list of upper covers, with letters as vertices:

sage: Poset(["a","b"],["b","c"],["c"])
Finite poset containing 3 elements

A list of upper covers and a dictionary of labels:

sage: elm_labs = {0:"a",1:"b",2:"c",3:"d",4:"e"}
sage: P = Poset([[1,2],[4],[3],[4],[[]], elm_labs, facade=False])
sage: P.list()
[a, b, c, d, e]

Warning: The special case where the argument data is a list or tuple of length 2 is handled by the case 2. So you cannot use this method to input a 2-element poset.

5. An acyclic DiGraph.

sage: dag = DiGraph({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]})
sage: Poset(dag)
Finite poset containing 6 elements

Any directed acyclic graph without loops or multiple edges, as long as cover_relations=False:

sage: dig = DiGraph({0:[2,3], 1:[3,4,5], 2:[5], 3:[5], 4:[5]})
sage: dig.allows_multiple_edges() False
sage: dig.allows_loops() False
sage: dig.transitive_reduction() == dig False
sage: Poset(dig, cover_relations=False)
Finite poset containing 6 elements
sage: Poset(dig, cover_relations=True) Traceback (most recent call last):
... ValueError: Hasse diagram is not transitively reduced

5.1. Comprehensive Module list
Default Linear extension

Every poset $P$ obtained with Poset comes equipped with a default linear extension, which is also used for enumerating its elements. By default, this linear extension is computed, and has no particular significance:

```
sage: P = Poset((divisors(12), attrcall("divides")))
sage: P.list()
[1, 2, 4, 3, 6, 12]
sage: P.linear_extension()
[1, 2, 4, 3, 6, 12]
```

You may enforce a specific linear extension using the `linear_extension` option:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: P.linear_extension()
[1, 2, 3, 4, 6, 12]
```

Depending on popular request, Poset might eventually get modified to always use the provided list of elements as default linear extension, when it is one.

See also:

`FinitePoset.linear_extensions()`

Facade posets

When `facade = False`, the elements of a poset are wrapped so as to make them aware that they belong to that poset:

```
sage: P = Poset(DiGraph({'d':[c,b],'c':[a],'b':[a]}), facade = False)
sage: d,c,b,a = list(P)
sage: a.parent() is P
True
```

This allows for comparing elements according to $P$:

```
sage: c < a
True
```

However, this may have surprising effects:

```
sage: my_elements = ['a','b','c','d']
sage: any(x in my_elements for x in P)
False
```

and can be annoying when one wants to manipulate the elements of the poset:

```
sage: a + b
Traceback (most recent call last):
  ...TypeError: unsupported operand parent(s) for +: 'Finite poset containing 4 elements' and 'Finite poset containing 4 elements'
sage: a.element + b.element
'ab'
```

By default, facade posets are constructed instead:
```python
sage: P = Poset(DiGraph({'d': ['c', 'b'], 'c': ['a'], 'b': ['a']}))
```

In this example, the elements of the poset remain plain strings:

```python
sage: d, c, b, a = list(P)
sage: type(a)
<... 'str'>
```

Of course, those strings are not aware of $P$. So to compare two such strings, one needs to query $P$:

```python
sage: a < b
True
sage: P.lt(a, b)
False
```

which models the usual mathematical notation $a <_{P} b$.

Most operations seem to still work, but at this point there is no guarantee whatsoever:

```python
sage: P.list()
['d', 'c', 'b', 'a']
sage: P.principal_order_ideal('a')
['d', 'c', 'b', 'a']
sage: P.principal_order_ideal('b')
['d', 'b']
sage: P.principal_order_ideal('d')
['d']
sage: TestSuite(P).run()
```

**Warning:** DiGraph is used to construct the poset, and the vertices of a DiGraph are converted to plain Python int's if they are Integer's:

```python
sage: G = DiGraph({0: [2, 3], 1: [3, 4], 2: [5], 3: [5], 4: [5]})
sage: type(G.vertices()[0])
<... 'int'>
```

This is worked around by systematically converting back the vertices of a poset to Integer's if they are int's:

```python
sage: P = Poset((divisors(15), attrcall("divides")), facade = False)
sage: type(P.an_element().element)
<... 'sage.rings.integer.Integer'>
sage: P = Poset((divisors(15), attrcall("divides")), facade=True)
sage: type(P.an_element())
<... 'sage.rings.integer.Integer'>
```

This may be abusive:

```python
sage: P = Poset((range(5), operator.le), facade = True)
sage: P.an_element().parent()
Integer Ring
```
### Unique representation

As most parents, `Poset` have unique representation (see `UniqueRepresentation`). Namely if two posets are created from two equal data, then they are not only equal but actually identical:

```python
sage: data1 = [[1, 2], [3], [3]]
sage: data2 = [[1, 2], [3], [3]]
sage: P1 = Poset(data1)
sage: P2 = Poset(data2)
sage: P1 == P2
True
sage: P1 is P2
True
```

In situations where this behaviour is not desired, one can use the `key` option:

```python
sage: P1 = Poset(data1, key = "foo")
sage: P2 = Poset(data2, key = "bar")
sage: P1 is P2
False
sage: P1 == P2
False
```

`key` can be any hashable value and is passed down to `UniqueRepresentation`. It is otherwise ignored by the poset constructor.

```python
sage.combinat.posets.posets.is_poset(dig)
```

Return `True` if a directed graph is acyclic and transitively reduced, and `False` otherwise.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.posets import is_poset
sage: dig = DiGraph({0:[2, 3], 1:[3, 4, 5], 2:[5], 3:[5], 4:[5]})
```

```python
sage: is_poset(dig)
False
sage: is_poset(dig.transitive_reduction())
True
```

### 5.1.188 $q$-Analogues

sage.combinat.q_analogues.gaussian_binomial (n, k, q=None, algorithm='auto')

This is an alias of `q_binomial()`.

See `q_binomial()` for the full documentation.

**EXAMPLES:**

```python
sage: gaussian_binomial(4,2)
q^4 + q^3 + 2*q^2 + q + 1
```

sage.combinat.q_analogues.gaussian_multinomial (seq, q=None, binomial_algorithm='auto')

Return the $q$-multinomial coefficient.

This is also known as the Gaussian multinomial coefficient, and is defined by

$$
\binom{n}{k_1, k_2, \ldots, k_m}_q = \frac{[n]_q!}{[k_1]_q! [k_2]_q! \cdots [k_m]_q!}
$$
where \( n = k_1 + k_2 + \cdots + k_m \).

If \( q \) is unspecified, then the variable is the generator \( q \) for a univariate polynomial ring over the integers.

**INPUT:**

- `seq` – an iterable of the values \( k_1 \) to \( k_m \) defined above
- `q` – (default: `None`) the variable \( q \); if `None`, then use a default variable in \( \mathbb{Z}[q] \)
- `binomial_algorithm` – (default: `'auto'`) the algorithm to use in \( q\text{-binomial}() \); see possible values there

**ALGORITHM:**

We use the equivalent formula

\[
\binom{k_1+\cdots+k_m}{k_1,\ldots,k_m}_q = \prod_{i=1}^{m} \left( \sum_{j=1}^{k_i} k_j \right)_q.
\]

**EXAMPLES:**

```python
sage: from sage.combinat.q_analogues import q_multinomial
sage: q_multinomial([1,2,1])
q^5 + 2*q^4 + 3*q^3 + 3*q^2 + 2*q + 1
sage: q_multinomial([1,2,1], q=1) == multinomial([1,2,1])
True
sage: q_multinomial([3,2]) == q_binomial(5,3)
True
sage: q_multinomial([])
1
```

\[ \binom{n}{k}_q = \frac{(1-q^n)(1-q^{n-1})\cdots(1-q^{n-k+1})}{(1-q)(1-q^2)\cdots(1-q^k)}. \]

See [Wikipedia article Gaussian_binomial_coefficient](https://en.wikipedia.org/wiki/Gaussian_binomial_coefficient).

If \( q \) is unspecified, then the variable is the generator \( q \) for a univariate polynomial ring over the integers.

**INPUT:**

- `n`, `k` – the values \( n \) and \( k \) defined above
- `q` – (default: `None`) the variable \( q \); if `None`, then use a default variable in \( \mathbb{Z}[q] \)
- `algorithm` – (default: `'auto'`) the algorithm to use and can be one of the following:
  - `'auto'` – automatically choose the algorithm; see the algorithm section below
  - `'naive'` – use the naive algorithm
  - `'cyclotomic'` – use cyclotomic algorithm

**ALGORITHM:**

The naive algorithm uses the product formula. The cyclotomic algorithm uses a product of cyclotomic polynomials (cf. [CH2006]).

When the algorithm is set to `'auto'`, we choose according to the following rules:
• If $q$ is a polynomial:

  When $n$ is small or $k$ is small with respect to $n$, one uses the naive algorithm. When both $n$ and $k$ are big, one uses the cyclotomic algorithm.

• If $q$ is in the symbolic ring, one uses the cyclotomic algorithm.

• Otherwise one uses the naive algorithm, unless $q$ is a root of unity, then one uses the cyclotomic algorithm.

**EXAMPLES:**

By default, the variable is the generator of $\mathbb{Z}[q]$:

```
sage: from sage.combinat.q_analogues import q_binomial
sage: g = q_binomial(5,1) ; g
q^4 + q^3 + q^2 + q + 1
sage: g.parent()
Univariate Polynomial Ring in q over Integer Ring
```

The $q$-binomial coefficient vanishes unless $0 \leq k \leq n$:

```
sage: q_binomial(4,5)
0
sage: q_binomial(5,-1)
0
```

Other variables can be used, given as third parameter:

```
sage: p = ZZ['p'].gen()
sage: q_binomial(4,2,p)
p^4 + p^3 + 2*p^2 + p + 1
```

The third parameter can also be arbitrary values:

```
sage: q_binomial(5,1,2) == g.subs(q=2)
True
sage: q_binomial(5,1,1)
5
sage: q_binomial(4,2,-1)
2
sage: q_binomial(4,2,3.14)
152.030056160000
sage: R = GF(25, 't')
sage: t = R.gen(0)
sage: q_binomial(6, 3, t)
2*t + 3
```

We can also do this for more complicated objects such as matrices or symmetric functions:

```
sage: q_binomial(4,2,matrix([[2,1],[-1,3]]))
[-6  84]
[-84  78]
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: q_binomial(4,1, s[2]*s[1])
```
REFERENCES:

AUTHORS:

• Frédéric Chapoton, David Joyner and William Stein

sage.combinat.q_analogues.q_catalan_number(n, q=None)

Return the \( q \)-Catalan number of index \( n \).

If \( q \) is unspecified, then it defaults to using the generator \( q \) for a univariate polynomial ring over the integers.

There are several \( q \)-Catalan numbers. This procedure returns the one which can be written using the \( q \)-binomial coefficients.

EXAMPLES:

```
sage: from sage.combinat.q_analogues import q_catalan_number
sage: q_catalan_number(4)
q^12 + q^10 + q^9 + 2\cdot q^8 + q^7 + 2\cdot q^6 + q^5 + 2\cdot q^4 + q^3 + q^2 + 1
sage: p = ZZ['p'].0
sage: q_catalan_number(4, p)
p^12 + p^10 + p^9 + 2\cdot p^8 + p^7 + 2\cdot p^6 + p^5 + 2\cdot p^4 + p^3 + p^2 + 1
```

The \( q \)-Catalan number of index \( n \) is only defined for \( n \) a nonnegative integer (trac ticket \#11411):

```
sage: q_catalan_number(-2)
Traceback (most recent call last):
... 
ValueError: argument (-2) must be a nonnegative integer
```

sage.combinat.q_analogues.q_factorial(n, q=None)

Return the \( q \)-analogue of the factorial \( n! \).

This is the product

\[
[1]_q \cdot [2]_q \cdots [n]_q = 1 \cdot (1 + q) \cdot (1 + q^2) \cdots (1 + q^2 + \cdots + q^{n-1}).
\]

If \( q \) is unspecified, then this function defaults to using the generator \( q \) for a univariate polynomial ring over the integers.

EXAMPLES:

```
sage: from sage.combinat.q_analogues import q_factorial
sage: q_factorial(3)
q^3 + 2\cdot q^2 + 2\cdot q + 1
sage: p = ZZ['p'].0
sage: q_factorial(3, p)
p^3 + 2\cdot p^2 + 2\cdot p + 1
```

The \( q \)-analogue of \( n! \) is only defined for \( n \) a non-negative integer (trac ticket \#11411):

```
sage: q_factorial(-2)
Traceback (most recent call last):
... 
ValueError: argument (-2) must be a nonnegative integer
```

sage.combinat.q_analogues.q_int(n, q=None)

Return the \( q \)-analogue of the integer \( n \).
The \( q \)-analogue of the integer \( n \) is given by
\[
[n]_q = \begin{cases} 
1 + q + \cdots + q^{n-1}, & \text{if } n \geq 0, \\
-q^{-n}[-n]_q, & \text{if } n \leq 0.
\end{cases}
\]
Consequently, if \( q = 1 \) then \( [n]_1 = n \) and if \( q \neq 1 \) then \( [n]_q = (q^n - 1)/(q - 1) \).

If the argument \( q \) is not specified then it defaults to the generator \( q \) of the univariate polynomial ring over the integers.

**EXAMPLES:**

```python
sage: from sage.combinat.q_analogues import q_int
sage: q_int(3)
q^2 + q + 1
sage: q_int(-3)
(-q^2 - q - 1)/q^3
sage: p = ZZ['p'].0
sage: q_int(3,p)
p^2 + p + 1
sage: q_int(3/2)
Traceback (most recent call last):
  ... ValueError: 3/2 must be an integer
```

sage.combinat.q_analogues.q_jordan\( t, q=None \)

Return the \( q \)-Jordan number of \( t \).

If \( q \) is the power of a prime number, the output is the number of complete flags in \( \mathbb{F}_q^N \) (where \( N \) is the size of \( t \)) stable under a linear nilpotent endomorphism \( f_t \) whose Jordan type is given by \( t \), i.e. such that for all \( i \):
\[
\dim(\ker f_t^i) = t[0] + \cdots + t[i-1]
\]

If \( q \) is unspecified, then it defaults to using the generator \( q \) for a univariate polynomial ring over the integers.

The result is cached.

**INPUT:**
- \( t \) – an integer partition, or an argument accepted by \( \text{Partition} \)
- \( q \) – (default: \( \text{None} \)) the variable \( q \); if \( \text{None} \), then use a default variable in \( \mathbb{Z}[q] \)

**EXAMPLES:**

```python
sage: from sage.combinat.q_analogues import q_jordan
sage: q_jordan(mu, 2) for mu in Partitions(5)]
[9765, 1029, 213, 93, 29, 9, 1]
sage: q_jordan(mu, 2) for mu in Partitions(6)]
[615195, 40635, 5643, 2331, 1491, 515, 147, 87, 47, 11, 1]
sage: q_jordan([3,2,1])
16*q^4 + 24*q^3 + 14*q^2 + 5*q + 1
sage: q_jordan([2,1], x)
2*x + 1
```

If the partition is trivial (i.e. has only one part), we get the \( q \)-factorial (in this case, the nilpotent endomorphism is necessarily 0):
AUTHOR:

- Xavier Caruso (2012-06-29)

Return the $q$-multinomial coefficient.

This is also known as the Gaussian multinomial coefficient, and is defined by

$$\binom{n}{k_1, k_2, \ldots, k_m}_q = \frac{[n]_q!}{[k_1]_q! [k_2]_q! \cdots [k_m]_q!}$$

where $n = k_1 + k_2 + \cdots + k_m$.

If $q$ is unspecified, then the variable is the generator $q$ for a univariate polynomial ring over the integers.

**INPUT:**

- `seq` – an iterable of the values $k_1$ to $k_m$ defined above
- `q` – (default: None) the variable $q$; if None, then use a default variable in $\mathbb{Z}[q]$
- `binomial_algorithm` – (default: 'auto') the algorithm to use in `q_binomial()`; see possible values there

**ALGORITHM:**

We use the equivalent formula

$$\binom{k_1 + \cdots + k_m}{k_1, \ldots, k_m}_q = \prod_{i=1}^{m} \binom{\sum_{j=1}^{i} k_j}{k_i}_q.$$

**EXAMPLES:**

```
sage: from sage.combinat.q_analogues import q_multinomial
sage: q_multinomial([1,2,1])
q^5 + 2*q^4 + 3*q^3 + 3*q^2 + 2*q + 1
sage: q_multinomial([1,2,1], q=1) == multinomial([1,2,1])
True
sage: q_multinomial((3,2)) == q_binomial(5,3)
True
sage: q_multinomial([])
1
```

Return the $q$-Pochhammer $(a; q)_n$.

The $q$-Pochhammer symbol is defined by

$$(a; q)_n = \prod_{k=0}^{n-1} (1 - aq^k)$$

with $(a; q)_0 = 1$ for all $a, q$ and $n \in \mathbb{N}$. By using the identity

$$\binom{a}{n} = \frac{(a; q)_n}{(aq^n; q)_\infty}.$$
we can extend the definition to \( n < 0 \) by

\[
(a; q)_n = \frac{1}{(aq^n; q)_n} = \prod_{k=1}^{n} \frac{1}{1 - a/q^k}.
\]

EXAMLES:

```python
sage: from sage.combinat.q_analogues import q_pochhammer
sage: q_pochhammer(3, 1/7)
6/343*q^3 - 6/49*q^2 - 6/49*q + 6/7
sage: q_pochhammer(3, 3)
-18*q^3 + 6*q^2 + 6*q - 2
sage: q_pochhammer(3, 1)
0
sage: R.<q> = ZZ[]
sage: q_pochhammer(4, q)
q^10 - q^9 - q^8 + 2*q^5 - q^2 - q + 1
sage: q_pochhammer(4, q^2)
q^14 - q^12 - q^11 - q^10 + q^8 + 2*q^7 + q^6 - q^4 - q^3 - q^2 + 1
sage: q_pochhammer(-3, q)
1/(-q^9 + q^7 + q^6 + q^5 - q^4 - q^3 - q^2 + 1)
```

REFERENCES:

- Wikipedia article Q-Pochhammer_symbol

```
sage.combinat.q_analogues.q_stirling_number1(n, k, q=None)
Return the (unsigned) q-Stirling number of the first kind.
This is a q-analogue of sage.combinat.combinat.stirling_number1().

INPUT:

- n, k – integers with 1 <= k <= n
- q – optional variable (default q)

OUTPUT: a polynomial in the variable q

These polynomials satisfy the recurrence

\[
s_{n,k} = s_{n-1,k-1} + [n - 1]_q s_{n-1,k}.
\]

EXAMPLES:

```python
sage: from sage.combinat.q_analogues import q_stirling_number1
sage: q_stirling_number1(4,2)
q^3 + 3*q^2 + 4*q + 3
sage: all(stirling_number1(6,k) == q_stirling_number1(6,k)(1)
.....: for k in range(1,7))
True
sage: x = polygen(QQ['q'],'x')
sage: S = sum(q_stirling_number1(5,k)*x**k for k in range(1, 6))
sage: factor(S)
x*(x + 1)*(x + q + 1)*(x + q^2 + q + 1)*(x + q^3 + q^2 + q + 1)
```

REFERENCES:

- [Ca1948]
• [Ca1954]

sage.combinat.q_analogues.q_stirling_number2\(n, k, q=\text{None}\)

Return the (unsigned) \(q\)-Stirling number of the second kind.

This is a \(q\)-analogue of \sage.combinat.combinat.stirling_number2().

**INPUT:**

- \(n, k\) – integers with \(1 \leq k \leq n\)
- \(q\) – optional variable (default \(q\))

**OUTPUT:** a polynomial in the variable \(q\)

These polynomials satisfy the recurrence

\[
S_{n,k} = q^{k-1}S_{n-1,k-1} + [k]qS_{n-1,k}.
\]

**EXAMPLES:**

```
sage: from sage.combinat.q_analogues import q_stirling_number2
sage: q_stirling_number2(4,2)
q^3 + 3*q^2 + 3*q
sage: all(stirling_number2(6,k) == q_stirling_number2(6,k)(1)
    ....: for k in range(7))
True
```
The formula from [Delsarte48] works as follows: Let $\lambda$ and $\mu$ be partitions. Let $(s_1, s_2, \ldots, s_l)$ and $(r_1, r_2, \ldots, r_k)$ denote the parts of the partitions conjugate to $\lambda$ and $\mu$ respectively. Let

$$\mathfrak{F}(\xi_1, \ldots, \xi_k) = \xi_1^{r_1} \xi_2^{r_2} \cdots \xi_k^{r_k} \prod_{i_1=r_1}^{r_1-1} (\xi_1 - q^{i_1}) \prod_{i_2=r_2}^{r_2-1} (\xi_2 - q^{i_2}) \cdots \prod_{i_k=r_k}^{r_k-1} (\xi_k - q^{-i_k}).$$

Then the number of subgroups of type $\mu$ in a group of type $\lambda$ is given by

$$\frac{\mathfrak{F}(q^{s_1}, q^{s_2}, \ldots, q^{s_l})}{\mathfrak{F}(q^{r_1}, q^{r_2}, \ldots, q^{r_k})}.$$

EXAMPLES:

```python
sage: from sage.combinat.q_analogues import q_subgroups_of_abelian_group
sage: q_subgroups_of_abelian_group([1,1], [1])
q + 1
sage: q_subgroups_of_abelian_group([3,3,2,1], [2,1])
q^6 + 2*q^5 + 3*q^4 + 2*q^3 + q^2
sage: R.<t> = QQ[]
sage: q_subgroups_of_abelian_group([5,3,1], [3,1], t)
t^4 + 2*t^3 + t^2
sage: q_subgroups_of_abelian_group([5,3,1], [3,1], 3)
144
sage: q_subgroups_of_abelian_group([1,1,1], [1,1]) == q_subgroups_of_abelian_group([1,1,1], [1,1])
True
sage: q_subgroups_of_abelian_group([5], [3])
1
sage: q_subgroups_of_abelian_group([1], [2])
0
sage: q_subgroups_of_abelian_group([2], [1,1])
0
```

```
sage.combinat.q_analogues.qt_catalan_number(n)
```

Return the $q, t$-Catalan number of index $n$.

EXAMPLES:

```python
sage: from sage.combinat.q_analogues import qt_catalan_number
sage: qt_catalan_number(1)
1
sage: qt_catalan_number(2)
q + t
sage: qt_catalan_number(3)
q^3 + q^2*t + q*t^2 + t^3 + q*t
sage: qt_catalan_number(4)
q^6 + q^5*t + q^4*t^2 + q^3*t^3 + q^2*t^4 + q*t^5 + t^6 + q^4*t + q^3*t^2 + q^2*t^3
```

The $q, t$-Catalan number of index $n$ is only defined for $n$ a nonnegative integer (trac ticket #11411):
\texttt{sage}: qt\_catalan\_number(-2)  
Traceback (most recent call last):  
...  
ValueError: Argument (-2) must be a nonnegative integer.

5.1.189 $q$-Bernoulli Numbers and Polynomials

\texttt{sage\_combinat.q\_bernoulli.q\_bernoulli}(m, p=None)  
Compute Carlitz’s $q$-analogue of the Bernoulli numbers.  

For every nonnegative integer $m$, the $q$-Bernoulli number $\beta_m$ is a rational function of the indeterminate $q$ whose value at $q = 1$ is the usual Bernoulli number $B_m$.

**INPUT:**

- $m$ – a nonnegative integer
- $p$ (default: \texttt{None}) – an optional value for $q$

**OUTPUT:**

A rational function of the indeterminate $q$ (if $p$ is \texttt{None})

Otherwise, the rational function is evaluated at $p$.

**EXAMPLES:**

\begin{verbatim}
sage: from sage.combinat.q_bernoulli import q_bernoulli  
sage: q_bernoulli(0)  
1  
sage: q_bernoulli(1)  
-1/(q + 1)  
sage: q_bernoulli(2)  
q/(q^3 + 2*q^2 + 2*q + 1)  
sage: all(q_bernoulli(i)(q=1) == bernoulli(i) for i in range(12))  
True
\end{verbatim}

One can evaluate the rational function by giving a second argument:

\begin{verbatim}
sage: x = PolynomialRing(GF(2),'x').gen()  
sage: q_bernoulli(5,x)  
x/(x^6 + x^5 + x + 1)
\end{verbatim}

The function does not accept negative arguments:

\begin{verbatim}
sage: q_bernoulli(-1)  
Traceback (most recent call last):  
...  
ValueError: the argument must be a nonnegative integer
\end{verbatim}

**REFERENCES:**

\texttt{sage.combinat.q\_bernoulli.q\_bernoulli\_polynomial}(m)  
Compute Carlitz’s $q$-analogue of the Bernoulli polynomials.

For every nonnegative integer $m$, the $q$-Bernoulli polynomial is a polynomial in one variable $x$ with coefficients in $\mathbb{Q}(q)$ whose value at $q = 1$ is the usual Bernoulli polynomial $B_m(x)$.  

5.1. Comprehensive Module list
The original $q$-Bernoulli polynomials introduced by Carlitz were polynomials in $q^y$ with coefficients in $\mathbb{Q}(q)$. This function returns these polynomials but expressed in the variable $x = (q^y - 1)/(q - 1)$. This allows to let $q = 1$ to recover the classical Bernoulli polynomials.

**INPUT:**

- $m$ – a nonnegative integer

**OUTPUT:**

A polynomial in one variable $x$.

**EXAMPLES:**

```sage
from sage.combinat.q_bernoulli import q_bernoulli_polynomial, q_bernoulli
sage: q_bernoulli_polynomial(0)
1
sage: q_bernoulli_polynomial(1)
(2/(q + 1))*x - 1/(q + 1)

sage: x = q_bernoulli_polynomial(1).parent().gen()

sage: all(q_bernoulli_polynomial(i)(q=1)==bernoulli_polynomial(x,i) for i in range(12))
True
sage: all(q_bernoulli_polynomial(i)(x=0)==q_bernoulli(i) for i in range(12))
True
```

The function does not accept negative arguments:

```sage
sage: q_bernoulli_polynomial(-1)
Traceback (most recent call last):
  ...
ValueError: the argument must be a nonnegative integer
```

### 5.1.190 Combinatorics quickref

**Integer Sequences:**

```sage
s = oeis([1,3,19,211]); s  # optional - internet
0: A000275: Coefficients of a Bessel function (reciprocal of J_0(z)); also pairs of...
  ...permutations with rise/rise forbidden.

sage: s[0].programs()  # optional - internet
[('maple', ...),
 ('mathematica', ...),
 ('pari',
  0: {a(n) = if( n<0, 0, n!*^2 * 4^n * polcoeff( 1 / besselj(0, x + x * O(x^(2*n)))); /* _Michael Somos_, May 17 2004 */})
```

**Combinatorial objects:**

```sage
S = Subsets([1,2,3,4]); S.list(); S.<tab>  # not tested
sage: P = Partitions(10000); P.cardinality()
3616...3156...3156504220818686058795256875406420592310556052906916435144
sage: Combinations([1,3,7]).random_element()  # random
sage: Compositions(5, max_part = 3).unrank(3)
```

(continues on next page)
\[ [2, 2, 1] \]

```python
sage: DyckWord([1,0,1,0,1,0,0]).to_binary_tree()
[., [, ., [[[., .], .]], .]]
sage: Permutation([3,1,4,2]).robinson_schensted()
[[[1, 2], [3, 4]], [[1, 3], [2, 4]]]
sage: StandardTableau([[1, 4], [2, 5], [3]]).schuetzenberger_involution()
[[[1, 3], [2, 4], [5]]]
```

Constructions and Species:

```python
sage: for (p, s) in cartesian_product([P,S]): print((p, s)) # not tested
sage: DisjointUnionEnumeratedSets(Family(lambda n: IntegerVectors(n, 3),...
˓
...NonNegativeIntegers)) # not tested
```

Words:

```python
sage: Words('abc', 4).list()
[word: aaaa, ..., word: cccc]
sage: Word('aabcaabaa').is_palindrome()
True
sage: WordMorphism('a->ab,b->a').fixed_point('a')
word: abaababaabaababaababaababaababaababaababaababaababa...
```

Polytopes:

```python
sage: points = random_matrix(ZZ, 6, 3, x=7).rows()
sage: L = LatticePolytope(points)
sage: L.npoints(); L.plot3d() # random
```

Root systems, Coxeter and Weyl groups:

```python
sage: WeylGroup(["B",3]).bruhat_poset()
Finite poset containing 48 elements
sage: RootSystem(["A",2,1]).weight_lattice().plot() # not tested
```

Crystals:

```python
sage: CrystalOfTableaux(["A",3], shape = [3,2]).some_flashy_feature() # not tested
```

Symmetric functions and combinatorial Hopf algebras:

```python
sage: Sym = SymmetricFunctions(QQ); Sym.inject_shorthands(verbos=False)
sage: m( ( h[2,1] * (1 + 3 * p[2,1]) ) + s[2](s[3]) )
3*m[1, 1, 1] + ... + 10*m[5, 1] + 4*m[6]
```

Discrete groups, Permutation groups:

```python
sage: S = SymmetricGroup(4)
sage: M = PolynomialRing(QQ, 'x0,x1,x2,x3')
sage: M.an_element() * S.an_element()
x0
```

Graph theory, posets, lattices (Graph Theory, Posets):

5.1. Comprehensive Module list
5.1.191 Rankers

`sage.combinat.ranker.from_list(l)`

Returns a ranker from the list l.

**INPUT:**
- `l` - a list

**OUTPUT:**
- `[rank, unrank]` - functions

**EXAMPLES:**

```
sage: import sage.combinat.ranker as ranker
sage: l = [1,2,3]
sage: r, u = ranker.from_list(l)
sage: r(1)
0
sage: r(3)
2
sage: u(2)
3
sage: u(0)
1
```

`sage.combinat.ranker.on_fly()`

Returns a pair of enumeration functions rank / unrank.

rank assigns on the fly an integer, starting from 0, to any object passed as argument. The object should be hashable. unrank is the inverse function; it returns None for indices that have not yet been assigned.

**EXAMPLES:**

```
sage: [rank, unrank] = sage.combinat.ranker.on_fly()
sage: rank('a')
0
sage: rank('b')
1
sage: rank('c')
2
sage: rank('a')
0
sage: unrank(3)
'd'
sage: unrank(2)
'c'
sage: unrank(3)
sage: rank('d')
3
sage: unrank(3)
'd'
```

**Todo:** add tests as in combinat::rankers
sage.combinat.ranker.rank_from_list(l)
Return a rank function for the elements of l.

INPUT:
- $l$ – a duplicate free list (or iterable) of hashable objects

OUTPUT:
- a function from the elements of $l$ to $0, \ldots, \text{len}(l)$

EXAMPLES:

```python
sage: import sage.combinat.ranker as ranker
sage: l = ['a', 'b', 'c']
sage: r = ranker.rank_from_list(l)
sage: r('a')
0
sage: r('c')
2
```

For non elements a ValueError is raised, as with the usual index method of lists:

```python
sage: r('blah')
Traceback (most recent call last):
  ... ValueError: 'blah' is not in dict
```

Currently, the rank function is a CallableDict; but this is an implementation detail:

```python
sage: type(r)
<... 'sage.misc.callable_dict.CallableDict'>
sage: r
{'a': 0, 'b': 1, 'c': 2}
```

With the current implementation, no error is issued in case of duplicate value in $l$. Instead, the rank function returns the position of some of the duplicates:

```python
sage: r = ranker.rank_from_list(['a', 'b', 'a', 'c'])
sage: r('a')
2
```

Constructing the rank function itself is of complexity $O(\text{len}(l))$. Then, each call to the rank function consists of an essentially constant time dictionary lookup.

sage.combinat.ranker.unrank(L, i)
Return the $i$-th element of $L$.

INPUT:
- $L$ – a list, tuple, finite enumerated set, ...
- $i$ – an int or Integer

The purpose of this utility is to give a uniform idiom to recover the $i$-th element of an object $L$, whether $L$ is a list, tuple (or more generally a collections.abc.Sequence), an enumerated set, some old parent of Sage still implementing unranking in the method \_\_getitem\_\_, or an iterable (see collections.abc.Iterable). See trac ticket #15919.

EXAMPLES:
Lists, tuples, and other sequences:
sage: from sage.combinat.ranker import unrank
sage: unrank(["a","b","c"], 2)
"c"
sage: unrank(["a","b","c"], 1)
"b"
sage: unrank(range(3,13,2), 1)
5

Enumerated sets:

sage: unrank(GF(7), 2)
2
sage: unrank(IntegerModRing(29), 10)
10

An iterable:

sage: unrank(NN, 4)
4

An iterator:

sage: unrank(("a{}".format(i) for i in range(20)), 0)
"a0"
sage: unrank(("a{}".format(i) for i in range(20)), 2)
"a2"

**Warning:** When unranking an iterator, it returns the \(i\)-th element beyond where it is currently at:

sage: from sage.combinat.ranker import unrank
sage: it = iter(range(20))
sage: unrank(it, 2)
2
sage: unrank(it, 2)
5

sage.combinat.ranker.unrank_from_list(l)
Returns an unrank function from a list.

**EXAMPLES:**

sage: import sage.combinat.ranker as ranker
sage: l = [1,2,3]
sage: u = ranker.unrank_from_list(l)
sage: u(2)
3
sage: u(0)
1
5.1.192 Restricted growth arrays

These combinatorial objects are in bijection with set partitions.

```python
class sage.combinat.restricted_growth.RestrictedGrowthArrays(n):
    Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

EXAMPLES:

sage: from sage.combinat.restricted_growth import RestrictedGrowthArrays
sage: R = RestrictedGrowthArrays(3)
sage: R == loads(dumps(R))
True
sage: TestSuite(R).run(skip=['_test_an_element', '....: '_test_enumerated_set_contains', '_test_some_elements'])

 cardinality()
EXAMPLES:

sage: from sage.combinat.restricted_growth import RestrictedGrowthArrays
sage: R = RestrictedGrowthArrays(6)
sage: R.cardinality()
203```

5.1.193 Ribbons

5.1.194 Ribbon Shaped Tableaux

```python
class sage.combinat.ribbon_shaped_tableau.RibbonShapedTableau(parent, t):
    Bases: sage.combinat.skew_tableau.SkewTableau

A ribbon shaped tableau.

For the purposes of this class, a ribbon shaped tableau is a skew tableau whose shape is a skew partition which:

- has at least one cell in row 1;
- has at least one cell in column 1;
- has exactly one cell in each of \( q \) consecutive diagonals, for some nonnegative integer \( q \).

A ribbon is given by a list of the rows from top to bottom.

EXAMPLES:

sage: x = RibbonShapedTableau([[None, None, None, 2, 3], [None, 1, 4, 5], [3, 2]]); x
 [[None, None, None, 2, 3], [None, 1, 4, 5], [3, 2]]
sage: x.pp()
 . . 2 3
 . 1 4 5
 3 2
sage: x.shape()
[5, 4, 2] / [3, 1]
```

The entries labeled by None correspond to the inner partition. Using None is optional; the entries will be shifted accordingly.
sage: x = RibbonShapedTableau([[2,3],[1,4,5],[3,2]]); x.pp()
 .  .  .  .  .
  2 3
  1 4 5
  3 2

height()

Return the height of self.

The height is given by the number of rows in the outer partition.

EXAMPLES:

sage: RibbonShapedTableau([[2,3],[1,4,5]]).height()
2

spin()

Return the spin of self.

EXAMPLES:

sage: RibbonShapedTableau([[2,3],[1,4,5]]).spin()
1/2

width()

Return the width of the ribbon.

This is given by the length of the longest row in the outer partition.

EXAMPLES:

sage: RibbonShapedTableau([[2,3],[1,4,5]]).width()
4
sage: RibbonShapedTableau([]).width()
0

class sage.combinat.ribbon_shaped_tableau.RibbonShapedTableaux(category=None)

Bases: sage.combinat.skew_tableau.SkewTableaux

The set of all ribbon shaped tableaux.

Element

alias of RibbonShapedTableau

from_shape_and_word(shape, word)

Return the ribbon corresponding to the given ribbon shape and word.

EXAMPLES:

sage: RibbonShapedTableaux().from_shape_and_word([1,3],[1,3,3,7])
[[None, None, 1], [3, 3, 7]]

options(*get_value, **set_value)

Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:

* ascii_art – (default: repr) Controls the ascii art output for tableaux
  - compact – minimal length ascii art
  - repr – display using the diagram string representation
- table – display as a table

- convention – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention

- display – (default: list) Controls the way in which tableaux are printed
  - array – alias for diagram
  - compact – minimal length string representation
  - diagram – display as Young diagram (similar to \textit{pp()})
  - ferrers_diagram – alias for diagram
  - list – print tableaux as lists
  - young_diagram – alias for diagram

- latex – (default: diagram) Controls the way in which tableaux are latexed
  - array – alias for diagram
  - diagram – as a Young diagram
  - ferrers_diagram – alias for diagram
  - list – as a list
  - young_diagram – alias for diagram

- notation – alternative name for convention

**Note:** Changing the convention for tableaux also changes the convention for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

**EXAMPLES:**

```sage
sage: T = Tableau([[1,2,3],[4,5]])
sage: T
[[1, 2, 3], [4, 5]]
sage: Tableaux.options.display="array"
sage: T
1 2 3
4 5
sage: Tableaux.options.convention="french"
sage: T
4 5
1 2 3
```

Changing the convention for tableaux also changes the convention for partitions and vice versa:

```sage
sage: P = Partition([3,3,1])
sage: print(P.ferrers_diagram())
*
***
***
sage: Partitions.options.convention="english"
sage: print(P.ferrers_diagram())
```

(continues on next page)
The ASCII art can also be changed:

```python
sage: t = Tableau([[1,2,3],[4,5]])
sage: ascii_art(t)
1 2 3
4 5
sage: Tableaux.options.ascii_art = "table"
sage: ascii_art(t)
+---+---+---+
| 1 | 2 | 3 |
+---+---+---+
| 4 | 5 |
+---+
sage: Tableaux.options.ascii_art = "compact"
sage: ascii_art(t)
|1|2|3|
|4|5|
sage: Tableaux.options._reset()
```

See `GlobalOptions` for more features of these options.

```python
class sage.combinat.ribbon_shaped_tableau.Ribbon_class (parent, t)
Bases: sage.combinat.ribbon_shaped_tableau.RibbonShapedTableau

This exists solely for unpickling `Ribbon_class` objects.

class sage.combinat.ribbon_shaped_tableau.StandardRibbonShapedTableaux (category=None)
Bases: sage.combinat.skew_tableau.StandardSkewTableaux

The set of all standard ribbon shaped tableaux.

INPUT:

• shape – (optional) the composition shape of the rows

Element

alias of `RibbonShapedTableau`

from_permutation(p)

Return a standard ribbon of size `len(p)` from a permutation `p`. The lengths of each row are given by the distance between the descents of the permutation `p`.

EXAMPLES:

```python
sage: import sage.combinat.ribbon_shaped_tableau as rst
sage: [StandardRibbonShapedTableaux().from_permutation(p) for p in Permutations(3)]
[[[1, 2, 3]],
 [[None, 2], [1, 3]],
 [[1, 3], [2]],
 [[None, 1], [2, 3]],
 [[1, 2], [3]],
 [[1], [2], [3]]]
```
from_shape_and_word \((shape, word)\)
Return the ribbon corresponding to the given ribbon shape and word.

EXAMPLES:

```
sage: StandardRibbonShapedTableaux().from_shape_and_word([2,3],[1,2,3,4,5])
[[None, None, 1, 2], [3, 4, 5]]
```

options \((*get_value, **set_value)\)
Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:

- ascii_art – (default: repr) Controls the ascii art output for tableaux
  - compact – minimal length ascii art
  - repr – display using the diagram string representation
  - table – display as a table
- convention – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention
- display – (default: list) Controls the way in which tableaux are printed
  - array – alias for diagram
  - compact – minimal length string representation
  - diagram – display as Young diagram (similar to \pp()\)
  - ferrers_diagram – alias for diagram
  - list – print tableaux as lists
  - young_diagram – alias for diagram
- latex – (default: diagram) Controls the way in which tableaux are latexed
  - array – alias for diagram
  - diagram – as a Young diagram
  - ferrers_diagram – alias for diagram
  - list – as a list
  - young_diagram – alias for diagram
- notation – alternative name for convention

Note: Changing the convention for tableaux also changes the convention for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:
Changing the convention for tableaux also changes the convention for partitions and vice versa:

```
sage: P = Partition([3, 3, 1])
sage: print(P.ferrers_diagram())
***
***

sage: Partitions.options.convention = "english"
sage: print(P.ferrers_diagram())
***
***
```

The ASCII art can also be changed:

```
sage: t = Tableau([[1, 2, 3], [4, 5]])
sage: ascii_art(t)
+---+---+---+
| 1 | 2 | 3 |
+---+---+---+
| 4 | 5 |
+---+---+
sage: Tableaux.options.ascii_art = "table"
sage: ascii_art(t)
+--------+
| 1 | 2 | 3 |
+--------+
| 4 | 5 |
+--------+
sage: Tableaux.options.ascii_art = "compact"
sage: ascii_art(t)
|1|2|3|
|4|5|
```

See `GlobalOptions` for more features of these options.

class sage.combinat.ribbon_shaped_tableau.StandardRibbonShapedTableaux_shape
Bases: sage.combinat.ribbon_shaped_tableau.StandardRibbonShapedTableaux

Class of standard ribbon shaped tableaux of ribbon shape `shape`.

EXAMPLES:

```
sage: StandardRibbonShapedTableaux([2, 2])
Standard ribbon shaped tableaux of shape [2, 2]
```
sage: StandardRibbonShapedTableaux([2,2]).first()
[[None, 2, 4], [1, 3]]
sage: StandardRibbonShapedTableaux([2,2]).last()
[[None, 1, 2], [3, 4]]
sage: StandardRibbonShapedTableaux([2,2]).cardinality()
5
sage: StandardRibbonShapedTableaux([2,2]).list()
[[[None, 1, 3], [2, 4]],
 [[None, 1, 2], [3, 4]],
 [[None, 2, 3], [1, 4]],
 [[None, 2, 4], [1, 3]],
 [[None, 1, 4], [2, 3]]]
sage: StandardRibbonShapedTableaux([3,2,2]).cardinality()
155

first()
Return the first standard ribbon of self.

EXAMPLES:

sage: StandardRibbonShapedTableaux([2,2]).first()
[[None, 2, 4], [1, 3]]

last()
Return the last standard ribbon of self.

EXAMPLES:

sage: StandardRibbonShapedTableaux([2,2]).last()
[[None, 1, 2], [3, 4]]

5.1.195 Ribbon Tableaux

class sage.combinat.ribbon_tableau.MultiSkewTableau(parent, *args, **kwds)
    Bases: sage.combinat.combinat.CombinatorialElement

A multi skew tableau which is a tuple of skew tableaux.

EXAMPLES:

sage: s = MultiSkewTableau([ [[[None],1],[2,3]], [[[1,2],[2]]] ])  
sage: s.size()  
6
sage: s.weight()  
[2, 3, 1]

sage: s.shape()  
[[[2, 2] / [1], [2, 1] / []]

inversion_pairs()
Return a list of the inversion pairs of self.

EXAMPLES:

sage: s = MultiSkewTableau([ [[[2,3],[5,5]], [[[1,1],[3,3]], [[[2],[6]]]]]

(continues on next page)
inversions()

Return the number of inversion pairs of self.

EXAMPLES:

```python
sage: t1 = SkewTableau([[1]])
sage: t2 = SkewTableau([[2]])
sage: MultiSkewTableau([t1,t1]).inversions() 0
dsage: MultiSkewTableau([t1,t2]).inversions() 0
dsage: MultiSkewTableau([t2,t2]).inversions() 0
dsage: MultiSkewTableau([t2,t1]).inversions() 1
dsage: s = MultiSkewTableau([ [[2,3],[5,5]], [[1,1],[3,3]], [[2],[6]] ])  
sage: s.inversions()
1
```

shape()

Return the shape of self.

EXAMPLES:

```python
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
sage: a.shape()
[[2, 2] / [1], [2, 2] / [1], [2, 2] / [1]]
```

size()

Return the size of self, which is the sum of the sizes of the skew tableaux in self.

EXAMPLES:

```python
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
sage: a.size()
9
```

weight()

Return the weight of self.

EXAMPLES:

```python
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
sage: a.weight()
[5, 3, 1]
```

```python
class sage.combinat.ribbon_tableau.MultiSkewTableaux(category=Non
```
Multiskew tableaux.

Element

alias of MultSkewTableau

class sage.combinat.ribbon_tableau.RibbonTableau(parent, st)

Bases: sage.combinat.skew_tableau.SkewTableau

A ribbon tableau.

A ribbon is a connected skew shape which does not contain any 2 × 2 boxes. A ribbon tableau is a skew tableau whose shape is partitioned into ribbons, each of which is filled with identical entries.

EXAMPLES:

```python
siclude
sage: rt = RibbonTableau([[None, 1],[2,3]]); rt
[[None, 1], [2, 3]]
sage: rt.inner_shape()
[1]
sage: rt.outer_shape()
[2, 2]
sage: rt = RibbonTableau([[None, None, 0, 0, 0], [None, 0, 0, 2], [1, 0, 1]]); rt.pp()
. . 0 0 0
. 0 0 2
1 0 1
```

In the previous example, each ribbon is uniquely determined by a non-zero entry. The 0 entries are used to fill in the rest of the skew shape.

Note: Sanity checks are not performed; lists can contain any object.

```python
siclude
sage: RibbonTableau(expr=[[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

length()

Return the length of the ribbons into a ribbon tableau.

EXAMPLES:

```python
siclude
sage: RibbonTableau([[None, 1],[2,3]]).length()
1
sage: RibbonTableau([[1,0],[2,0]]).length()
2
```

to_word()

Return a word obtained from a row reading of self.

Warning: Unlike the to_word method on skew tableaux (which are a superclass of this), this method does not filter out None entries.

EXAMPLES:
R = RibbonTableau([[0, 0, 3, 0], [1, 1, 0], [2, 0, 4]])
R.to_word()
word: 2041100030

class sage.combinat.ribbon_tableau.RibbonTableau_class(parent, st)
Bases: sage.combinat.ribbon_tableau.RibbonTableau

This exists solely for unpickling RibbonTableau_class objects.

class sage.combinat.ribbon_tableau.RibbonTableaux
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Ribbon tableaux.
A ribbon tableau is a skew tableau whose skew shape shape is tiled by ribbons of length length. The weight weight is calculated from the labels on the ribbons.

Note: Here we impose the condition that the ribbon tableaux are semistandard.

INPUT (Optional):
• shape – skew shape as a list of lists or an object of type SkewPartition
• length – integer, shape is partitioned into ribbons of length length
• weight – list of integers, computed from the values of non-zero entries labeling the ribbons

EXAMPLES:

sage: RibbonTableaux([[2,1],[]], [1,1,1], 1)
Ribbon tableaux of shape [2, 1] / [] and weight [1, 1, 1] with 1-ribbons
sage: R = RibbonTableaux([[5,4,3],[2,1]], [2,1], 3)
sage: for i in R: i.pp(); print("\n")
 . . 0 0 0
 . 0 0 2
 1 0 1
 . . 1 0 0
 . 0 0 0
 1 0 2
 . . 0 0 0
 . 1 0 1
 2 0 0

REFERENCES:

Element
alias of RibbonTableau

from_expr (l)
Return a RibbonTableau from a MuPAD-Combinat expr for a skew tableau. The first list in expr is the inner shape of the skew tableau. The second list are the entries in the rows of the skew tableau from bottom to top.

Provided primarily for compatibility with MuPAD-Combinat.

EXAMPLES:
RibbonTableaux().from_expr([[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]

options(*get_value, **set_value)
Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:
- ascii_art – (default: repr) Controls the ascii art output for tableaux
  - compact – minimal length ascii art
  - repr – display using the diagram string representation
  - table – display as a table
- convention – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention
- display – (default: list) Controls the way in which tableaux are printed
  - array – alias for diagram
  - compact – minimal length string representation
  - diagram – display as Young diagram (similar to pp())
  - ferrers_diagram – alias for diagram
  - list – print tableaux as lists
  - young_diagram – alias for diagram
- latex – (default: diagram) Controls the way in which tableaux are latexed
  - array – alias for diagram
  - diagram – as a Young diagram
  - ferrers_diagram – alias for diagram
  - list – as a list
  - young_diagram – alias for diagram
- notation – alternative name for convention

Note: Changing the convention for tableaux also changes the convention for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:

```python
sage: T = Tableau([[1,2,3],[4,5]])
sage: T
[[1, 2, 3], [4, 5]]
sage: Tableaux.options.display="array"
sage: T
1 2 3
4 5
```
Changing the convention for tableaux also changes the convention for partitions and vice versa:

```
sage: P = Partition([3,3,1])
sage: print(P.ferrers_diagram())
***
***
sage: Partitions.options.convention="english"
sage: print(P.ferrers_diagram())
***
***
sage: T
1 2 3
4 5
```

The ASCII art can also be changed:

```
sage: t = Tableau([[1,2,3],[4,5]])
sage: ascii_art(t)
 1 2 3
 4 5
sage: Tableaux.options.ascii_art = "table"
sage: ascii_art(t)
+---+---+---+
| 1 | 2 | 3 |
+---+---+---+
| 4 | 5 |
+---+---+
sage: Tableaux.options.ascii_art = "compact"
sage: ascii_art(t)
|1|2|3|
|4|5|
sage: Tableaux.options._reset()
```

See `GlobalOptions` for more features of these options.

```
class sage.combinat.ribbon_tableau.RibbonTableaux_shape_weight_length(shape, weight, length)

Bases: sage.combinat.ribbon_tableau.RibbonTableaux

Ribbon tableaux of a given shape, weight, and length.

cardinality()
Return the cardinality of self.

EXAMPLES:

```
sage: RibbonTableaux([[2,1],[]],[1,1,1,1]).cardinality()
2
sage: RibbonTableaux([[2,2],[]],[1,1,2]).cardinality()
2
```
```
class sage.combinat.ribbon_tableau.SemistandardMultiSkewTableaux(shape, weight)

Semistandard multi skew tableaux.

A multi skew tableau is a $k$-tuple of skew tableaux of given shape with a specified total weight.

EXAMPLES:

```python
sage: S = SemistandardMultiSkewTableaux([[2,1],[2,2]], [2,2,2]); S
Semistandard multi skew tableaux of shape [[2, 1], [2, 2]] and weight [2, 2, 2]
sage: S.list()
[[[[1, 1], [2]], [[None, 2], [3, 3]]],
 [[[1, 2], [2]], [[None, 1], [3, 3]]],
 [[[1, 3], [2]], [[None, 2], [1, 3]]],
 [[[1, 3], [2]], [[None, 1], [2, 3]]],
 [[[1, 2], [3]], [[None, 1], [2, 3]]],
 [[[1, 2], [3]], [[None, 1], [2, 3]]],
 [[[2, 2], [3]], [[None, 1], [1, 3]]],
 [[[2, 3], [3]], [[None, 1], [2, 2]]],
 [[[2, 3], [3]], [[None, 1], [1, 2]]]]
```

sage.combinat.ribbon_tableau.cospin_polynomial(part, weight, length)

Return the cospin polynomial associated to part, weight, and length.

EXAMPLES:

```python
sage: from sage.combinat.ribbon_tableau import cospin_polynomial
sage: cospin_polynomial([6,6,6],[4,2],3)
t^4 + t^3 + 2*t^2 + t + 1
sage: cospin_polynomial([3,3,3,2,1], [3,1], 3)
sage: cospin_polynomial([3,3,3,2,1], [2,2], 3)
t + 1
sage: cospin_polynomial([3,3,3,2,1], [2,1,1], 3)
t^2 + 2*t + 2
sage: cospin_polynomial([3,3,3,2,1], [1,1,1,1], 3)
t^3 + 3*t^2 + 5*t + 3
sage: cospin_polynomial([5,4,3,2,1,1], [2,2,1], 3)
2*t^2 + 6*t + 2
sage: cospin_polynomial([[6]*6, [3,3]], [4,4,2], 3)
3*t^4 + 6*t^3 + 9*t^2 + 5*t + 3
```

sage.combinat.ribbon_tableau.count_rec(nexts, current, part, weight, length)

INPUT:

- `nexts`, `current`, `part` - skew partitions
- `weight` - non-negative integer list
- `length` - integer

sage.combinat.ribbon_tableau.graph_implementation_rec(skp, weight, length, function)
sage.combinatribbon_tableau.insertion_tableau\((skp, perm, evaluation, tableau, length)\)

**INPUT:**

- `skp` - skew partitions
- `perm`, `evaluation` - non-negative integers
- `tableau` - skew tableau
- `length` - integer

sage.combinat.ribbon_tableau.list_rec\((nexts, current, part, weight, length)\)

**INPUT:**

- `nexts, current, part` - skew partitions
- `weight` - non-negative integer list
- `length` - integer

sage.combinat.ribbon_tableau.spin_polynomial\((part, weight, length)\)

Returns the spin polynomial associated to `part`, `weight`, and `length`.

**EXAMPLES:**

```
sage: from sage.combinat.ribbon_tableau import spin_polynomial
sage: spin_polynomial([6,6,6],[4,2],3)
t^6 + t^5 + 2*t^4 + t^3 + t^2
sage: spin_polynomial([6,6,6],[4,1,1],3)
t^6 + 2*t^5 + 3*t^4 + 2*t^3 + t^2
sage: spin_polynomial([[3,3,3,2,1], [2,2], 3)
t^(7/2) + t^(5/2)
sage: spin_polynomial([[3,3,3,2,1], [2,1,1], 3)
2*t^(7/2) + 2*t^(5/2) + t^(3/2)
sage: spin_polynomial([[3,3,3,2,1], [1,1,1,1], 3)
3*t^(7/2) + 5*t^(5/2) + 3*t^(3/2) + sqrt(t)
sage: spin_polynomial([[5,4,3,2,1,1,1], [2,2,1], 3)
2*t^(9/2) + 6*t^(7/2) + 2*t^(5/2)
sage: spin_polynomial([[6]*6, [3,3]], [4,4,2], 3)
3*t^9 + 5*t^8 + 9*t^7 + 6*t^6 + 3*t^5
```

sage.combinat.ribbon_tableau.spin_polynomial_square\((part, weight, length)\)

Returns the spin polynomial associated with `part`, `weight`, and `length`, with the substitution $t \to t^2$ made.

**EXAMPLES:**

```
sage: from sage.combinat.ribbon_tableau import spin_polynomial_square
sage: spin_polynomial_square([6,6,6],[4,2],3)
t^12 + t^10 + 2*t^8 + t^6 + t^4
sage: spin_polynomial_square([6,6,6],[4,1,1],3)
t^12 + 2*t^10 + 3*t^8 + 2*t^6 + t^4
sage: spin_polynomial_square([[3,3,3,2,1], [2,2], 3)
t^7 + t^5
sage: spin_polynomial_square([[3,3,3,2,1], [2,1,1], 3)
2*t^7 + 2*t^5 + t^3
sage: spin_polynomial_square([[3,3,3,2,1], [1,1,1,1], 3)
3*t^7 + 5*t^5 + 3*t^3 + t
sage: spin_polynomial_square([[5,4,3,2,1,1,1], [2,2,1], 3)
2*t^9 + 6*t^7 + 2*t^5
sage: spin_polynomial_square([[6]*6, [3,3]], [4,4,2], 3)
3*t^18 + 5*t^16 + 9*t^14 + 6*t^12 + 3*t^10
```
sage.combinat.ribbon_tableau.spin_rec(t, nexts, current, part, weight, length)
Routine used for constructing the spin polynomial.

INPUT:
- weight – list of non-negative integers
- length – the length of the ribbons we’re tiling with
- t – the variable

EXAMPLES:

```sage
def spin_rec(t, nexts, current, part, weight, length):
    if current == part or not weight:
        return 1
    result = 0
    for i in range(length):
        next = nexts[current][i]
        result += spin_rec(t, nexts[current][i], next, current + 1, weight, length)
    return weight[0] * result
```

5.1.196 Rigged Configurations

Todo: Proofread / point to the main classes rather than the modules?

- Crystal of Rigged Configurations
- Rigged Configurations of \( \mathcal{B}(\infty) \)
- Rigged Configurations
- Rigged Configuration Elements
- Tensor Product of Kirillov-Reshetikhin Tableaux
- Tensor Product of Kirillov-Reshetikhin Tableaux Elements

  - Bijection classes for type $A_{2n}^{(2)}$
  - Bijection classes for type $A_{2n}^{(2),\dagger}$
  - Bijection classes for type $D_{n+1}^{(2)}$
  - Bijection classes for type $D_4^{(3)}$
- Bijection between rigged configurations for $B(\infty)$ and marginally large tableaux

5.1.197 Features that are imported by default in the interpreter namespace

5.1.198 Abstract classes for the rigged configuration bijections

This file contains two sets of classes, one for the bijection from KR tableaux to rigged configurations and the other for the reverse bijection. We do this for two reasons, one is because we can store a state in the bijection locally, so we do not have to constantly pass it around between functions. The other is because it makes the code easier to read in the _element.py files.

These classes are not meant to be used by the user and are only supposed to be used internally to perform the bijections between TensorProductOfKirillovReshetikhinTableaux and RiggedConfigurations.

AUTHORS:

```python
class sage.combinat.rigged_configurations.bij_abstract_class.KRTToRCBijectionAbstract(tp_krt):
    bases: object
    Root abstract class for the bijection from KR tableaux to rigged configurations.
    This class holds the state of the bijection and generates the next state. This class should never be created directly.

    next_state(val)
    Build the next state in the bijection.

    run(verbos=False)
    Run the bijection from a tensor product of KR tableaux to a rigged configuration.
```

INPUT:
- val – The value we are adding
- tp_krt – A tensor product of KR tableaux
- verbose – (Default: False) Display each step in the bijection
EXAMPLES:

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 4, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_A import KRTToRCBijectionTypeA
sage: KRTToRCBijectionTypeA(KRT(pathlist=[[5, 2]])).run()
-1[ ]-1
 1[ ]1
 0[ ]0
-1[ ]-1
```

class sage.combinat.rigged_configurations.bij_abstract_class.RCToKRTBijectionAbstract

Root abstract class for the bijection from rigged configurations to tensor product of Kirillov-Reshetikhin tableaux.

This class holds the state of the bijection and generates the next state. This class should never be created directly.

next_state(height)

Build the next state in the bijection.

run(verbosethink, build_graph=False)

Run the bijection from rigged configurations to tensor product of KR tableaux.

INPUT:

• verbose = (default: False) display each step in the bijection
• build_graph = (default: False) build the graph of each step of the bijection

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 1]])
sage: x = RC(partition_list=[[1], [1], [1], [1]])
sage: from sage.combinat.rigged_configurations.bij_type_A import RCToKRTBijectionTypeA
sage: RCToKRTBijectionTypeA(x).run()([[2], [5]]
sage: bij = RCToKRTBijectionTypeA(x)
sage: bij.run(build_graph=True)([[2], [5]]
sage: bij._graph
Digraph on 3 vertices
```
5.1.199 Bijection between rigged configurations for $B(\infty)$ and marginally large tableaux

AUTHORS:

- Travis Scrimshaw (2015-07-01): Initial version

REFERENCES:

```python
class sage.combinat.rigged_configurations.bij_infinity.FromRCIsomorphism
    Bases: sage.categories.morphism.Morphism

     Crystal isomorphism of $B(\infty)$ in the rigged configuration model to the tableau model.

class sage.combinat.rigged_configurations.bij_infinity.FromTableauIsomorphism
    Bases: sage.categories.morphism.Morphism

     Crystal isomorphism of $B(\infty)$ in the tableau model to the rigged configuration model.

class sage.combinat.rigged_configurations.bij_infinity.MLTToRCBijectionTypeB(tp_krt)
    Bases: sage.combinat.rigged_configurations.bij_type_B.KRTToRCBijectionTypeB

    run()
    Run the bijection from a marginally large tableaux to a rigged configuration.

    EXAMPLES:

        sage: vct = CartanType(['B',4]).as_folding()
        sage: RC = crystals.infinity.RiggedConfigurations(vct)
        sage: T = crystals.infinity.Tableaux(['B',4])
        sage: Psi = T.crystal_morphism({T.module_generators[0]: RC.module_generators[0]})
        sage: TS = [x.value for x in T.subcrystal(max_depth=4)]
        sage: all(Psi(b) == RC(b) for b in TS)  # long time # indirect doctest
        True

    class sage.combinat.rigged_configurations.bij_infinity.MLTToRCBijectionTypeD(tp_krt)
    Bases: sage.combinat.rigged_configurations.bij_type_D.KRTToRCBijectionTypeD

    run()
    Run the bijection from a marginally large tableaux to a rigged configuration.

    EXAMPLES:

        sage: RC = crystals.infinity.RiggedConfigurations(['D',4])
        sage: T = crystals.infinity.Tableaux(['D',4])
        sage: Psi = T.crystal_morphism({T.module_generators[0]: RC.module_generators[0]})
        sage: TS = [x.value for x in T.subcrystal(max_depth=4)]
        sage: all(Psi(b) == RC(b) for b in TS)  # long time # indirect doctest
        True

    class sage.combinat.rigged_configurations.bij_infinity.RCToMLTBijectionTypeB(RC_element)
    Bases: sage.combinat.rigged_configurations.bij_type_B.RCKRTBijectionTypeB

    run()
    Run the bijection from rigged configurations to a marginally large tableau.

    EXAMPLES:
```
sage: vct = CartanType(['B',4]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: T = crystals.infinity.Tableaux(['B',4])
sage: Psi = RC.crystal_morphism({RC.module_generators[0]: T.module_generators[0]})
sage: RCS = [x.value for x in RC.subcrystal(max_depth=4)]
\[\text{all}(\text{Psi}(\text{nu}) == \text{T}(\text{nu}) \text{ for } \text{nu} \text{ in } \text{RCS})\] # long time # indirect doctest
True

class sage.combinat.rigged_configurations.bij_infinity.RCToMLTBijectionTypeD(RC_element)
    Bases: sage.combinat.rigged_configurations.bij_abstract_class.RCToKRTBijectionAbstract

Run the bijection from rigged configurations to a marginally large tableau.

EXAMPLES:

sage: RC = crystals.infinity.RiggedConfigurations(['D',4])
sage: T = crystals.infinity.Tableaux(['D',4])
sage: Psi = RC.crystal_morphism({RC.module_generators[0]: T.module_generators[0]})
sage: RCS = [x.value for x in RC.subcrystal(max_depth=4)]
\[\text{all}(\text{Psi}(\text{nu}) == \text{T}(\text{nu}) \text{ for } \text{nu} \text{ in } \text{RCS})\] # long time # indirect doctest
True

5.1.200 Bijection classes for type $A_n^{(1)}$

Part of the (internal) classes which run the bijection between rigged configurations and tensor products of Kirillov-Reshetikhin tableaux of type $A_n^{(1)}$.

AUTHORS:

• Travis Scrimshaw (2011-04-15): Initial version

class sage.combinat.rigged_configurations.bij_type_A.KRTToRCBijectionTypeA(tp_krt)
    Bases: sage.combinat.rigged_configurations.bij_abstract_class.KRTToRCBijectionAbstract

Specific implementation of the bijection from KR tableaux to rigged configurations for type $A_n^{(1)}$.

next_state(val)
    Build the next state for type $A_n^{(1)}$.

EXAMPLES:

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 4, 1], \[\text{pathlist}=[[2,1]]\])
sage: from sage.combinat.rigged_configurations.bij_type_A import \_ \_\_\_\_\_\_\_
    KRTToRCBijectionTypeA
sage: bijection = KRTToRCBijectionTypeA(KRT(pathlist=[[4,3]]))
sage: bijection.cur_path.insert(0, [0])
sage: bijection.cur_dims.insert(0, [0, 1])
sage: bijection.cur_path[0].insert(0, [3])
sage: bijection.next_state(3)

class sage.combinat.rigged_configurations.bij_type_A.RCToKRTBijectionTypeA(RC_element)
    Bases: sage.combinat.rigged_configurations.bij_abstract_class.RCToKRTBijectionAbstract

5.1. Comprehensive Module list 1949
Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $A_n^{(1)}$.

**next_state**(height)

Build the next state for type $A_n^{(1)}$.

**EXAMPLES:**

```sage
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_A import ...
$\rightarrow$RCToKRTBijectionTypeA
sage: bijection = RCToKRTBijectionTypeA(RC(partition_list=[[1],[1],[1],[1]]))
sage: bijection.next_state(1)
```

### 5.1.201 Bijection classes for type $A_{2n}^{(2)\dagger}$

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $A_{2n}^{(2)\dagger}$.

**AUTHORS:**

- Travis Scrimshaw (2012-12-21): Initial version

```python
class sage.combinat.rigged_configurations.bij_type_A2_dual.KRTToRCBijectionTypeA2Dual(tp_krt):
    Bases: sage.combinat.rigged_configurations.bij_type_C.KRTToRCBijectionTypeC

    Specific implementation of the bijection from KR tableaux to rigged configurations for type $A_{2n}^{(2)\dagger}$.

    This inherits from type $C_n^{(1)}$ because we use the same methods in some places.

    **next_state**(val)

    Build the next state for type $A_{2n}^{(2)\dagger}$.

class sage.combinat.rigged_configurations.bij_type_A2_dual.RCToKRTBijectionTypeA2Dual(RC_element):
    Bases: sage.combinat.rigged_configurations.bij_type_C.RCToKRTBijectionTypeC

    Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $A_{2n}^{(2)\dagger}$.

    **next_state**(height)

    Build the next state for type $A_{2n}^{(2)\dagger}$.
```

### 5.1.202 Bijection classes for type $A_{2n}^{(2)}$

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $A_{2n}^{(2)}$.

**AUTHORS:**

- Travis Scrimshaw (2012-12-21): Initial version

```python
class sage.combinat.rigged_configurations.bij_type_A2_even.KRTToRCBijectionTypeA2Even(tp_krt):
    Bases: sage.combinat.rigged_configurations.bij_type_C.KRTToRCBijectionTypeC

    Specific implementation of the bijection from KR tableaux to rigged configurations for type $A_{2n}^{(2)}$.

    This inherits from type $C_n^{(1)}$ because we use the same methods in some places.

    **next_state**(val)

    Build the next state for type $A_{2n}^{(2)}$.
```
5.1.203 Bijection classes for type $A^{(2)}_{2n-1}$.

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $A^{(2)}_{2n-1}$.

AUTHORS:

- Travis Scrimshaw (2012-12-21): Initial version

5.1.204 Bijection classes for type $B^{(1)}_n$.

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $B^{(1)}_n$.

AUTHORS:

- Travis Scrimshaw (2012-12-21): Initial version
run (verbose=False)
Run the bijection from a tensor product of KR tableaux to a rigged configuration.

INPUT:
- tp_krt – A tensor product of KR tableaux
- verbose – (Default: False) Display each step in the bijection

EXAMPLES:

```python
crystals.TensorProductOfKirillovReshetikhinTableaux(['B', 3, 1], [[2, 1]])
crystals.TensorProductOfKirillovReshetikhinTableaux(['B', 3, 1], [[3, 1]])
```

class sage.combinat.rigged_configurations.bij_type_B.RCToKRTBijectionTypeB (RC_element)
Bases: sage.combinat.rigged_configurations.bij_type_C.RCToKRTBijectionTypeC

Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $B_n^{(1)}$.

next_state (height)
Build the next state for type $B_n^{(1)}$.

run (verbose=False, build_graph=False)
Run the bijection from rigged configurations to tensor product of KR tableaux for type $B_n^{(1)}$.

INPUT:
- verbose – (default: False) display each step in the bijection
- build_graph – (default: False) build the graph of each step of the bijection

EXAMPLES:
sage: RC = RiggedConfigurations(['B', 3, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_B import _
    RCToKRTBijectionTypeB

5.1.205 Bijection classes for type $C_n^{(1)}$

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $C_n^{(1)}$.

AUTHORS:
- Travis Scrimshaw (2012-12-21): Initial version

```python
class sage.combinat.rigged_configurations.bij_type_C.KRTToRCBijectionTypeC (tp_krt)
    Bases: sage.combinat.rigged_configurations.bij_type_A.KRTToRCBijectionTypeA
    Specific implementation of the bijection from KR tableaux to rigged configurations for type $C_n^{(1)}$.
    This inherits from type $A_n^{(1)}$ because we use the same methods in some places.
    next_state(val)
        Build the next state for type $C_n^{(1)}$.
```

```python
class sage.combinat.rigged_configurations.bij_type_C.RCToKRTBijectionTypeC (RC_element)
    Bases: sage.combinat.rigged_configurations.bij_type_A.RCToKRTBijectionTypeA
    Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $C_n^{(1)}$.
    next_state(height)
        Build the next state for type $C_n^{(1)}$.
```

5.1.206 Bijection classes for type $D_n^{(1)}$

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $D_n^{(1)}$.

AUTHORS:

```python
class sage.combinat.rigged_configurations.bij_type_D.KRTToRCBijectionTypeD (tp_krt)
    Bases: sage.combinat.rigged_configurations.bij_type_A.KRTToRCBijectionTypeA
    Specific implementation of the bijection from KR tableaux to rigged configurations for type $D_n^{(1)}$.
    This inherits from type $A_n^{(1)}$ because we use the same methods in some places.
```
doubling_map()
Perform the doubling map of the rigged configuration at the current state of the bijection.

This is the map $B(\Lambda) \mapsto B(2\Lambda)$ which doubles each of the rigged partitions and updates the vacancy numbers accordingly.

doubling_map()
Perform the doubling map of the rigged configuration at the current state of the bijection.

This is the map $B(\Lambda) \mapsto B(2\Lambda)$ which doubles each of the rigged partitions and updates the vacancy numbers accordingly.

halving_map()
Perform the halving map of the rigged configuration at the current state of the bijection.

This is the inverse map to $B(\Lambda) \mapsto B(2\Lambda)$ which halves each of the rigged partitions and updates the vacancy numbers accordingly.

halving_map()
Perform the halving map of the rigged configuration at the current state of the bijection.

This is the inverse map to $B(\Lambda) \mapsto B(2\Lambda)$ which halves each of the rigged partitions and updates the vacancy numbers accordingly.

next_state(val)
Build the next state for $D_n^{(1)}$.

next_state(val)
Build the next state for $D_n^{(1)}$.

run(verbosetrue=False)
Run the bijection from a tensor product of KR tableaux to a rigged configuration for type $D_n^{(1)}$.

run(verbosetrue=False)
Run the bijection from a tensor product of KR tableaux to a rigged configuration for type $D_n^{(1)}$.

INPUT:

• tp_krt – A tensor product of KR tableaux
• verbose – (Default: False) Display each step in the bijection

EXAMPLES:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], →[[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_D import →KRTToRCBijectionTypeD
sage: KRTToRCBijectionTypeD(KRT(pathlist=[[3,2]])).run()
-1[ ]-1
 2[ ]
-1[ ]-1
```

class sage.combinat.rigged_configurations.bij_type_D.RCToKRTBijectionTypeD (RC_element)
Bases: sage.combinat.rigged_configurations.bij_type_A.RCToKRTBijectionTypeA

Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $D_n^{(1)}$.

doubling_map()
Perform the doubling map of the rigged configuration at the current state of the bijection.

This is the map $B(\Lambda) \mapsto B(2\Lambda)$ which doubles each of the rigged partitions and updates the vacancy numbers accordingly.

doubling_map()
Perform the doubling map of the rigged configuration at the current state of the bijection.

This is the map $B(\Lambda) \mapsto B(2\Lambda)$ which doubles each of the rigged partitions and updates the vacancy numbers accordingly.

halving_map()
Perform the halving map of the rigged configuration at the current state of the bijection.

This is the inverse map to $B(\Lambda) \mapsto B(2\Lambda)$ which halves each of the rigged partitions and updates the vacancy numbers accordingly.

halving_map()
Perform the halving map of the rigged configuration at the current state of the bijection.

This is the inverse map to $B(\Lambda) \mapsto B(2\Lambda)$ which halves each of the rigged partitions and updates the vacancy numbers accordingly.

next_state(height)
Build the next state for $D_n^{(1)}$.

next_state(height)
Build the next state for $D_n^{(1)}$.

run(verbosetrue=False, build_graphfalse)
Run the bijection from rigged configurations to tensor product of KR tableaux for type $D_n^{(1)}$.

run(verbosetrue=False, build_graphfalse)
Run the bijection from rigged configurations to tensor product of KR tableaux for type $D_n^{(1)}$. 

1954 Chapter 5. Comprehensive Module List
INPUT:

- `verbose` – (default: False) display each step in the bijection
- `build_graph` – (default: False) build the graph of each step of the bijection

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 1]])
sage: x = RC(partition_list=[[1],[1],[1],[1]])
sage: from sage.combinat.rigged_configurations.bij_type_D import RCToKRTBijectionTypeD
sage: RCToKRTBijectionTypeD(x).run()  # [[2], [-3]]
sage: bij = RCToKRTBijectionTypeD(x)
sage: bij.run(build_graph=True)  # [[2], [-3]]
sage: bij._graph
Digraph on 3 vertices
```

### 5.1.207 Bijection classes for type \( D_{n+1}^{(2)} \)

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type \( D_{n+1}^{(2)} \).

AUTHORS:

```python
class sage.combinat.rigged_configurations.bij_type_D_twisted.KRTToRCBijectionTypeDTwisted(tp_krt):
    Bases: sage.combinat.rigged_configurations.bij_type_D.KRTToRCBijectionTypeD,
           sage.combinat.rigged_configurations.bij_type_A2_even.KRTToRCBijectionTypeA2Even

    Specific implementation of the bijection from KR tableaux to rigged configurations for type \( D_{n+1}^{(2)} \).
    This inherits from type \( C_n^{(1)} \) and \( D_n^{(1)} \) because we use the same methods in some places.

    next_state(val)
    Build the next state for type \( D_{n+1}^{(2)} \).

    run(verbosе=False)
    Run the bijection from a tensor product of KR tableaux to a rigged configuration for type \( D_{n+1}^{(2)} \).
```

INPUT:

- `tp_krt` – A tensor product of KR tableaux
- `verbose` – (Default: False) Display each step in the bijection

EXAMPLES:

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 2], [[3, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_D_twisted import KRTToRCBijectionTypeDTwisted
sage: KRTToRCBijectionTypeDTwisted(KRT(pathlist=[[[-1,3,2]]])).run()
  -1[ ] -1
  0[ ] 0
```

(continues on next page)
class sage.combinat.rigged_configurations.bij_type_D_twisted.RCToKRTBijectionTypeDTwisted(RC_element):
    Bases: sage.combinat.rigged_configurations.bij_type_D.RCToKRTBijectionTypeD, sage.combinat.rigged_configurations.bij_type_A2_even.RCToKRTBijectionTypeA2Even

Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $D_{n+1}^{(2)}$.

next_state(height)
    Build the next state for type $D_{n+1}^{(2)}$.

run(verbos=False, build_graph=False)
    Run the bijection from rigged configurations to tensor product of KR tableaux for type $D_{n+1}^{(2)}$.

    INPUT:
    • verbose – (default: False) display each step in the bijection
    • build_graph – (default: False) build the graph of each step of the bijection

EXAMPLES:

sage: RC = RiggedConfigurations(['D', 4, 2], [[[3, 1]]])
sage: x = RC(partition_list=[[[],[1],[1]]])
sage: from sage.combinat.rigged_configurations.bij_type_D_twisted import RCToKRTBijectionTypeDTwisted
sage: RCToKRTBijectionTypeDTwisted(x).run()
[[1], [3], [-2]]
sage: bij = RCToKRTBijectionTypeDTwisted(x)
sage: bij.run(build_graph=True)
[[1], [3], [-2]]
sage: bij._graph
Digraph on 6 vertices

5.1.208 Bijection classes for type $D_4^{(3)}$

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $D_4^{(3)}$.

AUTHORS:
• Travis Scrimshaw (2014-09-10): Initial version

class sage.combinat.rigged_configurations.bij_type_D_tri.KRTToRCBijectionTypeDTri(tp_krt):
    Bases: sage.combinat.rigged_configurations.bij_type_A.KRTToRCBijectionTypeA

    Specific implementation of the bijection from KR tableaux to rigged configurations for type $D_4^{(3)}$.

    This inherits from type $A_n^{(1)}$ because we use the same methods in some places.

next_state(val)
    Build the next state for type $D_4^{(3)}$.
Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $D_4^{(3)}$.

`next_state(height)`

Build the next state for type $D_4^{(3)}$.

### 5.1.209 Bijection between rigged configurations and KR tableaux

Functions which are big switch statements to create the bijection class of the correct type.

**AUTHORS:**
- Travis Scrimshaw (2012-12-21): Added all non-exceptional bijection types
- Travis Scrimshaw (2014-09-10): Added type $D_4^{(3)}$

```python
sage.combinat.rigged_configurations.bijection.KRTToRCBijection(tp_krt)
```

Return the correct KR tableaux to rigged configuration bijection helper class.

```python
sage.combinat.rigged_configurations.bijection.RCToKRTBijection(rigged_configuration_elt)
```

Return the correct rigged configuration to KR tableaux bijection helper class.

### 5.1.210 Kleber Trees

A Kleber tree is a tree of weights generated by Kleber’s algorithm [Kleber1]. The nodes correspond to the weights in the positive Weyl chamber obtained by subtracting a (non-zero) positive root. The edges are labeled by the coefficients of the roots of the difference.

**AUTHORS:**
- Travis Scrimshaw (2011-05-03): Initial version
- Travis Scrimshaw (2013-02-13): Added support for virtual trees and improved \LaTeX output

**EXAMPLES:**

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KleberTree(['A', 3, 1], [[3,2], [2,1], [1,1], [1,1]])
Kleber tree of Cartan type ['A', 3, 1] and B = ((3, 2), (2, 1), (1, 1), (1, 1))
sage: KleberTree(['D', 4, 1], [[2,2]])
Kleber tree of Cartan type ['D', 4, 1] and B = ((2, 2),)
```

```python
class sage.combinat.rigged_configurations.kleber_tree.KleberTree(cartan_type, B, classical_ct)
```

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

The tree that is generated by Kleber’s algorithm.

A Kleber tree is a tree of weights generated by Kleber’s algorithm [Kleber1]. It is used to generate the set of all admissible rigged configurations for the simply-laced affine types $A_n^{(1)}, D_n^{(1)}, E_6^{(1)}, E_7^{(1)},$ and $E_8^{(1)}$.

See also:

There is a modified version for non-simply-laced affine types at `VirtualKleberTree`. 

---

### 5.1. Comprehensive Module list

1957
The nodes correspond to the weights in the positive Weyl chamber obtained by subtracting a (non-zero) positive root. The edges are labeled by the coefficients of the roots, and \(X\) is a child of \(Y\) if \(Y\) is the root else if the edge label of \(Y\) to its parent \(Z\) is greater (in every component) than the label from \(X\) to \(Y\).

For a Kleber tree, one needs to specify an affine (simply-laced) Cartan type and a sequence of pairs \( (r, s) \), where \(s\) is any positive integer and \(r\) is a node in the Dynkin diagram. Each \( (r, s) \) can be viewed as a rectangle of width \(s\) and height \(r\).

**INPUT:**

- `cartan_type` – an affine simply-laced Cartan type
- `B` – a list of dimensions of rectangles by \([r, c]\) where \(r\) is the number of rows and \(c\) is the number of columns

**REFERENCES:**

**EXAMPLES:**

Simply-laced example:

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A', 3, 1], [[3,2], [1,1]])

Kleber tree node with weight [1, 0, 2] and upwards edge root [0, 0, 0],
Kleber tree node with weight [0, 0, 1] and upwards edge root [1, 1, 1]

sage: KT.cardinality()
10
sage: KT = KleberTree(['A', 3, 1], [[3,2], [2,1], [1,1], [1,1]])

sage: KT.cardinality()
3
sage: KT = KleberTree(['D', 4, 1], [[2,2]])

sage: KT.cardinality()
1
```

From [Kleber2]:

```python
sage: KT = KleberTree(['E', 6, 1], [[4, 2]])

sage: KT.cardinality()  # long time
12
```

We check that relabelled types work (trac ticket #16876):

```python
sage: ct = CartanType(['A',3,1]).relabel(lambda x: x+2)
sage: kt = KleberTree(ct, [[3,1],[5,1]])

Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 0, 0],
Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 1, 1]
```

**Element**

alias of `KleberTreeNode`

**breadth_first_iter()**

Iterate over all nodes in the tree following a breadth-first traversal.

**EXAMPLES:**
```
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A', 3, 1], [[2, 2], [2, 3]])
sage: for x in KT.breadth_first_iter(): x
Kleber tree node with weight [0, 5, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 3, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 3, 0] and upwards edge root [1, 2, 1]
Kleber tree node with weight [2, 1, 2] and upwards edge root [0, 1, 0]
Kleber tree node with weight [1, 1, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 1, 0] and upwards edge root [1, 2, 1]
```

cartan_type()

Return the Cartan type of this Kleber tree.

EXAMPLES:
```
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A', 3, 1], [[1, 1]])
sage: KT.cartan_type()
['A', 3, 1]
```

depth_first_iter()

Iterate (recursively) over the nodes in the tree following a depth-first traversal.

EXAMPLES:
```
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A', 3, 1], [[2, 2], [2, 3]])
sage: for x in KT.depth_first_iter(): x
Kleber tree node with weight [0, 5, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 3, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [2, 1, 2] and upwards edge root [0, 1, 0]
Kleber tree node with weight [1, 1, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 1, 0] and upwards edge root [1, 2, 1]
```

digraph()

Return a DiGraph representation of this Kleber tree.

EXAMPLES:
```
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['D', 4, 1], [[2, 2]])
sage: KT.digraph()
Digraph on 3 vertices
```

latex_options(**options)

Return the current latex options if no arguments are passed, otherwise set the corresponding latex option.

OPTIONS:
- `hspace` – (default: 2.5) the horizontal spacing of the tree nodes
- `vspace` – (default: $x$) the vertical spacing of the tree nodes, here $x$ is the minimum of $-2.5$ or $-0.75n$ where $n$ is the rank of the classical type
- `edge_labels` – (default: True) display edge labels
- `use_vector_notation` – (default: False) display edge labels using vector notation instead of a linear combination

EXAMPLES:
```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['D', 3, 1], [[2,1], [2,1]])
sage: KT.latex_options(vspace=-4, use_vector_notation=True)
sage: sorted(KT.latex_options().items())
[('edge_labels', True), ('hspace', 2.5), ('use_vector_notation', True), ('vspace', -4)]
```

```
plot(**options)

Return the plot of self as a directed graph.

EXAMPLES:
```
```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['D', 4, 1], [[2, 2]])
sage: print(KT.plot())
Graphics object consisting of 8 graphics primitives
```

```
class sage.combinat.rigged_configurations.kleber_tree.KleberTreeNode

Bases: sage.structure.element.Element

A node in the Kleber tree.

This class is meant to be used internally by the Kleber tree class and should not be created directly by the user. For more on the Kleber tree and the nodes, see KleberTree.

The dominating root is the up_root which is the difference between the parent node’s weight and this node’s weight.

INPUT:

- `parent_obj` – The parent object of this element
- `node_weight` – The weight of this node
- `dominant_root` – The dominating root
- `parent_node` – (default:None) The parent node of this node

depth()

Return the depth of this node in the tree.

EXAMPLES:
```
```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: RS = RootSystem(['A', 2])
sage: WS = RS.weight_lattice()
sage: R = RS.root_lattice()
sage: KT = KleberTree(['A', 2, 1], [[1,1]])
sage: n = KT(WS.sum_of_terms([(1,5), (2,2)]), R.zero())
sage: n.depth
0
sage: n2 = KT(WS.sum_of_terms([(1,5), (2,2)]), R.zero(), n)
sage: n2.depth
1
```
multiplicity()
Return the multiplicity of self.

The multiplicity of a node \( x \) of depth \( d \) weight \( \lambda \) in a simply-laced Kleber tree is equal to:

\[
\prod_{i>0} \prod_{a \in T} \left( p_i^{(a)} + m_i^{(a)} \right)
\]

Recall that

\[
m_i^{(a)} = \left( \lambda^{(i-1)} - 2\lambda^{(i)} + \lambda^{(i+1)} \mid \gamma_a \right),
\]

\[
p_i^{(a)} = \left( \alpha_a \mid \lambda^{(i)} \right) - \sum_{j>i} (j-i) L_j^{(a)},
\]

where \( \lambda^{(i)} \) is the weight node at depth \( i \) in the path to \( x \) from the root and we set \( \lambda^{(j)} = \lambda \) for all \( j \geq d \).

Note that \( m_i^{(a)} = 0 \) for all \( i > d \).

EXAMPLES:

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A',3,1], [[3,2],[2,1],[1,1],[1,1]])
```

```python
sage: for x in KT: x, x.multiplicity()
(Kleber tree node with weight [2, 1, 2] and upwards edge root [0, 0, 1], 1)
(Kleber tree node with weight [3, 0, 1] and upwards edge root [1, 1, 0], 1)
(Kleber tree node with weight [0, 2, 2] and upwards edge root [1, 0, 0], 1)
(Kleber tree node with weight [1, 0, 3] and upwards edge root [1, 1, 0], 2)
(Kleber tree node with weight [1, 1, 1] and upwards edge root [1, 1, 1], 4)
(Kleber tree node with weight [0, 0, 2] and upwards edge root [2, 2, 1], 2)
```

```python
class sage.combinat.rigged_configurations.kleber_tree.KleberTreeTypeA2Even (cartan_type, B)
Kleber tree for types \( A_{2n}^{(2)} \) and \( A_{2n}^{(2)} \).

Note that here for \( A_{2n}^{(2)} \) we use \( \tilde{\gamma}_a \) in place of \( \gamma_a \) in constructing the virtual Kleber tree, and so we end up selecting all nodes since \( \tilde{\gamma}_a = 1 \) for all \( a \in T \). For type \( A_{2n}^{(2)} \), we have \( \gamma_a = 1 \) for all \( a \in T \).

See also:

VirtualKleberTree

breadth_first_iter (all_nodes=False)
Iterate over all nodes in the tree following a breadth-first traversal.

INPUT:

- all_nodes – (default: False) if True, output all nodes in the tree

EXAMPLES:

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import ...
sage: KT = VirtualKleberTree(['A', 4, 2], [[2,1]])
sage: for x in KT.breadth_first_iter(): x
```

(continues on next page)
```python
Kleber tree node with weight [0, 2, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 2, 1]
sage: for x in KT.breadth_first_iter(True): x
Kleber tree node with weight [0, 2, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 2, 1]
```

**depth_first_iter (all_nodes=False)**

Iterate (recursively) over the nodes in the tree following a depth-first traversal.

**INPUT:**

- all_nodes – (default: False) if True, output all nodes in the tree

**EXAMPLES:**

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
gvit = VirtualKleberTree(['A', 4, 2], [[2,1]])
sage: for x in gvit.depth_first_iter(): x
Kleber tree node with weight [0, 2, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 2, 1]
sage: for x in gvit.depth_first_iter(True): x
Kleber tree node with weight [0, 2, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 2, 1]
```

```python
class sage.combinat.rigged_configurations.kleber_tree.VirtualKleberTree(cartan_type, B)

Bases: sage.combinat.rigged_configurations.kleber_tree.KleberTree

A virtual Kleber tree.

We can use a modified version of the Kleber algorithm called the virtual Kleber algorithm [OSS03] to compute all admissible rigged configurations for non-simply-laced types. This uses the following embeddings into the simply-laced types:

\[
C_n^{(1)}, A_{2n}^{(2)}, A_{2n+1}^{(2)}, D_{n+1}^{(2)} \hookrightarrow A_{2n-1}^{(1)}
\]

\[
A_{2n-1}^{(2)}, B_{n}^{(1)} \hookrightarrow D_{n+1}^{(1)}
\]

\[
E_{6}^{(2)}, F_{4}^{(1)} \hookrightarrow E_{6}^{(1)}
\]

\[
D_{4}^{(3)}, G_{2}^{(1)} \hookrightarrow D_{4}^{(1)}
\]

One then selects the subset of admissible nodes which are translates of the virtual requirements. In the graph, the selected nodes are indicated by brackets [].

**Note:** Because these are virtual nodes, all information is given in the corresponding simply-laced type.

**See also:**

For more on the Kleber algorithm, see *KleberTree*.

**REFERENCES:**

**INPUT:**
• `cartan_type` – an affine non-simply-laced Cartan type

• `B` – a list of dimensions of rectangles by \([r, c]\) where \(r\) is the number of rows and \(c\) is the number of columns

EXAMPLES:

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
sage: KT = VirtualKleberTree(['C', 4, 1], [[2,2]])
3
sage: KT.base_tree().cardinality()
6
sage: KT = VirtualKleberTree(['C', 4, 1], [[4,5]])
1
sage: KT.base_tree().cardinality()
8
sage: KT = VirtualKleberTree(['D', 5, 2], [[2,1], [1,1]])
sage: KT.base_tree().cardinality()
8
sage: KT = VirtualKleberTree(CartanType(['A', 4, 2]).dual(), [[1,1], [2,2]])
15
```

`base_tree()`

Return the underlying virtual Kleber tree associated to `self`.

EXAMPLES:

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
sage: KT = VirtualKleberTree(['C', 2, 1], [[1,1], [2,1]])
Kleber tree of Cartan type ['A', 7, 1] and B = ((2, 2), (6, 2))
```

`breadth_first_iter(all_nodes=False)`

Iterate over all nodes in the tree following a breadth-first traversal.

INPUT:

• `all_nodes` – (default: `False`) if `True`, output all nodes in the tree

EXAMPLES:

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
sage: KT = VirtualKleberTree(['C', 2, 1], [[1,1], [2,1]])
Kleber tree node with weight [1, 2, 1] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
```

`depth_first_iter(all_nodes=False)`

Iterate (recursively) over the nodes in the tree following a depth-first traversal.

INPUT:

• `all_nodes` – (default: `False`) if `True`, output all nodes in the tree

EXAMPLES:
5.1.211 Kirillov-Reshetikhin Tableaux

Kirillov-Reshetikhin tableaux are rectangular tableaux with $r$ rows and $s$ columns that naturally arise under the bijection between rigged configurations and tableaux [RigConBijection]. They are in bijection with the elements of the Kirillov-Reshetikhin crystal $B_{r,s}$ under the (inverse) filling map [OSS13] [SS2015]. They do not have to satisfy the semistandard row or column restrictions. These tensor products are the result from the bijection from rigged configurations [RigConBijection].

For more information, see KirillovReshetikhinTableaux and TensorProductOfKirillovReshetikhinTableaux.

                   r, s)
Bases: sage.combinat.rigged_configurations.kr_tableaux.KRTableauxRectangle

Kirillov-Reshetikhin tableaux $B^{r,s}$ of type $D_n^{(1)}$ with $r = n, n - 1$.

Element
alias of KRTableauxSpinElement
class sage.combinat.rigged_configurations.kr_tableaux.KRTableauxSpinElement(parent, list, **options)
Bases: sage.combinat.rigged_configurations.kr_tableaux.KirillovReshetikhinTableauxElement

Kirillov-Reshetikhin tableau for spinors.
Here we are in the embedding $B(\Lambda_n) \to B(2\Lambda_n)$, so $e_i$ and $f_i$ act by $c_i^2$ and $f_i^2$ respectively for all $i \neq 0$. We do this so our columns are full width (as opposed to half width and/or uses a $\pm$ representation).
classical_weight()
Return the classical weight of self.

EXAMPLES:
Calculate the action of $e_i$ on self.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 4, 1, model='KR')
sage: KRT.module_generators[0].classical_weight()
(1/2, 1/2, 1/2, 1/2)
```

\( e_i \)

\text{Calculate the action of } e_i \text{ on self.}

\text{EXAMPLES:}

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 4, 1, model='KR')
sage: KRT(-1, -4, 3, 2).e(1)
[[1], [3], [-4], [-2]]
sage: KRT(-1, -4, 3, 2).e(3)
```

\( \text{epsilon}(i) \)

\text{Compute } \epsilon_i \text{ of self.}

\text{EXAMPLES:}

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 4, 1, model='KR')
sage: KRT(-1, -4, 3, 2).epsilon(1)
1
sage: KRT(-1, -4, 3, 2).epsilon(3)
0
```

\( f(i) \)

\text{Calculate the action of } f_i \text{ on self.}

\text{EXAMPLES:}

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 4, 1, model='KR')
sage: KRT(-1, -4, 3, 2).f(1)
sage: KRT(-1, -4, 3, 2).f(3)
[[2], [4], [-3], [-1]]
```

\( \text{left_split()} \)

\text{Return the image of self under the left column splitting map.}

\text{EXAMPLES:}

```
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 4, 3, model='KR')
sage: elt = KRT(-3,-4,2,1,-3,-4,2,1,-2,-4,3,1); elt.pp()
 1 1 1
 2 2 3
-4 -4 -4
-3 -3 -2
sage: elt.left_split().pp()
 1 (X) 1 1
 2 2 3
-4 -4 -4
-3 -3 -2
```

\( \text{phi}(i) \)

\text{Compute } \phi_i \text{ of self.}

\text{EXAMPLES:}

```
```
```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 4, 1, model='KR')
sage: KRT(-1, -4, 3, 2).phi(1)
0
sage: KRT(-1, -4, 3, 2).phi(3)
1
```

**to_array**(rows=True)

Return a 2-dimensional array representation of this Kirillov-Reshetikhin element.

If the output is in rows, then it outputs the top row first (in the English convention) from left to right.

For example: if the reading word is [2, 1, 4, 3], so as a 2 × 2 tableau:

```
1 3
2 4
```

we output [[1, 3], [2, 4]].

If the output is in columns, then it outputs the leftmost column first with the bottom element first. In other words this parses the reading word into its columns.

Continuing with the previous example, the output would be [[2, 1], [4, 3]].

INPUT:

- **rows** – (Default: True) Set to True if the resulting array is by row, otherwise it is by column.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 4, 3, model='KR')
sage: elt = KRT(-3,-4,2,1,-3,-4,2,1,-2,-4,3,1)
sage: elt.to_array()    # Default: rows=True
[[1, 1, 1], [2, 2, 3], [-4, -4, -4], [-3, -3, -2]]
sage: elt.to_array(False)  # rows=False
[[2, 1], [4, 3]]
```

class sage.combinat.rigged_configurations.kr_tableaux.KRTableauxTypeBox(cartan_type, r, s) Bases: sage.combinat.rigged_configurations.kr_tableaux.KRTableauxTypeVertical

Kirillov-Reshetikhin tableaux $B^{r,s}$ of type:

- $A^{(2)}_{2n}$ for all $r \leq n$,
- $D^{(2)}_{n+1}$ for all $r < n$,
- $D^{(3)}_{4}$ for $r = 1$.

class sage.combinat.rigged_configurations.kr_tableaux.KRTableauxTypeFromRC(cartan_type, r, s) Bases: sage.combinat.rigged_configurations.kr_tableaux.KirillovReshetikhinTableaux

Kirillov-Reshetikhin tableaux $B^{r,s}$ constructed from rigged configurations under the bijection $\Phi$.

**Warning:** The Kashiwara-Nakashima version is not implemented due to the non-trivial multiplicities of classical components, so `classical_decomposition()` does not work.
Element

alias of \texttt{KRTTableauxTypeFromRCElement}

\textbf{module\_generators()}

The module generators of \texttt{self}.

EXAMPLES:

\begin{verbatim}
sage: KRT = crystals.KirillovReshetikhin(['D',4,3], 2, 1, model='KR')
sage: KRT.module_generators
([[1], [2]], [[1], [0]], [[1], [E]], [[E], [E]])
\end{verbatim}

class \texttt{sage.combinat.rigged_configurations.kr_tableaux.KRTTableauxTypeFromRCElement}(parent, list, **options)

\text{Bases:} \texttt{sage.combinat.rigged_configurations.kr_tableaux.KirillovReshetikhinTableauxElement, KirillovReshetikhinTableauxElement}

A Kirillov-Reshetikhin tableau constructed from rigged configurations under the bijection $\Phi$.

\textbf{e}(i)

Perform the action of $e_i$ on \texttt{self}.

\textbf{Todo:} Implement a direct action of $e_0$ without moving to rigged configurations.

EXAMPLES:

\begin{verbatim}
sage: KRT = crystals.KirillovReshetikhin(['D',4,3], 2, 1, model='KR')
sage: KRT.module_generators[0].e(0)
[[2], [E]]
\end{verbatim}

\textbf{epsilon}(i)

Compute $\epsilon_i$ of \texttt{self}.

\textbf{Todo:} Implement a direct action of $\epsilon_0$ without moving to KR crystals.

EXAMPLES:

\begin{verbatim}
sage: KRT = crystals.KirillovReshetikhin(['D',4,3], 2, 2, model='KR')
sage: KRT.module_generators[0].epsilon(0)
6
\end{verbatim}

\textbf{f}(i)

Perform the action of $f_i$ on \texttt{self}.

\textbf{Todo:} Implement a direct action of $f_0$ without moving to rigged configurations.

EXAMPLES:

\begin{verbatim}
sage: KRT = crystals.KirillovReshetikhin(['D',4,3], 2, 1, model='KR')
sage: KRT.module_generators[0].f(0)
sage: KRT.module_generators[3].f(0)
[[1], [0]]
\end{verbatim}

1968 Chapter 5. Comprehensive Module List
\texttt{phi}(i)
\begin{itemize}

\end{itemize}

\textbf{EXAMPLES:}
\begin{verbatim}
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 3, model='KR')
sage: C = crystals.KirillovReshetikhin(['D', 4, 1], 2, 3, model='KN')
sage: krc = C(4,3); krc
[[3], [4]]
sage: KRT.from_kirillov_reshetikhin_crystal(krc)
[[3, -2, 1], [4, -1, 2]]
\end{verbatim}
class sage.combinat.rigged_configurations.kr_tableaux.KirillovReshetikhinTableaux(cartan_type, r, s)

Bases: sage.combinat.crystals.tensor_product.CrystalOfWords

Kirillov-Reshetikhin tableaux.

Kirillov-Reshetikhin tableaux are rectangular tableaux with \( r \) rows and \( s \) columns that naturally arise under the bijection between rigged configurations and tableaux [RigConBijection]. They are in bijection with the elements of the Kirillov-Reshetikhin crystal \( B^{r,s} \) under the (inverse) filling map.

Whenever \( B^{r,s} \cong B(s\Lambda_r) \) as a classical crystal (which is the case for \( B^{r,s} \) in type \( A^{(1)}_n \), \( B^{n,s} \) in type \( C^{(1)}_n \) and \( D^{(2)}_{n+1}, B^{n,s} \) and \( B^{n-1,s} \) in type \( D^{(1)}_n \)) then the filling map is trivial.

For \( B^{r,s} \) in:
- type \( D^{(1)}_n \) when \( r \leq n - 2 \),
- type \( B^{(1)}_n \) when \( r < n \),
- type \( A^{(2)}_{2n-1} \) for all \( r \),
the filling map is defined in [OSS2011].

For the spinor cases in type \( D^{(1)}_n \), the crystal \( B^{k,s} \) where \( k = n - 1, n \) is isomorphic as a classical crystal to \( B(s\Lambda_k) \), and here we consider the Kirillov-Reshetikhin tableaux as living in \( B(2s\Lambda_k) \) under the natural doubling map. In this case, the crystal operators \( e_i \) and \( f_i \) act as \( e_i^2 \) and \( f_i^2 \) respectively. See [BijectionDn].

For the spinor case in type \( B^{(1)}_n \), the crystal \( B^{n,s} \), we consider the images under the natural doubling map into \( B^{n,2s} \). The classical components of this crystal are now given by removing \( 2 \times 2 \) boxes. The filling map is the same as below (see the non-spin type \( C^{(1)}_n \)).

For \( B^{r,s} \) in:
- type \( C^{(1)}_n \) when \( r < n \),
- type \( A^{(2)}_{2n} \) for all \( r \),
the filling map is given as follows. Suppose we are considering the (classically) highest weight element in the classical component \( B(\lambda) \). Then we fill it in with the horizontal dominos \([i,i] \) in the \( i \)-th row from the top (in English notation) and reordering the columns so that they are increasing. Recall from above that \( B^{n,s} \cong B(s\Lambda_n) \) in type \( C^{(1)}_n \).

For \( B^{r,s} \) in:
- type \( A^{(2)}_{2n} \) for all \( r \),
- type \( D^{(2)}_{n+1} \) when \( r < n \),
- type \( D^{(3)}_{1} \) when \( r = 1 \),
the filling map is the same as given in [OSS2011] except for the rightmost column which is given by the column \([1, 2, \ldots, k, \emptyset, \ldots, \emptyset] \) where \( k = (r + x - 1)/2 \) in Step 3 of [OSS2011].

For the spinor case in type \( D^{(2)}_{n+1} \), the crystal \( B^{n,s} \), we define the filling map in the same way as in type \( D^{(1)}_n \).

---

Note: The filling map and classical decompositions in non-spinor cases can be classified by how the special node 0 connects with the corresponding classical diagram.

The classical crystal structure is given by the usual Kashiwara-Nakashima tableaux rules. That is to embed this into \( B(\Lambda_1)^{\otimes n^s} \) by using the reading word and then applying the classical crystal operator. The affine crystal
structure is given by converting to the corresponding KR crystal element, performing the affine crystal operator, and pulling back to a KR tableau.

For more information about the bijection between rigged configurations and tensor products of Kirillov-Reshetikhin tableaux, see \texttt{TensorProductOfKirillovReshetikhinTableaux}.

\textbf{Note:} The tableaux for all non-simply-laced types are provably correct if the bijection with \textit{rigged configurations} holds. Therefore this is currently only proven for $B_{n,1}$ or $B_{1,n}$ and in general for types $A_{n}^{(1)}$ and $D_{n}^{(1)}$.

\textbf{INPUT:}

- \texttt{cartan\_type} – the Cartan type
- \texttt{r} – the Dynkin diagram index (typically the number of rows)
- \texttt{s} – the number of columns

\textbf{EXAMPLES:}

\begin{verbatim}
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR') sage: elt = KRT(4, 3); elt [[3], [4]]
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 1, model='KR') sage: elt = KRT(-1, 1); elt [[1], [-1]]
\end{verbatim}

We can create highest weight crystals from a given shape or weight:

\begin{verbatim}
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR') sage: KRT.module_generator(shape=[1,1]) [[1, 1], [2, 1]] sage: KRT.module_generator(column_shape=[2]) [[1, 1], [2, -1]] sage: WS = RootSystem(['D',4,1]).weight_space() sage: KRT.module_generator(weight=WS.sum_of_terms([[0,-2],[2,1]])) [[1, 1], [2, -1]] sage: WSC = RootSystem(['D',4]).weight_space() sage: KRT.module_generator(classical_weight=WSC.fundamental_weight(2)) [[1, 1], [2, -1]]
\end{verbatim}

We can go between \texttt{KashiwaraNakashimaTableaux()} and \texttt{KirillovReshetikhinTableaux} elements:

\begin{verbatim}
sage: KRCrys = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KN') sage: KRTab = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR') sage: elt = KRCrys(3, 2); elt [[2], [3]] sage: k = KRTab(elt); k [[2, 1], [3, -1]] sage: KRCrys(k) [[2], [3]]
\end{verbatim}

We check that the classical weights in the classical decompositions agree in a few different type:

\begin{verbatim}
sage: KRCrys = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KN') sage: KRTab = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
\end{verbatim}
sage: all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)
True

sage: KRCrys = crystals.KirillovReshetikhin(['B', 3, 1], 2, 2, model='KN')
sage: KRTab = crystals.KirillovReshetikhin(['B', 3, 1], 2, 2, model='KR')
sage: all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)
True

sage: KRCrys = crystals.KirillovReshetikhin(['C', 3, 1], 2, 2, model='KN')
sage: KRTab = crystals.KirillovReshetikhin(['C', 3, 1], 2, 2, model='KR')
sage: all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)
True

sage: KRCrys = crystals.KirillovReshetikhin(['D', 4, 2], 2, 2, model='KN')
sage: KRTab = crystals.KirillovReshetikhin(['D', 4, 2], 2, 2, model='KR')
sage: all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)
True

sage: KRCrys = crystals.KirillovReshetikhin(['A', 4, 2], 2, 2, model='KN')
sage: KRTab = crystals.KirillovReshetikhin(['A', 4, 2], 2, 2, model='KR')
sage: all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)
True

Element

alias of KirillovReshetikhinTableauxElement
classical_decomposition()

Return the classical crystal decomposition of self.

EXAMPLES:

sage: crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR').classical_decomposition()
The crystal of tableaux of type ['D', 4] and shape(s) [[], [1, 1], [2, 2]]

from_kirillov_reshetikhin_crystal(krc)

Construct an element of self from the Kirillov-Reshetikhin crystal element krc.

EXAMPLES:

sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR')
sage: C = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KN')
sage: krc = C(4,3); krc
[[3], [4]]
sage: KRT.from_kirillov_reshetikhin_crystal(krc)
[[3], [4]]

kirillov_reshetikhin_crystal()

Return the corresponding KR crystal in the Kashiwara-Nakashima model.

EXAMPLES:

sage: crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR').kirillov_reshetikhin_crystal()
Kirillov-Reshetikhin crystal of type ['A', 4, 1] with (r,s)=(2,1)

module_generator(i=None, **options)

Return the specified module generator.

INPUT:

• i – the index of the module generator
We can also get a module generator by using one of the following optional arguments:

- **shape** – the associated shape
- **column_shape** – the shape given as columns (a column of length $k$ correspond to a classical weight $\omega_k$)
- **weight** – the weight
- **classical_weight** – the classical weight

If no arguments are specified, then return the unique module generator of classical weight $s\Lambda_r$.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
sage: KRT.module_generator(1)
[[1, 1], [2, -1]]
sage: KRT.module_generator(shape=[1,1])
[[1, 1], [2, -1]]
sage: KRT.module_generator(column_shape=[2])
[[1, 1], [2, -1]]
sage: WS = RootSystem(['D',4,1]).weight_space()
sage: KRT.module_generator(weight=WS.sum_of_terms([[0,-2],[2,1]]))
[[1, 1], [2, -1]]
sage: WSC = RootSystem(['D',4]).weight_space()
sage: KRT.module_generator(classical_weight=WSC.fundamental_weight(2))
[[1, 1], [2, -1]]
sage: KRT.module_generator()
[[1, 1], [2, 2]]
```

**r()**

Return the value $r$ for this tableaux class which corresponds to the number of rows.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR')
sage: KRT.r()
2
```

**s()**

Return the value $s$ for this tableaux class which corresponds to the number of columns.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR')
sage: KRT.s()
1
```

**tensor(**crystals, **options)**

Return the tensor product of `self` with `crystals`.

If `crystals` is a list of (a tensor product of) KR tableaux, this returns a `TensorProductOfKirillovReshetikhinTableaux`.

**EXAMPLES:**

```python
.. code-block:: python

    sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2, model='KR')
    sage: TP = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1],
        ... [[1, 3], [3, 1]])
    sage: K.tensor(TP, K)
    Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1]
    and factor(s) ((2, 2), (1, 3), (3, 1), (2, 2))
    sage: C = crystals.KirillovReshetikhin(['A',3,1], 3, 1, model='KN')
    sage: K.tensor(K, C)
    Full tensor product of the crystals
    [Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (2, 2),
    Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (2, 2),
    Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(3,1)]

.. autoclass:: sage.combinat.rigged_configurations.kr_tableaux.KirillovReshetikhinTableauxElement

    Bases: \[\text{sage.combinat.crystals.tensor_product_element.}\]
    \[\text{TensorProductOfRegularCrystalsElement}\]

    A Kirillov-Reshetikhin tableau.

    For more information, see \texttt{KirillovReshetikhinTableaux} and
    \texttt{TensorProductOfKirillovReshetikhinTableaux}.

    .. automethod:: classical_weight

    .. automethod:: e

    .. automethod:: epsilon

    **classical_weight**

    Return the classical weight of \texttt{self}.

    EXAMPLES:

    .. code-block:: python

        sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
        sage: elt = KRT(3,2,-1,1); elt
        [[2, 1], [3, -1]]
        sage: elt.classical_weight()
        (0, 1, 1, 0)

    **e**

    Perform the action of \(e_i\) on \texttt{self}.

    **Todo:** Implement a direct action of \(e_0\) without moving to KR crystals.

    EXAMPLES:

    .. code-block:: python

        sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
        sage: KRT.module_generators[0].e(0)
        [[-2, 1], [-1, -1]]

    **epsilon**

    Compute \(\varepsilon_i\) of \texttt{self}.

    **Todo:** Implement a direct action of \(\varepsilon_0\) without moving to KR crystals.

    EXAMPLES:
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: KRT.module_generators[0].epsilon(0)
2

\( f(i) \)
Perform the action of \( f_i \) on \texttt{self}.

**Todo:** Implement a direct action of \( f_0 \) without moving to KR crystals.

**EXAMPLES:**

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: KRT.module_generators[0].f(0)
[[1, 1], [2, -1]]
```

\( \text{left\_split()} \)
Return the image of \texttt{self} under the left column splitting map.

**EXAMPLES:**

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 3, model='KR')
sage: mg = KRT.module_generators[1]; mg.pp()
1 -2 1
2 -1 2
sage: ls = mg.left_split(); ls.pp()
1 (X) -2 1
2 -1 2
sage: ls.parent()
Tensor product of Kirillov-Reshetikhin tableaux of type ['D', 4, 1] and
˓→factor(s) ((2, 1), (2, 2))
```

\( \phi(i) \)
Compute \( \phi_i \) of \texttt{self}.

**Todo:** Compute \( \phi_0 \) without moving to KR crystals.

**EXAMPLES:**

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: KRT.module_generators[0].phi(0)
2
```

\( \text{pp()} \)
Pretty print \texttt{self}.

**EXAMPLES:**

```
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 2, model='KR')
sage: elt = KRT(2, 1, 4, 3); elt
[[1, 3], [2, 4]]
sage: elt.pp()
1 3
2 4
```

5.1. Comprehensive Module list 1975
right_split()
Return the image of self under the right column splitting map.

Let * denote the Lusztig involution, and ls as the left splitting map. The right splitting map is defined as rs := * ∘ ls ∘ *.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 3, model='KR')
sage: mg = KRT.module_generators[1]; mg.pp()
  1 -2  1
  2 -1  2
sage: ls = mg.right_split(); ls.pp()
  -2  1  (X)
  -1  2  2
sage: ls.parent()
Tensor product of Kirillov-Reshetikhin tableaux of type ['D', 4, 1] and _
  →factor(s) ((2, 2), (2, 1))
```

to_array(rows=True)
Return a 2-dimensional array representation of this Kirillov-Reshetikhin element.

If the output is in rows, then it outputs the top row first (in the English convention) from left to right.

For example: if the reading word is [2, 1, 4, 3], so as a 2 × 2 tableau:

```
  1  3
  2  4
```

we output [[[1, 3], [2, 4]].

If the output is in columns, then it outputs the leftmost column first with the bottom element first. In other words this parses the reading word into its columns.

Continuing with the previous example, the output would be [[2, 1], [4, 3]].

INPUT:
• rows – (Default: True) Set to True if the resulting array is by row, otherwise it is by column.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 2, model='KR')
sage: elt = KRT(2, 1, 4, 3)
sage: elt.to_array()
[[1, 3], [2, 4]]
sage: elt.to_array(False)
[[2, 1], [4, 3]]
```

to_classical_highest_weight(index_set=None)
Return the classical highest weight element corresponding to self.

INPUT:
• index_set – (Default: None) Return the highest weight with respect to the index set. If None is passed in, then this uses the classical index set.

OUTPUT:
A pair [H, f_str] where H is the highest weight element and f_str is a list of aᵢ of fᵢᵢ needed to reach H.

EXAMPLES:
```python
sage: KRTab = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: elt = KRTab(3,2,-1,1); elt
[[2, 1], [3, -1]]
sage: elt.to_classical_highest_weight()
[[[1, 1], [2, -1]], [1, 2]]
```

**to_kirillov_reshetikhin_crystal()**

Construct a KashiwaraNakashimaTableaux() element from self.

We construct the Kirillov-Reshetikhin crystal element as follows:

1. Determine the shape $\lambda$ of the KR crystal from the weight.
2. Determine a path $e_{i_1} e_{i_2} \cdots e_{i_k}$ to the highest weight.
3. Apply $f_{i_k} \cdots f_{i_2} f_{i_1}$ to a highest weight KR crystal of shape $\lambda$.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: elt = KRT(3,2,-1,1); elt
[[2, 1], [3, -1]]
sage: elt.to_kirillov_reshetikhin_crystal()
[[2], [3]]
```

**to_tableau()**

Return a Tableau object of self.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 2, model='KR')
sage: elt = KRT(2, 1, 4, 3); elt
[[1, 3], [2, 4]]
sage: t = elt.to_tableau(); t
[[1, 3], [2, 4]]
sage: type(t)
<class 'sage.combinat.tableau.Tableaux_all_with_category.element_class'>
```

**weight()**

Return the weight of self.

**EXAMPLES:**

```python
sage: KR = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: KR.module_generators[1].weight()
-2*Lambda[0] + Lambda[2]
```

### 5.1.212 Crystal of Rigged Configurations

**AUTHORS:**

- Travis Scrimshaw (2010-09-26): Initial version

We only consider the highest weight crystal structure, not the Kirillov-Reshetikhin structure, and we extend this to symmetrizable types.

```python
class sage.combinat.rigged_configurations.rc_crystal.CrystalOfNonSimplyLacedRC(wcr, wr, WLR)
```
Highest weight crystal of rigged configurations in non-simply-laced type.

**Element**

*alias of* `sage.combinat.rigged_configurations.rigged_configuration_element.RCHWNonSimplyLacedElement`

**from_virtual** *(vrc)*

Convert `vrc` in the virtual crystal into a rigged configuration of the original Cartan type.

**INPUT:**

- `vrc` – a virtual rigged configuration

**EXAMPLES:**

```python
sage: La = RootSystem(['C', 3]).weight_lattice().fundamental_weights()
sage: vct = CartanType(['C', 3]).as_folding()
sage: RC = crystals.RiggedConfigurations(vct, La[2])
sage: elt = RC(partition_list=[[0], [1], [1]])
sage: elt == RC.from_virtual(RC.to_virtual(elt))
True
```

**to_virtual** *(rc)*

Convert `rc` into a rigged configuration in the virtual crystal.

**INPUT:**

- `rc` – a rigged configuration element

**EXAMPLES:**

```python
sage: La = RootSystem(['C', 3]).weight_lattice().fundamental_weights()
sage: vct = CartanType(['C', 3]).as_folding()
sage: RC = crystals.RiggedConfigurations(vct, La[2])
sage: elt = RC(partition_list=[[0], [1], [1]])

(/)
0[ ]0
-1[ ]-1
```

**virtual** *(rc)*

Return the corresponding virtual crystal.

**EXAMPLES:**

```python
sage: La = RootSystem(['C', 3]).weight_lattice().fundamental_weights()
sage: vct = CartanType(['C', 3]).as_folding()
sage: RC = crystals.RiggedConfigurations(vct, La[2])
sage: elt = RC(partition_list=[[0], [1], [1]])

(/)
0[ ]0
-2[ ][ ]-2
0[ ]0
(/{
```
```python
sage: La = RootSystem(['C', 2, 1]).weight_lattice().fundamental_weights()
sage: vct = CartanType(['C', 2, 1]).as_folding()
sage: RC = crystals.RiggedConfigurations(vct, La[0])
sage: RC
Crystal of rigged configurations of type ['C', 2, 1] and weight Lambda[0]
sage: RC.virtual
Crystal of rigged configurations of type ['A', 3, 1] and weight 2*Lambda[0]
```

```python
class sage.combinat.rigged_configurations.rc_crystal.CrystalOfRiggedConfigurations(wt, WLR)
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

A highest weight crystal of rigged configurations.

The crystal structure for finite simply-laced types is given in [CrysStructSchilling06]. These were then shown to be the crystal operators in all finite types in [SS2015], all simply-laced and a large class of foldings of simply-laced types in [SS2015II], and all symmetrizable types (uniformly) in [SS2017].

INPUT:
- cartan_type – (optional) a Cartan type or a Cartan type given as a folding
- wt – the highest weight vector in the weight lattice

EXAMPLES:
For simplicity, we display the rigged configurations horizontally:

```python
sage: RiggedConfigurations.options.display='horizontal'
```

We start with a simply-laced finite type:

```python
sage: La = RootSystem(['A', 2]).weight_lattice().fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[1] + La[2])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([1,2])
0[ ]0 0[ ]-1
sage: mg.f_string([1,2,2])
0[ ]0 -2[ ][]-2
sage: mg.f_string([1,2,2,2])
sage: mg.f_string([2,1,1,2])
-1[ ][]-1 -1[ ][]-1
sage: RC.cardinality()
8
sage: T = crystals.Tableaux(['A', 2], shape=[2,1])
sage: RC.digraph().is_isomorphic(T.digraph(), edge_labels=True)
True
```

We construct a non-simply-laced affine type:

```python
sage: La = RootSystem(['C', 3]).weight_lattice().fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[2])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([2,3])
(//) 1[ ]1 -1[ ]-1
sage: T = crystals.Tableaux(['C', 3], shape=[1,1])
sage: RC.digraph().is_isomorphic(T.digraph(), edge_labels=True)
True
```

5.1. Comprehensive Module list 1979
We can construct rigged configurations using a diagram folding of a simply-laced type. This yields an equivalent but distinct crystal:

```
sage: vct = CartanType(['C', 3]).as_folding()
sage: RC = crystals.RiggedConfigurations(vct, La[2])
sage: mg = RC.highest_weight_vector()
/ 0 [ ] 0 -1 [ ] -1
sage: T = crystals.Tableaux(['C', 3], shape=[1,1])
sage: RC.digraph().is_isomorphic(T.digraph(), edge_labels=True)
True
```

We reset the global options:

```
sage: RiggedConfigurations.options._reset()
```

REFERENCES:

- [SS2015]
- [SS2015II]
- [SS2017]

Element

alias of `sage.combinat.rigged_configurations.rigged_configuration_element.RCHighestWeightElement`

options(*set_value, **set_value)

Sets and displays the options for rigged configurations. If no parameters are set, then the function returns a copy of the options dictionary.

The options to partitions can be accessed as the method `RiggedConfigurations.options` of `RiggedConfigurations`.

OPTIONS:

- convention – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention
- display – (default: vertical) Specifies how rigged configurations should be printed
  - horizontal – displayed horizontally
  - vertical – displayed vertically
- element_ascii_art – (default: True) display using the repr option element_ascii_art
- half_width_boxes_type_B – (default: True) display the last rigged partition in affine type B as half width boxes
- notation – alternative name for convention

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A',3,1], [[2,2],[1,1],[1,1]])
sage: elt = RC(partition_list=[[3,1], [3], [1]])
sage: elt
-3[ ][ ][-3]
```
Changing the convention for rigged configurations also changes the convention option for tableaux and vice versa:

```python
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
   4 5
  1 2 3
sage: Tableaux.options.convention="english"
sage: elt
-3[ ][ ][ ]-3 1[ ][ ][ ]1 -1[ ][ ]-1
-1[ ][ ]-1
sage: T.pp()
   1 2 3
  4 5
sage: RiggedConfigurations.options._reset()
```

See `GlobalOptions` for more features of these options.

**weight_lattice_realization()**

Return the weight lattice realization used to express the weights of elements in `self`.

**EXAMPLES:**

```python
sage: La = RootSystem(['A', 2, 1]).weight_lattice(extended=True).fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[0])
sage: RC.weight_lattice_realization()
Extended weight lattice of the Root system of type ['A', 2, 1]
```

### 5.1.213 Rigged Configurations of \( B(\infty) \)

**AUTHORS:**
- Travis Scrimshaw (2013-04-16): Initial version

```python
class sage.combinat.rigged_configurations.rc_infinity.InfinityCrystalOfNonSimplyLacedRC(vct)
Bases: sage.combinat.rigged_configurations.rc_infinity.
InfinityCrystalOfRiggedConfigurations
```

Rigged configurations for \( B(\infty) \) in non-simply-laced types.

```python
class Element (parent, rigged_partitions=[], **options)
Bases: sage.combinat.rigged_configurations.rigged_configuration_element.
RCNonSimplyLacedElement
```

A rigged configuration in \( B(\infty) \) in non-simply-laced types.
weight ()
Return the weight of self.

EXAMPLES:

```python
sage: vct = CartanType(['C', 3]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: elt = RC(partition_list=[[1],[1],[1]], rigging_list=[[0],[-1,-1],
                   [0]])
sage: elt.weight()
(-1, -1, 0)
```

from_virtual (vrc)
Convert vrc in the virtual crystal into a rigged configuration of the original Cartan type.

INPUT:

- vrc – a virtual rigged configuration

EXAMPLES:

```python
sage: vct = CartanType(['C', 2]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: elt = RC(partition_list=[[3],[2]], rigging_list=[[-2],[0]])
sage: vrc_elt = RC.to_virtual(elt)
sage: ret = RC.from_virtual(vrc_elt); ret
-3[ ][ ][ ]-2
-1[ ][ ]0
sage: ret == elt
True
```

to_virtual (rc)
Convert rc into a rigged configuration in the virtual crystal.

INPUT:

- rc – a rigged configuration element

EXAMPLES:

```python
sage: vct = CartanType(['C', 2]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: mg = RC.highest_weight_vector()
sage: elt = mg.f_string([1,2,2,1,1]); elt
-3[ ][ ][ ]-2
```
virtual()  
Return the corresponding virtual crystal.

EXAMPLES:

```python
sage: vct = CartanType(['C', 3]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: RC
The infinity crystal of rigged configurations of type ['C', 3]
sage: RC.virtual
The infinity crystal of rigged configurations of type ['A', 5]
```

```
5.1. Comprehensive Module list 1983
```
Next we consider a non-simply-laced finite type:

```python
sage: RC = crystals.infinity.RiggedConfigurations(['C', 3])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([2,1,3,2])
0[ ] 0 -1[ ] -1 0[ ] 0
-1[ ] -1
sage: mg.f_string([2,3,2,1,3,2])
0[ ] -1[ ] -1 -1[ ] [ ] -1
-2[ ] -1
```

We can construct rigged configurations using a diagram folding of a simply-laced type. This yields an equivalent but distinct crystal:

```python
sage: vct = CartanType(['C', 3]).as_folding()
sage: VRC = crystals.infinity.RiggedConfigurations(vct)
sage: mg = VRC.highest_weight_vector()
sage: mg.f_string([2,1,3,2])
0[ ] 0 -2[ ] -1 0[ ] 0
-2[ ] -1
sage: mg.f_string([2,3,2,1,3,2])
-1[ ] -1 -2[ ] [ ] -1 -1[ ] [ ] 0
-1[ ] 0
```

We can also construct \( B(\infty) \) using rigged configurations in affine types:

```python
sage: RC = crystals.infinity.RiggedConfigurations(['A', 3, 1])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([0,1,2,3,0,1,3])
-1[ ] 0 -1[ ] -1 1[ ] 1 -1[ ] [ ] -1
-1[ ] 0 -1[ ] -1
sage: RC = crystals.infinity.RiggedConfigurations(['C', 3, 1])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([1,2,3,0,1,2,3,3,0])
-2[ ][ ] -1 0[ ] 1 0[ ] 0 -4[ ][ ][ ] -2
0[ ] 0 0[ ] -1
sage: RC = crystals.infinity.RiggedConfigurations(['A', 6, 2])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([1,2,3,0,1,2,3,3,0])
0[ ] -1 0[ ] 1 0[ ] 0 -4[ ][ ][ ] -2
0[ ] -1 0[ ] -1
```

We reset the global options:
sage: RiggedConfigurations.options._reset()

class Element (parent, rigged_partitions=[], **options)
    Bases: sage.combinat.rigged_configurations.rigged_configuration_element. RiggedConfigurationElement

A rigged configuration in $\mathcal{B}(\infty)$ in simply-laced types.

weight ()
    Return the weight of self.

    EXAMPLES:
    sage: RC = crystals.infinity.RiggedConfigurations(['A', 3, 1])
    sage: elt = RC(partition_list=[[1,1]]*4, rigging_list=[[1,1], [0,0], [0, -0], [-1,-1]])
    sage: elt.weight()
    -2*delta

options (*get_value, **set_value)
    Sets and displays the options for rigged configurations. If no parameters are set, then the function returns a copy of the options dictionary.

    The options to partitions can be accessed as the method RiggedConfigurations.options of RiggedConfigurations.

    OPTIONS:
    - convention – (default: English) Sets the convention used for displaying tableaux and partitions
      - English – use the English convention
      - French – use the French convention
    - display – (default: vertical) Specifies how rigged configurations should be printed
      - horizontal – displayed horizontally
      - vertical – displayed vertically
    - element_ascii_art – (default: True) display using the repr option element_ascii_art
    - half_width_boxes_type_B – (default: True) display the last rigged partition in affine type B as half width boxes
    - notation – alternative name for convention

    EXAMPLES:
    sage: RC = RiggedConfigurations(['A',3,1], [[2,2],[1,1],[1,1]])
    sage: elt = RC(partition_list=[[3,1], [3], [1]])
    sage: elt
    -3[ ][ ][ ]-3
    -1[ ]-1
    1[ ][ ][ ]1
    -1[ ]-1
    sage: RiggedConfigurations.options(display="horizontal", convention="french")
    sage: elt
    (continues on next page)
Changing the convention for rigged configurations also changes the convention option for tableaux and vice versa:

```python
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
4 5
1 2 3
sage: Tableaux.options.convention="english"
sage: elt
-3[ ][][ ][-3] 1[ ][][ ]1 -1[ ]-1
-1[ ]-1
sage: T.pp()
1 2 3
4 5
sage: RiggedConfigurations.options._reset()
```

See `GlobalOptions` for more features of these options.

`weight_lattice_realization()`

Return the weight lattice realization used to express the weights of elements in `self`.

EXAMPLES:

```python
sage: RC = crystals.infinity.RiggedConfigurations(['A', 2, 1])
sage: RC.weight_lattice_realization()
Extended weight lattice of the Root system of type ['A', 2, 1]
```

### 5.1.214 Rigged Configuration Elements

A rigged configuration element is a sequence of `RiggedPartition` objects.

AUTHORS:

- Travis Scrimshaw (2010-09-26): Initial version
- Travis Scrimshaw (2012-10-25): Added virtual rigged configurations

```python
Bases: sage.combinat.rigged_configurations.rigged_configuration_element.KRRiggedConfigurationElement

U_q(g) rigged configurations in non-simply-laced types.

cc()

Compute the cocharge statistic.

Computes the cocharge statistic [OSS03] on this rigged configuration \((\nu, J)\) by computing the cocharge as a virtual rigged configuration \((\hat{\nu}, \hat{J})\) and then using the identity \(cc(\nu, J) = \gamma_0 cc(\hat{\nu}, \hat{J})\).

EXAMPLES:
```
cocharge()  
Compute the cocharge statistic. 

Computes the cocharge statistic [OSS03] on this rigged configuration \((\nu, J)\) by computing the cocharge as a virtual rigged configuration \((\hat{\nu}, \hat{J})\) and then using the identity \(cc(\hat{\nu}, \hat{J}) = \gamma_0 cc(\nu, J)\). 

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['C', 3, 1], [[2,1], [1,1]])
sage: RC(partition_list=[[1,1],[2,1],[1,1]]).cocharge()
1
```

\(e(a)\)  
Return the action of \(e_a\) on \(self\). 

This works by lifting into the virtual configuration, then applying 

\[ e_a^{\nu} = \prod_{j \in i(a)} \hat{e}_{j}^{\gamma_j} \]

and pulling back. 

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A',6,2], [[1,1]*7])
sage: elt = RC(partition_list=[[1]*5,[2,1,1],[2,1]], rigging_list=[[0]*5,[0,1,-1],[1,0]])
sage: elt.e(3)
```

\(f(a)\)  
Return the action of \(f_a\) on \(self\). 

This works by lifting into the virtual configuration, then applying 

\[ f_a^{\nu} = \prod_{j \in i(a)} \hat{f}_{j}^{\gamma_j} \]

and pulling back. 

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A',6,2], [[1,1]*7])
sage: elt = RC(partition_list=[[1]*5,[2,1,1],[2,1]], rigging_list=[[0]*5,[0,1,-1],[1,0]])
```

(continues on next page)
sage: elt.f(3)
0[ ]0
0[ ]0
0[ ]0
0[ ]0
0[ ]0
1[ ][ ]1
1[ ]1
1[ ]1
-1[ ][ ][ ]-1
0[ ][ ]0

class sage.combinat.rigged_configurations.rigged_configuration_element.KRRCSimplyLacedElement

Bases: sage.combinat.rigged_configurations.rigged_configuration_element.KRRiggedConfigurationElement

$U'_q(g)$ rigged configurations in simply-laced types.

cc()
Compute the cocharge statistic of self.

Computes the cocharge statistic \cite{CrysStructSchilling06} on this rigged configuration $(\nu, J)$. The cocharge statistic is defined as:

$$cc(\nu, J) = \frac{1}{2} \sum_{a, b \in I_0} \sum_{j, k > 0} (\alpha_a | \alpha_b) \min(j, k) m_j^{(a)} m_k^{(b)} + \sum_{a \in I} \sum_{i > 0} |J^{(a, i)}|.$$

EXAMPLES:

```sage
RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [2, 1], [1, 1]])
RC(partition_list=[[1], [1], []]).cocharge()
```

charge()
Compute the charge statistic of self.

Let $B$ denote a set of rigged configurations. The charge $c$ of a rigged configuration $b$ is computed as

$$c(b) = \max(cc(b) \mid b \in B) - cc(b).$$

EXAMPLES:

```sage
RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [2, 1], [1, 1]])
RC(partition_list=[[1], [1], []]).charge()
```

cocharge()
Compute the cocharge statistic of self.
Computes the cocharge statistic \[\text{CrysStructSchilling06}\] on this rigged configuration \((\nu, J)\). The cocharge statistic is defined as:

\[
cc(\nu, J) = \frac{1}{2} \sum_{a,b \in I_0} \sum_{j,k > 0} (\alpha_a | \alpha_b) \min(j, k) m_j^{(a)} m_k^{(b)} + \sum_{a \in I} \sum_{i > 0} |f^{(a,i)}|.
\]

**EXAMPLES:**

```sage
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [2, 1], [1,1]])
sage: RC(partition_list=[[1], [1], []]).cocharge()
1
```

```python
class sage.combinat.rigged_configurations.rigged_configuration_element.KRRCTypeA2DualElement

Bases: sage.combinat.rigged_configurations.rigged_configuration_element.KRRCNonSimplyLacedElement

\(U_q'(g)\) rigged configurations in type \(A_{2n}^{(2)}\).

\[cc()\]

Compute the cocharge statistic.

Computes the cocharge statistic \[\text{RigConBijection}\] on this rigged configuration \((\nu, J)\). The cocharge statistic is computed as:

\[
cc(\nu, J) = \frac{1}{2} \sum_{a \in I_0} \sum_{i > 0} t_a^\nu m_i^{(a)} \left( \sum_{j > 0} \min(i, j) L_j^{(a)} - p_i^{(a)} \right) + \sum_{a \in I} \sum_{i > 0} t_a^\nu \sum_{i > 0} |f^{(a,i)}|.
\]

**EXAMPLES:**

```sage
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,1], [2,2]])
sage: sc = RC.cartan_type().as_folding().scaling_factors()
sage: all(mg.cocharge() * sc[0] == mg.to_virtual_configuration().cocharge() for mg in RC.module_generators)
True
```

\[cocharge()\]

Compute the cocharge statistic.

Computes the cocharge statistic \[\text{RigConBijection}\] on this rigged configuration \((\nu, J)\). The cocharge statistic is computed as:

\[
cc(\nu, J) = \frac{1}{2} \sum_{a \in I_0} \sum_{i > 0} t_a^\nu m_i^{(a)} \left( \sum_{j > 0} \min(i, j) L_j^{(a)} - p_i^{(a)} \right) + \sum_{a \in I} \sum_{i > 0} t_a^\nu \sum_{i > 0} |f^{(a,i)}|.
\]

**EXAMPLES:**

```sage
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,1], [2,2]])
sage: sc = RC.cartan_type().as_folding().scaling_factors()
sage: all(mg.cocharge() * sc[0] == mg.to_virtual_configuration().cocharge() for mg in RC.module_generators)
True
```

\[\epsilon(a)\]

Return the value of \(\epsilon_a\) of \text{self}.

5.1. Comprehensive Module list 1989
Here we need to modify the usual definition by $\epsilon'_n := 2\epsilon_n$.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,1], [2,2]])
sage: def epsilon(x, i):
    x = x.e(i)
    eps = 0
    while x is not None:
        x = x.e(i)
        eps = eps + 1
    return eps
sage: all(epsilon(rc, 2) == rc.epsilon(2) for rc in RC)
True
```

$\phi(a)$

Return the value of $\varphi_a$ of self.

Here we need to modify the usual definition by $\varphi'_n := 2\varphi_n$.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,1], [2,2]])
sage: def phi(x, i):
    x = x.f(i)
    ph = 0
    while x is not None:
        x = x.f(i)
        ph = ph + 1
    return ph
sage: all(phi(rc, 2) == rc.phi(2) for rc in RC)
True
```

```python
class sage.combinat.rigged_configurations.rigged_configuration_element.KRRiggedConfigurationElement

Bases: sage.combinat.rigged_configurations.rigged_configuration_element.RiggedConfigurationElement

$U'_q(g)$ rigged configurations.

**EXAMPLES:**

We can go between rigged configurations and tensor products of tensor products of KR tableaux:

```python
sage: RC = RiggedConfigurations(['D', 4, 1], [[1,1], [2,1]])
sage: rc_elt = RC(partition_list=[[1], [1,1], [1], [1]])
sage: tp_krtab = rc_elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); tp_krtab
[[[-2]], [1], [2]]
sage: tp_krcrys = rc_elt.to_tensor_product_of_kirillov_reshetikhin_crystals(); tp_krcrys
[[[-2]], [1], [2]]
sage: True
```

(continues on next page)
True
\texttt{sage: tp_krtab.to_rigged_configuration()} == rc_elt
True

\texttt{check}()

Make sure all of the riggings are less than or equal to the vacancy number.

\texttt{classical_weight}()

Return the classical weight of self.

The classical weight $\Lambda$ of a rigged configuration is

$$
\Lambda = \sum_{a \in \mathcal{I}} \sum_{i > 0} i L_i^{(a)} \Lambda_a - \sum_{a \in \mathcal{I}} \sum_{i > 0} i m_i^{(a)} \alpha_a.
$$

\textbf{EXAMPLES:}

\texttt{sage: RC = RiggedConfigurations([‘D’,4,1], [[2,2]])}
\texttt{sage: elt = RC(partition_list=[[2],[2,1],[1],[1]])}
\texttt{sage: elt.classical_weight()}
(0, 1, 1, 0)

This agrees with the corresponding classical weight as KR tableaux:

\texttt{sage: krt = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); krt}
[[2, 1], [3, -1]]
\texttt{sage: krt.classical_weight() == elt.classical_weight()}
True

\texttt{complement_rigging(reverse_factors=False)}

Apply the complement rigging morphism $\theta$ to self.

Consider a highest weight rigged configuration $(\nu, J)$, the complement rigging morphism $\theta : RC(L) \to RC(L)$ is given by sending $(\nu, J) \mapsto (\nu, J')$, where $J'$ is obtained by taking the coriggings $x' = p_i^{(a)} - x$, and then extending as a crystal morphism. (The name comes from taking the complement partition for the riggings in a $m_i^{(a)} \times p_i^{(a)}$ box.)

\textbf{INPUT:}

- \texttt{reverse_factors} – (default: False) if True, then this returns an element in $RC(B')$ where $B'$ is the tensor factors of self in reverse order

\textbf{EXAMPLES:}

\texttt{sage: RC = RiggedConfigurations([‘D’,4,1], [[1,1],[2,2]])}
\texttt{sage: mg = RC.module_generators[-1]}
\texttt{sage: ascii_art(mg)}
\begin{verbatim}
1[ ][ ][ ]1 0[ ][ ]0 0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
\end{verbatim}
\texttt{sage: ascii_art(mg.complement_rigging())}
\begin{verbatim}
1[ ][ ]0 0[ ][ ]0 0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
\end{verbatim}
\texttt{sage: lw = mg.to_lowest_weight([1,2,3,4])[0]}
\texttt{sage: ascii_art(lw)}
\begin{verbatim}
-1[ ][ ][ ]-1 0[ ][ ]0 0[ ][ ]0 0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
\end{verbatim}
sage: ascii_art(lw.complement_rigging())
-1[ | ]0 0[ | ]0 0[ | ]0 0[ | ]0
-1[ | ]0 0[ | ]0
sage: lw.complement_rigging() == mg.complement_rigging().to_lowest_weight([1, -2, 3, 4])[0]
True

sage: mg.complement_rigging(True).parent()
Rigged configurations of type ['D', 4, 1] and factor(s) ((2, 2), (1, 1))

We check that the Lusztig involution (under the modification of also mapping to the highest weight element) intertwines with the complement map $\theta$ (that reverses the tensor factors) under the bijection $\Phi$:

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2], [2, 1], [1, 2]])
sage: for mg in RC.module_generators:
    # long time
    ....: y = mg.to_tensor_product_of_kirillov_reshetikhin_tableaux()
    ....: hw = y.lusztig_involution().to_highest_weight([1,2,3,4])[0]
    ....: c = mg.complement_rigging(True)
    ....: hwc = c.to_tensor_product_of_kirillov_reshetikhin_tableaux()
    ....: assert hw == hwc
```

```
delta (return_b=False)
Return the image of self under the left box removal map $\delta$.

The map $\delta : RC(B_r^1 \otimes B) \to RC(B_r^{-1,1} \otimes B)$ (if $r = 1$, then we remove the left-most factor) is the basic map in the bijection $\Phi$ between rigged configurations and tensor products of Kirillov-Reshetikhin tableaux.

For more information, see `to_tensor_product_of_kirillov_reshetikhin_tableaux()`.

We can extend $\delta$ when the left-most factor is not a single column by precomposing with a `left_split()`.

**Note:** Due to the special nature of the bijection for the spinor cases in types $D_n^{(1)}$, $B_n^{(1)}$, and $A_{2n-1}^{(2)}$, this map is not defined in these cases.

**INPUT:**

* return_b – (default: False) whether to return the resulting letter from $\delta$

**OUTPUT:**

The resulting rigged configuration or if return_b is True, then a tuple of the resulting rigged configuration and the letter.

**EXAMPLES:**

```
sage: RC = RiggedConfigurations(['C',4,1], [[3,2]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
0[ | ]0 0[ | ]0 0[ | ]0 0[ ]0
0[ | ]0 0[ | ]0 0[ | ]0
0[ | ]0 0[ | ]0
sage: ascii_art(mg.left_box())
0[ ]0 0[ ]0 0[ ]0 0[ ]0
0[ ]0 0[ ]0 0[ ]0
sage: x, b = mg.left_box(True)
sage: b
```

(continues on next page)
-1
sage: b.parent()
The crystal of letters for type ['C', 4]

\( e(a) \)

Return the action of the crystal operator \( e_a \) on \( \text{self} \).

For the classical operators, this implements the method defined in [CrysStructSchilling06]. For \( e_0 \), this converts the class to a tensor product of KR tableaux and does the corresponding \( e_0 \) and pulls back.

**Todo:** Implement \( e_0 \) without appealing to tensor product of KR tableaux.

**INPUT:**

- \( a \) – the index of the partition to remove a box

**OUTPUT:**

The resulting rigged configuration element.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2,1]])
sage: elt = RC(partition_list=[[1], [1], [1], [1]])
sage: elt.e(3)
sage: elt.e(1)
```

\( -1 \)

\( \epsilon(a) \)

Return \( \epsilon_a \) of \( \text{self} \).

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2]])
sage: I = RC.index_set()
sage: matrix([[mg.epsilon(i) for i in I] for mg in RC.module_generators])
```

\[ \begin{bmatrix}
4 & 0 & 0 & 0 & 0 \\
3 & 0 & 0 & 0 & 0 \\
2 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
\end{bmatrix} \]

\( f(a) \)

Return the action of the crystal operator \( f_a \) on \( \text{self} \).

For the classical operators, this implements the method defined in [CrysStructSchilling06]. For \( f_0 \), this converts the class to a tensor product of KR tableaux and does the corresponding \( f_0 \) and pulls back.

**Todo:** Implement \( f_0 \) without appealing to tensor product of KR tableaux.

**INPUT:**
• a – the index of the partition to add a box

OUTPUT:

The resulting rigged configuration element.

EXAMPLES:

sage: RC = RiggedConfigurations(['A', 4, 1], [[2,1]])
sage: elt = RC(partition_list=[[1], [1], [1], [1]])
sage: elt.f(1)
sage: elt.f(2)

\[
\begin{array}{|c|c|c|c|}
\hline
0 & 0 & -1 & 0 \\
\hline
-1 & -1 & -1 & -1 \\
\hline
0 & 1 & 1 & 1 \\
\hline
-1 & -1 & -1 & -1 \\
\hline
\end{array}
\]

left_box (return_b=False)

Return the image of self under the left box removal map $\delta$.

The map $\delta : RC(B^r_1 \otimes B) \rightarrow RC(B^{r-1}_1 \otimes B)$ (if $r = 1$, then we remove the left-most factor) is the basic map in the bijection $\Phi$ between rigged configurations and tensor products of Kirillov-Reshetikhin tableaux. For more information, see to_tensor_product_of_kirillov_reshetikhin_tableaux(). We can extend $\delta$ when the left-most factor is not a single column by precomposing with a left_split().

Note: Due to the special nature of the bijection for the spinor cases in types $D_n^{(1)}$, $B_n^{(1)}$, and $A_{2n-1}^{(2)}$, this map is not defined in these cases.

INPUT:

• return_b – (default: False) whether to return the resulting letter from $\delta$

OUTPUT:

The resulting rigged configuration or if return_b is True, then a tuple of the resulting rigged configuration and the letter.

EXAMPLES:

sage: RC = RiggedConfigurations(['C',4,1], [[3,2]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)

\[
\begin{array}{|c|c|c|c|c|c|c|c|c|c|}
\hline
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{array}
\]

sage: ascii_art(mg.left_box())

\[
\begin{array}{|c|c|c|c|c|c|c|c|c|c|}
\hline
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{array}
\]

sage: x,b = mg.left_box(True)
sage: b
-1
sage: b.parent()
The crystal of letters for type ['C', 4]
left_column_box()
Return the image of self under the left column box splitting map γ.

Consider the map γ : \(RC(B^r \otimes B) \rightarrow RC(B^{1,1} \otimes B^{r-1,1} \otimes B)\) for \(r > 1\), which is a natural strict classical crystal injection. On rigged configurations, the map γ adds a singular string of length 1 to \(\nu^{(0)}\).

We can extend γ when the left-most factor is not a single column by precomposing with a left_split().

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C',3,1], [[3,1], [2,1]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
0[ ][ ]0 0[ ][ ]0
sage: ascii_art(mg.left_column_box())
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
0[ ][ ]0 0[ ][ ]0
0[ ][ ]0
sage: RC = RiggedConfigurations(['C',3,1], [[2,1], [1,1], [3,1]])
sage: mg = RC.module_generators[7]
sage: ascii_art(mg)
i[ ][ ]0 0[ ][ ]0 0[ ][ ]0
0[ ][ ]0 0[ ][ ]0
sage: ascii_art(mg.left_column_box())
i[ ][ ]i 0[ ][ ]0 0[ ][ ]0
i[ ][ ]0 0[ ][ ]0
```

left_split()
Return the image of self under the left column splitting map β.

Consider the map \(\beta : RC(B^r \otimes B) \rightarrow RC(B^{1,1} \otimes B^{r-1,1} \otimes B)\) for \(s > 1\) which is a natural classical crystal injection. On rigged configurations, the map \(\beta\) does nothing (except possibly changing the vacancy numbers).

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C',4,1], [[3,3]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
0[ ][ ][ ][ ]0 0[ ][ ][ ][ ]0 0[ ][ ][ ][ ]0
0[ ][ ][ ][ ]0
sage: ascii_art(mg.left_split())
0[ ][ ][ ][ ]0 0[ ][ ][ ][ ]0 0[ ][ ][ ][ ]0
0[ ][ ][ ][ ]0
1[ ][ ][ ][ ]0
1[ ][ ][ ][ ]0
```

phi\(a\)
Return \(\phi_a\) of self.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2]])
sage: I = RC.index_set()
sage: matrix([[mg.phi(i) for i in I] for mg in RC.module_generators])
[0 0 2 0 0]
```

(continues on next page)
right_column_box()

Return the image of self under the right column box splitting map $\gamma^*$.

Consider the map $\gamma^* : RC(B \otimes B^{r,1}) \to RC(B \otimes B^{r-1,1} \otimes B^{1,1})$ for $r > 1$, which is a natural strict classical crystal injection. On rigged configurations, the map $\gamma$ adds a string of length 1 with rigging 0 to $\nu^{(a)}$ for all $a < r$ to a classically highest weight element and extended as a classical crystal morphism.

We can extend $\gamma^*$ when the right-most factor is not a single column by precomposing with a right_split().

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C',3,1], [[2,1], [1,1], [3,1]])
sage: mg = RC.module_generators[7]
sage: ascii_art(mg)
1[ ]0 0[ ]0 0[ ]0
0[ ]0 0[ ]0
sage: ascii_art(mg.right_column_box())
1[ ]0 0[ ]0 0[ ]0
1[ ]0 0[ ]0
0[ ]0
```

right_split()

Return the image of self under the right column splitting map $\beta^*$.

Let $\theta$ denote the complement rigging map which reverses the tensor factors and $\beta$ denote the left splitting map, we define the right splitting map by $\beta^* := \theta \circ \beta \circ \theta$.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C',4,1], [[3,3]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
0[ ]0 0[ ]0 0[ ]0 0[ ]0
0[ ]0 0[ ]0
sage: ascii_art(mg.right_split())
0[ ]0 0[ ]0 1[ ]1 0[ ]0
0[ ]0 1[ ]1 0[ ]0
1[ ]1 0[ ]0
sage: RC = RiggedConfigurations(['D',4,1], [[2,2],[1,2]])
sage: elt = RC(partition_list=[[3,1], [2,2,1], [2,1], [2]])
sage: ascii_art(elt)
-1[ ]1[ ]-1 0[ ]0 -1[ ]1[ ]-1 1[ ]1
0[ ]0 0[ ]0 -1[ ]-1
sage: ascii_art(elt.right_split())
-1[ ]1[ ]-1 0[ ]0 -1[ ]1[ ]-1 1[ ]1
-1[ ]-1 0[ ]0 -1[ ]-1
0[ ]0
```

We check that the bijection commutes with the right splitting map:

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[1,1], [2,2]])
sage: all(rc.right_split().to_tensor_product_of_kirillov_reshetikhin_tableaux() for rc in RC)
True
to_tensor_product_of_kirillov_reshetikhin_crystals (display_steps=False, build_graph=False)

Return the corresponding tensor product of Kirillov-Reshetikhin crystals.
This is a composition of the map to a tensor product of KR tableaux, and then to a tensor product of KR crystals.

INPUT:

• display_steps – (default: False) boolean which indicates if we want to print each step in the algorithm
• build_graph – (default: False) boolean which indicates if we want to construct and return a graph of the bijection whose vertices are rigged configurations obtained at each step and edges are labeled by either the return value of δ or the doubling/halving map

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2]])
sage: elt = RC(partition_list=[[2], [2,2], [1], [1]])
sage: krc = elt.to_tensor_product_of_kirillov_reshetikhin_crystals(); krc
[[[2, 3], [3, -2]]]
We can recover the rigged configuration:

```python
sage: ret = RC(krc); ret
0[ ]0
-2[ ]-2
-2[ ]-2
0[ ]0
0[ ]0
sage: elt == ret
True
We can also construct and display a graph of the bijection as follows:

```python
sage: ret, G = elt.to_tensor_product_of_kirillov_reshetikhin_crystals(build_graph=True)
sage: view(G) # not tested
to_tensor_product_of_kirillov_reshetikhin_tableaux (display_steps=False, build_graph=False)

Perform the bijection from this rigged configuration to a tensor product of Kirillov-Reshetikhin tableaux given in [RigConBijection] for single boxes and with [BijectionLRT] and [BijectionDn] for multiple columns and rows.

5.1. Comprehensive Module list 1997
Note: This is only proven to be a bijection in types $A_n^{(1)}$ and $D_n^{(1)}$, as well as $\otimes_j B_{r_j}^{s_j}$ and $\otimes_j B_{r_j}^{s_j}$ for general affine types.

INPUT:

- `display_steps` – (default: `False`) boolean which indicates if we want to print each step in the algorithm
- `build_graph` – (default: `False`) boolean which indicates if we want to construct and return a graph of the bijection whose vertices are rigged configurations obtained at each step and edges are labeled by either the return value of $\delta$ or the doubling/halving map

OUTPUT:

- The tensor product of KR tableaux element corresponding to this rigged configuration.

EXAMPLES:

```sage
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RC(partition_list=[[2], [2,2], [2], [2]]).to_tensor_product_of_kirillov_reshetikhin_tableaux()
[[3, 3], [5, 5]]
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2]])
sage: elt = RC(partition_list=[[2], [2,2], [1], [1]])
sage: tp_krt = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); tp_krt
[[2, 3], [3, -2]]
```

This is invertible by calling `to_rigged_configuration()`:

```sage
sage: ret = tp_krt.to_rigged_configuration(); ret
0[ ][ ]0
-2[ ][ ]-2
-2[ ][ ]-2
0[ ]0
0[ ]0

sage: elt == ret
True
```

To view the steps of the bijection in the output, run with the `display_steps=True` option:

```sage
sage: elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(True)
```

(continues on next page)
0[ ]0
--------------------
[[3, 2]]
--------------------
...
[[2, 3], [3, -2]]

We can also construct and display a graph of the bijection as follows:

```python
sage: ret, G = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(build_˓→graph=True)
sage: view(G) # not tested
```

**weight()**

Return the weight of `self`.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['E', 6, 1], [[2,2]])
sage: [x.weight() for x in RC.module_generators]
[-4*Lambda[0] + 2*Lambda[2], -2*Lambda[0] + Lambda[2], 0]
sage: KR = crystals.KirillovReshetikhin(['E',6,1], 2,2)
sage: [x.weight() for x in KR.module_generators]  # long time
[0, -2*Lambda[0] + Lambda[2], -4*Lambda[0] + 2*Lambda[2]]
sage: RC = RiggedConfigurations(['D', 6, 1], [[4,2]])
sage: [x.weight() for x in RC.module_generators]
[-4*Lambda[0] + 2*Lambda[4], -4*Lambda[0] + Lambda[2] + Lambda[4],
 -2*Lambda[0] + Lambda[4], -4*Lambda[0] + 2*Lambda[2],
 -2*Lambda[0] + Lambda[2], 0]
```

**class** `sage.combinat.rigged_configurations.rigged_configuration_element.RCHWNonSimplyLacedElement`  

Bases: `sage.combinat.rigged_configurations.rigged_configuration_element.RCNonSimplyLacedElement`

Rigged configurations in highest weight crystals.

**check()**

Make sure all of the riggings are less than or equal to the vacancy number.

**f(a)**

Return the action of $f_a$ on `self`.

This works by lifting into the virtual configuration, then applying

$$f'_a = \prod_{j \in \mathfrak{g}(a)} \hat{f}_{\gamma_j}$$

and pulling back.

**EXAMPLES:**

```python
sage: La = RootSystem(['C',2,1]).weight_lattice(extended=True).fundamental_˓→weights()
sage: vct = CartanType(['C',2,1]).as_folding()
```
sage: RC = crystals.RiggedConfigurations(vct, La[0])
sage: elt = RC(partition_list=[[1,1],[2],[2]])
sage: elt.f(0)

ascii_art(elt.f(1))

0[ ]0 0[ ]0 -1[ ]-1
0[ ]0 -1[ ]-1

sage: elt.f(2)

weight()

Return the weight of self.

EXAMPLES:

sage: La = RootSystem(['C',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: vct = CartanType(['C',2,1]).as_folding()
sage: B = crystals.RiggedConfigurations(vct, La[0])
sage: mg = B.module_generators[0]
sage: mg.f_string([0,1,2]).weight()

class sage.combinat.rigged_configurations.rigged_configuration_element.RCHighestWeightElement

Bases: sage.combinat.rigged_configurations.rigged_configuration_element.RiggedConfigurationElement

Rigged configurations in highest weight crystals.

check()

Make sure all of the riggings are less than or equal to the vacancy number.

f(a)

Return the action of the crystal operator $f_a$ on self.

This implements the method defined in [CrysStructSchilling06] which finds the value $k$ which is the length of the string with the smallest nonpositive rigging of largest length. Then it adds a box from a string of length $k$ in the $a$-th rigged partition, keeping all colabels fixed and decreasing the new label by one. If no such string exists, then it adds a new string of length 1 with label $-1$. If any of the resulting vacancy numbers are larger than the labels (i.e. it is an invalid rigged configuration), then $f_a$ is undefined.

INPUT:

- $a$ – the index of the partition to add a box

OUTPUT:

The resulting rigged configuration element.

EXAMPLES:

sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: RC = crystals.RiggedConfigurations(['A',2,1], La[0])
sage: elt = RC(partition_list=[[1,1],[1],[2]])
sage: elt.f(0)

-2[ ][ ]-2

(continues on next page)
-1[-1]
1[1]
0[0][0]
sage: elt.f(1)
0[0]
0[0]
-1[-1]
-1[-1]
0[0][0]
sage: elt.f(2)

weight()
Return the weight of self.

EXAMPLES:

sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: B = crystals.RiggedConfigurations(['A',2,1], La[0])
sage: mg = B.module_generators[0]
sage: mg.f_string([0,1,2,0]).weight()

class sage.combinat.rigged_configurations.rigged_configuration_element.RCNonSimplyLacedElement

Bases: sage.combinat.rigged_configurations.rigged_configuration_element.RiggedConfigurationElement

Rigged configuration elements for non-simply-laced types.

e(a)
Return the action of $e_a$ on self.

This works by lifting into the virtual configuration, then applying

$$e_a^{\nu} = \prod_{j \in \iota(a)} \hat{e}_j^{\gamma_j}$$

and pulling back.

EXAMPLES:

sage: vct = CartanType(['C',2,1]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: elt = RC(partition_list=[[2],[1,1],[2]], rigging_list=[[1],[-1],[2,-1]])
sage: ascii_art(elt.e(0))
0[0] -2[-1] -2[]-1
-2[-1]
Return the action of $f_a$ on self.

This works by lifting into the virtual configuration, then applying

$$f_a' = \prod_{j \in \iota(a)} \bar{f}_j$$

and pulling back.

**EXAMPLES:**

```python
sage: vct = CartanType(['C',2,1]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: elt = RC(partition_list=[[2],[1,1],[2]], rigging_list=[[-1],[-1,-1],[-1]])
sage: ascii_art(elt.f(0))
-4[ ][ ][ ]-2  -2[ ][ ]-1  -2[ ][ ]-1
-2[ ][ ]-1
sage: ascii_art(elt.f(1))
-1[ ][ ]0  -2[ ][ ]-2  -1[ ][ ]0
-2[ ][ ]-1
sage: ascii_art(elt.f(2))
-2[ ][ ]-1  -2[ ][ ]-1  -4[ ][ ][ ]-2
-2[ ][ ]-1
```

**to_virtual_configuration()**

Return the corresponding rigged configuration in the virtual crystal.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['C',2,1], [[1,2],[1,1],[2,1]])
sage: elt = RC(partition_list=[[3],[2]]); elt
0[ ][ ][ ]0
0[ ][ ]0
sage: elt.to_virtual_configuration()
0[ ][ ][ ]0
0[ ][ ][ ]0
```

`class sage.combinat.rigged_configurations.rigged_configuration_element.RiggedConfigurationElement`

Bases: `sage.structure.list_clone.ClonableArray`

A rigged configuration for simply-laced types.
For more information on rigged configurations, see `RiggedConfigurations`. For rigged configurations for non-simply-laced types, use `RCNonSimplyLacedElement`.

Typically to create a specific rigged configuration, the user will pass in the optional argument `partition_list` and if the user wants to specify the rigging values, give the optional argument `rigging_list` as well. If `rigging_list` is not passed, the rigging values are set to the corresponding vacancy numbers.

**INPUT:**

- `parent` – the parent of this element
- `rigged_partitions` – a list of rigged partitions

There are two optional arguments to explicitly construct a rigged configuration. The first is `partition_list` which gives a list of partitions, and the second is `rigging_list` which is a list of corresponding lists of riggings. If only `partition_list` is specified, then it sets the rigging equal to the calculated vacancy numbers.

If we are constructing a rigged configuration from a rigged configuration (say of another type) and we don’t want to recompute the vacancy numbers, we can use the `use_vacancy_numbers` to avoid the recomputation.

**EXAMPLES:**

Type $A_1^{(1)}$ examples:

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RC(partition_list=[[2], [2, 2], [2], [2]])
```

```

   /) 1[ ]0 0[ ]0 0[ ]0 0[ ]0 0[ ]0 0[ ]0
   0[ ]0
```

```
check()

Check the rigged configuration is properly defined.

There is nothing to check here.

EXAMPLES:
```
sage: RC = crystals.infinity.RiggedConfigurations(['A', 4])
sage: b = RC.module_generators[0].f_string([1,2,1,2,4,2,3,3,2])
sage: b.check()
```

```
e(a)

Return the action of the crystal operator \( e_a \) on \( \text{self} \).

This implements the method defined in [CrysStructSchilling06] which finds the value \( k \) which is the length of the string with the smallest negative rigging of smallest length. Then it removes a box from a string of length \( k \) in the \( a \)-th rigged partition, keeping all colabels fixed and increasing the new label by one. If no such string exists, then \( e_a \) is undefined.
```
This method can also be used when the underlying Cartan matrix is a Borcherds-Cartan matrix. In this case, then method of [SS2018] is used, where the new label is increased by half of the \( a \)-th diagonal entry of the underlying Borcherds-Cartan matrix. This method will also return None if \( a \) is imaginary and the smallest rigging in the \( a \)-th rigged partition is not exactly half of the \( a \)-th diagonal entry of the Borcherds-Cartan matrix.

**INPUT:**

- \( a \) – the index of the partition to remove a box

**OUTPUT:**

The resulting rigged configuration element.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2,1]])
sage: elt = RC(partition_list=[[1, [1], [1], [1]])
sage: elt.e(3)
( /)
0[ ]0
0[ ]0
-1[ ]-1

sage: A = CartanMatrix([[[-2,-1],[-1,-2]], borcherds=True])
sage: RC = crystals.infinity.RiggedConfigurations(A)
sage: nu0 = RC(partition_list=[[[]]])
sage: nu = nu0.f_string([1,0,0,0])
sage: ascii_art(nu.e(0))
5[ ]3 4[ ]3
5[ ]1
```

**epsilon** \((a)\)

Return \( \varepsilon_a \) of self.

Let \( x_\ell \) be the smallest string of \( \nu(a) \) or 0 if \( \nu(a) = \emptyset \), then we have \( \varepsilon_a = -\min(0, x_\ell) \).

**EXAMPLES:**

```python
sage: La = RootSystem(['B',2]).weight_lattice().fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[1]+La[2])
sage: I = RC.index_set()
sage: matrix([[rc.epsilon(i) for i in I] for rc in RC[:4]])
[0 0]
[1 0]
[0 1]
[0 2]
```

**f** \((a)\)

Return the action of the crystal operator \( f_a \) on self.

This implements the method defined in [CrysStructSchilling06] which finds the value \( k \) which is the length of the string with the smallest nonpositive rigging of largest length. Then it adds a box from a string of length \( k \) in the \( a \)-th rigged partition, keeping all colabels fixed and decreasing the new label by one. If no
such string exists, then it adds a new string of length 1 with label $-1$. However we need to modify the definition to work for $B(\infty)$ by removing the condition that the resulting rigged configuration is valid.

This method can also be used when the underlying Cartan matrix is a Borcherds-Cartan matrix. In this case, then method of [SS2018] is used, where the new label is decreased by half of the $\alpha$-th diagonal entry of the underlying Borcherds-Cartan matrix.

INPUT:

- $a$ – the index of the partition to add a box

OUTPUT:

The resulting rigged configuration element.

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations(['A', 3])
sage: nu0 = RC.module_generators[0]
sage: nu0.f(2)

(-2[- ]-1)
```

```
sage: A = CartanMatrix([[-2,-1],[-1,-2]], borcherds=True)
sage: RC = crystals.infinity.RiggedConfigurations(A)
sage: nu0 = RC(partition_list=[[],[[]]])
sage: nu = nu0.f_string([1,0,0,0])
sage: ascii_art(nu.f(0))

9[ ]7 6[ ]5
9[ ]5
9[ ]3
9[ ]1
```

**nu()**

Return the list $\nu$ of rigged partitions of this rigged configuration element.

OUTPUT:

The $\nu$ array as a list.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RC(partition_list=[[2], [2,2], [2], [2]]).nu()

[0[ ][ ]0
 , -2[ ]-2
 , -2[ ][ ]-2
 , 2[ ][ ]2
 , -2[ ][ ]-2
 ]
```

**partition_rigging_lists()**

Return the list of partitions and the associated list of riggings of $\text{self}$.

EXAMPLES:
\begin{verbatim}
sage: RC = RiggedConfigurations(['A',3,1], [[[1,2],[2,2]]])
sage: rc = RC(partition_list=[[2],[1],[1]], rigging_list=[[-1],[0],[-1]]); rc
-1[ ][ ]-1
1[ ]0
-1[ ]-1
sage: rc.partition_rigging_lists()
[[[2], [1], [1]], [[-1], [0], [-1]]]

phi(a)
Return $\phi_a$ of self.

Let $x_\ell$ be the smallest string of $\nu^{(a)}$ or 0 if $\nu^{(a)} = \emptyset$, then we have $\infty = p^{(a)} - \min(0, x_\ell)$.

EXAMPLES:

\begin{verbatim}
sage: La = RootSystem(['B',2]).weight_lattice().fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[1]+La[2])
sage: I = RC.index_set()
sage: matrix([[rc.phi(i) for i in I] for rc in RC[:4]])
[1 1]
[0 3]
[0 2]
[1 1]
\end{verbatim}

vacancy_number(a, i)
Return the vacancy number $p^{(a)}_{i}$.

INPUT:

- a – the index of the rigged partition
- i – the row of the rigged partition

EXAMPLES:

\begin{verbatim}
sage: RC = RiggedConfigurations(['A', 4, 1], [[[2, 2]]])
sage: elt = RC(partition_list=[[1], [2,1], [1], []])
sage: elt.vacancy_number(2, 3)
-2
sage: elt.vacancy_number(2, 2)
-2
sage: elt.vacancy_number(2, 1)
-1
sage: RC = RiggedConfigurations(['D',4,1], [[[2,1], [2,1]]])
sage: x = RC(partition_list=[[[3], [3,1,1], [2], [3,1]]]); ascii_art(x)
-1[ ][ ][ ]-1 1 1[ ]1 0[ ][ ]0 -3 0 0 0
 0[ ]0 -3[ ][ ]-3
 0[ ]0
sage: x.vacancy_number(2,2)
1
\end{verbatim}
\end{verbatim}
5.1.215 Rigged Configurations

AUTHORS:

- Travis Scrimshaw (2010-09-26): Initial version

```
sage.combinat.rigged_configurations.rigged_configurations.KirillovReshetikhinCrystal(cartan_type, r, s)
```

Return the KR crystal $B^{r,s}$ using \textit{rigged configurations}.

This is the rigged configuration $RC(B^{r,s})$ or $RC(L)$ with $L = (L_i^{(a)})$ and $L_i^{(a)} = \delta_{a,r}\delta_{i,s}$.

EXAMPLES:

```
sage: K1 = crystals.kirillov_reshetikhin.RiggedConfigurations(['A',6,2], 2, 1)
sage: K2 = crystals.kirillov_reshetikhin.LSPaths(['A',6,2], 2, 1)
sage: K1.digraph().is_isomorphic(K2.digraph(), edge_labels=True)
True
```

```
class sage.combinat.rigged_configurations.rigged_configurations.RCNonSimplyLaced(cartan_type, dims)
```

Rigged configurations in non-simply-laced types.

These are rigged configurations which lift to virtual rigged configurations in a simply-laced type.

For more on rigged configurations, see \textit{RiggedConfigurations}.

```
Element
```

```
krrcnonsimplylacedelement
```

from\_virtual (vrc)

Convert \texttt{vrc} in the virtual crystal into a rigged configuration of the original Cartan type.

INPUT:

- \texttt{vrc} – a virtual rigged configuration

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C',2,1], [[1,2],[1,1],[2,1]])
sage: elt = RC(partition_list=[[3],[2]])
sage: vrc_elt = RC.to\_virtual(elt)
sage: ret = RC.from\_virtual(vrc\_elt); ret
0[] [ ] 0
0[] [ ] 0
sage: ret == elt
True
```

```
kleber\_tree()
```

Return the underlying (virtual) Kleber tree used to generate all highest weight rigged configurations.

EXAMPLES:
sage: RC = RiggedConfigurations([['C',3,1], [[1,1], [2,1]]])
sage: RC.kleber_tree()
Virtual Kleber tree of Cartan type ['C', 3, 1] and B = ((1, 1), (2, 1))

module_generators()
Module generators for this set of rigged configurations.

Iterate over the highest weight rigged configurations by moving through the KleberTree and then setting appropriate values of the partitions.

EXAMPLES:

sage: RC = RiggedConfigurations([['C',3,1], [[1,2]]])
sage: for x in RC.module_generators: x

sage: RC = RiggedConfigurations([['D',4,3], [[1,1]]])
sage: RC.module_generators

... (continues on next page)

to_virtual(rc)
Convert rc into a rigged configuration in the virtual crystal.

INPUT:
- rc – a rigged configuration element

EXAMPLES:

sage: RC = RiggedConfigurations([['C',2,1], [[1,2],[1,1],[2,1]]])
sage: elt = RC(partition_list=[[3],[2]]); elt

(continues on next page)
virtual()

Return the corresponding virtual crystal.

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['C',2,1], [[1,2],[1,1],[2,1]])
sage: RC
Rigged configurations of type ['C', 2, 1] and factor(s) ((1, 2), (1, 1), (2, 1))
sage: RC.virtual
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 2), (3, 2), (1, 1), (3, 1), (2, 2))
```

class sage.combinat.rigged_configurations.rigged_configurations.RCTYPEA2Dual(cartan_type, dims)

Bases: sage.combinat.rigged_configurations.rigged_configurations.RCTYPEA2Even

Rigged configurations of type $A_{2n}^{(2)\dagger}$.

For more on rigged configurations, see RiggedConfigurations.

EXAMPLES:

```python
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,2],[1,1],[2,1]])
sage: RC
Rigged configurations of type ['BC', 2, 2]^* and factor(s) ((1, 2), (1, 1), (2, 1))
sage: RC.cardinality()
750
sage: RC = RiggedConfigurations(CartanType(['A',2,2]).dual(), [[1,1]])
sage: RC.cardinality()
3
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[2,1]])
sage: TestSuite(RC).run() # long time
```

Element

alias of sage.combinat.rigged_configurations.rigged_configuration_element.KRRCTypeA2DualElement

from_virtual(vrc)

Convert vrc in the virtual crystal into a rigged configuration of the original Cartan type.

INPUT:

- vrc – a virtual rigged configuration element

EXAMPLES:
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[2,2]])
sage: elt = RC(partition_list=[[1],[1]])
sage: velt = RC.to_virtual(elt)
sage: ret = RC.from_virtual(velt); ret

-1[ ]-1
1[ ]1

sage: ret == elt
True

module_generators()
Module generators for rigged configurations of type $A^{(2)}_{2n}$.

Iterate over the highest weight rigged configurations by moving through the KleberTree and then setting appropriate values of the partitions. This also skips rigged configurations where $P_i^{(n)} < 1$ when $i$ is odd.

EXAMPLES:

sage: RC = RiggedConfigurations(CartanType(['A', 4, 2]).dual(), [[1,1]])
sage: for x in RC.module_generators: x

module_generators()

sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,1]])

sage: for x in RC.module_generators: x

+/+

sage: elt = RC(partition_list=[[1],[1]]); elt

-1[ ]-1
1[ ]1

sage: velt = RC.to_virtual(elt); velt

-1[ ]-1
2[ ]2
-1[ ]-1

sage: velt.parent()

sage.combinat.rigged_configurations.rigged_configurations.RCTypeA2Even

Bases: sage.combinat.rigged_configurations.rigged_configurations.RCNonSimplyLaced

class sage.combinat.rigged_configurations.rigged_configurations.RCTypeA2Even(cartan_type, dims)

5.1. Comprehensive Module list 2011
Rigged configurations for type $A_{2n}^{(2)}$.

For more on rigged configurations, see `RiggedConfigurations`.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 4, 2], [[2,1], [1,2]])
sage: RC.cardinality() 150
sage: RC = RiggedConfigurations(['A', 2, 2], [[1,1]])
sage: RC.cardinality() 3
sage: RC = RiggedConfigurations(['A', 2, 2], [[1,2],[1,1]])
```

```python
sage: TestSuite(RC).run() # long time
sage: RC = RiggedConfigurations(['A', 4, 2], [[2,1]])
```

`cardinality()`

Return the cardinality of `self`.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 4, 2], [[1,1], [2,2]])
sage: RC.cardinality() 250
```

`from_virtual(vrc)`

Convert `vrc` in the virtual crystal into a rigged configuration of the original Cartan type.

**INPUT:**

- `vrc` – a virtual rigged configuration element

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 4, 2], [[2,2]])
sage: elt = RC(partition_list=[[1],[1]]); elt
-1[]-1
1[ ]1
sage: velt = RC.to_virtual(elt)
sage: ret = RC.from_virtual(velt); ret
-1[ ]-1
1[ ]1
```

`to_virtual(rc)`

Convert `rc` into a rigged configuration in the virtual crystal.

**INPUT:**

- `rc` – a rigged configuration element

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 4, 2], [[2,2]])
sage: elt = RC(partition_list=[[1],[1]]); elt
-1[ ]-1
```

(continues on next page)
sage: velt = RC.to_virtual(elt); velt
-1[-1]
2[2]
-1[-1]
sage: velt.parent()
Rigged configurations of type ['A', 3, 1] and factor(s) ((2, 2), (2, 2))

virtual()

Return the corresponding virtual crystal.

EXAMPLES:

sage: RC = RiggedConfigurations(['A',4,2], [[1,2],[1,1],[2,1]])
sage: RC
Rigged configurations of type ['BC', 2, 2] and factor(s) ((1, 2), (1, 1), (2,-1))
sage: RC.virtual
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 2), (3, 2), (1,-1), (3, 1), (2, 1), (2, 1))

class sage.combinat.rigged_configurations.rigged_configurations.RiggedConfigurations(cartan_type, \n\nsage: B)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.\nstructure.parent.Parent

Rigged configurations as $U'_q(\mathfrak{g})$-crystals.

Let $\mathcal{T}$ denote the classical index set associated to the Cartan type of the rigged configurations. A rigged configuration of multiplicity array $L_i^{(a)}$ and dominant weight $\Lambda$ is a sequence of partitions $\{\nu^{(a)} \mid a \in \mathcal{T}\}$ such that

$$\sum_{T \times \mathbb{Z}_{>0}} im_i^{(a)} \alpha_a = \sum_{T \times \mathbb{Z}_{>0}} i L_i^{(a)} \Lambda_a - \Lambda$$

where $\alpha_a$ is a simple root, $\Lambda_a$ is a fundamental weight, and $m_i^{(a)}$ is the number of rows of length $i$ in the partition $\nu^{(a)}$.

Each partition $\nu^{(a)}$, in the sequence also comes with a sequence of statistics $p_i^{(a)}$ called vacancy numbers and a weakly decreasing sequence $J_i^{(a)}$ of length $m_i^{(a)}$ called riggings. Vacancy numbers are computed based upon the partitions and $L_i^{(a)}$, and the riggings must satisfy $\max J_i^{(a)} \leq p_i^{(a)}$. We call such a partition a rigged partition. For more, see [RigConBijection] [CrysStructSchilling06] [BijectionLRT].

Rigged configurations form combinatorial objects first introduced by Kerov, Kirillov and Reshetikhin that arose from studies of statistical mechanical models using the Bethe Ansatz. They are sequences of rigged partitions. A rigged partition is a partition together with a label associated to each part that satisfy certain constraints. The labels are also called riggings.

Rigged configurations exist for all affine Kac-Moody Lie algebras. See for example [HKOTT2002]. In Sage they are specified by providing a Cartan type and a list of rectangular shapes $B$. The list of all (highest weight) rigged configurations for given $B$ is computed via the (virtual) Kleber algorithm (see also KleberTree and VirtualKleberTree).
Rigged configurations in simply-laced types all admit a classical crystal structure [CrysStructSchilling06]. For non-simply-laced types, the crystal is given by using virtual rigged configurations [OSS03]. The highest weight rigged configurations are those where all riggings are nonnegative. The list of all rigged configurations is computed from the highest weight ones using the crystal operators.

Rigged configurations are conjecturally in bijection with \texttt{TensorProductOfKirillovReshetikhinTableaux} of non-exceptional affine types where the list \( B \) corresponds to the tensor factors \( B^{r,s} \). The bijection has been proven in types \( A_n^{(1)} \) and \( D_n^{(1)} \) and when the only non-zero entries of \( L_i^{(a)} \) are either only \( L_1^{(a)} \) or only \( L_i^{(1)} \) (corresponding to single columns or rows respectively) [RigConBijection], [BijectionLRT], [BijectionDn].

KR crystals are implemented in Sage, see \texttt{KirillovReshetikhinCrystal()}, however, in the bijection with rigged configurations a different realization of the elements in the crystal are obtained, which are coined KR tableaux, see \texttt{KirillovReshetikhinTableaux}. For more details see [OSS2011].

**Note:** All non-simply-laced rigged configurations have not been proven to give rise to aligned virtual crystals (i.e. have the correct crystal structure or isomorphic as affine crystals to the tensor product of KR tableaux).

**INPUT:**
- \texttt{cartan\_type} – a Cartan type
- \( B \) – a list of positive integer tuples \((r, s)\) corresponding to the tensor factors in the bijection with tensor product of Kirillov-Reshetikhin tableaux or equivalently the sequence of width \( s \) and height \( r \) rectangles

**REFERENCES:**

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [1, 2], [1, 1]])
sage: RC
Rigged configurations of type ['A', 3, 1] and factor(s) ((3, 2), (1, 2), (1, 1))
sage: RC = RiggedConfigurations(['A', 3, 1], [[2, 1]]); RC
Rigged configurations of type ['A', 3, 1] and factor(s) ((2, 1)),
sage: RC.cardinality()
6
sage: len(RC.list()) == RC.cardinality()
True
sage: RC.list() # random
[['', '', '', '', ''], ['0[ ]0', '/( )/( )', '-1[ ]-1', '-1[ ]-1'], ['/', '-1[ ]-1', '0[ ]0', '0[ ]0', '1[ ]1', '-1[ ]-1'], ['/', ' ', '-1[ ]-1', '/', ' ', '-1[ ]-1', '0[ ]0'], [' ', ' ', ' ', ' ', ' ', ' ']]
```

A rigged configuration element with all riggings equal to the vacancy numbers can be created as follows:

```python
code:
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [2, 1], [1, 1], [1, 1]]); RC
Rigged configurations of type ['A', 3, 1] and factor(s) ((3, 2), (2, 1), (1, 1), (1, 1))
sage: elt = RC(partition_list=[[1],[],[]]); elt
0[ ]0
```

(continues on next page)
If on the other hand we also want to specify the riggings, this can be achieved as follows:

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[[3, 2], [1, 2], [1, 1]]])

sage: RC(partition_list=[[2],[2],[2]])
1[ ][ ]1
0[ ][ ]0
0[ ][ ]0

sage: RC(partition_list=[[2],[2],[2]], rigging_list=[[0],[0],[0]])
1[ ][ ]0
0[ ][ ]0
0[ ][ ]0
```

A larger example:

```python
sage: RC = RiggedConfigurations(['D', 7, 1], [[[3,3],[5,2],[4,3],[2,3],[4,4],[3,1],
    [1,4],[2,2]]])

sage: elt = RC(partition_list=[[2],[3,2,1],[2,2,1,1],[2,2,1,1,1],[3,2,1,1,1,1],
    [2,1,1],[2,2]],
    ....: rigging_list=[[2],[1,0,0],[4,1,2,1],[1,0,0,0,0,0],[0,1,0,0,0,0],[0,
    0,0,0,0]])

sage: elt
3[ ][ ]2
1[ ][ ][ ]1
2[ ][ ]0
1[ ]0

4[ ][ ]4
4[ ][ ]1
3[ ]2
3[ ]1
2[ ][ ]1
2[ ][ ]0
0[ ]0
0[ ]0
0[ ]0
0[ ]0
0[ ][ ][ ]0
2[ ][ ]1
0[ ]0
0[ ]0
0[ ]0
0[ ]0
```

(continues on next page)
To obtain the KR tableau under the bijection between rigged configurations and KR tableaux, we can type the following. This example was checked against Reiho Sakamoto’s Mathematica program on rigged configurations:

```python
sage: output = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); output
[[1, 1, 1], [2, 3, 3], [3, 4, -5]] (X) [[1, 1], [2, 2], [3, 3], [5, -6], [6, -5]]
    (X) [[1, 1, 2], [2, 2, 3], [3, 3, 7], [4, 4, -7]]
    (X) [[1, 1, 1, 3], [2, 2, 3, 4], [3, 3, 4, 5], [4, 4, 5, 6]]
    (X) [[1], [2], [3]]
    (X) [[1, 1, 1, 1]]
```

We can also convert between rigged configurations and tensor products of KR crystals:

```python
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 1]])
sage: elt = RC(partition_list=[[1],[1,1],[1],[1]])
sage: tp_krc = elt.to_tensor_product_of_kirillov_reshetikhin_crystals(); tp_krc
[[[++++, []], [++++, [1], [2], [4], [-4]]]]
sage: ret = RC(tp_krc)
sage: ret == elt
True
```

Element

*alias of `sage.combinat.rigged_configurations.rigged_configuration_element.KRRCSimplyLacedElement`

`classically_highest_weight_vectors()`

Return the classically highest weight elements of `self`.

`fermionic_formula(q=None, only_highest_weight=False, weight=None)`

Return the fermionic formula associated to `self`. 

2016 Chapter 5. Comprehensive Module List
Given a set of rigged configurations $RC(\lambda, L)$, the fermionic formula is defined as:

$$M(\lambda, L; q) = \sum_{(\nu, J)} q^{cc(\nu, J)}$$

where we sum over all (classically highest weight) rigged configurations of weight $\lambda$ where $cc$ is the cocharge statistic. This is known to reduce to

$$M(\lambda, L; q) = \sum_{\nu} q^{cc(\nu)} \prod_{(a, i) \in I \times \mathbb{Z}} \left[ p_i^{(a)} + m_i^{(a)} \right] q.$$

The generating function of $M(\lambda, L; q)$ in the weight algebra subsumes all fermionic formulas:

$$M(L; q) = \sum_{\lambda \in P} M(\lambda, L; q)\lambda.$$

This is conjecturally equal to the one dimensional configuration sum of the corresponding tensor product of Kirillov-Reshetikhin crystals, see [HKOTT2002]. This has been proven in general for type $A_n^{(1)}$ [BijectionLRT], single factors $B^{r,s}$ in type $D_n^{(1)}$ [OSS2011] with the result from [Sakamoto13], as well as for a tensor product of single columns [OSS2003], [BijectionDn] or a tensor product of single rows [OSS03] for all non-exceptional types.

**INPUT:**

- $q$ – the variable $q$
- **only_highest_weight** – use only the classically highest weight rigged configurations
- $\lambda$ – return the fermionic formula $M(\lambda, L; q)$ where $\lambda$ is the classical weight

**REFERENCES:**

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 2, 1], [[1,1], [1,1]])
sage: RC.fermionic_formula()
B[-2*Lambda[1] + 2*Lambda[2]] + (q+1)*B[-Lambda[1]]
 + (q+1)*B[2*Lambda[1]]
 + B[-2*Lambda[2]] + (q+1)*B[Lambda[2]]
sage: t = QQ['t'].gen(0)
sage: RC.fermionic_formula(t)
B[-2*Lambda[1] + 2*Lambda[2]] + (t+1)*B[-Lambda[1]]
 + (t+1)*B[2*Lambda[1]]
 + B[-2*Lambda[2]] + (t+1)*B[Lambda[2]]
sage: La = RC.weight_lattice_realization().classical().fundamental_weights()
sage: RC.fermionic_formula(weight=La[2])
q + 1
sage: RC.fermionic_formula(only_highest_weight=True, weight=La[2])
q
```

Only using the highest weight elements on other types:

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[3,1], [2,2]])
sage: RC.fermionic_formula(only_highest_weight=True)
sage: RC = RiggedConfigurations(['D', 4, 1], [[3,1], [4,1], [2,1]])
sage: RC.fermionic_formula(only_highest_weight=True)
(q^4+q^3+q^2)*B[Lambda[1]] + (q^2+q)*B[Lambda[1] + Lambda[2]]
```

(continues on next page)
+ B[\Lambda_2] + \Lambda_3 + \Lambda_4] + (q^3+2q^2+q)\cdot B[\Lambda_3] + \\
\Rightarrow \Lambda_4]
sage: RC = RiggedConfigurations(['E', 6, 1], [[2,2]])
sage: RC.fermionic_formula(only_highest_weight=True)
q^2\cdot B[0] + q\cdot B[\Lambda_2] + B[2\cdot \Lambda_2] + \\
\Rightarrow \Lambda_3]
sage: RC = RiggedConfigurations(['B', 3, 1], [[3,1], [2,2]])
sage: RC.fermionic_formula(only_highest_weight=True) # long time
q\cdot B[\Lambda_1 + \Lambda_3] + q^2\cdot B[\Lambda_1 + \Lambda_3] + \\
\Rightarrow \Lambda_2]
sage: RC = RiggedConfigurations(['C', 3, 1], [[3,1], [2,2]])
sage: RC.fermionic_formula(only_highest_weight=True) # long time
(q^3+q^2)\cdot B[\Lambda_1 + \Lambda_3] + (q^2+q)\cdot B[\Lambda_1 + \\
\Rightarrow \Lambda_2]
sage: RC = RiggedConfigurations(['D', 4, 2], [[3,1], [2,2]])
sage: RC.fermionic_formula(only_highest_weight=True) # long time
(q^5+2q^4+q^3)\cdot B[\Lambda_1 + \Lambda_3] + (q^3+q^2)\cdot B[\Lambda_2 + \\
\Rightarrow \Lambda_3]
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,1], [2,2]])
sage: RC.fermionic_formula(only_highest_weight=True)
(q^3+q^2)\cdot B[\Lambda_1] + (q^2+q)\cdot B[\Lambda_1 + \Lambda_2] + \\
\Rightarrow \Lambda_3]}
kleber_tree()
Return the underlying Kleber tree used to generate all highest weight rigged configurations.

EXAMPLES:

sage: RC = RiggedConfigurations(['A',3,1], [[1,1], [2,1]])
sage: RC.kleber_tree()
Kleber tree of Cartan type ['A', 3, 1] and B = ((1, 1), (2, 1))

module_generators()
Module generators for this set of rigged configurations.

Iterate over the highest weight rigged configurations by moving through the KleberTree and then setting appropriate values of the partitions.

EXAMPLES:

sage: RC = RiggedConfigurations(['D', 4, 1], [[2,1]])
sage: for x in RC.module_generators: x

(continues on next page)
options(**get_value, **set_value)**

Sets and displays the options for rigged configurations. If no parameters are set, then the function returns a copy of the options dictionary.

The options to partitions can be accessed as the method `RiggedConfigurations.options` of `RiggedConfigurations`.

OPTIONS:

- **convention** – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention
- **display** – (default: vertical) Specifies how rigged configurations should be printed
  - horizontal – displayed horizontally
  - vertical – displayed vertically
- **element_ascii_art** – (default: True) display using the repr option `element_ascii_art`
- **half_width_boxes_type_B** – (default: True) display the last rigged partition in affine type B as half width boxes
- **notation** – alternative name for `convention`

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A',3,1], [[2,2],[1,1],[1,1]])
sage: elt = RC(partition_list=[[3,1], [3], [1]])
sage: elt
-3[ ][ ][ ]-3
-1[ ][ ]-1
1[ ][ ][ ]1
-1[ ][ ]-1
```

```
sage: RiggedConfigurations.options(display="horizontal", convention="french")
sage: elt
-1[ ][ ]-1 1[ ][ ][ ]1 -1[ ][ ]-1
-3[ ][ ][ ]-3
```

Changing the `convention` for rigged configurations also changes the `convention` option for tableaux and vice versa:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
  4  5
  1  2  3
```

(continues on previous page)
sage: Tableaux.options.convention="english"
sage: elt
-3[ ][ ][ ]-3 1[ ][ ][ ]1 -1[ ][ ]-1
-1[ ][ ]-1
sage: T.pp()
 1 2 3
 4 5
sage: RiggedConfigurations.options._reset()

See GlobalOptions for more features of these options.

tensor(*crystals, **options)
Return the tensor product of self with crystals.

If crystals is a list of rigged configurations of the same Cartan type, then this returns a new
RiggedConfigurations.

EXAMPLES:

sage: RC = RiggedConfigurations(['A', 3, 1], [[2,1],[1,3]])
sage: RC2 = RiggedConfigurations(['A', 3, 1], [[1,1],[3,3]])
sage: RC.tensor(RC2, RC2)
Rigged configurations of type ['A', 3, 1] and factor(s) ((2, 1), (1, 3), (1, 1), (3, 3), (1, 1), (3, 3))
sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2, model='KR')
sage: RC.tensor(K)
Full tensor product of the crystals
[Rigged configurations of type ['A', 3, 1] and factor(s) ((2, 1), (1, 3)),
Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (2, 2)]

tensor_product_of_kirillov_reshetikhin_crystals()
Return the corresponding tensor product of Kirillov-Reshetikhin crystals.

EXAMPLES:

sage: RC = RiggedConfigurations(['A', 3, 1], [[3,1],[2,2]])
sage: RC.tensor_product_of_kirillov_reshetikhin_crystals()
Full tensor product of the crystals
[Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(3,1),
Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(2,2)]

tensor_product_of_kirillov_reshetikhin_tableaux()
Return the corresponding tensor product of Kirillov-Reshetikhin tableaux.

EXAMPLES:

sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [1, 2]])
sage: RC.tensor_product_of_kirillov_reshetikhin_tableaux()
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and
factor(s) ((3, 2), (1, 2))
5.1.216 Rigged Partitions

Class and methods of the rigged partition which are used by the rigged configuration class. This is an internal class used by the rigged configurations and KR tableaux during the bijection, and is not to be used by the end-user.

We hold the partitions as an 1-dim array of positive integers where each value corresponds to the length of the row. This is the shape of the partition which can be accessed by the regular index.

The data for the vacancy number is also stored in a 1-dim array which each entry corresponds to the row of the tableau, and similarly for the partition values.

AUTHORS:

- Travis Scrimshaw (2010-09-26): Initial version

Todo: Convert this to using multiplicities $m_i$ (perhaps with a dictionary)?

class sage.combinat.rigged_configurations.rigged_partition.RiggedPartition
Bases: sage.structure.sage_object.SageObject

The RiggedPartition class which is the data structure of a rigged (i.e. marked or decorated) Young diagram of a partition.

Note that this class as a stand-alone object does not make sense since the vacancy numbers are calculated using the entire rigged configuration. For more, see RiggedConfigurations.

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[[2, 2]]])
sage: RP = RC(partition_list=[[2],[2,2],[2,1],[2]])[2]
sage: RP
-1[ ]0
-1[ ]

get_num_cells_to_column (end_column, t=1)
Get the number of cells in all columns before the end_column.

INPUT:

- end_column – The index of the column to end at
- t – The scaling factor

OUTPUT:

- The number of cells

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[[2, 2]]])
sage: RP = RC(partition_list=[[2],[2,2],[2,1],[2]])[2]
sage: RP.get_num_cells_to_column(1)
2
sage: RP.get_num_cells_to_column(2)
3
sage: RP.get_num_cells_to_column(3)
3
sage: RP.get_num_cells_to_column(3, 2)
5
```
**insert_cell** (*max_width*)

Insert a cell given at a singular value as long as its less than the specified width.

Note that `insert_cell()` does not update riggings or vacancy numbers, but it does prepare the space for them. Returns the width of the row we inserted at.

**INPUT:**

- *max_width* – The maximum width (i.e. row length) that we can insert the cell at

**OUTPUT:**

- The width of the row we inserted at.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RP = RC(partition_list=[[2],[2,2],[2,1],[2]])[[2]
sage: RP.insert_cell(2)
2
sage: RP
0[ ][ ]None
-1[ ]-1
```

**remove_cell** (*row, num_cells=1*)

Removes a cell at the specified *row*.

Note that `remove_cell()` does not set/update the vacancy numbers or the riggings, but guarantees that the location has been allocated in the returned index.

**INPUT:**

- *row* – the row to remove the cell from
- *num_cells* – (default: 1) the number of cells to remove

**OUTPUT:**

- The location of the newly constructed row or None if unable to remove row or if deleted a row.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RP = RC(partition_list=[[2],[2,2],[2,1],[2]])[[2]
sage: RP.remove_cell(0)
0
sage: RP
None[ ]None
-1[ ]-1
```

**vacancy_numbers**

**rigging**

**class** `sage.combinat.rigged_configurations.rigged_partition.RiggedPartitionTypeB`

Bases: `sage.combinat.rigged_configurations.rigged_partition.RiggedPartition`

Rigged partitions for type $B_n^{(1)}$ which has special printing rules which comes from the fact that the $n$-th partition can have columns of width $\frac{n}{2}$.
5.1.217 Tensor Product of Kirillov-Reshetikhin Tableaux

A tensor product of $\text{KirillovReshetikhinTableaux}$ which are tableaux of $r$ rows and $s$ columns which naturally arise in the bijection between rigged configurations and tableaux and which are in bijection with the elements of the Kirillov-Reshetikhin crystal $B^{r,s}$, see $\text{KirillovReshetikhinCrystal()}$.

AUTHORS:

- Travis Scrimshaw (2010-09-26): Initial version

EXAMPLES:

Type $A_n^{(1)}$ examples:

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[3,1], [2, 1]])
sage: KRT
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and factor(s) ((3, 1), (2, 1))
sage: KRT.cardinality()
24
```

Type $D_n^{(1)}$ examples:

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[1, 1], [2, 1], [1, 1]])
sage: KRT
Tensor product of Kirillov-Reshetikhin tableaux of type ['D', 4, 1] and factor(s) ((1, 1), (2, 1), (1, 1))
sage: T = KRT(pathlist=[[1], [-2, 2], [1]])
tsage: T
[[1]] (X) [[2], [-2]] (X) [[1]]
sage: T2 = KRT(pathlist=[[1], [2, -2], [1]])
tsage: T2
[[1]] (X) [[2], [2]] (X) [[1]]
sage: T == T2
False
```

```
class sage.combinat.rigged_configurations.tensor_product_kr_tableaux.HighestWeightTensorKRT(tp_krt)
    Bases: sage.structure.unique_representation.UniqueRepresentation

    Class so we do not have to build the module generators for $\text{TensorProductOfKirillovReshetikhinTableaux}$ at initialization.

    Warning: This class is for internal use only!
```
cardinality()

Return the cardinality of self, which is the number of highest weight elements.

EXAMPLES:

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D',4,1], [[2,2]])
sage: HW = HighestWeightTensorKRT(KRT)
sage: HW.cardinality()
3

class sage.combinat.rigged_configurations.tensor_product_kr_tableaux.TensorProductOfKirillovReshetikhinTableaux(cartan_type, B)

Bases: sage.combinat.crystals.tensor_product.FullTensorProductOfRegularCrystals

A tensor product of KirillovReshetikhinTableaux.

Through the bijection with rigged configurations, the tableaux that are produced in all nonexceptional types are all of rectangular shapes and do not necessarily obey the usual strict increase in columns and weak increase in rows. The relation between the elements of the Kirillov-Reshetikhin crystal, given by the Kashiwara-Nakashima tableaux, and the Kirillov-Reshetikhin tableaux is given by a filling map.

Note: The tableaux for all non-simply-laced types are provably correct if the bijection with rigged configurations holds. Therefore this is currently only proven for \(B^{r,s}\) or \(B^{1,1}\) and in general for types \(A_n^{(1)}\) and \(D_n^{(1)}\).

For more information see [OSS2011] and KirillovReshetikhinTableaux.

For more information on KR crystals, see sage.combinat.crystals.kirillov_reshetikhin.

INPUT:

- cartan_type – a Cartan type
- B – an (ordered) list of pairs \((r, s)\) which give the dimension of a rectangle with \(r\) rows and \(s\) columns and corresponds to a Kirillov-Reshetikhin tableau factor of \(B^{r,s}\).

REFERENCES:

EXAMPLES:

We can go between tensor products of KR crystals and rigged configurations:

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[3,1], [[2,2]]])
sage: tp_krt = KRT(pathlist=[[3,2,1],[3,2,3,2]]); tp_krt
[ [1], [2], [3]] (X) [ [2, 2], [3, 3]]
sage: RC = RiggedConfigurations(['A',3,1], [[3,1],[2,2]])
sage: rc_elt = tp_krt.to_rigged_configuration(); rc_elt
-2[-] -2
 0[-] [ ]
 0[-] [ ]
(continues on next page)
We can get the highest weight elements by using the attribute `module_generators`:

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[3,2], [1,2], [2,1]])
sage: list(KRT.module_generators)
[[[1], [2], [3]] (X) [[1], [2]], [[1], [3], [4]] (X) [[1], [2]]]
```

To create elements directly (i.e. not passing in KR tableaux elements), there is the `pathlist` option which will receive a list of lists which contain the reversed far-eastern reading word of the tableau. That is to say, in English notation, the word obtained from reading bottom-to-top, left-to-right.

```python
sage: elt = KRT(pathlist=[[3, 2, 1, 4, 2, 1], [1, 3], [3, 1]])
```

One can still create elements in the same way as tensor product of crystals:

```python
sage: K1 = crystals.KirillovReshetikhin(['A',3,1], 3, 2, model='KR')
sage: K2 = crystals.KirillovReshetikhin(['A',3,1], 1, 2, model='KR')
sage: K3 = crystals.KirillovReshetikhin(['A',3,1], 2, 1, model='KR')
sage: eltlong = KRT(K1(3, 2, 1, 4, 2, 1), K2(1, 3), K3(3, 1))
sage: eltlong == elt
True
```

```
Element

Element alias of `sage.combinat.rigged_configurations.tensor_product_kr_tableaux_element.TensorProductOfKirillovReshetikhinTableauxElement`

`rigged_configurations()`

Return the corresponding set of rigged configurations.

**EXAMPLES:**

5.1. Comprehensive Module list
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1],
    \rightarrow[[1,3], [2,1]])
sage: KRT.rigged_configurations()
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 3), (2, 1))

\texttt{tensor (**crystals, **options)}

Return the tensor product of \texttt{self} with \texttt{crystals}.

If \texttt{crystals} is a list of (a tensor product of) KR tableaux, this returns a \texttt{TensorProductOfKirillovReshetikhinTableaux}.

\textbf{EXAMPLES:}

sage: TP = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1],
    \rightarrow[[1,3],[3,1]])
sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2, model='KR')
sage: TP.tensor(K, TP)
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1]
and factor(s) ((1, 3), (3, 1), (2, 2), (1, 3), (3, 1))
sage: C = crystals.KirillovReshetikhin(['A',3,1], 3, 1, model='KN')
sage: TP.tensor(K, C)
Full tensor product of the crystals [Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (1, 3),
Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (3, 1),
Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (2, 2),
Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(3,1)]

\texttt{tensor_product_of_kirillov_reshetikhin_crystals()}  

Return the corresponding tensor product of Kirillov-Reshetikhin crystals.

\textbf{EXAMPLES:}

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1],
    \rightarrow[[3,1],[2,2]])
sage: KRT.tensor_product_of_kirillov_reshetikhin_crystals()
Full tensor product of the crystals [Kirillov-Reshetikhin crystal of type ['A' \rightarrow', 3, 1] with (r,s)=(3,1),
Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(2,2)]

5.1.218 Tensor Product of Kirillov-Reshetikhin Tableaux Elements

A tensor product of \texttt{KirillovReshetikhinTableauxElement}.

\textbf{AUTHORS:}

- Travis Scrimshaw (2010-09-26): Initial version

\textbf{class} \texttt{sage.combinat.rigged_configurations.tensor_product_kr_tableaux_element.TensorProductOfKirillovReshetikhinTableauxElement}

\textbf{Bases:} \texttt{sage.combinat.crystals.tensor_product_element.TensorProductOfRegularCrystalsElement}

An element in a tensor product of Kirillov-Reshetikhin tableaux.

For more on tensor product of Kirillov-Reshetikhin tableaux, see \texttt{TensorProductOfKirillovReshetikhinTableaux}. 

2026 Chapter 5. Comprehensive Module List
The most common way to construct an element is to specify the option `pathlist` which is a list of lists which will be used to generate the individual factors of `KirillovReshetikhinTableauxElement`.

**EXAMPLES:**

Type $A_n^{(1)}$ examples:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1], [[1, \rightarrow 1], [2,1], [1,1], [2,1], [2,1], [2,1]])
sage: T = KRT(pathlist=[[2], [4,1], [3], [4,2], [3,1], [2,1]])
sage: T
[[2]] (X) [[1], [4]] (X) [[3]] (X) [[2], [4]] (X) [[1], [3]] (X) [[1], [2]]
sage: T.to_rigged_configuration()

0[ ][ ] 0
1[ ] 1

sage: T.to_rigged_configuration().to_tensor_product_of_kirillov_reshetikhin_tableaux()

[[2], [3]] (X) [[1]] (X) [[-1]] (X) [[1]]

classical_weight()

Return the classical weight of self.

EXAMPLES:

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D',4,1],
                  [[2,2]])
sage: elt = KRT(pathlist=[[3,2,-1,1]]); elt
[[2, 1], [3, -1]]
sage: elt.classical_weight()
(0, 1, 1, 0)
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1],
                  [[2,2],[1,3]])
sage: elt = KRT(pathlist=[[2,1,3,2],[1,4,4]]); elt
[[1, 2], [2, 3]] (X) [[1, 4, 4]]
sage: elt.classical_weight()
(2, 2, 1, 2)

left_split()

Return the image of self under the left column splitting map.

EXAMPLES:

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1],
                  [[2,2],[1,3]])
sage: elt = KRT(pathlist=[[2,1,3,2],[1,4,4]]); elt.pp()

1 2 (X) 1 4 4
2 3
sage: elt.left_split().pp()

1 (X) 2 (X) 1 4 4
2 3

lusztig_involution()

Return the result of the classical Lusztig involution on self.

EXAMPLES:

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1],
                  [[2,2],[1,3]])
**sage:** elt = KRT(pathlist=[[2,1,3,2],[1,4,4]])
**sage:** li = elt.lusztig_involution(); li

```
[[1, 1, 4]] (X) [[2, 3], [3, 4]]
```

**sage:** li.parent()  
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and

\[\to\text{factor(s) } ((1, 3), (2, 2))\]

**pp()**
Pretty print self.

**EXAMPLES:**

```
sage: TPKRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',4,1],
\to[[2,2],[3,1],[3,3]])
sage: TPKRT.module_generators[0].pp()
1 1 (X) 1 (X) 1 1 1
2 2 2 2 2 2
3 3 3 3 3
```

**right_split()**
Return the image of self under the right column splitting map.

**EXAMPLES:**

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1],
\to[[2,2],[1,3]])
sage: elt = KRT(pathlist=[[2,1,3,2],[1,4,4]]); elt.pp()
1 2 (X) 1 4 4
2 3
sage: elt.right_split().pp()
1 2 (X) 1 4 (X) 4
2 3
```

Let \( \ast \) denote the Lusztig involution, we check that \( \ast \circ \text{ls} \circ \ast = \text{rs} \):

```
sage: all(x.lusztig_involution().left_split().lusztig_involution() == x.right_
\to\text{split()} for x in KRT)
True
```

**to_rigged_configuration** *(display_steps=False)*
Perform the bijection from self to a rigged configuration which is described in [RigConBijection], [BijectionLRT], and [BijectionDn].

**Note:** This is only proven to be a bijection in types \( A_n^{(1)} \) and \( D_n^{(1)} \), as well as \( \bigotimes_i B_n^{1,1} \) and \( \bigotimes_i B_{1,si} \) for general affine types.

**INPUT:**

- display_steps — (default: False) Boolean which indicates if we want to output each step in the algorithm.

**OUTPUT:**

The rigged configuration corresponding to self.

**EXAMPLES:**

Type \( A_n^{(1)} \) example:
```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1],
               [[2,1], [2,1], [2,1]])
sage: T = KRT(pathlist=[[4, 2], [3, 1], [2, 1]])
sage: T
[[2], [4]] (X) [[1], [3]] (X) [[1], [2]]
sage: T.to_rigged_configuration()
[ ]
[1]
[1]
[0]

Type $D_{n(1)}$ example:

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1],
               [[2,2]])
sage: T = KRT(pathlist=[[2,1,4,3]])
sage: T
[[1, 3], [2, 4]]
sage: T.to_rigged_configuration()
[ ]
[0]
[-1]
[-1]
[ ]
(1)
```

Type $D_{n(1)}$ spinor example:

```python
sage: CP = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 5, 1],
               [[5,1],[2,1],[1,1],[1,1],[1,1]])
sage: elt = CP(pathlist=[[-2,-5,4,3,1],[-1,2],[1],[1],[1]])
sage: elt
[[1], [3], [4], [-5], [-2]] (X) [[2], [-1]] (X) [[1]] (X) [[1]] (X) [[1]]
sage: elt.to_rigged_configuration()
[ ]
[2]
[0]
[0]
[0]
[0]
[0]
[0]
[0]

This is invertible by calling `to_tensor_product_of_kirillov_reshetikhin_tableaux()`:

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1],
               [[2,2]])
```
```
sage: T = KRT(pathlist=[[2,1,4,3]])
sage: rc = T.to_rigged_configuration()
sage: ret = rc.to_tensor_product_of_kirillov_reshetikhin_tableaux(); ret
[[1, 3], [2, 4]]
sage: ret == T
True

to_tensor_product_of_kirillov_reshetikhin_crystals()
Return a tensor product of Kirillov-Reshetikhin crystals corresponding to self.

This works by performing the filling map on each individual factor. For more on the filling map, see KirillovReshetikhinTableaux.

EXAMPLES:

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D',4,1],
    \rightarrow[[1,1],[2,2]])
sage: elt = KRT(pathlist=[[-1],[-1,2,-1,1]]); elt
[[[-1]] (X) [[2, 1], [-1, -1]]
sage: tp_krc = elt.to_tensor_product_of_kirillov_reshetikhin_crystals(); tp_\rightarrow krc
[[[-1]], [[2], [-1]]]

We can recover the original tensor product of KR tableaux:

sage: ret = KRT(tp_krc); ret
[[[-1]] (X) [[2, 1], [-1, -1]]
sage: ret == elt
True

5.1.220 Root system features that are imported by default in the interpreter names-
pace

5.1.221 Ambient lattices and ambient spaces

```python
class sage.combinat.root_system.ambient_space.AmbientSpace(root_system, base_ring, index_set=None):
    Bases: sage.combinat.free_module.CombinatorialFreeModule

Abstract class for ambient spaces

All subclasses should implement a class method smallest_base_ring taking a Cartan type as input, and a
method dimension working on a partially initialized instance with just root_system as attribute. There is
no safe default implementation for the later, so none is provided.

EXAMPLES:

```sage```
AL = RootSystem(['A',2]).ambient_lattice()
```

Note: This is only used so far for finite root systems.

Caveat: Most of the ambient spaces currently have a basis indexed by 0,...,n, unlike the usual mathematical
convention:

```sage```
e = AL.basis()
e[0], e[1], e[2]
((1, 0, 0), (0, 1, 0), (0, 0, 1))
```

This will be cleaned up!

See also:

• sage.combinat.root_system.type_A.AmbientSpace
• sage.combinat.root_system.type_B.AmbientSpace
• sage.combinat.root_system.type_C.AmbientSpace
• sage.combinat.root_system.type_D.AmbientSpace
• sage.combinat.root_system.type_E.AmbientSpace
• `sage.combinat.root_system.type_F.AmbientSpace`
• `sage.combinat.root_system.type_G.AmbientSpace`
• `sage.combinat.root_system.type_dual.AmbientSpace`
• `sage.combinat.root_system.type_affine.AmbientSpace`

**Element**

alias of `AmbientSpaceElement`

**coroot_lattice()**

EXAMPLES:

```
sage: e = RootSystem(['A', 3]).ambient_lattice()
sage: e.coroot_lattice()
Ambient lattice of the Root system of type ['A', 3]
```

**dimension()**

Return the dimension of this ambient space.

EXAMPLES:

```
sage: from sage.combinat.root_system.ambient_space import AmbientSpace
e = RootSystem(['F',4]).ambient_space()
sage: AmbientSpace.dimension(e)
Traceback (most recent call last):
  ... 
  Not ImplementedError
```

**from_vector_notation** *(weight, style='lattice')*  

INPUT:

• `weight` - a vector or tuple representing a weight

Returns an element of self. If the weight lattice is not of full rank, it coerces it into the weight lattice, or its ambient space by orthogonal projection. This arises in two cases: for SL(r+1), the weight lattice is contained in a hyperplane of codimension one in the ambient space, and for types E6 and E7, the weight lattice is contained in a subspace of codimensions 2 or 3, respectively.

If style=”coroots” and the data is a tuple of integers, it is assumed that the data represent a linear combination of fundamental weights. If style=”coroots”, and the root lattice is not of full rank in the ambient space, it is projected into the subspace corresponding to the semisimple derived group. This arises with Cartan type A, E6 and E7.

EXAMPLES:

```
sage: RootSystem('A2').ambient_space().from_vector_notation((1,0,0))
(1, 0, 0)
sage: RootSystem('A2').ambient_space().from_vector_notation([1,0,0])
(1, 0, 0)
sage: RootSystem('A2').ambient_space().from_vector_notation((1,0),style='coroots')
(2/3, -1/3, -1/3)
```

**fundamental_weight** *(i)*  

Returns the fundamental weight $\Lambda_i$ in self

In several of the ambient spaces, it is more convenient to construct all fundamental weights at once. To support this, we provide this default implementation of `fundamental_weight` using the method
fundamental_weights. Beware that this will cause a loop if neither fundamental_weight nor fundamental_weights is implemented.

EXAMPLES:

```python
sage: e = RootSystem(['F',4]).ambient_space()
sage: e.fundamental_weight(3)
(3/2, 1/2, 1/2, 1/2)
sage: e = RootSystem(['G',2]).ambient_space()
sage: e.fundamental_weight(1)
(1, 0, -1)
sage: e = RootSystem(['E',6]).ambient_space()
sage: e.fundamental_weight(3)
(-1/2, 1/2, 1/2, 1/2, 1/2, -5/6, -5/6, 5/6)
```

reflection (root, coroot=None)

EXAMPLES:

```python
sage: e = RootSystem(['A', 3]).ambient_lattice()
sage: a = e.simple_root(0); a
(-1, 0, 0, 0)
sage: b = e.simple_root(1); b
(1, -1, 0, 0)
sage: s_a = e.reflection(a)
sage: s_a(b)
(0, -1, 0, 0)
```

simple_coroot (i)

Returns the i-th simple coroot, as an element of this space

EXAMPLES:

```python
sage: R = RootSystem(['A',3])
sage: L = R.ambient_lattice()
sage: L.simple_coroot(1)
(1, -1, 0, 0)
sage: L.simple_coroot(2)
(0, 1, -1, 0)
sage: L.simple_coroot(3)
(0, 0, 1, -1)
```

classmethod smallest_base_ring (cartan_type=None)

Return the smallest ground ring over which the ambient space can be realized.

This class method will get called with the Cartan type as input. This default implementation returns \( \mathbb{Q} \); subclasses should override it as appropriate.

EXAMPLES:

```python
sage: e = RootSystem(['F',4]).ambient_space()
sage: e.smallest_base_ring()
Rational Field
```

to_ambient_space_morphism()

Return the identity map on self.

This is present for uniformity of use; the corresponding method for abstract root and weight lattices/spaces, is not trivial.
EXAMPLES:

```python
sage: P = RootSystem(['A',2]).ambient_space()
sage: f = P.to_ambient_space_morphism()
sage: p = P.an_element()
sage: p
(2, 2, 3)
sage: f(p)
(2, 2, 3)
sage: f(p)==p
True
```

```python
class sage.combinat.root_system.ambient_space.AmbientSpaceElement
Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

associated_coroot()

EXAMPLES:

```python
sage: e = RootSystem(['F',4]).ambient_space()
sage: a = e.simple_root(0); a
(1/2, -1/2, -1/2, -1/2)
sage: a.associated_coroot()
(1, -1, -1, -1)
```

```python
coerce_to_e6()
For type E7 or E8, orthogonally projects an element of the root lattice into the E6 root lattice. This
operation on weights corresponds to intersection with the semisimple subgroup E6.

EXAMPLES:

```python
sage: [b.coerce_to_e6() for b in RootSystem("E8").ambient_space().basis()]
[(1, 0, 0, 0, 0, 0, 0), (0, 1, 0, 0, 0, 0, 0), (0, 1, 0, 0, 0, 0, 0),
(0, 0, 1, 0, 0, 0, 0), (0, 0, 0, 1, 0, 0, 0), (0, 0, 0, 1, 0, 0, 0),
(0, 0, 0, 0, 1, 0, 0, 0), (0, 0, 0, 0, 0, 1/3, 1/3, -1/3),
(0, 0, 0, 0, 0, -1/3, -1/3, 1/3), (0, 0, 0, 0, 0, -1/3, -1/3, 1/3)]
```

```python
coerce_to_e7()
For type E8, this orthogonally projects the given element of the E8 root lattice into the E7 root lattice. This
operation on weights corresponds to intersection with the semisimple subgroup E7.

EXAMPLES:

```python
sage: [b.coerce_to_e7() for b in RootSystem("E8").ambient_space().basis()]
[(1, 0, 0, 0, 0, 0, 0), (0, 1, 0, 0, 0, 0, 0), (0, 1, 0, 0, 0, 0, 0),
(0, 0, 1, 0, 0, 0, 0), (0, 0, 0, 1, 0, 0, 0), (0, 0, 0, 1, 0, 0, 0),
(0, 0, 0, 0, 1, 0, 0, 0), (0, 0, 0, 0, 0, 1/2, -1/2), (0, 0, 0, 0, 0, -1/2, 1/2)]
```

```python
coerce_to_sl()
For type ['A',r], this coerces the element of the ambient space into the root space by orthogonal projection.
The root space has codimension one and corresponds to the Lie algebra of SL(r+1,CC), whereas the full
weight space corresponds to the Lie algebra of GL(r+1,CC). So this operation corresponds to multiplication
by a (possibly fractional) power of the determinant to give a weight determinant one.

EXAMPLES:

```python
sage: [fw.coerce_to_sl() for fw in RootSystem("A2").ambient_space().fundamental_weights()]
[(2/3, -1/3, -1/3), (1/3, 1/3, -2/3)]
```
```
sage: L = RootSystem("A2xA3").ambient_space()
sage: L([1,2,3,4,5,0,0]).coerce_to_sl()
(-1, 0, 1, 7/4, 11/4, -9/4, -9/4)

**dot_product** *(\lambda^\vee)*
The scalar product with elements of the coroot lattice embedded in the ambient space.

**EXAMPLES:**

```python
sage: e = RootSystem(['A',2]).ambient_space()
sage: a = e.simple_root(0); a
(-1, 0, 0)
sage: a.inner_product(a)
2
```

**inner_product** *(\lambda^\vee)*
The scalar product with elements of the coroot lattice embedded in the ambient space.

**EXAMPLES:**

```python
sage: e = RootSystem(['A',2]).ambient_space()
sage: a = e.simple_root(0); a
(-1, 0, 0)
sage: a.inner_product(a)
2
```

**is_positive_root** ()

**EXAMPLES:**

```python
sage: R = RootSystem(['A',3]).ambient_space()
sage: r=R.simple_root(1)+R.simple_root(2)
sage: r.is_positive_root()
True
sage: r=R.simple_root(1)-R.simple_root(2)
sage: r.is_positive_root()
False
```

**scalar** *(\lambda^\vee)*
The scalar product with elements of the coroot lattice embedded in the ambient space.

**EXAMPLES:**

```python
sage: e = RootSystem(['A',2]).ambient_space()
sage: a = e.simple_root(0); a
(-1, 0, 0)
sage: a.inner_product(a)
2
```

**to_ambient** ()

Map self to the ambient space.

This exists for uniformity. Its analogue for root and weight lattice realizations, is not trivial.

**EXAMPLES:**

```python
sage: v = CartanType(['C',3]).root_system().ambient_space().an_element(); v
(2, 2, 3)
```
5.1.222 Associahedron

Todo:

- fix adjacency matrix
- edit graph method to get proper vertex labellings
- UniqueRepresentation?

AUTHORS:

- Christian Stump

sage.combinat.root_system.associahedron.Associahedra(base_ring, ambient_dim, backend='ppl')

Construct a parent class of Associahedra according to backend.

See also:

Associahedra_base.

class sage.combinat.root_system.associahedron.Associahedra_base

Bases: object

Base class of parent of Associahedra of specified dimension

EXAMPLES:

Importantly, the parent knows the dimension of the ambient space. If you try to construct an associahedron of a different dimension, a ValueError is raised:

class sage.combinat.root_system.associahedron.Associahedra_cdd(base_ring, ambient_dim, backend)

Element

alias of Associahedron_class_cdd

5.1. Comprehensive Module list
class sage.combinat.root_system.associahedron.Associahedra_field(base_ring, ambient_dim, backend)

Element
    alias of Associahedron_class_field

class sage.combinat.root_system.associahedron.Associahedra_normaliz(base_ring, ambient_dim, backend)

Element
    alias of Associahedron_class_normaliz

class sage.combinat.root_system.associahedron.Associahedra_polymake(base_ring, ambient_dim, backend)

Element
    alias of Associahedron_class_polymake

class sage.combinat.root_system.associahedron.Associahedra_ppl(base_ring, ambient_dim, backend)

Element
    alias of Associahedron_class_ppl

sage.combinat.root_system.associahedron.Associahedron(cartan_type, backend='ppl')

Construct an associahedron.

The generalized associahedron is a polytopal complex with vertices in one-to-one correspondence with clusters in the cluster complex, and with edges between two vertices if and only if the associated two clusters intersect in codimension 1.

The associahedron of type $A_n$ is one way to realize the classical associahedron as defined in the Wikipedia article Associahedron.

A polytopal realization of the associahedron can be found in [CFZ2002]. The implementation is based on [CFZ2002], Theorem 1.5, Remark 1.6, and Corollary 1.9.

INPUT:

- cartan_type -- a cartan type according to sage.combinat.root_system.cartan_type.CartanTypeFactory
- backend -- string ('ppl'); the backend to use; see sage.geometry.polyhedron.constructor.Polyhedron()

EXAMPLES:
sage: Asso = polytopes.associahedron(['A',2]); Asso
Generalized associahedron of type ['A', 2] with 5 vertices

sage: sorted(Asso.Hrepresentation(), key=repr)
[An inequality (-1, 0) x + 1 >= 0,
 An inequality (0, -1) x + 1 >= 0,
 An inequality (0, 1) x + 1 >= 0,
 An inequality (1, 0) x + 1 >= 0,
 An inequality (1, 1) x + 1 >= 0]

sage: Asso.Vrepresentation()
(A vertex at (1, -1), A vertex at (1, 1), A vertex at (-1, 1),
 A vertex at (-1, 0), A vertex at (0, -1))

sage: polytopes.associahedron(['B',2])
Generalized associahedron of type ['B', 2] with 6 vertices

The two pictures of [CFZ2002] can be recovered with:

sage: Asso = polytopes.associahedron(['A',3]); Asso
Generalized associahedron of type ['A', 3] with 14 vertices
sage: Asso.plot()  # long time
Graphics3d Object

sage: Asso = polytopes.associahedron(['B',3]); Asso
Generalized associahedron of type ['B', 3] with 20 vertices
sage: Asso.plot()  # long time
Graphics3d Object

class sage.combinat.root_system.associahedron.Associahedron_class_base(parent, Vrep, Hrep, cartan_type=None, **kwds)

Bases: object

The base class of the Python class of an associahedron

You should use the Associahedron() convenience function to construct associahedra from the Cartan type.

cartan_type()
Return the Cartan type of self.

EXAMPLES:

sage: polytopes.associahedron(['A',3]).cartan_type()
['A', 3]

vertices_in_root_space()
Return the vertices of self as elements in the root space.

EXAMPLES:

sage: Asso = polytopes.associahedron(['A',2])
sage: Asso.vertices()
(A vertex at (1, -1), A vertex at (1, 1),
 A vertex at (-1, 1), A vertex at (-1, 0),
(continues on next page)
class sage.combinat.root_system.associahedron.Associahedron_class_cdd (parent, Vrep, Hrep, cartesian_type=None, **kwds)

Bases:  
sage.combinat.root_system.associahedron.Associahedron_class_base,  
sage.geometry.polyhedron.backend_cdd.Polyhedron_QQ_cdd

class sage.combinat.root_system.associahedron.Associahedron_class_field (parent, Vrep, Hrep, cartesian_type=None, **kwds)

Bases:  
sage.combinat.root_system.associahedron.Associahedron_class_base,

5.1.223 Braid Move Calculator

AUTHORS:

• Dinakar Muthiah (2014-06-03): initial version

class sage.combinat.root_system.braid_move_calculator.BraidMoveCalculator(coxeter_group)
Bases: object

Helper class to compute braid moves.

chain_of_reduced_words(start_word, end_word)

Compute the chain of reduced words from start_word to end_word.

INPUT:

• start_word, end_word – two reduced expressions for the long word

EXAMPLES:

```
sage: from sage.combinat.root_system.braid_move_calculator import *
sage: W = CoxeterGroup(['A',5]) sage: B = BraidMoveCalculator(W) sage: B.chain_of_reduced_words((1,2,1,3,2,1,4,3,2,1,5,4,3,2,1), # not tested ....: (5,4,5,3,4,5,2,3,4,5,1,2,3,4,5))
```

put_in_front(k, input_word)

Return a list of reduced words starting with input_word and ending with a reduced word whose first letter is k. There still remains an issue with 0 indices.

EXAMPLES:

```
sage: from sage.combinat.root_system.braid_move_calculator import *
sage: W = CoxeterGroup(['C',3]) sage: B = BraidMoveCalculator(W) sage: B.put_in_front(2, (3, 2, 3, 1, 2, 3, 1, 2, 1)) ((3, 2, 3, 1, 2, 3, 1, 2, 1), (3, 2, 1, 3, 2, 3, 1, 2, 1), (3, 2, 1, 3, 2, 3, 2, 1, 2), (3, 2, 1, 2, 3, 2, 3, 1, 2), (3, 1, 2, 1, 3, 2, 3, 1, 2), (1, 3, 2, 1, 3, 2, 3, 1, 2))
sage: B.put_in_front(1, (3, 2, 3, 2, 1, 2, 3, 2)) ((1, 3, 2, 3, 2, 1, 2, 3, 2),)
sage: B.put_in_front(1, (1, 3, 2, 3, 2, 1, 2, 3, 2))
```
5.1.224 Braid Orbit

Cython function to compute the orbit of the braid moves on a reduced word.

```
sage.combinat.root_system.braid_orbit.BraidOrbit(word, rels)
```

Return the orbit of `word` by all replacements given by `rels`.

**INPUT:**
- `word` – list of integers
- `rels` – list of pairs `(A, B)`, where `A` and `B` are lists of integers the same length

**EXAMPLES:**

```
sage: from sage.combinat.root_system.braid_orbit import BraidOrbit
sage: word = [1,2,1,3,2,1]
sage: rels = [[[2, 1, 2], [1, 2, 1]], [[3, 1], [1, 3]], [[3, 2, 3], [2, 3, 2]]]
sage: sorted(BraidOrbit(word, rels))
[(1, 2, 1, 3, 2, 1),
 (1, 2, 3, 1, 2, 1),
 (1, 2, 3, 2, 1, 2),
 (1, 3, 2, 1, 3, 2),
 (2, 1, 2, 3, 2, 1),
 (2, 1, 3, 2, 1, 3),
 (2, 1, 3, 2, 3, 1),
 (2, 3, 1, 2, 1, 3),
 (2, 3, 1, 2, 3, 1),
 (2, 3, 2, 1, 2, 3),
 (3, 1, 2, 1, 3, 2),
 (3, 1, 2, 3, 1, 2),
 (3, 2, 1, 2, 3, 2),
 (3, 2, 1, 3, 2, 3),
 (3, 2, 3, 1, 2, 3)]
sage: len(_)
16
```

5.1.225 Branching Rules

```
class sage.combinat.root_system.branching_rules.BranchingRule(R, S, f,
name='default',
intermediate_types=[],
intermediate_names=[])`
```

Bases: sage.structure.sage_object.SageObject

A class for branching rules.

**Rtype()**

In a branching rule `R => S`, returns the Cartan Type of the ambient group `R`.

**EXAMPLES:**

```
sage: branching_rule("A3","A2","levi").Rtype()
[\"A\", 3]
```
Stype()

In a branching rule $R \Rightarrow S$, returns the Cartan Type of the subgroup $S$.

**EXAMPLES:**

```python
sage: branching_rule("A3","A2","levi").Stype()
['A', 2]
```

branch($\chi$, style=None)

**INPUT:**

- $\chi$ – A character of the WeylCharacterRing with Cartan type self.Rtype().

Returns the branched character.

**EXAMPLES:**

```python
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: chi=G2(1,1); chi.degree()
64
sage: b=G2.maximal_subgroup("A2"); b
extended branching rule G2 => A2
sage: b.branch(chi)
A2(0,1) + A2(1,0) + A2(0,2) + 2*A2(1,1) + A2(2,0) + A2(1,2) + A2(2,1)
```

describe($\text{verbose=False, debug=False, no_r=False}$)

Describes how extended roots restrict under self.

**EXAMPLES:**

```python
sage: branching_rule("G2","A2","extended").describe()
3
0<=0---0
1 2 0
G2

root restrictions G2 => A2:

0---0
1 2
A2

0 => 2
2 => 1

For more detailed information use verbose=True
```

In this example, 0 is the affine root, that is, the negative of the highest root, for "G2". If $i \Rightarrow j$ is printed, this means that the $i$-th simple (or affine) root of the ambient group restricts to the $j$-th simple root of the subgroup. For reference the Dynkin diagrams are also printed. The extended Dynkin diagram of the ambient group is printed if the affine root restricts to a simple root. More information is printed if the parameter $\text{verbose}$ is true.

```python
sage.combinat.root_system.branching_rules.branch_weyl_character($\chi, \ R, \ S, \ \text{rule='default'}$)
```

**INPUT:**
- \( \chi \) – a character of \( G \)
- \( R \) – the Weyl Character Ring of \( G \)
- \( S \) – the Weyl Character Ring of \( H \)
- \( \text{rule} \) – an element of the BranchingRule class or one (most usually) a keyword such as:
  - "levi"
  - "automorphic"
  - "symmetric"
  - "extended"
  - "orthogonal_sum"
  - "tensor"
  - "triality"
  - "miscellaneous"

The BranchingRule class is a wrapper for functions from the weight lattice of \( G \) to the weight lattice of \( H \). An instance of this class encodes an embedding of \( H \) into \( G \). The usual way to specify an embedding is to supply a keyword, which tells Sage to use one of the built-in rules. We will discuss these first.

To explain the predefined rules, we survey the most important branching rules. These may be classified into several cases, and once this is understood, the detailed classification can be read off from the Dynkin diagrams.

Dynkin classified the maximal subgroups of Lie groups in Mat. Sbornik N.S. 30(72):349-462 (1952).

We will list give predefined rules that cover most cases where the branching rule is to a maximal subgroup. For convenience, we also give some branching rules to subgroups that are not maximal. For example, a Levi subgroup may or may not be maximal.

For example, there is a “levi” branching rule defined from \( SL(5) \) (with Cartan type \( A_4 \)) to \( SL(4) \) (with Cartan type \( A_3 \)), so we may compute the branching rule as follows:

**EXAMPLES:**

```sage
sage: A3=WeylCharacterRing("A3",style="coroots")
sage: A2=WeylCharacterRing("A2",style="coroots")
sage: [A3(fw).branch(A2,rule="levi") for fw in A3.fundamental_weights()]
[(A2(0,0) + A2(1,0), A2(0,1) + A2(1,0), A2(0,0) + A2(0,1))]
```

In this case the Levi branching rule is the default branching rule so we may omit the specification rule="levi".

If a subgroup is not maximal, you may specify a branching rule by finding a chain of intermediate subgroups. For this purpose, branching rules may be multiplied as in the following example.

**EXAMPLES:**

```sage
```
A4=WeylCharacterRing("A4",style="coroots")
A2=WeylCharacterRing("A2",style="coroots")
br=branching_rule("A4","A3")*branching_rule("A3","A2")
A4(1,0,0,0).branch(A2,rule=br)
2*A2(0,0) + A2(1,0)

You may try omitting the rule if it is “obvious”. Default rules are provided for the following cases:

\[
\begin{align*}
A_{2s} & \Rightarrow B_s, \\
A_{2s-1} & \Rightarrow C_s, \\
A_{2s+1} & \Rightarrow D_s.
\end{align*}
\]

The above default rules correspond to embedding the group \(SO(2s+1), Sp(2s)\) or \(SO(2s)\) into the corresponding general or special linear group by the standard representation. Default rules are also specified for the following cases:

\[
\begin{align*}
B_{s+1} & \Rightarrow D_s, \\
D_s & \Rightarrow B_s.
\end{align*}
\]

These correspond to the embedding of \(O(n)\) into \(O(n+1)\) where \(n = 2s\) or \(2s + 1\). Finally, the branching rule for the embedding of a Levi subgroup is also implemented as a default rule.

EXAMPLES:

def try_default_rule(R,S):
    return [R(f).branch(S) for f in R.fundamental_weights()]
sage: try_default_rule(A2,A1)
[A1(0) + A1(1), A1(0) + A1(1)]
sage: try_default_rule(D4,B3)
[B3(0,0,0) + B3(1,0,0), B3(1,0,0) + B3(0,1,0), B3(0,0,1), B3(0,0,1)]
sage: try_default_rule(B4,D4)
[D4(0,0,0,0) + D4(1,0,0,0), D4(1,0,0,0) + D4(0,1,0,0),
 D4(0,1,0,0) + D4(0,0,1,1), D4(0,0,1,0) + D4(0,0,0,1)]
sage: try_default_rule(A7,D4)
[D4(1,0,0,0), D4(0,1,0,0), D4(0,0,1,1), D4(0,0,2,0) + D4(0,0,0,2),
 D4(0,0,1,1), D4(0,1,0,0), D4(1,0,0,0)]
sage: try_default_rule(A6,B3)
[B3(1,0,0), B3(0,1,0), B3(0,0,2), B3(0,0,2), B3(0,1,0), B3(1,0,0)]

If a default rule is not known, you may cue Sage as to what the Lie group embedding is by supplying a rule from the list of predefined rules. We will treat these next.
Levi Type

These can be read off from the Dynkin diagram. If removing a node from the Dynkin diagram produces another Dynkin diagram, there is a branching rule. A Levi subgroup may or may not be maximal. If it is maximal, there may or may not be a built-in branching rule for but you may obtain the Levi branching rule by first branching to a suitable maximal subgroup. For these rules use the option rule="levi":

\[
\begin{align*}
A_r & \Rightarrow A_{r-1} \\
B_r & \Rightarrow B_{r-1} \\
C_r & \Rightarrow A_{r-1} \\
C_r & \Rightarrow C_{r-1} \\
D_r & \Rightarrow A_{r-1} \\
D_r & \Rightarrow D_{r-1} \\
E_r & \Rightarrow A_{r-1} \quad r = 7, 8 \\
E_r & \Rightarrow D_{r-1} \quad r = 6, 7, 8 \\
E_r & \Rightarrow E_{r-1} \\
F_4 & \Rightarrow B_3 \\
F_4 & \Rightarrow C_3 \\
G_2 & \Rightarrow A_1 \text{(short root)}
\end{align*}
\]

Not all Levi subgroups are maximal subgroups. If the Levi is not maximal there may or may not be a pre-programmed rule="levi" for it. If there is not, the branching rule may still be obtained by going through an intermediate subgroup that is maximal using rule="extended". Thus the other Levi branching rule from \(G_2 \Rightarrow A_1\) corresponding to the long root is available by first branching \(G_2 \Rightarrow A_2\) then \(A_2 \Rightarrow A_1\). Similarly the branching rules to the Levi subgroup:

\[
E_r \Rightarrow A_{r-1} \quad r = 6, 7, 8
\]

may be obtained by first branching \(E_6 \Rightarrow A_5 \times A_1\), \(E_7 \Rightarrow A_7\) or \(E_8 \Rightarrow A_8\).

EXAMPLES:

```python
sage: A1 = WeylCharacterRing("A1")
sage: A2 = WeylCharacterRing("A2")
sage: A3 = WeylCharacterRing("A3")
sage: A4 = WeylCharacterRing("A4")
sage: A5 = WeylCharacterRing("A5")
sage: B2 = WeylCharacterRing("B2")
sage: B3 = WeylCharacterRing("B3")
sage: B4 = WeylCharacterRing("B4")
sage: C2 = WeylCharacterRing("C2")
sage: C3 = WeylCharacterRing("C3")
sage: D3 = WeylCharacterRing("D3")
sage: D4 = WeylCharacterRing("D4")
sage: G2 = WeylCharacterRing("G2")
sage: F4 = WeylCharacterRing("F4",style="coroots")
sage: E6=WeylCharacterRing("E6",style="coroots")
sage: E7=WeylCharacterRing("E7",style="coroots")
sage: D5=WeylCharacterRing("D5",style="coroots")
sage: D6=WeylCharacterRing("D6",style="coroots")
sage: B3(w).branch(A2,rule="levi") for w in B3.fundamental_weights()]
[A2(0,0,0) + A2(1,0,0) + A2(0,0,-1),
A2(0,0,0) + A2(1,0,0) + A2(1,1,0) + A2(1,0,-1) + A2(0,-1,-1) + A2(0,0,-1),
A2(-1/2,-1/2,-1/2) + A2(1/2,-1/2,-1/2) + A2(1/2,1/2,-1/2) + A2(1/2,1/2,1/2)]
```
The last example must be understood as follows. The representation of $B_3$ being branched is spin, which is not a representation of $SO(7)$ but of its double cover $spin(7)$. The group $A_2$ is really $GL(3)$ and the double cover of $SO(7)$ induces a cover of $GL(3)$ that is trivial over $SL(3)$ but not over the center of $GL(3)$. The weight lattice for this $GL(3)$ consists of triples $(a, b, c)$ of half integers such that $a - b$ and $b - c$ are in $\mathbb{Z}$, and this is reflected in the last decomposition.

```python
sage: [C3(w).branch(A2, rule='levi') for w in C3.fundamental_weights()]
[2*B2(0,0) + B2(1,0), B2(0,0) + 2*B2(1,0) + B2(1,1), C2(1,0) + 2*C2(1,1)]
```

(continues on next page)
sage: [F4(fw).branch(B3,rule="levi") for fw in F4.fundamental_weights()] # long
˓→time (1s)
[B3(0,0,0) + 2*B3(1/2,1/2,1/2) + 2*B3(1,0,0) + B3(1,1,0),
B3(0,0,0) + 6*B3(1/2,1/2,1/2) + 5*B3(1,0,0) + 7*B3(1,1,0) + 3*B3(1,1,1)
+ 6*B3(3/2,1/2,1/2) + 2*B3(3/2,3/2,1/2) + B3(2,0,0) + 2*B3(2,1,0) + B3(2,1,1),
3*B3(0,0,0) + 6*B3(1/2,1/2,1/2) + 4*B3(1,0,0) + 3*B3(1,1,0) + B3(1,1,1) + 2*B3(3/2,1/2,1/2),
3*B3(0,0,0) + 2*B3(1/2,1/2,1/2) + B3(1,0,0)]
sage: [F4(fw).branch(C3,rule="levi") for fw in F4.fundamental_weights()] # long
˓→time (1s)
[3*C3(0,0,0) + 2*C3(1,1,1) + C3(2,0,0),
3*C3(0,0,0) + 6*C3(1,1,1) + 4*C3(2,0,0) + 2*C3(2,1,0) + 3*C3(2,2,0) + C3(2,2,2),
+ C3(3,1,0) + 2*C3(3,1,1),
2*C3(1,0,0) + 3*C3(1,1,0) + C3(2,0,0) + 2*C3(2,1,0) + C3(2,1,1),
2*C3(1,0,0) + C3(1,1,0)]
sage: A1xA1 = WeylCharacterRing("A1xA1")
sage: [A3(hwv).branch(A1xA1,rule="levi") for hwv in A3.fundamental_weights()]
[A1xA1(1,0,0,0,0) + A1xA1(0,0,1,0,0),
A1xA1(1,1,0,0,0) + A1xA1(1,0,1,0,0) + A1xA1(0,0,1,1,0),
A1xA1(1,1,1,0,0) + A1xA1(1,0,1,1,0)]
sage: A1xB1=WeylCharacterRing("A1xB1",style="coroots")
sage: [B3(x).branch(A1xB1,rule="levi") for x in B3.fundamental_weights()]
[2*A1xB1(1,0) + A1xB1(0,2),
3*A1xB1(0,0) + 2*A1xB1(1,2) + A1xB1(2,0) + A1xB1(0,2),
A1xB1(1,1) + 2*A1xB1(0,1)]

**Automorphic Type**

If the Dynkin diagram has a symmetry, then there is an automorphism that is a special case of a branching rule. There is also an exotic “triality” automorphism of $D_4$ having order 3. Use `rule="automorphic"` (or for $D_4$ `rule="triality"`):

\[
A_r \Rightarrow A_r \\
D_r \Rightarrow D_r \\
E_6 \Rightarrow E_6
\]

**EXAMPLES:**

```python
sage: [A3(chi).branch(A3,rule="automorphic") for chi in A3.fundamental_weights()]
[A3(0,0,0,-1), A3(0,0,-1,-1), A3(0,-1,-1,-1)]
sage: [D4(chi).branch(D4,rule="automorphic") for chi in D4.fundamental_weights()]
[D4(1,0,0,0), D4(1,1,0,0), D4(1/2,1/2,1/2,1/2), D4(1/2,1/2,1/2,-1/2), D4(1/2,1/2,1/2,-1/2)]
```

Here is an example with $D_4$ triality:

```python
sage: [D4(chi).branch(D4,rule="triality") for chi in D4.fundamental_weights()]
[D4(1/2,1/2,1/2,-1/2), D4(1,1,0,0), D4(1/2,1/2,1/2,1/2), D4(1,0,0,0)]
```
Symmetric Type

Related to the automorphic type, when $G$ admits an outer automorphism (usually of degree 2) we may consider the branching rule to the isotropy subgroup $H$. Outer automorphisms correspond to symmetries of the Dynkin diagram. For such isotropy subgroups use `rule="symmetric"`. We may thus obtain the following branching rules.

\[
\begin{align*}
A_{2r} &\Rightarrow B_r \\
A_{2r-1} &\Rightarrow C_r \\
A_{2r-1} &\Rightarrow D_r \\
D_r &\Rightarrow B_{r-1} \\
E_6 &\Rightarrow F_4 \\
E_6 &\Rightarrow C_4 \\
D_4 &\Rightarrow G_2
\end{align*}
\]

The last branching rule, $D_4 \Rightarrow G_2$ is not to a maximal subgroup since $D_4 \Rightarrow B_3 \Rightarrow G_2$, but it is included for convenience.

In some cases, two outer automorphisms that differ by an inner automorphism may have different fixed subgroups. Thus, while the Dynkin diagram of $E_6$ has a single involutory automorphism, there are two involutions of the group (differing by an inner automorphism) with fixed subgroups $F_4$ and $C_4$. Similarly $SL(2r)$, of Cartan type $A_{2r-1}$, has subgroups $SO(2r)$ and $Sp(2r)$, both fixed subgroups of outer automorphisms that differ from each other by an inner automorphism.

In many cases the Dynkin diagram of $H$ can be obtained by folding the Dynkin diagram of $G$.

**EXAMPLES:**

```python
sage: [w.branch(B2,rule="symmetric") for w in [A4(1,0,0,0,0),A4(1,1,0,0,0),A4(1,1,1,0,0),A4(2,0,0,0,0)]]
[B2(1,0), B2(1,1), B2(1,1), B2(0,0) + B2(2,0)]
sage: [A5(w).branch(C3,rule="symmetric") for w in A5.fundamental_weights()]
[C3(1,0,0), C3(0,0,0) + C3(1,1,0), C3(1,0,0) + C3(1,1,1), C3(0,0,0) + C3(1,1,0), C3(1,0,0)]
sage: [A5(w).branch(D3,rule="symmetric") for w in A5.fundamental_weights()]
[D3(1,0,0), D3(1,1,1) + D3(1,1,0), D3(1,1,0), D3(1,0,0), D3(1,0,0)]
sage: [D4(x).branch(B3,rule="symmetric") for x in D4.fundamental_weights()]
[B3(0,0,0) + B3(1,0,0), B3(1,0,0) + B3(1,1,0), B3(1/2,1/2,1/2), B3(1/2,1/2,1/2)]
sage: [D4(x).branch(G2,rule="symmetric") for x in D4.fundamental_weights()]
[G2(0,0,0) + G2(1,0,-1), 2*G2(1,0,-1) + G2(2,-1,-1), G2(0,0,0) + G2(1,0,-1), G2(0,0,0) + G2(1,0,-1)]
sage: [E6(fw).branch(F4,rule="symmetric") for fw in E6.fundamental_weights()]
long time (4s)
[F4(0,0,0,0) + F4(0,0,0,1), F4(0,0,0,1) + F4(0,0,0,0), F4(0,0,0,0) + F4(0,0,0,1), 2*F4(0,0,0,0) + F4(0,0,0,1) + F4(0,1,0,0), F4(0,0,0,0) + F4(0,0,0,1) + F4(1,0,0,0) + F4(0,0,1,0), F4(0,0,0,0) + F4(0,0,0,1) + F4(1,0,0,0) + F4(0,0,1,0), F4(0,0,0,0) + F4(0,0,0,1)]
sage: E6=WeylCharacterRing("E6",style="coroots")
sage: C4=WeylCharacterRing("C4",style="coroots")
sage: chi = E6(1,0,0,0,0,0); chi.degree()
27
sage: chi.branch(C4,rule="symmetric")
C4(0,1,0,0)
```
Extended Type

If removing a node from the extended Dynkin diagram results in a Dynkin diagram, then there is a branching rule. Use `rule="extended"` for these. We will also use this classification for some rules that are not of this type, mainly involving type \( B \), such as \( D_6 \Rightarrow B_3 \times B_3 \).

Here is the extended Dynkin diagram for \( D_6 \):

```
0 6
0 0
| |
O---O---O---O---O
1 2 3 4 6
```

Removing the node 3 results in an embedding \( D_3 \times D_3 \Rightarrow D_6 \). This corresponds to the embedding \( SO(6) \times SO(6) \Rightarrow SO(12) \), and is of extended type. On the other hand the embedding \( SO(5) \times SO(7) \Rightarrow SO(12) \) (e.g. \( B_2 \times B_3 \Rightarrow D_6 \)) cannot be explained this way but for uniformity is implemented under `rule="extended"`.

The following rules are implemented as special cases of `rule="extended"`:

\[
E_6 \Rightarrow A_5 \times A_1, A_2 \times A_2 \times A_2 \\
E_7 \Rightarrow A_7, D_6 \times A_1, A_3 \times A_1 \times A_1 \\
E_8 \Rightarrow A_8, D_8, E_7 \times A_1, A_4 \times A_1 \times A_1, D_5 \times A_3, E_6 \times A_2 \\
F_4 \Rightarrow B_4, C_3 \times A_1, A_2 \times A_2, A_3 \times A_1 \\
G_2 \Rightarrow A_1 \times A_1
\]

Note that \( E_8 \) has only a limited number of representations of reasonably low degree.

EXAMPLES:

```
sage: [B3(x).branch(D3,rule="extended") for x in B3.fundamental_weights()]
[D3(0,0,0) + D3(1,0,0),
 D3(1,0,0) + D3(1,1,0),
 D3(1/2,1/2,1/2) + D3(1,1/2,1/2)]
sage: [G2(w).branch(A2, rule="extended") for w in G2.fundamental_weights()]
[A2(0,0,0) + A2(1/3,1/3,1/3),
 A2(1,0,0),
 A2(1/3,1/3,1/3) + A2(1/3,1/3,1/3) + A2(1,0,0)]
sage: [F4(fw).branch(B4,rule="extended") for fw in F4.fundamental_weights()]
# long time (2s)
[ B4(1/2,1/2,1/2,1/2) + B4(1,0,0),
 B4(1,1,0) + B4(1,1,0) + B4(3/2,1/2,1/2,1/2) + B4(3/2,3/2,1/2,1/2) + B4(3/2,3/2,1/2,1/2),
 B4(1/2,1/2,1/2,1/2) + B4(1,0,0) + B4(1,1,0) + B4(1,1,0) + B4(3/2,1/2,1/2,1/2),
 B4(1,0,0,0) + B4(1,0,0,0) + B4(3/2,1/2,1/2,1/2) + B4(1,0,0)]
sage: E6 = WeylCharacterRing("E6", style="coroots")
sage: A2xA2xA2 = WeylCharacterRing("A2xA2xA2",style="coroots")
sage: A5xA1 = WeylCharacterRing("A5xA1",style="coroots")
sage: G2 = WeylCharacterRing("G2", style="coroots")
sage: A1xA1 = WeylCharacterRing("A1xA1", style="coroots")
sage: F4 = WeylCharacterRing("F4",style="coroots")
sage: A3xA1 = WeylCharacterRing("A3xA1", style="coroots")

sage: F4(1,0,0,0).branch(A1xC3,rule="extended")  # (0.05s)
A1xC3(1,0,0,1) + A1xC3(2,0,0,0) + A1xC3(0,2,0,0)
sage: F4(0,0,0,1).branch(A2xA2, rule="extended")  # (0.4s)
A2xA2(0,1,0,1) + A2xA2(1,0,1,0) + A2xA2(0,0,1,1)
sage: F4(0,0,0,1).branch(A3xA1,rule="extended")  # (0.34s)
A3xA1(0,0,0,0) + A3xA1(0,1,0,1) + A3xA1(0,1,1,0) + A3xA1(1,0,1,0) + A3xA1(0,0,0,2)
sage: D4=WeylCharacterRing("D4",style="coroots")
sage: D2xD2=WeylCharacterRing("D2xD2",style="coroots")  # We get D4 => A1xA1xA1xA1
by remembering that A1xA1 = D2.
sage: [D4(fw).branch(D2xD2, rule="extended") for fw in D4.fundamental_weights()]
[D2xD2(1,1,0,0,0) + D2xD2(0,0,1,1),
D2xD2(2,0,0,0) + D2xD2(0,2,0,0) + D2xD2(1,1,1,1) + D2xD2(0,0,2,0) + D2xD2(0,0,0,2),
D2xD2(1,0,0,1) + D2xD2(0,1,1,0),
D2xD2(1,0,1,0) + D2xD2(0,1,0,1)]

**Orthogonal Sum**

Using rule="orthogonal_sum", for \( n = a + b + c + \cdots \), you can get any branching rule

\[
SO(n) \Rightarrow SO(a) \times SO(b) \times SO(c) \times \cdots,
Sp(2n) \Rightarrow Sp(2a) \times Sp(2b) \times Sp(2c)x \times \cdots,
\]

where \( O(a) \) is type \( D_a \) for \( a = 2r \) or \( B_r \) for \( a = 2r + 1 \) and \( Sp(2r) \) is type \( C_r \). In some cases these are also of extended type, as in the case \( D_3 \times D_3 \Rightarrow D_6 \) discussed above. But in other cases, for example \( B_3 \times B_3 \Rightarrow D_7 \), they are not of extended type.
Tensor

There are branching rules:

\[ A_{rs-1} \Rightarrow A_{r-1} \times A_{s-1}, \]
\[ B_{2rs+r+s} \Rightarrow B_r \times B_s, \]
\[ D_{2rs+s} \Rightarrow D_r \times D_s, \]
\[ D_{2rs} \Rightarrow C_r \times C_s, \]
\[ C_{2rs+s} \Rightarrow B_r \times C_s, \]
\[ C_{2rs} \Rightarrow C_r \times D_s. \]

corresponding to the tensor product homomorphism. For type \( A \), the homomorphism is \( GL(r) \times GL(s) \Rightarrow GL(rs) \). For the classical types, the relevant fact is that if \( V, W \) are orthogonal or symplectic spaces, that is, spaces endowed with symmetric or skew-symmetric bilinear forms, then \( V \otimes W \) is also an orthogonal space (if \( V \) and \( W \) are both orthogonal or both symplectic) or symplectic (if one of \( V \) and \( W \) is orthogonal and the other symplectic).

The corresponding branching rules are obtained using rule="tensor".

EXAMPLES:

```
sage: A5=WeylCharacterRing("A5", style="coroots")
sage: A2xA1=WeylCharacterRing("A2xA1", style="coroots")
sage: [A5(hwv).branch(A2xA1, rule="tensor") for hwv in A5.fundamental_weights()]
[A2xA1(1,0,1),
 A2xA1(0,1,2) + A2xA1(2,0,0),
 A2xA1(1,1,1) + A2xA1(0,0,3),
 A2xA1(1,0,2) + A2xA1(0,2,0),
 A2xA1(0,1,1)]
sage: B4=WeylCharacterRing("B4",style="coroots")
sage: B1xB1=WeylCharacterRing("B1xB1",style="coroots")
sage: [B4(f).branch(B1xB1,rule="tensor") for f in B4.fundamental_weights()]
[B1xB1(2,2),
 B1xB1(2,0) + B1xB1(2,4) + B1xB1(4,2) + B1xB1(0,2),
 B1xB1(2,0) + B1xB1(2,2) + B1xB1(2,4) + B1xB1(4,4) + B1xB1(6,0) + B1xB1(0,2) + B1xB1(0,6),
 B1xB1(1,3) + B1xB1(3,1)]
sage: D4=WeylCharacterRing("D4",style="coroots")
sage: C2xC1=WeylCharacterRing("C2xC1",style="coroots")
sage: [D4(f).branch(C2xC1,rule="tensor") for f in D4.fundamental_weights()]
[C2xC1(1,0,1),
 C2xC1(0,1,2) + C2xC1(2,0,0) + C2xC1(0,0,2),
 C2xC1(1,0,1),
 C2xC1(0,1,0) + C2xC1(0,0,2)]
sage: C3=WeylCharacterRing("C3",style="coroots")
sage: B1xC1=WeylCharacterRing("B1xC1",style="coroots")
sage: [C3(f).branch(B1xC1,rule="tensor") for f in C3.fundamental_weights()]
[B1xC1(2,1), B1xC1(2,2) + B1xC1(4,0), B1xC1(4,1) + B1xC1(0,3)]
```
Symmetric Power

The $k$-th symmetric and exterior power homomorphisms map

$$GL(n) \Rightarrow GL\left(\frac{n+k-1}{k}\right) \times GL\left(\binom{n}{k}\right).$$

The corresponding branching rules are not implemented but a special case is. The $k$-th symmetric power homomorphism $SL(2) \Rightarrow GL(k+1)$ has its image inside of $SO(2r+1)$ if $k = 2r$ and inside of $Sp(2r)$ if $k = 2r-1$. Hence there are branching rules:

$$B_r \Rightarrow A_1$$
$$C_r \Rightarrow A_1$$

and these may be obtained using the rule "symmetric_power".

EXAMPLES:

```python
sage: A1=WeylCharacterRing("A1",style="coroots")
sage: B3=WeylCharacterRing("B3",style="coroots")
sage: C3=WeylCharacterRing("C3",style="coroots")
sage: [B3(fw).branch(A1,rule="symmetric_power") for fw in B3.fundamental_weights()]
[A1(6), A1(2) + A1(6) + A1(10), A1(0) + A1(6)]
sage: [C3(fw).branch(A1,rule="symmetric_power") for fw in C3.fundamental_weights()]
```

Miscellaneous

Use rule="miscellaneous" for the following embeddings of maximal subgroups, all involving exceptional groups.

$$B_3 \Rightarrow G_2,$$
$$E_6 \Rightarrow G_2,$$
$$E_6 \Rightarrow A_2,$$
$$F_4 \Rightarrow G_2 \times A_1,$$
$$E_6 \Rightarrow G_2 \times A_2,$$
$$E_7 \Rightarrow G_2 \times C_3,$$
$$E_7 \Rightarrow F_4 \times A_1,$$
$$E_7 \Rightarrow A_1 \times A_1,$$
$$E_7 \Rightarrow G_2 \times A_1,$$
$$E_8 \Rightarrow G_2 \times F_4,$$
$$E_8 \Rightarrow A2 \times A_1.$$ 

Except for those embeddings available by rule="extended", these are the only embeddings of these groups as maximal subgroups. There may be other embeddings besides these. For example, there are other more obvious embeddings of $A_2$ and $G_2$ into $E_6$. However the embeddings in this table are characterized as embeddings as maximal subgroups. Regarding the embeddings of $A_2$ and $G_2$ in $E_6$, the embeddings in question may be characterized by the condition that the 27-dimensional representations of $E_6$ restrict irreducibly to $A_2$ or $G_2$. Since $G_2$ has a subgroup isomorphic to $A_2$, it is worth mentioning that the composite branching rules:
branching_rule("E6","G2","miscellaneous") * branching_rule("G2","A2","extended")
branching_rule("E6","A2","miscellaneous")

are distinct.

These embeddings are described more completely (with references to the literature) in the thematic tutorial at:

EXAMPLES:

```
sage: G2 = WeylCharacterRing("G2")
sage: [fw1, fw2, fw3] = B3.fundamental_weights()
sage: G2(1,0,-1) + G2(2,-1,-1) + G2(2,0,-2)
sage: G2 = WeylCharacterRing("G2",style="coroots")
sage: G2(1,0,0,0,0,0).branch(G2,"miscellaneous")
sage: A2=WeylCharacterRing("A2",style="coroots")
sage: F4=WeylCharacterRing("F4",style="coroots")
sage: E6 = WeylCharacterRing("E6",style="coroots")
sage: A2xG2 = WeylCharacterRing("A2xG2",style="coroots")
sage: G2xC3=WeylCharacterRing("G2xC3",style="coroots")
sage: E7=WeylCharacterRing("E7",style="coroots")
sage: A1xA2=WeylCharacterRing("A1xA2",style="coroots")
sage: A2=WeylCharacterRing("A2",style="coroots")
sage: G2xA1=WeylCharacterRing("G2xA1",style="coroots")
sage: E8 = WeylCharacterRing("E8",style="coroots")
sage: E8=WeylCharacterRing("E8",style="coroots")
sage: A1xA2=WeylCharacterRing("A1xA2",style="coroots")
```

(continues on next page)
sage: E8(0,0,0,0,0,0,0,1).branch(A1xA2,rule="miscellaneous")  # long time (0.76s)
A1xA2(2,0,0) + A1xA2(2,2,2) + A1xA2(4,0,3) + A1xA2(4,3,0) + A1xA2(6,1,1) +
→A1xA2(0,1,1)
sage: B2=WeylCharacterRing("B2",style="coroots")
sage: E8(0,0,0,0,0,0,0,1).branch(B2,rule="miscellaneous")  # long time (0.53s)
B2(0,2) + B2(0,6) + B2(3,2)

A1 maximal subgroups of exceptional groups

There are seven cases where the exceptional group \( G_2, F_4, E_7 \) or \( E_8 \) contains a maximal subgroup of type \( A_1 \). These are tabulated in Theorem 1 of Testerman, The construction of the maximal \( A_1 \)'s in the exceptional algebraic groups, Proc. Amer. Math. Soc. 116 (1992), no. 3, 635-644. The names of these branching rules are roman numerals referring to the seven cases of her Theorem 1. Use these branching rules as in the following examples.

EXAMPLES:

```
sage: A1=WeylCharacterRing("A1",style="coroots")
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: F4=WeylCharacterRing("F4",style="coroots")
sage: E7=WeylCharacterRing("E7",style="coroots")
sage: E8=WeylCharacterRing("E8",style="coroots")
sage: [G2(f).branch(A1,rule="i") for f in G2.fundamental_weights()]
[A1(6), A1(2) + A1(10)]
sage: F4(1,0,0,0).branch(A1,rule="ii")
A1(2) + A1(10) + A1(14) + A1(22)
sage: E7(0,0,0,0,0,0,1).branch(A1,rule="iii")
A1(9) + A1(17) + A1(27)
sage: E7(0,0,0,0,0,0,1).branch(A1,rule="iv")
sage: E8(0,0,0,0,0,0,0,1).branch(A1,rule="v")  # long time (0.6s)
→A1(46)
sage: E8(0,0,0,0,0,0,0,1).branch(A1,rule="vi")  # long time (0.6s)
→A1(34) + A1(38)
```

Branching Rules From Plethysms

Nearly all branching rules \( G \Rightarrow H \) where \( G \) is of type \( A, B, C \) or \( D \) are covered by the preceding rules. The function `branching_rule_from_plethysm()` covers the remaining cases.

This is a general rule that includes any branching rule from types \( A, B, C, \) or \( D \) as a special case. Thus it could be used in place of the above rules and would give the same results. However it is most useful when branching from \( G \) to a maximal subgroup \( H \) such that \( \text{rank}(H) < \text{rank}(G) - 1 \).

We consider a homomorphism \( H \Rightarrow G \) where \( G \) is one of \( SL(r+1), SO(2r+1), Sp(2r) \) or \( SO(2r) \). The function `branching_rule_from_plethysm()` produces the corresponding branching rule. The main ingredient is the character \( \chi \) of the representation of \( H \) that is the homomorphism to \( GL(r+1), GL(2r+1) \) or \( GL(2r) \).

This rule is so powerful that it contains the other rules implemented above as special cases. First let us consider the symmetric fifth power representation of \( SL(2) \).
This confirms that the character has degree 6 and is symplectic, so it corresponds to a homomorphism $SL(2) \to Sp(6)$, and there is a corresponding branching rule $C_3 \to A_1$.

This is identical to the results we would obtain using rule="symmetric_power". The next example gives a branching not available by other standard rules.

We have confirmed that the adjoint representation of $G_2$ gives a homomorphism into $SO(14)$, and that the pullback of the one of the two 64 dimensional spin representations to $SO(14)$ is an irreducible representation of $G_2$.

We do not actually have to create the character or its parent WeylCharacterRing to create the branching rule:

Isomorphic Type

Although not usually referred to as a branching rule, the effects of the accidental isomorphisms may be handled using rule="isomorphic":

EXAMPLES:
Here $A_3(x, y, z, w)$ can be understood as a representation of $SL(4)$. The weights $x, y, z, w$ and $x + t, y + t, z + t, w + t$ represent the same representation of $SL(4)$ - though not of $GL(4)$ - since $A_3(x + t, y + t, z + t, w + t)$ is the same as $A_3(x, y, z, w)$ tensored with $\det t$. So as a representation of $SL(4)$, $A_3(1/4,1/4,1/4,-3/4)$ is the same as $A_3(1,1,1,0)$. The exterior square representation $SL(4) \Rightarrow GL(6)$ admits an invariant symmetric bilinear form, so is a representation $SL(4) \Rightarrow SO(6)$ that lifts to an isomorphism $SL(4) \Rightarrow Spin(6)$. Conversely, there are two isomorphisms $SO(6) \Rightarrow SL(4)$, of which we’ve selected one.

In cases like this you might prefer style="coroots":

```python
sage: A3 = WeylCharacterRing("A3",style="coroots")
sage: D3 = WeylCharacterRing("D3",style="coroots")
sage: [D3(fw).branch(A3,rule="isomorphic") for fw in D3.fundamental_weights()]
[D3(1,0,0), D3(0,1,0), D3(0,0,1)]
sage: [D2(fw).branch(D3,rule="isomorphic") for fw in D3.fundamental_weights()]
[D2(1,0), D2(0,1)]
sage: [D2(fw).branch(A1xA1,rule="isomorphic") for fw in D2.fundamental_weights()]
[D2(1,0), D2(0,1)]
sage: [D2(fw).branch(A1xA1,rule="isomorphic") for fw in D2.fundamental_weights()]
[D2(1,0), D2(0,1)]
```

Branching From a Reducible WeylCharacterRing

If the Cartan Type of R is reducible, we may project a character onto any of the components, or any combination of components. The rule to project on the first component is specified by the string "proj1", the rule to project on the second component is "proj2". To project on the first and third components, use `"proj13"` and so on.

**EXAMPLES:**

```python
sage: A2xG2=WeylCharacterRing("A2xG2",style="coroots")
sage: A2=WeylCharacterRing("A2",style="coroots")
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: A2xG2(1,0,1,0).branch(A2,rule="proj1")
7*A2(1,0)
sage: A2xG2(1,0,1,0).branch(G2,rule="proj2")
3*G2(1,0)
sage: A2xA2xG2=WeylCharacterRing("A2xA2xG2",style="coroots")
sage: A2xA2xG2(0,1,1,0,1).branch(A2xG2,rule="proj13")
8*A2xG2(0,1,0,1)
```

A more general way of specifying a branching rule from a reducible type is to supply a list of rules, one component rule for each component type in the root system. In the following example, we branch the fundamental representations of $D_4$ down to $A_1 \times A_1 \times A_1 \times A_1$ through the intermediate group $D_2 \times D_2$. We use multiplicative notation to compose the branching rules. There is no need to construct the intermediate WeylCharacterRing with type $D_2 \times D_2$. 

5.1. Comprehensive Module list
EXAMPLES:

```python
sage: D4 = WeylCharacterRing("D4", style="coroots")
sage: b = branching_rule("D2","A1xA1", "isomorphic")
sage: br = branching_rule("D4","D2xD2", "extended")*branching_rule("D2xD2", "A1xA1xA1xA1", [b, b])
sage: [D4(fw).branch(A1xA1xA1xA1, rule=br)
     for fw in D4.fundamental_weights()]
[A1xA1xA1xA1(1,1,0,0) + A1xA1xA1xA1(0,0,1,1),
 A1xA1xA1xA1(1,1,1,1) + A1xA1xA1xA1(2,0,0,0) + A1xA1xA1xA1(0,2,0,0) +
  A1xA1xA1xA1(0,0,2,0) + A1xA1xA1xA1(0,0,0,2),
 A1xA1xA1xA1(1,0,0,1) + A1xA1xA1xA1(0,1,1,0),
 A1xA1xA1xA1(1,0,1,0) + A1xA1xA1xA1(0,1,0,1)]
```

In the list of rules to be supplied in branching from a reducible root system, we may use two key words "omit" and "identity". The term "omit" means that we omit one factor, projecting onto the remaining factors. The term "identity" is supplied when the irreducible factor Cartan Types of both the target and the source are the same, and the component branching rule is to be the identity map. For example, we have projection maps from $A_3 \times A_2$ to $A_3$ and $A_2$, and the corresponding branching may be accomplished as follows. In this example the same could be accomplished using `rule="proj2"`.

EXAMPLES:

```python
sage: A3xA2=WeylCharacterRing("A3xA2", style="coroots")
sage: A3=WeylCharacterRing("A3", style="coroots")
sage: chi = A3xA2(0,1,0,1,0)
sage: chi.branch(A3, rule=["identity","omit"])
3*A3(0,1,0)
sage: A2=WeylCharacterRing("A2", style="coroots")
sage: chi.branch(A2, rule=["omit","identity"])
6*A2(1,0)
```

Yet another way of branching from a reducible root system with repeated Cartan types is to embed along the diagonal. The branching rule is equivalent to the tensor product, as the example shows:

```python
sage: G2=WeylCharacterRing("G2", style="coroots")
sage: G2xG2=WeylCharacterRing("G2xG2", style="coroots")
sage: G2=WeylCharacterRing("G2", style="coroots")
sage: G2xG2(1,0,0,1).branch(G2, rule="diagonal")
G2(1,0) + G2(2,0) + G2(1,1)
sage: G2xG2(1,0,0,1).branch(G2, rule="diagonal") == G2(1,0)*G2(0,1)
True
```

Writing Your Own (Branching) Rules

Suppose you want to branch from a group $G$ to a subgroup $H$. Arrange the embedding so that a Cartan subalgebra $U$ of $H$ is contained in a Cartan subalgebra $T$ of $G$. There is thus a mapping from the weight spaces $\text{Lie}(T)^* \Rightarrow \text{Lie}(U)^*$. Two embeddings will produce identical branching rules if they differ by an element of the Weyl group of $H$.

The rule is this map $\text{Lie}(T)^*$, which is $G\text{.space}()$, to $\text{Lie}(U)^*$, which is $H\text{.space}()$, which you may implement as a function. As an example, let us consider how to implement the branching rule $A_3 \Rightarrow C_2$. Here $H = C_2 = \text{Sp}(4)$ embedded as a subgroup in $A_3 = \text{GL}(4)$. The Cartan subalgebra $U$ consists of diagonal matrices with eigenvalues $u_1, u_2, -u_2, -u_1$. The $C_2\text{.space}()$ is the two dimensional vector spaces consisting of the linear functionals $u_1$ and $u_2$ on $U$. On the other hand $\text{Lie}(T)$ is $\mathbb{R}^4$. A convenient way to see the restriction is to think of it as the adjoint of the map $(u_1,u_2) \mapsto (u_1,u_2,-u_2,-u_1)$, that is, $(x_0,x_1,x_2,x_3) \mapsto (x_0-x_3,x_1-x_2)$. Hence we may encode the rule as follows:

```python
2060 Chapter 5. Comprehensive Module List
```python
def rule(x):
    return [x[0]-x[3], x[1]-x[2]]
```
or simply:
```
rule = lambda x: [x[0]-x[3], x[1]-x[2]]
```

We may now make and use the branching rule as follows.

**EXAMPLES:**
```
sage: br = BranchingRule("A3", "C2", lambda x: [x[0]-x[3], x[1]-x[2]], "homemade");
˓→ br
homemade branching rule A3 => C2
sage: [A3,C2]=[WeylCharacterRing(x,style="coroots") for x in ["A3","C2"]]
sage: A3(0,1,0).branch(C2,rule=br)
C2(0,0) + C2(0,1)
```

```
sage.combinat.root_system.branching_rules.branching_rule(Rtype, Stype, rule='default')
```
Creates a branching rule.

**INPUT:**
- `R` – the Weyl Character Ring of \( G \)
- `S` – the Weyl Character Ring of \( H \)
- `rule` – a string describing the branching rule as a map from the weight space of \( S \) to the weight space of \( R \).

If the rule parameter is omitted, in some cases, a default rule is supplied. See `branch_weyl_character()`.

**EXAMPLES:**
```
sage: rule = branching_rule(CartanType("A3"),CartanType("C2"),"symmetric")
sage: [rule(x) for x in WeylCharacterRing("A3").fundamental_weights()]
[[1, 0], [1, 1], [1, 0]]
```

```
sage.combinat.root_system.branching_rules.branching_rule_from_plethysm(chi, cartan_type, return_matrix=False)
```
Create the branching rule of a plethysm.

**INPUT:**
- `chi` – the character of an irreducible representation \( \pi \) of a group \( G \)
- `cartan_type` – a classical Cartan type (\( A, B, C \) or \( D \)).

It is assumed that the image of the irreducible representation \( \pi \) naturally has its image in the group \( G \).

Returns a branching rule for this plethysm.

**EXAMPLES:**

The adjoint representation \( SL(3) \to GL(8) \) factors through \( SO(8) \). The branching rule in question will describe how representations of \( SO(8) \) composed with this homomorphism decompose into irreducible characters of \( SL(3) \):

---

**5.1. Comprehensive Module list**
This confirms that $ad$ has degree 8 and is orthogonal, hence factors through $SO(8)$ which is type $D_4$:

```
sage: br = branching_rule_from_plethysm(ad,"D4")
sage: D4 = WeylCharacterRing("D4")
sage: [D4(f).branch(A2,rule = br) for f in D4.fundamental_weights()]
[A2(1,1), A2(0,3) + A2(1,1) + A2(3,0), A2(1,1), A2(1,1)]
```

sage.combinat.root_system.branching_rules.get_branching_rule(Rtype, Stype, rule='default')

Creates a branching rule.

**INPUT:**
- $R$ – the Weyl Character Ring of $G$
- $S$ – the Weyl Character Ring of $H$
- $rule$ – a string describing the branching rule as a map from the weight space of $S$ to the weight space of $R$.

If the rule parameter is omitted, in some cases, a default rule is supplied. See `branch_weyl_character()`.

**EXAMPLES:**

```
sage: rule = branching_rule(CartanType("A3"),CartanType("C2"),"symmetric")
sage: [rule(x) for x in WeylCharacterRing("A3").fundamental_weights()]
[[1, 0], [1, 1], [1, 0]]
```

sage.combinat.root_system.branching_rules.maximal_subgroups(ct, mode='print_rules')

Given a classical Cartan type (of rank less than or equal to 8) this prints the Cartan types of maximal subgroups, with a method of obtaining the branching rule. The string to the right of the colon in the output is a command to create a branching rule.

**INPUT:**
- $ct$ – a classical irreducible Cartan type

Returns a list of maximal subgroups of $ct$.

**EXAMPLES:**

```
sage: from sage.combinat.root_system.branching_rules import maximal_subgroups
sage: maximal_subgroups("D4")
B3:branching_rule("D4","B3","symmetric")
A2:branching_rule("D4","A2(1,1)","plethysm")
A1xClxC2:branching_rule("D4","C1xClxC2","tensor")+branching_rule("ClxC2","A1xC2",[branching_rule("C1","A1","isomorphic"),"identity")]
A1xA1xAlxA1:branching_rule("D4","D2xD2","orthogonal_sum")+branching_rule("D2","A1xA1","isomorphic")\branching_rule("D2","A1xA1","isomorphic")])
```

maximal_subgroups()

## 5.1.226 Cartan matrices

**AUTHORS:**

```python
class sage.combinat.root_system.cartan_matrix.CartanMatrix:
Bases: sage.matrix.matrix_integer_sparse.Matrix_integer_sparse,
sage.combinat.root_system.cartan_type.CartanType_abstract
```

A (generalized) Cartan matrix.

A matrix $A = (a_{ij})_{i,j \in I}$ for some index set $I$ is a generalized Cartan matrix if it satisfies the following properties:

- $a_{ii} = 2$ for all $i$,
- $a_{ij} \leq 0$ for all $i \neq j$,
- $a_{ij} = 0$ if and only if $a_{ji} = 0$ for all $i \neq j$.

Additionally some reference assume that a Cartan matrix is *symmetrizable* (see `is_symmetrizable()`). However following Kac, we do not make that assumption here.

An even, integral Borcherds–Cartan matrix is an integral matrix $A = (a_{ij})_{i,j \in I}$ for some countable index set $I$ which satisfies the following properties:

- $a_{ii} \in \{2\} \cup 2\mathbb{Z}_{<0}$ for all $i$,
- $a_{ij} \leq 0$ for all $i \neq j$,
- $a_{ij} = 0$ if and only if $a_{ji} = 0$ for all $i \neq j$.

**INPUT:**

Can be anything which is accepted by `CartanType` or a matrix.

If given a matrix, one can also use the keyword `cartan_type` when giving a matrix to explicitly state the type. Otherwise this will try to check the input matrix against possible standard types of Cartan matrices. To disable this check, use the keyword `cartan_type_check = False`.

If one wants to initialize a Borcherds-Cartan matrix using matrix data, use the keyword `borcherds=True`. To specify the diagonal entries of corresponding to a Cartan type (a Cartan matrix is treated as matrix data), use `borcherds` with a list of the diagonal entries.

**EXAMPLES:**

```
sage: CartanMatrix(['A', 4])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -1]
[ 0  0 -1  2]
sage: CartanMatrix(['B', 6])
[ 2 -1  0  0  0  0]
```

(continues on next page)
This is different from MuPAD-Combinat, due to different node convention?

```python
sage: CartanMatrix(['G', 2])
[ 2 -3]
[-1 2]
sage: CartanMatrix(['A', 1, 1])
[ 2 -2]
[-2 2]
sage: CartanMatrix(['A', 3, 1])
[ 2 -1 0 -1]
```

(continues on next page)
\begin{verbatim}
[-1  2 -1  0]
[ 0 -1  2 -1]

[-1  0  0  0  0  0  0 -1  2 -1]
sage: CartanMatrix(['F', 4, 1])
[ 2 -1  0  0  0  0]
[-1  2 -1  0  0  0]
[ 0 -1  2 -1  0  0]
[ 0  0 -2  2 -1]
[ 0  0  0 -1  2]
sage: CartanMatrix(['G', 2, 1])
[ 2  0 -1]
[ 0  2 -3]
[-1 -1  2]
\end{verbatim}

5.1. Comprehensive Module list 2065
Examples of Borcherds-Cartan matrices:

```python
sage: CartanMatrix([[2,-1],[-1,-2]], borcherds=True)
[ 2 -1]
[-1 -2]
sage: CartanMatrix('B3', borcherds=[-4,-6,2])
[-4 -1 0]
[-1 -6 -1]
[ 0 -2 2]
```

**Note:** Since this is a matrix, `row()` and `column()` will return the standard row and column respectively. To get the row with the indices as in Dynkin diagrams/Cartan types, use `row_with_indices()` and `column_with_indices()` respectively.

### cartan_matrix()

Return the Cartan matrix of `self`.

**EXAMPLES:**

```python
sage: CartanMatrix(['C',3]).cartan_matrix()
[ 2 -1 0]
[-1 2 -2]
[ 0 -1 2]
```

### cartan_type()

Return the Cartan type of `self` or `self` if unknown.

**EXAMPLES:**

```python
sage: C = CartanMatrix(['A',4,1])
sage: C.cartan_type()
['A', 4, 1]
```

If the Cartan type is unknown:

```python
sage: C = CartanMatrix([[2,-1,-2], [-1,2,-1], [-2,-1,2]])
sage: C.cartan_type()
[ 2 -1 -2]
[-1 2 -1]
[-2 -1 2]
```

### column_with_indices(j)

Return the `j`th column of `self` as a container (or iterator) of tuples `(i, a_{i,j})`.

**EXAMPLES:**

```python
sage: M = CartanMatrix(['B',4])
sage: [ (i,a) for (i,a) in M.column_with_indices(3) ]
[(3, 2), (2, -1), (4, -2)]
```

### dual()

Return the dual Cartan matrix of `self`, which is obtained by taking the transpose.

**EXAMPLES:**

```python
sage: ct = CartanType(['C',3])
sage: M = CartanMatrix(ct); M
```

(continues on next page)
[ 2 -1 0]  
[-1 2 -2]  
[ 0 -1 2]  
sage: M.dual()  
[ 2 -1 0]  
[-1 2 -1]  
[ 0 -2 2]  
sage: M.dual() == CartanMatrix(ct.dual())  
True  
sage: M.dual().cartan_type() == ct.dual()  
True

An example with arbitrary Cartan matrices:

sage: cm = CartanMatrix([[2,-5], [-2, 2]]); cm  
[ 2 -5]  
[-2 2]  
sage: cm.dual()  
[ 2 -2]  
[-5 2]  
sage: cm.dual() == CartanMatrix(cm.transpose())  
True  
sage: cm.dual().dual() == cm  
True

dynkin_diagram()  
Return the Dynkin diagram corresponding to self.

EXAMPLES:

sage: C = CartanMatrix(['A',2])  
sage: C.dynkin_diagram()  
O---O  
1 2  
A2  
sage: C = CartanMatrix(['F',4,1])  
sage: C.dynkin_diagram()  
O---O---O=>=O---O  
0 1 2 3 4  
F4~  
sage: C = CartanMatrix([[2,-4],[-4,2]])  
sage: C.dynkin_diagram()  
Dynkin diagram of rank 2

indecomposable_blocks()  
Return a tuple of all indecomposable blocks of self.

EXAMPLES:

sage: M = CartanMatrix(['A',2])  
sage: M.indecomposable_blocks()  
(  
[ 2 -1]  
[-1 2]  
)  
sage: M = CartanMatrix(['A',2],['A',3,1])  
sage: M.indecomposable_blocks()  
(continues on next page)
Return the index set of self.

EXAMPLES:

```python
sage: C = CartanMatrix(['A',1,1])
sage: C.index_set()
(0, 1)
sage: C = CartanMatrix(['E',6])
sage: C.index_set()
(1, 2, 3, 4, 5, 6)
```

Return True if self is an affine type or False otherwise.

A generalized Cartan matrix is affine if all of its indecomposable blocks are either finite (see is_finite()) or have zero determinant with all proper principal minors positive.

EXAMPLES:

```python
sage: M = CartanMatrix(['C',4])
sage: M.is_affine()
False
sage: M = CartanMatrix(['D',4,1])
sage: M.is_affine()
True
sage: M = CartanMatrix([[2, -4], [-3, 2]])
sage: M.is_affine()
False
```

Implements CartanType_abstract.is_crystallographic().

A Cartan matrix is crystallographic if it is symmetrizable.

EXAMPLES:

```python
sage: CartanMatrix(['F',4]).is_crystallographic()
True
```

Return True if self is a finite type or False otherwise.

A generalized Cartan matrix is finite if the determinant of all its principal submatrices (see principal_submatrices()) is positive. Such matrices have a positive definite symmetrized matrix. Note that a finite matrix may consist of multiple blocks of Cartan matrices each having finite Cartan type.

EXAMPLES:
is_hyperbolic (compact=False)
Return if True if self is a (compact) hyperbolic type or False otherwise.
An indecomposable generalized Cartan matrix is hyperbolic if it has negative determinant and if any proper connected subdiagram of its Dynkin diagram is of finite or affine type. It is compact hyperbolic if any proper connected subdiagram has finite type.

INPUT:
• compact – if True, check if matrix is compact hyperbolic

EXAMPLES:

```python
sage: M = CartanMatrix([[2,-2,0],[-2,2,-1],[0,-1,2]])
sage: M.is_hyperbolic()  
True
sage: M.is_hyperbolic(compact=True) 
False
sage: M = CartanMatrix([[2, -3], [-3, 2]])
true
sage: M.is_hyperbolic()  
True
sage: M.is_hyperbolic()  
False
```

is_indecomposable ()
Return if self is an indecomposable matrix or False otherwise.

EXAMPLES:

```python
sage: M = CartanMatrix(['A',5])
sage: M.is_indecomposable() 
True
sage: M = CartanMatrix([[2,-1,0],[-1,2,0],[0,0,2]])
sage: M.is_indecomposable()  
False
```

is_indefinite ()
Return if self is an indefinite type or False otherwise.

EXAMPLES:

```python
sage: M = CartanMatrix([[2,-3],[-3,2]])
sage: M.is_indefinite()  
True
sage: M = CartanMatrix("A2")
sage: M.is_indefinite()  
False
```
**is_lorentzian()**
Return True if self is a Lorentzian type or False otherwise.

A generalized Cartan matrix is Lorentzian if it has negative determinant and exactly one negative eigenvalue.

**EXAMPLES:**

```python
sage: M = CartanMatrix([[2,-3],[-3,2]])
sage: M.is_lorentzian()
True
sage: M = CartanMatrix([[2,-1],[-1,2]])
sage: M.is_lorentzian()
False
```

**is_simply_laced()**
Implements `CartanType_abstract.is_simply_laced()`.

A Cartan matrix is simply-laced if all non diagonal entries are 0 or -1.

**EXAMPLES:**

```python
sage: cm = CartanMatrix(['A', 3])
sage: cm.is_simply_laced()
True
```

**matrix_space(nrows=None, ncols=None, sparse=None)**
Return a matrix space over the integers.

**INPUT:**
- `nrows` - number of rows
- `ncols` - number of columns
- `sparse` - (boolean) sparseness

**EXAMPLES:**

```python
sage: cm = CartanMatrix(['A', 3])
sage: cm.matrix_space()
Full MatrixSpace of 3 by 3 sparse matrices over Integer Ring
sage: cm.matrix_space(2, 2)
Full MatrixSpace of 2 by 2 sparse matrices over Integer Ring
sage: cm[:2,1:
\[-1 0
[ 2 -1
```

**principal_submatrices(proper=False)**
Return a list of all principal submatrices of self.

**INPUT:**
- `proper` - if True, return only proper submatrices

**EXAMPLES:**

```python
sage: M = CartanMatrix(['A',2])
sage: M.principal_submatrices()
[...
[ 2 -1]
```

(continues on next page)
rank()

Return the rank of self.

EXAMPLES:

```python
sage: CartanMatrix(['C',3]).rank()
3
sage: CartanMatrix(['A2','B2','F4']).rank()
8
```

reflection_group(type='matrix')

Return the reflection group corresponding to self.

EXAMPLES:

```python
sage: C = CartanMatrix(['A',3])
sage: C.reflection_group()
Weyl Group of type ['A', 3] (as a matrix group acting on the root space)
```

relabel(relabelling)

Return the relabelled Cartan matrix.

EXAMPLES:

```python
sage: CM = CartanMatrix(['C',3])
sage: R = CM.relabel({1:0, 2:4, 3:1}); R
[ 2 0 -1]
[ 0 2 -1]
[-1 -2 2]
sage: R.index_set()
(0, 1, 4)
sage: CM
[ 2 -1 0]
[-1 2 -2]
[ 0 -1 2]
```

root_space()

Return the root space corresponding to self.

EXAMPLES:

```python
sage: C = CartanMatrix(['A',3])
sage: C.root_space()
Root space over the Rational Field of the Root system of type ['A', 3]
```

root_system()

Return the root system corresponding to self.

EXAMPLES:

```python
sage: C = CartanMatrix(['A',3])
sage: C.root_system()
Root system of type ['A', 3]
```
row_with_indices(i)
    Return the i^{th} row \((a_{i,j})\) of self as a container (or iterator) of tuples \((j, a_{i,j})\)

EXAMPLES:

```
sage: M = CartanMatrix(['C',4])
sage: [ (i,a) for (i,a) in M.row_with_indices(3) ]
[(3, 2), (2, -1), (4, -2)]
```

subtype(index_set)
    Return a subtype of self given by index_set.

A subtype can be considered the Dynkin diagram induced from the Dynkin diagram of self by index_set.

EXAMPLES:

```
sage: C = CartanMatrix(['F',4])
sage: S = C.subtype([1,2,3])
sage: S
[ [ 2 -1 0 ]
 [ -1 2 -1 ]
 [ 0 -2  2 ]
sage: S.index_set()
(1, 2, 3)
```

symmetrized_matrix()
    Return the symmetrized matrix of self if symmetrizable.

EXAMPLES:

```
sage: cm = CartanMatrix(['B',4,1])
sage: cm.symmetrized_matrix()
[ [ 4  0 -2  0  0 ]
 [ 0  4 -2  0  0 ]
 [ 0  0  2  4 -2 ]
 [ 0  0 -2  4 -2 ]
 [ 0  0  0  4 -2 ]
```

symmetrizer()
    Return the symmetrizer of self.

EXAMPLES:

```
sage: cm = CartanMatrix([[2,-5],[-2,2]])
sage: cm.symmetrizer()
Finite family {0: 2, 1: 5}
```

doctest::

    sage.combinat.root_system.cartan_matrix.find_cartan_type_from_matrix(CM)
    Find a Cartan type by direct comparison of Dynkin diagrams given from the generalized Cartan matrix CM and return None if not found.

INPUT:

- CM - a generalized Cartan matrix

EXAMPLES:
```python
sage: from sage.combinat.root_system.cartan_matrix import find_cartan_type_from_matrix
sage: CM = CartanMatrix([[2,-1,-1], [-1,2,-1], [-1,-1,2]])
```

```
from sage.combinat.root_system.cartan_matrix import is_borcherds_cartan_matrix
```

Return True if $M$ is an even, integral Borcherds-Cartan matrix. For a definition of such a matrix, see `CartanMatrix`.

**EXAMPLES:**

```python
sage: from sage.combinat.root_system.cartan_matrix import is_borcherds_cartan_matrix
sage: M = Matrix([[2,-1],[2,-1]])
```

```python
sage: is_borcherds_cartan_matrix(M)
True
```

```python
sage: N = Matrix([[2,-1],[0,-1]])
```

```python
sage: is_borcherds_cartan_matrix(N)
False
```

```python
sage: O = Matrix([[2,-1],[2,-2]])
```

```python
sage: is_borcherds_cartan_matrix(O)
True
```

```python
sage: O = Matrix([[2,-1],[2,-3]])
```

```python
sage: is_borcherds_cartan_matrix(O)
False
```

```python
sage: from sage.combinat.root_system.cartan_matrix import is_generalized_cartan_matrix
```

Return True if $M$ is a generalized Cartan matrix. For a definition of a generalized Cartan matrix, see `CartanMatrix`.

**EXAMPLES:**

```python
sage: from sage.combinat.root_system.cartan_matrix import is_generalized_cartan_matrix
sage: M = matrix([[2,-1,-2], [-1,2,-1], [-2,-1,2]])
```

```python
sage: is_generalized_cartan_matrix(M)
True
```

```python
sage: M = matrix([[2,-1,-2], [-1,2,-1], [0,-1,2]])
```

```python
sage: is_generalized_cartan_matrix(M)
False
```

```python
sage: M = matrix([[2,-1,-2], [-1,2,-1], [-1,-1,2]])
```

```python
sage: is_generalized_cartan_matrix(M)
True
```

A non-symmetrizable example:

```python
sage: M = matrix([[2,-1,-2], [-1,2,-1], [-1,-1,2]])
```

```python
sage: is_generalized_cartan_matrix(M)
True
```
5.1.227 Cartan types

Todo: Why does sphinx complain if I use sections here?

Introduction

Loosely speaking, Dynkin diagrams (or equivalently Cartan matrices) are graphs which are used to classify root systems, Coxeter and Weyl groups, Lie algebras, Lie groups, crystals, etc. up to an isomorphism. Cartan types are a standard set of names for those Dynkin diagrams (see Wikipedia article Dynkin_diagram).

Let us consider, for example, the Cartan type $A_4$:

```
sage: T = CartanType(['A', 4])
sage: T
['A', 4]
```

It is the name of the following Dynkin diagram:

```
sage: DynkinDiagram(T)
O---O---O---O
1 2 3 4
A4
```

Note: For convenience, the following shortcuts are available:

```
sage: DynkinDiagram(['A',4])
O---O---O---O
1 2 3 4
A4
sage: DynkinDiagram('A4')
O---O---O---O
1 2 3 4
A4
sage: T.dynkin_diagram()
O---O---O---O
1 2 3 4
A4
```

See `DynkinDiagram` for how to further manipulate Dynkin diagrams.

From this data (the Cartan datum), one can construct the associated root system:

```
sage: RootSystem(T)
Root system of type ['A', 4]
```

The associated Weyl group of $A_n$ is the symmetric group $S_{n+1}$:

```
sage: W = WeylGroup(T)
sage: W
Weyl Group of type ['A', 4] (as a matrix group acting on the ambient space)
sage: W.cardinality()
120
```

while the Lie algebra is $sl_{n+1}$, and the Lie group $SL_{n+1}$ (TODO: illustrate this once this is implemented).

One may also construct crystals associated to various Dynkin diagrams. For example:
\texttt{sage: C = crystals.Letters(T)}
\texttt{sage: C}
The crystal of letters for type \['A', 4\]
\texttt{sage: C.list()}
\[1, 2, 3, 4, 5\]
\texttt{sage: C = crystals.Tableaux(T, shape=[2])}
\texttt{sage: C}
The crystal of tableaux of type \(['A', 4]\) and shape(s) \([2]\)
\texttt{sage: C.cardinality()}
15

Here is a sample of all the finite irreducible crystallographic Cartan types:

\texttt{sage: CartanType.samples(finite = True, crystallographic = True)}
\[[\text{'A}, 1\]’, \text{'A}, 5\]’, \text{'B}, 1\]’, \text{'B}, 5\]’, \text{'C}, 1\]’, \text{'C}, 5\]’, \text{'D}, 2\]’, \text{'D}, 3\]’, \text{'D}, 5\]’,
\text{'E}, 6\]’, \text{'E}, 7\]’, \text{'E}, 8\]’, \text{'F}, 4\]’, \text{'G}, 2\]’

One can also get latex representations of the crystallographic Cartan types and their corresponding Dynkin diagrams:

\texttt{sage: [latex(ct) \text{ for } ct \text{ in } CartanType.samples(crystallographic=True)]}
\[[A_{1}, A_{5}, B_{1}, B_{5}, C_{1}, C_{5}, D_{2}, D_{3}, D_{5},
E_{6}, E_{7}, E_{8}, F_{4}, G_{2},
A_{1}^{(1)}, A_{5}^{(1)}, B_{1}^{(1)}, B_{5}^{(1)}, C_{1}^{(1)}, C_{5}^{(1)}, D_{3}^{(1)}, D_{5}^{(1)},
E_{6}^{(1)}, E_{7}^{(1)}, E_{8}^{(1)}, F_{4}^{(1)}, G_{2}^{(1)},
B_{5}^{(1)}, C_{4}^{(1)}, F_{4}^{(1)}, G_{2}^{(1)}, BC_{1}^{(2)}, BC_{5}^{(2)},
E_{6}^{(1)}, E_{7}^{(1)}, E_{8}^{(1)}, BC_{1}^{(2)}, BC_{5}^{(2)}\]
\texttt{sage: view([DynkinDiagram(ct) \text{ for } ct \text{ in } CartanType.samples(crystallographic=True)])}
\# not tested

Non-crystallographic Cartan types are also partially supported:

\texttt{sage: CartanType.samples(finite = True, crystallographic = False)}
\[[\text{'I}, 5\]’, \text{'H}, 3\]’, \text{'H}, 4\]’

In Sage, a Cartan type is used as a database of type-specific information and algorithms (see e.g. \texttt{sage.combinat. root_system.type_A}). This database includes how to construct the Dynkin diagram, the ambient space for the root system (see Wikipedia article \texttt{Root_system}), and further mathematical properties:

\texttt{sage: T.is_finite(), T.is_simply_laced(), T.is_affine(), T.is_crystallographic()}
(True, True, False, True)

In particular, a Sage Cartan type is endowed with a fixed choice of labels for the nodes of the Dynkin diagram. This choice follows the conventions of Nicolas Bourbaki, Lie Groups and Lie Algebras: Chapter 4-6, Elements of Mathematics, Springer (2002). ISBN 978-3540426509. For example:

\texttt{sage: T = CartanType(['D', 4])}
\texttt{sage: DynkinDiagram(T)}
\begin{verbatim}
  O 4
  |   |---0---0
  1 2 3
D4
\end{verbatim}
Note: The direction of the arrows is the opposite (i.e. the transpose) of Bourbaki’s convention, but agrees with Kac’s.

For example, in type $C_2$, we have:

```
sage: C2 = DynkinDiagram(['C',2]); C2
O=<<=O
1 2
C2
sage: C2.cartan_matrix()
[ 2 -2]
[-1  2]
```

However Bourbaki would have the Cartan matrix as:

\[
\begin{pmatrix}
2 & -1 \\
-2 & 2
\end{pmatrix}
\]

If desired, other node labelling conventions can be achieved. For example the Kac labelling for type $E_6$ can be obtained via:

```
sage: E6.relabel({1:1, 2:6, 3:2, 4:3, 5:4, 6:5}).dynkin_diagram()
O 6
|   
| 1 2 3 4 5
E6 relabelled by {1: 1, 2: 6, 3: 2, 4: 3, 5: 4, 6: 5}
```

Contributions implementing other conventions are very welcome.

Another option is to build from scratch a new Dynkin diagram. The architecture has been designed to make it fairly easy to add other labelling conventions. In particular, we strived at choosing type free algorithms whenever possible, so in principle most features should remain available even with custom Cartan types. This has not been used much yet, so some rough corners certainly remain.

Here, we construct the hyperbolic example of Exercise 4.9 p. 57 of Kac, Infinite Dimensional Lie Algebras. We start with an empty Dynkin diagram, and add a couple nodes:

```
sage: g = DynkinDiagram()  
sage: g.add_vertices([1,2,3])
```

Note that the diagonal of the Cartan matrix is already initialized:

```
sage: g.cartan_matrix()
[2  0  0]
```

(continues on next page)
Then we add a couple edges:

```python
sage: g.add_edge(1,2,2)
sage: g.add_edge(1,3)
sage: g.add_edge(2,3)
```

and we get the desired Cartan matrix:

```python
sage: g.cartan_matrix()
[2 0 0]
[0 2 0]
[0 0 2]
```

Oops, the Cartan matrix did not change! This is because it is cached for efficiency (see `cached_method`). In general, a Dynkin diagram should not be modified after having been used.

**Warning:** this is not checked currently

**Todo:** add a method `set_mutable()` as, say, for matrices

Here, we can work around this by clearing the cache:

```python
sage: delattr(g, 'cartan_matrix')
```

Now we get the desired Cartan matrix:

```python
sage: g.cartan_matrix()
[ 2 -1 -1]
[-2 2 -1]
[-1 -1 2]
```

Note that backward edges have been automatically added:

```python
sage: g.edges()
[(1, 2, 2), (1, 3, 1), (2, 1, 1), (2, 3, 1), (3, 1, 1), (3, 2, 1)]
```

### Reducible Cartan types

Reducible Cartan types can be specified by passing a sequence or list of irreducible Cartan types:

```python
sage: CartanType(['A',2],['B',2])
A2xB2
sage: CartanType([['A',2],['B',2]])
A2xB2
sage: CartanType(['A',2],['B',2]).is_reducible()
True
```

or using the following short hand notation:
Degenerate cases

When possible, type $I_n$ is automatically converted to the isomorphic crystallographic Cartan types (any reason not to do so?):

```
sage: CartanType(['I',1])
['A', 1]
sage: CartanType(['I',3])
['A', 2]
sage: CartanType(['I',4])
['C', 2]
sage: CartanType(['I',6])
['G', 2]
```

The Dynkin diagrams for types $B_1$, $C_1$, $D_2$, and $D_3$ are isomorphic to that for $A_1$, $A_1$, $A_1 \times A_1$, and $A_3$, respectively. However their natural ambient space realizations (stemming from the corresponding infinite families of Lie groups) are different. Therefore, the Cartan types are considered as distinct:

```
sage: CartanType(['B',1])
['B', 1]
sage: CartanType(['C',1])
['C', 1]
sage: CartanType(['D',2])
['D', 2]
sage: CartanType(['D',3])
['D', 3]
```

Affine Cartan types

For affine types, we use the usual conventions for affine Coxeter groups: each affine type is either untwisted (that is arise from the natural affinisation of a finite Cartan type):

```
sage: CartanType(['A', 4, 1]).dynkin_diagram()
  0
O-------+-------
 |       |       
 |       |       
O---O---O---O
 1 2 3 4
A4~
sage: CartanType(['B', 4, 1]).dynkin_diagram()
  0
O 0
 |       
 |       
O----O----O
 1 2 3 4
B4~
```

or dual thereof:
or is of type $\widetilde{BC}_n$ (which yields an irreducible, but nonreduced root system):

```
sage: CartanType(['BC', 4, 2]).dynkin_diagram()  
O=<=O---O---O=<=O  
0 1 2 3 4  
BC4~
```

This includes the two degenerate cases:

```
sage: CartanType(['A', 1, 1]).dynkin_diagram()  
O<=>O  
0 1  
A1~  

sage: CartanType(['BC', 1, 2]).dynkin_diagram()  
4  
O=<=O  
0 1  
BC1~
```

For the user convenience, Kac’s notations for twisted affine types are automatically translated into the previous ones:

```
sage: CartanType(['A', 9, 2])  
['B', 5, 1]^*  
sage: CartanType(['A', 9, 2]).dynkin_diagram()  
O 0  
|  
|  
O---O---O---O=<=O  
1 2 3 4 5  
B5~

sage: CartanType(['A', 10, 2]).dynkin_diagram()  
O=<=O---O---O---O=<=O  
0 1 2 3 4 5  
BC5~  
sage: CartanType(['D', 5, 2]).dynkin_diagram()  
O=<=O---O---O=>=O  
0 1 2 3 4  
C4~*  
sage: CartanType(['D', 4, 3]).dynkin_diagram()  
3  
0=>=0---0  
2 1 0  
G2~* relabelled by {0: 0, 1: 2, 2: 1}  
sage: CartanType(['E', 6, 2]).dynkin_diagram()  
O---O---O=<=O---O---O  
0 1 2 3 4  
F4~*
```

Additionally one can set the notation option to use Kac’s notation:
Infinite Cartan types

There are minimal implementations of the Cartan types $A_{\infty}$ and $A_{+\infty}$. In sage oo is the same as $+Infinity$, so NN and ZZ are used to differentiate between the $A_{+\infty}$ and $A_{\infty}$ root systems:
Abstract classes for Cartan types

- CartanType_abstract
- CartanType_crystallographic
- CartanType_simply_laced
- CartanType_simple
- CartanType_finite
- CartanType_affine (see also Root system data for affine Cartan types)
- sage.combinat.root_system.cartan_type.CartanType
- Root system data for dual Cartan types
- Root system data for reducible Cartan types
- Root system data for relabelled Cartan types

Concrete classes for Cartan types

- CartanType_standard
- CartanType_standard_finite
- CartanType_standard_affine
- CartanType_standard_untwisted_affine

Type specific data

The data essentially consists of a description of the Dynkin/Coxeter diagram and, when relevant, of the natural embedding of the root system in an Euclidean space. Everything else is reconstructed from this data.

- Root system data for type A
- Root system data for type B
- Root system data for type C
- Root system data for type D
- Root system data for type E
- Root system data for type F
- Root system data for type G
- Root system data for type H
- Root system data for type I
- Root system data for super type A
- Root system data for type Q
- Root system data for (untwisted) type A affine
- Root system data for (untwisted) type B affine
- Root system data for (untwisted) type C affine
- Root system data for (untwisted) type D affine
- Root system data for (untwisted) type E affine
- Root system data for (untwisted) type F affine
Todo: Should those indexes come before the introduction?

Introduction

Loosely speaking, Dynkin diagrams (or equivalently Cartan matrices) are graphs which are used to classify root systems, Coxeter and Weyl groups, Lie algebras, Lie groups, crystals, etc. up to an isomorphism. Cartan types are a standard set of names for those Dynkin diagrams (see Wikipedia article Dynkin_diagram).

Let us consider, for example, the Cartan type $A_4$:

```python
sage: T = CartanType(['A', 4])
sage: T
['A', 4]
```

It is the name of the following Dynkin diagram:

```python
sage: DynkinDiagram(T)
O---O---O---O
  1  2  3  4
A4
```

Note: For convenience, the following shortcuts are available:

```python
sage: DynkinDiagram(['A',4])
O---O---O---O
  1  2  3  4
A4
sage: DynkinDiagram('A4')
O---O---O---O
  1  2  3  4
A4
sage: T.dynkin_diagram()
O---O---O---O
  1  2  3  4
A4
```

See `DynkinDiagram` for how to further manipulate Dynkin diagrams.

From this data (the Cartan datum), one can construct the associated root system:

```python
sage: RootSystem(T)
Root system of type ['A', 4]
```

The associated Weyl group of $A_n$ is the symmetric group $S_{n+1}$:
sage: W = WeylGroup(T)
sage: W
Weyl Group of type ['A', 4] (as a matrix group acting on the ambient space)
sage: W.cardinality()
120

while the Lie algebra is $sl_{n+1}$, and the Lie group $SL_{n+1}$ (TODO: illustrate this once this is implemented).

One may also construct crystals associated to various Dynkin diagrams. For example:

sage: C = crystals.Letters(T)
sage: C
The crystal of letters for type ['A', 4]
sage: C.list()
[1, 2, 3, 4, 5]
sage: C = crystals.Tableaux(T, shape=[2])
sage: C
The crystal of tableaux of type ['A', 4] and shape(s) [2]
sage: C.cardinality()
15

Here is a sample of all the finite irreducible crystallographic Cartan types:

sage: CartanType.samples(finite = True, crystallographic = True)
[['A', 1], ['A', 5], ['B', 1], ['B', 5], ['C', 1], ['C', 5], ['D', 2], ['D', 3], ['D', 5],
 ['E', 6], ['E', 7], ['E', 8], ['F', 4], ['G', 2],
['A^{(1)}', 1], ['A^{(1)}', 5], ['B^{(1)}', 1], ['B^{(1)}', 5], ['C^{(1)}', 1], ['C^{(1)}', 5],
['D^{(1)}', 2], ['D^{(1)}', 3], ['D^{(1)}', 5],
['E^{(1)}', 6], ['E^{(1)}', 7], ['E^{(1)}', 8], ['F^{(1)}', 4], ['G^{(1)}', 2],
['BC^{(2)}', 1], ['BC^{(2)}', 5],

One can also get latex representations of the crystallographic Cartan types and their corresponding Dynkin diagrams:

sage: [latex(ct) for ct in CartanType.samples(crystallographic=True)]
['A_{1}', 'A_{5}', 'B_{1}', 'B_{5}', 'C_{1}', 'C_{5}', 'D_{2}', 'D_{3}', 'D_{5}',
 'E_6', 'E_7', 'E_8', 'F_4', 'G_2',
'A_{1}^{(1)}', 'A_{5}^{(1)}', 'B_{1}^{(1)}', 'B_{5}^{(1)}', 'C_{1}^{(1)}', 'C_{5}^{(1)}',
'D_{2}^{(1)}', 'D_{3}^{(1)}', 'D_{5}^{(1)}',
'E_6^{(1)}', 'E_7^{(1)}', 'E_8^{(1)}', 'F_4^{(1)}', 'G_2^{(1)}',
'BC_{1}^{(2)}', 'BC_{5}^{(2)}',

Non-crystallographic Cartan types are also partially supported:

sage: CartanType.samples(finite = True, crystallographic = False)
[['I', 5], ['H', 3], ['H', 4]]

In Sage, a Cartan type is used as a database of type-specific information and algorithms (see e.g. sage.combinat.root_system.type_A). This database includes how to construct the Dynkin diagram, the ambient space for the root system (see Wikipedia article Root_system), and further mathematical properties:

sage: T.is_finite(), T.is_simply_laced(), T.is_affine(), T.is_crystallographic()
(True, True, False, True)

In particular, a Sage Cartan type is endowed with a fixed choice of labels for the nodes of the Dynkin diagram. This choice follows the conventions of Nicolas Bourbaki, Lie Groups and Lie Algebras: Chapter 4-6, Elements 5.1. Comprehensive Module list 2083

```python
sage: T = CartanType(['D', 4])
sage: DynkinDiagram(T)
O 4 |
    |
O---O---O
1 2 3
D4

sage: E6 = CartanType(['E',6])
sage: DynkinDiagram(E6)
O 2 |
    |
O---O---O---O---O
1 3 4 5 6
E6
```

**Note:** The direction of the arrows is the **opposite** (i.e. the transpose) of Bourbaki’s convention, but agrees with Kac’s.

For example, in type $C_2$, we have:

```python
sage: C2 = DynkinDiagram(['C',2]); C2
O=<<=O
1 2
C2

sage: C2.cartan_matrix()
[ 2 -2]
[-1 2]
```

However Bourbaki would have the Cartan matrix as:

\[
\begin{pmatrix}
2 & -1 \\
-2 & 2
\end{pmatrix}
\]

If desired, other node labelling conventions can be achieved. For example the Kac labelling for type $E_6$ can be obtained via:

```python
sage: E6.relabel({1:1, 2:6, 3:2, 4:3, 5:4, 6:5}).dynkin_diagram()
O 6 |
    |
O---O---O---O---O
1 2 3 4 5
E6 relabelled by \{1: 1, 2: 6, 3: 2, 4: 3, 5: 4, 6: 5\}
```

Contributions implementing other conventions are very welcome.

Another option is to build from scratch a new Dynkin diagram. The architecture has been designed to make it fairly easy to add other labelling conventions. In particular, we strived at choosing type free algorithms whenever possible, so in principle most features should remain available even with custom Cartan types. This has not been used much yet, so some rough corners certainly remain.

Here, we construct the hyperbolic example of Exercise 4.9 p. 57 of Kac, Infinite Dimensional Lie Algebras. We start with an empty Dynkin diagram, and add a couple nodes:
sage: g = DynkinDiagram()
sage: g.add_vertices([1,2,3])

Note that the diagonal of the Cartan matrix is already initialized:

sage: g.cartan_matrix()
[2 0 0]
[0 2 0]
[0 0 2]

Then we add a couple edges:

sage: g.add_edge(1,2,2)
sage: g.add_edge(1,3)
sage: g.add_edge(2,3)

and we get the desired Cartan matrix:

sage: g.cartan_matrix()
[2 0 0]
[0 2 0]
[0 0 2]

Oops, the Cartan matrix did not change! This is because it is cached for efficiency (see \texttt{cached\_method}). In general, a Dynkin diagram should not be modified after having been used.

\textbf{Warning:} this is not checked currently

\textbf{Todo:} add a method \texttt{set\_mutable()} as, say, for matrices

Here, we can work around this by clearing the cache:

sage: delattr(g, 'cartan_matrix')

Now we get the desired Cartan matrix:

sage: g.cartan_matrix()
[2 -1 -1]
[-2 2 -1]
[-1 -1 2]

Note that backward edges have been automatically added:

sage: g.edges()
[(1, 2, 2), (1, 3, 1), (2, 1, 1), (2, 3, 1), (3, 1, 1), (3, 2, 1)]
Reducible Cartan types

Reducible Cartan types can be specified by passing a sequence or list of irreducible Cartan types:

```
sage: CartanType(['A',2],['B',2])
A2xB2
sage: CartanType([['A',2],['B',2]])
A2xB2
sage: CartanType(['A',2],['B',2]).is_reducible()
True
```
or using the following short hand notation:

```
sage: CartanType("A2xB2")
A2xB2
sage: CartanType("A2","B2") == CartanType("A2xB2")
True
```

Degenerate cases

When possible, type $I_n$ is automatically converted to the isomorphic crystallographic Cartan types (any reason not to do so?):

```
sage: CartanType("I",1)
A1xA1
sage: CartanType("I",3)
['A', 2]
['C', 2]
sage: CartanType("I",6)
['G', 2]
```

The Dynkin diagrams for types $B_1$, $C_1$, $D_2$, and $D_3$ are isomorphic to that for $A_1$, $A_1$, $A_1 \times A_1$, and $A_3$, respectively. However their natural ambient space realizations (stemming from the corresponding infinite families of Lie groups) are different. Therefore, the Cartan types are considered as distinct:

```
sage: CartanType(['B',1])
['B', 1]
sage: CartanType(['C',1])
['C', 1]
sage: CartanType(['D',2])
['D', 2]
sage: CartanType(['D',3])
['D', 3]
```
Affine Cartan types

For affine types, we use the usual conventions for affine Coxeter groups: each affine type is either untwisted (that is arise from the natural affinisation of a finite Cartan type):

```
sage: CartanType(["A", 4, 1]).dynkin_diagram()
0
O-----------+
| |
| |
O---O---O---O
1 2 3 4
A4~
sage: CartanType(["B", 4, 1]).dynkin_diagram()
O 0
| |
O---O---O=>=O
1 2 3 4
B4~
```
or dual thereof:

```
sage: CartanType(["B", 4, 1]).dual().dynkin_diagram()
O 0
| |
O---O---O<==O
1 2 3 4
B4~*
```
or is of type \(\widetilde{BC}_n\) (which yields an irreducible, but nonreduced root system):

```
sage: CartanType(["BC", 4, 2]).dynkin_diagram()
O=<=O---O---O=<=O
0 1 2 3 4
BC4~
```

This includes the two degenerate cases:

```
sage: CartanType(["A", 1, 1]).dynkin_diagram()
O<=>O
0 1
A1~
sage: CartanType(["BC", 1, 2]).dynkin_diagram()
4
O<=>O
0 1
BC1~
```

For the user convenience, Kac’s notations for twisted affine types are automatically translated into the previous ones:

```
sage: CartanType(["A", 9, 2])
["B", 5, 1]^*
sage: CartanType(["A", 9, 2]).dynkin_diagram()
```

(continues on next page)
Additionally one can set the notation option to use Kac’s notation:

```
sage: CartanType.options['notation'] = 'Kac'
sage: CartanType(['A', 9, 2])
['A', 9, 2]
sage: CartanType(['A', 9, 2]).dynkin_diagram()
O---O---O---O=<=O
 1 2 3 4 5
A9^2
sage: CartanType(['A', 10, 2]).dynkin_diagram()
O=<=O---O---O---O=<=O
 0 1 2 3 4 5
A10^2
sage: CartanType(['D', 5, 2]).dynkin_diagram()
O=<=O---O---O=>=O
 0 1 2 3 4
D5^2
sage: CartanType(['D', 4, 3]).dynkin_diagram()
3
O=>=O---O
 2 1 0
D4^3
sage: CartanType(['E', 6, 2]).dynkin_diagram()
O---O---O=<=O---O
 0 1 2 3 4
E6^2
sage: CartanType.options['notation'] = 'BC'
```
Infinite Cartan types

There are minimal implementations of the Cartan types $A_\infty$ and $A_{\infty}$. In Sage, $oo$ is the same as $+\text{Infinity}$, so $NN$ and $ZZ$ are used to differentiate between the $A_{\infty}$ and $A_\infty$ root systems:

```python
sage: CartanType(['A', NN])
['A', NN]
sage: print(CartanType(['A', NN]).ascii_art())
O---O---O---O---O---O---O---..<br>0 1 2 3 4 5 6
sage: CartanType(['A', ZZ])
['A', ZZ]
sage: print(CartanType(['A', ZZ]).ascii_art())
..---O---O---O---O---O---O---O---..<br>-3 -2 -1 0 1 2 3
```

There are also the following shorthands:

```python
sage: CartanType("Aoo")
['A', ZZ]
sage: CartanType("A+oo")
['A', NN]
```

Abstract classes for Cartan types

- `CartanType_abstract`
- `CartanType_crystallographic`
- `CartanType_simply_laced`
- `CartanType_simple`
- `CartanType_finite`
- `CartanType_affine` (see also Root system data for affine Cartan types)

Concrete classes for Cartan types

- `CartanType_standard`
- `CartanType_standard_finite`
- `CartanType_standard_affine`
- `CartanType_standard_untwisted_affine`

Type specific data

The data essentially consists of a description of the Dynkin/Coxeter diagram and, when relevant, of the natural embedding of the root system in an Euclidean space. Everything else is reconstructed from this data.

- Root system data for type A
- Root system data for type B
• Root system data for type C
• Root system data for type D
• Root system data for type E
• Root system data for type F
• Root system data for type G
• Root system data for type H
• Root system data for type I
• Root system data for super type A
• Root system data for type Q
• Root system data for (untwisted) type A affine
• Root system data for (untwisted) type B affine
• Root system data for (untwisted) type C affine
• Root system data for (untwisted) type D affine
• Root system data for (untwisted) type E affine
• Root system data for (untwisted) type F affine
• Root system data for (untwisted) type G affine
• Root system data for type BC affine
• Root system data for type A infinity

Todo: Should those indexes come before the introduction?

```python
class sage.combinat.root_system.cartan_type.CartanTypeFactory
    Bases: sage.structure.sage_object.SageObject

classmethod color(i)
    Default color scheme for the vertices of a Dynkin diagram (and associated objects)

    EXAMPLES:

    sage: CartanType.color(1)
    'blue'
    sage: CartanType.color(2)
    'red'
    sage: CartanType.color(3)
    'green'

    The default color is black:

    sage: CartanType.color(0)
    'black'

    Negative indices get the same color as their positive counterparts:

    sage: CartanType.color(-1)
    'blue'
    sage: CartanType.color(-2)
```

(continues on next page)
options(**get_value, **set_value)
Sets and displays the options for Cartan types. If no parameters are set, then the function returns a copy of the options dictionary.

The options to partitions can be accessed as the method CartanType.options of CartanType.

OPTIONS:

• dual_latex – (default: \vee) The latex used for dual CartanTypes when latexing
• dual_str – (default: *) The string used for dual Cartan types when printing
• latex_marked – (default: True) Indicate in the latex output if a Cartan type has been marked
• latex_relabel – (default: True) Indicate in the latex output if a Cartan type has been relabelled
• mark_special_node – (default: none) Make the special nodes
  – both – both in latex and printing
  – latex – only in latex
  – none – no markup
  – printing – only in printing
• marked_node_str – (default: X) The string used to indicate a marked node when printing
• notation – (default: Stembridge) Specifies which notation Cartan types should use when printed
  – BC – alias for Stembridge
  – Kac – use Kac’s notation
  – Stembridge – use Stembridge’s notation
  – tilde – alias for Stembridge
  – twisted – alias for Kac
• special_node_str – (default: @) The string used to indicate which node is special when printing

EXAMPLES:

sage: ct = CartanType(['D', 5, 2]); ct
['C', 4, 1]^*
sage: ct.dynkin_diagram()
O<=O---O---O=>=O
0 1 2 3 4
C4~*

sage: latex(ct)
C_{4}^{(1)\vee}
sage: CartanType.options(dual_str='#', dual_latex='\ast',)
sage: ct
['C', 4, 1]^#
sage: ct.dynkin_diagram()
O<=O---O---O=>=O
0 1 2 3 4
C4~#
sage: latex(ct)
\text{C}_{4}^{(1)\ast}
sage: CartanType.options(notation='kac', mark_special_node='both')
sage: ct
['D', 5, 2]
sage: ct.dynkin_diagram()
@=<=O---O---O=>=O
0 1 2 3 4
D_{5\ast}^2
sage: latex(ct)
D_{5}^{(2)}

For type $A_{2n}^{(2)}$, the dual string/latex options are automatically overriden:

sage: dct = CartanType(['A',8,2]).dual(); dct
['A', 8, 2]^+
sage: latex(dct)
A_{8}^{(2)\dagger}
sage: dct.dynkin_diagram()
@=>=O---O---O=>=O
0 1 2 3 4
A_{8}^{2+}
sage: CartanType.options._reset()

See `GlobalOptions` for more features of these options.

**samples** (finite=None, affine=None, crystallographic=None)

Return a sample of the available Cartan types.

**INPUT:**

- finite - a boolean or None (default: None)
- affine - a boolean or None (default: None)
- crystallographic - a boolean or None (default: None)

The sample contains all the exceptional finite and affine Cartan types, as well as typical representatives of the infinite families.

**EXAMPLES:**

sage: CartanType.samples()
[[['A', 1], ['A', 5], ['B', 1], ['B', 5], ['C', 1], ['C', 5], ['D', 2], ['D', 3], ['D', 5], ['E', 6], ['E', 7], ['E', 8], ['F', 4], ['G', 2], ['I', 5], ['H', 3], ['H', 4], ['A', 1, 1], ['A', 5, 1], ['B', 1, 1], ['B', 5, 1], ['C', 1, 1], ['C', 5, 1], ['D', 3, 1], ['D', 5, 1], ['E', 6, 1], ['E', 7, 1], ['E', 8, 1], ['F', 4, 1], ['G', 2, 1], ['BC', 1, 1], ['BC', 2, 1], ['BC', 3, 1], ['BC', 5, 2], ['BC', 5, 1]^*, ['C', 4, 1]^*, ['F', 4, 1]^*, ['G', 2, 1]^*, ['BC', 1, 2]^*, ['BC', 5, 2]^*]

The finite, affine and crystallographic options allow respectively for restricting to (non) finite, (non) affine, and (non) crystallographic Cartan types:

sage: CartanType.samples(finite=True)
[[['A', 1], ['A', 5], ['B', 1], ['B', 5], ['C', 1], ['C', 5], ['D', 2], ['D', 3], ['D', 5], ['E', 6], ['E', 7], ['E', 8], ['F', 4], ['G', 2, 1]^*, ['BC', 1, 2]^*, ['BC', 5, 2]^*]

(continues on next page)
Todo: add some reducible Cartan types (suggestions?)

class sage.combinat.root_system.cartan_type.CartanType_abstract
Bases: object

Abstract class for Cartan types

Subclasses should implement:

• dynkin_diagram()
• cartan_matrix()
• is_finite()
• is_affine()
• is_irreducible()

as_folding(folding_of=None, sigma=None)
Return self realized as a folded Cartan type.

For finite and affine types, this is realized by the Dynkin diagram foldings:

\[
\begin{align*}
C_n^{(1)}, A_n^{(2)}, A_{2n-1}^{(1)}, D_{2n}^{(2)} & \rightarrow A_{2n-1}^{(1)}, \\
A_{2n}^{(2)}, B_1^{(1)}, E_6^{(1)} & \rightarrow D_{n+1}^{(1)}, \\
D_4^{(3)}, G_2^{(1)} & \rightarrow D_4^{(1)}, \\
C_n & \rightarrow A_{2n-1}, \\
B_n & \rightarrow D_{n+1}, \\
F_4 & \rightarrow E_6, \\
G_2 & \rightarrow D_4.
\end{align*}
\]
For general types, this returns `self` as a folded type of `self` with \( \sigma \) as the identity map.

For more information on these foldings and folded Cartan types, see `sage.combinat.root_system.type_folded.CartanTypeFolded`.

If the optional inputs `folding_of` and `sigma` are specified, then this returns the folded Cartan type of `self` in `folding_of` given by the automorphism `sigma`.

**EXAMPLES:**

```python
sage: CartanType(['B', 3, 1]).as_folding()
['B', 3, 1] as a folding of ['D', 4, 1]
sage: CartanType(['F', 4]).as_folding()
['F', 4] as a folding of ['E', 6]
sage: CartanType(['BC', 3, 2]).as_folding()
['BC', 3, 2] as a folding of ['A', 5, 1]
sage: CartanType(['D', 4, 3]).as_folding()
['G', 2, 1]^* relabelled by {0: 0, 1: 2, 2: 1} as a folding of ['D', 4, 1]
```

### coxeter_diagram()

Return the Coxeter diagram for `self`.

**EXAMPLES:**

```python
sage: CartanType(['B', 3]).coxeter_diagram()
Graph on 3 vertices
sage: CartanType(['A', 3]).coxeter_diagram().edges()
[(1, 2, 3), (2, 3, 3)]
sage: CartanType(['B', 3]).coxeter_diagram().edges()
[(1, 2, 3), (2, 3, 4)]
sage: CartanType(['G', 2]).coxeter_diagram().edges()
[(1, 2, 6)]
sage: CartanType(['F', 4]).coxeter_diagram().edges()
[(1, 2, 3), (2, 3, 4), (3, 4, 3)]
```

### coxeter_matrix()

Return the Coxeter matrix for `self`.

**EXAMPLES:**

```python
sage: CartanType(['A', 4]).coxeter_matrix()
[1 3 2 2]
[3 1 3 2]
[2 3 1 3]
[2 2 3 1]
```

### coxeter_type()

Return the Coxeter type for `self`.

**EXAMPLES:**

```python
sage: CartanType(['A', 4]).coxeter_type()
Coxeter type of ['A', 4]
```

### dual()

Return the dual Cartan type, possibly just as a formal dual.

**EXAMPLES:**
index_set()

Return the index set for self.

This is the list of the nodes of the associated Coxeter or Dynkin diagram.

EXAMPLES:

```python
sage: CartanType(['A', 3]).index_set()
(0, 1, 2, 3)
sage: CartanType(['D', 4]).index_set()
(1, 2, 3, 4)
sage: CartanType(['A', 7, 2]).index_set()
(0, 1, 2, 3, 4)
sage: CartanType(['A', 7, 2]).index_set()
(0, 1, 2, 3, 4)
sage: CartanType(['A', 6, 2]).index_set()
(0, 1, 2, 3)
sage: CartanType(['D', 6, 2]).index_set()
(0, 1, 2, 3, 4, 5)
sage: CartanType(['E', 6, 1]).index_set()
(0, 1, 2, 3, 4, 5, 6)
sage: CartanType(['E', 6, 2]).index_set()
(0, 1, 2, 3, 4)
sage: CartanType(['A', 2, 2]).index_set()
(0, 1)
sage: CartanType(['G', 2, 1]).index_set()
(0, 1, 2)
sage: CartanType(['F', 4, 1]).index_set()
(0, 1, 2, 3, 4)
```

is_affine()

Return whether self is affine.

EXAMPLES:

```python
sage: CartanType(['A', 3]).is_affine()
False
sage: CartanType(['A', 3, 1]).is_affine()
True
```

is_atomic()

This method is usually equivalent to is_reducible(), except for the Cartan type $D_2$.

$D_2$ is not a standard Cartan type. It is equivalent to type $A_1 \times A_1$ which is reducible; however the isomorphism from its ambient space (for the orthogonal group of degree 4) to that of $A_1 \times A_1$ is non trivial, and it is useful to have it.
From a programming point of view its implementation is more similar to the irreducible types, and so the method `is_atomic()` is supplied.

EXAMPLES:

```python
sage: CartanType("D2").is_atomic()
True
sage: CartanType("D2").is_irreducible()
False
```

`is_compound()`

A short hand for not `is_atomic()`.

`is_crystallographic()`

Return whether this Cartan type is crystallographic.

This returns `False` by default. Derived class should override this appropriately.

EXAMPLES:

```python
sage: [[t, t.is_crystallographic()] for t in CartanType.
˓→samples(finite=True)]
[['A', 1], True], [['A', 5], True], [['B', 1], True], [['B', 5], True], [['C', 1], True], [['C', 5], True], [['D', 2], True], [['D', 3], True], [['D', 5], True], [['E', 6], True], [['E', 7], True], [['E', 8], True], [['F', 4], True], [['G', 2], True], [['I', 5], False], [['H', 3], False], [['H', 4], False]]
```

`is_finite()`

Return whether this Cartan type is finite.

EXAMPLES:

```python
sage: from sage.combinat.root_system.cartan_type import CartanType_abstract
sage: C = CartanType_abstract()
Traceback (most recent call last):
... Not ImplementedError: <abstract method is_finite at ...>
```

```python
sage: CartanType(['A',4]).is_finite()
True
sage: CartanType(['A',4, 1]).is_finite()
False
```

`is_implemented()`

Check whether the Cartan datum for `self` is actually implemented.

EXAMPLES:

```python
sage: CartanType(['A',4,1]).is_implemented()
True
sage: CartanType(['H',3]).is_implemented()
True
```

`is_irreducible()`

Report whether this Cartan type is irreducible (i.e. simple). This should be overridden in any subclass.
This returns False by default. Derived class should override this appropriately.

```
sage: from sage.combinat.root_system.cartan_type import CartanType_abstract
sage: C = CartanType_abstract()
sage: C.is_irreducible()
False
```

**is_reducible()**

Report whether the root system is reducible (i.e. not simple), that is whether it can be factored as a product of root systems.

```
sage: CartanType("A2xB3").is_reducible()
True
sage: CartanType(['A',2]).is_reducible()
False
```

**is_simply_laced()**

Return whether this Cartan type is simply laced.

This returns False by default. Derived class should override this appropriately.

```
sage: [ [t, t.is_simply_laced() ] for t in CartanType.samples() ]
[['A', 1], True], [['A', 5], True], [['B', 1], True], [['B', 5], False], [['C', 1], True], [['C', 5], False], [['D', 2], True], [['D', 3], True], [['D', 5], True], [['E', 6], True], [['E', 7], True], [['E', 8], True], [['F', 4], False], [['G', 2], False], [['H', 3], False], [['H', 4], False], [['A', 1, 1], False], [['A', 5, 1], True], [['B', 1, 1], False], [['B', 5, 1], False], [['C', 1, 1], False], [['C', 5, 1], False], [['D', 3, 1], True], [['D', 5, 1], True], [['E', 6, 1], True], [['E', 7, 1], True], [['E', 8, 1], True], [['E', 4, 1], False], [['G', 2, 1], False], [['BC', 1, 2], False], [['BC', 5, 2], False], [['BC', 1, 2]^*, False], [['BC', 5, 2]^*, False], [['BC', 1, 2]^*, False], [['BC', 5, 2]^*, False], [['BC', 1, 2]^*, False], [['BC', 5, 2]^*, False]]
```

**marked_nodes**

Return a Cartan type with the nodes marked

INPUT:

* marked_nodes – a list of nodes to mark

```
sage: CartanType(['F',4]).marked_nodes([1, 3]).dynkin_diagram()
X---O=>=X---O
1 2 3 4
F4 with nodes (1, 3) marked
```
**options(**get_value, **set_value\)**
Sets and displays the options for Cartan types. If no parameters are set, then the function returns a copy of the options dictionary.

The options to partitions can be accessed as the method `CartanType.options` of `CartanType`.

**OPTIONS:**

- **dual_latex** – (default: \\vee) The latex used for dual CartanTypes when latexing
- **dual_str** – (default: +) The string used for dual Cartan types when printing
- **latex_marked** – (default: True) Indicate in the latex output if a Cartan type has been marked
- **latex_relabel** – (default: True) Indicate in the latex output if a Cartan type has been relabelled
- **mark_special_node** – (default: none) Make the special nodes
  - both – both in latex and printing
  - latex – only in latex
  - none – no markup
  - printing – only in printing
- **marked_node_str** – (default: X) The string used to indicate a marked node when printing
- **notation** – (default: Stembridge) Specifies which notation Cartan types should use when printed
  - BC – alias for Stembridge
  - Kac – use Kac’s notation
  - Stembridge – use Stembridge’s notation
  - tilde – alias for Stembridge
  - twisted – alias for Kac
- **special_node_str** – (default: @) The string used to indicate which node is special when printing

**EXAMPLES:**

```
sage: ct = CartanType(['D', 5, 2]); ct
['C', 4, 1]^*
sage: ct.dynkin_diagram()
O=<=O---O---O=>=O
0 1 2 3 4
C4~*
sage: latex(ct)
C_{4}^{(1)\vee}
sage: CartanType.options(dual_str='\#', dual_latex='\\ast',)
sage: ct
['C', 4, 1]^\#
sage: ct.dynkin_diagram()
O=<=O---O---O=>=O
0 1 2 3 4
C4~\
sage: latex(ct)
C_{4}^{(1)\ast}
sage: CartanType.options(notation='kac', mark_special_node='both')
sage: ct
['D', 5, 2]
```

(continues on next page)
For type $A^{(2)}_{2n}$, the dual string/latex options are automatically overridden:

```python
sage: dct = CartanType(['A', 8, 2]).dual(); dct
['A', 8, 2]^+
```

```python
sage: latex(dct)
A_{8}^{(2)\dagger}
```

```python
sage: dct.dynkin_diagram()
\xrightarrow{=}\xrightarrow{=}O---O---O\xrightarrow{=}O
0 1 2 3 4
```

**A8^2+**

```python
sage: CartanType.options._reset()
```

See `GlobalOptions` for more features of these options.

### rank()
Return the rank of `self`.

This is the number of nodes of the associated Coxeter or Dynkin diagram.

**EXAMPLES:**

```python
sage: CartanType(['A', 4]).rank()
4
```

```python
sage: CartanType(['A', 7, 2]).rank()
5
```

```python
sage: CartanType(['I', 8]).rank()
2
```

### relabel (relabelling)
Return a relabelled copy of this Cartan type.

**INPUT:**

- relabelling – a function (or a list or dictionary)

**OUTPUT:**

an isomorphic Cartan type obtained by relabelling the nodes of the Dynkin diagram. Namely, the node with label $i$ is relabelled $f(i)$ (or, by $f[i]$ if $f$ is a list or dictionary).

**EXAMPLES:**

```python
sage: CartanType(['F', 4]).relabel({1: 4, 2: 3, 3: 2, 4: 1}).dynkin_diagram()
```

```python
\xrightarrow{=}\xrightarrow{=}0---0\xrightarrow{=}0---0
4 3 2 1
```

**F4 relabelled by {1: 4, 2: 3, 3: 2, 4: 1}**

### root_system()
Return the root system associated to `self`.

**EXAMPLES:**

```python
```
sage: CartanType(['A',4]).root_system()
Root system of type ['A', 4]

subtype (index_set)
Return a subtype of self given by index_set.

A subtype can be considered the Dynkin diagram induced from the Dynkin diagram of self by index_set.

EXAMPLES:

sage: ct = CartanType(['A',6,2])
sage: ct.dynkin_diagram()
O=<=O---O=<=O
0 1 2 3
BC3~
sage: ct.subtype([1,2,3])
['C', 3]

type()
Return the type of self, or None if unknown.
This method should be overridden in any subclass.

EXAMPLES:

sage: from sage.combinat.root_system.cartan_type import CartanType_abstract
sage: C = CartanType_abstract()
sage: C.type() is None
True

class sage.combinat.root_system.cartan_type.CartanType_affine
    Bases: sage.combinat.root_system.cartan_type.CartanType_simple, sage.combinat.root_system.cartan_type.CartanType_crystallographic

An abstract class for simple affine Cartan types

AmbientSpace
    alias of sage.combinat.root_system.type_affine.AmbientSpace

a()
Return the unique minimal non trivial annihilating linear combination of $\alpha_0^\vee, \alpha_1^\vee, \ldots, \alpha_\nu^\vee$ with nonnegative coefficients (or alternatively, the unique minimal non trivial annihilating linear combination of the columns of the Cartan matrix with non-negative coefficients).

Throw an error if the existence or uniqueness does not hold

FIXME: the current implementation assumes that the Cartan matrix is indexed by $[0, 1, \ldots]$, in the same order as the index set.

EXAMPLES:

sage: RootSystem(['C',2,1]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 1}
sage: RootSystem(['D',4,1]).cartan_type().a()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
sage: RootSystem(['F',4,1]).cartan_type().a()
Finite family {0: 1, 1: 1, 2: 2, 3: 3, 4: 4, 5: 1}
sage: RootSystem(['BC',4,2]).cartan_type().a()
Finite family {0: 2, 1: 1, 2: 2, 3: 2, 4: 1}
a is a shortcut for \texttt{col\_annihilator}:

\begin{verbatim}
sage: RootSystem(['BC',4,2]).cartan_type().col_annihilator()
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}
\end{verbatim}

\texttt{acheck} \texttt{(m=None)}

Return the unique minimal non trivial annihilating linear combination of \(\alpha_0, \alpha_1, \ldots, \alpha_n\) with nonnegative coefficients (or alternatively, the unique minimal non trivial annihilating linear combination of the rows of the Cartan matrix with non-negative coefficients).

Throw an error if the existence of uniqueness does not hold

The optional argument \texttt{m} is for internal use only.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: RootSystem(['C',2,1]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 1}
sage: RootSystem(['D',4,1]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
sage: RootSystem(['F',4,1]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 3, 3: 2, 4: 1}
sage: RootSystem(['BC',4,2]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
\end{verbatim}

\texttt{acheck} is a shortcut for \texttt{row\_annihilator}:

\begin{verbatim}
sage: RootSystem(['BC',4,2]).cartan_type().row_annihilator()
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
\end{verbatim}

\textbf{FIXME:}

- The current implementation assumes that the Cartan matrix is indexed by \([0, 1, \ldots]\), in the same order as the index set.

- This really should be a method of \texttt{CartanMatrix}.

\texttt{basic\_untwisted()}

Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type \(X_n^{(r)}\), the basic untwisted type is \(X_n\). In other words, it is the classical Cartan type that is twisted to obtain \texttt{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: CartanType(['A', 1, 1]).basic_untwisted()
['A', 1]
sage: CartanType(['A', 3, 1]).basic_untwisted()
['A', 3]
sage: CartanType(['B', 3, 1]).basic_untwisted()
['B', 3]
sage: CartanType(['E', 6, 1]).basic_untwisted()
['E', 6]
sage: CartanType(['G', 2, 1]).basic_untwisted()
['G', 2]
sage: CartanType(['A', 2, 2]).basic_untwisted()
['A', 2]
sage: CartanType(['A', 4, 2]).basic_untwisted()
['A', 4]
\end{verbatim}
sage: CartanType(['A', 11, 2]).basic_untwisted()
['A', 11]
sage: CartanType(['D', 5, 2]).basic_untwisted()
['D', 5]
sage: CartanType(['E', 6, 2]).basic_untwisted()
['E', 6]
sage: CartanType(['D', 4, 3]).basic_untwisted()
['D', 4]

Returns the family $(c_i)_i$ of integer coefficients defined by
\[ c_i = \max(1, a_i / a_\nu \varepsilon_i) \] (see e.g. [FSS07] p. 3)

FIXME: the current implementation assumes that the Cartan matrix is indexed by $[0, 1, ...]$, in the same order as the index set.

EXAMPLES:

sage: RootSystem(['C',2,1]).cartan_type().c()
Finite family {0: 1, 1: 2, 2: 1}
sage: RootSystem(['D',4,1]).cartan_type().c()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 1}
sage: RootSystem(['F',4,1]).cartan_type().c()
Finite family {0: 1, 1: 1, 2: 1, 3: 2, 4: 2}
sage: RootSystem(['BC',4,2]).cartan_type().c()
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 1}

REFERENCES:

classical()

Return the classical Cartan type associated with this affine Cartan type.

EXAMPLES:

sage: CartanType(['A', 1, 1]).classical()
['A', 1]
sage: CartanType(['A', 3, 1]).classical()
['A', 3]
sage: CartanType(['B', 3, 1]).classical()
['B', 3]
sage: CartanType(['A', 2, 2]).classical()
['C', 1]
sage: CartanType(['BC', 1, 2]).classical()
['C', 1]
sage: CartanType(['A', 4, 2]).classical()
['C', 2]
sage: CartanType(['BC', 2, 2]).classical()
['C', 2]
sage: CartanType(['A', 10, 2]).classical()
['C', 5]
sage: CartanType(['BC', 5, 2]).classical()
['C', 5]
We check that `classical()`, `sage.combinat.root_system.cartan_type.CartanType_crystallographic.dynkin_diagram()`, and `special_node()` are consistent:

```
sage: for ct in CartanType.samples(affine = True):
    ....:     g1 = ct.classical().dynkin_diagram()
    ....:     g2 = ct.dynkin_diagram()
    ....:     g2.delete_vertex(ct.special_node())
    ....:     assert sorted(g1.vertices()) == sorted(g2.vertices())
    ....:     assert sorted(g1.edges()) == sorted(g2.edges())
```

---

### col_annihilator()

Return the unique minimal non trivial annihilating linear combination of \( \alpha_0^\vee, \alpha_1^\vee, \ldots, \alpha_k^\vee \) with nonnegative coefficients (or alternatively, the unique minimal non trivial annihilating linear combination of the columns of the Cartan matrix with non-negative coefficients).

Throw an error if the existence or uniqueness does not hold

**FIXME:** the current implementation assumes that the Cartan matrix is indexed by \([0, 1, \ldots]\), in the same order as the index set.

**EXAMPLES:**

```
sage: RootSystem(['C',2,1]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 1}
sage: RootSystem(['D',4,1]).cartan_type().a()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
sage: RootSystem(['F',4,1]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 3, 3: 4, 4: 2}
sage: RootSystem(['BC',4,2]).cartan_type().a()
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}
```

`a` is a shortcut for `col_annihilator`:

```
sage: RootSystem(['BC',4,2]).cartan_type().col_annihilator()
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}
```

---

### is_affine()

**EXAMPLES:**

```
sage: CartanType(['A', 3, 1]).is_affine()
True
```

---

### is_finite()

**EXAMPLES:**

```
sage: CartanType(['A', 3, 1]).is_finite()
False
```

---

### is_untwisted_affine()

Return whether `self` is untwisted affine
A Cartan type is untwisted affine if it is the canonical affine extension of some finite type. Every affine type is either untwisted affine, dual thereof, or of type BC.

**EXAMPLES:**

```python
sage: CartanType(['A', 3, 1]).is_untwisted_affine()
True
sage: CartanType(['A', 3, 1]).dual().is_untwisted_affine()  # this one is self, dual!
True
sage: CartanType(['B', 3, 1]).dual().is_untwisted_affine()
False
sage: CartanType(['BC', 3, 2]).is_untwisted_affine()
False
```

**other_affinization()**

Return the other affinization of the same classical type.

**EXAMPLES:**

```python
sage: CartanType(['A', 3, 1]).other_affinization()
['A', 3, 1]
sage: CartanType(['B', 3, 1]).other_affinization()
['C', 3, 1]^*
sage: CartanType(['C', 3, 1]).dual().other_affinization()
['B', 3, 1]
```

Is this what we want?:

```python
sage: CartanType(['BC', 3, 2]).dual().other_affinization()
['B', 3, 1]
```

**row_annihilator (m=None)**

Return the unique minimal non trivial annihilating linear combination of $\alpha_0, \alpha_1, \ldots, \alpha_n$ with nonnegative coefficients (or alternatively, the unique minimal non trivial annihilating linear combination of the rows of the Cartan matrix with non-negative coefficients).

Throw an error if the existence of uniqueness does not hold

The optional argument $m$ is for internal use only.

**EXAMPLES:**

```python
sage: RootSystem(['C',2,1]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 1}
sage: RootSystem(['D',4,1]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
sage: RootSystem(['F',4,1]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 3, 3: 2, 4: 1}
sage: RootSystem(['BC',4,2]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

acheck is a shortcut for row_annihilator:

```python
sage: RootSystem(['BC',4,2]).cartan_type().row_annihilator()
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

**FIXME:**

"2104 Chapter 5. Comprehensive Module List"
• The current implementation assumes that the Cartan matrix is indexed by \([0, 1, ...]\), in the same order as the index set.

• This really should be a method of \texttt{CartanMatrix}.

\texttt{special\_node()}

Return a special node of the Dynkin diagram.

A \textit{special} node is a node of the Dynkin diagram such that pruning it yields a Dynkin diagram for the associated classical type (see \texttt{classical()}).

This method returns the label of some special node. This is usually 0 in the standard conventions.

**EXAMPLES:**

\begin{verbatim}
sage: CartanType(['A', 3, 1]).special_node()
0
\end{verbatim}

The choice is guaranteed to be consistent with the indexing of the nodes of the classical Dynkin diagram:

\begin{verbatim}
sage: CartanType(['A', 3, 1]).index_set()
(0, 1, 2, 3)
sage: CartanType(['A', 3, 1]).classical().index_set()
(1, 2, 3)
\end{verbatim}

\texttt{special\_nodes()}

Return the set of special nodes of the affine Dynkin diagram.

**EXAMPLES:**

\begin{verbatim}
sage: CartanType(['A',3,1]).special_nodes()
(0, 1, 2, 3)
sage: CartanType(['C',2,1]).special_nodes()
(0, 2)
sage: CartanType(['D',4,1]).special_nodes()
(0, 1, 3, 4)
sage: CartanType(['E',6,1]).special_nodes()
(0, 1, 6)
sage: CartanType(['D',3,2]).special_nodes()
(0, 2)
sage: CartanType(['A',4,2]).special_nodes()
(0,)
\end{verbatim}

\texttt{translation\_factors()}

Returns the translation factors for \texttt{self}. Those are the smallest factors \(t_i\) such that the translation by \(t_i\alpha_i\) maps the fundamental polygon to another polygon in the alcove picture.

**OUTPUT:** a dictionary from \texttt{self.index\_set()} to \(\mathbb{Z}\) (or \(\mathbb{Q}\) for affine type \(BC\)).

Those coefficients are all 1 for dual untwisted, and in particular for simply laced. They coincide with the usual \(c_i\) coefficients (see \texttt{c()}) for untwisted and dual thereof. See the discussion below for affine type \(BC\).

Note: one usually realizes the alcove picture in the coweight lattice, with translations by coroots; in that case, one will use the translation factors for the dual Cartan type.

**FIXME:** the current implementation assumes that the Cartan matrix is indexed by \([0, 1, ...]\), in the same order as the index set.

**EXAMPLES:**
We proceed with systematic tests taken from MuPAD-Combinat's testsuite:

```python
sage: list(CartanType(['A', 1, 1]).translation_factors())
[1, 1]
sage: list(CartanType(['A', 5, 1]).translation_factors())
[1, 1, 1, 1, 1, 1]
sage: list(CartanType(['B', 5, 1]).translation_factors())
[1, 1, 1, 1, 1, 2]
sage: list(CartanType(['C', 5, 1]).translation_factors())
[1, 2, 2, 2, 2, 1]
sage: list(CartanType(['D', 5, 1]).translation_factors())
[1, 1, 1, 1, 1, 1]
sage: list(CartanType(['E', 6, 1]).translation_factors())
[1, 1, 1, 1, 1, 1, 1]
sage: list(CartanType(['E', 7, 1]).translation_factors())
[1, 1, 1, 1, 1, 1, 1, 1]
sage: list(CartanType(['E', 8, 1]).translation_factors())
[1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: list(CartanType(['F', 4, 1]).translation_factors())
[1, 1, 1, 2, 2]
sage: list(CartanType(['G', 2, 1]).translation_factors())
[1, 3, 1]
sage: list(CartanType(['A', 2, 2]).translation_factors())
[1, 1/2]
sage: list(CartanType(['A', 2, 2]).dual().translation_factors())
[1/2, 1]
sage: list(CartanType(['A', 10, 2]).translation_factors())
[1, 1, 1, 1, 1, 1/2]
sage: list(CartanType(['A', 10, 2]).dual().translation_factors())
[1/2, 1, 1, 1, 1, 1]
sage: list(CartanType(['A', 9, 2]).translation_factors())
[1, 1, 1, 1, 1]
sage: list(CartanType(['D', 5, 2]).translation_factors())
[1, 1, 1, 1, 1]
sage: list(CartanType(['D', 4, 3]).translation_factors())
[1, 1, 1]
sage: list(CartanType(['E', 6, 2]).translation_factors())
[1, 1, 1, 1, 1]
```

We conclude with a discussion of the appropriate value for affine type $BC$. Let us consider the alcove picture realized in the weight lattice. It is obtained by taking the level-1 affine hyperplane in the weight lattice, and projecting it along $\Lambda_0$:
Here are the levels of the fundamental weights:

```python
sage: Lambda[0].level(), Lambda[1].level(), Lambda[2].level()
(1, 2, 2)
```

So the “center” of the fundamental polygon at level 1 is:

```python
sage: O = Lambda[0]
sage: O.level()
1
```

We take the projection $\omega_1$ at level 0 of $\Lambda_1$ as unit vector on the $x$-axis, and the projection $\omega_2$ at level 0 of $\Lambda_2$ as unit vector of the $y$-axis:

```python
sage: omega1 = Lambda[1]-2*Lambda[0]
sage: omega2 = Lambda[2]-2*Lambda[0]
sage: omega1.level(), omega2.level()
(0, 0)
```

The projections of the simple roots can be read off:

```python
sage: alpha[0]
2*Lambda[0] - Lambda[1]
sage: alpha[1]
sage: alpha[2]
```

Namely $\alpha_0 = -\omega_1, \alpha_1 = 2\omega_1 - \omega_2$ and $\alpha_2 = -2\omega_1 + 2\omega_2$.

The reflection hyperplane defined by $\alpha_0^\vee$ goes through the points $O + 1/2\omega_1$ and $O + 1/2\omega_2$:

```python
sage: (O+(1/2)*omega1).scalar(alphacheck[0])
0
sage: (O+(1/2)*omega2).scalar(alphacheck[0])
0
```

Hence, the fundamental alcove is the triangle $(O, O + 1/2\omega_1, O + 1/2\omega_2)$. By successive reflections, one can tile the full plane. This induces a tiling of the full plane by translates of the fundamental polygon.

**Todo:** Add the picture here, once root system plots in the weight lattice will be implemented. In the mean time, the reader may look up the dual picture on Figure 2 of [HST09] which was produced by MuPAD-Combinat.

From this picture, one can read that translations by $\alpha_0, \alpha_1,$ and $1/2\alpha_2$ map the fundamental polygon to translates of it in the alcove picture, and are smallest with this property. Hence, the translation factors for affine type $BC$ are $t_0 = 1, t_1 = 1, t_2 = 1/2$:

```python
sage: CartanType(['BC',2,2]).translation_factors()
Finite family {0: 1, 1: 1, 2: 1/2}
```

REFERENCES:

5.1. Comprehensive Module list 2107
class sage.combinat.root_system.cartan_type.CartanType_crystallographic
Bases: sage.combinat.root_system.cartan_type.CartanType_abstract

An abstract class for crystallographic Cartan types.

ascii_art (label=’lambda x: x’, node=None)

Return an ascii art representation of the Dynkin diagram.

INPUT:

• label – (default: the identity) a relabeling function for the nodes

• node – (optional) a function which returns the character for a node

EXAMPLES:

```
sage: cartan_type = CartanType(['B',5,1])
sage: print(cartan_type.ascii_art())
O 0
|  |
O---O---O---O=>=O
1 2 3 4 5
```

The label option is useful to visualize various statistics on the nodes of the Dynkin diagram:

```
sage: a = cartan_type.col_annihilator(); a
Finite family {0: 1, 1: 1, 2: 2, 3: 2, 4: 2, 5: 2}
sage: print(CartanType(['B',5,1]).ascii_art(label=a.__getitem__))
O 1
|  |
O---O---O---O=>=O
1 2 2 2 2
```

cartan_matrix()

Return the Cartan matrix associated with self.

EXAMPLES:

```
sage: CartanType(['A',4]).cartan_matrix()
[ 2 -1 0 0]
[-1 2 -1 0]
[ 0 -1 2 -1]
[ 0 0 -1 2]
```

coxeter_diagram()

Return the Coxeter diagram for self.

This implementation constructs it from the Dynkin diagram.

See also:

CartanType_abstract.coxeter_diagram()

EXAMPLES:

```
sage: CartanType(['A',3]).coxeter_diagram()
Graph on 3 vertices
sage: CartanType(['A',3]).coxeter_diagram().edges()
[(1, 2, 3), (2, 3, 3)]
```
```
sage: CartanType(['B',3]).coxeter_diagram().edges()
[(1, 2, 3), (2, 3, 4)]
sage: CartanType(['G',2]).coxeter_diagram().edges()
[(1, 2, 6)]
sage: CartanType(['F',4]).coxeter_diagram().edges()
[(1, 2, 3), (2, 3, 4), (3, 4, 3)]
sage: CartanType(['A',2,2]).coxeter_diagram().edges()
[(0, 1, +Infinity)]
```

```
dynkin_diagram()
Return the Dynkin diagram associated with self.

EXAMPLES:
```
sage: CartanType(['A',4]).dynkin_diagram()
O---O---O---O
1 2 3 4
A4
```

**Note:** Derived subclasses should typically implement this as a cached method.

```
index_set_bipartition()
Return a bipartition \{L, R\} of the vertices of the Dynkin diagram.

For \(i\) and \(j\) both in \(L\) (or both in \(R\)), the simple reflections \(s_i\) and \(s_j\) commute.

Of course, the Dynkin diagram should be bipartite. This is always the case for all finite types.

EXAMPLES:
```
sage: CartanType(['A',5]).index_set_bipartition()
({1, 3, 5}, {2, 4})
sage: CartanType(['A',2,1]).index_set_bipartition()
Traceback (most recent call last):
...
ValueError: the Dynkin diagram must be bipartite
```

```
is_crystallographic()
Implements `CartanType_abstract.is_crystallographic()` by returning True.

EXAMPLES:
```
sage: CartanType(['A', 3, 1]).is_crystallographic()
True
```

```
symmetrizer()
Return the symmetrizer of the Cartan matrix of self.

A Cartan matrix \(M\) is symmetrizable if there exists a non trivial diagonal matrix \(D\) such that \(DM\) is a symmetric matrix, that is \(DM = M^t D\). In that case, \(D\) is unique, up to a scalar factor for each connected component of the Dynkin diagram.

This method computes the unique minimal such \(D\) with positive integral coefficients. If \(D\) exists, it is returned as a family. Otherwise `None` is returned.

The coefficients are coerced to `base_ring`.
```
EXAMPLES:

```python
sage: CartanType(['B',5]).symmetrizer()
Finite family {1: 2, 2: 2, 3: 2, 4: 2, 5: 1}
```

Here is a neat trick to visualize it better:

```python
sage: T = CartanType(['B',5])
sage: print(T.ascii_art(T.symmetrizer().__getitem__))
O---O---O---O=>=O
2 2 2 2 1

sage: T = CartanType(['BC',5, 2])
sage: print(T.ascii_art(T.symmetrizer().__getitem__))
O=<=O---O---O---O=<=O
1 2 2 2 2 4
```

Here is the symmetrizer of some reducible Cartan types:

```python
sage: T = CartanType(['D', 2])
sage: print(T.ascii_art(T.symmetrizer().__getitem__))
O O
1 1

sage: T = CartanType(['B',5],["BC",5, 2])
sage: print(T.ascii_art(T.symmetrizer().__getitem__))
O---O---O---O=>=O
2 2 2 2 1
O=<=O---O---O---O=<=O
1 2 2 2 2 4
```

Property: up to an overall scalar factor, this gives the norm of the simple roots in the ambient space:

```python
sage: T = CartanType(['C',5])
sage: print(T.ascii_art(lambda i: alpha[i].scalar(alpha[i])))
O---O---O---O=<=O
2 2 2 2 4
```

```python
class sage.combinat.root_system.cartan_type.CartanType_decorator(ct)
Bases:    sage.structure.unique_representation.UniqueRepresentation,  sage.
structure.sage_object.SageObject,    sage.combinat.root_system.cartan_type.
CartanType_abstract

Concrete base class for Cartan types that decorate another Cartan type.

index_set()

EXAMPLES:
```

```python
sage: ct = CartanType(['F', 4, 1]).dual()
sage: ct.index_set()
(0, 1, 2, 3, 4)
```
is_affine()  
EXAMPLES:

```python
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.is_affine()
False
```

is_crystallographic()  
EXAMPLES:

```python
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.is_crystallographic()
True
```

is_finite()  
EXAMPLES:

```python
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.is_finite()
True
```

is_irreducible()  
EXAMPLES:

```python
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.is_irreducible()
True
```

rank()  
EXAMPLES:

```python
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.rank()
2
```

class sage.combinat.root_system.cartan_type.CartanType_finite  
Bases: sage.combinat.root_system.cartan_type.CartanType_abstract  

An abstract class for simple affine Cartan types.

is_affine()  
EXAMPLES:

```python
sage: CartanType(['A', 3]).is_affine()
False
```

is_finite()  
EXAMPLES:

```python
sage: CartanType(['A', 3]).is_finite()
True
```

class sage.combinat.root_system.cartan_type.CartanType_simple  
Bases: sage.combinat.root_system.cartan_type.CartanType_abstract  

An abstract class for simple Cartan types.

is_irreducible()  
Return whether self is irreducible, which is True.
EXAMPLES:

```
sage: CartanType(['A', 3]).is_irreducible()
True
```

class sage.combinat.root_system.cartan_type.CartanType_simple_finite

Bases: object

class sage.combinat.root_system.cartan_type.CartanType_simply_laced

Bases: sage.combinat.root_system.cartan_type.CartanType_crystallographic

An abstract class for simply laced Cartan types.

dual()

Simply laced Cartan types are self-dual, so return self.

EXAMPLES:

```
sage: CartanType(['A', 3]).dual()
['A', 3]
sage: CartanType(['A', 3, 1]).dual()
['A', 3, 1]
sage: CartanType(['D', 3]).dual()
['D', 3]
sage: CartanType(['D', 4, 1]).dual()
['D', 4, 1]
sage: CartanType(['E', 6]).dual()
['E', 6]
sage: CartanType(['E', 6, 1]).dual()
['E', 6, 1]
```

is_simply_laced()

Return whether self is simply laced, which is True.

EXAMPLES:

```
sage: CartanType(['A',3,1]).is_simply_laced()
True
sage: CartanType(['A',2]).is_simply_laced()
True
```

class sage.combinat.root_system.cartan_type.CartanType_standard

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.
structure.sage_object.SageObject

class sage.combinat.root_system.cartan_type.CartanType_standard_affine(letter, n, affine=1)

Bases: sage.combinat.root_system.cartan_type.CartanType_standard, sage.
combinat.root_system.cartan_type.CartanType_affine

A concrete class for affine simple Cartan types.

index_set()

Implements CartanType_abstract.index_set().

The index set for all standard affine Cartan types is of the form \{0,\ldots,n\}.

EXAMPLES:
sage: CartanType(['A', 5, 1]).index_set()
(0, 1, 2, 3, 4, 5)

\textbf{rank()} \hspace{1cm} \\
Return the rank of \texttt{self} which for type $X_n^{(1)}$ is $n + 1$.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: CartanType(['A', 4, 1]).rank()
5
sage: CartanType(['B', 4, 1]).rank()
5
sage: CartanType(['C', 3, 1]).rank()
4
sage: CartanType(['D', 4, 1]).rank()
5
sage: CartanType(['E', 6, 1]).rank()
7
sage: CartanType(['E', 7, 1]).rank()
8
sage: CartanType(['F', 4, 1]).rank()
5
sage: CartanType(['G', 2, 1]).rank()
3
sage: CartanType(['A', 2, 2]).rank()
2
sage: CartanType(['A', 6, 2]).rank()
4
sage: CartanType(['A', 7, 2]).rank()
5
sage: CartanType(['D', 5, 2]).rank()
5
sage: CartanType(['E', 6, 2]).rank()
5
sage: CartanType(['D', 4, 3]).rank()
3
\end{verbatim}

\textbf{special_node()} \hspace{1cm} \\
Implement \texttt{CartanType\_abstract.special\_node()}. \\
With the standard labelling conventions, 0 is always a special node.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: CartanType(['A', 3, 1]).special_node()
0
\end{verbatim}

\textbf{type()} \hspace{1cm} \\
Return the type of \texttt{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: CartanType(['A', 4, 1]).type()
'A'
\end{verbatim}

\textbf{class} \texttt{sage.combinat.root_system.cartan_type.CartanType\_standard\_finite}(\texttt{letter}, \texttt{n}) \\
\textbf{Bases:} \texttt{sage.combinat.root_system.cartan_type.CartanType\_standard}, \texttt{sage.combinat.root_system.cartan_type.CartanType\_finite}
A concrete base class for the finite standard Cartan types.
This includes for example $A_3$, $D_4$, or $E_8$.

**affine()**

Return the corresponding untwisted affine Cartan type.

```
sage: CartanType(['A', 3]).affine()
['A', 3, 1]
```

**coxeter_number()**

Return the Coxeter number associated with `self`.

The Coxeter number is the order of a Coxeter element of the corresponding Weyl group.
See Bourbaki, Lie Groups and Lie Algebras V.6.1 or Wikipedia article Coxeter_element for more information.

```
sage: CartanType(['A', 4]).coxeter_number()
5
sage: CartanType(['B', 4]).coxeter_number()
8
sage: CartanType(['C', 4]).coxeter_number()
8
```

**dual_coxeter_number()**

Return the Coxeter number associated with `self`.

```
sage: CartanType(['A', 4]).dual_coxeter_number()
5
sage: CartanType(['B', 4]).dual_coxeter_number()
7
sage: CartanType(['C', 4]).dual_coxeter_number()
5
```

**index_set()**

Implements `CartanType_abstract.index_set()`.

The index set for all standard finite Cartan types is of the form \{1, \ldots, n\}. (See `type_I` for a slight abuse of this).

```
sage: CartanType(['A', 5]).index_set()
(1, 2, 3, 4, 5)
```

**opposition_automorphism()**

Returns the opposition automorphism

The *opposition automorphism* is the automorphism $i \mapsto i^*$ of the vertices Dynkin diagram such that, for $w_0$ the longest element of the Weyl group, and any simple root $\alpha_i$, one has $\alpha_i^* = -w_0(\alpha_i)$.

The automorphism is returned as a `Family`.

```
sage: CartanType(['A', 5]).opposition_automorphism()
```

sage: ct = CartanType(['A', 5])
sage: ct.opposition_automorphism()
Finite family {1: 5, 2: 4, 3: 3, 4: 2, 5: 1}

sage: ct = CartanType(['D', 4])
sage: ct.opposition_automorphism()
Finite family {1: 1, 2: 2, 3: 3, 4: 4}

sage: ct = CartanType(['D', 5])
sage: ct.opposition_automorphism()
Finite family {1: 1, 2: 2, 3: 3, 4: 5, 5: 4}

sage: ct = CartanType(['C', 4])
sage: ct.opposition_automorphism()
Finite family {1: 1, 2: 2, 3: 3, 4: 4}

\textbf{rank}()

Return the rank of \texttt{self} which for type $X_n$ is $n$.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: CartanType(['A', 3]).rank()
3
sage: CartanType(['B', 3]).rank()
3
sage: CartanType(['C', 3]).rank()
3
sage: CartanType(['D', 4]).rank()
4
sage: CartanType(['E', 6]).rank()
6
\end{verbatim}

\textbf{type}()

Returns the type of \texttt{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: CartanType(['A', 4]).type()
'A'
sage: CartanType(['A', 4, 1]).type()
'A'
\end{verbatim}

\textbf{class} \texttt{sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine}(\texttt{letter}, \texttt{n}, \texttt{affine=1})

Bases: \texttt{sage.combinat.root_system.cartan_type.CartanType_standard_affine}

A concrete class for the standard untwisted affine Cartan types.

\textbf{basic_untwisted}()

Return the basic_untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic_untwisted type is $X_n$. In other words, it is the classical Cartan type that is twisted to obtain \texttt{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: CartanType(['A', 1, 1]).basic_untwisted()
['A', 1]
\end{verbatim}
classical()

Return the classical Cartan type associated with self.

EXAMPLES:

```python
sage: CartanType(['A', 3, 1]).classical()
['A', 3]
sage: CartanType(['B', 3, 1]).classical()
['B', 3]
sage: CartanType(['C', 3, 1]).classical()
['C', 3]
sage: CartanType(['D', 4, 1]).classical()
['D', 4]
sage: CartanType(['E', 6, 1]).classical()
['E', 6]
sage: CartanType(['F', 4, 1]).classical()
['F', 4]
sage: CartanType(['G', 2, 1]).classical()
['G', 2]
```

is_untwisted_affine()

Implement `CartanType_affine.is_untwisted_affine()` by returning True.

EXAMPLES:

```python
sage: CartanType(['B', 3, 1]).is_untwisted_affine()
True
```

```python
class sage.combinat.root_system.cartan_type.SuperCartanType_standard

Bases:
    sage.structure.unique_representation.UniqueRepresentation, sage.structure.sage_object.SageObject

options(*get_value, **set_value)

Sets and displays the options for Cartan types. If no parameters are set, then the function returns a copy of the options dictionary.

The options to partitions can be accessed as the method `CartanType.options` of `CartanType`.

OPTIONS:

- `dual_latex` – (default: \\vee) The latex used for dual CartanTypes when latexing
- `dual_str` – (default: \*) The string used for dual Cartan types when printing
- `latex_marked` – (default: True) Indicate in the latex output if a Cartan type has been marked
- `latex_relabel` – (default: True) Indicate in the latex output if a Cartan type has been relabelled
- `mark_special_node` – (default: none) Make the special nodes
  - `both` – both in latex and printing

– latex – only in latex
– none – no markup
– printing – only in printing
• marked_node_str – (default: X) The string used to indicate a marked node when printing
• notation – (default: Stembridge) Specifies which notation Cartan types should use when
printed
– BC – alias for Stembridge
– Kac – use Kac’s notation
– Stembridge – use Stembridge’s notation
– tilde – alias for Stembridge
– twisted – alias for Kac
• special_node_str – (default: @) The string used to indicate which node is special when printing
EXAMPLES:
sage: ct = CartanType(['D',5,2]); ct
['C', 4, 1]^*
sage: ct.dynkin_diagram()
O=<=O---O---O=>=O
0
1
2
3
4
C4~*
sage: latex(ct)
C_{4}^{(1)\vee}
sage: CartanType.options(dual_str='#', dual_latex='\\ast',)
sage: ct
['C', 4, 1]^#
sage: ct.dynkin_diagram()
O=<=O---O---O=>=O
0

5.1. Comprehensive Module list

2117


A8^2+
sage: CartanType.options._reset()

See GlobalOptions for more features of these options.

5.1.228 Coxeter Groups

sage.combinat.root_system.coxeter_group.CoxeterGroup(data, implementation='reflection', base_ring=None, index_set=None)

Return an implementation of the Coxeter group given by data.

INPUT:

• data – a Cartan type (or coercible into; see CartanType) or a Coxeter matrix or graph
• implementation – (default: 'reflection') can be one of the following:
  – 'permutation' - as a permutation representation
  – 'matrix' - as a Weyl group (as a matrix group acting on the root space); if this is not implemented, this uses the “reflection” implementation
  – 'coxeter3' - using the coxeter3 package
  – 'reflection' - as elements in the reflection representation; see CoxeterMatrixGroup
• base_ring – (optional) the base ring for the 'reflection' implementation
• index_set – (optional) the index set for the 'reflection' implementation

EXAMPLES:

Now assume that data represents a Cartan type. If implementation is not specified, the reflection representation is returned:

```
sage: W = CoxeterGroup(['A',2])
sage: W
Finite Coxeter group over Integer Ring with Coxeter matrix:
[1 3]
[3 1]
sage: W = CoxeterGroup(['A',3,1]); W
Coxeter group over Integer Ring with Coxeter matrix:
[1 3 2 3]
[3 1 3 2]
[2 3 1 3]
[3 2 3 1]
sage: W = CoxeterGroup(['H',3]); W
Finite Coxeter group over Number Field in a with defining polynomial x^2 - 5 with...
˓→a = 2.236067977499790? with Coxeter matrix:
[1 3 2]
[3 1 5]
[2 5 1]
```

We now use the implementation option:
```python
sage: W = CoxeterGroup(['A',2], implementation = "permutation")  # optional - gap3
sage: W  # optional - gap3
Permutation Group with generators [(1,4)(2,3)(5,6), (1,3)(2,5)(4,6)]

sage: W.category()  # optional - gap3
Join of Category of finite enumerated permutation groups
and Category of finite weyl groups
and Category of well generated finite irreducible complex reflection groups

sage: W = CoxeterGroup(['A',2], implementation="matrix")
sage: W
Weyl Group of type ['A', 2] (as a matrix group acting on the ambient space)

sage: W = CoxeterGroup(['H',3], implementation="matrix")
sage: W
Finite Coxeter group over Number Field in a with defining polynomial x^2 - 5 with
˓→a = 2.236067977499790? with Coxeter matrix:
\[
\begin{bmatrix}
1 & 3 & 2 \\
3 & 1 & 5 \\
2 & 5 & 1 \\
\end{bmatrix}
\]

sage: W = CoxeterGroup(['H',3], implementation="reflection")
sage: W
Finite Coxeter group over Number Field in a with defining polynomial x^2 - 5 with
˓→a = 2.236067977499790? with Coxeter matrix:
\[
\begin{bmatrix}
1 & 3 & 2 \\
3 & 1 & 5 \\
2 & 5 & 1 \\
\end{bmatrix}
\]

sage: W = CoxeterGroup(['A',4,1], implementation="permutation")
Traceback (most recent call last):
  ...
ValueError: the type must be finite

sage: W = CoxeterGroup(['A',4], implementation="chevie"); W  # optional - gap3
Irreducible real reflection group of rank 4 and type A4

We use the different options for the "reflection" implementation:

```
5.1.229 Coxeter Matrices

class sage.combinat.root_system.coxeter_matrix.CoxeterMatrix(parent, data, coxeter_type, index_set)

Bases: sage.combinat.root_system.coxeter_type.CoxeterType

A Coxeter matrix.

A Coxeter matrix $M = (m_{ij})_{i,j \in I}$ is a matrix encoding a Coxeter system $(W, S)$, where the relations are given by $(s_i s_j)^m_{ij}$. Thus $M$ is symmetric and has entries in $\{1, 2, 3, \ldots, \infty\}$ with $m_{ij} = 1$ if and only if $i = j$.

We represent $m_{ij} = \infty$ by any number $m_{ij} \leq -1$. In particular, we can construct a bilinear form $B = (b_{ij})_{i,j \in I}$ from $M$ by

$$b_{ij} = \begin{cases} m_{ij} & m_{ij} < 0 \text{ (i.e., } m_{ij} = \infty\text{),} \\ -\cos \left( \frac{\pi}{m_{ij}} \right) & \text{otherwise.} \end{cases}$$

EXAMPLES:

```
sage: CoxeterMatrix(['A', 4])
[1 3 2 2]
[3 1 3 2]
[2 3 1 3]
[2 2 3 1]
sage: CoxeterMatrix(['B', 4])
[1 3 2 2]
[3 1 3 2]
[2 3 1 4]
[2 2 4 1]
sage: CoxeterMatrix(['C', 4])
[1 3 2 2]
[3 1 3 2]
[2 3 1 4]
[2 2 4 1]
sage: CoxeterMatrix(['D', 4])
[1 3 2 2]
[3 1 3 3]
[2 3 1 2]
[2 3 2 1]
sage: CoxeterMatrix(['E', 6])
[1 2 3 2 2 2]
[2 1 2 3 2 2]
[3 2 1 3 2 2]
[2 3 3 1 3 2]
[2 2 2 3 1 3]
[2 2 2 2 3 1]
sage: CoxeterMatrix(['F', 4])
[1 3 2 2]
[3 1 4 2]
[2 4 1 3]
[2 2 3 1]
sage: CoxeterMatrix(['G', 2])
[1 6]
[6 1]
```
By default, entries representing $\infty$ are given by $-1$ in the Coxeter matrix:

```
sage: G = Graph([(0,1,None), (1,2,4), (0,2,oo)])
sage: CoxeterMatrix(G)
[ 1  3  -1]
[ 3  1  4]
[-1  4  1]
```

It is possible to give a number $\leq -1$ to represent an infinite label:

```
sage: CoxeterMatrix([[1,-1],[1,-1]])
[ 1  -1]
[-1  1]
sage: CoxeterMatrix([[1,-3/2],[1,-3/2]])
[ 1  -3/2]
[-3/2  1]
```

```
bilinear_form(R=None)
Return the bilinear form of self.
EXAMPLES:

sage: CoxeterType(['A', 2, 1]).bilinear_form()
[ 1  -1/2  -1/2]
[-1/2  1  -1/2]
[-1/2  -1/2  1]
sage: CoxeterType(['H', 3]).bilinear_form()
[ 1  -1/2]
[-1/2  1  1/2 *E(5)^2 + 1/2*E(5)^3]
[0  1/2 *E(5)^2 + 1/2*E(5)^3  1]
sage: C = CoxeterMatrix([[1,-1,-1],[-1,1,-1],[-1,-1,1]])
sage: C.bilinear_form()
[ 1  -1  -1]
[-1  1  -1]
[-1  -1  1]
```

```
coxeter_graph()
Return the Coxeter graph of self.
EXAMPLES:

sage: C = CoxeterMatrix(['A',3])
sage: C.coxeter_graph()
Graph on 3 vertices
sage: C = CoxeterMatrix(['A',3],['A',1])
sage: C.coxeter_graph()
Graph on 4 vertices
```

```
coxeter_matrix()
Return the Coxeter matrix of self.
EXAMPLES:

sage: CoxeterMatrix(['C',3]).coxeter_matrix()
[1  3  2]
[3  1  4]
[2  4  1]
```
**coxeter_type()**

Return the Coxeter type of `self` or `self` if unknown.

**EXAMPLES:**

```
sage: C = CoxeterMatrix(['A',4,1])
sage: C.coxeter_type()
Coxeter type of ['A', 4, 1]
```

If the Coxeter type is unknown:

```
sage: C = CoxeterMatrix([[1,3,4], [3,1,-1], [4,-1,1]])
sage: C.coxeter_type()
[ 1 3 4]
[ 3 1 -1]
[ 4 -1 1]
```

**index_set()**

Return the index set of `self`.

**EXAMPLES:**

```
sage: C = CoxeterMatrix(['A',1,1])
sage: C.index_set()
(0, 1)
sage: C = CoxeterMatrix(['E',6])
sage: C.index_set()
(1, 2, 3, 4, 5, 6)
```

**is_affine()**

Return if `self` is an affine type or `False` if unknown.

**EXAMPLES:**

```
sage: M = CoxeterMatrix(['C',4])
sage: M.is_affine()
False
sage: M = CoxeterMatrix(['D',4,1])
sage: M.is_affine()
True
sage: M = CoxeterMatrix([[1, 3],[3,1]])
sage: M.is_affine()
False
sage: M = CoxeterMatrix([[1, -1, 7], [-1, 1, 3], [7, 3, 1]])
sage: M.is_affine()
False
```

**is_crystallographic()**

Return whether `self` is crystallographic.

A Coxeter matrix is crystallographic if all non-diagonal entries are either 2, 3, 4, or 6.

**EXAMPLES:**

```
sage: CoxeterMatrix(['F',4]).is_crystallographic()
True
sage: CoxeterMatrix(['H',3]).is_crystallographic()
False
```
**is_finite()**

Return if `self` is a finite type or `False` if unknown.

**EXAMPLES:**

```python
sage: M = CoxeterMatrix(['C',4])
sage: M.is_finite()
True
sage: M = CoxeterMatrix(['D',4,1])
sage: M.is_finite()
False
sage: M = CoxeterMatrix([[1, -1], [-1, 1]])
sage: M.is_finite()
False
```

**is_irreducible()**

Return whether `self` is irreducible.

A Coxeter matrix is irreducible if the Coxeter graph is connected.

**EXAMPLES:**

```python
sage: CoxeterMatrix([['F',4],['A',1]]).is_irreducible()
False
sage: CoxeterMatrix(['H',3]).is_irreducible()
True
```

**is_simply_laced()**

Return if `self` is simply-laced.

A Coxeter matrix is simply-laced if all non-diagonal entries are either 2 or 3.

**EXAMPLES:**

```python
sage: cm = CoxeterMatrix([[1,3,3,3], [3,1,3,3], [3,3,1,3], [3,3,3,1]])
sage: cm.is_simply_laced()
True
```

**rank()**

Return the rank of `self`.

**EXAMPLES:**

```python
sage: CoxeterMatrix(['C',3]).rank()
3
sage: CoxeterMatrix(['A2','B2','F4']).rank()
8
```

**relabel (relabelling)**

Return a relabelled copy of this Coxeter matrix.

**INPUT:**

* relabelling – a function (or dictionary)

**OUTPUT:**

an isomorphic Coxeter type obtained by relabelling the nodes of the Coxeter graph. Namely, the node with label `i` is relabelled `f(i)` (or, by `f[i]` if `f` is a dictionary).

**EXAMPLES:**
sage: CoxeterMatrix(['F',4]).relabel({ 1:2, 2:3, 3:4, 4:1})
[[1 4 2 3]
 [4 1 3 2]
 [2 3 1 2]
 [3 2 2 1]]
sage: CoxeterMatrix(['F',4]).relabel(lambda x: x+1 if x<4 else 1)
[[1 4 2 3]
 [4 1 3 2]
 [2 3 1 2]
 [3 2 2 1]]

```
classmethod samples (finite=None, affine=None, crystallographic=None, higher_rank=None)
Return a sample of the available Coxeter types.

INPUT:
- finite – (default: None) a boolean or None
- affine – (default: None) a boolean or None
- crystallographic – (default: None) a boolean or None
- higher_rank – (default: None) a boolean or None

The sample contains all the exceptional finite and affine Coxeter types, as well as typical representatives of the infinite families.

Here the higher_rank term denotes non-finite, non-affine, Coxeter groups (including hyperbolic types).

Todo: Implement the hyperbolic and compact hyperbolic in the samples.
```

```
EXAMPLES:
sage: [CM.coxeter_type() for CM in CoxeterMatrix.samples()]
[ Coxeter type of ['A', 1], Coxeter type of ['A', 5],
  Coxeter type of ['B', 5], Coxeter type of ['D', 4],
  Coxeter type of ['D', 5], Coxeter type of ['E', 6],
  Coxeter type of ['E', 7], Coxeter type of ['E', 8],
  Coxeter type of ['F', 4], Coxeter type of ['H', 3],
  Coxeter type of ['H', 4], Coxeter type of ['I', 10],
  Coxeter type of ['A', 2, 1], Coxeter type of ['B', 5, 1],
  Coxeter type of ['C', 5, 1], Coxeter type of ['D', 5, 1],
  Coxeter type of ['E', 6, 1], Coxeter type of ['E', 7, 1],
  Coxeter type of ['E', 8, 1], Coxeter type of ['F', 4, 1],
  [1 -1 -1]
  [-1 1 -1]
  Coxeter type of ['G', 2, 1], Coxeter type of ['A', 1, 1], [-1 -1 1],
  (continues on next page)
```
The finite, affine and crystallographic options allow respectively for restricting to (non) finite, (non) affine, and (non) crystallographic Cartan types:

```python
sage: [CM.coxeter_type() for CM in CoxeterMatrix.samples(finite=True)]
[Coxeter type of ['A', 1], Coxeter type of ['A', 5],
 Coxeter type of ['B', 5], Coxeter type of ['D', 4],
 Coxeter type of ['D', 5], Coxeter type of ['E', 6],
 Coxeter type of ['E', 7], Coxeter type of ['E', 8],
 Coxeter type of ['F', 4], Coxeter type of ['H', 3],
 Coxeter type of ['H', 4], Coxeter type of ['I', 10]]

sage: [CM.coxeter_type() for CM in CoxeterMatrix.samples(affine=True)]
[Coxeter type of ['A', 2, 1], Coxeter type of ['B', 5, 1],
 Coxeter type of ['C', 5, 1], Coxeter type of ['D', 5, 1],
 Coxeter type of ['E', 6, 1], Coxeter type of ['E', 7, 1],
 Coxeter type of ['E', 8, 1], Coxeter type of ['F', 4, 1],
 Coxeter type of ['G', 2, 1], Coxeter type of ['A', 1, 1]]

sage: [CM.coxeter_type() for CM in CoxeterMatrix.samples(crystallographic=True)]
[Coxeter type of ['A', 1], Coxeter type of ['A', 5],
 Coxeter type of ['B', 5], Coxeter type of ['D', 4],
 Coxeter type of ['D', 5], Coxeter type of ['E', 6],
 Coxeter type of ['E', 7], Coxeter type of ['E', 8],
 Coxeter type of ['F', 4], Coxeter type of ['A', 2, 1],
 Coxeter type of ['B', 5, 1], Coxeter type of ['C', 5, 1],
 Coxeter type of ['D', 5, 1], Coxeter type of ['E', 6, 1],
 Coxeter type of ['E', 7, 1], Coxeter type of ['E', 8, 1],
 Coxeter type of ['F', 4, 1], Coxeter type of ['G', 2, 1]]

sage: CoxeterMatrix.samples(crystallographic=False)
[
  [1 3 2 2]
  [1 3 2]  [3 1 3 2]  [1 -1 -1]  [1 2 3]
  [3 1 5]  [2 3 1 5]  [1 10]  [1 -1]  [-1 1 -1]  [2 1 7]
  [2 5 1], [2 2 5 1], [10 1], [-1 1], [-1 -1 1], [3 7 1],
  [1 -2 3 2]
  [-2 1 2 3]
  [3 2 1 -8]
  [2 3 -8 1]
]
```

Todo: add some reducible Coxeter types (suggestions?)

```python
sage.combinat.root_system.coxeter_matrix.check_coxeter_matrix(m)
```
Check if \( m \) represents a generalized Coxeter matrix and raise and error if not.

EXAMPLES:
sage: from sage.combinat.root_system.coxeter_matrix import check_coxeter_matrix
sage: m = matrix([[1,3,2],[3,1,-1],[2,-1,1]])
sage: check_coxeter_matrix(m)
sage: m = matrix([[1,3],[3,1],[2,-1]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
  ... ValueError: not a square matrix
sage: m = matrix([[1,3,2],[3,1,-1],[2,-1,2]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
  ... ValueError: the matrix diagonal is not all 1
sage: m = matrix([[1,3,3],[3,1,-1],[2,-1,1]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
  ... ValueError: the matrix is not symmetric
sage: m = matrix([[1,3,1/2],[3,1,-1],[1/2,-1,1]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
  ... ValueError: invalid Coxeter label 1/2
sage: m = matrix([[1,3,1],[3,1,-1],[1,-1,1]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
  ... ValueError: invalid Coxeter label 1

sage.combinat.root_system.coxeter_matrix.coxeter_matrix_as_function(t)

Return the Coxeter matrix, as a function.

INPUT:

• t – a Cartan type

EXAMPLES:

sage: from sage.combinat.root_system.coxeter_matrix import coxeter_matrix_as_function
sage: f = coxeter_matrix_as_function(['A',4])
sage: matrix([[f(i,j) for j in range(1,5)] for i in range(1,5)])
[1 3 2 2]
[3 1 3 2]
[2 3 1 3]
[2 2 3 1]

sage.combinat.root_system.coxeter_matrix.recognize_coxeter_type_from_matrix(coxeter_matrix, index_set)

Return the Coxeter type of coxeter_matrix if known, otherwise return None.

EXAMPLES:

Some infinite ones:
Some finite ones:

```python
sage: C = CoxeterMatrix([[1,3,2],[3,1,-1],[2,-1,1]])
sage: C.is_finite()  # indirect doctest
False
sage: C = CoxeterMatrix([[-1,-1],[1,-1,1],[1,-1,1]])
sage: C.is_finite()  # indirect doctest
False
```

Some affine graphs:

```python
sage: m = matrix(CoxeterMatrix(['D', 4]))
sage: CoxeterMatrix(m).is_finite()  # indirect doctest
True
sage: m = matrix(CoxeterMatrix(['H', 4]))
sage: CoxeterMatrix(m).is_finite()  # indirect doctest
True
sage: C = CoxeterMatrix(CoxeterType(['A',10]).coxeter_graph()).coxeter_type()
Coxeter type of ['A', 10]
sage: C = CoxeterMatrix(CoxeterType(['B',10]).coxeter_graph()).coxeter_type()
Coxeter type of ['B', 10]
sage: C = CoxeterMatrix(CoxeterType(['C',10]).coxeter_graph()).coxeter_type()
Coxeter type of ['B', 10]
sage: C = CoxeterMatrix(CoxeterType(['D',10]).coxeter_graph()).coxeter_type()
Coxeter type of ['D', 10]
sage: C = CoxeterMatrix(CoxeterType(['E',6]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 6]
sage: C = CoxeterMatrix(CoxeterType(['E',7]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 7]
sage: C = CoxeterMatrix(CoxeterType(['E',8]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 8]
sage: C = CoxeterMatrix(CoxeterType(['F',4]).coxeter_graph()).coxeter_type()
Coxeter type of ['F', 4]
sage: C = CoxeterMatrix(CoxeterType(['G',2]).coxeter_graph()).coxeter_type()
Coxeter type of ['G', 2]
sage: C = CoxeterMatrix(CoxeterType(['H',3]).coxeter_graph()).coxeter_type()
Coxeter type of ['H', 3]
sage: C = CoxeterMatrix(CoxeterType(['H',4]).coxeter_graph()).coxeter_type()
Coxeter type of ['H', 4]
sage: C = CoxeterMatrix(CoxeterType(['I',100]).coxeter_graph()).coxeter_type()
Coxeter type of ['I', 100]
```

(continues on next page)
sage: CoxeterMatrix(CoxeterType(['E',8,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 8, 1]
sage: CoxeterMatrix(CoxeterType(['F',4,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['F', 4, 1]
sage: CoxeterMatrix(CoxeterType(['G',2,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['G', 2, 1]

5.1.230 Coxeter Types

class sage.combinat.root_system.coxeter_type.CoxeterType

Bases: sage.structure.sage_object.SageObject

Abstract class for Coxeter types.

bilinear_form(R=None)

Return the bilinear form over \( R \) associated to self.

INPUT:
- \( R \) – (default: universal cyclotomic field) a ring used to compute the bilinear form

EXAMPLES:

sage: CoxeterType(['A', 2, 1]).bilinear_form()
[ 1 -1/2 -1/2]
[-1/2 1 -1/2]
[-1/2 -1/2 1]
sage: CoxeterType(['H', 3]).bilinear_form()
[ 1 -1/2 0]
[-1/2 1 1/2 *E(5)^2 + 1/2*E(5)^3]
[ 0 1/2 *E(5)^2 + 1/2*E(5)^3 1]
sage: C = CoxeterMatrix([[1,-1,-1],[-1,1,-1],[-1,-1,1]])
sage: C.bilinear_form()
[ 1 -1 -1]
[-1 1 -1]
[-1 -1 1]

coxeter_graph()

Return the Coxeter graph associated to self.

EXAMPLES:

sage: CoxeterType(['A', 3]).coxeter_graph()
Graph on 3 vertices
sage: CoxeterType(['A', 3, 1]).coxeter_graph()
Graph on 4 vertices

coxeter_matrix()

Return the Coxeter matrix associated to self.

EXAMPLES:

sage: CoxeterType(['A', 3]).coxeter_matrix()
[1 3 2]
[3 1 3]
[2 3 1]
sage: CoxeterType(['A', 3, 1]).coxeter_matrix()
index_set()
Return the index set for self.
This is the list of the nodes of the associated Coxeter graph.

EXAMPLES:

```python
sage: CoxeterType(['A', 3, 1]).index_set()
(0, 1, 2, 3)
sage: CoxeterType(['D', 4]).index_set()
(1, 2, 3, 4)
sage: CoxeterType(['A', 7, 2]).index_set()
(0, 1, 2, 3, 4)
sage: CoxeterType(['A', 6, 2]).index_set()
(0, 1, 2, 3)
sage: CoxeterType(['D', 6, 2]).index_set()
(0, 1, 2, 3, 4, 5)
sage: CoxeterType(['E', 6, 1]).index_set()
(0, 1, 2, 3, 4, 5, 6)
sage: CoxeterType(['E', 6, 2]).index_set()
(0, 1, 2, 3, 4)
sage: CoxeterType(['A', 2, 2]).index_set()
(0, 1)
sage: CoxeterType(['G', 2, 1]).index_set()
(0, 1, 2)
sage: CoxeterType(['F', 4, 1]).index_set()
(0, 1, 2, 3, 4)
```

is_affine()
Return whether self is affine.

EXAMPLES:

```python
sage: CoxeterType(['A', 3]).is_affine()
False
sage: CoxeterType(['A', 3, 1]).is_affine()
True
```

is_crystallographic()
Return whether self is crystallographic.
This returns False by default. Derived class should override this appropriately.

EXAMPLES:

```python
sage: [ [t, t.is_crystallographic()] for t in CartanType.samples(finite=True) ]
```

(continues on next page)
is_finite()
Return whether self is finite.

EXAMPLES:

```python
sage: CoxeterType(['A', 4]).is_finite()
True
sage: CoxeterType(['A', 4, 1]).is_finite()
False
```

is_simply_laced()
Return whether self is simply laced.

This returns False by default. Derived class should override this appropriately.

EXAMPLES:

```python
sage: [ [t, t.is_simply_laced() ] for t in CartanType.samples() ]
[['A', 1], True], [['A', 5], True],
[['B', 1], True], [['B', 5], False],
[['C', 1], True], [['C', 5], False],
[['D', 2], True], [['D', 3], True], [['D', 5], True],
[['E', 6], True], [['E', 7], True], [['E', 8], True],
[['F', 4], False], [['G', 2], False],
[['I', 5], False], [['H', 3], False], [['H', 4], False],
[['A', 1, 1], False], [['A', 5, 1], True],
[['B', 1, 1], False], [['B', 5, 1], False],
[['C', 1, 1], False], [['C', 5, 1], False],
[['D', 3, 1], True], [['D', 5, 1], True],
[['E', 6, 1], True], [['E', 7, 1], True], [['E', 8, 1], True],
[['F', 4, 1], False], [['G', 2, 1], False],
[['BC', 1, 2], False], [['BC', 5, 2], False],
[['BC', 5, 1]^*, False], [['BC', 4, 1]^*, False],
[['F', 4, 1]^*, False], [['G', 2, 1]^*, False],
[['BC', 1, 2]^*, False], [['BC', 5, 2]^*, False]]
```

rank()
Return the rank of self.

This is the number of nodes of the associated Coxeter graph.

EXAMPLES:

```python
sage: CoxeterType(['A', 4]).rank()
4
sage: CoxeterType(['A', 7, 2]).rank()
5
sage: CoxeterType(['I', 8]).rank()
2
```

classmethod samples (finite=None, affine=None, crystallographic=None)
Return a sample of the available Coxeter types.

INPUT:
• finite – a boolean or None (default: None)
• affine – a boolean or None (default: None)
• crystallographic – a boolean or None (default: None)

The sample contains all the exceptional finite and affine Coxeter types, as well as typical representatives of the infinite families.

EXAMPLES:

```python
sage: CoxeterType.samples()
[Coxeter type of ['A', 1], Coxeter type of ['A', 5],
 Coxeter type of ['B', 1], Coxeter type of ['B', 5],
 Coxeter type of ['C', 1], Coxeter type of ['C', 5],
 Coxeter type of ['D', 4], Coxeter type of ['D', 5],
 Coxeter type of ['E', 6], Coxeter type of ['E', 7],
 Coxeter type of ['E', 8], Coxeter type of ['F', 4],
 Coxeter type of ['H', 3], Coxeter type of ['H', 4],
 Coxeter type of ['I', 10], Coxeter type of ['A', 2, 1],
 Coxeter type of ['B', 5, 1], Coxeter type of ['C', 5, 1],
 Coxeter type of ['D', 5, 1], Coxeter type of ['E', 6, 1],
 Coxeter type of ['E', 7, 1], Coxeter type of ['E', 8, 1],
 Coxeter type of ['F', 4, 1], Coxeter type of ['G', 2, 1],
 Coxeter type of ['A', 1, 1]]
```

The finite, affine and crystallographic options allow respectively for restricting to (non) finite, (non) affine, and (non) crystallographic Cartan types:

```python
sage: CoxeterType.samples(finite=True)
[Coxeter type of ['A', 1], Coxeter type of ['A', 5],
 Coxeter type of ['B', 1], Coxeter type of ['B', 5],
 Coxeter type of ['C', 1], Coxeter type of ['C', 5],
 Coxeter type of ['D', 4], Coxeter type of ['D', 5],
 Coxeter type of ['E', 6], Coxeter type of ['E', 7],
 Coxeter type of ['E', 8], Coxeter type of ['F', 4],
 Coxeter type of ['H', 3], Coxeter type of ['H', 4],
 Coxeter type of ['I', 10]]
```

```python
sage: CoxeterType.samples(affine=True)
[Coxeter type of ['A', 2, 1], Coxeter type of ['B', 5, 1],
 Coxeter type of ['C', 5, 1], Coxeter type of ['D', 5, 1],
 Coxeter type of ['E', 6, 1], Coxeter type of ['E', 7, 1],
 Coxeter type of ['E', 8, 1], Coxeter type of ['F', 4, 1],
 Coxeter type of ['G', 2, 1], Coxeter type of ['A', 1, 1]]
```

```python
sage: CoxeterType.samples(crystallographic=True)
[Coxeter type of ['A', 1], Coxeter type of ['A', 5],
 Coxeter type of ['B', 1], Coxeter type of ['B', 5],
 Coxeter type of ['C', 1], Coxeter type of ['C', 5],
 Coxeter type of ['D', 4], Coxeter type of ['D', 5],
 Coxeter type of ['E', 6], Coxeter type of ['E', 7],
 Coxeter type of ['E', 8], Coxeter type of ['F', 4],
 Coxeter type of ['A', 2, 1], Coxeter type of ['B', 5, 1],
 Coxeter type of ['C', 5, 1], Coxeter type of ['D', 5, 1],
 Coxeter type of ['E', 6, 1], Coxeter type of ['E', 7, 1],
 Coxeter type of ['E', 8, 1], Coxeter type of ['F', 4, 1],
 Coxeter type of ['G', 2, 1], Coxeter type of ['A', 1, 1]]
```

(continues on next page)
sage: CoxeterType.samples(crystallographic=False)
[Coxeter type of ['H', 3],
Coxeter type of ['H', 4],
Coxeter type of ['I', 10]]

Todo: add some reducible Coxeter types (suggestions?)

class sage.combinat.root_system.coxeter_type.CoxeterTypeFromCartanType(cartan_type)
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.combinat.root_system.coxeter_type.CoxeterType

A Coxeter type associated to a Cartan type.

cartan_type()
Return the Cartan type used to construct self.

EXAMPLES:

sage: C = CoxeterType(['C',3])
sage: C.cartan_type()
['C', 3]

component_types()
A list of Coxeter types making up the reducible type.

EXAMPLES:

sage: CoxeterType(['A',2],['B',2]).component_types()
[Coxeter type of ['A', 2], Coxeter type of ['B', 2]]
sage: CoxeterType('A4xB3').component_types()
[Coxeter type of ['A', 4], Coxeter type of ['B', 3]]
sage: CoxeterType(['A', 2]).component_types()
Traceback (most recent call last):
... ValueError: component types only defined for reducible types

coxeter_graph()
Return the Coxeter graph of self.

EXAMPLES:

sage: C = CoxeterType(['H',3])
sage: C.coxeter_graph().edges()
[(1, 2, 3), (2, 3, 5)]

coxeter_matrix()
Return the Coxeter matrix associated to self.

EXAMPLES:

sage: C = CoxeterType(['H',3])
sage: C.coxeter_matrix()
[1 3 2]
[3 1 5]
[2 5 1]
**index_set()**

Return the index set of self.

**EXAMPLES:**

```python
sage: C = CoxeterType(['A', 4])
sage: C.index_set()
(1, 2, 3, 4)
```

**is_affine()**

Return if self is an affine type.

**EXAMPLES:**

```python
sage: C = CoxeterType(['F', 4, 1])
sage: C.is_affine()
True
```

**is_crystallographic()**

Return if self is crystallographic.

**EXAMPLES:**

```python
sage: C = CoxeterType(['C', 3])
sage: C.is_crystallographic()
True
sage: C = CoxeterType(['H', 3])
sage: C.is_crystallographic()
False
```

**is_finite()**

Return if self is a finite type.

**EXAMPLES:**

```python
sage: C = CoxeterType(['E', 6])
sage: C.is_finite()
True
```

**is_irreducible()**

Return if self is irreducible.

**EXAMPLES:**

```python
sage: C = CoxeterType(['A', 5])
sage: C.is_irreducible()
True
sage: C = CoxeterType('B3xB3')
sage: C.is_irreducible()
False
```

**is_reducible()**

Return if self is reducible.

**EXAMPLES:**
is_simply_laced()
Return if self is simply-laced.

EXAMPLES:

```python
sage: C = CoxeterType(['A', 5])
sage: C.is_simply_laced()
True
sage: C = CoxeterType(['B', 3])
sage: C.is_simply_laced()
False
```

rank()
Return the rank of self.

EXAMPLES:

```python
sage: C = CoxeterType(['I', 16])
sage: C.rank()
2
```

relabel (relabelling)
Return a relabelled copy of self.

EXAMPLES:

```python
sage: ct = CoxeterType(['A', 2])
sage: ct.relabel({1:-1, 2:-2})
Coxeter type of ['A', 2] relabelled by {1: -1, 2: -2}
```

type()
Return the type of self.

EXAMPLES:

```python
sage: C = CoxeterType(['A', 4])
sage: C.type()
'A'
```
5.1.231 Dynkin diagrams

AUTHORS:

• Travis Scrimshaw (2012-04-22): Nicolas M. Thiery moved Cartan matrix creation to here and I cached results for speed.
• Travis Scrimshaw (2013-06-11): Changed inputs of Dynkin diagrams to handle other Dynkin diagrams and graphs. Implemented remaining Cartan type methods.

`sage.combinat.root_system.dynkin_diagram.DynkinDiagram(*args,**kwds)`
Return the Dynkin diagram corresponding to the input.

INPUT:

The input can be one of the following:

• empty to obtain an empty Dynkin diagram
• a Cartan type
• a Cartan matrix
• a Cartan matrix and an indexing set

One can also input an indexing set by passing a tuple using the optional argument `index_set`.

The edge multiplicities are encoded as edge labels. For the corresponding Cartan matrices, this uses the convention in Hong and Kang, Kac, Fulton and Harris, and crystals. This is the opposite convention in Bourbaki and Wikipedia’s Dynkin diagram (Wikipedia article Dynkin_diagram). That is for $i \neq j$:

\[
\begin{align*}
    i & \rightarrow k \leftarrow j \quad \Leftrightarrow \quad a_{ij} = -k \\
    & \Leftrightarrow \quad -\text{scalar}(\text{coroot}[i], \text{root}[j]) = k \\
    & \Leftrightarrow \quad \text{multiple arrows point from the longer root to the shorter one}
\end{align*}
\]

For example, in type $C_2$, we have:

```
sage: C2 = DynkinDiagram(['C',2]); C2

0---O---O
1 2
C2

sage: C2.cartan_matrix()

[ 2 -2]
[-1 2]
```

However Bourbaki would have the Cartan matrix as:

\[
\begin{bmatrix}
    2 & -1 \\
    -2 & 2
\end{bmatrix}
\]

EXAMPLES:

```
sage: DynkinDiagram(['A', 4])

O---O---O---0
1 2 3 4
A4

sage: DynkinDiagram(['A',1],['A',1])

O
```

(continues on next page)
We can also create Dynkin diagrams from arbitrary Cartan matrices:

```
sage: C = CartanMatrix([[2, -3], [-4, 2]])
sage: DynkinDiagram(C)
Dynkin diagram of rank 2
sage: C.index_set()
(0, 1)
sage: CI = CartanMatrix([[2, -3], [-4, 2]], [3, 5])
sage: DI = DynkinDiagram(CI)
sage: DI.index_set()
(3, 5)
sage: CII = CartanMatrix([[2, -3], [-4, 2]])
```
sage: DII = DynkinDiagram(CII, ('y', 'x'))
sage: DII.index_set()
('x', 'y')

See also:

\texttt{CartanType()} for a general discussion on Cartan types and in particular node labeling conventions.

class \texttt{sage.combinat.root_system.dynkin_diagram.DynkinDiagram\_class}(t=None,
in-
dex\_set=None,
odd\_isotropic\_roots=[], **op-
tions)

Bases: \texttt{sage.graphs.digraph.DiGraph}, \texttt{sage.combinat.root_system.cartan_type.
CartanType\_abstract}

A Dynkin diagram.

See also:

\texttt{DynkinDiagram()}

INPUT:

\begin{itemize}
\item \texttt{t} – a Cartan type, Cartan matrix, or \texttt{None}
\end{itemize}

EXAMPLES:

\begin{verbatim}
sage: DynkinDiagram(["A", 3])  
O---O---O  
1 2 3
A3
sage: C = CartanMatrix([[2, -3], [-4, 2]])
sage: DynkinDiagram(C)
Dynkin diagram of rank 2
sage: C.dynkin_diagram().cartan_matrix() == C
True
\end{verbatim}

\texttt{add\_edge}(i, j, label=1)

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.root_system.dynkin_diagram import DynkinDiagram\_class
sage: d = DynkinDiagram\_class(CartanType(["A",3]))
sage: sorted(d.edges())
[]
sage: d.add\_edge(2, 3)
sage: sorted(d.edges())
[(2, 3, 1), (3, 2, 1)]
\end{verbatim}

\texttt{static an\_instance()}

Returns an example of Dynkin diagram

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.root_system.dynkin_diagram import DynkinDiagram\_class
sage: g = DynkinDiagram\_class.an\_instance()
sage: g
Dynkin diagram of rank 3
\end{verbatim}
sage: g.cartan_matrix()
[ 2 -1 -1]
[-2 2 -1]
[-1 -1 2]

cartan_matrix()

Returns the Cartan matrix for this Dynkin diagram

EXAMPLES:

sage: DynkinDiagram(['C',3]).cartan_matrix()
[ 2 -1 0]
[-1 2 -2]
[ 0 -1 2]

cartan_type()

EXAMPLES:

sage: DynkinDiagram("A2","B2","F4").cartan_type()
A2xB2xF4

column(j)

Returns the $j^{th}$ column $(a_{i,j})$ of the Cartan matrix corresponding to this Dynkin diagram, as a container (or iterator) of tuples $(i, a_{i,j})$

EXAMPLES:

sage: g = DynkinDiagram(['B',4])
sage: [(i,a) for (i,a) in g.column(3)]
[(3, 2), (2, -1), (4, -2)]
dual()

Returns the dual Dynkin diagram, obtained by reversing all edges.

EXAMPLES:

sage: D = DynkinDiagram(['C',3])
sage: D.edges()
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]
sage: D.dual()
O---O=<=O
1 2 3
B3
sage: D.dual().edges()
[(1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1)]
sage: D.dual() == DynkinDiagram(['B',3])
True
dynkin_diagram()

EXAMPLES:

sage: DynkinDiagram(['C',3]).dynkin_diagram()
O---O=<=O
1 2 3
C3

index_set()

EXAMPLES:
```python
sage: DynkinDiagram(['C',3]).index_set()
(1, 2, 3)
sage: DynkinDiagram("A2","B2","F4").index_set()
(1, 2, 3, 4, 5, 6, 7, 8)
```

**is_affine()**

Check if self corresponds to an affine root system.

**EXAMPLES:**

```python
sage: CartanType(['F',4]).dynkin_diagram().is_affine()
False
sage: D = DynkinDiagram(CartanMatrix([[2, -4], [-3, 2]]))
sage: D.is_affine()
False
```

**is_crystallographic()**

Implements `CartanType_abstract.is_crystallographic()`

A Dynkin diagram always corresponds to a crystallographic root system.

**EXAMPLES:**

```python
sage: CartanType(['F',4]).dynkin_diagram().is_crystallographic()
True
```

**is_finite()**

Check if self corresponds to a finite root system.

**EXAMPLES:**

```python
sage: CartanType(['F',4]).dynkin_diagram().is_finite()
True
sage: D = DynkinDiagram(CartanMatrix([[2, -4], [-3, 2]]))
sage: D.is_finite()
False
```

**is_irreducible()**

Check if self corresponds to an irreducible root system.

**EXAMPLES:**

```python
sage: CartanType(['F',4]).dynkin_diagram().is_irreducible()
True
sage: CM = CartanMatrix([[2,-6],[-4,2]])
sage: CM.dynkin_diagram().is_irreducible()
True
sage: CartanType("A2xB3").dynkin_diagram().is_irreducible()
False
sage: CM = CartanMatrix([[2,-6,0],[-4,2,0],[0,0,2]])
sage: CM.dynkin_diagram().is_irreducible()
False
```

**odd_isotropic_roots()**

Return the odd isotropic roots of self.

**EXAMPLES:**

```python
```

---

5.1. Comprehensive Module list 2139
```python
sage: g = DynkinDiagram(['A',4])
sage: g.odd_isotropic_roots()
()  # No isotropic roots
sage: g = DynkinDiagram(['A',[4,3]])
sage: g.odd_isotropic_roots()
(0,)
```

**rank()**

Returns the index set for this Dynkin diagram

**EXAMPLES:**

```python
sage: DynkinDiagram(['C',3]).rank()
3
sage: DynkinDiagram("A2","B2","F4").rank()
8
```

**relabel(*args, **kwds)**

Return the relabelled Dynkin diagram of `self`.

**INPUT:** see `relabel()`

There is one difference: the default value for `inplace` is `False` instead of `True`.

**EXAMPLES:**

```python
sage: D = DynkinDiagram(['C',3])
sage: D.relabel({1:0, 2:4, 3:1})
O---O=<=O
0 4 1
C3 relabelled by {1: 0, 2: 4, 3: 1}
sage: D
O---O=<=O
1 2 3
C3

sage: _ = D.relabel({1:0, 2:4, 3:1}, inplace=True)
sage: D
O---O=<=O
0 4 1
C3 relabelled by {1: 0, 2: 4, 3: 1}

sage: D = DynkinDiagram(['A', [1,2]])
sage: Dp = D.relabel([-1:4, 0:-3, 1:3, 2:2])
sage: Dp
O---X---O---O
4 -3 3 2
A1|2 relabelled by {-1: 4, 0: -3, 1: 3, 2: 2}
sage: Dp.odd_isotropic_roots()
(-3,)
```

(continues on next page)
D5 relabelled by \{1: 0, 2: 1, 3: 2, 4: 3, 5: 4\}
\begin{verbatim}
sage: perm
{1: 0, 2: 1, 3: 2, 4: 3, 5: 4}
sage: perm = D.relabel(range(5), return_map=True, inplace=True)
sage: D
O 4
|   
O---O---O---O
0 1 2 3
D5 relabelled by \{1: 0, 2: 1, 3: 2, 4: 3, 5: 4\}
sage: perm
{1: 0, 2: 1, 3: 2, 4: 3, 5: 4}
\end{verbatim}

\textbf{row}(i)

Returns the \textit{i}-th row \((a_{ij})_j\) of the Cartan matrix corresponding to this Dynkin diagram, as a container (or iterator) of tuples \((j, a_{ij})\)

\textbf{EXAMPLES:}
\begin{verbatim}
sage: g = DynkinDiagram(['C',4])
sage: [(i,a) for (i,a) in g.row(3)]
[(3, 2), (2, -1), (4, -2)]
\end{verbatim}

\textbf{subtype}(\textit{index\_set})

Return a subtype of \textit{self} given by \textit{index\_set}.

A subtype can be considered the Dynkin diagram induced from the Dynkin diagram of \textit{self} by \textit{index\_set}.

\textbf{EXAMPLES:}
\begin{verbatim}
sage: D = DynkinDiagram(['A',6,2]); D
O=<=O---O=<=O
0 1 2 3
BC3~
sage: D.subtype([1,2,3])
Dynkin diagram of rank 3
\end{verbatim}

\textbf{symmetrizer}()

Return the symmetrizer of the corresponding Cartan matrix.

\textbf{EXAMPLES:}
\begin{verbatim}
sage: d = DynkinDiagram()
sage: d.add_edge(1,2,3)
sage: d.add_edge(2,3)
sage: d.add_edge(3,4,3)
sage: d.symmetrizer()
Finite family {1: 9, 2: 3, 3: 3, 4: 1}
\end{verbatim}

\textbf{sage.combinat.root_system.dynkin_diagram.precheck}(t, letter=None, length=None, affine=None, n_ge=None, n=None)
```python
sage: from sage.combinat.root_system.dynkin_diagram import precheck
sage: ct = CartanType(['A',4])
sage: precheck(ct, letter='C')
Traceback (most recent call last):...
ValueError: t[0] must be = 'C'
sage: precheck(ct, affine=1)
Traceback (most recent call last):...
ValueError: t[2] must be = 1
sage: precheck(ct, length=3)
Traceback (most recent call last):...
ValueError: len(t) must be = 3
sage: precheck(ct, n=3)
Traceback (most recent call last):...
ValueError: t[1] must be = 3
sage: precheck(ct, n_ge=5)
Traceback (most recent call last):...
ValueError: t[1] must be >= 5
```

### 5.1.232 Hecke algebra representations

```python
class sage.combinat.root_system.hecke_algebra_representation.CherednikOperatorsEigenvectors(T, T_Y=None, normalized=True):
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.sage_object.SageObject

A class for the family of eigenvectors of the $Y$ Cherednik operators for a module over a (Double) Affine Hecke algebra

**INPUT:**

- $T$ – a family $(T_i)_{i \in I}$ implementing the action of the generators of an affine Hecke algebra on $self$. The intertwiner operators are built from these.
- $T_Y$ – a family $(T_Y^i)_{i \in I}$ implementing the action of the generators of an affine Hecke algebra on $self$.
  By default, this is $T$. But this can be used to get the action of the full Double Affine Hecke Algebra. The $Y$ operators are built from the $T_Y$.

This returns a function $\mu \mapsto E_\mu$ which uses intertwining operators to calculate recursively eigenvectors $E_\mu$ for the action of the torus of the affine Hecke algebra with eigenvalue given by $f$. Namely:

$$E_\mu.Y^\lambda = f(\lambda^\vee, \mu)E_\mu$$

**Assumptions:**

- $\text{seed}(\mu)$ initializes the recurrence by returning an appropriate eigenvector $E_\mu$ for $\mu$ trivial enough. For example, for nonsymmetric Macdonald polynomials $\text{seed}(\mu)$ returns the monomial $X^\mu$ for a minuscule weight $\mu$.
- $f$ is almost equivariant. Namely, $f(\lambda^\vee, \mu) = f(\lambda^\vee s_i, \text{twist}(\mu, i))$ whenever $i$ is a descent of $\mu$.
- $\text{twist}(\mu, i)$ maps $\mu$ closer to the dominant chamber whenever $i$ is a descent of $\mu$.
```
Todo: Add tests for the above assumptions, and also that the classical operators $T_1,...,T_n$ from $T$ and $T_Y$ coincide.

Y() Return the Cherednik operators.

EXAMPLES:

```
sage: W = WeylGroup(['B',2])
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: E.Y()
Lazy family (...)_{i in Coroot lattice of the Root system of type ['B', 2, 1]}
```

affine_lift(mu) Lift the index \(\mu\) to a space admitting an action of the affine Weyl group.

INPUT:

- \(\mu\) – an element \(\mu\) of the indexing set

In this space, one should have first_descent and apply_simple_reflection act properly.

EXAMPLES:

```
sage: W = WeylGroup(['A',3])
sage: W.element_class._repr_=lambda x: ''.join(str(i) for i in x.reduced_˓→word())
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w = W.an_element(); w
123
sage: E.affine_lift(w)
121
```

affine_retract (mu) Retract \(\mu\) from a space admitting an action of the affine Weyl group.

EXAMPLES:

```
sage: W = WeylGroup(['A',3])
sage: W.element_class._repr_=lambda x: ''.join(str(i) for i in x.reduced_˓→word())
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w = W.an_element(); w
123
sage: E.affine_retract(E.affine_lift(w)) == w
True
```

cartan_type () Return Cartan type of self.
EXAMPLES:

```
sage: W = WeylGroup(['B', 3])
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: E.cartan_type()
['B', 3, 1]
sage: NonSymmetricMacdonaldPolynomials(['B', 2, 1]).cartan_type()
['B', 2, 1]
```

domain()

The module on which the affine Hecke algebra acts.

EXAMPLES:

```
sage: W = WeylGroup(['B', 3])
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: E.domain()
Algebra of Weyl Group of type ['B', 3] (as a matrix group acting on the ambient space) over Multivariate Polynomial Ring in q1, q2 over Rational Field
```

eigenvalue(mu, l)

Return the eigenvalue of $Y_{\lambda^\vee}$ on $E_\mu$ computed by applying $Y_{\lambda^\vee}$ on $E_\mu$.

INPUT:

- `mu` – the index $\mu$ of an eigenvector, or a tentative eigenvector
- `l` – the index $\lambda^\vee$ of a Cherednik operator in `self.Y_index_set`

This default implementation applies explicitly $Y_\mu$ to $E_\lambda$.

EXAMPLES:

```
sage: W = WeylGroup(['B', 2])
sage: K = QQ['q1, q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w0 = W.long_element()
sage: Y = E.Y()
sage: alphacheck = Y.keys().simple_roots()
sage: E.eigenvalue(w0, alphacheck[1])
q1/(-q2)
sage: E.eigenvalue(w0, alphacheck[2])
q1/(-q2)
sage: E.eigenvalue(w0, alphacheck[0])
q2^2/q1^2
```

The following checks that all $E_\omega$ are eigenvectors, with eigenvalue given by Lemma 7.5 of [HST2008] (checked for $A_2, A_3$):
sage: Pcheck = Y.keys()
sage: Wcheck = Pcheck.weyl_group()
sage: P0check = Pcheck.classical()
sage: def height(root):
    ....:     return sum(P0check(root).coefficients())
sage: def eigenvalue(w, mu):
    ....:     return (-q2/q1)**height(Wcheck.from_reduced_word(w.reduced_word()).
    action(mu))
sage: all(E.eigenvalue(w, a) == eigenvalue(w, a) for w in E.keys() for a in Y.
    keys().simple_roots()) # long time (2.5s)
True

eigenvalues (mu)
Return the eigenvalues of $Y_{\alpha_0}, \ldots, Y_{\alpha_n}$ on $E_\mu$.

INPUT:

• mu – the index $\mu$ of an eigenvector or a tentative eigenvector

EXAMPLES:

sage: W = WeylGroup(['B',2])
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w0 = W.long_element()
sage: E.eigenvalues(w0)
[q2^2/q1^2, q1/(-q2), q1/(-q2)]
sage: w = W.an_element()
sage: E.eigenvalues(w)
[(-q2)/q1, (-q2^2)/(-q1^2), q1^3/(-q2^3)]

hecke_parameters (i)
Return the Hecke parameters for index $i$.

EXAMPLES:

sage: W = WeylGroup(['B',3])
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: T = KW.demazure_lusztig_operators(q1, q2, affine=True)
sage: E = T.Y_eigenvectors()
sage: E.hecke_parameters(1)
(q1, q2)
sage: E.hecke_parameters(2)
(q1, q2)
sage: E.hecke_parameters(0)
(q1, q2)

keys ()
The index set for the eigenvectors.

By default, this assumes that the eigenvectors span the full affine Hecke algebra module and that the
eigenvectors have the same indexing as the basis of this module.

EXAMPLES:
recursion($\mu$)
Return the indices used in the recursion.

INPUT:

- $\mu$ – the index $\mu$ of an eigenvector

EXAMPLES:

```python
sage: W = WeylGroup("A", 3)
sage: W.element_class._repr_ = lambda x: ".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1, q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: E.recursion(W.long_element())
[]
sage: w = W.an_element(); w
123
sage: E.recursion(w)
[1, 2, 1]
```

seed($\mu$)
Return the eigenvector for $\mu$ minuscule.

INPUT:

- $\mu$ – an element $\mu$ of the indexing set

OUTPUT: an element of $T$.domain()

This default implementation returns the monomial indexed by $\mu$.

EXAMPLES:

```python
sage: W = WeylGroup("A", 3)
sage: W.element_class._repr_ = lambda x: ".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1, q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: E.seed(W.long_element())
123121
```

twist($\mu$, $i$)
Act by $s_i$ on $\mu$.

By default, this calls the method apply_simple_reflection.

EXAMPLES:
```python
sage: W = WeylGroup(['B',3])
sage: W.element_class._repr_ = lambda x: ''.join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: T = KW.demazure_lusztig_operators(q1, q2, affine=True)
sage: E = T.Y_eigenvectors()
sage: w = W.an_element(); w
123
sage: E.twist(w,1)
1231
```

```python
class sage.combinat.root_system.hecke_algebra_representation.HeckeAlgebraRepresentation(domain, on_basis, cartan_type, q1, q2, q=1, side='right')):
```

Bases: sage.misc.fast_methods.WithEqualityById, sage.structure.sage_object.SageObject

A representation of an (affine) Hecke algebra given by the action of the $T$ generators

Let $F_i$ be a family of operators implementing an action of the operators $(T_i)_{i \in I}$ of the Hecke algebra on some vector space $\text{domain}$, given by their action on the basis of $\text{domain}$. This constructs the family of operators $(F_w)_{w \in W}$ describing the action of all elements of the basis $(T_w)_{w \in W}$ of the Hecke algebra. This is achieved by linearity on the first argument, and applying recursively the $F_i$ along a reduced word for $w = s_i \cdots s_k$:

$$F_w(x) = F_{i_k} \circ \cdots \circ F_{i_1}(x).$$

INPUT:

- $\text{domain}$ – a vector space
- $\ell$ – a function $f(l,i)$ taking a basis element $l$ of $\text{domain}$ and an index $i$, and returning $F_i$
- $\text{cartan\_type}$ – The Cartan type of the Hecke algebra
- $q1, q2$ – The eigenvalues of the generators $T$ of the Hecke algebra
- $\text{side}$ – “left” or “right” (default: “right”) whether this is a left or right representation

EXAMPLES:

```python
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = WeylGroup(['A',3]).algebra(QQ)
sage: H = KW.demazure_lusztig_operators(q1,q2); H
A representation of the (q1, q2)-Hecke algebra of type ['A', 3, 1] on Algebra of Weyl Group of type ['A', 3] (as a matrix group acting on the ambient space) over Rational Field
```

Among other things, it implements the $T_w$ operators, their inverses and compositions thereof:

5.1. Comprehensive Module list
and the Cherednik operators $Y^\lambda$:

```python
sage: H.Y()
Lazy family (...)_{i in Coroot lattice of the Root system of type ['A', 3, 1]}
```

REFERENCES:

**Ti_inverse_on_basis**(x, i)
The $T_i^{-1}$ operators, on basis elements

**INPUT:**

- x – the index of a basis element
- i – the index of a generator

**EXAMPLES:**

```python
sage: W = WeylGroup("A3")
sage: W.element_class._repr_lambdify = lambda x: ''.join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1,q2)
sage: w = W.an_element()
sage: rho.Ti_inverse_on_basis(w, 1)
-1/q2*1231 + ((q1+q2)/(q1*q2))*123
```

**Ti_on_basis**(x, i)
The $T_i$ operators, on basis elements.

**INPUT:**

- x – the index of a basis element
- i – the index of a generator

**EXAMPLES:**

```python
sage: W = WeylGroup("A3")
sage: W.element_class._repr_lambdify = lambda x: ''.join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1,q2)
sage: w = W.an_element()
sage: rho.Ti_on_basis(w,1)
q1*1231
```

**Tw**(word, signs=None, scalar=None)
Return $T_w$.

**INPUT:**

- word – a word $i_1, \ldots, i_k$ for some element $w$ of the Weyl group. See `straighten_word()` for how this word can be specified.
• signs – a list $\epsilon_1, \ldots, \epsilon_k$ of the same length as word with $\epsilon_i = \pm 1$ or None for $1, \ldots, l$ (default: None)

• scalar – an element $c$ of the base ring or None for $1, \ldots, l$ (default: None)

OUTPUT:

a module morphism implementing

$$T_w = T_{i_k} \circ \cdots \circ T_{i_1}$$

in left action notation; that is $T_{i_1}$ is applied first, then $T_{i_2}$, etc.

More generally, if scalar or signs is specified, the morphism implements

$$cT_{\epsilon_{i_k}} \circ \cdots \circ T_{\epsilon_{i_1}}.$$

EXAMPLES:

```python
sage: W = WeylGroup("A3")

sage: W.element_class._repr_ = lambda x: ('e' if not x.reduced_word() else ''.join(str(i) for i in x.reduced_word()))

sage: K = QQ['q1,q2'].fraction_field()

sage: q1, q2 = K.gens()

sage: KW = W.algebra(K)

sage: x = KW.an_element(); x
123 + 3*32 + 2*3 + e

sage: T = KW.demazure_lusztig_operators(q1,q2)

sage: T12 = T.Tw( (1,2) )

sage: T12(KW.one())
q1^2*12

sage: T[2](T[1](KW.one()))
q1^2*12

sage: T[1](T[2](KW.one()))
q1^2*21

sage: T12(x) == T[2](T[1](x))
True

This is $T_2 \circ T_1$:

```python
sage: T[2](T[1](KW.one()))
q1^2*12

sage: T[1](T[2](KW.one()))
q1^2*21

sage: T12(x) == T[2](T[1](x))
True
```

Now with signs and scalar coefficient we construct $3T_2 \circ T_1^{-1}$:

```python
sage: phi = T.Tw((1,2), (-1,1), 3)

sage: phi(KW.one())
((-3*q1)/q2)*12 + ((3*q1+3*q2)/q2)*2

sage: phi(T[1](x)) == 3*T[2](x)
True
```

For debugging purposes, one can recover the input data:

```python
sage: phi.word
(1, 2)

sage: phi.signs
(-1, 1)

sage: phi.scalar
3
```
**Tw_inverse** *(word)*

Return $T_w^{-1}$.

This is essentially a shorthand for $Tw()$ with all minus signs.

**Todo:** Add an example where $T_i \neq T_i^{-1}$

**EXAMPLES:**

```python
sage: W = WeylGroup(['A', 3])
sage: W.element_class._repr_ = lambda x: ''.join(str(i) for i in x.reduced_word())
sage: KW = W.algebra(QQ)
sage: rho = KW.demazure_lusztig_operators(1, -1)
sage: x = KW.monomial(W.an_element()); x
123
sage: word = [1, 2]
sage: rho.Tw(word)(x)
12312
sage: rho.Tw_inverse(word)(x)
12321
```

**Y** *(base_ring=\texttt{Integer Ring})*

Return the Cherednik operators $Y$ for this representation of an affine Hecke algebra.

**INPUT:**

- **self** – a representation of an affine Hecke algebra
- **base_ring** – the base ring of the coroot lattice

This is a family of operators indexed by the coroot lattice for this Cartan type. In practice this is currently indexed instead by the affine coroot lattice, even if this indexing is not one to one, in order to allow for $Y[a_0^\vee]$.

**EXAMPLES:**

```python
sage: W = WeylGroup(['A', 3])
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q2, q1)
sage: Y = rho.Y(); Y
Lazy family (...(i))_{i in Coroot lattice of the Root system of type ['A', 3, 1]}"
Y_eigenvectors()  
Return the family of eigenvectors for the Cherednik operators $Y$ of this representation of an affine Hecke algebra.

INPUT:

- `self` – a representation of an affine Hecke algebra
- `base_ring` – the base ring of the coroot lattice

EXAMPLES:

```python
sage: W = WeylGroup(['B',2])
sage: W.element_class._repr_ = lambda x: ''.join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1, q2, affine=True)
sage: E = rho.Y_eigenvectors()
sage: E.keys()
Weyl Group of type ['B', 2] (as a matrix group acting on the ambient space)
sage: w0 = W.long_element()
To set the recurrence up properly, one often needs to customize the
CherednikOperatorsEigenvectors.affine_lift() and
CherednikOperatorsEigenvectors.affine_retract() methods. This would usually
be done by subclassing CherednikOperatorsEigenvectors; here we just override the methods
directly.
In this particular case, we multiply by $w_0$ to take into account that $w_0$ is the seed for the recursion:

```python
sage: E.affine_lift = w0._mul_
sage: E.affine_retract = w0._mul_
sage: E[w0]
2121
sage: E.eigenvalues(E[w0])
[q2^2/q1^2, q1/(-q2), q1/(-q2)]
```

This step is taken care of automatically if one instead calls the specialization `sage.coxeter_groups.CoxeterGroups.Algebras.demazure_lusztig_eigenvectors()`.

Now we can compute all eigenvectors:

```python
sage: [E[w] for w in W]
[2121 - 121 - 212 + 12 + 21 - 1 - 2 + ,
-2121 + 212,
(q2/(q1-q2))*2121 + (q2/(-q1+q2))*121 + (q2/(-q1+q2))*212 - 12 + ((-q2)/(-
->q1+q2))*21 + 2,
((-q2^2)/(-q1^2+q1*q2-q2^2))*2121 - 121 + (q2^2/(-q1^2+q1*q2-q2^2))*212 + 21,
((q1^2+q2^2)/(-q1^2+q1*q2-q2^2))*2121 - 121 + ((-q1^2+q2^2)/(-q1^2+q1*q2-q2^2))*212 + 12 -
-21 + 1,
2121,
2121,
(q2/(-q1+q2))*2121 + ((-q2)/(-q1+q2))*121 - 212 + 12,
-2121 + 212]
```

Y_lambdacheck(lambdacheck)  
Return the Cherednik operators $Y^\lambda$ for this representation of an affine Hecke algebra.

5.1. Comprehensive Module list 2151
INPUT:

- lambdacheck – an element of the coroot lattice for this Cartan type

EXAMPLES:

```
sage: W = WeylGroup("B",2)
sage: W.element_class._repr_ = lambda x: ".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
We take \(q_2\) and \(q_1\) as eigenvalues to match with the notations of [HST2008]
sage: rho = KW.demazure_lusztig_operators(q2, q1)
sage: L = rho.Y().keys()
sage: alpha = L.simple_roots()
sage: Y0 = rho.Y_lambdacheck(alpha[0])
sage: Y1 = rho.Y_lambdacheck(alpha[1])
sage: Y2 = rho.Y_lambdacheck(alpha[2])
```

We take \(q_2\) and \(q_1\) as eigenvalues to match with the notations of [HST2008]

```
sage: x = KW.monomial(W.an_element()); x
12
sage: Y1(x)
((-q1^2-2*q1*q2-q2^2)/(-q2^2))*2121 + ((q1^3+q1^2*q2+q1*q2^2+q2^3)/(-q1*q2^2))*121 + ((q1^2+q1*q2)/(-q2^2))*212 + ((-q1^2)/(-q2^2))*12
sage: Y2(x)
((-q1^4-q1^3*q2-q1*q2^3-q2^4)/(-q1^3*q2))*2121 + ((q1^3+q1^2*q2+q1*q2^2+q2^3)/(-q1^2*q2))*121 + (q2^3/(-q1^3))*12
sage: Y1(Y2(x))
((q1*q2+q2^2)/q1^2)*212 + ((-q2)/q1)*12
sage: Y2(Y1(x))
((q1*q2+q2^2)/q1^2)*212 + ((-q2)/q1)*12
The \(Y\) operators commute:

```
sage: Y0(Y1(x)) - Y1(Y0(x))
0
sage: Y2(Y1(x)) - Y1(Y2(x))
0
```

In the classical root lattice, \(\alpha_0 + \alpha_1 + \alpha_2 = 0\):

```
sage: Y0(Y1(Y2(x)))
12
```

Lemma 7.2 of [HST2008]:

```
sage: w0 = KW.monomial(W.long_element())
sage: rho.Tw(0)(w0)
q2
sage: rho.Tw_inverse(1)(w0)
1/q2*212
sage: rho.Tw_inverse(2)(w0)
1/q2*121
```

Lemma 7.5 of [HST2008]:
Todo: Add more tests
Add tests in type BC affine where the null coroot $\delta^\vee$ can have non trivial coefficient in term of $\alpha_0$

See also:

- [HST2008] for the formula in terms of $q_1, q_2$

cartan_type()
Return the Cartan type of self.

EXAMPLES:

```sage
sage: from sage.combinat.root_system.hecke_algebra_representation import ~ HeckeAlgebraRepresentation
sage: KW = SymmetricGroup(3).algebra(QQ)
sage: action = lambda x, i: KW.monomial(x.apply_simple_reflection(i, side="right"))
sage: H = HeckeAlgebraRepresentation(KW, action, CartanType(['A',2]), 1, -1)
sage: H.cartan_type() ['A', 2]
sage: H = WeylGroup(['A',3]).algebra(QQ).demazure_lusztig_operators(-1,1)
sage: H.cartan_type() ['A', 3, 1]
```

domain()
Return the domain of self.

EXAMPLES:

```sage
sage: H = WeylGroup(['A',3]).algebra(QQ).demazure_lusztig_operators(-1,1)
sage: H.domain()
Algebra of Weyl Group of type ['A', 3] (as a matrix group acting on the ambient space) over Rational Field
```

on_basis(x, word, signs=None, scalar=None)
Action of product of $T_i$ and $T_i^{-1}$ on $x$.

INPUT:

- $x$ – the index of a basis element
- word – word of indices of generators
- signs – (default: None) sequence of signs of same length as word; determines which operators are supposed to be taken as inverses.
- scalar – (default: None) scalar to multiply the answer by

EXAMPLES:
```python
sage: from sage.combinat.root_system.hecke_algebra_representation import HeckeAlgebraRepresentation
sage: W = SymmetricGroup(3)
sage: domain = W.algebra(QQ)
sage: action = lambda x, i: domain.monomial(x.apply_simple_reflection(i, side="right"))
sage: rho = HeckeAlgebraRepresentation(domain, action, CartanType(['A',2]), 1, -1)
sage: rho.on_basis(W.one(), (1,2,1))
(1,3)
sage: word = (1,2)
sage: u = W.from_reduced_word(word)
sage: for w in W:
    assert rho.on_basis(w, word) == domain.monomial(w*u)
```

The next example tests the signs:

```python
sage: W = WeylGroup("A3")
sage: W.element_class._repr_ = lambda x: ".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1,q2)
sage: w = W.an_element(); w
123
sage: rho.on_basis(w, (1,), signs=(-1,))
-1/q2*1231 + ((q1+q2)/(q1*q2))*123
sage: rho.on_basis(w, (1,), signs=(1,))
q1*1231
sage: rho.on_basis(w, (1,1), signs=(1,-1))
123
sage: rho.on_basis(w, (1,1), signs=(-1,1))
123
```

**parameters** *(i)*

Return \( q_1, q_2 \) such that \((T_i - q_1)(T_i - q_2) = 0\).

**EXAMPLES:**

```python
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = WeylGroup(['A',3]).algebra(QQ)
sage: H = KW.demazure_lusztig_operators(q1,q2)
sage: H.parameters(1)
(q1, q2)
sage: H.parameters(1, -1)
(1, -1)
```

**Todo:** At this point, this method is constant. It’s meant as a starting point for implementing parameters depending on the node \(i\) of the Dynkin diagram.

**straighten_word** *(word)*
Return a tuple of indices of generators after some straightening.

**INPUT:**

- `word` – a list/tuple of indices of generators, the index of a generator, or an object with a reduced word method

**OUTPUT:** a tuple of indices of generators

**EXAMPLES:**

```sage
sage: W = WeylGroup(["A",3])
sage: H = W.algebra(QQ).demazure_lusztig_operators(-1,1)
sage: H.straighten_word(1)
(1,)
sage: H.straighten_word((2,1))
(2, 1)
sage: H.straighten_word([2,1])
(2, 1)
sage: H.straighten_word(W.an_element())
(1, 2, 3)
```

### 5.1.233 Integrable Representations of Affine Lie Algebras

**class** `sage.combinat.root_system.integrable_representations.IntegrableRepresentation(Lam)`

**Bases:** `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.category_object.CategoryObject`

An irreducible integrable highest weight representation of an affine Lie algebra.

**INPUT:**

- `Lam` – a dominant weight in an extended weight lattice of affine type

**REFERENCES:**

- [Ka1990]

If $\Lambda$ is a dominant integral weight for an affine root system, there exists a unique integrable representation $V = V_{\Lambda}$ of highest weight $\Lambda$. If $\mu$ is another weight, let $m(\mu)$ denote the multiplicity of the weight $\mu$ in this representation. The set $\text{supp}(V)$ of $\mu$ such that $m(\mu) > 0$ is contained in the paraboloid

$$(\Lambda + \rho|\Lambda + \rho) - (\mu + \rho|\mu + \rho) \geq 0$$

where $(\cdot|\cdot)$ is the invariant inner product on the weight lattice and $\rho$ is the Weyl vector. Moreover if $m(\mu) > 0$ then $\mu \in \text{supp}(V)$ differs from $\Lambda$ by an element of the root lattice ([Ka1990], Propositions 11.3 and 11.4).

Let $\delta$ be the nullroot, which is the lowest positive imaginary root. Then by [Ka1990], Proposition 11.3 or Corollary 11.9, for fixed $\mu$ the function $m(\mu - k\delta)$ is a monotone increasing function of $k$. It is useful to take $\mu$ to be such that this function is nonzero if and only if $k \geq 0$. Therefore we make the following definition. If $\mu$ is such that $m(\mu) \neq 0$ but $m(\mu + \delta) = 0$ then $\mu$ is called maximal.

Since $\delta$ is fixed under the action of the affine Weyl group, and since the weight multiplicities are Weyl group invariant, the function $k \mapsto m(\mu - k\delta)$ is unchanged if $\mu$ is replaced by an equivalent weight. Therefore in tabulating these functions, we may assume that $\mu$ is dominant. There are only a finite number of dominant maximal weights.

Since every nonzero weight multiplicity appears in the string $\mu - k\delta$ for one of the finite number of dominant maximal weights $\mu$, it is important to be able to compute these. We may do this as follows.

**EXAMPLES:**
In this example, we construct the extended weight lattice of Cartan type $\mathcal{A}_3^{(1)}$, then define $\Lambda$ to be the fundamental weights $(\Lambda_i)_{i \in I}$. We find there are 5 maximal dominant weights in irreducible representation of highest weight $\Lambda_1 + \Lambda_2 + \Lambda_3$, and we determine their strings.

It was shown in [KacPeterson] that each string is the set of Fourier coefficients of a modular form.

Every weight $\mu$ such that the weight multiplicity $m(\mu)$ is nonzero has the form

$$\Lambda - n_0 \alpha_0 - n_1 \alpha_1 - \cdots,$$

where the $n_i$ are nonnegative integers. This is represented internally as a tuple $(n_0, n_1, n_2, \ldots)$. If you want an individual multiplicity you use the method $m()$ and supply it with this tuple:

```
sage: Lambda = RootSystem(['A',3,1]).weight_lattice(extended=true).fundamental_weights()
2*Lambda[0] + Lambda[2]: 4 31 161 665 2382 10054 37468 115683 322920 823510 2073601
Lambda[0] + 2*Lambda[1]: 2 18 99 430 1593 5274 12120 30882 75488 177957 420750
Lambda[0] + 2*Lambda[3]: 2 18 99 430 1593 5274 12120 30882 75488 177957 420750
Lambda[1] + Lambda[2] + Lambda[3]: 1 10 60 274 1056 3601 11199 32354 88009 227555 563390
3*Lambda[2] - delta: 3 21 107 450 1638 5367 16194 45687 121876 308829 757056

sage: Lambda = RootSystem(['D',4,1]).weight_lattice(extended=true).fundamental_weights()
sage: IntegrableRepresentation(Lambda[0]+Lambda[1]).print_strings()
# long time
Lambda[0] + Lambda[1]: 1 10 62 293 1165 4097 13120 38997 109036 289575 735870
1783324
```

The `IntegrableRepresentation` class has methods `to_weight()` and `from_weight()` to convert between this internal representation and the weight lattice:

```
sage: Lambda = RootSystem(['C',2,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[0]); V
Integrable representation of ['C', 2, 1] with highest weight 2*Lambda[0]
sage: V.m((3,5,3))
18
```

To get more values, use the depth parameter:

```
sage: delta = V.weight_lattice().null_root()
(4, 3, 2)
```

(continues on next page)
sage: IntegrableRepresentation(4*L0).print_strings(depth=20)
4*Lambda[0]: 1 1 3 6 13 23 44 75 131 215 354 561 878 1386 2082 3153 4712 6936
→10151 14677
→1880 2856 4256 6303 9222 13396 19262
→6936 10121 14677 21055

An example in type $C_2^{(1)}$:

sage: Lambda = RootSystem(['C',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: V.print_strings()  # long time
2*Lambda[0]: 1 2 9 26 77 194 477 1084 2387 5010 10227 20198
Lambda[0] + Lambda[2] - delta: 1 5 18 55 149 372 872 1941 4141 8523 17005 33019
2*Lambda[1] - delta: 1 4 15 44 122 304 721 1612 3469 7176 14414 28124

Examples for twisted affine types:

sage: Lambda = RootSystem(['A',2,2]).weight_lattice(extended=True).fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0]).strings()  # long time
{Lambda[0]: [1, 1, 2, 3, 5, 7, 11, 15, 22, 30, 42, 56]}
sage: Lambda = RootSystem(['G',2,1]).dual.weight_lattice(extended=True).fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0]+Lambda[1]+Lambda[2])
sage: V.print_strings()  # long time
6*Lambdacheck[0]: 4 28 100 320 944 2460 6064 14300 31968 69020 144676 293916

(continues on next page)
branch \((i=None, \text{weyl}\_\text{character}\_\text{ring}=None, \text{sequence}=None, \text{depth}=5)\)

Return the branching rule on \(\text{self}\).

Removing any node from the extended Dynkin diagram of the affine Lie algebra results in the Dynkin diagram of a classical Lie algebra, which is therefore a Lie subalgebra. For example removing the 0 node from the Dynkin diagram of type \([X, r, 1]\) produces the classical Dynkin diagram of \([X, r]\).

Thus for each \(i\) in the index set, we may restrict \(\text{self}\) to the corresponding classical subalgebra. Of course \(\text{self}\) is an infinite dimensional representation, but each weight \(\mu\) is assigned a grading by the number of times the simple root \(\alpha_i\) appears in \(A - \mu\). Thus the branched representation is graded and we get sequence of finite-dimensional representations which this method is able to compute.

OPTIONAL:

- \(i\) – (default: 0) an element of the index set
- \(\text{weyl}\_\text{character}\_\text{ring}\) – a WeylCharacterRing
- \(\text{sequence}\) – a dictionary
- \(\text{depth}\) – (default: 5) an upper bound for \(k\) determining how many terms to give

In the default case where \(i = 0\), you do not need to specify anything else, though you may want to increase the depth if you need more terms.

EXAMPLES:

```sage
Lambda = RootSystem(['A',2,1]).weight_lattice(extended=true).fundamental_weights()
V = IntegrableRepresentation(2*Lambda[0])
b = V.branch(); b
[A2(0,0),
 A2(1,1),
 A2(0,0) + 2*A2(1,1) + A2(2,2),
 2*A2(0,0) + 2*A2(0,3) + 4*A2(1,1) + 2*A2(3,0) + 2*A2(2,2),
 4*A2(0,0) + 3*A2(0,3) + 10*A2(1,1) + 3*A2(3,0) + A2(1,4) + 6*A2(2,2) + A2(4,1),
 6*A2(0,0) + 9*A2(0,3) + 20*A2(1,1) + 9*A2(3,0) + 3*A2(1,4) + 12*A2(2,2) + 3*A2(4,1) + A2(3,3)]
```

If the parameter \(\text{weyl}\_\text{character}\_\text{ring}\) is omitted, the ring may be recovered as the parent of one of the branched coefficients:

```sage
A2 = b[0].parent(); A2
The Weyl Character Ring of Type A2 with Integer Ring coefficients
```

If \(i\) is not zero then you should specify the \(\text{Weyl}\_\text{Character}\_\text{Ring}\) that you are branching to. This is determined by the Dynkin diagram:

```sage
Lambda = RootSystem(['B',3,1]).weight_lattice(extended=true).fundamental_weights()
V = IntegrableRepresentation(Lambda[0])
V.cartan_type().dynkin_diagram()
```

(continues on next page)
In this example, we observe that removing the \( i = 2 \) node from the Dynkin diagram produces a reducible diagram of type \( A_1 \times A_1 \times A_1 \). Thus we have a branching to \( \mathfrak{sl}(2) \times \mathfrak{sl}(2) \times \mathfrak{sl}(2) \):

\[
\text{sage: } A1xA1xA1 = \text{WeylCharacterRing}("A1xA1xA1", style="coroots") \\
\text{sage: } V.branch(i=2, weyl_character_ring=A1xA1xA1) \\
[A1xA1xA1(1,0,0), \\
A1xA1xA1(0,1,2), \\
A1xA1xA1(1,0,0) + A1xA1xA1(1,2,0) + A1xA1xA1(1,0,2), \\
A1xA1xA1(2,0,0) + A1xA1xA1(0,1,0) + 2*A1xA1xA1(0,1,0), \\
3*A1xA1xA1(1,0,0) + 2*A1xA1xA1(1,2,0) + A1xA1xA1(1,2,0) + 2*A1xA1xA1(1,0,2), \\
\rightarrow+ A1xA1xA1(1,0,4) + A1xA1xA1(1,0,2) + A1xA1xA1(1,0,0) + A1xA1xA1(1,4,0) + A1xA1xA1(0,1,2)
\]

If the nodes of the two Dynkin diagrams are not in the same order, you must specify an additional parameter, \( \text{sequence} \) which gives a dictionary to the affine Dynkin diagram to the classical one.

**EXAMPLES:**

\[
\text{sage: } \Lambda = \text{RootSystem(['F',4,1]).weight_lattice(extended=true).fundamental_weights()}
\]
\[
\text{sage: } V = \text{IntegrableRepresentation}(\Lambda[0])
\]
\[
\text{sage: } V.cartan_type().dynkin_diagram()
\]
\[
O---O---O=>=O---O
0 1 2 3 4
\]
\[
\text{F4~}
\]
\[
\text{sage: } A1xC3=\text{WeylCharacterRing("A1xC3", style="coroots")}
\]
\[
\text{sage: } A1xC3.dynkin_diagram()
\]
\[
O
1
0---O<==>O---O
0 1 2 3 4
\]
\[
A1xC3
\]

Observe that removing the \( i = 1 \) node from the \( F_4 \) Dynkin diagram gives the \( A_1 \times C_3 \) diagram, but the roots are in a different order. The nodes 0, 2, 3, 4 of \( F_4 \) correspond to 1, 4, 3, 2 of \( A_1 \times C_3 \) and so we encode this in a dictionary:

\[
\text{sage: } V.branch(i=1, weyl_character_ring=A1xC3, sequence={0:1,2:4,3:3,4:2}) \#
\]

\[
\text{long time}
\]
\[
[A1xC3(1,0,0,0), \\
A1xC3(0,0,0,1), \\
A1xC3(1,0,0,0) + A1xC3(1,2,0,0), \\
A1xC3(2,0,0,1) + A1xC3(0,0,0,1) + A1xC3(0,1,1,0), \\
2*A1xC3(1,0,0,0) + A1xC3(1,0,1,0) + 2*A1xC3(1,2,0,0) + A1xC3(1,0,2,0) + \\
\rightarrow A1xC3(3,0,0,0), \\
2*A1xC3(2,0,0,1) + A1xC3(2,1,1,0) + A1xC3(0,1,0,0) + 3*A1xC3(0,0,0,1) + \\
\rightarrow 2*A1xC3(0,1,1,0) + A1xC3(0,2,0,1)]
\]

The branch method gives a way of computing the graded dimension of the integrable representation:

\[
\text{sage: } \Lambda = \text{RootSystem("A1~").weight_lattice(extended=true).fundamental_weights()}
\]
\[
\text{sage: } V=\text{IntegrableRepresentation}(\Lambda[0])
\]
sage: r = [x.degree() for x in V.branch(depth=15)]; r
[1, 3, 4, 7, 13, 19, 29, 43, 62, 90, 126, 174, 239, 325, 435, 580]
sage: oeis(r)
#optional -- internet
0: A029552: Expansion of \( \frac{\phi(x)}{f(-x)} \) in powers of \( x \) where \( \phi(), f() \) are
\( \ldots \)Ramanujan theta functions.

cartan_type()
Return the Cartan type of self.

EXAMPLES:

sage: Lambda = RootSystem(['F',4,1]).weight_lattice(extended=true).
fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.cartan_type()
['F', 4, 1]

coxeter_number()
Return the Coxeter number of the Cartan type of self.

The Coxeter number is defined in [Ka1990] Chapter 6, and commonly denoted \( h \).

EXAMPLES:

sage: Lambda = RootSystem(['F',4,1]).weight_lattice(extended=true).
fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.coxeter_number()
12

dominant_maximal_weights()
Return the dominant maximal weights of self.

A weight \( \mu \) is maximal if it has nonzero multiplicity but \( \mu + \delta \) has multiplicity zero. There are a finite number of dominant maximal weights. Indeed, [Ka1990] Proposition 12.6 shows that the dominant maximal weights are in bijection with the classical weights in \( k \cdot F \) where \( F \) is the fundamental alcove and \( k \) is the level. The construction used in this method is based on that Proposition.

EXAMPLES:

sage: Lambda = RootSystem(['C',3,1]).weight_lattice(extended=true).
fundamental_weights()
sage: IntegrableRepresentation(2*Lambda[0]).dominant_maximal_weights()
(2*Lambda[0],
Lambda[0] + Lambda[2] - delta,
2*Lambda[1] - delta,
Lambda[1] + Lambda[3] - 2*delta,
2*Lambda[2] - 2*delta,
2*Lambda[3] - 3*delta)

dual_coxeter_number()
Return the dual Coxeter number of the Cartan type of self.

The dual Coxeter number is defined in [Ka1990] Chapter 6, and commonly denoted \( h^\vee \).

EXAMPLES:
from_weight (\(\mu\))

Return the tuple \((n_0, n_1, \ldots)\) such that \(\mu = \sum_{i \in I} n_i \alpha_i\) in self, where \(\Lambda\) is the highest weight of self.

EXAMPLES:

```python
sage: Lambda = RootSystem(['A',2,1]).weight_lattice(extended=true).
    fundamental_weights()

sage: V = IntegrableRepresentation(2*Lambda[2])

sage: V.to_weight((1,0,0))

sage: delta = V.weight_lattice().null_root()

(1, 0, 0)
```

highest_weight ()

Returns the highest weight of self.

EXAMPLES:

```python
sage: Lambda = RootSystem(['D',4,1]).weight_lattice(extended=true).
    fundamental_weights()

sage: IntegrableRepresentation(Lambda[0]+2*Lambda[2]).highest_weight()
Lambda[0] + 2*Lambda[2]
```

level ()

Return the level of self.

The level of a highest weight representation \(V_{\Lambda}\) is defined as \((\Lambda|\delta)\) See [Ka1990] section 12.4.

EXAMPLES:

```python
sage: Lambda = RootSystem(['G',2,1]).weight_lattice(extended=true).
    fundamental_weights()

sage: [IntegrableRepresentation(Lambda[i]).level() for i in [0,1,2]]
[1, 1, 2]
```

\(m(n)\)

Return the multiplicity of the weight \(\mu\) in self, where \(\mu = \Lambda - \sum_i n_i \alpha_i\).

INPUT:

- \(n\) – a tuple representing a weight \(\mu\).

EXAMPLES:

```python
sage: Lambda = RootSystem(['E',6,1]).weight_lattice(extended=true).
    fundamental_weights()

sage: V = IntegrableRepresentation(Lambda[0])

sage: u = V.highest_weight() - V.weight_lattice().null_root()

sage: V.m(V.from_weight(u))
(1, 1, 2, 2, 3, 2, 1)

sage: V.m(V.from_weight(u))
6
```
modular_characteristic(mu=None)

Return the modular characteristic of self.

The modular characteristic is a rational number introduced by Kac and Peterson [KacPeterson], required
to interpret the string functions as Fourier coefficients of modular forms. See [Ka1990] Section 12.7. Let
\(k\) be the level, and let \(h^\vee\) be the dual Coxeter number. Then
\[
m_\Lambda = \frac{|\Lambda + \rho|^2}{2(k + h^\vee)} - \frac{|\rho|^2}{2h^\vee}
\]

If \(\mu\) is a weight, then
\[
m_{\Lambda, \mu} = m_\Lambda - \frac{|\mu|^2}{2k}
\]

OPTIONAL:

- \(\mu\) – a weight; or alternatively:
- \(n\) – a tuple representing a weight \(\mu\).

If no optional parameter is specified, this returns \(m_\Lambda\). If \(\mu\) is specified, it returns \(m_{\Lambda, \mu}\). You may use the
tuple \(n\) to specify \(\mu\). If you do this, \(\mu\) is \(\Lambda - \sum_i n_i \alpha_i\).

EXAMPLES:

```python
sage: Lambda = RootSystem(['A',1,1]).weight_lattice(extended=true).
    fundamental_weights()
sage: V = IntegrableRepresentation(3*Lambda[0]+2*Lambda[1])
sage: [V.modular_characteristic(x) for x in V.dominant_maximal_weights()]
[11/56, -1/280, 111/280]
```

mult(mu)

Return the weight multiplicity of \(\mu\).

INPUT:

- \(\mu\) – an element of the weight lattice

EXAMPLES:

```python
sage: L = RootSystem("B3~").weight_lattice(extended=True)
sage: Lambda = L.fundamental_weights()
sage: delta = L.null_root()
sage: W = L.weyl_group(prefix="s")
sage: [s0,s1,s2,s3] = W.simple_reflections()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.mult(Lambda[2]-2*delta)
3
sage: V.mult(Lambda[2]-Lambda[1])
0
sage: weights = [w.action(Lambda[1]-4*delta) for w in [s1,s2,s0*s1*s2*s3]]
sage: weights
sage: [V.mult(mu) for mu in weights]
[35, 35, 35]
```

print_strings(depth=12)

Print the strings of self.
See also:

strings()

EXAMPLES:

```python
sage: Lambda = RootSystem(['A',1,1]).weight_lattice(extended=true).
        →fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: V.print_strings(depth=25)
2*Lambda[0]: 1 1 3 5 10 16 23 35 50 72 101 143 198 1
        →2741 3740 5096 6868 9233 12306 16357
2*Lambda[1] - delta: 1 2 4 7 13 21 35 55 86 130 196 287 420 602 858 1206 1687
        →2331 3206 4368 5922 7967 10670 14193 18803
```

class root_lattice()

Return the root lattice associated to self.

EXAMPLES:

```python
sage: V=IntegrableRepresentation(RootSystem(['F',4,1]).weight_lattice(extended=true).fundamental_weight(0))
sage: V.root_lattice()
Root lattice of the Root system of type ['F', 4, 1]
```

s(n, i)

Return the action of the i-th simple reflection on the internal representation of weights by tuples n in self.

EXAMPLES:

```python
sage: V = IntegrableRepresentation(RootSystem(['A',2,1]).weight_lattice(extended=true).fundamental_weight(0))
sage: [V.s((0,0,0),i) for i in V._index_set]
[(1, 0, 0), (0, 0, 0), (0, 0, 0)]
```

string(max_weight, depth=12)

Return the list of multiplicities \( m(\Lambda - k\delta) \) in self, where \( \Lambda \) is max_weight and \( k \) runs from 0 to depth.

INPUT:

- max_weight – a dominant maximal weight
- depth – (default: 12) the maximum value of \( k \)

EXAMPLES:

```python
sage: Lambda = RootSystem(['A',2,1]).weight_lattice(extended=true).
        →fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: V.string([2*Lambda[0]])
[1, 2, 8, 20, 52, 116, 256, 522, 1045, 1996, 3736, 6780]
sage: V.string(Lambda[1] + Lambda[2])
[0, 1, 4, 12, 32, 77, 172, 365, 740, 1445, 2736, 5041]
```

strings(depth=12)

Return the set of dominant maximal weights of self, together with the string coefficients for each.

OPTIONAL:

- depth – (default: 12) a parameter indicating how far to push computations

5.1. Comprehensive Module list
EXAMPLES:

```python
sage: Lambda = RootSystem(['A',1,1]).weight_lattice(extended=true).
    fundamental_weights()

sage: V = IntegrableRepresentation(2*Lambda[0])
sage: S = V.strings(depth=25)
sage: for k in S:
    ....: print("{}: {}".format(k, ' '.join(str(x) for x in S[k])))

2*Lambda[0]: 1 1 3 5 10 16 28 43 70 105 161 236 350 501 722 1016 1431 1981
    2741 3740 5096 6868 9233 12306 16357
2*Lambda[1] - delta: 1 2 4 7 13 21 35 55 86 120 186 278 420 602 858 1206 1687
    2331 3206 4368 5922 7967 10670 14193 18803
```

to_dominant \((n)\)

Return the dominant weight in \(\text{self}\) equivalent to \(n\) under the affine Weyl group.

EXAMPLES:

```python
sage: Lambda = RootSystem(['A',2,1]).weight_lattice(extended=true).
    fundamental_weights()

sage: V = IntegrableRepresentation(3*Lambda[0])
sage: n = V.to_dominant((13,11,7)); n
(4, 3, 3)
sage: V.to_weight(n)
```

to_weight \((n)\)

Return the weight associated to the tuple \(n\) in \(\text{self}\).

If \(n\) is the tuple \((n_1,n_2,...)\), then the associated weight is \(\Lambda - \sum n_i \alpha_i\), where \(\Lambda\) is the weight of the representation.

INPUT:

* \(n\) – a tuple representing a weight

EXAMPLES:

```python
sage: Lambda = RootSystem(['A',2,1]).weight_lattice(extended=true).
    fundamental_weights()

sage: V = IntegrableRepresentation(2*Lambda[2])
sage: V.to_weight((1,0,0))
```

weight_lattice()

Return the weight lattice associated to \(\text{self}\).

EXAMPLES:

```python
sage: V = IntegrableRepresentation(RootSystem(['E',6,1]).weight_lattice(extended=true).fundamental_weight(0))
sage: V.weight_lattice()
Extended weight lattice of the Root system of type ['E', 6, 1]
```
5.1.234 Nonsymmetric Macdonald polynomials

AUTHORS:

- Anne Schilling and Nicolas M. Thiery (2013): initial version

ACKNOWLEDGEMENTS:

The initial version of this code (together with \texttt{root\_lattice\_realization\_algebras.Algebras} and \texttt{hecke\_algebra\_representation.HeckeAlgebraRepresentation}) was written by Anne Schilling and Nicolas M. Thiery during the ICERM Semester Program on “Automorphic Forms, Combinatorial Representation Theory and Multiple Dirichlet Series” (January 28, 2013 - May 3, 2013) with the help of Dan Bump, Ben Brubaker, Bogdan Ion, Dan Orr, Arun Ram, Siddhartha Sahi, and Mark Shimozono. Special thanks go to Bogdan Ion and Mark Shimozono for their patient explanations and hand computations to check the code.

```python
class sage.combinat.root_system.non_symmetric_macdonald_polynomials.NonSymmetricMacdonaldPolynomials(KL, q, q1, q2, normalized):
    # implementation details...
```

This implementation covers all reduced affine root systems. The polynomials are constructed recursively by the application of intertwining operators.

Todo:

- Non-reduced case (Koornwinder polynomials).
- Non-equal parameters for the affine Hecke algebra.
- Choice of convention (dominant/anti-dominant, ...).
- More uniform implementation of the $T_0^\vee$ operator.
- Optimizations, in particular in the calculation of the eigenvalues for the recursion.

EXAMPLES:

We construct the family of nonsymmetric Macdonald polynomials in three variables in type $A$:

```python
sage: E = NonSymmetricMacdonaldPolynomials(["A",2,1])
```

They are constructed as elements of the group algebra of the classical weight lattice $L_0$ (or one of its realizations, such as the ambient space, which is used here) and indexed by elements of $L_0$:

```python
sage: L0 = E.keys(); L0
Ambient space of the Root system of type ['A', 2]
```
Here is the nonsymmetric Macdonald polynomial with leading term \([2, 0, 1]\):

```
sage: E[L0([2,0,1])]
((-q*q1-q*q2)/(-q*q1-q2))*B[(1, 1, 1)] + ((-q1-q2)/(-q*q1-q2))*B[(2, 1, 0)] +
→B[(2, 0, 1)]
```

It can be seen as a polynomial (or in general a Laurent polynomial) by interpreting each term as an exponent vector. The parameter \(q\) is the exponential of the null (co)root, whereas \(q_1\) and \(q_2\) are the two eigenvalues of each generator \(T_i\) of the affine Hecke algebra (see the background section for details).

By setting \(q_1 = t, q_2 = -1\) and using the `root_lattice_realization_algebras.Algebras.ElementMethods.expand()` method, we recover the nonsymmetric Macdonald polynomial as computed by [HHL06]'s combinatorial formula:

```
sage: K = QQ['q,t'].fraction_field()
sage: q,t = K.gens()
sage: E = NonSymmetricMacdonaldPolynomials("A",2,1, q=q, q1=t, q2=-1)
sage: vars = K['x0,x1,x2'].gens()
sage: E[L0([2,0,1])].expand(vars)
((-t + 1)/(-q*t + 1))*x0^2*x1 + x0^2*x2 + ((-q*t + q)/(-q*t + 1))*x0*x1*x2
```

Here is a type \(G(1)\) nonsymmetric Macdonald polynomial:

```
sage: E = NonSymmetricMacdonaldPolynomials("G",2,1)
sage: L0 = E.keys()
sage: omega = L0.fundamental_weights()
sage: E[omega[2]-omega[1]]
((-q1^3*q2-q*q1^2*q2^2)/(q*q1^4-q2^4))*B[(0, 0, 0)] + B[(1, -1, 0)] + ((-q1*q2^→3-q2^4)/(q*q1^4-q2^4))*B[(1, 0, -1)]
```

Many more examples are given after the background section.

### Background

#### The polynomial module

The nonsymmetric Macdonald polynomials are a distinguished basis of the “polynomial” module of the affine Hecke algebra. Given:

- a ground ring \(K\), which contains the input parameters \(q, q_1, q_2\)
- an affine root system, specified by a Cartan type \(C\)
- a realization \(L\) of the weight lattice of type \(C\)

the polynomial module is the group algebra \(K[L_0]\) of the classical weight lattice \(L_0\) with coefficients in \(K\). It is isomorphic to the Laurent polynomial ring over \(K\) generated by the formal exponentials of any basis of \(L_0\).

In our running example \(L\) is the ambient space of type \(C(1)\):
Affine Hecke algebra

The affine Hecke algebra is generated by elements $T_i$ for $i$ in the set of affine Dynkin nodes. They satisfy the same braid relations as the simple reflections $s_i$ of the affine Weyl group. The $T_i$ satisfy the quadratic relation

$$(T_i - q_1) \circ (T_i - q_2) = 0,$$

where $q_1$ and $q_2$ are the input parameters. Some of the representation theory requires that $q_1$ and $q_2$ satisfy additional relations; typically one uses the specializations $q_1 = u$ and $q_2 = -1/u$ or $q_1 = t$ and $q_2 = -1$. This can be achieved by constructing an appropriate field and passing $q_1$ and $q_2$ appropriately; see the examples. In principle, the parameter(s) could further depend on $i$; this is not yet implemented but the code has been designed in such a way that this feature is easy to add.

Demazure-Lusztig operators

The $i$-th Demazure-Lusztig operator is an operator on $K[L]$ which interpolates between the reflection $s_i$ and the Demazure operator $\pi_i$ (see root_lattice_realization.RootLatticeRealization.Algebras.ParentMethods.demazure_lusztig_operators()).

The affine Hecke algebra acts on $K[L]$ by letting the generators $T_i$ act by the Demazure-Lusztig operators. The class sage.combinat.root_system.hecke_algebra_representation.
HeckeAlgebraRepresentation implements some simple generic features for representations of affine Hecke algebras defined by the action of their $T$-generators.

```python
sage: T
A representation of the (q1, q2)-Hecke algebra of type ['C', 2, 1] on Algebra of
the Ambient space of the Root system of type ['C', 2, 1] over Fraction Field of
Multivariate Polynomial Ring in q, q1, q2 over Rational Field

sage: type(T)
<class 'sage.combinat.root_system.hecke_algebra_representation.HeckeAlgebraRepresentation'>

sage: T._test_relations()  # long time (1.3s)
```

Here we construct the operator $q_1T_2^{-1} \circ T_1^{-1}T_0$ from a signed reduced word:

```python
sage: T.Tw([0,1,2], [1,-1,-1], q1^2)
Generic endomorphism of Algebra of the Ambient space of the Root system of type ['C', 2, 1]
over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational Field
(note the reversal of the word). Inverses are computed using the quadratic relation.

Cherednik operators

The affine Hecke algebra contains elements $Y_\lambda$ indexed by the coroot lattice. Their action on $K[L]$ is implemented in Sage:

```python
sage: Y = T.Y(); Y
Lazy family (...)_{i in Coroot lattice of the Root system of type ['C', 2, 1]}

sage: alphacheck = Y.keys().simple_roots()

sage: Y1 = Y[alphacheck[1]]

sage: Y1(x)  # py2
((q1^3+q1^2*q2)/(-q2^3))*B[-e[0] - 2*e[1] - e['delta'] + e['deltacheck']]
+ ((q1^3+2*q1^2*q2+q1*q2^2)/(-q2^3))*B[-e[0] - 2*e[1] - 2*e['delta'] + e['deltacheck']]
+ ((q1^3+q1^2*q2)/(q2^3))*B[e[0] - 2*e[1] - e['delta'] + e['deltacheck']]
+ ((q1^3+q1^2*q2)/(q2^3))*B[e[0] - 2*e[1] - e['delta'] + e['deltacheck']]
+ ((q1^3+2*q1^2*q2+q1*q2^2)/(q2^3))*B[e[0] - 2*e['delta'] + e['deltacheck']] + (q1^3+q1^2*q2)/(q2^3))*B[2*e[0] - e['deltacheck']]  

sage: Y1(x)  # py3
((q1^2+2*q1*q2+q2^2)/(-q1*q2))*B[e[0] + e['deltacheck']]
```

(continues on next page)
The Cherednik operators span a Laurent polynomial ring inside the affine Hecke algebra; namely $\lambda \mapsto Y_\lambda$ is a group isomorphism from the classical root lattice (viewed additively) to the affine Hecke algebra (viewed multiplicatively). In practice, $Y_\lambda$ is constructed by computing combinatorially its signed reduced word (and an overall scalar factor) using the periodic orientation of the alcove model in the coweight lattice (see `hecke_algebra_representation.HeckeAlgebraRepresentation.Y_lambdacheck()`):

```
sage: Lcheck = L.root_system.coweight_lattice()
sage: w = Lcheck.reduced_word_of_translation(Lcheck(alphacheck[1])); w
[0, 2, 1, 0, 2, 1]
sage: Lcheck.signs_of_alcovewalk(w)
[1, -1, 1, -1, 1, 1]
```

### Level zero representation of the affine Hecke algebra

The action of the affine Hecke algebra on $K[L]$ induces an action on $K[L_0]$: the action of $T_i$ on $X^\lambda$ for $\lambda$ a classical weight in $L_0$ is obtained by embedding the weight at level zero in the affine weight lattice (see `weight_lattice_realizations.WeightLatticeRealizations.ParentMethods.embed_at_level()`) applying the Demazure-Lusztig operator there, and projecting from $K[L] \rightarrow K[L_0]$ mapping the exponential of $\delta$ to $q$ (see `root_lattice_realization_algebras.Algebras.ParentMethods.q_project()`). This is implemented in `root_lattice_realization_algebras.Algebras.ParentMethods.demazure_lusztig_operators_on_classical()`:

```
sage: T = KL.demazure_lusztig_operators_on_classical(q, q1,q2)
sage: omega = L0.fundamental_weights()
sage: x = KL0.monomial(omega[1])
sage: T[0](x)
(-q*q2)*B[(-1, 0)]
sage: T[1](x)
(q1+q2)*B[(1, 0)] + q1*B[(0, 1)]
```

For classical nodes these are the usual Demazure-Lusztig operators:

```
sage: T[1](x)
(q1+q2)*B[(1, 0)] + q1*B[(0, 1)]
```

### Nonsymmetric Macdonald polynomials

We can now finally define the nonsymmetric Macdonald polynomials. Because the Cherednik operators commute (and there is no radical), they can be simultaneously diagonalized; namely, $K[L_0]$ admits a $K$-basis of joint eigenvectors for the $Y_\lambda$. For $\mu \in L_0$, the nonsymmetric Macdonald polynomial $E_\mu$ is the unique eigenvector of the family of Cherednik operators $Y_\lambda$ having $\mu$ as leading term:

```
sage: E = NonSymmetricMacdonaldPolynomials(KL, q, q1, q2); E
The family of the Macdonald polynomials of type ['C', 2, 1] with parameters q, q1, q2
```

Or for short:
Recursive construction of the nonsymmetric Macdonald polynomials

The generators $T_i$ of the affine Hecke algebra almost skew commute with the Cherednik operators. More precisely, one can deform them into the so-called intertwining operators:

$$
\tau_i = T_i - (q_1 + q_2) \frac{Y_i^{a-1}}{1 - Y_i^a}.
$$

(where $a = 1$ except for $i = 0$ in type $BC$ where $a = a_0 = 2$) which satisfy the following skew commutation relations:

$$
\tau_i Y_\lambda = \tau_i Y_{s_i \lambda}.
$$

If $s_i \mu \neq \mu$, applying $\tau_i$ on an eigenvector $E_\mu$ produces a new eigenvector (essentially $E_{s_i \mu}$) with a distinct eigenvalue. It follows that the eigenvectors indexed by an affine Weyl orbit of weights, may be recursively computed from a single weight in the orbit.

In the case at hand, there is a little complication: namely, the simple reflections $s_i$ acting at level 0 do not act transitively on classical weights; in fact the orbits for the classical Weyl group and for the affine Weyl group are the same. Thus, one can construct the nonsymmetric Macdonald polynomials for all weights from those for the classical dominant weights, but one is lacking a creation operator to construct the nonsymmetric Macdonald polynomials for dominant weights.

Twisted Demazure-Lusztig operators

To compensate for this, one needs to consider another affinization of the action of the classical Demazure-Lusztig operators $T_1, \ldots, T_n$, which gives rise to the double affine Hecke algebra. Following Cherednik, one adds another operator $T'_0$ implemented in: root_lattice_realization_algebras.Algebras.ParentMethods.T0_check_on_basis(). See also: root_lattice_realization_algebras.Algebras.ParentMethods.twisted_demazure_lusztig_operators().

Depending on the type (untwisted or not), this is a representation of the affine Hecke algebra for another affinization of the classical Cartan type. The corresponding action of the affine Weyl group – which is used to compute the recursion on $\mu$ – occurs in the corresponding weight lattice realization:

```python
sage: E.L()
Ambient space of the Root system of type ['C', 2, 1]
sage: E.L_prime()
Coambient space of the Root system of type ['B', 2, 1]
sage: E.L_prime().classical()
Ambient space of the Root system of type ['C', 2]
```

See $L_{prime}$ and cartan_type.CartanType_affine.other_affinization().

REFERENCES:
More examples

We show how to create the nonsymmetric Macdonald polynomials in two different ways and check that they are the same:

```python
sage: K = QQ['q,u'].fraction_field()
sage: q, u = K.gens()
sage: E = NonSymmetricMacdonaldPolynomials(['D',3,1], q, u, -1/u)
sage: omega = E.keys().fundamental_weights()
((-q*u^2+q)/(-q*u^4+1))*B[(1/2, -1/2, 1/2)] + ((-q*u^2+q)/(-q*u^4+1))*B[(1/2, 1/2, -1/2)] + B[(3/2, 1/2, 1/2)]

sage: KL = RootSystem(['D',3,1]).ambient_space().algebra(K)
sage: P = NonSymmetricMacdonaldPolynomials(KL, q, u, -1/u)
True
sage: E[E.keys()((0,1,-1))]
((-q*u^2+q)/(-q*u^2+1))*B[(0, 0, 0)] + ((-u^2+1)/(-q*u^2+1))*B[(1, 1, 0)]
+ ((-u^2+1)/(-q*u^2+1))*B[(1, 0, -1)] + B[(0, 1, -1)]
```

In type $A$, there is also a combinatorial implementation of the nonsymmetric Macdonald polynomials in terms of augmented diagram fillings as in [HHL06]. See `sage.combinat.sf.ns_macdonald.E()`. First we check that these polynomials are indeed eigenvectors of the Cherednik operators:

```python
sage: K = QQ['q,t'].fraction_field()
sage: q,t = K.gens()
sage: q1 = t; q2 = -1
sage: KL = RootSystem(['A',2,1]).ambient_space().algebra(K)
sage: KL0 = KL.classical()
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, q1, q2)
sage: omega = E.keys().fundamental_weights()
sage: w = omega[1]
sage: import sage.combinat.sf.ns_macdonald as NS
sage: p = NS.E([1,0,0]); p
x0
sage: pp = KL0.from_polynomial(p)
sage: E.eigenvalues(KL0.from_polynomial(p))
[t, (-1)/(-q*t^2), t]
sage: def eig(l):
      return E.eigenvalues(KL0.from_polynomial(NS.E(l)))

sage: eig([1,0,0])
[t, (-1)/(-q*t^2), t]
sage: eig([2,0,0])
[q*t, (-1)/(-q^2*t^2), t]
sage: eig([3,0,0])
[q^2*t, (-1)/(-q^3*t^2), t]
sage: eig([2,0,4])
[(-1)/(-q^3*t), 1/(q^2*t), q^4*t^2]
```

Next we check explicitly that they agree with the current implementation:

```python
sage: K = QQ['q','t'].fraction_field()
sage: q,t = K.gens()
sage: KL = RootSystem(['A',1,1]).ambient_lattice().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, t, -1)
```

(continues on next page)
sage: L0 = E.keys()
sage: KL0 = KL.classical()
sage: P = K['x0,x1']
sage: def EE(weight):
    return E[L0(weight)].expand(P.gens())
sage: import sage.combinat.sf.ns_macdonald as NS
sage: EE([0,0])
1
sage: EE([1,0])
x0
sage: EE([1,0])
x0
sage: EE([0,1])
((-t + 1)/(-q*t + 1))*x0 + x1
sage: EE([0,1])
((-t + 1)/(-q*t + 1))*x0 + x1
sage: EE([2,0])
x0^2 + ((-q*t + q)/(-q*t + 1))*x0*x1
sage: EE([2,0])
x0^2 + ((-q*t + q)/(-q*t + 1))*x0*x1

The same, directly in the ambient lattice with several shifts:

sage: E[L0([2,0])]
((-q*t+q)/(-q*t+1))*B[(1, 1)] + B[(2, 0)]
sage: E[L0([1,-1])]
((-q*t+q)/(-q*t+1))*B[(0, 0)] + B[(1, -1)]
sage: E[L0([0,-2])]
((-q*t+q)/(-q*t+1))*B[(-1, -1)] + B[(0, -2)]

Systematic checks with Sage's implementation of [HHL06]:

sage: assert all(EE((x,y)) == NS.E((x,y))
for d in range(5) for x,y in IntegerVectors(d,2))

With the current implementation, we can compute nonsymmetric Macdonald polynomials for any type, for
example for type $E_6^{(1)}$:

sage: K=QQ['q,u'].fraction_field()
sage: q, u = K.gens()
sage: KL = RootSystem("E",6,1).weight_space(extended=True).algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q,u,-1/u)
sage: L0 = E.keys()
sage: E[L0.fundamental_weight(1).weyl_action([2,4,3,2,1])]
((-u^2+1)/(-q*u^16+1))*B[-Lambda[1] + Lambda[3]] + ((-u^2+1)/(-q*u^16+1))*B[0]
Lambda[5]] + ((-u^2+1)/(-q*u^16+1))*B[-Lambda[3] + Lambda[4]]

sage: E[L0.fundamental_weight(2).weyl_action([2,5,3,4,2])]  # long time (6s)
((-q^2*u^20+q^2*u^18+q*u^2-q)/(q^2*u^32+2*q*u^16-1))*B[0]
+ ((q*u^20+q*u^18*u^2-2)/(q^2*u^32+2*q*u^16-1))*B[-Lambda[2] + Lambda[4]]
+ ((q*u^20+q*u^18*u^2-2)/(q^2*u^32+2*q*u^16-1))*B[Lambda[2]]

\[
\text{We test various other types:}
\]

\[
\text{sage: } K=\mathbb{Q}[\{q,u\}].\text{fraction_field()}
\text{sage: } q, u = K.gens()
\text{sage: } KL = \text{RootSystem("A",5,2).ambient_space().algebra(K)}
\text{sage: } E = \text{NonSymmetricMacdonaldPolynomials(KL, q, u, -1/u)}
\text{sage: } L0 = E.keys()
\text{sage: } E[L0.fundamental_weight(6)]
\]

\[
\text{\# long time (13s)}
\]

\[
\begin{align*}
(q^2*u^10-q^2*u^8-q^2*u^2+q^2/(q^2*u^26-q*u^16-q*u^10+1))*B[0] \\
((q^2*u^2+q)/(q^2*u^26-q*u^16-q*u^10+1))*B[\Lambda[1] - \Lambda[2] + \Lambda[6]] \\
((q^2*u^2+q)/(q^2*u^26-q*u^16-q*u^10+1))*B[\Lambda[1] + \Lambda[2] - \Lambda[4] + \Lambda[6]] \\
((q^2*u^2+q)/(q^2*u^26-q*u^16-q*u^10+1))*B[\Lambda[1] - \Lambda[3] + \Lambda[5]] \\
((q^2*u^2+q)/(q^2*u^26-q*u^16-q*u^10+1))*B[\Lambda[3] - \Lambda[4] + \Lambda[5]] \\
\end{align*}
\]

(continues on next page)
Next we test a twisted type (checked against Maple computation by Bogdan Ion for $q_1 = t^2$ and $q_2 = -1$):

```
sage: E = NonSymmetricMacdonaldPolynomials("A",5,2)
sage: omega = E.keys()
sage: E[omega[1]]
B[1, 0, 0]
sage: E[-omega[1]]
B[-1, 0, 0] + ((-q*q1^6-q*q1^5*q2-q1*q2^5-q2^6)/(-q^3*q1^6-q^2*q1^5*q2-2*q^2*q1^6-3*q^2*q1^5*q2+q^2*q1^4*q2^2+2*q^2*q1^3*q2^3-q*q1^2*q2^4+q*q1*q2^5+q2^6))*B[0, 0, 0] + B[-1, 0, 0]
```

```
sage: E[omega[2]]
((-q1*q2^3-q2^4)/(-q^2+1))*B[1, 0, 0] + B[0, 1, 0]
sage: E[-omega[2]]
((-q^2+1)/(-q1)*B[1, 0, 0] + B[-1, 0, 0] + ((q1+q2)/(q*q1+q2))*B[-1, 0, 0] + ((-q1-q2)/(-q*q1-q2))*B[-1, 0, 0]
```

```
sage: E[-omega[1]-omega[2]]
((-q^3*q1^6-q^3*q1^5*q2-2*q^2*q1^6-3*q^2*q1^5*q2+q^2*q1^4*q2^2+2*q^2*q1^3*q2^3-q*q1^2*q2^4+q*q1*q2^5+q2^6))/(-q^4*q1^6-q^3*q1^5*q2+q^3*q1^4*q2^2-q*q1^3*q2^3-2*q1^2*q2^4+q1*q2^5+q2^6))*B[0, 0, 0] + B[-1, 0, 0] + ((q1+q2)/(q*q1+q2))*B[-1, 0, 0] + ((-q1-q2)/(-q*q1-q2))*B[-1, 0, 0] + ((q1+q2)/(q*q1+q2))*B[-1, 0, 0] + ((-q1-q2)/(-q*q1-q2))*B[-1, 0, 0]
```

(continues on next page)
Comparison with the energy function of crystals

Next we test that the nonsymmetric Macdonald polynomials at $t = 0$ match with the one-dimensional configuration sums involving Kirillov-Reshetikhin crystals for various types. See [LNSSS12]:

```python
sage: K = QQ['q,t'].fraction_field()
sage: q,t = K.gens()
sage: KL = RootSystem(['A',5,2]).ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL, q, t, -1)
sage: omega = E.keys().fundamental_weights()
sage: E[-omega[1]].map_coefficients(lambda x:x.subs(t=0))
B[(-1, 0, 0)] + B[(1, 0, 0)] + B[(0, -1, 0)] + B[(0, 1, 0)] + B[(0, 0, -1)] + B[(0, 0, 1)]
sage: E[-omega[2]].map_coefficients(lambda x:x.subs(t=0)) # long time (3s)
(q+2)*B[(0, 0, 0)] + B[(-1, -1, 0)] + B[(-1, 1, 0)] + B[(-1, 0, -1)] + B[(-1, 0, 1)] + B[(1, -1, 0)] + B[(1, 1, 0)] + B[(1, 0, -1)] + B[(1, 0, 1)] + B[(0, -1, -1)] + B[(0, -1, 1)] + B[(0, 1, -1)] + B[(0, 1, 1)]
```

```python
sage: KL = RootSystem(['C',3,1]).ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL, q, t, -1)
sage: omega = E.keys().fundamental_weights()
sage: E[-omega[2]].map_coefficients(lambda x:x.subs(t=0)) # long time (5s)
2*B[(0, 0, 0)] + B[(-1, -1, 0)] + B[(-1, 1, 0)] + B[(-1, 0, -1)] + B[(-1, 0, 1)] + B[(1, -1, 0)] + B[(1, 1, 0)] + B[(1, 0, -1)] + B[(1, 0, 1)] + B[(0, -1, -1)] + B[(0, -1, 1)] + B[(0, 1, -1)] + B[(0, 1, 1)]
```
sage: R = RootSystem(['C',3,1])
sage: KL = R.weight_lattice(extended=True).algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, t,-1)
sage: omega = E.keys().fundamental_weights()
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(2*La[1])

Some tests that the $T$ s are implemented properly by hand defining the $Y$ s in terms of them:

sage: T = E._T_Y
sage: Ye1 = T.Tw((1,2,1,0), scalar = (-1/(q1*q2))^2)
sage: Ye2 = T.Tw((2,1,0,1), signs = (1,1,1,-1), scalar = (-1/(q1*q2)))

(continues on next page)
sage: Yalpha0 = T.Tw((0,1,2,1), signs = (-1,-1,-1,-1), scalar = q^-1*(-q1*q2)^2)
sage: Yalpha1 = T.Tw((1,2,0,1,2,0), signs=(1,1,-1,1,-1,1), scalar = -1/(q1*q2))
sage: Yalpha2 = T.Tw((2,1,0,1,2,1,0,1), signs = (1,1,1,-1,1,1,1,-1), scalar = (1/(q1*q2))^2)

sage: Ye1(KL0.one())
q1^2/q2^2*B[(0, 0)]
sage: Ye2(KL0.one())
((-q1)/q2)*B[(0, 0)]
sage: Yalpha0(KL0.one())
q2^2/(q*q1^2)*B[(0, 0)]
sage: Yalpha1(KL0.one())
((-q1)/q2)*B[(0, 0)]
sage: Yalpha2(KL0.one())
q1^2/q2^2*B[(0, 0)]

Testing the $Y_s$ directly:

sage: Y = E.Y()
sage: Y.keys()
Coroot lattice of the Root system of type ['BC', 2, 2]
sage: alpha = Y.keys().simple_roots()
sage: L(alpha[0])
-2*e[0] + e['deltacheck']
sage: L(alpha[1])
e[0] - e[1]
sage: L(alpha[2])
e[1]

sage: Y[alpha[0]].word
(0, 1, 2, 1)
sage: Y[alpha[0]].signs
(-1, -1, -1, -1)
sage: Y[alpha[0]].scalar # mind that Sage's q is the usual q^{1/2}
q1^2*q2^2/q
sage: Y[alpha[0]](KL0.one())
q2^2/(q*q1^2)*B[(0, 0)]

sage: Y[alpha[1]].word
(1, 2, 0, 1, 2, 0)
sage: Y[alpha[1]].signs
(1, 1, -1, 1, -1, 1)
sage: Y[alpha[1]].scalar
1/(-q1*q2)

sage: Y[alpha[2]].word # Bogdan says it should be the square of that; do we need to take translation factors into account or not?
(2, 1, 0, 1)
sage: Y[alpha[2]].signs
(1, 1, 1, -1)
sage: Y[alpha[2]].scalar
1/(-q1*q2)

Checking the provided nonsymmetric Macdonald polynomial:
sage: E10 = KL0.monomial(L0((1,0))) + KL0( q+(1-(-q1/q2)) / (1-q^2*(-q1/q2)^4) )
True
sage: E10 == E[omega[1]]
True
sage: E.eigenvalues(E10) # not checked
[q*q1^2/q2^2, q2^3/(-q^2*q1^3), q1/(-q2)]

Checking T0check:
sage: T0check_on_basis = KL.T0_check_on_basis(q1,q2, convention="dominant")
(2, 0)
sage: T0check_on_basis.phi # note: this is in fact a0 phi
(2, 0)
sage: T0check_on_basis.v # what to match it with?
(1,)
sage: T0check_on_basis.j # what to match it with?
2
sage: T0check_on_basis(KL0.basis().keys().zero())
((-q1^2)/q2)*B[(1, 0)]
sage: T0check = E._T[0]

Systematic tests of nonsymmetric Macdonald polynomials in type $A_1^{(1)}$, in the weight lattice. Each time, we specify the eigenvalues for the action of $\gamma_{\alpha_0}$ and $\gamma_{\alpha_1}$:

As expected, $e^{-\omega}$ is not an eigenvector:

```
sage: E.eigenvalues(KL.classical().monomial(-omega[1]))
Traceback (most recent call last):
  ...
AssertionError
```

We proceed by comparing against the examples from the appendix of [HHL06] in type $A_2^{(1)}$:

```
sage: K = QQ['q','t'].fraction_field()
sage: q,t = K.gens()
sage: KL = RootSystem(['A',2,1]).ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, t, -1)
sage: L0 = E.keys()
sage: omega = L0.fundamental_weights()
sage: P = K['x1,x2,x3']
sage: def EE(weight):
  return E[L0(weight)].expand(P.gens())
sage: EE([0,0,0])
1
sage: EE([1,0,0])
x1
sage: EE([0,1,0])
((-t + 1)/(-q*t^2 + 1))*x1 + x2
sage: EE([0,0,1])
((-t + 1)/(-q*t + 1))*x1 + ((-t + 1)/(-q*t + 1))*x2 + x3
sage: EE([1,1,0])
x1*x2
sage: EE([1,0,1])
((-t + 1)/(-q*t^2 + 1))*x1*x2 + x1*x3
sage: EE([0,1,1])
((-t + 1)/(-q*t + 1))*x1*x2 + ((-t + 1)/(-q*t + 1))*x1*x3 + x2*x3
sage: EE([2,0,0])
x1^2 + ((-q*t + q)/(-q*t + 1))*x1*x2 + ((-q*t + q)/(-q*t + 1))*x1*x3
sage: EE([0,2,0])
```

(continues on next page)
((-t + 1)/(-q^2*t^2 + 1))*x1^2 + ((-q^2*t^3 + q^2*t^2 - q*t^2 + 2*q*t - q + t - 1)/(-q^3*t^3 + q^2*t^2 + q*t - 1))*x1*x2 + x2^2 + ((q*t^2 - 2*q*t + q)/(q^3*t^3 - q^2*t^2 - q*t + 1))*x1*x3 + ((-q*t + q)/(-q*t + 1))*x2*x3

Systematic checks with Sage’s implementation of [HHL06]:

```python
sage: import sage.combinat.sf.ns_macdonald as NS
sage: assert all(EE([x,y,z]) == NS.E([x,y,z]) for d in range(5) for x,y,z in IntegerVectors(d,3)) # long time (9s)
```

We check that we get eigenvectors for generic \( q_1, q_2 \):

```python
sage: K = QQ['q,q1,q2'].fraction_field()
sage: q,q1,q2 = K.gens()
sage: KL = RootSystem(['A',2,1]).ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, q1, q2)
sage: L0 = E.keys()
sage: omega = L0.fundamental_weights()
sage: E[2*omega[2]]
B[(1, 2, 1)] + B[(2, 1, 1)] + B[(2, 2, 0)]
```

Some type \( C \) calculations:

```python
sage: K = QQ['q','t'].fraction_field()
sage: q, t = K.gens()
sage: KL = RootSystem(['C',2,1]).ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, t, -1)
sage: L0 = E.keys()
sage: omega = L0.fundamental_weights()
sage: E[0*omega[1]]
B[(0, 0)]
```

```python
sage: E.eigenvalues(_)
[1/(q*t^3), t, t]
```

```python
sage: E[omega[1]]
B[(1, 0)]
```

```python
sage: E[-omega[1]]
B[(-1, 0)] + ((-t+1)/(-q*t^2+1))*B[(0, -1)] + ((-t+1)/(-q*t^2+1))*B[(0, 1)]
```

```python
sage: E[omega[1]-omega[2]]
((-t+1)/(-q*t^2+1))*B[(1, 0)] + B[(0, -1)] + ((-t+1)/(-q*t^2+1))*B[(0, 1)]
```

```python
sage: E[-omega[2]]
[1/(q^2*t^3), 1/(q*t), q*t^2]
```

(continues on next page)

\text{sage: } E.eigenvalues(0*\omega_1) \\
[q_2^4/(q^2*q_1^4), q_1/(-q_2), q_1/(-q_2)]
\]

Checking the \(T\) and \(T^{-1}\) s:

\[
\text{sage: } T = E._T_Y \\
\text{sage: } Tinv0 = T.Tw_inverse([0]) \\
\text{sage: } Tinv1 = T.Tw_inverse([1]) \\
\text{sage: } Tinv2 = T.Tw_inverse([2]) \\
\text{sage: } for x in [0*\epsilon_0, -\epsilon_0, -\epsilon_1, \epsilon_0, \epsilon_1]: \\
\quad \text{assert } Tinv0(T[0](x)) == x \text{ and } T[0](Tinv0(x)) == x \\
\quad \text{assert } Tinv1(T[1](x)) == x \text{ and } T[1](Tinv1(x)) == x \\
\quad \text{assert } Tinv2(T[2](x)) == x \text{ and } T[2](Tinv2(x)) == x
\]

\[
\text{sage: } start = E[\omega_1]; start \\
\left((-q^2*q_1^3*q_2-q^2*q_1^2*q_2^2)/(q^2*q_1^4-q_2^4)\right) * B[(0, 0)] + B[(1, 0)] \\
\text{sage: } Tinv1(Tinv2(Tinv1(Tinv0(Tinv1(Tinv2(Tinv1(Tinv0(start)))))))) * (q_1*q_2)^4/q^2 \rightarrow 2 == Y0(start) \\
True \\
\text{sage: } Y0(start) == q^2*q_1^4/q_2^4 * start \\
True
\]

Checking the relation between the \(Y\) s:

\[
\text{sage: } q^2 * Y0(Y1(Y2(Y2(start)))) == start \\
True
\]

(continues on next page)
KLO()  
Return the group algebra where the nonsymmetric Macdonald polynomials live.

EXAMPLES:

```python
sage: NonSymmetricMacdonaldPolynomials("B2~").KLO()
Algebra of the Ambient space of the Root system of type ['B', 2] over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational Field
```

L()  
Return the affinization of the classical weight space.

EXAMPLES:

```python
sage: NonSymmetricMacdonaldPolynomials(['B', 2, 1]).L()
Ambient space of the Root system of type ['B', 2, 1]
```

L0()  
Return the space indexing the monomials of the nonsymmetric Macdonald polynomials.

EXAMPLES:

```python
sage: NonSymmetricMacdonaldPolynomials("B2~").L0()
Ambient space of the Root system of type ['B', 2]
sage: NonSymmetricMacdonaldPolynomials("B2~").L0()
Ambient space of the Root system of type ['C', 2]
```

L_check()  
Return the other affinization of the classical weight space.

**Todo:** should this just return $L$ in the simply laced case?

EXAMPLES:

```python
sage: NonSymmetricMacdonaldPolynomials(['B', 2, 1]).L_check()
Coambient space of the Root system of type ['C', 2, 1]
sage: NonSymmetricMacdonaldPolynomials(['B', 2, 1]).L_check().classical()
Ambient space of the Root system of type ['B', 2]
```

L_prime()  
The affine space where classical weights are lifted for the recursion.

Also the parent of $\rho'$.

EXAMPLES:

In the twisted case, this is the affinization of the classical ambient space:
sage: NonSymmetricMacdonaldPolynomials("B2~*").L()
Ambient space of the Root system of type ['B', 2, 1]^*
sage: NonSymmetricMacdonaldPolynomials("B2~*").L().classical()
Ambient space of the Root system of type ['C', 2]

sage: NonSymmetricMacdonaldPolynomials("B2~*").L_prime()
Ambient space of the Root system of type ['B', 2, 1]^*

sage: NonSymmetricMacdonaldPolynomials("B2~*").L_prime().classical()
Ambient space of the Root system of type ['C', 2]

In the untwisted case, this is the other affinization of the classical ambient space:

sage: NonSymmetricMacdonaldPolynomials("B2~") L()
Ambient space of the Root system of type ['B', 2, 1]

sage: NonSymmetricMacdonaldPolynomials("B2~") L().classical()
Ambient space of the Root system of type ['B', 2]

sage: NonSymmetricMacdonaldPolynomials("B2~") L_prime()
Coambient space of the Root system of type ['C', 2, 1]

sage: NonSymmetricMacdonaldPolynomials("B2~") L_prime().classical()
Ambient space of the Root system of type ['B', 2]

For simply laced, the two affinizations coincide:

sage: NonSymmetricMacdonaldPolynomials("A2~") L()
Ambient space of the Root system of type ['A', 2, 1]

sage: NonSymmetricMacdonaldPolynomials("A2~") L().classical()
Ambient space of the Root system of type ['A', 2]

sage: NonSymmetricMacdonaldPolynomials("A2~") L_prime()
Coambient space of the Root system of type ['A', 2, 1]

sage: NonSymmetricMacdonaldPolynomials("A2~") L_prime().classical()
Ambient space of the Root system of type ['A', 2]

Note: do we want the coambient space of type A_2^{(1)} instead?

For type BC:

sage: NonSymmetricMacdonaldPolynomials(['BC', 3, 2]).L_prime()
Ambient space of the Root system of type ['BC', 3, 2]

Q_to_Qcheck()
The reindexing of the index set of the Y’s by the coroot lattice.

EXAMPLES:

sage: E = NonSymmetricMacdonaldPolynomials("C2~")
sage: alphacheck = E.Y().keys().simple_roots()
sage: E.Q_to_Qcheck(alphacheck[0])
alphacheck[0] - alphacheck[2]
sage: E.Q_to_Qcheck(alphacheck[1])
alphacheck[1]
sage: E.Q_to_Qcheck(alphacheck[2])
alphacheck[2]

sage: x.parent()
Root lattice of the Root system of type ['B', 2, 1]
sage: E.Q_to_Qcheck(x)
sage: _.parent()
Coroot lattice of the Root system of type ['C', 2, 1]

Y()

Return the family of $Y$ operators whose eigenvectors are the nonsymmetric Macdonald polynomials.

EXAMPLES:

sage: NonSymmetricMacdonaldPolynomials("C2~").Y()
Lazy family (<lambda>(i))_{i in Root lattice of the Root system of type ['B', 2]}
sage: _.keys().classical()
Root lattice of the Root system of type ['B', 2]

affine_lift($\mu$)

Return the affinization of $\mu$ in $L'$.

INPUT:

- $\mu$ – a classical weight $\mu$

See also:

- hecke_algebra_representation.CherednikOperatorsEigenvectors.affine_lift()
- affine_retract()
- L_prime()

EXAMPLES:

In the untwisted case, this is the other affinization at level 1:

sage: E = NonSymmetricMacdonaldPolynomials("B2~")
sage: L0 = E.keys(); L0
Ambient space of the Root system of type ['B', 2]
sage: omega = L0.fundamental_weights()
sage: E.affine_lift(omega[1])
e[0] + e['deltacheck']
sage: E.affine_lift(omega[1]).parent()
Coambient space of the Root system of type ['C', 2, 1]
In the twisted case, this is the usual affinization at level 1:

```
sage: E = NonSymmetricMacdonaldPolynomials("B2-\star")
sage: L0 = E.keys(); L0
Ambient space of the Root system of type ['C', 2]
sage: omega = L0.fundamental_weights()
sage: E.affine_lift(omega[1])
e[0] + e['deltacheck']
sage: E.affine_lift(omega[1]).parent()
Ambient space of the Root system of type ['B', 2, 1]^*
```

`affine_retract(mu)`

Retract the affine weight $\mu$ into a classical weight.

**INPUT:**

- $\mu$ – an affine weight $\mu$ in $L'$

**See also:**

- `hecke_algebra_representation.HeckeAlgebraRepresentation.affine_retract()`
- `affine_lift()`
- `L_prime()`

**EXAMPLES:**

```
sage: E = NonSymmetricMacdonaldPolynomials("B2-\star")
sage: L0 = E.keys(); L0
Ambient space of the Root system of type ['B', 2, 1]
sage: omega = L0.fundamental_weights()
sage: E.affine_lift(omega[1])
e[0] + e['deltacheck']
sage: E.affine_retract(E.affine_lift(omega[1]))
(1, 0)
```

`cartan_type()`

Return Cartan type of `self`.

**EXAMPLES:**

```
sage: NonSymmetricMacdonaldPolynomials("B", 2, 1).cartan_type()
['B', 2, 1]
```

`eigenvalueExperimental(mu, l)`

Return the eigenvalue of $Y^{\lambda \vee}$ acting on the macdonald polynomial $E_{\mu}$.

**INPUT:**

- $\mu$ – the index $\mu$ of an eigenvector
- $l$ – an index $\lambda \vee$ of some $Y$

**Note:**

- This method is currently not used; most tests below even test the naive method. They are left here as a basis for a future implementation.
- This is actually equivariant, as long as $s_i$ does not fix $\lambda$. 
This method is only really needed for $\lambda^\vee = \alpha_i^\vee$ with $i = 0, \ldots, n$.

See Corollary 6.11 of [Haiman06].

**EXAMPLES:**

```python
sage: K = QQ['q,t'].fraction_field()
sage: q,t = K.gens()
sage: q1 = t
dsage: q2 = -1
dsage: KL = RootSystem(['A',1,1]).ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, q1, q2)
sage: L0 = E.keys()
sage: E.eigenvalues(L0([0,0]))  # Checked by hand by Mark and Arun
[1/(q*t), t]
sage: alpha = E.Y().keys().simple_roots()
sage: E.eigenvalue_experimental(L0([0,0]), alpha[0])  # todo: not implemented
1/(q*t)
sage: E.eigenvalue_experimental(L0([0,0]), alpha[1])
t
Some examples of eigenvalues (not mathematically checked!!!):

```python
sage: E.eigenvalues(L0([1,0]))
[t, 1/(q*t)]
sage: E.eigenvalues(L0([0,1]))
[1/(q^2*t), q*t]
sage: E.eigenvalues(L0([1,1]))
[1/(q*t), t]
sage: E.eigenvalues(L0([2,1]))
[t, 1/(q*t)]
sage: E.eigenvalues(L0([-1,1]))
[(-1)/(-q^3*t), q^2*t]
sage: E.eigenvalues(L0([-2,1]))
[(-1)/(-q^4*t), q^3*t]
sage: E.eigenvalues(L0([-2,0]))
[(-1)/(-q^3*t), q^2*t]
```

Some type $B$ examples:

```python
sage: K = QQ['q,t'].fraction_field()
sage: q,t = K.gens()
sage: q1 = t
dsage: q2 = -1
dsage: L = RootSystem(['B',2,1]).ambient_space()
sage: KL = L.algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, q1, q2)
sage: L0 = E.keys()
sage: alpha = L.simple_coroots()
sage: E.eigenvalue(L0((0,0)), alpha[0])  # not checked # not tested
q/t
sage: E.eigenvalue(L0((1,0)), alpha[1])  # What Mark got by hand # not tested
q
sage: E.eigenvalue(L0((1,0)), alpha[2])  # not checked # not tested
t
sage: E.eigenvalue(L0((1,0)), alpha[0])  # not checked # not tested
1
```

(continues on next page)
sage: L = RootSystem("B2~*").ambient_space()
sage: KL = L.algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL, q, q1, q2)
sage: L0 = E.keys()
sage: alpha = L.simple_coroots()
sage: E.eigenvalue(L0((0,0)), alpha[0]) # assuming Mark's calculation is correct, one should get # not tested
1/(q*t^2)

The expected value can more or less be read off from equation (37), Corollary 6.15 of [Haiman06]

Todo:

• Use proposition 6.9 of [Haiman06] to check the action of the $Y$s on monomials.

• Generalize to any $q_1, q_2$.

• Check claim by Mark: all scalar products should occur in the finite weight lattice, with alpha 0 being the appropriate projection of the affine alpha 0. Question: can this be emulated by being at level 0?

rho_prime()  
Return the level 0 sum of the classical fundamental weights in $L'$.  

See also:  

L_prime()  

EXAMPLES:

Untwisted case:

sage: NonSymmetricMacdonaldPolynomials("B2~").rho_prime() # CHECKME
3/2*e[0] + 1/2*e[1]
sage: NonSymmetricMacdonaldPolynomials("B2~").rho_prime().parent()  
Coambient space of the Root system of type ['C', 2, 1]

Twisted case:

sage: NonSymmetricMacdonaldPolynomials("B2~*").rho_prime() # CHECKME
2*e[0] + e[1]
sage: NonSymmetricMacdonaldPolynomials("B2~*").rho_prime().parent()  
Ambient space of the Root system of type ['B', 2, 1]^*

seed(mu)  
Return $E_\mu$ for $\mu$ minuscule, i.e. in the fundamental alcove.  

INPUT:

• mu – the index $\mu$ of an eigenvector

EXAMPLES:

sage: E = NonSymmetricMacdonaldPolynomials(["A",2,1])  
sage: omega = E.keys().fundamental_weights()  
sage: E.seed(omega[1])  
B[[1, 0, 0]]

symmetric_macdonald_polynomial(mu)  
Return the symmetric Macdonald polynomial indexed by $\mu$. 
INPUT:

- \( \mu \) – a dominant weight \( \mu \)

**Warning:** The result is Weyl-symmetric only for Hecke parameters of the form \( q_1 = v \) and \( q_2 = -1/v \). In general the value of \( v \) below, should be the square root of \(-q_1/q_2\), but the use of \( q_1 = t \) and \( q_2 = -1 \) results in nonintegral powers of \( t \).

**EXAMPLES:**

```sage
sage: K = QQ['q,v,t'].fraction_field()
sage: q,v,t = K.gens()
sage: E = NonSymmetricMacdonaldPolynomials(['A',2,1], q, v, -1/v)
sage: om = E.L0().fundamental_weights()
sage: E.symmetric_macdonald_polynomial(om[2])
B[(1, 1, 0)] + B[(1, 0, 1)] + B[(0, 1, 1)]
sage: E.symmetric_macdonald_polynomial(2*om[1])
((q*v^2+v^2-q-1)/(q*v^2-1))*B[(1, 1, 0)] + ((q*v^2+v^2-q-1)/(q*v^2-1))*B[(1, 0, 1)] + B[(0, 1, 1)] + B[(0, 2, 0)] + B[(2, 0, 1)] + B[(0, 0, 2)]
sage: f = E.symmetric_macdonald_polynomial(E.L0()((2,1,0))); f
((2*q*v^4+v^4-q*v^2+v^2-q-2)/(q*v^4-1))*B[(1, 1, 1)] + B[(1, 2, 0)] + B[(1, 0, 2)] + B[(2, 1, 0)] + B[(2, 0, 1)] + B[(0, 1, 2)] + B[(0, 2, 1)]
```

We compare with the type \( A \) Macdonald polynomials coming from symmetric functions:

```sage
sage: P = SymmetricFunctions(K).macdonald().P()
sage: g = P[2,1].expand(3); g
x0^2*x1 + x0*x1^2 + x0^2*x2 + ((-2*q*t^2 + q*t - t^2 + q - t + 2)/(-q*t^2 + 1))*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
sage: fe = f.expand(g.parent().gens()); fe
x0^2*x1 + x0*x1^2 + x0^2*x2 + ((2*q*v^4 + v^4 - q*v^2 + v^2 - q - 2)/(q*v^4 - 1))*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
sage: g.map_coefficients(lambda x: x.subs(t=v*v)) == fe
True
```

```sage
sage: E = NonSymmetricMacdonaldPolynomials(['C',3,1], q, v, -1/v)
sage: om = E.L0().fundamental_weights()
sage: E.symmetric_macdonald_polynomial(om[1]+om[2])
B[(-2, -1, 0)] + B[(-2, 1, 0)] + B[(-2, 0, -1)] + B[(-2, 0, 1)] + ((4*q^3*v^14+2*q^2*v^14-2*q^3*v^12+2*q^2*v^12-2*q^3*v^10+q*v^12-5*q^2*v^10-5*q*v^4+q^2*v^2-2*v^4+2*q*v^2-2*v^2+2*q+4)/(q^3*v^14-q^2*v^10-q*v^4+1))*B[(0, 0, -1)] + ((4*q^3*v^14+2*q^2*v^14-2*q^3*v^12+2*q^2*v^12-2*q^3*v^10+q*v^12-5*q^2*v^10-5*q*v^4+q^2*v^2-2*v^4+2*q*v^2-2*v^2+2*q+4)/(q^3*v^14-q^2*v^10-q*v^4+1))*B[(0, 0, 1)]
```

(continues on next page)
An example for type $G$:

```python
sage: E = NonSymmetricMacdonaldPolynomials(['G',2,1], q, v, -1/v)
sage: om = E.L0().fundamental_weights()
sage: E.symmetric_macdonald_polynomial(2*om[1])
((3*q^6*v^22+3*q^5*v^22-3*q^6*v^20+q^4*v^22-4*q^5*v^18-q^5*v^16+q^+
\rightarrow 3*q^18-2*q^4*v^16+q^5*v^14-4*q^3*v^16+4*q^4*v^14-4*q^2*v^16+12*q^2*v^14+12*q^5*v^10-
\rightarrow 8*q^3*v^12+4*q^4*v^10-6*q^2*v^12+8*q^3*v^10+10-q^2*v^12-4*v^8+4*q^2*v^16-2*v^2*4+q^2*v^8-2*q^2*v^2+3*v^2-3*q^3)/\left(q^+
\rightarrow 6*v^22-3*q^5*v^20-3*q^4*v^20-3*q^3*v^10+q^2*v^10+q^2*v^2+10+q^v^2+2-1\right)\left(0, 0, 0\right)\_+
\rightarrow + \left((q*v^2+v^2-q-1)/(q*v^2-1)\right)\left(0, 0, 0\right)\_+
\rightarrow + \left((-q*v^2-v^2+q+1)/(q*v^2-1)\right)\left(0, 0, 0\right)\_+
```

**twist** $(\mu, i)$

Act by $s_i$ on the affine weight $\mu$.

This calls `simple_reflection`; which is semantically the same as the default implementation.

**EXAMPLES:**

```python
sage: W = WeylGroup(['B',3])
sage: W.element_class._repr_ = lambda x: ''.join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: T = KW.demazure_lusztig_operators(q1, q2, affine=True)
sage: E = T.Y_eigenvectors()
sage: w = W.an_element(); w
123
sage: E.twist(w,1)
1231
```
5.1.235 Pieri Factors

```python
class sage.combinat.root_system.pieri_factors.PieriFactors:
    Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

    An abstract class for sets of Pieri factors, used for constructing Stanley symmetric functions. The set of Pieri factors for a given type can be realized as an order ideal of the Bruhat order poset generated by a certain set of maximal elements.

    See also:

    - WeylGroups.ParentMethods.pieri_factors()
    - WeylGroups.ElementMethods.stanley_symmetric_function()

    EXAMPLES:
    sage: W = WeylGroup(['A',4])
    sage: PF = W.pieri_factors()
    sage: PF.an_element().reduced_word()
    [4, 3, 2, 1]
    sage: Waff = WeylGroup(['A',4,1])
    sage: PFaff = Waff.pieri_factors()
    sage: Waff.from_reduced_word(PF.an_element().reduced_word()) in PFaff
    True
    sage: W = WeylGroup(['B',3,1])
    sage: PF = W.pieri_factors()
    sage: W.from_reduced_word([2,3,2]) in PF.elements()
    True
    sage: PF.cardinality()
    47
    sage: W = WeylGroup(['C',3,1])
    sage: PF = W.pieri_factors()
    sage: PF.generating_series()
    6*z^6 + 14*z^5 + 18*z^4 + 15*z^3 + 9*z^2 + 4*z + 1
    sage: sorted(w.reduced_word() for w in PF if w.length() == 2)
    [[0, 1], [1, 0], [1, 2], [2, 0], [2, 1], [2, 3], [3, 0], [3, 1], [3, 2]]
```

REFERENCES:

- [FoSta1994]
- [BH1994]
- [Lam1996]
- [Lam2008]
- [LSS2009]
- [Pon2010]

**default_weight()**

Return the function \( i \mapsto z^i \), where \( z \) is the generator of \( \mathbb{Q}[z] \).

EXAMPLES:
sage: W = WeylGroup(['A', 3, 1])
sage: weight = W.pieri_factors().default_weight()
sage: weight(1)
z
sage: weight(5)
z^5

**elements()**

Return the elements of self.

Those are constructed as the elements below the maximal elements of self in Bruhat order.

OUTPUT: a `RecursivelyEnumeratedSet_generic` object

EXAMPLES:

```python
sage: PF = WeylGroup(['A',3]).pieri_factors()
sage: sorted(w.reduced_word() for w in PF.elements())
[[], [1], [2], [2, 1], [3], [3, 1], [3, 2], [3, 2, 1]]
```

See also:

`maximal_elements()`

**Todo:** Possibly remove this method and instead have this class inherit from `RecursivelyEnumeratedSet_generic`.

**generating_series**(weight=None)

Return a length generating series for the elements of self.

EXAMPLES:

```python
sage: PF = WeylGroup(['C',3,1]).pieri_factors()
sage: PF.generating_series()
6*z^6 + 14*z^5 + 18*z^4 + 15*z^3 + 9*z^2 + 4*z + 1
sage: PF = WeylGroup(['B',4]).pieri_factors()
sage: PF.generating_series()
z^7 + 6*z^6 + 14*z^5 + 18*z^4 + 15*z^3 + 9*z^2 + 4*z + 1
```

**max_length()**

Return the maximal length of a Pieri factor.

EXAMPLES:

In type A and A affine, this is $n$:

```python
sage: WeylGroup(['A',5]).pieri_factors().max_length()
5
sage: WeylGroup(['A',5,1]).pieri_factors().max_length()
5
```

In type B and B affine, this is $2n - 1$:

```python
sage: WeylGroup(['B',5,1]).pieri_factors().max_length()
9
sage: WeylGroup(['B',5]).pieri_factors().max_length()
9
```
In type C affine this is $2n$:

```python
sage: WeylGroup(['C',5,1]).pieri_factors().max_length()
sage: WeylGroup(['D',5,1]).pieri_factors().max_length()
```

In type D affine this is $2n - 2$:

```python
sage: WeylGroup(['A',4,1]).pieri_factors().max_length()
```

### class `sage.combinat.root_system.pieri_factors.PieriFactors_affine_type`

**Bases:** `sage.combinat.root_system.pieri_factors.PieriFactors`

**maximal_elements()**

Return the maximal elements of self with respect to Bruhat order.

The current implementation is via a conjectural type-free formula. Use `maximal_elements_combinatorial()` for proven type-specific implementations.

To compare type-free and type-specific (combinatorial) implementations, use method `_test_maximal_elements()`.

**EXAMPLES:**

```python
sage: W = WeylGroup(['A',4,1])
sage: PF = W.pieri_factors()
sage: sorted([w.reduced_word() for w in PF.maximal_elements()], key=str)
```

```python
sage: W = WeylGroup(RootSystem(['C',3,1]).weight_space())
sage: PF = W.pieri_factors()
sage: sorted([w.reduced_word() for w in PF.maximal_elements()], key=str)
```

```python
sage: W = WeylGroup(['B',3,1]).weight_space())
sage: PF = W.pieri_factors()
sage: sorted([w.reduced_word() for w in PF.maximal_elements()], key=str)
```

```python
sage: W = WeylGroup(['D',4,1])
sage: PF = W.pieri_factors()
sage: sorted([w.reduced_word() for w in PF.maximal_elements()], key=str)
```

### class `sage.combinat.root_system.pieri_factors.PieriFactors_finite_type`

**Bases:** `sage.combinat.root_system.pieri_factors.PieriFactors`

The Pieri factors of finite type A are the restriction of the Pieri factors of affine type A to finite permutations (under the canonical embedding of finite type A into the affine Weyl group), and the Pieri factors of finite type B are the restriction of the Pieri factors of affine type C. The finite type D Pieri factors are (weakly) conjectured to be the restriction of the Pieri factors of affine type D.

**maximal_elements()**

The current algorithm uses the fact that the maximal Pieri factors of affine type A,B,C, or D either contain a finite Weyl group element, or contain an affine Weyl group element whose reflection by $s_0$ gets a finite
Weyl group element, and that either of these finite group elements will serve as a maximal element for finite Pieri factors. A better algorithm is desirable.

**EXAMPLES:**

```python
sage: PF = WeylGroup(['A',5]).pieri_factors()
sage: [v.reduced_word() for v in PF.maximal_elements()]
[[5, 4, 3, 2, 1]]
sage: WeylGroup(['B',4]).pieri_factors().maximal_elements()

[[[-1  0  0  0],
  [ 0  1  0  0],
  [ 0  0  1  0],
  [ 0  0  0  1]]]
```

```python
class sage.combinat.root_system.pieri_factors.PieriFactors_type_A(W):
    Bases: sage.combinat.root_system.pieri_factors.PieriFactors_finite_type

    The set of Pieri factors for finite type A.
    This is the set of elements of the Weyl group that have a reduced word that is strictly decreasing. This may also be viewed as the restriction of affine type A Pieri factors to finite Weyl group elements.

    `maximal_elements_combinatorial()`
    Return the maximal Pieri factors, using the type A combinatorial description.

    **EXAMPLES:**

    ```python
    sage: W = WeylGroup(['A',4])
sage: PF = W.pieri_factors()
sage: PF.maximal_elements_combinatorial()[0].reduced_word()
    [4, 3, 2, 1]
    ```

```python
class sage.combinat.root_system.pieri_factors.PieriFactors_type_A_affine(W, min_length, max_length, min_support, max_support):
    Bases: sage.combinat.root_system.pieri_factors.PieriFactors_affine_type

    The set of Pieri factors for type A affine, that is the set of elements of the Weyl Group which are cyclically decreasing.

    Those are used for constructing (affine) Stanley symmetric functions.

    The Pieri factors are in bijection with the proper subsets of the `index_set`. The bijection is given by the support. Namely, let \( f \) be a Pieri factor, and \( \text{red} \) a reduced word for \( f \). No simple reflection appears twice in red, and the support \( S \) of \( \text{red} \) (that is the \( i \) such that \( s_i \) appears in \( \text{red} \)) does not depend on the reduced word.

    `cardinality()`
    Return the cardinality of `self`.  ```
EXAMPLES:

```
sage: WeylGroup(['A', 3, 1]).pieri_factors().cardinality()
sage: W.pieri_factors().cardinality()
sage: W.pieri_factors().generating_series()
15
4*z^3 + 6*z^2 + 4*z + 1
```

`generating_series (weight=None)`

Return a length generating series for the elements of `self`.

EXAMPLES:

```
sage: W = WeylGroup(['A', 3, 1])
sage: W.pieri_factors().cardinality()
sage: W.pieri_factors().generating_series()
15
4*z^3 + 6*z^2 + 4*z + 1
```

`maximal_elements_combinatorial()`

Return the maximal Pieri factors, using the affine type A combinatorial description.

EXAMPLES:

```
sage: W = WeylGroup(['A',4,1])
sage: PF = W.pieri_factors()
sage: [w.reduced_word() for w in PF.maximal_elements_combinatorial()]
[[3, 2, 1, 0], [2, 1, 0, 4], [1, 0, 4, 3], [0, 4, 3, 2], [4, 3, 2, 1]]
```

`stanley_symm_poly_weight (w)`

Weight used in computing (affine) Stanley symmetric polynomials for affine type A.

EXAMPLES:

```
sage: W = WeylGroup(['A',5,1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.one())
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5,4,2,1,0]))
0
```

`subset (length)`

Return the subset of the elements of `self` of length `length`.

INPUT:

- `length` – a non-negative integer

EXAMPLES:

```
sage: PF = WeylGroup(['A', 3, 1]).pieri_factors(); PF
Pieri factors for Weyl Group of type ['A', 3, 1] (as a matrix group acting on the root space)
sage: PF3 = PF.subset(length = 2)
sage: PF3.cardinality()
6
```

---

**class** `sage.combinat.root_system.pieri_factors.PieriFactors_type_B (W)`

**Bases:** `sage.combinat.root_system.pieri_factors.PieriFactors_finite_type`

The type B finite Pieri factors are realized as the set of elements that have a reduced word that is a subword of $12... (n-1) n (n-1)... 21$. They are the restriction of the type C affine Pieri factors to the set of finite Weyl group elements under the usual embedding.
maximal_elements_combinatorial()  
Return the maximal Pieri factors, using the type B combinatorial description.

EXAMPLES:

```python
sage: PF = WeylGroup(['B',4]).pieri_factors()
sage: PF.maximal_elements_combinatorial()[0].reduced_word()
[1, 2, 3, 4, 3, 2, 1]
```

stanley_symm_poly_weight(w)  
Weight used in computing Stanley symmetric polynomials of type $B$.

The weight for finite type $B$ is the number of components of the support of an element minus the number of occurrences of $n$ in a reduced word.

EXAMPLES:

```python
sage: W = WeylGroup(['B',5])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([3,1,5]))
2
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([3,4,5]))
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([1,2,3,4,5,4]))
0
```

class sage.combinat.root_system.pieri_factors.PieriFactors_type_B_affine(W)
Bases: sage.combinat.root_system.pieri_factors.PieriFactors_affine_type

The type B affine Pieri factors are realized as the order ideal (in Bruhat order) generated by the following elements:

- cyclic rotations of the element with reduced word $234...(n-1)n(n-1)...3210$, except for $123...n...320$ and $023...n...321$.
- $123...(n-1)n(n-1)...321$
- $023...(n-1)n(n-1)...320$

EXAMPLES:

```python
sage: W = WeylGroup(['B',4,1])
sage: PF = W.pieri_factors()
sage: W.from_reduced_word([2,3,4,3,2,1,0]) in PF.maximal_elements()
True
sage: W.from_reduced_word([0,2,3,4,3,2,1]) in PF.maximal_elements()
True
sage: W.from_reduced_word([1,0,2,3,4,3,2]) in PF.maximal_elements()
True
sage: W.from_reduced_word([0,2,3,4,3,2,0]) in PF.maximal_elements()
True
sage: W.from_reduced_word([0,2,0]) in PF
True
```

maximal_elements_combinatorial()  
Return the maximal Pieri factors, using the affine type B combinatorial description.

EXAMPLES:
stanley_symm_poly_weight (w)
Return the weight of a Pieri factor to be used in the definition of Stanley symmetric functions.

For type B, this weight involves the number of components of the complement of the support of an element, where we consider 0 and 1 to be one node – if 1 is in the support, then we pretend 0 in the support, and vice versa. We also consider 0 and 1 to be one node for the purpose of counting components of the complement (as if the Dynkin diagram were that of type C). Let n be the rank of the affine Weyl group in question (if type ['B',k,1] then we have n = k+1). Let \( \chi(v.\text{length}() < n-1) \) be the indicator function that is 1 if the length of v is smaller than n-1, and 0 if the length of v is greater than or equal to n-1. If we call \( c'(v) \) the number of components of the complement of the support of v, then the type B weight is given by \( \text{weight} = c'(v) - \chi(v.\text{length}() < n-1) \).

EXAMPLES:

```python
sage: W = WeylGroup(['B',5,1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([0,3]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([0,1,3]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([2,3]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([2,3,4,5]))
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([0,5]))
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([2,4,5,4,3,0]))
-1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([4,5,4,3,0]))
0
```

class sage.combinat.root_system.pieri_factors.PieriFactors_type_C_affine(W)
Bases: sage.combinat.root_system.pieri_factors.PieriFactors_affine_type

The type C affine Pieri factors are realized as the order ideal (in Bruhat order) generated by cyclic rotations of the element with unique reduced word 123...\((n-1)\)(n-1)...3210.

EXAMPLES:

```python
sage: W = WeylGroup(['C',3,1])
sage: PF = W.pieri_factors()
sage: sorted([u.reduced_word() for u in PF.maximal_elements()], key=str)
[[0, 1, 2, 3, 2, 1], [1, 0, 1, 2, 3, 2], [1, 2, 3, 2, 1, 0],
 [2, 1, 0, 2, 3, 2], [2, 3, 2, 1, 0, 1], [3, 2, 1, 0, 1, 2]]
```

maximal_elements_combinatorial()
Return the maximal Pieri factors, using the affine type C combinatorial description.

EXAMPLES:
sage: PF = WeylGroup(['C',3,1]).pieri_factors()
sage: [w.reduced_word() for w in PF.maximal_elements_combinatorial()]
[[0, 1, 2, 3, 2, 1], [1, 0, 1, 2, 3, 2], [2, 1, 0, 1, 2, 3], [3, 2, 1, 0, 1, 2], [2, 3, 2, 1, 0, 1], [1, 2, 3, 2, 1, 0]]

stanley_symm_poly_weight(w)
Return the weight of a Pieri factor to be used in the definition of Stanley symmetric functions.
For type C, this weight is the number of connected components of the support (the indices appearing in a reduced word) of an element.

EXAMPLES:

    sage: W = WeylGroup(['C',5,1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([1,3]))
2
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([1,3,2,0]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5,3,0]))
3
sage: PF.stanley_symm_poly_weight(W.one())
0

class sage.combinat.root_system.pieri_factors.PieriFactors_type_D_affine(W)
Bases: sage.combinat.root_system.pieri_factors.PieriFactors_affine_type

The type D affine Pieri factors are realized as the order ideal (in Bruhat order) generated by the following elements:

- cyclic rotations of the element with reduced word 234...\(n-2\)n(n-1)(n-2)...3210 such that 1 and 0 are always adjacent and (n-1) and n are always adjacent.
- 123...\(n-2\)n(n-1)(n-2)...321
- 023...\(n-2\)n(n-1)(n-2)...320
- \(n(n-2)...2102...(n-2)n\)
- \((n-1)(n-2)...2102...(n-2)(n-1)\)

EXAMPLES:

    sage: W = WeylGroup(['D',5,1])
sage: PF = W.pieri_factors()
sage: W.from_reduced_word([3,2,1,0]) in PF
True
sage: W.from_reduced_word([0,3,2,1]) in PF
False
sage: W.from_reduced_word([0,1,3,2]) in PF
True
sage: W.from_reduced_word([2,0,1,3]) in PF
True
sage: sorted([u.reduced_word() for u in PF.maximal_elements_combinatorial()], key=str)
[[0, 2, 3, 5, 4, 3, 2, 0], [1, 0, 2, 3, 5, 4, 3, 2], [1, 2, 3, 5, 4, 3, 2, 1], [2, 1, 0, 2, 3, 5, 4, 3], [2, 3, 5, 4, 3, 2, 1, 0], [3, 2, 1, 0, 2, 3, 5, 4], [3, 5, 4, 3, 2, 1, 0, 2], [4, 3, 2, 1, 0, 2, 3, 4], [5, 3, 2, 1, 0, 2, 3, 5], [5, 4, 3, 2, 1, 0, 2, 3]]

maximal_elements_combinatorial()
Return the maximal Pieri factors, using the affine type D combinatorial description.
**EXAMPLES:**

```python
sage: W = WeylGroup(['D',5,1])
sage: PF = W.pieri_factors()
sage: set(PF.maximal_elements_combinatorial()) == set(PF.maximal_elements())
True
```

**stanley_symm_poly_weight** *(w)*

Return the weight of *w*, to be used in the definition of Stanley symmetric functions.

**INPUT:**

- *w* – a Pieri factor for this type

For type *D*, this weight involves the number of components of the complement of the support of an element, where we consider 0 and 1 to be one node – if 1 is in the support, then we pretend 0 in the support, and vice versa. Similarly with *n* – 1 and *n*. We also consider 0 and 1, *n* – 1 and *n* to be one node for the purpose of counting components of the complement (as if the Dynkin diagram were that of type *C*).

Type D Stanley symmetric polynomial weights are still conjectural. The given weight comes from conditions on elements of the affine Fomin-Stanley subalgebra, but work is needed to show this weight is correct for affine Stanley symmetric functions – see [LSS2009, Pon2010] for details.

**EXAMPLES:**

```python
sage: W = WeylGroup(['D', 5, 1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5,2,1]))
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5,2,1,0]))
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5,2]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([]))
0

sage: W = WeylGroup(['D',7,1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([2,4,6]))
2
```

### 5.1.236 Tutorial: visualizing root systems

Root systems encode the positions of collections of hyperplanes in space, and form the fundamental combinatorial data underlying Coxeter and Weyl groups, Lie algebras and groups, etc. The theory can be a bit intimidating at first because of the many technical gadgets (roots, coroots, weights, . . . ). Visualizing them goes a long way toward building a geometric intuition.

This tutorial starts from simple plots and guides you all the way to advanced plots with your own combinatorial data drawn on top of it.

**See also:**

- *Root systems* – An overview of root systems in Sage
- *RootLatticeRealizations.ParentMethods.plot()* – the main plotting function, with pointers to all the subroutines
First plots

In this first plot, we draw the root system for type $A_2$ in the ambient space. It is generated from two hyperplanes at a 120 degree angle:

```
sage: L = RootSystem(['A',2]).ambient_space()
sage: L.plot()
Graphics object consisting of 13 graphics primitives
```

Each of those hyperplane $H_{\alpha^\vee}$ is described by a linear form $\alpha^\vee_i$ called simple coroot. To each such hyperplane corresponds a reflection along a vector called root. In this picture, the reflections are orthogonal and the two simple roots $\alpha_1$ and $\alpha_2$ are vectors which are normal to the reflection hyperplanes. The same color code is used uniformly: blue for 1, red for 2, green for 3, ... (see `CartanType.color()`). The fundamental weights, $\Lambda_1$ and $\Lambda_2$ form the dual basis of the coroots.

The two reflections generate a group of order six which is nothing but the usual symmetric group $S_3$, in its natural action by permutations of the coordinates of the ambient space. Wait, but the ambient space should be of dimension 3 then? That’s perfectly right. Here is the full picture in 3D:

```
sage: L = RootSystem(['A',2]).ambient_space()
sage: L.plot(projection=False)
Graphics3d Object
```

However in this space, the line $(1,1,1)$ is fixed by the action of the group. Therefore, the so called barycentric
projection orthogonal to \((1,1,1)\) gives a convenient 2D picture which contains all the essential information. The same projection is used by default in type \(G_2\):

```python
sage: L = RootSystem(['G',2]).ambient_space()
sage: L.plot(reflection_hyperplanes="all")
```

The group is now the dihedral group of order 12, generated by the two reflections \(s_1\) and \(s_2\). The picture displays the hyperplanes for all 12 reflections of the group. Those reflections delimit 12 chambers which are in one to one correspondence with the elements of the group. The fundamental chamber, which is grayed out, is associated with the identity of the group.

**Warning:** The fundamental chamber is currently plotted as the cone generated by the fundamental weights. As can be seen on the previous 3D picture this is not quite correct if the fundamental weights do not span the space.

Another caveat is that some plotting features may require manipulating elements with rational coordinates which will fail if one is working in, say, the weight lattice. It is therefore recommended to use the root, weight, or ambient spaces for plotting purposes rather than their lattice counterparts.

Coming back to the symmetric group, here is the picture in the weight space, with all roots and all reflection hyperplanes; remark that, unlike in the ambient space, a root is not necessarily orthogonal to its corresponding reflection hyperplane:

```python
sage: L = RootSystem(['A',2]).weight_space()
sage: L.plot(roots="all", reflection_hyperplanes="all").show(figsize=15)
```

**Note:** Setting a larger figure size as above can help reduce the overlap between the text labels when the figure gets crowded.

One can further customize which roots to display, as in the following example showing the positive roots in the weight space for type ['G',2], labelled by their coordinates in the root lattice:

```python
sage: Q = RootSystem(['G',2]).root_space()
sage: L = RootSystem(['G',2]).ambient_space()
sage: L.plot(roots=list(Q.positive_roots()), fundamental_weights=False)
```

5.1. Comprehensive Module list 2205
\[ H_{\alpha_1} + \alpha_2 \]

\[ H_{\alpha_1} \]

\[ H_{\alpha_2} \]

\[ H_{\alpha_1} + \alpha_2 \]

\[ H_{\alpha_1} \]

\[ H_{\alpha_2} \]

\[ H_{\alpha_1} + \alpha_2 \]

\[ H_{\alpha_1} \]

\[ H_{\alpha_2} \]

\[ H_{3\alpha_1 + \alpha_2} \]

\[ H_{2\alpha_1 + \alpha_2} \]

\[ H_{\alpha_1} \]

\[ H_{\alpha_2} \]

\[ H_{3\alpha_1 + 2\alpha_2} \]
One can also customize the projection by specifying a function. Here, we display all the roots for type $E_8$ using the projection from its eight dimensional ambient space onto 3D described on Wikipedia's $E_8$ 3D picture:

```
sage: M = matrix([[0., -0.556793440452, 0.19694925177, -0.19694925177, 0., 0.0805477263944, -0.385290876171, 0.], ....:               [0.180913155536, 0., 0.160212955043, 0.160212955043, 0., 0.0990170516545, 0.766360424875, 0.0990170516545], ....:               [0.338261212718, 0, 0, -0.338261212718, 0.672816364803, 0.171502564281, 0, -0.171502564281]])
sage: L = RootSystem(["E", 8]).ambient_space()
sage: L.plot(roots="all", reflection_hyperplanes=False, projection=lambda v: M*vector(v), labels=False)  # long time
```

The projection function should be linear or affine, and return a vector with rational coordinates. The rationale for the later constraint is to allow for using the PPL exact library for manipulating polytopes. Indeed exact calculations give cleaner pictures (adjacent objects, intersection with the bounding box, ...). Besides the interface to PPL is indeed currently faster than that for CDD, and it is likely to become even more so.

**Exercise**

Draw all finite root systems in 2D, using the canonical projection onto their Coxeter plane. See Stembridge’s page.

**Alcoves and chambers**

We now draw the root system for type $G_2$, with its alcoves (in finite type, those really are the chambers) and the corresponding elements of the Weyl group. We enlarge a bit the bounding box to make sure everything fits in the picture:

```
sage: RootSystem(["G", 2]).ambient_space().plot(alcoves=True, alcove_labels=True, bounding_box=5)
```

The same picture in 3D, for type $B_3$:
Exercise

Can you spot the fundamental chamber? The fundamental weights? The simple roots? The longest element of the Weyl group?

Alcove pictures for affine types

We now draw the usual alcove picture for affine type $A_2^{(1)}$:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: L.plot()  # long time
```

This picture is convenient because it is low dimensional and contains most of the relevant information. Beside, by choosing the ambient space, the elements of the Weyl group act as orthogonal affine maps. In particular, reflections are usual (affine) orthogonal reflections. However this is in fact only a slice of the real picture: the Weyl group
actually acts by linear maps on the full ambient space. Those maps stabilize the so-called level $l$ hyperplanes, and we are visualizing here what’s happening at level 1. Here is the full picture in 3D:

```
sage: L.plot(bounding_box=[[-3,3],[-3,3],[-1,1]], affine=False) # long time
Graphics3d Object
```

In fact, in type $A$, this really is a picture in 4D, but as usual the barycentric projection kills the boring extra dimension for us.

It’s usually more readable to only draw the intersection of the reflection hyperplanes with the level 1 hyperplane:

```
sage: L.plot(affine=False, level=1) # long time
Graphics3d Object
```

Such 3D pictures are useful to better understand technicalities, like the fact that the fundamental weights do not necessarily all live at level 1:

```
sage: L = RootSystem(["G",2,1]).ambient_space()
sage: L.plot(affine=False, level=1)
Graphics3d Object
```

**Note:** Such pictures may tend to be a bit flat, and it may be helpful to play with the aspect_ratio and more generally with the various options of the `show()` method:
sage: p = L.plot(affine=False, level=1)
sage: p.show(aspect_ratio=[1,1,2], frame=False)

Exercise

Draw the alcove picture at level 1, and compare the position of the fundamental weights and the vertices of the fundamental alcove.

As for finite root systems, the alcoves are indexed by the elements of the Weyl group \( W \). Two alcoves indexed by \( u \) and \( v \) respectively share a wall if \( u = vs_i \); the color of that wall is given by \( i \):

sage: L = RootSystem(["C",2,1]).ambient_space()
sage: L.plot(coroots="simple", alcove_labels=True) # long time

Graphics object consisting of 216 graphics primitives

Even 2D pictures of the rank \( 1 + 1 \) cases can give some food for thought. Here, we draw the root lattice, with the positive roots of small height in the root poset:

sage: L = RootSystem(["A",1,1]).root_lattice()
sage: seed = L.simple_roots()
sage: succ = attrcall("pred")
sage: positive_roots = RecursivelyEnumeratedSet(seed, succ, structure='graded')
sage: it = iter(positive_roots)
sage: first_positive_roots = [next(it) for i in range(10)]
sage: L.plot(roots=first_positive_roots, affine=False, alcoves=False)

Graphics object consisting of 24 graphics primitives

Exercises

1. Use the same trick to draw the reflection hyperplanes in the weight lattice for the coroots of small height. Add the indexing of the alcoves by elements of the Weyl group. See below for a solution.

2. Draw the positive roots in the weight lattice and in the extended weight lattice.

3. Draw the reflection hyperplanes in the root lattice
4. Recreate John Stembridge’s “Sandwich” arrangement pictures by choosing appropriate coroots for the reflection hyperplanes.

Here is a polished solution for the first exercise:

```plaintext
sage: L = RootSystem(['A',1,1]).weight_space()
sage: seed = L.simple_coroots()
sage: succ = attrcall("pred")
sage: positive_coroots = RecursivelyEnumeratedSet(seed, succ, structure='graded')
sage: it = iter(positive_coroots)
sage: first_positive_coroots = [next(it) for i in range(20)]
sage: p = L.plot(fundamental_chamber=True, reflection_hyperplanes=first_positive_coroots,
             affine=False, alcove_labels=1,
             bounding_box=[[-9,9],[-1,2]],
             projection=lambda x: matrix([[1,-1],[1,1]])*vector(x))
sage: p.show(figsize=20)  # long time
```

Higher dimension affine pictures

We now do some plots for rank 4 affine types, at level 1. The space is tiled by the alcoves, each of which is a 3D simplex:

```plaintext
sage: L = RootSystem(['A',3,1]).ambient_space()
sage: L.plot(reflection_hyperplanes=False, bounding_box=85/100)  # long time
Graphics3d Object
```

It is recommended to use a small bounding box here, for otherwise the number of simplices grows quicker than what Sage can handle smoothly. It can help to specify explicitly which alcoves to visualize. Here is the fundamental alcove, specified by an element of the Weyl group:

```plaintext
sage: W = L.weyl_group()
sage: L.plot(reflection_hyperplanes=False, alcoves=[W.one()], bounding_box=2)
Graphics3d Object
```

and the fundamental polygon, specified by the coordinates of its center in the root lattice:
Finally, we draw the alcoves in the classical fundamental chambers, using that those are indexed by the elements of the Weyl group having no other left descent than 0. In order to see the inner structure, we only draw the wireframe of the facets of the alcoves. Specifying the wireframe option requires a more flexible syntax for plots which will be explained later on in this tutorial:

```
sage: L = RootSystem(["B",3,1]).ambient_space()
sage: W = L.weyl_group()
sage: alcoves = [-w for d in range(12) for w in W.affine_grassmannian_elements_of_given_length(d)]
sage: p = L.plot_fundamental_chamber("classical")
sage: p += L.plot_alcoves(alcoves=alcoves, wireframe=True)
sage: p += L.plot_fundamental_weights()
sage: p.show(frame=False)
```

Exercises

1. Draw the fundamental alcove in the ambient space, just by itself (no reflection hyperplane, root, ...). The automorphism group of the Dynkin diagram for $A_3^{(1)}$ (a cycle of length 4) is the dihedral group. Visualize the
corresponding symmetries of the fundamental alcove.

2. Draw the fundamental alcoves for the other rank 4 affine types, and recover the automorphism groups of their Dynkin diagram from the pictures.

**Drawing on top of a root system plot**

The root system plots have been designed to be used as wallpaper on top of which to draw more information. In the following example, we draw an alcove walk, specified by a word of indices of simple reflections, on top of the weight lattice in affine type $A_{2,1}$:

```python
sage: L = RootSystem(\"A",2,1\).ambient_space()
sage: w1 = [0,2,1,2,0,2,1,0,2,1,2,0,2,0,1,2,0]
sage: L.plot(alcove_walk=w1, bounding_box=6)  # long time
```

Now, what about drawing several alcove walks, and specifying some colors? A single do-it-all plot method would be cumbersome; so instead, it is actually built on top of many methods (see the list below) that can be called independently and combined at will:

```python
sage: L.plot_roots() + L.plot_reflection_hyperplanes()
```

5.1. Comprehensive Module list 2215
Note: By default the axes are disabled in root system plots since they tend to pollute the picture. Annoyingly they come back when combining them. Here is a workaround:

```python
sage: p = L.plot_roots() + L.plot_reflection_hyperplanes()
sage: p.axes(False)
sage: p
Graphics object consisting of 12 graphics primitives
```

In order to specify common information for all the pieces of a root system plot (choice of projection, bounding box, color code for the index set, . . .), the easiest is to create an option object using `plot_parse_options()`, and pass it down to each piece. We use this to plot our two walks:

```python
sage: plot_options = L.plot_parse_options(bounding_box=[[[-2, 5]], [[-2, 6]]])
sage: w2 = [2, 1, 2, 0, 2, 2, 1, 2, 1, 2, 1, 0, 1, 2, 0, 2, 0, 1, 2, 0, 2]
sage: p = L.plot_alcoves(plot_options=plot_options) # long time
sage: p += L.plot_alcove_walk(w1, color="green", plot_options=plot_options) # long
    → time
sage: p += L.plot_alcove_walk(w2, color="orange", plot_options=plot_options) # long
    → time
sage: p # long time
Graphics object consisting of ... graphics primitives
```
And another with some foldings:

```python
sage: p += L.plot_alcove_walk([0,1,2,0,2,0,1,2,0,1],
    ....:     foldings=[False, False, True, False, False, False, True,
    ....:     color="purple")
```

```
Here we show a weight at level 0 and the reduced word implementing the translation by this weight:
```

```python
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: P = RootSystem(["A",2,1]).weight_space(extended=True)
sage: Lambda = P.fundamental_weights()
sage: walk = L.reduced_word_of_translation(L(t))
sage: plot_options = L.plot_parse_options(bounding_box=[[-2,5],[-2,5]])
sage: p = L.plot(plot_options=plot_options)
    # long time
sage: p += L.plot_alcove_walk(walk, color="green", plot_options=plot_options)  # long
    # time
sage: p += plot_options.family_of_vectors({t: L(t)})  # long time
sage: plot_options.finalize(p)  # long time
```

Graphics object consisting of ... graphics primitives
```

```python
sage: p.axes(False)
sage: p.show(figsize=20)
```

```
Graphics object consisting of ... graphics primitives
```

\[ \alpha_0, \alpha_1, \alpha_2, \Lambda_0, \Lambda_1, \Lambda_2, H_{\alpha_0}, H_{\alpha_1}, H_{\alpha_2}, H_{\alpha_0}, H_{\alpha_1}, H_{\alpha_2} \]
Note that the coloring of the translated alcove does not match with that of the fundamental alcove: the translation actually lives in the extended Weyl group and is the composition of the simple reflections indexed by the alcove walk together with a rotation implementing an automorphism of the Dynkin diagram.

We conclude with a rank $3 + 1$ alcove walk:

```python
sage: L = RootSystem(["B",3,1]).ambient_space()
sage: w3 = [0,2,1,3,2,0,2,1,0,2,3,1,2,1,3,2,0,2,0,1,2,0]
sage: L.plot_fundamental_weights() + L.plot_reflection_hyperplanes(bounding_box=2) + L.plot_alcove_walk(w3)
```

Graphics3d Object

Exercise

1. Draw the tiling of 3D space by the fundamental polygons for types A,B,C,D. Hints: use the `wireframe` option of `RootLatticeRealizations.ParentMethods.plot_alcoves()` and the `color` option of `plot()` to only draw the alcove facets indexed by 0.

Solution

```python
sage: L = RootSystem(["A",3,1]).ambient_space()
sage: alcoves = cartesian_product(([0,1],[0,1],[0,1]))
sage: color = lambda i: "black" if i==0 else None
sage: L.plot_alcoves(alcoves=alcoves, color=color, bounding_box=10, wireframe=True).show(frame=False) # long time
```
Hand drawing on top of a root system plot (aka Coxeter graph paper)

Taken from John Stembridge’s excellent data archive:

“If you’ve ever worked with affine reflection groups, you’ve probably wasted lots of time drawing the reflecting hyperplanes of the rank 2 groups on scraps of paper. You may also have wished you had pads of graph paper with these lines drawn in for you. If so, you’ve come to the right place. Behold! Coxeter graph paper!”

Now you can create your own customized color Coxeter graph paper:

```sage
L = RootSystem(['C',2,1]).ambient_space()
p = L.plot(bounding_box=[[-8,9],[-5,7]], coroots="simple") # long time (10 s)
sage: p
# long time
Graphics object consisting of ... graphics primitives
```

By default Sage’s plot are bitmap pictures which would come out ugly if printed on paper. Instead, we recommend saving the picture in postscript or svg before printing it:

```sage
p.save("C21paper.eps")
```

**Note:** Drawing pictures with a large number of alcoves is currently somewhat ridiculously slow. This is due to the use of generic code that works uniformly in all dimension rather than taylor-made code for 2D. Things should improve
with the fast interface to the PPL library (see e.g. trac ticket #12553).

**Drawing custom objects on top of a root system plot**

So far so good. Now, what if one wants to draw, on top of a root system plot, some object for which there is no preexisting plot method? Again, the `plot_options` object come in handy, as it can be used to compute appropriate coordinates. Here we draw the permutohedron, that is the Cayley graph of the symmetric group $W$, by positioning each element $w$ at $w(\rho)$, where $\rho$ is in the fundamental alcove:

```
sage: L = RootSystem("A",2).ambient_space()
sage: rho = L.rho()
sage: plot_options = L.plot_parse_options()
sage: W = L.weyl_group()
sage: g = W.cayley_graph(side="right")
sage: positions = {w: plot_options.projection(w.action(rho)) for w in W}
sage: p = L.plot_alcoves()
sage: p += g.plot(pos = positions, vertex_size=0, color_by_label=plot_options.color)
sage: p.axes(False)
sage: p
```

Todo: Could we have nice \LaTeX labels in this graph?

The same picture for $A_3$ gives a nice 3D permutohedron:

```
sage: L = RootSystem("A",3).ambient_space()
sage: rho = L.rho()
sage: plot_options = L.plot_parse_options()
sage: W = L.weyl_group()
sage: g = W.cayley_graph(side="right")
sage: positions = {w: plot_options.projection(w.action(rho)) for w in W}
sage: p = L.plot_roots()
sage: p += g.plot3d(pos3d=positions, color_by_label=plot_options.color)
sage: p
```

Todo: Could we have nice \LaTeX labels in this graph?
Exercises

1. Locate the identity element of $W$ in the previous picture
2. Rotate the picture appropriately to highlight the various symmetries of the permutohedron.
3. Make a function out of the previous example, and explore the Cayley graphs of all rank 2 and 3 Weyl groups.
4. Draw the root poset for type $B_2$ and $B_3$
5. Draw the root poset for type $E_8$ to recover the picture from Wikipedia article File:E8_3D.png

Similarly, we display a crystal graph by positioning each element according to its weight:

```python
sage: C = crystals.Tableaux("A", [4, 2])
sage: L = C.weight_lattice_realization()
sage: plot_options = L.plot_parse_options()

sage: g = C.digraph()
sage: positions = {x: plot_options.projection(x.weight()) for x in C}
sage: p = L.plot()
sage: p += g.plot(pos=positions,
            color_by_label=plot_options.color, vertex_size=0)

sage: p.axes(False)
sage: p.show(figsize=15)
```
Note: In the above picture, many pairs of tableaux have the same weight and are thus superposed (look for example near the center). Some more layout logic would be needed to separate those nodes properly, but the foundations are laid firmly and uniformly across all types of root systems for writing such extensions.

Here is an analogue picture in 3D:

```python
sage: C = crystals.Tableaux(['A',3], shape=[3,2,1])
sage: L = C.weight_lattice_realization()
sage: plot_options = L.plot_parse_options()
sage: g = C.digraph()
sage: positions = {x:plot_options.projection(x.weight()) for x in C}
sage: p = L.plot(reflection_hyperplanes=False, fundamental_weights=False)
sage: p += g.plot3d(pos3d=positions, vertex_labels=True,
    ....: color_by_label=plot_options.color, edge_labels=True)
sage: p
Graphics3d Object
```

Exercise

Explore the previous picture and notice how the edges of the crystal graph are parallel to the simple roots.

Enjoy and please post your best pictures on the Sage-Combinat wiki.

class sage.combinat.root_system.plot.PlotOptions(space, projection=True, bounding_box=3, color=<bound method CartanTypeFactory.color of <class 'sage.combinat.root_system.cartan_type.CartanTypeFactory'>>, labels=True, level=None, affine=None, arrowsize=5)

Bases: object

A class for plotting options for root lattice realizations.

See also:

- `RootLatticeRealizations.ParentMethods.plot()` for a description of the plotting options
- `Tutorial: visualizing root systems` for a tutorial on root system plotting

color (i)

Return the color to be used for objects indexed by i.

INPUT:

- i – an index

See also:

`index_of_object()`

EXAMPLES:

```python
sage: L = RootSystem(['A',2]).root_lattice()
sage: options = L.plot_parse_options(labels=False)
sage: alpha = L.simple_roots()
sage: options.color(1)
```

(continues on next page)
'blue'
sage: options.color(2)
'red'
sage: for alpha in L.roots():
    ....: print("{} {}".format(alpha, options.color(alpha)))
alpha[1] blue
alpha[2] red
-alpha[1] black
-alpha[2] black

cone (rays=[], lines=[], color='black', thickness=1, alpha=1, wireframe=False, label=None, draw_degenerate=True, as_polyhedron=False)
Return the cone generated by the given rays and lines.

INPUT:

- rays, lines – lists of elements of the root lattice realization (default: [])
- color – a color (default: "black")
- alpha – a number in the interval [0, 1] (default: 1) the desired transparency
- label – an object to be used as for this cone. The label itself will be constructed by calling latex() or repr() on the object depending on the graphics backend.
- draw_degenerate – a boolean (default: True) whether to draw cones with a degenerate intersection with the bounding box
- as_polyhedron – a boolean (default: False) whether to return the result as a polyhedron, without clipping it to the bounding box, and without making a plot out of it (for testing purposes)

OUTPUT:
A graphic object, a polyhedron, or 0.

EXAMPLES:

```
sage: L = RootSystem(["A",2]).root_lattice()
sage: options = L.plot_parse_options()
sage: alpha = L.simple_roots()
sage: p = options.cone(rays=[alpha[1]], lines=[alpha[2]], color='green', label=2)
sage: p
Graphics object consisting of 2 graphics primitives
sage: list(p)
[Polygon defined by 4 points, Text '$2$' at the point (3.15...,3.15...)]
sage: options.cone(rays=[alpha[1]], lines=[alpha[2]], color='green', label=2, as_polyhedron=True)
A 2-dimensional polyhedron in ZZ^2 defined as the convex hull of 1 vertex, 1 ray, 1 line
```

An empty result, being outside of the bounding box:

```
sage: options = L.plot_parse_options(labels=True, bounding_box=[[-10,-9]]*2)
sage: options.cone(rays=[alpha[1]], lines=[alpha[2]], color='green', label=2)
0
```

Test that the options are properly passed down:
This method is tested indirectly but extensively by the various plot methods of root lattice realizations.

**empty (*args)**

Return an empty plot.

**EXAMPLES:**

```
sage: L = RootSystem(['A',2]).root_lattice()
sage: options = L.plot_parse_options()
sage: p = options.empty()
sage: list(p)
[]
sage: sorted(p[0].options().items())
[('alpha', 0.500000000000000), ('legend_color', None), ('legend_label', None), ('rgbcolor', 'green'), ('thickness', 4), ('zorder', 1)]
```

```
This currently returns int(0):

sage: options.empty()
0
```

```
This is not a plot, so may cause some corner cases. On the other hand, 0 behaves as a fast neutral element, which is important given the typical idioms used in the plotting code:

sage: p = point([[0,0]])
sage: p + options.empty() is p
```

```
**family_of_vectors (vectors)**

Return a plot of a family of vectors.

**INPUT:**

- **vectors** – family or vectors in self

The vectors are labelled by their index.

**EXAMPLES:**

```
sage: L = RootSystem(['A',2]).root_lattice()
sage: options = L.plot_parse_options()
sage: alpha = L.simple_roots()
sage: p = options.family_of_vectors(alpha); p
Graphics object consisting of 4 graphics primitives
sage: list(p)
[Arrow from (0.0,0.0) to (1.0,0.0), Text '$1$' at the point (1.05,0.0), Arrow from (0.0,0.0) to (0.0,1.0), Text '$2$' at the point (0.0,1.05)]
```

Handling of colors and labels:

```
sage: color=lambda i: "purple" if i==1 else None
sage: options = L.plot_parse_options(labels=False, color=color)
```
Matplotlib emits a warning for arrows of length 0 and draws nothing anyway. So we do not draw them at all:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: options = L.plot_parse_options()
sage: Lambda = L.fundamental_weights()
sage: p = options.family_of_vectors(Lambda); p
Graphics object consisting of 5 graphics primitives
sage: list(p)
[Text '$0$' at the point (0.0,0.0),
  Arrow from (0.0,0.0) to (0.5,0.86602451838...),
  Text '$1$' at the point (0.525,0.909325744308...),
  Arrow from (0.0,0.0) to (-0.5,0.86602451838...),
  Text '$2$' at the point (-0.525,0.909325744308...)]
```

**finalize(G)**

Finalize a root system plot.

**INPUT:**

- `G` – a root system plot or 0

This sets the aspect ratio to 1 and remove the axes. This should be called by all the user-level plotting methods of root systems. This will become mostly obsolete when customization options won’t be lost anymore upon addition of graphics objects and there will be a proper empty object for 2D and 3D plots.

**EXAMPLES:**

```
sage: L = RootSystem(["B",2,1]).ambient_space()
sage: options = L.plot_parse_options()
sage: p = L.plot_roots(plot_options=options)
sage: p += L.plot_coroots(plot_options=options)
sage: p.axes()  # doctest: +HOST_INDEPENDENT
True
sage: p = options.finalize(p)
sage: p.axes()  # doctest: +HOST_INDEPENDENT
False
sage: p.aspect_ratio()  # doctest: +HOST_INDEPENDENT
1.0
```

If the input is 0, this returns an empty graphics object:

```
sage: type(options.finalize(0))
<class 'sage.plot.plot3d.base.Graphics3dGroup'>
```

(continues on next page)
sage: options = L.plot_parse_options()
sage: type(options.finalize(0))
<class 'sage.plot.graphics.Graphics'>
sage: list(options.finalize(0))
[]

in_bounding_box(x)
Return whether \( x \) is in the bounding box.

INPUT:

* \( x \) – an element of the root lattice realization

This method is currently one of the bottlenecks, and therefore cached.

EXAMPLES:

sage: L = RootSystem(["A",2,1]).ambient_space()
sage: options = L.plot_parse_options()
sage: alpha = L.simple_roots()
sage: options.in_bounding_box(alpha[1])
True
sage: options.in_bounding_box(3*alpha[1])
False

index_of_object(i)
Try to return the node of the Dynkin diagram indexing the object \( i \).

OUTPUT: a node of the Dynkin diagram or None

EXAMPLES:

sage: L = RootSystem(["A",3]).root_lattice()
sage: alpha = L.simple_roots()
sage: omega = RootSystem(["A",3]).weight_lattice().fundamental_weights()
sage: options = L.plot_parse_options(labels=False)
sage: options.index_of_object(3)
3
sage: options.index_of_object(alpha[1])
1
sage: options.index_of_object(omega[2])
2
30
sage: options.index_of_object("bla")

intersection_at_level_1(x)
Return \( x \) scaled at the appropriate level, if level is set; otherwise return \( x \).

INPUT:

* \( x \) – an element of the root lattice realization

EXAMPLES:

sage: L = RootSystem(["A",2,1]).weight_space()
sage: options = L.plot_parse_options()
sage: options.intersection_at_level_1(L.rho())

(continued from previous page)

sage: options = L.plot_parse_options(affine=False, level=2)
sage: options.intersection_at_level_1(L.rho())

When level is not set, x is returned:
sage: options = L.plot_parse_options(affine=False)
sage: options.intersection_at_level_1(L.rho())
Lambda[0] + Lambda[1] + Lambda[2]

projection(v)
Return the projection of v.
INPUT:
• x – an element of the root lattice realization
OUTPUT:
An immutable vector with integer or rational coefficients.
EXAMPLES:
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: options = L.plot_parse_options()
sage: options.projection(L.rho())
(0, 989/571)
sage: options = L.plot_parse_options(projection=False)
sage: options.projection(L.rho())
(2, 1, 0)

reflection_hyperplane(coroot, as_polyhedron=False)
Return a plot of the reflection hyperplane indexed by this coroot.
• coroot – a coroot
EXAMPLES:
sage: L = RootSystem(["B",2]).weight_space()
sage: alphacheck = L.simple_coroots()
sage: options = L.plot_parse_options()
sage: H = options.reflection_hyperplane(alphacheck[1]); H
Graphics object consisting of 2 graphics primitives

Todo: Display the periodic orientation by adding a + and a − sign close to the label. Typically by using
the associated root to shift a bit from the vertex upon which the hyperplane label is attached.
text(label, position, rgbcolor=0, 0, 0)
Return text widget with label label at position position
INPUT:
• label – a string, or a Sage object upon which latex will be called
• position – a position
• rgbcolor – the color as an RGB tuple
5.1. Comprehensive Module list

2227


EXAMPLES:

```python
sage: L = RootSystem(['A',2]).root_lattice()
sage: options = L.plot_parse_options()
sage: list(options.text('coucou', [0,1]))
[Text 'coucou' at the point (0.0,1.0)]
sage: list(options.text(L.simple_root(1), [0,1]))
[Text '$\alpha_{1}$' at the point (0.0,1.0)]
sage: list(options.text(L.simple_root(2), [1,0], rgbcolor=(1,0.5,0)))
[Text '$\alpha_{2}$' at the point (1.0,0.0)]
sage: options = RootSystem(['A',2]).root_lattice().plot_parse_options(labels=False)
sage: options.text('coucou', [0,1])
0
sage: options = RootSystem(['B',3]).root_lattice().plot_parse_options()
sage: print(options.text('coucou', [0,1,2]).x3d_str())
<Transform translation='0 1 2'>
  <Shape>
    <Text string='coucou' solid='true'/>
    <Appearance>
      <Material diffuseColor='0.0 0.0 0.0' shininess='1.0' specularColor='0.0 0.0 0.0'/>
    </Appearance>
  </Shape>
</Transform>
```

**thickness** (*i*)

Return the thickness to be used for lines indexed by *i*.

**INPUT:**

- *i* – an index

**See also:**

`index_of_object()`

**EXAMPLES:**

```python
sage: L = RootSystem(['A',2,1]).root_lattice()
sage: options = L.plot_parse_options(labels=False)
sage: alpha = L.simple_roots()
sage: options.thickness(0)
2
sage: options.thickness(1)
1
sage: options.thickness(2)
1
sage: for alpha in L.simple_roots():
    ....:     print("{} {}").format(alpha, options.thickness(alpha))
alpha[0] 2
alpha[1] 1
alpha[2] 1
```

`sage.combinat.root_system.plot.barycentric_projection_matrix(n, angle=0)`

Returns a family of *n* + 1 vectors evenly spaced in a real vector space of dimension *n*.

Those vectors are of norm 1, the scalar product between any two vector is 1/*n*, thus the distance between two tips is constant.

The family is built recursively and uniquely determined by the following property: the last vector is (0, ..., 0, -1), and the projection of the first *n* vectors in dimension *n* − 1, after appropriate rescaling to norm 1.
1. retrieves the family for \( n - 1 \).

**OUTPUT:**

A matrix with \( n + 1 \) columns of height \( n \) with rational or symbolic coefficients.

**EXAMPLES:**

One vector in dimension 0:

```python
sage: from sage.combinat.root_system.root_lattice_realizations import barycentric_projection_matrix
sage: m = barycentric_projection_matrix(0); m
[]
sage: matrix(QQ,0,1).nrows()
0
sage: matrix(QQ,0,1).ncols()
1
```

Two vectors in dimension 1:

```python
sage: barycentric_projection_matrix(1)
[ 1 -1]
```

Three vectors in dimension 2:

```python
sage: barycentric_projection_matrix(2)
[ 1/2*sqrt(3) -1/2*sqrt(3) 0]
[ 1/2 1/2 -1]
```

Four vectors in dimension 3:

```python
sage: m = barycentric_projection_matrix(3); m
[ 1/3*sqrt(3)*sqrt(2) -1/3*sqrt(3)*sqrt(2) 0]
[ 1/3*sqrt(2) 1/3*sqrt(2) -2/3*sqrt(2)]
[ 1/3 1/3 1/3]
```

The columns give four vectors that sum up to zero:

```python
sage: sum(m.columns())
(0, 0, 0)
```

and have regular mutual angles:

```python
sage: m.transpose()*m
[ 1 -1/3 -1/3 -1/3]
[-1/3 1 -1/3 -1/3]
[-1/3 -1/3 1 -1/3]
[-1/3 -1/3 -1/3 1]
```

Here is a plot of them:

```python
sage: sum(arrow((0,0,0),x) for x in m.columns())
Graphics3d Object
```

For 2D drawings of root systems, it is desirable to rotate the result to match with the usual conventions:
5.1.237 Finite complex reflection groups

Let $V$ be a finite-dimensional complex vector space. A reflection of $V$ is an operator $r \in \text{GL}(V)$ that has finite order and fixes pointwise a hyperplane in $V$.

For more definitions and classification types of finite complex reflection groups, see Wikipedia article Complex_reflection_group.

The point of entry to work with reflection groups is $\text{ReflectionGroup()}$ which can be used with finite Cartan-Killing types:

```
sage: ReflectionGroup(['A',2])  # optional - gap3
Irreducible real reflection group of rank 2 and type A2
sage: ReflectionGroup(['F',4])  # optional - gap3
Irreducible real reflection group of rank 4 and type F4
sage: ReflectionGroup(['H',3])  # optional - gap3
Irreducible real reflection group of rank 3 and type H3
```

or with Shephard-Todd types:

```
sage: ReflectionGroup((1,1,3))  # optional - gap3
Irreducible real reflection group of rank 2 and type A2
sage: ReflectionGroup((2,1,3))  # optional - gap3
Irreducible real reflection group of rank 3 and type B3
sage: ReflectionGroup((3,1,3))  # optional - gap3
Irreducible complex reflection group of rank 3 and type G(3,1,3)
sage: ReflectionGroup((4,2,3))  # optional - gap3
Irreducible complex reflection group of rank 3 and type G(4,2,3)
sage: ReflectionGroup((4))  # optional - gap3
Irreducible complex reflection group of rank 2 and type ST4
sage: ReflectionGroup(31)  # optional - gap3
Irreducible complex reflection group of rank 4 and type ST31
```

Also reducible types are allowed using concatenation:

```
sage: ReflectionGroup(['A',3],(4,2,3))  # optional - gap3
Reducible complex reflection group of rank 6 and type A3 x G(4,2,3)
```

Some special cases also occur, among them are:

```
sage: W = ReflectionGroup((2,2,2)); W
Reducible real reflection group of rank 2 and type A1 x A1
sage: W = ReflectionGroup((2,2,3)); W  # optional - gap3
Irreducible real reflection group of rank 3 and type A3
```

**Warning:** Uses the GAP3 package Chevie which is available as an experimental package (installed by `sage -i gap3`) or to download by hand from Jean Michel’s website.

A guided tour
We start with the example type 𝐵2 :
sage: W = ReflectionGroup(['B',2]); W
Irreducible real reflection group of rank 2 and type B2

# optional - gap3

Most importantly, observe that the group elements are usually represented by permutations of the roots:
sage: for w in W: print(w)
()
(1,3)(2,6)(5,7)
(1,5)(2,4)(6,8)
(1,7,5,3)(2,4,6,8)
(1,3,5,7)(2,8,6,4)
(2,8)(3,7)(4,6)
(1,7)(3,5)(4,8)
(1,5)(2,6)(3,7)(4,8)

# optional - gap3

This has the drawback that one can hardly see anything. Usually, one would look at elements with either of the
following methods:
sage: for w in W: w.reduced_word()
[]
[2]
[1]
[1, 2]
[2, 1]
[2, 1, 2]
[1, 2, 1]
[1, 2, 1, 2]

# optional - gap3

sage: for w in W: w.reduced_word_in_reflections()
[]
[2]
[1]
[1, 2]
[1, 4]
[3]
[4]
[1, 3]

# optional - gap3

sage: for w in W: w.reduced_word(); w.to_matrix(); print("")
[]
[1 0]
[0 1]

# optional - gap3

[2]
[ 1 1]
[ 0 -1]
[1]
[-1
[ 2

0]
1]

[1, 2]
[-1 -1]
[ 2 1]
(continues on next page)

5.1. Comprehensive Module list

2231


The standard references for actions of complex reflection groups have the matrices acting on the right, so:

```
sage: W.simple_reflection(1).to_matrix()  # optional - gap3
[[-1 0],
 [ 2 1]]
```

sends the simple root $\alpha_0$, or $(1,0)$ in vector notation, to its negative, while sending $\alpha_1$ to $2\alpha_0 + \alpha_1$.

**Todo:**

- properly provide root systems for real reflection groups
- element class should be unique to be able to work with large groups without creating elements multiple times
- `is_shephard_group`, `is_generalized_coxeter_group`
- exponents and coexponents
- coinvariant ring:
  - fake degrees from Torsten Hoge
  - operation of linear characters on all characters
  - harmonic polynomials
- linear forms for hyperplanes
- field of definition
- intersection lattice and characteristic polynomial:

```python
X = [ alpha(t) for t in W.distinguished_reflections() ]
X = Matrix(CF,X).transpose()
Y = Matroid(X)
```

- linear characters
- permutation $\pi$ on irreducibles
- hyperplane orbits (76.13 in Gap Manual)
- improve invariant_form with a code similar to the one in `reflection_group_real.py`
- add a method `reflection_to_root` or `distinguished_reflection_to_positive_root`
• diagrams in ASCII-art (76.15)
• standard (BMR) presentations
• character table directly from Chevie
• \texttt{GenericOrder} (76.20), \texttt{TorusOrder} (76.21)
• correct fundamental invariants for $G_{24}$, check the others
• copy hardcoded data (degrees, invariants, braid relations...) into sage
• add other hardcoded data from the tables in chevie (location is SAGEDIR/local/gap3/gap-jm5-2015-02-01/gap3/pkg/chevie/tbl): basic derivations, discriminant,...
• transfer code for \texttt{reduced\_word\_in\_reflections} into Gap4 or Sage
• list of reduced words for an element
• list of reduced words in reflections for an element
• Hurwitz action?
• \texttt{is\_crystallographic()} should be hardcoded

AUTHORS:
• Christian Stump (2015): initial version

\texttt{class} \texttt{sage.combinat.root\_system.reflection\_group\_complex.ComplexReflectionGroup}(W_types, \texttt{index\_set=None, \texttt{hyperplane\_index\_set=None, \texttt{reflection\_index\_set=None}}})

\texttt{Bases: sage.structure.unique\_representation.UniqueRepresentation, sage.groups.perm\_gps.perm\_group.PermutationGroup\_generic}

A complex reflection group given as a permutation group.

\texttt{See also: \texttt{ReflectionGroup()}}

\texttt{class Element}
\texttt{Bases: sage.combinat.root\_system.reflection\_group\_element.ComplexReflectionGroupElement,}

\texttt{ComplexReflectionGroupElement}

\texttt{conjugacy\_class()}
\texttt{Return the conjugacy class of self.}

\texttt{EXAMPLES:}
\begin{verbatim}
sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: for w in W: sorted(w.conjugacy_class()) # optional - gap3
  []
  [(1,3),(2,5),(4,6)], (1,4),(2,3),(5,6), (1,5),(2,4),(3,6)]
  [(1,3),(2,5),(4,6)], (1,4),(2,3),(5,6), (1,5),(2,4),(3,6)]
  [(1,2,6),(3,4,5), (1,6,2),(3,5,4)]
  [(1,2,6),(3,4,5), (1,6,2),(3,5,4)]
  [(1,3),(2,5),(4,6)], (1,4),(2,3),(5,6), (1,5),(2,4),(3,6)]
\end{verbatim}
conjugacy_class_representative()
Return a representative of the conjugacy class of self.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: for w in W: # optional - gap3
....:   print('%s %s' % (w.reduced_word(), w.conjugacy_class_representative().reduced_word())) # optional - gap3
[] [1]
[2] [1]
[1, 2] [1, 2]
[2, 1] [2]
[1, 2, 1] [1]
```

reflection_length (in_unitary_group=False)
Return the reflection length of self.
This is the minimal numbers of reflections needed to obtain self.

INPUT:
• in_unitary_group — (default: False) if True, the reflection length is computed in the
  unitary group which is the dimension of the move space of self

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: sorted([t.reflection_length() for t in W]) # optional - gap3
[0, 1, 1, 1, 2, 2]
sage: W = ReflectionGroup((2,1,2)) # optional - gap3
sage: sorted([t.reflection_length() for t in W]) # optional - gap3
[0, 1, 1, 1, 1, 2, 2, 2]
sage: W = ReflectionGroup((2,2,2)) # optional - gap3
sage: sorted([t.reflection_length() for t in W]) # optional - gap3
[0, 1, 1, 2]
sage: W = ReflectionGroup((3,1,2)) # optional - gap3
sage: sorted([t.reflection_length() for t in W]) # optional - gap3
[0, 1, 1, 1, 1, 1, 1, 1, 1, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2]
```

apply_vector_field (f, vf=None)
Returns a rational function obtained by applying the vector field vf to the rational function f.
If vf is not given, the primitive vector field is used.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: for x in W.primitive_vector_field()[0].parent().gens(): # optional - gap3
....:   print(W.apply_vector_field(x))
3*x1/(6*x0^2 - 6*x0*x1 - 12*x1^2)
1/(6*x0^2 - 6*x0*x1 - 12*x1^2)
```

braid_relations()
Return the braid relations of self.

EXAMPLES:
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.braid_relations()  # optional - gap3
[[[1, 2, 1], [2, 1, 2]]]

sage: W = ReflectionGroup((2,1,3))  # optional - gap3
sage: W.braid_relations()  # optional - gap3
[[[1, 2, 1, 2], [2, 1, 2, 1]], [[1, 3], [3, 1]], [[2, 3, 2], [3, 2, 3]]]

sage: W = ReflectionGroup((2,2,3))  # optional - gap3
sage: W.braid_relations()  # optional - gap3
[[[1, 2], [2, 1]], [[1, 3], [3, 1]], [[2, 3, 2], [3, 2, 3]]]

cartan_matrix()
Return the Cartan matrix associated with self.

If self is crystallographic, the returned Cartan matrix is an instance of CartanMatrix, and a normal
matrix otherwise.

Let $s_1, \ldots, s_n$ be a set of reflections which generate self with associated simple roots $s_1, \ldots, s_n$ and
simple coroots $s_i^\vee$. Then the Cartan matrix $C = (c_{ij})$ is given by $s_i^\vee(s_j)$. The Cartan matrix completely
determines the reflection representation if the $s_i$ are linearly independent.

EXAMPLES:

sage: ReflectionGroup(['A',4]).cartan_matrix()  # optional - gap3
[ 2 -1 0 0]
[-1 2 -1 0]
[ 0 -1 2 -1]
[ 0 0 -1 2]
sage: ReflectionGroup(['H',4]).cartan_matrix()  # optional - gap3
[ 2 E(5)^2 + E(5)^3 0 0]
[E(5)^2 + E(5)^3 2 -1 0]
[ 0 -1 2 -1]
[ 0 0 -1 2]
sage: ReflectionGroup(4).cartan_matrix()  # optional - gap3
[-2*E(3) - E(3)^2 E(3)^2]
[-E(3)^2 -2 *E(3) - E(3)^2]

codegrees()
Return the codegrees of self ordered within each irreducible component of self.

EXAMPLES:

sage: W = ReflectionGroup((1,1,4))  # optional - gap3
sage: W.codegrees()  # optional - gap3
(2, 1, 0)
sage: W = ReflectionGroup((2,1,4))  # optional - gap3
sage: W.codegrees()  # optional - gap3
(6, 4, 2, 0)

(continues on next page)
sage: W = ReflectionGroup((4,1,4))  # optional - gap3
sage: W.codegrees()                  # optional - gap3
(12, 8, 4, 0)

sage: W = ReflectionGroup((4,2,4))  # optional - gap3
sage: W.codegrees()                  # optional - gap3
(12, 8, 4, 0)

sage: W = ReflectionGroup((4,4,4))  # optional - gap3
sage: W.codegrees()                  # optional - gap3
(8, 8, 4, 0)

sage: W = ReflectionGroup((1,1,4), (3,1,2))  # optional - gap3
sage: W.codegrees()                  # optional - gap3
(2, 1, 0, 3, 0)

sage: W = ReflectionGroup((1,1,4), (6,1,12), 23)  # optional - gap3
   → # fails in GAP3
sage: W.codegrees()                  # optional - gap3
(2, 1, 0, 66, 60, 54, 48, 42, 36, 30, 24, 18, 12, 6, 0, 8, 4, 0)

conjugacy_classes()
Return the conjugacy classes of self.

EXAMPLES:

sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: for C in W.conjugacy_classes(): sorted(C)  # optional - gap3
[()]
[(1,3)(2,5)(4,6), (1,4)(2,3)(5,6), (1,5)(2,4)(3,6)]
[(1,2,6)(3,4,5), (1,6,2)(3,5,4)]

sage: W = ReflectionGroup((1,1,4))  # optional - gap3
sage: sum(len(C) for C in W.conjugacy_classes()) == W.cardinality()  # optional - gap3
True

conjugacy_classes_representatives()
Return the shortest representatives of the conjugacy classes of self.

EXAMPLES:

sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: [w.reduced_word() for w in W.conjugacy_classes_representatives()]  # optional - gap3
[[], [1], [1, 2]]
sage: W = ReflectionGroup((1,1,4))  # optional - gap3
sage: [w.reduced_word() for w in W.conjugacy_classes_representatives()]  # optional - gap3
[[], [1], [1, 3], [1, 2], [1, 3, 2]]

sage: W = ReflectionGroup((3,1,2))  # optional - gap3
sage: [w.reduced_word() for w in W.conjugacy_classes_representatives()]  # optional - gap3
[[], [1], [1, 1], [2, 1, 2, 1], [2, 1, 2, 1, 1],
 [2, 1, 1, 2, 1, 1], [2], [1, 2], [1, 1, 2]]

sage: W = ReflectionGroup(23)  # optional - gap3
sage: [w.reduced_word() for w in W.conjugacy_classes_representatives()]  # optional - gap3
[[], [1],
 [1, 2],
 [1, 3],
 [2, 3],
 [1, 2, 3],
 [1, 2, 1, 2],
 [1, 2, 1, 2, 3],
 [1, 2, 1, 2, 3, 2, 1, 2, 3],
 [1, 2, 1, 2, 1, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]]

coxeter_number(\(\chi=\text{None}\))

Return the Coxeter number associated to the irreducible character \(\chi\) of the reflection group \(W\).

The Coxeter number of a complex reflection group \(W\) is the trace in a character \(\chi\) of \(\sum_t (Id - t)\), where \(t\) runs over all reflections. The result is always an integer.

When \(\chi\) is the reflection representation, the Coxeter number is equal to \(N + N^*\), where \(N\) is the number of reflections, \(N^*\) is the number of reflection hyperplanes, and \(n\) is the rank of \(W\). If \(W\) is further well-generated, the Coxeter number is equal to the highest degree \(d_n\) and to the order of a Coxeter element \(c\) of \(W\).

EXAMPLES:

sage: W = ReflectionGroup(['H4'])  # optional - gap3
sage: W.coxeter_number()  # optional - gap3
30
sage: all(W.coxeter_number(chi).is_integer() for chi in W.irreducible_characters())  # optional - gap3
True
sage: W = ReflectionGroup(14)  # optional - gap3
sage: W.coxeter_number()  # optional - gap3
24

degrees()

Return the degrees of \(W\) ordered within each irreducible component of \(W\).

EXAMPLES:

sage: W = ReflectionGroup([1,1,4])  # optional - gap3
sage: W.degrees()  # optional - gap3
(2, 3, 4)
Examples of reducible types:

```python
sage: W = ReflectionGroup((1,1,4), (3,1,2)); W  # optional - gap3
Reducible complex reflection group of rank 5 and type A3 x G(3,1,2)
sage: W.degrees()  # optional - gap3
(2, 3, 4, 3, 6)
```

```python
sage: W = ReflectionGroup((1,1,4), (6,1,12), 23)  # optional - gap3
# fails in GAP3
sage: W.degrees()  # optional - gap3
(2, 3, 4, 6, 12, 18, 24, 30, 36, 42, 48, 54, 60, 66, 72, 2, 6, 10)
```

\textbf{discriminant()}

Return the discriminant of \texttt{self} in the polynomial ring on which the group acts.

This is the product

\[ \prod_H \alpha_H^{e_H}, \]

where \( \alpha_H \) is the linear form of the hyperplane \( H \) and \( e_H \) is its stabilizer order.

\textbf{EXAMPLES:}

```python
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: W.discriminant()  # optional - gap3
x0^6 - 3*x0^5*x1 - 3/4*x0^4*x1^2 + 13/2*x0^3*x1^3
- 3/4*x0^2*x1^4 - 3*x0*x1^5 + x1^6
```

```python
sage: W = ReflectionGroup(['B',2])  # optional - gap3
sage: W.discriminant()  # optional - gap3
x0^6*x1^2 - 6*x0^5*x1^3 + 13*x0^4*x1^4 - 12*x0^3*x1^5 + 4*x0^2*x1^6
```

\textbf{discriminant_in_invariant_ring}(invariants=None)

Return the discriminant of \texttt{self} in the invariant ring.

This is the function \( f \) in the invariants such that \( f(F_1(x), \ldots, F_n(x)) \) is the discriminant.

\textbf{EXAMPLES:}

```python
sage: W = ReflectionGroup(['A',3])  # optional - gap3
sage: W.discriminant_in_invariant_ring()  # optional - gap3
```

(continues on next page)
6*t0^3*t1^2 - 18*t0^4*t2 + 9*t1^4 - 36*t0*t1^2*t2 + 24*t0^2*t2^2 - 8*t2^3

sage: W = ReflectionGroup([['B', 3]])  # optional - gap3
sage: W.discriminant_in_invariant_ring()  # optional - gap3
-t0^2*t1^2*t2 + 16*t0^3*t2^2 + 2*t1^3*t2 - 36*t0*t1^2*t2 - 36*t0*t1*t2^2 + 108*t2^3

sage: W = ReflectionGroup([['H', 3]])  # optional - gap3
sage: W.discriminant_in_invariant_ring()  # long time # optional - gap3
(-829*E(5) - 1658*E(5)^2 - 1658*E(5)^3 - 829*E(5)^4)*t0^15
+ (213700*E(5) + 427400*E(5)^2 + 427400*E(5)^3 + 213700*E(5)^4)*t0^12*t1
+ (-22233750*E(5) - 44467500*E(5)^2 - 44467500*E(5)^3 - 22233750*E(5)^4)*t0^10*t2
+ (438750*E(5) + 877500*E(5)^2 + 877500*E(5)^3 + 438750*E(5)^4)*t0^8*t1^2
+ (-1162187500*E(5) + 2324375000*E(5)^2 + 2324375000*E(5)^3 + 1162187500*E(5)^4)*t0^6*t1^4
+ (438750*E(5) + 877500*E(5)^2 + 877500*E(5)^3 + 438750*E(5)^4)*t0^4*t1^6
+ (1162187500*E(5) + 2324375000*E(5)^2 + 2324375000*E(5)^3 + 1162187500*E(5)^4)*t0^2*t1^8
+ (1191796875*E(5) + 2383593750*E(5)^2 + 2383593750*E(5)^3 + 1191796875*E(5)^4)*t1^10
+ (395507812500*E(5) + 791015625000*E(5)^2 + 791015625000*E(5)^3 + 395507812500*E(5)^4)*t2^12

\textbf{distinguished_reflection}(i)

Return the $i$-th distinguished reflection of \texttt{self}.

These are the reflections in \texttt{self} acting on the complement of the fixed hyperplane $H$ as $\exp(2\pi i/n)$, where $n$ is the order of the reflection subgroup fixing $H$.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.distinguished_reflection(1)  # optional - gap3
(1,4)(2,3)(5,6)

sage: W.distinguished_reflection(2)  # optional - gap3
(1,3)(2,5)(4,6)

sage: W.distinguished_reflection(3)  # optional - gap3
(1,5)(2,4)(3,6)

sage: W = ReflectionGroup((3,1,1),hyperplane_index_set=['a'])  # optional - gap3
sage: W.distinguished_reflection('a')  # optional - gap3
(1,2,3)

sage: W = ReflectionGroup((1,1,3),(3,1,2))  # optional - gap3
sage: for i in range(W.number_of_reflection_hyperplanes()): # optional - gap3
    ....: W.distinguished_reflection(i+1)  # optional - gap3
(1,6)(2,5)(7,8)
\end{verbatim}
distinguished_reflections()

Return a finite family containing the distinguished reflections of self indexed by hyperplane_index_set().

These are the reflections in self acting on the complement of the fixed hyperplane $H$ as $\exp(2\pi i/n)$, where $n$ is the order of the reflection subgroup fixing $H$.

EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))
# optional - gap3
sage: W.distinguished_reflections()  # optional - gap3
Finite family {1: (1,4)(2,3)(5,6), 2: (1,3)(2,5)(4,6), 3: (1,5)(2,4)(3,6)}

sage: W = ReflectionGroup((1,1,3),hyperplane_index_set=['a','b','c'])  # optional - gap3
sage: W.distinguished_reflections()  # optional - gap3
Finite family {'a': (1,4)(2,3)(5,6), 'b': (1,3)(2,5)(4,6), 'c': (1,5)(2,4)(3,6)}

sage: W = ReflectionGroup((3,1,1))  # optional - gap3
sage: W.distinguished_reflections()  # optional - gap3
Finite family {1: (1,2,3)}

sage: W = ReflectionGroup((1,1,3),(3,1,2))  # optional - gap3
sage: W.distinguished_reflections()  # optional - gap3
```

fake_degrees()

Return the list of the fake degrees associated to self.

The fake degrees are $q$-versions of the degree of the character. In particular, they sum to Hilbert series of the coinvariant algebra of self.

**Note:** The ordering follows the one in Chevie and is not compatible with the current implementation of irreducible_characters().
EXAMPLES:

```python
sage: W = ReflectionGroup(12)  # optional - gap3
sage: W.fake_degrees()  # optional - gap3
[1, q^12, q^11 + q, q^8 + q^4, q^7 + q^5, q^6 + q^4 + q^2, 
  q^10 + q^8 + q^6, q^9 + q^7 + q^5 + q^3]
```

```python
sage: W = ReflectionGroup(["H",4])  # optional - gap3
sage: W.cardinality()  # optional - gap3
14400
```

```python
sage: sum(fdeg.subs(q=1)**2 for fdeg in W.fake_degrees())  # optional - gap3
14400
```

```python
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.fundamental_invariants()  # optional - gap3
(-2*x0^2 + 2*x0*x1 - 2*x1^2, 6*x0^2*x1 - 6*x0*x1^2)
```

```python
sage: W = ReflectionGroup((3,1,2))  # optional - gap3
sage: W.fundamental_invariants()  # optional - gap3
(x0^3 + x1^3, x0^3*x1^3)
```

```
```

```python
sage: W = ReflectionGroup((1,1,4))  # optional - gap3
sage: W.hyperplane_index_set()  # optional - gap3
(1, 2, 3, 4, 5, 6)
```

```python
sage: W = ReflectionGroup((1,1,4), hyperplane_index_set=[1,3,'asdf',7,9,11])  # optional - gap3
```

```python
sage: W.hyperplane_index_set()  # optional - gap3
(1, 3, 'asdf', 7, 9, 11)
```

```python
sage: W = ReflectionGroup((1,1,4),hyperplane_index_set=('a','b','c','d','e','f'))  # optional - gap3
```

```python
sage: W.hyperplane_index_set()  # optional - gap3
('a', 'b', 'c', 'd', 'e', 'f')
```

```
```

```python
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.independent_roots()  # optional - gap3
Finite family {1: (1, 0), 2: (0, 1)}
```

```python
sage: W = ReflectionGroup((4,2,3))  # optional - gap3
sage: W.simple_roots()  # optional - gap3
Finite family {1: (1, 0, 0), 2: (-E(4), 1, 0), 3: (-1, 1, 0), 4: (0, -1, 1)}
```

(continues on next page)
sage: W.independent_roots()             # optional - gap3
Finite family {1: (1, 0, 0), 2: (-E(4), 1, 0), 4: (0, -1, 1)}

index_set()

Return the index set of the simple reflections of self.

EXAMPLES:

sage: W = ReflectionGroup((1,1,4))       # optional - gap3
sage: W.index_set()                      # optional - gap3
(1, 2, 3)

sage: W = ReflectionGroup((1,1,4), index_set=[1,3,'asdf'])  # optional - gap3
sage: W.index_set()                      # optional - gap3
(1, 3, 'asdf')

sage: W = ReflectionGroup((1,1,4), index_set=('a', 'b', 'c'))     # optional - gap3
sage: W.index_set()                      # optional - gap3
('a', 'b', 'c')

invariant_form(brute_force=False)

Return the form that is invariant under the action of self.

This is unique only up to a global scalar on the irreducible components.

INPUT:

• brute_force – if True, the computation is done by applying the Reynolds operator; this is, the
invariant form of \( e_i \) and \( e_j \) is computed as the sum \( \langle w(e_i), w(e_j) \rangle \), where \( \langle \cdot, \cdot \rangle \) is the standard scalar product

EXAMPLES:

sage: W = ReflectionGroup(['A',3])       # optional - gap3
sage: F = W.invariant_form(); F           # optional - gap3
[ 1 -1/2 0]
[-1/2 1 -1/2]
[ 0 -1/2 1]

To check that this is indeed the invariant form, see:

sage: S = W.simple_reflections()          # optional - gap3
sage: all( F == S[i].matrix()*F*S[i].matrix().transpose() for i in W.index_set() )      # optional - gap3
True

sage: W = ReflectionGroup(['B',3])        # optional - gap3
sage: F = W.invariant_form(); F           # optional - gap3
[ 1 -1 0]
[-1 2 -1]
[ 0 -1 2]

sage: w = W.an_element().to_matrix()      # optional - gap3
sage: w * F * w.transpose().conjugate() == F  # optional - gap3
True

sage: S = W.simple_reflections()          # optional - gap3
sage: all( F == S[i].matrix()*F*S[i].matrix().transpose() for i in W.index_set() )      # optional - gap3
True

(continues on next page)
It also worked for badly generated groups:

```
sage: W = ReflectionGroup(7)  # optional - gap3
sage: W.is_well_generated()  # optional - gap3
False
sage: F = W.invariant_form(); F  # optional - gap3
[1 0]
[0 1]
sage: S = W.simple_reflections()  # optional - gap3
sage: all( F == S[i].matrix()*F*S[i].matrix().transpose().conjugate() for i in W.index_set() )  # optional - gap3
True
```

And also for reducible types:

```
sage: W = ReflectionGroup(['B',3],(4,2,3),4,7); W  # optional - gap3
Reducible complex reflection group of rank 10 and type B3 x G(4,2,3) x ST4 x ST7
sage: F = W.invariant_form(); S = W.simple_reflections()  # optional - gap3
sage: all( F == S[i].matrix()*F*S[i].matrix().transpose().conjugate() for i in W.index_set() )  # optional - gap3
True
```

### invariant_form_standardization()  
Return the transformation of the space that turns the invariant form of self into the standard scalar product.

Let $I$ be the invariant form of a complex reflection group, and let $A$ be the Hermitian matrix such that $A^2 = I$. The matrix $A$ defines a change of basis such that the identity matrix is the invariant form. Indeed, we have

$$(A^{-1}x)A(I(A^{-1}y)^*) = A^{-1}xIy^*A^{-1} = A^{-1}IA = I,$$

where $I$ is the identity matrix.

**EXAMPLES:**

```
sage: W = ReflectionGroup((4,2,5))  # optional - gap3
sage: I = W.invariant_form()  # optional - gap3
sage: A = W.invariant_form_standardization()  # optional - gap3
sage: A^2 == I  # optional - gap3
True
```

### irreducible_components()  
Return a list containing the irreducible components of self as finite reflection groups.
EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3))                      # optional - gap3
sage: W.irreducible_components()                        # optional - gap3
[Irreducible real reflection group of rank 2 and type A2]

sage: W = ReflectionGroup((1,1,3),(2,1,3))              # optional - gap3
sage: W.irreducible_components()                        # optional - gap3
[Irreducible real reflection group of rank 2 and type A2,
 Irreducible real reflection group of rank 3 and type B3]
```

**is_crystallographic()**

Return `True` if self is crystallographic.

This is, if the field of definition is the rational field.

**Todo:** Make this more robust and do not use the matrix representation of the simple reflections.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3)); W                  # optional - gap3
Irreducible real reflection group of rank 2 and type A2
sage: W.is_crystallographic()                          # optional - gap3
True

sage: W = ReflectionGroup((2,1,3)); W                  # optional - gap3
Irreducible real reflection group of rank 3 and type B3
sage: W.is_crystallographic()                          # optional - gap3
True

sage: W = ReflectionGroup(23); W                      # optional - gap3
Irreducible real reflection group of rank 3 and type H3
sage: W.is_crystallographic()                          # optional - gap3
False

sage: W = ReflectionGroup((3,1,3)); W                  # optional - gap3
Irreducible complex reflection group of rank 3 and type G(3,1,3)
sage: W.is_crystallographic()                          # optional - gap3
False

sage: W = ReflectionGroup((4,2,2)); W                  # optional - gap3
Irreducible complex reflection group of rank 2 and type G(4,2,2)
sage: W.is_crystallographic()                          # optional - gap3
False
```

**jacobian_of_fundamental_invariants** *(invs=None)*

Return the matrix \([\partial x_i F_j]\), where `invs` are any polynomials \(F_1, \ldots, F_n\) in \(x_1, \ldots, x_n\).

**INPUT:**

- `invs` – (default: the fundamental invariants) the polynomials \(F_1, \ldots, F_n\)

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])                     # optional - gap3
sage: W.fundamental_invariants()                        # optional - gap3
(-2*x0^2 + 2*x0*x1 - 2*x1^2, 6*x0^2*x1 - 6*x0*x1^2)
```
sage: W.jacobian_of_fundamental_invariants()  # optional - gap3
    [-4*x0 + 2*x1  2*x0 - 4*x1]
    [12*x0^2 - 6*x1^2  6*x0^2 - 12*x0*x1]

number_of_irreducible_components()
Return the number of irreducible components of self.

EXAMPLES:

sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.number_of_irreducible_components()  # optional - gap3
1
sage: W = ReflectionGroup((1,1,3),(2,1,3))  # optional - gap3
sage: W.number_of_irreducible_components()  # optional - gap3
2

primitive_vector_field(invs=None)
Return the primitive vector field of self is irreducible and well-generated.
The primitive vector field is given as the coefficients (being rational functions) in the basis \( \partial_{x_1}, \ldots, \partial_{x_n} \).
This is the partial derivation along the unique invariant of degree given by the Coxeter number. It can be computed as the row of the inverse of the Jacobian given by the highest degree.

EXAMPLES:

sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: W.primitive_vector_field()  # optional - gap3
(3*x1/(6*x0^2 - 6*x0*x1 - 12*x1^2), 1/(6*x0^2 - 6*x0*x1 - 12*x1^2))

rank()
Return the rank of self.
This is the dimension of the underlying vector space.

EXAMPLES:

sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.rank()  # optional - gap3
2
sage: W = ReflectionGroup((2,1,3))  # optional - gap3
sage: W.rank()  # optional - gap3
3
sage: W = ReflectionGroup((4,1,3))  # optional - gap3
sage: W.rank()  # optional - gap3
3
sage: W = ReflectionGroup((4,2,3))  # optional - gap3
sage: W.rank()  # optional - gap3
3

reflection(i)
Return the \( i \)-th reflection of self.

EXAMPLES:

sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.reflection(1)  # optional - gap3

reflection_character()  
Return the reflection characters of self.

EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.reflection_character()       # optional - gap3
[2, 0, -1]
```

reflection_eigenvalues(w, is_class_representative=False)  
Return the reflection eigenvalue of w in self.

INPUT:

- is_class_representative – boolean (default True) whether to compute instead on the conjugacy class representative.

See also:

reflection_eigenvalues_family()  

EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: for w in W:                    # optional - gap3
....: print('%s %s' % (w.reduced_word(), W.reflection_eigenvalues(w))) #
[0, 0]
[2, 1] [1/3, 2/3]
[1, 2, 1] [1/2, 0]
```

reflection_eigenvalues_family()  
Return the reflection eigenvalues of self as a finite family indexed by the class representatives of self.

OUTPUT:

- list with entries $k/n$ representing the eigenvalue $\zeta_n^k$.

EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.reflection_eigenvalues_family() # optional - gap3
Finite family {(): [0, 0], (1,4)(2,3)(5,6): [1/2, 0], (1,6,2)(3,5,4): [1/3, 2/3]}
```
reflection_hyperplane \(i, \text{as\_linear\_functional}=False, \text{with\_order}=False\)

Return the \(i\)-th reflection hyperplane of \(self\).

The \(i\)-th reflection hyperplane corresponds to the \(i\) distinguished reflection.

**INPUT:**

- \(i\) – an index in the index set
- \text{as\_linear\_functionals} – (default:False) flag whether to return the hyperplane or its linear functional in the basis dual to the given root basis

**EXAMPLES:**
sage: W = ReflectionGroup((2,1,2))  # optional - gap3
sage: W.reflection_hyperplane(3)    # optional - gap3
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 0]

One can ask for the result as a linear form:

sage: W.reflection_hyperplane(3, True)  # optional - gap3
(0, 1)

reflection_hyperplanes (as_linear_functionals=False, with_order=False)
Return the list of all reflection hyperplanes of self, either as a codimension 1 space, or as its linear functional.

INPUT:

• as_linear_functionals – (default:False) flag whether to return the hyperplane or its linear functional in the basis dual to the given root basis

EXAMPLES:

sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: for H in W.reflection_hyperplanes(): H  # optional - gap3
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 2]
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 1/2]
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 -1]
sage: for H in W.reflection_hyperplanes(as_linear_functionals=True): H  # optional - gap3
(1, -1/2)
(1, -2)
(1, 1)
sage: W = ReflectionGroup((2,1,2))  # optional - gap3
sage: for H in W.reflection_hyperplanes(): H  # optional - gap3
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 1]
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 1/2]
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 0]
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[0 1]
sage: for H in W.reflection_hyperplanes(as_linear_functionals=True): H  # optional - gap3
(continues on next page)
for H in W.reflection_hyperplanes(as_linear_functionals=True, with_order=True): H # optional - gap3
((1, -1), 2)
((1, -2), 2)
((0, 1), 2)
((1, 0), 2)

reflection_index_set()

Return the index set of the reflections of self.

EXAMPLES:

sage: W = ReflectionGroup((1,1,4))
# optional - gap3
sage: W.reflection_index_set()  # optional - gap3
(1, 2, 3, 4, 5, 6)

sage: W = ReflectionGroup((1,1,4), reflection_index_set=[1,3,'asdf',7,9,11])
# optional - gap3
sage: W.reflection_index_set()  # optional - gap3
(1, 3, 'asdf', 7, 9, 11)

sage: W = ReflectionGroup((1,1,4), reflection_index_set=['a','b','c','d','e','f'])
# optional - gap3
sage: W.reflection_index_set()  # optional - gap3
('a', 'b', 'c', 'd', 'e', 'f')

reflections()

Return a finite family containing the reflections of self, indexed by self.reflection_index_set().

EXAMPLES:

sage: W = ReflectionGroup((1,1,3))
# optional - gap3
sage: W.reflections()  # optional - gap3
Finite family {1: (1,4)(2,3)(5,6), 2: (1,3)(2,5)(4,6), 3: (1,5)(2,4)(3,6)}

sage: W = ReflectionGroup((1,1,3),reflection_index_set=['a','b','c'])
# optional - gap3
sage: W.reflections()  # optional - gap3
Finite family {'a': (1,4)(2,3)(5,6), 'b': (1,3)(2,5)(4,6), 'c': (1,5)(2,4)(3,6)}

sage: W = ReflectionGroup((3,1,1))
# optional - gap3
sage: W.reflections()  # optional - gap3
Finite family {1: (1,2,3), 2: (1,3,2)}

sage: W = ReflectionGroup((1,1,3),(3,1,2))
# optional - gap3
sage: W.reflections()  # optional - gap3
Finite family {1: (1,2,3), 2: (1,3,2), 3: (1,5)(2,4)(3,6), 4: (1,6)(2,5)(7,8), 5: (1,7)(2,6)(5,8),
3: (3,9,15)(4,10,16)(12,17,23)(14,18,24)(20,25,29)(21,22,26)(27,28,30),
5: (1,7)(2,6)(5,8),}
roots()

Return all roots corresponding to all reflections of self.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.roots()  # optional - gap3
[(1, 0), (0, 1), (1, 1), (-1, 0), (0, -1), (-1, -1)]
```

```
sage: W = ReflectionGroup((3,1,2))  # optional - gap3
sage: W.roots()  # optional - gap3
[(1, 0), (-1, 1), (E(3), 0), (-E(3), 1), (0, 1), (1, -1),
 (0, E(3)), (1, -E(3)), (E(3)^2, 0), (-E(3)^2, 1),
 (E(3), -1), (E(3), -E(3)), (0, E(3)^2), (1, -E(3)^2),
 (-1, E(3)), (-E(3), E(3)), (E(3)^2, -1), (E(3)^2, -E(3)),
 (E(3), -E(3)^2), (-E(3)^2, E(3)), (-1, E(3)^2),
 (-E(3), E(3)^2), (E(3)^2, -E(3)^2), (-E(3)^2, E(3)^2)]
```

```
sage: W = ReflectionGroup((4,2,2))  # optional - gap3
sage: W.roots()  # optional - gap3
[(1, 0), (-E(4), 1), (-1, 1), (-1, 0), (E(4), 1), (1, 1),
 (0, -E(4)), (E(4), -1), (E(4), E(4)), (0, E(4)),
 (E(4), -E(4)), (0, 1), (1, -E(4)), (1, -1), (0, -1),
 (1, E(4)), (-E(4), 0), (-1, E(4)), (E(4), 0), (-E(4), E(4)),
 (-E(4), -1), (-E(4), -E(4)), (1, -E(4)), (1, -1)]
```

```
sage: W = ReflectionGroup((1,1,4), (3,1,2))  # optional - gap3
sage: W.roots()  # optional - gap3
[(1, 0, 0, 0, 0), (0, 1, 0, 0, 0), (0, 0, 1, 0, 0),
 (0, 0, 0, 1, 0), (0, 0, 0, -1, 0), (1, 1, 0, 0, 0),
 (1, 0, 0, 0, 0), (1, 1, 1, 0, 0), (1, 1, 0, 0, 0),
 (0, -1, 0, 0, 0), (0, 0, -1, 0, 0), (-1, -1, 0, 0, 0),
 (0, -1, -1, 0, 0), (-1, -1, -1, 0, 0), (0, 0, 0, E(3), 0),
 (0, 0, -E(3), 1), (0, 0, 0, 0, 1), (0, 0, 0, 1, -1),
 (0, 0, 0, 0, E(3)), (0, 0, 0, 1, -E(3)), (0, 0, 0, E(3)^2, 0),
 (0, 0, 0, -E(3)^2, 1), (0, 0, 0, E(3), -1), (0, 0, 0, E(3), -E(3)),
 (0, 0, 0, 0, E(3)^2), (0, 0, 0, 1, -E(3)^2), (0, 0, 0, -1, E(3)),
 (0, 0, 0, -E(3), E(3)), (0, 0, 0, E(3)^2, -1),
 (0, 0, 0, E(3)^2, -E(3)), (0, 0, 0, E(3), -E(3)^2),
 (0, 0, 0, -E(3), E(3)^2), (0, 0, 0, E(3)^2, -E(3)^2),
 (0, 0, 0, -E(3)^2, E(3)^2)]
```

series()

Return the series of the classification type to which self belongs.

For real reflection groups, these are the Cartan-Killing classification types...

EXAMPLES:

```python
sage: ReflectionGroup((1,1,3)).series()  # optional - gap3
['A']
sage: ReflectionGroup((3,1,3)).series()  # optional - gap3
['ST']
```

set_reflection_representation(refl_repr=None)

Set the reflection representation of self.

INPUT:

- refl_repr – a dictionary representing the matrices of the generators of self with keys given by the index set, or None to reset to the default reflection representation

EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: for w in W: w.to_matrix(); print("-----")  # optional - gap3
[1 0]
[0 1]
-----
[ 1 1]
[ 0 -1]
-----
[-1 0]
[ 1 1]
-----
[-1 -1]
[ 1 0]
-----
[ 0 1]
[-1 -1]
-----
[ 0 -1]
[-1 0]
-----
sage: W.set_reflection_representation({1: matrix([[0,1,0],[1,0,0],[0,0,1]]), 2: matrix([[1,0,0],[0,0,1],[0,1,0]])})  # optional - gap3
sage: for w in W: w.to_matrix(); print("-----")  # optional - gap3
[1 0 0]
[0 1 0]
[0 0 1]
-----
[1 0 0]
[0 0 1]
[0 1 0]
-----
[0 1 0]
[1 0 0]
[0 0 1]
-----
[0 0 1]
[1 0 0]
[0 1 0]
```

(continues on next page)
simple_coroot(i)
Return the simple root with index i.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',3])
# optional - gap3
sage: W.simple_coroot(1)  # optional - gap3
(2, -1, 0)
```

simple_coroots()
Return the simple coroots of self.

These are the coroots corresponding to the simple reflections.

EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))
# optional - gap3
sage: W.simple_coroots()  # optional - gap3
Finite family {1: (2, -1), 2: (-1, 2)}
```

simple_reflection(i)
Return the i-th simple reflection of self.

EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))
# optional - gap3
sage: W.simple_reflection(1)  # optional - gap3
(1,4)(2,3)(5,6)
```

simple_root(i)
Return the simple root with index i.
EXAMPLES:

```python
sage: W = ReflectionGroup(['A',3])  # optional - gap3
sage: W.simple_root(1)  # optional - gap3
    (1, 0, 0)
```

- simple_roots()

  Return the simple roots of self.

  These are the roots corresponding to the simple reflections.

  EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.simple_roots()  # optional - gap3
  Finite family {1: (1, 0), 2: (0, 1)}
```

```python
sage: W = ReflectionGroup((1,1,4), (2,1,2))  # optional - gap3
sage: W.simple_roots()  # optional - gap3
  Finite family {1: (1, 0, 0, 0), 2: (0, 1, 0, 0), 3: (0, 0, 1, 0), 4: (-1, 0, 0, 0), 5: (0, 0, 0, 1)}
```

```python
sage: W = ReflectionGroup((3,1,2))  # optional - gap3
sage: W.simple_roots()  # optional - gap3
  Finite family {1: (1, 0), 2: (-1, 1)}
```

```python
sage: W = ReflectionGroup((1,1,4), (3,1,2))  # optional - gap3
sage: W.simple_roots()  # optional - gap3
  Finite family {1: (1, 0, 0, 0), 2: (0, 1, 0, 0), 3: (0, 0, 1, 0), 4: (-1, 0, 0, 0), 5: (0, 0, 0, -1, 1)}
```

class sage.combinat.root_system.reflection_group_complex.IrreducibleComplexReflectionGroup

Bases: sage.combinat.root_system.reflection_group_complex.ComplexReflectionGroup

class Element

is_coxeter_element(whichPrimitive=1, is_class_representative=False)

Return True if self is a Coxeter element.

This is, whether self has an eigenvalue that is a primitive $h$-th root of unity.

INPUT:

- whichPrimitive – (default:1) for which power of the first primitive $h$-th root of unity to look as a reflection eigenvalue for a regular element
• is_class_representative – boolean (default True) whether to compute instead on the conjugacy class representative

See also:

coxeter_element() coxeter_elements()

EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: for w in W:  # optional - gap3
.....: print('%s %s'(w.reduced_word(), w.is_coxeter_element()))  #
.....: optional - gap3
[] False
[2] False
[1] False
[1, 2] True
[2, 1] True
[1, 2, 1] False
```

```python
is_h_regular(is_class_representative=False)
Return whether self is regular.

This is if self has an eigenvector with eigenvalue $h$ and which does not lie in any reflection hyperplane. Here, $h$ denotes the Coxeter number.

EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: for w in W:  # optional - gap3
.....: print('%s %s'(w.reduced_word(), w.is_h_regular()))  #
.....: optional - gap3
[] False
[2] False
[1] False
[1, 2] True
[2, 1] True
[1, 2, 1] False
```

```python
is_regular(h, is_class_representative=False)
Return whether self is regular.

This is, if self has an eigenvector with eigenvalue of order $h$ and which does not lie in any reflection hyperplane.

INPUT:
  • $h$ – the order of the eigenvalue
  • is_class_representative – boolean (default True) whether to compute instead on the conjugacy class representative

EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: h = W.coxeter_number()  # optional - gap3
sage: for w in W:  # optional - gap3
.....: print('{} {}'.format(w.reduced_word(), w.is_regular(h)))
[] False
[2] False
[1] False
[1, 2] True
[2, 1] True
[1, 2, 1] False
```
sage: W = ReflectionGroup(23); h = W.coxeter_number()  # optional - gap3
sage: for w in W:  # optional - gap3
    ....: if w.is_regular(h):  # optional - gap3
        ....: w.reduced_word()  # optional - gap3
[1, 2, 3]
[2, 1, 3]
[1, 3, 2]
[3, 2, 1]
[2, 1, 2, 3, 2]
[2, 3, 2, 1, 2]
[1, 2, 1, 2, 3, 2, 1]
[1, 2, 3, 2, 1, 2, 1]
[1, 2, 1, 2, 3, 2, 1, 2, 3]
[2, 1, 2, 1, 3, 2, 1, 2, 3]
[2, 1, 2, 3, 2, 1, 2, 1, 3]
[1, 2, 3, 2, 1, 2, 1, 3, 2]
[3, 2, 1, 2, 1, 3, 2, 1, 2]
[1, 2, 1, 2, 1, 3, 2, 1, 2]
[2, 3, 2, 1, 2, 1, 3, 2, 1]
[2, 1, 2, 1, 3, 2, 1, 2, 1]
[2, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]
[1, 2, 1, 2, 1, 3, 2, 1, 2, 1, 3]
[1, 2, 3, 2, 1, 2, 1, 3, 2, 1]
[2, 1, 2, 3, 2, 1, 2, 1, 3, 2, 1]
[2, 1, 2, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]
[1, 2, 1, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]

Check that trac ticket #25478 is fixed:

sage: W = ReflectionGroup(['A',5])  # optional - gap3
sage: w = W.from_reduced_word([1,2,3,5])  # optional - gap3
sage: w.is_regular(4)  # optional - gap3
False
sage: W = ReflectionGroup(['A',3])  # optional - gap3
sage: len([w for w in W if w.is_regular(w.order())])  # optional - gap3
18

sage.combinat.root_system.reflection_group_complex.multi_partitions(n, S, i=None)

Return all vectors as lists of the same length as S whose standard inner product with S equals n.

EXAMPLES:

sage: from sage.combinat.root_system.reflection_group_complex import multi_partitions
sage: multi_partitions(10, [2,3,3,4])
[[5, 0, 0, 0],
 [3, 0, 0, 1],
 [2, 2, 0, 0],
 [2, 1, 1, 0],
 [2, 0, 2, 0],
 [1, 0, 0, 2],
 [0, 2, 0, 1],
 (continues on next page)
sage.combinat.root_system.reflection_group_complex.power(f, k)
Return \( f^k \) and caching all intermediate results.
Speeds the computation if one has to compute \( f^k \)'s for many values of \( k \).

EXAMPLES:
\[
\begin{align*}
\text{sage:} & \quad P.<x,y,z> = \text{PolynomialRing}(\mathbb{Q}) \\
\text{sage:} & \quad f = -2x^2 + 2x*y - 2y^2 + 2y*z - 2z^2 \\
\text{sage:} & \quad \text{all( } f^k == \text{power}(f,k) \text{ for } k \text{ in range(20) }) \quad \text{True}
\end{align*}
\]

5.1.238 Finite real reflection groups

Let \( V \) be a finite-dimensional real vector space. A reflection of \( V \) is an operator \( r \in \text{GL}(V) \) that has order 2 and fixes pointwise a hyperplane in \( V \). In the present implementation, finite real reflection groups are tied with a root system.

Finite real reflection groups with root systems have been classified according to finite Cartan-Killing types. For more definitions and classification types of finite complex reflection groups, see Wikipedia article Complex_reflection_group.

The point of entry to work with reflection groups is \texttt{ReflectionGroup()} \ which can be used with finite Cartan-Killing types:

\[
\begin{align*}
\text{sage:} & \quad \text{ReflectionGroup(['A',2])} \quad \text{# optional - gap3} \\
& \quad \text{Irreducible real reflection group of rank 2 and type A2} \\
\text{sage:} & \quad \text{ReflectionGroup(['F',4])} \quad \text{# optional - gap3} \\
& \quad \text{Irreducible real reflection group of rank 4 and type F4} \\
\text{sage:} & \quad \text{ReflectionGroup(['H',3])} \quad \text{# optional - gap3} \\
& \quad \text{Irreducible real reflection group of rank 3 and type H3}
\end{align*}
\]

    reflection_group_complex.ComplexReflectionGroup.Element

left_coset_representatives()

    Return the left coset representatives of self.

    See also:

    right_coset_representatives()

EXAMPILES:

    sage: W = ReflectionGroup(['A',2])            # optional - gap3
    sage: for w in W:                             # optional - gap3
    ....:  lcr = w.left_coset_representatives()  # optional - gap3
    ....:  print("%s %s"",(w.reduced_word(),   # optional - gap3
    ....:          [v.reduced_word() for v in lcr])) # optional - gap3
    ...
    [[], [2], [1], [1, 2], [2, 1], [1, 2, 1]]
    [] [[], [2], [1]]
    [] [[], [2, 1]]
    [1, 2] [[]]
    [2, 1] [[]]
    [1, 2, 1] [[]]

right_coset_representatives()

    Return the right coset representatives of self.

EXAMPILES:

    sage: W = ReflectionGroup(['A',2])            # optional - gap3
    sage: for w in W:                             # optional - gap3
    ....:  rcr = w.right_coset_representatives()  # optional - gap3
    ....:  print("%s %s"",(w.reduced_word(),  # optional - gap3
    ....:          [v.reduced_word() for v in rcr])) # optional - gap3
    ...
    (continues on next page)
almost_positive_roots()

Return the almost positive roots of self.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',3], ['B',2])
# optional - gap3
sage: W.almost_positive_roots()  # optional - gap3
[(-1, 0, 0, 0, 0),
 (0, -1, 0, 0, 0),
 (0, 0, -1, 0, 0),
 (0, 0, 0, -1, 0),
 (0, 0, 0, 0, -1),
 (1, 0, 0, 0, 0),
 (0, 1, 0, 0, 0),
 (0, 0, 1, 0, 0),
 (0, 0, 0, 1, 0),
 (0, 0, 0, 0, 1),
 (1, 1, 0, 0, 0),
 (0, 1, 1, 0, 0),
 (0, 0, 0, 1, 1),
 (1, 1, 1, 0, 0),
 (0, 0, 0, 2, 1)]
```

```python
sage: W = ReflectionGroup(['A',3])
# optional - gap3
sage: W.almost_positive_roots()  # optional - gap3
[(-1, 0, 0),
 (0, -1, 0),
 (0, 0, -1),
 (1, 0, 0),
 (0, 1, 0),
 (0, 0, 1),
 (1, 1, 0),
 (0, 1, 1),
 (1, 1, 1)]
```

bipartite_index_set()

Return the bipartite index set of a real reflection group.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',5])
# optional - gap3
sage: W.bipartite_index_set()  # optional - gap3
[[1, 3, 5], [2, 4]]
```

```python
sage: W = ReflectionGroup(['A',5], index_set=['a','b','c','d','e'])
# optional - gap3
sage: W.bipartite_index_set()  # optional - gap3
[['a', 'c', 'e'], ['b', 'd']]
```

cartan_type()

Return the Cartan type of self.
EXAMPLES:

```python
sage: W = ReflectionGroup(['A',3])  # optional - gap3
sage: W.cartan_type()  # optional - gap3
['A', 3]
```

```python
sage: W = ReflectionGroup(['A',3], ['B',3])  # optional - gap3
sage: W.cartan_type()  # optional - gap3
A3xB3 relabelled by {1: 3, 2: 2, 3: 1}
```

**coxeter_diagram()**

Return the Coxeter diagram associated to `self`.

EXAMPLES:

```python
sage: G = ReflectionGroup(['B',3])  # optional - gap3
sage: sorted(G.coxeter_diagram().edges(labels=True))  # optional - gap3
[(1, 2, 4), (2, 3, 3)]
```

**coxeter_matrix()**

Return the Coxeter matrix associated to `self`.

EXAMPLES:

```python
sage: G = ReflectionGroup(['A',3])  # optional - gap3
sage: G.coxeter_matrix()  # optional - gap3
[1 3 2]
[3 1 3]
[2 3 1]
```

**fundamental_weight(i)**

Return the fundamental weight with index `i`.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',3])  # optional - gap3
sage: [ W.fundamental_weight(i) for i in W.index_set() ]  # optional - gap3
[(3/4, 1/2, 1/4), (1/2, 1, 1/2), (1/4, 1/2, 3/4)]
```

**fundamental_weights()**

Return the fundamental weights of `self` in terms of the simple roots.

The fundamental weights are defined by $s_j(\omega_i) = \omega_i - \delta_{i=j}\alpha_j$ for the simple reflection $s_j$ with corresponding simple roots $\alpha_j$.

In other words, the transpose Cartan matrix sends the weight basis to the root basis. Observe again that the action here is defined as a right action, see the example below.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',3], ['B',2])  # optional - gap3
sage: W.fundamental_weights()  # optional - gap3
Finite family {1: (3/4, 1/2, 1/4, 0, 0), 2: (1/2, 1, 1/2, 0, 0), 3: (1/4, 1/2, 3/4, 0, 0), 4: (0, 0, 0, 1, 1/2), 5: (0, 0, 0, 1, 1)}

sage: W = ReflectionGroup(['A',3])  # optional - gap3
sage: W.fundamental_weights()  # optional - gap3
Finite family {1: (3/4, 1/2, 1/4), 2: (1/2, 1, 1/2), 3: (1/4, 1/2, 3/4)}
```
sage: W = ReflectionGroup(['A',3])  # optional - gap3
sage: S = W.simple_reflections()     # optional - gap3
sage: N = W.fundamental_weights()    # optional - gap3
sage: for i in W.index_set():
    ....: for j in W.index_set():
        ....: print("{} {} {} "format(i, j, N[i], N[i]*S[j].to_matrix()))
1 1 (3/4, 1/2, 1/4) (-1/4, 1/2, 1/4)
1 2 (3/4, 1/2, 1/4) (3/4, 1/2, 1/4)
1 3 (3/4, 1/2, 1/4) (3/4, 1/2, 1/4)
2 1 (1/2, 1, 1/2) (1/2, 1, 1/2)
2 2 (1/2, 1, 1/2) (1/2, 0, 1/2)
2 3 (1/2, 1, 1/2) (1/2, 1, 1/2)
3 1 (1/4, 1/2, 3/4) (1/4, 1/2, 3/4)
3 2 (1/4, 1/2, 3/4) (1/4, 1/2, 3/4)
3 3 (1/4, 1/2, 3/4) (1/4, 1/2, -1/4)

iteration(algorithm='breadth', tracking_words=True)
Return an iterator going through all elements in self.

INPUT:

• algorithm (default: 'breadth') – must be one of the following:
  – 'breadth' - iterate over in a linear extension of the weak order
  – 'depth' - iterate by a depth-first-search
  – 'parabolic' - iterate by using parabolic subgroups

• tracking_words (default: True) – whether or not to keep track of the reduced words and store them in _reduced_word

Note: The fastest iteration is the parabolic iteration and the depth first algorithm without tracking words is second. In particular, 'depth' is ~1.5x faster than 'breadth'.

Note: The 'parabolic' iteration does not track words and requires keeping the subgroup corresponding to $I \setminus \{i\}$ in memory (for each $i$ individually).

EXAMPLES:

sage: W = ReflectionGroup(['B',2])  # optional - gap3
sage: for w in W.iteration("breadth",True):
    ....: print("{} {} {} ".format(w, w._reduced_word))
() [1]
(1,3) (2,6) (5,7) [1]
(1,5) (2,4) (6,8) [0]
(1,7,5,3) (2,4,6,8) [0, 1]
(1,3,5,7) (2,8,6,4) [1, 0]
(2,8) (3,7) (4,6) [0, 0, 1]
(2,7) (3,5) (4,8) [0, 1, 0, 1]
(1,5) (2,6) (3,7) (4,8) [0, 1, 0, 1]

sage: for w in W.iteration("depth", False): w
()
positive_roots()  
Return the positive roots of self.

EXAMPLES:

```sage
sage: W = ReflectionGroup(['A',3], ['B',2])  # optional - gap3
sage: W.positive_roots()  # optional - gap3
[(1, 0, 0, 0, 0),
 (0, 1, 0, 0, 0),
 (0, 0, 1, 0, 0),
 (0, 0, 0, 1, 0),
 (0, 0, 0, 0, 1),
 (1, 1, 0, 0, 0),
 (0, 1, 1, 0, 0),
 (0, 0, 0, 1, 1),
 (1, 1, 1, 0, 0),
 (0, 0, 0, 2, 1)]

sage: W = ReflectionGroup(['A',3])  # optional - gap3
sage: W.positive_roots()  # optional - gap3
[(1, 0, 0), (0, 1, 0), (0, 0, 1), (1, 1, 0), (0, 1, 1), (1, 1, 1)]
```

reflection_to_positive_root(r)  
Return the positive root orthogonal to the given reflection.

EXAMPLES:

```sage
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: for r in W.reflections():  # optional - gap3
....: print(W.reflection_to_positive_root(r))
(1, 0)
(0, 1)
(1, 1)
```

right_coset_representatives(J)  
Return the right coset representatives of self for the parabolic subgroup generated by the simple reflections in J.

EXAMPLES:

```sage
sage: W = ReflectionGroup(['A',3])  # optional - gap3
sage: for J in Subsets([1,2,3]): W.right_coset_representatives(J)  # optional - gap3
```

(continues on next page)
root_to_reflection(root)
Return the reflection along the given root.

EXAMPLES:

```sage
W = ReflectionGroup(['A',2])
W.root_to_reflection(W.roots())
```

simple_root_index(i)
Return the index of the simple root \(\alpha_i\).

This is the position of \(\alpha_i\) in the list of simple roots.

EXAMPLES:

```sage
W = ReflectionGroup(['A',3])
W.simple_root_index(W.index_set())
```
sage.combinat.root_system.reflection_group_real.ReflectionGroup(*args,
**kwds)

Construct a finite (complex or real) reflection group as a Sage permutation group by fetching the permutation representation of the generators from chevie’s database.

INPUT:

can be one or multiple of the following:

• a triple \((r, p, n)\) with \(p\) divides \(r\), which denotes the group \(G(r, p, n)\)

• an integer between 4 and 37, which denotes an exceptional irreducible complex reflection group

• a finite Cartan-Killing type

EXAMPLES:

Finite reflection groups can be constructed from

Cartan-Killing classification types:

\[
\text{sage: } W = \text{ReflectionGroup(['A',3]); } W \quad \# \text{ optional - gap3}
\]
Irreducible real reflection group of rank 3 and type A3

\[
\text{sage: } W = \text{ReflectionGroup(['H',4]); } W \quad \# \text{ optional - gap3}
\]
Irreducible real reflection group of rank 4 and type H4

\[
\text{sage: } W = \text{ReflectionGroup(['I',5]); } W \quad \# \text{ optional - gap3}
\]
Irreducible real reflection group of rank 2 and type I2(5)

the complex infinite family \(G(r, p, n)\) with \(p\) divides \(r\):

\[
\text{sage: } W = \text{ReflectionGroup((1,1,4)); } W \quad \# \text{ optional - gap3}
\]
Irreducible real reflection group of rank 3 and type A3

\[
\text{sage: } W = \text{ReflectionGroup((2,1,3)); } W \quad \# \text{ optional - gap3}
\]
Irreducible real reflection group of rank 3 and type B3

Chevalley-Shepard-Todd exceptional classification types:

\[
\text{sage: } W = \text{ReflectionGroup(23); } W \quad \# \text{ optional - gap3}
\]
Irreducible real reflection group of rank 3 and type H3

Cartan types and matrices:

\[
\text{sage: } \text{ReflectionGroup(CartanType(['A',2]))} \quad \# \text{ optional - gap3}
\]
Irreducible real reflection group of rank 2 and type A2

\[
\text{sage: } \text{ReflectionGroup(CartanType([['A',2],[A',2]]))} \quad \# \text{ optional - gap3}
\]
Reducible real reflection group of rank 4 and type A2 x A2

\[
\text{sage: } C = \text{CartanMatrix(['A',2])} \quad \# \text{ optional - gap3}
\]

\[
\text{sage: } \text{ReflectionGroup(C)} \quad \# \text{ optional - gap3}
\]
Irreducible real reflection group of rank 2 and type A2

multiples of the above:

\[
\text{sage: } W = \text{ReflectionGroup(['A',2],[B',2]); } W \quad \# \text{ optional - gap3}
\]
Reducible real reflection group of rank 4 and type A2 x B2

\[
\text{sage: } W = \text{ReflectionGroup(['A',2],4); } W \quad \# \text{ optional - gap3}
\]
(continues on next page)
Reducible complex reflection group of rank 4 and type $A_2 \times ST_4$

```python
sage: W = ReflectionGroup((4,2,2),4); W
```

# optional - gap3
Reducible complex reflection group of rank 4 and type $G(4,2,2) \times ST_4$

```
sage.combinat.root_system.reflection_group_real.is_chevie_available()
Test whether the GAP3 Chevie package is available.
```

EXAMPLES:

```python
sage: from sage.combinat.root_system.reflection_group_real import is_chevie_available
sage: is_chevie_available()  # random
False
sage: is_chevie_available() in [True, False]
True
```

### 5.1.239 Group algebras of root lattice realizations

```python
class sage.combinat.root_system.root_lattice_realization_algebras.Algebras(category, *args):
    Bases: sage.categories.algebra_functor.AlgebrasCategory

The category of group algebras of root lattice realizations.
This includes typically weight rings (group algebras of weight lattices).

class ElementMethods
    Bases: object

    acted_upon(w)
    Implements the action of $w$ on $self$.
    INPUT:
    • $w$ – an element of the Weyl group acting on the underlying weight lattice realization

    EXAMPLES:

    ```python
    sage: L = RootSystem(["A",3]).ambient_space()
sage: W = L.weyl_group()
sage: M = L.algebra(QQ['q','t'])
sage: m = M.an_element(); m    # TODO: investigate why we don't get something more interesting
                     B[(2, 2, 3, 0)]
sage: m = (m+1)^2; m
                     B[(0, 0, 0, 0)] + 2*B[(2, 2, 3, 0)] + B[(4, 4, 6, 0)]
sage: w = W.an_element(); w.reduced_word()
                     [1, 2, 3]
sage: m.acted_upon(w)
                     B[(0, 0, 0, 0)] + 2*B[(0, 2, 2, 3)] + B[(0, 4, 4, 6)]
```

```python
expand(alphabet)
Expand $self$ into variables in the alphabet.

INPUT:
• alphabet – a non empty list/tuple of (invertible) variables in a ring to expand in

EXAMPLES:
```
sage: L = RootSystem(['A',2]).ambient_lattice()
sage: KL = L.algebra(QQ)
sage: p = KL.an_element() + KL.sum_of_monomials(L.some_elements()); p
B[(1, 0, 0)] + B[(1, -1, 0)] + B[(1, 1, 0)] + 2*B[(2, 2, 3)] + B[(0, 1, -1)]
sage: F = LaurentPolynomialRing(QQ, 'x,y,z')
sage: p.expand(F.gens())
2*x^2*y^2*z^3 + x*y + x + y*z^-1 + x*y^-1

class ParentMethods
Bases: object

T0_check_on_basis(q1, q2, convention='antidominant')
Return the $T_0^\vee$ operator acting on the basis.

This implements the formula for $T_0^\vee$ in Section 6.12 of [Haiman06].

REFERENCES:

Warning: The current implementation probably returns just nonsense, if the convention is not “dominant”.

EXAMPLES:

sage: K = QQ['q1,q2'].fraction_field()
sage: q1,q2 = K.gens()
sage: L = RootSystem(['A',1,1]).ambient_space()
sage: L0 = L.classical()
sage: KL = L.algebra(K)
sage: some_weights = L.fundamental_weights()
sage: f = KL.T0_check_on_basis(q1,q2, convention="dominant")
sage: f(L0.zero())
(q1+q2)*B[(0, 0)] + q1*B[(1, -1)]

sage: L = RootSystem(['A',3,1]).ambient_space()
sage: L0 = L.classical()
sage: KL = L.algebra(K)
sage: some_weights = L0.fundamental_weights()
sage: f = KL.T0_check_on_basis(q1,q2, convention="dominant")
sage: f(L0.zero())
# not checked
(q1+q2)*B[(0, 0, 0, 0)] + q1^3/q2^2*B[(1, 0, 0, -1)]

The following results have not been checked:

sage: for x in some_weights:
....: print("{} : {}\n".format(x, f(x)))
(1, 0, 0, 0) : q1*B[(1, 0, 0, 0)]
(1, 1, 0, 0) : q1*B[(1, 1, 0, 0)]
(1, 1, 1, 0) : q1*B[(1, 1, 1, 0)]

Some examples for type $B_2^{(1)}$ dual:

sage: L = RootSystem(['B',2,'~*']).ambient_space()
sage: L0 = L.classical()
sage: e = L.basis()

(continues on next page)
sage: K = QQ['q,u'].fraction_field()
sage: q,u = K.gens()
sage: q1 = u
sage: q2 = -1/u
sage: KL = L.algebra(K)
sage: KL0 = KL.classical()
sage: f = KL.T0_check_on_basis(q1,q2, convention="dominant")
sage: T = KL.twisted_demazure_lusztig_operators(q1,q2, convention="dominant")

Direct calculation:

sage: T.Tw(0)(KL0.monomial(L0([0,0])))
((u^2-1)/u)*B[(0, 0)] + u^3*B[(1, 1)]

Step by step calculation, comparing by hand with Mark Shimozono:

sage: res = T.Tw(2)(KL0.monomial(L0([0,0]))); res
u*B[(0, 0)]

sage: res = res * KL0.monomial(L0([-1,1])); res
(u^2-1)*B[(0, 0)] + u^2*B[(1, -1)]

sage: res = T.Tw_inverse(1)(res); res
((u^2-1)/u)*B[(0, 0)] + u^3*B[(1, 1)]

cartan_type()

Return the Cartan type of self.

EXAMPLES:

sage: A = RootSystem(['A',2,1]).ambient_space().algebra(QQ)
sage: A.cartan_type()
['A', 2, 1]

sage: A = RootSystem(['B',2]).weight_space().algebra(QQ)
sage: A.cartan_type()
['B', 2]

classical()

Return the group algebra of the corresponding classical lattice.

EXAMPLES:

sage: KL = RootSystem(['A',2,1]).ambient_space().algebra(QQ)
sage: KL.classical()
Algebra of the Ambient space of the Root system of type ['A', 2] over Rational Field

demazure_lusztig_operator_on_basis(weight, i, q1, q2, convention='antidominant')

Return the result of applying the \( i \)-th Demazure-Lusztig operator on \( \lambda \).

INPUT:

- weight – an element \( \lambda \) of the weight lattice
- \( i \) – an element of the index set
- \( q_1, q_2 \) – two elements of the ground ring
- convention – “antidominant”, “bar”, or “dominant” (default: “antidominant”)
See `demazure_lusztig_operators()` for the details.

**EXAMPLES:**

```python
sage: L = RootSystem(["A",1]).ambient_space()
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: KL.demazure_lusztig_operator_on_basis(L((2,2)), 1, q1, q2)
q1*B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_basis(L((3,0)), 1, q1, q2)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, q1, q2)
(-q1-q2)*B[(1, 2)] + (-q1-q2)*B[(2, 1)] + (-q2)*B[(3, 0)]
```

At $q_1 = 1$ and $q_2 = 0$ we recover the action of the isobaric divided differences $\pi_i$:

```python
sage: KL.demazure_lusztig_operator_on_basis(L((2,2)), 1, 1, 0)
B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_basis(L((3,0)), 1, 1, 0)
B[(1, 2)] + B[(2, 1)] + B[(3, 0)] + B[(0, 3)]
sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, 1, 0)
-B[(1, 2)] - B[(2, 1)]
```

Or $1 - \pi_i$ for \texttt{bar=True}:

```python
sage: KL.demazure_lusztig_operator_on_basis(L((2,2)), 1, 1, 0, convention="bar")
0
sage: KL.demazure_lusztig_operator_on_basis(L((3,0)), 1, 1, 0, convention="bar")
-B[(1, 2)] - B[(2, 1)] - B[(0, 3)]
sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, 1, 0, convention="bar")
B[(1, 2)] + B[(2, 1)] + B[(0, 3)]
```

At $q_1 = 1$ and $q_2 = -1$ we recover the action of the simple reflection $s_i$:

```python
sage: KL.demazure_lusztig_operator_on_basis(L((2,2)), 1, 1, -1)
B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_basis(L((3,0)), 1, 1, -1)
B[(0, 3)]
sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, 1, -1)
B[(3, 0)]
```

\texttt{demazure_lusztig_operator_on_classical_on_basis\ (weight, i, q, q1, q2, convention='antidominant')}

Return the result of applying the $i$-th Demazure-Lusztig operator on the classical weight \texttt{weight} embedded at level 0.

**INPUT:**
- \texttt{weight} – a classical weight $\lambda$
- \texttt{i} – an element of the index set
- \texttt{q1, q2} – two elements of the ground ring
- \texttt{convention} – “antidominant”, “bar”, or “dominant” (default: “antidominant”)

See \texttt{demazure_lusztig_operators()} for the details.

**Todo:**

---

5.1. Comprehensive Module list 2267
• Optimize the code to only do the embedding/projection for $T_0$
• Add an option to specify at which level one wants to work. Currently this is level 0.

EXAMPLES:

```
sage: L = RootSystem("A",1,1).ambient_space()
sage: L0 = L.classical()
sage: K = QQ['q,q1,q2']
sage: q, q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: KL0 = L0.algebra(K)
```
These operators coincide with the usual Demazure-Lusztig operators:

```
sage: KL.demazure_lusztig_operator_on_classical_on_basis(L0((2,2)), 1, q, -.q1, q2)
q1*B[(2, 2)]
sage: KL0.demazure_lusztig_operator_on_basis(L0((2,2)), 1, q1, q2)
q1*B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_classical_on_basis(L0((3,0)), 1, q, -.q1, q2)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
sage: KL0.demazure_lusztig_operator_on_basis(L0((3,0)), 1, q1, q2)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
```

except that we now have an action of $T_0$, which introduces some $q$ s:

```
sage: KL.demazure_lusztig_operator_on_classical_on_basis(L0((2,2)), 0, q, -.q1, q2)
q1*B[(2, 2)]
sage: KL0.demazure_lusztig_operator_on_classical_on_basis(L0((3,0)), 0, q, -.q1, q2)
(-q^2*q1-q^2*q2)*B[(1, 2)] + (-q*q1-q*q2)*B[(2, 1)] + (-q^3*q2)*B[(0, 3)]
```

demazure_lusztig_operators($q1$, $q2$, convention='antidominant')

Return the Demazure-Lusztig operators acting on self.

INPUT:
• $q1$, $q2$ – two elements of the ground ring
• convention – “antidominant”, “bar”, or “dominant” (default: “antidominant”)

If $R$ is the parent weight ring, the Demazure-Lusztig operator $T_i$ is the linear map $R \to R$ obtained by interpolating between the isobaric divided difference operator $\pi_i$ (see isobaric_divided_difference_on_basis()) and the simple reflection $s_i$.

\[(q_1 + q_2)\pi_i - q_2 s_i\]

The Demazure-Lusztig operators give the usual representation of the operator $T_i$ of the (affine) Hecke algebra with eigenvalues $q_1$ and $q_2$ associated to the Weyl group.

Several variants are available to match with various conventions used in the literature:
• “bar” replaces $\pi_i$ in the formula above by $\pi_i = (1 - \pi_i)$.
• “dominant” conjugates the operator by $x^\lambda \mapsto x^{-\lambda}$.

The names dominant and antidominant for the conventions were chosen with regards to the nonsymmetric Macdonald polynomials. The $Y$ operators for the Macdonal polynomials in the “dominant” convention satisfy $Y_\lambda = T_{\lambda\lambda}$ for $\lambda$ dominant. This is also the convention used in [Haiman06]. For the “antidominant” convention, $Y_\lambda = T_{\lambda\lambda}$ with $\lambda$ antidominant.
See also:

- demazure_lusztig_operator_on_basis()
- NonSymmetricMacdonaldPolynomials.

REFERENCES:

EXAMPLES:

```python
sage: L = RootSystem(\"A",1\)).ambient_space()
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: T = KL.demazure_lusztig_operators(q1, q2)
sage: Tbar = KL.demazure_lusztig_operators(q1, q2, convention=\"bar\")
sage: Tdominant = KL.demazure_lusztig_operators(q1, q2, convention=\"dominant\")
sage: x = KL.monomial(L((3,0)))
sage: T[1](x)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
sage: Tbar[1](x)
(-q1-q2)*B[(1, 2)] + (-q1-q2)*B[(2, 1)] + (-q1-2*q2)*B[(0, 3)]
sage: Tdominant[1](x)
(-q1-q2)*B[(1, 2)] + (-q1-q2)*B[(2, 1)] + (-q2)*B[(3, 0)]
sage: Tdominant.Tw_inverse(1)(KL.monomial(-L.simple_root(1)))
((-q1-q2)/(q1*q2))*B[(0, 0)] - 1/q2*B[(1, -1)]
```

We repeat similar computation in the affine setting:

```python
sage: L = RootSystem(\"A\",2,1\)).ambient_space()
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: T = KL.demazure_lusztig_operators(q1, q2)
sage: Tbar = KL.demazure_lusztig_operators(q1, q2, convention=\"bar\")
sage: Tdominant = KL.demazure_lusztig_operators(q1, q2, convention=\"dominant\")
sage: e = L.basis()
sage: x = KL.monomial(3*e[0])
sage: T[1](x)
(q1+q2)*B[e[0] + 2*e[1]] + (q1+q2)*B[2*e[0] + e[1]] + (q1+q2)*B[3*e[0]] +
q1*B[3*e[1]]
sage: Tbar[1](x)
(-q1-q2)*B[e[0] + 2*e[1]] + (-q1-q2)*B[2*e[0] + e[1]] + (-q1-2*q2)*B[3*e[1]]
sage: Tdominant[1](x)
(-q1-q2)*B[e[0] + 2*e[1]] + (-q1-q2)*B[2*e[0] + e[1]] + (-q2)*B[3*e[1]]
sage: Tdominant.Tw_inverse(1)(KL.monomial(-L.simple_root(1)))
((-q1-q2)/(q1*q2))*B[0] - 1/q2*B[e[0] - e[1]]
```

One can obtain iterated operators by passing a reduced word or an element of the Weyl group:

```python
sage: T[1,2](x)
(q1^2+2*q1*q2+q2^2)*B[e[0] + e[1] + e[2]] +
```

(continues on next page)
and use that to check, for example, the braid relations:

```
sage: T[1,2,1](x) - T[2,1,2](x)
0
```

The operators satisfy the relations of the affine Hecke algebra with parameters $q_1, q_2$:

```
sage: T._test_relations()
sage: Tdominant._test_relations()
sage: Tbar._test_relations()  # -q2, q1+2*q2  # todo: not implemented: set the appropriate eigenvalues!
```

And the $\bar{T}$ are basically the inverses of the $T$'s:

```
sage: Tinv = KL.demazure_lusztig_operators(2/q1+1/q2,-1/q1,convention="bar")
sage: [Tinv[1](T[1](x))-x for x in KL.some_elements()]
[0, 0, 0, 0, 0, 0, 0]
```

We check that $\Lambda_1 - \Lambda_0$ is an eigenvector for the $Y$'s in affine type:

```
sage: K = QQ['q,q1,q2'].fraction_field()
sage: q,q1,q2=K.gens()
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: L0 = L.classical()
sage: Lambda = L.fundamental_weights()
sage: alphacheck = L0.simple_coroots()
sage: KL = L.algebra(K)
sage: T = KL.demazure_lusztig_operators(q1, q2, convention="dominant")
sage: Y = T.Y()
sage: alphacheck = Y.keys().alpha()  # alpha of coroot lattice is alphacheck
sage: alphacheck
Finite family {0: alphacheck[0], 1: alphacheck[1], 2: alphacheck[2]}
sage: x = KL.monomial(Lambda[1]-Lambda[0]); x
B[e[0]]
```

In fact it is not exactly an eigenvector, but the extra ‘delta’ term is to be interpreted as a $q$ parameter:

```
sage: Y[alphacheck[0]](KL.one())
q^2*B[0]
sage: Y[alphacheck[1]](x)
((-q^2)/(q^2-q))*B[e[0]] - B['delta']
sage: Y[alphacheck[2]](x)
(q/(q^2-q))*B[e[0]]
sage: KL.q_project(Y[alphacheck[1]](x), q)
((-q^2)/(q^2-q))*B[(1, 0, 0)]
sage: KL.q_project(x, q)
B[(1, 0, 0)]
```
We now check systematically that the Demazure-Lusztig operators satisfy the relations of the Iwahori-Hecke algebra:

```python
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: for cartan_type in CartanType.samples(crystallographic=True): #
  ....:   L = RootSystem(cartan_type).root_lattice()
  ....:   KL = L.algebra(K)
  ....:   T = KL.demazure_lusztig_operators(q1,q2)
  ....:   T._test_relations()
```

Recall that the Demazure-Lusztig operators are only defined when all monomials belong to the weight lattice. Thus, in the group algebra of the ambient space, we need to specify explicitly the elements on which to run the tests:

```python
sage: for cartan_type in CartanType.samples(crystallographic=True): #
  ....:   L = RootSystem(cartan_type).weight_lattice()
  ....:   KL = L.algebra(K)
  ....:   T = KL.demazure_lusztig_operators(q1,q2)
  ....:   T._test_relations()
```

demazure_lusztig_operators_on_classical \((q, q1, q2, \text{convention}={}'antidominant')\)

Return the Demazure-Lusztig operators acting at level 1 on self.classical().

INPUT:
• \(q, q1, q2\) – three elements of the ground ring
• \text{convention} – “antidominant”, “bar”, or “dominant” (default: “antidominant”)

Let \(KL\) be the group algebra of an affine weight lattice realization \(L\). The Demazure-Lusztig operators for \(KL\) act on the group algebra of the corresponding classical weight lattice by embedding it at level 1, and projecting back.

See also:
• `demazure_lusztig_operators()`.
• `demazure_lusztig_operator_on_classical_on_basis()`.
• `q_project()`

EXAMPLES:
sage: L = RootSystem(["A",1,1]).ambient_space()
sage: K = QQ["q,q1,q2"].fraction_field()
sage: q, q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: KL0 = KL.classical()
sage: L0 = KL0.basis().keys()
sage: T = KL.demazure_lusztig_operators_on_classical(q, q1, q2)
sage: x = KL0.monomial(L0((3,0))); x
B[(3, 0)]

For $T_1$, we recover the usual Demazure-Lusztig operators:

sage: T[1](x)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]

For $T_0$, we can note that, in the projection, $\delta$ is mapped to $q$:

sage: T[0](x)
(-q^2*q1-q^2*q2)*B[(1, 2)] + (-q*q1-q*q2)*B[(2, 1)] + (-q^3*q2)*B[(0, 3)]

Note that there is no translation part, and in particular 1 is an eigenvector for all $T_i$'s:

sage: T[0](KL0.one())
q1*B[(0, 0)]
sage: T[1](KL0.one())
q1*B[(0, 0)]

Matching with Ion Bogdan’s hand calculations from 3/15/2013:

sage: L = RootSystem(["A",1,1]).weight_space(extended=True)
sage: K = QQ["q,u"].fraction_field()
sage: q, u = K.gens()
sage: KL = L.algebra(K)
sage: KL0 = KL.classical()
sage: L0 = KL0.basis().keys()
sage: omega = L0.fundamental_weights()
sage: T = KL.demazure_lusztig_operators_on_classical(q, u, -1/u, convention="dominant")
sage: Y = T.Y()
sage: alphacheck = Y.keys().simple_roots()
sage: Y[alphacheck[0]](KL0.one())
((-q2)/(q*q1))*B[(0, 0)]

sage: Y[alphacheck[1]]
((1, 0), (1, 1), 1)

sage: Y[alphacheck[0]]
((1, 0), (1, 1), 1)
sage: Y0.word, Y0.signs, Y0.scalar # This is 1/q T_1^-1 T_0^-1
((0, 1), (-1, -1), 1/q)

Note that the following computations use the “dominant” convention:

sage: T0 = T.Tw(0)
sage: T0(KL0.monomial(omega[1]))
q*u*B[-Lambda[1]] + ((u^2-1)/u)*B[Lambda[1]]
sage: T0(KL0.monomial(2*omega[1]))
((q*u^2-q)/u)*B[0] + q^2*u*B[-2*Lambda[1]] + ((u^2-1)/u)*B[2+Lambda[1]]
sage: T0(KL0.monomial(-omega[1]))
1/(q*u)*B[Lambda[1]]
sage: T0(KL0.monomial(-2*omega[1]))
((-u^2+1)/(q*u))*B[0] + 1/(q^2*u)*B[2+Lambda[1]]

demazure_operators()

Return the Demazure operators acting on self.

The i-th Demazure operator is defined by:

\[
\pi_i = \frac{1 - e^{-\alpha_i}s_i}{1 - e^{-\alpha_i}}
\]

It acts on \( e^\lambda \), for \( \lambda \) a weight, by:

\[
\pi_i e^\lambda = \frac{e^\lambda - e^{-\alpha_i+s_i\lambda}}{1 - e^{-\alpha_i}}
\]

This matches with Lascoux’ definition [Lascoux2003] of \( \pi_i \), and with the \( i \)-th Demazure operator of [Kumar1987], which also works for general Kac-Moody types.

REFERENCES:

EXAMPLES:

We compute some Schur functions, as images of dominant monomials under the action of the maximal isobaric divided difference \( \Delta_{w_0} \):

sage: L = RootSystem(['A',2]).ambient_lattice()
sage: KL = L.algebra(QQ)
sage: w0 = tuple(L.weyl_group().long_element().reduced_word())
sage: pi = KL.demazure_operators()
sage: pi0 = pi[w0]
sage: pi0(KL.monomial(L((2,1))))
2*B[(1, 1, 1)] + B[(1, 2, 0)] + B[(1, 0, 2)] + B[(2, 1, 0)] + B[(2, 0, -1)] + B[(0, 1, 2)] + B[(0, 2, 1)]

Let us make the result into an actual polynomial:

sage: P = QQ['x,y,z']
sage: pi0(KL.monomial(L((2,1)))) expand(P.gens())
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2

This is indeed a Schur function:

sage: s = SymmetricFunctions(QQ).s()
sage: s[2,1].expand(3, P.variable_names())
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
Let us check this systematically on Schur functions of degree 6:

```python
sage: for p in Partitions(6, max_length=3).list():
    ....:     assert s.monomial(p).expand(3, P.variable_names()) == pi0(KL.monomial(L(tuple(p))).expand(P.gens()))
```

We check systematically that these operators satisfy the Iwahori-Hecke algebra relations:

```python
sage: for cartan_type in CartanType.samples(crystallographic=True):  # long time 12s
    ....:     L = RootSystem(cartan_type).weight_lattice()
    ....:     KL = L.algebra(QQ)
    ....:     T = KL.demazure_operators()
    ....:     T._test_relations()
```

```python
sage: L = RootSystem(['A',1,1]).weight_lattice()
sage: KL = L.algebra(QQ)
sage: T = KL.demazure_operators()
sage: T._test_relations()
```

**Warning:** The Demazure operators are only defined if all the elements in the support have integral scalar products with the coroots (basically, they are in the weight lattice). Otherwise an error is raised:

```python
sage: L = RootSystem(CartanType(['G',2]).dual()).ambient_space()
sage: KL = L.algebra(QQ)
sage: pi = KL.demazure_operators()
sage: pi[1](KL.monomial(L([0,0,1])))
Traceback (most recent call last):
  ... ValueError: the weight does not have an integral scalar product with
  the coroot
```

### divided_difference_on_basis(weight, i)

Return the result of applying the $i$-th divided difference on `weight`.

**INPUT:**

- `weight` – a weight
- `i` – an element of the index set

**Todo:** type free definition (Viviane’s definition uses that we are in the ambient space)

**EXAMPLES:**

```python
sage: L = RootSystem(['A',1]).ambient_space()
sage: KL = L.algebra(QQ)
sage: KL.divided_difference_on_basis(L((2,2)), 1) # todo: not implemented
0
sage: KL.divided_difference_on_basis(L((3,0)), 1) # todo: not implemented
B[(2, 0)] + B[(1, 1)] + B[(0, 2)]
sage: KL.divided_difference_on_basis(L((0,3)), 1) # todo: not implemented
-B[(2, 0)] - B[(1, 1)] - B[(0, 2)]
```

In type $A$ and in the ambient lattice, we recover the usual action of divided differences polynomials:
from_polynomial\( (p) \)
Construct an element of \texttt{self} from a polynomial \( p \).

INPUT:
• \( p \) – a polynomial

EXAMPLES:

\begin{verbatim}
sage: L = RootSystem(["A",2]).ambient_lattice()
sage: KL = L.algebra(QQ)
sage: x,y,z = QQ['x,y,z'].gens()
sage: KL.from_polynomial(x)
B[(1, 0, 0)]
sage: KL.from_polynomial(x^2*y + 2*y - z)
B[(2, 1, 0)] + 2*B[(0, 1, 0)] - B[(0, 0, 1)]
\end{verbatim}

Todo: make this work for Laurent polynomials too

isobaric_divided_difference_on_basis\( (weight, i) \)
Return the result of applying the \( i \)-th isobaric divided difference on \( weight \).

INPUT:
• \( weight \) – a weight
• \( i \) – an element of the index set

See also:
\texttt{demazure_operators()}

EXAMPLES:

\begin{verbatim}
sage: L = RootSystem(["A",1]).ambient_space()
sage: KL = L.algebra(QQ)
sage: KL.isobaric_divided_difference_on_basis(L((2,2)), 1)
B[(2, 2)]
sage: KL.isobaric_divided_difference_on_basis(L((3,0)), 1)
B[(1, 2)] + B[(2, 1)] + B[(3, 0)] + B[(0, 3)]
sage: KL.isobaric_divided_difference_on_basis(L((0,3)), 1)
-B[(1, 2)] - B[(2, 1)]
\end{verbatim}

In type \( A \) and in the ambient lattice, we recover the usual action of divided differences on polynomials:

\begin{verbatim}
sage: x,y = QQ['x,y'].gens()
sage: d = lambda p: (x*p - (x*p)(y,x)) / (x-y)
sage: d(x^2*y^2)
x^2*y^2
sage: d(x^3)
x^3 + x^2*y + x*y^2 + y^3
sage: d(y^3)
-x^2*y - x*y^2
\end{verbatim}
REFERENCE:

**q_project** \((x, q)\)

Implement the \(q\)-projection morphism from \(\text{self}\) to the group algebra of the classical space.

INPUT:

- \(x\) – an element of the group algebra of \(\text{self}\)
- \(q\) – an element of the ground ring

This is an algebra morphism mapping \(\delta\) to \(q\) and \(X^b\) to its classical counterpart for the other elements \(b\) of the basis of the realization.

EXAMPLES:

```python
sage: K = QQ['q'].fraction_field()
sage: q = K.gen()
sage: KL = RootSystem(['A',2,1]).ambient_space().algebra(K)
sage: L = KL.basis().keys()
sage: e = L.basis()
sage: KL.q_project(x, q)
B[(2, 2, 3)] + 1/q^2*B[(0, 4, 3)]
```

**Warning:** Recall that the null root, usually denoted \(\delta\), is in fact \(a[0] \delta\) in Sage’s notation, in order to avoid half integer coefficients (this only makes a difference in type BC). Similarly, what’s usually denoted \(q\) is in fact \(q^a[0]\) in Sage’s notations, to avoid manipulating square roots:

```python
sage: KL.q_project(KL.monomial(L.null_root()),q)
q^2*B[(0, 0, 0)]
```

**q_project_on_basis** \((l, q)\)

Return the monomial \(c \cdot c(l)\) in the group algebra of the classical lattice.

INPUT:

- \(l\) – an element of the root lattice realization
- \(q\) – an element of the ground ring

Here, \(c(l)\) is the projection of \(l\) in the classical lattice, and \(c\) is the coefficient of \(l\) in \(\delta\).

See also:

- **q_project_on_basis**

EXAMPLES:
```python
sage: K = QQ['q'].fraction_field()
sage: q = K.gen()
sage: KL = RootSystem(['A',2,1]).ambient_space().algebra(K)
sage: L = KL.basis().keys()
sage: e = L.basis()
sage: KL.q_project_on_basis(4*e[1] + 3*e[2] + e['deltacheck'] - 2*e['delta'], q)
1/q^2*B[(0, 4, 3)]
```

### some_elements()

Return some elements of the algebra self.

Examples:

```python
sage: A = RootSystem(['A',2,1]).ambient_space().algebra(QQ)
sage: A.some_elements()
 B[-e[0] + e[2] + e['delta']],
 B[e[0] - e[1]],
 B[e[1] - e[2]],
 B[e['deltacheck']],
 B[e[0] + e['deltacheck']],
 B[e[0] + e[1] + e['deltacheck']]]
```

### twisted_demazure_lusztig_operator_on_basis(weight, i, q1, q2, convention='antidominant')

Return the twisted Demazure-Lusztig operator acting on the basis.

**INPUT:**

- `weight` – an element \( \lambda \) of the weight lattice
- `i` – an element of the index set
- `q1, q2` – two elements of the ground ring
- `convention` – “antidominant”, “bar”, or “dominant” (default: “antidominant”)

**See also:**

- `twisted_demazure_lusztig_operators()`

Examples:

```python
sage: L = RootSystem(['A',3,1]).ambient_space()
sage: e = L.basis()
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: Lambda = L.classical().fundamental_weights()
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1]+2*Lambda[2],
                      1, q1, q2, convention='dominant')
(-q2)*B[(2, 3, 0, 0)]
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1]+2*Lambda[2],
                      2, q1, q2, convention='dominant')
```

(continues on next page)
Continued from previous page)

```python
(-q1-q2)*B[(3, 1, 1, 0)] + (-q2)*B[(3, 0, 2, 0)]
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1]+2*Lambda[2], q1, q2, convention="dominant")
q1*B[(3, 2, 0, 0)]
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1]+2*Lambda[2], 0, q1, q2, convention="dominant")
((q1*q2+q2^2)/q1)*B[(1, 2, 1, 1)] + ((q1*q2+q2^2)/q1)*B[(1, 2, 2, 0)] + q2^2/q1*B[(1, 2, 0, 2)]
+ ((q1^2+2*q1*q2+q2^2)/q1)*B[(2, 1, 1, 1)] + ((q1^2+2*q1*q2+q2^2)/q1)*B[(2, 1, 2, 0)]
+ ((q1*q2+q2^2)/q1)*B[(2, 1, 0, 2)] + ((q1^2+2*q1*q2+q2^2)/q1)*B[(2, 2, 1, 0)]
+ ((q1*q2+q2^2)/q1)*B[(2, 2, 0, 1)]
twisted_demazure_lusztig_operators (q1, q2, convention='antidominant')
Return the twisted Demazure-Lusztig operators acting on self.
INPUT:
• q1, q2 – two elements of the ground ring
• convention – “antidominant”, “bar”, or “dominant” (default: “antidominant”)

Warning:
• the code is currently only tested for q1q2 = -1
• only the “dominant” convention is functional for i = 0

For T_1, ..., T_n, these operators are the usual Demazure-Lusztig operators. On the other hand, the
operator T_0 is twisted:
```
sage: L = RootSystem("A",3,1).ambient_space()
sage: e = L.basis()
sage: K = QQ[\"q1,q2\"].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: T = KL.twisted_demazure_lusztig_operators(q1, q2, convention="dominant")
sage: T._test_relations()
```

Todo: Choose a good set of Cartan Type to run on. Rank >4 is too big. But C_1 and B_1 are boring.

We now check systematically that those operators satisfy the relations of the Iwahori-Hecke algebra:
```
sage: K = QQ[\"q1,q2\"].fraction_field()
sage: q1, q2 = K.gens()
sage: for cartan_type in CartanType.samples(affine=True, crystallographic=True): # long time 12s
  ....:     if cartan_type.rank() > 4: continue
  ....:     if cartan_type.type() == 'BC': continue
  ....:     KL = RootSystem(cartan_type).weight_lattice().algebra(K)
  ....:     T = KL.twisted_demazure_lusztig_operators(q1, q2, convention="dominant")
  ....:     T._test_relations()
```

Todo: Investigate why T_0^\vee currently does not satisfy the quadratic relation in type BC. This should
hopefully be fixed when \( T_0 \) will have a more uniform implementation:

```python
sage: cartan_type = CartanType(['BC',1,2])
sage: KL = RootSystem(cartan_type).weight_lattice().algebra(K)
sage: T = KL.twisted_demazure_lusztig_operators(q1,q2, convention="dominant")
sage: T._test_relations()
Traceback (most recent call last):
... tester.assertTrue(Ti(Ti(x,i,-q2),i,-q1).is_zero()) ...
AssertionError: False is not true
```

Comparison with T0:

```python
sage: L = RootSystem(['A',2,1]).ambient_space()
sage: e = L.basis()
sage: K = QQ['t,q'].fraction_field()
sage: t,q = K.gens()
sage: q1 = t
sage: q2 = -1
sage: KL = L.algebra(K)
sage: L0 = L.classical()
sage: T = KL.demazure_lusztig_operators(q1,q2, convention="dominant")
sage: def T0(*l0):
    return KL.q_project(T[0].on_basis()(L.embed_at_level(L0(l0), 1)), q)
sage: T0_check_on_basis = KL.T0_check_on_basis(q1, q2, convention="dominant")
sage: def T0c(*l0):
    return T0_check_on_basis(L0(l0))
sage: T0(0,0,1) # not double checked
(-t+1)/q)*B[(1, 0, 0)] + 1/q^2*B[(2, 0, -1)]
sage: T0c(0,0,1)
t^2-t)*B[(1, 0, 0)] + (t^2-t)*B[(1, 1, -1)] + t^2*B[(2, 0, -1)] + (t-1)*B[(0, 0, 1)]
```

### 5.1.240 Root lattice realizations

```python
class sage.combinat.root_system.root_lattice_realizations.RootLatticeRealizations(base, name=None)

Bases: sage.categories.category_types.Category_over_base_ring

The category of root lattice realizations over a given base ring

A root lattice realization \( L \) over a base ring \( R \) is a free module (or vector space if \( R \) is a field) endowed with an embedding of the root lattice of some root system.

Typical root lattice realizations over \( \mathbb{Z} \) include the root lattice, weight lattice, and ambient lattice. Typical root lattice realizations over \( \mathbb{Q} \) include the root space, weight space, and ambient space.

To describe the embedding, a root lattice realization must implement a method `simple_root()` returning for each \( i \) in the index set the image of the simple root \( \alpha_i \) under the embedding.

A root lattice realization must further implement a method on elements `scalar()`, computing the scalar product with elements of the coroot lattice or coroot space.

Using those, this category provides tools for reflections, roots, the Weyl group and its action, ...
EXAMPLES:

Here, we consider the root system of type $A_7$, and embed the root lattice element $x = \alpha_2 + 2\alpha_6$ in several root lattice realizations:

```python
sage: R = RootSystem(['A',7])
sage: alpha = R.root_lattice().simple_roots()
sage: L = R.root_space()
sage: L(x)
sage: L = R.weight_lattice()
sage: L(x)
sage: L = R.ambient_space()
sage: L(x)
(0, 1, -1, 0, 2, -2, 0, 0)
```

We embed the root space element $x = \alpha_2 + 1/2\alpha_6$ in several root lattice realizations:

```python
sage: alpha = R.root_space().simple_roots()
sage: L = R.weight_space()
sage: L(x)
sage: L = R.ambient_space()
sage: L(x)
(0, 1, -1, 0, 1/2, -1/2, 0, 0)
```

Of course, one can’t embed the root space in the weight lattice:

```python
sage: L = R.weight_lattice()
sage: L(x)
Traceback (most recent call last):
  ...
TypeError: do not know how to make x (= alpha[2] + 1/2*alpha[5]) an element of
→self (=Weight lattice of the Root system of type ['A', 7])
```

If $K_1$ is a subring of $K_2$, then one could in theory have an embedding from the root space over $K_1$ to any root lattice realization over $K_2$; this is not implemented:

```python
sage: K1 = QQ
sage: K2 = QQ['q']
sage: L = R.weight_space(K2)
```
sage: alpha = R.root_space(K2).simple_roots()
sage: L(alpha[1])
sage: alpha = R.root_space(K1).simple_roots()
sage: L(alpha[1])
Traceback (most recent call last):
  ...TypeError: do not know how to make x (= alpha[1]) an element of self (=Weight_lattice przecinanie o space over the Univariate Polynomial Ring in q over Rational Field of the Root_lattice of type ['A', 7])

By a slight abuse, the embedding of the root lattice is not actually required to be faithful. Typically for an affine root system, the null root of the root lattice is killed in the non extended weight lattice:

sage: R = RootSystem(['A', 3, 1])
sage: delta = R.root_lattice().null_root()
sage: L = R.weight_lattice()
sage: L(delta)
0

Algebras

alias of sage.combinat.root_system.root_lattice_realization_algebras.

Algebras

class ElementMethods

Bases: object

affine_orbit()

The orbit of self under the dot or affine action of the Weyl group.

EXAMPLES:

sage: L = RootSystem(['A', 2]).ambient_lattice()
sage: sorted(L.rho().dot_orbit())
# the output order is not specified
[(-2, 1, 4), (-2, 3, 2), (2, -1, 2), (2, 1, 0), (0, -1, 4), (0, 3, 0)]
sage: L = RootSystem(['B',2]).weight_lattice()
sage: sorted(L.fundamental_weights()[1].dot_orbit())
# the output order is not specified

We compare the dot action orbit to the regular orbit:

sage: L = RootSystem(['A', 3]).weight_lattice()
sage: len(L.rho().dot_orbit())
24
sage: len((-L.rho()).dot_orbit())
1
sage: La = L.fundamental_weights()
sage: len(La[1].dot_orbit())

(continues on next page)
associated_coroot ()

Returns the coroot associated to this root

EXAMPLES:

```
sage: alpha = RootSystem(['A', 3]).root_space().simple_roots()
sage: alpha[1].associated_coroot()
alphacheck[1]
```

associated_reflection ()

Given a positive root self, returns a reduced word for the reflection orthogonal to self.

Since the answer is cached, it is a tuple instead of a list.

EXAMPLES:

```
sage: RootSystem(['C',3]).root_lattice().simple_root(3).weyl_action([1, ˓→2]).associated_reflection() (1, 2, 3, 2, 1)
sage: RootSystem(['C',3]).root_lattice().simple_root(2).associated_˓→reflection() (2,)
```

descents (index_set=None, positive=False)

Returns the descents of pt

EXAMPLES:

```
sage: space=RootSystem(['A',5]).weight_space()
sage: alpha=space.simple_roots()
[3, 5]
```

dot_action (w, inverse=False)

Act on self by w using the dot or affine action.

Let w be an element of the Weyl group. The dot action or affine action is given by:

\[ w \cdot \lambda = w(\lambda + \rho) - \rho, \]

where \( \rho \) is the sum of the fundamental weights.

INPUT:
- w – an element of a Coxeter or Weyl group of the same Cartan type, or a tuple or a list (such as a reduced word) of elements from the index set
- inverse – a boolean (default: False); whether to act by the inverse element

EXAMPLES:
sage: P = RootSystem(['B',3]).weight_lattice()
sage: La = P.fundamental_weights()
sage: mu.dot_action([1])
sage: mu.dot_action([3])
Lambda[1] + Lambda[3]
sage: mu.dot_action([1,2,3])

We check that the origin of this action is at \(-\rho\):

sage: all((-P.rho()).dot_action([i]) == -P.rho() for i in P.index_set())
True

REFERENCES:
• Wikipedia article Affine_action
dot_orbit()
The orbit of self under the dot or affine action of the Weyl group.

EXAMPLES:

sage: L = RootSystem(['A', 2]).ambient_lattice()
sage: sorted(L.rho().dot_orbit())

# the output order is not specified
[-2, 1, 4], (-2, 3, 2), (2, -1, 2),
(2, 1, 0), (0, -1, 4), (0, 3, 0)]
sage: L = RootSystem(['B',2]).weight_lattice()
sage: sorted(L.fundamental_weights()[1].dot_orbit())

# the output order is not specified
[-4*Lambda[1], -4*Lambda[1] + 4*Lambda[2],
Lambda[1], Lambda[1] - 6*Lambda[2],

We compare the dot action orbit to the regular orbit:

sage: L = RootSystem(['A', 3]).weight_lattice()
sage: len(L.rho().dot_orbit())
24
sage: len((-L.rho()).dot_orbit())
1
sage: La = L.fundamental_weights()
sage: len(La[1].dot_orbit())
24
sage: len(La[1].orbit())
4
sage: len((-L.rho()) + La[1]).dot_orbit())
4
sage: len(La[2].dot_orbit())
24
sage: len(La[2].orbit())
6
sage: len((-L.rho()) + La[2]).dot_orbit())
6
extraspecial_pair()  
Return the extraspecial pair of \self under the ordering defined by \mbox{positive_roots_by_height()}.  

The \textit{extraspecial pair} of a positive root \( \gamma \) with some total ordering \(<\) of the root lattice that respects height is the pair of positive roots \((\alpha, \beta)\) such that \( \gamma = \alpha + \beta \) and \(\alpha\) is as small as possible.  

\textbf{EXAMPLES:}  
\begin{verbatim}
sage: Q = RootSystem(['G', 2]).root_lattice()
sage: Q.highest_root().extraspecial_pair()
(alpha[2], 3*alpha[1] + alpha[2])
\end{verbatim}

first_descent (index_set=\texttt{None}, positive=\texttt{False})  
Returns the first descent of pt  
One can use the index_set option to restrict to the parabolic subgroup indexed by index_set.  

\textbf{EXAMPLES:}  
\begin{verbatim}
sage: space=RootSystem(['A',5]).weight_space()
sage: alpha=space.simple_roots()
sage: (alpha[1]+alpha[2]+alpha[4]).first_descent([1,2,5]) 5
sage: (alpha[1]+alpha[2]+alpha[4]).first_descent([1,2,5,3,4]) 5
\end{verbatim}

greater()  
Returns the elements in the orbit of \self which are greater than \self in the weak order.  

\textbf{EXAMPLES:}  
\begin{verbatim}
sage: L = RootSystem(['A',3]).ambient_lattice()
sage: e = L.basis()
sage: e[2].greater()
[(0, 0, 1, 0), (0, 0, 0, 1)]
sage: len(L.rho().greater())
24
sage: len((-L.rho()).greater())
1
sage: sorted([len(x.greater()) for x in L.rho().orbit()])
[1, 2, 2, 2, 3, 3, 3, 3, 4, 4, 4, 4, 5, 5, 6, 6, 6, 8, 8, 8, 8, 12, 12, 12, ...
...
24]
\end{verbatim}

has_descent \((i, positive=\texttt{False})\)  
Test if \self has a descent at position \(i\), that is if \self is on the strict negative side of the \(i\textsuperscript{th}\) simple reflection hyperplane.  
If positive if True, tests if it is on the strict positive side instead.  

\textbf{EXAMPLES:}  
\begin{verbatim}
sage: space=RootSystem(['A',5]).weight_space()
sage: alpha=RootSystem(['A',5]).weight_space().simple_roots()
sage: [alpha[i].has_descent(1) for i in space.index_set()]
[False, True, False, False, False]
sage: [(-alpha[i]).has_descent(1) for i in space.index_set()]
[True, False, False, False, False]
\end{verbatim}
(continues on next page)
sage: [alpha[i].has_descent(1, True) for i in space.index_set()]
[True, False, False, False, False]

sage: [(-alpha[i]).has_descent(1, True) for i in space.index_set()]
[False, True, False, False, False]

True
False
sage: (alpha[1]+alpha[2]+alpha[4]).has_descent(1, True)
True

height()

Return the height of self.

The height of a root \( \alpha = \sum i a_i \alpha_i \) is defined to be \( h(\alpha) := \sum i a_i \).

EXAMPLES:

sage: Q = RootSystem(['G', 2]).root_lattice()
sage: Q.highest_root().height()
5

is_dominant(index_set=None, positive=True)

Returns whether self is dominant.

This is done with respect to the subrootsystem indicated by the subset of Dynkin nodes index_set. If index_set is None then the entire Dynkin node set is used. If positive is False then the dominance condition is replaced by antidominance.

EXAMPLES:

sage: L = RootSystem(['A',2]).ambient_lattice()
sage: Lambda = L.fundamental_weights()
sage: [x.is_dominant() for x in Lambda]
[True, True]

sage: [x.is_dominant(positive=False) for x in Lambda]
[False, False]

sage: (Lambda[1]-Lambda[2]).is_dominant()
False
sage: (-Lambda[1]+Lambda[2]).is_dominant()
False
sage: (Lambda[1]-Lambda[2]).is_dominant([1])
True
sage: (Lambda[1]-Lambda[2]).is_dominant([2])
False
sage: [x.is_dominant() for x in L.roots()]
[False, True, False, False, False, False]

is_dominant_weight()

Test whether self is a dominant element of the weight lattice.

EXAMPLES:

sage: L = RootSystem(['A',2]).ambient_lattice()
sage: Lambda = L.fundamental_weights()
sage: [x.is_dominant() for x in Lambda]
sage: (3*Lambda[1]+Lambda[2]).is_dominant()
True
sage: (Lambda[1]-Lambda[2]).is_dominant()
False
sage: (-Lambda[1]+Lambda[2]).is_dominant()
False

Tests that the scalar products with the coroots are all nonnegative integers. For example, if \( x \) is the sum of a dominant element of the weight lattice plus some other element orthogonal to all coroots, then the implementation correctly reports \( x \) to be a dominant weight:

\[
sage: x = Lambda[1] + L([-1,-1,-1])
sage: x.is_dominant_weight()
True
\]

**is_imaginary_root()**  
Return True if self is an imaginary root.  
A root \( \alpha \) is imaginary if it is not \( W \) conjugate to a simple root where \( W \) is the corresponding Weyl group.

**EXAMPLES:**

\[
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_imaginary_root()
False
sage: elt.is_imaginary_root()
True
\]

**is_long_root()**  
Return True if self is a long (real) root.

**EXAMPLES:**

\[
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_long_root()
True
sage: alpha[1].is_long_root()
True
sage: alpha[2].is_long_root()
False
\]

**is_parabolic_root(index_set)**  
Supposing that self is a root, is it in the parabolic subsystem with Dynkin nodes index_set?

**INPUT:**  
• index_set – the Dynkin node set of the parabolic subsystem.

**Todo:** This implementation is only valid in the root or weight lattice

**EXAMPLES:**
is_real_root()  
Return True if self is a real root.

A root \( \alpha \) is real if it is \( W \) conjugate to a simple root where \( W \) is the corresponding Weyl group.

EXAMPLES:

```python
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_real_root()  # True
sage: elt.is_real_root()  # False
```

is_short_root()  
Return True if self is a short (real) root.

Returns False unless the parent is an irreducible root system of finite type having two root lengths and self is of the shorter length. There is no check of whether self is actually a root.

EXAMPLES:

```python
sage: Q = RootSystem(['C',2]).root_lattice()
sage: al = Q.simple_root(1).weyl_action([1,2]); al
sage: al.is_short_root()  # True
sage: bt = Q.simple_root(2).weyl_action([2,1,2]); bt
sage: bt.is_short_root()  # False
```

An example in affine type:

```python
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_short_root()  # False
sage: alpha[1].is_short_root()  # False
sage: alpha[2].is_short_root()  # True
```

level()  
EXAMPLES:
norm_squared()

Return the norm squared of \texttt{self} with respect to the symmetric form.

Examples:

```python
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[1].norm_squared()
4
sage: alpha[2].norm_squared()
2
sage: elt.norm_squared()
50
sage: elt.norm_squared()
0
```

orbit()

The orbit of \texttt{self} under the action of the Weyl group.

Examples:

\(\rho\) is a regular element whose orbit is in bijection with the Weyl group. In particular, it has 6 elements for the symmetric group \(S_3\):

```python
sage: L = RootSystem(['A', 2]).ambient_lattice()
sage: sorted(L.rho().orbit())  # the output order is not specified
[(1, 2, 0), (1, 0, 2), (2, 1, 0),
 (2, 0, 1), (0, 1, 2), (0, 2, 1)]
```

pred(index_set=None)

Return the immediate predecessors of \texttt{self} for the weak order.

Input:
- `index_set` - a subset (as a list or iterable) of the nodes of the Dynkin diagram; (default: None for all of them)

If `index_set` is specified, the successors for the corresponding parabolic subsystem are returned.

**EXAMPLES:**

```python
sage: L = RootSystem(['A',3]).weight_lattice()
sage: Lambda = L.fundamental_weights()
sage: Lambda[1].pred()
[]
sage: L.rho().pred()
[]
sage: (-L.rho()).pred(index_set=[1])
```

**reduced_word** *(index_set=None, positive=True)*

Returns a reduced word for the inverse of the shortest Weyl group element that sends the vector `self` into the dominant chamber.

With the `index_set` optional parameter, this is done with respect to the corresponding parabolic subgroup.

If `positive` is False, use the antidominant chamber instead.

**EXAMPLES:**

```python
sage: space=RootSystem(['A',5]).weight_space()
sage: alpha=RootSystem(['A',5]).weight_space().simple_roots()
sage: alpha[1].reduced_word()
[2, 3, 4, 5]
sage: alpha[1].reduced_word([1,2])
[2]
```

**reflection** *(root, use_coroot=False)*

Reflects `self` across the hyperplane orthogonal to `root`.

If `use_coroot` is True, `root` is interpreted as a coroot.

**EXAMPLES:**

```python
sage: R = RootSystem(['C',4])
sage: weight_lattice = R.weight_lattice()
sage: mu = weight_lattice.from_vector(vector([0,0,1,2]))
sage: coroot_lattice = R.coroot_lattice()
sage: alphavee = coroot_lattice.from_vector(vector([0,0,1,1]))
sage: mu.reflection(alphavee, use_coroot=True)
sage: root_lattice = R.root_lattice()
sage: beta = root_lattice.from_vector(vector([0,1,1,0]))
sage: mu.reflection(beta)
```

**scalar** *(lambdacheck)*

Implement the natural pairing with the coroot lattice.

**INPUT:**

- `self` – an element of a root lattice realization
• lambdacheck – an element of the coroot lattice or coroot space

OUTPUT: the scalar product of \textit{self} and \textit{lambdacheck}

\textbf{EXAMPLES:}

\begin{verbatim}
    sage: L = RootSystem(['A',4]).root_lattice()
    sage: alpha = L.simple_roots()
    sage: alphacheck = L.simple_coroots()
    sage: alpha[1].scalar(alphacheck[1])
    2
    sage: alpha[1].scalar(alphacheck[2])
    -1
    sage: matrix([[ alpha[i].scalar(alphacheck[j])
    ....: for i in L.index_set() ]
    ....: for j in L.index_set() ])
    [ 2 -1  0  0]
    [-1  2 -1  0]
    [ 0 -1  2 -1]
    [ 0  0 -1  2]
\end{verbatim}

\textbf{simple\_reflection}(i)

\begin{verbatim}
    \textit{Returns the image of} \textit{self} \textit{by the} \textit{i}-th \textit{simple reflection.}
\end{verbatim}

\textbf{EXAMPLES:}

\begin{verbatim}
    sage: alpha = RootSystem(['A', 3]).root_lattice().alpha()
    sage: alpha[1].simple_reflection(2)
    sage: Q = RootSystem(['A', 3, 1]).weight_lattice(extended = True)
    sage: Lambda = Q.fundamental_weights()
    sage: L = Lambda[0] + Q.null_root()
    sage: L.simple_reflection(0)
    -Lambda[0] + Lambda[1] + Lambda[3]
\end{verbatim}

\textbf{simple\_reflections()}

\begin{verbatim}
    \textit{The images of} \textit{self} \textit{by all the simple reflections}
\end{verbatim}

\textbf{EXAMPLES:}

\begin{verbatim}
    sage: alpha = RootSystem(['A', 3]).root_lattice().alpha()
    sage: alpha[1].simple_reflections()
    [-alpha[1], alpha[1] + alpha[2], alpha[1]]
\end{verbatim}

\textbf{smaller()}

\begin{verbatim}
    \textit{Returns the elements in the orbit of} \textit{self} \textit{which are smaller than} \textit{self} \textit{in the weak order.}
\end{verbatim}

\textbf{EXAMPLES:}

\begin{verbatim}
    sage: L = RootSystem(['A',3]).ambient_lattice()
    sage: e = L.basis()
    sage: e[2].smaller()
    [(0, 0, 1, 0), (0, 1, 0, 0), (1, 0, 0, 0)]
    sage: len(L.rho().smaller())
    1
    sage: len((-L.rho()).smaller())
    24
    sage: sorted([len(x.smaller()) for x in L.rho().orbit()])
    [1, 2, 2, 2, 3, 3, 3, 3, 4, 4, 4, 4, 5, 5, 6, 6, 6, 8, 8, 8, 8, 12, 12, 12, 24]
\end{verbatim}

(continues on next page)
succ \(\text{index}_\text{set}=\text{None}\)

Return the immediate successors of \texttt{self} for the weak order.

**INPUT:**

- **\texttt{index}\_\texttt{set}** - a subset (as a list or iterable) of the nodes of the Dynkin diagram; (default: \text{None} for all of them)

If \texttt{index}\_\texttt{set} is specified, the successors for the corresponding parabolic subsystem are returned.

**EXAMPLES:**

```python
sage: L = RootSystem(['A',3]).weight_lattice()
sage: Lambda = L.fundamental_weights()
sage: Lambda[1].succ()
[-Lambda[1] + Lambda[2]]
sage: L.rho().succ()
sage: (-L.rho()).succ()
[]
sage: L.rho().succ(index_set=[1])
sage: L.rho().succ(index_set=[2])
```

\textbf{symmetric}\_\textbf{form}(\texttt{alpha})

Return the symmetric form of \texttt{self} with \texttt{alpha}.

Consider the simple roots \(\alpha_i\) and let \((b_{ij})_{ij}\) denote the symmetrized Cartan matrix \((a_{ij})_{ij}\), we have

\[(\alpha_i | \alpha_j) = b_{ij}\]

and extended bilinearly. See Chapter 6 in Kac, Infinite Dimensional Lie Algebras for more details.

**EXAMPLES:**

```python
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[1].symmetric_form(alpha[0])
0
sage: alpha[1].symmetric_form(alpha[1])
4
sage: elt.symmetric_form(alpha[1])
-14
sage: elt.symmetric_form(alpha[0]+2*alpha[2])
14
```

5.1. Comprehensive Module list
to_ambient()

Map self to the ambient space.

EXAMPLES:

```python
sage: alpha = CartanType(['B',4]).root_system().root_lattice().an_element(); alpha
sage: alpha.to_ambient()
(2, 0, 1, -3)
sage: mu = CartanType(['B',4]).root_system().weight_lattice().an_element(); mu
sage: mu.to_ambient()
(7, 5, 3, 0)
sage: v = CartanType(['B',4]).root_system().ambient_space().an_element(); v
(2, 2, 3, 0)
sage: v.to_ambient()
(2, 2, 3, 0)
sage: alphacheck = CartanType(['B',4]).root_system().coroot_lattice().an_element(); alphacheck
sage: alphacheck.to_ambient()
(2, 0, 1, -3)
```

to_classical()

Map self to the classical lattice/space.

Only makes sense for affine type.

EXAMPLES:

```python
sage: R = CartanType(['A',3,1]).root_system()
sage: alpha = R.root_lattice().an_element(); alpha
sage: alb = alpha.to_classical(); alb
sage: alb.parent()
Root lattice of the Root system of type ['A', 3]
sage: v = R.ambient_space().an_element(); v
2*e[0] + 2*e[1] + 3*e[2]
sage: v.to_classical()
(2, 2, 3, 0)
```

to_dominant_chamber(index_set=None, positive=True, reduced_word=False)

Returns the unique dominant element in the Weyl group orbit of the vector self.

If positive is False, returns the antidominant orbit element.

With the index_set optional parameter, this is done with respect to the corresponding parabolic subgroup.

If reduced_word is True, returns the 2-tuple (weight, direction) where weight is the (anti)dominant orbit element and direction is a reduced word for the Weyl group element sending weight to self.

**Warning:** In infinite type, an orbit may not contain a dominant element. In this case the function may go into an infinite loop.
For affine root systems, errors are generated if the orbit does not contain the requested kind of representative. If the input vector is of positive (resp. negative) level, then there is a dominant (resp. antidominant) element in its orbit but not an antidominant (resp. dominant) one. If the vector is of level zero, then there are neither dominant nor antidominant orbit representatives, except for multiples of the null root, which are themselves both dominant and antidominant orbit representatives.

**EXAMPLES:**

```python
sage: space=RootSystem(['A',5]).weight_space()
sage: alpha=RootSystem(['A',5]).weight_space().simple_roots()
sage: alpha[1].to_dominant_chamber()
sage: alpha[1].to_dominant_chamber([1,2])
sage: wl=RootSystem(['A',2,1]).weight_lattice(extended=True)
sage: mu=wl.from_vector(vector([1,-3,0]))
sage: mu.to_dominant_chamber(positive=False, reduced_word = True)
(-Lambda[1] - Lambda[2] - delta, [0, 2])
sage: R = RootSystem(['A',1,1])
sage: rl = R.root_lattice()
sage: nu = rl.zero()
sage: nu.to_dominant_chamber()
0
sage: nu.to_dominant_chamber(positive=False)
0
sage: mu = rl.from_vector(vector([0,1]))
sage: mu.to_dominant_chamber()
Traceback (most recent call last):
...
ValueError: alpha[1] is not in the orbit of the fundamental chamber
sage: mu.to_dominant_chamber(positive=False)
Traceback (most recent call last):
...
ValueError: alpha[1] is not in the orbit of the negative of the fundamental chamber
```

**to_dual_type_cospace()**

Map `self` to the dual type cospace.

For example, if `self` is in the root lattice of type ['B', 2], send it to the coroot lattice of type ['C', 2].

**EXAMPLES:**

```python
sage: v = CartanType(['C',3]).root_system().weight_lattice().an_element(); v
sage: w = v.to_dual_type_cospace(); w
sage: w.parent()
Coweight lattice of the Root system of type ['B', 3]
```

**to_simple_root** *(reduced_word=False)*

Return (the index of) a simple root in the orbit of the positive root `self`.

**INPUT:**
• self – a positive root
• reduced_word – a boolean (default: False)

OUTPUT:
• The index \( i \) of a simple root \( \alpha_i \). If reduced_word is True, this returns instead a pair \( (i, \text{word}) \), where \( \text{word} \) is a sequence of reflections mapping \( \alpha_i \) up the root poset to self.

EXAMPLES:

```python
sage: L = RootSystem(["A",3]).root_lattice()
sage: positive_roots = L.positive_roots()
sage: for alpha in sorted(positive_roots):
    ....:     print("{} {}".format(alpha, alpha.to_simple_root()))
alpha[1] 1
alpha[2] 2
alpha[3] 3
sage: for alpha in sorted(positive_roots):
    ....:     print("{} {}".format(alpha, alpha.to_simple_root(reduced_word=True)))
alpha[1] (1, ())
alpha[2] (2, ())
alpha[3] (3, ())
```

ALGORITHM:
This method walks from self down to the antidominant chamber by applying successively the simple reflection given by the first descent. Since self is a positive root, each step goes down the root poset, and one must eventually cross a simple root \( \alpha_i \).

See also:
• first_descent()
• to_dominant_chamber()

**Warning:** The behavior is not specified if the input is not a positive root. For a finite root system, this is currently caught (albeit with a not perfect message):

```python
sage: alpha = L.simple_roots()
sage: (2*alpha[1]).to_simple_root()
Traceback (most recent call last):
  ...  
```

For an infinite root system, this method may run into an infinite recursion if the input is not a positive root.

**translation** \((x)\)

**INPUT:**
• self - an element \( t \) at level 0
• \( x \) - an element of the same space

Returns \( x \) translated by \( t \), that is \( x + \text{level}(x)t \)

**EXAMPLES:**
Let us look at the translation of an element of level 1:

```python
sage: Lambda[1].level()
1
sage: t.translation(Lambda[1])
-Lambda[0] + 2*Lambda[2]
```

and of an element of level 0:

```python
sage: alpha[1].level()
0
sage: t.translation(alpha[1])
```

The arguments are given in this seemingly unnatural order to make it easy to construct the translation function:

```python
sage: f = t.translation
sage: f(Lambda[1])
-Lambda[0] + 2*Lambda[2]
```

**weyl_action**(element, inverse=False)

Act on self by an element of the Coxeter or Weyl group.

**INPUT:**

- element – an element of a Coxeter or Weyl group of the same Cartan type, or a tuple or a list (such as a reduced word) of elements from the index set
- inverse – a boolean (default: False); whether to act by the inverse element

**EXAMPLES:**

```python
sage: wl = RootSystem(['A',3]).weight_lattice()
sage: mu = wl.from_vector(vector([1,0,-2]))
sage: mu
sage: mudom, rw = mu.to_dominant_chamber(positive=False, reduced_word=False)
sage: mudom
(-Lambda[2] - Lambda[3], [1, 2])
sage: mudom.weyl_action(rw)
sage: mu.weyl_action(rw, inverse = True)
```

Acting by a (reduced) word:

```python
sage: mudom.weyl_action(rw)
sage: mu.weyl_action(rw, inverse = True)
```

Acting by an element of the Coxeter or Weyl group on a vector in its own lattice of definition (implemented by matrix multiplication on a vector):
sage: w = wl.weyl_group().from_reduced_word([1, 2])
sage: mudom.weyl_action(w)

Acting by an element of an isomorphic Coxeter or Weyl group (implemented by the action of a corresponding reduced word):

sage: W = WeylGroup(['A',3], prefix="s")
sage: w = W.from_reduced_word([1, 2])
sage: wl.weyl_group() == W
False
sage: mudom.weyl_action(w)

weyl_stabilizer(index_set=None)

Returns the subset of Dynkin nodes whose reflections fix self.

If index_set is not None, only consider nodes in this set. Note that if self is dominant or antidominant, then its stabilizer is the parabolic subgroup defined by the returned node set.

EXAMPLES:

sage: wl = RootSystem(['A',2,1]).weight_lattice(extended = True)
sage: al = wl.null_root()
sage: al.weyl_stabilizer()
[0, 1, 2]
sage: wl = RootSystem(['A',4]).weight_lattice()
sage: mu = wl.from_vector(vector([1,1,0,0]))
sage: mu.weyl_stabilizer()
[3, 4]
sage: mu.weyl_stabilizer(index_set = [1,2,3])
[3]

class ParentMethods
Bases: object

a_long_simple_root()

Returns a long simple root, corresponding to the highest outgoing edge in the Dynkin diagram.

Caveat: this may be break in affine type $A_{2n}^{(2)}$
Caveat: meaningful/broken for non irreducible?

TODO: implement CartanType.nodes_by_length as in MuPAD-Combinat (using CartanType.symmetrizer), and use it here.

almost_positive_roots()

Returns the almost positive roots of self

These are the positive roots together with the simple negative roots.

See also:

almost_positive_root_decomposition(), tau_plus_minus()

EXAMPLES:

sage: L = RootSystem(['A',2]).root_lattice()
sage: L.almost_positive_roots()
[-alpha[1], alpha[1], alpha[1] + alpha[2], -alpha[2], alpha[2]]
almost_positive_roots_decomposition()
Returns the decomposition of the almost positive roots of self

This is the list of the orbits of the almost positive roots under the action of the dihedral group generated by the operators $\tau_+$ and $\tau_-.

See also:
• almost_positive_roots()
• tau_plus_minus()

EXAMPLES:

```python
sage: RootSystem(['A',2]).root_lattice().almost_positive_roots_→decomposition()
[[-alpha[1], alpha[1], alpha[1] + alpha[2], alpha[2], -alpha[2]]]
sage: RootSystem(['B',2]).root_lattice().almost_positive_roots_→decomposition()
[[-alpha[1], alpha[1], alpha[1] + 2*alpha[2]], [-alpha[2], alpha[2],
→alpha[1] + alpha[2]]]
sage: RootSystem(['D',4]).root_lattice().almost_positive_roots_→decomposition()
→alpha[4]],
→alpha[4]],
→alpha[3]]]
```

alpha()
Returns the family $(\alpha_i)_{i \in I}$ of the simple roots, with the extra feature that, for simple irreducible root systems, $\alpha_0$ yields the opposite of the highest root.

EXAMPLES:

```python
sage: alpha = RootSystem(['A',2]).root_lattice().alpha()
sage: alpha[1]
alpha[1]
sage: alpha[0]
```

alphacheck()
Returns the family $(\alpha_i^\vee)_{i \in I}$ of the simple coroots, with the extra feature that, for simple irreducible root systems, $\alpha_0^\vee$ yields the coroot associated to the opposite of the highest root (caveat: for non simply laced root systems, this is not the opposite of the highest coroot!)

EXAMPLES:

```python
sage: alphacheck = RootSystem(['A',2]).ambient_space().alphacheck()
sage: alphacheck
Finite family {1: (1, -1, 0), 2: (0, 1, -1)}
```

Here is now $\alpha_0^\vee$:
(-1, 0, 1)
Todo: add a non simply laced example

Finally, here is an affine example:

```
sage: RootSystem(['A',2,1]).weight_space().alphacheck()
Finite family {0: alphacheck[0], 1: alphacheck[1], 2: alphacheck[2]}
sage: RootSystem(['A',3]).ambient_space().alphacheck()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}
```

**basic_imaginary_roots()**
Return the basic imaginary roots of `self`.

The basic imaginary roots $\delta$ are the set of imaginary roots in $-C^\vee$ where $C$ is the dominant chamber (i.e., $\langle \beta, \alpha_i^\vee \rangle \leq 0$ for all $i \in I$). All imaginary roots are $W$-conjugate to a simple imaginary root.

**EXAMPLES:**

```
sage: RootSystem(['A', 2]).root_lattice().basic_imaginary_roots()

sage: Q = RootSystem(['A', 2, 1]).root_lattice()
sage: Q.basic_imaginary_roots()
(alpha[0] + alpha[1] + alpha[2],)
sage: delta = Q.basic_imaginary_roots()[0]
sage: all(delta.scalar(Q.simple_coroot(i)) <= 0 for i in Q.index_set())
True
```

**cartan_type()**
EXAMPLES:

```
sage: r = RootSystem(['A', 4]).root_space()
sage: r.cartan_type()
['A', 4]
```

**classical()**
Return the corresponding root/weight/ambient lattice/space.

**EXAMPLES:**

```
sage: RootSystem(['A',4,1]).root_lattice().classical()
Root lattice of the Root system of type ['A', 4]
sage: RootSystem(['A',4,1]).weight_lattice().classical()
Weight lattice of the Root system of type ['A', 4]
sage: RootSystem(['A',4,1]).ambient_space().classical()
Ambient space of the Root system of type ['A', 4]
```

**cohighest_root()**
Returns the associated coroot of the highest root.

**Note:** this is usually not the highest coroot.

**EXAMPLES:**

```
sage: RootSystem(['A', 3]).ambient_space().cohighest_root()
(1, 0, 0, -1)
```
coroot_lattice()  
Returns the coroot lattice.

EXAMPLES:

```
sage: RootSystem(['A',2]).root_lattice().coroot_lattice()
Coroot lattice of the Root system of type ['A', 2]
```

coroot_space(base_ring=Rational Field)  
Return the coroot space over base_ring.

INPUT:
• base_ring – a ring (default: Q)

EXAMPLES:

```
sage: RootSystem(['A',2]).root_lattice().coroot_space()
Coroot space over the Rational Field of the Root system of type ['A', 2]
sage: RootSystem(['A',2]).root_lattice().coroot_space(QQ['q'])
Coroot space over the Univariate Polynomial Ring in q over Rational Field of the Root system of type ['A', 2]
```

dual_type_cospace()  
Returns the cospace of dual type.

For example, if invoked on the root lattice of type ['B', 2], returns the coroot lattice of type ['C', 2].

**Warning:** Not implemented for ambient spaces.

EXAMPLES:

```
sage: CartanType(['B',2]).root_system().root_lattice().dual_type_cospace()
Coroot lattice of the Root system of type ['C', 2]
sage: CartanType(['F',4]).root_system().coweight_lattice().dual_type_cospace()
Weight lattice of the Root system of type ['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

dynkin_diagram()  
EXAMPLES:

```
sage: r = RootSystem(['A',4]).root_space()
sage: r.dynkin_diagram()
O---O---O---O
1 2 3 4
A4
```

fundamental_weights_from_simple_roots()  
Return the fundamental weights.

This is computed from the simple roots by using the inverse of the Cartan matrix. This method is therefore only valid for finite types and if this realization of the root lattice is large enough to contain them.

EXAMPLES:

In the root space, we retrieve the inverse of the Cartan matrix:
sage: L = RootSystem(["B",3]).root_space()
sage: L.fundamental_weights_from_simple_roots()
sage: ~L.cartan_type().cartan_matrix()
[ 1 1 1/2]
[ 1 2 1]
[ 1 2 3/2]

In the weight lattice and the ambient space, we retrieve the fundamental weights:

sage: L = RootSystem(["B",3]).weight_lattice()
sage: L.fundamental_weights_from_simple_roots()
Finite family {1: Lambda[1], 2: Lambda[2], 3: Lambda[3]}
sage: L = RootSystem(["B",3]).ambient_space()
sage: L.fundamental_weights()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
sage: L.fundamental_weights_from_simple_roots()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}

However the fundamental weights do not belong to the root lattice:

sage: L = RootSystem(["B",3]).root_lattice()
sage: L.fundamental_weights_from_simple_roots()
Traceback (most recent call last):
  ... ValueError: The fundamental weights do not live in this realization of
  the root lattice

Beware of the usual $GL_n$ vs $SL_n$ catch in type $A$:

sage: L = RootSystem(["A",3]).ambient_space()
sage: L.fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0)}
sage: L.fundamental_weights_from_simple_roots()
Finite family {1: (3/4, -1/4, -1/4, -1/4), 2: (1/2, 1/2, -1/2, -1/2),
          3: (-1/4, 1/4, 1/4, -3/4)}

sage: L = RootSystem(["A",3]).ambient_lattice()
sage: L.fundamental_weights_from_simple_roots()
Traceback (most recent call last):
  ... ValueError: The fundamental weights do not live in this realization of
  the root lattice

**generalized_nonnesting_partition_lattice**(m,facade=False)

Return the lattice of $m$-nonnesting partitions

This has been defined by Athanasiadis, see chapter 5 of [Arm06].

**INPUT:**

• $m$ – integer

**See also:**

nonnesting_partition_lattice()

**EXAMPLES:**
```python
sage: R = RootSystem(['A', 2])
sage: RS = R.root_lattice()
sage: P = RS.generalized_nonnesting_partition_lattice(2); P
Finite lattice containing 12 elements
sage: P.coxeter_transformation()**20 == 1
True
```

**highest_root()**

Returns the highest root (for an irreducible finite root system)

**EXAMPLES:**

```python
sage: RootSystem(['A',4]).ambient_space().highest_root()
(1, 0, 0, 0, -1)
sage: RootSystem(['E',6]).weight_space().highest_root()
Lambda[2]
```

**index_set()**

**EXAMPLES:**

```python
sage: r = RootSystem(['A',4]).root_space()
sage: r.index_set()
(1, 2, 3, 4)
```

**long_roots()**

Return a list of the long roots of self.

**EXAMPLES:**

```python
sage: L = RootSystem(['B',3]).root_lattice()
sage: sorted(L.long_roots())
 alpha[1], alpha[1] + alpha[2],
```

**negative_roots()**

Returns the negative roots of self.

**EXAMPLES:**

```python
sage: L = RootSystem(['A', 2]).weight_lattice()
sage: sorted(L.negative_roots())
 -2*Lambda[2]]
```

Algorithm: negate the positive roots

**nonnesting_partition_lattice (facade=False)**

Return the lattice of nonnesting partitions

This is the lattice of order ideals of the root poset.

This has been defined by Postnikov, see Remark 2 in [Reiner97].

See also:
generalized_nonnesting_partition_lattice(), root_poset()

EXAMPLES:

```
sage: R = RootSystem(['A', 3])
sage: RS = R.root_lattice()
sage: P = RS.nonnesting_partition_lattice(); P
Finite lattice containing 14 elements
sage: P.coxeter_transformation()**10 == 1
True
sage: R = RootSystem(['B', 3])
sage: RS = R.root_lattice()
sage: P = RS.nonnesting_partition_lattice(); P
Finite lattice containing 20 elements
sage: P.coxeter_transformation()**7 == 1
True
```

REFERENCES:

**nonparabolic_positive_root_sum** (*index_set=None*)
Return the sum of positive roots not in a parabolic subsystem.

The conventions for *index_set* are as in **nonparabolic_positive_roots()**.

EXAMPLES:

```
sage: Q = RootSystem(['A',3]).root_lattice()
sage: Q.nonparabolic_positive_root_sum((1,2))
sage: Q.nonparabolic_positive_root_sum()
0
sage: Q.nonparabolic_positive_root_sum(())
```

**nonparabolic_positive_roots** (*index_set=None*)
Return the positive roots of *self* that are not in the parabolic subsystem indicated by *index_set*.

If *index_set* is None, as in **positive_roots()** it is assumed to be the entire Dynkin node set. Then the parabolic subsystem consists of all positive roots and the empty list is returned.

EXAMPLES:

```
sage: L = RootSystem(['A',3]).root_lattice()
sage: L.nonparabolic_positive_roots()
[]
sage: sorted(L.nonparabolic_positive_roots((1,2)))
sage: sorted(L.nonparabolic_positive_roots(()))
  alpha[2] + alpha[3], alpha[3]]
```

null_coroot()
Returns the null coroot of *self*.

The null coroot is the smallest non trivial positive coroot which is orthogonal to all simple roots. It exists for any affine root system.

EXAMPLES:
null_root()

Returns the null root of self. The null root is the smallest non-trivial positive root which is orthogonal
to all simple coroots. It exists for any affine root system.

EXAMPLES:

```python
sage: RootSystem(['C',2,1]).root_lattice().null_root()
sage: RootSystem(['D',4,1]).root_lattice().null_root()
sage: RootSystem(['F',4,1]).root_lattice().null_root()
```

plot (roots='simple', coroots=False, reflection_hyperplanes='simple', fundamental_weights=None, fundamental_chamber=None, alcoves=None, alcove_labels=False, alcove_walk=None, **options)

Return a picture of this root lattice realization.

INPUT:

- **roots** – which roots to display, if any. Can be one of the following:
  - "simple" – The simple roots (the default)
  - "classical" – Not yet implemented
  - "all" – Only works in the finite case
  - A list or tuple of roots
  - False

- **coroots** – which coroots to display, if any. Can be one of the following:
  - "simple" – The simple coroots (the default)
  - "classical" – Not yet implemented
  - "all" – Only works in the finite case
  - A list or tuple of coroots
  - False

- **fundamental_weights** – a boolean or None (default: None) whether to display the fundamental weights. If None, the fundamental weights are drawn if available.

- **reflection_hyperplanes** – which reflection hyperplanes to display, if any. Can be one of the following:
  - "simple" – The simple roots
  - "classical" – Not yet implemented
  - "all" – Only works in the finite case
  - A list or tuple of roots
  - False (the default)

- **fundamental_chamber** – whether and how to draw the fundamental chamber. Can be one of the following:
  - A boolean – Set to True to draw the fundamental chamber
  - "classical" – Draw the classical fundamental chamber
  - None – (the default) The fundamental chamber is drawn except in the root lattice where this is not yet implemented. For affine types the classical fundamental chamber is drawn instead.

- **alcoves** – one of the following (default: True):
– A boolean – Whether to display the alcoves
– A list of alcoves – The alcoves to be drawn. Each alcove is specified by the coordinates of its center in the root lattice (affine type only). Otherwise the alcoves that intersect the bounding box are drawn.
• alcove_labels – one of the following (default: False):
  – A boolean – Whether to display the elements of the Weyl group indexing the alcoves. This currently requires to also set the alcoves option.
  – A number $l$ – The label is drawn at level $l$ (affine type only), which only makes sense if affine is False.
• bounding_box – a rational number or a list of pairs thereof (default: 3)
  Specifies a bounding box, in the coordinate system for this plot, in which to plot alcoves and other infinite objects. If the bounding box is a number $a$, then the bounding box is of the form $[-a, a]$ in all directions. Beware that there can be some border effects and the returned graphic is not necessarily strictly contained in the bounding box.
• alcove_walk – an alcove walk or None (default: None)
  The alcove walk is described by a list (or iterable) of vertices of the Dynkin diagram which specifies which wall is crossed at each step, starting from the fundamental alcove.
• projection – one of the following (default: True):
  – True – The default projection for the root lattice realization is used.
  – False – No projection is used.
  – barycentric – A barycentric projection is used.
  – A function – If a function is specified, it should implement a linear (or affine) map taking as input an element of this root lattice realization and returning its desired coordinates in the plot, as a vector with rational coordinates.
• color – a function mapping vertices of the Dynkin diagram to colors (default: "black" for 0, "blue" for 1, "red" for 2, "green" for 3)
  This is used to set the color for the simple roots, fundamental weights, reflection hyperplanes, alcove facets, etc. If the color is None, the object is not drawn.
• labels – a boolean (default: True) whether to display labels on the simple roots, fundamental weights, etc.

EXAMPLES:

sage: L = RootSystem(["A",2,1]).ambient_space().plot()  # long time

See also:

• plot_parse_options()
• plot_roots(), plot_coroots()
• plot_fundamental_weights()
• plot_fundamental_chamber()
• plot_reflection_hyperplane()
• plot_alcoves()
• plot_alcove_walk()
• plot_ls_paths()
• plot_mv_polytope()
• plot_crystal()

plot_alcove_walk (word, start=None, foldings=None, color=’orange’, **options)
  Plot an alcove walk.

INPUT:

• word – a list of elements of the index set
• foldings – a list of booleans or None (default: None)
• start – an element of this space (default: None for $\rho$)
• **options** – plotting options

See also:
• *plot()* for a description of the plotting options
• *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

An alcove walk of type $A_2^{(1)}$:

```python
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: w1 = [0,2,1,2,0,2,1,0,2,1,2,1,2,0,2,0,1,2,0]
sage: p = L.plot_alcoves(bounding_box=5)  # long time (5s)
sage: p += L.plot_alcove_walk(w1)  # long time
sage: p  # long time
Graphics object consisting of 375 graphics primitives
```

The same plot with another alcove walk:

```python
sage: w2 = [2,1,2,0,2,0,2,1,2,0,1,2,1,2,0,2,0,1,2,0,2]
sage: p += L.plot_alcove_walk(w2, color="orange")  # long time
```

And another with some foldings:

```python
sage: pic = L.plot_alcoves(bounding_box=3)  # long time
sage: pic += L.plot_alcove_walk([0,1,2,0,2,0,1,2,0,1],
                                             # long time (3s)
                                   foldings=[False, False, True, False, False, False, True, False],
                                   color="green"); pic
```

`plot_alcoves(alcoves=True, alcove_labels=False, wireframe=False, **options)`

Plot the alcoves and optionally their labels.

**INPUT:**
• alcoves – a list of alcoves or True (default: True)
• alcove_labels – a boolean or a number specifying at which level to put the label (default: False)
• **options** – Plotting options

See also:
• *plot()* for a description of the plotting options
• *Tutorial: visualizing root systems* for a tutorial on root system plotting, and in particular how the alcoves can be specified.

**EXAMPLES:**

2D plots:

```python
sage: RootSystem(["B",2,1]).ambient_space().plot_alcoves()
˓→  # long time (3s)
Graphics object consisting of 228 graphics primitives
```

3D plots:

```python
sage: RootSystem(["A",2,1]).weight_space().plot_alcoves(affine=False)
˓→  # long time (3s)
Graphics3d Object
```

(continues on next page)
sage: RootSystem(["G",2,1]).ambient_space().plot_alcoves(affine=False, level=1) # long time (3s)
Graphics3d Object

Here we plot a single alcove:

sage: L = RootSystem(["A",3,1]).ambient_space()
sage: W = L.weyl_group()
sage: L.plot(alcoves=[W.one()], reflection_hyperplanes=False, bounding_box=2)
Graphics3d Object

plot_bounding_box(**options)
Plot the bounding box.

INPUT:
• **options – Plotting options
  This is mostly for testing purposes.

See also:
• plot() for a description of the plotting options
• Tutorial: visualizing root systems for a tutorial on root system plotting

EXAMPLES:

sage: L = RootSystem(["A",2,1]).ambient_space()
sage: L.plot_bounding_box()
Graphics object consisting of 1 graphics primitive

plot_coroots(collection='simple', **options)
Plot the (simple/classical) coroots of this root lattice.

INPUT:
• collection – which coroots to display. Can be one of the following:
  – "simple" (the default)
  – "classical"
  – "all"
• **options – Plotting options

See also:
• plot() for a description of the plotting options
• Tutorial: visualizing root systems for a tutorial on root system plotting

EXAMPLES:

sage: RootSystem(["B",3]).ambient_space().plot_coroots()
Graphics3d Object

plot_crystal(crystal, plot_labels=True, label_color='black', edge_labels=False, circle_size=0.06, circle_thickness=1.6, **options)
Plot a finite crystal.

INPUT:
• crystal – the finite crystal to plot
• plot_labels – (default: True) can be one of the following:
  – True - use the latex labels
  – 'circles' - use circles for multiplicity up to 4; if the multiplicity is larger, then it uses the multiplicity
- 'multiplicities' - use the multiplicities
  * label_color - (default: 'black') the color of the labels
  * edge_labels - (default: False) if True, then draw in the edge label
  * circle_size - (default: 0.06) the size of the circles
  * circle_thickness - (default: 1.6) the thinkness of the extra rings of circles
  * **options - plotting options

See also:
- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

**EXAMPLES:**

```python
sage: L = RootSystem(['A',2]).ambient_space()
sage: C = crystals.Tableaux(['A',2], shape=[2,1])
sage: L.plot_crystal(C, plot_labels='multiplicities')
Graphics object consisting of 15 graphics primitives
sage: C = crystals.Tableaux(['A',2], shape=[8,4])
sage: p = L.plot_crystal(C, plot_labels='circles')
sage: p.show(figsize=15)
```

A 3-dimensional example:

```python
sage: L = RootSystem(['B',3]).ambient_space()
sage: C = crystals.Tableaux(['B',2], shape=[2,1])
sage: L.plot_crystal(C, plot_labels='circles', edge_labels=True) # long
˓→ time
Graphics3d Object
```

**plot_fundamental_chamber** *(style='normal', **options)*

Plot the (classical) fundamental chamber.

**INPUT:**
- style - "normal" or "classical" (default: "normal")
- **options - Plotting options

See also:
- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

**EXAMPLES:**

2D plots:

```python
sage: RootSystem(['B',2]).ambient_space().plot_fundamental_chamber()
Graphics object consisting of 1 graphics primitive
sage: RootSystem(['B',2,1]).ambient_space().plot_fundamental_chamber()
Graphics object consisting of 1 graphics primitive
sage: RootSystem(['B',2,1]).ambient_space().plot_fundamental_chamber(style='classical')
Graphics object consisting of 1 graphics primitive
```

3D plots:

```python
sage: RootSystem(['A',3,1]).weight_space().plot_fundamental_chamber()
Graphics3d Object
sage: RootSystem(['B',3,1]).ambient_space().plot_fundamental_chamber()
Graphics3d Object
```

This feature is currently not available in the root lattice/space:
sage: list(RootSystem(["A",2]).root_lattice().plot_fundamental_chamber())
Traceback (most recent call last):
...
TypeError: classical fundamental chamber not yet available in the root_lattice

plot_fundamental_weights(**options)
Plot the fundamental weights of this root lattice.

INPUT:
• **options – Plotting options

See also:
• plot() for a description of the plotting options
• Tutorial: visualizing root systems for a tutorial on root system plotting

EXAMPLES:
sage: RootSystem(["B",3]).ambient_space().plot_fundamental_weights()
Graphics3d Object

plot_hedron(**options)
Plot the polyhedron whose vertices are given by the orbit of $\rho$.

In type $A$, this is the usual permutohedron.

See also:
• plot() for a description of the plotting options
• Tutorial: visualizing root systems for a tutorial on root system plotting

EXAMPLES:
sage: RootSystem(["A",2]).ambient_space().plot_hedron()
Graphics object consisting of 8 graphics primitives
sage: RootSystem(["A",3]).ambient_space().plot_hedron()
Graphics3d Object
sage: RootSystem(["B",3]).ambient_space().plot_hedron()
Graphics3d Object
sage: RootSystem(["C",3]).ambient_space().plot_hedron()
Graphics3d Object
sage: RootSystem(["D",3]).ambient_space().plot_hedron()
Graphics3d Object
sage: RootSystem(["F",4]).ambient_space().plot_hedron()  # long time
Graphics3d Object

Surprise: polyhedra of large dimension know how to project themselves nicely:
sage: RootSystem(["F",4]).ambient_space().plot_hedron()

plot_ls_paths(paths, plot_labels=None, colored_labels=True, **options)
Plot LS paths.

INPUT:
• paths – a finite crystal or list of LS paths
• plot_labels – (default: None) the distance to plot the LS labels from the endpoint of the path; set to None to not display the labels
• colored_labels – (default: True) if True, then color the labels the same color as the LS path
• **options – plotting options

See also:
• \texttt{plot()} for a description of the plotting options
• \textit{Tutorial: visualizing root systems} for a tutorial on root system plotting

\textbf{EXAMPLES:}

\begin{verbatim}
sage: B = crystals.LSPaths(['A',2], [1,1])
sage: L = RootSystem(['A',2]).ambient_space()
sage: L.plot_fundamental_weights() + L.plot_ls_paths(B)
Graphics object consisting of 14 graphics primitives
\end{verbatim}

This also works in 3 dimensions:

\begin{verbatim}
sage: B = crystals.LSPaths(['B',3], [2,0,0])
sage: L = RootSystem(['B',3]).ambient_space()
sage: L.plot_ls_paths(B)
Graphics3d Object
\end{verbatim}

\texttt{plot\_mv\_polytope}(\texttt{mv\_polytope}, \texttt{mark\_endpoints=\texttt{True}, circle\_size=0.06, circle\_thickness=1.6, wireframe='blue', fill='green', alpha=1, **options})

Plot an MV polytope.

\textbf{INPUT:}

• \texttt{mv\_polytope} – an MV polytope
• \texttt{mark\_endpoints} – (default: \texttt{True}) mark the endpoints of the MV polytope
• \texttt{circle\_size} – (default: 0.06) the size of the circles
• \texttt{circle\_thickness} – (default: 1.6) the thinkness of the extra rings of circles
• \texttt{wireframe} – (default: 'blue') color to draw the wireframe of the polytope with
• \texttt{fill} – (default: 'green') color to fill the polytope with
• \texttt{alpha} – (default: 1) the alpha value (opacity) of the fill
• \texttt{**options} – plotting options

\textbf{See also:}

• \texttt{plot()} for a description of the plotting options
• \textit{Tutorial: visualizing root systems} for a tutorial on root system plotting

\textbf{EXAMPLES:}

\begin{verbatim}
sage: B = crystals.infinity.MVPolytopes(['C',2])
sage: L = RootSystem(['C',2]).ambient_space()
sage: p = B.highest_weight_vector().f_string([1,2,1,2])
sage: L.plot_fundamental_weights() + L.plot_mv_polytope(p)
Graphics object consisting of 14 graphics primitives
\end{verbatim}

This also works in 3 dimensions:

\begin{verbatim}
sage: B = crystals.infinity.MVPolytopes(['A',3])
sage: L = RootSystem(['A',3]).ambient_space()
sage: p = B.highest_weight_vector().f_string([2,1,3,2])
sage: L.plot_mv_polytope(p)
Graphics3d Object
\end{verbatim}

\texttt{plot\_parse\_options}(**\texttt{args})

Return an option object to be used for root system plotting.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: L = RootSystem(['A',2,1]).ambient_space()
sage: options = L.plot_parse_options()
\end{verbatim}

```python
sage: options
<sage.combinat.root_system.plot.PlotOptions object at ...>
```

See also:

- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

**plot_reflection_hyperplanes** *(collection='simple', **options)*

Plot the simple reflection hyperplanes.

**INPUT:**

- `collection` – which reflection hyperplanes to display. Can be one of the following:
  - "simple" (the default)
  - "classical"
  - "all"
- `**options` – Plotting options

See also:

- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

**EXAMPLES:**

```python
sage: RootSystem(['A',2,1]).ambient_space().plot_reflection_hyperplanes()  # Graphics object consisting of 6 graphics primitives
sage: RootSystem(['G',2,1]).ambient_space().plot_reflection_hyperplanes()  # Graphics object consisting of 6 graphics primitives
sage: RootSystem(['A',3]).weight_space().plot_reflection_hyperplanes()    # Graphics3d Object
sage: RootSystem(['B',3]).ambient_space().plot_reflection_hyperplanes()   # Graphics3d Object
sage: RootSystem(['A',3,1]).weight_space().plot_reflection_hyperplanes()  # Graphics3d Object
sage: RootSystem(['B',3,1]).ambient_space().plot_reflection_hyperplanes() # Graphics3d Object
sage: RootSystem(['A',2,1]).weight_space().plot_reflection_hyperplanes_  # Graphics3d Object
˓→hyperplanes(affine=False, level=1)
sage: RootSystem(['A',2]).root_lattice().plot_reflection_hyperplanes()   # Graphics object consisting of 4 graphics primitives
```

**Todo:** Provide an option for transparency?

**plot_roots** *(collection='simple', **options)*

Plot the (simple/classical) roots of this root lattice.

**INPUT:**

- `collection` – which roots to display can be one of the following:
  - "simple" (the default)
  - "classical"
  - "all"
- `**options` – Plotting options

See also:

- `plot()` for a description of the plotting options
• Tutorial: visualizing root systems for a tutorial on root system plotting

EXAMPLES:

```
sage: RootSystem(“B”, 3).ambient_space().plot_roots()
Graphics3d Object
sage: RootSystem(“B”, 3).ambient_space().plot_roots(“all”)
Graphics3d Object
```

**positive_imaginary_roots()**

Return the positive imaginary roots of self.

EXAMPLES:

```
sage: L = RootSystem(‘A’, 3).root_lattice()
sage: L.positive_imaginary_roots()

sage: L = RootSystem(‘A’, 3, 1).root_lattice()
sage: PIR = L.positive_imaginary_roots(); PIR
Positive imaginary roots of type [‘A’, 3, 1]
sage: [PIR.unrank(i) for i in range(5)]
  3*alpha[0] + 3*alpha[1] + 3*alpha[2] + 3*alpha[3],
```

**positive_real_roots()**

Return the positive real roots of self.

EXAMPLES:

```
sage: L = RootSystem(‘A’, 3).root_lattice()
sage: sorted(L.positive_real_roots())
sage: L = RootSystem(‘A’, 3, 1).root_lattice()
sage: PRR = L.positive_real_roots(); PRR
Positive real roots of type [‘A’, 3, 1]
sage: [PRR.unrank(i) for i in range(10)]
[alpha[1],
 alpha[2],
 alpha[3],
 alpha[1] + alpha[2],
 alpha[2] + alpha[3],
```

```
sage: Q = RootSystem(‘A’, 4, 2).root_lattice()
sage: PR = Q.positive_roots()
sage: [PR.unrank(i) for i in range(5)]
[alpha[1],
 alpha[2],
 alpha[1] + alpha[2],
```

(continues on next page)
positive_roots \,(index\_set=\text{None})

Return the positive roots of self.

If \text{index\_set} is not \text{None}, returns the positive roots of the parabolic subsystem with simple roots in \text{index\_set}.

Algorithm for finite type: generate them from the simple roots by applying successive reflections toward the positive chamber.

EXAMPLES:

\begin{verbatim}
sage: L = RootSystem(['A',3]).root_lattice()
sage: sorted(L.positive_roots())
[alpha[1], alpha[1] + alpha[2],
 alpha[2] + alpha[3], alpha[3]]
sage: sorted(L.positive_roots((1,2))
[alpha[1], alpha[1] + alpha[2], alpha[2]]
sage: sorted(L.positive_roots(()))
[]
sage: L = RootSystem(['A',3,1]).root_lattice()
sage: PR = L.positive_roots(); PR
Disjoint union of Family (Positive real roots of type ['A', 3, 1],
 Positive imaginary roots of type ['A', 3, 1])
sage: [PR.unrank(i) for i in range(10)]
[alpha[1],
 alpha[2],
 alpha[3],
 alpha[1] + alpha[2],
 alpha[2] + alpha[3],
\end{verbatim}

positive_roots_by_height \,(increasing=True)

Returns a list of positive roots in increasing order by height.

If \text{increasing} is False, returns them in decreasing order.

\begin{verbatim}
Warning: Raise an error if the Cartan type is not finite.
\end{verbatim}

EXAMPLES:
positive_roots_nonparabolic(index_set=None)

Returns the set of positive roots outside the parabolic subsystem with Dynkin node set index_set.

INPUT:

- index_set – (default: None) the Dynkin node set of the parabolic subsystem. It should be a tuple. The default value implies the entire Dynkin node set

EXAMPLES:

sage: lattice = RootSystem(['A', 3]).root_lattice()
sage: sorted(lattice.positive_roots_nonparabolic((1, 3)), key=str)
sage: sorted(lattice.positive_roots_nonparabolic((2, 3)), key=str)
sage: lattice.positive_roots_nonparabolic()
[]
sage: lattice.positive_roots_nonparabolic((1, 2, 3))
[]

Warning: This returns an error if the Cartan type is not finite.

positive_roots_nonparabolic_sum(index_set=None)

Returns the sum of positive roots outside the parabolic subsystem with Dynkin node set index_set.

INPUT:

- index_set – (default: None) the Dynkin node set of the parabolic subsystem. It should be a tuple. The default value implies the entire Dynkin node set

EXAMPLES:

sage: lattice = RootSystem(['A', 3]).root_lattice()
sage: lattice.positive_roots_nonparabolic_sum((1, 3))
sage: lattice.positive_roots_nonparabolic_sum((2, 3))
sage: lattice.positive_roots_nonparabolic_sum((1, 2, 3))
0
sage: lattice.positive_roots_nonparabolic_sum((1, 2, 3))
0
Warning: This returns an error if the Cartan type is not finite.

positive_roots_parabolic(index_set=None)

Return the set of positive roots for the parabolic subsystem with Dynkin node set index_set.

INPUT:

• index_set – (default: None) the Dynkin node set of the parabolic subsystem. It should be a tuple. The default value implies the entire Dynkin node set

EXAMPLES:

```
sage: lattice = RootSystem(['A',3]).root_lattice()
sage: sorted(lattice.positive_roots_parabolic((1,3)), key=str)
[alpha[1], alpha[3]]
sage: sorted(lattice.positive_roots_parabolic((2,3)), key=str)
[alpha[2], alpha[2] + alpha[3], alpha[3]]
sage: sorted(lattice.positive_roots_parabolic(), key=str)
˓
```

Warning: This returns an error if the Cartan type is not finite.

projection(root, coroot=None, to_negative=True)

Returns the projection along the root, and across the hyperplane define by coroot, as a function \( \pi \) from self to self. \( \pi \) is a half-linear map which stabilizes the negative half space, and acts by reflection on the positive half space.

If to_negative is False, then this project onto the positive half space instead.

EXAMPLES:

```
sage: space = RootSystem(['A',2]).weight_lattice()
sage: x=space.simple_roots()[1]
sage: y=space.simple_coroots()[1]
sage: pi = space.projection(x,y)
sage: x
sage: pi(x)
sage: pi(-x)
sage: pi = space.projection(x,y,False)
sage: pi(-x)
```

reflection(root, coroot=None)

Returns the reflection along the root, and across the hyperplane define by coroot, as a function from self to self.

EXAMPLES:

```
sage: space = RootSystem(['A',2]).weight_lattice()
sage: x=space.simple_roots()[1]
sage: y=space.simple_coroots()[1]
sage: s = space.reflection(x,y)
sage: x
(continues on next page)
root_poset \(\text{restricted} = \text{False}, \text{facade} = \text{False}\)

Returns the (restricted) root poset associated to \text{self}.

The elements are given by the positive roots (resp. non-simple, positive roots), and \(\alpha \leq \beta\) iff \(\beta - \alpha\) is a non-negative linear combination of simple roots.

**INPUT:**

- \text{restricted} – (default:False) if True, only non-simple roots are considered.
- \text{facade} – (default:False) passes facade option to the poset generator.

**EXAMPLES:**

```python
sage: Phi = RootSystem(['A',1]).root_poset(); Phi
Finite poset containing 1 elements
sage: Phi.cover_relations()
[]
sage: Phi = RootSystem(['A',2]).root_poset(); Phi
Finite poset containing 3 elements
sage: sorted(Phi.cover_relations(), key=str)
[[alpha[1], alpha[1] + alpha[2]]]
sage: Phi = RootSystem(['A',3]).root_poset(restricted=True); Phi
Finite poset containing 3 elements
sage: sorted(Phi.cover_relations(), key=str)
sage: Phi = RootSystem(['B',2]).root_poset(); Phi
Finite poset containing 4 elements
sage: sorted(Phi.cover_relations(), key=str)
```

roots()

Return the roots of \text{self}.

**EXAMPLES:**

```python
sage: RootSystem(['A',2]).ambient_lattice().roots()
[(1, -1, 0), (1, 0, -1), (0, 1, -1), (-1, 1, 0), (-1, 0, 1), (0, -1, 1)]
```

This matches with [Wikipedia article Root systems](https://en.wikipedia.org/wiki/Root_system):

```python
sage: for T in CartanType.samples(finite = True, crystallographic = True):
    ...
        print("$s \; \#s \; \#s\% (T, len(RootSystem(T).root_lattice().roots()),
        "len(RootSystem(T).weight_lattice().roots()))))
[A', 1] 2 2
[A', 5] 30 30
['B', 1] 2 2
```

(continues on next page)
Todo: The result should be an enumerated set, and handle infinite root systems.

\[ s() \]

Return the family \((s_i)_{i \in I}\) of the simple reflections of this root system.

**EXAMPLES:**

```
sage: r = RootSystem(['A', 2]).root_lattice()
sage: s = r.simple_reflections()
sage: s[1]( r.simple_root(1) )
-alpha[1]
```

\[ \text{short_roots()} \]

Return a list of the short roots of self.

**EXAMPLES:**

```
sage: L = RootSystem(['B',3]).root_lattice()
sage: sorted(L.short_roots())
 -alpha[2] - alpha[3],  
 alpha[2] + alpha[3],  
 -alpha[3],  
 alpha[3]]
```

\[ \text{simple_coroot}(i) \]

Returns the \(i\)th simple coroot.

**EXAMPLES:**

```
sage: RootSystem(['A',2]).root_lattice().simple_coroot(1)
alphacheck[1]
```

\[ \text{simple_coroots()} \]

Returns the family \((\alpha_i^\vee)_{i \in I}\) of the simple coroots.

**EXAMPLES:**

```
sage: alphacheck = RootSystem(['A',3]).root_lattice().simple_coroots()
sage: [alphacheck[i] for i in [1, 2, 3]]
[alphacheck[1], alphacheck[2], alphacheck[3]]
```
**simple_projection**(i, to_negative=True)

Returns the projection along the \(i\)th simple root, and across the hyperplane define by the \(i\)th simple coroot, as a function from self to self.

**INPUT:**

- \(i\) - \(i\) is in self’s index set

**EXAMPLES:**

```python
sage: space = RootSystem(['A',2]).weight_lattice()
sage: x = space.simple_roots()[1]
sage: pi = space.simple_projection(1)
sage: x
sage: pi(x)
sage: pi(-x)
sage: pi = space.simple_projection(1,False)
sage: pi(-x)
```

**simple_projections**(to_negative=True)

Returns the family \((s_i)_{i \in I}\) of the simple projections of this root system

**EXAMPLES:**

```python
sage: space = RootSystem(['A',2]).weight_lattice()
sage: pi = space.simple_projections()
sage: x = space.simple_roots()
sage: pi[1](x[2])
```

**simple_reflection**(i)

Returns the \(i\)th simple reflection, as a function from self to self.

**INPUT:**

- \(i\) - \(i\) is in self’s index set

**EXAMPLES:**

```python
sage: space = RootSystem(['A',2]).ambient_lattice()
sage: s = space.simple_reflection(1)
sage: x = space.simple_roots()[1]
sage: x
(1, -1, 0)
sage: s(x)
(-1, 1, 0)
```

**simple_reflections**()

Return the family \((s_i)_{i \in I}\) of the simple reflections of this root system.

**EXAMPLES:**

```python
sage: r = RootSystem(['A', 2]).root_lattice()
sage: s = r.simple_reflections()
sage: s[1]( r.simple_root(1) )
-alpha[1]
```

**simple_root**(i)

Returns the \(i\)th simple root.

---

5.1. Comprehensive Module list 2317
This should be overridden by any subclass, and typically implemented as a cached method for efficiency.

EXAMPLES:

```
sage: r = RootSystem(['A',3]).root_lattice()
sage: r.simple_root(1)
alpha[1]
```

**simple_roots()**

Returns the family \((\alpha_i)_{i \in I}\) of the simple roots.

EXAMPLES:

```
sage: alpha = RootSystem(['A',3]).root_lattice().simple_roots()
sage: [alpha[i] for i in [1,2,3]]
[alpha[1], alpha[2], alpha[3]]
```

**simple_roots_tilde()**

Return the family \((\tilde{\alpha}_i)_{i \in I}\) of the simple roots.

INPUT:

- `self` – an affine root lattice realization

The \(\tilde{\alpha}_i\) give the embedding of the root lattice of the other affinization of the same classical root lattice into this root lattice (space?).

This uses the fact that \(\alpha_i = \tilde{\alpha}_i\) for \(i\) not a special node, and that

\[
\delta = \sum a_i \alpha_i = \sum b_i \tilde{\alpha}_i
\]

EXAMPLES:

In simply laced cases, this is boring:

```
sage: RootSystem(['A',3, 1]).root_lattice().simple_roots_tilde()
Finite family {0: alpha[0], 1: alpha[1], 2: alpha[2], 3: alpha[3]}
```

This was checked by hand:

```
sage: RootSystem(['C',2,1]).coroot_lattice().simple_roots_tilde()
Finite family {0: alphacheck[0] - alphacheck[2], 1: alphacheck[1], 2: alphacheck[2]}
sage: RootSystem(['B',2,1]).coroot_lattice().simple_roots_tilde()
Finite family {0: alphacheck[0] - alphacheck[1], 1: alphacheck[1], 2: alphacheck[2]}
```

What about type BC?

**some_elements()**

Return some elements of this root lattice realization

EXAMPLES:

```
sage: L = RootSystem(['A',2]).weight_lattice()
sage: L.some_elements()
sage: L = RootSystem(['A',2]).root_lattice()
sage: L.some_elements()
```
The \( \tau_\epsilon \) operator on almost positive roots

Given a subset \( J \) of non adjacent vertices of the Dynkin diagram, this constructs the operator on the almost positive roots which fixes the negative simple roots \( \alpha_i \) for \( i \) not in \( J \), and acts otherwise by:

\[
\tau_+(\beta) = \left( \prod_{i \in J} s_i \right)(\beta)
\]

See Equation (1.2) of [CFZ2002].

**EXAMPLES:**

```python
sage: L = RootSystem(['A',4]).root_lattice()
sage: tau = L.tau_epsilon_operator_on_almost_positive_roots([1,3])
sage: alpha = L.simple_roots()
```

The action on a negative simple root not in \( J \):

```python
sage: tau(-alpha[2])
-\alpha[2]
```

The action on a negative simple root in \( J \):

```python
sage: tau(-alpha[1])
\alpha[1]
```

The action on all almost positive roots:

```python
sage: for root in L.almost_positive_roots():
    ...:     print('tau({:<41}) = {}'.format(str(root), tau(root)))
```

```
tau((-1, 1, 0) ) = (1, -1, 0)
tau((1, 0, 0) ) = (0, 1, 0)
tau((1, -1, 0) ) = (-1, 1, 0)
tau((1, 1, 0) ) = (1, 1, 0)
```

This method works on any root lattice realization:

```python
sage: L = RootSystem(['B',3]).ambient_space()
sage: tau = L.tau_epsilon_operator_on_almost_positive_roots([1,3])
sage: for root in L.almost_positive_roots():
    ...:     print('tau({:<41}) = {}'.format(str(root), tau(root)))
```

```
tau((-1, 1, 0) ) = (1, -1, 0)
tau((1, 0, 0) ) = (0, 1, 0)
tau((1, -1, 0) ) = (-1, 1, 0)
tau((1, 1, 0) ) = (1, 1, 0)
```
τ((1, 0, -1)) = (0, 1, 1)  
τ((1, 0, 1)) = (0, 1, -1)  
τ((0, -1, 1)) = (0, -1, 1)  
τ((0, 1, 0)) = (1, 0, 0)  
τ((0, 1, -1)) = (1, 0, 1)  
τ((0, 1, 1)) = (1, 0, -1)  
τ((0, 0, -1)) = (0, 0, 1)  
τ((0, 0, 1)) = (0, 0, -1)

See also:

\(\tau_{\pm}()\)

\(\tau_{\pm}()\)

Returns the \(\tau^{+}\) and \(\tau^{-}\) piecewise linear operators on \(\text{self}\)

Those operators are induced by the bipartition \(\{L, R\}\) of the simple roots of \(\text{self}\), and stabilize the almost positive roots. Namely, \(\tau^{+}\) fixes the negative simple roots \(\alpha_i\) for \(i\) in \(R\), and acts otherwise by:

\[
\tau^{+}(\beta) = \left( \prod_{i \in L} s_i \right)(\beta)
\]

\(\tau^{-}\) acts analogously, with \(L\) and \(R\) interchanged.

Those operators are used to construct the associahedron, a polytopal realization of the cluster complex (see Associahedron).

See also:

\(\tau_{\varepsilon}()\)

\(\tau_{\varepsilon}()\)

EXAMPLES:

We explore the example of [CFZ2002] Eq.(1.3):

```
sage: S = RootSystem(['A',2]).root_lattice()
sage: taup, taum = S.tau_plus_minus()
sage: for beta in S.almost_positive_roots(): print("{} , {} , {}".format(beta, taup(beta), taum(beta)))
```

to_ambient_space_morphism()
to_ambient_space_morphism()

Return the morphism to the ambient space.

EXAMPLES:

```
sage: CartanType(['B',2]).root_system().root_lattice().to_ambient_space_morphism()
Generic morphism:
From: Root lattice of the Root system of type ['B', 2]
To:    Ambient space of the Root system of type ['B', 2]
sage: CartanType(['B',2]).root_system().coroot_lattice().to_ambient_space_morphism()
Generic morphism:
From: Coroot lattice of the Root system of type ['B', 2]
To:    Ambient space of the Root system of type ['B', 2]
```

(continues on next page)
sage: CartanType(['B',2]).root_system().weight_lattice().to_ambient_space_.morphism()
Generic morphism:
From: Weight lattice of the Root system of type ['B', 2]
To: Ambient space of the Root system of type ['B', 2]

weyl_group (prefix=None)
Returns the Weyl group associated to self.

EXAMPLES:

sage: RootSystem(['F',4]).ambient_space().weyl_group()
Weyl Group of type ['F', 4] (as a matrix group acting on the ambient space)

sage: RootSystem(['F',4]).root_space().weyl_group()
Weyl Group of type ['F', 4] (as a matrix group acting on the root space)

super_categories()
EXAMPLES:

sage: from sage.combinat.root_system.root_lattice_realizations import RootLatticeRealizations
sage: RootLatticeRealizations(QQ).super_categories()
[Category of vector spaces with basis over Rational Field]

5.1.241 Root lattices and root spaces

class sage.combinat.root_system.root_space.RootSpace (root_system, base_ring)

The root space of a root system over a given base ring

INPUT:

• root_system - a root system

• base_ring: a ring $\mathbb{R}$

The root space (or lattice if base_ring is $\mathbb{Z}$) of a root system is the formal free module $\bigoplus_i R\alpha_i$ generated by the simple roots $(\alpha_i)_{i \in I}$ of the root system.

This class is also used for coroot spaces (or lattices).

See also:

• RootSystem()

• RootSystem.root_lattice() and RootSystem.root_space()

• RootLatticeRealizations()

Todo: standardize the variable used for the root space in the examples (P?)

Element

alias of RootSpaceElement

simple_root ()
Return the basis element indexed by $i$. 

5.1. Comprehensive Module list
INPUT:

- \( i \) – an element of the index set

EXAMPLES:

```python
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.monomial('a')
B['a']
```

\( F.\text{monomial} \) is in fact (almost) a map:

```python
sage: F.monomial
Term map from {'a', 'b', 'c'} to Free module generated by {'a', 'b', 'c'} over Rational Field
```

\texttt{to\_ambient\_space\_morphism}()

The morphism from \texttt{self} to its associated ambient space.

EXAMPLES:

```python
sage: CartanType(['A',2]).root_system().root_lattice().to_ambient_space_morphism()
Generic morphism:
From: Root lattice of the Root system of type ['A', 2]
To: Ambient space of the Root system of type ['A', 2]
```

\texttt{to\_coroot\_space\_morphism}()

Returns the \( \nu \) map to the coroot space over the same base ring, using the symmetrizer of the Cartan matrix.

It does not map the root lattice to the coroot lattice, but has the property that any root is mapped to some scalar multiple of its associated coroot.

EXAMPLES:

```python
sage: R = RootSystem(['A',3]).root_space()
sage: alpha = R.simple_roots()
sage: f = R.to_coroot_space_morphism()
sage: f(alpha[1])
alphacheck[1]
sage: f(alpha[1]+alpha[2])
sage: R = RootSystem(['A',3]).root_lattice()
sage: alpha = R.simple_roots()
sage: f = R.to_coroot_space_morphism()
sage: f(alpha[1])
alphacheck[1]
sage: f(alpha[1]+alpha[2])
sage: S = RootSystem(['G',2]).root_space()
sage: alpha = S.simple_roots()
sage: f = S.to_coroot_space_morphism()
sage: f(alpha[1])
alphacheck[1]
sage: f(alpha[1]+alpha[2])
```
class sage.combinat.root_system.root_space.RootSpaceElement
    Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

associated_coroot()
    Returns the coroot associated to this root

OUTPUT:
    An element of the coroot space over the same base ring; in particular the result is in the coroot lattice
    whenever self is in the root lattice.

EXAMPLES:

    sage: L = RootSystem(['B', 3]).root_space()
    sage: alpha = L.simple_roots()
    sage: alpha[1].associated_coroot()  # alpha_1
    alphacheck[1]
    sage: alpha[1].associated_coroot().parent()  # Parent is coroot space
    Coroot space over the Rational Field of the Root system of type ['B', 3]
    sage: L.highest_root()
    sage: L.highest_root().associated_coroot()  # Associated coroot of highest root
    sage: alpha = RootSystem(['B', 3]).root_lattice().simple_roots()
    sage: alpha[1].associated_coroot()  # alpha_1
    alphacheck[1]
    sage: alpha[1].associated_coroot().parent()  # Parent is coroot lattice
    Coroot lattice of the Root system of type ['B', 3]

is_positive_root()
    Checks whether an element in the root space lies in the nonnegative cone spanned by the simple roots.

EXAMPLES:

    sage: R=RootSystem(['A',3,1]).root_space()
    sage: B=R.basis()
    sage: w=B[0]+B[3]
    sage: w.is_positive_root()  # w = positive root + negative root
    True
    sage: w.is_positive_root()  # w = negative root - positive root
    False

max_coroot_le()
    Returns the highest positive coroot whose associated root is less than or equal to self.

INPUT:
    • self – an element of the nonnegative integer span of simple roots.

Returns None for the zero element.

Really self is an element of a coroot lattice and this method returns the highest root whose associated coroot is <= self.

Warning: This implementation only handles finite Cartan types

EXAMPLES:
sage: root_lattice = RootSystem(['C',2]).root_lattice()
sage: root_lattice.from_vector(vector([1,1])).max_coroot_le()
sage: root_lattice.from_vector(vector([2,1])).max_coroot_le()
sage: root_lattice = RootSystem(['B',2]).root_lattice()
sage: root_lattice.from_vector(vector([1,1])).max_coroot_le()
sage: root_lattice.from_vector(vector([1,2])).max_coroot_le()
sage: root_lattice.zero().max_coroot_le()
is None
True
sage: root_lattice.from_vector(vector([-1,0])).max_coroot_le()
Traceback (most recent call last):
...
ValueError: -alpha[1] is not in the positive cone of roots
sage: root_lattice = RootSystem(['A',2,1]).root_lattice()
sage: root_lattice.simple_root(1).max_coroot_le()
Traceback (most recent call last):
...
NotImplementedError: Only implemented for finite Cartan type

max_quantum_element()
Returns a reduced word for the longest element of the Weyl group whose shortest path in the quantum Bruhat graph to the identity, has sum of quantum coroots at most self.

INPUT:

• self – an element of the nonnegative integer span of simple roots.

Really self is an element of a coroot lattice.

Warning: This implementation only handles finite Cartan types

EXAMPLES:

sage: Qvee = RootSystem(['C',2]).coroot_lattice()
sage: Qvee.from_vector(vector([1,2])).max_quantum_element()
[2, 1, 2, 1]
sage: Qvee.from_vector(vector([1,1])).max_quantum_element()
[1, 2, 1]
sage: Qvee.from_vector(vector([0,2])).max_quantum_element()
[2]

quantum_root()
Returns True if self is a quantum root and False otherwise.

INPUT:

• self – an element of the nonnegative integer span of simple roots.

A root \( \alpha \) is a quantum root if \( \ell(s_{\alpha}) = \langle 2\rho, \alpha^\vee \rangle - 1 \) where \( \ell \) is the length function, \( s_{\alpha} \) is the reflection across the hyperplane orthogonal to \( \alpha \), and \( 2\rho \) is the sum of positive roots.
Warning: This implementation only handles finite Cartan types and assumes that self is a root.

Todo: Rename to is_quantum_root

EXAMPLES:

```
sage: Q = RootSystem(['C',2]).root_lattice()
sage: positive_roots = Q.positive_roots()
sage: for x in sorted(positive_roots):
    ....:     print("{}").format(x, x.quantum_root()))
alpha[1] True
alpha[2] True
```

**scalar** (*lambdacheck*)

The scalar product between the root lattice and the coroot lattice.

EXAMPLES:

```
sage: L = RootSystem(['B',4]).root_lattice()
sage: alpha = L.simple_roots()
sage: alphacheck = L.simple_coroots()
sage: alpha[1].scalar(alphacheck[1])
2
sage: alpha[1].scalar(alphacheck[2])
-1
```

The scalar products between the roots and coroots are given by the Cartan matrix:

```
sage: matrix([ [ alpha[i].scalar(alphacheck[j])
    ....:     for i in L.index_set() ]
    ....:     for j in L.index_set() ])
[ 2 -1 0 0]
[-1 2 -1 0]
[ 0 -1 2 -1]
[ 0 0 -2 2]
sage: L.cartan_type().cartan_matrix()
[ 2 -1 0 0]
[-1 2 -1 0]
[ 0 -1 2 -1]
[ 0 0 -2 2]
```

**to_ambient**

Map self to the ambient space.

EXAMPLES:

```
sage: alpha = CartanType(['B',2]).root_system().root_lattice().an_element(); alpha
sage: alpha.to_ambient()
(2, 0)
sage: alphavee = CartanType(['B',2]).root_system().coroot_lattice().an_element(); alphavee
```
(continues on next page)
2\times \text{alphacheck}[1] + 2\times \text{alphacheck}[2] 
\text{sage: alphavee.to_ambient()}
(2, 2)

5.1.242 Root systems

See Root Systems for an overview.

class sage.combinat.root_system.root_system.RootSystem(cartan_type, as_dual_of=None)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.sage_object.SageObject

A class for root systems.

EXAMPLES:

We construct the root system for type \(B_3\):

\[
\text{sage: R=RootSystem(['B',3]); R}
\text{Root system of type ['B', 3]}
\]

\(R\) models the root system abstractly. It comes equipped with various realizations of the root and weight lattices, where all computations take place. Let us play first with the root lattice:

\[
\text{sage: space = R.root_lattice()}
\text{sage: space}
\text{Root lattice of the Root system of type ['B', 3]}
\]

This is the free \(\mathbb{Z}\)-module \(\bigoplus_i \mathbb{Z} \alpha_i\) spanned by the simple roots:

\[
\text{sage: space.base_ring()}
\text{Integer Ring}
\text{sage: list(space.basis())}
[\text{alpha[1], alpha[2], alpha[3]}]
\]
