- properly provide root systems for real reflection groups
- element class should be unique to be able to work with large groups without creating elements multiple times
- `is_shephard_group`, `is_generalized_coxeter_group`
- exponents and coexponents
- coinvariant ring:
  - fake degrees from Torsten Hoge
  - operation of linear characters on all characters
  - harmonic polynomials
- linear forms for hyperplanes
- field of definition
- intersection lattice and characteristic polynomial:

```python
X = [ alpha(t) for t in W.distinguished_reflections() ]
X = Matrix(CF,X).transpose()
Y = Matroid(X)
```

- linear characters
- permutation \( \pi \) on irreducibles
- hyperplane orbits (76.13 in Gap Manual)
- improve invariant_form with a code similar to the one in `reflection_group_real.py`
- add a method `reflection_to_root` or `distinguished_reflection_to_positive_root`
- diagrams in ASCII-art (76.15)
- standard (BMR) presentations
- character table directly from Chevie
- `GenericOrder` (76.20), `TorusOrder` (76.21)
- correct fundamental invariants for \( G_3^4 \), check the others
- copy hardcoded data (degrees, invariants, braid relations...) into sage
- add other hardcoded data from the tables in chevie (location is SAGEDIR/local/gap3/gap-jm5-2015-02-01/gap3/pkg/chevie/tbl): basic derivations, discriminant, ...
- transfer code for `reduced_word_in_reflections` into Gap4 or Sage
- list of reduced words for an element
- list of reduced words in reflections for an element
• Hurwitz action?
• is_crystallographic() should be hardcoded

AUTHORS:
• Christian Stump (2015): initial version

class sage.combinat.root_system.reflection_group_complex.ComplexReflectionGroup(W_types, in-
dex_set=None, hyper-
plane_index_set=None, reflec-
tion_index_set=None)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.groups.perm_gps.
permgroup.PermutationGroup_generic
A complex reflection group given as a permutation group.
See also:
ReflectionGroup()
class Element
Bases: sage.combinat.root_system.reflection_group_element.ComplexReflectionGroupElement
conjugacy_class()
Return the conjugacy class of self.
EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: for w in W: sorted(w.conjugacy_class())  # optional - gap3
  ()
  [(1,3)(2,5)(4,6), (1,4)(2,3)(5,6), (1,5)(2,4)(3,6)]
  [(1,3)(2,5)(4,6), (1,4)(2,3)(5,6), (1,5)(2,4)(3,6)]
  [(1,2,6)(3,4,5), (1,6,2)(3,5,4)]
  [(1,2,6)(3,4,5), (1,6,2)(3,5,4)]
  [(1,3)(2,5)(4,6), (1,4)(2,3)(5,6), (1,5)(2,4)(3,6)]
```

conjugacy_class_representative()
Return a representative of the conjugacy class of self.
EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: for w in W:
  ....:     print('%s %s'%(w.reduced_word(), w.conjugacy_class_representative().reduced_word()))  # optional - gap3
  []
  [2] [1]
  [1] [1]
  [1, 2] [1, 2]
  [2, 1] [1, 2]
  [1, 2, 1] [1]
```

reflection_length(in_unitary_group=False)
Return the reflection length of self.
This is the minimal numbers of reflections needed to obtain self.

INPUT:
• `in_unitary_group` – (default: False) if True, the reflection length is computed in the unitary group which is the dimension of the move space of self

EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: sorted([t.reflection_length() for t in W])  # optional - gap3
[0, 1, 1, 1, 2, 2]
```

```python
sage: W = ReflectionGroup((2,1,2))  # optional - gap3
sage: sorted([t.reflection_length() for t in W])  # optional - gap3
[0, 1, 1, 1, 2, 2]
```

```python
sage: W = ReflectionGroup((2,2,2))  # optional - gap3
sage: sorted([t.reflection_length() for t in W])  # optional - gap3
[0, 1, 1, 1, 2, 2]
```

```python
sage: W = ReflectionGroup((3,1,2))  # optional - gap3
sage: sorted([t.reflection_length() for t in W])  # optional - gap3
[0, 1, 1, 1, 1, 1, 1, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2]
```

`apply_vector_field(f, vf=None)`

Returns a rational function obtained by applying the vector field vf to the rational function f.

If vf is not given, the primitive vector field is used.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: for x in W.primitive_vector_field()[0].parent().gens():  # optional - gap3
....:     print(W.apply_vector_field(x))  # optional - gap3
3*x1/(6*x0^2 - 6*x0*x1 - 12*x1^2)
1/(6*x0^2 - 6*x0*x1 - 12*x1^2)
```

`braid_relations()`

Return the braid relations of self.

EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.braid_relations()  # optional - gap3
[[[1, 2, 1], [2, 1, 2]]]
```

```python
sage: W = ReflectionGroup((2,1,3))  # optional - gap3
sage: W.braid_relations()  # optional - gap3
[[[1, 2, 1, 2], [2, 1, 2, 1]], [[1, 3], [3, 1]], [[2, 3, 2], [3, 2, 3]]]
```

```python
sage: W = ReflectionGroup((2,2,3))  # optional - gap3
sage: W.braid_relations()  # optional - gap3
[[[1, 2, 1], [2, 1, 2]], [[1, 3], [3, 1]], [[2, 3, 2], [3, 2, 3]]]
```

`cartan_matrix()`

Return the Cartan matrix associated with self.
If `self` is crystallographic, the returned Cartan matrix is an instance of `CartanMatrix`, and a normal matrix otherwise.

Let $s_1, \ldots, s_n$ be a set of reflections which generate `self` with associated simple roots $\alpha_i$ and simple coroots $\alpha_i^\vee$. Then the Cartan matrix $C = (c_{ij})$ is given by $s_i^\vee(s_j)$. The Cartan matrix completely determines the reflection representation if the $s_i$ are linearly independent.

**EXAMPLES:**

```python
sage: ReflectionGroup(['A',4]).cartan_matrix()  # optional - gap3
[ 2 -1 0 0]
[-1 2 -1 0]
[ 0 -1 2 -1]
[ 0 0 -1 2]
```

```python
sage: ReflectionGroup(['H',4]).cartan_matrix()  # optional - gap3
[ 2 E(5)^2 + E(5)^3 0 0]
[E(5)^2 + E(5)^3 2 -1 0]
[ 0 -1 2 -1]
[ 0 0 -1 2]
```

```python
sage: ReflectionGroup([4],4).cartan_matrix()  # optional - gap3
[-2*E(3) - E(3)^2 E(3)^2]
[-E(3)^2 -2*E(3) - E(3)^2]
```

```python
sage: ReflectionGroup((4,2,2)).cartan_matrix()  # optional - gap3
[ 2 -2*E(4) -2]
[E(4) 2 1 - E(4)]
[-1 1 + E(4) 2]
```

codegrees()

Return the codegrees of `self` ordered within each irreducible component of `self`.

**EXAMPLES:**

```python
sage: W = ReflectionGroup((1,1,4))  # optional - gap3
sage: W.codegrees()  # optional - gap3
(2, 1, 0)
```

```python
sage: W = ReflectionGroup((2,1,4))  # optional - gap3
sage: W.codegrees()  # optional - gap3
(6, 4, 2, 0)
```

```python
sage: W = ReflectionGroup((4,1,4))  # optional - gap3
sage: W.codegrees()  # optional - gap3
(12, 8, 4, 0)
```

```python
sage: W = ReflectionGroup((4,2,4))  # optional - gap3
sage: W.codegrees()  # optional - gap3
(12, 8, 4, 0)
```

```python
sage: W = ReflectionGroup((4,4,4))  # optional - gap3
sage: W.codegrees()  # optional - gap3
(8, 8, 4, 0)
```
sage: W = ReflectionGroup((1,1,4), (3,1,2))  # optional - gap3
sage: W.codegrees()                           # optional - gap3
(2, 1, 0, 3, 0)

sage: W = ReflectionGroup((1,1,4), (6,1,12), 23)  # optional - gap3
fails in GAP3
sage: W.codegrees()                           # optional - gap3
(2, 1, 0, 66, 60, 54, 48, 42, 36, 30, 24, 18, 12, 6, 0, 8, 4, 0)

conjugacy_classes()
Return the conjugacy classes of self.

EXAMPLES:

sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: for C in W.conjugacy_classes(): sorted(C)  # optional - gap3
[[], [(1,3)(2,5)(4,6), (1,4)(2,3)(5,6), (1,5)(2,4)(3,6)],
 [(1,2,4,3)(5,7), (1,2,5,7), (1,2,6,7), (1,2,7)]

sage: W = ReflectionGroup((1,1,4))  # optional - gap3
sage: sum(len(C) for C in W.conjugacy_classes()) == W.cardinality() # optional - gap3
True

sage: W = ReflectionGroup((3,1,2))  # optional - gap3
sage: sum(len(C) for C in W.conjugacy_classes()) == W.cardinality() # optional - gap3
True

sage: W = ReflectionGroup(23)  # optional - gap3
sage: sum(len(C) for C in W.conjugacy_classes()) == W.cardinality() # optional - gap3
True

conjugacy_classes_representatives()
Return the shortest representatives of the conjugacy classes of self.

EXAMPLES:

sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: [w.reduced_word() for w in W.conjugacy_classes_representatives()]  # optional - gap3
[[], [1], [1, 2]]

sage: W = ReflectionGroup((1,1,4))  # optional - gap3
sage: [w.reduced_word() for w in W.conjugacy_classes_representatives()]  # optional - gap3
[[], [1], [1, 2], [1, 3, 2]]

sage: W = ReflectionGroup((3,1,2))  # optional - gap3
sage: [w.reduced_word() for w in W.conjugacy_classes_representatives()]  # optional - gap3
[[], [1], [1, 2], [1, 3, 2]]
Combinatorics, Release 9.7

[[], [1], [1, 1], [2, 1, 2, 1], [2, 1, 2, 1, 1],
[2, 1, 1, 2, 1, 1], [2], [1, 2], [1, 1, 2]]
sage: W = ReflectionGroup(23)  # optional - gap3
sage: [w.reduced_word() for w in W.conjugacy_classes_representatives()]  #optional - gap3
[[], [1],
[1, 2],
[1, 3],
[2, 3],
[1, 2, 3],
[1, 2, 1, 2],
[1, 2, 1, 2, 3],
[1, 2, 1, 2, 3, 2, 1, 2, 3],
[1, 2, 1, 2, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]]

coxeter_number(chi=None)

Return the Coxeter number associated to the irreducible character chi of the reflection group self.

The Coxeter number of a complex reflection group \( W \) is the trace in a character \( \chi \) of \( \sum_t (Id - t) \), where \( t \) runs over all reflections. The result is always an integer.

When \( \chi \) is the reflection representation, the Coxeter number is equal to \( \frac{N + N^*}{n} \) where \( N \) is the number of reflections, \( N^* \) is the number of reflection hyperplanes, and \( n \) is the rank of \( W \). If \( W \) is further well-generated, the Coxeter number is equal to the highest degree \( d_n \) and to the order of a Coxeter element \( c \) of \( W \).

EXAMPLES:

sage: W = ReflectionGroup("H",4)  # optional - gap3
sage: W.coxeter_number()  # optional - gap3
30
sage: all(W.coxeter_number(chi).is_integer()  # optional - gap3
  ....: for chi in W.irreducible_characters())
True
sage: W = ReflectionGroup(14)  # optional - gap3
sage: W.coxeter_number()  # optional - gap3
24

degrees()

Return the degrees of self ordered within each irreducible component of self.

EXAMPLES:

sage: W = ReflectionGroup((1,1,4))  # optional - gap3
sage: W.degrees()  # optional - gap3
(2, 3, 4)
sage: W = ReflectionGroup((2,1,4))  # optional - gap3
sage: W.degrees()  # optional - gap3
(2, 4, 6, 8)
sage: W = ReflectionGroup((4,1,4))  # optional - gap3
(continues on next page)
Examples of reducible types:

```python
sage: W = ReflectionGroup((1,1,4), (3,1,2)); W  # optional - gap3
Reducible complex reflection group of rank 5 and type A3 x G(3,1,2)
sage: W.degrees()  # optional - gap3
(2, 3, 4, 3, 6)
```

```
discriminant()

Return the discriminant of self in the polynomial ring on which the group acts.

This is the product

\[ \prod_H \alpha_H^{e_H}, \]

where \( \alpha_H \) is the linear form of the hyperplane \( H \) and \( e_H \) is its stabilizer order.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',3])  # optional - gap3
gW = W.discriminant()  # optional - gap3
x0^6 - 18*t0^4*t2^2 + 9*t1^4 - 36*t0^2*t1^2*t2 + 24*t0^2*t2^2 - 8*t2^3
```

```
discriminant_in_invariant_ring(invariants=None)

Return the discriminant of self in the invariant ring.

This is the function \( f \) in the invariants such that \( f(F_1(x), \ldots, F_n(x)) \) is the discriminant.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',3])  # optional - gap3
gW = W.discriminant_in_invariant_ring()  # optional - gap3
6*t0^3*t1^2 - 18*t0^5*t2 + 9*t1^4 - 36*t0^3*t1^1*t2 + 24*t0^2*t2^2 - 8*t2^3
```

(continues on next page)
distinguished_reflection(i)
Return the i-th distinguished reflection of self.

These are the reflections in self acting on the complement of the fixed hyperplane \( H \) as \( \exp(2\pi i/n) \), where \( n \) is the order of the reflection subgroup fixing \( H \).

EXAMPLES:

```python
sage: W = ReflectionGroup([1,1,3])                      # optional - gap3
sage: W.distinguished_reflection(1)                    # optional - gap3
(1,4)(2,3)(5,6)
```
.... W.distinguished_reflection(i+1) # optional - gap3
(1,6)(2,5)(7,8)
(1,5)(2,7)(6,8)
(3,9,15)(4,10,16)(12,17,23)(14,18,24)(20,25,29)(21,22,26)(27,28,30)
30)
(1,7)(2,6)(5,8)
26)
28)

self.distinguished_reflections()
Return a finite family containing the distinguished reflections of self indexed by
hyperplane_index_set().

These are the reflections in self acting on the complement of the fixed hyperplane $H$ as $\exp(2\pi i/n)$, where $n$ is the order of the reflection subgroup fixing $H$.

EXAMPLES:

sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: W.distinguished_reflections() # optional - gap3
Finite family {1: (1,4)(2,3)(5,6), 2: (1,3)(2,5)(4,6), 3: (1,5)(2,4)(3,6)}

sage: W = ReflectionGroup((1,1,3),hyperplane_index_set=['a','b','c']) # optional - gap3
 Finite family {'a': (1,4)(2,3)(5,6), 'b': (1,3)(2,5)(4,6), 'c': (1,5)(2,4)(3,6)}

sage: W = ReflectionGroup((3,1,1)) # optional - gap3
sage: W.distinguished_reflections() # optional - gap3
Finite family {1: (1,2,3)}

sage: W = ReflectionGroup((1,1,3),(3,1,2)) # optional - gap3
sage: W.distinguished_reflections() # optional - gap3
Finite family {1: (1,6)(2,5)(7,8), 2: (1,5)(2,7)(6,8),
3: (3,9,15)(4,10,16)(12,17,23)(14,18,24)(20,25,29)(21,22,26)(27,28,30),
26)(29,30),
5: (1,7)(2,6)(5,8),
23)(24,26),
7: (4,21,27)(10,22,28)(11,13,19)(12,14,20)(16,26,30)(17,18,25)(23,24,29),
22)(25,28)}

self.fake_degrees()
Return the list of the fake degrees associated to self.

The fake degrees are $q$-versions of the degree of the character. In particular, they sum to Hilbert series of the coinvariant algebra of self.
Note: The ordering follows the one in Chevie and is not compatible with the current implementation of \texttt{irreduble_characters}().

EXAMPLES:

```
sage: W = ReflectionGroup(12)  # optional - gap3
sage: W.fake_degrees()          # optional - gap3
[1, q^12, q^11 + q, q^8 + q^4, q^7 + q^5, q^6 + q^4 + q^2,
 q^10 + q^8 + q^6, q^9 + q^7 + q^5 + q^3]

sage: W = ReflectionGroup("H",4)  # optional - gap3
sage: W.cardinality()             # optional - gap3
14400
sage: sum(fdeg.subs(q=1)**2 for fdeg in W.fake_degrees())  # optional - gap3
14400
```

\texttt{fundamental_invariants()}  
Return the fundamental invariants of \texttt{self}.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.fundamental_invariants()     # optional - gap3
(-2*x0^2 + 2*x0*x1 - 2*x1^2, 6*x0^2*x1 - 6*x0*x1^2)

sage: W = ReflectionGroup((3,1,2))  # optional - gap3
sage: W.fundamental_invariants()     # optional - gap3
(x0^3 + x1^3, x0^3*x1^3)
```

\texttt{hyperplane_index_set()}  
Return the index set of the hyperplanes of \texttt{self}.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,4))  # optional - gap3
sage: W.hyperplane_index_set()      # optional - gap3
(1, 2, 3, 4, 5, 6)

sage: W = ReflectionGroup((3,1,2), hyperplane_index_set=[1,3,'asdf',7,9,11])
    # optional - gap3
sage: W.hyperplane_index_set()      # optional - gap3
(1, 3, 'asdf', 7, 9, 11)

sage: W = ReflectionGroup((1,1,4),hyperplane_index_set=('a','b','c','d','e','f'))
    # optional - gap3
sage: W.hyperplane_index_set()      # optional - gap3
('a', 'b', 'c', 'd', 'e', 'f')
```

\texttt{independent_roots()}  
Return a collection of simple roots generating the underlying vector space of \texttt{self}.

For well-generated groups, these are all simple roots. Otherwise, a linearly independent subset of the simple roots is chosen.

EXAMPLES:
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.independent_roots()  # optional - gap3
Finite family {1: (1, 0), 2: (0, 1)}

sage: W = ReflectionGroup((4,2,3))  # optional - gap3
sage: W.simple_roots()  # optional - gap3
Finite family {1: (1, 0, 0), 2: (-E(4), 1, 0), 3: (-1, 1, 0), 4: (0, -1, 1)}

sage: W.independent_roots()  # optional - gap3
Finite family {1: (1, 0, 0), 2: (-E(4), 1, 0), 4: (0, -1, 1)}

index_set()

Return the index set of the simple reflections of self.

EXAMPLES:

sage: W = ReflectionGroup((1,1,4))  # optional - gap3
sage: W.index_set()  # optional - gap3
(1, 2, 3)

sage: W = ReflectionGroup((1,1,4), index_set=[1,3, 'asdf'])  # optional - gap3
sage: W.index_set()  # optional - gap3
(1, 3, 'asdf')

sage: W = ReflectionGroup((1,1,4), index_set=('a', 'b', 'c'))  # optional - gap3
sage: W.index_set()  # optional - gap3
('a', 'b', 'c')

invariant_form(brute_force=False)

Return the form that is invariant under the action of self.

This is unique only up to a global scalar on the irreducible components.

INPUT:

• brute_force – if True, the computation is done by applying the Reynolds operator; this is, the invariant form of \(e_i\) and \(e_j\) is computed as the sum \(\langle w(\text{\texttt{e}}_i), w(\text{\texttt{e}}_j) \rangle\), where \(\langle \cdot, \cdot \rangle\) is the standard scalar product

EXAMPLES:

sage: W = ReflectionGroup(['A',3])  # optional - gap3
sage: F = W.invariant_form(); F  # optional - gap3
[ 1 -1/2 0]
[-1/2 1 -1/2]
[ 0 -1/2 1]

To check that this is indeed the invariant form, see:

sage: S = W.simple_reflections()  # optional - gap3
sage: all( F == S[i].matrix()*F*S[i].matrix().transpose() for i in W.index_set() )  # optional - gap3
True

sage: W = ReflectionGroup(['B',3])  # optional - gap3
sage: F = W.invariant_form(); F  # optional - gap3
[ 1 -1 0]
[-1 2 -1]
Combinatorics, Release 9.7

sage: w = W.an_element().to_matrix()                # optional - gap3
sage: w * F * w.transpose().conjugate() == F         # optional - gap3
True

sage: S = W.simple_reflections()                    # optional - gap3
sage: all( F == S[i].matrix()*F*S[i].matrix().transpose().conjugate() for i in W.index_set() ) # optional - gap3
True

sage: W = ReflectionGroup((3,1,2))                  # optional - gap3
sage: F = W.invariant_form(); F                     # optional - gap3
[1 0]
[0 1]

sage: S = W.simple_reflections()                    # optional - gap3
sage: all( F == S[i].matrix()*F*S[i].matrix().transpose().conjugate() for i in W.index_set() ) # optional - gap3
True

It also worked for badly generated groups:

sage: W = ReflectionGroup(7)                        # optional - gap3
sage: W.is_well_generated()                         # optional - gap3
False

sage: F = W.invariant_form(); F                     # optional - gap3
[1 0]
[0 1]

sage: S = W.simple_reflections()                    # optional - gap3
sage: all( F == S[i].matrix()*F*S[i].matrix().transpose().conjugate() for i in W.index_set() ) # optional - gap3
True

And also for reducible types:

sage: W = ReflectionGroup(['B',3],[4,2,3],4,7); W  # optional - gap3
Reducible complex reflection group of rank 10 and type B3 x G(4,2,3) x ST4 x ST7
sage: F = W.invariant_form(); S = W.simple_reflections()     # optional - gap3
sage: all( F == S[i].matrix()*F*S[i].matrix().transpose().conjugate() for i in W.index_set() ) # optional - gap3
True

\texttt{invariant\_form\_standardization()}

Return the transformation of the space that turns the invariant form of \texttt{self} into the standard scalar product.

Let $I$ be the invariant form of a complex reflection group, and let $A$ be the Hermitian matrix such that $A^2 = I$. The matrix $A$ defines a change of basis such that the identity matrix is the invariant form. Indeed, we have

$$(A^{-1}x)I(A^{-1}y) = A^{-1}xIyA^{-1} = A^{-1}IA^{-1} = I,$$

where $I$ is the identity matrix.

\textbf{EXAMPLES:}

5.1. Comprehensive Module List 2373
sage: W = ReflectionGroup((4,2,5))  # optional - gap3
sage: I = W.invariant_form()  # optional - gap3
sage: A = W.invariant_form_standardization()  # optional - gap3
sage: A^2 == I  # optional - gap3
True

irreducible_components()
Return a list containing the irreducible components of self as finite reflection groups.

EXAMPLES:

sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.irreducible_components()  # optional - gap3
[Irreducible real reflection group of rank 2 and type A2]

sage: W = ReflectionGroup((1,1,3),(2,1,3))  # optional - gap3
sage: W.irreducible_components()  # optional - gap3
[Irreducible real reflection group of rank 2 and type A2,
Irreducible real reflection group of rank 3 and type B3]

is_crystallographic()
Return True if self is crystallographic.

This is, if the field of definition is the rational field.

Todo: Make this more robust and do not use the matrix representation of the simple reflections.

EXAMPLES:

sage: W = ReflectionGroup((1,1,3)); W  # optional - gap3
Irreducible real reflection group of rank 2 and type A2
sage: W.is_crystallographic()  # optional - gap3
True

sage: W = ReflectionGroup((2,1,3)); W  # optional - gap3
Irreducible real reflection group of rank 3 and type B3
sage: W.is_crystallographic()  # optional - gap3
True

sage: W = ReflectionGroup(23); W  # optional - gap3
Irreducible real reflection group of rank 3 and type H3
sage: W.is_crystallographic()  # optional - gap3
False

sage: W = ReflectionGroup((3,1,3)); W  # optional - gap3
Irreducible complex reflection group of rank 3 and type G(3,1,3)
sage: W.is_crystallographic()  # optional - gap3
False

sage: W = ReflectionGroup((4,2,2)); W  # optional - gap3
Irreducible complex reflection group of rank 2 and type G(4,2,2)
sage: W.is_crystallographic()  # optional - gap3
False
jacobian_of_fundamental_invariants(invs=None)

Return the matrix \([\partial_x F_j]\), where \(invs\) are any polynomials \(F_1, \ldots, F_n\) in \(x_1, \ldots, x_n\).

INPUT:

- \(invs\) – (default: the fundamental invariants) the polynomials \(F_1, \ldots, F_n\)

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])          # optional - gap3
sage: W.fundamental_invariants()             # optional - gap3
(-2*x0^2 + 2*x0*x1 - 2*x1^2, 6*x0^2*x1 - 6*x0*x1^2)
sage: W.jacobian_of_fundamental_invariants() # optional - gap3
[-4*x0 + 2*x1  2*x0 - 4*x1]
[12*x0*x1 - 6*x1^2  6*x0^2 - 12*x0*x1]
```

number_of_irreducible_components()

Return the number of irreducible components of \(self\).

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3))          # optional - gap3
sage: W.number_of_irreducible_components()  # optional - gap3
1
sage: W = ReflectionGroup((1,1,3),(2,1,3))  # optional - gap3
sage: W.number_of_irreducible_components()  # optional - gap3
2
```

primitive_vector_field(invs=None)

Return the primitive vector field of \(self\) is irreducible and well-generated.

The primitive vector field is given as the coefficients (being rational functions) in the basis \(\partial x_1, \ldots, \partial x_n\).

This is the partial derivation along the unique invariant of degree given by the Coxeter number. It can be computed as the row of the inverse of the Jacobian given by the highest degree.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])          # optional - gap3
sage: W.primitive_vector_field()             # optional - gap3
(3*x1/(6*x0^2 - 6*x0*x1 - 12*x1^2), 1/(6*x0^2 - 6*x0*x1 - 12*x1^2))
```

rank()

Return the rank of \(self\).

This is the dimension of the underlying vector space.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3))          # optional - gap3
sage: W.rank()                              # optional - gap3
2
sage: W = ReflectionGroup((2,1,3))          # optional - gap3
sage: W.rank()                              # optional - gap3
3
sage: W = ReflectionGroup((4,1,3))          # optional - gap3
```

(continues on next page)
reflection(i)
Return the i-th reflection of self.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3))
# optional - gap3
sage: W.reflection(1)  # optional - gap3
(1,4)(2,3)(5,6)
sage: W.reflection(2)  # optional - gap3
(1,3)(2,5)(4,6)
sage: W.reflection(3)  # optional - gap3
(1,5)(2,4)(3,6)
sage: W = ReflectionGroup((3,1,1),reflection_index_set=['a','b'])  # optional - gap3
sage: W.reflection('a')  # optional - gap3
(1,2,3)
sage: W.reflection('b')  # optional - gap3
(1,3,2)
```

reflection_character()
Return the reflection characters of self.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3))
# optional - gap3
sage: W.reflection_character()  # optional - gap3
[2, 0, -1]
```

reflection_eigenvalues(w, is_class_representative=False)
Return the reflection eigenvalue of w in self.

INPUT:

- **is_class_representative** – boolean (default True) whether to compute instead on the conjugacy class representative.

See also:

reflection_eigenvalues_family()

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3))
# optional - gap3
sage: for w in W:
    # optional - gap3
    ....: print('%s %s' % (w.reduced_word(), W.reflection_eigenvalues(w)))  # optional - gap3
[0, 0]
[2] [1/2, 0]
[1] [1/2, 0]
```
reflection_eigenvalues_family()

Return the reflection eigenvalues of \texttt{self} as a finite family indexed by the class representatives of \texttt{self}.

**OUTPUT:**

- list with entries $k/n$ representing the eigenvalue $\zeta_n^k$.

**EXAMPLES:**

```sage
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.reflection_eigenvalues_family()  # optional - gap3
Finite family {(): [0, 0], (1,4)(2,3)(5,6): [1/2, 0], (1,6,2)(3,5,4): [1/3, 2/3]}

sage: W = ReflectionGroup((3,1,2))  # optional - gap3
sage: reflection_eigenvalues = W.reflection_eigenvalues_family()  # optional - gap3
sage: for elt in sorted(reflection_eigenvalues.keys()):
....:     print("%s %s"%(elt, reflection_eigenvalues[elt]))  # optional - gap3
() [0, 0]
(1,3,9)(2,16,24)(4,20,21)(5,7,13)(6,12,23)(8,19,17)(10,15,22)(11,18,14) [1/3, 1/2]
(1,5)(2,6)(3,7)(4,8)(9,13)(10,14)(11,15)(12,16)(17,21)(18,22)(19,20)(23,24) [1/2, 0]
(1,7,3,13,9,5)(2,8,16,19,24,17)(4,14,20,11,21,18)(6,15,12,22,23,10) [1/6, 2/3]
(1,9,3)(2,10,4)(6,17,11)(8,18,12)(14,23,19)(15,20,16)(21,24,22) [2/3, 0]
(1,9,3)(2,20,22)(4,15,24)(5,7,13)(6,18,19)(8,23,11)(10,16,21)(12,14,17) [1/3, 2/3]
(1,9,3)(2,24,16)(4,21,20)(5,13,7)(6,23,12)(8,17,19)(10,22,15)(11,14,18) [2/3, 2/3]
(1,13,9,7,3,5)(2,14,24,18,16,11)(4,6,21,23,20,12)(8,22,17,15,19,10) [1/3, 5/6]

sage: W = ReflectionGroup(23)  # optional - gap3
sage: reflection_eigenvalues = W.reflection_eigenvalues_family()  # optional - gap3
sage: for elt in sorted(reflection_eigenvalues.keys()):
....:     print("%s %s"%(elt, reflection_eigenvalues[elt]))  # optional - gap3
() [0, 0, 0]
(1,8,4)(2,21,3)(5,10,11)(6,18,17)(7,9,12)(13,14,15)(16,23,19)(20,25,26)(22,24,27)(28,29,30) [1/3, 2/3, 0]
(1,16)(2,5)(4,7)(6,9)(8,10)(11,13)(12,14)(17,20)(19,22)(21,24)(23,25)(26,28)(27,29) [1/2, 0, 0]
(1,16)(2,9)(3,18)(4,10)(5,6)(7,8)(11,14)(12,13)(17,24)(19,25)(20,21)(22,23)(26,29)(27,28) [1/2, 1/2, 0]
(1,19,20,2,7)(3,6,11,13,9)(4,5,17,22,16)(8,12,15,14,10)(18,21,26,28,24)(23,27,29,30,25) [1/5, 4/5, 0]
(1,20,7,19,2)(3,11,9,6,13)(4,17,16,5,22)(8,15,10,12,14)(18,26,24,21,28)(23,30,25,27,29) [2/5, 3/5, 0]
```

(continues on next page)
reflection_hyperplane($i$, $as\_linear\_functionals=False$, $with\_order=False$)

Return the $i$-th reflection hyperplane of self.

The $i$-th reflection hyperplane corresponds to the $i$ distinguished reflection.

INPUT:

- $i$ – an index in the index set
- $as\_linear\_functionals$ – (default:False) flag whether to return the hyperplane or its linear functional in the basis dual to the given root basis

EXAMPLES:

```
sage: W = ReflectionGroup((2,1,2))
# optional - gap3
sage: W.reflection_hyperplane(3)
# optional - gap3
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 0]
```

One can ask for the result as a linear form:

```
sage: W.reflection_hyperplane(3, True)
# optional - gap3
(0, 1)
```

reflection_hyperplanes($as\_linear\_functionals=False$, $with\_order=False$)

Return the list of all reflection hyperplanes of self, either as a codimension 1 space, or as its linear functional.

INPUT:

- $as\_linear\_functionals$ – (default:False) flag whether to return the hyperplane or its linear functional in the basis dual to the given root basis

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3))
# optional - gap3
sage: for H in W.reflection_hyperplanes(): H
# optional - gap3
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 2]
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[ 1 1/2]
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[ 1 -1]
sage: for H in W.reflection_hyperplanes(as_linear_functionals=True): H
# optional - gap3
(0, 0)
```

sage: W = ReflectionGroup((2,1,2))  # optional - gap3
sage: for H in W.reflection_hyperplanes(): H  # optional - gap3
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 1]
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 1/2]
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 0]
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[0 1]

sage: for H in W.reflection_hyperplanes(as_linear_functionals=True): H  # optional - gap3
(1, -1)
(1, -1/2)
(1, -2)
(1, 1)

sage: for H in W.reflection_hyperplanes(as_linear_functionals=True, with_order=True): H  # optional - gap3
((1, -1), 2)
((1, -2), 2)
((0, 1), 2)
((1, 0), 2)

reflection_index_set()
Return the index set of the reflections of self.

EXAMPLES:

sage: W = ReflectionGroup((1,1,4))  # optional - gap3
sage: W.reflection_index_set()  # optional - gap3
(1, 2, 3, 4, 5, 6)
sage: W = ReflectionGroup((1,1,4), reflection_index_set=[1,3,'asdf',7,9,11])  # optional - gap3
sage: W.reflection_index_set()  # optional - gap3
(1, 2, 3, 4, 5, 6)
sage: W = ReflectionGroup((1,1,4), reflection_index_set=('a','b','c','d','e','f'))  # optional - gap3
sage: W.reflection_index_set()  # optional - gap3
('a', 'b', 'c', 'd', 'e', 'f')

reflections()
Return a finite family containing the reflections of self, indexed by self.reflection_index_set().

5.1. Comprehensive Module List
EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.reflections()  # optional - gap3
Finite family {1: (1,4)(2,3)(5,6), 2: (1,3)(2,5)(4,6), 3: (1,5)(2,4)(3,6)}

sage: W = ReflectionGroup((1,1,3), reflection_index_set=['a', 'b', 'c'])  # optional - gap3
sage: W.reflections()  # optional - gap3
Finite family {'a': (1,4)(2,3)(5,6), 'b': (1,3)(2,5)(4,6), 'c': (1,5)(2,4)(3,6)}

sage: W = ReflectionGroup((3,1,1))  # optional - gap3
sage: W.reflections()  # optional - gap3
Finite family {1: (1,2,3), 2: (1,3,2)}

sage: W = ReflectionGroup((1,1,3),(3,1,2))  # optional - gap3
sage: W.reflections()  # optional - gap3
```

**roots()**

Return all roots corresponding to all reflections of self.

EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.roots()  # optional - gap3
[(1, 0), (0, 1), (1, 1), (-1, 0), (0, -1), (-1, -1)]

sage: W = ReflectionGroup((3,1,2))  # optional - gap3
sage: W.roots()  # optional - gap3
[(1, 0), (-1, 1), (E(3), 0), (-E(3), 1), (0, 1), (1, -1), (0, E(3)), (1, -E(3)), (E(3)^2, 0), (-E(3)^2, 1), (E(3), -1), (E(3), -E(3)), (0, E(3)^2), (1, -E(3)^2), (-1, E(3)), (-E(3), E(3)), (E(3)^2, -1), (E(3)^2, -E(3)), (E(3), -E(3)^2), (-E(3)^2, E(3)), (1, E(3)^2), (-E(3)^2, -E(3)), (E(3)^2, -E(3)^2), (E(3), -E(3)^2), (E(3)^2, E(3)), (1, E(3)^2), (-E(3)^2, -E(3)), (E(3)^2, -E(3)^2), (-E(3)^2, E(3), E(3)^2)]

sage: W = ReflectionGroup((4,2,2))  # optional - gap3
sage: W.roots()  # optional - gap3
(continues on next page)
Combinatorics, Release 9.7

(0, 0, 0, -E(3), E(3)), (0, 0, 0, E(3)^2, -1),
(0, 0, 0, E(3)^2, -E(3)), (0, 0, 0, E(3), -E(3)^2),
(0, 0, 0, -E(3)^2, E(3)), (0, 0, 0, 0, -1, E(3)^2),
(0, 0, 0, -E(3), E(3)^2), (0, 0, 0, E(3)^2, -E(3)^2),
(0, 0, 0, -E(3)^2, E(3)^2)]

series()

Return the series of the classification type to which self belongs.

For real reflection groups, these are the Cartan-Killing classification types “A”, “B”, “C”, “D”, “E”, “F”, “G”, “H”, “T”, and for complex non-real reflection groups these are the Shephard-Todd classification type “ST”.

EXAMPLES:

sage: ReflectionGroup((1,1,3)).series() # optional - gap3
['A']

sage: ReflectionGroup((3,1,3)).series() # optional - gap3
['ST']

set_reflection_representation(refl_repr=None)

Set the reflection representation of self.

INPUT:

• refl_repr – a dictionary representing the matrices of the generators of self with keys given by the index set, or None to reset to the default reflection representation

EXAMPLES:

sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: for w in W: w.to_matrix(); print("-----") # optional - gap3
[1 0]
[0 1]
-----
[ 1 1]
[ 0 -1]
-----

(continues on next page)
sage: W.set_reflection_representation()  # optional - gap3

simple_coroot(i)
Return the simple root with index i.

EXAMPLES:

```
sage: W = ReflectionGroup(['A', 3])  # optional - gap3
sage: W.simple_coroot(1)  # optional - gap3
(2, -1, 0)
```

simple_coroots()
Return the simple coroots of self.
These are the coroots corresponding to the simple reflections.

**EXAMPLES:**

```python
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.simple_coroots()  # optional - gap3
Finite family {1: (2, -1), 2: (-1, 2))
```

```python
sage: W = ReflectionGroup((1,1,4), (2,1,2))  # optional - gap3
sage: W.simple_coroots()  # optional - gap3
Finite family {1: (2, -1, 0, 0, 0), 2: (-1, 2, -1, 0, 0), 3: (0, -1, 2, 0, 0), 4: (0, 0, 2, -2), 5: (0, 0, 0, -1, 2)}
```

```python
sage: W = ReflectionGroup((3,1,2))  # optional - gap3
sage: W.simple_coroots()  # optional - gap3
Finite family {1: (-2*E(3) - E(3)^2, 0), 2: (-1, 1)}
```

```python
sage: W = ReflectionGroup((1,1,4), (3,1,2))  # optional - gap3
sage: W.simple_coroots()  # optional - gap3
Finite family {1: (2, -1, 0, 0, 0), 2: (-1, 2, -1, 0, 0), 3: (0, -1, 2, 0, 0), 4: (0, 0, 0, -2*E(3) - E(3)^2, 0), 5: (0, 0, 0, -1, 1)}
```

**simple_reflection(i)**

Return the i-th simple reflection of self.

**EXAMPLES:**

```python
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.simple_reflection(1)  # optional - gap3
(1,4)(2,3)(5,6)
```

```python
sage: W.simple_reflections()  # optional - gap3
Finite family {1: (1,4)(2,3)(5,6), 2: (1,3)(2,5)(4,6)}
```

**simple_root(i)**

Return the simple root with index i.

**EXAMPLES:**

```python
sage: W = ReflectionGroup(['A',3])  # optional - gap3
sage: W.simple_root(1)  # optional - gap3
(1, 0, 0)
```

```python
sage: W.simple_root(2)  # optional - gap3
(0, 1, 0)
```

```python
sage: W.simple_root(3)  # optional - gap3
(0, 0, 1)
```

**simple_roots()**

Return the simple roots of self.

These are the roots corresponding to the simple reflections.

**EXAMPLES:**

```python
sage: W = ReflectionGroup((1,1,3))  # optional - gap3
sage: W.simple_roots()  # optional - gap3
Finite family {1: (1, 0), 2: (0, 1)}
```
sage: W = ReflectionGroup((1,1,4), (2,1,2)) # optional - gap3
sage: W.simple_roots() # optional - gap3
Finite family {1: (1, 0, 0, 0, 0), 2: (0, 1, 0, 0, 0), 3: (0, 0, 1, 0, 0), 4: (0, 0, 0, 1, 0), 5: (0, 0, 0, 0, 1)}

sage: W = ReflectionGroup((3,1,2)) # optional - gap3
sage: W.simple_roots() # optional - gap3
Finite family {1: (1, 0), 2: (-1, 1)}

sage: W = ReflectionGroup((1,1,4), (3,1,2)) # optional - gap3
sage: W.simple_roots() # optional - gap3
Finite family {1: (1, 0, 0, 0, 0), 2: (0, 1, 0, 0, 0), 3: (0, 0, 1, 0, 0), 4: (0, 0, 0, 1, 0), 5: (0, 0, 0, 0, -1)}

class sage.combinat.root_system.reflection_group_complex.IrreducibleComplexReflectionGroup(W_types, index_set=None, hyperplane_index_set=None, reflection_index_set=None):
    Bases: sage.combinat.root_system.reflection_group_complex.ComplexReflectionGroup

class Element:

    is_coxeter_element(which_primitive=1, is_class_representative=False)
    Return True if self is a Coxeter element.

    This is, whether self has an eigenvalue that is a primitive $h$-th root of unity.

    INPUT:
    • which_primitive – (default: 1) for which power of the first primitive $h$-th root of unity to look
    as a reflection eigenvalue for a regular element
    • is_class_representative – boolean (default True) whether to compute instead on the con-
    jugacy class representative

    See also:
    coxeter_element() coxeter_elements()

    EXAMPLES:

sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: for w in W:
    # optional - gap3
    ....: print('%s %s%%(w.reduced_word(), w.is_coxeter_element())') #~
        ....: optional - gap3
[0] False
[1] False
[2] False
[1, 2] True
[2, 1] True
is_h_regular(is_class_representative=False)

Return whether self is regular.

This is if self has an eigenvector with eigenvalue \( h \) and which does not lie in any reflection hyperplane. Here, \( h \) denotes the Coxeter number.

EXAMPLES:

```sage
gap
W = ReflectionGroup((1,1,3))
# optional - gap3
sage: W
# optional - gap3
sage: for w in W:
    # optional - gap3
    print('%s %s' % (w.reduced_word(), w.is_h_regular()))
    # optional - gap3
[] False
[2] False
[1] False
[1, 2] True
[2, 1] True
[1, 2, 1] False
sage:
W = ReflectionGroup((1,1,3))
# optional - gap3
sage: for w in W:
    # optional - gap3
    print('%s %s' % (w.reduced_word(), w.is_h_regular()))
    # optional - gap3
[] False
[2] False
[1] False
[1, 2] True
[2, 1] True
[1, 2, 1] False
```

is_regular(h, is_class_representative=False)

Return whether self is regular.

This is, if self has an eigenvector with eigenvalue of order \( h \) and which does not lie in any reflection hyperplane.

INPUT:

- \( h \) – the order of the eigenvalue
- \( \text{is_class_representative} \) – boolean (default True) whether to compute instead on the conjugacy class representative

EXAMPLES:

```sage
gap
sage: W = ReflectionGroup((1,1,3))
# optional - gap3
sage: h = W.coxeter_number()
# optional - gap3
sage: for w in W:
    # optional - gap3
    print("{} {}").format(w.reduced_word(), w.is_regular(h))
    # optional - gap3
[] False
[2] False
[1] False
[1, 2] True
[2, 1] True
[1, 2, 1] False
sage: W = ReflectionGroup(23); h = W.coxeter_number()
# optional - gap3
sage: for w in W:
    # optional - gap3
    if w.is_regular(h):
        # optional - gap3
        w.reduced_word()
        # optional - gap3
[1, 2, 3]
[2, 1, 3]
[1, 3, 2]
[3, 2, 1]
[2, 1, 2, 3, 2]
[2, 3, 2, 1, 2]
```

(continues on next page)
Combinatorics, Release 9.7

Check that trac ticket #25478 is fixed:

```
sage: W = ReflectionGroup(\"A\",5)   # optional - gap3
sage: w = W.from_reduced_word([1,2,3,5]) # optional - gap3
sage: w.is_regular(4) # optional - gap3
False
sage: W = ReflectionGroup(\"A\",3)    # optional - gap3
sage: len([w for w in W if w.is_regular(w.order())]) # optional - gap3
18
```

`sage.combinat.root_system.reflection_group_complex.multi_partitions(n, S, i=None)`

Return all vectors as lists of the same length as S whose standard inner product with S equals n.

**EXAMPLES:**

```
sage: from sage.combinat.root_system.reflection_group_complex import multi_partitions
sage: multi_partitions(10, [2,3,3,4])
[[5, 0, 0, 0],
 [3, 0, 0, 1],
 [2, 2, 0, 0],
 [2, 1, 1, 0],
 [2, 0, 2, 0],
 [1, 0, 0, 2],
 [0, 2, 0, 1],
 [0, 1, 1, 1],
 [0, 0, 2, 1]]
```

`sage.combinat.root_system.reflection_group_complex.power(f, k)`

Return \(f^k\) and caching all intermediate results.

Speeds the computation if one has to compute \(f^k\)'s for many values of k.

**EXAMPLES:**
5.1.233 Finite real reflection groups

Let $V$ be a finite-dimensional real vector space. A reflection of $V$ is an operator $r \in \text{GL}(V)$ that has order 2 and fixes pointwise a hyperplane in $V$. In the present implementation, finite real reflection groups are tied with a root system.

Finite real reflection groups with root systems have been classified according to finite Cartan-Killing types. For more definitions and classification types of finite complex reflection groups, see Wikipedia article Complex_reflection_group.

The point of entry to work with reflection groups is $\text{ReflectionGroup}()$ which can be used with finite Cartan-Killing types:

```python
sage: ReflectionGroup(['A',2])  # optional - gap3
Irreducible real reflection group of rank 2 and type A2
sage: ReflectionGroup(['F',4])  # optional - gap3
Irreducible real reflection group of rank 4 and type F4
sage: ReflectionGroup(['H',3])  # optional - gap3
Irreducible real reflection group of rank 3 and type H3
```

AUTHORS:

• Christian Stump (initial version 2011–2015)

**Warning:** Uses the GAP3 package Chevie which is available as an experimental package (installed by `sage -i gap3`) or to download by hand from Jean Michel’s website.
class sage.combinat.root_system.reflection_group_real.RealReflectionGroup(W_types, index_set=None, hyperplane_index_set=None, reflection_index_set=None)

Bases: sage.combinat.root_system.reflection_group_complex.ComplexReflectionGroup

A real reflection group given as a permutation group.

See also:
ReflectionGroup()

class Element

left_coset_representatives()
Return the left coset representatives of self.

See also:
right_coset_representatives()

EXAMPLES:

 sage: W = ReflectionGroup(["A",2]) # optional - gap3
 sage: for w in W: # optional - gap3
 ....:  lcr = w.left_coset_representatives() # optional - gap3
 ....:  print("%s %s"%(w.reduced_word(), # optional - gap3
 ....:          [v.reduced_word() for v in lcr])) # optional - gap3
almost_positive_roots()
Return the almost positive roots of self.

EXAMPLES:

```sage
W = ReflectionGroup(['A',3], ['B',2])  # optional - gap3
W.almost_positive_roots()  # optional - gap3
[(-1, 0, 0, 0, 0),
 (0, -1, 0, 0, 0),
 (0, 0, -1, 0, 0),
 (0, 0, 0, -1, 0),
 (0, 0, 0, 0, -1),
 (1, 0, 0, 0, 0),
 (0, 1, 0, 0, 0),
 (0, 0, 1, 0, 0),
 (0, 0, 0, 1, 0),
 (0, 0, 0, 0, 1),
 (1, 1, 0, 0, 0),
 (0, 1, 1, 0, 0),
 (0, 0, 0, 2, 1)]
```

```sage
W = ReflectionGroup(['A',3])  # optional - gap3
W.almost_positive_roots()  # optional - gap3
[(-1, 0, 0),
 (0, -1, 0),
 (0, 0, -1),
 (1, 0, 0),
 (0, 1, 0),
 (0, 0, 1),
 (1, 1, 0),
 (0, 1, 1),
 (1, 1, 1)]
```

bipartite_index_set()
Return the bipartite index set of a real reflection group.

EXAMPLES:

```sage
W = ReflectionGroup(['A',5])  # optional - gap3
W.bipartite_index_set()  # optional - gap3
[[1, 3, 5], [2, 4]]
```

```sage
W = ReflectionGroup(['A',5],index_set=['a','b','c','d','e'])  # optional - gap3
W.bipartite_index_set()  # optional - gap3
[[‘a’, ‘c’, ‘e’], [‘b’, ‘d’]]
```

cartan_type()
Return the Cartan type of self.

EXAMPLES:
```python
sage: W = ReflectionGroup(['A', 3])  # optional - gap3
sage: W.cartan_type()  # optional - gap3
['A', 3]

sage: W = ReflectionGroup(['A', 3], ['B', 3])  # optional - gap3
sage: W.cartan_type()  # optional - gap3
A3xB3 relabelled by {1: 3, 2: 2, 3: 1}
```

cocxeter_diagram()
Return the Coxeter diagram associated to self.

EXAMPLES:
```python
sage: G = ReflectionGroup(['B', 3])  # optional - gap3
sage: sorted(G.coxeter_diagram().edges(labels=True))  # optional - gap3
[(1, 2, 4), (2, 3, 3)]
```
coxeter_matrix()
Return the Coxeter matrix associated to self.

EXAMPLES:
```python
sage: G = ReflectionGroup(['A', 3])  # optional - gap3
sage: G.coxeter_matrix()  # optional - gap3
[1 3 2]
[3 1 3]
[2 3 1]
```

fundamental_weight(i)
Return the fundamental weight with index i.

EXAMPLES:
```python
sage: W = ReflectionGroup(['A', 3])  # optional - gap3
sage: [ W.fundamental_weight(i) for i in W.index_set() ]  # optional - gap3
[(3/4, 1/2, 1/4), (1/2, 1, 1/2), (1/4, 1/2, 3/4)]
```
fundamental_weights()
Return the fundamental weights of self in terms of the simple roots.

The fundamental weights are defined by $s_j(\omega_i) = \omega_i - \delta_{i=j} \alpha_j$ for the simple reflection $s_j$ with corresponding simple roots $\alpha_j$.

In other words, the transpose Cartan matrix sends the weight basis to the root basis. Observe again that the action here is defined as a right action, see the example below.

EXAMPLES:
```python
sage: W = ReflectionGroup(['A', 3], ['B', 2])  # optional - gap3
sage: W.fundamental_weights()  # optional - gap3
Finite family {1: (3/4, 1/2, 1/4, 0, 0), 2: (1/2, 1, 1/2, 0, 0), 3: (1/4, 1/2, 3/4, 0, 0), 4: (0, 0, 0, 1, 1/2), 5: (0, 0, 0, 1, 1)}

sage: W = ReflectionGroup(['A', 3])  # optional - gap3
sage: W.fundamental_weights()  # optional - gap3
Finite family {1: (3/4, 1/2, 1/4), 2: (1/2, 1, 1/2), 3: (1/4, 1/2, 3/4)}
```

(continues on next page)
sage: W = ReflectionGroup([['A',3]])                # optional - gap3
sage: S = W.simple_reflections()                      # optional - gap3
sage: N = W.fundamental_weights()                     # optional - gap3
sage: for i in W.index_set():                         # optional - gap3
    ....: for j in W.index_set():                    # optional - gap3
        .....:
            print("{} {} {} ".format(i, j, N[i], N[i]*S[j].to_matrix()))
1 1 (3/4, 1/2, 1/4) (-1/4, 1/2, 1/4)
1 2 (3/4, 1/2, 1/4) (3/4, 1/2, 1/4)
1 3 (3/4, 1/2, 1/4) (3/4, 1/2, 1/4)
2 1 (1/2, 1, 1/2) (1/2, 1, 1/2)
2 2 (1/2, 1, 1/2) (1/2, 0, 1/2)
2 3 (1/2, 1, 1/2) (1/2, 1, 1/2)
3 1 (1/4, 1/2, 3/4) (1/4, 1/2, 3/4)
3 2 (1/4, 1/2, 3/4) (1/4, 1/2, 3/4)
3 3 (1/4, 1/2, 3/4) (1/4, 1/2, -1/4)

iteration(algorithm='breadth', tracking_words=True)
Return an iterator going through all elements in self.

INPUT:

• algorithm (default: 'breadth') – must be one of the following:
  – 'breadth' - iterate over in a linear extension of the weak order
  – 'depth' - iterate by a depth-first-search
  – 'parabolic' - iterate by using parabolic subgroups

• tracking_words (default: True) – whether or not to keep track of the reduced words and store them in _reduced_word

Note: The fastest iteration is the parabolic iteration and the depth first algorithm without tracking words is second. In particular, 'depth' is ~1.5x faster than 'breadth'.

Note: The 'parabolic' iteration does not track words and requires keeping the subgroup corresponding to I \ {i} in memory (for each i individually).

EXAMPLES:

sage: W = ReflectionGroup([['B',2]])                 # optional - gap3
sage: for w in W.iteration("breadth",True):          # optional - gap3
    ....: print("%s %s"%(w, w._reduced_word))       # optional - gap3
() []
(1,3)(2,6)(5,7) [1]
(1,5)(2,4)(6,8) [0]
(1,7,5,3)(2,4,6,8) [0, 1]
(1,3,5,7)(2,8,6,4) [1, 0]
(2,8)(3,7)(4,6) [1, 0, 1]
(1,7)(3,5)(4,8) [0, 1, 0]
(1,5)(2,6)(3,7)(4,8) [0, 1, 0, 1]
sage: for w in W.iteration("depth", False): w                      # optional - gap3
(1,3)(2,6)(5,7)
(1,5)(2,4)(6,8)
(1,3,5,7)(2,8,6,4)
(1,7)(3,5)(4,8)
(1,7,5,3)(2,4,6,8)
(2,8)(3,7)(4,6)
(1,5)(2,6)(3,7)(4,8)

\textbf{positive\_roots()}

Return the positive roots of self.

\textbf{EXAMPLES:}

sage: W = ReflectionGroup(['A',3], ['B',2])                      # optional - gap3
sage: W.positive_roots()                                          # optional - gap3
[(1, 0, 0, 0, 0),
 (0, 1, 0, 0, 0),
 (0, 0, 1, 0, 0),
 (0, 0, 0, 1, 0),
 (0, 0, 0, 0, 1),
 (1, 1, 0, 0, 0),
 (0, 1, 1, 0, 0),
 (0, 0, 0, 1, 1),
 (1, 1, 1, 0, 0),
 (0, 0, 0, 2, 1)]

sage: W = ReflectionGroup(['A',3])                                # optional - gap3
sage: W.positive_roots()                                          # optional - gap3
[(1, 0, 0), (0, 1, 0), (0, 0, 1), (1, 1, 0), (0, 1, 1), (1, 1, 1)]

\textbf{reflection\_to\_positive\_root}(r)

Return the positive root orthogonal to the given reflection.

\textbf{EXAMPLES:}

sage: W = ReflectionGroup(['A',2])                                # optional - gap3
sage: for r in W.reflections():                                    # optional - gap3
....: print(W.reflection_to_positive_root(r))
(1, 0)
(0, 1)
(1, 1)

\textbf{right\_coset\_representatives}(J)

Return the right coset representatives of self for the parabolic subgroup generated by the simple reflections in J.

\textbf{EXAMPLES:}

sage: W = ReflectionGroup(['A',3])                                # optional - gap3
sage: for J in Subsets([1,2,3]): W.right_coset_representatives(J) # optional - gap3
(continues on next page)
root_to_reflection(root)

Return the reflection along the given root.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: for beta in W.roots(): W.root_to_reflection(beta) # optional - gap3
(1,4)(2,3)(5,6)
(1,3)(2,5)(4,6)
(1,5)(2,4)(3,6)
(1,4)(2,3)(5,6)
(1,3)(2,5)(4,6)
(1,5)(2,4)(3,6)
```

5.1. Comprehensive Module List 2393
**simple_root_index(i)**

Return the index of the simple root \( \alpha_i \).

This is the position of \( \alpha_i \) in the list of simple roots.

**EXAMPLES:**

```python
sage: W = ReflectionGroup(['A',3]) # optional - gap3
sage: [W.simple_root_index(i) for i in W.index_set()] # optional - gap3
[0, 1, 2]
```

`sage.combinat.root_system.reflection_group_real.ReflectionGroup(*args, **kwds)`

Construct a finite (complex or real) reflection group as a Sage permutation group by fetching the permutation representation of the generators from chevie’s database.

**INPUT:**

can be one or multiple of the following:

- a triple \((r, p, n)\) with \(p\) divides \(r\), which denotes the group \(G(r, p, n)\)
- an integer between 4 and 37, which denotes an exceptional irreducible complex reflection group
- a finite Cartan-Killing type

**EXAMPLES:**

Finite reflection groups can be constructed from

Cartan-Killing classification types:

```python
sage: W = ReflectionGroup(['A',3]); W # optional - gap3
Irreducible real reflection group of rank 3 and type A3
sage: W = ReflectionGroup(['H',4]); W # optional - gap3
Irreducible real reflection group of rank 4 and type H4
sage: W = ReflectionGroup(['I',5]); W # optional - gap3
Irreducible real reflection group of rank 2 and type I2(5)
```

the complex infinite family \(G(r, p, n)\) with \(p\) divides \(r\):

```python
sage: W = ReflectionGroup((1,1,4)); W # optional - gap3
Irreducible real reflection group of rank 3 and type A3
sage: W = ReflectionGroup((2,1,3)); W # optional - gap3
Irreducible real reflection group of rank 3 and type B3
```

Chevalley-Shepard-Todd exceptional classification types:

```python
sage: W = ReflectionGroup(23); W # optional - gap3
Irreducible real reflection group of rank 3 and type H3
```

Cartan types and matrices:

```python
sage: ReflectionGroup(CartanType(['A',2])) # optional - gap3
Irreducible real reflection group of rank 2 and type A2
sage: ReflectionGroup(CartanType([('A',2),['A',2]])) # optional - gap3
(continues on next page)```
Reducible real reflection group of rank 4 and type $A_2 \times A_2$

\[
\text{sage: } C = \text{CartanMatrix(} ['A', 2], [\text{'B'}, 2]) \quad \# \text{ optional - gap3}
\]
\[
\text{sage: } \text{ReflectionGroup}(C) \quad \# \text{ optional - gap3}
\]
Irreducible real reflection group of rank 2 and type $A_2$

multiples of the above:

\[
\text{sage: } W = \text{ReflectionGroup(} ['A', 2], [\text{'B'}, 2]) \quad \# \text{ optional - gap3}
\]
Reducible real reflection group of rank 4 and type $A_2 \times B_2$

\[
\text{sage: } W = \text{ReflectionGroup(} ['A', 2], 4) \quad \# \text{ optional - gap3}
\]
Reducible complex reflection group of rank 4 and type $A_2 \times \text{ST}_4$

\[
\text{sage: } W = \text{ReflectionGroup(} (4, 2, 2), 4) \quad \# \text{ optional - gap3}
\]
Reducible complex reflection group of rank 4 and type $G(4, 2, 2) \times \text{ST}_4$

\[
\text{sage.combinat.root_system.reflection_group_real.is_chevie_available()}
\]
Test whether the GAP3 Chevie package is available.

EXAMPLES:

\[
\text{sage: } \text{from sage.combinat.root_system.reflection_group_real import is_chevie_available}
\]
\[
\text{sage: } \text{is_chevie_available()} \quad \# \text{ random}
\]
False
\[
\text{sage: } \text{is_chevie_available()} \text{ in } [\text{True, False}]
\]
True

5.1.234 Group algebras of root lattice realizations

\[
\text{class sage.combinat.root_system.root_lattice_realization_algebras.Algebras(category, *args)}
\]
\[
\text{Bases: sage.categories.algebra_functor.AlgebrasCategory}
\]
The category of group algebras of root lattice realizations.

This includes typically weight rings (group algebras of weight lattices).

\[
\text{class ElementMethods}
\]
\[
\text{Bases: object}
\]
\[
\text{acted_upon}(w)
\]
Implements the action of $w$ on $self$.

INPUT:

• $w$ – an element of the Weyl group acting on the underlying weight lattice realization

EXAMPLES:

\[
\text{sage: } L = \text{RootSystem(} [\text{'A'}, 3]) \text{.ambient_space()}
\]
\[
\text{sage: } W = L \text{.weyl_group()}
\]
\[
\text{sage: } M = L \text{.algebra(QQ[}'q', 't'][})
\]
\[
\text{sage: } m = M \text{.an_element(); m} \quad \# \text{ TODO: investigate why we don't get something more interesting}
\]
B[(2, 2, 3, 0)]
sage: m = (m+1)^2; m
B[(0, 0, 0, 0)] + 2*B[(2, 2, 3, 0)] + B[(4, 4, 6, 0)]
sage: w = W.an_element(); w.reduced_word()
[1, 2, 3]
sage: m.acted_upon(w)
B[(0, 0, 0, 0)] + 2*B[(0, 2, 2, 3)] + B[(0, 4, 4, 6)]

expand(alphabet)
Expand self into variables in the alphabet.

INPUT:
• alphabet – a non empty list/tuple of (invertible) variables in a ring to expand in

EXAMPLES:
sage: L = RootSystem(['A',2]).ambient_lattice()
sage: KL = L.algebra(QQ)
sage: p = KL.an_element() + KL.sum_of_monomials(L.some_elements()); p
B[(1, 0, 0)] + B[(1, -1, 0)] + B[(1, 1, 0)] + 2*B[(2, 2, 3)] + B[(0, 1, -1)]
sage: F = LaurentPolynomialRing(QQ, 'x,y,z')
sage: p.expand(F.gens())
2*x^2*y^2*z^3 + x*y + x + y*z^-1 + x*y^-1

class ParentMethods
Bases: object

T0_check_on_basis(q1, q2, convention='antidominant')
Return the $T_0^\vee$ operator acting on the basis.

This implements the formula for $T_0^\vee$ in Section 6.12 of [Haiman06].

REFERENCES:

Warning: The current implementation probably returns just nonsense, if the convention is not
“dominant”.

EXAMPLES:
sage: K = QQ['q1,q2'].fraction_field()
sage: q1,q2 = K.gens()
sage: L = RootSystem(['A',1,1]).ambient_space()
sage: L0 = L.classical()
sage: KL = L.algebra(K)
sage: some_weights = L0.fundamental_weights()
sage: f = KL.T0_check_on_basis(q1,q2, convention="dominant")
sage: f(L0.zero())
(q1+q2)*B[(0, 0)] + q1*B[(1, -1)]

sage: L = RootSystem(['A',3,1]).ambient_space()
sage: L0 = L.classical()
sage: KL = L.algebra(K)
sage: some_weights = L0.fundamental_weights()
sage: f = KL.T0_check_on_basis(q1,q2, convention="dominant")
sage: f(L0.zero())  # not checked
(q1+q2)*B[(0, 0, 0, 0)] + q1^3/q2^2*B[(1, 0, 0, -1)]

The following results have not been checked:

sage: for x in some_weights:
....:   print("{}": ").format(x, f(x))
(1, 0, 0, 0) : q1*B[(1, 0, 0, 0)]
(1, 1, 0, 0) : q1*B[(1, 1, 0, 0)]
(1, 1, 1, 0) : q1*B[(1, 1, 1, 0)]

Some examples for type $B_2^{(1)}$ dual:

sage: L = RootSystem("B2~*").ambient_space()
sage: L0 = L.classical()
sage: e = L.basis()
sage: K = QQ['q,u'].fraction_field()
sage: q,u = K.gens()
sage: q1 = u
sage: q2 = -1/u
sage: KL = L.algebra(K)
sage: KL0 = KL.classical()
sage: f = KL.T0_check_on_basis(q1,q2, convention="dominant")
sage: T = KL.twisted_demazure_lusztig_operators(q1,q2, convention="dominant")

Direct calculation:

sage: T.Tw(0)(KL0.monomial(L0([0,0])))
((u^2-1)/u)*B[(0, 0)] + u^3*B[(1, 1)]
sage: KL.T0_check_on_basis(q1,q2, convention="dominant")(L0([0,0]))
((u^2-1)/u)*B[(0, 0)] + u^3*B[(1, 1)]

Step by step calculation, comparing by hand with Mark Shimozono:

sage: res = T.Tw(2)(KL0.monomial(L0([0,0]))); res
u*B([0, 0])
sage: res = res * KL0.monomial(L0([-1,1])); res
u*B([-1, 1])
sage: res = T.Tw_inverse(1)(res); res
(u^2-1)*B([0, 0]) + u^2*B([1, -1])
sage: res = T.Tw_inverse(2)(res); res
((u^2-1)/u)*B([0, 0]) + u^3*B([1, 1])

cartan_type()

Return the Cartan type of self.

EXAMPLES:

sage: A = RootSystem(['A',2,1]).ambient_space().algebra(QQ)
sage: A.cartan_type()
['A', 2, 1]
sage: A = RootSystem(['B',2]).weight_space().algebra(QQ)
sage: A.cartan_type()
['B', 2]

classical()
Return the group algebra of the corresponding classical lattice.

EXAMPLES:

sage: KL = RootSystem(["A",2,1]).ambient_space().algebra(QQ)
sage: KL.classical()
Algebra of the Ambient space of the Root system of type ['A', 2] over Rational Field

demazure_lusztig_operator_on_basis(weight, i, q1, q2, convention='antidominant')
Return the result of applying the $i$-th Demazure-Lusztig operator on weight.

INPUT:
• weight – an element $\lambda$ of the weight lattice
• $i$ – an element of the index set
• $q1,q2$ – two elements of the ground ring
• convention – “antidominant”, “bar”, or “dominant” (default: “antidominant”)

See demazure_lusztig_operators() for the details.

EXAMPLES:

sage: L = RootSystem(["A",1]).ambient_space()
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: KL.demazure_lusztig_operator_on_basis(L((2,2)), 1, q1, q2)
q1*B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_basis(L((3,0)), 1, q1, q2)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, q1, q2)
(-q1-q2)*B[(1, 2)] + (-q1-q2)*B[(2, 1)] + (-q2)*B[(3, 0)]

At $q_1 = 1$ and $q_2 = 0$ we recover the action of the isobaric divided differences $\pi_i$:

sage: KL.demazure_lusztig_operator_on_basis(L((2,2)), 1, 1, 0)
B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_basis(L((3,0)), 1, 1, 0)
B[(1, 2)] + B[(2, 1)] + B[(3, 0)] + B[(0, 3)]
sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, 1, 0)
-B[(1, 2)] - B[(2, 1)]

Or $1 - \pi_i$, for bar=True:

sage: KL.demazure_lusztig_operator_on_basis(L((2,2)), 1, 1, 0, convention="bar")

(continues on next page)
sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, 1, 0, convention="bar")
B[(1, 2)] + B[(2, 1)] + B[(0, 3)]

At $q_1 = 1$ and $q_2 = -1$ we recover the action of the simple reflection $s_i$:

sage: KL.demazure_lusztig_operator_on_basis(L((2,2)), 1, 1, -1)
B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_basis(L((3,0)), 1, 1, -1)
B[(0, 3)]
sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, 1, -1)
B[(3, 0)]

demazure_lusztig_operator_on_classical_on_basis(weight, i, q, q1, q2, convention='antidominant')

Return the result of applying the $i$-th Demazure-Lusztig operator on the classical weight $\lambda$ embedded at level 0.

INPUT:
• weight – a classical weight $\lambda$
• i – an element of the index set
• q1, q2 – two elements of the ground ring
• convention – “antidominant”, “bar”, or “dominant” (default: “antidominant”)

See demazure_lusztig_operators() for the details.

Todo:
• Optimize the code to only do the embedding/projection for $T_0$
• Add an option to specify at which level one wants to work. Currently this is level 0.

EXAMPLES:

sage: L = RootSystem(["A",1,1]).ambient_space()
sage: L0 = L.classical()
sage: K = QQ['q,q1,q2']
sage: q, q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: KL0 = L0.algebra(K)

These operators coincide with the usual Demazure-Lusztig operators:

sage: KL.demazure_lusztig_operator_on_classical_on_basis(L0((2,2)), 1, q, q1, q2)
q1*B[(2, 2)]
sage: KL0.demazure_lusztig_operator_on_basis(L0((2,2)), 1, q1, q2)
q1*B[(2, 2)]

sage: KL.demazure_lusztig_operator_on_classical_on_basis(L0((3,0)), 1, q1, q2)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
sage: KL0.demazure_lusztig_operator_on_basis(L0((3,0)), 1, q1, q2)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]

except that we now have an action of $T_0$, which introduces some $q$ s:
demazure_lusztig_operators(q1, q2, convention='antidominant')

Return the Demazure-Lusztig operators acting on self.

INPUT:
- q1, q2 – two elements of the ground ring
- convention – “antidominant”, “bar”, or “dominant” (default: “antidominant”)

If \( R \) is the parent weight ring, the Demazure-Lusztig operator \( T_i \) is the linear map \( R \rightarrow R \) obtained by interpolating between the isobaric divided difference operator \( \pi_i \) (see isobaric_divided_difference_on_basis()) and the simple reflection \( s_i \).

\[
(q_1 + q_2)\pi_i - q_2 s_i
\]

The Demazure-Lusztig operators give the usual representation of the operator \( T_i \) of the (affine) Hecke algebra with eigenvalues \( q_1 \) and \( q_2 \) associated to the Weyl group.

Several variants are available to match with various conventions used in the literature:
- “bar” replaces \( \pi_i \) in the formula above by \( \pi_i = (1 - \pi_i) \).
- “dominant” conjugates the operator by \( x^\lambda \mapsto x^{-\lambda} \).

The names dominant and antidominant for the conventions were chosen with regards to the nonsymmetric Macdonald polynomials. The \( Y \) operators for the Macdonald polynomials in the “dominant” convention satisfy \( Y_\lambda = T_{t_\lambda} \) for \( \lambda \) dominant. This is also the convention used in [Haiman06]. For the “antidominant” convention, \( Y_\lambda = T_{t_\lambda} \) with \( \lambda \) antidominant.

See also:
- demazure_lusztig_operator_on_basis().
- NonSymmetricMacdonaldPolynomials.

REFERENCES:

EXAMPLES:

```
sage: L = RootSystem(['A',1]).ambient_space()
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: T = KL.demazure_lusztig_operators(q1, q2)
sage: Tbar = KL.demazure_lusztig_operators(q1, q2, convention='bar')
sage: Tdominant = KL.demazure_lusztig_operators(q1, q2, convention='dominant')
sage: x = KL.monomial(L((3,0)))
sage: T[1](x)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
sage: Tbar[1](x)
(-q1-q2)*B[(1, 2)] + (-q1-q2)*B[(2, 1)] + (-q1-2*q2)*B[(0, 3)]
sage: Tbar[1](x) + T[1](x)
(q1+q2)*B[(3, 0)] + (-2*q2)*B[(0, 3)]
sage: Tdominant[1](x)
(-q1-q2)*B[(1, 2)] + (-q1-q2)*B[(2, 1)] + (-q2)*B[(0, 3)]
```
We repeat similar computation in the affine setting:

```python
sage: L = RootSystem(['A',2,1]).ambient_space()
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: T = KL.demazure_lusztig_operators(q1, q2)
sage: Tbar = KL.demazure_lusztig_operators(q1, q2, convention="bar")
sage: Tdominant = KL.demazure_lusztig_operators(q1, q2, convention="dominant")
sage: e = L.basis()
sage: x = KL.monomial(3*e[0])
sage: T[1](x)
(q1+q2)*B[e[0] + 2*e[1]] + (q1+q2)*B[2*e[0] + e[1]] + (q1+q2)*B[3*e[0]] - q1*B[3*e[1]]
sage: Tbar[1](x)
(-q1-q2)*B[e[0] + 2*e[1]] + (-q1-q2)*B[2*e[0] + e[1]] + (-q1-2*q2)*B[3*e[1]]
sage: Tbar[1](x) + T[1](x)
(q1+q2)*B[3*e[0]] + (-2*q2)*B[3*e[1]]
sage: Tdominant[1](x)
(-q1-q2)*B[e[0] + 2*e[1]] + (-q1-q2)*B[2*e[0] + e[1]] + (-q2)*B[3*e[1]]
sage: Tdominant.Tw_inverse(1)(KL.monomial(-L.simple_root(1)))
((-q1-q2)/(q1*q2))*B[0] - 1/q2*B[e[0] - e[1]]
```

One can obtain iterated operators by passing a reduced word or an element of the Weyl group:

```python
sage: T[1,2](x)
(q1^2+2*q1*q2+q2^2)*B[e[0] + e[1] + e[2]] + (q1^2+2*q1*q2+q2^2)*B[2*e[0] + 2*e[1]] + (q1^2+2*q1*q2+q2^2)*B[e[0] + 2*e[2]] + (q1^2+2*q1*q2+q2^2)*B[2*e[0] + e[1]] + (q1^2+2*q1*q2+q2^2)*B[e[0] + e[2]] + (q1^2+2*q1*q2+q2^2)*B[3*e[0]] + (q1^2+2*q1*q2+q2^2)*B[3*e[1]] + q1^2*B[3*e[2]]
```

and use that to check, for example, the braid relations:

```python
sage: T[1,2,1](x) - T[2,1,2](x)
0
```

The operators satisfy the relations of the affine Hecke algebra with parameters $q_1, q_2$:

```python
sage: T._test_relations()
sage: Tdominant._test_relations()
sage: Tbar._test_relations() # todo: not implemented: set the appropriate eigenvalues!
```

And the $\bar{T}$ are basically the inverses of the $T$ s:
We check that $\Lambda_1 - \Lambda_0$ is an eigenvector for the $Y$'s in affine type:

```
sage: q1, q2 = K.gens()
sage: L0 = L.classical()
sage: Lambda = L.fundamental_weights()
sage: alphacheck = L0.simple_coroots()
sage: KL = L.algebra(K)
sage: T = KL.demazure_lusztig_operators(q1, q2, convention="dominant")
sage: Y = T.Y()
sage: alphacheck = Y.keys().alpha() # alpha of coroot lattice is alphacheck
sage: alphacheck
Finite family {0: alphacheck[0], 1: alphacheck[1], 2: alphacheck[2]}
sage: x = KL.monomial(Lambda[1]-Lambda[0]); x
B[e[0]]
```

In fact it is not exactly an eigenvector, but the extra ‘delta’ term is to be interpreted as a $q$ parameter:

```
sage: KL.q_project(Y[alphacheck[1]](x), q1)
((-q2^2)/(-q*q1^2))*B[(1, 0, 0)]
sage: KL.q_project(Y[alphacheck[2]](x), q1)
((q1/(-q2))*B[(1, 0, 0)]
```

We now check systematically that the Demazure-Lusztig operators satisfy the relations of the Iwahori-Hecke algebra:

```
sage: for cartan_type in CartanType.samples(crystallographic=True):
    # long...
    ....: L = RootSystem(cartan_type).root_lattice()
    ....: KL = L.algebra(K)
    ....: T = KL.demazure_lusztig_operators(q1, q2)
    ....: T._test_relations()
```

(continues on next page)
sage: for cartan_type in CartanType.samples(crystallographic=True): # long...
˓→time 12s
....:   L = RootSystem(cartan_type).weight_lattice()
....:   KL = L.algebra(K)
....:   T = KL.demazure_lusztig_operators(q1,q2)
....:   T._test_relations()

Recall that the Demazure-Lusztig operators are only defined when all monomials belong to the weight lattice. Thus, in the group algebra of the ambient space, we need to specify explicitly the elements on which to run the tests:

sage: for cartan_type in CartanType.samples(crystallographic=True): # long...
˓→time 12s
....:   L = RootSystem(cartan_type).ambient_space()
....:   KL = L.algebra(K)
....:   weight_lattice = RootSystem(cartan_type).weight_lattice(extended=L.is_extended())
....:   elements = [ KL.monomial(L(weight)) for weight in weight_lattice.some_elements() ]
....:   T = KL.demazure_lusztig_operators(q1,q2)
....:   T._test_relations(elements=elements)

demazure_lusztig_operators_on_classical(q, q1, q2, convention='antidominant')

Return the Demazure-Lusztig operators acting at level 1 on self.classical().

INPUT:

• q, q1, q2 – three elements of the ground ring
• convention – “antidominant”, “bar”, or “dominant” (default: “antidominant”)

Let $KL$ be the group algebra of an affine weight lattice realization $L$. The Demazure-Lusztig operators for $KL$ act on the group algebra of the corresponding classical weight lattice by embedding it at level 1, and projecting back.

See also:

• demazure_lusztig_operators().
• demazure_lusztig_operator_on_classical_on_basis().
• q_project()

EXAMPLES:

sage: L = RootSystem(['A',1,1]).ambient_space()
sage: K = QQ['q,q1,q2'].fraction_field()
sage: q, q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: KL0 = KL.classical()
sage: L0 = KL0.basis().keys()
sage: T = KL.demazure_lusztig_operators_on_classical(q, q1, q2)
sage: x = KL0.monomial(L0((3,0))); x
\B[(3, 0)]

For $T_1, \ldots$ we recover the usual Demazure-Lusztig operators:

sage: T[1](x)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
For $T_0$, we can note that, in the projection, $\delta$ is mapped to $q$:

$$\text{sage: } T[0](x) = (-q^2*q_1-q^2*q_2)*B[(1, 2)] + (-q*q_1-q*q_2)*B[(2, 1)] + (-q^3*q_2)*B[(0, 3)]$$

Note that there is no translation part, and in particular $1$ is an eigenvector for all $T_i$'s:

$$\text{sage: } T[0](KL0.one()) = q_1*B[(0, 0)]$$
$$\text{sage: } T[1](KL0.one()) = q_1*B[(0, 0)]$$

Matching with Ion Bogdan's hand calculations from 3/15/2013:

$$\text{sage: } L = RootSystem(["A",1,1]).weight_space(extended=True)$$
$$\text{sage: } K = QQ['q,u'].fraction_field()$$
$$\text{sage: } q, u = K.gens()$$
$$\text{sage: } KL = L.algebra(K)$$
$$\text{sage: } KL0 = KL.classical()$$
$$\text{sage: } L0 = KL0.basis().keys()$$
$$\text{sage: } omega = L0.fundamental_weights()$$
$$\text{sage: } T = KL.demazure_lusztig_operators_on_classical(q, u, -1/u, convention=˓→"dominant")$$
$$\text{sage: } Y = T.Y()$$
$$\text{sage: } alphacheck = Y.keys().simple_roots()$$
$$\text{sage: } Y[alphacheck[0]](KL0.one()) = ((-q2)/(q*q1))*B[(0, 0)]$$

Note that the following computations use the “dominant” convention:

$$\text{sage: } T0 = T.Tw(0)$$
$$\text{sage: } T0(KL0.monomial(omega[1])) = q*u*B[-Lambda[1]] + ((u^2-1)/u)*B[Lambda[1]]$$

(continues on next page)
demazure_operators()

Return the Demazure operators acting on self.

The $i$-th Demazure operator is defined by:

$$\pi_i = \frac{1 - e^{-\alpha_i}s_i}{1 - e^{-\alpha_i}}$$

It acts on $e^\lambda$, for $\lambda$ a weight, by:

$$\pi_i e^\lambda = \frac{e^\lambda - e^{-\alpha_i + s_i\lambda}}{1 - e^{-\alpha_i}}$$

This matches with Lascoux’ definition [Lascoux2003] of $\pi_i$, and with the $i$-th Demazure operator of [Kumar1987], which also works for general Kac-Moody types.

REFERENCES:

EXAMPLES:

We compute some Schur functions, as images of dominant monomials under the action of the maximal isobaric divided difference $\Delta_{w_0}$:

```sage
sage: L = RootSystem(["A",2]).ambient_lattice()
sage: KL = L.algebra(QQ)
sage: w0 = tuple(L.weyl_group().long_element().reduced_word())
sage: pi = KL.demazure_operators()
sage: pi0 = pi[w0]
sage: pi0(KL.monomial(L((2,1))))
2*B[(1, 1, 1)] + B[(1, 2, 0)] + B[(1, 0, 2)] + B[(2, 1, 0)] + B[(2, 0, 1)] + B[(0, 1, 2)] + B[(0, 2, 1)]
```

Let us make the result into an actual polynomial:

```sage
sage: P = QQ["x,y,z"]
sage: pi0(KL.monomial(L((2,1)))) .expand(P.gens())
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
```

This is indeed a Schur function:

```sage
sage: s = SymmetricFunctions(QQ).s()
sage: s[2,1].expand(3, P.variable_names())
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
```

Let us check this systematically on Schur functions of degree 6:

```sage
sage: for p in Partitions(6, max_length=3).list():
...:     assert s.monomial(p).expand(3, P.variable_names()) == pi0(KL.monomial(L(tuple(p)))).expand(P.gens())
```

We check systematically that these operators satisfy the Iwahori-Hecke algebra relations:
sage: for cartan_type in CartanType.samples(crystallographic=True): # long...
˓→time 12s
....: L = RootSystem(cartan_type).weight_lattice()
....: KL = L.algebra(QQ)
....: T = KL.demazure_operators()
....: T._test_relations()

sage: L = RootSystem(['A',1,1]).weight_lattice()

sage: KL = L.algebra(QQ)

sage: T = KL.demazure_operators()

sage: T._test_relations()

Warning: The Demazure operators are only defined if all the elements in the support have integral scalar products with the coroots (basically, they are in the weight lattice). Otherwise an error is raised:

sage: L = RootSystem(CartanType(['G',2]).dual()).ambient_space()

sage: KL = L.algebra(QQ)

sage: pi = KL.demazure_operators()

sage: pi[1](KL.monomial(L([0,0,1])))
Traceback (most recent call last):
...
ValueError: the weight does not have an integral scalar product with the coroot

divided_difference_on_basis(weight, i)

Return the result of applying the \( i \)-th divided difference on weight.

INPUT:

- weight – a weight
- \( i \) – an element of the index set

Todo: type free definition (Viviane’s definition uses that we are in the ambient space)

EXAMPLES:

sage: L = RootSystem(['A',1]).ambient_space()

sage: KL = L.algebra(QQ)

sage: KL.divided_difference_on_basis(L((2,2)), 1) # todo: not implemented
\[0\]

sage: KL.divided_difference_on_basis(L((3,0)), 1) # todo: not implemented
\[B(2, 0) + B(1, 1) + B(0, 2)\]

sage: KL.divided_difference_on_basis(L((0,3)), 1) # todo: not implemented
\[-B(2, 0) - B(1, 1) - B(0, 2)\]

In type \( A \) and in the ambient lattice, we recover the usual action of divided differences polynomials:

sage: x,y = QQ['x,y'].gens()

sage: d = lambda p: (p - p(y,x)) / (x-y)

sage: d(x^2*y^2)
\[0\]
Combinatorics, Release 9.7

(continued from previous page)

\texttt{sage: d(x^3)}
\texttt{x^2 + x^2y + y^2}
\texttt{sage: d(y^3)}
\texttt{-x^2 - x^2y - y^2}

\textbf{from\_polynomial}(p)

Construct an element of \texttt{self} from a polynomial \(p\).

\textbf{INPUT:}

\begin{itemize}
  \item \(p\) – a polynomial
\end{itemize}

\textbf{EXAMPLES:}

\texttt{sage: L = RootSystem(["A",2]).ambient_lattice()}
\texttt{sage: KL = L.algebra(QQ)}
\texttt{sage: x,y,z = QQ['x,y,z'].gens()}
\texttt{sage: KL.from\_polynomial(x)}
\texttt{B[(1, 0, 0)]}
\texttt{sage: KL.from\_polynomial(x^2*y + 2*y - z)}
\texttt{B[(2, 1, 0)] + 2*B[(0, 1, 0)] - B[(0, 0, 1)]}

\textbf{Todo:} make this work for Laurent polynomials too

\textbf{isobaric\_divided\_difference\_on\_basis}(weight, \(i\))

Return the result of applying the \(i\)-th isobaric divided difference on \(weight\).

\textbf{INPUT:}

\begin{itemize}
  \item \texttt{weight} – a weight
  \item \texttt{\(i\)} – an element of the index set
\end{itemize}

\textbf{See also:}

\texttt{demazure\_operators()}

\textbf{EXAMPLES:}

\texttt{sage: L = RootSystem(["A",1]).ambient\_space()}
\texttt{sage: KL = L.algebra(QQ)}
\texttt{sage: KL.isobaric\_divided\_difference\_on\_basis(L((2,2)), 1)}
\texttt{B[(2, 2)]}
\texttt{sage: KL.isobaric\_divided\_difference\_on\_basis(L((3,0)), 1)}
\texttt{B[(1, 2)] + B[(2, 1)] + B[(3, 0)] + B[(0, 3)]}
\texttt{sage: KL.isobaric\_divided\_difference\_on\_basis(L((0,3)), 1)}
\texttt{-B[(1, 2)] - B[(2, 1)]}

In type \(A\) and in the ambient lattice, we recover the usual action of divided differences on polynomials:

\texttt{sage: x,y = QQ['x,y'].gens()}
\texttt{sage: d = lambda p: (x*p - (x*p)(y,x)) / (x-y)}
\texttt{sage: d(x^2*y^2)}
\texttt{x^2*y^2}
\texttt{sage: d(x^3)}
\texttt{x^3 + x^2y + x*y^2 + y^3}
\texttt{sage: d(y^3)}
\texttt{-x^2y - x*y^2 - y^2}
**REFERENCES:**

**q_project**(x, q)
Implement the $q$-projection morphism from `self` to the group algebra of the classical space.

**INPUT:**
- x – an element of the group algebra of `self`
- q – an element of the ground ring

This is an algebra morphism mapping $\delta$ to $q$ and $X^b$ to its classical counterpart for the other elements $b$ of the basis of the realization.

**EXAMPLES:**

```
sage: K = QQ['q'].fraction_field()
sage: q = K.gen()
sage: KL = RootSystem("A",2,1).ambient_space().algebra(K)
sage: L = KL.basis().keys()
sage: e = L.basis()
sage: KL.q_project(x, q)
B[(2, 2, 3)] + 1/q^2*B[(0, 4, 3)]
```

**Warning:** Recall that the null root, usually denoted $\delta$, is in fact $a[0] \delta$ in Sage’s notation, in order to avoid half integer coefficients (this only makes a difference in type BC). Similarly, what’s usually denoted $q$ is in fact $q^a[0]$ in Sage’s notations, to avoid manipulating square roots:

```
sage: KL.q_project(KL.monomial(L.null_root()),q)
q^2*B[(0, 0, 0)]
```

**q_project_on_basis**(l, q)
Return the monomial $c \cdot cl(l)$ in the group algebra of the classical lattice.

**INPUT:**
- l – an element of the root lattice realization
- q – an element of the ground ring

Here, $cl(l)$ is the projection of $l$ in the classical lattice, and $c$ is the coefficient of $l$ in $\delta$.

**See also:**
- `q_project_on_basis()`

**EXAMPLES:**

...
sage: K = QQ['q'].fraction_field()
sage: q = K.gen()
sage: KL = RootSystem(["A",2,1]).ambient_space().algebra(K)
sage: L = KL.basis().keys()
sage: e = L.basis()
sage: KL.q_project_on_basis( 4*e[1] + 3*e[2] + e['deltacheck'] - 2*e['delta']', q)
1/q^2*B[(0, 4, 3)]

some_elements()

Return some elements of the algebra self.

EXAMPLES:

sage: A = RootSystem(["A",2,1]).ambient_space().algebra(QQ)
sage: A.some_elements()
 B[-e[0] + e[2] + e['delta']],
 B[e[0] - e[1]],
 B[e[1] - e[2]],
 B[e['deltacheck']],
 B[e[0] + e['deltacheck']],
 B[e[0] + e[1] + e['deltacheck']]]

sage: A = RootSystem(["B",2]).weight_space().algebra(QQ)
sage: A.some_elements()
 B[-Lambda[1] + 2*Lambda[2]],
 B[0],
 B[2*Lambda[2]]]

twisted_demazure_lusztig_operator_on_basis(weight, i, q1, q2, convention='antidominant')

Return the twisted Demazure-Lusztig operator acting on the basis.

INPUT:
• weight – an element $\lambda$ of the weight lattice
• i – an element of the index set
• q1,q2 – two elements of the ground ring
• convention – “antidominant”, “bar”, or “dominant” (default: “antidominant”)

See also:
twisted_demazure_lusztig_operators()

EXAMPLES:

sage: L = RootSystem(["A",3,1]).ambient_space()
sage: e = L.basis()
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: Lambda = L.classical().fundamental_weights()
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1]+2*Lambda[2],
 -1, q1, q2, convention="dominant")
(-q2)*B[(2, 3, 0, 0)]
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1]+2*Lambda[2], q1=-2, q2, convention="dominant")
(-q1-q2)*B[(3, 1, 1, 0)] + (-q2)*B[(3, 0, 2, 0)]
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1]+2*Lambda[2], q1=-3, q2, convention="dominant")
q1*B[(3, 2, 0, 0)]
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1]+2*Lambda[2], q1=0, q2, convention="dominant")
((q1*q2+q2^2)/q1)*B[(1, 2, 0, 2)] + ((q1*q2+q2^2)/q1)*B[(1, 2, 1, 1)] + ((q1*q2+q2^2)/q1)*B[(2, 1, 0, 2)] + ((q1*q2+q2^2)/q1)*B[(2, 1, 1, 0)] + ((q1*q2+q2^2)/q1)*B[(2, 0, 1, 1)] + ((q1*q2+q2^2)/q1)*B[(2, 0, 2, 0)]

**twisted_demazure_lusztig_operators** *(q1, q2, convention='antidominant')*

Return the twisted Demazure-Lusztig operators acting on self.

**INPUT:**
- q1, q2 -- two elements of the ground ring
- convention -- “antidominant”, “bar”, or “dominant” (default: “antidominant”)

**Warning:**
- the code is currently only tested for \( q_1 q_2 = -1 \)
- only the “dominant” convention is functional for \( i = 0 \)

For \( T_1, \ldots, T_n \), these operators are the usual Demazure-Lusztig operators. On the other hand, the operator \( T_0 \) is twisted:

```
sage: L = RootSystem(['A',3,1]).ambient_space()
sage: e = L.basis()
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: T = KL.twisted_demazure_lusztig_operators(q1, q2, convention="dominant")
```

**Todo:** Choose a good set of Cartan Type to run on. Rank >4 is too big. But \( C_1 \) and \( B_1 \) are boring.

We now check systematically that those operators satisfy the relations of the Iwahori-Hecke algebra:

```
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: for cartan_type in CartanType.samples(affine=True, crystallographic=True): # long time 12s
.....:     if cartan_type.rank() > 4: continue
.....:     if cartan_type.type() == 'BC': continue
.....:     KL = RootSystem(cartan_type).weight_lattice().algebra(K)
```

(continues on next page)
Todo: Investigate why $T_0$ currently does not satisfy the quadratic relation in type $BC$. This should hopefully be fixed when $T_0$ will have a more uniform implementation:

```python
sage: cartan_type = CartanType(['BC',1,2])
sage: KL = RootSystem(cartan_type).weight_lattice().algebra(K)
sage: T = KL.twisted_demazure_lusztig_operators(q1,q2, convention="dominant")
sage: T._test_relations()
Traceback (most recent call last):
... testerassertTrue(Ti(Ti(x,i,-q2),i,-q1).is_zero()) ...
AssertionError: False is not true
```

Comparison with $T_0$:

```python
sage: L = RootSystem(['A',2,1]).ambient_space()
sage: e = L.basis()
sage: K = QQ['t,q'].fraction_field()
sage: t,q = K.gens()
sage: q1 = t
sage: q2 = -1
sage: KL = L.algebra(K)
sage: L0 = L.classical()
sage: T = KL.demazure_lusztig_operators(q1,q2, convention="dominant")
sage: def T0(*l0):
    return KL.q_project(T[0].on_basis()(L.embed_at_level(L0(l0), 1)), q)
sage: T0_check_on_basis = KL.T0_check_on_basis(q1, q2, convention="dominant")
sage: def T0c(*l0):
    return T0_check_on_basis(L0(l0))
sage: T0(0,0,1)  # not double checked
((-t+1)/q)*B[(1, 0, 0)] + 1/q^2*B[(2, 0, -1)]
sage: T0c(0,0,1)
(t^2-t)*B[(1, 0, 0)] + (t^2-t)*B[(1, 1, -1)] + t^2*B[(2, 0, -1)] + (t-1)*B[(0, 0, 1)]
```

### 5.1.235 Root lattice realizations

```python
class sage.combinat.root_system.root_lattice_realizations.RootLatticeRealizations(base, name=None)

Bases: sage.categories.category_types.Category_over_base_ring
```

The category of root lattice realizations over a given base ring

A root lattice realization $L$ over a base ring $R$ is a free module (or vector space if $R$ is a field) endowed with an embedding of the root lattice of some root system.
Typical root lattice realizations over \( \mathbb{Z} \) include the root lattice, weight lattice, and ambient lattice. Typical root lattice realizations over \( \mathbb{Q} \) include the root space, weight space, and ambient space.

To describe the embedding, a root lattice realization must implement a method `simple_root()` returning for each \( i \) in the index set the image of the simple root \( \alpha_i \) under the embedding.

A root lattice realization must further implement a method on elements `scalar()`, computing the scalar product with elements of the coroot lattice or coroot space.

Using those, this category provides tools for reflections, roots, the Weyl group and its action, …

See also:

- `RootSystem`
- `WeightLatticeRealizations`
- `RootSpace`
- `WeightSpace`
- `AmbientSpace`

EXAMPLES:

Here, we consider the root system of type \( A_7 \), and embed the root lattice element \( x = \alpha_2 + 2\alpha_6 \) in several root lattice realizations:

```python
sage: R = RootSystem(['A',7])
sage: alpha = R.root_lattice().simple_roots()
sage: L = R.root_space()
sage: L(x)
sage: L = R.weight_lattice()
sage: L(x)
sage: L = R.ambient_space()
sage: L(x)
(0, 1, -1, 0, 2, -2, 0, 0)
```

We embed the root space element \( x = \alpha_2 + 1/2\alpha_6 \) in several root lattice realizations:

```python
sage: alpha = R.root_space().simple_roots()
sage: L = R.weight_space()
sage: L(x)
sage: L = R.ambient_space()
sage: L(x)
(0, 1, -1, 0, 1/2, -1/2, 0, 0)
```

Of course, one can’t embed the root space in the weight lattice:
If $K_1$ is a subring of $K_2$, then one could in theory have an embedding from the root space over $K_1$ to any root lattice realization over $K_2$; this is not implemented:

```
sage: K1 = QQ
sage: K2 = QQ['q']
sage: L = R.weight_space(K2)
sage: alpha = R.root_space(K2).simple_roots()
sage: L(alpha[1])
sage: alpha = R.root_space(K1).simple_roots()
sage: L(alpha[1])
Traceback (most recent call last):
  ... TypeError: do not know how to make x (= alpha[1]) an element of self (=Weight space over the Univariate Polynomial Ring in q over Rational Field of the Root system of type ['A', 7])
```

By a slight abuse, the embedding of the root lattice is not actually required to be faithful. Typically for an affine root system, the null root of the root lattice is killed in the non extended weight lattice:

```
sage: R = RootSystem(['A', 3, 1])
sage: delta = R.root_lattice().null_root()
sage: L = R.weight_lattice()
sage: L(delta)
0
```

Algebras

alias of sage.combinat.root_system.root_lattice_realization_algebras.Algebras

class ElementMethods

Bases: object

affine_orbit()

The orbit of self under the dot or affine action of the Weyl group.

EXAMPLES:

```
sage: L = RootSystem(['A', 2]).ambient_lattice()
sage: sorted(L.rho().dot_orbit())
# the output order is not specified
[-2, 1, 4], (-2, 3, 2), (2, -1, 2),
(2, 1, 0), (0, -1, 4), (0, 3, 0)]
sage: L = RootSystem(['B',2]).weight_lattice()
sage: sorted(L.fundamental_weights()[1].dot_orbit())
# the output order is not specified
```
(continues on next page)
We compare the dot action orbit to the regular orbit:

```
sage: L = RootSystem(['A', 3]).weight_lattice()
sage: len(L.rho().dot_orbit())
24
sage: len((-L.rho()).dot_orbit())
1
sage: La = L.fundamental_weights()
sage: len(La[1].dot_orbit())
24
sage: len(La[1].orbit())
4
sage: len((-L.rho() + La[1]).dot_orbit())
4
sage: len(La[2].dot_orbit())
24
sage: len(La[2].orbit())
6
sage: len((-L.rho() + La[2]).dot_orbit())
6
```

associated_coroot()

Returns the coroot associated to this root

EXAMPLES:

```
sage: alpha = RootSystem(['A', 3]).root_space().simple_roots()
sage: alpha[1].associated_coroot()
alphacheck[1]
```

associated_reflection()

Given a positive root self, returns a reduced word for the reflection orthogonal to self.

Since the answer is cached, it is a tuple instead of a list.

EXAMPLES:

```
sage: RootSystem(['C',3]).root_lattice().simple_root(3).weyl_action([1,2]).
˓→associated_reflection()
(1, 2, 3, 2, 1)
sage: RootSystem(['C',3]).root_lattice().simple_root(2).associated_
˓→reflection()
(2,)
```

descents(index_set=None, positive=False)

Returns the descents of pt

EXAMPLES:
dot_action(w, inverse=False)
Act on self by w using the dot or affine action.

Let \( w \) be an element of the Weyl group. The dot action or affine action is given by:

\[
\omega \cdot \lambda = w(\lambda + \rho) - \rho,
\]

where \( \rho \) is the sum of the fundamental weights.

INPUT:
• \( w \) – an element of a Coxeter or Weyl group of the same Cartan type, or a tuple or a list (such as a reduced word) of elements from the index set
• \( \text{inverse} \) – a boolean (default: False); whether to act by the inverse element

EXAMPLES:

```
sage: P = RootSystem(['B', 3]).weight_lattice()
sage: La = P.fundamental_weights()
sage: mu.dot_action([1])
sage: mu.dot_action([3])
Lambda[1] + Lambda[3]
sage: mu.dot_action([1,2,3])
```

We check that the origin of this action is at \(-\rho\):

```
sage: all((-P.rho()).dot_action([i]) == -P.rho() for i in P.index_set())
True
```

REFERENCES:
• Wikipedia article Affine_action

dot_orbit()
The orbit of self under the dot or affine action of the Weyl group.

EXAMPLES:

```
sage: L = RootSystem(['A', 2]).ambient_lattice()
sage: sorted(L.rho().dot_orbit())  # the output order is not specified
[(-2, 1, 4), (-2, 3, 2), (2, -1, 2), (2, 1, 0), (0, -1, 4), (0, 3, 0)]
sage: L = RootSystem(['B',2]).weight_lattice()
sage: sorted(L.fundamental_weights()[1].dot_orbit())  # the output order is not specified
```
We compare the dot action orbit to the regular orbit:

```python
sage: L = RootSystem(['A', 3]).weight_lattice()
sage: len(L.rho().dot_orbit())
24
sage: len((-L.rho()).dot_orbit())
1
sage: La = L.fundamental_weights()
sage: len(La[1].dot_orbit())
24
sage: len(La[1].orbit())
4
sage: len((-L.rho() + La[1]).dot_orbit())
4
sage: len(La[2].dot_orbit())
24
sage: len(La[2].orbit())
6
sage: len((-L.rho() + La[2]).dot_orbit())
6
```

**extraspecial_pair()**
Return the extraspecial pair of self under the ordering defined by `positive_roots_by_height()`.

The *extraspecial pair* of a positive root \( \gamma \) with some total ordering \(<\) of the root lattice that respects height is the pair of positive roots \((\alpha, \beta)\) such that \( \gamma = \alpha + \beta \) and \( \alpha \) is as small as possible.

**EXAMPLES:**

```python
sage: Q = RootSystem(['G', 2]).root_lattice()
sage: Q.highest_root().extraspecial_pair()
(alpha[2], 3*alpha[1] + alpha[2])
```

**first_descent**(index_set=None, positive=False)
Returns the first descent of pt

One can use the index_set option to restrict to the parabolic subgroup indexed by index_set.

**EXAMPLES:**

```python
sage: space=RootSystem(['A',5]).weight_space()
sage: alpha=space.simple_roots()
3
sage: (alpha[1]+alpha[2]+alpha[4]).first_descent([1,2,5])
5
sage: (alpha[1]+alpha[2]+alpha[4]).first_descent([1,2,5,3,4])
5
```

**greater()**
Returns the elements in the orbit of self which are greater than self in the weak order.

**EXAMPLES:**
sage: L = RootSystem(['A',3]).ambient_lattice()
sage: e = L.basis()
sage: e[2].greater()
[(0, 0, 1, 0), (0, 0, 0, 1)]
sage: len(L.rho().greater())
24
sage: len((-L.rho()).greater())
1
sage: sorted([len(x.greater()) for x in L.rho().orbit()])
[1, 2, 2, 2, 3, 3, 3, 4, 4, 4, 5, 5, 6, 6, 6, 8, 8, 8, 8, 12, 12, 12, 24]

**has_descent**(*i, positive=False*)

Test if self has a descent at position *i*, that is if self is on the strict negative side of the *i*th simple reflection hyperplane.

If positive if True, tests if it is on the strict positive side instead.

**EXAMPLES:**

sage: space=RootSystem(['A',5]).weight_space()
sage: alpha=RootSystem(['A',5]).weight_space().simple_roots()
sage: [alpha[i].has_descent(1) for i in space.index_set()]
[False, True, False, False, False]
sage: [(-alpha[i]).has_descent(1) for i in space.index_set()]
[True, False, False, False, False]
sage: [alpha[i].has_descent(1, True) for i in space.index_set()]
[True, False, False, False, False]
sage: [(-alpha[i]).has_descent(1, True) for i in space.index_set()]
[False, True, False, False, False]
True
False
sage: (alpha[1]+alpha[2]+alpha[4]).has_descent(1, True)
True

**height**()

Return the height of self.

The height of a root \( \alpha = \sum_i a_i \alpha_i \) is defined to be \( h(\alpha) := \sum_i a_i \).

**EXAMPLES:**

sage: Q = RootSystem(['G', 2]).root_lattice()
sage: Q.highest_root().height()
5

**is_dominant**(*index_set=None, positive=True*)

Returns whether self is dominant.

This is done with respect to the subrootsystem indicated by the subset of Dynkin nodes index_set. If index_set is None then the entire Dynkin node set is used. If positive is False then the dominance condition is replaced by antidominance.

**EXAMPLES:**
sage: L = RootSystem(['A',2]).ambient_lattice()
sage: Lambda = L.fundamental_weights()
sage: [x.is_dominant() for x in Lambda]
[True, True]
sage: [x.is_dominant(positive=False) for x in Lambda]
[False, False]
sage: (Lambda[1]-Lambda[2]).is_dominant()
False
sage: (-Lambda[1]+Lambda[2]).is_dominant()
False
sage: (Lambda[1]-Lambda[2]).is_dominant([1])
True
sage: (Lambda[1]-Lambda[2]).is_dominant([2])
False
sage: [x.is_dominant() for x in L.roots()]
[False, True, False, False, False, False]
sage: [x.is_dominant(positive=False) for x in L.roots()]
[False, False, False, False, True, False]

is_dominant_weight()
Test whether self is a dominant element of the weight lattice.

EXAMPLES:

Tests that the scalar products with the coroots are all nonnegative integers. For example, if $x$ is the sum of a dominant element of the weight lattice plus some other element orthogonal to all coroots, then the implementation correctly reports $x$ to be a dominant weight:

sage: x = Lambda[1] + L([-1,-1,-1])
sage: x.is_dominant_weight()
True

is_imaginary_root()
Return True if self is an imaginary root.

A root $\alpha$ is imaginary if it is not $W$ conjugate to a simple root where $W$ is the corresponding Weyl group.

EXAMPLES:

sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_imaginary_root()
False
(continues on next page)
sage: elt.is_imaginary_root()
True

is_long_root()
Return True if self is a long (real) root.

EXAMPLES:

sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_long_root()
True
sage: alpha[1].is_long_root()
True
sage: alpha[2].is_long_root()
False

is_parabolic_root(index_set)
Supposing that self is a root, is it in the parabolic subsystem with Dynkin nodes index_set?

INPUT:
* index_set – the Dynkin node set of the parabolic subsystem.

Todo: This implementation is only valid in the root or weight lattice

EXAMPLES:

sage: alpha = RootSystem(['A',3]).root_lattice().from_vector(vector([1,1,˓→0]))
sage: alpha.is_parabolic_root([1,3])
False
sage: alpha.is_parabolic_root([1,2])
True
sage: alpha.is_parabolic_root([2])
False

is_real_root()
Return True if self is a real root.

A root $\alpha$ is real if it is $W$ conjugate to a simple root where $W$ is the corresponding Weyl group.

EXAMPLES:

sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_real_root()
True
sage: elt.is_real_root()
False

is_short_root()
Return True if self is a short (real) root.
Returns False unless the parent is an irreducible root system of finite type having two root lengths and self is of the shorter length. There is no check of whether self is actually a root.

EXAMPLES:

```
sage: Q = RootSystem(['C',2]).root_lattice()
sage: al = Q.simple_root(1).weyl_action([1,2]); al
sage: al.is_short_root()
True
sage: bt = Q.simple_root(2).weyl_action([2,1,2]); bt
sage: bt.is_short_root()
False
sage: RootSystem(['A',2]).root_lattice().simple_root(1).is_short_root()
False
```

An example in affine type:

```
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_short_root()
False
sage: alpha[1].is_short_root()
False
sage: alpha[2].is_short_root()
True
```

**level()**

EXAMPLES:

```
sage: L = RootSystem(['A',2,1]).weight_lattice()
sage: L.rho().level()
3
```

**norm_squared()**

Return the norm squared of self with respect to the symmetric form.

EXAMPLES:

```
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[1].norm_squared()
4
sage: alpha[2].norm_squared()
2
sage: elt.norm_squared()
50
sage: elt.norm_squared()
0
sage: Q = RootSystem(CartanType(['A',4,2]).dual()).root_lattice()
sage: Qc = RootSystem(['A',4,2]).coroot_lattice()
sage: alpha = Q.simple_roots()
```

(continues on next page)
sage: alphac = Qc.simple_roots()
sage: elt.norm_squared()
0
sage: eltc.norm_squared()
0

orbit()
The orbit of self under the action of the Weyl group.

EXAMPLES:

\( \rho \) is a regular element whose orbit is in bijection with the Weyl group. In particular, it has 6 elements for the symmetric group \( S_3 \):

sage: L = RootSystem(['A', 2]).ambient_lattice()
sage: sorted(L.rho().orbit())
[(1, 2, 0), (1, 0, 2), (2, 1, 0), (2, 0, 1), (0, 1, 2), (0, 2, 1)]
sage: L = RootSystem(['A', 3]).weight_lattice()
sage: len(L.rho().orbit())
24
sage: len(L.fundamental_weights()[1].orbit())
4
sage: len(L.fundamental_weights()[2].orbit())
6

pred(index_set=None)
Return the immediate predecessors of self for the weak order.

INPUT:

- index_set - a subset (as a list or iterable) of the nodes of the Dynkin diagram; (default: None for all of them)

If index_set is specified, the successors for the corresponding parabolic subsystem are returned.

EXAMPLES:

sage: L = RootSystem(['A', 3]).weight_lattice()
sage: Lambda = L.fundamental_weights()
sage: Lambda[1].pred()
[]
sage: L.rho().pred()
[]
sage: (-L.rho()).pred()
sage: (-L.rho()).pred(index_set=[1])

reduced_word(index_set=None, positive=True)
Returns a reduced word for the inverse of the shortest Weyl group element that sends the vector self into the dominant chamber.

5.1. Comprehensive Module List 2421
With the \texttt{index\_set} optional parameter, this is done with respect to the corresponding parabolic subgroup.

If \texttt{positive} is False, use the antidominant chamber instead.

**EXAMPLES:**

```python
sage: space=RootSystem(['A',5]).weight_space()
sage: alpha=RootSystem(['A',5]).weight_space().simple_roots()
sage: alpha[1].reduced_word()
[2, 3, 4, 5]
sage: alpha[1].reduced_word([1,2])
[2]
```

\texttt{reflection}(\texttt{root}, \texttt{use\_coroot=False})

Reflects \texttt{self} across the hyperplane orthogonal to \texttt{root}.

If \texttt{use\_coroot} is True, \texttt{root} is interpreted as a coroot.

**EXAMPLES:**

```python
sage: R = RootSystem(['C',4])
sage: weight_lattice = R.weight_lattice()
sage: mu = weight_lattice.from_vector(vector([0,0,1,2]))
sage: coroot_lattice = R.coroot_lattice()
sage: alphavee = coroot_lattice.from_vector(vector([0,0,1,1]))
sage: mu.reflection(alphavee, use_coroot=True)
sage: root_lattice = R.root_lattice()
sage: beta = root_lattice.from_vector(vector([0,1,1,0]))
sage: mu.reflection(beta)
```

\texttt{scalar}(\texttt{lambdacheck})

Implement the natural pairing with the coroot lattice.

**INPUT:**

- \texttt{self} – an element of a root lattice realization
- \texttt{lambdacheck} – an element of the coroot lattice or coroot space

**OUTPUT:** the scalar product of \texttt{self} and \texttt{lambdacheck}

**EXAMPLES:**

```python
sage: L = RootSystem(['A',4]).root_lattice()
sage: alpha = L.simple_roots()
sage: alphacheck = L.simple_coroots()
sage: alpha[1].scalar(alphacheck[1])
2
sage: alpha[1].scalar(alphacheck[2])
-1
sage: matrix([[ alpha[i].scalar(alphacheck[j])
            ....: for i in L.index_set() ]
            ....: for j in L.index_set()])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -1]
[ 0  0 -1  2]
```
simple_reflection(i)
Returns the image of self by the i-th simple reflection.

EXAMPLES:

```
sage: alpha = RootSystem(['A', 3]).root_lattice().alpha()
sage: alpha[1].simple_reflection(2)
sage: Q = RootSystem(['A', 3, 1]).weight_lattice(extended = True)
sage: Lambda = Q.fundamental_weights()
sage: L = Lambda[0] + Q.null_root()
sage: L.simple_reflection(0)
-Lambda[0] + Lambda[1] + Lambda[3]
```

simple_reflections()
The images of self by all the simple reflections

EXAMPLES:

```
sage: alpha = RootSystem(['A', 3]).root_lattice().alpha()
sage: alpha[1].simple_reflections()
[-alpha[1], alpha[1] + alpha[2], alpha[1]]
```

smaller()
Returns the elements in the orbit of self which are smaller than self in the weak order.

EXAMPLES:

```
sage: L = RootSystem(['A',3]).ambient_lattice()
sage: e = L.basis()
sage: e[2].smaller()
[(0, 0, 1, 0), (0, 1, 0, 0), (1, 0, 0, 0)]
sage: len(L.rho().smaller())
1
sage: len((-L.rho()).smaller())
24
sage: sorted([len(x.smaller()) for x in L.rho().orbit()])
[1, 2, 2, 2, 3, 3, 3, 3, 4, 4, 4, 5, 5, 6, 6, 6, 8, 8, 8, 8, 12, 12, 12, 24]
```

succ(index_set=None)
Return the immediate successors of self for the weak order.

INPUT:

- `index_set` - a subset (as a list or iterable) of the nodes of the Dynkin diagram; (default: None for all of them)

If `index_set` is specified, the successors for the corresponding parabolic subsystem are returned.

EXAMPLES:

```
sage: L = RootSystem(['A',3]).weight_lattice()
sage: Lambda = L.fundamental_weights()
sage: Lambda[1].succ()
[-Lambda[1] + Lambda[2]]
sage: L.rho().succ()
```

(continues on next page)
symmetric_form(alpha)
Return the symmetric form of self with alpha.

Consider the simple roots $\alpha_i$ and let $(b_{ij})_{ij}$ denote the symmetrized Cartan matrix $(a_{ij})_{ij}$, we have

$$(\alpha_i|\alpha_j) = b_{ij}$$

and extended bilinearly. See Chapter 6 in Kac, Infinite Dimensional Lie Algebras for more details.

EXAMPLES:

```python
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[1].symmetric_form(alpha[0])
0
sage: alpha[1].symmetric_form(alpha[1])
4
sage: elt.symmetric_form(alpha[1])
-14
sage: elt.symmetric_form(alpha[0]+2*alpha[2])
14
```

```python
sage: Qc = RootSystem(['A',4,2]).coroot_lattice()
sage: alpha = Q.simple_roots()
sage: alphac = Qc.simple_roots()
sage: elt.symmetric_form(alphac[1])
0
sage: eltc.symmetric_form(alphac[1])
0
```

to_ambient()
Map self to the ambient space.

EXAMPLES:

```python
sage: alpha = CartanType(['B',4]).root_system().root_lattice().an_element();
˓→ alpha
sage: alpha.to_ambient()
(2, 0, 1, -3)
sage: mu = CartanType(['B',4]).root_system().weight_lattice().an_element();
˓→ mu
sage: mu.to_ambient()
```

(continues on next page)
(continued from previous page)

```python
(7, 5, 3, 0)
sage: v = CartanType([\'B\', 4]).root_system().ambient_space().an_element(); v
(2, 2, 3, 0)
sage: v.to_ambient()
(2, 2, 3, 0)
sage: alphavee = CartanType([\'B\', 4]).root_system().coroot_lattice().an_element(); alphavee
sage: alphavee.to_ambient()
(2, 0, 1, -3)
```

### `to_classical()`

Map `self` to the classical lattice/space.

Only makes sense for affine type.

**EXAMPLES:**

```python
sage: R = CartanType([\'A\', 3, 1]).root_system()
sage: alpha = R.root_lattice().an_element(); alpha
sage: alb = alpha.to_classical(); alb
sage: alb.parent()
Root lattice of the Root system of type [\'A\', 3]
sage: v = R.ambient_space().an_element(); v
2*e[0] + 2*e[1] + 3*e[2]
sage: v.to_classical()
(2, 2, 3, 0)
```

### `to_dominant_chamber`(index_set=None, positive=True, reduced_word=False)

Returns the unique dominant element in the Weyl group orbit of the vector `self`.

If `positive` is False, returns the antidominant orbit element.

With the `index_set` optional parameter, this is done with respect to the corresponding parabolic subgroup.

If `reduced_word` is True, returns the 2-tuple (`weight`, `direction`) where `weight` is the (anti)dominant orbit element and `direction` is a reduced word for the Weyl group element sending `weight` to `self`.

**Warning:** In infinite type, an orbit may not contain a dominant element. In this case the function may go into an infinite loop.

For affine root systems, errors are generated if the orbit does not contain the requested kind of representative. If the input vector is of positive (resp. negative) level, then there is a dominant (resp. antidominant) element in its orbit but not an antidominant (resp. dominant) one. If the vector is of level zero, then there are neither dominant nor antidominant orbit representatives, except for multiples of the null root, which are themselves both dominant and antidominant orbit representatives.

**EXAMPLES:**
sage: space=RootSystem(['A',5]).weight_space()
sage: alpha=RootSystem(['A',5]).weight_space().simple_roots()
sage: alpha[1].to_dominant_chamber()
sage: alpha[1].to_dominant_chamber([1,2])
sage: wl=RootSystem(['A',2,1]).weight_lattice(extended=True)
sage: mu=wl.from_vector(vector([1,-3,0]))
sage: mu.to_dominant_chamber(positive=False, reduced_word=True)
(-Lambda[1] - Lambda[2] - delta, [0, 2])
sage: R = RootSystem(['A',1,1])
sage: rl = R.root_lattice()
sage: nu = rl.zero()
sage: nu.to_dominant_chamber()
0
sage: nu.to_dominant_chamber(positive=False)
0
sage: mu = rl.from_vector(vector([0,1]))
sage: mu.to_dominant_chamber()
Traceback (most recent call last):
... ValueError: alpha[1] is not in the orbit of the fundamental chamber
sage: mu.to_dominant_chamber(positive=False)
Traceback (most recent call last):
... ValueError: alpha[1] is not in the orbit of the negative of the fundamental chamber

to_dual_type_cospace()
Map self to the dual type cospace.

For example, if self is in the root lattice of type ['B', 2], send it to the coroot lattice of type ['C', 2].

EXAMPLES:

sage: v = CartanType(['C',3]).root_system().weight_lattice().an_element(); v
sage: w = v.to_dual_type_cospace(); w
sage: w.parent()
Coweight lattice of the Root system of type ['B', 3]

to_simple_root(reduced_word=False)
Return (the index of) a simple root in the orbit of the positive root self.

INPUT:
• self – a positive root
• reduced_word – a boolean (default: False)

OUTPUT:
• The index i of a simple root \( \alpha_i \). If reduced_word is True, this returns instead a pair \( (i, \text{word}) \), where word is a sequence of reflections mapping \( \alpha_i \) up the root poset to self.

EXAMPLES:
sage: L = RootSystem(['A',3]).root_lattice()
sage: positive_roots = L.positive_roots()
sage: for alpha in sorted(positive_roots):
    ....:     print("{} {}".format(alpha, alpha.to_simple_root()))
alpha[1] 1
alpha[2] 2
alpha[3] 3
sage: for alpha in sorted(positive_roots):
    ....:     print("{} {}".format(alpha, alpha.to_simple_root(reduced_word=True)))
alpha[1] (1, ())
alpha[2] (2, ())
alpha[3] (3, ())

ALGORITHM:
This method walks from self down to the antidominant chamber by applying successively the simple reflection given by the first descent. Since self is a positive root, each step goes down the root poset, and one must eventually cross a simple root $\alpha_i$.

See also:
• first_descent()
• to_dominant_chamber()

Warning: The behavior is not specified if the input is not a positive root. For a finite root system, this is currently caught (albeit with a not perfect message):
sage: alpha = L.simple_roots()
sage: (2*alpha[1]).to_simple_root()
Traceback (most recent call last):

For an infinite root system, this method may run into an infinite recursion if the input is not a positive root.

translation($x$)

INPUT:
• self - an element $t$ at level 0
• $x$ - an element of the same space

Returns $x$ translated by $t$, that is $x + \text{level}(x)t$

EXAMPLES:
sage: L = RootSystem(['A',2,1]).weight_lattice()
sage: alpha = L.simple_roots()
Let us look at the translation of an element of level 1:

```python
sage: Lambda[1].level()
1
sage: t.translation(Lambda[1])
-Lambda[0] + 2*Lambda[2]
sage: Lambda[1] + t
-Lambda[0] + 2*Lambda[2]
```

and of an element of level 0:

```python
sage: alpha[1].level()
0
sage: t.translation(alpha[1])
sage: alpha[1] + 0*t
```

The arguments are given in this seemingly unnatural order to make it easy to construct the translation function:

```python
sage: f = t.translation
sage: f(Lambda[1])
-Lambda[0] + 2*Lambda[2]
```

The function `weyl_action(element, inverse=False)`

Act on `self` by an element of the Coxeter or Weyl group.

**INPUT:**

- `element` – an element of a Coxeter or Weyl group of the same Cartan type, or a tuple or a list
  (such as a reduced word) of elements from the index set
- `inverse` – a boolean (default: `False`); whether to act by the inverse element

**EXAMPLES:**

```python
sage: wl = RootSystem(['A',3]).weight_lattice()
sage: mu = wl.from_vector(vector([1,0,-2]))
sage: mu
sage: mu.translation, rw = mu.to_dominant_chamber(positive=False, reduced_word=True)
sage: mu.translation, rw
(-Lambda[2] - Lambda[3], [1, 2])
```

Acting by a (reduced) word:

```python
sage: mu.translation.weyl_action(rw)
sage: mu.translation.weyl_action(rw, inverse = True)
```
Acting by an element of the Coxeter or Weyl group on a vector in its own lattice of definition (implemented by matrix multiplication on a vector):

```sage
w = wl.weyl_group().from_reduced_word([1, 2])
sage: mudom.weyl_action(w)
```

Acting by an element of an isomorphic Coxeter or Weyl group (implemented by the action of a corresponding reduced word):

```sage
W = WeylGroup(['A',3], prefix='s')
w = W.from_reduced_word([1, 2])
sage: wl.weyl_group() == W
False
sage: mudom.weyl_action(w)
```

**weyl_stabilizer(**index_set=None**)**

Returns the subset of Dynkin nodes whose reflections fix `self`.

If `index_set` is not None, only consider nodes in this set. Note that if `self` is dominant or antiodominant, then its stabilizer is the parabolic subgroup defined by the returned node set.

**EXAMPLES:**

```sage
wl = RootSystem(['A',2,1]).weight_lattice(extended = True)
w = wl.null_root()
w = wl.weyl_group()([0, 1, 2])
w = RootSystem(['A',4]).weight_lattice()
mu = wl.from_vector(vector([1,1,0,0]))
mu = mu.weyl_stabilizer()
mu = mu.weyl_stabilizer(index_set = [1,2,3])
mu.weyl_stabilizer(index_set = [1,2,3])
```

**class ParentMethods**

Bases: object

**a_long_simple_root()**

Returns a long simple root, corresponding to the highest outgoing edge in the Dynkin diagram.

Caveat: this may be break in affine type $A^{(2)}_n$

Caveat: meaningful/broken for non irreducible?

TODO: implement CartanType.nodes_by_length as in MuPAD-Combinat (using CartanType.symmetrizer), and use it here.

**almost_positive_roots()**

Returns the almost positive roots of `self`

These are the positive roots together with the simple negative roots.

**See also:**

almost_positive_root_decomposition(), tau_plus_minus()

**EXAMPLES:**
almost_positive_roots_decomposition()

Returns the decomposition of the almost positive roots of self.

This is the list of the orbits of the almost positive roots under the action of the dihedral group generated
by the operators $\tau_+$ and $\tau_-.$

See also:
- almost_positive_roots()
- tau_plus_minus()

EXAMPLES:

```python
sage: RootSystem(['A',2]).root_lattice().almost_positive_roots_decomposition()
[[[-alpha[1], alpha[1], alpha[1] + alpha[2], alpha[2], -alpha[2]]]]

sage: RootSystem(['B',2]).root_lattice().almost_positive_roots_decomposition()

sage: RootSystem(['D',4]).root_lattice().almost_positive_roots_decomposition()
```

alpha()

Returns the family $(\alpha_i)_{i \in I}$ of the simple roots, with the extra feature that, for simple irreducible root systems, $\alpha_0$ yields the opposite of the highest root.

EXAMPLES:

```python
sage: alpha = RootSystem(['A',2]).root_lattice().alpha()
sage: alpha[1]
alpha[1]
sage: alpha[0]
```

alphacheck()

Return the family $(\alpha_i^\vee)_{i \in I}$ of the simple coroots, with the extra feature that, for simple irreducible root systems, $\alpha_0^\vee$ yields the coroot associated to the opposite of the highest root (caveat: for non-simply-laced root systems, this is not the opposite of the highest coroot!).

EXAMPLES:

```python
sage: alphacheck = RootSystem(['A',2]).ambient_space().alphacheck()
sage: alphacheck
Finite family {1: (1, -1, 0), 2: (0, 1, -1)}
```
Here is now $\alpha_0^\vee$:

$$(-1, 0, 1)$$

**Todo:** add a non simply laced example

Finally, here is an affine example:

```
sage: RootSystem(['A', 2, 1]).weight_space().alphacheck()
Finite family {0: alphacheck[0], 1: alphacheck[1], 2: alphacheck[2]}
sage: RootSystem(['A', 3]).ambient_space().alphacheck()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}
```

### basic_imaginary_roots()

Return the basic imaginary roots of self.

The basic imaginary roots $\delta$ are the set of imaginary roots in $-C^\vee$ where $C$ is the dominant chamber (i.e., $\langle \beta, \alpha_i^\vee \rangle \leq 0$ for all $i \in I$). All imaginary roots are $W$-conjugate to a simple imaginary root.

**EXAMPLES:**

```
sage: RootSystem(['A', 2]).root_lattice().basic_imaginary_roots()
()  
sage: Q = RootSystem(['A', 2, 1]).root_lattice()  
sage: Q.basic_imaginary_roots()
(\alpha[0] + \alpha[1] + \alpha[2],)
sage: delta = Q.basic_imaginary_roots()[0]  
sage: all(delta.scalar(Q.simple_coroot(i)) <= 0 for i in Q.index_set())
True
```

### cartan_type()

**EXAMPLES:**

```
sage: r = RootSystem(['A', 4]).root_space()  
sage: r.cartan_type()
['A', 4]
```

### classical()

Return the corresponding root/weight/ambient lattice/space.

**EXAMPLES:**

```
sage: RootSystem(['A', 4, 1]).root_lattice().classical()
Root lattice of the Root system of type ['A', 4]
sage: RootSystem(['A', 4, 1]).weight_lattice().classical()
Weight lattice of the Root system of type ['A', 4]
sage: RootSystem(['A', 4, 1]).ambient_space().classical()
Ambient space of the Root system of type ['A', 4]
```

### cohighest_root()

Returns the associated coroot of the highest root.

**Note:** this is usually not the highest coroot.

**EXAMPLES:**
coroot_lattice()

Returns the coroot lattice.

EXAMPLES:

```
sage: RootSystem(['A', 2]).root_lattice().coroot_lattice()
Co套路 lattice of the Root system of type ['A', 2]
```

coroot_space(base_ring=Rational Field)

Return the coroot space over base_ring.

INPUT:
• base_ring – a ring (default: Q)

EXAMPLES:

```
sage: RootSystem(['A', 2]).root_lattice().coroot_space()
Coroot space over the Rational Field of the Root system of type ['A', 2]
sage: RootSystem(['A', 2]).root_lattice().coroot_space(QQ['q'])
Coroot space over the Univariate Polynomial Ring in q over Rational Field...
```

dual_type_cospa ce()

Returns the cospace of dual type.

For example, if invoked on the root lattice of type ['B', 2], returns the coroot lattice of type ['C', 2].

**Warning:** Not implemented for ambient spaces.

EXAMPLES:

```
sage: CartanType(['B', 2]).root_system().root_lattice().dual_type_cospa ce()  
Coroot lattice of the Root system of type ['C', 2]
sage: CartanType(['F', 4]).root_system().coweight_lattice().dual_type_cospa ce()  
Weight lattice of the Root system of type ['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

dynkin_diagram()

EXAMPLES:

```
sage: r = RootSystem(['A', 4]).root_space()  
sage: r.dynkin_diagram()  
O---O---O---O
1 2 3 4
A4
```

fundamental_weights_from_simple_roots()

Return the fundamental weights.

This is computed from the simple roots by using the inverse of the Cartan matrix. This method is therefore only valid for finite types and if this realization of the root lattice is large enough to contain
them.

EXAMPLES:
In the root space, we retrieve the inverse of the Cartan matrix:

```python
sage: L = RootSystem(['B',3]).root_space()
sage: L.fundamental_weights_from_simple_roots()
sage: ~L.cartan_type().cartan_matrix()
[ 1 1 1/2]
[ 1 2 1]
[ 1 2 3/2]
```

In the weight lattice and the ambient space, we retrieve the fundamental weights:

```python
sage: L = RootSystem(['B',3]).weight_lattice()
sage: L.fundamental_weights_from_simple_roots()
Finite family {1: Lambda[1], 2: Lambda[2], 3: Lambda[3]}
sage: L = RootSystem(['B',3]).ambient_space()
sage: L.fundamental_weights()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
sage: L.fundamental_weights_from_simple_roots()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
```

However the fundamental weights do not belong to the root lattice:

```python
sage: L = RootSystem(['B',3]).root_lattice()
sage: L.fundamental_weights_from_simple_roots()
Traceback (most recent call last):
... ValueError: The fundamental weights do not live in this realization of the root lattice
```

Beware of the usual $GL_n$ vs $SL_n$ catch in type $A$:

```python
sage: L = RootSystem(['A',3]).ambient_space()
sage: L.fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0)}
sage: L.fundamental_weights_from_simple_roots()
Finite family {1: (3/4, -1/4, -1/4, -1/4), 2: (1/2, 1/2, -1/2, -1/2), 3: (1/4, 1/4, 1/4, -3/4)}
sage: L = RootSystem(['A',3]).ambient_lattice()
sage: L.fundamental_weights_from_simple_roots()
Traceback (most recent call last):
... ValueError: The fundamental weights do not live in this realization of the root lattice
```

**generalized_nonnesting_partition_lattice**($m$, facade=False)
Return the lattice of $m$-nonnesting partitions
This has been defined by Athanasiadis, see chapter 5 of [Arm06].

INPUT:
• \( m \) – integer

See also:
nonnesting_partition_lattice()

EXAMPLES:

```
sage: R = RootSystem(['A', 2])
sage: RS = R.root_lattice()
sage: P = RS.generalized_nonnesting_partition_lattice(2); P
Finite lattice containing 12 elements
sage: P.coxeter_transformation()**20 == 1
True
```

highest_root()
Returns the highest root (for an irreducible finite root system)

EXAMPLES:

```
sage: RootSystem(['A',4]).ambient_space().highest_root()
(1, 0, 0, 0, -1)
sage: RootSystem(['E',6]).weight_space().highest_root()
Lambda[2]
```

index_set()
EXAMPLES:

```
sage: r = RootSystem(['A',4]).root_space()
sage: r.index_set()
(1, 2, 3, 4)
```

long_roots()
Return a list of the long roots of self.

EXAMPLES:

```
sage: L = RootSystem(['B',3]).root_lattice()
sage: sorted(L.long_roots())
 alpha[1], alpha[1] + alpha[2],
```

negative_roots()
Returns the negative roots of self.

EXAMPLES:

```
sage: L = RootSystem(['A', 2]).weight_lattice()
sage: sorted(L.negative_roots())
```
Algorithm: negate the positive roots

**nonnesting_partition_lattice**(facade=False)

Return the lattice of nonnesting partitions

This is the lattice of order ideals of the root poset.

This has been defined by Postnikov, see Remark 2 in [Reiner97].

See also:

*generalized_nonnesting_partition_lattice*, *root_poset*

EXAMPLES:

```
sage: R = RootSystem(['A', 3])
sage: RS = R.root_lattice()
sage: P = RS.nonnesting_partition_lattice(); P
Finite lattice containing 14 elements
sage: P.coxeter_transformation()**10 == 1
True

sage: R = RootSystem(['B', 3])
sage: RS = R.root_lattice()
sage: P = RS.nonnesting_partition_lattice(); P
Finite lattice containing 20 elements
sage: P.coxeter_transformation()**7 == 1
True
```

REFERENCES:

**nonparabolic_positive_root_sum**(index_set=None)

Return the sum of positive roots not in a parabolic subsystem.

The conventions for index_set are as in *nonparabolic_positive_roots*.

EXAMPLES:

```
sage: Q = RootSystem(['A',3]).root_lattice()
sage: Q.nonparabolic_positive_root_sum((1,2))
sage: Q.nonparabolic_positive_root_sum()
0
sage: Q.nonparabolic_positive_root_sum(())
```

**nonparabolic_positive_roots**(index_set=None)

Return the positive roots of self that are not in the parabolic subsystem indicated by index_set.

If index_set is None, as in *positive_roots* it is assumed to be the entire Dynkin node set. Then the parabolic subsystem consists of all positive roots and the empty list is returned.

EXAMPLES:

```
sage: L = RootSystem(['A',3]).root_lattice()
sage: L.nonparabolic_positive_roots()
[]
sage: sorted(L.nonparabolic_positive_roots((1,2)))
```
null_coroot()  
Returns the null coroot of self.

The null coroot is the smallest non trivial positive coroot which is orthogonal to all simple roots. It exists for any affine root system.

EXAMPLES:

sage: RootSystem(['C',2,1]).root_lattice().null_coroot()  

sage: RootSystem(['D',4,1]).root_lattice().null_coroot()  

sage: RootSystem(['F',4,1]).root_lattice().null_coroot()  

null_root()  
Returns the null root of self. The null root is the smallest non trivial positive root which is orthogonal to all simple coroots. It exists for any affine root system.

EXAMPLES:

sage: RootSystem(['C',2,1]).root_lattice().null_root()  

sage: RootSystem(['D',4,1]).root_lattice().null_root()  

sage: RootSystem(['F',4,1]).root_lattice().null_root()  

plot(roots='simple', coroots=False, reflection_hyperplanes='simple', fundamental_weights=None, fundamental_chamber=None, alcoves=None, alcove_labels=False, alcove_walk=None, **options)  
Return a picture of this root lattice realization.

INPUT:

• roots – which roots to display, if any. Can be one of the following:
  – "simple" – The simple roots (the default)
  – "classical" – Not yet implemented
  – "all" – Only works in the finite case
  – A list or tuple of roots
  – False

• coroots – which coroots to display, if any. Can be one of the following:
  – "simple" – The simple coroots (the default)
  – "classical" – Not yet implemented
  – "all" – Only works in the finite case
  – A list or tuple of coroots
  – False

• fundamental_weights – a boolean or None (default: None) whether to display the fundamental weights. If None, the fundamental weights are drawn if available.
• reflection_hyperplanes – which reflection hyperplanes to display, if any. Can be one of the following:
  – "simple" – The simple roots
  – "classical" – Not yet implemented
  – "all" – Only works in the finite case
  – A list or tuple of roots
  – False (the default)

• fundamental_chamber – whether and how to draw the fundamental chamber. Can be one of the following:
  – A boolean – Set to True to draw the fundamental chamber
  – "classical" – Draw the classical fundamental chamber
  – None – (the default) The fundamental chamber is drawn except in the root lattice where this is not yet implemented. For affine types the classical fundamental chamber is drawn instead.

• alcoves – one of the following (default: True):
  – A boolean – Whether to display the alcoves
  – A list of alcoves – The alcoves to be drawn. Each alcove is specified by the coordinates of its center in the root lattice (affine type only). Otherwise the alcoves that intersect the bounding box are drawn.

• alcove_labels – one of the following (default: False):
  – A boolean – Whether to display the elements of the Weyl group indexing the alcoves. This currently requires to also set the alcoves option.
  – A number \( l \) – The label is drawn at level \( l \) (affine type only), which only makes sense if affine is False.

• bounding_box – a rational number or a list of pairs thereof (default: 3)
  Specifies a bounding box, in the coordinate system for this plot, in which to plot alcoves and other infinite objects. If the bounding box is a number \( a \), then the bounding box is of the form \([-a, a]\) in all directions. Beware that there can be some border effects and the returned graphic is not necessarily strictly contained in the bounding box.

• alcove_walk – an alcove walk or None (default: None)
  The alcove walk is described by a list (or iterable) of vertices of the Dynkin diagram which specifies which wall is crossed at each step, starting from the fundamental alcove.

• projection – one of the following (default: True):
  – True – The default projection for the root lattice realization is used.
  – False – No projection is used.
  – barycentric – A barycentric projection is used.
  – A function – If a function is specified, it should implement a linear (or affine) map taking as input an element of this root lattice realization and returning its desired coordinates in the plot, as a vector with rational coordinates.

• color – a function mapping vertices of the Dynkin diagram to colors (default: "black" for 0, "blue" for 1, "red" for 2, "green" for 3)
  This is used to set the color for the simple roots, fundamental weights, reflection hyperplanes, alcove facets, etc. If the color is None, the object is not drawn.

• labels – a boolean (default: True) whether to display labels on the simple roots, fundamental weights, etc.

EXAMPLES:

```python
sage: L = RootSystem(["A",2,1]).ambient_space().plot()  # long time
```

See also:

• plot_parse_options()
• plot_roots(), plot_coroots()
• plot_fundamental_weights()
Combinatorics, Release 9.7

- plot_fundamental_chamber()
- plot_reflection_hyperplanes()
- plot_alcoves()
- plot_alcove_walk()
- plot_ls_paths()
- plot_mv_polytope()
- plot_crystal()

plot_alcove_walk(word, start=None, foldings=None, color='orange', **options)
Plot an alcove walk.

INPUT:
- word – a list of elements of the index set
- foldings – a list of booleans or None (default: None)
- start – an element of this space (default: None for \( \rho \))
- **options – plotting options

See also:
- plot() for a description of the plotting options
- Tutorial: visualizing root systems for a tutorial on root system plotting

EXAMPLES:
An alcove walk of type \( \mathcal{A}_2^{(1)} \):

```
sage: L = RootSystem(['A',2,1]).ambient_space()
sage: w1 = [0,2,1,2,0,2,1,0,2,1,2,0,2,0,1,2,0]  # long time (5s)
sage: p = L.plot_alcove_walk(w1)  # long time
```
Graphics object consisting of 375 graphics primitives

The same plot with another alcove walk:

```
sage: w2 = [2,1,2,0,2,0,2,1,2,0,1,2,1,2,0,2,0,1,2,0,2]
sage: p += L.plot_alcove_walk(w2, color="orange")  # long time
```

And another with some foldings:

```
sage: pic = L.plot_alcove_walk([0,1,2,0,2,0,1,2,0,1,2,0], foldings=[False, False, True, False, False], color="green"); pic
```
Graphics object consisting of 155 graphics primitives

plot_alcoves(alcoves=True, alcove_labels=False, wireframe=False, **options)
Plot the alcoves and optionally their labels.

INPUT:
- alcoves – a list of alcoves or True (default: True)
- alcove_labels – a boolean or a number specifying at which level to put the label (default: False)
- **options – Plotting options

See also:
- plot() for a description of the plotting options
• *Tutorial: visualizing root systems* for a tutorial on root system plotting, and in particular how the alcoves can be specified.

**EXAMPLES:**

2D plots:

```python
sage: RootSystem(["B",2,1]).ambient_space().plot_alcoves()
# long time (3s)
Graphics object consisting of 228 graphics primitives
```

3D plots:

```python
sage: RootSystem(["A",2,1]).weight_space().plot_alcoves(affine=False)
# long time (3s)
Graphics3d Object
sage: RootSystem(["G",2,1]).ambient_space().plot_alcoves(affine=False,
level=1)
# long time (3s)
Graphics3d Object
```

Here we plot a single alcove:

```python
sage: L = RootSystem(["A",3,1]).ambient_space()
sage: W = L.weyl_group()
sage: L.plot(alcoves=[W.one()], reflection_hyperplanes=False,
bounding_box=2)
Graphics3d Object
```

`plot_bounding_box(**options)`

Plot the bounding box.

**INPUT:**

• **options – Plotting options**
  
This is mostly for testing purposes.

**See also:**

• `plot()` for a description of the plotting options
  
• *Tutorial: visualizing root systems* for a tutorial on root system plotting

**EXAMPLES:**

```python
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: L.plot_bounding_box()
Graphics object consisting of 1 graphics primitive
```

`plot_coroots(collection='simple', **options)`

Plot the (simple/classical) coroots of this root lattice.

**INPUT:**

• `collection` – which coroots to display. Can be one of the following:
  
  - "simple" (the default)
  - "classical"
  - "all"

• **options – Plotting options**

**See also:**

• `plot()` for a description of the plotting options
  
• *Tutorial: visualizing root systems* for a tutorial on root system plotting
EXAMPLES:

```python
sage: RootSystem(['B',3]).ambient_space().plot_coroots()
Graphics3d Object
```

`plot_crystal(crytasl, plot_labels=True, label_color='black', edge_labels=False, circle_size=0.06, circle_thickness=1.6, **options)`

Plot a finite crystal.

**INPUT:**
- `crystal` – the finite crystal to plot
- `plot_labels` – (default: True) can be one of the following:
  - True - use the latex labels
  - 'circles' - use circles for multiplicity up to 4; if the multiplicity is larger, then it uses the multiplicity
  - 'multiplicities' - use the multiplicities
- `label_color` – (default: 'black') the color of the labels
- `edge_labels` – (default: False) if True, then draw in the edge label
- `circle_size` – (default: 0.06) the size of the circles
- `circle_thickness` – (default: 1.6) the thickness of the extra rings of circles
- `**options` – plotting options

**See also:**
- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

**EXAMPLES:**

```python
sage: L = RootSystem(['A',2]).ambient_space()
sage: C = crystals.Tableaux(['A',2], shape=[2,1])
sage: L.plot_crystal(C, plot_labels='multiplicities')
Graphics object consisting of 15 graphics primitives
sage: C = crystals.Tableaux(['A',2], shape=[8,4])
sage: p = L.plot_crystal(C, plot_labels='circles')
sage: p.show(figsize=15)
```

A 3-dimensional example:

```python
sage: L = RootSystem(['B',3]).ambient_space()
sage: C = crystals.Tableaux(['B',3], shape=[2,1])
sage: L.plot_crystal(C, plot_labels='circles', edge_labels=True) # long time
```

`plot_fundamental_chamber(style='normal', **options)`

Plot the (classical) fundamental chamber.

**INPUT:**
- `style` – "normal" or "classical" (default: "normal")
- `**options` – Plotting options

**See also:**
- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

**EXAMPLES:**

2D plots:
```python
sage: RootSystem(["B",2]).ambient_space().plot_fundamental_chamber()
Graphics object consisting of 1 graphics primitive
sage: RootSystem(["B",2,1]).ambient_space().plot_fundamental_chamber()
Graphics object consisting of 1 graphics primitive
sage: RootSystem(["B",2,1]).ambient_space().plot_fundamental_chamber(˓→"classical")
Graphics object consisting of 1 graphics primitive
```

3D plots:

```python
sage: RootSystem(["A",3,1]).weight_space().plot_fundamental_chamber()
Graphics3d Object
sage: RootSystem(["B",3,1]).ambient_space().plot_fundamental_chamber()
Graphics3d Object
```

This feature is currently not available in the root lattice/space:

```python
sage: list(RootSystem(["A",2]).root_lattice().plot_fundamental_chamber())
Traceback (most recent call last):
  ...TypeError: classical fundamental chamber not yet available in the root␣˓→lattice
```

`plot_fundamental_weights(**options)`
Plot the fundamental weights of this root lattice.

```
INPUT:
  • **options – Plotting options

See also:
  • plot() for a description of the plotting options
  • Tutorial: visualizing root systems for a tutorial on root system plotting

EXAMPLES:
```
```python
sage: RootSystem(["B",3]).ambient_space().plot_fundamental_weights()
Graphics3d Object
```

`plot_hedron(**options)`
Plot the polyhedron whose vertices are given by the orbit of $\rho$.

In type $A$, this is the usual permutohedron.

```
See also:
  • plot() for a description of the plotting options
  • Tutorial: visualizing root systems for a tutorial on root system plotting

EXAMPLES:
```
```python
sage: RootSystem(["A",2]).ambient_space().plot_hedron()
Graphics object consisting of 8 graphics primitives
sage: RootSystem(["A",3]).ambient_space().plot_hedron()
Graphics3d Object
sage: RootSystem(["B",3]).ambient_space().plot_hedron()
Graphics3d Object
sage: RootSystem(["C",3]).ambient_space().plot_hedron()
```
Surprise: polyhedra of large dimension know how to project themselves nicely:

```
sage: RootSystem(['F', 4]).ambient_space().plot_hedron()  # long time
```

```
plot_ls_paths(paths, plot_labels=None, colored_labels=True, **options)
```
Plot LS paths.

**INPUT:**
- `paths` – a finite crystal or list of LS paths
- `plot_labels` – (default: None) the distance to plot the LS labels from the endpoint of the path; set to None to not display the labels
- `colored_labels` – (default: True) if True, then color the labels the same color as the LS path
- `**options` – plotting options

**See also:**
- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

**EXAMPLES:**

```
sage: B = crystals.LSPaths(['A', 2], [1, 1])
sage: L = RootSystem(['A', 2]).ambient_space()
sage: L.plot_fundamental_weights() + L.plot_ls_paths(B)
```
Graphics object consisting of 14 graphics primitives

This also works in 3 dimensions:

```
sage: B = crystals.LSPaths(['B', 3], [2, 0, 0])
sage: L = RootSystem(['B', 3]).ambient_space()
sage: L.plot_ls_paths(B)
```
Graphics3d Object

```
plot_mv_polytope(mv_polytope, mark_endpoints=True, circle_size=0.06, circle_thickness=1.6,
wireframe='blue', fill='green', alpha=1, **options)
```
Plot an MV polytope.

**INPUT:**
- `mv_polytope` – an MV polytope
- `mark_endpoints` – (default: True) mark the endpoints of the MV polytope
- `circle_size` – (default: 0.06) the size of the circles
- `circle_thickness` – (default: 1.6) the thickness of the extra rings of circles
- `wireframe` – (default: 'blue') color to draw the wireframe of the polytope with
- `fill` – (default: 'green') color to fill the polytope with
- `alpha` – (default: 1) the alpha value (opacity) of the fill
- `**options` – plotting options

**See also:**
- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

**EXAMPLES:**
sage: B = crystals.infinity.MVPolytopes(['C',2])
sage: L = RootSystem(['C',2]).ambient_space()
sage: p = B.highest_weight_vector().f_string([1,2,1,2])
sage: L.plot_fundamental_weights() + L.plot_mv_polytope(p)
Graphics object consisting of 14 graphics primitives

This also works in 3 dimensions:

sage: B = crystals.infinity.MVPolytopes(['A',3])
sage: L = RootSystem(['A',3]).ambient_space()
sage: p = B.highest_weight_vector().f_string([2,1,3,2])
sage: L.plot_mv_polytope(p)
Graphics3d Object

plot_parse_options(**args)
Return an option object to be used for root system plotting.

EXAMPLES:

sage: L = RootSystem(['A',2,1]).ambient_space()
sage: options = L.plot_parse_options()
sage: options
<sage.combinat.root_system.plot.PlotOptions object at ...>

See also:
• plot() for a description of the plotting options
• Tutorial: visualizing root systems for a tutorial on root system plotting

plot_reflection_hyperplanes(collection='simple', **options)
Plot the simple reflection hyperplanes.

INPUT:
• collection – which reflection hyperplanes to display. Can be one of the following:
  – "simple" (the default)
  – "classical"
  – "all"
• **options – Plotting options

See also:
• plot() for a description of the plotting options
• Tutorial: visualizing root systems for a tutorial on root system plotting

EXAMPLES:

sage: RootSystem(['A',2,1]).ambient_space().plot_reflection_hyperplanes()
Graphics object consisting of 6 graphics primitives
sage: RootSystem(['G',2,1]).ambient_space().plot_reflection_hyperplanes()
Graphics object consisting of 6 graphics primitives
sage: RootSystem(['A',3]).weight_space().plot_reflection_hyperplanes()
Graphics3d Object
sage: RootSystem(['B',3]).ambient_space().plot_reflection_hyperplanes()
Graphics3d Object
sage: RootSystem(['A',3,1]).weight_space().plot_reflection_hyperplanes()
Graphics3d Object
sage: RootSystem(['B',3,1]).ambient_space().plot_reflection_hyperplanes()
(continues on next page)
Graphics3d Object

sage: RootSystem(["A",2,1]).weight_space().plot_reflection_hyperplanes(affine=False, level=1)
Graphics3d Object
sage: RootSystem(["A",2]).root_lattice().plot_reflection_hyperplanes()
Graphics object consisting of 4 graphics primitives

Todo: Provide an option for transparency?

plot_roots(collection='simple', **options)
Plot the (simple/classical) roots of this root lattice.

INPUT:
• collection – which roots to display can be one of the following:
  – "simple" (the default)
  – "classical"
  – "all"
• **options – Plotting options

See also:
• plot() for a description of the plotting options
• Tutorial: visualizing root systems for a tutorial on root system plotting

EXAMPLES:

sage: RootSystem(["B",3]).ambient_space().plot_roots()
Graphics3d Object
sage: RootSystem(["B",3]).ambient_space().plot_roots("all")
Graphics3d Object

positive_imaginary_roots()
Return the positive imaginary roots of self.

EXAMPLES:

sage: L = RootSystem(["A",3]).root_lattice()
sage: L.positive_imaginary_roots()
()  # Note: The positive imaginary roots are empty for type A

sage: L = RootSystem(["A",3,1]).root_lattice()
sage: PIR = L.positive_imaginary_roots(); PIR
Positive imaginary roots of type ['A', 3, 1]
sage: [PIR.unrank(i) for i in range(5)]
  3*alpha[0] + 3*alpha[1] + 3*alpha[2] + 3*alpha[3],

positive_real_roots()
Return the positive real roots of self.

EXAMPLES:
sage: L = RootSystem(['A',3]).root_lattice()
sage: sorted(L.positive_real_roots())
 alpha[2], alpha[2] + alpha[3], alpha[3]]

sage: L = RootSystem(['A',3,1]).root_lattice()
sage: PRR = L.positive_real_roots(); PRR
Positive real roots of type ['A', 3, 1]
sage: [PRR.unrank(i) for i in range(10)]
[alpha[1],
 alpha[2],
 alpha[3],
 alpha[1] + alpha[2],
 alpha[2] + alpha[3],

sage: Q = RootSystem(['A',4,2]).root_lattice()
sage: PR = Q.positive_roots()
sage: [PR.unrank(i) for i in range(5)]
[alpha[1],
 alpha[2],
 alpha[1] + alpha[2],
 2*alpha[1] + alpha[2],
 alpha[0] + alpha[1] + alpha[2]]

sage: Q = RootSystem(['D',3,2]).root_lattice()
sage: PR = Q.positive_roots()
sage: [PR.unrank(i) for i in range(5)]
[alpha[1],
 alpha[2],
 alpha[1] + 2*alpha[2],
 alpha[1] + alpha[2],
 alpha[0] + alpha[1] + 2*alpha[2]]

**positive_roots(index_set=None)**

Return the positive roots of **self**.

If **index_set** is not **None**, returns the positive roots of the parabolic subsystem with simple roots in **index_set**.

Algorithm for finite type: generate them from the simple roots by applying successive reflections toward the positive chamber.

**EXAMPLES:**

sage: L = RootSystem(['A',3]).root_lattice()
sage: sorted(L.positive_roots())
 alpha[2], alpha[2] + alpha[3], alpha[3]]

(continues on next page)
sage: sorted(L.positive_roots((1,2)))
[alpha[1], alpha[1] + alpha[2], alpha[2]]
sage: sorted(L.positive_roots(()))
[]
sage: L = RootSystem(['A',3,1]).root_lattice()
sage: PR = L.positive_roots(); PR
Disjoint union of Family (Positive real roots of type ['A', 3, 1],
Positive imaginary roots of type ['A', 3, 1])
sage: [PR.unrank(i) for i in range(10)]
[alpha[1],
alpha[2],
alpha[3],
alpha[1] + alpha[2],
alpha[2] + alpha[3],

positive_roots_by_height(increasing=True)
Returns a list of positive roots in increasing order by height.
If increasing is False, returns them in decreasing order.

Warning: Raise an error if the Cartan type is not finite.

EXAMPLES:
sage: L = RootSystem(['C',2]).root_lattice()
sage: sorted(lattice.positive_roots_nonparabolic((1,3)), key=str)

positive_roots_nonparabolic(index_set=None)
Returns the set of positive roots outside the parabolic subsystem with Dynkin node set index_set.

INPUT:
• index_set – (default:None) the Dynkin node set of the parabolic subsystem. It should be a tuple.
The default value implies the entire Dynkin node set

EXAMPLES:
sage: lattice = RootSystem(['A',3]).root_lattice()
sage: sorted(lattice.positive_roots_nonparabolic((1,3)), key=str)
positive_roots_nonparabolic_sum(index_set=None)

Returns the sum of positive roots outside the parabolic subsystem with Dynkin node set index_set.

INPUT:

• index_set – (default: None) the Dynkin node set of the parabolic subsystem. It should be a tuple. The default value implies the entire Dynkin node set.

EXAMPLES:

sage: lattice = RootSystem(['A',3]).root_lattice()
sage: lattice.positive_roots_nonparabolic_sum((1,3))
sage: lattice.positive_roots_nonparabolic_sum((2,3))
sage: lattice.positive_roots_nonparabolic_sum(())
sage: lattice.positive_roots_nonparabolic_sum()
0
sage: lattice.positive_roots_nonparabolic_sum((1,2,3))
0

Warning: This returns an error if the Cartan type is not finite.

Warning: This returns an error if the Cartan type is not finite.

positive_roots_parabolic(index_set=None)

Return the set of positive roots for the parabolic subsystem with Dynkin node set index_set.

INPUT:

• index_set – (default: None) the Dynkin node set of the parabolic subsystem. It should be a tuple. The default value implies the entire Dynkin node set.

EXAMPLES:

sage: lattice = RootSystem(['A',3]).root_lattice()
sage: sorted(lattice.positive_roots_parabolic((1,3)), key=str)
[alpha[1], alpha[3]]
sage: sorted(lattice.positive_roots_parabolic((2,3)), key=str)
[alpha[2], alpha[2] + alpha[3], alpha[3]]
sage: sorted(lattice.positive_roots_parabolic((1,3)), key=str)
[alpha[2], alpha[2] + alpha[3], alpha[3]]
sage: sorted(lattice.positive_roots_parabolic((1,2,3)), key=str)
**Warning:** This returns an error if the Cartan type is not finite.

**projection**(root, coroot=None, to_negative=True)

Returns the projection along the root, and across the hyperplane define by coroot, as a function \( \pi \) from self to self. \( \pi \) is a half-linear map which stabilizes the negative half space, and acts by reflection on the positive half space.

If to_negative is False, then this project onto the positive half space instead.

**EXAMPLES:**

```python
sage: space = RootSystem(['A', 2]).weight_lattice()
sage: x = space.simple_roots()[1]
sage: y = space.simple_coroots()[1]
sage: pi = space.projection(x, y)
sage: x
sage: pi(x)
sage: pi(-x)
sage: pi = space.projection(x, y, False)
sage: pi(-x)
```

**reflection**(root, coroot=None)

Returns the reflection along the root, and across the hyperplane define by coroot, as a function from self to self.

**EXAMPLES:**

```python
sage: space = RootSystem(['A', 2]).weight_lattice()
sage: x = space.simple_roots()[1]
sage: y = space.simple_coroots()[1]
sage: s = space.reflection(x, y)
sage: x
sage: s(x)
sage: s(-x)
```

**root_poset**(restricted=False, facade=False)

Returns the (restricted) root poset associated to self.

The elements are given by the positive roots (resp. non-simple, positive roots), and \( \alpha \leq \beta \) iff \( \beta - \alpha \) is a non-negative linear combination of simple roots.

**INPUT:**
- **restricted** – (default:False) if True, only non-simple roots are considered.
- **facade** – (default:False) passes facade option to the poset generator.

**EXAMPLES:**

```python
sage: Phi = RootSystem(['A', 1]).root_poset(); Phi
Finite poset containing 1 elements
```
sage: Phi.cover_relations()
[]

sage: Phi = RootSystem(['A',2]).root_poset(); Phi
Finite poset containing 3 elements

sage: sorted(Phi.cover_relations(), key=str)

sage: Phi = RootSystem(['A',3]).root_poset(restricted=True); Phi
Finite poset containing 3 elements

sage: sorted(Phi.cover_relations(), key=str)

sage: Phi = RootSystem(['B',2]).root_poset(); Phi
Finite poset containing 4 elements

sage: sorted(Phi.cover_relations(), key=str)
 [alpha[1], alpha[1] + alpha[2]],
 [alpha[2], alpha[1] + alpha[2]]]

roots()

Return the roots of self.

EXAMPLES:

sage: RootSystem(['A',2]).ambient_lattice().roots()
[(1, -1, 0), (1, 0, -1), (0, 1, -1), (-1, 1, 0), (-1, 0, 1), (0, -1, 1)]

This matches with Wikipedia article Root_systems:

```
sage: for T in CartanType.samples(finite = True, crystallographic = True):
    ....:    print("%s %3s %3s"%(T, len(RootSystem(T).root_lattice().roots()),
        len(RootSystem(T).weight_lattice().roots())))
['A', 1]  2  2
['A', 5]  30  30
['B', 1]  2  2
['B', 5]  50  50
['C', 1]  2  2
['C', 5]  50  50
['D', 2]  4  4
['D', 3]  12 12
['D', 5]  40 40
['E', 6]  72 72
['E', 7] 126 126
['E', 8] 240 240
['F', 4]  48 48
['G', 2]  12 12
```

Todo: The result should be an enumerated set, and handle infinite root systems.
s()  
Return the family \((s_i)_{i \in I}\) of the simple reflections of this root system.

EXAMPLES:

```sage
sage: r = RootSystem(['A', 2]).root_lattice()
sage: s = r.simple_reflections()
sage: s[1]( r.simple_root(1) )
-\alpha[1]
```

short_roots()  
Return a list of the short roots of self.

EXAMPLES:

```sage
sage: L = RootSystem(['B',3]).root_lattice()
sage: sorted(L.short_roots())
[-\alpha[1] - \alpha[2] - \alpha[3],
 \alpha[1] + \alpha[2] + \alpha[3],
 -\alpha[2] - \alpha[3],
 \alpha[2] + \alpha[3],
 -\alpha[3],
 \alpha[3]]
```

simple_coroot(i)  
Returns the \(i^{th}\) simple coroot.

EXAMPLES:

```sage
sage: alphacheck = RootSystem(['A', 3]).root_lattice().simple_coroots()
[sage: alphacheck[i] for i in [1, 2, 3]]
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

simple_coroots()  
Returns the family \((\alpha_i^\vee)_{i \in I}\) of the simple coroots.

EXAMPLES:

```sage
sage: alphacheck = RootSystem(['A', 3]).root_lattice().simple_coroots()
sage: [alphacheck[i] for i in [1, 2, 3]]
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

simple_projection(i, to_negative=True)  
Returns the projection along the \(i^{th}\) simple root, and across the hyperplane defined by the \(i^{th}\) simple coroot, as a function from self to self.

INPUT:
- \(i\) - \(i\) is in self’s index set

EXAMPLES:

```sage
sage: space = RootSystem(['A', 2]).weight_lattice()
sage: x = space.simple_roots()[1]
sage: pi = space.simple_projection(1)
sage: x
sage: pi(x)
```
Combinatorics, Release 9.7

Continued from previous page

```python
sage: pi(-x)
```

```python
sage: pi = space.simple_projection(1,False)
sage: pi(-x)
```

**simple_projections(to_negative=True)**

Returns the family \( (s_i)_{i \in I} \) of the simple projections of this root system.

**EXAMPLES:**

```python
sage: space = RootSystem(['A',2]).weight_lattice()
sage: pi = space.simple_projections()
sage: x = space.simple_roots()
sage: pi[1](x[2])
```

**simple_reflection(i)**

Returns the \( i \)th simple reflection, as a function from self to self.

**INPUT:**
- \( i \) - \( i \) is in self's index set

**EXAMPLES:**

```python
sage: space = RootSystem(['A',2]).ambient_lattice()
sage: s = space.simple_reflection(1)
sage: x = space.simple_roots()[1]
sage: x
(1, -1, 0)
sage: s(x)
(-1, 1, 0)
```

**simple_reflections()**

Return the family \( (s_i)_{i \in I} \) of the simple reflections of this root system.

**EXAMPLES:**

```python
sage: r = RootSystem(['A',2]).root_lattice()
sage: s = r.simple_reflections()
sage: s[1]( r.simple_root(1) )
-alpha[1]
```

**simple_root(i)**

Returns the \( i \)th simple root.

This should be overridden by any subclass, and typically implemented as a cached method for efficiency.

**EXAMPLES:**

```python
sage: r = RootSystem(['A',3]).root_lattice()
sage: r.simple_root(1)
alpha[1]
```

**simple_roots()**

Returns the family \( (\alpha_i)_{i \in I} \) of the simple roots.
EXAMPLES:

```
sage: alpha = RootSystem(['A',3]).root_lattice().simple_roots()
sage: [alpha[i] for i in [1,2,3]]
[alpha[1], alpha[2], alpha[3]]
```

**simple_roots_tilde()**

Return the family \((\tilde{\alpha}_i)_{i \in I}\) of the simple roots.

**INPUT:**

- **self** – an affine root lattice realization

The \(\tilde{\alpha}_i\) give the embedding of the root lattice of the other affinization of the same classical root lattice into this root lattice.

This uses the fact that \(\alpha_i = \tilde{\alpha}_i\) for \(i\) not a special node, and that

\[
\delta = \sum a_i \alpha_i = \sum b_i \tilde{\alpha}_i
\]

**EXAMPLES:**

In simply laced cases, this is boring:

```
sage: RootSystem(['A',3,1]).root_lattice().simple_roots_tilde()
Finite family {0: alpha[0], 1: alpha[1], 2: alpha[2], 3: alpha[3]}
```

This was checked by hand:

```
sage: RootSystem(['C',2,1]).coroot_lattice().simple_roots_tilde()
Finite family {0: alphacheck[0] - alphacheck[2], 1: alphacheck[1], 2: alphacheck[2]}
sage: RootSystem(['B',2,1]).coroot_lattice().simple_roots_tilde()
Finite family {0: alphacheck[0] - alphacheck[1], 1: alphacheck[1], 2: alphacheck[2]}
```

What about type BC?

**some_elements()**

Return some elements of this root lattice realization

**EXAMPLES:**

```
sage: L = RootSystem(['A',2]).weight_lattice()
sage: L.some_elements()
sage: L = RootSystem(['A',2]).root_lattice()
sage: L.some_elements()
```

**tau_epsilon_operator_on_almost_positive_roots(J)**

The \(\tau_\epsilon\) operator on almost positive roots

Given a subset \(J\) of non adjacent vertices of the Dynkin diagram, this constructs the operator on the almost positive roots which fixes the negative simple roots \(\alpha_i\) for \(i\) not in \(J\), and acts otherwise by:

\[
\tau_+ (\beta) = \left(\prod_{i \in J} s_i\right)(\beta)
\]

See Equation (1.2) of [CFZ2002].
EXAMPLES:

```python
sage: L = RootSystem(['A',4]).root_lattice()
sage: tau = L.tau_epsilon_operator_on_almost_positive_roots([1,3])
sage: alpha = L.simple_roots()
```

The action on a negative simple root not in $J$:

```python
sage: tau(-alpha[2])
-alpha[2]
```

The action on a negative simple root in $J$:

```python
sage: tau(-alpha[1])
alpha[1]
```

The action on all almost positive roots:

```python
sage: for root in L.almost_positive_roots():
    ....:    print('tau(' + str(root) + ') = ' + str(tau(root)))
```

This method works on any root lattice realization:

```python
sage: L = RootSystem(['B',3]).ambient_space()
sage: tau = L.tau_epsilon_operator_on_almost_positive_roots([1,3])
sage: for root in L.almost_positive_roots():
    ....:    print('tau(' + str(root) + ') = ' + str(tau(root)))
```

(continues on next page)
tau((0, 0, -1)) = (0, 0, 1)
tau((0, 0, 1)) = (0, 0, -1)

See also:

\( \tau_{\pm} \)

\textbf{tau_plus_minus()}

Returns the \( \tau^+ \) and \( \tau^- \) piecewise linear operators on self

Those operators are induced by the bipartition \( \{L, R\} \) of the simple roots of self, and stabilize the almost positive roots. Namely, \( \tau^+ \) fixes the negative simple roots \( \alpha_i \) for \( i \) in \( R \), and acts otherwise by:

\[
\tau^+(\beta) = (\prod_{i \in L} s_i)(\beta)
\]

\( \tau^- \) acts analogously, with \( L \) and \( R \) interchanged.

Those operators are used to construct the associahedron, a polytopal realization of the cluster complex (see Associahedron).

See also:

\textbf{tau_epsilon_operator_on_almost_positive_roots()}

\textbf{EXAMPLES:}

We explore the example of [CFZ2002] Eq.(1.3):

\begin{verbatim}
sage: S = RootSystem(['A',2]).root_lattice()
sage: taup, taum = S.tau_plus_minus()
sage: for beta in S.almost_positive_roots():
    print("{},{},{}".format(beta, taup(beta), taum(beta)))
-alpha[1], alpha[1], -alpha[1]
alpha[1], -alpha[1], alpha[1] + alpha[2]
-alpha[2], -alpha[2], alpha[2]
\end{verbatim}

\textbf{to_ambient_space_morphism()}

Return the morphism to the ambient space.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: CartanType(['B',2]).root_system().root_lattice().to_ambient_space_morphism()
Generic morphism:
From: Root lattice of the Root system of type ['B', 2]
To: Ambient space of the Root system of type ['B', 2]
sage: CartanType(['B',2]).root_system().coroot_lattice().to_ambient_space_morphism()
Generic morphism:
From: Coroot lattice of the Root system of type ['B', 2]
To: Ambient space of the Root system of type ['B', 2]
sage: CartanType(['B',2]).root_system().weight_lattice().to_ambient_space_morphism()
Generic morphism:
\end{verbatim}

(continues on next page)
From: Weight lattice of the Root system of type ['B', 2]
To: Ambient space of the Root system of type ['B', 2]

weyl_group(prefix=None)

Returns the Weyl group associated to self.

EXAMPLES:

sage: RootSystem(['F',4]).ambient_space().weyl_group()
Weyl Group of type ['F', 4] (as a matrix group acting on the ambient space)
sage: RootSystem(['F',4]).root_space().weyl_group()
Weyl Group of type ['F', 4] (as a matrix group acting on the root space)

super_categories()

EXAMPLES:

sage: from sage.combinat.root_system.root_lattice_realizations import RootLatticeRealizations
sage: RootLatticeRealizations(QQ).super_categories()
[Category of vector spaces with basis over Rational Field]

5.1.236 Root lattices and root spaces

class sage.combinat.root_system.root_space.RootSpace(root_system, base_ring)

Bases: sage.combinat.free_module.CombinatorialFreeModule

The root space of a root system over a given base ring

INPUT:

• root_system - a root system
• base_ring: a ring \( R \)

The root space (or lattice if base_ring is \( \mathbb{Z} \)) of a root system is the formal free module \( \bigoplus_{i \in I} R\alpha_i \) generated by the simple roots \( (\alpha_i)_{i \in I} \) of the root system.

This class is also used for coroot spaces (or lattices).

See also:

• RootSystem()
• RootSystem.root_lattice() and RootSystem.root_space()
• RootLatticeRealizations()

Todo: standardize the variable used for the root space in the examples (P?)

Element
alias of RootSpaceElement

simple_root()

Return the basis element indexed by \( i \).

INPUT:

• i – an element of the index set
EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.monomial('a')
B['a']
```

F.monomial is in fact (almost) a map:

```
sage: F.monomial
Term map from {'a', 'b', 'c'} to Free module generated by {'a', 'b', 'c'} over Rational Field
```

to_ambient_space_morphism()

The morphism from self to its associated ambient space.

EXAMPLES:

```
sage: CartanType(['A',2]).root_system().root_lattice().to_ambient_space_morphism()
Generic morphism:
   From: Root lattice of the Root system of type ['A', 2]
   To: Ambient space of the Root system of type ['A', 2]
```

to_coroot_space_morphism()

Returns the nu map to the coroot space over the same base ring, using the symmetrizer of the Cartan matrix

It does not map the root lattice to the coroot lattice, but has the property that any root is mapped to some scalar multiple of its associated coroot.

EXAMPLES:

```
sage: R = RootSystem(['A',3]).root_space()
sage: alpha = R.simple_roots()
sage: f = R.to_coroot_space_morphism()
sage: f(alpha[1])
alphacheck[1]
sage: f(alpha[1]+alpha[2])
sage: R = RootSystem(['A',3]).root_lattice()
sage: alpha = R.simple_roots()
sage: f = R.to_coroot_space_morphism()
sage: f(alpha[1])
alphacheck[1]
sage: f(alpha[1]+alpha[2])
sage: S = RootSystem(['G',2]).root_space()
sage: alpha = S.simple_roots()
sage: f = S.to_coroot_space_morphism()
sage: f(alpha[1])
alphacheck[1]
sage: f(alpha[1]+alpha[2])
```
class sage.combinat.root_system.root_space.RootSpaceElement
    Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

    associated_coroot()
    Returns the coroot associated to this root

    OUTPUT:
    An element of the coroot space over the same base ring; in particular the result is in the coroot lattice
    whenever self is in the root lattice.

    EXAMPLES:

    sage: L = RootSystem(['B', 3]).root_space()
    sage: alpha = L.simple_roots()
    sage: alpha[1].associated_coroot()
    alphacheck[1]
    sage: alpha[1].associated_coroot().parent()
    Coroot space over the Rational Field of the Root system of type ['B', 3]
    sage: L.highest_root()
    sage: L.highest_root().associated_coroot()
    sage: alpha = RootSystem(['B', 3]).root_lattice().simple_roots()
    sage: alpha[1].associated_coroot()
    alphacheck[1]
    sage: alpha[1].associated_coroot().parent()
    Coroot lattice of the Root system of type ['B', 3]

    is_positive_root()
    Checks whether an element in the root space lies in the nonnegative cone spanned by the simple roots.

    EXAMPLES:

    sage: R=RootSystem(['A','3',1]).root_space()
    sage: B=R.basis()
    sage: w=B[0]+B[3]
    sage: w.is_positive_root()
    True
    sage: w.is_positive_root()
    False

    max_coroot_le()
    Returns the highest positive coroot whose associated root is less than or equal to self.

    INPUT:
    
    • self – an element of the nonnegative integer span of simple roots.

    Returns None for the zero element.

    Really self is an element of a coroot lattice and this method returns the highest root whose associated
    coroot is <= self.
**Warning:** This implementation only handles finite Cartan types

**EXAMPLES:**

```python
sage: root_lattice = RootSystem(['C',2]).root_lattice()
sage: root_lattice.from_vector(vector([1,1])).max_coroot_le()
sage: root_lattice.from_vector(vector([2,1])).max_coroot_le()
sage: root_lattice = RootSystem(['B',2]).root_lattice()
sage: root_lattice.from_vector(vector([1,1])).max_coroot_le()
sage: root_lattice.from_vector(vector([1,2])).max_coroot_le()
sage: root_lattice.zero().max_coroot_le() is None
True
sage: root_lattice.from_vector(vector([-1,0])).max_coroot_le()
Traceback (most recent call last):
  ... ValueError: -alpha[1] is not in the positive cone of roots
sage: root_lattice = RootSystem(['A',2,1]).root_lattice()
sage: root_lattice.simple_root(1).max_coroot_le()
Traceback (most recent call last):
  ... NotImplementedError: Only implemented for finite Cartan type
```

**max_quantum_element()**

Returns a reduced word for the longest element of the Weyl group whose shortest path in the quantum Bruhat graph to the identity, has sum of quantum coroots at most `self`.

**INPUT:**

- `self` – an element of the nonnegative integer span of simple roots.

Really `self` is an element of a coroot lattice.

**Warning:** This implementation only handles finite Cartan types

**EXAMPLES:**

```python
sage: Qvee = RootSystem(['C',2]).coroot_lattice()
sage: Qvee.from_vector(vector([1,2])).max_quantum_element()
[2, 1, 2, 1]
sage: Qvee.from_vector(vector([1,1])).max_quantum_element()
[1, 2, 1]
sage: Qvee.from_vector(vector([0,2])).max_quantum_element()
[2]
```

**quantum_root()**

Returns `True` if `self` is a quantum root and `False` otherwise.

**INPUT:**
• **self** – an element of the nonnegative integer span of simple roots.

A root \( \alpha \) is a quantum root if \( \ell(s_\alpha) = \langle 2\rho, \alpha^\vee \rangle - 1 \) where \( \ell \) is the length function, \( s_\alpha \) is the reflection across the hyperplane orthogonal to \( \alpha \), and \( 2\rho \) is the sum of positive roots.

**Warning:** This implementation only handles finite Cartan types and assumes that `self` is a root.

**Todo:** Rename to `is_quantum_root`

**EXAMPLES:**

```python
sage: Q = RootSystem(['C',2]).root_lattice()
sage: positive_roots = Q.positive_roots()
sage: for x in sorted(positive_roots):
    ....:     print("{} {}\nalpha[1] True
alpha[2] True
```

**scalar(lambdacheck)**

The scalar product between the root lattice and the coroot lattice.

**EXAMPLES:**

```python
sage: L = RootSystem(['B',4]).root_lattice()
sage: alpha = L.simple_roots()
sage: alphacheck = L.simple_coroots()
sage: alpha[1].scalar(alphacheck[1])
2
sage: alpha[1].scalar(alphacheck[2])
-1
```

The scalar products between the roots and coroots are given by the Cartan matrix:

```python
sage: matrix([[ alpha[1].scalar(alphacheck[j])
    ....:     for i in L.index_set() ]
    ....:     for j in L.index_set() ])
```

```
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -1]
[ 0  0 -2  2]
```

**to_ambient()**

Map `self` to the ambient space.

**EXAMPLES:**
5.1.237 Root systems

See Root Systems for an overview.

class sage.combinat.root_system.root_system.RootSystem(cartan_type, as_dual_of=None)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.sage_object.SageObject

A class for root systems.

EXAMPLES:

We construct the root system for type $B_3$:

```
sage: R=RootSystem(['B',3]); R
Root system of type ['B', 3]
```

$R$ models the root system abstractly. It comes equipped with various realizations of the root and weight lattices, where all computations take place. Let us play first with the root lattice:

```
sage: space = R.root_lattice()
sage: space
Root lattice of the Root system of type ['B', 3]
```

This is the free $\mathbb{Z}$-module $\bigoplus_i \mathbb{Z}\alpha_i$ spanned by the simple roots:

```
sage: space.base_ring()
Integer Ring
sage: list(space.basis())
[alpha[1], alpha[2], alpha[3]]
```

Let us do some computations with the simple roots:

```
sage: alpha = space.simple_roots()
```

There is a canonical pairing between the root lattice and the coroot lattice:

```
sage: R.coroot_lattice()
Coroot lattice of the Root system of type ['B', 3]
```
We construct the simple coroots, and do some computations (see comments about duality below for some caveat):

```python
sage: alphacheck = space.simple_coroots()
sage: list(alphacheck)
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

We can carry over the same computations in any of the other realizations of the root lattice, like the root space $\bigoplus_i \mathbb{Q}.\alpha_i$, the weight lattice $\bigoplus_i \mathbb{Z}.\Lambda_i$, the weight space $\bigoplus_i \mathbb{Q}.\Lambda_i$. For example:

```python
sage: space = R.weight_space()
sage: space
Weight space over the Rational Field of the Root system of type ['B', 3]
sage: space.base_ring()
Rational Field
sage: list(space.basis())
[Lambda[1], Lambda[2], Lambda[3]]
sage: alpha = space.simple_roots()
```

The fundamental weights are the dual basis of the coroots:

```python
sage: Lambda = space.fundamental_weights()
sage: Lambda[1]
Lambda[1]
sage: alphacheck = space.simple_coroots()
sage: list(alphacheck)
[alphacheck[1], alphacheck[2], alphacheck[3]]
sage: [Lambda[i].scalar(alphacheck[1]) for i in space.index_set()]
[1, 0, 0]
sage: [Lambda[i].scalar(alphacheck[2]) for i in space.index_set()]
[0, 1, 0]
sage: [Lambda[i].scalar(alphacheck[3]) for i in space.index_set()]
[0, 0, 1]
```

Let us use the simple reflections. In the weight space, they work as in the number game: firing the node $i$ on an element $x$ adds $c$ times the simple root $\alpha_i$, where $c$ is the coefficient of $i$ in $x$:

```python
sage: s = space.simple_reflections()
sage: Lambda[1].simple_reflection(1)
sage: Lambda[2].simple_reflection(1)
Lambda[2]
sage: Lambda[3].simple_reflection(1)
Lambda[3]
```

It can be convenient to manipulate the simple reflections themselves:
Ambient spaces

The root system may also come equipped with an ambient space. This is a $\mathbb{Q}$-module, endowed with its canonical Euclidean scalar product, which admits simultaneous embeddings of the (extended) weight and the (extended) coweight lattice, and therefore the root and the coroot lattice. This is implemented on a type by type basis for the finite crystallographic root systems following Bourbaki’s conventions and is extended to the affine cases. Coefficients permitting, this is also available as an ambient lattice.

See also:
ambient_space() and ambient_lattice() for details

In finite type $A$, we recover the natural representation of the symmetric group as group of permutation matrices:

```
sage: RootSystem(["A",2]).ambient_space().weyl_group().simple_reflections()
Finite family {1: [[0 1 0]
    [1 0 0]
    [0 0 1]],
   2: [[1 0 0]
    [0 0 1]
    [0 1 0]}
```

In type $B$, $C$, and $D$, we recover the natural representation of the Weyl group as groups of signed permutation matrices:

```
sage: RootSystem(["B",3]).ambient_space().weyl_group().simple_reflections()
Finite family {1: [[0 1 0]
    [1 0 0]
    [0 0 1]],
   2: [[1 0 0]
    [0 0 1]
    [0 1 0]],
   3: [[ 1 0 0]
    [ 0 1 0]
    [ 0 0 -1]]
```

In (untwisted) affine types $A$, ..., $D$, one can recover from the ambient space the affine permutation representation, in window notation. Let us consider the ambient space for affine type $A$:

```
sage: L = RootSystem(["A",2,1]).ambient_space(); L
Ambient space of the Root system of type ['A', 2, 1]
```

Define the “identity” by an appropriate vector at level $-3$:

```
sage: e = L.basis(); Lambda = L.fundamental_weights()
sage: id = e[0] + 2*e[1] + 3*e[2] - 3*Lambda[0]
```
The corresponding permutation is obtained by projecting it onto the classical ambient space:

```
sage: L.classical()
Ambient space of the Root system of type ['A', 2]
sage: L.classical()(id)
(1, 2, 3)
```

Here is the orbit of the identity under the action of the finite group:

```
sage: W = L.weyl_group()
sage: S3 = [ w.action(id) for w in W.classical() ]
sage: [L.classical()(x) for x in S3]
[(1, 2, 3), (3, 1, 2), (2, 3, 1), (2, 1, 3), (1, 3, 2), (3, 2, 1)]
```

And the action of $s_0$ on these yields:

```
sage: s = W.simple_reflections()
sage: [L.classical()(s[0].action(x)) for x in S3]
[(0, 2, 4), (-1, 1, 6), (-2, 3, 5), (0, 1, 5), (-1, 3, 4), (-2, 2, 6)]
```

We can also plot various components of the ambient spaces:

```
sage: L = RootSystem(['A',2]).ambient_space()
sage: L.plot()
Graphics object consisting of 13 graphics primitives
```

For more on plotting, see Tutorial: visualizing root systems.

**Dual root systems**

The root system is aware of its dual root system:

```
sage: R.dual
Dual of root system of type ['B', 3]
```

`R.dual` is really the root system of type $C_3$:

```
sage: R.dual.cartan_type()
['C', 3]
```

And the coroot lattice that we have been manipulating before is really implemented as the root lattice of the dual root system:

```
sage: R.dual.root_lattice()
Coroot lattice of the Root system of type ['B', 3]
```

In particular, the coroots for the root lattice are in fact the roots of the coroot lattice:

```
sage: list(R.root_lattice().simple_coroots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
sage: list(R.coroot_lattice().simple_roots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
sage: list(R.dual.root_lattice().simple_roots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
```
The coweight lattice and space are defined similarly. Note that, to limit confusion, all the output have been tweaked appropriately.

See also:

• `sage.combinat.root_system`
• `RootSpace`
• `WeightSpace`
• `AmbientSpace`
• `RootLatticeRealizations`
• `WeightLatticeRealizations`

`ambient_lattice()`

Return the ambient lattice for this root_system.

This is the ambient space, over \( \mathbb{Z} \).

See also:

• `ambient_space()`
• `root_lattice()`
• `weight_lattice()`

EXAMPLES:

```python
sage: RootSystem(['A',4]).ambient_lattice()
Ambient lattice of the Root system of type ['A', 4]
sage: RootSystem(['A',4,1]).ambient_lattice()
Ambient lattice of the Root system of type ['A', 4, 1]
```

Except in type A, only an ambient space can be realized:

```python
sage: RootSystem(['B',4]).ambient_lattice()
sage: RootSystem(['C',4]).ambient_lattice()
sage: RootSystem(['D',4]).ambient_lattice()
sage: RootSystem(['E',6]).ambient_lattice()
sage: RootSystem(['F',4]).ambient_lattice()
sage: RootSystem(['G',2]).ambient_lattice()
```

`ambient_space(base_ring=Rational Field)`

Return the usual ambient space for this root_system.

INPUT:

• `base_ring` – a base ring (default: \( \mathbb{Q} \))

This is a base_ring-module, endowed with its canonical Euclidean scalar product, which admits simultaneous embeddings into the weight and the coweight lattice, and therefore the root and the coroot lattice, and preserves scalar products between elements of the coroot lattice and elements of the root or weight lattice (and dually).

There is no mechanical way to define the ambient space just from the Cartan matrix. Instead it is constructed from hard coded type by type data, according to the usual Bourbaki conventions. Such data is provided for all the finite (crystallographic) types. From this data, ambient spaces can be built as well for dual types,
reducible types and affine types. When no data is available, or if the base ring is not large enough, None is returned.

**Warning:** for affine types

See also:

- The section on ambient spaces in *RootSystem*
- `ambient_lattice()`
- `AmbientSpace`
- `AmbientSpace`
- `root_space()`
- `weight:space()`

**EXAMPLES:**

```sage```
RootSystem(['A',4]).ambient_space()
Ambient space of the Root system of type ['A', 4]

RootSystem(['B',4]).ambient_space()
Ambient space of the Root system of type ['B', 4]

RootSystem(['C',4]).ambient_space()
Ambient space of the Root system of type ['C', 4]

RootSystem(['D',4]).ambient_space()
Ambient space of the Root system of type ['D', 4]

RootSystem(['E',6]).ambient_space()
Ambient space of the Root system of type ['E', 6]

RootSystem(['F',4]).ambient_space()
Ambient space of the Root system of type ['F', 4]

RootSystem(['G',2]).ambient_space()
Ambient space of the Root system of type ['G', 2]
```

An alternative base ring can be provided as an option:

```sage```
RootSystem(['B',3]).ambient_space(RR)
TestSuite(e).run()
```

It should contain the smallest ring over which the ambient space can be defined (Z in type A or Q otherwise). Otherwise None is returned:

```sage```
RootSystem(['B',2]).ambient_space(ZZ)
```

The base ring should also be totally ordered. In practice, only Z and Q are really supported at this point, but you are welcome to experiment:
```python
sage: e = RootSystem(['G',2]).ambient_space(RR)
sage: TestSuite(e).run()
Failure in _test_root_lattice_realization:
Traceback (most recent call last):
  ...
AssertionError: 2.00000000000000 != 2.00000000000000
------------------------------------------------------------
The following tests failed: _test_root_lattice_realization
```

cartan_matrix()
EXAMPLES:

```python
sage: RootSystem(['A',3]).cartan_matrix()
[ 2 -1  0]
[-1  2 -1]
[ 0 -1  2]
```

cartan_type()
Returns the Cartan type of the root system.
EXAMPLES:

```python
sage: R = RootSystem(['A',3])
sage: R.cartan_type()
['A', 3]
```

coambient_space(base_ring=Rational Field)
Return the coambient space for this root system.
This is the ambient space of the dual root system.
See also:

- ambient_space()

EXAMPLES:

```python
sage: L = RootSystem(['B',2]).ambient_space(); L
Ambient space of the Root system of type ['B', 2]
sage: coL = RootSystem(['B',2]).coambient_space(); coL
Coambient space of the Root system of type ['B', 2]
```
The roots and coroots are interchanged:

```python
sage: coL.simple_roots()
Finite family {1: (1, -1), 2: (0, 1)}
sage: L.simple_coroots()
Finite family {1: (1, -1), 2: (0, 2)}
```

coroot_lattice()
Returns the coroot lattice associated to self.

```python
sage: coL.simple_roots()
Finite family {1: (1, -1), 2: (0, 1)}
sage: L.simple_coroots()
Finite family {1: (1, -1), 2: (0, 2)}
```
EXAMPLES:

```python
sage: RootSystem(['A',3]).coroot_lattice()
Coroot lattice of the Root system of type ['A', 3]
```

coroot_lattice\((base\_ring=Rational\ Field)\)

Returns the coroot lattice associated to self.

EXAMPLES:

```python
sage: RootSystem(['A',3]).coroot_lattice()
Coroot lattice of the Root system of type ['A', 3]
```

coroot_space\((base\_ring=Rational\ Field)\)

Returns the coroot space associated to self.

EXAMPLES:

```python
sage: RootSystem(['A',3]).coroot_space()
Coroot space over the Rational Field of the Root system of type ['A', 3]
```

coweight_lattice\((extended=False)\)

Returns the coweight lattice associated to self.

This is the weight lattice of the dual root system.

See also:

- `coweight_space()`
- `weight_space(), weight_lattice()`
- `WeightSpace`

EXAMPLES:

```python
sage: RootSystem(['A',3]).coweight_lattice()
Coweight lattice of the Root system of type ['A', 3]
```

```python
sage: RootSystem(['A',3,1]).coweight_lattice(extended=True)
Extended coweight lattice of the Root system of type ['A', 3, 1]
```

coweight_space\((base\_ring=Rational\ Field, extended=False)\)

Returns the coweight space associated to self.

This is the weight space of the dual root system.

See also:

- `coweight_lattice()`
- `weight_space(), weight_lattice()`
- `WeightSpace`

EXAMPLES:

```python
sage: RootSystem(['A',3]).coweight_space()
Coweight space over the Rational Field of the Root system of type ['A', 3]
```

```python
sage: RootSystem(['A',3,1]).coweight_space(extended=True)
Extended coweight space over the Rational Field of the Root system of type ['A', 3, 1]
```

dynkin_diagram()

Returns the Dynkin diagram of the root system.

EXAMPLES:
sage: R = RootSystem(['A',3])
sage: R.dynkin_diagram()
O---O---O
1  2  3
A3

index_set()
EXAMPLES:

sage: RootSystem(['A',3]).index_set()
(1, 2, 3)

is_finite()
Returns True if self is a finite root system.
EXAMPLES:

sage: RootSystem(['A',3]).is_finite()
True
sage: RootSystem(['A',3,1]).is_finite()
False

is_irreducible()
Returns True if self is an irreducible root system.
EXAMPLES:

sage: RootSystem(['A',3]).is_irreducible()
True
sage: RootSystem('A2xB2').is_irreducible()
False

root_lattice()
Returns the root lattice associated to self.
EXAMPLES:

sage: RootSystem(['A',3]).root_lattice()
Root lattice of the Root system of type ['A', 3]

root_poset(restricted=False, facade=False)
Returns the (restricted) root poset associated to self.
The elements are given by the positive roots (resp. non-simple, positive roots), and $\alpha \leq \beta$ iff $\beta - \alpha$ is a non-negative linear combination of simple roots.

INPUT:

• restricted – (default:False) if True, only non-simple roots are considered.
• facade – (default:False) passes facade option to the poset generator.

EXAMPLES:

sage: Phi = RootSystem(['A',2]).root_poset(); Phi
Finite poset containing 3 elements
sage: sorted(Phi.cover_relations(), key=str)

(continues on next page)
sage: Phi = RootSystem(['A',3]).root_poset(restricted=True); Phi
Finite poset containing 3 elements
sage: sorted(Phi.cover_relations(), key=str)

sage: Phi = RootSystem(['B',2]).root_poset(); Phi
Finite poset containing 4 elements
sage: Phi.cover_relations()

root_space(base_ring=Rational Field)
Returns the root space associated to self.

EXAMPLES:

sage: RootSystem(['A',3]).root_space()
Root space over the Rational Field of the Root system of type ['A', 3]

weight_lattice(extended=False)
Returns the weight lattice associated to self.

See also:

• weight_space()
• coweight_space(), coweight_lattice()
• WeightSpace

EXAMPLES:

sage: RootSystem(['A',3]).weight_lattice()
Weight lattice of the Root system of type ['A', 3]

sage: RootSystem(['A',3,1]).weight_space(extended=True)
Extended weight space over the Rational Field of the Root system of type ['A', 3, 1]

weight_space(base_ring=Rational Field, extended=False)
Returns the weight space associated to self.

See also:

• weight_lattice()
• coweight_space(), coweight_lattice()
• WeightSpace

EXAMPLES:
sage: RootSystem(['A',3]).weight_space()
Weight space over the Rational Field of the Root system of type ['A', 3]

sage: RootSystem(['A',3,1]).weight_space(extended = True)
Extended weight space over the Rational Field of the Root system of type ['A', 3, 1]

sage.combinat.root_system.root_system.WeylDim(ct, coeffs)
The Weyl Dimension Formula.

INPUT:

• type - a Cartan type
• coeffs - a list of nonnegative integers

The length of the list must equal the rank type[1]. A dominant weight hwv is constructed by summing the fundamental weights with coefficients from this list. The dimension of the irreducible representation of the semisimple complex Lie algebra with highest weight vector hwv is returned.

EXAMPLES:

For \(SO(7)\), the Cartan type is \(B_3\), so:

sage: WeylDim(['B',3],[1,0,0])  # standard representation of SO(7)
7
sage: WeylDim(['B',3],[0,1,0])  # exterior square
21
sage: WeylDim(['B',3],[0,0,1])  # spin representation of spin(7)
8
sage: WeylDim(['B',3],[1,0,1])  # sum of the first and third fundamental weights
48
sage: [WeylDim(['F',4],x) for x in ( [1,0,0,0],[0,1,0,0],[0,0,1,0],[0,0,0,1])]
[52, 1274, 273, 26]

sage: [WeylDim(['E',6], x) for x in ( [0, 0, 0, 0, 0, 0], [0, 1, 0, 0, 0, 0], [0, 0, 1, 0, 0, 0], [0, 0, 0, 1, 0, 0], [1, 0, 0, 0, 0, 0], [0, 0, 0, 0, 1, 0], [0, 0, 0, 0, 0, 1], [1, 0, 0, 0, 0, 0], [2, 0, 0, 0, 0, 0])]
[1, 78, 27, 351, 351, 351, 27, 650, 351]

5.1.238 Root system data for super type A

class sage.combinat.root_system.type超级_A.AmbientSpace(root_system, base_ring, index_set=None)
Bases: sage.combinat.root_system.ambient_space.AmbientSpace
The ambient space for (super) type \(A(m|n)\).

EXAMPLES:

sage: R = RootSystem(['A', [2,1]])
sage: AL = R.ambient_space(); AL
Ambient space of the Root system of type ['A', [2, 1]]
sage: AL.basis()
Finite family {-3: (1, 0, 0, 0), -2: (0, 1, 0, 0), (continues on next page)
class Element

    Bases: sage.combinat.root_system.ambient_space.AmbientSpaceElement

    associated_coroot()

    Return the coroot associated to self.

    EXAMPLES:

    sage: L = RootSystem(['A', [3,2]]).ambient_space()
    sage: al = L.simple_roots()
    sage: al[-1].associated_coroot()
    (0, 0, 1, -1, 0, 0)
    sage: al[0].associated_coroot()
    (0, 0, 0, 1, -1, 0)
    sage: al[1].associated_coroot()
    (0, 0, 0, 0, -1, 1)
    sage: a = al[-1] + al[0] + al[1]; a
    (0, 0, 1, 0, 0, -1)
    sage: a.associated_coroot()
    (0, 0, 1, 0, -2, 1)
    sage: h = L.simple_coroots()
    sage: h[-1] + h[0] + h[1]
    (0, 0, 1, 0, -2, 1)
    sage: (al[-1] + al[0] + al[2]).associated_coroot()
    (0, 0, 1, 0, -1, 1)

    dot_product(lambdacheck)

    The scalar product with elements of the coroot lattice embedded in the ambient space.

    EXAMPLES:

    sage: L = RootSystem(['A', [2,1]]).ambient_space()
    sage: a = L.simple_roots()
    sage: matrix([[a[i].inner_product(a[j]) for j in L.index_set()] for i in L.index_set()])
    [ 2 -1  0  0]
    [-1  2 -1  0]
    [ 0 -1  0  1]
    [ 0  0  1 -2]

    has_descent(i, positive=False)

    Test if self has a descent at position i, that is if self is on the strict negative side of the ith simple reflection hyperplane.

    If positive is True, tests if it is on the strict positive side instead.

    EXAMPLES:
\begin{verbatim}
sage: L = RootSystem(['A', [2,1]]).ambient_space()
sage: al = L.simple_roots()
sage: [al[i].has_descent(1) for i in L.index_set()]  
[False, False, True, False]
sage: [(-al[i]).has_descent(1) for i in L.index_set()]  
[False, False, False, True]
sage: [al[i].has_descent(1, True) for i in L.index_set()]  
[False, False, False, True]
sage: [(-al[i]).has_descent(1, True) for i in L.index_set()]  
[False, False, True, False]
sage: (al[-2] + al[0] + al[1]).has_descent(-1)  
True
sage: (al[-2] + al[0] + al[1]).has_descent(1)  
False
sage: (al[-2] + al[0] + al[1]).has_descent(1, positive=True)  
True

inner_product(lambdacheck)
The scalar product with elements of the coroot lattice embedded in the ambient space.

EXAMPLES:
\end{verbatim}

\begin{verbatim}
sage: L = RootSystem(['A', [2,1]]).ambient_space()
sage: a = L.simple_roots()
sage: matrix([[a[i].inner_product(a[j]) for j in L.index_set()] for i in L.index_set()])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  0  1]
[ 0  0  1 -2]
\end{verbatim}

\begin{verbatim}
is_dominant_weight()
Test whether self is a dominant element of the weight lattice.

EXAMPLES:
\end{verbatim}

\begin{verbatim}
sage: L = RootSystem(['A',2]).ambient_lattice()
sage: Lambda = L.fundamental_weights()
sage: [x.is_dominant() for x in Lambda]
[True, True]
sage: (3*Lambda[1]+Lambda[2]).is_dominant()  
True
sage: (Lambda[1]-Lambda[2]).is_dominant()  
False
sage: (-Lambda[1]+Lambda[2]).is_dominant()  
False
\end{verbatim}

Tests that the scalar products with the coroots are all nonnegative integers. For example, if \(x\) is the sum of a dominant element of the weight lattice plus some other element orthogonal to all coroots, then the implementation correctly reports \(x\) to be a dominant weight:
```python
sage: x = Lambda[1] + L([-1,-1,-1])
sage: x.is_dominant_weight()
True
```

**scalar** *(lambdacheck)*

The scalar product with elements of the coroot lattice embedded in the ambient space.

**EXAMPLES:**

```python
sage: L = RootSystem(['A', [2,1]]).ambient_space()
sage: a = L.simple_roots()
sage: matrix([[a[i].inner_product(a[j]) for j in L.index_set()] for i in L.index_set()])
```
```
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  0  1]
[ 0  0  1 -2]
```

**dimension()**

Return the dimension of this ambient space.

**EXAMPLES:**

```python
sage: e = RootSystem(['A', [4,2]]).ambient_space()
sage: e.dimension()
8
```

**fundamental_weight(i)**

Return the fundamental weight \( \Lambda_i \) of self.

**EXAMPLES:**

```python
sage: L = RootSystem(['A', [3,2]]).ambient_space()
sage: L.fundamental_weight(-1)
(1, 1, 1, 0, 0, 0, 0)
sage: L.fundamental_weight(0)
(1, 1, 1, 1, 0, 0, 0)
sage: L.fundamental_weight(2)
(1, 1, 1, -1, -1, -2)
sage: list(L.fundamental_weights())
[(1, 0, 0, 0, 0, 0, 0),
 (1, 1, 0, 0, 0, 0, 0),
 (1, 1, 1, 0, 0, 0, 0),
 (1, 1, 1, 1, 0, 0, 0),
 (1, 1, 1, 1, -1, -2, -2),
 (1, 1, 1, 1, -1, -1, -2)]
```

```python
sage: L = RootSystem(['A', [2,3]]).ambient_space()
sage: La = L.fundamental_weights()
sage: al = L.simple_roots()
sage: I = L.index_set()
sage: matrix([[al[i].scalar(La[j]) for i in I] for j in I])
```
```
[ 1  0  0  0  0  0]
[ 0  1  0  0  0  0]
```

(continues on next page)
highest_root()
Return the highest root of self.

EXAMPLES:

```
sage: e = RootSystem(['A', [4,2]]).ambient_lattice()
sage: e.highest_root()
(1, 0, 0, 0, 0, 0, 0, -1)
```

negative_even_roots()
Return the negative even roots of self.

EXAMPLES:

```
sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.negative_even_roots()
[(0, -1, 1, 0, 0), (-1, 0, 1, 0, 0),
 (-1, 1, 0, 0, 0), (0, 0, 0, -1, 1)]
```

negative_odd_roots()
Return the negative odd roots of self.

EXAMPLES:

```
sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.negative_odd_roots()
[(0, 0, -1, 1, 0),
 (0, 0, -1, 0, 1),
 (0, -1, 0, 1, 0),
 (0, -1, 0, 0, 1),
 (-1, 0, 0, 1, 0),
 (-1, 0, 0, 0, 1)]
```

negative_roots()
Return the negative roots of self.

EXAMPLES:

```
sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.negative_roots()
[(0, -1, 1, 0, 0),
 (-1, 0, 1, 0, 0),
 (-1, 1, 0, 0, 0),
 (0, 0, 0, -1, 1),
 (0, 0, -1, 1, 0),
 (0, 0, -1, 0, 1),
 (0, -1, 0, 0, 1),
 (-1, 0, 0, 1, 0),
 (-1, 0, 0, 0, 1)]
```
**positive_even_roots()**
Return the positive even roots of self.

**EXAMPLES:**
```
sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.positive_even_roots()
[(0, 1, -1, 0, 0), (1, 0, -1, 0, 0),
 (1, -1, 0, 0, 0), (0, 0, 0, 1, -1)]
```

**positive_odd_roots()**
Return the positive odd roots of self.

**EXAMPLES:**
```
sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.positive_odd_roots()
[(0, 0, 1, -1, 0),
 (0, 0, 1, 0, -1),
 (0, 1, 0, -1, 0),
 (0, 1, 0, 0, -1),
 (1, 0, 0, -1, 0),
 (1, 0, 0, 0, -1)]
```

**positive_roots()**
Return the positive roots of self.

**EXAMPLES:**
```
sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.positive_roots()
[(0, 1, -1, 0, 0),
 (1, 0, -1, 0, 0),
 (1, -1, 0, 0, 0),
 (0, 0, 0, 1, -1),
 (0, 0, 1, -1, 0),
 (0, 0, 1, 0, -1),
 (0, 1, 0, -1, 0),
 (0, 1, 0, 0, -1),
 (1, 0, 0, -1, 0),
 (1, 0, 0, 0, -1)]
```

**simple_coroot(i)**
Return the simple coroot \(h_i\) of self.

**EXAMPLES:**
```
sage: L = RootSystem(['A', [3,2]]).ambient_space()
sage: L.simple_coroot(-2)
(0, 1, -1, 0, 0, 0, 0)
sage: L.simple_coroot(0)
(0, 0, 0, 1, -1, 0, 0)
sage: L.simple_coroot(2)
(0, 0, 0, 0, 0, -1, 1)
sage: list(L.simple_coroots())
[(1, -1, 0, 0, 0, 0, 0),
```

(continues on next page)
simple_root(i)
Return the i-th simple root of self.

EXAMPLES:

```
sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: list(e.simple_roots())
[(1, -1, 0, 0, 0), (0, 1, -1, 0, 0),
 (0, 0, 1, -1, 0), (0, 0, 0, 1, -1)]
```

classmethod smallest_base_ring(cartan_type=None)
Return the smallest base ring the ambient space can be defined upon.

See also:
smallest_base_ring()

EXAMPLES:

```
sage: e = RootSystem(['A', [3,1]]).ambient_space()
sage: e.smallest_base_ring()
Integer Ring
```

class sage.combinat.root_system.type_super_A.CartanType(m, n)
Cartan Type $A(m\mid n)$.

See also:
CartanType()

AmbientSpace
alias of AmbientSpace

ascii_art(label=<function CartanType.<lambda> at 0x7fb371d0cb80>, node=None)
Return an ascii art representation of the Dynkin diagram.

EXAMPLES:

```
sage: t = CartanType(['A', [3,2]])
sage: print(t.ascii_art())
0---0---0---X---0---0
-3 -2 -1 0 1 2
sage: t = CartanType(['A', [3,7]])
sage: print(t.ascii_art())
0---0---0---X---0---0---0---0---0---0
-3 -2 -1 0 1 2 3 4 5 6 7
sage: t = CartanType(['A', [0,7]])
sage: print(t.ascii_art())
```

Combinatorics, Release 9.7

(continued from previous page)

```python
sage: t = CartanType(['A', [0,0]])
sage: print(t.ascii_art())
X
-
0
sage: t = CartanType(['A', [5,0]])
sage: print(t.ascii_art())
O---O---O---O---O---X
-5 -4 -3 -2 -1 0
```

cartan_matrix()
Return the Cartan matrix associated to self.
EXAMPLES:

```python
sage: ct = CartanType(['A', [2,3]])
sage: ct.cartan_matrix()
[ 2 -1 0 0 0 0]
[-1 2 -1 0 0 0]
[ 0 -1 0 1 0 0]
[ 0 0 -1 2 -1 0]
[ 0 0 0 -1 2 -1]
[ 0 0 0 0 -1 2]
```

dual()
Return dual of self.
EXAMPLES:

```python
sage: CartanType(['A', [2,3]]).dual()
['A', [2, 3]]
```

dynkin_diagram()
Return the Dynkin diagram of super type A.
EXAMPLES:

```python
sage: a = CartanType(['A', [4,2]]).dynkin_diagram()
sage: a
O---O---O---O---X---O---O
-4 -3 -2 -1 0 1 2
A4|2
sage: a.edges(sort=True)
[(-4, -3, 1), (-3, -4, 1), (-3, -2, 1), (-2, -3, 1),
 (-2, -1, 1), (-1, -2, 1), (-1, 0, 1), (0, -1, 1),
 (0, 1, 1), (1, 0, -1), (1, 2, 1), (2, 1, 1)]
```

index_set()
Return the index set of self.
EXAMPLES:

```python
sage: CartanType(['A', [2,3]]).index_set()
(-2, -1, 0, 1, 2, 3)
```

5.1. Comprehensive Module List 2477
is_affine()
Return whether self is affine or not.

EXAMPLES:

```
sage: CartanType(['A', [2,3]]).is_affine()
False
```

is_finite()
Return whether self is finite or not.

EXAMPLES:

```
sage: CartanType(['A', [2,3]]).is_finite()
True
```

is_irreducible()
Return whether self is irreducible, which is True.

EXAMPLES:

```
sage: CartanType(['A', [3,4]]).is_irreducible()
True
```

relabel(relabelling)
Return a relabelled copy of this Cartan type.

INPUT:

• relabelling – a function (or a list or dictionary)

OUTPUT:

an isomorphic Cartan type obtained by relabelling the nodes of the Dynkin diagram. Namely, the node with label \( i \) is relabelled \( f(i) \) (or, by \( f[i] \) if \( f \) is a list or dictionary).

EXAMPLES:

```
sage: ct = CartanType(['A', [1,2]])
sage: ct.dynkin_diagram()
0---X---0---0
-1  0  1  2
A1|2
sage: f={1:2,2:1,0:0,-1:-1}
sage: ct.relabel(f)
['A', [1, 2]] relabelled by {-1: -1, 0: 0, 1: 2, 2: 1}
sage: ct.relabel(f).dynkin_diagram()
0---X---0---0
-1  0  2  1
A1|2 relabelled by {-1: -1, 0: 0, 1: 2, 2: 1}
```

root_system()
Return root system of self.

EXAMPLES:

```
sage: CartanType(['A', [2,3]]).root_system()
Root system of type ['A', [2, 3]]
```
symmetrizer()
Return symmetrizing matrix for self.

EXAMPLES:

```
sage: CartanType(['A', [2,3]]).symmetrizer()
Finite family {-2: 1, -1: 1, 0: 1, 1: -1, 2: -1, 3: -1}
```

type()
Return type of self.

EXAMPLES:

```
sage: CartanType(['A', [2,3]]).type()
'A'
```

5.1.239 Root system data for type A

class sage.combinat.root_system.type_A.AmbientSpace(root_system, base_ring, index_set=None)
Bases: sage.combinat.root_system.ambient_space.AmbientSpace

EXAMPLES:

```
sage: R = RootSystem(['A',3])
sage: e = R.ambient_space(); e
Ambient space of the Root system of type ['A', 3]
sage: TestSuite(e).run()
```

By default, this ambient space uses the barycentric projection for plotting:

```
sage: L = RootSystem(['A',2]).ambient_space()
sage: e = L.basis()
sage: L._plot_projection(e[0])
(1/2, 989/1142)
sage: L._plot_projection(e[1])
(-1, 0)
sage: L._plot_projection(e[2])
(1/2, -989/1142)
sage: L = RootSystem(['A',3]).ambient_space()
sage: l = L.an_element(); l
(2, 2, 3, 0)
sage: L._plot_projection(l)
(0, -1121/1189, 7/3)
```

See also:

- sage.combinat.root_system.root_lattice_realizations.RootLatticeRealizations.
  ParentMethods._plot_projection()

det(k=1)
returns the vector (1, ..., 1) which in the ['A',r] weight lattice, interpreted as a weight of GL(r+1,CC) is the determinant. If the optional parameter k is given, returns (k, ..., k), the k-th power of the determinant.

EXAMPLES:
sage: e = RootSystem(['A',3]).ambient_space()
sage: e.det(1/2)
(1/2, 1/2, 1/2, 1/2)

**dimension()**

EXAMPLES:
```
sage: e = RootSystem(['A',3]).ambient_space()
sage: e.dimension()
4
```

**fundamental_weight(i)**

EXAMPLES:
```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0)}
```

**highest_root()**

EXAMPLES:
```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.highest_root()
(1, 0, 0, -1)
```

**negative_roots()**

EXAMPLES:
```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.negative_roots()
[(-1, 1, 0, 0),
 (-1, 0, 1, 0),
 (-1, 0, 0, 1),
 (0, -1, 1, 0),
 (0, -1, 0, 1),
 (0, 0, -1, 1)]
```

**positive_roots()**

EXAMPLES:
```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.positive_roots()
[(1, -1, 0, 0),
 (1, 0, -1, 0),
 (0, 1, -1, 0),
 (1, 0, 0, -1),
 (0, 1, 0, -1),
 (0, 0, 1, -1)]
```

**root(i,j)**

Note that indexing starts at 0.

EXAMPLES:
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.root(0,1)
(1, -1, 0, 0)

**simple_root**(i)

**EXAMPLES:**

```python
code
```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}
```

**classmethod smallest_base_ring**(cartan_type=None)

Returns the smallest base ring the ambient space can be defined upon

**See also:**

smallest_base_ring()

**EXAMPLES:**

```python
code
```
sage: e = RootSystem(['A',3]).ambient_space()
sage: e.smallest_base_ring()
Integer Ring
```

class sage.combinat.root_system.type_A.CartanType(n)

**Bases:** sage.combinat.root_system.cartan_type.CartanType_standard_finite, sage.combinat.root_system.cartan_type.CartanType_simply_laced, sage.combinat.root_system.cartan_type.CartanType_simple

Cartan Type $A_n$

**See also:** CartanType()

**AmbientSpace**

alias of AmbientSpace

**PieriFactors**

alias of sage.combinat.root_system.pieri_factors.PieriFactors_type_A

**ascii_art**(label=<function CartanType.<lambda> at 0x7fb371ce8ee0>, node=None)

Return an ascii art representation of the Dynkin diagram.

**EXAMPLES:**

```python
code
```
sage: print(CartanType(['A',0]).ascii_art())
sage: print(CartanType(['A',1]).ascii_art())
0
1
sage: print(CartanType(['A',3]).ascii_art())
0---0---0
1 2 3
sage: print(CartanType(['A',12]).ascii_art())
0---0---0---0---0---0---0---0---0---0---0---0---0---0---0
1 2 3 4 5 6 7 8 9 10 11 12
sage: print(CartanType(['A',5]).ascii_art(label = lambda x: x+2))
0---0---0---0---0---0
(continues on next page)
```python
3 4 5 6 7
sage: print(CartanType(['A',5]).ascii_art(label = lambda x: x-2))
O---O---O---O---O
-1 0 1 2 3
```

**coxeter_number()**

Return the Coxeter number associated with self.

EXAMPLES:

```python
sage: CartanType(['A',4]).coxeter_number()
5
```

**dual_coxeter_number()**

Return the dual Coxeter number associated with self.

EXAMPLES:

```python
sage: CartanType(['A',4]).dual_coxeter_number()
5
```

**dynkin_diagram()**

Returns the Dynkin diagram of type A.

EXAMPLES:

```python
sage: a = CartanType(['A',3]).dynkin_diagram()
sage: a
O---O---O
1 2 3
A3
sage: a.edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 1)]
```

### 5.1.240 Root system data for (untwisted) type A affine

**class** `sage.combinat.root_system.type_A_affine.CartanType(n)`

Bases: `sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine`

EXAMPLES:

```python
sage: ct = CartanType(['A',4,1])
sage: ct
['A', 4, 1]
sage: ct._repr_(compact = True)
'A4~'
sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
```
### Combinatorics, Release 9.7

(continued from previous page)

```python
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
True
sage: ct.classical()
['A', 4]
sage: ct.dual()
['A', 4, 1]
```

```python
sage: ct = CartanType(['A', 1, 1])
sage: ct.is_simply_laced()
False
sage: ct.dual()
['A', 1, 1]
```

#### PieriFactors
alias of `sage.combinat.root_system.pieri_factors.PieriFactors_type_A_affine`

#### ascii_art

*Function CartanType.<lambda> at 0x7fb371cdc430*, `node=None`

return an ascii art representation of the extended Dynkin diagram.

**Examples:**

```python
sage: print(CartanType(['A',3,1]).ascii_art())

0
0--------+
| |
| |
0---0----0
1 2 3
```

```python
sage: print(CartanType(['A',5,1]).ascii_art(label = lambda x: x+2))

2
0----------------+
| |
| |
0---0---0---0---0
3 4 5 6 7
```

```python
sage: print(CartanType(['A',1,1]).ascii_art())

0<=>0
0 1
```

```python
sage: print(CartanType(['A',1,1]).ascii_art(label = lambda x: x+2))

0<=>0
2 3
```

#### dual()

type $A_1^\dagger$ is self dual despite not being simply laced.

**Examples:**
**Combinatorics, Release 9.7**

```python
sage: CartanType(['A',1,1]).dual()
['A', 1, 1]
```

**dynkin_diagram()**  
Returns the extended Dynkin diagram for affine type A.

**EXAMPLES:**

```python
sage: a = CartanType(['A',3,1]).dynkin_diagram()
sage: a
O-------+
| |
| |
O---O---O
 1 2 3
A3~
sage: a.edges(sort=True)
[(0, 1, 1),
 (0, 3, 1),
 (1, 0, 1),
 (1, 2, 1),
 (2, 1, 1),
 (2, 3, 1),
 (3, 0, 1),
 (3, 2, 1)]
sage: a = DynkinDiagram(['A',1,1])
sage: a
O<=>O
 0 1
A1~
sage: a.edges(sort=True)
[(0, 1, 2), (1, 0, 2)]
```

### 5.1.241 Root system data for type A infinity

**class** `sage.combinat.root_system.type_A_infinity.CartanType(index_set)`

**Bases:** `sage.combinat.root_system.cartan_type.CartanType_standard`, `sage.combinat.root_system.cartan_type.CartanType_simple`

The Cartan type $A_\infty$.

We use $\mathbb{N}$ and $\mathbb{Z}$ to explicitly differentiate between the $A_+\infty$ and $A_\infty$ root systems, respectively. While $\infty$ is the same as $+\text{Infinity}$ in Sage, it is used as an alias for $\mathbb{Z}$.

**ascii_art**(label=<function CartanType.<lambda> at 0x7fb371d0cee0>, node=None)

Return an ascii art representation of the extended Dynkin diagram.

**EXAMPLES:**

```python
sage: print(CartanType(['A', ZZ]).ascii_art())
..---O---O---O---O---O---O---O---O---O---
   -3 -2 -1 0 1 2 3
```

Combinatorics, Release 9.7

sage: print(CartanType(['A', NN]).ascii_art())
O---O---O---O---O---O---O---..<br>0 1 2 3 4 5 6

dual()
Simply laced Cartan types are self-dual, so return self.

EXAMPLES:

sage: CartanType(['A', NN]).dual()
['A', NN]
sage: CartanType(['A', ZZ]).dual()
['A', ZZ]

index_set()
Return the index set for the Cartan type self.
The index set for all standard finite Cartan types is of the form \{1, \ldots, n\}. (See type_I for a slight abuse of this).

EXAMPLES:

sage: CartanType(['A', NN]).index_set()
Non negative integer semiring
sage: CartanType(['A', ZZ]).index_set()
Integer Ring

is_affine()
Return False because self is not (untwisted) affine.

EXAMPLES:

sage: CartanType(['A', NN]).is_affine()
False
sage: CartanType(['A', ZZ]).is_affine()
False

is_crystallographic()
Return False because self is not crystallographic.

EXAMPLES:

sage: CartanType(['A', NN]).is_crystallographic()
True
sage: CartanType(['A', ZZ]).is_crystallographic()
True

is_finite()
Return True because self is not finite.

EXAMPLES:

sage: CartanType(['A', NN]).is_finite()
False
sage: CartanType(['A', ZZ]).is_finite()
False
is_simply_laced()
Return True because self is simply laced.

EXAMPLES:

```python
sage: CartanType(['A', NN]).is_simply_laced()
True
sage: CartanType(['A', ZZ]).is_simply_laced()
True
```

is_untwisted_affine()
Return False because self is not (untwisted) affine.

EXAMPLES:

```python
sage: CartanType(['A', NN]).is_untwisted_affine()
False
sage: CartanType(['A', ZZ]).is_untwisted_affine()
False
```

rank()
Return the rank of self which for type $X_n$ is $n$.

EXAMPLES:

```python
sage: CartanType(['A', NN]).rank()
+Infinity
sage: CartanType(['A', ZZ]).rank()
+Infinity
```

As this example shows, the rank is slightly ambiguous because the root systems of type ['A', NN] and type ['A', ZZ] have the same rank. Instead, it is better to use index_set() to differentiate between these two root systems.

type()
Return the type of self.

EXAMPLES:

```python
sage: CartanType(['A', NN]).type()
'A'
sage: CartanType(['A', ZZ]).type()
'A'
```

5.1.242 Root system data for type B

class sage.combinat.root_system.type_B.AmbientSpace(root_system, base_ring, index_set=None)
Bases: sage.combinat.root_system.ambient_space.AmbientSpace
dimension()
EXAMPLES:

```python
sage: e = RootSystem(['B', 3]).ambient_space()
sage: e.dimension()
3
```
fundamental_weight(i)

EXAMPLES:

```python
sage: RootSystem(['B',3]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
```

negative_roots()

EXAMPLES:

```python
sage: RootSystem(['B',3]).ambient_space().negative_roots()
[(-1, 1, 0),
 (-1, -1, 0),
 (-1, 0, 1),
 (-1, 0, -1),
 (0, -1, 1),
 (0, -1, -1),
 (-1, 0, 0),
 (0, -1, 0),
 (0, 0, -1)]
```

positive_roots()

EXAMPLES:

```python
sage: RootSystem(['B',3]).ambient_space().positive_roots()
[(1, -1, 0),
 (1, 1, 0),
 (1, 0, -1),
 (1, 0, 1),
 (0, 1, -1),
 (0, 1, 1),
 (1, 0, 0),
 (0, 1, 0),
 (0, 0, 1)]
```

root(i, j)

Note that indexing starts at 0.

EXAMPLES:

```python
sage: e = RootSystem(['B',3]).ambient_space()
```

```python
sage: e.root(0,1)
(1, -1, 0)
```

simple_root(i)

EXAMPLES:

```python
sage: e = RootSystem(['B',4]).ambient_space()
```

```python
sage: e.simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1), 4: (0, 0, 0, 1)}
```

```python
sage: e.positive_roots()
[(1, -1, 0, 0),
 (1, 1, 0, 0),
 (1, 0, -1, 0),
 (1, 0, 1, 0),
 (0, 1, -1),
 (0, 1, 1),
 (1, 0, 0),
 (0, 1, 0),
 (0, 0, 1)]
```

(continues on next page)
sage: e.fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0), 4: (1/2, 1/2, 1/2, 1/2)}

class sage.combinat.root_system.type_B.CartanType(n)
Bases: sage.combinat.root_system.cartan_type.CartanType_standard_finite, sage.combinat.root_system.cartan_type.CartanType_simple, sage.combinat.root_system.cartan_type.CartanType_crystallographic

EXAMPLES:

```python
sage: ct = CartanType(['B',4])
sage: ct
['B', 4]
sage: ct._repr_(compact = True)
'B4'
sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_affine()
False
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.affine()
['B', 4, 1]
sage: ct.dual()
['C', 4]
```

AmbientSpace
alias of AmbientSpace
PieriFactors
alias of sage.combinat.root_system.pieri_factors.PieriFactors_type_B

ascii_art(label=<function CartanType.<lambda> at 0x7fb371cf5790>, node=None)
Return an ascii art representation of the Dynkin diagram.

EXAMPLES:

```python
sage: print(CartanType(['B',1]).ascii_art())
O
1
sage: print(CartanType(['B',2]).ascii_art())
O=>=O
1 2
sage: print(CartanType(['B',5]).ascii_art(label = lambda x: x+2))
O---O---O---O=>=O
3 4 5 6 7
```

coxeter_number()
Return the Coxeter number associated with self.

EXAMPLES:

```python
sage: CartanType(['B',4]).coxeter_number()
8
```

dual()
Types B and C are in duality:

EXAMPLES:

```python
sage: CartanType(['C', 3]).dual()
['B', 3]
```

dual_coxeter_number()
Return the dual Coxeter number associated with self.

EXAMPLES:

```python
sage: CartanType(['B',4]).dual_coxeter_number()
7
```

dynkin_diagram()
Returns a Dynkin diagram for type B.

EXAMPLES:

```python
sage: b = CartanType(['B',3]).dynkin_diagram()
sage: b
O---O=>=O
1 2 3
B3
sage: b.edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1)]
sage: b = CartanType(['B',1]).dynkin_diagram()
sage: b
(continues on next page)```
5.1.243 Root system data for type BC affine

class sage.combinat.root_system.type_BC_affine.CartanType(n)
    Bases: sage.combinat.root_system.cartan_type.CartanType_standard_affine

EXAMPLES:

sage: ct = CartanType(['BC',4,2])
sage: ct
['BC', 4, 2]
sage: ct._repr_(compact = True)
'BC4~'
sage: ct.dynkin_diagram()
O=<=O---O---O=<=O
0 1 2 3 4
BC4~

sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.classical()
['C', 4]

sage: dual = ct.dual()
sage: dual.dynkin_diagram()
O=>=O---O---O=>=O
0 1 2 3 4
BC4~*

sage: dual.special_node()
0
sage: dual.classical().dynkin_diagram()
O---O---0=<=0
1 2 3 4
B4

sage: CartanType(['BC',1,2]).dynkin_diagram()
ascii_art(label=<function CartanType.<lambda> at 0x7fb371d06940>, node=None)

Return a ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```
sage: print(CartanType(['BC',2,2]).ascii_art())
O=<=O=<=O
0 1 2

sage: print(CartanType(['BC',3,2]).ascii_art())
O=<=O---O=<=O
0 1 2 3

sage: print(CartanType(['BC',5,2]).ascii_art(label = lambda x: x+2))
O=<=O---O---O---O=<=O
2 3 4 5 6 7

sage: print(CartanType(['BC',1,2]).ascii_art(label = lambda x: x+2))
4
O=<=O
2 3
```

basic_untwisted()

Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_{n}(r)$, the basic untwisted type is $X_{n}$. In other words, it is the classical Cartan type that is twisted to obtain self.

EXAMPLES:

```
sage: CartanType(['A', 2, 2]).basic_untwisted()
['A', 2]

sage: CartanType(['A', 4, 2]).basic_untwisted()
['A', 4]

sage: CartanType(['BC', 4, 2]).basic_untwisted()
['A', 8]
```

classical()

Returns the classical Cartan type associated with self

```
sage: CartanType(['BC', 3, 2]).classical()
['C', 3]
```

dynkin_diagram()

Returns the extended Dynkin diagram for affine type BC.

EXAMPLES:

```
sage: c = CartanType(['BC',3,2]).dynkin_diagram()
sage: c
O=<=O---O=<=O
0 1 2 3
BC3~
sage: c.edges(sort=True)
```

(continues on next page)
5.1.244 Root system data for (untwisted) type B affine

class sage.combinat.root_system.type_B_affine.CartanType(n)

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine

EXAMPLES:

sage: ct = CartanType(['B',4,1])
sage: ct
['B', 4, 1]
sage: ct._repr_(compact = True)
'B4~'

sage: ct.is_irreducible()  
True
sage: ct.is_finite()       
False
sage: ct.is_affine()       
True
sage: ct.is_untwisted_affine()  
True
sage: ct.is_crystallographic()  
True
```python
sage: ct.is_simply_laced()

sage: ct.classical()
['B', 4]
sage: ct.dual()
['B', 4, 1]^*
sage: ct.dual().is_untwisted_affine()
False
```

**PieriFactors**

alias of `sage.combinat.root_system.pieri_factors.PieriFactors_type_B_affine`

**ascii_art** *(label=<function CartanType.<lambda> at 0x7fb371cdc9d0>, node=None)*

Return an ascii art representation of the extended Dynkin diagram.

**EXAMPLES:**

```python
sage: print(CartanType(['B',3,1]).ascii_art())
O 0
| |
O---O=>=O
1 2 3

sage: print(CartanType(['B',5,1]).ascii_art(label = lambda x: x+2))
O 2
| |
O---O---O---O=>=O
3 4 5 6 7

sage: print(CartanType(['B',2,1]).ascii_art(label = lambda x: x+2))
0>=0=<0
2 4 3

sage: print(CartanType(['B',1,1]).ascii_art(label = lambda x: x+2))
0=<0
2 3
```

**dynkin_diagram()**

Return the extended Dynkin diagram for affine type $B$.

**EXAMPLES:**

```python
sage: b = CartanType(['B',3,1]).dynkin_diagram()
sage: b
O 0
| |
O---O=>=O
1 2 3
B3~
sage: b.edges(sort=True)
[(0, 2, 1), (1, 2, 1), (2, 0, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1)]
```

5.1.245 Root system data for type C

```python
sage: b = CartanType(['B', 2, 1]).dynkin_diagram(); b
O=>=O=<=O
0 2 1
B2~
sage: b.edges(sort=True)
[(0, 2, 2), (1, 2, 2), (2, 0, 1), (2, 1, 1)]

sage: b = CartanType(['B', 1, 1]).dynkin_diagram(); b
O<=>O
0 1
B1~
sage: b.edges(sort=True)
[(0, 1, 2), (1, 0, 2)]

5.1.245 Root system data for type C

['C', 1, 1]
```

---

**AmbientSpace**

alias of `AmbientSpace`

**ascii_art**

(`label=<function CartanType.<lambda> at 0x7fb371f735e0>, node=None`)

Return a ascii art representation of the extended Dynkin diagram.

**EXAMPLES:**

```python
sage: print(CartanType(['C',1]).ascii_art())
```

```
O
1
```

```python
sage: print(CartanType(['C',2]).ascii_art())
```

```

```
O---O---O---O=<=O
3 4 5 6 7
```

**coxeter_number()**

Return the Coxeter number associated with `self`

**EXAMPLES:**

```python
sage: CartanType(['C',4]).coxeter_number()
8
```

**dual()**

Types B and C are in duality:

**EXAMPLES:**

```python
sage: CartanType(['C',3]).dual()
['B', 3]
```

**dual_coxeter_number()**

Return the dual Coxeter number associated with `self`

**EXAMPLES:**
sage: CartanType(['C',4]).dual_coxeter_number()
5

dynkin_diagram()
Returns a Dynkin diagram for type C.
EXAMPLES:

sage: c = CartanType(['C',3]).dynkin_diagram()
sage: c
O---O=<=O
1 2 3
C3
sage: c.edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]

5.1.247 Root system data for type D

class sage.combinat.root_system.type_D.AmbientSpace(root_system, base_ring, index_set=None)
Bases: sage.combinat.root_system.ambient_space.AmbientSpace
dimension
EXAMPLES:

sage: e = RootSystem(['D',3]).ambient_space()
sage: e.dimension()
3

**fundamental_weight(i)**

EXAMPLES:

```python
sage: RootSystem(['D',4]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1/2, 1/2, 1/2, -1/2), 4: (1/2, 1/2, 1/2, 1/2)}
```

**negative_roots()**

EXAMPLES:

```python
sage: RootSystem(['D',4]).ambient_space().negative_roots()
[(-1, 1, 0, 0),
 (-1, 0, 1, 0),
 (0, -1, 1, 0),
 (-1, 0, 0, 1),
 (0, -1, 0, 1),
 (0, 0, -1, 1),
 (-1, -1, 0, 0),
 (-1, 0, -1, 0),
 (0, -1, -1, 0),
 (-1, 0, 0, -1),
 (0, -1, 0, -1),
 (0, 0, -1, -1)]
```

**positive_roots()**

EXAMPLES:

```python
sage: RootSystem(['D',4]).ambient_space().positive_roots()
[(1, 1, 0, 0),
 (1, 0, 1, 0),
 (0, 1, 1, 0),
 (1, 0, 0, 1),
 (0, 1, 0, 1),
 (0, 0, 1, 1),
 (1, -1, 0, 0),
 (1, 0, -1, 0),
 (0, 1, -1, 0),
 (1, 0, 0, -1),
 (0, 1, 0, -1),
 (0, 0, 1, -1)]
```

**root(i, j, p1, p2)**

Note that indexing starts at 0.

EXAMPLES:

```python
sage: e = RootSystem(['D',3]).ambient_space()
sage: e.root(0, 1, 1, 1)
(-1, -1, 0)
sage: e.root(0, 0, 1, 1)
(-1, 0, 0)
```

**simple_root(i)**

EXAMPLES:
sage: RootSystem(['D',4]).ambient_space().simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1), 4: (0, 0, -1, 1)}

class sage.combinat.root_system.type_D.CartanType(n)
    Bases: sage.combinat.root_system.cartan_type.CartanType_standard_finite, sage.combinat.root_system.cartan_type.CartanType_simply_laced

EXAMPLES:

sage: ct = CartanType(['D',4])
sage: ct
['D', 4]
sage: ct._repr_(compact = True)
'D4'
sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
True
sage: ct.dual()
['D', 4]
sage: ct.affine()
['D', 4, 1]

sage: ct = CartanType(['D',2])
sage: ct.is_irreducible()
False
sage: ct.dual()
['D', 2]
sage: ct.affine()
Traceback (most recent call last):
...
ValueError: ['D', 2, 1] is not a valid Cartan type

AmbientSpace
    alias of AmbientSpace

ascii_art(label=<function CartanType.<lambda> at 0x7fb371f78040>, node=None)
    Return a ascii art representation of the extended Dynkin diagram.

EXAMPLES:

sage: print(CartanType(['D',3]).ascii_art())
  0  3
  |
  0--0
  1  2
sage: print(CartanType(['D',4]).ascii_art())
Combinatorics, Release 9.7

3 4 5 6 7

coxeter_number()
Return the Coxeter number associated with self.

EXAMPLES:

sage: CartanType(['D',4]).coxeter_number()
6

dual_coxeter_number()
Return the dual Coxeter number associated with self.

EXAMPLES:

sage: CartanType(['D',4]).dual_coxeter_number()
6
dynkin_diagram()
Returns a Dynkin diagram for type D.

EXAMPLES:

sage: d = CartanType(['D',5]).dynkin_diagram(); d
O 5
| |
| |
0---0---0---0
1 2 3 4
D5
sage: d.edges(sort=True)

(continues on next page)
is_atomic()

Implements CartanType_abstract.is_atomic()

$D_2$ is atomic, like all $D_n$, despite being non irreducible.

EXAMPLES:

```
sage: CartanType(['D',2]).is_atomic()
True
sage: CartanType(['D',2]).is_irreducible()
False
```
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
True
sage: ct.classical()
['D', 4]
sage: ct.dual()
['D', 4, 1]

PieriFactors
alias of sage.combinat.root_system.pieri_factors.PieriFactors_type_D_affine

ascii_art(label=<function CartanType.<lambda> at 0x7fb371ce8310>, node=None)
    Return an ascii art representation of the extended Dynkin diagram.

dynkin_diagram()
    Returns the extended Dynkin diagram for affine type D.

EXAMPLES:

sage: d = CartanType(['D', 6, 1]).dynkin_diagram()
sage: d
d
O 0 0 6
| |
| |
0-0-0-0-0-0-0

5.1.249 Root system data for type E

class sage.combinat.root_system.type_E.AmbientSpace(root_system, baseRing)

Bases: sage.combinat.root_system.ambient_space.AmbientSpace

The lattice behind E6, E7, or E8. The computations are based on Bourbaki, Groupes et Algèbres de Lie, Ch. 4,5,6 (planche V-VII).

**dimension()**

EXAMPLES:

```python
dimension()
sage: e = RootSystem(['E',6]).ambient_space()
sage: e.dimension()
8
```

**fundamental_weights()**

EXAMPLES:

```python
fundamental_weights()
sage: e = RootSystem(['E',6]).ambient_space()
sage: e.fundamental_weights()
Finite family {1: (0, 0, 0, 0, 0, -2/3, -2/3, 2/3), 2: (1/2, 1/2, 1/2, 1/2, 1/2, -1/2, -1/2, 1/2), 3: (-1/2, 1/2, 1/2, 1/2, 1/2, -5/6, -5/6, 5/6), 4: (0, 0, -1, 1, 1, -1, -1, 1), 5: (0, 0, 0, 1, 1, -2/3, -2/3, 2/3), 6: (0, 0, 0, 0, 1, -1/3, -1/3, 1/3)}
```

**negative_roots()**

The negative roots.

EXAMPLES:

```python
negative_roots()
sage: e = RootSystem(['E',6]).ambient_space()
sage: e.negative_roots()
[(-1, -1, 0, 0, 0, 0, 0, 0),
 (-1, 0, -1, 0, 0, 0, 0, 0),
 (-1, 0, 0, -1, 0, 0, 0, 0),
 (-1, 0, 0, -1, 0, 0, 0, 0),
 (-1, 0, 0, 0, -1, 0, 0, 0),
 (-1, 0, 0, 0, 0, -1, 0, 0),
 (-1, 0, 0, 0, 0, 0, -1, 0),
 (-1, 0, 0, 0, 0, 0, 0, -1),
 (-1, 0, 0, 0, 0, 0, 0, 0)]
```

(1/2, 1/2, 1/2, 1/2, -1/2, 1/2, 1/2, -1/2)]

positive_roots()
These are the roots positive w.r. to lexicographic ordering of the basis elements (e1<...<e4).
EXAMPLES:

sage: e = RootSystem(['E',6]).ambient_space()
sage: e.positive_roots()
[(1, 1, 0, 0, 0, 0, 0, 0),
 (1, 1, 0, 0, 0, 0, 0, 0),
 (1, 1, 0, 1, 0, 0, 0, 0),
 (1, 1, 0, 0, 1, 0, 0, 0),
 (0, 1, 1, 0, 0, 0, 0, 0),
 (0, 1, 1, 0, 0, 0, 0, 0),
 (0, 1, 1, 0, 0, 0, 0, 0),
 (0, 1, 1, 0, 0, 0, 0, 0),
 (-1, 1, 0, 0, 0, 0, 0, 0),
 (-1, 1, 0, 0, 0, 0, 0, 0),
 (-1, 0, 1, 0, 0, 0, 0, 0),
 (-1, 0, 1, 0, 0, 0, 0, 0),

\end{verbatim}

\textbf{root}(i1=None, i2=None, i3=None, i4=None, i5=None, i6=None, i7=None, i8=None, p1=0, p2=0, p3=0, p4=0, p5=0, p6=0, p7=0, p8=0)

Compute an element of the underlying lattice, using the specified elements of the standard basis, with signs dictated by the corresponding \textquote{pi} arguments. We rely on the caller to provide the correct arguments. This is typically used to generate roots, although the generated elements need not be roots themselves. We assume
that if one of the indices is not given, the rest are not as well. This should work for E6, E7, E8.

EXAMPLES:

```
sage: e = RootSystem(["E",6]).ambient_space()
sage: [ e.root(i, j, p3=1) for i in range(e.n) for j in range(i+1, e.n) ]
[(1, 1, 0, 0, 0, 0, 0, 0),
 (1, 1, 1, 0, 0, 0, 0, 0),
 (1, 0, 0, 1, 0, 0, 0, 0),
 (1, 0, 0, 0, 1, 0, 0, 0),
 (1, 0, 0, 0, 0, 1, 0, 0),
 (1, 0, 0, 0, 0, 0, 1, 0),
 (1, 0, 0, 0, 0, 0, 0, 1),
 (0, 1, 1, 0, 0, 0, 0, 0),
 (0, 1, 0, 1, 0, 0, 0, 0),
 (0, 1, 0, 0, 1, 0, 0, 0),
 (0, 0, 1, 1, 0, 0, 0, 0),
 (0, 1, 0, 0, 0, 1, 0, 0),
 (0, 0, 1, 1, 0, 0, 0, 0),
 (0, 0, 0, 1, 1, 0, 0, 0),
 (0, 0, 1, 0, 1, 0, 0, 0),
 (0, 0, 0, 0, 1, 1, 0, 0),
 (0, 0, 0, 1, 0, 1, 0, 0),
 (0, 0, 0, 0, 0, 1, 1, 0),
 (0, 0, 0, 0, 0, 0, 1, 1),
```

The simple_root(i)

There are computed as what Bourbaki calls the Base: a1 = e2-e3, a2 = e3-e4, a3 = e4, a4 = 1/2*(e1-e2-e3-e4)

EXAMPLES:

```
sage: LE6 = RootSystem(["E",6]).ambient_space()
sage: LE6.simple_roots()
Finite family {1: (1/2, -1/2, -1/2, -1/2, -1/2, -1/2, -1/2, 1/2),
  2: (1, 1, 0, 0, 0, 0, 0, 0),
  3: (-1, 1, 0, 0, 0, 0, 0, 0),
  4: (0, -1, 1, 0, 0, 0, 0, 0),
  5: (0, 0, -1, 1, 0, 0, 0, 0),
  6: (0, 0, 0, -1, 1, 0, 0, 0)}
```

class sage.combinat.root_system.type_E.CartanType(n)

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_finite, sage.combinat.root_system.cartan_type.CartanType_simply_laced

EXAMPLES:
sage: ct = CartanType(['E',6])
sage: ct
['E', 6]
sage: ct._repr_(compact = True)
'E6'
sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_affine()
False
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
True
sage: ct.affine()
['E', 6, 1]
sage: ct.dual()
['E', 6]

AmbientSpace
alias of AmbientSpace

ascii_art(label=<function CartanType.<lambda> at 0x7fb371f789d0>, node=None)
Return a ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```python
sage: print(CartanType(['E',6]).ascii_art(label = lambda x: x+2))
  0
  |
  |
0---0---0---0---0---0---0
3  5  6  7  8  9
sage: print(CartanType(['E',7]).ascii_art(label = lambda x: x+2))
  0
  |
  |
0---0---0---0---0---0---0---0---0---0---0---0---0
3  5  6  7  8  9 10
sage: print(CartanType(['E',8]).ascii_art(label = lambda x: x+1))
  0
  |
  |
0---0---0---0---0---0---0---0---0---0---0---0---0---0---0---0---0---0---0
2  4  5  6  7  8  9 10
```

coxeter_number()
Return the Coxeter number associated with self.

EXAMPLES:

```python
sage: CartanType(['E',6]).coxeter_number()
12
```
sage: CartanType(['E',7]).coxeter_number()
18
sage: CartanType(['E',8]).coxeter_number()
30

dual_coxeter_number()
Return the dual Coxeter number associated with self.

EXAMPLES:
sage: CartanType(['E',6]).dual_coxeter_number()
12
sage: CartanType(['E',7]).dual_coxeter_number()
18
sage: CartanType(['E',8]).dual_coxeter_number()
30

dynkin_diagram()
Returns a Dynkin diagram for type E.

EXAMPLES:
sage: e = CartanType(['E',6]).dynkin_diagram()
sage: e
O 2
| |
0---0---0---0---0---0
1 3 4 5 6
E6
sage: e.edges(sort=True)
[(1, 3, 1), (2, 4, 1), (3, 1, 1), (3, 4, 1), (4, 2, 1), (4, 3, 1), (4, 5, 1),
 (5, 4, 1), (5, 6, 1), (6, 5, 1)]
sage: e = CartanType(['E',7]).dynkin_diagram()
sage: e
O 2
| |
0---0---0---0---0---0---0---0
1 3 4 5 6 7
E7
sage: e.edges(sort=True)
[(1, 3, 1), (2, 4, 1), (3, 1, 1), (3, 4, 1), (4, 2, 1), (4, 3, 1), (4, 5, 1),
 (5, 4, 1), (5, 6, 1), (6, 5, 1), (6, 7, 1), (7, 6, 1)]
sage: e = CartanType(['E',8]).dynkin_diagram()
sage: e
O 2
| |
0---0---0---0---0---0---0---0---0---0
1 3 4 5 6 7 8
E8
(continues on next page)
5.1.250 Root system data for (untwisted) type E affine

class sage.combinat.root_system.type_E_affine.CartanType(n):
    Bases: sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine,
           sage.combinat.root_system.cartan_type.CartanType_simply_laced

    EXAMPLES:

    sage: ct = CartanType(['E',6,1])
    sage: ct
    ['E', 6, 1]
    sage: ct._repr_(compact = True)
    'E6~'
    sage: ct.is_irreducible()
    True
    sage: ct.is_finite()
    False
    sage: ct.is_affine()
    True
    sage: ct.is_untwisted_affine()
    True
    sage: ct.is_crystallographic()
    True
    sage: ct.is_simply_laced()
    True
    sage: ct.classical()
    ['E', 6]
    sage: ct.dual()
    ['E', 6, 1]

    ascii_art(label=<function CartanType.<lambda> at 0x7fb371f78e50>, node=None)

        Return an ascii art representation of the extended Dynkin diagram.

        EXAMPLES:

        sage: print(CartanType(['E',6,1]).ascii_art(label = lambda x: x+2))

                O 2
               |
               O 4
               |
               O---O---O---O---O
               3 5 6 7 8

        sage: print(CartanType(['E',7,1]).ascii_art(label = lambda x: x+2))

                O 4

(continues on next page)
sage: print(CartanType(['E', 8, 1]).ascii_art(label = lambda x: x-3))

\end{verbatim}

5.1.251 Root system data for type $F$

\textbf{class} \texttt{sage.combinat.root_system.type_F.AmbientSpace(root_system, base_ring)}
Bases: \texttt{sage.combinat.root_system.ambient_space.AmbientSpace}

The lattice behind $F_4$. The computations are based on Bourbaki, Groupes et Algèbres de Lie, Ch. 4, 5, 6 (planche VIII).

\textbf{dimension}()
Return the dimension of \texttt{self}.

\textbf{EXAMPLES:}
\begin{verbatim}
sage: e = RootSystem(['F',4]).ambient_space()
sage: e.dimension()
4
\end{verbatim}

\textbf{fundamental_weights}()
Return the fundamental weights of \texttt{self}.

\textbf{EXAMPLES:}
\begin{verbatim}
sage: e = RootSystem(['F',4]).ambient_space()
sage: e.fundamental_weights()
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3/2, 1/2, 1/2, 1/2), 4: (1, → 0, 0, 0)}
\end{verbatim}

\textbf{negative_roots}()
Return the negative roots.

\textbf{EXAMPLES:}
\begin{verbatim}
sage: e = RootSystem(['F',4]).ambient_space()
sage: e.negative_roots()
[(-1, 0, 0, 0),
 (0, -1, 0, 0),
 (0, 0, -1, 0),
 (0, 0, 0, -1),
 (-1, -1, 0, 0),
 (-1, 0, -1, 0),
(-1, 0, 0, 0)]
\end{verbatim}
Combinatorics, Release 9.7

(continued from previous page)

\((-1, \, 0, \, 0, \, -1),
(0, \, -1, \, -1, \, 0),

(-1/2, \, 1/2, \, 1/2, \, -1/2),
(-1/2, \, 1/2, \, 1/2, \, 1/2)]

positive_roots()
Return the positive roots.

These are the roots which are positive with respect to the lexicographic ordering of the basis elements $(\epsilon_1 < \epsilon_2 < \epsilon_3 < \epsilon_4)$.

EXAMPLES:

sage: e = RootSystem(['F',4]).ambient_space()

sage: e.positive_roots()
[(1, 0, 0, 0),
(0, 1, 0, 0),
(0, 0, 1, 0),
(0, 0, 0, 1),
(1, 1, 0, 0),
(1, 0, 1, 0),
(1, 0, 0, 1),
(0, 1, 1, 0),
(0, 1, 0, 1),
(0, 0, 1, 1),

(1/2, 1/2, 1/2, -1/2),
(1/2, 1/2, -1/2, 1/2),
(1/2, 1/2, -1/2, -1/2),
(1/2, -1/2, 1/2, 1/2),
(1/2, -1/2, 1/2, -1/2),
(1/2, -1/2, -1/2, 1/2),
(1/2, -1/2, -1/2, -1/2)]

(continues on next page)
Combinatorics, Release 9.7

```python
sage: e.rho()
(11/2, 5/2, 3/2, 1/2)
```

**root** *(i, j=None, k=None, l=None, p1=0, p2=0, p3=0, p4=0)*

Compute a root from base elements of the underlying lattice. The arguments specify the basis elements and the signs. Sadly, the base elements are indexed zero-based. We assume that if one of the indices is not given, the rest are not as well.

**EXAMPLES:**

```python
sage: e = RootSystem(['F',4]).ambient_space()
sage: [ e.root(i,j,p2=1) for i in range(e.n) for j in range(i+1,e.n) ]
[(1, -1, 0, 0), (1, 0, -1, 0), (1, 0, 0, -1), (0, 1, -1, 0), (0, 1, 0, -1), (0, 0, 1, -1), (0, 0, 0, 1), (1/2, -1/2, -1/2, -1/2)]
```

**simple_root** *(i)*

Return the $i$-th simple root.

It is computed according to what Bourbaki calls the Base:

$$\alpha_1 = \epsilon_2 - \epsilon_3, \alpha_2 = \epsilon_3 - \epsilon_4, \alpha_3 = \epsilon_4, \alpha_4 = \frac{1}{2}(\epsilon_1 - \epsilon_2 - \epsilon_3 - \epsilon_4).$$

**EXAMPLES:**

```python
sage: e = RootSystem(['F',4]).ambient_space()
sage: e.simple_roots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 1), 4: (1/2, -1/2, -1/2, -1/2)}
```

**class** `sage.combinat.root_system.type_F.CartanType`

**Bases:** `sage.combinat.root_system.cartan_type.CartanType_standard_finite, sage.combinat.root_system.cartan_type.CartanType_simple, sage.combinat.root_system.cartan_type.CartanType_crystallographic`

**EXAMPLES:**

```python
sage: ct = CartanType(['F',4])
sage: ct
['F', 4]
sage: ct._repr_(compact = True)
'F4'
sage: ct.is_irreducible() True
c sage: ct.is_finite() True
c sage: ct.is_crystallographic() True
c sage: ct.is_simply_laced() False
c sage: ct.dual() ['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
c sage: ct.affine() ['F', 4, 1]
```
AmbientSpace
alias of AmbientSpace

ascii_art(label=<function CartanType.<lambda> at 0x7fb371f8c9d0>, node=None)
Return an ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```
sage: print(CartanType(['F',4]).ascii_art(label = lambda x: x+2))
O---O=>=O---O
 3 4 5 6
sage: print(CartanType(['F',4]).ascii_art(label = lambda x: x-2))
O---O=>=O---O
-1 0 1 2
```

coxeter_number()
Return the Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['F',4]).coxeter_number()
12
```

dual()
Return the dual Cartan type.

This uses that $F_4$ is self-dual up to relabelling.

EXAMPLES:

```
sage: F4 = CartanType(['F',4])
sage: F4.dual()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: F4.dynkin_diagram()
O---O=>=O---O
 1 2 3 4
F4
sage: F4.dual().dynkin_diagram()
O---O=>=O---O
 4 3 2 1
F4 relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

dual_coxeter_number()
Return the dual Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['F',4]).dual_coxeter_number()
9
```

dynkin_diagram()
Returns a Dynkin diagram for type F.

EXAMPLES:

```
sage: f = CartanType(['F',4]).dynkin_diagram()
sage: f
```

(continues on next page)
Combinatorics, Release 9.7

(continued from previous page)

```
0---0=>=0---0
1  2  3  4
F4
sage: f.edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1), (3, 4, 1), (4, 3, 1)]
```

5.1.252 Root system data for (untwisted) type F affine

class sage.combinat.root_system.type_F_affine.CartanType

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine

EXAMPLES:

```
sage: ct = CartanType(['F',4,1])
sage: ct
['F', 4, 1]
sage: ct._repr_(compact = True)
'F4~'
sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.classical()
['F', 4]
sage: ct.dual()
['F', 4, 1]^*
sage: ct.dual().is_untwisted_affine()
False
```

ascii_art(label=<function CartanType.<lambda> at 0x7fb371f8cee0>, node=None)

Returns a ascii art representation of the extended Dynkin diagram

EXAMPLES:

```
sage: print(CartanType(['F',4,1]).ascii_art(label = lambda x: x+2))
0---0=>=0---0
2  3  4  5  6
```

dynkin_diagram()

Returns the extended Dynkin diagram for affine type F.

EXAMPLES:
sage: f = CartanType(['F', 4, 1]).dynkin_diagram()
sage: f
O---O---O=>=O---O
0 1 2 3 4
F4~
sage: f.edges(sort=True)
[(0, 1, 1), (1, 0, 1), (1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1), (3, 4, 1), ...
   (4, 3, 1)]

5.1.253 Root system data for type G

class sage.combinat.root_system.type_G.AmbientSpace(root_system, base_ring, index_set=None)
    Bases: sage.combinat.root_system.ambient_space.AmbientSpace

EXAMPLES:

sage: e = RootSystem(['G',2]).ambient_space(); e
Ambient space of the Root system of type ['G', 2]

One can not construct the ambient lattice because the simple coroots have rational coefficients:

sage: e.simple_coroots()
Finite family {1: (0, 1, -1), 2: (1/3, -2/3, 1/3)}
sage: e.smallest_base_ring()
Rational Field

By default, this ambient space uses the barycentric projection for plotting:

sage: L = RootSystem(['G',2]).ambient_space()
sage: e = L.basis()
sage: L._plot_projection(e[0])
(1/2, 989/1142)
sage: L._plot_projection(e[1])
(-1, 0)
sage: L._plot_projection(e[2])
(1/2, -989/1142)
sage: L = RootSystem(['A',3]).ambient_space()
sage: l = L.an_element(); l
(2, 2, 3, 0)
sage: L._plot_projection(l)
(0, -1121/1189, 7/3)

See also:

• sage.combinat.root_system.root_lattice_realizations.RootLatticeRealizations.
  ParentMethods._plot_projection()

dimension()
    EXAMPLES:

sage: e = RootSystem(['G',2]).ambient_space()
sage: e.dimension()
3
**fundamental_weights()**

EXAMPLES:

```
sage: CartanType(['G',2]).root_system().ambient_space().fundamental_weights()
Finite family {1: (1, 0, -1), 2: (2, -1, -1)}
```

**negative_roots()**

EXAMPLES:

```
sage: CartanType(['G',2]).root_system().ambient_space().negative_roots()
[(0, -1, 1), (-1, 2, -1), (-1, 1, 0), (-1, 0, 1), (-1, -1, 2), (-2, 1, 1)]
```

**positive_roots()**

EXAMPLES:

```
sage: CartanType(['G',2]).root_system().ambient_space().positive_roots()
[(0, 1, -1), (1, -2, 1), (1, -1, 0), (1, 0, -1), (1, 1, -2), (2, -1, -1)]
```

**simple_root(i)**

EXAMPLES:

```
sage: CartanType(['G',2]).root_system().ambient_space().simple_roots()
Finite family {1: (0, 1, -1), 2: (1, -2, 1)}
```

**class sage.combinat.root_system.type_G.CartonType**

Bases: `sage.combinat.root_system.cartan_type.CartanType_standard_finite, sage.combinat.root_system.cartan_type.CartanType_simple, sage.combinat.root_system.cartan_type.CartonType_crystallographic`

EXAMPLES:

```
sage: ct = CartanType(['G',2])
sage: ct
['G', 2]
sage: ct._repr_(compact = True)
'G2'
```

```
sage: ct.is_irreducible()
True
```

```
sage: ct.is_finite()
True
```

```
sage: ct.is_crystallographic()
True
```

```
sage: ct.is_simply_laced()
False
```

```
sage: ct.dual()
['G', 2] relabelled by {1: 2, 2: 1}
sage: ct.affine()
['G', 2, 1]
```

**AmbientSpace**

alias of `AmbientSpace`

**ascii_art**(label=<function CartanType.<lambda> at 0x7fb371f9d820>, node=None)

Return an ascii art representation of the Dynkin diagram.

EXAMPLES:
```python
sage: print(CartanType(['G',2]).ascii_art(label=lambda x: x+2))
3
0<=0
3  4
```

coxeter_number()
Return the Coxeter number associated with self.

EXAMPLES:

```python
sage: CartanType(['G',2]).coxeter_number()
6
```
dual()
Return the dual Cartan type.

This uses that $G_2$ is self-dual up to relabelling.

EXAMPLES:

```python
sage: G2 = CartanType(['G',2])
sage: G2.dual()
['G', 2] relabelled by {1: 2, 2: 1}
sage: G2.dynkin_diagram()
3
0<=0
1  2
G2
dual
sage: G2.dual().dynkin_diagram()
3
0<=0
2  1
G2 relabelled by {1: 2, 2: 1}
```
dual_coxeter_number()
Return the dual Coxeter number associated with self.

EXAMPLES:

```python
sage: CartanType(['G',2]).dual_coxeter_number()
4
```
dynkin_diagram()
Returns a Dynkin diagram for type G.

EXAMPLES:

```python
sage: g = CartanType(['G',2]).dynkin_diagram()
sage: g
3
0<=0
1  2
G2
dynkin_diagram
sage: g.edges(sort=True)
[(1, 2, 1), (2, 1, 3)]
```
5.1.254 Root system data for (untwisted) type G affine

```python
sage: ct = CartanType(['G',2,1])
sage: ct
['G', 2, 1]
sage: ct._repr_(compact = True)
'G2~'
sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.classical()
['G', 2]
sage: ct.dual()
['G', 2, 1]^*
sage: ct.dual().is_untwisted_affine()
False
```

**ascii_art**

```
sage: print(CartanType(['G',2,1]).ascii_art(label = lambda x: x+2))
3
0---0 0---0
3 4 2
```

**dynkin_diagram()**

```
sage: g = CartanType(['G',2,1]).dynkin_diagram()
sage: g
3
0---0 0---0
1 2 0
G2~
sage: g.edges(sort=True)
[(0, 2, 1), (1, 2, 1), (2, 0, 1), (2, 1, 3)]
```
5.1.255 Root system data for type H

```python
class sage.combinat.root_system.type_H.CartanType(n):
    Bases: sage.combinat.root_system.cartan_type.CartanType_standard_finite, 
           sage.combinat.root_system.cartan_type.CartanType_simple

    EXAMPLES:
    sage: ct = CartanType(['H', 3])
    sage: ct
    ['H', 3]
    sage: ct._repr_(compact = True)
    'H3'
    sage: ct.rank()
    3
    sage: ct.is_irreducible()
    True
    sage: ct.is_finite()
    True
    sage: ct.is_affine()
    False
    sage: ct.is_crystallographic()
    False
    sage: ct.is_simply_laced()
    False

    coxeter_diagram()
    Returns a Coxeter diagram for type H.

    EXAMPLES:
    sage: ct = CartanType(['H', 3])
    sage: ct.coxeter_diagram()
    Graph on 3 vertices
    sage: ct.coxeter_diagram().edges(sort=True)
    [(1, 2, 3), (2, 3, 5)]
    sage: ct.coxeter_matrix()
    [1 3 2]
    [3 1 5]
    [2 5 1]

    coxeter_number()
    Return the Coxeter number associated with self.
```
5.1.256 Root system data for type \( \text{I} \)

class sage.combinat.root_system.type_I.CartanType(n)
Bases: sage.combinat.root_system.cartan_type.CartanType_standard_finite, sage.combinat.root_system.cartan_type.CartanType_simple

EXAMPLES:

```python
sage: ct = CartanType(['I',5])
sage: ct
['I', 5]
sage: ct._repr_(compact = True)
'I5'
sage: ct.rank()
2
sage: ct.index_set()
(1, 2)
sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_affine()
False
sage: ct.is_crystallographic()
False
sage: ct.is_simply_laced()
False
```

coxeter_diagram()
Returns the Coxeter matrix for this type.

EXAMPLES:

```python
sage: ct = CartanType(['I', 4])
sage: ct.coxeter_diagram()
Graph on 2 vertices
sage: ct.coxeter_diagram().edges(sort=True)
[(1, 2, 4)]
sage: ct.coxeter_matrix()
[1 4]
[4 1]
```

coxeter_number()
Return the Coxeter number associated with \( \text{self} \).

EXAMPLES:
sage: CartanType(['I',3]).coxeter_number()
3
sage: CartanType(['I',12]).coxeter_number()
12

index_set()
Type $I_2(p)$ is indexed by \{1, 2\}.

EXAMPLES:

sage: CartanType(['I', 5]).index_set()
(1, 2)

rank()
Type $I_2(p)$ is of rank 2.

EXAMPLES:

sage: CartanType(['I', 5]).rank()
2

5.1.257 Root system data for type Q

class sage.combinat.root_system.type_Q.CartanType(m)
    Bases: sage.combinat.root_system.cartan_type.CartanType_standard_finite
    Cartan Type $Q_n$

    See also:
    CartanType()

dual()
    Return dual of self.

    EXAMPLES:

    sage: Q = CartanType(['Q',3])
    sage: Q.dual()
    ['Q', 3]

index_set()
    Return the index set for Cartan type Q.
    The index set for type Q is of the form \{-n, \ldots, -1, 1, \ldots, n\}.

    EXAMPLES:

    sage: CartanType(['Q', 3]).index_set()
    (1, 2, -2, -1)

is_irreducible()
    Return whether this Cartan type is irreducible.

    EXAMPLES:
Combinatorics, Release 9.7

```plaintext
sage: Q = CartanType(['Q',3])
sage: Q.is_irreducible()
True

is_simply_laced()
Return whether this Cartan type is simply-laced.
EXAMPLES:

```plaintext
sage: Q = CartanType(['Q',3])
sage: Q.is_simply_laced()
True
```

root_system()
Return the root system of self.
EXAMPLES:

```plaintext
sage: Q = CartanType(['Q',3])
sage: Q.root_system()
Root system of type ['A', 2]
```

5.1.258 Root system data for affine Cartan types

class sage.combinat.root_system.type_affine.AmbientSpace(root_system, base_ring)

Ambient space for affine types.

This is constructed from the data in the corresponding classical ambient space. Namely, this space is obtained by adding two elements $\delta$ and $\delta^\vee$ to the basis of the classical ambient space, and by endowing it with the canonical scalar product.

The coefficient of an element in $\delta^\vee$, thus its scalar product with $\delta^\vee$ gives its level, and dually for the colevel. The canonical projection onto the classical ambient space (by killing $\delta$ and $\delta^\vee$) maps the simple roots (except $\alpha_0$) onto the corresponding classical simple roots, and similarly for the coroots, fundamental weights, ... Altogether, this uniquely determines the embedding of the root, coroot, weight, and coweight lattices. See `simple_root()` and `fundamental_weight()` for the details.

**Warning:** In type $BC$, the null root is in fact:

```plaintext
sage: R = RootSystem(['BC',3,2]).ambient_space()
sage: R.null_root()
2*e['delta']
```

**Warning:** In the literature one often considers a larger affine ambient space obtained from the classical ambient space by adding four dimensions, namely for the fundamental weight $\Lambda_0$ the fundamental coweight $\Lambda_0^\vee$, the null root $\delta$, and the null coroot $c$ (aka central element). In this larger ambient space, the scalar product is degenerate: $\langle \delta, \delta \rangle = 0$ and similarly for the null coroot.

In the current implementation, $\Lambda_0$ and the null coroot are identified:
Therefore the scalar product of the null coroot with itself differs from the larger ambient space:

```
.sage: L.null_coroot().scalar(L.null_coroot())
1
```

In general, scalar products between two elements that do not live on “opposite sides” won’t necessarily match.

**EXAMPLES:**

```sage
R = RootSystem(['A', 3, 1])
sage: e = R.ambient_space(); e
Ambient space of the Root system of type ['A', 3, 1]
sage: TestSuite(e).run()
```

Systematic checks on all affine types:

```sage
for ct in CartanType.samples(affine=True, crystallographic=True):
    if ct.classical().root_system().ambient_space() is not None:
        print(ct)
        L = ct.root_system().ambient_space()
        assert L
        TestSuite(L).run()
```

```yaml
['A', 1, 1]
['A', 5, 1]
['B', 1, 1]
['B', 5, 1]
['C', 1, 1]
['C', 5, 1]
['D', 3, 1]
['D', 5, 1]
['E', 6, 1]
['E', 7, 1]
['E', 8, 1]
['F', 4, 1]
['G', 2, 1]
['BC', 1, 2]
['BC', 5, 2]
['B', 5, 1]**
['C', 4, 1]**
['F', 4, 1]**
['G', 2, 1]**
['BC', 1, 2]**
['BC', 5, 2]**
```

```python
class Element
    Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

    associated_coroot()
        Return the coroot associated to self.

        INPUT:
            * self – a root
```

5.1. Comprehensive Module List
EXAMPLES:
sage: alpha = RootSystem(['C',2,1]).ambient_space().simple_roots()
sage: alpha
Finite family {0: -2*e[0] + e['delta'], 1: e[0] - e[1], 2: 2*e[1]}
sage: alpha[0].associated_coroot()
-e[0] + e['deltacheck']
sage: alpha[1].associated_coroot()
e[0] - e[1]
sage: alpha[2].associated_coroot()
e[1]

inner_product(other)
Implement the canonical inner product of self with other.
EXAMPLES:
sage: e = RootSystem(['B',3,1]).ambient_space()
sage: B = e.basis()
sage: matrix([[x.inner_product(y) for x in B] for y in B])
\[
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1 \\
\end{bmatrix}
\]
sage: x = e.an_element(); x
2*e[0] + 2*e[1] + 3*e[2]
sage: x.inner_product(x)
17

scalar() is an alias for this method:
sage: x.scalar(x)
17

Todo: Lift to CombinatorialFreeModule.Element as canonical_inner_product

scalar(other)
Implement the canonical inner product of self with other.
EXAMPLES:
sage: e = RootSystem(['B',3,1]).ambient_space()
sage: B = e.basis()
sage: matrix([[x.inner_product(y) for x in B] for y in B])
\[
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1 \\
\end{bmatrix}
\]
sage: x = e.an_element(); x
2*e[0] + 2*e[1] + 3*e[2]
sage: x.inner_product(x)
17
scalar() is an alias for this method:

```python
sage: x.scalar(x)
17
```

Todo: Lift to CombinatorialFreeModule.Element as canonical_inner_product

coroot_lattice()
EXAMPLES:

```python
sage: RootSystem(["A",3,1]).ambient_lattice().coroot_lattice()
Ambient lattice of the Root system of type ['A', 3, 1]
```

Todo: Factor out this code with the classical ambient space.

fundamental_weight(i)

Return the fundamental weight $\Lambda_i$ in this ambient space.

It is constructed by taking the corresponding fundamental weight of the classical ambient space (or 0 for $\Lambda_0$) and raising it to the appropriate level by adding a suitable multiple of $\delta^\vee$.

EXAMPLES:

```python
sage: RootSystem(["A",3,1]).ambient_space().fundamental_weight(2)
e[0] + e[1] + e['deltacheck']
sage: RootSystem(["A",3,1]).ambient_space().fundamental_weights()
sage: RootSystem(["A",3]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0)}
sage: RootSystem(["A",3,1]).weight_lattice().fundamental_weights().map(attrcall("level"))
Finite family {0: 1, 1: 1, 2: 1, 3: 1}
```

```python
sage: RootSystem(["B",3,1]).ambient_space().fundamental_weights()
sage: RootSystem(["B",3]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
sage: RootSystem(["B",3,1]).weight_lattice().fundamental_weights().map(attrcall("level"))
Finite family {0: 1, 1: 1, 2: 2, 3: 1}
```

In type $BC$ dual, the coefficient of ‘delta^vee’ is the level divided by 2 to take into account that the null coroot is $2\delta^\vee$:

```python
sage: R = CartanType(['BC',3,2]).dual().root_system()
sage: R.ambient_space().fundamental_weights()
```

(continues on next page)
Finite family {0: e['deltacheck'], 1: e[0] + e['deltacheck'],
2: e[0] + e[1] + e['deltacheck'],
sage: R.weight_lattice().fundamental_weights().map(attrcall("level"))
Finite family {0: 2, 1: 2, 2: 2, 3: 1}
sage: R.ambient_space().null_coroot()
2*e['deltacheck']

By a slight naming abuse this function also accepts "delta" as input so that it can be used to implement the embedding from the extended weight lattice:

sage: RootSystem(['A',3,1]).ambient_space().fundamental_weight("delta")
e['delta']

**is_extended()**

Return whether this is a realization of the extended weight lattice: yes!

**See also:**

- *sage.combinat.root_system.weight_space.WeightSpace*
- *sage.combinat.root_system.weight_lattice_realizations.*
  WeightLatticeRealizations.ParentMethods.is_extended()**

**EXAMPLES:**

```python
sage: RootSystem(['A',3,1]).ambient_space().is_extended()
True
```

**simple_coroot(i)**

Return the $i$-th simple coroot $\alpha_i^\vee$ of this affine ambient space.

**EXAMPLES:**

```python
sage: RootSystem(['A',3,1]).ambient_space().simple_coroot(1)
e[0] - e[1]
```

It is built as the coroot associated to the simple root $\alpha_i$:

```python
sage: RootSystem(['B',3,1]).ambient_space().simple_roots()
sage: RootSystem(['B',3,1]).ambient_space().simple_coroots()
```

**Todo:** Factor out this code with the classical ambient space.

**simple_root(i)**

Return the $i$-th simple root of this affine ambient space.

**EXAMPLES:**
It is built straightforwardly from the corresponding simple root $\alpha_i$ in the classical ambient space:

```
sage: RootSystem(["A",3,1]).ambient_space().simple_root(1)
e[0] - e[1]
```

For the special node (typically $i = 0$), $\alpha_0$ is built from the other simple roots using the column annihilator of the Cartan matrix and adding $\delta$, where $\delta$ is the null root:

```
sage: RootSystem(["A",3,1]).ambient_space().simple_roots()
```

Here is a twisted affine example:

```
sage: RootSystem(CartanType(["B",3,1]).dual()).ambient_space().simple_roots()
```

In fact $\delta$ is really $1/a_0$ times the null root (see the discussion in `WeightSpace`) but this only makes a difference in type $BC$:

```
sage: L = RootSystem(CartanType(["BC",3,2])).ambient_space()
sage: L.simple_roots()
Finite family {0: -e[0] + e['delta'], 1: e[0] - e[1], 2: e[1] - e[2], 3: 2*e[2]}
sage: L.null_root()
2*e['delta']
```

Note: An alternative would have been to use the default implementation of the simple roots as linear combinations of the fundamental weights. However, as in type $A_n$ it is preferable to take a slight variant to avoid rational coefficient (the usual $GL_n$ vs $SL_n$ issue).

See also:

- `simple_root()`
- `WeightSpace`
- `CartanType.col_annihilator()`
- `null_root()`

**classmethod** `smallest_base_ring(cartan_type)`

Return the smallest base ring the ambient space can be defined on.

This is the smallest base ring for the associated classical ambient space.

See also:

`smallest_base_ring()`

**EXAMPLES:**

```
sage: cartan_type = CartanType(["A",3,1])
sage: cartan_type.AmbientSpace.smallest_base_ring(cartan_type)
```
Combinatorics, Release 9.7

Integer Ring
sage: cartan_type = CartanType(['B',3,1])
sage: cartan_type.AmbientSpace.smallest_base_ring(cartan_type)
Rational Field

5.1.259 Root system data for dual Cartan types

class sage.combinat.root_system.type_dual.AmbientSpace(root_system, base_ring, index_set=None)

Ambient space for a dual finite Cartan type.

It is constructed in the canonical way from the ambient space of the original Cartan type by switching the roles of simple roots, fundamental weights, etc.

Note: Recall that, for any finite Cartan type, and in particular the a simply laced one, the dual Cartan type is constructed as another preexisting Cartan type. Furthermore the ambient space for an affine type is constructed from the ambient space for its classical type. Thus this code is not actually currently used.

It is kept for cross-checking and for reference in case it could become useful, e.g., for dual of general Kac-Moody types.

For the doctests, we need to explicitly create a dual type. Subsequently, since reconstruction of the dual of type $F_4$ is the relabelled Cartan type, pickling fails on the TestSuite run.

EXAMPLES:

sage: ct = sage.combinat.root_system.type_dual.CartanType(CartanType(['F',4]))

sage: L = ct.root_system().ambient_space(); L
Ambient space of the Root system of type ['F', 4]^*  

sage: TestSuite(L).run(skip=['_test_elements','_test_pickling'])

dimension()

Return the dimension of this ambient space.

See also:
sage.combinat.root_system.ambient_space.AmbientSpace.dimension()

EXAMPLES:

sage: ct = sage.combinat.root_system.type_dual.CartanType(CartanType(['F',4]))

sage: L = ct.root_system().ambient_space()

sage: L.dimension()
4

fundamental_weights()

Return the fundamental weights.

They are computed from the simple roots by inverting the Cartan matrix. This is acceptable since this is only about ambient spaces for finite Cartan types. Also, we do not have to worry about the usual $GL_n$ vs $SL_n$ catch because type $A$ is self dual.

An alternative would have been to start from the fundamental coweights in the dual ambient space, but those are not yet implemented.
EXAMPLES:

```python
sage: ct = sage.combinat.root_system.type_dual.CartanType(CartanType(['F',4]))
sage: L = ct.root_system().ambient_space()
sage: L.fundamental_weights()
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3, 1, 1, 1), 4: (2, 0, 0, 0)}
```

Note that this ambient space is isomorphic, but not equal, to that obtained by constructing \( F_4 \) dual by relabelling:

```python
sage: ct = CartanType(['F',4]).dual(); ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: ct.root_system().ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (3/2, 1/2, 1/2, 1/2), 3: (2, 1, 1, 0), 4: (1, 1, 0, 0)}
```

### simple_root(i)

Return the \( i \)-th simple root.

It is constructed by looking up the corresponding simple coroot in the ambient space for the dual Cartan type.

EXAMPLES:

```python
sage: ct = sage.combinat.root_system.type_dual.CartanType(CartanType(['F',4]))
sage: ct.root_system().ambient_space().simple_root(1)
(0, 1, -1, 0)
sage: ct.root_system().ambient_space().simple_roots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2), 4: (1, -1, -1, -1)}
```

Note that this ambient space is isomorphic, but not equal, to that obtained by constructing \( F_4 \) dual by relabelling:

```python
sage: ct = CartanType(['F',4]).dual(); ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: ct.root_system().ambient_space().simple_roots()
Finite family {1: (1/2, -1/2, -1/2, -1/2), 2: (0, 0, 0, 1), 3: (0, 0, 1, -1), 4: (0, 1, -1, 0)}
```

class sage.combinat.root_system.type_dual.CartanType(type)

Bases: sage.combinat.root_system.cartan_type.CartanType_decorator, sage.combinat.root_system.cartan_type.CartanType_crystallographic

A class for dual Cartan types.

The dual of a (crystallographic) Cartan type is a Cartan type with the same index set, but all arrows reversed in the Dynkin diagram (otherwise said, the Cartan matrix is transposed). It shares a lot of properties in common with its dual. In particular, the Weyl group is isomorphic to that of the dual as a Coxeter group.

EXAMPLES:
For all finite Cartan types, and in particular the simply laced ones, the dual Cartan type is given by another preexisting Cartan type:

```python
sage: CartanType(['A',4]).dual()
['A', 4]
sage: CartanType(['B',4]).dual()
['C', 4]
sage: CartanType(['C',4]).dual()
['B', 4]
sage: CartanType(['F',4]).dual()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

So to exercise this class we consider some non simply laced affine Cartan types and also create explicitly $F_4^*$ as a dual cartan type:

```python
sage: from sage.combinat.root_system.type_dual import CartanType as CartanTypeDual
sage: F4d = CartanTypeDual(CartanType(['F',4])); F4d
['F', 4]^*
sage: G21d = CartanType(['G',2,1]).dual(); G21d
['G', 2, 1]^*
```

They share many properties with their original Cartan types:

```python
sage: F4d.is_irreducible()
True
sage: F4d.is_crystallographic()
True
sage: F4d.is_simply_laced()
False
sage: F4d.is_finite()
False
sage: G21d.is_finite()
True
sage: F4d.is_affine()
False
sage: G21d.is_affine()
True
```

**Note:** F4d is pickled by construction as F4.dual() hence the above failure.

**ascii_art** *(label=<function CartanType.<lambda> at 0x7fb371f9e8b0>, node=None)*

Return an ascii art representation of this Cartan type
(by hacking the ascii art representation of the dual Cartan type)

**EXAMPLES:**

```python
sage: print(CartanType(['B', 3, 1]).dual().ascii_art())
  0 0
  |
  |
0--0<=0
 1 2 3

(continues on next page)
sage: print(CartanType(['C', 4, 1]).dual().ascii_art())
O=<=O---O---O=>=O
0 1 2 3 4
sage: print(CartanType(['G', 2, 1]).dual().ascii_art())
O=>=O---O
1 2 0
sage: print(CartanType(['F', 4, 1]).dual().ascii_art())
O---O---O=<=O---O
0 1 2 3 4
sage: print(CartanType(['BC', 4, 2]).dual().ascii_art())
O=>=O---O---O=>=O
0 1 2 3 4

dual()
EXAMPLES:

sage: ct = CartanType(['F', 4, 1]).dual()
sage: ct.dual()
['F', 4, 1]

dynkin_diagram()
EXAMPLES:

sage: ct = CartanType(['F', 4, 1]).dual()
sage: ct.dynkin_diagram()
O---O---O=<=O---O
0 1 2 3 4
F4~*

class sage.combinat.root_system.type_dual.CartanType_affine(type)
Bases: sage.combinat.root_system.type_dual.CartanType, sage.combinat.root_system.cartan_type.CartanType_affine

basic_untwisted()
Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic untwisted type is $X_n$. In other words, it is the classical Cartan type that is twisted to obtain self.

EXAMPLES:

sage: CartanType(['A', 7, 2]).basic_untwisted()
['A', 7]
sage: CartanType(['E', 6, 2]).basic_untwisted()
['E', 6]
sage: CartanType(['D', 4, 3]).basic_untwisted()
['D', 4]

classical()
Return the classical Cartan type associated with self (which should be affine).

EXAMPLES:
sage: CartanType(['A', 3, 1]).dual().classical()
['A', 3]
sage: CartanType(['B', 3, 1]).dual().classical()
['C', 3]
sage: CartanType(['F', 4, 1]).dual().classical()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: CartanType(['BC', 4, 2]).dual().classical()
['B', 4]

special_node()
Implement `CartanType_affine.special_node()`

The special node of the dual of an affine type \( T \) is the special node of \( T \).

EXAMPLES:

sage: CartanType(['A', 3, 1]).dual().special_node()
0
sage: CartanType(['B', 3, 1]).dual().special_node()
0
sage: CartanType(['F', 4, 1]).dual().special_node()
0
sage: CartanType(['BC', 4, 2]).dual().special_node()
0

class sage.combinat.root_system.type_dual.CartanType_finite(type)
Bases: sage.combinat.root_system.type_dual.CartanType, sage.combinat.root_system.cartan_type.CartanType_finite

sage.combinat.root_system.extended_affine_weyl_group.ExtendedAffineWeylGroup(cartan_type, general_linear=None, **print_options)

The extended affine Weyl group.

INPUT:

- `cartan_type` – An affine or finite Cartan type (a finite Cartan type is an abbreviation for its untwisted affinization)
• **general_linear** – (default: None) If True and **cartan_type** indicates untwisted type A, returns the universal central extension

• **print_options** – Special instructions for printing elements (see below)

### Mnemonics

- “P” – subgroup of translations
- “Pv” – subgroup of translations in a dual form
- “W0” – classical Weyl group
- “W” – affine Weyl group
- “F” – fundamental group of length zero elements

There are currently six realizations: “PW0”, “W0P”, “WF”, “FW”, “PvW0”, and “W0Pv”.

“PW0” means the semidirect product of “P” with “W0” acting from the right. “W0P” is similar but with “W0” acting from the left. “WF” is the semidirect product of “W” with “F” acting from the right, etc.

Recognized arguments for **print_options** are:

- **print_tuple** – True or False (default: False) If True, elements are printed \((a, b)\), otherwise as \(a \ast b\)
- **affine** – Prefix for simple reflections in the affine Weyl group
- **classical** – Prefix for simple reflections in the classical Weyl group
- **translation** – Prefix for the translation elements
- **fundamental** – Prefix for the elements of the fundamental group

These options are not mutable.

The *extended affine Weyl group* was introduced in the following references.

**REFERENCES:**

- [Ka1990]

### Notation

- **R** – An irreducible affine root system
- **I** – Set of nodes of the Dynkin diagram of **R**
- **R_0** – The classical subsystem of **R**
- **I_0** – Set of nodes of the Dynkin diagram of **R_0**
- **E** – Extended affine Weyl group of type **R**
- **W** – Affine Weyl group of type **R**
- **W_0** – finite (classical) Weyl group (of type **R_0**)
- **M** – translation lattice for **W**
- **L** – translation lattice for **E**
- **F** – Fundamental subgroup of **E** (the length zero elements)
- **P** – Finite weight lattice
• $Q$ – Finite root lattice
• $P^\vee$ – Finite coweight lattice
• $Q^\vee$ – Finite coroot lattice

Translation lattices

The styles “PW0” and “W0P” use the following lattices:
• Untwisted affine: $L = P^\vee, M = Q^\vee$
• Dual of untwisted affine: $L = P, M = Q$
• $BC_n (A_2^{(2)}): L = M = P$
• Dual of $BC_n (A_2^{(2)}): L = M = P^\vee$

The styles “PvW0” and “W0Pv” use the following lattices:
• Untwisted affine: The weight lattice of the dual finite Cartan type.
• Dual untwisted affine: The same as for “PW0” and “W0P”.

For mixed affine type ($A_2^{(2)},$ aka $BC_n,$ and their affine duals) the styles “PvW0” and “W0Pv” are not implemented.

Finite and affine Weyl groups $W_0$ and $W$

The finite Weyl group $W_0$ is generated by the simple reflections $s_i$ for $i \in I_0$ where $s_i$ is the reflection across a suitable hyperplane $H_i$ through the origin in the real span $V$ of the lattice $M.$

$R$ specifies another (affine) hyperplane $H_0.$ The affine Weyl group $W$ is generated by $W_0$ and the reflection $S_0$ across $H_0.$

Extended affine Weyl group $E$

The complement in $V$ of the set $H$ of hyperplanes obtained from the $H_i$ by the action of $W,$ has connected components called alcoves. $W$ acts freely and transitively on the set of alcoves. After the choice of a certain alcove (the fundamental alcove), there is an induced bijection from $W$ to the set of alcoves under which the identity in $W$ maps to the fundamental alcove.

Then $L$ is the largest sublattice of $V,$ whose translations stabilize the set of alcoves.

There are isomorphisms

\[
W \cong M \rtimes W_0 \cong W_0 \rtimes M
\]
\[
E \cong L \rtimes W_0 \cong W_0 \rtimes L
\]
Fundamental group of affine Dynkin automorphisms

Since $L$ acts on the set of alcoves, the group $F = L/M$ may be viewed as a subgroup of the symmetries of the fundamental alcove or equivalently the symmetries of the affine Dynkin diagram. $F$ acts on the set of alcoves and hence on $W$. Conjugation by an element of $F$ acts on $W$ by permuting the indices of simple reflections.

There are isomorphisms

$$E \cong F \ltimes W \cong W \rtimes F$$

An affine Dynkin node is special if it is conjugate to the zero node under some affine Dynkin automorphism.

There is a bijection $i \mapsto \pi_i$ from the set of special nodes to the group $F$, where $\pi_i$ is the unique element of $F$ that sends 0 to $i$. When $L = P$ (resp. $L = P^\vee$) the element $\pi_i$ is induced (under the isomorphism $F \cong L/M$) by addition of the coset of the $i$-th fundamental weight (resp. coweight).

The length function of the Coxeter group $W$ may be extended to $E$ by $\ell(w\pi) = \ell(w)$ where $w \in W$ and $\pi \in F$. This is the number of hyperplanes in $H$ separating the fundamental alcove from its image by $w\pi$ (or equivalently $w$).

It is known that if $G$ is the compact Lie group of adjoint type with root system $R_0$ then $F$ is isomorphic to the fundamental group of $G$, or to the center of its simply-connected covering group. That is why we call $F$ the fundamental group.

In the future we may want to build an element of the group from an appropriate linear map $f$ on some of the root lattice realizations for this Cartan type: $W.\text{from\_endomorphism}(f)$.

EXAMPLES:

```sage
sage: E = ExtendedAffineWeylGroup(['A',2,1]); E
Extended affine Weyl group of type ['A', 2, 1]
sage: type(E)
<class 'sage.combinat.root_system.extended_affine_weyl_group.
   ExtendedAffineWeylGroup_Class_with_category'>
sage: PW0=E.PW0(); PW0
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
   Multiplicative form of Coweight lattice of the Root system of type ['A', 2] acted
   upon by Weyl Group of type ['A', 2] (as a matrix group acting on the coweight␣
   lattice)
sage: W0P = E.W0P(); W0P
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
   Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
   acting on Multiplicative form of Coweight lattice of the Root system of type ['A',
   2]
sage: PvW0 = E.PvW0(); PvW0
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
   Multiplicative form of Weight lattice of the Root system of type ['A', 2] acted
   upon by Weyl Group of type ['A', 2] (as a matrix group acting on the weight␣
   lattice)
sage: W0Pv = E.W0Pv(); W0Pv
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
   Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice)
   acting on Multiplicative form of Weight lattice of the Root system of type ['A',␣
   2]
```

(continues on next page)
sage: WF = E.WF(); WF
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice)
acted upon by Fundamental group of type ['A', 2, 1]

sage: FW = E.FW(); FW
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
Fundamental group of type ['A', 2, 1] acting on Weyl Group of type ['A', 2, 1]

When the realizations are constructed from each other as above, there are built-in coercions between them.

sage: F = E.fundamental_group()
sage: x = WF.from_reduced_word([0,1,2]) * WF(F(2)); x
S0*S1*S2 * pi[2]
sage: FW(x)
pi[2] * S0*S1
sage: W0P(x)
s1*s2*s1 * t[-2*Lambda[1] - Lambda[2]]
sage: PW0(x)
t[Lambda[1] + 2*Lambda[2]] * s1*s2*s1
sage: PvW0(x)
t[2*Lambda[1] + 2*Lambda[2]] * s1*s2*s1

The translation lattice and its distinguished basis are obtained from E:

sage: L = E.lattice(); L
Coweight lattice of the Root system of type ['A', 2]
sage: b = E.lattice_basis(); b
Finite family {1: Lambda[1], 2: Lambda[2]}

Translation lattice elements can be coerced into any realization:

sage: PW0(b[1]-b[2])
t[Lambda[1] - Lambda[2]]
sage: FW(b[1]-b[2])
pi[2] * S0*S1

The dual form of the translation lattice and its basis are similarly obtained:

sage: Lv = E.dual_lattice(); Lv
Weight lattice of the Root system of type ['A', 2]
sage: bv = E.dual_lattice_basis(); bv
Finite family {1: Lambda[1], 2: Lambda[2]}
sage: FW(bv[1]-bv[2])
pi[2] * S0*S1

The abstract fundamental group is accessed from E:

sage: F = E.fundamental_group(); F
Fundamental group of type ['A', 2, 1]

Its elements are indexed by the set of special nodes of the affine Dynkin diagram:
```sage
E.cartan_type().special_nodes()
(0, 1, 2)
sage: F.special_nodes()
(0, 1, 2)
sage: [F(i) for i in F.special_nodes()]
[pi[0], pi[1], pi[2]]
```

There is a coercion from the fundamental group into each realization:

```sage
F(2)
pi[2]
```

Using $E$ one may access the classical and affine Weyl groups and their morphisms into each realization:

```sage
W0 = E.classical_weyl(); W0
Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
```

```sage
v = W0.from_reduced_word([1,2,1]); v
s1*s2*s1
```

```sage
PW0(v)
s1*s2*s1
```

```sage
WF(v)
S1*S2*S1
```

```sage
W = E.affine_weyl(); W
Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice)
```

```sage
w = W.from_reduced_word([2,1,0]); w
S2*S1*S0
```

```sage
WF(w)
S2*S1*S0
```

```sage
PW0(w)
t[Lambdacheck[1] - 2*Lambdacheck[2]] * s1
```

Note that for untwisted affine type, the dual form of the classical Weyl group is isomorphic to the usual one, but acts on a different lattice and is therefore different to sage:

```sage
W0v = E.dual_classical_weyl(); W0v
Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice)
```

```sage
v = W0v.from_reduced_word([1,2])
```

```sage
x = PvW0(v); x
s1*s2
```

```sage
y = PW0(v); y
s1*s2
```

```sage
x.parent() == y.parent()
False
```

However, because there is a coercion from $PvW0$ to $PW0$, the elements $x$ and $y$ compare as equal:

```sage
x == y
```

True
An element can be created directly from a reduced word:

```python
sage: PW0.from_reduced_word([2,1,0])
t[Lambdacheck[1] - 2*Lambdacheck[2]] * s1
```

Here is a demonstration of the printing options:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1], affine="sx", classical="Sx",
   translation="x",fundamental="pix")
sage: PW0 = E.PW0()
sage: y = PW0(E.lattice_basis()[1])
sage: y
x[Lambdacheck[1]]
sage: FW = E.FW()
sage: FW(y)
 pix[1] * sx2*sx1
sage: PW0.an_element()
```

**Todo:**
- Implement a “slow” action of $E$ on any affine root or weight lattice realization.
- Implement the level $m$ actions of $E$ and $W$ on the lattices of finite type.
- Implement the relevant methods from the usual affine Weyl group
- Implementation by matrices: style “M”.
- Use case: implement the Hecke algebra on top of this

The semidirect product construction in Sage currently only admits multiplicative groups. Therefore for the styles involving “P” and “Pv”, one must convert the additive group of translations $L$ into a multiplicative group by applying the `sage.groups.group_exp.GroupExp` functor.

**The general linear case**

The general linear group is not semisimple. Sage can build its extended affine Weyl group:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1], general_linear=True); E
Extended affine Weyl group of GL(3)
```

If the Cartan type is ['A', n-1, 1] and the parameter `general_linear` is not True, the extended affine Weyl group that is built will be for $SL_n$, not $GL_n$. But if `general_linear` is True, let $W_a$ and $W_e$ be the affine and extended affine Weyl groups. We make the following nonstandard definition: the extended affine Weyl group $W_e(GL_n)$ is defined by

$$ W_e(GL_n) = P(GL_n) \rtimes W $$

where $W$ is the finite Weyl group (the symmetric group $S_n$) and $P(GL_n)$ is the weight lattice of $GL_n$, which is usually identified with the lattice $\mathbb{Z}^n$ of $n$-tuples of integers:

```python
sage: PW0 = E.PW0(); PW0
Extended affine Weyl group of GL(3) realized by Semidirect product of
Multiplicative form of Ambient space of the Root system of type ['A', 2] acted
upon by Weyl Group of type ['A', 2] (as a matrix group acting on the ambient
space)
```
There is an isomorphism

\[ W_\omega(GL_n) = \mathbb{Z} \ltimes W_a \]

where the group of integers \( \mathbb{Z} \) (with generator \( \pi \)) acts on \( W_a \) by

\[ \pi s_i \pi^{-1} = s_{i+1} \]

and the indices of the simple reflections are taken modulo \( n \):

```python
sage: FW = E.FW(); FW
Extended affine Weyl group of GL(3) realized by Semidirect product of Fundamental group of GL(3) acting on Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice)
```

We regard \( \mathbb{Z} \) as the fundamental group of affine type \( GL_n \):

```python
sage: F = E.fundamental_group(); F
Fundamental group of GL(3)
```

```python
sage: x = FW.from_fundamental(F(10)); x
pi[10]
```

```python
sage: E.PvW0()(x*x)
t[(7, 7, 6)] * s2*s1
```

```
Bases: sage.combinat.root_system.extended_affine_weyl_group.ExtendedAffineWeylGroup_class

Combinatorics, Release 9.7
```

5.1. Comprehensive Module List

2543
Combinatorics, Release 9.7

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).FW()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Fundamental group of type ['A', 2, 1] acting on Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice)
```

**Element**

alias of `ExtendedAffineWeylGroup_Class.ExtendedAffineWeylGroupFWElement`

**from_affine_weyl**(w)

Return the image of w under the map of the affine Weyl group into the right (affine Weyl group) factor in the “FW” style.

**EXAMPLES:**

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1],print_tuple=True)
sage: E.FW().from_affine_weyl(E.affine_weyl().from_reduced_word([0,2,1]))
(pi[0], S0*S2*S1)
```

**from_fundamental**(f)

Return the image of the fundamental group element f into self.

**EXAMPLES:**

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1],print_tuple=True)
sage: E.FW().from_fundamental(E.fundamental_group()(2))
(pi[2], 1)
```

**simple_reflections**()

Return the family of simple reflections of self.

**EXAMPLES:**

```python
sage: ExtendedAffineWeylGroup(['A',2,1],print_tuple=True).FW().simple_reflections()
Finite family {0: (pi[0], S0), 1: (pi[0], S1), 2: (pi[0], S2)}
```

**class** `ExtendedAffineWeylGroupFWElement`

Bases: `sage.groups.group_semidirect_product.GroupSemidirectProductElement`

The element class for the “FW” realization.

**action_on_affine_roots**(beta)

Act by self on the affine root lattice element beta.

**EXAMPLES:**

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1],affine="s")
sage: x = E.FW().an_element(); x
pi[2] * s0*s1*s2
sage: v = RootSystem(['A',2,1]).root_lattice().an_element(); v
sage: x.action_on_affine_roots(v)
alpha[0] + alpha[1]
```

**has_descent**(i, side='right', positive=False)

Return whether self has descent at i.

**INPUT:**
• $i$ – an affine Dynkin index.

OPTIONAL:
• side – ‘left’ or ‘right’ (default: ‘right’)
• positive – True or False (default: False)

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.FW().an_element(); x
pi[2] * S0*S1*S2
sage: [(i, x.has_descent(i)) for i in E.cartan_type().index_set()]
[(0, False), (1, False), (2, True)]
```

to_affine_weyl_right()

Project self to the right (affine Weyl group) factor in the “FW” style.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.FW().from_translation(E.lattice_basis()[1]); x
pi[1] * S2*S1
sage: x.to_affine_weyl_right()
S2*S1
```

to_fundamental_group()

Return the projection of self to the fundamental group in the “FW” style.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.FW().from_translation(E.lattice_basis()[2]); x
pi[2] * S1*S2
sage: x.to_fundamental_group()
pi[2]
```

class ExtendedAffineWeylGroupPW0(E)

Bases: sage.groups.group_semidirect_product.GroupSemidirectProduct, sage.misc.bindable_classBindableClass

Extended affine Weyl group, realized as the semidirect product of the translation lattice by the finite Weyl group.

INPUT:
• $E$ – A parent with realization in ExtendedAffineWeylGroup_Class

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).PW0()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicative form of Coweight lattice of the Root system of type ['A', 2] acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
```

Element

alias of ExtendedAffineWeylGroup_Class.ExtendedAffineWeylGroupPW0Element

$S0()$

Return the affine simple reflection.
from classical weyl($w$)
Return the image of $w$ under the homomorphism of the classical Weyl group into self.

EXAMPLES:

sage: E = ExtendedAffineWeylGroup("A3", print_tuple=True)
sage: E.PW0().from_classical_weyl(E.classical_weyl().from_reduced_word([1, -2]))
(t[0], s1*s2)

from_translation($la$)
Map the translation lattice element $la$ into self.

EXAMPLES:

sage: E = ExtendedAffineWeylGroup("A', 2, 1", translation="tau", print_tuple=True)
sage: la = E.lattice().an_element(); la

sage: E.PW0().from_translation(la)

simple_reflection($i$)
Return the $i$-th simple reflection in self.

EXAMPLES:

sage: E = ExtendedAffineWeylGroup("G2")
sage: [(i, E.PW0().simple_reflection(i)) for i in E.cartan_type().index_set()]
[(0, t[Lambdacheck[2]] * s2*s1*s2*s1*s2), (1, s1), (2, s2)]

simple_reflections()
Return a family for the simple reflections of self.

EXAMPLES:

sage: ExtendedAffineWeylGroup("A3").PW0().simple_reflections()
Finite family {0: t[Lambdacheck[1] + Lambdacheck[3]] * s1*s2*s3*s2*s1, 1:
  s1, 2: s2, 3: s3}

class ExtendedAffineWeylGroupPW0Element
Bases: sage.groups.group_semidirect_product.GroupSemidirectProductElement

The element class for the “PW0” realization.

action($la$)
Return the action of self on an element $la$ of the translation lattice.

EXAMPLES:

sage: E = ExtendedAffineWeylGroup(["A", 2, 1]); PW0=E.PW0()
sage: x = PW0.an_element(); x
(continues on next page)
Combinatorics, Release 9.7

(continued from previous page)

```python
sage: la = E.lattice().an_element(); la
sage: x.action(la)
```

**has_descent**(i, side='right', positive=False)

Return whether self has i as a descent.

INPUT:
- i – an affine Dynkin node

OPTIONAL:
- side – 'left' or 'right' (default: 'right')
- positive – True or False (default: False)

EXAMPLES:

```python
sage: w = ExtendedAffineWeylGroup(['A',4,2]).PW0().from_reduced_word([0,1]);
   w
Lambda[1] * s1*s2
sage: w.has_descent(0, side='left')
True
```

**to_classical_weyl**()

Return the image of self under the homomorphism that projects to the classical Weyl group factor after rewriting it in either style "PW0" or "W0P".

EXAMPLES:

```python
sage: s = ExtendedAffineWeylGroup(['A',2,1]).PW0().S0(); s
Lambda[1] + Lambda[2] * s1*s2*s1
sage: s.to_classical_weyl()
s1*s2*s1
```

**to_translation_left**()

The image of self under the map that projects to the translation lattice factor after factoring it to the left as in style "PW0".

EXAMPLES:

```python
sage: s = ExtendedAffineWeylGroup(['A',2,1]).PW0().S0(); s
Lambda[1] + Lambda[2] * s1*s2*s1
sage: s.to_translation_left()
```

class ExtendedAffineWeylGroupPvW0(E)

Bases: sage.groups.group_semidirect_product.GroupSemidirectProduct, sage.misc.bindable_classBindableClass

Extended affine Weyl group, realized as the semidirect product of the dual form of the translation lattice by the finite Weyl group.

INPUT:
- E – A parent with realization in ExtendedAffineWeylGroup_Class

EXAMPLES:
sage: ExtendedAffineWeylGroup(["A",2,1]).PvW0()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicative form of Weight lattice of the Root system of type ['A', 2] acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice)

Element
alias of ExtendedAffineWeylGroup_Class.ExtendedAffineWeylGroupPvW0Element

from_dual_classical_weyl(w)
Return the image of w under the homomorphism of the dual form of the classical Weyl group into self.

EXAMPLES:

sage: E = ExtendedAffineWeylGroup(['A',3,1],print_tuple=True)
sage: E.PvW0().from_dual_classical_weyl(E.dual_classical_weyl().from_reduced_word([1,2]))
(t[0], s1*s2)

from_dual_translation(la)
Map the dual translation lattice element la into self.

EXAMPLES:

sage: E = ExtendedAffineWeylGroup(['A',2,1], translation="tau", print_tuple=True)
sage: la = E.dual_lattice().an_element(); la
sage: E.PvW0().from_dual_translation(la)

simple_reflections()
Return a family for the simple reflections of self.

EXAMPLES:

sage: ExtendedAffineWeylGroup(['A',3,1]).PvW0().simple_reflections()
Finite family {0: t[Lambda[1] + Lambda[3]] * s1*s2*s3*s2*s1, 1: s1, 2: s2, 3: s3}

class ExtendedAffineWeylGroupPvW0Element
Bases: sage.groups.group_semidirect_product.GroupSemidirectProductElement

The element class for the “PvW0” realization.

dual_action(la)
Return the action of self on an element la of the dual version of the translation lattice.

EXAMPLES:

sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.PvW0().an_element(); x
sage: la = E.dual_lattice().an_element(); la
Combinatorics, Release 9.7

```python
sage: x.dual_action(la)
```

_func_ {\text{has\_descent}}(\text{i, side='right', positive=False})

Return whether self has \(i\) as a descent.

**INPUT:**
- \(i\) - an affine Dynkin index

**OPTIONAL:**
- \(\text{side}\) – ‘left’ or ‘right’ (default: ‘right’)
- \(\text{positive}\) – True or False (default: False)

**EXAMPLES:**

```python
sage: E = ExtendedAffineWeylGroup(['A',4,2])
sage: w = E.PvW0().from_reduced_word([0,1]); w
t[\Lambda[1]] * s1*s2
sage: [(i, w.has_descent(i, side='left')) for i in E.cartan_type().index_set()]
[(0, True), (1, False), (2, False)]
```

\text{to\_dual\_classical\_weyl}()

Return the image of self under the homomorphism that projects to the dual classical Weyl group factor after rewriting it in either style “PvW0” or “W0Pv”.

**EXAMPLES:**

```python
sage: s = ExtendedAffineWeylGroup(['A',2,1]).PvW0().simple_reflection(0); s
t[\Lambda[1] + \Lambda[2]] * s1*s2*s1
sage: s.to_dual_classical_weyl()
s1*s2*s1
```

\text{to\_dual\_translation\_left}()

The image of self under the map that projects to the dual translation lattice factor after factoring it to the left as in style “PvW0”.

**EXAMPLES:**

```python
sage: s = ExtendedAffineWeylGroup(['A',2,1]).PvW0().simple_reflection(0); s
t[\Lambda[1] + \Lambda[2]] * s1*s2*s1
sage: s.to_dual_translation_left()
\Lambda[1] + \Lambda[2]
```

\text{class ExtendedAffineWeylGroupW0P}(\text{E})

Extended affine Weyl group, realized as the semidirect product of the finite Weyl group by the translation lattice.

**INPUT:**
- \(E\) – A parent with realization in \text{ExtendedAffineWeylGroup\_Class}

**EXAMPLES:**
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice) acting on Multiplicative form of Coweight lattice of the Root system of type ['A', 2]

Element
alias of `ExtendedAffineWeylGroup.Class. ExtendedAffineWeylGroupW0PElement`

S0()
Return the zero-th simple reflection in style “W0P”.

EXAMPLES:

```sage
sage: ExtendedAffineWeylGroup(['A',3,1]).W0P().S0()
s1*s2*s3*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[3]]
```

from_classical_weyl(w)
Return the image of the classical Weyl group element w in self.

EXAMPLES:

```sage
sage: E = ExtendedAffineWeylGroup(['A',2,1],print_tuple=True)
sage: E.W0P().from_classical_weyl(E.classical_weyl().from_reduced_word([2,1]))
(s2*s1, t[0])
```

from_translation(la)
Return the image of the lattice element la in self.

EXAMPLES:

```sage
sage: E = ExtendedAffineWeylGroup(['A',2,1],print_tuple=True)
sage: E.W0P().from_translation(E.lattice().an_element())
```

simple_reflection(i)
Return the i-th simple reflection in self.

EXAMPLES:

```sage
sage: E = ExtendedAffineWeylGroup(['A',3,1]); W0P = E.W0P()
sage: [(i, W0P.simple_reflection(i)) for i in E.cartan_type().index_set()]
[(0, s1*s2*s3*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[3]]), (1, s1), (2, s2), (3, s3)]
```

simple_reflections()
Return the family of simple reflections.

EXAMPLES:

```sage
sage: ExtendedAffineWeylGroup(['A',3,1]).W0P().simple_reflections()
Finite family {0: s1*s2*s3*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[3]], 1:
--s1, 2: s2, 3: s3}
```

class `ExtendedAffineWeylGroupW0PElement`
Bases: `sage.groups.group_semidirect_product.GroupSemidirectProductElement`
The element class for the W0P realization.

```
has_descent(i, side='right', positive=False)
```

Return whether self has \( i \) as a descent.

**INPUT:**
- \( i \) - an index.

**OPTIONAL:**
- side - 'left' or 'right' (default: 'right')
- positive - True or False (default: False)

**EXAMPLES:**

```
sage: W0P = ExtendedAffineWeylGroup(['A',4,2]).W0P()
sage: w = W0P.from_reduced_word([0,1]); w
s1*s2 * t[\Lambda[1] - \Lambda[2]]
sage: w.has_descent(0, side='left')
True
```

```
to_classical_weyl()
```

Project self into the classical Weyl group.

**EXAMPLES:**

```
sage: x = ExtendedAffineWeylGroup(['A',2,1]).W0P().simple_reflection(0); x
s1*s2*s1 * t[\Lambda\check[1] - \Lambda\check[2]]
sage: x.to_classical_weyl()
s1*s2*s1
```

```
to_translation_right()
```

Project onto the right (translation) factor in the “W0P” style.

**EXAMPLES:**

```
sage: x = ExtendedAffineWeylGroup(['A',2,1]).W0P().simple_reflection(0); x
s1*s2*s1 * t[\Lambda\check[1] - \Lambda\check[2]]
sage: x.to_translation_right()
-\Lambda\check[1] - \Lambda\check[2]
```

**class** `ExtendedAffineWeylGroupW0Pv(E)`

**Bases:** `sage.groups.group_semidirect_product.GroupSemidirectProduct`, `sage.misc.bindable_classBindableClass`

Extended affine Weyl group, realized as the semidirect product of the finite Weyl group, acting on the dual form of the translation lattice.

**INPUT:**
- \( E \) – A parent with realization in `ExtendedAffineWeylGroup_Class`

**EXAMPLES:**

```
sage: ExtendedAffineWeylGroup(['A',2,1]).W0Pv()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice) acting on Multiplicative form of Weight lattice of the Root system of type ['A', 2]
```

**Element**

alias of `ExtendedAffineWeylGroup_Class.ExtendedAffineWeylGroupW0PvElement`
from_dual_classical_weyl(w)
    Return the image of \( w \) under the homomorphism of the dual form of the classical Weyl group into self.

EXAMPLES:

    sage: E = ExtendedAffineWeylGroup(['A',3,1],print_tuple=True)
sage: E.W0Pv().from_dual_classical_weyl(E.dual_classical_weyl().from_reduced_word([1,2]))
    (s1*s2, t[0])

from_dual_translation(la)
    Map the dual translation lattice element \( la \) into self.

EXAMPLES:

    sage: E = ExtendedAffineWeylGroup(['A',2,1], translation="tau", print_tuple=True)
sage: la = E.dual_lattice().an_element(); la
sage: E.W0Pv().from_dual_translation(la)

simple_reflections()
    Return a family for the simple reflections of self.

EXAMPLES:

    sage: ExtendedAffineWeylGroup(['A',3,1]).W0Pv().simple_reflections()
    Finite family {0: s1*s2*s3*s2*s1 * t[-Lambda[1] - Lambda[3]], 1: s1, 2: s2, 3: s3}

class ExtendedAffineWeylGroupW0PvElement
    Bases: sage.groups.group_semidirect_product.GroupSemdirectProductElement

    The element class for the “W0Pv” realization.

dual_action(la)
    Return the action of self on an element \( la \) of the dual version of the translation lattice.

EXAMPLES:

    sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.W0Pv().an_element(); x
sage: la = E.dual_lattice().an_element(); la
sage: x.dual_action(la)

has_descent(i, side='right', positive=False)
    Return whether self has \( i \) as a descent.

INPUT:
    • \( i \) - an affine Dynkin index

OPTIONAL:
    • \( side \) - ‘left’ or ‘right’ (default: ‘right’)
    • \( positive \) - True or False (default: False)
EXAMPLES:

```python
sage: w = ExtendedAffineWeylGroup(['A',4,2]).W0Pv().from_reduced_word([0, -1]); w
s1*s2 * t[Lambda[1] - Lambda[2]]
sage: w.has_descent(0, side='left')
True
```

to_dual_classical_weyl()
Return the image of self under the homomorphism that projects to the dual classical Weyl group
factor after rewriting it in either style “PvW0” or “W0Pv”.

EXAMPLES:

```python
sage: s = ExtendedAffineWeylGroup(['A',2,1]).W0Pv().simple_reflection(0); s
s1*s2*s1 * t[-Lambda[1] - Lambda[2]]
sage: s.to_dual_classical_weyl()
s1*s2*s1
```

to_dual_translation_right()
The image of self under the map that projects to the dual translation lattice factor after factoring it
to the right as in style “W0Pv”.

EXAMPLES:

```python
sage: s = ExtendedAffineWeylGroup(['A',2,1]).W0Pv().simple_reflection(0); s
s1*s2*s1 * t[-Lambda[1] - Lambda[2]]
sage: s.to_dual_translation_right()
```

class ExtendedAffineWeylGroupWF(E)

Bases: `sage.groups.group_semidirect_product.GroupSemidirectProduct`, `sage.misc.bindeable_classBindableClass`

Extended affine Weyl group, realized as the semidirect product of the affine Weyl group by the fundamental
group.

INPUT:

* E – A parent with realization in `ExtendedAffineWeylGroup_Class`

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1],print_tuple=True)
sage: E.WF().from_affine_weyl(E.affine_weyl().from_reduced_word([1,2,1,0]))
(S1*S2*S1*S0, pi[0])
```

5.1. Comprehensive Module List
from_fundamental(f)

Return the image of f under the homomorphism from the fundamental group into the right (fundamental group) factor in “WF” style.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['E',6,1],print_tuple=True); WF = E.WF();
˓→F = E.fundamental_group()
sage: [(x,WF.from_fundamental(x)) for x in F]
[(pi[0], (1, pi[0])), (pi[1], (1, pi[1])), (pi[6], (1, pi[6]))]
```

simple_reflections()

Return the family of simple reflections.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',3,1],affine="r").WF().simple_reflections()
Finite family {0: r0, 1: r1, 2: r2, 3: r3}
```

class ExtendedAffineWeylGroupWFElement

Bases: sage.groups.group_semidirect_product.GroupSemidirectProductElement

Element class for the “WF” realization.

bruhat_le(x)

Return whether self is less than or equal to x in the Bruhat order.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1],affine="s", print_tuple=True);␣
˓→WF=E.WF()
sage: r = E.affine_weyl().from_reduced_word
sage: v = r([1,0])
sage: w = r([1,2,0])
sage: v.bruhat_le(w)
True
sage: vv = WF.from_affine_weyl(v); vv
(s1*s0, pi[0])
sage: ww = WF.from_affine_weyl(w); ww
(s1*s2*s0, pi[0])
sage: vv.bruhat_le(ww)
True
sage: f = E.fundamental_group()(2); f
pi[2]
sage: ff = WF.from_fundamental(f); ff
(1, pi[2])
sage: vv.bruhat_le(ww*ff)
False
sage: (vv*ff).bruhat_le(ww*ff)
True
```

has_descent(i, side=’right’, positive=False)

Return whether self has i as a descent.

INPUT:

• i – an affine Dynkin index

OPTIONAL:
• side – ‘left’ or ‘right’ (default: ‘right’)
• positive – True or False (default: False)

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.WF().an_element(); x
S0*S1*S2 * pi[2]
sage: [(i, x.has_descent(i)) for i in E.cartan_type().index_set()]
[(0, True), (1, False), (2, False)]
```

to_affine_weyl_left()

Project self to the left (affine Weyl group) factor in the “WF” style.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.WF().from_translation(E.lattice_basis()[1]); x
S0*S2 * pi[1]
sage: x.to_affine_weyl_left()
S0*S2
```

to_fundamental_group()

Project self to the right (fundamental group) factor in the “WF” style.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.WF().from_translation(E.lattice_basis()[1]); x
S0*S2 * pi[1]
sage: x.to_fundamental_group()
pi[1]
```

FW()

Realizes self in “FW”-style.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).FW()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Fundamental group of type ['A', 2, 1] acting on Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice)
```

PW0()

Realizes self in “PW0”-style.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).PW0()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicative form of Coweight lattice of the Root system of type ['A', 2] acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
```

PW0_to_WF_func(x)

Implements coercion from style “PW0” to “WF”.

EXAMPLES:
```python
sage: E = ExtendedAffineWeylGroup(['A', 2, 1])
sage: x = E.PW0().an_element(); x
sage: E.PW0_to_WF_func(x)
S0*S1*S2*S0*S1*S0
```

**Warning:** This function cannot use coercion, because it is used to define the coercion maps.

**PvW0()**

Realizes self in “PvW0”-style.

**EXAMPLES:**

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).PvW0()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product...
...
acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the...
...
weight lattice)
```

**class Realizations(parent_with_realization)**

Bases: `sage.categories.realizations.Category_realization_of_parent`

The category of the realizations of an extended affine Weyl group.

**class ElementMethods**

Bases: `object`

**action(la)**

Action of self on a lattice element la.

**INPUT:**

- `self` – an element of the extended affine Weyl group
- `la` – an element of the translation lattice of the extended affine Weyl group, the lattice denoted by the mnemonic “P” in the documentation for `ExtendedAffineWeylGroup()`.

**EXAMPLES:**

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1],affine="s")
sage: x = E.FW().an_element(); x
pi[2] * s0*s1*s2
sage: la = E.lattice().an_element(); la
sage: x.action(la)
```

**Warning:** Must be implemented by style “PW0”.

**action_on_affine_roots(beta)**

Act by self on the affine root lattice element beta.
EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(["A",2,1])
sage: beta = E.cartan_type().root_system().root_lattice().an_element(); beta
sage: x = E.FW().an_element(); x
pi[2] * S0*S1*S2
sage: x.action_on_affine_roots(beta)
alpha[0] + alpha[1]
```

**Warning:** Must be implemented by style “FW”.

### alcove_walk_signs()

Return a signed alcove walk for `self`.

**INPUT:**

- An element `self` of the extended affine Weyl group.

**OUTPUT:**

- A 3-tuple `(g, rw, signs)`.

**ALGORITHM:**

The element `self` can be uniquely written `self = g * w` where `g` has length zero and `w` is an element of the nonextended affine Weyl group. Let `w` have reduced word `rw`. Starting with `g` and applying simple reflections from `rw`, one obtains a sequence of extended affine Weyl group elements (that is, alcoves) and simple roots. The signs give the sequence of sides on which the alcoves lie, relative to the face indicated by the simple roots.

**EXAMPLES:**

```
sage: E = ExtendedAffineWeylGroup(["A",3,1]); FW=E.FW()
sage: w = FW.from_reduced_word([0,2,1,3,0])*FW.from_fundamental(1); w
pi[1] * S3*S1*S2*S0*S3
sage: w.alcove_walk_signs()
(pi[1], [3, 1, 2, 0, 3], [-1, 1, -1, -1, 1])
```

### apply_simple_projection(i, side='right', length_increasing=True)

Return the product of `self` by the simple reflection `s_i` if that product is of greater length than `self` and otherwise return `self`.

**INPUT:**

- `self` – an element of the extended affine Weyl group
- `i` – a Dynkin node (index of a simple reflection `s_i`)
- `side` – ‘right’ or ‘left’ (default: ‘right’) according to which side of `self` the reflection `s_i` should be multiplied
- `length_increasing` – True or False (default True). If False do the above with the word “greater” replaced by “less”.

**EXAMPLES:**

```
sage: x = ExtendedAffineWeylGroup(["A",3,1]).WF().an_element(); x
S0*S1*S2*S3 * pi[3]
sage: x.apply_simple_projection(1)
S0*S1*S2*S3*S0 * pi[3]
```
**apply_simple_projection**

Apply the simple projection to the element.

```python
sage: x.apply_simple_projection(1, length_increasing=False)
S0*S1*S2*S3 * pi[3]
```

**apply_simple_reflection**

Apply the i-th simple reflection to self.

```python
apply_simple_reflection(i, side='right')

EXAMPLES:

```python
sage: x = ExtendedAffineWeylGroup(['A',3,1]).WF().an_element(); x
S0*S1*S2*S3 * pi[3]
sage: x.apply_simple_reflection(1)
S0*S1*S2*S3*S0 * pi[3]
sage: x.apply_simple_reflection(0, side='left')
S1*S2*S3 * pi[3]
```

**bruhat_le**

Return whether self <= x in Bruhat order.

```python
bruhat_le(x)

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1],print_tuple=True); WF=E.WF()
sage: W = E.affine_weyl()
sage: v = W.from_reduced_word([2,1,0])
sage: w = W.from_reduced_word([2,0,1,0])
sage: v.bruhat_le(w)
True
sage: vx = WF.from_affine_weyl(v); vx
(S2*S1*S0, pi[0])
sage: wx = WF.from_affine_weyl(w); wx
(S2*S0*S1*S0, pi[0])
sage: vx.bruhat_le(wx)
True
sage: F = E.fundamental_group()
sage: f = WF.from_fundamental(F(2))
sage: vx.bruhat_le(wx*f)
False
sage: (vx*f).bruhat_le(wx*f)
True
```

**Warning:** Must be implemented by “WF”.

**coset_repre sentative**

Return the minimum length representative in the coset of self with respect to the subgroup generated by the reflections given by index_set.

**INPUT:**

- self – an element of the extended affine Weyl group
- index_set – a subset of the set of Dynkin nodes
- side – ‘right’ or ‘left’ (default: ‘right’) the side on which the subgroup acts

**EXAMPLES:**
dual_action($la$)
Action of self on a dual lattice element $la$.

**INPUT:**
- self – an element of the extended affine Weyl group
- $la$ – an element of the dual translation lattice of the extended affine Weyl group, the lattice
  denoted by the mnemonic “Pv” in the documentation for ExtendedAffineWeylGroup().

**EXAMPLES:**

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1], affine="s")
sage: x = E.FW().an_element(); x
pi[2] * s0*s1*s2
sage: la = E.dual_lattice().an_element(); la
sage: x.dual_action(la)
```

**Warning:** Must be implemented by style “PvW0”.

face_data($i$)
Return a description of one of the bounding hyperplanes of the alcove of an extended affine Weyl

group element.

**INPUT:**
- self – An element of the extended affine Weyl group
- $i$ – an affine Dynkin node

**OUTPUT:**
- A 2-tuple $(m, \beta)$ defined as follows.

**ALGORITHM:**

Each element of the extended affine Weyl group corresponds to an alcove, and each alcove has a
face for each affine Dynkin node. Given the data of self and $i$, let the extended affine Weyl group

element self act on the affine simple root $\alpha_i$, yielding a real affine root, which can be expressed
uniquely as

$$"self" \cdot \alpha_i = m\delta + \beta$$

where $m$ is an integer (the height of the $i$-th bounding hyperplane of the alcove of self) and $\beta$ is

**EXAMPLES:**
sage: x = ExtendedAffineWeylGroup(['A',2,1]).PW0().an_element(); x
\tau[2*\Lambda_1 + 2*\Lambda_2] * s1*s2
sage: x.face_data(0)
(-1, \alpha[1])

\texttt{first\_descent}(side='right', positive=False, index\_set=None)

Return the first descent of \texttt{self}.

INPUT:
- \texttt{side} – ‘left’ or ‘right’ (default: ‘right’)
- \texttt{positive} – True or False (default: False)
- \texttt{index\_set} – an optional subset of Dynkin nodes

If \texttt{index\_set} is not None, then the descent must be in the \texttt{index\_set}.

EXAMPLES:

sage: x = ExtendedAffineWeylGroup(['A',3,1]).WF().an_element(); x
S0*S1*S2*S3 * pi[3]
sage: x.first_descent()
0
sage: x.first_descent(side='left')
0
sage: x.first_descent(positive=True)
1
sage: x.first_descent(side='left',positive=True)
1

\texttt{has\_descent}(i, side='right', positive=False)

Return whether \texttt{self} * \texttt{s}_i < \texttt{self} where \texttt{s}_i is the \texttt{i}-th simple reflection in the realized group.

INPUT:
- \texttt{i} – an affine Dynkin index

OPTIONAL:
- \texttt{side} – ‘right’ or ‘left’ (default: ‘right’)
- \texttt{positive} – True or False (default: False)

If \texttt{side}='left' then the reflection acts on the left. If \texttt{\_positive} = True then the inequality is reversed.

EXAMPLES:

sage: E = ExtendedAffineWeylGroup(['A',3,1]); WF=E.WF()
sage: F = E.fundamental_group()
sage: x = WF.an_element(); x
S0*S1*S2*S3 * pi[3]
sage: I = E.cartan_type().index_set()
sage: [(i, x.has_descent(i)) \text{ for } i \text{ in } I]
[(0, True), (1, False), (2, False), (3, False)]
sage: [(i, x.has_descent(i,side='left')) \text{ for } i \text{ in } I]
[(0, True), (1, False), (2, False), (3, False)]
sage: [(i, x.has_descent(i,positive=True)) \text{ for } i \text{ in } I]
[(0, False), (1, True), (2, True), (3, True)]

\textbf{Warning:} This method is abstract because it is used in the recursive coercions between “PW0” and “WF” and other methods use this coercion.
**is_affine_grassmannian()**
Return whether `self` is affine Grassmannian.

**EXAMPLES:**
```
sage: E = ExtendedAffineWeylGroup(['A',2,1]); PW0=E.PW0()
sage: F = E.fundamental_group()
sage: [x,PW0.from_fundamental(x).is_affine_grassmannian()) for x in F]
[(pi[0], True), (pi[1], True), (pi[2], True)]
sage: b = E.lattice_basis()
sage: [(-x,PW0.from_translation(-x).is_affine_grassmannian()) for x in b]
[(-Lambdacheck[1], True), (-Lambdacheck[2], True)]
```

**is_grassmannian(index_set, side='right')**
Return whether `self` is of minimum length in its coset with respect to the subgroup generated by the reflections of `index_set`.

**EXAMPLES:**
```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0=E.PW0()
sage: x = PW0.from_translation(E.lattice_basis()[1]); x.t[Lambdacheck[1]]
sage: I = E.cartan_type().index_set()
sage: [(i, x.is_grassmannian(index_set=[i])) for i in I]
[(0, True), (1, False), (2, True), (3, True)]
sage: [(i, x.is_grassmannian(index_set=[i], side='left')) for i in I]
[(0, False), (1, True), (2, True), (3, True)]
```

**is_translation()**
Return whether `self` is a translation element or not.

**EXAMPLES:**
```
sage: E = ExtendedAffineWeylGroup(['A',2,1]); FW=E.FW()
sage: F = E.fundamental_group()
sage: FW.from_affine_weyl(E.affine_weyl().from_reduced_word([1,2,1,0])).__is_translation()
True
sage: FW.from_translation(E.lattice_basis()[1]).is_translation()
True
sage: FW.simple_reflection(0).is_translation()
False
```

**length()**
Return the length of `self` in the Coxeter group sense.

**EXAMPLES:**
```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0=E.PW0()
sage: I0 = E.cartan_type().classical().index_set()
sage: [PW0.from_translation(E.lattice_basis()[i]).length() for i in I0]
[3, 4, 3]
```

**to_affine_grassmannian()**
Return the unique affine Grassmannian element in the same coset of `self` with respect to the finite Weyl group acting on the right.
EXAMPLES:

```python
sage: elts = ExtendedAffineWeylGroup(['A',2,1]).PW0().some_elements()
sage: [(x, x.to_affine_grassmannian()) for x in elts]
    2*Lambdacheck[2]] * s1*s2*s1)]
```

```python
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0 = E.PW0()
sage: b = E.lattice_basis()
sage: [(x,PW0.from_translation(x).to_affine_weyl_left()) for x in b]
[(Lambdacheck[1], S0*S3*S2), (Lambdacheck[2], S0*S3*S1*S0), (Lambdacheck[3], S0*S1*S2)]
```

**Warning:** Must be implemented in style “WF”.

**to_affine_weyl_left()**

Return the projection of self to the affine Weyl group on the left, after factorizing using the style “WF”.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0 = E.PW0()
sage: b = E.lattice_basis()
sage: [(x,PW0.from_translation(x).to_affine_weyl_left()) for x in b]
[(Lambdacheck[1], S3*S2*S1), (Lambdacheck[2], S2*S3*S1*S2), (Lambdacheck[3], S1*S2*S3)]
```

**Warning:** Must be implemented in style “FW”.

**to_affine_weyl_right()**

Return the projection of self to the affine Weyl group on the right, after factorizing using the style “FW”.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0 = E.PW0()
sage: b = E.lattice_basis()
sage: [(x,PW0.from_translation(x).to_affine_weyl_right()) for x in b]
[(Lambdacheck[1], S0*S3*S2), (Lambdacheck[2], S0*S3*S1*S0), (Lambdacheck[3], S0*S1*S2)]
```

**Warning:** Must be implemented in style “FW”.

**to_classical_weyl()**

Return the image of self under the homomorphism to the classical Weyl group.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',3,1]).WF().simple_reflection(0).to_classical_weyl()
s1*s2*s3*s2*s1
```

**Warning:** Must be implemented in style “PW0”.

**to_dual_classical_weyl()**

Return the image of self under the homomorphism to the dual form of the classical Weyl group.

EXAMPLES:
Combinatorics, Release 9.7

```python
sage: x = ExtendedAffineWeylGroup(['A',3,1]).WF().simple_reflection(0).
to_dual_classical_weyl(); x
s1*s2*s3*s2*s1
sage: x.parent()
Weyl Group of type ['A', 3] (as a matrix group acting on the weight˓→lattice)
```

**Warning:** Must be implemented in style “PvW0”.

**to_dual_translation_left()**
Return the projection of `self` to the dual translation lattice after factorizing it to the left using the style “PvW0”.

**EXAMPLES:**
```python
sage: ExtendedAffineWeylGroup(['A',3,1]).PvW0().simple_reflection(0).to_˓→dual_translation_left()
Lambda[1] + Lambda[3]
```

**Warning:** Must be implemented in style “PvW0”.

**to_dual_translation_right()**
Return the projection of `self` to the dual translation lattice after factorizing it to the right using the style “W0Pv”.

**EXAMPLES:**
```python
sage: ExtendedAffineWeylGroup(['A',3,1]).PW0().simple_reflection(0).to_˓→dual_translation_right()
```

**Warning:** Must be implemented in style “W0Pv”.

**to_fundamental_group()**
Return the image of `self` under the homomorphism to the fundamental group.

**EXAMPLES:**
```python
sage: PW0 = ExtendedAffineWeylGroup(['A',3,1]).PW0()
sage: b = PW0.realization_of().lattice_basis()
sage: [(x, PW0.from_translation(x).to_fundamental_group()) for x in b]
[(Lambdacheck[1], pi[1]), (Lambdacheck[2], pi[2]), (Lambdacheck[3],␣˓→pi[3])]
```

**Warning:** Must be implemented in style “WF”.

**to_translation_left()**
Return the projection of `self` to the translation lattice after factorizing it to the left using the style
“PW0”.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',3,1]).PW0().simple_reflection(0).to_translation_left()
Lambdacheck[1] + Lambdacheck[3]
```

**Warning:** Must be implemented in style “PW0”.

### to_translation_right()

Return the projection of self to the translation lattice after factorizing it to the right using the style “W0P”.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',3,1]).PW0().simple_reflection(0).to_translation_right()
```

**Warning:** Must be implemented in style “W0P”.

### class ParentMethods

Bases: object

**from_affine_weyl**(w)

Return the image of w under the homomorphism from the affine Weyl group into self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0=E.PW0()
sage: W = E.affine_weyl()
sage: w = W.from_reduced_word([2,1,3,0])
sage: x = PW0.from_affine_weyl(w); x
\text{t}[\text{Lambdacheck}[1] - 2*\text{Lambdacheck}[2] + \text{Lambdacheck}[3]] * s3*s1
```

```
sage: FW = E.FW()
sage: y = FW.from_affine_weyl(w); y
S2*S3*S1*S0
```

```
sage: FW(x) == y
True
```

**Warning:** Must be implemented in style “WF” and “FW”.

**from_classical_weyl**(w)

Return the image of w from the finite Weyl group into self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0=E.PW0()
sage: W0 = E.classical_weyl()
sage: w = W0.from_reduced_word([2,1,3])
```

(continues on next page)
from_dual_classical_weyl($w$)

Return the image of $w$ from the finite Weyl group of dual form into self.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PvW0 = E.PvW0()
sage: W0v = E.dual_classical_weyl()
sage: w = W0v.from_reduced_word([2,1,3])
sage: y = PvW0.from_dual_classical_weyl(w); y
s2*s3*s1
sage: y.parent() == PvW0
True
sage: y.to_classical_weyl() == w
True
sage: x = E.FW().from_dual_classical_weyl(w); x
S2*S3*S1
sage: x.parent() == FW
True
sage: FW(y) == x
True
sage: FW(z) == x
True
```

**Warning:** Must be implemented in style “PvW0” and “W0Pv”.

from_dual_translation($la$)

Return the image of $la$ under the homomorphism of the dual version of the translation lattice into self.

```python
sage: y = PW0.from_classical_weyl(w); y
s2*s3*s1
sage: y.parent() == PW0
True
sage: y.to_classical_weyl() == w
True
sage: W0P = E.W0P()
sage: z = W0P.from_classical_weyl(w); z
s2*s3*s1
sage: z.parent() == W0P
True
sage: W0P(y) == z
True
sage: FW = E.FW()
sage: x = FW.from_classical_weyl(w); x
S2*S3*S1
sage: x.parent() == FW
True
sage: FW(y) == x
True
sage: FW(z) == x
True
```

**Warning:** Must be implemented in style “PW0” and “W0P”.

5.1. Comprehensive Module List 2565
EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1]); PvW0 = E.PvW0()
Finite family {1: Lambda[1], 2: Lambda[2]}
sage: x = PvW0.from_dual_translation(2*bv[1]-bv[2]); x
sage: FW = E.FW()
sage: y = FW.from_dual_translation(2*bv[1]-bv[2]); y
S0*S2*S0*S1
sage: FW(x) == y
True
```

**from_fundamental**($x$)

Return the image of $x$ under the homomorphism from the fundamental group into self.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',3,1])
sage: PW0=E.PW0()
sage: F = E.fundamental_group()
sage: Is = F.special_nodes()
sage: [(i, PW0.from_fundamental(F(i))) for i in Is]
[(0, 1), (1, t[Lambdacheck[1]] * s1*s2*s3), (2, t[Lambdacheck[2]] * s2*s3*s1*s2),
(3, t[Lambdacheck[3]] * s3*s2*s1)]

sage: [(i, E.W0P().from_fundamental((F(i)))) for i in Is]
[(0, 1), (1, s1*s2*s3 * t[-Lambdacheck[3]]), (2, s2*s3*s1*s2 * t[-Lambdacheck[2]]),
(3, s3*s2*s1 * t[-Lambdacheck[1]])]

sage: [(i, E.WF().from_fundamental(F(i))) for i in Is]
[(0, 1), (1, pi[1]), (2, pi[2]), (3, pi[3])]
```

**Warning**: This method must be implemented by the “WF” and “FW” realizations.

**from_reduced_word**(word)

Converts an affine or finite reduced word into a group element.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).PW0().from_reduced_word([1,0,1,2])
t[-Lambdacheck[1] + 2*Lambdacheck[2]]
```

**from_translation**(la)

Return the element of translation by $la$ in self.

**INPUT:**
- self – a realization of the extended affine Weyl group
- la – an element of the translation lattice

In the notation of the documentation for `ExtendedAffineWeylGroup()`, la must be an element of “P”.

EXAMPLES:
```python
sage: E = ExtendedAffineWeylGroup(['A',2,1]); PW0=E.PW0()
sage: b = E.lattice_basis(); b
Finite family {1: Lambda[1], 2: Lambda[2]}
sage: x = PW0.from_translation(2*b[1]-b[2]); x
sage: FW = E.FW()
sage: y = FW.from_translation(2*b[1]-b[2]); y
S0*S2*S0*S1
sage: FW(x) == y
True
```

Since the implementation as a semidirect product requires wrapping the lattice group to make it multiplicative, we cannot declare that this map is a morphism for sage Groups().

**Warning:** This method must be implemented by the “PW0” and “W0P” realizations.

### simple_reflection(i)
Return the \(i\)-th simple reflection in self.

**INPUT:**
- `self` – a realization of the extended affine Weyl group
- `i` – An affine Dynkin node

**EXAMPLES:**

```python
sage: ExtendedAffineWeylGroup(['A',3,1]).PW0().simple_reflection(0)
t[2*Lambda[1] + Lambda[3]] * s1*s2*s3*s2*s1
sage: ExtendedAffineWeylGroup(['C',2,1]).WF().simple_reflection(0)
S0
sage: ExtendedAffineWeylGroup(['D',3,2]).PvW0().simple_reflection(1)
s1
```

### simple_reflections()
Return a family from the set of affine Dynkin nodes to the simple reflections in the realization of the extended affine Weyl group.

**EXAMPLES:**

```python
sage: ExtendedAffineWeylGroup(['A',3,1]).W0P().simple_reflections()
Finite family {0: s1*s2*s3*s2*s1 * t[-Lambda[1] - Lambda[3]], 1: s1, 2: s2, 3: s3}
sage: ExtendedAffineWeylGroup(['A',3,1]).WF().simple_reflections()
Finite family {0: S0, 1: S1, 2: S2, 3: S3}
sage: ExtendedAffineWeylGroup(['A',3,1], print_tuple=True).FW().simple_reflections()
Finite family {0: (pi[0], S0), 1: (pi[0], S1), 2: (pi[0], S2), 3: (pi[0], S3)}
sage: ExtendedAffineWeylGroup(['A',3,1], fundamental="f",print_tuple=True).FW().simple_reflections()
Finite family {0: (f[0], S0), 1: (f[0], S1), 2: (f[0], S2), 3: (f[0], S3)}
sage: ExtendedAffineWeylGroup(['A',3,1]).PvW0().simple_reflections()
Finite family {0: t[2*Lambda[1] + Lambda[3]] * s1*s2*s3*s2*s1, 1: s1, 2: s2, 3: s3}
```

5.1. Comprehensive Module List 2567
super_categories()
EXAMPLES:

```
sage: R = ExtendedAffineWeylGroup(['A',2,1]).Realizations(); R
category of realizations of Extended affine Weyl group of type ['A', 2, 1]
sage: R.super_categories()
[Category of associative inverse realizations of unital magmas]
```

W0P()
Realizes self in “W0P”-style.
EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).W0P()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice) acting on Multiplicative form of Coweight lattice of the Root system, of type ['A', 2]
```

W0Pv()
Realizes self in “W0Pv”-style.
EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).W0Pv()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice) acting on Multiplicative form of Weight lattice of the Root system, of type ['A', 2]
```

WF()
Realizes self in “WF”-style.
EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).WF()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice) acted upon by Fundamental group of type ['A', 2, 1]
```

WF_to_PW0_func(x)
Coercion from style “WF” to “PW0”.
EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A', 2, 1])
sage: x = E.WF().an_element(); x
S0*S1*S2 * pi[2]
sage: E.WF_to_PW0_func(x)
t[Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2*s1
```

```
Warning: Since this is used to define some coercion maps it cannot itself use coercion.
```

a_realization()
Return the default realization of an extended affine Weyl group.
EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).a_realization()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicative form of Coweight lattice of the Root system of type ['A', 2] acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
```

**affine_weyl()**

Return the affine Weyl group of self.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).affine_weyl()
Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice)
sage: ExtendedAffineWeylGroup(['A',5,2]).affine_weyl()
Weyl Group of type ['B', 3, 1]^* (as a matrix group acting on the root lattice)
sage: ExtendedAffineWeylGroup(['A',4,2]).affine_weyl()  # dual)
Weyl Group of type ['BC', 2, 2] (as a matrix group acting on the root lattice)
sage: ExtendedAffineWeylGroup(CartanType(['A',4,2]).dual()).affine_weyl()
Weyl Group of type ['BC', 2, 2]^* (as a matrix group acting on the root lattice)
```

**cartan_type()**

The Cartan type of self.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['D',3,2]).cartan_type()
['C', 2, 1]^*
```

**classical_weyl()**

Return the classical Weyl group of self.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).classical_weyl()
Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
sage: ExtendedAffineWeylGroup(['A',5,2]).classical_weyl()
Weyl Group of type ['C', 3] (as a matrix group acting on the weight lattice)
sage: ExtendedAffineWeylGroup(['A',4,2]).classical_weyl()  # dual)
Weyl Group of type ['C', 2] (as a matrix group acting on the weight lattice)
sage: ExtendedAffineWeylGroup(CartanType(['A',4,2]).dual()).classical_weyl()
Weyl Group of type ['C', 2] (as a matrix group acting on the coweight lattice)
```

**classical_weyl_to_affine(w)**

The image of \( w \) under the homomorphism from the classical Weyl group into the affine Weyl group.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: W0 = E.classical_weyl()
sage: w = W0.from_reduced_word([1,2]); w
s1*s2
sage: v = E.classical_weyl_to_affine(w); v
s1*s2
```
dual_classical_weyl()

Return the dual version of the classical Weyl group of self.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).dual_classical_weyl()
Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice)
sage: ExtendedAffineWeylGroup(['A',5,2]).dual_classical_weyl()
Weyl Group of type ['C', 3] (as a matrix group acting on the weight lattice)
```

dual_classical_weyl_to_affine(w)

The image of \( w \) under the homomorphism from the dual version of the classical Weyl group into the affine Weyl group.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: W0v = E.dual_classical_weyl()
sage: w = W0v.from_reduced_word([[1,2]]); w
s1*s2
sage: v = E.dual_classical_weyl_to_affine(w); v
S1*S2
```

dual_lattice()

Return the dual version of the translation lattice for self.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).dual_lattice()
Weight lattice of the Root system of type ['A', 2]
sage: ExtendedAffineWeylGroup(['A',5,2]).dual_lattice()
Weight lattice of the Root system of type ['C', 3]
```

dual_lattice_basis()

Return the distinguished basis of the dual version of the translation lattice for self.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).dual_lattice_basis()
Finite family {1: Lambda[1], 2: Lambda[2]}
sage: ExtendedAffineWeylGroup(['A',5,2]).dual_lattice_basis()
Finite family {1: Lambda[1], 2: Lambda[2], 3: Lambda[3]}
```

exp_dual_lattice()

Return the multiplicative version of the dual version of the translation lattice for self.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).exp_dual_lattice()
Multiplicative form of Weight lattice of the Root system of type ['A', 2]
```

exp_lattice()

Return the multiplicative version of the translation lattice for self.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).exp_lattice()
Multiplicative form of Coweight lattice of the Root system of type ['A', 2]
```
**fundamental_group()**

Return the abstract fundamental group.

EXAMPLES:

```python
sage: F = ExtendedAffineWeylGroup(['D',5,1]).fundamental_group(); F
Fundamental group of type ['D', 5, 1]

sage: [a for a in F]
[pi[0], pi[1], pi[4], pi[5]]
```

**group_generators()**

Return a set of generators for the default realization of self.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).group_generators()
(t[Lambdacheck[1]], t[Lambdacheck[2]], s1, s2)
```

**lattice()**

Return the translation lattice for self.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).lattice()
Coweight lattice of the Root system of type ['A', 2]

sage: ExtendedAffineWeylGroup(['A',5,2]).lattice()
Weight lattice of the Root system of type ['C', 3]

sage: ExtendedAffineWeylGroup(['A',4,2]).lattice()
Weight lattice of the Root system of type ['C', 2]

sage: ExtendedAffineWeylGroup(CartanType(['A',4,2]).dual()).lattice()
Coweight lattice of the Root system of type ['B', 2]

sage: ExtendedAffineWeylGroup(CartanType(['A',2,1]), general_linear=True).lattice()
Ambient space of the Root system of type ['A', 2]
```

**lattice_basis()**

Return the distinguished basis of the translation lattice for self.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).lattice_basis()
Finite family {1: Lambdacheck[1], 2: Lambdacheck[2]}

sage: ExtendedAffineWeylGroup(['A',5,2]).lattice_basis()
Finite family {1: Lambda[1], 2: Lambda[2], 3: Lambda[3]}

sage: ExtendedAffineWeylGroup(['A',4,2]).lattice_basis()
Finite family {1: Lambda[1], 2: Lambda[2]}

sage: ExtendedAffineWeylGroup(CartanType(['A',4,2]).dual()).lattice_basis()
Finite family {1: Lambdacheck[1], 2: Lambdacheck[2]}
```
5.1.261 Fundamental Group of an Extended Affine Weyl Group

AUTHORS:

- Mark Shimozono (2013) initial version

class sage.combinat.root_system.fundamental_group.FundamentalGroupElement(parent, x)

   Bases: sage.structure.element.MultiplicativeGroupElement

   This should not be called directly

   EXAMPLES:

   sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
   sage: x = FundamentalGroupOfExtendedAffineWeylGroup(['A',4,1], prefix="f").an_element()
   sage: TestSuite(x).run()

   act_on_affine_lattice(wt)
   Act by self on the element wt of an affine root/weight lattice realization.

   EXAMPLES:

   sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
   sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1])
   sage: wt = RootSystem(F.cartan_type()).weight_lattice().an_element(); wt
   sage: F(3).act_on_affine_lattice(wt)

   Warning: Doesn’t work on ambient spaces.

   act_on_affine_weyl(w)
   Act by self on the element w of the affine Weyl group.

   EXAMPLES:

   sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
   sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1])
   sage: W = WeylGroup(F.cartan_type(),prefix="s")
   sage: w = W.from_reduced_word([2,3,0])
   sage: F(1).act_on_affine_weyl(w).reduced_word()
   [3, 0, 1]

   inverse()
   Return the inverse element of self.

   EXAMPLES:

   sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
   sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1])
   sage: F(1).inverse()
\begin{verbatim}
pi[3]
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['E', 6, 1], prefix='f')
sage: F(1).inverse()

\end{verbatim}

\texttt{value()}
Return the special node which indexes the special automorphism \texttt{self}.

\textbf{EXAMPLES:}
\begin{verbatim}
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A', 4, 1], prefix='f')
sage: F.special_nodes()
(0, 1, 2, 3, 4)
sage: x = F(4); x
f[4]
sage: x.value()
4
\end{verbatim}

\begin{class}
\texttt{sage.combinat.root_system.fundamental_group.FundamentalGroupGL(cartan_type, prefix='pi')}
\texttt{Bases: sage.combinat.root_system.fundamental_group.FundamentalGroupOfExtendedAffineWeylGroup.Class}
\end{class}
Fundamental group of $GL_n$. It is just the integers with extra privileges.

\textbf{Element}
\texttt{alias of FundamentalGroupGLElement}

\texttt{action(i)}
The action of the $i$-th automorphism on the affine Dynkin node set.

\textbf{EXAMPLES:}
\begin{verbatim}
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A', 2, 1], general_linear=True)
sage: F.action(4)(2)
0
sage: F.action(-4)(2)
1
\end{verbatim}

\texttt{an_element()}
An element of \texttt{self}.

\textbf{EXAMPLES:}
\begin{verbatim}
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A', 2, 1], general_linear=True).an_element()
pi[5]
\end{verbatim}

\texttt{dual_node(i)}
The node whose special automorphism is inverse to that of $i$.

\textbf{EXAMPLES:}

5.1. Comprehensive Module List 2573
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True)
sage: F.dual_node(2)
-2

family()
The family associated with the set of special nodes.

EXAMPLES:

sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: fam = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).family() # indirect doctest
sage: fam
Lazy family (<lambda>(i))_{i in Integer Ring}
sage: fam[-3]
-3

group_generators()
Return group generators for self.

EXAMPLES:

sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).group_generators()
(pi[1],)

one()
Return the identity element of the fundamental group.

EXAMPLES:

sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).one()
pi[0]

product(x, y)
Return the product of x and y.

EXAMPLES:

sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True)
sage: F.special_nodes()
Integer Ring
sage: F(2)*F(3)
(continues on next page)
sage: F(1)*F(3)^(-1)
pi[-2]

reduced_word(i)
A reduced word for the finite permutation part of the special automorphism indexed by $i$.

More precisely, return a reduced word for the finite Weyl group element $u$ where $i$-th automorphism (expressed in the extended affine Weyl group) has the form $tu$ where $t$ is a translation element.

EXAMPLES:

sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True)

sage: F.reduced_word(10)
(1, 2)

some_elements()
Return some elements of self.

EXAMPLES:

sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).some_elements()
[pi[-2], pi[2], pi[5]]

class sage.combinat.root_system.fundamental_group.FundamentalGroupGLElement

Act by self on the classical ambient weight vector wt.

EXAMPLES:

sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True)

sage: f = F.an_element(); f
pi[5]

sage: la = F.cartan_type().classical().root_system().ambient_space().an_element(); la
(2, 2, 3)

sage: f.act_on_classical_ambient(la)
(2, 3, 2)

Factory for the fundamental group of an extended affine Weyl group.

5.1. Comprehensive Module List
INPUT:

- `cartan_type` – a Cartan type that is either affine or finite, with the latter being a shorthand for the untwisted affinization
- `prefix` (default: ‘pi’) – string that labels the elements of the group
- `general_linear` – (default: None, meaning False) In untwisted type A, if True, use the universal central extension

**Fundamental group**

Associated to each affine Cartan type $\tilde{X}$ is an extended affine Weyl group $E$. Its subgroup of length-zero elements is called the fundamental group $F$. The group $F$ can be identified with a subgroup of the group of automorphisms of the affine Dynkin diagram. As such, every element of $F$ can be viewed as a permutation of the set $I$ of affine Dynkin nodes.

Let $0 \in I$ be the distinguished affine node; it is the one whose removal produces the associated finite Cartan type (call it $X$). A node $i \in I$ is called special if some automorphism of the affine Dynkin diagram, sends $0$ to $i$. The node $0$ is always special due to the identity automorphism. There is a bijection of the set of special nodes with the fundamental group. We denote the image of $i$ by $\pi_i$. The structure of $F$ is determined as follows.

- $\tilde{X}$ is untwisted – $F$ is isomorphic to $P^\vee / Q^\vee$ where $P^\vee$ and $Q^\vee$ are the coweight and coroot lattices of type $X$. The group $P^\vee / Q^\vee$ consists of the cosets $\omega_i^\vee + Q^\vee$ for special nodes $i$, where $\omega_0^\vee = 0$ by convention. In this case the special nodes $i$ are the *cominuscule* nodes, the ones such that $\omega_j^\vee (\alpha_i)$ is $0$ or $1$ for all $j \in I_0 = I \setminus \{0\}$. For $i$ special, addition by $\omega_i^\vee + Q^\vee$ permutes $P^\vee / Q^\vee$ and therefore permutes the set of special nodes. This permutation extends uniquely to an automorphism of the affine Dynkin diagram.

- $\tilde{X}$ is dual untwisted – (that is, the dual of $\tilde{X}$ is untwisted) $F$ is isomorphic to $P/Q$ where $P$ and $Q$ are the weight and root lattices of type $X$. The group $P/Q$ consists of the cosets $\omega_i + Q$ for special nodes $i$, where $\omega_0 = 0$ by convention. In this case the special nodes $i$ are the *minuscule* nodes, the ones such that $\alpha_j^\vee (\omega_i)$ is $0$ or $1$ for all $j \in I_0$. For $i$ special, addition by $\omega_i + Q$ permutes $P/Q$ and therefore permutes the set of special nodes. This permutation extends uniquely to an automorphism of the affine Dynkin diagram.

- $\tilde{X}$ is mixed – (that is, not of the above two types) $F$ is the trivial group.

**EXAMPLES:**

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1]); F

(2, 3, 2)
sage: w = WeylGroup(F.cartan_type(),prefix="s").an_element(); w
s0*s1*s2
sage: x.act_on_affine_weyl(w)
s2*s0*s1
```
class sage.combinat.root_system.fundamental_group.FundamentalGroupOfExtendedAffineWeylGroup_Class(cartan_type, prefix, finite=True):

    Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

    The group of length zero elements in the extended affine Weyl group.

    Element
        alias of FundamentalGroupElement

    action(i)
        Return a function which permutes the affine Dynkin node set by the i-th special automorphism.

    EXAMPLES:

    sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
    sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A', 2, 1])
    sage: [(i, j, F.action(i)(j)) for j in F.index_set() for i in F.special_nodes()]
    [(0, 0, 0), (0, 1, 1), (0, 2, 2), (1, 0, 1), (1, 1, 2), (1, 2, 0), (2, 0, 2), (2, 1, 0), (2, 2, 1)]
    sage: G = FundamentalGroupOfExtendedAffineWeylGroup(['D', 4, 1])
    sage: [(i, j, G.action(i)(j)) for j in G.index_set() for i in G.special_nodes()]
    [(0, 0, 0), (0, 1, 1), (0, 2, 2), (0, 3, 3), (0, 4, 4), (1, 0, 1), (1, 1, 0), (1, 2, 2), (1, 3, 4), (1, 4, 3),
     (2, 0, 2), (2, 1, 0), (2, 3, 2), (2, 4, 3), (3, 0, 3), (3, 1, 4), (3, 2, 2), (3, 3, 0), (3, 4, 1), (4, 0, 4), (4, 1, 3),
     (4, 2, 2), (4, 3, 1), (4, 4, 0)]

    an_element()
        Return an element of self.

        EXAMPLES:

        sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
        sage: FundamentalGroupOfExtendedAffineWeylGroup(['A', 4, 1], prefix="f").an_element()
        f[4]

    cartan_type()
        The Cartan type of self.

        EXAMPLES:

        sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
        sage: FundamentalGroupOfExtendedAffineWeylGroup(['A', 3, 1]).cartan_type()
        ['A', 3, 1]

    dual_node(i)
        Return the node that indexes the inverse of the i-th element.

        EXAMPLES:
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',4,1])
sage: [(i, F.dual_node(i)) for i in F.special_nodes()]
[(0, 0), (1, 4), (2, 3), (3, 2), (4, 1)]
sage: G = FundamentalGroupOfExtendedAffineWeylGroup(['E',6,1])
sage: [(i, G.dual_node(i)) for i in G.special_nodes()]
[(0, 0), (1, 6), (6, 1)]
sage: H = FundamentalGroupOfExtendedAffineWeylGroup(['D',5,1])
sage: [(i, H.dual_node(i)) for i in H.special_nodes()]
[(0, 0), (1, 1), (4, 5), (5, 4)]

\section*{group generators()}

Return a tuple of generators of the fundamental group.

\textbf{WARNING:} This returns the entire group, a necessary behavior because it is used in \texttt{\_\_iter\_\_}().

\section*{index_set()}

The node set of the affine Cartan type of \texttt{self}.

\section*{one()}

Return the identity element of the fundamental group.

\section*{product(x, y)}

Return the product of \(x\) and \(y\).
```
sage: F.special_nodes()
(0, 1, 2, 3)
sage: F(2)*F(3)
pi[1]
sage: F(1)*F(3)^(-1)
pi[2]
```

**reduced_word(i)**

Return a reduced word for the finite Weyl group element associated with the $i$-th special automorphism.

More precisely, for each special node $i$, self.reduced_word($i$) is a reduced word for the element $v$ in the finite Weyl group such that in the extended affine Weyl group, the $i$-th special automorphism is equal to $tv$ where $t$ is a translation element.

**EXAMPLES:**

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1])
sage: [(i, F.reduced_word(i)) for i in F.special_nodes()]
[(0, ()), (1, (1, 2, 3)), (2, (2, 1, 3, 2)), (3, (3, 2, 1))]
```

**special_nodes()**

Return the special nodes of self.

See sage.combinat.root_system.cartan_type.special_nodes().

**EXAMPLES:**

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['D',4,1]).special_nodes()
(0, 1, 3, 4)
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1]).special_nodes()
(0, 1, 2)
sage: FundamentalGroupOfExtendedAffineWeylGroup(['C',3,1]).special_nodes()
(0, 3)
sage: FundamentalGroupOfExtendedAffineWeylGroup(['D',4,2]).special_nodes()
(0, 3)
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).
special_nodes()
Integer Ring
```

### 5.1.262 Root system data for folded Cartan types

**AUTHORS:**

- Travis Scrimshaw (2013-01-12) - Initial version

**class** `sage.combinat.root_system.type_folded.CartanTypeFolded(cartan_type, folding_of, orbit)`

Bases: `sage.structure.unique_representation.UniqueRepresentation, sage.structure.sage_object.SageObject`

A Cartan type realized from a (Dynkin) diagram folding.
Given a Cartan type $X$, we say $\hat{X}$ is a folded Cartan type of $X$ if there exists a diagram folding of the Dynkin diagram of $X$ onto $X$.

A folding of a simply-laced Dynkin diagram $D$ with index set $I$ is an automorphism $\sigma$ of $D$ where all nodes any orbit of $\sigma$ are not connected. The resulting Dynkin diagram $\hat{D}$ is induced by $I/\sigma$ where we identify edges in $D$ which are not incident and add a $k$-edge if we identify $k$ incident edges and the arrow is pointing towards the incident note. We denote the index set of $\hat{D}$ by $I$, and by abuse of notation, we denote the folding by $\sigma$.

We also have scaling factors $\gamma_i$ for $i \in \hat{I}$ and defined as the unique numbers such that the map $\Lambda_j \mapsto \gamma_j \sum_{i \in \sigma^{-1}(j)} \Lambda_i$ is the smallest proper embedding of the weight lattice of $X$ to $\hat{X}$.

If the Cartan type is simply laced, the default folding is the one induced from the identity map on $D$.

If $X$ is affine type, the default embeddings we consider here are:

- $C_n^{(1)} \twoheadrightarrow A_{2n-1}^{(2)}$
- $A_{2n-1}^{(2)} \twoheadrightarrow B_n^{(1)}$
- $E_6^{(2)} \twoheadrightarrow E_6^{(3)}$
- $F_4 \twoheadrightarrow D_4^{(1)}$

and were chosen based on virtual crystals. In particular, the diagram foldings extend to crystal morphisms and gives a realization of Kirillov-Reshetikhin crystals for non-simply-laced types as simply-laced types. See [OSShimo03] and [FOS2009] for more details. Here we can compute $\gamma_i = \max(c_i/c_4)$ where $(c_i)_i$ are the translation factors of the root system. In a more type-dependent way, we can define $\gamma_i$ as follows:

1. There exists a unique arrow (multiple bond) in $X$.
   a. Suppose the arrow points towards 0. Then $\gamma_i = 1$ for all $i \in I$.
   b. Otherwise $\gamma_i$ is the order of $\sigma$ for all $i$ in the connected component of 0 after removing the arrow, else $\gamma_i = 1$.

2. There is not a unique arrow. Thus $\hat{X} = A_{2n-1}^{(1)}$ and $\gamma_i = 1$ for all $1 \leq i \leq n - 1$. If $i \in \{0, n\}$, then $\gamma_i = 2$ if the arrow incident to $i$ points away and is 1 otherwise.

We note that $\gamma_i$ only depends upon $X$.

If the Cartan type is finite, then we consider the classical foldings/embeddings induced by the above affine foldings/embeddings:

- $C_n \hookrightarrow A_{2n-1}$
- $B_n \hookrightarrow D_{n+1}$
- $F_4 \hookrightarrow E_6$
- $G_2 \hookrightarrow D_4$

For more information on Cartan types, see sage.combinat.root_system.cartan_type.

Other foldings may be constructed by passing in an optional folding_of second argument. See below.

**INPUT:**

- *cartan_type* – the Cartan type $X$ to create the folded type
- *folding_of* – the Cartan type $\hat{X}$ which $X$ is a folding of
- *orbit* – the orbit of the Dynkin diagram automorphism $\sigma$ given as a list of lists where the $a$-th list corresponds to the $a$-th entry in $I$ or a dictionary with keys in $I$ and values as lists

**Note:** If $X$ is an affine type, we assume the special node is fixed under $\sigma$.

**EXAMPLES:**
A simply laced Cartan type can be considered as a virtual type of itself:

```
sage: fct = CartanType(['A',4,1]).as_folding(); fct
['A', 4, 1] as a folding of ['A', 4, 1]
sage: fct.scaling_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 1}
sage: fct.folding_orbit()
Finite family {0: (0,), 1: (1,), 2: (2,), 3: (3,), 4: (4,)}
```

Finite types:

```
sage: fct = CartanType(['C',4]).as_folding(); fct
['C', 4] as a folding of ['A', 7]
sage: fct.scaling_factors()
Finite family {1: 1, 2: 1, 3: 2, 4: 2}
sage: fct.folding_orbit()
Finite family {1: (1, 6), 2: (3, 5), 3: (4,), 4: (2,)}
```

REFERENCES:

- Wikipedia article Dynkin_diagram#Folding

```
cartan_type()
Return the Cartan type of self.

EXAMPLES:
```
sage: fct = CartanType(['C', 4, 1]).as_folding()
sage: fct.cartan_type()
['C', 4, 1]
```

```
folding_of()
Return the Cartan type of the virtual space.

EXAMPLES:
```
sage: fct = CartanType(['C', 4, 1]).as_folding()
sage: fct.folding_of()
['A', 7, 1]
```

```
folding_orbit()
Return the orbits under the automorphism \( \sigma \) as a dictionary (of tuples).
```

5.1. Comprehensive Module List
EXAMPLES:

```python
sage: fct = CartanType(['C', 4, 1]).as_folding()
sage: fct.folding_orbit()
Finite family {0: (0,), 1: (1, 7), 2: (2, 6), 3: (3, 5), 4: (4,)}
```

**scaling_factors()**

Return the scaling factors of self.

EXAMPLES:

```python
sage: fct = CartanType(['C', 4, 1]).as_folding()
sage: fct.scaling_factors()
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 2}
sage: fct = CartanType(['BC', 4, 2]).as_folding()
sage: fct.scaling_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 2}
sage: fct = CartanType(['BC', 4, 2]).dual().as_folding()
sage: fct.scaling_factors()
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 1}
sage: CartanType(['BC', 4, 2]).relabel({0:4, 1:3, 2:2, 3:1, 4:0}).as_folding().
˓→scaling_factors()
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 1}
```

### 5.1.263 Root system data for Cartan types with marked nodes

**class** `sage.combinat.root_system.type_marked.AmbientSpace`(*root_system*, *base_ring*, *index_set=None*)

Bases: `sage.combinat.root_system.ambient_space.AmbientSpace`

Ambient space for a marked finite Cartan type.

It is constructed in the canonical way from the ambient space of the original Cartan type.

EXAMPLES:

```python
sage: L = CartanType(['F',4]).marked_nodes([1,3]).root_system().ambient_space(); L
Ambient space of the Root system of type ['F', 4] with nodes (1, 3) marked
sage: TestSuite(L).run()
```

**dimension()**

Return the dimension of this ambient space.

See also:

`sage.combinat.root_system.ambient_space.AmbientSpace.dimension()`

EXAMPLES:

```python
sage: L = CartanType(['F',4]).marked_nodes([1,3]).root_system().ambient_space()
sage: L.dimension()  
4
```

**fundamental_weight(i)**

Return the i-th fundamental weight.

It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.
EXAMPLES:

```python
sage: L = CartanType(['F',4]).marked_nodes([1,3]).root_system().ambient_space()
sage: L.fundamental_weight(1)
(1, 1, 0, 0)
sage: L.fundamental_weights()
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0),
            3: (3/2, 1/2, 1/2, 1/2), 4: (1, 0, 0, 0)}
```

**simple_root(i)**

Return the i-th simple root.

It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.

EXAMPLES:

```python
sage: L = CartanType(['F',4]).marked_nodes([1,3]).root_system().ambient_space()
sage: L.simple_root(1)
(0, 1, -1, 0)
sage: L.simple_roots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1),
            3: (0, 0, 0, 1), 4: (1/2, -1/2, -1/2, -1/2)}
sage: L.simple_coroots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1),
            3: (0, 0, 0, 2), 4: (1, -1, -1, -1)}
```

class `sage.combinat.root_system.type_marked.CartanType(ct, marked_nodes)`

Bases: `sage.combinat.root_system.cartan_type.CartanType_decorator`  
A class for Cartan types with marked nodes.

INPUT:

- ct – a Cartan type
- marked_nodes – a list of marked nodes

EXAMPLES:

We take the Cartan type $B_4$:

```python
sage: T = CartanType(['B',4])
sage: T.dynkin_diagram()
O---O---O=>=O
  1  2  3  4
'B4'
```

And mark some of its nodes:

```python
sage: T = T.marked_nodes([2,3])
sage: T.dynkin_diagram()
O---X---X=>=O
  0   1  2  3  4
'B4 with nodes (2, 3) marked'
```

Markings are not additive:
Combinatorics, Release 9.7

```python
sage: T.marked_nodes([1,4]).dynkin_diagram()
X---O---O=>=X
1 2 3 4
B4 with nodes (1, 4) marked
```

And trivial relabelling are honoured nicely:

```python
sage: T = T.marked_nodes([])
sage: T.dynkin_diagram()
O---O---O=>=O
1 2 3 4
B4
```

```python
ascii_art(label=<function CartanType.<lambda> at 0x7fb371addc10>, node=None)
```

Return an ascii art representation of this Cartan type.

**EXAMPLES:**

```python
sage: print(CartanType(["G", 2]).marked_nodes([2]).ascii_art())
3
O=<=X
1 2
sage: print(CartanType(["B", 3, 1]).marked_nodes([0, 3]).ascii_art())
X 0
| |
O---O=>=X
1 2 3
sage: print(CartanType(["F", 4, 1]).marked_nodes([0, 2]).ascii_art())
X---O---X=>=O---O
0 1 2 3 4
dual()
```

Implements `sage.combinat.root_system.cartan_type.CartanType_abstract.dual()`, using that taking the dual and marking nodes are commuting operations.

**EXAMPLES:**

```python
sage: T = CartanType(["BC",3, 2])
sage: T.marked_nodes([1,3]).dual().dynkin_diagram()
O=>=X---O=>=X
0 1 2 3
BC3~* with nodes (1, 3) marked
sage: T.dual().marked_nodes([1,3]).dynkin_diagram()
O=>=X---O=>=X
0 1 2 3
BC3~* with nodes (1, 3) marked
```

```python
dynkin_diagram()
```

Return the Dynkin diagram for this Cartan type.

**EXAMPLES:**

```python
sage: CartanType(["G", 2]).marked_nodes([2]).dynkin_diagram()
3
```

(continues on next page)
marked_nodes(marked_nodes)
Return self with nodes marked_nodes marked.

EXAMPLES:

```python
sage: ct = CartanType(['A',12])
sage: m = ct.marked_nodes([1,4,6,7,8,12]); m
['A', 12] with nodes (1, 4, 6, 7, 8, 12) marked
sage: m.marked_nodes([2])
['A', 12] with node 2 marked
sage: m.marked_nodes([]) is ct
True
```

relabel(relabelling)
Return the relabelling of self.

EXAMPLES:

```python
sage: T = CartanType(['BC',3, 2])
sage: T.marked_nodes([1,3]).relabel(lambda x: x+2).dynkin_diagram()
[O=<=X---O=<=X] 2 3 4 5
BC3~ relabelled by {0: 2, 1: 3, 2: 4, 3: 5} with nodes (3, 5) marked
sage: T.relabel(lambda x: x+2).marked_nodes([3,5]).dynkin_diagram()
[O=<=X---O=<=X] 2 3 4 5
BC3~ relabelled by {0: 2, 1: 3, 2: 4, 3: 5} with nodes (3, 5) marked
```

type()
Return the type of self or None if unknown.

EXAMPLES:

```python
sage: ct = CartanType(['F', 4]).marked_nodes([1,3])
sage: ct.type()
'F'
```

class sage.combinat.root_system.type_marked.CartanType_affine(ct, marked_nodes)
Bases: sage.combinat.root_system.type_marked.CartanType, sage.combinat.root_system.cartan_type.CartanType_affine

basic_untwisted()
Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic untwisted type is $X_n$. In other words, it is the classical Cartan type that is twisted to obtain self.

EXAMPLES:

```python
sage: CartanType(['A', 7, 2]).marked_nodes([1,3]).basic_untwisted()
['A', 7] with nodes (1, 3) marked
```
classical()
Return the classical Cartan type associated with self.

EXAMPLES:

```
sage: T = CartanType(['A',4,1]).marked_nodes([0,2,4])
sage: T.dynkin_diagram()
  O---X---O---X
  0 1 2 3 4
A4 with nodes (0, 2, 4) marked

sage: T0 = T.classical()
sage: T0
['A', 4] with nodes (2, 4) marked
sage: T0.dynkin_diagram()
  O---X---O---X
  0 1 2 3 4
A4 with nodes (2, 4) marked
```

is_untwisted_affine()
Implement CartanType_affine.is_untwisted_affine().
A marked Cartan type is untwisted affine if the original is.

EXAMPLES:

```
sage: CartanType(['B', 3, 1]).marked_nodes([1,3]).is_untwisted_affine()
True
```

special_node()
Return the special node of the Cartan type.

See also:
special_node()
It is the special node of the non-marked Cartan type.

EXAMPLES:

```
sage: CartanType(['B', 3, 1]).marked_nodes([1,3]).special_node()
0
```

class sage.combinat.root_system.type_marked.CartanType_finite(ct, marked_nodes)
Bases: sage.combinat.root_system.type_marked.CartanType, sage.combinat.root_system.cartan_type.CartanType_finite

AmbientSpace
alias of AmbientSpace
affine()
Return the affine Cartan type associated with self.

EXAMPLES:

```
sage: B4 = CartanType(['B',4]).marked_nodes([1,3])
sage: B4.dynkin_diagram()
X---O---X=>=O
1  2  3  4
B4 with nodes (1, 3) marked
sage: B4.affine().dynkin_diagram()
O 0
|    |
X---O---X=>=O
1  2  3  4
B4~ with nodes (1, 3) marked
```

5.1.264 Root system data for reducible Cartan types

class sage.combinat.root_system.type_reducible.AmbientSpace(root_system, base_ring, index_set=None)

Bases: sage.combinat.root_system.ambient_space.AmbientSpace

EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space()
Ambient space of the Root system of type A2xB2
```

ambient_spaces()
Returns a list of the irreducible Cartan types of which the given reducible Cartan type is a product.

EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space().ambient_spaces()
[ Ambient space of the Root system of type ['A', 2],
  Ambient space of the Root system of type ['B', 2]]
```

cartan_type()

EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space().cartan_type()
A2xB2
```

component_types()

EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space().component_types()
[[['A', 2], ['B', 2]]
```

dimension()

EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space().dimension()
5
```
**fundamental_weights()**

EXAMLES:

```python
sage: RootSystem("A2xB2").ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0, 0), 2: (1, 1, 0, 0, 0), 3: (0, 0, 0, 1, 0), 4:
→(0, 0, 0, 1/2, 1/2)}
```

**inject_weights(i, v)**

Produces the corresponding element of the lattice.

INPUT:

- `i` - an integer in range(self.components)
- `v` - a vector in the i-th component weight lattice

EXAMLES:

```python
sage: V = RootSystem("A2xB2").ambient_space()
sage: [V.inject_weights(i,V.ambient_spaces()[i].fundamental_weights()[1]) for i␣
→in range(2)]
[(1, 0, 0, 0, 0), (0, 0, 0, 1, 0)]
sage: [V.inject_weights(i,V.ambient_spaces()[i].fundamental_weights()[2]) for i␣
→in range(2)]
[(1, 1, 0, 0, 0), (0, 0, 0, 1/2, 1/2)]
```

**negative_roots()**

EXAMLES:

```python
sage: RootSystem("A1xA2").ambient_space().negative_roots()
[(-1, 1, 0, 0, 0), (0, 0, -1, 1, 0), (0, 0, -1, 0, 1), (0, 0, 0, -1, 1)]
```

**positive_roots()**

EXAMLES:

```python
sage: RootSystem("A1xA2").ambient_space().positive_roots()
[(1, -1, 0, 0, 0), (0, 0, 1, -1, 0), (0, 0, 1, 0, -1), (0, 0, 0, 1)]
```

**simple_coroot(i)**

EXAMLES:

```python
sage: A = RootSystem("A1xB2").ambient_space()
sage: A.simple_coroot(2)
(0, 0, 1, -1)
sage: A.simple_coroots()
Finite family {1: (1, -1, 0, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 1)}
```

**simple_root(i)**

EXAMLES:

```python
sage: A = RootSystem("A1xB2").ambient_space()
sage: A.simple_root(2)
(0, 0, 1, -1)
sage: A.simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 1)}
```
class sage.combinat.root_system.type_reducible.CartanType(types)
Bases: sage.structure.sage_object.SageObject, sage.combinat.root_system.cartan_type.CartanType_abstract

A class for reducible Cartan types.

Reducible root systems are ones that can be factored as direct products. Strictly speaking type $D_2$ (corresponding
to orthogonal groups of degree 4) is reducible since it is isomorphic to $A_1 \times A_1$. However type $D_2$ is not built
using this class for our purposes.

INPUT:

• types – a list of simple Cartan types

EXAMPLES:

```python
t1, t2 = [CartanType(x) for x in [['A',1], ['B',2]]]
sage: CartanType([t1, t2])
A1xB2
sage: t = CartanType("A2xB2")
```

A reducible Cartan type is finite (resp. crystallographic, simply laced) if all its components are:

```python
t.is_finite()
True
t.is_crystallographic()
True
t.is_simply_laced()
False
```

This is implemented by inserting the appropriate abstract super classes (see _add_abstract_superclass()):

```python
t.__class__.mro()
[<class 'sage.combinat.root_system.type_reducible.CartanType_with_superclass'>, ...
<class 'object'>]
```

The index set of the reducible Cartan type is obtained by relabelling successively the nodes of the Dynkin dia-
grams of the components by 1,2,...:

```python
t = CartanType(['A',4], ['BC',5,2], ['C',3])
t.index_set()
(1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13)
t.dynkin_diagram()
0---0---0---0
1 2 3 4
0=<=0---0---0=<=0
5 6 7 8 9 10
0---0=<=0
11 12 13
A4xB5~xC3
```

5.1. Comprehensive Module List
AmbientSpace
    alias of AmbientSpace

ascii_art(label=<function CartanType.<lambda> at 0x7fb371ae7160>, node=None)
    Return an ascii art representation of this reducible Cartan type.

    EXAMPLES:
    >>> print(CartanType("F4xA2").ascii_art(label = lambda x: x+2))
    O---O=>=O---O
    3 4 5 6
    O---0
    7 8
    >>> print(CartanType(["BC",5,2], ["A",4]).ascii_art())
    O=<=O---O---O---O=<=O
    1 2 3 4 5 6
    O---O---O---O
    7 8 9 10
    >>> print(CartanType(["A",4], ["BC",5,2], ["C",3]).ascii_art())
    O---O---O---O
    1 2 3 4
    O=<=O---O---O---O=<=O
    5 6 7 8 9 10
    O---O=<=O
    11 12 13

cartan_matrix(subdivide=True)
    Return the Cartan matrix associated with self. By default the Cartan matrix is a subdivided block matrix showing the reducibility but the subdivision can be suppressed with the option subdivide = False.

    EXAMPLES:
    >>> ct = CartanType("A2","B2")
    >>> ct.cartan_matrix()
    [ 2 -1  0  0]
    [ -1  2  0  0]
    [-------]
    [ 0  0  2 -1]
    [ 0  0 -2  2]
    >>> ct.cartan_matrix(subdivide=False)
    [ 2 -1  0  0]
    [ -1  2  0  0]
    [ 0  0  2 -1]
    [ 0  0 -2  2]
    >>> ct.index_set() == ct.cartan_matrix().index_set()
    True

component_types()
    A list of Cartan types making up the reducible type.

    EXAMPLES:
    >>> CartanType(["A",2],["B",2]).component_types()
    [["A", 2], ["B", 2]]
**coxeter_diagram()**

Return the Coxeter diagram for self.

**EXAMPLES:**

```python
sage: cd = CartanType("A2xB2xF4").coxeter_diagram()
sage: cd
Graph on 8 vertices
sage: cd.edges(sort=True)
[(1, 2, 3), (3, 4, 4), (5, 6, 3), (6, 7, 4), (7, 8, 3)]
```

```python
sage: CartanType("F4xA2").coxeter_diagram().edges(sort=True)
[(1, 2, 3), (2, 3, 4), (3, 4, 3), (5, 6, 3)]
```

```python
sage: cd = CartanType("A1xH3").coxeter_diagram(); cd
Graph on 4 vertices
sage: cd.edges(sort=True)
[(2, 3, 3), (3, 4, 5)]
```

**dual()**

**EXAMPLES:**

```python
sage: CartanType("A2xB2").dual()
A2xC2
```

**dynkin_diagram()**

Returns a Dynkin diagram for type reducible.

**EXAMPLES:**

```python
sage: dd = CartanType("A2xB2xF4").dynkin_diagram()
sage: dd
O---O
 1 2
O=>=O
 3 4
O---O=>=O---O
 5 6 7 8
A2xB2xF4
sage: dd.edges(sort=True)
[(1, 2, 1), (2, 1, 1), (3, 4, 2), (4, 3, 1), (5, 6, 1), (6, 5, 1), (6, 7, 2), (7, 6, 1), (7, 8, 1), (8, 7, 1)]
```

```python
sage: CartanType("F4xA2").dynkin_diagram()
O---0
 1 2 3 4
O---0
 5 6
F4xA2
```

**index_set()**

Implements `CartanType_abstract.index_set()`.

For the moment, the index set is always of the form \{1, \ldots, n\}.

**EXAMPLES:**
Combinatorics, Release 9.7

```python
sage: CartanType("A2","A1").index_set()
(1, 2, 3)
```

**is_affine()**

Report that this reducible Cartan type is not affine

EXAMPLES:

```python
sage: CartanType(['A',2],['B',2]).is_affine()
False
```

**is_finite()**

EXAMPLES:

```python
sage: ct1 = CartanType(['A',2],['B',2])
sage: ct1.is_finite()
True
sage: ct2 = CartanType(['A',2],['B',2,1])
sage: ct2.is_finite()
False
```

**is_irreducible()**

Report that this Cartan type is not irreducible.

EXAMPLES:

```python
sage: ct = CartanType(['A',2],['B',2])
sage: ct.is_irreducible()
False
```

**rank()**

Returns the rank of self.

EXAMPLES:

```python
sage: CartanType("A2","A1").rank()
3
```

**type()**

Returns “reducible” since the type is reducible.

EXAMPLES:

```python
sage: CartanType(['A',2],['B',2]).type()
'reducible'
```
5.1.265 Root system data for relabelled Cartan types

```python
class sage.combinat.root_system.type_relabel.AmbientSpace(root_system, base_ring, index_set=None):
   _bases: sage.combinat.root_system.ambient_space.AmbientSpace
    Ambient space for a relabelled finite Cartan type.
    It is constructed in the canonical way from the ambient space of the original Cartan type, by relabelling the simple roots, fundamental weights, etc.

    EXAMPLES:
    sage: cycle = {1:2, 2:3, 3:4, 4:1}
    sage: L = CartanType(['F',4]).relabel(cycle).root_system().ambient_space(); L
    Ambient space of the Root system of type ['F', 4] relabelled by {1: 2, 2: 3, 3: 4, 4: 1}
    sage: TestSuite(L).run()

dimension()
    Return the dimension of this ambient space.

    See also:
    sage.combinat.root_system.ambient_space.AmbientSpace.dimension()

    EXAMPLES:
    sage: cycle = {1:2, 2:3, 3:4, 4:1}
    sage: L = CartanType(['F',4]).relabel(cycle).root_system().ambient_space()
    sage: L.dimension()  # optional: sage_free
    4

fundamental_weight(i)
    Return the i-th fundamental weight.

    It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.

    EXAMPLES:
    sage: cycle = {1:2, 2:3, 3:4, 4:1}
    sage: L = CartanType(['F',4]).relabel(cycle).root_system().ambient_space()
    sage: K = CartanType(['F',4]).root_system().ambient_space()
    sage: K.fundamental_weights()
    Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3/2, 1/2, 1/2, 1/2), 4: (1, 0, 0, 0)}
    sage: L.fundamental_weight(1)
    (1, 0, 0, 0)
    sage: L.fundamental_weights()
    Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (2, 1, 1, 0), 4: (3/2, 1/2, 1/2, 1/2)}

simple_root(i)
    Return the i-th simple root.

    It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.
EXAMPLES:

```python
sage: cycle = {1: 2, 2: 3, 3: 4, 4: 1}
sage: L = CartanType(['F', 4]).relabel(cycle).root_system().ambient_space()
sage: K = CartanType(['F', 4]).root_system().ambient_space()
sage: K.simple_roots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 1),
                      4: (1/2, -1/2, -1/2, -1/2)}
sage: K.simple_coroots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2),
                        4: (1, -1, -1, -1)}
sage: L.simple_root(1)
(1/2, -1/2, -1/2, -1/2)
sage: L.simple_roots()
Finite family {1: (1/2, -1/2, -1/2, -1/2), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1),
                       4: (0, 0, 0, 1)}
sage: L.simple_coroots()
Finite family {1: (1, -1, -1, -1), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1),
                        4: (0, 0, 0, 2)}
```

class sage.combinat.root_system.type_relabel.CartanType(type, relabelling)

Bases: sage.combinat.root_system.cartan_type.CartanType_decorator

A class for relabelled Cartan types.

ascii_art(label=<function CartanType.<lambda> at 0x7fb371ae7f70>, node=None)

Return an ascii art representation of this Cartan type.

EXAMPLES:

```python
sage: print(CartanType(['G', 2]).relabel({1:2,2:1}).ascii_art())
  3
 O<=<O
 2 1
sage: print(CartanType(['B', 3, 1]).relabel([1,3,2,0]).ascii_art())
  0
 |           |
O---O=>=O---O
 0 3 2 1
sage: print(CartanType(['F', 4, 1]).relabel(lambda n: 4-n).ascii_art())
          0--0--0=>=0--0--0
          3 2 1
```

coxeter_diagram()

Return the Coxeter diagram for self.

EXAMPLES:

```python
sage: ct = CartanType(['H', 3]).relabel({1:2,2:1,3:3}).
sage: G = ct.coxeter_diagram(); G
Graph on 3 vertices
sage: G.edges(sort=True)
[(1, 2, 5), (2, 3, 3)]
```
**dual()**

Implements `sage.combinat.root_system.cartan_type.CartanType_abstract.dual()`, using that taking the dual and relabelling are commuting operations.

**EXAMPLES:**

```python
sage: T = CartanType(['BC',3,2])
sage: cycle = {1:2, 2:3, 3:0, 0:1}
sage: T.relabel(cycle).dual().dynkin_diagram()
O=>=O---O=>=O
1 2 3 0
BC3~* relabelled by {0: 1, 1: 2, 2: 3, 3: 0}
sage: T.dual().relabel(cycle).dynkin_diagram()
O=>=O---O=>=O
1 2 3 0
BC3~* relabelled by {0: 1, 1: 2, 2: 3, 3: 0}
```

**dynkin_diagram()**

Returns the Dynkin diagram for this Cartan type.

**EXAMPLES:**

```python
sage: CartanType(['G', 2]).relabel({1:2,2:1}).dynkin_diagram()
3
O=<=O
2 1
G2 relabelled by {1: 2, 2: 1}
```

**index_set()**

**EXAMPLES:**

```python
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.index_set()
(1, 2)
```

**type()**

Return the type of self or None if unknown.

**EXAMPLES:**

```python
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.type()
'G'
```

---

**class** `sage.combinat.root_system.type_relabel.CartanType_affine(type, relabelling)`

**Bases:** `sage.combinat.root_system.type_relabel.CartanType`, `sage.combinat.root_system.cartan_type.CartanType_affine`

**basic_untwisted()**

Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic untwisted type is $X_n$. In other words, it is the classical Cartan type that is twisted to obtain self.

**EXAMPLES:**
sage: ct = CartanType(['A', 5, 2]).relabel({0:1, 1:0, 2:2, 3:3})
sage: ct.basic_untwisted()
['A', 5]

classical()
Return the classical Cartan type associated with self.

EXAMPLES:

sage: A41 = CartanType(['A',4,1])
sage: A41.dynkin_diagram()
O-----------+
| | |                      
| | |                      
O---O---O---O
1 2 3 4
A4~
sage: T = A41.relabel({0:1, 1:2, 2:3, 3:4, 4:0})
sage: T
['A', 4, 1] relabelled by {0: 1, 1: 2, 2: 3, 3: 4, 4: 0}
sage: T.dynkin_diagram()
1
O-----------+
| | |                      
| | |                      
O---O---O---O
2 3 4 0
A4~ relabelled by {0: 1, 1: 2, 2: 3, 3: 4, 4: 0}
sage: T0 = T.classical()
sage: T0
['A', 4] relabelled by {1: 2, 2: 3, 3: 4, 4: 0}
sage: T0.dynkin_diagram()
0---0---0---0
2 3 4 0
A4 relabelled by {1: 2, 2: 3, 3: 4, 4: 0}

is_untwisted_affine()
Implement CartanType_affine.is_untwisted_affine()
A relabelled Cartan type is untwisted affine if the original is.

EXAMPLES:

sage: CartanType(['B', 3, 1]).relabel({1:2, 2:3, 3:0, 0:1}).is_untwisted_affine()
True

special_node()
Returns a special node of the Dynkin diagram

See also:
special_node()
It is obtained by relabelling of the special node of the non relabelled Dynkin diagram.

**EXAMPLES:**

```python
sage: CartanType(['B', 3, 1]).special_node()
0
sage: CartanType(['B', 3, 1]).relabel({1: 2, 2: 3, 3: 0, 0: 1}).special_node()
1
```

```python
class sage.combinat.root_system.type_relabel.CartanType_finite(type, relabelling)

Bases: sage.combinat.root_system.type_relabel.CartanType, sage.combinat.root_system.cartan_type.CartanType_finite

AmbientSpace

alias of AmbientSpace

affine()

Return the affine Cartan type associated with self.

**EXAMPLES:**

```python
sage: B4 = CartanType(['B', 4])
sage: B4.dynkin_diagram()
O---O---O=>=O
1 2 3 4
B4
sage: B4.affine().dynkin_diagram()
O 0
| |
O---O---O=>=O
1 2 3 4
B4~
```

If possible, this reuses the original label for the special node:

```python
sage: T = B4.relabel({1: 2, 2: 3, 3: 4, 4: 1}); T.dynkin_diagram()
O---O---O=>=O
2 3 4 1
B4 relabelled by {1: 2, 2: 3, 3: 4, 4: 1}
sage: T.affine().dynkin_diagram()
O 0
| |
O---O---O=>=O
2 3 4 1
B4~ relabelled by {0: 0, 1: 2, 2: 3, 3: 4, 4: 1}
```

Otherwise, it chooses a label for the special_node in 0, 1, ...:

```python
sage: T = B4.relabel({1: 0, 2: 1, 3: 2, 4: 3}); T.dynkin_diagram()
O---O---O=>=O
0 1 2 3
B4 relabelled by {1: 0, 2: 1, 3: 2, 4: 3}
sage: T.affine().dynkin_diagram()
0 4
```
(continues on next page)
This failed before trac ticket #13724:

```python
sage: ct = CartanType(['G', 2]).dual(); ct
['G', 2] relabelled by {1: 2, 2: 1}
sage: ct.affine()
['G', 2, 1] relabelled by {0: 0, 1: 2, 2: 1}
sage: ct = CartanType(['F', 4]).dual(); ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: ct.affine()
['F', 4, 1] relabelled by {0: 0, 1: 4, 2: 3, 3: 2, 4: 1}
```

Check that we don’t inadvertently change the internal relabelling of `ct`:

```python
sage: ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

## 5.1.266 Weight lattice realizations

```python
class sage.combinat.root_system.weight_lattice_realizations.WeightLatticeRealizations(base, name=None):
    Bases: sage.categories.category_types.Category_over_base_ring
```

The category of weight lattice realizations over a given base ring

A weight lattice realization $L$ over a base ring $R$ is a free module (or vector space if $R$ is a field) endowed with an embedding of the root lattice of some root system. By restriction, this embedding defines an embedding of the root lattice of this root system, which makes $L$ a root lattice realization.

Typical weight lattice realizations over $\mathbb{Z}$ include the weight lattice, and ambient lattice. Typical weight lattice realizations over $\mathbb{Q}$ include the weight space, and ambient space.

To describe the embedding, a weight lattice realization must implement a method `fundamental_weight` returning for each $i$ in the index set the image of the fundamental weight $\Lambda_i$ under the embedding.

In order to be a proper root lattice realization, a weight lattice realization should also implement the scalar product with the coroot lattice; on the other hand, the embedding of the simple roots is given for free.

See also:

- `RootSystem`
- `RootLatticeRealizations`
- `WeightSpace`
- `AmbientSpace`

EXAMPLES:
Here, we consider the root system of type $A_7$, and embed the weight lattice element $x = \Lambda_1 + 2\Lambda_3$ in several root lattice realizations:

```sage
sage: R = RootSystem(['A',7])
sage: Lambda = R.weight_lattice().fundamental_weights()

sage: L = R.weight_space()
sage: L(x)

sage: L = R.ambient_lattice()
sage: L(x)
(3, 3, 2, 2, 2, 0, 0, 0)

We embed the weight space element $x = \Lambda_1 + 1/2\Lambda_3$ in the ambient space:

```sage
sage: Lambda = R.weight_space().fundamental_weights()

sage: L = R.ambient_space()
sage: L(x)
(3/2, 3/2, 1/2, 1/2, 1/2, 0, 0, 0)

Of course, one can’t embed the weight space in the ambient lattice:

```sage
sage: L = R.ambient_lattice()
sage: L(x)
Traceback (most recent call last):
...  TypeError: do not know how to make x (= Lambda[2] + 1/2*Lambda[5]) an element of self (=Ambient lattice of the Root system of type ['A', 7])
```

If $K_1$ is a subring of $K_2$, then one could in theory have an embedding from the weight space over $K_1$ to any weight lattice realization over $K_2$; this is not implemented:

```sage
sage: K1 = QQ
sage: K2 = QQ['q']
sage: L = R.ambient_space(K2)

sage: Lambda = R.weight_space(K2).fundamental_weights()
sage: L(Lambda[1])
(1, 0, 0, 0, 0, 0, 0, 0)

sage: Lambda = R.weight_space(K1).fundamental_weights()
sage: L(Lambda[1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= Lambda[1]) an element of self (=Ambient space of the Root system of type ['A', 7])
```

```python
class ElementMethods
    Bases: object
```
**symmetric_form(la)**

Return the symmetric form of self with la.

Return the pairing (|) on the weight lattice. See Chapter 6 in Kac, Infinite Dimensional Lie Algebras for more details.

**Warning:** For affine root systems, if you are not working in the extended weight lattice/space, this may return incorrect results.

**EXAMPLES:**

```python
sage: P = RootSystem(['C',2]).weight_lattice()
sage: al = P.simple_roots()
sage: al[1].symmetric_form(al[1])
2
sage: al[1].symmetric_form(al[2])
-2
sage: al[2].symmetric_form(al[1])
-2
sage: Q = RootSystem(['C',2]).root_lattice()
sage: alQ = Q.simple_roots()
sage: all(al[i].symmetric_form(al[j]) == alQ[i].symmetric_form(alQ[j])
....:     for i in P.index_set() for j in P.index_set())
True
```

```python
sage: P = RootSystem(['C',2,1]).weight_lattice(extended=True)
sage: al = P.simple_roots()
sage: al[1].symmetric_form(al[1])
2
sage: al[1].symmetric_form(al[2])
-2
sage: al[1].symmetric_form(al[0])
-2
sage: al[0].symmetric_form(al[1])
-2
sage: Q = RootSystem(['C',2,1]).root_lattice()
sage: alQ = Q.simple_roots()
sage: all(al[i].symmetric_form(al[j]) == alQ[i].symmetric_form(alQ[j])
....:     for i in P.index_set() for j in P.index_set())
True
```
The result of \((\Lambda_0 | \alpha_0)\) should be 1, however we get 0 because we are not working in the extended weight lattice:

```
sage: La = P.basis()
sage: [La[0].symmetric_form(al) for al in P.simple_roots()]
[0, 0, 0]
```

**to_weight_space**(*base_ring*=*None*)

Map self to the weight space.

**Warning:** Implemented for finite Cartan type.

**EXAMPLES:**

```
sage: b = CartanType(['B',2]).root_system().ambient_space().from_˓→vector(vector([1,-2])); b
(1, -2)
sage: b.to_weight_space()
sage: b = CartanType(['B',2]).root_system().ambient_space().from_˓→vector(vector([1/2,0])); b
(1/2, 0)
sage: b.to_weight_space()
1/2*Lambda[1]  
sage: b.to_weight_space(ZZ)
Traceback (most recent call last):
...  
TypeError: no conversion of this rational to integer
```

**class ParentMethods**

Bases: object

**dynkin_diagram_automorphism_of_alcove_morphism**(\(f\))

Return the Dynkin diagram automorphism induced by an alcove morphism

**INPUT:**

- \(f\) - a linear map from self to self which preserves alcoves

This method returns the Dynkin diagram automorphism for the decomposition \(f = dw\) (see \(\text{reduced_word_of_alcove_morphism()}\)), as a dictionary mapping elements of the index set to itself.

**EXAMPLES:**

```
sage: R = RootSystem(['A',2,1]).weight_lattice()
sage: alpha = R.simple_roots()
sage: Lambda = R.fundamental_weights()
```

Translations by elements of the root lattice induce a trivial Dynkin diagram automorphism:
This is no more the case for translations by general elements of the (classical) weight lattice at level 0:

```
sage: omega1 = Lambda[1] - Lambda[0]
sage: omega2 = Lambda[2] - Lambda[0]

sage: R.dynkin_diagram_automorphism_of_alcove_morphism(omega1.translation)
{0: 1, 1: 0, 2: 2, 3: 3, 4: 5, 5: 4}

sage: R.dynkin_diagram_automorphism_of_alcove_morphism(omega2.translation)
{0: 0, 1: 1, 2: 2, 3: 3, 4: 4, 5: 5}
```

Algorithm: computes $w$ of the decomposition, and see how $f \circ w^{-1}$ permutes the simple roots.

**embed_at_level** $(x, level=1)$

Embed the classical weight $x$ in the level $level$ hyperplane

This is achieved by translating the straightforward embedding of $x$ by $c\Lambda_0$ for $c$ some appropriate scalar.

**INPUT:**
- $x$ – an element of the corresponding classical weight/ambient lattice
- $level$ – an integer or element of the base ring (default: 1)

**EXAMPLES:**

```
sage: L = RootSystem(["B",3,1]).weight_space()
sage: L0 = L.classical()
sage: alpha = L0.simple_roots()
sage: omega = L0.fundamental_weights()
sage: L.embed_at_level(omega[1], 1)
Lambda[1]

sage: L.embed_at_level(omega[2], 1)
-Lambda[0] + Lambda[2]

sage: L.embed_at_level(omega[3], 1)
Lambda[3]
```

(continues on next page)
Combinatorics, Release 9.7

```
sage: L.embed_at_level(alpha[1], 1)
```

**fundamental_weight(i)**

Returns the $i^{th}$ fundamental weight

**INPUT:**

- $i$ – an element of the index set

By a slight notational abuse, for an affine type this method should also accept "delta" as input, and return the image of $\delta$ of the extended weight lattice in this realization.

This should be overridden by any subclass, and typically be implemented as a cached method for efficiency.

**EXAMPLES:**

```
sage: L = RootSystem(['A',3]).ambient_lattice()
sage: L.fundamental_weight(1)
(1, 0, 0, 0)
sage: L = RootSystem(['A',3,1]).weight_lattice(extended=True)
sage: L.fundamental_weight(1)
Lambda[1]
sage: L.fundamental_weight("delta")
delta
```

**fundamental_weights()**

Returns the family $(\Lambda_i)_{i \in I}$ of the fundamental weights.

**EXAMPLES:**

```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: f = e.fundamental_weights()
sage: [f[i] for i in [1,2,3]]
[(1, 0, 0, 0), (1, 1, 0, 0), (1, 1, 1, 0)]
```

**is_extended()**

Return whether this is a realization of the extended weight lattice

**See also:**

`sage.combinat.root_system.weight_space.WeightSpace`

**EXAMPLES:**

```
sage: RootSystem(['A',3,1]).weight_lattice().is_extended()
False
sage: RootSystem(['A',3,1]).weight_lattice(extended=True).is_extended()
True
```

This method is irrelevant for finite root systems, since the weight lattice need not be extended to ensure that the root lattice embeds faithfully:

```
sage: RootSystem(['A',3]).weight_lattice().is_extended()
False
```
**reduced_word_of_alcove_morphism(f)**

Return the reduced word of an alcove morphism.

**INPUT:**

- `f` – a linear map from `self` to `self` which preserves alcoves

Let $A$ be the fundamental alcove. This returns a reduced word $i_1, \ldots, i_k$ such that the affine Weyl group element $w = s_{i_1} \circ \cdots \circ s_{i_k}$ maps the alcove $f(A)$ back to $A$. In other words, the alcove walk $i_1, \ldots, i_k$ brings the fundamental alcove to the corresponding translated alcove.

Let us throw in a bit of context to explain the main use case. It is customary to realize the alcove picture in the coroot or coweight lattice $R^\vee$. The extended affine Weyl group is then the group of linear maps on $R^\vee$ which preserve the alcoves. By [Kac “Infinite-dimensional Lie algebra”, Proposition 6.5] the affine Weyl group is the semidirect product of the associated finite Weyl group and the group of translations in the coroot lattice (the extended affine Weyl group uses the coweight lattice instead). In other words, an element of the extended affine Weyl group admits a unique decomposition of the form:

$$f = dw,$$

where $w$ is in the Weyl group, and $d$ is a function which maps the fundamental alcove to itself. As $d$ permutes the walls of the fundamental alcove, it permutes accordingly the corresponding simple roots, which induces an automorphism of the Dynkin diagram.

This method returns a reduced word for $w$, whereas the method `dynkin_diagram_automorphism_of_alcove_morphism()` returns $d$ as a permutation of the nodes of the Dynkin diagram.

Nota bene: recall that the coroot (resp. coweight) lattice is implemented as the root (resp weight) lattice of the dual root system. Hence, this method is implemented for weight lattice realizations, but in practice is most of the time used on the dual side.

**EXAMPLES:**

We start with type $A$ which is simply laced; hence we do not have to worry about the distinction between the weight and coweight lattice:

```sage
sage: R = RootSystem(['A',2,1]).weight_lattice()
sage: alpha = R.simple_roots()
sage: Lambda = R.fundamental_weights()
```

We consider first translations by elements of the root lattice:

```sage
sage: R.reduced_word_of_alcove_morphism(alpha[0].translation) [1, 2, 1, 0]
sage: R.reduced_word_of_alcove_morphism(alpha[1].translation) [0, 2, 0, 1]
sage: R.reduced_word_of_alcove_morphism(alpha[2].translation) [0, 1, 0, 2]
```

We continue with translations by elements of the classical weight lattice, embedded at level 0:

```sage
sage: R.reduced_word_of_alcove_morphism(omega1.translation) [0, 2]
sage: R.reduced_word_of_alcove_morphism(omega2.translation) [0, 1]
```

The following tests ensure that the code agrees with the tables in Kashiwara’s private notes on affine quantum algebras (2008).

**reduced_word_of_translation(t)**

Given an element of the root lattice, this returns a reduced word $i_1, \ldots, i_k$ such that the Weyl group element $s_{i_1} \circ \cdots \circ s_{i_k}$ implements the “translation” where $x$ maps to $x + \text{level}(x) \ast t$. In other words,
the alcove walk \(i_1, \ldots, i_k\) brings the fundamental alcove to the corresponding translated alcove.

**Note:** There are some technical conditions for \(t\) to actually be a translation; those are not tested (TODO: detail).

**EXAMPLES:**

```
sage: R = RootSystem(['A',2,1]).weight_lattice()
sage: alpha = R.simple_roots()
sage: R.reduced_word_of_translation(alpha[1])
[0, 2, 0, 1]
sage: R.reduced_word_of_translation(alpha[2])
[0, 1, 0, 2]
sage: R.reduced_word_of_translation(alpha[0])
[1, 2, 1, 0]
```

```
sage: R = RootSystem(['D',5,1]).weight_lattice()
sage: Lambda = R.fundamental_weights()
sage: omega1 = Lambda[1] - Lambda[0]
sage: R.reduced_word_of_translation(omega1)
[0, 2, 3, 4, 5, 3, 2, 0]
sage: R.reduced_word_of_translation(omega2)
[0, 2, 1, 3, 2, 4, 3, 5, 3, 2, 1, 4, 3, 2]
```

A non simply laced case:

```
sage: R = RootSystem(['C',2,1]).weight_lattice()
sage: Lambda = R.fundamental_weights()
sage: c = R.cartan_type().translation_factors()
sage: c
Finite family {0: 1, 1: 2, 2: 1}
sage: R.reduced_word_of_translation((Lambda[1]-Lambda[0]) * c[1])
[0, 1, 2, 1]
sage: R.reduced_word_of_translation((Lambda[2]-Lambda[0]) * c[2])
[0, 1, 0]
```

See also `_test_reduced_word_of_translation()`.

**Todo:**
- Add a picture in the doc
- Add a method which, given an element of the classical weight lattice, constructs the appropriate value for \(\rho\)

**rho()**

**EXAMPLES:**

```
sage: RootSystem(['A',3]).ambient_lattice().rho()
(3, 2, 1, 0)
```

**rho_classical()**

Return the embedding at level 0 of \(\rho\) of the classical lattice.
EXAMPLES:

```python
sage: RootSystem(['C',4,1]).weight_lattice().rho_classical()
sage: L = RootSystem(['D',4,1]).weight_lattice()
sage: L.rho_classical().scalar(L.null_coroot())
0
```

**Warning:** In affine type BC dual, this does not live in the weight lattice:

```python
c sage: L = CartanType(['BC',2,2]).dual().root_system().weight_space()
sage: L.rho_classical()
sage: L = CartanType(['BC',2,2]).dual().root_system().weight_lattice()
sage: L.rho_classical()
Traceback (most recent call last):
... ValueError: 5 is not divisible by 2
```

**signs_of_alcovewalk**(*walk*)

Let \( \text{walk} = [i_1, \ldots, i_n] \) denote an alcove walk starting from the fundamental alcove \( y_0 \), crossing at step 1 the wall \( i_1 \), and so on.

For each \( k \), set \( w_k = s_{i_1} \circ s_{i_k} \), and denote by \( y_k = w_k(y_0) \) the alcove reached after \( k \) steps. Then, \( y_k \) is obtained recursively from \( y_{k-1} \) by applying the following reflection:

\[
y_k = s_{w_{k-1}^{-1} \alpha_{i_k}} y_{k-1}.
\]

The step is said positive if \( w_{k-1}^{-1} \alpha_{i_k} \) is a negative root (considering \( w_{k-1}^{-1} \) as element of the classical Weyl group and \( \alpha_{i_k} \) as a classical root) and negative otherwise. The algorithm implemented here use the equivalent property:

\[
\langle w_{k-1}^{-1} \rho_0, \alpha_{i_k}^\vee \rangle > 0
\]

Where \( \rho_0 \) is the sum of the classical fundamental weights embedded at level 0 in this space (see \( \text{rho_classical()} \)), and \( \alpha_{i_k}^\vee \) is the simple coroot associated to \( \alpha_{i_k} \).

This function returns a list of the form \([+1, +1, -1, \ldots] \), where the \( k^{th} \) entry denotes whether the \( k^{th} \) step was positive or negative.

See equation 3.4, of Ram: Alcove walks ..., arXiv math/0601343v1

EXAMPLES:

```python
sage: L = RootSystem(['C',2,1]).weight_lattice()
sage: L.signs_of_alcovewalk([1,2,0,1,2,1,2,0,1,2])
[-1, -1, 1, -1, 1, 1, 1, 1, 1, 1]
sage: L = RootSystem(['A',2,1]).weight_lattice()
sage: L.signs_of_alcovewalk([0,1,2,1,2,0,1,2,0,1,2])
[1, 1, 1, 1, -1, 1, -1, 1, -1, 1, -1]
sage: L = RootSystem(['B',2,1]).coweight_lattice()
sage: L.signs_of_alcovewalk([0,1,2,0,1,2])
[1, -1, 1, -1, 1, 1]
```
**Warning:** This method currently does not work in the weight lattice for type BC dual because $\rho_0$ does not live in this lattice (but an integral multiple of it would do the job as well).

`simple_root(i)`

Returns the $i$-th simple root

This default implementation takes the $i$-th simple root in the weight lattice and embeds it in `self`.

**EXAMPLES:**

Since all the weight lattice realizations in Sage currently implement a `simple_root` method, we have to call this one by hand:

```python
sage: from sage.combinat.root_system.weight_lattice_realizations import...
    WeightLatticeRealizations
sage: simple_root = WeightLatticeRealizations(QQ).parent_class.simple_root.f
sage: L = RootSystem("A3").ambient_space()
sage: simple_root(L, 1)
(1, -1, 0, 0)
sage: simple_root(L, 2)
(0, 1, -1, 0)
sage: simple_root(L, 3)
(1, 1, 2, 0)
```

Note that this last root differs from the one implemented in L by a multiple of the vector $(1,1,1,1)$:

```python
sage: L.simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}
```

This is a harmless artefact of the $SL$ versus $GL$ interpretation of type $A$; see the thematic tutorial on Lie Methods and Related Combinatorics in Sage for details.

`weyl_dimension(highest_weight)`

Return the dimension of the highest weight representation of highest weight `highest_weight`.

**EXAMPLES:**

```python
sage: RootSystem(["A",3]).ambient_lattice().weyl_dimension([2,1,0,0])
20
sage: P = RootSystem(["C",2]).weight_lattice()
sage: La = P.basis()
sage: P.weyl_dimension(La[1]+La[2])
16
sage: type(RootSystem(["A",3]).ambient_lattice().weyl_dimension([2,1,0,0]))
<class 'sage.rings.integer.Integer'>
```

`super_categories()`

**EXAMPLES:**

```python
sage: from sage.combinat.root_system.weight_lattice_realizations import...
    WeightLatticeRealizations
sage: WeightLatticeRealizations(QQ).super_categories()
[Category of root lattice realizations over Rational Field]
```
5.1.267 Weight lattices and weight spaces

class sage.combinat.root_system.weight_space.WeightSpace(root_system, base_ring, extended)

Bases: sage.combinat.free_module.CombinatorialFreeModule

INPUT:
- root_system – a root system
- base_ring – a ring \( R \)
- extended – a boolean (default: False)

The weight space (or lattice if \( \text{base}_\text{ring} = \mathbb{Z} \)) of a root system is the formal free module \( \bigoplus_{\alpha \in \Phi} RA_\alpha \) generated by the fundamental weights \( (\Lambda_\alpha)_{\alpha \in \Phi} \) of the root system.

This class is also used for coweight spaces (or lattices).

See also:
- RootSystem()
- RootSystem.weight_lattice() and RootSystem.weight_space()
- WeightLatticeRealizations()

EXAMPLES:

```
sage: Q = RootSystem(['A', 3]).weight_lattice(); Q
Weight lattice of the Root system of type ['A', 3]
sage: Q.simple_roots()
Finite family
{1: 2*Lambda[1] - Lambda[2],
sage: Q = RootSystem(['A', 3, 1]).weight_lattice(); Q
Weight lattice of the Root system of type ['A', 3, 1]
sage: Q.simple_roots()
Finite family
{0: 2*Lambda[0] - Lambda[1] - Lambda[3],
  1: -Lambda[0] + 2*Lambda[1] - Lambda[2],
```

For infinite types, the Cartan matrix is singular, and therefore the embedding of the root lattice is not faithful:

```
sage: sum(Q.simple_roots())
0
```

In particular, the null root is zero:

```
sage: Q.null_root()
0
```

This can be compensated by extending the basis of the weight space and slightly deforming the simple roots to make them linearly independent, without affecting the scalar product with the coroots. This feature is currently only implemented for affine types. In that case, if \( \text{extended} \) is set, then the basis of the weight space is extended by an element \( \delta \):
sage: Q = RootSystem(['A', 3, 1]).weight_lattice(extended = True); Q
Extended weight lattice of the Root system of type ['A', 3, 1]
sage: Q.basis().keys()
{0, 1, 2, 3, 'delta'}

And the simple root $\alpha_0$ associated to the special node is deformed as follows:

sage: Q.simple_roots()
               1: -Lambda[0] + 2*Lambda[1] - Lambda[2],

Now, the null root is nonzero:

sage: Q.null_root()
delta

Warning: By a slight notational abuse, the extra basis element used to extend the fundamental weights is called \delta in the current implementation. However, in the literature, \delta usually denotes instead the null root. Most of the time, those two objects coincide, but not for type $BC$ (aka. $A_{2n}^{(2)}$). Therefore we currently have:

sage: Q = RootSystem(['A',4,2]).weight_lattice(extended=True)
sage: Q.simple_root(0)
2*Lambda[0] - Lambda[1] + delta
sage: Q.null_root()
2*delta

whereas, with the standard notations from the literature, one would expect to get respectively $2\Lambda_0 - \Lambda_1 + 1/2\delta$ and $\delta$.

Other than this notational glitch, the implementation remains correct for type $BC$.

The notations may get improved in a subsequent version, which might require changing the index of the extra basis element. To guarantee backward compatibility in code not included in Sage, it is recommended to use the following idiom to get that index:

sage: F = Q.basis_extension(); F
Finite family {'delta': delta}
sage: index = F.keys()[0]; index
'delta'

Then, for example, the coefficient of an element of the extended weight lattice on that basis element can be recovered with:

sage: Q.null_root()[index]
2

Element
    alias of WeightSpaceElement

basis_extension()
    Return the basis elements used to extend the fundamental weights

EXAMPLES:
This method is irrelevant for finite types:

```python
sage: Q = RootSystem(['A', 3]).weight_lattice()
sage: Q.basis_extension()
Family ()
```

```python
sage: Q = RootSystem(['A', 3, 1]).weight_lattice(extended=True)
sage: Q.basis_extension()
Finite family {'delta': delta}
```

### fundamental_weight(i)

Returns the $i$-th fundamental weight

**INPUT:**

- $i$ – an element of the index set or "delta"

By a slight notational abuse, for an affine type this method also accepts "delta" as input, and returns the image of $\delta$ of the extended weight lattice in this realization.

**See also:**

- `fundamental_weight()`

**EXAMPLES:**

```python
sage: Q = RootSystem(['A', 3]).weight_lattice()
sage: Q.fundamental_weight(1)
Lambda[1]
sage: Q = RootSystem(['A', 3, 1]).weight_lattice(extended=True)
sage: Q.fundamental_weight(1)
Lambda[1]
sage: Q.fundamental_weight('delta')
delta
```

### is_extended()

Return whether this is an extended weight lattice.

**See also:**

- `is_extended()`

**EXAMPLES:**

```python
sage: RootSystem(['A', 3, 1]).weight_lattice().is_extended()
False
sage: RootSystem(['A', 3, 1]).weight_lattice(extended=True).is_extended()
True
```

### simple_root(j)

Returns the $j^{th}$ simple root

**EXAMPLES:**

```python
```
Its coefficients are given by the corresponding column of the Cartan matrix:

```
sage: L.cartan_type().cartan_matrix()[,2]
[ 0]
[-1]
[ 2]
[-1]
```

Here are all simple roots:

```
sage: L.simple_roots()
Finite family {1: 2*Lambda[1] - Lambda[2],
```

For the extended weight lattice of an affine type, the simple root associated to the special node is deformed by adding $\delta$, where $\delta$ is the null root:

```
sage: L = RootSystem(["C",4,1]).weight_lattice(extended=True)
sage: L.simple_root(0)
```

In fact $\delta$ is really $1/a_0$ times the null root (see the discussion in `WeightSpace`) but this only makes a difference in type $BC$:

```
sage: L = RootSystem(CartanType(["BC",4,2])).weight_lattice(extended=True)
sage: L.simple_root(0)
2*Lambda[0] - Lambda[1] + delta
sage: L.null_root()
2*delta
```

See also:

- `simple_root()`
- `CartanType.col_annihilator()`

**to_ambient_space_morphism()**

The morphism from `self` to its associated ambient space.

**EXAMPLES:**

```
sage: CartanType(['A',2]).root_system().weight_lattice().to_ambient_space_morphism()
Generic morphism:
From: Weight lattice of the Root system of type ['A', 2]
To:   Ambient space of the Root system of type ['A', 2]
```
Warning: Implemented only for finite Cartan type.

class sage.combinat.root_system.weight_space.WeightSpaceElement
Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

is_dominant()
Checks whether an element in the weight space lies in the positive cone spanned by the basis elements (fundamental weights).

EXAMPLES:

```sage
W = RootSystem(['A',3]).weight_space()
Lambda = W.basis()
w = Lambda[1]+Lambda[3]
w.is_dominant()
True
t = Lambda[1]-Lambda[2]
t.is_dominant()
False
```

In the extended affine weight lattice, ‘delta’ is orthogonal to the positive coroots, so adding or subtracting it should not effect dominance

```sage
P = RootSystem(['A',2,1]).weight_lattice(extended=True)
Lambda = P.fundamental_weights()
delta = P.null_root()
w = Lambda[1]-delta
w.is_dominant()
True
```

scalar(lambdacheck)
The canonical scalar product between the weight lattice and the coroot lattice.

Todo:
• merge with_apply_multi_module_morphism
• allow for any root space / lattice
• define properly the return type (depends on the base rings of the two spaces)
• make this robust for extended weight lattices (i might be “delta”)

EXAMPLES:

```sage
L = RootSystem(['C',4,1]).weight_lattice()
Lambda = L.fundamental_weights()
alphacheck = L.simple_coroots()
Lambda[1].scalar(alphacheck[1])
1
Lambda[1].scalar(alphacheck[2])
0
```

The fundamental weights and the simple coroots are dual bases:
```python
sage: matrix([ [ Lambda[i].scalar(alphacheck[j])
.....: for i in L.index_set() ]
.....: for j in L.index_set() ])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
```

Note that the scalar product is not yet implemented between the weight space and the coweight space; in any cases, that won’t be the job of this method:

```python
sage: R = RootSystem(['A',3])
sage: alpha = R.weight_space().roots()
sage: alphacheck = R.coweight_space().roots()
sage: alpha[1].scalar(alphacheck[1])
Traceback (most recent call last):
...
˓coroot space
```

### to_ambient()
Maps self to the ambient space.

**EXAMPLES:**

```python
sage: mu = CartanType(['B',2]).root_system().weight_lattice().an_element(); mu
sage: mu.to_ambient()
(3, 1)
```

**Warning:** Only implemented in finite Cartan type. Does not work for coweight lattices because there is no implemented map from the coweight lattice to the ambient space.

### to_weight_space()
Map self to the weight space.

Since `self.parent()` is the weight space, this map just returns self. This overrides the generic method in `WeightSpaceRealizations`.

**EXAMPLES:**

```python
sage: mu = CartanType(['A',2]).root_system().weight_lattice().an_element(); mu
sage: mu.to_weight_space()
```
5.1.268 Weyl Character Rings

class sage.combinat.root_system.weyl_characters.WeightRing(parent, prefix)

    Bases: sage.combinat.free_module.CombinatorialFreeModule

    The weight ring, which is the group algebra over a weight lattice.

    A Weyl character may be regarded as an element of the weight ring. In fact, an element of the weight ring is an
    element of the Weyl character ring if and only if it is invariant under the action of the Weyl group.

    The advantage of the weight ring over the Weyl character ring is that one may conduct calculations in the weight
    ring that involve sums of weights that are not Weyl group invariant.

    EXAMPLES:

    sage: A2 = WeylCharacterRing(['A',2])
    sage: a2 = WeightRing(A2)
    sage: wd = prod(a2(x/2)-a2(-x/2) for x in a2.space().positive_roots()); wd
    a2(-1,1,0) - a2(-1,0,1) - a2(1,-1,0) + a2(1,0,-1) + a2(0,-1,1) - a2(0,1,-1)
    sage: chi = A2([5,3,0]); chi
    A2(5,3,0)
    sage: a2(chi)
    a2(1,2,5) + 2*a2(1,3,4) + 2*a2(1,4,3) + a2(1,5,2) + a2(2,1,5)
    + 2*a2(2,2,4) + 3*a2(2,3,3) + 2*a2(2,4,2) + a2(2,5,1) + 2*a2(3,1,4)
    + 3*a2(3,2,3) + 3*a2(3,3,2) + 2*a2(3,4,1) + a2(3,5,0) + a2(3,0,5)
    + 2*a2(4,1,3) + 2*a2(4,2,2) + 2*a2(4,3,1) + a2(4,4,0) + a2(4,0,4)
    + a2(5,1,2) + a2(5,2,1) + a2(5,3,0) + a2(5,0,3) + a2(0,3,5)
    + a2(0,4,4) + a2(0,5,3)
    sage: a2(chi)*wd
    -a2(-1,3,6) + a2(-1,6,3) + a2(3,-1,6) - a2(3,6,-1) - a2(6,-1,3) + a2(6,3,-1)
    sage: sum((-1)^w.length()*a2([6,3,-1]).weyl_group_action(w) for w in a2.space().weyl_group())
    -a2(-1,3,6) + a2(-1,6,3) + a2(3,-1,6) - a2(3,6,-1) - a2(6,-1,3) + a2(6,3,-1)
    sage: sum((-1)^w.length()*a2([6,3,-1]).weyl_group_action(w) for w in a2.space().weyl_group()) == a2(chi)*wd
    True

class Element

    Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

    A class for weight ring elements.

    cartan_type()

        Return the Cartan type.

    EXAMPLES:

    sage: A2 = WeylCharacterRing("A2")
    sage: a2 = WeightRing(A2)
    sage: a2([0,1,0]).cartan_type()
    ['A', 2]

character()

    Assuming that self is invariant under the Weyl group, this will express it as a linear combination of
    characters. If self is not Weyl group invariant, this method will not terminate.

    EXAMPLES:
sage: A2 = WeylCharacterRing(['A',2])
sage: a2 = WeightRing(A2)
sage: W = a2.space().weyl_group()
sage: mu = a2(2,1,0)
sage: nu = sum(mu.weyl_group_action(w) for w in W) ; nu
a2(1,2,0) + a2(1,0,2) + a2(2,1,0) + a2(2,0,1) + a2(0,1,2) + a2(0,2,1)
sage: nu.character()
-2*A2(1,1,1) + A2(2,1,0)

demazure(\(w, \text{debug=False}\))
Return the result of applying the Demazure operator \(\partial_w\) to \(\text{self}\).

INPUT:
- \(w\) – a Weyl group element, or its reduced word
If \(w = s_i\) is a simple reflection, the operation \(\partial_w\) sends the weight \(\lambda\) to
\[
\lambda - s_i \cdot \lambda + \alpha_i
def \frac{1}{1 + \alpha_i},
\]
where the numerator is divisible by the denominator in the weight ring. This is extended by multiplicativity to all \(w\) in the Weyl group.

EXAMPLES:

sage: B2 = WeylCharacterRing("B2",style="coroots")
sage: b2 = WeightRing(B2)
sage: b2(1,0).demazure([1])
b2(1,0) + b2(-1,2)
sage: b2(1,0).demazure([2])
b2(1,0)
sage: r = b2(1,0).demazure([1,2]); r
b2(1,0) + b2(-1,2)
sage: r.demazure([1])
b2(1,0) + b2(-1,2)
sage: r.demazure([2])
b2(0,0) + b2(1,0) + b2(1,-2) + b2(-1,2)

demazure_lusztig(i, v)
Return the result of applying the Demazure-Lusztig operator \(T_i\) to \(\text{self}\).

INPUT:
- \(i\) – an element of the index set (or a reduced word or Weyl group element)
- \(v\) – an element of the base ring
If \(R\) is the parent WeightRing, the Demazure-Lusztig operator \(T_i\) is the linear map \(R \rightarrow R\) that sends (for a weight \(\lambda\)) \(R(\lambda)\) to
\[
(R(\alpha_i) - 1)^{-1}(R(\lambda) - R(s_i\lambda) - v(R(\lambda) - R(\alpha_i + s_i\lambda)))
\]
where the numerator is divisible by the denominator in \(R\). The Demazure-Lusztig operators give a representation of the Iwahori–Hecke algebra associated to the Weyl group. See
In the examples, we confirm the braid and quadratic relations for type \(B_2\).

EXAMPLES:
```python
sage: P.<v> = PolynomialRing(QQ)
˓→ambient()
sage: def T1(f): return f.demazure_lusztig(1,v)
sage: def T2(f): return f.demazure_lusztig(2,v)
sage: T1(T2(T1(T2(b2(1,-1)))))
(\v^2-\v)*b2(0,-1) + \v^2*b2(-1,1)
sage: [T1(T2(f))==(\v-1)*T1(f)+\v*f for f in [b2(0,0), b2(1,0), b2(2,3)]]
[True, True, True]
sage: [T1(T2(T1(T2(b2(i,j))))) == T2(T1(T2(T1(b2(i,j)))))) for i in [-2..2]→
˓→for j in [-1,1]]
[True, True, True, True, True, True, True, True, True, True]
```

Instead of an index $i$ one may use a reduced word or Weyl group element:

```python
sage: b2(1,0).demazure_lusztig([2,1],v)==T2(T1(b2(1,0)))
True
sage: W = B2.space().weyl_group(prefix="s")
sage: [s1,s2]=W.simple_reflections()
sage: b2(1,0).demazure_lusztig(s2*s1,v)==T2(T1(b2(1,0)))
True
```

**scale** ($k$)

Multiply a weight by $k$.

The operation is extended by linearity to the weight ring.

**INPUT:**

- $k$ – a nonzero integer

**EXAMPLES:**

```python
sage: g2 = WeylCharacterRing("G2",style="coroots").ambient()
sage: g2(2,3).scale(2)
g2(4,6)
```

**shift** ($\mu$)

Add $\mu$ to any weight.

Extended by linearity to the weight ring.

**INPUT:**

- $\mu$ – a weight

**EXAMPLES:**

```python
sage: g2 = WeylCharacterRing("G2",style="coroots").ambient()
sage: [g2(1,2).shift(fw) for fw in g2.fundamental_weights()]
[\text{g2(2,2), g2(1,3)}]
```

**weyl_group_action** ($w$)

Return the action of the Weyl group element $w$ on self.

**EXAMPLES:**

```python
sage: G2 = WeylCharacterRing(["G",2])
sage: g2 = WeightRing(G2)
sage: L = g2.space()
(continues on next page)
```

(continues on next page)
sage: [fw1, fw2] = L.fundamental_weights()
sage: sum(g2(fw2).weyl_group_action(w) for w in L.weyl_group())
2*g2(-2,1,1) + 2*g2(-1,-1,2) + 2*g2(-1,2,-1) + 2*g2(1,-2,1) + 2*g2(1,1,-2) +
... + 2*g2(2,-1,-1)

**cartan_type()**

Return the Cartan type.

**EXAMPLES:**

```
sage: A2 = WeylCharacterRing("A2")
sage: WeightRing(A2).cartan_type()
['A', 2]
```

**fundamental_weights()**

Return the fundamental weights.

**EXAMPLES:**

```
sage: WeightRing(WeylCharacterRing("G2")).fundamental_weights()
Finite family {1: (1, 0, -1), 2: (2, -1, -1)}
```

**one_basis()**

Return the index of 1.

**EXAMPLES:**

```
sage: A3 = WeylCharacterRing("A3")
sage: WeightRing(A3).one_basis()
(0, 0, 0, 0)
sage: WeightRing(A3).one()
a3(0,0,0,0)
```

**parent()**

Return the parent Weyl character ring.

**EXAMPLES:**

```
sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: a2.parent()
The Weyl Character Ring of Type A2 with Integer Ring coefficients
sage: a2.parent() == A2
True
```

**positive_roots()**

Return the positive roots.

**EXAMPLES:**

```
sage: WeightRing(WeylCharacterRing("G2")).positive_roots()
[(0, 1, -1), (1, -2, 1), (1, -1, 0), (1, 0, -1), (1, 1, -2), (2, -1, -1)]
```

**product_on_basis(a, b)**

Return the product of basis elements indexed by a and b.

**EXAMPLES:**

```
```
```python
sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: a2(1,0,0) * a2(0,1,0) # indirect doctest
   a2(1,1,0)
```

**simple_roots()**

Return the simple roots.

**EXAMPLES:**

```python
sage: WeightRing(WeylCharacterRing("G2")).simple_roots()
    Finite family {1: (0, 1, -1), 2: (1, -2, 1)}
```

**some_elements()**

Return some elements of `self`.

**EXAMPLES:**

```python
sage: A3 = WeylCharacterRing("A3")
sage: a3 = WeightRing(A3)
sage: a3.some_elements()
    [a3(1,0,0,0), a3(1,1,0,0), a3(1,1,1,0)]
```

**space()**

Return the weight space realization associated to `self`.

**EXAMPLES:**

```python
sage: E8 = WeylCharacterRing(['E',8])
sage: e8 = WeightRing(E8)
sage: e8.space()
    Ambient space of the Root system of type ['E', 8]
```

**weyl_character_ring()**

Return the parent Weyl Character Ring.

A synonym for `self.parent()`.

**EXAMPLES:**

```python
sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: a2.weyl_character_ring()
    The Weyl Character Ring of Type A2 with Integer Ring coefficients
```

**wt_repr(wt)**

Return a string representing the irreducible character with highest weight vector `wt`.

Uses coroot notation if the associated Weyl character ring is defined with `style="coroots"`.

**EXAMPLES:**

```python
sage: G2 = WeylCharacterRing("G2")
sage: [G2.ambient().wt_repr(x) for x in G2.fundamental_weights()]
    ['g2(1,0,-1)', 'g2(2,-1,-1)']
sage: G2 = WeylCharacterRing("G2", style="coroots")
sage: [G2.ambient().wt_repr(x) for x in G2.fundamental_weights()]
    ['g2(1,0)', 'g2(0,1)']
```

class sage.combinat.root_system.weyl_characters.WeylCharacterRing(ct, base_ring=Integer Ring, prefix=None, style='lattice', k=None, conjugate=False, cyclotomic_order=None)

Bases: sage.combinat.free_module.CombinatorialFreeModule

A class for rings of Weyl characters.

Let $K$ be a compact Lie group, which we assume is semisimple and simply-connected. Its complexified Lie algebra $L$ is the Lie algebra of a complex analytic Lie group $G$. The following three categories are equivalent: finite-dimensional representations of $K$; finite-dimensional representations of $L$; and finite-dimensional analytic representations of $G$. In every case, there is a parametrization of the irreducible representations by their highest weight vectors. For this theory of Weyl, see (for example):

- Adams, Lectures on Lie groups
- Broecker and Tom Dieck, Representations of Compact Lie groups
- Bump, Lie Groups
- Fulton and Harris, Representation Theory
- Goodman and Wallach, Representations and Invariants of the Classical Groups
- Hall, Lie Groups, Lie Algebras and Representations
- Humphreys, Introduction to Lie Algebras and their representations
- Procesi, Lie Groups
- Samelson, Notes on Lie Algebras
- Varadarajan, Lie groups, Lie algebras, and their representations
- Zhelobenko, Compact Lie Groups and their Representations.

Computation that you can do with these include computing their weight multiplicities, products (thus decomposing the tensor product of a representation into irreducibles) and branching rules (restriction to a smaller group).

There is associated with $K$, $L$ or $G$ as above a lattice, the weight lattice, whose elements (called weights) are characters of a Cartan subgroup or subalgebra. There is an action of the Weyl group $W$ on the lattice, and elements of a fixed fundamental domain for $W$, the positive Weyl chamber, are called dominant. There is for each representation a unique highest dominant weight that occurs with nonzero multiplicity with respect to a certain partial order, and it is called the highest weight vector.

EXAMPLES:

```
sage: L = RootSystem("A2").ambient_space()
sage: [fw1, fw2] = L.fundamental_weights()
sage: R = WeylCharacterRing(['A',2], prefix="R")
sage: [R(1), R(fw1), R(fw2)]
[R(0,0,0), R(1,0,0), R(1,1,0)]
```

Here $R(1)$, $R(fw1)$, and $R(fw2)$ are irreducible representations with highest weight vectors $0$, $\Lambda_1$, and $\Lambda_2$ respectively (the first two fundamental weights).

For type $A$ (also $G_2$, $F_4$, $E_6$ and $E_7$) we will take as the weight lattice not the weight lattice of the semisimple group, but for a larger one. For type $A$, this means we are concerned with the representation theory of $K = U(n)$ or $G = GL(n, \mathbb{C})$ rather than $SU(n)$ or $SU(n, \mathbb{C})$. This is useful since the representation theory of $GL(n)$ is ubiquitous, and also since we may then represent the fundamental weights (in `sage.combinat.root_system.root_system`) by vectors with integer entries. If you are only interested in $SL(3)$, say, use `WeylCharacterRing(['A',2])` as above but be aware that $R([a,b,c])$ and $R([a+1,b+1,c+1])$ represent the same character of $SL(3)$ since $R([1,1,1])$ is the determinant.
For more information, see the thematic tutorial *Lie Methods and Related Combinatorics in Sage*, available at: https://doc.sagemath.org/html/en/thematic_tutorials/lie.html

class Element
Bases: `sage.modules.with_basis.indexed_element.IndexedFreeModuleElement`

A class for Weyl characters.

\textbf{adams} \texttt{operation} \((r)\)
Return the \(r\)-th Adams operation of \texttt{self}.

\textbf{INPUT}:
\begin{itemize}
\item \texttt{r} – a positive integer
\end{itemize}

This is a virtual character, whose weights are the weights of \texttt{self}, each multiplied by \(r\).

\textbf{EXAMPLES}:

\begin{verbatim}
sage: A2 = WeylCharacterRing("A2")
sage: A2(1,1,0).adams_operation(3)
A2(2,2,2) - A2(3,2,1) + A2(3,3,0)
\end{verbatim}

\textbf{branch} \((S, rule=\textquoteleft default\textquoteright)\)
Return the restriction of the character to the subalgebra.

If no rule is specified, we will try to specify one.

\textbf{INPUT}:
\begin{itemize}
\item \texttt{S} – a Weyl character ring for a Lie subgroup or subalgebra
\item \texttt{rule} – a branching rule
\end{itemize}

See \texttt{branch} \texttt{weyl} \texttt{character()} \texttt{for} more information about branching rules.

\textbf{EXAMPLES}:

\begin{verbatim}
sage: B3 = WeylCharacterRing(['B',3])
sage: A2 = WeylCharacterRing(['A',2])
sage: [B3(w).branch(A2,rule='levi') for w in B3.fundamental_weights()]
[A2(0,0,0) + A2(1,0,0) + A2(0,0,-1),
 A2(0,0,0) + A2(1,0,0) + A2(1,1,0) + A2(1,0,-1) + A2(0,-1,-1) + A2(0,0,-1),
 A2(-1/2,-1/2,-1/2) + A2(1/2,-1/2,-1/2) + A2(1/2,1/2,-1/2) + A2(1/2,1/2,1/2) + A2(1/2,1/2,1/2)]
\end{verbatim}

\textbf{cartan} \texttt{type}()
Return the Cartan type of \texttt{self}.

\textbf{EXAMPLES}:

\begin{verbatim}
sage: A2 = WeylCharacterRing("A2")
sage: A2([1,0,0]).cartan_type()
['A', 2]
\end{verbatim}

\textbf{degree}()
Return the degree of \texttt{self}.

This is the dimension of the associated module.

\textbf{EXAMPLES}:

\begin{verbatim}
sage: B3 = WeylCharacterRing(['B',3])
sage: [B3(x).degree() for x in B3.fundamental_weights()]
[7, 21, 8]
\end{verbatim}
dual()  
The involution that replaces a representation with its contragredient. (For Fusion rings, this is the  
conjugation map.)  

EXAMPLES:  

```sage
sage: A3 = WeylCharacterRing("A3", style="coroots")
sage: A3(1,0,0)^2
A3(0,1,0) + A3(2,0,0)
sage: (A3(1,0,0)^2).dual()
A3(0,1,0) + A3(0,0,2)
```

exterior_power(k)  
Return the k-th exterior power of self.  

INPUT:  
• k – a nonnegative integer  
The algorithm is based on the identity $ke^k = \sum_{r=1}^{k} (-1)^{k-1} p_k e^{k-r}$ relating the power-sum and elementary symmetric polynomials. Applying this to the eigenvalues of an element of the parent Lie group in the representation self, the $e_k$ become exterior powers and the $p_k$ become Adams operations, giving an efficient recursive implementation.  

EXAMPLES:  

```sage
sage: B3 = WeylCharacterRing("B3",style="coroots")
sage: spin = B3(0,0,1)
sage: spin.exterior_power(6)
B3(1,0,0) + B3(0,1,0)
```

exterior_square()  
Return the exterior square of the character.  

EXAMPLES:  

```sage
sage: A2 = WeylCharacterRing("A2",style="coroots")
sage: A2(1,0).exterior_square()
A2(0,1)
```

frobenius_schur_indicator()  
Return:  
• 1 if the representation is real (orthogonal)  
• -1 if the representation is quaternionic (symplectic)  
• 0 if the representation is complex (not self dual)  
The Frobenius-Schur indicator of a character $\chi$ of a compact group $G$ is the Haar integral over the group of $\chi(g^2)$. Its value is 1, -1 or 0. This method computes it for irreducible characters of compact Lie groups by checking whether the symmetric and exterior square characters contain the trivial character.  

Todo:  Try to compute this directly without actually calculating the full symmetric and exterior squares.  

EXAMPLES:  

```sage
sage: B2 = WeylCharacterRing("B2",style="coroots")
sage: B2(1,0).frobenius_schur_indicator()
1
```
Combinatorics, Release 9.7

sage: B2(0,1).frobenius_schur_indicator()
-1

highest_weight()
This method is only available for basis elements. Returns the parametrizing dominant weight of an
irreducible character.

EXAMPLES:

sage: G2 = WeylCharacterRing("G2", style="coroots")
sage: [x.highest_weight() for x in [G2(1,0),G2(0,1)]]
[(1, 0, -1), (2, -1, -1)]

inner_product(other)
Compute the inner product with another character.
The irreducible characters are an orthonormal basis with respect to the usual inner product of charac-
ters, interpreted as functions on a compact Lie group, by Schur orthogonality.

INPUT:
• other – another character

EXAMPLES:

sage: A2 = WeylCharacterRing("A2")
sage: [f1,f2] = A2.fundamental_weights()
sage: r1 = A2(f1)*A2(f2); r1
A2(1,1,1) + A2(2,1,0)
sage: r2 = A2(f1)^3; r2
A2(1,1,1) + 2*A2(2,1,0) + A2(3,0,0)
sage: r1.inner_product(r2)
3

invariant_degree()
Return the multiplicity of the trivial representation in self.

Multiplicities of other irreducibles may be obtained using multiplicity().

EXAMPLES:

sage: A2 = WeylCharacterRing("A2",style="coroots")
sage: rep = A2(1,0)^2*A2(0,1)^2; rep
2*A2(0,0) + A2(0,3) + 4*A2(1,1) + A2(3,0) + A2(2,2)
sage: rep.invariant_degree()
2

is_irreducible()
Return whether self is an irreducible character.

EXAMPLES:

sage: B3 = WeylCharacterRing(['B',3])
sage: [B3(x).is_irreducible() for x in B3.fundamental_weights()]
[True, True, True]
sage: sum(B3(x) for x in B3.fundamental_weights()).is_irreducible()
False
mul\textit{tiplicity}(\textit{other})

Return the multiplicity of the irreducible \textit{other} in \textit{self}.

\textbf{INPUT:}

\begin{itemize}
\item \textit{other} – an irreducible character
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: B2 = WeylCharacterRing("B2",style="coroots") sage: rep = B2(1,1)^2; rep B2(0,0) + B2(1,0) + 2*B2(0,2) + B2(2,0) + 2*B2(1,2) + B2(0,4) + B2(3,0) + B2(2,2) sage: rep.multiplicity(B2(0,2)) 2
\end{verbatim}

\textit{symmetric\_power}(\textit{k})

Return the \textit{k}-th symmetric power of \textit{self}.

\textbf{INPUT:}

\begin{itemize}
\item \textit{k} – a nonnegative integer
\end{itemize}

The algorithm is based on the identity \(k h_k = \sum_{r=1}^{k} p_k h_{k-r}\) relating the power-sum and complete symmetric polynomials. Applying this to the eigenvalues of an element of the parent Lie group in the representation \textit{self}, the \(h_k\) become symmetric powers and the \(p_k\) become Adams operations, giving an efficient recursive implementation.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: B3 = WeylCharacterRing("B3",style="coroots") sage: spin = B3(0,0,1) sage: spin.symmetric_power(6) B3(0,0,0) + B3(0,0,2) + B3(0,0,4) + B3(0,0,6)
\end{verbatim}

\textit{symmetric\_square}()

Return the symmetric square of the character.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: A2 = WeylCharacterRing("A2",style="coroots") sage: A2(1,0).symmetric_square() A2(2,0)
\end{verbatim}

\textit{weight\_multiplicities}()

Return the dictionary of weight multiplicities for the Weyl character \textit{self}.

The character does not have to be irreducible.

\textbf{EXAMPLES:}

\begin{verbatim}
\end{verbatim}

\textit{adjoint\_representation}()

Return the adjoint representation as an element of the WeylCharacterRing.

\textbf{EXAMPLES:}
sage: G2 = WeylCharacterRing("G2", style="coroots")
sage: G2.adjoint_representation()
G2(0,1)

affine_reflect(wt, k=0)

INPUT:

• wt – a weight
• k – (optional) a positive integer

Returns the reflection of wt in the hyperplane \( \theta \). Optionally shifts by a multiple \( k \).

EXAMPLES:

sage: B22 = FusionRing("B2",2)
sage: fw = B22.fundamental_weights(); fw
Finite family {1: (1, 0), 2: (1/2, 1/2)}
sage: [B22.affine_reflect(x,2) for x in fw]
[(2, 1), (3/2, 3/2)]

ambient()

Return the weight ring of self.

EXAMPLES:

sage: WeylCharacterRing("A2").ambient()
The Weight ring attached to The Weyl Character Ring of Type A2 with Integer...
˓→Ring coefficients

base_ring()

Return the base ring of self.

EXAMPLES:

sage: R = WeylCharacterRing([\'A\',3], base_ring = CC); R.base_ring()
Complex Field with 53 bits of precision

cartan_type()

Return the Cartan type of self.

EXAMPLES:

sage: WeylCharacterRing("A2").cartan_type()
[\'A\', 2]

char_from_weights(mdict)

Construct a Weyl character from an invariant linear combination of weights.

INPUT:

• mdict – a dictionary mapping weights to coefficients, and representing a linear combination of weights which shall be invariant under the action of the Weyl group

OUTPUT: the corresponding Weyl character

EXAMPLES:
sage: A2 = WeylCharacterRing("A2")
sage: v = A2._space([3,1,0]); v
(3, 1, 0)
sage: d = dict([(x,1) for x in v.orbit()]); d
dict{
    (1, 3, 0): 1,
    (1, 0, 3): 1,
    (3, 1, 0): 1,
    (3, 0, 1): 1,
    (0, 1, 3): 1,
    (0, 3, 1): 1}
sage: A2.char_from_weights(d)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)

demazure_character(hwv, word, debug=False)

Compute the Demazure character.

INPUT:

• hwv – a (usually dominant) weight
• word – a Weyl group word

Produces the Demazure character with highest weight hwv and word as an element of the weight ring. Only available if style="coroots". The Demazure operators are also available as methods of WeightRing elements, and as methods of crystals. Given a CrystalOfTableaux with given highest weight vector, the Demazure method on the crystal will give the equivalent of this method, except that the Demazure character of the crystal is given as a sum of monomials instead of an element of the WeightRing.

See WeightRing.Element.demazure() and sage.categories.classical_crystals.ClassicalCrystals.ParentMethods.demazure_character()

EXAMPLES:

sage: A2 = WeylCharacterRing("A2",style="coroots")
sage: h = sum(A2.fundamental_weights()); h
(2, 1, 0)
sage: A2.demazure_character(h,word=[1,2])
a2(0,0) + a2(-2,1) + a2(2,-1) + a2(1,1) + a2(-1,2)
sage: A2.demazure_character((1,1),word=[1,2])
a2(0,0) + a2(-2,1) + a2(2,-1) + a2(1,1) + a2(-1,2)

dot_reduce(a)

Auxiliary function for product_on_basis().

Return a pair [ε, b] where b is a dominant weight and ε is 0, 1 or -1. To describe b, let w be an element of the Weyl group such that w(a + ρ) is dominant. If w(a + ρ) − ρ is dominant, then ε is the sign of w and b is w(a + ρ) − ρ. Otherwise, ε is zero.

INPUT:

• a – a weight

EXAMPLES:

sage: A2 = WeylCharacterRing("A2")
sage: weights = sorted(A2(2,1,0).weight_multiplicities().keys(), key=str); weights
[(0, 1, 2), (0, 2, 1), (1, 0, 2), (1, 1, 1), (1, 2, 0), (2, 0, 1), (2, 1, 0)]
sage: [A2.dot_reduce(x) for x in weights]
[[0, (0, 0, 0)], [-1, (1, 1, 1)], [-1, (1, 1, 1)], [1, (1, 1, 1)], [0, (0, 0, -\infty)], [0, (0, 0, 0)], [1, (2, 1, 0)]]

dynkin_diagram()
Return the Dynkin diagram of self.

EXAMPLES:

sage: WeylCharacterRing("E7").dynkin_diagram()
O 2
|  |
0---O---O---O---O---O---O
1 3 4 5 6 7
E7

extended_dynkin_diagram()
Return the extended Dynkin diagram, which is the Dynkin diagram of the corresponding untwisted affine type.

EXAMPLES:

sage: WeylCharacterRing("E7").extended_dynkin_diagram()
O 2
|  |
0---O---O---O---O---O---O
0 1 3 4 5 6 7
E7~

fundamental_weights()
Return the fundamental weights.

EXAMPLES:

sage: WeylCharacterRing("G2").fundamental_weights()
Finite family {1: (1, 0, -1), 2: (2, -1, -1)}

highest_root()
Return the highest root.

EXAMPLES:

sage: WeylCharacterRing("G2").highest_root()
(2, -1, -1)
inr_repr(hwv)
Return a string representing the irreducible character with highest weight vector hwv.

EXAMPLES:

sage: B3 = WeylCharacterRing("B3")
sage: [B3.irr_repr(v) for v in B3.fundamental_weights()]
['B3(1,0,0)', 'B3(1,1,0)', 'B3(1/2,1/2,1/2)']
sage: B3 = WeylCharacterRing("B3", style="coroots")
sage: [B3.irr_repr(v) for v in B3.fundamental_weights()]
'[B3(1,0,0)', 'B3(0,1,0)', 'B3(0,0,1)']

**level**

Return the level of the weight, defined to be the value of the weight on the coroot associated with the highest root.

**EXAMPLES:**

```python
sage: R = FusionRing("F4", 2); [R.level(x) for x in R.fundamental_weights()]
[2, 3, 2, 1]
sage: [CartanType("F4~").dual().a()[x] for x in [1..4]]
[2, 3, 2, 1]
```

**lift()**

The embedding of self into its weight ring.

**EXAMPLES:**

```python
sage: A2 = WeylCharacterRing("A2")
sage: A2.lift
Generic morphism:
   From: The Weyl Character Ring of Type A2 with Integer Ring coefficients
   To: The Weight ring attached to The Weyl Character Ring of Type A2 with...
   → Integer Ring coefficients

sage: x = -A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
sage: A2.lift(x)
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
```

As a shortcut, you may also do:

```python
sage: x.lift()
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
```

Or even:

```python
sage: a2 = WeightRing(A2)
sage: a2(x)
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
```

**lift_on_basis**

Expand the basis element indexed by the weight irr into the weight ring of self.

**INPUT:**

- **irr** – a dominant weight

This is used to implement **lift()**.

**EXAMPLES:**

```python
sage: A2 = WeylCharacterRing("A2")
sage: v = A2._space([2,1,0]); v
(2, 1, 0)
```
sage: A2.lift_on_basis(\nu)
2*a2(1,1,1) + a2(1,2,0) + a2(2,1,0) + a2(2,0,1) + a2(0,1,2) + a2(0,2,1)

This is consistent with the analogous calculation with symmetric Schur functions:

sage: s = SymmetricFunctions(QQ).s()
sage: s[2,1].expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2

maximal_subgroup(ct)
Return a branching rule or a list of branching rules.

INPUT:

- ct – the Cartan type of a maximal subgroup of self.

In rare cases where there is more than one maximal subgroup (up to outer automorphisms) with the given Cartan type, the function returns a list of branching rules.

EXAMPLES:

sage: WeylCharacterRing("E7").maximal_subgroup("A2")
miscellaneous branching rule E7 => A2

sage: WeylCharacterRing("E7").maximal_subgroup("A1")
[iii branching rule E7 => A1, iv branching rule E7 => A1]

For more information, see the related method maximal_subgroups().

maximal_subgroups()
This method is only available if the Cartan type of self is irreducible and of rank no greater than 8. This method produces a list of the maximal subgroups of self, up to (possibly outer) automorphisms. Each line in the output gives the Cartan type of a maximal subgroup followed by a command that creates the branching rule.

EXAMPLES:

sage: WeylCharacterRing("E6").maximal_subgroups()
D5:branching_rule("E6","D5","levi")
C4:branching_rule("E6","C4","symmetric")
F4:branching_rule("E6","F4","symmetric")
A2:branching_rule("E6","A2","miscellaneous")
G2:branching_rule("E6","G2","miscellaneous")
A2xG2:branching_rule("E6","A2xG2","miscellaneous")
A1xA5:branching_rule("E6","A1xA5","extended")
A2xA2xA2:branching_rule("E6","A2xA2xA2","extended")

Note that there are other embeddings of (for example \(A_2\) into \(E_6\) as nonmaximal subgroups. These embeddings may be constructed by composing branching rules through various subgroups.

Once you know which maximal subgroup you are interested in, to create the branching rule, you may either paste the command to the right of the colon from the above output onto the command line, or alternatively invoke the related method maximal_subgroup():

sage: branching_rule("E6","G2","miscellaneous")
miscellaneous branching rule E6 => G2
sage: WeylCharacterRing("E6").maximal_subgroup("G2")

miscellaneous branching rule E6 => G2

It is believed that the list of maximal subgroups is complete, except that some subgroups may not be invarient under outer automorphisms. It is reasonable to want a list of maximal subgroups that is complete up to conjugation, but to obtain such a list you may have to apply outer automorphisms. The group of outer automorphisms modulo inner automorphisms is isomorphic to the group of symmetries of the Dynkin diagram, and these are available as branching rules. The following example shows that while a branching rule from $D_4$ to $A_1 \times C_2$ is supplied, another different one may be obtained by composing it with the triality automorphism of $D_4$:

sage: [D4,A1xC2]=[WeylCharacterRing(x,style="coroots") for x in ["D4","A1xC2"]]
sage: fw = D4.fundamental_weights()
sage: b = D4.maximal_subgroup("A1xC2")
sage: [D4(fw).branch(A1xC2,rule=b) for fw in D4.fundamental_weights()]
[A1xC2(1,1,0),
 A1xC2(2,0,0) + A1xC2(2,0,1) + A1xC2(0,2,0),
 A1xC2(1,1,0),
 A1xC2(2,0,0) + A1xC2(0,0,1)]
sage: b1 = branching_rule("D4","D4","triality")*b
sage: [D4(fw).branch(A1xC2,rule=b1) for fw in D4.fundamental_weights()]
[A1xC2(1,1,0),
 A1xC2(2,0,0) + A1xC2(2,0,1) + A1xC2(0,2,0),
 A1xC2(2,0,0) + A1xC2(0,0,1),
 A1xC2(1,1,0)]

one_basis()
Return the index of 1 in self.

EXAMPLES:

sage: WeylCharacterRing("A3").one_basis()
(0, 0, 0, 0)
sage: WeylCharacterRing("A3").one()
A3(0,0,0,0)

positive_roots()
Return the positive roots.

EXAMPLES:

sage: WeylCharacterRing("G2").positive_roots()
[(0, 1, -1), (1, -2, 1), (1, -1, 0), (1, 0, -1), (1, 1, -2), (2, -1, -1)]

product_on_basis(a, b)
Compute the tensor product of two irreducible representations $a$ and $b$.

EXAMPLES:

sage: D4 = WeylCharacterRing(['D',4])
sage: spin_plus = D4(1/2,1/2,1/2,1/2)
sage: spin_minus = D4(1/2,1/2,1/2,-1/2)
sage: spin_plus * spin_minus # indirect doctest
D4(1,0,0,0) + D4(1,1,1,0)
sage: spin_minus * spin_plus
D4(1,0,0,0) + D4(1,1,1,0)

Uses the Brauer-Klimyk method.

\texttt{rank()} \\
Return the rank.

\textbf{EXAMPLES:}

sage: WeylCharacterRing("G2").rank()
2

\texttt{retract()} \\
The partial inverse map from the weight ring into \texttt{self}.

\textbf{EXAMPLES:}

sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: A2.retract
Generic morphism:
  From: The Weight ring attached to The Weyl Character Ring of Type A2 with Integer Ring coefficients
  To:   The Weyl Character Ring of Type A2 with Integer Ring coefficients

sage: v = A2._space([3,1,0]); v
(3, 1, 0)
sage: chi = a2.sum_of_monomials(v.orbit()); chi
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
sage: A2.retract(chi)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)

The input should be invariant:

sage: A2.retract(a2.monomial(v))
Traceback (most recent call last):
   ... ValueError: multiplicity dictionary may not be Weyl group invariant

As a shortcut, you may use conversion:

sage: A2(chi)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
sage: A2(a2.monomial(v))
Traceback (most recent call last):
   ... ValueError: multiplicity dictionary may not be Weyl group invariant

\texttt{simple_coroots()} \\
Return the simple coroots.

\textbf{EXAMPLES:}
sage: WeylCharacterRing("G2").simple_coroots()
Finite family {1: (0, 1, -1), 2: (1/3, -2/3, 1/3)}

simple_roots()
Return the simple roots.

EXAMPLES:

sage: WeylCharacterRing("G2").simple_roots()
Finite family {1: (0, 1, -1), 2: (1, -2, 1)}

some_elements()
Return some elements of self.

EXAMPLES:

sage: WeylCharacterRing("A3").some_elements()
[A3(1,0,0,0), A3(1,1,0,0), A3(1,1,1,0)]

space()
Return the weight space associated to self.

EXAMPLES:

sage: WeylCharacterRing(["E",8]).space()
Ambient space of the Root system of type ['E', 8]

sage.combinat.root_system.weyl_characters.irreducible_character_freudenthal(hwv, debug=False)

Return the dictionary of multiplicities for the irreducible character with highest weight λ.

The weight multiplicities are computed by the Freudenthal multiplicity formula. The algorithm is based on recursion relation that is stated, for example, in Humphrey’s book on Lie Algebras. The multiplicities are invariant under the Weyl group, so to compute them it would be sufficient to compute them for the weights in the positive Weyl chamber. However after some testing it was found to be faster to compute every weight using the recursion, since the use of the Weyl group is expensive in its current implementation.

INPUT:

• hwv – a dominant weight in a weight lattice.
• L – the ambient space

EXAMPLES:

sage: WeylCharacterRing("A2")(2,1,0).weight_multiplicities() # indirect doctest
{(1, 1, 1): 2, (1, 2, 0): 1, (1, 0, 2): 1, (2, 1, 0): 1, (2, 0, 1): 1, (0, 1, 2): 1, (0, 2, 1): 1}
5.1.269 Fusion Rings

class sage.combinat.root_system.fusion_ring.FusionRing(ct, base_ring=Integer Ring, prefix=None, style='lattice', k=None, conjugate=False, cyclotomic_order=None)

Bases: sage.combinat.root_system.weyl_characters.WeylCharacterRing

Return the Fusion Ring (Verlinde Algebra) of level k.

INPUT:

• ct – the Cartan type of a simple (finite-dimensional) Lie algebra
• k – a nonnegative integer
• conjugate – (default False) set True to obtain the complex conjugate ring
• cyclotomic_order – (default computed depending on ct and k)

The cyclotomic order is an integer N such that all computations will return elements of the cyclotomic field of N-th roots of unity. Normally you will never need to change this but consider changing it if root_of_unity() ever returns None.

This algebra has a basis (sometimes called primary fields but here called simple objects) indexed by the weights of level ≤ k. These arise as the fusion algebras of Wess-Zumino-Witten (WZW) conformal field theories, or as Grothendieck groups of tilting modules for quantum groups at roots of unity. The FusionRing class is implemented as a variant of the WeylCharacterRing.

REFERENCES:

• [BaKi2001] Chapter 3
• [DFMS1996] Chapter 16
• [EGNO2015] Chapter 8
• [Feingold2004]
• [Fuchs1994]
• [Row2006]
• [Walton1990]
• [Wan2010]

EXAMPLES:

```sage
A22 = FusionRing("A2",2)
sage: [f1, f2] = A22.fundamental_weights()
sage: M = [A22(x) for x in [0*f1, 2*f1, 2*f2, f1+f2, f2, f1]]
sage: [M[3] * x for x in M]
[A22(1,1),
A22(0,1),
A22(1,0),
A22(0,0) + A22(1,1),
A22(0,1) + A22(2,0),
A22(1,0) + A22(0,2)]
```

You may assign your own labels to the basis elements. In the next example, we create the SO(5) fusion ring of level 2, check the weights of the basis elements, then assign new labels to them while injecting them into the global namespace:
A fixed order of the basis keys is available with `get_order()`. This is the order used by methods such as `s_matrix()`. You may use `CombinatorialFreeModule.set_order()` to reorder the basis:

```python
sage: B22.set_order([x.weight() for x in [I0,Y1,Y2,X,Xp,Z]])
sage: [B22(x) for x in B22.get_order()]
[I0, Y1, Y2, X, Xp, Z]
```

To reset the labels, you may run `fusion_labels()` with no parameter:

```python
sage: B22.fusion_labels()
sage: [B22(x) for x in B22.get_order()]
[B22(0,0), B22(1,0), B22(0,1), B22(2,0), B22(1,1), B22(0,2)]
```

To reset the order to the default, simply set it to the list of basis element keys:

```python
sage: B22.set_order(B22.basis().keys().list())
sage: [B22(x) for x in B22.get_order()]
[B22(0,0), B22(1,0), B22(0,1), B22(2,0), B22(1,1), B22(0,2)]
```

The fusion ring has a number of methods that reflect its role as the Grothendieck ring of a modular tensor category (MTC). These include twist methods `Element.twist()` and `Element.ribbon()` for its elements related to the ribbon structure, and the S-matrix `s_ij()`. There are two natural normalizations of the S-matrix. Both are explained in Chapter 3 of [BaKi2001]. The one that is computed by the method `s_matrix()`, or whose individual entries are computed by `s_ij()` is denoted \( \tilde{s} \) in [BaKi2001]. It is not unitary.

The unitary S-matrix is \( s = D^{-1/2} \tilde{s} \) where

\[
D = \sum_V d_i(V)^2.
\]

The sum is over all simple objects \( V \) with \( d_i(V) \) the quantum dimension. We will call quantity \( D \) the global quantum dimension and \( \sqrt{D} \) the total quantum order. They are computed by `global_q_dimension()` and `total_q_order()`. The unitary S-matrix \( s \) may be obtained using `s_matrix()` with the option `unitary=True`.  

5.1. Comprehensive Module List 2635
Let us check the Verlinde formula, which is [DFMS1996] (16.3). This famous identity states that

\[ N^k_{ij} = \sum_l \frac{s(i, \ell) s(j, \ell) s(k, \ell)}{s(I, \ell)}, \]

where \( N^k_{ij} \) are the fusion coefficients, i.e. the structure constants of the fusion ring, and \( I \) is the unit object. The S-matrix has the property that if \( i^* \) denotes the dual object of \( i \), implemented in Sage as \( i.dual() \), then

\[ s(i^*, j) = s(i, j^*) = \overline{s(i, j)}. \]

This is equation (16.5) in [DFMS1996]. Thus with \( N^k_{ij} = N^k_{ij}^* \) the Verlinde formula is equivalent to

\[ N^k_{ij} = \sum_l \frac{s(i, \ell) s(j, \ell) s(k, \ell)}{s(I, \ell)}, \]

In this formula \( s \) is the normalized unitary S-matrix denoted \( s \) in [BaKi2001]. We may define a function that corresponds to the right-hand side, except using \( \tilde{s} \) instead of \( s \):

```python
sage: def V(i, j, k):
    R = i.parent()
    return sum(R.s_ij(i, l) * R.s_ij(j, l) * R.s_ij(k, l) / R.s_ij(R.one(), l)
                for l in R.basis())
```

This does not produce \( \text{self.N}_ijk(i, j, k) \) exactly, because of the missing normalization factor. The following code to check the Verlinde formula takes this into account:

```python
sage: def test_verlinde(R):
    b0 = R.one()
    c = R.global_q_dimension()
    return all(V(i, j, k) == c * R.N_ijk(i, j, k) for i in R.basis()
               for j in R.basis() for k in R.basis())
```

Every fusion ring should pass this test:

```python
sage: test_verlinde(FusionRing("A2", 1))
True
sage: test_verlinde(FusionRing("B4", 2)) # long time (.56s)
True
```

As an exercise, the reader may verify the examples in Section 5.3 of [RoStWa2009]. Here we check the example of the Ising modular tensor category, which is related to the BPZ minimal model \( M(4, 3) \) or to an \( E_8 \) coset model. See [DFMS1996] Sections 7.4.2 and 18.4.1. [RoStWa2009] Example 5.3.4 tells us how to construct it as the conjugate of the \( E_8 \) level 2 FusionRing:

```python
sage: I = FusionRing("E8", 2, conjugate=True)
sage: I.fusion_labels(["i0", "p", "s"], inject_variables=True)
sage: b = I.basis().list(); b
[i0, p, s]
sage: [[x*y for x in b] for y in b]
[[i0, p, s], [p, i0, s], [s, s, s + i0 + p]]
sage: [x.twist() for x in b]
[0, 1, 1/8]
sage: [x.ribbon() for x in b]
[1, -1, zeta128^8]
```

(continues on next page)
The term modular tensor category refers to the fact that associated with the category there is a projective representation of the modular group $SL(2, \mathbb{Z})$. We recall that this group is generated by $S = \begin{pmatrix} -1 & 1 \\ 1 & 0 \end{pmatrix}$, $T = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$ subject to the relations $(ST)^3 = S^2$, $S^2T = TS^2$, and $S^4 = I$. Let $s$ be the normalized $S$-matrix, and $t$ the diagonal matrix whose entries are the twists of the simple objects. Let $s$ the unitary $S$-matrix and $t$ the matrix of twists, and $C$ the conjugation matrix $\text{conj}_\text{matrix}()$. Let

$$D_+ = \sum_i d_i^2 \theta_i, \quad D_- = d_i^2 \theta_i^{-1},$$

where $d_i$ and $\theta_i$ are the quantum dimensions and twists of the simple objects. Let $c$ be the Virasoro central charge, a rational number that is computed in $\text{virasoro}_\text{central}_\text{charge}()$. It is known that

$$\sqrt{D_+/D_-} = e^{i\pi c/4}.$$ 

It is proved in [BaKi2001] Equation (3.1.17) that

$$(st)^3 = e^{i\pi c/4} s^2, \quad s^2 = C, \quad C^2 = 1, \quad Ct = tC.$$

Therefore $S \mapsto s, T \mapsto t$ is a projective representation of $SL(2, \mathbb{Z})$. Let us confirm these identities for the Fibonacci MTC $\text{FusionRing}(\text{"G2"}, 1)$:

```sage
R = FusionRing("G2",1)
sage: S = R.s_matrix(unitary=True)
sage: T = R.twists_matrix()
sage: C = R.conj_matrix()
sage: c = R.virasoro_central_charge(); c
14/5

sage: (S*T)^3 == R.root_of_unity(c/4) * S^2
True
```

(continued on next page)
True

sage: S^2 == C
True

sage: C*T == T*C
True

\textbf{D\_minus()}

Return $\sum d_i^2 \theta_i^{-1}$ where $i$ runs through the simple objects, $d_i$ is the quantum dimension and $\theta_i$ is the twist.

This is denoted $p_-$ in [BaKi2001] Chapter 3.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: E83 = FusionRing("E8",3,conjugate=True)
sage: [Dp,Dm] = [E83.D_plus(), E83.D_minus()]
sage: Dp*Dm == E83.global_q_dimension()
True
sage: c = E83.virasoro_central_charge(); c
-248/11
sage: Dp*Dm == E83.global_q_dimension()
True
\end{verbatim}

\textbf{D\_plus()}

Return $\sum d_i^2 \theta_i$ where $i$ runs through the simple objects, $d_i$ is the quantum dimension and $\theta_i$ is the twist.

This is denoted $p_+$ in [BaKi2001] Chapter 3.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: B31 = FusionRing("B3",1)
sage: Dp = B31.D_plus(); Dp
2*zeta48^13 - 2*zeta48^5
sage: Dm = B31.D_minus(); Dm
-2*zeta48^3
sage: Dp*Dm == B31.global_q_dimension()
True
sage: c = B31.virasoro_central_charge(); c
7/2
sage: Dp/Dm == B31.root_of_unity(c/2)
True
\end{verbatim}

\textbf{class Element}

\textbf{Bases:} \texttt{sage.combinat.root_system.weyl_characters.WeylCharacterRing.Element}

A class for FusionRing elements.

\textbf{is\_simple\_object()}

Determine whether \texttt{self} is a simple object of the fusion ring.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: A22 = FusionRing("A2", 2)
sage: x = A22(1,0); x
A22(1,0)
sage: x.is_simple_object()
True
\end{verbatim}
sage: x^2
A22(0,1) + A22(2,0)
sage: (x^2).is_simple_object()
False

q_dimension()

Return the quantum dimension as an element of the cyclotomic field of the $2\ell$-th roots of unity, where $l = m(k + h\vee)$ with $m = 1, 2, 3$ depending on whether type is simply, doubly or triply laced, $k$ is the level and $h\vee$ is the dual Coxeter number.

EXAMPLES:

sage: B22 = FusionRing("B2",2)
sage: [(b.q_dimension())^2 for b in B22.basis()]
[1, 4, 5, 1, 5, 4]

ribbon()

Return the twist or ribbon element of self.

If $h$ is the rational number modulo 2 produced by self.twist(), this method produces $e^{i\pi h}$.

See also:

An additive version of this is available as twist().

EXAMPLES:

sage: F = FusionRing("A1",3)
sage: [x.twist() for x in F.basis()]
[0, 3/10, 4/5, 3/2]
sage: [x.ribbon() for x in F.basis()]
[1, zeta40^6, zeta40^12 - zeta40^8 + zeta40^4 - 1, -zeta40^10]
sage: [F.root_of_unity(x) for x in [0, 3/10, 4/5, 3/2]]
[1, zeta40^6, zeta40^12 - zeta40^8 + zeta40^4 - 1, -zeta40^10]

twist(reduced=True)

Return a rational number $h$ such that $\theta = e^{i\pi h}$ is the twist of self. The quantity $e^{i\pi h}$ is also available using ribbon().

This method is only available for simple objects. If $\lambda$ is the weight of the object, then $h = \langle \lambda, \lambda + 2\rho \rangle$, where $\rho$ is half the sum of the positive roots. As in [Row2006], this requires normalizing the invariant bilinear form so that $\langle \alpha, \alpha \rangle = 2$ for short roots.

INPUT:

- reduced – (default: True) boolean; if True then return the twist reduced modulo 2

EXAMPLES:

sage: G21 = FusionRing("G2", 1)
sage: [x.twist() for x in G21.basis()]
[0, 4/5]
sage: [G21.root_of_unity(x.twist()) for x in G21.basis()]
[1, zeta60^14 - zeta60^4]
sage: zeta60 = G21.field().gen()
sage: zeta60^((4/5)*(60/2))
zeta60^14 - zeta60^4
(continues on next page)
sage: F42 = FusionRing("F4", 2)
sage: [x.twist() for x in F42.basis()]
[0, 18/11, 2/11, 12/11, 4/11]

sage: E62 = FusionRing("E6", 2)
sage: [x.twist() for x in E62.basis()]
[0, 26/21, 12/7, 8/21, 8/21, 26/21, 2/3, 4/7, 2/3]

weight()
Return the parametrizing dominant weight in the level \( k \) alcove.
This method is only available for basis elements.

```python
sage: A21 = FusionRing("A2",1)
sage: [x.weight() for x in A21.basis().list()]
[(0, 0, 0), (2/3, -1/3, -1/3), (1/3, 1/3, -2/3)]
```

\( N_{ijk}(\text{elt}_i, \text{elt}_j, \text{elt}_k) \)
Return the symmetric fusion coefficient \( N_{ijk} \).

**INPUT:**

* \( \text{elt}_i, \text{elt}_j, \text{elt}_k \) – elements of the fusion basis

This is the same as \( N^{k*}_{ij} \), where \( N_{ij}^k \) are the structure coefficients of the ring (see \( Nk_{ij}() \)), and \( k^* \) denotes the dual element. The coefficient \( N_{ijk} \) is unchanged under permutations of the three basis vectors.

**EXAMPLES:**

```python
sage: G23 = FusionRing("G2", 3)
sage: G23.fusion_labels("g")
sage: b = G23.basis().list(); b
[g0, g1, g2, g3, g4, g5]
sage: [(x,y,z) for x in b for y in b for z in b if G23.N_ijk(x,y,z) > 1]
[(g3, g3, g3), (g3, g3, g4), (g3, g4, g3)]
sage: all(G23.N_ijk(x,y,z)==G23.N_ijk(y,z,x) for x in b for y in b for z in b) True
sage: all(G23.N_ijk(x,y,z)==G23.N_ijk(y,x,z) for x in b for y in b for z in b) True
```

\( Nk_{ij}(\text{elt}_i, \text{elt}_j, \text{elt}_k) \)
Return the fusion coefficient \( N^k_{ij} \).

These are the structure coefficients of the fusion ring, so

\[ i \ast j = \sum_k N^k_{ij}. \]

**EXAMPLES:**

```python
sage: A22 = FusionRing("A2", 2)
sage: b = A22.basis().list()
sage: all(x*y == sum(A22.Nk_ij(x,y,k)*k for k in b) for x in b for y in b) True
```
conj_matrix()
Return the conjugation matrix, which is the permutation matrix for the conjugation (dual) operation on basis elements.

EXAMPLES:

```
sage: FusionRing("A2",1).conj_matrix()
[1 0 0]
[0 0 1]
[0 1 0]
```

field()
Return a cyclotomic field large enough to contain the $2\ell$-th roots of unity, as well as all the S-matrix entries.

EXAMPLES:

```
sage: FusionRing("A2",2).field()
Cyclotomic Field of order 60 and degree 16
sage: FusionRing("B2",2).field()
Cyclotomic Field of order 40 and degree 16
```

fusion_l()
Return the product $\ell = m_g(k + h^\vee)$, where $m_g$ denotes the square of the ratio of the lengths of long to short roots of the underlying Lie algebra, $k$ denotes the level of the FusionRing, and $h^\vee$ denotes the dual Coxeter number of the underlying Lie algebra.

This value is used to define the associated root $2\ell$-th of unity $q = e^{i\pi/\ell}$.

EXAMPLES:

```
sage: B22 = FusionRing("B2",2)
sage: B22.fusion_l()
10
sage: D52 = FusionRing("D5",2)
sage: D52.fusion_l()
10
```

fusion_labels(labels=None, inject_variables=False)
Set the labels of the basis.

INPUT:

- labels – (default: None) a list of strings or string
- inject_variables – (default: False) if True, then inject the variable names into the global namespacing; note that this could override objects already defined

If labels is a list, the length of the list must equal the number of basis elements. These become the names of the basis elements.

If labels is a string, this is treated as a prefix and a list of names is generated.

If labels is None, then this resets the labels to the default.

EXAMPLES:

```
sage: A13 = FusionRing("A1", 3)
sage: A13.fusion_labels("x")
sage: fb = list(A13.basis()); fb
```

(continues on next page)
We give an example where the variables are injected into the global namespace:

```python
sage: A13.fusion_labels("y", inject_variables=True)
sage: y0
y0
sage: y0.parent() is A13
True
```

We reset the labels to the default:

```python
sage: A13.fusion_labels()
```

`fusion_level()`

Return the level \( k \) of `self`. 

Examples:

```python
sage: B22 = FusionRing('B2',2)
sage: B22.fusion_level()
2
```

`get_order()`

Return the weights of the basis vectors in a fixed order.

You may change the order of the basis using `CombinatorialFreeModule.set_order()`.

Examples:

```python
sage: A14 = FusionRing("A1",4)
sage: w = A14.get_order(); w
[(0, 0), (1/2, -1/2), (1, -1), (3/2, -3/2), (2, -2)]
sage: A14.set_order([w[k] for k in [0,4,1,3,2]])
sage: [A14(x) for x in A14.get_order()]
[A14(0), A14(4), A14(1), A14(3), A14(2)]
```

Warning: This duplicates `get_order()` from `CombinatorialFreeModule` except the result is not cached. Caching of `CombinatorialFreeModule.get_order()` causes inconsistent results after calling `CombinatorialFreeModule.set_order()`.

`global_q_dimension()`

Return \( \sum d_i^2 \), where the sum is over all simple objects and \( d_i \) is the quantum dimension. It is a positive real number.
EXAMPLES:

```python
sage: FusionRing("E6",1).global_q_dimension()
3
```

\textbf{r_matrix}(i, j, k)

Return the R-matrix entry corresponding to the subobject \( k \) in the tensor product of \( i \) with \( j \).

\textbf{Warning:} This method only gives complete information when \( N_{ij}^k = 1 \) (an important special case). Tables of MTC including R-matrices may be found in Section 5.3 of [RoStWa2009] and in [Bond2007].

The R-matrix is a homomorphism \( i \otimes j \to j \otimes i \). This may be hard to describe since the object \( i \otimes j \) may be reducible. However if \( k \) is a simple subobject of \( i \otimes j \) it is also a subobject of \( j \otimes i \). If we fix embeddings \( k \to i \otimes j, k \to j \otimes i \) we may ask for the scalar automorphism of \( k \) induced by the R-matrix. This method computes that scalar. It is possible to adjust the set of embeddings \( k \to i \otimes j \) (called a \textit{gauge}) so that this scalar equals

\[
\pm \sqrt{\frac{\theta_k}{\theta_i \theta_j}}.
\]

If \( i \neq j \), the gauge may be used to control the sign of the square root. But if \( i = j \) then we must be careful about the sign. These cases are computed by a formula of [BDGRTW2019], Proposition 2.3.

EXAMPLES:

```python
sage: I = FusionRing("E8", 2, conjugate=True) # Ising MTC
sage: I.fusion_labels(["i0","p","s"], inject_variables=True)

sage: I.r_matrix(s,s,i0) == I.root_of_unity(-1/8)
True
sage: I.r_matrix(p,p,i0)
-1
sage: I.r_matrix(p,s,s) == I.root_of_unity(-1/2)
True
sage: I.r_matrix(s,p,s) == I.root_of_unity(-1/2)
True
sage: I.r_matrix(s,s,p) == I.root_of_unity(3/8)
True
```

\textbf{root_of_unity}(r)

Return \( e^{i \pi r} \) as an element of \texttt{self.field()} if possible.

INPUT:

- \( r \) – a rational number

EXAMPLES:

```python
sage: A11 = FusionRing("A1",1)
sage: A11.field()
Cyclotomic Field of order 24 and degree 8
sage: [A11.root_of_unity(2/x) for x in [1..7]]
[1, -1, zeta24^4 - 1, zeta24^6, None, zeta24^4, None]
```

\textbf{s_ij}(elt_i, elt_j)

Return the element of the S-matrix of this fusion ring corresponding to the given elements.

5.1. Comprehensive Module List 2643
This is computed using the formula

\[ s_{i,j} = \frac{1}{\theta_i \theta_j} \sum_k N_{ik}^j d_k \theta_k, \]

where \( \theta_k \) is the twist and \( d_k \) is the quantum dimension. See [Row2006] Equation (2.2) or [EGNO2015] Proposition 8.13.8.

INPUT:

- \( \text{elt}_i, \text{elt}_j \) – elements of the fusion basis

EXAMPLES:

```python
sage: G21 = FusionRing("G2", 1)
sage: b = G21.basis()
sage: [G21.s_ij(x, y) for x in b for y in b]
[1, -zeta60^14 + zeta60^6 + zeta60^4, -zeta60^14 + zeta60^6 + zeta60^4, -1]
```

**s_matrix**(unitary=False)

Return the S-matrix of this fusion ring.

OPTIONAL:

- \( \text{unitary} \) – (default: False) set to True to obtain the unitary S-matrix

Without the \( \text{unitary} \) parameter, this is the matrix denoted \( \tilde{s} \) in [BaKi2001].

EXAMPLES:

```python
sage: D91 = FusionRing("D9", 1)
sage: D91.s_matrix()
[ 1 1 1 1]
[ 1 1 -1 -1]
[ 1 -1 -zeta136^34 zeta136^34]
[ 1 -1 zeta136^34 -zeta136^34]
sage: S = D91.s_matrix(unitary=True); S
[1/2 1/2 1/2 1/2]
[1/2 1/2 -1/2 -1/2]
[1/2 -1/2 -1/2*zeta136^34 1/2*zeta136^34]
[1/2 -1/2 1/2*zeta136^34 -1/2*zeta136^34]
sage: S*S.conjugate()
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

**some_elements**( )

Return some elements of self.

EXAMPLES:

```python
sage: D41 = FusionRing('D4', 1)
sage: D41.some_elements()
[D41(1,0,0,0), D41(0,0,1,0), D41(0,0,0,1)]
```

**total_q_order**( )

Return the positive square root of \( \text{self.global_q_dimension()} \) as an element of \( \text{self.field()} \).

EXAMPLES:
sage: F = FusionRing("G2",1)
sage: tqo=F.total_q_order(); tqo
zeta60^15 - zeta60^11 - zeta60^9 + 2*zeta60^3 + zeta60
sage: tqo.is_real_positive()
True
sage: tqo^2 == F.global_q_dimension()
True

twists_matrix()

Return a diagonal matrix describing the twist corresponding to each simple object in the FusionRing.

EXAMPLES:

sage: B21=FusionRing("B2",1)
sage: [x.twist() for x in B21.basis().list()]
[0, 1, 5/8]
sage: [B21.root_of_unity(x.twist()) for x in B21.basis().list()]
[1, -1, zeta32^10]
sage: B21.twists_matrix()
[ 1 0 0]
[ 0 -1 0]
[ 0 0 zeta32^10]

virasoro_central_charge()

Return the Virasoro central charge of the WZW conformal field theory associated with the Fusion Ring.

If \( g \) is the corresponding semisimple Lie algebra, this is

\[
\frac{k \dim g}{k + h^\vee}
\]

where \( k \) is the level and \( h^\vee \) is the dual Coxeter number. See [DFMS1996] Equation (15.61).

Let \( d_i \) and \( \theta_i \) be the quantum dimensions and twists of the simple objects. By Proposition 2.3 in [RoStWa2009], there exists a rational number \( c \) such that \( D_+ / \sqrt{D} = e^{i\pi c / 4} \), where \( D_+ = \sum d_i^2 \theta_i \) is computed in \( D_+() \) and \( D = \sum d_i^2 > 0 \) is computed by \( \text{global_q_dimension}() \). Squaring this identity and remembering that \( D_+ D_- = D \) gives

\[
D_+ / D_- = e^{i\pi c / 2}.
\]

EXAMPLES:

sage: R = FusionRing("A1", 2)
sage: c = R.virasoro_central_charge(); c
3/2
sage: Dp = R.D_plus(); Dp
2*zeta32^6
sage: Dm = R.D_minus(); Dm
-2*zeta32^10
sage: Dp / Dm == R.root_of_unity(c/2)
True
5.1.270 Weyl Groups

AUTHORS:
- Daniel Bump (2008): initial version
- Mike Hansen (2008): initial version
- Anne Schilling (2008): initial version
- Nicolas Thiery (2008): initial version
- Volker Braun (2013): LibGAP-based matrix groups

EXAMPLES:
More examples on Weyl Groups should be added here...

The Cayley graph of the Weyl Group of type ['A', 3]:

```sage
sage: w = WeylGroup(['A',3])
sage: d = w.cayley_graph(); d
Digraph on 24 vertices
sage: d.show3d(color_by_label=True, edge_size=0.01, vertex_size=0.03)
```

The Cayley graph of the Weyl Group of type ['D', 4]:

```sage
sage: w = WeylGroup(['D',4])
sage: d = w.cayley_graph(); d
Digraph on 192 vertices
sage: d.show3d(color_by_label=True, edge_size=0.01, vertex_size=0.03) #long time (less...
˓→than one minute)
```

class sage.combinat.root_system.weyl_group.ClassicalWeylSubgroup(domain, prefix)
Bases: sage.combinat.root_system.weyl_group.WeylGroup_gens

A class for Classical Weyl Subgroup of an affine Weyl Group

EXAMPLES:

```sage
sage: G = WeylGroup(['A',3,1]).classical()
sage: G
Parabolic Subgroup of the Weyl Group of type ['A', 3, 1] (as a matrix group acting...
˓→on the root space)
sage: G.category()
Category of finite irreducible weyl groups
sage: G.cardinality()
24
sage: G.index_set()
(1, 2, 3)
sage: TestSuite(G).run()
```

Todo: implement:
- Parabolic subrootsystems
- Parabolic subgroups with a set of nodes as argument
example.combinat.root_system.weyl_group.WeylGroup(x, prefix=None, implementation='matrix')

Returns the Weyl group of the root system defined by the Cartan type (or matrix) ct.

INPUT:

• x - a root system or a Cartan type (or matrix)

OPTIONAL:

• prefix – changes the representation of elements from matrices to products of simple reflections

• implementation – one of the following: * 'matrix' - as matrices acting on a root system * "permutation" - as a permutation group acting on the roots

EXAMPLES:

The following constructions yield the same result, namely a weight lattice and its corresponding Weyl group:

```python
sage: G = WeylGroup(['F',4])
sage: L = G.domain()
```

or alternatively and equivalently:
Either produces a weight lattice, with access to its roots and weights.

The default representation of Weyl group elements is as matrices. If you prefer, you may specify a prefix, in which case the elements are represented as products of simple reflections.

We can also do the same for arbitrary Cartan matrices:
Same Cartan matrix, but with a prefix to display using simple reflections:

```python
sage: W = WeylGroup(cm, prefix='s')
sage: s0, s1, s2 = W.gens()
sage: (s1*s2)**3
sage: (s0*s1)**5
```

class `sage.combinat.root_system.weyl_group.WeylGroupElement`

Bases: `sage.groups.matrix_gps.group_element.MatrixGroupElement_gap`

Class for a Weyl Group elements

`action(v)`

Return the action of self on the vector v.

EXAMPLES:

```python
sage: W = WeylGroup(['A',2])
sage: s = W.simple_reflections()
sage: v = W.domain()([1,0,0])
sage: s[1].action(v)
(0, 1, 0)
```

```python
sage: W = WeylGroup(RootSystem(['A',2]).root_lattice())
sage: s = W.simple_reflections()
sage: alpha = W.domain().simple_roots()
sage: s[1].action(alpha[1])
-alpha[1]
```
```python
sage: W = WeylGroup(['A', 2, 1])
sage: alpha = W.domain().simple_roots()
sage: s = W.simple_reflections()
sage: s[1].action(alpha[1])
-alpha[1]
sage: s[1].action(alpha[0])
alpha[0] + alpha[1]
```
\begin{verbatim}
sage: [w.has_descent(i) for i in W.domain().index_set()]
[True, False, True, False]
sage: [w.has_descent(i, side = "left") for i in W.domain().index_set()]
[True, False, True, False]
sage: W = WeylGroup(['A',3])
sage: W.one().has_descent(0)
True
sage: W.w0.has_descent(0)
False
\end{verbatim}

**has_left_descent(i)**

Test if self has a left descent at position i.

**EXAMPLES:**

\begin{verbatim}
sage: W = WeylGroup(['A',3])
sage: s = W.simple_reflections()
sage: [W.one().has_left_descent(i) for i in W.domain().index_set()]
[False, False, False]
sage: [s[1].has_left_descent(i) for i in W.domain().index_set()]
[True, False, False]
sage: [s[2].has_left_descent(i) for i in W.domain().index_set()]
[False, True, False]
sage: [s[3].has_left_descent(i) for i in W.domain().index_set()]
[False, False, True]
sage: [(s[3]*s[2]).has_left_descent(i) for i in W.domain().index_set()]
[False, True, False]
\end{verbatim}

**has_right_descent(i)**

Test if self has a right descent at position i.

**EXAMPLES:**

\begin{verbatim}
sage: W = WeylGroup(['A',3])
sage: s = W.simple_reflections()
sage: [W.one().has_right_descent(i) for i in W.domain().index_set()]
[False, False, False]
sage: [s[1].has_right_descent(i) for i in W.domain().index_set()]
[True, False, False]
sage: [s[2].has_right_descent(i) for i in W.domain().index_set()]
[False, True, False]
sage: [s[3].has_right_descent(i) for i in W.domain().index_set()]
[False, False, True]
sage: [(s[3]*s[2]).has_right_descent(i) for i in W.domain().index_set()]
[False, True, False]
\end{verbatim}

**to_matrix()**

Return self as a matrix.

**EXAMPLES:**

\begin{verbatim}
sage: G = WeylGroup(['A',2])
sage: s1 = G.simple_reflection(1)
\end{verbatim}
 sage: s1.to_matrix() == s1.matrix()
 True

to_permutation()
A first approximation of to_permutation ...
This assumes types A,B,C,D on the ambient lattice
This further assume that the basis is indexed by 0,1,... and returns a permutation of (5,4,2,3,1) (beuargl), as a tuple

to_permutation_string()
EXAMPLES:
 sage: W = WeylGroup(['A',3])
 sage: s = W.simple_reflections()
 sage: (s[1]*s[2]*s[3]).to_permutation_string()
 '2341'

class sage.combinat.root_system.weyl_group.WeylGroup_gens(domain, prefix)
 Bases: sage.structure.unique_representation.UniqueRepresentation, sage.groups.matrix_gps.finitely_generated.FinitelyGeneratedMatrixGroup_gap

EXAMPLES:
 sage: G = WeylGroup(['B',3])
 sage: TestSuite(G).run()
 sage: cm = CartanMatrix([[2,-5,0],[-2,2,-1],[0,-1,2]])
 sage: W = WeylGroup(cm)
 sage: TestSuite(W).run() # long time

Element
alias of WeylGroupElement
cartan_type()
Returns the CartanType associated to self.
EXAMPLES:
 sage: G = WeylGroup(['F',4])
 sage: G.cartan_type()
 ['F', 4]

character_table()
Returns the character table as a matrix
Each row is an irreducible character. For larger tables you may preface this with a command such as
gap.eval("SizeScreen([120,40])") in order to widen the screen.
EXAMPLES:
 sage: WeylGroup(['A',3]).character_table()
 CT1
  2  3  2  2 .  3
 3 1 . . 1 .
<table>
<thead>
<tr>
<th>Index</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1a</td>
<td>4a</td>
</tr>
<tr>
<td>2a</td>
<td>3a</td>
</tr>
<tr>
<td>2b</td>
<td></td>
</tr>
<tr>
<td>X.1</td>
<td>1 -1</td>
</tr>
<tr>
<td>X.2</td>
<td>3 1 -1</td>
</tr>
<tr>
<td>X.3</td>
<td>2 . .  -1</td>
</tr>
<tr>
<td>X.4</td>
<td>3 -1</td>
</tr>
<tr>
<td>X.5</td>
<td>1 1 1</td>
</tr>
</tbody>
</table>

**classical()**

If `self` is a Weyl group from an affine Cartan Type, this give the classical parabolic subgroup of `self`.

Caveat: we assume that 0 is a special node of the Dynkin diagram

TODO: extract parabolic subgroup method

**EXAMPLES:**

```python
sage: G = WeylGroup(['A',3,1])
sage: G.classical()
Parabolic Subgroup of the Weyl Group of type ['A', 3, 1] (as a matrix group acting on the root space)
sage: WeylGroup(['A',3]).classical()
Traceback (most recent call last):
  ...:
ValueError: classical subgroup only defined for affine types
```

**domain()**

Returns the domain of the element of `self`, that is the root lattice realization on which they act.

**EXAMPLES:**

```python
sage: G = WeylGroup(['F',4])
sage: G.domain()
Ambient space of the Root system of type ['F', 4]
sage: G = WeylGroup(['A',3,1])
sage: G.domain()
Root space over the Rational Field of the Root system of type ['A', 3, 1]
```

**from_morphism(f)**

**index_set()**

Returns the index set of `self`.

**EXAMPLES:**

```python
sage: G = WeylGroup(['F',4])
sage: G.index_set()
(1, 2, 3, 4)
sage: G = WeylGroup(['A',3,1])
sage: G.index_set()
(0, 1, 2, 3)
```

**long_element_hardcoded()**

Returns the long Weyl group element (hardcoded data)

Do we really want to keep it? There is a generic implementation which works in all cases. The hardcoded should have a better complexity (for large classical types), but there is a cache, so does this really matter?
EXAMPLES:

```python
sage: [WeylGroup(t).long_element().length() for t in types]
[15, 9, 9, 12, 6, 24, 36]
sage: all( WeylGroup(t).long_element() == WeylGroup(t).long_element_hardcoded() for t in types )  # long time (17s on sage.math, 2011)
True
```

**morphism_matrix**(f)

one()

Returns the unit element of the Weyl group

**EXAMPLES:**

```python
sage: W = WeylGroup(['A',3])
sage: e = W.one(); e
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: type(e) == W.element_class
True
```

**reflections**()

Return the reflections of `self`.

The reflections of a Coxeter group `W` are the conjugates of the simple reflections. They are in bijection with the positive roots, for given a positive root, we may have the reflection in the hyperplane orthogonal to it. This method returns a family indexed by the positive roots taking values in the reflections. This requires `self` to be a finite Weyl group.

**Note:** Prior to trac ticket #20027, the reflections were the keys of the family and the values were the positive roots.

**EXAMPLES:**

```python
sage: W = WeylGroup("B2", prefix="s")
sage: refdict = W.reflections(); refdict
Finite family {(1, -1): s1, (0, 1): s2, (1, 1): s2*s1*s2, (1, 0): s1*s2*s1}
sage: [r+refdict[r].action(r) for r in refdict.keys()]
[(0, 0), (0, 0), (0, 0), (0, 0)]
sage: W = WeylGroup(['A',2,1], prefix="s")
sage: W.reflections()
Lazy family (real root to reflection(i))_{i in Positive real roots of type ['A', 2, 1]}
```

**simple_reflection**(i)

Returns the `i`th simple reflection.

**EXAMPLES:**
sage: G = WeylGroup(['F',4])
 sage: G.simple_reflection(1)
 [1 0 0 0]
 [0 0 1 0]
 [0 1 0 0]
 [0 0 0 1]

sage: W=WeylGroup(['A',2,1])
 sage: W.simple_reflection(1)
 [1 0 0]
 [1 -1 1]
 [0 0 1]

simple_reflections()  
Returns the simple reflections of self, as a family.

EXAMPLES:

There are the simple reflections for the symmetric group:

sage: W=WeylGroup(['A',2])
 sage: s = W.simple_reflections(); s
 Finite family {1: [0 1 0]
 [1 0 0]
 [0 0 1], 2: [1 0 0]
 [0 0 1]
 [0 1 0]}

As a special feature, for finite irreducible root systems, s[0] gives the reflection along the highest root:

sage: s[0]
[0 0 1]
[0 1 0]
[1 0 0]

We now look at some further examples:

sage: W=WeylGroup(['A',2,1])
 sage: W.simple_reflections()
 Finite family {0: [-1 1 1]
 [1 0 0]
 [1 -1 1]
 [0 0 1], 1: [ 1 0 0]
 [0 0 1], 2: [ 1 0 0]
 [0 1 0]
 [0 1 0]}

sage: W = WeylGroup(['F',4])
 sage: [s1,s2,s3,s4] = W.simple_reflections()
 sage: w = s1*s2*s3*s4; w
 [1/2 1/2 1/2 1/2]
 [-1/2 1/2 1/2 -1/2]
 [1/2 1/2 -1/2 -1/2]
 [-1/2 -1/2 1/2 -1/2]

sage: s4^2 == W.one()
True
sage: type(w) == W.element_class
True

unit()
Returns the unit element of the Weyl group

EXAMPLES:

sage: W = WeylGroup(['A',3])
sage: e = W.one(); e
[r| 1 0 0 0 |
[| 0 1 0 0 |
| 0 0 1 0 |
| 0 0 0 1 |
sage: type(e) == W.element_class
True

class sage.combinat.root_system.weyl_group.WeylGroup_permutation(cartan_type, prefix)
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.groups.perm_gps.permgroup.PermutationGroup_generic
A Weyl group given as a permutation group.

class Element
Bases: sage.combinat.root_system.reflection_group_element.RealReflectionGroupElement

cartan_type()
Return the Cartan type of self.

EXAMPLES:

sage: W = WeylGroup(['A',4], implementation="permutation")
sage: W.cartan_type()
['A', 4]

distinguished_reflections()
Return the reflections of self.

EXAMPLES:

sage: W = WeylGroup(['B',2], implementation="permutation")
sage: W.distinguished_reflections()
Finite family {1: (1,5)(2,4)(6,8), 2: (1,3)(2,6)(5,7),
3: (2,8)(3,7)(4,6), 4: (1,7)(3,5)(4,8)}

independent_roots()
Return the simple roots of self.

EXAMPLES:

sage: W = WeylGroup(['A',4], implementation="permutation")
sage: W.simple_roots()
Finite family {1: (1, 0, 0, 0), 2: (0, 1, 0, 0),
3: (0, 0, 1, 0), 4: (0, 0, 0, 1)}
**index_set()**

Return the index set of self.

EXAMPLES:

```
sage: W = WeylGroup(["A",4], implementation="permutation")
sage: W.index_set()
(1, 2, 3, 4)
```

**iteration(algorithm='breadth', tracking_words=True)**

Return an iterator going through all elements in self.

INPUT:

- **algorithm** (default: 'breadth') – must be one of the following:
  - 'breadth' - iterate over in a linear extension of the weak order
  - 'depth' - iterate by a depth-first-search
- **tracking_words** (default: True) – whether or not to keep track of the reduced words and store them in `_reduced_word`

Note: The fastest iteration is the depth first algorithm without tracking words. In particular, 'depth' is ~1.5x faster.

EXAMPLES:

```
sage: W = WeylGroup(["B",2], implementation="permutation")
sage: for w in W.iteration("breadth", True):
    ....:     print("%s %s"%(w, w._reduced_word))
() []
(1,3)(2,6)(5,7) [1]
(1,5)(2,4)(6,8) [0]
(1,7,5,3)(2,4,6,8) [0, 1]
(1,3,5,7)(2,8,6,4) [1, 0]
(2,8)(3,7)(4,6) [1, 0, 1]
(1,7)(3,5)(4,8) [0, 1, 0]
(1,5)(2,6)(3,7)(4,8) [0, 1, 0, 1]
sage: for w in W.iteration("depth", False): w
() (1,3)(2,6)(5,7)
(1,5)(2,4)(6,8)
(1,3,5,7)(2,8,6,4)
(1,7)(3,5)(4,8)
(1,7,5,3)(2,4,6,8)
(2,8)(3,7)(4,6)
(1,5)(2,6)(3,7)(4,8)
```

**number_of_reflections()**

Return the number of reflections in self.

EXAMPLES:
sage: W = WeylGroup(['D',4], implementation="permutation")
sage: W.number_of_reflections()
12

**positive_roots()**

Return the positive roots of self.

EXEMPLARY:

```sage
sage: W = WeylGroup(['C',3], implementation="permutation")
sage: W.positive_roots()
((1, 0, 0),
 (0, 1, 0),
 (0, 0, 1),
(1, 1, 0),
(0, 1, 1),
(0, 2, 1),
(1, 1, 1),
(2, 2, 1),
(1, 2, 1))
```

**rank()**

Return the rank of self.

EXEMPLARY:

```sage
sage: W = WeylGroup(['A',4], implementation="permutation")
sage: W.rank()
4
```

**reflection_index_set()**

Return the index set of reflections of self.

EXEMPLARY:

```sage
sage: W = WeylGroup(['A',3], implementation="permutation")
sage: W.reflection_index_set()
(1, 2, 3, 4, 5, 6)
```

**reflections()**

Return the reflections of self.

EXEMPLARY:

```sage
sage: W = WeylGroup(['B',2], implementation="permutation")
sage: W.distinguished_reflections()
Finite family {1: (1,5)(2,4)(6,8), 2: (1,3)(2,6)(5,7),
  3: (2,8)(3,7)(4,6), 4: (1,7)(3,5)(4,8)}
```

**roots()**

Return the roots of self.

EXEMPLARY:

```sage
sage: W = WeylGroup(['G',2], implementation="permutation")
sage: W.roots()
(continues on next page)```
(continued from previous page)

```plaintext
((1, 0),
 (0, 1),
 (1, 1),
 (3, 1),
 (2, 1),
 (3, 2),
 (-1, 0),
 (0, -1),
 (-1, -1),
 (-3, -1),
 (-2, -1),
 (-3, -2))
```

**simple_reflection**(*i*)
Return the *i*-th simple reflection of *self*.

**EXAMPLES:**
```python
sage: W = WeylGroup(['A',4], implementation="permutation")
sage: W.simple_reflection(1)
(1,11)(2,5)(6,8)(9,10)(12,15)(16,18)(19,20)
sage: W.simple_reflections()
 Finite family {1: (1,11)(2,5)(6,8)(9,10)(12,15)(16,18)(19,20),
 2: (1,5)(2,12)(3,6)(7,9)(11,15)(13,16)(17,19),
 3: (2,6)(3,13)(4,7)(5,8)(12,16)(14,17)(15,18),
 4: (3,7)(4,14)(6,9)(8,10)(13,17)(16,19)(18,20)}
```

**simple_root_index**(*i*)
Return the index of the simple root \(\alpha_i\).
This is the position of \(\alpha_i\) in the list of simple roots.

**EXAMPLES:**
```python
sage: W = WeylGroup(['A',3], implementation="permutation")
sage: [W.simple_root_index(i) for i in W.index_set()]
[0, 1, 2]
```

**simple_roots**()
Return the simple roots of *self*.

**EXAMPLES:**
```python
sage: W = WeylGroup(['A',4], implementation="permutation")
sage: W.simple_roots()
 Finite family {1: (1, 0, 0, 0), 2: (0, 1, 0, 0),
 3: (0, 0, 1, 0), 4: (0, 0, 0, 1)}
```
5.1.271 Rooted (Unordered) Trees

AUTHORS:

- Florent Hivert (2011): initial version

```
class sage.combinat.rooted_tree.LabelledRootedTree(parent, children, label=None, check=True)
    Bases: sage.combinat.abstract_tree.AbstractLabelledClonableTree, sage.combinat.rooted_tree.RootedTree

Labelled rooted trees.
A labelled rooted tree is a rooted tree with a label attached at each node.

More formally: The labelled rooted trees are an inductive datatype defined as follows: A labelled rooted tree is a
multiset of labelled rooted trees, endowed with a label (which can be any object, including None). The trees
that belong to this multiset are said to be the children of the tree. (Notice that the labels of these children may
and may not be of the same type as the label of the tree). A labelled rooted tree which has no children (so the
only information it carries is its label) is said to be a leaf.

Every labelled rooted tree gives rise to an unlabelled rooted tree (RootedTree) by forgetting the labels. (This is
implemented as a conversion.)

INPUT:

- children – a list or tuple or more generally any iterable of trees or objects convertible to trees
- label – any hashable Sage object (default is None)

EXAMPLES:

```sage```

```
x = LabelledRootedTree([], label = 3); x
3[]
sage: LabelledRootedTree([x, x, x], label = 2)
2[3[], 3[], 3[]]
sage: LabelledRootedTree((x, x, x), label = 2)
2[3[], 3[], 3[]]
sage: LabelledRootedTree([[[], [], []]], label = 3)
3[[None[], None[], None]]]
```

Children are reordered using the value of the `sort_key()` method:

```
y = LabelledRootedTree([], label = 5); y
5[]
sage: xyy2 = LabelledRootedTree((x, y, y), label = 2); xyy2
2[3[], 5[], 5[]]
sage: xyy2 = LabelledRootedTree((y, x, y), label = 2); xyy2
2[3[], 5[], 5[]]
sage: xyy2 == xyy2
True
```

Converting labelled into unlabelled rooted trees by forgetting the labels, and back (the labels are initialized as None):

```
xyy2crude = RootedTree(xyy2); xyy2crude
[[], [], []]
sage: LabelledRootedTree(xyy2crude)
None[None[], None[], None[]]
```
sort_key()

Return a tuple of nonnegative integers encoding the labelled rooted tree self.

The first entry of the tuple is a pair consisting of the number of children of the root and the label of the root. Then the rest of the tuple is obtained as follows: List the tuples corresponding to all children (we are regarding the children themselves as trees). Order this list (not the tuples!) in lexicographically increasing order, and flatten it into a single tuple.

This tuple characterizes the labelled rooted tree uniquely, and can be used to sort the labelled rooted trees provided that the labels belong to a type which is totally ordered.

Note: The tree self must be normalized before calling this method (see normalize()). This doesn’t matter unless you are inside the clone() context manager, because outside of it every rooted tree is already normalized.

Note: This method overrides RootedTree.sort_key() and returns a result different from what the latter would return, as it wants to encode the whole labelled tree including its labelling rather than just the unlabelled tree. Therefore, be careful with using this method on subclasses of RootedOrderedTree; under some circumstances they could inherit it from another superclass instead of from RootedTree, which would cause the method to forget the labelling. See the docstrings of RootedTree.sort_key() and sage.combinat.ordered_tree.OrderedTree.sort_key().

EXAMPLES:

```python
sage: LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
sage: x = LRT([], label = 3); x
3[

sage: x.sort_key()
((0, 3),)

sage: y = LRT([x, x, x], label = 2); y
2[3[], 3[], 3[]]

sage: y.sort_key()
((3, 2), (0, 3), (0, 3), (0, 3))

sage: LRT.an_element().sort_key()
((3, 'alpha'), (0, 3), (1, 5), (0, None), (2, 42), (0, 3), (0, 3))

sage: lb = RootedTrees()([[[]], [[]], [[]]]).canonical_labelling()

sage: lb.sort_key()
((2, 1), (0, 2), (2, 3), (0, 4), (0, 5))
```

class sage.combinat.rooted_tree.LabelledRootedTrees

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

This is a parent stub to serve as a factory class for labelled rooted trees.

EXAMPLES:

```python
sage: LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
sage: x = LRT([], label = 3); x
3[

sage: x.parent() is LRT
```
True
sage: y = LRT([x, x, x], label = 2); y
2[3[], 3[], 3[]]
sage: y.parent() is LRT
True

Todo: Add the possibility to restrict the labels to a fixed set.

class sage.combinat.rooted_tree.LabelledRootedTrees_all(category=None)
    Bases: sage.combinat.rooted_tree.LabelledRootedTrees

    Class of all (unordered) labelled rooted trees.
    See LabelledRootedTree for a definition.

    Element
        alias of LabelledRootedTree

    labelled_trees()
        Return the set of labelled trees associated to self.
        EXAMPLES:
            sage: LabelledRootedTrees().labelled_trees()
            Labelled rooted trees

    unlabelled_trees()
        Return the set of unlabelled trees associated to self.
        EXAMPLES:
            sage: LabelledRootedTrees().unlabelled_trees()

class sage.combinat.rooted_tree.RootedTree(parent=None, children=[], check=True)
    Bases: sage.combinat.abstract_tree.AbstractClonableTree, sage.structure.list_clone.NormalizedClonableList

    The class for unordered rooted trees.

    The unordered rooted trees are an inductive datatype defined as follows: An unordered rooted tree is a multiset of unordered rooted trees. The trees that belong to this multiset are said to be the children of the tree. The tree that has no children is called a leaf.

    The labelled rooted trees (LabelledRootedTree) form a subclass of this class; they carry additional data.

    One can create a tree from any list (or more generally iterable) of trees or objects convertible to a tree.

    EXAMPLES:
        sage: RootedTree([])
        []
        sage: RootedTree([[], []])
        [[], []]
        sage: RootedTree([[[]], []])
        [[[]], []]
One can also enter any small rooted tree ("small" meaning that no vertex has more than 15 children) by using a simple numerical encoding of rooted trees, namely, the `from_hexacode()` function. (This function actually parametrizes ordered trees, and here we make it parametrize unordered trees by forgetting the ordering.)

```sage
sage: from sage.combinat.abstract_tree import from_hexacode
sage: RT = RootedTrees()
sage: from_hexacode('32001010', RT)
[[[[]], [[]], [[]], []], [[[]], [[]], [[[]]], [[][]]], [[[]], [[]], [[]], []]]
```

**Note:** Unlike an ordered tree, an (unordered) rooted tree is a multiset (rather than a list) of children. That is, two ordered trees which differ from each other by switching the order of children are equal to each other as (unordered) rooted trees. Internally, rooted trees are encoded as `sage.structure.list_clone.NormalizedClonableList` instances, and instead of storing their children as an actual multiset, they store their children as a list which is sorted according to their `sort_key()` value. This is as good as storing them as multisets, since the `sort_key()` values are sortable and distinguish different (unordered) trees. However, if you wish to define a subclass of `RootedTree` which implements rooted trees with extra structure (say, a class of edge-colored rooted trees, or a class of rooted trees with a cyclic order on the list of children), then the inherited `sort_key()` method will no longer distinguish different trees (and, as a consequence, equal trees will be regarded as distinct). Thus, you will have to override the method by one that does distinguish different trees.

### `graft_list(other)`

Return the list of trees obtained by grafting `other` on `self`.

Here grafting means that one takes the disjoint union of `self` and `other`, chooses a node of `self`, and adds the root of `other` to the list of children of this node. The root of the resulting tree is the root of `self`. (This can be done for each node of `self`; this method returns the list of all results.)

This is useful for free pre-Lie algebras.

**EXAMPLES:**

```sage
sage: RT = RootedTree
sage: x = RT([])
sage: y = RT([x, x])
sage: x.graft_list(x)
[[[]]]
sage: l = y.graft_list(x); l
[[[[], [], []], [[], [[[]]]], [[], [[[]]]]]
sage: [parent(i) for i in l]
[Rooted trees, Rooted trees, Rooted trees]
```

### `graft_on_root(other)`

Return the tree obtained by grafting `other` on the root of `self`.

Here grafting means that one takes the disjoint union of `self` and `other`, and adds the root of `other` to the list of children of `self`. The root of the resulting tree is the root of `self`.

This is useful for free Nap algebras.

**EXAMPLES:**
is_empty()
Return if self is the empty tree.
For rooted trees, this always returns False.

Note: This is not the same as bool(t), which returns whether t has some child or not.

EXAMPLES:

```
sage: t = RootedTrees(4)([[],[]])
sage: t.is_empty()
False
sage: bool(t)
True
sage: t = RootedTrees(1)([])
sage: t.is_empty()
False
sage: bool(t)
False
```

normalize()
Normalize self.
This function is at the core of the implementation of rooted (unordered) trees. The underlying structure is provided by ordered rooted trees. Every rooted tree is represented by a normalized element in the set of its planar embeddings.

There should be no need to call normalize directly as it is called automatically upon creation and cloning or modification (by NormalizedClonableList).

The normalization has a recursive definition. It means first that every sub-tree is itself normalized, and also that sub-trees are sorted. Here the sort is performed according to the values of the sort_key() method.

EXAMPLES:

```
sage: RT = RootedTree
sage: RT([[[]],[]]) == RT([[[]],[[]]])  # indirect doctest
True
sage: rt1 = RT([[[]],[]])
sage: rt2 = RT([[[]],[[]]])
sage: rt1 is rt2
False
sage: rt1 == rt2
True
```
sage: rt1._get_list() == rt2._get_list()
True

**single_graft**(x, grafting_function, path_prefix=())

Graft subtrees of x on self using the given function.

Let \(x_1, x_2, \ldots, x_p\) be the children of the root of \(x\). For each \(i\), the subtree of \(x\) comprising all descendants of \(x_i\) is joined by a new edge to the vertex of self specified by the \(i\)-th path in the grafting function (i.e., by the path grafting_function[i]).

The number of vertices of the result is the sum of the numbers of vertices of self and \(x\) minus one, because the root of \(x\) is not used.

This is used to define the product of the Grossman-Larson algebras.

**INPUT:**

- \(x\) – a rooted tree
- grafting_function – a list of paths in self
- path_prefix – optional tuple (default ()

The path_prefix argument is only used for internal recursion.

**EXAMPLES:**

```
sage: LT = LabelledRootedTrees()
sage: y = LT([LT([],label='b')], label='a')
sage: x = LT([LT([],label='d')], label='c')
sage: y.single_graft(x,[(0,)])
a[b[d[]]]
sage: t = LT([LT([],label='b'),LT([],label='c')], label='a')
sage: s = LT([LT([],label='d'),LT([],label='e')], label='f')
sage: t.single_graft(s,[(0,),(1,)])
a[b[d[]], c[e[]]]
```

**sort_key()**

Return a tuple of nonnegative integers encoding the rooted tree self.

The first entry of the tuple is the number of children of the root. Then the rest of the tuple is obtained as follows: List the tuples corresponding to all children (we are regarding the children themselves as trees). Order this list (not the tuples!) in lexicographically increasing order, and flatten it into a single tuple.

This tuple characterizes the rooted tree uniquely, and can be used to sort the rooted trees.

**Note:** The tree self must be normalized before calling this method (see normalize()). This doesn’t matter unless you are inside the clone() context manager, because outside of it every rooted tree is already normalized.

**Note:** By default, this method does not encode any extra structure that self might have. If you have a subclass inheriting from RootedTree which allows for some extra structure, you need to override sort_key() in order to preserve this structure (for example, the LabelledRootedTree class does this in LabelledRootedTree.sort_key()). See the note in the docstring of sage.combinat.ordered_tree.OrderedTree.sort_key() for a pitfall.
EXAMPLES:

```python
sage: RT = RootedTree
dsage: RT([[[]], [[]]]).sort_key()
(2, 0, 1, 0)
dsage: RT([[[]], [[]]]).sort_key()
(2, 0, 1, 0)
```

class sage.combinat.rooted_tree.RootedTrees
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Factory class for rooted trees.

INPUT:

• size – (optional) an integer

OUTPUT:

the set of all rooted trees (of the given size size if specified)

EXAMPLES:

```python
sage: RootedTrees()
Rooted trees
sage: RootedTrees(2)
Rooted trees with 2 nodes
```

class sage.combinat.rooted_tree.RootedTrees_all
Bases: sage.sets.disjoint_unionEnumeratedSets.DisjointUnionEnumeratedSets, sage.combinat.rooted_tree.RootedTrees

Class of all (unordered, unlabelled) rooted trees.

See RootedTree for a definition.

Element
alias of RootedTree

labelled_trees()

Return the set of labelled trees associated to self.

EXAMPLES:

```python
sage: RootedTrees().labelled_trees()
Labelled rooted trees
```

As a consequence:

```python
sage: lb = RootedTrees([[[]], [[]], [[]]]).canonical_labelling()
sage: lb
1[2[], 3[4[], 5[]]]
sage: lb.__class__
<class 'sage.combinat.rooted_tree.LabelledRootedTrees_all_with_category.element_class'>
sage: lb.parent()
Labelled rooted trees
```
leaf()
Return a leaf tree with self as parent.

EXAMPLES:
```
sage: RootedTrees().leaf()
[]
```

unlabelled_trees()
Return the set of unlabelled trees associated to self.

EXAMPLES:
```
sage: RootedTrees().unlabelled_trees()
Rooted trees
```

class sage.combinat.rooted_tree.RootedTrees_size(n)
Bases: sage.combinat.rooted_tree.RootedTrees

The enumerated set of rooted trees with a given number of nodes.

The number of nodes of a rooted tree is defined recursively: The number of nodes of a rooted tree with \(a\) children is \(a\) plus the sum of the number of nodes of each of these children.

cardinality()
Return the cardinality of self.

EXAMPLES:
```
sage: RootedTrees(1).cardinality()
1
sage: RootedTrees(3).cardinality()
2
```

check_element(el, check=True)
Check that a given tree actually belongs to self.
This just checks the number of vertices.

EXAMPLES:
```
sage: RT3 = RootedTrees(3)
sage: RT3([[[],[]]])  # indirect doctest
[[[], []]]
sage: RT3([[[],[],[]]])  # indirect doctest
Traceback (most recent call last):
... ValueError: wrong number of nodes
```

element_class()

sage.combinat.rooted_tree.number_of_rooted_trees(n)
Return the number of rooted trees with \(n\) nodes.

Compute the number \(a(n)\) of rooted trees with \(n\) nodes using the recursive formula ([SL000081]):

\[
a(n + 1) = \frac{1}{n} \sum_{k=1}^{n} \left( \sum_{d|k} da(d) \right) a(n - k + 1)
\]

EXAMPLES:
Combinatorics, Release 9.7

```
sage: from sage.combinat.rooted_tree import number_of_rooted_trees
sage: [number_of_rooted_trees(i) for i in range(10)]
[0, 1, 1, 2, 4, 9, 20, 48, 115, 286]
```

Introduction

The Robinson-Schensted-Knuth (RSK) correspondence is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, ...) and pairs of semi-standard Young tableaux \((P, Q)\) of identical shape.

The basic operation in the RSK correspondence is a row insertion \(P \leftarrow k\) (where \(P\) is a given semi-standard Young tableau, and \(k\) is an integer). Different insertion algorithms have been implemented for the RSK correspondence and can be specified as an argument in the function call.

EXAMPLES:

We can perform RSK and its inverse map on a variety of objects:

```
sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: gp = RSK_inverse(p, q); gp
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK(*gp) # RSK of a biword
[[[1, 2, 2], [2]], [[1, 3, 3], [2]]]
sage: RSK([2,3,2,1,2,3]) # Robinson-Schensted of a word
[[[1, 2, 2, 3], [2], [3]], [[1, 2, 5, 6], [3], [4]]]
sage: RSK([2,3,2,1,2,3], insertion=RSK.rules.EG) # Edelman-Greene
[[[1, 2, 3], [2, 3], [3]], [[1, 2, 6], [3, 5], [4]]]
sage: m = RSK_inverse(p, q, 'matrix'); m # output as matrix
[0 1]
[1 0]
[0 2]
sage: RSK(m) # RSK of a matrix
[[[1, 2, 2], [2]], [[1, 3, 3], [2]]]
```
**Insertions currently available**

The following insertion algorithms for RSK correspondence are currently available:

- **RSK** insertion (*RuleRSK*).
- Edelman-Greene insertion (*RuleEG*), an algorithm defined in [EG1987] Definition 6.20 (where it is referred to as Coxeter-Knuth insertion).
- Hecke RSK algorithm (*RuleHecke*), defined using the Hecke insertion studied in [BKSTY06] (but using rows instead of columns).
- **Dual RSK** insertion (*RuleDualRSK*).
- CoRSK insertion (*RuleCoRSK*), defined in [GR2018v5sol].
- Super RSK insertion (*RuleSuperRSK*), a combination of row and column insertions defined in [Muth2019].
- **Star** insertion (*RuleStar*), defined in [MPPS2020].

**Implementing your own insertion rule**

The functions *RSK()* and *RSK_inverse()* are written so that it is easy to implement insertion algorithms you come across in your research.

To implement your own insertion algorithm, you first need to import the base class for a rule:

```sage
sage: from sage.combinat.rsk import Rule
```

Using the *Rule* class as parent class for your insertion rule, first implement the insertion and the reverse insertion algorithm for *RSK()* and *RSK_inverse()* respectively (as methods *forward_rule* and *backward_rule*). If your insertion algorithm uses the same forward and backward rules as *RuleRSK*, differing only in how an entry is inserted into a row, then this is not necessary, and it suffices to merely implement the *insertion* and *reverse_insertion* methods.

For more information, see *Rule*.

5.1. Comprehensive Module List 2669
Perform the Robinson-Schensted-Knuth (RSK) correspondence.

The Robinson-Schensted-Knuth (RSK) correspondence (also known as the RSK algorithm) is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, ...) and pairs of semi-standard Young tableaux $(P, Q)$ of identical shape. The tableau $P$ is known as the insertion tableau, and $Q$ is known as the recording tableau.

The basic operation is known as row insertion $P \leftarrow k$ (where $P$ is a given semi-standard Young tableau, and $k$ is an integer). Row insertion is a recursive algorithm which starts by setting $k_0 = k$, and in its $i$-th step inserts the number $k_i$ into the $i$-th row of $P$ (we start counting the rows at 0) by replacing the first integer greater than $k_i$ in the row by $k_i$ and defines $k_{i+1}$ as the integer that has been replaced. If no integer greater than $k_i$ exists in the $i$-th row, then $k_i$ is simply appended to the row and the algorithm terminates at this point.

A generalized permutation (or biword) is a list $((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$ of pairs such that the letters $j_0, j_1, \ldots, j_{\ell-1}$ are weakly increasing (that is, $j_0 \leq j_1 \leq \cdots \leq j_{\ell-1}$), whereas the letters $k_i$ satisfy $k_i \leq k_{i+1}$ whenever $j_i = j_{i+1}$. The $\ell$-tuple $(j_0, j_1, \ldots, j_{\ell-1})$ is called the top line of this generalized permutation, whereas the $\ell$-tuple $(k_0, k_1, \ldots, k_{\ell-1})$ is called its bottom line.

Now the RSK algorithm, applied to a generalized permutation $p = ((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$ (encoded as a lexicographically sorted list of pairs) starts by initializing two semi-standard tableaux $P_0$ and $Q_0$ as empty tableaux. For each nonnegative integer $t$ starting at 0, take the pair $(j_t, k_t)$ from $p$ and set $P_{t+1} = P_t \leftarrow k_t$, and define $Q_{t+1}$ by adding a new box filled with $j_t$ to the tableau $Q_t$ at the same location the row insertion on $P_t$ ended (that is to say, adding a new box with entry $j_t$ such that $P_{t+1}$ and $Q_{t+1}$ have the same shape). The iterative process stops when $t$ reaches the size of $p$, and the pair $(P_t, Q_t)$ at this point is the image of $p$ under the Robinson-Schensted-Knuth correspondence.

This correspondence has been introduced in [Knu1970], where it has been referred to as “Construction A”.

For more information, see Chapter 7 in [Sta-EC2].

We also note that integer matrices are in bijection with generalized permutations. Furthermore, we can convert any word $w$ (and, in particular, any permutation) to a generalized permutation by considering the top row to be $(1, 2, \ldots, n)$ where $n$ is the length of $w$.

The optional argument insertion allows to specify an alternative insertion procedure to be used instead of the standard Robinson-Schensted-Knuth insertion.

**INPUT:**

- **obj1, obj2** – can be one of the following:
  - a word in an ordered alphabet (in this case, obj1 is said word, and obj2 is `None`)
  - an integer matrix
  - two lists of equal length representing a generalized permutation (namely, the lists $(j_0, j_1, \ldots, j_{\ell-1})$ and $(k_0, k_1, \ldots, k_{\ell-1})$ represent the generalized permutation $((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$)
  - any object which has a method `_rsk_iter()` which returns an iterator over the object represented as generalized permutation or a pair of lists (in this case, obj1 is said object, and obj2 is `None`).

- **insertion** – (default: RSK.rules.RSK) the following types of insertion are currently supported:
  - RSK.rules.RSK (or 'RSK') – Robinson-Schensted-Knuth insertion (`RuleRSK`)
  - RSK.rules.EG (or 'EG') – Edelman-Greene insertion (only for reduced words of permutations/elements of a type $A$ Coxeter group) (`RuleEG`)

sage.combinat.rsk.RSK(obj1=None, obj2=None, insertion=<class 'sage.combinat.rsk.RuleRSK'>, check_standard=False, **options)

The optional argument `check_standard` (default: `False`) checks whether the input is a standard RSK tableau.
- **RSK.rules.Hecke** (or 'hecke') – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) (*RuleHecke*)

- **RSK.rules.dualRSK** (or 'dualRSK') – Dual RSK insertion (only for strict biwords) (*RuleDualRSK*)

- **RSK.rules.coRSK** (or 'coRSK') – CoRSK insertion (only for strict cobiwords) (*RuleCoRSK*)

- **RSK.rules.superRSK** (or 'super') – Super RSK insertion (only for restricted super biwords) (*RuleSuperRSK*)

- **RSK.rules.Star** (or 'Star') – $\star$-insertion (only for fully commutative words in the 0-Hecke monoid) (*RuleStar*)

  - **check_standard** – (default: False) check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

For precise information about constraints on the input and output, as well as the definition of the algorithm (if it is not standard RSK), see the particular *Rule* class.

**EXAMPLES:**

If we only input one row, it is understood that the top row should be $(1, 2, \ldots, n)$:

```python
sage: RSK([3,3,2,4,1])
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
```

```python
sage: RSK(Word([3,3,2,4,1]))
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
```

```python
sage: RSK(Word([2,3,3,2,1,3,2,3]))
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
```

We can provide a generalized permutation:

```python
sage: RSK([1, 2, 2, 2], [2, 1, 1, 2])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

```python
sage: RSK(Word([1,1,3,4,4]), [1,4,2,1,3])
[[[1, 1, 3], [2], [4]], [[1, 1, 4], [3], [4]]]
```

```python
sage: RSK([1,3,3,4,4], Word([6,2,2,1,7]))
[[[1, 2, 7], [2], [6]], [[1, 3, 4], [3], [4]]]
```

We can provide a matrix:

```python
sage: RSK(matrix([[0,1],[2,1]]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

We can also provide something looking like a matrix:

```python
sage: RSK([[0,1],[2,1]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

There is also **RSK_inverse()** which performs the inverse of the bijection on a pair of semistandard tableaux.

We note that the inverse function takes 2 separate tableaux as inputs, so to compose with **RSK()**, we need to use the python `*` on the output:

```python
sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 1, 1, 2]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

```python
sage: P,Q = RSK([1, 2, 2, 2], [2, 1, 1, 2])
sage: RSK_inverse(P, Q)
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```
sage.combinat.rsk.RSK_inverse(p, q, output='array', insertion=<class 'sage.combinat.rsk.RuleRSK'>)

Return the generalized permutation corresponding to the pair of tableaux \((p, q)\) under the inverse of the Robinson-Schensted-Knuth correspondence.

For more information on the bijection, see RSK().

INPUT:

- \(p, q\) – two semi-standard tableaux of the same shape, or (in the case when Hecke insertion is used) an increasing tableau and a set-valued tableau of the same shape (see the note below for the format of the set-valued tableau)
- output – (default: 'array') if \(q\) is semi-standard:
  - 'array' – as a two-line array (i.e. generalized permutation or biword)
  - 'matrix' – as an integer matrix

and if \(q\) is standard, we can also have the output:
- 'word' – as a word

and additionally if \(p\) is standard, we can also have the output:
- 'permutation' – as a permutation

- insertion – (default: RSK.rules.RSK) the insertion algorithm used in the bijection. Currently the following are supported:
  - RSK.rules.RSK (or 'RSK') – Robinson-Schensted-Knuth insertion (RuleRSK)
  - RSK.rules.EG (or 'EG') – Edelman-Greene insertion (only for reduced words of permutations/elements of a type \(A\) Coxeter group) (RuleEG)
  - RSK.rules.Hecke (or 'hecke') – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) (RuleHecke)
  - RSK.rules.dualRSK (or 'dualRSK') – Dual RSK insertion (only for strict biwords) (RuleDualRSK)
  - RSK.rules.coRSK (or 'coRSK') – CoRSK insertion (only for strict cobiwords) (RuleCoRSK)
  - RSK.rules.superRSK (or 'super') – Super RSK insertion (only for restricted super biwords) (RuleSuperRSK)
  - RSK.rules.Star (or 'Star') – ⋆-insertion (only for fully commutative words in the 0-Hecke monoid) (RuleStar)

For precise information about constraints on the input and output, see the particular Rule class.

Note: In the case of Hecke insertion, the input variable \(q\) should be a set-valued tableau, encoded as a tableau whose entries are strictly increasing tuples of positive integers. Each such tuple encodes the set of its entries.

EXAMPLES:

If both \(p\) and \(q\) are standard:

```python
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word')
word: 14532
```
sage: RSK_inverse(t1, t2, 'matrix')
[[0 0 0 0]
 [0 0 1 0]
 [0 0 0 1]
 [0 1 0 0]
 [0 1 0 0]]
sage: RSK_inverse(t1, t2, 'permutation')
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation')
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation')
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation')
[1, 5, 4, 2, 3]

If the first tableau is semistandard:

sage: p = Tableau([[1,2,2],[3]]); q = Tableau([[1,2,4],[3]])
sage: ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]
sage: RSK_inverse(p, q, 'word')
word: 1322

In general:

sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: RSK_inverse(p, q)
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK_inverse(p, q, 'matrix')
[[0 1]
 [1 0]
 [0 2]]

Using Hecke insertion:

sage: w = [5, 4, 3, 1, 4, 2, 5, 5]
sage: pq = RSK(w, insertion=RSK.rules.Hecke)
sage: RSK_inverse(*pq, insertion=RSK.rules.Hecke, output='list')
[5, 4, 3, 1, 4, 2, 5, 5]

Note: The constructor of Tableau accepts not only semistandard tableaux, but also arbitrary lists that are fillings of a partition diagram. (And such lists are used, e.g., for the set-valued tableau q that is passed to RSK_inverse(p, q, insertion='hecke').) The user is responsible for ensuring that the tableaux passed to RSK_inverse are of the right types (semistandard, standard, increasing, set-valued as needed).

class sage.combinat.rsk.Rule
Bases: sage.structure.unique_representation.UniqueRepresentation

Generic base class for an insertion rule for an RSK-type correspondence.

An instance of this class should implement a method insertion() (which can be applied to a letter j and a list r, and modifies r in place by “bumping” j into it appropriately; it then returns the bumped-out entry or None if no such entry exists) and a method reverse_insertion() (which does the same but for reverse
bumping). It may also implement \_backward_format_output() and \_forward_format_output() if the RSK correspondence should return something other than (semi)standard tableaux (in the forward direction) and matrices or biwords (in the backward direction). The \texttt{to_pairs()} method should also be overridden if the input for the (forward) RSK correspondence is not the usual kind of biwords (i.e., pairs of two $n$-tuples $[a_1, a_2, \ldots, a_n]$ and $[b_1, b_2, \ldots, b_n]$ satisfying $(a_1, b_1) \leq (a_2, b_2) \leq \cdots \leq (a_n, b_n)$ in lexicographic order).

Finally, it \texttt{forward_rule()} and \texttt{backward_rule()} have to be overridden if the overall structure of the RSK correspondence differs from that of classical RSK (see, e.g., the case of Hecke insertion, in which a letter bumped into a row may change a different row).

\textbf{backward_rule}(p, q, output)

Return the generalized permutation obtained by applying reverse insertion to a pair of tableaux \((p, q)\).

**INPUT:**

- \(p, q\) – two tableaux of the same shape.
- \texttt{output} – (default: \texttt{array}) if \(q\) is semi-standard:
  - \texttt{array} – as a two-line array (i.e. generalized permutation or biword)
  - \texttt{matrix} – as an integer matrix

and if \(q\) is standard, we can also have the output:

- \texttt{word} – as a word

and additionally if \(p\) is standard, we can also have the output:

- \texttt{permutation} – as a permutation

**EXAMPLES:**

```python
sage: from sage.combinat.rsk import RuleRSK
sage: t1 = Tableau([[1, 3, 4], [2], [3]])
sage: t2 = Tableau([[1, 2, 4], [3], [5]])
sage: RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [3, 3, 2, 4, 1]]
sage: t1 = Tableau([[1, 1, 1, 3, 7]])
sage: t2 = Tableau([[1, 2, 3, 4, 5]])
sage: RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [1, 1, 1, 3, 7]]
sage: t1 = Tableau([[1, 3], [3], [6], [7]])
sage: t2 = Tableau([[1, 4], [2], [3], [5]])
sage: RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [7, 6, 3, 3, 1]]
```

\textbf{forward_rule}(obj1, obj2, check_standard=False, check=True)

Return a pair of tableaux obtained by applying forward insertion to the generalized permutation \([\text{obj1}, \text{obj2}]\).

**INPUT:**

- \texttt{obj1, obj2} – can be one of the following ways to represent a generalized permutation (or, equivalently, biword):
  - two lists \texttt{obj1} and \texttt{obj2} of equal length, to be interpreted as the top row and the bottom row of the biword
  - a matrix \texttt{obj1} of nonnegative integers, to be interpreted as the generalized permutation in matrix form (in this case, \texttt{obj2} is None)
– a word obj1 in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, obj2 is None; the top row of the biword is understood to be (1, 2, ..., n) by default)

– any object obj1 which has a method _rsk_iter(), as long as this method returns an iterator yielding pairs of numbers, which then are interpreted as top entries and bottom entries in the biword (in this case, obj2 is None)

• check_standard – (default: False) check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

• check – (default: True) whether to check that obj1 and obj2 actually define a valid biword

EXAMPLES:

```python
sage: from sage.combinat.rsk import RuleRSK
sage: RuleRSK().forward_rule([3, 3, 2, 4, 1], None)
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]

sage: RuleRSK().forward_rule([1, 1, 1, 3, 7], None)
[[[1, 1, 1, 3, 7]], [[1, 2, 3, 4, 5]]]

sage: RuleRSK().forward_rule([7, 6, 3, 3, 1], None)
[[[1, 3], [3], [6], [7]], [[1, 4], [2], [3], [5]]]
```

to_pairs(obj1=None, obj2=None, check=True)

Given a valid input for the RSK algorithm, such as two n-tuples obj1 = [a_1, a_2, ..., a_n] and obj2 = [b_1, b_2, ..., b_n] forming a biword (i.e., satisfying a_1 ≤ a_2 ≤ ... ≤ a_n, and if a_i = a_{i+1}, then b_i ≤ b_{i+1}), or a matrix (“generalized permutation”), or a single word, return the array [(a_1, b_1), (a_2, b_2), ..., (a_n, b_n)].

INPUT:

• obj1, obj2 – anything representing a biword (see the doc of forward_rule() for the encodings accepted).

• check – (default: True) whether to check that obj1 and obj2 actually define a valid biword.

EXAMPLES:

```python
sage: from sage.combinat.rsk import Rule
sage: list(Rule().to_pairs([1, 2, 2, 2], [2, 1, 1, 2]))
[(1, 2), (2, 1), (2, 1), (2, 2)]

sage: m = Matrix(ZZ, 3, 2, [0,1,1,0,0,2]) ; m
[0 1]
[1 0]
[0 2]

sage: list(Rule().to_pairs(m))
[(1, 2), (2, 1), (3, 2), (3, 2)]
```

class sage.combinat.rsk.RuleCoRSK

Bases: sage.combinat.rsk.RuleRSK

Rule for coRSK insertion.

CoRSK insertion differs from classical RSK insertion in the following ways:

• The input (in terms of biwords) is no longer a biword, but rather a strict cobiword – i.e., a pair of two lists [a_1, a_2, ..., a_n] and [b_1, b_2, ..., b_n] that satisfy the strict inequalities (a_1, b_1) ≺ (a_2, b_2) ≺ ... ≺ (a_n, b_n), where the binary relation ≺ on pairs of integers is defined by having (u_1, v_1) ≺ (u_2, v_2) if and only if either u_1 < u_2 or (u_1 = u_2 and v_1 > v_2). In terms of matrices, this means that the input is not an arbitrary matrix with nonnegative integer entries, but rather a \{0, 1\}-matrix (i.e., a matrix whose entries are 0’s and 1’s).
• The output still consists of two tableaux \((P, Q)\) of equal shapes, but rather than both of them being semistandard, now \(Q\) is row-strict (i.e., its transpose is semistandard) while \(P\) is semistandard.

Bumping proceeds in the same way as for RSK insertion.

The RSK and coRSK algorithms agree for permutation matrices.

For more information, see Section A.4 in [Ful1997] (specifically, construction (1d)) or the second solution to Exercise 2.7.12(a) in [GR2018v5sol].

**EXAMPLES:**

```python
sage: RSK([[1,2,5,3,1], insertion = RSK.rules.coRSK)
[[[1, 1, 3], [2], [5]], [[1, 2, 3], [4], [5]]

sage: RSK(Word([2,3,3,2,1,3,2,3]), insertion = RSK.rules.coRSK)
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 4], [3], [5]]

sage: RSK(Word([3,2,4,1]), insertion = RSK.rules.coRSK)
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]

sage: from sage.combinat.rsk import to_matrix
sage: RSK(to_matrix([1, 1, 3, 3, 4], [3, 2, 2, 1, 3]), insertion = RSK.rules.coRSK)
[[[1, 2, 3], [2], [3]], [[1, 3, 4], [1], [3]]

Using coRSK insertion with a \{0,1\}-matrix:

```python
sage: RSK(matrix([[0,1],[1,0]]), insertion = RSK.rules.coRSK)
[[[1], [2]], [[1], [2]]]
```

We can also give it something looking like a matrix:

```python
sage: RSK([[0,1],[1,0]], insertion = RSK.rules.coRSK)
[[[1], [2]], [[1], [2]]]
```

We can also use the inverse correspondence:

```python
sage: RSK_inverse(RSK([[1, 2, 5, 3, 1], [2], [5]], [[1, 2, 3], [4], [5]])
[[[1, 2, 5, 3, 1], [2], [5]], [[1, 2, 3], [4], [5]]

When applied to two standard tableaux, backwards coRSK insertion behaves identically to the usual backwards RSK insertion:

```python
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, 'word', insertion=RSK.rules.coRSK)
word: 14532

sage: RSK_inverse(t1, t2, 'matrix', insertion=RSK.rules.coRSK)
[[1 0 0 0 0]
 [0 0 0 1 0]
 [0 0 0 0 1]
 [0 0 1 0 0]
 [0 1 0 0 0]]
```

(continues on next page)
sage: RSK_inverse(t1, t2, 'permutation', insertion=RSK.rules.coRSK)
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation', insertion=RSK.rules.coRSK)
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation', insertion=RSK.rules.coRSK)
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation', insertion=RSK.rules.coRSK)
[1, 5, 4, 2, 3]

For coRSK, the first tableau is semistandard while the second tableau is transpose semistandard:

sage: p = Tableau([[1,2,2], [5]]); q = Tableau([[1,2,4], [3]])
sage: ret = RSK_inverse(p, q, insertion=RSK.rules.coRSK); ret
[[1, 2, 3, 4], [1, 5, 2, 2]]
sage: RSK_inverse(p, q, 'word', insertion=RSK.rules.coRSK)
word: 1522

backward_rule(p, q, output)
Return the strict cobiword obtained by applying reverse coRSK insertion to a pair of tableaux (p, q).

INPUT:
• p, q – two tableaux of the same shape
• output – (default: 'array') if q is row-strict:
  – 'array' – as a two-line array (i.e. strict cobiword)
  – 'matrix' – as a \{0,1\}-matrix
and if q is standard, we can have the output:
  – 'word' – as a word
and additionally if p is standard, we can also have the output:
  – 'permutation' – as a permutation

EXAMPLES:

sage: from sage.combinat.rsk import RuleCoRSK
sage: t1 = Tableau([[1, 1, 2], [2, 3], [4]])
    t2 = Tableau([[1, 4, 5], [1, 4], [2]])
    RuleCoRSK().backward_rule(t1, t2, 'array')
[[[1, 1, 2, 4, 4, 5], [4, 2, 1, 3, 1, 2]]

to_pairs(obj1=None, obj2=None, check=True)
Given a valid input for the coRSK algorithm, such as two n-tuples obj1 = [a_1, a_2, \ldots, a_n] and obj2 = [b_1, b_2, \ldots, b_n] forming a strict cobiword (i.e., satisfying a_1 \leq a_2 \leq \cdots \leq a_n, and if a_i = a_{i+1}, then b_i > b_{i+1}), or a \{0,1\}-matrix ("rook placement"), or a single word, return the array [[(a_1, b_1), (a_2, b_2), \ldots, (a_n, b_n)].

INPUT:
• obj1, obj2 – anything representing a strict cobiword (see the doc of forward_rule() for the encodings accepted)
• check – (default: True) whether to check that obj1 and obj2 actually define a valid strict cobiword

EXAMPLES:
sage: from sage.combinat.rsk import RuleCoRSK
sage: list(RuleCoRSK().to_pairs([1, 2, 2, 2], [2, 3, 2, 1]))
[(1, 2), (2, 3), (2, 2), (2, 1)]

sage: RuleCoRSK().to_pairs([1, 2, 2, 2], [1, 2, 3, 3])
Traceback (most recent call last):
  ... ValueError: invalid strict cobiword

sage: m = Matrix(ZZ, 3, 2, [0,1,1,1,0,1]) ; m
[0 1]
[1 1]
[0 1]
sage: list(RuleCoRSK().to_pairs(m))
[(1, 2), (2, 2), (2, 1), (3, 2)]

sage: m = Matrix(ZZ, 3, 2, [0,1,1,0,0,2]) ; m
[0 1]
[1 0]
[0 2]
sage: RuleCoRSK().to_pairs(m)
Traceback (most recent call last):
  ... ValueError: coRSK requires a \{0, 1\}-matrix

class sage.combinat.rsk.RuleDualRSK
Bases: sage.combinat.rsk.Rule

Rule for dual RSK insertion.

Dual RSK insertion differs from classical RSK insertion in the following ways:

- The input (in terms of biwords) is no longer an arbitrary biword, but rather a strict biword (i.e., a pair of two lists \([a_1, a_2, \ldots, a_n]\) and \([b_1, b_2, \ldots, b_n]\) that satisfy the strict inequalities \((a_1, b_1) < (a_2, b_2) < \cdots < (a_n, b_n)\) in lexicographic order). In terms of matrices, this means that the input is not an arbitrary matrix with nonnegative integer entries, but rather a \{0, 1\}-matrix (i.e., a matrix whose entries are 0’s and 1’s).

- The output still consists of two tableaux \((P, Q)\) of equal shapes, but rather than both of them being semistandard, now \(P\) is row-strict (i.e., its transpose is semistandard) while \(Q\) is semistandard.

- The main difference is in the way bumping works. Namely, when a number \(k_i\) is inserted into the \(i\)-th row of \(P\), it bumps out the first integer greater or equal to \(k_i\) in this row (rather than greater than \(k_i\)).

The RSK and dual RSK algorithms agree for permutation matrices.

For more information, see Chapter 7, Section 14 in [Sta-EC2] (where dual RSK is called RSK*) or the third solution to Exercise 2.7.12(a) in [GR2018v5sol].

EXAMPLES:

sage: RSK([[3,3,2,4,1], insertion=RSK.rules.dualRSK])
[[[1, 4], [2], [3], [3]], [[1, 4], [2], [3], [5]]]

sage: RSK(Word([3,3,2,4,1]), insertion=RSK.rules.dualRSK)
[[[1, 4], [2], [3], [3]], [[1, 4], [2], [3], [5]]]

sage: RSK(Word([2,3,3,2,1,3,2,3]), insertion=RSK.rules.dualRSK)
[[[1, 2, 3], [2, 3], [2, 3], [3]], [[1, 2, 8], [3, 6], [4, 7], [5]]]

Using dual RSK insertion with a strict biword:
Using dual RSK insertion with a \(0,1\)-matrix:

\[
\text{sage: } \text{RSK(matrix([[[0,1],[1,1]]]), insertion=RSK.rules.dualRSK)}
\]
\[
[[[1, 2], [2]], [[1, 2], [2]]]
\]

We can also give it something looking like a matrix:

\[
\text{sage: } \text{RSK([[0,1],[1,1]], insertion=RSK.rules.dualRSK)}
\]
\[
[[[1, 2], [2]], [[1, 2], [2]]]
\]

Let us now call the inverse correspondence:

\[
\text{sage: } \text{RSK\_inverse(\text{RSK([1, 2, 2, 2], [2, 1, 2, 3], \ldots}})
\]
\[
[[[1, 2, 2, 2], [2, 1, 2, 3]]]
\]

When applied to two standard tableaux, reverse dual RSK insertion behaves identically to the usual reverse RSK insertion:

\[
\text{sage: } \text{t1 = Tableau([[1, 2, 5], [3], [4]])}
\]
\[
\text{sage: } \text{t2 = Tableau([[1, 2, 3], [4], [5]])}
\]

\[
\text{sage: } \text{RSK\_inverse(t1, t2, insertion=RSK.rules.dualRSK)}
\]
\[
[[1, 4, 5, 3, 2]]
\]

\[
\text{sage: } \text{RSK\_inverse(t1, t2, 'word', insertion=RSK.rules.dualRSK)}
\]
\[
\text{word: 14532}
\]

\[
\text{sage: } \text{RSK\_inverse(t1, t2, 'matrix', insertion=RSK.rules.dualRSK)}
\]
\[
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
\end{bmatrix}
\]

\[
\text{sage: } \text{RSK\_inverse(t1, t2, 'permutation', insertion=RSK.rules.dualRSK)}
\]
\[
[1, 4, 5, 3, 2]
\]

\[
\text{sage: } \text{RSK\_inverse(t1, t1, 'permutation', insertion=RSK.rules.dualRSK)}
\]
\[
[1, 4, 3, 2, 5]
\]

\[
\text{sage: } \text{RSK\_inverse(t2, t2, 'permutation', insertion=RSK.rules.dualRSK)}
\]
\[
[1, 2, 5, 4, 3]
\]

\[
\text{sage: } \text{RSK\_inverse(t2, t1, 'permutation', insertion=RSK.rules.dualRSK)}
\]
\[
[1, 5, 4, 2, 3]
\]
Let us check that forward and backward dual RSK are mutually inverse when the first tableau is merely transpose semistandard:

```sage
p = Tableau([[1,2,2],[1]])
q = Tableau([[1,2,4],[3]])
ret = RSK_inverse(p, q, insertion=RSK.rules.dualRSK); ret
RSK_inverse(p, q, 'word', insertion=RSK.rules.dualRSK)
```

```
[[1, 2, 3, 4], [1, 2, 1, 2]]
word: 1212
```

In general for dual RSK:

```sage
p = Tableau([[1,1,2],[1]])
q = Tableau([[1,3,3],[2]])
RSK_inverse(p, q, insertion=RSK.rules.dualRSK)
RSK_inverse(p, q, 'matrix', insertion=RSK.rules.dualRSK)
```

```
[[1, 2, 3, 3], [1, 1, 1, 2]]
[1 0]
[1 0]
[1 1]
```

`insertion(j, r)`

Insert the letter $j$ from the second row of the biword into the row $r$ using dual RSK insertion, if there is bumping to be done. The row $r$ is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

**EXAMPLES:**

```sage
from sage.combinat.rsk import RuleDualRSK
r = [1, 3, 4, 5]
j = RuleDualRSK().insertion(4, r);
j
```

```
4
```

```sage
r = [1, 3, 4, 5]
j = RuleDualRSK().insertion(4, r);
j
```

```
6
```

`reverse_insertion(x, row)`

Reverse bump the row $row$ of the current insertion tableau with the number $x$ using dual RSK insertion. The row $row$ is modified in place. The bumped-out entry is returned.

**EXAMPLES:**

```sage
from sage.combinat.rsk import RuleDualRSK
r = [1, 3, 4, 5]
x = RuleDualRSK().reverse_insertion(6, r); r
```

```
[1, 2, 3, 4, 7]
```

```sage
r = [1, 3]
```

```
[1, 3]
```

```sage
x = RuleDualRSK().reverse_insertion(6, r); r
```

```
[1, 2, 4, 6, 7]
```

```sage: x
```

```
[1, 2, 4, 6, 7]
```
sage: r = [1, 2, 4, 5, 7]
sage: x = RuleDualRSK().reverse_insertion(6, r); r
[1, 2, 4, 6, 7]
sage: x
5
to_pairs(obj1=None, obj2=None, check=True)

Given a valid input for the dual RSK algorithm, such as two \( n \)-tuples \( \text{obj1} = [a_1, a_2, \ldots, a_n] \) and \( \text{obj2} = [b_1, b_2, \ldots, b_n] \) forming a strict biword (i.e., satisfying \( a_1 \leq a_2 \leq \cdots \leq a_n \), and if \( a_i = a_{i+1} \), then \( b_i < b_{i+1} \)) or a \( \{0, 1\} \)-matrix (“rook placement”), or a single word, return the array \([(a_1, b_1), (a_2, b_2), \ldots, (a_n, b_n)]\).

INPUT:

- \text{obj1, obj2} – anything representing a strict biword (see the doc of forward_rule() for the encodings accepted)
- \text{check} – (default: True) whether to check that \text{obj1} and \text{obj2} actually define a valid strict biword

EXAMPLES:

sage: from sage.combinat.rsk import RuleDualRSK
sage: list(RuleDualRSK().to_pairs([1, 2, 2, 2], [2, 1, 2, 3]))
[(1, 2), (2, 1), (2, 2), (2, 3)]
sage: RuleDualRSK().to_pairs([1, 2, 2, 2], [1, 2, 3, 3])
Traceback (most recent call last):
  ... ValueError: invalid strict biword
sage: m = Matrix(ZZ, 3, 2, [0,1,1,1,0,1]) ; m
[0 1]
[1 1]
[0 1]
sage: list(RuleDualRSK().to_pairs(m))
[(1, 2), (2, 1), (2, 2), (3, 2)]
sage: m = Matrix(ZZ, 3, 2, [0,1,1,0,0,2]) ; m
[0 1]
[1 0]
[0 2]
sage: RuleDualRSK().to_pairs(m)
Traceback (most recent call last):
  ... ValueError: dual RSK requires a \{0, 1\}-matrix

class sage.combinat.rsk.RuleEG

Bases: sage.combinat.rsk.Rule

Rule for Edelman-Greene insertion.

For a reduced word of a permutation (i.e., an element of a type \( A \) Coxeter group), one can use Edelman-Greene insertion, an algorithm defined in [EG1987] Definition 6.20 (where it is referred to as Coxeter-Knuth insertion). The Edelman-Greene insertion is similar to the standard row insertion except that (using the notations in the documentation of RSK()) if \( k_i \) and \( k_i + 1 \) both exist in row \( i \), we only set \( k_{i+1} = k_i + 1 \) and continue.

EXAMPLES:

Let us reproduce figure 6.4 in [EG1987]:

5.1. Comprehensive Module List 2681
The RSK algorithm \((\text{RSK}())\) built using the Edelman-Greene insertion rule \text{RuleEG} is a bijection from reduced words of permutations/elements of a type \(A\) Coxeter group to pairs consisting of an increasing tableau and a standard tableau of the same shape (see [EG1987] Theorem 6.25). The inverse of this bijection is obtained using \(\text{RSK\_inverse()}.\) If the optional parameter \text{output = 'permutation'}\ is set in \(\text{RSK\_inverse()}.\) then the function returns not the reduced word itself but the permutation (of smallest possible size) whose reduced word it is (although the order of the letters is reverse to the usual Sage convention):

```python
sage: w = RSK_inverse("pq", insertion=RSK.rules.EG, output='permutation'); w
[4, 3, 1, 2]
sage: list(reversed(a)) in w.reduced_words()
True
```

**insertion**\((j, r)\)

Insert the letter \(j\) from the second row of the biword into the row \(r\) using Edelman-Greene insertion, if there is bumping to be done.

The row \(r\) is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

**EXAMPLES:**

```python
sage: from sage.combinat.rsk import RuleEG
sage: qr, r = [1,2,3,4,5], [3,3,2,4,8]
sage: j = RuleEG().insertion(9, r)
sage: j is None
True
sage: qr, r = [1,2,3,4,5], [2,3,4,5,8]
sage: j = RuleEG().insertion(3, r); r
[2, 3, 4, 5, 8]
sage: j
4
sage: qr, r = [1,2,3,4,5], [2,3,5,5,8]
sage: j = RuleEG().insertion(3, r); r
[2, 3, 3, 5, 8]
sage: j
5
```

**reverse_insertion**\((x, row)\)

Reverse bump the row \(row\) of the current insertion tableau with the number \(x.\)

The row \(row\) is modified in place. The bumped-out entry is returned.

**EXAMPLES:**
sage: from sage.combinat.rsk import RuleEG
sage: r = [1,1,1,2,3,3]
sage: x = RuleEG().reverse_insertion(3, r); r
[1, 1, 1, 2, 3, 3]
sage: x
2

class sage.combinat.rsk.RuleHecke
Bases: sage.combinat.rsk.Rule

Rule for Hecke insertion.

The Hecke RSK algorithm is similar to the classical RSK algorithm, but is defined using the Hecke insertion introduced in [BKSTY06] (but using rows instead of columns). It is not clear in what generality it works; thus, following [BKSTY06], we shall assume that our biword \( p \) has top row \((1, 2, \ldots, n)\) (or, at least, has its top row strictly increasing).

The Hecke RSK algorithm returns a pair of an increasing tableau and a set-valued standard tableau. If \( p = ((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1})) \), then the algorithm recursively constructs pairs \((P_0, Q_0), (P_1, Q_1), \ldots, (P_\ell, Q_\ell)\) of tableaux. The construction of \( P_{t+1} \) and \( Q_{t+1} \) from \( P_t, Q_t, j_t \) and \( k_t \) proceeds as follows: Set \( i = j_t \), \( x = k_t \), \( P = P_t \) and \( Q = Q_t \). We are going to insert \( x \) into the increasing tableau \( P \) and update the set-valued “recording tableau” \( Q \) accordingly. As in the classical RSK algorithm, we first insert \( x \) into row 1 of \( P \), then into row 2 of the resulting tableau, and so on, until the construction terminates.

The details are different: Suppose we are inserting \( x \) into row \( R \) of \( P \). If (Case 1) there exists an entry \( y \) in row \( R \) such that \( x < y \), then let \( y \) be the minimal such entry. We replace this entry \( y \) with \( x \) if the result is still an increasing tableau; in either subcase, we then continue recursively, inserting \( y \) into the next row of \( P \). If, on the other hand, (Case 2) no such \( y \) exists, then we append \( x \) to the end of \( R \) if the result is an increasing tableau (Subcase 2.1), and otherwise (Subcase 2.2) do nothing. Furthermore, in Subcase 2.1, we add the box that we have just filled with \( x \) in \( P \) to the shape of \( Q \), and fill it with the one-element set \( \{i\} \). In Subcase 2.2, we find the bottommost box of the column containing the rightmost box of row \( R \), and add \( i \) to the entry of \( Q \) in this box (this entry is a set, since \( Q \) is set-valued). In either subcase, we terminate the recursion, and set \( P_{t+1} = P \) and \( Q_{t+1} = Q \).

Notice that set-valued tableaux are encoded as tableaux whose entries are tuples of positive integers; each such tuple is strictly increasing and encodes a set (namely, the set of its entries).

EXAMPLES:
As an example of Hecke insertion, we reproduce Example 2.1 in arXiv 0801.1319v2:

```
sage: w = [5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: P,Q = RSK(w, insertion=RSK.rules.Hecke); [P,Q]
[[[1, 2, 4, 5], [2, 4, 5], [3, 5], [4], [5]],
 [[(1,), (4,), (5,), (7,)],
  [(2,), (9,), (11, 13)],
  [(3,), (12,)],
  [(6,)],
  [(8, 10)]]]
sage: wp = RSK_inverse(P, Q, insertion=RSK.rules.Hecke, ....:
  output='list'); wp
[5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: wp == w
True
```

backward_rule(p, q, output)

Return the generalized permutation obtained by applying reverse Hecke insertion to a pair of tableaux \((p, q)\).
INPUT:

• p, q – two tableaux of the same shape

• output – (default: 'array') if q is semi-standard:
  • 'array' – as a two-line array (i.e. generalized permutation or biword)

and if q is standard set-valued, we can have the output:

• 'word' – as a word

• 'list' – as a list

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleHecke
sage: t1 = Tableau([[1, 4], [2], [3]])
sage: t2 = Tableau([[1, 2], (4,)], [(3,)], [(5,)])
sage: RuleHecke().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [3, 3, 2, 4, 1]]
sage: t1 = Tableau([[1, 4], [2, 3]])
sage: t2 = Tableau([[1, 2], (4,)], [(3,)], [(5,)])
sage: RuleHecke().backward_rule(t1, t2, 'array')
Traceback (most recent call last):
  ... ValueError: p(=[[1, 4], [2, 3]]) and q(=[[1, 2], (4,), [(3,), [(5,)]]) must have the same shape
```

forward_rule(obj1, obj2, check_standard=False)

Return a pair of tableaux obtained by applying Hecke insertion to the generalized permutation [obj1, obj2].

INPUT:

• obj1, obj2 – can be one of the following ways to represent a generalized permutation (or, equivalently, biword):
  • two lists obj1 and obj2 of equal length, to be interpreted as the top row and the bottom row of the biword
  • a word obj1 in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, obj2 is None; the top row of the biword is understood to be (1, 2, ..., n) by default)

• check_standard – (default: False) check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleHecke
sage: p, q = RuleHecke().forward_rule([3,3,2,4,1], None); p
[[1, 4], [2], [3]]
sage: q
[[1, 2], (4,), [(3,), [(5,)]]]
sage: isinstance(p, SemistandardTableau)
True
sage: isinstance(q, Tableau)
True
```
**insertion**($j, ir, r, p$)

Insert the letter $j$ from the second row of the biword into the row $r$ of the increasing tableau $p$ using Hecke insertion, provided that $r$ is the $ir$-th row of $p$, and provided that there is bumping to be done.

The row $r$ is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

**EXAMPLES:**

```python
sage: from sage.combinat.rsk import RuleHecke
sage: from bisect import bisect_right
sage: p, q, r = [], [], [3,3,8,8,8,9]
sage: j, ir = 8, 1
sage: j1 = RuleHecke().insertion(j, ir, r, p)
sage: j1 == r[bisect_right(r, j)]
True
```

**reverse_insertion**($i, x, row, p$)

Reverse bump the row $row$ of the current insertion tableau $p$ with the number $x$, provided that $row$ is the $i$-th row of $p$.

The row $row$ is modified in place. The bumped-out entry is returned.

**EXAMPLES:**

```python
sage: from sage.combinat.rsk import RuleHecke
sage: from bisect import bisect_left
sage: r = [2,3,3,4,8,9]

sage: x, i, p = 9, 1, [1, 2]

sage: x1 = RuleHecke().reverse_insertion(i, x, r, p)

sage: x1 == r[bisect_left(r,x) - 1]
True
```

**class** sage.combinat.rsk.RuleRSK

Bases: sage.combinat.rsk.Rule

Rule for the classical Robinson-Schensted-Knuth insertion.

See RSK() for the definition of this operation.

**EXAMPLES:**

```python
sage: RSK([[1, 2], [2], [2], [2]], [[1, 1, 2], [2], [2]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]

sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,2],[2]])

sage: RSK_inverse(p, q, insertion=RSK.rules.RSK)
[[[1, 2, 3, 3], [2, 1, 2, 2]]]
```

**insertion**($j, r$)

Insert the letter $j$ from the second row of the biword into the row $r$ using classical Schensted insertion, if there is bumping to be done.

The row $r$ is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

**EXAMPLES:**

```python
sage: from sage.combinat.rsk import RuleRSK

sage: qr, r = [1,2,3,4,5], [3,3,2,4,8]

sage: j = RuleRSK().insertion(9, r)
```

(continues on next page)
reverse_insertion\((x, \text{row})\)
Reverse bump the row \(\text{row}\) of the current insertion tableau with the number \(x\).

The row \(\text{row}\) is modified in place. The bumped-out entry is returned.

EXAMPLES:

```python
sage: from sage.combinat.rsk import RuleRSK
sage: r = [2,3,3,4,8]
sage: x = RuleRSK().reverse_insertion(4, r); r
[2, 3, 4, 4, 8]
sage: x
3
```

class sage.combinat.rsk.RuleStar
Bases: sage.combinat.rsk.Rule
Rule for \(\star\)-insertion.

The \(\star\)-insertion is similar to the classical RSK algorithm and is defined in [MPPS2020]. The bottom row of the increasing Hecke biword is a word in the 0-Hecke monoid that is fully commutative. When inserting a letter \(x\) into a row \(R\), there are three cases:

- Case 1: If \(R\) is empty or \(x > \max(R)\), append \(x\) to row \(R\) and terminate.
- Case 2: Otherwise if \(x\) is not in \(R\), locate the smallest \(y\) in \(R\) with \(y > x\). Bump \(y\) with \(x\) and insert \(y\) into the next row.
- Case 3: Otherwise, if \(x\) is in \(R\), locate the smallest \(y\) in \(R\) with \(y \leq x\) and interval \([y, x]\) contained in \(R\). Row \(R\) remains unchanged and \(y\) is to be inserted into the next row.

The \(\star\)-insertion returns a pair consisting a conjugate of a semistandard tableau and a semistandard tableau. It is a bijection from the collection of all increasing Hecke biwords whose bottom row is a fully commutative word to pairs \((P, Q)\) of tableaux of the same shape such that \(P\) is conjugate semistandard, \(Q\) is semistandard and the row reading word of \(P\) is fully commutative [MPPS2020].

EXAMPLES:
As an example of \(\star\)-insertion, we reproduce Example 28 in [MPPS2020]:

```python
sage: from sage.combinat.rsk import RuleStar
sage: p,q = RuleStar().forward_rule([1,1,2,2,4,4], [1,3,2,4,2,4])
sage: ascii_art(p, q)
1 2 4 1 1 2
1 4 2 4
3 4
sage: line1,line2 = RuleStar().backward_rule(p, q)
sage: line1,line2
([1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4])
sage: RSK_inverse(p, q, output='DecreasingHeckeFactorization', insertion='Star')
```
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorization

sage: h = DecreasingHeckeFactorization([[4, 2], [], [4, 2], [3, 1]])
sage: RSK_inverse("RSK(h,insertion='Star'), insertion='Star',...:
output='DecreasingHeckeFactorization')
((4, 2)(4, 2)(3, 1))
sage: p, q = RSK(h, insertion='Star')

sage: ascii_art(p, q)
1 2 4 1 1 2
1 4 2 4
3 4

sage: RSK_inverse(p, q, insertion='Star')
[[1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4]]
sage: f = RSK_inverse(p, q, output='DecreasingHeckeFactorization', insertion='Star')
sage: f == h
True

**Warning:** When output is set to 'DecreasingHeckeFactorization', the inverse of \(-\)-insertion of \((P, Q)\) returns a decreasing factorization whose number of factors is the maximum entry of \(Q\):

sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorization

sage: h1 = DecreasingHeckeFactorization([[],[3,1],[1]]); h1
((3, 1)(1))
sage: P, Q = RSK(h1, insertion='Star')

sage: ascii_art(P, Q)
1 3 1 2
1 2

sage: h2 = RSK_inverse(P, Q, insertion='Star',....:
output='DecreasingHeckeFactorization'); h2
((3, 1)(1))

backward_rule(p, q, output='array')
Return the increasing Hecke biword obtained by applying reverse \(+\)-insertion to a pair of tableaux \((p, q)\).

**INPUT:**

- \(p, q\) – two tableaux of the same shape, where \(p\) is the conjugate of a semistandard tableau, whose reading word is fully commutative and \(q\) is a semistandard tableau.
- \(output\) – (default: 'array') if \(q\) is semi-standard:
  - 'array' – as a two-line array (i.e. generalized permutation or biword) that is an increasing Hecke biword
  - 'DecreasingHeckeFactorization' – as a decreasing factorization in the 0-Hecke monoid and if \(q\) is standard:
    - 'word' – as a (possibly non-reduced) word in the 0-Hecke monoid
**Warning:** When output is 'DecreasingHeckeFactorization', the number of factors in the output is the largest number in obj1.

**EXAMPLES:**

```python
sage: from sage.combinat.rsk import RuleStar
sage: p,q = RuleStar().forward_rule([1,1,2,2,4,4], [1,3,2,4,2,4])
sage: ascii_art(p, q)
    1 2 4 1 1 2
    1 4 2 4
    3 4
sage: line1,line2 = RuleStar().backward_rule(p, q); line1,line2
([1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4])
sage: RuleStar().backward_rule(p, q, output = 'DecreasingHeckeFactorization')
(4, 2)(4, 2)(3, 1)
```

**forward_rule**(obj1, obj2=None, check_braid=True)

Return a pair of tableaux obtained by applying forward insertion to the increasing Hecke biword [obj1, obj2].

**INPUT:**

- obj1, obj2 – can be one of the following ways to represent a biword (or, equivalently, an increasing 0-Hecke factorization) that is fully commutative:
  - two lists obj1 and obj2 of equal length, to be interpreted as the top row and the bottom row of the biword.
  - a word obj1 in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, obj2 is None; the top row of the biword is understood to be (1, 2, ..., n) by default).
  - a DecreasingHeckeFactorization obj1, the whose increasing Hecke biword will be interpreted as the bottom row; the top row is understood to be the indices of the factors for each letter in this biword.

- check_braid – (default: True) indicator to validate that input is associated to a fully commutative word in the 0-Hecke monoid; validation is performed if set to True; otherwise, this validation is ignored.

**EXAMPLES:**

```python
sage: from sage.combinat.rsk import RuleStar
sage: p,q = RuleStar().forward_rule([1,1,2,3,3], [2,3,3,1,3]); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])
```

**insertion**(b, r)

Insert the letter b from the second row of the biword into the row r using ⋆-insertion defined in [MPPS2020].
The row $r$ is modified in place if bumping occurs and $b$ is not in row $r$. The bumped-out entry, if it exists, is returned.

**EXAMPLES:**

```python
sage: from sage.combinat.rsk import RuleStar
sage: RuleStar().insertion(3, [1,2,4,5])
4
sage: RuleStar().insertion(3, [1,2,3,5])
1
sage: RuleStar().insertion(6, [1,2,3,5]) is None
True
```

**reverse_insertion**$(x, r)$

Reverse bump the row $r$ of the current insertion tableau $p$ with number $x$, provided that $r$ is the $i$-th row of $p$.

The row $r$ is modified in place. The bumped-out entry is returned.

**EXAMPLES:**

```python
sage: from sage.combinat.rsk import RuleStar
sage: RuleStar().reverse_insertion(4, [1,2,3,5])
3
sage: RuleStar().reverse_insertion(1, [1,2,3,5])
3
sage: RuleStar().reverse_insertion(5, [1,2,3,5])
5
```

**class** `sage.combinat.rsk.RuleSuperRSK`

Bases: `sage.combinat.rsk.RuleRSK`

Rule for super RSK insertion.

Super RSK is based on $\epsilon$-insertion, a combination of row and column classical RSK insertion.

Super RSK insertion differs from the classical RSK insertion in the following ways:

- The input (in terms of biwords) is no longer an arbitrary biword, but rather a restricted super biword (i.e., a pair of two lists $[a_1, a_2, \ldots, a_n]$ and $[b_1, b_2, \ldots, b_n]$ that contains entries with even and odd parity and pairs with mixed parity entries do not repeat).

- The output still consists of two tableaux $(P, Q)$ of equal shapes, but rather than both of them being semistandard, now they are semistandard super tableaux.

- The main difference is in the way bumping works. Instead of having only row bumping super RSK uses $\epsilon$-insertion, a combination of classical RSK bumping along the rows and a dual RSK like bumping (i.e. when a number $k_i$ is inserted into the $i$-th row of $P$, it bumps out the first integer greater or equal to $k_i$ in the column) along the column.

**EXAMPLES:**

```python
sage: RSK([[1], [1]], insertion='superRSK')
[[[1], [1]]]

sage: RSK([[1, 2], [1, 3], insertion='superRSK'])
[[[1], [1, 2]]]

sage: RSK([[1, 2, 3], [1, 3, "3p"], insertion='superRSK'])
[[[1, 3], [3]], [[1, 2], [3]]]

sage: RSK([[1, 3, "3p", "2p"], insertion='superRSK'])

(continues on next page)
We apply super RSK on Example 5.1 in [Muth2019]:

\[
\begin{align*}
\text{sage: } & P, Q = \text{RSK}(\text{["1p", "2p", 2, 2, "3p", "3p", 3, 3]}, \text{["3p", 1, 2, 3, "3p", "3p", "2p", "1p"]}, \\
& \quad \quad \quad \quad \text{insertion='superRSK')} \\
\end{align*}
\]

Example 6.1 in [Muth2019]:

\[
\begin{align*}
& \quad \quad \quad \quad \text{insertion='superRSK')} \\
\end{align*}
\]

Let us now call the inverse correspondence:

\[
\begin{align*}
\text{sage: } & P, Q = \text{RSK_inverse}(P, Q, \text{insertion=RSK.rules.superRSK}) \\
\end{align*}
\]

When applied to two tableaux with only even parity elements, reverse super RSK insertion behaves identically to the usual reverse RSK insertion:
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, insertion=RSK.rules.RSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: t1 = SemistandardSuperTableau([[1, 2, 5], [3], [4]])
sage: t2 = SemistandardSuperTableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, insertion=RSK.rules.superRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]

backward_rule(p, q, output='array')

Return the restricted super biword obtained by applying reverse super RSK insertion to a pair of tableaux (p, q).

INPUT:

• p, q – two tableaux of the same shape
• output – (default: 'array') if q is row-strict:
  – 'array' – as a two-line array (i.e. restricted super biword)
  and if q is standard, we can have the output:
  – 'word' – as a word

EXAMPLES:

sage: from sage.combinat.rsk import RuleSuperRSK
sage: t1 = SemistandardSuperTableau([[1, 2, 5], [3], [4]])
sage: t2 = SemistandardSuperTableau([[1, 2, 3], [4], [5]])
sage: RuleSuperRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: t1 = SemistandardSuperTableau([[1, 3], [3]])
sage: t2 = SemistandardSuperTableau([[1, 2], [3]])
sage: RuleSuperRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3], [1, 3, 3]]

forward_rule(obj1, obj2, check_standard=False, check=True)

Return a pair of tableaux obtained by applying forward insertion to the restricted super biword [obj1, obj2].

INPUT:

• obj1, obj2 – can be one of the following ways to represent a generalized permutation (or, equivalently, biword):
  – two lists obj1 and obj2 of equal length, to be interpreted as the top row and the bottom row of the biword
  – a word obj1 in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, obj2 is None; the top row of the biword is understood to be (1, 2, ..., n) by default)
  – any object obj1 which has a method _rsk_iter(), as long as this method returns an iterator yielding pairs of numbers, which then are interpreted as top entries and bottom entries in the biword (in this case, obj2 is None)
• check_standard – (default: False) check if either of the resulting tableaux is a standard super tableau, and if so, typecast it as such
• check – (default: True) whether to check that obj1 and obj2 actually define a valid restricted super biword
Combinatorics, Release 9.7

EXAMPLES:

```python
sage: from sage.combinat.rsk import RuleSuperRSK
sage: p, q = RuleSuperRSK().forward_rule([1, 2], [1, 3]); p
[[1, 3]]
sage: q
[[1, 2]]
sage: isinstance(p, SemistandardSuperTableau)
True
sage: isinstance(q, SemistandardSuperTableau)
True
```

`insertion(j, r, epsilon=0)`

Insert the letter `j` from the second row of the biword into the row `r` using dual RSK insertion or classical Schensted insertion depending on the value of `epsilon`, if there is bumping to be done.

The row `r` is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```python
sage: from sage.combinat.rsk import RuleSuperRSK
sage: from bisect import bisect_left, bisect_right
sage: r = [1, 3, 3, 3, 4]
sage: j = 3
sage: j, y_pos = RuleSuperRSK().insertion(j, r, epsilon=0); r
[1, 3, 3, 3, 3]
sage: j
4
sage: y_pos
4
sage: r = [1, 3, 3, 3, 4]
sage: j = 3
sage: j, y_pos = RuleSuperRSK().insertion(j, r, epsilon=1); r
[1, 3, 3, 3, 4]
sage: j
3
sage: y_pos
1
```

`reverse_insertion(x, row, epsilon=0)`

Reverse bump the row `row` of the current insertion tableau with the number `x` using dual RSK insertion or classical Schensted insertion depending on the value of `epsilon`.

The row `row` is modified in place. The bumped-out entry is returned along with the bumped position.

EXAMPLES:

```python
sage: from sage.combinat.rsk import RuleSuperRSK
sage: from bisect import bisect_left, bisect_right
sage: r = [1, 3, 3, 3, 4]
sage: j = 2
sage: j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=0); r
[2, 3, 3, 3, 4]
sage: j
1
sage: y
```

(continues on next page)
Combinatorics, Release 9.7
(continued from previous page)

sage: r = [1, 3, 3, 3, 4]
sage: j = 3
sage: j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=0); r
[3, 3, 3, 3, 4]
sage: j
1
sage: y
0
sage: r = [1, 3, 3, 3, 4]
sage: j = (3)
sage: j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=1); r
[1, 3, 3, 3, 4]
sage: j
3
sage: y
3
to_pairs(obj1=None, obj2=None, check=True)
Given a valid input for the super RSK algorithm, such as two \( n \)-tuples \( \text{obj1} = [a_1, a_2, \ldots, a_n] \) and \( \text{obj2} = [b_1, b_2, \ldots, b_n] \) forming a restricted super biword (i.e., entries with even and odd parity and no repetition of corresponding pairs with mixed parity entries) return the array \([(a_1, b_1), (a_2, b_2), \ldots, (a_n, b_n)]\).

INPUT:

* \text{obj1, obj2} – anything representing a restricted super biword (see the doc of \text{forward_rule()} for the encodings accepted)
* \text{check} – (default: \text{True}) whether to check that \text{obj1} and \text{obj2} actually define a valid restricted super biword

EXAMPLES:

sage: from sage.combinat.rsk import RuleSuperRSK
sage: list(RuleSuperRSK().to_pairs([2, '1p', 1],[1, 1, '1p']))
[(2, 1), ('1p', 1), (1, '1p')]
sage: list(RuleSuperRSK().to_pairs([1, '1p', '2p']))
[(1, '1p'), ('2p', '1p')]
sage: list(RuleSuperRSK().to_pairs([1, 1], ['1p', '1p']))
Traceback (most recent call last):
... ValueError: invalid restricted superbiword

sage.combinat.rsk.robinson_schensted_knuth(obj1=None, obj2=None, insertion=<class 'sage.combinat.rsk.RuleRSK'>, check_standard=False, **options)
Perform the Robinson-Schensted-Knuth (RSK) correspondence.

The Robinson-Schensted-Knuth (RSK) correspondence (also known as the RSK algorithm) is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, ...) and pairs of semi-standard Young tableaux \((P, Q)\) of identical shape. The tableau \(P\) is known as the insertion tableau, and \(Q\) is known as the recording tableau.

The basic operation is known as row insertion \(P \leftarrow k\) (where \(P\) is a given semi-standard Young tableau, and \(k\) is an integer). Row insertion is a recursive algorithm which starts by setting \(k_0 = k\), and in its \(i\)-th step inserts the number \(k_i\) into the \(i\)-th row of \(P\) (we start counting the rows at 0) by replacing the first integer greater than
Now the RSK algorithm, applied to a generalized permutation encoded as a lexicographically sorted list of pairs) starts by initializing two semi-standard tableaux $P_0$ and $Q_0$ as empty tableaux. For each nonnegative integer $t$ starting at 0, take the pair $(j_t, k_t)$ from $p$ and set $P_{t+1} = P_t \leftarrow k_t$, and define $Q_{t+1}$ by adding a new box filled with $j_t$ to the tableau $Q_t$ at the same location the row insertion on $P_t$ ended (that is to say, adding a new box with entry $j_t$ such that $P_{t+1}$ and $Q_{t+1}$ have the same shape). The iterative process stops when $t$ reaches the size of $p$, and the pair $(P_t, Q_t)$ at this point is the image of $p$ under the Robinson-Schensted-Knuth correspondence.

This correspondence has been introduced in [Knu1970], where it has been referred to as “Construction A.”

For more information, see Chapter 7 in [Sta-EC2].

We also note that integer matrices are in bijection with generalized permutations. Furthermore, we can convert any word $w$ (and, in particular, any permutation) to a generalized permutation by considering the top row to be $(1, 2, \ldots, n)$ where $n$ is the length of $w$.

The optional argument insertion allows to specify an alternative insertion procedure to be used instead of the standard Robinson-Schensted-Knuth insertion.

**INPUT:**

- obj1, obj2 – can be one of the following:
  - a word in an ordered alphabet (in this case, obj1 is said word, and obj2 is None)
  - an integer matrix
  - two lists of equal length representing a generalized permutation (namely, the lists $(j_0, j_1, \ldots, j_{\ell-1})$ and $(k_0, k_1, \ldots, k_{\ell-1})$ represent the generalized permutation $((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$
  - any object which has a method _rsk_iter() which returns an iterator over the object represented as generalized permutation or a pair of lists (in this case, obj1 is said object, and obj2 is None).

- insertion – (default: RSK.rules.RSK) the following types of insertion are currently supported:
  - RSK.rules.RSK (or 'RSK') – Robinson-Schensted-Knuth insertion (RuleRSK)
  - RSK.rules.EG (or 'EG') – Edelman-Greene insertion (only for reduced words of permutations/elements of a type $A$ Coxeter group) (RuleEG)
  - RSK.rules.Hecke (or 'hecke') – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) (RuleHecke)
  - RSK.rules.dualRSK (or 'dualRSK') – Dual RSK insertion (only for strict biwords) (RuleDualRSK)
  - RSK.rules.coRSK (or 'coRSK') – CoRSK insertion (only for strict cobiwords) (RuleCoRSK)
  - RSK.rules.superRSK (or 'super') – Super RSK insertion (only for restricted super biwords) (RuleSuperRSK)
  - RSK.rules.Star (or 'Star') – insertion (only for fully commutative words in the 0-Hecke monoid) (RuleStar)

- check_standard – (default: False) check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such
For precise information about constraints on the input and output, as well as the definition of the algorithm (if it is not standard RSK), see the particular `Rule` class.

**EXAMPLES:**

If we only input one row, it is understood that the top row should be \((1, 2, \ldots, n)\):

```python
sage: RSK([3,3,2,4,1])
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([3,3,2,4,1]))
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([2,3,3,2,1,3,2,3]))
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
```

We can provide a generalized permutation:

```python
sage: RSK([1, 2, 2, 2], [2, 1, 1, 2])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
sage: RSK(Word([1,1,3,4,4]), [1,4,2,1,3])
[[[1, 1, 3], [2], [4]], [[1, 1, 4], [3], [4]]]
sage: RSK([1,3,3,4,4], Word([6,2,2,1,7]))
[[[1, 2, 7], [2], [6]], [[1, 3, 4], [3], [4]]]
```

We can provide a matrix:

```python
sage: RSK(matrix([[0,1],[2,1]]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

We can also provide something looking like a matrix:

```python
sage: RSK([[0,1],[2,1]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

There is also `RSK_inverse()` which performs the inverse of the bijection on a pair of semistandard tableaux. We note that the inverse function takes 2 separate tableaux as inputs, so to compose with `RSK()`, we need to use the python `*` on the output:

```python
sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 1, 1, 2]))
[[[1, 2, 2, 2], [2, 1, 1, 2]]]
sage: P,Q = RSK([1, 2, 2, 2], [2, 1, 1, 2])
sage: RSK_inverse(P, Q)
[[[1, 2, 2, 2], [2, 1, 1, 2]]]
```

```
sage.combinat.rsk.robinson_schensted_knuth_inverse(p, q, output='array', insertion=<class 'sage.combinat.rsk.RuleRSK'>)
```

Return the generalized permutation corresponding to the pair of tableaux \((p, q)\) under the inverse of the Robinson-Schensted-Knuth correspondence.

For more information on the bijection, see `RSK()`.

**INPUT:**

- \(p, q\) – two semi-standard tableaux of the same shape, or (in the case when Hecke insertion is used) an increasing tableau and a set-valued tableau of the same shape (see the note below for the format of the set-valued tableau)
- **output** – (default: `'array'`) if \(q\) is semi-standard:
  - `'array'` – as a two-line array (i.e. generalized permutation or biword)
- 'matrix' – as an integer matrix

and if q is standard, we can also have the output:
- 'word' – as a word

and additionally if p is standard, we can also have the output:
- 'permutation' – as a permutation

- insertion – (default: RSK.rules.RSK) the insertion algorithm used in the bijection. Currently the following are supported:
  - RSK.rules.RSK (or 'RSK') – Robinson-Schensted-Knuth insertion (RuleRSK)
  - RSK.rules.EG (or 'EG') – Edelman-Greene insertion (only for reduced words of permutations/elements of a type A Coxeter group) (RuleEG)
  - RSK.rules.Hecke (or 'hecke') – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) (RuleHecke)
  - RSK.rules.dualRSK (or 'dualRSK') – Dual RSK insertion (only for strict biwords) (RuleDualRSK)
  - RSK.rules.coRSK (or 'coRSK') – CoRSK insertion (only for strict cobiwords) (RuleCoRSK)
  - RSK.rules.superRSK (or 'super') – Super RSK insertion (only for restricted super biwords) (RuleSuperRSK)
  - RSK.rules.Star (or 'Star') – ⋆-insertion (only for fully commutative words in the 0-Hecke monoid) (RuleStar)

For precise information about constraints on the input and output, see the particular Rule class.

Note: In the case of Hecke insertion, the input variable q should be a set-valued tableau, encoded as a tableau whose entries are strictly increasing tuples of positive integers. Each such tuple encodes the set of its entries.

EXAMPLES:

If both p and q are standard:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word')
word: 14532
sage: RSK_inverse(t1, t2, 'matrix')
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: RSK_inverse(t1, t2, 'permutation')
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation')
[1, 4, 5, 3, 2]
sage: RSK_inverse(t2, t2, 'permutation')
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation')
[1, 5, 4, 2, 3]
```
If the first tableau is semistandard:

\begin{verbatim}
sage: p = Tableau([[1,2,2],[3]]); q = Tableau([[1,2,4],[3]])
sage: ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]
sage: RSK_inverse(p, q, 'word')
word: 1322
\end{verbatim}

In general:

\begin{verbatim}
sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: RSK_inverse(p, q)
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK_inverse(p, q, 'matrix')
\begin{bmatrix}
0 & 1
1 & 0
0 & 2
\end{bmatrix}
\end{verbatim}

Using Hecke insertion:

\begin{verbatim}
sage: w = [5, 4, 3, 1, 4, 2, 5, 5]
sage: pq = RSK(w, insertion=RSK.rules.Hecke)
sage: RSK_inverse(*pq, insertion=RSK.rules.Hecke, output='list')
[5, 4, 3, 1, 4, 2, 5, 5]
\end{verbatim}

**Note:** The constructor of Tableau accepts not only semistandard tableaux, but also arbitrary lists that are fillings of a partition diagram. (And such lists are used, e.g., for the set-valued tableau \( q \) that is passed to \( \text{RSK\_inverse}(p, q, \text{insertion}='\text{hecke}') \).) The user is responsible for ensuring that the tableaux passed to \( \text{RSK\_inverse} \) are of the right types (semistandard, standard, increasing, set-valued as needed).

\begin{verbatim}
sage.combinat.rsk.to_matrix(t, b)
Return the integer matrix corresponding to a two-line array.

INPUT:

* t – the top row of the array
* b – the bottom row of the array

OUTPUT:

An \( m \times n \)-matrix (where \( m \) and \( n \) are the maximum entries in \( t \) and \( b \) respectively) whose \((i, j)\)-th entry, for any \( i \) and \( j \), is the number of all positions \( k \) satisfying \( t_k = i \) and \( b_k = j \).

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.rsk import to_matrix
sage: to_matrix([1, 1, 3, 3, 4], [2, 3, 1, 1, 3])
\begin{bmatrix}
0 & 1 & 1
0 & 0 & 0
2 & 0 & 0
0 & 0 & 1
\end{bmatrix}
\end{verbatim}
\end{verbatim}
5.1.273 Schubert Polynomials

See Wikipedia article Schubert_polynomial and SymmetricFunctions.com. Schubert polynomials are representatives of cohomology classes in flag varieties. In \( n \) variables, they are indexed by permutations \( w \in S_n \). They also form a basis for the coinvariant ring of the \( S_n \) action on \( \mathbb{Z}[x_1, x_2, \ldots, x_n] \).

EXAMPLES:

```python
sage: X = SchubertPolynomialRing(ZZ)
sage: w = [1,2,5,4,3];  # a list representing an element of 'S_5'
sage: X(w)
X[1, 2, 5, 4, 3]
```

This can be expanded in terms of polynomial variables:

```python
sage: X(w).expand()
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2
  + x0^2*x2^2 + x1*x2^2 + x0^2*x3 + x0*x1*x3 + x1^2*x3
  + x0*x2*x3 + x1*x2*x3 + x2^2*x3
```

We can also convert back from polynomial variables. For example, the longest permutation is a single term. In \( S_5 \), this is the element (in one line notation) \( w_0 = 54321 \):

```python
sage: w0 = [5,4,3,2,1]
sage: R.<x0, x1, x2, x3, x4> = PolynomialRing(ZZ)
sage: Sw0 = X(x0^4*x1^3*x2^2*x3); Sw0
X[5, 4, 3, 2, 1]
```

The polynomials also have the property that if the indexing permutation \( w \) is multiplied by a simple transposition \( s_i = (i, i+1) \) such that the length of \( w \) is more than the length of \( w s_i \), then the Schubert polynomial of the permutation \( w s_i \) is computed by applying the divided difference operator \( \text{divided\_difference()} \) to the polynomial indexed by \( w \). For example, applying the divided difference operator \( \partial_2 \) to the Schubert polynomial \( x_0^5 x_1^3 \):

```python
sage: Sw0.divided_difference(2)
X[5, 3, 4, 2, 1]
```

We can also check the properties listed in Wikipedia article Schubert_polynomial:

```python
sage: X([[1,2,3,4,5]])  # the identity in one-line notation
X[1]
sage: X([[1,3,2,4,5]]).expand()  # the transposition swapping 2 and 3
x0 + x1
sage: X([[2,4,5,3,1]]).expand()
x0^2*x1^2*x2^2*x3 + x0^2*x1*x2^2*x3 + x0*x1^2*x2^2*x3
sage: w = [4,5,1,2,3]
sage: s = SymmetricFunctions(QQ).schur()
sage: s[3,3].expand(2)
x0^3*x1^3
sage: X(w).expand()
x0^3*x1^3
```

`sage.combinat.schubert_polynomial.SchubertPolynomialRing(R)`

Return the Schubert polynomial ring over \( R \) on the \( X \) basis.

This is the basis made of the Schubert polynomials.
EXAMPLES:

```python
sage: X = SchubertPolynomialRing(ZZ); X
Schubert polynomial ring with X basis over Integer Ring
sage: TestSuite(X).run()
sage: X(1)
X[1]
sage: X([1,2,3])*X([2,1,3])
X[2, 1]
sage: X([2,1,3])*X([2,1,3])
X[3, 1, 2]
sage: X([2,1,3])+X([3,1,2,4])
X[2, 1] + X[3, 1, 2]
sage: a = X([2,1,3])+X([3,1,2,4])
sage: a^2
X[3, 1, 2] + 2*X[4, 1, 2, 3] + X[5, 1, 2, 3, 4]
```

```python
class sage.combinat.schubert_polynomial.SchubertPolynomialRing_xbasis(R)
    Bases: sage.combinat.free_module.CombinatorialFreeModule

EXAMPLES:

sage: X = SchubertPolynomialRing(QQ)
sage: X == loads(dumps(X))
True
```

```python
Element
    alias of SchubertPolynomial_class

one_basis()
    Return the index of the unit of this algebra.

    EXAMPLES:

    ```python
    sage: X = SchubertPolynomialRing(QQ)
sage: X.one()  # indirect doctest
    X[1]
    ```

product_on_basis(left, right)

    EXAMPLES:

    ```python
    sage: p1 = Permutation([3,2,1])
sage: p2 = Permutation([2,1,3])
sage: X = SchubertPolynomialRing(QQ)
sage: X.product_on_basis(p1,p2)
x[4, 2, 1, 3]
    ```

some_elements()
    Return some elements.

    EXAMPLES:

    ```python
    sage: X = SchubertPolynomialRing(QQ)
sage: X.some_elements()
    [X[1], X[1] + 2*X[2, 1], -X[3, 2, 1] + X[4, 2, 1, 3]]
    ```
class sage.combinat.schubert_polynomial.SchubertPolynomial_class
Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

divided_difference(i, algorithm='sage')

Return the \( i \)-th divided difference operator, applied to self.

Here, \( i \) can be either a permutation or a positive integer.

INPUT:

- \( i \) – permutation or positive integer
- \( \text{algorithm} \) – (default: 'sage') either 'sage' or 'symmetrica'; this determines which software is called for the computation

OUTPUT:

The result of applying the \( i \)-th divided difference operator to self.

If \( i \) is a positive integer, then the \( i \)-th divided difference operator \( \delta_i \) is the linear operator sending each polynomial \( f = f(x_1, x_2, \ldots, x_n) \) (in \( n \geq i + 1 \) variables) to the polynomial

\[
\frac{f - f_i}{x_i - x_{i+1}}, \quad \text{where} \quad f_i = f(x_1, x_2, \ldots, x_{i-1}, x_{i+1}, x_i, x_{i+1}, \ldots, x_n).
\]

If \( \sigma \) is a permutation in the \( n \)-th symmetric group, then the \( \sigma \)-th divided difference operator \( \delta_\sigma \) is the composition \( \delta_{i_1} \delta_{i_2} \cdots \delta_{i_k} \), where \( \sigma = s_{i_1} \circ s_{i_2} \circ \cdots \circ s_{i_k} \) is any reduced expression for \( \sigma \) (the precise choice of reduced expression is immaterial).

Note: The \texttt{expand()} method results in a polynomial in \( n \) variables named \( x0, x1, \ldots, x(n-1) \) rather than \( x_1, x_2, \ldots, x_n \). The variable named \( xi \) corresponds to \( x_{i+1} \). Thus, \texttt{self.divided_difference(i)} involves the variables \( x(i-1) \) and \( xi \) getting switched (in the numerator).

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,1])
sage: a.divided_difference(1)
X[2, 3, 1]
sage: a.divided_difference([3,2,1])
X[1]
sage: a.divided_difference(5)
0
```

Any divided difference of 0 is 0:

```
sage: X.zero().divided_difference(2)
0
```

This is compatible when a permutation is given as input:

```
sage: a = X([3,2,4,1])
sage: a.divided_difference([2,3,1])
0
sage: a.divided_difference(1).divided_difference(2)
0
```
sage: a = X([4,3,2,1])
sage: a.divided_difference([2,3,1])
X[3, 2, 4, 1]
sage: a.divided_difference(1).divided_difference(2)
0
sage: b = X([4, 1, 3, 2])
sage: b.divided_difference(1).divided_difference(2)
X[1, 3, 4, 2]
sage: b.divided_difference(1).divided_difference(2).divided_difference(3).
˓→
0
sage: b.divided_difference(1).divided_difference(2).divided_difference(3).
˓→
0

expand()

EXAMPLES:

sage: X = SchubertPolynomialRing(ZZ)
sage: X([2,1,3]).expand()
x0
sage: [X(p).expand() for p in Permutations(3)]
[1, x0 + x1, x0, x0*x1, x0^2, x0^2*x1]

multiply_variable(i)

Return the Schubert polynomial obtained by multiplying self by the variable \(x_i\).

EXAMPLES:

sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,4,1])
sage: a.multiply_variable(0)
X[4, 2, 3, 1]
sage: a.multiply_variable(1)
X[3, 4, 2, 1]
sage: a.multiply_variable(2)
sage: a.multiply_variable(3)
X[3, 2, 4, 5, 1]

scalar_product(x)

Return the standard scalar product of self and x.

EXAMPLES:

sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,4,1])
sage: a.scalar_product(a)

(continues on next page)
0
sage: b = X([4,3,2,1])
sage: b.scalar_product(a)
X[1, 3, 4, 6, 2, 5]
sage: Permutation([1, 3, 4, 6, 2, 5]).to_lehmer_code()
[0, 1, 1, 2, 0, 0, 0]
sage: s = SymmetricFunctions(ZZ).schur()
sage: c = s([2,1,1])
sage: b.scalar_product(a).expand()
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3 + x0^2*x2*x3 +
→3*x0*x1*x2*x3 + x1^2*x2*x3 + x0*x2^2*x3 + x1*x2^2*x3 + x0*x1*x3^2 + x0*x2*x3^2
→2 + x1*x2*x3^2
sage: c.expand(4)
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3 + x0^2*x2*x3 +
→3*x0*x1*x2*x3 + x1^2*x2*x3 + x0*x2^2*x3 + x1*x2^2*x3 + x0*x1*x3^2 + x0*x2*x3^2
→2 + x1*x2*x3^2

5.1.274 Set Partitions

AUTHORS:

• Mike Hansen
• MuPAD-Combinat developers (for algorithms and design inspiration).
• Travis Scrimshaw (2013-02-28): Removed CombinatorialClass and added entry point through SetPartition.
• Martin Rubey (2017-10-10): Cleanup, add crossings and nestings, add random generation.

This module defines a class for immutable partitioning of a set. For mutable version see DisjointSet().

class sage.combinat.set_partition.AbstractSetPartition
Bases: sage.structure.list_clone.ClonableArray

Methods of set partitions which are independent of the base set

base_set()
Return the base set of self, which is the union of all parts of self.

EXAMPLES:

sage: SetPartition([[1, [2, 3], [4]]]).base_set()
{1, 2, 3, 4}
sage: SetPartition([[1,2,3,4]]).base_set()
{1, 2, 3, 4}
sage: SetPartition([]).base_set()
{}

base_set_cardinality()
Return the cardinality of the base set of self, which is the sum of the sizes of the parts of self.

This is also known as the size (sometimes the weight) of a set partition.

EXAMPLES:
sage: SetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
sage: SetPartition([[1,2,3,4]]).base_set_cardinality()
4

coarsenings()
Return a list of coarsenings of self.

See also:
refinements()

EXAMPLES:

sage: SetPartition([[1,3],[2,4]]).coarsenings()
[[{1, 2, 3, 4}, {1, 3}, {2, 4}]]
sage: SetPartition([[1],[2,4],[3]]).coarsenings()
[[{1, 2, 3, 4},
  {1, 2, 4}, {3}],
  {{1, 3}, {2, 4}},
  {{1}, {2, 3}, {4}},
  {{1}, {2, 4}, {3}}]
sage: SetPartition([]).coarsenings()
[{}]

conjugate()
An involution exchanging singletons and circular adjacencies.

This method implements the definition of the conjugate of a set partition defined in [Cal2005].

INPUT:
• self – a set partition of an ordered set

OUTPUT:
• a set partition

EXAMPLES:

sage: SetPartition([[1,6,7],[2,8],[3,4,5]]).conjugate()
{{1, 4, 7}, {2, 8}, {3}, {5}, {6}}
sage: all(sp.conjugate().conjugate()==sp for sp in SetPartitions([1,3,5,7]))
True
sage: SetPartition([]).conjugate()
{}

inf(other)
The product of the set partitions self and other.

The product of two set partitions $B$ and $C$ is defined as the set partition whose parts are the nonempty intersections between each part of $B$ and each part of $C$. This product is also the infimum of $B$ and $C$ in the classical set partition lattice (that is, the coarsest set partition which is finer than each of $B$ and $C$). Consequently, $\inf$ acts as an alias for this method.

See also:
sup()

EXAMPLES:
Combinatorics, Release 9.7

```python
sage: x = SetPartition([ [1,2], [3,5,4] ])
sage: y = SetPartition(( (3,1,2), (5,4) ))
sage: x * y
{{1, 2}, {3}, {4, 5}}
sage: S = SetPartitions(4)
sage: sp1 = S([[2,3,4], [1]])
sage: sp2 = S([[1,3], [2,4]])
sage: s = S([[2,4], [3], [1]])
sage: sp1.inf(sp2) == s
True
```

**max_block_size()**

The maximum block size of the diagram.

EXAMPLES:

```python
sage: from sage.combinat.diagram_algebras import PartitionDiagram,
    PartitionDiagrams
sage: pd = PartitionDiagram([[1,-3,-5],[2,4],[3,-1,-2],[5],[-4]])
sage: pd.max_block_size()
3
sage: sorted(d.max_block_size() for d in PartitionDiagrams(2))
[1, 2, 2, 2, 2, 2, 2, 2, 2, 2, 3, 3, 3, 3, 4]
sage: sorted(sp.max_block_size() for sp in SetPartitions(3))
[1, 2, 2, 2, 3]
```

**standard_form()**

Return self as a list of lists.

When the ground set is totally ordered, the elements of each block are listed in increasing order.

This is not related to standard set partitions (which simply means set partitions of \([n] = \{1,2,\ldots,n\}\) for some integer \(n\)) or standardization (standardization()).

EXAMPLES:

```python
sage: [x.standard_form() for x in SetPartitions(4, [2,2])]
[[[1, 2], [3, 4]], [[1, 4], [2, 3]], [[1, 3], [2, 4]]]
```

**sup()**

Return the supremum of self and t in the classical set partition lattice.

The supremum of two set partitions \(B\) and \(C\) is obtained as the transitive closure of the relation which relates \(i\) to \(j\) if and only if \(i\) and \(j\) are in the same part in at least one of the set partitions \(B\) and \(C\).

See also:

- __mul__()

EXAMPLES:

```python
sage: S = SetPartitions(4)
sage: sp1 = S([[2,3,4], [1]])
sage: sp2 = S([[1,3], [2,4]])
sage: s = S([[1,2,3,4]])
sage: sp1.sup(sp2) == s
True
```
class sage.combinat.set_partition.SetPartition(parent, s, check=True)

Bases: sage.combinat.set_partition.AbstractSetPartition

A partition of a set.

A set partition \( p \) of a set \( S \) is a partition of \( S \) into subsets called parts and represented as a set of sets. By extension, a set partition of a nonnegative integer \( n \) is the set partition of the integers from 1 to \( n \). The number of set partitions of \( n \) is called the \( n \)-th Bell number.

There is a natural integer partition associated with a set partition, namely the nonincreasing sequence of sizes of all its parts.

There is a classical lattice associated with all set partitions of \( n \). The infimum of two set partitions is the set partition obtained by intersecting all the parts of both set partitions. The supremum is obtained by transitive closure of the relation \( i \) related to \( j \) if and only if they are in the same part in at least one of the set partitions.

We will use terminology from partitions, in particular the length of a set partition \( A = \{A_1, \ldots, A_k\} \) is the number of parts of \( A \) and is denoted by \( |A| := k \). The size of \( A \) is the cardinality of \( S \). We will also sometimes use the notation \([n] := \{1, 2, \ldots, n\} \).

EXAMPLES:

There are 5 set partitions of the set \( \{1, 2, 3\} \):

\[\text{sage: SetPartitions(3).cardinality()}
\]
\[5\]

Here is the list of them:

\[\text{sage: SetPartitions(3).list()}
\]
\[
[\{\{1, 2, 3\}\}, \{\{1, 2\}, \{3\}\}, \{\{1, 3\}, \{2\}\}, \{\{1\}, \{2, 3\}\}, \{\{1\}, \{2\}, \{3\}\}]
\]

There are 6 set partitions of \( \{1, 2, 3, 4\} \) whose underlying partition is \([2, 1, 1]\):

\[\text{sage: SetPartitions(4, [2,1,1]).list()}
\]
\[
[\{\{1\}, \{2, 4\}, \{3\}\}, \{\{1\}, \{2\}, \{3, 4\}\}, \{\{1, 4\}, \{2\}, \{3\}\}, \{\{1, 3\}, \{2\}, \{4\}\}, \{\{1, 2\}, \{3\}, \{4\}\}, \{\{1\}, \{2, 3\}, \{4\}\}]
\]

Since trac ticket #14140, we can create a set partition directly by \texttt{SetPartition}, which creates the base set by taking the union of the parts passed in:

\[\text{sage: s = SetPartition([[1,3],[2,4]]); s}
\]
\[
\{\{1, 3\}, \{2, 4\}\}
\]
\[\text{sage: s.parent()}
\]
Set partitions

\texttt{apply\_permutation}(p)

Apply \( p \) to the underlying set of \texttt{self}.

INPUT:

\[\begin{itemize}
\item p – a permutation
\end{itemize}\]

EXAMPLES:
Combinatorics, Release 9.7

```
sage: x = SetPartition([[1,2], [3,5,4]])
sage: p = Permutation([2,1,4,5,3])
sage: x.apply_permutation(p)
{{1, 2}, {3, 4, 5}}
sage: q = Permutation([3,2,1,5,4])
sage: x.apply_permutation(q)
{{1, 4, 5}, {2, 3}}

sage: m = PerfectMatching([(1,4),(2,6),(3,5)])
sage: m.apply_permutation(Permutation([4,1,5,6,3,2]))
[(1, 2), (3, 5), (4, 6)]
```

**arcs()**
Return self as a list of arcs.
Assuming that the blocks are sorted, the arcs are the pairs of consecutive elements in the blocks.

**cardinality()**
Return the len of self

**check()**
Check that we are a valid set partition.

**closers()**
Return the maximal elements of the blocks.

**crossings()**
Return the crossing arcs of a set partition on a totally ordered set.

```python
sage: A = SetPartition([[1],[2,3],[4]])
sage: A.arcs()
[(2, 3)]
sage: B = SetPartition([[1,3,6,7],[2,5],[4]])
sage: B.arcs()
[(1, 3), (3, 6), (6, 7), (2, 5)]

sage: from sage.structure.list_clone_demo import IncreasingArrays
sage: len(IncreasingArrays()([1,2,3]))
3

sage: S = SetPartitions(4)
sage: s = S([[1, 3], [2, 4]])
sage: s.check()

sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: P.closers()
[7, 8, 9, 12, 13]
```
We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns a list of the pairs of crossing lines (as a line correspond to a pair, it returns a list of pairs of pairs).

**EXAMPLES:**

```
sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: p.crossings()
[((1, 4), (2, 5)), ((1, 4), (3, 6)), ((2, 5), (3, 6)), ((3, 6), (5, 7))]
```

**crossings_iterator()**

Return the crossing arcs of a set partition on a totally ordered set.

**OUTPUT:**

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns an iterator over the pairs of crossing lines (as a line correspond to a pair, the iterator produces pairs of pairs).

**EXAMPLES:**

```
sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: next(p.crossings_iterator())
((1, 4), (2, 5))
```

**is_atomic()**

Return if *self* is an atomic set partition.

A (standard) set partition $A$ can be split if there exist $j < i$ such that $\max(A_j) < \min(A_i)$ where $A$ is ordered by minimal elements. This means we can write $A = B | C$ for some nonempty set partitions $B$ and $C$. We call a set partition *atomic* if it cannot be split and is nonempty. Here, the pipe symbol $|$ is as defined in method *pipe()*.

**EXAMPLES:**

```
sage: SetPartition([[1,3], [2]]).is_atomic()
True
sage: SetPartition([[1,3], [2], [4]]).is_atomic()
False
sage: SetPartition([[1], [2,4], [3]]).is_atomic()
False
sage: SetPartition([[1,2,3,4]]).is_atomic()
True
sage: SetPartition([[1,4], [2], [3]]).is_atomic()
True
sage: SetPartition([]).is_atomic()
False
```

**is_noncrossing()**

Check if *self* is noncrossing.

**OUTPUT:**

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns *True* if the picture obtained this way has no crossings.

**EXAMPLES:**
```
sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: p.is_noncrossing()
False
```

```
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.is_noncrossing()
False
```

```
sage: PerfectMatching([(1, 4), (2, 3), (5, 6)]).is_noncrossing()
True
```

**is_nonnesting()**

Return if self is nonnesting or not.

**OUTPUT:**

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns True if the picture obtained this way has no nestings.

**EXAMPLES:**

```
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.is_nonnesting()
False
```

```
sage: PerfectMatching([(1, 3), (2, 5), (4, 6)]).is_nonnesting()
True
```

**latex_options()**

Return the latex options for use in the \_latex\_ function as a dictionary. The default values are set using the global options.

Options can be found in set\_latex\_options()

**EXAMPLES:**

```
sage: SP = SetPartition([[1,6], [3,5,4]]); SP.latex_options()
{'angle': 0,
 'color': 'black',
 'fill': False,
 'plot': None,
 'radius': '1cm',
 'show_labels': True,
 'tikz_scale': 1}
```

**nestings()**

Return the nestings of self.

**OUTPUT:**

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns the list of the pairs of nesting lines (as a line correspond to a pair, it returns a list of pairs of pairs).

**EXAMPLES:**
sage: m = PerfectMatching([(1, 6), (2, 7), (3, 5), (4, 8)])
sage: m.nestings()
[(1, 6), (3, 5), (2, 7), (3, 5)]

sage: n = PerfectMatching([3, 8, 1, 7, 6, 5, 4, 2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]

sage: n.nestings()
[(2, 8), (4, 7), (2, 8), (5, 6), (4, 7), (5, 6)]

nestings_iterator()
Iterate over the nestings of self.

OUTPUT:
We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns an iterator over the pairs of nesting lines (as a line correspond to a pair, the iterator produces pairs of pairs).

EXAMPLES:

sage: n = PerfectMatching([(1, 6), (2, 7), (3, 5), (4, 8)])
sage: it = n.nestings_iterator()
sage: next(it)
((1, 6), (3, 5))
sage: next(it)
((2, 7), (3, 5))

sage: next(it)
Traceback (most recent call last):
...  
StopIteration

number_of_crossings()
Return the number of crossings.

OUTPUT:
We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns the number the pairs of crossing lines.

EXAMPLES:

sage: p = SetPartition([[1, 4], [2, 5, 7], [3, 6]])
sage: p.number_of_crossings()
4

sage: n = PerfectMatching([3, 8, 1, 7, 6, 5, 4, 2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.number_of_crossings()
1

number_of_nestings()
Return the number of nestings of self.

OUTPUT:
We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns the number the pairs of nesting lines.
EXAMPLES:

```
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.number_of_nestings()
3
```

openers()
Return the minimal elements of the blocks.

EXAMPLES:

```
sage: P = SetPartition([1,2,4,7],[3,9],[5,6,10,11,13],[8],[12])
sage: P.openers()
[1, 3, 5, 8, 12]
```

ordered_set_partition_action(s)
Return the action of an ordered set partition s on self.

Let \( A = \{A_1, A_2, \ldots, A_k\} \) be a set partition of some set \( S \) and \( s \) be an ordered set partition (i.e., set composition) of a subset of \( [k] \). Let \( A^\dagger \) denote the standardization of \( A \), and \( A_{i_1, i_2, \ldots, i_m} \) denote the subpartition \( \{A_{i_1}, A_{i_2}, \ldots, A_{i_m}\} \) for any subset \( \{i_1, \ldots, i_m\} \) of \( \{1, \ldots, k\} \). We define the set partition \( s(A) \) by

\[
s(A) = A_{s_1}^\dagger | A_{s_2}^\dagger | \cdots | A_{s_q}^\dagger,
\]

where \( s = (s_1, s_2, \ldots, s_q) \). Here, the pipe symbol \( | \) is as defined in method pipe().

This is \( s[A] \) in section 2.3 in [LM2011].

INPUT:

- \( s \) – an ordered set partition with base set a subset of \( \{1, \ldots, k\} \)

EXAMPLES:

```
sage: A = SetPartition([[1], [2,4], [3]])
sage: s = OrderedSetPartition([[1,3], [2]])
sage: A.ordered_set_partition_action(s)
{{1}, {2}, {3, 4}}
sage: s = OrderedSetPartition([[2,3], [1]])
sage: A.ordered_set_partition_action(s)
{{1, 3}, {2}, {4}}
```

We create Figure 1 in [LM2011] (we note that there is a typo in the lower-left corner of the table in the published version of the paper, whereas the arXiv version gives the correct partition):

```
sage: A = SetPartition([[1,3], [2,9], [4,5,8], [7]])
sage: B = SetPartition([[1,3], [2,8], [4,5,6], [7]])
sage: C = SetPartition([[1,5], [2,8], [3,4,6], [7]])
sage: s = OrderedSetPartition([[1,3], [2]])
sage: t = OrderedSetPartition([[2], [3,4]])
sage: u = OrderedSetPartition([[1], [2,3,4]])
sage: A.ordered_set_partition_action(s)
{{1, 2}, {3, 4, 5}, {6, 7}}
sage: A.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 6}, {5}}
```
sage: A.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 7}, {6}}
sage: B.ordered_set_partition_action(s)
{{1, 2}, {3, 4, 5}, {6, 7}}
sage: B.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 5}, {6}}
sage: B.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 6}, {7}}
sage: C.ordered_set_partition_action(s)
{{1, 4}, {2, 3, 5}, {6, 7}}
sage: C.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 5}, {6}}
sage: C.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 6}, {7}}

REFERENCES:

• [LM2011]

pipe(self, other)

Return the pipe of the set partitions self and other.

The pipe of two set partitions is defined as follows:

For any integer $k$ and any subset $I$ of $\mathbb{Z}$, let $I + k$ denote the subset of $\mathbb{Z}$ obtained by adding $k$ to every element of $k$.

If $B$ and $C$ are set partitions of $[n]$ and $[m]$, respectively, then the pipe of $B$ and $C$ is defined as the set partition

$$\{B_1, B_2, \ldots, B_b, C_1 + n, C_2 + n, \ldots, C_c + n\}$$

of $[n + m]$, where $B = \{B_1, B_2, \ldots, B_b\}$ and $C = \{C_1, C_2, \ldots, C_c\}$. This pipe is denoted by $B|C$.

EXAMPLES:

sage: SetPartition([[1,3],[2,4]]).pipe(SetPartition([[1,3],[2]]))
{{1, 3}, {2, 4}, {5, 7}, {6}}
sage: SetPartition([]).pipe(SetPartition([[1,2],[3,5],[4]]))
{{1, 2}, {3, 5}, {4}}
sage: SetPartition([[1,2],[3,5],[4]]).pipe(SetPartition([]))
{{1, 2}, {3, 5}, {4}}
sage: SetPartition([[1,2],[3]]).pipe(SetPartition([[1]]))
{{1, 2}, {3}, {4}}

plot(angle=None, color='black', base_set_dict=None)

Return a plot of self.

INPUT:

• angle – (default: $\pi/4$) the angle at which the arcs take off (if angle is negative, the arcs are drawn below the horizontal line)

• color – (default: 'black') color of the arcs

• base_set_dict – (optional) dictionary with keys elements of base_set() and values as integer or float

EXAMPLES:
sage: p = SetPartition([[1,10,11],[2,3,7],[4,5,6],[8,9]])
sage: p.plot()
Graphics object consisting of 29 graphics primitives

sage: p = SetPartition([[1,3,4],[2,5]])
sage: print(p.plot().description())

  angle 0.0 inside the sector (0.785398163397...,2.35619449019...)
Arc with center (1.0,-1.0) radii (1.4142135623...,1.4142135623...)
  angle 0.0 inside the sector (0.785398163397...,2.35619449019...)

refinements()  
Return a list of refinements of self.

See also:

cooarsenings()

EXAMPLES:

sage: SetPartition([[1,3],[2,4]]).refinements()
[{{1, 3}, {2, 4}},
 {{1, 3}, {2}, {4}},
 {{1}, {2, 4}, {3}},
 {{1}, {2}, {3}, {4}}]
sage: SetPartition([[[1],[2,4],[3]]].refinements()
[[[1], {2, 4}, {3}], {{1}}, {2}, {3}, {4}]]
sage: SetPartition([]).refinements()
[[]]
**restriction(I)**

Return the restriction of `self` to a subset `I` (which is given as a set or list or any other iterable).

**EXAMPLES:**

```
sage: A = SetPartition([[1], [2,3]])
sage: A.restriction([1,2])
{{1}, {2}}
sage: A.restriction([2,3])
{{2, 3}}
sage: A.restriction([])
{}
sage: A.restriction([4])
{}
```

**set_latex_options(**kwargs)**

Set the latex options for use in the `_latex_` function

- `tikz_scale` – (default: 1) scale for use with tikz package
- `plot` – (default: None) None returns the set notation, `linear` returns a linear plot, `cyclic` returns a cyclic plot
- `color` – (default: 'black') the arc colors
- `fill` – (default: False) if True then fills `color`, else you can pass in a color to alter the fill color - only works with cyclic plot
- `show_labels` – (default: True) if True shows labels - only works with plots
- `radius` – (default: "1cm") radius of circle for cyclic plot - only works with cyclic plot
- `angle` – (default: 0) angle for linear plot

**EXAMPLES:**

```
sage: SP = SetPartition([[1,6], [3,5,4]])
sage: SP.set_latex_options(tikz_scale=2, plot='linear', fill=True, color='blue', angle=45)
sage: SP.set_latex_options(plot='cyclic')
sage: SP.latex_options()
{'angle': 45, 'color': 'blue', 'fill': True, 'plot': 'cyclic', 'radius': '1cm', 'show_labels': True, 'tikz_scale': 2}
```

**shape()**

Return the integer partition whose parts are the sizes of the sets in `self`.

**EXAMPLES:**

```
sage: S = SetPartitions(5)
sage: x = S([[1,2], [3,5,4]])
sage: x.shape()
[3, 2]
sage: y = S([[2], [3,1], [5,4]])
```
Combinatorics, Release 9.7

(continued from previous page)

```python
sage: y.shape()
[2, 2, 1]
```

**shape_partition()**

Return the integer partition whose parts are the sizes of the sets in `self`.

**EXAMPLES:**

```python
sage: S = SetPartitions(5)
sage: x = S([[1,2], [3,5,4]])
sage: x.shape()
[3, 2]
sage: y = S([[2], [3,1], [5,4]])
sage: y.shape()
[2, 2, 1]
```

**size()**

Return the cardinality of the base set of `self`, which is the sum of the sizes of the parts of `self`.

This is also known as the *size* (sometimes the *weight*) of a set partition.

**EXAMPLES:**

```python
sage: SetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
sage: SetPartition([[1,2,3,4]]).base_set_cardinality()
4
```

**standardization()**

Return the standardization of `self`.

Given a set partition \( A = \{A_1, \ldots, A_n\} \) of an ordered set \( S \), the standardization of \( A \) is the set partition \( S = \{1, 2, \ldots, |S|\} \) obtained by replacing the elements of the parts of \( A \) by the integers 1, 2, \ldots, \( |S| \) in such a way that their relative order is preserved (i.e., the smallest element in the whole set partition is replaced by 1, the next-smallest by 2, and so on).

**EXAMPLES:**

```python
sage: SetPartition([[4], [1, 3]]).standardization()
{{1, 2}, {3}}
sage: SetPartition([[4], [6, 3]]).standardization()
{{1, 3}, {2}}
sage: Set Partition([]).standardization()
{}
sage: SetPartition([('c','b'),('d','f'),('e','a')]).standardization()
{{1, 5}, {2, 3}, {4, 6}}
```

**strict_coarsenings()**

Return all strict coarsenings of `self`.

Strict coarsening is the binary relation on set partitions defined as the transitive-and-reflexive closure of the relation \( \prec \) defined as follows: For two set partitions \( A \) and \( B \), we have \( A \prec B \) if there exist parts \( A_i, A_j \) of \( A \) such that \( \max(A_i) < \min(A_j) \) and \( B = A \setminus \{A_i, A_j\} \cup \{A_i \cup A_j\} \).

**EXAMPLES:**
\begin{verbatim}
sage: A = SetPartition([[1],[2,3],[4]])
sage: A.strict_coarsenings()

\texttt{[[\{1\}, \{2, 3\}, \{4\}], \{\{1, 2, 3\}, \{4\}\}, \{\{1, 4\}, \{2, 3\}\},
\{\{1\}, \{2, 3, 4\}\}, \{\{1, 2, 3, 4\}\}]
}

sage: SetPartition([[1],[2,4],[3]]).strict_coarsenings()

\texttt{[[\{1\}, \{2, 4\}, \{3\}], \{\{1, 2, 4\}, \{3\}\}, \{\{1, 3\}, \{2, 4\}\}]
}

sage: SetPartition([]).strict_coarsenings()

\texttt{[\{\}]
}

\texttt{to_partition()}

Return the integer partition whose parts are the sizes of the sets in self.

EXAMPLES:

\begin{verbatim}
sage: S = SetPartitions(5)
sage: x = S([[1,2], [3,5,4]])
sage: x.shape()

\texttt{[3, 2]
}

sage: y = S([[2], [3,1], [5,4]])
sage: y.shape()

\texttt{[2, 2, 1]
}

\texttt{to_permutation()}

Convert a set partition of \{1, \ldots, n\} to a permutation by considering the blocks of the partition as cycles.

The cycles are such that the number of excedences is maximised, that is, each cycle is of the form (a_1, a_2, \ldots, a_k) with a_1 < a_2 < \ldots < a_k.

EXAMPLES:

\begin{verbatim}
sage: s = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: s.to_permutation()

\texttt{[3, 4, 1, 2]
}

\texttt{to_restricted_growth_word(bijection='blocks')}

Convert a set partition of \{1, \ldots, n\} to a word of length n with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before.

INPUT:

* bijection (default: blocks) – defines the map from set partitions to restricted growth functions.
  These are currently:
  
  \begin{itemize}
  \item blocks: \texttt{to_restricted_growth_word_blocks()}. \item intertwining: \texttt{to_restricted_growth_word_intertwining()}. \end{itemize}

OUTPUT:

A restricted growth word.

See also:

\texttt{SetPartitions.from_restricted_growth_word()}

EXAMPLES:

\begin{verbatim}
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_restricted_growth_word()

\texttt{(continues on next page)}
\end{verbatim}
\end{verbatim}
Combinatorics, Release 9.7

\[ [0, 1, 2, 0, 2, 2, 3, 1, 2] \]
\[ \text{sage: } P \text{.to_restricted_growth_word("intertwining")} \]
\[ [0, 1, 2, 2, 1, 0, 3, 3, 2] \]
\[ \text{sage: } P = \text{SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])} \]
\[ \text{sage: } P \text{.to_restricted_growth_word()} \]
\[ [0, 0, 1, 0, 2, 2, 0, 3, 1, 2, 2, 4, 2] \]
\[ \text{sage: } P \text{.to_restricted_growth_word("intertwining")} \]
\[ [0, 0, 1, 1, 2, 0, 1, 3, 3, 3, 0, 4, 1] \]

**to_restricted_growth_word_blocks()**

Convert a set partition of \([1, \ldots, n]\) to a word of length \(n\) with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before.

The word is obtained by sorting the blocks by their minimal element and setting the letters at the positions of the elements in the \(i\)-th block to \(i\).

**OUTPUT:**

- a restricted growth word.

**See also:**

- to_restricted_growth_word() SetPartitions.from_restricted_growth_word()

**EXAMPLES:**

\[ \text{sage: } P = \text{SetPartition([[1,4],[2,8],[3,5,6,9],[7]])} \]
\[ \text{sage: } P \text{.to_restricted_growth_word_blocks()} \]
\[ [0, 1, 2, 0, 2, 2, 3, 1, 2] \]

**to_restricted_growth_word_intertwining()**

Convert a set partition of \([1, \ldots, n]\) to a word of length \(n\) with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before.

The \(i\)-th letter of the word is the numbers of crossings of the arc (or half-arc) in the extended arc diagram ending at \(i\), with arcs (or half-arcs) beginning at a smaller element and ending at a larger element.

**OUTPUT:**

- a restricted growth word.

**See also:**

- to_restricted_growth_word() SetPartitions.from_restricted_growth_word()

**EXAMPLES:**

\[ \text{sage: } P = \text{SetPartition([[1,4],[2,8],[3,5,6,9],[7]])} \]
\[ \text{sage: } P \text{.to_restricted_growth_word_intertwining()} \]
\[ [0, 1, 1, 2, 0, 1, 3, 3, 3, 0, 4, 1] \]

**to_rook_placement(bijection='arcs')**

Return a set of pairs defining a placement of non-attacking rooks on a triangular board.

The cells of the board corresponding to a set partition of \([1, \ldots, n]\) are the pairs \((i, j)\) with \(0 < i < j < n + 1\).
INPUT:

- bijection (default: arcs) – defines the bijection from set partitions to rook placements. These are currently:
  - arcs: arcs()
  - gamma: to_rook_placement_gamma()
  - rho: to_rook_placement_rho()
  - psi: to_rook_placement_psi()

See also:

SetPartitions.from_rook_placement()

EXAMPLES:

```sage
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: P.to_rook_placement()
[(1, 2), (2, 4), (4, 7), (3, 9), (5, 6), (6, 10), (10, 11), (11, 13)]
sage: P.to_rook_placement("gamma")
[(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
sage: P.to_rook_placement("rho")
[(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11, 13)]
sage: P.to_rook_placement("psi")
[(1, 2), (2, 6), (3, 4), (5, 9), (6, 7), (7, 10), (9, 11), (11, 13)]
```

to_rook_placement_gamma()

Return the rook diagram obtained by placing rooks according to Wachs and White’s bijection gamma.

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with \((i, j)\) to the cell in the \(i\)-th column from the right and the \(j\)-th row from the top.

The algorithm proceeds as follows: non-attacking rooks are placed beginning at the left column. If \(n + 1 - i\) is an opener, column \(i\) remains empty. Otherwise, we place a rook into column \(i\), such that the number of cells below the rook, which are not yet attacked by another rook, equals the index of the block to which \(n + 1 - i\) belongs.

OUTPUT:

A list of coordinates.

See also:

- to_rook_placement()
- SetPartitions.from_rook_placement()
- SetPartitions.from_rook_placement_gamma()

EXAMPLES:

```sage
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_rook_placement_gamma()
[(1, 3), (2, 7), (4, 5), (5, 6), (6, 9)]
```

Figure 5 in [WW1991]:
sage: P = SetPartition([[1, 2, 4, 7], [3, 9], [5, 6, 10, 11, 13], [8], [12]])
sage: r = P.to_rook_placement_gamma(); r
[(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]

to_rook_placement_psi()
Return the rook diagram obtained by placing rooks according to Yip’s bijection psi.

OUTPUT:
A list of coordinates.

See also:
• to_rook_placement()
• SetPartitions.from_rook_placement()
• SetPartitions.from_rook_placement_psi()

EXAMPLES:
Example 36 (arXiv version: Example 4.5) in [Yip2018]:

sage: P = SetPartition([[1, 5], [2], [3, 8, 9], [4], [6, 7]])
sage: P.to_rook_placement_psi()
[(1, 7), (3, 8), (4, 5), (7, 9)]

Note that the columns corresponding to the minimal elements of the blocks remain empty.

to_rook_placement_rho()
Return the rook diagram obtained by placing rooks according to Wachs and White’s bijection rho.

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with \((i, j)\) to the cell in the \(i\)-th column from the right and the \(j\)-th row from the top.

The algorithm proceeds as follows: non-attacking rooks are placed beginning at the top row. The columns corresponding to the closers of the set partition remain empty. Let \(rs_j\) be the number of closers which are larger than \(j\) and whose block is before the block of \(j\).

We then place a rook into row \(j\), such that the number of cells to the left of the rook, which are not yet attacked by another rook and are not in a column corresponding to a closer, equals \(rs_j\), unless there are not enough cells in this row available, in which case the row remains empty.

One can show that the precisely those rows which correspond to openers of the set partition remain empty.

OUTPUT:
A list of coordinates.

See also:
• to_rook_placement()
• SetPartitions.from_rook_placement()
• SetPartitions.from_rook_placement_rho()

EXAMPLES:
```python
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_rook_placement_rho()
[(1, 5), (2, 6), (3, 4), (5, 9), (6, 8)]
```

Figure 6 in [WW1991]:

```python
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: r = P.to_rook_placement_rho(); r
[(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11, 13)]
sage: sorted(P.closers() + [i for i, _ in r]) == list(range(1,14))
True
sage: sorted(P.openers() + [j for _, j in r]) == list(range(1,14))
True
```

```python
class sage.combinat.set_partition.SetPartitions
    Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

An (unordered) partition of a set $S$ is a set of pairwise disjoint nonempty subsets with union $S$, and is represented by a sorted list of such subsets.

SetPartitions($s$) returns the class of all set partitions of the set $s$, which can be given as a set or a string; if a string, each character is considered an element.

SetPartitions($n$), where $n$ is an integer, returns the class of all set partitions of the set $\{1,2,\ldots,n\}$.

You may specify a second argument $k$. If $k$ is an integer, SetPartitions returns the class of set partitions into $k$ parts; if it is an integer partition, SetPartitions returns the class of set partitions whose block sizes correspond to that integer partition.

The Bell number $B_n$, named in honor of Eric Temple Bell, is the number of different partitions of a set with $n$ elements.

EXAMPLES:

```python
sage: S = [1,2,3,4]
sage: SetPartitions(S, 2)
Set partitions of \{1, 2, 3, 4\} with 2 parts
sage: SetPartitions([1,2,3,4], [3,1]).list()
[[\{1\}, \{2, 3, 4\}], [[1, 2, 3], \{4\}], [[1, 2, 4], \{3\}], [[1, 3, 4], \{2\}]]
sage: SetPartitions(7, [3,3,1]).cardinality()
70
```

In strings, repeated letters are not considered distinct as of trac ticket #14140:

```python
sage: SetPartitions('abcde').cardinality()
52
sage: SetPartitions('aabcd').cardinality()
15
```

REFERENCES:

- Wikipedia article Partition_of_a_set

**Element**

alias of SetPartition
**from_arcs** *(arcs, n)*

Return the coarsest set partition of \( \{1, \ldots, n\} \) such that any two elements connected by an arc are in the same block.

**INPUT:**

- \( n \) – an integer specifying the size of the set partition to be produced.
- \( \text{arcs} \) – a list of pairs specifying which elements are in the same block.

**See also:**

- *from_rook_placement()
- *SetPartition.to_rook_placement()
- *SetPartition.arcs()

**EXAMPLES:**

```sage
SetPartitions().from_arcs([(2,3)], 5)
{{1}, {2, 3}, {4}, {5}}
```

**from_restricted_growth_word** *(w, bijection=’blocks’)*

Convert a word of length \( n \) with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before to a set partition of \( \{1, \ldots, n\} \).

**INPUT:**

- \( w \) – a restricted growth word.
- \( \text{bijection} \) (default: blocks) – defines the map from restricted growth functions to set partitions. These are currently:
  - blocks: .
  - intertwining: *from_restricted_growth_word_intertwining()*

**OUTPUT:**

A set partition.

**See also:**

*SetPartition.to_restricted_growth_word()*

**EXAMPLES:**

```sage
SetPartitions().from_restricted_growth_word([0, 1, 2, 0, 2, 2, 3, 1, 2])
{{1, 4}, {2, 8}, {3, 5, 6, 9}, {7}}
```

```sage
SetPartitions().from_restricted_growth_word([0, 0, 1, 0, 2, 2, 0, 3, 1, 2, → 2, 4, 2])
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

```sage
SetPartitions().from_restricted_growth_word([0, 0, 1, 0, 2, 2, 0, 3, 1, 2, → 2, 4, 2], "intertwining")
{{1, 2, 6, 7, 9}, {3, 4}, {5, 10, 13}, {8, 11}, {12}}
```

**from_restricted_growth_word_blocks** *(w)*

Convert a word of length \( n \) with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before to a set partition of \( \{1, \ldots, n\} \).
from_restricted_growth_word() SetPartition.to_restricted_growth_word()

EXAMPLES:

```sage
sage: SetPartitions().from_restricted_growth_word_blocks([0, 0, 1, 0, 2, 2, 0, 3, 1, 2, 4, 2])
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

from_restricted_growth_word_intertwining(w)

Convert a word of length \(n\) with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before to a set partition of \(\{1, \ldots, n\}\).

The \(i\)-th letter of the word is the numbers of crossings of the arc (or half-arc) in the extended arc diagram ending at \(i\), with arcs (or half-arcs) beginning at a smaller element and ending at a larger element.

INPUT:

- \(w\) – a restricted growth word.

OUTPUT:

A set partition.

See also:

from_restricted_growth_word() SetPartition.to_restricted_growth_word()

EXAMPLES:

```sage
sage: SetPartitions().from_restricted_growth_word_intertwining([0, 0, 1, 0, 2, 2, 0, 3, 1, 2, 4, 2])
{{1, 2, 6, 7, 9}, {3, 4}, {5, 10, 13}, {8, 11}, {12}}
```

from_rook_placement(rooks, bijection='arcs', n=None)

Convert a rook placement of the triangular grid to a set partition of \(\{1, \ldots, n\}\).

If \(n\) is not given, it is first checked whether it can be determined from the parent, otherwise it is the maximal occurring integer in the set of rooks.

INPUT:

- \(rooks\) – a list of pairs \((i, j)\) satisfying \(0 < i < j < n + 1\).
- \(bijection\) (default: \(arcs\)) – defines the map from rook placements to set partitions. These are currently:
  - \(arcs\): \(from_arcs()\).
  - \(gamma\): \(from_rook_placement_gamma()\).
  - \(rho\): \(from_rook_placement_rho()\).
  - \(psi\): \(from_rook_placement_psi()\).
• n – (optional) the size of the ground set.

See also:

SetPartition.to_rook_placement()

EXAMPLES:

```
sage: SetPartitions(9).from_rook_placement([[1,4],[2,8],[3,5],[5,6],[6,9]])
{{1, 4}, {2, 8}, {3, 5, 6, 9}, {7}}
sage: SetPartitions(13).from_rook_placement([[12,13],[10,12],[8,9],[7,11],[5,8],
                                          →[4,6],[3,5],[1,4]], "gamma")
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

from_rook_placement_gamma(rooks, n)

Return the set partition of \{1, ..., n\} corresponding to the given rook placement by applying Wachs and White’s bijection gamma.

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with \((i, j)\) to the cell in the \(i\)-th column from the right and the \(j\)-th row from the top.

INPUT:

• n – an integer specifying the size of the set partition to be produced.
• rooks – a list of pairs \((i, j)\) such that \(0 < i < j < n + 1\).

OUTPUT:

A set partition.

See also:

• from_rook_placement()
• SetPartition.to_rook_placement()
• SetPartition.to_rook_placement_gamma()

EXAMPLES:

Figure 5 in [WW1991] concerns the following rook placement:

```
sage: r = [(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
```

Note that the rook \((1, 4)\), translated into Wachs and White’s convention, is a rook in row 4 from the top and column 13 from the left. The corresponding set partition is:

```
sage: SetPartitions().from_rook_placement_gamma(r, 13)
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

from_rook_placement_psi(rooks, n)

Return the set partition of \{1, ..., n\} corresponding to the given rook placement by applying Yip’s bijection psi.

INPUT:

• n – an integer specifying the size of the set partition to be produced.
• rooks – a list of pairs \((i, j)\) such that \(0 < i < j < n + 1\).
OUTPUT:
A set partition.

See also:

- `from_rook_placement()`
- `SetPartition.to_rook_placement()`
- `SetPartition.to_rook_placement_psi()`

EXAMPLES:
Example 36 (arXiv version: Example 4.5) in [Yip2018] concerns the following rook placement:

```
sage: r = [(4,5), (1,7), (3, 8), (7,9)]
sage: SetPartitions().from_rook_placement_psi(r, 9)
{{1, 5}, {2}, {3, 8, 9}, {4}, {6, 7}}
```

`from_rook_placement_rho(rooks, n)`

Return the set partition of \{1, ..., n\} corresponding to the given rook placement by applying Wachs and White’s bijection rho.

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with \((i, j)\) to the cell in the \(i\)-th column from the right and the \(j\)-th row from the top.

INPUT:

- `n` – an integer specifying the size of the set partition to be produced.
- `rooks` – a list of pairs \((i, j)\) such that \(0 < i < j < n + 1\).

OUTPUT:
A set partition.

See also:

- `from_rook_placement()`
- `SetPartition.to_rook_placement()`
- `SetPartition.to_rook_placement_rho()`

EXAMPLES:
Figure 5 in [WW1991] concerns the following rook placement:

```
sage: r = [(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11, 13)]
sage: SetPartitions().from_rook_placement_rho(r, 13)
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

`is_less_than(s, t)`

Check if \(s < t\) in the refinement ordering on set partitions.

This means that \(s\) is a refinement of \(t\) and satisfies \(s \neq t\).
A set partition \( s \) is said to be a refinement of a set partition \( t \) of the same set if and only if each part of \( s \) is a subset of a part of \( t \).

**EXAMPLES:**

```python
sage: S = SetPartitions(4)
sage: s = S([[1,3],[2,4]])
sage: t = S([[1],[2],[3],[4]])
sage: S.is_less_than(t, s)  # True
sage: S.is_less_than(s, t)  # False
sage: S.is_less_than(s, s)  # False
```

**is_strict_refinement** \((s, t)\)

Return True if \( s \) is a strict refinement of \( t \) and satisfies \( s \neq t \).

A set partition \( s \) is said to be a strict refinement of a set partition \( t \) of the same set if and only if one can obtain \( t \) from \( s \) by repeatedly combining pairs of parts whose convex hulls don’t intersect (i.e., whenever we are combining two parts, the maximum of each of them should be smaller than the minimum of the other).

**EXAMPLES:**

```python
sage: S = SetPartitions(4)
sage: s = S([[1],[2],[3],[4]])
sage: t = S([[1,3],[2,4]])
sage: u = S([[1,2,3,4]])
sage: S.is_strict_refinement(s, t)  # True
sage: S.is_strict_refinement(t, u)  # False
sage: A = SetPartition([[1,3],[2,4]])
sage: B = SetPartition([[1,2,3,4]])
sage: S.is_strict_refinement(s, A)  # True
sage: S.is_strict_refinement(t, B)  # False
```

**lt** \((s, t)\)

Check if \( s < t \) in the refinement ordering on set partitions.

This means that \( s \) is a refinement of \( t \) and satisfies \( s \neq t \).

A set partition \( s \) is said to be a refinement of a set partition \( t \) of the same set if and only if each part of \( s \) is a subset of a part of \( t \).

**EXAMPLES:**

```python
sage: S = SetPartitions(4)
sage: s = S([[1,3],[2,4]])
sage: t = S([[1],[2],[3],[4]])
sage: S.is_less_than(t, s)  # True
sage: S.is_less_than(s, t)  # False
```

(continues on next page)
class sage.combinat.set_partition.SetPartitions_all
Bases: sage.combinat.set_partition.SetPartitions
All set partitions.
subset(size=None, **kwargs)
Return the subset of set partitions of a given size and additional keyword arguments.

EXAMPLES:

```python
sage: P = SetPartitions()
sage: P.subset(4)
Set partitions of {1, 2, 3, 4}
```

class sage.combinat.set_partition.SetPartitions_set(s)
Bases: sage.combinat.set_partition.SetPartitions
Set partitions of a fixed set \( S \).
base_set()
Return the base set of self.

EXAMPLES:

```python
sage: SetPartitions(3).base_set()
{1, 2, 3}
sage: sorted(SetPartitions(['a', 'b', 'c']).base_set())
['a', 'b', 'c']
```

base_set_cardinality()
Return the cardinality of the base set of self.

EXAMPLES:

```python
sage: SetPartitions(3).base_set_cardinality()
3
```

cardinality()
Return the number of set partitions of the set \( S \).

The cardinality is given by the \( n \)-th Bell number where \( n \) is the number of elements in the set \( S \).

EXAMPLES:

```python
sage: SetPartitions([1,2,3,4]).cardinality()
15
sage: SetPartitions(3).cardinality()
5
sage: SetPartitions(3,2).cardinality()
3
sage: SetPartitions([]).cardinality()
1
```
random_element()

Return a random set partition.

This is a very naive implementation of Knuth's outline in F3B, 7.2.1.5.

EXAMPLES:

```
sage: S = SetPartitions(10)
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s
sage: S = SetPartitions(['a', 'b', 'c'])
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s
```

class sage.combinat.set_partition.SetPartitions_setn(s, k)

Bases: sage.combinat.set_partition.SetPartitions_set

Set partitions with a given number of blocks.

cardinality()

The Stirling number of the second kind is the number of partitions of a set of size \(n\) into \(k\) blocks.

EXAMPLES:

```
sage: SetPartitions(5, 3).cardinality()
25
sage: stirling_number2(5,3)
25
```

self.n is deprecated; use number_of_blocks() instead.

number_of_blocks()

Return the number of blocks of the set partitions in self.

EXAMPLES:

```
sage: SetPartitions(5, 3).number_of_blocks()
3
```

random_element()

Return a random set partition of self.

See https://mathoverflow.net/questions/141999.

EXAMPLES:

```
sage: S = SetPartitions(10, 4)
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s
```

(continues on next page)
sage: S = SetPartitions(['a', 'b', 'c'], 2)
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s

class sage.combinat.set_partition.SetPartitions_setparts(s, parts)

Bases: sage.combinat.set_partition.SetPartitions_set

Set partitions with fixed partition sizes corresponding to an integer partition \( \lambda \).

cardinality()

Return the cardinality of self.

This algorithm counts for each block of the partition the number of ways to fill it using values from the set. Then, for each distinct value \( v \) of block size, we divide the result by the number of ways to arrange the blocks of size \( v \) in the set partition.

For example, if we want to count the number of set partitions of size 13 having \([3,3,3,2,2]\) as underlying partition we compute the number of ways to fill each block of the partition, which is \( \binom{13}{3} \binom{10}{3} \binom{7}{3} \binom{4}{2} \binom{2}{2} \) and as we have three blocks of size 3 and two blocks of size 2, we divide the result by \( 3!2! \) which gives us 600600.

EXAMPLES:

sage: SetPartitions(3, [2,1]).cardinality()
3
sage: SetPartitions(13, Partition([3,3,3,2,2])).cardinality()
600600

parts

self.parts is deprecated; use shape() instead.

random_element()

Return a random set partition of self.

ALGORITHM:

Based on the cardinality method. For each block size \( k_i \), we choose a uniformly random subset \( X_i \subseteq S_i \) of size \( k_i \) of the elements \( S_i \) that have not yet been selected. Thus, we define \( S_{i+1} = S_i \setminus X_i \) with \( S_0 = S \) being the defining set. This is not yet proven to be uniformly distributed, but numerical tests show this is likely uniform.

EXAMPLES:

sage: S = SetPartitions(10, [4,3,2,1])
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s
sage: S = SetPartitions(['a', 'b', 'c', 'd'], [2,2])
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s
**shape()**

Return the partition of block sizes of the set partitions in `self`.

EXAMPLES:

```
sage: SetPartitions(5, [2,2,1]).shape()
[2, 2, 1]
```

`sage.combinat.set_partition.cyclic_permutations_of_set_partition(set_part)`

Return all combinations of cyclic permutations of each cell of the set partition.

AUTHORS:

• Robert L. Miller

EXAMPLES:

```
sage: from sage.combinat.set_partition import cyclic_permutations_of_set_partition
sage: cyclic_permutations_of_set_partition([[1,2,3,4],[5,6,7]])
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
```

`sage.combinat.set_partition.cyclic_permutations_of_set_partition_iterator(set_part)`

Iterates over all combinations of cyclic permutations of each cell of the set partition.

AUTHORS:

• Robert L. Miller

EXAMPLES:

```
sage: from sage.combinat.set_partition import cyclic_permutations_of_set_partition_iterator
sage: list(cyclic_permutations_of_set_partition_iterator([[1,2,3,4],[5,6,7]]))
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
```
5.1.275 Ordered Set Partitions

AUTHORS:

• Mike Hansen
• MuPAD-Combinat developers (for algorithms and design inspiration)
• Travis Scrimshaw (2013-02-28): Removed CombinatorialClass and added entry point through OrderedSetPartition.

class sage.combinat.set_partition_ordered.OrderedSetPartition(parent, s)

Bases: sage.structure.list_clone.ClonableArray

An ordered partition of a set.

An ordered set partition \( p \) of a set \( s \) is a list of pairwise disjoint nonempty subsets of \( s \) such that the union of these subsets is \( s \). These subsets are called the parts of the partition. We represent an ordered set partition as a list of sets. By extension, an ordered set partition of a nonnegative integer \( n \) is the set partition of the integers from 1 to \( n \). The number of ordered set partitions of \( n \) is called the \( n \)-th ordered Bell number.

There is a natural integer composition associated with an ordered set partition, that is the sequence of sizes of all its parts in order.

The number \( T_n \) of ordered set partitions of \( \{1, 2, \ldots, n\} \) is the so-called \( n \)-th Fubini number (also known as the \( n \)-th ordered Bell number; see Wikipedia article Ordered Bell number). Its exponential generating function is

\[
\sum_n \frac{T_n}{n!} x^n = \frac{1}{2 - e^x}.
\]

(See sequence OEIS sequence A000670 in OEIS.)

INPUT:

• \texttt{parts} – an object or iterable that defines an ordered set partition (e.g., a list of pairwise disjoint sets) or a packed word (e.g., a list of letters on some alphabet). If there is ambiguity and if the input should be treated as a packed word, the keyword \texttt{from_word} should be used.

EXAMPLES:

There are 13 ordered set partitions of \( \{1, 2, 3\} \):

```python
sage: OrderedSetPartitions(3).cardinality()
13
```

Here is the list of them:

```python
sage: OrderedSetPartitions(3).list()
[[[1], [2], [3]],
 [[1], [3], [2]],
 [[2], [1], [3]],
 [[3], [1], [2]],
 [[2], [3], [1]],
 [[3], [2], [1]],
 [[1], [2, 3]],
 [[2], [1, 3]],
 [[3], [1, 2]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[2, 3], [1]],
 [[1, 2, 3]]]
```
There are 12 ordered set partitions of \{1, 2, 3, 4\} whose underlying composition is [1, 2, 1]:

\[
\begin{align*}
\text{sage: } & \text{OrderedSetPartitions(4,[1,2,1]).list()} \\
& \begin{bmatrix}
\{1\}, \{2, 3\}, \{4\}, \\
\{1\}, \{2, 4\}, \{3\}, \\
\{1\}, \{3, 4\}, \{2\}, \\
\{2\}, \{1, 3\}, \{4\}, \\
\{2\}, \{1, 4\}, \{3\}, \\
\{3\}, \{1, 2\}, \{4\}, \\
\{4\}, \{1, 2\}, \{3\}, \\
\{3\}, \{1, 4\}, \{2\}, \\
\{4\}, \{1, 3\}, \{2\}, \\
\{2\}, \{3, 4\}, \{1\}, \\
\{3\}, \{2, 4\}, \{1\}, \\
\{4\}, \{2, 3\}, \{1\}
\end{bmatrix}
\end{align*}
\]

Since trac ticket #14140, we can create an ordered set partition directly by \text{OrderedSetPartition} which creates the parent object by taking the union of the partitions passed in. However it is recommended and (marginally) faster to create the parent first and then create the ordered set partition from that.

\[
\begin{align*}
\text{sage: } & s = \text{OrderedSetPartition([[1,3],[2,4]])}; \\
& s \\
\text{sage: } & s\text{.parent()} \\
\text{Ordered set partitions of }\{1, 2, 3, 4\}
\end{align*}
\]

We can construct the ordered set partition from a word, which we consider as packed:

\[
\begin{align*}
\text{sage: } & \text{OrderedSetPartition([2,4,1,2])} \\
& \begin{bmatrix}
\{3\}, \{1, 4\}, \{2\}
\end{bmatrix} \\
\text{sage: } & \text{OrderedSetPartition(from_word=[2,4,1,2])} \\
& \begin{bmatrix}
\{3\}, \{1, 4\}, \{2\}
\end{bmatrix} \\
\text{sage: } & \text{OrderedSetPartition(from_word='bdab')} \\
& \begin{bmatrix}
\{3\}, \{1, 4\}, \{2\}
\end{bmatrix}
\end{align*}
\]

\textbf{REFERENCES:}

Wikipedia article \text{Ordered_partition_of_a_set}

\textbf{base_set()}

Return the base set of \text{self}, which is the union of all parts of \text{self}.

\textbf{EXAMPLES:}

\[
\begin{align*}
\text{sage: } & \text{OrderedSetPartition([[1], [2,3], [4]])}\text{.base_set()} \\
& \begin{bmatrix}
1, 2, 3, 4
\end{bmatrix} \\
\text{sage: } & \text{OrderedSetPartition([1,2,3,4])}\text{.base_set()} \\
& \begin{bmatrix}
1, 2, 3, 4
\end{bmatrix} \\
\text{sage: } & \text{OrderedSetPartition([])}\text{.base_set()} \\
& \begin{bmatrix}
\end{bmatrix}
\end{align*}
\]

\textbf{base_set_cardinality()}

Return the cardinality of the base set of \text{self}, which is the sum of the sizes of the parts of \text{self}.

This is also known as the \text{size} (sometimes the \text{weight}) of an ordered set partition.

\textbf{EXAMPLES:}
sage: OrderedSetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
sage: OrderedSetPartition([[1,2,3,4]]).base_set_cardinality()
4

**static bottom_up_osp(X, comp)**

Return the ordered set partition obtained by listing the elements of the set \(X\) in increasing order, and placing bars between some of them according to the integer composition \(comp\) (namely, the bars are placed in such a way that the lengths of the resulting blocks are exactly the entries of \(comp\)).

**INPUT:**

- \(X\) – a finite set (or list or tuple)
- \(comp\) – a composition whose sum is the size of \(X\) (can be given as a list or tuple or composition)

**EXAMPLES:**

| sage: |
|------|------------------|
| buo = OrderedSetPartition.bottom_up_osp |
| buo(Set([1, 4, 7, 9]), [2, 1, 1]) |
| [[1, 4], {7}, {9}] |
| buo(Set([1, 4, 7, 9]), [1, 3]) |
| [{}  |
| buo(Set([1, 4, 7, 9]), [1, 1, 1]) |
| [{}  |
| buo(range(8), [1, 4, 2, 1]) |
| [{}  |
| buo([], []) |
|

**check()**

Check that we are a valid ordered set partition.

**EXAMPLES:**

| sage: |
|------|------------------|
| OS = OrderedSetPartitions(4) |
| s = OS([[1, 3], [2, 4]]) |
| s.check() |
| |

**complement()**

Return the complement of the ordered set partition \(self\).

This assumes that \(self\) is an ordered set partition of an interval of \(Z\).

Let \((P_1, P_2, \ldots, P_k)\) be an ordered set partition of some interval \(I\) of \(Z\). Let \(\omega\) be the unique strictly decreasing bijection \(I \to I\). Then, the complement of \((P_1, P_2, \ldots, P_k)\) is defined to be the ordered set partition \((\omega(P_1), \omega(P_2), \ldots, \omega(P_k))\).

**EXAMPLES:**

| sage: |
|------|------------------|
| OrderedSetPartition([[1, 2], [3]]).complement() |
| [[2, 3], {1}] |
| OrderedSetPartition([[1, 3], [2]]).complement() |
| [[1, 3], {2}] |
| OrderedSetPartition([[2, 3]]).complement() |
| [{} |
| OrderedSetPartition([[1, 5], [2, 3], [4]]).complement() |
| [{} | (continues on next page)
\[
\begin{align*}
&\{1, 5\}, \{3, 4\}, \{2\} \\
\text{sage: } &\text{OrderedSetPartition(}\{-1\}, \{-2\}, \{1, 2\}, \{0\})\text{.complement()} \\
&\{1\}, \{2\}, \{-2\}, \{-1\}, \{0\} \\
\text{sage: } &\text{OrderedSetPartition(}\{\}\text{.complement()} \\
&\{}
\end{align*}
\]

\textbf{fatten}(\textit{grouping})

Return the ordered set partition fatter than \textit{self}, obtained by grouping together consecutive parts according to the integer composition \textit{grouping}.

See \textit{finer()} for the definition of “fatter”.

**INPUT:**

- \textit{grouping} – a composition whose sum is the length of \textit{self}

**EXAMPLES:**

Let us start with the ordered set partition:

\textbf{sage: } c = \text{OrderedSetPartition(}[[2, 5], [1], [3, 4]]\text{)}

With \textit{grouping} equal to (1, \ldots, 1), \textit{c} is left unchanged:

\textbf{sage: } c.\text{fatten}(\text{Composition(}[1,1,1])) \\
\{2, 5\}, \{1\}, \{3, 4\}

With \textit{grouping} equal to (\ell) where \ell is the length of \textit{c}, this yields the coarsest ordered set partition above \textit{c}:

\textbf{sage: } c.\text{fatten}(\text{Composition(}[3])) \\
\{1, 2, 3, 4, 5\}

Other values for \textit{grouping} yield (all the) other ordered set partitions coarser than \textit{c}:

\textbf{sage: } c.\text{fatten}(\text{Composition(}[2,1])) \\
\{1, 2, 5\}, \{3, 4\} \\
\textbf{sage: } c.\text{fatten}(\text{Composition(}[1,2])) \\
\{2, 5\}, \{1, 3, 4\}

\textbf{fatter()}

Return the set of ordered set partitions which are fatter than \textit{self}.

See \textit{finer()} for the definition of “fatter”.

**EXAMPLES:**

\textbf{sage: } C = \text{OrderedSetPartition(}[[2, 5], [1], [3, 4]]\text{)}.\text{fatter()} \\
\textbf{sage: } C.\text{cardinality()} \\
4 \\
\textbf{sage: } \text{sorted(C)} \\
\text{return: } \{[1, 2, 3, 4, 5], \} \\
\{[1, 2, 5], \{3, 4\}, \} \\
\{[2, 5], \{1, 3, 4\}, \} \\
\{[2, 5], \{1\}, \{3, 4\}\}
Some extreme cases:

```
sage: list(OrderedSetPartition([ [5] ]).fatter())
[[[5]]]
sage: list(Composition([]).fatter())
[[[]]]
sage: sorted(OrderedSetPartition([ [1], [2], [3], [4] ]).fatter())
[[[1, 2, 3, 4]],
 [[1, 2, 3], {4}],
 [[1, 2], {3, 4}],
 [[1], {2, 3, 4}],
 [[1], {2}, {3, 4}],
 [[1], {2}, {3}, {4}]]
```

### finer()

Return the set of ordered set partitions which are finer than `self`.

See `is_finer()` for the definition of “finer”.

**EXAMPLES:**

```
sage: C = OrderedSetPartition([ [1, 3], [2] ]).finer()
sage: C.cardinality()
3
sage: C.list()
[[[1], {3}, {2}], [[3], {1}, {2}], [[1, 3], {2}]]
sage: OrderedSetPartition([]).finer()
[]
sage: W = OrderedSetPartition([ [4, 9], [-1, 2] ])
sage: W.finer().list()
[[[9], {4}, {2}, {-1}],
 [[9], {4}, {-1}, {2}],
 [[9], {4}, {-1, 2}],
 [[4], {9}, {2}, {-1}],
 [[4], {9}, {-1}, {2}],
 [[4], {9}, {-1, 2}],
 [[4, 9], {2}, {-1}],
 [[4, 9], {-1}, {2}],
 [[4, 9], {-1, 2}]]
```

### is_finer(co2)

Return True if the ordered set partition `self` is finer than the ordered set partition `co2`; otherwise, return False.

If `A` and `B` are two ordered set partitions of the same set, then `A` is said to be finer than `B` if `B` can be obtained from `A` by (repeatedly) merging consecutive parts. In this case, we say that `B` is fatter than `A`.

**EXAMPLES:**
sage: A = OrderedSetPartition([[1, 3], [2]])
sage: B = OrderedSetPartition([[1], [3], [2]])
sage: A.is_finer(B)
False
sage: B.is_finer(A)
True
sage: C = OrderedSetPartition([[3], [1], [2]])
sage: A.is_finer(C)
False
sage: C.is_finer(A)
True
sage: OrderedSetPartition([[2], [5], [1], [4]]).is_finer(OrderedSetPartition([[2, 5], [1, 4]]))
True
sage: OrderedSetPartition([[5], [2], [1], [4]]).is_finer(OrderedSetPartition([[2, 5], [1, 4]]))
False
sage: OrderedSetPartition([[2], [1], [5], [4]]).is_finer(OrderedSetPartition([[2, 5], [1, 4]]))
False

is_strongly_finer(self, co2)
Return True if the ordered set partition self is strongly finer than the ordered set partition co2; otherwise, return False.

If A and B are two ordered set partitions of the same set, then A is said to be strongly finer than B if B can be obtained from A by (repeatedly) merging consecutive parts, provided that every time we merge two consecutive parts C_i and C_{i+1}, we have max C_i < min C_{i+1}. In this case, we say that B is strongly fatter than A.

EXAMPLES:

sage: A = OrderedSetPartition([[1, 3], [2]])
sage: B = OrderedSetPartition([[1], [3], [2]])
sage: A.is_strongly_finer(B)
False
sage: B.is_strongly_finer(A)
True
sage: C = OrderedSetPartition([[3], [1], [2]])
sage: A.is_strongly_finer(C)
False
sage: C.is_strongly_finer(A)
False
sage: OrderedSetPartition([[2], [5], [1], [4]]).is_strongly_finer(OrderedSetPartition([[2, 5], [1, 4]]))
True
sage: OrderedSetPartition([[5], [2], [1], [4]]).is_strongly_finer(OrderedSetPartition([[2, 5], [1, 4]]))
False
sage: OrderedSetPartition([[2], [1], [5], [4]]).is_strongly_finer(OrderedSetPartition([[2, 5], [1, 4]]))
False
False

```
sage: OrderedSetPartition([[2, 5, 1], [4]]).is_strongly_finer(OrderedSetPartition([[2, 5], [1, 4]]))
False
```

**length()**

Return the number of parts of self.

**EXAMPLES:**

```
sage: OS = OrderedSetPartitions(4)
sage: s = OS([[1, 3], [2, 4]])
sage: s.length()
2
```

**number_of_inversions()**

Return the number of inversions in self.

An inversion of an ordered set partition with blocks \([B_1, B_2, \ldots, B_k]\) is a pair of letters \(i, j\) with \(i < j\) such that \(i\) is minimal in \(B_m, j \in B_l,\) and \(l < m\).

**REFERENCES:**
• [Wilson2016]

**EXAMPLES:**

```
sage: OrderedSetPartition([[2,5],[4,6],[1,3]]).number_of_inversions()
5
sage: OrderedSetPartition([[1,3,8],[2,4],[5,6,7]]).number_of_inversions()
3
```

**reversed()**

Return the reversal of the ordered set partition self.

The reversal of an ordered set partition \((P_1, P_2, \ldots, P_k)\) is defined to be the ordered set partition \((P_k, P_{k-1}, \ldots, P_1)\).

**EXAMPLES:**

```
sage: OrderedSetPartition([[1, 3], [2]]).reversed()
[[2], [1, 3]]
sage: OrderedSetPartition([[1, 5], [2, 4]]).reversed()
[[2, 4], [1, 5]]
sage: OrderedSetPartition([[-1], [-2], [3, 4], [0]]).reversed()
[[0], [3, 4], [-2], [-1]]
sage: OrderedSetPartition([]).reversed()
[]
```

**size()**

Return the cardinality of the base set of self, which is the sum of the sizes of the parts of self.

This is also known as the size (sometimes the weight) of an ordered set partition.

**EXAMPLES:**
strongly_fatter()

Return the set of ordered set partitions which are strongly fatter than self.

See strongly_finer() for the definition of “strongly fatter”.

EXAMPLES:

```
sage: C = OrderedSetPartition([[2, 5], [1], [3, 4]]).strongly_fatter()
sage: C.cardinality()
2
sage: sorted(C)
[[[2, 5], {1, 3, 4}],
 [2, 5], {1}, {3, 4}]`
```

Some extreme cases:

```
sage: list(OrderedSetPartition([[5]]).strongly_fatter())
[[[5]]]
sage: list(OrderedSetPartition([]).strongly_finer())
[[]]
sage: sorted(OrderedSetPartition([[1], [2], [3], [4]]).strongly_fatter())
[[[1, 2, 3, 4]],
 [[1, 2], {3, 4}],
 [[1, 2], {3}, {4}],
 [[1], {2, 3, 4}],
 [[1], {2, 3}, {4}],
 [[1], {2}, {3, 4}],
 [[1], {2}, {3}, {4}]]
sage: sorted(OrderedSetPartition([[1], [3], [2], [4]]).strongly_fatter())
[[[1, 3], {2, 4}],
 [[1, 3], {2}, {4}],
 [[1], {3}, {2, 4}],
 [[1], {3}, {2}, {4}]]
sage: sorted(OrderedSetPartition([[4], [1, 5], [3]]).strongly_fatter())
[[[4], {1, 5}, {3}], [[4], {1}, {5}, {3}]]`
```

strongly_finer()

Return the set of ordered set partitions which are strongly finer than self.

See is_strongly_finer() for the definition of “strongly finer”.

EXAMPLES:

```
sage: C = OrderedSetPartition([[1, 3], [2]]).strongly_finer()
sage: C.cardinality()
2
```
sage: C.list()
[[[1], {3}, {2}], [{1, 3}, {2}]]

sage: OrderedSetPartition([]).strongly_finer()
{[]}

sage: W = OrderedSetPartition([[-1, 2], [4, 9]])

sage: W.strongly_finer().list()
[[{4}, {9}, {-1}, {2}],
[{4}, {9}, {-1, 2}],
[{4, 9}, {-1}, {2}],
[{4, 9}, {-1, 2}]]

\textbf{static sum}(osps)

Return the concatenation of the given ordered set partitions osps (provided they have no elements in common).

\textbf{INPUT:}

\begin{itemize}
  \item osps – a list (or iterable) of ordered set partitions
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: OrderedSetPartition.sum([OrderedSetPartition([[4, 1], [3]]),
   OrderedSetPartition([[7], [2]]), OrderedSetPartition([[5, 6]])])
[[{1, 4}, {3}, {7}, {2}, {5, 6}]]
\end{verbatim}

Any iterable can be provided as input:

\begin{verbatim}
sage: Composition.sum([OrderedSetPartition([2*i,2*i+1]) for i in [4,1,3]])
[[8, 9}, {2, 3}, {6, 7}]
\end{verbatim}

Empty inputs are handled gracefully:

\begin{verbatim}
sage: OrderedSetPartition.sum([]) == OrderedSetPartition([])
True
\end{verbatim}

\textbf{to_composition}()

Return the integer composition whose parts are the sizes of the sets in self.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: S = OrderedSetPartitions(5)
sage: x = S([[3,5,4], [1, 2]])
sage: x.to_composition()
[3, 2]
sage: y = S([[3,1], [2], [5,4]])
sage: y.to_composition()
[2, 1, 2]
\end{verbatim}

\textbf{to_packed_word}()

Return the packed word on alphabet \{1, 2, 3, \ldots\} corresponding to self.

A \textit{packed word} on alphabet \{1, 2, 3, \ldots\} is any word whose maximum letter is the same as its total number of distinct letters. Let $P$ be an ordered set partition of a set $X$. The corresponding packed word $w_1 w_2 \cdots w_n$ is constructed by having letter $w_i = j$ if the $i$-th smallest entry in $X$ occurs in the $j$-th block of $P$. 
See also:

Word.to_ordered_set_partition()

**Warning:** This assumes there is a total order on the underlying set (self._base_set).

**EXAMPLES:**

```python
sage: S = OrderedSetPartitions()
sage: x = S([[3,5], [2], [1,4,6]])
sage: x.to_packed_word()
word: 321313
```

```python
sage: x = S([['a', 'c', 'e'], ['b', 'd']])
sage: x.to_packed_word()
word: 12121
```

class sage.combinat.set_partition_ordered.OrderedSetPartitions(s)
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Return the combinatorial class of ordered set partitions of s.

The optional argument c, if specified, restricts the parts of the partition to have certain sizes (the entries of c).

**EXAMPLES:**

```python
sage: OS = OrderedSetPartitions([1,2,3,4]); OS
Ordered set partitions of {1, 2, 3, 4}
sage: OS.cardinality()
75
sage: OS.first()
[[1], [2], [3], [4]]
sage: OS.last()
[[1, 2, 3, 4]]
sage: OS.random_element().parent() is OS
True
```

```python
sage: OS = OrderedSetPartitions([1,2,3,4], [2,2]); OS
Ordered set partitions of {1, 2, 3, 4} into parts of size [2, 2]
sage: OS.cardinality()
6
sage: OS.first()
[[1, 2], [3, 4]]
sage: OS.last()
[[3, 4], [1, 2]]
sage: OS.list()
[[[1, 2], [3, 4]],
 [[1, 3], [2, 4]],
 [[1, 4], [2, 3]],
 [[2, 3], [1, 4]],
 [[2, 4], [1, 3]],
 [[3, 4], [1, 2]]]
```
sage: OS = OrderedSetPartitions("cat")
sage: OS  # random
Ordered set partitions of {'a', 't', 'c'}
sage: sorted(OS.list(), key=str)
[[{'a', 't'}, {'c'}],
 [{'a', 'c'}, {'t'}],
 [{'a'}, {'c', 't'}],
 [{'c'}, {'a', 't'}],
 [{'t'}, {'a'}, {'c'}]]
Combinatorics, Release 9.7

```python
cardinality()

EXAMPLES:

```sage```:
    OrderedSetPartitions(0).cardinality()
    1
    sage:
    OrderedSetPartitions(1).cardinality()
    1
    sage:
    OrderedSetPartitions(2).cardinality()
    3
    sage:
    OrderedSetPartitions(3).cardinality()
    13
    sage:
    OrderedSetPartitions([1,2,3]).cardinality()
    13
    sage:
    OrderedSetPartitions(4).cardinality()
    75
    sage:
    OrderedSetPartitions(5).cardinality()
    541

class sage.combinat.set_partition_ordered.OrderedSetPartitions_scomp(s, comp)
Bases: sage.combinat.set_partition_ordered.OrderedSetPartitions

cardinality()

Return the cardinality of self.

The number of ordered set partitions of a set of length \( k \) with composition shape \( \mu \) is equal to

\[
\frac{k!}{\prod_{\mu_i \neq 0} \mu_i !}.
\]

EXAMPLES:

```sage```:
    OrderedSetPartitions(5,[2,3]).cardinality()
    10
    sage:
    OrderedSetPartitions(0, []).cardinality()
    1
    sage:
    OrderedSetPartitions(0, [0]).cardinality()
    1
    sage:
    OrderedSetPartitions(0, [0,0]).cardinality()
    1
    sage:
    OrderedSetPartitions(5, [2,0,3]).cardinality()
    10

class sage.combinat.set_partition_ordered.OrderedSetPartitions_sn(s, n)
Bases: sage.combinat.set_partition_ordered.OrderedSetPartitions

cardinality()

Return the cardinality of self.

The number of ordered partitions of a set of size \( n \) into \( k \) parts is equal to \( k!S(n,k) \) where \( S(n,k) \) denotes the Stirling number of the second kind.

EXAMPLES:

```sage```:
    OrderedSetPartitions(4,2).cardinality()
    14
    sage:
    OrderedSetPartitions(4,1).cardinality()
    1
```

5.1. Comprehensive Module List
class sage.combinat.set_partition_ordered.SplitNK(s, comp)
    Bases: sage.combinat.set_partition_ordered.OrderedSetPartitions_scomp

5.1.277 Characters of the symmetric group as bases of the symmetric functions

Just as the Schur functions are the irreducible characters of \( GL_n \) and form a basis of the symmetric functions, the irreducible symmetric group character basis are the irreducible characters of of \( S_n \) when the group is realized as the permutation matrices.

REFERENCES:

class sage.combinat.sf.character.generic_character(Sym, basis_name=None, prefix=None, graded=True)

Bases: sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic

class sage.combinat.sf.character.induced_trivial_character_basis(Sym, prefix)

Bases: sage.combinat.sf.character.generic_character

The induced trivial symmetric group character basis of the symmetric functions.

This is a basis of the symmetric functions that has the property that \( \text{self(la)}. \text{character_to_frobenius_image}(n) \) is equal to \( h([n-\text{sum(la)}]+1) \).

It has the property that the (outer) structure constants are the analogue of the stable Kronecker coefficients on the complete basis.

This basis is introduced in [OZ2015].

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: h = Sym.h()
sage: ht = SymmetricFunctions(QQ).ht()
sage: st = SymmetricFunctions(QQ).st()
sage: st(ht[s[2,1]])
sage: st(s(ht[2,1]))
sage: st(ht[h[2,1]])
ht[1] + 2*ht[1, 1] + ht[2, 1]
sage: st(s(ht[2,1]))
h[1] - 2*h[1, 1] + h[2, 1]
sage: st(ht[st[2,1]])
sage: ht[2]*ht[1,1]
ht[1, 1] + 2*ht[1, 1, 1] + ht[2, 1, 1]
sage: h[4,2].kronecker_product(h[4,1,1])
h[2, 2, 1, 1] + 2*h[3, 1, 1, 1] + h[4, 1, 1]
sage: s(st[2,1])
sage: s(st[s[2,1]])
sage: st[2]*st[1]
sage: s[4,2].kronecker_product(s[5,1])
```
class sage.combinat.sf.character.irreducible_character_basis(Sym, prefix)
    Bases: sage.combinat.sf.character.generic_character

The irreducible symmetric group character basis of the symmetric functions.

This is a basis of the symmetric functions that has the property that self(la).
character_to_frobenius_image(n) is equal to s([n-sum(la)]+la).

It should also have the property that the (outer) structure constants are the analogue of the stable Kronecker
coefficients on the Schur basis.

This basis is introduced in [OZ2015].

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: h = Sym.h()
sage: st = SymmetricFunctions(QQ).st()
sage: st(ht[2,1])
sage: st(ht[2,1])
sage: st[s(2,1)]
sage: st[2]*st[1]
sage: s[4,2].kronecker_product(s[5,1])
sage: st[1,1,1].counit()
-1sage: all(sum(c*st(la)*st(mu).antipode() for ((la,mu),c) in st(ga).coproduct())==st(st(ga).counit()) for ga in Partitions(3))
True
```

5.1.278 Classical symmetric functions

class sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical(Sym, basis_name=None, prefix=None, graded=True)

Bases: sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic

The class of classical symmetric functions.

Todo: delete this class once all coercions will be handled by Sage's coercion model

class Element
    Bases: sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic.Element

    A symmetric function.
sage.combinat.sf.classical.init()
Set up the conversion functions between the classical bases.

EXAMPLES:

```python
sage: from sage.combinat.sf.classical import init
sage: sage.combinat.sf.classical.conversion_functions = {}
```

The following checks if the bug described in trac ticket #15312 is fixed.

```python
sage: change = sage.combinat.sf.classical.conversion_functions[('powersum', 'Schur '\rightarrow')]
sage: hideme = change({Partition([1]*47):ZZ(1)})  # long time
sage: change({Partition([2,2]):QQ(1)})
```

5.1.279 Generic dual bases symmetric functions

```python
class sage.combinat.sf.dual.SymmetricFunctionAlgebra_dual(dual_basis, scalar, scalar_name='',
                                basis_name=None, prefix=None)
```

Bases: `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical`

Generic dual basis of a basis of symmetric functions.

INPUT:

- **dual_basis** – a basis of the ring of symmetric functions
- **scalar** – A function \( z \) on partitions which determines the scalar product on the power sum basis by \( \langle p_\mu, p_\nu \rangle = z(\mu) \). (Independently on the function chosen, the power sum basis will always be orthogonal; the function scalar only determines the norms of the basis elements.) This defaults to the function \( \text{zee} \) defined in `sage.combinat.sf.sfa`, that is, the function is defined by:

\[
\lambda \mapsto \prod_{i=1}^{\infty} m_i(\lambda)!!^{m_i(\lambda)},
\]

where \( m_i(\lambda) \) means the number of times \( i \) appears in \( \lambda \). This default function gives the standard Hall scalar product on the ring of symmetric functions.
- **scalar_name** – (default: the empty string) a string giving a description of the scalar product specified by the parameter scalar
- **basis_name** – (optional) a string to serve as name for the basis to be generated (such as “forgotten” in “the forgotten basis”); don’t set it to any of the already existing basis names (such as homogeneous, monomial, forgotten, etc.).
- **prefix** – (default: 'd' and the prefix for dual_basis) a string to use as the symbol for the basis

OUTPUT:

The basis of the ring of symmetric functions dual to the basis dual_basis with respect to the scalar product determined by scalar.

EXAMPLES:
sage: e = SymmetricFunctions(QQ).e()
sage: f = e.dual_basis(prefix = "m", basis_name="Forgotten symmetric functions"); f
Symmetric Functions over Rational Field in the Forgotten symmetric functions basis
sage: TestSuite(f).run(elements = [f[1,1]+2*f[2], f[1]+3*f[1,1]])
sage: TestSuite(f).run()  # long time (11s on sage.math, 2011)

This class defines canonical coercions between self and self^*, as follow:

Lookup for the canonical isomorphism from self to P (=powersum), and build the adjoint isomorphism from P^* to self^*. Since P is self-adjoint for this scalar product, derive an isomorphism from P to self^*, and by composition with the above get an isomorphism from self to self^* (and similarly for the isomorphism self^* to self).

This should be stripped down to just (auto?) defining canonical isomorphism by adjunction (as in MuPAD-Combinat), and let the coercion handle the rest.

Inversions may not be possible if the base ring is not a field:

sage: m = SymmetricFunctions(ZZ).m()
sage: h = m.dual_basis(lambda x: 1)
sage: h[2,1]
Traceback (most recent call last):
... 
TypeError: no conversion of this rational to integer

By transitivity, this defines indirect coercions to and from all other bases:

class Element(A, dictionary=None, dual=None)

An element in the dual basis.

INPUT:

At least one of the following must be specified. The one (if any) which is not provided will be computed.

  • dictionary – an internal dictionary for the monomials and coefficients of self
  • dual – self as an element of the dual basis.

dual()

Return self in the dual basis.

OUTPUT:

  • the element self expanded in the dual basis to self.parent()

EXAMPLES:

sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
Combinatorics, Release 9.7

sage: a = h([2,1])
sage: a.parent()
Dual basis to Symmetric Functions over Rational Field in the monomial basis
sage: a.dual()
3*m[1, 1, 1] + 2*m[2, 1] + m[3]

expand(n, alphabet='x')

Expand the symmetric function self as a symmetric polynomial in n variables.

INPUT:
• n – a nonnegative integer
• alphabet – (default: 'x') a variable for the expansion

OUTPUT:
A monomial expansion of self in the n variables labelled by alphabet.

EXAMPLES:

sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual basis(zee)
sage: a = h([2,1])+h([3])
sage: a.expand(2)
2*x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + 2*x1^3
sage: a.dual().expand(2)
2*x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + 2*x1^3
sage: a.expand(2,alphabet='y')
2*y0^3 + 3*y0^2*y1 + 3*y0*y1^2 + 2*y1^3
sage: a.expand(2,alphabet='x,y')
2*x^3 + 3*x^2*y + 3*x*y^2 + 2*y^3
sage: h([1]).expand(0)
0
sage: (3*h([1])).expand(0)
3

omega()

Return the image of self under the omega automorphism.

The omega automorphism is defined to be the unique algebra endomorphism \( \omega \) of the ring of symmetric functions that satisfies \( \omega(e_k) = h_k \) for all positive integers \( k \) (where \( e_k \) stands for the \( k \)-th elementary symmetric function, and \( h_k \) stands for the \( k \)-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function \( p_k \) to \((-1)^{k-1} p_k \) for every positive integer \( k \).

The images of some bases under the omega automorphism are given by

\[
\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{\ell(\lambda)} p_{\lambda'}, \quad \omega(s_\lambda) = s_{\lambda'},
\]

where \( \lambda \) is any partition, where \( \ell(\lambda) \) denotes the length (length()) of the partition \( \lambda \), where \( \lambda' \) denotes the conjugate partition (conjugate()) of \( \lambda \), and where the usual notations for bases are used (\( e = \) elementary, \( h = \) complete homogeneous, \( p = \) powersum, \( s = \) Schur).

omega_involution() is a synonym for the omega() method.

OUTPUT:
• the result of applying omega to self

5.1. Comprehensive Module List 2747
omega_involution()  

Return the image of self under the omega automorphism.  

The *omega automorphism* is defined to be the unique algebra endomorphism $\omega$ of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers $k$ (where $e_k$ stands for the $k$-th elementary symmetric function, and $h_k$ stands for the $k$-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function $p_k$ to $(-1)^{k-1}p_k$ for every positive integer $k$.  

The images of some bases under the omega automorphism are given by  

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$  

where $\lambda$ is any partition, where $\ell(\lambda)$ denotes the length ($\text{length}(\lambda)$) of the partition $\lambda$, where $\lambda'$ denotes the conjugate partition ($\text{conjugate}()$) of $\lambda$, and where the usual notations for bases are used ($e$ = elementary, $h$ = complete homogeneous, $p$ = powersum, $s$ = Schur).

*omega_involution()* is a synonym for the *omega()* method.

**OUTPUT:**  
• the result of applying omega to self

**EXAMPLES:**

```python
sage: m = SymmetricFunctions(QQ).monomial()  
sage: zee = sage.combinat.sf.sfa.zee  
sage: h = m.dual_basis(zee)  
sage: hh = SymmetricFunctions(QQ).homogeneous()  
sage: hh([2,1]).omega()  
h[1, 1, 1] - h[2, 1]  
sage: h([2,1]).omega()  
d_m[1, 1, 1] - d_m[2, 1]
```

**scalar(x)**  

Return the standard scalar product of self and x.

**INPUT:**  
• x — element of the symmetric functions

**OUTPUT:**  
• the scalar product between x and self

**EXAMPLES:**

```python
sage: m = SymmetricFunctions(QQ).monomial()  
sage: zee = sage.combinat.sf.sfa.zee  
sage: h = m.dual_basis(scalar=zee)  
sage: a = h([2,1])
(continues on next page)```
Combinatorics, Release 9.7

sage: a.scalar(a)
2

**scalar_hl(x)**

Return the Hall-Littlewood scalar product of `self` and `x`.

**INPUT:**
- `x` – element of the same dual basis as `self`

**OUTPUT:**
- the Hall-Littlewood scalar product between `x` and `self`

**EXAMPLES:**

```python
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2,1])
sage: a.scalar_hl(a)
(-t - 2)/(t^4 - 2*t^3 + 2*t - 1)
```

**product(left, right)**

Return product of `left` and `right`.

Multiplication is done by performing the multiplication in the dual basis of `self` and then converting back to `self`.

**INPUT:**
- `left`, `right` – elements of `self`

**OUTPUT:**
- the product of `left` and `right` in the basis `self`

**EXAMPLES:**

```python
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2])
sage: b = a*a; b  # indirect doctest
d_m[2, 2]
sage: b.dual()
6*m[1, 1, 1, 1] + 4*m[2, 1, 1] + 3*m[2, 2] + 2*m[3, 1] + m[4]
```

**transition_matrix(basis, n)**

Returns the transition matrix between the `n`th homogeneous components of `self` and `basis`.

**INPUT:**
- `basis` – a target basis of the ring of symmetric functions
- `n` – nonnegative integer

**OUTPUT:**
- A transition matrix from `self` to `basis` for the elements of degree `n`. The indexing order of the rows and columns is the order of `Partitions(n)`.

**EXAMPLES:**

5.1. Comprehensive Module List
```python
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: e = Sym.elementary()
sage: f = e.dual_basis()
sage: f.transition_matrix(s, 5)
\[
[ 1 -1 0 1 0 -1 1 ]
[-2 1 1 -1 1 0 0 ]
[-2 2 -1 -1 1 0 0 ]
[ 3 -1 -1 1 0 0 0 ]
[ 3 -2 1 0 0 0 0 ]
[-4 1 0 0 0 0 0 ]
[ 1 0 0 0 0 0 0 ]
\]
sage: Partitions(5).list()
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: s(f[2,2,1])
sage: e.transition_matrix(s, 5).inverse().transpose()
\[
[ 1 -1 0 1 0 -1 1 ]
[-2 1 1 -1 1 0 0 ]
[-2 2 -1 -1 1 0 0 ]
[ 3 -1 -1 1 0 0 0 ]
[ 3 -2 1 0 0 0 0 ]
[-4 1 0 0 0 0 0 ]
[ 1 0 0 0 0 0 0 ]
\]
```

### 5.1.280 Elementary symmetric functions

#### class sage.combinat.sf.elementary.SymmetricFunctionAlgebra_elementary(Sym)

Bases: `sage.combinat.sf.multiplicative.SymmetricFunctionAlgebra_multiplicative`

A class for methods for the elementary basis of the symmetric functions.

**INPUT:**

- `self` – an elementary basis of the symmetric functions
- `Sym` – an instance of the ring of symmetric functions

#### class Element

**expand**(*n*, *alphabet='x'*)

Expand the symmetric function `self` as a symmetric polynomial in `n` variables.

**INPUT:**

- `n` – a nonnegative integer
- `alphabet` – (default: 'x') a variable for the expansion

**OUTPUT:**

A monomial expansion of `self` in the `n` variables labelled by `alphabet`.

**EXAMPLES:**

```python
sage: e = SymmetricFunctions(QQ).e()
sage: e([2,1]).expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 3*x0^2*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
```
Combinatorics, Release 9.7

sage: e([1,1,1]).expand(2)
x0^3 + 3*x0*x1^2 + 3*x0*x1^2 + x1^3
sage: e([3]).expand(2)
0
sage: e([3]).expand(4,alphabet='x,y,z,t')
x*y*z + x*y*t + x*z*t + y*z*t
sage: e([3]).expand(4,alphabet='y')
y0*y1*y2 + y0*y1*y3 + y0*y2*y3 + y1*y2*y3
sage: e([]).expand(2)
1
sage: e([]).expand(0)
1
sage: (3*e([])).expand(0)
3

exponential_specialization(t=None, q=1)

Return the exponential specialization of a symmetric function (when \( q = 1 \)), or the \( q \)-exponential specialization (when \( q \neq 1 \)).

The exponential specialization \( ex \) at \( t \) is a \( K \)-algebra homomorphism from the \( K \)-algebra of symmetric functions to another \( K \)-algebra \( R \). It is defined whenever the base ring \( K \) is a \( Q \)-algebra and \( t \) is an element of \( R \). The easiest way to define it is by specifying its values on the powersum symmetric functions to be \( p_1 = t \) and \( p_n = 0 \) for \( n > 1 \). Equivalently, on the homogeneous functions it is given by \( ex(h_n) = t^n/n! \); see Proposition 7.8.4 of [EnumComb2].

By analogy, the \( q \)-exponential specialization is a \( K \)-algebra homomorphism from the \( K \)-algebra of symmetric functions to another \( K \)-algebra \( R \) that depends on two elements \( t \) and \( q \) of \( R \) for which the elements \( 1 - q^i \) for all positive integers \( i \) are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

\[
ex_q(h_n) = t^n/[n]_q!,
\]

where \([n]_q\) is the \( q \)-factorial. Equivalently, for \( q \neq 1 \) and a homogeneous symmetric function \( f \) of degree \( n \), we have

\[
ex_q(f) = (1-q)^n t^n p_s_q(f),
\]

where \( p_s_q(f) \) is the stable principal specialization of \( f \) (see principal_specialization()). (See (7.29) in [EnumComb2].)

The limit of \( ex_q \) as \( q \to 1 \) is \( ex \).

INPUT:

• \( t \) (default: None) – the value to use for \( t \); the default is to create a ring of polynomials in \( t \).
• \( q \) (default: 1) – the value to use for \( q \). If \( q \) is None, then a ring (or fraction field) of polynomials in \( q \) is created.

EXAMPLES:

sage: e = SymmetricFunctions(QQ).e()
sage: x = e[3,2]
sage: x.exponential_specialization()
1/12*t^5
sage: x = 5*e[2] + 3*e[1] + 1

5.1. Comprehensive Module List 2751
omega()

Return the image of self under the omega automorphism.

The omega automorphism is defined to be the unique algebra endomorphism \( \omega \) of the ring of symmetric functions that satisfies \( \omega(e_k) = h_k \) for all positive integers \( k \) (where \( e_k \) stands for the \( k \)-th elementary symmetric function, and \( h_k \) stands for the \( k \)-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function \( p_k \) to \((-1)^{k-1}p_k \) for every positive integer \( k \).

The images of some bases under the omega automorphism are given by

\[
\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda^\prime},
\]

where \( \lambda \) is any partition, where \( \ell(\lambda) \) denotes the length (\( \text{length}() \)) of the partition \( \lambda \), where \( \lambda^\prime \) denotes the conjugate partition (\( \text{conjugate}() \)) of \( \lambda \), and where the usual notations for bases are used (\( e = \text{elementary}, h = \text{complete homogeneous}, p = \text{powersum}, s = \text{Schur} \)).

\text{omega_involution()} is a synonym for the \text{omega()} method.

EXAMPLES:

\begin{verbatim}
sage: e = SymmetricFunctions(QQ).e()
sage: a = e([2,1]); a
e[2, 1]
sage: a.omega()
e[1, 1, 1] - e[2, 1]
\end{verbatim}

\begin{verbatim}
sage: h = SymmetricFunctions(QQ).h()
sage: h(e([2,1]).omega())
h[2, 1]
\end{verbatim}

omega_involution()

Return the image of self under the omega automorphism.

The omega automorphism is defined to be the unique algebra endomorphism \( \omega \) of the ring of symmetric functions that satisfies \( \omega(e_k) = h_k \) for all positive integers \( k \) (where \( e_k \) stands for the \( k \)-th elementary symmetric function, and \( h_k \) stands for the \( k \)-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function \( p_k \) to \((-1)^{k-1}p_k \) for every positive integer \( k \).

The images of some bases under the omega automorphism are given by

\[
\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda^\prime},
\]

where \( \lambda \) is any partition, where \( \ell(\lambda) \) denotes the length (\( \text{length}() \)) of the partition \( \lambda \), where \( \lambda^\prime \) denotes the conjugate partition (\( \text{conjugate}() \)) of \( \lambda \), and where the usual notations for bases are used (\( e = \text{elementary}, h = \text{complete homogeneous}, p = \text{powersum}, s = \text{Schur} \)).

\text{omega_involution()} is a synonym for the \text{omega()} method.

EXAMPLES:
sage: e = SymmetricFunctions(QQ).e()
sage: a = e([2,1]); a
e[2, 1]
sage: a.omega()
e[1, 1, 1] - e[2, 1]

sage: h = SymmetricFunctions(QQ).h()
sage: h(e([2,1]).omega())
h[2, 1]

principal_specialization(n=+ Infinity, q=None)

Return the principal specialization of a symmetric function.

The principal specialization of order \( n \) at \( q \) is the ring homomorphism \( ps_{n, q} \) from the ring of symmetric functions to another commutative ring \( R \) given by \( x_i \mapsto q^{i-1} \) for \( i \in \{1, \ldots, n\} \) and \( x_i \mapsto 0 \) for \( i > n \). Here, \( q \) is a given element of \( R \), and we assume that the variables of our symmetric functions are \( x_1, x_2, x_3, \ldots \). (To be more precise, \( ps_{n, q} \) is a \( K \)-algebra homomorphism, where \( K \) is the base ring.) See Section 7.8 of [EnumComb2].

The stable principal specialization at \( q \) is the ring homomorphism \( ps_q \) from the ring of symmetric functions to another commutative ring \( R \) given by \( x_i \mapsto q^{i-1} \) for all \( i \). This is well-defined only if the resulting infinite sums converge; thus, in particular, setting \( q = 1 \) in the stable principal specialization is an invalid operation.

INPUT:

- \( n \) (default: infinity) – a nonnegative integer or infinity, specifying whether to compute the principal specialization of order \( n \) or the stable principal specialization.
- \( q \) (default: None) – the value to use for \( q \); the default is to create a ring of polynomials in \( q \) (or a field of rational functions in \( q \)) over the given coefficient ring.

We use the formulas from Proposition 7.8.3 of [EnumComb2] (using Gaussian binomial coefficients \( \binom{n}{\lambda_i}^q \)):

\[
ps_{n,q}(e_{\lambda}) = \prod_i q^{\binom{\lambda_i}{2}} \binom{n}{\lambda_i}^q,\\
ps_{n,1}(e_{\lambda}) = \prod_i \binom{n}{\lambda_i},\\
ps_q(e_{\lambda}) = \prod_i q^{\binom{\lambda_i}{2}} / \prod_{j=1}^n (1 - q^j).
\]

EXAMPLES:

sage: e = SymmetricFunctions(QQ).e()
sage: x = e[3,1]
sage: x.principal_specialization(3)
q^5 + q^4 + q^3
sage: x = 5*e[1,1,1] + 3*e[2,1] + 1
sage: x.principal_specialization(3)
5*q^6 + 18*q^5 + 36*q^4 + 44*q^3 + 36*q^2 + 18*q + 6

By default, we return a rational functions in \( q \). Sometimes it is better to obtain an element of the symbolic ring:

By default, we return a rational functions in \( q \). Sometimes it is better to obtain an element of the symbolic ring:
verschiebung($n$)

Return the image of the symmetric function self under the $n$-th Verschiebung operator.

The $n$-th Verschiebung operator $V_n$ is defined to be the unique algebra endomorphism $V$ of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer $r$ divisible by $n$, and satisfies $V(h_r) = 0$ for every positive integer $r$ not divisible by $n$. This operator $V_n$ is a Hopf algebra endomorphism. For every nonnegative integer $r$ with $n \mid r$, it satisfies

$$V_n(h_r) = h_{r/n} \quad V_n(p_r) = np_{r/n} \quad V_n(e_r) = (-1)^{r-r/n}e_{r/n}$$

(where $h$ is the complete homogeneous basis, $p$ is the powersum basis, and $e$ is the elementary basis). For every nonnegative integer $r$ with $n \nmid r$, it satisfies

$$V_n(h_r) = V_n(p_r) = V_n(e_r) = 0.$$  

The $n$-th Verschiebung operator is also called the $n$-th Verschiebung endomorphism. Its name derives from the Verschiebung (German for 'shift') endomorphism of the Witt vectors.

The $n$-th Verschiebung operator is adjoint to the $n$-th Frobenius operator (see `frobenius()` for its definition) with respect to the Hall scalar product (`scalar()`).

The action of the $n$-th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley [STA].

Let $\lambda$ be a partition. Let $n$ be a positive integer. If the $n$-core of $\lambda$ is nonempty, then $V_n(s_{\lambda}) = 0$. Otherwise, the following method computes $V_n(s_{\lambda})$: Write the partition $\lambda$ in the form $(\lambda_1, \lambda_2, \ldots, \lambda_{ns})$ for some nonnegative integer $s$. (If $n$ does not divide the length of $\lambda$, then this is achieved by adding trailing zeroes to $\lambda$.) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \ldots, ns\}$. Then, $(\beta_1, \beta_2, \ldots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo $n$. Let $\xi$ be the sign of the permutation that is used for this sorting. Let $\psi$ be the sign of the permutation that is used to stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo $n$. (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $V_n(s_{\lambda}) = \xi\psi\prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \ldots, \lambda^{(n-1)})$ is the $n$-quotient of $\lambda$.

INPUT:

• $n$ – a positive integer

OUTPUT:

The result of applying the $n$-th Verschiebung operator (on the ring of symmetric functions) to self.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: e[3].verschiebung(2)
\emptyset
e[4].verschiebung(4)
-e[1]
```

The Verschiebung endomorphisms are multiplicative:

```
sage: all( all( e(lam).verschiebung(2) * e(mu).verschiebung(2) == (e(lam) * e(mu)).verschiebung(2) ) for lam in partitions(4) for mu in partitions(4) )
```

(continues on next page)
....:     for mu in Partitions(4) )
....:     for lam in Partitions(4) )
True

coproduct_on_generators(i)
Returns the coproduct on \textit{self}[i].

INPUT:
- \textit{self} – an elementary basis of the symmetric functions
- \textit{i} – a nonnegative integer

OUTPUT:
- returns the coproduct on the elementary generator \(e(i)\)

EXAMPLES:

\begin{verbatim}
sage: Sym = SymmetricFunctions(QQ)
sage: e = Sym.elementary()
sage: e.coproduct_on_generators(2)
sage: e.coproduct_on_generators(0)
e[] # e[]
\end{verbatim}

5.1.281 Hall-Littlewood Polynomials

Notation used in the definitions follows mainly [Mac1995].

\textbf{class} \texttt{sage.combinat.sf.hall_littlewood.HallLittlewood(Sym, t='t')}

\texttt{Bases: sage.structure.unique_representation.UniqueRepresentation}

The family of Hall-Littlewood symmetric function bases.

The Hall-Littlewood symmetric functions are a family of symmetric functions that depend on a parameter \(t\).

INPUT:

By default the parameter for these functions is \(t\), and whatever the parameter is, it must be in the base ring.

EXAMPLES:

\begin{verbatim}
sage: SymmetricFunctions(QQ).hall_littlewood(1)
Hall-Littlewood polynomials with \(t=1\) over Rational Field
sage: SymmetricFunctions(QQ['t']).fraction_field().hall_littlewood()
Hall-Littlewood polynomials over Fraction Field of Univariate Polynomial Ring in \(t\) over Rational Field
\end{verbatim}

\texttt{P()}

Return the algebra of symmetric functions in the Hall-Littlewood \(P\) basis. This is the same as the \(HL\) basis in John Stembridge’s SF examples file.

INPUT:
- \texttt{self} – a class of Hall-Littlewood symmetric function bases

OUTPUT:

The class of the Hall-Littlewood \(P\) basis.
EXAMPLES:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P(); HLP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the Hall-Littlewood P basis
sage: SP = Sym.hall_littlewood(t=-1).P(); SP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the Hall-Littlewood P with t=-1 basis
sage: s = Sym.schur()
sage: s(HLP([2,1]))
(-t^2-t)*s[1, 1, 1] + s[2, 1]
```

The Hall-Littlewood polynomials in the $P$ basis at $t = 0$ are the Schur functions:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: HLP = Sym.hall_littlewood(t=0).P()
sage: s = Sym.schur()
sage: s(HLP([2,1])) == s([2,1])
True
```

The Hall-Littlewood polynomials in the $P$ basis at $t = 1$ are the monomial symmetric functions:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: HLP = Sym.hall_littlewood(t=1).P()
sage: m = Sym.monomial()
sage: m(HLP([2,2,1])) == m([2,2,1])
True
```

We end with some examples of coercions between:

1. Hall-Littlewood $P$ basis.
2. Hall-Littlewood polynomials in the $Q$ basis
3. Hall-Littlewood polynomials in the $Q'$ basis (via the Schurs)
4. Classical symmetric functions

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQp = Sym.hall_littlewood().Qp()
sage: s = Sym.schur()
sage: p = Sym.power()
sage: HLP(HLQ([[2]])) # indirect doctest
(-t+1)*HLP[2]
sage: HLP(HLQp([[2]]))
t*HLP[1, 1] + HLP[2]
sage: HLP(s([2]))
t*HLP[1, 1] + HLP[2]
sage: HLP(p([2]))
(t-1)*HLP[1, 1] + HLP[2]
sage: s = HLQp.symmetric_function_ring().s()
sage: HLQp.transition_matrix(s,3)
[     1     0     0]
```

(continues on next page)
\[ \begin{bmatrix} t & 1 & 0 \\ t^3 & t^2 + t & 1 \end{bmatrix} \]

\[
sage: s.transition_matrix(HLP, 3)
\begin{bmatrix} 1 & t & t^3 \\ 0 & 1 & t^2 + t \\ 0 & 0 & 1 \end{bmatrix}
\]

The method `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element.hl_creation_operator()` is a creation operator for the $Q$ basis:

\[
sage: HLQp[1].hl_creation_operator([3]).hl_creation_operator([3])
HLQp[3, 3, 1]
\]

Transitions between bases with the parameter $t$ specialized:

\[
sage: Sym = SymmetricFunctions(FractionField(QQ['y','z']))
sage: (y,z) = Sym.base_ring().gens()
sage: HLY = Sym.hall_littlewood(t=y)
sage: HLZ = Sym.hall_littlewood(t=z)
sage: Qy = HLY.Qp()
sage: Qpz = HLZ.Qp()
sage: s = Sym.schur()
sage: s(Qpy[3,1] + z*Qpy[2,2])
z*s[2, 2] + (y^2z+y)*s[3, 1] + (y^2z+y)*s[4]
sage: s(Qpy[3,1] + y*Qpz[2,2])
y*s[2, 2] + (y^2z+y)*s[3, 1] + (y^2z+y)*s[4]
sage: s(Qpy[3,1] + y*Qpy[2,2])
y*s[2, 2] + (y^2z+y)*s[3, 1] + (y^3+y)*s[4]
sage: Qy = HLY.Q()
sage: Qz = HLZ.Q()
sage: Py = HLY.P()
sage: Pz = HLZ.P()
sage: Pz(Qpy[2,1])
(y^3z^3z^2z+2)^HLP[1, 1, 1] + (y^2z+1)^HLP[2, 1] + y^HLP[3]
sage: Pz(Qz[2,1])
(z^2-2z+1)^HLP[2, 1]
sage: Qz(Py[2])
((-y+z)/(y^3z^2z^2-2z+1))^HLQ[1, 1] + (1/(-z+1))^HLQ[2]
sage: Qy(Pz[2])
((y-z)/(y^3z^2z^2-1))^HLQ[1, 1] + (1/(-y+1))^HLQ[2]
sage: Qy.hall_littlewood_family() == HLY
True
sage: Qy.hall_littlewood_family() == HLZ
False
sage: Qz.symmetric_function_ring() == Qy.symmetric_function_ring()
True
sage: Sym = SymmetricFunctions(FractionField(QQ['q']))
sage: q = Sym.base_ring().gen()
sage: HL = Sym.hall_littlewood(t=q)
sage: HLQp = HL.Qp()
\]

(continues on next page)
The $P$ and $Q$-Schur at $t = -1$ indexed by strict partitions are a basis for the space algebraically generated by the odd power sum symmetric functions:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: SP = Sym.hall_littlewood(t=-1).P()
sage: SQ = Sym.hall_littlewood(t=-1).Q()
sage: p = Sym.power()
sage: SP(SQ[3,2,1])
8*HLP[3, 2, 1]
sage: SP(SQ[2,2,1])
0
sage: p(SP[3,2,1])
1/45*p[1, 1, 1, 1, 1, 1] - 1/9*p[3, 1, 1, 1, 1] - 1/9*p[3, 3] + 1/5*p[5, 1]
sage: SP(p[3,3])
```

Q()

Returns the algebra of symmetric functions in Hall-Littlewood $Q$ basis. This is the same as the $Q$ basis in John Stembridge’s SF examples file.

More extensive examples can be found in the documentation for the Hall-Littlewood $P$ basis.

INPUT:

- `self` – a class of Hall-Littlewood symmetric function bases

OUTPUT:

- returns the class of the Hall-Littlewood $Q$ basis

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLQ = Sym.hall_littlewood().Q(); HLQ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the Hall-Littlewood Q basis
sage: SQ = SymmetricFunctions(QQ).hall_littlewood(t=-1).Q(); SQ
Symmetric Functions over Rational Field in the Hall-Littlewood Q with t=-1 basis
```

Qp() Returns the algebra of symmetric functions in Hall-Littlewood $Q'$ (Qp) basis. This is dual to the Hall-Littlewood $P$ basis with respect to the standard scalar product.

More extensive examples can be found in the documentation for the Hall-Littlewood $P$ basis.
INPUT:

- `self` – a class of Hall-Littlewood symmetric function bases

OUTPUT:

- returns the class of the Hall-Littlewood $Q_p$-basis

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLQp = Sym.hall_littlewood().Qp(); HLQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the Hall-Littlewood Qp basis
```

`base_ring()`

Returns the base ring of the symmetric functions where the Hall-Littlewood symmetric functions live

INPUT:

- `self` – a class of Hall-Littlewood symmetric function bases

OUTPUT:

The base ring of the symmetric functions.

EXAMPLES:

```python
sage: HL = SymmetricFunctions(QQ['t'].fraction_field()).hall_littlewood(t=1)
sage: HL.base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

`symmetric_function_ring()`

The ring of symmetric functions associated to the class of Hall-Littlewood symmetric functions

INPUT:

- `self` – a class of Hall-Littlewood symmetric function bases

OUTPUT:

- returns the ring of symmetric functions

EXAMPLES:

```python
sage: HL = SymmetricFunctions(FractionField(QQ['t'])).hall_littlewood()
sage: HL.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

`class` `sage.combinat.sf.hall_littlewood.HallLittlewood_generic(hall_littlewood)`

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic`

A class with methods for working with Hall-Littlewood symmetric functions which are common to all bases.

INPUT:

- `self` – a Hall-Littlewood symmetric function basis
- `hall_littlewood` – a class of Hall-Littlewood bases

`class Element`

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element`

Methods for elements of a Hall-Littlewood basis that are common to all bases.
**expand**\((n, \text{alphabet}='x')\)

Expands the symmetric function as a symmetric polynomial in \(n\) variables.

**INPUT:**
- **self** – an element of a Hall-Littlewood basis
- **n** – a positive integer
- **alphabet** – a string representing a variable name (default: 'x')

**OUTPUT:**
- returns a symmetric polynomial of **self** in \(n\) variables

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))

sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQp = Sym.hall_littlewood().Qp()
sage: HLP([2]).expand(2)
\(x0^2 + (-t + 1)^*x0^*x1 + x1^2\)
sage: HLQ([2]).expand(2)
\((-t + 1)^*x0^*x2 + (t^2 - 2*t + 1)^*x0^*x1 + (-t + 1)^*x1^2\)
sage: HLQp([2]).expand(2)
\(x0^2 + x0^*x1 + x1^2\)
sage: HLQp([2]).expand(2, 'y')
\(y0^2 + y0^*y1 + y1^2\)
sage: HLQp([2]).expand(1)
x^2
```

**scalar**\((x, \text{zee}=\text{None})\)

Returns standard scalar product between **self** and **x**.

This is the default implementation that converts both **self** and **x** into Schur functions and performs the scalar product that basis. The Hall-Littlewood \(P\) basis is dual to the \(Qp\) basis with respect to this scalar product.

**INPUT:**
- **self** – an element of a Hall-Littlewood basis
- **x** – another symmetric element of the symmetric functions

**OUTPUT:**
- returns the scalar product between **self** and **x**

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))

sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQp = Sym.hall_littlewood().Qp()
sage: HLP([2]).scalar(HLQp([2]))
1
sage: HLP([2]).scalar(HLQp([1,1]))
0
sage: HLP([2]).scalar(HLQ([2]), lambda mu: mu.centralizer_size(t = HLP.t))
1
sage: HLP([2]).scalar(HLQ([1,1]), lambda mu: mu.centralizer_size(t = HLP.t))
0
```

**scalar_hl**\((x, t=\text{None})\)

Returns the Hall-Littlewood (with parameter \(t\)) scalar product of **self** and **x**.
The Hall-Littlewood scalar product is defined in Macdonald’s book [Mac1995]. The power sum basis is orthogonal and \( \langle p_\mu, p_\nu \rangle = z_\mu \prod_i 1/(1 - t^\mu_i) \)

The Hall-Littlewood \( P \) basis is dual to the \( Q \) basis with respect to this scalar product.

INPUT:
- `self` – an element of a Hall-Littlewood basis
- `x` – another symmetric element of the symmetric functions
- `t` – an optional parameter, if this parameter is not specified then the value of the \( t \) from the basis is used in the calculation

OUTPUT:
- returns the Hall-Littlewood scalar product between `self` and `x`

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLP([2]).scalar_hl(HLQ([2]))
1
sage: HLP([2]).scalar_hl(HLQ([1,1]))
0
sage: HLQ([2]).scalar_hl(HLQ([2]))
-t + 1
sage: HLQ([2]).scalar_hl(HLQ([1,1]))
0
sage: HLP([2]).scalar_hl(HLP([2]))
-1/(t - 1)
```

`hall_littlewood_family()`

The family of Hall-Littlewood bases associated to `self`

INPUT:
- `self` – a Hall-Littlewood symmetric function basis

OUTPUT:
- returns the class of Hall-Littlewood bases

EXAMPLES:

```python
sage: HLP = SymmetricFunctions(FractionField(QQ['t'])).hall_littlewood(1).P()
sage: HLP.hall_littlewood_family()
Hall-Littlewood polynomials with t=1 over Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

`product(left, right)`

Multiply an element of the Hall-Littlewood symmetric function basis `self` and another symmetric function

Convert to the Schur basis, do the multiplication there, and convert back to `self` basis.

INPUT:
- `self` – a Hall-Littlewood symmetric function basis
- `left` – an element of the basis `self`
- `right` – another symmetric function

OUTPUT:
the product of left and right expanded in the basis self

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLP([2])**2 # indirect doctest
(t+1)*HLP[2, 2] + (-t+1)*HLP[3, 1] + HLP[4]

sage: HLP = Sym.hall_littlewood().P()
sage: HLP([2])**2 # indirect doctest
HLQ[2, 2] + (-t+1)*HLQ[3, 1] + (-t+1)*HLQ[4]

sage: HLQp = Sym.hall_littlewood().Qp()
sage: HLQp([2])**2 # indirect doctest
```

**transition_matrix(basis, n)**

Returns the transitions matrix between self and basis for the homogeneous component of degree n.

**INPUT:**

- `self` – a Hall-Littlewood symmetric function basis
- `basis` – another symmetric function basis
- `n` – a non-negative integer representing the degree

**OUTPUT:**

- Returns a $r \times r$ matrix of elements of the base ring of self where $r$ is the number of partitions of n.

   The entry corresponding to row $\mu$, column $\nu$ is the coefficient of basis $(\nu)$ in self $(\mu)$

**EXAMPLES:**

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: s = Sym.schur()
sage: HLP.transition_matrix(s, 4)
[  1 -t 0 t^2 -t^3]
[  0  1 -t -t t^3 + t^2]
[  0  0  1 -t t^3]
[  0  0  0  1 -t^3 - t^2 - t]
[  0  0  0  0  1]

sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQ.transition_matrix(s, 3)
[  1 -t + 1 t^2 - t 0]
[ 0 t^2 - 2*t + 1 -t^4 + t^3]
[ 0 -t^3 + t^2 - t 0]
[ 0 0 -t^6 + t^5 + t^4 0]

sage: HLQp = Sym.hall_littlewood().Qp()
sage: HLQp.transition_matrix(s, 3)
[ 1 0 0]
[ t 1 0]
[ t^3 t^2 + t 1]
```

2762 Chapter 5. Comprehensive Module List
class sage.combinat.sf.hall_littlewood.HallLittlewood_p(hall_littlewood)
Bases: sage.combinat.sf.hall_littlewood.HallLittlewood_generic

A class representing the Hall-Littlewood \( P \) basis of symmetric functions

class Element
    Bases: sage.combinat.sf.hall_littlewood.HallLittlewood_generic.Element
class sage.combinat.sf.hall_littlewood.HallLittlewood_q(hall_littlewood)
Bases: sage.combinat.sf.hall_littlewood.HallLittlewood_generic

The \( Q \) basis is defined as a normalization of the \( P \) basis.
INPUT:

- \texttt{self} – an instance of the Hall-Littlewood \( P \) basis
- \texttt{hall_littlewood} – a class for the family of Hall-Littlewood bases

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: Q = Sym.hall_littlewood().Q()
sage: TestSuite(Q).run(skip=['_test_associativity', '_test_distributivity', '_test_⁻→prod']) # products are too expensive, long time (3s on sage.math, 2012)
sage: TestSuite(Q).run(elements = [Q.t*Q[1,1]+Q[2], Q[1]+(1+Q.t)*Q[1,1]]) # long_⁻→time (depends on previous)

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Qp()
sage: s = Sym.schur(); p = Sym.power()
sage: HLQ( HLP([2,1]) + HLP([3]) )
(t/(t^2-2*t+1))*HLQ[2, 1] - (1/(t-1))*HLQ[3]
sage: HLQ(HLQp([2]))
(t/(t^3-t^2-t+1))*HLQ[1, 1] - (1/(t-1))*HLQ[2]
sage: HLQ(p([2]))
(t/(t^2-1))*HLQ[1, 1] - (1/(t-1))*HLQ[2]
```

class Element
    Bases: sage.combinat.sf.hall_littlewood.HallLittlewood_generic.Element
class sage.combinat.sf.hall_littlewood.HallLittlewood_qp(hall_littlewood)
Bases: sage.combinat.sf.hall_littlewood.HallLittlewood_generic

The Hall-Littlewood \( Q_p \) basis is calculated through the symmetrica library (see the function HallLittlewood_qp._to_s()).

INPUT:

- \texttt{self} – an instance of the Hall-Littlewood \( P \) basis
- \texttt{hall_littlewood} – a class for the family of Hall-Littlewood bases

EXAMPLES:
Combinatorics, Release 9.7

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))

sage: Qp = Sym.hall_littlewood().Q()

sage: TestSuite(Qp).run(skip=['_test_passociativity', '_test_distributivity', '_test_prod']) # products are too expensive, long time (3s on sage.math, 2012)

sage: TestSuite(Qp).run(elements = [Qp.t*Qp[1,1]+Qp[2], Qp[1]+(1+Qp.t)*Qp[1,1]]) # long time (depends on previous)

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))

sage: HLP = Sym.hall_littlewood().P()

sage: HLQ = Sym.hall_littlewood().Q()

sage: HLQp = Sym.hall_littlewood().Qp()

sage: s = Sym.schur(); p = Sym.power()

sage: HLQp(HLP([2])) # indirect doctest
-t*HLQp[1, 1] + (t^2+1)*HLQp[2]

sage: HLQp(HLP([2])) # work around bug reported in ticket #12969
(t^2-t)*HLQp[1, 1] + (-t^3+t^2-t+1)*HLQp[2]

sage: HLQp(s([2]))

sage: HLQp(p([2]))

-HLQp[1, 1] + (t+1)*HLQp[2]

sage: s = HLQp.symmetric_function_ring().s()

sage: HLQp.transition_matrix(s,3)
[ 1 0 0]
[ t 1 0]
[ t^3 t^2 + t 1]

sage: s.transition_matrix(HLP,3)
[ 1 t t^3]
[ 0 1 t^2 + t]
[ 0 0 1]
```

class Element

Bases: `sage.combinat.sf.hall_littlewood.HallLittlewood_generic.Element`

### 5.1.282 Hecke Character Basis

The basis of symmetric functions given by characters of the Hecke algebra (of type $A$).

**AUTHORS:**

- Travis Scrimshaw (2017-08): Initial version

```python
class sage.combinat.sf.hecke.HeckeCharacter(sym, q='q')

Bases: `sage.combinat.sf.multiplicative.SymmetricFunctionAlgebra_multiplicative`

Basis of the symmetric functions that gives the characters of the Hecke algebra in analogy to the Frobenius formula for the symmetric group.

Consider the Hecke algebra $H_n(q)$ with quadratic relations

$$T_i^2 = (q - 1)T_i + q.$$ 

Let $\mu$ be a partition of $n$ with length $\ell$. The character $\chi$ of a $H_n(q)$-representation is completely determined by the elements $T_{\gamma_{\mu}}$, where

$$\gamma_{\mu} = (\mu_1, \ldots, 1)(\mu_2 + \mu_1, \ldots, 1 + \mu_1) \cdots (n, \ldots, 1 + \sum_{i<\ell} \mu_i),$$
```

Chapter 5. Comprehensive Module List
(written in cycle notation). We define a basis of the symmetric functions by

\[ \bar{q}_\mu = \sum_{\lambda \vdash n} \chi^\lambda(T_{\gamma_\mu})s_\lambda. \]

INPUT:

- `sym` – the ring of symmetric functions
- `q` – (default: `'q'`) the parameter `q`

EXAMPLES:

```python
sage: q = ZZ['q'].fraction_field().gen()
sage: Sym = SymmetricFunctions(q.parent())
sage: qbar = Sym.hecke_character(q)
qbar[3, 3, 2, 1]
sage: s = Sym.s()
sage: s(qbar([2]))
-s[1, 1] + q*s[2]
sage: s(qbar([4]))
-s[1, 1, 1, 1] + q^2*s[2, 1, 1] - q^2*s[3, 1] + q^3*s[4]
sage: qbar(s([2]))
(1/(q+1))*qbar[1, 1] + (1/(q+1))*qbar[2]
sage: qbar(s([1,1]))
(q/(q+1))*qbar[1, 1] - (1/(q+1))*qbar[2]
sage: s(qbar([2,1]))
-s[1, 1, 1] + (q-1)*s[2, 1] + q*s[3]
sage: qbar(s([2,1]))
(q/(q^2+q+1))*qbar[1, 1, 1] + ((q-1)/(q^2+q+1))*qbar[2, 1] - (1/(q^2+q+1))*qbar[3]
```

We compute character tables for Hecke algebras, which correspond to the transition matrix from the \( \bar{q} \) basis to the Schur basis:

```python
sage: qbar.transition_matrix(s, 1)
[1]
sage: qbar.transition_matrix(s, 2)
[ q -1]
[ 1 1]
sage: qbar.transition_matrix(s, 3)
[ q^2 -q 1]
[ q q - 1 -1]
[ 1 2 1]
sage: qbar.transition_matrix(s, 4)
[ q^3 -q^2 0 q -1]
[ q^2 q^2 - q -q -q + 1 1]
[ q^2 q^2 - 2*q q^2 + 1 -2*q + 1 1]
[ q 2*q - 1 q - 1 q - 2 -1]
[ 1 3 2 3 1]
```

We can do computations with a specialized `q` to a generic element of the base ring. We compute some examples with `q = 2`:  

5.1. Comprehensive Module List 2765
```python
sage: qbar = Sym.qbar(q=2)
sage: s = Sym.schur()
sage: qbar(s[2,1])
2/7*qbar[1, 1, 1] + 1/7*qbar[2, 1] - 1/7*qbar[3]
sage: s(qbar[2,1])
-s[1, 1, 1] + s[2, 1] + 2*s[3]
```

REFERENCES:
- [Ram1991]
- [RR1997]

```python
coprodct_on_generators(r)
```

Return the coproduct on the generator $\bar{q}_r$ of `self`.

Define the coproduct on $\bar{q}_r$ by

$$
\Delta(\bar{q}_r) = \bar{q}_0 \otimes \bar{q}_r + (q - 1) \sum_{j=1}^{r-1} \bar{q}_j \otimes \bar{q}_{r-j} + \bar{q}_r \otimes \bar{q}_0.
$$

EXAMPLES:
```python
sage: q = ZZ['q'].fraction_field().gen()
sage: Sym = SymmetricFunctions(q.parent())
sage: qbar = Sym.hecke_character()
sage: s = Sym.s()
sage: qbar[2].coproduct()
```

### 5.1.283 Homogeneous symmetric functions

By this we mean the basis formed of the complete homogeneous symmetric functions $h_\lambda$, not an arbitrary graded basis.

```python
class sage.combinat.sf.homogeneous.SymmetricFunctionAlgebra_homogeneous(Sym)
```

A class of methods specific to the homogeneous basis of symmetric functions.

INPUT:
- `self` – a homogeneous basis of symmetric functions
- `Sym` – an instance of the ring of symmetric functions

```python
class Element
```

Expand the symmetric function `self` as a symmetric polynomial in $n$ variables.

INPUT:
- `n` – a nonnegative integer
- `alphabet` – (default: `'x'`) a variable for the expansion

OUTPUT:
A monomial expansion of `self` in the $n$ variables labelled by `alphabet`.

EXAMPLES:
Combinatorics, Release 9.7

```python
sage: h = SymmetricFunctions(QQ).h()
sage: h([3]).expand(2)
x0^3 + x0^2*x1 + x0*x1^2 + x1^3
sage: h([1,1,1]).expand(2)
x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + x1^3
sage: h([2,1]).expand(3)
x0^3 + 2*x0^2*x1 + 2*x0*x1^2 + x1^3 + 2*x0^2*x2 + 3*x0*x1*x2 + 2*x1^2*x2 + ...
   \cdots 2*x0^2*x2 + 2*x0*x1^2*x2 + x2^3
sage: h([3]).expand(2, alphabet='y')
y0^3 + y0^2*y1 + y0*y1^2 + y1^3
sage: h([3]).expand(2, alphabet='x,y')
x^3 + x^2*y + x*y^2 + y^3
sage: h([3]).expand(3, alphabet='x,y,z')
x^3 + x^2*y + x*y^2 + y^3 + x^2*z + x*y*z + y^2*z + x*z^2 + y*z^2 + z^3
sage: (h([]) + 2*h([1])).expand(3)
2*x0 + 2*x1 + 2*x2 + 1
sage: h([1]).expand(0)
0
sage: (3*h([])).expand(0)
3
```

**exponential_specialization**(t=None, q=1)

Return the exponential specialization of a symmetric function (when \( q = 1 \)), or the \( q \)-exponential specialization (when \( q \neq 1 \)).

The exponential specialization \( ex \) at \( t \) is a \( K \)-algebra homomorphism from the \( K \)-algebra of symmetric functions to another \( K \)-algebra \( R \). It is defined whenever the base ring \( K \) is a \( Q \)-algebra and \( t \) is an element of \( R \). The easiest way to define it is by specifying its values on the power sum symmetric functions to be \( p_1 = t \) and \( p_n = 0 \) for \( n > 1 \). Equivalently, on the homogeneous functions it is given by \( ex(h_n) = t^n/n! \); see Proposition 7.8.4 of [EnumComb2].

By analogy, the \( q \)-exponential specialization is a \( K \)-algebra homomorphism from the \( K \)-algebra of symmetric functions to another \( K \)-algebra \( R \) that depends on two elements \( t \) and \( q \) of \( R \) for which the elements \( 1 - q^i \) for all positive integers \( i \) are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

\[
ex_q(h_n) = t^n/[n]_q!,
\]

where \([n]_q!\) is the \( q \)-factorial. Equivalently, for \( q \neq 1 \) and a homogeneous symmetric function \( f \) of degree \( n \), we have

\[
ex_q(f) = (1 - q)^n t^n p_s_q(f),
\]

where \( p_s_q(f) \) is the stable principal specialization of \( f \) (see principal_specialization()). (See (7.29) in [EnumComb2].)

The limit of \( ex_q \) as \( q \to 1 \) is \( ex \).

**INPUT:**
- \( t \) (default: None) – the value to use for \( t \); the default is to create a ring of polynomials in \( t \).
- \( q \) (default: 1) – the value to use for \( q \). If \( q \) is None, then a ring (or fraction field) of polynomials in \( q \) is created.

**EXAMPLES:**
sage: h = SymmetricFunctions(QQ).h()
sage: x = h[5,3]
sage: x.exponential_specialization()
1/720*t^8
sage: factorial(5)*factorial(3)
720
sage: x = 5*h[1,1,1] + 3*h[2,1] + 1
sage: x.exponential_specialization()
13/2*t^3 + 1

We also support the \(q\)-exponential_specialization:

sage: factor(h[3].exponential_specialization(q=var("q"), t=var("t")))
t^3/((q^2 + q + 1)*(q + 1))

**omega()**

Return the image of self under the omega automorphism.

The **omega automorphism** is defined to be the unique algebra endomorphism \(\omega\) of the ring of symmetric functions that satisfies \(\omega(e_k) = h_k\) for all positive integers \(k\) (where \(e_k\) stands for the \(k\)-th elementary symmetric function, and \(h_k\) stands for the \(k\)-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the **omega involution**. It sends the power-sum symmetric function \(p_k\) to \((-1)^{k-1}p_k\) for every positive integer \(k\).

The images of some bases under the omega automorphism are given by

\[
\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},
\]

where \(\lambda\) is any partition, where \(\ell(\lambda)\) denotes the length (\(\text{length}\)) of the partition \(\lambda\), where \(\lambda'\) denotes the conjugate partition (\(\text{conjugate}\)) of \(\lambda\), and where the usual notations for bases are used (\(e = \text{elementary}, \, h = \text{complete homogeneous}, \, p = \text{powersum}, \, s = \text{Schur}\)).

**omega_involution()** is a synonym for the **omega()** method.

**OUTPUT:**

- the image of self under the omega automorphism

**EXAMPLES:**

sage: h = SymmetricFunctions(QQ).h()
sage: a = h([2,1]); a
h[2, 1]
sage: a.omega()
h[1, 1, 1] - h[2, 1]
sage: e = SymmetricFunctions(QQ).e()
sage: e(h([2,1]).omega())
e[2, 1]

**omega_involution()**

Return the image of self under the omega automorphism.

The **omega automorphism** is defined to be the unique algebra endomorphism \(\omega\) of the ring of symmetric functions that satisfies \(\omega(e_k) = h_k\) for all positive integers \(k\) (where \(e_k\) stands for the \(k\)-th elementary symmetric function, and \(h_k\) stands for the \(k\)-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the
omega involution. It sends the power-sum symmetric function \( p_k \) to \((-1)^{k-1}p_k\) for every positive integer \( k \).

The images of some bases under the omega automorphism are given by

\[
\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},
\]

where \( \lambda \) is any partition, where \( \ell(\lambda) \) denotes the length (\texttt{length()} of the partition \( \lambda \), where \( \lambda' \) denotes the conjugate partition (\texttt{conjugate()}) of \( \lambda \), and where the usual notations for bases are used (\( e = \) elementary, \( h = \) complete homogeneous, \( p = \) powersum, \( s = \) Schur).

\texttt{omega_involution()} is a synonym for the \texttt{omega()} method.

OUTPUT:
• the image of \texttt{self} under the omega automorphism

EXAMPLES:

```sage
sage: h = SymmetricFunctions(QQ).h()
sage: a = h([2,1]); a
h[2, 1]
sage: a.omega()

h[1, 1, 1] - h[2, 1]
sage: e = SymmetricFunctions(QQ).e()
sage: e(h([2,1]).omega())
e[2, 1]
```

\texttt{principal_specialization}(\(n=+\ Infinity, q=None\))

Return the principal specialization of a symmetric function.

The \textit{principal specialization} of order \( n \) at \( q \) is the ring homomorphism \( ps_{n,q} \) from the ring of symmetric functions to another commutative ring \( R \) given by \( x_i \mapsto q^{i-1} \) for \( i \in \{1, \ldots, n\} \) and \( x_i \mapsto 0 \) for \( i > n \). Here, \( q \) is a given element of \( R \), and we assume that the variables of our symmetric functions are \( x_1, x_2, x_3, \ldots \). (To be more precise, \( ps_{n,q} \) is a \( K \)-algebra homomorphism, where \( K \) is the base ring.) See Section 7.8 of [EnumComb2].

The \textit{stable principal specialization} at \( q \) is the ring homomorphism \( ps_q \) from the ring of symmetric functions to another commutative ring \( R \) given by \( x_i \mapsto q^{i-1} \) for all \( i \). This is well-defined only if the resulting infinite sums converge; thus, in particular, setting \( q = 1 \) in the stable principal specialization is an invalid operation.

INPUT:
• \( n \) (default: \texttt{infinity}) – a nonnegative integer or \texttt{infinity}, specifying whether to compute the principal specialization of order \( n \) or the stable principal specialization.
• \( q \) (default: \texttt{None}) – the value to use for \( q \); the default is to create a ring of polynomials in \( q \) (or a field of rational functions in \( q \)) over the given coefficient ring.

We use the formulas from Proposition 7.8.3 of [EnumComb2] (using Gaussian binomial coefficients \( \binom{n}{i}_q \)):

\[
ps_{n,q}(h_\lambda) = \prod_i \binom{n + \lambda_i - 1}{\lambda_i}_q,
\]

\[
ps_{n,1}(h_\lambda) = \prod_i \binom{n + \lambda_i - 1}{\lambda_i},
\]

\[
ps_q(h_\lambda) = 1/\prod_i \prod_{j=1}^{\lambda_i} (1 - q^j).
\]

EXAMPLES:
sage: h = SymmetricFunctions(QQ).h()
sage: x = h[2,1]
sage: x.principal_specialization(3)
q^6 + 2*q^5 + 4*q^4 + 4*q^3 + 4*q^2 + 2*q + 1
sage: x = 3*h[2] + 2*h[1] + 1
sage: x.principal_specialization(3, q=var("q"))
2*(q^3 - 1)/(q - 1) + 3*(q^4 - 1)*(q^3 - 1)/((q^2 - 1)*(q - 1)) + 1

coproduct_on_generators(i)

Return the coproduct on \( h_i \).

INPUT:

- \( \text{self} \) – a homogeneous basis of symmetric functions
- \( i \) – a nonnegative integer

OUTPUT:

- the sum \( \sum_{i=r}^{i} h_r \otimes h_{i-r} \)

EXAMPLES:

sage: Sym = SymmetricFunctions(QQ)
sage: h = Sym.homogeneous()
sage: h.coproduct_on_generators(2)
sage: h.coproduct_on_generators(0)
h[] # h[]

5.1.284 Jack Symmetric Functions

Jack’s symmetric functions appear in \([Ma1995]\) Chapter VI, section 10. Zonal polynomials are the subject of \([Ma1995]\) Chapter VII. The parameter \( \alpha \) in that reference is the parameter \( t \) in this implementation in sage.

REFERENCES:

class sage.combinat.sf.jack.Jack(Sym, t='t')

Bases: sage.structure.unique_representation.UniqueRepresentation

The family of Jack symmetric functions including the \( P, Q, J, Qp \) bases. The default parameter is \( t \).

INPUT:

- \( \text{self} \) – the family of Jack symmetric function bases
- \( \text{Sym} \) – a ring of symmetric functions
- \( \text{t} \) – an optional parameter (default : ‘t’)

EXAMPLES:

sage: SymmetricFunctions(FractionField(QQ['t'])).jack() Jack polynomials over Fraction Field of Univariate Polynomial Ring in t over Rational Field sage: SymmetricFunctions(QQ).jack(1) Jack polynomials with t=1 over Rational Field
\textbf{\texttt{J()}}

Returns the algebra of Jack polynomials in the $J$ basis.

**INPUT:**

- \texttt{self} – the family of Jack symmetric function bases

**OUTPUT:** the $J$ basis of the Jack symmetric functions

**EXAMPLES:**

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JJ = Sym.jack().J(); JJ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over \text{Rational Field in the Jack J basis}
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.jack(t=-1).J()
Symmetric Functions over Rational Field in the Jack J with t=-1 basis
```

At $t = 1$, the Jack polynomials in the $J$ basis are scalar multiples of the Schur functions with the scalar given by a Partition’s \texttt{hook_product()} method at 1:

```
sage: Sym = SymmetricFunctions(QQ)
sage: JJ = Sym.jack(t=1).J()
sage: s = Sym.schur()
sage: p = Partition([3,2,1,1])
sage: s(JJ(p)) == p.hook_product(1)*s(p)  # long time (4s on sage.math, 2012)
True
```

At $t = 2$, the Jack polynomials in the $J$ basis are scalar multiples of the zonal polynomials with the scalar given by a Partition’s \texttt{hook_product()} method at 2.

```
sage: Sym = SymmetricFunctions(QQ)
sage: JJ = Sym.jack(t=2).J()
sage: Z = Sym.zonal()
sage: p = Partition([2,2,1])
sage: Z(JJ(p)) == p.hook_product(2)*Z(p)
True
```

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JJ = Sym.jack().J()
sage: JP = Sym.jack().P()
sage: JJ(sum(JP(p) for p in Partitions(3)))
1/6*JackJ[1, 1, 1] + (1/(t+2))*JackJ[2, 1] + (1/2/(t^2+3/2*t+1/2))*JackJ[3]
```

```
sage: s = Sym.schur()
sage: JJ(s([3]))  # indirect doctest
((1/6*t^2-1/2*t+1/3)/(t^2+3*t+2))*JackJ[1, 1, 1] + ((t-1)/(t^2+5/2*t+1))*JackJ[2, 1] + (1/2/(t^2+3/2*t+1/2))*JackJ[3]
sage: JJ(s([2,1]))
((1/3*t-1/3)/(t+2))*JackJ[1, 1, 1] + (1/(t+2))*JackJ[2, 1]
sage: JJ(s([1,1,1]))
1/6*JackJ[1, 1, 1]
```

\textbf{\texttt{P()}}

Returns the algebra of Jack polynomials in the $P$ basis.
INPUT:

• self – the family of Jack symmetric function bases

OUTPUT:

• the $P$ basis of the Jack symmetric functions

EXAMPLES:

\[
sage: Sym = \text{SymmetricFunctions}(\text{FractionField}(\text{QQ}['t']))
\]
\[
sage: JP = Sym.jack().P(); JP
\]
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the Jack P basis
\[
sage: Sym.jack(t=-1).P()
\]
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the Jack P with t=-1 basis

At $t = 1$, the Jack polynomials in the $P$ basis are the Schur symmetric functions.

\[
sage: Sym = \text{SymmetricFunctions}(\text{QQ})
\]
\[
sage: JP = Sym.jack(t=1).P()
\]
\[
sage: s[2, 2, 1]
\]
\[
sage: JP(s([2, 2, 1]))
\]
JackP[2, 2, 1]
\[
sage: JP([2, 2, 1])^2
\]

At $t = 2$, the Jack polynomials in the $P$ basis are the zonal polynomials.

\[
sage: Sym = \text{SymmetricFunctions}(\text{QQ})
\]
\[
sage: JP = Sym.jack(t=2).P()
\]
\[
sage: Z = Sym.zonal()
\]
\[
sage: Z(JP([2, 2, 1]))
\]
Z[2, 2, 1]
\[
sage: JP(Z[2, 2, 1])
\]
JackP[2, 2, 1]
\[
sage: JP([2])^2
\]
\[
sage: Z([2])^2
\]

(continues on next page)
(continued from previous page)

\[
\frac{6}{(b+2)} \cdot m[1, 1, 1] + m[2, 1]
\]

sage: m(a^2 JPb([2,1]) + b^2 JPa([2,1]))
\[
(\frac{6a^2+6b^2+12a+12b}{a^2+b^2+2a+2b+4}) \cdot m[1, 1, 1] + (a+b)^2 m[2, 1]
\]

sage: JPa(JPb([2,1]))
\[
(\frac{6a-6b}{a^2+b^2+2a+2b+4}) \cdot JackP[1, 1, 1] + JackP[2, 1]
\]

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))

sage: JQ = Sym.jack().Q()

sage: JP = Sym.jack().P()

sage: JJ = Sym.jack().J()

sage: JP(JQ([2,1]))
\[
(\frac{1/2+t+1}{t^3+1/2+t^2}) \cdot JackP[2, 1]
\]

sage: JP(JQ([3]))
\[
(\frac{1/3+t^2+1/2+t+1/6}{t^3}) \cdot JackP[3]
\]

sage: JP(JQ([1,1,1]))
\[
(\frac{6}{t^3+3t^2+2t}) \cdot JackP[1, 1, 1]
\]

Q()

Returns the algebra of Jack polynomials in the \(Q\) basis.

INPUT:

• self – the family of Jack symmetric function bases

OUTPUT:

• the \(Q\) basis of the Jack symmetric functions

EXAMPLES:

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))

sage: JQ = Sym.jack().Q(); JQ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the Jack Q basis

sage: Sym = SymmetricFunctions(QQ)

sage: Sym.jack(t=-1).Q()
Symmetric Functions over Rational Field in the Jack Q with \(t=-1\) basis

5.1. Comprehensive Module List
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JQ = Sym.jack().Q()
sage: JP = Sym.jack().P()
sage: JQ(sum(JP(p) for p in Partitions(3)))
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1] + (3*t^3/(t^2+3/2*t+1/2))*JackQ[3]

sage: s = Sym.schur()
sage: JQ(s([3]))
# indirect doctest
(1/6*t^3-1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3-2*t^2)/(t+2))*JackQ[2, 1] + (3*t^3/(t^2+3/2*t+1/2))*JackQ[3]

Qp()
Returns the algebra of Jack polynomials in the Qp, which is dual to the P basis with respect to the standard scalar product.

INPUT:

• self – the family of Jack symmetric function bases

OUTPUT:

• the Q' basis of the Jack symmetric functions

EXAMPLES:

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P()
sage: JQp = Sym.jack().Qp(); JQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the Jack Qp basis
sage: a = JQp([2])
sage: a.scalar(JP([2]))
1
sage: a.scalar(JP([1,1]))
0
sage: JP(JQp([2]))
# todo: missing auto normalization
((t-1)/(t+1))*JackP[1, 1] + JackP[2]

base_ring()
Returns the base ring of the symmetric functions in which the Jack symmetric functions live.

INPUT:

• self – the family of Jack symmetric function bases

OUTPUT:

• the base ring of the symmetric functions ring of self

EXAMPLES:
```python
sage: J2 = SymmetricFunctions(QQ).jack(t=2)
sage: J2.base_ring()
Rational Field
```

**symmetric_function_ring()**

Returns the base ring of the symmetric functions of the Jack symmetric function bases

**INPUT:**

- `self` – the family of Jack symmetric function bases

**OUTPUT:**

- the symmetric functions ring of `self`

**EXAMPLES:**

```python
sage: Jacks = SymmetricFunctions(FractionField(QQ['t'])).jack()
sage: Jacks.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

### class `sage.combinat.sf.jack.JackPolynomials_generic(jack)`

**Bases:** `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic`

A class of methods which are common to all Jack bases of the symmetric functions

**INPUT:**

- `self` – a Jack basis of the symmetric functions
- `jack` – a family of Jack symmetric function bases

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P(); JP.base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
sage: Sym = SymmetricFunctions(QQ)
sage: JP = Sym.jack(t=2).P(); JP.base_ring()
Rational Field
```

### class `Element`

**Bases:** `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element`

**scalar_jack**

A scalar product where the power sums are orthogonal and \( \langle p_{\mu}, p_{\mu} \rangle = z_{\mu}^\text{length}(\mu) \)

**INPUT:**

- `self` – an element of a Jack basis of the symmetric functions
- `x` – an element of the symmetric functions
- `t` – an optional parameter (default: [None uses the parameter from the basis])

**OUTPUT:**

- returns the Jack scalar product between `x` and `self`

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P()
sage: JQ = Sym.jack().Q()
```
sage: p = Partitions(3).list()
sage: matrix([[JP(a).scalar_jack(JQ(b)) for a in p] for b in p])
[[1 0 0]
 [0 1 0]
 [0 0 1]]

\texttt{c1(part)}

Returns the $t$-Jack scalar product between $J(part)$ and $P(part)$.

\textbf{INPUT:}
- \texttt{self} – a Jack basis of the symmetric functions
- \texttt{part} – a partition
- \texttt{t} – an optional parameter (default: uses the parameter $t$ from the Jack basis)

\textbf{OUTPUT:}
- a polynomial in the parameter $t$ which is equal to the scalar product of $J(part)$ and $P(part)$

\textbf{EXAMPLES:}

sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: JP.c1(Partition([2,1]))
t + 2

\texttt{c2(part)}

Returns the $t$-Jack scalar product between $J(part)$ and $Q(part)$.

\textbf{INPUT:}
- \texttt{self} – a Jack basis of the symmetric functions
- \texttt{part} – a partition
- \texttt{t} – an optional parameter (default: uses the parameter $t$ from the Jack basis)

\textbf{OUTPUT:}
- a polynomial in the parameter $t$ which is equal to the scalar product of $J(part)$ and $Q(part)$

\textbf{EXAMPLES:}

sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: JP.c2(Partition([2,1]))
2*t^3 + t^2

\texttt{coproduct\_by\_coercion(elt)}

Returns the coproduct of the element \texttt{elt} by coercion to the Schur basis.

\textbf{INPUT:}
- \texttt{self} – a Jack symmetric function basis
- \texttt{elt} – an instance of this basis

\textbf{OUTPUT:}
- The coproduct acting on \texttt{elt}, the result is an element of the tensor squared of the Jack symmetric function basis

\textbf{EXAMPLES:}
```python
sage: Sym = SymmetricFunctions(QQ['t']).fraction_field()
sage: Sym.jack().P()[2,2].coproduct() # indirect doctest
JackP[] + (2/(t+1))*JackP[1] # JackP[2, 1] + ((8*t+4)/(t^3+4*t^2+5*t+2))*JackP[1, 1] # JackP[2, 1]
```

**jack_family()**

Returns the family of Jack bases associated to the basis \texttt{self}

**INPUT:**

- \texttt{self} – a Jack basis of the symmetric functions

**OUTPUT:**

- the family of Jack symmetric functions associated to \texttt{self}

**EXAMPLES:**

```python
sage: JackP = SymmetricFunctions(QQ).jack(t=2).P()
sage: JackP.jack_family()
Jack polynomials with t=2 over Rational Field
```

**product(left, right)**

The product of two Jack symmetric functions is done by multiplying the elements in the \( P \) basis and then expressing the elements in the basis \texttt{self}.

**INPUT:**

- \texttt{self} – a Jack basis of the symmetric functions
- \texttt{left, right} – symmetric function elements

**OUTPUT:**

the product of \texttt{left} and \texttt{right} expanded in the basis \texttt{self}

**EXAMPLES:**

```python
sage: JJ = SymmetricFunctions(FractionField(QQ['t'])).jack().J()
sage: JJ([1])^2  # indirect doctest
(t/(t+1))*JackJ[1, 1] + (1/(t+1))*JackJ[2]
sage: JJ([2])^2
(t^2/(t^2+3/2*t+1/2))*JackJ[2, 2] + (4/3*t/(t^2+4/3*t+1/3))*JackJ[3, 1] + ((1/6*t+1/6)/(t^2+5/6*t+1/6))*JackJ[4]
sage: JQ = SymmetricFunctions(FractionField(QQ['t'])).jack().Q()
sage: JQ([1])^2  # indirect doctest
JackQ[1, 1] + (2/(t+1))*JackQ[2]
sage: JQ([2])^2
JackQ[2, 2] + (2/(t+1))*JackQ[3, 1] + ((t+1)/(t^2+5/6*t+1/6))*JackQ[4]
```

**class** \texttt{sage.combinat.sf.jack.JackPolynomials}\texttt{.j}(jack)

**Bases:** \texttt{sage.combinat.sf.jack.JackPolynomials\_generic}

The \( J \) basis is defined as a normalized form of the \( P \) basis.

**INPUT:**

- \texttt{self} – an instance of the Jack \( P \) basis of the symmetric functions
- \texttt{jack} – a family of Jack symmetric function bases
EXAMPLES:

```python
sage: J = SymmetricFunctions(FractionField(QQ['t'])).jack().J()
sage: TestSuite(J).run(skip=['_test_associativity', '_test_distributivity', '_test_prod'])  # products are too expensive
sage: TestSuite(J).run(elements = [J.t^3*[1,1]+J[2], J[1]+(1+J.t)*J*[1,1]])  # long time (3s on sage.math, 2012)
```

```python
class Element
class sage.combinat.sf.jack.JackPolynomials_p(jack)
    Bases: sage.combinat.sf.jack.JackPolynomials_generic

The :math:`P` basis is uni-triangularly related to the monomial basis and orthogonal with respect to the Jack scalar product.

INPUT:
- :code:`self` -- an instance of the Jack :math:`P` basis of the symmetric functions
- :code:`jack` -- a family of Jack symmetric function bases

EXAMPLES:

```python
sage: P = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: TestSuite(P).run(skip=['_test_associativity', '_test_distributivity', '_test_prod'])  # products are too expensive
sage: TestSuite(P).run(elements = [P.t^3*[1,1]+P[2], P[1]+(1+P.t)*P*[1,1]])
```

```python
class Element

scalar_jack(x, t=None)

The scalar product on the symmetric functions where the power sums are orthogonal and
:math:`\langle p_\mu, p_\nu \rangle = z_\mu t^{\text{length}(\mu)}` where the \(t\) parameter from the Jack symmetric function family.

INPUT:
- :code:`self` -- an element of the Jack :math:`P` basis
- :code:`x` -- an element of the :math:`P` basis

EXAMPLES:

```python
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: l = [JP(p) for p in Partitions(3)]
sage: matrix([[a.scalar_jack(b) for a in l] for b in l])
```

```python
product(left, right)

The product of two Jack symmetric functions is done by multiplying the elements in the monomial basis and then expressing the elements the basis :code:`self`.

INPUT:
- :code:`self` -- a Jack basis of the symmetric functions
```
• left, right – symmetric function elements

OUTPUT:
the product of left and right expanded in the basis self

EXAMPLES:

```python
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: m = JP.symmetrical_function_ring().m()
sage: JP([1])**2 # indirect doctest
(2*t/(t+1))*JackP[1, 1] + JackP[2]
sage: m(_)
2*m[1, 1] + m[2]
sage: JP = SymmetricFunctions(QQ).jack(t=2).P()
sage: JP([2,1])**2
sage: m(_)
45*m[1, 1, 1, 1, 1] + 51/2*m[2, 1, 1, 1, 1] + 29/2*m[2, 2, 1, 1] + 33/4*m[2,␣
˓→2, 2] + 9*m[3, 1, 1, 1] + 5*m[3, 2, 1] + 2*m[3, 3] + 2*m[4, 1, 1] + m[4, 2]
```

`scalar_jack_basis(part1, part2=None)`

Returns the scalar product of $P(part1)$ and $P(part2)$.

This is equation (10.16) of [Mc1995] on page 380.

INPUT:
• self – an instance of the Jack $P$ basis of the symmetric functions
• part1 – a partition
• part2 – an optional partition (default : None)

OUTPUT:
• the scalar product between $P(part1)$ and $P(part2)$ (or itself if part2 is None)

REFERENCES:

EXAMPLES:

```python
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: JJ = SymmetricFunctions(FractionField(QQ['t'])).jack().J()
sage: JP.scalar_jack_basis(Partition([2,1]), Partition([1,1,1]))
0
sage: JP._normalize_coefficients(JP.scalar_jack_basis(Partition([3,2,1]),
˓→Partition([3,2,1])))
(6*t^6 + 10*t^5 + 11/2*t^4 + t^3)/(t^3 + 11/2*t^2 + 10*t + 6)
sage: JJ(JP[3,2,1]).scalar_jack(JP[3,2,1])
(6*t^6 + 10*t^5 + 11/2*t^4 + t^3)/(t^3 + 11/2*t^2 + 10*t + 6)
```

With a single argument, takes part2 = part1:

```python
sage: JP.scalar_jack_basis(Partition([2,1]), Partition([2,1]))
(2*t^3 + t^2)/(t + 2)
sage: JJ(JP[2,1]).scalar_jack(JP[2,1])
(2*t^3 + t^2)/(t + 2)
```
class sage.combinat.sf.jack.JackPolynomials_q(jack)
    Bases: sage.combinat.sf.jack.JackPolynomials_generic

    The \( Q \) basis is defined as a normalized form of the \( P \) basis

    INPUT:
    
    • self – an instance of the Jack \( Q \) basis of the symmetric functions
    • jack – a family of Jack symmetric function bases

    EXAMPLES:

    sage: Q = SymmetricFunctions(FractionField(QQ['t'])).jack().Q()
    sage: TestSuite(Q).run(skip=['_test_associativity', '_test_distributivity', '_test_prod'])  # products are too expensive
    sage: TestSuite(Q).run(elements=[Q.t*Q[1,1]+Q[2], Q[1]+(1+Q.t)*Q[1,1]])  # long time

class Element

class sage.combinat.sf.jack.JackPolynomials_qp(jack)
    Bases: sage.combinat.sf.jack.JackPolynomials_generic

    The \( Q_p \) basis is the dual basis to the \( P \) basis with respect to the standard scalar product

    INPUT:
    
    • self – an instance of the Jack \( Q_p \) basis of the symmetric functions
    • jack – a family of Jack symmetric function bases

    EXAMPLES:

    sage: Qp = SymmetricFunctions(FractionField(QQ['t'])).jack().Qp()
    sage: TestSuite(Qp).run(skip=['_test_associativity', '_test_distributivity', '_test_prod'])  # products are too expensive
    sage: TestSuite(Qp).run(elements=[Qp.t*Qp[1,1]+Qp[2], Qp[1]+(1+Qp.t)*Qp[1,1]])  # long time

class Element

coproduct_by_coercion(elt)

    Returns the coproduct of the element elt by coercion to the Schur basis.

    INPUT:
    
    • elt – an instance of the \( Q_p \) basis

    OUTPUT:
    
    • The coproduct acting on elt, the result is an element of the tensor squared of the \( Q_p \) symmetric function basis

    EXAMPLES:

    sage: Sym = SymmetricFunctions(QQ['t']).fraction_field()
    sage: JQp = Sym.jack().Qp()
    sage: JQp[2,2].coproduct()  # indirect doctest
    JackQp[2, 1] + ((2*t^3+4*t^2)/(t^3+5/2*t^2+2*t+1/2))*JackQp[2] + JackQp[1, 1]
product(left, right)
The product of two Jack symmetric functions is done by multiplying the elements in the monomial basis and then expressing the elements the basis self.

INPUT:
- `self` – an instance of the Jack $Q_p$ basis of the symmetric functions
- `left`, `right` – symmetric function elements

OUTPUT:
the product of `left` and `right` expanded in the basis `self`

EXAMPLES:
```
sage: JQp = SymmetricFunctions(FractionField(QQ['t'])).jack().Qp()
sage: h = JQp.symmetric_function_ring().h()
sage: JQp([1])^2  # indirect doctest
JackQp[1, 1] + (2/(t+1))*JackQp[2]
sage: h(_)
h[1, 1]
sage: JQp = SymmetricFunctions(QQ).jack(t=2).Qp()
sage: h = SymmetricFunctions(QQ).h()
sage: JQp([2,1])^2
˓→75*JackQp[4, 2]
sage: h(_)
h[2, 2, 1, 1] - 6/5*h[3, 2, 1] + 9/25*h[3, 3]
```

class sage.combinat.sf.jack.SymmetricFunctionAlgebra_zonal(Sym)
Bases: sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic

Returns the algebra of zonal polynomials.

INPUT:
- `self` – a zonal basis of the symmetric functions
- `Sym` – a ring of the symmetric functions

EXAMPLES:
```
sage: Z = SymmetricFunctions(QQ).zonal()
sage: Z([2])^2
sage: Z = SymmetricFunctions(QQ).zonal()
sage: TestSuite(Z).run(skip=['_test_associativity', '_test_distributivity', '_test_...
˓→prod']) # products are too expensive
```

class Element
Bases: sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element

scalar_zonal(x)
The zonal scalar product has the power sum basis and the zonal symmetric functions are orthogonal. In particular, $\langle p_\mu, p_\mu \rangle = z_\mu 2^{\text{length}(\mu)}$.  

5.1. Comprehensive Module List 2781
INPUT:
• self – an element of the zonal basis
• x – an element of the symmetric function

OUTPUT:
• the scalar product between self and x

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: Z = Sym.zonal()
sage: parts = Partitions(3).list()
sage: matrix([[Z(a).scalar_zonal(Z(b)) for a in parts] for b in parts])
```
```
[16/5 0 0]
[ 0 5 0]
[ 0 0 4]
```

```python
sage: p = Z.symmetric_function_ring().power()
sage: matrix([[Z(p(a)).scalar_zonal(p(b)) for a in parts] for b in parts])
```
```
[ 6 0 0]
[ 0 8 0]
[ 0 0 48]
```

product( left, right)
The product of two zonal symmetric functions is done by multiplying the elements in the monomial basis and then expressing the elements in the basis self.

INPUT:

• self – a zonal basis of the symmetric functions
• left, right – symmetric function elements

OUTPUT:

the product of left and right expanded in the basis self

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: Z = Sym.zonal()
sage: JP = Sym.jack(t=1).P()
sage: Z([2])*Z([3])
# indirect doctest
sage: Z([2])*JP([2])
sage: JP = Sym.jack(t=2).P()
sage: Z([2])*JP([2])
```

sage.combinat.sf.jack.c1(part, t)
Returns the $t$-Jack scalar product between $J(part)$ and $P(part)$.

INPUT:

• part – a partition
• t – an optional parameter (default: uses the parameter $t$ from the Jack basis)

OUTPUT:

• a polynomial in the parameter $t$ which is equal to the scalar product of $J(part)$ and $P(part)$
EXAMPLES:

```python
sage: from sage.combinat.sf.jack import c1
sage: t = QQ['t'].gen()
sage: [c1(p,t) for p in Partitions(3)]
[2*t^2 + 3*t + 1, t + 2, 6]
```

`sage.combinat.sf.jack.c2(part, t)`
Returns the t-Jack scalar product between \( J(part) \) and \( Q(part) \).

**INPUT:**
- `self` – a Jack basis of the symmetric functions
- `part` – a partition
- `t` – an optional parameter (default: uses the parameter \( t \) from the Jack basis)

**OUTPUT:**
- a polynomial in the parameter \( t \) which is equal to the scalar product of \( J(part) \) and \( Q(part) \)

EXAMPLES:

```python
sage: from sage.combinat.sf.jack import c2
sage: t = QQ['t'].gen()
sage: [c2(p,t) for p in Partitions(3)]
[6*t^3, 2*t^3 + t^2, t^3 + 3*t^2 + 2*t]
```

`sage.combinat.sf.jack.normalize_coefficients(self, c)`
If our coefficient ring is the field of fractions over a univariate polynomial ring over the rationals, then we should clear both the numerator and denominator of the denominators of their coefficients.

**INPUT:**
- `self` – a Jack basis of the symmetric functions
- `c` – a coefficient in the base ring of `self`

**OUTPUT:**
- divide numerator and denominator by the greatest common divisor

EXAMPLES:

```python
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: t = JP.base_ring().gen()
sage: a = 2/(1/2*t+1/2)
sage: JP._normalize_coefficients(a)
4/(t + 1)
sage: a = 1/(1/3+1/6*t)
sage: JP._normalize_coefficients(a)
6/(t + 2)
sage: a = 24/(4*t^2 + 12*t + 8)
sage: JP._normalize_coefficients(a)
6/(t^2 + 3*t + 2)
```

`sage.combinat.sf.jack.part_scalar_jack(part1, part2, t)`
Returns the Jack scalar product between \( p(part1) \) and \( p(part2) \) where \( p \) is the power-sum basis.

**INPUT:**
• part1, part2 – two partitions
• t – a parameter

OUTPUT:
• returns the scalar product between the power sum indexed by part1 and part2

EXAMPLES:
```sage
code
sage: Q.<t> = QQ[]
sage: from sage.combinat.sf.jack import part_scalar_jack
sage: matrix([[part_scalar_jack(p1,p2,t) for p1 in Partitions(4)] for p2 in Partitions(4)])
[ 4*t 0 0 0 0]
[ 0 3*t^2 0 0 0]
[ 0 0 8*t^2 0 0]
[ 0 0 0 4*t^3 0]
[ 0 0 0 0 24*t^4]
```

5.1.285 Quotient of symmetric function space by ideal generated by Hall-Littlewood symmetric functions

The quotient of symmetric functions by the ideal generated by the Hall-Littlewood P symmetric functions indexed by partitions with first part greater than $k$. When $t = 1$ this space is the quotient of the symmetric functions by the ideal generated by the monomial symmetric functions indexed by partitions with first part greater than $k$.

AUTHORS:
• Chris Berg (2012-12-01)
• Mike Zabrocki - $k$-bounded Hall Littlewood P and dual $k$-Schur functions (2012-12-02)

class sage.combinat.sf.k_dual.AffineSchurFunctions(kBoundedRing)

Bases: sage.combinat.sf.k_dual.KBoundedQuotientBasis

This basis is dual to the $k$-Schur functions at $t = 1$. This realization follows the monomial expansion given by Lam [Lam2006].

REFERENCES:

class sage.combinat.sf.k_dual.DualkSchurFunctions(kBoundedRing)

Bases: sage.combinat.sf.k_dual.KBoundedQuotientBasis

This basis is dual to the $k$-Schur functions. The expansion is given in Section 4.12 of [LLMSSZ]. When $t = 1$ this basis is equal to the AffineSchurFunctions and that basis is more efficient in this case.

REFERENCES:

class sage.combinat.sf.k_dual.KBoundedQuotient(Sym, k, t='t')

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Initialization of the ring of Symmetric functions modulo the ideal of monomial symmetric functions which are indexed by partitions whose first part is greater than $k$.

INPUT:
• Sym – an element of class sage.combinat.sf.sf.SymmetricFunctions
• k – a positive integer
• R – a ring

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
```

```python
sage: Q = Sym.kBoundedQuotient(3, t=1)
```

```python
sage: Q
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1
```

```python
sage: km = Q.km()
```

```python
sage: km
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the 3-
bounded monomial basis
```

```python
sage: F = Q.affineSchur()
```

```python
sage: km(F[km([3,1,1])]) == F[3,1,1]
```

```python
True
```

```python
sage: km(F(km([3,2]))) == km[3,2]
```

```python

True
sage: dks[2,1]*dks[2,1]
(t^3+t^2)*dks3[1, 1, 1, 1, 1, 1] + (2*t^2+2*t)*dks3[2, 1, 1, 1, 1] + (t^2+2*t+1)*dks3[2, 2, 2] + (t+1)*dks3[3, 1, 1, 1] + (2*t+2)*dks3[3, 2, 1] + (t+1)*dks3[3, 3]

AffineGrothendieckPolynomial(la, m)
Returns the affine Grothendieck polynomial indexed by the partition la. Because this belongs to the completion of the algebra, and hence is an infinite sum, it computes only up to those symmetric functions of degree at most m. See _AffineGrothendieckPolynomial() for the code.

INPUT:
• la – A k-bounded partition
• m – An integer

EXAMPLES:

sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.AffineGrothendieckPolynomial([2,1],4)
2*m3[1, 1, 1] - 8*m3[1, 1, 1, 1] + m3[2, 1] - 3*m3[2, 1, 1] - m3[2, 2]

F() The affine Schur basis of the k-bounded quotient of symmetric functions, indexed by k-bounded partitions. This is also equal to the affine Stanley symmetric functions (see WeylGroups.ElementMethods.stanley_symmetric_function()) indexed by an affine Grassmannian permutation.

EXAMPLES:

sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).affineSchur()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the 2-bounded affine Schur basis

a_realization() Returns a particular realization of self (the basis of k-bounded monomials if t = 1 and the basis of k-bounded Hall-Littlewood functions otherwise).

EXAMPLES:

sage: Sym = SymmetricFunctions(QQ)
sage: Q = Sym.kBoundedQuotient(3,t=1)
sage: Q.a_realization()
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the 3-bounded monomial basis
sage: Q = Sym.kBoundedQuotient(3,t=2)
sage: Q.a_realization()
3-Bounded Quotient of Symmetric Functions over Rational Field with t=2 in the 3-bounded Hall-Littlewood P basis

affineSchur() The affine Schur basis of the k-bounded quotient of symmetric functions, indexed by k-bounded partitions. This is also equal to the affine Stanley symmetric functions (see WeylGroups.ElementMethods.stanley_symmetric_function()).
stanley_symmetric_function() indexed by an affine Grassmannian permutation.

EXAMPLES:

```python
sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).affineSchur()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the 2-bounded affine Schur basis
```

ambient()

Returns the Symmetric Functions over the same ring as self. This is needed to realize our ring as a quotient.

EXAMPLES:

```python
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.an_element()
2*m3[] + 2*m3[1] + 3*m3[2]
```

dks()

The dual k-Schur basis of the k-bounded quotient of symmetric functions, indexed by k-bounded partitions. At \( t = 1 \) this is also equal to the affine Schur basis and calculations will be faster using elements in the affineSchur() basis.

EXAMPLES:

```python
sage: SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(2).dual_k_Schur()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the dual 2-Schur basis
```

dual_k_Schur()

The dual k-Schur basis of the k-bounded quotient of symmetric functions, indexed by k-bounded partitions. At \( t = 1 \) this is also equal to the affine Schur basis and calculations will be faster using elements in the affineSchur() basis.

EXAMPLES:

```python
sage: SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(2).dual_k_Schur()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the dual 2-Schur basis
```

kHLP()

The Hall-Littlewood P basis of the k-bounded quotient of symmetric functions, indexed by k-bounded partitions. At \( t = 1 \) this basis is equal to the k-bounded monomial basis and calculations will be faster using elements in the k-bounded monomial basis (see kmonomial()).}

EXAMPLES:

```python
sage: SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(2).kHallLittlewoodP()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the 2-bounded Hall-Littlewood P basis
```
The Hall-Littlewood P basis of the $k$-bounded quotient of symmetric functions, indexed by $k$-bounded partitions. At $t = 1$ this basis is equal to the $k$-bounded monomial basis and calculations will be faster using elements in the $k$-bounded monomial basis (see `kmonomial()`).

**EXAMPLES:**

```python
sage: SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(2).kHallLittlewoodP()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the 2-bounded Hall-Littlewood P basis
```

The monomial basis of the $k$-bounded quotient of symmetric functions, indexed by $k$-bounded partitions.

**EXAMPLES:**

```python
sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).kmonomial()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the 2-bounded monomial basis
```

Gives the lift map from the quotient ring of $k$-bounded symmetric functions to the symmetric functions. This method is here to make the TestSuite run properly.

**INPUT:**

- `la` – A $k$-bounded partition

**OUTPUT:**

- The monomial element or a Hall-Littlewood P element of the symmetric functions indexed by the partition `la`.

**EXAMPLES:**

```python
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.lift([2,1])
m[2, 1]
sage: Q = SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(3)
sage: Q.lift([2,1])
HLP[2, 1]
```

Returns the unit of the quotient ring of $k$-bounded symmetric functions. This method is here to make the TestSuite run properly.

**EXAMPLES:**

```python
```
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.one()
m3[]

realizations()
A list of realizations of the $k$-bounded quotient.

EXAMPLES:

sage: kQ = SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(3)
sage: kQ.realizations()
[3-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate
 → Polynomial Ring in t over Rational Field in the 3-bounded monomial basis, 3-
 → Bounded Quotient of Symmetric Functions over Fraction Field of Univariate,
 → Polynomial Ring in t over Rational Field in the 3-bounded Hall-Littlewood P
 → basis, 3-Bounded Quotient of Symmetric Functions over Fraction Field of,
 → Univariate Polynomial Ring in t over Rational Field in the 3-bounded affine
 → Schur basis, 3-Bounded Quotient of Symmetric Functions over Fraction Field of,
 → Univariate Polynomial Ring in t over Rational Field in the dual 3-Schur basis]
sage: HLP = kQ.ambient().hall_littlewood().P()
sage: all( rzn(HLP[3,2,1]).lift() == HLP[3,2,1] for rzn in kQ.realizations())
True
sage: kQ = SymmetricFunctions(QQ).kBoundedQuotient(3,1)
sage: kQ.realizations()
[3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the
 → 3-bounded monomial basis, 3-Bounded Quotient of Symmetric Functions over,
 → Rational Field with t=1 in the 3-bounded Hall-Littlewood P basis, 3-Bounded
 → Quotient of Symmetric Functions over Rational Field with t=1 in the 3-bounded,
 → affine Schur basis, 3-Bounded Quotient of Symmetric Functions over Rational
 → Field with t=1 in the dual 3-Schur basis]
sage: m = kQ.ambient().m()
sage: all( rzn(m[3,2,1]).lift() == m[3,2,1] for rzn in kQ.realizations())
True

retract($la$)
Gives the retract map from the symmetric functions to the quotient ring of $k$-bounded symmetric functions. This method is here to make the TestSuite run properly.

INPUT:

• $la$ – A partition

OUTPUT:

• The monomial element of the $k$-bounded quotient indexed by $la$.

EXAMPLES:

sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.retract([2,1])
m3[2, 1]

class sage.combinat.sf.k_dual.KBoundedQuotientBases(base)
Bases: sage.categories.realizations.Category_realization_of_parent

The category of bases for the $k$-bounded subspace of symmetric functions.
class ElementMethods
    Bases: object

class ParentMethods
    Bases: object

    ambient()
    Returns the symmetric functions.
    EXAMPLES:

    sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
    sage: km.ambient()
    Symmetric Functions over Rational Field

    antipode(element)
    Return the antipode of element via lifting to the symmetric functions and then retracting into the k-bounded quotient basis.
    INPUT:
        • element – an element in a basis of the ring of symmetric functions
    EXAMPLES:

    sage: dks3 = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).dual_k_Schur()
    sage: dks3[3,2].antipode()
    -dks3[1, 1, 1, 1]
    sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
    sage: km[3,2].antipode()
    m3[3, 2]
    sage: km.antipode(km[3,2])
    m3[3, 2]
    sage: m = SymmetricFunctions(QQ).m()
    sage: m[3,2].antipode()
    m[3, 2] + 2*m[5]
    sage: km = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3).
    → km()
    sage: km[1,1,1,1].antipode()
    (-t^3-3*t^2-3*t)*m3[1, 1, 1, 1] + (-t^2+2*t)*m3[2, 1, 1] + m3[2, 2] +
    -t^2*m3[1, 1]
    sage: kHP = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3).
    → kHP()
    sage: kHP[2,2].antipode()
    (t^9-t^6-t^5+t)*HLP3[1, 1, 1] + (t^6-t^3-t^2+t)*HLP3[2, 1, 1] + (t^5-t^2+1)*HLP3[2, 2] +
    (t^4-t)*HLP3[3, 1]
    sage: dks = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3).
    → dks()
    sage: dks[2,2].antipode()
    dks3[2, 2]
    sage: dks[3,2].antipode()
    -t^2*dks3[1, 1, 1, 1] + (t^2-1)*dks3[2, 2, 1] + (-t^5+t)*dks3[3, 2]

    coproduct(element)
    Return the coproduct of element via lifting to the symmetric functions and then returning to the k-bounded quotient basis. This method is implemented for all t but is (weakly) conjectured to not be
the correct operation for arbitrary $t$ because the coproduct on dual-$k$-Schur functions does not have a positive expansion.

INPUT:
• element – an element in a basis of the ring of symmetric functions

EXAMPLES:

```
sage: Q3 = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: km = Q3.km()
sage: km[3,2].coproduct()
sage: dks3 = Q3.dual_k_Schur()
sage: dks3[2,2].coproduct()
dks3[] # dks3[2, 2] + dks3[1] # dks3[2, 1] + dks3[1, 1] # dks3[1, 1] +
sage: Q3t = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3)
sage: km = Q3t.km()
sage: km[3,2].coproduct()
sage: dks = Q3t.dks()
sage: dks[2,1,1].coproduct()
dks3[] # dks3[2, 1, 1] + (-t+1)*dks3[1] # dks3[1, 1, 1] + dks3[1] # dks3[2, 1] #
sage: kHLP = Q3t.kHLP()
sage: kHLP[2,1].coproduct()
sage: km.coproduct(km[3,2])
counit(element)
Return the counit of element.
The counit is the constant term of element.

INPUT:
• element – an element in a basis

EXAMPLES:

```
sage: km = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3).
    km()
sage: f = 2*km[2,1] - 3*km([])
sage: f.counit()
-3
sage: km.counit(f)
-3
degree_on_basis(b)
Return the degree of the basis element indexed by b.

INPUT:
• b – a partition

EXAMPLES:
Combinatorics, Release 9.7

```python
sage: F = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).affineSchur()
sage: F.degree_on_basis(Partition([3,2]))
5
```

**indices()**

The set of $k$-bounded partitions of all non-negative integers.

**EXAMPLES:**

```python
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.indices()
3-Bounded Partitions
```

**lift(la)**

Implements the lift map from the basis `self` to the monomial basis of symmetric functions.

**INPUT:**

- `la` – A $k$-bounded partition.

**OUTPUT:**

- A symmetric function in the monomial basis.

**EXAMPLES:**

```python
sage: F = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).affineSchur()
sage: F.lift([3,1])
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1]
sage: Sym = SymmetricFunctions(QQ['t']).fraction_field()
sage: dks = Sym.kBoundedQuotient(3).dual_k_Schur()
sage: dks.lift([3,1])
t^5*HLP[1, 1, 1, 1] + t^2*HLP[2, 1, 1] + t*HLP[2, 2] + HLP[3, 1]
sage: dks = Sym.kBoundedQuotient(3,t=1).dual_k_Schur()
sage: dks.lift([3,1])
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1]
```

**one_basis()**

Return the basis element indexing 1.

**EXAMPLES:**

```python
sage: F = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).affineSchur()
sage: F.one()  # indirect doctest
F3[]
```

**product(x, y)**

Returns the product of two elements $x$ and $y$.

**INPUT:**

- `x, y` – Elements of the $k$-bounded quotient of symmetric functions.

**OUTPUT:**

- A $k$-bounded symmetric function in the dual $k$-Schur function basis

**EXAMPLES:**

```python
sage: dks3 = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).dual_k_Schur()
sage: dks3.product(dks3[2,1],dks3[1,1])
2*dks3[1, 1, 1, 1] + 2*dks3[2, 1, 1] + 2*dks3[2, 2, 1] + dks3[3, 1, 1] + dks3[3, 2]
sage: dks3.product(dks3[2,1]+dks3[1], dks3[1,1])
(continues on next page)
```
\[\text{dks3}[1, 1, 1] + 2^*\text{dks3}[1, 1, 1, 1] + \text{dks3}[2, 1] + 2^*\text{dks3}[2, 1, 1, 1] + \ldots\]

**retract** *(la)*

Gives the retract map from the symmetric functions to the quotient ring of $k$-bounded symmetric functions. This method is here to make the TestSuite run properly.

**INPUT:**
- `la` - A partition

**OUTPUT:**
- The monomial element of the $k$-bounded quotient indexed by $la$.

**EXAMPLES:**

```python
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.retract([2,1])
m3[2, 1]
```

**super_categories()**

The super categories of `self`.

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ['t'])
sage: from sage.combinat.sf.k_dual import KBoundedQuotientBases
sage: Q = Sym.kBoundedQuotient(3,t=1)
sage: KQB = KBoundedQuotientBases(Q)
sage: KQB.super_categories()
[Category of realizations of 3-Bounded Quotient of Symmetric Functions over Univariate Polynomial Ring in t over Rational Field with t=1, Join of Category of graded hopf algebras with basis over Univariate Polynomial Ring in t over Rational Field and Category of quotients of algebras over Univariate Polynomial Ring in t over Rational Field]
```
class sage.combinat.sf.k_dual.KBoundedQuotientBasis(kBoundedRing, prefix)
    Bases: sage.combinat.free_module.CombinatorialFreeModule

Abstract base class for the bases of the $k$-bounded quotient.

class sage.combinat.sf.k_dual.kMonomial(kBoundedRing)
    Bases: sage.combinat.sf.k_dual.KBoundedQuotientBasis

The basis of monomial symmetric functions indexed by partitions with first part less than or equal to $k$.

**lift($la$)**

Implements the lift function on the monomial basis. Given a $k$-bounded partition $la$, the lift will return the corresponding monomial basis element.

**INPUT:**

- $la$ – A $k$-bounded partition

**OUTPUT:**

- A monomial symmetric function.

**EXAMPLES:**

```python
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.lift(Partition([3,1]))
m[3, 1]
sage: km.lift([])
m[]
sage: km.lift(Partition([4,1]))
Traceback (most recent call last):
  ...TypeError: do not know how to make x (= [4, 1]) an element of self (=3-Bounded˓
  → Quotient of Symmetric Functions over Rational Field with t=1 in the 3-bounded˓
  → monomial basis)
```

**retract($la$)**

Implements the retract function on the monomial basis. Given a partition $la$, the retract will return the corresponding $k$-bounded monomial basis element if $la$ is $k$-bounded; zero otherwise.

**INPUT:**

- $la$ – A partition

**OUTPUT:**

- A $k$-bounded monomial symmetric function in the $k$-quotient of symmetric functions.

**EXAMPLES:**

```python
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.retract(Partition([3,1]))
m3[3, 1]
sage: km.retract(Partition([4,1]))
0
sage: km.retract([])
```

(continues on next page)

\end{verbatim}

class sage.combinat.sf.k_dual.kbounded_HallLittlewoodP(kBoundedRing)
Bases: sage.combinat.sf.k_dual.KBoundedQuotientBasis

The basis of P Hall-Littlewood symmetric functions indexed by partitions with first part less than or equal to k.

\texttt{\textbf{lift}(la)}

Implements the lift function on the Hall-Littlewood P basis. Given a \(k\)-bounded partition \(la\), the lift will return the corresponding \(k\)-bounded Hall-Littlewood P basis element.

INPUT:

- \(la\) – A \(k\)-bounded partition

OUTPUT:

- A Hall-Littlewood symmetric function.

EXAMPLES:

\begin{verbatim}
sage: kHLP = SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(3).
kHallLittlewoodP()
sage: kHLP.lift(Partition([3,1]))
HLP[3, 1]
sage: kHLP.lift([])
HLP[]
sage: kHLP.lift(Partition([4,1]))
Traceback (most recent call last):
...
TypeError: do not know how to make x (= [4, 1]) an element of self (=3-BoundedQuotient of Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the 3-bounded Hall-Littlewood P basis)
\end{verbatim}

\texttt{\textbf{retract}(la)}

Implements the retract function on the Hall-Littlewood P basis. Given a partition \(la\), the retract will return the corresponding \(k\)-bounded Hall-Littlewood P basis element if \(la\) is \(k\)-bounded; zero otherwise.

INPUT:
• $\lambda$ – A partition

OUTPUT:

• A $k$-bounded Hall-Littlewood $P$ symmetric function in the $k$-quotient of symmetric functions.

EXAMPLES:

```python
sage: kHLP = SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(3)
    \rightarrow kHallLittlewoodP()
sage: kHLP.retract(Partition([3,1]))
HLP3[3, 1]
sage: kHLP.retract(Partition([4,1]))
0
euse: kHLP.retract([])
HLP3[]
sage: m = kHLP.realization_of().ambient().m()
sage: kHLP(m[2, 2])
(t^4-t^3-t+1)*HLP3[1, 1, 1, 1] + (t-1)*HLP3[2, 1, 1] + HLP3[2, 2]
```

5.1.286 Kostka-Foulkes Polynomials

Based on the algorithms in John Stembridge’s SF package for Maple which can be found at http://www.math.lsa.umich.edu/~jrs/maple.html.

`sage.combinat.sf.kfpoly.KostkaFoulkesPolynomial(mu, nu, t=None)`

Returns the Kostka-Foulkes polynomial $K_{\mu, \nu}(t)$.

**INPUT:**

• $\mu$, $\nu$ – partitions
• $t$ – an optional parameter (default: None)

**OUTPUT:**

• the Koskta-Foulkes polynomial indexed by partitions $\mu$ and $\nu$ and evaluated at the parameter $t$. If $t$ is None the resulting polynomial is in the polynomial ring $\mathbb{Z}[[t]]$.

**EXAMPLES:**

```python
sage: KostkaFoulkesPolynomial([2,2],[2,2])
1
sage: KostkaFoulkesPolynomial([2,2],[4])
0
sage: KostkaFoulkesPolynomial([2,2],[1,1,1,1])
t^4 + t^2
sage: KostkaFoulkesPolynomial([2,2],[2,1,1])
t
sage: q = PolynomialRing(QQ,'q').gen()
sage: KostkaFoulkesPolynomial([2,2],[2,1,1],q)
q
```

`sage.combinat.sf.kfpoly.compat(n, mu, nu)`

Generate all possible partitions of $n$ that can precede $\mu, \nu$ in a rigging sequence.

**INPUT:**

• $n$ – a positive integer

5.1. Comprehensive Module List
• \( \mu, \nu \) – partitions

OUTPUT:

• a list of partitions

EXAMPLES:

```python
sage: from sage.combinat.sf.kfpoly import *

sage: compat(4, [1], [2,1])
[[1, 1, 1, 1], [2, 1, 1], [2, 2], [3, 1], [4]]

sage: compat(3, [1], [2,1])
[[1, 1, 1], [2, 1], [3]]

sage: compat(2, [1], [])
[[2]]

sage: compat(3, [1], [])
[[2, 1], [3]]

sage: compat(3, [2], [1])
[[3]]

sage: compat(4, [1,1], [])
[[2, 2], [3, 1], [4]]

sage: compat(4, [2], [])
[[4]]
```

```

sage.combinat.sf.kfpoly.dom(mu, nu)

Return True if \( \sum(\mu[:i+1]) \geq \nu[i] \) for all \( 0 \leq i < \text{len}(\nu) \); otherwise, it returns False.

INPUT:

• \( \mu \) – a partition conjugate to \( \mu \)

• \( \nu \) – a sequence of positive integers

OUTPUT:

• a boolean value

EXAMPLES:

```python
sage: from sage.combinat.sf.kfpoly import *

sage: dom([3,2,1],[2,4,5])
True

sage: dom([3,2,1],[2,4,7])
False

sage: dom([3,2,1],[2,6,5])
False

sage: dom([3,2,1],[4,4,4])
False
```

```

sage.combinat.sf.kfpoly.kfpoly(mu, nu, t=None)

Return the Kostka-Foulkes polynomial \( K_{\mu,\nu}(t) \) by generating all rigging sequences for the shape \( \mu \), and then selecting those of content \( \nu \).

INPUT:

• \( \mu, \nu \) – partitions

• \( t \) – an optional parameter (default: None)

OUTPUT:

```python
```
• the Koskta-Foulkes polynomial indexed by partitions \( \mu \) and \( \nu \) and evaluated at the parameter \( t \). If \( t \) is \( \text{None} \) the resulting polynomial is in the polynomial ring \( \mathbb{Z}[t'] \).

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import kfpoly
sage: kfpoly([2,2], [2,1,1])
t
sage: kfpoly([4], [2,1,1])
t^3
sage: kfpoly([4], [2,2])
t^2
sage: kfpoly([1,1,1,1], [2,2])
0
```

\[\textbf{sage.combinat.sf.kfpoly.riggings(part)}\]

Generate all possible rigging sequences for a fixed partition \( \text{part} \).

INPUT:

• \( \text{part} \) – a partition

OUTPUT:

• a list of riggings associated to the partition \( \text{part} \)

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import *

sage: riggings([3])
[[[1, 1, 1]], [[2, 1]], [[3]]]

sage: riggings([2,1])
[[[2, 1], [1]], [[3], [1]]]

sage: riggings([1,1,1])
[[[3], [2], [1]]]

sage: riggings([2,2])
[[[2, 2], [1, 1]], [[3, 2], [1, 1]], [[4, 2], [1, 1]], [[5, 1], [2, 2], [1, 1]], [[6], [2, 2], [1, 1]], [[5, 1], [3, 1], [1, 1]], [[6], [3, 1], [1, 1]], [[6], [4], [2]]]
```

\[\textbf{sage.combinat.sf.kfpoly.schur_to_hl(\mu, t=\text{None})}\]

Return a dictionary corresponding to \( s_\mu \) in Hall-Littlewood \( P \) basis.

INPUT:

• \( \mu \) – a partition

• \( t \) – an optional parameter (default: the generator from \( \mathbb{Z}[t'] \))

OUTPUT:

• a dictionary with the coefficients \( K_{\mu \nu}(t) \) for \( \nu \) smaller in dominance order than \( \mu \)

EXAMPLES:
sage: from sage.combinat.sf.kfpoly import *
sage: schur_to_hl([1,1,1])
{[1, 1, 1]: 1}
sage: a = schur_to_hl([2,1])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1], t^2 + t)
([2, 1], 1)
sage: a = schur_to_hl([3])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1], t^3)
([2, 1], t)
([3], 1)
sage: a = schur_to_hl([4])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], t^6)
([2, 2, 1], t^2)
([2, 1, 1], t^3)
([3, 1], t)
([4], 1)
sage: a = schur_to_hl([3,1])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], t^5 + t^4 + t^3)
([2, 2, 1], t^2 + t)
([2, 1, 1], t^3)
([3], 1)
sage: a = schur_to_hl([2,2])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], t^4 + t^2)
([2, 2, 1], t)
([2], 1)
sage: a = schur_to_hl([2,1,1])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], t^3 + t^2 + t)
([2, 1, 1], 1)
sage: a = schur_to_hl([1,1,1,1])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], 1)
sage: a = schur_to_hl([2,2,2])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1, 1, 1], t^9 + t^7 + t^6 + t^5 + t^3)
([2, 1, 1, 1], t^4 + t^2)
([2, 1, 1], t)
([2, 2, 2], 1)

sage.combinat.sf.kfpoly.weight(rg, t=None)

Return the weight of a rigging.

INPUT:

• rg – a rigging, a list of partitions

• t – an optional parameter, (default: the generator from \(\mathbb{Z}[t']\))

OUTPUT:

• a polynomial in the parameter t
EXAMPLES:

```python
sage: from sage.combinat.sf.kfpoly import weight
sage: weight([[2,1], [1]])
1
sage: weight([[3], [1]])
t^2 + t
sage: weight([[2,1], [3]])
t^4
sage: weight([[2, 2], [1, 1]])
1
sage: weight([[3, 1], [1, 1]])
t
sage: weight([[4], [1, 1]], 2)
16
sage: weight([[4], [2]], t=2)
4
```

5.1.287 LLT symmetric functions

REFERENCES:

class sage.combinat.sf.llt.LLT_class(Sym, k, t='t')
Bases: sage.structure.unique_representation.UniqueRepresentation

A class for working with LLT symmetric functions.

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: L3 = Sym.llt(3); L3
level 3 LLT polynomials over Fraction Field of Univariate Polynomial Ring in t over Rational Field
sage: L3.cospin([3,2,1])
(t+1)*m[1, 1] + m[2]
sage: HC3 = L3.hcospin(); HC3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the level 3 LLT cospin basis
sage: m = Sym.monomial()
sage: m( HC3[1,1] )
(t+1)*m[1, 1] + m[2]
```

We require that the parameter \( t \) must be in the base ring:

```python
sage: Symxt = SymmetricFunctions(QQ['x','t'].fraction_field())
sage: (x,t) = Symxt.base_ring().gens()
sage: LLT3x = Symxt.llt(3,t=x)
sage: LLT3 = Symxt.llt(3)
sage: HS3x = LLT3x.hspin()
sage: HS3t = LLT3.hspin()
sage: s = Symxt.schur()
sage: s(HS3x[2,1])
s[2, 1] + x*s[3]
sage: s(HS3t[2,1])
```

(continues on next page)
**base_ring**

Returns the base ring of `self`.

**INPUT:**

- `self` – a family of LLT symmetric functions bases

**OUTPUT:**

- returns the base ring of the symmetric function ring associated to `self`

**EXAMPLES:**

```python
sage: SymmetricFunctions(FractionField(QQ['t'])).llt(3).base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

**cospin**(`skp`)

Calculate a single instance of the cospin symmetric functions.

These are the functions defined in [LLT1997] equation (26).

**INPUT:**

- `self` – a family of LLT symmetric functions bases
- `skp` – a partition or a list of partitions or a list of skew partitions

**OUTPUT:**

the monomial expansion of the LLT symmetric function cospin functions indexed by `skp`

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: L3 = Sym.llt(3)
sage: L3.cospin([2,1])
m[1]
sage: L3.cospin([3,2,1])
(t+1)*m[1, 1] + m[2]
sage: s = Sym.schur()
sage: s(L3.cospin([[2],[1],[2]]))
t^4*s[2, 2, 1] + t^3*s[3, 1, 1] + (t^3+t^2)*s[3, 2] + (t^2+t)*s[4, 1] + s[5]
```

**hcospin**

Returns the HCospin basis. This basis is defined [LLT1997] equation (27).

**INPUT:**

- `self` – a family of LLT symmetric functions bases

**OUTPUT:**
• returns the h-cospin basis of the LLT symmetric functions

EXAMPLES:

```sage
Sym = SymmetricFunctions(FractionField(QQ['t']))
HCosp3 = Sym.llt(3).hcospin(); HCosp3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the level 3 LLT cospin basis
HCosp3([1])^2
1/t*HCosp3[1, 1] + ((t-1)/t)*HCosp3[2]
s = Sym.schur()
sage: HCosp3(s([2]))
HCosp3[2]
sage: HCosp3(s([1,1]))
1/t*HCosp3[1, 1] - 1/t*HCosp3[2]
sage: s(HCosp3([2,1]))
t*s[2, 1] + s[3]
```

hspin()

Returns the HSpin basis. This basis is defined \cite{LLT1997} equation (28).

INPUT:

• self – a family of LLT symmetric functions bases

OUTPUT:

• returns the h-spin basis of the LLT symmetric functions

EXAMPLES:

```sage
Sym = SymmetricFunctions(FractionField(QQ['t']))
HSp3 = Sym.llt(3).hspin(); HSp3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the level 3 LLT spin basis
HSp3([1])^2
HSp3[1, 1] + (-t+1)*HSp3[2]
s = Sym.schur()
sage: HSp3(s([2]))
HSp3[2]
sage: HSp3(s([1,1]))
HSp3[1, 1] - t*HSp3[2]
sage: s(HSp3([2,1]))
s[2, 1] + t*s[3]
```

level()

Returns the level of `self`.

INPUT:

• self – a family of LLT symmetric functions bases

OUTPUT:

• the level is the parameter of $k$ in the basis

EXAMPLES:
spin_square\( (skp) \)

Calculate a single instance of a spin squared LLT symmetric function associated with a partition, list of partitions, or a list of skew partitions.

This family of symmetric functions is defined in [LT2000] equation (43).

**INPUT:**
- `self` – a family of LLT symmetric functions bases
- `skp` – a partition of a list of partitions or a list of skew partitions

**OUTPUT:**
the monomial expansion of the LLT symmetric function spin-square functions indexed by `skp`

**EXAMPLES:**

```sage
sage: L3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3)
sage: L3.spin_square([2,1])
t*m[1]
sage: L3.spin_square([3,2,1])
(t^3+t)*m[1, 1] + t^3*m[2]
sage: L3.spin_square([[[1],[1]],[1]])
(t^6+2*t^4+2*t^2+1)*m[1, 1, 1] + (t^6+t^4+t^2)*m[2, 1] + t^6*m[3]
sage: L3.spin_square([[2],[1]],[[2,1]])
(2*t^4+3*t^2+1)*m[1, 1, 1] + (t^4+t^2)*m[2, 1, 1] + t^4*m[2, 2]
```

symmetric_function_ring()

The symmetric function algebra associated to the family of LLT symmetric function bases

**INPUT:**
- `self` – a family of LLT symmetric functions bases

**OUTPUT:**
- returns the symmetric function ring associated to `self`

**EXAMPLES:**

```sage
sage: L3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3)
sage: L3.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

### class sage.combinat.sf.llt.LLT_cospin(llt)

Bases: `sage.combinat.sf.llt.LLT_generic`

A class of methods for the h-cospin LLT basis of the symmetric functions.

**INPUT:**
- `self` – an instance of the LLT hcospin basis
- `llt` – a family of LLT symmetric function bases

### class Element

Bases: `sage.combinat.sf.llt.LLT_generic.Element`
class sage.combinat.sf.llt.LLT_generic(ltt, prefix)
    Bases: sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic

A class of methods which are common to both the hspin and hcospin of the LLT symmetric functions.

INPUT:

- `self` – an instance of the LLT hspin or hcospin basis
- `llt` – a family of LLT symmetric functions

EXAMPLES:

```python
sage: SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the level 3 LLT spin basis
sage: SymmetricFunctions(QQ).llt(3,t=2).hspin()
Symmetric Functions over Rational Field in the level 3 LLT spin with t=2 basis
sage: QQz = FractionField(QQ['z']); z = QQz.gen()
Sage: SymmetricFunctions(QQz).llt(3,t=z).hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in z over Rational Field in the level 3 LLT spin with t=z basis
```

class Element
    Bases: sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element

level()
    Returns the level of `self`.

INPUT:

- `self` – an instance of the LLT hspin or hcospin basis

OUTPUT:

- returns the level associated to the basis `self`.

EXAMPLES:

```python
sage: HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
sage: HSp3.level()
3
```

llt_family()
    The family of the llt bases of the symmetric functions.

INPUT:

- `self` – an instance of the LLT hspin or hcospin basis

OUTPUT:

- returns an instance of the family of LLT bases associated to `self`.

EXAMPLES:

```python
sage: HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
sage: HSp3.ltt_family()
level 3 LLT polynomials over Fraction Field of Univariate Polynomial Ring in t over Rational Field
```
Combinatorics, Release 9.7

**product** *(left, right)*

Convert to the monomial basis, do the multiplication there, and convert back to the basis *self*.

**INPUT:**

- *self* – an instance of the LLT hspin or hcospin basis
- *left, right* – elements of the symmetric functions

**OUTPUT:**

the product of *left* and *right* expanded in the basis *self*

**EXAMPLES:**

```python
sage: HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
sage: HSp3.product(HSp3([1]), HSp3([2]))
HSp3[2, 1] + (-t+1)*HSp3[3]
sage: HCosp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hcospin()
sage: HCosp3.product(HCosp3([1]), HSp3([2]))
1/t*HCosp3[2, 1] + ((t-1)/t)*HCosp3[3]
```

**class** *sage.combinat.sf.llt.LLT_spin(llt)*

Bases: *sage.combinat.sf.llt.LLT_generic*

A class of methods for the h-spin LLT basis of the symmetric functions.

**INPUT:**

- *self* – an instance of the LLT hcospin basis
- *llt* – a family of LLT symmetric function bases

**class** *Element*

Bases: *sage.combinat.sf.llt.LLT_generic.Element*

### 5.1.288 Macdonald Polynomials

Notation used in the definitions follows mainly [Mac1995].

The integral forms of the bases $H$ and $H_t$ do not appear in Macdonald’s book. They correspond to the two bases $H_{\mu}[X; q, t] = \sum_{\nu} K_{\nu\mu}(q, t)s_{\mu}[X]$ and $H_{\mu}[X; q, t] = t^{n(\mu)} \sum_{\nu} K_{\nu\mu}(q, 1/t)s_{\nu}[X]$ where $K_{\mu\nu}(q, t)$ are the Macdonald $q, t$-Koskta coefficients.

The $H_t$ in this case is short for $H$ and is the basis which is the graded Frobenius image of the Garsia-Haiman modules [GH1993].

**REFERENCES:**

- [Mac1995]

**class** *sage.combinat.sf.macdonald.Macdonald(Sym, q='q', t='t')*

Bases: *sage.structure.unique_representation.UniqueRepresentation*

Macdonald Symmetric functions including $P, Q, J, H, H_t$ bases also including the S basis which is the plethystic transformation of the Schur basis (that which is dual to the Schur basis with respect to the Macdonald $q, t$-scalar product)

**INPUT:**

- *self* – a family of Macdonald symmetric function bases

**EXAMPLES:**
sage: t = QQ['t'].gen(); SymmetricFunctions(QQ['t'].fraction_field()).macdonald(q=t, t=1)
Macdonald polynomials with q=t and t=1 over Fraction Field of Univariate Polynomial Ring in t over Rational Field
sage: Sym = SymmetricFunctions(FractionField(QQ['t'])).macdonald()
Traceback (most recent call last):
...
TypeError: unable to evaluate 'q' in Fraction Field of Univariate Polynomial Ring in t over Rational Field

H()

Returns the Macdonald polynomials on the H basis. When the H basis is expanded on the Schur basis, the coefficients are the $qt$-Kostka numbers.

INPUT:
• self – a family of Macdonald symmetric function bases

OUTPUT:
• returns the $H$ Macdonald basis of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: H = Sym.macdonald().H(); H
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field in the Macdonald H basis
sage: s = Sym.schur()
sage: s(H([2]))
q*s[1, 1] + s[2]
sage: s(H([1,1]))
s[1, 1] + t*s[2]
```

Coercions to/from the Schur basis are implemented:

```
sage: H = Sym.macdonald().H()
sage: s = Sym.schur()
sage: H(s([2]))
(q/(q*t-1))*McdH[1, 1] - (1/(q*t-1))*McdH[2]
```

Ht()

Returns the Macdonald polynomials on the $Ht$ basis. The elements of the $Ht$ basis are eigenvectors of the $\nabla$ operator. When expanded on the Schur basis, the coefficients are the modified $qt$-Kostka numbers.

INPUT:
• self – a family of Macdonald symmetric function bases

OUTPUT:
• returns the $Ht$ Macdonald basis of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: Ht = Sym.macdonald().Ht(); Ht
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field in the Macdonald Ht basis
```

(continues on next page)
Coercions to/from the Schur basis are implemented:

```python
sage: Ht = Sym.macdonald().Ht()
sage: s = Sym.schur()
sage: Ht(s([2,1]))
(q/(q*t^2-t^3-q^2+q*t))*McdHt[1, 1, 1] + ((-q^2-q*t-t^2)/(q^2*t^2-q^3-t^3+q*t))*McdHt[2, 1] + (t/(-q^3+q^2*t+q*t-t^2))*McdHt[3]
```

\(J()\)

Returns the Macdonald polynomials on the \(J\) basis also known as the integral form of the Macdonald polynomials. These are scalar multiples of both the \(P\) and \(Q\) bases. When expressed in the \(P\) or \(Q\) basis, the scaling coefficients are polynomials in \(q\) and \(t\) rather than rational functions.

The \(J\) basis is calculated using determinantal formulas of Lapointe-Lascoux-Morse giving the action on the \(S\)-basis [LLM1998].

INPUT:

- \(self\) – a family of Macdonald symmetric function bases

OUTPUT:

- returns the \(J\) Macdonald basis of symmetric functions

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: J = Sym.macdonald().J(); J
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field in the Macdonald J basis
sage: P = Sym.macdonald().P()
sage: Q = Sym.macdonald().Q()
sage: P(J([2]))
(q^3-t^2-q*t+t+1)*McdP[2]
sage: P(J([1,1]))
t^3*t^2-t+1)*McdP[1, 1]
sage: Q(J([2]))
(q^3-q^2-q+1)*McdQ[2]
```
Coercions from the $Q$ and $J$ basis (proportional) and to/from the Schur basis are implemented:

\[
\begin{align*}
\text{sage: } & Q(J([1,1])) \\
& (q^{2}t^{-}q^{3}t^{-}q+1)*McdQ[1, 1]
\end{align*}
\]

\[
\begin{align*}
\text{sage: } & P = \text{Sym.macdonald().P()} \\
\text{sage: } & Q = \text{Sym.macdonald().Q()} \\
\text{sage: } & J = \text{Sym.macdonald().J()} \\
\text{sage: } & s = \text{Sym.schur()}
\end{align*}
\]

\[
\begin{align*}
\text{sage: } & J(P([2])) \\
& (1/(q^{2}t^{2}-q^{3}t^{-}t+1))*McdJ[2]
\end{align*}
\]

\[
\begin{align*}
\text{sage: } & J(Q([2])) \\
& (1/(q^{3}-q^{2}-q+1))*McdJ[2]
\end{align*}
\]

\[
\begin{align*}
\text{sage: } & s(J([2])) \\
& (-q^{2}t^{2}+q^{2}t^{-}q+q+t)*s[1, 1] + (q^{3}t^{2}-q^{3}t^{-}t+1)*s[2]
\end{align*}
\]

\[
\begin{align*}
\text{sage: } & J(s([2])) \\
& ((q-t)/(q^{2}t^{4}-q^{2}t^{3}-q^{2}t^{2}+q^{2}t^{2}+q^{2}t-t-1))*McdJ[1, 1] + (1/(q^{2}t^{2}-q^{3}t^{-}t+1))*McdJ[2]
\end{align*}
\]

\[\textbf{P()}\]

Returns Macdonald polynomials in $P$ basis. The $P$ basis is defined here as a normalized form of the $J$ basis.

INPUT:

- \texttt{self} – a family of Macdonald symmetric function bases

OUTPUT:

- returns the $P$ Macdonald basis of symmetric functions

EXAMPLES:

\[
\begin{align*}
\text{sage: } & \text{Sym} = \text{SymmetricFunctions(FractionField(QQ['q','t'])} \\
\text{sage: } & P = \text{Sym.macdonald().P(); P} \\
& \text{Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field in the Macdonald P basis} \\
\text{sage: } & P[2] \\
& \text{McdP[2]}
\end{align*}
\]

The $P$ Macdonald basis is upper triangularly related to the monomial symmetric functions and are orthogonal with respect to the $q,t$-Hall scalar product:
When \( q = 0 \), the Macdonald polynomials on the \( P \) basis are the same as the Hall-Littlewood polynomials on the \( P \) basis.

Coercions from the \( Q \) and \( J \) basis (proportional) are implemented:

By transitivity, one get coercions from the classical bases:

(continues on next page)
sage: P3 = Maczx.P()
sage: m(P1[2, 1])
((-2*x*y^2+x*y-y^2+2x+y+2)/(-x*y^2+1))*m[1, 1, 1] + m[2, 1]
sage: m(P2[2, 1])
((-2*y*z^2+2*y*z-2*y+z+2)/(-y*z^2+1))*m[1, 1, 1] + m[2, 1]
sage: m(P1(P2(P3[2, 1])))
((-2*x^2*z-x^2*x*z-z+x+2)/(-x^2*z+1))*m[1, 1, 1] + m[2, 1]
sage: P1(P2[2])
((-x*y^2+2*x*y*z-y^2*z-x+2*y-z)/(x*y^2*z-x*y-y*z+1))*McdP[1, 1] + McdP[2]
sage: m(P1[2])
((-x*y^2+2*x*y*z-y^2*z-x+2*y-z)/(x*y^2*z-x*y-y*z+1))*McdP[1, 1] + McdP[2]

\textbf{Q}\par

Returns the Macdonald polynomials on the $Q$ basis. These are dual to the Macdonald polynomials on the $P$ basis with respect to the $qt$-Hall scalar product. The $Q$ basis is defined to be a normalized form of the $J$ basis.

\textbf{INPUT:}

\begin{itemize}
\item \texttt{self} – a family of Macdonald symmetric function bases
\end{itemize}

\textbf{OUTPUT:}

\begin{itemize}
\item returns the $Q$ Macdonald basis of symmetric functions
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: Q = Sym.macdonald().Q(); Q
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field in the Macdonald Q basis
sage: P = Sym.macdonald().P()
sage: Q([[2]]).scalar_qt(P([[2]]))
1
sage: Q([[2]]).scalar_qt(P([[1,1]]))
0
sage: Q([[1,1]]).scalar_qt(P([[2]]))
0
sage: Q([[1,1]]).scalar_qt(P([[1,1]]))
1
sage: Q(P([[2]]))
((q^3-q^2-q+1)/(q*t^2-q*t-t+1))*McdQ[2]
sage: Q(P([[1,1]]))
((q^2*t-q*t-q+1)/(t^3-t^2-t+1))*McdQ[1, 1]
\end{verbatim}

Coercions from the $P$ and $J$ basis (proportional) are implemented:

\begin{verbatim}
sage: P = Sym.macdonald().P()
sage: Q = Sym.macdonald().Q()
sage: J = Sym.macdonald().J()
sage: s = Sym.schur()
sage: Q(J([[2]]))
(q^3-q^2-q+1)*McdQ[2]
\end{verbatim}
By transitivity, one gets coercions from the classical bases:

\[
\text{sage: } Q(s([2])) \\
((q^2 - q*t - q + 1)/(t^3 - t^2 - t + 1)) * \text{McdQ}[2] \\
\text{sage: } P(Q(s([2]))) \\
\text{McdP}[2] \\
\text{sage: } Q(P(Q([2]))) \\
\text{McdQ}[2]
\]

\(S()\)
Returns the modified Schur functions defined by the plethystic substitution \(S_\mu = s_\mu \frac{X(1-t)}{(1-q)}\). When the Macdonald polynomials in the J basis are expressed in terms of the modified Schur functions at \(q = 0\), the coefficients are \(qt\)-Kostka numbers.

INPUT:
- \texttt{self} – a family of Macdonald symmetric function bases

OUTPUT:
- returns the \(S\) Macdonald basis of symmetric functions

EXAMPLES:

\[
\text{sage: } \text{Sym} = \text{SymmetricFunctions}(\text{FractionField}(\text{QQ}'[q',t'])) \\
\text{sage: } S = \text{Sym.macdonald()}.S(); S \\
\text{Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field in the Macdonald S basis} \\
\text{sage: } p = \text{Sym.power()} \\
\text{sage: } p(S[2,1]) \\
((1/3*t^3-t^2+t-1/3)/(q^3-3*q^2+3*q-1))*p[1, 1, 1] + ((-1/3*t^3+1/3)/(q^3-1))*p[3] \\
\text{sage: } J = \text{Sym.macdonald()}.J() \\
\text{sage: } S(J([2])) \\
(q^3-q^2-q+1)*\text{McdS}[2] \\
\text{sage: } S(J([1,1])) \\
(q^2*t-q*t-q+1)*\text{McdS}[1, 1] + (q^2-q*t-q+t)*\text{McdS}[2] \\
\text{sage: } S = \text{Sym.macdonald(q=0)}.S() \\
\text{sage: } S(J[1,1]) \\
\text{McdS}[1, 1] + t*\text{McdS}[2] \\
\text{sage: } S(J[2]) \\
q^2*\text{McdS}[1, 1] + \text{McdS}[2] \\
\text{sage: } p(S[2,1]) \\
(-1/3*t^3+t^2-t+1/3)*p[1, 1, 1] + (1/3*t^3-1/3)*p[3] \\
\text{sage: from sage.combinat.sf.macdonald import qt_kostka} \\
\text{sage: qt_kostka([2],[1,1])} \\
t \\
\text{sage: qt_kostka([1,1],[2])} \\
q
\]

Coercions to/from the Schur basis are implemented:
```python
sage: S = Sym.macdonald().S()
sage: s = Sym.schur()
sage: S(s([2]))
((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdS[1, 1] + ((-q^2*t+q*t+q-1)/(-t^3+t^2+t-1))*McdS[2]
sage: s(S([1,1]))
((-q*t^2+q*t+t-1)/(-q^3+q^2+q-1))*s[1, 1] + ((q*t-t^2-q+t)/(-q^3+q^2+q-1))*s[2]
```

### base_ring()
Returns the base ring of the symmetric functions where the Macdonald symmetric functions live

**INPUT:**
- `self` – a family of Macdonald symmetric function bases

**OUTPUT:**
- the base ring associated to the corresponding symmetric function ring

**EXAMPLES:**
```python
sage: Sym = SymmetricFunctions(QQ['q'].fraction_field())
sage: Mac = Sym.macdonald(t=0)
sage: Mac.base_ring()
Fraction Field of Univariate Polynomial Ring in q over Rational Field
```

### symmetric_function_ring()
Returns the base ring of the symmetric functions where the Macdonald symmetric functions live

**INPUT:**
- `self` – a family of Macdonald symmetric function bases

**OUTPUT:**
- the symmetric function ring associated to the Macdonald bases

**EXAMPLES:**
```python
sage: Mac = SymmetricFunctions(QQ['q'].fraction_field()).macdonald(t=0)
sage: Mac.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in q over Rational Field
```

### class sage.combinat.sf.macdonald.MacdonaldPolynomials_generic(macdonald)
Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic`
A class for methods for one of the Macdonald bases of the symmetric functions

**INPUT:**
- `self` – a Macdonald basis
- `macdonald` – a family of Macdonald symmetric function bases

**EXAMPLES:**
```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q,t'])); Sym.rename("Sym"); Sym
Sym
sage: Sym.macdonald().P()
Sym in the Macdonald P basis
```
sage: Sym.macdonald(t=2).P()
Sym in the Macdonald P with t=2 basis
sage: Sym.rename()

class Element
Bases: sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element

nabla(q=None, t=None, power=1)

Return the value of the nabla operator applied to self.

The eigenvectors of the nabla operator are the Macdonald polynomials in the $Ht$ basis. For more information see: [BGHT1999].

The operator nabla acts on symmetric functions and has the Macdonald $Ht$ basis as eigenfunctions and the eigenvalues are $q^n(\mu')t^n(\mu)$ where $n(\mu) = \sum (i - 1)\mu_i$ and $\mu'$ is the conjugate shape of $\mu$.

If the parameter power is an integer then it calculates nabla to that integer. The default value of power is 1.

INPUT:
• self – an element of a Macdonald basis
• q, t – optional parameters to specialize
• power – an integer (default: 1)

OUTPUT:
• returns the symmetric function of $\nabla$ acting on self

EXAMPLES:

sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: P([1,1]).nabla()
((q^2*t+q*t^2-2*t)/(q*t-1))*McdP[1, 1] + McdP[2]
sage: P([1,1]).nabla(t=1)
((q^2*t+q*t-t-1)/(q*t-1))*McdP[1, 1] + McdP[2]
sage: H = Sym.macdonald().H()
sage: H([1,1]).nabla()
t*McdH[1, 1] + (-t^2+1)*McdH[2]
sage: H([1,1]).nabla(q=1)
((t^2+q-t-1)/(q*t-1))*McdH[1, 1] + ((-t^3+t^2+t-1)/(q*t-1))*McdH[2]
sage: H([1,1]).nabla()
0
sage: H([2,2,1]).nabla(t=1/H.t)
((-q^2)/(-t^4))*McdH[2, 2, 1]
sage: H([2,2,1]).nabla(t=1/H.t,power=-1)
((-t^4)/(-q^2))*McdH[2, 2, 1]

c1(part)

Returns the qt-Hall scalar product between $J(part)$ and $P(part)$.

INPUT:
• self – a Macdonald basis
• part – a partition

OUTPUT:
• returns the $qt$-Hall scalar product between $J(part)$ and $P(part)$
EXAMPLES:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: P.c1(Partition([2,1]))
-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1
```

**c2(part)**
Returns the $qt$-Hall scalar product between $J(part)$ and $Q(part)$.

**INPUT:**
- `self` – a Macdonald basis
- `part` – a partition

**OUTPUT:**
- returns the $qt$-Hall scalar product between $J(part)$ and $Q(part)$

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: P.c2(Partition([2,1]))
-q*t^4 + 2*q*t^3 - q*t^2 + t^2 - 2*t + 1
```

**macdonald_family()**
Returns the family of Macdonald bases associated to the basis `self`

**INPUT:**
- `self` – a Macdonald basis

**OUTPUT:**
- the family of Macdonald symmetric functions associated to `self`

**EXAMPLES:**

```python
sage: MacP = SymmetricFunctions(QQ['q'].fraction_field()).macdonald(t=0).P()
sage: MacP.macdonald_family()
Macdonald polynomials with t=0 over Fraction Field of Univariate Polynomial Ring in q over Rational Field
```

**product(left, right)**
Multiply an element of the Macdonald symmetric function basis `self` and another symmetric function
Convert to the Schur basis, do the multiplication there, and convert back to `self` basis.

**INPUT:**
- `self` – a Macdonald symmetric function basis
- `left` – an element of the basis `self`
- `right` – another symmetric function

**OUTPUT:**
the product of `left` and `right` expanded in the basis `self`

**EXAMPLES:**
macdonald feminizing basis

```
sage: Mac = SymmetricFunctions(FractionField(QQ['q', 't'])).macdonald()
sage: H = Mac.H()
sage: J = Mac.J()
sage: P = Mac.P()
sage: Q = Mac.Q()
sage: Ht = Mac.Ht()
sage: J([1])^2
#indirect doctest
((q-1)/(q*t-1))*McdJ[1, 1] + ((t-1)/(q*t-1))*McdJ[2]
sage: J.product( J[1], J[2] )
((-q^2+1)/(-q^2*t+1))*McdJ[2, 1] + ((-t+1)/(-q^2*t+1))*McdJ[3]
sage: H.product( H[1], H[2] )
((q^2-1)/(q^2*t-1))*McdH[2, 1] + ((-t+1)/(-q^2*t+1))*McdH[3]
sage: P.product( P[1], P[2] )
((-q^3*t^2+q*t^2+q^2-1)/(-q^3*t^2+q^2*t+q*t-1))*McdP[2, 1] + McdP[3]
sage: Q.product(Q[1],Q[2])
McdQ[2, 1] + ((q^2*t-q^2+q*t-q+t-1)/(q^2*t-1))*McdQ[3]
sage: Ht.product(Ht[1],Ht[2])
((q^2-1)/(q^2-t))*McdHt[2, 1] + ((t-1)/(-q^2+t))*McdHt[3]
```
If the parameter `power` is an integer then it calculates nabla to that integer. The default value of `power` is 1.

**INPUT:**
- `self` – an element of the Macdonald $Ht$ basis
- `q, t` – optional parameters to specialize
- `power` – an integer (default: 1)

**OUTPUT:**
- returns the symmetric function of $\nabla$ acting on `self`

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: Ht = Sym.macdonald().Ht()
sage: t = Ht.t; q = Ht.q
sage: s = Sym.schur()
sage: a = sum(Ht(p) for p in Partitions(3))
sage: Ht(0).nabla()
0
sage: a.nabla() == t^3*Ht([1,1,1])+q*t*Ht([2,1]) + q^3*Ht([3])
True
```

```python
class sage.combinat.sf.macdonald.MacdonaldPolynomials_j(macdonald)
Bases: sage.combinat.sf.macdonald.MacdonaldPolynomials_generic
```

The $J$ basis is calculated using determinantal formulas of Lapointe-Lascoux-Morse giving the action on the $S$-basis.

**INPUT:**
- `self` – a Macdonald $J$ basis
- `macdonald` – a family of Macdonald bases

```python
class Element
```

```python
class sage.combinat.sf.macdonald.MacdonaldPolynomials_p(macdonald)
Bases: sage.combinat.sf.macdonald.MacdonaldPolynomials_generic
```

The $P$ basis is defined here as the $J$ basis times a normalizing coefficient $c2$.

**INPUT:**
• self – a Macdonald \( P \) basis
• macdonald – a family of Macdonald bases

class Element

\texttt{scalar\_qt\_basis}(part1, part2=None)
Returns the scalar product of \( P(part1) \) and \( P(part2) \) This scalar product formula is given in equation (4.11) p.323 and (6.19) p.339 of Macdonald’s book [Mac1995].

INPUT:
• self – a Macdonald \( P \) basis
• part1, part2 – partitions

OUTPUT:
• returns the scalar product of \( P(part1) \) and \( P(part2) \)

EXAMPLES:

\begin{verbatim}
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: P.scalar_qt_basis(Partition([2,1]), Partition([1,1,1]))
0
sage: f = P.scalar_qt_basis(Partition([3,2,1]), Partition([3,2,1]))
sage: factor(f.numerator())
(q^4*t^3 + 2*q^3*t^2 - q^2*t + q^2 + 2) * (q^3*t^2 - 1)
sage: factor(f.denominator())
(t - 1)^3 * (q*t^2 - 1)^2 * (q^2*t^3 - 1)
\end{verbatim}

With a single argument, takes \( part2 = part1 \):

\begin{verbatim}
sage: P.scalar_qt_basis(Partition([2,1]), Partition([2,1]))
(-q^4*t^2 + 2*q^3*t - q^2*t + q^2 + 1)/(q^4*t^3 + 2*q^3*t^2 - q^2*t + 1)
\end{verbatim}

class sage.combinat.sf.macdonald.MacdonaldPolynomials_q(macdonald)
Bases: sage.combinat.sf.macdonald.MacdonaldPolynomials_generic

The \( Q \) basis is defined here as the \( J \) basis times a normalizing coefficient.

INPUT:
• self – a Macdonald \( Q \) basis
• macdonald – a family of Macdonald bases

class Element

class sage.combinat.sf.macdonald.MacdonaldPolynomials_s(macdonald)
Bases: sage.combinat.sf.macdonald.MacdonaldPolynomials_generic

An implementation of the basis \( s_\lambda[(1-t)X/(1-q)] \)

This is perhaps misnamed as a ‘Macdonald’ basis for the symmetric functions but is used in the calculation of the Macdonald \( J \) basis (see method ‘creation’ below) but does use both of the two parameters and can be specialized to \( s_\lambda[(1-t)X] \) and \( s_\lambda[X/(1-t)] \).

INPUT:
• **self** – a Macdonald $S$ basis

• **macdonald** – a family of Macdonald bases

class Element

definition creation($k$)

This function is a creation operator for the J-basis for which the action is known on the ‘Macdonald’ $S$-basis by formula from [LLM1998].

**INPUT:**
- **self** – an element of the Macdonald $S$ basis
- **$k$** – a positive integer

**OUTPUT:**
- returns the column adding operator on the $J$ basis on self

**EXAMPLES:**

```sage
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: S = Sym.macdonald().S()
sage: a = S(1)
sage: a.creation(1)
(-q+1)*McdS[1]
sage: a.creation(2)
(q^2*t-q*t-q+1)*McdS[1, 1] + (q^2-q*t-q+t)*McdS[2]
```

**product**($left$, $right$)

The multiplication of the modified Schur functions behaves the same as the multiplication of the Schur functions.

**INPUT:**
- **self** – a Macdonald $S$ basis
- **left, right** – a symmetric functions

**OUTPUT:**

the product of left and right

**EXAMPLES:**

```sage
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: S = Sym.macdonald().S()
sage: S([2])^2  #indirect doctest
```

`sage.combinat.sf.macdonald.c1(part, q, t)`

This function returns the qt-Hall scalar product between $J(part)$ and $P(part)$.

This coefficient is $c_\lambda$ in equation (8.1') p. 352 of Macdonald’s book [Mac1995].

**INPUT:**
- **part** – a partition
- **q, t** – parameters

**OUTPUT:**
- returns a polynomial of the scalar product between the $J$ and $P$ bases

**EXAMPLES:**

5.1. Comprehensive Module List 2819
sage: from sage.combinat.sf.macdonald import c1
sage: R.<q,t> = QQ[
  ...
]  # Assuming QQ is the field of rational numbers
sage: c1(Partition([2,1]),q,t)
-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1
sage: c1(Partition([1,1]),q,t)
q^2*t - q*t - q + 1

sage.combinat.sf.macdonald.c2(part, q, t)

This function returns the qt-Hall scalar product between J(part) and Q(part).

This coefficient is $c_\lambda$ in equation (8.1) p. 352 of Macdonald’s book [Mac1995].

**INPUT:**

- `part` – a partition
- `q`, `t` – parameters

**OUTPUT:**

- returns a polynomial of the scalar product between the $J$ and $P$ bases

**EXAMPLES:**

sage: from sage.combinat.sf.macdonald import c2
sage: R.<q,t> = QQ[
  ...
]  # Assuming QQ is the field of rational numbers
sage: c2(Partition([1,1]),q,t)
t^3 - t^2 - t + 1
sage: c2(Partition([2,1]),q,t)
-q*t^4 + 2*q*t^3 - q*t^2 + t^2 - 2*t + 1

sage.combinat.sf.macdonald.cmunu(mu, nu)

Return the coefficient of $\tilde{H}_\nu$ in $h_\lambda^\perp \tilde{H}_\mu$.

Proposition 5 of F. Bergeron and M. Haiman [BH2013] states

$$c_{\mu\nu} = \sum_{\alpha \in \nu} c_{\mu\alpha} B_{\alpha/\nu} B_{\mu/\nu}$$

where $c_{\mu\nu}$ is the coefficient of $\tilde{H}_\nu$ in $h_\lambda^\perp \tilde{H}_\mu$ and $B_{\mu/\nu}$ is the bi-exponent generator implemented in the function `sage.combinat.sf.macdonald.Bmu()`.

**INPUT:**

- `mu`, `nu` – partitions with `nu` contained in `mu`

**OUTPUT:**

- an element of the fraction field of polynomials in $q$ and $t$

**EXAMPLES:**

sage: from sage.combinat.sf.macdonald import cmunu
sage: cmunu(Partition([2,1]),Partition([1]))
q + t + 1
sage: cmunu(Partition([2,2]),Partition([1,1]))
(-q^3 - q^2 + q^*t + t)/(-q + t)

...
sage: all(Ht[2,2].skew_by(h[r]).coefficient(nu)
.....: == cmunu(Partition([2,2]),nu)
.....: for r in range(1,5) for nu in Partitions(4-r))
True

sage.combinat.sf.macdonald.cmunu1(mu, nu)
Return the coefficient of $\tilde{H}_\mu$ in $h_1^\perp \tilde{H}_{\nu}$.

INPUT:
• mu, nu – partitions with nu precedes mu

OUTPUT:
• an element of the fraction field of polynomials in $q$ and $t$

EXAMPLES:

sage: from sage.combinat.sf.macdonald import cmunu1
sage: cmunu1(Partition([2,1]),Partition([2]))
(-t^2 + q)/(q - t)
sage: cmunu1(Partition([2,1]),Partition([1,1]))
(-q^2 + t)/(-q + t)
sage: Sym = SymmetricFunctions(QQ['q','t'].fraction_field())
sage: h = Sym.h()
sage: Ht = Sym.macdonald().Ht()
sage: all(Ht[3,2,1].skew_by(h[1]).coefficient(nu)
.....: == cmunu1(Partition([3,2,1]),nu)
.....: for nu in Partition([3,2,1]).down_list())
True

sage.combinat.sf.macdonald.qt_kostka(lam, mu)
Returns the $K_{\lambda\mu}(q,t)$ by computing the change of basis from the Macdonald H basis to the Schurs.

INPUT:
• lam, mu – partitions of the same size

OUTPUT:
• returns the $q,t$-Kostka polynomial indexed by the partitions lam and mu

EXAMPLES:

sage: from sage.combinat.sf.macdonald import qt_kostka
sage: qt_kostka([2,1,1],[1,1,1,1])
t^3 + t^2 + t
sage: qt_kostka([1,1,1,1],[2,1,1])
q
sage: qt_kostka([1,1,1,1],[3,1])
q^3
sage: qt_kostka([1,1,1,1],[1,1,1,1])
1
sage: qt_kostka([2,1,1],[2,2])
q^2*t + q^2*t + q
sage: qt_kostka([2,2],[2,2])
q^2*t^2 + 1

(continues on next page)
sage: qt_kostka([4],[3,1])
tsage: qt_kostka([2,2],[3,1])
q^2*t + qtsage: qt_kostka([3,1],[2,1,1])
q*t^3 + t^2 + ttsage: qt_kostka([2,1,1],[2,1,1])
q*t^2 + q*t + 1tsage: qt_kostka([2,1],[1,1,1,1])
0

5.1.289 Monomial symmetric functions

class sage.combinat.sf.monomial.SymmetricFunctionAlgebra_monomial(Sym)

Bases: sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical

A class for methods related to monomial symmetric functions

INPUT:

• self – a monomial symmetric function basis
• Sym – an instance of the ring of the symmetric functions
class Element

expand(n, alphabet='x')

Expand the symmetric function self as a symmetric polynomial in n variables.

INPUT:

• n – a nonnegative integer
• alphabet – (default: 'x') a variable for the expansion

OUTPUT:

A monomial expansion of self in the n variables labelled by alphabet.

EXAMPLES:

sage: m = SymmetricFunctions(QQ).m()
sage: m([2,1]).expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2sage: m([1,1,1]).expand(2)
0tsage: m([2,1]).expand(3,alphabet='z')
z0^2*z1 + z0*z1^2 + z0^2*z2 + z1^2*z2 + z0*z2^2 + z1*z2^2sage: m([2,1]).expand(3,alphabet='x,y,z')
x^2*y + x*y^2 + x^2*z + y^2*z + x*z^2 + y*z^2sage: m([1]).expand(0)
0tsage: (3*m([])).expand(0)
3

exponential_specialization(t=None, q=1)

Return the exponential specialization of a symmetric function (when q = 1), or the q-exponential specialization (when q ≠ 1).
The exponential specialization $e_x$ at $t$ is a $K$-algebra homomorphism from the $K$-algebra of symmetric functions to another $K$-algebra $R$. It is defined whenever the base ring $K$ is a $Q$-algebra and $t$ is an element of $R$. The easiest way to define it is by specifying its values on the powersum symmetric functions to be $p_1 = t$ and $p_n = 0$ for $n > 1$. Equivalently, on the homogeneous functions it is given by $e_x(h_n) = t^n/n!$; see Proposition 7.8.4 of [EnumComb2].

By analogy, the $q$-exponential specialization is a $K$-algebra homomorphism from the $K$-algebra of symmetric functions to another $K$-algebra $R$ that depends on two elements $t$ and $q$ of $R$ for which the elements $1 - q^i$ for all positive integers $i$ are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

$$e_x(q)_n = t^n/[n]_q!,$$

where $[n]_q!$ is the $q$-factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function $f$ of degree $n$, we have

$$e_x(q)(f) = (1 - q)^n t^n p_s(q)(f),$$

where $p_s(q)(f)$ is the stable principal specialization of $f$ (see principal_specialization()). (See (7.29) in [EnumComb2].)

The limit of $e_x(q)$ as $q \to 1$ is $e_x$.

INPUT:

- t (default: None) – the value to use for $t$; the default is to create a ring of polynomials in $t$.
- q (default: 1) – the value to use for $q$. If q is None, then a ring (or fraction field) of polynomials in q is created.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: (m[3]+m[2,1]+m[1,1,1]).exponential_specialization()
1/6*t^3
sage: x = 5*m[1,1,1] + 3*m[2,1] + 1
sage: x.exponential_specialization()
5/6*t^3 + 1
```

We also support the $q$-exponential specialization:

```
sage: factor(m[3].exponential_specialization(q=var("q"), t=var("t")))
(q - 1)^2*t^3/(q^2 + q + 1)
```

principal_specialization($n=\infty$, $q=\text{None}$)

Return the principal specialization of a symmetric function.

The principal specialization of order $n$ at $q$ is the ring homomorphism $p_{sn,q}$ from the ring of symmetric functions to another commutative ring $R$ given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \ldots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, $q$ is a given element of $R$, and we assume that the variables of our symmetric functions are $x_1, x_2, x_3, \ldots$. (To be more precise, $p_{sn,q}$ is a $K$-algebra homomorphism, where $K$ is the base ring.) See Section 7.8 of [EnumComb2].

The stable principal specialization at $q$ is the ring homomorphism $ps_q$ from the ring of symmetric functions to another commutative ring $R$ given by $x_i \mapsto q^{i-1}$ for all $i$. This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

INPUT:
Combinatorics, Release 9.7

• n (default: infinity) – a nonnegative integer or infinity, specifying whether to compute the principal specialization of order n or the stable principal specialization.
• q (default: None) – the value to use for q; the default is to create a ring of polynomials in q (or a field of rational functions in q) over the given coefficient ring.

For q=1 and finite n we use the formula from Proposition 7.8.3 of [EnumComb2]:

\[ \psi_{n,1}(\mu) = \binom{n}{\ell(\mu)} \binom{\mu_1, \mu_2, \ldots}{\ell(\mu)}, \]

where \( \ell(\lambda) \) denotes the length of \( \lambda \).

In all other cases, we convert to complete homogeneous symmetric functions.

EXAMPLES:

```sage
sage: m = SymmetricFunctions(QQ).m()
sage: x = m[3,1]
sage: x.principal_specialization(3)
q^7 + q^6 + q^5 + q^3 + q^2 + q
sage: x = 5*m[2] + 3*m[1] + 1
sage: x.principal_specialization(3, q=var("q"))
-10*(q^3 - 1)*q/(q - 1) + 5*(q^3 - 1)^2/(q - 1)^2 + 3*(q^3 - 1)/(q - 1) + 1
```

antipode_by_coercion(element)

The antipode of element via coercion to and from the power-sum basis or the Schur basis (depending on whether the power sums really form a basis over the given ground ring).

INPUT:

• element – element in a basis of the ring of symmetric functions

EXAMPLES:

```sage
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: m[3,2].antipode()
m[3, 2] + 2*m[5]
sage: m.antipode_by_coercion(m[3,2])
m[3, 2] + 2*m[5]
```

Todo: Is there a not too difficult way to get the power-sum computations to work over any ring, not just one with coercion from \( \mathbb{Q} \)?

from_polynomial(f, check=True)

Return the symmetric function in the monomial basis corresponding to the polynomial f.

INPUT:

• self – a monomial symmetric function basis
- $f$ – a polynomial in finitely many variables over the same base ring as $\text{self}$. It is assumed that this polynomial is symmetric.
- check – boolean (default: True), checks whether the polynomial is indeed symmetric

**OUTPUT:**

- This function converts a symmetric polynomial $f$ in a polynomial ring in finitely many variables to a symmetric function in the monomial basis of the ring of symmetric functions over the same base ring.

**EXAMPLES:**

```python
sage: m = SymmetricFunctions(QQ).m()
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: m.from_polynomial(f)
m[1]
sage: f = x[0]**2+x[1]**2+x[2]**2
sage: m.from_polynomial(f)
m[2]
sage: f = x[0]**2+x[1]
Traceback (most recent call last):
... ValueError: x0^2 + x1 is not a symmetric polynomial
sage: f = (m[2,1]+m[1,1]).expand(3)
sage: m.from_polynomial(f)
m[1, 1] + 2*m[2, 1] + 3*m[3]
```

### from_polynomial_exp($p$)

Conversion from polynomial in exponential notation

**INPUT:**

- $\text{self}$ – a monomial symmetric function basis
- $p$ – a multivariate polynomial over the same base ring as $\text{self}$

**OUTPUT:**

- This returns a symmetric function by mapping each monomial of $p$ with exponents $\exp$ into $m_\lambda$ where $\lambda$ is the partition with exponential notation $\exp$.

**EXAMPLES:**

```python
sage: m = SymmetricFunctions(QQ).m()
sage: P = PolynomialRing(QQ, 'x', 5)
sage: x = P.gens()

The exponential notation of the partition (5, 5, 5, 3, 1, 1) is:

```python
sage: Partition(([5,5,5,3,1,1])).to_exp()
[2, 0, 1, 0, 3]
```

Therefore, the monomial:
Combinatorics, Release 9.7

\[ f = x[0]^2 \cdot x[2] \cdot x[4]^3 \]

is mapped to:

\[ m[5, 5, 5, 3, 1, 1] \]

Furthermore, this function is linear:

\[ f = 3 \cdot x[3] + 2 \cdot x[0]^2 \cdot x[2] \cdot x[4]^3 \]
\[ m[4] + 2 \cdot m[5, 5, 5, 3, 1, 1] \]

See also: 
\( \text{Partition()}, \text{Partition.to_exp()} \)

\[ \text{product}(\text{left}, \text{right}) \]

Return the product of \( \text{left} \) and \( \text{right} \).

\( \text{left}, \text{right} \) – symmetric functions written in the monomial basis \( \text{self} \).

**OUTPUT:**

\( \text{the product of \( \text{left} \) and \( \text{right} \), expanded in the monomial basis, as a dictionary whose keys are partitions and whose values are the coefficients of these partitions (more precisely, their respective monomial symmetric functions) in the product.} \)

**EXAMPLES:**

\[ m = \text{SymmetricFunctions}(\text{QQ}).m() \]
\[ a = m([2, 1]) \]
\[ a^2 \]
\[ 4 \cdot m[2, 2, 1, 1] + 6 \cdot m[2, 2, 2] + 2 \cdot m[3, 2, 1] + 2 \cdot m[3, 3] + 2 \cdot m[4, 1, 1] + m[4, \ldots, \ldots, 2] \]

\[ \text{QQx.<x> = QQ['x']} \]
\[ m = \text{SymmetricFunctions}(\text{QQx}).m() \]
\[ a = m([2, 1]) + x \]
\[ 2 \cdot a \] # indirect doctest
\[ 2 \cdot x \cdot m[] + 2 \cdot m[2, 1] \]
\[ a^2 \]
\[ x^2 \cdot m[] + 2 \cdot x \cdot m[2, 1] + 4 \cdot m[2, 2, 1, 1] + 6 \cdot m[2, 2, 2] + 2 \cdot m[3, 2, 1] + 2 \cdot m[3, \ldots, \ldots, 3] + 2 \cdot m[4, 1, 1] + m[4, 2] \]

### 5.1.290 Multiplicative symmetric functions

A realization \( h \) of the ring of symmetric functions is multiplicative if for a partition \( \lambda = (\lambda_1, \lambda_2, \ldots) \) we have \( h_\lambda = h_{\lambda_1} h_{\lambda_2} \cdots \).

\textbf{class} \ \texttt{sage.combinat.sf.multiplicative.SymmetricFunctionAlgebra_multiplicative(Sym, basis_name=None, prefix=None, graded=True)}

\texttt{Bases: sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical}
The class of multiplicative bases of the ring of symmetric functions.

A realization $q$ of the ring of symmetric functions is multiplicative if for a partition $\lambda = (\lambda_1, \lambda_2, \ldots)$ we have $q_\lambda = q_{\lambda_1}q_{\lambda_2}\cdots$ (with $q_0$ meaning 1).

Examples of multiplicative realizations are the elementary symmetric basis, the complete homogeneous basis, the powersum basis (if the base ring is a $\mathbb{Q}$-algebra), and the Witt basis (but not the Schur basis or the monomial basis).

coproduct_on_basis($\mu$)

Return the coproduct on a basis element for multiplicative bases.

INPUT:

- $\mu$ – a partition

OUTPUT:

- the image of self[\mu] under comultiplication; this is an element of the tensor square of self

EXAMPLES:

```sage
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.powersum()
sage: p.coproduct_on_basis([2,1])

sage: e = Sym.elementary()
sage: e.coproduct_on_basis([3,1])

sage: h = Sym.homogeneous()
sage: h.coproduct_on_basis([3,1])
```

product_on_basis($left$, $right$)

Return the product of $left$ and $right$.

INPUT:

- $left$, $right$ – partitions

OUTPUT:

- an element of self

EXAMPLES:

```sage
sage: e = SymmetricFunctions(QQ).e()
sage: e([2,1])^2  # indirect doctest
e[2, 2, 1, 1]

sage: h = SymmetricFunctions(QQ).h()
sage: h([2,1])^2
h[2, 2, 1, 1]
```
Combinatorics, Release 9.7

```python
sage: p = SymmetricFunctions(QQ).p()
sage: p([2,1])**2
p[2, 2, 1, 1]
```

```python
sage: QQx.<x> = QQ[]
sage: p = SymmetricFunctions(QQx).p()
sage: (x*p([2]))**2
x^2*p[2, 2]
```

```python
sage: TestSuite(p).run() # to silence sage -coverage
```

### 5.1.291 $k$-Schur Functions

```python
class sage.combinat.sf.new_kschur.KBoundedSubspace(Sym, k, t='t')
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent
```

This class implements the subspace of the ring of symmetric functions spanned by \( \{ s_{\lambda}(X/(1-t)) \}_{\lambda \leq k} = \{ s^{(k)}_{\lambda}(X;t) \}_{\lambda \leq k} \) over the base ring \( \mathbb{Q}[t] \). When \( t = 1 \), this space is in fact a subring of the ring of symmetric functions generated by the complete homogeneous symmetric functions \( h_i \) for \( 1 \leq i \leq k \).

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ)
sage: KB = Sym.kBoundedSubspace(3,1); KB
3-bounded Symmetric Functions over Rational Field with t=1
sage: Sym = SymmetricFunctions(QQ['t'])
sage: KB = Sym.kBoundedSubspace(3); KB
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field
```

The $k$-Schur function basis can be constructed as follows:

```python
sage: ks = KB.kschur(); ks
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field in the 3-Schur basis
```

**K_kschur()**

Return the $k$-bounded basis called the K-$k$-Schur basis.

See [Morse11] and [LamSchillingShimozono10].

**REFERENCES:**

**EXAMPLES:**

```python
sage: kB = SymmetricFunctions(QQ).kBoundedSubspace(3,1)
sage: g = kB.K_kschur()
sage: g
3-bounded Symmetric Functions over Rational Field with t=1 in the K-3-Schur basis
sage: kB = SymmetricFunctions(QQ['t']).kBoundedSubspace(3)
sage: g = kB.K_kschur()
```

(continues on next page)
Traceback (most recent call last):
...
ValueError: This basis only exists for t=1

khomogeneous()
The homogeneous basis of this algebra.

See also:
kHomogeneous()

EXAMPLES:

sage: kh3 = SymmetricFunctions(QQ).kBoundedSubspace(3,1).khomogeneous()
sage: TestSuite(kh3).run()

kschur()
The $k$-Schur basis of this algebra.

See also:
kSchur()

EXAMPLES:

sage: ks3 = SymmetricFunctions(QQ).kBoundedSubspace(3,1).kschur()
sage: TestSuite(ks3).run()

ksplit()
The $k$-split basis of this algebra.

See also:
kSplit()

EXAMPLES:

sage: ksp3 = SymmetricFunctions(QQ).kBoundedSubspace(3,1).ksplit()
sage: TestSuite(ksp3).run()

realizations()
A list of realizations of this algebra.

EXAMPLES:

sage: SymmetricFunctions(QQ).kBoundedSubspace(3,1).realizations()
[3-bounded Symmetric Functions over Rational Field with t=1 in the 3-Schur basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the 3-split basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the 3-bounded homogeneous basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the K-3-Schur basis]
sage: SymmetricFunctions(QQ['t']).kBoundedSubspace(3).realizations()
[3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field in the 3-Schur basis,
 3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field in the 3-split basis]
retract(sym)

Return the retract of sym from the ring of symmetric functions to self.

INPUT:

• sym – a symmetric function

OUTPUT:

• the analogue of the symmetric function in the $k$-bounded subspace (if possible)

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: KB = Sym.kBoundedSubspace(3,1); KB
3-bounded Symmetric Functions over Rational Field with t=1
sage: KB.retract(s[2]+s[3])
sage: KB.retract(s[2,1,1])
Traceback (most recent call last):
... ValueError: s[2, 1, 1] is not in the image
```

class sage.combinat.sf.new_kschur.KBoundedSubspaceBases(base, t='t')

Bases: sage.categories.realizations.Category_realization_of_parent

The category of bases for the $k$-bounded subspace of symmetric functions.

class ElementMethods

Bases: object

expand(*args, **kwargs)

Return the monomial expansion of self in $n$ variables.

INPUT:

• n – positive integer

OUTPUT: monomial expansion of self in $n$ variables

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: ks[3,1].expand(2)
x0^4 + 2*x0^3*x1 + 2*x0^2*x1^2 + 2*x0*x1^3 + x1^4
sage: s = Sym.schur()
sage: ks[3,1].expand(2) == s(ks[3,1]).expand(2)
True

sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks = Sym.kschur(3)
sage: f = ks[3,2]-ks[1]
sage: f.expand(2)
t^2*x0^5 + (t^2 + t)*x0^4*x1 + (t^2 + t + 1)*x0^3*x1^2 + (t^2 + t + 1)*x0^2*x1^3 + t^2*x1^5 - x0 - x1
```
**hl_creation_operator***(nu, t=None)*

This is the vertex operator that generalizes Jing’s operator.

It is a linear operator that raises the degree by \(|\nu|\). This creation operator is a \(t\)-analogue of multiplication by \(s(\nu)\).

See also:

Proposition 5 in [SZ2001].

INPUT:

- \(\nu\) – a partition or a list of integers
- \(t\) – (default: None, in which case \(t\) is used) an element of the base ring

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: ks = Sym.kschur(4)
sage: s = Sym.schur()
sage: s(s(ks([3,1,1])).hl_creation_operator([1]))
t\^2 s[2, 2, 1, 1] + t\^2 s[3, 1, 1, 1] + (t^3+t^2-t) s[3, 2, 1] + (t^3-t^2) s[3, 3] + (t^4+t^3) s[4, 1, 1] + t^4 s[4, 2] + t^5 s[5, 1]
```

**is_schur_positive**(*args, **kwargs)*

Return whether \(self\) is Schur positive.

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3, 1)
sage: f = ks[3,2]+ks[1]
sage: f.is_schur_positive()
True
sage: f = ks[3,2]-ks[1]
sage: f.is_schur_positive()
False
```

**omega**()

Return the \(\omega\) operator on \(self\).

At \(t = 1\), \(\omega\) maps the \(k\)-Schur function \(s^{(k)}_{\lambda}\) to \(s^{(k)}_{\lambda^k}\), where \(\lambda^k\) is the \(k\)-conjugate of the partition \(\lambda\).
See also:

\texttt{k_conjugate()}. 

For generic \( t \), \( \omega \) sends \( s_{\lambda}^{(k)}[X; t] \) to \( t^d s_{\lambda(ks(k))}^{(k)}[X; 1/t] \), where \( d \) is the size of the core of \( \lambda \) minus the size of \( \lambda \). Most of the time, this result is not in the \( k \) bounded subspace.

See also:

\texttt{omega_t_inverse()}. 

EXAMPLES:

\begin{verbatim}
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: ks[2,2,1,1].omega()
sage: kh = Sym.khomogeneous(3)
sage: kh[3].omega()
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: ks = Sym.kschur(3)
sage: kh[3].omega()  # Traceback (most recent call last):
... ValueEval: t*s[2, 1, 1, 1] + s[3, 1, 1] is not in the image
\end{verbatim}

\texttt{omega_t_inverse()}

Return the map \( t \to 1/t \) composed with \( \omega \) on self.

Unlike the map \texttt{omega()}, the result of \texttt{omega_t_inverse()} lives in the \( k \)-bounded subspace and hence will return an element even for generic \( t \). For \( t = 1 \), \texttt{omega()} and \texttt{omega_t_inverse()} return the same result.

EXAMPLES:

\begin{verbatim}
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: ks = Sym.kschur(3)
sage: ks[3,1,1].omega_t_inverse()
sage: 1/t*ks[2, 1, 1, 1]
sage: 1/t^2*ks[1, 1, 1, 1]
\end{verbatim}

\texttt{scalar}(x, zee=\texttt{None})

Return standard scalar product between self and \( x \).

INPUT:

\begin{itemize}
  \item \( x \) – element of the ring of symmetric functions over the same base ring as self
  \item \( zee \) – an optional function on partitions giving the value for the scalar product between \( p_{\mu} \) and \( p_{\lambda} \) (default is to use the standard \texttt{zee()} function)
\end{itemize}

See also:

\texttt{scalar()}

EXAMPLES:

\begin{verbatim}
sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks3 = Sym.kschur(3)
\end{verbatim}
Combinatorics, Release 9.7

sage: ks3[3,2,1].scalar( ks3[2,2,2] )
t^3 + t

sage: dks3 = Sym.kBoundedQuotient(3).dks()
sage: [ks3[3,2,1].scalar(dks3(la)) for la in Partitions(6, max_part=3)]
[0, 1, 0, 0, 0, 0, 0]

sage: dks3 = Sym.kBoundedQuotient(3,1).dks()
sage: [ks3[2,2,2].scalar(dks3(la)) for la in Partitions(6, max_part=3)]
[0, t - 1, 0, 1, 0, 0, 0]

sage: ks3 = Sym.kschur(3,1)
sage: [ks3[2,2,2].scalar(dks3(la)) for la in Partitions(6, max_part=3)]
[0, 0, 0, 1, 0, 0, 0]

sage: kH = Sym.khomogeneous(4)
sage: kH([2,2,1]).scalar(ks3[2,2,1])
3

class ParentMethods
Bases: object

an_element()
Return an element of self.

EXAMPLES:

sage: SymmetricFunctions(QQ['t']).kschur(3).an_element()
2*ks3[] + 2*ks3[1] + 3*ks3[2]

antipode(element)
Return the antipode on self by lifting to the space of symmetric functions, computing the antipode, and then converting to self.parent(). This is only the antipode for \( t = 1 \) and for other values of \( t \) the result may not be in the space where the \( k \)-Schur functions live.

INPUT:
• element – an element in a basis of the ring of symmetric functions

EXAMPLES:

sage: Sym = SymmetricFunctions(QQ)
sage: ks3 = Sym.kschur(3,1)
sage: ks3[2,2].antipode()
-ks3[1, 1, 1, 1, 1]
sage: ks3.antipode(ks3[2,2])
-ks3[1, 1, 1, 1, 1]

coproduct(element)
Return the coproduct operation on element.

The coproduct is first computed on the homogeneous basis if \( t = 1 \) and on the Hall-Littlewood Qp basis otherwise. The result is computed then converted to the tensor squared of self.parent().

INPUT:
• element – an element in a basis of the ring of symmetric functions

EXAMPLES:

sage: Sym = SymmetricFunctions(QQ)
sage: ks3 = Sym.kschur(3,1)
sage: ks3[2,1].coproduct()
(continues on next page)
counit(element)

Return the counit of element.

The counit is the constant term of element.

INPUT:
• element – an element in a basis of the ring of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks3 = Sym.kschur(3,1)
sage: f = 2*ks3[2,1] + 3*ks3[]
sage: f.counit()
sage: 3
sage: ks3.counit(f)
sage: 3
```

degree_on_basis(b)

Return the degree of the basis element indexed by b.

INPUT:
• b – a partition

EXAMPLES:

```
sage: ks3 = SymmetricFunctions(QQ).kschur(3,1)
sage: ks3.degree_on_basis(Partition([3,2]))
sage: 5
```

one_basis()

Return the basis element indexing 1.

EXAMPLES:

```
sage: ks3 = SymmetricFunctions(QQ).kschur(3,1)
sage: ks3.one()  # indirect doctest
ks3[]
```
transition_matrix(other, n)

Return the degree n transition matrix between self and other.

INPUT:
• other – a basis in the ring of symmetric functions
• n – a positive integer

The entry in the i-th row and j-th column is the coefficient obtained by writing the i-th element of the basis of self in terms of the basis other, and extracting the j-th coefficient.

EXAMPLES:

sage: Sym = SymmetricFunctions(QQ); s = Sym.schur()
sage: ks3 = Sym.kschur(3,1)
sage: ks3.transition_matrix(s,5)
[1 1 0 0 0 0]
[0 1 1 0 0 0]
[0 0 1 1 0 0]
[0 0 0 1 1 0]
[0 0 0 0 1 1]

sage: Sym = SymmetricFunctions(QQ['t'])
sage: s = Sym.schur()
sage: ks = Sym.kschur(3)
sage: ks.transition_matrix(s,5)
[t^2 t 1 0 0 0]
[0 t 0 1 0 0]
[0 0 t 0 1 0]
[0 0 0 t 0 1]
[0 0 0 0 t^2 t]

super_categories()

The super categories of self.

EXAMPLES:

sage: Sym = SymmetricFunctions(QQ['t'])
sage: from sage.combinat.sf.new_kschur import KBoundedSubspaceBases
sage: KB = Sym.kBoundedSubspace(3)
sage: KBB = KBoundedSubspaceBases(KB); KBB
Category of k bounded subspace bases of 3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field
sage: KBB.super_categories()

class sage.combinat.sf.new_kschur.K_kSchur(kBoundedRing)
Bases: sage.combinat.free_module.CombinatorialFreeModule

This class implements the basis of the k-bounded subspace called the K-k-Schur basis.

See [Morse2011], [LamSchillingShimozono2010].

REFERENCES:
K_k_Schur_non_commutative_variables(la)
Return the K-k-Schur function, as embedded inside the affine zero Hecke algebra.

INPUT:
• la – A k-bounded Partition

OUTPUT:
• An element of the affine zero Hecke algebra.

EXAMPLES:

sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).Kkschur()
sage: g.K_k_Schur_non_commutative_variables([2,1])
T[3,1,0] + T[1,2,0] + T[3,2,0] + T[0,1,0] + T[2,0,1] + T[0,3,0] + T[2,0,3] +
sage: g.K_k_Schur_non_commutative_variables([[]])
1
go.K_k_Schur_non_commutative_variables([4,1])
Traceback (most recent call last):
...
ValueError: Partition should be 3-bounded

homogeneous_basis_noncommutative_variables_zero_Hecke(la)
Return the homogeneous basis element indexed by la, viewed as an element inside the affine zero Hecke algebra. For the code, see method_homogeneous_basis.

INPUT:
• la – A k-bounded partition

OUTPUT:
• An element of the affine zero Hecke algebra.

EXAMPLES:

sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).Kkschur()
sage: g.homogeneous_basis_noncommutative_variables_zero_Hecke([2,1])
T[2,1,0] + T[3,1,0] + T[1,2,0] + T[3,2,0] + T[0,1,0] + T[2,0,1] + T[1,0,3] +
sage: g.homogeneous_basis_noncommutative_variables_zero_Hecke([])
1

lift(x)
Return the lift of a k-bounded symmetric function.

INPUT:
• x – An expression in the K-k-Schur basis. Equivalently, x can be a k-bounded partition (then x corresponds to the basis element indexed by x)

OUTPUT:
• A symmetric function.

EXAMPLES:
sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: g.lift([2,1])
sage: g.lift([1])
h[]  
sage: g.lift([4,1])  
Traceback (most recent call last):
  ...  
TypeError: do not know how to make x (= [4, 1]) an element of self (=3-bounded→Symmetric Functions over Rational Field with t=1 in the K-3-Schur basis)

**product**\((x, y)\)

Return the product of the two \(K-k\)-Schur functions.

**INPUT:**

- \(x, y\) – elements of the \(k\)-bounded subspace, in the \(K-k\)-Schur basis.

**OUTPUT:**

- An element of the \(k\)-bounded subspace, in the \(K-k\)-Schur basis

**EXAMPLES:**

```python
sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: g.product(g([2,1]), g[1])
sage: g.product(g([2,1]), g([]))  
Kks3[2, 1]
```

**retract**\((x)\)

Return the retract of a symmetric function.

**INPUT:**

- \(x\) – A symmetric function.

**OUTPUT:**

- A \(k\)-bounded symmetric function in the \(K-k\)-Schur basis.

**EXAMPLES:**

```python
sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: m = SymmetricFunctions(QQ).m()
sage: g.retract(m[2,1])
sage: g.retract(m([]))
Kks3[3]
```

class **sage.combinat.sf.new_kschur.kHomogeneous**\((kBoundedRing)\)

Bases: **sage.combinat.free_module.CombinatorialFreeModule**

Space of \(k\)-bounded homogeneous symmetric functions.

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ)
sage: kH = Sym.khomogeneous(3)
```
class sage.combinat.sf.new_kschur.kSchur(kBoundedRing)

Bases: sage.combinat.free_module.CombinatorialFreeModule

Space of $k$-Schur functions.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'])
sage: KB = Sym.kBoundedSubspace(3); KB
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field

The $k$-Schur function basis can be constructed as follows:

```
sage: ks3 = KB.kschur(); ks3
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field in the 3-Schur basis

We can convert to any basis of the ring of symmetric functions and, whenever it makes sense, also the other way round:

```
sage: s = Sym.schur()
sage: s(ks3([3,2,1]))
\texttt{s}[3, 2, 1] + t*\texttt{s}[4, 1, 1] + t^2*\texttt{s}[4, 2] + t^2*\texttt{s}[5, 1]
sage: t = Sym.base_ring().gen()
sage: ks3(s([3,2,1]))
sage: s(ks3([3,2,1])) + t*s([4,1,1]) + t*s([4,2]) + t^2*s([5,1])
sage: ks3(s([2,1,1]))
sage: ks3(s([2,1,1]) + t*s([3,1]))
ks3[2, 1, 1]
```

$k$-Schur functions are indexed by partitions with first part $\leq k$. Constructing a $k$-Schur function for a larger partition raises an error:

```
sage: ks3([4,3,2,1])
Traceback (most recent call last):
...  
TypeError: do not know how to make x (= [4, 3, 2, 1]) an element of self (=3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field in the 3-Schur basis)
```

Similarly, attempting to convert a function that is not in the linear span of the $k$-Schur functions raises an error:

```
sage: ks3(s([4]))
Traceback (most recent call last):
...  
ValueError: s[4] is not in the image
```
Note that the product of $k$-Schur functions is not guaranteed to be in the space spanned by the $k$-Schurs. In general, we only have that a $k$-Schur times a $j$-Schur function is in the $(k+j)$-bounded subspace. The multiplication of two $k$-Schur functions thus generally returns the product of the lift of the functions to the ambient symmetric function space. If the result happens to lie in the $k$-bounded subspace, then the result is cast into the $k$-Schur basis:

```
sage: ks2 = Sym.kBoundedSubspace(2).kschur()
ks2[1, 1] + ks2[2]
s[2, 1] + s[3]
```

Because the target space of the product of a $k$-Schur and a $j$-Schur has several possibilities, the product of a $k$-Schur and $j$-Schur function is not implemented for distinct $k$ and $j$. Let us show how to get around this ‘manually’:

```
sage: ks3 = Sym.kBoundedSubspace(3).kschur()
sage: ks2([2,1]) * ks3([3,1])
Traceback (most recent call last):
  ...
TypeError: unsupported operand parent(s) for *: '2-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field in the 2-Schur basis' and '3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field in the 3-Schur basis'
```

The workaround:

```
sage: f = s(ks2([2,1])) * s(ks3([3,1])); f  # Convert to Schur functions first and multiply there.
s[3, 2, 1, 1] + s[3, 2, 2] + (t+1)*s[3, 3, 1] + s[4, 1, 1, 1]
  + (2*t^2+2)*s[4, 2, 1] + (t^2+t+1)*s[4, 3]
  + (t^2+2*t+1)*s[5, 1, 1] + (t^2+2*t)*s[6, 1] + t^2*s[7]
```

or:

```
sage: f = ks2[2,1].lift() * ks3[3,1].lift()
sage: ks5 = Sym.kBoundedSubspace(5).kschur()
sage: ks5(f)  # The product of a 'ks2' with a 'ks3' is a 'ks5'.
ks5[3, 2, 1, 1] + ks5[3, 2, 2] + (t+1)*ks5[3, 3, 1] + ks5[4, 1, 1, 1]
  + (t+2)*ks5[4, 2, 1] + (t^2+t+1)*ks5[4, 3]
  + (t+1)*ks5[5, 1, 1] + ks5[5, 2]
```

For other technical reasons, taking powers of $k$-Schur functions is not implemented, even when the answer is still in the $k$-bounded subspace:

```
sage: ks2([1])^2
Traceback (most recent call last):
  ...
TypeError: unsupported operand parent(s) for ^: '2-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field in the 2-Schur basis' and 'Integer Ring'
```

Todo: Get rid of said technical “reasons”.

---

5.1. Comprehensive Module List 2839
However, at $t = 1$, the product of $k$-Schur functions is in the span of the $k$-Schur functions always. Below are some examples at $t = 1$

```
sage: ks3 = Sym.kBoundedSubspace(3, t=1).kschur(); ks3
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field with t=1 in the 3-Schur basis
```
```
sage: s = SymmetricFunctions(ks3.base_ring()).schur()
sage: ks3(s([3]))
ks3[3]
sage: s(ks3([3,2,1]))
s[3, 2, 1] + s[4, 1, 1] + s[4, 2] + s[5, 1]
sage: ks3([2,1])^2  # taking powers works for t=1
ks3[2, 2, 1, 1] + ks3[2, 2, 2] + ks3[3, 1, 1, 1]
```

**product_on_basis**(left, right)

Take the product of two $k$-Schur functions.

If $t \neq 1$, then take the product by lifting to the Schur functions and then retracting back into the $k$-bounded subspace (if possible).

If $t = 1$, then the product calls \_product_on_basis\_via\_rectangles().

**INPUT:**

- left, right – partitions

**OUTPUT:**

- an element of the $k$-Schur functions

**EXAMPLES:**

```
sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks3 = Sym.kschur(3,1)
sage: kH = Sym.khomogeneous(3)
sage: ks3(kH[2,1,1])
ks3[2, 1, 1] + ks3[2, 2] + ks3[3, 1]
sage: ks3([[]])*kH[2,1,1]
ks3[2, 1, 1] + ks3[2, 2] + ks3[3, 1]
sage: ks3([3,3,3,2,2,1,1,1,1,1])^2
ks3[3, 3, 3, 3, 3, 3, 2, 2, 2, 2, 2, 1, 1, 1, 1, 1, 1]
sage: ks3([3,3,3,2,2,1,1,1,1,1,1])*ks3([2,2,2,2,2,1,1,1,1,1,1])
ks3[3, 3, 3, 3, 3, 3, 2, 2, 2, 2, 2, 2, 2, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
```

**class** sage.combinat.sf.new_kschur.kSplit(kBoundedRing)

Bases: sage.combinat.free_module.CombinatorialFreeModule

The $k$-split basis of the space of $k$-bounded-symmetric functions

Fix $k$ a positive integer and $t$ an element of the base ring.
The $k$-split functions are a basis for the space of $k$-bounded symmetric functions that also have the bases

\[ \{ Q'_\lambda[X;t] \}_{\lambda_1 \leq k} = \{ s^{(k)}_\lambda[X;t] \}_{\lambda_1 \leq k} \]

where $Q'_\lambda[X;t]$ are the Hall-Littlewood symmetric functions (using the notation of [MAC]) and $s^{(k)}_\lambda[X;t]$ are the $k$-Schur functions. If $t$ is not a root of unity, then

\[ \{ s_\lambda[X/(1-t)] \}_{\lambda_1 \leq k} \]

is also a basis of this space.

The $k$-split basis has the property that $Q'_\lambda[X;t]$ expands positively in the $k$-split basis and the $k$-split basis conjecturally expands positively in the $k$-Schur functions. See [LLMSSZ] p. 81.

The $k$-split basis is defined recursively using the Hall-Littlewood creation operator defined in [SZ2001]. If a partition $\lambda$ is the concatenation (as lists) of a partition $\mu$ and $\nu$ where $\mu$ has maximal hook length equal to $k$ then $ksp(\lambda) = ksp(\nu).hl_creation_operator(\mu)$. If the hook length of $\lambda$ is less than or equal to $k$, then $ksp(\lambda)$ is equal to the Schur function indexed by $\lambda$.

**EXAMPLES:**

```sage
sage: Symt = SymmetricFunctions(QQ['t'].fraction_field())
sage: kBS3 = Symt.kBoundedSubspace(3)
sage: ks3 = kBS3.kschur()
sage: ksp3 = kBS3.ksplit()
sage: ks3[ksp3[2,1,1]] + t*ks3[2,2]
sage: ksp3[2,1,1] - t*ksp3[2,2]
sage: ksp3[2,1]*ksp3[1]
sage: Qp = Symt.hall_littlewood().Qp()
sage: ksp3(Qp[3,2,1]) + t*ksp3[3,3]
sage: kBS4 = Symt.kBoundedSubspace(4)
sage: ksp4 = kBS4.ksplit()
sage: ksp4[3,2,1] - t*ksp4[3,3] + t*ksp4[4,1,1]
sage: ks4 = kBS4.kschur()
sage: ks4[3,2,2,1] + t*ks4[3,3,1,1] + t*ks4[3,3,2]
```

### 5.1.292 Non-symmetric Macdonald Polynomials

**class** `sage.combinat.sf.ns_macdonald.AugmentedLatticeDiagramFilling(l, pi=None)`

**Bases:** `sage.combinat.combinat.CombinatorialObject`

**EXAMPLES:**
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a == loads(dumps(a))
True
sage: pi = Permutation([2,3,1]).to_permutation_group_element()
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]],pi)
sage: a == loads(dumps(a))
True

**are_attacking**(i,j,ii,jj)

Return True if the boxes (i,j) and (ii,jj) in self are attacking.

**EXAMPLES:**

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: all( a.are_attacking(i,j,ii,jj) for (i,j),(ii,jj) in a.attacking_boxes() )
True
sage: a.are_attacking(1,1,3,2)
False

**attacking_boxes**(())

Return a list of pairs of boxes in self that are attacking.

**EXAMPLES:**

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.attacking_boxes()[:5]
[((1, 1), (2, 1)),
 (1, 1), (3, 1)),
 (1, 1), (6, 1)),
 (1, 1), (2, 0)),
 (1, 1), (3, 0))]

**boxes**(())

Return a list of the coordinates of the boxes of self, including the ‘basement row’.

**EXAMPLES:**

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.boxes()
[(1, 1),
 (1, 2),
 (2, 1),
 (3, 1),
 (3, 2),
 (3, 3),
 (6, 1),
 (6, 2),
 (1, 0),
 (2, 0),
 (3, 0),
 (4, 0),
 (5, 0),
 (6, 0)]

**coeff**(q,t)

Return the coefficient in front of self in the HHL formula for the expansion of the non-symmetric Mac-
donald polynomial \( E(\text{self.shape}) \).

**EXAMPLES:**

```python
sage: a = AugmentedLatticeDiagramFilling([[1, 6], [2], [3, 4, 2], [], [], [5, 5]])
sage: q, t = var('q, t')
sage: a.coeff(q, t)
(t - 1)^4/((q^2*t^3 - 1)^2*(q*t^2 - 1)^2)
```

**coeff_integral**

Return the coefficient in front of \( \text{self} \) in the HHL formula for the expansion of the integral non-symmetric Macdonald polynomial \( E(\text{self.shape}) \).

**EXAMPLES:**

```python
sage: a = AugmentedLatticeDiagramFilling([[1, 6], [2], [3, 4, 2], [], [], [5, 5]])
sage: q, t = var('q, t')
sage: a.coeff_integral(q, t)
(q^2*t^3 - 1)^2*(q*t^2 - 1)^2*(t - 1)^4
```

**coinv**

Return \( \text{self} \)'s co-inversion statistic.

**EXAMPLES:**

```python
sage: a = AugmentedLatticeDiagramFilling([[1, 6], [2], [3, 4, 2], [], [], [5, 5]])
sage: a.coinv()
2
```

**descents**

Return a list of the descents of \( \text{self} \).

**EXAMPLES:**

```python
sage: a = AugmentedLatticeDiagramFilling([[1, 6], [2], [3, 4, 2], [], [], [5, 5]])
sage: a.descents()
[(1, 2), (3, 2)]
```

**inv**

Return \( \text{self} \)'s inversion statistic.

**EXAMPLES:**

```python
sage: a = AugmentedLatticeDiagramFilling([[1, 6], [2], [3, 4, 2], [], [], [5, 5]])
sage: a.inv()
15
```

**inversions**

Return a list of the inversions of \( \text{self} \).

**EXAMPLES:**

```python
sage: a = AugmentedLatticeDiagramFilling([[1, 6], [2], [3, 4, 2], [], [], [5, 5]])
sage: a.inversions()[:5]
[((6, 2), (3, 2)),
 ((1, 2), (6, 1)),
 ((1, 2), (3, 1)),
```

(continues on next page)
is_non_attacking()  
Return True if self is non-attacking.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[1],[5,5]])
sage: a.is_non_attacking()
True
sage: a = AugmentedLatticeDiagramFilling([[1,1,1],[2,3],[3]])
sage: a.is_non_attacking()
False
sage: a = AugmentedLatticeDiagramFilling([[2,2],[1]])
sage: a.is_non_attacking()
False
sage: pi = Permutation([2,1]).to_permutation_group_element()
sage: a = AugmentedLatticeDiagramFilling([[2,2],[1]],pi)
sage: a.is_non_attacking()
True
```

maj()  
Return the major index of self.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[1],[5,5]])
sage: a.maj()
3
```

permuted_filling(sigma)  
EXAMPLES:

```
sage: pi=Permutation([2,1,4,3]).to_permutation_group_element()
sage: fill=[[2],[1,2,3],[3],[1]]
sage: AugmentedLatticeDiagramFilling(fill).permuted_filling(pi)
[[2, 1], [1, 2, 1, 4], [4], [3, 4, 2]]
```

reading_order()  
Return a list of coordinates of the boxes in self, starting from the top right, and reading from right to left. Note that this includes the ‘basement row’ of self.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[1],[5,5]])
sage: a.reading_order()
[(3, 3),
 (6, 2),
 (3, 2),
 (1, 2),
 (6, 1),
]```
(3, 1),
(2, 1),
(1, 1),
(6, 0),
(5, 0),
(4, 0),
(3, 0),
(2, 0),
(1, 0)]

reading_word()
Return the reading word of self, obtained by reading the boxes entries of self from right to left, starting in the upper right.

EXAMPLES:

```python
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[1],[5],[5]])
sage: a.reading_word()
word: 25465321
```

shape()
Return the shape of self.

EXAMPLES:

```python
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[1],[5],[5]])
sage: a.shape()
[2, 1, 3, 0, 0, 2]
```

weight()
Return the weight of self.

EXAMPLES:

```python
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[1],[5],[5]])
sage: a.weight()
[1, 2, 1, 1, 2, 1]
```

sage.combinat.sf.ns_macdonald.E(mu, q=None, t=None, pi=None)
Return the non-symmetric Macdonald polynomial in type A corresponding to a shape mu, with basement permuted according to pi.

Note that if both q and t are specified, then they must have the same parent.

REFERENCE:

See also:

``NonSymmetricMacdonaldPolynomials`` for a type free implementation where the polynomials are constructed recursively by the application of intertwining operators.

EXAMPLES:
sage: from sage.combinat.sf.ns_macdonald import E

sage: E([0,0,0])
1
sage: E([1,0,0])
x0
sage: E([0,1,0])
(t - 1)/(q*t^2 - 1)*x0 + x1
sage: E([0,0,1])
(t - 1)/(q*t - 1)*x0 + (t - 1)/(q*t - 1)*x1 + x2
sage: E([1,1,0])
x0*x1
sage: E([1,0,1])
(t - 1)/(q*t^2 - 1)*x0*x1 + x0*x2
sage: E([0,1,1])
(-q*t^2 + 1)*x0 + (-t + 1)*x1
sage: E([0,0,1])
(-q*t + 1)*x0 + (-q*t + 1)*x1 + (-t + 1)*x2
sage: E([1,1,0])
(t^2 - 2*t + 1)*x0*x1
sage: E([1,0,1])
(q*t^3 - q*t^2 - t + 1)*x0*x1 + (q^2*t^2 - q*t - t)*x1 + (t^2 - 2*t + 1)*x0*x2
sage: E([0,1,1])
(q^2*t^3 + q*t^4 - q^2*t^3 - q*t^2 - q^2*t^2 + t - 1)/(q^2*t^4 - q*t^3 - q^2*t^2 - q^2*t + t - 1)*x0*x1 + (q^2*t^2 - q*t - t)*x1 + (t^2 - 2*t + 1)*x0*x2
sage: E([2,0,0])
(q^2*t^3 - q^2*t^2 - t + 1)*x0*x1 + (q^4*t^3 - q^3*t^2 - q^2*t^2 - q*t^2 - q + t)*x0*x1 + (q^2*t^2 - q^2*t - q*t + q)*x1*x2

sage.combinat.sf.ns_macdonald.E_integral(mu, q=None, t=None, pi=None)

Return the integral form for the non-symmetric Macdonald polynomial in type A corresponding to a shape mu.

Note that if both q and t are specified, then they must have the same parent.

REFERENCE:

EXAMPLES:

sage: from sage.combinat.sf.ns_macdonald import E_integral

sage: E_integral([0,0,0])
1
sage: E_integral([1,0,0])
(t + 1)*x0
sage: E_integral([0,1,0])
(-q^2*t + 1)*x0 + (t^2 + 1)*x1
sage: E_integral([0,0,1])
(-q*t + 1)*x0 + (-q*t + 1)*x1 + (-t + 1)*x2
sage: E_integral([1,1,0])
(t^2 - 2*t + 1)*x0*x1
sage: E_integral([1,0,1])
(q^2*t^2 - q^2*t - q*t + q)*x0*x1 + (q^2*t - q*t - q)*x1 + (t^2 - 2*t + 1)*x0*x2
sage: E_integral([0,1,1])
(q^2*t^2 - q^2*t - q*t + q)*x0*x1 + (t^2 - 2*t + 1)*x0*x2 + (q^4*t^2 - q^3*t - q^2*t^2 - q^2*t + q - t)*x1 + (t^2 - 2*t + 1)*x0*x2
sage: E_integral([2,0,0])
(q^2*t^2 - q^2*t - q*t + q)*x0*x1 + (q^4*t^3 - q^3*t^2 - q^2*t^2 - q^2*t + q - t)*x0*x1 + (q^2*t - q*t - q)*x1*x2

(continues on next page)
sage.combinat.sf.ns_macdonald.Ht(mu=q=None, t=None, pi=None)
Return the symmetric Macdonald polynomial using the Haiman, Haglund, and Loehr formula.

Note that if both \(q\) and \(t\) are specified, then they must have the same parent.

REFERENCE:

EXAMPLES:
\[
\begin{align*}
\text{sage: from sage.combinat.sf.ns_macdonald import Ht} \\
\text{sage: HHt = SymmetricFunctions(QQ['q','t'].fraction_field()).macdonald().Ht()} \\
\text{sage: HHt([1]).expand(3)} \\
& x0 + x1 + x2 \\
\text{sage: HHt([2]).expand(3)} \\
& x0^2 + (q + 1)*x0*x1 + x1^2 + (q + 1)*x0*x2 + (q + 1)*x1*x2 + x2^2
\end{align*}
\]

class sage.combinat.sf.ns_macdonald.LatticeDiagram(l, copy=True)
Bases: sage.combinat.combination.CombinatorialObject

\[a(i,j)\]
Return the length of the arm of the box \((i,j)\) in \(self\).

EXAMPLES:
\[
\begin{align*}
\text{sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])} \\
\text{sage: a.a(5,2)} \\
& 3
\end{align*}
\]

arm((i,j))
Return the arm of the box \((i,j)\) in \(self\).

EXAMPLES:
\[
\begin{align*}
\text{sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])} \\
\text{sage: a.arm(5,2)} \\
& [(1, 2), (3, 2), (8, 1)]
\end{align*}
\]

arm_left((i,j))
Return the left arm of the box \((i,j)\) in \(self\).

EXAMPLES:
\[
\begin{align*}
\text{sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])} \\
\text{sage: a.arm_left(5,2)} \\
& [(1, 2), (3, 2), (8, 1)]
\end{align*}
\]

arm_right((i,j))
Return the right arm of the box \((i,j)\) in \(self\).

EXAMPLES:
Combinatorics, Release 9.7

```python
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.arm_right(5,2)
[(8, 1)]
```

**boxes()**

EXAMPLES:

```python
sage: a = LatticeDiagram([3,0,2])
sage: a.boxes()
[(1, 1), (1, 2), (1, 3), (3, 1), (3, 2)]
sage: a = LatticeDiagram([2, 1, 3, 0, 0, 2])
sage: a.boxes()
[(1, 1), (1, 2), (2, 1), (3, 1), (3, 2), (3, 3), (6, 1), (6, 2)]
```

**boxes_same_and_lower_right**(ii, jj)

Return a list of the boxes of self that are in row jj but not identical with (ii, jj), or lie in the row jj - 1 (the row directly below jj; this might be the basement) and strictly to the right of (ii, jj).

EXAMPLES:

```python
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[1],[1],[5,5]])
sage: a = a.shape()
sage: a.boxes_same_and_lower_right(1,1)
[(2, 1), (3, 1), (6, 1), (2, 0), (3, 0), (4, 0), (5, 0), (6, 0)]
sage: a.boxes_same_and_lower_right(1,2)
[(3, 2), (6, 2), (2, 1), (3, 1), (6, 1)]
sage: a.boxes_same_and_lower_right(3,3)
[(6, 2)]
sage: a.boxes_same_and_lower_right(2,3)
[(3, 3), (3, 2), (6, 2)]
```

**flip()**

Return the flip of self, where flip is defined as follows. Let \( r = \max(self) \). Then \( self.flip()[i] = r - self[i] \).

EXAMPLES:

```python
sage: a = LatticeDiagram([3,0,2])
sage: a.flip()
[0, 3, 1]
```

\( l(i,j) \)

Return \( self[i] - j \).

EXAMPLES:

```python
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.l(5,2)
1
```

\( leg(i,j) \)

Return the leg of the box \((i,j)\) in self.

EXAMPLES:
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.leg(5,2)
[(5, 3)]

size()
Return the number of boxes in self.
EXAMPLES:

sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.size()
22

class sage.combinat.sf.ns_macdonald.NonattackingBacktracker(shape, pi=None)
Bases: sage.combinat.backtrack.GenericBacktracker
EXAMPLES:

sage: from sage.combinat.sf.ns_macdonald import NonattackingBacktracker
sage: n = NonattackingBacktracker(LatticeDiagram([0,1,2]))
sage: n._ending_position
(3, 2)
sage: n._initial_state
(2, 1)

get_next_pos(ii, jj)
EXAMPLES:

sage: from sage.combinat.sf.ns_macdonald import NonattackingBacktracker
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: n = NonattackingBacktracker(a.shape())
sage: n.get_next_pos(1, 1)
(2, 1)
sage: n.get_next_pos(6, 1)
(1, 2)
sage: n = NonattackingBacktracker(LatticeDiagram([2,2,2]))
sage: n.get_next_pos(3, 1)
(1, 2)

sage.combinat.sf.ns_macdonald.NonattackingFillings(shape, pi=None)
Returning the finite set of nonattacking fillings of a given shape.
EXAMPLES:

sage: NonattackingFillings([0,1,2])
Nonattacking fillings of [0, 1, 2]

sage: NonattackingFillings([0,1,2]).list()
[[[1], [2, 1], [3, 2, 1]],
 [[1], [2, 1], [3, 2, 2]],
 [[1], [2, 1], [3, 2, 3]],
 [[1], [2, 1], [3, 3, 1]],
 [[1], [2, 1], [3, 3, 2]],
 [[1], [2, 1], [3, 3, 3]],
 [[1], [2, 2], [3, 1, 1]],
 [[1], [2, 2], [3, 1, 2]],

(continues on next page)
\[[[1], [2, 2], [3, 1, 3]],
[[1], [2, 2], [3, 3, 1]],
[[1], [2, 2], [3, 3, 2]],
[[1], [2, 2], [3, 3, 3]]\]

class sage.combinat.sf.ns_macdonald.NonattackingFillings_shape(shape, pi=None)
Bases: sage.structure.parent.Parent, sage.structure.unique_representation.UniqueRepresentation

EXAMPLES:
sage: n = NonattackingFillings([0,1,2])
sage: n == loads(dumps(n))
True

flip()
Return the nonattacking fillings of the flipped shape.

EXAMPLES:
sage: NonattackingFillings([0,1,2]).flip()
Nonattacking fillings of [2, 1, 0]

5.1.293 Orthogonal Symmetric Functions

AUTHORS:
- Travis Scrimshaw (2013-11-10): Initial version

class sage.combinat.sf.orthogonal.SymmetricFunctionAlgebra_orthogonal(Sym)
Bases: sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic

The orthogonal symmetric function basis (or orthogonal basis, to be short).
The orthogonal basis \{o_\lambda\} where \lambda is taken over all partitions is defined by the following change of basis with the Schur functions:

\[ s_\lambda = \sum_\mu \left( \sum_{\nu \in H} c^\lambda_{\mu\nu} \right) o_\mu \]

where \(H\) is the set of all partitions with even-width rows and \(c^\lambda_{\mu\nu}\) is the usual Littlewood-Richardson (LR) coefficients. By the properties of LR coefficients, this can be shown to be a upper unitriangular change of basis.

Note: This is only a filtered basis, not a \(\mathbb{Z}\)-graded basis. However this does respect the induced \((\mathbb{Z}/2\mathbb{Z})\)-grading.

INPUT:
- \(Sym\) – an instance of the ring of the symmetric functions

REFERENCES:
- [ChariKleber2000]
- [KoikeTerada1987]
- [ShimozonoZabrocki2006]
EXAMPLES:

Here are the first few orthogonal symmetric functions, in various bases:

```sage
sage: Sym = SymmetricFunctions(QQ)
sage: o = Sym.o()
sage: e = Sym.e()
sage: h = Sym.h()
sage: p = Sym.p()
sage: s = Sym.s()
sage: m = Sym.m()

sage: p(o([1]))
p[1]
sage: m(o([1]))
m[1]
sage: e(o([1]))
e[1]
sage: h(o([1]))
h[1]
sage: s(o([1]))
s[1]

sage: p(o([2]))
sage: m(o([2]))
-m[1] + m[1, 1] + m[2]
sage: e(o([2]))
sage: h(o([2]))
sage: s(o([2]))
-s[1] + s[2]

sage: p(o([3]))
sage: m(o([3]))
-m[1] + m[1, 1, 1] + m[2, 1] + m[3]
sage: e(o([3]))
sage: h(o([3]))
-h[1] + h[3]
sage: s(o([3]))
-s[1] + s[3]

sage: Sym = SymmetricFunctions(ZZ)
sage: o = Sym.o()
sage: e = Sym.e()
sage: h = Sym.h()
sage: p = Sym.p()
sage: s = Sym.s()
sage: m = Sym.m()

sage: m(o([4]))
```

(continues on next page)
sage: e(o([4]))

sage: h(o([4]))

sage: s(o([4]))

Some examples of conversions the other way:

sage: o(h[3])
o[1] + o[3]
sage: o(e[3])
o[1, 1, 1]
sage: o(m[2,1])
o[1] - 2*o[1, 1, 1] + o[2, 1]
sage: o(p[3])
o[1, 1, 1] - o[2, 1] + o[3]

Some multiplication:

sage: o([2]) * o([1,1])
o[1, 1] + o[2, 1, 1] + o[3, 1]
sage: o([2,1,1]) * o([2])
o[1, 1] + o[1, 1, 1] + 2*o[2, 1, 1] + o[2, 2] + o[2, 2, 1, 1]
+ o[3, 1, 1] + o[3, 2] + o[4, 1, 1]
sage: o([1,1]) * o([2,1])
o[1] + o[1, 1, 1] + 2*o[2, 1, 1] + o[2, 1, 1, 1] + o[2, 2, 1, 1]

Examples of the Hopf algebra structure:

sage: o([1]).antipode()
-o[1]
sage: o([2]).antipode()
-o[] + o[1, 1]
sage: o([1]).coproduct()
o[] # o[1] + o[1] # o[]
sage: o([2]).coproduct()
sage: o([1]).counit()
0
sage: o.one().counit()
1
5.1.294 Symmetric functions defined by orthogonality and triangularity

One characterization of Schur functions is that they are upper triangularly related to the monomial symmetric functions and orthogonal with respect to the Hall scalar product. We can use the class SymmetricFunctionAlgebra_orthotriang to obtain the Schur functions from this definition.

```python
sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur functions')
sage: s([2,1])**2
```

```python
sage: s2 = SymmetricFunctions(QQ).s()
sage: s2([2,1])**2
```

```python
class sage.combinat.sf.orthotriang.SymmetricFunctionAlgebra_orthotriang(Sym, base, scalar, prefix, basis_name, leading_coeff=None)

Bases: sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic

Initialization of the symmetric function algebra defined via orthotriangular rules.

INPUT:

- **self** – a basis determined by an orthotriangular definition
- **Sym** – ring of symmetric functions
- **base** – an instance of a basis of the ring of symmetric functions (e.g. the Schur functions)
- **scalar** – a function zee on partitions. The function zee determines the scalar product on the power sum basis with normalization \( \langle p_\mu, p_\mu \rangle = zee(\mu) \).
- **prefix** – the prefix used to display the basis
- **basis_name** – the name used for the basis

Note: The base ring is required to be a \( \mathbb{Q} \)-algebra for this method to be usable, since the scalar product is defined by its values on the power sum basis.

EXAMPLES:

```python
sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur'); s
Symmetric Functions over Rational Field in the Schur basis
```

```python
class Element

Bases: sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element
```
product(left, right)
Return left * right by converting both to the base and then converting back to self.

INPUT:
• self – a basis determined by an orthotriangular definition
• left, right – elements in self

OUTPUT:
• the expansion of the product of left and right in the basis self.

EXAMPLES:
```
sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur_˓→functions')
sage: s([1])*s([2,1]) #indirect doctest
s[2, 1, 1] + s[2, 2] + s[3, 1]
```

5.1.295 Power sum symmetric functions

class sage.combinat.sf.powersum.SymmetricFunctionAlgebra_power(Sym)
Bases: sage.combinat.sf.multiplicative.SymmetricFunctionAlgebra_multiplicative

A class for methods associated to the power sum basis of the symmetric functions

INPUT:
• self – the power sum basis of the symmetric functions
• Sym – an instance of the ring of symmetric functions

class Element

adams_operation(n)
Return the image of the symmetric function self under the $n$-th Frobenius operator.

The $n$-th Frobenius operator $f_n$ is defined to be the map from the ring of symmetric functions to itself
that sends every symmetric function $P(x_1, x_2, x_3, \ldots)$ to $P(x_1^n, x_2^n, x_3^n, \ldots)$. This operator $f_n$ is a
Hopf algebra endomorphism, and satisfies

$$f_n m(\lambda_1, \lambda_2, \lambda_3, \ldots) = m(n \lambda_1, n \lambda_2, n \lambda_3, \ldots)$$

for every partition $(\lambda_1, \lambda_2, \lambda_3, \ldots)$ (where $m$ means the monomial basis). Moreover, $f_n(p_r) = p_{nr}$
for every positive integer $r$ (where $p_k$ denotes the $k$-th powersum symmetric function).

The $n$-th Frobenius operator is also called the $n$-th Frobenius endomorphism. It is not related to the
Frobenius map which connects the ring of symmetric functions with the representation theory of the
symmetric group.

The $n$-th Frobenius operator is also the $n$-th Adams operator of the $\Lambda$-ring of symmetric functions over
the integers.
The $n$-th Frobenius operator can also be described via plethysm: Every symmetric function $P$ satisfies $f_n(P) = p_n \circ P = P \circ p_n$, where $p_n$ is the $n$-th powersum symmetric function, and $\circ$ denotes (outer) plethysm.

INPUT:

• $n$ – a positive integer

OUTPUT:

The result of applying the $n$-th Frobenius operator (on the ring of symmetric functions) to self.

EXAMPLES:

```sage
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: p[3].frobenius(2)
p[6]
sage: p[4,2,1].frobenius(3)
p[12, 6, 3]
sage: p([]).frobenius(4)
p[]
sage: p[3].frobenius(1)
p[3]
sage: (p([3]) - p([2]) + p([])).frobenius(3)
```

See also:

`plethysm()`

`eval_at_permutation_roots(rho)`

Evaluate at eigenvalues of a permutation matrix.

Evaluate an element of the power sum basis at the eigenvalues of a permutation matrix with cycle structure $\rho$.

This function evaluates an element at the roots of unity

$$\Xi_{\rho_1}, \Xi_{\rho_2}, \ldots, \Xi_{\rho_k}$$

where

$$\Xi_m = 1, \zeta_m, \zeta_m^2, \ldots, \zeta_m^{m-1}$$

and $\zeta_m$ is an $m$ root of unity. These roots of unity represent the eigenvalues of permutation matrix with cycle structure $\rho$.

INPUT:

• $\rho$ – a partition or a list of non-negative integers

OUTPUT:

• an element of the base ring

EXAMPLES:

```sage
sage: p = SymmetricFunctions(QQ).p()
sage: p([3,3]).eval_at_permutation_roots([6])
0
sage: p([3,3]).eval_at_permutation_roots([3])
9
sage: p([3,3]).eval_at_permutation_roots([1])
```

(continues on next page)
**Combinatorics, Release 9.7**

```
1
sage: p([3,3]).eval_at_permutation_roots([3,3])
36
sage: p([3,3]).eval_at_permutation_roots([1,1,1,1])
25
5
```

**expand**($n$, **alphabet**=’x’)

Expand the symmetric function *self* as a symmetric polynomial in *n* variables.

**INPUT:**
- *n* – a nonnegative integer
- **alphabet** – (default: 'x') a variable for the expansion

**OUTPUT:**
A monomial expansion of *self* in the *n* variables labelled by **alphabet**.

**EXAMPLES:**

```
sage: p = SymmetricFunctions(QQ).p()
sage: a = p([2])
sage: a.expand(2)
x0^2 + x1^2
sage: a.expand(3, alphabet=[‘a’, ‘b’, ‘c’])
a^2 + b^2 + c^2
sage: p([2,1,1]).expand(2)
x0^4 + 2*x0^3*x1 + 2*x0^2*x1^2 + 2*x0*x1^3 + x1^4
sage: p([7]).expand(4)
x0^7 + x1^7 + x2^7 + x3^7
sage: p([7]).expand(4, alphabet=’t’)
t0^7 + t1^7 + t2^7 + t3^7
sage: p([7]).expand(4, alphabet=’x,y,z,t’)
x^7 + y^7 + z^7 + t^7
sage: p([1]).expand(4)
1
sage: p([0]).expand(4)
0
sage: (p([1]) + 2*p([1])).expand(3)
2*x0 + 2*x1 + 2*x2 + 1
sage: p([1]).expand(0)
0
sage: (3*p([1])).expand(0)
3
```

**exponential_specialization**(t=**None**, q=1)

Return the exponential specialization of a symmetric function (when *q* = 1), or the *q*-exponential specialization (when *q* ≠ 1).

The exponential specialization *ex* at *t* is a $K$-algebra homomorphism from the $K$-algebra of symmetric functions to another $K$-algebra $R$. It is defined whenever the base ring $K$ is a $Q$-algebra and $t$ is an element of $R$. The easiest way to define it is by specifying its values on the powersum symmetric functions to be $p_1 = t$ and $p_n = 0$ for $n > 1$. Equivalently, on the homogeneous functions it is given by $ex(h_n) = t^n/n!$; see Proposition 7.8.4 of [EnumComb2].
By analogy, the $q$-exponential specialization is a $K$-algebra homomorphism from the $K$-algebra of symmetric functions to another $K$-algebra $R$ that depends on two elements $t$ and $q$ of $R$ for which the elements $1 - q^i$ for all positive integers $i$ are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

$$ex_q(h_n) = t^n/[n]_q!,$$

where $[n]_q!$ is the $q$-factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function $f$ of degree $n$, we have

$$ex_q(f) = (1 - q)^n t^n ps_q(f),$$

where $ps_q(f)$ is the stable principal specialization of $f$ (see principal_specialization()). (See (7.29) in [EnumComb2].)

The limit of $ex_q$ as $q \to 1$ is $ex$.

INPUT:

- $t$ (default: None) – the value to use for $t$; the default is to create a ring of polynomials in $t$.
- $q$ (default: 1) – the value to use for $q$. If $q$ is None, then a ring (or fraction field) of polynomials in $q$ is created.

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: x = p[8,7,3,1]
sage: x.exponential_specialization()
0
sage: x.exponential_specialization(t=var("t"))
5*t^2 + 2*t + 1
```

We also support the $q$-exponential_specialization:

```
sage: factor(p[3].exponential_specialization(q=var("q"), t=var("t")))
(q - 1)^2*t^3/(q^2 + q + 1)
```

$frobenius(n)$

Return the image of the symmetric function self under the $n$-th Frobenius operator.

The $n$-th Frobenius operator $f_n$ is defined to be the map from the ring of symmetric functions to itself that sends every symmetric function $P(x_1, x_2, x_3, \ldots)$ to $P(x_1^n, x_2^n, x_3^n, \ldots)$. This operator $f_n$ is a Hopf algebra endomorphism, and satisfies

$$f_n m(\lambda_1, \lambda_2, \lambda_3, \ldots) = m(n\lambda_1, n\lambda_2, n\lambda_3, \ldots)$$

for every partition $(\lambda_1, \lambda_2, \lambda_3, \ldots)$ (where $m$ means the monomial basis). Moreover, $f_n(p_r) = p_{nr}$ for every positive integer $r$ (where $p_k$ denotes the $k$-th powersum symmetric function).

The $n$-th Frobenius operator is also called the $n$-th Frobenius endomorphism. It is not related to the Frobenius map which connects the ring of symmetric functions with the representation theory of the symmetric group.

The $n$-th Frobenius operator is also the $n$-th Adams operator of the $\Lambda$-ring of symmetric functions over the integers.

The $n$-th Frobenius operator can also be described via plethysm: Every symmetric function $P$ satisfies $f_n(P) = p_n \circ P = P \circ p_n$, where $p_n$ is the $n$-th powersum symmetric function, and $\circ$ denotes (outer) plethysm.

INPUT:
• $n$ – a positive integer

OUTPUT:

The result of applying the $n$-th Frobenius operator (on the ring of symmetric functions) to self.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: p[3].frobenius(2)
p[6]
sage: p[4,2,1].frobenius(3)
p[12, 6, 3]
sage: p([]).frobenius(4)
p[]
sage: p[3].frobenius(1)
p[3]
sage: (p([3]) - p([2]) + p([])).frobenius(3)
```

See also:

`plethysm()`

omega() Return the image of self under the omega automorphism.

The omega automorphism is defined to be the unique algebra endomorphism $\omega$ of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers $k$ (where $e_k$ stands for the $k$-th elementary symmetric function, and $h_k$ stands for the $k$-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function $p_k$ to $(-1)^{k-1}p_k$ for every positive integer $k$.

The images of some bases under the omega automorphism are given by

$$
\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},
$$

where $\lambda$ is any partition, where $\ell(\lambda)$ denotes the length (length()) of the partition $\lambda$, where $\lambda'$ denotes the conjugate partition (conjugate()) of $\lambda$, and where the usual notations for bases are used ($e$ = elementary, $h$ = complete homogeneous, $p$ = powersum, $s$ = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT:

• the image of self under the omega automorphism

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: a = p([2,1]); a
p[2, 1]
sage: a.omega()
-p[2, 1]
sage: p([]).omega()
p[]
sage: p([]).omega()
0
sage: p = SymmetricFunctions(ZZ).p()
```

(continues on next page)
omega_involution()

Return the image of self under the omega automorphism.

The omega automorphism is defined to be the unique algebra endomorphism \( \omega \) of the ring of symmetric functions that satisfies \( \omega(e_k) = h_k \) for all positive integers \( k \) (where \( e_k \) stands for the \( k \)-th elementary symmetric function, and \( h_k \) stands for the \( k \)-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function \( p_k \) to \((-1)^{k-1}p_k\) for every positive integer \( k \).

The images of some bases under the omega automorphism are given by

\[
\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},
\]

where \( \lambda \) is any partition, where \( \ell(\lambda) \) denotes the length \( \text{length}(\lambda) \) of the partition \( \lambda \), where \( \lambda' \) denotes the conjugate partition \( \text{conjugate}(\lambda) \) of \( \lambda \), and where the usual notations for bases are used (\( e = \text{elementary}, h = \text{complete homogeneous}, p = \text{powersum}, s = \text{Schur} \)).

omega_involution() is a synonym for the omega() method.

OUTPUT:

• the image of self under the omega automorphism

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: a = p([2,1]); a
p[2, 1]
sage: a.omega()
-p[2, 1]
sage: p([3,1,1]).omega()
p[3, 1, 1]
sage: p([2,1]).omega()
p[2, 1]
sage: p([[]]).omega()
p[]
sage: p([0]).omega()
0
```

principal_specialization(n=Infinity, q=None)

Return the principal specialization of a symmetric function.

The principal specialization of order \( n \) at \( q \) is the ring homomorphism \( ps_{n,q} \) from the ring of symmetric functions to another commutative ring \( R \) given by \( x_i \mapsto q^{i-1} \) for \( i \in \{1, \ldots, n\} \) and \( x_i \mapsto 0 \) for \( i > n \). Here, \( q \) is a given element of \( R \), and we assume that the variables of our symmetric functions are \( x_1, x_2, x_3, \ldots \). (To be more precise, \( ps_{n,q} \) is a \( K \)-algebra homomorphism, where \( K \) is the base ring.) See Section 7.8 of [EnumComb2].

The stable principal specialization at \( q \) is the ring homomorphism \( ps_q \) from the ring of symmetric functions to another commutative ring \( R \) given by \( x_i \mapsto q^{i-1} \) for all \( i \). This is well-defined only if the resulting infinite sums converge; thus, in particular, setting \( q = 1 \) in the stable principal specialization is an invalid operation.

INPUT:

• \( n \) (default: infinity) – a nonnegative integer or infinity, specifying whether to compute the principal specialization of order \( n \) or the stable principal specialization.
• \(q\) (default: \(\text{None}\)) – the value to use for \(q\); the default is to create a ring of polynomials in \(q\) (or a field of rational functions in \(q\)) over the given coefficient ring.

We use the formulas from Proposition 7.8.3 of [EnumComb2]:

\[
\psi_{n,q}(p_{\lambda}) = \prod_i \frac{(1 - q^{n\lambda_i})}{(1 - q^{\lambda_i})},
\]

\[
\psi_{n,1}(p_{\lambda}) = n^{\ell(\lambda)},
\]

\[
\psi_{q}(p_{\lambda}) = 1 / \prod_i (1 - q^{\lambda_i}),
\]

where \(\ell(\lambda)\) denotes the length of \(\lambda\), and where the products range from \(i = 1\) to \(i = \ell(\lambda)\).

**EXAMPLES:**

```sage
sage: p = SymmetricFunctions(QQ).p()
sage: x = p[8,7,3,1]
sage: x.principal_specialization(3, q=var("q"))
(q^24 - 1)*(q^21 - 1)*(q^9 - 1)/((q^8 - 1)*(q^7 - 1)*(q - 1))
sage: x = 5*p[1,1,1] + 3*p[2,1] + 1
sage: x.principal_specialization(3, q=var("q"))
5*(q^3 - 1)^3/(q - 1)^3 + 3*(q^6 - 1)*(q^3 - 1)/((q^2 - 1)*(q - 1)) + 1
```

By default, we return a rational function in \(q\):

```sage
sage: x.principal_specialization(3)
8*q^6 + 18*q^5 + 36*q^4 + 38*q^3 + 36*q^2 + 18*q + 9
```

If \(n\) is not given we return the stable principal specialization:

```sage
sage: x.principal_specialization(q=var("q"))
3/((q^2 - 1)*(q - 1)) - 5/(q - 1)^3 + 1
```

**scalar**\((x, \text{zee=\text{None}})\)

Return the standard scalar product of \(self\) and \(x\).

**INPUT:**

• \(x\) – a power sum symmetric function

• \(\text{zee} \ (\text{default: uses standard \text{zee} function})\) optional input specifying the scalar product on the power sum basis with normalization \(\langle p_{\mu}, p_{\mu} \rangle = \text{zee}(\mu)\). \text{zee} should be a function on partitions.

Note that the power-sum symmetric functions are orthogonal under this scalar product. With the default value of \text{zee}, the value of \(\langle p_{\lambda}, p_{\lambda} \rangle\) is given by the size of the centralizer in \(S_n\) of a permutation of cycle type \(\lambda\).

**OUTPUT:**

• the standard scalar product between \(self\) and \(x\), or, if the optional parameter \text{zee} is specified, then the scalar product with respect to the normalization \(\langle p_{\mu}, p_{\mu} \rangle = \text{zee}(\mu)\) with the power sum basis elements being orthogonal

**EXAMPLES:**

```sage
sage: p = SymmetricFunctions(QQ).p()
sage: p4 = Partitions(4)
sage: matrix([[ p(a).scalar(p(b)) for a in p4 for b in p4]])
[4 0 0 0 0]
[0 3 0 0 0]
```

(continues on next page)
verschiebung(n)

Return the image of the symmetric function self under the n-th Verschiebung operator.

The n-th Verschiebung operator V_n is defined to be the unique algebra endomorphism V of the ring of symmetric functions that satisfies V(h_r) = h_r/n for every positive integer r divisible by n, and satisfies V(h_r) = 0 for every positive integer r not divisible by n. This operator V_n is a Hopf algebra endomorphism. For every nonnegative integer r with n \mid r, it satisfies

V_n(h_r) = h_r/n, \quad V_n(p_r) = np_r/n, \quad V_n(e_r) = (-1)^{r-r/n}e_{r/n}

(where h is the complete homogeneous basis, p is the powersum basis, and e is the elementary basis).

For every nonnegative integer r with n \not\mid r, it satisfies

V_n(h_r) = V_n(p_r) = V_n(e_r) = 0.

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The n-th Verschiebung operator is adjoint to the n-th Frobenius operator (see frobenius() for its definition) with respect to the Hall scalar product (scalar()).

The action of the n-th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley’s [STA].

Let \lambda be a partition. Let n be a positive integer. If the n-core of \lambda is nonempty, then V_n(s_\lambda) = 0. Otherwise, the following method computes V_n(s_\lambda): Write the partition \lambda in the form (\lambda_1, \lambda_2, \ldots, \lambda_{ns}) for some nonnegative integer s. (If n does not divide the length of \lambda, then this is achieved by adding trailing zeroes to \lambda.) Set \beta_i = \lambda_i + ns - i for every s \in \{1, 2, \ldots, ns\}. Then, (\beta_1, \beta_2, \ldots, \beta_{ns}) is a strictly decreasing sequence of nonnegative integers. Stably sort the list (1, 2, \ldots, ns) in order of (weakly) increasing remainder of \lambda_i - 1 modulo n. Let \xi be the sign of the permutation that is used for this sorting. Let \psi be the sign of the permutation that is used to stably sort the list (1, 2, \ldots, ns) in order of (weakly) increasing remainder of \lambda_i - 1 modulo n. (Notice that \psi = (-1)^{n(n-1)s(s-1)/4}.) Then, V_n(s_\lambda) = \xi\psi \prod_{i=0}^{n-1} s_{\lambda(i)}, where (\lambda^{(0)}, \lambda^{(1)}, \ldots, \lambda^{(n-1)}) is the n-quotient of \lambda.

INPUT:

• n – a positive integer

OUTPUT:

The result of applying the n-th Verschiebung operator (on the ring of symmetric functions) to self.

EXAMPLES:
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: p[3].verschiebung(2)
0
sage: p[4].verschiebung(4)
4*p[1]

The Verschiebung endomorphisms are multiplicative:

sage: all( all( p(lam).verschiebung(2) * p(mu).verschiebung(2)
....: == (p(lam) * p(mu)).verschiebung(2)
....: for mu in Partitions(4) )
....: for lam in Partitions(4) )
True

Testing the adjointness between the Frobenius operators \( f_n \) and the Verschiebung operators \( V_n \):

sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: all( all( p(lam).verschiebung(2).scalar(p(mu))
....: == p(lam).scalar(p(mu).frobenius(2))
....: for mu in Partitions(2) )
....: for lam in Partitions(4) )
True

antipode_on_basis(partition)

Return the antipode of \( self[partition] \).

The antipode on the generator \( p_i \) (for \( i > 0 \)) is \( -p_i \), and the antipode on \( p_\mu \) is \((-1)^{\text{length}(\mu)} p_\mu \).

INPUT:
- \( self \) – the power sum basis of the symmetric functions
- \( partition \) – a partition

OUTPUT:
- the result of the antipode on \( self(partition) \)

EXAMPLES:

sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: p.antipode_on_basis([2])
-p[2]
sage: p.antipode_on_basis([3])
-p[3]
sage: p.antipode_on_basis([2,2])
-p[2, 2]
sage: p.antipode_on_basis([])
p[]

bottom_schur_function(partition, degree=None)

Return the least-degree component of \( s[partition] \), where \( s \) denotes the Schur basis of the symmetric functions, and the grading is not the usual grading on the symmetric functions but rather the grading which gives every \( p_i \) degree 1.
This least-degree component has its degree equal to the Frobenius rank of partition, while the degree with respect to the usual grading is still the size of partition.

This method requires the base ring to be a (commutative) $\mathbb{Q}$-algebra. This restriction is unavoidable, since the least-degree component (in general) has noninteger coefficients in all classical bases of the symmetric functions.

The optional keyword degree allows taking any homogeneous component rather than merely the least-degree one. Specifically, if degree is set, then the degree-th component will be returned.

REFERENCES:

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: p.bottom_schur_function([2,2,1])
-1/6*p[3, 2] + 1/4*p[4, 1]
sage: p.bottom_schur_function([2,1])
-1/3*p[3]
sage: p.bottom_schur_function([3])
1/3*p[3]
sage: p.bottom_schur_function([1,1,1])
1/3*p[3]
sage: p.bottom_schur_function(Partition([1,1,1]))
1/3*p[3]
sage: p.bottom_schur_function([2,1], degree=1)
-1/3*p[3]
sage: p.bottom_schur_function([2,1], degree=2)
0
sage: p.bottom_schur_function([2,1], degree=3)
1/3*p[1, 1, 1]
sage: p.bottom_schur_function([2,2,1], degree=3)
1/8*p[2, 2, 1] - 1/6*p[3, 1, 1]
```

coproduct_on_generators($i$)

Return coproduct on generators for power sums $p_i$ (for $i > 0$).

The elements $p_i$ are primitive elements.

INPUT:

• self – the power sum basis of the symmetric functions

• $i$ – a positive integer

OUTPUT:

• the result of the coproduct on the generator $p(i)$

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.powersum()
sage: p.coproduct_on_generators(2)
```

eval_at_permutation_roots_on_generators($k, \rho$)

Evaluate $p_k$ at eigenvalues of permutation matrix.
This function evaluates a symmetric function $p([k])$ at the eigenvalues of a permutation matrix with cycle structure $\rho$.

This function evaluates a $p_k$ at the roots of unity

$$\Xi_{\rho_1}, \Xi_{\rho_2}, \ldots, \Xi_{\rho_{\ell}}$$

where

$$\Xi_m = 1, \zeta_m, \zeta_m^2, \ldots, \zeta_m^{m-1}$$

and $\zeta_m$ is an $m$ root of unity. This is characterized by $p_k[A, B] = p_k[A] + p_k[B]$ and $p_k[\Xi_m] = 0$ unless $m$ divides $k$ and $p_m[\Xi_m] = m$.

**INPUT:**

- $k$ – a non-negative integer
- $\rho$ – a partition or a list of non-negative integers

**OUTPUT:**

- an element of the base ring

**EXAMPLES:**

```sage
def main():
    p = SymmetricFunctions(QQ).p()
    print(p.eval_at_permutation_roots_on_generators(3, [6]))
    print(p.eval_at_permutation_roots_on_generators(3, [3]))
    print(p.eval_at_permutation_roots_on_generators(3, [1]))
    print(p.eval_at_permutation_roots_on_generators(3, [3,3]))
    print(p.eval_at_permutation_roots_on_generators(3, [1,1,1,1,1]))

if __name__ == '__main__':
    main()
```

### 5.1.296 Schur symmetric functions

**class** `sage.combinat.sf.schur.SymmetricFunctionAlgebra_schur(Sym)`

**Bases:** `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical`

A class for methods related to the Schur symmetric function basis

**INPUT:**

- `self` – a Schur symmetric function basis
- `Sym` – an instance of the ring of the symmetric functions

**class** `Element`

**Bases:** `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical.Element`

**expand**($n$, `alphabet='x'`)

Expand the symmetric function `self` as a symmetric polynomial in $n$ variables.

**INPUT:**

- `n` – a non-negative integer
- `alphabet` – (default: `'x'`) a variable for the expansion
OUTPUT:

A monomial expansion of self in the n variables labelled by alphabet.

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: a.expand(2)
x0^2*x1 + x0*x1^2
sage: a.expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0^2*x1^2
sage: a.expand(4)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0^2*x1^2 + x0^2*x0*x1*x3 + x1^2*x3 + 2*x0^2*x2^2*x3 + x2^2*x3 + x0^2*x3^2
sage: a.expand(2, alphabet='y')
y0^2*y1 + y0*y1^2
sage: a.expand(2, alphabet=['a', 'b'])
a^2*b + a*b^2
sage: s([1,1,1,1]).expand(3)
0
sage: (s([]) + 2*s([1])).expand(3)
2*x0 + 2*x1 + 2*x2 + 1
sage: s([1]).expand(0)
0
sage: (3*s([])).expand(0)
3
```

**exponential_specialization**(r=None, q=1)

Return the exponential specialization of a symmetric function (when $q = 1$), or the $q$-exponential specialization (when $q \neq 1$).

The exponential specialization $ex$ at $t$ is a $K$-algebra homomorphism from the $K$-algebra of symmetric functions to another $K$-algebra $R$. It is defined whenever the base ring $K$ is a $Q$-algebra and $t$ is an element of $R$. The easiest way to define it is by specifying its values on the powersum symmetric functions to be $p_1 = t$ and $p_n = 0$ for $n > 1$. Equivalently, on the homogeneous functions it is given by $ex(h_n) = t^n/n!$; see Proposition 7.8.4 of [EnumComb2].

By analogy, the $q$-exponential specialization is a $K$-algebra homomorphism from the $K$-algebra of symmetric functions to another $K$-algebra $R$ that depends on two elements $t$ and $q$ of $R$ for which the elements $1 - q^i$ for all positive integers $i$ are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

$$ex_q(h_n) = t^n/[n]_q!,$$

where $[n]_q!$ is the $q$-factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function $f$ of degree $n$, we have

$$ex_q(f) = (1 - q)^n t^n ps_q(f),$$

where $ps_q(f)$ is the stable principal specialization of $f$ (see principal_specialization()). (See (7.29) in [EnumComb2].)

The limit of $ex_q$ as $q \to 1$ is $ex$.

INPUT:

- t (default: None) – the value to use for $t$; the default is to create a ring of polynomials in $t$. 

5.1. Comprehensive Module List 2865
• $q$ (default: 1) – the value to use for $q$. If $q$ is None, then a ring (or fraction field) of polynomials in $q$ is created.

We use the formula in the proof of Corollary 7.21.6 of [EnumComb2]

$$ex_q(s_\lambda) = t^{\ell(\lambda)} \prod_{u \in \lambda} (1 + q + q^2 + \cdots + q^{h(u) - 1})$$

where $h(u)$ is the hook length of a cell $u$ in $\lambda$.

As a limit case, we obtain a formula for $q = 1$

$$ex_1(s_\lambda) = f^\lambda_t^{|\lambda|}/|\lambda|!$$

where $f^\lambda$ is the number of standard Young tableaux of shape $\lambda$.

**EXAMPLES:**

```python
sage: s = SymmetricFunctions(QQ).s()
sage: x = s[5,3]
sage: x.exponential_specialization()
1/1440*t^8
sage: x = 5*s[1,1,1] + 3*s[2,1] + 1
sage: x.exponential_specialization()
11/6*t^3 + 1
```

We also support the $q$-exponential_specialization:

```python
sage: factor(s[3].exponential_specialization(q=var("q"), t=var("t")))
t^3/((q^2 + q + 1)*(q + 1))
```

**omega()**

Return the image of self under the omega automorphism.

The **omega automorphism** is defined to be the unique algebra endomorphism $\omega$ of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers $k$ (where $e_k$ stands for the $k$-th elementary symmetric function, and $h_k$ stands for the $k$-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the **omega involution**. It sends the power-sum symmetric function $p_k$ to $(-1)^{k-1}p_k$ for every positive integer $k$.

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where $\lambda$ is any partition, where $\ell(\lambda)$ denotes the length (**length()**) of the partition $\lambda$, where $\lambda'$ denotes the conjugate partition (**conjugate()**) of $\lambda$, and where the usual notations for bases are used ($e$ = elementary, $h$ = complete homogeneous, $p$ = powersum, $s$ = Schur).

**omega_involution()** is a synonym for the **omega()** method.

**OUTPUT:**

• the image of self under the omega automorphism

**EXAMPLES:**

```python
sage: s = SymmetricFunctions(QQ).s()
sage: s([2,1]).omega()
s[2, 1]
sage: s([2,1,1]).omega()
s[3, 1]
```

omega_involution() is a synonym for the omega() method.

**OUTPUT:**

• the image of self under the omega automorphism

**EXAMPLES:**

```python
sage: s = SymmetricFunctions(QQ).s()
sage: s([2,1]).omega()
s[2, 1]
sage: s([2,1,1]).omega()
s[3, 1]
```
omega_involution()

Return the image of self under the omega automorphism.

The omega automorphism is defined to be the unique algebra endomorphism \( \omega \) of the ring of symmetric functions that satisfies \( \omega(e_k) = h_k \) for all positive integers \( k \) (where \( e_k \) stands for the \( k \)-th elementary symmetric function, and \( h_k \) stands for the \( k \)-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function \( p_k \) to \((-1)^{k-1} p_k\) for every positive integer \( k \).

The images of some bases under the omega automorphism are given by

\[
\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},
\]

where \( \lambda \) is any partition, where \( \ell(\lambda) \) denotes the length (\text{length}()) of the partition \( \lambda \), where \( \lambda' \) denotes the conjugate partition (\text{conjugate}()) of \( \lambda \), and where the usual notations for bases are used (\( e = \) elementary, \( h = \) complete homogeneous, \( p = \) powersum, \( s = \) Schur).

omega_involution() is a synonym for the omega() method.

OUTPUT:
• the image of self under the omega automorphism

EXAMPLES:

sage: s = SymmetricFunctions(QQ).s()
sage: s([2,1]).omega()
s[2, 1]
sage: s([2,1,1]).omega()
s[3, 1]

principal_specialization(n=+ infinity, q=None)

Return the principal specialization of a symmetric function.

The principal specialization of order \( n \) at \( q \) is the ring homomorphism \( ps_{n,q} \) from the ring of symmetric functions to another commutative ring \( R \) given by \( x_i \mapsto q^{i-1} \) for \( i \in \{1, \ldots, n\} \) and \( x_i \mapsto 0 \) for \( i > n \). Here, \( q \) is a given element of \( R \), and we assume that the variables of our symmetric functions are \( x_1, x_2, x_3, \ldots \). (To be more precise, \( ps_{n,q} \) is a \( K \)-algebra homomorphism, where \( K \) is the base ring.) See Section 7.8 of [EnumComb2].

The stable principal specialization at \( q \) is the ring homomorphism \( ps_q \) from the ring of symmetric functions to another commutative ring \( R \) given by \( x_i \mapsto q^{i-1} \) for all \( i \). This is well-defined only if the resulting infinite sums converge; thus, in particular, setting \( q = 1 \) in the stable principal specialization is an invalid operation.

INPUT:
• \( n \) (default: \( \text{infinity} \)) – a nonnegative integer or \( \text{infinity} \), specifying whether to compute the principal specialization of order \( n \) or the stable principal specialization.
• \( q \) (default: \( \text{None} \)) – the value to use for \( q \); the default is to create a ring of polynomials in \( q \) (or a field of rational functions in \( q \)) over the given coefficient ring.

For \( q = 1 \) we use the formula from Corollary 7.21.4 of [EnumComb2]:

\[
ps_{n,1}(s_\lambda) = \prod_{u \in \lambda} (n + c(u))/h(u),
\]

where \( h(u) \) is the hook length of a cell \( u \) in \( \lambda \), and where \( c(u) \) is the content of a cell \( u \) in \( \lambda \).

For \( n = \text{infinity} \) we use the formula from Corollary 7.21.3 of [EnumComb2]

\[
ps_q(s_\lambda) = q^{\sum_i (i-1)\lambda_i}/\prod_{u \in \lambda} (1 - q^{h(u)}).
\]
Otherwise, we use the formula from Theorem 7.21.2 of [EnumComb2],
\[
ps_{n,q}(s_\lambda) = q^{\sum (i-1) \lambda_i} \prod_{u \in \lambda} (1 - q^{u+c(u)})/(1 - q^{h(u)}).
\]

**EXAMPLES:**

```python
sage: s = SymmetricFunctions(QQ).s()
sage: x = s[2]
sage: x.principal_specialization(3)
q^4 + q^3 + 2*q^2 + q + 1
sage: x = 3*s[2,2] + 2*s[1] + 1
sage: x.principal_specialization(3, q=var("q"))
3*(q^4 - 1)*(q^3 - 1)*q^2/((q^2 - 1)*(q - 1)) + 2*(q^3 - 1)/(q - 1) + 1
```

**scalar**

The standard scalar product between \(\text{self}\) and \(x\).

Note that the Schur functions are self-dual with respect to this scalar product. They are also lowertriangularly related to the monomial symmetric functions with respect to this scalar product.

**INPUT:**
- \(x\) – element of the ring of symmetric functions over the same base ring as \(\text{self}\)
- \(zee\) – an optional function on partition giving the value for the scalar product between the power-sum symmetric function \(p_\mu\) and itself (the default value is the standard \(zee()\) function)

**OUTPUT:**
- the scalar product between \(\text{self}\) and \(x\)

**EXAMPLES:**

```python
sage: s = SymmetricFunctions(ZZ).s()
sage: a = s([2,1])
sage: b = s([1,1,1])
sage: c = 2*s([1,1,1])
sage: d = a + b
sage: a.scalar(a)
1
sage: b.scalar(b)
1
sage: b.scalar(a)
0
sage: b.scalar(c)
2
sage: c.scalar(c)
4
sage: d.scalar(a)
1
sage: d.scalar(b)
1
sage: d.scalar(c)
2
```
verschiebung($n$)

Return the image of the symmetric function self under the $n$-th Verschiebung operator.

The $n$-th Verschiebung operator $V_n$ is defined to be the unique algebra endomorphism $V$ of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer $r$ divisible by $n$, and satisfies $V(h_r) = 0$ for every positive integer $r$ not divisible by $n$. This operator $V_n$ is a Hopf algebra endomorphism. For every nonnegative integer $r$ with $n \mid r$, it satisfies

$$V_n(h_r) = h_{r/n}, \quad V_n(p_r) = np_{r/n}, \quad V_n(e_r) = (-1)^{r-r/n}e_{r/n}$$

(where $h$ is the complete homogeneous basis, $p$ is the powersum basis, and $e$ is the elementary basis). For every nonnegative integer $r$ with $n \not\mid r$, it satisfies

$$V_n(h_r) = V_n(p_r) = V_n(e_r) = 0.$$

The $n$-th Verschiebung operator is also called the $n$-th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The $n$-th Verschiebung operator is adjoint to the $n$-th Frobenius operator (see frobenius() for its definition) with respect to the Hall scalar product (scalar()).

The action of the $n$-th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley’s [STA].

Let $\lambda$ be a partition. Let $n$ be a positive integer. If the $n$-core of $\lambda$ is nonempty, then $V_n(s_\lambda) = 0$. Otherwise, the following method computes $V_n(s_\lambda)$: Write the partition $\lambda$ in the form $(\lambda_1, \lambda_2, \ldots, \lambda_{ns})$ for some nonnegative integer $s$. (If $n$ does not divide the length of $\lambda$, then this is achieved by adding trailing zeroes to $\lambda$.) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \ldots, ns\}$. Then, $(\beta_1, \beta_2, \ldots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo $n$. Let $\xi$ be the sign of the permutation that is used for this sorting. Let $\psi$ be the sign of the permutation that is used to stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo $n$. (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $V_n(s_\lambda) = \xi \psi \prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \ldots, \lambda^{(n-1)})$ is the $n$-quotient of $\lambda$.

INPUT:
• $n$ – a positive integer

OUTPUT:

The result of applying the $n$-th Verschiebung operator (on the ring of symmetric functions) to self.

EXAMPLES:

sage: m = SymmetricFunctions(ZZ).monomial()
sage: p4 = Partitions(4)
sage: l = [ [s(p).scalar(m(q)) for q in p4] for p in p4]
sage: matrix(l)

\[
\begin{pmatrix}
1 & 0 & 0 & 0 & 0 \\
-1 & 1 & 0 & 0 & 0 \\
0 & -1 & 1 & 0 & 0 \\
1 & -1 & -1 & 1 & 0 \\
-1 & 2 & 1 & -3 & 1
\end{pmatrix}
\]

verschiebung($n$)

Return the image of the symmetric function self under the $n$-th Verschiebung operator.

The $n$-th Verschiebung operator $V_n$ is defined to be the unique algebra endomorphism $V$ of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer $r$ divisible by $n$, and satisfies $V(h_r) = 0$ for every positive integer $r$ not divisible by $n$. This operator $V_n$ is a Hopf algebra endomorphism. For every nonnegative integer $r$ with $n \mid r$, it satisfies

$$V_n(h_r) = h_{r/n}, \quad V_n(p_r) = np_{r/n}, \quad V_n(e_r) = (-1)^{r-r/n}e_{r/n}$$

(where $h$ is the complete homogeneous basis, $p$ is the powersum basis, and $e$ is the elementary basis). For every nonnegative integer $r$ with $n \not\mid r$, it satisfies

$$V_n(h_r) = V_n(p_r) = V_n(e_r) = 0.$$

The $n$-th Verschiebung operator is also called the $n$-th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The $n$-th Verschiebung operator is adjoint to the $n$-th Frobenius operator (see frobenius() for its definition) with respect to the Hall scalar product (scalar()).

The action of the $n$-th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley’s [STA].

Let $\lambda$ be a partition. Let $n$ be a positive integer. If the $n$-core of $\lambda$ is nonempty, then $V_n(s_\lambda) = 0$. Otherwise, the following method computes $V_n(s_\lambda)$: Write the partition $\lambda$ in the form $(\lambda_1, \lambda_2, \ldots, \lambda_{ns})$ for some nonnegative integer $s$. (If $n$ does not divide the length of $\lambda$, then this is achieved by adding trailing zeroes to $\lambda$.) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \ldots, ns\}$. Then, $(\beta_1, \beta_2, \ldots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo $n$. Let $\xi$ be the sign of the permutation that is used for this sorting. Let $\psi$ be the sign of the permutation that is used to stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo $n$. (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $V_n(s_\lambda) = \xi \psi \prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \ldots, \lambda^{(n-1)})$ is the $n$-quotient of $\lambda$.

INPUT:
• $n$ – a positive integer

OUTPUT:

The result of applying the $n$-th Verschiebung operator (on the ring of symmetric functions) to self.

EXAMPLES:

sage: Sym = SymmetricFunctions(ZZ)
sage: s = Sym.s()
sage: s[5].verschiebung(2)
sage: s[6].verschiebung(6)
s[1]
sage: s[6,3].verschiebung(3)
s[2, 1] + s[3]
sage: s[6,3,1].verschiebung(2)
-s[3, 2]
sage: s[3,2,1].verschiebung(1)
s[3, 2, 1]
sage: s([]).verschiebung(1)
s[]
sage: s([]).verschiebung(4)
s[]

coproduct_on_basis(mu)
Returns the coproduct of self(mu).

Here self is the basis of Schur functions in the ring of symmetric functions.

INPUT:

• self – a Schur symmetric function basis
• mu – a partition

OUTPUT:

• the image of the mu-th Schur function under the comultiplication of the Hopf algebra of symmetric functions; this is an element of the tensor square of the Schur basis

EXAMPLES:

sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: s.coproduct_on_basis([2])

product_on_basis(left, right)
Return the product of left and right.

INPUT:

• self – a Schur symmetric function basis
• left, right – partitions

OUTPUT:

• an element of the Schur basis, the product of left and right
5.1.297 Symplectic Symmetric Functions

AUTHORS:

- Travis Scrimshaw (2013-11-10): Initial version

```python
class sage.combinat.sf.symplectic.SymmetricFunctionAlgebra_symplectic(Sym):
    Bases: sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic
```

The symplectic symmetric function basis (or symplectic basis, to be short).

The symplectic basis \( \{ sp_\lambda \} \) where \( \lambda \) is taken over all partitions is defined by the following change of basis with the Schur functions:

\[
s_\lambda = \sum_{\mu} \left( \sum_{\nu \in V} c_{\mu \nu}^\lambda \right) sp_\mu
\]

where \( V \) is the set of all partitions with even-height columns and \( c_{\mu \nu}^\lambda \) is the usual Littlewood-Richardson (LR) coefficients. By the properties of LR coefficients, this can be shown to be a upper unitriangular change of basis.

**Note:** This is only a filtered basis, not a \( \mathbb{Z} \)-graded basis. However this does respect the induced \( (\mathbb{Z}/2\mathbb{Z}) \)-grading.

INPUT:

- `Sym` – an instance of the ring of the symmetric functions

REFERENCES:

EXAMPLES:

Here are the first few symplectic symmetric functions, in various bases:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: sp = Sym.sp()
sage: e = Sym.e()
sage: h = Sym.h()
sage: p = Sym.p()
sage: m = Sym.m()
sage: s = Sym.s()

sage: p(sp([1]))
p[1]
sage: m(sp([1]))
m[1]
sage: e(sp([1]))
e[1]
sage: h(sp([1]))
h[1]
sage: s(sp([1]))
s[1]

sage: p(sp([2]))
1/2*p[1, 1] + 1/2*p[2]
sage: m(sp([2]))
m[1, 1] + m[2]
sage: e(sp([2]))
```

(continues on next page)
\begin{verbatim}
Combinatorics, Release 9.7

(continued from previous page)

sage: Sym = SymmetricFunctions(ZZ)
sage: sp = Sym.sp()
sage: e = Sym.e()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: p = Sym.p()
sage: m(sp([4]))
  m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1] + m[4]
sage: e(sp([4]))
sage: h(sp([4]))
h[4]
sage: s(sp([4]))
s[4]

Some examples of conversions the other way:

sage: sp(h[3])
sp[3]
sage: sp(e[3])
sp[1] + sp[1, 1, 1]
sage: sp(m([2,1]))
-sp[1] - 2*sp[1, 1, 1] + sp[2, 1]
sage: sp(p([3]))
sp[1, 1, 1] - sp[2, 1] + sp[3]

Some multiplication:

sage: sp([2])*sp([1,1])
sage: sp([2,1,1])*sp([2])
sage: sp([1,1])*sp([2,1])
\end{verbatim}

Examples of the Hopf algebra structure:

```python
sage: sp([1]).antipode()
-sp[1]
sage: sp([2]).antipode()
sp[] + sp[1, 1]
sage: sp([1]).coproduct()
sp[] # sp[1] + sp[1] # sp[]
sage: sp([2]).coproduct()
sage: sp([1]).counit()
0
sage: sp.one().counit()
1
```

5.1.298 Symmetric functions, with their multiple realizations

```python
class sage.combinat.sf.sf.SymmetricFunctions(R)
    Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

    The abstract algebra of commutative symmetric functions
```

Symmetric Functions in Sage

*Author: Jason Bandlow, Anne Schilling, Nicolas M. Thiery, Mike Zabrocki*

This document is an introduction to working with symmetric function theory in Sage. It is not intended to be an introduction to the theory of symmetric functions ([MAC] and [STA], Chapter 7, are two excellent references.) The reader is also expected to be familiar with Sage.

The algebra of symmetric functions

The algebra of symmetric functions is the unique free commutative graded connected algebra over the given ring, with one generator in each degree. It can also be thought of as the inverse limit (in the category of graded algebras) of the algebra of symmetric polynomials in \( n \) variables as \( n \to \infty \). Sage allows us to construct the algebra of symmetric functions over any ring. We will use a base ring of rational numbers in these first examples:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: Sym
Symmetric Functions over Rational Field
```

Sage knows certain categorical information about this algebra:

```python
sage: Sym.category()
Join of Category of hopf algebras over Rational Field
    and Category of graded algebras over Rational Field
    and Category of commutative algebras over Rational Field
```
and Category of monoids with realizations
and Category of graded coalgebras over Rational Field
and Category of coalgebras over Rational Field with realizations
and Category of cocommutative coalgebras over Rational Field

Notice that \texttt{Sym} is an \textit{abstract} algebra. This reflects the fact that there are multiple natural bases. To work with specific elements, we need a \textit{realization} of this algebra. In practice, this means we need to specify a basis.

**An example basis - power sums**

Here is an example of how one might use the power sum realization:

```python
sage: p = Sym.powersum()
sage: p
Symmetric Functions over Rational Field in the powersum basis
```

\(p\) now represents the realization of the symmetric function algebra on the power sum basis. The basis itself is accessible through:

```python
sage: p.basis()
Lazy family (Term map from Partitions to Symmetric Functions over Rational Field in \(i\) \rightarrow the powersum basis(i))_{i in Partitions}
sage: p.basis().keys()
Partitions
```

This last line means that \(p\).basis() is an association between the set of Partitions and the basis elements of the algebra \(p\). To construct a specific element one can therefore do:

```python
sage: p.basis()[Partition([2, 1, 1])]
p[2, 1, 1]
```

As this is rather cumbersome, realizations of the symmetric function algebra allow for the following abuses of notation:

```python
sage: p[Partition([2, 1, 1])]
p[2, 1, 1]
sage: p[[2, 1, 1]]
p[2, 1, 1]
sage: p[2, 1, 1]
p[2, 1, 1]
sage: p[[i for i in [2, 1, 1]]]
p[2, 1, 1]
```

or even:

```python
sage: p[(i for i in [2, 1, 1])]
p[2, 1, 1]
```

In the special case of the empty partition, due to a limitation in Python syntax, one cannot use:

```python
sage: p[] # todo: not implemented
```

Please use instead:
Combinatorics, Release 9.7

Note: When elements are constructed using the \texttt{p[something ]} syntax, an error will be raised if the input cannot be interpreted as a partition. This is not the case when \texttt{p.basis()} is used:

\begin{verbatim}
sage: p['something']
Traceback (most recent call last):
  ... ValueError: all parts of 'something' should be nonnegative integers
sage: p.basis()['something']
p'something'
\end{verbatim}

Elements of \texttt{p} are linear combinations of such compositions:

\begin{verbatim}
sage: p.an_element()
\end{verbatim}

\textbf{Algebra structure}

Algebraic combinations of basis elements can be entered in a natural way:

\begin{verbatim}
3*p[2, 1, 1] + 2*p[4, 1]
\end{verbatim}

Let us explore the other operations of \texttt{p}. We can ask for the mathematical properties of \texttt{p}:

\begin{verbatim}
sage: p.categories()
[Category of graded bases of Symmetric Functions over Rational Field,
 Category of filtered bases of Symmetric Functions over Rational Field,
 Category of bases of Symmetric Functions over Rational Field,
 Category of graded hopf algebras with basis over Rational Field,
 ...]
\end{verbatim}

To start with, \texttt{p} is a graded algebra, the grading being induced by the size of the partitions. Due to this, the one is the basis element indexed by the empty partition:

\begin{verbatim}
sage: p.one()
p[]
\end{verbatim}

The \texttt{p} basis is multiplicative; that is, multiplication is induced by linearity from the (nonincreasingly sorted) concatenation of partitions:

\begin{verbatim}
sage: p[3,1] * p[2,1]
p[3, 2, 1, 1]
sage: (p.one() + 2 * p[3,1]) * p[4, 2]
p[4, 2] + 2*p[4, 3, 2, 1]
\end{verbatim}
The classical bases

In addition to the power sum basis, other classical bases of the symmetric function algebra include the elementary, complete homogeneous, monomial, and Schur bases:

```
sage: e = Sym.elementary()
sage: h = Sym.homogeneous()
sage: m = Sym.monomial()
sage: s = Sym.schur()
```

These and others can be defined all at once with the single command:

```
sage: Sym.inject_shorthands()
Defining e as shorthand for Symmetric Functions over Rational Field in the elementary basis
Defining f as shorthand for Symmetric Functions over Rational Field in the forgotten basis
Defining h as shorthand for Symmetric Functions over Rational Field in the homogeneous basis
Defining m as shorthand for Symmetric Functions over Rational Field in the monomial basis
Defining p as shorthand for Symmetric Functions over Rational Field in the powersum basis
Defining s as shorthand for Symmetric Functions over Rational Field in the Schur basis
```

We can then do conversions from one basis to another:

```
sage: s(p[2,1])
-s[1, 1, 1] + s[3]
sage: m(p[3])
m[3]
sage: m(p[3,2])
m[3, 2] + m[5]
```

For computations which mix bases, Sage will return a result with respect to a single (not necessarily predictable) basis:

```
p[1] + 1/12*p[1, 1, 1, 1, 1] - 1/6*p[2, 1, 1, 1] - 1/4*p[2, 2, 1, 1] + 1/6*p[3, 1, 1, 1] + 1/6*p[3, 2, 1]
```

The one for different bases such as the power sum and Schur function is the same:

```
sage: s.one() == p.one()
True
```
Basic computations

In this section, we explore some of the many methods that can be applied to an arbitrary symmetric function:

```sage
f = s[2]^2; f
```

For more methods than discussed here, create a symmetric function as above, and use `f.<tab>`.

Representation theory of the symmetric group

The Schur functions $s_\lambda$ can also be interpreted as irreducible characters of the symmetric group $S_n$, where $n$ is the size of the partition $\lambda$. Since the Schur functions of degree $n$ form a basis of the symmetric functions of degree $n$, it follows that an arbitrary symmetric function (homogeneous of degree $n$) may be interpreted as a function on the symmetric group. In this interpretation the power sum symmetric function $p_\lambda$ is the characteristic function of the conjugacy class with shape $\lambda$, multiplied by the order of the centralizer of an element. Hence the irreducible characters can be computed as follows:

```sage
Sym = SymmetricFunctions(QQ)
s = Sym.schur()
p = Sym.power()
P = Partitions(5).list()
P = [P[i] for i in range(len(P)-1,-1,-1)]
M = matrix([[s[P[i]].scalar(p[P[j]]) for j in range(len(P)) for i in range(len(P))]])
```

We can indeed check that this agrees with the character table of $S_5$:

```sage
SymmetricGroup(5).character_table() == M
True
```

In this interpretation of symmetric functions as characters on the symmetric group, the multiplication and co-multiplication are interpreted as induction (from $S_n \times S_m$ to $S_{n+m}$) and restriction, respectively. The Schur functions can also be interpreted as characters of $GL_n$, see Partitions and Schur functions.

The omega involution

The $\omega$ involution is the linear extension of the map which sends $e_\lambda$ to $h_\lambda$:

```sage
h(f)
h[2, 2]
e(f.omega())
e[2, 2]
```
The Hall scalar product

The Hall scalar product on the algebra of symmetric functions makes the Schur functions into an orthonormal basis:

```
sage: f.scalar(f)
3
```

Skewing

Skewing is the adjoint operation to multiplication with respect to this scalar product:

```
sage: f.skew_by(s[1])
2*s[2, 1] + 2*s[3]
```

In general, `s[la].skew_by(s[mu])` is the symmetric function typically denoted $s_{\lambda\setminus\mu}$ or $s_{\lambda/\mu}$.

Expanding into variables

We can expand a symmetric function into a symmetric polynomial in a specified number of variables:

```
sage: f.expand(2)
x0^4 + 2*x0^3*x1 + 3*x0^2*x1^2 + 2*x0*x1^3 + x1^4
```

See the documentation for `expand` for more examples.

The Kronecker product

As in the section on the Representation theory of the symmetric group, a symmetric function may be considered as a class function on the symmetric group where the elements $p\mu/z\mu$ are the indicators of a permutation having cycle structure $\mu$. The Kronecker product of two symmetric functions corresponds to the pointwise product of these class functions.

Since the Schur functions are the irreducible characters of the symmetric group under this identification, the Kronecker product of two Schur functions corresponds to the internal tensor product of two irreducible symmetric group representations.

Under this identification, the Kronecker product of $p\mu/z\mu$ and $p\nu/z\nu$ is $p\mu/z\mu$ if $\mu = \nu$, and the result is equal to 0 otherwise.

`internal_product`, `kronecker_product`, `inner_tensor` and `itensor` are different names for the same function.

```
sage: f.kronecker_product(f)
s[1, 1, 1, 1] + 3*s[2, 1, 1] + 4*s[2, 2] + 5*s[3, 1] + 3*s[4]
```
Plethysm

The plethysm of symmetric functions is the operation corresponding to composition of representations of the general linear group. See [STA] Chapter 7, Appendix 2 for details.

```sage
s[2].plethysm(s[2])
s[2, 2] + s[4]
```

Plethysm can also be written as a composition of functions:

```sage
s[2]( s[2] )
s[2, 2] + s[4]
```

If the coefficient ring contains degree 1 elements, these are handled properly by plethysm:

```sage
R.<t> = QQ[]; s = SymmetricFunctions(R).schur()
s[2]( (1-t)*s[1] )
(t^2-t)*s[1, 1] + (-t+1)*s[2]
```

See the documentation for `plethysm` for more information.

Inner plethysm

The operation of inner plethysm `f.inner_plethysm(g)` models the composition of the \( S_n \) representation represented by \( g \) with the \( GL_m \) representation whose character is \( f \). See the documentation of `inner_plethysm`, [ST94] or [STA], exercise 7.74 solutions for more information:

```sage
s = SymmetricFunctions(QQ).schur()
f = s[2]^2
f.inner_plethysm(s[2])
s[2]
```

Hopf algebra structure

The ring of symmetric functions is further endowed with a coalgebra structure. The coproduct is an algebra morphism, and therefore determined by its values on the generators; the power sum generators are primitive:

```sage
p[1].coproduct()
p[2].coproduct()
```

The coproduct, being cocommutative on the generators, is cocommutative everywhere:

```sage
p[2, 1].coproduct()
```

This coproduct, along with the counit which sends every symmetric function to its 0-th homogeneous component, makes the ring of symmetric functions into a graded connected bialgebra. It is known that every graded connected bialgebra has an antipode. For the ring of symmetric functions, the antipode can be characterized explicitly: The antipode is an anti-algebra morphism (thus an algebra morphism, since our algebra is commutative) which sends \( p_\lambda \) to \((-1)^{\text{length} (\lambda)} p_\lambda\) for every partition \( \lambda \). Thus, in particular, it sends the generators on the \( p \) basis to their opposites:
The graded connected bialgebra of symmetric functions over a $\mathbb{Q}$-algebra has a rather simply-understood structure: It is (isomorphic to) the symmetric algebra of its space of primitives (which is spanned by the power-sum symmetric functions).

Here are further examples:

```
sage: f = s[2]^2
sage: f.antipode()
s[1, 1, 1, 1] + s[2, 1, 1] + s[2, 2]
sage: f.coproduct()
sage: f.coproduct().apply_multilinear_morphism(lambda x,y: x*y.antipode())
0
```

Transformations of symmetric functions

There are many methods in Sage which make it easy to manipulate symmetric functions. For example, if we have some function which acts on partitions (say, conjugation), it is a simple matter to apply it to the support of a symmetric function. Here is an example:

```
sage: conj = lambda mu: mu.conjugate()
sage: f.map_support(conj)
h[1, 1, 1, 1] + 2*h[2, 1, 1]
```

We can also easily modify the coefficients:

```
sage: def foo(mu, coeff):
    return mu.conjugate(), -coeff
sage: f.map_item(foo)
-h[1, 1, 1, 1] - 2*h[2, 1, 1]
```

See also `map_coefficients`.

There are also methods for building functions directly:

```
sage: s.sum_of_monomials(mu for mu in Partitions(3))
s[1, 1, 1] + s[2, 1] + s[3]
sage: s.sum_of_monomials(Partitions(3))
s[1, 1, 1] + s[2, 1] + s[3]
sage: s.sum_of_terms( (mu, mu[0]) for mu in Partitions(3))
s[1, 1, 1] + 2*s[2, 1] + 3*s[3]
```

These are the preferred way to build elements within a program; the result will usually be faster than using `sum()`.

It also guarantees that empty sums yields the zero of $s$ (see also `s.sum`).

Note also that it is a good idea to use:
instead of \(s(1)\) and \(s(0)\) within programs where speed is important, in order to prevent unnecessary coercions.

### Different base rings

Depending on the base ring, the different realizations of the symmetric function algebra may not span the same space:

```
sage: SZ = SymmetricFunctions(ZZ)
sage: p = SZ.power(); s = SZ.schur()
sage: p(s[1,1,1])
Traceback (most recent call last):
...  
TypeError: no conversion of this rational to integer
```

Because of this, some functions may not behave as expected when working over the integers, even though they make mathematical sense:

```
sage: s[1,1,1].plethysm(s[1,1,1])
Traceback (most recent call last):
...  
TypeError: no conversion of this rational to integer
```

It is possible to work over different base rings simultaneously:

```
sage: s = SymmetricFunctions(QQ).schur()
sage: p = SymmetricFunctions(QQ).power()
sage: sz = SymmetricFunctions(ZZ).schur(); sz._prefix = 'sz'
sage: pz = SymmetricFunctions(ZZ).power(); pz._prefix = 'pz'
sage: p(sz[1,1,1])
1/6*p[1, 1, 1] - 1/2*p[2, 1] + 1/3*p[3] 
sz[1, 1, 1]
```

As shown in this example, if you are working over multiple base rings simultaneously, it is a good idea to change the prefix in some cases, so that you can tell from the output which realization your result is in.

Let us change the notation back for the remainder of this tutorial:

```
sage: sz._prefix = 's'
sage: pz._prefix = 'p'
```

One can also use the Sage standard renaming idiom to get shorter outputs:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.rename("Sym")
sage: Sym
Sym
sage: Sym.rename()
```
And we name it back:

```python
sage: Sym.rename("Symmetric Functions over Rational Field"); Sym
Symmetric Functions over Rational Field
```

### Other bases

There are two additional basis of the symmetric functions which are not considered as classical bases:

- forgotten basis
- Witt basis

The forgotten basis is the dual basis of the elementary symmetric functions basis with respect to the Hall scalar product. The Witt basis can be constructed by

\[
\prod_{d=1}^{\infty} (1 - w_d t^d)^{-1} = \sum_{n=0}^{\infty} h_n t^n
\]

where \( t \) is a formal variable.

There are further bases of the ring of symmetric functions, in general over fields with parameters such as \( q \) and \( t \):

- Hall-Littlewood bases
- Jack bases
- Macdonald bases
- \( k \)-Schur functions
- Hecke character basis

We briefly demonstrate how to access these bases. For more information, see the documentation of the individual bases.

The *Jack polynomials* can be obtained as:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: Jack = Sym.jack()
sage: J(P[2,1])
(1/(t+2))*JackJ[2, 1]
```

The parameter \( t \) can be specialized as follows:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: Jack = Sym.jack(t = 1)
sage: J(P[2,1])
1/3*JackJ[2, 1]
```

Similarly one can access the Hall-Littlewood and Macdonald polynomials, etc:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: Mcd = Sym.macdonald()
```

(continues on next page)
We can also construct the $\bar{q}$ basis that can be used to determine character tables for Hecke algebras (with quadratic relation $T_i^2 = (1 - q)T_i + q$):

```python
sage: Sym = SymmetricFunctions(ZZ['q'].fraction_field())
sage: qbar = Sym.hecke_character()
sage: s = Sym.s()
sage: s(qbar[2,1])
-s[1, 1, 1] + (q-1)*s[2, 1] + q*s[3]
```

$k$-Schur functions

The $k$-Schur functions live in the $k$-bounded subspace of the ring of symmetric functions. It is possible to compute in the $k$-bounded subspace directly:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: f = ks[2,1]*ks[2,1]; f
ks3[2, 2, 1, 1] + ks3[2, 2, 2] + ks3[3, 1, 1, 1]
```

or to lift to the ring of symmetric functions:

```python
sage: f.lift()
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[4, 1, 1] +
- s[4, 2]
```

However, it is not always possible to convert a symmetric function to the $k$-bounded subspace:

```python
sage: s = Sym.schur()
sage: ks(s[2,1,1])
Traceback (most recent call last):
  ...
ValueError: s[2, 1, 1] is not in the image
```

The $k$-Schur functions are more generally defined with a parameter $t$ and they are a basis of the subspace spanned by the Hall-Littlewood Qp symmetric functions indexed by partitions whose first part is less than or equal to $k$:

```python
sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: SymS3 = Sym.kBoundedSubspace(3) # default t='t'
sage: ks = SymS3.kschur()
sage: Qp = Sym.hall_littlewood().Qp()
sage: ks(Qp[2,1,1])
ks3[2, 1, 1, 1] + (t^2+t)*ks3[2, 2, 1] + (t^3+t^2)*ks3[3, 1, 1] + t^4*ks3[3, 2]
```

The subspace spanned by the $k$-Schur functions with a parameter $t$ are not known to form a natural algebra. However it is known that the product of a $k$-Schur function and an $\ell$-Schur function is in the linear span of the $k + \ell$-Schur functions:

```python
sage: ks(ks[2,1]*ks[1,1])
Traceback (most recent call last):
```
ValueError: s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] is not in the image

sage: ks = Sym.kBoundedSubspace(6).kschur()
sage: ks6 = ks(ks[3,1,1]*ks[3])

The $k$-split basis is a second basis of the ring spanned by the $k$-Schur functions with a parameter $t$. The $k$-split basis has the property that $Q'_k[X;t]$ expands positively in the $k$-split basis and the $k$-split basis conjecturally expands positively in the $k$-Schur functions. The definition can be found in [LLMSSZ] p. 81.:

sage: ksp3 = SymS3.ksplit()
sage: ksp3(Qp[2,1,1,1])
ksp3[2, 1, 1, 1] + t^2*ksp3[2, 2, 1] + (t^3+t^2)*ksp3[3, 1, 1] + t^4*ksp3[3, 2]

The dual $k$-Schur functions

The dual space to the subspace spanned by the $k$-Schur functions is most naturally realized as a quotient of the ring of symmetric functions by an ideal. When $t = 1$ the ideal is generated by the monomial symmetric functions indexed by partitions whose first part is greater than $k$.:

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLP[3,1]
HLP3[3, 1]
sage: kHLP(HLP[4])
0
In this space, the basis which is dual to the \( k \)-Schur functions conjecturally expands positively in the \( k \)-bounded Hall-Littlewood functions and has positive structure coefficients.:

\[
\begin{align*}
sage: & \text{dks} = \text{SymQ3} \cdot \text{dual\_k\_Schur}() \\
sage: & k\text{HLP}(\text{dks}[2,2]) \\
& (t^4 + t^2) \cdot \text{HLP3}[1, 1, 1, 1] + t \cdot \text{HLP3}[2, 1, 1] + \text{HLP3}[2, 2] \\
sage: & \text{dks}[2,1] \cdot \text{dks}[1,1] \\
& (t^2 + t) \cdot \text{dks3}[1, 1, 1, 1, 1] + (t + 1) \cdot \text{dks3}[2, 1, 1, 1] + (t + 1) \cdot \text{dks3}[2, 2, 1] + \text{dks3}[3, 1, 1] + \text{dks3}[3, 2]
\end{align*}
\]

At \( t = 1 \) the \( k \)-bounded Hall-Littlewood basis is equal to the \( k \)-bounded monomial basis and the dual \( k \)-Schur elements are equal to the affine Schur basis. The \( k \)-bounded monomial basis and affine Schur functions are faster and should be used instead of the \( k \)-bounded Hall-Littlewood P basis and dual \( k \)-Schur functions when \( t = 1 \):

\[
\begin{align*}
sage: & \text{SymQ3} = \text{Sym} \cdot \text{k\_Bounded\_Quotient}(3, t=1) \\
sage: & \text{dks} = \text{SymQ3} \cdot \text{dual\_k\_Schur}() \\
sage: & \text{F} = \text{SymQ3} \cdot \text{affine\_Schur}() \\
sage: & \text{F}[3,1]==\text{dks}[3,1] \\
& \text{True}
\end{align*}
\]

### Implementing new bases

In order to implement a new symmetric function basis, Sage will need to know at a minimum how to change back and forth between at least one other basis (although they do not necessarily have to be the same basis). All of the standard functions associated with the basis will have a default implementation (although a more specific implementation may be more efficient).

To present an idea of how this is done, we will create here the example of how to implement the basis \( s_\mu[X(1-t)] \).

To begin, we import the class `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic()`. Our new basis will inherit all of the default methods from this class:

\[
\begin{align*}
sage: & \text{from sage.combinat.sf.sfa import SymmetricFunctionAlgebra\_generic as SFA\_generic} \\
& \text{sage: class SFA\_st(SFA\_generic):} \\
& \quad \text{def \_init\_2(self, Sym, t):} \\
& \quad \quad \text{SFA\_generic\_\_init\_2(self, Sym, basis\_name=} \\
& \quad \quad \quad \quad \quad \text{"Schur functions with a plethystic substitution of } X \to X(1-t)," \\
& \quad \quad \quad \quad \quad \text{prefix='st')} \\
& \quad \quad \text{self\_s = Sym.s()} \\
& \quad \quad \text{self\_t = Sym.base\_ring()}(t) \\
& \quad \quad \text{cat = HopfAlgebras(Sym.base\_ring()).WithBasis()} \\
& \quad \quad \text{self\_register\_coercion(} \\
& \quad \quad \quad \quad \text{SetMorphism(Hom(self\_s, self, cat), self\_s\_to\_self))} \\
& \quad \quad \text{self\_s\_register\_coercion(} \\
& \quad \quad \quad \quad \text{SetMorphism(Hom(self, self\_s, cat), self\_s\_to\_self))} \\
& \quad \quad \text{def \_s\_to\_self(self, f):}
\end{align*}
\]

(continues on next page)
An instance of this basis is created by calling it with a symmetric function ring \( \text{Sym} \) and a parameter \( t \) which is in the base ring of \( \text{Sym} \). The \texttt{Element} class inherits all of the methods from \texttt{sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element}.

In the reference [MAC] on page 354, this basis is denoted \( S_\lambda(x; t) \) and the change of basis coefficients of the Macdonald \( J \) basis are the coefficients \( K_{\lambda \mu}(q, t) \). Here is an example of its use:

```python
sage: QQqt = QQ['q','t'].fraction_field()
sage: (q,t) = QQqt.gens()
sage: st = SFA_st(SymmetricFunctions(QQqt),t)
sage: st
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field in the Schur functions with a plethystic substitution of X -> X(1-t) basis
q^2*st[1, 1, 1] + (q*t+1)*st[2, 1] + t*st[3]
```

Acknowledgements

The design is heavily inspired from the implementation of symmetric functions in MuPAD-Combinat (see [HT04] and [FD06]).

REFERENCES:

Further tests

Todo:

- Introduce fields with degree 1 elements as in MuPAD-Combinat, to get proper plethysm.
- Use \texttt{UniqueRepresentation} to get rid of all the manual cache handling for the bases
- Devise a mechanism so that pickling bases of symmetric functions pickles the coercions which have a cache.

Schur()

The Schur basis of the Symmetric Functions

EXAMPLES:
sage: SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis

Witt(coerce_h=True, coerce_e=False, coerce_p=False)
The Witt basis of the symmetric functions.

EXAMPLES:

sage: SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_p=True)
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_h=False, coerce_e=True, coerce_p=True)
Symmetric Functions over Rational Field in the Witt basis

a_realization()
Return a particular realization of self (the Schur basis).

EXAMPLES:

sage: Sym = SymmetricFunctions(QQ)
sage: Sym.a_realization()
Symmetric Functions over Rational Field in the Schur basis

complete()
The complete basis of the Symmetric Functions

EXAMPLES:

sage: SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis

e()
The elementary basis of the Symmetric Functions

EXAMPLES:

sage: SymmetricFunctions(QQ).elementary()
Symmetric Functions over Rational Field in the elementary basis

elementary()
The elementary basis of the Symmetric Functions

EXAMPLES:

sage: SymmetricFunctions(QQ).elementary()
Symmetric Functions over Rational Field in the elementary basis

f()
The forgotten basis of the Symmetric Functions (or the basis dual to the elementary basis with respect to the Hall scalar product).

EXAMPLES:

sage: SymmetricFunctions(QQ).forgotten()
Symmetric Functions over Rational Field in the forgotten basis

5.1. Comprehensive Module List
The forgotten basis of the Symmetric Functions (or the basis dual to the elementary basis with respect to the Hall scalar product).

**EXAMPLES:**

```
sage: SymmetricFunctions(QQ).forgotten()
Symmetric Functions over Rational Field in the forgotten basis
```

**from_polynomial**(*f*)

Converts a symmetric polynomial *f* to a symmetric function.

**INPUT:**

- *f* – a symmetric polynomial

This function converts a symmetric polynomial *f* in a polynomial ring in finitely many variables to a symmetric function in the monomial basis of the ring of symmetric functions over the same base ring.

**EXAMPLES:**

```
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: S = SymmetricFunctions(QQ)
sage: S.from_polynomial(f)
m[1]
sage: f = x[0] + 2*x[1] + x[2]
sage: S.from_polynomial(f)
Traceback (most recent call last):
  ...
ValueError: x0 + 2*x1 + x2 is not a symmetric polynomial
```

**h()**

The complete basis of the Symmetric Functions

**EXAMPLES:**

```
sage: SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

**hall_littlewood**(*t=*θ*)

Returns the entry point for the various Hall-Littlewood bases.

**INPUT:**

- *t* – parameter

Hall-Littlewood symmetric functions including bases P, Q, Qp. The Hall-Littlewood P and Q functions at *t* = −1 are the Schur-P and Schur-Q functions when indexed by strict partitions.

The parameter *t* must be in the base ring of parent.

**EXAMPLES:**

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: P = Sym.hall_littlewood().P(); P
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over \mathbb{Q} in the Hall-Littlewood P basis
```
hecke_character($q='q'$)
The basis of symmetric functions that determines the character tables for Hecke algebras.

EXAMPLES:

```python
sage: SymmetricFunctions(ZZ['q'].fraction_field()).hecke_character()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in q over Integer Ring
in the Hecke character with q=q basis
sage: SymmetricFunctions(QQ).hecke_character(1/2)
Symmetric Functions over Rational Field in the Hecke character with q=1/2 basis
```

homogeneous()
The complete basis of the Symmetric Functions

EXAMPLES:

```python
sage: SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

ht()
The induced trivial character basis of the Symmetric Functions.
The trivial character of

$$S_{n-|\lambda|} \times S_{\lambda_1} \times S_{\lambda_2} \times \cdots \times S_{\lambda_\ell(\lambda)}$$

induced to the group $S_n$ is a symmetric function in the eigenvalues of a permutation matrix. This basis is that character.

It has the property that if the element indexed by the partition $\lambda$ is evaluated at the roots of a permutation of cycle structure $\rho$ then the value is the coefficient $\langle h_{(n-|\lambda|,\lambda)} , p_\rho \rangle$.

In terms of methods that are implemented in Sage, if $n$ is a sufficiently large integer, then $ht(lam)$.character_to_frobenius_image(n) is equal the complete function indexed by $[n-\text{sum}(lam)]+lam$.

This basis is introduced in [OZ2015].

See also:

- character_to_frobenius_image(), eval_at_permutation_roots()

EXAMPLES:
Combinatorics, Release 9.7

```
sage: SymmetricFunctions(QQ).induced_trivial_character()
symmetric Functions over Rational Field in the induced trivial symmetric group_
→ character basis
sage: ht = SymmetricFunctions(QQ).ht()
sage: h = SymmetricFunctions(QQ).h()
sage: h(ht([3,2]).character_to_frobenius_image(9))
h[4, 3, 2]
sage: h(ht([3,2]).character_to_frobenius_image(7))
h[3, 2, 2]
sage: h(ht([3,2]).character_to_frobenius_image(5))
h[3, 2]
sage: h(ht([3,2]).character_to_frobenius_image(4))
0
sage: p = SymmetricFunctions(QQ).p()
sage: [h([4,1]).scalar(p(rho)) for rho in Partitions(5)]
[0, 1, 0, 2, 1, 3, 5]
sage: [ht([1]).eval_at_permutation_roots(rho) for rho in Partitions(5)]
[0, 1, 0, 2, 1, 3, 5]
```

induced_trivial_character()
The induced trivial character basis of the Symmetric Functions.

The trivial character of

\[ S_n^{-|\lambda|} \times S_{\lambda_1} \times S_{\lambda_2} \times \cdots \times S_{\lambda_\ell}(\lambda) \]

induced to the group \( S_n \) is a symmetric function in the eigenvalues of a permutation matrix. This basis is that character.

It has the property that if the element indexed by the partition \( \lambda \) is evaluated at the roots of a permutation of cycle structure \( \rho \) then the value is the coefficient \( \langle h_{(n-|\lambda|,\lambda)},p_\rho \rangle \).

In terms of methods that are implemented in Sage, if \( n \) is a sufficiently large integer, then \( ht(\lambda) \cdot character_to_frobenius_image(n) \) is equal the complete function indexed by \([n-\text{sum}(\lambda)]+\lambda\).

This basis is introduced in [OZ2015].

See also:

character_to_frobenius_image(), eval_at_permutation_roots()

EXAMPLES:

```
sage: SymmetricFunctions(QQ).induced_trivial_character()
symmetric Functions over Rational Field in the induced trivial symmetric group_
→ character basis
sage: ht = SymmetricFunctions(QQ).ht()
sage: h = SymmetricFunctions(QQ).h()
sage: h(ht([3,2]).character_to_frobenius_image(9))
h[4, 3, 2]
sage: h(ht([3,2]).character_to_frobenius_image(7))
h[3, 2, 2]
sage: h(ht([3,2]).character_to_frobenius_image(5))
h[3, 2]
sage: h(ht([3,2]).character_to_frobenius_image(4))
0
sage: p = SymmetricFunctions(QQ).p()
```
irreducible_symmetric_group_character()

The irreducible $S_n$ character basis of the Symmetric Functions.

This basis has the property that if the element indexed by the partition $\lambda$ is evaluated at the roots of a permutation of cycle structure $\rho$ then the value is the irreducible character $\chi^{(|\rho|-|\lambda|,\lambda)}(\rho)$.

In terms of methods that are implemented in Sage, if $n$ is a sufficiently large integer, then $st(lam).character_to_frobenius_image(n)$ is equal the Schur function indexed by $[n-\text{sum}(lam)]+lam$.

This basis is introduced in [OZ2015].

See also:

character_to_frobenius_image(), eval_at_permutation_roots()

EXAMPLES:

```sage
sage: SymmetricFunctions(QQ).irreducible_symmetric_group_character()
Symmetric Functions over Rational Field in the irreducible symmetric group.
Symmetric Functions over Rational Field in the irreducible symmetric group.

sage: st = SymmetricFunctions(QQ).st()
sage: s = SymmetricFunctions(QQ).s()
sage: s(st([3,2]).character_to_frobenius_image(9))
[0, 1, 0, 2, 1, 3, 5]

sage: s(st([3,2]).character_to_frobenius_image(7))
[0, 1, 0, 2, 1, 3, 5]
```

jack($t$='t')

Returns the entry point for the various Jack bases.

INPUT:

* $t$ – parameter

Jack symmetric functions including bases $P, Q, Qp$.

The parameter $t$ must be in the base ring of parent.

EXAMPLES:

```sage
sage: Sym = SymmetricFunctions(FractionField(QQ[q])
sage: JP = Sym.jack().P(); JP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in q over Rational Field in the Jack P basis

sage: JQ = Sym.jack().Q(); JQ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in q over Rational Field in the Jack Q basis
```

5.1. Comprehensive Module List 2891
kBoundedQuotient\((k, t=’t’)\)

Returns the \(k\)-bounded quotient space of the ring of symmetric functions.

INPUT:

- \(k\) - a positive integer

The quotient of the ring of symmetric functions ...

See also:

sage.combinat.sf.k_dual.KBoundedQuotient()

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: KB = Sym.kBoundedQuotient(3); KB
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1
```

kBoundedSubspace\((k, t=’t’)\)

Return the \(k\)-bounded subspace of the ring of symmetric functions.

INPUT:

- \(k\) - a positive integer
- \(t\) a formal parameter

The subspace of the ring of symmetric functions spanned by \(\{s_{\lambda}(X)/(1-t)\}_{\lambda \leq k}\) over the base ring \(\mathbb{Q}[t]\). When \(t=1\), this space is in fact a subalgebra of the ring of symmetric functions generated by the complete homogeneous symmetric functions \(h_i\) for \(1 \leq i \leq k\).

See also:

sage.combinat.sf.new_kschur.KBoundedSubspace()

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: KB = Sym.kBoundedSubspace(3,1); KB
3-Bounded Subspace of Symmetric Functions over Rational Field with t=1
```

(continues on next page)
3-bounded Symmetric Functions over Univariate Polynomial Ring in \( t \) over \( \mathbb{Q} \)

\[
\text{\texttt{sage}}: \text{Sym} = \text{SymmetricFunctions}(\mathbb{Q}[z])
\]
\[
\text{\texttt{sage}}: \ z = \text{Sym.base_ring().gens()}[0]
\]
\[
\text{\texttt{sage}}: \text{Sym.kBoundedSubspace}(3, t=z)
\]

3-bounded Symmetric Functions over Univariate Polynomial Ring in \( z \) over \( \mathbb{Q} \)

\[
\text{\texttt{sage}}: \text{Sym} = \text{SymmetricFunctions}(\mathbb{Q}[t])
\]
\[
\text{\texttt{sage}}: \text{Sym.kBoundedSubspace}(3, t=t)
\]

\[
\text{\texttt{khomogeneous}}(k)
\]

Returns the homogeneous symmetric functions in the \( k \)-bounded subspace.

**EXAMPLES:**

\[
\text{\texttt{sage}}: \text{Sym} = \text{SymmetricFunctions}(\mathbb{Q})
\]
\[
\text{\texttt{sage}}: \text{kh} = \text{Sym.khomogeneous}(4)
\]
\[
\text{\texttt{sage}}: \text{kh}[3]*\text{kh}[4]
\]
\[
\text{\texttt{h4[4, 3]}}
\]
\[
\text{\texttt{sage}}: \text{kh}[4].\text{lift()}
\]
\[
\text{\texttt{h4}}
\]

\[
\text{\texttt{kschur}}(k, t='t')
\]

Returns the \( k \)-Schur functions.

**EXAMPLES:**

\[
\text{\texttt{sage}}: \text{Sym} = \text{SymmetricFunctions}(\mathbb{Q})
\]
\[
\text{\texttt{sage}}: \text{ks} = \text{Sym.kschur}(3,1)
\]
\[
\text{\texttt{sage}}: \text{ks}[2]*\text{ks}[2]
\]
\[
\text{\texttt{ks3[2, 2] + ks3[3, 1]}}
\]
\[
\text{\texttt{sage}}: \text{ks}[2,1,1].\text{lift()}
\]
\[
\text{\texttt{s[2, 1, 1] + s[3, 1]}}
\]
\[
\text{\texttt{sage}}: \text{Sym} = \text{SymmetricFunctions}(\mathbb{Q}[t])
\]
\[
\text{\texttt{sage}}: \text{ks} = \text{Sym.kschur}(3)
\]
\[
\text{\texttt{sage}}: \text{ks}[2,2,1].\text{lift()}
\]
\[
\text{\texttt{s[2, 2, 1] + t*s[3, 2]}}
\]

\[
\text{\texttt{ksplit}}(k, t='t')
\]

Return the \( k \)-split basis of the \( k \)-bounded subspace.

**EXAMPLES:**

\[
\text{\texttt{sage}}: \text{Sym} = \text{SymmetricFunctions}(\mathbb{Q})
\]
\[
\text{\texttt{sage}}: \text{ksp} = \text{Sym.ksplit}(3,1)
\]
\[
\text{\texttt{sage}}: \text{ksp}[2]*\text{ksp}[2]
\]
\[
\text{\texttt{ksp3[2, 2] + ksp3[3, 1]}}
\]
\[
\text{\texttt{sage}}: \text{ksp}[2,1,1].\text{lift()}
\]
\[
\text{\texttt{s[2, 1, 1] + s[2, 2] + s[3, 1]}}
\]
\[
\text{\texttt{sage}}: \text{Sym} = \text{SymmetricFunctions}(\mathbb{Q}[t])
\]
\[
\text{\texttt{sage}}: \text{ksp} = \text{Sym.ksplit}(3)
\]
\[
\text{\texttt{sage}}: \text{ksp}[2,1,1].\text{lift()}
\]
\[
\text{\texttt{s[2, 1, 1] + t*s[2, 2] + t*s[3, 1]}}
\]
\texttt{llt}(k, t='t')

The LLT symmetric functions.

\textbf{INPUT:}

\begin{itemize}
  \item $k$ – a positive integer indicating the level
  \item $t$ – a parameter (default: $t$)
\end{itemize}

LLT polynomials in $hspin$ and $hcospin$ bases.

\textbf{EXAMPLES:}

\begin{verbatim}sage: llt3 = SymmetricFunctions(QQ['t'].fraction_field()).llt(3); llt3
level 3 LLT polynomials over Fraction Field of Univariate Polynomial Ring in t
˓→ over Rational Field
sage: llt3.hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over␣˓→ Rational Field in the level 3 LLT spin basis
sage: llt3.hcospin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over␣˓→ Rational Field in the level 3 LLT cospin basis
\end{verbatim}

\texttt{m()}

The monomial basis of the Symmetric Functions

\textbf{EXAMPLES:}

\begin{verbatim}sage: Sym = SymmetricFunctions(QQ).monomial()
Symmetric Functions over Rational Field in the monomial basis
\end{verbatim}

\texttt{macdonald}(q='q', t='t')

Returns the entry point for the various Macdonald bases.

\textbf{INPUT:}

\begin{itemize}
  \item $q$, $t$ – parameters
\end{itemize}

Macdonald symmetric functions including bases $P$, $Q$, $J$, $H$, $H_t$. This also contains the $S$ basis which is dual to the Schur basis with respect to the $q,t$ scalar product.

The parameters $q$ and $t$ must be in the base_ring of parent.

\textbf{EXAMPLES:}

\begin{verbatim}sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P(); P
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t˓→ over Rational Field in the Macdonald P basis
sage: P[2]
McdP[2]
sage: Q = Sym.macdonald().Q(); Q
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t˓→ over Rational Field in the Macdonald Q basis
sage: S = Sym.macdonald().S()
sage: s = Sym.schur()
\end{verbatim}
sage: matrix([[S(la).scalar_qt(s(mu)) for la in Partitions(3)] for mu in Partitions(3))
[1 0 0]
[0 1 0]
[0 0 1]
sage: H = Sym.macdonald().H()
sage: s(H[[2,2]])
q^2*s[1, 1, 1] + (q^2*t+q*t+q)*s[2, 1, 1] + (q^2*t^2+1)*s[2, 2] + (q*t^2+q*t+t)*s[3, 1] + t^2*s[4]
sage: Sym = SymmetricFunctions(QQ['z','q']).fraction_field()
sage: (z,q) = Sym.base_ring().gens()
sage: Hzq = Sym.macdonald(q=z,t=q).H()
sage: H1z = Sym.macdonald(q=1,t=z).H()
sage: s = Sym.schur()
sage: s(H1z(Hzq[[2,2]])
s[1, 1, 1, 1] + (2*z+1)*s[2, 1, 1] + (z^2+1)*s[2, 2] + (z^2+2*z)*s[3, 1] + z^2*s[4]
sage: s(Hzq[[2,2]])
z^2*s[1, 1, 1, 1] + (z^2*q+z*q+z)*s[2, 1, 1] + (z^2*q^2+1)*s[2, 2] + (z*q^2+z*q+q)*s[3, 1] + q^2*s[4]
sage: s(H1z(Hzq([2,2]))
z^2*s[1, 1, 1, 1] + (z^2*q+z*q+z)*s[2, 1, 1] + (z^2*q^2+1)*s[2, 2] + (z*q^2+z*q+q)*s[3, 1] + q^2*s[4]

monomial()

The monomial basis of the Symmetric Functions

EXAMPLES:

sage: SymmetricFunctions(QQ).monomial()
Symmetric Functions over Rational Field in the monomial basis

o()

The orthogonal basis of the symmetric functions.

See also:

 SymmetricFunctionAlgebra_orthogonal

EXAMPLES:

sage: SymmetricFunctions(QQ).orthogonal()
Symmetric Functions over Rational Field in the orthogonal basis

orthogonal()

The orthogonal basis of the symmetric functions.

See also:

 SymmetricFunctionAlgebra_orthogonal

EXAMPLES:

sage: SymmetricFunctions(QQ).orthogonal()
Symmetric Functions over Rational Field in the orthogonal basis
The power sum basis of the Symmetric Functions

**EXAMPLES:**

```python
sage: SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis
```

### power()

The power sum basis of the Symmetric Functions

**EXAMPLES:**

```python
sage: SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis
```

### powersum()

The power sum basis of the Symmetric Functions

**EXAMPLES:**

```python
sage: SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis
```

### qbar(q='q')

The basis of symmetric functions that determines the character tables for Hecke algebras.

**EXAMPLES:**

```python
sage: SymmetricFunctions(ZZ['q']).fraction_field()).hecke_character()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in q over Integer Ring in the Hecke character with q=q basis
sage: SymmetricFunctions(QQ).hecke_character(1/2)
Symmetric Functions over Rational Field in the Hecke character with q=1/2 basis
```

### register_isomorphism(morphism, only_conversion=False)

Register an isomorphism between two bases of self, as a canonical coercion (unless the optional keyword only_conversion is set to True, in which case the isomorphism is registered as conversion only).

**EXAMPLES:**

We override the canonical coercion from the Schur basis to the powersum basis by a (stupid!) map $s_{\lambda} \mapsto 2p_\lambda$.

```python
sage: Sym = SymmetricFunctions(QQ['zorglub']) # make sure we are not going to_ ˓→screw up later tests
sage: s = Sym.s(); p = Sym.p().dual_basis()
```

```python
sage: phi = s.module_morphism(diagonal = lambda t: 2, codomain = p)
sage: phi(s[2, 1])
2*d_p[2, 1]
sage: Sym.register_isomorphism(phi)
sage: p(s[2,1])
2*d_p[2, 1]
```

The map is supposed to implement the canonical isomorphism between the two bases. Otherwise, the results will be mathematically wrong, as above. Use with care!
s()  
The Schur basis of the Symmetric Functions  

EXAMPLES:

```python
sage: SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

schur()  
The Schur basis of the Symmetric Functions  

EXAMPLES:

```python
sage: SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

sp()  
The symplectic basis of the symmetric functions.  

See also:  

SymmetricFunctionAlgebra_symplectic  

EXAMPLES:

```python
sage: SymmetricFunctions(QQ).symplectic()
Symmetric Functions over Rational Field in the symplectic basis
```

st()  
The irreducible $S_n$ character basis of the Symmetric Functions.  

This basis has the property that if the element indexed by the partition $\lambda$ is evaluated at the roots of a permutation of cycle structure $\rho$ then the value is the irreducible character $\chi^{(\rho|-\lambda,\lambda)}(\rho)$.  

In terms of methods that are implemented in Sage, if $n$ is a sufficiently large integer, then $st(lam)$.character_to_frobenius_image(n) is equal the Schur function indexed by $[n-\text{sum}(lam)]+\lambda$.  

This basis is introduced in [OZ2015].  

See also:  

character_to_frobenius_image(), eval_at_permutation_roots()  

EXAMPLES:

```python
sage: SymmetricFunctions(QQ).irreducible_symmetric_group_character()
Symmetric Functions over Rational Field in the irreducible symmetric group character basis

sage: st = SymmetricFunctions(QQ).st()
sage: s = SymmetricFunctions(QQ).s()
sage: s(st([3,2]).character_to_frobenius_image(9))
s[4, 3, 2]
sage: s(st([3,2]).character_to_frobenius_image(7))
\emptyset
sage: s(st([3,2]).character_to_frobenius_image(6))
-s[2, 2, 2]
sage: list(SymmetricGroup(5).character_table()[-2])
[4, 2, 0, 1, -1, 0, -1]
sage: list(reversed([st([1]).eval_at_permutation_roots(rho)
(continues on next page)```
Combinatorics, Release 9.7

......: for rho in Partitions(5))]
[4, 2, 0, 1, -1, 0, -1]

symplectic()
The symplectic basis of the symmetric functions.

See also:
SymmetricFunctionAlgebra_symplectic

EXAMPLES:
sage: SymmetricFunctions(QQ).symplectic()
Symmetric Functions over Rational Field in the symplectic basis

w(coerce_h=True, coerce_e=False, coerce_p=False)
The Witt basis of the symmetric functions.

EXAMPLES:
sage: SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_p=True)
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_h=False, coerce_e=True, coerce_p=True)
Symmetric Functions over Rational Field in the Witt basis

witt(coerce_h=True, coerce_e=False, coerce_p=False)
The Witt basis of the symmetric functions.

EXAMPLES:
sage: SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_p=True)
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_h=False, coerce_e=True, coerce_p=True)
Symmetric Functions over Rational Field in the Witt basis

zonal()
The zonal basis of the Symmetric Functions

EXAMPLES:
sage: SymmetricFunctions(QQ).zonal()
Symmetric Functions over Rational Field in the zonal basis

class sage.combinat.sf.sf.SymmetricaConversionOnBasis(t, domain, codomain)
Bases: object

Initialization of self.

INPUT:

• t – a function taking a monomial in CombinatorialFreeModule(QQ, Partitions()), and returning a
(partition, coefficient) list.
• domain, codomain – parents
Construct a function mapping a partition to an element of codomain.

This is a temporary quick hack to wrap around the existing symmetrica conversions, without changing their specs.

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ['x'])
sage: p = Sym.p(); s = Sym.s()
sage: def t(x) : [(p,c)] = x; return [(p,2*c), (p.conjugate(), c)]
sage: f = sage.combinat.sf.sf.SymmetricaConversionOnBasis(t, p, s)
sage: f(Partition([3,1]))
s[2, 1, 1] + 2*s[3, 1]
```

### 5.1.299 Symmetric Functions

For a comprehensive tutorial on how to use symmetric functions in Sage

**See also:**

*SymmetricFunctions()*

We define the algebra of symmetric functions in the Schur and elementary bases:

```python
sage: s = SymmetricFunctions(QQ).schur()
sage: e = SymmetricFunctions(QQ).elementary()
```

Each is actually a graded Hopf algebra whose basis is indexed by integer partitions:

```python
sage: s.category()
Category of graded bases of Symmetric Functions over Rational Field
sage: s.basis().keys()
Partitions
```

Let us compute with some elements in different bases:

```python
sage: f1 = s([2,1]); f1
s[2, 1]
sage: f2 = e(f1); f2 # basis conversion
e[2, 1] - e[3]
sage: f1 == f2
True
sage: f1.expand(3, alphabet=['x','y','z'])
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
sage: f2.expand(3, alphabet=['x','y','z'])
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
```

```python
sage: m = SymmetricFunctions(QQ).monomial()
sage: m([3,1])
m[3, 1]
sage: m(4) # This is the constant 4, not the partition 4.
4*m[]
sage: m([4]) # This is the partition 4.
m[4]
```

(continues on next page)
Combinatorics, Release 9.7

sage: 3*m([3,1]) - 1/2*m([4])
3*m[3, 1] - 1/2*m[4]

sage: p = SymmetricFunctions(QQ).power()
sage: f = p(3)
sage: f
3*p[]

sage: f + p([3,2])
3*p[] + p[3, 2]

One can convert symmetric functions to symmetric polynomials and vice versa:

sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.powersum()
sage: h = Sym.homogeneous()
sage: f = h[2,1] + 2*p[3,1]
sage: poly = f.expand(3); poly
2*x0^4 + 2*x0^3*x1 + 2*x0*x1^3 + 2*x1^4 + 2*x0^3*x2 + 2*x1^3*x2 + 2*x0^2*x2^3 + 2*x1*x2^3
˓→ 2*x2^4
+ x0^3 + 2*x0^2*x1 + 2*x0*x1^2 + x1^3 + 2*x0^2*x2 + 3*x0*x1*x2 + 2*x1^2*x2 + 2*x0*x2^2 + 2*x1*x2^2 + x2^3
sage: Sym.from_polynomial(poly)
sage: Sym.from_polynomial(poly) == f
True

sage: g = h[1,1,1,1]
sage: poly = g.expand(3)
sage: Sym.from_polynomial(poly) == g
False

sage: s[3, 1] = s(a)

Chapter 5. Comprehensive Module List
Here are further examples:

```
sage: h(m([1]))
  h[1]
sage: h( m([2]) + m([1,1]) )
  h[2]
sage: h( m([3]) + m([2,1]) + m([1,1,1]) )
  h[3]
sage: h( m([4]) + m([3,1]) + m([2,2]) + m([2,1,1]) + m([1,1,1,1]) )
  h[4]
sage: k = 5
sage: h( sum([ m(part) for part in Partitions(k) ]) )
  h[5]
sage: k = 10
sage: h( sum([ m(part) for part in Partitions(k) ]) )
  h[10]
```

```
sage: P3 = Partitions(3)
sage: P3.list()
[[3], [2, 1], [1, 1, 1]]
sage: m = SymmetricFunctions(QQ).monomial()
sage: f = sum([m(p) for p in P3])
sage: m.get_print_style()
'lex'
sage: f
m[1, 1, 1] + m[2, 1] + m[3]
sage: m.set_print_style('length')
sage: f
m[3] + m[2, 1] + m[1, 1, 1]
sage: m.set_print_style('maximal_part')
sage: f
m[1, 1, 1] + m[2, 1] + m[3]
sage: m.set_print_style('lex')
```

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: m = Sym.m()
sage: m([3])*s([2,1])
2^2*m[3, 1, 1, 1] + m[3, 2, 1] + 2^2*m[4, 1, 1] + m[4, 2] + m[5, 1]
sage: s(m([3])*s([2,1]))
s[2, 1, 1, 1, 1] - s[2, 2, 2] - s[3, 3] + s[5, 1]
sage: e = Sym.e()
sage: e([4])*e([3])*e([1])
e[4, 3, 1]
```

```
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([2,1]) + s([1,1,1])
sage: z.coefficient([2,1])
```

AUTHORS:

• Mike Hansen (2007-06-15)
• Nicolas M. Thiery (partial refactoring)
• Mike Zabrocki, Anne Schilling (2012)
• Darij Grinberg (2013) Sym over rings that are not characteristic 0

class sage.combinat.sf.sfa.FilteredSymmetricFunctionsBases(parent_with_realization)

   Bases: sage.categories.realizations.Category_realization_of_parent

   The category of filtered bases of the ring of symmetric functions.

   super_categories()
      The super categories of self.

   EXAMPLES:

   sage: from sage.combinat.sf.sfa import FilteredSymmetricFunctionsBases
   sage: Sym = SymmetricFunctions(QQ)
   sage: bases = FilteredSymmetricFunctionsBases(Sym)
   sage: bases.super_categories()
     [Category of bases of Symmetric Functions over Rational Field,
      Category of commutative filtered hopf algebras with basis over Rational Field]

class sage.combinat.sf.sfa.GradedSymmetricFunctionsBases(parent_with_realization)

   Bases: sage.categories.realizations.Category_realization_of_parent

   The category of graded bases of the ring of symmetric functions.

   These are further required to have the property that the basis element indexed by the empty partition is 1.

class ElementMethods

   Bases: object

   degree_negation()
      Return the image of self under the degree negation automorphism of the ring of symmetric functions.

      The degree negation is the automorphism which scales every homogeneous element of degree \( k \) by \((-1)^k\) (for all \( k \)).

      Calling degree_negation(self) is equivalent to calling self.parent().

   EXAMPLES:

   sage: Sym = SymmetricFunctions(ZZ)
   sage: m = Sym.monomial()
   sage: f = 2*m[2,1] + 4*m[1,1] - 5*m[1] - 3*m[[]]
   sage: f.degree_negation()
\[-3*m[] + 5*m[1] + 4*m[1, 1] - 2*m[2, 1]\]

```python
sage: x = m.zero().degree_negation(); x
0
sage: parent(x) is m
True
```

### degree_zero_coefficient()

Return the degree zero coefficient of self.

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: f = 2*m[2,1] + 3*m[]
sage: f.degree_zero_coefficient()
3
```

class ParentMethods

    Bases: object

    **antipode_by_coercion(element)**

    The antipode of element.

    **INPUT:**
    
    - `element` – element in a basis of the ring of symmetric functions

    **EXAMPLES:**

    ```python
    sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: s = Sym.s()
sage: e = Sym.e()
sage: h = Sym.h()
sage: (h([]) + h([1])).antipode() # indirect doctest
h[] - h[1]
sage: (s([]) + s([1]) + s[2]).antipode()
s[] - s[1] + s[1, 1]
sage: (p([2]) + p([3])).antipode()
sage: (e([2]) + e([3])).antipode()
sage: f = Sym.f()
sage: f([3,2,1]).antipode()
```

The antipode is an involution:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: s = Sym.s()
sage: all( s[u].antipode().antipode() == s[u] for u in Partitions(4) )
True
```

The antipode is an algebra homomorphism:
```
sage: Sym = SymmetricFunctions(FiniteField(23))
sage: h = Sym.h()
sage: all( all( (s[u] * s[v]).antipode() == s[u].antipode() * s[v].antipode() 
        for u in Partitions(3) )
        for v in Partitions(3) )
True
```

count\(\text{it}(\text{element})\)

Return the counit of \text{element}.

The counit is the constant term of \text{element}.

INPUT:

\text{• element} – element in a basis of the ring of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: f = 2*m[2,1] + 3*m[]
sage: f.counit()
3
```

degree_negation\(\text{element}\)

Return the image of \text{element} under the degree negation automorphism of the ring of symmetric functions.

The degree negation is the automorphism which scales every homogeneous element of degree \(k\) by \((-1)^k\) (for all \(k\)).

INPUT:

\text{• element} – symmetric function written in self

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.monomial()
sage: f = 2*m[2,1] + 4*m[1,1] - 5*m[1] - 3*m[
```

\text{super_categories()}\)

The super categories of self.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import GradedSymmetricFunctionsBases
sage: Sym = SymmetricFunctions(QQ)
sage: bases = GradedSymmetricFunctionsBases(Sym)
sage: bases.super_categories()
[Category of filtered bases of Symmetric Functions over Rational Field, 
Category of commutative graded hopf algebras with basis over Rational Field]
```

class \text{sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic}(\text{Sym}, \text{basis}\_\text{name}=\text{None}, \text{prefix}=\text{None}, \text{graded}=\text{True})

Bases: \text{sage.combinat.free_module.CombinatorialFreeModule}

Abstract base class for symmetric function algebras.
Todo: Most of the methods in this class are generic (manipulations of morphisms, ...) and should be generalized (or removed)

**Element**

alias of `SymmetricFunctionAlgebra_generic_Element`

**basis_name()**

Return the name of the basis of self.

This is used for output and, for the classical bases of symmetric functions, to connect this basis with Symmetrica.

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: s.basis_name()
'Schur'
sage: p = Sym.p()
sage: p.basis_name()
'powersum'
sage: h = Sym.h()
sage: h.basis_name()
'homogeneous'
sage: e = Sym.e()
sage: e.basis_name()
'elementary'
sage: m = Sym.m()
sage: m.basis_name()
'monomial'
sage: f = Sym.f()
sage: f.basis_name()
'forgotten'
```

coproduct_by_coercion(elt)

Return the coproduct of the element elt by coercion to the Schur basis.

**INPUT:**

- elt – an instance of this basis

**OUTPUT:**

- The image of elt under the comultiplication (=coproduct) of the coalgebra of symmetric functions. The result is an element of the tensor squared of the basis self.

**EXAMPLES:**

```python
sage: m = SymmetricFunctions(QQ).m()
sage: m[3,1,1].coproduct()
˓→m[1] + m[3, 1, 1] # m[]
sage: m.coproduct_by_coercion(m[2,1])
sage: m.coproduct_by_coercion(m[2,1]) == m([2,1]).coproduct()
True
```
Combinatorics, Release 9.7

(continued from previous page)

```python
sage: McdH = SymmetricFunctions(QQ['q','t'].fraction_field()).macdonald().H()
sage: McdH[2,1].coproduct()
McdH[] # McdH[2, 1] + ((q^2*t-1)/(q^t-1))*McdH[0] # McdH[1, 1] + ((q^2*t-1)/(q^t-1))*McdH[0] # McdH[0] + ((q^2*t-1)/(q^t-1))*McdH[1] # McdH[1] + ((q^2*t-1)/(q^t-1))*McdH[1] # McdH[0] + McdH[2, 1] # McdH[]
sage: HLQp = SymmetricFunctions(QQ['t'].fraction_field()).hall_littlewood().Qp()
sage: HLQp[2,1].coproduct()
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: LLT = Sym.llt(3)
sage: LLT.cospin([3,2,1]).coproduct()
(t+1)*m[] # m[1, 1] + m[] # m[2] + (t+1)*m[1] # m[1] + (t+1)*m[1] # m[] + m[2] # m[]
sage: f = SymmetricFunctions(ZZ).f()
sage: f[3].coproduct()
sage: f[3,2,1].coproduct()
```

dual_basis(\text{scalar=\text{None}, scalar\_name='\=', basis\_name=\text{None}, prefix=\text{None}})

Return the dual basis of self with respect to the scalar product scalar.

\textbf{INPUT:}

- \texttt{scalar} – A function \texttt{zee} from partitions to the base ring which specifies the scalar product by 
  \[ \langle p_\lambda, p_\mu \rangle = \text{zee}(\lambda). \] (Independently on the function chosen, the power sum basis will always be orthogonal; the function \texttt{scalar} only determines the norms of the basis elements.) If \texttt{scalar} is \texttt{None}, then the standard (Hall) scalar product is used.

- \texttt{scalar\_name} – name of the scalar function

- \texttt{prefix} – prefix used to display the basis

\textbf{EXAMPLES:}

The duals of the elementary symmetric functions with respect to the Hall scalar product are the forgotten symmetric functions.

```python
sage: e = SymmetricFunctions(QQ).e()
sage: f = e.dual_basis(pREFIX='f'); f
Dual basis to Symmetric Functions over Rational Field in the elementary basis with respect to the Hall scalar product
sage: f[[2,1]]^2
sage: f[[2,1]].scalar(e[[2,1]])
1
sage: f[[2,1]].scalar(e[[1,1,1]])
0
```

Since the power-sum symmetric functions are orthogonal, their duals with respect to the Hall scalar product are scalar multiples of themselves.
Combinatorics, Release 9.7

\begin{verbatim}
sage: p = SymmetricFunctions(QQ).p()
sage: q = p.dual_basis(prefix='q'); q
Dual basis to Symmetric Functions over Rational Field in the powersum basis with respect to the Hall scalar product
sage: q([2,1])**2
4*q[2, 2, 1, 1]
sage: p([2,1]).scalar(q([2,1]))
1
sage: p([2,1]).scalar(q([1,1,1]))
0

\textbf{from\_polynomial}(\textit{poly, check=True})

Convert polynomial to a symmetric function in the monomial basis and then to the basis \textit{self}.

INPUT:

- \textit{poly} – a symmetric polynomial
- \textit{check} – (default: True) boolean, specifies whether the computation checks that the polynomial is indeed symmetric

EXAMPLES:

\begin{verbatim}
sage: Sym = SymmetricFunctions(QQ)
sage: h = Sym.homogeneous()
sage: f = (h([]) + h([2,1]) + h([3])).expand(3)
sage: h.from_polynomial(f)
h[] + h[2, 1] + h[3]
sage: s = Sym.s()
sage: g = (s([]) + s([2,1])).expand(3); g
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2 + 1
sage: s.from_polynomial(g)
s[] + s[2, 1]
\end{verbatim}

\textbf{get\_print\_style}()

Return the value of the current print style for \textit{self}.

EXAMPLES:

\begin{verbatim}
sage: s = SymmetricFunctions(QQ).s()
sage: s.get_print_style()
'lex'
sage: s.set_print_style('length')
sage: s.get_print_style()
'length'
sage: s.set_print_style('lex')
\end{verbatim}

\textbf{prefix}()

Return the prefix on the elements of \textit{self}.

EXAMPLES:

\begin{verbatim}
sage: schur = SymmetricFunctions(QQ).schur()
sage: schur([3,2,1])
s[3, 2, 1]
sage: schur.prefix()
's'
\end{verbatim}
\end{verbatim}
**product_by_coercion***(left, right)***

Return the product of elements *left* and *right* by coercion to the Schur basis.

**INPUT:**

- *left*, *right* – instances of this basis

**OUTPUT:**

- the product of *left* and *right* expressed in the basis *self*

**EXAMPLES:**

```python
sage: p = SymmetricFunctions(QQ).p()
sage: p.product_by_coercion(p[3,1,1], p[2,2])
p[3, 2, 2, 1, 1]
sage: m = SymmetricFunctions(QQ).m()
sage: m.product_by_coercion(m[2,1],m[1,1]) == m[2,1]*m[1,1]
True```

**set_print_style***(ps)***

Set the value of the current print style to *ps*.

**INPUT:**

- *ps* – a string specifying the printing style

**EXAMPLES:**

```python
sage: s = SymmetricFunctions(QQ).s()
sage: s.get_print_style() 'lex'
sage: s.set_print_style('length')
sage: s.get_print_style() 'length'
sage: s.set_print_style('lex')```

**symmetric_function_ring**()

Return the family of symmetric functions associated to the basis *self*.

**OUTPUT:**

- returns an instance of the ring of symmetric functions

**EXAMPLES:**

```python
sage: schur = SymmetricFunctions(QQ).schur()
sage: schur.symmetric_function_ring()
Symmetric Functions over Rational Field
```

**transition_matrix***(basis, n)***

Return the transition matrix between *self* and *basis* for the homogeneous component of degree *n*.

**INPUT:**

- *basis* – a basis of the ring of symmetric functions
- *n* – a nonnegative integer
OUTPUT:

• a matrix of coefficients giving the expansion of the homogeneous degree-$n$ elements of self in the degree-$n$ elements of basis

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: m = SymmetricFunctions(QQ).m()
sage: s.transition_matrix(m,5)
[1 1 1 1 1 1]
[0 1 1 2 2 3 4]
[0 0 1 1 2 3 5]
[0 0 0 1 1 3 6]
[0 0 0 0 1 2 5]
[0 0 0 0 0 1 4]
[0 0 0 0 0 0 1]
sage: s.transition_matrix(m,1)
[1]
sage: s.transition_matrix(m,0)
[1]
sage: p = SymmetricFunctions(QQ).p()
sage: s.transition_matrix(p, 4)
[1/4 1/3 1/8 1/4 1/24]
[-1/4 0 -1/8 1/4 1/8]
[0 -1/3 1/4 0 1/12]
[1/4 0 -1/8 -1/4 1/8]
[-1/4 1/3 1/8 -1/4 1/24]
sage: StoP = s.transition_matrix(p,4)
sage: a = s([3,1])+5*s([1,1,1,1])-s([4])
sage: a
5*s[1, 1, 1, 1] + s[3, 1] - s[4]
sage: mon = sorted(a.support())
sage: coeffs = [a[i] for i in mon]
sage: coeffs
[5, 1, -1]
sage: mon
[[1, 1, 1, 1], [3, 1], [4]]
sage: cm = matrix([[[-1,1,0,0],5]])
sage: cm * StoP
[-7/4 4/3 3/8 -5/4 7/24]
sage: p(a)
```

```
sage: h = SymmetricFunctions(QQ).h()
sage: e = SymmetricFunctions(QQ).e()
sage: s.transition_matrix(m,7) == h.transition_matrix(s,7).transpose()
True
```

```
sage: h.transition_matrix(m, 7) == h.transition_matrix(m, 7).transpose()
True
```
\begin{verbatim}
sage: h.transition_matrix(e, 7) == e.transition_matrix(h, 7)
True

sage: p.transition_matrix(s, 5)
[[ 1 -1 0 1 0 -1 1]
 [ 1 0 -1 0 1 0 -1]
 [ 1 -1 1 0 -1 1 -1]
 [ 1 1 -1 0 -1 1 1]
 [ 1 0 1 -2 1 0 1]
 [ 1 2 1 0 -1 -2 -1]
 [ 1 4 5 6 5 4 1]]

sage: e.transition_matrix(m,7) == e.transition_matrix(m,7).transpose()
True
\end{verbatim}

class sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element
Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

Class of generic elements for the symmetric function algebra.

\textbf{arithmetic_product}(x)
Return the arithmetic product of \texttt{self} and \texttt{x} in the basis of \texttt{self}.

The arithmetic product is a binary operation $\square$ on the ring of symmetric functions which is bilinear in its two arguments and satisfies

\[ p_\lambda \square p_\mu = \prod_{i \geq 1, j \geq 1} \gcd(\lambda_i, \mu_j) \text{lcm}(\lambda_i, \mu_j) \]

for any two partitions $\lambda = (\lambda_1, \lambda_2, \lambda_3, \ldots)$ and $\mu = (\mu_1, \mu_2, \mu_3, \ldots)$ (where $p_\nu$ denotes the power-sum symmetric function indexed by the partition $\nu$, and $p_i$ denotes the $i$-th power-sum symmetric function). This is enough to define the arithmetic product if the base ring is torsion-free as a $\mathbb{Z}$-module; for all other cases the arithmetic product is uniquely determined by requiring it to be functorial in the base ring. See http://mathoverflow.net/questions/138148/ for a discussion of this arithmetic product.

If $f$ and $g$ are two symmetric functions which are homogeneous of degrees $a$ and $b$, respectively, then $f \square g$ is homogeneous of degree $ab$.

The arithmetic product is commutative and associative and has unity $e_1 = p_1 = h_1$.

**INPUT:**

- \texttt{x} – element of the ring of symmetric functions over the same base ring as \texttt{self}

**OUTPUT:**

Arithmetic product of \texttt{self} with \texttt{x}; this is a symmetric function over the same base ring as \texttt{self}.

**EXAMPLES:**

\begin{verbatim}
sage: s = SymmetricFunctions(QQ).s()
sage: s([[2]]).arithmetic_product(s([[2]]))
s[1, 1, 1, 1] + 2*s[2, 2] + s[4]
sage: s([[2]]).arithmetic_product(s([[1,1]]))
s[2, 1, 1] + s[3, 1]
\end{verbatim}

The symmetric function $e[1]$ is the unity for the arithmetic product:
The arithmetic product is commutative:

```python
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).arithmetic_product(m(q)) == m(q).arithmetic_product(e(p))
for q in Partitions(4) )
for p in Partitions(4) )
True
```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a \( Q \)-algebra (in which case the arithmetic product can be easily computed using the power sum basis) from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over \( Q \) (using the `corresponding_basis_over` hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).

bernstein_creation_operator\( (n) \)

Return the image of self under the \( n \)-th Bernstein creation operator.

Let \( n \) be an integer. The \( n \)-th Bernstein creation operator \( B_n \) is defined as the endomorphism of the space \( Sym \) of symmetric functions which sends every \( f \) to

\[
\sum_{i \geq 0} (-1)^i h_{n+i} e_i^\perp,
\]

where usual notations are in place (\( h \) stands for the complete homogeneous symmetric functions, \( e \) for the elementary ones, and \( e_i^\perp \) means skewing (\( \text{skew_by()} \) by \( e_i \)).

This has been studied in [BBSSZ2012], section 2.2, where the following rule is given for computing \( B_n \) on a Schur function: If \( (\alpha_1, \alpha_2, \ldots, \alpha_n) \) is an \( n \)-tuple of integers (positive or not), then

\[
B_n s_{(\alpha_1, \alpha_2, \ldots, \alpha_n)} = s_{(n, \alpha_1, \alpha_2, \ldots, \alpha_n)}.
\]

Here, \( s_{(\alpha_1, \alpha_2, \ldots, \alpha_n)} \) is the “Schur function” associated to the \( n \)-tuple \( (\alpha_1, \alpha_2, \ldots, \alpha_n) \), and defined by literally applying the Jacobi-Trudi identity, i.e., by

\[
s_{(\alpha_1, \alpha_2, \ldots, \alpha_n)} = \det ( (h_{\alpha_i-j+i})_{i,j=1,2,\ldots,n} ) .
\]

This notion of a Schur function clearly extends the classical notion of Schur function corresponding to a partition, but is easily reduced to the latter (in fact, for any \( n \)-tuple \( \alpha \) of integers, one easily sees that \( s_\alpha \) is either 0 or minus-plus a Schur function corresponding to a partition; and it is easy to determine which of these is the case and find the partition by a combinatorial algorithm).

EXAMPLES:

Let us check that what this method computes agrees with the definition:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
```
sage: h = Sym.h()
sage: s = Sym.s()
sage: def bernstein_creation_by_def(n, f):
    # `n`-th Bernstein creation operator applied to `f`
    # computed according to its definition.
    res = f.parent().zero()
    if not f:
        return res
    max_degree = max(sum(m) for m, c in f)
    for i in range(max_degree + 1):
        if n + i >= 0:
            res += (-1) ** i * h[n + i] * f.skew_by(e[i])
    return res
sage: all( bernstein_creation_by_def(n, s[l]) == s[l].bernstein_creation_operator(n) for n in range(-2, 3) for l in Partitions(4) )
True
sage: all( bernstein_creation_by_def(n, s[l]) == s[l].bernstein_creation_operator(n) for n in range(-3, 4) for l in Partitions(3) )
True
sage: all( bernstein_creation_by_def(n, e[l]) == e[l].bernstein_creation_operator(n) for n in range(-3, 4) for k in range(3) for l in Partitions(k) )
True

Some examples:

calculate the value of the symmetric function self at the eigenvalues of a permutation of cycle structure \( \rho \). The Frobenius image is then defined as \( \sum_{\rho \vdash n} f[\Xi\rho] p_\rho / z_\rho \).

See also:

eval_at_permutation_roots()
INPUT:
• \( n \) – a non-negative integer to interpret \( \text{self} \) as a character of \( GL_n \)

OUTPUT:
• a symmetric function of degree \( n \)

EXAMPLES:

```sage
s = SymmetricFunctions(QQ).s()
s[3, 1, 1] + s[4, 1]
s[3]
```

**degree()**

Return the degree of \( \text{self} \) (which is defined to be 0 for the zero element).

EXAMPLES:

```sage
s = SymmetricFunctions(QQ).s()
zs = s([4]) + s([2,1]) + s([1,1,1]) + s([1]) + 3
tsage: zs.degree()
4
tsage: s(1).degree()
0
tsage: s(0).degree()
0
```

**derivative_with_respect_to_p1**

Return the symmetric function obtained by taking the derivative of \( \text{self} \) with respect to the power-sum symmetric function \( p_1 \) when the expansion of \( \text{self} \) in the power-sum basis is considered as a polynomial in \( p_k \)'s (with \( k \geq 1 \)).

This is the same as skewing \( \text{self} \) by the first power-sum symmetric function \( p_1 \).

INPUT:
• \( n \) – (default: 1) nonnegative integer which determines which power of the derivative is taken

EXAMPLES:

```sage
p = SymmetricFunctions(QQ).p()
a = p([1,1,1])
a.derivative_with_respect_to_p1()
3*p[1, 1]
a.derivative_with_respect_to_p1(1)
3*p[1, 1]
a.derivative_with_respect_to_p1(2)
6*p[1]
a.derivative_with_respect_to_p1(3)
6*p[]
```
Let us check that taking the derivative with respect to $p[1]$ is equivalent to skewing by $p[1]$:

```
sage: p1 = s([1])
sage: all( s(lam).derivative_with_respect_to_p1() == s(lam).skew_by(p1) for lam in Partitions(4) )
True
```

**eval_at_permutation_roots(rho)**
Evaluate at eigenvalues of a permutation matrix.

Evaluate a symmetric function at the eigenvalues of a permutation matrix whose cycle structure is rho. This computation is computed by coercing to the power sum basis where the value may be computed on the generators.

This function evaluates an element at the roots of unity

$$\Xi_{\rho_1}, \Xi_{\rho_2}, \ldots, \Xi_{\rho_\ell}$$

where

$$\Xi_m = 1, \zeta_m, \zeta_m^2, \ldots, \zeta_m^{m-1}$$

and $\zeta_m$ is an $m$ root of unity. These roots of unity represent the eigenvalues of permutation matrix with cycle structure $\rho$.

**INPUT:**

- `rho` – a partition or a list of non-negative integers

**OUTPUT:**

- an element of the base ring

**EXAMPLES:**

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([3,3]).eval_at_permutation_roots([6])
0
sage: s([3,3]).eval_at_permutation_roots([3])
1
sage: s([3,3]).eval_at_permutation_roots([1])
0
sage: s([3,3]).eval_at_permutation_roots([3,3])
(continues on next page)
```
sage: s([3, 3]).eval_at_permutation_roots([1, 1, 1, 1, 1])
175
sage: (s[1]+s[2]+s[3]).eval_at_permutation_roots([3, 2])
2

expand\(n, \text{alphabet='x'}\)
Expand the symmetric function \(\text{self}\) as a symmetric polynomial in \(n\) variables.

INPUT:
- \(n\) – a nonnegative integer
- \(\text{alphabet}\) – (default: 'x') a variable for the expansion

OUTPUT:
A monomial expansion of \(\text{self}\) in the \(n\) variables labelled \(x_0, x_1, \ldots, x_{n-1}\) (or just \(x\) if \(n = 1\)), where \(x\) is \(\text{alphabet}\).

EXAMPLES:

```
sage: J = SymmetricFunctions(QQ).jack(t=2).J()
sage: J([2,1]).expand(3)
4*x0^2*x1 + 4*x0*x1^2 + 4*x0^2*x2 + 6*x0*x1*x2 + 4*x1^2*x2 + 4*x0*x2^2 + ...
˓→4*x1^2*x2^2
sage: (2*J([2])).expand(0)
0
sage: (3*J([])).expand(0)
3
```

exponential_specialization\(t=None, q=1\)
Return the exponential specialization of a symmetric function (when \(q = 1\)), or the \(q\)-exponential specialization (when \(q \neq 1\)).

The exponential specialization \(ex\) at \(t\) is a \(K\)-algebra homomorphism from the \(K\)-algebra of symmetric functions to another \(K\)-algebra \(R\). It is defined whenever the base ring \(K\) is a \(Q\)-algebra and \(t\) is an element of \(R\). The easiest way to define it is by specifying its values on the powersum symmetric functions to be \(p_1 = t\) and \(p_n = 0\) for \(n > 1\). Equivalently, on the homogeneous functions it is given by \(ex(h_n) = t^n/n!\); see Proposition 7.8.4 of [EnumComb2].

By analogy, the \(q\)-exponential specialization is a \(K\)-algebra homomorphism from the \(K\)-algebra of symmetric functions to another \(K\)-algebra \(R\) that depends on two elements \(t\) and \(q\) of \(R\) for which the elements \(1-q^i\) for all positive integers \(i\) are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

\[
ex_q(h_n) = t^n/[n]_q!,
\]

where \([n]_q!\) is the \(q\)-factorial. Equivalently, for \(q \neq 1\) and a homogeneous symmetric function \(f\) of degree \(n\), we have

\[
ex_q(f) = (1-q)^{n}t^n ps_q(f),
\]

where \(ps_q(f)\) is the stable principal specialization of \(f\) (see \texttt{principal_specialization()}). (See (7.29) in [EnumComb2].)

The limit of \(ex_q\) as \(q \to 1\) is \(ex\).

INPUT:
• \(t\) (default: None) – the value to use for \(t\); the default is to create a ring of polynomials in \(t\).

• \(q\) (default: 1) – the value to use for \(q\). If \(q\) is None, then a ring (or fraction field) of polynomials in \(q\) is created.

EXAMPLES:

```python
sage: m = SymmetricFunctions(QQ).m()
sage: (m[2,1]+m[1,1]).exponential_specialization()
1/2*t^2
sage: (m[2,1]+m[1,1]).exponential_specialization(q=1)
1/2*t^2
sage: m[1,1].exponential_specialization(q=None)
(q/(q + 1))*t^2
sage: Qq = PolynomialRing(QQ, "q"); q = Qq.gen()
sage: m[1,1].exponential_specialization(q=q)
(q/(q + 1))*t^2
sage: Qt = PolynomialRing(QQ, "t"); t = Qt.gen()
sage: m[1,1].exponential_specialization(t=t)
1/2*t^2
sage: Qqt = PolynomialRing(QQ, ["q", "t"]); q, t = Qqt.gens()
sage: m[1,1].exponential_specialization(q=q, t=t)
q*t^2/(q + 1)
```

```python
sage: x = m[3]+m[2,1]+m[1,1,1]
sage: d = x.homogeneous_degree()
sage: var("q t")
(q, t)
sage: factor((x.principal_specialization()*(1-q)^d*t^d))
t^3/((q^2 + q + 1)*(q + 1))
sage: factor(x.exponential_specialization(q=q, t=t))
t^3/((q^2 + q + 1)*(q + 1))
```

\[ \text{frobenius}(n) \]

Return the image of the symmetric function \(\text{self}\) under the \(n\)-th Frobenius operator.

The \(n\)-th Frobenius operator \(f_n\) is defined to be the map from the ring of symmetric functions to itself that sends every symmetric function \(P(x_1, x_2, x_3, \ldots)\) to \(P(x_1^n, x_2^n, x_3^n, \ldots)\). This operator \(f_n\) is a Hopf algebra endomorphism, and satisfies

\[ f_n m_{(\lambda_1, \lambda_2, \lambda_3, \ldots)} = m_{(n\lambda_1, n\lambda_2, n\lambda_3, \ldots)} \]

for every partition \((\lambda_1, \lambda_2, \lambda_3, \ldots)\) (where \(m\) means the monomial basis). Moreover, \(f_n(p_r) = p_{nr}\) for every positive integer \(r\) (where \(p_k\) denotes the \(k\)-th powersum symmetric function).

The \(n\)-th Frobenius operator is also called the \(n\)-th Frobenius endomorphism. It is not related to the Frobenius map which connects the ring of symmetric functions with the representation theory of the symmetric group.

The \(n\)-th Frobenius operator is also the \(n\)-th Adams operator of the \(\Lambda\)-ring of symmetric functions over the integers.

The \(n\)-th Frobenius operator can also be described via plethysm: Every symmetric function \(P\) satisfies \(f_n(P) = p_n \circ P = P \circ p_n\), where \(p_n\) is the \(n\)-th powersum symmetric function, and \(\circ\) denotes (outer) plethysm.

INPUT:

• \(n\) – a positive integer
OUTPUT:

The result of applying the \(n\)-th Frobenius operator (on the ring of symmetric functions) to \(\self\).

EXAMPLES:

\[
\begin{align*}
\text{sage: Sym} &= \text{SymmetricFunctions}(\mathbb{Z}) \\
\text{sage: p} &= \text{Sym.p}() \\
\text{sage: h} &= \text{Sym.h}() \\
\text{sage: s} &= \text{Sym.s}() \\
\text{sage: m} &= \text{Sym.m}() \\
\text{sage: m[4,2,1].frobenius(3)} &= m[12, 6, 3] \\
\text{sage: p[4,2,1].frobenius(3)} &= p[12, 6, 3] \\
\end{align*}
\]

The Frobenius endomorphisms are multiplicative:

\[
\begin{align*}
\text{sage: all( all( s(lam).frobenius(3) * s(mu).frobenius(3) # long time } \\
\text{.....:} &= (s(lam) * s(mu)).frobenius(3) \\
\text{.....:} \quad \text{for mu in Partitions(3) ) } \\
\text{.....:} \quad \text{for lam in Partitions(3) ) } \\
\text{True}
\end{align*}
\]

\[
\begin{align*}
\text{sage: all( all( m(lam).frobenius(2) * m(mu).frobenius(2) } \\
\text{.....:} &= (m(lam) * m(mu)).frobenius(2) \\
\text{.....:} \quad \text{for mu in Partitions(4) ) } \\
\text{.....:} \quad \text{for lam in Partitions(4) ) } \\
\text{True}
\end{align*}
\]

\[
\begin{align*}
\text{sage: all( all( p(lam).frobenius(2) * p(mu).frobenius(2) } \\
\text{.....:} &= (p(lam) * p(mu)).frobenius(2) \\
\text{.....:} \quad \text{for mu in Partitions(3) ) } \\
\text{.....:} \quad \text{for lam in Partitions(4) ) } \\
\text{True}
\end{align*}
\]

Being Hopf algebra endomorphisms, the Frobenius operators commute with the antipode:

\[
\begin{align*}
\text{sage: all( p(lam).frobenius(4).antipode() } \\
\text{.....:} &= p(lam).antipode().frobenius(4) \\
\text{.....:} \quad \text{for lam in Partitions(3) ) } \\
\text{True}
\end{align*}
\]

Testing the \(f_n(P) = p_n \circ P = P \circ p_n\) equality (over \(\mathbb{Q}\), since plethysm is currently not defined over \(\mathbb{Z}\) in Sage):

\[
\begin{align*}
\text{sage: Sym} &= \text{SymmetricFunctions}(\mathbb{Q}) \\
\text{sage: s} &= \text{Sym.s}() \\
\text{sage: p} &= \text{Sym.p}() \\
\text{sage: all( s(lam).frobenius(3) == s(lam).plethysm(p[3]) } \\
\text{.....:} &= s(p[3].plethysm(s(lam))) \\
\text{.....:} \quad \text{for lam in Partitions(4) ) } \\
\text{True}
\end{align*}
\]
By Exercise 7.61 in Stanley’s EC2 [STA] (see the errata on his website), $f_n(h_m)$ is a linear combination of Schur polynomials (of straight shapes) using coefficients 0, 1 and $-1$ only; moreover, all partitions whose Schur polynomials occur with coefficient $\neq 0$ in this combination have empty $n$-cores. Let us check this on examples:

```
sage: all(all( all( (coeff == -1 or coeff == 1) ....: and lam.core(n) == Partition([]) ....: for lam, coeff in s([m]).frobenius(n) ) ....: for n in range(2, 4) ) ....: for m in range(4) )
True
```

See also:

`plethysm()`

Todo: This method is fast on the monomial and the powersum bases, while all other bases get converted to the monomial basis. For most bases, this is probably the quickest way to do, but at least the Schur basis should have a better option. (Quoting from Stanley’s EC2 [STA]: “D. G. Duncan, J. London Math. Soc. 27 (1952), 235-236, or Y. M. Chen, A. M. Garsia, and J. B. Remmel, Contemp. Math. 34 (1984), 109-153”.)

**hl_creation_operator**(nu, *t=None*)

This is the vertex operator that generalizes Jing’s operator.

It is a linear operator that raises the degree by $|\nu|$. This creation operator is a $t$-analogue of multiplication by $s(\nu)$.

See also:

Proposition 5 in [SZ2001].

INPUT:

- nu – a partition or a list of integers
- $t$ – (default: None, in which case $t$ is used) an element of the base ring

REFERENCES:

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ['t']).s()
sage: s([2]).hl_creation_operator([3,2])
s[3, 2, 2] + t*s[3, 3, 1] + t*s[4, 2, 1] + t^2*s[4, 3] + t^2*s[5, 2]
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLQp = Sym.hall_littlewood().Qp()
sage: s = Sym.s()
sage: HLQp(s([2])).hl_creation_operator([2]).hl_creation_operator([3])
HLQp[3, 2, 2]
sage: s([2,2]).hl_creation_operator([2,1])
t^2*s[2, 2, 2, 1] + t^2*s[3, 2, 1, 1] + t^3*s[3, 3, 1] + t^3*s[4, 2, 1] + t^4*s[4, 3]
sage: s([1]).hl_creation_operator([2,1,1])
s[2, 1, 1]
sage: s(0).hl_creation_operator([2,1,1])
0
```

(continues on next page)
inner_plethysm(x)
Return the inner plethysm of self with x.

Whenever \( R \) is a \( \mathbb{Q} \)-algebra, and \( f \) and \( g \) are two symmetric functions over \( R \) such that the constant term of \( f \) is zero, the inner plethysm of \( f \) with \( g \) is a symmetric function over \( R \), and the degree of this symmetric function is the same as the degree of \( g \). We will denote the inner plethysm of \( f \) with \( g \) by \( f \{ g \} \) (in contrast to the notation of outer plethysm which is generally denoted \( f[g] \)); in Sage syntax, it is \( f \cdot \text{inner_plethysm}(g) \).

First we describe the axiomatic definition of the operation; see below for a representation-theoretic interpretation. In the following equations, we denote the outer product (i.e., the standard product on the ring of symmetric functions, \( \text{product()} \)) by \( \cdot \) and the Kronecker product (\( \text{itensor()} \)) by \( * \).

\[
(f + g)\{h\} = f\{h\} + g\{h\}
\]
\[
(f \cdot g)\{h\} = (f\{h\}) * (g\{h\})
\]
\[
p_k\{f + g\} = p_k\{f\} + p_k\{g\}
\]

where \( p_k \) is the \( k \)-th power-sum symmetric function for every \( k > 0 \).

Let \( \sigma \) be a permutation of cycle type \( \mu \) and let \( \mu^k \) be the cycle type of \( \sigma^k \). Then,

\[
p_k\{p_{\mu}/z_\mu\} = \sum_{\nu: \nu^k = \mu} p_\nu/z_\nu
\]

Since \( (p_{\mu}/z_\mu)_\mu \) is a basis for the symmetric functions, these four formulas define the symmetric function operation \( f\{g\} \) for any symmetric functions \( f \) and \( g \) (where \( f \) has constant term 0) by expanding \( f \) in the power sum basis and \( g \) in the dual basis \( p_{\mu}/z_\mu \).

See also:
\text{itensor()}, \text{partition_power()}, \text{plethysm()}

This operation admits a representation-theoretic interpretation in the case where \( f \) is a Schur function \( s_\lambda \) and \( g \) is a homogeneous degree \( n \) symmetric function with nonnegative integral coefficients in the Schur basis. The symmetric function \( f\{g\} \) is the Frobenius image of the \( S_n \)-representation constructed as follows.

The assumptions on \( g \) imply that \( g \) is the Frobenius image of a representation \( \rho \) of the symmetric group \( S_n \):

\[
\rho : S_n \to GL_N.
\]
If the degree $N$ of this representation is greater than or equal to the number of parts of $\lambda$, then $f$, which denotes $s_\lambda$, corresponds to the character of some irreducible $GL_N$-representation, say

$$\sigma : GL_N \rightarrow GL_M.$$ 

The composition $\sigma \circ \rho : S_n \rightarrow GL_M$ is a representation of $S_n$ whose Frobenius image is precisely $f\{g\}$. If $N$ is less than the number of parts of $\lambda$, then $f\{g\}$ is 0 by definition.

When $f$ is a symmetric function with constant term $\neq 0$, the inner plethysm $f\{g\}$ isn’t well-defined in the ring of symmetric functions. Indeed, it is not clear how to define $1\{g\}$. The most sensible way to get around this probably is defining it as the infinite sum $h_0 + h_1 + h_2 + \cdots$ (where $h_i$ means the $i$-th complete homogeneous symmetric function) in the completion of this ring with respect to its grading. This is how [SchaThi1994] defines $1\{g\}$. The present method, however, sets it to be the sum of $h_i$ over all $i$ for which the $i$-th homogeneous component of $g$ is nonzero. This is rather a hack than a reasonable definition. Use with caution!

**Note:** If a symmetric function $g$ is written in the form $g = g_0 + g_1 + g_2 + \cdots$ with each $g_i$ homogeneous of degree $i$, then $f\{g\} = f\{g_0\} + f\{g_1\} + f\{g_2\} + \cdots$ for every $f$ with constant term 0. But in general, inner plethysm is not linear in the second variable.

**REFERENCES:**

**INPUT:**

- $x$ – element of the ring of symmetric functions over the same base ring as `self`

**OUTPUT:**

- an element of symmetric functions in the parent of `self`

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: p = Sym.power()
sage: h = Sym.complete()
sage: s([2,1]).inner_plethysm(s([1,1,1]))
0
sage: s([2]).inner_plethysm(s([2,1]))
[2, 1] + [3]
sage: s([1,1]).inner_plethysm(s([2,1]))
[1, 1, 1]
sage: s([2,1]).inner_tensor(s([2,1]))
[1, 1, 1] + [2, 1] + [3]
```

```python
sage: f = s([2,1]) + 2*s([3,1])
sage: f.itensor(f)
sage: s( h([1,1]).inner_plethysm(f) )
```

```python
sage: s([1]).inner_plethysm(s([1,1]) + 2*s([2,1]) + s([3]))
[2] + [3]
sage: [s([1]).inner_plethysm(s([la])) for la in Partitions(4)]
[[4], [4], [4], [4], [4]]
```

(continues on next page)
inner_tensor(x)

Return the internal (tensor) product of self and x in the basis of self.

The internal tensor product can be defined as the linear extension of the definition on power sums \( p_\lambda \star p_\mu = \delta_{\lambda,\mu} z_\lambda p_\lambda \), where \( z_\lambda = (1^{r_1} 2^{r_2} \cdots) \) for \( \lambda = (1^{r_1} 2^{r_2} \cdots) \) and where \( \star \) denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

Note: The internal product is sometimes referred to as “inner product” in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see scalar()).

INPUT:

• x – element of the ring of symmetric functions over the same base ring as self

OUTPUT:

• the internal product of self with x (an element of the ring of symmetric functions in the same basis as self)

The methods itensor(), internal_product(), kronecker_product(), inner_tensor() are all synonyms.

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.itensor(c)
```
There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function $f$ of degree $n$ with the $n$-th complete homogeneous symmetric function $h[n]$ (a.k.a. s[n]) is $f$:

```
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```

The Kronecker product of a Schur function $s_{\lambda}$ with the $n$-th elementary symmetric function $e[n]$, where $n = |\lambda|$, is $s_{\lambda'}$ (where $\lambda'$ is the conjugate partition of $\lambda$):

```
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

The Kronecker product is commutative:

```
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in Partitions(4) ) for p in Partitions(4) )
True
```

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Non-commutative symmetric functions”, arXiv hep-th/9407124, for $r = 2$:

```
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w):
    # computes $\mu ((u \otimes v) \ast \Delta(w))$ with
    # * meaning Kronecker product and $\mu$ meaning
    # the usual multiplication.
    result = w.parent().zero()
    for partition_pair, coeff in w.coproduct():
        result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.
        parent()(v).itensor(partition_pair[1])
```

(continues on next page)
....: return result

sage: all( all( all( tensor_copr(e[u], s[v], m[w])
....: == (e[u] * s[v]).itensor(m[w])
....: for w in Partitions(5) )
....: for v in Partitions(2) )
....: for u in Partitions(3) )
True

Some examples from Briand, Orellana, Rosas, “The stability of the Kronecker products of Schur functions.”
arXiv 0907.4652:

sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,2].itensor(s[2,2])
s[1, 1, 1, 1] + s[2, 2] + s[4]
sage: s[3,2].itensor(s[3,2])
sage: s[4,2].itensor(s[4,2])
˓→s[6]

An example from p. 220 of Thibon, “Hopf algebras of symmetric functions and tensor products of symmetric group representations”, International Journal of Algebra and Computation, 1991:

sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a $\mathbb{Q}$-algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over $\mathbb{Q}$ (using the corresponding_basis_over hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).

```python
internal_coproduct()
```

Return the inner coproduct of self in the basis of self.

The inner coproduct (also known as the Kronecker coproduct, as the internal coproduct, or as the second comultiplication on the ring of symmetric functions) is a ring homomorphism $\Delta^\times$ from the ring of symmetric functions to the tensor product (over the base ring) of this ring with itself. It is uniquely characterized by the formula

$$
\Delta^\times(h_n) = \sum_{\lambda \vdash n} s_\lambda \otimes s_\lambda = \sum_{\lambda \vdash n} h_\lambda \otimes m_\lambda = \sum_{\lambda \vdash n} m_\lambda \otimes h_\lambda,
$$

where $\lambda \vdash n$ means $\lambda$ is a partition of $n$, and $n$ is any nonnegative integer. It also satisfies

$$
\Delta^\times(p_n) = p_n \otimes p_n
$$

for any positive integer $n$. If the base ring is a $\mathbb{Q}$-algebra, it also satisfies

$$
\Delta^\times(h_n) = \sum_{\lambda \vdash n} z_\lambda^{-1} p_\lambda \otimes p_\lambda,
$$
where
\[
z_\lambda = \prod_{i=1}^{\infty} i^{m_i(\lambda)} m_i(\lambda)!
\]
with \(m_i(\lambda)\) meaning the number of appearances of \(i\) in \(\lambda\) (see \(\text{zee}()\)).

The method \texttt{kronecker_coproduct()} is a synonym of \texttt{internal_coproduct()}. EXAMPLES:

```python
sage: s = SymmetricFunctions(ZZ).s()
sage: a = s([2,1])
sage: a.internal_coproduct()

sage: e = SymmetricFunctions(QQ).e()
sage: b = e([2])
sage: b.internal_coproduct()
```

The internal coproduct is adjoint to the internal product with respect to the Hall inner product: Any three symmetric functions \(f, g\) and \(h\) satisfy
\[
\langle f * g, h \rangle = \sum_i \langle f, h'_i \rangle \langle g, h''_i \rangle,
\]
where we write \(\Delta \times (h_n)\) as
\[
\sum_i h'_i \otimes h''_i.
\]
Let us check this in degree 4:

```python
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_incorp(f, g, h):
   # computes \(\sum_i \left< f, h'_i \right> \left< g, h''_i \right>\)
   result = h.base_ring().zero()
   for partition_pair, coeff in h.internal_coproduct():
       result += coeff * h.parent()(f).scalar(partition_pair[0]) * h.parent()(g).scalar(partition_pair[1])
   return result
sage: all( all( all( tensor_incorp(e[u], s[v], m[w]) == (e[u].itensor(s[v])).scalar(m[w])) for w in Partitions(n) ) for v in Partitions(2) ) for u in Partitions(3) )
True
```

Let us check the formulas for \(\Delta \times (h_n)\) and \(\Delta \times (p_n)\) given in the description of this method:

```python
sage: e = SymmetricFunctions(QQ).e()
sage: p = SymmetricFunctions(QQ).p()
sage: h = SymmetricFunctions(QQ).h()
sage: s = SymmetricFunctions(QQ).s()
sage: all( (h([n])).internal_coproduct() == sum([tensor([s(lam), s(lam)]) for lam in Partitions(n)]) for n in range(6) )
True
```

(continues on next page)
True

**internal_product(x)**

Return the internal (tensor) product of `self` and `x` in the basis of `self`.

The internal tensor product can be defined as the linear extension of the definition on power sums \( p_{\lambda} \ast p_{\mu} = \delta_{\lambda,\mu} z_{\lambda} p_{\lambda} \), where \( z_{\lambda} = (1^{r_1} r_1!)(2^{r_2} r_2! \cdots \) for \( \lambda = (1^{r_1} 2^{r_2} \cdots) \) and where \( \ast \) denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

**Note:** The internal product is sometimes referred to as “inner product” in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see `scalar()`).

**INPUT:**
- `x` – element of the ring of symmetric functions over the same base ring as `self`

**OUTPUT:**
- the internal product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

The methods `itensor()`, `internal_product()`, `kronecker_product()`, `inner_tensor()` are all synonyms.

**EXAMPLES:**

```python
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.itensor(c)
```

There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function \( f \) of degree \( n \) with the \( n \)-th complete homogeneous symmetric function \( h[n] \) (a.k.a. \( s[n] \)) is \( f \):

```python
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```
The Kronecker product of a Schur function $s_\lambda$ with the $n$-th elementary symmetric function $e[n]$, where $n = |\lambda|$, is $s_{\lambda'}$ (where $\lambda'$ is the conjugate partition of $\lambda$):

```
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

The Kronecker product is commutative:

```
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in Partitions(4) ) for p in Partitions(4) )
True
```

```
sage: F = FractionField(QQ['q','t'])
sage: mq = SymmetricFunctions(F).macdonald().Q()
sage: mh = SymmetricFunctions(F).macdonald().H()
sage: all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p)) for r in Partitions(4) ) for p in Partitions(3) )
True
```

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Non-commutative symmetric functions”, arXiv hep-th/9407124, for $r = 2$:

```
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w):
    # computes $\mu ((u \otimes v) \Delta(w))$ with
    # $\Delta$ meaning Kronecker product and $\mu$ meaning usual
    # multiplication.
    result = w.parent().zero()
    for partition_pair, coeff in w.coproduct():
        result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.parent()(v).itensor(partition_pair[1])
    return result
sage: all( all( all( tensor_copr(e[u], s[v], m[w]) == (e[u] * s[v]).itensor(m[w]) for w in Partitions(5) ) for v in Partitions(2) ) for u in Partitions(3) )
True
```

Some examples from Briand, Orellana, Rosas, “The stability of the Kronecker products of Schur functions.” arXiv 0907.4652:

```
sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,2].itensor(s[2,2])
s[1, 1, 1, 1] + s[2, 2] + s[4]
```

(continues on next page)
An example from p. 220 of Thibon, “Hopf algebras of symmetric functions and tensor products of symmetric group representations”, International Journal of Algebra and Computation, 1991:

```python
sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]
```

**Note:** The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a $\mathbb{Q}$-algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over $\mathbb{Q}$ (using the `corresponding_basis_over` hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).

**is_schur_positive()**

Return True if and only if self is Schur positive.

If $s$ is the space of Schur functions over self’s base ring, then this is the same as `self._is_positive(s)`.

**EXAMPLES:**

```python
sage: QQx = QQ['x']
sage: s = SymmetricFunctions(QQx).s()
sage: x = QQx.gen()
sage: a = (1+x)*s([2,1])
sage: a.is_schur_positive()
True
sage: a = (1-x)*s([2,1])
sage: a.is_schur_positive()
False
```

**itensor()**

Return the internal (tensor) product of self and x in the basis of self.

The internal tensor product can be defined as the linear extension of the definition on power sums $p_\lambda \ast p_\mu =$
\( \delta_{\lambda, \mu} z_\lambda p_\lambda \), where \( z_\lambda = (1^{r_1} r_1!)(2^{r_2} r_2!) \cdots \) for \( \lambda = (1^{r_1} 2^{r_2} \cdots) \) and where \( \ast \) denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

**Note:** The internal product is sometimes referred to as “inner product” in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see `scalar()`).

**INPUT:**

- x – element of the ring of symmetric functions over the same base ring as self

**OUTPUT:**

- the internal product of self with x (an element of the ring of symmetric functions in the same basis as self)

The methods `itensor()`, `internal_product()`, `kronecker_product()`, `inner_tensor()` are all synonyms.

**EXAMPLES:**

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
sage: c = s([3,2,1])
sage: c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2] + 4*s[3, 2, 1, 1] + 5*s[3, 3, 1] + 2*s[4, 2, 1, 1] + 3*s[4, 3, 1] + 2*s[5, 1, 1, 1] + s[6, 1]
```

There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function \( f \) of degree \( n \) with the \( n \)-th complete homogeneous symmetric function \( h[n] \) (a.k.a. \( s[n] \)) is \( f \):  

```
sage: h = SymmetricFunctions(ZZ).h()  
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```

The Kronecker product of a Schur function \( s_\lambda \) with the \( n \)-th elementary symmetric function \( e[n] \), where \( n = |\lambda| \), is \( s_\lambda' \) (where \( \lambda' \) is the conjugate partition of \( \lambda \)):

```
sage: F = CyclotomicField(12)  
sage: s = SymmetricFunctions(F).s()  
sage: e = SymmetricFunctions(F).e()  
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

The Kronecker product is commutative:
Combinatorics, Release 9.7

sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p))  
for q in Partitions(4)  
for p in Partitions(4) ) 
True

sage: F = FractionField(QQ['q','t'])
sage: mq = SymmetricFunctions(F).macdonald().Q()
sage: mh = SymmetricFunctions(F).macdonald().H()
sage: all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p))  
# long time  
for r in Partitions(4) )  
for p in Partitions(3) )
True

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Non-commutative symmetric functions”, arXiv hep-th/9407124, for \( r = 2 \):

sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w):
# computes \( \mu ((u \otimes v) \Delta(w)) \) with
# * meaning Kronecker product and \( \mu \) meaning
# usual multiplication.
# the
.....: result = w.parent().zero()
.....: for partition_pair, coeff in w.coproduct():
.....:     result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.  
#parent()(v).itensor(partition_pair[1])
.....: return result
sage: all( all( all( tensor_copr(e[u], s[v], m[w])  
# long time  
== (e[u] * s[v]).itensor(m[w])  
for w in Partitions(5) )  
for v in Partitions(2) )  
for u in Partitions(3) )
True

Some examples from Briand, Orellana, Rosas, “The stability of the Kronecker products of Schur functions.”
arXiv 0907.4652:

sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,2].itensor(s[2,2])
s[1, 1, 1, 1] + s[2, 2] + s[4]
sage: s[3,2].itensor(s[3,2])
sage: s[4,2].itensor(s[4,2])
  s[6]

An example from p. 220 of Thibon, “Hopf algebras of symmetric functions and tensor products of symmetric group representations”, International Journal of Algebra and Computation, 1991:

sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a $\mathbb{Q}$-algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over $\mathbb{Q}$ (using the corresponding_basis_over hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).

**kronecker_coproduct()**

Return the inner coproduct of `self` in the basis of `self`.

The inner coproduct (also known as the Kronecker coproduct, as the internal coproduct, or as the second comultiplication on the ring of symmetric functions) is a ring homomorphism $\Delta^\times$ from the ring of symmetric functions to the tensor product (over the base ring) of this ring with itself. It is uniquely characterized by the formula

$$\Delta^\times(h_n) = \sum_{\lambda \vdash n} s_\lambda \otimes s_\lambda = \sum_{\lambda \vdash n} h_\lambda \otimes m_\lambda = \sum_{\lambda \vdash n} m_\lambda \otimes h_\lambda,$$

where $\lambda \vdash n$ means $\lambda$ is a partition of $n$, and $n$ is any nonnegative integer. It also satisfies

$$\Delta^\times(p_n) = p_n \otimes p_n$$

for any positive integer $n$. If the base ring is a $\mathbb{Q}$-algebra, it also satisfies

$$\Delta^\times(h_n) = \sum_{\lambda \vdash n} z_\lambda^{-1}p_\lambda \otimes p_\lambda,$$

where

$$z_\lambda = \prod_{i=1}^{\infty} i^{m_i(\lambda)}m_i(\lambda)!$$

with $m_i(\lambda)$ meaning the number of appearances of $i$ in $\lambda$ (see `zee()`).

The method `kronecker_coproduct()` is a synonym of `internal_coproduct()`.

**EXAMPLES:**

```
sage: s = SymmetricFunctions(ZZ).s()
sage: a = s([2,1])
sage: a.internal_coproduct()

sage: e = SymmetricFunctions(QQ).e()
sage: b = e([2])
sage: b.internal_coproduct()
```

The internal coproduct is adjoint to the internal product with respect to the Hall inner product: Any three symmetric functions $f$, $g$ and $h$ satisfy $\langle f \ast g, h \rangle = \sum_i \langle f, h'_i \rangle \langle g, h''_i \rangle$, where we write $\Delta^\times(h)$ as $\sum_i h'_i \otimes h''_i$. Let us check this in degree 4:
Let us check the formulas for $\Delta^\times(h_n)$ and $\Delta^\times(p_n)$ given in the description of this method:

```python
sage: e = SymmetricFunctions(QQ).e()
sage: p = SymmetricFunctions(QQ).p()
sage: h = SymmetricFunctions(QQ).h()
sage: s = SymmetricFunctions(QQ).s()
sage: all( h([n]).internal_coproduct() == sum([factorial(n) * h([n]).internal_coproduct()] for n in range(6) ) )
True
sage: all( h([n]).internal_coproduct() == sum([factorial(n) * h([n]).internal_coproduct()] for n in range(6) ) )
True
sage: all( h([n]).internal_coproduct() == sum([factorial(n) * h([n]).internal_coproduct()] for n in range(6) ) )
True
```

**kronecker_product**

Return the internal (tensor) product of self and x in the basis of self.

The internal tensor product can be defined as the linear extension of the definition on power sums $p_\lambda * p_\mu = \delta_{\lambda,\mu} z_\lambda p_\lambda$, where $z_\lambda = (1^{r_1} r_1!) (2^{r_2} r_2!) \cdots$ for $\lambda = (1^{r_1} 2^{r_2} \cdots)$ and where $*$ denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

**Note:** The internal product is sometimes referred to as “inner product” in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see scalar()).

**INPUT:**
• $x$ – element of the ring of symmetric functions over the same base ring as $\text{self}$

**OUTPUT:**

• the internal product of $\text{self}$ with $x$ (an element of the ring of symmetric functions in the same basis as $\text{self}$)

The methods `itensor()`, `internal_product()`, `kronecker_product()`, `inner_tensor()` are all synonyms.

**EXAMPLES:**

```python
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.itensor(c)
```

There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function $f$ of degree $n$ with the $n$-th complete homogeneous symmetric function $h[n]$ (a.k.a. $s[n]$) is $f$:

```python
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```

The Kronecker product of a Schur function $s_\lambda$ with the $n$-th elementary symmetric function $e[n]$, where $n = |\lambda|$, is $s_{\lambda'}$ (where $\lambda'$ is the conjugate partition of $\lambda$):

```python
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

The Kronecker product is commutative:

```python
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in Partitions(4) )
    for p in Partitions(4) )
True
```

```python
sage: F = FractionField(QQ['q','t'])
sage: mq = SymmetricFunctions(F).macdonald().Q()
sage: mh = SymmetricFunctions(F).macdonald().H()
sage: all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p)) for r in Partitions(4) )
    for p in Partitions(4) )
(continues on next page)
```
Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Non-commutative symmetric functions”, arXiv hep-th/9407124, for \( r = 2 \):

```python
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w):
    # computes \( \mu ((u \otimes v) * \Delta(w)) \) with
    # * meaning Kronecker product and \( \mu \) meaning,
    # the
    result = w.parent().zero()
    for partition_pair, coeff in w.coproduct():
        result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.
        parent()(v).itensor(partition_pair[1])
    return result
sage: all( all( all( tensor_copr(e[u], s[v], m[w])
    # long time == (e[u] * s[v]).itensor(m[w])
    # for w in Partitions(5) )
    # for v in Partitions(2) )
    # for u in Partitions(3) )
True
```

Some examples from Briand, Orellana, Rosas, “The stability of the Kronecker products of Schur functions.” arXiv 0907.4652:

```python
sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]
sage: s[3,2].itensor(s[3,2])
sage: s[4,2].itensor(s[4,2])
```

An example from p. 220 of Thibon, “Hopf algebras of symmetric functions and tensor products of symmetric group representations”, International Journal of Algebra and Computation, 1991:

```python
sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]
```

**Note:** The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a \( \mathbb{Q} \)-algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over \( \mathbb{Q} \) (using the corresponding_basis_over hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).
**left_padded_kronecker_product(x)**

Return the left-padded Kronecker product of `self` and `x` in the basis of `self`.

The left-padded Kronecker product is a bilinear map mapping two symmetric functions to another, not necessarily preserving degree. It can be defined as follows: Let $\ast$ denote the Kronecker product (``itensor()``) on the space of symmetric functions. For any partitions $\alpha$, $\beta$, $\gamma$, let $g_{\alpha,\beta}^{\gamma}$ denote the coefficient of the complete homogeneous symmetric function $h\gamma$ in the Kronecker product $h\alpha \ast h\beta$. For every partition $\lambda = (\lambda_1, \lambda_2, \lambda_3, \ldots)$ and every integer $n > |\lambda| + \lambda_1$, let $\lambda[n]$ denote the $n$-completion of $\lambda$ (this is the partition $(n - |\lambda|, \lambda_1, \lambda_2, \lambda_3, \ldots)$; see `t_completion()`). Then, for any partitions $\alpha$ and $\beta$ and every integer $n \geq |\alpha| + |\beta| + \alpha_1 + \beta_1$, we can write the Kronecker product $h\alpha[n] \ast h\beta[n]$ in the form

$$h\alpha[n] \ast h\beta[n] = \sum_{\gamma} g_{\alpha[n],\beta[n]}^{\gamma} h\gamma[n]$$

with $\gamma$ ranging over all partitions. The coefficients $g_{\alpha[n],\beta[n]}^{\gamma}$ are independent on $n$. These coefficients $g_{\alpha[n],\beta[n]}^{\gamma}$ are denoted by $\overline{g}_{\alpha,\beta}^{\gamma}$, and the symmetric function

$$\sum_{\gamma} \overline{g}_{\alpha,\beta}^{\gamma} h\gamma$$

is said to be the **left-padded Kronecker product** of $h\alpha$ and $h\beta$. By bilinearity, this extends to a definition of a left-padded Kronecker product of any two symmetric functions.

This notion of left-padded Kronecker product can be lifted to the non-commutative symmetric functions (`left_padded_kronecker_product()`).

**Warning:** Do not mistake this product for the reduced Kronecker product (`reduced_kronecker_product()`), which uses the Schur functions instead of the complete homogeneous functions in its definition.

**INPUT:**

- `x` – element of the ring of symmetric functions over the same base ring as `self`

**OUTPUT:**

- the left-padded Kronecker product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

**EXAMPLES:**

```sage
code: Sym = SymmetricFunctions(QQ)  
sage: h = Sym.h()  
sage: h[2,1].left_padded_kronecker_product(h[3])  
h[1, 1, 1] + h[2, 1] + h[2, 1, 1] + h[2, 1, 1, 1] + h[2, 2, 1] + h[3, 2, 1]  
sage: h[2,1].left_padded_kronecker_product(h[1])  
h[1, 1, 1] + h[2, 1] + h[2, 1, 1]  
sage: h[1].left_padded_kronecker_product(h[2,1])  
h[1, 1, 1] + h[2, 1] + h[2, 1, 1]  
sage: h[1,1].left_padded_kronecker_product(h[2])  
h[1, 1] + 2*h[1, 1, 1] + h[2, 1, 1]  
sage: h[1].left_padded_kronecker_product(h[2,1,1])  
h[1, 1, 1] + 2*h[2, 1, 1] + h[2, 1, 1, 1]  
sage: h[2].left_padded_kronecker_product(h[3])  
h[2, 1] + h[2, 1, 1] + h[3, 2]  
```
Taking the left-padded Kronecker product with \(1 = h_\emptyset\) is the identity map on the ring of symmetric functions:

```python
sage: all( h[Partition([])].left_padded_kronecker_product(h[lam])
       == h[lam] for i in range(4)
       for lam in Partitions(i) )
True
```

Here is a rule for the left-padded Kronecker product of \(h_1\) (this is the same as \(h_{(1)}\)) with any complete homogeneous function: Let \(\lambda\) be a partition. Then, the left-padded Kronecker product of \(h_1\) and \(h_\lambda\) is \(\sum_\mu a_\mu h_\mu\), where the sum runs over all partitions \(\mu\), and the coefficient \(a_\mu\) is defined as the number of ways to obtain \(\mu\) from \(\lambda\) by one of the following two operations:

- Insert a 1 into \(\lambda\).
- Subtract 1 from one of the entries of \(\lambda\) (and remove the entry if it thus becomes 0), and insert a 1 into \(\lambda\).

We check this for partitions of size \(\leq 4\):

```python
sage: def mults1(I):
    # Left-padded Kronecker multiplication by h[1].
    res = h[I[:]] + [1]
    for k in range(len(I)):
        I2 = I[:]
        if I2[k] == 1:
            I2 = I2[:k] + I2[k+1:]
        else:
            I2[k] -= 1
        res += h[sorted(I2 + [1], reverse=True)]
    return res
sage: all( mults1(I) == h[I].left_padded_kronecker_product(h[1])
       == h[I].left_padded_kronecker_product(h[I])
       for i in range(5) for I in Partitions(i) )
True
```

The left-padded Kronecker product is commutative:

```python
sage: all( h[lam].left_padded_kronecker_product(h[mu])
       == h[mu].left_padded_kronecker_product(h[lam])
       for lam in Partitions(3) for mu in Partitions(3) )
True
```

`nabla(q=None, t=None, power=1)`
Return the value of the nabla operator applied to `self`.

The eigenvectors of the nabla operator are the Macdonald polynomials in the Ht basis.

If the parameter `power` is an integer then it calculates nabla to that integer. The default value of `power` is 1.

**INPUT:**
- `q`, `t` – optional parameters (default: `None`, in which case `q` and `t` are used)
- `power` – (default: 1) an integer indicating how many times to apply the operator \(\nabla\). Negative values of `power` indicate powers of \(\nabla^{-1}\).

**EXAMPLES:**
omega()

Return the image of self under the omega automorphism.

The **omega automorphism** is defined to be the unique algebra endomorphism \( \omega \) of the ring of symmetric functions that satisfies \( \omega(e_k) = h_k \) for all positive integers \( k \) (where \( e_k \) stands for the \( k \)-th elementary symmetric function, and \( h_k \) stands for the \( k \)-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the **omega involution**. It sends the power-sum symmetric function \( p_k \) to \((-1)^{k-1} p_k \) for every positive integer \( k \).

The images of some bases under the omega automorphism are given by

\[
\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)} p_\lambda, \quad \omega(s_\lambda) = s_\lambda',
\]

where \( \lambda \) is any partition, where \( \ell(\lambda) \) denotes the length (\( \text{length}() \)) of the partition \( \lambda \), where \( \lambda' \) denotes the conjugate partition (\( \text{conjugate}() \)) of \( \lambda \), and where the usual notations for bases are used (\( e = \text{elementary} \), \( h = \text{complete homogeneous} \), \( p = \text{powersum} \), \( s = \text{Schur} \)).

The default implementation converts to the Schur basis, then performs the automorphism and changes back.

**omega_involution()** is a synonym for the **omega()** method.

**EXAMPLES:**

```
sage: J = SymmetricFunctions(QQ).jack(t=1).P()
sage: a = J([2,1]) + J([1,1,1])
sage: a.omega()
sage: J(0).omega()
0
sage: J(1).omega()
JackP[
```

The forgotten symmetric functions are the images of the monomial symmetric functions under omega:
sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.m()
sage: f = Sym.f()
sage: all( f(lam) == m(lam).omega() for lam in Partitions(3) )
True
sage: all( m(lam) == f(lam).omega() for lam in Partitions(3) )
True

**omega_involution()**

Return the image of self under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism \( \omega \) of the ring of symmetric functions that satisfies \( \omega(e_k) = h_k \) for all positive integers \( k \) (where \( e_k \) stands for the \( k \)-th elementary symmetric function, and \( h_k \) stands for the \( k \)-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function \( p_k \) to \((-1)^{k-1}p_k \) for every positive integer \( k \).

The images of some bases under the omega automorphism are given by

\[
\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},
\]

where \( \lambda \) is any partition, where \( \ell(\lambda) \) denotes the length (\texttt{length()}) of the partition \( \lambda \), where \( \lambda' \) denotes the conjugate partition (\texttt{conjugate()}) of \( \lambda \), and where the usual notations for bases are used (\( e = \text{elementary}, h = \text{complete homogeneous}, p = \text{powersum}, s = \text{Schur} \)).

The default implementation converts to the Schur basis, then performs the automorphism and changes back. \texttt{omega_involution()} is a synonym for the \texttt{omega()} method.

**EXAMPLES:**

```python
sage: J = SymmetricFunctions(QQ).jack(t=1).P()
sage: a = J([2,1]) + J([1,1,1])
sage: a.omega()
sage: J(0).omega()
0
sage: J(1).omega()
JackP[1]
```

The forgotten symmetric functions are the images of the monomial symmetric functions under omega:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.m()
sage: f = Sym.f()
sage: all( f(lam) == m(lam).omega() for lam in Partitions(3) )
True
sage: all( m(lam) == f(lam).omega() for lam in Partitions(3) )
True
```

**omega_qt**

Return the image of self under the \( q, t \)-deformed omega automorphism which sends \( p_k \) to \((-1)^{k-1} \cdot \frac{1-q^k}{1-t^k} \cdot p_k \) for all positive integers \( k \).

In general, this is well-defined outside of the powersum basis only if the base ring is a \( Q \)-algebra.

If \( q = t \), then this is the omega automorphism (\texttt{omega()}).

5.1. Comprehensive Module List 2937
INPUT:

• q, t – parameters (default: None, in which case 'q' and 't' are used)

EXAMPLES:

```python
sage: QQqt = QQ['q,t'].fraction_field()
sage: q,t = QQqt.gens()
sage: p = SymmetricFunctions(QQqt).p()
sage: p[5].omega_qt()
((-q^5+1)/(-t^5+1))*p[5]
sage: p[5].omega_qt(q,t)
((-q^5+1)/(-t^5+1))*p[5]
sage: p([2]).omega_qt(q,t)
((q^2-1)/(-t^2+1))*p[2]
sage: p([2,1]).omega_qt(q,t)
((-q^3+q^2+q-1)/(t^3-t^2-t+1))*p[2, 1]
sage: p([3,2]).omega_qt(5,q)
-(2976/(q^5-q^3-q^2+1))*p[3, 2]
sage: p(0).omega_qt()
0
sage: p(1).omega_qt()
p[]
sage: H = SymmetricFunctions(QQqt).macdonald().H()
sage: H([1,1]).omega_qt()
((2*q^2-2*q*t-2*q+2*t)/(t^3-t^2-t+1))*McdH[1, 1] + ((q-1)/(t-1))*McdH[2]
sage: H([1,1]).omega_qt(q,t)
((2*q^2-2*q*t-2*q+2*t)/(t^3-t^2-t+1))*McdH[1, 1] + ((q-1)/(t-1))*McdH[2]
sage: H([1,1]).omega_qt(t,q)
((t^3-t^2-t+1)/(q^3+q^2+q-1))*McdH[2]
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: S = Sym.macdonald().S()
sage: S([1,1]).omega_qt()
((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdS[1, 1] + ((q^2*t+q*t-q-1)/(-t^3+t^2+t-
˓→1))*McdS[2]
sage: s = Sym.schur()
sage: s(S([1,1]).omega_qt())
s[2]
```

**plethysm(x, include=None, exclude=None)**

Return the outer plethysm of *self* with *x*.

This is implemented only over base rings which are \(\mathbb{Q}\)-algebras. (To compute outer plethysms over general binomial rings, change bases to the fraction field.)

The outer plethysm of \(f\) with \(g\) is commonly denoted by \(f \triangleright g\) or by \(f \circ g\). It is an algebra map in \(f\), but not (generally) in \(g\).

By default, the degree one elements are taken to be the generators for the *self*’s base ring. This setting can be modified by specifying the include and exclude keywords.

INPUT:

• x – a symmetric function over the same base ring as *self*

• include – a list of variables to be treated as degree one elements instead of the default degree one elements

• exclude – a list of variables to be excluded from the default degree one elements
EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: h = Sym.h()
sage: s( h([3])( h([2]) ) )
sage: p = Sym.p()
sage: p([3])( s([2,1]) )
1/3*p[3, 3, 3] - 1/3*p[9]
sage: e = Sym.e()
sage: e([3])( e([2]) )
```

```python
sage: R.<t> = QQ[]
sage: s = SymmetricFunctions(R).s()
sage: a = s([3])
sage: f = t^3*s([2])
sage: a(f)
t^3*s[2, 2, 2] + t^3*s[4, 2] + t^3*s[6]
sage: f(a)
t^3*s[4, 2] + t^3*s[6]
sage: s(0).plethysm(s([1]))
0
sage: s(1).plethysm(s([1]))
s[]
sage: s(1).plethysm(s(0))
s[]
```

Sage also handles plethysm of tensor products of symmetric functions:

```python
sage: X = tensor([s[1], s[[]]])
sage: Y = tensor([s[[]], s[1]])
sage: s[1, 1, 1](X+Y)
```

One can use this to work with symmetric functions in two sets of commuting variables. For example, we verify the Cauchy identities (in degree 5):

```python
sage: m = SymmetricFunctions(QQ).m()
sage: P5 = Partitions(5)
sage: sum(s[mu](X)*s[mu](Y) for mu in P5) == sum(m[mu](X)*h[mu](Y) for mu in P5)
True
sage: sum(s[mu](X)*s[mu().conjugate()](Y) for mu in P5) == sum(m[mu](X)*e[mu](Y) for mu in P5)
True
```

See also:

```
frobenius()
```

5.1. Comprehensive Module List 2939
principal_specialization($n=\infty, q=None$)

Return the principal specialization of a symmetric function.

The principal specialization of order $n$ at $q$ is the ring homomorphism $p_{sn,q}$ from the ring of symmetric functions to another commutative ring $R$ given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \ldots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, $q$ is a given element of $R$, and we assume that the variables of our symmetric functions are $x_1, x_2, x_3, \ldots$. (To be more precise, $p_{sn,q}$ is a $K$-algebra homomorphism, where $K$ is the base ring.) See Section 7.8 of [EnumComb2].

The stable principal specialization at $q$ is the ring homomorphism $p_{s,q}$ from the ring of symmetric functions to another commutative ring $R$ given by $x_i \mapsto q^{i-1}$ for all $i$. This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

INPUT:

- $n$ (default: infinity) – a nonnegative integer or infinity, specifying whether to compute the principal specialization of order $n$ or the stable principal specialization.
- $q$ (default: None) – the value to use for $q$; the default is to create a ring of polynomials in $q$ (or a field of rational functions in $q$) over the given coefficient ring.

EXAMPLES:

```python
sage: m = SymmetricFunctions(QQ).m()
sage: x = m[1,1]
sage: x.principal_specialization(3)
q^3 + q^2 + q
```

By default we return a rational function in $q$. Sometimes it is better to obtain an element of the symbolic ring:

```python
sage: h = SymmetricFunctions(QQ).h()
sage: (h[3]+h[2]).principal_specialization(q=var("q"))
1/((q^2 - 1)*(q - 1)) - 1/((q^3 - 1)*(q^2 - 1)*(q - 1))
```

In case $q$ is in the base ring, it must be passed explicitly:

```python
sage: R = QQ['q,t']
sage: Ht = SymmetricFunctions(R).macdonald().Ht()
sage: Ht[2].principal_specialization()
Traceback (most recent call last):
  ... ValueError: the variable q is in the base ring, pass it explicitly
sage: Ht[2].principal_specialization(q=R("q"))
(q^2 + 1)/(q^3 - q^2 - q + 1)
```

Note that the principal specialization can be obtained as a plethysm:

```python
sage: R = QQ['q'].fraction_field()
sage: s = SymmetricFunctions(R).s()
sage: one = s.one()
sage: q = R("q")
sage: f = s[3,2,2]
sage: f.principal_specialization(q=q) == f(one/(1-q)).coefficient([])
True
```

(continues on next page)
sage: f.principal_specialization(n=4, q=q) == f(one*(1-q^4)/(1-q)).
coefficient([])
True

reduced_kronecker_product(x)
Return the reduced Kronecker product of self and x in the basis of self.

The reduced Kronecker product is a bilinear map mapping two symmetric functions to another, not necessarily preserving degree. It can be defined as follows: Let * denote the Kronecker product (itensor()) on the space of symmetric functions. For any partitions \( \alpha, \beta, \gamma \), let \( g_{\gamma}^{\alpha, \beta} \) denote the coefficient of the Schur function \( s_{\gamma} \) in the Kronecker product \( s_{\alpha} * s_{\beta} \) (this is called a Kronecker coefficient). For every partition \( \lambda = (\lambda_1, \lambda_2, \lambda_3, \ldots) \) and every integer \( n > |\lambda| + 1 \), let \( \lambda[n] \) denote the \( n \)-completion of \( \lambda \) (this is the partition \( (n - |\lambda|, \lambda_1, \lambda_2, \lambda_3, \ldots) \); see t_completion()). Then, Theorem 1.2 of [BOR2009] shows that for any partitions \( \alpha \) and \( \beta \) and every integer \( n \geq |\alpha| + |\beta| + \lambda_1 + \beta_1 \), we can write the Kronecker product \( s_{\alpha[n]} * s_{\beta[n]} \) in the form

\[
s_{\alpha[n]} * s_{\beta[n]} = \sum_{\gamma} g_{\alpha[n], \beta[n]}^{\gamma} s_{\gamma[n]}
\]

with \( \gamma \) ranging over all partitions. The coefficients \( g_{\alpha[n], \beta[n]}^{\gamma} \) are independent on \( n \). These coefficients \( g_{\alpha[n], \beta[n]}^{\gamma} \) are denoted by \( \tilde{g}_{\alpha, \beta}^{\gamma} \), and the symmetric function

\[
\sum_{\gamma} \tilde{g}_{\alpha, \beta}^{\gamma} s_{\gamma}
\]

is said to be the reduced Kronecker product of \( s_{\alpha} \) and \( s_{\beta} \). By bilinearity, this extends to a definition of a reduced Kronecker product of any two symmetric functions.

The definition of the reduced Kronecker product goes back to Murnaghan, and has recently been studied in [BOR2009], [BdVO2012] and other places (our notation \( \tilde{g}_{\alpha, \beta}^{\gamma} \) appears in these two sources).

INPUT:

• x – element of the ring of symmetric functions over the same base ring as self

OUTPUT:

• the reduced Kronecker product of self with x (an element of the ring of symmetric functions in the same basis as self)

EXAMPLES:

The example from page 2 of [BOR2009]:

sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: s[2].reduced_kronecker_product(s[2])

Taking the reduced Kronecker product with 1 = s_{\emptyset} is the identity map on the ring of symmetric functions:

sage: all( s[Partition([])].reduced_kronecker_product(s[lam])
....: == s[lam] for i in range(4)
....: for lam in Partitions(i) )
True
While reduced Kronecker products are hard to compute in general, there is a rule for taking reduced Kronecker products with $s_1$. Namely, for every partition $\lambda$, the reduced Kronecker product of $s_\lambda$ with $s_1$ is $\sum \mu a_\mu s_\mu$, where the sum runs over all partitions $\mu$, and the coefficient $a_\mu$ is defined as the number of ways to obtain $\mu$ from $\lambda$ by one of the following three operations:

- Add an addable cell ($\text{addable\_cells()}$) to $\lambda$.
- Remove a removable cell ($\text{removable\_cells()}$) from $\lambda$.
- First remove a removable cell from $\lambda$, then add an addable cell to the resulting Young diagram.

This is, in fact, Proposition 5.15 of [CO2010] in an elementary wording. We check this for partitions of size $\leq 4$:

```python
sage: def mults1(lam):
    ....: # Reduced Kronecker multiplication by $s[1]$, according
    ....: # to [CO2010]_.
    ....: res = s.zero()
    ....: for mu in lam.up_list():
    ....:     res += s(mu)
    ....: for mu in lam.down_list():
    ....:     res += s(mu)
    ....: for nu in mu.up_list():
    ....:     res += s(nu)
    ....: return res

sage: all( mults1(lam) == s[1].reduced_kronecker_product(s[lam])
    ....:       for i in range(5) for lam in Partitions(i) )
True
```

Here is the example on page 3 of Christian Gutschwager’s arXiv 0912.4411v3:

```python
sage: s[1,1].reduced_kronecker_product(s[2])
```

```python
sage: s[3].reduced_kronecker_product(s[2,1])
```

Todo: This implementation of the reduced Kronecker product is painfully slow.

```
restrict_degree(d, exact=True)
Return the degree d component of self.
INPUT:
• d – positive integer, degree of the terms to be returned
• exact – boolean, if True, returns the terms of degree exactly d, otherwise returns all terms of degree less than or equal to d
OUTPUT:
```
• the homogeneous component of self of degree d

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.restrict_degree(2)
0
sage: z.restrict_degree(1)
s[1]
sage: z.restrict_degree(3)
s[1, 1, 1] + s[2, 1]
sage: z.restrict_degree(3, exact=False)
s[1] + s[1, 1, 1] + s[2, 1]
sage: z.restrict_degree(0)
0
```

`restrict_partition_lengths(l, exact=True)`

Return the terms of self labelled by partitions of length $l$.

INPUT:

• $l$ – nonnegative integer
  • exact – boolean, defaulting to True

OUTPUT:

• if True, returns the terms labelled by partitions of length precisely $l$; otherwise returns all terms labelled by partitions of length less than or equal to $l$

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.restrict_partition_lengths(2)
s[2, 1]
sage: z.restrict_partition_lengths(0)
0
sage: z.restrict_partition_lengths(2, exact = False)
```

`restrict_parts(n)`

Return the terms of self labelled by partitions $\lambda$ with $\lambda_1 \leq n$.

INPUT:

• $n$ – positive integer, to restrict the parts of the partitions of the terms to be returned

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.restrict_parts(2)
s[2, 1]
sage: z.restrict_parts(1)
s[1] + s[1, 1, 1]
```

`sscalar(x, zee=None)`

Return the standard scalar product between self and x.
This is also known as the “Hall inner product” or the “Hall scalar product”.

**INPUT:**

- \( x \) – element of the ring of symmetric functions over the same base ring as \( \text{self} \)
- \( \text{zee} \) – an optional function on partitions giving the value for the scalar product between \( p_\mu \) and \( p_\mu \) (default is to use the standard \( \text{zee}() \) function)

This is the default implementation that converts both \( \text{self} \) and \( x \) into either Schur functions (if \( \text{zee} \) is not specified) or power-sum functions (if \( \text{zee} \) is specified) and performs the scalar product in that basis.

**EXAMPLES:**

```python
sage: e = SymmetricFunctions(QQ).e()
sage: h = SymmetricFunctions(QQ).h()
sage: m = SymmetricFunctions(QQ).m()
sage: p4 = Partitions(4)
sage: matrix([[e(a).scalar(h(b)) for a in p4] for b in p4])
[ 0 0 0 0 1]
[ 0 0 0 1 4]
[ 0 0 1 2 6]
[ 0 1 2 5 12]
[ 1 4 6 12 24]
sage: matrix([[h(a).scalar(e(b)) for a in p4] for b in p4])
[ 0 0 0 0 1]
[ 0 0 0 1 4]
[ 0 0 1 2 6]
[ 0 1 2 5 12]
[ 1 4 6 12 24]
sage: matrix([[m(a).scalar(e(b)) for a in p4] for b in p4])
[-1  2  1 -3  1]
[ 0  1  0 -2  1]
[ 0  0  1 -2  1]
[ 0  0  0 -1  1]
[ 0  0  0  0  1]
sage: matrix([[m(a).scalar(h(b)) for a in p4] for b in p4])
[1  0  0  0  0]
[0  1  0  0  0]
[0  0  1  0  0]
[0  0  0  1  0]
[0  0  0  0  1]
sage: p = SymmetricFunctions(QQ).p()
sage: m(p[3,2]).scalar(p[3,2], zee=lambda mu: 2**mu.length())
4
sage: m(p[3,2]).scalar(p[2,2,1], lambda mu: 1)
0
sage: m[3,2].scalar(h[3,2], zee=lambda mu: 2**mu.length())
2/3
```

\( \text{scalar_hl}(x, t=None) \)

Return the \( t \)-deformed standard Hall-Littlewood scalar product of \( \text{self} \) and \( x \).

**INPUT:**

- \( x \) – element of the ring of symmetric functions over the same base ring as \( \text{self} \)
• \( t \) – parameter (default: \texttt{None}, in which case \( t \) is used)

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: sp = a.scalar_t(a); sp
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
sage: sp.parent()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

**\texttt{scalar_jack}(x, t=None)**

Return the Jack-scalar product between \( \text{self} \) and \( x \).

This scalar product is defined so that the power sum elements \( p_\mu \) are orthogonal and \( \langle p_\mu, p_\nu \rangle = z_\mu t^{\ell(\mu)} \), where \( \ell(\mu) \) denotes the length of \( \mu \).

INPUT:

• \( x \) – element of the ring of symmetric functions over the same base ring as \( \text{self} \)
• \( t \) – an optional parameter (default: \texttt{None} in which case \( t \) is used)

EXAMPLES:

```python
sage: p = SymmetricFunctions(QQ['t']).power()
sage: matrix([[(p(mu).scalar_jack(p(nu)) for nu in Partitions(4)) for mu in Partitions(4)] for mu in Partitions(4)]
[ 4*t  0  0  0  0]
[ 0  3*t^2  0  0  0]
[ 0  0  8*t^2  0  0]
[ 0  0  0  4*t^3  0]
[ 0  0  0  0  24*t^4]
sage: matrix([[(p(mu).scalar_jack(p(nu),2) for nu in Partitions(4)) for mu in Partitions(4)] for mu in Partitions(4)]
[ 8  0  0  0  0]
[ 0 12  0  0  0]
[ 0  0 32  0  0]
[ 0  0  0 32  0]
[ 0  0  0  0 384]
sage: JQ = SymmetricFunctions(QQ['t'].fraction_field()).jack().Q()
sage: matrix([[(JQ(mu).scalar_jack(JQ(nu)) for nu in Partitions(3)) for mu in Partitions(3)] for mu in Partitions(3)]
[(1/3*t^2 + 1/2*t + 1/6)/t^3  0  0]
[ 0  0 (1/2*t + 1)/(t^3 + 1/2*t^2)  0]
[ 0  0  6/(t^3 + 3*t^2 + t)  0]
```

**\texttt{scalar_qt}(x, q=None, t=None)**

Return the \( q,t \)-deformed standard Hall-Littlewood scalar product of \( \text{self} \) and \( x \).

INPUT:

• \( x \) – element of the ring of symmetric functions over the same base ring as \( \text{self} \)
• \( q, t \) – parameters (default: \texttt{None} in which case \( q \) and \( t \) are used)
EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: sp = a.scalar_qt(a); factor(sp)
(t - 1)^{-3} * (q - 1) * ((t^2 + t + 1)^{-1} * (q^2*t^2 - q^2 + 2*q*t + t^2 - 1) - q + 1)
sage: sp.parent()
Fraction Field of Univariate Polynomial Ring in q, t over Rational Field
sage: a.scalar_qt(a,q=0)
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
sage: a.scalar_qt(a,t=0)
-t^3 + 2*t^2 - 2*t + 1
sage: a.scalar_qt(a,5,7)  # q=5 and t=7
490/1539
sage: (x,y) = var('x,y')
sage: a.scalar_qt(a,q=x,t=y)
1/3*(x^3 - 1)/(y^3 - 1) + 2/3*(x - 1)^3/(y - 1)^3
sage: Rn = QQ['q','t','y','z'].fraction_field()
sage: (q,t,y,z) = Rn.gens()
sage: Mac = SymmetricFunctions(Rn).macdonald(q=y,t=z)
sage: a = Mac._sym.schur()([2,1])
sage: factor(Mac.P()(a).scalar_qt(Mac.Q()(a),q,t))
(t - 1)^{-3} * (q - 1) * ((t^2 + t + 1)^{-1} * (q^2*t^2 - q^2 + 2*q*t + t^2 - 1) - q + 1)
sage: factor(Mac.P()(a).scalar_qt(Mac.Q()(a)))
(z - 1)^{-3} * (y - 1) * ((z^2 + z + 1)^{-1} * (y^2*z^2 - y*z^2 + y^2 - 2*y*z + z^2 - 1) - y + 1)
```

`scalar_t(x, t=None)`

Return the $t$-deformed standard Hall-Littlewood scalar product of `self` and `x`.

**INPUT:**

- `x` – element of the ring of symmetric functions over the same base ring as `self`
- `t` – parameter (default: None, in which case `t` is used)

**EXAMPLES:**

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: sp = a.scalar_t(a); sp
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
sage: sp.parent()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

`skew_by(x)`

Return the result of skewing `self` by `x`. (Skewing by `x` is the endomorphism (as additive group) of the ring of symmetric functions adjoint to multiplication by `x` with respect to the Hall inner product.)

**INPUT:**

- `x` – element of the ring of symmetric functions over the same base ring as `self`

**EXAMPLES:**
sage: s = SymmetricFunctions(QQ).s()
sage: s([3,2]).skew_by(s([2]))
s[2, 1] + s[3]
sage: s([3,2]).skew_by(s([1,1,1]))
0
sage: s([3,2,1]).skew_by(s([2,1]))
s[1, 1, 1] + 2*s[2, 1] + s[3]
sage: p = SymmetricFunctions(QQ).powersum()
sage: p([4,3,3,2,2,1]).skew_by(p([2,1]))
4*p[4, 3, 3, 2]
sage: zee = sage.combinat.sf.sfa.zee
sage: zee([4,3,3,2,2,1])/zee([4,3,3,2])
4
sage: s(0).skew_by(s([1]))
0
sage: s(1).skew_by(s([1]))
0
sage: s([]).skew_by(s([]))
s[]
sage: s([]).skew_by(s[1])
0

theta(a)
Return the image of self under the theta endomorphism which sends \( p_k \) to \( a \cdot p_k \) for every positive integer \( k \).

In general, this is well-defined outside of the powersum basis only if the base ring is a \( \mathbb{Q} \)-algebra.

INPUT:
• a – an element of the base ring

EXAMPLES:

sage: s = SymmetricFunctions(QQ).s()
sage: s([2,1]).theta(2)
2*s[1, 1, 1] + 6*s[2, 1] + 2*s[3]
sage: p = SymmetricFunctions(QQ).p()
sage: p([2]).theta(2)
2*p[2]
sage: p(0).theta(2)
0
sage: p(1).theta(2)
p[]

theta_qt(q=None, t=None)
Return the image of self under the \( q, t \)-deformed theta endomorphism which sends \( p_k \) to \( \frac{1-q^k}{1-t^k} \cdot p_k \) for all positive integers \( k \).

In general, this is well-defined outside of the powersum basis only if the base ring is a \( \mathbb{Q} \)-algebra.

INPUT:
• q, t – parameters (default: None, in which case ‘q’ and ‘t’ are used)

EXAMPLES:
Combinatorics, Release 9.7

```python
sage: QQqt = QQ['q,t'].fraction_field()
sage: q,t = QQqt.gens()
sage: p = SymmetricFunctions(QQqt).p()
sage: p([2]).theta_qt(q,t)
((-q^2+1)/(-t^2+1))*p[2]
sage: p([2,1]).theta_qt(q,t)
((q^3-q^2-q+1)/(t^3-t^2-t+1))*p[2, 1]
sage: p(0).theta_qt(q=1,t=3)
0
sage: p([2,1]).theta_qt(q=2,t=3)
3/16*p[2, 1]
sage: s = p.realization_of().schur()
sage: s([3]).theta_qt(q=0)*(1-t)*(1-t^2)*(1-t^3)
t^3*s[1, 1, 1] + (t^2+t)*s[2, 1] + s[3]
sage: p(1).theta_qt()
p[]
```

**verschiebung**

Return the image of the symmetric function `self` under the $n$-th Verschiebung operator.

The $n$-th Verschiebung operator $V_n$ is defined to be the unique algebra endomorphism $V$ of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer $r$ divisible by $n$, and satisfies $V(h_r) = 0$ for every positive integer $r$ not divisible by $n$. This operator $V_n$ is a Hopf algebra endomorphism. For every nonnegative integer $r$ with $n \nmid r$, it satisfies

$$
V_n(h_r) = h_{r/n}, \quad V_n(p_r) = np_{r/n}, \quad V_n(e_r) = (-1)^{r-r/n}e_{r/n}
$$

(where $h$ is the complete homogeneous basis, $p$ is the powersum basis, and $e$ is the elementary basis). For every nonnegative integer $r$ with $n \nmid r$, it satisfies

$$
V_n(h_r) = V_n(p_r) = V_n(e_r) = 0.
$$

The $n$-th Verschiebung operator is also called the $n$-th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The $n$-th Verschiebung operator is adjoint to the $n$-th Frobenius operator (see `frobenius()` for its definition) with respect to the Hall scalar product (`scalar()`).

The action of the $n$-th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley's [STA].

Let $\lambda$ be a partition. Let $n$ be a positive integer. If the $n$-core of $\lambda$ is nonempty, then $V_n(s_\lambda) = 0$. Otherwise, the following method computes $V_n(s_\lambda)$: Write the partition $\lambda$ in the form $(\lambda_1, \lambda_2, \ldots, \lambda_{ns})$ for some nonnegative integer $s$. (If $n$ does not divide the length of $\lambda$, then this is achieved by adding trailing zeroes to $\lambda$.) Set $\beta_s = \lambda_i + ns - i$ for every $s \in \{1, 2, \ldots, ns\}$. Then, $(\beta_1, \beta_2, \ldots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $i - 1 - \beta_i$ modulo $n$. Let $\xi$ be the sign of the permutation that is used for this sorting. Let $\psi$ be the sign of the permutation that is used to stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo $n$. (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $V_n(s_\lambda) = \xi \psi \prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \ldots, \lambda^{(n-1)})$ is the $n$-quotient of $\lambda$.

**INPUT:**
- $n$ – a positive integer

**OUTPUT:**
The result of applying the $n$-th Verschiebung operator (on the ring of symmetric functions) to self.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: s[3].verschiebung(2)
0
sage: s[3].verschiebung(3)
s[1]
sage: p[3].verschiebung(3)
3*p[1]
sage: m[3,2,1].verschiebung(3)
-18*m[1, 1] - 3*m[2]
sage: p[3,2,1].verschiebung(3)
0
sage: h[4].verschiebung(2)
h[2]
sage: p[2].verschiebung(2)
2*p[1]
sage: m[3,2,1].verschiebung(6)
12*m[1]
```

The Verschiebung endomorphisms are multiplicative:

```
sage: all( all( s(lam).verschiebung(2) * s(mu).verschiebung(2)
.....:            == (s(lam) * s(mu)).verschiebung(2)
.....:                  for mu in Partitions(4) )
.....:              for lam in Partitions(4) )
True
```

Being Hopf algebra endomorphisms, the Verschiebung operators commute with the antipode:

```
sage: all( p(lam).verschiebung(3).antipode()
.....:            == p(lam).antipode().verschiebung(3)
.....:                  for lam in Partitions(6) )
True
```

Testing the adjointness between the Frobenius operators $f_n$ and the Verschiebung operators $V_n$:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: p = Sym.p()
sage: all( all( s(lam).verschiebung(2).scalar(p(mu))
......:                == s(lam).scalar(p(mu).frobenius(2))
......:                       for mu in Partitions(3) )
......:                  for lam in Partitions(6) )
True
```

```
```

5.1. Comprehensive Module List

The category of bases of the ring of symmetric functions.
INPUT:
• `self` – a category of bases for the symmetric functions
• `base` – ring of symmetric functions

class ParentMethods
Bases: object

eulerian(n, j, k=None)
Return the Eulerian symmetric function \( Q_{n,j} \) (with \( n \) either an integer or a partition) or \( Q_{n,j,k} \) (if the optional argument \( k \) is specified) in terms of the basis `self`.

It is known that the Eulerian quasisymmetric functions are in fact symmetric functions \([SW2010] \). For more information, see `QuasiSymmetricFunctions.Fundamental.Eulerian()`, which accepts the same syntax as this method.

INPUT:
• `n` – the nonnegative integer \( n \) or a partition
• `j` – the number of excedances
• `k` – (optional) if specified, determines the number of fixed points of the permutations which are being summed over

EXAMPLES:
```
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: m.Eulerian(3, 1)
4*m[1, 1, 1] + 3*m[2, 1] + 2*m[3]
sage: h = Sym.h()
sage: h.Eulerian(4, 2)
sage: s = Sym.s()
sage: s.Eulerian(5, 2)
sage: s.Eulerian([2,2,1], 2)
sage: s.Eulerian(5, 2, 2)
sage: h.Eulerian([6], 3)
h[3, 2, 1] - h[4, 1, 1] + 2*h[4, 2] + h[5, 1]
sage: s.Eulerian([6], 3)
```

carlitz_shareshian_wachs(n, d, s, comparison=None)
Return the Carlitz-Shareshian-Wachs symmetric function \( X_{n,d,s} \) (if `comparison` is `None`), or \( U_{n,d,s} \) (if `comparison` is `-1`), or \( V_{n,d,s} \) (if `comparison` is `0`), or \( W_{n,d,s} \) (if `comparison` is `1`) written in the basis `self`. These functions are defined below.

The Carlitz-Shareshian-Wachs symmetric functions have been introduced in [GriRei18], Exercise 2.9.11, as refinements of a certain particular case of chromatic quasisymmetric functions defined by Shareshian and Wachs. Their definitions are as follows:

Let \( n, d \) and \( s \) be three nonnegative integers. Let \( W(n, d, s) \) denote the set of all \( n \)-tuples \((w_1, w_2, \ldots, w_n)\) of positive integers having the property that there exist precisely \( d \) elements \( i \) of \( \{1, 2, \ldots, n - 1\} \) satisfying \( w_i > w_{i+1} \), and precisely \( s \) elements \( i \) of \( \{1, 2, \ldots, n - 1\} \) satisfying...
\( w_i = w_{i+1} \). For every \( w = (w_1, w_2, \ldots, w_n) \in W(n, d, s) \), let \( x_w \) be the monomial \( x_{w_1} x_{w_2} \cdots x_{w_n} \).

We then define the power series \( X_{n,d,s} \) by

\[
X_{n,d,s} = \sum_{w \in W(n,d,s)} x_w.
\]

This is a symmetric function (according to [GriRei18], Exercise 2.9.11(b)), and for \( s = 0 \) equals the \( t^d \)-coefficient of the descent enumerator of Smirnov words of length \( n \) (an example of a chromatic quasisymmetric function which happens to be symmetric – see [ShaWach2014], Example 2.5).

Assume that \( n > 0 \). Then, we can define three further power series as follows:

\[
U_{n,d,s} = \sum_{w_1 < w_n} x_w; \quad V_{n,d,s} = \sum_{w_1 = w_n} x_w; \quad W_{n,d,s} = \sum_{w_1 > w_n} x_w,
\]

where all three sums range over \( w = (w_1, w_2, \ldots, w_n) \in W(n, d, s) \). These three power series \( U_{n,d,s}, V_{n,d,s} \) and \( W_{n,d,s} \) are symmetric functions as well ([GriRei18], Exercise 2.9.11(c)). Their sum is \( X_{n,d,s} \).

REFERENCES:

INPUT:

• \( n \) – a nonnegative integer
• \( d \) – a nonnegative integer
• \( s \) – a nonnegative integer
• \( \text{comparison} \) (default: None) – a variable which can take the forms None, -1, 0 and 1

OUTPUT:

The Carlitz-Shareshian-Wachs symmetric function \( X_{n,d,s} \) (if \( \text{comparison} \) is None), or \( U_{n,d,s} \) (if \( \text{comparison} \) is -1), or \( V_{n,d,s} \) (if \( \text{comparison} \) is 0), or \( W_{n,d,s} \) (if \( \text{comparison} \) is 1) written in the basis \( \text{self} \).

EXAMPLES:

The power series \( X_{n,d,s} \):

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.m()
sage: m.carlitz_shareshian_wachs(3, 2, 1)
\emptyset
sage: m.carlitz_shareshian_wachs(3, 1, 1)
m[2, 1]
sage: m.carlitz_shareshian_wachs(3, 2, 0)
m[1, 1, 1]
sage: m.carlitz_shareshian_wachs(3, 0, 2)
m[3]
sage: m.carlitz_shareshian_wachs(3, 1, 0)
4*m[1, 1, 1] + m[2, 1]
sage: m.carlitz_shareshian_wachs(3, 0, 1)
m[2, 1]
sage: m.carlitz_shareshian_wachs(3, 0, 0)
m[1, 1, 1]
sage: m.carlitz_shareshian_wachs(5, 2, 2)
m[2, 2, 1] + m[3, 1, 1]
sage: m.carlitz_shareshian_wachs(1, 0, 0)
m[1]
sage: m.carlitz_shareshian_wachs(0, 0, 0)
m[1]
```
The power series $U_{n,d,s}$:

\[
sage: m.carlitz_shareshian_wachs(3, 2, 1, \text{comparison=-1})
\]
\[
0
\]
\[
sage: m.carlitz_shareshian_wachs(3, 1, 1, \text{comparison=-1})
\]
\[
0
\]
\[
sage: m.carlitz_shareshian_wachs(3, 2, 0, \text{comparison=-1})

\[
sage: m.carlitz_shareshian_wachs(3, 0, 2, \text{comparison=0})
\]
\[
m[3]
\]
\[
sage: m.carlitz_shareshian_wachs(3, 1, 0, \text{comparison=0})
\]
\[
m[2, 1]
\]
\[
sage: m.carlitz_shareshian_wachs(3, 0, 1, \text{comparison=0})
\]
\[
0
\]
\[
sage: m.carlitz_shareshian_wachs(3, 0, 0, \text{comparison=0})
\]
\[
0
\]
\[
sage: m.carlitz_shareshian_wachs(5, 2, 2, \text{comparison=0})
\]
\[
0
\]
\[
sage: m.carlitz_shareshian_wachs(4, 2, 0, \text{comparison=0})
\]
\[
m[2, 1, 1]
\]
\[
sage: m.carlitz_shareshian_wachs(1, 0, 0, \text{comparison=0})
\]
\[
m[1]
\]

The power series $W_{n,d,s}$:

\[
sage: m.carlitz_shareshian_wachs(3, 2, 1, \text{comparison=1})
\]
\[
0
\]
\[
sage: m.carlitz_shareshian_wachs(3, 1, 1, \text{comparison=1})
\]
\[
m[2, 1]
\]
\[
sage: m.carlitz_shareshian_wachs(3, 2, 0, \text{comparison=1})
\]
\[
m[1, 1, 1]
\]

(continues on next page)
corresponding\_basis\_over(\textit{R})

Return the realization of symmetric functions corresponding to \textit{self} but over the base ring \textit{R}. Only works when \textit{self} is one of the classical bases, not one of the $q,t$-dependent ones. In the latter case, None is returned instead.

**INPUT:**
- \textit{R} – a commutative ring

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: m.corresponding_basis_over(ZZ)
Symmetric Functions over Integer Ring in the monomial basis

sage: Sym = SymmetricFunctions(CyclotomicField())
sage: s = Sym.schur()
sage: s.corresponding_basis_over(Integers(13))
Symmetric Functions over Ring of integers modulo 13 in the Schur basis

sage: P = ZZ['\textbackslash q','\textbackslash t']
sage: Sym = SymmetricFunctions(P)
sage: mj = Sym.macdonald().J()
sage: mj.corresponding_basis_over(Integers(13))
```

**Todo:** This function is an ugly hack using strings. It should be rewritten as soon as the bases of SymmetricFunctions are put on a more robust and systematic footing.

\textbf{degree\_on\_basis(\textit{b})}

Return the degree of the basis element indexed by \textit{b}.

**INPUT:**
- \textit{self} – a basis of the symmetric functions
- \textit{b} – a partition

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ['\textbackslash q','\textbackslash t'].fraction_field())
sage: m = Sym.monomial()
```
Combinatorics, Release 9.7

```
sage: m.degree_on_basis(Partition([3,2]))
sage: P = Sym.macdonald().P()
sage: P.degree_on_basis(Partition([[]])
```

**formal_series_ring()**

Return the completion of all formal linear combinations of `self` with finite linear combinations in each homogeneous degree (computed lazily).

**EXAMPLES:**

```
sage: s = SymmetricFunctions(ZZ).s()
sage: L = s.formal_series_ring()
sage: L
Lazy completion of Symmetric Functions over Integer Ring in the Schur basis
```

**gessel_reutenauer(lam)**

Return the Gessel-Reutenauer symmetric function corresponding to the partition `lam` written in the basis `self`.

Let $\lambda$ be a partition. The Gessel-Reutenauer symmetric function $GR_{\lambda}$ corresponding to $\lambda$ is the symmetric function denoted $L_{\lambda}$ in [GR1993] and in Exercise 7.89 of [STA] and denoted $GR_{\lambda}$ in Definition 6.6.34 of [GriRei18]. It is also called the higher Lie character, for instance in [Sch2003b]. It can be defined in several ways:

- It is the sum of the monomials $x_w$ over all words $w$ over the alphabet $\{1, 2, 3, \ldots \}$ which have CFL type $\lambda$. Here, the monomial $x_w$ for a word $w = (w_1, w_2, \ldots, w_k)$ is defined as $x_{w_1} x_{w_2} \cdots x_{w_k}$, and the CFL type of a word $w$ is defined as the partition obtained by sorting (in decreasing order) the lengths of the factors in the Lyndon factorization ($lyndon_factorization()$) of $w$. The fact that this power series $GR_{\lambda}$ is symmetric is not obvious.

- It is the sum of the fundamental quasisymmetric functions $F_{\text{Des} \sigma}$ over all permutations $\sigma$ that have cycle type $\lambda$. See `sage.combinat.ncsf_qsym.qsym.QuasiSymmetricFunctions.Fundamental` for the definition of fundamental quasisymmetric functions, and `cycle_type()` for that of cycle type. For a permutation $\sigma$, we use $\text{Des} \sigma$ to denote the descent composition ($\text{descents_composition()}$) of $\sigma$. Again, this definition does not make the symmetry of $GR_{\lambda}$ obvious.

- For every positive integer $n$, we have
  \[
  GR_{(n)} = \frac{1}{n!} \sum_{d \mid n} \mu(d) p_d^{n/d},
  \]
  where $p_d$ denotes the $d$-th power-sum symmetric function. This $GR_{(n)}$ is also denoted by $L_n$, and is called the Lie character. Now, the higher Lie character $GR_{\lambda}$ is defined as the product:
  \[
  h_{m_1} [L_1] \cdot h_{m_2} [L_2] \cdot h_{m_3} [L_3] \cdots,
  \]
  where $m_i$ denotes the multiplicity of the part $i$ in $\lambda$, and where the square brackets stand for plethysm ($\text{plethysm()}$). This definition makes the symmetry (but not the integrality!) of $GR_{\lambda}$ obvious.

The equivalences of these three definitions are proven in [GR1993] Sections 2-3. (See also [GriRei18] Subsection 6.6.2 for the equivalence of the first two definitions and further formulas.)

$GR_{\lambda}$ has further significance in representations afforded by the tensor algebra $T(V)$ of a finite dimensional vector space. The Poincaré-Birkhoff-Witt theorem describes the universal enveloping algebra of a Lie algebra. It gives a decomposition of the degree-$n$ component $T_n(V)$ of $T(V)$ into $GL(V)$
representations indexed by partitions. The higher Lie characters are the symmetric group $S_n$ characters corresponding to this decomposition via Schur-Weyl duality.

Another important question, Thrall’s problem (see e.g. [Sch2003b]) asks, for $\lambda$ a partition of $n$, can we combinatorially interpret the coefficients $\alpha_\mu^\lambda$ in the Schur-expansion of $GR_\lambda$:

$$GR_\lambda = \sum_{\mu \vdash n} \alpha_\mu^\lambda s_\mu.$$ 

INPUT:

- $\text{lam}$ – a partition or a positive integer (in the latter case, it is understood to mean the partition $[\text{lam}]$)

OUTPUT:

The Gessel-Reutenauer symmetric function $GR_\lambda$, where $\lambda$ is $\text{lam}$, expanded in the basis $\text{self}$.

EXAMPLES:

The first few values of $GR_{(n)} = L_n$:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: h = Sym.h()
sage: h.gessel_reutenauer(1)
h[1]
sage: h.gessel_reutenauer(2)
h[1, 1] - h[2]
sage: h.gessel_reutenauer(3)
h[2, 1] - h[3]
sage: h.gessel_reutenauer(4)
h[2, 1, 1] - h[2, 2]
sage: h.gessel_reutenauer(5)
sage: h.gessel_reutenauer(6)
h[2, 1, 1, 1, 1] - h[2, 2, 1, 1] - h[2, 2, 2]
  - 2*h[3, 1, 1, 1] + 5*h[3, 2, 1] - 2*h[3, 3] + h[4, 1, 1]
```

Gessel-Reutenauer functions indexed by partitions:

```
sage: h.gessel_reutenauer([2, 1])
h[1, 1, 1] - h[2, 1]
sage: h.gessel_reutenauer([2, 2])
```

The Gessel-Reutenauer functions are Schur-positive:

```
sage: s = Sym.s()
sage: s.gessel_reutenauer([2, 1])
s[1, 1, 1] + s[2, 1]
sage: s.gessel_reutenauer([2, 2, 1])
s[1, 1, 1, 1] + s[2, 1, 1] + s[2, 2, 1] + s[3, 2]
```

They do not form a basis, as the following example (from [GR1993] p. 201) shows:

```
sage: s.gessel_reutenauer([4]) == s.gessel_reutenauer([2, 1, 1])
True
```
They also go by the name *higher Lie character*:

```python
sage: s.higher_lie_character([2, 2, 1]) == s.gessel_reutenauer([2, 2, 1])
True
```

Of the above three equivalent definitions of \( GR_\lambda \), we use the third one for computations. Let us check that the second one gives the same results:

```python
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F() # fundamental basis
sage: def GR_def2(lam):
    n = lam.size()
    r = F.sum_of_monomials([sigma.descents_composition() for sigma in Permutations(n) if sigma.cycle_type() == lam])
    return r.to_symmetric_function()

sage: all( GR_def2(lam) == h.gessel_reutenauer(lam) for n in range(5) for lam in Partitions(n) )
True
```

And the first one, too (assuming symmetry):

```python
sage: m = Sym.m()
sage: def GR_def1(lam):
    n = lam.size()
    Permus_mset = sage.combinat.permutation.Permutations_mset
    def coeff_of_m_mu_in_result(mu):
        words_to_check = Permus_mset([i for (i, l) in enumerate(mu) for _ in range(l)])
        return sum((1 for w in words_to_check if Partition(list(reversed(sorted([len(v) for v in Word(w).lyndon_factorization()])))) == lam))
    r = m.sum_of_terms([mu, coeff_of_m_mu_in_result(mu)] for mu in Partitions(n), distinct=True)
    return r

sage: all( GR_def1(lam) == h.gessel_reutenauer(lam) for n in range(5) for lam in Partitions(n) )
True
```

**Note:** The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a \( \mathbb{Q} \)-algebra from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over \( \mathbb{Q} \) (using the corresponding_basis_over hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).

**higher_lie_character**(*lam*)

Return the Gessel-Reutenauer symmetric function corresponding to the partition *lam* written in the basis *self*.

Let \( \lambda \) be a partition. The *Gessel-Reutenauer symmetric function* \( GR_\lambda \) corresponding to \( \lambda \) is the symmetric function denoted \( L_\lambda \) in [GR1993] and in Exercise 7.89 of [STA] and denoted \( GR_\lambda \) in Definition
It is also called the higher Lie character, for instance in [Sch2003b]. It can be defined in several ways:

• It is the sum of the monomials $x_w$ over all words $w$ over the alphabet $\{1, 2, 3, \ldots\}$ which have CFL type $\lambda$. Here, the monomial $x_w$ for a word $w = (w_1, w_2, \ldots, w_k)$ is defined as $x_{w_1}x_{w_2}\cdots x_{w_k}$, and the CFL type of a word $w$ is defined as the partition obtained by sorting (in decreasing order) the lengths of the factors in the Lyndon factorization (lyndon_factorization()) of $w$. The fact that this power series $GR_\lambda$ is symmetric is not obvious.

• It is the sum of the fundamental quasisymmetric functions $F_{\text{Des} \sigma}$ over all permutations $\sigma$ that have cycle type $\lambda$. See sage.combinat.ncsf_qsym.qsym.QuasiSymmetricFunctions. Fundamental for the definition of fundamental quasisymmetric functions, and cycle_type() for that of cycle type. For a permutation $\sigma$, we use $\text{Des} \sigma$ to denote the descent composition (descents_composition()) of $\sigma$. Again, this definition does not make the symmetry of $GR_\lambda$ obvious.

• For every positive integer $n$, we have

$$GR_n = \frac{1}{n!} \sum_{d|n} \mu(d) p_d^{n/d},$$

where $p_d$ denotes the $d$-th power-sum symmetric function. This $GR_n$ is also denoted by $L_n$, and is called the Lie character. Now, the higher Lie character $GR_\lambda$ is defined as the product:

$$h_{m_1} [L_1] \cdot h_{m_2} [L_2] \cdot h_{m_3} [L_3] \cdots,$$

where $m_i$ denotes the multiplicity of the part $i$ in $\lambda$, and where the square brackets stand for plethysm (plethysm()). This definition makes the symmetry (but not the integrality!) of $GR_\lambda$ obvious.

The equivalences of these three definitions are proven in [GR1993] Sections 2-3. (See also [GriRei18] Subsection 6.6.2 for the equivalence of the first two definitions and further formulas.)

$GR_\lambda$ has further significance in representations afforded by the tensor algebra $T(V)$ of a finite dimensional vector space. The Poincaré-Birkhoff-Witt theorem describes the universal enveloping algebra of a Lie algebra. It gives a decomposition of the degree-$n$ component $T_n(V)$ of $T(V)$ into $GL(V)$ representations indexed by partitions. The higher Lie characters are the symmetric group $S_n$ characters corresponding to this decomposition via Schur-Weyl duality.

Another important question, Thrall’s problem (see e.g. [Sch2003b]) asks, for $\lambda$ a partition of $n$, can we combinatorially interpret the coefficients $\alpha^\lambda_\mu$ in the Schur-expansion of $GR_\lambda$:

$$GR_\lambda = \sum_{\mu \vdash n} \alpha^\lambda_\mu s_\mu.$$

**INPUT:**

• $\text{lam}$ – a partition or a positive integer (in the latter case, it is understood to mean the partition $[\text{lam}]$)

**OUTPUT:**

The Gessel-Reutenauer symmetric function $GR_\lambda$, where $\lambda$ is $\text{lam}$, expanded in the basis $\text{self}$.

**EXAMPLES:**

The first few values of $GR_\lambda$ are $L_n$:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: h = Sym.h()
sage: h.gessel_reutenauer(1)
h[1]
sage: h.gessel_reutenauer(2)
```

(continues on next page)
Combinatorics, Release 9.7

Gessel-Reutenauer functions indexed by partitions:

\[
\begin{align*}
\text{sage: } & \text{h.gessel_reutenauer([2, 1])} \\
& \text{h[1, 1, 1] - h[2, 1]} \\
\text{sage: } & \text{h.gessel_reutenauer([2, 2])} \\
& \text{h[1, 1, 1, 1] - 3*h[2, 1, 1] + 2*h[2, 2] + h[3, 1] - h[4]} \\
\end{align*}
\]

The Gessel-Reutenauer functions are Schur-positive:

\[
\begin{align*}
\text{sage: } & \text{s = Sym.s()} \\
\text{sage: } & \text{s.gessel_reutenauer([2, 1])} \\
& s[1, 1, 1] + s[2, 1] \\
\text{sage: } & \text{s.gessel_reutenauer([2, 2])} \\
& s[1, 1, 1, 1] + s[2, 1, 1] + s[2, 2, 1] + s[3, 2] \\
\end{align*}
\]

They do not form a basis, as the following example (from [GR1993] p. 201) shows:

\[
\begin{align*}
\text{sage: } & \text{s.gessel_reutenauer([4]) == s.gessel_reutenauer([2, 1, 1])} \\
& \text{True} \\
\end{align*}
\]

They also go by the name higher Lie character:

\[
\begin{align*}
\text{sage: } & \text{s.higher_lie_character([2, 2, 1]) == s.gessel_reutenauer([2, 2, 1])} \\
& \text{True} \\
\end{align*}
\]

Of the above three equivalent definitions of $\mathbf{GR}_\lambda$, we use the third one for computations. Let us check that the second one gives the same results:

\[
\begin{align*}
\text{sage: } & \text{QSym = QuasiSymmetricFunctions(ZZ)} \\
\text{sage: } & \text{F = QSym.F()} \ # \text{fundamental basis} \\
\text{sage: } & \text{def GR_def2(lam): } \ # \text{`\mathbf{GR}_\lambda' expression} \\
& \quad \text{...: } n = lam.size() \\
& \quad \text{...: } r = F.sum_of_monomials([sigma.descents_composition() for sigma in Permutations(n) if sigma.cycle_type() == lam]) \\
& \quad \text{...: } \text{return } r.to_symmetric_function() \\
\text{sage: } & \text{all( GR_def2(lam) == h.gessel_reutenauer(lam) for n in range(5) for lam in Partitions(n) )} \\
& \text{True} \\
\end{align*}
\]

And the first one, too (assuming symmetry):
Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a \(\mathbb{Q}\)-algebra from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over \(\mathbb{Q}\) (using the corresponding_basis_over hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).

is_commutative()
Return whether this symmetric function algebra is commutative.
INPUT:
  • self – a basis of the symmetric functions
EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s.is_commutative()
True
```

is_field(proof=True)
Return whether self is a field. (It is not.)
INPUT:
  • self – a basis of the symmetric functions
  • proof – an optional argument (default value: True)
EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s.is_field()
False
```

is_integral_domain(proof=True)
Return whether self is an integral domain. (It is if and only if the base ring is an integral domain.)
INPUT:
  • self – a basis of the symmetric functions

5.1. Comprehensive Module List
• proof – an optional argument (default value: True)

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: s.is_integral_domain()
True
```

The following doctest is disabled pending trac ticket #15475:

```python
sage: s = SymmetricFunctions(Zmod(14)).s()  # not tested
sage: s.is_integral_domain()  # not tested
False
```

**lehrer_solomon(lam)**

Return the Lehrer-Solomon symmetric function (also known as the Whitney homology character) corresponding to the partition `lam` written in the basis `self`.

Let \( \lambda \vdash n \) be a partition. The **Lehrer-Solomon symmetric function** \( LS_\lambda \) corresponding to \( \lambda \) is the Frobenius characteristic of the representation denoted \( \text{Ind}^{S_n}_{Z_\lambda}(\xi_\lambda) \) in Theorem 4.5 of [LS1986] or \( W_\lambda \) in Theorem 2.7 of [HR2017]. It was first computed as a symmetric function in [Sun1994].

It is the symmetric group representation corresponding to a summand of the Whitney homology of the set partition lattice. The summand comes from the orbit of set partitions with block sizes corresponding to \( \lambda \) (after reordering appropriately).

It can be computed using Sundaram’s plethystic formula (see [Sun1994] Theorem 1.8):

\[
LS_\lambda = \prod_{\text{odd } j \geq 1} h_{m_j}[\pi_j] \prod_{\text{even } j \geq 2} e_{m_j}[\pi_j],
\]

where \( h_{m_j} \) are complete homogeneous symmetric functions, \( e_{m_j} \) are elementary symmetric functions, and \( \pi_j \) are the images of the Gessel-Reutenauer symmetric function \( GR_{(j)} \) (see `gessel_reutenauer()`) under the involution \( \omega \) (i.e. \( \omega_involution() \)):

```python
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: pi_2 = (s.gessel_reutenauer(2)).omega_involution()
sage: pi_1 = (s.gessel_reutenauer(1)).omega_involution()
sage: s.lehrer_solomon([2,1]) == pi_2 * pi_1  # since h_1, e_1 are..._plethystic_identities
True
```

Note that this also gives the \( S_n \)-equivariant structure of the Orlik-Solomon algebra of the braid arrangement (also known as the type-\( A \) reflection arrangement).

The representation corresponding to \( LS_\lambda \) exhibits representation stability [Chu2012], and a sharp bound is given in [HR2017].

INPUT:

• `lam` – a partition or a positive integer (in the latter case, it is understood to mean the partition \([1\, \ldots \, n]\))

OUTPUT:

The Lehrer-Solomon symmetric function \( LS_\lambda \), where \( \lambda \) is \( lam \), expanded in the basis `self`.

EXAMPLES:

The first few values of \( LS_{(n)} \):
sage: Sym = SymmetricFunctions(ZZ)
sage: h = Sym.h()
sage: h.lehrer_solomon(1)
h[1]
sage: h.lehrer_solomon(2)
h[2]
sage: h.lehrer_solomon(3)
h[2, 1] - h[3]
sage: h.lehrer_solomon(4)
h[2, 1, 1] - h[2, 2]
sage: h.lehrer_solomon(5)

The \texttt{whitney_homology_character()} method is an alias:

sage: Sym = SymmetricFunctions(ZZ)
sage: s = Sym.schur()
sage: s.lehrer_solomon([2, 2, 1]) == s.whitney_homology_character([2, 2, 1])
True

Lehrer-Solomon functions indexed by partitions:

sage: h.lehrer_solomon([2, 1])
h[2, 1]
sage: h.lehrer_solomon([2, 2])

The Lehrer-Solomon functions are Schur-positive:

sage: s = Sym.s()
sage: s.lehrer_solomon([2, 1])
s[2, 1] + s[3]
sage: s.lehrer_solomon([2, 2, 1])
s[3, 1, 1] + s[3, 2] + s[4, 1]
sage: s.lehrer_solomon([4, 1])
s[2, 1, 1, 1] + s[2, 2, 1] + 2*s[3, 1, 1] + s[3, 2] + s[4, 1]

\texttt{one\_basis()}

Return the empty partition, as per \texttt{AlgebrasWithBasis.ParentMethods.one\_basis}

**INPUT:**

• \texttt{self} – a basis of the ring of symmetric functions

**EXAMPLES:**

sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: s = Sym.s()
sage: s.one_basis()
[]
sage: Q = Sym.hall_littlewood().Q()
sage: Q.one_basis()
[]

\texttt{Todo:} generalize to Modules.Graded.Connected.ParentMethods

5.1. Comprehensive Module List
skew_schur(x)
Return the skew Schur function indexed by x in self.

INPUT:
• x – a skew partition

EXAMPLES:

```
sage: sp = SkewPartition([[5,3,3,1], [3,2,1]])
sage: s = SymmetricFunctions(QQ).s()
sage: s.skew_schur(sp)
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 3*s[3, 2, 1] 
+ s[3, 3] + 2*s[4, 1, 1] + 2*s[4, 2] + s[5, 1]
```

whitney_homology_character(lam)
Return the Lehrer-Solomon symmetric function (also known as the Whitney homology character) corresponding to the partition lam written in the basis self.

Let \( \lambda \vdash n \) be a partition. The \textit{Lehrer-Solomon symmetric function} \( \text{LS}_\lambda \) corresponding to \( \lambda \) is the Frobenius characteristic of the representation denoted \( \text{Ind}_{S_\lambda}^S \xi_\lambda \) in Theorem 4.5 of [LS1986] or \( W_\lambda \) in Theorem 2.7 of [HR2017]. It was first computed as a symmetric function in [Sun1994].

It is the symmetric group representation corresponding to a summand of the Whitney homology of the set partition lattice. The summand comes from the orbit of set partitions with block sizes corresponding to \( \lambda \) (after reordering appropriately).

It can be computed using Sundaram’s plethystic formula (see [Sun1994] Theorem 1.8):

\[
\text{LS}_\lambda = \prod_{\text{odd } j \geq 1} h_{m_j}[\pi_j] \prod_{\text{even } j \geq 2} e_{m_j}[\pi_j],
\]

where \( h_{m_j} \) are complete homogeneous symmetric functions, \( e_{m_j} \) are elementary symmetric functions, and \( \pi_j \) are the images of the Gessel-Reutenauer symmetric function \( \text{GR}_{(j)} \) (see \textit{gessel_reutenauer()}; see \textit{omega_involution()})

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: pi_2 = (s.gessel_reutenauer(2)).omega_involution()
sage: pi_1 = (s.gessel_reutenauer(1)).omega_involution()
sage: s.lehrer_solomon([2,1]) == pi_2 * pi_1 # since h_1, e_1 are...
-plethystic identities
True
```

Note that this also gives the \( S_n \)-equivariant structure of the Orlik-Solomon algebra of the braid arrangement (also known as the type-A reflection arrangement).

The representation corresponding to \( \text{LS}_\lambda \) exhibits representation stability [Chu2012], and a sharp bound is given in [HR2017].

INPUT:
• lam – a partition or a positive integer (in the latter case, it is understood to mean the partition [lam])
The Lehrer-Solomon symmetric function $LS_\lambda$, where $\lambda$ is a partition, expanded in the basis `self`.

**EXAMPLES:**

The first few values of $LS_\lambda$:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: h = Sym.h()
sage: h.lehrer_solomon(1)
h[1]
sage: h.lehrer_solomon(2)
h[2]
sage: h.lehrer_solomon(3)
h[2, 1] - h[3]
sage: h.lehrer_solomon(4)
h[2, 1, 1] - h[2, 2]
sage: h.lehrer_solomon(5)
```

The `whitney_homology_character()` method is an alias:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: s = Sym.schur()
sage: s.lehrer_solomon([2, 2, 1]) == s.whitney_homology_character([2, 2, 1])
True
```

Lehrer-Solomon functions indexed by partitions:

```python
sage: h.lehrer_solomon([2, 1])
h[2, 1]
sage: h.lehrer_solomon([2, 2])
```

The Lehrer-Solomon functions are Schur-positive:

```python
sage: s = Sym.s()
sage: s.lehrer_solomon([2, 1])
s[2, 1] + s[3]
sage: s.lehrer_solomon([2, 2, 1])
s[3, 1, 1] + s[3, 2] + s[4, 1]
sage: s.lehrer_solomon([4, 1])
s[2, 1, 1, 1] + s[2, 2, 1] + 2*s[3, 1, 1] + s[3, 2] + s[4, 1]
```

**super_categories()**

The super categories of `self`.

**EXAMPLES:**

```python
sage: from sage.combinat.sf.sfa import SymmetricFunctionsBases
sage: Sym = SymmetricFunctions(QQ)
sage: bases = SymmetricFunctionsBases(Sym)
sage: bases.super_categories()
[Category of realizations of Symmetric Functions over Rational Field,
 Category of commutative hopf algebras with basis over Rational Field,
 (continues on next page)
```

(continues on next page)
sage.combinat.sf.sfa.is_SymmetricFunction(\(x\))
Checks whether \(x\) is a symmetric function.

EXAMPLES:

```python
sage: from sage.combinat.sf.sfa import is_SymmetricFunction
sage: s = SymmetricFunctions(QQ).s()
sage: is_SymmetricFunction(2)
False
sage: is_SymmetricFunction(s(2))
True
sage: is_SymmetricFunction(s([2,1]))
True
```

sage.combinat.sf.sfa.is_SymmetricFunctionAlgebra(\(x\))
Checks whether \(x\) is a symmetric function algebra.

EXAMPLES:

```python
sage: from sage.combinat.sf.sfa import is_SymmetricFunctionAlgebra
sage: is_SymmetricFunctionAlgebra(5)
False
sage: is_SymmetricFunctionAlgebra(ZZ)
False
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(ZZ).schur())
True
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(QQ).e())
True
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(QQ).macdonald(q=1,t=1).P())
True
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(FractionField(QQ['q','t'])).˓→macdonald().P())
True
```

sage.combinat.sf.sfa.zee(\(part\))
Return the size of the centralizer of any permutation of cycle type \(part\).

Note that the size of the centralizer is the inner product between \(p(part)\) and itself, where \(p\) is the power-sum symmetric functions.

INPUT:

- \(part\) – an integer partition (for example, [2,1,1])

OUTPUT:

- the integer \(\prod_i m_i(part) m_i(part)!\) where \(m_i(part)\) is the number of parts in the partition \(part\) equal to \(i\)

EXAMPLES:

```python
sage: from sage.combinat.sf.sfa import zee
sage: zee([2,1,1])
4
```
5.1.300 Witt symmetric functions

class sage.combinat.sf.witt.SymmetricFunctionAlgebra_witt(Sym, coerce_h=True, coerce_e=False, coerce_p=False)

Bases: sage.combinat.sf.multiplicative.SymmetricFunctionAlgebra_multiplicative

The Witt symmetric function basis (or Witt basis, to be short).

The Witt basis of the ring of symmetric functions is denoted by \((x_\lambda)\) in [HazWitt1], section 9.63, and by \((q_\lambda)\) in [DoranIV1996]. We will denote this basis by \((w_\lambda)\) (which is precisely how it is denoted in [GriRei18], Exercise 2.9.3(d)). It is a multiplicative basis (meaning that \(w_\emptyset = 1\) and that every partition \(\lambda\) satisfies \(w_\lambda = w_\lambda_1 w_\lambda_2 w_\lambda_3 \cdots\), where \(w_i\) means \(w(i)\) for every nonnegative integer \(i\)).

This basis can be defined in various ways. Probably the most well-known one is using the equation

\[
\prod_{d=1}^{\infty} (1 - w_d t^d)^{-1} = \sum_{n=0}^{\infty} h_n t^n
\]

where \(t\) is a formal variable and \(h_n\) are the complete homogeneous symmetric functions, extended to 0 by \(h_0 = 1\). This equation allows one to uniquely determine the functions \(w_1, w_2, w_3, \ldots\) by recursion; one consequently extends the definition to all \(w_\lambda\) by requiring multiplicativity.

A way to rewrite the above equation without power series is:

\[
h_n = \sum_{\lambda \vdash n} w_\lambda
\]

for all nonnegative integers \(n\), where \(\lambda \vdash n\) means that \(\lambda\) is a partition of \(n\).

A similar equation (which is easily seen to be equivalent to the former) is

\[
e_n = \sum_{\lambda} (-1)^{n - \ell(\lambda)} w_\lambda,
\]

with the sum running only over strict partitions \(\lambda\) of \(n\) this time. This equation can also be used to recursively define the \(w_n\). Furthermore, every positive integer \(n\) satisfies

\[
p_n = \sum_{d|n} d w_n^{n/d},
\]

and this can be used to define the \(w_n\) recursively over any ring which is torsion-free as a \(\mathbb{Z}\)-module. While these equations all yield easy formulas for classical bases of the ring of symmetric functions in terms of the Witt symmetric functions, it seems difficult to obtain explicit formulas in the other direction.

The Witt symmetric functions owe their name to the fact that the ring of symmetric functions can be viewed as the coordinate ring of the group scheme of Witt vectors, and the Witt symmetric functions are the functions that send a Witt vector to its components (whereas the powersum symmetric functions send a Witt vector to its ghost components). Details can be found in [HazWitt1] or section 3.2 of [BorWi2004].

**INPUT:**

- `Sym` – an instance of the ring of the symmetric functions.
- `coerce_h` – (default: True) a boolean that determines whether the transition maps between the Witt basis and the complete homogeneous basis will be cached and registered as coercions.
- `coerce_e` – (default: False) a boolean that determines whether the transition maps between the Witt basis and the elementary symmetric basis will be cached and registered as coercions.
- `coerce_p` – (default: False) a boolean that determines whether the transition maps between the Witt basis and the powersum basis will be cached and registered as coercions (or conversions, if the base ring is not a \(\mathbb{Q}\)-algebra).
REFERENCES:

EXAMPLES:

Here are the first few Witt symmetric functions, in various bases:

```
sage: Sym = SymmetricFunctions(QQ)
sage: w = Sym.w()
sage: e = Sym.e()
sage: h = Sym.h()
sage: p = Sym.p()
sage: s = Sym.s()
sage: m = Sym.m()

sage: p(w([1]))
p[1]
sage: m(w([1]))
m[1]
sage: e(w([1]))
e[1]
sage: h(w([1]))
h[1]
sage: s(w([1]))
s[1]

sage: p(w([2]))
-1/2*p[1, 1] + 1/2*p[2]
sage: m(w([2]))
-m[1, 1]
sage: e(w([2]))
e[2]
sage: h(w([2]))
-h[1, 1] + h[2]
sage: s(w([2]))
s[2]

sage: p(w([3]))
-1/3*p[1, 1, 1] + 1/3*p[3]
sage: m(w([3]))
-2*m[1, 1, 1] - m[2, 1]
sage: e(w([3]))
-e[2, 1] + e[3]
sage: h(w([3]))
-h[2, 1] + h[3]
sage: s(w([3]))
s[3]

sage: Sym = SymmetricFunctions(ZZ)
sage: w = Sym.w()
sage: e = Sym.e()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: p = Sym.p()
```
Some examples of conversions the other way:

\begin{verbatim}
\texttt{sage: } w(h[3])
\texttt{w[1, 1, 1] + w[2, 1] + w[3]}
\texttt{sage: } w(e[3])
\texttt{-w[2, 1] + w[3]}
\texttt{sage: } w(m[2, 1])
\texttt{2*w[2, 1] - 3*w[3]}
\texttt{sage: } w(p[3])
\texttt{w[1, 1, 1] + 3*w[3]}
\end{verbatim}

Antipodes:

\begin{verbatim}
\texttt{sage: } w([1]).antipode()
\texttt{-w[1]}
\texttt{sage: } w([2]).antipode()
\texttt{-w[1, 1] - w[2]}
\end{verbatim}

The following holds for all odd \(i\) and is easily proven by induction:

\begin{verbatim}
\texttt{sage: } all( w([i]).antipode() == -w([i]) \texttt{ for } i \texttt{ in range(1, 10, 2) } )
\texttt{True}
\end{verbatim}

The Witt basis does not allow for simple expressions for comultiplication and antipode in general (this is related to the fact that the sum of two Witt vectors isn't easily described in terms of the components). Therefore, most computations with Witt symmetric functions, as well as conversions and coercions, pass through the complete homogeneous symmetric functions by default. However, one can also use the elementary symmetric functions instead, or (if the base ring is a \(\mathbb{Q}\)-algebra) the powersum symmetric functions. This is what the optional keyword variables \texttt{coerce\_e}, \texttt{coerce\_h} and \texttt{coerce\_p} are for. These variables do not affect the results of the (non-underscored) methods of \texttt{self}, but they affect the speed of the computations (the more of these variables are set to \texttt{True}, the faster these are) and the size of the cache (the more of these variables are set to \texttt{True}, the bigger the cache). Let us check that the results are the same no matter to what the variables are set:

\begin{verbatim}
\texttt{sage: } Sym = SymmetricFunctions(QQ)
\texttt{sage: } p = Sym.p()
\texttt{sage: } wh = Sym.w()
\texttt{sage: } we = Sym.w(coerce_h=False, coerce_e=True)
\texttt{sage: } wp = Sym.w(coerce_h=False, coerce_p=True)
\texttt{sage: } all( p(wh(lam)) == p(we(lam)) == p(wp(lam)) \texttt{ for } lam \texttt{ in Partitions(4) } )
\texttt{True}
\texttt{sage: } all ( wh(p(lam)).monomial_coefficients() \\
\texttt{...:} == we(p(lam)).monomial_coefficients() \\
\texttt{...:} == wp(p(lam)).monomial_coefficients() \texttt{ for } lam \texttt{ in Partitions(4) } )
\texttt{True}
\end{verbatim}
**coproduct**(elt)

Return the coproduct of the element elt.

**INPUT:**

- elt – a symmetric function written in this basis

**OUTPUT:**

- The coproduct acting on elt; the result is an element of the tensor squared of the basis self

**EXAMPLES:**

```sage
sage: w = SymmetricFunctions(QQ).w()
sage: w[1].coproduct()
```

```output
```

```sage
sage: w.coproduct(w[1])
```

```output
```

```sage
sage: w[2,1].coproduct()
```

```output
```

```sage
sage: w.coproduct(w[2,1])
```

```output
```

**from_other_uncached**(u)

Return an element u of another basis of the ring of symmetric functions, expanded in the Witt basis self. The result is the same as self(u), but the from_other_uncached method does not precompute a cache with transition matrices. Thus, from_other_uncached is faster when u is sparse.

**INPUT:**

- u – an element of self.realization_of()

**OUTPUT:**

- the expansion of u in the Witt basis self

**EXAMPLES:**

```sage
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: w = Sym.w()
sage: a = p([3,2]) - p([4,1]) + 27 * p([3])
sage: w.from_other_uncached(a) == w(a)
```

```output
True
```

Here’s a verification of an obvious fact that would take long with regular coercion:

```sage
sage: fouc = w.from_other_uncached
sage: fouc(p([15]))
```

```output
w[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1] + 3^5 w[3, 3, 3, 3, 3, 3, 3] + 5^5 w[5, 5, 5, 5, 5, 5, 5, 5, 5] + 15^5 w[15]
```

```sage
sage: fouc(p([15])) * fouc(p([14])) == fouc(p([15, 14]))
```

```output
True
```

Other bases:
verschiebung(n)

Return the image of the symmetric function self under the n-th Verschiebung operator.

The n-th Verschiebung operator \( V_n \) is defined to be the unique algebra endomorphism \( V \) of the ring of symmetric functions that satisfies \( V(h_r) = h_{r/n} \) for every positive integer \( r \) divisible by \( n \), and satisfies \( V(h_r) = 0 \) for every positive integer \( r \) not divisible by \( n \). This operator \( V_n \) is a Hopf algebra endomorphism. For every nonnegative integer \( r \) with \( n \mid r \), it satisfies

\[
V_n(h_r) = h_{r/n}, \quad V_n(p_r) = np_{r/n}, \quad V_n(e_r) = (-1)^{r-r/n} e_{r/n}, \quad V_n(w_r) = w_{r/n},
\]

(where \( h \) is the complete homogeneous basis, \( p \) is the powersum basis, \( e \) is the elementary basis, and \( w \) is the Witt basis). For every nonnegative integer \( r \) with \( n \mid r \), it satisfies

\[
V_n(h_r) = V_n(p_r) = V_n(e_r) = V_n(w_r) = 0.
\]

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The n-th Verschiebung operator is adjoint to the n-th Frobenius operator (see frobenius() for its definition) with respect to the Hall scalar product (scalar()).

The action of the n-th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumser than necessary) description can be obtained by solving exercise 7.61 in Stanley’s [STA].

Let \( \lambda \) be a partition. Let \( n \) be a positive integer. If the \( n \)-core of \( \lambda \) is nonempty, then \( V_n(s_\lambda) = 0 \). Otherwise, the following method computes \( V_n(s_\lambda) \): Write the partition \( \lambda \) in the form \((\lambda_1, \lambda_2, \ldots, \lambda_{ns})\) for some nonnegative integer \( s \). (If \( n \) does not divide the length of \( \lambda \), then this is achieved by adding trailing zeroes to \( \lambda \).) Set \( \beta_i = \lambda_i + ns - i \) for every \( s \in \{1, 2, \ldots, ns\} \). Then, \((\beta_1, \beta_2, \ldots, \beta_{ns})\) is a strictly decreasing sequence of nonnegative integers. Stably sort the list \((1, 2, \ldots, ns)\) in order of (weakly) increasing remainder of \(-1 - \beta_i \) modulo \( n \). Let \( \xi \) be the sign of the permutation that is used for this sorting. Let \( \psi \) be the sign of the permutation that is used to stably sort the list \((1, 2, \ldots, ns)\) in order of (weakly) increasing remainder of \( i - 1 \) modulo \( n \). (Notice that \( \psi = (-1)^{n(n-1)s(s-1)/4} \).) Then, \( V_n(s_\lambda) = \xi \psi \prod_{i=0}^{n-1} s_{\lambda(\xi)} \), where \((\lambda^{(0)}, \lambda^{(1)}, \ldots, \lambda^{(n-1)})\) is the \( n \)-quotient of \( \lambda \).

INPUT:

\* n – a positive integer

OUTPUT:

The result of applying the n-th Verschiebung operator (on the ring of symmetric functions) to self.

EXAMPLES:
sage: Sym = SymmetricFunctions(ZZ)
sage: w = Sym.w()
sage: w[3].verschiebung(2)

0

sage: w[4].verschiebung(4)
w[1]

5.1.301 Shard intersection order

This file builds a combinatorial version of the shard intersection order of type A (in the classification of finite Coxeter groups). This is a lattice on the set of permutations, closely related to noncrossing partitions and the weak order.

For technical reasons, the elements of the posets are not permutations, but can be easily converted from and to permutations:

sage: from sage.combinat.shard_order import ShardPosetElement
sage: p0 = Permutation([1,3,4,2])

sage: e0 = ShardPosetElement(p0); e0
(1, 3, 4, 2)

sage: Permutation(list(e0)) == p0
True

See also:

A general implementation for all finite Coxeter groups is available as shard_poset()

REFERENCES:

class sage.combinat.shard_order.ShardPosetElement(p)

    Bases: tuple

    An element of the shard poset.

    This is basically a permutation with extra stored arguments:

    • p – the permutation itself as a tuple
    • runs – the decreasing runs as a tuple of tuples
    • run_indices – a list integer -> index of the run
    • dpg – the transitive closure of the shard preorder graph
    • spg – the transitive reduction of the shard preorder graph

    These elements can easily be converted from and to permutations:

sage: from sage.combinat.shard_order import ShardPosetElement
sage: p0 = Permutation([1,3,4,2])

sage: e0 = ShardPosetElement(p0); e0
(1, 3, 4, 2)

sage: Permutation(list(e0)) == p0
True

sage.combinat.shard_order.shard_poset(n)

    Return the shard intersection order on permutations of size n.

    This is defined on the set of permutations. To every permutation, one can attach a pre-order, using the descending runs and their relative positions.
The shard intersection order is given by the implication (or refinement) order on the set of pre-orders defined from all permutations.

This can also be seen in a geometrical way. Every pre-order defines a cone in a vector space of dimension \( n \). The shard poset is given by the inclusion of these cones.

**See also:**

*shard_preorder_graph(*runs*)

**EXAMPLES:**

```python
sage: P = posets.ShardPoset(4); P  # indirect doctest
Finite poset containing 24 elements
sage: P.chain_polynomial()
34*q^4 + 90*q^3 + 79*q^2 + 24*q + 1
sage: P.characteristic_polynomial()
q^3 - 11*q^2 + 23*q - 13
sage: P.zeta_polynomial()
17/3*q^3 - 6*q^2 + 4/3*q
sage: P.is_self_dual()
False
```

sage.combinat.shard_order.shard_preorder_graph(*runs*)

Return the preorder attached to a tuple of decreasing runs.

This is a directed graph, whose vertices correspond to the runs.

There is an edge from a run \( R \) to a run \( S \) if \( R \) is before \( S \) in the list of runs and the two intervals defined by the initial and final indices of \( R \) and \( S \) overlap.

This only depends on the initial and final indices of the runs. For this reason, this input can also be given in that shorten way.

**INPUT:**

- a tuple of tuples, the runs of a permutation, or
- a tuple of pairs \((i, j)\), each one standing for a run from \( i \) to \( j \).

**OUTPUT:**

a directed graph, with vertices labelled by integers

**EXAMPLES:**

```python
sage: from sage.combinat.shard_order import shard_preorder_graph
sage: s = Permutation([2,8,3,9,6,4,5,1,7])
....:     return tuple((r[0], r[-1]) for r in lr)
sage: P = shard_preorder_graph(s.decreasing_runs())
Digraph on 5 vertices
sage: s = Permutation([9,4,3,2,8,6,5,1,7])
```

```python
sage: P = shard_preorder_graph(s.decreasing_runs())
```

```python
sage: P.is_isomorphic(digraphs.TransitiveTournament(3))
True
```
5.1.302 Shifted primed tableaux

AUTHORS:

• Kirill Paramonov (2017-08-18): initial implementation
• Chaman Agrawal (2019-08-12): add parameter to allow primed diagonal entry

class sage.combinat.shifted_primed_tableau.CrystalElementShiftedPrimedTableau(parent, T, skew=None, check=True, processed=False)

Bases: sage.combinat.shifted_primed_tableau.ShiftedPrimedTableau

Class for elements of crystals.ShiftedPrimedTableau.

e(ind)

Compute the action of the crystal operator \( e_i \) on a shifted primed tableau using cases from the papers [HPS2017] and [AO2018].

INPUT:

• ind – an element in the index set of the crystal

OUTPUT:

Primed tableau or None.

EXAMPLES:

```python
sage: SPT = ShiftedPrimedTableaux([5,4,2])
sage: t = SPT([[1,1,1,'2p','3p'], [2,'3p',3,3],[3,4]])
sage: t.pp()
1 1 1 2' 3'
 2 3' 3 3
 3 4
sage: s = t.e(2)
sage: s.pp()
1 1 1 2' 3'
 2 2 3 3
 3 4
sage: t == s.f(2)
True
sage: SPT = ShiftedPrimedTableaux([2,1])
sage: t = SPT([[2,'3p'],[3]])
sage: t.e(-1).pp()
1 3'
 3
sage: t.e(1).pp()
1 3'
 3
sage: t.e(2).pp()
2 2
 3
sage: r = SPT([[2, 2],[3]])
```

(continues on next page)
Compute the action of the crystal operator $f_i$ on a shifted primed tableau using cases from the papers [HPS2017] and [AO2018].

**INPUT:**

- **ind** – element in the index set of the crystal
OUTPUT:
Primed tableau or None.

EXAMPLES:

```python
sage: SPT = ShiftedPrimedTableaux([5,4,2])
sage: t = SPT([[1,1,1,1,'3p'],[2,2,2,'3p'],[3,3]])
sage: t.pp()
 1 1 1 3'
 2 2 2 3'
 3 3
sage: s = t.f(2)
sage: s is None
True

sage: t = SPT([[1,1,1,'2p','3p'],[2,2,3,3],[3,4]])
sage: t.pp()
 1 1 1 2' 3'
 2 2 3 3
 3 4
sage: s = t.f(2)
sage: s.pp()
 1 1 1 2' 3'
 2 3' 3 3
 3 4

sage: SPT = ShiftedPrimedTableaux([2,1])
sage: t = SPT([[1,1],[2]])
sage: t.f(-1).pp()
 1 2'
 2
sage: t.f(1).pp()
 1 2'
 2
sage: t.f(2).pp()
 1 1
 3

sage: r = SPT([[1,'2p'],[2]])
sage: r.f(-1) is None
True
sage: r.f(1) is None
True
sage: r.f(2).pp()
 1 2'
 3
```

(continues on next page)
sage: r.f(2) is None
True

sage: r = SPT([[1,2],[3]])
sage: r.f(-1).pp()
2 2
3
sage: r.f(1).pp()
2 2
3
sage: r.f(2) is None
True

sage: t = SPT([[1,1],[2]])
sage: t.f(-1).f(2).f(2).f(-1) == t.f(2).f(1).f(-1).f(2)
True
sage: t.f(-1).f(2).f(2).f(-1).pp()
2 3'
3
sage: all(t.f(-1).f(2).f(2).f(-1).f(i) is None for i in {-1, 1, 2})
True

sage: SPT = ShiftedPrimedTableaux([4])
sage: t = SPT([[1,1,1,1]])
sage: t.f(-1).pp()
1 1 1 2'
sage: t.f(1).pp()
1 1 1 2
sage: t.f(-1).f(-1) is None
True
sage: t.f(1).f(-1).pp()
1 1 2
2 3'
2
sage: t.f(1).f(1).pp()
1 1 2 2
sage: t.f(1).f(1).f(-1).pp()
1 2 2
2
sage: t.f(1).f(1).f(1).pp()
1 2 2 2
sage: t.f(1).f(1).f(1).f(-1).pp()
2 2 2
2
sage: t.f(1).f(1).f(1).f(1).pp()
2 2 2
2
sage: t.f(1).f(1).f(1).f(1).f(-1) is None
True

```

**is_highest_weight**(index_set=None)

Return whether self is a highest weight element of the crystal.

An element is highest weight if it vanishes under all crystal operators \(e_i\).

EXAMPLES:

5.1. Comprehensive Module List

2975
sage: SPT = ShiftedPrimedTableaux([5,4,2])
sage: t = SPT([(1, 1, 1, 1, 1), (2, 2, 2, "3p"), (3, 3)])
sage: t.is_highest_weight()
True
sage: SPT = ShiftedPrimedTableaux([5,4])
sage: s = SPT([(1, 1, 1, 1, 1), (2, 2, "3p", 3)])
sage: s.is_highest_weight(index_set=[1])
True

reading_word()

Return the reading word of self.

The reading word of a shifted primed tableau is constructed as follows:

1. List all primed entries in the tableau, column by column, in decreasing order within each column, moving from the rightmost column to the left, and with all the primes removed (i.e. all entries are increased by half a unit).

2. Then list all unprimed entries, row by row, in increasing order within each row, moving from the bottommost row to the top.

EXAMPLES:

sage: SPT = ShiftedPrimedTableaux([4,2])
sage: t = SPT([[1, '2p', 2, 2], [2, '3p']])
sage: t.reading_word()
[3, 2, 2, 1, 2, 2]

weight()

Return the weight of self.

The weight of a shifted primed tableau is defined to be the vector with \(i\)-th component equal to the number of entries \(i\) and \(i'\) in the tableau.

EXAMPLES:

sage: t = ShiftedPrimedTableau([[1, '2p', 2, 2], [2, '3p']])
sage: t.weight()
(1, 4, 1)

class sage.combinat.shifted_primed_tableau.PrimedEntry(entry=None, double=None)

Bases: sage.structure.sage_object.SageObject

The class of entries in shifted primed tableaux.

An entry in a shifted primed tableau is an element in the alphabet \(\{1' < 1 < 2' < 2 < \cdots < n' < n\}\). The difference between two elements \(i\) and \(i - 1\) counts as a whole unit, whereas the difference between \(i\) and \(i'\) counts as half a unit. Internally, we represent an unprimed element \(x\) as \(2x\) and the primed elements as the corresponding odd integer that respects the total order.

INPUT:

- `entry` – a half integer or a string of an integer possibly ending in p or '
- `double` – the doubled value

decrease_half()

Decrease self by half a unit.
Decrease self by one unit.

**increase_half()**
Increase self by half a unit.

**increase_one()**
Increase self by one unit.

**integer()**
Return the corresponding integer \( i \) for primed entries of the form \( i \) or \( i' \).

**is_primed()**
Checks if self is a primed element.

**is_unprimed()**
Checks if self is an unprimed element.

**primed()**
Prime self if it is an unprimed element.

**unprimed()**
Unprime self if it is a primed element.

```python
class sage.combinat.shifted_primed_tableau.ShiftedPrimedTableau(parent, T, skew=None, check=True, preprocessed=False):
```

Bases: `sage.structure.list_clone.ClonableArray`

A shifted primed tableau.

A primed tableau is a tableau of shifted shape in the alphabet \( X' = \{1', 1 < 2', 2 < 3', \ldots, n', n\} \) such that

1. the entries are weakly increasing along rows and columns;
2. a row cannot have two repeated primed elements, and a column cannot have two repeated non-primed elements;

Skew shape of the shifted primed tableaux is specified either with an optional argument `skew` or with `None` entries.

Primed entries in the main diagonal can be allowed with the optional boolean parameter `primed_diagonal`` (default: ```False)``.

**EXAMPLES:**

```python
sage: T = ShiftedPrimedTableaux([4,2])
sage: T([[1,"2'","3'"],[2,"3'"],[2,2.5],[2.5,3]])[[1]]
(2, 3')
sage: t = ShiftedPrimedTableau([[1,"2p",2.5,3],[2,2.5]])
sage: t[1]
(2, 3')
sage: ShiftedPrimedTableau([["2p",2,3],["2p","3p"],[2]], skew=[2,1])
[[None, None, 2', 3], (None, 2', 3'), (2,2)]
sage: ShiftedPrimedTableau([[None,None,"2p"],[None,"2p"],[None,"2p"],[None,2,3]])
[[None, None, 2', (None, 2'), (None, 2')]

sage: T = ShiftedPrimedTableaux([4,2], primed_diagonal=True)
sage: T([[1,"2'","3'"],[2,"2'","3'"],[2,"2'","3'"],[2,2.5],[2.5,3]])[[1]] # With primed diagonal entry
(2', 3')
```
check()
Check that self is a valid primed tableau.

EXAMPLES:

```
sage: T = ShiftedPrimedTableaux([4,2])
sage: t = T([[1,'2p',2,2],[2,'3p']])
sage: t.check()
sage: s = ShiftedPrimedTableau([["2p",2,3],["2p"],[2]],skew=[2,1])
sage: s.check()
sage: t = T([["1p","2p",2,2],[2,'3p']])
Traceback (most recent call last):
...
ValueError: [['1p', '2p', 2, 2], [2, '3p']] is not an element of
Shifted Primed Tableaux of shape [4, 2]
sage: T = ShiftedPrimedTableaux([4,2], primed_diagonal=True)
sage: t = T([["1p","2p",2,2],[2,'3p']])  # primed_diagonal allowed
sage: t.check()
sage: t = T([["1p","1p",2,2],[2,'3p']])
Traceback (most recent call last):
...
ValueError: [['1p', '1p', 2, 2], [2, '3p']] is not an element of
Shifted Primed Tableaux of shape [4, 2] and maximum entry 6
```

is_standard()
Return True if the entries of self are in bijection with positive primed integers $1', 1', 2', \ldots, n$.

EXAMPLES:

```
sage: ShiftedPrimedTableau([["1'", 1, "2'"], [2, "3'"]],
....:     primed_diagonal=True).is_standard()  True
sage: ShiftedPrimedTableau([["1'", 1, 2], ["2'", "3'"]],
....:     primed_diagonal=True).is_standard()  True
sage: ShiftedPrimedTableau([["1'", 1, 1], ["2'", 2]],
....:     primed_diagonal=True).is_standard()  False
sage: ShiftedPrimedTableau([[1, "2'"], [2]]).is_standard()  False
sage: s = ShiftedPrimedTableau([[None, None,"1p","2p",2],[None,"1'"]])
sage: s.is_standard()  True
```

max_entry()
Return the minimum unprimed letter $x > y$ for all $y$ in self.

EXAMPLES:

```
sage: Tab = ShiftedPrimedTableau([(1,1,'2p','3p'),(2,2)])
sage: Tab.max_entry()
3
```

pp()
Pretty print self.
### Examples:

```python
t = ShiftedPrimedTableau([[1,'2p',2,2],[2,'3p']])
t.pp()
```

1 2' 2 2
2 3'

```python
t = ShiftedPrimedTableau([[10,'11p',11,11],[11,'12']])
t.pp()
```

10 11' 11 11
11 12

```python
ts = ShiftedPrimedTableau(['2p',2,3],['2p'], skew=[2,1])
tt = ShiftedPrimedTableau([[1,'2p',2,2],[2,'3p']])
tt.restrict(2).pp()
```

1 2 2
2

```python
t.restrict("2p").pp()
```

1 2'

```python	s.restrict(1.5).pp()
```

. . 2' 2
. 2'

### restrict(n)

Return the restriction of the shifted tableau to all the numbers less than or equal to n.

**Note:** If only the outer shape of the restriction, rather than the whole restriction, is needed, then the faster method `restriction_outer_shape()` is preferred. Similarly if only the skew shape is needed, use `restriction_shape()`.

### Examples:

```python
t = ShiftedPrimedTableau([[1,'2p',2,2],[2,'3p']])
t restrict(2).pp()
```

1 2' 2 2
2

```python
t restrict("2p").pp()
```

1 2'

```python	s.restrict(1.5).pp()
```

. . 2' 2
. 2'

### restriction_outer_shape(n)

Return the outer shape of the restriction of the shifted tableau self to n.

If T is a (skew) shifted tableau and n is a half-integer, then the restriction of T to n is defined as the (skew) shifted tableau obtained by removing all cells filled with entries greater than n from T.

This method computes merely the outer shape of the restriction. For the restriction itself, use `restrict()`.

### Examples:

```python	s = ShiftedPrimedTableau(['2p',2,3],['2p'], skew=[2,1])
tt = ShiftedPrimedTableau([[1,'2p',2,2],[2,'3p']])
tt.restrict(2).pp()
```

1 2 2
2

```python
tt = ShiftedPrimedTableau([[1,'2p',2,2],[2,'3p']])
tt.restrict("2p").pp()
```

1 2'

```python	s = ShiftedPrimedTableau(['2p',2,3],['2p'], skew=[2,1])
tt = ShiftedPrimedTableau([[1,'2p',2,2],[2,'3p']])
tt.restrict(1.5).pp()
```

. . 2' 2
. 2'
sage: s.restriction_outer_shape(2)
[4, 2]
sage: s.restriction_outer_shape("2p")
[3, 2]

**restriction_shape**(n)

Return the skew shape of the restriction of the skew tableau *self* to *n*.

If *T* is a shifted tableau and *n* is a half-integer, then the restriction of *T* to *n* is defined as the (skew) shifted tableau obtained by removing all cells filled with entries greater than *n* from *T*.

This method computes merely the skew shape of the restriction. For the restriction itself, use `restrict()`.

**EXAMPLES:**

```python
sage: s = ShiftedPrimedTableau(["2p",2,3],["2p"], skew=[2,1])
sage: s.pp()
 . 2' 2 3
 . 2'
sage: s.restriction_shape(2)
[4, 2] / [2, 1]
```

**shape()**

Return the shape of the underlying partition of *self*.

**EXAMPLES:**

```python
sage: t = ShiftedPrimedTableau([[1,'2p',2,2],[2,'3p']])
sage: t.shape()
[4, 2]
sage: s = ShiftedPrimedTableau(["2p",2,3],["2p"],skew=[2,1])
sage: s.shape()
[5, 2] / [2, 1]
```

**to_chain()**

Return the chain of partitions corresponding to the (skew) shifted tableau *self*, interlaced by one of the colours 1 if the added cell is on the diagonal, 2 if an ordinary entry is added and 3 if a primed entry is added.

**EXAMPLES:**

```python
sage: s = ShiftedPrimedTableau((1, 3.5), (2,), (6,))
sage: s.pp()
 . . 1 4'
 . 3'
sage: s.to_chain()
[[], [1, [1], 2, [2], 1, [2, 1], 3, [3, 1], 2, [4, 1], 3, [4, 2], 3, [5, 2]]
```

(continues on next page)
sage: s.to_chain()
[[2, 1], 2, [3, 1], 0, [3, 1], 3, [3, 2], 3, [4, 2], 0, [4, 2], 1, [4, 2, 1]]

weight()
Return the weight of self.

The weight of a shifted primed tableau is defined to be the vector with $i$-th component equal to the number of entries $i$ and $i'$ in the tableau.

EXAMPLES:
sage: t = ShiftedPrimedTableau([[2p',2,2],[2,3p']],[skew=[1]])
sage: t.weight()
(0, 4, 1)

class sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux(skew=None, primed_diagonal=False)
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Returns the combinatorial class of shifted primed tableaux subject to the constraints given by the arguments.

A primed tableau is a tableau of shifted shape on the alphabet $X' = \{1' < 1 < 2' < 2 < \cdots < n' < n\}$ such that

1. the entries are weakly increasing along rows and columns
2. a row cannot have two repeated primed entries, and a column cannot have two repeated non-primed entries

INPUT:

Valid optional keywords:
- shape – the (outer skew) shape of tableaux
- weight – the weight of tableaux
- max_entry – the maximum entry of tableaux
- skew – the inner skew shape of tableaux
- primed_diagonal – allow primed entries in main diagonal of tableaux

The weight of a tableau is defined to be the vector with $i$-th component equal to the number of entries $i$ and $i'$ in the tableau. The sum of the coordinates in the weight vector must be equal to the number of entries in the partition.

The shape and skew must be strictly decreasing partitions. The primed_diagonal is a boolean (default: False).

EXAMPLES:
sage: SPT = ShiftedPrimedTableaux(weight=(1,2,2), shape=[3,2]); SPT
Shifted Primed Tableaux of weight (1, 2, 2) and shape [3, 2]
sage: SPT.list()
[[[1, 2, 2], (3, 3)],
 [[1, 2', 3'], (2, 3)],

See also:
```
• ShiftedPrimedTableau

Element
alias of ShiftedPrimedTableau

options(*get_value, **set_value)
Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:
• ascii_art – (default: repr) Controls the ascii art output for tableaux
  – compact – minimal length ascii art
  – repr – display using the diagram string representation
  – table – display as a table
• convention – (default: English) Sets the convention used for displaying tableaux and partitions
  – English – use the English convention
  – French – use the French convention
• display – (default: list) Controls the way in which tableaux are printed
  – array – alias for diagram
  – compact – minimal length string representation
  – diagram – display as Young diagram (similar to pp())
  – ferrers_diagram – alias for diagram
  – list – print tableaux as lists
  – young_diagram – alias for diagram
• latex – (default: diagram) Controls the way in which tableaux are latexed
  – array – alias for diagram
  – diagram – as a Young diagram
  – ferrers_diagram – alias for diagram
  – list – as a list
  – young_diagram – alias for diagram
• notation – alternative name for convention

Note: Changing the convention for tableaux also changes the convention for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T
[[1, 2, 3], [4, 5]]
sage: Tableaux.options.display="array"
sage: T
```

(continues on next page)
Changing the convention for tableaux also changes the convention for partitions and vice versa:

```python
sage: P = Partition([3,3,1])
sage: print(P.ferrers_diagram())
* ***
*** ***
sage: Partitions.options.convention="english"
sage: print(P.ferrers_diagram())
*** *** *
sage: T
1 2 3
4 5
```

The ASCII art can also be changed:

```python
sage: t = Tableau([[1,2,3],[4,5]])
sage: ascii_art(t)
   1 2 3
   4 5
sage: Tableaux.options.ascii_art = "table"
sage: ascii_art(t)
+---+---+---+
| 1 | 2 | 3 |
+---+---+---+
| 4 | 5 |
+---+
sage: Tableaux.options.ascii_art = "compact"
sage: ascii_art(t)
1 2 3
4 5
sage: Tableaux.options._reset()
```

See :func:GlobalOptions for more features of these options.

```python
class sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux_all
    Bases: sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux
    The class of all shifted primed tableaux.

class sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux_shape
    Bases: sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux
```

2984 Chapter 5. Comprehensive Module List
Shifted primed tableaux of a fixed shape.

Shifted primed tableaux admit a type $A_n$ classical crystal structure with highest weights corresponding to a given shape.

The list of module generators consists of all elements of the crystal with nonincreasing weight entries.

The crystal is constructed following operations described in [HPS2017] and [AO2018].

The optional `primed_diagonal` allows primed entries in the main diagonal of all the Shifted primed tableaux of a fixed shape. If the `max_entry` is `None` then `max_entry` is set to the total number of entries in the tableau if `primed_diagonal` is `True`.

EXAMPLES:

```
sage: SPTC = crystals.ShiftedPrimedTableaux([3,2], 3)
sage: T = SPTC.module_generators[-1]
sage: T
[(1, 1, 2'), (2, 3')]
sage: T.f(2)
[(1, 1, 3'), (2, 3')]
sage: len(SPTC.module_generators)
7
sage: SPTC[0]
[(1, 1, 1), (2, 2)]
sage: SPTC.cardinality()
24
```

We compare this implementation with the $q(n)$-crystal on (tensor products) of letters:

```
sage: tableau_crystal = crystals.ShiftedPrimedTableaux([4,1], 3)
sage: tableau_digraph = tableau_crystal.digraph()
sage: c = crystals.Letters(['Q'], 3)
sage: tensor_crystal = tensor([c]*5)
sage: u = tensor_crystal(c(1), c(1), c(1), c(2), c(1))
sage: subcrystal = tensor.crystal.subcrystal(generators=[u],
   ....:   index_set=[1,2,-1])
sage: tensor_digraph = subcrystal.digraph()
sage: tensor_digraph.is_isomorphic(tableau_digraph, edge_labels=True)
True
```

If we allow primed entries in the main diagonal:

```
sage: ShiftedPrimedTableaux([4,3,1], max_entry=4,
   ....:   primed_diagonal=True)
Shifted Primed Tableaux of shape [4, 3, 1] and maximum entry 4
sage: ShiftedPrimedTableaux([4,3,1], max_entry=4,
   ....:   primed_diagonal=True).cardinality()
3072
```
sage: SPTC = ShiftedPrimedTableaux([3,2], max_entry=3, primed_diagonal=True)
sage: T = SPTC[-1]
sage: T
[(1', 2', 2), (3', 3)]
sage: SPTC[0]
[(1, 1, 1), (2, 2)]
sage: SPTC.cardinality()
96

module_generators()
Return the generators of self as a crystal.

shape()
Return the shape of the shifted tableaux self.

class sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux_weight(weight, skew=None, primed_diagonal=False)
Bases: sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux
Shifted primed tableaux of fixed weight.

EXAMPLES:

sage: ShiftedPrimedTableaux(weight=(2,3,1))
Shifted Primed Tableaux of weight (2, 3, 1)
sage: ShiftedPrimedTableaux(weight=(2,3,1)).cardinality()
17
sage: SPT = ShiftedPrimedTableaux(weight=(2,3,1), primed_diagonal=True)
sage: SPT.cardinality()
64
sage: T = ShiftedPrimedTableaux(weight=(3,2), primed_diagonal=True)
sage: T[:5]
[[1, 1, 1, 2, 2]],
[(1', 1, 1, 1'), (2),
[(1', 1, 1, 1'), (2),
[(1', 1, 1, 1', 2),
[(1', 1, 1, 1', 2),
[(1, 1, 1), (2,)]
sage: T.cardinality()
16

class sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux_weight_shape(weight, shape, skew=None, primed_diagonal=False)
Bases: sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux
Shifted primed tableaux of the fixed weight and shape.

EXAMPLES:

sage: ShiftedPrimedTableaux([4,2,1], weight=(2,3,2))
Shifted Primed Tableaux of weight (2, 3, 2) and shape [4, 2, 1]
sage: ShiftedPrimedTableaux([4,2,1], weight=(2,3,2)).cardinality()
4
sage: T = ShiftedPrimedTableaux([4,2,1], weight=(2,3,2)),
5.1.303 Shuffle product of iterables

The shuffle product of two sequences of lengths $m$ and $n$ is a sum over the $\binom{m+n}{n}$ ways of interleaving the two sequences. That could be defined inductively by:

$$(a_n)_{n\geq 0} \shuffle (b_m)_{m\geq 0} = a_0 \cdot ((a_n)_{n\geq 1} \shuffle (b_m)_{m\geq 0}) + b_0 \cdot ((a_n)_{n\geq 0} \shuffle (b_m)_{m\geq 1})$$

with $(a_n)$ and $(b_m)$ two non-empty sequences and if one of them is empty then the product is equals to the other.

The shuffle product has been introduced by S. Eilenberg and S. Mac Lane in 1953 [EilLan53].

EXAMPLES:

```python
sage: from sage.combinat.shuffle import ShuffleProduct
sage: list(ShuffleProduct([1,2], ["a", "b", "c"]))
[[1, 2, 'a', 'b', 'c'], ['a', 1, 2, 'b', 'c'], [1, 'a', 2, 'b', 'c'], ['a', 'b', 1, 2, 'c'], ['a', 1, 'b', 2, 'c'], [1, 'a', 'b', 2, 'c'], ['a', 'b', 'c', 1, 2], ['a', 'b', 1, 'c', 2], ['a', 1, 'b', 'c', 2], [1, 'a', 'b', 'c', 2]]
```

5.1.303 Shuffle product of iterables

The shuffle product of two sequences of lengths $m$ and $n$ is a sum over the $\binom{m+n}{n}$ ways of interleaving the two sequences. That could be defined inductively by:

$$(a_n)_{n\geq 0} \shuffle (b_m)_{m\geq 0} = a_0 \cdot ((a_n)_{n\geq 1} \shuffle (b_m)_{m\geq 0}) + b_0 \cdot ((a_n)_{n\geq 0} \shuffle (b_m)_{m\geq 1})$$

with $(a_n)$ and $(b_m)$ two non-empty sequences and if one of them is empty then the product is equals to the other.

The shuffle product has been introduced by S. Eilenberg and S. Mac Lane in 1953 [EilLan53].

EXAMPLES:

```python
sage: from sage.combinat.shuffle import ShuffleProduct
sage: list(ShuffleProduct([1,2], ["a", "b", "c"]))
[[1, 2, 'a', 'b', 'c'], ['a', 1, 2, 'b', 'c'], [1, 'a', 2, 'b', 'c'], ['a', 'b', 1, 2, 'c'], ['a', 1, 'b', 2, 'c'], [1, 'a', 'b', 2, 'c'], ['a', 'b', 'c', 1, 2], ['a', 'b', 1, 'c', 2], ['a', 1, 'b', 'c', 2], [1, 'a', 'b', 'c', 2]]
```

5.1.303 Shuffle product of iterables

The shuffle product of two sequences of lengths $m$ and $n$ is a sum over the $\binom{m+n}{n}$ ways of interleaving the two sequences. That could be defined inductively by:

$$(a_n)_{n\geq 0} \shuffle (b_m)_{m\geq 0} = a_0 \cdot ((a_n)_{n\geq 1} \shuffle (b_m)_{m\geq 0}) + b_0 \cdot ((a_n)_{n\geq 0} \shuffle (b_m)_{m\geq 1})$$

with $(a_n)$ and $(b_m)$ two non-empty sequences and if one of them is empty then the product is equals to the other.

The shuffle product has been introduced by S. Eilenberg and S. Mac Lane in 1953 [EilLan53].

EXAMPLES:

```python
sage: from sage.combinat.shuffle import ShuffleProduct
sage: list(ShuffleProduct([1,2], ["a", "b", "c"]))
[[1, 2, 'a', 'b', 'c'], ['a', 1, 2, 'b', 'c'], [1, 'a', 2, 'b', 'c'], ['a', 'b', 1, 2, 'c'], ['a', 1, 'b', 2, 'c'], [1, 'a', 'b', 2, 'c'], ['a', 'b', 'c', 1, 2], ['a', 'b', 1, 'c', 2], ['a', 1, 'b', 'c', 2], [1, 'a', 'b', 'c', 2]]
```
cardinality()

The cardinality is defined by the sum of the cardinality of all shuffles. That means by a sum of binomials.

class sage.combinat.shuffle.ShuffleProduct(l1, l2, element_constructor=None)
Bases: sage.combinat.shuffle.ShuffleProduct_abstract
Shuffle product of two iterables.

EXAMPLES:

```python
sage: from sage.combinat.shuffle import ShuffleProduct
sage: list(ShuffleProduct("abc", "de", element_constructor="".join))
['abcde',
 'adbc',
 'dabc',
 'abd',
 'ade',
 'daeb',
 'deabc']
```

```
```

cardinality()

Return the number of shuffles of \( l_1 \) and \( l_2 \), respectively of lengths \( m \) and \( n \), which is \( \binom{m+n}{n} \).

class sage.combinat.shuffle.ShuffleProduct_abstract(l1, l2, element_constructor=None)
Bases: sage.structure.parent.Parent
Abstract base class for shuffle products.

class sage.combinat.shuffle.ShuffleProduct_overlapping(w1, w2, element_constructor=None,
 add=<built-in function add>)
Bases: sage.combinat.shuffle.ShuffleProduct_abstract
The overlapping shuffle product of the two words \( w_1 \) and \( w_2 \).

If \( u \) and \( v \) are two words whose letters belong to an additive monoid or to another kind of alphabet on which addition is well-defined, then the overlapping shuffle product of \( u \) and \( v \) is a certain multiset of words defined as follows: Let \( a \) and \( b \) be the lengths of \( u \) and \( v \), respectively. Let \( A \) be the set \( \{(0,1),(0,2),\ldots,(0,a)\} \), and let \( B \) be the set \( \{(1,1),(1,2),\ldots,(1,b)\} \). Notice that the sets \( A \) and \( B \) are disjoint. We can make \( A \) and \( B \) into posets by setting \( (k,i) \leq (k,j) \) for all \( k \in \{0,1\} \) and \( i \leq j \). Then, \( A \cup B \) becomes a poset by disjoint union
(we don’t set \((0, i) \leq (1, i)\)). Let \(p\) be the map from \(A \cup B\) to the set of all letters which sends every \((0, i)\) to the \(i\)-th letter of \(u\), and every \((1, j)\) to the \(j\)-th letter of \(v\). For every nonnegative integer \(c\) and every surjective map \(f : A \cup B \to \{1, 2, \cdots, c\}\) for which both restrictions \(f |_A\) and \(f |_B\) are strictly increasing, let \(w(f)\) be the length-\(c\) word such that for every \(1 \leq k \leq c\), the \(k\)-th letter of \(w(f)\) equals \(\sum_{ j \in f^{-1}(k)} p(j)\) (this sum always has either one or two addends). The overlapping shuffle product of \(u\) and \(v\) is then the multiset of all \(w(f)\) with \(c\) ranging over all nonnegative integers and \(f\) ranging over the surjective maps \(f : A \cup B \to \{1, 2, \cdots, c\}\) for which both restrictions \(f |_A\) and \(f |_B\) are strictly increasing.

If one restricts \(c\) to a particular fixed nonnegative integer, then the multiset is instead called the overlapping shuffle product with precisely \(a + b - c\) overlaps. This is nonempty only if \(\max\{a, b\} \leq c \leq a + b\).

If \(c = a + b\), then the overlapping shuffle product with precisely \(a + b - c\) overlaps is plainly the shuffle product (\(\text{ShuffleProduct}_w1w2\)).

INPUT:

- \(w1, w2\) – iterables
- \textbf{element\_constructor} – (default: the parent of \(w1\)) the function used to construct the output
- \textbf{add} – (default: \(+\)) the addition function

EXAMPLES:

```
sage: from sage.combinat.shuffle import ShuffleProduct_overlapping
sage: w, u = [[2, 9], [9, 1]]
sage: S = ShuffleProduct_overlapping(w, u)
sage: sorted(S)
[[2, 9, 1, 9],
 [2, 9, 9, 1],
 [2, 9, 9, 1],
 [2, 9, 10],
 [2, 18, 1],
 [9, 1, 2, 9],
 [9, 2, 2, 9],
 [9, 2, 2, 9],
 [9, 2, 10],
 [9, 3, 9],
 [11, 1, 9],
 [11, 9, 1],
 [11, 10]]
sage: A = [{1,2}, {3,4}]
sage: B = [{2,3}, {4,5,6}]
sage: S = ShuffleProduct_overlapping(A, B, add=lambda X,Y: X.union(Y))
sage: list(S)
[[{1, 2}, {3, 4}, {2, 3}, {4, 5, 6}],
 [{1, 2}, {2, 3}, {3, 4}, {4, 5, 6}],
 [{1, 2}, {2, 3}, {4, 5, 6}, {3, 4}],
 [{2, 3}, {1, 2}, {3, 4}, {4, 5, 6}],
 [{2, 3}, {1, 2}, {4, 5, 6}, {3, 4}],
 [{2, 3}, {4, 5, 6}, {1, 2}, {3, 4}],
 [{1, 2, 3}, {3, 4}, {4, 5, 6}],
 [{1, 2}, {2, 3, 4}, {4, 5, 6}],
 [{1, 2, 3}, {4, 5, 6}, {3, 4}],
 [{1, 2}, {2, 3}, {3, 4, 5, 6}],
 [{2, 3}, {1, 2, 4, 5, 6}, {3, 4}],
 [{2, 3}, {1, 2}, {4, 5, 6}, {3, 4}],
 [{2, 3}, {1, 2}, {4, 5, 6}, {3, 4}],
 [{2, 3}, {1, 2}, {4, 5, 6}, {3, 4}],
 [{2, 3}, {1, 2}, {4, 5, 6}, {3, 4}],
 [{2, 3}, {1, 2, 4, 5, 6}, {3, 4}],
 ...
```
class sage.combinat.shuffle.ShuffleProduct_overlapping_r(w1, w2, r, element_constructor=None, add=<built-in function add>)

Bases: sage.combinat.shuffle.ShuffleProduct_abstract

The overlapping shuffle product of the two words \(w1\) and \(w2\) with precisely \(r\) overlaps.

See ShuffleProduct_overlapping for a definition.

EXAMPLES:

sage: from sage.combinat.shuffle import ShuffleProduct_overlapping_r
sage: w, u = map(Words(range(20)), [[2, 9], [9, 1]])

sage: S = ShuffleProduct_overlapping_r(w, u, 1)

sage: list(S)
[word: 11, 9, 1,
 word: 2, 18, 1,
 word: 11, 1, 9,
 word: 2, 9, 10,
 word: 9, 3, 9,
 word: 9, 2, 10]

5.1.304 Sidon sets and their generalizations, Sidon \(g\)-sets

AUTHORS:

• Martin Raum (07-25-2011)

sage.combinat.sidon_sets.sidon_sets\(\)\(N, g=1\)

Return the set of all Sidon-\(g\) sets that have elements less than or equal to \(N\).

A Sidon-\(g\) set is a set of positive integers \(A \subset [1, N]\) such that any integer \(M\) can be obtain at most \(g\) times as sums of unordered pairs of elements of \(A\) (the two elements are not necessary distinct):

\[
\#\{(a_i, a_j) | a_i, a_j \in A, a_i + a_j = M, a_i \leq a_j\} \leq g
\]

INPUT:

• \(N\) – A positive integer.

• \(g\) – A positive integer (default: 1).

OUTPUT:

• A Sage set with categories whose element are also set of integers.

EXAMPLES:

sage: S = sidon_sets(3, 2)

sage: sorted(S, key=str)
[[1, 2, 3], [1, 2], [1, 3], [1], [2, 3], [2], [3], []]
Combinatorics, Release 9.7

(continued from previous page)

```plaintext
sage: sid = S.an_element()
sage: sid
{2}
sage: sid.category()
Category of finite enumerated sets
```

sage.combinat.sidon_sets.sidon_sets_rec(N, g=1)

Return the set of all Sidon-\(g\) sets that have elements less than or equal to \(N\) without checking the arguments.
This internal function should not be call directly by user.

5.1.305 Similarity class types of matrices with entries in a finite field

The notion of a matrix conjugacy class type was introduced by J. A. Green in [Green55], in the context of computing
the irreducible characters of finite general linear groups. The class types are equivalence classes of similarity classes
of square matrices with entries in a finite field which, roughly speaking, have the same qualitative properties.

For example, all similarity classes of the same class type have centralizers of the same cardinality and the same degrees
of elementary divisors. Qualitative properties of similarity classes such as semisimplicity and regularity descend to
class types.

The most important feature of similarity class types is that, for any \(n\), the number of similarity class types of \(n \times n\)
matrices is independent of \(q\). This makes it possible to perform many combinatorial calculations treating \(q\) as a formal
variable.

In order to define similarity class types, recall that similarity classes of \(n \times n\) matrices with entries in \(\mathbf{F}_q\) correspond
to functions

\[
c : \text{Irr}_{\mathbf{F}_q[t]} \to \Lambda
\]

such that

\[
\sum_{f \in \text{Irr}_{\mathbf{F}_q[t]}} |c(f)| \deg f = n,
\]

where we denote the set of irreducible monic polynomials in \(\mathbf{F}_q[t]\) by \(\text{Irr}_{\mathbf{F}_q[t]}\), the set of all partitions by \(\Lambda\), and the
size of \(\lambda \in \Lambda\) by \(|\lambda|\).

Similarity classes indexed by functions \(c_1\) and \(c_2\) as above are said to be of the same type if there exists a degree-
preserving self-bijection \(\sigma\) of \(\text{Irr}_{\mathbf{F}_q[t]}\) such that \(c_2 = c_1 \circ \sigma\). Thus, the type of \(c\) remembers only the degrees of the
polynomials (and not the polynomials themselves) for which \(c\) takes a certain value \(\lambda\). Replacing each irreducible
polynomial of degree \(d\) for which \(c\) takes a non-trivial value \(\lambda\) by the pair \((d, \lambda)\), we obtain a multiset of such pairs.
Clearly, \(c_1\) and \(c_2\) have the same type if and only if these multisets are equal. Thus a similarity class type may be viewed
as a multiset of pairs of the form \((d, \lambda)\).

For \(2 \times 2\) matrices there are four types:

```plaintext
sage: for tau in SimilarityClassTypes(2):
    ....:     print(tau)
[[[1, [1]], [1, [1]]],
 [[1, [2]]],
 [[[1, [1], 1]],
 [[2, [1]]]]
```

These four types correspond to the regular split semisimple matrices, the non-semisimple matrices, the central matrices
and the irreducible matrices respectively.

5.1. Comprehensive Module List 2991
For any matrix $A$ in a given similarity class type, it is possible to calculate the number elements in the similarity class of $A$, the dimension of the algebra of matrices in $M_n(A)$ that commute with $A$, and the cardinality of the subgroup of $GL_n(F_q)$ that commute with $A$. For each similarity class type, it is also possible to compute the number of classes of that type (and hence, the total number of matrices of that type). All these calculations treat the cardinality $q$ of the finite field as a formal variable:

```sage
M = SimilarityClassType([[1, [1]], [1, [1]]])
M.class_card()
q^2 + q
M.centralizer_algebra_dim()
2
M.centralizer_group_card()
q^2 - 2q + 1
M.number_of_classes()
1/2*q^2 - 1/2*q
M.number_of_matrices()
1/2*q^4 - 1/2*q^2
```

We now describe two applications of similarity class types.

We say that an $n \times n$ matrix has rational canonical form type $\lambda$ for some partition $\lambda$ of $n$ if the diagonal blocks in the rational canonical form have sizes given by the parts of $\lambda$. Thus the matrices with rational canonical type $(n)$ are the regular ones, while the matrices with rational canonical type $(1^n)$ are the central ones.

Using similarity class types, it becomes easy to get a formula for the number of matrices with a given rational canonical type:

```sage
def matrices_with_rcf(la):
    ....:    return sum([tau.number_of_matrices() for tau in filter(lambda tau: tau.rcf()==la, SimilarityClassTypes(la.size()))])
matrices_with_rcf(Partition([2,1]))
q^6 + q^5 + q^4 - q^3 - q^2 - q
```

Similarity class types can also be used to calculate the number of simultaneous similarity classes of $k$-tuples of $n \times n$ matrices with entries in $F_q$ by using Burnside's lemma:

```sage
from sage.combinat.similarity_class_type import order_of_general_linear_group,
    centralizer_algebra_dim
q = ZZ['q'].gen()
def simultaneous_similarity_classes(n,k):
    ....:    return SimilarityClassTypes(n).sum(lambdas la: q**(k*centralizer_algebra_dim(la)), invertible = True)/order_of_general_linear_group(n)
simultaneous_similarity_classes(3, 2)
q^10 + q^8 + 2*q^7 + 2*q^6 + 2*q^5 + q^4
```

Similarity class types can be used to compute the coefficients of generating functions coming from the cycle index type techniques of Kung and Stong (see Morrison [Morrison06]).

They can also be used to compute the number of invariant subspaces for a matrix over a finite field of any given dimension. For this we use the elegant recursive formula of Ramaré [R17] (see also [PR22]).

Along with the results of [PSS13], similarity class types can be used to calculate the number of similarity classes of matrices of order $n$ with entries in a principal ideal local ring of length two with residue field of cardinality $q$ with centralizer of any given cardinality up to $n = 4$. Among these, the classes which are selftranspose can also be counted:
**sage:** from sage.combinat.similarity_class_type import matrix_centralizer_cardinalities_length_two

**sage:** list(matrix_centralizer_cardinalities_length_two(3))

```
[(q^6 - 3*q^5 + 3*q^4 - q^3, 1/6*q^6 - 1/2*q^5 + 1/3*q^4),
(q^6 - 2*q^5 + q^4, q^5 - q^4),
(q^8 - 3*q^7 + 3*q^6 - q^5, 1/2*q^5 - q^4 + 1/2*q^3),
(q^8 - 2*q^7 + q^6, q^6 - q^5),
(q^10 - 2*q^9 + 2*q^8 - q^7 - q^6, q^6 - q^5 - q^4 - q^3),
(q^8 - q^7 - q^6 + q^5, 1/2*q^5 - q^4 + 1/2*q^3),
(q^6 - q^5 - q^4 + q^3, 1/2*q^6 - q^5 - q^3),
(q^6 - q^5, q^4),
(q^10 - 2*q^9 + q^8, q^8),
(q^8 - 2*q^7 + q^6, q^6 - q^5),
(q^8 - q^7, q^3 + q^2),
(q^12 - 3*q^11 + 3*q^10 - q^9, 1/6*q^4 - 1/2*q^3 + 1/3*q^2),
(q^12 - 2*q^11 + q^10, q^3 - q^2),
(q^14 - 2*q^13 + 2*q^12 - q^11 - q^10, q^3 - q^2),
(q^12 - q^11 - q^10 + q^9, 1/2*q^4 - 1/2*q^3),
(q^12 - q^11, q^2),
(q^14 - 2*q^13 + q^12, q^2),
(q^18 - q^17 - q^16 + q^15 + q^14 - q^13, q^2),
(q^12 - q^9, 1/3*q^4 - 1/3*q^2),
(q^6 - q^4 - 1/3*q^4)]
```

**class** sage.combinat.similarity_class_type.PrimarySimilarityClassType(*parent, deg, par*)

**Bases:** sage.structure.element.Element

A primary similarity class type is a pair consisting of a partition and a positive integer.

For a partition \( \lambda \) and a positive integer \( d \), the primary similarity class type \((d, \lambda)\) represents similarity classes of square matrices of order \(|\lambda| \cdot d\) with entries in a finite field of order \( q \) which correspond to the \( F_q[t]/p(t) \)-module

\[
\frac{F_q[t]}{p(t)^{\lambda_1}} \oplus \frac{F_q[t]}{p(t)^{\lambda_2}} \oplus \cdots
\]

for some irreducible polynomial \( p(t) \) of degree \( d \).

**centralizer_algebra_dim()**

Return the dimension of the algebra of matrices which commute with a matrix of type \texttt{self}.

For a partition \((d, \lambda)\) this dimension is given by \( d(\lambda_1 + 3\lambda_2 + 5\lambda_3 + \cdots) \).

**EXAMPLES:**

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.centralizer_algebra_dim()
28
```

---

**5.1. Comprehensive Module List**

2993
centralizer_group_card\((q=None)\)  
Return the cardinality of the centralizer group of a matrix of type self in a field of order q.

**INPUT:**  
• q – an integer or an indeterminate

**EXAMPLES:**

```
sage: PT = PrimarySimilarityClassType(1, [])
sage: PT.centralizer_group_card()
sage: PT = PrimarySimilarityClassType(2, [1, 1])
sage: PT.centralizer_group_card()
q^8 - q^6 - q^4 + q^2
```

degree()  
Return degree of self.

**EXAMPLES:**

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.degree()
2
```

invariant_subspace_generating_function\((q=None, t=None)\)  
Return the invariant subspace generating function of self.

**INPUT:**  
• q – (optional) an integer or an indeterminate  
• t – (optional) an indeterminate

**EXAMPLES:**

```
sage: PrimarySimilarityClassType(1, [2, 2]).invariant_subspace_generating_function()
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
```

partition()  
Return partition corresponding to self.

**EXAMPLES:**

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.partition()
[3, 2, 1]
```

size()  
Return the size of self.

**EXAMPLES:**

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.size()
12
```

statistic\((func, q=None)\)  
Return \(n_\lambda(q^d)\) where \(n_\lambda\) is the value returned by func upon input \(\lambda\), if self is \((d, \lambda)\).
**EXAMPLES:**

```python
sage: PT = PrimarySimilarityClassType(2, [3, 1])
sage: q = ZZ['q'].gen()
sage: PT.statistic(lambda la: q**la.size(), q = q)
q^8
```

```python
class sage.combinat.similarity_class_type.PrimarySimilarityClassTypes(n, min)
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

All primary similarity class types of size $n$ whose degree is greater than that of $\text{min}$ or whose degree is that of $\text{min}$ and whose partition is less than of $\text{min}$ in lexicographic order.

A primary similarity class type of size $n$ is a pair $(\lambda, d)$ consisting of a partition $\lambda$ and a positive integer $d$ such that $|\lambda|d = n$.

**INPUT:**

- $n$ – a positive integer
- $\text{min}$ – a primary matrix type of size $n$

**EXAMPLES:**

If $\text{min}$ is not specified, then the class of all primary similarity class types of size $n$ is created:

```python
sage: PTC = PrimarySimilarityClassTypes(2)
sage: for PT in PTC:
    ....:     print(PT)
[1, [2]]
[1, [1, 1]]
[2, [1]]
```

If $\text{min}$ is specified, then the class consists of only those primary similarity class types whose degree is greater than that of $\text{min}$ or whose degree is that of $\text{min}$ and whose partition is less than of $\text{min}$ in lexicographic order:

```python
sage: PTC = PrimarySimilarityClassTypes(2, min = PrimarySimilarityClassType(1, [1, \rightarrow 1]))
sage: for PT in PTC:
    ....:     print(PT)
[1, [1, 1]]
[2, [1]]
```

**Element**

alias of `PrimarySimilarityClassType`

**size()**

Return size of elements of self.

The size of a primary similarity class type $(d, \lambda)$ is $d|\lambda|$.

**EXAMPLES:**

```python
sage: PTC = PrimarySimilarityClassTypes(2)
sage: PTC.size()
2
```

**class** `sage.combinat.similarity_class_type.SimilarityClassType(parent, tau)`

Bases: `sage.combinat.combinat.CombinatorialElement`
A similarity class type.
A matrix type is a multiset of primary similarity class types.

INPUT:
• \( \tau \) – a list of primary similarity class types or a square matrix over a finite field

EXAMPLES:

```
sage: tau1 = SimilarityClassType([[3, [3, 2, 1]], [2, [2, 1]]]); tau1
[[2, [2, 1]], [3, [3, 2, 1]]]
sage: SimilarityClassType(Matrix(GF(2), [[1, 1], [0, 1]]))
[[1, [2]]]
```

`as_partition_dictionary()`

Return a dictionary whose keys are the partitions of types occurring in \( \text{self} \) and the value at the key \( \lambda \) is the partition formed by sorting the degrees of primary types with partition \( \lambda \).

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.as_partition_dictionary()
{[1]: [1, 1]}
```

`centralizer_algebra_dim()`

Return the dimension of the algebra of matrices which commute with a matrix of type \( \text{self} \).

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.centralizer_algebra_dim()
2
```

`centralizer_group_card(q=None)`

Return the cardinality of the group of matrices in \( GL_n(F_q) \) which commute with a matrix of type \( \text{self} \).

INPUT:
• \( q \) – an integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.centralizer_group_card()
q^2 - 2*q + 1
```

`class_card(q=None)`

Return the number of matrices in each similarity class of type \( \text{self} \).

INPUT:
• \( q \) – an integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1, 1, 1, 1]], [1, [1]]])
sage: tau.class_card()
1
```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.class_card()
q^2 + q

**invariant_subspace_generating_function** *(q=None, t=None)*

Return the invariant subspace generating function of *self*.

The invariant subspace generating function is the function is the polynomial

\[
\sum_{j \geq 0} a_j(q)t^j,
\]

where \(a_j(q)\) denotes the number of \(j\)-dimensional invariant subspaces of dimension \(j\) for any matrix with the similarity class type *self* with entries in a field of order \(q\).

**EXAMPLES:**

```python
sage: SimilarityClassType([[1, [2, 2]]]).invariant_subspace_generating_function()
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
sage: A = Matrix(GF(2),[(0, 1, 0, 0), (0, 1, 1, 1), (1, 0, 1, 0), (1, 1, 0, 0)])
sage: SimilarityClassType(A).invariant_subspace_generating_function()
t^4 + 1
```

**is_regular**

Return True if every primary type in *self* has partition with one part.

**EXAMPLES:**

```python
sage: tau = SimilarityClassType([[2, [1]], [1, [3]]])
sage: tau.is_regular()
True
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [1]]])
sage: tau.is_regular()
False
```

**is_semisimple**

Return True if every primary similarity class type in *self* has all parts equal to 1.

**EXAMPLES:**

```python
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [1]]])
sage: tau.is_semisimple()
True
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [2]]])
sage: tau.is_semisimple()
False
```

**number_of_classes**(invertible=False, q=None)

Return the number of similarity classes of matrices of type *self*.

**INPUT:**

- **invertible** – Boolean; return number of invertible classes if set to **True**
- **q** – An integer or an indeterminate

**EXAMPLES:**
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.number_of_classes()
1/2*q^2 - 1/2*q

\textbf{number\_of\_matrices}(invertible=False, q=None)

Return the number of matrices of type \texttt{self}.

\textbf{INPUT:}

\begin{itemize}
  \item invertible – A boolean; return the number of invertible matrices if set
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: tau = SimilarityClassType([[1, [1]]])
sage: tau.number_of_matrices()
q
sage: tau.number_of_matrices(invertible = True)
q - 1
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.number_of_matrices()
1/2*q^4 - 1/2*q^2
\end{verbatim}

\textbf{rcf()}

Return the partition corresponding to the rational canonical form of a matrix of type \texttt{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: tau = SimilarityClassType([[2, [1, 1, 1]], [1, [3, 2]]])
sage: tau.rcf()
[5, 4, 2]
\end{verbatim}

\textbf{size()}

Return the sum of the sizes of the primary parts of \texttt{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: tau = SimilarityClassType([[3, [3, 2, 1]], [2, [2, 1]]])
sage: tau.size()
24
\end{verbatim}

\textbf{statistic}(func, q=None)

Return

\[ \prod_{(d, \lambda) \in \tau} n_\lambda(q^d) \]

where \( n_\lambda(q) \) is the value returned by \texttt{func} on the input \texttt{\lambda}.

\textbf{INPUT:}

\begin{itemize}
  \item func – a function that takes a partition to a polynomial in \texttt{q}
  \item q – an integer or an indeterminate
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: tau = SimilarityClassType([[1, [1]], [1, [2, 1]], [2, [1, 1]]])
sage: from sage.combinat.similarity_class_type import fq
\end{verbatim}
sage: tau.statistic(lambda la: prod([fq(m) for m in la.to_exp()])))
(q^9 - 3*q^8 + 2*q^7 + 2*q^6 - 4*q^5 + 4*q^4 - 2*q^3 - 2*q^2 + 3*q - 1)/q^9
sage: q = ZZ['q'].gen()
sage: tau.statistic(lambda la: q**la.size(), q = q)
q^8

class sage.combinat.similarity_class_type.SimilarityClassTypes(n, min)
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Class of all similarity class types of size n with all primary matrix types greater than or equal to the primary matrix type min.

A similarity class type is a multiset of primary matrix types.

INPUT:

• n – a non-negative integer
• min – a primary similarity class type

EXAMPLES:

If min is not specified, then the class of all matrix types of size n is constructed:

```python
sage: M = SimilarityClassTypes(2)
sage: for tau in M:
    print(tau)
[[[1, [1]]], [[1, [1]]], [[[1, [1, 1]]], [[2, [1]]]]
```

If min is specified, then the class consists of only those similarity class types which are multisets of primary matrix types which either have size greater than that of min, or if they have size equal to that of min, then they occur after min in the iterator for PrimarySimilarityClassTypes(n), where n is the size of min:

```python
sage: M = SimilarityClassTypes(2, min = [[1, [1, 1]]])
sage: for tau in M:
    print(tau)
[[[1, [1, 1]]], [[2, [1]]]]
```

Element

alias of SimilarityClassType

size()

Return size of self.

EXAMPLES:

```python
sage: tau = SimilarityClassType([[3, [3, 2, 1]], [2, [2, 1]]])
sage: tau.parent().size()
24
```

sum(stat, sumover='matrices', invertible=False, q=None)

Return the sum of a local statistic over all types.
Given a set of functions $n_\lambda(q)$ (these could be polynomials or rational functions in $q$), for each similarity class type $\tau$ define

$$n_\tau(q) = \prod_{(d,\lambda) \in \tau} n_\lambda(q^d).$$

This function returns

$$\sum n_{\tau(g)}(q)$$

where $\tau(g)$ denotes the type of a matrix $g$, and the sum is over all $n \times n$ matrices if `sumover` is set to "matrices", is over all $n \times n$ similarity classes if `sumover` is set to "classes", and over all $n \times n$ types if `sumover` is set to "types". If `invertible` is set to `True`, then the sum is only over invertible matrices or classes.

**INPUT:**
- stat – a function which takes partitions and returns a function of $q$
- sumover – can be one of the following:
  - "matrices"
  - "classes"
  - "types"
- q – an integer or an indeterminate

**OUTPUT:**
A function of $q$.

**EXAMPLES:**
```
sage: M = SimilarityClassTypes(2)
sage: M.sum(lambda la:1)
q^4
sage: M.sum(lambda la:1, invertible = True)
q^4 - q^3 - q^2 + q
sage: M.sum(lambda la:1, sumover = "classes")
q^2 + q
sage: M.sum(lambda la:1, sumover = "classes", invertible = True)
q^2 - 1
```

Burside’s lemma can be used to calculate the number of similarity classes of matrices:
```
sage: from sage.combinat.similarity_class_type import centralizer_algebra_dim,
         order_of_general_linear_group
sage: q = ZZ['q'].gen()
sage: M.sum(lambda la:q**centralizer_algebra_dim(la), invertible = True)/order_of_general_linear_group(2)
q^2 + q
```

`sage.combinat.similarity_class_type.centralizer_algebra_dim(la)`
Return the dimension of the centralizer algebra in $M_n(F_q)$ of a nilpotent matrix whose Jordan blocks are given by $l_a$.  

**EXAMPLES:**
sage: from sage.combinat.similarity_class_type import centralizer_algebra_dim
sage: centralizer_algebra_dim(Partition([2, 1]))
5

Note: If it is a list, la is expected to be sorted in decreasing order.

sage.combinat.similarity_class_type.centralizer_group_cardinality(la, q=None)
Return the cardinality of the centralizer group in $GL_n(F_q)$ of a nilpotent matrix whose Jordan blocks are given by la.

INPUT:
• lambda – a partition
• q – an integer or an indeterminate

OUTPUT:
A polynomial function of q.

EXAMPLES:

sage: from sage.combinat.similarity_class_type import centralizer_group_cardinality
sage: q = ZZ['q'].gen()
sage: centralizer_group_cardinality(Partition([2, 1]))
q^5 - 2*q^4 + q^3

sage.combinat.similarity_class_type.dictionary_from_generator(gen)
Given a generator for a list of pairs $(c, f)$, construct a dictionary whose keys are the distinct values for $c$ and whose value at $c$ is the sum of $f$ over all pairs of the form $(c', f)$ such that $c = c'$.

EXAMPLES:

sage: from sage.combinat.similarity_class_type import dictionary_from_generator
sage: dictionary_from_generator(((x // 2, x) for x in range(10)))
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}

It also works with lists:

sage: dictionary_from_generator([(x // 2, x) for x in range(10)])
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}

Note: Since the generator is first converted to a list, memory usage could be high.

sage.combinat.similarity_class_type.ext_orbit_centralizers(input_data, q=None, selftranspose=False)
Generate pairs consisting of centralizer cardinalities of orbits in $\text{Ext}^1(M, M)$ for the action of $\text{Aut}(M, M)$, where $M$ is the $F_{q[t]}$-module constructed from input and their frequencies.

INPUT:
• input_data – input for input_parsing()
• q – (default: q) an integer or an indeterminate
• selftranspose – (default: False) boolean stating if we only want selftranspose type
sage.combinat.similarity_class_type.ext_orbits(input_data, q=None, selftranspose=False)

Return the number of orbits in $\text{Ext}^1(M, M)$ for the action of $\text{Aut}(M, M)$, where $M$ is the $F_q[t]$-module constructed from input_data.

INPUT:

- input_data -- input for input_parsing()
- q -- (default: $q$) an integer or an indeterminate
- selftranspose -- (default: False) boolean stating if we only want selftranspose type

sage.combinat.similarity_class_type.fq(n, q=None)

Return $(1 - q^{-1})(1 - q^{-2}) \cdots (1 - q^{-n})$.

INPUT:

- n -- a non-negative integer
- q -- an integer or an indeterminate

OUTPUT:

A rational function in $q$.

EXAMPLES:

```python
sage: from sage.combinat.similarity_class_type import fq
sage: fq(0)
1
sage: fq(3)
(q^6 - q^5 - q^4 + q^2 + q - 1)/q^6
```

sage.combinat.similarity_class_type.input_parsing(data)

Recognize and return the intended type of input.

sage.combinat.similarity_class_type.invariant_subspace_generating_function(la, q=None, t=None)

Return the invariant subspace generating function of a nilpotent matrix with Jordan block sizes given by la.

INPUT:

- la -- a partition
- q -- (optional) an integer or an indeterminate
- t -- (optional) an indeterminate

OUTPUT:

A polynomial in $t$ whose coefficients are polynomials in $q$.

EXAMPLES:

```python
sage: from sage.combinat.similarity_class_type import invariant_subspace_generating_function
sage: invariant_subspace_generating_function([2,2])
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
```

sage.combinat.similarity_class_type.matrix_centralizer_cardinalities(n, q=None, invertible=False)

Generate pairs consisting of centralizer cardinalities of matrices over a finite field and their frequencies.
sage.combinat.similarity_class_type.matrix_centralizer_cardinalities_length_two(n, q=None, selftranspose=False, \ invertible=False)

Generate pairs consisting of centralizer cardinalities of matrices over a principal ideal local ring of length two with residue field of order \(q\) and their frequencies.

**INPUT:**
- \(n\) – the order
- \(q\) – (default: \(q\)) an integer or an indeterminate
- \texttt{selftranspose} – (default: False) boolean stating if we only want selftranspose type
- \texttt{invertible} – (default: False) boolean stating if we only want invertible type

sage.combinat.similarity_class_type.matrix_similarity_classes(n, q=None, invertible=False)

Return the number of matrix similarity classes over a finite field of order \(q\).

sage.combinat.similarity_class_type.matrix_similarity_classes_length_two(n, q=None, selftranspose=False, invertible=False)

Return the number of similarity classes of matrices of order \(n\) with entries in a principal ideal local ring of length two.

**INPUT:**
- \(n\) – the order
- \(q\) – (default: \(q\)) an integer or an indeterminate
- \texttt{selftranspose} – (default: False) boolean stating if we only want selftranspose type
- \texttt{invertible} – (default: False) boolean stating if we only want invertible type

**EXAMPLES:**

We can generate Table 6 of [PSS13):

```
sage: from sage.combinat.similarity_class_type import matrix_similarity_classes_length_two
sage: matrix_similarity_classes_length_two(2)
q^4 + q^3 + q^2
sage: matrix_similarity_classes_length_two(2, invertible=True)
q^4 - q
sage: matrix_similarity_classes_length_two(3)
q^6 + q^5 + 2*q^4 + q^3 + 2*q^2
sage: matrix_similarity_classes_length_two(3, invertible=True)
q^6 - q^3 + 2*q^2 - 2*q
sage: matrix_similarity_classes_length_two(4)
q^8 + q^7 + 3*q^6 + 3*q^5 + 5*q^4 + 3*q^3 + 3*q^2
sage: matrix_similarity_classes_length_two(4, invertible=True)
q^8 + q^6 - q^5 + 2*q^4 - 2*q^3 + 2*q^2 - 3*q
```

And also Table 7:

```
sage: matrix_similarity_classes_length_two(2, selftranspose=True)
q^4 + q^3 + q^2
```
(continues on next page)
sage: matrix_similarity_classes_length_two(2, selftranspose = True, invertible = True)
q^4 - q

sage: matrix_similarity_classes_length_two(3, selftranspose = True)
q^6 + q^5 + 2*q^4 + q^3

sage: matrix_similarity_classes_length_two(3, selftranspose = True, invertible = True)
q^6 - q^3

sage: matrix_similarity_classes_length_two(4, selftranspose = True)
q^8 + q^7 + 3*q^6 + 3*q^5 + 3*q^4 + q^3 + q^2

sage: matrix_similarity_classes_length_two(4, selftranspose = True, invertible = True)
q^8 + q^6 - q^5 - q

sage.combinat.similarity_class_type.order_of_general_linear_group(n, q=None)
Return the cardinality of the group of \( n \times n \) invertible matrices with entries in a field of order \( q \).

INPUT:

- \( n \) – a non-negative integer
- \( q \) – an integer or an indeterminate

EXAMPLES:

sage: from sage.combinat.similarity_class_type import order_of_general_linear_group
sage: order_of_general_linear_group(0)
1
sage: order_of_general_linear_group(2)
q^4 - q^3 - q^2 + q

sage.combinat.similarity_class_type.primitives(n, invertible=False, q=None)
Return the number of similarity classes of simple matrices of order \( n \) with entries in a finite field of order \( q \). This is the same as the number of irreducible polynomials of degree \( d \).

If \( \text{invertible} \) is True, then only the number of similarity classes of invertible matrices is returned.

Note: All primitive classes are invertible unless \( n \) is 1.

INPUT:

- \( n \) – a positive integer
- \( \text{invertible} \) – boolean; if set, only number of non-zero classes is returned
- \( q \) – an integer or an indeterminate

OUTPUT:

- a rational function of the variable \( q \)

EXAMPLES:

sage: from sage.combinat.similarity_class_type import primitives
sage: primitives(1)
q
sage: primitives(1, invertible = True)
5.1.306 sine-Gordon Y-system plotter

This class builds the triangulations associated to sine-Gordon and reduced sine-Gordon Y-systems as constructed in [NS].

AUTHORS:

• Salvatore Stella (2014-07-18): initial version

EXAMPLES:

A reduced sine-Gordon example with 3 generations:

```
sage: Y = SineGordonYsystem('A', (6,4,3)); Y
A sine-Gordon Y-system of type A with defining integer tuple (6, 4, 3)
sage: Y.plot()  #not tested
```

The same integer tuple but for the non-reduced case:

```
sage: Y = SineGordonYsystem('D', (6,4,3)); Y
A sine-Gordon Y-system of type D with defining integer tuple (6, 4, 3)
sage: Y.plot()  #not tested
```

Todo: The code for plotting is extremely slow.

REFERENCES:

class sage.combinat.sine_gordon.SineGordonYsystem(X, na)
Bases: sage.structure.sage_object.SageObject

A class to model a (reduced) sine-Gordon Y-system

Note that the generations, together with all integer tuples, in this implementation are numbered from 0 while in [NS] they are numbered from 1

INPUT:

• X – the type of the Y-system to construct (either ‘A’ or ‘D’)

• na – the tuple of positive integers defining the Y-system with na[0] > 2

See [NS]

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6,4,3)); Y
A sine-Gordon Y-system of type A with defining integer tuple (6, 4, 3)
sage: Y.intervals()
((0, 0, 'R'),),
((0, 17, 'L'),
```
F()  
Return the number of generations in self.

EXAMPLES:

```sage
Y = SineGordonYsystem('A',(6,4,3))
sage: Y.F()
3
```

intervals()  
Return, divided by generation, the list of intervals used to construct the initial triangulation.

Each such interval is a triple (p, q, X) where p and q are the two extremal vertices of the interval and X is the type of the interval (one of ‘L’, ‘R’, ‘NL’, ‘NR’).

ALGORITHM:

The algorithm used here is the one described in section 5.1 of [NS]. The only difference is that we get rid of the special case of the first generation by treating the whole disk as a type ‘R’ interval.

EXAMPLES:

```sage
Y = SineGordonYsystem('A',(6,4,3))
sage: Y.intervals()
(((0, 0, 'R'),),
 (0, 17, 'L'),
 (17, 34, 'L'),
 ...
 (104, 105, 'R'),
 (105, 0, 'R')))```

na()  
Return the sequence of the integers $n_a$ defining self.

EXAMPLES:

```sage
Y = SineGordonYsystem('A',(6,4,3))
sage: Y.na()
(6, 4, 3)
```

pa()  
Return the sequence of integers $p_a$, i.e. the total number of intervals of types ‘NL’ and ‘NR’ in the $(a+1)$-th generation.
EXAMPLES:

```python
sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.pa()
(1, 6, 25)
```

```plot(**kwds)```
Plot the initial triangulation associated to `self`.

**INPUT:**
- `radius` - the radius of the disk; by default the length of the circle is the number of vertices
- `points_color` - the color of the vertices; default 'black'
- `points_size` - the size of the vertices; default 7
- `triangulation_color` - the color of the arcs; default 'black'
- `triangulation_thickness` - the thickness of the arcs; default 0.5
- `shading_color` - the color of the shading used on neuter intervals; default 'lightgray'
- `reflections_color` - the color of the reflection axes; default 'blue'
- `reflections_thickness` - the thickness of the reflection axes; default 1

**EXAMPLES:**

```python
sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.plot()  # long time 2s
```

```qa()```
Return the sequence of integers \( q_a \), i.e. the total number of intervals of types ‘L’ and ‘R’ in the \( (a+1) \)-th generation.

**EXAMPLES:**

```python
sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.qa()
(6, 25, 81)
```

```r()```
Return the number of vertices in the polygon realizing `self`.

**EXAMPLES:**

```python
sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.r()
106
```

```rk()```
Return the sequence of integers \( r^k \), i.e. the width of an interval of type ‘L’ or ‘R’ in the \( k \)-th generation.

**EXAMPLES:**

```python
sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.rk()
(106, 17, 4)
```
triangulation()  
Return the initial triangulation of the polygon realizing self as a tuple of pairs of vertices.

**Warning:** In type ‘D’ the returned triangulation does NOT contain the two radii.

**ALGORITHM:**
We implement the four cases described by Figure 14 in [NS].

**EXAMPLES:**

```python
sage: Y = SineGordonYsystem('A', (6, 4, 3))
sage: Y.triangulation()
((17, 89),  
 (17, 72),  
 ...  
 (102, 105),  
 (103, 105))
```

type()  
Return the type of self.

**EXAMPLES:**

```python
sage: Y = SineGordonYsystem('A', (6, 4, 3))
sage: Y.type()
'A'
```

vertices()  
Return the vertices of the polygon realizing self as the ring of integers modulo self.r().

**EXAMPLES:**

```python
sage: Y = SineGordonYsystem('A', (6, 4, 3))
sage: Y.vertices()
Ring of integers modulo 106
```

### 5.1.307 Six Vertex Model

**class** `sage.combinat.six_vertex_model.SixVertexConfiguration`

**Bases:** `sage.structure.list_clone.ClonableArray`

A configuration in the six vertex model.

**check()**  
Check if self is a valid 6 vertex configuration.

**EXAMPLES:**

```python
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: M[0].check()
```

**energy(epsilon)**  
Return the energy of the configuration.
The energy of a configuration \( \nu \) is defined as

\[
E(\nu) = n_0 \epsilon_0 + n_1 \epsilon_1 + \cdots + n_5 \epsilon_5
\]

where \( n_i \) is the number of vertices of type \( i \) and \( \epsilon_i \) is the \( i \)-th energy constant.

**Note:** We number our configurations as:

0. LR
1. LU
2. LD
3. UD
4. UR
5. RD

which differs from [Wikipedia article Ice-type_model](https://en.wikipedia.org/wiki/Ice-type_model).

**EXAMPLES:**

```python
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: nu = M[2]; nu
\[
\begin{array}{c c c c c c}
\uparrow & \uparrow & \uparrow \\
\mid & \mid & \mid \\
\rightarrow & \# & \rightarrow & \# & \leftarrow & \# & \leftarrow \\
\uparrow & \mid & \uparrow \\
\mid & \cap & \mid \\
\rightarrow & \# & \leftarrow & \# & \leftarrow & \# & \leftarrow \\
\mid & \uparrow & \mid \\
\mid & \mid & \mid \\
\mid & \mid & \mid \\
\end{array}
\]
sage: nu.energy([1,2,1,2,1,2])
15
```

A KDP energy:

```python
sage: nu.energy([1,1,0,1,0,1])
7
```

A Rys \( F \) energy:

```python
sage: nu.energy([0,1,1,0,1,1])
4
```

The zero field assumption:

```python
sage: nu.energy([1,2,3,1,3,2])
15
```

```
plot(color='sign')
```

Return a plot of `self`.

**INPUT:**
• color – can be any of the following:
  – 4 - use 4 colors: black, red, blue, and green with each corresponding to up, right, down, and left respectively
  – 2 - use 2 colors: red for horizontal, blue for vertical arrows
  – 'sign' - use red for right and down arrows, blue for left and up arrows
  – a list of 4 colors for each direction
  – a function which takes a direction and a boolean corresponding to the sign

EXAMPLES:

```python
sage: M = SixVertexModel(2, boundary_conditions='ice')
sage: print(M[0].plot().description())
Arrow from (-1.0,0.0) to (0.0,0.0)
Arrow from (-1.0,1.0) to (0.0,1.0)
Arrow from (0.0,0.0) to (0.0,-1.0)
Arrow from (0.0,0.0) to (1.0,0.0)
Arrow from (0.0,1.0) to (0.0,0.0)
Arrow from (0.0,1.0) to (0.0,2.0)
Arrow from (1.0,0.0) to (1.0,-1.0)
Arrow from (1.0,0.0) to (1.0,1.0)
Arrow from (1.0,1.0) to (0.0,1.0)
Arrow from (1.0,1.0) to (1.0,2.0)
Arrow from (2.0,0.0) to (1.0,0.0)
Arrow from (2.0,1.0) to (1.0,1.0)
```

`to_signed_matrix()`

Return the signed matrix of self.

The signed matrix corresponding to a six vertex configuration is given by 0 if there is a cross flow, a 1 if the outward arrows are vertical and −1 if the outward arrows are horizontal.

EXAMPLES:

```python
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: [x.to_signed_matrix() for x in M]
[[[1 0 0] [1 0 0] [0 1 0] [0 1 0] [0 0 1] [0 0 1]]
 [[0 1 0] [0 0 1] [1 1 1] [1 0 0] [0 0 1] [1 0 0]]
 [[0 0 1], [0 1 0], [0 1 0], [0 1 0], [0 1 0], [1 0 0]]
```

```
```
2. LU:

3. LD:

4. UD:

5. UR:

6. RD:

INPUT:

- \( n \) – the number of rows
- \( m \) – (optional) the number of columns, if not specified, then the number of columns is the number of rows
- boundary_conditions – (optional) a quadruple of tuples whose entries are either:
  - True for an inward arrow,
  - False for an outward arrow, or
  - None for no boundary condition.
There are also the following predefined boundary conditions:

- 'ice' - The top and bottom boundary conditions are outward and the left and right boundary conditions are inward; this gives the square ice model. Also called domain wall boundary conditions.
- 'domain wall' - Same as 'ice'.
- 'alternating' - The boundary conditions alternate between inward and outward.
- 'free' - There are no boundary conditions.

EXAMPLES:

Here are the six types of vertices that can be created:

```python
sage: M = SixVertexModel(1)
sage: list(M)
[ |
 V |
<-- # --> <-- # <-- <-- # <-- --> # --> --> # -->
 |
 , , V , V , , V ]
```

When using the square ice model, it is known that the number of configurations is equal to the number of alternating sign matrices:

```python
sage: M = SixVertexModel(1, boundary_conditions='ice')
sage: len(M)
1
sage: M = SixVertexModel(4, boundary_conditions='ice')
sage: len(M)
42
sage: all(len(SixVertexModel(n, boundary_conditions='ice')) == AlternatingSignMatrices(n).cardinality() for n in range(1, 7))
True
```

An example with a specified non-standard boundary condition and non-rectangular shape:

```python
sage: M = SixVertexModel(2, 1, [[None], [True], [None], [None, None]])
sage: list(M)
[ |
 ^ ^ |
| | V |
<-- # <-- <-- # <-- <-- # <-- --> # <--
^ ^ |
| | V V
|<-- # <-- --> # <-- # <-- # <-- # <--
^ |
| | V V
| , V , V , V ]
```

REFERENCES:

- Wikipedia article Vertex_model
- Wikipedia article Ice-type_model
Element

alias of SixVertexConfiguration

boundary_conditions()

Return the boundary conditions of self.

EXAMPLES:

```
sage: M = SixVertexModel(2, boundary_conditions='ice')
sage: M.boundary_conditions()
((False, False), (True, True), (False, False), (True, True))
```

partition_function(beta, epsilon)

Return the partition function of self.

The partition function of a 6 vertex model is defined by:

\[ Z = \sum_{\nu} e^{-\beta E(\nu)} \]

where we sum over all configurations and \( E \) is the energy function. The constant \( \beta \) is known as the inverse temperature and is equal to \( 1/k_B T \) where \( k_B \) is Boltzmann’s constant and \( T \) is the system’s temperature.

INPUT:

- `beta` – the inverse temperature constant \( \beta \)
- `epsilon` – the energy constants, see `energy()`

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: M.partition_function(2, [1,2,1,2,1,2])
e^(-24) + 2*e^(-28) + e^(-30) + 2*e^(-32) + e^(-36)
```

REFERENCES:

Wikipedia article Partition_function_(statistical_mechanics)

```python
class sage.combinat.six_vertex_model.SquareIceModel(n)
Bases: sage.combinat.six_vertex_model.SixVertexModel

The square ice model.

The square ice model is a 6 vertex model on an \( n \times n \) grid with the boundary conditions that the top and bottom boundaries are pointing outward and the left and right boundaries are pointing inward. These boundary conditions are also called domain wall boundary conditions.

Configurations of the 6 vertex model with domain wall boundary conditions are in bijection with alternating sign matrices.

```
sage: M = SixVertexModel(4, boundary_conditions='ice')
sage: M[6].to_alternating_sign_matrix()
[1 0 0 0]
[0 0 0 1]
[0 0 1 0]
[0 1 0 0]
sage: M[7].to_alternating_sign_matrix()
[ 0 1 0 0]
[ 1 -1 1 0]
[ 0 1 -1 1]
[ 0 0 1 0]

\textbf{from_alternating_sign_matrix}(asm)

Return a configuration from the alternating sign matrix asm.

EXAMPLES:

sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: asm = AlternatingSignMatrix([[0,1,0],[1,-1,1],[0,1,0]])
sage: M.from_alternating_sign_matrix(asm)

| ^ |
** V **
--> # <- # <- # <--
| | |
V V V

5.1.308 Skew Partitions

A skew partition \( skp \) of size \( n \) is a pair of partitions \( [p_1, p_2] \) where \( p_1 \) is a partition of the integer \( n_1 \), \( p_2 \) is a partition of the integer \( n_2 \), \( p_2 \) is an inner partition of \( p_1 \), and \( n = n_1 - n_2 \). We say that \( p_1 \) and \( p_2 \) are respectively the \textit{inner} and \textit{outer} partitions of \( skp \).

A skew partition can be depicted by a diagram made of rows of cells, in the same way as a partition. Only the cells of the outer partition \( p_1 \) which are not in the inner partition \( p_2 \) appear in the picture. For example, this is the diagram of the skew partition \([5,4,3,1],[3,3,1]\).

sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).diagram())
**
* **
*

A skew partition can be \textit{connected}, which can easily be described in graphic terms: for each pair of consecutive rows, there are at least two cells (one in each row) which have a common edge. This is the diagram of the connected skew partition \([[[5,4,3,1],[3,1]]]:\)
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
***
***
*
sage: SkewPartition([[5,4,3,1],[3,1]]).is_connected()
True

The first example of a skew partition is not a connected one.

Applying a reflection with respect to the main diagonal yields the diagram of the conjugate skew partition, here [[4, 3, 3, 2, 1],[3, 3, 2]]:

sage: SkewPartition([[5,4,3,1],[3,3,1]]).conjugate()
[4, 3, 3, 2, 1] / [3, 2, 2]
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).conjugate().diagram())
**
*
*
*

The outer corners of a skew partition are the corners of its outer partition. The inner corners are the internal corners of the outer partition when the inner partition is taken off. Shown below are the coordinates of the inner and outer corners.

sage: SkewPartition([[5,4,3,1],[3,3,1]]).outer_corners()
[(0, 4), (1, 3), (2, 2), (3, 0)]
sage: SkewPartition([[5,4,3,1],[3,3,1]]).inner_corners()
[(0, 3), (2, 1), (3, 0)]

EXAMPLES:

There are 9 skew partitions of size 3, with no empty row nor empty column:

sage: SkewPartitions(3).cardinality()
9
sage: SkewPartitions(3).list()
[[3] / [],
[2, 1] / [],
[3, 1] / [1],
[2, 2] / [1],
[3, 2] / [2],
[1, 1, 1] / [],
[2, 2, 1] / [1, 1],
[2, 1, 1] / [1],
[3, 2, 1] / [2, 1]]

There are 4 connected skew partitions of size 3:

sage: SkewPartitions(3, overlap=1).cardinality()
4
sage: SkewPartitions(3, overlap=1).list()

This is the conjugate of the skew partition [[4,3,1], [2]]
Geometrically, we just applied a reflection with respect to the main diagonal on the diagram of the partition. Of course, this operation is an involution:

```
 sage: SkewPartition([[4,3,1],[2]]).conjugate().conjugate()
```

The `jacobi_trudi()` method computes the Jacobi-Trudi matrix. See [Mac1995] for a definition and discussion.

```
 sage: SkewPartition([[4,3,1],[2]]).jacobi_trudi()
[[h[2]  h[]  0]
```

This example shows how to compute the corners of a skew partition.

```
 sage: SkewPartition([[4,3,1],[2]]).inner_corners()
[(0, 2), (1, 0)]
 sage: SkewPartition([[4,3,1],[2]]).outer_corners()
[(0, 3), (1, 2), (2, 0)]
```

AUTHORS:

- Mike Hansen: Initial version
- Travis Scrimshaw (2013-02-11): Factored out CombinatorialClass

```
class sage.combinat.skew_partition.SkewPartition(parent, skp)

    Bases: sage.combinat.combinat.CombinatorialElement

    A skew partition.

    A skew partition of shape \(\lambda/\mu\) is the Young diagram from the partition \(\lambda\) and removing the partition \(\mu\) from the upper-left corner in English convention.

    cell_poset(orientation='SE')

        Return the Young diagram of \(self\) as a poset. The optional keyword variable \texttt{orientation} determines the order relation of the poset.

        The poset always uses the set of cells of the Young diagram of \(self\) as its ground set. The order relation of the poset depends on the \texttt{orientation} variable (which defaults to "SE"). Concretely, \texttt{orientation} has to be specified to one of the strings "NW", "NE", "SW", and "SE", standing for “northwest”, “northeast”, “southwest” and “southeast”, respectively. If \texttt{orientation} is "SE", then the order relation of the poset is such that a cell \(u\) is greater or equal to a cell \(v\) in the poset if and only if \(u\) lies weakly southeast of \(v\) (this means that \(u\) can be reached from \(v\) by a sequence of south and east steps; the sequence is allowed to consist of south steps only, or of east steps only, or even be empty). Similarly the order relation is defined for the other three orientations. The Young diagram is supposed to be drawn in English notation.

        The elements of the poset are the cells of the Young diagram of \(self\), written as tuples of zero-based coordinates (so that \((3, 7)\) stands for the 8-th cell of the 4-th row, etc.).

        EXAMPLES:
```
 sage: p = SkewPartition([[3,3,1],[2,1]])
 sage: Q = p.cell_poset(); Q
 Finite poset containing 4 elements
```
sage: sorted(Q)
[(0, 2), (1, 1), (1, 2), (2, 0)]
sage: sorted(Q.maximal_elements())
[(1, 2), (2, 0)]
sage: sorted(Q.minimal_elements())
[(0, 2), (1, 1), (2, 0)]
sage: sorted(Q.upper_covers((1, 1)))
[(1, 2)]
sage: sorted(Q.upper_covers((0, 2)))
[(1, 2)]
sage: P = p.cell_poset(orientation="NW"); P
Finite poset containing 4 elements
sage: sorted(P)
[(0, 2), (1, 1), (1, 2), (2, 0)]
sage: sorted(P.minimal_elements())
[(1, 2), (2, 0)]
sage: sorted(P.maximal_elements())
[(0, 2), (1, 1), (2, 0)]
sage: sorted(P.upper_covers((1, 2)))
[(0, 2), (1, 1)]
sage: R = p.cell_poset(orientation="NE"); R
Finite poset containing 4 elements
sage: sorted(R)
[(0, 2), (1, 1), (1, 2), (2, 0)]
sage: R.maximal_elements()
[(0, 2)]
sage: R.minimal_elements()
[(2, 0)]
sage: R.upper_covers((2, 0))
[(1, 1)]
sage: sorted([len(R.upper_covers(v)) for v in R])
[0, 1, 1, 1]

cells()
Return the coordinates of the cells of self. Coordinates are given as (row-index, column-index) and are 0 based.

EXAMPLES:

sage: SkewPartition([[4, 3, 1], [2]]).cells()
[(0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: SkewPartition([[4, 3, 1], []]).cells()
[(0, 0), (0, 1), (0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: SkewPartition([[2], []]).cells()
[(0, 0), (0, 1)]

column_lengths()
Return the column lengths of self.

EXAMPLES:
columns_intersection_set()  
Return the set of cells in the columns of the outer shape of self which columns intersect the skew diagram of self.

EXAMPLES:

```
sage: skp = SkewPartition([[3,2,1],[2,1]])
sage: cells = Set([(0,0), (0, 1), (0,2), (1, 0), (1, 1), (2, 0)])
sage: skp.columns_intersection_set() == cells
True
```

conjugate()  
Return the conjugate of the skew partition skp.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[2]]).conjugate()
[3, 2, 1] / [1, 1]
```

diagram()  
Return the Ferrers diagram of self.

EXAMPLES:

```
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).ferrers_diagram())
 **
 *
 **
 sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
 ***
 ***
 ***
 sage: SkewPartitions.options(diagram_str='#', convention="French")
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
#
###
##
```

ferrers_diagram()  
Return the Ferrers diagram of self.

EXAMPLES:

```
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).ferrers_diagram())
 **
 *
```
**sage:** print(SkewPartition([[5,4,3,1],[3,1]]).diagram())

**sage:** SkewPartitions.options(diagram_str='#', convention="French")

**sage:** print(SkewPartition([[5,4,3,1],[3,1]]).diagram())

---

**frobenius_rank()**

Return the Frobenius rank of the skew partition self.

The Frobenius rank of a skew partition $\lambda/\mu$ can be defined in various ways. The quickest one is probably the following: Writing $\lambda$ as $(\lambda_1, \lambda_2, \ldots, \lambda_N)$, and writing $\mu$ as $(\mu_1, \mu_2, \ldots, \mu_N)$, we define the Frobenius rank of $\lambda/\mu$ to be the number of all $1 \leq i \leq N$ such that

$$\lambda_i - i \notin \{ \mu_1 - 1, \mu_2 - 2, \ldots, \mu_N - N \}.$$

In other words, the Frobenius rank of $\lambda/\mu$ is the number of rows in the Jacobi-Trudi matrix of $\lambda/\mu$ which don’t contain $h_0$. Further definitions have been considered in [Sta2002] (where Frobenius rank is just being called rank).

If $\mu$ is the empty shape, then the Frobenius rank of $\lambda/\mu$ is just the usual Frobenius rank of the partition $\lambda$ (see `frobenius_rank()`).

**EXAMPLES:**

```python
sage: SkewPartition([[8,8,7,4], [4,1,1]]).frobenius_rank()
4
sage: SkewPartition([[2,1], [1]]).frobenius_rank()
2
sage: SkewPartition([[2,1,1], [1]]).frobenius_rank()
2
sage: SkewPartition([[2,1,1], [1,1]]).frobenius_rank()
2
sage: SkewPartition([[5,4,3,2], [2,1,1]]).frobenius_rank()
3
sage: SkewPartition([[4,2,1], [3,1,1]]).frobenius_rank()
2
sage: SkewPartition([[4,2,1], [3,2,1]]).frobenius_rank()
1
```

If the inner shape is empty, then the Frobenius rank of the skew partition is just the standard Frobenius rank of the partition:

```python
sage: all( SkewPartition([lam, Partition([])]).frobenius_rank() == lam.frobenius_rank() for i in range(6) for lam in Partitions(i) )
True
```
If the inner and outer shapes are equal, then the Frobenius rank is zero:

```python
sage: all( SkewPartition([lam, lam]).frobenius_rank() == 0
....: for i in range(6) for lam in Partitions(i) )
True
```

**inner()**

Return the inner partition of self.

**EXAMPLES:**

```python
sage: SkewPartition([[3,2,1],[1,1]]).inner()
[1, 1]
```

**inner_corners()**

Return a list of the inner corners of self.

**EXAMPLES:**

```python
sage: SkewPartition([[4, 3, 1], [2]]).inner_corners()
[(0, 2), (1, 0)]
```

```python
sage: SkewPartition([[4, 3, 1], []]).inner_corners()
[(0, 0)]
```

**is_connected()**

Return True if self is a connected skew partition.

A skew partition is said to be connected if for each pair of consecutive rows, there are at least two cells (one in each row) which have a common edge.

**EXAMPLES:**

```python
sage: SkewPartition([[5,4,3,1],[3,1]]).is_connected()
False
```

```python
sage: SkewPartition([[5,4,3,1],[3,3,1]]).is_connected()
True
```

**is_overlap(n)**

Return True if the overlap of self is at most n.

**See also:**

`overlap()`

**EXAMPLES:**

```python
sage: SkewPartition([[5,4,3,1],[3,3,1]]).is_overlap(1)
True
```

**is_ribbon()**

Return True if and only if self is a ribbon.

This means that if it has exactly one cell in each of q consecutive diagonals for some nonnegative integer q.

**EXAMPLES:**

```python
sage: P = SkewPartition([[4,4,3,3],[3,2,2]])
sage: P.pp()
*```

(continues on next page)
Combinatorics, Release 9.7

```
**
* ***
sage: P.is_ribbon()
True

sage: P = SkewPartition([[4,3,3],[1,1]])
sage: P.pp()
***
**
** ***
sage: P.is_ribbon()
False

sage: P = SkewPartition([[4,4,3,2],[3,2,2]])
sage: P.pp()
*
**
*
**
sage: P.is_ribbon()
False

sage: P = SkewPartition([[4,4,3,3],[4,2,2,1]])
sage: P.pp()

**
*
**

sage: P.is_ribbon()
True

sage: P = SkewPartition([[4,4,3,3],[4,2,2]])
sage: P.pp()

**
*
**

sage: P.is_ribbon()
True

sage: SkewPartition([[2,2,1],[2,2,1]]).is_ribbon()
True
```

```
jacobi_trudi()
Return the Jacobi-Trudi matrix of self.

EXAMPLES:

sage: SkewPartition([[3,2,1],[2,1]]).jacobi_trudi()
[h[1]  0  0]
```

(continues on next page)
sage: SkewPartition([[4,3,2],[2,1]]).jacobi_trudi()
[h[2] h[] 0]

\textbf{k_conjugate} (k)

Return the \( k \)-conjugate of the skew partition.

\textbf{EXAMPLES:}

sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(3)
[2, 1, 1, 1, 1] / [2, 1]

sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(4)
[2, 2, 1, 1] / [2, 1]

sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(5)
[3, 2, 1] / [2, 1]

\textbf{outer}()

Return the outer partition of \texttt{self}.

\textbf{EXAMPLES:}

sage: SkewPartition([[3,2,1],[1,1]]).outer()
[3, 2, 1]

\textbf{outer_corners}()

Return a list of the outer corners of \texttt{self}.

\textbf{EXAMPLES:}

sage: SkewPartition([[4, 3, 1], [2]]).outer_corners()
[(0, 3), (1, 2), (2, 0)]

\textbf{overlap}()

Return the overlap of \texttt{self}.

The overlap of two consecutive rows in a skew partition is the number of pairs of cells (one in each row) that share a common edge. This number can be positive, zero, or negative.

The overlap of a skew partition is the minimum of the overlap of the consecutive rows, or infinity in the case of at most one row. If the overlap is positive, then the skew partition is called \textit{connected}.

\textbf{EXAMPLES:}

sage: SkewPartition([[],[]]).overlap()
+Infinity
sage: SkewPartition([[1],[]]).overlap()
+Infinity
sage: SkewPartition([[10],[]]).overlap()
+Infinity
sage: SkewPartition([[10],[2]]).overlap()
+Infinity
sage: SkewPartition([[10,1],[2]]).overlap()
-1
sage: SkewPartition([[10,10],[1]]).overlap()
9
pieri_macdonald_coeffs()

Computation of the coefficients which appear in the Pieri formula for Macdonald polynomials given in his book (Chapter 6.6 formula 6.24(ii))

EXAMPLES:

```sage
sage: SkewPartition([[3,2,1],[2,1]]).pieri_macdonald_coeffs()
1
sage: SkewPartition([[3,2,1],[2,2]]).pieri_macdonald_coeffs()
(q^2*t^3 - q^2*t - t^2 + 1)/(q^2*t^3 - q^2*t - q^3 + t)
```

```
sage: SkewPartition([[3,2,1],[2,2,1]]).pieri_macdonald_coeffs()
(q^6*t^8 - q^6*t^6 - q^4*t^7 - q^5*t^6 + q^4*t^5 - q^3*t^4 + 2*q^3*t^3 + q^3*t^2 + q^3*t + 1)/(q^6*t^8 - q^5*t^7 - q^4*t^6 + 2*q^3*t^5 + q^3*t^4 + q^3*t^3 + q^2*t^2 + q^2*t + q^2)
```

```
sage: SkewPartition([[3,3,2,2],[3,2,2,1]]).pieri_macdonald_coeffs()
(q^5*t^6 - q^5*t^5 + q^4*t^6 - q^4*t^5 - q^4*t^3 + q^4*t^2 - q^4*t^3 - q^3*t^4 + q^3*t^3 - q^2*t^4 + q^2*t^3 + q*t^4 + q^2*t^2 - q^2*t - t^2 + 1)/(q^5*t^6 - q^4*t^5 - q^3*t^4 + 2*q^3*t^3 + q^3*t^2 + q^3*t + q^3)
```

pp()

Pretty-print self.

EXAMPLES:

```sage
sage: SkewPartition([[5,4,3,1],[3,3,1]]).pp()
```

```
* * *
```

quotient(k)

The quotient map extended to skew partitions.

EXAMPLES:

```sage
sage: SkewPartition([[3,3,2,2],[3,2,2,1]]).quotient(2)
[[3] / [], [], []]
```

row_lengths()

Return the row lengths of self.

EXAMPLES:

```sage
sage: SkewPartition([[3,2,1],[1,1]]).row_lengths()
[2, 1, 1]
```

rows_intersection_set()

Return the set of cells in the rows of the outer shape of self which rows intersect the skew diagram of self.

EXAMPLES:

```sage
skp = SkewPartition([[3,2,1],[2,2,1]])
cells = Set([(0,0), (0,1), (0,2), (1,0), (1,1), (2,0)])
sage: skp.rows_intersection_set() == cells
True
```
size()

Return the size of self.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).size()
sage: 4
```

to_dag(\text{format}='\text{string}')

Return a directed acyclic graph corresponding to the skew partition self.

The directed acyclic graph corresponding to a skew partition $p$ is the digraph whose vertices are the cells of $p$, and whose edges go from each cell to its lower and right neighbors (in English notation).

INPUT:

- \text{format} – either 'string' or 'tuple' (default: 'string'); determines whether the vertices of the resulting dag will be strings or 2-tuples of coordinates

EXAMPLES:

```
sage: dag = SkewPartition([[3, 3, 1], [1, 1]]).to_dag()
sage: dag.edges(sort=True)
[('0,1', '0,2', None), ('0,1', '1,1', None), ('0,2', '1,2', None), ('1,1', '1,2', None)]
sage: dag.vertices(sort=True)
[('0,1'), ('0,2'), ('1,1'), ('1,2'), ('2,0')]
sage: dag = SkewPartition([[3, 2, 1], [1, 1]]).to_dag(format="tuple")
sage: dag.edges(sort=True)
[(0, 1), (0, 2), None), (0, 1), (1, 1), None]
sage: dag.vertices(sort=True)
[(0, 1), (0, 2), (1, 1), (2, 0)]
```

to_list()

Return self as a list of lists.

EXAMPLES:

```
sage: s = SkewPartition([[4,3,1],[2]])
sage: s.to_list()
[[4, 3, 1], [2]]
sage: type(s.to_list())
<class 'list'>
```

class sage.combinat.skew_partition.SkewPartitions(is_infinite=False)

Skew partitions.

\textbf{Warning:}  The iterator of this class only yields skew partitions which are reduced, in the sense that there are no empty rows before the last nonempty row, and there are no empty columns before the last nonempty column.

EXAMPLES:
sage: SkewPartitions(4)
Skew partitions of 4
sage: SkewPartitions(4).cardinality()
28
sage: SkewPartitions(row_lengths=[2,1,2])
Skew partitions with row lengths [2, 1, 2]
sage: SkewPartitions(4, overlap=2)
Skew partitions of 4 with a minimum overlap of 2
sage: SkewPartitions(4, overlap=2).list()

Element

alias of SkewPartition
from_row_and_column_length(rowL, colL)

Construct a partition from its row lengths and column lengths.

INPUT:

• rowL – A composition or a list of positive integers
• colL – A composition or a list of positive integers

OUTPUT:

• If it exists the unique skew-partitions with row lengths rowL and column lengths colL.
• Raise a ValueError if rowL and colL are not compatible.

EXAMPLES:

sage: S = SkewPartitions()
sage: print(S.from_row_and_column_length([3,1,2,2],[2,3,1,1,1]).diagram())
***
*
**
sage: S.from_row_and_column_length([],[])
[] / []
sage: S.from_row_and_column_length([1],[1])
[1] / []
sage: S.from_row_and_column_length([2,1],[2,1])
[2, 1] / []
sage: S.from_row_and_column_length([1,2],[1,2])
[2, 2] / [1]
sage: S.from_row_and_column_length([1,2],[1,3])
Traceback (most recent call last):
...
ValueError: Sum mismatch : [1, 2] and [1, 3]
sage: S.from_row_and_column_length([3,2,1,2],[2,3,1,1,1])
Traceback (most recent call last):
...
ValueError: Incompatible row and column length : [3, 2, 1, 2] and [2, 3, 1, 1, 1]
Warning: If some rows and columns have length zero, there is no way to retrieve unambiguously the skew partition. We therefore raise a ValueError. For examples here are two skew partitions with the same row and column lengths:

```python
sage: skp1 = SkewPartition([[2,2],[2,2]])
sage: skp2 = SkewPartition([[2,1],[2,1]])
sage: skp1.row_lengths(), skp1.column_lengths()
(0, 0), (0, 0)
sage: skp2.row_lengths(), skp2.column_lengths()
(0, 0), (0, 0)
sage: SkewPartitions().from_row_and_column_length([0,0], [0,0])
Traceback (most recent call last):
  ... ValueError: row and column length must be positive
```

**options(***get_value, **set_value*)

Sets and displays the options for elements of the skew partition classes. If no parameters are set, then the function returns a copy of the options dictionary.

The options to skew partitions can be accessed as the method `SkewPartitions.options` of `SkewPartitions` and related parent classes.

OPTIONS:

* convention – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention
* diagram_str – (default: *) The character used for the cells when printing Ferrers diagrams
* display – (default: quotient) Specifies how skew partitions should be printed
  - array – alias for diagram
  - diagram – as a skew Ferrers diagram
  - ferrers_diagram – alias for diagram
  - lists – displayed as a pair of lists
  - pair – alias for lists
  - quotient – displayed as a quotient of partitions
  - young_diagram – alias for diagram
* latex – (default: young_diagram) Specifies how skew partitions should be latexed
  - array – alias for diagram
  - diagram – latex as a skew Ferrers diagram
  - ferrers_diagram – alias for diagram
  - marked – latex as a partition where the skew shape is marked
  - young_diagram – latex as a skew Young diagram
* latex_diagram_str – (default: \ast) The character used for the cells when latexing Ferrers diagrams
• \texttt{latex\_marking\_str} – (default: \texttt{X}) The character used to marked the deleted cells when latexing marked partitions

• \texttt{notation} – alternative name for \texttt{convention}

EXAMPLES:

```python
sage: SP = SkewPartition([[4,2,2,1], [3, 1, 1]])
sage: SP
[4, 2, 2, 1] / [3, 1, 1]
sage: SkewPartitions.options.display="lists"
sage: SP
[[4, 2, 2, 1], [3, 1, 1]]
```

Changing the convention for skew partitions also changes the convention option for partitions and tableaux and vice versa:

```python
sage: SkewPartitions.options(display="diagram", convention='French')
sage: SP
*
*
*
*
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
4 5
1 2 3
sage: P = Partition([4, 2, 2, 1])
sage: P.pp()
*
**
**
****
sage: Tableaux.options.convention="english"
sage: SP
*
*
*
*
sage: T.pp()
1 2 3
4 5
sage: SkewPartitions.options._reset()
```

See \texttt{GlobalOptions} for more features of these options.

\texttt{class sage.combinat.skew_partition.SkewPartitions\_all}

Bases: \texttt{sage.combinat.skew_partition.SkewPartitions}

Class of all skew partitions.

\texttt{class sage.combinat.skew_partition.SkewPartitions\_n(n, overlap)}

Bases: \texttt{sage.combinat.skew_partition.SkewPartitions}

The set of skew partitions of \texttt{n} with overlap at least \texttt{overlap} and no empty row.

INPUT:
• n – a non-negative integer
• overlap – an integer (default: 0)

Caveat: this set is stable under conjugation only for overlap equal to 0 or 1. What exactly happens for negative overlaps is not yet well specified and subject to change (we may want to introduce vertical overlap constraints as well).

Todo: As is, this set is essentially the composition of Compositions(n) (which give the row lengths) and SkewPartition(n, row_lengths=...), and one would want to “inherit” list and cardinality from this composition.

cardinality()
Return the number of skew partitions of the integer n (with given overlap, if specified; and with no empty rows before the last row).

EXAMPLES:

sage: SkewPartitions(0).cardinality()
sage: SkewPartitions(4).cardinality()
sage: SkewPartitions(5).cardinality()
sage: SkewPartitions(4, overlap=1).cardinality()
sage: SkewPartitions(5, overlap=1).cardinality()
sage: s = SkewPartitions(5, overlap=-1)
sage: s.cardinality() == len(s.list())

class sage.combinat.skew_partition.SkewPartitions_rowlengths(co, overlap)
Bases: sage.combinat.skew_partition.SkewPartitions

All skew partitions with given row lengths.

sage.combinat.skew_partition.row_lengths_aux(skp)
EXAMPLES:

sage: from sage.combinat.skew_partition import row_lengths_aux
sage: row_lengths_aux([[5,4,3,1],[3,3,1]])
[2, 1, 2]
sage: row_lengths_aux([[5,4,3,1],[3,1]])
[2, 3]
5.1.309 Skew Tableaux

AUTHORS:

- Mike Hansen: Initial version
- Travis Scrimshaw, Arthur Lubovsky (2013-02-11): Factored out CombinatorialClass

class sage.combinat.skew_tableau.SemistandardSkewTableaux(category=None)

Bases: sage.combinat.skew_tableau.SkewTableaux

Semistandard skew tableaux.

This class can be initialized with several optional variables: the size of the skew tableaux (as a nameless integer variable), their shape (as a nameless skew partition variable), their weight (weight), as a nameless second variable after either the size or the shape) and their maximum entry (as an optional keyword variable called \texttt{max}._entry, unless the weight has been specified). If neither the weight nor the maximum entry is specified, the maximum entry defaults to the size of the tableau.

Note that “maximum entry” does not literally mean the highest entry; instead it is just an upper bound that no entry is allowed to surpass.

EXAMPLES:
The (infinite) class of all semistandard skew tableaux:

```python
sage: SemistandardSkewTableaux()
Semistandard skew tableaux
```

The (still infinite) class of all semistandard skew tableaux with maximum entry 2:

```python
sage: SemistandardSkewTableaux(max_entry=2)
Semistandard skew tableaux with maximum entry 2
```

The class of all semistandard skew tableaux of given size 3 and maximum entry 3:

```python
sage: SemistandardSkewTableaux(3)
Semistandard skew tableaux of size 3 and maximum entry 3
```

To set a different maximum entry:

```python
sage: SemistandardSkewTableaux(3, max_entry = 7)
Semistandard skew tableaux of size 3 and maximum entry 7
```

Specifying a shape:

```python
sage: SemistandardSkewTableaux([[2,1],[1]])
Semistandard skew tableaux of shape [2, 1] / [1] and maximum entry 3
```

Specifying both a shape and a maximum entry:

```python
sage: S = SemistandardSkewTableaux([[2,1],[1]], max_entry = 3); S
Semistandard skew tableaux of shape [2, 1] / [1] and maximum entry 3
sage: S.list()
[[[None, 1], [1]],
 [[None, 2], [1]],
 [[None, 1], [2]],
 [[None, 3], [1]],
```

(continues on next page)
\[
\begin{align*}
&[[\text{None}, 1], [3]], \\
&[[\text{None}, 2], [2]], \\
&[[\text{None}, 3], [2]], \\
&[[\text{None}, 2], [3]], \\
&[[\text{None}, 3], [3]]
\end{align*}
\]

```
sage: for n in range(5):
    ....:    print("{} {}".format(n, len(SemistandardSkewTableaux([[2,2,1],[1]], max_entry = n))))
0 0
1 0
2 1
3 9
4 35
```

Specifying a shape and a weight:
```
sage: SemistandardSkewTableaux([[2,1],[[]],[2,1]])
Semistandard skew tableaux of shape [2, 1] / [] and weight [2, 1]
```

(the maximum entry is redundant in this case and thus is ignored).

Specifying a size and a weight:
```
sage: SemistandardSkewTableaux(3, [2,1])
Semistandard skew tableaux of size 3 and weight [2, 1]
```

**Warning:** If the shape is not specified, the iterator of this class yields only skew tableaux whose shape is reduced, in the sense that there are no empty rows before the last nonempty row, and there are no empty columns before the last nonempty column. (Otherwise it would go on indefinitely.)

**Warning:** This class acts as a factory. The resulting classes are mainly useful for iteration. Do not rely on their containment tests, as they are not correct, e. g.:
```
sage: SkewTableau([[\text{None}]]) in SemistandardSkewTableaux(2)
True
```

class sage.combinat.skew_tableau.SemistandardSkewTableaux_all(max_entry)
Bases: sage.combinat.skew_tableau.SemistandardSkewTableaux

Class of all semistandard skew tableaux, possibly with a given maximum entry.

class sage.combinat.skew_tableau.SemistandardSkewTableaux_shape(p, max_entry)
Bases: sage.combinat.skew_tableau.SemistandardSkewTableaux

Class of semistandard skew tableaux of a fixed skew shape $\lambda/\mu$ with a given max entry.

A semistandard skew tableau with max entry $i$ is required to have all its entries less or equal to $i$. It is not required to actually contain an entry $i$.

**INPUT:**
- $p$ – A skew partition
• max_entry – The max entry; defaults to the size of p.

**Warning:** Input is not checked; please use `SemistandardSkewTableaux` to ensure the options are properly parsed.

```plaintext
cardinality()
EXAMPLES:
sage: SemistandardSkewTableaux([[2,1],[1]]).cardinality()
8
sage: SemistandardSkewTableaux([[2,1],[1]], max_entry=2).cardinality()
2
```

class sage.combinat.skew_tableau.SemistandardSkewTableaux_shape_weight(p, mu)

Bases: sage.combinat.skew_tableau.SemistandardSkewTableaux

Class of semistandard skew tableaux of a fixed skew shape \( \lambda/\nu \) and weight \( \mu \).

class sage.combinat.skew_tableau.SemistandardSkewTableaux_size(n, max_entry)

Bases: sage.combinat.skew_tableau.SemistandardSkewTableaux

Class of all semistandard skew tableaux of a fixed size \( n \), possibly with a given maximum entry.

```plaintext
cardinality()
EXAMPLES:
sage: SemistandardSkewTableaux(2).cardinality()
8
```

class sage.combinat.skew_tableau.SemistandardSkewTableaux_size_weight(n, mu)

Bases: sage.combinat.skew_tableau.SemistandardSkewTableaux

Class of semistandard tableaux of a fixed size \( n \) and weight \( \mu \).

```plaintext
cardinality()
EXAMPLES:
sage: SemistandardSkewTableaux(2,[1,1]).cardinality()
4
```

class sage.combinat.skew_tableau.SkewTableau(parent, st)

Bases: sage.structure.list_clone.ClonableList

A skew tableau.

Note that Sage by default uses the English convention for partitions and tableaux. To change this, see Tableaux. options().

```plaintext
EXAMPLES:
sage: st = SkewTableau([[None, 1],[2,3]]); st
[[None, 1], [2, 3]]
sage: st.inner_shape()
[1]
sage: st.outer_shape()
[2, 2]
```
The **expr** form of a skew tableau consists of the inner partition followed by a list of the entries in each row from bottom to top:

```sage
SkewTableau(expr=[[1,1],[[5],[3,4],[1,2]]])
```

The **chain** form of a skew tableau consists of a list of partitions \(\lambda_1, \lambda_2, \ldots\), such that all cells in \(\lambda_i+1\) that are not in \(\lambda_i\) have entry \(i\):

```sage
SkewTableau(chain=[[2], [2, 1], [3, 1], [4, 3, 2, 1]])
```

**bender_knuth_involution**(*k*, **rows=None**, **check=True**)

Return the image of self under the \(k\)-th Bender–Knuth involution, assuming self is a skew semistandard tableau.

Let \(T\) be a tableau, then a *lower free* \(k\) *in* \(T\) means a cell of \(T\) which is filled with the integer \(k\) and whose direct lower neighbor is not filled with the integer \(k+1\) (in particular, this lower neighbor might not exist at all). Let an *upper free* \(k+1\) *in* \(T\) mean a cell of \(T\) which is filled with the integer \(k+1\) and whose direct upper neighbor is not filled with the integer \(k\) (in particular, this neighbor might not exist at all). It is clear that for any row \(r\) of \(T\), the lower free \(k\)'s and the upper free \(k+1\)'s in \(r\) together form a contiguous interval or \(r\).

The \(k\)-th Bender–Knuth switch at row \(i\) changes the entries of the cells in this interval in such a way that if it used to have \(a\) entries of \(k\) and \(b\) entries of \(k+1\), it will now have \(b\) entries of \(k\) and \(a\) entries of \(k+1\). For fixed \(k\), the \(k\)-th Bender–Knuth switches for different \(i\) commute. The composition of the \(k\)-th Bender–Knuth switches for all rows is called the \(k\)-th Bender–Knuth involution. This is used to show that the Schur functions defined by semistandard (skew) tableaux are symmetric functions.

**INPUT:**

- **k** – an integer
- **rows** – (Default None) When set to None, the method computes the \(k\)-th Bender–Knuth involution as defined above. When an iterable, this computes the composition of the \(k\)-th Bender–Knuth switches at row \(i\) over all \(i\) in rows. When set to an integer \(i\), the method computes the \(k\)-th Bender–Knuth switch at row \(i\). Note the indexing of the rows starts with 1.
- **check** – (Default: True) Check to make sure self is semistandard. Set to False to avoid this check.

**OUTPUT:**

The image of self under either the \(k\)-th Bender–Knuth involution, the \(k\)-th Bender–Knuth switch at a certain row, or the composition of such switches, as detailed in the INPUT section.

**EXAMPLES:**

```sage
sage: t = SkewTableau([[None,None,None,4,4,5,6,7],[None,2,4,6,7,7,7],
.....: [None,4,5,8,8,9],[None,6,7,10],[None,8,8,11],[None],[4]])
sage: t
[[None, None, None, 4, 4, 5, 6, 7], [None, 2, 4, 6, 7, 7, 7],
 [None, 4, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]
sage: t.bender_knuth_involution(1)
[[None, None, None, 4, 4, 5, 6, 7], [None, 1, 4, 6, 7, 7, 7],
 [None, 4, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]
sage: t.bender_knuth_involution(4)
[[None, None, None, 4, 5, 5, 6, 7], [None, 2, 4, 6, 7, 7, 7],
 [None, 5, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [5]]
```
The Bender–Knuth involution is an involution:

```python
sage: t = SkewTableau([[None,3,4,4],[None,6,10],[7,7,11],[18]])
sage: all(t.bender_knuth_involution(k).bender_knuth_involution(k) == t for k in range(1,5))
True
```

The same for the single switches:

```python
sage: all(t.bender_knuth_involution(k, j).bender_knuth_involution(k, j) == t for k in range(1,5) for j in range(1, 5))
True
```

Locality of the Bender–Knuth involutions:

```python
sage: all(t.bender_knuth_involution(k).bender_knuth_involution(l) == t.bender_knuth_involution(l).bender_knuth_involution(k) for k in range(1,5) for l in range(1,5) if abs(k - l) > 1)
True
```

AUTHORS:

- Darij Grinberg (2013-05-14)

`cells()`

Return the cells in `self`.

EXAMPLES:

```python
sage: s = SkewTableau([[None,1,2],[3],[6]])
sage: s.cells()
[(0, 1), (0, 2), (1, 0), (2, 0)]
```

`cells_by_content(c)`

Return the coordinates of the cells in `self` with content `c`.

EXAMPLES:

```python
sage: s = SkewTableau([[None,1,2],[3,4,5],[6]])
sage: s.cells_by_content(0)
[(1, 1)]
```
cells_containing(i)
Return the list of cells in which the letter \( i \) appears in the tableau \( \text{self} \). The list is ordered with cells appearing from left to right.

Cells are given as pairs of coordinates \((a, b)\), where both rows and columns are counted from 0 (so \( a = 0 \) means the cell lies in the leftmost column of the tableau, etc.).

EXAMPLES:

```python
sage: t = SkewTableau([[None, None, 3], [None, 3, 5], [4, 5]])
sage: t.cells_containing(5)
[(2, 1), (1, 2)]
sage: t.cells_containing(4)
[(2, 0)]
sage: t.cells_containing(2)
[]
sage: t = SkewTableau([[None, None, None], [None, 4, 5], [None, 5, 6], [None, 9], [None]])
sage: t.cells_containing(2)
[]
sage: t.cells_containing(4)
[(1, 1)]
sage: t.cells_containing(5)
[(2, 1), (1, 2)]
sage: SkewTableau([]).cells_containing(3)
[]
sage: SkewTableau([[None, None], [None]]).cells_containing(3)
[]
```

check()
Check that \( \text{self} \) is a valid skew tableau. This is currently far too liberal, and only checks some trivial things.

EXAMPLES:

```python
sage: t = SkewTableau([[None, 1, 1], [2]])
sage: t.check()

sage: t = SkewTableau([[None, None, 1], [2, 4], [], [3, 4, 5]])
Traceback (most recent call last):
  ...
TypeError: a skew tableau cannot have an empty list for a row
```
sage: s = SkewTableau([[1, None, None],[2, None],[3]])
Traceback (most recent call last):
...:
TypeError: not a valid skew tableau

conjugate()
Return the conjugate of self.

EXAMPLES:

sage: SkewTableau([[None,1],[2,3]]).conjugate()
[[None, 2], [1, 3]]

entries_by_content(c)
Return the entries in self with content c.

EXAMPLES:

sage: s = SkewTableau([[None,1,2],[3,4,5],[6]])
sage: s.entries_by_content(0)
[4]
sage: s.entries_by_content(1)
[1, 5]
sage: s.entries_by_content(2)
[2]
sage: s.entries_by_content(-1)
[3]
sage: s.entries_by_content(-2)
[6]

evaluation()
Return the weight (aka evaluation) of the tableau self. Trailing zeroes are omitted when returning the weight.

The weight of a skew tableau $T$ is the sequence $(a_1, a_2, a_3, \ldots)$, where $a_k$ is the number of entries of $T$ equal to $k$. This sequence contains only finitely many nonzero entries.

The weight of a skew tableau $T$ is the same as the weight of the reading word of $T$, for any reading order. $evaluation()$ is a synonym for this method.

EXAMPLES:

sage: SkewTableau([[1,2],[3,4]]).weight()
[1, 1, 1, 1]
sage: SkewTableau([[None,2],[None,4],[None,5],[None]]).weight()
[0, 1, 0, 1, 1]
sage: SkewTableau([]).weight()
[]
sage: SkewTableau([[None,None,None],[None]]).weight()
[]

(continues on next page)
Combinatorics, Release 9.7

(continued from previous page)

```python
sage: SkewTableau([[None,3,4],[None,6,7],[4,8],[5,13],[6],[7]]).weight()
[0, 0, 1, 2, 1, 2, 2, 1, 0, 0, 0, 0, 1]
```

**filling()**

Return a list of the non-empty entries in self.

EXAMPLES:

```python
sage: t = SkewTableau([[None,1],[2,3]])
sage: t.filling()
[[1], [2, 3]]
```

**inner_shape()**

Return the inner shape of self.

EXAMPLES:

```python
sage: SkewTableau([[None,1,2],[None,3],[4]]).inner_shape()
[1, 1]
sage: SkewTableau([[1,2],[3,4],[7]]).inner_shape()
[]
sage: SkewTableau([[None,None,None,2,3],[None,1],[None],[2]]).inner_shape()
[3, 1, 1]
```

**inner_size()**

Return the size of the inner shape of self.

EXAMPLES:

```python
sage: SkewTableau([[None,2,4],[None,3],[1]]).inner_size()
2
sage: SkewTableau([[None,2],[1,3]]).inner_size()
1
```

**is_k_tableau(k)**

Checks whether self is a valid skew weak $k$-tableau.

EXAMPLES:

```python
sage: t = SkewTableau([[None,2,3],[2,3],[3]])
sage: t.is_k_tableau(3)
True
sage: t.is_k_tableau(3)
False
```

**is_ribbon()**

Return True if and only if the shape of self is a ribbon, that is, if it has exactly one cell in each of $q$ consecutive diagonals for some nonnegative integer $q$.

EXAMPLES:

```python
sage: S = SkewTableau([[None, None, 1, 2],[None, None, 3],[1, 3, 4]])
sage: S.pp()
```

(continues on next page)
is_semistandard()

Return True if self is a semistandard skew tableau and False otherwise.

EXAMPLES:

```python
sage: SkewTableau([[None, 2, 2], [1, 3]]).is_semistandard()
True
sage: SkewTableau([[None, 2, 2], [1, 3, 4]]).is_semistandard()
False
```
Combinatorics, Release 9.7

is_standard()  
Return True if self is a standard skew tableau and False otherwise.

EXAMPLES:

```python
sage: SkewTableau([[None, 2], [1, 3]]).is_standard()
True
sage: SkewTableau([[None, 2], [2, 4]]).is_standard()
False
sage: SkewTableau([[None, 3], [2, 4]]).is_standard()
False
sage: SkewTableau([[None, 2], [2, 4]]).is_standard()
False
```

outer_shape()  
Return the outer shape of self.

EXAMPLES:

```python
sage: SkewTableau([[None, 1,2],[None,3],[4]]).outer_shape()
[3, 2, 1]
```

outer_size()  
Return the size of the outer shape of self.

EXAMPLES:

```python
sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).outer_size()
6
sage: SkewTableau([[None, 2], [1, 3]]).outer_size()
4
```

pp()  
Return a pretty print string of the tableau.

EXAMPLES:

```python
sage: SkewTableau([[None, 2,3],[None,4],[5]]).pp()
 . 2 3
```
rectify(algorithm=None)

Return a StandardTableau, SemistandardTableau, or just Tableau formed by applying the jeu de taquin process to self.

See page 15 of [Ful1997].

INPUT:

- algorithm – optional: if set to 'jdt', rectifies by jeu de taquin; if set to 'schensted', rectifies by Schensted insertion of the reading word; otherwise, guesses which will be faster.

EXAMPLES:

```
sage: S = SkewTableau([[None,1],[2,3]])
sage: S.rectify()
[[1, 3], [2]]
sage: T = SkewTableau([[None, None, None, 4],[None,None,1,6],[None,None,5],[2, 3]])
sage: T.rectify()
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='jdt')
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='schensted')
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='spaghetti')
Traceback (most recent call last):
  ...
ValueError: algorithm must be 'jdt', 'schensted', or None
```

restrict(n)

Return the restriction of the (semi)standard skew tableau to all the numbers less than or equal to n.

Note: If only the outer shape of the restriction, rather than the whole restriction, is needed, then the faster method restriction_outer_shape() is preferred. Similarly if only the skew shape is needed, use restriction_shape().

EXAMPLES:

```
sage: SkewTableau([[None,1],[2],[3]]).restrict(2)
[[None, 1], [2]]
sage: SkewTableau([[None,1],[2],[3]]).restrict(1)
[[None, 1]]
sage: SkewTableau([[None,1],[1],[2]]).restrict(1)
[[None, 1], [1]]
```

restriction_outer_shape(n)

Return the outer shape of the restriction of the semistandard skew tableau self to n.

If T is a semistandard skew tableau and n is a nonnegative integer, then the restriction of T to n is defined as the (semistandard) skew tableau obtained by removing all cells filled with entries greater than n from T.

This method computes merely the outer shape of the restriction. For the restriction itself, use restrict().
EXAMPLES:

```python
sage: SkewTableau([[None,None],[2,3],[3,4]]).restriction_outer_shape(3)
[2, 2, 1]
sage: SkewTableau([[None],[None],[4],[5]]).restriction_outer_shape(2)
[2, 1]
sage: T = SkewTableau([[None,None,3,5],[None,4,4],[17]])
sage: T.restriction_outer_shape(0)
[2, 1]
sage: T.restriction_outer_shape(2)
[2, 1]
sage: T.restriction_outer_shape(3)
[3, 1]
sage: T.restriction_outer_shape(4)
[3, 3]
sage: T.restriction_outer_shape(19)
[4, 3, 1]
```

**restriction_shape**(n)

Return the skew shape of the restriction of the semistandard skew tableau `self` to `n`.

If `T` is a semistandard skew tableau and `n` is a nonnegative integer, then the restriction of `T` to `n` is defined as the (semistandard) skew tableau obtained by removing all cells filled with entries greater than `n` from `T`.

This method computes merely the skew shape of the restriction. For the restriction itself, use `restrict()`.

EXAMPLES:

```python
sage: SkewTableau([[None,None],[2,3],[3,4]]).restriction_shape(3)
sage: SkewTableau([[None],[None],[4],[5]]).restriction_shape(2)
sage: T = SkewTableau([[None,None,3,5],[None,4,4],[17]])
sage: T.restriction_shape(0)
sage: T.restriction_shape(2)
sage: T.restriction_shape(3)
[1] / [1, 1]
sage: T.restriction_shape(4)
```

**shape()**

Return the shape of `self`.

EXAMPLES:

```python
sage: SkewTableau([[None,1,2],[None,3],[4]]).shape()
[2, 1] / [1, 1]
```

**shuffle**(t2)

Shuffle the standard tableaux `self` and `t2`.

Let `t1 = self`. The shape of `t2` must extend the shape of `t1`, that is, `self.outer_shape() == t2.inner_shape()`. Then this function computes the pair of tableaux `(t2_new, t1_new)` obtained by using jeu de taquin slides to move the boxes of `t2` behind the boxes of `self`. 
The entries of $t_{2\_new}$ are obtained by performing successive inwards jeu de taquin slides on $t_{2}$ in the order indicated by the entries of $t_{1}$, from largest to smallest. The entries of $t_{1}$ then slide outwards one by one and land in the squares vacated successively by $t_{2}$, forming $t_{1\_new}$.

**Note:** Equivalently, the entries of $t_{1\_new}$ are obtained by performing outer jeu de taquin slides on $t_{1}$ in the order indicated by the entries of $t_{2}$, from smallest to largest. In this case the entries of $t_{2}$ slide backwards and fill the squares successively vacated by $t_{1}$ and so form $t_{2\_new}$. (This is not how the algorithm is implemented.)

**INPUT:**
- $self, t_{2}$ – a pair of standard SkewTableaux with $self.outер\_shape() == t_{2}.inner\_shape()$

**OUTPUT:**
- $t_{2\_new}, t_{1\_new}$ – a pair of standard SkewTableaux with $t_{2\_new}.outer\_shape() == t_{1\_new}.inner\_shape()$

**EXAMPLES:**

```sage
t1 = SkewTableau([[None, 1, 2], [3, 4]])
t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
(t2_new, t1_new) = t1.shuffle(t2)
t1_new
[[None, None, None, 2], [None, None, 1], [None, 3, 4]]
t2_new
[[None, 2, 3], [1, 4], [5]]
t1_new.outer\_shape() == t2.outer\_shape()
True
t2_new.inner\_shape() == t1.inner\_shape()
True
```

Shuffling is an involution:

```sage
t1 = SkewTableau([[None, 1, 2], [3, 4]])
t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
sh = lambda x,y : x.shuffle(y)
(t1, t2) == sh(sh(t1, t2))
True
```

Both tableaux must be standard:

```sage
t1 = SkewTableau([[None, 1, 2], [2, 4]])
t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
t1.shuffle(t2)
Traceback (most recent call last):
  ...
ValueError: the tableaux must be standard
```

The shapes (not just the nonempty cells) must be adjacent:
Combinatorics, Release 9.7

```
sage: t1 = SkewTableau([[None, None, None], [1]])
sage: t2 = SkewTableau([[None], [None], [1]])
sage: t1.shuffle(t2)
Traceback (most recent call last):
  ... ValueError: the shapes must be adjacent

size()
Return the number of cells in self.
EXAMPLES:
```
sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).size()
4
sage: SkewTableau([[None, 2], [1, 3]]).size()
3

slide(corner=None, return_vacated=False)
Apply a jeu de taquin slide to self on the specified inner corner and return the resulting tableau.
If no corner is given, the topmost inner corner is chosen.
The optional parameter return_vacated=True causes the output to be the pair (t, (i, j)) where t is the new tableau and (i, j) are the coordinates of the vacated square.
EXAMPLES:
```
sage: st = SkewTableau([[None, None, None, None, 2], [None, None, None, None, _, _]
                      [[None, 2, 4, 4], [2, 3, 6], [5, 5]])
sage: st.slide((2, 0))
[[None, None, None, None, 2], [None, None, None, None, 6], [2, 2, 4, 4], [3, 5, _
                      [[None, None, 3], [1, 2, 4], [5], (2, 1)]

standardization(check=True)
Return the standardization of self, assuming self is a semistandard skew tableau.
The standardization of a semistandard skew tableau T is the standard skew tableau st(T) of the same shape as T whose reversed reading word is the standardization of the reversed reading word of T.
The standardization of a word w can be formed by replacing all 1's in w by 1, 2, ..., k_1 from left to right, all 2's in w by k_1 + 1, k_1 + 2, ..., k_2, and repeating for all letters that appear in w. See also Word.standard_permutation().
INPUT:
- check – (Default: True) Check to make sure self is semistandard. Set to False to avoid this check.
EXAMPLES:
```
sage: t = SkewTableau([[None,None,3,4,7,19],[None,4,4,8],[None,5,16,17],[None],
                   [[None, 3, 6, 8, 12], [None, 4, 5, 9], [None, 7, 10, 11], [None], [1, _
                   [[None, None, 3, 6, 8, 12], [None, 4, 5, 9], [None, 7, 10, 11], [None], [1, _
                   [[None, None, 3, 6, 8, 12], [None, 4, 5, 9], [None, 7, 10, 11], [None], [1, _
```
Standard skew tableaux are fixed under standardization:

```python
sage: p = Partition([4,3,3,2])
sage: q = Partitions(3).random_element()
sage: all((t == t.standardization() for t in StandardSkewTableaux([p, q])))
True
```

The reading word of the standardization is the standardization of the reading word:

```python
sage: t = SkewTableau([[None,3,4,4],[None,6,10],[7,7,11],[18]])
sage: t.to_word().standard_permutation() == t.standardization().to_permutation()
True
```

to_chain(max_entry=None)

Return the chain of partitions corresponding to the (semi)standard skew tableau self.

The optional keyword parameter max_entry can be used to customize the length of the chain. Specifically, if this parameter is set to a nonnegative integer n, then the chain is constructed from the positions of the letters 1, 2, ..., n in the tableau.

EXAMPLES:

```python
sage: SkewTableau([[None,1],[2],[3]]).to_chain()
[[1], [2], [2, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain()
[[1], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain(max_entry=2)
[[1], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain(max_entry=3)
[[1], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain(max_entry=1)
[[1], [2, 1]]
sage: SkewTableau([[None,None,2],[None,3],[None,5]]).to_chain(max_entry=6)
[[2, 1, 1], [2, 1, 1], [3, 1, 1], [3, 2, 1], [3, 2, 1], [3, 2, 2], [3, 2, 2]]
sage: SkewTableau([]).to_chain()
[]
sage: SkewTableau([]).to_chain(max_entry=1)
[]
```

to_expr()

The first list in a result corresponds to the inner partition of the skew shape. The second list is a list of the rows in the skew tableau read from the bottom up.

Provided for compatibility with MuPAD-Combinat. In MuPAD-Combinat, if t is a skew tableau, then to_expr gives the same result as expr(t) would give in MuPAD-Combinat.

EXAMPLES:

```python
sage: SkewTableau([[None,1,1,3],[None,2,2],[1]]).to_expr()
[[1, 1], [[1], [2, 2], [1, 1, 3]]]
sage: SkewTableau([]).to_expr()
[]
```

to_list()

Return a (mutable) list representation of self.

EXAMPLES:
```python
sage: stlist = [[None, None, 3], [None, 1, 3], [2, 2]]
sage: st = SkewTableau(stlist)
sage: st.to_list()
[[None, None, 3], [None, 1, 3], [2, 2]]
sage: st.to_list() == stlist
True

to_permutation()
Return a permutation with the entries of self obtained by reading self row by row, from the bottommost to the topmost row, with each row being read from left to right, in English convention. See to_word_by_row().

EXAMPLES:

```python
sage: SkewTableau([[None,2],[3,4],[None],[1]]).to_permutation()
[1, 3, 4, 2]
sage: SkewTableau([[None,2],[None,4],[1],[3]]).to_permutation()
[3, 1, 4, 2]
sage: SkewTableau([[None]]).to_permutation()
[]
```

to_ribbon(check_input=True)
Return self as a ribbon-shaped tableau (RibbonShapedTableau), provided that the shape of self is a ribbon.

INPUT:

• check_input – (default: True) whether or not to check that self indeed has ribbon shape

EXAMPLES:

```python
sage: SkewTableau([[None,1],[2,3]]).to_ribbon()
[[None, 1], [2, 3]]
```

to_tableau()
Returns a tableau with the same filling. This only works if the inner shape of the skew tableau has size zero.

EXAMPLES:

```python
sage: SkewTableau([[1,2],[3,4]]).to_tableau()
[[1, 2], [3, 4]]
```

to_word()
Return a word obtained from a row reading of self.

This is the word obtained by concatenating the rows from the bottommost one (in English notation) to the topmost one.

EXAMPLES:

```python
sage: s = SkewTableau([[None,1],[2,3]])
sage: s.pp()
  . 1
  2 3
sage: s.to_word_by_row()
word: 231
sage: s = SkewTableau([[None, 2, 4], [None, 3], [1]])
```
sage: s.pp()
  2 4
  3
 1
sage: s.to_word_by_row()
word: 1324

to_word_by_column()
Return the word obtained from a column reading of the skew tableau.

This is the word obtained by concatenating the columns from the rightmost one (in English notation) to the leftmost one.

EXAMPLES:

sage: s = SkewTableau([[None, 1], [2, 3]])
sage: s.pp()
  . 1
  2 3
sage: s.to_word_by_column()
word: 132

sage: s = SkewTableau([[None, 2, 4], [None, 3], [1]])
sage: s.pp()
  2 4
  3
 1
sage: s.to_word_by_column()
word: 4231

to_word_by_row()
Return a word obtained from a row reading of self.

This is the word obtained by concatenating the rows from the bottommost one (in English notation) to the topmost one.

EXAMPLES:

sage: s = SkewTableau([[None, 1], [2, 3]])
sage: s.pp()
  . 1
  2 3
sage: s.to_word_by_row()
word: 231
sage: s = SkewTableau([[None, 2, 4], [None, 3], [1]])
sage: s.pp()
  2 4
  3
 1
sage: s.to_word_by_row()
word: 1324

weight()
Return the weight (aka evaluation) of the tableau self. Trailing zeroes are omitted when returning the weight.
The weight of a skew tableau $T$ is the sequence $(a_1, a_2, a_3, \ldots)$, where $a_k$ is the number of entries of $T$ equal to $k$. This sequence contains only finitely many nonzero entries.

The weight of a skew tableau $T$ is the same as the weight of the reading word of $T$, for any reading order. 

`evaluation()` is a synonym for this method.

**EXAMPLES:**

```python
sage: SkewTableau([[1,2],[3,4]]).weight()
[1, 1, 1, 1]

sage: SkewTableau([[None,2],[None,4],[None,5],[None]]).weight()
[0, 1, 0, 1, 1]

sage: SkewTableau([]).weight()
[]

sage: SkewTableau([[None,None,None],[None]]).weight()
[]

sage: SkewTableau([[None,3,4],[None,6,7],[4,8],[5,13],[6],[7]]).weight()
[0, 0, 1, 2, 1, 2, 2, 1, 0, 0, 0, 0, 1]
```

class sage.combinat.skew_tableau.SkewTableau_class(parent, st)

Bases: sage.combinat.skew_tableau.SkewTableau

This exists solely for unpickling `SkewTableau_class` objects.

class sage.combinat.skew_tableau.SkewTableaux(category=None)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Class of all skew tableaux.

**Element**

alias of `SkewTableau`

**from_chain**(chain)

Return the tableau corresponding to the chain of partitions.

**EXAMPLES:**

```python
sage: SkewTableaux().from_chain([[1,1],[2,1],[3,1],[3,2],[3,3],[3,3,1]])
[[None, 1, 2], [None, 3, 4], [5]]
```

**from_expr**(expr)

Return a `SkewTableau` from a MuPAD-Combinat expr for a skew tableau.

The first list in `expr` is the inner shape of the skew tableau. The second list are the entries in the rows of the skew tableau from bottom to top.

Provided primarily for compatibility with MuPAD-Combinat.

**EXAMPLES:**

```python
sage: SkewTableaux().from_expr([[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```
from_shape_and_word(shape, word)
Return the skew tableau corresponding to the skew partition shape and the word word obtained from the row reading.

EXAMPLES:
```
sage: t = SkewTableau([[None, 1, 3], [None, 2], [4]])
sage: shape = t.shape()
sage: word = t.to_word()
sage: SkewTableaux().from_shape_and_word(shape, word)
[[None, 1, 3], [None, 2], [4]]
```

options(*get_value, **set_value)
Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:

- ascii_art – (default: repr) Controls the ascii art output for tableaux
  - compact – minimal length ascii art
  - repr – display using the diagram string representation
  - table – display as a table
- convention – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention
- display – (default: list) Controls the way in which tableaux are printed
  - array – alias for diagram
  - compact – minimal length string representation
  - diagram – display as Young diagram (similar to \( pp() \))
  - ferrers_diagram – alias for diagram
  - list – print tableaux as lists
  - young_diagram – alias for diagram
- latex – (default: diagram) Controls the way in which tableaux are latexed
  - array – alias for diagram
  - diagram – as a Young diagram
  - ferrers_diagram – alias for diagram
  - list – as a list
  - young_diagram – alias for diagram
- notation – alternative name for convention

Note: Changing the convention for tableaux also changes the convention for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:
Combinatorics, Release 9.7

```python
sage: T = Tableau([[1,2,3],[4,5]])
sage: T
[[1, 2, 3], [4, 5]]
sage: Tableaux.options.display="array"
sage: T
1 2 3
4 5
sage: Tableaux.options.convention="french"
sage: T
4 5
1 2 3
```

Changing the convention for tableaux also changes the convention for partitions and vice versa:

```python
sage: P = Partition([3,3,1])
sage: print(P.ferrers_diagram())
*
***
***
sage: Partitions.options.convention="english"
sage: print(P.ferrers_diagram())
***
***
*
sage: T
1 2 3
4 5
```

The ASCII art can also be changed:

```python
sage: t = Tableau([[1,2,3],[4,5]])
sage: ascii_art(t)
1 2 3
4 5
sage: Tableaux.options.ascii_art = "table"
sage: ascii_art(t)
+---+---+---+
| 1 | 2 | 3 |
+---+---+---+
| 4 | 5 |
+---+
sage: Tableaux.options.ascii_art = "compact"
sage: ascii_art(t)
|1|2|3|
|4|5|
sage: Tableaux.options._reset()
```

See `GlobalOptions` for more features of these options.

```python
class sage.combinat.skew_tableau.StandardSkewTableaux(category=None)
Bases: sage.combinat.skew_tableau.SkewTableaux

Standard skew tableaux.

EXAMPLES:
```
sage: S = StandardSkewTableaux(); S
Standard skew tableaux
sage: S.cardinality()
+Infinity

sage: S = StandardSkewTableaux(2); S
Standard skew tableaux of size 2
sage: S.cardinality()
4

sage: StandardSkewTableaux([[3, 2, 1], [1, 1]]).list()

[[[None, 2, 3], [None, 4], [1]],
 [[None, 1, 2], [None, 3], [4]],
 [[None, 1, 2], [None, 4], [3]],
 [[None, 1, 3], [None, 4], [2]],
 [[None, 1, 4], [None, 3], [2]],
 [[None, 1, 4], [None, 2], [3]],
 [[None, 1, 3], [None, 2], [4]],
 [[None, 2, 4], [None, 3], [1]]]

class sage.combinat.skew_tableau.StandardSkewTableaux_all
    Bases: sage.combinat.skew_tableau.StandardSkewTableaux

Class of all standard skew tableaux.

class sage.combinat.skew_tableau.StandardSkewTableaux_shape(skp)
    Bases: sage.combinat.skew_tableau.StandardSkewTableaux

Standard skew tableaux of a fixed skew shape $\lambda/\mu$.

cardinality()
    Return the number of standard skew tableaux with shape of the skew partition skp. This uses a formula
due to Aitken (see Cor. 7.16.3 of [Sta-EC2]).

    EXAMPLES:

    sage: StandardSkewTableaux([[3, 2, 1], [1, 1]]).cardinality()
    8

class sage.combinat.skew_tableau.StandardSkewTableaux_size(n)
    Bases: sage.combinat.skew_tableau.StandardSkewTableaux

Standard skew tableaux of a fixed size $n$.

cardinality()
    EXAMPLES:

    sage: StandardSkewTableaux(1).cardinality()
    1
    sage: StandardSkewTableaux(2).cardinality()
    4
    sage: StandardSkewTableaux(3).cardinality()
    24
    sage: StandardSkewTableaux(4).cardinality()
    194
5.1.310 Functions that compute some of the sequences in Sloane’s tables

EXAMPLES:
Type `sloane.[tab]` to see a list of the sequences that are defined.

```
sage: a = sloane.A000005; a
The integer sequence tau(n), which is the number of divisors of n.
sage: a(1)
1
sage: a(6)
4
sage: a(100)
9
```

Type `d._eval??` to see how the function that computes an individual term of the sequence is implemented.

The input must be a positive integer:

```
sage: a(0)
Traceback (most recent call last):
  ...  
ValueError: input n (=0) must be a positive integer
sage: a(1/3)
Traceback (most recent call last):
  ...  
TypeError: input must be an int or Integer
```

You can also change how a sequence prints:

```
sage: a = sloane.A000005; a
The integer sequence tau(n), which is the number of divisors of n.
sage: a.rename('\(\ldots, \tau(n), \ldots\)')
sage: a
(\ldots, \tau(n), \ldots)
sage: a.reset_name()
sage: a
The integer sequence tau(n), which is the number of divisors of n.
```

See also:

- If you want to get more informations relative to a sequence (references, links, examples, programs, ...), you can use the On-Line Encyclopedia of Integer Sequences provided by the OEIS module.
- If you plan to do a lot of automatic searches for subsequences, you should consider installing SloaneEncyclopedia, a local partial copy of the OEIS.

cf() 

EXAMPLES:
```
sage: it = sloane.A000009.cf()
sage: [next(it) for i in range(14)]
[1, 1, 1, 2, 2, 3, 4, 5, 6, 8, 10, 12, 15, 18]
```
list(n)
EXAMPLES:

```python
sage: sloane.A000009.list(14)
[1, 1, 1, 2, 2, 3, 4, 5, 6, 8, 10, 12, 15, 18]
```

class sage.combinat.sloane_functions.A000010
Bases: sage.combinat.sloane_functions.SloaneSequence

The integer sequence A000010 is Euler's totient function.
Number of positive integers i < n that are relative prime to n. Number of totatives of n.
Euler totient function \( \phi(n) \): count numbers \( n \) and prime to \( n \). euler_phi is a standard Sage function implemented in PARI

INPUT:
- \( n \) – non negative integer

OUTPUT:
- integer – function value

EXAMPLES:

```python
sage: a = sloane.A000010; a
Euler's totient function
sage: a(1)
1
sage: a(0)

```

**AUTHORS:**

- Jaap Spies (2007-01-18)

### class `sage.combinat.sloane_functions.A000027`

**Bases:** `sage.combinat.sloane_functions.SloaneSequence`

The natural numbers. Also called the whole numbers, the counting numbers or the positive integers.

The following examples are tests of `SloaneSequence` more than A000027.

**EXAMPLES:**

```sage
sage: s = sloane.A000027; s
The natural numbers.
sage: s(10)
10
```

Index n is interpreted as `_eval(n):`

```sage
sage: s[10]
10
```

Slices are interpreted with absolute offsets, so the following returns the terms of the sequence up to but not including the third term:

```sage
sage: s[:3]
[1, 2]
sage: s[3:6]
[3, 4, 5]
sage: s.list(5)
[1, 2, 3, 4, 5]
```

### class `sage.combinat.sloane_functions.A000030`

**Bases:** `sage.combinat.sloane_functions.SloaneSequence`

Initial digit of $n$. 

---

3056  Chapter 5. Comprehensive Module List
INPUT:
• n – non negative integer

OUTPUT:
• integer – function value

EXAMPLES:

class sage.combinat.sloane_functions.A000045
Bases: sage.combinat.sloane_functions.SloaneSequence

Sequence of Fibonacci numbers, offset 0,4.

REFERENCES:

We have one more. Our first Fibonacci number is 0.

INPUT:

- n – non negative integer

OUTPUT:

- integer – function value

EXAMPLES:

```
sage: a = sloane.A000045; a
Fibonacci numbers with index n >= 0
sage: a(0)
0
sage: a(1)
1
sage: a.list(12)
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]
sage: a(1/3)
Traceback (most recent call last):
  ... TypeError: input must be an int or Integer
```

AUTHORS:

- Jaap Spies (2007-01-13)
fib()
 Returns a generator over all Fibonacci numbers, starting with 0.

EXAMPLES:

```python
sage: it = sloane.A000045.fib()
sage: [next(it) for i in range(10)]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34]
```

list(n)
EXAMPLES:

```python
sage: sloane.A000045.list(10)
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34]
```

class sage.combinat.sloane_functions.A000069
Bases: sage.combinat.sloane_functions.SloaneSequence
Odious numbers: odd number of 1’s in binary expansion.

INPUT:

• n – non negative integer

OUTPUT:

• integer – function value

EXAMPLES:

```python
sage: a = sloane.A000069; a
Odious numbers: odd number of 1's in binary expansion.
sage: a(0)
1
sage: a(2)
4

class sage.combinat.sloane_functions.A000110

Bases: sage.combinat.sloane_functions.ExponentialNumbers

The sequence of Bell numbers.

The Bell number $B_n$ counts the number of ways to put $n$ distinguishable things into indistinguishable boxes such that no box is empty.

Let $S(n, k)$ denote the Stirling number of the second kind. Then

$$B_n = \sum k = 0^n S(n, k).$$

INPUT:

• $n$ – non negative integer

OUTPUT:

• integer – $B_n$

EXAMPLES:

```plaintext
sage: a = sloane.A000110; a

class sage.combinat.sloane_functions.A000587
Bases: sage.combinat.sloane_functions.ExponentialNumbers

The sequence of Uppuluri-Carpenter numbers.

The Uppuluri-Carpenter number \( C_n \) counts the imbalance in the number of ways to put \( n \) distinguishable things into an even number of indistinguishable boxes versus into an odd number of indistinguishable boxes, such that no box is empty.
Let $S(n, k)$ denote the Stirling number of the second kind. Then

$$C_n = \sum k = 0^n (-1)^k S(n, k).$$

**INPUT:**
- $n$ – non negative integer

**OUTPUT:**
- integer – $C_n$

**EXAMPLES:**

```
sage: a = sloane.A000587; a

AUTHORS:

- Jaap Spies (2007-01-26)

```python
class sage.combinat.sloane_functions.A001694
Bases: sage.combinat.sloane_functions.SloaneSequence

This function returns the \( n \)-th Powerful Number:

A positive integer \( n \) is powerful if for every prime \( p \) dividing \( n \), \( p^2 \) also divides \( n \).

INPUT:

- \( n \) – non negative integer

OUTPUT:

- integer – function value

EXAMPLES:

```python
sage: a = sloane.A001694; a
Powerful Numbers (also called squarefull, square-full or 2-full numbers).

sage: a(-1)
Traceback (most recent call last):
... ValueError: input n (=1) must be a positive integer
```

AUTHORS:
is_powerful($n$)
Return True if and only if $n$ is a powerful number.

A positive integer $n$ is powerful if for every prime $p$ dividing $n$, $p^2$ also divides $n$.

See OEIS sequence A001694.

INPUT:
• $n$ – integer

OUTPUT:
True if $n$ is a powerful number, else False

EXAMPLES:

```sage
a = sloane.A001694
sage: a.is_powerful(2500)
True
sage: a.is_powerful(20)
False
```

AUTHORS:

```

class sage.combinat.sloane_functions.A001836

Bases: sage.combinat.sloane_functions.SloaneSequence

Numbers $n$ such that $\phi(2n - 1) < \phi(2n)$, where $\phi$ is Euler's totient function.

Euler’s totient function is also known as euler_phi, euler_phi is a standard Sage function.

INPUT:
• $n$ – non negative integer

OUTPUT:
• integer – function value

EXAMPLES:

```sage
a = sloane.A001836; a
Numbers n such that phi(2n-1) < phi(2n), where phi is Euler's totient function.

class **sage.combinat.sloane_functions.A083216**

Bases: *sage.combinat.sloane_functions.RecurrenceSequence2*

Second-order linear recurrence sequence with \( a(n) = a(n-1) + a(n-2) \).

\( a(0) = 2061567420555510, a(1) = 3794765361567513 \). This is a second-order linear recurrence sequence with \( a(0) \) and \( a(1) \) co-prime that does not contain any primes. It was found by Herbert Wilf in 1990.

INPUT:

- \( n \) – non negative integer

OUTPUT:

- integer – function value

EXAMPLES:

```sage
a = sloane.A083216; a
Second-order linear recurrence sequence with a(n) = a(n-1) + a(n-2).
sage: a(0)
2061567420555510

class sage.combinat.sloane_functions.A109814
Bases: sage.combinat.sloane_functions.SloaneSequence

The \( n \) th term of the sequence \( a(n) \) is the largest \( k \) such that \( n \) can be written as sum of \( k \) consecutive integers.

5.1. Comprehensive Module List

3127
By definition, $n$ is the sum of at most $a(n)$ consecutive positive integers. Suppose $n$ is to be written as sum of $k$ consecutive integers starting with $m$, then $2n = k(2m + k - 1)$. Only one of the factors is odd. For each odd divisor $d$ of $n$ there is a unique corresponding $k = \min(d, 2n/d)$. $a(n)$ can be alternatively defined as the largest among those $k$.

See also:

- Wikipedia article Polite_number
- An exercise sheet (with answers) about sums of consecutive integers.

INPUT:
- $n$ – non negative integer

OUTPUT:
- integer – function value

EXAMPLES:

```sage
sage: a = sloane.A109814; a
a(n) is the largest k such that n can be written as sum of k consecutive positive integers.
sage: a(0)

AUTHORS:
- Jaap Spies (2007-01-13)

class `sage.combinat.sloane_functions.A111774`

Bases: `sage.combinat.sloane_functions.SloaneSequence`

Sequence of numbers of the third kind, i.e., numbers that can be written as a sum of at least three consecutive positive integers.

Odd primes can only be written as a sum of two consecutive integers. Powers of 2 do not have a representation as a sum of $k$ consecutive integers (other than the trivial $n = n$ for $k = 1$).

INPUT:
- $n$ – non negative integer

OUTPUT:
- integer – function value

EXAMPLES:

```sage
sage: a = sloane.A111774; a
Numbers that can be written as a sum of at least three consecutive positive integers.
sage: a(1)
```

(continues on next page)
AUTHORS:

• Jaap Spies (2007-01-13)

**is_number_of_the_third_kind** (*n*)

Return True if and only if *n* is a number of the third kind.

A number is of the third kind if it can be written as a sum of at least three consecutive positive integers. Odd primes can only be written as a sum of two consecutive integers. Powers of 2 do not have a representation as a sum of *k* consecutive integers (other than the trivial *n* = *n* for *k* = 1).

**INPUT:**

• *n* – positive integer

**OUTPUT:**

True if *n* is not prime and not a power of 2

**EXAMPLES:**

```sage
a = sloane.A111774
sage: a.is_number_of_the_third_kind(6)
True
sage: a.is_number_of_the_third_kind(100)
True
sage: a.is_number_of_the_third_kind(16)
False
sage: a.is_number_of_the_third_kind(97)
False
```

AUTHORS:

• Jaap Spies (2006-12-09)

**list** (*n*)

**EXAMPLES:**
class sage.combinat.sloane_functions.A111775
Bases: sage.combinat.sloane_functions.SloaneSequence

Number of ways $n$ can be written as a sum of at least three consecutive integers.

Powers of 2 and (odd) primes cannot be written as a sum of at least three consecutive integers. $a(n)$ strongly depends on the number of odd divisors of $n$ (A001227): Suppose $n$ is to be written as sum of $k$ consecutive integers starting with $m$, then $2n = k(2m + k - 1)$. Only one of the factors is odd. For each odd divisor of $n$ there is a unique corresponding $k$, $k = 1$ and $k = 2$ must be excluded.

INPUT:

• $n$ – non negative integer

OUTPUT:

• integer – function value

EXAMPLES:

```python
sage: a = sloane.A111775; a
Number of ways $n$ can be written as a sum of at least three consecutive integers.

sage: a(1)
0
sage: a(0)
0

We have $a(15) = 2$ because $15 = 4+5+6$ and $15 = 1+2+3+4+5$. The number of odd divisors of 15 is 4.

```

AUTHORS:

• Jaap Spies (2006-12-09)

class sage.combinat.sloane_functions.A111787
Bases: sage.combinat.sloane_functions.SloaneSequence

This function returns the $n$-th number of Sloane's sequence A111787
\( a(n) = 0 \) if \( n \) is an odd prime or a power of 2. For numbers of the third kind (see A111774) we proceed as follows: suppose \( n \) is to be written as sum of \( k \) consecutive integers starting with \( m \), then \( 2n = k(2m + k - 1) \). Let \( p \) be the smallest odd prime divisor of \( n \) then \( a(n) = \min(p, 2n/p) \).

INPUT:

• \( n \) – non negative integer

OUTPUT:

• integer – function value

EXAMPLES:

```python
sage: a = sloane.A111787; a
(a) is the least \( k \geq 3 \) such that \( n \) can be written as sum of \( k \) consecutive integers. \( a(n)=0 \) if such a \( k \) does not exist.

```

AUTHORS:

• Jaap Spies (2007-01-14)

class `sage.combinat.sloane_functions.ExponentialNumbers`(*\( a \))

Bases: `sage.combinat.sloane_functions.SloaneSequence`

A sequence of Exponential numbers.

EXAMPLES:

```python
sage: from sage.combinat.sloane_functions import ExponentialNumbers
sage: ExponentialNumbers(0)
Sequence of Exponential numbers around 0
```

class `sage.combinat.sloane_functions.ExtemesOfPermanentsSequence`(*\( offset=1 \))

Bases: `sage.combinat.sloane_functions.SloaneSequence`

gen(*\( a0, al, d \))

EXAMPLES:
sage: it = sloane.A000153.gen(0,1,2)
sage: [next(it) for i in range(5)]
[0, 1, 2, 7, 32]

list(n)
EXAMPLES:

sage: sloane.A000153.list(8)
[0, 1, 2, 7, 32, 181, 1214, 9403]

class sage.combinat.sloane_functions.ExtremesOfPermanentsSequence2(offset=1)
Bases: sage.combinat.sloane_functions.ExtremesOfPermanentsSequence
gen(a0, a1, d)
EXAMPLES:

sage: from sage.combinat.sloane_functions import ExtremesOfPermanentsSequence2
sage: e = ExtremesOfPermanentsSequence2()
sage: it = e.gen(6,43,6)
sage: [next(it) for i in range(5)]
[6, 43, 307, 2542, 23799]

class sage.combinat.sloane_functions.RecurrenceSequence(offset=1)
Bases: sage.combinat.sloane_functions.SloaneSequence
list(n)
EXAMPLES:

sage: sloane.A001110.list(8)
[0, 1, 36, 1225, 41616, 1413721, 48024900, 1631432881]

class sage.combinat.sloane_functions.RecurrenceSequence2(offset=1)
Bases: sage.combinat.sloane_functions.SloaneSequence
list(n)
EXAMPLES:

sage: sloane.A001906.list(10)
[0, 1, 3, 8, 21, 55, 144, 377, 987, 2584]

class sage.combinat.sloane_functions.Sloane
Bases: sage.structure.sage_object.SageObject

A collection of Sloane generating functions.
This class inspects sage.combinat.sloane_functions, accumulating all the SloaneSequence classes starting with
'A'. These are listed for tab completion, but not instantiated until requested.

EXAMPLES:

Ensure we have lots of entries:

sage: len(sloane.__dir__()) > 100
True

Ensure none are being incorrectly returned:
sage: [ None for n in sloane.__dir__() if not n.startswith('A') ]
[]

Ensure we can access dynamic constructions and cache correctly:

sage: s = sloane.A000587
sage: s is sloane.A000587
True

Ensure that we can access other functions in parent classes:

sage: sloane.__class__
<class 'sage.combinat.sloane_functions.Sloane'>

AUTHORS:
• Nick Alexander

class sage.combinat.sloane_functions.SloaneSequence
Bases: sage.structure.sage_object.SageObject

Base class for a Sloane integer sequence.

list(n)
Return n terms of the sequence:

sequence[offset], sequence[offset+1], ..., sequence[offset+n-1].

EXAMPLES:

sage: sloane.A000012.list(4)
[1, 1, 1, 1]

sage.combinat.sloane_functions.perm_mh(m, h)
This functions calculates \( f(g, h) \) from Sloane’s sequences A079908-A079928

INPUT:
• m – positive integer
• h – non negative integer

OUTPUT: permanent of the \( m \times (m + h) \) matrix, etc.

EXAMPLES:

sage: from sage.combinat.sloane_functions import perm_mh
sage: perm_mh(3,3)
36
sage: perm_mh(3,4)
76

AUTHORS:
• Jaap Spies (2006)

sage.combinat.sloane_functions.recur_gen2(a0, a1, a2, a3)
homogeneous general second-order linear recurrence generator with fixed coefficients
\[ a(0) = a_0, a(1) = a_1, a(n) = a_2a(n-1) + a_3a(n-2) \]
EXAMPLES:

```python
sage: from sage.combinat.sloane_functions import recur_gen2
sage: it = recur_gen2(1,1,1,1)
sage: [next(it) for i in range(10)]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55]
```

sage.combinat.sloane_functions.recur_gen2b(a0, a1, a2, a3, b)

Inhomogeneous second-order linear recurrence generator with fixed coefficients and \( b = f(n) \)

\[ a(0) = a0, a(1) = a1, a(n) = a2 \times a(n-1) + a3 \times a(n-2) + f(n). \]

EXAMPLES:

```python
sage: from sage.combinat.sloane_functions import recur_gen2b
sage: it = recur_gen2b(1,1,1,1, lambda n: 0)
sage: [next(it) for i in range(10)]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55]
```

sage.combinat.sloane_functions.recur_gen3(a0, a1, a2, a3, a4, a5)

Homogeneous general third-order linear recurrence generator with fixed coefficients

\[ a(0) = a0, a(1) = a1, a(2) = a2, a(n) = a3 \times a(n-1) + a4 \times a(n-2) + a5 \times a(n-3) \]

EXAMPLES:

```python
sage: from sage.combinat.sloane_functions import recur_gen3
sage: it = recur_gen3(1,1,1,1,1)
sage: [next(it) for i in range(10)]
[1, 1, 1, 3, 5, 9, 17, 31, 57, 105]
```

5.1.311 Combinatorial species

Todo: Short blurb about species

Todo: Proofread / point to the main classes rather than the modules?

Introductory material

- Enumeration of trees using generating functions
- Species, decomposable combinatorial classes
Lazy Power Series

- Streams or Infinite Arrays
- Series Order
- Lazy Power Series
- Generating Series

Basic Species

- Combinatorial Species
- Empty Species
- Recursive Species
- Characteristic Species
- Cycle Species
- Partition Species
- Permutation species
- Linear-order Species
- Set Species
- Subset Species
- Examples of Combinatorial Species

Operations on Species

- Sum species
- Product species
- Composition species
- Functorial composition species

Miscellaneous

- Species structures
- Miscellaneous Functions

5.1.312 Characteristic Species

class sage.combinat.species.characteristic_species.CharacteristicSpecies(n, min=None, max=None, weight=None)

Bases: sage.combinat.species.species.GenericCombinatorialSpecies, sage.structure.unique_representation.UniqueRepresentation

Return the characteristic species of order \( n \).
This species has exactly one structure on a set of size $n$ and no structures on sets of any other size.

EXAMPLES:

```python
sage: X = species.CharacteristicSpecies(1)
sage: X.structures([1]).list()
[1]
sage: X.structures([1,2]).list()
[]
sage: X.generating_series().coefficients(4)
[0, 1, 0, 0]
sage: X.isotype_generating_series().coefficients(4)
[0, 1, 0, 0]
sage: X.cycle_index_series().coefficients(4)
[0, p[1], 0, 0]
sage: F = species.CharacteristicSpecies(3)
sage: c = F.generating_series().coefficients(4)
[0, 1, 0, 0]
sage: F._check()
True
sage: F == loads(dumps(F))
True
```

class `sage.combinat.species.characteristic_species.CharacteristicSpeciesStructure`(
  `parent`,
  `labels`,
  `list`
)

Bases: `sage.combinat.species.structure.GenericSpeciesStructure`

`automorphism_group()`
Returns the group of permutations whose action on this structure leave it fixed. For the characteristic species, there is only one structure, so every permutation is in its automorphism group.

EXAMPLES:

```python
sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.automorphism_group()
Symmetric group of order 3! as a permutation group
```

`canonical_label()`

EXAMPLES:

```python
sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.canonical_label()
{'a', 'b', 'c'}
```

`transport(perm)`
Returns the transport of this structure along the permutation `perm`.

EXAMPLES:

```python
sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
```
```python
{'a', 'b', 'c'}
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
{'a', 'b', 'c'}
```

```
sage.combinat.species.characteristic_species.CharacteristicSpecies_class
alias of sage.combinat.species.characteristic_species.CharacteristicSpecies
class sage.combinat.species.characteristic_species.EmptySetSpecies(
    min=None, max=None, weight=None)

    Bases: sage.combinat.species.characteristic_species.CharacteristicSpecies

Returns the empty set species.

This species has exactly one structure on the empty set. It is the same (and is implemented) as CharacteristicSpecies(0).

EXAMPLES:
```
sage: X = species.EmptySetSpecies()
sage: X.structures([]).list()
[{}]
sage: X.structures([1,2]).list()
[]
sage: X.generating_series().coefficients(4)
[1, 0, 0, 0]
sage: X.isotype_generating_series().coefficients(4)
[1, 0, 0, 0]
sage: X.cycle_index_series().coefficients(4)
[p[], 0, 0, 0]
```
```
sage.combinat.species.characteristic_species.EmptySetSpecies_class
alias of sage.combinat.species.characteristic_species.EmptySetSpecies
class sage.combinat.species.characteristic_species.SingletonSpecies(
    min=None, max=None, weight=None)

    Bases: sage.combinat.species.characteristic_species.CharacteristicSpecies

Returns the species of singletons.

This species has exactly one structure on a set of size 1. It is the same (and is implemented) as CharacteristicSpecies(1).

EXAMPLES:
```
sage: X = species.SingletonSpecies()
sage: X.structures([1]).list()
[1]
sage: X.structures([1,2]).list()
[]
sage: X.generating_series().coefficients(4)
[0, 1, 0, 0]
sage: X.isotype_generating_series().coefficients(4)
[0, 1, 0, 0]
sage: X.cycle_index_series().coefficients(4)
[0, p[1], 0, 0]
```
```
Combinatorics, Release 9.7

sage.combinat.species.characteristic_species.SingletonSpecies_class
alias of sage.combinat.species.characteristic_species.SingletonSpecies

5.1.313 Composition species

class sage.combinat.species.composition_species.CompositionSpecies(F, G, min=None, max=None, weight=None)

Bases: sage.combinat.species.species.GenericCombinatorialSpecies, sage.structure.unique_representation.UniqueRepresentation

Returns the composition of two species.

EXAMPLES:

```python
sage: E = species.SetSpecies()
sage: C = species.CycleSpecies()
sage: S = E(C)
sage: S.generating_series().coefficients(5)
[1, 1, 1, 1, 1]
sage: E(C) is S
True
```

weight_ring()

Returns the weight ring for this species. This is determined by asking Sage’s coercion model what the result is when you multiply (and add) elements of the weight rings for each of the operands.

EXAMPLES:

```python
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: L = E(C)
sage: L.weight_ring()
Rational Field
```

class sage.combinat.species.composition_species.CompositionSpeciesStructure(parent, labels, pi, f, gs)

Bases: sage.combinat.species.structure.GenericSpeciesStructure

change_labels(labels)

Return a relabelled structure.

INPUT:

• labels, a list of labels.

OUTPUT:

A structure with the i-th label of self replaced with the i-th label of the list.

EXAMPLES:

```python
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: L = E(C)
sage: S = L.structures(['a','b','c']).list()
sage: a = S[2]; a
F-structure: {{'a', 'c'}}, {{'b'}}; G-structures: ({{'a', 'c'}}, ({{b}}))
sage: a.change_labels([1,2,3])
F-structure: {{1, 3}, {2}}; G-structures: [(1, 3), (2)]
```
transport$(perm)$

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: L = E(C)
sage: S = L.structures(['a','b','c']).list()
sage: a = S[2]; a
F-structure: {{'a', 'c'}}, {{'b'}}; G-structures: (('a', 'c'), ('b'))
sage: a.transport(p)
F-structure: {{'a', 'b'}}, {{'c'}}; G-structures: (('a', 'c'), ('b'))
```

5.1.314 Cycle Species

```
class sage.combinat.species.cycle_species.CycleSpecies$(min=None, max=None, weight=None)$
Bases:  sage.combinat.species.species.GenericCombinatorialSpecies,  sage.structure.unique_representation.UniqueRepresentation

Returns the species of cycles.

EXAMPLES:

```
sage: C = species.CycleSpecies(); C
Cyclic permutation species
sage: C.structures([1,2,3,4]).list()
[(1, 2, 3, 4),
 (1, 2, 4, 3),
 (1, 3, 2, 4),
 (1, 3, 4, 2),
 (1, 4, 2, 3),
 (1, 4, 3, 2)]
```
```
class sage.combinat.species.cycle_species.CycleSpeciesStructure$(parent, labels, list)$
Bases:  sage.combinat.species.structure.GenericSpeciesStructure

automorphism_group()

Returns the group of permutations whose action on this structure leave it fixed.

EXAMPLES:

```
sage: P = species.CycleSpecies()
sage: a = P.structures([1, 2, 3, 4])[0]; a
(1, 2, 3, 4)
sage: a.automorphism_group()
Permutation Group with generators [(1,2,3,4)]
sage: [a.transport(perm) for perm in a.automorphism_group()]
[(1, 2, 3, 4), (1, 2, 3, 4), (1, 2, 3, 4), (1, 2, 3, 4)]
```
```
canonical_label()

EXAMPLES:
```
```
sage: P = species.CycleSpecies()
sage: P.structures(["a", "b", "c"]).random_element().canonical_label()
('a', 'b', 'c')

permutation_group_element()
Returns this cycle as a permutation group element.

EXAMPLES:

sage: F = species.CycleSpecies()
sage: a = F.structures(["a", "b", "c"])[0]; a
('a', 'b', 'c')
sage: a.permutation_group_element()
(1,2,3)

transport(perm)
Returns the transport of this structure along the permutation perm.

EXAMPLES:

sage: F = species.CycleSpecies()
sage: a = F.structures(["a", "b", "c"])[0]; a
('a', 'b', 'c')
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
('a', 'c', 'b')

sage.combinat.species.cycle_species.CycleSpecies_class
alias of sage.combinat.species.cycle_species.CycleSpecies

5.1.315 Empty Species

class sage.combinat.species.empty_species.EmptySpecies(min=None, max=None, weight=None)
Bases: sage.combinat.species.species.GenericCombinatorialSpecies, sage.structure.unique_representation.UniqueRepresentation

Returns the empty species. This species has no structure at all. It is the zero of the semi-ring of species.

EXAMPLES:

sage: X = species.EmptySpecies(); X
Empty species
sage: X.structures([]).list()
[]
sage: X.structures([1]).list()
[]
sage: X.structures([1,2]).list()
[]
sage: X.generating_series().coefficients(4)
[0, 0, 0, 0]
sage: X.isotype_generating_series().coefficients(4)
[0, 0, 0, 0]
sage: X.cycle_index_series().coefficients(4)
[0, 0, 0, 0]
The empty species is the zero of the semi-ring of species. The following tests that it is neutral with respect to addition:

```python
sage: Empt = species.EmptySpecies()
sage: S = species.CharacteristicSpecies(2)
sage: X = S + Empt
sage: X == S  # TODO: Not Implemented
True
sage: (X.generating_series().coefficients(4) ==
    S.generating_series().coefficients(4))
True
sage: (X.isotype_generating_series().coefficients(4) ==
    S.isotype_generating_series().coefficients(4))
True
sage: (X.cycle_index_series().coefficients(4) ==
    S.cycle_index_series().coefficients(4))
True
```

The following tests that it is the zero element with respect to multiplication:

```python
sage: Y = Empt*S
sage: Y == Empt  # TODO: Not Implemented
True
sage: Y.generating_series().coefficients(4)
[0, 0, 0, 0]
sage: Y.isotype_generating_series().coefficients(4)
[0, 0, 0, 0]
sage: Y.cycle_index_series().coefficients(4)
[0, 0, 0, 0]
```

sage.combinat.species.empty_species.EmptySpecies_class
alias of sage.combinat.species.empty_species.EmptySpecies

### 5.1.316 Functorial composition species

class sage.combinat.species.functorial_composition_species.FunctorialCompositionSpecies($F$, $G$, $min=None$, $max=None$, $weight=None$)

Bases: sage.combinat.species.species.GenericCombinatorialSpecies

Returns the functorial composition of two species.

EXAMPLES:

```python
sage: E = species.SetSpecies()
sage: E2 = species.SetSpecies(size=2)
sage: WP = species.SubsetSpecies()
sage: P2 = E2*E
sage: G = WP.functorial_composition(P2)
sage: G.isotype_generating_series().coefficients(5)
[1, 1, 2, 4, 11]
```
sage: G = species.SimpleGraphSpecies()
sage: c = G.generating_series().coefficients(2)
sage: type(G)
<class 'sage.combinat.species.functorial_composition_species.FunctorialCompositionSpecies'>
sage: G == loads(dumps(G))
True
sage: G._check() #False due to isomorphism types not being implemented
False

weight_ring()

Returns the weight ring for this species. This is determined by asking Sage’s coercion model what the result
is when you multiply (and add) elements of the weight rings for each of the operands.

EXAMPLES:

sage: G = species.SimpleGraphSpecies()
sage: G.weight_ring()
Rational Field

sage.combinat.species.functorial_composition_species.FunctorialCompositionSpecies_class
alias of sage.combinat.species.functorial_composition_species.FunctorialCompositionSpecies
class sage.combinat.species.functorial_composition_species.FunctorialCompositionStructure(parent, labels, list)

Bases: sage.combinat.species.structure.GenericSpeciesStructure

5.1.317 Generating Series

This file makes a number of extensions to lazy power series by endowing them with some semantic content for how
they’re to be interpreted.

This code is based on the work of Ralf Hemmecke and Martin Rubey’s Aldor-Combinat, which can be found at
http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html. In particular, the relevant section for this
file can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse10.html. One notable
difference is that we use power-sum symmetric functions as the coefficients of our cycle index series.

REFERENCES:
class sage.combinat.species.generating_series.CycleIndexSeries(A, stream=None, order=None,
aorder=None, aorder_changed=True, is_initialized=False, name=None)

Bases: sage.combinat.species.series.LazyPowerSeries

arithmetic_product(g, check_input=True)

Return the arithmetic product of self with g.

For species $M$ and $N$ such that $M[\text{varnothing}] = N[\text{varnothing}] =
**varnothing**, their arithmetic product is the species $M \boxdot N$ of “$M$-assemblies of cloned $N$-structures”. This operation is defined and several examples are given in [MM].

The cycle index series for $M \boxdot N$ can be computed in terms of the component series $Z_M$ and $Z_N$, as implemented in this method.

**INPUT:**

- $g$ – a cycle index series having the same parent as `self`.
- `check_input` – (default: `True`) a Boolean which, when set to `False`, will cause input checks to be skipped.

**OUTPUT:**

The arithmetic product of `self` with $g$. This is a cycle index series defined in terms of `self` and $g$ such that if `self` and $g$ are the cycle index series of two species $M$ and $N$, their arithmetic product is the cycle index series of the species $M \boxdot N$.

**EXAMPLES:**

For $C$ the species of (oriented) cycles and $L_+$ the species of nonempty linear orders, $C \boxdot L_+$ corresponds to the species of “regular octopuses”: a $(C \boxdot L_+)$-structure is a cycle of some length, each of whose elements is an ordered list of a length which is consistent for all the lists in the structure.

```sage
C = species.CycleSpecies().cycle_index_series()
Lplus = species.LinearOrderSpecies(min=1).cycle_index_series()
RegOctSpeciesSeq = C.arithmetic_product(Lplus).generating_series().counts(8)
sage: RegOctSpeciesSeq
[0, 1, 3, 8, 42, 144, 1440, 5760]
```

It is shown in [MM] that the exponential generating function for regular octopuses satisfies $(C \boxdot L_+)(x) = \sum_{n \geq 1} \sigma(n)(n - 1)!/n!$ (where $\sigma(n)$ is the sum of the divisors of $n$).

```sage
sage: RegOctDirectSeq = [0] + [sum(divisors(i))*factorial(i-1) for i in range(1, 9)]
sage: RegOctDirectSeq == RegOctSpeciesSeq
True
```

**AUTHORS:**

- Andrew Gainer-Dewar (2013)

**REFERENCES:**

- `coefficient_cycle_type(t)`
  Returns the coefficient of a cycle type $t$ in `self`.

**EXAMPLES:**

```sage
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: p = SymmetricFunctions(QQ).power() (continues on next page)```
```python
sage: CIS = CycleIndexSeriesRing(QQ)
sage: f = CIS([0, p([1]), 2*p([1,1]),3*p([2,1])])
sage: f.coefficient_cycle_type([1])
1
sage: f.coefficient_cycle_type([1,1])
2
sage: f.coefficient_cycle_type([2,1])
3
```

**compositional_inverse()**

Return the compositional inverse of self if possible.

(Specifically, if self is of the form \(0 + p_1 + \cdots\).)

The compositional inverse is the inverse with respect to plethystic substitution. This is the operation on cycle index series which corresponds to substitution, a.k.a. partitional composition, on the level of species. See Section 2.2 of [BLL] for a definition of this operation.

**EXAMPLES:**

```python
sage: Eplus = species.SetSpecies(min=1).cycle_index_series()
sage: Eplus(Eplus.compositional_inverse()).coefficients(8)
[0, p[1], 0, 0, 0, 0, 0, 0]
```

**ALGORITHM:**

Let \(F\) be a species satisfying \(F = 0 + X + F_2 + F_3 + \cdots\) for \(X\) the species of singletons. (Equivalently, \(|F|_{\emptyset} = 0\) and \(|F|_{\{1\}} = 1\).) Then there exists a (virtual) species \(G\) satisfying \(F \circ G = G \circ F = X\).

It follows that \((F - X) \circ G = F \circ G - X \circ G = X - G\). Rearranging, we obtain the recursive equation \(G = X - (F - X) \circ G\), which can be solved using iterative methods.

**Warning:** This algorithm is functional but can be very slow. Use with caution!

**See also:**

The compositional inverse \(\Omega\) of the species \(E_+\) of nonempty sets can be handled much more efficiently using specialized methods. See \(\texttt{LogarithmCycleIndexSeries()}\)

**AUTHORS:**

• Andrew Gainer-Dewar

**count(t)**

Return the number of structures corresponding to a certain cycle type \(t\).

**EXAMPLES:**

```python
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: p = SymmetricFunctions(QQ).power()
sage: CIS = CycleIndexSeriesRing(QQ)
sage: f = CIS([0, p([1]), 2*p([1,1]),3*p([2,1])])
sage: f.count([1])
1
sage: f.count([1,1])
4
```

(continues on next page)
Combinatorics, Release 9.7

(continued from previous page)

```python
sage: f.count([2,1])
6
```

**derivative** *(order=1)*

Return the species-theoretic \( n \)-th derivative of \( \text{self} \), where \( n \) is order.

For a cycle index series \( F(p_1, p_2, p_3, \ldots) \), its derivative is the cycle index series \( F' = D_{p_1} F \) (that is, the formal derivative of \( F \) with respect to the variable \( p_1 \)).

If \( F \) is the cycle index series of a species \( S \) then \( F' \) is the cycle index series of an associated species \( S' \) of \( S \)-structures with a “hole”.

**EXAMPLES:**

The species \( E \) of sets satisfies the relationship \( E' = E \):

```python
sage: E = species.SetSpecies().cycle_index_series()
sage: E.coefficients(8) == E.derivative().coefficients(8)
True
```

The species \( C \) of cyclic orderings and the species \( L \) of linear orderings satisfy the relationship \( C' = L \):

```python
sage: C = species.CycleSpecies().cycle_index_series()
sage: L = species.LinearOrderSpecies().cycle_index_series()
sage: L.coefficients(8) == C.derivative().coefficients(8)
True
```

**expand_as_sf** *(\( n, \text{alphabet='x'\})]*

Returns the expansion of a cycle index series as a symmetric function in \( n \) variables.

Specifically, this returns a LazyPowerSeries whose \( i \)th term is obtained by calling `expand()` on the \( i \)th term of \( \text{self} \).

This relies on the (standard) interpretation of a cycle index series as a symmetric function in the power sum basis.

**INPUT:**

- \( \text{self} \) – a cycle index series
- \( n \) – a positive integer
- \( \text{alphabet} \) – a variable for the expansion (default: \( x \))

**EXAMPLES:**

```python
sage: from sage.combinat.species.set_species import SetSpecies
sage: SetSpecies().cycle_index_series().expand_as_sf(2).coefficients(4)
[1, x0 + x1, x0^2 + x0*x1 + x1^2, x0^3 + x0^2*x1 + x0*x1^2 + x1^3]
```

**exponential()**

Return the species-theoretic exponential of \( \text{self} \).

For a cycle index \( Z_F \) of a species \( F \), its exponential is the cycle index series \( Z_E \circ Z_F \), where \( Z_E \) is the `ExponentialCycleIndexSeries()`.

The exponential \( Z_E \circ Z_F \) is then the cycle index series of the species \( E \circ F \) of “sets of \( F \)-structures”.

**EXAMPLES:**

5.1. Comprehensive Module List 3145
Let \( \mathcal{B} \mathcal{T} \) be the species of binary trees, \( \mathcal{B} \mathcal{F} \) the species of binary forests, and \( \mathcal{E} \) the species of sets. Then we have \( \mathcal{B} \mathcal{F} = \mathcal{E} \circ \mathcal{B} \mathcal{T} \):

```python
sage: BT = species.BinaryTreeSpecies().cycle_index_series()
sage: BF = species.BinaryForestSpecies().cycle_index_series()
sage: BT.exponential().isotype_generating_series().coefficients(8) == BF.
   → isotype_generating_series().coefficients(8)
True
```

**functorial_composition**(*g*)

Returns the functorial composition of *self* and *g*.

If \( \mathcal{F} \) and \( \mathcal{G} \) are species, their functorial composition is the species \( \mathcal{F} \square \mathcal{G} \) obtained by setting \( (\mathcal{F} \square \mathcal{G})[A] = \mathcal{F}[\mathcal{G}[A]] \). In other words, an \( (\mathcal{F} \square \mathcal{G}) \)-structure on a set \( A \) of labels is an \( \mathcal{F} \)-structure whose labels are the set of all \( \mathcal{G} \)-structures on \( A \).

It can be shown (as in section 2.2 of [BLL]) that there is a corresponding operation on cycle indices:

\[
Z_{\mathcal{F} \square \mathcal{G}} = \sum_{n \geq 0} \frac{1}{n!} \sum_{\sigma \in S_n} \text{fix } \mathcal{F}[\mathcal{G}[\sigma]], (\mathcal{G}[\sigma])_2, \ldots \] \( p_1^\sigma_1 p_2^\sigma_2 \cdots \).

This method implements that operation on cycle index series.

**EXAMPLES:**

The species \( \mathcal{G} \) of simple graphs can be expressed in terms of a functorial composition: \( \mathcal{G} = \mathcal{P} \square \mathcal{P}_2 \), where \( \mathcal{P} \) is the \( \text{SubsetSpecies} \). This is how it is implemented in \( \text{SimpleGraphSpecies()} \):

```python
sage: S = species.SimpleGraphSpecies()
sage: S.cycle_index_series().coefficients(5)
[1, 1, 1, 5/6, 5/8]
```

**generating_series()**

**EXAMPLES:**

```python
sage: P = species.PartitionSpecies()
sage: cis = P.cycle_index_series()
sage: f = cis.generating_series()
sage: f.coefficients(5)
[1, 1, 1, 5/6, 5/8]
```

**integral**(*args*)

Given a cycle index \( G \), it is not in general possible to recover a single cycle index \( F \) such that \( F' = G \) (even up to addition of a constant term).

More broadly, it may be the case that there are many non-isomorphic species \( \mathcal{S} \) such that \( \mathcal{S}' = \mathcal{T} \) for a given species \( \mathcal{T} \). For example, the species \( 3\mathcal{C}_3 \) of 3-cycles from three distinct classes and the species \( \mathcal{X}^3 \) of 3-sets are not isomorphic, but \( (3\mathcal{C}_3)' = (\mathcal{X}^3)' = 3\mathcal{X}^2 \).

**EXAMPLES:**

```python
sage: C3 = species.CycleSpecies(size=3).cycle_index_series()
sage: X = species.SingletonSpecies().cycle_index_series()
```
sage: (3*C3).derivative().coefficients(8) == (3*X^2).coefficients(8)
True
sage: (X*3).derivative().coefficients(8) == (3*X^2).coefficients(8)
True

**Warning:** This method has no implementation and exists only to prevent you from doing something strange. Calling it raises a `NotImplementedError`!

### isotype_generating_series()

**EXAMPLES:**

```python
sage: P = species.PermutationSpecies()
sage: cis = P.cycle_index_series()
sage: f = cis.isotype_generating_series()
sage: f.coefficients(10)
[1, 1, 2, 3, 5, 7, 11, 15, 22, 30]
```

### logarithm()

Return the combinatorial logarithm of `self`.

For a cycle index $Z_F$ of a species $F$, its logarithm is the cycle index series $Z_\Omega \circ Z_F$, where $Z_\Omega$ is the `LogarithmCycleIndexSeries()`.

The logarithm $Z_\Omega \circ Z_F$ is then the cycle index series of the (virtual) species $\Omega \circ F$ of “connected $F$-structures”. In particular, if $F = E^+ \circ G$ for $E^+$ the species of nonempty sets and $G$ some other species, then $\Omega \circ F = G$.

**EXAMPLES:**

Let $G$ be the species of nonempty graphs and $CG$ be the species of nonempty connected graphs. Then $G = E^+ \circ CG$, so $CG = \Omega \circ G$:

```python
sage: G = species.SimpleGraphSpecies().cycle_index_series() - 1
sage: from sage.combinat.species.generating_series import...
sage: CG = LogarithmCycleIndexSeries().compose(G)
sage: CG.isotype_generating_series().coefficients(8)
[0, 1, 1, 2, 6, 21, 112, 853]
```

### pointing()

Return the species-theoretic pointing of `self`.

For a cycle index $F$, its pointing is the cycle index series $F^* = p_1 \cdot F'$. If $F$ is the cycle index series of a species $S$ then $F^*$ is the cycle index series of an associated species $S^*$ of $S$-structures with a marked “root”.

**EXAMPLES:**

The species $E^*$ of “pointed sets” satisfies $E^* = X \cdot E$:

```python
sage: E = species.SetSpecies().cycle_index_series()
sage: X = species.SingletonSpecies().cycle_index_series()
sage: E.pointing().coefficients(8) == (X*E).coefficients(8)
True
```
stretch \(k\)
Return the stretch of the cycle index series \(\text{self}\) by a positive integer \(k\).

If
\[
f = \sum_{n=0}^{\infty} f_n(p_1, p_2, p_3, \ldots),
\]
then the stretch \(g\) of \(f\) by \(k\) is
\[
g = \sum_{n=0}^{\infty} f_n(p_{nk}, p_{2nk}, p_{3nk}, \ldots).
\]

**EXAMPLES:**
```python
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: p = SymmetricFunctions(QQ).power()
sage: CIS = CycleIndexSeriesRing(QQ)
sage: f = CIS([p([]), p([1]), p([2]), p.zero()])
```
```
sage: f.stretch(3).coefficients(10)
[p[], 0, 0, p[3], 0, 0, p[6], 0, 0, 0]
```

weighted_composition \(y\_species\)
Return the composition of this cycle index series with the cycle index series of the weighted species \(y\_species\).

Note that this is basically the same algorithm as composition except we can not use the optimization that the powering of cycle index series commutes with 'stretching'.

**EXAMPLES:**
```python
sage: E = species.SetSpecies(); C = species.CycleSpecies()
```
```
sage: E_cis = E.cycle_index_series()
```
```
sage: E_cis.weighted_composition(C).coefficients(4)
```
```
sage: E(C).cycle_index_series().coefficients(4)
```

sage.combinat.species.generating_series.CycleIndexSeriesRing \(R\)
Return the ring of cycle index series over \(R\).

This is the ring of formal power series \(\Lambda[x]\), where \(\Lambda\) is the ring of symmetric functions over \(R\) in the \(p\)-basis. Its purpose is to house the cycle index series of species (in a somewhat nonstandard notation tailored to Sage): If \(F\) is a species, then the **cycle index series** of \(F\) is defined to be the formal power series
\[
\sum_{n \geq 0} \frac{1}{n!} \left( \sum_{\sigma \in S_n} \text{fix } F[\sigma] \prod_{z \text{ is a cycle of } \sigma} p_{\text{length of } z} x^{\text{length of } z} \right) x^n \in \Lambda Q[x],
\]
where \(\text{fix } F[\sigma]\) denotes the number of fixed points of the permutation \(F[\sigma]\) of \(F[n]\). We notice that this power series is “equigraded” (meaning that its \(x^n\)-coefficient is homogeneous of degree \(n\)). A more standard convention in combinatorics would be to use \(x_i\) instead of \(p_i\), and drop the \(x\) (that is, evaluate the above power series at \(x = 1\)); but this would be more difficult to implement in Sage, as it would be an element of a power series ring in infinitely many variables.

Note that it is just a **LazyPowerSeriesRing** (whose base ring is \(\Lambda\)) whose elements have some extra methods.

**EXAMPLES:**
```python
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: R = CycleIndexSeriesRing(QQ); R
Cycle Index Series Ring over Symmetric Functions over Rational Field in the \powersum basis
sage: R([1]).coefficients(4) # This is not combinatorially meaningful.
[1, 1, 1, 1]
```

class `sage.combinat.species.generating_series.CycleIndexSeriesRing_class`(R)

Bases: `sage.combinat.species.series.LazyPowerSeriesRing`

EXAMPLES:

```python
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: R = CycleIndexSeriesRing(QQ); R
Cycle Index Series Ring over Symmetric Functions over Rational Field in the \powersum basis
sage: R == loads(dumps(R))
True
```

`sage.combinat.species.generating_series.ExponentialCycleIndexSeries`(R=Rational Field)

Return the cycle index series of the species $E$ of sets.

This cycle index satisfies

$$Z_E = \sum_{n \geq 0} \sum_{\lambda \vdash n} \frac{p_\lambda}{z_\lambda}.$$  

EXAMPLES:

```python
sage: from sage.combinat.species.generating_series import ExponentialCycleIndexSeries
sage: ExponentialCycleIndexSeries().coefficients(5)
```

class `sage.combinat.species.generating_series.ExponentialGeneratingSeries`(A, stream=None, order=None, aorder=None, aorder_changed=True, is_initialized=False, name=None)

Bases: `sage.combinat.species.series.LazyPowerSeries`

`count`(n)

Return the number of structures of size $n$.

EXAMPLES:

```python
sage: from sage.combinat.species.generating_series import ExponentialGeneratingSeries
sage: R = ExponentialGeneratingSeriesRing(QQ)
sage: f = R([1])
sage: [f.count(i) for i in range(7)]
[1, 1, 2, 6, 24, 120, 720]
```

counts\((n)\)
Return the number of structures on a set for size \(i\) for each \(i\) in \(\text{range}(n)\).

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import ExponentialGeneratingSeriesRing
sage: R = ExponentialGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.counts(5)
[0, 1, 4, 18, 96]
```

functorial_composition\((y)\)
Return the exponential generating series which is the functorial composition of \(self\) with \(y\).

If \(f = \sum_{n=0}^{\infty} f_n \frac{x^n}{n!}\) and \(g = \sum_{n=0}^{\infty} g_n \frac{x^n}{n!}\), then functorial composition \(f \square g\) is defined as

\[
f \square g = \sum_{n=0}^{\infty} f_n g_n \frac{x^n}{n!}
\]

REFERENCES:
• Section 2.2 of [BLL].

EXAMPLES:

```
sage: G = species.SimpleGraphSpecies()
sage: g = G.generating_series()
sage: g.coefficients(10)
[1, 1, 1, 4/3, 8/3, 128/15, 2048/45, 131072/315, 2097152/315, 536870912/2835]
```

sage.combinat.species.generating_series.ExponentialGeneratingSeriesRing\((R)\)
Return the ring of exponential generating series over \(R\).

Note that it is just a *LazyPowerSeriesRing* whose elements have some extra methods.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import ExponentialGeneratingSeriesRing
sage: R = ExponentialGeneratingSeriesRing(QQ); R
Lazy Power Series Ring over Rational Field
sage: R([1]).coefficients(4)
[1, 1, 1, 1]
sage: R([1]).counts(4)
[1, 1, 2, 6]
```

class sage.combinat.species.generating_series.ExponentialGeneratingSeriesRing_class\((R)\)
Bases: *sage.combinat.species.series.LazyPowerSeriesRing*

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import ExponentialGeneratingSeriesRing
sage: R = ExponentialGeneratingSeriesRing(QQ)
sage: R == loads(dumps(R))
True
```
sage.combinat.species.generating_series.LogarithmCycleIndexSeries(R=Rational Field)

Return the cycle index series of the virtual species $\Omega$, the compositional inverse of the species $E^+$ of nonempty sets.

The notion of virtual species is treated thoroughly in [BLL]. The specific algorithm used here to compute the cycle index of $\Omega$ is found in [Labelle2008].

EXAMPLES:
The virtual species $\Omega$ is ‘properly virtual’, in the sense that its cycle index has negative coefficients:

```
sage: from sage.combinat.species.generating_series import LogarithmCycleIndexSeries
sage: LogarithmCycleIndexSeries().coefficients(4)
[0, p[1], -1/2*p[1, 1] - 1/2*p[2], 1/3*p[1, 1, 1] - 1/3*p[3]]
```

Its defining property is that $\Omega \circ E^+ = E^+ \circ \Omega = X$ (that is, that composition with $E^+$ in both directions yields the multiplicative identity $X$):

```
sage: Eplus = sage.combinat.species.set_species.SetSpecies(min=1).cycle_index_series()
sage: LogarithmCycleIndexSeries().compose(Eplus).coefficients(4)
[0, p[1], 0, 0]
```

class sage.combinat.species.generating_series.OrdinaryGeneratingSeries(A, stream=None, order=None, aorder=None, aorder_changed=True, is_initialized=False, name=None)

Bases: sage.combinat.species.series.LazyPowerSeries

count(n)
Return the number of structures on a set of size $n$.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.count(10)
10
```

counts(n)
Return the number of structures on a set for size $i$ for each $i$ in range($n$).

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.counts(10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

sage.combinat.species.generating_series.OrdinaryGeneratingSeriesRing(R)
Return the ring of ordinary generating series over $R$. 
Note that it is just a \textit{LazyPowerSeriesRing} whose elements have some extra methods.

\begin{verbatim}
EXAMPLES:
sage: from sage.combinat.species.generating_series import OrdinaryGeneratingSeriesRing
    R = OrdinaryGeneratingSeriesRing(QQ); R
Lazy Power Series Ring over Rational Field
sage: R([1]).coefficients(4)
[1, 1, 1, 1]
sage: R([1]).counts(4)
[1, 1, 1, 1]
\end{verbatim}

\texttt{class sage.combinat.species.generating_series.OrdinaryGeneratingSeriesRing_class(R)}
Bases: \texttt{sage.combinat.species.series.LazyPowerSeriesRing}

\begin{verbatim}
EXAMPLES:
sage: from sage.combinat.species.generating_series import OrdinaryGeneratingSeriesRing
    R = OrdinaryGeneratingSeriesRing(QQ)
sage: R == loads(dumps(R))
True
\end{verbatim}

\texttt{sage.combinat.species.generating_series.factorial_gen()}
A generator for the factorials starting at 0.

\begin{verbatim}
EXAMPLES:
sage: from sage.combinat.species.generating_series import factorial_gen
    g = factorial_gen()
sage: [next(g) for i in range(5)]
[1, 1, 2, 6, 24]
\end{verbatim}

5.1.318 Examples of Combinatorial Species

\texttt{sage.combinat.species.library.BinaryForestSpecies()}
Returns the species of binary forests. Binary forests are defined as sets of binary trees.

\begin{verbatim}
EXAMPLES:
sage: F = species.BinaryForestSpecies()
sage: F.generating_series().counts(10)
[1, 1, 3, 19, 49171, 1084483, 82845729, 4917108353, 848456353, 28245729, 848456353]
sage: F.isotype_generating_series().counts(10)
[1, 1, 2, 4, 10, 26, 77, 235, 758, 2504]
sage: F.cycle_index_series().coefficients(7)
[p[], p[1],
 3/2*p[1, 1] + 1/2*p[2],
 19/6*p[1, 1, 1] + 1/2*p[2, 1] + 1/3*p[3],
\end{verbatim}
sage.combinat.species.library.BinaryTreeSpecies()
Return the species of binary trees on n leaves.

The species of binary trees B is defined by B = X + B*B where X is the singleton species.

EXAMPLES:

```
sage: B = species.BinaryTreeSpecies()
sage: B.generating_series().counts(10)
[0, 1, 2, 12, 120, 1680, 30240, 665280, 17297280, 518918400]
sage: B.isotype_generating_series().counts(10)
[0, 1, 1, 2, 5, 14, 42, 132, 429, 1430]
sage: B._check()
True
```

sage.combinat.species.library.SimpleGraphSpecies()
Returns the species of simple graphs.

EXAMPLES:

```
sage: S = species.SimpleGraphSpecies()
sage: S.generating_series().counts(10)
[1, 1, 2, 8, 64, 1024, 32768, 2097152, 268435456, 68719476736]
sage: S.cycle_index_series().coefficients(5)
[p[],
p[1],
p[1, 1] + p[2],
4/3*p[1, 1, 1] + 2*p[2, 1] + 2/3*p[3],
sage: S.isotype_generating_series().coefficients(6)
[1, 1, 2, 4, 11, 34]
```

5.1.319 Linear-order Species

class sage.combinat.species.linear_order_species.LinearOrderSpecies(min=None, max=None, weight=None)

Bases: sage.combinat.species.species.GenericCombinatorialSpecies, sage.structure.unique_representation.UniqueRepresentation

Returns the species of linear orders.

EXAMPLES:

```
sage: L = species.LinearOrderSpecies()
sage: L.generating_series().coefficients(5)
[1, 1, 1, 1, 1]
```

(continues on next page)
Combinatorics, Release 9.7

(continued from previous page)

```python
sage: L = species.LinearOrderSpecies()
sage: L._check()
True
sage: L == loads(dumps(L))
True
```

class sage.combinat.species.linear_order_species.LinearOrderSpeciesStructure

Bases: sage.combinat.species.structure.GenericSpeciesStructure

automorphism_group()

Returns the group of permutations whose action on this structure leave it fixed. For the species of linear orders, there is no non-trivial automorphism.

EXAMPLES:

```python
sage: F = species.LinearOrderSpecies()
sage: a = F.structures(['a', 'b', 'c'])[0]; a
['a', 'b', 'c']
sage: a.automorphism_group()
Symmetric group of order 1! as a permutation group
```

canonical_label()

EXAMPLES:

```python
sage: P = species.LinearOrderSpecies()
sage: s = P.structures(['a', 'b', 'c']).random_element()
sage: s.canonical_label()
['a', 'b', 'c']
```

transport(perm)

Returns the transport of this structure along the permutation perm.

EXAMPLES:

```python
sage: F = species.LinearOrderSpecies()
sage: a = F.structures(['a', 'b', 'c'])[0]; a
['a', 'b', 'c']
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
['b', 'a', 'c']
```

sage.combinat.species.linear_order_species.LinearOrderSpecies_class

alias of sage.combinat.species.linear_order_species.LinearOrderSpecies
5.1.320 Miscellaneous Functions

`sage.combinat.species.misc.accept_size(f)`

The purpose of this decorator is to change calls like `species.SetSpecies(size=1)` to `species.SetSpecies(min=1, max=2)`. This is to make caching species easier and to restrict the number of parameters that the lower level code needs to know about.

```
sage: from sage.combinat.species.misc import accept_size
c sage: def f(*args, **kwds):
c ...:         print("{} {}".format(args, sorted(kwds.items())))
c sage: f = accept_size(f)
c sage: f(min=1)
() [(\'min\', 1)]
c sage: f(size=2)
() [(\'max\', 3), (\'min\', 2)]
```

`sage.combinat.species.misc.change_support(perm, support, change_perm=None)`

Changes the support of a permutation defined on `[1, ..., n]` to `support`.

```
sage: from sage.combinat.species.misc import change_support
c sage: p = PermutationGroupElement((1,2,3)); p
(1,2,3)
c sage: change_support(p, [3,4,5])
(3,4,5)
```

5.1.321 Partition Species

`class sage.combinat.species.partition_species.PartitionSpecies(min=None, max=None, weight=None)`

Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`

Returns the species of partitions.

```
sage: P = species.PartitionSpecies()
sage: P.generating_series().coefficients(5)
[1, 1, 1, 5/6, 5/8]
sage: P.isotype_generating_series().coefficients(5)
[1, 1, 2, 3, 5]
sage: P = species.PartitionSpecies()
sage: P._check()
True
sage: P == loads(dumps(P))
True
```

`class sage.combinat.species.partition_species.PartitionSpeciesStructure(parent, labels, list)`

Bases: `sage.combinat.species.structure.GenericSpeciesStructure`

EXAMPLES:
Combinatorics, Release 9.7

```python
sage: from sage.combinat.species.partition_species import PartitionSpeciesStructure
sage: P = species.PartitionSpecies()
sage: s = PartitionSpeciesStructure(P, ['a', 'b', 'c'], [[1,2],[3]]); s
{{'a', 'b'}, {'c'}}
sage: s == loads(dumps(s))
True
```

**automorphism_group()**

Returns the group of permutations whose action on this set partition leave it fixed.

EXAMPLES:

```python
sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2,3,4], [[1,2],[3]]); a
{{2, 3}, {4}}
sage: a.automorphism_group()
Permutation Group with generators [(1,2)]
```

**canonical_label()**

EXAMPLES:

```python
sage: P = species.PartitionSpecies()

sage: S = P.structures(['a', 'b', 'c'])

sage: [s.canonical_label() for s in S]

[[{'a', 'b', 'c'}],
 [{'a', 'b'}, {'c'}],
 [{'a', 'b'}, {'c'}],
 [{'a', 'b'}, {'c'}],
 [{'a'}, {'b'}, {'c'}]]
```

**change_labels(labels)**

Return a relabelled structure.

INPUT:

- `labels`, a list of labels.

OUTPUT:

A structure with the i-th label of self replaced with the i-th label of the list.

EXAMPLES:

```python
sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2,3,4], [[1,2],[3]]); a
{{2, 3}, {4}}
sage: a.change_labels([1,2,3])
{{1, 2}, {3}}
```

**transport(perm)**

Returns the transport of this set partition along the permutation perm. For set partitions, this is the direct product of the automorphism groups for each of the blocks.

EXAMPLES:
sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2,3,4], [[1,2],[3]]); a
{{2, 3}, {4}}
sage: a.transport(p)
{{2, 4}, {3}}

sage.combinat.species.partition_species.PartitionSpecies_class
alias of sage.combinat.species.partition_species.PartitionSpecies

5.1.322 Permutation species

class sage.combinat.species.permutation_species.PermutationSpecies

min=None, max=None, weight=None)

Bases: sage.combinat.species.species.GenericCombinatorialSpecies, sage.structure.unique_representation.UniqueRepresentation

Returns the species of permutations.

EXAMPLES:

sage: P = species.PermutationSpecies()
sage: P.generating_series().coefficients(5)
[1, 1, 1, 1, 1]
sage: P.isotype_generating_series().coefficients(5)
[1, 1, 2, 3, 5]

sage: P = species.PermutationSpecies()
sage: c = P.generating_series().coefficients(3)
sage: P._check()
True
sage: P == loads(dumps(P))
True

class sage.combinat.species.permutation_species.PermutationSpeciesStructure

parent, labels, list)

Bases: sage.combinat.species.structure.GenericSpeciesStructure

automorphism_group()

Returns the group of permutations whose action on this structure leave it fixed.

EXAMPLES:

sage: set_random_seed(0)
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"][2]; a
["a", "c", "b", "d"]
sage: a.automorphism_group()
Permutation Group with generators [(2,3), (1,4)]

sage: [a.transport(perm) for perm in a.automorphism_group()]
[['a', 'c', 'b', 'd'],
['a', 'c', 'd', 'b'],
['a', 'c', 'b', 'd'],
['a', 'c', 'd', 'b']]

(continues on next page)
\[
[\{'a', 'c', 'b', 'd'\}],
[\{'a', 'c', 'b', 'd'\}],
[\{'a', 'c', 'b', 'd'\}]
\]

\textbf{canonical_label()}

\textbf{EXAMPLES:}

```
sage: P = species.PermutationSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.canonical_label() for s in S]
[[\{'a', 'b', 'c'\}],
 [\{'b', 'a', 'c'\}],
 [\{'b', 'c', 'a'\}],
 [\{'b', 'a', 'c'\}]]
```

\textbf{permutation_group_element()}

Returns self as a permutation group element.

\textbf{EXAMPLES:}

```
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"])[2]; a
[\{'a', 'c', 'b', 'd'\}]
sage: a.permutation_group_element()
(2,3)
```

\textbf{transport(\textit{perm})}

Returns the transport of this structure along the permutation \textit{perm}.

\textbf{EXAMPLES:}

```
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"])[2]; a
[\{'a', 'c', 'b', 'd'\}]
sage: a.transport(p)
[\{'a', 'd', 'c', 'b'\}]
```

\textbf{SageCombinatSpeciesPermutationSpeciesClass}

alias of \texttt{sage.combinat.species.permutation_species.PermutationSpeciesClass}
5.1.323 Product species

class sage.combinat.species.product_species.ProductSpecies(F, G, min=None, max=None, weight=None):
    Bases: sage.combinat.species.species.GenericCombinatorialSpecies, sage.structure.unique_representation.UniqueRepresentation

    EXAMPLES:

    sage: X = species.SingletonSpecies()
sage: A = X*X
    sage: A.generating_series().coefficients(4)
    [0, 0, 1, 0]
    sage: P = species.PermutationSpecies()
sage: F = P * P; F
    Product of (Permutation species) and (Permutation species)
sage: F == loads(dumps(F))
    True
    sage: F._check()
    True

    left_factor()
    Returns the left factor of this product.

    EXAMPLES:

    sage: P = species.PermutationSpecies()
sage: X = species.SingletonSpecies()
sage: F = P*X
    sage: F.left_factor()
    Permutation species

    right_factor()
    Returns the right factor of this product.

    EXAMPLES:

    sage: P = species.PermutationSpecies()
sage: X = species.SingletonSpecies()
sage: F = P*X
    sage: F.right_factor()
    Singleton species

    weight_ring()
    Returns the weight ring for this species. This is determined by asking Sage’s coercion model what the result
    is when you multiply (and add) elements of the weight rings for each of the operands.

    EXAMPLES:

    sage: S = species.SetSpecies()
sage: C = S*S
    sage: C.weight_ring()
    Rational Field
sage: S = species.SetSpecies(weight=QQ['t'].gen())
sage: C = S*S
sage: C.weight_ring()
Univariate Polynomial Ring in t over Rational Field

sage: S = species.SetSpecies()
sage: C = (S*S).weighted(QQ['t'].gen())
sage: C.weight_ring()
Univariate Polynomial Ring in t over Rational Field

class sage.combinat.species.product_species.ProductSpeciesStructure(parent, labels, subset, left, right)

Bases: sage.combinat.species.structure.GenericSpeciesStructure

automorphism_group()

EXAMPLES:

sage: p = PermutationGroupElement((2,3))
sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures([1,2,3,4])[1]; a
{1}*{2, 3, 4}
sage: a.automorphism_group()
Permutation Group with generators [(2,3), (2,3,4)]

sage: [a.transport(g) for g in a.automorphism_group()]
[{{1}*{2, 3, 4},
  {1}*{2, 3, 4},
  {1}*{2, 3, 4},
  {1}*{2, 3, 4},
  {1}*{2, 3, 4},
  {1}*{2, 3, 4}]

sage: a = F.structures([1,2,3,4])[8]; a
{2, 3}*{1, 4}
sage: [a.transport(g) for g in a.automorphism_group()]
[{{2, 3}*{1, 4}, {2, 3}*{1, 4}, {2, 3}*{1, 4}, {2, 3}*{1, 4}, {2, 3}*{1, 4}}

canonical_label()

EXAMPLES:

sage: S = species.SetSpecies()
sage: F = S * S
sage: S = F.structures(['a','b','c']).list(); S
[[]*['a', 'b', 'c'],
 {'a'}*{'b', 'c'},
 {'b'}*{'a', 'c'},
 {'c'}*{'a', 'b'},
 {'a', 'b'}*{'c'},
 {'a', 'c'}*{'b'},
 {'b', 'c'}*{'a'},
 {'a', 'b', 'c'}*{[]}]}
change_labels(labels)
Return a relabelled structure.

INPUT:

• labels, a list of labels.

OUTPUT:

A structure with the i-th label of self replaced with the i-th label of the list.

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures(['a','b','c'])[0]; a
{}*{'a', 'b', 'c'}
sage: a.change_labels([1,2,3])
{}*{1, 2, 3}
```

transport(perm)
EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures(['a','b','c'])[4]; a
{'a', 'b'}*{'c'}
sage: a.transport(p)
{'a', 'c'}*{'b'}
```

sage.combinat.species.product_species.ProductSpecies_class
alias of sage.combinat.species.product_species.ProductSpecies
5.1.324 Recursive Species

class sage.combinat.species.recursive_species.CombinatorialSpecies

    Bases: sage.combinat.species.species.GenericCombinatorialSpecies

EXAMPLES:

    sage: F = CombinatorialSpecies()
    sage: loads(dumps(F))
    Combinatorial species

    sage: X = species.SingletonSpecies()
    sage: E = species.EmptySetSpecies()
    sage: L = CombinatorialSpecies()
    sage: L.define(E+X*L)
    sage: L.generating_series().coefficients(4)
    [1, 1, 1, 1]
    sage: LL = loads(dumps(L))
    sage: LL.generating_series().coefficients(4)
    [1, 1, 1, 1]

    define(x)

    Define self to be equal to the combinatorial species x.

    This is used to define combinatorial species recursively. All of the real work is done by calling the .set() method for each of the series associated to self.

    EXAMPLES: The species of linear orders L can be recursively defined by \( L = 1 + X \times L \) where 1 represents the empty set species and X represents the singleton species.

    sage: X = species.SingletonSpecies()
    sage: E = species.EmptySetSpecies()
    sage: L = CombinatorialSpecies()
    sage: L.define(E+X*L)
    sage: L.generating_series().coefficients(4)
    [1, 1, 1, 1]
    sage: L.structures([1,2,3]).cardinality()
    6
    sage: L.structures([1,2,3]).list()
    [[1*(2*(3*{}))],
     [1*(3*(2*{}))],
     [2*(1*(3*{}))],
     [2*(3*(1*{}))],
     [3*(1*(2*{}))],
     [3*(2*(1*{}))]]

    sage: L = species.LinearOrderSpecies()
    sage: L.generating_series().coefficients(4)
    [1, 1, 1, 1]
    sage: L.structures([1,2,3]).cardinality()
    6
    sage: L.structures([1,2,3]).list()
    [[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
weight_ring()

EXAMPLES:

```python
sage: F = species.CombinatorialSpecies()
sage: F.weight_ring()
Rational Field
```

```python
sage: X = species.SingletonSpecies()
sage: E = species.EmptySetSpecies()
sage: L = CombinatorialSpecies()
sage: L.define(E+X*L)
sage: L.weight_ring()
Rational Field
```

class sage.combinat.species.recursive_species.CombinatorialSpeciesStructure(parent, s, **options)

Bases: sage.combinat.species.structure.SpeciesStructureWrapper

5.1.325 Lazy Power Series

This file provides an implementation of lazy univariate power series, which uses the stream class for its internal data structure. The lazy power series keep track of their approximate order as much as possible without forcing the computation of any additional coefficients. This is required for recursively defined power series.

This code is based on the work of Ralf Hemmecke and Martin Rubey’s Aldor-Combinat, which can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html. In particular, the relevant section for this file can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse9.html.

class sage.combinat.species.series.LazyPowerSeries(A, stream=None, order=None, aorder=None, aorder_changed=True, is_initialized=False, name=None)

Bases: sage.structure.element.AlgebraElement

EXAMPLES:

```python
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L()
sage: loads(dumps(f))
Uninitialized lazy power series
```

add(y)

EXAMPLES: Test Plus 1

```python
sage: from sage.combinat.species.series import *
sage: from sage.combinat.species.stream import Stream
sage: L = LazyPowerSeriesRing(QQ)
sage: gs0 = L([-1])
sage: gs1 = L([1])
sage: sum1 = gs0 + gs1
sage: sum2 = gs1 + gs0
sage: sum3 = gs1 + gs0
sage: [gs0.coefficient(i) for i in range(11)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
sage: [gs1.coefficient(i) for i in range(11)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
```

(continues on next page)
Test Plus 2

```python
sage: gs1 = L([1,2,4,8,0])
sage: gs2 = L([-1, 0, -1, -9, 22, 0])
sage: sum = gs1 + gs2
sage: sum2 = gs2 + gs1
sage: [ sum.coefficient(i) for i in range(5) ]
[0, 2, 3, -1, 22]
sage: [ sum.coefficient(i) for i in range(5, 11) ]
[0, 0, 0, 0, 0, 0]
sage: [ sum2.coefficient(i) for i in range(5) ]
[0, 2, 3, -1, 22]
sage: [ sum2.coefficient(i) for i in range(5, 11) ]
[0, 0, 0, 0, 0, 0]
```

**coefficient** (*n*)

Return the coefficient of *x^n* in self.

**EXAMPLES:**

```python
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L(ZZ)
sage: [f.coefficient(i) for i in range(5)]
[0, 1, -1, 2, -2]
```

**coefficients** (*n*)

Return the first *n* coefficients of self.

**EXAMPLES:**

```python
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L([1,2,3,0])
sage: f.coefficients(5)
[1, 2, 3, 0, 0]
```

**compose** (*y*)

Return the composition of this power series and the power series *y*.

**EXAMPLES:**

```python
sage: L = LazyPowerSeriesRing(QQ)
sage: s = L([1])
sage: t = L([0,0,1])
sage: u = s(t)
sage: u.coefficients(11)
[1, 0, 1, 1, 2, 3, 5, 8, 13, 21, 34]
```
Test Compose 2

```python
sage: s = L([1])
sage: t = L([0,0,1,0])
sage: u = s(t)
sage: u.aorder
0
sage: u.order
Unknown series order
sage: u.coefficients(10)
[1, 0, 1, 0, 1, 0, 1, 0, 1, 0]
sage: u.aorder
0
sage: u.order
0
```

Test Compose 3 $s = 1/(1-x), t = x/(1-x) s(t) = (1-x)/(1-2x)$

```python
sage: s = L([1])
sage: t = L([0,1])
sage: u = s(t)
sage: u.coefficients(14)
[1, 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096]
```

composition(y)

Return the composition of this power series and the power series $y$.

**EXAMPLES:**

```python
sage: L = LazyPowerSeriesRing(QQ)
sage: s = L([1])
sage: t = L([0,0,1])
sage: u = s(t)
sage: u.coefficients(11)
[1, 0, 1, 1, 2, 3, 5, 8, 13, 21, 34]
```

Test Compose 2

```python
sage: s = L([1])
sage: t = L([0,0,1,0])
sage: u = s(t)
sage: u.aorder
0
sage: u.order
Unknown series order
sage: u.coefficients(10)
[1, 0, 1, 0, 1, 0, 1, 0, 1, 0]
sage: u.aorder
0
sage: u.order
0
```

Test Compose 3 $s = 1/(1-x), t = x/(1-x) s(t) = (1-x)/(1-2x)$

```python
```
sage: s = L([1])
sage: t = L([0, 1])
sage: u = s(t)
sage: u.coefficients(14)
[1, 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096]

compute_aorder(*args, **kwargs)
The default compute_aorder does nothing.

EXAMPLES:

sage: L = LazyPowerSeriesRing(QQ)
sage: a = L(1)
sage: a.compute_aorder() is None
True

compute_coefficients(i)
Computes all the coefficients of self up to i.

EXAMPLES:

sage: L = LazyPowerSeriesRing(QQ)
sage: a = L([1, 2, 3])
sage: a.compute_coefficients(5)
sage: a
1 + 2*x + 3*x^2 + 3*x^3 + 3*x^4 + 3*x^5 + ...

define(x)
EXAMPLES: Test Recursive 0

sage: L = LazyPowerSeriesRing(QQ)
sage: one = L(1)
sage: monom = L.gen()
sage: s = L()
sage: s._name = 's'
sage: s.define(one+monom*s)
sage: s.aorder
0
sage: s.order
Unknown series order
sage: [s.coefficient(i) for i in range(6)]
[1, 1, 1, 1, 1, 1]

Test Recursive 1

sage: s = L()
sage: s._name = 's'
sage: s.define(one+monom*s*s)
sage: s.aorder
0
sage: s.order
Unknown series order
sage: [s.coefficient(i) for i in range(6)]
[1, 1, 2, 5, 14, 42]
Test Recursive 1b

```python
sage: s = L()
sage: s._name = 's'
sage: s.define(monom + s*s)
sage: s.aorder
1
sage: s.order
Unknown series order
sage: [s.coefficient(i) for i in range(7)]
[0, 1, 1, 2, 5, 14, 42]
```

Test Recursive 2

```python
sage: s = L()
sage: s._name = 's'
sage: t = L()
sage: t._name = 't'
sage: s.define(one+monom*t*t*t)
sage: t.define(one+monom*s*s)
sage: [s.coefficient(i) for i in range(9)]
[1, 1, 3, 9, 34, 132, 546, 2327, 10191]
sage: [t.coefficient(i) for i in range(9)]
[1, 1, 2, 7, 24, 95, 386, 1641, 7150]
```

Test Recursive 2b

```python
sage: s = L()
sage: s._name = 's'
sage: t = L()
sage: t._name = 't'
sage: s.define(monom + t*t*t)
sage: t.define(monom + s*s)
sage: [s.coefficient(i) for i in range(9)]
[0, 1, 0, 1, 3, 3, 7, 30, 63]
sage: [t.coefficient(i) for i in range(9)]
[0, 1, 1, 0, 2, 6, 7, 20, 75]
```

Test Recursive 3

```python
sage: s = L()
sage: s._name = 's'
sage: s.define(one+monom*s*s*s)
sage: [s.coefficient(i) for i in range(10)]
[1, 1, 3, 12, 55, 273, 1428, 7752, 43263, 246675]
```

**derivative()**

**EXAMPLES:**

```python
sage: from sage.combinat.species.stream import Stream
sage: L = LazyPowerSeriesRing(QQ)
sage: one = L(1)
sage: monom = L.gen()
sage: s = L([1])
```

(continues on next page)
\begin{verbatim}
sage: u = s.derivative()
sage: u.coefficients(10)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]

sage: s = L()
sage: s._name = 's'
sage: s.define(one+monom*s*s)
sage: u = s.derivative()
sage: u.coefficients(5) # [1*1, 2*2, 3*5, 4*14, 5*42]
[1, 4, 15, 56, 210]

sage: s = L([1])
sage: t = L([0,1])
sage: u = s(t).derivative()
sage: v = (s.derivative().compose(t))*t.derivative()
sage: u.coefficients(11)
[0, 2, 3, 4, 30, 72, 133, 552, 1791, 4260, 11264]
sage: v.coefficients(11)
[0, 2, 3, 4, 30, 72, 133, 552, 1791, 4260, 11264]
sage: u.coefficients(10) == v.coefficients(10)
True

sage: f = L._new_initial(2, Stream([0,0,4,5,6,0]))
sage: d = f.derivative()
sage: d.get_aorder() 1
sage: d.coefficients(5)
[0, 8, 15, 24, 0]

\end{verbatim}

\textbf{div}\text{(other)}

Divide this power series by \text{sage: other\text{.}}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: L = LazyPowerSeriesRing(QQ)
sage: x = L.gen()

Fibonacci numbers:
sage: b = x / (1-x-x^2); b.compute_coefficients(10); b
x + x^2 + 2*x^3 + 3*x^4 + 5*x^5 + 8*x^6
\end{verbatim}
\[ + 13x^7 + 21x^8 + 34x^9 + 55x^{10} + O(x^{11}) \]

**exponential()**

**get_aorder()**

Return the approximate order of self.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L.gen()
sage: a.get_aorder()
1
```

**get_order()**

Return the order of self.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L.gen()
sage: a.get_order()
1
```

**get_stream()**

Return self’s underlying Stream object.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L.gen()
sage: s = a.get_stream()
sage: [s[i] for i in range(5)]
[0, 1, 0, 0, 0]
```

**initialize_coefficient_stream**(compute_coefficients)

Initializes the coefficient stream.

INPUT: compute_coefficients

**integral**(integration_constant=0)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: zero = L(0)
sage: s = zero
sage: t = s.integral()
sage: t.is_zero()
True
```

```
sage: s = zero
sage: t = s.integral(1)
sage: t.coefficients(6)
[1, 0, 0, 0, 0, 0]
sage: t._stream.is_constant()
True
```
Combinatorics, Release 9.7

```sage
sage: s = L.term(1, 0)
sage: t = s.integral()
sage: t.coefficients(6)
[0, 1, 0, 0, 0, 0]
sage: t._stream.is_constant()
True
```

```sage
sage: s = L.term(1, 0)
sage: t = s.integral(1)
sage: t.coefficients(6)
[1, 1, 0, 0, 0, 0]
sage: t._stream.is_constant()
True
```

```sage
sage: s = L.term(1, 4)
sage: t = s.integral()
sage: t.coefficients(10)
[0, 0, 0, 0, 0, 1/5, 0, 0, 0, 0]
sage: s = L.term(1,4)
sage: t = s.integral(1)
sage: t.coefficients(10)
[1, 0, 0, 0, 0, 1/5, 0, 0, 0, 0]
```

invert()
Return 1 over this power series, i.e. invert this power series.

EXAMPLES:

```sage
sage: L = LazyPowerSeriesRing(QQ)
sage: x = L.gen()
```

Geometric series:

```sage
sage: a = ~(1-x); a.compute_coefficients(10); a
1 + x + x^2 + x^3 + x^4 + x^5 + x^6 + x^7 + x^8 + x^9 + x^10 + O(x^11)
```

(Shifted) Fibonacci numbers:

```sage
sage: b = ~(1-x-x^2); b.compute_coefficients(10); b
1 + x + 2*x^2 + 3*x^3 + 5*x^4 + 8*x^5 + 13*x^6 + 21*x^7 + 34*x^8 + 55*x^9 + 89*x^10 + O(x^11)
```

Series whose constant coefficient is 0 cannot be inverted:

```sage
sage: ~x
Traceback (most recent call last):
  ....
ZeroDivisionError: cannot invert x because constant coefficient is 0
```

is_finite(n=None)
EXAMPLES:
```python
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L([0,0,1,0,0]); a
O(1)
sage: a.is_finite()
False
sage: c = a[4]
sage: a.is_finite()
False
sage: a.is_finite(4)
False
sage: c = a[5]
sage: a.is_finite()
True
sage: a.is_finite(4)
True
```

**is_zero()**
Return True if and only if self is zero.

**EXAMPLES:**

```python
sage: L = LazyPowerSeriesRing(QQ)
sage: s = L([0,2,3,0])
sage: s.is_zero()
False
sage: s = L(0)
sage: s.is_zero()
True
sage: s = L([0])
sage: s.is_zero()
False
sage: s.coefficient(0)
0
sage: s.coefficient(1)
0
sage: s.is_zero()
True
```

**iterator**(n=0, initial=None)
Return an iterator for the coefficients of self starting at n.

**EXAMPLES:**

```python
sage: from sage.combinat.species.stream import Stream
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L(range(10))
sage: g = f.iterator(2)
[2, 3, 4, 5, 6]
sage: g = f.iterator(2, initial=[0,0])
[0, 0, 2, 3, 4]
```

5.1. Comprehensive Module List
refine_aorder()
Refines the approximate order of self as much as possible without computing any coefficients.

EXAMPLES:

```python
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L([0,0,0,0,1])
sage: a.aorder
0
sage: a.coefficient(2)
0
sage: a.aorder
0
sage: a.refine_aorder()
sage: a.aorder
3
```

```python
sage: a = L([0,0])
sage: a.aorder
0
sage: a.coefficient(5)
0
sage: a.refine_aorder()
sage: a.aorder
Infinite series order
```

```python
sage: a = L([0,0,1,0,0,0])
sage: a[4]
0
sage: a.refine_aorder()
sage: a.aorder
2
```

restricted(min=None, max=None)
Return the power series restricted to the coefficients starting at `min` and going up to, but not including `max`.

If `min` is not specified, then it is assumed to be zero. If `max` is not specified, then it is assumed to be infinity.

EXAMPLES:

```python
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L([1])
sage: a.restricted().coefficients(10)
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: a.restricted(min=2).coefficients(10)
[0, 0, 1, 1, 1, 1, 1, 1, 1, 1]
sage: a.restricted(max=5).coefficients(10)
[1, 1, 1, 1, 1, 0, 0, 0, 0, 0]
sage: a.restricted(min=2, max=6).coefficients(10)
[0, 0, 1, 1, 1, 1, 0, 0, 0, 0]
```

set_approximate_order(new_order)
Sets the approximate order of self and returns True if the approximate order has changed otherwise it will return False.

EXAMPLES:
Combinatorics, Release 9.7

```
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L([0,0,0,3,2,1,0])
sage: f.get_approximate_order()
0
sage: f.set_approximate_order(3)
True
sage: f.set_approximate_order(3)
False
```

tail()

Return the power series whose coefficients obtained by subtracting the constant term from this series and then dividing by x.

EXAMPLES:

```
sage: from sage.combinat.species.stream import Stream
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L(range(20))
sage: g = f.tail()
sage: g.coefficients(10)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```
times(y)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: gs0 = L(0)
sage: gs1 = L([1])

sage: prod0 = gs0 * gs1
sage: [prod0.coefficient(i) for i in range(11)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]

sage: prod1 = gs1 * gs0
sage: [prod1.coefficient(i) for i in range(11)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]

sage: prod2 = gs1 * gs1
sage: [prod2.coefficient(i) for i in range(11)]
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11]

sage: gs1 = L([1,2,4,8,0])
sage: gs2 = L([-1, 0,-1,-9,22,0])

sage: prod1 = gs1 * gs2
sage: [prod1.coefficient(i) for i in range(11)]
[-1, -2, -5, -19, 0, 0, 16, 176, 0, 0, 0]

sage: prod2 = gs2 * gs1
sage: [prod2.coefficient(i) for i in range(11)]
[-1, -2, -5, -19, 0, 0, 16, 176, 0, 0, 0]
```
class sage.combinat.species.series.LazyPowerSeriesRing(R, names=None, element_class=None)

Bases: sage.rings.ring.Algebra

gen(i=0)

EXAMPLES:

```python
sage: L = LazyPowerSeriesRing(QQ)
sage: L.gen().coefficients(5)
[0, 1, 0, 0, 0]
```

identity_element()

Return the one power series.

EXAMPLES:

```python
sage: L = LazyPowerSeriesRing(QQ)
sage: L.identity_element()
1
```

ngens()

EXAMPLES:

```python
sage: LazyPowerSeriesRing(QQ).ngens()
1
```

product_generator(g)

EXAMPLES:

```python
sage: L = LazyPowerSeriesRing(QQ)
sage: s1 = L([1,1,0])
sage: s2 = L([1,0,1,0])
sage: s3 = L([1,0,0,1,0])
sage: s4 = L([1,0,0,0,1,0])
sage: s5 = L([1,0,0,0,0,1,0])
sage: s6 = L([1,0,0,0,0,0,1,0])
sage: s = [s1, s2, s3, s4, s5, s6]
sage: def g():
.....:     for a in s:
.....:         yield a
sage: p = L.product_generator(g())
sage: p.coefficients(26)
[1, 1, 1, 2, 2, 3, 4, 4, 4, 4, 5, 5, 5, 5, 4, 4, 4, 3, 2, 2, 1, 1, 1, 0, 0, 0, 0]
```

```python
sage: def m(n):
.....:     yield 1
.....:     while True:
.....:         for i in range(n-1):
.....:             yield 0
.....:     yield 1
sage: def s(n):
.....:     q = 1/n
.....:     yield 0
.....:     while True:
.....:         for i in range(n-1):
```

(continues on next page)
yield 0
yield q

sage: def lhs_gen():
    n = 1
    while True:
        yield L(m(n))
        n += 1

sage: def rhs_gen():
    n = 1
    while True:
        yield L(s(n))
        n += 1

sage: lhs = L.product_generator(lhs_gen())
sage: rhs = L.sum_generator(rhs_gen()).exponential()
sage: lhs.coefficients(10)
[1, 1, 2, 3, 5, 7, 11, 15, 22, 30]
sage: rhs.coefficients(10)
[1, 1, 2, 3, 5, 7, 11, 15, 22, 30]

sum(a)
EXAMPLES:

sage: L = LazyPowerSeriesRing(QQ)
sage: l = [L(ZZ)]*3
sage: L.sum(l).coefficients(10)
[0, 3, -3, 6, -6, 9, -9, 12, -12, 15]

sum_generator(g)
EXAMPLES:

sage: L = LazyPowerSeriesRing(QQ)
sage: g = [L([1])]**6 + [L([0])]
sage: t = L.sum_generator(g)
sage: t.coefficients(10)
[1, 2, 3, 4, 5, 6, 6, 6, 6, 6]

sage: s = L([1])
sage: def g():
    while True:
        yield s
sage: t = L.sum_generator(g())
sage: t.coefficients(9)
[1, 2, 3, 4, 5, 6, 7, 8, 9]

term(r, n)
EXAMPLES:

sage: L = LazyPowerSeriesRing(QQ)
sage: L.term(0,0)
0
sage: L.term(3,2).coefficients(5)
[0, 0, 3, 0, 0]

zero()
Return the zero power series.
EXAMPLES:

sage: L = LazyPowerSeriesRing(QQ)
sage: L.zero()
0

sage.combinat.species.series.uninitialized()
EXAMPLES:

sage: from sage.combinat.species.series import uninitialized
sage: uninitialized()
Traceback (most recent call last):
... RuntimeWarning: we should never be here

5.1.326 Series Order
This file provides some utility classes which are useful when working with unknown, known, and infinite series orders
for univariate power series.

This code is based on the work of Ralf Hemmecke and Martin Rubey’s Aldor-Combinat, which can be found at
http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html. In particular, the relevant section for this file

class sage.combinat.species.series_order.InfiniteSeriesOrder
Bases: sage.combinat.species.series_order.SeriesOrderElement

class sage.combinat.species.series_order.SeriesOrderElement
Bases: object

class sage.combinat.species.series_order.UnknownSeriesOrder
Bases: sage.combinat.species.series_order.SeriesOrderElement

sage.combinat.species.series_order.bounded_decrement(x)
EXAMPLES:

sage: from sage.combinat.species.series_order import *
sage: u = UnknownSeriesOrder()
sage: bounded_decrement(u)
Unknown series order
sage: bounded_decrement(4)
3
sage: bounded_decrement(0)
0

sage.combinat.species.series_order.increment(x)
EXAMPLES:
5.1.327 Set Species

```python
sage: from sage.combinat.species.series_order import *
sage: u = UnknownSeriesOrder()
sage: increment(u)
Unknown series order
sage: increment(2)
3
```

Returns the species of sets.

**EXAMPLES:**

```python
sage: E = species.SetSpecies()
sage: E.structures([1,2,3]).list()
[[1, 2, 3]]
sage: E.isotype_generating_series().coefficients(4)
[1, 1, 1, 1]
sage: S = species.SetSpecies()
sage: c = S.generating_series().coefficients(3)
sage: S._check()
True
sage: S == loads(dumps(S))
True
```

**automorphism_group()**

```
Returns the group of permutations whose action on this set leave it fixed. For the species of sets, there is only one isomorphism class, so every permutation is in its automorphism group.
```

**EXAMPLES:**

```python
sage: F = species.SetSpecies()
sage: a = F.structures("a", "b", "c").random_element(); a
{'a', 'b', 'c'}
sage: a.automorphism_group()
Symmetric group of order 3! as a permutation group
```

**canonical_label()**

**EXAMPLES:**

```python
sage: S = species.SetSpecies()
sage: a = S.structures("a","b","c").random_element(); a
{'a', 'b', 'c'}
sage: a.canonical_label()
{'a', 'b', 'c'}
```
transport(perm)
Returns the transport of this set along the permutation perm.

EXAMPLES:

sage: F = species.SetSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
{'a', 'b', 'c'}

5.1.328 Combinatorial Species

This file defines the main classes for working with combinatorial species, operations on them, as well as some implementations of basic species required for other constructions.

This code is based on the work of Ralf Hemmecke and Martin Rubey’s Aldor-Combinat, which can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html. In particular, the relevant section for this file can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse8.html.

Weighted Species:
As a first application of weighted species, we count unlabeled ordered trees by total number of nodes and number of internal nodes. To achieve this, we assign a weight of 1 to the leaves and of $q$ to internal nodes:

```
sage: q = QQ['q'].gen()
sage: leaf = species.SingletonSpecies()
sage: internal_node = species.SingletonSpecies(weight=q)
sage: L = species.LinearOrderSpecies(min=1)
sage: T = species.CombinatorialSpecies()
sage: T.define(leaf + internal_node*L(T))
sage: T.isotype_generating_series().coefficients(6)
[0, 1, q, q^2 + q, q^3 + 3*q^2 + q, q^4 + 6*q^3 + 6*q^2 + q]
```

Consider the following:

```
sage: T.isotype_generating_series().coefficient(4)
q^3 + 3*q^2 + q
```

This means that, among the trees on 4 nodes, one has a single internal node, three have two internal nodes, and one has three internal nodes.

```
class sage.combinat.species.species.GenericCombinatorialSpecies(min=None, max=None, weight=None)
```

algebraic_equation_system()
Return a system of algebraic equations satisfied by this species.

The nodes are numbered in the order that they appear as vertices of the associated digraph.

EXAMPLES:
sage: B = species.BinaryTreeSpecies()
sage: B.algebraic_equation_system()
[-node3^2 + node1, -node1 + node3 + (-z)]

sage: sorted(B.digraph().vertex_iterator(), key=str)
[Combinatorial species,
 Product of (Combinatorial species) and (Combinatorial species),
 Singleton species,
 Sum of (Singleton species) and (Product of (Combinatorial species) and
 →(Combinatorial species))]

sage: B.algebraic_equation_system()[0].parent()
Multivariate Polynomial Ring in node0, node1, node2, node3 over Fraction Field
 →of Univariate Polynomial Ring in z over Rational Field

composition(g)

EXAMPLES:

sage: S = species.SetSpecies()
sage: S(S)
Composition of (Set species) and (Set species)

cycle_index_series(base_ring=None)

Return the cycle index series for this species.

The cycle index series is a sequence of symmetric functions.

EXAMPLES:

sage: P = species.PermutationSpecies()
sage: g = P.cycle_index_series()
sage: g.coefficients(4)

digraph()

Return a directed graph where the vertices are the individual species that make up this one.

EXAMPLES:

sage: X = species.SingletonSpecies()
sage: B = species.CombinatorialSpecies()
sage: B.define(X+B*B)
sage: g = B.digraph(); g
Multi-digraph on 4 vertices
sage: sorted(g, key=str)
[Combinatorial species,
 Product of (Combinatorial species) and (Combinatorial species),
 Singleton species,
 Sum of (Singleton species) and (Product of (Combinatorial species) and
 →(Combinatorial species))]
sage: d = {sp: i for i, sp in enumerate(g)}
sage: g.relabel(d)

(continues on next page)
functorial_composition(g)

Return the functorial composition of self with g.

EXAMPLES:

```
sage: E = species.SetSpecies()
sage: E2 = E.restricted(min=2, max=3)
sage: WP = species.SubsetSpecies()
sage: P2 = E2*E
sage: G = WP.functorial_composition(P2)
sage: G.isotype_generating_series().coefficients(5)
[1, 1, 2, 4, 11]
```

generating_series(base_ring=None)

Return the generating series for this species.

This is an exponential generating series so the $n$-th coefficient of the series corresponds to the number of labeled structures with $n$ labels divided by $n!$.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: g = P.generating_series()
sage: g.coefficients(4)
[1, 1, 1, 1]
sage: g.counts(4)
[1, 1, 2, 6]
sage: P.structures([1,2,3]).list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
sage: len(_)
6
```

is_weighted()

Return True if this species has a nontrivial weighting associated with it.

EXAMPLES:

```
sage: C = species.CycleSpecies()
sage: C.is_weighted()
False
```

isotype_generating_series(base_ring=None)

Return the isotype generating series for this species.

The $n$-th coefficient of this series corresponds to the number of isomorphism types for the structures on $n$ labels.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: g = P.isotype_generating_series()
sage: g.coefficients(4)
[1, 1, 2, 3]
```

sage: g.counts(4)
[1, 1, 2, 3]
sage: P.isotypes([1,2,3]).list()
[[2, 3, 1], [2, 1, 3], [1, 2, 3]]
sage: len(_)
3

isotypes(labels, structure_class=None)
EXAMPLES:

sage: F = CombinatorialSpecies()
sage: F.isotypes([1,2,3]).list()
Traceback (most recent call last):
  ...  
NotImplementedError

product(g)
Return the product of self and g.

EXAMPLES:

sage: P = species.PermutationSpecies()
sage: F = P * P; F
Product of (Permutation species) and (Permutation species)

restricted(*args, **kwds)
Return the restriction of the species.

INPUT:
• min – optional integer
• max – optional integer

EXAMPLES:

sage: S = species.SetSpecies().restricted(min=3); S
Set species with min=3
sage: S.structures([1,2]).list()
[]
sage: S.generating_series().coefficients(5)
[0, 0, 0, 1/6, 1/24]

structures(labels, structure_class=None)
EXAMPLES:

sage: F = CombinatorialSpecies()
sage: F.structures([1,2,3]).list()
Traceback (most recent call last):
  ... NotImplementedError

sum(g)
Return the sum of self and g.

EXAMPLES:
sage: P = species.PermutationSpecies()
sage: F = F + P; F
Sum of (Permutation species) and (Permutation species)
sage: F.structures([1,2]).list()
[[1, 2], [2, 1], [1, 2], [2, 1]]

weight_ring()
Return the ring in which the weights of this species occur.
By default, this is just the field of rational numbers.

EXAMPLES:

sage: species.SetSpecies().weight_ring()
Rational Field

weighted(weight)
Return a version of this species with the specified weight.

EXAMPLES:

sage: t = ZZ['t'].gen()
sage: C = species.CycleSpecies(); C
Cyclic permutation species
sage: C.weighted(t)
Cyclic permutation species with weight=t

5.1.329 Streams or Infinite Arrays

This code is based on the work of Ralf Hemmecke and Martin Rubey’s Aldor-Combinat, which can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html. In particular, the relevant section for this file can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse12.html.

sage.combinat.species.stream.Stream(x=None, const=None)
Returns a stream.

EXAMPLES: We can create a constant stream by just passing a

sage: from sage.combinat.species.stream import Stream
sage: s = Stream(const=0)
sage: [s[i] for i in range(10)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0]

class sage.combinat.species.stream.Stream_class(gen=None, const=None, func=None)
Bases: sage.structure.sage_object.SageObject

EXAMPLES:

sage: from sage.combinat.species.stream import Stream
sage: from builtins import zip
sage: s = Stream(const=0)
sage: len(s)
1
sage: [x for (x,i) in zip(s, range(4))]
[0, 0, 0, 0]
sage: len(s)
1

sage: s = Stream(const=4)
sage: g = iter(s)
sage: l1 = [x for (x,i) in zip(g, range(10))]
sage: l = [4 for k in range(10)]
sage: l == l1
True

sage: h = lambda l: 1 if len(l) < 2 else l[-1] + l[-2]
sage: fib = Stream(h)
sage: [x for (x,i) in zip(fib, range(11))]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]

sage: r = [4, 3, 5, 2, 6, 1, 1, 1, 1, 1]
sage: l = [4, 3, 5, 2, 6, 1]
sage: s = Stream(l)
sage: s[3] = -1
sage: [x for (x,i) in zip(s, r)]
[4, 3, 5, -1, 6, 1, 1, 1, 1]
sage: [x for (x,i) in zip(s, r)]
[4, 3, 5, -1, 6, -2, 1, 1, 1]
sage: s[6] = -3
sage: [x for (x,i) in zip(s, r)]
[4, 3, 5, -1, 6, -2, -3, 1, 1]
sage: s[8] = -4
sage: [x for (x,i) in zip(s, r)]
[4, 3, 5, -1, 6, -2, -3, -4, 1]
sage: a = Stream(const=0)
sage: [x for (x,i) in zip(a, range(4))]
[0, 0, 3, 0]

data()

Returns a list of all the coefficients computed so far.

EXAMPLES:

sage: from sage.combinat.species.stream import Stream, _integers_from
sage: s = Stream(_integers_from(3))
sage: s.data()
[]
sage: s[5]
8
sage: s.data()
[3, 4, 5, 6, 7, 8]

is_constant()

Returns True if and only if

EXAMPLES:
```
sage: from sage.combinat.species.stream import Stream
sage: s = Stream([1,2,3])
sage: s.is_constant()
False
sage: s[3]
3
sage: s.data()
[1, 2, 3]
sage: s.is_constant()
True
```

`map(f)`

EXAMPLES:
```
sage: from sage.combinat.species.stream import Stream
sage: s = Stream(ZZ)
sage: square = lambda x: x^2
sage: ss = s.map(square)
sage: [ss[i] for i in range(10)]
[0, 1, 1, 4, 4, 9, 9, 16, 16, 25]
```

`number_computed()`

Returns the number of coefficients computed so far.

EXAMPLES:
```
sage: from sage.combinat.species.stream import Stream
sage: l = [4,3,5,7,4,1,9,7]
sage: s = Stream(l)
sage: s[3]
7
sage: len(s)
4
sage: s[3]
7
sage: len(s)
4
sage: s[1]
3
sage: len(s)
4
sage: s[4]
4
sage: len(s)
5
```

`set_gen(gen)`

EXAMPLES:
```
sage: from sage.combinat.species.stream import Stream
sage: from builtins import zip
sage: fib = Stream()
sage: def g():
....:     yield 1
sage: ```
....:    yield 1
....:    n = 0
....:    while True:
....:        yield fib[n] + fib[n+1]
....:        n += 1
sage: fib.set_gen(g())
sage: [x for (x,i) in zip(fib, range(11))]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]
sage: l = [4,3,5,2,6,1]
sage: s = Stream(l)
sage: s[3]
2
sage: len(s)
4
sage: g = iter(l)
sage: s.set_gen(g)
sage: s[5]
3
sage: len(s)
6

**stretch**\((k)\)

EXAMPLES:

```python
sage: from sage.combinat.species.stream import Stream
sage: s = Stream(range(1, 10))
sage: s2 = s.stretch(2)
sage: [s2[i] for i in range(10)]
[1, 0, 2, 0, 3, 0, 4, 0, 5, 0]
```

### 5.1.330 Species structures

We will illustrate the use of the structure classes using the “balls and bars” model for integer compositions. An integer composition of 6 such as [2, 1, 3] can be represented in this model as ‘oooooo’ where the 6 o’s correspond to the balls and the 2’s correspond to the bars. If BB is our species for this model, it satisfies the following recursive definition:

\[
BB = o + o*BB + o*|*BB
\]

Here we define this species using the default structures:

```python
sage: ball = species.SingletonSpecies(); o = var('o')
sage: bar = species.EmptySetSpecies()
sage: BB = CombinatorialSpecies()
sage: BB.define(ball + ball*BB + ball*bar*BB)
sage: BB.isotypes([o]*3).list()
[o*(o*o), o*((o*{})*o), (o*{})*(o*o), (o*{})*((o*{})*o)]
```

If we ignore the parentheses, we can read off that the integer compositions are [3], [2, 1], [1, 2], and [1, 1, 1].

**class** `sage.combinat.species.structure.GenericSpeciesStructure`  
**Bases:** `sage.combinat.combinat.CombinatorialObject`
This is a base class from which the classes for the structures inherit.

EXAMPLES:

```python
sage: from sage.combinat.species.structure import GenericSpeciesStructure
sage: a = GenericSpeciesStructure(None, [2,3,4], [1,2,3])
sage: a
[2, 3, 4]
sage: a.parent() is None
True
sage: a == loads(dumps(a))
True
```

**change_labels(labels)**

Return a relabelled structure.

**INPUT:**

- labels, a list of labels.

**OUTPUT:**

A structure with the i-th label of self replaced with the i-th label of the list.

**EXAMPLES:**

```python
sage: P = species.SubsetSpecies()
sage: S = P.structures(['a', 'b', 'c'])
sage: [s.change_labels([1,2,3]) for s in S]
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]
```

**is_isomorphic(x)**

**EXAMPLES:**

```python
sage: S = species.SetSpecies()
sage: a = S.structures([1,2,3]).random_element(); a
{1, 2, 3}
sage: b = S.structures(['a','b','c']).random_element(); b
{'a', 'b', 'c'}
sage: a.is_isomorphic(b)
True
```

**labels()**

Returns the labels used for this structure.

**Note:** This includes labels which may not “appear” in this particular structure.

**EXAMPLES:**

```python
sage: P = species.SubsetSpecies()
sage: s = P.structures(["a", "b", "c"]).random_element()
sage: s.labels()
['a', 'b', 'c']
```

**parent()**

Returns the species that this structure is associated with.
Examples:
```
sage: L = species.LinearOrderSpecies()
sage: a,b = L.structures([1,2])
sage: a.parent()
Linear order species
```

```
class sage.combinat.species.structure.IsotypesWrapper(species, labels, structure_class)
Bases: sage.combinat.species.structure.SpeciesWrapper

A base class for the set of isotypes of a species with given set of labels. An object of this type is returned when you call the isotypes() method of a species.

Examples:
```
sage: F = species.SetSpecies()
sage: S = F.isotypes([1,2,3])
sage: S == loads(dumps(S))
True
```

```
class sage.combinat.species.structure.SimpleIsotypesWrapper(species, labels, structure_class)
Bases: sage.combinat.species.structure.SpeciesWrapper

Warning: This is deprecated and currently not used for anything.

Examples:
```
sage: F = species.SetSpecies()
sage: S = F.structures([1,2,3])
sage: S == loads(dumps(S))
True
```

```
class sage.combinat.species.structure.SimpleStructuresWrapper(species, labels, structure_class)
Bases: sage.combinat.species.structure.SpeciesWrapper

Warning: This is deprecated and currently not used for anything.

Examples:
```
sage: F = species.SetSpecies()
sage: S = F.structures([1,2,3])
sage: S == loads(dumps(S))
True
```

```
sage.combinat.species.structure.SpeciesStructure
alias of sage.combinat.species.structure.GenericSpeciesStructure
```

```
class sage.combinat.species.structure.SpeciesStructureWrapper(parent, s, **options)
Bases: sage.combinat.species.structure.GenericSpeciesStructure

This is a class for the structures of species such as the sum species that do not provide “additional” structure. For example, if you have the sum $C$ of species $A$ and $B$, then a structure of $C$ will either be either something from $A$ or $B$. Instead of just returning one of these directly, a “wrapper” is put around them so that they have their parent is $C$ rather than $A$ or $B$:

5.1. Comprehensive Module List 3187
sage: X = species.SingletonSpecies()
sage: X2 = X*X
sage: s = X2.structures([1]).random_element(); s
1
sage: s.parent()
Sum of (Singleton species) and (Singleton species)
sage: from sage.combinat.species.structure import SpeciesStructureWrapper
sage: issubclass(type(s), SpeciesStructureWrapper)
True

EXAMPLES:

sage: E = species.SetSpecies(); B = E+E
sage: s = B.structures([1,2,3]).random_element()
sage: s.parent()
Sum of (Set species) and (Set species)
sage: s == loads(dumps(s))
True

canonical_label()

EXAMPLES:

sage: P = species.PartitionSpecies()
sage: s = (P+P).structures([1,2,3])[1]; s
{{1, 3}, {2}}
sage: s.canonical_label()
{{1, 2}, {3}}

change_labels(labels)

Return a relabelled structure.

INPUT:

• labels, a list of labels.

OUTPUT:

A structure with the i-th label of self replaced with the i-th label of the list.

EXAMPLES:

sage: X = species.SingletonSpecies()
sage: X2 = X*X
sage: s = X2.structures([1]).random_element(); s
1
sage: s.change_labels(['a'])
'a'

transport(perm)

EXAMPLES:

sage: P = species.PartitionSpecies()
sage: s = (P+P).structures([1,2,3])[1]; s
{{1, 3}, {2}}
sage: s.transport(PermutationGroupElement((2,3)))
{{1, 2}, {3}}
class sage.combinat.species.structure.SpeciesWrapper(species, labels, iterator, generating_series, name, structure_class)

Bases: sage.combinat.combinat.CombinatorialClass

This is a abstract base class for the set of structures of a species as well as the set of isotypes of the species.

Note: One typically does not use SpeciesWrapper directly, but instead instantiates one of its subclasses: StructuresWrapper or IsotypesWrapper.

EXAMPLES:

```
sage: from sage.combinat.species.structure import SpeciesWrapper
sage: F = species.SetSpecies()
sage: S = SpeciesWrapper(F, [1,2,3], "_structures", "generating_series", 'Structures', None)
sage: S
Structures for Set species with labels [1, 2, 3]
sage: S.list()
[[1, 2, 3]]
sage: S.cardinality()
1
```

cardinality()
Returns the number of structures in this set.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: F.structures([1,2,3]).cardinality()
1
```

labels()
Returns the labels used on these structures. If \( X \) is the species, then \( \text{labels()} \) returns the preimage of these structures under the functor \( X \).

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: F.structures([1,2,3]).labels()
[1, 2, 3]
```

class sage.combinat.species.structure.StructuresWrapper(species, labels, structure_class)

Bases: sage.combinat.species.structure.SpeciesWrapper

A base class for the set of structures of a species with given set of labels. An object of this type is returned when you call the \text{structures()} method of a species.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: S = F.structures([1,2,3])
sage: S == loads(dumps(S))
True
```
5.1.331 Subset Species

class sage.combinat.species.subset_species.SubsetSpecies(min=None, max=None, weight=None)
Bases: sage.combinat.species.species.GenericCombinatorialSpecies, sage.structure.unique_representation.UniqueRepresentation

Return the species of subsets.

EXAMPLES:

sage: S = species.SubsetSpecies()
sage: S.generating_series().coefficients(5)
[1, 2, 2, 4/3, 2/3]
sage: S.isotype_generating_series().coefficients(5)
[1, 2, 3, 4, 5]

sage: S = species.SubsetSpecies()
sage: c = S.generating_series().coefficients(3)
sage: S._check()
True
sage: S == loads(dumps(S))
True

class sage.combinat.species.subset_species.SubsetSpeciesStructure(parent, labels, list)
Bases: sage.combinat.species.structure.GenericSpeciesStructure

automorphism_group()
Return the group of permutations whose action on this subset leave it fixed.

EXAMPLES:

sage: F = species.SubsetSpecies()
sage: a = F.structures([1,2,3,4])[6]; a
{1, 3}
sage: a.automorphism_group()
Permutation Group with generators [(2,4), (1,3)]

sage: [a.transport(g) for g in a.automorphism_group()]
[{1, 3}, {1, 3}, {1, 3}, {1, 3}]

canonical_label()
Return the canonical label of self.

EXAMPLES:

sage: P = species.SubsetSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.canonical_label() for s in S]
[[], ['a'], ['a'], ['a', 'b'], ['a', 'b'], ['a', 'b', 'c']]

complement()
Return the complement of self.

EXAMPLES:
```python
sage: F = species.SubsetSpecies()
sage: a = F.structures(["a", "b", "c"])[5]; a
{'a', 'c'}
sage: a.complement()
{'b'}
```

**label_subset()**

Return a subset of the labels that “appear” in this structure.

**EXAMPLES:**

```python
sage: P = species.SubsetSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.label_subset() for s in S]
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]
```

**transport**(perm)

Return the transport of this subset along the permutation perm.

**EXAMPLES:**

```python
sage: F = species.SubsetSpecies()
sage: a = F.structures(["a", "b", "c"])[5]; a
{'a', 'c'}
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
{'b', 'c'}
sage: p = PermutationGroupElement((1,3))
sage: a.transport(p)
{'a', 'c'}
```

---

**5.1.332 Sum species**

```python
sage.combinat.species.sum_species.SumSpecies_class
alias of sage.combinat.species.sum_species.SumSpecies
```

**class** `sage.combinat.species.sum_species.SumSpecies(F, G, min=None, max=None, weight=None)`

Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`, `sage.structure.unique_representation.UniqueRepresentation`

Returns the sum of two species.

**EXAMPLES:**

```python
sage: S = species.PermutationSpecies()
sage: A = S+S
sage: A.generating_series().coefficients(5)
[2, 2, 2, 2, 2]
sage: P = species.PermutationSpecies()
sage: F = P + P
sage: F._check()
True
sage: F == loads(dumps(F))
True
```
left_summand()

Returns the left summand of this species.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: F = P + P*P
sage: F.left_summand()
Permutation species
```

right_summand()

Returns the right summand of this species.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: F = P + P*P
sage: F.right_summand()
Product of (Permutation species) and (Permutation species)
```

weight_ring()

Returns the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you add elements of the weight rings for each of the operands.

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: C = S+S
sage: C.weight_ring()
Rational Field
```

```
sage: S = species.SetSpecies(weight=QQ['t'].gen())
sage: C = S + S
sage: C.weight_ring()
Univariate Polynomial Ring in t over Rational Field
```

5.1.333 Subsets

The set of subsets of a finite set. The set can be given as a list or a Set or else as an integer \( n \) which encodes the set \( \{1, 2, \ldots, n\} \). See `Subsets` for more information and examples.

AUTHORS:

- Mike Hansen: initial version
- Florent Hivert (2009/02/06): doc improvements + new methods

class `sage.combinat.subset.SubMultiset_s`

Bases: `sage.structure.parent.Parent`

The combinatorial class of the sub multisets of \( s \).

EXAMPLES:
```python
sage: S = Subsets([1,2,2,3], submultiset=True)
sage: S.cardinality()
12
sage: S.list()
[[], [1], [2], [3], [1, 2], [1, 3], [2, 2], [2, 3], [1, 2, 2], [1, 2, 3], [2, 2, 3], [1, 2, 2, 3]]
sage: S.first()
[]
sage: S.last()
[1, 2, 2, 3]
```

cardinality()

Return the cardinality of self.

EXAMPLES:

```python
sage: S = Subsets([1,1,2,3], submultiset=True)
sage: S.cardinality()
12
sage: len(S.list())
12

sage: S = Subsets([1,1,2,2,3], submultiset=True)
sage: S.cardinality()
18
sage: len(S.list())
18

sage: S = Subsets([1,1,1,2,2,3], submultiset=True)
sage: S.cardinality()
24
sage: len(S.list())
24
```

element_class

alias of builtins.list
generating_serie(\textit{variable}='x')

Return the polynomial associated to the counting of the elements of self weighted by the number of element they contain.

EXAMPLES:

```python
sage: Subsets([1,1], submultiset=True).generating_serie()
x^2 + x + 1
```

sage: Subsets([1,1,2,3],submultiset=True).generating_serie()
x^4 + 3*x^3 + 4*x^2 + 3*x + 1
sage: Subsets([1,1,1,2,2,3,3,4],submultiset=True).generating_serie()
x^8 + 4*x^7 + 9*x^6 + 14*x^5 + 16*x^4 + 14*x^3 + 9*x^2 + 4*x + 1
sage: S = Subsets([1,1,1,2,2,3,3,4],submultiset=True)
sage: S.cardinality()
72
sage: sum(S.generating_serie())
72
random_element()
Return a random element of self with uniform law.

EXAMPLES:

sage: S = Subsets([1,1,2,3], submultiset=True)
sage: s = S.random_element()
sage: s in S
True

class sage.combinat.subset.SubMultiset_sk(s, k)
Bases: sage.combinat.subset.SubMultiset_s
The combinatorial class of the subsets of size k of a multiset s. Note that each subset is represented by a list of
the elements rather than a set since we can have multiplicities (no multiset data structure yet in sage).

EXAMPLES:

sage: S = Subsets([1,2,3,3],2,submultiset=True)
sage: S._k
2
sage: S.cardinality()
4
sage: S.first()
[1, 2]
sage: S.last()
[3, 3]
sage: [sub for sub in S]
[[1, 2], [1, 3], [2, 3], [3, 3]]
cardinality()
Return the cardinality of self.

EXAMPLES:

sage: S = Subsets([1,2,2,3,3,3],4,submultiset=True)
sage: S.cardinality()
5
sage: len(list(S))
5
sage: S = Subsets([1,2,2,3,3,3],3,submultiset=True)
sage: S.cardinality()
6
(continues on next page)
```
sage: len(list(S))
6
```

**generating_serie** *(variable='x')*

Return the polynomial associated to the counting of the elements of self weighted by the number of elements they contains

EXAMPLES:

```
sage: x = ZZ['x'].gen()
sage: l = [1,1,1,1,2,2,3]
sage: for k in range(len(l)):
    ....:     S = Subsets(l,k,submultiset=True)
    ....:     print(S.generating_serie('x') == S.cardinality()*x**k)
True
True
True
True
True
True
True
```

**random_element()**

Return a random submultiset of given length

EXAMPLES:

```
sage: s = Subsets(7,3).random_element()
sage: s in Subsets(7,3)
True
sage: s = Subsets(7,5).random_element()
sage: s in Subsets(7,5)
True
```

**sage.combinat.set.Subsets** *(s, k=None, submultiset=False)*

Return the combinatorial class of the subsets of the finite set s. The set can be given as a list, Set or any iterable convertible to a set. Alternatively, a non-negative integer n can be provided in place of s; in this case, the result is the combinatorial class of the subsets of the set \{1, 2, . . . , n\} (i.e. of the Sage range(1,n+1)).

A second optional parameter k can be given. In this case, Subsets returns the combinatorial class of subsets of s of size k.

**Warning:** The subsets are returned as Sets. Do not assume that these Sets are ordered; they often are not! (E.g., Subsets(10).list()[619] returns \{10, 4, 5, 6, 7\} on my system.) See SubsetsSorted for a similar class which returns the subsets as sorted tuples.

Finally the option submultiset allows one to deal with sets with repeated elements, usually called multisets. The method then returns the class of all multisets in which every element is contained at most as often as it is contained in s. These multisets are encoded as lists.

EXAMPLES:
sage: S = Subsets([1, 2, 3]); S
Subsets of {1, 2, 3}
sage: S.cardinality()
8
sage: S.first()
{}
sage: S.last()
{1, 2, 3}
sage: S.random_element() in S
True
sage: S.list()
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]

Here is the same example where the set is given as an integer:

sage: S = Subsets(3)
sage: S.list()
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]

We demonstrate various the effect of the various options:

sage: S = Subsets(3, 2); S
Subsets of {1, 2, 3} of size 2
sage: S.list()
[{{1, 2}, {1, 3}, {2, 3}}]
sage: S = Subsets([1, 2, 2], submultiset=True); S
SubMultiset of [1, 2, 2]
sage: S.list()
[[], [1], [2], [1, 2], [2, 2], [1, 2, 2]]
sage: S = Subsets([1, 2, 2, 3], 3, submultiset=True); S
SubMultiset of [1, 2, 2, 3] of size 3
sage: S.list()
[[1, 2, 2], [1, 2, 3], [2, 2, 3]]
sage: S = Subsets(['a', 'b', 'a', 'b'], 2, submultiset=True); S.list()
[['a', 'a'], ['a', 'b'], ['b', 'b']]

And it is possible to play with subsets of subsets:

sage: S = Subsets(3)
sage: S2 = Subsets(S); S2
Subsets of Subsets of {1, 2, 3}
sage: S2.cardinality()
256
sage: it = iter(S2)
sage: [next(it) for _ in range(8)]
[{}, {{}}, {{1}}, {{2}}, {{3}}, {{1, 2}}, {{1, 3}}, {{2, 3}}]
sage: S2.random_element()  # random
{{2}, {1, 2, 3}, {}}
sage: [S2.unrank(k) for k in range(256)] == S2.list()
True

(continues on next page)
```python
sage: S3 = Subsets(S2)
sage: S3.cardinality()
1157920892373161954357985008687907853269984665640564039457584007913129639936
sage: S3.unrank(14123091480)  # random
{{2}, {1, 2, 3}, {1, 2}, {3}, {}},
{{1, 2, 3}, {2}, {1}, {1, 3}},
{{}, {2}, {2, 3}, {1, 2}},
{{}, {2}, {1, 2, 3}, {1, 2}},
{},
{}, {1}, {1, 2, 3}}
```

```python
sage: T = Subsets(S2, 10)
sage: T.cardinality()
278826214642518400
sage: T.unrank(1441231049)  # random
{{1, 2, 3}, {2}, {2, 3}}, {{3}, {1, 3}, ..., {3}, {1}, {}, {1, 3}}
```

```python
class sage.combinat.subset.SubsetsSorted(s)

    Bases: sage.combinat.subset.Subsets_s

    Lightweight class of all subsets of some set \(S\), with each subset being encoded as a sorted tuple.

    Used to model indices of algebras given by subsets (so we don’t have to explicitly build all \(2^n\) subsets in memory). For example, CliffordAlgebra.

    element_class
        alias of builtins.tuple

    first()
        Return the first element of self.

        EXAMPLES:

        ```
sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))
sage: S.first()
()    
```

    last()
        Return the last element of self.

        EXAMPLES:

        ```
sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))
sage: S.last()
(0, 1, 2)    
```

    random_element()
        Return a random element of self.

        EXAMPLES:

        ```
sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))
```
```
(continues on next page)
sage: isinstance(S.random_element(), tuple)
True

unrank(r)
Return the subset which has rank r.

EXAMPLES:

```python
sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))
sage: S.unrank(4)
(0, 1)
```

class sage.combinat.subset.Subsets_s
Bases: sage.structure.parent.Parent

Subsets of a given set.

EXAMPLES:

```python
sage: S = Subsets(4); S
Subsets of {1, 2, 3, 4}
sage: S.cardinality()
16
sage: Subsets(4).list()
[[], [1], [2], [3], [4],
 [1, 2], [1, 3], [1, 4], [2, 3], [2, 4], [3, 4],
 [1, 2, 3], [1, 2, 4], [1, 3, 4], [2, 3, 4],
 [1, 2, 3, 4]]
```

cardinality()
Return the number of subsets of the set s.

This is given by \(2^{|s|}\).

EXAMPLES:

```python
sage: Subsets(Set([1,2,3])).cardinality()
8
```

element_class
alias of sage.sets.set.Set_objectEnumerated
first()

Returns the first subset of $s$. Since we aren’t restricted to subsets of a certain size, this is always the empty set.

EXAMPLES:

```python
sage: Subsets([1,2,3]).first()
{}  
sage: Subsets(3).first()
{}
```

last()

Return the last subset of $s$. Since we aren’t restricted to subsets of a certain size, this is always the set $s$ itself.

EXAMPLES:

```python
sage: Subsets([1,2,3]).last()
{1, 2, 3}  
sage: Subsets(3).last()
{1, 2, 3}
```

lattice()

Return the lattice of subsets ordered by containment.

EXAMPLES:

```python
sage: X = Subsets([7,8,9])
sage: X.lattice()
Finite lattice containing 8 elements  
sage: Y = Subsets(0)
sage: Y.lattice()
Finite lattice containing 1 elements
```

random_element()

Return a random element of the class of subsets of $s$ (in other words, a random subset of $s$).

EXAMPLES:

```python
sage: Subsets(3).random_element()  # random
{2}  
sage: Subsets([4,5,6]).random_element()  # random
{5}  
sage: S = Subsets(Subsets(Subsets([0,1,2])))
sage: S.cardinality()
115792089237316195423570985008687907853269984665640564039457584007913129639936
sage: s = S.random_element()
sage: s  # random
{{1, 2}, {2}, {0}, {1}}, {{1, 2}, {0, 1, 2}, {0, 2}, {0}, {0, 1}}, ..., {{1, 2} \rightarrow, {2}, {1}}, {{2}, {0, 2}, {0}, {1}}
sage: s in S
True
```

rank(sub)

Return the rank of `sub` as a subset of `s`.  

5.1. Comprehensive Module List 3199
EXAMPLES:

```python
sage: Subsets(3).rank([])
0
sage: Subsets(3).rank([1,2])
4
sage: Subsets(3).rank([1,2,3])
7
sage: Subsets(3).rank([2,3,4])
Traceback (most recent call last):
... ValueError: {2, 3, 4} is not a subset of {1, 2, 3}
```

`underlying_set()`
Return the set of elements.

EXAMPLES:

```python
sage: Subsets(GF(13)).underlying_set()
{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12}
```

`unrank(r)`
Return the subset of \( s \) that has rank \( k \).

EXAMPLES:

```python
sage: Subsets(3).unrank(0)
{}
sage: Subsets([2,4,5]).unrank(1)
{2}
sage: Subsets([1,2,3]).unrank(257)
Traceback (most recent call last):
... IndexError: index out of range
```

```
class sage.combinat.subset.Subsets_sk(s, k)
Bases: sage.combinat.subset.Subsets_s
Subsets of fixed size of a set.

EXAMPLES:

```python
sage: S = Subsets([0,1,2,5,7], 3); S
Subsets of {0, 1, 2, 5, 7} of size 3
sage: S.cardinality()
10
sage: S.first(), S.last()
({0, 1, 2}, {2, 5, 7})
sage: S.random_element()  # random
{0, 5, 7}
sage: S([0,2,7])
{0, 2, 7}
sage: S([0,3,5])
Traceback (most recent call last):
... ValueError: {0, 3, 5} not in Subsets of {0, 1, 2, 5, 7} of size 3
```
sage: S([0])
Traceback (most recent call last):
...
ValueError: {0} not in Subsets of {0, 1, 2, 5, 7} of size 3

an_element()
Returns an example of subset.

EXAMPLES:

sage: Subsets(0,0).an_element()
{}
sage: Subsets(3,2).an_element()
{1, 3}
sage: Subsets([2,4,5],2).an_element()
{2, 5}

cardinality()
EXAMPLES:

sage: Subsets(Set([1,2,3]), 2).cardinality()
3
sage: Subsets([1,2,3,3], 2).cardinality()
3
sage: Subsets([1,2,3], 1).cardinality()
3
sage: Subsets([1,2,3], 3).cardinality()
1
sage: Subsets([1,2,3], 0).cardinality()
1
sage: Subsets([1,2,3], 4).cardinality()
0
sage: Subsets(3,2).cardinality()
3
sage: Subsets(3,4).cardinality()
0

first()
Return the first subset of s of size k.

EXAMPLES:

sage: Subsets(Set([1,2,3]), 2).first()
{1, 2}
sage: Subsets([1,2,3,3], 2).first()
{1, 2}
sage: Subsets(3,2).first()
{1, 2}
sage: Subsets(3,4).first()
Traceback (most recent call last):
...
EmptySetError
last()  
Return the last subset of s of size k.

EXAMPLES:

```
sage: Subsets(Set([1,2,3]), 2).last()  
{2, 3}
sage: Subsets([1,2,3,3], 2).last()  
{2, 3}
sage: Subsets(3,2).last()  
{2, 3}
sage: Subsets(3,4).last()  
Traceback (most recent call last):  
...  
EmptySetError
```

random_element()  
Return a random element of the class of subsets of s of size k (in other words, a random subset of s of size k).

EXAMPLES:

```
sage: s = Subsets(3, 2).random_element()  
sage: s in Subsets(3, 2)  
True

sage: Subsets(3,4).random_element()  
Traceback (most recent call last):  
...  
EmptySetError
```

rank(sub)  
Return the rank of sub as a subset of s of size k.

EXAMPLES:

```
sage: Subsets(3,2).rank([1,2])  
0
sage: Subsets([2,3,4],2).rank([3,4])  
2
sage: Subsets([2,3,4],2).rank([2])  
Traceback (most recent call last):  
...  
ValueError: {2} is not a subset of length 2 of {2, 3, 4}
sage: Subsets([2,3,4],4).rank([2,3,4,5])  
Traceback (most recent call last):  
...  
ValueError: {2, 3, 4, 5} is not a subset of length 4 of {2, 3, 4}
```

unrank(r)  
Return the subset of s of size k that has rank r.

EXAMPLES:

```
sage: Subsets(3,2).unrank(0)  
{1, 2}
```
sage: Subsets([2,4,5],2).unrank(0)
{2, 4}
sage: Subsets([1,2,8],3).unrank(42)
Traceback (most recent call last):
  ... IndexError: index out of range

sage.combinat.subset.dict_to_list(d)
Return a list whose elements are the elements of i of d repeated with multiplicity d[i].

EXAMPLES:

sage: from sage.combinat.subset import dict_to_list
sage: dict_to_list({'a':1, 'b':3})
['a', 'b', 'b', 'b']

sage.combinat.subset.list_to_dict(l)
Return a dictionary of multiplicities and the list of its keys.

INPUT:

a list l with possibly repeated elements

The keys are the elements of l (in the same order in which they appear) and values are the multiplicities of each element in l.

EXAMPLES:

sage: from sage.combinat.subset import list_to_dict
sage: list_to_dict(['a', 'b', 'b', 'b'])
({'a': 1, 'b': 3}, ['a', 'b'])

5.1.334 Subsets satisfying a hereditary property

sage.combinat.subsets_hereditary.subsets_with_hereditary_property(f, X,
  max_obstruction_size=None,
  ncpus=1)

Return all subsets S of X such that f(S) is true.

The boolean function f must be decreasing, i.e. f(S) \Rightarrow f(S') if S' \subseteq S.

This function is implemented to call f as few times as possible. More precisely, f will be called on all sets S such that f(S) is true, as well as on all inclusionwise minimal sets S such that f(S) is false.

The problem that this function answers is also known as the learning problem on monotone boolean functions, or as computing the set of winning coalitions in a simple game.

INPUT:

• f – a boolean function which takes as input a list of elements from X.
• X – a list/iterable.
• max_obstruction_size (integer) – if you know that there is a k such that f(S') is true if and only if f(S') is true for all S' \subseteq S with S' \leq k, set max_obstruction_size=k. It may dramatically decrease the number of calls to f. Set to None by default, meaning k = |X|.
• `ncpus` – number of cpus to use for this computation. Note that changing the value from 1 (default) to anything different enables parallel computations which can have a cost by itself, so it is not necessarily a good move. In some cases, however, it is a great move. Set to `None` to automatically detect and use the maximum number of cpus available.

**Note:** Parallel computations are performed through the `parallel()` decorator. See its documentation for more information, in particular with respect to the memory context.

### EXAMPLES:

Sets whose elements all have the same remainder mod 2:

```python
sage: from sage.combinat.subsets_hereditary import subsets_with_hereditary_property
sage: f = lambda x: (not x) or all(xx%2 == x[0]%2 for xx in x)

sage: list(subsets_with_hereditary_property(f, range(4)))
```

```python
[[], [0], [1], [2], [3], [0, 2], [1, 3]]
```

Same, on two threads:

```python
sage: sorted(subsets_with_hereditary_property(f, range(4), ncpus=2))
```

```python
[[], [0], [0, 2], [1], [1, 3], [2], [3]]
```

One can use this function to compute the independent sets of a graph. We know, however, that in this case the maximum obstructions are the edges, and have size 2. We can thus set `max_obstruction_size=2`, which reduces the number of calls to `f` from 91 to 56:

```python
sage: num_calls=0
sage: g = graphs.PetersenGraph()
sage: def is_independent_set(S):
    global num_calls
    num_calls+=1
    return g.subgraph(S).size()==0

sage: l1=list(subsets_with_hereditary_property(is_independent_set, g.vertices(sort=False)))
sage: num_calls
91
sage: num_calls=0
sage: l2=list(subsets_with_hereditary_property(is_independent_set, g.vertices(sort=False), max_obstruction_size=2))
sage: num_calls
56
sage: l1==l2
True
```
5.1.335 Subsets whose elements satisfy a predicate pairwise

```python
class sage.combinat.subsets_pairwise.PairwiseCompatibleSubsets(ambient, predicate, maximal=False, element_class=<class 'sage.sets.set.Set_object_enumerated'>):
    Bases: sage.sets.recursivelyEnumeratedSet.RecursivelyEnumeratedSet_forest
    The set of all subsets of ambient whose elements satisfy predicate pairwise
    INPUT:
    • ambient – a set (or iterable)
    • predicate – a binary predicate
    Assumptions: predicate is symmetric (predicate(x,y) == predicate(y,x)) and reflexive (predicate(x,x) == True).
    
    Note: in fact, predicate(x,x) is never called.
```

**Warning:** The current name is suboptimal and is subject to change. Suggestions for a good name, and a good user entry point are welcome. Maybe Subsets(..., independent = predicate).

**EXAMPLES:**
We construct the set of all subsets of \(\{4, 5, 6, 8, 9\}\) whose elements are pairwise relatively prime:

```python
sage: from sage.combinat.subsets_pairwise import PairwiseCompatibleSubsets
sage: def predicate(x,y):
    return gcd(x,y) == 1
sage: P = PairwiseCompatibleSubsets([4,5,6,8,9], predicate); P
An enumerated set with a forest structure
sage: P.list()
[[], [4], [4, 5], [9, 4, 5], [9, 4], [5], [5, 6], [8, 5], [8, 9, 5], [9, 5], [6], →[8], [8, 9], [9]]
sage: P.cardinality()
14
sage: P.category()
Category of finite enumerated sets
```

Here we consider only those subsets which are maximal for inclusion (not yet implemented):

```python
sage: P = PairwiseCompatibleSubsets([4,5,6,8,9], predicate, maximal = True); P
An enumerated set with a forest structure
sage: P.list() # todo: not implemented
[[9, 4, 5], [5, 6], [8, 9, 5]]
sage: P.cardinality() # todo: not implemented
14
sage: P.category()
Category of finite enumerated sets
```
Algorithm

In the following, we order the elements of the ambient set by order of apparition. The elements of self are generated by organizing them in a search tree. Each node of this tree is of the form (subset, rest), where:

- subset represents an element of self, represented by an increasing tuple.
- rest is the set of all y’s such that y appears after x in the ambient set and predicate(x,y) holds, represented by a decreasing tuple.

The root of this tree is ((), ambient). All the other elements are generated by recursive depth first search, which gives lexicographic order.

children(subset_rest)
Returns the children of a node in the tree.

post_process(subset_rest)

5.1.336 Subwords

A subword of a word w is a word obtained by deleting the letters at some (non necessarily adjacent) positions in w. It is not to be confused with the notion of factor where one keeps adjacent positions in w. Sometimes it is useful to allow repeated uses of the same letter of w in a “generalized” subword. We call this a subword with repetitions.

For example:
- “bnjr” is a subword of the word “bonjour” but not a factor;
- “njo” is both a factor and a subword of the word “bonjour”;
- “nr” is a subword of “bonjour”;
- “rn” is not a subword of “bonjour”;
- “nnu” is not a subword of “bonjour”;
- “nnu” is a subword with repetitions of “bonjour”;

A word can be given either as a string, as a list or as a tuple.

As repetition can occur in the initial word, in general subwords of a given word form an enumerated multiset rather than a set!

Todo:

- implement subwords with repetitions
- implement the category of EnumeratedMultiset and inheritate from it when needed (i.e. the initial word has repeated letters)

AUTHORS:

- Mike Hansen: initial version
- Florent Hivert (2009/02/06): doc improvements + new methods + bug fixes

sage.combinat.subword.Subwords(w, k=None, element_constructor=None)
Return the set of subwords of w.

INPUT:
- w – a word (can be a list, a string, a tuple or a word)
• **k** – an optional integer to specify the length of subwords

• **element_constructor** – an optional function that will be used to build the subwords

**EXAMPLES:**

```python
sage: S = Subwords(['a', 'b', 'c']); S
Subwords of ['a', 'b', 'c']
sage: S.first()
[]
sage: S.last()
['a', 'b', 'c']
sage: S.list()
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]
```

The same example using string, tuple or a word:

```python
sage: S = Subwords('abc'); S
Subwords of 'abc'
sage: S.list()
['', 'a', 'b', 'c', 'ab', 'ac', 'bc', 'abc']

sage: S = Subwords((1, 2, 3)); S
Subwords of (1, 2, 3)
sage: S.list()
[(), (1,), (2,), (3,), (1, 2), (1, 3), (2, 3), (1, 2, 3)]

sage: w = Word([1, 2, 3])
sage: S = Subwords(w); S
Subwords of word: 123
sage: S.list()
[word: , word: 1, word: 2, word: 3, word: 12, word: 13, word: 23, word: 123]
```

Using word with specified length:

```python
sage: S = Subwords(['a', 'b', 'c'], 2); S
Subwords of ['a', 'b', 'c'] of length 2
sage: S.list()
[['a', 'b'], ['a', 'c'], ['b', 'c']]
```

An example that uses the **element_constructor** argument:

```python
sage: p = Permutation([3, 2, 1])
sage: Subwords(p, element_constructor=tuple).list()
[(), (3,), (2,), (1,), (3, 2), (3, 1), (2, 1), (3, 2, 1)]
sage: Subwords(p, 2, element_constructor=tuple).list()
[(3, 2), (3, 1), (2, 1)]
```

```python
class sage.combinat.subword.Subwords_w(w, element_constructor)
Bases: sage.structure.parent.Parent

Subwords of a given word.

cardinality()

EXAMPLES:
```
Subwords([1,2,3]).cardinality()
8

**first()**

**EXAMPLES:**

```python
sage: Subwords([1,2,3]).first()
[]
sage: Subwords((1,2,3)).first()
()
sage: Subwords('123').first()
'
```

**last()**

**EXAMPLES:**

```python
sage: Subwords([1,2,3]).last()
[1, 2, 3]
sage: Subwords((1,2,3)).last()
(1, 2, 3)
sage: Subwords('123').last()
'123'
```

**random_element()**

Return a random subword with uniform law.

**EXAMPLES:**

```python
sage: S1 = Subwords([1,2,3,2,1,3])
sage: S2 = Subwords([4,6,6,6,7,4,5,5])
sage: for i in range(100):
    ....:     w = S1.random_element()
    ....:     if w in S2:
    ....:         assert(w)
    ....:     w = S2.random_element()
    ....:     if w in S1:
    ....:         assert(w)
```

### class sage.combinat.subword.Subwords_wk(w, k, element_constructor)

Bases: sage.combinat.subword.Subwords_w

Subwords with fixed length of a given word.

**cardinality()**

Return the number of subwords of w of length k.

**EXAMPLES:**

```python
sage: Subwords([1,2,3], 2).cardinality()
3
```

**first()**

**EXAMPLES:**
```python
sage: Subwords([1,2,3],2).first()
[1, 2]
sage: Subwords([1,2,3],0).first()
[]
sage: Subwords((1,2,3),2).first()
(1, 2)
sage: Subwords((1,2,3),0).first()
()
sage: Subwords('123',2).first()
'12'
sage: Subwords('123',0).first()
''
```

last()

EXAMPLES:

```python
sage: Subwords([1,2,3],2).last()
[2, 3]
sage: Subwords([1,2,3],0).last()
[]
sage: Subwords((1,2,3),2).last()
(2, 3)
sage: Subwords((1,2,3),0).last()
()
sage: Subwords('123',2).last()
'23'
sage: Subwords('123',0).last()
''
```

random_element()

Return a random subword of given length with uniform law.

EXAMPLES:

```python
sage: S1 = Subwords([1,2,3,2,1],3)
sage: S2 = Subwords([4,4,5,5,4,5,4,4],3)
sage: for i in range(100):
    ....:     w = S1.random_element()
    ....:     if w in S2:
    ....:         assert(not w)
    ...
sage: for i in range(100):
    ....:     w = S2.random_element()
    ....:     if w in S1:
    ....:         assert(not w)
```

sage.combinat.subword.smallest_positions(word, subword, pos=0)

Return the smallest positions for which subword appears as a subword of word.

If pos is specified, then it returns the positions of the first appearance of subword starting at pos.

If subword is not found in word, then return False.

EXAMPLES:
5.1.337 Subword complex

Fix a Coxeter system \((W, S)\). The subword complex \(SC(Q, w)\) associated to a word \(Q \in S^*\) and an element \(w \in W\) is the simplicial complex whose ground set is the set of positions in \(Q\) and whose facets are complements of sets of positions defining a reduced expression for \(w\).

A subword complex is a shellable sphere if and only if the Demazure product of \(Q\) equals \(w\), otherwise it is a shellable ball.

The code is optimized to be used with ReflectionGroup, it works as well with CoxeterGroup, but many methods fail for WeylGroup.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',3]); I = list(W.index_set()) # optional - gap3
sage: Q = I + W.w0.coxeter_sorting_word(I); Q # optional - gap3
[1, 2, 3, 1, 2, 3, 1, 2, 1]

sage: S = SubwordComplex(Q,W.w0) # optional - gap3
sage: for F in S: print("{} {}").format(F, F.root_configuration()) # optional - gap3
(0, 1, 2) [(1, 0, 0), (0, 1, 0), (0, 0, 1)]
(0, 1, 8) [(1, 0, 0), (0, 1, 0), (0, 0, -1)]
(0, 2, 6) [(1, 0, 0), (0, 1, 1), (0, -1, 0)]
(0, 6, 7) [(1, 0, 0), (0, 0, 1), (0, -1, -1)]
(0, 7, 8) [(1, 0, 0), (0, -1, 0), (0, 0, -1)]
(1, 2, 3) [(1, 1, 0), (0, 0, 1), (-1, 0, 0)]
(1, 3, 8) [(1, 1, 0), (-1, 0, 0), (0, 0, -1)]
```

(continues on next page)
Testing that the implementation also works with CoxeterGroup:

```
sage: W = CoxeterGroup(['A',3]); I = list(W.index_set())
sage: Q = I + W.w0.coxeter_sorting_word(I); Q
[1, 2, 3, 1, 2, 3, 1, 2, 1]
sage: S = SubwordComplex(Q,W.w0); S
Subword complex of type ['A', 3] for Q = (1, 2, 3, 1, 2, 3, 1, 2, 1) and pi = [1, 2, 3, -1, 2, 1]
sage: P = S.increasing_flip_poset(); P; len(P.cover_relations())
Finite poset containing 14 elements
21
```

The root configuration works:

```
sage: for F in S: print("{} {}").format(F, F.root_configuration())
(0, 1, 2) [(1, 0, 0), (0, 1, 0), (0, 0, 1)]
(0, 1, 8) [(1, 0, 0), (0, 1, 0), (0, 0, -1)]
(0, 2, 6) [(1, 0, 0), (0, 1, 1), (0, -1, 0)]
(0, 6, 7) [(1, 0, 0), (0, 0, 1), (0, -1, -1)]
(0, 7, 8) [(1, 0, 0), (0, -1, 0), (0, 0, -1)]
(1, 2, 3) [(1, 1, 0), (0, 0, 1), (0, -1, 0)]
(1, 3, 8) [(1, 1, 0), (-1, 0, 0), (0, 0, 1)]
(2, 3, 4) [(1, 1, 1), (0, 1, 0), (-1, -1, 0)]
(2, 4, 6) [(1, 1, 1), (-1, 0, 0), (0, -1, 0)]
(3, 4, 5) [(0, 1, 0), (0, 0, 1), (-1, -1, 1)]
(3, 5, 8) [(0, 1, 0), (-1, -1, 0), (0, 0, -1)]
(4, 5, 6) [(0, 1, 1), (-1, -1, -1), (0, -1, 0)]
(5, 6, 7) [(-1, 0, 0), (0, 0, 1), (0, -1, -1)]
(5, 7, 8) [(-1, 0, 0), (0, -1, 0), (0, 0, -1)]
```

And the weight configuration also works:

```
sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([[1,2,1,2,1],w])
sage: F = SC([1,2])
sage: F.extended_weight_configuration()
[(4/3, 2/3), (2/3, 4/3), (-2/3, 2/3), (2/3, 4/3), (-2/3, 2/3)]
sage: F.extended_weight_configuration(coefficients=(1,2))
[(4/3, 2/3), (4/3, 8/3), (-2/3, 2/3), (4/3, 8/3), (-2/3, 2/3)]
```

One finally can compute the brick polytope, using all functionality on weight configurations, though it does not realize to live in real space:
### Class `sage.combinat.subword_complex.SubwordComplex(Q, w, algorithm='inductive')`

**Bases:** `sage.structure.unique_representation.UniqueRepresentation`, `sage.topology.simplicial_complex.SimplicialComplex`

Fix a Coxeter system \((W, S)\). The subword complex \(\mathcal{SC}(Q, w)\) associated to a word \(Q \in S^*\) and an element \(w \in W\) is the simplicial complex whose ground set is the set of positions in \(Q\) and whose facets are complements of sets of positions defining a reduced expression for \(w\).

A subword complex is a shellable sphere if and only if the Demazure product of \(Q\) equals \(w\), otherwise it is a shellable ball.

**Warning:** This implementation only works for groups build using `CoxeterGroup`, and does not work with groups build using `WeylGroup`.

### Examples

As an example, dual associahedra are subword complexes in type \(A_{n-1}\) given by the word \([1, \ldots, n, 1, \ldots, n, 1, \ldots, n-1, \ldots, 1, 2, 1]\) and the permutation \(w_0\).

```
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: w = W.from_reduced_word([1,2,1])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w); SC  # optional - gap3
Subword complex of type ['A', 2] for Q = (1, 2, 1, 2, 1) and pi = [1, 2, 1]
sage: SC.facets()  # optional - gap3
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
```

```
sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w); SC
Subword complex of type ['A', 2] for Q = (1, 2, 1, 2, 1) and pi = [1, 2, 1]
sage: SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
```

### References

- [KnuMil]
- [PilStu]
Element

alias of SubwordComplexFacet

barycenter()

Return the barycenter of the brick polytope of self.

See also:

brick_polytope()

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)  # optional - gap3
sage: SC.barycenter()  # optional - gap3
(2/3, 4/3)

sage: W = CoxeterGroup(['A',2])

sage: SC = SubwordComplex([1,2,1,2,1], W.w0)

sage: SC.barycenter()  # optional - gap3
(4/3, 8/3)
```

brick_fan()

Return the brick fan of self.

It is the normal fan of the brick polytope of self. It is formed by the cones generated by the weight configurations of the facets of self.

See also:

weight_cone

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: w = W.from_reduced_word([1,2,1])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w)

sage: SC.brick_fan()  # optional - gap3
Rational polyhedral fan in 2-d lattice N

sage: W = CoxeterGroup(['A',2])

sage: w = W.from_reduced_word([1,2,1])

sage: SC = SubwordComplex([1,2,1,2,1], w)

sage: SC.brick_fan()  # optional - gap3
Rational polyhedral fan in 2-d lattice N
```

brick_polytope(coefficients=None)

Return the brick polytope of self.

This polytope is the convex hull of the brick vectors of self.

INPUT:

- coefficients – (optional) a list of coefficients used to scale the fundamental weights

See also:

brick_vectors()

EXAMPLES:
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: SC = SubwordComplex([[1,2,1,2,1], W.w0])  # optional - gap3
sage: X = SC.brick_polytope(); X
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices

sage: Y = SC.brick_polytope(coefficients=[1,2]); Y  # optional - gap3
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices

sage: X == Y  # optional - gap3
False

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([[1,2,1,2,1], W.w0])
sage: X = SC.brick_polytope(); X
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices

brick_vectors(coefficients=None)
Return the list of all brick vectors of facets of self.

INPUT:

- coefficients – (optional) a list of coefficients used to scale the fundamental weights

See also:

brick_vector

EXAMPLES:

sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: SC = SubwordComplex([[1,2,1,2,1], W.w0])  # optional - gap3
sage: SC.brick_vectors()  # optional - gap3
[(5/3, 7/3), (5/3, 1/3), (2/3, 7/3), (-1/3, 4/3), (-1/3, 1/3)]

sage: SC.brick_vectors(coefficients=(1,2))  # optional - gap3
[(10/3, 14/3), (10/3, 2/3), (4/3, 14/3), (-2/3, 8/3), (-2/3, 2/3)]

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([[1,2,1,2,1], W.w0])
sage: SC.brick_vectors()  # optional - gap3

cartan_type()
Return the Cartan type of self.

EXAMPLES:
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: w = W.from_reduced_word([1,2,1])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w)  # optional - gap3
sage: SC.cartan_type()  # optional - gap3
['A', 2]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.cartan_type()
['A', 2]

cover_relations(label=False)
Return the set of cover relations in the associated poset.

INPUT:

- label – boolean (default False) whether or not to label the cover relations by the position of flip

OUTPUT:

a list of pairs of facets

EXAMPLES:

sage: W = ReflectionGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: sorted(SC.cover_relations())  # optional - gap3
[((0, 1), (0, 4)),
 ((0, 1), (1, 2)),
 ((0, 4), (3, 4)),
 ((1, 2), (2, 3)),
 ((2, 3), (3, 4))]

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: sorted(SC.cover_relations())
[((0, 1), (0, 4)),
 ((0, 1), (1, 2)),
 ((0, 4), (3, 4)),
 ((1, 2), (2, 3)),
 ((2, 3), (3, 4))]

dimension()
Return the dimension of self.

EXAMPLES:

sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)  # optional - gap3
sage: SC.dimension()  # optional - gap3
1

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
facets()

Return all facets of self.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',2])
# optional - gap3
sage: w = W.from_reduced_word([1,2,1])
# optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w)
# optional - gap3
sage: SC.facets()
# optional - gap3
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
```

```python
sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
```

greedy_facet(side='positive')

Return the negative (or positive) greedy facet of self.

This is the lexicographically last (or first) facet of self.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',2])
# optional - gap3
sage: w = W.from_reduced_word([1,2,1])
# optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w)
# optional - gap3
sage: SC.greedy_facet(side="positive")
# optional - gap3
(0, 1)
```

```python
sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.greedy_facet(side="positive")
(0, 1)
sage: SC.greedy_facet(side="negative")
(3, 4)
```

group()

Return the group associated to self.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',2])
# optional - gap3
sage: w = W.from_reduced_word([1,2,1])
# optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w)
# optional - gap3
sage: SC.group()
# optional - gap3
Irreducible real reflection group of rank 2 and type A2
```

```python
sage: W = CoxeterGroup(['A',2])
(continues on next page)
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.group()

Finite Coxeter group over Integer Ring with Coxeter matrix:
\[
\begin{bmatrix}
1 & 3 \\
3 & 1
\end{bmatrix}
\]

increasing_flip_graph(label=True)

Return the increasing flip graph of the subword complex.

OUTPUT:

a directed graph

EXAMPLES:

sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)  # optional - gap3
sage: SC.increasing_flip_graph()  # optional - gap3

Digraph on 5 vertices

sage: W = CoxeterGroup(['A',2])

sage: SC = SubwordComplex([1,2,1,2,1], W.w0)

sage: SC.increasing_flip_graph()

Digraph on 5 vertices

increasing_flip_poset()

Return the increasing flip poset of the subword complex.

OUTPUT:

a poset

EXAMPLES:

sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)  # optional - gap3
sage: SC.increasing_flip_poset()  # optional - gap3

Finite poset containing 5 elements

sage: W = CoxeterGroup(['A',2])

sage: SC = SubwordComplex([1,2,1,2,1], W.w0)

sage: SC.increasing_flip_poset()

Finite poset containing 5 elements

interval(I, J)

Return the interval [I,J] in the increasing flip graph subword complex.

INPUT:

- I, J – two facets

OUTPUT:

a set of facets

EXAMPLES:
```python
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)  # optional - gap3
sage: F = SC([1,2])  # optional - gap3
sage: SC.interval(F, F)  # optional - gap3
{(1, 2)}
```

### is_ball()
Return True if the subword complex `self` is a ball.

This is the case if and only if it is not a sphere.

#### EXAMPLES:
```python
sage: W = ReflectionGroup(['A',3])  # optional - gap3
sage: w = W.from_reduced_word([2,3,2])  # optional - gap3
sage: SC = SubwordComplex([3,2,3,2,3], w)  # optional - gap3
sage: SC.is_ball()  # optional - gap3
False
```

```python
sage: SC = SubwordComplex([3,2,1,3,2,3], w)  # optional - gap3
sage: SC.is_ball()  # optional - gap3
True
```

```python
sage: W = CoxeterGroup(['A',3])
```

```python
sage: w = W.from_reduced_word([2,3,2])
sage: SC = SubwordComplex([3,2,3,2,3], w)
sage: SC.is_ball()  # optional - gap3
False
```

### is_double_root_free()
Return True if `self` is double-root-free.

This means that the root configurations of all facets do not contain a root twice.

#### EXAMPLES:
```python
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: w = W.from_reduced_word([1,2,1])  # optional - gap3
```

```python
sage: SC = SubwordComplex([1,2,1,2,1], w)  # optional - gap3
sage: SC.is_double_root_free()  # optional - gap3
True
```

```python
sage: SC = SubwordComplex([1,1,2,2,1,1], w)  # optional - gap3
sage: SC.is_double_root_free()  # optional - gap3
True
```

```python
sage: SC = SubwordComplex([1,2,1,2,1,2], w)  # optional - gap3
sage: SC.is_double_root_free()  # optional - gap3
False
```
is_double_root_free()  
Return True if all subword complexes are double root-free.

EXAMPLES:

```
sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.is_double_root_free()  
True
```

is_pure()  
Return True since all subword complexes are pure.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',3])  # optional - gap3
sage: w = W.from_reduced_word([2,3,2])  # optional - gap3
sage: SC = SubwordComplex([3,2,3,2,3], w)  # optional - gap3
sage: SC.is_pure()  # optional - gap3
True
```

is_root_independent()  
Return True if self is root-independent. This means that the root configuration of any (or equivalently all) facets is linearly independent.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)  # optional - gap3
sage: SC.is_root_independent()  # optional - gap3
True
```

is_sphere()  
Return True if the subword complex self is a sphere.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',3])  # optional - gap3
sage: w = W.from_reduced_word([2,3,2])  # optional - gap3
sage: SC = SubwordComplex([3,2,3,2,3], w)  # optional - gap3
sage: SC.is_sphere()  # optional - gap3
True
```
sage: SC = SubwordComplex([3,2,1,3,2,3], w)  # optional - gap3
sage: SC.is_sphere()                            # optional - gap3
False

sage: W = CoxeterGroup(['A',3])
sage: w = W.from_reduced_word([2,3,2])
sage: SC = SubwordComplex([3,2,3,2,3], w)
sage: SC.is_sphere()                            # optional - gap3
True

\textbf{kappa\_preimages()}

Return a dictionary containing facets of self as keys, and list of elements of self.group() as values.

See also:

\textbf{kappa\_preimage}

EXAMPLES:

sage: W = ReflectionGroup(['A',2])            # optional - gap3
sage: w = W.from_reduced_word([1,2,1])        # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w)     # optional - gap3
sage: kappa = SC.kappa\_preimages()            # optional - gap3
sage: for F in SC: print("{} {}".format(F, [w.reduced_word() for w in kappa[F]])) # optional - gap3
(0, 1) [[]]
(0, 4) [[2], [2, 1]]
(1, 2) [[1]]
(2, 3) [[1, 2]]
(3, 4) [[1, 2, 1]]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: kappa = SC.kappa\_preimages()
sage: for F in SC: print("{} {}".format(F, [w.reduced_word() for w in kappa[F]])) # optional - gap3
(0, 1) [[]]
(0, 4) [[2], [2, 1]]
(1, 2) [[1]]
(2, 3) [[1, 2]]
(3, 4) [[1, 2, 1]]

\textbf{minkowski\_summand(i)}

Return the $i$ th Minkowski summand of self.

INPUT:

\begin{itemize}
\item \textit{i} – an integer defining a position in the word $Q$
\end{itemize}

EXAMPLES:

sage: W = ReflectionGroup(['A',2])            # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)  # optional - gap3

(continues on next page)
```
sage: SC.minkowski_summand(1)  # optional - gap3
A 0-dimensional polyhedron in QQ^2 defined as the convex hull of 1 vertex

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.minkowski_summand(1)
A 0-dimensional polyhedron in QQ^2 defined as the convex hull of 1 vertex
```

\textbf{pi()}

Return the element in the Coxeter group associated to \texttt{self}.

\textbf{EXAMPLES:}
```
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: w = W.from_reduced_word([1,2,1])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.pi().reduced_word()
[1, 2, 1]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.pi().reduced_word()
[1, 2, 1]
```

\textbf{word()}

Return the word in the simple generators associated to \texttt{self}.

\textbf{EXAMPLES:}
```
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: w = W.from_reduced_word([1,2,1])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.word()
(1, 2, 1, 2, 1)

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.word()
(1, 2, 1, 2, 1)
```

\textbf{class sage.combinat.subword_complex.SubwordComplexFacet(parent, positions, facet_test=True)}

\textbf{Bases:} \texttt{sage.topology.simplicial_complex.Simplex, sage.structure.element.Element}

A facet of a subword complex.

Facets of the subword complex $SC(Q, w)$ are complements of sets of positions in $Q$ defining a reduced expression for $w$.

\textbf{EXAMPLES:}
```
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: w = W.from_reduced_word([1,2,1])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w)
```

(continues on next page)
sage: F = SC[0]; F
(0, 1) # optional - gap3

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: F = SC[0]; F
(0, 1)

brick_vector(coefficients=None)

Return the brick vector of self.

This is the sum of the weight vectors in the extended weight configuration.

INPUT:

- coefficients – (optional) a list of coefficients used to scale the fundamental weights

See also:

extended_weight_configuration()

EXAMPLES:

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w) # optional - gap3
sage: F = SC([1,2]); F # optional - gap3
(1, 2)
sage: F.extended_weight_configuration() # optional - gap3
[(2/3, 1/3), (1/3, 2/3), (-1/3, 1/3), (1/3, 2/3), (-1/3, 1/3)]
sage: F.brick_vector() # optional - gap3
(2/3, 7/3)
sage: F.brick_vector(coefficients=[1,2]) # optional - gap3
(4/3, 11/3)

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: F = SC([1,2])
sage: F.brick_vector() # optional - gap3
(4/3, 14/3)
sage: F.brick_vector(coefficients=[1,2]) # optional - gap3
(8/3, 22/3)

extended_root_configuration()

Return the extended root configuration of self.

Let $Q = q_1 \ldots q_m \in S^*$ and $w \in W$. The extended root configuration of a facet $I$ of $SC(Q, w)$ is the sequence $r(I, 1), \ldots, r(I, m)$ of roots defined by $r(I, k) = \Pi Q_{[k-1] \setminus I} (\alpha_{q_k})$, where $\Pi Q_{[k-1] \setminus I}$ is the product of the simple reflections $q_i$ for $i \in [k-1] \setminus I$ in this order.

The extended root configuration is used to perform flips efficiently.

See also:

flip()
EXAMPLES:

```python
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: w = W.from_reduced_word([1,2,1])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1],w)  # optional - gap3
sage: F = SC([1,2]); F
(1, 2)
sage: F.extended_root_configuration()  # optional - gap3
[(1, 0), (1, 1), (-1, 0), (1, 1), (0, 1)]
```

```python
sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.extended_root_configuration()  # optional - gap3
[(1, 0), (1, 1), (-1, 0), (1, 1), (0, 1)]
```

**extended_weight_configuration**(coefficients=None)

Return the extended weight configuration of self.

Let $Q = q_1 \ldots q_m \in S^*$ and $w \in W$. The extended weight configuration of a facet $I$ of $SC(Q, w)$ is the sequence $w(I, 1), \ldots, w(I, m)$ of weights defined by $w(I, k) = \Pi Q_{k-1} \setminus I(\omega_{q_k})$, where $\Pi Q_{k-1} \setminus I$ is the product of the simple reflections $q_i$ for $i \in [k-1] \setminus I$ in this order.

The extended weight configuration is used to compute the brick vector.

INPUT:

- coefficients – (optional) a list of coefficients used to scale the fundamental weights

See also:

brick_vector()

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: w = W.from_reduced_word([1,2,1])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.extended_weight_configuration()  # optional - gap3
[(2/3, 1/3), (1/3, 2/3), (-1/3, 1/3), (1/3, 2/3), (-1/3, 1/3)]
sage: F.extended_weight_configuration(coefficients=(1,2))  # optional - gap3
[(2/3, 1/3), (1/3, 4/3), (-1/3, 1/3), (1/3, 4/3), (-1/3, 1/3)]
```

```python
sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.extended_weight_configuration()  # optional - gap3
[(4/3, 2/3), (2/3, 4/3), (-2/3, 2/3), (2/3, 4/3), (-2/3, 2/3)]
sage: F.extended_weight_configuration(coefficients=(1,2))  # optional - gap3
[(4/3, 2/3), (4/3, 8/3), (-2/3, 2/3), (4/3, 8/3), (-2/3, 2/3)]
```

**flip**(i, return_position=False)

Return the facet obtained after flipping position $i$ in self.
INPUT:

- $i$ – position in the word $Q$ (integer).
- $\text{return\_position}$ – boolean (default: False) tells whether the new position should be returned as well.

OUTPUT:

- The new subword complex facet.
- The new position if $\text{return\_position}$ is True.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: w = W.from_reduced_word([1,2,1])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1],w)  # optional - gap3
sage: F = SC([1,2]); F  # optional - gap3
(1, 2)
sage: F.flip(1)  # optional - gap3
(2, 3)
sage: F.flip(1, return_position=True)  # optional - gap3
((2, 3), 3)
```

```python
sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F  # optional - gap3
(1, 2)
sage: F.flip(1)  # optional - gap3
(2, 3)
sage: F.flip(1, return_position=True)  # optional - gap3
((2, 3), 3)
```

`is_vertex()`

Return True if self is a vertex of the brick polytope of self.parent.

A facet is a vertex of the brick polytope if its root cone is pointed. Note that this property is always satisfied for root-independent subword complexes.

See also:

`root\_cone()`

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',1])  # optional - gap3
sage: w = W.from_reduced_word([1])  # optional - gap3
sage: SC = SubwordComplex([1,1,1],w)
sage: F = SC([0,1]); F.is_vertex()  # optional - gap3
True
sage: F = SC([0,2]); F.is_vertex()  # optional - gap3
False
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: w = W.from_reduced_word([1,2,1])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1,2,1],w)
sage: F = SC([0,1,2,3]); F.is_vertex()  # optional - gap3
True
```

(continues on next page)
True
sage: F = SC([0,1,2,6]); F.is_vertex() # optional - gap3
False

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1,2,1],w)
sage: F = SC([0,1,2,3]); F.is_vertex() True
sage: F = SC([0,1,2,6]); F.is_vertex() False

kappa_preimage()

Return the fiber of self under the $\kappa$ map.

The $\kappa$ map sends an element $w \in W$ to the unique facet of $I \in SC(Q, w)$ such that the root configuration of $I$ is contained in $w(\Phi^+)$. In other words, $w$ is in the preimage of self under $\kappa$ if and only if $w^{-1}$ sends every root in the root configuration to a positive root.

EXAMPLES:

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1],w) # optional - gap3
sage: F = SC([1,2]); F (1, 2)
sage: F.kappa_preimage() # optional - gap3
[(1,4)(2,3)(5,6)]

sage: F = SC([0,4]); F (0, 4)
sage: F.kappa_preimage() # optional - gap3
[(1,3)(2,5)(4,6), (1,2,6)(3,4,5)]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F (1, 2)
sage: F.kappa_preimage() # optional - gap3
[
[-1  1]
[ 0  1]
]

sage: F = SC([0,4]); F (0, 4)
sage: F.kappa_preimage() # optional - gap3
[
[ 1  0] [-1  1]
[ 1 -1], [-1  0]
]
plot(list_colors=None, labels=[], thickness=3, fontsize=14, shift=(0, 0), compact=False, roots=True, **args)

In type $A$ or $B$, plot a pseudoline arrangement representing the facet $\text{self}$.

Pseudoline arrangements are graphical representations of facets of types $A$ or $B$ subword complexes.

**INPUT:**

- `list_colors` – list (default: `[]`) to change the colors of the pseudolines.
- `labels` – list (default: `[]`) to change the labels of the pseudolines.
- `thickness` – integer (default: `3`) for the thickness of the pseudolines.
- `fontsize` – integer (default: `14`) for the size of the font used for labels.
- `shift` – couple of coordinates (default: `(0, 0)`) to change the origin.
- `compact` – boolean (default: `False`) to require a more compact representation.
- `roots` – boolean (default: `True`) to print the extended root configuration.

**EXAMPLES:**

```sage
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: w = W.from_reduced_word([1,2,1])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1],w)  # optional - gap3
sage: F = SC([1,2]); F.plot()  # optional - gap3
Graphics object consisting of 26 graphics primitives
```

```sage
sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F.plot()
Graphics object consisting of 26 graphics primitives
```

```sage
sage: W = ReflectionGroup(['B',3])  # optional - gap3
sage: c = W.from_reduced_word([1,2,3])  # optional - gap3
sage: Q = c.reduced_word()**2 + W.w0.coxeter_sorting_word(c)  # optional - gap3
sage: SC = SubwordComplex(Q, W.w0)
sage: F = SC[15]; F.plot()  # optional - gap3
Graphics object consisting of 52 graphics primitives
```

**REFERENCES:** [PilStu]

**root_cone()**

Return the polyhedral cone generated by the root configuration of `self`.

See also:

**root_configuration()**

**EXAMPLES:**

```sage
sage: W = ReflectionGroup(['A',1])  # optional - gap3
sage: w = W.from_reduced_word([1])  # optional - gap3
sage: SC = SubwordComplex([1,1,1],w)  # optional - gap3
```
sage: F = SC([0,2]); F.root_cone() # optional - gap3
1-d cone in 1-d lattice N

sage: W = CoxeterGroup(['A',1])
sage: w = W.from_reduced_word([1])
sage: SC = SubwordComplex([1,1,1],w)
sage: F = SC([0,2]); F.root_cone()
1-d cone in 1-d lattice N

### root_configuration()

Return the root configuration of self.

Let $Q = q_1 \ldots q_m \in S^*$ and $w \in W$. The root configuration of a facet $I = [i_1, \ldots, i_n]$ of $\mathcal{SC}(Q, w)$ is the sequence $r(I, i_1), \ldots, r(I, i_n)$ of roots defined by $r(I, k) = \Pi Q_{[k-1] \setminus I}(\alpha_{q_k})$, where $\Pi Q_{[k-1] \setminus I}$ is the product of the simple reflections $q_i$ for $i \in [k-1] \setminus I$ in this order.

**EXAMPLES:**

```python
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.root_configuration() # optional - gap3
[(1, 1), (-1, 0)]
```

### show(*kwds, **args)

Show the facet self.

See also:

**plot()**

**EXAMPLES:**

```python
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F.show() # optional - gap3
```

### upper_root_configuration()

Return the positive roots of the root configuration of self.

**EXAMPLES:**

```python
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F.show() # optional - gap3
```
weight_cone()  
Return the polyhedral cone generated by the weight configuration of self.

See also:

weight_configuration()  

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: w = W.from_reduced_word([1,2,1])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1],w)  # optional - gap3
sage: F = SC([1,2]); F  # optional - gap3
(1, 2)
sage: F.weight_cone(); WC  # optional - gap3
2-d cone in 2-d lattice N
sage: WC.rays()  # optional - gap3
N((-1, 1),
in 2-d lattice N
```

weight_configuration()  
Return the weight configuration of self.

Let $Q = q_1 \ldots q_m \in S^*$ and $w \in W$. The weight configuration of a facet $I = [i_1, \ldots, i_n]$ of $SC(Q, w)$ is the sequence $w(I, i_1), \ldots, w(I, i_n)$ of weights defined by $w(I, k) = \Pi_{Q[k-1]\setminus I} (\omega_{q_k})$, where $\Pi_{Q[k-1]\setminus I}$ is the product of the simple reflections $q_i$ for $i \in [k-1] \setminus I$ in this order.

EXAMPLES:
**5.1.338 Super Tableaux**

AUTHORS:

- Matthew Lancellotti (2007): initial version

```python
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([[1,2,1,2,1],w]) # optional - gap3
sage: F = SC([1,2]); F # optional - gap3
(1, 2)
sage: F.weight_configuration() # optional - gap3
[(1/3, 2/3), (-1/3, 1/3)]
```

```python
sage: W = CoxeterGroup(['A',2])
```

```python
sage: w = W.from_reduced_word([1,2,1])

sage: SC = SubwordComplex([[1,2,1,2,1],w])

sage: F = SC([1,2]); F
(1, 2)
sage: F.weight_configuration()
[(2/3, 4/3), (-2/3, 2/3)]
```

### 5.1.338 Super Tableaux

A semistandard super tableau is a tableau with primed positive integer entries. As defined in [Muth2019], a semistandard super tableau weakly increases along the rows and down the columns. Also, the letters of even parity (unprimed) strictly increases down the columns, and letters of odd parity (primed) strictly increases along the rows. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

**INPUT:**

- `t` – a tableau, a list of iterables, or an empty list

**EXAMPLES:**

```python
sage: t = SemistandardSuperTableau([['1p','2','3'],[2,3]]); t
[[1', 2, 3'], [2, 3]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1' 2 3'
2 3
sage: t = Tableau([['1p','2'],[2]])
sage: s = SemistandardSuperTableau(t); s
[[1', 2], [2]]
sage: SemistandardSuperTableau([]) # The empty tableau
[]
```
check()
    Check that self is a valid semistandard super tableau.

class sage.combinat.super_tableau.SemistandardSuperTableaux(**kwds)
    Bases: sage.combinat.tableau.SemistandardTableaux
    The set of semistandard super tableaux.
    A semistandard super tableau is a tableau with primed positive integer entries. As defined in [Muth2019], a
    semistandard super tableau weakly increases along the rows and down the columns. Also, the letters of even
    parity (unprimed) strictly increases down the columns, and letters of odd parity (primed) strictly increases
    along the rows. Note that Sage uses the English convention for partitions and tableaux; the longer rows are
    displayed on top.
    EXAMPLES:
    
    sage: SST = SemistandardSuperTableaux(); SST
    Semistandard super tableaux

    Element
        alias of SemistandardSuperTableau

class sage.combinat.super_tableau.SemistandardSuperTableaux_all
    Bases: sage.combinat.super_tableau.SemistandardSuperTableaux
    All semistandard super tableaux.

class sage.combinat.super_tableau.StandardSuperTableau(parent, t, check=True, preprocessed=False)
    Bases: sage.combinat.super_tableau.SemistandardSuperTableau
    A standard super tableau.
    A standard super tableau is a semistandard super tableau whose entries are in bijection with positive primed
    integers $1', 1, 2', 2, 3', 3, 4'$. For more information refer [Muth2019].
    INPUT:
    * t – a Tableau, a list of iterables, or an empty list
    EXAMPLES:
    
    sage: t = StandardSuperTableau([['1'''],1,''2''',2,'''3'''],[3,'''4''']); t
    [[1', 1, 2', 2, 3'], [3, 4']]
    sage: t.shape()
    [5, 2]
    sage: t.pp() # pretty printing
    1' 1 2' 2 3'
    3 4'
    sage: t.is_standard()
    True
    sage: StandardSuperTableau([]) # The empty tableau
    []

    check()
        Check that self is a standard tableau.

    is_standard()
        Return True since self is a standard super tableau.
    EXAMPLES:
class sage.combinat.super_tableau.StandardSuperTableaux(**kwds)

The set of standard super tableaux.

A standard super tableau is a tableau whose entries are primed positive integers, which are strictly increasing in rows and down columns and contains each letters from 1',1,2'...n exactly once.

For more information refer [Muth2019].

INPUT:

• n – a non-negative integer or a partition.

EXAMPLES:

sage: SST = StandardSuperTableaux()
sage: SST
Standard super tableaux
sage: SST([["1'",1,"2'"],2,["3'"],3])
[[1', 1, 2'], [3', 2], [3, 4']]
sage: SST = StandardSuperTableaux(3)
sage: SST
Standard super tableaux of size 3
sage: SST.first()
[[1', 1, 2']]
sage: SST.last()
[[1'], [1], [2']]
sage: SST.cardinality()
4
sage: SST.list()
[[[1', 1, 2'], [[1', 2'], [1]], [[1', 1], [2']], [[1'], [1], [2']]]

sage: SST = StandardSuperTableaux([3,2])
sage: SST
Standard super tableaux of shape [3, 2]

Element

alias of StandardSuperTableau

class sage.combinat.super_tableau.StandardSuperTableaux_all

All standard super tableaux.

class sage.combinat.super_tableau.StandardSuperTableaux_shape(p)

Bases: sage.combinat.super_tableau.StandardSuperTableaux

Standard super tableaux of a fixed shape p.

cardinality()

Return the number of standard super tableaux of given shape.

The standard super tableaux of a fixed shape p are in bijection with the corresponding standard tableaux (under the alphabet relabeling). Refer sage.combinat.tableau.StandardTableaux_shape for more details.
EXAMPLES:

```python
sage: StandardSuperTableaux([3,2,1]).cardinality()
16
sage: StandardSuperTableaux([2,2]).cardinality()
2
sage: StandardSuperTableaux([5]).cardinality()
1
sage: StandardSuperTableaux([6,5,5,3]).cardinality()
6651216
sage: StandardSuperTableaux([]).cardinality()
1
```

class sage.combinat.super_tableau.StandardSuperTableaux_size(n)

Standard super tableaux of fixed size $n$.

EXAMPLES:

```python
sage: [ t for t in StandardSuperTableaux(1) ]
[[[1]]]
sage: [ t for t in StandardSuperTableaux(2) ]
[[[1', 1]], [[1', [1]]]]
sage: [ t for t in StandardSuperTableaux(3) ]
[[[1', 1, 2']], [[1', 2'], [1]], [[1', 1], [2']], [[1'], [1], [2']]]
sage: StandardSuperTableaux(4)[:]
[[[1', 1, 2', 2]],
 [[1', 2', 2], [1]],
 [[1', 1, 2'], [2']],
 [[1', 2'], [1, 2]],
 [[1', 1], [2', 2]],
 [[1', 2], [1', 2']],
 [[1', 2'], [1], [2']],
 [[1', 2'], [1], [2]],
 [[1', 1], [2'], [2]],
 [[1'], [1], [2'], [2]]]
```

cardinality()

Return the number of all standard super tableaux of size $n$.

The standard super tableaux of size $n$ are in bijection with the corresponding standard tableaux (under the alphabet relabeling). Refer `sage.combinat.tableau.StandardTableaux_size` for more details.

EXAMPLES:

```python
sage: StandardSuperTableaux(3).cardinality()
4
sage: ns = [1,2,3,4,5,6]
sage: sts = [StandardSuperTableaux(n) for n in ns]
sage: all(st.cardinality() == len(st.list()) for st in sts)
True
sage: StandardSuperTableaux(50).cardinality()  # long time
27886995605342342839104615869259776
```

3232 Chapter 5. Comprehensive Module List
5.1.339 Super Partitions

AUTHORS:

- Mike Zabrocki

A super partition of size $n$ and fermionic sector $m$ is a pair consisting of a strict partition of some integer $r$ of length $m$ (that may end in a 0) and an integer partition of $n - r$.

This module provides tools for manipulating super partitions.

Super partitions are the indexing set for symmetric functions in super space.

Super partitions may be input in two different formats: one as a pair consisting of fermionic (strict partition) and a bosonic (partition) part and the other as a list of integer values where the negative entries come first and are listed in strict order followed by the positive values in weak order.

A super partition is displayed as two partitions separated by a semicolon as a default. Super partitions may also be displayed as a weakly increasing sequence of integers that are strict if the numbers are not positive.

These combinatorial objects index the space of symmetric polynomials in two sets of variables, one commuting and one anti-commuting, and they are known as symmetric functions in super space (hence the origin of the name super partitions).

EXAMPLES:

```python
sage: SuperPartitions()
Super Partitions
sage: SuperPartitions(2)
Super Partitions of 2
sage: SuperPartitions(2).cardinality()
8
sage: SuperPartitions(4,2)
Super Partitions of 4 and of fermionic sector 2
sage: [[2,0],[1,1]] in SuperPartitions(4,2)
True
sage: [[1,0],[1,1]] in SuperPartitions(4,2)
False
sage: [[1,0],[2,1]] in SuperPartitions(4)
True
sage: [[1,0],[2,2,1]] in SuperPartitions(4)
False
sage: [[1,0],[2,1]] in SuperPartitions()
True
sage: [[1,1],[2,1]] in SuperPartitions()
False
sage: [-2, 0, 1, 1] in SuperPartitions(4,2)
True
sage: [-1, 0, 1, 1] in SuperPartitions(4,2)
False
sage: [-2, -2, 2, 1] in SuperPartitions(7,2)
False
```

REFERENCES:

- [JL2016]

```python
class sage.combinat.superpartition.SuperPartition(parent, lst, check=True, immutable=True)
    Bases: sage.structure.list_clone.ClonableArray
```
A super partition.

A super partition of size $n$ and fermionic sector $m$ is a pair consisting of a strict partition of some integer $r$ of length $m$ (that may end in a 0) and an integer partition of $n - r$.

**EXAMPLES:**

```python
sage: sp = SuperPartition([[1,0],[2,2,1]]); sp
[1, 0; 2, 2, 1]
sage: sp[0]
(1, 0)
sage: sp[1]
(2, 2, 1)
sage: sp.fermionic_degree()
2
sage: sp.bosonic_degree()
6
sage: sp.length()
5
sage: sp.conjugate()
[4, 2; ]
```

**a_part()**

The antisymmetric part as a list of strictly decreasing integers.

**OUTPUT:**

- a list

**EXAMPLES:**

```python
sage: SuperPartition([[3,1],[2,2,1]]).antisymmetric_part()
[3, 1]
```

**add_horizontal_border_strip_star(h)**

Return a list of super partitions that differ from `self` by a horizontal strip.

The notion of horizontal strip comes from the Pieri rule for the Schur-star basis of symmetric functions in super space (see Theorem 7 from [JL2016]).

**INPUT:**

- h – number of cells in the horizontal strip

**OUTPUT:**

- a list of super partitions

**EXAMPLES:**

```python
sage: SuperPartition([[4,1],[3]]).add_horizontal_border_strip_star(3)
[[[3, 1; 7],
  [4, 1; 6],
  [3, 0; 6, 2],
  [3, 1; 6, 1],
  [4, 0; 5, 2],
  [4, 1; 5, 1],
```

(continues on next page)
add_horizontal_border_strip_star_bar($h$)

List super partitions that differ from \texttt{self} by a horizontal strip.

The notion of horizontal strip comes from the Pieri rule for the Schur-star-bar basis of symmetric functions in super space (see Theorem 10 from [JL2016]).

**INPUT:**

• $h$ – number of cells in the horizontal strip

**OUTPUT:**

• a list of super partitions

**EXAMPLES:**

```python
sage: SuperPartition([[4,1],[5,4]]).add_horizontal_border_strip_star_bar(3)
[[4, 1; 8, 4],
 [4, 1; 7, 5],
 [4, 2; 7, 4],
 [4, 1; 7, 4, 1],
 [4, 2; 6, 5],
 [4, 1; 6, 5, 1],
 [4, 3; 6, 4],
 [4, 2; 6, 4, 1],
 [4, 1; 6, 4, 2],
 [4, 3; 5, 5],
 [4, 2; 5, 5, 1],
 [4, 1; 5, 5, 2],
 [4, 3; 5, 4, 1],
 [4, 1; 5, 4, 3]]
```
Combinatorics, Release 9.7

```python
sage: SuperPartition([[3,1],[2,2,1]]).antisymmetric_part()
[3, 1]
sage: SuperPartition([[2,1,0],[3,3]]).antisymmetric_part()
[2, 1, 0]
```

**bi_degree()**
Return the bidegree of `self`, which is a pair consisting of the bosonic and fermionic degree.

**OUTPUT:**
• a tuple of two integers

**EXAMPLES:**
```python
sage: SuperPartition([[3,1],[2,2,1]]).bi_degree()
(9, 2)
sage: SuperPartition([[2,1,0],[3,3]]).bi_degree()
(9, 3)
```

**bosonic_degree()**
Return the bosonic degree of `self`.

The `bosonic degree` is the sum of the sizes of the antisymmetric and symmetric parts.

**OUTPUT:**
• an integer

**EXAMPLES:**
```python
sage: SuperPartition([[3,1],[2,2,1]]).bosonic_degree()
9
sage: SuperPartition([[2,1,0],[3,3]]).bosonic_degree()
9
```

**bosonic_length()**
Return the length of the partition of the symmetric part.

**OUTPUT:**
• an integer

**EXAMPLES:**
```python
sage: SuperPartition([[3,1],[2,2,1]]).bosonic_length()
3
sage: SuperPartition([[2,1,0],[3,3]]).bosonic_length()
2
```

**check()**
Check that `self` is a valid super partition.

**EXAMPLES:**
```python
sage: SP = SuperPartition([[1],[1]])
sage: SP.check()
```

**conjugate()**
Conjugate of a super partition.
The *conjugate* of a super partition is defined by conjugating the circled diagram.

**OUTPUT:**

- a `SuperPartition`

**EXAMPLES:**

```python
sage: SuperPartition([[3, 1, 0], [4, 3, 2, 1]]).conjugate()
[6, 4, 1; 3]
sage: all(sp == sp.conjugate().conjugate() for sp in SuperPartitions(4))
True
sage: all(sp.conjugate() in SuperPartitions(3,2) for sp in SuperPartitions(3,2))
True
```

**degree()**

Return the bosonic degree of `self`.

The *bosonic degree* is the sum of the sizes of the antisymmetric and symmetric parts.

**OUTPUT:**

- an integer

**EXAMPLES:**

```python
sage: SuperPartition([[3,1],[2,2,1]]).bosonic_degree()
9
sage: SuperPartition([[2,1,0],[3,3]]).bosonic_degree()
9
```

**dominates(other)**

Return True if and only if `self` dominates `other`.

If the symmetric and anti-symmetric parts of `self` and `other` are not the same size then the result is False.

**EXAMPLES:**

```python
sage: LA = SuperPartition([[2,1],[2,1,1]])
sage: LA.dominates([[2,1],[3,1]])
False
sage: LA.dominates([[2,1],[1,1,1,1]])
True
sage: LA.dominates([[2,1],[1,1,1,1]])
False
sage: LA.dominates([[3],[2,1,1]])
False
sage: LA.dominates([[1],[1]*6])
False
```

**fermionic_degree()**

Return the fermionic degree of `self`.

The *fermionic degree* is the length of the antisymmetric part.

**OUTPUT:**

- an integer

**EXAMPLES:**
fermionic_degree()  
Return the fermionic degree of self.  
The fermionic degree is the length of the antisymmetric part.  

OUTPUT:  
• an integer  

EXAMPLES:  

```sage  
SuperPartition([[3,1],[2,2,1]]).fermionic_degree()  
2  
SuperPartition([[2,1,0],[3,3]]).fermionic_degree()  
3  
```

static from_circled_diagram(shape, corners)  
Construct a super partition from a circled diagram.  

A circled diagram consists of a partition of the concatenation of the antisymmetric and symmetric parts 
and a list of addable cells of the partition which indicate the location of the circled cells.  

INPUT:  
• shape – a partition or list of integers  
• corners – a list of removable cells of shape  

OUTPUT:  
• a SuperPartition  

EXAMPLES:  

```sage  
SuperPartition.from_circled_diagram([3, 2, 2, 1, 1], [(0, 3), (3, 1)])  
[3, 1; 2, 2, 1]  
SuperPartition.from_circled_diagram([3, 3, 2, 1], [(2, 2), (3, 1), (4, 0)])  
[2, 1, 0; 3, 3]  
from_cd = SuperPartition.from_circled_diagram  
all(sp == from_cd(*sp.to_circled_diagram()) for sp in SuperPartitions(4))  
True  
```

length()  
Return the length of self, which is the sum of the lengths of the antisymmetric and symmetric part.  

OUTPUT:  
• an integer  

EXAMPLES:  

```sage  
SuperPartition([[3,1],[2,2,1]]).length()  
5  
SuperPartition([[2,1,0],[3,3]]).length()  
5  
```
s_part()
The symmetric part as a list of weakly decreasing integers.

OUTPUT:
• a list

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).symmetric_part()
[2, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).symmetric_part()
[3, 3]
```

shape_circled_diagram()
A concatenated partition with an extra cell for each antisymmetric part

OUTPUT:
• a partition

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).shape_circled_diagram()
[4, 2, 2, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).shape_circled_diagram()
[3, 3, 3, 2, 1]
```

sign()
Return the sign of a permutation of cycle type the symmetric part of self.

OUTPUT:
• either 1 or −1

EXAMPLES:

```
sage: SuperPartition([[1,0],[3,1,1]]).sign()
-1
sage: SuperPartition([[1,0],[3,2,1]]).sign()
1
sage: sum(sp.sign()/sp.zee() for sp in SuperPartitions(6,0))
0
```

symmetric_part()
The symmetric part as a list of weakly decreasing integers.

OUTPUT:
• a list

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).symmetric_part()
[2, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).symmetric_part()
[3, 3]
```

to_circled_diagram()
The shape of the circled diagram and a list of addable cells
A circled diagram consists of a partition for the outer shape and a list of removable cells of the partition indicating the location of the circled cells.

**OUTPUT:**

- A list consisting of a partition and a list of pairs of integers

**EXAMPLES:**

```python
sage: SuperPartition([[3,1],[2,2,1]]).to_circled_diagram()
[[3, 2, 2, 1, 1], [(0, 3), (3, 1)]]
sage: SuperPartition([[2,1,0],[3,3]]).to_circled_diagram()
[[3, 3, 2, 1, 1], [(2, 2), (3, 1), (4, 0)]]
sage: from_cd = SuperPartition.from_circled_diagram
sage: all(sp == from_cd(*sp.to_circled_diagram()) for sp in SuperPartitions(4))
True
```

**to_composition()**

Concatenate the antisymmetric and symmetric parts to a composition.

**OUTPUT:**

- A (possibly weak) composition

**EXAMPLES:**

```python
sage: SuperPartition([[3,1],[2,2,1]]).to_composition()
[3, 1, 2, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).to_composition()
[2, 1, 0, 3, 3]
sage: SuperPartition([[2,1,0],[3,3]]).to_composition().parent()
Compositions of non-negative integers
```

**to_list()**

The list of two lists with the antisymmetric and symmetric parts.

**EXAMPLES:**

```python
sage: SuperPartition([[1],[1]]).to_list()
[[1], [1]]
sage: SuperPartition([[],[1]]).to_list()
[[], [1]]
```

**to_partition()**

Concatenate and sort the antisymmetric and symmetric parts to a partition.

**OUTPUT:**

- A partition

**EXAMPLES:**

```python
sage: SuperPartition([[3,1],[2,2,1]]).to_partition()
[3, 2, 2, 1, 1]
sage: SuperPartition([[2,1,0],[3,3]]).to_partition()
[3, 3, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).to_partition().parent()
Partitions
```
zee()  
Return the centralizer size of a permutation of cycle type symmetric part of self.

OUTPUT:
• a positive integer

EXAMPLES:

```
sage: SuperPartition([[1,0],[3,1,1]]).zee()
6
sage: SuperPartition([[1],[2,2,1]]).zee()
8
sage: sum(1/sp.zee() for sp in SuperPartitions(6,0))
1
```

class sage.combinat.superpartition.SuperPartitions(is_infinite=False)
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Super partitions.
A super partition of size \( n \) and fermionic sector \( m \) is a pair consisting of a strict partition of some integer \( r \) of length \( m \) (that may end in a 0) and an integer partition of \( n - r \).

INPUT:
• \( n \) – an integer (optional: default None)
• \( m \) – if \( n \) is specified, an integer (optional: default None)

Super partitions are the indexing set for symmetric functions in super space.

EXAMPLES:

```
sage: SuperPartitions()
Super Partitions
sage: SuperPartitions(2)
Super Partitions of 2
sage: SuperPartitions(2).cardinality()
8
sage: SuperPartitions(4,2)
Super Partitions of 4 and of fermionic sector 2
sage: [[2,0],[1,1]] in SuperPartitions(4,2)
True
sage: [[1,0],[1,1]] in SuperPartitions(4,2)
False
sage: [[1,0],[2,1]] in SuperPartitions(4)
True
sage: [[1,0],[2,2,1]] in SuperPartitions(4)
False
sage: [[1,0],[2,1]] in SuperPartitions()
True
sage: [[1,1],[2,1]] in SuperPartitions()
False
```

Element
alias of SuperPartition
options(*get_value, **set_value)

OPTIONS:

- display – (default: default) Specifies how the super partitions should be printed
  - default – the super partition is displayed in a form [fermionic part; bosonic part]
  - list – the super partitions are displayed in a list of two lists
  - pair – the super partition is displayed as a list of integers

See GlobalOptions for more features of these options.

class sage.combinat.superpartition.SuperPartitions_all
    Bases: sage.combinat.superpartition.SuperPartitions

    Initialize self.

class sage.combinat.superpartition.SuperPartitions_n(n)
    Bases: sage.combinat.superpartition.SuperPartitions

    Initialize self.

class sage.combinat.superpartition.SuperPartitions_n_m(n, m)
    Bases: sage.combinat.superpartition.SuperPartitions

    Initialize self.

5.1.340 Symmetric Group Algebra

sage.combinat.symmetric_group_algebra.HeckeAlgebraSymmetricGroupT(R, n=q=None)

Return the Hecke algebra of the symmetric group $S_n$ on the T-basis with quantum parameter $q$ over the ring $R$.

If $R$ is a commutative ring and $q$ is an invertible element of $R$, and if $n$ is a nonnegative integer, then the Hecke algebra of the symmetric group $S_n$ over $R$ with quantum parameter $q$ is defined as the algebra generated by the generators $T_1, T_2, \ldots, T_{n-1}$ with relations

$$T_iT_{i+1}T_i = T_{i+1}T_iT_{i+1}$$

for all $i < n - 1$ ("braid relations"),

$$T_iT_j = T_jT_i$$

for all $i$ and $j$ such that $|i - j| > 1$ ("locality relations"), and

$$T_i^2 = q + (q - 1)T_i$$

for all $i$ (the "quadratic relations", also known in the form $(T_i + 1)(T_i - q) = 0$). (This is only one of several existing definitions in literature, not all of which are fully equivalent. We are following the conventions of [Go1993]). For any permutation $w \in S_n$, we can define an element $T_w$ of this Hecke algebra by setting $T_w = T_{i_1}T_{i_2}\cdots T_{i_k}$, where $w = s_{i_1}s_{i_2}\cdots s_{i_k}$ is a reduced word for $w$ (with $s_i$ meaning the transposition $(i, i+1)$, and the product of permutations being evaluated by first applying $s_{i_k}$, then $s_{i_{k-1}}$, etc.). This element is independent of the choice of the reduced decomposition, and can be computed in Sage by calling $H[w]$ where $H$ is the Hecke algebra and $w$ is the permutation.

The Hecke algebra of the symmetric group $S_n$ with quantum parameter $q$ over $R$ can be seen as a deformation of the group algebra $RS_n$; indeed, it becomes $RS_n$ when $q = 1$. 

3242 Chapter 5. Comprehensive Module List
Warning: The multiplication on the Hecke algebra of the symmetric group does not follow the global option mult of the Permutations class (see options()). It is always as defined above. It does not match the default option (mult=l2r) of the symmetric group algebra!

EXAMPLES:

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3)
Hecke algebra of the symmetric group of order 3 on the T basis over Univariate Polynomial Ring in q over Rational Field

sage: HeckeAlgebraSymmetricGroupT(QQ, 3, 2)
Hecke algebra of the symmetric group of order 3 with q=2 on the T basis over Rational Field
```

The multiplication on the Hecke algebra follows a different convention than the one on the symmetric group algebra does by default:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: H3([1,3,2]) * H3([2,1,3])
T[3, 1, 2]
sage: S3 = SymmetricGroupAlgebra(QQ, 3)
sage: S3([1,3,2]) * S3([2,1,3])
[2, 3, 1]
sage: TestSuite(H3).run()
```

class sage.combinat.symmetric_group_algebra.HeckeAlgebraSymmetricGroup_generic(R, n, q=None)

Bases: sage.combinat.free_module.CombinatorialFreeModule

one_basis()

Return the identity permutation.

EXAMPLES:

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3).one()
T[1, 2, 3]
```

q()

Return the variable or parameter $q$.

EXAMPLES:

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3).q()
q
sage: HeckeAlgebraSymmetricGroupT(QQ, 3, 2).q()
2
```

class sage.combinat.symmetric_group_algebra.HeckeAlgebraSymmetricGroup_t(R, n, q=None)

Bases: sage.combinat.symmetric_group_algebra.HeckeAlgebraSymmetricGroup_generic

algebra_generators()

Return the generators of the algebra.

EXAMPLES:
Combinatorics, Release 9.7

```
sage: HeckeAlgebraSymmetricGroupT(QQ,3).algebra_generators()
[T[2, 1, 3], T[1, 3, 2]]
```

**jucys_murphy** (*k*)

Return the Jucys-Murphy element \( J_k \) of the Hecke algebra.

These Jucys-Murphy elements are defined by

\[
J_k = (T_{k-1}T_{k-2}\cdots T_1)(T_1T_2\cdots T_{k-1}).
\]

More explicitly,

\[
J_k = q^{k-1} + \sum_{i=1}^{k-1} (q^l - q^{l-1})T_{(l,k)}.
\]

For generic \( q \), the \( J_k \) generate a maximal commutative sub-algebra of the Hecke algebra.

**Warning:** The specialization \( q = 1 \) does not map these elements \( J_k \) to the Young-Jucys-Murphy elements of the group algebra \( RS_n \). (Instead, it maps the “reduced” Jucys-Murphy elements \((J_k - q^{k-1})/(q - 1)\) to the Young-Jucys-Murphy elements of \( RS_n \).)

**EXAMPLES:**

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ,3)
sage: j2 = H3.jucys_murphy(2); j2
q*T[1, 2, 3] + (q-1)*T[2, 1, 3]
sage: j3 = H3.jucys_murphy(3); j3
q^2*T[1, 2, 3] + (q^2-q)*T[1, 3, 2] + (q-1)*T[3, 2, 1]
sage: j2*j3 == j3*j2
True
sage: j0 = H3.jucys_murphy(1); j0 == H3.one()
True
sage: H3.jucys_murphy(0)
Traceback (most recent call last):
  ... ValueError: k (= 0) must be between 1 and n (= 3)
```

**product_on_basis** (*perm1, perm2*)

**EXAMPLES:**

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3, 1)
sage: a = H3([2,1,3])+2*H3([1,2,3])-H3([3,2,1])
sage: a^2 #indirect doctest
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: a = QS3([2,1,3])+2*QS3([1,2,3])-QS3([3,2,1])
sage: a^2
6*[1, 2, 3] + 4*[2, 1, 3] - [2, 3, 1] - [3, 1, 2] - 4*[3, 2, 1]
```

**t** (*i*)

Return the element \( T_i \) of the Hecke algebra \( self \).

**EXAMPLES:**
Combinatorics, Release 9.7

```python
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: H3.t(1)
T[2, 1, 3]
sage: H3.t(2)
T[1, 3, 2]
sage: H3.t(0)
Traceback (most recent call last):
... ValueError: i (= 0) must be between 1 and n-1 (= 2)
```

\textbf{t\_action}(a, i)

Return the product \( T_i \cdot a \).

\textbf{EXAMPLES:}

```python
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: a = H3([2,1,3])+2*H3([1,2,3])
sage: H3.t\_action(a, 1)
q*T[1, 2, 3] + (q+1)*T[2, 1, 3]
sage: H3.t(1)*a
q*T[1, 2, 3] + (q+1)*T[2, 1, 3]
```

\textbf{t\_action\_on\_basis}(perm, i)

Return the product \( T_i \cdot T_{\text{perm}} \), where \( \text{perm} \) is a permutation in the symmetric group \( S_n \).

\textbf{EXAMPLES:}

```python
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: H3.t\_action\_on\_basis(Permutation([2,1,3]), 1)
q*T[1, 2, 3] + (q-1)*T[2, 1, 3]
sage: H3.t\_action\_on\_basis(Permutation([1,2,3]), 1)
T[2, 1, 3]
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3, 1)
sage: H3.t\_action\_on\_basis(Permutation([2,1,3]), 1)
T[1, 2, 3]
sage: H3.t\_action\_on\_basis(Permutation([1,3,2]), 2)
T[1, 2, 3]
```

```
sage.combinat.symmetric_group_algebra.SymmetricGroupAlgebra(R, W, category=None)

Return the symmetric group algebra of order \( W \) over the ring \( R \).

\textbf{INPUT:}

- \( W \) – a symmetric group; alternatively an integer \( n \) can be provided, as shorthand for \( \text{Permutations}(n) \).
- \( R \) – a base ring
- \text{category} – a category (default: the category of \( W \))

This supports several implementations of the symmetric group. At this point this has been tested with \( W=\text{Permutations}(n) \) and \( W=\text{SymmetricGroup}(n) \).

\textbf{Warning:} Some features are failing in the latter case, in particular if the domain of the symmetric group is not \( 1, \ldots, n \).
```
Note: The brave can also try setting \( W = \text{WeylGroup}(\['A', n-1\]) \), but little support for this currently exists.

**EXAMPLES:**

```python
sage: QS3 = SymmetricGroupAlgebra(QQ, 3); QS3
Symmetric group algebra of order 3 over Rational Field
sage: QS3(1)
[1, 2, 3]
sage: QS3(2)
2*[1, 2, 3]
sage: basis = [QS3(p) for p in Permutations(3)]
sage: a = sum(basis); a
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: a^2
6*[1, 2, 3] + 6*[1, 3, 2] + 6*[2, 1, 3] + 6*[2, 3, 1] + 6*[3, 1, 2] + 6*[3, 2, 1]
sage: a^2 == 6*a
True
sage: b = QS3([3, 1, 2])
sage: b
[3, 1, 2]
sage: b*a
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: b*a == a
True
```

We now construct the symmetric group algebra by providing explicitly the underlying group:

```python
sage: SGA = SymmetricGroupAlgebra(QQ, Permutations(4)); SGA
Symmetric group algebra of order 4 over Rational Field
sage: SGA.group()
Standard permutations of 4
sage: SGA.an_element()
[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 3*[1, 3, 2, 4] + [4, 1, 2, 3]
sage: SGA = SymmetricGroupAlgebra(QQ, SymmetricGroup(4)); SGA
Symmetric group algebra of order 4 over Rational Field
sage: SGA.group()
Symmetric group of order 4! as a permutation group
sage: SGA.an_element()
() + (2,3,4) + 2*(1,3)(2,4) + 3*(1,4)(2,3)
sage: SGA = SymmetricGroupAlgebra(QQ, WeylGroup(['A', 3], prefix='s')); SGA
Symmetric group algebra of order 4 over Rational Field
sage: SGA.group()
Weyl Group of type ['A', 3] (as a matrix group acting on the ambient space)
sage: SGA.an_element()
s1*s2*s3 + 3*s3*s2 + 2*s3 + 1
```

The preferred way to construct the symmetric group algebra is to go through the usual algebra method:

```python
sage: SGA = Permutations(3).algebra(QQ); SGA
Symmetric group algebra of order 3 over Rational Field
```
Combinatorics, Release 9.7

The canonical embedding from the symmetric group algebra of order $n$ to the symmetric group algebra of order $p > n$ is available as a coercion:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.coerce_map_from(QS3)
Generic morphism:
  From: Symmetric group algebra of order 3 over Rational Field
  To: Symmetric group algebra of order 4 over Rational Field
sage: x3 = QS3([3,1,2]) + 2 * QS3([2,3,1]); x3
2*[2, 3, 1] + [3, 1, 2]
sage: QS4(x3)
2*[2, 3, 1, 4] + [3, 1, 2, 4]
```

This allows for mixed expressions:

```
sage: x4 = 3*QS4([3, 1, 4, 2])
sage: x3 + x4
2*[2, 3, 1, 4] + [3, 1, 2, 4] + 3*[3, 1, 4, 2]
sage: QS0 = SymmetricGroupAlgebra(QQ, 0)
sage: QS1 = SymmetricGroupAlgebra(QQ, 1)
sage: x0 = QS0([])
sage: x1 = QS1([1])
sage: x0 * x1
[1]
sage: x3 - (2*x0 + x1) - x4
-3*[1, 2, 3, 4] + 2*[2, 3, 1, 4] + [3, 1, 2, 4] - 3*[3, 1, 4, 2]
```

Caveat: to achieve this, constructing `SymmetricGroupAlgebra(QQ, 10)` currently triggers the construction of all symmetric group algebras of smaller order. Is this a feature we really want to have?

**Warning:** The semantics of multiplication in symmetric group algebras with index set `Permutations(n)` is determined by the order in which permutations are multiplied, which currently defaults to “in such a way that multiplication is associative with permutations acting on integers from the right”, but can be changed to the opposite order at runtime by setting the global variable `Permutations.options['mult']` (see `sage.combinat.permutation.Permutations.options()`). On the other hand, the semantics of multiplication in symmetric group algebras with index set `SymmetricGroup(n)` does not depend on this global variable. (This has the awkward consequence that the coercions between these two sorts of symmetric group algebras do not respect multiplication when this global variable is set to 'r2l'.) In view of this, it is recommended that code not rely on the usual multiplication function, but rather use the methods `left_action_product()` and `right_action_product()` for multiplying permutations (these methods don’t depend on the setting). See `trac ticket #14885` for more information.
We conclude by constructing the algebra of the symmetric group as a monoid algebra:

```python
sage: QS3 = SymmetricGroupAlgebra(QQ, 3, category=Monoids())
sage: QS3.category()
Category of finite dimensional cellular monoid algebras over Rational Field
sage: TestSuite(QS3).run(skip=['_test_construction'])
```

```python
class sage.combinat.symmetric_group_algebra.SymmetricGroupAlgebra_n(R, W, category)
  Bases: sage.algebras.group_algebra.GroupAlgebra_class

  algebra_generators()
  Return generators of this group algebra (as algebra) as a list of permutations.

  The generators used for the group algebra of \(S_n\) are the transposition \((2, 1)\) and the \(n\)-cycle \((1, 2, \ldots, n)\), unless \(n \leq 1\) (in which case no generators are needed).

  EXAMPLES:

  ```python
  sage: SymmetricGroupAlgebra(ZZ,5).algebra_generators()
  Family ([2, 1, 3, 4, 5], [2, 3, 4, 5, 1])
  sage: SymmetricGroupAlgebra(QQ,0).algebra_generators()
  Family ()
  sage: SymmetricGroupAlgebra(QQ,1).algebra_generators()
  Family ()
  ```

  antipode(\(x\))
  Return the image of the element \(x\) of self under the antipode of the Hopf algebra self (where the comultiplication is the usual one on a group algebra).

  Explicitly, this is obtained by replacing each permutation \(\sigma\) by \(\sigma^{-1}\) in \(x\) while keeping all coefficients as they are.

  EXAMPLES:

  ```python
  sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.antipode(2 * QS4([1, 3, 4, 2]) - 1/2 * QS4([1, 4, 2, 3]))
  -1/2*[1, 3, 4, 2] + 2*[1, 4, 2, 3]
sage: all( QS4.antipode(QS4(p)) == QS4(p.inverse())
  ....:     for p in Permutations(4) )
  True
  sage: ZS3 = SymmetricGroupAlgebra(ZZ, 3)
sage: ZS3.antipode(ZS3.zero())
  0
  sage: ZS3.antipode(-ZS3(Permutation([2, 3, 1])))
  [-3, 1, 2]
  ```

  binary_unshuffle_sum\((k)\)
  Return the \(k\)-th binary unshuffle sum in the group algebra self.

  The \(k\)-th binary unshuffle sum in the symmetric group algebra \(RS_n\) over a ring \(R\) is defined as the sum of all permutations \(\sigma \in S_n\) satisfying \(\sigma(1) < \sigma(2) < \cdots < \sigma(k)\) and \(\sigma(k + 1) < \sigma(k + 2) < \cdots < \sigma(n)\).

  This element has the property that, if it is denoted by \(t_k\), and if the \(k\)-th semi-RSW element (see `semi_rsw_element()`) is denoted by \(s_k\), then \(s_kS(t_k)\) and \(t_kS(s_k)\) both equal the \(k\)-th Reiner-Saliola-Welker shuffling element of \(RS_n\) (see `rsw_shuffling_element()`).
The $k$-th binary unshuffle sum is the image of the complete non-commutative symmetric function $S^{(k,n-k)}$ in the ring of non-commutative symmetric functions under the canonical projection on the symmetric group algebra (through the descent algebra).

**EXAMPLES:**

The binary unshuffle sums on $Q\_S_3$:

```sage
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.binary_unshuffle_sum(0)
[1, 2, 3]
sage: QS3.binary_unshuffle_sum(1)
[1, 2, 3] + [2, 1, 3] + [3, 1, 2]
sage: QS3.binary_unshuffle_sum(2)
[1, 2, 3] + [1, 3, 2] + [2, 3, 1]
sage: QS3.binary_unshuffle_sum(3)
[1, 2, 3]
sage: QS3.binary_unshuffle_sum(4)
0
```

Let us check the relation with the $k$-th Reiner-Saliola-Welker shuffling element stated in the docstring:

```sage
def test_rsw(n):
    ZSn = SymmetricGroupAlgebra(ZZ, n)
    for k in range(1, n):
        a = ZSn.semi_rsw_element(k)
        b = ZSn.binary_unshuffle_sum(k)
        c = ZSn.left_action_product(a, ZSn.antipode(b))
        d = ZSn.left_action_product(b, ZSn.antipode(a))
        e = ZSn.rsw_shuffling_element(k)
        if c != e or d != e:
            return False
    return True
	sage: test_rsw(3)
True
	sage: test_rsw(4)  # long time
True
	sage: test_rsw(5)  # long time
True
```

Let us also check the statement about the complete non-commutative symmetric function:

```sage
def test_rsw_ncsf(n):
    ZSn = SymmetricGroupAlgebra(ZZ, n)
    NSym = NonCommutativeSymmetricFunctions(ZZ)
    S = NSym.S()
    for k in range(1, n):
        a = S(Composition([k, n-k])).to_symmetric_group_algebra()
        if a != ZSn.binary_unshuffle_sum(k):
            return False
    return True
	sage: test_rsw_ncsf(3)
True
	sage: test_rsw_ncsf(4)
True
```

(continues on next page)
sage: test_rsw_nscf(5)  # long time
True

canonical_embedding(other)
Return the canonical coercion of \texttt{self} into a symmetric group algebra \texttt{other}.

INPUT:

• \texttt{other} – a symmetric group algebra with order \(p\) satisfying \(p \geq n\), where \(n\) is the order of \texttt{self}, over a ground ring into which the ground ring of \texttt{self} coerces.

EXAMPLES:

\begin{verbatim}
sage: QS2 = SymmetricGroupAlgebra(QQ, 2)
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: phi = QS2.canonical_embedding(QS4); phi
Generic morphism:
    From: Symmetric group algebra of order 2 over Rational Field
    To:   Symmetric group algebra of order 4 over Rational Field

sage: x = QS2([2,1]) + 2 * QS2([1,2])
sage: phi(x)
2*[1, 2, 3, 4] + [2, 1, 3, 4]

sage: loads(dumps(phi))
Generic morphism:
    From: Symmetric group algebra of order 2 over Rational Field
    To:   Symmetric group algebra of order 4 over Rational Field

sage: ZS2 = SymmetricGroupAlgebra(ZZ, 2)
sage: phi = ZS2.canonical_embedding(QS4); phi
Generic morphism:
    From: Symmetric group algebra of order 2 over Integer Ring
    To:   Symmetric group algebra of order 4 over Rational Field

sage: phi = ZS2.canonical_embedding(QS2); phi
Generic morphism:
    From: Symmetric group algebra of order 2 over Integer Ring
    To:   Symmetric group algebra of order 2 over Rational Field

sage: QS4.canonical_embedding(QS2)
Traceback (most recent call last):
...
ValueError: There is no canonical embedding from Symmetric group algebra of order 2 over Rational Field to Symmetric group algebra of order 4 over Rational Field

sage: QS4g = SymmetricGroup(4).algebra(QQ)
sage: QS4.canonical_embedding(QS4g)(QS4([1,3,2,4]))
(2,3)
sage: QS4g.canonical_embedding(QS4)(QS4g([2,3]))
[1, 3, 2, 4]
sage: ZS2.canonical_embedding(QS4g)(ZS2([2,1]))
(1,2)
\end{verbatim}
Combinatorics, Release 9.7

<table>

</tbody>
</table>

**cell_module**(la, **kwds)**

Return the cell module indexed by la.

**EXAMPLES:**

```
sage: S = SymmetricGroupAlgebra(QQ, 3)
sage: M = S.cell_module(Partition([2,1])); M
Cell module indexed by [2, 1] of Cellular basis of Symmetric group algebra of order 3 over Rational Field
```

We check that the input la is standardized:

```
sage: N = S.cell_module([2,1])
sage: M is N
True
```

**cell_module_indices**(la)**

Return the indices of the cell module of self indexed by la.

This is the finite set $M(\lambda)$.

**EXAMPLES:**

```
sage: S = SymmetricGroupAlgebra(QQ, 4)
sage: S.cell_module_indices([3,1])
Standard tableaux of shape [3, 1]
```

**cell_poset()**

Return the cell poset of self.

**EXAMPLES:**

```
sage: S = SymmetricGroupAlgebra(QQ, 4)
sage: S.cell_poset()
Finite poset containing 5 elements
```

**central_orthogonal_idempotent**(la, block=True)**

Return the central idempotent for the symmetric group of order $n$ corresponding to the indecomposable block to which the partition la is associated.

If self.base_ring() contains Q, this corresponds to the classical central idempotent corresponding to the irreducible representation indexed by la.

Alternatively, if self.base_ring() has characteristic $p > 0$, then Theorem 2.8 in [Mur1983] provides that la is associated to an idempotent $f_\mu$, where $\mu$ is the $p$-core of la. This $f_\mu$ is a sum of classical idempotents,

$$f_\mu = \sum_{\lambda: c(\lambda) = \mu} e_\lambda,$$

where the sum ranges over the partitions $\lambda$ of $n$ with $p$-core equal to $\mu$.

**INPUT:**
Combinatorics, Release 9.7

- la – a partition of self.n or a self.base_ring().characteristic()-core of such a partition
- block – boolean (default: True); when False, this returns the classical idempotent associated to la (defined over Q)

OUTPUT:

If block=False and the corresponding coefficients are not defined over self.base_ring(), then return None. Otherwise return an element of self.

EXAMPLES:

Asking for block idempotents in any characteristic, by passing a partition of self.n:

```sage
S0 = SymmetricGroup(4).algebra(QQ)
sage: S2 = SymmetricGroup(4).algebra(GF(2))
sage: S3 = SymmetricGroup(4).algebra(GF(3))
sage: S0.central_orthogonal_idempotent([2,1,1])
3/8*() - 1/8*(3,4) - 1/8*(2,3) - 1/8*(2,4) - 1/8*(1,2) - 1/8*(1,2,3,4) + 1/8*(1,2,4,3) + 1/8*(1,3,4,2) - 1/8*(1,3) - 1/8*(1,3)(2,4) + 1/8*(1,4,3,2) - 1/8*(1,4) + 1/8*(1,4,2,3) - 1/8*(1,4)(2,3)
sage: S2.central_orthogonal_idempotent([2,1,1])
()sage: idem = S3.central_orthogonal_idempotent([4]); idem
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
sage: idem == S3.central_orthogonal_idempotent([1,1,1,1])
True
sage: S3.central_orthogonal_idempotent([2,2])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
```

Asking for block idempotents in any characteristic, by passing p-cores:

```sage
S0.central_orthogonal_idempotent([1,1])
Traceback (most recent call last):
... ValueError: [1, 1] is not a partition of integer 4
Sage: S2.central_orthogonal_idempotent([1])
()sage: S2.central_orthogonal_idempotent([1])
Traceback (most recent call last):
... ValueError: the 2-core of [1] is not a 2-core of a partition of 4
Sage: S3.central_orthogonal_idempotent([1])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
sage: S3.central_orthogonal_idempotent([7])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
```

Asking for classical idempotents:

```sage
S3.central_orthogonal_idempotent([2,2], block=False) is None
True
Sage: S3.central_orthogonal_idempotent([2,1,1], block=False)
(3,4) + (2,3) + (2,4) + (1,2) + (1,2)(3,4) + 2*(1,2,3,4) + 2*(1,2,4,3) + 2*(1,3,4,2) + (1,3) + (1,3)(2,4)
```

(continues on next page)
\[
+ 2^\ast(1,3,2,4) + 2^\ast(1,4,3,2) + (1,4) + 2^\ast(1,4,2,3) \\
+ (1,4)(2,3)
\]

See also:

- \texttt{sage.combinat.partition.Partition.core()}

\textbf{central\_orthogonal\_idempotents()}

Return a maximal list of central orthogonal idempotents for \texttt{self}.

This method does not require that \texttt{self} be semisimple, relying on Nakayama's Conjecture whenever \texttt{self}. \texttt{base\_ring()} has positive characteristic.

**EXAMPLES:**

```python
sage: QS3 = SymmetricGroupAlgebra(QQ,3)
sage: a = QS3.central_orthogonal_idempotents()
sage: a[0]  # [3]
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] \\
+ 1/6*[3, 1, 2] + 1/6*[3, 2, 1]
sage: a[1]  # [2, 1]
2/3*[1, 2, 3] - 1/3*[2, 3, 1] - 1/3*[3, 1, 2]
```

See also:

- \texttt{central\_orthogonal\_idempotent()}

\textbf{dft(form='seminormal', mult=l2r')}

Return the discrete Fourier transform for \texttt{self}.

**INPUT:**

- \texttt{mult} – string (default: \texttt{l2r}). If set to \texttt{r2l}, this causes the method to use the antipodes (\texttt{antipode()}) of the seminormal basis instead of the seminormal basis.

**EXAMPLES:**

```python
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.dft()
[ 1 1 1 1 1 1]
[ 1 1/2 -1 -1/2 -1/2 1/2]
[ 0 3/4 0 3/4 -3/4 -3/4]
[ 0 1 0 -1 1 -1]
[ 1 -1/2 1 -1/2 -1/2 -1/2]
[ 1 -1 -1 1 1 -1]
```

\textbf{epsilon\_ik(itab, ktab, star=0, mult='l2r')}

Return the seminormal basis element of \texttt{self} corresponding to the pair of tableaux \texttt{itab} and \texttt{ktab} (or restrictions of these tableaux, if the optional variable \texttt{star} is set).

**INPUT:**

- \texttt{itab, ktab} – two standard tableaux of size \texttt{n}.
- \texttt{star} – integer (default: \texttt{0}).
- \texttt{mult} – string (default: \texttt{l2r}). If set to \texttt{r2l}, this causes the method to return the antipode (\texttt{antipode()}) of \(\epsilon(I, K)\) instead of \(\epsilon(I, K)\) itself.
OUTPUT:
The element \( \epsilon(I, K) \), where \( I \) and \( K \) are the tableaux obtained by removing all entries higher than \( n - \text{star} \) from \( itab \) and \( ktab \), respectively. Here, we are using the notations from \texttt{seminormal_basis()}.

EXAMPLES:

```python
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: a = QS3.epsilon_ik([[1,2,3]], [[1,2,3]]); a
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] +
    1/6*[3, 2, 1]
sage: QS3.dft()*vector(a)
(1, 0, 0, 0, 0, 0)
sage: a = QS3.epsilon_ik([[1,2],[3]], [[1,2],[3]]); a
1/3*[1, 2, 3] - 1/6*[1, 3, 2] + 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2] -
    1/6*[3, 2, 1]
sage: QS3.dft()*vector(a)
(0, 0, 0, 0, 1, 0)
```

Let us take some properties of the seminormal basis listed in the docstring of \texttt{seminormal_basis()}, and verify them on the situation of \( S_3 \).

First, check the formula

\[ \epsilon(T) = \frac{1}{\kappa_{sh(T)}} \epsilon(T) \epsilon(T). \]

In fact:

```python
sage: from sage.combinat.symmetric_group_algebra import e
def test_sn1(n):
    QSn = SymmetricGroupAlgebra(QQ, n)
    mul = QSn.left_action_product
    for T in StandardTableaux(n):
        TT = T.restrict(n-1)
        eTT = QSn1.epsilon_ik(TT, TT)
        eT = QSn.epsilon_ik(T, T)
        kT = prod(T.shape().hooks())
        if kT * eT != eTT * e(T) * eTT:
            return False
    return True
sage: test_sn1(3)
True
sage: test_sn1(4)  # long time
True
```

Next, we check the identity

\[ \epsilon(T, S) = \frac{1}{\kappa_{sh(T)}} \epsilon(S) \pi_{T,S} \epsilon(T) \epsilon(T) \]

which we used to define \( \epsilon(T, S) \). In fact:

```python
sage: from sage.combinat.symmetric_group_algebra import e
def test_sn2(n):
    QSn = SymmetricGroupAlgebra(QQ, n)
    mul = QSn.left_action_product
    (continues on next page)
```
Combinatorics, Release 9.7

(continued from previous page)

```python
QSn1 = SymmetricGroupAlgebra(QQ, n - 1)
for lam in Partitions(n):
    k = prod(lam.hooks())
    for T in StandardTableaux(lam):
        for S in StandardTableaux(lam):
            TT = T.restrict(n-1)
            SS = S.restrict(n-1)
            eTT = QSn1.epsilon_ik(TT, TT)
            eSS = QSn1.epsilon_ik(SS, SS)
            eTS = QSn1.epsilon_ik(T, S)
            piTS = [0] * n
            for (i, j) in T.cells():
                piTS[T[i][j] - 1] = S[i][j]
            piTS = QSn(Permutation(piTS))
            if k * eTS != mul(mul(eSS, piTS), mul(e(T), eTT)):
                return False
    return True
```

```
sage: test_sn2(3)
True
sage: test_sn2(4)  # long time
True
```

Let us finally check the identity

$$\epsilon(T, S)\epsilon(U, V) = \delta_{T, V}\epsilon(U, S)$$

In fact:

```
sage: def test_sn3(lam):
    n = lam.size()
    QSn = SymmetricGroupAlgebra(QQ, n)
    mul = QSn.left_action_product
    for T in StandardTableaux(lam):
        for S in StandardTableaux(lam):
            for U in StandardTableaux(lam):
                for V in StandardTableaux(lam):
                    lhs = mul(QSn.epsilon_ik(T, S), QSn.epsilon_ik(U, V))
                    if T == V:
                        rhs = QSn.epsilon_ik(U, S)
                    else:
                        rhs = QSn.zero()
                    if rhs != lhs:
                        return False
    return True
```

```
sage: all( test_sn3(lam) for lam in Partitions(3) )
True
sage: all( test_sn3(lam) for lam in Partitions(4) )  # long time
True
```

gucys_murphy($k$)
Return the Jucys-Murphy element $J_k$ (also known as a Young-Jucys-Murphy element) for the symmetric group algebra $self$.

The Jucys-Murphy element $J_k$ in the symmetric group algebra $RS_n$ is defined for every $k \in \{1, 2, \ldots, n\}$
by

\[ J_k = (1, k) + (2, k) + \cdots + (k - 1, k) \in RS_n, \]

where the addends are transpositions in \( S_n \) (regarded as elements of \( RS_n \)). We note that there is not a dependence on \( n \), so it is often suppressed in the notation.

EXAMPLES:

```python
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.jucys_murphy(1)
0
sage: QS3.jucys_murphy(2)
[2, 1, 3]
sage: QS3.jucys_murphy(3)
[1, 3, 2] + [3, 2, 1]

sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: j3 = QS4.jucys_murphy(3); j3
[1, 3, 2, 4] + [3, 2, 1, 4]
sage: j4 = QS4.jucys_murphy(4); j4
[1, 2, 4, 3] + [1, 4, 3, 2] + [4, 2, 3, 1]
sage: j3*j4 == j4*j3
True

sage: QS5 = SymmetricGroupAlgebra(QQ, 5)
sage: QS5.jucys_murphy(4)
[1, 2, 4, 3, 5] + [1, 4, 3, 2, 5] + [4, 2, 3, 1, 5]
```

```python
left_action_product(left, right)
```n
Return the product of two elements \( \text{left} \) and \( \text{right} \) of \( \text{self} \), where multiplication is defined in such a way that for two permutations \( p \) and \( q \), the product \( pq \) is the permutation obtained by first applying \( q \) and then applying \( p \). This definition of multiplication is tailored to make multiplication of permutations associative with their action on numbers if permutations are to act on numbers from the left.

EXAMPLES:

```python
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: p1 = Permutation([2, 1, 3])
sage: p2 = Permutation([3, 1, 2])
sage: QS3.left_action_product(QS3(p1), QS3(p2))
[3, 2, 1]
sage: x = QS3([1, 2, 3]) - 2*QS3([1, 3, 2])
sage: y = 1/2 * QS3([3, 1, 2]) + 3*QS3([1, 2, 3])
sage: QS3.left_action_product(x, y)
3*[1, 2, 3] - 6*[1, 3, 2] - [2, 1, 3] + 1/2*[3, 1, 2]
sage: QS3.left_action_product(0, x)
0
```

The method coerces its input into the algebra \( \text{self} \):

```python
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.left_action_product(QS3([1, 2, 3]), QS3([2, 1, 3]))
[2, 1, 3, 4]
sage: QS4.left_action_product(1, Permutation([4, 1, 2, 3]))
[4, 1, 2, 3]
```
**Warning:** Note that coercion presently works from permutations of \( n \) into the \( n \)-th symmetric group algebra, and also from all smaller symmetric group algebras into the \( n \)-th symmetric group algebra, but not from permutations of integers smaller than \( n \) into the \( n \)-th symmetric group algebra.

### monomial_from_smaller_permutation(permutation)

Convert permutation into a permutation, possibly extending it to the appropriate size, and return the corresponding basis element of \( \text{self} \).

**EXAMPLES:**

```sage
sage: QS5 = SymmetricGroupAlgebra(QQ, 5)
sage: QS5.monomial_from_smaller_permutation([])
[1, 2, 3, 4, 5]
sage: QS5.monomial_from_smaller_permutation(Permutation([3,1,2]))
[3, 1, 2, 4, 5]
sage: QS5.monomial_from_smaller_permutation([5,3,4,1,2])
[5, 3, 4, 1, 2]
sage: QS5.monomial_from_smaller_permutation(SymmetricGroup(2)((1,2)))
[2, 1, 3, 4, 5]
sage: QS5g = SymmetricGroup(5).algebra(QQ)
sage: QS5g.monomial_from_smaller_permutation([2,1])
(1,2)
```

### retract_direct_product(f, m)

Return the direct-product retract of the element \( f \in RS_n \) to \( RS_m \), where \( m \leq n \) (and where \( RS_n \) is \( \text{self} \)).

If \( m \) is a nonnegative integer less or equal to \( n \), then the direct-product retract from \( S_n \) to \( S_m \) is defined as an \( R \)-linear map \( S_n \rightarrow S_m \) which sends every permutation \( p \in S_n \) to

\[
\begin{cases} 
\text{dret}(p) & \text{if dret}(p) \text{ is defined;} \\
0 & \text{otherwise }
\end{cases}
\]

Here \( \text{dret}(p) \) denotes the direct-product retract of the permutation \( p \) to \( S_m \), which is defined in `retract_direct_product()`.

**EXAMPLES:**

```sage
sage: SGA3 = SymmetricGroupAlgebra(QQ, 3)
sage: SGA3.retract_direct_product(2*SGA3([1,2,3]) - 4*SGA3([2,1,3]) + 7*SGA3([1,3,2]), 2)
2*[1, 2] - 4*[2, 1]
sage: SGA3.retract_direct_product(2*SGA3([1,3,2]) - 5*SGA3([2,3,1]), 2)
0
sage: SGA5 = SymmetricGroupAlgebra(QQ, 5)
sage: SGA5.retract_direct_product(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) +...
  11*[3, 2, 1, 4, 5]), 4)
sage: SGA5.retract_direct_product(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) +...
  11*[3, 2, 1, 4, 5]), 3)
sage: SGA5.retract_direct_product(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) +...
  11*[3, 2, 1, 4, 5]), 2)
```

(continues on next page)
\[ 0 \]

\[
\text{sage: } \text{SGA5.retract_direct_product}(8 \times \text{SGA5}([1, 2, 3, 4, 5]) - 6 \times \text{SGA5}([1, 3, 2, 4, 5]), 1) \\
2 \times [1]
\]

\[
\text{sage: } \text{SGA5.retract_direct_product}(8 \times \text{SGA5}([1, 2, 3, 4, 5]) - 6 \times \text{SGA5}([1, 3, 2, 4, 5]), 3) \\
8 \times [1, 2, 3] - 6 \times [1, 3, 2]
\]

\[
\text{sage: } \text{SGA5.retract_direct_product}(8 \times \text{SGA5}([1, 2, 3, 4, 5]) - 6 \times \text{SGA5}([1, 3, 2, 4, 5]), 1) \\
2 \times [1]
\]

\[
\text{sage: } \text{SGA5.retract_direct_product}(8 \times \text{SGA5}([1, 2, 3, 4, 5]) - 6 \times \text{SGA5}([1, 3, 2, 4, 5]), 0) \\
2 \times []
\]

See also:

\text{retract_plain()}, \text{retract_okounkov_vershik()}

\text{retract_okounkov_vershik}(f, m)

Return the Okounkov-Vershik retract of the element \( f \in RS_n \) to \( RS_m \), where \( m \leq n \) (and where \( RS_n \) is self).

If \( m \) is a nonnegative integer less or equal to \( n \), then the Okounkov-Vershik retract from \( S_n \) to \( S_m \) is defined as an \( R \)-linear map \( S_n \rightarrow S_m \) which sends every permutation \( p \in S_n \) to the Okounkov-Vershik retract of the permutation \( p \) to \( S_m \), which is defined in \text{retract_okounkov_vershik()}. 

EXAMPLES:

\[
\text{sage: } \text{SGA3 = SymmetricGroupAlgebra(QQ, 3)} \\
\text{sage: } \text{SGA3.retract_okounkov_vershik}(2 \times \text{SGA3}([1, 2, 3]) - 4 \times \text{SGA3}([2, 1, 3]), 2) \\
9 \times [1, 2] - 4 \times [2, 1]
\]

\[
\text{sage: } \text{SGA3.retract_okounkov_vershik}(2 \times \text{SGA3}([1, 3, 2]), 2) \\
2 \times [1, 2] - 5 \times [2, 1]
\]

\[
\text{sage: } \text{SGA5 = SymmetricGroupAlgebra(QQ, 5)} \\
\text{sage: } \text{SGA5.retract_okounkov_vershik}(8 \times \text{SGA5}([1, 4, 2, 5, 3]) - 6 \times \text{SGA5}([1, 3, 2, 5, 4]) + 11 \times \text{SGA5}([3, 2, 1, 4, 5]), 4) \\
-6 \times [1, 3, 2, 4] + 8 \times [1, 4, 2, 3] + 11 \times [3, 2, 1, 4]
\]

\[
\text{sage: } \text{SGA5.retract_okounkov_vershik}(8 \times \text{SGA5}([1, 4, 2, 5, 3]) - 6 \times \text{SGA5}([1, 3, 2, 5, 4]) + 11 \times \text{SGA5}([3, 2, 1, 4, 5]), 3) \\
2 \times [1, 3, 2] + 11 \times [3, 2, 1]
\]

\[
\text{sage: } \text{SGA5.retract_okounkov_vershik}(8 \times \text{SGA5}([1, 4, 2, 5, 3]) - 6 \times \text{SGA5}([1, 3, 2, 5, 4]) + 11 \times \text{SGA5}([3, 2, 1, 4, 5]), 2) \\
13 \times [1, 2]
\]

\[
\text{sage: } \text{SGA5.retract_okounkov_vershik}(8 \times \text{SGA5}([1, 4, 2, 5, 3]) - 6 \times \text{SGA5}([1, 3, 2, 5, 4]) + 11 \times \text{SGA5}([3, 2, 1, 4, 5]), 1) \\
13 \times [1]
\]

\[
\text{sage: } \text{SGA5.retract_okounkov_vershik}(8 \times \text{SGA5}([1, 2, 3, 4, 5]) - 6 \times \text{SGA5}([1, 3, 2, 4, 5]), 3) \\
8 \times [1, 2, 3] - 6 \times [1, 3, 2]
\]

\[
\text{sage: } \text{SGA5.retract_okounkov_vershik}(8 \times \text{SGA5}([1, 2, 3, 4, 5]) - 6 \times \text{SGA5}([1, 3, 2, 4, 5]), 1) \\
2 \times [1]
\]

\[
\text{sage: } \text{SGA5.retract_okounkov_vershik}(8 \times \text{SGA5}([1, 2, 3, 4, 5]) - 6 \times \text{SGA5}([1, 3, 2, 4, 5]), 0)
\]

(continues on next page)
See also:

`retract_plain()`, `retract_direct_product()`

**retract_plain**\(f, m\)
Return the plain retract of the element \(f \in RS_n\) to \(RS_m\), where \(m \leq n\) (and where \(RS_n\) is self).

If \(m\) is a nonnegative integer less or equal to \(n\), then the plain retract from \(S_n\) to \(S_m\) is defined as an \(R\)-linear map \(S_n \to S_m\) which sends every permutation \(p \in S_n\) to

\[
\begin{cases}
\text{pret}(p) & \text{if } \text{pret}(p) \text{ is defined;}
0 & \text{otherwise}
\end{cases}
\]

Here \(\text{pret}(p)\) denotes the plain retract of the permutation \(p\) to \(S_m\), which is defined in \(\text{retract\_plain()}\).

**EXAMPLES:**

```python
sage: SGA3 = SymmetricGroupAlgebra(QQ, 3)
sage: SGA3.retract_plain(2*SGA3([1,2,3]) - 4*SGA3([2,1,3]) + 7*SGA3([1,3,2]), 2)
2*[1, 2] - 4*[2, 1]
sage: SGA3.retract_plain(2*SGA3([1,3,2]) - 5*SGA3([2,3,1]), 2)
0
sage: SGA5 = SymmetricGroupAlgebra(QQ, 5)
sage: SGA5.retract_plain(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) + 11*SGA5([3, ˓→2,1,4,5]), 4)
11*[3, 2, 1, 4, 5]
sage: SGA5.retract_plain(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) + 11*SGA5([3, ˓→2,1,4,5]), 3)
11*[3, 2, 1]
sage: SGA5.retract_plain(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) + 11*SGA5([3, ˓→2,1,4,5]), 2)
0
```

See also:

`retract_direct_product()`, `retract_okounkov_vershik()`

**right_action_product**\(\text{left}, \text{right}\)
Return the product of two elements \(\text{left}\) and \(\text{right}\) of self, where multiplication is defined in such a way that for two permutations \(p\) and \(q\), the product \(pq\) is the permutation obtained by first applying \(p\) and then applying \(q\). This definition of multiplication is tailored to make multiplication of permutations associative with their action on numbers if permutations are to act on numbers from the right.

**EXAMPLES:**
Combinatorics, Release 9.7

sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: p1 = Permutation([2, 1, 3])
sage: p2 = Permutation([3, 1, 2])
sage: QS3.right_action_product(QS3(p1), QS3(p2))
[1, 3, 2]
sage: x = QS3([1, 2, 3]) - 2*QS3([1, 3, 2])
sage: y = 1/2 * QS3([3, 1, 2]) + 3*QS3([1, 2, 3])
sage: QS3.right_action_product(x, y)
3*[1, 2, 3] - 6*[1, 3, 2] + 1/2*[3, 1, 2] - [3, 2, 1]
sage: QS3.right_action_product(0, x)
0

The method coerces its input into the algebra self:

sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.right_action_product(QS3([1, 2, 3]), QS3([2, 1, 3]))
[2, 1, 3, 4]
sage: QS4.right_action_product(1, Permutation([4, 1, 2, 3]))
[4, 1, 2, 3]

Warning: Note that coercion presently works from permutations of \( n \) into the \( n \)-th symmetric group algebra, and also from all smaller symmetric group algebras into the \( n \)-th symmetric group algebra, but not from permutations of integers smaller than \( n \) into the \( n \)-th symmetric group algebra.

\[ rsw\text{-}shuffling\text{-}element(k) \]
Return the \( k \)-th Reiner-Saliola-Welker shuffling element in the group algebra self.

The \( k \)-th Reiner-Saliola-Welker shuffling element in the symmetric group algebra \( R S_n \) over a ring \( R \) is defined as the sum \( \sum_{\sigma \in S_n} \text{noninv}_k(\sigma) \cdot \sigma \), where for every permutation \( \sigma \), the number \( \text{noninv}_k(\sigma) \) is the number of all \( k \)-noninversions of \( \sigma \) (that is, the number of all \( k \)-element subsets of \( \{1, 2, \ldots, n\} \) on which \( \sigma \) restricts to a strictly increasing map). See sage.combinat.permutation.number_of_noninversions() for the \( \text{noninv} \) map.

This element is more or less the operator \( \nu_{k,1^{n-k}} \) introduced in [RSW2011]; more precisely, \( \nu_{k,1^{n-k}} \) is the left multiplication by this element.

It is a nontrivial theorem (Theorem 1.1 in [RSW2011]) that the operators \( \nu_{k,1^{n-k}} \) (for fixed \( n \) and varying \( k \)) pairwise commute. It is a conjecture (Conjecture 1.2 in [RSW2011]) that all their eigenvalues are integers (which, in light of their commutativity and easily established symmetry, yields that they can be simultaneously diagonalized over \( Q \) with only integer eigenvalues).

**EXAMPLES:**

The Reiner-Saliola-Welker shuffling elements on \( QS_3 \):

sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.rsw_shuffling_element(0)
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: QS3.rsw_shuffling_element(1)
3*[1, 2, 3] + 3*[1, 3, 2] + 3*[2, 1, 3] + 3*[2, 3, 1] + 3*[3, 1, 2] + 3*[3, 2, 1]
sage: QS3.rsw_shuffling_element(2)
3*[1, 2, 3] + 2*[1, 3, 2] + 2*[2, 1, 3] + 2*[2, 3, 1] + [3, 1, 2]
sage: QS3.rsw_shuffling_element(3)

(continues on next page)
Checking the commutativity of Reiner-Saliola-Welker shuffling elements (we leave out the ones for which it is trivial):

```
sage: def test_rsw_comm(n):
    ....:     QSn = SymmetricGroupAlgebra(QQ, n)
    ....:     rsws = [QSn.rsw_shuffling_element(k) for k in range(2, n)]
    ....:     return all( all( rsws[i] * rsws[j] == rsws[j] * rsws[i]
    ....:                          for j in range(i) )
    ....:                          for i in range(len(rsws)) )

sage: test_rsw_comm(3)
True
sage: test_rsw_comm(4)
True
sage: test_rsw_comm(5)  # long time
True
```

Note: For large k (relative to n), it might be faster to call QSn.left_action_product(QSn. semi_rsw_element(k), QSn.antipode(binary_unshuffle_sum(k))) than QSn. rsw_shuffling_element(n).

See also:

- `semi_rsw_element()`, `binary_unshuffle_sum()`
- `semi_rsw_element(k)`

Return the $k$-th semi-RSW element in the group algebra `self`.

The $k$-th semi-RSW element in the symmetric group algebra $RS_n$ over a ring $R$ is defined as the sum of all permutations $\sigma \in S_n$ satisfying $\sigma(1) < \sigma(2) < \cdots < \sigma(k)$.

This element has the property that, if it is denoted by $s_k$, then $s_k S(s_k)$ is $(n-k)!$ times the $k$-th Reiner-Saliola-Welker shuffling element of $RS_n$ (see `rsw_shuffling_element()`). Here, $S$ denotes the antipode of the group algebra $RS_n$.

The $k$-th semi-RSW element is the image of the complete non-commutative symmetric function $S^{(k,1^{n-k})}$ in the ring of non-commutative symmetric functions under the canonical projection on the symmetric group algebra (through the descent algebra).

EXAMPLES:

The semi-RSW elements on $QS_3$:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.semi_rsw_element(0)
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: QS3.semi_rsw_element(1)
[1, 2, 3] + [1, 3, 2] + [2, 3, 1]
sage: QS3.semi_rsw_element(2)
[1, 2, 3] + [1, 3, 2] + [2, 3, 1]
sage: QS3.semi_rsw_element(3)
```

(continues on next page)
Let us check the relation with the $k$-th Reiner-Saliola-Welker shuffling element stated in the docstring:

```
sage: def test_rsw(n):
    ...:    ZSn = SymmetricGroupAlgebra(ZZ, n)
    ...:    for k in range(1, n):
    ...:        a = ZSn.semi_rsw_element(k)
    ...:        b = ZSn.left_action_product(a, ZSn.antipode(a))
    ...:        if factorial(n-k) * ZSn.rsw_shuffling_element(k) != b:
    ...:            return False
    ...:    return True
sage: test_rsw(3)
True
sage: test_rsw(4)
True
sage: test_rsw(5)  # long time
True
```

Let us also check the statement about the complete non-commutative symmetric function:

```
sage: def test_rsw_ncsf(n):
    ...:    ZSn = SymmetricGroupAlgebra(ZZ, n)
    ...:    NSym = NonCommutativeSymmetricFunctions(ZZ)
    ...:    S = NSym.S()
    ...:    for k in range(1, n):
    ...:        a = S(Composition([k] + [1]*(n-k))).to_symmetric_group_algebra()
    ...:        if a != ZSn.semi_rsw_element(k):
    ...:            return False
    ...:    return True
sage: test_rsw_ncsf(3)
True
sage: test_rsw_ncsf(4)
True
sage: test_rsw_ncsf(5)  # long time
True
```

**seminormal_basis**

Return a list of the seminormal basis elements of self.

The seminormal basis of a symmetric group algebra is defined as follows:

Let $n$ be a nonnegative integer. Let $R$ be a $Q$-algebra. In the following, we will use the "left action" convention for multiplying permutations. This means that for all permutations $p$ and $q$ in $S_n$, the product $pq$ is defined in such a way that $(pq)(i) = p(q(i))$ for each $i \in \{1, 2, \ldots, n\}$ (this is the same convention as in left_action_product(), but not the default semantics of the $*$ operator on permutations in Sage).

Thus, for instance, $s_2s_1$ is the permutation obtained by first transposing 1 with 2 and then transposing 2 with 3 (where $s_i = (i, i+1)$).

For every partition $\lambda$ of $n$, let

$$\kappa_{\lambda} = \frac{n!}{f_{\lambda}}$$
where \( f^\lambda \) is the number of standard Young tableaux of shape \( \lambda \). Note that \( \kappa_\lambda \) is an integer, namely the product of all hook lengths of \( \lambda \) (by the hook length formula). In Sage, this integer can be computed by using `sage.combinat.symmetric_group_algebra.kappa()`.

Let \( T \) be a standard tableau of size \( n \).

Let \( a(T) \) denote the formal sum (in \( RS_n \)) of all permutations in \( S_n \) which stabilize the rows of \( T \) (as sets), i.e., which map each entry \( i \) of \( T \) to an entry in the same row as \( i \). (See `sage.combinat.symmetric_group_algebra.a()` for an implementation of this.)

Let \( b(T) \) denote the signed formal sum (in \( RS_n \)) of all permutations in \( S_n \) which stabilize the columns of \( T \) (as sets). Here, “signed” means that each permutation is multiplied with its sign. (This is implemented in `sage.combinat.symmetric_group_algebra.b()`.)

Define an element \( \varepsilon(T) \) of \( RS_n \) to be \( a(T)b(T) \). (This is implemented in `sage.combinat.symmetric_group_algebra.epsilon()` for \( R = \mathbb{Q} \).)

Let \( \text{sh}(T) \) denote the shape of \( T \). (See `shape()`.)

Let \( \bar{T} \) denote the standard tableau of size \( n-1 \) obtained by removing the letter \( n \) (along with its cell) from \( T \) (if \( n \geq 1 \)).

Now, we define an element \( \varepsilon(T) \) of \( RS_n \). We define it by induction on the size \( n \) of \( T \), so we set \( \varepsilon(\emptyset) = 1 \) and only need to define \( \varepsilon(T) \) for \( n \geq 1 \), assuming that \( \varepsilon(T') \) is already defined. We do this by setting

\[
\varepsilon(T) = \frac{1}{\kappa_{\text{sh}(T)}} \varepsilon(T')\varepsilon(T). 
\]

This element \( \varepsilon(T) \) is implemented as `sage.combinat.symmetric_group_algebra.epsilon()` for \( R = \mathbb{Q} \), but it is also a particular case of the elements \( \varepsilon(T, S) \) defined below.

Now let \( S \) be a further tableau of the same shape as \( T \) (possibly equal to \( T \)). Let \( \pi_{T, S} \) denote the permutation in \( S_n \) such that applying this permutation to the entries of \( T \) yields the tableau \( S \). Define an element \( \varepsilon(T, S) \) of \( RS_n \) by

\[
\varepsilon(T, S) = \frac{1}{\kappa_{\text{sh}(T)}} \varepsilon(S)\pi_{T, S}\varepsilon(T) = \frac{1}{\kappa_{\text{sh}(T)}} \varepsilon(S)a(S)\pi_{T, S}b(T)\varepsilon(T). 
\]

This element \( \varepsilon(T, S) \) is called Young’s seminormal unit corresponding to the bitableau \( \langle T, S \rangle \), and is the return value of `epsilon_ik()` applied to \( T \) and \( S \). Note that \( \varepsilon(T, T) = \varepsilon(T) \).

If we let \( \lambda \) run through all partitions of \( n \), and \( \langle T, S \rangle \) run through all pairs of tableaux of shape \( \lambda \), then the elements \( \varepsilon(T, S) \) form a basis of \( RS_n \). This basis is called Young’s seminormal basis and has the properties that

\[
\varepsilon(T, S)\varepsilon(U, V) = \delta_{T, V} \varepsilon(U, S) 
\]

(where \( \delta \) stands for the Kronecker delta).

**Warning:** Because of our convention, we are multiplying our elements in reverse of those given in some papers, for example [Ram1997]. Using the other convention of multiplying permutations, we would instead have \( \varepsilon(U, V)\varepsilon(T, S) = \delta_{T, V} \varepsilon(U, S) \).

In other words, Young’s seminormal basis consists of the matrix units in a (particular) Artin-Wedderburn decomposition of \( RS_n \) into a direct product of matrix algebras over \( \mathbb{Q} \).

The output of `seminormal_basis()` is a list of all elements of the seminormal basis of `self`.

INPUT:
• mult – string (default: 'l2r'). If set to 'r2l', this causes the method to return the list of the antipodes \((\text{antipode})\) of all \(\epsilon(T, S)\) instead of the \(\epsilon(T, S)\) themselves.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ,3)
sage: QS3.seminormal_basis()
[1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] -
  + 1/6*[3, 2, 1],
1/3*[1, 2, 3] + 1/6*[1, 3, 2] - 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2] +
  + 1/6*[3, 2, 1],
1/3*[1, 3, 2] + 1/3*[2, 3, 1] - 1/3*[3, 1, 2] - 1/3*[3, 2, 1],
1/4*[1, 3, 2] - 1/4*[2, 3, 1] + 1/4*[3, 1, 2] - 1/4*[3, 2, 1],
1/3*[1, 2, 3] - 1/6*[1, 3, 2] + 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2] -
  - 1/6*[3, 2, 1],
1/6*[1, 2, 3] - 1/6*[1, 3, 2] - 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] -
  - 1/6*[3, 2, 1]]
```

The row projection operator corresponding to the Young tableau \(\text{tableau}\) (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard).

This is the sum (in the group algebra of the relevant symmetric group over \(\mathbb{Q}\)) of all the permutations which preserve the rows of \(\text{tableau}\). It is called \(\alpha_{\text{tableau}}\) in [EGHLSVY], Section 4.2.

INPUT:

- \(\text{tableau}\) – Young tableau which contains every integer from 1 to its size precisely once.
- \(\text{star}\) – nonnegative integer (default: 0). When this optional variable is set, the method computes not the row projection operator of \(\text{tableau}\), but the row projection operator of the restriction of \(\text{tableau}\) to the entries 1, 2, ..., \(\text{tableau}.\text{size()}\) - \(\text{star}\) instead.
- \(\text{base_ring}\) – commutative ring (default: \(\mathbb{Q}\)). When this optional variable is set, the row projection operator is computed over a user-determined base ring instead of \(\mathbb{Q}\). (Note that symmetric group algebras currently don’t preserve coercion, so e. g. a symmetric group algebra over \(\mathbb{Z}\) does not coerce into the corresponding one over \(\mathbb{Q}\); so convert manually or choose your base rings wisely!)

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import a
sage: a([[1,2]])
[1, 2] + [2, 1]
sage: a([[1,],[2]])
[1, 2]
sage: a([[]])
[]
sage: a([[1, 5], [2, 3], [4]])
[1, 2, 3, 4, 5] + [1, 3, 2, 4, 5] + [5, 2, 3, 4, 1] + [5, 3, 2, 4, 1]
sage: a([[[1,4], [2,3]], base_ring=ZZ])
[1, 2, 3, 4] + [1, 3, 2, 4] + [4, 2, 3, 1] + [4, 3, 2, 1]
```

The column projection operator corresponding to the Young tableau \(\text{tableau}\) (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard).

This is the signed sum (in the group algebra of the relevant symmetric group over \(\mathbb{Q}\)) of all the permutations which preserve the column of \(\text{tableau}\) (where the signs are the usual signs of the permutations). It is called
INPUT:

- **tableau** – Young tableau which contains every integer from 1 to its size precisely once.
- **star** – nonnegative integer (default: 0). When this optional variable is set, the method computes not the column projection operator of `tableau`, but the column projection operator of the restriction of `tableau` to the entries 1, 2, ..., `tableau.size()` - `star` instead.
- **base_ring** – commutative ring (default: `QQ`). When this optional variable is set, the column projection operator is computed over a user-determined base ring instead of `QQ`. (Note that symmetric group algebras currently don’t preserve coercion, so e. g. a symmetric group algebra over `Z` does not coerce into the corresponding one over `QQ`; so convert manually or choose your base rings wisely!)

EXAMPLES:

```python
sage: from sage.combinat.symmetric_group_algebra import b
sage: b([[1,2]])
[1, 2]
sage: b([[1],[2]])
[1, 2] - [2, 1]
sage: b([[]])
[]
sage: b([[1, 2, 4], [5, 3]])
[1, 2, 3, 4, 5] - [1, 3, 2, 4, 5] - [5, 2, 3, 4, 1] + [5, 3, 2, 4, 1]
sage: b([[1, 4], [2, 3]], base_ring=ZZ)
[1, 2, 3, 4] - [1, 2, 4, 3] - [2, 1, 3, 4] + [2, 1, 4, 3]
sage: b([[1, 4], [2, 3]], base_ring=Integer(5))
[1, 2, 3, 4] + 4*[1, 2, 4, 3] + 4*[2, 1, 3, 4] + [2, 1, 4, 3]
```

With the l2r setting for multiplication, the unnormalized Young symmetrizer \( e(\text{tableau}) \) should be the product \( b(\text{tableau}) \times a(\text{tableau}) \) for every tableau. Let us check this on the standard tableaux of size 5:

```python
sage: from sage.combinat.symmetric_group_algebra import a, b, e
sage: all( e(t) == b(t) * a(t) for t in StandardTableaux(5) )
True
```

The unnormalized Young projection operator corresponding to the Young tableau `tableau` (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard).

If \( n \) is a nonnegative integer, and \( T \) is a Young tableau containing every integer from 1 to \( n \) exactly once, then the unnormalized Young projection operator \( e(T) \) is defined by

\[
e(T) = a(T) b(T) \in \mathbb{Q} S_n,
\]

where \( a(T) \in \mathbb{Q} S_n \) is the sum of all permutations in \( S_n \) which fix the rows of \( T \) (as sets), and \( b(T) \in \mathbb{Q} S_n \) is the signed sum of all permutations in \( S_n \) which fix the columns of \( T \) (as sets). Here, “signed” means that each permutation is multiplied with its sign; and the product on the group \( S_n \) is defined in such a way that \( (pq)(i) = p(q(i)) \) for any permutations \( p \) and \( q \) and any \( 1 \leq i \leq n \).

Note that the definition of \( e(T) \) is not uniform across literature. Others define it as \( b(T) a(T) \) instead, or include certain scalar factors (we do not, whence “unnormalized”).

EXAMPLES:
There are differing conventions for the order of the symmetrizers and antisymmetrizers. This example illustrates our conventions:

```
sage: e([[1,2],[3]])
[1, 2, 3] + [2, 1, 3] - [3, 1, 2] - [3, 2, 1]
```

To obtain the product $b(T)a(T)$, one has to take the antipode of this:

```
sage: QS3 = parent(e([[1,2],[3]]))
sage: QS3.antipode(e([[1,2],[3]]))
[1, 2, 3] + [2, 1, 3] - [2, 3, 1] - [3, 2, 1]
```

See also:

```
e_hat()
```

The Young projection operator corresponding to the Young tableau $\text{tab}$ (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard). This is an idempotent in the rational group algebra.

If $n$ is a nonnegative integer, and $T$ is a Young tableau containing every integer from 1 to $n$ exactly once, then the Young projection operator $\hat{e}(T)$ is defined by

$$
\hat{e}(T) = \frac{1}{\kappa_\lambda}a(T)b(T) \in QS_n,
$$

where $\lambda$ is the shape of $T$, where $\kappa_\lambda$ is $n!$ divided by the number of standard tableaux of shape $\lambda$, where $a(T) \in QS_n$ is the sum of all permutations in $S_n$ which fix the rows of $T$ (as sets), and where $b(T) \in QS_n$ is the signed sum of all permutations in $S_n$ which fix the columns of $T$ (as sets). Here, “signed” means that each permutation is multiplied with its sign; and the product on the group $S_n$ is defined in such a way that $(pq)(i) = p(q(i))$ for any permutations $p$ and $q$ and any $1 \leq i \leq n$.

Note that the definition of $\hat{e}(T)$ is not uniform across literature. Others define it as $\frac{1}{\kappa_\lambda}b(T)a(T)$ instead.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import e_hat
e_hat([[1,2,3]])
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] + 1/6*[3, 2, 1]
sage: e_hat([[1],[2]])
1/2*[1, 2] - 1/2*[2, 1]
```

There are differing conventions for the order of the symmetrizers and antisymmetrizers. This example illustrates our conventions:

```
sage: e_hat([[1,2],[3]])
1/3*[1, 2, 3] + 1/3*[2, 1, 3] - 1/3*[3, 1, 2] - 1/3*[3, 2, 1]
```
See also:

e()

sage.combinat.symmetric_group_algebra.e_ik(itab, ktab, star=0)

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import e_ik
e_ik([[1,2,3],[1,2,3]]);
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
e_ik([[1,2,3],[1,2,3]], star=1)
[1, 2] + [2, 1]
```

sage.combinat.symmetric_group_algebra.epsilon(tab, star=0)
The \((T, T)\)-th element of the seminormal basis of the group algebra \(\mathbb{Q}S_n\), where \(T\) is the tableau \(\text{tab}\) (with its \(\text{star}\) highest entries removed if the optional variable \(\text{star}\) is set).

See the docstring of \(\text{seminormal\_basis()}\) for the notation used herein.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import epsilon
epsilon([[1,2],[2]]);
1/2*[1, 2] + 1/2*[2, 1]
epsilon([[1],[2]]);
1/2*[1, 2] - 1/2*[2, 1]
```

sage.combinat.symmetric_group_algebra.epsilon_ik(itab, ktab, star=0)
Return the seminormal basis element of the symmetric group algebra \(\mathbb{Q}S_n\) corresponding to the pair of tableaux \(\text{itab}\) and \(\text{ktab}\) (or restrictions of these tableaux, if the optional variable \(\text{star}\) is set).

INPUT:

- \(\text{itab}, \text{ktab}\) – two standard tableaux of same size.
- \(\text{star}\) – integer (default: 0).

OUTPUT:
The element \(\epsilon(I, K) \in \mathbb{Q}S_n\), where \(I\) and \(K\) are the tableaux obtained by removing all entries higher than \(n - \text{star}\) from \(\text{itab}\) and \(\text{ktab}\), respectively (where \(n\) is the size of \(\text{itab}\) and \(\text{ktab}\)). Here, we are using the notations from \(\text{seminormal\_basis()}\).

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import epsilon_ik
e_ik([[1,2],[3]], [[1,3],[2]]);
1/4*[1, 3, 2] - 1/4*[2, 3, 1] + 1/4*[3, 1, 2] - 1/4*[3, 2, 1]
e_ik([[1,2],[3]], [[1,3],[2]], star=1)
Traceback (most recent call last):
... ValueError: the two tableaux must be of the same shape
```

sage.combinat.symmetric_group_algebra.kappa(alpha)
Return \(\kappa_\alpha\), which is \(n!\) divided by the number of standard tableaux of shape \(\alpha\) (where \(\alpha\) is a partition of \(n\)).

INPUT:

- \(\alpha\) – integer partition (can be encoded as a list).
OUTPUT:

The factorial of the size of \texttt{alpha}, divided by the number of standard tableaux of shape \texttt{alpha}. Equivalently, the product of all hook lengths of \texttt{alpha}.

EXAMPLES:

```python
sage: from sage.combinat.symmetric_group_algebra import kappa
sage: kappa(Partition([2,1]))
3
sage: kappa([2,1])
3
```

```python
sage.combinat.symmetric_group_algebra.pi_ik(itab, ktab)
```

Return the permutation \(p\) which sends every entry of the tableau \texttt{itab} to the respective entry of the tableau \texttt{ktab}, as an element of the corresponding symmetric group algebra.

This assumes that \texttt{itab} and \texttt{ktab} are tableaux (possibly given just as lists of lists) of the same shape.

EXAMPLES:

```python
sage: from sage.combinat.symmetric_group_algebra import pi_ik
sage: pi_ik([[1,3],[2]], [[1,2],[3]])
[1, 3, 2]
```

```python
sage.combinat.symmetric_group_algebra.seminormal_test(n)
```

Run a variety of tests to verify that the construction of the seminormal basis works as desired. The numbers appearing are results in James and Kerber’s ‘Representation Theory of the Symmetric Group’ [JK1981].

EXAMPLES:

```python
sage: from sage.combinat.symmetric_group_algebra import seminormal_test
sage: seminormal_test(3)
True
```

### 5.1.341 Representations of the Symmetric Group

**Todo:**

- construct the product of two irreducible representations.
- implement Induction/Restriction of representations.

**Warning:** This code uses a different convention than in Sagan’s book “The Symmetric Group”

```python
class sage.combinat.symmetric_group_representations.SpechtRepresentation(parent, partition)
Bases: sage.combinat.symmetric_group_representations.SymmetricGroupRepresentation_generic_class
```

```python
representation_matrix(permutation)
```

Return the matrix representing the permutation in this irreducible representation.

**Note:** This method caches the results.
EXAMPLES:

```python
sage: spc = SymmetricGroupRepresentation([3,1], 'specht')
sage: spc.representation_matrix(Permutation([2,1,3,4]))
[ 0 -1 0]
[-1 0 0]
[ 0 0 1]
sage: spc.representation_matrix(Permutation([3,2,1,4]))
[0 0 1]
[0 1 0]
[1 0 0]
```

```python
scalar_product(u, v)
```

Return 0 if \( u + v \) is not a permutation, and the signature of the permutation otherwise.

This is the scalar product of a vertex \( u \) of the underlying Yang-Baxter graph with the vertex \( v \) in the ‘dual’ Yang-Baxter graph.

EXAMPLES:

```python
sage: spc = SymmetricGroupRepresentation([3,2], 'specht')
sage: spc.scalar_product((1,0,2,1,0),(0,3,0,3,0))
-1
sage: spc.scalar_product((1,0,2,1,0),(3,0,0,3,0))
0
```

```
scalar_product_matrix(permutation=None)
```

Return the scalar product matrix corresponding to \( permutation \).

The entries are given by the scalar products of \( u \) and \( permutation.action(v) \), where \( u \) is a vertex in the underlying Yang-Baxter graph and \( v \) is a vertex in the dual graph.

EXAMPLES:

```python
sage: spc = SymmetricGroupRepresentation([3,1], 'specht')
sage: spc.scalar_product_matrix()
[ 1 0 0]
[ 0 -1 0]
[ 0 0 1]
```

```python
class sage.combinat.symmetric_group_representations.SpechtRepresentations(n, ring=None, cache_matrices=True)
```

The irreducible representation of the symmetric group corresponding to \( partition \).

INPUT:

- \( partition \) – a partition of a positive integer
• implementation – string (default: "specht"), one of:
  – "seminormal" - for Young's seminormal representation
  – "orthogonal" - for Young's orthogonal representation
  – "specht" - for Specht's representation
• ring – the ring over which the representation is defined
• cache_matrices – boolean (default: True) if True, then any representation matrices that are computed are cached

EXAMPLES:

Young’s orthogonal representation: the matrices are orthogonal.

```python
sage: orth = SymmetricGroupRepresentation([2,1], "orthogonal"); orth
Orthogonal representation of the symmetric group corresponding to [2, 1]
sage: all(a*a.transpose() == a.parent().identity_matrix() for a in orth)
True
```

```python
sage: orth = SymmetricGroupRepresentation([3,2], "orthogonal"); orth
Orthogonal representation of the symmetric group corresponding to [3, 2]
sage: orth([2,1,3,4,5])
[ 1 0 0 0 0]
[ 0 1 0 0 0]
[ 0 0 -1 0 0]
[ 0 0 0 1 0]
[ 0 0 0 0 -1]
sage: orth([1,3,2,4,5])
[ 1 0 0 0 0]
[ 0 1 0 0 0]
[ -1/2 1/2*sqrt(3) 0 0 0]
[ 1/2*sqrt(3) 1/2 0 0 0]
[ 0 0 0 1/2*sqrt(3) 1/2]
sage: orth([1,2,4,3,5])
[ -1/3 2/3*sqrt(2) 0 0 0]
[2/3*sqrt(2) 1/3 0 0 0]
[ 0 0 1 0 0]
[ 0 0 0 1 0]
[ 0 0 0 0 -1]
```

The Specht representation:

```python
sage: spc = SymmetricGroupRepresentation([3,2], "specht")
sage: spc.scalar_product_matrix(Permutation([1,2,3,4,5]))
[ 1 0 0 0 0]
[ 0 -1 0 0 0]
[ 0 0 1 0 0]
[ 0 0 0 1 0]
[-1 0 0 0 -1]
sage: spc.scalar_product_matrix(Permutation([5,4,3,2,1]))
[ 1 -1 0 1 0]
[ 0 0 1 0 -1]
[ 0 0 0 -1 1]
[ 0 1 -1 -1 1]
```

(continues on next page)
[-1 0 0 0 -1]
sage: spc([5,4,3,2,1])
[ 1 -1 0 1 0]
[ 0 0 -1 0 1]
[ 0 0 0 -1 1]
[ 0 1 -1 -1 1]
[ 0 1 0 -1 1]
sage: spc.verify_representation()
True

By default, any representation matrices that are computed are cached:

```
sage: spc = SymmetricGroupRepresentation([3,2], "specht")
sage: spc([5,4,3,2,1])
[ 1 -1 0 1 0]
[ 0 0 -1 0 1]
[ 0 0 0 -1 1]
[ 0 1 -1 -1 1]
[ 0 1 0 -1 1]
sage: spc._cache__representation_matrix
{(([5, 4, 3, 2, 1],), ()): 
 [ 1 -1 0 1 0]
 [ 0 0 -1 0 1]
 [ 0 0 0 -1 1]
 [ 0 1 -1 -1 1]
 [ 0 1 0 -1 1]}
```

This can be turned off with the keyword `cache_matrices`:

```
sage: spc = SymmetricGroupRepresentation([3,2], "specht", cache_matrices=False)
sage: spc([5,4,3,2,1])
[ 1 -1 0 1 0]
[ 0 0 -1 0 1]
[ 0 0 0 -1 1]
[ 0 1 -1 -1 1]
[ 0 1 0 -1 1]
sage: hasattr(spc, '_cache__representation_matrix')
False
```

**Note:** The implementation is based on the paper [Las].

**REFERENCES:**

**AUTHORS:**

• Franco Saliola (2009-04-23)

class sage.combinat.symmetric_group_representations.SymmetricGroupRepresentation_generic_class(parent, partition)

Bases: sage.structure.element.Element

Generic methods for a representation of the symmetric group.
to_character()
Return the character of the representation.

EXAMPLES:
The trivial character:

```python
sage: rho = SymmetricGroupRepresentation([3])
sage: chi = rho.to_character(); chi
Character of Symmetric group of order 3! as a permutation group
sage: chi.values()
[1, 1, 1]
sage: all(chi(g) == 1 for g in SymmetricGroup(3))
True
```

The sign character:

```python
sage: rho = SymmetricGroupRepresentation([1,1,1])
sage: chi = rho.to_character(); chi
Character of Symmetric group of order 3! as a permutation group
sage: chi.values()
[1, -1, 1]
sage: all(chi(g) == g.sign() for g in SymmetricGroup(3))
True
```

The defining representation:

```python
sage: triv = SymmetricGroupRepresentation([4])
sage: hook = SymmetricGroupRepresentation([3,1])
sage: def_rep = lambda p : triv(p).block_sum(hook(p)).trace()
sage: list(map(def_rep, Permutations(4)))
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 0, 0, 1, 1, 1, 2, 0, 0]
sage: [p.to_matrix().trace() for p in Permutations(4)]
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 0, 0, 1, 1, 1, 2, 0, 0]
```

verify_representation()
Verify the representation.

This tests that the images of the simple transpositions are involutions and tests that the braid relations hold.

EXAMPLES:

```python
sage: spc = SymmetricGroupRepresentation([1,1,1])
sage: spc.verify_representation()
True
sage: spc = SymmetricGroupRepresentation([4,2,1])
sage: spc.verify_representation()
True
```

sage.combinat.symmetric_group_representations.SymmetricGroupRepresentations(n, implementation='specht', ring=None, cache_matrices=True)

Irreducible representations of the symmetric group.

INPUT:

• n – positive integer
• implementation – string (default: "specht"), one of:
  – "seminormal" - for Young’s seminormal representation
  – "orthogonal" - for Young’s orthogonal representation
  – "specht" - for Specht’s representation

• ring – the ring over which the representation is defined

• cache_matrices – boolean (default: True) if True, then any representation matrices that are computed are cached

EXAMPLES:

Young’s orthogonal representation: the matrices are orthogonal.

```
sage: orth = SymmetricGroupRepresentations(3, "orthogonal"); orth
Orthogonal representations of the symmetric group of order 3! over Symbolic Ring
sage: orth.list()
[Orthogonal representation of the symmetric group corresponding to [3],
  Orthogonal representation of the symmetric group corresponding to [2, 1],
  Orthogonal representation of the symmetric group corresponding to [1, 1, 1]]
sage: orth([2,1])([1,2,3])
[1 0]
[0 1]
```

Young’s seminormal representation.

```
sage: snorm = SymmetricGroupRepresentations(3, "seminormal"); snorm
Seminormal representations of the symmetric group of order 3! over Rational Field
sage: sgn = snorm([1,1,1]); sgn
Seminormal representation of the symmetric group corresponding to [1, 1, 1]
sage: list(map(sgn, Permutations(3)))
[[1], [-1], [-1], [1], [1], [-1]]
```

The Specht Representation.

```
sage: spc = SymmetricGroupRepresentations(5, "specht"); spc
Specht representations of the symmetric group of order 5! over Integer Ring
sage: spc([3,2])([5,4,3,2,1])
[ 1 -1 0 1 0]
[ 0 0 -1 0 1]
[ 0 0 0 -1 1]
[ 0 -1 1 -1 1]
[ 0 1 0 -1 1]
```

Note: The implementation is based on the paper [Las].

AUTHORS:

• Franco Saliola (2009-04-23)
Generic methods for the CombinatorialClass of irreducible representations of the symmetric group.

**cardinality()**  
Return the cardinality of self.

EXAMPLES:

```python
sage: sp = SymmetricGroupRepresentations(4, "specht")
sage: sp.cardinality()
5
```

class sage.combinat.symmetric_group_representations.YoungRepresentation_Orthogonal(parent, partition)

Bases: `sage.combinat.symmetric_group_representations.YoungRepresentation_generic`

class sage.combinat.symmetric_group_representations.YoungRepresentation_Seminormal(parent, partition)

Bases: `sage.combinat.symmetric_group_representations.YoungRepresentation_generic`

class sage.combinat.symmetric_group_representations.YoungRepresentation_generic(parent, partition)

Bases: `sage.combinat.symmetric_group_representations.SymmetricGroupRepresentation_generic_class`

Generic methods for Young’s representations of the symmetric group.

**representation_matrix(permutation)**

Return the matrix representing permutation.

EXAMPLES:

```python
sage: orth = SymmetricGroupRepresentation([2,1], "orthogonal")
sage: orth.representation_matrix(Permutation([2,1,3]))
[ 1 0]
[ 0 -1]
sage: orth.representation_matrix(Permutation([1,3,2]))
[-1/2 1/2*sqrt(3)]
[1/2*sqrt(3) 1/2]

sage: norm = SymmetricGroupRepresentation([2,1], "seminormal")
sage: p = PermutationGroupElement([2,1,3])
sage: norm.representation_matrix(p)
[ 1 0]
[ 0 -1]
sage: p = PermutationGroupElement([1,3,2])
sage: norm.representation_matrix(p)
[-1/2 3/2]
[ 1/2 1/2]
```

**representation_matrix_for_simple_transposition(i)**

Return the matrix representing the transposition that swaps i and i+1.

EXAMPLES:

```python
sage: orth = SymmetricGroupRepresentation([2,1], "orthogonal")
sage: orth.representation_matrix_for_simple_transposition(1)
```

(continues on next page)
Combinatorics, Release 9.7

(continued from previous page)

```
[ 1  0]
[ 0 -1]
sage: orth.representation_matrix_for_simple_transposition(2)
[ -1/2 1/2*sqrt(3)]
[1/2*sqrt(3) 1/2]

sage: norm = SymmetricGroupRepresentation([2,1], "seminormal")
sage: norm.representation_matrix_for_simple_transposition(1)
[ 1  0]
[ 0 -1]
sage: norm.representation_matrix_for_simple_transposition(2)
[-1/2 3/2]
[ 1/2 1/2]
```

class sage.combinat.symmetric_group_representations.YoungRepresentations_Orthogonal(n, ring=None, cache_matrices=True)

Bases: sage.combinat.symmetric_group_representations.SymmetricGroupRepresentations_class

Element

alias of YoungRepresentation_Orthogonal

class sage.combinat.symmetric_group_representations.YoungRepresentations_Seminormal(n, ring=None, cache_matrices=True)

Bases: sage.combinat.symmetric_group_representations.SymmetricGroupRepresentations_class

Element

alias of YoungRepresentation_Seminormal

sage.combinat.symmetric_group_representations.partition_to_vector_of_contents(partition, reverse=False)

Return the "vector of contents" associated to partition.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_representations import partition_to_vector_of_contents
sage: partition_to_vector_of_contents([3,2])
(0, 1, 2, -1, 0)
```

5.1.342 Tableaux

AUTHORS:

- Mike Hansen (2007): initial version
- Jason Bandlow (2011): updated to use Parent/Element model, and many minor fixes
- Andrew Mathas (2012-13): completed the transition to the parent/element model begun by Jason Bandlow
- Travis Scrimshaw (11-22-2012): Added tuple options, changed *katabolism* to *catabolism*. Cleaned up documentation.
- Andrew Mathas (2016-08-11): Row standard tableaux added

5.1. Comprehensive Module List
• Oliver Pechenik (2018): Added increasing tableaux.

This file consists of the following major classes:

Element classes:

- Tableau
- SemistandardTableau
- StandardTableau
- RowStandardTableau
- IncreasingTableau

Factory classes:

- Tableaux
- SemistandardTableaux
- StandardTableaux
- RowStandardTableaux
- IncreasingTableaux

Parent classes:

- Tableaux_all
- Tableaux_size
- SemistandardTableaux_all (facade class)
- SemistandardTableaux_size
- SemistandardTableaux_size_inf
- SemistandardTableaux_size_weight
- SemistandardTableaux_shape
- SemistandardTableaux_shape_inf
- SemistandardTableaux_shape_weight
- StandardTableaux_all (facade class)
- StandardTableaux_size
- StandardTableaux_shape
- IncreasingTableaux_all (facade class)
- IncreasingTableaux_size
- IncreasingTableaux_size_inf
- IncreasingTableaux_size_weight
- IncreasingTableaux_shape
- IncreasingTableaux_shape_inf
- IncreasingTableaux_shape_weight
- RowStandardTableaux_all (facade class)
- RowStandardTableaux_size
Todo:

- Move methods that only apply to semistandard tableaux from tableau to semistandard tableau
- Copy/move functionality to skew tableaux
- Add a class for tableaux of a given shape (eg Tableaux_shape)

\texttt{class \ sage.combinat.tableau.IncreasingTableau(parent, t, check=True)}
\texttt{Bases: \ sage.combinat.tableau.Tableau}

A class to model an increasing tableau.

\texttt{INPUT:}

- \texttt{t} – a tableau, a list of iterables, or an empty list

An \textit{increasing tableau} is a tableau whose entries are positive integers that are strictly increasing across rows and strictly increasing down columns.

\texttt{EXAMPLES:}

\begin{verbatim}
\texttt{sage: t = IncreasingTableau([[1,2,3],[2,3]]); t}
[[1, 2, 3], [2, 3]]
\texttt{sage: t.shape()}
[3, 2]
\texttt{sage: t.pp() \ # pretty printing}
1 2 3
2 3
\texttt{sage: t = Tableau([[1,2],[2]])}
\texttt{sage: s = IncreasingTableau(t); s}
[[1, 2], [2]]
\texttt{sage: IncreasingTableau([]) \ # The empty tableau}
[]
\end{verbatim}

You can also construct an \textit{IncreasingTableau} from the appropriate \textit{Parent} object:

\begin{verbatim}
\texttt{sage: IT = IncreasingTableaux()}
\texttt{sage: IT([[1, 2, 3], [4, 5]])}
[[1, 2, 3], [4, 5]]
\end{verbatim}

See also:

- Tableaux
- Tableau
- SemistandardTableaux
- SemistandardTableau
- StandardTableaux
- StandardTableau
- IncreasingTableaux
**K_bender_knuth(i)**

Return the \(i\)-th K-Bender-Knuth operator (as defined in [DPS2017]) applied to `self`.

The \(i\)-th K-Bender-Knuth operator swaps the letters \(i\) and \(i+1\) everywhere where doing so would not break increasingness.

**EXAMPLES:**

```python
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.K_bender_knuth(2)
[[1, 2, 4], [3, 4, 5]]
sage: T.K_bender_knuth(3)
[[1, 3, 4], [2, 4, 5]]
```

**K_evacuation(ceiling=None)**

Return the K-evacuation involution from [TY2009] to `self`.

**EXAMPLES:**

```python
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.K_evacuation()
[[1, 2, 4], [2, 3, 5]]
sage: T.K_evacuation(6)
[[2, 3, 5], [3, 4, 6]]
sage: U = IncreasingTableau([[1,3,4],[3,4,5],[5]])
sage: U.K_evacuation()
[[1, 2, 3], [2, 3, 5], [3]]
```

**K_promotion(ceiling=None)**

Return the K-promotion operator from [Pec2014] applied to `self`.

**EXAMPLES:**

```python
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.K_promotion()
[[1, 2, 3], [3, 4, 5]]
sage: T.K_promotion(6)
[[1, 2, 3], [3, 5, 6]]
sage: U = IncreasingTableau([[1,3,4],[3,4,5],[5]])
sage: U.K_promotion()
[[2, 3, 4], [3, 4, 5], [4]]
```

**K_promotion_inverse(ceiling=None)**

Return the inverse of K-promotion operator applied to `self`.

**EXAMPLES:**

```python
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.K_promotion_inverse()
[[1, 2, 4], [3, 4, 5]]
sage: T.K_promotion_inverse(6)
[[2, 4, 5], [3, 5, 6]]
sage: U = IncreasingTableau([[1,3,4],[3,4,5],[5]])
sage: U.K_promotion_inverse()
[[1, 2, 4], [2, 4, 5], [4]]
```
**check()**

Check that \texttt{self} is a valid increasing tableau.

**descent_set()**

Compute the descents of the increasing tableau \texttt{self} as defined in [DPS2017].

The number \(i\) is a descent of an increasing tableau if some instance of \(i + 1\) appears in a lower row than some instance of \(i\).

**Note:** This notion is close to the notion of descent for a standard tableau but is unrelated to the notion for semistandard tableaux.

**EXAMPLES:**

```python
sage: T = IncreasingTableau([[1,2,4],[3,5,6]])
sage: T.descent_set()
[2, 4]
sage: U = IncreasingTableau([[1,3,4],[2,4,5]])
sage: U.descent_set()
[1, 3, 4]
sage: V = IncreasingTableau([[1,3,4],[3,4,5],[4,5]])
sage: V.descent_set()
[3, 4]
```

**dual_K_evacuation(ceiling=None)**

Return the dual K-evacuation involution applied to \texttt{self}.

**EXAMPLES:**

```python
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.dual_K_evacuation()
[[1, 2, 4], [2, 3, 5]]
sage: T.dual_K_evacuation(6)
[[2, 3, 5], [3, 4, 6]]
sage: U = IncreasingTableau([[1,3,4],[3,4,5],[5]])
sage: U.dual_K_evacuation()
[[1, 2, 3], [2, 3, 5], [3]]
```

**class** `sage.combinat.tableau.IncreasingTableaux(**kwds)`

**Bases:** `sage.combinat.tableau.Tableaux`

A factory class for the various classes of increasing tableaux.

An increasing tableau is a tableau whose entries are positive integers that are strictly increasing across rows and strictly increasing down columns. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

**INPUT:**

Keyword arguments:

- **size** – the size of the tableaux
- **shape** – the shape of the tableaux
- **eval** – the weight (also called binary content) of the tableaux, where values can be either 0 or 1 with position \(i\) being 1 if and only if \(i\) can appear in the tableaux
• **max_entry** – positive integer or infinity (\(\infty\)); the maximum entry for the tableaux; if size or shape are specified, max_entry defaults to be size or the size of shape

Positional arguments:

• the first argument is interpreted as either size or shape according to whether it is an integer or a partition
• the second keyword argument will always be interpreted as eval

**Warning:** The eval is not the usual notion of eval or weight, where the \(i\)-th entry counts how many \(i\)'s appear in the tableau.

**EXAMPLES:**

```python
sage: IT = IncreasingTableaux([2,1]); IT
Increasing tableaux of shape [2, 1] and maximum entry 3
sage: IT.list()
[[[1, 3], [2]], [[1, 2], [3]], [[1, 2], [2]], [[1, 3], [3]], [[2, 1], [3]]]

sage: IT = IncreasingTableaux(3); IT
Increasing tableaux of size 3 and maximum entry 3
sage: IT.list()
[[[1, 2, 3]],
[[1, 3], [2]],
[[1, 2], [3]],
[[1, 2], [2]],
[[1, 3], [3]],
[[2, 3], [3]],
[[1], [2], [3]]]

sage: IT = IncreasingTableaux(3, max_entry=2); IT
Increasing tableaux of size 3 and maximum entry 2
sage: IT.list()
[[[1, 2], [2]]]

sage: IT = IncreasingTableaux(3, max_entry=4); IT
Increasing tableaux of size 3 and maximum entry 4
sage: IT.list()
[[[1, 2, 3]],
[[1, 2, 4]],
[[1, 3, 4]],
[[2, 3, 4]],
[[1, 3], [2]],
[[1, 2], [3]],
[[1, 4], [2]],
[[1, 2], [4]],
[[1, 2], [2]],
[[1, 4], [3]],
[[1, 3], [4]],
[[1, 3], [3]],
[[1, 4], [4]],
[[2, 4], [3]],
[[2, 3], [4]],
[[2, 4], [3]],

(continues on next page)
[[2, 3], [3]],
[[2, 4], [4]],
[[3, 4], [4]],
[[1], [2], [3]],
[[1], [2], [4]],
[[1], [3], [4]],
[[2], [3], [4]]

sage: IT = IncreasingTableaux(3, max_entry=oo); IT
Increasing tableaux of size 3
sage: IT[123]
[[5, 7], [6]]

sage: IT = IncreasingTableaux(max_entry=2)
sage: list(IT)
[[], [[1]], [[2]], [[1, 2]], [[1], [2]]]

sage: IT[4]
[[1], [2]]

sage: IncreasingTableaux()[0]
[]

See also:

- Tableaux
- Tableau
- SemistandardTableaux
- SemistandardTableau
- StandardTableaux
- StandardTableau
- IncreasingTableau

Element

alias of IncreasingTableau

class sage.combinat.tableau.IncreasingTableaux_all(max_entry=None)
Bases: sage.combinat.tableau.IncreasingTableaux, sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets

All increasing tableaux.

EXAMPLES:

sage: T = IncreasingTableaux()
sage: T.cardinality()
+Infinity

sage: T = IncreasingTableaux(max_entry=3)
sage: list(T)
[][]
[[1]]
class sage.combinat.tableau.IncreasingTableaux_shape(p, max_entry=None)
    Bases: sage.combinat.tableau.IncreasingTableaux
    Increasing tableaux of fixed shape \(p\) with a given max entry.
    An increasing tableau with max entry \(i\) is required to have all its entries less or equal to \(i\). It is not required to actually contain an entry \(i\).
    INPUT:
    - \(p\) – a partition
    - \(max_entry\) – the max entry; defaults to the size of \(p\)

class sage.combinat.tableau.IncreasingTableaux_shape_inf(p)
    Bases: sage.combinat.tableau.IncreasingTableaux
    Increasing tableaux of fixed shape \(p\) and no maximum entry.

class sage.combinat.tableau.IncreasingTableaux_shape_weight(p, wt)
    Bases: sage.combinat.tableau.IncreasingTableaux_shape
    Increasing tableaux of fixed shape \(p\) and binary weight \(wt\).

class sage.combinat.tableau.IncreasingTableaux_size(n, max_entry=None)
    Bases: sage.combinat.tableau.IncreasingTableaux
    Increasing tableaux of fixed size \(n\).

class sage.combinat.tableau.IncreasingTableaux_size_inf(n)
    Bases: sage.combinat.tableau.IncreasingTableaux
    Increasing tableaux of fixed size \(n\) with no maximum entry.

class sage.combinat.tableau.IncreasingTableaux_size_weight(n, wt)
    Bases: sage.combinat.tableau.IncreasingTableaux
    Increasing tableaux of fixed size \(n\) and weight \(wt\).

class sage.combinat.tableau.RowStandardTableau(parent, t, check=True)
    Bases: sage.combinat.tableau.Tableau
    A class to model a row standard tableau.
    A row standard tableau is a tableau whose entries are positive integers from 1 to \(m\) that increase along rows.
INPUT:

- t – a Tableau, a list of iterables, or an empty list

EXAMPLES:

```python
sage: t = RowStandardTableau([[3,4,5],[1,2]]); t
[[3, 4, 5], [1, 2]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
3 4 5
1 2
sage: t.is_standard()
False
sage: RowStandardTableau([]) # The empty tableau
[]
sage: RowStandardTableau([[3,4,5],[1,2]]) in StandardTableaux()
False
sage: RowStandardTableau([[1,2,5],[3,4]]) in StandardTableaux()
True
```

When using code that will generate a lot of tableaux, it is more efficient to construct a `RowStandardTableau` from the appropriate `Parent` object:

```python
sage: ST = RowStandardTableaux()
sage: ST([[3, 4, 5], [1, 2]])
[[3, 4, 5], [1, 2]]
```

See also:

- `Tableau`
- `StandardTableau`
- `SemistandardTableau`
- `Tableaux`
- `StandardTableaux`
- `RowStandardTableaux`
- `SemistandardTableaux`

`check()`

Check that self is a valid row standard tableau.

```python
class sage.combinat.tableau.RowStandardTableaux
Bases: sage.combinat.tableau.Tableaux
A factory for the various classes of row standard tableaux.
```

INPUT:

- either a non-negative integer (possibly specified with the keyword n) or a partition

OUTPUT:

- with no argument, the class of all standard tableaux
- with a non-negative integer argument, n, the class of all standard tableaux of size n
with a partition argument, the class of all standard tableaux of that shape

A row standard tableau is a tableau that contains each of the entries from 1 to \( n \) exactly once and is increasing along rows.

All classes of row standard tableaux are iterable.

EXAMPLES:

```python
sage: ST = RowStandardTableaux(3); ST
Row standard tableaux of size 3
sage: ST.first()
[[1, 2, 3]]
```

```python
sage: ST.last()
[[3], [1], [2]]
```

```python
sage: ST.cardinality()
10
```

```python
sage: ST.list()
[[[1, 2, 3]],
 [[2, 3], [1]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[3], [2], [1]],
 [[2], [3], [1]],
 [[1], [3], [2]],
 [[1], [2], [3]],
 [[2], [1], [3]],
 [[3], [1], [2]]]
```

See also:

- *Tableaux*
- *Tableau*
- *SemistandardTableaux*
- *SemistandardTableau*
- *RowStandardTableau*
- *StandardSkewTableaux*

```
```
EXAMPLES:

```
sage: RowStandardTableaux([3,2,1]).cardinality()
60
sage: RowStandardTableaux([2,2]).cardinality()
6
sage: RowStandardTableaux([5]).cardinality()
1
sage: RowStandardTableaux([6,5,5,3]).cardinality()
1955457504
sage: RowStandardTableaux([]).cardinality()
1
```

### class sage.combinat.tableau.RowStandardTableaux_size(n)

**Bases:** `sage.combinat.tableau.RowStandardTableaux`, `sage.sets.disjoint_union Enumerated Sets.DisjointUnionEnumeratedSets`

Row standard tableaux of fixed size `n`.

**EXAMPLES:**

```
sage: [ t for t in RowStandardTableaux(1) ]
[[[1]]]
sage: [ t for t in RowStandardTableaux(2) ]
[[[1, 2]], [[2], [1]], [[1], [2]]]
sage: list(RowStandardTableaux(3))
[[[1, 2, 3]],
 [[2], [1], [3]],
 [[1], [2], [3]],
 [[1], [3], [2]],
 [[2], [3], [1]],
 [[1], [2], [3]],
 [[1], [3], [2]],
 [[2], [1], [3]],
 [[2], [3], [1]],
 [[1], [2], [3]]]
```

**an_element()**

Return a particular element of the class.

**EXAMPLES:**

```
sage: RowStandardTableaux(4).an_element()
[[1, 2, 3, 4]]
```

### class sage.combinat.tableau.SemistandardTableau(parent, t, check=True)

**Bases:** `sage.combinat.tableau.Tableau`

A class to model a semistandard tableau.

**INPUT:**

- `t` – a tableau, a list of iterables, or an empty list

**OUTPUT:**

- A SemistandardTableau object constructed from `t`.  

---

5.1. Comprehensive Module List

---

3285
A semistandard tableau is a tableau whose entries are positive integers, which are weakly increasing in rows and strictly increasing down columns.

EXAMPLES:

```python
sage: t = SemistandardTableau([[1,2,3],[2,3]]); t
[[1, 2, 3], [2, 3]]
sage: t.shape()
[3, 2]
sage: t.pp()  # pretty printing
 1 2 3
 2 3
sage: t = Tableau([[1,2],[2]])
sage: s = SemistandardTableau(t); s
[[1, 2], [2]]
sage: SemistandardTableau([])  # The empty tableau
[]
```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a SemistandardTableau from the appropriate Parent object:

```python
sage: SST = SemistandardTableaux()
sage: SST([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

See also:

- Tableaux
- Tableau
- SemistandardTableaux
- StandardTableaux
- StandardTableau

**check()**

Check that `self` is a valid semistandard tableau.

```python
class sage.combinat.tableau.SemistandardTableaux(**kwds)
Bases: sage.combinat.tableau.Tableaux

A factory class for the various classes of semistandard tableaux.

INPUT:

Keyword arguments:

- `size` -- The size of the tableaux
- `shape` -- The shape of the tableaux
- `eval` -- The weight (also called content or evaluation) of the tableaux
- `max_entry` -- A maximum entry for the tableaux. This can be a positive integer or infinity (oo). If `size` or `shape` are specified, `max_entry` defaults to be `size` or the size of `shape`.

Positional arguments:

- The first argument is interpreted as either `size` or `shape` according to whether it is an integer or a partition.
The second keyword argument will always be interpreted as `eval`.

OUTPUT:

- The appropriate class, after checking basic consistency tests. (For example, specifying `eval` implies a value for `max_entry`).

A semistandard tableau is a tableau whose entries are positive integers, which are weakly increasing in rows and strictly increasing down columns. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

Classes of semistandard tableaux can be iterated over if and only if there is some restriction.

EXAMPLES:

```
sage: SST = SemistandardTableaux([2,1]); SST
Semistandard tableaux of shape [2, 1] and maximum entry 3
sage: SST.list()
[[[1, 1], [2]],
 [[1, 1], [3]],
 [[1, 2], [2]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[1, 3], [3]],
 [[2, 2], [3]],
 [[2, 3], [3]]]
```

```
sage: SST = SemistandardTableaux(3); SST
Semistandard tableaux of size 3 and maximum entry 3
sage: SST.list()
[[[1, 1, 1]],
 [[1, 1, 2]],
 [[1, 1, 3]],
 [[1, 2, 2]],
 [[1, 2, 3]],
 [[1, 3, 3]],
 [[2, 2, 2]],
 [[2, 2, 3]],
 [[2, 3, 3]],
 [[3, 3, 3]],
 [[1, 1], [2]],
 [[1, 1], [3]],
 [[1, 2], [2]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[1, 3], [3]],
 [[2, 2], [3]],
 [[2, 3], [3]],
 [[1], [2], [3]]]
```

```
sage: SST = SemistandardTableaux(3, max_entry=2); SST
Semistandard tableaux of size 3 and maximum entry 2
sage: SST.list()
[[[1, 1, 1]],
 [[1, 1, 2]],
 [[1, 2, 2]],
 (continues on next page)
```
sage: SST = SemistandardTableaux(3, max_entry=oo); SST
Semistandard tableaux of size 3
sage: SST[123]
[[3, 4], [6]]

sage: SemistandardTableaux(max_entry=2)[11]
[[1, 1], [2]]

sage: SemistandardTableaux()[0]
[]

See also:

- Tableaux
- Tableau
- SemistandardTableau
- StandardTableaux
- StandardTableau

**Element**

alias of SemistandardTableau

```python
class sage.combinat.tableau.SemistandardTableaux_all(max_entry=None)
    Bases: sage.combinat.tableau.SemistandardTableaux, sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets
    All semistandard tableaux.

    list()

class sage.combinat.tableau.SemistandardTableaux_shape(p, max_entry=None)
    Bases: sage.combinat.tableau.SemistandardTableaux
    Semistandard tableaux of fixed shape p with a given max entry.

    A semistandard tableau with max entry i is required to have all its entries less or equal to i. It is not required to actually contain an entry i.

    INPUT:

    - p – a partition
    - max_entry – the max entry; defaults to the size of p

    cardinality(algorithm='hook')
        Return the cardinality of self.

        INPUT:

        - algorithm – (default: 'hook') any one of the following:
            - 'hook' – use Stanley’s hook length formula
```
- 'sum' – sum over the compositions of max_entry the number of semistandard tableau with shape and given weight vector

This is computed using *Stanley's hook length formula:

\[ f_\lambda = \prod_{u \in \lambda} \frac{n + c(u)}{h(u)}. \]

where \( n \) is the max_entry, \( c(u) \) is the content of \( u \), and \( h(u) \) is the hook length of \( u \). See [Sta-EC2] Corollary 7.21.4.

**EXAMPLES:**

```python
sage: SemistandardTableaux([2,1]).cardinality()
8
sage: SemistandardTableaux([2,2,1]).cardinality()
75
sage: SymmetricFunctions(QQ).schur()([2,2,1]).expand(5)(1,1,1,1,1) # cross check
75
sage: SemistandardTableaux([5]).cardinality()
126
sage: SemistandardTableaux([3,2,1]).cardinality()
896
sage: SemistandardTableaux([3,2,1], max_entry=7).cardinality()
2352
sage: SemistandardTableaux([6,5,4,3,2,1], max_entry=30).cardinality()
208361017592001331200
sage: ssts = [SemistandardTableaux(p, max_entry=6) for p in Partitions(5)]
```

```python
sage: all(sst.cardinality() == sst.cardinality(algorithm='sum') for sst in ssts)
True
```

**random_element()**

Return a uniformly distributed random tableau of the given shape and max_entry.

**Uses the algorithm from [Kra1999] based on the Novelli-Pak-Stoyanovskii bijection**

```
```

**EXAMPLES:**

```python
sage: S = SemistandardTableaux([2, 2, 1, 1])
sage: S.random_element() in S
True
sage: S = SemistandardTableaux([2, 2, 1, 1], max_entry=7)
sage: S.random_element() in S
True
```

**class** `sage.combinat.tableau.SemistandardTableaux_shape_inf(p)`

Bases: `sage.combinat.tableau.SemistandardTableaux`

Semistandard tableaux of fixed shape \( p \) and no maximum entry.

**class** `sage.combinat.tableau.SemistandardTableaux_shape_weight(p, mu)`

Bases: `sage.combinat.tableau.SemistandardTableaux_shape`

Semistandard tableaux of fixed shape \( p \) and weight \( \mu \).
cardinality()
Return the number of semistandard tableaux of the given shape and weight, as computed by 
kostka_number function of symmetrica.

EXAMPLES:

sage: SemistandardTableaux([2,2], [2, 1, 1]).cardinality()
1
sage: SemistandardTableaux([2,2], [2, 1, 1]).cardinality()
1
sage: SemistandardTableaux([2,2], [2, 1, 1]).cardinality()
1
sage: SemistandardTableaux([3,2,1], [2, 2, 2]).cardinality()
2

list()
Return a list of all semistandard tableaux in self generated by symmetrica.

EXAMPLES:

sage: SemistandardTableaux([2,2], [2, 1, 1]).list()
[[[1, 1], [2, 3]]]
sage: SemistandardTableaux([2,2,2], [2, 2, 1,1]).list()
[[[1, 1], [2, 2], [3, 4]]]
sage: SemistandardTableaux([2,2,2], [2, 2, 2]).list()
[[[1, 1], [2, 2], [3, 3]]]
sage: SemistandardTableaux([3,2,1], [2, 2, 2]).list()
[[[1, 1, 2], [2, 3], [3]], [[1, 1, 3], [2, 2], [3]]]

class sage.combinat.tableau.SemistandardTableaux_size(n, max_entry=None)
Bases: sage.combinat.tableau.SemistandardTableaux

Semistandard tableaux of fixed size n.

cardinality()
Return the cardinality of self.

EXAMPLES:

sage: SemistandardTableaux(3).cardinality()
19
sage: SemistandardTableaux(4).cardinality()
116
sage: SemistandardTableaux(4, max_entry=2).cardinality()
9
sage: SemistandardTableaux(4, max_entry=10).cardinality()
4225
sage: ns = list(range(1, 6))
sage: ssts = [ SemistandardTableaux(n) for n in ns ]
sage: all(sst.cardinality() == len(sst.list()) for sst in ssts)
True

random_element()
Generate a random SemistandardTableau with uniform probability.

The RSK algorithm gives a bijection between symmetric $k \times k$ matrices of nonnegative integers that sum
to $n$ and semistandard tableaux with size $n$ and maximum entry $k$. 
The number of $k \times k$ symmetric matrices of nonnegative integers having sum of elements on the diagonal $i$ and sum of elements above the diagonal $j$ is \( \binom{k+i-1}{i-1} \binom{k+j-1}{j-1} \). We first choose the sum of the elements on the diagonal randomly weighted by the number of matrices having that trace. We then create random integer vectors of length $k$ having that sum and use them to generate a $k \times k$ diagonal matrix. Then we take a random integer vector of length $\binom{k}{2}$ summing to half the remainder and distribute it symmetrically to the remainder of the matrix.

Applying RSK to the random symmetric matrix gives us a pair of identical *SemistandardTableau* of which we choose the first.

**EXAMPLES:**

```python
sage: SemistandardTableaux(6).random_element() # random
[[1, 1, 2], [3, 5, 5]]
```

```python
sage: SemistandardTableaux(6, max_entry=7).random_element() # random
[[2, 4, 4, 6, 6, 6]]
```

**class** `sage.combinat.tableau.SemistandardTableaux_size_inf(n)`

Bases: `sage.combinat.tableau.SemistandardTableaux` Semistandard tableaux of fixed size $n$ with no maximum entry.

**list()**

**class** `sage.combinat.tableau.SemistandardTableaux_size_weight(n, mu)`

Bases: `sage.combinat.tableau.SemistandardTableaux` Semistandard tableaux of fixed size $n$ and weight $\mu$.

**cardinality()**

Return the cardinality of self.

**EXAMPLES:**

```python
sage: SemistandardTableaux(3, [2,1]).cardinality()
2
```

```python
sage: SemistandardTableaux(4, [2,2]).cardinality()
3
```

**class** `sage.combinat.tableau.StandardTableau(parent, t, check=True)`

Bases: `sage.combinat.tableau.SemistandardTableau` A class to model a standard tableau.

**INPUT:**

- $t$ – a Tableau, a list of iterables, or an empty list

A standard tableau is a semistandard tableau whose entries are exactly the positive integers from 1 to $n$, where $n$ is the size of the tableau.

**EXAMPLES:**

```python
sage: t = StandardTableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
```

```python
sage: t.shape()
[3, 2]
```

```python
sage: t.pp() # pretty printing
1 2 3
4 5
```

(continues on next page)
When using code that will generate a lot of tableaux, it is more efficient to construct a StandardTableau from the appropriate Parent object:

```
sage: ST = StandardTableaux()
sage: ST([[1, 2, 3], [4, 5]])
[[[1, 2, 3], [4, 5]]]
```

See also:

- `Tableaux`
- `Tableau`
- `SemistandardTableaux`
- `SemistandardTableau`
- `StandardTableaux`

### check()

Check that `self` is a standard tableau.

### dominates(t)

Return True if `self` dominates the tableau `t`.

That is, if the shape of the tableau restricted to \( k \) dominates the shape of \( t \) restricted to \( k \), for \( k = 1, 2, \ldots, n \).

When the two tableaux have the same shape, then this ordering coincides with the Bruhat ordering for the corresponding permutations.

**INPUT:**

- `t` – a tableau

**EXAMPLES:**

```
sage: s = StandardTableau([[1, 2, 3], [4, 5]])
sage: t = StandardTableau([[1, 2], [3, 5], [4]])
sage: s.dominates(t)
True
sage: t.dominates(s)
False
sage: all(StandardTableau(s).dominates(t) for t in StandardTableaux([3, 2]))
True
sage: s.dominates([[1, 2, 3, 4, 5]])
False
```

### down()

An iterator for all the standard tableaux that can be obtained from `self` by removing a cell. Note that this iterates just over a single tableau (or nothing if `self` is empty).

**EXAMPLES:**

```
down_list()

Return a list of all the standard tableaux that can be obtained from self by removing a cell. Note that this is just a singleton list if self is nonempty, and an empty list otherwise.

EXAMPLES:

sage: t = StandardTableau([[1,2],[3]])
sage: [x for x in t.down()]
[[[1, 2]]]
sage: t = StandardTableau([])
sage: [x for x in t.down()]
[]

is_standard()

Return True since self is a standard tableau.

EXAMPLES:

sage: StandardTableau([[1, 3], [2, 4]]).is_standard()
True

promotion(n=None)

Return the image of self under the promotion operator.

The promotion operator, applied to a standard tableau $t$, does the following:

Remove the letter $n$ from $t$, thus leaving a hole where it used to be. Apply jeu de taquin to move this hole southwest (in French notation) until it reaches the inner boundary of $t$. Fill 0 into the hole once jeu de taquin has completed. Finally, add 1 to each letter in the tableau. The resulting standard tableau is the image of $t$ under the promotion operator.

This definition of promotion is precisely the one given in [Hai1992] (p. 90). It is the inverse of the maps called “promotion” in [Sag2011] (p. 23) and in [Stan2009].

See the promotion() method for a more general operator.

EXAMPLES:

sage: ST = StandardTableaux(7)
sage: all( st.promotion().promotion_inverse() == st for st in ST )  # long time
True
sage: all( st.promotion_inverse().promotion() == st for st in ST )  # long time
True
sage: st = StandardTableau([[1,2,5],[3,4]])
sage: parent(st.promotion())
Standard tableaux

promotion_inverse(n=None)

Return the image of self under the inverse promotion operator. The optional variable $m$ should be set to the size of self minus 1 for a minimal speedup; otherwise, it defaults to this number.
The inverse promotion operator, applied to a standard tableau \( t \), does the following:

Remove the letter 1 from \( t \), thus leaving a hole where it used to be. Apply jeu de taquin to move this hole northeast (in French notation) until it reaches the outer boundary of \( t \). Fill \( n + 1 \) into this hole, where \( n \) is the size of \( t \). Finally, subtract 1 from each letter in the tableau. This yields a new standard tableau.

This definition of inverse promotion is the map called “promotion” in [Sag2011] (p. 23) and in [Stan2009], and is the inverse of the map called “promotion” in [Hai1992] (p. 90).

See the promotion_inverse() method for a more general operator.

**EXAMPLES:**

```
sage: t = StandardTableau([[1,3],[2,4]])
sage: t.promotion_inverse()
[[1, 2], [3, 4]]
```

We check the equivalence of two definitions of inverse promotion on standard tableaux:

```
sage: ST = StandardTableaux(7)
sage: def bk_promotion_inverse7(st):
....:     st2 = st
....:     for i in range(1, 7):
....:         st2 = st2.bender_knuth_involution(i, check=False)
....:     return st2
sage: all( bk_promotion_inverse7(st) == st.promotion_inverse() for st in ST ) # long time
True
```

**standard_descents()**

Return a list of the integers \( i \) such that \( i \) appears strictly further north than \( i + 1 \) in \( self \) (this is not to say that \( i \) and \( i + 1 \) must be in the same column). The list is sorted in increasing order.

**EXAMPLES:**

```
sage: StandardTableau( [[1,3,4],[2,5]]) .standard_descents()
[1, 4]
sage: StandardTableau( [[1,2],[3,4]]) .standard_descents()
[2]
sage: StandardTableau( [[1,2,5],[3,4],[6,7],[8],[9]]) .standard_descents()
[2, 5, 7, 8]
sage: StandardTableau( [] ) .standard_descents()
[]
```

**standard_major_index()**

Return the major index of the standard tableau \( self \) in the standard meaning of the word. The major index is defined to be the sum of the descents of \( self \) (see standard_descents() for their definition).

**EXAMPLES:**

```
sage: StandardTableau( [[1,4,5],[2,6],[3]]) .standard_major_index()
8
sage: StandardTableau( [[1,2],[3,4]]) .standard_major_index()
2
sage: StandardTableau( [[1,2,3],[4,5]]) .standard_major_index()
3
```
standard_number_of_descents()

Return the number of all integers \( i \) such that \( i \) appears strictly further north than \( i + 1 \) in \texttt{self} (this is not to say that \( i \) and \( i + 1 \) must be in the same column). A list of these integers can be obtained using the \texttt{standard_descents()} method.

EXAMPLES:

\begin{verbatim}
sage: StandardTableau([ [1,2],[3,4],[5] ]).standard_number_of_descents()
sage: StandardTableau([ [] ]).standard_number_of_descents()
sage: tabs = StandardTableaux(5)
sage: all( t.standard_number_of_descents() == t.schuetzenberger_involution().schuetzenberger_involution().standard_number_of_descents() for t in tabs )
\end{verbatim}
True

up()

An iterator for all the standard tableaux that can be obtained from \texttt{self} by adding a cell.

EXAMPLES:

\begin{verbatim}
sage: t = StandardTableau([[1,2]])
sage: [x for x in t.up()]
[[[1, 2, 3]], [[1, 2], [3]]]
\end{verbatim}

up_list()

Return a list of all the standard tableaux that can be obtained from \texttt{self} by adding a cell.

EXAMPLES:

\begin{verbatim}
sage: t = StandardTableau([[1,2]])
sage: t.up_list()
[[[1, 2, 3]], [[1, 2], [3]]]
\end{verbatim}

\texttt{class} sage.combinat.tableau.StandardTableaux(**kwds)

\texttt{Bases:} sage.combinat.tableau.SemistandardTableaux

A factory for the various classes of standard tableaux.

INPUT:

- Either a non-negative integer (possibly specified with the keyword \texttt{n}) or a partition.

OUTPUT:

- With no argument, the class of all standard tableaux
- With a non-negative integer argument, \texttt{n}, the class of all standard tableaux of size \texttt{n}
- With a partition argument, the class of all standard tableaux of that shape.

A standard tableau is a semistandard tableau which contains each of the entries from 1 to \texttt{n} exactly once.

All classes of standard tableaux are iterable.

EXAMPLES:

\begin{verbatim}
sage: ST = StandardTableaux(3); ST
Standard tableaux of size 3
sage: ST.first()
\end{verbatim}
\[[1, 2, 3]\]
\[\text{sage: ST.last()\]}
\[[[1]], [[2]], [[3]]\]
\[\text{sage: ST.cardinality()\]}
4
\[\text{sage: ST.list()\]}
\[\[[[1, 2, 3]], [[1, 3]], [[2]], [[1, 2]], [[3]], [[1]], [[2]], [[3]]\]\]

See also:

- \text{Tableaux}
- \text{Tableau}
- \text{SemistandardTableaux}
- \text{SemistandardTableau}
- \text{StandardTableau}
- \text{StandardSkewTableaux}

\text{Element}

alias of \text{StandardTableau}

class \text{sage.combinat.tableau.StandardTableaux_all}

\text{Bases: sage.combinat.tableau.StandardTableaux, sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets}

All standard tableaux.

class \text{sage.combinat.tableau.StandardTableaux_shape}(p)

\text{Bases: sage.combinat.tableau.StandardTableaux}

Semistandard tableaux of a fixed shape $p$.

cardinality()

Return the number of standard Young tableaux of this shape.

This method uses the so-called \textit{hook length formula}, a formula for the number of Young tableaux associated with a given partition. The formula says the following: Let $\lambda$ be a partition. For each cell $c$ of the Young diagram of $\lambda$, let the \textit{hook length} of $c$ be defined as 1 plus the number of cells horizontally to the right of $c$ plus the number of cells vertically below $c$. The number of standard Young tableaux of shape $\lambda$ is then $n!$ divided by the product of the hook lengths of the shape of $\lambda$, where $n = |\lambda|$.

For example, consider the partition $[3, 2, 1]$ of 6 with Ferrers diagram:

\[
\begin{array}{ccc}
\# & \# & \\
\# & \# & \\
\# & \\
\end{array}
\]

When we fill in the cells with their respective hook lengths, we obtain:

\[
\begin{array}{ccc}
5 & 3 & 1 \\
3 & 1 & \\
1 & \\
\end{array}
\]
The hook length formula returns

\[
\frac{6!}{5 \cdot 3 \cdot 1 \cdot 3 \cdot 1 \cdot 1} = 16.
\]

### EXAMPLES:

<table>
<thead>
<tr>
<th>Sage Code</th>
<th>Result</th>
</tr>

<td>2</td>
</tr>
<tr>
<td><code>sage: StandardTableaux([5]).cardinality()</code></td>
<td>1</td>
</tr>
<tr>
<td><code>sage: StandardTableaux([6,5,5,3]).cardinality()</code></td>
<td>6651216</td>
</tr>
<tr>
<td><code>sage: StandardTableaux([]).cardinality()</code></td>
<td>1</td>
</tr>
</tbody>
</table>

### REFERENCES:

### `list()`

Return a list of the standard Young tableaux of the specified shape.

### EXAMPLES:

<table>
<thead>
<tr>
<th>Sage Code</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sage: StandardTableaux([2,2]).list()</code></td>
<td><code>[[[1, 3], [2, 4]], [[1, 2], [3, 4]]]</code></td>
</tr>
<tr>
<td><code>sage: StandardTableaux([5]).list()</code></td>
<td><code>[[1, 2, 3, 4, 5]]</code></td>
</tr>
<tr>
<td><code>sage: StandardTableaux([3,2,1]).list()</code></td>
<td><code>[[[1, 4, 6], [2, 5], [3]], [[1, 3, 6], [2, 5], [4]], [[1, 2, 6], [3, 5], [4]], [[1, 3, 6], [2, 4], [5]], [[1, 2, 6], [3, 4], [5]], [[1, 4, 5], [2, 6], [3]], [[1, 3, 5], [2, 6], [4]], [[1, 2, 5], [3, 6], [4]], [[1, 3, 4], [2, 6], [5]], [[1, 2, 4], [3, 6], [5]], [[1, 2, 3], [4, 6], [5]], [[1, 3, 5], [2, 4], [6]], [[1, 2, 5], [3, 4], [6]], [[1, 3, 4], [2, 5], [6]], [[1, 2, 4], [3, 5], [6]], [[1, 2, 3], [4, 5], [6]]]</code></td>
</tr>
</tbody>
</table>

### `random_element()`

Return a random standard tableau of the given shape using the Greene-Nijenhuis-Wilf Algorithm.

### EXAMPLES:

<table>
<thead>
<tr>
<th>Sage Code</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sage: t = StandardTableaux([2,2]).random_element()</code></td>
<td><code>[[2, 2]]</code></td>
</tr>
</tbody>
</table>
class sage.combinat.tableau.StandardTableaux_size(n)
Bases: sage.combinat.tableau.StandardTableaux, sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets
Standard tableaux of fixed size $n$.

EXAMPLES:

```python
sage: [ t for t in StandardTableaux(1) ]
[[[1]]]
sage: [ t for t in StandardTableaux(2) ]
[[[1, 2]], [[1], [2]]]
sage: [ t for t in StandardTableaux(3) ]
[[[1, 2, 3]], [[1, 3], [2]], [[1, 2], [3]], [[1], [2], [3]]]
sage: StandardTableaux(4)[:]
[[[1, 2, 3, 4]],
[[1, 3, 4], [2]],
[[1, 2, 4], [3]],
[[1, 2, 3], [4]],
[[1, 3], [2], [4]],
[[1, 2], [3, 4]],
[[1, 4], [2], [3]],
[[1, 3], [2], [4]],
[[1, 2], [3], [4]],
[[1], [2], [3], [4]]]
```

cardinality()

Return the number of all standard tableaux of size $n$.

The number of standard tableaux of size $n$ is equal to the number of involutions in the symmetric group $S_n$. This is a consequence of the symmetry of the RSK correspondence, that if $\sigma \mapsto (P, Q)$, then $\sigma^{-1} \mapsto (Q, P)$. For more information, see Wikipedia article Robinson-Schensted-Knuth_correspondence#Symmetry.

ALGORITHM:
The algorithm uses the fact that standard tableaux of size $n$ are in bijection with the involutions of size $n$, (see page 41 in section 4.1 of [Ful1997]). For each number of fixed points, you count the number of ways to choose those fixed points multiplied by the number of perfect matchings on the remaining values.

EXAMPLES:

```python
sage: StandardTableaux(3).cardinality()
4
sage: ns = [1,2,3,4,5,6]
sage: sts = [StandardTableaux(n) for n in ns]
sage: all(st.cardinality() == len(st.list()) for st in sts)
True
```

The cardinality can be computed without constructing all elements in this set, so this computation is fast (see also trac ticket #28273):
random_element()

Return a random StandardTableau with uniform probability.

This algorithm uses the fact that the Robinson-Schensted correspondence returns a pair of identical standard
Young tableaux (SYTs) if and only if the permutation was an involution. Thus, generating a random SYT
is equivalent to generating a random involution.

To generate an involution, we first need to choose its number of fixed points $k$ (if the size of the involution is
even, the number of fixed points will be even, and if the size is odd, the number of fixed points will be odd).
To do this, we choose a random integer $r$ between 0 and the number $N$ of all involutions of size $n$. We then
decompose the interval $\{1, 2, \ldots, N\}$ into subintervals whose lengths are the numbers of involutions of
size $n$ with respectively 0, 1, $\ldots$, $\lfloor N/2 \rfloor$ fixed points. The interval in which our random integer $r$ lies then
decides how many fixed points our random involution will have. We then place those fixed points randomly
and then compute a perfect matching (an involution without fixed points) on the remaining values.

EXAMPLES:

```sage
sage: StandardTableaux(10).random_element() # random
[[1, 3, 6], [2, 5, 7], [4, 8], [9], [10]]
sage: StandardTableaux(0).random_element()
[]
sage: StandardTableaux(1).random_element()
[[1]]
```

class sage.combinat.tableau.Tableau(parent, t, check=True)

Bases: sage.structure.list_clone.ClonableList

A class to model a tableau.

INPUT:

• $t$ – a Tableau, a list of iterables, or an empty list

OUTPUT:

• A Tableau object constructed from $t$.

A tableau is abstractly a mapping from the cells in a partition to arbitrary objects (called entries). It is often
represented as a finite list of nonempty lists (or, more generally an iterator of iterables) of weakly decreasing
lengths. This list, in particular, can be empty, representing the empty tableau.

Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

EXAMPLES:

```sage
t = Tableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1 2 3
4 5
sage: t.is_standard()
True
```
(continues on next page)
When using code that will generate a lot of tableaux, it is slightly more efficient to construct a Tableau from the appropriate Parent object:

```
sage: T = Tableaux()
sage: T([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

See also:
• `Tableaux`
• `SemistandardTableaux`
• `SemistandardTableau`
• `StandardTableaux`
• `StandardTableau`

**add_entry**(cell, m)

Return the result of setting the entry in cell `cell` equal to `m` in the tableau `self`.

This tableau has larger size than `self` if `cell` does not belong to the shape of `self`; otherwise, the tableau has the same shape as `self` and has the appropriate entry replaced.

**INPUT:**
• `cell` – a pair of nonnegative integers

**OUTPUT:**
The tableau `self` with the entry in cell `cell` set to `m`. This entry overwrites an existing entry if `cell` already belongs to `self`, or is added to the tableau if `cell` is a cocorner of the shape `self`. (Either way, the input is not modified.)

**Note:** Both coordinates of `cell` are interpreted as starting at 0. So, `cell == (0, 0)` corresponds to the northwesternmost cell.

**EXAMPLES:**

```
sage: s = StandardTableau([[1,2,5],[3,4]]); s.pp()
   1 2 5
   3 4
sage: t = s.add_entry( (1,2), 6); t.pp()
   1 2 5
   3 4 6
sage: t.category()
Category of elements of Standard tableaux
sage: s.add_entry( (2,0), 6).pp()
   1 2 5
   3 4
```
sage: u = s.add_entry( (1,2), 3); u.pp()
1 2 5
3 4 3
sage: u.category()
Category of elements of Tableaux
sage: s.add_entry( (2,2),3)
Traceback (most recent call last):
  ... IndexError: (2, 2) is not an addable cell of the tableau

anti_restrict(n)
Return the skew tableau formed by removing all of the cells from self that are filled with a number at most n.

EXAMPLES:

sage: t = Tableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.anti_restrict(1)
[[None, 2, 3], [4, 5]]
sage: t.anti_restrict(2)
[[None, None, 3], [4, 5]]
sage: t.anti_restrict(3)
[[None, None, None], [4, 5]]
sage: t.anti_restrict(4)
[[None, None, None], [None, 5]]
sage: t.anti_restrict(5)
[[None, None, None], [None, None]]

atom()
EXAMPLES:

sage: Tableau([[1,2],[3,4]]).atom()
[2, 2]
sage: Tableau([[1,2,3],[4,5],[6]]).atom()
[3, 2, 1]

bender_knuth_involution(k, rows=None, check=True)
Return the image of self under the k-th Bender–Knuth involution, assuming self is a semistandard tableau.

Let T be a tableau, then a lower free ‘k’ in T means a cell of T which is filled with the integer k and whose direct lower neighbor is not filled with the integer k + 1 (in particular, this lower neighbor might not exist at all). Let an upper free ‘k + 1’ in T mean a cell of T which is filled with the integer k + 1 and whose direct upper neighbor is not filled with the integer k (in particular, this neighbor might not exist at all). It is clear that for any row r of T, the lower free k’s and the upper free k + 1’s in r together form a contiguous interval or r.

The ‘k’-th Bender–Knuth switch at row i changes the entries of the cells in this interval in such a way that if it used to have a entries of k and b entries of k + 1, it will now have b entries of k and a entries of k + 1. For fixed k, the k-th Bender–Knuth switches for different i commute. The composition of the k-th Bender–Knuth switches for all rows is called the ‘k’-th Bender–Knuth involution. This is used to show that the Schur functions defined by semistandard tableaux are symmetric functions.
INPUT:

- **k** – an integer
- **rows** – (Default None) When set to None, the method computes the \( k \)-th Bender–Knuth involution as defined above. When an iterable, this computes the composition of the \( k \)-th Bender–Knuth switches at row \( i \) over all \( i \) in \( \text{rows} \). When set to an integer \( i \), the method computes the \( k \)-th Bender–Knuth switch at row \( i \). Note the indexing of the rows starts with 1.
- **check** – (Default: True) Check to make sure \( \text{self} \) is semistandard. Set to False to avoid this check.

OUTPUT:
The image of \( \text{self} \) under either the \( k \)-th Bender–Knuth involution, the \( k \)-th Bender–Knuth switch at a certain row, or the composition of such switches, as detailed in the INPUT section.

EXAMPLES:

```python
sage: t = Tableau([[1,1,3,4,5,6,7],[2,2,4,6,7,7,7],[3,4,5,8,8,9],[6,6,7,10],
                [7,8,8,11],[8]])
sage: t.bender_knuth_involution(1) == t
True
sage: t.bender_knuth_involution(2) == t
True
sage: t.bender_knuth_involution(3)
[[1, 1, 2, 4, 4, 5, 6, 7], [2, 3, 4, 6, 7, 7, 7], [3, 4, 5, 8, 8, 9], [6, 6, 7, 10],
 [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(4)
[[1, 1, 3, 3, 3, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 4, 5, 8, 8, 9], [6, 6, 7, 10],
 [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(5)
[[1, 1, 3, 4, 4, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 4, 5, 8, 8, 9], [6, 6, 7, 10],
 [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(666) == t
True
sage: t.bender_knuth_involution(4, 2) == t
True
sage: t.bender_knuth_involution(4, 3)
[[1, 1, 3, 4, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 5, 5, 8, 8, 9], [6, 6, 7, 10],
 [7, 8, 8, 11], [8]]
```

The \( \text{rows} \) keyword can be an iterator:

```python
sage: t.bender_knuth_involution(6, iter([1,2])) == t
False
sage: t.bender_knuth_involution(6, iter([3,4])) == t
True
```

The Bender–Knuth involution is an involution:

```python
sage: T = SemistandardTableaux(shape=[3,1,1], max_entry=4)
sage: all(all(t.bender_knuth_involution(k).bender_knuth_involution(k) == t for k in range(1,5)) for t in T)
True
```

The same holds for the single switches:
Combinatorics, Release 9.7

```python
sage: all(all(t.bender_knuth_involution(k, j).bender_knuth_involution(k, j) == t for k in range(1,5) for j in range(1, 5)) for t in T)
True
```

Locality of the Bender–Knuth involutions:

```python
sage: all(all(t.bender_knuth_involution(k).bender_knuth_involution(l) == t.bender_knuth_involution(l).bender_knuth_involution(k) for k in range(1,5) for l in range(1,5) if abs(k - l) > 1) for t in T)
True
```

Berenstein and Kirillov [KB1995] have shown that $(s_1s_2)^6 = id$ (for tableaux of straight shape):

```python
sage: p = lambda t, k: t.bender_knuth_involution(k).bender_knuth_involution(k + 1)

sage: all(p(p(p(p(p(p(t,1),1),1),1),1),1) == t for t in T)
True
```

However, $(s_2s_3)^6 = id$ is false:

```python
sage: p = lambda t, k: t.bender_knuth_involution(k).bender_knuth_involution(k + 1)

sage: t = Tableau([[1,2,2],[3,4]])
sage: x = t
sage: for i in range(6): x = p(x, 2)
sage: x
[[1, 2, 3], [2, 4]]
sage: x == t
False
```

*bump*$(x)$

Insert $x$ into *self* using Schensted’s row-bumping (or row-insertion) algorithm.

**EXAMPLES:**

```python
sage: t = Tableau([[1,2],[3]])
sage: t.bump(1)
[[1, 1], [2], [3]]
sage: t
[[1, 2], [3]]
sage: t.bump(2)
[[1, 2, 2], [3]]
sage: t.bump(3)
[[1, 2, 3], [3]]
sage: t
[[1, 2], [3]]
sage: t.bump(1)
[[1, 1, 2, 3], [2, 5, 5], [3, 4, 6], [4, 6], [5]]
sage: t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t.bump(2)
[[1, 2, 2, 2], [2, 3, 3, 5], [4, 4, 5], [5, 6, 6]]
sage: t.bump(1)
[[1, 1, 2, 3], [2, 2, 5, 5], [3, 4, 6], [4, 6], [5]]
```

*bump_multiply*$(other)$

Multiply two tableaux using Schensted’s bump.

5.1. Comprehensive Module List 3303
This product makes the set of semistandard tableaux into an associative monoid. The empty tableau is the unit in this monoid. See pp. 11-12 of [Ful1997].

The same product operation is implemented in a different way in `slide_multiply()`.  

**EXAMPLES:**

```sage
t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
t2 = Tableau([[1,2],[3]])
t.bump_multiply(t2)
[[1, 1, 2, 2, 3], [2, 2, 3, 5], [3, 4, 5], [4, 6, 6], [5]]
```

catabolism()  
Remove the top row of `self` and insert it back in using column Schensted insertion (starting with the largest letter).  

**EXAMPLES:**

```sage:
Tableau([]).catabolism()
[]
sage: Tableau([[1,2,3,4,5]]).catabolism()
[[1, 2, 3, 4, 5]]
sage: Tableau([[1,1,3,3],[2,3],[3]]).catabolism()
[[1, 1, 2, 3, 3, 3], [3]]
sage: Tableau([[1, 1, 2, 3, 3, 3], [3]]).catabolism()
[[1, 1, 2, 3, 3, 3, 3]]
```

catabolism_projector(parts)  

**EXAMPLES:**

```sage:
t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.catabolism_projector([[4,2,1]])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.catabolism_projector([[1]])
[]
sage: t.catabolism_projector([[2,1],[1]])
[]
sage: t.catabolism_projector([[1],[4,1]])
[[1, 1, 3, 3], [2, 3], [3]]
```

catabolism_sequence()  
Perform `catabolism()` on `self` until it returns a tableau consisting of a single row.  

**EXAMPLES:**

```sage:
t = Tableau([[1,2,3,4,5,6,8],[7,9]])
sage: t.catabolism_sequence()
[[[1, 2, 3, 4, 5, 6, 8], [7, 9]],
 [[1, 2, 3, 4, 5, 6, 7, 9], [8]],
 [[1, 2, 3, 4, 5, 6, 7, 8], [9]],
 [[1, 2, 3, 4, 5, 6, 7, 8, 9]]]
sage: Tableau([]).catabolism_sequence()
[][]
```

cells()  
Return a list of the coordinates of the cells of `self`.  

Coordinates start at 0, so the northwesternmost cell (in English notation) has coordinates (0, 0).

**EXAMPLES:**

```python
sage: Tableau([[1,2],[3,4]]).cells()
[(0, 0), (0, 1), (1, 0), (1, 1)]
```

**cells_containing(i)**

Return the list of cells in which the letter $i$ appears in the tableau `self`. The list is ordered with cells appearing from left to right.

Cells are given as pairs of coordinates $(a, b)$, where both rows and columns are counted from 0 (so $a = 0$ means the cell lies in the leftmost column of the tableau, etc.).

**EXAMPLES:**

```python
sage: t = Tableau([[1,1,3],[2,3,5],[4,5]])
sage: t.cells_containing(5)
[(2, 1), (1, 2)]
sage: t.cells_containing(4)
[(2, 0)]
sage: t.cells_containing(6)
[]
sage: t = Tableau([[1,1,2,4],[2,4,4],[4]])
sage: t.cells_containing(4)
[(2, 0), (1, 1), (1, 2), (0, 3)]
sage: t = Tableau([[1,1,2,8,9],[2,5,6,11],[3,7,7,13],[4,8,9],[5],[13],[14]])
sage: t.cells_containing(8)
[(3, 1), (0, 3)]
sage: Tableau([]).cells_containing(3)
[]
```

**charge()**

Return the charge of the reading word of `self`. See `charge()` for more information.

**EXAMPLES:**

```python
sage: Tableau([[1,1],[2,2],[3]]).charge()
0
sage: Tableau([[1,1,3],[2,2]]).charge()
1
sage: Tableau([[1,1,2],[2],[3]]).charge()
1
sage: Tableau([[1,1,2],[2,3]]).charge()
2
sage: Tableau([[1,1,2,3],[2]]).charge()
2
sage: Tableau([[1,1,2,2],[3]]).charge()
3
sage: Tableau([[1,1,2,2,3]]).charge()
4
```

**check()**

Check that `self` is a valid straight-shape tableau.
**EXAMPLES:**

```python
sage: t = Tableau([[1,1], [2]])
sage: t.check()
sage: t = Tableau([[None, None, 1], [2, 4], [3, 4, 5]])  # indirect doctest
Traceback (most recent call last):
  ... ValueError: a tableau must be a list of iterables of weakly decreasing length
```

**cocharge()**

Return the cocharge of the reading word of `self`. See `cocharge()` for more information.

**EXAMPLES:**

```python
sage: Tableau([[1,1],[2,2],[3]]).cocharge()
4
sage: Tableau([[1,1],[2,2]]).cocharge()
3
sage: Tableau([[1,1,2],[2],[3]]).cocharge()
3
sage: Tableau([[1,1,2],[2,3]]).cocharge()
2
sage: Tableau([[1,1,2,3],[2]]).cocharge()
2
sage: Tableau([[1,1,2,2],[3]]).cocharge()
1
sage: Tableau([[1,1,2,2,3]]).cocharge()
0
```

**codegree**

The codegree of a tableau is an integer that is defined recursively by successively stripping off the number \( k \), for \( k = n, n - 1, \ldots, 1 \) and at stage adding the number of addable cell of the same residue minus the number of removable cells of the same residue as \( k \) and are above \( k \) in the diagram.

The codegree of the tableau \( T \) gives the degree of “dual” homogeneous basis element of the Graded Specht module that is indexed by \( T \).

**INPUT:**

- `e` – the quantum characteristic
- `multicharge` – (default: [0]) the multicharge

**OUTPUT:**

The codegree of the tableau `self`, which is an integer.

**EXAMPLES:**

```python
sage: StandardTableau([[1,3,5],[2,4]]).codegree(3)
0
sage: StandardTableau([[1,2,5],[3,4]]).codegree(3)
1
sage: StandardTableau([[1,2,5],[3,4]]).codegree(4)
0
```
column_stabilizer()
Return the PermutationGroup corresponding to the column stabilizer of self.
This assumes that every integer from 1 to the size of self appears exactly once in self.

EXAMPLES:

```
sage: cs = Tableau(
[ [1,2,3],
  [4,5] ])\ .column_stabilizer()
sage: cs.order() == factorial(2)\*factorial(2)
True
sage: PermutationGroupElement([ (1,3,2), (4,5) ]) in cs
False
sage: PermutationGroupElement([ (1,4) ]) in cs
True
```

components()
This function returns a list containing itself. It exists mainly for compatibility with TableauTuple as it allows constructions like the example below.

EXAMPLES:

```
sage: t = Tableau(
[ [1,2,3],
  [4,5] ])
sage: for s in t.components(): print(s.to_list())
[[1, 2, 3], [4, 5]]
```

conjugate()
Return the conjugate of self.

EXAMPLES:

```
sage: Tableau([ [1,2],[3,4] ]).conjugate()
[[1, 3], [2, 4]]
sage: c = StandardTableau([ [1,2],[3,4] ]).conjugate()
sage: c.parent()
Standard tableaux
```

content(k, multicharge=[0])
Return the content of k in the standard tableau self.

The content of k is c – r if k appears in row r and column c of the tableau.

The multicharge is a list of length 1 which gives an offset for all of the contents. It is included mainly for compatibility with sage.combinat.tableau_tuple.TableauTuple().

EXAMPLES:

```
sage: StandardTableau([ [1,2],[3,4] ]).content(3)
-1
sage: StandardTableau([ [1,2],[3,4] ]).content(6)
Traceback (most recent call last):
  ... ValueError: 6 does not appear in tableau
```

corners()
Return the corners of the tableau self.

EXAMPLES:
sage: Tableau([[1, 4, 6], [2, 5], [3]]).corners()
[(0, 2), (1, 1), (2, 0)]
sage: Tableau([[1, 3], [2, 4]]).corners()
[(1, 1)]

\textbf{degree}(e, \text{multicharge}=(0,))

The \textit{degree} is an integer that is defined recursively by successively stripping off the number \( k \), for \( k = n, n - 1, \ldots, 1 \) and at stage adding the number of addable cell of the same residue minus the number of removable cells of the same residue as \( k \) and which are below \( k \) in the diagram.

The degrees of the tableau \( T \) gives the degree of the homogeneous basis element of the graded Specht module that is indexed by \( T \).

\textbf{INPUT}:

\begin{itemize}
  \item \texttt{e} – the \textit{quantum characteristic}
  \item \texttt{multicharge} – (default: [0]) the multicharge
\end{itemize}

\textbf{OUTPUT}:

The degree of the tableau \texttt{self}, which is an integer.

\textbf{EXAMPLES}:

\begin{itemize}
  \item \texttt{sage: StandardTableau([[1,2,5],[3,4]]).degree(3)} \hspace{1cm} 0
  \item \texttt{sage: StandardTableau([[1,2,5],[3,4]]).degree(4)} \hspace{1cm} 1
\end{itemize}

\textbf{descents}()

Return a list of the cells \((i, j)\) such that \( \texttt{self}[i][j] > \texttt{self}[i-1][j] \).

\textbf{Warning}: This is not to be confused with the descents of a standard tableau.

\textbf{EXAMPLES}:

\begin{itemize}
  \item \texttt{sage: Tableau([[1,4],[2,3]]).descents()} \hspace{1cm} [(1, 0)]
  \item \texttt{sage: Tableau([[1,2],[3,4]]).descents()} \hspace{1cm} [(1, 0), (1, 1)]
  \item \texttt{sage: Tableau([[1,2,3],[4,5]]).descents()} \hspace{1cm} [(1, 0), (1, 1)]
\end{itemize}

\textbf{entries}()

Return the tuple of all entries of \texttt{self}, in the order obtained by reading across the rows from top to bottom (in English notation).

\textbf{EXAMPLES}:

\begin{itemize}
  \item \texttt{sage: t = Tableau([[1,3],[2]])}
  \item \texttt{sage: t.entries()} \hspace{1cm} (1, 3, 2)
\end{itemize}
entry\(\)\(\)\(\)\(\)\(\)
Return the entry of cell cell in the tableau self. Here, cell should be given as a tuple \((i, j)\) of zero-based coordinates (so the northwesternmost cell in English notation is \((0, 0)\)).

EXAMPLES:

```
sage: t = Tableau([[1,2],[3,4]])
sage: t.entry( (0,0) )
1
sage: t.entry( (1,1) )
4
```

evacuation\(n=None, check=True\)\(\)
Return the evacuation of the tableau self.

This is an alias for schuetzenberger_involution().

This method relies on the analogous method on words, which reverts the word and then complements all letters within the underlying ordered alphabet. If \(n\) is specified, the underlying alphabet is assumed to be \([1, 2, \ldots, n]\). If no alphabet is specified, \(n\) is the maximal letter appearing in self.

INPUT:

- \(n\) – an integer specifying the maximal letter in the alphabet (optional)
- \(check\) – (Default: True) Check to make sure self is semistandard. Set to False to avoid this check.

OUTPUT:

- a tableau, the evacuation of self

EXAMPLES:

```
sage: t = Tableau([[1,1,1],[2,2]])
sage: t.evacuation(3)
[[2, 2, 3], [3, 3]]
sage: t = Tableau([[1,2,3],[4,5]])
sage: t.evacuation()
[[1, 2, 5], [3, 4]]
sage: t = Tableau([[1,3,5,7],[2,4,6],[8,9]])
sage: t.evacuation()
[[1, 2, 6, 8], [3, 4, 9], [5, 7]]
sage: t = Tableau([])
sage: t.evacuation()
[]
sage: t = StandardTableau([[1,2,3],[4,5]])
sage: s = t.evacuation()
sage: s.parent()
Standard tableaux
```

evaluation\(\)
Return the weight of the tableau self. Trailing zeroes are omitted when returning the weight.
The weight of a tableau $T$ is the sequence $(a_1, a_2, a_3, \ldots)$, where $a_k$ is the number of entries of $T$ equal to $k$. This sequence contains only finitely many nonzero entries.

The weight of a tableau $T$ is the same as the weight of the reading word of $T$, for any reading order.

```python
sage: Tableau([[1,2],[3,4]]).weight()
[1, 1, 1, 1]
sage: Tableau([]).weight()
[]
sage: Tableau([[1,3,3,7],[4,2],[2,3]]).weight()
[1, 2, 3, 1, 0, 0, 1]
```

**first_column_descent()**

Return the first cell where `self` is not column standard.

Cells are ordered left to right along the rows and then top to bottom. That is, the cell $(r, c)$ with $r$ and $c$ minimal such that the entry in position $(r, c)$ is bigger than the entry in position $(r, c + 1)$. If there is no such cell then `None` is returned - in this case the tableau is column strict.

**OUTPUT:**

The first cell which there is a descent or `None` if no such cell exists.

**EXAMPLES:**

```python
sage: Tableau([[1,4,5],[2,3]]).first_column_descent()
(0, 1)
sage: Tableau([[1,2,3],[4]]).first_column_descent() is None
True
```

**first_row_descent()**

Return the first cell where the tableau `self` is not row standard.

Cells are ordered left to right along the rows and then top to bottom. That is, the cell $(r, c)$ with $r$ and $c$ minimal such that the entry in position $(r, c)$ is bigger than the entry in position $(r, c + 1)$. If there is no such cell then `None` is returned - in this case the tableau is row strict.

**OUTPUT:**

The first cell which there is a descent or `None` if no such cell exists.

**EXAMPLES:**

```python
sage: t = Tableau([[1,3,2],[4]]); t.first_row_descent()
(0, 1)
sage: Tableau([[1,2,3],[4]]).first_row_descent() is None
True
```

**flush()**

Return the number of flush segments in `self`, as in [Sal2014].

Let $1 \leq i < k \leq r + 1$ and suppose $\ell$ is the smallest integer greater than $k$ such that there exists an $\ell$-segment in the $(i + 1)$-st row of $T$. A $k$-segment in the $i$-th row of $T$ is called flush if the leftmost box in the $k$-segment and the leftmost box of the $\ell$-segment are in the same column of $T$. If, however, no such $\ell$ exists, then this $k$-segment is said to be flush if the number of boxes in the $k$-segment is equal to $\theta_i$, where
θ_i = λ_i - λ_{i+1} and the shape of T is λ = (λ_1 > λ_2 > \cdots > λ_r). Denote the number of flush k-segments in T by \text{flush}(T).

EXAMPLES:

```python
sage: t = Tableau([[1,1,2,3,5],[2,3,5,5],[3,4]])
sage: t.flush()
3
sage: B = crystals.Tableaux("A4",shape=[4,3,2,1])
sage: t = B[32].to_tableau()
sage: t.flush()
4
```

height()

Return the height of self.

EXAMPLES:

```python
sage: Tableau([[1,2,3],[4,5]]).height()
2
sage: Tableau([[1,2,3]]).height()
1
sage: Tableau([]).height()
0
```

hillman_grassl()

Return the image of the λ-array self under the Hillman-Grassl correspondence (as a WeakReversePlanePartition).

This relies on interpreting self as a λ-array in the sense of hillman_grassl.

Fix a partition λ (see Partition()). We draw all partitions and tableaux in English notation.

A λ-array will mean a tableau of shape λ whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A weak reverse plane partition of shape λ (short: λ-rpp) will mean a λ-array whose entries weakly increase along each row and weakly increase along each column.

The Hillman-Grassl correspondence H is the map that sends a λ-array M to a λ-rpp H(M) defined recursively as follows:

• If all entries of M are 0, then H(M) = M.

• Otherwise, let s be the index of the leftmost column of M containing a nonzero entry. Let r be the index of the bottommost nonzero entry in the s-th column of M. Let M' be the λ-array obtained from M by subtracting 1 from the (r, s)-th entry of M. Let Q = (q_{i,j}) be the image H(M') (which is already defined by recursion).

• Define a sequence ((i_1, j_1), (i_2, j_2), \ldots, (i_n, j_n)) of boxes in the diagram of λ (actually a lattice path made of southward and westward steps) as follows: Set (i_1, j_1) = (r, \lambda_r) (the rightmost box in the r-th row of λ). If (i_k, j_k) is defined for some k ≥ 1, then (i_{k+1}, j_{k+1}) is constructed as follows: If q_{i_k+1, j_k} is well-defined and equals q_{i_k, j_k}, then we set (i_{k+1}, j_{k+1}) = (i_k + 1, j_k). Otherwise, if j_k = s, then the sequence ends here. Otherwise, we set (i_{k+1}, j_{k+1}) = (i_k, j_k - 1).

• Let H(M) be the array obtained from Q by adding 1 to the (i_k, j_k)-th entry of Q for each k \in \{1, 2, \ldots, n\}.

See [Gans1981] (Section 3) for this construction.
See also:

hillman_grassl() for the Hillman-Grassl correspondence as a standalone function.

hillman_grassl_inverse() for the inverse map.

**EXAMPLES:**

```sage
a = Tableau([[2, 1, 1], [0, 2, 0], [1, 1]])
A = a.hillman_grassl(); A
[[2, 2, 4], [2, 3, 4], [3, 5]]
a.parent(), a.parent()
(Weak Reverse Plane Partitions, Tableaux)
```

**insert_word**(w, left=True)

Insert the word w into the tableau self letter by letter using Schensted insertion. By default, the word w is being processed from left to right, and the insertion used is row insertion. If the optional keyword left is set to True, the word w is being processed from right to left, and column insertion is used instead.

**EXAMPLES:**

```sage
t0 = Tableau([])
w = [1,1,2,3,3,3,3]
t0.insert_word(w)
[[1, 1, 2, 3, 3, 3, 3]]
t0.insert_word(w,left=True)
[[1, 1, 2, 3, 3, 3, 3]]
w.reverse()
t0.insert_word(w)
[[1, 1, 3, 3], [2, 3], [3]]
t0.insert_word(w,left=True)
[[1, 1, 3, 3], [2, 3], [3]]
t1 = Tableau([[1,3],[2]])
t1.insert_word([4,5])
[[1, 3, 4, 5], [2]]
t1.insert_word([4,5], left=True)
[[1, 3], [2, 5], [4]]
```

**inversion_number()**

Return the inversion number of self.

The inversion number is defined to be the number of inversions of self minus the sum of the arm lengths of the descents of self (see the inversions() and descents() methods for the relevant definitions).

**Warning:** This has none of the meanings in which the word “inversion” is used in the theory of standard tableaux.

**EXAMPLES:**

```sage
t = Tableau([[1,2,3],[2,5]])
t.inversion_number()
0
t = Tableau([[1,2,4],[3,5]])
t.inversion_number()
0
```
inversions()
Return a list of the inversions of self.

Let T be a tableau. An inversion is an attacking pair (c, d) of the shape of T (see attacking_pairs() for a definition of this) such that the entry of c in T is greater than the entry of d.

Warning: Do not mistake this for the inversions of a standard tableau.

EXAMPLES:

```python
sage: t = Tableau([[1,2,3],[2,5]])
\sage: t.inversions()
[[(1, 1), (0, 0)]]

sage: t = Tableau([[1,4,3],[5,2],[2,6],[3]])
\sage: t.inversions()
[[(0, 1), (0, 2)), ((1, 0), (1, 1)), ((1, 1), (0, 0)), ((2, 1), (1, 0))]
```

is_column_increasing(weak=False)
Return True if the entries in each column are in increasing order, and False otherwise.

By default, this checks for strictly increasing columns. Set weak to True to test for weakly increasing columns.

EXAMPLES:

```python
sage: T = Tableau([[1, 1, 3], [1, 2]])
\sage: T.is_column_increasing(weak=True)
True
\sage: T.is_column_increasing()
False
\sage: Tableau([[2], [1]]).is_column_increasing(weak=True)
False
```

is_column_strict()
Return True if self is a column strict tableau and False otherwise.

A tableau is column strict if the entries in each column are in (strictly) increasing order.

EXAMPLES:

```python
sage: Tableau([[1, 3], [2, 4]]).is_column_strict()
True
sage: Tableau([[1, 2], [2, 4]]).is_column_strict()
True
sage: Tableau([[2, 3], [2, 4]]).is_column_strict()
False
sage: Tableau([[5, 3], [2, 4]]).is_column_strict()
False
sage: Tableau([]).is_column_strict()
True
sage: Tableau([[1, 4, 2]]).is_column_strict()
True
sage: Tableau([[1, 4, 2], [2, 5]]).is_column_strict()
True
```

(continues on next page)
sage: Tableau([[1, 4, 2], [2, 3]]).is_column_strict()
False

is_increasing()
Return True if self is an increasing tableau and False otherwise.
A tableau is increasing if it is both row strict and column strict.
EXAMPLES:

sage: Tableau([[1, 3], [2, 4]]).is_increasing()
True
sage: Tableau([[1, 2], [2, 4]]).is_increasing()
True
sage: Tableau([[2, 3], [2, 4]]).is_increasing()
False
sage: Tableau([[5, 3], [2, 4]]).is_increasing()
False
sage: Tableau([[1, 2, 3], [2, 3], [3]]).is_increasing()
True

is_k_tableau(k)
Checks whether self is a valid weak k-tableau.
EXAMPLES:

sage: t = Tableau([[1,2,3],[2,3],[3]])
sage: t.is_k_tableau(3)
True
sage: t = Tableau([[1,1,3],[2,2],[3]])
sage: t.is_k_tableau(3)
False

is_key_tableau()
Return True if self is a key tableau or False otherwise.
A tableau is a key tableau if the set of entries in the j-th column is a subset of the set of entries in the (j - 1)-st column.
REFERENCES:
• [LS1990]
• [Wil2010]
EXAMPLES:

sage: t = Tableau([[1,1,1],[2,3],[3]])
sage: t.is_key_tableau()
True
sage: t = Tableau([[1,1,2],[2,3],[3]])
sage: t.is_key_tableau()
False

is_rectangular()
Return True if the tableau self is rectangular and False otherwise.
EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).is_rectangular()
True
sage: Tableau([[1,2,3],[4,5],[6]]).is_rectangular()
False
sage: Tableau([]).is_rectangular()
True
```

**is_row_increasing**(weak=False)

Return True if the entries in each row are in increasing order, and False otherwise.

By default, this checks for strictly increasing rows. Set weak to True to test for weakly increasing rows.

EXAMPLES:

```
sage: T = Tableau([[1, 1, 3], [1, 2]])
sage: T.is_row_increasing(weak=True)
True
sage: T.is_row_increasing()
False
sage: Tableau([[2, 1]]).is_row_increasing(weak=True)
False
```

**is_row_strict()**

Return True if self is a row strict tableau and False otherwise.

A tableau is row strict if the entries in each row are in (strictly) increasing order.

EXAMPLES:

```
sage: Tableau([[1, 3], [2, 4]]).is_row_strict()
True
sage: Tableau([[1, 2], [2, 4]]).is_row_strict()
True
sage: Tableau([[2, 3], [2, 4]]).is_row_strict()
True
sage: Tableau([[5, 3], [2, 4]]).is_row_strict()
False
```

**is_semistandard()**

Return True if self is a semistandard tableau, and False otherwise.

A tableau is semistandard if its rows weakly increase and its columns strictly increase.

EXAMPLES:

```
sage: Tableau([[1,1],[1,2]]).is_semistandard()
False
sage: Tableau([[1,2],[1,2]]).is_semistandard()
False
sage: Tableau([[1,1],[2,2]]).is_semistandard()
True
sage: Tableau([[1,2],[2,3]]).is_semistandard()
True
sage: Tableau([[4,1],[3,2]]).is_semistandard()
False
```

5.1. Comprehensive Module List
**is_standard()**

Return True if `self` is a standard tableau and False otherwise.

**EXAMPLES:**

```python
sage: Tableau([[1, 3], [2, 4]]).is_standard()
True
sage: Tableau([[1, 2], [2, 4]]).is_standard()
False
sage: Tableau([[2, 3], [2, 4]]).is_standard()
False
sage: Tableau([[5, 3], [2, 4]]).is_standard()
False
```

**k_weight(k)**

Return the $k$-weight of `self`.

A tableau has $k$-weight $\alpha = (\alpha_1, ..., \alpha_n)$ if there are exactly $\alpha_i$ distinct residues for the cells occupied by the letter $i$ for each $i$. The residue of a cell in position $(a, b)$ is $a - b$ modulo $k + 1$.

This definition is the one used in [Ive2012] (p. 12).

**EXAMPLES:**

```python
sage: Tableau([[1, 2], [2, 3]]).k_weight(1)
[1, 1, 1]

sage: Tableau([[1, 2], [2, 3]]).k_weight(2)
[1, 2, 1]

sage: t = Tableau([[1, 1, 1, 2, 5], [2, 3, 6], [3], [4]])

sage: t.k_weight(1)
[2, 1, 1, 1, 1]

sage: t.k_weight(2)
[3, 2, 1, 1, 1]

sage: t.k_weight(3)
[3, 1, 2, 1, 1]

sage: t.k_weight(4)
[3, 2, 2, 1, 1]

sage: t.k_weight(5)
[3, 2, 2, 1, 1]
```

**lambda_catabolism(part)**

Return the part-catabolism of `self`, where `part` is a partition (which can be just given as an array).

For a partition $\lambda$ and a tableau $T$, the $\lambda$-catabolism of $T$ is defined by performing the following steps.

1. Truncate the parts of $\lambda$ so that $\lambda$ is contained in the shape of $T$. Let $m$ be the length of this partition.
2. Let $T_a$ be the first $m$ rows of $T$, and $T_b$ be the remaining rows.
3. Let $S_a$ be the skew tableau $T_a/\lambda$.
4. Concatenate the reading words of $S_a$ and $T_b$, and insert into a tableau.

**EXAMPLES:**

```python
sage: Tableau([[1,1,3],[2,4,5]]).lambda_catabolism([2,1])
[[3, 5], [4]]

sage: t = Tableau([[1,1,3,3],[2,3],[3]])

sage: t.lambda_catabolism([[]])
(continues on next page)
```
last_letter_lequal(tab2)

Return True if self is less than or equal to tab2 in the last letter ordering.

EXAMPLES:

```
sage: st = StandardTableaux([3,2])
sage: f = lambda b: 1 if b else 0
sage: matrix( [ [ f(t1.last_letter_lequal(t2)) for t2 in st] for t1 in st ] )
[1 1 1 1]
[0 1 1 1]
[0 0 1 1]
[0 0 0 1]
```

left_key_tableau()

Return the left key tableau of self.

The left key tableau of a tableau $T$ is the key tableau whose entries are weakly lesser than the corresponding entries in $T$, and whose column reading word is subject to certain conditions. See [LS1990] for the full definition.

ALGORITHM:

The following algorithm follows [Wil2010]. Note that if $T$ is a key tableau then the output of the algorithm is $T$.

To compute the left key tableau $L$ of a tableau $T$ we iterate over the columns of $T$. Let $T_j$ be the $j$-th column of $T$ and iterate over the entries in $T_j$ from bottom to top. Initialize the corresponding entry $k$ in $L$ as the largest entry in $T_j$. Scan the columns to the left of $T_j$ and with each column update $k$ to be the lowest entry in that column which is weakly less than $k$. Update $T_j$ and all columns to the left by removing all scanned entries.

See also:

- is_key_tableau()

EXAMPLES:

```
sage: t = Tableau([[1,2],[2,3]])
sage: t.left_key_tableau()
[[1, 1], [2, 2]]
```
sage: t = Tableau([[1,1,2,4],[2,3,3],[4],[5]])
sage: t.left_key_tableau()
[[1, 1, 1, 2], [2, 2, 2], [4], [5]]

```
def leq(secondtab):
    """Check whether each entry of self is less-or-equal to the corresponding entry of a further tableau secondtab.
    """
    INPUT:
    • secondtab – a tableau of the same shape as self

    EXAMPLES:
    sage: T = Tableau([[1, 2], [3]])
sage: S = Tableau([[1, 3], [3]])
sage: G = Tableau([[2, 1], [4]])
sage: H = Tableau([[1, 2], [4]])
sage: T.leq(S)
    True
    sage: T.leq(T)
    True
    sage: T.leq(G)
    False
    sage: T.leq(H)
    True
    sage: S.leq(T)
    False
    sage: S.leq(G)
    False
    sage: S.leq(H)
    False
    sage: G.leq(H)
    False
    sage: H.leq(G)
    False
```

```
def level():
    """Return the level of self, which is always 1.
    This function exists mainly for compatibility with TableauTuple.
    """
    EXAMPLES:
    sage: Tableau([[1,2,3],[4],[5]]).level()
    1
```

```
def major_index():
    """Return the major index of self.
    The major index of a tableau T is defined to be the sum of the number of descents of T (defined in descents()) with the sum of their legs' lengths.
    """
    Warning: This is not to be confused with the major index of a standard tableau.
```

EXAMPLES:

```
sage: Tableau( [[1,4],[2,3]] ).major_index()
1
sage: Tableau( [[1,2],[3,4]] ).major_index()
2
```

If the major index would be defined in the sense of standard tableaux theory, then the following would give 3 for a result:

```
sage: Tableau( [[1,2,3],[4,5]] ).major_index()
2
```

```
plot(descents=False)
```

Return a plot of self.

INPUT:

- `descents` - boolean (default: False); if True, then the descents are marked in the tableau; only valid if self is a standard tableau

EXAMPLES:

```
sage: t = Tableau([[1,2,4],[3]])
sage: t.plot()
Graphics object consisting of 11 graphics primitives
sage: t.plot(descents=True)
Graphics object consisting of 12 graphics primitives
sage: t = Tableau([[2,2,4],[3]])
sage: t.plot()
Graphics object consisting of 11 graphics primitives
sage: t.plot(descents=True)
Traceback (most recent call last):
  ... ValueError: the tableau must be standard for 'descents=True'
```

```
pp()
```

Pretty print a string of the tableau.

EXAMPLES:

```
sage: T = Tableau([[1,2,3],[3,4],[5]])
sage: T.pp()
  1 2 3
  3 4
  5
sage: Tableaux.options.convention="french"
sage: T.pp()
  5
  3 4
  1 2 3
sage: Tableaux.options._reset()
```

```
promotion(n)
```

Return the image of self under the promotion operator.
The promotion operator, applied to a tableau \( t \), does the following:

Iterate over all letters \( n + 1 \) in the tableau \( t \), from left to right. For each of these letters, do the following:

- Remove the letter from \( t \), thus leaving a hole where it used to be.
- Apply jeu de taquin to move this hole southwest (in French notation) until it reaches the inner boundary of \( t \).
- Fill 0 into the hole once jeu de taquin has completed.

Once this all is done, add 1 to each letter in the tableau. This is not always well-defined. Restricted to the class of semistandard tableaux whose entries are all \( \leq n + 1 \), this is the usual promotion operator defined on this class.

When \( \text{self} \) is a standard tableau of size \( n + 1 \), this definition of promotion is precisely the one given in [Hai1992] (p. 90). It is the inverse of the maps called “promotion” in [Sag2011] (p. 23) and in [Stan2009].

**REFERENCES:**
- [Hai1992]
- [Sag2011]

**EXAMPLES:**

```python
sage: t = Tableau([[1,2],[3,3]])
sage: t.promotion(2)
[[1, 1], [2, 3]]

sage: t = Tableau([[1,1,1],[2,2,3],[3,4,4]])
sage: t.promotion(3)
[[1, 1, 2], [2, 2, 3], [3, 4, 4]]

sage: t = Tableau([[1,2],[3],[3]])
sage: t.promotion(3)
[[2, 3], [3]]

sage: t = Tableau([[1,1,3],[2,3]])
sage: t.promotion(2)
[[1, 1, 2], [2, 3]]

sage: t = Tableau([])
```
Combinatorics, Release 9.7

sage: t.promotion(2)
[]

\textbf{promotion\_inverse}(n)
\hspace{1em} Return the image of self under the inverse promotion operator.

\textbf{Warning}: You might know this operator as the promotion operator (without “inverse”) – literature does not agree on the name.

The inverse promotion operator, applied to a tableau \( t \), does the following:

Iterate over all letters 1 in the tableau \( t \), from right to left. For each of these letters, do the following:

\begin{itemize}
  \item Remove the letter from \( t \), thus leaving a hole where it used to be.
  \item Apply jeu de taquin to move this hole northeast (in French notation) until it reaches the outer boundary of \( t \).
  \item Fill \( n + 2 \) into the hole once jeu de taquin has completed.
\end{itemize}

Once this all is done, subtract 1 from each letter in the tableau. This is not always well-defined. Restricted to the class of semistandard tableaux whose entries are all \( \leq n + 1 \), this is the usual inverse promotion operator defined on this class.

When \( \text{self} \) is a standard tableau of size \( n + 1 \), this definition of inverse promotion is the map called “promotion” in [Sag2011] (p. 23) and in [Stan2009], and is the inverse of the map called “promotion” in [Hai1992] (p. 90).

\textbf{Warning}: To my (Darij’s) knowledge, the fact that the above “inverse promotion operator” really is the inverse of the promotion operator \texttt{promotion()} for semistandard tableaux has never been proven in literature. Corrections are welcome.

\textbf{EXAMPLES}:

sage: t = Tableau([[1,2],[3,3]])
sage: t.promotion\_inverse(2)
[[1, 2], [2, 3]]

sage: t = Tableau([[1,2],[2,3]])
sage: t.promotion\_inverse(2)
[[1, 1], [2, 3]]

sage: t = Tableau([[1,2,5],[3,3,6],[4,7]])
sage: t.promotion\_inverse(8)
[[1, 2, 4], [2, 5, 9], [3, 6]]

sage: t = Tableau([])
sage: t.promotion\_inverse(2)
[]

\textbf{promotion\_operator}(i)
\hspace{1em} Return a list of semistandard tableaux obtained by the \( i \)-th Lapointe-Lascoux-Morse promotion operator from the semistandard tableau \texttt{self}.

5.1. Comprehensive Module List 3321
Warning: This is not Schützenberger’s jeu de taquin promotion! For the latter, see promotion() and promotion_inverse().

This operator is defined by taking the maximum entry $m$ of $T$, then adding a horizontal $i$-strip to $T$ in all possible ways, each time filling this strip with $m+1$’s, and finally letting the permutation $\sigma_1 \sigma_2 \cdots \sigma_m = (2, 3, \ldots, m + 1, 1)$ act on each of the resulting tableaux via the Lascoux-Schützenberger action (symmetric_group_action_on_values()). This method returns the list of all resulting tableaux. See [LLM2003] for the purpose of this operator.

EXAMPLES:

```
sage: t = Tableau([[1,2],[3]])
sage: t.promotion_operator(1)
[[[1, 2, 4], [3]], [[1, 2], [3, 4]], [[1, 2], [3], [4]]]
sage: t.promotion_operator(2)
[[[1, 1, 2, 4], [3]], [[1, 1, 4], [2, 3]], [[1, 1, 2], [3], [4]], [[1, 1], [2, 3], [4]]]
sage: Tableau([[1]]).promotion_operator(2)
[[[1, 1], [2]]]
sage: Tableau([[1],[2]]).promotion_operator(3)
[[[1, 1, 1, 2, 3], [2]], [[1, 1, 1, 3], [2, 2]], [[1, 1, 1, 2], [2], [3]], [[1, 1, 1], [2, 2], [3]]]
```

The example from [LLM2003] p. 12:

```
sage: Tableau([[1,1],[2,2]]).promotion_operator(3)
[[[1, 1, 1, 3, 3], [2, 2]], [[1, 1, 1, 3], [2, 2], [3]], [[1, 1, 1], [2, 2], [3, 3]]
```

raise_action_from_words($f$, *args)

EXAMPLES:

```
sage: from sage.combinat.tableau import symmetric_group_action_on_values
sage: import functools
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: f = functools.partial(t.raise_action_from_words, symmetric_group_action_on_values)
sage: f([1,2,3])
[[1, 1, 3, 3], [2, 3], [3]]
sage: f([3,2,1])
[[1, 1, 1], [2, 3], [3]]
sage: f([1,3,2])
[[1, 1, 2, 2], [2, 2], [3]]
```

reading_word_permutation()

Return the permutation obtained by reading the entries of the standardization of self row by row, starting with the bottommost row (in English notation).

EXAMPLES:
sage: StandardTableau([[1,2],[3,4]]).reading_word_permutation()
[3, 4, 1, 2]

Check that trac ticket #14724 is fixed:

sage: SemistandardTableau([[1,1]]).reading_word_permutation()
[1, 2]

\texttt{reduced\_column\_word()}\n
Return the lexicographically minimal reduced expression for the permutation that maps the conjugate of the initial_tableau() to self.

This reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the columns of the tableau in order from top to bottom.

EXAMPLES:

sage: StandardTableau([[1,4,6],[2,5],[3]]).reduced_column_word()
[]
sage: StandardTableau([[1,4,5],[2,6],[3]]).reduced_column_word()
[5]
sage: StandardTableau([[1,3,6],[2,5],[4]]).reduced_column_word()
[3]
sage: StandardTableau([[1,3,5],[2,6],[4]]).reduced_column_word()
[3, 5]
sage: StandardTableau([[1,2,5],[3,6],[4]]).reduced_column_word()
[3, 2, 5]

\texttt{reduced\_lambda\_catabolism}(part)\n
EXAMPLES:

sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.reduced_lambda_catabolism([])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.reduced_lambda_catabolism([1])
[[1, 2, 3, 3, 3], [3]]
sage: t.reduced_lambda_catabolism([2,1])
[[3, 3, 3, 3, 3]]
sage: t.reduced_lambda_catabolism([4,2,1])
[]
sage: t.reduced_lambda_catabolism([5,1])
0
sage: t.reduced_lambda_catabolism([4,1])
0

\texttt{reduced\_row\_word()}\n
Return the lexicographically minimal reduced expression for the permutation that maps the initial_tableau() to self.

This reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the rows of the tableau in order from top to bottom.
EXAMPLES:

```python
sage: StandardTableau([[1,2,3],[4,5],[6]]).reduced_row_word()
[]
sage: StandardTableau([[1,2,3],[4,6],[5]]).reduced_row_word()
[5]
sage: StandardTableau([[1,2,4],[3,6],[5]]).reduced_row_word()
[3, 5]
sage: StandardTableau([[1,2,5],[3,6],[4]]).reduced_row_word()
[3, 5, 4]
sage: StandardTableau([[1,2,6],[3,5],[4]]).reduced_row_word()
[3, 4, 5, 4]
```

`residue(k, e, multicharge=(0,))`

Return the residue of the integer \( k \) in the tableau \( \text{self} \).

The residue of \( k \) in a standard tableau is \( c - r + m \) in \( \mathbb{Z}/e\mathbb{Z} \), where \( k \) appears in row \( r \) and column \( c \) of the tableau with multicharge \( m \).

**INPUT:**

- \( k \) – an integer in \( \{1, 2, \ldots, n\} \)
- \( e \) – an integer in \( \{0, 2, 3, 4, 5, \ldots\} \)
- \( \text{multicharge} \) – (default: \([0]\)) a list of length 1

Here \( n \) is its size of \( \text{self} \).

The multicharge is a list of length 1 which gives an offset for all of the contents. It is included mainly for compatibility with `residue()`.

**OUTPUT:**

The residue in \( \mathbb{Z}/e\mathbb{Z} \).

**EXAMPLES:**

```python
sage: StandardTableau([[1,2,5],[3,4]]).residue(1,3)
0
sage: StandardTableau([[1,2,5],[3,4]]).residue(2,3)
1
sage: StandardTableau([[1,2,5],[3,4]]).residue(3,3)
2
sage: StandardTableau([[1,2,5],[3,4]]).residue(4,3)
0
sage: StandardTableau([[1,2,5],[3,4]]).residue(5,3)
2
sage: StandardTableau([[1,2,5],[3,4]]).residue(6,3)
Traceback (most recent call last):
... ValueError: 6 does not appear in the tableau
```

`residue_sequence(e, multicharge=(0,))`

Return the `sage.combinat.tableau_residues.ResidueSequence` of the tableau \( \text{self} \).

**INPUT:**

- \( e \) – an integer in \( \{0, 2, 3, 4, 5, \ldots\} \)
- \( \text{multicharge} \) – (default: \([0]\)) a sequence of integers of length 1
The **multicharge** is a list of length 1 which gives an offset for all of the contents. It is included mainly for compatibility with `residue()`.

**OUTPUT:**

The corresponding residue sequence of the tableau; see `ResidueSequence`.

**EXAMPLES:**

```python
sage: StandardTableauTuple([[1,2],[3,4]]).residue_sequence(2)
2-residue sequence (0,1,1,0) with multicharge (0)
sage: StandardTableauTuple([[1,2],[3,4]]).residue_sequence(3)
3-residue sequence (0,1,2,0) with multicharge (0)
sage: StandardTableauTuple([[1,2],[3,4]]).residue_sequence(4)
4-residue sequence (0,1,3,0) with multicharge (0)
```

**restrict(n)**

Return the restriction of the semistandard tableau `self` to `n`. If possible, the restricted tableau will have the same parent as this tableau.

If `T` is a semistandard tableau and `n` is a nonnegative integer, then the restriction of `T` to `n` is defined as the (semistandard) tableau obtained by removing all cells filled with entries greater than `n` from `T`.

**Note:** If only the shape of the restriction, rather than the whole restriction, is needed, then the faster method `restriction_shape()` is preferred.

**EXAMPLES:**

```python
sage: Tableau([[1,2],[3],[4]]).restrict(3)
[[1, 2], [3]]
sage: StandardTableau([[1,2],[3],[4]]).restrict(2)

sage: Tableau([[1,2],[3],[4],[5]]).restrict(0)
[]
sage: Tableau([[1,2],[3],[4],[5]]).restrict(2)
[[1, 2], [2]]
sage: Tableau([[1,2],[3],[4],[5]]).restrict(3)
[[1, 2, 3], [2], [3]]
sage: Tableau([[1,2],[3],[4],[5]]).restrict(5)
[[1, 2, 3], [2, 4, 4], [3]]
```

If possible the restricted tableau will belong to the same category as the original tableau:

```python
sage: S = StandardTableau([[1,2,4,7],[3,5],[6]]); S.category()
Category of elements of Standard tableaux
sage: S.restrict(4).category()
Category of elements of Standard tableaux
sage: SS=StandardTableaux([4,2,1])([[1,2,4,7],[3,5],[6]]); SS.category()
Category of elements of Standard tableaux of shape [4, 2, 1]
sage: SS.restrict(4).category()
Category of elements of Standard tableaux
sage: Tableau([[1,2],[3],[4]]).restrict(3)
[[1, 2], [3]]
sage: Tableau([[1,2],[3],[4]]).restrict(2)
```

(continues on next page)
**restriction_shape** \((n)\)

Return the shape of the restriction of the semistandard tableau \(self\) to \(n\).

If \(T\) is a semistandard tableau and \(n\) is a nonnegative integer, then the restriction of \(T\) to \(n\) is defined as the (semistandard) tableau obtained by removing all cells filled with entries greater than \(n\) from \(T\).

This method computes merely the shape of the restriction. For the restriction itself, use \(restrict()\).

**EXAMPLES:**

```
sage: Tableau([[1,2],[2,3],[3,4]]).restriction_shape(3)
[2, 2, 1]
sage: StandardTableau([[1,2],[3],[4],[5]]).restriction_shape(2)
[2]
sage: Tableau([[1,3,3,5],[2,4,4],[17]]).restriction_shape(0)
[]
sage: Tableau([[1,3,3,5],[2,4,4],[17]]).restriction_shape(2)
[1, 1]
sage: Tableau([[1,3,3,5],[2,4,4],[17]]).restriction_shape(3)
[3, 1]
sage: Tableau([[1,3,3,5],[2,4,4],[17]]).restriction_shape(5)
[4, 3]
sage: all( T.restriction_shape(i) == T.restrict(i).shape()  
     ....:     for T in StandardTableaux(5) for i in range(1, 5) )
True
```

**reverse_bump** \((loc)\)

Reverse row bump the entry of \(self\) at the specified location \(loc\) (given as a row index or a corner \((r, c)\) of the tableau).

This is the reverse of Schensted’s row-insertion algorithm. See Section 1.1, page 8, of Fulton’s [Ful1997].

**INPUT:**

- \(loc\) – Can be either of the following:
  - The coordinates \((r, c)\) of the square to reverse-bump (which must be a corner of the tableau);
  - The row index \(r\) of this square.

  Note that both \(r\) and \(c\) are 0-based, i.e., the topmost row and the leftmost column are the 0-th row and the 0-th column.

**OUTPUT:**

An ordered pair consisting of:

1. The resulting (smaller) tableau;
2. The entry bumped out at the end of the process.
See also:

\texttt{bump()}\n
EXAMPLES:

This is the reverse of Schensted's bump:

\begin{verbatim}
sage: T = Tableau([[1, 1, 2, 2, 4], [2, 3, 3], [3, 4], [4]])
sage: T.reverse_bump(2)(([[1, 1, 2, 3, 4], [2, 3, 4], [3], [4]], 2)
sage: T == T.reverse_bump(2)[0].bump(2)
True
sage: T.reverse_bump((3, 0))(([[1, 2, 2, 2, 4], [3, 3, 3], [4, 4]], 1)
\end{verbatim}

Some errors caused by wrong input:

\begin{verbatim}
sage: T.reverse_bump((3, 1))
Traceback (most recent call last):
...
ValueError: invalid corner
sage: T.reverse_bump(4)
Traceback (most recent call last):
...
IndexError: list index out of range
sage: Tableau([[2, 2, 1], [3, 3]]).reverse_bump(0)
Traceback (most recent call last):
...
ValueError: reverse bumping is only defined for semistandard tableaux
\end{verbatim}

Some edge cases:

\begin{verbatim}
sage: Tableau([[1]]).reverse_bump(0)(([], 1)
sage: Tableau([[1,1]]).reverse_bump(0)(([[1]], 1)
sage: Tableau([]).reverse_bump(0)
Traceback (most recent call last):
...
IndexError: list index out of range
\end{verbatim}

\textbf{Note:} Reverse row bumping is only implemented for tableaux with weakly increasing and strictly increasing columns (though the tableau does not need to be an instance of class \texttt{SemistandardTableau}).

\begin{verbatim}
right_key_tableau()
\end{verbatim}

\texttt{right_key_tableau()} returns the right \texttt{key_tableau} of \texttt{self}.

The right key tableau of a tableau $T$ is a key tableau whose entries are weakly greater than the corresponding entries in $T$, and whose column reading word is subject to certain conditions. See [LS1990] for the full definition.

\textbf{ALGORITHM:}

The following algorithm follows [Wil2010]. Note that if $T$ is a key tableau then the output of the algorithm is $T$. 

5.1. Comprehensive Module List 3327
To compute the right key tableau $R$ of a tableau $T$ we iterate over the columns of $T$. Let $T_j$ be the $j$-th column of $T$ and iterate over the entries in $T_j$ from bottom to top. Initialize the corresponding entry $k$ in $R$ to be the largest entry in $T_j$. Scan the bottom of each column of $T$ to the right of $T_j$, updating $k$ to be the scanned entry whenever the scanned entry is weakly greater than $k$. Update $T_j$ and all columns to the right by removing all scanned entries.

See also:

- `is_key_tableau()`

**EXAMPLES:**

```
sage: t = Tableau([[1,2],[2,3]])
sage: t.right_key_tableau()
[[2, 2], [3, 3]]
sage: t = Tableau([[1,1,2,4],[2,3,3],[4],[5]])
sage: t.right_key_tableau()
[[2, 2, 2, 4], [3, 4, 4], [4], [5]]
```

**rotate_180()**

Return the tableau obtained by rotating self by 180 degrees.

This only works for rectangular tableaux.

**EXAMPLES:**

```
sage: Tableau([[1,2],[3,4]]).rotate_180()
[[4, 3], [2, 1]]
```

**row_stabilizer()**

Return the `PermutationGroup` corresponding to the row stabilizer of `self`.

This assumes that every integer from 1 to the size of `self` appears exactly once in `self`.

**EXAMPLES:**

```
sage: rs = Tableau([[1,2,3],[4,5]]).row_stabilizer()
sage: rs.order() == factorial(3)*factorial(2)
True
sage: PermutationGroupElement([(1,3,2),(4,5)]) in rs
True
sage: PermutationGroupElement([(1,4)]) in rs
False
sage: rs = Tableau([[1, 2],[3]]).row_stabilizer()
sage: PermutationGroupElement([(1,2),(3,)]) in rs
True
sage: rs.one().domain()
[1, 2, 3]
sage: rs = Tableau([[1],[2],[3]]).row_stabilizer()
sage: rs.order()
1
sage: rs = Tableau([[2,4,5],[1,3]]).row_stabilizer()
sage: rs.order()
12
sage: rs = Tableau([]).row_stabilizer()
sage: rs.order()
1
```
**schensted_insert**(*i*, *left=False*)

Insert *i* into *self* using Schensted’s row-bumping (or row-insertion) algorithm.

**INPUT:**

- *i* – a number to insert
- *left* – (default: *False*) boolean; if set to *True*, the insertion will be done from the left. That is, if one thinks of the algorithm as appending a letter to the reading word of *self*, we append the letter to the left instead of the right

**EXAMPLES:**

```python
def example_schensted_insert():
    t = Tableau([[3, 5], [7]])
    t.schensted_insert(8)
    print(t)  # Output: [[3, 5, 8], [7]]
    t.schensted_insert(8, left=True)
    print(t)  # Output: [[3, 5], [7], [8]]
```

**schuetzenberger_involution**(*n=None, check=True*)

Return the Schuetzenberger involution of the tableau *self*.

This method relies on the analogous method on words, which reverts the word and then complements all letters within the underlying ordered alphabet. If *n* is specified, the underlying alphabet is assumed to be [1, 2, ..., *n*]. If no alphabet is specified, *n* is the maximal letter appearing in *self*.

**INPUT:**

- *n* – an integer specifying the maximal letter in the alphabet (optional)
- *check* – (Default: *True*) Check to make sure *self* is semistandard. Set to *False* to avoid this check. (optional)

**OUTPUT:**

- a tableau, the Schuetzenberger involution of *self*

**EXAMPLES:**

```python
def example_schuetzenberger_involution():
    t = Tableau([[1, 1, 1], [2, 2]])
    t.schuetzenberger_involution(3)
    print(t)  # Output: [[2, 2, 3], [3, 3]]
    t = Tableau([[1, 2, 3], [4, 5]])
    t.schuetzenberger_involution()
    print(t)  # Output: [[1, 2, 5], [3, 4]]
    t = Tableau([[1, 3, 5, 7], [2, 4, 6], [8, 9]])
    t.schuetzenberger_involution()
    print(t)  # Output: [[1, 2, 6, 8], [3, 4, 9], [5, 7]]
    t = Tableau([])
    t.schuetzenberger_involution()
    print(t)  # Output: []
    t = StandardTableau([[1, 2, 3], [4, 5]])
    s = t.schuetzenberger_involution()
    print(s.parent())  # Output: Standard tableaux
```
seg()

Return the total number of segments in self, as in [Sal2014].

Let $T$ be a tableau. We define a $k$-segment of $T$ (in the $i$-th row) to be a maximal consecutive sequence of $k$-boxes in the $i$-th row for any $i+1 \leq k \leq r+1$. Denote the total number of $k$-segments in $T$ by $\text{seg}(T)$.

REFERENCES:

• [Sal2014]

EXAMPLES:

```sage
t = Tableau([[1,1,2,3,5],[2,3,5,5],[3,4]])
sage: t.seg()

6
```

```sage:B = crystals.Tableaux("A4",shape=[4,3,2,1])
sage: t = B[31].to_tableau()
sage: t.seg()
3
```

shape()

Return the shape of a tableau self.

EXAMPLES:

```sage:
Tableau([[1,2,3],[4,5],[6]]).shape()
[3, 2, 1]
```

size()

Return the size of the shape of the tableau self.

EXAMPLES:

```sage:
Tableau([[1, 4, 6], [2, 5], [3]]).size()
6
sage:
Tableau([[1, 3], [2, 4]]).size()
4
```

slide_multiply(other)

Multiply two tableaux using jeu de taquin.

This product makes the set of semistandard tableaux into an associative monoid. The empty tableau is the unit in this monoid.

See pp. 15 of [Ful1997].

The same product operation is implemented in a different way in $\text{bump}_\text{multiply}()$.

EXAMPLES:

```sage:
t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t2 = Tableau([[1,2],[3]])
sage: t.slide_multiply(t2)
[[1, 1, 2, 2, 3], [2, 2, 3, 5], [3, 4, 5], [4, 6, 6], [5]]
```

socle()

EXAMPLES:
standardization\( (check=True) \)
Return the standardization of self, assuming self is a semistandard tableau.

The standardization of a semistandard tableau \( T \) is the standard tableau \( st(T) \) of the same shape as \( T \) whose reversed reading word is the standardization of the reversed reading word of \( T \).

The standardization of a word \( w \) can be formed by replacing all 1’s in \( w \) by 1, 2, \ldots, \( k_1 \) from left to right, all 2’s in \( w \) by \( k_1 + 1, k_1 + 2, \ldots, k_2 \), and repeating for all letters which appear in \( w \). See also Word.

standard_permutation().

INPUT:

• check – (Default: True) Check to make sure self is semistandard. Set to False to avoid this check.

EXAMPLES:

```python
sage: t = Tableau([[1,3,3,4],[2,4,4],[5,16]])
sage: t.standardization()
[[1, 3, 4, 7], [2, 5, 6], [8, 9]]
```

Standard tableaux are fixed under standardization:

```python
sage: all((t == t.standardization() for t in StandardTableaux(6)))
True
```

The reading word of the standardization is the standardization of the reading word:

```python
sage: T = SemistandardTableaux(shape=[5,2,2,1], max_entry=4)
sage: all(t.to_word().standard_permutation() == t.standardization().reading_word_permutation() for t in T) # long time
True
```

sulzgruber_correspondence()

Return the image of the \( \lambda \)-array self under the Sulzgruber correspondence (as a WeakReversePlanePartition).

This relies on interpreting self as a \( \lambda \)-array in the sense of hillman_grassl. See hillman_grassl for definitions of the objects involved.

The Sulzgruber correspondence is the map \( \Phi_\lambda \) from [Sulzg2017] Section 7, and is the map \( \xi_\lambda^{-1} \) from [Pak2002] Section 5. It is denoted by \( RSK \) in [Hopkins2017]. It is the inverse of the Pak correspondence (pak_correspondence()). The following description of the Sulzgruber correspondence follows [Hopkins2017] (which denotes it by \( RSK \)):

Fix a partition \( \lambda \) (see Partition()). We draw all partitions and tableaux in English notation.

A \( \lambda \)-array will mean a tableau of shape \( \lambda \) whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A weak reverse plane partition of shape \( \lambda \) (short: \( \lambda \)-rpp) will mean a \( \lambda \)-array whose entries weakly increase along each row and weakly increase along each column.
We shall also use the following notation: If \((u, v)\) is a cell of \(\lambda\), and if \(\pi\) is a \(\lambda\)-rpp, then:

- the **lower bound** of \(\pi\) at \((u, v)\) (denoted by \(\pi_{u,v}^-\)) is defined to be \(\max\{\pi_{u-1,v}, \pi_{u,v-1}\}\) (where \(\pi_{0,v}\) and \(\pi_{u,0}\) are understood to mean 0).

- the **upper bound** of \(\pi\) at \((u, v)\) (denoted by \(\pi_{u,v}^+\)) is defined to be \(\min\{\pi_{u+1,v}, \pi_{u,v+1}\}\) (where \(\pi_{i,j}\) is understood to mean \(+\infty\) if \((i, j)\) is not in \(\lambda\); thus, the upper bound at a corner cell is \(+\infty\).

- **toggling** \(\pi\) at \((u, v)\) means replacing the entry \(\pi_{u,v}\) of \(\pi\) at \((u, v)\) by \(\pi_{u,v}^- + \pi_{u,v}^+ - \pi_{u,v}\) (this is well-defined as long as \((u, v)\) is not a corner of \(\lambda\)).

Note that every \(\lambda\)-rpp \(\pi\) and every cell \((u, v)\) of \(\lambda\) satisfy \(\pi_{u,v}^- \leq \pi_{u,v} \leq \pi_{u,v}^+\). Note that toggling a \(\lambda\)-rpp (at a cell that is not a corner) always results in a \(\lambda\)-rpp. Also, toggling is an involution.

The Pak correspondence \(\xi_\lambda\) sends a \(\lambda\)-rpp \(\pi\) to a \(\lambda\)-array \(\xi_\lambda(\pi)\). It is defined by recursion on \(\lambda\) (that is, we assume that \(\xi_\mu\) is already defined for every partition \(\mu\) smaller than \(\lambda\)), and its definition proceeds as follows:

- If \(\lambda = \emptyset\), then \(\xi_\lambda\) is the obvious bijection sending the only \(\emptyset\)-rpp to the only \(\emptyset\)-array.

- Pick any corner \(c = (i, j)\) of \(\lambda\), and let \(\mu\) be the result of removing this corner \(c\) from the partition \(\lambda\). (The exact choice of \(c\) is immaterial.)

- Let \(\pi'\) be what remains of \(\pi\) when the corner cell \(c\) is removed.

- For each positive integer \(k\) such that \((i-k, j-k)\) is a cell of \(\lambda\), toggle \(\pi'\) at \((i-k, j-k)\). (All these togglings commute, so the order in which they are made is immaterial.)

- Let \(M = \xi_\mu(\pi')\).

- Extend the \(\mu\)-array \(M\) to a \(\lambda\)-array \(M'\) by adding the cell \(c\) and writing the number \(\pi_{i,j} - \pi_{u,v}^-\) into this cell.

- Set \(\xi_\lambda(\pi) = M'\).

See also:

- *sulzgruber_correspondence()* for the Sulzgruber correspondence as a standalone function.
- *pak_correspondence()* for the inverse map.

**EXAMPLES:**

```
sage: a = Tableau([[2, 1, 1], [0, 2, 0], [1, 1]])
sage: A = a.sulzgruber_correspondence(); A
[ [0, 1, 4], [1, 5, 5], [3, 6] ]
sage: A.parent(), a.parent()
(Weak Reverse Plane Partitions, Tableaux)
sage: a = Tableau([[1, 3], [0, 1]])
sage: a.sulzgruber_correspondence()
[ [0, 4], [1, 5] ]
```

**symmetric_group_action_on_entries(\(w\))**

Return the tableau obtained form this tableau by acting by the permutation \(w\).

Let \(T\) be a standard tableau of size \(n\), then the action of \(w \in S_n\) is defined by permuting the entries of \(T\) (recall they are \(1, 2, \ldots, n\)). In particular, suppose the entry at cell \((i, j)\) is \(a\), then the entry becomes \(w(a)\).

In general, the resulting tableau \(wT\) may not be standard.
**Note:** This is different than `symmetric_group_action_on_values()` which is defined on semistandard tableaux and is guaranteed to return a semistandard tableau.

**INPUT:**

- `w` – a permutation

**EXAMPLES:**

```python
sage: StandardTableau([[1,2,4],[3,5]]).symmetric_group_action_on_entries(Permutation(((4,5))) )
[[1, 2, 5], [3, 4]]
sage: _.category()
Category of elements of Standard tableaux
sage: StandardTableau([[1,2,4],[3,5]]).symmetric_group_action_on_entries(Permutation(((1,2))) )
[[2, 1, 4], [3, 5]]
sage: _.category()
Category of elements of Tableaux
```

`symmetric_group_action_on_values(perm)`

Return the image of the semistandard tableau `self` under the action of the permutation `perm` using the Lascoux-Schuetzenberger action of the symmetric group $S_n$ on the semistandard tableaux with ceiling $n$.

If $n$ is a nonnegative integer, then the Lascoux-Schuetzenberger action is a group action of the symmetric group $S_n$ on the set of semistandard Young tableaux with ceiling $n$ (that is, with entries taken from the set $\{1,2,...,n\}$). It is defined as follows:

Let $i \in \{1,2,...,n-1\}$, and let $T$ be a semistandard tableau with ceiling $n$. Let $w$ be the reading word (`to_word()`) of $T$. Replace all letters $i$ in $w$ by closing parentheses, and all letters $i+1$ in $w$ by opening parentheses. Whenever an opening parenthesis stands left of a closing parenthesis without there being any parentheses in between (it is allowed to have letters in-between as long as they are not parentheses), consider these two parentheses as matched with each other, and replace them back by the letters $i$ and $i+1$. Repeat this procedure until there are no more opening parentheses standing left of closing parentheses. Then, let $a$ be the number of opening parentheses in the word, and $b$ the number of closing parentheses (notice that all opening parentheses are right of all closing parentheses). Replace the first $a$ parentheses by the letters $i$, and replace the remaining $b$ parentheses by the letters $i+1$. Let $w'$ be the resulting word. Let $T'$ be the tableau with the same shape as $T$ but with reading word $w'$. This tableau $T'$ can be shown to be semistandard. We define the image of $T$ under the action of the simple transposition $s_i = (i, i+1) \in S_n$ to be this tableau $T'$. It can be shown that these actions of the transpositions $s_1, s_2, \ldots, s_{n-1}$ satisfy the Moore-Coxeter relations of $S_n$, and thus this extends to a unique action of the symmetric group $S_n$ on the set of semistandard tableaux with ceiling $n$. This is the Lascoux-Schuetzenberger action.

This action of the symmetric group $S_n$ on the set of all semistandard tableaux of given shape $\lambda$ with entries in $\{1,2,...,n\}$ is the one defined in [Loth02] Theorem 5.6.3. In particular, the action of $s_i$ is denoted by $\sigma_i$ in said source. (Beware of the typo in the definition of $\sigma_i$: it should say $\sigma_i(a^r_ia^s_{i+1}) = a^s_ia^r_{i+1}$, not $\sigma_i(a^r_ia^s_{i+1}) = a^s_ia^r_{i+1}$.)

**EXAMPLES:**

```python
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.symmetric_group_action_on_values([1,2,3])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.symmetric_group_action_on_values([2,1,3])
[[1, 2, 3, 3], [2, 3], [3]]
```

(continues on next page)
sage: t.symmetric_group_action_on_values([3, 1, 2])
[[1, 2, 2, 2], [2, 3], [3]]
sage: t.symmetric_group_action_on_values([2, 3, 1])
[[1, 1, 1, 1], [2, 2], [3]]
sage: t.symmetric_group_action_on_values([3, 2, 1])
[[1, 1, 1, 1], [2, 3], [3]]
sage: t.symmetric_group_action_on_values([1, 3, 2])
[[1, 1, 2, 2], [2, 2], [3]]

\textbf{to\_Gelfand\_Tsetlin\_pattern()}

Return the Gelfand-Tsetlin pattern corresponding to self when semistandard.

\textbf{EXAMPLES:}

sage: T = Tableau([[1,2,3],[2,3],[3]])
sage: G = T.to_Gelfand_Tsetlin_pattern()
[[3, 2, 1], [2, 1], [1]]
sage: G.to_tableau() == T
True
sage: T = Tableau([[1,3],[2]])
sage: T.to_Gelfand_Tsetlin_pattern()
[[2, 1, 0], [1, 1], [1]]

\textbf{to\_chain(max\_entry=None)}

Return the chain of partitions corresponding to the (semi)standard tableau self.

The optional keyword parameter max_entry can be used to customize the length of the chain. Specifically, if this parameter is set to a nonnegative integer $n$, then the chain is constructed from the positions of the letters $1, 2, \ldots, n$ in the tableau.

\textbf{EXAMPLES:}

sage: Tableau([[1,2],[3],[4]]).to_chain()
[[], [1], [2], [2, 1], [2, 1, 1]]
sage: Tableau([[1,1],[2]]).to_chain()
[[], [2], [2, 1]]
sage: Tableau([[1,1],[3]]).to_chain()
[[], [2], [2], [2, 1]]
sage: Tableau([]).to_chain()
[[], []]
sage: Tableau([[1,1],[2],[3]]).to_chain(max_entry=2)
[[], [2], [2, 1]]
sage: Tableau([[1,1],[2],[3]]).to_chain(max_entry=3)
[[], [2], [2, 1], [2, 1, 1]]
sage: Tableau([[1,1],[2],[3]]).to_chain(max_entry=4)
[[], [2], [2, 1], [2, 1, 1], [2, 1, 1]]
sage: Tableau([[1,1,2],[2,3],[4,5]]).to_chain(max_entry=6)
[[], [2], [3, 1], [3, 2], [3, 2, 1], [3, 2, 2], [3, 2, 2]]

\textbf{to\_list()}

Return self as a list of lists (not tuples!).

\textbf{EXAMPLES:}
sage: t = Tableau([[1,2],[3,4]])
sage: l = t.to_list(); l
[[1, 2], [3, 4]]
sage: l[0][0] = 2
sage: t
[[1, 2], [3, 4]]

to_sign_matrix(max_entry=None)
Return the sign matrix of self.

A sign matrix is an $m \times n$ matrix of 0's, 1's and -1's such that the partial sums of each column is either 0 or 1 and the partial sums of each row is non-negative. [Ava2007]

INPUT:

• max_entry – A non-negative integer, the maximum allowable number in the tableau. Defaults to the largest entry in the tableau if not specified.

EXAMPLES:

sage: t = SemistandardTableau([[1,1,1,2,4],[3,3,4],[4,5],[6,6]])
sage: t.to_sign_matrix(6)
[ 0 0 0 1 0 0]
[ 0 1 0 -1 0 0]
[ 1 -1 0 1 0 0]
[ 0 0 1 -1 1 1]
[ 0 0 0 1 -1 0]
sage: t = Tableau([[1,2,4],[3,5]])
sage: t.to_sign_matrix(7)
[ 0 0 0 1 0 0 0]
[ 0 1 0 -1 1 0 0]
[ 1 -1 1 0 -1 0 0]
sage: t = Tableau(((4,5,4,3),(2,1,3))
sage: t.to_sign_matrix(5)
[ 0 0 1 0 0]
[ 0 0 0 1 0]
[ 1 0 -1 -1 1]
[-1 1 0 1 -1]
sage: s = Tableau(((1,0,-2,4),(3,4,5))
sage: s.to_sign_matrix(6)
Traceback (most recent call last):
... ValueError: the entries must be non-negative integers

to_word()
An alias for to_word_by_row().

EXAMPLES:

sage: Tableau([[1,2],[3,4]]).to_word()
word: 3412
sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word()
word: 325146

to_word_by_column()
Return the word obtained from a column reading of the tableau self (starting with the leftmost column,
reading every column from bottom to top).

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).to_word_by_column()
word: 3142
sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word_by_column()
word: 321546
```

to_word_by_row()

Return the word obtained from a row reading of the tableau self (starting with the lowermost row, reading every row from left to right).

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).to_word_by_row()
word: 3412
sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word_by_row()
word: 325146
```

vertical_flip()

Return the tableau obtained by vertically flipping the tableau self.

This only works for rectangular tableaux.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).vertical_flip()
[[3, 4], [1, 2]]
```

weight()

Return the weight of the tableau self. Trailing zeroes are omitted when returning the weight.

The weight of a tableau $T$ is the sequence $(a_1, a_2, a_3, \ldots)$, where $a_k$ is the number of entries of $T$ equal to $k$. This sequence contains only finitely many nonzero entries.

The weight of a tableau $T$ is the same as the weight of the reading word of $T$, for any reading order.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).weight()
[1, 1, 1, 1]
sage: Tableau([]).weight()
[]
sage: Tableau([[1,3,3,7],[4,2],[2,3]]).weight()
[1, 2, 3, 1, 0, 0, 1]
```

class sage.combinat.tableau.Tableau_class(parent, t, check=True)

Bases: sage.combinat.tableau.Tableau

This exists solely for unpickling Tableau_class objects.

class sage.combinat.tableau.Tableaux

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

A factory class for the various classes of tableaux.
INPUT:

- n (optional) – a non-negative integer

OUTPUT:

- If n is specified, the class of tableaux of size n. Otherwise, the class of all tableaux.

A tableau in Sage is a finite list of lists, whose lengths are weakly decreasing, or an empty list, representing the empty tableau. The entries of a tableau can be any Sage objects. Because of this, no enumeration through the set of Tableaux is possible.

EXAMPLES:

```python
sage: T = Tableaux(); T
Tableaux
sage: T3 = Tableaux(3); T3
Tableaux of size 3
sage: [['a','b']] in T
True
sage: [['a','b']] in T3
False
sage: t = T3([[1,1,1]]); t
[[1, 1, 1]]
sage: t in T
True
sage: t.parent()
Tableaux of size 3
sage: T([]) # the empty tableau
[]
```

See also:

- Tableau
- SemistandardTableaux
- SemistandardTableau
- StandardTableaux
- StandardTableau

Element

alias of Tableau

options(*get_value, **set_value)

Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:

- ascii_art – (default: repr) Controls the ascii art output for tableaux
  - compact – minimal length ascii art
  - repr – display using the diagram string representation
  - table – display as a table
• **convention** – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention

• **display** – (default: list) Controls the way in which tableaux are printed
  - array – alias for diagram
  - compact – minimal length string representation
  - diagram – display as Young diagram (similar to \texttt{pp()})
  - ferrers_diagram – alias for diagram
  - list – print tableaux as lists
  - young_diagram – alias for diagram

• **latex** – (default: diagram) Controls the way in which tableaux are latexed
  - array – alias for diagram
  - diagram – as a Young diagram
  - ferrers_diagram – alias for diagram
  - list – as a list
  - young_diagram – alias for diagram

• **notation** – alternative name for convention

**Note:** Changing the convention for tableaux also changes the convention for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

**EXAMPLES:**

```sage
sage: T = Tableau([[1,2,3],[4,5]])
sage: T
[[1, 2, 3], [4, 5]]
sage: Tableaux.options.display="array"
sage: T
1 2 3
4 5
sage: Tableaux.options.convention="french"
sage: T
4 5
1 2 3
```

Changing the convention for tableaux also changes the convention for partitions and vice versa:

```sage
sage: P = Partition([3,3,1])
sage: print(P.ferrers_diagram())
***
***
sage: Partitions.options.convention="english"
sage: print(P.ferrers_diagram())
```

(continues on next page)
The ASCII art can also be changed:

```python
sage: t = Tableau([[1,2,3],[4,5]])
sage: ascii_art(t)
1 2 3
4 5

sage: Tableaux.options.ascii_art = "table"
sage: ascii_art(t)
+---+---+---+
| 1 | 2 | 3 |
+---+---+---+
| 4 | 5 |
+-+-++

sage: Tableaux.options.ascii_art = "compact"
sage: ascii_art(t)
|1|2|3|
|4|5|

sage: Tableaux.options._reset()
```

See `GlobalOptions` for more features of these options.

```python
class sage.combinat.tableau.Tableaux_all
    Bases: `sage.combinat.tableau.Tableaux`

    Initializes the class of all tableaux

    .. method:: an_element()

        Return a particular element of the class.

class sage.combinat.tableau.Tableaux_size(n)
    Bases: `sage.combinat.tableau.Tableaux`

    Tableaux of a fixed size $n$.

    .. method:: an_element()

        Return a particular element of the class.

sage.combinat.tableau.from_chain(chain)

    Return a semistandard tableau from a chain of partitions.

    EXAMPLES:

    ```python
    sage: from sage.combinat.tableau import from_chain
    sage: from_chain([[[], [2], [2, 1], [3, 2, 1]])
    [[1, 1, 3], [2, 3], [3]]
    ```

sage.combinat.tableau.from_shape_and_word(shape, w, convention='French')

    Return a tableau from a shape and word.

    INPUT:
• shape – a partition
• w – a word whose length equals that of the partition
• convention – a string which can take values "French" or "English"; the default is "French"

OUTPUT:
A tableau, whose shape is shape and whose reading word is w. If the convention is specified as "French", the reading word is to be read starting from the top row in French convention (= the bottom row in English convention). If the convention is specified as "English", the reading word is to be read starting with the top row in English convention.

EXAMPLES:
```
sage: from sage.combinat.tableau import from_shape_and_word
sage: t = Tableau([[1, 3], [2], [4]])
sage: shape = t.shape(); shape
[2, 1, 1]
sage: word = t.to_word(); word
word: 4213
sage: from_shape_and_word(shape, word)
[[1, 3], [2], [4]]
sage: word = Word(flatten(t))
sage: from_shape_and_word(shape, word, convention="English")
[[1, 3], [2], [4]]
```

```
sage.combinat.tableau.symmetric_group_action_on_values(word, perm)
Return the image of the word word under the Lascoux-Schuetzenberger action of the permutation perm.
See Tableau.symmetric_group_action_on_values() for the definition of the Lascoux-Schuetzenberger action on semistandard tableaux. The transformation that the reading word of the tableau undergoes in said definition is precisely the Lascoux-Schuetzenberger action on words.

EXAMPLES:
```
sage: from sage.combinat.tableau import symmetric_group_action_on_values
sage: symmetric_group_action_on_values([1,1,1],[1,3,2])
[1, 1, 1]
sage: symmetric_group_action_on_values([1,1,1],[2,1,3])
[2, 2, 2]
sage: symmetric_group_action_on_values([1,2,1],[2,1,3])
[2, 2, 1]
sage: symmetric_group_action_on_values([2,2,2],[2,1,3])
[1, 1, 1]
sage: symmetric_group_action_on_values([2,1,2],[2,1,3])
[2, 1, 1]
sage: symmetric_group_action_on_values([2,2,3,1,1,2,2,3],[1,3,2])
[2, 3, 3, 1, 1, 2, 2, 3]
sage: symmetric_group_action_on_values([2,1,1],[2,1])
[2, 1, 2]
sage: symmetric_group_action_on_values([2,2,1],[2,1])
[1, 2, 1]
sage: symmetric_group_action_on_values([1,2,1],[2,1])
[2, 2, 1]
```

sage.combinat.tableau.unmatched_places(w, open, close)
Given a word w and two letters open and close to be treated as opening and closing parentheses (respectively),
return a pair \((xs, ys)\) that encodes the positions of the unmatched parentheses after the standard parenthesis matching procedure is applied to \(w\).

More precisely, \(xs\) will be the list of all \(i\) such that \(w[i]\) is an unmatched closing parenthesis, while \(ys\) will be the list of all \(i\) such that \(w[i]\) is an unmatched opening parenthesis. Both lists returned are in increasing order.

### EXAMPLES:

```sage
from sage.combinat.tableau import unmatched_places
sage: unmatched_places([2,2,2,1,1,1],2,1)
([], [])
sage: unmatched_places([1,1,1,2,2,2],2,1)
([0, 1, 2], [3, 4, 5])
sage: unmatched_places([], 2, 1)
([], [])
sage: unmatched_places([1,2,4,6,2,1,5,3],2,1)
([0], [1])
sage: unmatched_places([2,2,1,2,4,6,2,1,5,3], 2, 1)
([], [0, 3])
sage: unmatched_places([3,1,1,1,2,1,2], 2, 1)
([1, 2, 3], [6])
```

### 5.1.343 Residue sequences of tableaux

A **residue sequence** for a `StandardTableau`, or `StandardTableauTuple`, of size \(n\) is an \(n\)-tuple \((i_1, i_2, \ldots, i_n)\) of elements of \(\mathbb{Z}/e\mathbb{Z}\) for some positive integer \(e \geq 1\). Such sequences arise in the representation theory of the symmetric group and the closely related cyclotomic Hecke algebras, and cyclotomic quiver Hecke algebras, where the residue sequences play a similar role to weights in the representations of Lie groups and Lie algebras. These Hecke algebras are semisimple when \(e\) is “large enough” and in these cases residue sequences are essentially the same as content sequences (see `sage.combinat.partition.Partition.content()`) and it is not difficult to see that residue sequences are in bijection with the set of standard tableaux. In the non-semisimple case, when \(e\) is “small”, different standard tableaux can have the same residue sequence. In this case the residue sequences describe how to decompose modules into generalised eigenspaces for the Jucys-Murphy elements for these algebras.

By definition, if \(t\) is a `StandardTableau` of size \(n\) then the residue sequence of \(t\) is the \(n\)-tuple \((i_1, i_2, \ldots, i_n)\) where \(i_m = c - r + e\mathbb{Z}\) if \(m\) appears in row \(r\) and column \(c\) of \(t\). If \(p\) is prime then such sequence arise in the representation theory of the symmetric group \(n\) characteristic \(p\). More generally, \(e\)-residue sequences arise in he representation theory of the Iwahori-Hecke algebra (see `IwahoriHeckeAlgebra`) the symmetric group with Hecke parameter at an \(e\)-th root of unity.

More generally, the \(e\)-residue sequence of a `StandardTableau` of size \(n\) and level \(l\) is the \(n\)-tuple \((i_1, \ldots, i_n)\) determined by \(e\) and a **multicharge** \(\kappa = (\kappa_1, \ldots, \kappa_l)\) by setting \(i_m = \kappa_k + c - r + e\mathbb{Z}\), if \(m\) appears in component \(k\), row \(r\) and column \(c\) of \(t\). These sequences arise in the representation theory of the cyclotomic Hecke algebras of type A, which are also known as Ariki-Koike algebras.

The residue classes are constructed from standard tableaux:

```sage
sage: StandardTableau([[1,2],[3,4]]).residue_sequence(2)
2-residue sequence (0,1,1,0) with multicharge (0)
sage: StandardTableau([[1,2],[3,4]]).residue_sequence(3)
3-residue sequence (0,1,2,0) with multicharge (0)
sage: StandardTableauTuple([[1,2],[3,4]]).residue_sequence(3,[0,0])
3-residue sequence (0,1,2,0) with multicharge (0,0)
sage: StandardTableauTuple([[1,2],[3,4]]).residue_sequence(3,[0,1])
```

(continues on next page)
3-residue sequence (1,2,0,1,0) with multicharge (0,1)

sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).residue_sequence(3,[0,2])

3-residue sequence (2,0,1,2,0) with multicharge (0,2)

One of the most useful functions of a ResidueSequence is that it can return the StandardTableaux_residue and StandardTableaux_residue_shape that contain all of the tableaux with this residue sequence. Again, these are best accessed via the standard tableaux classes:

sage: res = StandardTableau([[1,2],[3,4]]).residue_sequence(2)
sage: res.standard_tableaux()
Standard tableaux with 2-residue sequence (0,1,1,0) and multicharge (0)

sage: res.standard_tableaux()[:]
[[[1, 2, 4], [3]],
 [[1, 2], [3, 4]],
 [[1, 2], [3], [4]],
 [[1, 3, 4], [2]],
 [[1, 3], [2, 4]],
 [[1, 3], [2], [4]]]

sage: res.standard_tableaux(shape=[4])
Standard (4)-tableaux with 2-residue sequence (0,1,1,0) and multicharge (0)

sage: res.standard_tableaux(shape=[4])[:]
[]

sage: res=StandardTableauTuple([[[5]],[[1,2],[3,4]]]).residue_sequence(3,[0,0])
sage: res.standard_tableaux()
Standard tableaux with 3-residue sequence (0,1,2,0,0) and multicharge (0,0)

sage: res.standard_tableaux(shape=[1],[2,2])[:]
[[[[5]], [[1, 2], [3, 4]]], [[[4]], [[1, 2], [3, 5]]]]

These residue sequences are particularly useful in the graded representation theory of the cyclotomic KLR algebras and the cyclotomic Hecke algebras of type~A; see [DJM1998] and [BK2009].

This module implements the following classes:

- ResidueSequence
- ResidueSequences

See also:

- Partitions
- PartitionTuples
- StandardTableaux_residue
- StandardTableaux_residue_shape
- RowStandardTableauTuples_residue
- RowStandardTableauTuples_residue_shape
- StandardTableaux
- StandardTableauTuples
- Tableaux
- TableauTuples
Todo: Strictly speaking this module implements residue sequences of type $A_e^{(1)}$. Residue sequences of other types also need to be implemented.

AUTHORS:
- Andrew Mathas (2016-07-01): Initial version

```python
class sage.combinat.tableau_residues.ResidueSequence(parent, residues, check)
    Bases: sage.structure.list_clone.ClonableArray

A residue sequence.

The residue sequence of a tableau $t$ (of partition or partition tuple shape) is the sequence $(i_1, i_2, \ldots, i_n)$ where $i_k$ is the residue of $l$ in $t$, for $k = 1, 2, \ldots, n$, where $n$ is the size of $t$. Residue sequences are important in the representation theory of the cyclotomic Hecke algebras of type $G(r, 1, n)$, and of the cyclotomic quiver Hecke algebras, because they determine the eigenvalues of the Jucys-Murphy elements upon all modules. More precisely, they index and completely determine the irreducible representations of the (cyclotomic) Gelfand-Tsetlin algebras.

Rather than being called directly, residue sequences are best accessed via the standard tableaux classes $\texttt{StandardTableau}$ and $\texttt{StandardTableauTuple}$.

INPUT:

Can be of the form:
- $\texttt{ResidueSequence(e, res)}$.
- $\texttt{ResidueSequence(e, multicharge, res)}$.

where $e$ is a positive integer not equal to 1 and $\texttt{res}$ is a sequence of integers (the residues).

EXAMPLES:

```python
sage: res = StandardTableauTuple([[1,3],[6]],[[2,7],[4],[5]]).residue_sequence(3, \rightarrow(0,5))
sage: res
3-residue sequence $(0,2,1,1,0,2,0)$ with multicharge $(0,2)$
sage: res.quantum_characteristic()
3
sage: res.level()
2
sage: res.size()
7
sage: res.residues()
[0, 2, 1, 1, 0, 2, 0]
```

```python
def restrict(2)
3-residue sequence $(0,2)$ with multicharge $(0,2)$
sage: res.standard_tableaux([[2,1],[1],[2,1]])
Standard $(2,1|1|2,1)$-tableaux with 3-residue sequence $(0,2,1,1,0,2,0)$ and
\rightarrow multicharge $(0,2)$
```
sage: res.standard_tableaux()[:10]
[[[1, 3, 6, 7], [2, 5], [4]], []],
[[[1, 3, 6], [2, 5], [4], [7]], []],
[[[1, 3], [2, 5], [4, 6], [7]], []],
[[[1, 3], [2, 5], [4], [7]], [[6]]],
[[[1, 3], [2, 5], [4]], [[6], 7]]],
[[[1, 3, 6, 7], [2], [4], [5]], []],
[[[1, 3, 6], [2, 7], [4], [5]], []],
[[[1, 3], [2, 7], [4], [5], [6]], []],
[[[1, 3], [2, 7], [4], [5]], [[6]]],
[[[1, 3], [2], [4], [5]], [[6, 7]]]]

The TestSuite fails _test_pickling because __getitem__ does not support slices, so we skip this.

**base_ring()**

Return the base ring for the residue sequence.

If the quantum_characteristic() of the residue sequence self is $e$ then the base ring for the sequence is $\mathbb{Z}/e\mathbb{Z}$, or $\mathbb{Z}$ if $e = 0$.

**EXAMPLES:**

```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).base_ring()
Ring of integers modulo 3
```

**block()**

Return a dictionary $\beta$ that determines the block associated to the residue sequence self.

Two Specht modules for a cyclotomic Hecke algebra of type $A$ belong to the same block, in this sense, if and only if the residue sequences of their standard tableaux have the same block in this sense. The blocks of these algebras are actually indexed by positive roots in the root lattice of an affine special linear group. Instead of than constructing the root lattice, this method simply returns a dictionary $\beta$ where the keys are residues $i$ and where the value of the key $i$ is equal to the numbers of nodes in the residue sequence self that are equal to $i$. The dictionary $\beta$ corresponds to the positive root:

$$\sum_{i \in I} \beta_i \alpha_i \in Q^+,$$

These positive roots also index the blocks of the cyclotomic KLR algebras of type $A$.

We return a dictionary because when the quantum_characteristic() is 0, the Cartan type is $A_\infty$, in which case the simple roots are indexed by the integers, which is infinite.

**EXAMPLES:**

```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,0,0], [0,0,1,1,2,2,3,3,3]).block()
{0: 3, 1: 3, 2: 3}
```

**check()**

Raise a ValueError if self is not a residue sequence.

**EXAMPLES:**
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,0,1], [0,0,1,1,2,2,3,3]).check()
sage: ResidueSequence(3, [0,0,1], [2,0,1,1,2,2,3,3]).check()

level()  
Return the level of the residue sequence. That is, the level of the corresponding (tuples of) standard tableaux. 

The level of a residue sequence is the length of its multicharge(). This is the same as the level of the standard_tableaux() that belong to the residue class of tableaux determined by self.

EXAMPLES:

sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).level()
3

multicharge()  
Return the multicharge for the residue sequence self.

The e-residue sequences are associated with a cyclotomic Hecke algebra with Hecke parameter q of quantum_characteristic() e and multicharge (κ1, ..., κl). This means that the cyclotomic parameters of the Hecke algebra are q^κ1, ..., q^κl. Equivalently, the Hecke algebra is determined by the dominant weight

$$\sum_{r \in \mathbb{Z}/e\mathbb{Z}} \kappa_r \Lambda_r \in P^+.$$ 

EXAMPLES:

sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).multicharge()
(0, 0, 1)

negative()  
Return the negative of the residue sequence self.

That is, if self is the residue sequence (i1, ..., in) then return (−i1, ..., −in). Taking the negative residue sequences is a shadow of tensoring with the sign representation from the cyclotomic Hecke algebras of type A.

EXAMPLES:

sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,0,1], [0,0,1,1,2,2,3,3]).negative()
3-residue sequence (0,0,2,2,1,1,0,0) with multicharge (0,0,1)

quantum_characteristic()  
Return the quantum characteristic of the residue sequence self.

The e-residue sequences are associated with a cyclotomic Hecke algebra that has a parameter q of quantum characteristic e. This is the smallest positive integer such that 1 + q + ... + q^{e-1} = 0, or e = 0 if no such integer exists.

EXAMPLES:

sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).quantum_characteristic()
residues()  
Return a list of the residue sequence.

EXAMPLES:

```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence((3,(0,0,1),[0,0,1,1,2,2,3,3]).residues()
[0, 0, 1, 1, 2, 2, 0, 0]
```

restrict(m)  
Return the subsequence of this sequence of length m.

The residue sequence self is of the form \((r_1, \ldots, r_n)\). The function returns the residue sequence \((r_1, \ldots, r_m)\), with the same quantum_characteristic() and multicharge().

EXAMPLES:

```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]).restrict(7)
3-residue sequence (0,0,1,1,2,2) with multicharge (0,0,1)
sage: ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]).restrict(6)
3-residue sequence (0,0,1,1,2,2) with multicharge (0,0,1)
sage: ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]).restrict(4)
3-residue sequence (0,0,1,1) with multicharge (0,0,1)
```

restrict_row(cell, row)  
Return a residue sequence for the tableau obtained by swapping the row in ending in cell with the row that is row rows above it and which has the same length.

The residue sequence self is of the form \((r_1, \ldots, r_n)\). The function returns the residue sequence \((r_1, \ldots, r_m)\), with the same quantum_characteristic() and multicharge().

EXAMPLES:

```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,1,2,2,0,1]).restrict_row((1,2),1)
3-residue sequence (2,0,1,0,1) with multicharge (0)
sage: ResidueSequence(3, [1,0], [0,1,2,2,0,1]).restrict_row((1,1,2),1)
3-residue sequence (2,0,1,0,1) with multicharge (0)
```

row_standard_tableaux(shape=None)  
Return the residue-class of row standard tableaux that have residue sequence self.

INPUT:

- shape – (optional) a partition or partition tuple of the correct level

OUTPUT:

An iterator for the row standard tableaux with this residue sequence. If the shape is given then only tableaux of this shape are returned, otherwise all of the full residue-class of row standard tableaux, or row standard tableaux tuples, is returned. The residue sequence self specifies the multicharge() of the tableaux which, in turn, determines the level() of the tableaux in the residue class.

EXAMPLES:

```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,(0,0,0),[0,1,2,0,1,2,0,1,2]).row_standard_tableaux()
Row standard tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and multicharge (0,0,0)
```
Row standard $(3|3|3)$-tableaux with $3$-residue sequence $(0,1,2,0,1,2,0,1,2)$ and $\rightarrow$ multicharge $(0,0,0)$

**size()**

Return the size of the residue sequence.

This is the size, or length, of the residue sequence, which is the same as the size of the *standard_tableaux()* that belong to the residue class of tableaux determined by *self*.

**EXAMPLES:**

```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).size()
sage: 8
```

**standard_tableaux**(shape=None)

Return the residue-class of standard tableaux that have residue sequence *self*.

**INPUT:**

- shape – (optional) a partition or partition tuple of the correct level

**OUTPUT:**

An iterator for the standard tableaux with this residue sequence. If the *shape* is given then only tableaux of this shape are returned, otherwise all of the full residue-class of standard tableaux, or standard tableau tuples, is returned. The residue sequence *self* specifies the *multicharge()* of the tableaux which, in turn, determines the *level()* of the tableaux in the residue class.

**EXAMPLES:**

```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,0), [0,1,2,0,1,2,0,1,2]).standard_tableaux()
Standard tableaux with $3$-residue sequence $(0,1,2,0,1,2,0,1,2)$ and $\rightarrow$ multicharge $(0,0,0)$
sage: ResidueSequence(3, (0,0,0), [0,1,2,0,1,2,0,1,2]).standard_tableaux([[3],[3]], $\rightarrow$ multicharge $(0,0,0)$
```

**swap_residues**(i, j)

Return the new residue sequence obtained by swapping the residues for *i* and *j*.

**INPUT:**

- *i* and *j* – two integers between $1$ and the length of the residue sequence

If residue sequence *self* is of the form $(r_1, \ldots, r_n)$, and $i < j$, then the residue sequence $(r_1, \ldots, r_j, \ldots, r_i, \ldots, r_m)$, with the same *quantum_characteristic()* and *multicharge()* is returned.

**EXAMPLES:**

```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: res = ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]); res
3-residue sequence $(0,0,1,1,2,2,0,0)$ with multicharge $(0,0,1)$
```

(continues on next page)
sage: res = res.swap_residues(2, 6); res
3-residue sequence (0, 2, 1, 1, 2, 0, 0, 0) with multicharge (0, 0, 1)
sage: res == ser
False

class sage.combinat.tableau_residues.ResidueSequences(e, multicharge=(0,))

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

A parent class for ResidueSequence.

This class exists because ResidueSequence needs to have a parent. Apart from being a parent the only useful method that it provides is cell_residue(), which is a short-hand for computing the residue of a cell using the ResidueSequence.quantum_characteristic() and ResidueSequence.multicharge() for the residue class.

EXAMPLES:

sage: from sage.combinat.tableau_residues import ResidueSequences
sage: ResidueSequences(e=0, multicharge=(0,1,2))
0-residue sequences with multicharge (0, 1, 2)
sage: ResidueSequences(e=0, multicharge=(0,1,2)) == ResidueSequences(e=0, multicharge=(0,1,2))
True
sage: ResidueSequences(e=0, multicharge=(0,1,2)) == ResidueSequences(e=3, multicharge=(0,1,2))
False
sage: ResidueSequences(e=0, multicharge=(0,1,2)).element_class
<class 'sage.combinat.tableau_residues.ResidueSequences_with_category.element_class'>

Element

alias of ResidueSequence

an_element()

Return a particular element of self.

EXAMPLES:

sage: TableauTuples().an_element()
([[1]], [[2]], [[3]], [[4]], [[5]], [[6]], [[7]])

cell_residue(*args)

Return the residue a cell with respect to the quantum characteristic and the multicharge of the residue sequence.

INPUT:

• r and c – the row and column indices in level one
• k, r and c – the component, row and column indices in higher levels

EXAMPLES:

sage: from sage.combinat.tableau_residues import ResidueSequences
sage: ResidueSequences(3).cell_residue(1,1)
0
Combinatorics, Release 9.7

sage: ResidueSequences(3).cell_residue(2,1)
2
sage: ResidueSequences(3).cell_residue(3,1)
1
sage: ResidueSequences(3).cell_residue(3,2)
2
sage: ResidueSequences(3,(0,1,2)).cell_residue(0,0,0)
0
sage: ResidueSequences(3,(0,1,2)).cell_residue(0,1,0)
2
sage: ResidueSequences(3,(0,1,2)).cell_residue(0,1,2)
1
sage: ResidueSequences(3,(0,1,2)).cell_residue(1,0,0)
1
sage: ResidueSequences(3,(0,1,2)).cell_residue(1,1,0)
0
sage: ResidueSequences(3,(0,1,2)).cell_residue(1,0,1)
2
sage: ResidueSequences(3,(0,1,2)).cell_residue(2,0,0)
2

1
sage: ResidueSequences(3,(0,1,2)).cell_residue(2,0,1)
0

\textbf{check_element}(\textit{element})

Check that \textit{element} is a residue sequence with multicharge \textit{self.multicharge}().

This is weak criteria in that we only require that \textit{element} is a tuple of elements in the underlying base ring of \textit{self}. Such a sequence is always a valid residue sequence, although there may be no tableaux with this residue sequence.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]) # indirect doctest
3-residue sequence (0,0,1,1,2,2,0,0) with multicharge (0,0,1)
sage: ResidueSequence(3,(0,0,1),[2,0,1,4,2,2,5,3]) # indirect doctest
3-residue sequence (2,0,1,1,2,2,2,0) with multicharge (0,0,1)
sage: ResidueSequence(3,(0,0,1),[2,0,1,1,2,2,3,3]) # indirect doctest
3-residue sequence (2,0,1,1,2,2,0,0) with multicharge (0,0,1)
\end{verbatim}

5.1.344 TableauTuples

A \textit{TableauTuple} is a tuple of tableaux. These objects arise naturally in representation theory of the wreath products of cyclic groups and the symmetric groups where the standard tableau tuples index bases for the ordinary irreducible representations. This generalises the well-known fact the ordinary irreducible representations of the symmetric groups have bases indexed by the standard tableaux of a given shape. More generally, \textit{TableauTuples}, or multitableaux, appear in the representation theory of the degenerate and non-degenerate cyclotomic Hecke algebras and in the crystal theory of the integral highest weight representations of the affine special linear groups.

A \textit{TableauTuple} is an ordered tuple \((t^{(1)}, t^{(2)}, \ldots, t^{(l)})\) of tableaux. The length of the tuple is its \textit{level} and the tableaux \(t^{(1)}, t^{(2)}, \ldots, t^{(l)}\) are the components of the \textit{TableauTuple}.
A tableaux can be thought of as the labelled diagram of a partition. Analogously, a TableauTuple is the labelled diagram of a PartitionTuple. That is, a TableauTuple is a tableau of PartitionTuple shape. As much as possible, TableauTuples behave in exactly the same way as Tableaux. There are obvious differences in that the cells of a partition are ordered pairs \((r, c)\), where \(r\) is a row index and \(c\) a column index, whereas the cells of a PartitionTuple are ordered triples \((k, r, c)\), with \(r\) and \(c\) as before and \(k\) indexes the component.

Frequently, we will call a TableauTuple a tableau, or a tableau of PartitionTuple shape. If the shape of the tableau is known this should not cause any confusion.

**Warning:** In sage the convention is that the \((k, r, c)\)-th entry of a tableau tuple \(t\) is the entry in row \(r\), column \(c\) and component \(k\) of the tableau. This is because it makes much more sense to let \(t[k]\) be component of the tableau. In particular, we want \(t(k, r, c) = t[k][r][c]\). In the literature, the cells of a tableau tuple are usually written in the form \((r, c, k)\), where \(r\) is the row index, \(c\) is the column index, and \(k\) is the component index.

The same convention applies to the cells of PartitionTuples.

**Note:** As with partitions and tableaux, the cells are 0-based. For example, the (lexicographically) first cell in any non-empty tableau tuple is \([0, 0, 0]\).

**EXAMPLES:**

```python
sage: TableauTuple([[1,2,3],[4,5]])
[[1, 2, 3], [4, 5]]
sage: t = TableauTuple([[6,7],[8,9],[1,2,3],[4,5]]); t
([[6, 7], [8, 9]], [[1, 2, 3], [4, 5]])
sage: t.pp()
 6 7  1 2 3
8 9  4 5
sage: t(0,0,1)
7
sage: t(1,0,1)
2
sage: t.shape()
[[2, 2], [3, 2]]
sage: t.size()
9
sage: t.level()
2
sage: t.components()
[[[6, 7], [8, 9]], [[1, 2, 3], [4, 5]]]
sage: t.entries()
[6, 7, 8, 9, 1, 2, 3, 4, 5]
sage: t.parent()
Tableau tuples
sage: t.category()
Category of elements of Tableau tuples
```

One reason for implementing TableauTuples is to be able to consider StandardTableauTuples. These objects arise in many areas of algebraic combinatorics. In particular, they index bases for the Specht modules of the cyclotomic Hecke algebras of type \(G(r, 1, n)\). A StandardTableauTuple of tableau whose entries are increasing along rows and down columns in each component and which contain the numbers \(1, 2, \ldots, n\), where the shape of the StandardTableauTuple is a PartitionTuple of \(n\).
As tableaux (of partition shape) are in natural bijection with 1-tuples of tableaux all of the TableauTuple classes return an ordinary Tableau when given TableauTuple of level 1.

There is one situation where a 1-tuple of tableau is not actually a Tableau: tableaux generated by the StandardTableauTuples() iterators must have the correct parents, so in this one case 1-tuples of tableaux are different from Tableaux:

Todo: Implement semistandard tableau tuples as defined in [DJM1998].

Much of the combinatorics implemented here is motivated by this and subsequent papers on the representation theory of these algebras.

class sage.combinat.tableau_tuple.RowStandardTableauTuple(parent, t, check=True)
Bases: sage.combinat.tableau_tuple.TableauTuple

A class for row standard tableau tuples of shape a partition tuple.

A row standard tableau tuple of size \( n \) is an ordered tuple of row standard tableaux (see RowStandardTableau), with entries 1, 2, \ldots, \( n \) such that, in each component, the entries are in increasing order along each row. If the tableau in component \( k \) has shape \( \lambda(k) \) then \( \lambda = (\lambda(1), \ldots, \lambda(l)) \) is a PartitionTuple.

Note: The tableaux appearing in a RowStandardTableauTuple are row strict, but individually they are not standard tableaux because the entries in any single component of a RowStandardTableauTuple will typically not be in bijection with \( \{1, 2, \ldots, n\} \).

INPUT:
• \( t \) – a tableau, a list of (standard) tableau or an equivalent list

OUTPUT:
• A RowStandardTableauTuple object constructed from \( t \).

Note: Sage uses the English convention for (tuples of) partitions and tableaux: the longer rows are displayed on top. As with PartitionTuple, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is \([0, 0, 0]\). Further, the coordinates \([k, r, c]\) in a TableauTuple refer to the component, row and column indices, respectively.

EXAMPLES:

sage: t = RowStandardTableauTuple([[4,7],[3]], [[2,6,8],[1,5]], [[9]]); t
([[4, 7], [3]], [[2, 6, 8], [1, 5]], [[9]])
sage: t.pp()
  4 7
  3 1 5
sage: t.shape()
([2, 1], [3, 2], [1])
sage: t[0].pp()  # pretty printing
  4 7
  3
sage: t.is_row_strict()
True
sage: t[0].is_standard()
False
sage: RowStandardTableauTuple([[],[],[]])  # An empty tableau tuple
([], [], [])
sage: RowStandardTableauTuple([[[4,5],[6]],[[1,2,3]]]) in StandardTableauTuples()
(continues on next page)
When using code that will generate a lot of tableaux, it is slightly more efficient to construct a RowStandardTableauTuple from the appropriate parent object:

```
sage: RST = RowStandardTableauTuples()
sage: RST([[4, 5], [7]], [[1, 2, 3], [6, 8]], [[9]])
([[4, 5], [7]], [[1, 2, 3], [6, 8]], [[9]])
```

See also:

- RowTableaux
- TableauTuples
- TableauTuple
- StandardTableauTuples
- StandardTableauTuple
- RowStandardTableauTuples

**codegree** *(e, multicharge)*

The codegree of a tableau is an integer that is defined recursively by successively stripping off the number \(k\), for \(k = n, n - 1, \ldots, 1\) and at stage adding the number of addable cell of the same residue minus the number of removable cells of the same residue as \(k\) and which are above \(k\) in the diagram.

The codegree of the tableau self gives the degree of “dual” homogeneous basis element of the graded Specht module which is indexed by self.

**INPUT:**
- \(e\) – the quantum characteristic
- \(\text{multicharge}\) – the multicharge

**OUTPUT:**

The codegree of the tableau self, which is an integer.

**EXAMPLES:**
```
sage: StandardTableauTuple([[[1]], [], []]).codegree(0,(0,0,0))
0
sage: StandardTableauTuple([[],[[1]], []]).codegree(0,(0,0,0))
1
sage: StandardTableauTuple([[], [], [[1]]]).codegree(0,(0,0,0))
2
sage: StandardTableauTuple([[[1]], [[2]], []]).codegree(0,(0,0,0))
-1
sage: StandardTableauTuple([[[1]], [], [[2]]]).codegree(0,(0,0,0))
0
```
sage: StandardTableauTuple([[1], [], [2]]).codegree(0,(0,0,0))
sage: StandardTableauTuple([[2],[1], []]).codegree(0,(0,0,0))
sage: StandardTableauTuple([[2], [], [1]]).codegree(0,(0,0,0))
sage: StandardTableauTuple([], [2], [1]).codegree(0,(0,0,0))

degree(e, multicharge)

The degree of a tableau is an integer that is defined recursively by successively stripping off the number \( k \), for \( k = n, n-1, \ldots, 1 \), and at stage adding the count of the number of addable cell of the same residue minus the number of removable cells of them same residue as \( k \) and that are below \( k \) in the diagram.

Note that even though this degree function was defined by Brundan-Kleshchev-Wang [BKW2011] the underlying combinatorics is much older, going back at least to Misra and Miwa.

The degrees of the tableau \( T \) gives the degree of the homogeneous basis element of the graded Specht module which is indexed by \( T \).

INPUT:

- \( e \) – the quantum characteristic \( e \)
- \( \text{multicharge} \) – (default: [0]) the multicharge

OUTPUT:

The degree of the tableau self, which is an integer.

EXAMPLES:

sage: StandardTableauTuple([[1], [], []]).degree(0,(0,0,0))
sage: StandardTableauTuple([[1], [2], []]).degree(0,(0,0,0))
sage: StandardTableauTuple([], [], []).degree(0,(0,0,0))
sage: StandardTableauTuple([], [1], [2]).degree(0,(0,0,0))

inverse(k)

Return the cell containing \( k \) in the tableau tuple self.

EXAMPLES:
Combinatorics, Release 9.7

```python
sage: RowStandardTableauTuple([[3,4],[1,2],[5,6,7],[8],[9,10],[11],[12]]).inverse(1)
(0, 1, 0)
```

```python
sage: RowStandardTableauTuple([[3,4],[1,2],[5,6,7],[8],[9,10],[11],[12]]).inverse(2)
(0, 1, 1)
```

```python
sage: RowStandardTableauTuple([[3,4],[1,2],[5,6,7],[8],[9,10],[11],[12]]).inverse(3)
(0, 0, 0)
```

```python
sage: RowStandardTableauTuple([[3,4],[1,2],[5,6,7],[8],[9,10],[11],[12]]).inverse(4)
(0, 0, 1)
```

```python
sage: StandardTableauTuple([[1,2],[3,4],[5,6,7],[8],[9,10],[11],[12]]).inverse(1)
(0, 0, 0)
```

```python
sage: StandardTableauTuple([[1,2],[3,4],[5,6,7],[8],[9,10],[11],[12]]).inverse(2)
(0, 0, 1)
```

```python
sage: StandardTableauTuple([[1,2],[3,4],[5,6,7],[8],[9,10],[11],[12]]).inverse(3)
(0, 1, 0)
```

```python
sage: StandardTableauTuple([[1,2],[3,4],[5,6,7],[8],[9,10],[11],[12]]).inverse(12)
(2, 2, 0)
```

#### residue_sequence (e, multicharge)

Return the `sage.combinat.tableau_residues.ResidueSequence` of `self`.

**INPUT:**

- `e` – integer in `{0, 2, 3, 4, 5, ...}`
- `multicharge` – a sequence of integers of length equal to the level/length of `self`

**OUTPUT:**

The residue sequence of the tableau.

**EXAMPLES:**

```python
sage: RowStandardTableauTuple([[5],[3,4],[1,2]]).residue_sequence(3,[0,0])
3-residue sequence (2,0,1,0) with multicharge (0,0)
```

```python
sage: StandardTableauTuple([[5],[1,2],[3,4]]).residue_sequence(3,[0,1])
3-residue sequence (1,2,0,1) with multicharge (0,1)
```

```python
sage: StandardTableauTuple([[5],[1,2],[3,4]]).residue_sequence(3,[0,2])
3-residue sequence (2,0,1,2) with multicharge (0,2)
```

#### class `sage.combinat.tableau_tuple.RowStandardTableauTuples`

**Bases:** `sage.combinat.tableau_tuple.TableauTuples`

A factory class for the various classes of tuples of row standard tableau.

**INPUT:**

There are three optional arguments:

- `level` – the `level()` of the tuples of tableaux
- `size` – the `size()` of the tuples of tableaux
• **shape** – a list or a partition tuple specifying the `shape()` of the row standard tableau tuples

It is not necessary to use the keywords. If they are not used then the first integer argument specifies the `level()` and the second the `size()` of the tableau tuples.

**OUTPUT:**

The appropriate subclass of `RowStandardTableauTuples`.

A tuple of row standard tableau is a tableau whose entries are positive integers which increase from left to right along the rows in each component. The entries do NOT need to increase from left to right along the components.

**Note:** Sage uses the English convention for (tuples of) partitions and tableaux: the longer rows are displayed on top. As with `PartitionTuple`, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is `[0, 0, 0]`.

**EXAMPLES:**

```python
sage: tabs = RowStandardTableauTuples([[2],[1,1]]); tabs
Row standard tableau tuples of shape ([2], [1, 1])
sage: tabs.cardinality()
12
sage: tabs[:]
[([3, 4], [2], [1]), ([2, 4], [3], [1]), ([1, 4], [3], [2]), ([1, 2], [4], [3]), ([1, 3], [4], [2]), ([2, 3], [4], [1]), ([1, 4], [2], [3]), ([1, 3], [2], [4]), ([1, 2], [3], [4]), ([2, 3], [1], [4]), ([2, 4], [1], [3]), ([3, 4], [1], [2])]
```

```python
sage: tabs = RowStandardTableauTuples(level=3); tabs
Row standard tableau tuples of level 3
sage: tabs[100]
([], [], [[2, 3], [1]])
```

```python
sage: RowStandardTableauTuples()[0]
([], [])
```

See also:

- `TableauTuples`
- `Tableau`
- `RowStandardTableau`
- `RowStandardTableauTuples`

**Element**

alias of `RowStandardTableauTuple`

---

**5.1. Comprehensive Module List**
level_one_parent_class
    alias of sage.combinat.tableau.RowStandardTableaux_all

shape()
    Return the shape of the set of RowStandardTableauTuples, or None if it is not defined.

    EXAMPLES:
    sage: tabs=RowStandardTableauTuples(shape=[[5,2],[3,2],[[]],[[1,1,1],[3]]]); tabs
    Row standard tableau tuples of shape ([5, 2], [3, 2], [], [[1, 1, 1], [3]])
    sage: tabs.shape()
    ([5, 2], [3, 2], [], [1, 1, 1], [3])
    sage: RowStandardTableauTuples().shape() is None
    True

class sage.combinat.tableau_tuple.RowStandardTableauTuples_all
    Bases: sage.combinat.tableau_tuple.RowStandardTableauTuples, sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets
    Default class of all RowStandardTableauTuples with an arbitrary level() and size().

an_element()
    Return a particular element of the class.

    EXAMPLES:
    sage: RowStandardTableauTuples().an_element()
    ([[4, 5, 6, 7]], [[2, 3]], [[1]])

class sage.combinat.tableau_tuple.RowStandardTableauTuples_level(level)
    Bases: sage.combinat.tableau_tuple.RowStandardTableauTuples, sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets
    Class of all RowStandardTableauTuples with a fixed level and arbitrary size.

an_element()
    Return a particular element of self.

    EXAMPLES:
    sage: RowStandardTableauTuples(2).an_element()
    ([[1]], [[2, 3]])
    sage: RowStandardTableauTuples(3).an_element()
    ([[1]], [[2, 3]], [[4, 5, 6, 7]])

class sage.combinat.tableau_tuple.RowStandardTableauTuples_level_size(level, size)
    Bases: sage.combinat.tableau_tuple.RowStandardTableauTuples, sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets
    Class of all RowStandardTableauTuples with a fixed level and a fixed size.

an_element()
    Return a particular element of self.

    EXAMPLES:
    sage: RowStandardTableauTuples(5, size=2).an_element()
    ([], [], [], [], [[1], [2]])
    sage: RowStandardTableauTuples(2, size=4).an_element()
    ([[1]], [[2, 3], [4]])
class sage.combinat.tableau_tuple.RowStandardTableauTuples_residue(residue)
    Bases: sage.combinat.tableau_tuple.RowStandardTableauTuples

Class of all row standard tableau tuples with a fixed residue sequence.

Implicitly, this also specifies the quantum characteristic, multicharge and hence the level and size of the tableaux.

Note: This class is not intended to be called directly, but rather, it is accessed through the row standard tableaux.

EXAMPLES:

sage: RowStandardTableau([[3,4,5],[1,2]]).residue_sequence(2).row_standard_tableaux()
Row standard tableaux with 2-residue sequence (1,0,0,1,0) and multicharge (0)
sage: RowStandardTableau([[3,4,5],[1,2]]).residue_sequence(3).row_standard_tableaux()
Row standard tableaux with 3-residue sequence (2,0,0,1,2) and multicharge (0)

sage: RowStandardTableauTuple([[[5,6],[7]],[[1,2,3],[4]]]).residue_sequence(2,(0,0)).row_standard_tableaux()
Row standard tableaux with 2-residue sequence (0,1,0,1,0,1,1) and multicharge (0,0)
sage: RowStandardTableauTuple([[[5,6],[7]],[[1,2,3],[4]]]).residue_sequence(3,(0,1)).row_standard_tableaux()
Row standard tableaux with 3-residue sequence (1,2,0,0,0,1,2) and multicharge (0,1)

an_element()
    Return a particular element of self.

EXAMPLES:

sage: RowStandardTableau([[2,3],[1]]).residue_sequence(3).row_standard_tableaux().an_element()
[[2, 3], [1]]
sage: StandardTableau([[1,3],[2]]).residue_sequence(3).row_standard_tableaux().an_element()
[[1, 3], [2]]
sage: RowStandardTableauTuple([[[4],[2,3],[1]]]).residue_sequence(3,(0,1)).row_standard_tableaux().an_element()
[[4], [3], [1], [2]], []

level()
    Return the level of self.

EXAMPLES:

sage: RowStandardTableau([[2,3],[1]]).residue_sequence(3,(0,1)).row_standard_tableaux().level()
2
sage: StandardTableau([[1,2],[3]]).residue_sequence(3,(0,1)).row_standard_tableaux().level()
2
sage: RowStandardTableauTuple([[[4],[2,3],[1]]]).residue_sequence(3,(0,1)).row_standard_tableaux().level()
2

(continues on next page)
sage: StandardTableauTuple([[4],[1,3],[2]]).residue_sequence(3,(0,1)).row_standard_tableaux().level()
2

multicharge()

Return the multicharge of self.

EXAMPLES:

sage: RowStandardTableau([[2,3],[1]]).residue_sequence(3,(0,1)).row_standard_tableaux().multicharge()
(0, 1)
sage: StandardTableau([[1,2],[3]]).residue_sequence(3,(0,1)).row_standard_tableaux().multicharge()
(0, 1)
sage: RowStandardTableauTuple([[4],[2,3],[1]]).residue_sequence(3,(0,1)).row_standard_tableaux().multicharge()
(0, 1)
sage: StandardTableauTuple([[4],[1,3],[2]]).residue_sequence(3,(0,1)).row_standard_tableaux().multicharge()
(0, 1)

quantum_characteristic()

Return the quantum characteristic of self.

EXAMPLES:

sage: RowStandardTableau([[2,3],[1]]).residue_sequence(3,(0,1)).row_standard_tableaux().quantum_characteristic()
3
sage: StandardTableau([[1,2],[3]]).residue_sequence(3,(0,1)).row_standard_tableaux().quantum_characteristic()
3
sage: RowStandardTableauTuple([[4],[2,3],[1]]).residue_sequence(3,(0,1)).row_standard_tableaux().quantum_characteristic()
3
sage: StandardTableauTuple([[4],[1,3],[2]]).residue_sequence(3,(0,1)).row_standard_tableaux().quantum_characteristic()
3

residue_sequence()

Return the residue sequence of self.

EXAMPLES:

sage: RowStandardTableau([[2,3],[1]]).residue_sequence(3,(0,1)).row_standard_tableaux().residue_sequence()
3-residue sequence (2,0,1) with multicharge (0,1)
sage: StandardTableau([[1,2],[3]]).residue_sequence(3,(0,1)).row_standard_tableaux().residue_sequence()
3-residue sequence (0,1,2) with multicharge (0,1)
sage: RowStandardTableauTuple([[4],[2,3],[1]]).residue_sequence(3,(0,1)).row_standard_tableaux().residue_sequence()
3-residue sequence (0,1,2,0) with multicharge (0,1)
sage: StandardTableauTuple([[4],[1,3],[2]]).residue_sequence(3,(0,1)).row_standard_tableaux().residue_sequence()
3-residue sequence (0,1,2,0) with multicharge (0,1)
sage: StandardTableauTuple([[4],[[1,3],[2]])].residue_sequence(3,(0,1)).row_standard_tableaux().residue_sequence()
3-residue sequence (1,0,2,0) with multicharge (0,1)

size()
Return the size of self.

EXAMPLES:

sage: RowStandardTableau([[2,3],[1]]) .residue_sequence(3,(0,1)).row_standard_tableaux().size() 3
sage: StandardTableau([[1,2],[3]]) .residue_sequence(3,(0,1)).row_standard_tableaux().size() 3
sage: RowStandardTableauTuple([[4],[[2,3],[1]]) .residue_sequence(3,(0,1)).row_standard_tableaux().size() 4
sage: StandardTableauTuple([[4],[[1,3],[2]]) .residue_sequence(3,(0,1)).row_standard_tableaux().size() 4

class sage.combinat.tableau_tuple.RowStandardTableauTuples_residue_shape(residue, shape)

Bases: sage.combinat.tableau_tuple.RowStandardTableauTuples_residue

All row standard tableau tuples with a fixed residue and shape.

INPUT:

- shape – the shape of the partitions or partition tuples
- residue – the residue sequence of the label

EXAMPLES:

sage: res = RowStandardTableauTuple([[3,6],[1]], [[5,7],[4],[2]]) .residue_sequence(3,(0,0))
sage: tabs = res .row_standard_tableaux([[2,1],[2,1],[1]]) ; tabs
Row standard (2,1,1^2)-tableaux with 3-residue sequence (2,1,0,2,0,1,1) and multicharge (0,0)

sage: tabs .shape()
([2, 1], [2, 1], [1])
sage: tabs .level()
2

sage: tabs[:6]
[[[5, 7], [4], [[3, 6], [1], [2]]],
 [[[5, 7], [1], [[3, 6], [4], [2]]],
 [[[3, 7], [4], [[5, 6], [1], [2]]],
 [[[3, 7], [1], [[5, 6], [4], [2]]],
 [[[5, 6], [4], [[3, 7], [1], [2]]],
 [[[5, 6], [1], [[3, 7], [4], [2]]]]

class sage.combinat.tableau_tuple.RowStandardTableauTuples_shape(shape)

Bases: sage.combinat.tableau_tuple.RowStandardTableauTuples_residue_shape

Class of all RowStandardTableauTuples of a fixed shape.

5.1. Comprehensive Module List
an_element()
Return a particular element of self.

EXAMPLES:

```
sage: RowStandardTableauTuples([[2],[2,1]]).an_element()
([[4, 5]], [[1, 3], [2]])
sage: RowStandardTableauTuples([[10],[1],[1]]).an_element()
([[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]], [], [])
```

cardinality()
Return the number of row standard tableau tuples of with the same shape as the partition tuple self.
This is just the index of the corresponding Young subgroup in the full symmetric group.

EXAMPLES:

```
sage: RowStandardTableauTuples([[3,2,1],[1]]).cardinality()
60
sage: RowStandardTableauTuples([[1],[1],[1]]).cardinality()
6
sage: RowStandardTableauTuples([[2,1],[1],[1]]).cardinality()
60
```

class sage.combinat.tableau_tuple.RowStandardTableauTuples_size(size)
Bases: sage.combinat.tableau_tuple.RowStandardTableauTuples, sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets
Class of all RowStandardTableauTuples with an arbitrary level and a fixed size.
an_element()
Return a particular element of the class.

EXAMPLES:

```
sage: RowStandardTableauTuples(size=2).an_element()
([[1]], [[2]], [], [])
sage: RowStandardTableauTuples(size=4).an_element()
([[1]], [[2, 3, 4]], [], [])
```

class sage.combinat.tableau_tuple.StandardTableauTuple(parent, t, check=True)
Bases: sage.combinat.tableau_tuple.RowStandardTableauTuple
A class to model a standard tableau of shape a partition tuple. This is a tuple of standard tableau with entries 1, 2, ..., n, where n is the size of the underlying partition tuple, such that the entries increase along rows and down columns in each component of the tuple.

```
sage: s = StandardTableauTuple([[1,2,3],[4,5]])
sage: t = StandardTableauTuple([[1,2],[3,5],[4]])
sage: s.dominates(t) True
sage: t.dominates(s) False
sage: StandardTableauTuple([[1,2,3],[4,5]]) in RowStandardTableauTuples() True
```

The tableaux appearing in a StandardTableauTuple are both row and column strict, but individually they are not standard tableaux because the entries in any single component of a StandardTableauTuple will typically not be in bijection with \{1, 2, ..., n\}.

INPUT:

• t – a tableau, a list of (standard) tableau or an equivalent list

OUTPUT:
• A **StandardTableauTuple** object constructed from `t`.

**Note:** Sage uses the English convention for (tuples of) partitions and tableaux: the longer rows are displayed on top. As with **PartitionTuple**, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is `[0, 0, 0]`. Further, the coordinates `[k, r, c]` in a **TableauTuple** refer to the component, row and column indices, respectively.

**EXAMPLES:**

```
sage: t = TableauTuple([[[1,3,4],[7,9]], [[2,8,11],[6]], [[5,10]]])
sage: t
([[1, 3, 4], [7, 9]], [[2, 8, 11], [6]], [[5, 10]])
sage: t[0][0][0]
1
sage: t[1][1][0]
6
sage: t[2][0][0]
5
sage: t[2][0][1]
10
```

```
sage: t = StandardTableauTuple([[[4,5],[7]],[[1,2,3],[6,8]],[[9]]]); t
([[4, 5], [7]], [[1, 2, 3], [6, 8]], [[9]])
sage: t.pp()
4 5 1 2 3 9
7 6 8
sage: t.shape()
([2, 1], [3, 2], [1])
sage: t[0].pp()  # pretty printing
4 5
7
sage: t.is_standard()
True
sage: t[0].is_standard()
False
```

```
sage: STT = StandardTableauTuples()
sage: STT([[[4,5],[7]],[[1,2,3],[6,8]],[[9]]])
([[4, 5], [7]], [[1, 2, 3], [6, 8]], [[9]])
```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a **StandardTableauTuple** from the appropriate parent object:

```
sage: STT = StandardTableauTuples()
sage: STT([[[4,5],[7]],[[1,2,3],[6,8]],[[9]]])
([[4, 5], [7]], [[1, 2, 3], [6, 8]], [[9]])
```

**See also:**

• **Tableau**
• **Tableaux**
• **TableauTuples**
• **TableauTuple**
• **StandardTableauTuples**

**dominates**(*t*)

Return True if the tableau (tuple) self dominates the tableau t. The two tableaux do not need to be of the same shape.

EXAMPLES:

```
sage: s = StandardTableauTuple([[1,2,3],[4,5]])
sage: t = StandardTableauTuple([[1,2],[3,5],[4]])
sage: s.dominates(t)
True
tage: t.dominates(s)
False
```

**restrict**(*m=None*)

Return the restriction of the standard tableau self to m, which defaults to one less than the current *size()*. EXAMPLES:

```
sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).restrict(6)
([5], [[1, 2], [3, 4]])
sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).restrict(5)
([5], [[1, 2], [3, 4]])
sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).restrict(4)
([], [[1, 2], [3, 4]])
sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).restrict(3)
([], [[1, 2], [3]])
sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).restrict(2)
([], [[1, 2]])
sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).restrict(1)
([], [])
sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).restrict(0)
([], [])
```

Where possible the restricted tableau belongs to the same category as the tableau self:

```
sage: TableauTuple([[5],[[1,2],[3,4]]]).restrict(3).category()
Category of elements of Tableau tuples
sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).restrict(3).category()
Category of elements of Standard tableau tuples
sage: StandardTableauTuples([[1],[2,2]]).restrict(3).category()
Category of elements of Standard tableau tuples
sage: StandardTableauTuples(level=2).restrict(3).category()
Category of elements of Standard tableau tuples of level 2
```

**to_chain()**

Return the chain of partitions corresponding to the standard tableau tuple self.

EXAMPLES:

```
sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).to_chain()([[], []]),
```

(continues on next page)
class sage.combinat.tableau_tuple.StandardTableauTuples
Bases: sage.combinat.tableau_tuple.RowStandardTableauTuples

A factory class for the various classes of tuples of standard tableau.

INPUT:

There are three optional arguments:

- `level` – the `level()` of the tuples of tableaux
- `size` – the `size()` of the tuples of tableaux
- `shape` – a list or a partition tuple specifying the `shape()` of the standard tableau tuples

It is not necessary to use the keywords. If they are not used then the first integer argument specifies the `level()` and the second the `size()` of the tableau tuples.

OUTPUT:

The appropriate subclass of `StandardTableauTuples`.

A tuple of standard tableau is a tableau whose entries are positive integers which increase from left to right along the rows, and from top to bottom down the columns, in each component. The entries do NOT need to increase from left to right along the components.

Note: Sage uses the English convention for (tuples of) partitions and tableaux: the longer rows are displayed on top. As with `PartitionTuple`, in Sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is `[0, 0, 0]`.

EXAMPLES:

```sage
sage: tabs=StandardTableauTuples([[3],[2,2]]); tabs
Standard tableau tuples of shape ([3], [2, 2])
sage: tabs.cardinality()
70
sage: tabs[10:16]
[[[1, 2, 3]], [[4, 6], [5, 7]]],
[[[1, 2, 4]], [[3, 6], [5, 7]]],
[[[1, 3, 4]], [[2, 6], [5, 7]]],
[[[2, 3, 4]], [[1, 6], [5, 7]]],
[[[1, 2, 5]], [[3, 6], [4, 7]]],
[[[1, 3, 5]], [[2, 6], [4, 7]]]]

sage: tabs=StandardTableauTuples(level=3); tabs
Standard tableau tuples of level 3
sage: tabs[100]
([[1, 2], [3]], [], [[4]])
```
sage: StandardTableauTuples()[0]
()

See also:

- TableauTuples
- Tableau
- StandardTableau
- StandardTableauTuples

Element
alias of StandardTableauTuple

level_one_parent_class
alias of sage.combinat.tableau.StandardTableaux_all

shape()
Return the shape of the set of StandardTableauTuples, or None if it is not defined.

EXAMPLES:

sage: tabs=StandardTableauTuples(shape=[[5,2],[3,2],[1,1,1],[3]]); tabs
Standard tableau tuples of shape ([5, 2], [3, 2], [1, 1, 1], [3])
sage: tabs.shape()
([5, 2], [3, 2], [1, 1, 1], [3])
sage: StandardTableauTuples().shape() is None
True

class sage.combinat.tableau_tuple.StandardTableauTuples_all
    Bases: sage.combinat.tableau_tuple.StandardTableauTuples, sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets
    Default class of all StandardTableauTuples with an arbitrary level() and size().

class sage.combinat.tableau_tuple.StandardTableauTuples_level
    Bases: sage.combinat.tableau_tuple.StandardTableauTuples, sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets
    Class of all StandardTableauTuples with a fixed level and arbitrary size.

    an_element()
    Return a particular element of the class.

    EXAMPLES:

    sage: StandardTableauTuples(size=2).an_element()
    ([[1]], [[2]], [], [])
sage: StandardTableauTuples(size=4).an_element()
    ([[1]], [[2, 3, 4]], [], [])

class sage.combinat.tableau_tuple.StandardTableauTuples_level_size
    Bases: sage.combinat.tableau_tuple.StandardTableauTuples, sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets
    Class of all StandardTableauTuples with a fixed level and a fixed size.
an_element()  
Return a particular element of the class.

EXAMPLES:
```python
sage: StandardTableauTuples(5, size=2).an_element()
([], [], [], [], [[1], [2]])
sage: StandardTableauTuples(2, size=4).an_element()
([[1]], [[2], [3], [4]])
```
cardinality()  
Return the number of elements in this set of tableaux.

EXAMPLES:
```python
sage: StandardTableauTuples(3, 2).cardinality()
12
sage: StandardTableauTuples(4, 6).cardinality()
31936
```

class sage.combinat.tableau_tuple.StandardTableauTuples_shape(shape)
Bases: sage.combinat.tableau_tuple.StandardTableauTuples

Class of all StandardTableauTuples of a fixed shape.

an_element()  
Return a particular element of the class.

EXAMPLES:
```python
sage: StandardTableauTuples([[2], [2, 1]]).an_element()
([[2, 4]], [[1, 3], [5]])
sage: StandardTableauTuples([[10], [], []]).an_element()
([[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]], [], [])
```
cardinality()

Return the number of standard Young tableau tuples of with the same shape as the partition tuple self.

Let \( \mu = (\mu^{(1)}, \ldots, \mu^{(l)}) \) be the shape of the tableaux in self and let \( m_k = |\mu^{(k)}| \) for \( 1 \leq k \leq l \). Multiplying by a (unique) coset representative of the Young subgroup \( S_{m_1} \times \cdots \times S_{m_l} \) inside the symmetric group \( S_n \), we can assume that \( l \) is standard and the numbers \( 1, 2, \ldots, n \) are entered in order from to right along the components of the tableau. Therefore, there are

\[
\binom{n}{m_1, \ldots, m_l} \prod_{k=1}^{l} |\text{Std}(\mu^{(k)})|
\]

standard tableau tuples of this shape, where \( |\text{Std}(\mu^{(k)})| \) is the number of standard tableau of shape \( \mu^{(k)} \), for \( 1 \leq k \leq l \). This is given by the hook length formula.

EXAMPLES:
```python
sage: StandardTableauTuples([[3, 2, 1], []]).cardinality()
16
sage: StandardTableauTuples([[1], [1], [1]]).cardinality()
6
sage: StandardTableauTuples([[2, 1], [1], [1]]).cardinality()
40
```
Combinatorics, Release 9.7

(continued from previous page)

```python
sage: StandardTableauTuples([[3,2,1],[3,2]]).cardinality()
36960
```

**last()**

Return the last standard tableau tuple in `self`, with respect to the order that they are generated by the iterator.

This is just the standard tableau tuple with the numbers 1, 2, ..., `n`, where `n` is `size()`, entered in order down the columns form right to left along the components.

**EXAMPLES:**

```python
sage: StandardTableauTuples([[2],[2,2]]).last().pp()

5 6 1 3
2 4
```

**random_element()**

Return a random standard tableau in `self`.

We do this by randomly selecting addable nodes to place 1, 2, ..., `n`. Of course we could do this recursively, but it is more efficient to keep track of the (changing) list of addable nodes as we go.

**EXAMPLES:**

```python
sage: StandardTableauTuples([[2],[2,1]]).random_element()

# random
([[1, 2]], [[3, 4], [5]])
```

**class sage.combinat.tableau_tuple.StandardTableauTuples_size(size)**

Bases: `sage.combinat.tableau_tuple.StandardTableauTuples`, `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`

Class of all `StandardTableauTuples` with an arbitrary level and a fixed size.

**an_element()**

Return a particular element of the class.

**EXAMPLES:**

```python
sage: StandardTableauTuples(size=2).an_element()

([1], [2], [], [])
```

```python
sage: StandardTableauTuples(size=4).an_element()

([1], [2, 3, 4], [], [])
```

**class sage.combinat.tableau_tuple.StandardTableaux_residue(residue)**

Bases: `sage.combinat.tableau_tuple.StandardTableauTuples`

Class of all `StandardTableaux` with a fixed residue sequence.

Implicitly, this also specifies the quantum characteristic, multicharge and hence the level and size of the tableaux.

**Note:** This class is not intended to be called directly, but rather, it is accessed through the standard tableaux.

**EXAMPLES:**

```python
sage: StandardTableau([1,2,3],[4,5]).residue_sequence(2).standard_tableaux()  # 2-standard tableaux
```

(continues on next page)
Combinatorics, Release 9.7

(continued from previous page)

```python
sage: StandardTableau([[1,2,3],[4,5]]).residue_sequence(3).standard_tableaux()
Standard tableaux with 3-residue sequence (0,1,2,2,0) and multicharge (0)
sage: StandardTableauTuple(((5,6),(7)),([[1,2,3],[4]])).residue_sequence(2,(0,0)).
→ standard_tableaux()
Standard tableaux with 2-residue sequence (0,1,0,1,0,1,1) and multicharge (0,0)
sage: StandardTableauTuple(((5,6),(7)),([[1,2,3],[4]])).residue_sequence(3,(0,1)).
→ standard_tableaux()
Standard tableaux with 3-residue sequence (1,2,0,0,0,1,2) and multicharge (0,1)
```

class `sage.combinat.tableau_tuple.StandardTableaux_residue_shape`(residue, shape)
Bases: `sage.combinat.tableau_tuple.StandardTableaux_residue`
All standard tableau tuples with a fixed residue and shape.

INPUT:
- shape – the shape of the partitions or partition tuples
- residue – the residue sequence of the label

EXAMPLES:

```python
sage: res = StandardTableauTuple(((1,3),(6)),([[2,7],[4],[5]])).residue_sequence(3,
→(0,0))
sage: tabs = res.standard_tableaux(((2,1),(2,1,1))); tabs
Standard (2,1|2,1^2)-tableaux with 3-residue sequence (0,0,1,2,1,2,1) and...
→multicharge (0,0)
sage: tabs.shape()
([2, 1], [2, 1, 1])
sage: tabs.level()
2
sage: tabs[:6]
[(([2, 7], [6]), ([1, 3], [4], [5])),
([[1, 7], [6]], [[2, 3], [4], [5]]),
([[2, 3], [6]], [[1, 7], [4], [5]]),
([[1, 3], [6]], [[2, 7], [4], [5]]),
([[2, 5], [6]], [[1, 3], [4], [7]]),
([[1, 5], [6]], [[2, 3], [4], [7]]))
```

an_element()
Return a particular element of self.

EXAMPLES:

```python
sage: T = StandardTableau([[1,3],[2]]).residue_sequence(3).standard_tableaux([2,
→1])
sage: T.an_element()
[[1, 3], [2]]
```

class `sage.combinat.tableau_tuple.TableauTuple`(parent, t, check=True)
Bases: `sage.combinat.combinat.CombinatorialElement`
A class to model a tuple of tableaux.

INPUT:
- t – a list or tuple of `Tableau`, a list or tuple of lists of lists
• The Tableau tuple object constructed from \( t \).

A TableauTuple is a tuple of tableau of shape a PartitionTuple. These combinatorial objects are useful in several areas of algebraic combinatorics. In particular, they are important in:

• the representation theory of the complex reflection groups of type \( G(l, 1, n) \) and the representation theory of the associated (degenerate and non-degenerate) Hecke algebras. See, for example, [DJM1998]

• the crystal theory of (quantum) affine special linear groups and its integral highest weight modules and their canonical bases. See, for example, [BK2009].

These apparently different and unrelated contexts are, in fact, intimately related as in characteristic zero the cyclotomic Hecke algebras categorify the canonical bases of the integral highest weight modules of the quantum affine special linear groups.

The \( \text{level()} \) of a tableau tuple is the length of the tuples. This corresponds to the level of the corresponding highest weight module.

In sage a TableauTuple looks an behaves like a real tuple of (level 1) Tableaux. Many of the operations which are defined on Tableau extend to TableauTuples. Tableau tuples of level 1 are just ordinary Tableau.

In sage, the entries of Tableaux can be very general, including arbitrarily nested lists, so some lists can be interpreted either as a tuple of tableaux or simply as tableaux. If it is possible to interpret the input to TableauTuple as a tuple of tableaux then TableauTuple returns the corresponding tuple. Given a 1-tuple of tableaux the tableau itself is returned.

EXAMPLES:

```
sage: t = TableauTuple([ [[6,9,10],[11]], [[1,2,3],[4,5]], [[7],[8]] ]); t
([[6, 9, 10], [11]], [[1, 2, 3], [4, 5]], [[7], [8]])
sage: t.level() 3
sage: t.size() 11
sage: t.shape() ([3, 1], [3, 2], [1, 1])
sage: t.is_standard() True
sage: t.pp() # pretty printing
  6 9 10 1 2 3 7
  11 4 5 8
sage: t.category() Category of elements of Tableau tuples
sage: t.parent() Tableau tuples
sage: s = TableauTuple([ ['a', 'c', 'b'], ['d', 'e'], [[[2,1]]] ]); s
([[a', 'c', 'b'], ['d', 'e']], [[[2, 1]]])
sage: s.shape() ([3, 2], [1])
sage: s.size() 6
sage: TableauTuple([[[],[],[]]]) # The empty 3-tuple of tableaux
([], [], []
```

(continues on next page)
sage: TableauTuple([[1,2,3],[4,5]])
[[1, 2, 3], [4, 5]]
sage: TableauTuple([[1,2,3],[4,5]]) == Tableau([[1,2,3],[4,5]])
True

See also:

- StandardTableauTuples
- StandardTableau
- StandardTableaux
- TableauTuple
- TableauTuples
- Tableau
- Tableaux

**Element**

alias of `sage.combinat.tableau.Tableau`

**add_entry**(cell, m)

Set the entry in cell equal to m. If the cell does not exist then extend the tableau, otherwise just replace the entry.

**EXAMPLES:**

```python
sage: s = StandardTableauTuple([ [[3,4,7],[6,8]], [[9,13],[12]], [[1,5],[2,11]], ...
\hspace{1cm} \rightarrow [10]] ); s.pp()
3 4 7 9 13 1 5
6 8 12 2 11
\hspace{1cm} 10
sage: t = s.add_entry( (0,0,3),14); t.pp(); t.category()
3 4 7 14 9 13 1 5
6 8 12 2 11
\hspace{1cm} 10
Category of elements of Standard tableau tuples
sage: t = s.add_entry( (0,0,3),15); t.pp(); t.category()
3 4 7 15 9 13 1 5
6 8 12 2 11
\hspace{1cm} 10
Category of elements of Tableau tuples
sage: t = s.add_entry( (1,1,1),14); t.pp(); t.category()
3 4 7 9 13 1 5
6 8 12 14 2 11
\hspace{1cm} 10
Category of elements of Standard tableau tuples
sage: t = s.add_entry( (2,1,1),14); t.pp(); t.category()
3 4 7 9 13 1 5
6 8 12 2 14
\hspace{1cm} 10
Category of elements of Tableau tuples
```
sage: t = s.add_entry((2,1,2),14); t.pp(); t.category()
Traceback (most recent call last):
...
IndexError: (2, 1, 2) is not an addable cell of the tableau

cells_containing(m)
Return the list of cells in which the letter m appears in the tableau self.
The list is ordered with cells appearing from left to right.

EXAMPLES:

sage: t = TableauTuple([[4,5],[[1,1,2,4],[2,4,4],[4]],[[1,3,4],[3,4]]])
(sage: t.cells_containing(4)
[(0, 0, 0),
 (1, 2, 0),
 (1, 1, 1),
 (1, 1, 2),
 (1, 0, 3),
 (2, 1, 1),
 (2, 0, 2)]
sage: t.cells_containing(6)
[]

charge()
Return the charge of the reading word of self.
See charge() for more information.

EXAMPLES:

sage: TableauTuple([[4,5],[[1,1,2,4],[2,4,4],[4]],[[1,3,4],[3,4]]]).charge()
4

cocharge()
Return the cocharge of the reading word of self.
See cocharge() for more information.

EXAMPLES:

sage: TableauTuple([[4,5],[[1,1,2,4],[2,4,4],[4]],[[1,3,4],[3,4]]]).charge()
4

column_stabilizer()
Return the PermutationGroup corresponding to self. That is, return subgroup of the symmetric group of degree size() which is the column stabilizer of self.

EXAMPLES:

sage: cs = TableauTuple([[1,2,3],[4,5],[[6,7],[8],[9]]]).column_stabilizer()
sage: cs.order()
8
sage: PermutationGroupElement(((1,3,2),(4,5))) in cs
False
sage: PermutationGroupElement(((1,4))) in cs
True
components()

Return a list of the components of tableau tuple self.

The components are the individual Tableau which are contained in the tuple self.

For compatibility with TableauTuples of level() 1, components() should be used to iterate over the components of TableauTuples.

EXAMPLES:

```python
sage: for t in TableauTuple([[1,2,3],[4,5]]).components(): t.pp()
  1  2  3
  4  5

sage: for t in TableauTuple([ [[1,2,3],[4,5]], [[6,7],[8,9]] ]).components(): t.pp()
  1  2  3
  4  5
  6  7
  8  9
```

conjugate()

Return the conjugate of the tableau tuple self.

The conjugate tableau tuple $T'$ is the TableauTuple obtained from $T$ by reversing the order of the components and conjugating each component – that is, swapping the rows and columns of the all of Tableau in $T$ (see `sage.combinat.tableau.Tableau.conjugate()`).

EXAMPLES:

```python
sage: TableauTuple([[[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11,12]]]).conjugate()
([[9, 11, 12], [10]], [[5, 8], [6], [7]], [[1, 3], [2, 4]])
```

content($k$, multicharge)

Return the content $k$ in self.

The content of $k$ in a standard tableau. That is, if $k$ appears in row $r$ and column $c$ of the tableau, then we return $c - r + a_k$, where the multicharge is $(a_1, a_2, \ldots, a_l)$ and $l$ is the level of the tableau.

The multicharge determines the dominant weight

$$\Lambda = \sum_{i=1}^{l} a_i$$

of the affine special linear group. In the combinatorics, the multicharge simply offsets the contents in each component so that the cell $(k, r, c)$ has content $a_k + c - r$.

INPUT:

• $k$ – an integer in $\{1, 2, \ldots, n\}$

• multicharge – a sequence of integers of length $l$

Here $l$ is the level() and $n$ is the size() of self.

EXAMPLES:

```python
sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).content(3,[0,0])
-1
sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).content(3,[0,1])
0
```

(continues on next page)
sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).content(3,[0,2])
1
sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).content(6,[0,2])
Traceback (most recent call last):
  ... ValueError: 6 must be contained in the tableaux entries

Return a sorted list of all entries of self, in the order obtained by reading across the rows.

EXAMPLES:

sage: TableauTuple([[1,2],[3,4],[5,6,7],[8],[9,10],[11],[12]]).entries()
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12]
sage: TableauTuple([[1,2],[3,4],[9,10],[11],[12],[5,6,7],[8]]).entries()
[1, 2, 3, 4, 9, 10, 11, 12, 5, 6, 7, 8]

Return the entry of the cell (l, r, c) in self.

A cell is a tuple (l, r, c) of coordinates, where l is the component index, r is the row index, and c is the column index.

EXAMPLES:

sage: t = TableauTuple([[1,2],[3,4],[5,6,7],[8],[9,10],[11],[12]])
sage: t.entry(1, 0, 0)
5
sage: t.entry(1, 1, 1)
Traceback (most recent call last):
  ... IndexError: tuple index out of range

Return the first cell of self that is not row standard.

Cells are ordered left to right along the rows and then top to bottom. That is, the cell minimal (k, r, c) such that the entry in position (k, r, c) is bigger than the entry in position (k, r, c + 1). If there is no such cell then None is returned - in this case the tableau is row strict.

OUTPUT:

The cell corresponding to the first column descent or None if the tableau is column strict.

EXAMPLES:

sage: TableauTuple([[3,5,6],[2,4,5],[1,4,5],[2,3]]).first_column_descent()
(0, 0, 0)sage: Tableau([[1,2,3],[4],[5,6,7],[8,9]]).first_column_descent() is None
True

Return the first cell of self that is not row standard.

Cells are ordered left to right along the rows and then top to bottom. That is, the cell minimal (k, r, c) such that the entry in position (k, r, c) is bigger than the entry in position (k, r, c + 1). If there is no such cell then None is returned - in this case the tableau is row strict.
OUTPUT:
The cell corresponding to the first row descent or None if the tableau is row strict.

EXAMPLES:

```python
sage: TableauTuple([[[5,6,7],[1,2]],[[1,3,2],[4]]]).first_row_descent()
(1, 0, 1)
sage: TableauTuple([[[1,2,3],[4]],[[6,7,8],[1,2,3]],[[1,11]]]).first_row_descent() is None
True
```

```

is_column_strict()
Return True if the tableau self is column strict and False otherwise.

A tableau tuple is column strict if the entries in each column of each component are in increasing order, when read from top to bottom.

EXAMPLES:

```python
sage: TableauTuple([[[5,7],[8]],[[1,3],[2,4]],[[6]]]).is_column_strict()
True
sage: TableauTuple([[[1,2],[2,4]],[[4,5,6],[7,8]]]).is_column_strict()
True
sage: TableauTuple([[[1]],[[2,3],[2,4]]]).is_column_strict()
False
sage: TableauTuple([[[1],[2,2],[4,5]]]).is_column_strict()
True
sage: TableauTuple([[[1,2],[6,7]],[[4,8],[6,9],[[]]].is_column_strict()
True
```

```

is_row_strict()
Return True if the tableau self is row strict and False otherwise.

A tableau tuple is row strict if the entries in each row of each component are in increasing order, when read from left to right.

EXAMPLES:

```python
sage: TableauTuple([[[5,7],[8]],[[1,3],[2,4]],[[6]]]).is_row_strict()
True
sage: TableauTuple([[[1,2],[2,4]],[[4,5,6],[7,8]]]).is_row_strict()
True
sage: TableauTuple([[[1]],[[2,3],[2,4]]]).is_row_strict()
True
sage: TableauTuple([[[1],[2,2],[4,5]]]).is_row_strict()
False
sage: TableauTuple([[[1,2],[6,7]],[[4,8],[6,9],[[]]].is_row_strict()
True
```

```

is_standard()
Return True if the tableau self is a standard tableau and False otherwise.

A tableau tuple is standard if it is row standard, column standard and the entries in the tableaux are 1, 2, ..., n, where n is the size() of the underlying partition tuple of self.

EXAMPLES:
Combinatorics, Release 9.7

```python
sage: TableauTuple([[5,7],[8],[1,3],[2,4],[6]]).is_standard()
True
sage: TableauTuple([[1,2],[2,4],[4,5,6],[7,8]]).is_standard()
False
sage: TableauTuple([[1],[2,3],[2,4]]).is_standard()
False
sage: TableauTuple([[1],[2,2],[4,5]]).is_row_strict()
False
sage: TableauTuple([[1,2],[6,7],[4,8],[6,9],[10],[11],[12],[13]]).is_standard()
False
```

**level()**

Return the level of the tableau `self`.

This is just the number of components in the tableau `self`.

**EXAMPLES:**

```python
sage: TableauTuple([[7,8,9]],[],[[1,2,3],[4,5],[6]]).level()
3
```

**pp()**

Pretty printing for the tableau tuple `self`.

**EXAMPLES:**

```python
sage: TableauTuple([ [[1,2,3],[4,5]], [[1,2,3],[4,5]] ]).pp()
  1 2 3 1 2 3
  4 5 4 5
sage: TableauTuple([ [[1,2],[3],[4]],[],[[6,7,8],[10,11],[12],[13]] ]).pp()
  1 2  - 6 7 8
  3 10 11
  4 12
  13
sage: t = TableauTuple([ [[1,2,3],[4,5],[6],[9]], [[1,2,3],[4,5,8]], [[11,12,13],[14]] ])
```

```python
sage: t.pp()
  1 2 3 1 2 3 11 12 13
  4 5 4 5 8 14
  6
  9
```

```python
sage: TableauTuples.options(convention="french")
```

```python
sage: t.pp()
  9
  6
  4 5 4 5 8 14
  1 2 3 1 2 3 11 12 13
```

```python
sage: TableauTuples.options._reset()
```

**reduced_column_word()**

Return the lexicographically minimal reduced expression for the permutation that maps the `initial_column_tableau()` to `self`.

This reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the rows of the tableau from top to bottom in each component, and then left to right along the components.
EXAMPLES:

```python
sage: StandardTableauTuple([[[7,9],[8]],[[1,4,6],[2,5],[3]]]).reduced_column_word()
[]
sage: StandardTableauTuple([[[7,9],[8]],[[1,3,6],[2,5],[4]]]).reduced_column_word()
[3]
sage: StandardTableauTuple([[[6,9],[8]],[[1,3,7],[2,5],[4]]]).reduced_column_word()
[3, 6]
sage: StandardTableauTuple([[[6,8],[9]],[[1,3,7],[2,5],[4]]]).reduced_column_word()
[3, 6, 8]
sage: StandardTableauTuple([[[5,8],[9]],[[1,3,7],[2,6],[4]]]).reduced_column_word()
[3, 6, 5, 8]
```

**reduced_row_word()**

Return the lexicographically minimal reduced expression for the permutation that maps the initial_tableau() to self.

This reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the rows of the tableau from top to bottom in each component, and then left to right along the components.

EXAMPLES:

```python
sage: StandardTableauTuple([[[1,2],[3]],[[4,5,6],[7,8],[9]]]).reduced_row_word()
[]
sage: StandardTableauTuple([[[1,2],[3]],[[4,5,6],[7,9],[8]]]).reduced_row_word()
[8]
sage: StandardTableauTuple([[[1,2],[3]],[[4,5,7],[6,9],[8]]]).reduced_row_word()
[6, 8]
sage: StandardTableauTuple([[[1,2],[3]],[[4,5,8],[6,9],[7]]]).reduced_row_word()
[6, 8, 7]
sage: StandardTableauTuple([[[1,2],[3]],[[4,5,9],[6,8],[7]]]).reduced_row_word()
[6, 7, 8, 7]
sage: StandardTableauTuple([[[7,9],[8]],[[1,3,5],[2,6],[4]]]).reduced_row_word()
[2, 3, 2, 1, 4, 3, 2, 5, 4, 3, 6, 5, 4, 3, 2, 7, 6, 5, 8, 7, 6, 5, 4]
```

**residue(k, e, multicharge)**

Return the residue of the integer k in the tableau self.

The residue of k is \( c - r + a_k \) in \( \mathbb{Z}/e\mathbb{Z} \), where k appears in row r and column c of the tableau and the multicharge is \( (a_1, a_2, \ldots, a_l) \).

The multicharge determines the dominant weight

\[
\sum_{i=1}^{l} \Lambda_{a_i}
\]

for the affine special linear group. In the combinatorics, it simply offsets the contents in each component so that the cell \((k, 0, 0)\) has content \(a_k\).

INPUT:

• k – an integer in \( \{1, 2, \ldots, n\} \)
• e – an integer in \{0, 2, 3, 4, \ldots\}

• multicharge – a list of integers of length \(l\)

Here \(l\) is the \textit{level()} and \(n\) is the \textit{size()} of self.

**OUTPUT:**

The residue of \(k\) in a standard tableau. That is,

**EXAMPLES:**

```python
sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).residue(1, 3,[0,0])
0
sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).residue(1, 3,[0,1])
1
sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).residue(1, 3,[0,2])
2
sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).residue(6, 3,[0,2])
Traceback (most recent call last):
  ...
ValueError: 6 must be contained in the tableaux
```

**restrict(\(m=\text{None}\))**

Return the restriction of the standard tableau \textit{self} to \(m\).

The restriction is the subtableau of \textit{self} whose entries are less than or equal to \(m\).

By default, \(m\) is one less than the current size.

**EXAMPLES:**

```python
sage: TableauTuple([[5],[[1,2],[3,4]]]).restrict()
([], [[1, 2], [3, 4]])
sage: TableauTuple([[5],[[1,2],[3,4]]]).restrict(6)
([[5]], [[1, 2], [3, 4]])
sage: TableauTuple([[5],[[1,2],[3,4]]]).restrict(5)
([[5]], [[1, 2], [3, 4]])
sage: TableauTuple([[5],[[1,2],[3,4]]]).restrict(4)
([], [[1, 2], [3, 4]])
sage: TableauTuple([[5],[[1,2],[3,4]]]).restrict(3)
([], [[1, 2], [3]])
sage: TableauTuple([[5],[[1,2],[3,4]]]).restrict(2)
([], [[1, 2]])
sage: TableauTuple([[5],[[1,2],[3,4]]]).restrict(1)
([], [[1]])
sage: TableauTuple([[5],[[1,2],[3,4]]]).restrict(0)
([], [])
```

Where possible the restricted tableau belongs to the same category as the original tableaux:

```python
sage: TableauTuple([[5],[[1,2],[3,4]]]).restrict(3).category()
Category of elements of Tableau tuples
sage: TableauTuple([[5],[[1,2],[3,4]]]).restrict(3).category()
Category of elements of Tableau tuples
sage: TableauTuples(level=2)([[5],[[1,2],[3,4]]]).restrict(3).category()
Category of elements of Tableau tuples of level 2
```
row_stabilizer()

Return the PermutationGroup corresponding to self. That is, return subgroup of the symmetric group of degree size() which is the row stabilizer of self.

EXAMPLES:

```
sage: rs = TableauTuple([[1,2,3],[4,5]],[[6,7]],[[8],[9]]).row_stabilizer()
sage: rs.order()
24
sage: PermutationGroupElement(((1,3,2),(4,5))) in rs
True
sage: PermutationGroupElement(((1,4))) in rs
False
sage: rs.one().domain()
[1, 2, 3, 4, 5, 6, 7, 8, 9]
```

shape()

Return the PartitionTuple which is the shape of the tableau tuple self.

EXAMPLES:

```
sage: TableauTuple([[7,8,9],[1,2,3],[4,5],[6]]).shape()
([3], [], [3, 2, 1])
```

size()

Return the size of the tableau tuple self.

This is just the number of boxes, or the size, of the underlying PartitionTuple.

EXAMPLES:

```
sage: TableauTuple([[7,8,9],[1,2,3],[4,5],[6]]).size()
9
```

symmetric_group_action_on_entries(w)

Return the action of a permutation w on self.

Consider a standard tableau tuple $T = (t^{(1)}, t^{(2)}, \ldots, t^{(l)})$ of size $n$, then the action of $w \in S_n$ is defined by permuting the entries of $T$ (recall they are $1, 2, \ldots, n$). In particular, suppose the entry at cell $(k, i, j)$ is $a$, then the entry becomes $w(a)$. In general, the resulting tableau tuple $wT$ may not be standard.

INPUT:

• w – a permutation

EXAMPLES:

```
sage: TableauTuple([[1,2],[4]],[[3,5]]).symmetric_group_action_on_entries(Permutation(((4,5))) )
([[1, 2], [5]], [[3, 4]])
sage: TableauTuple([[1,2],[4]],[[3,5]]).symmetric_group_action_on_entries(Permutation(((1,2))))
([[2, 1], [4]], [[3, 5]])
```

to_list()

Return the list representation of the tableaux tuple self.

EXAMPLES:
sage: TableauTuple([[[1,2,3],[4,5]], [[6,7],[8,9]]]).to_list()

[[[1, 2, 3], [4, 5]], [[6, 7], [8, 9]]]

to_permutation()  
Return a permutation with the entries in the tableau tuple self.

The permutation is obtained from self by reading the entries of the tableau tuple in order from left to right along the rows, and then top to bottom, in each component and then left to right along the components.

EXAMPLES:

sage: TableauTuple([[1,2],[3,4]], [[5,6,7],[8]], [[9,10],[11],[12]]).to_permutation()

[12, 11, 9, 10, 8, 5, 6, 7, 3, 4, 1, 2]

to_word()  
Return a word obtained from a row reading of the tableau tuple self.

EXAMPLES:

sage: TableauTuple([[1,2],[3,4]], [[5,6,7],[8]], [[9,10],[11],[12]]).to_word()

word: 12,11,9,10,8,5,6,7,3,4,1,2

to_word_by_column()  
Return the word obtained from a column reading of the tableau tuple self.

EXAMPLES:

sage: TableauTuple([[1,2],[3,4]], [[5,6,7],[8]], [[9,10],[11],[12]]).to_word_by_column()

word: 12,11,9,10,8,5,6,7,3,1,4,2

to_word_by_row()  
Return a word obtained from a row reading of the tableau tuple self.

EXAMPLES:

sage: TableauTuple([[1,2],[3,4]], [[5,6,7],[8]], [[9,10],[11],[12]]).to_word_by_row()

word: 12,11,9,10,8,5,6,7,3,4,1,2

up(n=None)  
An iterator for all the TableauTuple that can be obtained from self by adding a cell with the label n. If n is not specified then a cell with label n will be added to the tableau tuple, where n-1 is the size of the tableau tuple before any cells are added.

EXAMPLES:

sage: list(TableauTuple([[1,2]], [[3]]).up())

[[[[1, 2, 4], [4]], [[3]]],
 [[[1, 2], [4]], [[3]]],
 [[[1, 2]], [3, 4]],
 [[[1, 2]], [3], [4]]]
A factory class for the various classes of tableau tuples.

INPUT:

There are three optional arguments:

- shape – determines a \texttt{PartitionTuple} which gives the shape of the \texttt{TableauTuples}
- level – the level of the tableau tuples (positive integer)
- size – the size of the tableau tuples (non-negative integer)

It is not necessary to use the keywords. If they are not specified then the first integer argument specifies the level and the second the size of the tableaux.

OUTPUT:

- The corresponding class of tableau tuples.

The entries of a tableau can be any sage object. Because of this, no enumeration of the set of \texttt{TableauTuples} is possible.

EXAMPLES:

```sage
sage: T3 = TableauTuples(3); T3
Tableau tuples of level 3
sage: [['a','b']] in TableauTuples()
True
sage: [['a','b']] in TableauTuples(level=3)
False
sage: t = TableauTuples(level=3)([[''],[1,1,1]],[]); t
([], [[1, 1, 1]], [])
sage: t in T3
True
sage: t in TableauTuples()
True
sage: t in TableauTuples(size=3)
True
sage: t in TableauTuples(size=4)
False
sage: t in StandardTableauTuples()
False
sage: t.parent()
Tableau tuples of level 3
sage: t.category()
Category of elements of Tableau tuples of level 3
```

See also:

- \texttt{Tableau}
- \texttt{StandardTableau}
- \texttt{StandardTableauTuples}

\texttt{Element}

alias of \texttt{TableauTuple}

\texttt{level()}

Return the level of a tableau tuple in \texttt{self}, or \texttt{None} if different tableau tuples in \texttt{self} can have different sizes. The level of a tableau tuple is just the level of the underlying \texttt{PartitionTuple}. 

5.1. Comprehensive Module List
EXAMPLES:

```python
sage: TableauTuples().level() is None
True
sage: TableauTuples(7).level()
7
```

`level_one_parent_class`

alias of `sage.combinat.tableau.Tableaux_all`

`list()`

If the set of tableau tuples `self` is finite then this function returns the list of these tableau tuples. If the class is infinite an error is returned.

EXAMPLES:

```python
sage: StandardTableauTuples([[2,1],[2]]).list()
[[[[1, 2], [3]], [[4, 5]]],
 [[[1, 3], [2]], [[4, 5]]],
 [[[1, 2], [4]], [[3, 5]]],
 [[[1, 3], [4]], [[2, 5]]],
 [[[2, 3], [4]], [[1, 5]]],
 [[[1, 4], [2]], [[3, 5]]],
 [[[1, 4], [3]], [[2, 5]]],
 [[[2, 4], [3]], [[1, 5]]],
 [[[1, 2], [5]], [[3, 4]]],
 [[[1, 3], [5]], [[2, 4]]],
 [[[2, 3], [5]], [[1, 4]]],
 [[[1, 4], [5]], [[2, 3]]],
 [[[2, 4], [5]], [[1, 3]]],
 [[[3, 4], [5]], [[1, 2]]],
 [[[1, 5], [2]], [[3, 4]]],
 [[[1, 5], [3]], [[2, 4]]],
 [[[2, 5], [3]], [[1, 4]]],
 [[[1, 5], [4]], [[2, 3]]],
 [[[2, 5], [4]], [[1, 3]]],
 [[[3, 5], [4]], [[1, 2]]]]
```

`options(*get_value, **set_value)`

Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:

- `ascii_art` – (default: `repr`) Controls the ascii art output for tableaux
  - compact – minimal length ascii art
  - `repr` – display using the diagram string representation
  - `table` – display as a table
- `convention` – (default: `English`) Sets the convention used for displaying tableaux and partitions
  - `English` – use the English convention
  - `French` – use the French convention
- `display` – (default: `list`) Controls the way in which tableaux are printed
- array – alias for diagram
- compact – minimal length string representation
- diagram – display as Young diagram (similar to \texttt{pp()})
- ferrers_diagram – alias for diagram
- list – print tableaux as lists
- young_diagram – alias for diagram

- latex – (default: diagram) Controls the way in which tableaux are latexed
  - array – alias for diagram
  - diagram – as a Young diagram
  - ferrers_diagram – alias for diagram
  - list – as a list
  - young_diagram – alias for diagram

- notation – alternative name for convention

**Note:** Changing the convention for tableaux also changes the convention for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

**EXAMPLES:**

```sage
sage: T = Tableau([[1,2,3],[4,5]])
sage: T
[[1, 2, 3], [4, 5]]
sage: Tableaux.options.display="array"
sage: T
1 2 3
4 5
sage: Tableaux.options.convention="french"
sage: T
4 5
1 2 3
```

Changing the convention for tableaux also changes the convention for partitions and vice versa:

```sage
sage: P = Partition([3,3,1])
sage: print(P.ferrers_diagram())
* ***
***
sage: Partitions.options.convention="english"
sage: print(P.ferrers_diagram())
*** ***
*
sage: T
1 2 3
4 5
```
The ASCII art can also be changed:

```sage
sage: t = Tableau([[1,2,3],[4,5]])
sage: ascii_art(t)
  \begin{tableau}{3}
    1 & 2 & 3 \\
    4 & 5
  \end{tableau}
sage: Tableaux.options.ascii_art = "table"
sage: ascii_art(t)
+---+---+---+
| 1 | 2 | 3 |
+---+---+---+
| 4 | 5 |
+---+
sage: Tableaux.options.ascii_art = "compact"
sage: ascii_art(t)
|1|2|3|
|4|5|
sage: Tableaux.options._reset()
```

See `GlobalOptions` for more features of these options.

### size()

Return the size of a tableau tuple in `self`, or `None` if different tableau tuples in `self` can have different sizes. The size of a tableau tuple is just the size of the underlying `PartitionTuple`.

**EXAMPLES:**

```sage
sage: TableauTuples(size=14).size()
14
```

---

### class sage.combinat.tableau_tuple.TableauTuples_all

Bases: `sage.combinat.tableau_tuple.TableauTuples`

The parent class of all `TableauTuples`, with arbitrary level and size.

#### an_element()

Return a particular element of the class.

**EXAMPLES:**

```sage
sage: TableauTuples().an_element()
```

---

### class sage.combinat.tableau_tuple.TableauTuples_level(level)

Bases: `sage.combinat.tableau_tuple.TableauTuples`

Class of all `TableauTuples` with a fixed level and arbitrary size.

#### an_element()

Return a particular element of the class.

**EXAMPLES:**

```sage
sage: TableauTuples(3).an_element()
([], [], [])
sage: TableauTuples(5).an_element()
([], [], [], [], [])
sage: T = TableauTuples(0)
```
class sage.combinat.tableau_tuple.TableauTuples_level_size(level, size)
    Bases: sage.combinat.tableau_tuple.TableauTuples
    Class of all TableauTuples with a fixed level and a fixed size.
    an_element()
    Return a particular element of the class.
    EXAMPLES:
    sage: TableauTuples(3,0).an_element()
    ([], [], [])
    sage: TableauTuples(3,1).an_element()
    ([[1]], [], [])
    sage: TableauTuples(3,2).an_element()
    ([[1, 2]], [], [])

class sage.combinat.tableau_tuple.TableauTuples_size(size)
    Bases: sage.combinat.tableau_tuple.TableauTuples
    Class of all TableauTuples with a arbitrary level and fixed size.
    an_element()
    Return a particular element of the class.
    EXAMPLES:
    sage: TableauTuples(size=3).an_element()
    ([], [[1, 2, 3]], [])
    sage: TableauTuples(size=0).an_element()
    ([], [], [])

5.1.345 Generalized Tamari lattices

These lattices depend on three parameters $a$, $b$ and $m$, where $a$ and $b$ are coprime positive integers and $m$ is a nonnegative integer.

The elements are *Dyck paths* in the $(a \times b)$-rectangle. The order relation depends on $m$.

To use the provided functionality, you should import Generalized Tamari lattices by typing:

```python
sage: from sage.combinat.tamari_lattices import GeneralizedTamariLattice
```

Then,

```python
sage: GeneralizedTamariLattice(3,2)
Finite lattice containing 2 elements
sage: GeneralizedTamariLattice(4,3)
Finite lattice containing 5 elements
```

The classical *Tamari lattices* are special cases of this construction and are also available directly using the catalogue of posets, as follows:
sage: posets.TamariLattice(3)
Finite lattice containing 5 elements

See also:
For more detailed information see TamariLattice(), GeneralizedTamariLattice().

sage.combinat.tamari_lattices.DexterSemilattice(n)
Return the \(n\)-th Dexter meet-semilattice.

INPUT:
• \(n\) – a nonnegative integer (the index)

OUTPUT:
a finite meet-semilattice
The elements of the semilattice are Dyck paths in the \((n + 1 \times n)\)-rectangle.

EXAMPLES:

sage: posets.DexterSemilattice(3)
Finite meet-semilattice containing 5 elements

sage: P = posets.DexterSemilattice(4); P
Finite meet-semilattice containing 14 elements

sage: len(P.maximal_chains())
15

sage: len(P.maximal_elements())
4

sage: P.chain_polynomial()
\(q^5 + 19q^4 + 47q^3 + 42q^2 + 14q + 1\)

REFERENCES:
• [Cha18]

sage.combinat.tamari_lattices.GeneralizedTamariLattice(a, b, m=1, check=True)
Return the \((a, b)\)-Tamari lattice of parameter \(m\).

INPUT:
• \(a\) and \(b\) – coprime integers with \(a \geq b\)
• \(m\) – a nonnegative integer such that \(a \geq bm\)

OUTPUT:
• a finite lattice (the lattice property is only conjectural in general)
The elements of the lattice are Dyck paths in the \((a \times b)\)-rectangle.
The parameter \(m\) (slope) is used only to define the covering relations. When the slope \(m\) is 0, two paths are comparable if and only if one is always above the other.
The usual Tamari lattice of index \(b\) is the special case \(a = b + 1\) and \(m = 1\).
Other special cases give the \(m\)-Tamari lattices studied in [BMFPR].

EXAMPLES:
Combinatorics, Release 9.7

```python
sage: from sage.combinat.tamari_lattices import GeneralizedTamariLattice
sage: GeneralizedTamariLattice(3,2)
Finite lattice containing 2 elements
sage: GeneralizedTamariLattice(4,3)
Finite lattice containing 5 elements
sage: GeneralizedTamariLattice(4,4)
Traceback (most recent call last):
...
ValueError: the numbers a and b must be coprime with a>=b
sage: GeneralizedTamariLattice(7,5,2)
Traceback (most recent call last):
...
ValueError: the condition a>=b*m does not hold
sage: P = GeneralizedTamariLattice(5,3);P
Finite lattice containing 7 elements
```

REFERENCES:
sage.combinat.tamari_lattices.TamariLattice(n, m=1)
Return the \( n \)-th Tamari lattice.

Using the slope parameter \( m \), one can also get the \( m \)-Tamari lattices.

INPUT:

- \( n \) – a nonnegative integer (the index)
- \( m \) – an optional nonnegative integer (the slope, default to 1)

OUTPUT:

a finite lattice

In the usual case, the elements of the lattice are *Dyck paths* in the \((n + 1 \times n)\)-rectangle. For a general slope \( m \), the elements are Dyck paths in the \((mn + 1 \times n)\)-rectangle.

See Tamari lattice for mathematical background.

EXAMPLES:

```python
sage: posets.TamariLattice(3)
Finite lattice containing 5 elements
sage: posets.TamariLattice(3, 2)
Finite lattice containing 12 elements
```

REFERENCES:

- [BMFPR]

sage.combinat.tamari_lattices.paths_in_triangle(i, j, a, b)
Return all Dyck paths from \((0, 0)\) to \((i, j)\) in the \((a \times b)\)-rectangle.

This means that at each step of the path, one has \( ay \geq bx \).

A path is represented by a sequence of 0 and 1, where 0 is an horizontal step \((1, 0)\) and 1 is a vertical step \((0, 1)\).

INPUT:

- \( a \) and \( b \) – coprime integers with \( a \geq b \)
- \( i \) and \( j \) – nonnegative integers with \( 1 \geq \frac{i}{b} \geq \frac{b}{a} \geq 0 \)
OUTPUT:

- a list of paths

EXAMPLES:

```python
def paths_in_triangle(a, b, c, d):
    # Implementation...
```

```python
def swap(p, i, m=1):
    # Implementation...
```

```python
def swap_dexter(p, i):
    # Implementation...
```

sage.combinat.tamari_lattices.swap(p, i, m=1)
Perform a covering move in the \((a, b)\)-Tamari lattice of parameter \(m\).

The letter at position \(i\) in \(p\) must be a 0, followed by at least one 1.

INPUT:

- \(p\) – a Dyck path in the \((a \times b)\)-rectangle
- \(i\) – an integer between 0 and \(a + b - 1\)

OUTPUT:

- a Dyck path in the \((a \times b)\)-rectangle

EXAMPLES:

```python
def swap_dexter(p, i):
    # Implementation...
```

```python
def swap_dexter(p, i):
    # Implementation...
```

sage.combinat.tamari_lattices.swap_dexter(p, i)
Perform covering moves in the \((a, b)\)-Dexter posets.

The letter at position \(i\) in \(p\) must be a 0, followed by at least one 1.

INPUT:

- \(p\) – a Dyck path in the \((a \times b)\)-rectangle
- \(i\) – an integer between 0 and \(a + b - 1\)

OUTPUT:

- a list of Dyck paths in the \((a \times b)\)-rectangle

EXAMPLES:
5.1.346 Tiling Solver

Tiling a n-dimensional polyomino with n-dimensional polyominoes.

This module defines two classes:

- `sage.combinat.tiling.Polyomino` class, to represent polyominoes in arbitrary dimension. The goal of this class is to return all the rotated, reflected and/or translated copies of a polyomino that are contained in a certain box.

- `sage.combinat.tiling.TilingSolver` class, to solve the problem of tiling a n-dimensional polyomino with a set of n-dimensional polyominoes. One can specify if rotations and reflections are allowed or not and if pieces can be reused or not. This class convert the tiling data into rows of a matrix that are passed to the DLX solver. It also allows to compute the number of solutions.

This uses dancing links code which is in Sage. Dancing links were originally introduced by Donald Knuth in 2000 [Knuth1]. Knuth used dancing links to solve tilings of a region by 2d pentaminoes. Here we extend the method to any dimension.

In particular, the `sage.games.quantumino` module is based on the Tiling Solver and allows to solve the 3d Quantumino puzzle.

AUTHOR:

- Sébastien Labbé, June 2011, initial version
- Sébastien Labbé, July 2015, count solutions up to rotations
- Sébastien Labbé, April 2017, tiling a polyomino, not only a rectangular box

EXAMPLES:

### 2d Easy Example

Here is a 2d example. Let us try to fill the $3 \times 2$ rectangle with a $1 \times 2$ rectangle and a $2 \times 2$ square. Obviously, there are two solutions:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([((0,0), (0,1))])
sage: q = Polyomino([((0,0), (0,1), (1,0), (1,1))])
sage: T = TilingSolver([p,q], box=[3,2])
sage: it = T.solve()
sage: next(it)
[Polyomino: [(0, 0), (0, 1), (1, 0), (1, 1)], Color: gray, Polyomino: [(2, 0), (2, 1)], Color: gray]
sage: next(it)
[Polyomino: [(1, 0), (1, 1), (2, 0), (2, 1)], Color: gray, Polyomino: [(0, 0), (0, 1)], Color: gray]
sage: next(it)
Traceback (most recent call last):
```
Scott's pentamino problem

As mentioned in the introduction of [Knuth1], Scott's pentamino problem consists in tiling a chessboard leaving the center four squares vacant with the 12 distinct pentaminoes.

The 12 pentaminoes:

```
sage: from sage.combinat.tiling import Polyomino
sage: I = Polyomino([(0,0),(1,0),(2,0),(3,0),(4,0)], color='brown')
sage: N = Polyomino([(1,0),(1,1),(1,2),(0,2),(0,3)], color='yellow')
sage: L = Polyomino([(0,0),(1,0),(0,1),(0,2),(0,3)], color='magenta')
sage: U = Polyomino([(0,0),(1,0),(0,1),(0,2),(1,2)], color='violet')
sage: X = Polyomino([(1,0),(0,1),(1,1),(1,2),(2,1)], color='pink')
sage: W = Polyomino([(2,0),(2,1),(1,1),(1,2),(0,2)], color='green')
sage: P = Polyomino([(1,0),(2,0),(0,1),(1,1),(2,1)], color='orange')
sage: F = Polyomino([(1,0),(1,1),(0,1),(2,1),(2,2)], color='gray')
sage: Z = Polyomino([(0,0),(1,0),(1,1),(1,2),(2,2)], color='yellow')
sage: T = Polyomino([(0,0),(0,1),(1,1),(2,1),(0,2)], color='red')
sage: Y = Polyomino([(0,0),(1,0),(2,0),(3,0),(2,1)], color='green')
sage: V = Polyomino([(0,0),(0,1),(0,2),(1,0),(2,0)], color='blue')
```

A $8 \times 8$ chessboard leaving the center four squares vacant:

```
sage: import itertools
sage: s = set(itertools.product(range(8), repeat=2))
sage: s.difference_update([(3,3), (3,4), (4,3), (4,4)])
sage: chessboard = Polyomino(s)
sage: len(chessboard)
60
```

This problem is represented by a matrix made of 1568 rows and 72 columns. It has 65 different solutions up to isometries:

```
sage: from sage.combinat.tiling import TilingSolver
sage: T
Tiling solver of 12 pieces into a box of size 60
Rotation allowed: True
Reflection allowed: True
Reusing pieces allowed: False
sage: len(T.rows()) # long time
1568
sage: T.number_of_solutions() # long time
520
sage: 520 / 8
65
```

Showing one solution:
sage: solution = next(T.solve())  # long time
sage: G = sum([piece.show2d() for piece in solution], Graphics())  # long time
sage: G.show(aspect_ratio=1, axes=False)  # long time

1d Easy Example

Here is an easy one dimensional example where we try to tile a stick of length 6 with three sticks of length 1, 2 and 3. There are six solutions:

sage: p = Polyomino([[0]])
sage: q = Polyomino([[0],[1]])
sage: r = Polyomino([[0],[1],[2]])
sage: T = TilingSolver([p,q,r], box=[6])
sage: len(T.rows())
15
sage: it = T.solve()
sage: next(it)
[Polyomino: [(0)], Color: gray, Polyomino: [(1), (2)], Color: gray, Polyomino: [(3), (4), (5)], Color: gray]
sage: next(it)
[Polyomino: [(0)], Color: gray, Polyomino: [(1), (2), (3)], Color: gray, Polyomino: [(4), (5)], Color: gray]
sage: T.number_of_solutions()
6

2d Puzzle allowing reflections

The following is a puzzle owned by Florent Hivert:

sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: L = []
sage: L.append(Polyomino(((0,0),(0,1),(0,2),(0,3),(1,0),(1,1),(1,2),(1,3]), 'yellow'))
sage: L.append(Polyomino(((0,0),(0,1),(0,2),(0,3),(1,0),(1,1),(1,2),(1,3)), 'black'))
sage: L.append(Polyomino(((0,0),(0,1),(0,2),(0,3),(1,0),(1,1),(1,3)), 'gray'))
sage: L.append(Polyomino(((0,0),(0,1),(0,2),(0,3),(1,0),(1,2)), 'cyan'))
sage: L.append(Polyomino(((0,0),(0,1),(0,2),(0,3),(1,0),(1,1)), 'red'))
sage: L.append(Polyomino(((0,0),(0,1),(0,2),(0,3),(1,1),(1,2),), 'blue'))
sage: L.append(Polyomino(((0,0),(0,1),(0,2),(0,3),(1,1),(1,3),), 'green'))
sage: L.append(Polyomino(((0,1),(0,2),(0,3),(1,0),(1,1),(1,3),), 'magenta'))
sage: L.append(Polyomino(((0,1),(0,2),(0,3),(1,0),(1,1),(1,2),), 'orange'))
sage: L.append(Polyomino(((0,0),(0,1),(0,2),(1,0),(1,1),(1,2),), 'pink'))

By default, rotations are allowed and reflections are not. In this case, there are no solution for tiling a \(8 \times 8\) rectangular box:

sage: T = TilingSolver(L, box=(8,8))
sage: T.number_of_solutions()  # long time (2.5 s)
0

If reflections are allowed, there are solutions. Solve the puzzle and show one solution:
Combinatorics, Release 9.7

```python
sage: T = TilingSolver(L, box=(8,8), reflection=True)  # long time (7s)
sage: solution = next(T.solve())  # long time (<1s)
sage: G = sum([piece.show2d() for piece in solution], Graphics())  # long time (2s)
sage: G.show(aspect_ratio=1, axes=False)  # long time (2s)

Compute the number of solutions:

```python
sage: T.number_of_solutions()  # long time (2.6s)
```

```text
328
```

Create a animation of all the solutions:

```python
sage: a = T.animate()  # not tested
sage: a  # not tested
```

Animation with 328 frames

3d Puzzle

The same thing done in 3d without allowing reflections this time:

```python
sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: L = []
sage: L.append(Polyomino(((0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,2,0),(1,3,0))))
sage: L.append(Polyomino(((0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,2,0),(1,3,0))))
sage: L.append(Polyomino(((0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,3,0),(1,0,0))))
sage: L.append(Polyomino(((0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,2,0),(1,3,0))))
sage: L.append(Polyomino(((0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,2,0),(1,3,0))))
sage: L.append(Polyomino(((0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,2,0),(1,3,0))))
sage: L.append(Polyomino(((0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,2,0),(1,3,0))))
sage: L.append(Polyomino(((0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,2,0),(1,3,0))))
sage: L.append(Polyomino(((0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,2,0),(1,3,0))))
sage: L.append(Polyomino(((0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,2,0),(1,3,0))))

Solve the puzzle and show one solution:

```python
sage: T = TilingSolver(L, box=(8,8,1))
sage: solution = next(T.solve())  # long time (8s)
sage: G = sum([p.show3d(size=0.85) for p in solution], Graphics())  # long time (<1s)
sage: G.show(aspect_ratio=1, viewer='tachyon')  # long time (2s)

Let us compute the number of solutions:

```python
sage: T.number_of_solutions()  # long time (3s)
```

```text
328
```
Donald Knuth example: the Y pentamino

Donald Knuth [Knuth1] considered the problem of packing 45 Y pentaminoes into a $15 \times 15$ square:

```python
sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: y = Polyomino([(0,0),(1,0),(2,0),(3,0),(2,1)])
sage: T = TilingSolver([y], box=(5,10), reusable=True, reflection=True)
sage: T.number_of_solutions()
10
sage: solution = next(T.solve())
sage: G = sum([p.show2d() for p in solution], Graphics())
sage: G.show(aspect_ratio=1)  # long time (2s)
```

Up to the symmetries of the square, there are 212 distinct solutions:

```python
sage: 1696 // 8
212
```

Animation of Donald Knuth’s dancing links

Animation of the solutions:

```python
sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: Y = Polyomino([(0,0),(1,0),(2,0),(3,0),(2,1)], color='yellow')
sage: T = TilingSolver([Y], box=(15,15), reusable=True, reflection=True)
sage: a = T.animate(stop=40)  # long time # optional -- ImageMagick
sage: a  # long time # optional -- ImageMagick
```

Incremental animation of the solutions (one piece is removed/added at a time):

```python
sage: a = T.animate('incremental', stop=40)  # long time # optional -- ImageMagick
sage: a  # long time # optional -- ImageMagick
```

5d Easy Example

Here is a 5d example. Let us try to fill the $2 \times 2 \times 2 \times 2 \times 2$ rectangle with reusable $1 \times 1 \times 1 \times 1 \times 1$ rectangles. Obviously, there is one solution:

```python
sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: p = Polyomino([(0,0,0,0,0)])
sage: T = TilingSolver([p], box=(2,2,2,2), reusable=True)
sage: rows = T.rows()  # long time (3s)
sage: rows  # long time (fast)
[[[0], [1], [2], [3], [4], [5], [6], [7], [8], [9], [10], [11], [12], [13], [14], [15], ...
  [16], [17], [18], [19], [20], [21], [22], [23], [24], [25], [26], [27], [28], [29],...
  [30], [31]]
```

(continues on next page)
REFERENCES:

class \texttt{sage.combinat.tiling.Polyomino}(\texttt{coords, color='gray', dimension=None})

Bases: \texttt{sage.structure.sage_object.SageObject}

A polyomino in $\mathbb{Z}^d$.

The polyomino is the union of the unit square (or cube, or n-cube) centered at those coordinates. Such an object should be connected, but the code does not make this assumption.

INPUT:

- \texttt{coords} – iterable of integer coordinates in $\mathbb{Z}^d$
- \texttt{color} – string (default: 'gray'), color for display
- \texttt{dimension} – integer (default: None), dimension of the space, if None, it is guessed from the \texttt{coords} if \texttt{coords} is non empty

EXAMPLES:

\begin{verbatim}
  sage: from sage.combinat.tiling import Polyomino
  sage: Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
  Polyomino: [(0, 0, 0), (0, 1, 0), (1, 1, 0), (1, 1, 1)], Color: blue
\end{verbatim}

\texttt{boundary}()

Return the boundary of a 2d polyomino.

INPUT:

- \texttt{self} - a 2d polyomino

OUTPUT:

- list of edges (an edge is a pair of adjacent 2d coordinates)

EXAMPLES:

\begin{verbatim}
  sage: from sage.combinat.tiling import Polyomino
  sage: p = Polyomino([(0,0), (1,0), (0,1), (1,1)])
  sage: sorted(p.boundary())
  [((-0.5, -0.5), (-0.5, 0.5)), ((-0.5, 0.5), (-0.5, -0.5)), ((-0.5, -0.5), (-0.5, 0.5)), ((-0.5, 0.5), (-0.5, -0.5)), ((-0.5, 0.5), (-0.5, -0.5)), ((-0.5, -0.5), (-0.5, 0.5)), ((-0.5, 0.5), (-0.5, -0.5)), ((-0.5, 0.5), (-0.5, -0.5))]
  sage: len(_)
  8
  sage: p = Polyomino([(5,5)])
  sage: sorted(p.boundary())
  [((4.5, 4.5), (4.5, 5.5)), ((4.5, 4.5), (5.5, 4.5)), ((4.5, 5.5), (5.5, 5.5)), ((5.5, 4.5), (5.5, 5.5))]
\end{verbatim}

\texttt{bounding_box}()

EXAMPLES:

\begin{verbatim}
  sage: from sage.combinat.tiling import Polyomino
  sage: p = Polyomino([(0,0,0), (1,0,0), (1,1,0), (1,1,1), (1,2,0)], color='deeppink')
  (continues on next page)
\end{verbatim}
sage: p.bounding_box()
[[0, 0, 0], [1, 2, 1]]

canonical()
Return the translated copy of self having minimal and nonnegative coordinates

EXAMPLES:

sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0),(1,0,0),(1,1,0),(1,1,1),(1,2,0)], color='deeppink')
sage: p
Polyomino: [(0, 0, 0), (1, 0, 0), (1, 1, 0), (1, 1, 1), (1, 2, 0)], Color: 
→ deeppink
sage: p.canonical()
Polyomino: [(0, 0, 0), (1, 0, 0), (1, 1, 0), (1, 1, 1), (1, 2, 0)], Color: 
→ deeppink

canonical_isometric_copies(orientation_preserving=True, mod_box_isometries=False)
Return the list of image of self under isometries of the n-cube where the coordinates are all nonnegative and minimal.

INPUT:

• orientation_preserving – bool (optional, default: True); if True, the group of isometries of the n-cube is restricted to those that preserve the orientation, i.e. of determinant 1.

• mod_box_isometries – bool (default: False), whether to quotient the group of isometries of the n-cube by the subgroup of isometries of the \(a_1 \times a_2 \cdots \times a_n\) rectangular box where are the \(a_i\) are assumed to be distinct.

OUTPUT:

set of Polyomino

EXAMPLES:

sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
sage: s = p.canonical_isometric_copies()
sage: len(s)
12

With the non orientation-preserving:

sage: s = p.canonical_isometric_copies(orientation_preserving=False)
sage: len(s)
24

Modulo rotation by angle 180 degrees:

sage: s = p.canonical_isometric_copies(mod_box_isometries=True)
sage: len(s)
3

center()
Return the center of the polyomino.

EXAMPLES:
Combinatorics, Release 9.7

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0),(0,1)])
sage: p.center()
(0, 0, 1/2)
```

In 3d:

```
sage: p = Polyomino([(0,0),(1,0),(1,1),(1,1,1),(1,2,0)], color='deppink')
sage: p.center()
(4/5, 4/5, 1/5)
```

In 2d:

```
sage: p = Polyomino([(0,0),(1,0),(1,1),(1,2)])
sage: p.center()
(3/4, 3/4)
```

**color**(color=None)

Return or change the color of the polyomino.

**INPUT:**

- color – string, RBG tuple or None (default: None), if None, it returns the current color

**EXAMPLES:**

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
sage: p.color()
'blue'
```

**frozenset()**

Return the elements of \( \mathbb{Z}^d \) in the polyomino as a frozenset.

**EXAMPLES:**

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='red')
sage: p.frozenset()
frozenset({(0, 0, 0), (0, 1, 0), (1, 1, 0), (1, 1, 1)})
```

**intersection**(other)

Return the intersection of self and other.

**INPUT:**

- other - a polyomino

**OUTPUT:**

polyomino

**EXAMPLES:**

```
sage: from sage.combinat.tiling import Polyomino
sage: a = Polyomino([(0,0)])
sage: b = Polyomino([(0,0), (0,1), (1,1), (2,1)])
sage: a.intersection(b)
```

(continues on next page)
Combinatorics, Release 9.7

(continued from previous page)

Polyomino: [(0, 0)], Color: gray
\[
sage: a.intersection(b+(1,1))
\]
Polyomino: [], Color: gray

isometric_copies(box, orientation_preserving=True, mod_box_isometries=False)

Return the translated and isometric images of self that lies in the box.

INPUT:

- box – Polyomino or tuple of integers (size of a box)
- orientation_preserving – bool (optional, default: True); If True, the group of isometries of the \(n\)-cube is restricted to those that preserve the orientation, i.e. of determinant 1.
- mod_box_isometries – bool (default: False), whether to quotient the group of isometries of the \(n\)-cube by the subgroup of isometries of the \(a_1 \times a_2 \cdots \times a_n\) rectangular box where are the \(a_i\) are assumed to be distinct.

EXAMPLES:

\[
\begin{align*}
sage: & \text{from sage.combinat.tiling import Polyomino} \\
sage: & p = Polyomino([(0,0,0),(1,0,0),(1,1,0),(1,1,1),(1,2,0)], color='deppink') \\
sage: & L = list(p.isometric_copies(box=(5,8,2))) \\
sage: & len(L) \\
& 360 \\
sage: & p = Polyomino([(0,0,0),(1,0,0),(1,1,0),(1,2,0),(1,2,1)], color='orange') \\
sage: & L = list(p.isometric_copies(box=(5,8,2))) \\
sage: & len(L) \\
& 180 \\
sage: & L = list(p.isometric_copies((5,8,2), False)) \\
sage: & len(L) \\
& 360 \\
sage: & L = list(p.isometric_copies((5,8,2), mod_box_isometries=True)) \\
sage: & len(L) \\
& 45 \\
sage: & p = Polyomino([(0,0), (1,0), (0,1)]) \\
sage: & b = Polyomino([(0,0), (1,0), (2,0), (0,1), (1,1), (0,2)]) \\
sage: & sorted(p.isometric_copies(b), key=lambda p: p.sorted_list()) \\
& [Polyomino: [(0, 0), (0, 1), (1, 0)], Color: gray, \\
Polyomino: [(0, 0), (0, 1), (1, 1)], Color: gray, \\
Polyomino: [(0, 0), (1, 0), (1, 1)], Color: gray, \\
Polyomino: [(0, 1), (0, 2), (1, 1)], Color: gray, \\
Polyomino: [(0, 1), (1, 0), (1, 1)], Color: gray, \\
Polyomino: [(1, 0), (1, 1), (2, 0)], Color: gray]
\end{align*}
\]

isometric_copies_intersection(box, orientation_preserving=True)

Return the set of non empty intersections of isometric images of self with a polyomino.

INPUT:

- box – Polyomino or tuple of integers (size of a box)
- orientation_preserving – bool (optional, default: True); if True, the group of isometries of the \(n\)-cube is restricted to those that preserve the orientation, i.e. of determinant 1.
EXAMPLES:

```python
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0),(1,0)], color='deeppink')
```

```python
sage: sorted(sorted(a.frozenset()) for a in p.isometric_copies_
    \rightarrow intersection(box=(2,3)))
```

```python
[(0, 0),
 [(0, 0), (0, 1)],
 [(0, 0), (1, 0)],
 [(0, 1)],
 [(0, 1), (0, 2)],
 [(0, 1), (1, 1)],
 [(0, 2)],
 [(0, 2), (1, 2)],
 [(1, 0)],
 [(1, 0), (1, 1)],
 [(1, 1)],
 [(1, 1), (1, 2)],
 [(1, 2)]
```

neighbor_edges()  
Return an iterator over the pairs of neighbor coordinates inside of the polyomino.

Two points \( P \) and \( Q \) in the polyomino are neighbor if \( P - Q \) has one coordinate equal to +1 or −1 and zero everywhere else.

EXAMPLES:

```python
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0),(0,0,1)])
```

```python
sage: [sorted(edge) for edge in p.neighbor_edges()]
```

```python
[[[0, 0, 0], (0, 0, 1)]
```

In 3d:

```python
sage: p = Polyomino([(0,0,0),(1,0,0),(1,1,0),(1,1,1),(1,2,0)], color='deeppink')
```

```python
sage: L = sorted(sorted(edge) for edge in p.neighbor_edges())
```

```python
sage: for a in L: a
```

```python
[(0, 0, 0), (1, 0, 0)]
[(1, 0, 0), (1, 1, 0)]
[(1, 1, 0), (1, 1, 1)]
[(1, 1, 0), (1, 2, 0)]
```

In 2d:

```python
sage: p = Polyomino([(0,0),(1,0),(1,1),(1,2)])
```

```python
sage: L = sorted(sorted(edge) for edge in p.neighbor_edges())
```

```python
sage: for a in L: a
```

```python
[(0, 0), (1, 0)]
[(1, 0), (1, 1)]
[(1, 1), (1, 2)]
```

self_surrounding(radius, remove_incomplete_copies=True, ncpus=None)

Return a list of isometric copies of self surrounding it with an annulus of given radius.

INPUT:
• self - a polyomino of dimension 2
• radius - integer
• remove_incomplete_copies – bool (default: True), whether to keep only complete copies of self in the output

• ncpus – integer (default: None), maximal number of subprocesses to use at the same time. If None, it detects the number of effective CPUs in the system using sage.parallel.ncpus.ncpus(). If ncpus=1, the first solution is searched serially.

OUTPUT:
list of polyominoes

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino/nsage: H = Polyomino([(-1, 1), (-1, 4), (-1, 7), (0, 0), (0, 1), (0, 2),
......: (0, 3), (0, 4), (0, 5), (0, 6), (0, 7), (0, 8), (1, 1), (1, 2),
......: (1, 3), (1, 4), (1, 5), (1, 6), (1, 7), (1, 8), (2, 0), (2, 2),
......: (2, 3), (2, 5), (2, 6), (2, 8)])
sage: solution = H.self_surrounding(8)
sage: G = sum([p.show2d() for p in solution], Graphics())
sage: solution = H.self_surrounding(8, remove_incomplete_copies=False)
sage: G = sum([p.show2d() for p in solution], Graphics())
```

\texttt{show2d(size=0.7, color='black', thickness=1)}
Return a 2d Graphic object representing the polyomino.

INPUT:
• self - a polyomino of dimension 2
• size - number (optional, default: 0.7), the size of each square.
• color - color (optional, default: 'black'), color of the boundary line.
• thickness - number (optional, default: 1), how thick the boundary line is.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0),(1,0),(1,1),(1,2)], color='deppink')
sage: p.show2d() # long time (0.5s)
```

\texttt{show3d(size=1)}
Return a 3d Graphic object representing the polyomino.

INPUT:
• self - a polyomino of dimension 3
• size - number (optional, default: 1), the size of each \texttt{1 \times 1 \times 1} cube. This does a homothety with respect to the center of the polyomino.

EXAMPLES:
Combinatorics, Release 9.7

```python
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
sage: p.show3d()  # long time (2s)
Graphics3d Object
```

**sorted_list()**

Return the color of the polyomino.

**EXAMPLES:**

```python
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
sage: p.sorted_list()
[(0, 0, 0), (0, 1, 0), (1, 1, 0), (1, 1, 1)]
```

**translated_copies(box)**

Return an iterator over the translated images of `self` inside a polyomino.

**INPUT:**

- box – Polyomino or tuple of integers (size of a box)

**OUTPUT:**

iterator of 3d polyominoes

**EXAMPLES:**

```python
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0),(1,0,0),(1,1,0),(1,1,1),(1,2,0)], color='deeppink')
sage: for t in p.translated_copies(box=(5,8,2)): t
Polyomino: [(0, 0, 0), (1, 0, 0), (1, 1, 0), (1, 1, 1), (1, 2, 0)], Color: → deeppink
Polyomino: [(0, 1, 0), (1, 1, 0), (1, 2, 0), (1, 2, 1), (1, 3, 0)], Color: → deeppink
Polyomino: [(0, 2, 0), (1, 2, 0), (1, 3, 0), (1, 3, 1), (1, 4, 0)], Color: → deeppink
Polyomino: [(0, 3, 0), (1, 3, 0), (1, 4, 0), (1, 4, 1), (1, 5, 0)], Color: → deeppink
Polyomino: [(0, 4, 0), (1, 4, 0), (1, 5, 0), (1, 5, 1), (1, 6, 0)], Color: → deeppink
Polyomino: [(0, 5, 0), (1, 5, 0), (1, 6, 0), (1, 6, 1), (1, 7, 0)], Color: → deeppink
Polyomino: [(1, 0, 0), (2, 0, 0), (2, 1, 0), (2, 1, 1), (2, 2, 0)], Color: → deeppink
Polyomino: [(1, 1, 0), (2, 1, 0), (2, 2, 0), (2, 2, 1), (2, 3, 0)], Color: → deeppink
Polyomino: [(1, 2, 0), (2, 2, 0), (2, 3, 0), (2, 3, 1), (2, 4, 0)], Color: → deeppink
Polyomino: [(1, 3, 0), (2, 3, 0), (2, 4, 0), (2, 4, 1), (2, 5, 0)], Color: → deeppink
Polyomino: [(1, 4, 0), (2, 4, 0), (2, 5, 0), (2, 5, 1), (2, 6, 0)], Color: → deeppink
Polyomino: [(1, 5, 0), (2, 5, 0), (2, 6, 0), (2, 6, 1), (2, 7, 0)], Color: → deeppink
Polyomino: [(2, 0, 0), (3, 0, 0), (3, 1, 0), (3, 1, 1), (3, 2, 0)], Color: → deeppink
```

(continues on next page)
This method is independent of the translation of the polyomino:

\[
\text{sage: } q = \text{Polyomino}([\{(0,0,0), (1,0,0)\}])
\]

\[
\text{sage: } \text{list}(q.\text{translated_copies}((2,2,1)))
\]

[F] Polyomino: [(0, 0, 0), (1, 0, 0)], Color: gray

\[
\text{sage: } q = \text{Polyomino}([\{(34,7,-9), (35,7,-9)\}])
\]

\[
\text{sage: } \text{list}(q.\text{translated_copies}((2,2,1)))
\]

[F] Polyomino: [(0, 0, 0), (1, 0, 0)], Color: gray

Inside smaller boxes:

\[
\text{sage: } \text{list}(p.\text{translated_copies}\text{.(box=(2,2,3))})
\]

[ ]

\[
\text{sage: } \text{list}(p.\text{translated_copies}\text{.(box=(2,3,2))})
\]

[F] Polyomino: [(0, 0, 0), (1, 0, 0), (1, 1, 0), (1, 1, 1), (1, 2, 0)], Color: deeppink

\[
\text{sage: } \text{list}(p.\text{translated_copies}\text{.(box=(3,2,2))})
\]

[ ]

\[
\text{sage: } \text{list}(p.\text{translated_copies}\text{.(box=(1,1,1))})
\]

[ ]

Using a Polyomino as input:

\[
\text{sage: } b = \text{Polyomino}([\{(0,0), (0,1), (0,2), (1,0), (1,1), (1,2)\}])
\]

\[
\text{sage: } p = \text{Polyomino}([\{(0,0)\}])
\]

\[
\text{sage: } \text{list}(p.\text{translated_copies}(b))
\]

[F] Polyomino: [(0, 0)], Color: gray

(F) Polyomino: [(0, 1)], Color: gray
Polyomino: [(0, 2)], Color: gray,
Polyomino: [(1, 0)], Color: gray,
Polyomino: [(1, 1)], Color: gray,
Polyomino: [(1, 2)], Color: gray

sage: p = Polyomino(((0, 0), (1, 0), (0, 1)))
sage: b = Polyomino(((0, 0), (1, 0), (2, 0), (0, 1), (1, 1), (0, 2)))
sage: list(p.translated_copies(b))

translated_copies_intersection(box)

Return the set of non empty intersections of translated images of self with a polyomino.

INPUT:

• box – Polyomino or tuple of integers (size of a box)

OUTPUT:

set of 3d polyominoes

EXAMPLES:

sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino(((0, 0), (1, 0)), color='deppink')
sage: sorted(sorted(a.frozenset()) for a in p.translated_copies_intersection(box=(2, 3)))

[(0, 0), (0, 0), (1, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2)]

Using a Polyomino as input:

sage: b = Polyomino(((0, 0), (0, 2), (1, 0), (2, 0)))
sage: p = Polyomino(((0, 0), (1, 0)))
sage: sorted(sorted(a.frozenset()) for a in p.translated_copies_intersection(b))

[[0, 0], [0, 0], [0, 1], [0, 2], [1, 0], [2, 0], [2, 0], [2, 0]]

class sage.combinat.tiling.TilingSolver(pieces, box, rotation=True, reflection=False, reusable=False, outside=False)

Tiling solver

Solve the problem of tiling a polyomino with a certain number of polyominoes.

INPUT:

• pieces – iterable of Polyominoes
• box – Polyomino or tuple of integers (size of a box)
• rotation – bool (optional, default: True), whether to allow rotations
• reflection – bool (optional, default: False), whether to allow reflections
• reusable – bool (optional, default: False), whether to allow the pieces to be reused
• outside – bool (optional, default: False), whether to allow pieces to partially go outside of the box (all non-empty intersection of the pieces with the box are considered)

Examples:

By default, rotations are allowed and reflections are not allowed:

```sage
from sage.combinat.tiling import TilingSolver, Polyomino
p = Polyomino([(0,0,0)])
q = Polyomino([(0,0,0), (0,0,1)])
r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
T = TilingSolver([p,q,r], box=(1,1,6))
T
```
Tiling solver of 3 pieces into a box of size 6
Rotation allowed: True
Reflection allowed: False
Reusing pieces allowed: False

Solutions are given by an iterator:

```sage
it = T.solve()
for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2)], Color: gray
Polyomino: [(0, 0, 3), (0, 0, 4), (0, 0, 5)], Color: gray
```

Another solution:

```sage
for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2), (0, 0, 3)], Color: gray
Polyomino: [(0, 0, 4), (0, 0, 5)], Color: gray
```

Tiling of a polyomino by polyominos:

```sage
b = Polyomino([(0,0), (1,0), (1,1), (2,1), (1,2), (2,2), (0,3), (1,3)])
p = Polyomino([(0,0), (1,0)])
T = TilingSolver([p], box=b, reusable=True)
T.number_of_solutions()
```

2

```
animate(partial=None, stop=None, size=0.75, axes=False)
```
Return an animation of evolving solutions.

Input:

• partial - string (optional, default: None), whether to include partial (incomplete) solutions. It can be one of the following:
  – None - include only complete solutions
  – 'common_prefix' - common prefix between two consecutive solutions
Combinatorics, Release 9.7

- 'incremental' - one piece change at a time

• stop - integer (optional, default: None), number of frames

• size - number (optional, default: 0.75), the size of each 1 \times 1 square. This does a homothety with respect to the center of each polyomino.

• axes - bool (optional, default: False), whether the x and y axes are shown.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino, TilingSolver
t sage: y = Polyomino([[0,0,0], [1,0,0], [2,0,0], [3,0,0], [2,1,0]], color='cyan')
sage: T = TilingSolver([y], box=(5,10), reusable=True, reflection=True)
sage: a = T.animate()
sage: a  # optional -- ImageMagick  # long time
Animation with 10 frames
```

Include partial solutions (common prefix between two consecutive solutions):

```
sage: a = T.animate('common_prefix')  
sage: a  # optional -- ImageMagick  # long time
Animation with 19 frames
```

Incremental solutions (one piece removed or added at a time):

```
sage: a = T.animate('incremental')  # long time (2s)
sage: a  # optional -- ImageMagick  # long time
Animation with 123 frames
```

```
sage: a.show()  # optional -- ImageMagick  # long time
```

The show function takes arguments to specify the delay between frames (measured in hundredths of a second, default value 20) and the number of iterations (default value 0, which means to iterate forever). To iterate 4 times with half a second between each frame:

```
sage: a.show(delay=50, iterations=4)  # optional -- ImageMagick  # long time
```

Limit the number of frames:

```
sage: a = T.animate('incremental', stop=13)  # not tested
sage: a  # not tested
Animation with 13 frames
```

```
coord_to_int_dict()
```

Return a dictionary mapping coordinates to integers.

OUTPUT:

dict

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
t sage: p = Polyomino([[0,0,0]])
sage: q = Polyomino([[0,0,0], (0,0,1)])
sage: r = Polyomino([[0,0,0], (0,0,1), (0,0,2)])
```

(continues on next page)
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: A = T.coord_to_int_dict()
sage: sorted(A.items())
[((0, 0, 0), 3), ((0, 0, 1), 4), ((0, 0, 2), 5), ((0, 0, 3), 6), ((0, 0, 4), 7),
  ((0, 0, 5), 8)]

Reusable pieces:

sage: p = Polyomino([(0,0), (0,1)])
sage: q = Polyomino([(0,0), (0,1), (1,0), (1,1)])
sage: T = TilingSolver([p,q], box=[3,2], reusable=True)
sage: B = T.coord_to_int_dict()
sage: sorted(B.items())
[((0, 0), 0), ((0, 1), 1), ((1, 0), 2), ((1, 1), 3), ((2, 0), 4), ((2, 1), 5)]

dlx_solver()  
Return the sage DLX solver of that tiling problem.

OUTPUT:
DLX Solver

EXAMPLES:

sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0), (0,1)])
sage: q = Polyomino([(0,0), (0,1), (1,0), (1,1)])
sage: r = Polyomino([(0,0), (0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: B = T.dlx_solver()
Dancing links solver for 9 columns and 15 rows

int_to_coord_dict()  
Return a dictionary mapping integers to coordinates.

EXAMPLES:

sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0), (0,1)])
sage: q = Polyomino([(0,0), (0,1), (1,0), (1,1)])
sage: r = Polyomino([(0,0), (0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: B = T.int_to_coord_dict()
sage: sorted(B.items())
[((3, (0, 0, 0)), (4, (0, 0, 1)), (5, (0, 0, 2)), (6, (0, 0, 3)), (7, (0, 0, 4)),
  (8, (0, 0, 5)))]

Reusable pieces:

sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: p = Polyomino([(0,0), (0,1)])
sage: q = Polyomino([(0,0), (0,1), (1,0), (1,1)])
sage: T = TilingSolver([p,q], box=[3,2], reusable=True)
sage: B = T.int_to_coord_dict()

```python
sage: sorted(B.items())
[(0, (0, 0)), (1, (0, 1)), (2, (1, 0)), (3, (1, 1)), (4, (2, 0)), (5, (2, 1))]
```

**is_suitable()**

Return whether the volume of the box is equal to sum of the volume of the polyominoes and the number of rows sent to the DLX solver is larger than zero.

If these conditions are not verified, then the problem is not suitable in the sense that there are no solution.

**EXAMPLES:**

```python
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T.is_suitable()
True
sage: T = TilingSolver([p,q,r], box=(1,1,7))
sage: T.is_suitable()
False
```

**nrows_per_piece()**

Return the number of rows necessary by each piece.

**OUTPUT:**

list

**EXAMPLES:**

```python
sage: from sage.games.quantumino import QuantuminoSolver
c sage: q = QuantuminoSolver(0)
sage: T = q.tiling_solver()
sage: T.nrows_per_piece()  # long time (10s)
[360, 360, 360, 360, 360, 180, 180, 672, 672, 360, 360, 180, 180, 360, 360, 180]
```

**number_of_solutions()**

Return the number of distinct solutions.

**OUTPUT:**

integer

**EXAMPLES:**

```python
sage: from sage.combinat.tiling import TilingSolver, Polyomino
c sage: p = Polyomino([(0,0)])
sage: q = Polyomino([(0,0), (0,1)])
sage: r = Polyomino([(0,0), (0,1), (0,2)])
sage: T = TilingSolver([p,q,r], box=(1,6))
sage: T.number_of_solutions()
6
```

```python
sage: T = TilingSolver([p,q,r], box=(1,7))
sage: T.number_of_solutions()
0
```
pieces()  
Return the list of pieces.

OUTPUT:
list of 3d polyominoes

EXAMPLES:

```sage
from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([[(0,0,0)]])
sage: q = Polyomino([[(0,0,0), (0,0,1)]])
sage: r = Polyomino([[(0,0,0), (0,0,1), (0,0,2)]])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: for p in T._pieces: p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 0), (0, 0, 1)], Color: gray
Polyomino: [(0, 0, 0), (0, 0, 1), (0, 0, 2)], Color: gray
```

row_to_polyomino(row_number)  
Return a polyomino associated to a row.

INPUT:
- row_number – integer, the i-th row

OUTPUT:
polyomino

EXAMPLES:

```sage
from sage.combinat.tiling import TilingSolver, Polyomino
sage: a = Polyomino([(0,0,0), (0,0,1), (1,0,0)], color='blue')
sage: b = Polyomino([(0,0,0), (1,0,0), (0,1,0)], color='red')
sage: T = TilingSolver([a,b], box=(2,1,3))
sage: len(T.rows())
16

sage: T.row_to_polyomino(7)
Polyomino: [(0, 0, 2), (1, 0, 1), (1, 0, 2)], Color: blue

sage: T.row_toPolyomino(13)
Polyomino: [(0, 0, 1), (1, 0, 1), (1, 0, 2)], Color: red
```

rows()  
Creation of the rows

EXAMPLES:

```sage
from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([[(0,0,0)]])
sage: q = Polyomino([[(0,0,0), (0,0,1)]])
sage: r = Polyomino([[(0,0,0), (0,0,1), (0,0,2)]])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: rows = T.rows()
sage: for row in rows: row
[0, 3]
```

(continues on next page)
rows_for_piece(i, mod_box_isometries=False)
Return the rows for the i-th piece.

INPUT:
• i – integer, the i-th piece
• mod_box_isometries – bool (default: False), whether to consider only rows for positions up to the action of the quotient the group of isometries of the $n$-cube by the subgroup of isometries of the

$$a_1 \times a_2 \cdots \times a_n$$

rectangular box where are the $a_i$ are assumed to be distinct.

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T.rows_for_piece(0)
[[0, 3], [0, 4], [0, 5], [0, 6], [0, 7], [0, 8]]
sage: T.rows_for_piece(1)
[[1, 3, 4], [1, 4, 5], [1, 5, 6], [1, 6, 7], [1, 7, 8]]
sage: T.rows_for_piece(2)
[[2, 3, 4, 5], [2, 4, 5, 6], [2, 5, 6, 7], [2, 6, 7, 8]]
```

Less rows when using mod_box_isometries=True:

```
sage: a = Polyomino([(0,0,0), (0,0,1), (1,0,0)])
sage: b = Polyomino([(0,0,0), (1,0,0), (0,1,0)])
sage: T = TilingSolver([a,b], box=(2,1,3))
sage: T.rows_for_piece(0)
[[0, 2, 3, 5],
 [0, 3, 4, 6],
 [0, 2, 3, 6],
 [0, 3, 4, 7],
 [0, 2, 5, 6],
 [0, 3, 6, 7],
 [0, 3, 5, 6],
 [0, 4, 6, 7]]
```
solve

Return an iterator of list of polyominoes that are an exact cover of the box.

INPUT:

- **partial** - string (optional, default: `None`), whether to include partial (incomplete) solutions. It can be one of the following:
  - `None` - include only complete solution
  - `'common_prefix'` - common prefix between two consecutive solutions
  - `'incremental'` - one piece change at a time

OUTPUT:

iterator of list of polyominoes

EXAMPLES:

```python
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0)])
sage: q = Polyomino([(0,0), (0,1)])
sage: r = Polyomino([(0,0), (0,1), (0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: it = T.solve()
sage: for p in next(it): p
Polyomino: [(0, 0)], Color: gray
Polyomino: [(0, 1), (0, 2)], Color: gray
Polyomino: [(0, 3), (0, 4), (0, 5)], Color: gray
sage: for p in next(it): p
Polyomino: [(0, 0)], Color: gray
Polyomino: [(0, 1), (0, 2), (0, 3)], Color: gray
Polyomino: [(0, 4), (0, 5)], Color: gray
```

Including the partial solutions:

```python
sage: it = T.solve(partial='common_prefix')
sage: for p in next(it): p
Polyomino: [(0, 0)], Color: gray
Polyomino: [(0, 1), (0, 2)], Color: gray
Polyomino: [(0, 3), (0, 4), (0, 5)], Color: gray
```

(continues on next page)
Polyomino: [(0, 0, 4), (0, 0, 5)], Color: gray
sage: for p in next(it): p
Polyomino: [(0, 0, 0), (0, 0, 1)], Color: gray
Polyomino: [(0, 0, 2), (0, 0, 3), (0, 0, 4)], Color: gray
Polyomino: [(0, 0, 5)], Color: gray

Colors are preserved when the polyomino can be reused:

sage: p = Polyomino([(0,0,0)], color='yellow')
sage: q = Polyomino([(0,0,0), (0,0,1)], color='yellow')
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)], color='yellow')
sage: T = TilingSolver([p,q,r], box=(1,1,6), reusable=True)
sage: it = T.solve()
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: yellow
Polyomino: [(0, 0, 1)], Color: yellow
Polyomino: [(0, 0, 2)], Color: yellow
Polyomino: [(0, 0, 3)], Color: yellow
Polyomino: [(0, 0, 4)], Color: yellow
Polyomino: [(0, 0, 5)], Color: yellow

space()
Return an iterator over all the non negative integer coordinates contained in the space to tile.

EXAMPLES:

sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: list(T.space())
[(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 0, 3), (0, 0, 4), (0, 0, 5)]

starting_rows()
Return the starting rows for each piece.

EXAMPLES:

sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T.starting_rows()
[0, 6, 11, 15]

sage.combinat.tiling.ncube_isometry_group(n, orientation_preserving=True)
Return the isometry group of the $n$-cube as a list of matrices.

INPUT:

- n – positive integer, dimension of the space
- orientation_preserving – bool (optional, default: True), whether the orientation is preserved
OUTPUT:
list of matrices

EXAMPLES:

```python
sage: from sage.combinat.tiling import ncube_isometry_group
sage: ncube_isometry_group(2)
[
[1 0] [0 1] [-1 0] [0 -1]
[0 1], [-1 0], [0 -1], [1 0]
]
sage: ncube_isometry_group(2, orientation_preserving=False)
[
[1 0] [0 -1] [1 0] [0 1] [1 0] [0 -1] [-1 0]
[0 1], [-1 0], [0 -1], [-1 0], [1 0], [0 -1], [0 1]
]
```

There are 24 orientation preserving isometries of the 3-cube:

```python
sage: ncube_isometry_group(3)
[
[1 0 0] [1 0 0] [1 0 0] [0 1 0] [0 1 0] [0 0 1]
[0 1 0] [0 0 1] [0 0 1] [-1 0 0] [0 0 1] [0 -1 0]
[0 0 1], [0 -1 0], [0 1 0], [0 0 1], [1 0 0], [1 0 0],

[-1 0 0] [0 -1 0] [-1 0 0] [-1 0 0] [0 -1 0] [0 0 -1]
[0 -1 0] [0 0 -1] [0 0 -1] [0 1 0] [0 0 -1] [1 0 0]
[0 0 -1], [1 0 0], [0 -1 0], [0 0 -1], [-1 0 0], [0 -1 0],

[0 1 0] [0 0 1] [0 0 1] [0 -1 0] [0 0 -1] [-1 0 0]
[1 0 0] [0 1 0] [1 0 0] [1 0 0] [0 1 0] [0 0 1]
[0 0 -1], [-1 0 0], [0 1 0], [0 0 1], [1 0 0], [0 1 0],

[0 -1 0] [0 0 -1] [0 0 -1] [1 0 0] [0 0 -1] [0 1 0]
[-1 0 0] [-1 0 0] [-1 0 0] [0 -1 0] [0 -1 0] [0 0 -1]
[0 0 -1], [0 1 0], [0 -1 0], [0 0 -1], [-1 0 0], [-1 0 0]
]
```

sage.combinat.tiling.ncube_isometry_group_cosets(n, orientation_preserving=True)

Return the quotient of the isometry group of the $n$-cube by the the isometry group of the rectangular parallelepiped.

INPUT:

- $n$ – positive integer, dimension of the space
- `orientation_preserving` – bool (optional, default: True), whether the orientation is preserved

OUTPUT:
list of cosets, each coset being a sorted list of matrices

EXAMPLES:

```python
sage: from sage.combinat.tiling import ncube_isometry_group_cosets
sage: sorted(ncube_isometry_group_cosets(2))
```

5.1.347 Transitive ideal closure tool

```
sage.combinat.tools.transitive_ideal(f, x)
```

Return a list of all elements reachable from \( x \) in the abstract reduction system whose reduction relation is given by the function \( f \).

In more elementary terms:

If \( S \) is a set, and \( f \) is a function sending every element of \( S \) to a list of elements of \( S \), then we can define a digraph on the vertex set \( S \) by drawing an edge from \( s \) to \( t \) for every \( s \in S \) and every \( t \in f(s) \).

If \( x \in S \), then an element \( y \in S \) is said to be reachable from \( x \) if there is a path \( x \to y \) in this graph.

Given \( f \) and \( x \), this method computes the list of all elements of \( S \) reachable from \( x \).

Note that if there are infinitely many such elements, then this method will never halt.

For more powerful versions, see `sage.combinat.backtrack`

**EXAMPLES:**

```
sage: f = lambda x: [x-1] if x > 0 else []
sage: sage.combinat.tools.transitive_ideal(f, 10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

5.1.348 Tuples

```
class sage.combinat.tuple.Tuples(S, k)
```

Bases: `sage.structure.parent.Parent`, `sage.structure.unique_representation.UniqueRepresentation`

Return the enumerated set of ordered tuples of \( S \) of length \( k \).

An ordered tuple of length \( k \) of set is an ordered selection with repetition and is represented by a list of length \( k \) containing elements of set.

**EXAMPLES:**

```
sage: S = [1,2]
sage: Tuples(S,3).list()
[[1, 1, 1], [2, 1, 1], [1, 2, 1], [2, 2, 1], [1, 1, 2], [2, 1, 2], [1, 2, 2], [2, 2, 2]]
sage: mset = ['s','t','e','i','n']
sage: Tuples(mset,2).list()
[['s', 's'], ['t', 's'], ['e', 's'], ['i', 's'], ['n', 's'], ['s', 't'], ['t', 't'], ['e', 't'], ['i', 't'], ['n', 't'], ['s', 'e'], ['t', 'e'], ['e', 'e'], ['i', 'e'], ['n', 'e'], ['s', 'i'], ['t', 'i'], ['e', 'i'], ['i', 'i'], ['n', 'i'], ['s', 'n'], ['t', 'n'], ['e', 'n'], ['i', 'n'], ['n', 'n']]
```

```
sage: K.<a> = GF(4, 'a')
sage: mset = [x for x in K if x != 0]
sage: Tuples(mset,2).list()
[[a, a], [a + 1, a], [1, a], [a, a + 1], [a + 1, a + 1], [1, a + 1], [a, 1], [a + 1, 1], [1, 1]]
```
cardinality()

EXAMPLES:

```
sage: S = [1,2,3,4,5]
sage: Tuples(S,2).cardinality()
25
sage: S = [1,1,2,3,4,5]
sage: Tuples(S,2).cardinality()
25
```

```
sage.combinat.tuple.Tuples_sk
alias of sage.combinat.tuple.Tuples
class sage.combinat.tuple.UnorderedTuples(S, k)
  Bases:          sage.structure.parent.Parent, sage.structure.unique_representation.UniqueRepresentation
  Return the enumerated set of unordered tuples of S of length k.
  An unordered tuple of length k of set is a unordered selection with repetitions of set and is represented by a sorted list of length k containing elements from set.
  EXAMPLES:

```
sage: S = [1,2]
sage: UnorderedTuples(S,3).list()
[[1, 1, 1], [1, 1, 2], [1, 2, 2], [2, 2, 2]]
sage: UnorderedTuples(["a","b","c"],2).list()
[['a', 'a'], ['a', 'b'], ['a', 'c'], ['b', 'b'], ['b', 'c'], ['c', 'c']]
```

cardinality()

EXAMPLES:

```
sage: S = [1,2,3,4,5]
sage: UnorderedTuples(S,2).cardinality()
15
```

list()

EXAMPLES:

```
sage: S = [1,2]
sage: UnorderedTuples(S,3).list()
[[1, 1, 1], [1, 1, 2], [1, 2, 2], [2, 2, 2]]
sage: UnorderedTuples(["a","b","c"],2).list()
[['a', 'a'], ['a', 'b'], ['a', 'c'], ['b', 'b'], ['b', 'c'], ['c', 'c']]
```

alias of sage.combinat.tuple.UnorderedTuples
5.1.349 Introduction to combinatorics in Sage

This thematic tutorial is a translation by Hugh Thomas of the combinatorics chapter written by Nicolas M. Thiéry in the book “Calcul Mathématique avec Sage” [CMS2012]. It covers mainly the treatment in Sage of the following combinatorial problems: enumeration (how many elements are there in a set S?), listing (generate all the elements of S, or iterate through them), and random selection (choosing an element at random from a set S according to a given distribution, for example the uniform distribution). These questions arise naturally in the calculation of probabilities (what is the probability in poker of obtaining a straight or a four-of-a-kind of aces?), in statistical physics, and also in computer algebra (the number of elements in a finite field), or in the analysis of algorithms. Combinatorics covers a much wider domain (partial orders, representation theory, ...) for which we only give a few pointers towards the possibilities offered by Sage.

**Todo:** Add link to some thematic tutorial on graphs

A characteristic of computational combinatorics is the profusion of types of objects and sets that one wants to manipulate. It would be impossible to describe them all or, a fortiori, to implement them all. After some Initial examples, this chapter illustrates the underlying method: supplying the basic building blocks to describe common combinatorial sets Common enumerated sets, tools for combining them to construct new examples Constructions, and generic algorithms for solving uniformly a large class of problems Generic algorithms.

This is a domain in which Sage has much more extensive capabilities than most computer algebra systems, and it is rapidly expanding; at the same time, it is still quite new, and has many unnecessary limitations and incoherences.

**Initial examples**

**Poker and probability**

We begin by solving a classic problem: enumerating certain combinations of cards in the game of poker, in order to deduce their probability.

A card in a poker deck is characterized by a suit (hearts, diamonds, spades, or clubs) and a value (2, 3, ..., 10, jack, queen, king, ace). The game is played with a full deck, which consists of the Cartesian product of the set of suits and the set of values:

\[
\text{Cards} = \text{Suits} \times \text{Values} = \{(s, v) \mid s \in \text{Suits} \text{ et } v \in \text{Values}\}.
\]

We construct these examples in Sage:

```
sage: Suits = Set(["Hearts", "Diamonds", "Spades", "Clubs"])
sage: Values = Set([2, 3, 4, 5, 6, 7, 8, 9, 10,
.....: "Jack", "Queen", "King", "Ace"])
sage: Cards = cartesian_product([Values, Suits])
```

There are 4 suits and 13 possible values, and therefore \(4 \times 13 = 52\) cards in the poker deck:

```
sage: Suits.cardinality()
4
sage: Values.cardinality()
13
sage: Cards.cardinality()
52
```

Draw a card at random:
Combinatorics, Release 9.7

```
sage: Cards.random_element() # random
(6, 'Clubs')
```

Now we can define a set of cards:

```
sage: Set([Cards.random_element(), Cards.random_element()]) # random
{(2, 'Hearts'), (4, 'Spades')}
```

This problem should eventually disappear: it is planned to change the implementation of Cartesian products so that their elements are immutable by default.

Returning to our main topic, we will be considering a simplified version of poker, in which each player directly draws five cards, which form his hand. The cards are all distinct and the order in which they are drawn is irrelevant; a hand is therefore a subset of size 5 of the set of cards. To draw a hand at random, we first construct the set of all possible hands, and then we ask for a randomly chosen element:

```
sage: Hands = Subsets(Cards, 5)
sage: Hands.random_element() # random
{(4, 'Hearts', 4), (9, 'Diamonds'), (8, 'Spades'), (9, 'Clubs'), (7, 'Hearts')}
```

The total number of hands is given by the number of subsets of size 5 of a set of size 52, which is given by the binomial coefficient $\binom{52}{5}$:

```
sage: binomial(52,5)
2598960
```

One can also ignore the method of calculation, and simply ask for the size of the set of hands:

```
sage: Hands.cardinality()
2598960
```

The strength of a poker hand depends on the particular combination of cards present. One such combination is the flush; this is a hand all of whose cards have the same suit. (In principle, straight flushes should be excluded; this will be the goal of an exercise given below.) Such a hand is therefore characterized by the choice of five values from among the thirteen possibilities, and the choice of one of four suits. We will construct the set of all flushes, so as to determine how many there are:

```
sage: Flushes = cartesian_product([Subsets(Values, 5), Suits])
sage: Flushes.cardinality()
5148
```

The probability of obtaining a flush when drawing a hand at random is therefore:

```
sage: Flushes.cardinality() / Hands.cardinality()
33/16660
```

or about two in a thousand:

```
sage: 1000.0 * Flushes.cardinality() / Hands.cardinality()
1.98079231692677
```

We will now attempt a little numerical simulation. The following function tests whether a given hand is a flush or not:
```python
sage: def is_flush(hand):
    ....:     return len(set(suit for (val, suit) in hand)) == 1
```

We now draw 10000 hands at random, and count the number of flushes obtained (this takes about 10 seconds):

```python
sage: n = 10000
sage: nflush = 0
sage: for i in range(n):  # long time
    ....:     hand = Hands.random_element()
    ....:     if is_flush(hand):
    ....:         nflush += 1
sage: n, nflush
# random (10000, 18)
```

**Exercises**

A hand containing four cards of the same value is called a *four of a kind*. Construct the set of four of a kind hands (Hint: use *Arrangements* to choose a pair of distinct values at random, then choose a suit for the first value). Calculate the number of four of a kind hand, list them, and then determine the probability of obtaining a four of a kind when drawing a hand at random.

A hand all of whose cards have the same suit, and whose values are consecutive, is called a *straight flush* rather than a *flush*. Count the number of straight flushes, and then deduce the correct probability of obtaining a flush when drawing a hand at random.

Calculate the probability of each of the poker hands (see Wikipedia article *Poker hands*), and compare them with the results of simulations.

**Enumeration of trees using generating functions**

In this section, we discuss the example of complete binary trees, and illustrate in this context many techniques of enumeration in which formal power series play a natural role. These techniques are quite general, and can be applied whenever the combinatorial objects in question admit a recursive definition (grammar) (see *Species, decomposable combinatorial classes* for an automated treatment). The goal is not a formal presentation of these methods; the calculations are rigorous, but most of the justifications will be skipped.

A *complete binary tree* is either a leaf $L$, or a node to which two complete binary trees are attached (see Figure: The five complete binary trees with four leaves).

![Fig. 1: Figure: The five complete binary trees with four leaves](image)

**Exercise: enumeration of binary trees**

Find by hand all the complete binary trees with $n = 1, 2, 3, 4, 5$ leaves (see *Exercise: complete binary tree iterator* to find them using Sage).
Our goal is to determine the number $c_n$ of complete binary trees with $n$ leaves (in this section, except when explicitly stated otherwise, “trees” always means complete binary trees). This is a typical situation in which one is not only interested in a single set, but in a family of sets, typically parameterized by $n \in \mathbb{N}$.

According to the solution of Exercise: enumeration of binary trees, the first terms are given by $c_1, \ldots, c_5 = 1, 1, 2, 5, 14$. The simple fact of knowing these few numbers is already very valuable. In fact, this permits research in a gold mine of information: the Online Encyclopedia of Integer Sequences, commonly called “Sloane”, the name of its principal author, which contains more than 190000 sequences of integers:

```
sage: oeis([1,1,2,5,14])
# optional -- internet
0: A000108: Catalan numbers: ...
1: ...
2: ...
```

The result suggests that the trees are counted by one of the most famous sequences, the Catalan numbers. Looking through the references supplied by the Encyclopedia, we see that this is really the case: the few numbers above form a digital fingerprint of our objects, which enable us to find, in a few seconds, a precise result from within an abundant literature.

Our next goal is to recover this result using Sage. Let $C_n$ be the set of trees with $n$ leaves, so that $c_n = |C_n|$; by convention, we will define $C_0 = \emptyset$ and $c_0 = 0$. The set of all trees is then the disjoint union of the sets $C_n$:

$$C = \bigsqcup_{n \in \mathbb{N}} C_n.$$

Having named the set $C$ of all trees, we can translate the recursive definition of trees into a set-theoretic equation:

$$C \approx \{L\} \uplus C \times C.$$

In words: a tree $t$ (which is by definition in $C$) is either a leaf (so in $\{L\}$) or a node to which two trees $t_1$ and $t_2$ have been attached, and which we can therefore identify with the pair $(t_1, t_2)$ (in the Cartesian product $C \times C$).

The founding idea of algebraic combinatorics, introduced by Euler in a letter to Goldbach of 1751 to treat a similar problem, is to manipulate all the numbers $c_n$ simultaneously, by encoding them as coefficients in a formal power series, called the generating function of the $c_n$’s:

$$C(z) = \sum_{n \in \mathbb{N}} c_n z^n,$$

where $z$ is a formal variable (which means that we do not have to worry about questions of convergence). The beauty of this idea is that set-theoretic operations ($A \uplus B, A \times B$) translate naturally into algebraic operations on the corresponding series ($A(z) + B(z), A(z) \cdot B(z)$), in such a way that the set-theoretic equation satisfied by $C$ can be translated directly into an algebraic equation satisfied by $C(z)$:

$$C(z) = z + C(z) \cdot C(z).$$

Now we can solve this equation with Sage. In order to do so, we introduce two variables, $C$ and $z$, and we define the equation:

```
sage: C, z = var('C, z')
sage: sys = [ C == z + C*C ]
```

There are two solutions, which happen to have closed forms:

```
sage: sol = solve(sys, C, solution_dict=True); sol
[{C: -1/2*sqrt(-4*z + 1) + 1/2}, {C: 1/2*sqrt(-4*z + 1) + 1/2}]
sage: s0 = sol[0][C]; s1 = sol[1][C]
```

3418 Chapter 5. Comprehensive Module List
and whose Taylor series begin as follows:

```
sage: s0.series(z, 6)
1*z + 1*z^2 + 2*z^3 + 5*z^4 + 14*z^5 + Order(z^6)
sage: s1.series(z, 6)
1 + (-1)*z + (-1)*z^2 + (-2)*z^3 + (-5)*z^4 + (-14)*z^5 + Order(z^6)
```

The second solution is clearly aberrant, while the first one gives the expected coefficients. Therefore, we set:

```
sage: C = s0
```

We can now calculate the next terms:

```
sage: C.series(z, 11)
1*z + 1*z^2 + 2*z^3 + 5*z^4 + 14*z^5 + 42*z^6 + 132*z^7 + 429*z^8 + 1430*z^9 + 4862*z^10 + Order(z^11)
```

or calculate, more or less instantaneously, the 100-th coefficient:

```
sage: C.series(z, 101).coefficient(z,100)
22750883079422934966181954039568853956041682601541047340
```

It is unfortunate to have to recalculate everything if at some point we wanted the 101-st coefficient. Lazy power series (see `sage.combinat.species.series`) come into their own here, in that one can define them from a system of equations without solving it, and, in particular, without needing a closed form for the answer. We begin by defining the ring of lazy power series:

```
sage: L.<z> = LazyPowerSeriesRing(QQ)
```

Then we create a “free” power series, which we name, and which we then define by a recursive equation:

```
sage: C = L()
sage: C._name = 'C'
sage: C.define( z + C * C )
```

```
[0, 1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
```

At any point, one can ask for any coefficient without having to redefine $C$:

```
sage: C.coefficient(100)
22750883079422934966181954039568853956041682601541047340
```

```
sage: C.coefficient(200)
129013158064429114001222907669676675134349530552728882499810851598901419013348319045534580850847735528280
```

We now return to the closed form of $C(z)$:

```
sage: z = var('z')
sage: C = s0; C
-1/2*sqrt(-4*z + 1) + 1/2
```

The $n$-th coefficient in the Taylor series for $C(z)$ being given by $\frac{1}{n!}C(z)^(n)(0)$, we look at the successive derivatives $C(z)^(n)(z)$:
This suggests the existence of a simple explicit formula, which we will now seek. The following small function returns $d_n = n!c_n$:

```
sage: def d(n):
    return derivative(s0, n).subs(z=0)
```

Taking successive quotients:

```
sage: [ (d(n+1) / d(n)) for n in range(1,17) ]
[2, 6, 10, 14, 18, 22, 26, 30, 34, 38, 42, 46, 50, 54, 58, 62]
```

we observe that $d_n$ satisfies the recurrence relation $d_{n+1} = (4n - 2)d_n$, from which we deduce that $c_n$ satisfies the recurrence relation $c_{n+1} = \frac{(4n-2)}{n+1}c_n$. Simplifying, we find that $c_n$ is the $(n - 1)$-th Catalan number:

\[
c_n = \text{Catalan}(n - 1) = \frac{1}{n} \binom{2(n-1)}{n-1}.
\]

We check this:

```
sage: n = var('n')
sage: c = 1/n*binomial(2*(n-1),n-1)
sage: [c.subs(n=k) for k in range(1, 11)]
[1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
sage: [catalan_number(k-1) for k in range(1, 11)]
[1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
```

We can now calculate coefficients much further; here we calculate $c_{100000}$ which has more than 60000 digits:

```
sage: cc = c(n = 100000)
```

This takes a couple of seconds:

```
sage: %time cc = c(100000) # not tested
CPU times: user 2.34 s, sys: 0.00 s, total: 2.34 s
Wall time: 2.34 s
sage: ZZ(cc).ndigits()
60198
```

The methods which we have used generalize to all recursively defined objects: the system of set-theoretic equations can be translated into a system of equations on the generating function, which enables the recursive calculation of its coefficients. If the set-theoretic equations are simple enough (for example, if they only involve Cartesian products and disjoint unions), the equation for $C(z)$ is algebraic. This equation has, in general, no closed-form solution. However, using confinement, one can deduce a linear differential equation which $C(z)$ satisfies. This differential equation, in turn, can be translated into a recurrence relation of fixed length on its coefficients $c_n$. In this case, the series is called D-finite. After the initial calculation of this recurrence relation, the calculation of coefficients is very fast. All these steps are purely algorithmic, and it is planned to port into Sage the implementations which exist in Maple (the gfun and combstruct packages) or MuPAD-Combinat (the decomposableObjects library).
For the moment, we illustrate this general procedure in the case of complete binary trees. The generating function $C(z)$ is a solution to an algebraic equation $P(z, C(z)) = 0$, where $P = P(x, y)$ is a polynomial with coefficients in $\mathbb{Q}$. In the present case, $P = y^2 - y + x$. We formally differentiate this equation with respect to $z$:

```
sage: x, y, z = var('x, y, z')
sage: P = function('P')(x, y)
sage: C = function('C')(z)
sage: equation = P(x=z, y=C) == 0
sage: diff(equation, z)
```

or, in a more readable format,

$$\frac{dC(z)}{dz} = - \frac{\partial P}{\partial x}(z, C(z)).$$

From this we deduce:

$$\frac{dC(z)}{dz} = - \frac{\partial P}{\partial y}(z, C(z)).$$

In the case of complete binary trees, this gives:

```
sage: P = y^2 - y + x
sage: Px = diff(P, x); Py = diff(P, y)
sage: - Px / Py
```

Recall that $P(z, C(z)) = 0$. Thus, we can calculate this fraction mod $P$ and, in this way, express the derivative of $C(z)$ as a polynomial in $C(z)$ with coefficients in $\mathbb{Q}(z)$. In order to achieve this, we construct the quotient ring $R = \mathbb{Q}(x)[y]/(P)$:

```
sage: Qx = QQ['x'].fraction_field()
sage: Qxy = Qx['y']
sage: R = Qxy.quo(P); R
Univariate Quotient Polynomial Ring in ybar over Fraction Field of Univariate Polynomial Ring in x over Rational Field with modulus y^2 - y + x
```

Note: ybar is the name of the variable $y$ in the quotient ring.

**Todo:** add link to some tutorial on quotient rings

We continue the calculation of this fraction in $R$:

```
sage: fraction = - R(Px) / R(Py); fraction
```

```
(1/2/(x - 1/4))*ybar - 1/4/(x - 1/4)
```

**Note:** The following variant does not work yet:

```
sage: fraction = R(- Px / Py); fraction  # todo: not implemented
```

Traceback (most recent call last):
```
...
```

Type Error: denominator must be a unit
We lift the result to $\mathbb{Q}(x)[y]$ and then substitute $z$ and $C(z)$ to obtain an expression for $\frac{d}{dz} C(z)$:

```
sage: fraction = fraction.lift(); fraction
(1/2/(x - 1/4))*y - 1/4/(x - 1/4)
sage: fraction(x=z, y=C)
2*C(z)/(4*z - 1) - 1/(4*z - 1)
```
or, more legibly,

$$\frac{\partial C(z)}{\partial z} = \frac{1}{1-4z} - \frac{2}{1-4z} C(z).$$

In this simple case, we can directly deduce from this expression a linear differential equation with coefficients in $\mathbb{Q}[z]$:

```
sage: equadiff = diff(C,z) == fraction(x=z, y=C)
sage: equadiff
diff(C(z), z) == 2*C(z)/(4*z - 1) - 1/(4*z - 1)
sage: equadiff = equadiff.simplify_rational()
sage: equadiff = equadiff.simplify_rational()
sage: equadiff = equadiff * equadiff.rhs().denominator()
sage: equadiff = equadiff - equadiff.rhs()
sage: equadiff
(4*z - 1)*diff(C(z), z) - 2*C(z) + 1 == 0
```
or, more legibly,

$$(1 - 4z)\frac{\partial C(z)}{\partial z} + 2C(z) - 1 = 0.$$

It is trivial to verify this equation on the closed form:

```
sage: Cf = sage.symbolic.function_factory.function('C')
sage: equadiff = equadiff.substitute_function(Cf, s0.function(z))
sage: (4*z - 1)/sqrt(-4*z + 1) + sqrt(-4*z + 1) == 0
True
```

In the general case, one continues to calculate successive derivatives of $C(z)$. These derivatives are confined in the quotient ring $\mathbb{Q}(z)[C]/(P)$ which is of finite dimension $\deg P$ over $\mathbb{Q}(z)$. Therefore, one will eventually find a linear relation among the first $\deg P$ derivatives of $C(z)$. Putting it over a single denominator, we obtain a linear differential equation of degree $\leq \deg P$ with coefficients in $\mathbb{Q}[z]$. By extracting the coefficient of $z^n$ in the differential equation, we obtain the desired recurrence relation on the coefficients; in this case we recover the relation we had already found, based on the closed form:

$$c_{n+1} = \frac{4n-2}{n+1} c_n$$

After fixing the correct initial conditions, it becomes possible to calculate the coefficients of $C(z)$ recursively:

```
sage: def C(n): return 1 if n <= 1 else (4*n-6)/n * C(n-1)
sage: [ C(i) for i in range(10) ]
[1, 1, 1, 2, 5, 14, 42, 132, 429, 1430]
```

If $n$ is too large for the explicit calculation of $c_n$, a sequence asymptotically equivalent to the sequence of coefficients $c_n$ may be sought. Here again, there are generic techniques. The central tool is complex analysis, specifically, the study of the generating function around its singularities. In the present instance, the singularity is at $z_0 = 1/4$ and one would obtain $c_n \sim \frac{4^n}{n!^2 \sqrt{\pi}}$. 
Summary

We see here a general phenomenon of computer algebra: the best data structure to describe a complicated mathematical object (a real number, a sequence, a formal power series, a function, a set) is often an equation defining the object (or a system of equations, typically with some initial conditions). Attempting to find a closed-form solution to this equation is not necessarily of interest: on the one hand, such a closed form rarely exists (e.g., the problem of solving a polynomial by radicals), and on the other hand, the equation, in itself, contains all the necessary information to calculate algorithmically the properties of the object under consideration (e.g., a numerical approximation, the initial terms or elements, an asymptotic equivalent), or to calculate with the object itself (e.g., performing arithmetic on power series). Therefore, instead of solving the equation, we look for the equation describing the object which is best suited to the problem we want to solve.

As we saw in our example, confinement (for example, in a finite dimensional vector space) is a fundamental tool for studying such equations. This notion of confinement is widely applicable in elimination techniques (linear algebra, Gröbner bases, and their algebro-differential generalizations). The same tool is central in algorithms for automatic summation and automatic verification of identities (Gosper’s algorithm, Zeilberger’s algorithm, and their generalizations; see also Exercise: alternating sign matrices).

Todo: add link to some tutorial on summation

All these techniques and their many generalizations are at the heart of very active topics of research: automatic combinatorics and analytic combinatorics, with major applications in the analysis of algorithms. It is likely, and desirable, that they will be progressively implemented in Sage.

Common enumerated sets

First example: the subsets of a set

Fix a set $E$ of size $n$ and consider the subsets of $E$ of size $k$. We know that these subsets are counted by the binomial coefficients $\binom{n}{k}$. We can therefore calculate the number of subsets of size $k = 2$ of $E = \{1, 2, 3, 4\}$ with the function binomial:

```
sage: binomial(4, 2)
6
```

Alternatively, we can construct the set $\mathcal{P}_2(E)$ of all the subsets of size 2 of $E$, then ask its cardinality:

```
sage: S = Subsets([1,2,3,4], 2)
sage: S.cardinality()
6
```

Once $S$ has been constructed, we can also obtain the list of its elements:

```
sage: S.list()
[[1, 2], [1, 3], [1, 4], [2, 3], [2, 4], [3, 4]]
```

or select an element at random:

```
sage: S.random_element()  # random
{1, 4}
```

More precisely, the object $S$ models the set $\mathcal{P}_2(E)$ equipped with a fixed order (here, lexicographic order). It is therefore possible to ask for its 5-th element, keeping in mind that, as with Python lists, the first element is numbered zero:
As a shortcut, in this setting, one can also use the notation:

```sage
S[4]
{2, 4}
```

but this should be used with care because some sets have a natural indexing other than by \((0, 1, \ldots)\).

Conversely, one can calculate the position of an object in this order:

```sage
s = S([2,4]); s
{2, 4}
sage: S.rank(s)
4
```

Note that S is not the list of its elements. One can, for example, model the set \(\mathcal{P}(\mathcal{P}(\mathcal{P}(E)))\) and calculate its cardinality \(2^{2^4}\):

```sage
E = Set([1,2,3,4])
sage: S = Subsets(Subsets(Subsets(Subsets(E)))); S
Subsets of Subsets of Subsets of {1, 2, 3, 4}
sage: n = S.cardinality(); n
200329930406846464979072351560255750447825475569751419265016973...
```

which is roughly \(2 \cdot 10^{19728}\):

```sage
sage: n.ndigits()
19729
```

or ask for its 237102124-th element:

```sage
sage: S.unrank(237102123)  # random print output
{{{2, 4}, {1, 4}, {}}, {1, 3, 4}, {1, 2, 4}, {4}, {2, 3}, {1, 3}, {2}},
{{1, 3}, {2, 4}, {1, 2, 4}, {}}, {3, 4}}}
```

It would be physically impossible to construct explicitly all the elements of \(S\), as there are many more of them than there are particles in the universe (estimated at \(10^{82}\)).

Remark: it would be natural in Python to use `len(S)` to ask for the cardinality of \(S\). This is not possible because Python requires that the result of `len` be an integer of type `int`; this could cause overflows, and would not permit the return of `{Infinity}` for infinite sets:

```sage
sage: len(S)
Traceback (most recent call last):
...
OverflowError: cannot fit 'int' into an index-sized integer
```
Partitions of integers

We now consider another classic problem: given a positive integer \( n \), in how many ways can it be written in the form of a sum \( n = i_1 + i_2 + \cdots + i_\ell \), where \( i_1, \ldots, i_\ell \) are positive integers? There are two cases to distinguish:

- the order of the elements in the sum is not important, in which case we call \((i_1, \ldots, i_\ell)\) a partition of \( n \);
- the order of the elements in the sum is important, in which case we call \((i_1, \ldots, i_\ell)\) a composition of \( n \).

We will begin with the partitions of \( n = 5 \); as before, we begin by constructing the set of these partitions:

```plaintext
sage: P5 = Partitions(5); P5
Partitions of the integer 5
```

then we ask for its cardinality:

```plaintext
sage: P5.cardinality()
7
```

We look at these 7 partitions; the order being irrelevant, the entries are ordered, by convention, in decreasing order.

```plaintext
sage: P5.list()
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1],
 [1, 1, 1, 1, 1]]
```

The calculation of the number of partitions uses the Rademacher formula (Wikipedia article Partition_(number_theory)), implemented in C and highly optimized, which makes it very fast:

```plaintext
sage: Partitions(100000).cardinality()
27493510569775696512677516320986352688173429315980054758203125984302147328114964173055050741660736621590157844774296248940...
```

Partitions of integers are combinatorial objects naturally equipped with many operations. They are therefore returned as objects that are richer than simple lists:

```plaintext
sage: P7 = Partitions(7)
sage: p = P7.unrank(5); p
[4, 2, 1]
sage: type(p)
<class 'sage.combinat.partition.Partitions_n_with_category.element_class'>
```

For example, they can be represented graphically by a Ferrers diagram:

```plaintext
sage: print(p.ferrers_diagram())
****
** *
```

We leave it to the user to explore by introspection the available operations.

Note that we can also construct a partition directly by:

```plaintext
sage: Partition([4,2,1])
[4, 2, 1]
```
If one wants to restrict the possible values of the parts $i_1, \ldots, i_\ell$ of the partition as, for example, when giving change, one can use `WeightedIntegerVectors`. For example, the following calculation:

```sage
WeightedIntegerVectors(8, [2,3,5]).list()
```

shows that to make 8 dollars using 2, 3, and 5 dollar bills, one can use a 3 and a 5 dollar bill, or a 2 and two 3 dollar bills, or four 2 dollar bills.

Compositions of integers are manipulated the same way:

```sage
C5 = Compositions(5); C5
```

The number 16 above seems significant and suggests the existence of a formula. We look at the number of compositions of $n$ ranging from 0 to 9:

```sage
[ Compositions(n).cardinality() for n in range(10) ]
```

Similarly, if we consider the number of compositions of 5 by length, we find a line of Pascal’s triangle:

```sage
x = var('x')
sage: sum( x^len(c) for c in C5 )
x^5 + 4*x^4 + 6*x^3 + 4*x^2 + x
```

The above example uses a functionality which we have not seen yet: `C5` being iterable, it can be used like a list in a `for` loop or a comprehension (Set comprehension and iterators).

Prove the formulas suggested by the above examples for the number of compositions of $n$ and the number of compositions of $n$ of length $k$; investigate by introspection whether `Sage` uses these formulas for calculating cardinalities.

**Some other finite enumerated sets**

Essentially, the principle is the same for all the finite sets with which one wants to do combinatorics in `Sage`; begin by constructing an object which models this set, and then supply appropriate methods, following a uniform interface\(^1\).

We now give a few more typical examples.

Intervals of integers:

```sage
C = IntegerRange(3, 21, 2); C
```

---

\(^1\) Or at least that should be the case; there are still many corners to clean up.
Combinatorics, Release 9.7

Permutations:

sage: C = Permutations(4); C
Standard permutations of 4
sage: C.cardinality()
24
sage: C.list()
[[1, 2, 3, 4], [1, 2, 4, 3], [1, 3, 2, 4], [1, 3, 4, 2],
[1, 4, 2, 3], [1, 4, 3, 2], [2, 1, 3, 4], [2, 1, 4, 3],
[2, 3, 1, 4], [2, 3, 4, 1], [2, 4, 1, 3], [2, 4, 3, 1],
[3, 1, 2, 4], [3, 1, 4, 2], [3, 2, 1, 4], [3, 2, 4, 1],
[3, 4, 1, 2], [3, 4, 2, 1], [4, 1, 2, 3], [4, 1, 3, 2],
[4, 2, 1, 3], [4, 2, 3, 1], [4, 3, 1, 2], [4, 3, 2, 1]]

Set partitions:

sage: C = SetPartitions(['a', 'b', 'c'])
sage: C # random print output
Set partitions of {'a', 'c', 'b'}
sage: C.cardinality()
5
sage: C.list()
[{{'a', 'b', 'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a', 'c'}, {'b'}},
 {{'a'}, {'b', 'c'}},
 {{'a'}, {'b'}, {'c'}}]

Partial orders on a set of 8 elements, up to isomorphism:

sage: C = Posets(8); C
Posets containing 8 elements
sage: C.cardinality()
16999
sage: C.unrank(20).plot()
Graphics object consisting of 20 graphics primitives

5.1. Comprehensive Module List
One can iterate through all graphs up to isomorphism. For example, there are 34 simple graphs with 5 vertices:

```
sage: len(list(graphs(5)))
34
```

Here are those with at most 4 edges:

```
sage: up_to_four_edges = list(graphs(5, lambda G: G.size() <= 4))
sage: pretty_print(*up_to_four_edges)
```
However, the set \( C \) of these graphs is not yet available in Sage; as a result, the following commands are not yet implemented:

\begin{verbatim}
sage: C = Graphs(5) # todo: not implemented
sage: C.cardinality() # todo: not implemented
34
sage: Graphs(19).cardinality() # todo: not implemented
24637809253125004524383007491432768
sage: Graphs(19).random_element() # todo: not implemented
Graph on 19 vertices
\end{verbatim}

What we have seen so far also applies, in principle, to finite algebraic structures like the dihedral groups:

5.1. Comprehensive Module List
Combinatorics, Release 9.7

`sage: G = DihedralGroup(4); G`
Dihedral group of order 8 as a permutation group

`sage: G.cardinality()

```

`sage: C.cardinality()
16`

**Exercise**

List all the monomials of degree 5 in three variables (see `IntegerVectors`). Manipulate the ordered set partitions `OrderedSetPartitions` and standard tableaux (`StandardTableaux`).

**Exercise**

List the alternating sign matrices of size 3, 4, and 5 (`AlternatingSignMatrices`), and try to guess the definition. The discovery and proof of the formula for the enumeration of these matrices (see the method `cardinality`), motivated by calculations of determinants in physics, is quite a story. In particular, the first proof, given by Zeilberger in 1992 was automatically produced by a computer program. It was 84 pages long, and required nearly a hundred people to verify it.

**Exercise**

Calculate by hand the number of vectors in $(\mathbb{Z}/2\mathbb{Z})^5$, and the number of matrices in $GL_3(\mathbb{Z}/2\mathbb{Z})$ (that is to say, the number of invertible $3 \times 3$ matrices with coefficients in $\mathbb{Z}/2\mathbb{Z}$). Verify your answer with Sage. Generalize to $GL_n(\mathbb{Z}/q\mathbb{Z})$. 

3430 Chapter 5. Comprehensive Module List
Set comprehension and iterators

We will now show some of the possibilities offered by Python for constructing (and iterating through) sets, with a notation that is flexible and close to usual mathematical usage, and in particular the benefits this yields in combinatorics.

We begin by constructing the finite set \( \{i^2 \mid i \in \{1, 3, 7\}\} \):

```python
sage: [ i^2 for i in [1, 3, 7] ]
[1, 9, 49]
```

and then the same set, but with \( i \) running from 1 to 9:

```python
sage: [ i^2 for i in range(1,10) ]
[1, 4, 9, 16, 25, 36, 49, 64, 81]
```

A construction of this form in Python is called set comprehension. A clause can be added to keep only those elements with \( i \) prime:

```python
sage: [ i^2 for i in range(1,10) if is_prime(i) ]
[4, 9, 25, 49]
```

Combining more than one set comprehension, it is possible to construct the set \( \{(i, j) \mid 1 \leq j < i < 5\}\):

```python
sage: [ (i,j) for i in range(1,6) for j in range(1,i) ]
[(2, 1), (3, 1), (3, 2), (4, 1), (4, 2), (4, 3),
 (5, 1), (5, 2), (5, 3), (5, 4)]
```

or to produce Pascal’s triangle:

```python
sage: [[[binomial(n,i) for i in range(n+1)] for n in range(10)]]
[[[1],
  [1, 1],
  [1, 2, 1],
  [1, 3, 3, 1],
  [1, 4, 6, 4, 1],
  [1, 5, 10, 10, 5, 1],
  [1, 6, 15, 20, 15, 6, 1],
  [1, 7, 21, 35, 35, 21, 7, 1],
  [1, 8, 28, 56, 70, 56, 28, 8, 1],
  [1, 9, 36, 84, 126, 126, 84, 36, 9, 1]]
```

The execution of a set comprehension is accomplished in two steps; first an iterator is constructed, and then a list is filled with the elements successively produced by the iterator. Technically, an iterator is an object with a method `next` which returns a new value each time it is called, until it is exhausted. For example, the following iterator `it`:

```python
sage: it = (binomial(3, i) for i in range(4))
```

returns successively the binomial coefficients \( \binom{3}{i} \) with \( i = 0, 1, 2, 3 \):

```python
sage: next(it)
1
sage: next(it)
3
sage: next(it)
3
```
When the iterator is finally exhausted, an exception is raised:

```
sage: next(it)
Traceback (most recent call last):
...  
StopIteration
```

More generally, an *iterable* is a Python object \( L \) (a list, a set, ...) over whose elements it is possible to iterate. Technically, the iterator is constructed by \( \text{iter}(L) \). In practice, the commands \( \text{iter} \) and \( \text{next} \) are used very rarely, since \( \text{for} \) loops and list comprehensions provide a much pleasanter syntax:

```
sage: for s in Subsets(3):
    ....:    print(s)
{}  
{1}  
{2}  
{3}  
{1, 2}  
{1, 3}  
{2, 3}  
{1, 2, 3}
```

```
sage: [ s.cardinality() for s in Subsets(3) ]
[0, 1, 1, 1, 2, 2, 2, 3]
```

What is the point of an iterator? Consider the following example:

```
sage: sum( [ binomial(8, i) for i in range(9) ] )
256
```

When it is executed, a list of 9 elements is constructed, and then it is passed as an argument to \( \text{sum} \) to add them up. If, on the other hand, the iterator is passed directly to \( \text{sum} \) (note the absence of square brackets):

```
sage: sum( binomial(8, i) for i in range(9) )
256
```

the function \( \text{sum} \) receives the iterator directly, and can short-circuit the construction of the intermediate list. If there are a large number of elements, this avoids allocating a large quantity of memory to fill a list which will be immediately destroyed\(^2\).

Most functions that take a list of elements as input will also accept an iterator (or an iterable) instead. To begin with, one can obtain the list (or the tuple) of elements of an iterator as follows:

```
sage: list(binomial(8, i) for i in range(9))
[1, 8, 28, 56, 70, 56, 28, 8, 1]
sage: tuple(binomial(8, i) for i in range(9))
(1, 8, 28, 56, 70, 56, 28, 8, 1)
```

We now consider the functions \( \text{all} \) and \( \text{any} \) which denote respectively the \( n \)-ary \( \text{and} \) and \( \text{or} \):

\(^2\) Technical detail: \( \text{range} \) returns an iterator on \( \{0, \ldots, 8\} \) while \( \text{range} \) returns the corresponding list. Starting in Python 3.0, \( \text{range} \) will behave like \( \text{range} \), and \( \text{range} \) will no longer be needed.
The following example verifies that all primes from 3 to 99 are odd:

```
sage: all( is_odd(p) for p in range(3,100) if is_prime(p) )
True
```

A Mersenne prime is a prime of the form $2^p - 1$. We verify that, for $p < 1000$, if $2^p - 1$ is prime, then $p$ is also prime:

```
sage: def mersenne(p):
    return 2^p -1
sage: [ is_prime(p)....: for p in range(1000) if is_prime(mersenne(p)) ]
[True, True, True, True, True, True, True, True, True, True,
 True, True, True, True]
```

Is the converse true?

**Exercise**

Try the two following commands and explain the considerable difference in the length of the calculations:

```
sage: all( is_prime(mersenne(p))
....: for p in range(1000) if is_prime(p) )
False
sage: all( [ is_prime(mersenne(p))
....: for p in range(1000) if is_prime(mersenne(p)) ] )
False
```

We now try to find the smallest counter-example. In order to do this, we use the Sage function `exists`:

```
sage: exists( (p for p in range(1000) if is_prime(p)),
....: lambda p: not is_prime(mersenne(p)) )
(True, 11)
```

Alternatively, we could construct an iterator on the counter-examples:

```
sage: counter_examples = (p for p in range(1000)
....: if is_prime(p) and not is_prime(mersenne(p)))
sage: next(counter_examples)
11
sage: next(counter_examples)
23
```
Combinatorics, Release 9.7

Exercise
What do the following commands do?
sage: cubes = [t**3
sage: exists([(x,y)
....:
lambda
(True, (-125, 343))
sage: exists(((x,y)
....:
lambda
(True, (-125, 343))

for t in range(-999,1000)]
for x in cubes for y in cubes],
x_y: x_y[0] + x_y[1] == 218)
for x in cubes for y in cubes),
x_y: x_y[0] + x_y[1] == 218)

# long time (3s, 2012)

# long time (2s, 2012)

Which of the last two is more economical in terms of time? In terms of memory? By how much?

Exercise
Try each of the following commands, and explain its result. If possible, hide the result first and try to guess it before
launching the command.
Todo: hide the results by default

Warning: it will be necessary to interrupt the execution of some of the commands
sage: x = var('x')
sage: sum( x^len(s) for s in Subsets(8) )
x^8 + 8*x^7 + 28*x^6 + 56*x^5 + 70*x^4 + 56*x^3 + 28*x^2 + 8*x + 1
sage: sum( x^p.length() for p in Permutations(3) )
x^3 + 2*x^2 + 2*x + 1
sage: factor(sum( x^p.length() for p in Permutations(3) ))
(x^2 + x + 1)*(x + 1)
sage: P = Permutations(5)
sage: all( p in P for p in P )
True
sage: for p in GL(2, 2): print(p); print("")
[1 0]
[0 1]
[0 1]
[1 0]
[0 1]
[1 1]
[1 1]

3434
[1 1]

Chapter 5. Comprehensive Module List


Operations on iterators

Python provides numerous tools for manipulating iterators; most of them are in the itertools library, which can be imported by:

```
sage: import itertools
```

We will demonstrate some applications, taking as a starting point the permutations of 3:

```
sage: list(Permutations(3))
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

We can list the elements of a set by numbering them:
sage: list(enumerate(Permutations(3)))
[(0, [1, 2, 3]), (1, [1, 3, 2]), (2, [2, 1, 3]),
 (3, [2, 3, 1]), (4, [3, 1, 2]), (5, [3, 2, 1])]

or select only the elements in positions 2, 3, and 4 (analogue of \texttt{l[1:4]}):

sage: import itertools
sage: list(itertools.islice(Permutations(3), int(1), int(4)))
[[1, 3, 2], [2, 1, 3], [2, 3, 1]]

To apply a function to all the elements, one can do:

sage: [z.cycle_type() for z in Permutations(3)]
[[1, 1, 1], [2, 1], [2, 1], [3], [3], [2, 1]]

and similarly to select the elements satisfying a certain condition:

sage: [z for z in Permutations(3) if z.has_pattern([1,2])]
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2]]

**Implementation of new iterators**

It is easy to construct new iterators, using the keyword \texttt{yield} instead of \texttt{return} in a function:

```
sage: def f(n):
    ....:     for i in range(n):
    ....:         yield i
```

After the \texttt{yield}, execution is not halted, but only suspended, ready to be continued from the same point. The result of the function is therefore an iterator over the successive values returned by \texttt{yield}:

```
sage: g = f(4)
sage: next(g)
0
sage: next(g)
1
sage: next(g)
2
sage: next(g)
3
```

```
sage: next(g)
Traceback (most recent call last):
  ...
StopIteration
```

The function could be used as follows:

```
sage: [ x for x in f(5) ]
[0, 1, 2, 3, 4]
```

This model of computation, called \textit{continuation}, is very useful in combinatorics, especially when combined with recursion. Here is how to generate all words of a given length on a given alphabet:
sage: def words(alphabet, l):
....:     if l == 0:
....:         yield []
....:     else:
....:         for word in words(alphabet, l-1):
....:             for l in alphabet:
....:                 yield word + [l]

sage: [ w for w in words(['a', 'b'], 3) ]
[['a', 'a', 'a'], ['a', 'a', 'b'], ['a', 'b', 'a'],
 ['b', 'b', 'a'], ['b', 'b', 'b']]

These words can then be counted by:

sage: sum(1 for w in words(['a', 'b', 'c', 'd'], 10))
1048576

Counting the words one by one is clearly not an efficient method in this case, since the formula $n^l$ is also available; note, though, that this is not the stupidest possible approach - it does, at least, avoid constructing the entire list in memory.

We now consider Dyck words, which are well-parenthesized words in the letters “(“ and “)”. The function below generates all the Dyck words of a given length (where the length is the number of pairs of parentheses), using the recursive definition which says that a Dyck word is either empty or of the form $(w_1)w_2$ where $w_1$ and $w_2$ are Dyck words:

sage: def dyck_words(l):
....:     if l==0:
....:         yield ''
....:     else:
....:         for k in range(l):
....:             for w1 in dyck_words(k):
....:                 for w2 in dyck_words(l-k-1):
....:                     yield '({}+w1+{})'.format(w1, w2)

Here are all the Dyck words of length 4:

sage: list(dyck_words(4))
['()()()()', '()()(())', '()(()())', '(()())()', '(()())', '()(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())', '(()())']

Counting them, we recover a well-known sequence:

sage: [ sum(1 for w in dyck_words(l)) for l in range(10) ]
[1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]

Exercise: complete binary tree iterator

Construct an iterator on the set $C_n$ of complete binary trees with $n$ leaves (see Enumeration of trees using generating functions).

Hint: Sage 4.8.2 does not yet have a native data structure to represent complete binary trees. One simple way to represent them is to define a formal variable Leaf for the leaves and a formal 2-ary function Node:
Combinatorics, Release 9.7

```sage
sage: var('Leaf')
Leaf
sage: function('Node', nargs=2)
Node
```

The second tree in *Figure: The five complete binary trees with four leaves* can be represented by the expression:

```sage
sage: tr = Node(Node(Leaf, Node( Leaf, Leaf)), Leaf)
```

### Constructions

We will now see how to construct new sets starting from these building blocks. In fact, we have already begun to do this with the construction of \( P(P(P\{1, 2, 3, 4\})) \) in the previous section, and to construct the example of sets of cards in *Initial examples*.

Consider a large Cartesian product:

```sage
sage: C = cartesian_product([Compositions(8), Permutations(20)]); C
The Cartesian product of (Compositions of 8, Standard permutations of 20)
sage: C.cardinality()
311411457046609920000
```

Clearly, it is impractical to construct the list of all the elements of this Cartesian product! And, in the following example, \( H \) is equipped with the usual combinatorial operations and also its structure as a product group:

```sage
sage: G = DihedralGroup(4)
sage: H = cartesian_product([G,G])
sage: H in Groups()
True
sage: H.an_element()
((1,3), (1,3))
sage: t = H([G.gen(0), G.gen(0)])
sage: t
((1,2,3,4), (1,2,3,4))
sage: t*t
((1,3)(2,4), (1,3)(2,4))
```

We now construct the union of two existing disjoint sets:

```sage
sage: C = DisjointUnionEnumeratedSets(  ....: [ Compositions(4), Permutations(3)] )
sage: C
Disjoint union of Family (Compositions of 4, Standard permutations of 3)
sage: C.cardinality()
14
sage: C.list()
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1], [4], [1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

It is also possible to take the union of more than two disjoint sets, or even an infinite number of them. We will now construct the set of all permutations, viewed as the union of the sets \( P_n \) of permutations of size \( n \). We begin by
constructing the infinite family $F = (P_n)_{n \in \mathbb{N}}$:

```
 sage: F = Family(NonNegativeIntegers(), Permutations); F
 Lazy family (<class 'sage.combinat.permutation.Permutations'>>(i))_{i in Non negative integers}
 sage: F.keys()
 Non negative integers
 sage: F[1000]
 Standard permutations of 1000
```

Now we can construct the disjoint union $\bigcup_{n \in \mathbb{N}} P_n$:

```
 sage: U = DisjointUnionEnumeratedSets(F); U
 Disjoint union of
 Lazy family (<class 'sage.combinat.permutation.Permutations'>>(i))_{i in Non negative integers}
```

It is an infinite set:

```
 sage: U.cardinality()
 +Infinity
```

which doesn’t prohibit iteration through its elements, though it will be necessary to interrupt it at some point:

```
 sage: for p in U:
 ....:     print(p)  # not tested
 []
 [1]
 [1, 2]
 [2, 1]
 [1, 2, 3]
 [1, 3, 2]
 [2, 1, 3]
 [2, 3, 1]
 [3, 1, 2]
 ...
```

Note: the above set could also have been constructed directly with:

```
 sage: U = Permutations(); U
 Standard permutations
```

**Summary**

Sage provides a library of common enumerated sets, which can be combined by standard constructions, giving a toolbox that is flexible (but which could still be expanded). It is also possible to add new building blocks to Sage with a few lines (see the code in `FiniteEnumeratedSets().example()`). This is made possible by the uniformity of the interfaces and the fact that Sage is based on an object-oriented language. Also, very large or even infinite sets can be manipulated thanks to lazy evaluation strategies (iterators, etc.).

There is no magic to any of this: under the hood, Sage applies the usual rules (for example, that the cardinality of $E \times E$ is $|E|^2$); the added value comes from the capacity to manipulate complicated constructions. The situation is comparable to Sage’s implementation of differential calculus: Sage applies the usual rules for differentiation of functions and their
compositions, where the added value comes from the possibility of manipulating complicated formulas. In this sense, Sage implements a calculus of finite enumerated sets.

**Generic algorithms**

**Lexicographic generation of lists of integers**

Among the classic enumerated sets, especially in algebraic combinatorics, a certain number are composed of lists of integers of fixed sum, such as partitions, compositions, or integer vectors. These examples can also have supplementary constraints added to them. Here are some examples. We start with the integer vectors with sum 10 and length 3, with parts bounded below by 2, 4 and 2 respectively:

```
sage: IntegerVectors(10, 3, min_part=2, max_part=5, inner=[2, 4, 2]).list()
[[4, 4, 2], [3, 5, 2], [3, 4, 3], [2, 5, 3], [2, 4, 4]]
```

The compositions of 5 with each part at most 3, and with length 2 or 3:

```
sage: Compositions(5, max_part=3, min_length=2, max_length=3).list()
[[3, 2], [3, 1, 1], [2, 3], [2, 2, 1], [2, 1, 2], [1, 3, 1], [1, 2, 2], [1, 1, 3]]
```

The strictly decreasing partitions of 5:

```
sage: Partitions(5, max_slope=-1).list()
[[5], [4, 1], [3, 2]]
```

These sets share the same underlying algorithmic structure, implemented in the more general (and slightly more cumbersome) class `IntegerListsLex`. This class models sets of vectors \((\ell_0, \ldots, \ell_k)\) of non-negative integers, with constraints on the sum and the length, and bounds on the parts and on the consecutive differences between the parts. Here are some more examples:

```
sage: IntegerListsLex(10, length=3, min_part=2, max_part=5, floor=[2, 4, 2]).list()
[[4, 4, 2], [3, 5, 2], [3, 4, 3], [2, 5, 3], [2, 4, 4]]
```

```
sage: IntegerListsLex(5, min_part=1, max_part=3, floor=[2, 4, 2]).list()
[[3, 2], [3, 1, 1], [2, 3], [2, 2, 1], [2, 1, 2], [1, 3, 1], [1, 2, 2], [1, 1, 3]]
```

```
sage: IntegerListsLex(5, min_part=1, max_slope=-1).list()
[[5], [4, 1], [3, 2]]
```

```
sage: list(Compositions(5, max_length=2))
[[5], [4, 1], [3, 2], [2, 3], [1, 4]]
```

```
sage: list(IntegerListsLex(5, max_length=2, min_part=1))
[[5], [4, 1], [3, 2], [2, 3], [1, 4]]
```

The point of the model of `IntegerListsLex` is in the compromise between generality and efficiency. The main algorithm permits iteration through the elements of such a set \(S\) in reverse lexicographic order with a good complexity.
in most practical use cases. Roughly speaking, the time needed to iterate through all the elements of $S$ is proportional to the number of elements, where the proportion factor is controlled by the length $l$ of the longest element of $S$. In addition, the memory usage is also controlled by $l$, which is to say negligible in practice.

This algorithm is based on a very general principle for traversing a decision tree, called \textit{branch and bound}: at the top level, we run through all the possible choices for $\ell_0$; for each of these choices, we run through all the possible choices for $\ell_1$, and so on. Mathematically speaking, we have put the structure of a prefix tree on the elements of $S$: a node of the tree at depth $k$ corresponds to a prefix $\ell_0, \ldots, \ell_k$ of one (or more) elements of $S$ (see Figure: The prefix tree of the partitions of 5.).

![Figure: The prefix tree of the partitions of 5.](image)

The usual problem with this type of approach is to avoid bad decisions which lead to leaving the prefix tree and exploring dead branches; this is particularly problematic because the growth of the number of elements is usually exponential in the depth. It turns out that the constraints listed above are simple enough to be able to reasonably predict when a sequence $\ell_0, \ldots, \ell_k$ is a prefix of some element $S$. Hence, most dead branches can be pruned.

**Integer points in polytopes**

Although the algorithm for iteration in \texttt{IntegerListsLex} is efficient, its counting algorithm is naive: it just iterates over all the elements.

There is an alternative approach to treating this problem: modelling the desired lists of integers as the set of integer points of a polytope, that is to say, the set of solutions with integer coordinates of a system of linear inequalities. This is a very general context in which there exist advanced counting algorithms (e.g. Barvinok), which are implemented in libraries like \texttt{LattE}. Iteration does not pose a hard problem in principle. However, there are two limitations that justify the existence of \texttt{IntegerListsLex}. The first is theoretical: lattice points in a polytope only allow modelling of problems of a fixed dimension (length). The second is practical: at the moment only the library PALP has a \texttt{Sage} interface, and though it offers multiple capabilities for the study of polytopes, in the present application it only produces a list of lattice points, without providing either an iterator or non-naive counting:
sage: A = random_matrix(ZZ, 6, 3, x=7)

sage: L = LatticePolytope(A.rows())

sage: L.points()  # random
M(4, 1, 0),
M(0, 3, 5),
M(2, 2, 3),
M(6, 1, 3),
M(1, 3, 6),
M(6, 2, 3),
M(3, 2, 4),
M(3, 2, 3),
M(4, 2, 4),
M(4, 2, 3),
M(5, 2, 3)
in 3-d lattice M

sage: L.npoints()  # random
11

This polytope can be visualized in 3D with L.plot3d() (see Figure: The polytope L and its integer points, in cross-eyed stereographic perspective.)

Fig. 3: Figure: The polytope $L$ and its integer points, in cross-eyed stereographic perspective.
Species, decomposable combinatorial classes

In *Enumeration of trees using generating functions*, we showed how to use the recursive definition of binary trees to count them efficiently using generating functions. The techniques we used there are very general, and apply whenever the sets involved can be defined recursively (depending on who you ask, such a set is called a decomposable combinatorial class or, roughly speaking, a combinatorial species). This includes all the types of trees, but also permutations, compositions, functional graphs, etc.

Here, we illustrate just a few examples using the Sage library on combinatorial species:

```python
sage: from sage.combinat.species.library import *
sage: o = var('o')
```

We begin by redefining the complete binary trees; to do so, we stipulate the recurrence relation directly on the sets:

```python
sage: BT = CombinatorialSpecies()
sage: Leaf = SingletonSpecies()
sage: BT.define( Leaf + (BT*BT) )
```

Now we can construct the set of trees with five nodes, list them, count them…:

```python
sage: BT5 = BT.isotypes([o]*5)
sage: BT5.cardinality()
14
sage: BT5.list()
[o*(o*(o*(o*o))), o*(o*((o*o)*o)), o*((o*o)*(o*o)), o*((o*(o*o))*o), o*(((o*o)*o)*o), (o*o)*(o*(o*o)),
 (o*o)*((o*o)*o), (o*(o*o))*(o*o), ((o*o)*o)*(o*o),
 ((o*(o*o))*o)*o, (o*((o*o)*o))*o, ((o*o)*(o*o))*o,
 ((o*(o*(o*o)))*o, (o*((o*o)*o))*o, ((o*o)*(o*o))*o]
```

The trees are constructed using a generic recursive structure; the display is therefore not wonderful. To do better, it would be necessary to provide Sage with a more specialized data structure with the desired display capabilities.

We recover the generating function for the Catalan numbers:

```python
sage: g = BT.isotype_generating_series(); g
x + x^2 + 2*x^3 + 5*x^4 + 14*x^5 + O(x^6)
```

which is returned in the form of a lazy power series:

```python
sage: g[100]
22750883079422934966181954039568853956041682601541047340
```

We finish with the Fibonacci words, which are binary words without two consecutive “1”s. They admit a natural recursive definition:

```python
sage: Eps = EmptySetSpecies()
sage: Z0 = SingletonSpecies()
sage: Z1 = Eps*SingletonSpecies()
sage: FW = CombinatorialSpecies()
sage: FW.define(Eps + Z0*FW + Z1*Eps + Z1*Z0*FW)
```

The Fibonacci sequence is easily recognized here, hence the name:
sage: L = FW.isotype_generating_series().coefficients(15); L
[1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987]

sage: oeis(L)  # optional -- internet
0: A000045: Fibonacci numbers: F(n) = F(n-1) + F(n-2) with F(0) = 0 and F(1) = 1.
1: ...
2: ...

This is an immediate consequence of the recurrence relation. One can also generate immediately all the Fibonacci words of a given length, with the same limitations resulting from the generic display.

sage: FW3 = FW.isotypes([o]*3)
sage: FW3.list()
[o*(o*(o*{})), o*(o*(({}*o)*{})), o*((({}*o)*o)*{}), (({}*o)*o)*(o*{}), (({}*o)*o)*(({}*o)*{})]

Graphs up to isomorphism

We saw in Some other finite enumerated sets that Sage could generate graphs and partial orders up to isomorphism. We will now describe the underlying algorithm, which is the same in both cases, and covers a substantially wider class of problems.

We begin by recalling some notions. A graph $G = (V, E)$ is a set $V$ of vertices and a set $E$ of edges connecting these vertices; an edge is described by a pair $\{u, v\}$ of distinct vertices of $V$. Such a graph is called labelled; its vertices are typically numbered by considering $V = \{1, 2, 3, 4, 5\}$.

In many problems, the labels on the vertices play no role. Typically a chemist wants to study all the possible molecules with a given composition, for example the alkanes with $n = 8$ atoms of carbon and $2n + 2 = 18$ atoms of hydrogen. He therefore wants to find all the graphs consisting of 8 vertices with 4 neighbours, and 18 vertices with a single neighbour. The different carbon atoms, however, are all considered to be identical, and the same for the hydrogen atoms. The problem of our chemist is not imaginary; this type of application is actually at the origin of an important part of the research in graph theory on isomorphism problems.

Working by hand on a small graph it is possible, as in the example of Some other finite enumerated sets, to make a drawing, erase the labels, and “forget” the geometrical information about the location of the vertices in the plane. However, to represent a graph in a computer program, it is necessary to introduce labels on the vertices so as to be able to describe how the edges connect them together. To compensate for the extra information which we have introduced, we then say that two labelled graphs $g_1$ and $g_2$ are isomorphic if there is a bijection from the vertices of $g_1$ to those of $g_2$, which maps bijectively the edges of $g_1$ to those of $g_2$; an unlabelled graph is then an equivalence class of labelled graphs.

In general, testing if two labelled graphs are isomorphic is expensive. However, the number of graphs, even unlabelled, grows very rapidly. Nonetheless, it is possible to list unlabelled graphs very efficiently considering their number. For example, the program Nauty can list the 12005168 simple graphs with 10 vertices in 20 seconds.

As in Lexicographic generation of lists of integers, the general principle of the algorithm is to organize the objects to be enumerated into a tree that one traverses.

For this, in each equivalence class of labelled graphs (that is to say, for each unlabelled graph) one fixes a convenient canonical representative. The following are the fundamental operations:

- Testing whether a labelled graph is canonical
- Calculating the canonical representative of a labelled graph

These unavoidable operations remain expensive; one therefore tries to minimize the number of calls to them.
The canonical representatives are chosen in such a way that, for each canonical labelled graph \( G \), there is a canonical choice of an edge whose removal produces a canonical graph again, which is called the father of \( G \). This property implies that it is possible to organize the set of canonical representatives as a tree: at the root, the graph with no edges; below it, its unique child, the graph with one edge; then the graphs with two edges, and so on. The set of children of a graph \( G \) can be constructed by augmentation, adding an edge in all the possible ways to \( G \), and then selecting, from among those graphs, the ones that are still canonical\(^3\). Recursively, one obtains all the canonical graphs.

In what sense is this algorithm generic? Consider for example planar graphs (graphs which can be drawn in the plane without edges crossing): by removing an edge from a planar graph, one obtains another planar graph; so planar graphs form a subtree of the previous tree. To generate them, exactly the same algorithm can be used, selecting only the children which are planar:

```python
sage: [len(list(graphs(n, property = lambda G: G.is_planar()))) for n in range(7)]
[1, 1, 2, 4, 11, 33, 142]
```

In a similar fashion, one can generate any family of graphs closed under deletion of an edge, and in particular any family characterized by a forbidden subgraph. This includes for example forests (graphs without cycles), bipartite graphs (graphs without odd cycles), etc. This can be applied to generate:

- partial orders, via the bijection with Hasse diagrams which are oriented graphs without cycles and without edges implied by the transitivity of the order relation;
- lattices (not implemented in Sage), via the bijection with the meet semi-lattice obtained by deleting the maximal vertex; in this case an augmentation by vertices rather than by edges is used.

5.1.350 Vector Partitions

AUTHORS:

- Amritanshu Prasad (2013): Initial version

`sage.combinat.vector_partition.IntegerVectorsIterator(vect, min=None)`

Return an iterator over the list of integer vectors which are componentwise less than or equal to \( \text{vect} \), and lexicographically greater than or equal to \( \text{min} \).

INPUT:

- \( \text{vect} \) – A list of non-negative integers
- \( \text{min} \) – A list of non-negative integers dominated elementwise by \( \text{vect} \)

OUTPUT:

A list in lexicographic order of all integer vectors (as lists) which are dominated elementwise by \( \text{vect} \) and are greater than or equal to \( \text{min} \) in lexicographic order.

EXAMPLES:

```python
sage: from sage.combinat.vector_partition import IntegerVectorsIterator
sage: list(IntegerVectorsIterator([1, 1]))
[[0, 0], [0, 1], [1, 0], [1, 1]]
```

\(^3\) In practice, an efficient implementation would exploit the symmetries of \( G \), i.e., its automorphism group, to reduce the number of children to explore, and to reduce the cost of each test of canonicity.
Fig. 4: Figure: The generation tree of simple graphs with 4 vertices.
sage: list(IntegerVectorsIterator([1, 1], min = [1, 0]))
[[[1, 0], [1, 1]]]

class sage.combinat.vector_partition.VectorPartition(parent, vecpar)

Bases: sage.combinat.combinat.CombinatorialElement

A vector partition is a multiset of integer vectors.

partition_at_vertex(i)

Return the partition obtained by sorting the i-th elements of the vectors in the vector partition.

EXAMPLES:

sage: V = VectorPartition([[1, 2, 1], [2, 4, 1]])
sage: V.partition_at_vertex(1)
[4, 2]

sum()

Return the sum vector as a list.

EXAMPLES:

sage: V = VectorPartition([[3, 2, 1], [2, 2, 1]])
sage: V.sum()
[5, 4, 2]

class sage.combinat.vector_partition.VectorPartitions(vec, min)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Class of all vector partitions of vec with all parts greater than or equal to min in lexicographic order.

A vector partition of vec is a list of vectors with non-negative integer entries whose sum is vec.

INPUT:

• vec – a list of non-negative integers.

EXAMPLES:

If min is not specified, then the class of all vector partitions of vec is created:

sage: VP = VectorPartitions([2, 2])
sage: for vecpar in VP:
   ....:     print(vecpar)
[[0, 1], [0, 1], [1, 0], [1, 0]]
[[0, 1], [0, 1], [2, 0]]
[[0, 1], [1, 0], [1, 1]]
[[0, 1], [2, 1]]
[[0, 2], [1, 0], [1, 0]]
[[0, 2], [2, 0]]
[[1, 0], [1, 2]]
[[1, 1], [1, 1]]
[[2, 2]]

If min is specified, then the class consists of only those vector partitions whose parts are all greater than or equal to min in lexicographic order:
sage: VP = VectorPartitions([2, 2], min = [1, 0])
sage: for vecpar in VP:
    ....:   print(vecpar)
[[1, 0], [1, 2]]
[[1, 1], [1, 1]]
[[2, 2]]

Element

alias of VectorPartition

sage.combinat.vector_partition.find_min(vect)

Return a string of 0’s with one 1 at the location where the list vect has its last entry which is not equal to 0.

INPUT:

• vec – A list of integers

OUTPUT:

A list of the same length with 0’s everywhere, except for a 1 at the last position where vec has an entry not equal to 0.

EXAMPLES:

sage: from sage.combinat.vector_partition import find_min
sage: find_min([2, 1])
[0, 1]
sage: find_min([2, 1, 0])
[0, 1, 0]

5.1.351 Abstract word (finite or infinite)

This module gathers functions that works for both finite and infinite words.

AUTHORS:

• Sébastien Labbé
• Franco Saliola

EXAMPLES:

sage: a = 0.618
sage: g = words.CodingOfRotationWord(alpha=a, beta=1-a, x=a)
sage: f = words.FibonacciWord()
sage: p = f.longest_common_prefix(g, length='finite')
sage: p
word: 0100101001001010010100100101001001010010...
sage: p.length()
231

class sage.combinat.words.abstract_word.Word_class

Bases: sage.structure.sage_object.SageObject

apply_morphism(morphism)

Returns the word obtained by applying the morphism to self.

INPUT:
• morphism - Can be an instance of WordMorphism, or anything that can be used to construct one.

EXAMPLES:

```python
sage: w = Word("ab")
sage: d = {'a':'ab', 'b':'ba'}
sage: w.apply_morphism(d)
word: abba
sage: w.apply_morphism(WordMorphism(d))
word: abba

sage: w = Word('ababa')
sage: d = dict(a='ab', b='ba')
sage: d
{'a': 'ab', 'b': 'ba'}
sage: w.apply_morphism(d)
word: abbaabbaab
```

For infinite words:

```python
sage: t = words.ThueMorseWord([0,1]); t
word: 0110100110010110100101100110100110010110...
sage: t.apply_morphism({0:8,1:9})
word: 8998989898989898989898989898989898989898...
```

complete_return_words_iterator(fact)

Returns an iterator over all the complete return words of fact in self (without unicity).

A complete return words \( u \) of a factor \( v \) is a factor starting by the given factor \( v \) and ending just after the next occurrence of this factor \( v \). See for instance \[1\].

INPUT:

• fact - a non empty finite word

OUTPUT:

iterator

EXAMPLES:

```python
sage: TM = words.ThueMorseWord()
sage: fact = Word([0,1,1,0,1])
sage: it = TM.complete_return_words_iterator(fact)
sage: next(it)
word: 01101001100101101
sage: next(it)
word: 01101001011001101
sage: next(it)
word: 011010011001011001101
sage: next(it)
word: 0110100101101
sage: next(it)
word: 01101001100101101
```

REFERENCES:

**delta()**
Returns the image of self under the delta morphism.
This is the word composed of the length of consecutive runs of the same letter in a given word.

**OUTPUT:**
Word over integers

**EXAMPLES:**
For finite words:
```
sage: W = Words('0123456789')
sage: W('22112122').delta()
word: 22112
sage: W('555008').delta()
word: 321
sage: W('').delta()
word:
sage: W('aabbaba').delta()
word: 22112
```
For infinite words:
```
sage: t = words.ThueMorseWord()
sage: t.delta()
word: 1211222112112221122112112221122211222112112112221...
```

**factor_occurrences_iterator(fact)**
Returns an iterator over all occurrences (including overlapping ones) of fact in self in their order of appearance.

**INPUT:**
- fact - a non empty finite word

**OUTPUT:**
iterator

**EXAMPLES:**
```
sage: TM = words.ThueMorseWord()
sage: fact = Word([0,1,1,0,1])
sage: it = TM.factor_occurrences_iterator(fact)
sage: next(it)
0
sage: next(it)
12
sage: next(it)
24

sage: u = Word('121')
sage: w = Word('121213211213')
```

sage: list(w.factor_occurrences_iterator(u))
[0, 2, 8]

finite_differences(\text{mod} = \text{None})

Return the word obtained by the differences of consecutive letters of \textit{self}.

\textbf{INPUT:}

- \textit{self} - A word over the integers.
- \textit{mod} - (default: None) It can be one of the following:
  - None or 0: result is over the integers
  - integer: result is over the integers modulo \textit{mod}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: w = Word([x^2 for x in range(10)])
sage: w.finite_differences()
word: 1,3,5,7,9,11,13,15,17
sage: w.finite_differences(mod=4)
word: 131313131
sage: w.finite_differences(mod=0)
word: 1,3,5,7,9,11,13,15,17
\end{verbatim}

first_occurrence(\textit{other}, \textit{start}=0)

Return the position of the first occurrence of \textit{other} in \textit{self}.

If \textit{other} is not a factor of \textit{self}, it returns None or loops forever when \textit{self} is an infinite word.

\textbf{INPUT:}

- \textit{other} – a finite word
- \textit{start} – integer (default: 0), where the search starts

\textbf{OUTPUT:}

integer or None

\textbf{EXAMPLES:}

\begin{verbatim}
sage: w = Word('01234567890123456789')
sage: w.first_occurrence(Word('3456'))
3
sage: w.first_occurrence(Word('3456'), start=7)
13
\end{verbatim}

When the factor is not present, None is returned:

\begin{verbatim}
sage: w.first_occurrence(Word('3456'), start=17) is None
True
sage: w.first_occurrence(Word('3333')) is None
True
\end{verbatim}

Also works for searching a finite word in an infinite word:
sage: w = Word('0123456789')^oo
sage: w.first_occurrence(Word('3456'))
3
sage: w.first_occurrence(Word('3456'), start=1000)
1003

But it will loop for ever if the factor is not found:

sage: w.first_occurrence(Word('3333'))  # not tested -- infinite loop

The empty word occurs in a word:

sage: Word('123').first_occurrence(Word(''), 0)
0
sage: Word('').first_occurrence(Word(''), 0)
0

**is_empty()**

Returns True if the length of self is zero, and False otherwise.

**EXAMPLES:**

sage: it = iter([])
sage: Word(it).is_empty()
True
sage: it = iter([1,2,3])
sage: Word(it).is_empty()
False
sage: from itertools import count
sage: Word(count()).is_empty()
False

**is_finite()**

Returns whether this word is known to be finite.

**Warning:** A word defined by an iterator such that its end has never been reached will returns False.

**EXAMPLES:**

sage: Word([]).is_finite()
True
sage: Word('a').is_finite()
True
sage: TM = words.ThueMorseWord()
sage: TM.is_finite()
False

sage: w = Word(iter('a'*100))
sage: w.is_finite()
False

**iterated_right_palindromic_closure** *(f=None, algorithm='recursive'*)

Returns the iterated \( f \)-palindromic closure of self.
INPUT:

- \( f \) - involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism).
- \texttt{algorithm} - string (default: 'recursive') specifying which algorithm to be used when computing the iterated palindromic closure. It must be one of the two following values:
  - 'definition' - computed using the definition
  - 'recursive' - computation based on an efficient formula that recursively computes the iterated right palindromic closure without having to recompute the longest \( f \)-palindromic suffix at each iteration [2].

OUTPUT:

word – the iterated (\( f \))-palindromic closure of self

EXAMPLES:

```python
sage: Word('123').iterated_right_palindromic_closure()
word: 1213121

sage: w = Word('abc')
sage: w.iterated_right_palindromic_closure()
word: abacaba

sage: w = Word('aaa')
sage: w.iterated_right_palindromic_closure()
word: aaa

sage: w = Word('abbab')
sage: w.iterated_right_palindromic_closure()
word: ababaabababaababa
```

A right \( f \)-palindromic closure:

```python
sage: f = WordMorphism('a->b,b->a')
sage: w = Word('abbab')
sage: w.iterated_right_palindromic_closure(f=f)
word: abbaabbaababbaabababbaababbaabab
```

An infinite word:

```python
sage: t = words.ThueMorseWord('ab')
sage: t.iterated_right_palindromic_closure()
word: ababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababa... 
```

There are two implementations computing the iterated right \( f \)-palindromic closure, the latter being much more efficient:

```python
sage: w = Word('abaab')
sage: u = w.iterated_right_palindromic_closure(algorithm='definition')
sage: v = w.iterated_right_palindromic_closure(algorithm='recursive')
sage: u
word: abaabaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababaababa... 
```

(continues on next page)
REFERENCES:

length()
Returns the length of self.

lex_greater(other)
Returns True if self is lexicographically greater than other.

EXAMPLES:

```python
sage: w = Word([1,2,3])
sage: u = Word([1,3,2])
sage: v = Word([3,2,1])
sage: w.lex_greater(u)
False
sage: v.lex_greater(w)
True
sage: a = Word("abba")
sage: b = Word("abbb")
sage: a.lex_greater(b)
False
sage: b.lex_greater(a)
True
```

For infinite words:

```python
sage: t = words.ThueMorseWord()
sage: t[:10].lex_greater(t)
False
sage: t.lex_greater(t[:10])
True
```

lex_less(other)
Returns True if self is lexicographically less than other.

EXAMPLES:

```python
sage: w = Word([1,2,3])
sage: u = Word([1,3,2])
sage: v = Word([3,2,1])
sage: w.lex_less(u)
True
```
Combinatorics, Release 9.7

(continued from previous page)

```python
sage: v.lex_less(w)
False
sage: a = Word("abba")
sage: b = Word("abbb")
sage: a.lex_less(b)
True
sage: b.lex_less(a)
False
```

For infinite words:

```python
sage: t = words.ThueMorseWord()
sage: t.lex_less(t[:10])
False
sage: t[:10].lex_less(t)
True
```

**longest_common_prefix**(other, length='unknown')

Returns the longest common prefix of self and other.

**INPUT:**

- **other** - word
- **length** - string (optional, default: 'unknown') the length type of the resulting word if known. It may be one of the following:
  - 'unknown'
  - 'finite'
  - 'infinite'

**EXAMPLES:**

```python
sage: f = lambda n : add(Integer(n).digits(2)) % 2
sage: t = Word(f)
sage: u = t[:10]
sage: t.longest_common_prefix(u)
word: 0110100110

The longest common prefix of two equal infinite words:

```python
sage: t1 = Word(f)
sage: t2 = Word(f)
sage: t1.longest_common_prefix(t2)
word: 011010001011001100101100110010110...
```

Useful to study the approximation of an infinite word:

```python
sage: a = 0.618
sage: g = words.CodingOfRotationWord(alpha=a, beta=1-a, x=a)
sage: f = words.FibonacciWord()
sage: p = f.longest_common_prefix(g, length='finite')
sage: p.length()
231
```
**longest_periodic_prefix**(*period=1*)

Returns the longest prefix of self having the given period.

**INPUT:**

- **period** - positive integer (optional, default 1)

**OUTPUT:**

**EXAMPLES:**

```python
sage: Word([]).longest_periodic_prefix()
word: 
sage: Word([1]).longest_periodic_prefix()
word: 1
sage: Word([1,2]).longest_periodic_prefix()
word: 1
sage: Word([1,1,2]).longest_periodic_prefix()
word: 11
sage: Word([1,2,1,2,1,3]).longest_periodic_prefix(2)
word: 12121
sage: type(_)
<class 'sage.combinat.words.word.FiniteWord_iter_with_caching'>
sage: Word(lambda n:0).longest_periodic_prefix()
word: 0000000000000000000000000000000000000000...
```

**palindrome_prefixes_iterator**(*max_length=None*)

Returns an iterator over the palindrome prefixes of self.

**INPUT:**

- **max_length** - non negative integer or None (optional, default: None) the maximum length of the prefixes

**OUTPUT:**

**iterator**

**EXAMPLES:**

```python
sage: w = Word('abaaba')
sage: for pp in w.palindrome_prefixes_iterator(): pp
word: a
word: aba
word: abaaba
sage: for pp in w.palindrome_prefixes_iterator(max_length=4): pp
word: a
word: aba
```

You can iterate over the palindrome prefixes of an infinite word:

```python
sage: f = words.FibonacciWord()
sage: for pp in f.palindrome_prefixes_iterator(max_length=20): pp
word: 0
```

(continues on next page)
parent()
Returns the parent of self.

partial_sums(start, mod=None)
Returns the word defined by the partial sums of its prefixes.

INPUT:
• self - A word over the integers.
• start - integer, the first letter of the resulting word.
• mod - (default: None) It can be one of the following:
  – None or 0: result is over the integers
  – integer: result is over the integers modulo mod.

EXAMPLES:

```sage
w = Word(range(10))
print(w.partial_sums(0))  # word: 0,0,1,3,6,10,15,21,28,36
print(w.partial_sums(1))  # word: 1,1,2,4,7,11,16,22,29,37
w = Word([1,2,3,1,2,3,2,2,2,2])
partial_sums(0, mod=None)
word: 0,1,3,6,9,12,14,16,18,20
print(w.partial_sums(0, mod=8))
word: 01367146024
print(w.partial_sums(0, mod=4))
word: 01323102020
print(w.partial_sums(0, mod=2))
word: 0110100000
print(w.partial_sums(0, mod=1))
word: 0000000000
```

prefixes_iterator(max_length=None)
Returns an iterator over the prefixes of self.

INPUT:
• max_length - non negative integer or None (optional, default: None) the maximum length of the prefixes

OUTPUT:
iterator

EXAMPLES:
You can iterate over the prefixes of an infinite word:

```
sage: f = words.FibonacciWord()
sage: for p in f.prefixes_iterator(max_length=8): p
  word: 0
  word: 01
  word: 010
  word: 0100
  word: 01001
  word: 010010
  word: 0100101
  word: 01001010
```

`return_words_iterator(fact)`

Returns an iterator over all the return words of fact in self (without unicity).

INPUT:

- fact - a non empty finite word

OUTPUT:

iterator

EXAMPLES:

```
sage: w = Word('baccabcbacbacbca')
sage: b = Word('b')
sage: list(w.return_words_iterator(b))
[word: bacca, word: bcc, word: bac]
sage: TM = words.ThueMorseWord()
sage: fact = Word([0,1,1,0,1])
sage: it = TM.return_words_iterator(fact)
sage: next(it)
word: 011010011001
sage: next(it)
word: 011010010110
sage: next(it)
```

(continues on next page)
word: 0110100110010110
sage: next(it)
word: 01101001
sage: next(it)
word: 011010011001
sage: next(it)
word: 011010010110

string_rep()
Returns the (truncated) raw sequence of letters as a string.

EXAMPLES:

sage: Word('abbabaab').string_rep()
'abbabaab'
sage: Word([0, 1, 0, 0, 1]).string_rep()
'01001'
sage: Word([0, 1, 10, 101]).string_rep()
'0,1,10,101'
sage: WordOptions(letter_separator=' - ')
sage: Word([0, 1, 10, 101]).string_rep()
'0-1-10-101'
sage: WordOptions(letter_separator=', ')

sum_digits(base=2, mod=None)
Return the sequence of the sum modulo mod of the digits written in base base of self.

INPUT:

• self - word over natural numbers
• base - integer (default : 2), greater or equal to 2
• mod - modulo (default: None), can take the following values:
  – integer – the modulo
  – None - the value base is considered for the modulo.

EXAMPLES:
The Thue-Morse word:

sage: from itertools import count
sage: Word(count()).sum_digits()
word: 0110100110010110100101100110100110010110...

Sum of digits modulo 2 of the prime numbers written in base 2:

sage: Word(primes(1000)).sum_digits()
word: 1001110100111010111011001011101110011011...

Sum of digits modulo 3 of the prime numbers written in base 3:

sage: Word(primes(1000)).sum_digits(base=3)
word: 210000202000222122212102222102212211022...
sage: Word(primes(1000)).sum_digits(base=3, mod=3)
word: 210000202000222122212102222102212211022...
Sum of digits modulo 2 of the prime numbers written in base 3:

```
sage: Word(primes(1000)).sum_digits(base=3, mod=2)
word: 0111111111111111111111111111111111111111...
```

Sum of digits modulo 7 of the prime numbers written in base 10:

```
sage: Word(primes(1000)).sum_digits(base=10, mod=7)
word: 235024135443504100613243241353546006304...
```

Negative entries:

```
sage: w = Word([-1,0,1,2,3,4,5])
sage: w.sum_digits()
Traceback (most recent call last):
...  
NotImplementedError: nth digit of Thue-Morse word is not implemented for negative value of n
```

`to_integer_word()`

Returns a word over the integers whose letters are those output by `self._to_integer_iterator()`

**EXAMPLES:**

```
sage: from itertools import count
sage: w = Word(count()); w
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,27,
      28,29,30,31,32,33,34,35,36,37,38,39,...
sage: w.to_integer_word()
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,27,
      28,29,30,31,32,33,34,35,36,37,38,39,...
```

5.1.352 Combinatorics on words

Main modules and their methods:

- Abstract word (finite or infinite)
- Finite word
- Infinite word
- Alphabet
- Set of words
- Word paths
- Word morphisms/substitutions
• *Shuffle product of words*

• *Suffix Tries and Suffix Trees*

Main classes and functions meant to be used by the user:

\[
\text{Word()}, \text{FiniteWords}, \text{InfiniteWords}, \text{Words()}, \text{Alphabet()}, \text{WordMorphism}, \text{WordPaths}.
\]

A list of common words can be accessed through \texttt{words.<tab>} and are listed in the \texttt{words catalog}.

**Internal representation of words:**

• *Word classes*

• *Fast word datatype using an array of unsigned char*

• *Datatypes for finite words*

• *Datatypes for words defined by iterators and callables*

**Options:**

• *User-customizable options for words*

See \texttt{WordOptions()}.  

### 5.1.353 Alphabet

**AUTHORS:**

• Franco Saliola (2008-12-17) : merged into sage

• Vincent Delecroix and Stepan Starosta (2012): remove classes for alphabet and use other Sage classes otherwise (TotallyOrderedFiniteSet, FiniteEnumeratedSet, …). More shortcut to standard alphabets.

**EXAMPLES:**

```python
sage: build_alphabet("ab")
{'a', 'b'}
sage: build_alphabet([0,1,2])
{0, 1, 2}
sage: build_alphabet(name="PP")
Positive integers
sage: build_alphabet(name="NN")
Non negative integers
sage: build_alphabet(name="lower")
{'a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k', 'l', 'm', 'n', 'o', 'p', 'q', 'r', 's', 't', 'u', 'v', 'w', 'x', 'y', 'z'}
```

\[\text{sage.combinat.words.alphabet.Alphabet}(data=None, names=None, name=None)\]

Return an object representing an ordered alphabet.

**INPUT:**

• \texttt{data} – the letters of the alphabet; it can be:
  
  – a list/tuple/iterable of letters; the iterable may be infinite

  – an integer \( n \) to represent \( \{1, \ldots, n\} \), or infinity to represent \( \mathbb{N} \)

• \texttt{names} – (optional) a list for the letters (i.e. variable names) or a string for prefix for all letters; if given a list, it must have the same cardinality as the set represented by \texttt{data}
• name – (optional) if given, then return a named set and can be equal to: 'lower', 'upper', 'space', 'underscore', 'punctuation', 'printable', 'binary', 'octal', 'decimal', 'hexadecimal', 'radix64'.

You can use many of them at once, separated by spaces: 'lower punctuation' represents the union of the two alphabets 'lower' and 'punctuation'.

Alternatively, name can be set to "positive integers" (or "PP") or "natural numbers" (or "NN").

name cannot be combined with data.

EXAMPLES:

If the argument is a Set, it just returns it:

```python
sage: build_alphabet(ZZ) is ZZ
True
sage: F = FiniteEnumeratedSet('abc')
sage: build_alphabet(F) is F
True
```

If a list, tuple or string is provided, then it builds a proper Sage class (TotallyOrderedFiniteSet):

```python
sage: build_alphabet([0,1,2])
{0, 1, 2}
sage: F = build_alphabet('abc'); F
{'a', 'b', 'c'}
sage: print(type(F).__name__)
TotallyOrderedFiniteSet_with_category
```

If an integer and a set is given, then it constructs a TotallyOrderedFiniteSet:

```python
sage: build_alphabet(3, ['a', 'b', 'c'])
{'a', 'b', 'c'}
```

If an integer and a string is given, then it considers that string as a prefix:

```python
sage: build_alphabet(3, 'x')
{'x0', 'x1', 'x2'}
```

If no data is provided, name may be a string which describe an alphabet. The available names decompose into two families. The first one are 'positive integers', 'PP', 'natural numbers' or 'NN' which refer to standard set of numbers:

```python
sage: build_alphabet(name="positive integers")
Positive integers
sage: build_alphabet(name="PP")
Positive integers
sage: build_alphabet(name="natural numbers")
Non negative integers
sage: build_alphabet(name="NN")
Non negative integers
```

The other families for the option name are among 'lower', 'upper', 'space', 'underscore', 'punctuation', 'printable', 'binary', 'octal', 'decimal', 'hexadecimal', 'radix64' which refer to standard set of characters. Theses names may be combined by separating them by a space.
In the case the alphabet is built from a list or a tuple, the order on the alphabet is given by the elements themselves:

```python
sage: A = build_alphabet([0,2,1])
sage: A(0) < A(2)
True
sage: A(2) < A(1)
False
```

If a different order is needed, you may use ` TotallyOrderedFiniteSet ` and set the option ` facade ` to ` False `. That way, the comparison fits the order of the input:

```python
sage: A = TotallyOrderedFiniteSet([4,2,6,1], facade=False)
sage: A(4) < A(2)
True
sage: A(1) < A(6)
False
```

Be careful, the element of the set in the last example are no more integers and do not compare equal with integers:

```python
sage: type(A.an_element())
<class 'sage.sets.totally_ordered_finite_set.TotallyOrderedFiniteSet_with_category.element_class'>
sage: A(1) == 1
False
sage: 1 == A(1)
False
```

We give an example of an infinite alphabet indexed by the positive integers and the prime numbers:

```python
sage: build_alphabet(oo, 'x')
Lazy family (x(i))_{i in Non negative integers}
sage: build_alphabet(Primes(), 'y')
Lazy family (y(i))_{i in Set of all prime numbers: 2, 3, 5, 7, ...}
```

`sage.combinat.words.alphabet.build_alphabet(data=None, names=None, name=None)`
Return an object representing an ordered alphabet.

**INPUT:**

- **data** – the letters of the alphabet; it can be:
  - a list/tuple/iterable of letters; the iterable may be infinite
  - an integer \( n \) to represent \( \{1, \ldots, n\} \), or infinity to represent \( \mathbb{N} \)
- **names** – (optional) a list for the letters (i.e. variable names) or a string for prefix for all letters; if given a list, it must have the same cardinality as the set represented by `data`
**name** – (optional) if given, then return a named set and can be equal to: 'lower', 'upper', 'space', 'underscore', 'punctuation', 'printable', 'binary', 'octal', 'decimal', 'hexadecimal', 'radix64'.

You can use many of them at once, separated by spaces: 'lower punctuation' represents the union of the two alphabets 'lower' and 'punctuation'.

Alternatively, name can be set to "positive integers" (or "PP") or "natural numbers" (or "NN"). name cannot be combined with data.

**EXAMPLES:**

If the argument is a Set, it just returns it:

```python
sage: build_alphabet(ZZ) is ZZ
True
sage: F = FiniteEnumeratedSet('abc')
sage: build_alphabet(F) is F
True
```

If a list, tuple or string is provided, then it builds a proper Sage class (**TotallyOrderedFiniteSet**):

```python
sage: build_alphabet([0,1,2])
{0, 1, 2}
sage: F = build_alphabet('abc'); F
{'a', 'b', 'c'}
sage: print(type(F).__name__)
TotallyOrderedFiniteSet_with_category
```

If an integer and a set is given, then it constructs a **TotallyOrderedFiniteSet**:

```python
sage: build_alphabet(3, ['a', 'b', 'c'])
{'a', 'b', 'c'}
```

If an integer and a string is given, then it considers that string as a prefix:

```python
sage: build_alphabet(3, 'x')
{'x0', 'x1', 'x2'}
```

If no data is provided, name may be a string which describe an alphabet. The available names decompose into two families. The first one are 'positive integers', 'PP', 'natural numbers' or 'NN' which refer to standard set of numbers:

```python
sage: build_alphabet(name="positive integers")
Positive integers
sage: build_alphabet(name="PP")
Positive integers
sage: build_alphabet(name="natural numbers")
Non negative integers
sage: build_alphabet(name="NN")
Non negative integers
```

The other families for the option name are among 'lower', 'upper', 'space', 'underscore', 'punctuation', 'printable', 'binary', 'octal', 'decimal', 'hexadecimal', 'radix64' which refer to standard set of characters. Theses names may be combined by separating them by a space:
In the case the alphabet is built from a list or a tuple, the order on the alphabet is given by the elements themselves:

```
sage: A = build_alphabet([0,2,1])
sage: A(0) < A(2)
True
sage: A(2) < A(1)
False
```

If a different order is needed, you may use ` TotallyOrderedFiniteSet ` and set the option ` facade ` to ` False `. That way, the comparison fits the order of the input:

```
sage: A = TotallyOrderedFiniteSet([4,2,6,1], facade=False)
sage: A(4) < A(2)
True
sage: A(1) < A(6)
False
```

Be careful, the element of the set in the last example are no more integers and do not compare equal with integers:

```
sage: type(A.an_element())
<class 'sage.sets.totally_ordered_finite_set.TotallyOrderedFiniteSet_with_category.element_class'>
sage: A(1) == 1
False
sage: 1 == A(1)
False
```

We give an example of an infinite alphabet indexed by the positive integers and the prime numbers:

```
sage: build_alphabet(oo, 'x')
Lazy family (x(i))_{i in Non negative integers}
sage: build_alphabet(Primes(), 'y')
Lazy family (y(i))_{i in Set of all prime numbers: 2, 3, 5, 7, ...}
```

### 5.1.354 Finite word

**AUTHORS:**
- Arnaud Bergeron
- Amy Glen
- Sébastien Labbé
- Franco Saliola
Combinatorics, Release 9.7

- Julien Leroy (March 2010): reduced_rauzy_graph

EXAMPLES:

**Creation of a finite word**

Finite words from Python strings, lists and tuples:

```python
sage: Word("abbabaab")
word: abbabaab
sage: Word([0, 1, 1, 0, 1, 0, 0, 1])
word: 01101001
sage: Word( ('a', 0, 5, 7, 'b', 9, 8) )
word: a057b98
```

Finite words from functions:

```python
sage: f = lambda n : n%3
sage: Word(f, length=13)
word: 0120120120120
```

Finite words from iterators:

```python
sage: from itertools import count
sage: Word(count(), length=10)
word: 0123456789
sage: Word( iter('abbccdef') )
word: abbccdef
```

Finite words from words via concatenation:

```python
sage: u = Word("abccabba")
sage: v = Word([0, 4, 8, 8, 3])
sage: u * v
word: abccabba04883
sage: v * u
word: 04883abccabba
sage: u + v
word: abccabba04883
sage: u^3 * v^(8/5)
word: abccabbaabccabbaabccabba04883048
```

Finite words from infinite words:

```python
sage: vv = v^Infinity
sage: vv[10000:10015]
word: 0488304883048
```

Finite words in a specific combinatorial class:

```python
sage: W = Words("ab")
sage: W
Finite and infinite words over {'a', 'b'}
```

(continues on next page)
sage: W("abbabaab")
word: abbabaab
sage: W(['a', 'b', 'b', 'a', 'b', 'a', 'a', 'b'])
word: abbabaab
sage: W( iter('ababab') )
word: ababab

Finite word as the image under a morphism:

sage: m = WordMorphism({0:[4,4,5,0],5:[0,5,5],4:[4,0,0,0]})
sage: m(0)
word: 4450
sage: m(0, order=2)
word: 40004000554450
sage: m(0, order=3)
word: 4000445044504450400044504450445044500550...

Note: The following two finite words have the same string representation:

sage: w = Word('010120')
sage: z = Word([0, 1, 0, 1, 2, 0])
sage: w
word: 010120
sage: z
word: 010120
but are not equal:

sage: w == z
False

Indeed, w and z are defined on different alphabets:

sage: w[2]
'0'
sage: z[2]
0

Functions and algorithms

There are more than 100 functions defined on a finite word. Here are some of them:

sage: w = Word('abaabbbba'); w
word: abaabbbba
sage: w.is_palindrome()
False
sage: w.is_lyndon()
False
sage: w.number_of_factors()
28
sage: w.critical_exponent()
3

sage: print(w.lyndon_factorization())
(ab, aabbb, a)
sage: print(w.crochemore_factorization())
(a, b, a, ab, bb, a)

sage: st = w.suffix_tree()
sage: st
Implicit Suffix Tree of the word: abaabba
sage: st.show(word_labels=True)

sage: T = words.FibonacciWord('ab')
sage: T.longest_common_prefix(Word('abaababbbbbbb'))
word: abaababa

As matrix and many other Sage objects, words have a parent:

sage: u = Word('xyxxyxyyy')
sage: u.parent()
Finite words over Set of Python objects of class 'object'

sage: v = Word('xyxxyxyyy', alphabet='xy')
sage: v.parent()
Finite words over {'x', 'y'}

**Factors and Rauzy Graphs**

Enumeration of factors, the successive values returned by next(it) can appear in a different order depending on hardware. Therefore we mark the three first results of the test random. The important test is that the iteration stops properly on the fourth call:

sage: w = Word([4,5,6])**7
sage: it = w.factor_iterator(4)
sage: next(it) # random
word: 6456
sage: next(it) # random
word: 5645
sage: next(it) # random
word: 4564
sage: next(it)
Traceback (most recent call last):
  ...
StopIteration

The set of factors:

sage: sorted(w.factor_set(3))
[word: 456, word: 564, word: 645]

(continues on next page)
Combinatorics, Release 9.7

(continued from previous page)

```
sage: sorted(w.factor_set(4))
[word: 4564, word: 5645, word: 6456]
sage: w.factor_set().cardinality()
61
```

Rauzy graphs:

```
sage: f = words.FibonacciWord()[:30]
sage: f.rauzy_graph(4)
Looped digraph on 5 vertices
sage: f.reduced_rauzy_graph(4)
Looped multi-digraph on 2 vertices
```

Left-special and bispecial factors:

```
sage: f.number_of_left_special_factors(7)
1
sage: f.bispecial_factors()
[word: , word: 0, word: 010, word: 010010, word: 01001010010]
```

```python
class sage.combinat.words.finite_word.CallableFromListOfWords
    Bases: tuple
    A class to create a callable from a list of words. The concatenation of a list of words is obtained by creating a word from this callable.

class sage.combinat.words.finite_word.Factorization
    Bases: list
    A list subclass having a nicer representation for factorization of words.

class sage.combinat.words.finite_word.FiniteWord_class
    Bases: sage.combinat.words.abstract_word.Word_class

    BWT()
    Return the Burrows-Wheeler Transform (BWT) of self.

    The Burrows-Wheeler transform of a finite word $w$ is obtained from $w$ by first listing the conjugates of $w$ in lexicographic order and then concatenating the final letters of the conjugates in this order. See [BW1994].

    EXAMPLES:

```
sage: Word('abaccaaba').BWT()
word: cbaabaaca
sage: Word('abaab').BWT()
word: bbaaa
sage: Word('bbabbaca').BWT()
word: cbbbbaca
sage: Word('aabaab').BWT()
word: bbaaaa
sage: Word().BWT()
word:
sage: Word('a').BWT()
word: a
```

    LZ_decomposition()
    Return the Crochemore factorization of self as an ordered list of factors.
```
The Crochemore factorization or the Lempel-Ziv decomposition of a finite word $w$ is the unique factorization: $(x_1, x_2, \ldots, x_n)$ of $w$ with each $x_i$ satisfying either: C1. $x_i$ is a letter that does not appear in $u = x_1 \ldots x_{i-1}$; C2. $x_i$ is the longest prefix of $v = x_i \ldots x_n$ that also has an occurrence beginning within $u = x_1 \ldots x_{i-1}$. See [Cro1983].

**EXAMPLES:**

```python
sage: x = Word('abababb')
sage: x.crochemore_factorization()
(a, b, abab, b)
sage: mul(x.crochemore_factorization()) == x
True
sage: y = Word('abaabacabba')
sage: y.crochemore_factorization()
(a, b, a, aba, ba, c, ab, ba)
sage: mul(y.crochemore_factorization()) == y
True
sage: x = Word([0,1,0,1,0,1,1])
sage: x.crochemore_factorization()
(0, 1, 0101, 1)
sage: mul(x.crochemore_factorization()) == x
True
```

**abelian_complexity($n$)**

Return the number of abelian vectors of factors of length $n$ of self.

**EXAMPLES:**

```python
sage: w = words.FibonacciWord()[:100]
sage: [w.abelian_complexity(i) for i in range(20)]
[1, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2]
sage: w = words.ThueMorseWord()[:100]
sage: [w.abelian_complexity(i) for i in range(20)]
[1, 2, 3, 2, 3, 2, 3, 2, 3, 2, 3, 2, 3, 2, 3, 2, 3, 2, 3, 2]
```

**abelian_vector()**

Return the abelian vector of self counting the occurrences of each letter.

The vector is defined w.r.t. the order of the alphabet of the parent. See also `evaluation_dict()`.

**INPUT:**

- self – word having a parent on a finite alphabet

**OUTPUT:**

a list

**EXAMPLES:**

```python
sage: W = Words('ab')
sage: W('aaabbbb').abelian_vector()
[3, 5]
sage: W('a').abelian_vector()
[1, 0]
sage: W().abelian_vector()
[0, 0]
```
The result depends on the alphabet of the parent:

```python
sage: W = Words('abc')
sage: W('aabaa').abelian_vector()
[4, 1, 0]
```

**abelian_vectors**<sub>(n)</sub>

Return the abelian vectors of factors of length n of self.

The vectors are defined w.r.t. the order of the alphabet of the parent.

**OUTPUT:**

a set of tuples

**EXAMPLES:**

```python
sage: W = Words([0,1,2])
sage: w = W([0,1,1,0,1,2,0,2,0,2])
sage: w.abelian_vectors(3)
{(1, 0, 2), (1, 1, 1), (1, 2, 0), (2, 0, 1)}
sage: w[:5].abelian_vectors(3)
{(1, 2, 0)}
sage: w[5:].abelian_vectors(3)
{(1, 0, 2), (2, 0, 1)}
sage: w = words.FibonacciWord()[:100]
sage: sorted(w.abelian_vectors(0))
[(0, 0)]
sage: sorted(w.abelian_vectors(1))
[(0, 1), (1, 0)]
sage: sorted(w.abelian_vectors(7))
[(4, 3), (5, 2)]
```

The word must be defined with a parent on a finite alphabet:

```python
sage: from itertools import count
sage: w = Word(count(), alphabet=NN)
sage: w[:2].abelian_vectors(2)
Traceback (most recent call last):
  ...
TypeError: The alphabet of the parent is infinite; define the word with a parent on a finite alphabet
```

**apply_permutation_to_letters**<sub>(permutation)</sub>

Return the word obtained by applying the permutation permutation of the alphabet of self to each letter of self.

**EXAMPLES:**

```python
sage: w = Words('abcd')('abcd')
sage: p = [2,1,4,3]
sage: w.apply_permutation_to_letters(p)
word: badc
sage: u = Words('dabc')('abcd')
sage: u.apply_permutation_to_letters(p)
(continues on next page)```
apply_permutation_to_positions(permutation)
Return the word obtained by permuting the positions of the letters in self according to the permutation permutation.

EXAMPLES:

```
sage: w = Words('abcd')(abcd)
sage: w.apply_permutation_to_positions([2,1,4,3])
word: badc
sage: u = Words('dabc')(abcd)
sage: u.apply_permutation_to_positions([2,1,4,3])
word: badc
sage: w.apply_permutation_to_positions(Permutation([2,1,4,3]))
word: badc
sage: w.apply_permutation_to_positions(PermutationGroupElement([2,1,4,3]))
word: badc
sage: Word([1,2,3,4]).apply_permutation_to_positions([3,4,2,1])
word: 3421
```

balance()
Return the balance of self.

The balance of a word is the smallest number q such that self is q-balanced [FV2002].

A finite or infinite word w is said to be q-balanced if for any two factors u, v of w of the same length, the difference between the number of x’s in each of u and v is at most q for all letters x in the alphabet of w. A 1-balanced word is simply said to be balanced. See Chapter 2 of [Lot2002].

OUTPUT:

integer

EXAMPLES:

```
sage: Word('111111').balance()
0
sage: Word('001010101011').balance()
2
sage: Word('101010101').balance()
1
sage: w = Word('1112222')
sage: w.is_balanced(2)
False
sage: w.is_balanced(3)
False
sage: w.is_balanced(4)
True
sage: w.is_balanced(5)
```

(continues on next page)
True
sage: w.balance()
4

**bispecial_factors** *(n=None)*

Return the bispecial factors (of length `n`).

A factor `u` of a word `w` is *bispecial* if it is right special and left special.

**INPUT:**

- `n` – integer (optional, default: `None`). If `None`, it returns all bispecial factors.

**OUTPUT:**

a list of words

**EXAMPLES:**

```python
sage: w = words.FibonacciWord()[:30]
sage: w.bispecial_factors()
[word: , word: 0, word: 010, word: 010010, word: 01001010010]
```

```python
sage: w = words.ThueMorseWord()[:30]
sage: for i in range(10):
    ....:     for u in sorted(w.bispecial_factors_iterator(i)):
    ....:         print("{} {}".format(i,u))
0
1 0
1 1
2 01
2 10
```

**bispecial_factors_iterator** *(n=None)*

Return an iterator over the bispecial factors (of length `n`).

A factor `u` of a word `w` is *bispecial* if it is right special and left special.

**INPUT:**

- `n` – integer (optional, default: `None`). If `None`, it returns an iterator over all bispecial factors.

**EXAMPLES:**

```python
sage: w = words.ThueMorseWord()[:30]
sage: for i in range(10):
    ....:     for u in sorted(w.bispecial_factors_iterator(i)):
    ....:         print("{} {}".format(i,u))
0
1 0
1 1
2 01
2 10
```
sage: key = lambda u: (len(u), u)
sage: for u in sorted(w.bispecial_factors_iterator(), key=key): u

word: 0
word: 1
word: 01
word: 10
word: 010
word: 101
word: 0110
word: 1001
word: 011001
word: 100110
word: 10010110

border()
Return the longest word that is both a proper prefix and a proper suffix of self.

EXAMPLES:

sage: Word('121212').border()
word: 1212
sage: Word('12321').border()
word: 1
sage: Word().border() is None
True

charge(check=True)
Return the charge of self. This is defined as follows.

If \( w \) is a permutation of length \( n \), (in other words, the evaluation of \( w \) is \((1, 1, \ldots, 1)\)), the statistic \( \text{charge}(w) \) is given by \( \sum_{i=1}^{n} c_i(w) \) where \( c_1(w) = 0 \) and \( c_i(w) \) is defined recursively by setting \( p_i \) equal to 1 if \( i \) appears to the right of \( i - 1 \) in \( w \) and 0 otherwise. Then we set \( c_i(w) = c_{i-1}(w) + p_i \).

EXAMPLES:

sage: Word([1, 2, 3]).charge()
3
sage: Word([3, 5, 1, 4, 2]).charge() == 0 + 1 + 1 + 2 + 2
True

If \( w \) is not a permutation, but the evaluation of \( w \) is a partition, the charge of \( w \) is defined to be the sum of its charge subwords (each of which will be a permutation). The first charge subword is found by starting at the end of \( w \) and moving left until the first 1 is found. This is marked, and we continue to move to the left until the first 2 is found, wrapping around from the beginning of the word back to the end, if necessary. We mark this 2, and continue on until we have marked the largest letter in \( w \). The marked letters, with
relative order preserved, form the first charge subword of \( w \). This subword is removed, and the next charge subword is found in the same manner from the remaining letters. In the following example, \( w_1, w_2, w_3 \) are the charge subwords of \( w \).

**EXAMPLES:**

```python
sage: w = Word([5,2,3,4,4,1,1,1,2,2,3])
sage: w1 = Word([5,2,4,1,3])
sage: w2 = Word([3,4,1,2])
sage: w3 = Word([1,2])
sage: w.charge() == w1.charge() + w2.charge() + w3.charge()
True
```

Finally, if \( w \) does not have partition content, we apply the Lascoux-Schützenberger standardization operators \( s_i \) in such a manner as to obtain a word with partition content. (The word we obtain is independent of the choice of operators.) The charge is then defined to be the charge of this word:

```python
sage: W = Word([3,3,2,1,1]).charge()
sage: W
0
```

Note that this differs from the definition of charge given in Macdonald's book. The difference amounts to a choice of reading a word from left-to-right or right-to-left. The choice in Sage was made to agree with the definition of a reading word of a tableau in Sage, and seems to be the more common convention in the literature.

See [Mac1995], [LLM2003], and [LLT].

**cocharge()**

Return the cocharge of \( \text{self} \). For a word \( w \), this can be defined as \( n_{ev} - ch(w) \), where \( ch(w) \) is the charge of \( w \) and \( ev \) is the evaluation of \( w \), and \( n_{ev} = \sum_{i<j} \min(ev_i, ev_j) \).

**EXAMPLES:**

```python
sage: W = Word([1,2,3]).cocharge()
sage: W
0
```

**coerce** (other)

Try to return a pair of words with a common parent; raise an exception if this is not possible.

This function begins by checking if both words have the same parent. If this is the case, then no work is done and both words are returned as-is.

Otherwise it will attempt to convert \( \text{other} \) to the domain of \( \text{self} \). If that fails, it will attempt to convert \( \text{self} \) to the domain of \( \text{other} \). If both attempts fail, it raises a TypeError to signal failure.

**EXAMPLES:**

```python
sage: W1 = Words('abc'); W2 = Words('ab')
sage: w1 = W1('abc'); w2 = W2('abba'); w3 = W1('baab')
```
sage: w1.parent() is w2.parent()
False
sage: a, b = w1.coerce(w2)
sage: a.parent() is b.parent()
True
sage: w1.parent() is w2.parent()
False

colored_vector(x=0, y=0, width='default', height=1, cmap='hsv', thickness=1, label=None)

Return a vector (Graphics object) illustrating self. Each letter is represented by a coloured rectangle.

If the parent of self is a class of words over a finite alphabet, then each letter in the alphabet is assigned a
unique colour, and this colour will be the same every time this method is called. This is especially useful
when plotting and comparing words defined on the same alphabet.

If the alphabet is infinite, then the letters appearing in the word are used as the alphabet.

INPUT:

• x – (default: 0) bottom left x-coordinate of the vector
• y – (default: 0) bottom left y-coordinate of the vector
• width – (default: 'default') width of the vector. By default, the width is the length of self.
• height – (default: 1) height of the vector
• thickness – (default: 1) thickness of the contour
• cmap – (default: 'hsv') color map; for available color map names type: import matplotlib.cm; list(matplotlib.cm.datad)
• label – string (default: None) a label to add on the colored vector

OUTPUT:

Graphics

EXAMPLES:

sage: Word(range(20)).colored_vector()
Graphics object consisting of 21 graphics primitives
sage: Word(range(100)).colored_vector(0,0,10,1)
Graphics object consisting of 101 graphics primitives
sage: Words(range(100))(range(10)).colored_vector()
Graphics object consisting of 11 graphics primitives
sage: w = Word('abbabaab')
sage: w.colored_vector()
Graphics object consisting of 9 graphics primitives
sage: w.colored_vector(cmap='autumn')
Graphics object consisting of 9 graphics primitives
sage: Word(range(20)).colored_vector(label='Rainbow')
Graphics object consisting of 23 graphics primitives

When two words are defined under the same parent, same letters are mapped to same colors:

sage: W = Words(range(20))
sage: w = W(range(20))
sage: y = W(range(10,20))

(continues on next page)
sage: y.colored_vector(y=1, x=10) + w.colored_vector()
Graphics object consisting of 32 graphics primitives

commutes_with(other)

Return True if self commutes with other, and False otherwise.

EXAMPLES:

sage: Word('12').commutes_with(Word('12'))
True
sage: Word('12').commutes_with(Word('11'))
False
sage: Word().commutes_with(Word('21'))
True

complete_return_words(fact)

Return the set of complete return words of fact in self.

This is the set of all factors starting by the given factor and ending just after the next occurrence of this factor. See for instance [JV2000].

INPUT:

• fact – a non-empty finite word

OUTPUT:

a Python set of finite words

EXAMPLES:

sage: s = Word('21331233213231').complete_return_words(Word('2'))
sage: sorted(s)
[word: 2132, word: 213312, word: 2332]
sage: Word('').complete_return_words(Word('213'))
set()
sage: Word('121212').complete_return_words(Word('1212'))
{word: 121212}

concatenate(other)

Return the concatenation of self and other.

INPUT:

• other – a word over the same alphabet as self

EXAMPLES:

Concatenation may be made using + or * operations:

sage: w = Word('abadafd')
sage: y = Word([5,3,5,8,7])
sage: w * y
word: abadafd53587
sage: w + y
word: abadafd53587
sage: w.concatenate(y)
word: abadafd53587
Both words must be defined over the same alphabet:

```python
sage: z = Word('12223', alphabet = '123')
sage: z + y
Traceback (most recent call last):
 ... ValueError: 5 not in alphabet
```

Eventually, it should work:

```python
sage: z = Word('12223', alphabet = '123')
```

```python
sage: z + y  #todo: not implemented
```

#### conjugate(pos)

Return the conjugate at `pos` of `self`.

`pos` can be any integer, the distance used is the modulo by the length of `self`.

**EXAMPLES:**

```python
sage: Word('12112').conjugate(1)
word: 21112
sage: Word().conjugate(2)
word:
```

```python
sage: Word('12112').conjugate(8)
word: 12112
```

```python
sage: Word('12112').conjugate(-1)
word: 21112
```

#### conjugate_position(other)

Return the position where `self` is conjugate with `other`. Return `None` if there is no such position.

**EXAMPLES:**

```python
sage: Word('12113').conjugate_position(Word('31211'))
1
```

```python
sage: Word('12131').conjugate_position(Word('12113')) is None
True
```

```python
sage: Word().conjugate_position(Word('123')) is None
True
```

#### conjugates()

Return the list of unique conjugates of `self`.

**EXAMPLES:**

```python
sage: Word(range(6)).conjugates()
[word: 012345, word: 123450, word: 234501, word: 345012, word: 450123, word: 501234]
sage: Word('cbbca').conjugates()
[word: cbbca, word: bbcac, word: bcacb, word: cacbb, word: acbbc]
```
The result contains each conjugate only once:

```
sage: Word('abcabc').conjugates()
[word: abcbca, word: bcabca, word: cabcab]
```

**conjugates_iterator()**

Return an iterator over the conjugates of `self`.

**EXAMPLES:**

```
sage: it = Word(range(4)).conjugates_iterator()
sage: for w in it: w
word: 0123
word: 1230
word: 2301
word: 3012
```

**content**(\(n=None\))

Return content of `self`.

**INPUT:**

- \(n\) – (optional) an integer specifying the maximal letter in the alphabet

**OUTPUT:**

- a list where the \(i\)-th entry indicates the multiplicity of the \(i\)-th letter in the alphabet in `self`

**EXAMPLES:**

```
sage: w = Word([1,2,4,3,2,2,2])
sage: w.content()
[1, 4, 1, 1]
sage: w = Word([3,1])
sage: w.content()
[1, 1]
sage: w.content(n=3)
[1, 0, 1]
sage: w = Word([2,4],alphabet=[1,2,3,4])
sage: w.content(n=3)
[0, 1, 0]
sage: w.content()
[0, 1, 0, 1]
```

**count**(\(letter\))

Return the number of occurrences of `letter` in `self`.

**INPUT:**

- `letter` - a letter

**OUTPUT:**

- integer

**EXAMPLES:**

```
sage: w = Word('abbabaab')
sage: w.number_of_letter_occurrences('a')
```

(continues on next page)
This method is equivalent to `list(w).count(letter)` and `tuple(w).count(letter)`, thus `count` is an alias for the method `number_of_letter_occurrences`:

```
sage: list(w).count('a')
4
sage: w.count('a')
4
```

But notice that if `s` and `w` are strings, `Word(s).count(w)` counts the number occurrences of `w` as a letter in `Word(s)` which is not the same as `s.count(w)` which counts the number of occurrences of the string `w` inside `s`:

```
sage: s = 'abbabaab'
sage: s.count('ab')
3
sage: Word(s).count('ab')
0
```

See also:

`sage.combinat.words.finite_word.FiniteWord_class.number_of_factor_occurrences()`

`critical_exponent()`

Return the critical exponent of `self`.

The critical exponent of a word is the supremum of the order of all its (finite) factors. See [Dej1972].

**Note:** The implementation here uses the suffix tree to enumerate all the factors. It should be improved (especially when the critical exponent is larger than 2).

**EXAMPLES:**

```
sage: Word('aaba').critical_exponent()
2
sage: Word('aabaa').critical_exponent()
2
sage: Word('aababa').critical_exponent()
7/3
sage: Word('ab').critical_exponent()
1
sage: Word('aba').critical_exponent()
3/2
sage: words.ThueMorseWord()[:20].critical_exponent()
2
```

For the Fibonacci word, the critical exponent is known to be \((5 + \sqrt{5})/2\). With a prefix of length 500, we obtain a lower bound:

```
sage: words.FibonacciWord()[:500].critical_exponent()
320/89
```
It is an error to compute the critical exponent of the empty word:

```
sage: Word('').critical_exponent()
Traceback (most recent call last):
...
ValueError: no critical exponent for empty word
```

crochemore_factorization()

Return the Crochemore factorization of `self` as an ordered list of factors.

The Crochemore factorization or the Lempel-Ziv decomposition of a finite word \( w \) is the unique factorization: \( (x_1, x_2, \ldots, x_n) \) of \( w \) with each \( x_i \) satisfying either: C1. \( x_i \) is a letter that does not appear in \( u = x_1 \ldots x_{i-1} \); C2. \( x_i \) is the longest prefix of \( v = x_i \ldots x_n \) that also has an occurrence beginning within \( u = x_1 \ldots x_{i-1} \). See [Cro1983].

EXAMPLES:

```
sage: x = Word('abababb')
sage: x.crochemore_factorization()
(a, b, abab, b)
sage: mul(x.crochemore_factorization()) == x
True
sage: y = Word('abaabacabba')
sage: y.crochemore_factorization()
(a, b, a, aba, ba, c, ab, ba)
sage: mul(y.crochemore_factorization()) == y
True
sage: x = Word([0,1,0,1,0,1,1])
sage: x.crochemore_factorization()
(0, 1, 0101, 1)
sage: mul(x.crochemore_factorization()) == x
True
```

defect(f=None)

Return the defect of `self`.

The defect of a finite word \( w \) is given by the difference between the maximum number of possible palindromic factors in a word of length \( |w| \) and the actual number of palindromic factors contained in \( w \). It is well known that the maximum number of palindromic factors in \( w \) is \( |w| + 1 \) (see [DJP2001]).

An optional involution on letters \( f \) can be given. In that case, the \( f \)-palindromic defect (or pseudopalindromic defect, or theta-palindromic defect) of \( w \) is returned. It is a generalization of defect to \( f \)-palindromes. More precisely, the defect is \( D(w) = |w| + 1 - g_f(w) - |PAL_f(w)| \), where \( PAL_f(w) \) denotes the set of \( f \)-palindromic factors of \( w \) (including the empty word) and \( g_f(w) \) is the number of pairs \( \{a, f(a)\} \) such that \( a \) is a letter, \( a \) is not equal to \( f(a) \), and \( a \) or \( f(a) \) occurs in \( w \). In the case of usual palindromes (i.e., for \( f \) not given or equal to the identity), \( g_f(w) = 0 \) for all \( w \). See [BHNR2004] for usual palindromes and [Star2011] for \( f \)-palindromes.

INPUT:

- \( f \) – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`). The default value corresponds to usual palindromes, i.e., \( f \) equal to the identity.

OUTPUT:

an integer – If \( f \) is `None`, the palindromic defect of `self`; otherwise, the \( f \)-palindromic defect of `self`.

EXAMPLES:
It is known that Sturmian words (see [DJP2001]) have zero defect:

```
sage: words.FibonacciWord()[:100].defect()
0
```

It is even conjectured that the defect of an aperiodic word which is a fixed point of a primitive morphism is either 0 or infinite (see [BBGL2008]):

```
sage: w = words.ThueMorseWord()
sage: w[:50].defect()
12
sage: w[:100].defect()
16
sage: w[:300].defect()
52
```

For generalized defect with an involution different from the identity, there is always a letter which is not a palindrome! This is the reason for the modification of the definition:

```
sage: f = WordMorphism('a->b,b->a')
sage: Word('a').defect(f)
0
sage: Word('ab').defect(f)
0
sage: Word('aa').defect(f)
1
sage: Word('abbabaabbaababba').defect(f)
3
```

```
sage: f = WordMorphism('a->b,b->a,c->c')
sage: Word('cabc').defect(f)
0
sage: Word('abcaab').defect(f)
2
```

Other examples:

```
sage: Word('00000000000000').defect()
0
sage: Word('011010011001').defect()
```
Combinatorics, Release 9.7

(continued from previous page)

```python
2
sage: Word('0101001010001').defect()
0
sage: Word().defect()
0
sage: Word('abbabaabbaababba').defect()
2
```

def_inv_lex_less(other, weights=None)

Return True if the word self is degree inverse lexicographically less than other.

EXAMPLES:

```python
sage: Word([1,2,4]).deg_inv_lex_less(Word([1,3,2]))
False
sage: Word([3,2,1]).deg_inv_lex_less(Word([1,2,3]))
True
```

def_lex_less(other, weights=None)

Return True if self is degree lexicographically less than other, and False otherwise. The weight of each letter in the ordered alphabet is given by weights, which defaults to [1, 2, 3, ...].

EXAMPLES:

```python
sage: Word([1,2,3]).deg_lex_less(Word([1,3,2]))
True
sage: Word([3,2,1]).deg_lex_less(Word([1,2,3]))
False
```

deg_rev_lex_less(other, weights=None)

Return True if self is degree reverse lexicographically less than other.

EXAMPLES:

```python
sage: Word([3,2,1]).deg_rev_lex_less(Word([1,2,3]))
False
sage: Word([1,2,4]).deg_rev_lex_less(Word([1,3,2]))
False
sage: Word([1,2,3]).deg_rev_lex_less(Word([1,2,4]))
True
```

degree(weights=None)

Return the weighted degree of self, where the weighted degree of each letter in the ordered alphabet is given by weights, which defaults to [1, 2, 3, ...].
INPUT:

- weights – a list or a tuple, or a dictionary keyed by the letters occurring in self.

EXAMPLES:

```python
sage: Word([1,2,3]).degree()
sage: Word([3,2,1]).degree()
sage: Words("ab")("abba").degree()
sage: Words("ab")("abba").degree([0,2])
sage: Words("ab")("abba").degree([-1,-1])
sage: Words("ab")("aabba").degree([1,1])
sage: Words([1,2,4])([1,2,4]).degree()
sage: Word([1,2,4]).degree()
sage: Word([0,1,0]).degree({0:17,1:0})
```

```
delta()

Return the image of self under the delta morphism.

The delta morphism, also known as the run-length encoding, is the word composed of the length of consecutive runs of the same letter in a given word.

EXAMPLES:

```python
sage: W = Words('0123456789')
sage: W('22112122').delta()
word: 22112
sage: W('555008').delta()
word: 321
sage: W().delta()
word:
sage: Word('aabbabaa').delta()
word: 22112
```

```
delta_derivate(W=None)

Return the derivative under delta for self.

EXAMPLES:

```python
sage: W = Words('12')
sage: W('12211').delta_derivate()
word: 22
sage: W('1').delta_derivate(Words([1]))
word: 1
sage: W('2112').delta_derivate()
```

(continues on next page)
word: 2
sage: W("2211").delta_derivate()
word: 22
sage: W("112").delta_derivate()
word: 2
sage: W("11222").delta_derivate( Words([1, 2, 3]) )
word: 3

**delta_derivate_left**(W=None)

Return the derivative under delta for self.

EXAMPLES:

```
sage: W = Words('12')
sage: W("12211").delta_derivate_left()
word: 22
sage: W("1").delta_derivate_left( Words([1]) )
word: 1
sage: W("2112").delta_derivate_left()
word: 21
sage: W("2211").delta_derivate_left()
word: 22
sage: W("112").delta_derivate_left()
word: 21
sage: W("11222").delta_derivate_left( Words([1, 2, 3]) )
word: 3
```

**delta_derivate_right**(W=None)

Return the right derivative under delta for self.

EXAMPLES:

```
sage: W = Words('12')
sage: W("12211").delta_derivate_right()
word: 122
sage: W("1").delta_derivate_right( Words([1]) )
word: 1
sage: W("2112").delta_derivate_right()
word: 12
sage: W("2211").delta_derivate_right()
word: 22
sage: W("112").delta_derivate_right()
word: 2
sage: W("11222").delta_derivate_right( Words([1, 2, 3]) )
word: 23
```

**delta_inv**(W=None, s=None)

Lift self via the delta operator to obtain a word containing the letters in alphabet (default is [0, 1]). The letters used in the construction start with s (default is alphabet[0]) and cycle through alphabet.

INPUT:

- alphabet – an iterable
- s – an object in the iterable
EXAMPLES:

```python
sage: W = Words([1, 2])
sage: W([2, 2, 1, 1]).delta_inv()
word: 112212
sage: W([1, 1, 1, 1]).delta_inv(Words('123'))
word: 1231
sage: W([2, 2, 1, 1, 2]).delta_inv(s=2)
word: 2211222
```

evaluation()  
Return the abelian vector of self counting the occurrences of each letter.  
The vector is defined w.r.t. the order of the alphabet of the parent. See also evaluation_dict().  

INPUT:  
• self – word having a parent on a finite alphabet  

OUTPUT:  
a list  

EXAMPLES:

```python
sage: W = Words('ab')
sage: W('aaabbbbb').abelian_vector()
[3, 5]
sage: W('a').abelian_vector()
[1, 0]
sage: W().abelian_vector()
[0, 0]
```

The result depends on the alphabet of the parent:

```python
sage: W = Words('abc')
sage: W('aabaa').abelian_vector()
[4, 1, 0]
```

evaluation_dict()  
Return a dictionary keyed by the letters occurring in self with values the number of occurrences of the letter.  

EXAMPLES:

```python
sage: Word([2,1,4,2,3,4,2]).evaluation_dict()
{1: 1, 2: 3, 3: 1, 4: 2}
sage: Word('badcde').evaluation_dict()
{"a": 1, "b": 3, "c": 1, "d": 2}
sage: Word().evaluation_dict()
{}
```

```python
sage: f = Word('123121').evaluation_dict()  # keys appear in random order
{'1': 4, '2': 2, '3': 1}
```

evaluation_partition()  
Return the evaluation of the word w as a partition.  

EXAMPLES:
evaluation_partition()  
Return a list representing the evaluation of self. The entries of the list are two-element lists \([a, n]\), where \(a\) is a letter occurring in self and \(n\) is the number of occurrences of \(a\) in self.

EXAMPLES:

sage: sorted(Word([1,2,4,2,3,4,2]).evaluation_partition())  
[[3, 2, 1, 1]]

sage: sorted(Word([4,4,2,5,2,1,4,1]).evaluation_partition())  
[[1, 2), (2, 2), (4, 3), (5, 1)]

exponent()  
Return the exponent of self.

OUTPUT:

integer – the exponent

EXAMPLES:

sage: Word('1231').exponent()  
1  
sage: Word('121212').exponent()  
3  
sage: Word().exponent()  
0

factor_complexity(n)  
Return the number of distinct factors of length \(n\) of self.

INPUT:

* \(n\) – the length of the factors.

EXAMPLES:

sage: w = words.FibonacciWord()[:100]  
sage: [w.factor_complexity(i) for i in range(20)]  
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20]

sage: w = words.ThueMorseWord()[:1000]  
sage: [w.factor_complexity(i) for i in range(20)]  
[1, 2, 4, 6, 10, 12, 16, 20, 22, 24, 28, 32, 36, 40, 42, 44, 46, 48, 52, 56]

factor_iterator(n=None)  
Generate distinct factors of self.

INPUT:

* \(n\) – an integer, or None.

OUTPUT:
If \( n \) is an integer, returns an iterator over all distinct factors of length \( n \). If \( n \) is \texttt{None}, returns an iterator generating all distinct factors.

**EXAMPLES:**

```python
sage: w = Word('1213121')
sage: sorted( w.factor_iterator(0) )
[word: ]
sage: sorted( w.factor_iterator(10) )
[]
sage: sorted( w.factor_iterator(1) )
[word: 1, word: 2, word: 3]
sage: sorted( w.factor_iterator(4) )
[word: 1213, word: 1312, word: 2131, word: 3121]
sage: sorted( w.factor_iterator() )
[word: , word: 1, word: 12, word: 121, word: 1212, word: 12123, word: 123, word: 2, word: 21, word: 212, word: 2123, word: 23, word: 3]
```

```python
sage: u = Word([1,2,1,2,3])
sage: sorted( u.factor_iterator(0) )
[word: ]
sage: sorted( u.factor_iterator(10) )
[]
sage: sorted( u.factor_iterator(1) )
[word: 1, word: 2, word: 3]
sage: sorted( u.factor_iterator(5) )
[word: 12123]
sage: sorted( u.factor_iterator() )
[word: , word: 1, word: 12, word: 121, word: 1212, word: 12123, word: 123, word: 2, word: 21, word: 212, word: 2123, word: 23, word: 3]
```

```python
sage: xxx = Word("xxx")
sage: sorted( xxx.factor_iterator(0) )
[word: ]
sage: sorted( xxx.factor_iterator(4) )
[]
sage: sorted( xxx.factor_iterator(2) )
[word: xx]
sage: sorted( xxx.factor_iterator() )
[word: , word: x, word: xx, word: xxx]
```

```python
sage: e = Word()
sage: sorted( e.factor_iterator(0) )
[word: ]
sage: sorted( e.factor_iterator(17) )
[]
sage: sorted( e.factor_iterator() )
[word: ]
```

**factor_occurrences_in** \((\text{other})\)

Return an iterator over all occurrences (including overlapping ones) of \texttt{self} in \texttt{other} in their order of appearance.
**Warning:** This method is deprecated since 2020 and will be removed in a later version of SageMath. Use `factor_occurrences_iterator()` instead.

**EXAMPLES:**
```
sage: u = Word('121')
sage: w = Word('121312131213')
sage: list(u.factor_occurrences_in(w))
doctest:warning
...
DeprecationWarning: f.factor_occurrences_in(w) is deprecated.
Use w.factor_occurrences_iterator(f) instead.
See https://trac.sagemath.org/30187 for details.
[0, 2, 8]
```

`factor_set(n=None, algorithm='suffix tree')`

Return the set of factors (of length \(n\)) of `self`.

**INPUT:**
- \(n\) – an integer or `None` (default: `None`).
- `algorithm` – string (default: `'suffix tree'`), takes the following values:
  - `'suffix tree'` – construct and use the suffix tree of the word
  - `'naive'` – algorithm uses a sliding window

**OUTPUT:**

If \(n\) is an integer, returns the set of all distinct factors of length \(n\). If \(n\) is `None`, returns the set of all distinct factors.

**EXAMPLES:**
```
sage: w = Word('121')
sage: sorted(w.factor_set())
[word: , word: 1, word: 12, word: 121, word: 2, word: 21]
sage: sorted(w.factor_set(algorithm='naive'))
[word: , word: 1, word: 12, word: 121, word: 2, word: 21]
```
```
sage: w = Word('1213121')
sage: for i in range(w.length()): sorted(w.factor_set(i))
[word: ]
[word: 1, word: 2, word: 3]
[word: 12, word: 13, word: 21, word: 31]
[word: 121, word: 131, word: 213, word: 312]
[word: 1213, word: 1312, word: 2131, word: 3121]
[word: 12131, word: 13121, word: 21312]
[word: 121312, word: 213121]
```
```
sage: w = Word([1,2,1,2,3])
sage: s = w.factor_set()
sage: sorted(s)
[word: , word: 1, word: 12, word: 121, word: 1212, word: 12123, word: 123, word: 2, word: 21, word: 212, word: 2123, word: 23, word: 3]
```

5.1. Comprehensive Module List 3489
**find**(sub, start=0, end=None)

Return the index of the first occurrence of sub in self, such that sub is contained within self[start:end]. Return -1 on failure.

**INPUT:**

- sub – string, list, tuple or word to search for.
- start – non-negative integer (default: 0) specifying the position from which to start the search.
- end – non-negative integer (default: `None`) specifying the position at which the search must stop. If `None`, then the search is performed up to the end of the string.

**OUTPUT:**

a non-negative integer or -1

**EXAMPLES:**

```sage
sage: w = Word([0,1,0,0,1])
sage: w.find(Word([1,0]))
1
```

The sub argument can also be a tuple or a list:

```sage
sage: w.find([1,0])
1
sage: w.find((1,0))
1
```

Examples using start and end:

```sage
sage: w.find(Word([0,1]), start=1)
3
sage: w.find(Word([0,1]), start=1, end=5)
3
sage: w.find(Word([0,1]), start=1, end=4) == -1
True
sage: w.find(Word([1,1])) == -1
True
sage: w.find("aa")
-1
```

Instances of `Word_str` handle string inputs as well:

```sage
sage: w = Word('abac')
sage: w.find('a')
0
sage: w.find('ba')
1
```

**first_pos_in**(other)

Return the position of the first occurrence of self in other, or `None` if self is not a factor of other.

**Warning:** This method is deprecated since 2020 and will be removed in a later version of SageMath. Use `first_occurrence()` instead.
EXAMPLES:

```python
sage: Word('12').first_pos_in(Word('131231'))
doctest:warning...
DeprecationWarning: f.first_pos_in(w) is deprecated.
Use w.first_occurrence(f) instead.
See https://trac.sagemath.org/30187 for details.
2
sage: Word('32').first_pos_in(Word('131231')) is None
True
```

```python
foata_bijection()

Return word `self` under the Foata bijection.

The Foata bijection $\phi$ is a bijection on the set of words of given content (by a slight generalization of Section 2 in [FS1978]). It can be defined by induction on the size of the word: Given a word $w_1 w_2 \cdots w_n$, start with $\phi(w_1) = w_1$. At the $i$-th step, if $\phi(w_1 w_2 \cdots w_i) = v_1 v_2 \cdots v_i$, we define $\phi(w_1 w_2 \cdots w_i w_{i+1})$ by placing $w_{i+1}$ on the end of the word $v_1 v_2 \cdots v_i$ and breaking the word up into blocks as follows. If $w_{i+1} \geq v_i$, place a vertical line to the right of each $v_k$ for which $w_{i+1} \geq v_k$. Otherwise, if $w_{i+1} < v_i$, place a vertical line to the right of each $v_k$ for which $w_{i+1} < v_k$. In either case, place a vertical line at the start of the word as well. Now, within each block between vertical lines, cyclically shift the entries one place to the right.

For instance, to compute $\phi([4, 1, 5, 4, 2, 2, 3])$, the sequence of words is

- $4$,
- $|4|1 \rightarrow 41$,
- $|4|15 \rightarrow 415$,
- $|415|4 \rightarrow 5414$,
- $|5|41|2 \rightarrow 54412$,
- $|5441|2|2 \rightarrow 154422$,
- $|1|5442|2|3 \rightarrow 1254423$.

So $\phi([4, 1, 5, 4, 2, 2, 3]) = [1, 2, 5, 4, 4, 2, 3]$.

See also:

Foata bijection on Permutations.
```

EXAMPLES:

```python
sage: w = Word([2,2,2,1,1,1])
sage: w.foata_bijection()
word: 112221
sage: w = Word([2,2,1,2,2,1,1,2,1])
sage: w.foata_bijection()
word: 212221221
sage: w = Word([4,1,5,4,2,2,3])
sage: w.foata_bijection()
word: 1254423
```

```python
good_suffix_table()

Return a table of the maximum skip you can do in order not to miss a possible occurrence of `self` in a word.
```
This is a part of the Boyer-Moore algorithm to find factors. See [BM1977].

EXAMPLES:

```
sage: Word('121321').good_suffix_table()
[5, 5, 5, 5, 3, 3, 1]
sage: Word('12412').good_suffix_table()
[3, 3, 3, 3, 3, 1]
```

**has_period(p)**

Return True if `self` has the period `p`, False otherwise.

**Note:** By convention, integers greater than the length of `self` are periods of `self`.

**INPUT:**

- `p` – an integer to check if it is a period of `self`.

**EXAMPLES:**

```
sage: w = Word('ababa')
sage: w.has_period(2)
True
tsage: w.has_period(3)
False
tsage: w.has_period(4)
True
tsage: w.has_period(-1)
False
tsage: w.has_period(5)
True
tsage: w.has_period(6)
True
```

**has_prefix(other)**

Test whether `self` has other as a prefix.

**INPUT:**

- `other` – a word, or data describing a word

**OUTPUT:**

boolean

**EXAMPLES:**

```
sage: w = Word("abbabaabababa")
sage: u = Word("abbab")
sage: w.has_prefix(u)
True
sage: u.has_prefix(w)
False
sage: u.has_prefix("abbab")
True
```
Combinatorics, Release 9.7

```
sage: w = Word([0,1,1,0,1,0,0,1,0,1,0,1,0])
sage: u = Word([0,1,1,0,1])
sage: w.has_prefix(u)
True
sage: u.has_prefix(w)
False
sage: u.has_prefix([0,1,1,0,1])
True
```

**has_suffix(other)**

Test whether `self` has `other` as a suffix.

**Note:** Some word datatype classes, like `WordDatatype_str`, override this method.

**INPUT:**

- `other` – a word, or data describing a word

**OUTPUT:**

boolean

**EXAMPLES:**

```
sage: w = Word("ababaabababa")
sage: u = Word("ababa")
sage: w.has_suffix(u)
True
sage: u.has_suffix(w)
False
sage: u.has_suffix("ababa")
True
```

```
sage: w = Word([0,1,1,0,1,0,0,1,0,1,0,1,0])
sage: u = Word([0,1,0,1,0])
sage: w.has_suffix(u)
True
sage: u.has_suffix(w)
False
sage: u.has_suffix([0,1,0,1,0])
True
```

**implicit_suffix_tree()**

Return the implicit suffix tree of `self`.

The suffix tree of a word `w` is a compactification of the suffix trie for `w`. The compactification removes all nodes that have exactly one incoming edge and exactly one outgoing edge. It consists of two components: a tree and a word. Thus, instead of labelling the edges by factors of `w`, we can label them by indices of the occurrence of the factors in `w`.

Type `sage.combinat.words.suffix_trees.ImplicitSuffixTree?` for more information.

**EXAMPLES:**
sage: w = Word("cacao")
sage: w.implicit_suffix_tree()
Implicit Suffix Tree of the word: cacao

sage: w = Word([0,1,0,1,1])
sage: w.implicit_suffix_tree()
Implicit Suffix Tree of the word: 01011

inv_lex_less(other)
Return True if self is inverse lexicographically less than other.

EXAMPLES:

sage: Word([1,2,4]).inv_lex_less(Word([1,3,2]))
False
sage: Word([3,2,1]).inv_lex_less(Word([1,2,3]))
True

inversions()
Return a list of the inversions of self. An inversion is a pair (i, j) of non-negative integers i < j such that self[i] > self[j].

EXAMPLES:

sage: Word([1,2,3,2,2,1]).inversions()
[[1, 5], [2, 3], [2, 4], [2, 5], [3, 5], [4, 5]]

sage: Words([3,2,1])([1,2,3,2,2,1]).inversions()
[[0, 1], [0, 2], [0, 3], [0, 4], [1, 2]]

sage: Word('abbaba').inversions()
[[1, 3], [1, 5], [2, 3], [2, 5], [4, 5]]

sage: Words('ba')('abbaba').inversions()
[[0, 1], [0, 2], [0, 4], [3, 4]]

is_balanced(q=1)
Return True if self is q-balanced, and False otherwise.

A finite or infinite word w is said to be q-balanced if for any two factors u, v of w of the same length, the difference between the number of x's in each of u and v is at most q for all letters x in the alphabet of w. A 1-balanced word is simply said to be balanced. See for instance [CFZ2000] and Chapter 2 of [Lot2002].

INPUT:

• q – integer (default: 1), the balance level

OUTPUT:

boolean – the result

EXAMPLES:

sage: Word('1213121').is_balanced()
True
sage: Word('1122').is_balanced()
False
sage: Word('121333121').is_balanced() (continues on next page)
is_cadence(seq)
Return True if seq is a cadence of self, and False otherwise.
A cadence is an increasing sequence of indexes that all map to the same letter.

EXAMPLES:

```python
sage: Word('121132123').is_cadence([0, 2, 6])
True
sage: Word('121132123').is_cadence([0, 1, 2])
False
sage: Word('121132123').is_cadence([])
True
```

is_christoffel()
Return True if self is a Christoffel word, and False otherwise.
The Christoffel word of slope \( \frac{p}{q} \) is obtained from the Cayley graph of \( \mathbb{Z}/(p + q)\mathbb{Z} \) with generator \( q \) as follows. If \( u \rightarrow v \) is an edge in the Cayley graph, then, \( v = u + p \mod p + q \). Let \( a, b \) be the alphabet of \( w \). Label the edge \( u \rightarrow v \) by \( a \) if \( u < v \) and \( b \) otherwise. The Christoffel word is the word obtained by reading the edge labels along the cycle beginning from 0.
Equivalently, \( w \) is a Christoffel word iff \( w \) is a symmetric non-empty word and \( w[1 : n - 1] \) is a palindrome.

See for instance [Ber2007] and [BLRS2009].

INPUT:
- self – word

OUTPUT:
boolean – True if self is a Christoffel word, False otherwise.

EXAMPLES:

```python
sage: Word('00100101').is_christoffel()
True
sage: Word('aab').is_christoffel()
True
sage: Word().is_christoffel()
False
sage: Word('123123123').is_christoffel()
False
sage: Word('00100').is_christoffel()
False
sage: Word('0').is_christoffel()
True
```
is_conjugate_with(other)
Return True if self is a conjugate of other, and False otherwise.

INPUT:
• other – a finite word

OUTPUT:
bool

EXAMPLES:

```
sage: w = Word([0..20])
sage: z = Word([7..20] + [0..6])
sage: w
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20
sage: z
word: 7,8,9,10,11,12,13,14,15,16,17,18,19,20,0,1,2,3,4,5,6
sage: w.is_conjugate_with(z)
True
sage: z.is_conjugate_with(w)
True
sage: u = Word([4]*21)
sage: u.is_conjugate_with(w)
False
sage: u.is_conjugate_with(z)
False
```

Both words must be finite:

```
sage: w = Word(iter([2]*100),length='unknown')
sage: z = Word([2]*100)
sage: z.is_conjugate_with(w) #TODO: Not implemented for word of unknown length
True
sage: wf = Word(iter([2]*100),length='finite')
sage: z.is_conjugate_with(wf)
True
sage: wf.is_conjugate_with(z)
True
```

is_cube()
Return True if self is a cube, and False otherwise.

EXAMPLES:

```
sage: Word('012012012').is_cube()
True
sage: Word('01010101').is_cube()
False
sage: Word().is_cube()
True
sage: Word('012012').is_cube()
False
```

is_cube_free()
Return True if self does not contain cubes, and False otherwise.
EXAMPLES:

```python
sage: Word('12312').is_cube_free()
True
sage: Word('32221').is_cube_free()
False
sage: Word().is_cube_free()
True
```

`is_empty()`

Return True if the length of `self` is zero, and False otherwise.

EXAMPLES:

```python
sage: Word([]).is_empty()
True
sage: Word('a').is_empty()
False
```

`is_factor(other)`

Return True if `self` is a factor of `other`, and False otherwise.

A finite word $u \in A^*$ is a factor of a finite word $v \in A^*$ if there exists $p, s \in A^*$ such that $v = pus$.

EXAMPLES:

```python
sage: u = Word('2113')
sage: w = Word('1231232131233121132123')
sage: u.is_factor(w)
True
sage: u = Word('321')
sage: w = Word('1231241231312312312')
sage: u.is_factor(w)
False
```

The empty word is factor of another word:

```python
sage: Word().is_factor(Word())
True
sage: Word().is_factor(Word('a'))
True
sage: Word().is_factor(Word([1,2,3]))
True
sage: Word().is_factor(Word(lambda n:n, length=5))
True
```

`is_finite()`

Return True.

EXAMPLES:

```python
sage: Word([]).is_finite()
True
sage: Word('a').is_finite()
True
```
is_full($f$=None)
Return True if self has defect 0, and False otherwise.

A word is full (or rich) if its defect is zero (see [BHNRE2004]).
If $f$ is given, then the $f$-palindromic defect is used (see [PeSt2011]).

INPUT:

- $f$ – involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism).

OUTPUT:
boolean – If $f$ is None, whether self is full; otherwise, whether self is full of $f$-palindromes.

EXAMPLES:

```
sage: words.ThueMorseWord()[:100].is_full()
False
sage: words.FibonacciWord()[:100].is_full()
True
sage: Word('000000000000000').is_full()
True
sage: Word('011010011001').is_full()
False
sage: Word('2194').is_full()
True
sage: Word().is_full()
True
```

```
sage: f = WordMorphism('a->b,b->a')
sage: Word().is_full(f)
True
sage: w = Word('ab')
sage: w.is_full()
True
sage: w.is_full(f)
True
```

```
sage: f = WordMorphism('a->b,b->a')
sage: Word('abab').is_full(f)
True
sage: Word('abba').is_full(f)
False
```

A simple example of an infinite word full of $f$-palindromes:

```
sage: p = WordMorphism({0:'abc',1:'ab'})
sage: f = WordMorphism('a->b,b->a,c->c')
sage: p(words.FibonacciWord()[:50]).is_full(f)
True
sage: p(words.FibonacciWord()[:150]).is_full(f)
True
```

is_lyndon()
Return True if self is a Lyndon word, and False otherwise.
A Lyndon word is a non-empty word that is lexicographically smaller than each of its proper suffixes (for the given order on its alphabet). That is, $w$ is a Lyndon word if $w$ is non-empty and for each factorization $w = uv$ (with $u, v$ both non-empty), we have $w < v$.

Equivalently, $w$ is a Lyndon word iff $w$ is a non-empty word that is lexicographically smaller than each of its proper conjugates for the given order on its alphabet.

See for instance [Lot1983].

EXAMPLES:

```python
sage: W = Word('123132133').is_lyndon()
True
sage: Word().is_lyndon()
False
sage: Word('122112').is_lyndon()
False
```

**is_overlap()**

Return True if self is an overlap, and False otherwise.

EXAMPLES:

```python
sage: W = Word('12121').is_overlap()
True
sage: Word('123').is_overlap()
False
sage: Word('1231').is_overlap()
False
sage: Word('123123').is_overlap()
False
sage: Word('1231231').is_overlap()
True
sage: Word().is_overlap()
False
```

**is_palindrome()**

Return True if self is a palindrome (or a $f$-palindrome), and False otherwise.

Let $f : \Sigma \to \Sigma$ be an involution that extends to a morphism on $\Sigma^*$. We say that $w \in \Sigma^*$ is a $f$-palindrome if $w = f(\tilde{w})$ [Lab2008]. Also called $f$-pseudo-palindrome [AZZ2005].

**INPUT:**

- $f$ – involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism). The default value corresponds to usual palindromes, i.e., $f$ equal to the identity.

**EXAMPLES:**

```python
sage: W = Word('esope reste ici et se repose').is_palindrome()
False
sage: Word('esoperesteicietserepose').is_palindrome()
True
sage: Word('I saw I was I').is_palindrome()
True
sage: Word('abcbba').is_palindrome()
True
```

(continues on next page)
sage: Word('abcdba').is_palindrome()
False

Some $f$-palindromes:

```
sage: f = WordMorphism('a->b,b->a')
sage: Word('aababb').is_palindrome(f)
True
```

```
sage: f = WordMorphism('a->b,b->a,c->c')
sage: Word('abacbabab').is_palindrome(f)
True
```

```
sage: f = WordMorphism({'a':'b','b':'a'})
sage: Word('aababb').is_palindrome(f)
True
```

```
sage: f = WordMorphism({0:[1],1:[0]})
sage: w = words.ThueMorseWord()[:8]; w
word: 01101001
sage: w.is_palindrome(f)
True
```

The word must be in the domain of the involution:

```
sage: f = WordMorphism('a->a')
sage: Word('aababb').is_palindrome(f)
Traceback (most recent call last):
  ... KeyError: 'b'
```

is_prefix($other$)

Return True if self is a prefix of other, and False otherwise.

```
EXAMPLES:
```

```
sage: w = Word('0123456789')
sage: y = Word('012345')
sage: y.is_prefix(w)
True
```
EXAMPLES:

```python
sage: Word('1231').is_primitive()
True
sage: Word('111').is_primitive()
False
```

**is_proper_prefix**(other)

Return True if self is a proper prefix of other, and False otherwise.

EXAMPLES:

```python
sage: Word('12').is_proper_prefix(Word('123'))
True
sage: Word('12').is_proper_prefix(Word('12'))
False
sage: Word().is_proper_prefix(Word('123'))
True
sage: Word('123').is_proper_prefix(Word('12'))
False
sage: Word().is_proper_prefix(Word())
False
```

**is_proper_suffix**(other)

Return True if self is a proper suffix of other, and False otherwise.

EXAMPLES:

```python
sage: Word('23').is_proper_suffix(Word('123'))
True
sage: Word('12').is_proper_suffix(Word('12'))
False
sage: Word().is_proper_suffix(Word('123'))
True
sage: Word('123').is_proper_suffix(Word('12'))
False
```

**is_quasiperiodic**()

Return True if self is quasiperiodic, and False otherwise.

A finite or infinite word \( w \) is **quasiperiodic** if it can be constructed by concatenations and superpositions of one of its proper factors \( u \), which is called a **quasiperiod** of \( w \). See for instance [AE1993], [Mar2004], and [GLR2008].

EXAMPLES:

```python
sage: Word('abaababaabaababaaba').is_quasiperiodic()
True
sage: Word('abacaba').is_quasiperiodic()
False
sage: Word('a').is_quasiperiodic()
False
sage: Word().is_quasiperiodic()
False
sage: Word('abaaba').is_quasiperiodic()
True
```
is_rich\((f=None)\)

Return True if self has defect 0, and False otherwise.

A word is full (or rich) if its defect is zero (see [BHNR2004]).

If f is given, then the f-palindromic defect is used (see [PeSt2011]).

INPUT:

• f – involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism).

OUTPUT:

boolean – If f is None, whether self is full; otherwise, whether self is full of f-palindromes.

EXAMPLES:

```
[sage]: words.ThueMorseWord()[:100].is_full()
False
[sage]: words.FibonacciWord()[:100].is_full()
True
[sage]: Word('000000000000000').is_full()
True
[sage]: Word('011010011001').is_full()
False
[sage]: Word('2194').is_full()
True
[sage]: Word().is_full()
True
```

```
[sage]: f = WordMorphism('a->b,b->a')
[sage]: w = Word('ab')
[sage]: w.is_full()
True
[sage]: w.is_full(f)
True
```

```
[sage]: f = WordMorphism('a->b,b->a')
[sage]: p = WordMorphism({0:'abc',1:'ab'})
[sage]: f = WordMorphism('a->b,b->a,c->c')
[sage]: p(words.FibonacciWord()[:50]).is_full(f)
True
[sage]: p(words.FibonacciWord()[:150]).is_full(f)
True
```

is_smooth_prefix()

Return True if self is the prefix of a smooth word, and False otherwise.
Let $A_k = \{1, \ldots, k\}, k \geq 2$. An infinite word $w$ in $A_k^\omega$ is said to be smooth if and only if for all positive integers $m$, $\Delta^m(w)$ is in $A_k^\omega$, where $\Delta(w)$ is the word obtained from $w$ by composing the length of consecutive runs of the same letter in $w$. See for instance [BL2003] and [BDLV2006].

**INPUT:**

- `self` – must be a word over the integers to get something other than False

**OUTPUT:**

boolean – whether `self` is a smooth prefix or not

**EXAMPLES:**

```python
sage: W = Words([1, 2])
sage: W([1, 1, 2, 2, 1, 2, 1, 1]).is_smooth_prefix()
True
sage: W([1, 2, 1, 2, 1, 2]).is_smooth_prefix()
False
```

**is_square()**

Return True if `self` is a square, and False otherwise.

**EXAMPLES:**

```python
sage: Word([1,0,0,1]).is_square()
False
sage: Word('1212').is_square()
True
sage: Word('1213').is_square()
False
sage: Word('12123').is_square()
False
sage: Word().is_square()
True
```

**is_square_free()**

Return True if `self` does not contain squares, and False otherwise.

**EXAMPLES:**

```python
sage: Word('12312').is_square_free()
True
sage: Word('31212').is_square_free()
False
sage: Word().is_square_free()
True
```

**is_sturmian_factor()**

Tell whether `self` is a factor of a Sturmian word.

The finite word `self` must be defined on a two-letter alphabet.

Equivalently, tells whether `self` is balanced. The advantage over the `is_balanced` method is that this one runs in linear time whereas `is_balanced` runs in quadratic time.

**OUTPUT:**

boolean – the result

**EXAMPLES:**
sage: w = Word('011011011011101101',alphabet='01')
sage: w.is_sturmian_factor()
True

sage: words.LowerMechanicalWord(random(),alphabet='01')[100].is_sturmian_factor()
True
sage: words.CharacteristicSturmianWord(random())[100].is_sturmian_factor()
True

sage: w = Word('aabb',alphabet='ab')
sage: w.is_sturmian_factor()
False

sage: s1 = WordMorphism('a->ab,b->b')
sage: s2 = WordMorphism('a->ba,b->b')
sage: s3 = WordMorphism('a->a,b->ba')
sage: s4 = WordMorphism('a->a,b->ab')
sage: W = Words('ab')
sage: w = W('ab')
sage: for i in range(8): w = choice([s1,s2,s3,s4])(w)
sage: w.is_sturmian_factor()
True

Famous words:

sage: words.FibonacciWord()[100].is_sturmian_factor()
True
sage: words.ThueMorseWord()[1000].is_sturmian_factor()
False
sage: words.KolakoskiWord()[1000].is_sturmian_factor()
False

See [Arn2002], [Ser1985], and [SU2009].

AUTHOR:

• Thierry Monteil

is_subword_of(other)

Return True if self is a subword of other, and False otherwise.

A finite word u is a subword of a finite word v if u is a subsequence of v. See Chapter 6 on Subwords in [Lot1997].

Some references define subword as a consecutive subsequence. Use is_factor() if this is what you need.

INPUT:

other – a finite word

EXAMPLES:

sage: Word('bb').is_subword_of(Word('ababa'))
True
sage: Word('bbb').is_subword_of(Word('ababa'))
False
sage: Word().is_subword_of(Word('123'))
True
sage: Word('123').is_subword_of(Word('3211333213233321'))
True
sage: Word('321').is_subword_of(Word('11122212112213311222332'))
False

See also:

`longest_common_subword()` `number_of_subword_occurrences()` `is_factor()`

**is_suffix**(other)

Return True if self is a suffix of other, and False otherwise.

EXAMPLES:

```python
sage: w = Word('0123456789')
sage: y = Word('56789')
sage: y.is_suffix(w)
True
sage: w.is_suffix(y)
False
sage: Word('579').is_suffix(w)
False
sage: Word().is_suffix(y)
True
sage: w.is_suffix(Word())
False
sage: Word().is_suffix(Word())
True
```

**is_symmetric**(f=None)

Return True if self is symmetric (or f-symmetric), and False otherwise.

A word is symmetric (resp. f-symmetric) if it is the product of two palindromes (resp. f-palindromes). See [BHNR2004] and [DeLuca2006].

INPUT:

- f – involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. `WordMorphism`).

EXAMPLES:

```python
sage: Word('abbabab').is_symmetric()
True
sage: Word('ababa').is_symmetric()
True
sage: Word('aababaabba').is_symmetric()
False
sage: Word('aabbbaabba').is_symmetric()
False
sage: f = WordMorphism('a->b,b->a')
sage: Word('aabbbaabba').is_symmetric(f)
True
```
is_tangent()
Tell whether self is a tangent word.

The finite word self must be defined on a two-letter alphabet.

A binary word is said to be tangent if it can appear in infinitely many cutting sequences of a smooth curve, where each cutting sequence is observed on a progressively smaller grid.

This class of words strictly contains the class of 1-balanced words, and is strictly contained in the class of 2-balanced words.

This method runs in linear time.

OUTPUT:
boolean – the result

EXAMPLES:

sage: w = Word('01101101110111011101',alphabet='01')
sage: w.is_tangent()
True

Some tangent words may not be balanced:

sage: Word('aabb',alphabet='ab').is_balanced()
False
sage: Word('aabb',alphabet='ab').is_tangent()
True

Some 2-balanced words may not be tangent:

sage: Word('aaabb',alphabet='ab').is_tangent()
False
sage: Word('aaabb',alphabet='ab').is_balanced(2)
True

Famous words:

sage: words.FibonacciWord()[:100].is_tangent()
True
sage: words.ThueMorseWord()[:1000].is_tangent()
True
sage: words.KolakoskiWord()[:1000].is_tangent()
False

See [Mon2010].

AUTHOR:
• Thierry Monteil

is_yamanouchi(n=None)
Return whether self is Yamanouchi.

A word w is Yamanouchi if, when read from right to left, it always has weakly more i's than i + 1's for all i that appear in w.

INPUT:
• n – (optional) an integer specifying the maximal letter in the alphabet
EXAMPLES:

```python
sage: w = Word([1,2,4,3,2,2,2])
sage: w.is_yamanouchi()
False
sage: w = Word([2,3,4,3,1,2,1,1,2,1])
sage: w.is_yamanouchi()
True
sage: w = Word([3,1])
sage: w.is_yamanouchi(n=3)
False
sage: w.is_yamanouchi()
True
sage: w = Word([3,1],alphabet=[1,2,3])
sage: w.is_yamanouchi()
False
sage: w = Word([2,1,1,2])
sage: w.is_yamanouchi()
False
```

**iterated_left_palindromic_closure** *(f=None)*

Return the iterated left \(f\)-palindromic closure of self.

**INPUT:**

- \(f\) – involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism).

**OUTPUT:**

word – the left iterated \(f\)-palindromic closure of self.

**EXAMPLES:**

```python
sage: Word('123').iterated_left_palindromic_closure()
word: 3231323
sage: f = WordMorphism('a->b,b->a')
sage: Word('ab').iterated_left_palindromic_closure(f=f)
word: abbaab
sage: Word('aab').iterated_left_palindromic_closure(f=f)
word: abbaabbaab
```

**lacunas** *(f=None)*

Return the list of all the lacunas of self.

A lacuna is a position in a word where the longest \((f)\)-palindromic suffix is not unioccurrent (see [BMBL2008]).

**INPUT:**

- \(f\) – involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism). The default value corresponds to usual palindromes, i.e., \(f\) equal to the identity.

**OUTPUT:**

a list – list of all the lacunas of self

**EXAMPLES:**
Combinatorics, Release 9.7

```
sage: w = Word([0,1,1,2,3,4,5,1,13,3])
sage: w.lacunas()
[7, 9]
sage: words.ThueMorseWord()[:100].lacunas()
[8, 9, 24, 25, 32, 33, 34, 35, 36, 37, 38, 39, 96, 97, 98, 99]
sage: f = WordMorphism({0:[1],1:[0]})
sage: words.ThueMorseWord()[:50].lacunas(f)
[0, 2, 4, 12, 16, 17, 18, 19, 48, 49]
```

last_position_dict()

Return a dictionary that contains the last position of each letter in self.

EXAMPLES:

```
sage: Word('1231232').last_position_dict()
{'1': 3, '2': 6, '3': 5}
```

left_special_factors(n=None)

Return the left special factors (of length n).

A factor u of a word w is left special if there are two distinct letters a and b such that au and bu are factors of w.

INPUT:

• n – integer (optional, default: None). If None, it returns all left special factors.

OUTPUT:

a list of words

EXAMPLES:

```
sage: alpha, beta, x = 0.54, 0.294, 0.1415
sage: w = words.CodingOfRotationWord(alpha, beta, x)[:40]
sage: for i in range(5):
    ....:     print("{} {}\n    0 [word: ]
    1 [word: 0]
    2 [word: 00, word: 01]
    3 [word: 000, word: 010]
    4 [word: 0000, word: 0101]
```

left_special_factors_iterator(n=None)

Return an iterator over the left special factors (of length n).

A factor u of a word w is left special if there are two distinct letters a and b such that au and bu are factors of w.

INPUT:

• n – integer (optional, default: None). If None, it returns an iterator over all left special factors.

EXAMPLES:

```
sage: alpha, beta, x = 0.54, 0.294, 0.1415
sage: w = words.CodingOfRotationWord(alpha, beta, x)[:40]
sage: sorted(w.left_special_factors_iterator(3))
[word: 000, word: 010]
```
sage: sorted(w.left_special_factors_iterator(4))
[word: 0000, word: 0101]
sage: sorted(w.left_special_factors_iterator(5))
[word: 00000, word: 01010]

length()
Return the length of self.

length_border()
Return the length of the border of self.
The border of a word is the longest word that is both a proper prefix and a proper suffix of self.

EXAMPLES:

sage: Word('121').length_border()
1
sage: Word('1').length_border()
0
sage: Word('1212').length_border()
2
sage: Word('111').length_border()
2
sage: Word().length_border() is None
True

length_maximal_palindrome(j, m=None, f=None)
Return the length of the longest palindrome centered at position j.

INPUT:

• j – rational, position of the symmetry axis of the palindrome. Must return an integer when doubled. It is an integer when the center of the palindrome is a letter.

• m – integer (default: None), minimal length of palindrome, if known. The parity of m can’t be the same as the parity of 2j.

• f – involution (default: None), on the alphabet. It must be callable on letters as well as words (e.g. WordMorphism).

OUTPUT:

length of the longest f-palindrome centered at position j

EXAMPLES:

sage: Word('01001010').length_maximal_palindrome(3/2)
0
sage: Word('01101001').length_maximal_palindrome(3/2)
4
sage: Word('01010').length_maximal_palindrome(j=3, f='0->1,1->0')
0
sage: Word('01010').length_maximal_palindrome(j=2.5, f='0->1,1->0')
4
sage: Word('0222220').length_maximal_palindrome(3, f='0->1,1->0,2->2')
5
Combinatorics, Release 9.7

```python
sage: w = Word('abcdcbaxyzzxyx')
sage: w.length_maximal_palindrome(3)
7
sage: w.length_maximal_palindrome(3, 3)
7
sage: w.length_maximal_palindrome(3.5)
0
sage: w.length_maximal_palindrome(9.5)
6
sage: w.length_maximal_palindrome(9.5, 2)
6
```

**lengths_maximal_palindromes** *(f=None)*

Return the length of maximal palindromes centered at each position.

**INPUT:**

• f – involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism).

**OUTPUT:**

a list – The length of the maximal palindrome (or f-palindrome) with a given symmetry axis (letter or space between two letters).

**EXAMPLES:**

```python
sage: Word('01101001').lengths_maximal_palindromes()
[0, 1, 0, 1, 4, 1, 0, 3, 0, 3, 0, 1, 4, 1, 0, 1, 0]
sage: Word('00000').lengths_maximal_palindromes()
[0, 1, 2, 3, 4, 5, 4, 3, 2, 1, 0]
sage: Word('0').lengths_maximal_palindromes()
[0, 1, 0]
sage: Word('').lengths_maximal_palindromes()
[0]
sage: f = WordMorphism('a->b,b->a')
sage: Word('abbabaab').lengths_maximal_palindromes(f)
[0, 0, 2, 0, 0, 0, 2, 0, 8, 0, 2, 0, 0, 0, 2, 0, 0]
```

**lengths_unioccurrent_lps** *(f=None)*

Return the list of the lengths of the unioccurrent longest (f)-palindromic suffixes (lps) for each non-empty prefix of self. No unioccurrent lps are indicated by None.

It corresponds to the function $H_w$ defined in [BMBL2008] and [BMBFLR2008].

**INPUT:**

• f – involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism). The default value corresponds to usual palindromes, i.e., f equal to the identity.

**OUTPUT:**

a list – list of the length of the unioccurrent longest palindromic suffix (lps) for each non-empty prefix of self. No unioccurrent lps are indicated by None.

**EXAMPLES:**

```python
```
sage: w = Word([0,1,1,2,3,4,5,1,13,3])
sage: w.lengths_unioccurrent_lps()
[1, 1, 2, 1, 1, 1, None, 1, None]
sage: f = words.FibonacciWord()[:20]
sage: f.lengths_unioccurrent_lps() == f.lps_lengths()[1:]
True
sage: t = words.ThueMorseWord()
sage: t[:20].lengths_unioccurrent_lps()
[1, 1, 2, 4, 3, 3, 2, 4, None, None, 6, 8, 10, 12, 14, 16, 6, 8, 10, 12]
sage: f = WordMorphism({1:[0],0:[1]})
sage: t[:15].lengths_unioccurrent_lps(f)
[None, 2, None, 2, None, 4, 6, 8, 4, 6, 4, 6, None, 4, 6]

letters()
Return the list of letters that appear in this word, listed in the order of first appearance.

EXAMPLES:

sage: Word([0,1,1,0,1,0,0,1]).letters()
[0, 1]
sage: Word("cacao").letters()
['c', 'a', 'o']

longest_backward_extension(x, y)
Compute the length of the longest factor of self that ends at x and that matches a factor that ends at y.

INPUT:

• x, y – positions in self

EXAMPLES:

sage: w = Word('0011001')
sage: w.longest_backward_extension(6, 2)
3
sage: w.longest_backward_extension(1, 4)
1
sage: w.longest_backward_extension(1, 3)
0

The method also accepts negative positions indicating the distance from the end of the word (in order to be consistent with how negative indices work with lists). For instance, for a word of length 7, using positions 6 and −5 is the same as using positions 6 and 2:

sage: w.longest_backward_extension(6, -5)
3
sage: w.longest_backward_extension(-6, 4)
1

longest_common_subword(other)
Return a longest subword of self and other.

A subword of a word is a subset of the word’s letters, read in the order in which they appear in the word.

For more information, see Wikipedia article Longest_common_subsequence_problem.

INPUT:
• other – a word

ALGORITHM:
For any indices $i, j$, we compute the longest common subword $lcs[i, j]$ of $self[:i]$ and $other[:j]$. This can be easily obtained as the longest of
• $lcs[i-1, j]$
• $lcs[i, j-1]$
• $lcs[i-1, j-1] + self[i]$ if $self[i] == other[j]$

EXAMPLES:

```
sage: v1 = Word("abc")
sage: v2 = Word("ace")
sage: v1.longest_common_subword(v2)
word: ac
```

```
sage: w1 = Word("1010101010101010101010101010101010101010")
sage: w2 = Word("00110011001100110011001100110011")
sage: w1.longest_common_subword(w2)
word: 00110011001100110011010101010
```

See also:

is_subword_of()

longest_common_suffix(other)
Return the longest common suffix of $self$ and $other$.

EXAMPLES:

```
sage: w = Word('112345678')
sage: u = Word('1115678')
sage: w.longest_common_suffix(u)
word: 5678
```

```
sage: w.longest_common_suffix(w)
word: 112345678
```

```
sage: y = Word('549332345')
sage: w.longest_common_suffix(y)
word: 
```

longest_forward_extension(x, y)
Compute the length of the longest factor of $self$ that starts at $x$ and that matches a factor that starts at $y$.

INPUT:
• $x, y$ – positions in $self$

EXAMPLES:

```
sage: w = Word('0011001')
sage: w.longest_forward_extension(0, 4)
3
```

(continues on next page)
The method also accepts negative positions indicating the distance from the end of the word (in order to be consist with how negative indices work with lists). For instance, for a word of length 7, using positions $-3$ and 2 is the same as using positions 4 and 2:

\[
\begin{array}{l}
sage: w.longest_forward_extension(1, -2) \\
2 \\
sage: w.longest_forward_extension(4, -3) \\
3
\end{array}
\]

\texttt{lps}($f=\text{None}, l=\text{None}$)

Return the longest palindromic (or $f$-palindromic) suffix of \texttt{self}.

\textbf{INPUT:}

- \texttt{f} – involution (default: \texttt{None}) on the alphabet of \texttt{self}. It must be callable on letters as well as words (e.g. \texttt{WordMorphism}).
- \texttt{l} – integer (default: \texttt{None}) the length of the longest palindrome suffix of `\texttt{self[:-1]}` , if known.

\textbf{OUTPUT:}

\texttt{word} – If \texttt{f} is \texttt{None}, the longest palindromic suffix of \texttt{self}; otherwise, the longest \texttt{f}-palindromic suffix of \texttt{self}.

\textbf{EXAMPLES:}

\[
\begin{array}{l}
sage: Word('0111').lps() \\
word: 111 \\
sage: Word('011101').lps() \\
word: 101 \\
sage: Word('6667').lps() \\
word: 7 \\
sage: Word('abbabaab').lps() \\
word: baab \\
sage: Word().lps() \\
word: \\
sage: f = WordMorphism('a->b,b->a') \\
sage: Word('abbabaab').lps(f=f) \\
word: abbabaab \\
sage: w = Word('33412321') \\
sage: w.lps(l=3) \\
word: 12321 \\
sage: Y = Word \\
sage: w = Y('01101001') \\
sage: w.lps(l=2) \\
word: 1001 \\
sage: w.lps() \\
word: 1001 \\
sage: w.lps(l=\text{None}) \\
word: 1001 \\
sage: Y().lps(l=2) \\
\end{array}
\]
...  
IndexError: list index out of range
sage: v = Word('abbabaab')
sage: pal = v[:0]
sage: for i in range(1, v.length()+1):
    ....: pal = v[:i].lps(l=pal.length())
    ....: pal
word: a
word: b
word: bb
word: abba
word: bab
word: aba
word: aa
word: baab
sage: f = WordMorphism('a->b,b->a')
sage: v = Word('abbabaab')
sage: pal = v[:0]
sage: for i in range(1, v.length()+1):
    ....: pal = v[:i].lps(f=f, l=pal.length())
    ....: pal
word: ab
word: ba
word: ab
word: baba
word: bbabaa
word: abbabaab

lps_lengths(f=None)
Return the length of the longest palindromic suffix of each prefix.

INPUT:

- f – involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism).

OUTPUT:

a list – The length of the longest palindromic (or f-palindromic) suffix of each prefix of self.

EXAMPLES:

sage: Word('01101001').lps_lengths()
[0, 1, 1, 2, 4, 3, 3, 2, 4]
sage: Word('00000').lps_lengths()
[0, 1, 2, 3, 4, 5]
sage: Word('0').lps_lengths()
[0, 1]
sage: Word('').lps_lengths()
[0]
sage: f = WordMorphism('a->b,b->a')
Combinatorics, Release 9.7

sage: Word('abbabaab').lps_lengths(f)
[0, 0, 2, 0, 2, 2, 4, 6, 8]

lyndon_factorization()

Return the Lyndon factorization of self.

The Lyndon factorization of a finite word $w$ is the unique factorization of $w$ as a non-increasing product of Lyndon words, i.e., $w = l_1 \cdots l_n$ where each $l_i$ is a Lyndon word and $l_1 \geq \cdots \geq l_n$. See for instance [Duv1983].

OUTPUT:

the list $[l_1, \ldots, l_n]$ of factors obtained

EXAMPLES:

sage: Word('010010010001000').lyndon_factorization()
(01, 001, 001, 0001, 0, 0, 0)
sage: Words('10')('010010010001000').lyndon_factorization()
(0, 10010010001000)
sage: Word('abababaababba').lyndon_factorization()
(abb, ababb, aababb, a)
sage: Words('ba')('abababaababba').lyndon_factorization()
(a, bbabbaaba, bba)
sage: Word([1,2,1,3,1,2,1]).lyndon_factorization()
(1213, 12, 1)

major_index(final_descent=False)

Return the major index of self.

The major index of a word $w$ is the sum of the descents of $w$.

With the final_descent option, the last position of a non-empty word is also considered as a descent.

See also:

major index on Permutations.

EXAMPLES:

sage: w = Word([2,1,3,3,2])
sage: w.major_index()
5
sage: w = Word([2,1,3,3,2])
sage: w.major_index(final_descent=True)
10

minimal_conjugate()

Return the lexicographically minimal conjugate of this word (see Wikipedia article Lexicographically_minimal_string_rotation).

EXAMPLES:

sage: Word('213').minimal_conjugate()
word: 132
sage: Word('11').minimal_conjugate()
word: 11

(continues on next page)
mineral_period()

Return the period of self.

Let $A$ be an alphabet. An integer $p \geq 1$ is a period of a word $w = a_1a_2 \cdots a_n$ where $a_i \in A$ if $a_i = a_{i+p}$ for $i = 1, \ldots, n - p$. The smallest period of $w$ is called the period of $w$. See Chapter 1 of [Lot2002].

EXAMPLES:

```python
sage: Word('aba').minimal_period()
2
sage: Word('abab').minimal_period()
2
sage: Word('ababa').minimal_period()
2
sage: Word('ababaa').minimal_period()
5
sage: Word('ababac').minimal_period()
6
sage: Word('aaaaa').minimal_period()
1
sage: Word('a').minimal_period()
1
sage: Word().minimal_period()
1
```

nb_factor_occurrences_in(other)

Return the number of times self appears as a factor in other.

**Warning:** This method is deprecated since 2020 and will be removed in a later version of SageMath. Use `number_of_factor_occurrences()` instead.

EXAMPLES:

```python
sage: Word('123').nb_factor_occurrences_in(Word('112332312313112332121123'))
doctest:warning
... DeprecationWarning: f.nb_factor_occurrences_in(w) is deprecated.
Use w.number_of_factor_occurrences(f) instead.
See https://trac.sagemath.org/30187 for details.
4
sage: Word('321').nb_factor_occurrences_in(Word('1123323123131123322121123'))
0
```

An error is raised for the empty word:
Combinatorics, Release 9.7

```python
sage: Word().nb_factor_occurrences_in(Word('123'))
Traceback (most recent call last):
...
NotImplementedError: The factor must be non empty
```

**nb_subword_occurrences_in**(other)

Return the number of times self appears in other as a subword.

This corresponds to the notion of binomial coefficient of two finite words whose properties are presented in the chapter of Lothaire’s book written by Sakarovitch and Simon [Lot1997].

**Warning:** This method is deprecated since 2020 and will be removed in a later version of SageMath. Use `number_of_subword_occurrences()` instead.

**INPUT:**

* other – finite word

**EXAMPLES:**

```python
sage: tm = words.ThueMorseWord()
sage: u = Word([0,1,0,1])
sage: u.nb_subword_occurrences_in(tm[:1000])
doctest:warning
...
DeprecationWarning: f.nb_subword_occurrences_in(w) is deprecated.
Use w.number_of_subword_occurrences(f) instead.
See https://trac.sagemath.org/30187 for details.
2604124996
sage: u = Word([0,1,0,1,1,0])
sage: u.nb_subword_occurrences_in(tm[:100])
20370432
```

**Note:** This code, based on [MSSY2001], actually compute the number of occurrences of all prefixes of self as subwords in all prefixes of other. In particular, its complexity is bounded by `len(self) * len(other)`.

**number_of_factor_occurrences**(other)

Return the number of times other appears as a factor in self.

**INPUT:**

other – a non empty word

**EXAMPLES:**

```python
sage: w = Word('112332312313112332121123')
sage: w.number_of_factor_occurrences(Word('123'))
4
sage: w = Word('11233231231311233221123')
sage: w.number_of_factor_occurrences(Word('321'))
0
```
Combinatorics, Release 9.7

```python
sage: Word().number_of_factor_occurrences(Word('123'))
0
```

An error is raised for the empty word:

```python
sage: Word('123').number_of_factor_occurrences(Word(''))
Traceback (most recent call last):
  ...
NotImplementedError: The factor must be non empty
```

**number_of_factors** (*n=*, None, algorithm='suffix tree')

Count the number of distinct factors of self.

**INPUT:**

- *n* – an integer, or None.
- *algorithm* – string (default: 'suffix tree'), takes the following values:
  - 'suffix tree' – construct and use the suffix tree of the word
  - 'naive' – algorithm uses a sliding window

**OUTPUT:**

If *n* is an integer, returns the number of distinct factors of length *n*. If *n* is None, returns the total number of distinct factors.

**EXAMPLES:**

```python
sage: w = Word([1,2,1,2,3])
sage: w.number_of_factors()
13
sage: [w.number_of_factors(i) for i in range(6)]
[1, 3, 3, 3, 2, 1]

sage: w = words.ThueMorseWord()[:100]
sage: [w.number_of_factors(i) for i in range(10)]
[1, 2, 4, 6, 10, 12, 16, 20, 22, 24]

sage: Word('1213121').number_of_factors()
22
sage: Word('1213121').number_of_factors(1)
3

sage: Word('a'*100).number_of_factors()
101
sage: Word('a'*100).number_of_factors(77)
1

sage: Word().number_of_factors()
1
sage: Word().number_of_factors(17)
0
```
sage: blueberry = Word("blueberry")
sage: blueberry.number_of_factors()
43
sage: [blueberry.number_of_factors(i) for i in range(10)]
[1, 6, 8, 7, 6, 5, 4, 3, 2, 1]

number_of_inversions()
Return the number of inversions in self.
An inversion of a word \( w = w_1 \ldots w_n \) is a pair of indices \( (i, j) \) with \( i < j \) and \( w_i > w_j \).

See also:
number of inversions on Permutations.

EXAMPLES:

sage: w = Word([2,1,3,3,2])
sage: w.number_of_inversions()
3

number_of_left_special_factors(n)
Return the number of left special factors of length \( n \).
A factor \( u \) of a word \( w \) is left special if there are two distinct letters \( a \) and \( b \) such that \( au \) and \( bu \) are factors of \( w \).

INPUT:
- \( n \) – integer

OUTPUT:
a non-negative integer

EXAMPLES:

sage: w = words.FibonacciWord()[:100]
sage: [w.number_of_left_special_factors(i) for i in range(10)]
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: w = words.ThueMorseWord()[:100]
sage: [w.number_of_left_special_factors(i) for i in range(10)]
[1, 2, 2, 4, 2, 4, 4, 2, 2, 4]

number_of_letter_occurrences(letter)
Return the number of occurrences of letter in self.

INPUT:
- letter - a letter

OUTPUT:
- integer

EXAMPLES:

sage: w = Word('abbabaab')
sage: w.number_of_letter_occurrences('a')
5

(continues on next page)
This method is equivalent to \( \text{list}(w).\text{count}(\text{letter}) \) and \( \text{tuple}(w).\text{count}(\text{letter}) \), thus \text{count} is an alias for the method \text{number_of_letter_occurrences}:

```python
sage: list(w).count('a')
4
sage: w.count('a')
4
```

But notice that if \( s \) and \( w \) are strings, \( \text{Word}(s).\text{count}(w) \) counts the number occurrences of \( w \) as a letter in \( \text{Word}(s) \) which is not the same as \( s.\text{count}(w) \) which counts the number of occurrences of the string \( w \) inside \( s \):

```python
sage: s = 'abbabaab'
sage: s.count('ab')
3
sage: Word(s).count('ab')
0
```

See also:

`sage.combinat.words.finite_word.FiniteWord_class.number_of_factor_occurrences()`

\textbf{number_of_right_special_factors}(n)

Return the number of right special factors of length \( n \).

A factor \( u \) of a word \( w \) is \textit{right special} if there are two distinct letters \( a \) and \( b \) such that \( ua \) and \( ub \) are factors of \( w \).

INPUT:

- \( n \) – integer

OUTPUT:

a non-negative integer

EXAMPLES:

```python
sage: w = words.FibonacciWord()[:100]
sage: [w.number_of_right_special_factors(i) for i in range(10)]
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
```

```python
sage: w = words.ThueMorseWord()[:100]
sage: [w.number_of_right_special_factors(i) for i in range(10)]
[1, 2, 4, 2, 4, 4, 2, 2, 4]
```

\textbf{number_of_subword_occurrences}(other)

Return the number of times \( other \) appears in \( \text{self} \) as a subword.

This corresponds to the notion of \textit{binomial coefficient} of two finite words whose properties are presented in the chapter of Lothaire’s book written by Sakarovitch and Simon [Lot1997].

INPUT:

- \( other \) – finite word
EXAMPLES:

```python
sage: tm = words.ThueMorseWord()
sage: u = Word([0,1,0,1])
sage: tm[:1000].number_of_subword_occurrences(u)
2604124996
sage: u = Word([0,1,0,1,1,0])
sage: tm[:100].number_of_subword_occurrences(u)
20370432
```

**Note:** This code, based on [MSSY2001], actually computes the number of occurrences of all prefixes of `self` as subwords in all prefixes of `other`. In particular, its complexity is bounded by `len(self) * len(other)`.

---

**order()**

Return the order of `self`.

Let \( p(w) \) be the period of a word \( w \). The positive rational number \( |w|/p(w) \) is the *order* of \( w \). See Chapter 8 of [Lot2002].

**OUTPUT:**

c Rational – the order

**EXAMPLES:**

```python
sage: Word('abaaba').order()
2
sage: Word('ababaaba').order()
8/5
sage: Word('a').order()
1
sage: Word('aa').order()
2
sage: Word().order()
0
```

---

**overlap_partition**(other, delay=0, p=None, involution=None)

Return the partition of the alphabet induced by the overlap of `self` and `other` with the given delay.

The partition of the alphabet is given by the equivalence relation obtained from the symmetric, reflexive and transitive closure of the set of pairs of letters \( R_{u,v,d} = \{(u_k, v_{k-d}) : 0 \leq k < n, 0 \leq k - d < m\} \) where \( u = u_0u_1\cdots u_{n-1}, v = v_0v_1\cdots v_{m-1} \) are two words on the alphabet \( A \) and \( d \) is an integer.

The equivalence relation defined by \( R \) is inspired from [Lab2008].

**INPUT:**

- **other** – word on the same alphabet as `self`

- **delay** – integer (default: 0)

- **p** – disjoint sets data structure (optional, default: `None`), a partition of the alphabet into disjoint sets to start with. If `None`, each letter start in distinct equivalence classes.

- **involution** – callable (optional, default: `None`), an involution on the alphabet. If `involution` is not `None`, the relation \( R_{u,v,d} \cup R_{\text{involution}(u),\text{involution}(v),d} \) is considered.
OUTPUT:

a disjoint set data structure

EXAMPLES:

```
sage: W = Words(list('abc012345'))
sage: u = W('abc')
sage: v = W('01234')
sage: u.overlap_partition(v)
{{'0', 'a'}, {'1', 'b'}, {'2', 'c'}, {'3'}, {'4'}, {'5'}}
sage: u.overlap_partition(v, 2)
{{'0', 'c'}, {'1'}, {'2'}, {'3'}, {'4', '5'}, {'a'}, {'b'}}
sage: u.overlap_partition(v, -1)
{{'0'}, {'1', 'a'}, {'2'}, {'3', 'c'}, {'4'}, {'5'}}
```

You can re-use the same disjoint set and do more than one overlap:

```
sage: p = u.overlap_partition(v, 2)
sage: p
{{'0', 'c'}, {'1'}, {'2'}, {'3'}, {'4'}, {'5'}, {'a'}, {'b'}}
sage: u.overlap_partition(v, 1, p)
{{'0', '1', 'b', 'c'}, {'2'}, {'3'}, {'4'}, {'5'}, {'a'}}
```

The function `overlap_partition` can be used to study equations on words. For example, if a word $w$ overlaps itself with delay $d$, then $d$ is a period of $w$:

```
sage: W = Words(range(20))
sage: w = W(range(14)); w
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13
sage: d = 5
sage: p = w.overlap_partition(w, d)
sage: m = WordMorphism(p.element_to_root_dict())
sage: w2 = m(w); w2
word: 56789567895678
sage: w2.minimal_period() == d
True
```

If a word is equal to its reversal, then it is a palindrome:

```
sage: W = Words(range(20))
sage: w = W(range(17)); w
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16
sage: p = w.overlap_partition(w.reversal(), 0)
sage: m = WordMorphism(p.element_to_root_dict())
sage: w2 = m(w); w2
word: 01234567876543210
sage: w2.parent()
Finite words over {0, 1, 2, 3, 4, 5, 6, 7, 8, 17, 18, 19}
sage: w2.is_palindrome()
True
```

If the reversal of a word $w$ is factor of its square $w^2$, then $w$ is symmetric, i.e. the product of two palindromes:

```
sage: W = Words(range(20))
sage: w = W(range(17)); w
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16
sage: p = w.overlap_partition(w.reversal(), 0)
sage: m = WordMorphism(p.element_to_root_dict())
sage: w2 = m(w); w2
word: 01234567876543210
sage: w2.parent()
Finite words over {0, 1, 2, 3, 4, 5, 6, 7, 8, 17, 18, 19}
sage: w2.is_palindrome()
True
```
sage: W = Words(range(10))
sage: w = W(range(10)); w
word: 0123456789

sage: p = (w*w).overlap_partition(w.reversal(), 4)
sage: m = WordMorphism(p.element_to_root_dict())
sage: w2 = m(w); w2
word: 0110456654

sage: w2.is_symmetric()
True

If the image of the reversal of a word \( w \) under an involution \( f \) is factor of its square \( w^2 \), then \( w \) is \( f \)-symmetric:

sage: W = Words([-11,-9,...,11])
sage: w = W([1,3,...,11])
sage: w
word: 1,3,5,7,9,11

sage: inv = lambda x:-x
sage: f = WordMorphism(dict( (a, inv(a)) for a in W.alphabet()))
sage: p = (w*w).overlap_partition(f(w).reversal(), 2, involution=f)
sage: m = WordMorphism(p.element_to_root_dict())
sage: m(w)
word: 1,-1,5,7,-7,-5

sage: m(w).is_symmetric(f)
True

palindrome_prefixes()
Return a list of all palindrome prefixes of self.

OUTPUT:
a list – A list of all palindrome prefixes of self.

EXAMPLES:

sage: w = Word('abaaba')

sage: w.palindrome_prefixes()
[word:, word: a, word: aba, word: abaaba]

sage: w = Word('abbbbbbbbb')

sage: w.palindrome_prefixes()
[word:, word: a]

palindromes(f=None)
Return the set of all palindromic (or \( f \)-palindromic) factors of self.

INPUT:
• \( f \) – involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism).

OUTPUT:
a set – If \( f \) is None, the set of all palindromic factors of self; otherwise, the set of all \( f \)-palindromic factors of self.

EXAMPLES:
sage: sorted(Word('01101001').palindromes())
[word: , word: 0, word: 00, word: 010, word: 0110, word: 1, word: 1001, word: ˓→101, word: 11]
sage: sorted(Word('00000').palindromes())
[word: , word: 0, word: 00, word: 000, word: 0000, word: 00000]
sage: sorted(Word('').palindromes())
[word: ]
sage: f = WordMorphism('a->b,b->a')
sage: sorted(Word('abbabaab').palindromes(f))
[word: , word: ab, word: abbbabaab, word: ba, word: baba, word: bbababaa]

palindromic_closure(side='right', f=None)
Return the shortest palindrome having self as a prefix (or as a suffix if side is 'left').
See [DeLuca2006].

INPUT:
- side – 'right' or 'left' (default: 'right') the direction of the closure
- f – involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism).

OUTPUT:
a word – If f is None, the right palindromic closure of self; otherwise, the right f-palindromic closure of self. If side is 'left', the left palindromic closure.

EXAMPLES:

sage: Word('1233').palindromic_closure()
word: 123321
sage: Word('12332').palindromic_closure()
word: 123321
sage: Word('0110343').palindromic_closure()
word: 01103430110
sage: Word('0110343').palindromic_closure(side='left')
word: 3430110343
sage: Word('01105678').palindromic_closure(side='left')
word: 876501105678
sage: w = Word('abbabaab')
sage: w.palindromic_closure()
word: abbababba

sage: f = WordMorphism('a->b,b->a')
sage: w.palindromic_closure(f=f)
word: abbabaab
sage: w.palindromic_closure(f=f, side='left')
word: babaabbaba

palindromic_complexity(n)
Return the number of distinct palindromic factors of length n of self.
INPUT:

- \( n \) – the length of the factors.

EXAMPLES:

```
sage: w = words.FibonacciWord()[:100]
sage: [w.palindromic_complexity(i) for i in range(20)]
[1, 2, 1, 2, 1, 2, 1, 2, 1, 2, 1, 2, 1, 2, 1, 2, 1, 2, 1, 2]
sage: w = words.ThueMorseWord()[:1000]
sage: [w.palindromic_complexity(i) for i in range(20)]
[1, 2, 2, 2, 2, 0, 4, 0, 4, 0, 4, 0, 4, 0, 2, 0, 2, 0, 4, 0]
```

`palindromic_lacunas_study(f=None)`

Return interesting statistics about longest \((f-)\)palindromic suffixes and lacunas of \( \text{self} \) (see [BMBL2008] and [BMBFLR2008]).

Note that a word \( w \) has at most \(|w| + 1 \) different palindromic factors (see [DJP2001]). For \( f \)-palindromes (or pseudopalindromes or theta-palindromes), the maximum number of \( f \)-palindromic factors is \(|w| + 1 - g_f(w) \), where \( g_f(w) \) is the number of pairs \( \{a, f(a)\} \) such that \( a \) is a letter, \( a \) is not equal to \( f(a) \), and \( a \) or \( f(a) \) occurs in \( w \), see [Star2011].

INPUT:

- \( f \) – involution (default: None) on the alphabet of \( \text{self} \). It must be callable on letters as well as words (e.g. `WordMorphism`). The default value corresponds to usual palindromes, i.e., \( f \) equal to the identity.

OUTPUT:

- list – list of the length of the longest palindromic suffix (lps) for each non-empty prefix of \( \text{self} \)
- list – list of all the lacunas, i.e. positions where there is no unioccurrent lps
- set – set of palindromic factors of \( \text{self} \)

EXAMPLES:

```
sage: a,b,c = Word('abbaabbaa').palindromic_lacunas_study()
sage: a
[1, 1, 2, 4, 3, 3, 2, 4, 2, 4, 6, 8]
sage: b
[8, 9]
sage: c # random order
set([word: , word: b, word: bab, word: abba, word: bb, word: aa, word: baabbaab, word: bab, word: aba, word: aabbaa, word: a])
sage: f = WordMorphism('a->b,b->a')
sage: a,b,c = Word('abbaabbaa').palindromic_lacunas_study(f=f)
sage: a
[0, 2, 0, 2, 2, 4, 6, 8]
sage: b
[0, 2, 4]
sage: c # random order
set([word: , word: ba, word: baba, word: ab, word: bbaba, word: ababaab])
sage: c == set([Word(), Word('ba'), Word('baba'), Word('ab'), Word('bbaba'), ...
Word('ababaab'))]
```

5.1. Comprehensive Module List 3525
periods(divide_length=False)

Return a list containing the periods of self between 1 and \( n - 1 \), where \( n \) is the length of self.

INPUT:

* divide_length – boolean (default: False). When set to True, then only periods that divide the length of self are considered.

OUTPUT:

a list of positive integers

EXAMPLES:

```
sage: w = Word('ababab')
sage: w.periods()
[2, 4]
sage: w.periods(divide_length=True)
[2]
sage: w = Word('ababa')
sage: w.periods()
[2, 4]
sage: w.periods(divide_length=True)
[]
```

phi()

Apply the phi function to self and return the result. This is the word obtained by taking the first letter of the words obtained by iterating delta on self.

OUTPUT:

a word – the result of the phi function

EXAMPLES:

```
sage: W = Words([1, 2])
sage: W([2,2,1,1,2,1,2,1,2,2,1,2,1,2,1,2]).phi()
word: 222222
sage: W([2,1,2,2,1,2,1,2,1,2,1,2,1]).phi()
word: 212113
sage: W().phi()
word: 
sage: w = Word([2,1,2,2,1,2,1,2,1,2,1,2,1]).phi()
word: 212113
sage: Word([2,3,1,1,2,1,2,3,3,1,1,2,1,2,3,1,2]).phi()
word: 21215
sage: Word("aabbabaabaaba").phi()
word: a22222
sage: w = Word([2,3,1,1,2,1,2,3,1,2,2,3,1,2])
```

See [BL2003] and [BDLV2006].

phi_inv(W=None)

Apply the inverse of the phi function to self.

INPUT:

* self – a word over the integers
* W – a parent object of words defined over integers
OUTPUT:

a word – the inverse of the phi function

EXAMPLES:

```sage
sage: W = Words([1, 2])
sage: W([2, 2, 2, 2, 1, 2]).phi_inv()
word: 22112122
sage: W([2, 2, 2]).phi_inv(Words([2, 3]))
word: 2233
```

`prefix_function_table()`

Return a vector containing the length of the proper prefix-suffixes for all the non-empty prefixes of `self`.

EXAMPLES:

```sage
sage: Word('121321').prefix_function_table()
[0, 0, 1, 0, 0, 1]
sage: Word('1241245').prefix_function_table()
[0, 0, 0, 1, 2, 3, 0]
sage: Word().prefix_function_table()
[]
```

`primitive()`

Return the primitive of `self`.

EXAMPLES:

```sage
sage: Word('12312').primitive()
word: 12312
sage: Word('121212').primitive()
word: 12
```

`primitive_length()`

Return the length of the primitive of `self`.

EXAMPLES:

```sage
sage: Word('1231').primitive_length()
4
sage: Word('121212').primitive_length()
2
```

`quasiperiods()`

Return the quasiperiods of `self` as a list ordered from shortest to longest.

Let `w` be a finite or infinite word. A quasiperiod of `w` is a proper factor `u` of `w` such that the occurrences of `u` in `w` entirely cover `w`, i.e., every position of `w` falls within some occurrence of `u` in `w`. See for instance [AE1993], [Mar2004], and [GLR2008].

EXAMPLES:

```sage
sage: Word('abaababaabaabaabaaba').quasiperiods()
[word: aba, word: abaaba, word: abaababaaba]
sage: Word('abaaba').quasiperiods()
[word: aba]
```

(continues on next page)
sage: Word('abacaba').quasiperiods()
[]

rauzy_graph($n$)
Return the Rauzy graph of the factors of length $n$ of self.

The vertices are the factors of length $n$ and there is an edge from $u$ to $v$ if $ua = bv$ is a factor of length $n + 1$ for some letters $a$ and $b$.

INPUT:

• $n$ – integer

EXAMPLES:

sage: w = Word(range(10)); w
word: 0123456789
sage: g = w.rauzy_graph(3); g
Looped digraph on 8 vertices
sage: WordOptions(identifier='')

sage: g.vertices(sort=True)
[012, 123, 234, 345, 456, 567, 678, 789]

sage: g.edges(sort=True)
[(012, 123, 3),
 (123, 234, 4),
 (234, 345, 5),
 (345, 456, 6),
 (456, 567, 7),
 (567, 678, 8),
 (678, 789, 9)]

sage: WordOptions(identifier='word: ')

sage: f = words.FibonacciWord()[:100]
sage: f.rauzy_graph(8)
Looped digraph on 9 vertices

sage: w = Word('1111111111')
sage: g = w.rauzy_graph(3)

sage: g.edges(sort=True)
[(word: 111, word: 111, word: 1)]

sage: w = Word('111')
sage: for i in range(5) : w.rauzy_graph(i)
Looped multi-digraph on 1 vertex
Looped digraph on 1 vertex
Looped digraph on 1 vertex
Looped digraph on 0 vertices

Multi-edges are allowed for the empty word:

sage: W = Words('abcde')
sage: w = W('abc')
sage: w.rauzy_graph(0)
Looped multi-digraph on 1 vertex
sage: _.edges(sort=True)
[(word: , word: , word: a),
 (word: , word: , word: b),
 (word: , word: , word: c)]

Reduced Rauzy Graph

Return the reduced Rauzy graph of order $n$ of self.

INPUT:

- $n$ – a non-negative integer. Every vertex of a reduced Rauzy graph of order $n$ is a factor of length $n$ of self.

OUTPUT:

a looped multi-digraph

DEFINITION:

For infinite periodic words (resp. for finite words of type $u^i u[0:j]$), the reduced Rauzy graph of order $n$ (resp. for $n$ smaller or equal to $(i-1)|u|+j$) is the directed graph whose unique vertex is the prefix $p$ of length $n$ of self and which has an only edge which is a loop on $p$ labelled by $w[n+1:|w|]p$ where $w$ is the unique return word to $p$.

In other cases, it is the directed graph defined as followed. Let $G_n$ be the Rauzy graph of order $n$ of self. The vertices are the vertices of $G_n$ that are either special or not prolongable to the right or to the left. For each couple $(u, v)$ of such vertices and each directed path in $G_n$ from $u$ to $v$ that contains no other vertices that are special, there is an edge from $u$ to $v$ in the reduced Rauzy graph of order $n$ whose label is the label of the path in $G_n$.

Note: In the case of infinite recurrent non-periodic words, this definition corresponds to the following one that can be found in [BDLGZ2009] and [BPS2008] where a simple path is a path that begins with a special factor, ends with a special factor and contains no other vertices that are special:

The reduced Rauzy graph of factors of length $n$ is obtained from $G_n$ by replacing each simple path $P = v_1 v_2 ... v_\ell$ with an edge $v_1 v_\ell$ whose label is the concatenation of the labels of the edges of $P$.

Examples:

sage: w = Word(range(10)); w
word: 0123456789
sage: g = w.reduced_rauzy_graph(3); g
Looped multi-digraph on 2 vertices
sage: g.vertices(sort=True)
[word: 012, word: 789]
sage: g.edges(sort=True)
[(word: 012, word: 789, word: 3456789)]

For the Fibonacci word:

sage: f = words.FibonacciWord()[:100]
sage: g = f.reduced_rauzy_graph(8); g
Looped multi-digraph on 2 vertices
sage: g.vertices(sort=True)
[word: 01001010, word: 01010010]
sage: g.edges(sort=True)
[(word: 01000101, word: 01010010, word: 010),
 (word: 01010010, word: 01001010, word: 010),
 (word: 01010010, word: 01001010, word: 10)]

For periodic words:

sage: from itertools import cycle
sage: w = Word(cycle('abcd'))[:100]
sage: g = w.reduced_rauzy_graph(3)
sage: g.edges(sort=True)
[(word: abc, word: abc, word: dabc)]

sage: w = Word('111')
sage: for i in range(5) : w.reduced_rauzy_graph(i)
Looped digraph on 1 vertex
Looped digraph on 1 vertex
Looped digraph on 1 vertex
Looped multi-digraph on 1 vertex
Looped multi-digraph on 0 vertices

AUTHOR:
Julien Leroy (March 2010): initial version

\textbf{return\_words}(\textit{fact})

Return the set of return words of \textit{fact} in \textit{self}.

This is the set of all factors starting by the given factor and ending just before the next occurrence of this factor. See [Dur1998] and [HZ1999].

INPUT:
- \textit{fact} – a non-empty finite word

OUTPUT:
a Python set of finite words

EXAMPLES:

sage: Word('21331233213231').return_words(Word('2'))
\{word: 213, word: 21331, word: 233\}
sage: Word().return_words(Word('213'))
(continued from previous page)

```python
set()
sage: Word('121212').return_words(Word('1212'))
{word: 12}
```

```python
sage: TM = words.ThueMorseWord()[:1000]
sage: sorted(TM.return_words(Word([0])))
[word: 0, word: 01, word: 011]
```

**return_words_derivate(factor)**

Return the word generated by mapping a letter to each occurrence of the return words for the given factor dropping any dangling prefix and suffix. See for instance [Dur1998].

**EXAMPLES:**

```python
sage: Word('12131221312313122').return_words_derivate(Word('1'))
word: 123242
```

**rev_lex_less(other)**

Return True if the word self is reverse lexicographically less than other.

**EXAMPLES:**

```python
sage: Word([1,2,4]).rev_lex_less(Word([1,3,2]))
True
sage: Word([3,2,1]).rev_lex_less(Word([1,2,3]))
False
```

**reversal()**

Return the reversal of self.

**EXAMPLES:**

```python
sage: Word('124563').reversal()
word: 365421
```

**rfind(sub, start=0, end=None)**

Return the index of the last occurrence of sub in self, such that sub is contained within self[start:end]. Return -1 on failure.

**INPUT:**

- sub – string, list, tuple or word to search for.
- start – non-negative integer (default: 0) specifying the position at which the search must stop.
- end – non-negative integer (default: None) specifying the position from which to start the search. If None, then the search is performed up to the end of the string.

**OUTPUT:**

a non-negative integer or -1

**EXAMPLES:**

```python
sage: w = Word([0,1,0,0,1])
sage: w.rfind(Word([0,1]))
3
```
The `sub` parameter can also be a list or a tuple:

```python
sage: w.rfind([0,1])
3
sage: w.rfind((0,1))
3
```

Examples using the argument `start` and `end`:

```python
sage: w.rfind(Word([0,1]), end=4)
0
sage: w.rfind(Word([0,1]), end=5)
3
sage: w.rfind(Word([0,0]), start=2, end=5)
2
sage: w.rfind(Word([0,0]), start=3, end=5)
-1
```

Instances of `Word_str` handle string inputs as well:

```python
sage: w = Word('abac')
sage: w.rfind('a')
2
sage: w.rfind(Word('a'))
2
sage: w.rfind([0,1])
-1
```

**right_special_factors** *(n=None)*

Return the right special factors (of length n).

A factor u of a word w is right special if there are two distinct letters a and b such that ua and ub are factors of w.

**INPUT:**

- n – integer (optional, default: None). If None, it returns all right special factors.

**OUTPUT:**

a list of words

**EXAMPLES:**

```python
sage: w = words.ThueMorseWord()[:30]
sage: for i in range(5):
    ....:     print("{} {}".format(i, sorted(w.right_special_factors(i)))))
0 [word: ]
1 [word: 0, word: 1]
2 [word: 01, word: 10]
3 [word: 001, word: 010, word: 101, word: 110]
4 [word: 0110, word: 1001]
```

**right_special_factors_iterator** *(n=None)*

Return an iterator over the right special factors (of length n).

A factor u of a word w is right special if there are two distinct letters a and b such that ua and ub are factors of w.
INPUT:

• n – integer (optional, default: None). If None, it returns an iterator over all right special factors.

EXAMPLES:

```
sage: alpha, beta, x = 0.61, 0.54, 0.3
sage: w = words.CodingOfRotationWord(alpha, beta, x)[:40]
sage: sorted(w.right_special_factors_iterator(3))
["word: 010", "word: 101"]
sage: sorted(w.right_special_factors_iterator(4))
["word: 0101", "word: 1010"]
sage: sorted(w.right_special_factors_iterator(5))
["word: 00101", "word: 11010"]
```

`robinson_schensted()`

Return the semistandard tableau and standard tableau pair obtained by running the Robinson-Schensted algorithm on `self`.

This can also be done by running `RSK()` on `self`.

EXAMPLES:

```
sage: Word([1,1,3,1,2,3,1]).robinson_schensted()
[[[1, 1, 1, 1, 3], [2]], [[1, 2, 3, 5, 6], [4], [7]]]
```

`schuetzenberger_involution(n=None)`

Return the Schützenberger involution of the word `self`, which is obtained by reverting the word and then complementing all letters within the underlying ordered alphabet. If `n` is specified, the underlying alphabet is assumed to be \([1, 2, \ldots, n]\). If no alphabet is specified, `n` is the maximal letter appearing in `self`.

INPUT:

• `self` – a word

• `n` – an integer specifying the maximal letter in the alphabet (optional)

OUTPUT:

a word, the Schützenberger involution of `self`

EXAMPLES:

```
sage: w = Word([9,7,4,1,6,2,3])
sage: v = w.schuetzenberger_involution(); v
word: 7849631
sage: v.parent()
Finite words over Set of Python objects of class 'object'
sage: w = Word([1,2,3],alphabet=[1,2,3,4,5])
sage: v = w.schuetzenberger_involution(); v
word: 345
sage: v.parent()
Finite words over {1, 2, 3, 4, 5}
sage: w = Word([1,2,3])
sage: v = w.schuetzenberger_involution(n=5); v
word: 345
sage: v.parent()
```
Finite words over Set of Python objects of class 'object'

```python
tsage: w = Word([11, 32, 69, 2, 53, 1, 2, 3, 18, 41])
tsage: w.schuetzenberger_involution()
word: 29, 52, 67, 68, 69, 17, 68, 1, 38, 59
```

```python
tsage: w = Word([], alphabet=[1, 2, 3, 4, 5])
tsage: w.schuetzenberger_involution()
word:
```

```python
tsage: w = Word([])
tsage: w.schuetzenberger_involution()
word:
```

### shifted_shuffle(\(\text{other}, \text{shift}=\text{None}\))

Return the combinatorial class representing the shifted shuffle product between words \(\text{self}\) and \(\text{other}\). This is the same as the shuffle product of \(\text{self}\) with the word obtained from \(\text{other}\) by incrementing its values (i.e. its letters) by the given \(\text{shift}\).

**INPUT:**
- \(\text{other}\) – finite word over the integers
- \(\text{shift}\) – integer or None (default: None) added to each letter of \(\text{other}\). When \(\text{shift}\) is None, it is replaced by \(\text{self}.\text{length()}\)

**OUTPUT:**
combinatorial class of shifted shuffle products of \(\text{self}\) and \(\text{other}\)

**EXAMPLES:**

```python
sage: w = Word([0, 1, 1])
sage: sp = w.shifted_shuffle(w); sp
Shuffle product of word: 011 and word: 344
sage: sp = w.shifted_shuffle(w, 2); sp
Shuffle product of word: 011 and word: 233
sage: sp.cardinality()
20
sage: WordOptions(identifier='')
sage: sp.list()
[011233, 012133, 012313, 012331, 021133, 021313, 021331, 023113, 023131, 023311, 023331, 031123, 031213, 031231, 031313, 031331, 033113, 033131, 033311, 033331, 102133, 102313, 102331, 103113, 103131, 103311, 103331, 120133, 120313, 120331, 123013, 123031, 123301, 123331, 130213, 130231, 130313, 130331, 133021, 133031, 133201, 133231, 133301, 133321, 201331, 201333, 203131, 203311, 203331, 230131, 230133, 230311, 230331, 233011, 233031, 233301, 233321, 233331]
sage: WordOptions(identifier='word: ')
sage: y = Word('aba')
sage: y.shifted_shuffle(w, 2)
Traceback (most recent call last):
... ValueError: for shifted shuffle, words must only contain integers as letters
```

### shuffle(\(\text{other}, \text{overlap}=0\))

Return the combinatorial class representing the shuffle product between words \(\text{self}\) and \(\text{other}\). This consists of all words of length \(\text{self}.\text{length()} + \text{other}.\text{length()}\) that have both \(\text{self}\) and \(\text{other}\) as subwords.
If \( \text{overlap} \) is non-zero, then the combinatorial class representing the shuffle product with overlaps is returned. The calculation of the shift in each overlap is done relative to the order of the alphabet. For example, \( a \) shifted by \( a \) is \( b \) in the alphabet \([a, b, c]\) and \( 0 \) shifted by \( 1 \) in \([0, 1, 2, 3]\) is 2.

**INPUT:**
- \( \text{other} \) – finite word
- \( \text{overlap} \) – (default: 0) integer or \( \text{True} \)

**OUTPUT:**
combinatorial class of shuffle product of \( \text{self} \) and \( \text{other} \)

**EXAMPLES:**

```python
sage: ab = Word("ab")
sage: cd = Word("cd")
sage: sp = ab.shuffle(cd); sp
Shuffle product of word: ab and word: cd
sage: sp.cardinality()
6
sage: sp.list()
[word: abcd, word: acbd, word: acdb, word: cabd, word: cadb, word: cdab]
sage: w = Word([0,1])
sage: u = Word([2,3])
sage: w.shuffle(u)
Shuffle product of word: 01 and word: 01
sage: u.shuffle(u)
Shuffle product of word: 23 and word: 23
sage: w.shuffle(u)
Shuffle product of word: 01 and word: 23
sage: sp2 = w.shuffle(u,2); sp2
Overlapping shuffle product of word: 01 and word: 23 with 2 overlaps
sage: list(sp2)
[word: 24]
```

**squares()**

Returns a set of all distinct squares of \( \text{self} \).

**EXAMPLES:**

```python
sage: sorted(Word('cacao').squares())
[word: , word: caca]
sage: sorted(Word('1111').squares())
[word: , word: 11, word: 1111]
sage: w = Word('00110011010')
sage: sorted(w.squares())
[word: , word: 00, word: 00110011, word: 01100110, word: 1010, word: 11]
```

**standard_factorization()**

Return the standard factorization of \( \text{self} \).

The standard factorization of a word \( w \) of length greater than 1 is the factorization \( w = uv \) where \( v \) is the longest proper suffix of \( w \) that is a Lyndon word.

Note that if \( w \) is a Lyndon word of length greater than 1 with standard factorization \( w = uv \), then \( u \) and \( v \) are also Lyndon words and \( u < v \).
See for instance [CFL1958], [Duv1983] and [Lot2002].

INPUT:

• \texttt{self} – finite word of length greater than 1

OUTPUT:

2-tuple \((u, v)\)

EXAMPLES:

\begin{verbatim}
sage: Words('01')('0010110011').standard_factorization()
\texttt{(word: 001011, word: 0011)}
sage: Words('123')('1223312').standard_factorization()
\texttt{(word: 12233, word: 12)}
sage: Word([3,2,1]).standard_factorization()
\texttt{(word: 32, word: 1)}
\end{verbatim}

\begin{verbatim}
sage: w = Word('0010110011', alphabet='01')
sage: w.standard_factorization()
\texttt{(word: 001011, word: 0011)}
sage: w = Word('0010110011', alphabet='10')
sage: w.standard_factorization()
\texttt{(word: 001011001, word: 1)}
sage: w = Word('1223312', alphabet='123')
sage: w.standard_factorization()
\texttt{(word: 12233, word: 12)}
\end{verbatim}

\texttt{standard_permutation()}

Return the standard permutation of the word \texttt{self} on the ordered alphabet. It is defined as the permutation with exactly the same inversions as \texttt{self}. Equivalently, it is the permutation of minimal length whose inverse sorts \texttt{self}.

EXAMPLES:

\begin{verbatim}
sage: w = Word([1,2,3,2,2,1]); w
\texttt{word: 123221}
sage: p = w.standard_permutation(); p
\texttt{[1, 3, 6, 4, 5, 2]}
sage: v = Word(p.inverse().action(w)); v
\texttt{word: 112223}
sage: [q for q in Permutations(w.length())
.....: if q.length() <= p.length() and
.....: q.inverse().action(w) == list(v)]
\texttt{[[1, 3, 6, 4, 5, 2]]}
\end{verbatim}

\begin{verbatim}
sage: w = Words([1,2,3])([1,2,3,2,2,1,2,1]); w
\texttt{word: 12322121}
sage: p = w.standard_permutation(); p
\texttt{[1, 4, 8, 5, 6, 2, 7, 3]}
sage: Word(p.inverse().action(w))
\texttt{word: 11122223}
\end{verbatim}

\begin{verbatim}
sage: w = Words([3,2,1])([1,2,3,2,2,1,2,1]); w
\texttt{word: 12322121}
\end{verbatim}
sturmian_desubstitute_as_possible()

Sturmian-desubstitute the word self as much as possible.

The finite word self must be defined on a two-letter alphabet or use at most two letters.

It can be Sturmian desubstituted if one letter appears isolated: the Sturmian desubstitution consists in removing one letter per run of the non-isolated letter. The accelerated Sturmian desubstitution consists in removing a run equal to the length of the shortest inner run from any run of the non-isolated letter (including possible leading and trailing runs even if they have shorter length). The (accelerated) Sturmian desubstitution is done as much as possible. A word is a factor of a Sturmian word if, and only if, the result is the empty word.

OUTPUT:

a finite word defined on a two-letter alphabet

EXAMPLES:

AUTHOR:

• Thierry Monteil

subword_complementaries(other)

Return the possible complementaries other minus self if self is a subword of other (empty list otherwise). The complementary is made of all the letters that are in other once we removed the letters of self. There can be more than one.
To check whether `self` is a subword of `other` (without knowing its complementaries), use `self.is_subword_of(other)`, and to count the number of occurrences of `self` in `other`, use `other.number_of_subword_occurrences(self)`.

**INPUT:**
- `other` – finite word

**OUTPUT:**
- list of all the complementary subwords of `self` in `other`

**EXAMPLES:**

```python
sage: Word('tamtam').subword_complementaries(Word('ta'))
[]
sage: Word('mta').subword_complementaries(Word('tamtam'))
[word: tam]
sage: Word('ta').subword_complementaries(Word('tamtam'))
[word: mtam, word: amtm, word: tamm]
sage: Word('a').subword_complementaries(Word('a'))
[word: ]
```

**suffix_tree()**

Alias for `implicit_suffix_tree()`.

**EXAMPLES:**

```python
sage: Word('abbabaab').suffix_tree()
Implicit Suffix Tree of the word: abbabaab
```

**suffix_trie()**

Return the suffix trie of `self`.

The suffix trie of a finite word `w` is a data structure representing the factors of `w`. It is a tree whose edges are labelled with letters of `w`, and whose leafs correspond to suffixes of `w`.

Type `sage.combinat.words.suffix_trees.SuffixTrie?` for more information.

**EXAMPLES:**

```python
sage: w = Word("cacao")
sage: w.suffix_trie()
Suffix Trie of the word: cacao
```

```python
sage: w = Word([0,1,0,1,1])
sage: w.suffix_trie()
Suffix Trie of the word: 01011
```

**swap**(i, j=None)

Return the word `w` with entries at positions `i` and `j` swapped. By default, `j = i+1`.

**EXAMPLES:**
sage: Word([1,2,3]).swap(0,2)
word: 321
sage: Word([1,2,3]).swap(1)
word: 132
sage: Word("abba").swap(1,-1)
word: aabb

\texttt{swap\_decrease}(i)

Return the word with positions $i$ and $i+1$ exchanged if $\text{self}[i] < \text{self}[i+1]$. Otherwise, it returns $\text{self}$.

EXAMPLES:

\begin{verbatim}
sage: w = Word([1,3,2])
sage: w.swap_decrease(0)
word: 312
sage: w.swap_decrease(1)
word: 132
sage: w.swap_decrease(1) is w
True
sage: Words("ab")("abba").swap_decrease(0)
word: baba
sage: Words("ba")("abba").swap_decrease(0)
word: abba
\end{verbatim}

\texttt{swap\_increase}(i)

Return the word with positions $i$ and $i+1$ exchanged if $\text{self}[i] > \text{self}[i+1]$. Otherwise, it returns $\text{self}$.

EXAMPLES:

\begin{verbatim}
sage: w = Word([1,3,2])
sage: w.swap_increase(1)
word: 123
sage: w.swap_increase(0)
word: 132
sage: w.swap_increase(0) is w
True
sage: Words("ab")("abba").swap_increase(0)
word: abba
sage: Words("ba")("abba").swap_increase(0)
word: baba
\end{verbatim}

\texttt{to\_integer\_list}()

Return a list of integers from $[0,1,...,\text{self.length()}-1]$ in the same relative order as the letters in $\text{self}$ in the parent.

EXAMPLES:

\begin{verbatim}
sage: from itertools import count
sage: w = Word('ababbaab')
sage: w.to_integer_list()
[0, 1, 1, 0, 1, 0, 0, 1]
sage: w = Word(iter("cacao"), length="finite")
\end{verbatim}

(continues on next page)
\[ [1, 0, 1, 0, 2] \]
\[
\text{sage: } w = \text{Words}([3, 2, 1])([2, 3, 3, 1]) \\
\text{sage: } w.\text{to_integer_list()} \\
[1, 0, 1, 0, 2]
\]

\section*{to_integer_word()}

Return a word over the alphabet \([0, 1, \ldots, \text{self.length()} - 1]\) whose letters are in the same relative order as the letters of \text{self} in the parent.

\textbf{EXAMPLES:}

\[
\text{sage: } \text{from itertools import count} \\
\text{sage: } w = \text{Word('abbbabab')} \\
\text{sage: } w.\text{to_integer_word()} \\
\text{word: 01101001}
\]

\[
\text{sage: } w = \text{Word(iter("cacao"), length="finite")} \\
\text{sage: } w.\text{to_integer_word()} \\
\text{word: 10102}
\]

\[
\text{sage: } w = \text{Words([3, 2, 1])([2, 3, 3, 1])} \\
\text{sage: } w.\text{to_integer_word()} \\
\text{word: 1002}
\]

\section*{to_monoid_element()}

Return \text{self} as an element of the free monoid with the same alphabet as \text{self}.

\textbf{EXAMPLES:}

\[
\text{sage: } w = \text{Word('aabb')} \\
\text{sage: } w.\text{to_monoid_element()} \\
a^2b^2
\]

\[
\text{sage: } W = \text{Words('abc')} \\
\text{sage: } w = W(w) \\
\text{sage: } w.\text{to_monoid_element()} \\
a^2b^2
\]

\section*{to_ordered_set_partition()}

Return the ordered set partition correspond to \text{self}.

If \(w\) is a finite word of length \(n\), then the corresponding ordered set partition is an ordered set partition \((P_1, P_2, \ldots, P_k)\) of \(\{1, 2, \ldots, n\}\), where each block \(P_i\) is the set of positions at which the \(i\)-th smallest letter occurring in \(w\) occurs in \(w\).

\textbf{EXAMPLES:}

\[
\text{sage: } w = \text{Word('abbbabab')} \\
\text{sage: } w.\text{to_ordered_set_partition()} \\
[[[1, 4, 6, 7], [2, 3, 5, 8]]]
\]

\[
\text{sage: } \text{Word([-10, 3, -10, 2]).to_ordered_set_partition()} \\
[[1, 3], [4], [2]]
\]

\[
\text{sage: } \text{Word([]).to_ordered_set_partition()} \\
[]
\]

\[
\text{sage: } \text{Word('aaaaa').to_ordered_set_partition()} \\
[[1, 2, 3], [4, 5]]
\]
**topological_entropy**(n)

Return the topological entropy for the factors of length n.

The topological entropy of a sequence \( u \) is defined as the exponential growth rate of the complexity of \( u \) as the length increases: \( H_{\text{top}}(u) = \lim_{n \to \infty} \frac{\log d(p_u(n))}{n} \) where \( d \) denotes the cardinality of the alphabet and \( p_u(n) \) is the complexity function, i.e. the number of factors of length \( n \) in the sequence \( u \) [Fog2002].

**INPUT:**

- **self** – a word defined over a finite alphabet
- **n** – positive integer

**OUTPUT:**

real number (a symbolic expression)

**EXAMPLES:**

```sage
sage: W = Words([0, 1])
sage: w = W([0, 1, 0, 0, 0, 1, 1, 0, 0, 1, 0, 1])
sage: t = w.topological_entropy(3); t
1/3*log(7)/log(2)
sage: n(t)
0.935784974019201
```

```sage
sage: w = words.ThueMorseWord()[:100]
sage: topo = w.topological_entropy
sage: for i in range(0, 41, 5):
....:     print("{} {}"
....:           .format(i, n(topo(i), digits=5)))
0 1.0000
5 0.71699
10 0.48074
15 0.36396
20 0.28774
25 0.23628
30 0.20075
35 0.17270
40 0.14827
```

If no alphabet is specified, an error is raised:

```sage
sage: w = Word(range(20))
sage: w.topological_entropy(3)
Traceback (most recent call last):
  ...
TypeError: The word must be defined over a finite alphabet
```

The following is ok:

```sage
sage: W = Words(range(20))
sage: w = W(range(20))
sage: w.topological_entropy(3)
1/3*log(18)/log(20)
```

**sage.combinat.words.finite_word.evaluation_dict**(w)

Return a dictionary keyed by the letters occurring in \( w \) with values the number of occurrences of the letter.
INPUT:

- $w$ – a word

sage.combinat.words.finite_word.word_to_ordered_set_partition($w$)

Return the ordered set partition corresponding to a finite word $w$.

If $w$ is a finite word of length $n$, then the corresponding ordered set partition is an ordered set partition $(P_1, P_2, \ldots, P_k)$ of $\{1, 2, \ldots, n\}$, where each block $P_i$ is the set of positions at which the $i$-th smallest letter occurring in $w$ occurs in $w$. (Positions are 1-based.)

This is the same functionality that to_ordered_set_partition() provides, but without the wrapping: The input $w$ can be given as a list or tuple, not necessarily as a word; and the output is returned as a list of lists (which are the blocks of the ordered set partition in increasing order), not as an ordered set partition.

EXAMPLES:

```python
sage: from sage.combinat.words.finite_word import word_to_ordered_set_partition
sage: word_to_ordered_set_partition([3, 6, 3, 1])
[[4], [1, 3], [2]]
sage: word_to_ordered_set_partition((1, 3, 3, 7))
[[1], [2, 3], [4]]
sage: word_to_ordered_set_partition("noob")
[[4], [1], [2, 3]]
sage: word_to_ordered_set_partition(Word("hell"))
[[2], [1], [3, 4]]
sage: word_to_ordered_set_partition([1])
[[1]]
sage: word_to_ordered_set_partition([])
[]
```

5.1.355 Infinite word

AUTHORS:

- Sebastien Labbe
- Franco Saliola

EXAMPLES:

Creation of an infinite word

Periodic infinite words:

```python
sage: v = Word([0, 4, 8, 8, 3])
sage: vv = v^Infinity
sage: vv
word: 04883048830488304883048830488304883048830...
```

Infinite words from a function $f : \mathbb{N} \rightarrow A$ over an alphabet $A$:

```python
sage: Word(lambda n: n%3)
word: 0120120120120120120120120120120120120120...
```
sage: def t(n):
    ....:     return add(Integer(n).digits(base=2)) % 2
sage: Word(t, alphabet = [0, 1])
word: 0110100110010110100101100110100110010110...

or as a one-liner:

sage: Word(lambda n : add(Integer(n).digits(base=2)) % 2, alphabet = [0, 1])
word: 0110100110010110100101100110100110010110...

Infinite words from iterators:

sage: from itertools import count,repeat
sage: Word( repeat(4) )
word: 4444444444444444444444444444444444444444...

sage: Word( count() )
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,27,28,29,30,...

Infinite words from morphism

For example, let $A = \{a, b\}$ and $\mu : A^* \to A^*$ be the morphism defined by $a \mapsto ab, b \mapsto ba$:

sage: mu = WordMorphism('a->ab,b->ba'); mu
WordMorphism: a->ab, b->ba
sage: mu.fixed_point('a')
word: abbabaabbaabbbabaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabba...

Infinite words in a specific combinatorial class:

sage: W = InfiniteWords("ab"); W
Infinite words over {"a", "b"}
sage: f = lambda n : 'a' if n % 2 == 1 else 'b'
sage: W(f)
word: babababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababababab...
5.1.356 Lyndon words

sage.combinat.words.lyndon_word.LyndonWord(data, check=True)

Construction of a Lyndon word.

INPUT:

• data – list
  • check – bool (optional, default: True) if True, check that the input data represents a Lyndon word.

OUTPUT:

A Lyndon word.

EXAMPLES:

sage: LyndonWord([1,2,2])
word: 122
sage: LyndonWord([1,2,3])
word: 123
sage: LyndonWord([2,1,2,3])
Traceback (most recent call last):
... ValueError: not a Lyndon word

If check is False, then no verification is done:

sage: LyndonWord([2,1,2,3], check=False)
word: 2123

sage.combinat.words.lyndon_word.LyndonWords(e=None, k=None)

Return the combinatorial class of Lyndon words.

A Lyndon word \( w \) is a word that is lexicographically less than all of its rotations. Equivalently, whenever \( w \) is split into two non-empty substrings, \( w \) is lexicographically less than the right substring.

See Wikipedia article Lyndon_word

INPUT:

• no input at all
  or
  • e – integer, size of alphabet
  • k – integer, length of the words
  or
  • e – a composition

OUTPUT:

A combinatorial class of Lyndon words.

EXAMPLES:

sage: LyndonWords()
Lyndon words

If e is an integer, then e specifies the length of the alphabet; k must also be specified in this case:
Combinatorics, Release 9.7

```python
sage: LW = LyndonWords(3, 4); LW
Lyndon words from an alphabet of size 3 of length 4
sage: LW.first()
word: 1112
sage: LW.last()
word: 2333
sage: LW.random_element() # random
word: 1232
sage: LW.cardinality()
18
```

If e is a (weak) composition, then it returns the class of Lyndon words that have evaluation e:

```python
sage: LyndonWords([2, 0, 1]).list()
[word: 113]
sage: LyndonWords([2, 0, 1, 0, 1]).list()
[word: 1135, word: 1153, word: 1315]
sage: LyndonWords([2, 1, 1]).list()
[word: 1123, word: 1132, word: 1213]
```

```python
class sage.combinat.words.lyndon_word.LyndonWords_class(alphabet=None):
    Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent
    The set of all Lyndon words.

class sage.combinat.words.lyndon_word.LyndonWords_evaluation(e):
    Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent
    The set of Lyndon words on a fixed multiset of letters.

    cardinality()
    Return the number of Lyndon words with the evaluation e.

    EXAMPLES:

    sage: L = LyndonWords([1,2,1])
    sage: L
    Lyndon words with evaluation [1, 2, 1]
    sage: L.list()
    [word: 1223, word: 1232, word: 1322]
```

Check to make sure that the count matches up with the number of Lyndon words generated:

```python
sage: comps = [[], [2, 2], [3, 2, 7], [4, 2]] + Compositions(4).list()
sage: lws = [LyndonWords(comp) for comp in comps]
```
sage: all(lw.cardinality() == len(lw.list()) for lw in lws)
    True

class sage.combinat.words.lyndon_word.LyndonWords_nk(n, k)
    Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

    Lyndon words of fixed length \(k\) over the alphabet \(\{1,2,...,n\}\).

    INPUT:
    
    • \(n\) – the size of the alphabet
    • \(k\) – the length of the words

    EXAMPLES:

    sage: L = LyndonWords(3, 4)
sage: L.list()
    [word: 1112,  
     word: 1113,  
     word: 1122,  
     word: 1123,  
     ...  
     word: 1333,  
     word: 2223,  
     word: 2233,  
     word: 2333]

    cardinality()

sage.combinat.words.lyndon_word.StandardBracketedLyndonWords_nk(n, k)
    Return the combinatorial class of standard bracketed Lyndon words from \([1, ..., n]\) of length \(k\).

    These are in one to one correspondence with the Lyndon words and form a basis for the subspace of degree \(k\) of the free Lie algebra of rank \(n\).

    EXAMPLES:

    sage: SBLW33 = StandardBracketedLyndonWords(3,3); SBLW33
    Standard bracketed Lyndon words from an alphabet of size 3 of length 3
    sage: SBLW33.first()
    [1, [1, 2]]
sage: SBLW33.last()
    [[2, 3], 3]
sage: SBLW33.cardinality()
    8
    sage: SBLW33.random_element() in SBLW33
    True

class sage.combinat.words.lyndon_word.StandardBracketedLyndonWords_nk(n, k)
    Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

    cardinality()

    EXAMPLES:
sage: StandardBracketedLyndonWords(3, 3).cardinality()
8
sage: StandardBracketedLyndonWords(3, 4).cardinality()
18

sage.combinat.words.lyndon_word.standard_bracketing(lw)
Return the standard bracketing of a Lyndon word lw.

EXAMPLES:

sage: import sage.combinat.words.lyndon_word as lyndon_word
sage: [lyndon_word.standard_bracketing(u) for u in LyndonWords(3,3)]
[[1, [1, 2]],
 [1, [1, 3]],
 [[1, 2], 2],
 [1, [2, 3]],
 [[1, 3], 1],
 [2, [2, 3]],
 [[2, 3], 3]]

sage.combinat.words.lyndon_word.standard_unbracketing(sblw)
Return flattened sblw if it is a standard bracketing of a Lyndon word, otherwise raise an error.

EXAMPLES:

sage: from sage.combinat.words.lyndon_word import standard_unbracketing
sage: standard_unbracketing([[1, 2], 3])
word: 123
sage: standard_unbracketing([[1, 2], 3])
Traceback (most recent call last):
  ... ValueError: not a standard bracketing of a Lyndon word

5.1.357 Word morphisms/substitutions

This module implements morphisms over finite and infinite words.

AUTHORS:
- Sébastien Labbé (2007-06-01): initial version
- Sébastien Labbé (2008-07-01): merged into sage-words
- Sébastien Labbé (2008-12-17): merged into sage
- Sébastien Labbé (2009-02-03): words next generation
- Stepan Starosta (2012-11-09): growing letters

EXAMPLES:

Creation of a morphism from a dictionary or a string:

sage: n = WordMorphism({0:[0,2,2,1],1:[0,2],2:[2,2,1]})
```

sage: m = WordMorphism('x->xyxsxs,x->xyss,y->ys')
```

```

sage: n
WordMorphism: 0->0221, 1->02, 2->221
sage: m
WordMorphism: s->xyss, x->xyxsxs, y->ys
```

The codomain may be specified:

```

sage: WordMorphism({0:[0,2,2,1],1:[0,2],2:[2,2,1]}, codomain=Words([0,1,2,3,4]))
WordMorphism: 0->0221, 1->02, 2->221
```

Power of a morphism:

```

sage: n^2
WordMorphism: 0->022122122102, 1->0221221, 2->22122102
```

Image under a morphism:

```

sage: m('y')
word: ys
sage: m('xxxsy')
word: xyxsxsxyxsxssxyxssxyssys
```

Iterated image under a morphism:

```

sage: m('y', 3)
word: ysxysxyxsyxsxssyxsxssyssyss
```

See more examples in the documentation of the call method (m.__call__).

Infinite fixed point of morphism:

```

sage: fix = m.fixed_point('x')
sage: fix
word: xyxsxsxyxsxssxyxssxyxsyssxyssysxys...
sage: fix.length()
+Infinity
```

Incidence matrix:

```

sage: matrix(m)
[2 3 1]
[1 3 0]
[1 1 1]
```

Many other functionalities...:

```

sage: m.is_identity()
False
sage: m.is_endomorphism()
True
```

```

class sage.combinat.words.morphism.PeriodicPointIterator(m, cycle)
    Bases: object
```

3548 Chapter 5. Comprehensive Module List
(Lazy) constructor of the periodic points of a word morphism.

This class is mainly used in `WordMorphism.periodic_point` and `WordMorphism.periodic_points`.

**EXAMPLES:**

```python
sage: from sage.combinat.words.morphism import PeriodicPointIterator
sage: s = WordMorphism('a->bacca,b->cba,c->aab')
sage: p = PeriodicPointIterator(s, ['a', 'b', 'c'])
```

```python
sage: p._cache[0]
lazy list ['a', 'a', 'b', 'c', 'c', 'c', 'a']
```

```python
sage: p._cache[1]
lazy list ['b', 'a', 'c', 'b', 'a', 'a', 'b']
```

```python
sage: p._cache[2]
lazy list ['c', 'b', 'a', 'b', 'c', 'a', 'b']
```

```python
sage: p.get_iterator(0)
<generator object ...get_iterator at ...>
```

```python
class sage.combinat.words.morphism.WordMorphism(data, domain=None, codomain=None)

Bases: sage.structure.sage_object.SageObject

WordMorphism class

INPUT:

- **data** – dict or str or an instance of WordMorphism, the map giving the image of letters
- **domain** – (optional: None) set of words over a given alphabet. If None, the domain alphabet is computed from data and is sorted.
- **codomain** – (optional: None) set of words over a given alphabet. If None, the codomain alphabet is computed from data and is sorted.

**Note:** When the domain or the codomain are not explicitly given, it is expected that the letters are comparable because the alphabets of the domain and of the codomain are sorted.

**EXAMPLES:**

From a dictionary:

```python
sage: n = WordMorphism({0:[0,2,2,1],1:[0,2],2:[2,2,1]})
sage: n
WordMorphism: 0->0221, 1->02, 2->221
```

From a string with '->' as separation:

```python
sage: m = WordMorphism('x->xyxsxss,s->xyss,y->ys')
sage: m
```

(continues on next page)
Combinatorics, Release 9.7

WordMorphism: s->xyss, x->xyxsxs, y->ys
sage: m.domain()
Finite words over {'s', 'x', 'y'}
sage: m.codomain()
Finite words over {'s', 'x', 'y'}

Specifying the domain and codomain:

```python
sage: W = FiniteWords([0,1,2])
sage: d = {0:[0,1], 1:[0,1,0], 2:[0]}
sage: m = WordMorphism(d, domain=W, codomain=W)
sage: m([0]).parent()
Finite words over {0, 1, 2}
```

When the alphabet is non-sortable, the domain and/or codomain must be explicitly given:

```python
sage: W = FiniteWords(['a',6])
sage: d = {'a':['a',6,'a'],6:[6,6,6,'a']}
sage: WordMorphism(d, domain=W, codomain=W)
WordMorphism: 6->666a, a->a6a
```

`abelian_rotation_subspace()`

Return the subspace on which the incidence matrix of `self` acts by roots of unity.

EXAMPLES:

```python
sage: WordMorphism('0->1,1->0').abelian_rotation_subspace()
Vector space of degree 2 and dimension 2 over Rational Field
Basis matrix:
[1 0]
[0 1]
sage: WordMorphism('0->01,1->0').abelian_rotation_subspace()
Vector space of degree 2 and dimension 0 over Rational Field
Basis matrix:
[]
sage: WordMorphism('0->01,1->1').abelian_rotation_subspace()
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[0 1]
sage: WordMorphism('1->122,2->211').abelian_rotation_subspace()
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[ 1 -1]
sage: WordMorphism('0->1,1->102,2->3,3->4,4->2').abelian_rotation_subspace()
Vector space of degree 5 and dimension 3 over Rational Field
Basis matrix:
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
```

The domain needs to be equal to the codomain:
sage: WordMorphism('0->1,1->').codomain=Words('01')).abelian_rotation_subspace()
Vector space of degree 2 and dimension 0 over Rational Field
Basis matrix:
[]

codomain()
Return the codomain of self.
EXAMPLES:

sage: WordMorphism('a->ab,b->a').codomain()
Finite words over {'a', 'b'}
sage: WordMorphism('6->ab,y->5,0->asd').codomain()
Finite words over {'5', 'a', 'b', 'd', 's'}

conjugate(pos)
Return the morphism where the image of the letter by self is conjugated of parameter pos.
INPUT:
• pos - integer
EXAMPLES:

sage: m = WordMorphism('a->abcde')
sage: m.conjugate(0) == m
True
sage: m.conjugate(1)
WordMorphism: a->bcdea
sage: m.conjugate(3)
WordMorphism: a->deabc
sage: WordMorphism('').conjugate(4)
WordMorphism:
sage: m = WordMorphism('a->abcde,b->xyz')
sage: m.conjugate(2)
WordMorphism: a->cdeab, b->zxy

domain()
Return domain of self.
EXAMPLES:

sage: WordMorphism('a->ab,b->a').domain()
Finite words over {'a', 'b'}
sage: WordMorphism('b->ba,a->ab').domain()
Finite words over {'a', 'b'}
sage: WordMorphism('6->ab,y->5,0->asd').domain()
Finite words over {'0', '6', 'y'}

dual_map(k=1)
Return the dual map $E_k^*$ of self (see [1]).

Note: It is actually implemented only for $k = 1$. 

INPUT:
• self - unimodular endomorphism defined on integers 1, 2, \ldots, d
• k - integer (optional, default: 1)

OUTPUT:
an instance of E1Star - the dual map

EXAMPLES:

```
sage: sigma = WordMorphism({1:[2], 2:[3], 3:[1,2]})
sage: sigma.dual_map()
E_1^*(1->2, 2->3, 3->12)
```

```
sage: sigma.dual_map(k=2)
Traceback (most recent call last):
...
NotImplementedError: the dual map E_k^* is implemented only for k = 1 (not 2)
```

REFERENCES:

extend_by(other)
Return self extended by other.

Let \( \varphi_1 : A^* \to B^* \) and \( \varphi_2 : C^* \to D^* \) be two morphisms. A morphism \( \mu : (A \cup C)^* \to (B \cup D)^* \) corresponds to \( \varphi_1 \) extended by \( \varphi_2 \) if \( \mu(a) = \varphi_1(a) \) if \( a \in A \) and \( \mu(a) = \varphi_2(a) \) otherwise.

INPUT:
• other - a WordMorphism.

OUTPUT:
WordMorphism

EXAMPLES:

```
sage: m = WordMorphism('a->ab, b->ba')
sage: n = WordMorphism({'@': '1', '1': '@', 'a': '5'})
sage: m.extend_by(n)
WordMorphism: @->1, 1->@, a->ab, b->ba
```

```
sage: m.extend_by(m)
WordMorphism: a->ab, b->ba
```

fixed_point(letter)
Return the fixed point of self beginning by the given letter.

A fixed point of morphism \( \varphi \) is a word \( w \) such that \( \varphi(w) = w \).

INPUT:
• self - an endomorphism (or more generally a self-composable morphism), must be prolongable on letter
• letter - in the domain of self, the first letter of the fixed point.

OUTPUT:
Combinatorics, Release 9.7

• word - the fixed point of self beginning with letter.
EXAMPLES:
sage: W = FiniteWords('abc')
1. Infinite fixed point:
sage:
word:
sage:
word:
sage:
word:

WordMorphism('a->ab,b->ba').fixed_point(letter='a')
abbabaabbaababbabaababbaabbabaabbaababba...
WordMorphism('a->ab,b->a').fixed_point(letter='a')
abaababaabaababaababaabaababaabaababaaba...
WordMorphism('a->ab,b->b,c->ba', codomain=W).fixed_point(letter='a')
abbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbb...

2. Infinite fixed point of an erasing morphism:
sage: WordMorphism('a->ab,b->,c->ba', codomain=W).fixed_point(letter='a')
word: ab
3. Finite fixed point:
sage: WordMorphism('a->ab,b->b,c->ba', codomain=W).fixed_point(letter='b')
word: b
sage: _.parent()
Finite words over {'a', 'b', 'c'}
sage: WordMorphism('a->ab,b->cc,c->', codomain=W).fixed_point(letter='a')
word: abcc
sage: _.parent()
Finite words over {'a', 'b', 'c'}
sage: m = WordMorphism('a->abc,b->,c->')
sage: fp = m.fixed_point('a'); fp
word: abc
sage:
sage:
word:
sage:
word:

m = WordMorphism('a->ba,b->')
m('ba')
ba
m.fixed_point('a') #todo: not implemented
ba

5. Fixed point of a power of a morphism:
sage: m = WordMorphism('a->ba,b->ab')
sage: (m^2).fixed_point(letter='a')
word: abbabaabbaababbabaababbaabbabaabbaababba...
6. With a self-composable but not endomorphism
sage: m = WordMorphism(‘a->cbc,b->bc,c->b’) sage: m.is_endomorphism() False sage:
m.fixed_point(‘b’) word: bcbbcbcbbcbbcbcbbcbcbbcbbcbcbbcbbcbcbbcb. . .
fixed_points()
Return the list of all fixed points of self.
5.1. Comprehensive Module List

3553


EXAMPLES:

```python
sage: f = WordMorphism('a->ab,b->ba')
sage: for w in f.fixed_points(): print(w)
abbabaababababaabababababab...  
baababbaababababaabababababab...  
sage: f = WordMorphism('a->ab,b->c,c->a')
sage: for w in f.fixed_points(): print(w)
abcaabacabcaabcaabcaabcaabcaabcaabcaabca...  
sage: f = WordMorphism('a->ab,b->cab,c->bcc')
sage: for w in f.fixed_points(): print(w)
abcabbccabcabbccabcabbccabcabbccabcabbcc...  
```

This shows that ticket trac ticket #13668 has been resolved:

```python
d = {1: [1, 2], 2: [2, 3], 3: [4], 4: [5], 5: [6], 6: [7], 7: [8], 8: [9], 9: [10], 10: [1]}
sage: s = WordMorphism(d)
sage: s7 = s**7
sage: s7.fixed_points()
[word: 12232342..., word: 2,3,4,5,6,7,8...]
sage: s7r = s7.reversal()
sage: s7r.periodic_point(2)
word: 2,1,1,10,9,8,7,6,5,4,3,2,1,10,9,8,7,6,5,4,3,2,1,10,9,8,7,6,5,4,3,2,9,8,7,6,
˓→5,4,3,2,8,...
```

This shows that ticket trac ticket #13668 has been resolved:

```python
sage: s = "1->32133132133133,2->133321331332133133,3->21331331333213313321331333"  
sage: s = WordMorphism(s)
sage: (s**2).fixed_points()
[]
```

growing_letters()

Return the list of growing letters.

See is_growing() for more information.

EXAMPLES:

```python
sage: WordMorphism('0->01,1->10').growing_letters()
['0', '1']
sage: WordMorphism('0->01,1->1').growing_letters()
['0']
sage: WordMorphism('0->01,1->0,2->1', codomain=Words('012')).growing_letters()
['0', '1', '2']
sage: WordMorphism('a->b,b->a').growing_letters()
[]
sage: WordMorphism('a->b,b->c,c->d,d->c', codomain=Words('abcd')).growing__letters()
[]
```

has_conjugate_in_classP(f=None)

Return True if self has a conjugate in class f-P.
DEFINITION : Let $A$ be an alphabet. We say that a primitive substitution $S$ is in the class $P$ if there exists a palindrome $p$ and for each $b \in A$ a palindrome $q_b$ such that $S(b) = pq_b$ for all $b \in A$. [1]

Let $f$ be an involution on $A$. We say that a morphism $\varphi$ is in class $f$-$P$ if there exists an $f$-palindrome $p$ and for each $\alpha \in A$ there exists an $f$-palindrome $q_\alpha$ such that $\varphi(\alpha) = pq_\alpha$. [2]

INPUT:

- $f$ - involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism).

REFERENCES:

EXAMPLES:

```python
sage: fibo = WordMorphism('a->ab,b->a')
sage: fibo.has_conjugate_in_classP()
True
sage: (fibo^2).is_in_classP()
False
sage: (fibo^2).has_conjugate_in_classP()
True
```

`has_left_conjugate()`

Return True if all the non empty images of self begins with the same letter.

EXAMPLES:

```python
sage: m = WordMorphism('a->abcde,b->xyz')
sage: m.has_left_conjugate()
False
sage: WordMorphism('b->xyz').has_left_conjugate()
True
sage: WordMorphism('').has_left_conjugate()
True
sage: WordMorphism('a->,b->xyz').has_left_conjugate()
True
sage: WordMorphism('a->abbab,b->abb').has_left_conjugate()
True
sage: WordMorphism('a->abbab,b->abb,c->').has_left_conjugate()
True
```

`has_right_conjugate()`

Return True if all the non empty images of self ends with the same letter.

EXAMPLES:

```python
sage: m = WordMorphism('a->abcde,b->xyz')
sage: m.has_right_conjugate()
False
sage: WordMorphism('b->xyz').has_right_conjugate()
True
```

(continues on next page)
Combinatorics, Release 9.7

sage: WordMorphism('').has_right_conjugate()
True
sage: WordMorphism('a->b,b->xyz').has_right_conjugate()
True
sage: WordMorphism('a->abb,b->abb').has_right_conjugate()
True
sage: WordMorphism('a->abbab,b->abb,c->').has_right_conjugate()
True

**image**(letter)

Return the image of a letter.

**INPUT:**

- letter – a letter in the domain alphabet

**OUTPUT:**

word

**Note:** The letter is assumed to be in the domain alphabet (no check done). Hence, this method is faster than the `__call__` method suitable for words input.

**EXAMPLES:**

sage: m = WordMorphism('a->ab,b->ac,c->a')
sage: m.image('b')
word: ac

sage: s = WordMorphism({'a':[1], 'b':[1,2], 'a':[2,3,4], 'z':[9,8,7]})
sage: s.image('b')
word: 12
sage: s.image('a')
word: 234
sage: s.image('z')
word: 987

**images()**

Return the list of all the images of the letters of the alphabet under self.

**EXAMPLES:**

sage: sorted(WordMorphism('a->ab,b->a').images())
[word: a, word: ab]
sage: sorted(WordMorphism('6->ab,y->5,0->asd').images())
[word: 5, word: ab, word:asd]

**immortal_letters()**

Return the list of immortal letters.
A letter $a$ is immortal for the morphism $s$ if the length of the iterates of $|s^n(a)|$ is larger than zero as $n$ goes to infinity.

Requires this morphism to be self-composable.

EXAMPLES:

```python
sage: WordMorphism('a->a').immortal_letters()
['a']
sage: WordMorphism('a->b,b->a').immortal_letters()
['a', 'b']
sage: WordMorphism('a->abcd,b->cd,c->dd,d->').immortal_letters()
['a']
sage: WordMorphism('a->bc,b->cac,c->de,d->,e->').immortal_letters()
['a', 'b']
sage: WordMorphism('a->', domain=Words('a'), codomain=Words('a')).immortal_letters()
[]
sage: WordMorphism('a->').immortal_letters()
[]
```

`incidence_matrix()`

Return the incidence matrix of the morphism. The order of the rows and column are given by the order defined on the alphabet of the domain and the codomain.

The matrix returned is over the integers. If a different ring is desired, use either the `change_ring` function or the `matrix` function.

EXAMPLES:

```python
sage: m = WordMorphism('a->abc,b->a,c->c')
sage: m.incidence_matrix()
[1 1 0]
[1 0 0]
[1 0 1]
sage: m = WordMorphism('a->abc,b->a,c->c,d->abbccccabca,e->abc')
sage: m.incidence_matrix()
[1 1 0 3 1]
[1 0 0 3 1]
[1 0 1 5 1]
```

`infinite_repetitions_primitive_roots(w=None, allow_growing=None)`

Return the set of primitive roots (up to conjugacy) of infinite repetitions from the language $\{m^n(w) | n \geq 0\}$, where $m$ is this morphism and $w$ is a word inputted as a parameter.

Requires this morphism to be an endomorphism.

The word $v^w$ is an infinite repetition (in other words, an infinite periodic factor) of a language, if $v$ is a non-empty word and for each positive integer $k$ the word $v^k$ is a factor of some word from the language. It turns out that a language created by iterating a morphism has a finite number of primitive roots of infinite repetitions.

If $v$ is a primitive root of an infinite repetition, then all its conjugations are also primitive roots of an infinite repetition. For simplicity’s sake this method returns only the lexicographically minimal one from each conjugacy class.

INPUT:
• \( w \) – finite iterable (default: \( \text{self.domain().alphabet()} \)). Represents a word used to start the language.

• allow_growing – boolean or None (default: None). If False, return only the primitive roots that contain no growing letters. If True, return only the primitive roots that contain at least one growing letter. If None, return both.

ALGORITHM:
The algorithm used is described in detail in [KS2015].

EXAMPLES:

```python
sage: m = WordMorphism('a->aba,b->aba,c->cd,d->e,e->d')
sage: inf_reps = m.infinite_repetitions_primitive_roots('ac')
sage: sorted(inf_reps)
[word: aab, word: de]
```

allow_growing parameter:

```python
sage: sorted(m.infinite_repetitions_primitive_roots('ac', True))  # with growing
[word: aab]
sage: sorted(m.infinite_repetitions_primitive_roots('ac', False))  # without growing
[word: de]
```

Incomplete check that these words are indeed the primitive roots of infinite repetitions:

```python
sage: SL = m._language_naive(10, Word('ac'))
sage: all(x in SL for x in inf_reps)
True
sage: all(x^2 in SL for x in inf_reps)
True
sage: all(x^3 in SL for x in inf_reps)
True
```

Large example:

```python
sage: m = WordMorphism('a->1b5,b->fcg,c->dae,d->432,e->678,f->f,g->g,1->2,2->3,˓→3->4,4->1,5->6,6->7,7->8,8->5')
sage: sorted(m.infinite_repetitions_primitive_roots('a'))
[word: 1432f2143f3214f4321f, word: 5678g8567g7856g6785g]
```

is_empty()

Return True if the cardinality of the domain is zero and False otherwise.

EXAMPLES:

```python
sage: WordMorphism('').is_empty()
True
sage: WordMorphism('a->a').is_empty()
False
```

is_endomorphism()

Return whether \( \text{self} \) is an endomorphism, that is if the domain coincide with the codomain.

EXAMPLES:
We check that trac ticket #8674 is fixed:

```python
sage: P = WordPaths('abcd')
sage: m = WordMorphism('a->adab,b->ab,c->cbcd,d->cd', domain=P, codomain=P)
sage: m.is_endomorphism()
True
```

**is_erasing()**

Return True if `self` is an erasing morphism, i.e. the image of a letter is the empty word.

**EXAMPLES:**

```python
sage: WordMorphism('a->ab,b->a').is_erasing()
False
sage: WordMorphism('6->ab,y->5,0->asd').is_erasing()
False
sage: WordMorphism('6->ab,y->5,0->asd,7->').is_erasing()
True
sage: WordMorphism('').is_erasing()
False
```

**is_growing** *(letter=None)*

Return True if `letter` is a growing letter.

A letter `a` is growing for the morphism `s` if the length of the iterates of `|s^n(a)|` tend to infinity as `n` goes to infinity.

**INPUT:**

- `letter` – None or a letter in the domain of `self`

**Note:** If `letter` is None, this returns True if `self` is everywhere growing, i.e., all letters are growing letters (see [CassNic10]), and that `self` must be an endomorphism.

**EXAMPLES:**

```python
sage: WordMorphism('0->01,1->1').is_growing('0')
True
sage: WordMorphism('0->01,1->1').is_growing('1')
False
sage: WordMorphism('0->01,1->10').is_growing()
True
sage: WordMorphism('0->1,1->2,2->01').is_growing()
False
```

(continues on next page)
True
sage: WordMorphism('0->01,1->1').is_growing()
False

The domain needs to be equal to the codomain:
sage: WordMorphism('0->01,1->0,2->1', codomain=Words('012')).is_growing()
True

Test of erasing morphisms:
sage: WordMorphism('0->01,1->').is_growing('0')
False
sage: m = WordMorphism('a->bc,b->bcc,c->', codomain=Words('abc'))
sage: m.is_growing('a')
False
sage: m.is_growing('b')
False
sage: m.is_growing('c')
False

REFERENCES:
is_identity()
Return True if self is the identity morphism.

EXAMPLES:
sage: m = WordMorphism('a->a,b->b,c->c,d->e')
sage: m.is_identity()
False
sage: WordMorphism('a->a,b->b,c->c').is_identity()
True
sage: WordMorphism('a->a,b->b,c->cb').is_identity()
False
sage: m = WordMorphism('a->b,b->c,c->a')
sage: (m^2).is_identity()
False
sage: (m^3).is_identity()
True
sage: (m^4).is_identity()
False
sage: WordMorphism('').is_identity()
True
sage: WordMorphism({0:[0],1:[1]}).is_identity()
True

We check that trac ticket #8618 is fixed:
sage: t = WordMorphism({'a1':['a2'], 'a2':['a1']})
sage: (t*t).is_identity()
True

is_in_classP(f=None)
Return True if self is in class $P$ (or $f$-$P$).
DEFINITION: Let $A$ be an alphabet. We say that a primitive substitution $S$ is in the class $P$ if there exists a palindrome $p$ and for each $b \in A$ a palindrome $q_b$ such that $S(b) = pq_b$ for all $b \in A$. [1]

Let $f$ be an involution on $A$. We say that a morphism $\varphi$ is in class $f$-$P$ if there exists an $f$-palindrome $p$ and for each $\alpha \in A$ there exists an $f$-palindrome $q_\alpha$ such that $\varphi(\alpha) = pq_\alpha$. [2]

INPUT:
- $f$ - involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism).

REFERENCES:

EXAMPLES:

```sage
sage: WordMorphism('a->bbaba,b->bba').is_in_classP()
True
sage: tm = WordMorphism('a->ab,b->ba')
sage: tm.is_in_classP()
False
sage: f = WordMorphism('a->b,b->a')
sage: tm.is_in_classP(f=f)
True
sage: (tm^2).is_in_classP()
True
sage: (tm^2).is_in_classP(f=f)
False
sage: fibo = WordMorphism('a->ab,b->a')
sage: fibo.is_in_classP()
True
sage: fibo.is_in_classP(f=f)
False
sage: (fibo^2).is_in_classP()
False
sage: f = WordMorphism('a->b,b->a,c->c')
sage: WordMorphism('a->acbcb,b->acbab,c->acbba').is_in_classP(f)
True
```

**is_injective()**
Return whether this morphism is injective.

ALGORITHM:
Uses a version of Wikipedia article Sardinas–Patterson_algorithm. Time complexity is on average quadratic with regards to the size of the morphism.

EXAMPLES:

```sage
sage: WordMorphism('a->0,b->10,c->110,d->111').is_injective()
True
sage: WordMorphism('a->00,b->01,c->012,d->20001').is_injective()
False
```
**is_involution()**

Return True if `self` is an involution, i.e. its square is the identity.

**INPUT:**

- `self` - an endomorphism

**EXAMPLES:**

```python
sage: WordMorphism('a->b,b->a').is_involution()
True
sage: WordMorphism('a->b,b->ba').is_involution()
False
sage: WordMorphism({0:[1],1:[0]}).is_involution()
True
```

**is_primitive()**

Return True if `self` is primitive.

A morphism \( \varphi \) is primitive if there exists a positive integer \( k \) such that for all \( \alpha \in \Sigma \), \( \varphi^k(\alpha) \) contains all the letters of \( \Sigma \).

**INPUT:**

- `self` - an endomorphism

**ALGORITHM:**

Exercises 8.7.8, p.281 in [1]: (c) Let \( y(M) \) be the least integer \( e \) such that \( M^e \) has all positive entries. Prove that, for all primitive matrices \( M \), we have \( y(M) \leq (d - 1)^2 + 1 \). (d) Prove that the bound \( y(M) \leq (d - 1)^2 + 1 \) is best possible.

**EXAMPLES:**

```python
sage: tm = WordMorphism('a->ab,b->ba')
sage: tm.is_primitive()
True
sage: fibo = WordMorphism('a->ab,b->a')
sage: fibo.is_primitive()
True
sage: m = WordMorphism('a->bb,b->aa')
sage: m.is_primitive()
False
sage: f = WordMorphism({0:[1],1:[0]})
sage: f.is_primitive()
False
sage: s = WordMorphism('a->b,b->c,c->ab')
sage: s.is_primitive()
True
sage: s = WordMorphism('a->b,b->c,c->d,d->e,e->f,f->g,g->h,h->ab')
sage: s.is_primitive()
True
```

**REFERENCES:**

**is_prolongable***(letter)***

Return True if self is prolongable on letter.

A morphism \( \varphi \) is prolongable on a letter \( a \) if \( a \) is a prefix of \( \varphi(a) \).

**INPUT:**

- **self** - its codomain must be an instance of Words
- **letter** - a letter in the domain alphabet

**OUTPUT:**

Boolean

**EXAMPLES:**

```sage
sage: WordMorphism('a->ab,b->a').is_prolongable(letter='a')
True
sage: WordMorphism('a->ab,b->a').is_prolongable(letter='b')
False
sage: WordMorphism('a->ba,b->ab').is_prolongable(letter='b')
False
sage: (WordMorphism('a->ba,b->ab')^2).is_prolongable(letter='b')
True
sage: WordMorphism('a->ba,b->b').is_prolongable(letter='b')
False
sage: WordMorphism('a->bb,b->aac').is_prolongable(letter='a')
False
```

We check that trac ticket #8595 is fixed:

```sage
sage: s = WordMorphism({('a', 1) : [('a', 1), ('a', 2)], ('a', 2) : [('a', 1)])
sage: s.is_prolongable(('a',1))
True
```

**is_pushy**(w=None)

Return whether the language \( \{m^n(w) | n \geq 0 \} \) is pushy, where \( m \) is this morphism and \( w \) is a word inputted as a parameter.

Requires this morphism to be an endomorphism.

A language created by iterating a morphism is pushy, if its words contain an infinite number of factors containing no growing letters. It turns out that this is equivalent to having at least one infinite repetition containing no growing letters.

See `infinite_repetitions_primitive_roots()` and `is_growing()`.

**INPUT:**

- **w** – finite iterable (default: `self.domain().alphabet()`). Represents a word used to start the language.

**EXAMPLES:**

```sage
sage: WordMorphism('a->abca,b->bc,c->c').is_pushy()
False
sage: WordMorphism('a->abc,b->,c->bcb').is_pushy()
True
```
is_repetitive(w=None)
Return whether the language \{m^n(w) | n \geq 0\} is repetitive, where \(m\) is this morphism and \(w\) is a word inputted as a parameter.

Requires this morphism to be an endomorphism.

A language is repetitive, if for each positive integer \(k\) there exists a word \(u\) such that \(u^k\) is a factor of some word of the language.

It turns out that for languages created by iterating a morphism this is equivalent to having at least one infinite repetition (this property is also known as strong repetitiveness).

See infinite_repetitions_primitive_roots().

INPUT:
• \(w\) – finite iterable (default: self.domain().alphabet()). Represents a word used to start the language.

EXAMPLES:
This method can be used to check whether a purely morphic word is not \(k\)-power free for all positive integers \(k\). For example, the language containing just the Thue-Morse word and its prefixes is not repetitive, since the Thue-Morse word is cube-free:

sage: WordMorphism('a->ab,b->ba').is_repetitive('a')
False

Similarly, the Hanoi word is square-free:

sage: WordMorphism('a->aC,A->ac,b->cb,B->cb,c->bA,C->ba').is_repetitive('a')
False

However, this method solves a more general problem, as it can be called on any morphism \(m\) and with any word \(w\):

sage: WordMorphism('a->c,b->cda,c->a,d->abc').is_repetitive('bd')
True

is_self_composable()
Return whether the codomain of self is contained in the domain.

EXAMPLES:

sage: f = WordMorphism('a->a,b->a')
sage: f.is_endomorphism()
False
sage: f.is_self_composable()
True

is_unboundedly_repetitive(w=None)
Return whether the language \{m^n(w) | n \geq 0\} is unboundedly repetitive, where \(m\) is this morphism and \(w\) is a word inputted as a parameter.

Requires this morphism to be an endomorphism.

A language created by iterating a morphism is unboundedly repetitive, if it has at least one infinite repetition containing at least one growing letter.

See infinite_repetitions_primitive_roots() and is_growing().
INPUT:

• w – finite iterable (default: self.domain().alphabet()). Represents a word used to start the language.

EXAMPLES:

```
sage: WordMorphism('a->abca,b->bc,c->').is_unboundedly_repetitive()
True
sage: WordMorphism('a->abc,b->c,bcb').is_unboundedly_repetitive()
False
```

is_uniform\((k=None)\)
Return True if self is a \(k\)-uniform morphism.

Let \(k\) be a positive integer. A morphism \(\phi\) is called \(k\)-uniform if for every letter \(\alpha\), we have \(|\phi(\alpha)| = k\). In other words, all images have length \(k\). A morphism is called uniform if it is \(k\)-uniform for some positive integer \(k\).

INPUT:

• \(k\) - a positive integer or None. If set to a positive integer, then the function return True if self is \(k\)-uniform. If set to None, then the function return True if self is uniform.

EXAMPLES:

```
sage: phi = WordMorphism('a->ab,b->a')
sage: phi.is_uniform()
False
sage: phi.is_uniform(k=1)
False
sage: tau = WordMorphism('a->ab,b->ba')
sage: tau.is_uniform()
True
sage: tau.is_uniform(k=1)
False
sage: tau.is_uniform(k=2)
True
```

language\((n, u=None)\)
Return the words of length \(n\) in the language generated by this substitution.

Given a non-erasing substitution \(s\) and a word \(u\) the DOL-language generated by \(s\) and \(u\) is the union of the factors of \(s^n(u)\) where \(n\) is a non-negative integer.

INPUT:

• \(n\) – non-negative integer - length of the words in the language
• \(u\) – a word or None (optional, default None) - if set to None some letter of the alphabet is used

OUTPUT: a Python set

EXAMPLES: The fibonacci morphism:

```
sage: s = WordMorphism({0: [0,1], 1:[0]})
sage: sorted(s.language(3))
[word: 001, word: 010, word: 100, word: 101]
```

A growing but non-primitive example. The DOL-languages generated by $0$ and $2$ are different:

```python
sage: s = WordMorphism({0: [0,1], 1:[0], 2:[2,0,2]})
sage: u = s.fixed_point(0)
sage: A0 = u[:200].factor_set(5)
sage: B0 = s.language(5, [0])
sage: set(A0) == B0
True
sage: v = s.fixed_point(2)
sage: A2 = v[:200].factor_set(5)
sage: B2 = s.language(5, [2])
sage: set(A2) == B2
True
sage: len(A0), len(A2)
(6, 20)
```

The Chacon transformation (non-primitive):

```python
sage: s = WordMorphism({0: [0,0,1,0], 1:[1]})
sage: sorted(s.language(10))
[word: 0001000101, word: 0001010010, ...
  word: 1010010001, word: 1010010100]
```

**latex_layout**(layout=None)
Get or set the actual latex layout (oneliner vs array).

**INPUT:**

- layout - string (default: None), can take one of the following values:
  - None - Returns the actual latex layout. By default, the layout is 'array'
  - 'oneliner' - Set the layout to 'oneliner'
  - 'array' - Set the layout to 'array'

**EXAMPLES:**

```python
sage: s = WordMorphism('a->ab,b->ba')
sage: s.latex_layout()
'array'
sage: s.latex_layout('oneliner')
sage: s.latex_layout()
'oneliner'
```
letter_growth_types()

Return the mortal, polynomial and exponential growing letters.

The growth of $|s^n(a)|$ as $n$ goes to $\infty$ is always of the form $\alpha^n n^\beta$ (where $\alpha$ is a Perron number and $\beta$ an integer).

Without doing any linear algebra three cases can be differentiated: mortal (ultimately empty or $\alpha = 0$); polynomial ($\alpha = 1$); exponential ($\alpha > 1$). This is what is done in this method.

It requires this morphism to be an endomorphism.

OUTPUT:

The output is a 3-tuple of lists (mortal, polynomial, exponential) where:

- mortal: list of mortal letters
- polynomial: a list of lists where polynomial[i] is the list of letters with growth $n^i$.
- exponential: list of at least exponentionally growing letters

EXAMPLES:

```sage
sage: s = WordMorphism('a->abc,b->bc,c->c')
sage: mortal, poly, expo = s.letter_growth_types()
sage: mortal
[]
sage: poly
[['c'], ['b'], ['a']]
sage: expo
[]
sage: s = WordMorphism('a->bc,b->cac,c->de,d->,e->')
sage: s^20
WordMorphism: a->cacde, b->debcde, c->, d->, e->
sage: mortal, poly, expo = s.letter_growth_types()
sage: mortal
['c', 'd', 'e']
sage: poly
[['a', 'b']]
sage: expo
[]
sage: s = WordMorphism('a->abcd,b->bc,c->c,d->a')
sage: mortal, poly, expo = s.letter_growth_types()
sage: mortal
[]
sage: poly
[['c'], ['b']]
sage: expo
['a', 'd']
```

list_of_conjugates()

Return the list of all the conjugate morphisms of self.

DEFINITION:
Recall from Lothaire [1] (Section 2.3.4) that \( \varphi \) is right conjugate of \( \varphi' \), noted \( \varphi \triangleleft \varphi' \), if there exists \( u \in \Sigma^* \) such that

\[
\varphi(\alpha)u = u\varphi'(\alpha),
\]

for all \( \alpha \in \Sigma \), or equivalently that \( \varphi(x)u = u\varphi'(x) \), for all words \( x \in \Sigma^* \). Clearly, this relation is not symmetric so that we say that two morphisms \( \varphi \) and \( \varphi' \) are conjugate, noted \( \varphi \bowtie \varphi' \), if \( \varphi \triangleleft \varphi' \) or \( \varphi' \triangleleft \varphi \). It is easy to see that conjugacy of morphisms is an equivalence relation.

REFERENCES:

EXAMPLES:

```python
sage: m = WordMorphism('a->abbab,b->abb')
```

```python
sage: m.list_of_conjugates()
[WordMorphism: a->babba, b->bab,
WordMorphism: a->abbab, b->abb,
WordMorphism: a->bbaba, b->bba,
WordMorphism: a->babab, b->bab,
WordMorphism: a->ababb, b->abb,
WordMorphism: a->babba, b->bba,
WordMorphism: a->abbab, b->bab]
```

```python
sage: m = WordMorphism('a->aaa,b->aa')
```

```python
sage: m.list_of_conjugates()
[WordMorphism: a->aaa, b->aa]
```

```python
sage: m = WordMorphism('a->aba,b->aba')
```

```python
sage: m.list_of_conjugates()
[WordMorphism: a->baa, b->baa,
WordMorphism: a->aab, b->aab,
WordMorphism: a->aba, b->aba]
```

```python
sage: m = WordMorphism('a->abb,b->abbab,c->')
```

```python
sage: m.list_of_conjugates()
[WordMorphism: a->bab, b->babba, c->,
WordMorphism: a->abb, b->abbab, c->,
WordMorphism: a->bba, b->bbaba, c->,
WordMorphism: a->bab, b->babab, c->,
WordMorphism: a->abb, b->babbb, c->,
WordMorphism: a->bba, b->babba, c->]
```

**partition_of_domain_alphabet()**

Return a partition of the domain alphabet.

Let \( \varphi : \Sigma^* \rightarrow \Sigma^* \) be an involution. There exists a triple of sets \((A, B, C)\) such that

• \( A \cup B \cup C = \Sigma \);

• \( A, B \) and \( C \) are mutually disjoint and

• \( \varphi(A) = B, \varphi(B) = A, \varphi(C) = C \).

These sets are not unique.

**INPUT:**

• self - An involution.
OUTPUT:
A tuple of three sets

EXAMPLES:

```
sage: m = WordMorphism('a->b,b->a')
sage: m.partition_of_domain_alphabet()  # random ordering
({'a'}, {'b'}, {})
sage: m = WordMorphism('a->b,b->a,c->c')
sage: m.partition_of_domain_alphabet()  # random ordering
({'a'}, {'b'}, {'c'})
sage: m = WordMorphism('A->T,T->A,C->G,G->C')
sage: m.partition_of_domain_alphabet()  # random ordering
({'A', 'C'}, {'T', 'G'}, {})
sage: I = WordMorphism({0:oo, oo:0, 1:-1, -1:1, 2:-2, -2:2, 3:-3, -3:3})
sage: I.partition_of_domain_alphabet()  # random ordering
({0, -1, -3, -2}, {1, 2, 3, +Infinity}, {})
```

**periodic_point**(letter)
Return the periodic point of self that starts with letter.

**EXAMPLES:**

```
sage: f = WordMorphism('a->bab,b->ab')
sage: f.periodic_point('a')
word: abbababbababbababbababbabababbababa...
sage: f.fixed_point('a')
Traceback (most recent call last):
  ...:  TypeError: self must be prolongable on a
```

Make sure that trac ticket #31759 is fixed:

```
sage: WordMorphism('a->b,b->a').periodic_point('a')
word: a
```

**periodic_points()**
Return the periodic points of f as a list of tuples where each tuple is a periodic orbit of f.

**EXAMPLES:**

```
sage: f = WordMorphism('a->aba,b->baa')
sage: for p in f.periodic_points():
    ....:    print("{} , {}".format(len(p), p[0]))
1, ababaababaaaababaaababaabababababaababaabababaabababaabababaababba...
1, baaaabababaaaababaaaababaababbaabababababababaababbaabababaababbaababaaa...
```

(continues on next page)
This shows that ticket trac ticket #13668 has been resolved:

```python
sage: d = {1:[1,2], 2:[2,3], 3:[4], 4:[5], 5:[6], 6:[7], 7:[8], 8:[9], 9:[10], 10:[1]}
sage: s = WordMorphism(d)
sage: s7 = s^7
sage: s7r = s7.reversal()
sage: for p in s7r.periodic_points(): p
```

Make sure that trac ticket #31454 is fixed:

```python
sage: WordMorphism('a->a,b->bb').periodic_points()
[[word: bbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbb...]]
```

**pisot_eigenvector_left()**

Return the left eigenvector of the incidence matrix associated to the largest eigenvalue (in absolute value).

Unicity of the result is guaranteed when the multiplicity of the largest eigenvalue is one, for example when self is a Pisot irreductible substitution.

A substitution is Pisot irreducible if the characteristic polynomial of its incidence matrix is irreducible over \( \mathbb{Q} \) and has all roots, except one, of modulus strictly smaller than 1.

**INPUT:**

- *self* - a Pisot irreducible substitution.

**EXAMPLES:**

```python
sage: m = WordMorphism('a->aaaabc,b->aaabbc,c->aabc')
sage: matrix(m)
[4 3 2]
[2 2 1]
[1 1 1]
sage: m.pisot_eigenvector_left()
(1, 0.839286755214161?, 0.5436890126920763?)
```

**pisot_eigenvector_right()**

Return the right eigenvector of the incidence matrix associated to the largest eigenvalue (in absolute value).

Unicity of the result is guaranteed when the multiplicity of the largest eigenvalue is one, for example when self is a Pisot irreductible substitution.

A substitution is Pisot irreducible if the characteristic polynomial of its incidence matrix is irreducible over \( \mathbb{Q} \) and has all roots, except one, of modulus strictly smaller than 1.
INPUT:

- **self** - a Pisot irreducible substitution.

EXAMPLES:

```python
sage: m = WordMorphism('a->aaaabbc,b->aaabbc,c->aabc')
sage: matrix(m)

[[4 3 2],
 [2 2 1],
 [1 1 1]]
sage: m.pisot_eigenvector_right()

(1.00000000000000, 0.5436890126920763?, 0.2955977425220848?)
```

**rauzy_fractal_plot**

```
rauzy_fractal_plot(n=None, exchange=False, eig=None, translate=None, prec=53, colormap='hsv',
opacity=None, plot_origin=None, plot_basis=False, point_size=None)
```

Return a plot of the Rauzy fractal associated with a substitution.

The substitution does not have to be irreducible. The usual definition of a Rauzy fractal requires that its
dominant eigenvalue is a Pisot number but the present method doesn’t require this, allowing to plot some
interesting pictures in the non-Pisot case (see the examples below).

For more details about the definition of the fractal and the projection which is used, see Section 3.1 of [1].

Plots with less than 100,000 points take a few seconds, and several millions of points can be plotted in
reasonable time.

Other ways to draw Rauzy fractals (and more generally projections of paths) can be found in
`sage.combinat.words.paths.FiniteWordPath_all.plot_projection()` or in `sage.combinat.e_one_star()`.

**OUTPUT:**

A Graphics object.

**INPUT:**

- **n** - integer (default: None) The number of points used to plot the fractal. Default values: 10000 for a
  1D fractal, 50000 for a 2D fractal, 100000 for a 3D fractal.
- **exchange** - boolean (default: False). Plot the Rauzy fractal with domain exchange.
- **eig** - a real element of QQbar of degree >= 2 (default: None). The eigenvalue used to plot the fractal.
  It must be an eigenvalue of `self.incidence_matrix()`. The one used by default the maximal
  eigenvalue of `self.incidence_matrix()` (usually a Pisot number), but for substitutions with more
  than 3 letters other interesting choices are sometimes possible.
- **translate** - a list of vectors of RR^size_alphabet, or a dictionary from the alphabet to lists of
  vectors (default: None). Plot translated copies of the fractal. This option allows to plot tilings easily.
  The projection used for these vectors is the same as the projection used for the canonical basis to plot
  the fractal. If the input is a list, all the pieces will be translated and plotted. If the input is a dictionary,
  each piece will be translated and plotted accordingly to the vectors associated with each letter in the
  dictionary. Note: by default, the Rauzy fractal placed at the origin is not plotted with the translate
  option; the vector `(0,0,...,0)` has to be added manually.
- **prec** - integer (default: 53). The number of bits used in the floating point representations of the points
  of the fractal.
- **colormap** - color map or dictionary (default: 'hsv'). It can be one of the following:
  - string - a coloring map. For available coloring map names type: `sorted(colormaps)`
  - dict - a dictionary of the alphabet mapped to colors.
• **opacity** - a dictionary from the alphabet to the real interval $[0,1]$ (default: None). If none is specified, all letters are plotted with opacity 1.

• **plot_origin** - a couple $(k,c)$ (default: None). If specified, mark the origin by a point of size $k$ and color $c$.

• **plot_basis** - boolean (default: False). Plot the projection of the canonical basis with the fractal.

• **point_size** - float (default: None). The size of the points used to plot the fractal.

**EXAMPLES:**

1. The Rauzy fractal of the Tribonacci substitution:

```
sage: s = WordMorphism('1->12,2->13,3->1')
sage: s.rauzy_fractal_plot() # long time
```

Graphics object consisting of 3 graphics primitives

2. The “Hokkaido” fractal. We tweak the plot using the plotting options to get a nice reusable picture, in which we mark the origin by a black dot:

```
sage: s = WordMorphism('a->ab,b->c,c->d,d->e,e->a')
sage: G = s.rauzy_fractal_plot(n=100000, point_size=3, plot_origin=(50, "black")) # not tested
sage: G.show(figsize=10, axes=false) # not tested
```

3. Another “Hokkaido” fractal and its domain exchange:

```
sage: s = WordMorphism({1:[2], 2:[4,3], 3:[4], 4:[5,3], 5:[6], 6:[1]})
sage: s.rauzy_fractal_plot() # not tested takes > 1 second
sage: s.rauzy_fractal_plot(exchange=True) # not tested takes > 1 second
```

4. A three-dimensional Rauzy fractal:

```
sage: s = WordMorphism('1->12,2->13,3->14,4->1')
sage: s.rauzy_fractal_plot() # not tested takes > 1 second
```

5. A one-dimensional Rauzy fractal (very scattered):

```
sage: s = WordMorphism('1->2122,2->1')
sage: s.rauzy_fractal_plot().show(figsize=20) # not tested takes > 1 second
```

6. A high resolution plot of a complicated fractal:

```
sage: s = WordMorphism('1->23,2->123,3->112233')
sage: G = s.rauzy_fractal_plot(n=300000) # not tested takes > 1 second
sage: G.show(axes=false, figsize=20) # not tested takes > 1 second
```

7. A nice colorful animation of a domain exchange:

```
sage: s = WordMorphism('1->21,2->3,3->4,4->25,5->6,6->7,7->1')
sage: L = [s.rauzy_fractal_plot(), s.rauzy_fractal_plot(exchange=True)]
```

# not tested takes > 1 second
```
sage: animate(L, axes=false).show(delay=100) # not tested takes > 1 second
```

8. Plotting with only one color:
Combinatorics, Release 9.7

9. Different fractals can be obtained by choosing another (non-Pisot) eigenvalue:

```
sage: s = WordMorphism('1->12,2->3,3->45,4->5,5->6,6->7,7->8,8->1')
```
```
sage: E = s.incidence_matrix().eigenvalues()
sage: x = [x for x in E if -0.8 < x < -0.7][0]
sage: s.rauzy_fractal_plot(eig=x)  # not tested takes > 1 second
```

10. A Pisot reducible substitution with seemingly overlapping tiles:

```
sage: s = WordMorphism({1: [1,2], 2: [2,3], 3: [4], 4: [5], 5: [6], 6: [7], 7: [8], 8: [9], 9: [10], 10: [1]})
```
```
sage: s.rauzy_fractal_plot()  # not tested takes > 1 second
```

11. A non-Pisot reducible substitution with a strange Rauzy fractal:

```
sage: s = WordMorphism({1: [3,2], 2: [3,3], 3: [4], 4: [1]})
```
```
sage: s.rauzy_fractal_plot()  # not tested takes > 1 second
```

12. A substitution with overlapping tiles. We use the options colormap and opacity to study how the tiles overlap:

```
sage: s = WordMorphism('1->213,2->4,3->5,4->1,5->21')
```
```
sage: s.rauzy_fractal_plot()  # not tested takes > 1 second
```
```
sage: s.rauzy_fractal_plot(colormap={'1':'red', '4':'purple'})  # not tested takes > 1 second
```
```
sage: s.rauzy_fractal_plot(opacity={'1:0.1, '2:1,'3:0.1,'4:0.1,'5:0.1,n=150000})  # not tested takes > 1 second
```

13. Funny experiments by playing with the precision of the float numbers used to plot the fractal:

```
sage: s = WordMorphism('1->12,2->31,3->1')
```
```
sage: s.rauzy_fractal_plot(prec=6)  # not tested
```
```
sage: s.rauzy_fractal_plot(prec=9)  # not tested
```
```
sage: s.rauzy_fractal_plot(prec=15)  # not tested
```
```
sage: s.rauzy_fractal_plot(prec=19)  # not tested
```
```
sage: s.rauzy_fractal_plot(prec=25)  # not tested
```

14. Using the translate option to plot periodic tilings:

```
sage: s = WordMorphism('1->12,2->31,3->1')
```
```
sage: s.rauzy_fractal_plot(n=10000, translate=[(0,0,0),(-1,0,1),(0,-1,1),(1,-1,0),(1,0,-1),(0,1,-1),(-1,1,0)])  # not tested takes > 1 second
```
```
sage: t = WordMorphism("a->aC,b->d,C->de,d->a,e->ab")  # substitution
```
```
sage: V = [vector((0,0,1,0,-1)), vector((0,0,1,-1,0))]
```

(continues on next page)
sage: S = set(map(tuple, [i*V[0] + j*V[1] for i in [-1,0,1] for j in [-1,0,1]]))
sage: t.rauzy_fRACTal_plot(n=10000, translate=S, exchange=true)  # not tested takes > 1 second

15. Using the translate option to plot arbitrary tilings with the fractal pieces. This can be used for example to plot the self-replicating tiling of the Rauzy fractal:

sage: s = WordMorphism({1:[1,2], 2:[3], 3:[4,3], 4:[5], 5:[6], 6:[1]})
sage: s.rauzy_fRACTal_plot()  # not tested takes > 1 second
sage: D = {1:[[0,0,0,0,0,0], (0,1,0,0,0,0)], 3:[[0,0,0,0,0,0], (0,1,0,0,0,0)], 6:[[0,1,0,0,0,0]]}
sage: s.rauzy_fRACTal_plot(n=30000, translate=D)  # not tested takes > 1 second

16. Plot the projection of the canonical basis with the fractal:

sage: s = WordMorphism({1:[2,1], 2:[3], 3:[6,4], 4:[5,1], 5:[6], 6:[7], 7:[8], 8:[9], 9:[1]})
sage: s.rauzy_fRACTal_plot(plot_bASis=True)  # not tested takes > 1 second

REFERENCES:

AUTHOR:

Timo Jolivet (2012-06-16)

rauzy_fRACTal_points(n=None, exchange=False, eig=None, translate=None, prec=53)
Return a dictionary of list of points associated with the pieces of the Rauzy fractal of self.

INPUT:

See the method rauzy_fRACTal_plot() for a description of the options and more examples.

OUTPUT:

dictionary of list of points

EXAMPLES:

The Rauzy fractal of the Tribonacci substitution and the number of points in the piece of the fractal associated with '1', '2' and '3' are respectively:

sage: s = WordMorphism('1->12,2->13,3->1')
sage: D = s.rauzy_fRACTal_points(n=100)
sage: len(D['1'])
54
sage: len(D['2'])
30
sage: len(D['3'])
16

AUTHOR:

Timo Jolivet (2012-06-16)
rauzy_fractal_projection\((eig=None, \text{prec}=53)\)

Return a dictionary giving the projection of the canonical basis.

See the method \texttt{rauzy_fractal_plot()} for more details about the projection.

**INPUT:**

- \texttt{eig} - a real element of \texttt{QQbar} of degree \texttt{>= 2} (default: \texttt{None}). The eigenvalue used for the projection. It must be an eigenvalue of \texttt{self.incidence_matrix()}. The one used by default is the maximal eigenvalue of \texttt{self.incidence_matrix()} (usually a Pisot number), but for substitutions with more than 3 letters other interesting choices are sometimes possible.

- \texttt{prec} - integer (default: \texttt{53}). The number of bits used in the floating point representations of the coordinates.

**OUTPUT:**

dictionary, letter -> vector, giving the projection

**EXAMPLES:**

The projection for the Rauzy fractal of the Tribonacci substitution is:

```
sage: s = WordMorphism('1->12,2->13,3->1')
sage: s.rauzy_fractal_projection()
{'1': (1.00000000000000, 0.00000000000000),
 '2': (-1.41964337760708, -0.606290729207199),
 '3': (-0.771844506346038, 1.11514250803994)}
```

**AUTHOR:**

Timo Jolivet (2012-06-16)

restrict_domain\((alphabet)\)

Return a restriction of \texttt{self} to the given alphabet.

**INPUT:**

- \texttt{alphabet} - an iterable

**OUTPUT:**

\texttt{WordMorphism}

**EXAMPLES:**

```
sage: m = WordMorphism('a->b,b->a')
sage: m.restrict_domain('a')
WordMorphism: a->b
sage: m.restrict_domain('A')
WordMorphism: a->b
sage: m.restrict_domain('Aa')
WordMorphism: a->b
```

The input alphabet must be iterable:

```
sage: m.restrict_domain(66)
Traceback (most recent call last):
...  
TypeError: 'sage.rings.integer.Integer' object is not iterable
```
reversal()

Return the reversal of self.

EXAMPLES:

sage: WordMorphism('6->ab,y->5,θ->asd').reversal()
WordMorphism: 6->ba, y->5
sage: WordMorphism('a->ab,b->a').reversal()
WordMorphism: a->ba, b->a

simplify_alphabet_size(Z=None)

If this morphism is simplifiable, return morphisms \( h \) and \( k \) such that this morphism is simplifiable with respect to \( h \) and \( k \), otherwise raise ValueError.

This method is quite fast if this morphism is non-injective, but very slow if it is injective.

Let \( f : X^* \rightarrow Y^* \) be a morphism. Then \( f \) is simplifiable with respect to morphisms \( h : X^* \rightarrow Z^* \) and \( k : Z^* \rightarrow Y^* \), if \( f = k \circ h \) and \( |Z| < |X| \). If also \( Y \subseteq X \), then the morphism \( g : Z^* \rightarrow Z^* = h \circ k \) is a simplification of \( f \) (with respect to \( h \) and \( k \)).

Loosely speaking, a morphism is simplifiable if it contains “more letters than is needed”. Non-injectivity implies simplifiability. Simplification preserves some properties of the original morphism (e.g. repetitiveness).

For more information see Section 3 in [KO2000].

INPUT:

• \( Z \) – iterable (default: self.domain().alphabet()), whose elements are used as an alphabet for the simplification.

EXAMPLES:

Example of a simplifiable (non-injective) morphism:

sage: f = WordMorphism('a->aca,b->badc,c->acab,d->adc')
sage: h, k = f.simplify_alphabet_size('xyz'); h, k
(WordMorphism: a->x, b->zy, c->xz, d->y, WordMorphism: x->aca, y->adc, z->b)
sage: k * h == f
True
sage: g = h * k; g
WordMorphism: x->xxzx, y->xyxz, z->zy

Example of a simplifiable (injective) morphism:

sage: f = WordMorphism('a->abcc,b->abcd,c->abdc,d->abdd')
sage: h, k = f.simplify_alphabet_size('xyz'); h, k
(WordMorphism: a->xyy, b->xyz, c->xzy, d->xzz, WordMorphism: x->ab, y->c, z->d)
sage: k * h == f
True
sage: g = h * k; g
WordMorphism: x->xyyxyz, y->xzy, z->xzz

Example of a non-simplifiable morphism:

sage: WordMorphism('a->aa').simplify_alphabet_size()
Traceback (most recent call last):
...
ValueError: self (a->aa) is not simplifiable
Example of an erasing morphism:

```
sage: f = WordMorphism('a->abc,b->cc,c->')
sage: h, k = f.simplify_alphabet_size(); h, k
(WordMorphism: a->a, b->b, c->, WordMorphism: a->abc, b->cc)
sage: k * h == f
True
sage: g = h * k; g
WordMorphism: a->ab, b->
```

Example of a morphism, that is not an endomorphism:

```
sage: f = WordMorphism('a->xx,b->xy,c->yx,d->yy')
sage: h, k = f.simplify_alphabet_size(NN); h, k
(WordMorphism: a->00, b->01, c->10, d->11, WordMorphism: 0->x, 1->y)
sage: k * h == f
True
sage: len(k.domain().alphabet()) < len(f.domain().alphabet())
True
```

`simplify_until_injective()`
Return a quadruplet \((g, h, k, i)\), where \(g\) is an injective simplification of this morphism with respect to \(h\), \(k\) and \(i\).

Requires this morphism to be an endomorphism.

This method basically calls `simplify_alphabet_size()` until the returned simplification is injective. If this morphism is already injective, a quadruplet \((g, h, k, i)\) is still returned, where \(g\) is this morphism, \(h\) and \(k\) are the identity morphisms and \(i\) is 0.

Let \(f : X^* \rightarrow Y^*\) be a morphism and \(Y \subseteq X\). Then \(g : Z^* \rightarrow Z^*\) is an injective simplification of \(f\) with respect to morphisms \(h : X^* \rightarrow Z^*\) and \(k : Z^* \rightarrow Y^*\) and a positive integer \(i\), if \(g\) is injective, \(|Z| < |X|\), \(g^i = h \circ k\) and \(f^i = k \circ h\).

For more information see Section 4 in [KO2000].

EXAMPLES:

```
sage: f = WordMorphism('a->abc,b->a,c->bc')
sage: g, h, k, i = f.simplify_until_injective(); g, h, k, i
(WordMorphism: a->aa, WordMorphism: a->aa, b->a, c->a, WordMorphism: a->abc, 2)
sage: g.is_injective()  # g is injective
True
sage: g**i == h * k  # g^i = h \circ k
True
sage: f**i == k * h  # f^i = k \circ h
True
```

`sage.combinat.words.morphism.get_cycles(f, domain)`
Return the list of cycles of the function \(f\) contained in \(domain\).

INPUT:

- \(f\) - function.
- \(domain\) - iterable, a subdomain of the domain of definition of \(f\).

EXAMPLES:
5.1.358 Word paths

This module implements word paths, which is an application of Combinatorics on Words to Discrete Geometry. A word path is the representation of a word as a discrete path in a vector space using a one-to-one correspondence between the alphabet and a set of vectors called steps. Many problems surrounding 2d lattice polygons (such as questions of self-intersection, area, inertia moment, etc.) can be solved in linear time (linear in the length of the perimeter) using theory from Combinatorics on Words.

On the square grid, the encoding of a path using a four-letter alphabet (for East, North, West and South directions) is also known as the Freeman chain code [1,2] (see [3] for further reading).

AUTHORS:

• Arnaud Bergeron (2008) : Initial version, path on the square grid
• Sebastien Labbe (2009-01-14) : New classes and hierarchy, doc and functions.

EXAMPLES:

The combinatorial class of all paths defined over three given steps:

```
sage: P = WordPaths('abc', steps=[(1,2), (-3,4), (0,-3)]); P
Word Paths over 3 steps
```

This defines a one-to-one correspondence between alphabet and steps:

```
sage: d = P.letters_to_steps()
sage: sorted(d.items())
[('a', (1, 2)), ('b', (-3, 4)), ('c', (0, -3))]
```

Creation of a path from the combinatorial class P defined above:

```
sage: p = P('abaccba'); p
Path: abaccba
```

Many functions can be used on p: the coordinates of its trajectory, ask whether p is a closed path, plot it and many other:

```
sage: list(p.points())
[(0, 0), (1, 2), (-2, 6), (-1, 8), (-1, 5), (-1, 2), (-4, 6), (-3, 8)]
sage: p.is_closed()
False
```

(continues on next page)
sage: p.plot()
Graphics object consisting of 3 graphics primitives

To obtain a list of all the available word path specific functions, use help(p):

```
sage: help(p)
Help on FiniteWordPath_2d_str in module sage.combinat.words.paths object:
...
Methods inherited from FiniteWordPath_2d:
...
Methods inherited from FiniteWordPath_all:
...
```

Since `p` is a finite word, many functions from the word library are available:

```
sage: p.crochemore_factorization()
(a, b, a, c, c, ba)
sage: p.is_palindrome()
False
sage: p[:3]
Path: aba
```

P also inherits many functions from Words:

```
sage: P = WordPaths('rs', steps=[(1,2), (-1,4)]); P
Word Paths over 2 steps
sage: P.alphabet()
{'r', 's'}
sage: list(P.iterate_by_length(3))
```

When the number of given steps is half the size of alphabet, the opposite of vectors are used:

```
sage: P = WordPaths('abcd', [(1,0), (0,1)]);
P
Word Paths over 2 steps
sage: sorted(P.letters_to_steps().items())
[('a', (1, 0)), ('b', (0, 1)), ('c', (-1, 0)), ('d', (0, -1))]
```

Some built-in combinatorial classes of paths:

```
sage: P = WordPaths('abAB', steps='square_grid'); P
Word Paths on the square grid
```

```
sage: D = WordPaths('()', steps='dyck'); D
Finite Dyck paths
```

(continues on next page)
sage: d = D(('()(()(()'))); d
Path: ()(()(()))
sage: d.plot()
Graphics object consisting of 3 graphics primitives

sage: P = WordPaths('abcdef', steps='triangle_grid')
sage: p = P('babadefadabcdefafadfabacdefa')
sage: p.plot()
Graphics object consisting of 3 graphics primitives

Vector steps may be in more than 2 dimensions:

sage: d = [(1,0,0), (0,1,0), (0,0,1)]
sage: P = WordPaths(alphabet='abc', steps=d); P
Word Paths over 3 steps
sage: p = P('abcabcabcaababcababcaabcabcacabcacabcacacbcac')
sage: p.plot()
Graphics3d Object

sage: d = [(1,3,5,1), (-5,1,-6,0), (0,0,1,9), (4,2,-1,0)]
sage: P = WordPaths(alphabet='rstu', steps=d); P
Word Paths over 4 steps
sage: p = P('rtusuususuturrsus'); p
Path: rtusuususuturrsus
sage: p.end_point()
(5, 31, -26, 30)

sage: CubePaths = WordPaths('abcABC', steps='cube_grid'); CubePaths
Word Paths on the cube grid
sage: CubePaths('abcabaabcabAAAA').plot()
Graphics3d Object

The input data may be a str, a list, a tuple, a callable or a finite iterator:

sage: P = WordPaths([0, 1, 2, 3])
sage: P([0,1,2,3,2,1,2,3,2])
Path: 012321232
sage: P((0,1,2,3,2,1,2,3,2))
Path: 012321232
sage: P(lambda n:n%4, length=10)
Path: 0123012301
sage: P(iter([0,3,2,1]), length='finite')
Path: 0321

REFERENCES:

 animate()

Returns an animation object illustrating the path growing step by step.

EXAMPLES:

```
sage: P = WordPaths('abAB')
sage: p = P('aaababbb')
```

```
sage: a = p.animate(); a       # optional -- ImageMagick
```

```
Animation with 9 frames
```

```
sage: show(a)                  # optional -- ImageMagick
```

```
sage: a.gif(delay=35, iterations=3) # optional -- ImageMagick
```

If the path is closed, the plain polygon is added at the end of the animation:

```
sage: P = WordPaths('abAB')
sage: p = P('aababABaB')
sage: a = p.animate(); a       # optional -- ImageMagick
```

```
Animation with 14 frames
```

Another example illustrating a Fibonacci tile:

```
sage: w = words.fibonacci_tile(2)
sage: show(w.animate())       # optional -- ImageMagick
```

The first 4 Fibonacci tiles in an animation:

```
sage: a = words.fibonacci_tile(0).animate()
 sage: b = words.fibonacci_tile(1).animate()
 sage: c = words.fibonacci_tile(2).animate()
 sage: d = words.fibonacci_tile(3).animate()
 sage: (a*b*c*d).show()         # optional -- ImageMagick   # long time
```

Note: If ImageMagick is not installed, you will get an error message like this:

```
convert: not found
```

Error: ImageMagick does not appear to be installed. Saving an animation to a GIF file or displaying an animation requires ImageMagick, so please install it and try again.

See www.imagemagick.org, for example.
area()

Returns the area of a closed path.

INPUT:

• self - a closed path

EXAMPLES:

```python
sage: P = WordPaths('abcd', steps=[(1,1),(-1,1),(-1,-1),(1,-1)])
sage: p = P('abcd')
sage: p.area()                # todo: not implemented
2
```

height()

Returns the height of self.

The height of a 2d-path is merely the difference between the highest and the lowest y-coordinate of each points traced by it.

OUTPUT:

non negative real number

EXAMPLES:

```python
sage: Freeman = WordPaths('abAB')
sage: Freeman('aababaabbbAA').height() 5
```

The function is well-defined if self is not simple or close:

```python
sage: Freeman('aabAAB').height() 1
sage: Freeman('abbABA').height() 2
```

This works for any 2d-paths:

```python
sage: Paths = WordPaths('ab', steps=[(1,0),(1,1)])
sage: p = Paths('abbaa')
sage: p.height() 2
sage: DyckPaths = WordPaths('ab', steps='dyck')
sage: p = DyckPaths('abaabb')
sage: p.height() 2
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.height() 2.59807621135332
```

height_vector()

Return the height at each point.

EXAMPLES:

```python
sage: Paths = WordPaths('ab', steps=[(1,0),(0,1)])
sage: p = Paths('abbba')
```
Combinatorics, Release 9.7

(continued from previous page)

**sage:** p.height_vector()

```
[0, 0, 1, 2, 3, 3]
```

**plot**

```python
plot(pathoptions={'rgbcolor': 'red', 'thickness': 3}, fill=True, filloptions={'rgbcolor': 'red', 'alpha': 0.2},
    startpoint=True, startoptions={'rgbcolor': 'red', 'pointsize': 100}, endarrow=True,
    arrowoptions={'rgbcolor': 'red', 'arrowsize': 20, 'width': 3}, gridlines=False, gridoptions={})
```

Returns a 2d Graphics illustrating the path.

**INPUT:**

- **pathoptions** - (dict, default:dict(rgbcolor='red',thickness=3)), options for the path drawing
- **fill** - (boolean, default: True), if fill is True and if the path is closed, the inside is colored
- **filloptions** - (dict, default:dict(rgbcolor='red',alpha=0.2)), options for the inside filling
- **startpoint** - (boolean, default: True), draw the start point?
- **startoptions** - (dict, default:dict(rgbcolor='red',pointsize=100)) options for the start point drawing
- **endarrow** - (boolean, default: True), draw an arrow end at the end?
- **arrowoptions** - (dict, default:dict(rgbcolor='red',arrowsize=20, width=3)) options for the end point arrow
- **gridlines** - (boolean, default: False), show gridlines?
- **gridoptions** - (dict, default: {}), options for the gridlines

**EXAMPLES:**

A non closed path on the square grid:

```python
sage: P = WordPaths('abAB')
sage: P('abababAABAB').plot()
```

Graphics object consisting of 3 graphics primitives

A closed path on the square grid:

```python
sage: P('abababAABABB').plot()
```

Graphics object consisting of 4 graphics primitives

A Dyck path:

```python
sage: P = WordPaths('()', steps='dyck')
sage: P('()()(()())').plot()
```

Graphics object consisting of 3 graphics primitives

A path in the triangle grid:

```python
sage: P = WordPaths('abcdef', steps='triangle_grid')
sage: P('abcdeededefab').plot()
```

Graphics object consisting of 3 graphics primitives

A polygon of length 220 that tiles the plane in two ways:
Combinatorics, Release 9.7

```python
sage: P = WordPaths('abAB')
sage: P(‘→’).plot()  # Graphics object consisting of 4 graphics primitives

With gridlines:

```python
sage: P('ababababab').plot(gridlines=True)
```

**plot_directive_vector**(options={‘rgbcolor’: ‘blue’})

Returns an arrow 2d graphics that goes from the start of the path to the end.

**INPUT:**

- options - dictionary, default: {‘rgbcolor’: ‘blue’} graphic options for the arrow

If the start is the same as the end, a single point is returned.

**EXAMPLES:**

```python
sage: P = WordPaths('abcd'); P
Word Paths on the square grid
sage: p = P('aaaccacacccccccbbdd'); p
Path: aaaccacacacccccccbbdd
sage: R = p.plot() + p.plot_directive_vector()
sage: R.axes(False)
sage: R.set_aspect_ratio(1)
sage: R.plot()  # Graphics object consisting of 4 graphics primitives
```

**width()**

Returns the width of self.

The height of a 2d-path is merely the difference between the rightmost and the leftmost x-coordinate of each points traced by it.

**OUTPUT:**

- non negative real number

**EXAMPLES:**

```python
sage: Freeman = WordPaths('abAB')
sage: Freeman('aababaabbba').width()
5
```

The function is well-defined if self is not simple or close:

```python
sage: Freeman('aabAB').width()
2
sage: Freeman('abbBa').width()
1
```

This works for any 2d-paths:
```python
sage: Paths = WordPaths('ab', steps=[(1,0),(1,1)])
sage: p = Paths('abbaa')
sage: p.width()
5
sage: DyckPaths = WordPaths('ab', steps='dyck')
sage: p = DyckPaths('abaabb')
sage: p.width()
6
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaaBC')
sage: w.width()
4.50000000000000
```

**width_vector()**

Return the width at each point.

**EXAMPLES:**

```python
sage: Paths = WordPaths('ab', steps=[(1,0),(0,1)])
sage: p = Paths('abbba')
sage: p.width_vector()
[0, 1, 1, 1, 1, 2]
```

**xmax()**

Returns the maximum of the x-coordinates of the path.

**EXAMPLES:**

```python
sage: P = WordPaths('0123')
sage: p = P('0101013332')
sage: p.xmax()
3
```

This works for any 2d-paths:

```python
sage: Paths = WordPaths('ab', steps=[(1,-1),(-1,1)])
sage: p = Paths('ababa')
sage: p.xmax()
1
sage: DyckPaths = WordPaths('ab', steps='dyck')
sage: p = DyckPaths('abaabb')
sage: p.xmax()
6
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaaBC')
sage: w.xmax()
4.50000000000000
```

**xmin()**

Returns the minimum of the x-coordinates of the path.

**EXAMPLES:**

```python
sage: P = WordPaths('0123')
sage: p = P('0101013332')
sage: p.xmin()
0
```
This works for any $2d$-paths:

```python
sage: Paths = WordPaths('ab', steps=[[1,0],(-1,1)])
sage: p = Paths('abbbba')
sage: p.xmin()
-2
sage: DyckPaths = WordPaths('ab', steps='dyck')
sage: p = DyckPaths('abaabb')
sage: p.xmin()
0
sage: w = WordPaths('abcABC', steps='triangle')('ababcaABC')
sage: w.xmin()
0.000000000000000
```

ymax()

Returns the maximum of the y-coordinates of the path.

```python
sage: P = WordPaths('0123')
sage: p = P('0101013332')
sage: p.ymax()
3
```

This works for any $2d$-paths:

```python
sage: Paths = WordPaths('ab', steps=[[1,-1],(-1,1)])
sage: p = Paths('ababa')
sage: p.ymax()
0
sage: DyckPaths = WordPaths('ab', steps='dyck')
sage: p = DyckPaths('abaabb')
sage: p.ymax()
2
sage: w = WordPaths('abcABC', steps='triangle')('ababcaABC')
sage: w.ymax()
2.59807621135332
```

ymin()

Returns the minimum of the y-coordinates of the path.

```python
sage: P = WordPaths('0123')
sage: p = P('0101013332')
sage: p.ymin()
0
```

This works for any $2d$-paths:

```python
sage: Paths = WordPaths('ab', steps=[[1,-1],(-1,1)])
sage: p = Paths('ababa')
sage: p.ymin()
-1
sage: DyckPaths = WordPaths('ab', steps='dyck')
```

(continues on next page)
sage: p = DyckPaths('abaabb')
sage: p.ymin()
0
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.ymin()
0.000000000000000

```python

Bases: sage.structure.sage_object.SageObject

directive_vector()

Returns the directive vector of self.

The directive vector is the vector starting at the start point and ending at the end point of the path self.

EXAMPLES:

sage: WordPaths('abcdef')('ababab').directive_vector()
(6, 2*sqrt3)
sage: WordPaths('abAB')('ababab').directive_vector()
(4, 4)
sage: P = WordPaths('abcABC', steps='cube_grid')
sage: P('abababababCC').directive_vector()
(4, 4, -2)
sage: WordPaths('abababababCC').directive_vector()
(0, 0)
sage: P = WordPaths('abc', steps=[(1,3,7,9),(-4,1,0,0),(0,32,1,8)])
sage: P('ababababababababab').directive_vector()
(-16, 254, 63, 128)

end_point()
Returns the end point of the path.

EXAMPLES:

sage: WordPaths('ababab').end_point()
(6, 2*sqrt3)
sage: WordPaths('abAB').end_point()
(4, 4)
sage: P = WordPaths('abcABC', steps='cube_grid')
sage: P('abababab').end_point()
(4, 4, -2)
sage: WordPaths('abcdef').end_point()
(0, 0)
sage: P = WordPaths('abc', steps=[(1,3,7,9),(-4,1,0,0),(0,32,1,8)])
sage: P('ababababababababab').end_point()
(-16, 254, 63, 128)

is_closed()
Returns True if the path is closed, i.e. if the origin and the end of the path are equal.

EXAMPLES:

sage: P = WordPaths('abcd', steps='triangle_grid'); P
Word Paths on the triangle grid
sage: P('abcd').is_closed()
True
sage: P('abc').is_closed()
False
sage: P().is_closed()
True
sage: P('aacacc').is_closed()
True

is_simple()
Returns True if the path is simple, i.e. if all its points are distincts.
If the path is closed, the last point is not considered.

EXAMPLES:

sage: P = WordPaths('abcdef', steps='triangle_grid'); P
Word Paths on the triangle grid
sage: P('abc').is_simple()
True
sage: P('abcde').is_simple()
True
sage: P('abcdef').is_simple()
True
\texttt{sage: P('ad').is_simple()}
True
\texttt{sage: P('aabdee').is_simple()}
False

\textbf{\texttt{is\_tangent}()}

The \texttt{is\_tangent()} method, which is implemented for words, has an extended meaning for word paths, which is not implemented yet.

\textbf{AUTHOR:}

- Thierry Monteil

\textbf{\texttt{plot\_projection}(v=None, letters=None, color=None, ring=None, size=12, kind='right')}

Return an image of the projection of the successive points of the path into the space orthogonal to the given vector.

\textbf{INPUT:}

- \texttt{self} - a word path in a 3 or 4 dimension vector space
- \texttt{v} - vector (optional, default: None) If None, the directive vector (i.e. the end point minus starting point) of the path is considered.
- \texttt{letters} - iterable (optional, default: None) of the letters to be projected. If None, then all the letters are considered.
- \texttt{color} - dictionary (optional, default: None) of the letters mapped to colors. If None, automatic colors are chosen.
- \texttt{ring} - ring (optional, default: None) where to do the computations. If None, RealField(53) is used.
- \texttt{size} - number (optional, default: 12) size of the points.
- \texttt{kind} - string (optional, default: 'right') either 'right' or 'left'. The color of a letter is given to the projected prefix to the right or the left of the letter.

\textbf{OUTPUT:}

2d or 3d Graphic object.

\textbf{EXAMPLES:}

The Rauzy fractal:

\texttt{sage: s = WordMorphism('1->12,2->13,3->1')}
\texttt{sage: D = s.fixed_point('1')}
\texttt{sage: v = s.pisot_eigenvector_right()}
\texttt{sage: P = WordPaths('123',[(1,0,0),(0,1,0),(0,0,1)])}
\texttt{sage: w = P(D[:200])}
\texttt{sage: w.plot_projection(v) \# long time (2s)}

Graphics object consisting of 200 graphics primitives

In this case, the abelianized vector doesn't give a good projection:

\texttt{sage: w.plot_projection() \# long time (2s)}

Graphics object consisting of 200 graphics primitives

You can project only the letters you want:
You can increase or decrease the precision of the computations by changing the ring of the projection matrix:

```
sage: w.plot_projection(v, ring=RealField(20))  # long time (2s)
Graphics object consisting of 200 graphics primitives
```

You can change the size of the points:

```
sage: w.plot_projection(v, size=30)  # long time (2s)
Graphics object consisting of 200 graphics primitives
```

You can assign the color of a letter to the projected prefix to the right or the left of the letter:

```
sage: w.plot_projection(v, kind='left')  # long time (2s)
Graphics object consisting of 200 graphics primitives
```

To remove the axis, do like this:

```
sage: r = w.plot_projection(v)
sage: r.axes(False)
sage: r  # long time (2s)
Graphics object consisting of 200 graphics primitives
```

You can assign different colors to each letter:

```
sage: color = {'1': 'purple', '2': (.2, .3, .4), '3': 'magenta'}
sage: w.plot_projection(v, color=color)  # long time (2s)
Graphics object consisting of 200 graphics primitives
```

The 3d-Rauzy fractal:

```
sage: s = WordMorphism('1->12,2->13,3->14,4->1')
sage: D = s.fixed_point('1')
sage: w = s.pisot_eigenvector_right()
sage: P = WordPaths('1234', [(1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1)])
sage: w.plot_projection(v)
Graphics3d Object
```

The dimension of vector space of the parent must be 3 or 4:

```
sage: P = WordPaths('ab', [(1, 0), (0, 1)])
sage: p = P('aabababab')
sage: p.plot_projection()
Traceback (most recent call last):
  ...
TypeError: The dimension of the vector space (=2) must be 3 or 4
```

points(include_last=True)

Returns an iterator yielding a list of points used to draw the path represented by this word.

INPUT:
• include_last - bool (default: True) whether to include the last point

EXAMPLES:
A simple closed square:

```
sage: P = WordPaths('abAB')
sage: list(P('abAB').points())
[(0, 0), (1, 0), (1, 1), (0, 1), (0, 0)]
```

A simple closed square without the last point:

```
sage: list(P('abAB').points(include_last=False))
[(0, 0), (1, 0), (1, 1), (0, 1)]
```

```
sage: list(P('abaB').points())
[(0, 0), (1, 0), (1, 1), (2, 1), (2, 0)]
```

projected_path(v=None, ring=None)
Return the path projected into the space orthogonal to the given vector.

INPUT:
• v - vector (optional, default: None) If None, the directive vector (i.e. the end point minus starting point) of the path is considered.
• ring - ring (optional, default: None) where to do the computations. If None, RealField(53) is used.

OUTPUT:
word path

EXAMPLES:
The projected path of the tribonacci word:

```
sage: s = WordMorphism('1->12,2->13,3->1')
sage: D = s.fixed_point('1')
sage: v = s.pisot_eigenvector_right()
sage: P = WordPaths('123', [(1, 0, 0), (0, 1, 0), (0, 0, 1)])
sage: w = P(D[:1000])
sage: p = w.projected_path(v)
sage: p
Path: 1213121121312121312112131213121121312121...
sage: p[:20].plot()
Graphics object consisting of 3 graphics primitives
```

The ring argument allows to change the precision of the projected steps:

```
sage: p = w.projected_path(v, RealField(10))
sage: p
Path: 121312112131213121312131213121312131213121...
sage: p.parent().letters_to_steps()
{1': (-0.53, 0.00), 2': (0.75, -0.48), 3': (0.41, 0.88)}
```

projected_point_iterator(v=None, ring=None)
Return an iterator of the projection of the orbit points of the path into the space orthogonal to the given vector.

INPUT:
• \(v\) - vector (optional, default: None) If None, the directive vector (i.e. the end point minus starting point) of the path is considered.

• ring - ring (optional, default: None) where to do the computations. If None, RealField(53) is used.

OUTPUT:
iterator of points

EXAMPLES:
Projected points of the Rauzy fractal:

```sage
s = WordMorphism('1->12,2->13,3->1')
s = s.fixed_point('1')
v = s.pisot_eigenvector_right()
P = WordPaths('123',[(1,0,0),(0,1,0),(0,0,1)])
w = P(D[:200])
it = w.projected_point_iterator(v)
for i in range(6): next(it)
```

Projected points of a 2d path:

```sage
P = WordPaths('ab','ne')
p = P('aabbabab')
it = p.projected_point_iterator(ring=RealField(20))
for i in range(8): next(it)
```

```
\textbf{start\_point()}

Return the starting point of self.

OUTPUT:
vector

EXAMPLES:
```
```sage
WordPaths('abcdef')('abcdef').start_point()
(0, 0)
sage: WordPaths('abcdef', steps='cube_grid')('abcdef').start_point()
(0, 0, 0)
sage: P = WordPaths('ab', steps=[(1,0,0,0),(0,1,0,0)])
sage: P('abba').start_point()
(0, 0, 0, 0)
```
tikz_trajectory()

Returns the trajectory of self as a tikz str.

EXAMPLES:

```python
sage: P = WordPaths('abcdef')
sage: p = P('abcde')
sage: p.tikz_trajectory()
'(0.000, 0.000) -- (1.00, 0.000) -- (1.50, 0.866) -- (1.00, 1.73) -- (0.000, 1.73) -- (-0.500, 0.866)'
```

```python
class sage.combinat.words.paths.FiniteWordPath_all_callable(parent, callable, length=None)

```

```python
class sage.combinat.words.paths.FiniteWordPath_all_callable_with_caching(parent, callable, length=None)

```

```python
class sage.combinat.words.paths.FiniteWordPath_all_iter(parent, iter, length=None)

```

```python
class sage.combinat.words.paths.FiniteWordPath_all_iter_with_caching(parent, iter, length=None)

```

```python
class sage.combinat.words.paths.FiniteWordPath_all_list

```

```python
class sage.combinat.words.paths.FiniteWordPath_all_str

```

```python
class sage.combinat.words.paths.FiniteWordPath_all_tuple

```

```python
class sage.combinat.words.paths.FiniteWordPath_cube_grid

Bases: sage.combinat.words.paths.FiniteWordPath_3d
```

```python
class sage.combinat.words.paths.FiniteWordPath_cube_grid_callable(parent, callable, length=None)

```

```python
class sage.combinat.words.paths.FiniteWordPath_cube_grid_callable_with_caching(parent, callable, length=None)

```
<table>
<thead>
<tr>
<th>Class</th>
<th>Bases</th>
</tr>
</thead>
</table>
class sage.combinat.words.paths.FiniteWordPath_hexagonal_grid
Bases: sage.combinat.words.paths.FiniteWordPath_triangle_grid

INPUT:

- parent - a parent object inheriting from Words_all that has the alphabet attribute defined
- *args, **kwds - arguments accepted by AbstractWord

EXAMPLES:

```
sage: F = WordPaths('abcdef', steps='hexagon'); F
Word Paths on the hexagonal grid
sage: f = F('aaabbbccddeef'); f
Path: aaabbbccddeef
```

```sage
f == loads(dumps(f))
True
```
class sage.combinat.words.paths.FiniteWordPath_north_east_callable(parent, callable, length=None)

class sage.combinat.words.paths.FiniteWordPath_north_east_callable_with_caching(parent, callable, length=None)

class sage.combinat.words.paths.FiniteWordPath_north_east_iter(parent, iter, length=None)

class sage.combinat.words.paths.FiniteWordPath_north_east_iter_with_caching(parent, iter, length=None)

class sage.combinat.words.paths.FiniteWordPath_north_east_list

class sage.combinat.words.paths.FiniteWordPath_north_east_str

class sage.combinat.words.paths.FiniteWordPath_north_east_tuple

class sage.combinat.words.paths.FiniteWordPath_square_grid

Bases: sage.combinat.words.paths.FiniteWordPath_2d

area()

Returns the area of a closed path.

INPUT:

• self - a closed path

EXAMPLES:

sage: P = WordPaths('abAB', steps='square_grid')
sage: P('abAB').area()
1
sage: P('aabbAABB').area()
4
sage: P('aabbABAB').area()
3

The area of the Fibonacci tiles:
sage: [words.fibonacci_tile(i).area() for i in range(6)]
[1, 5, 29, 169, 985, 5741]

sage: [words.dual_fibonacci_tile(i).area() for i in range(6)]
[1, 5, 29, 169, 985, 5741]

sage: oeis(_)[0]  # optional -- internet
A001653: Numbers k such that 2*k^2 - 1 is a square.

sage: _.first_terms()  # optional -- internet
(1,

10181446324101389,
59341817924539925)

is_closed()
Returns True if self represents a closed path and False otherwise.

EXAMPLES:

sage: P = WordPaths('abAB', steps='square_grid')
sage: P('aA').is_closed()
True
sage: P('abAB').is_closed()
True
sage: P('ababAABB').is_closed()
True
sage: P('aaabbAABB').is_closed()
False
sage: P('ab').is_closed()
False

is_simple()
Returns True if the path is simple, i.e. if all its points are distincts.
If the path is closed, the last point is not considered.
**Note:** The linear algorithm described in the thesis of Xavier Provençal should be implemented here.

**EXEMPLARY:**

```python
sage: P = WordPaths('abAB', steps='square_grid')
sage: P('abab').is_simple()
True
sage: P('abAB').is_simple()
True
sage: P('abA').is_simple()
True
sage: P('aabABB').is_simple()
False
sage: P().is_simple()
True
sage: P('A').is_simple()
True
sage: P('aA').is_simple()
True
sage: P('aaA').is_simple()
False
```

**REFERENCES:**

**tikz_trajectory()**

Returns the trajectory of self as a tikz str.

**EXAMPLES:**

```python
sage: f = words.fibonacci_tile(1)
sage: f.tikz_trajectory()
'(0, 0) -- (0, -1) -- (-1, -1) -- (-1, -2) -- (0, -2) -- (0, -3) -- (1, -3) -- (1, -2) -- (2, -2) -- (2, -1) -- (1, -1) -- (1, 0) -- (0, 0)'
```

**class** `sage.combinat.words.paths.FiniteWordPath_square_grid_callable(parent, callable, length=None)`

Based on:

- `sage.combinat.words.word_infinite_datatypes.WordDatatype_callable`
- `sage.combinat.words.paths.FiniteWordPath_square_grid`
- `sage.combinat.words.finite_word.FiniteWord_class`

**class** `sage.combinat.words.paths.FiniteWordPath_square_grid_callable_with_caching(parent, callable, length=None)`

Based on:

- `sage.combinat.words.word_infinite_datatypes.WordDatatype_callable_with_caching`
- `sage.combinat.words.paths.FiniteWordPath_square_grid`
- `sage.combinat.words.finite_word.FiniteWord_class`

**class** `sage.combinat.words.paths.FiniteWordPath_square_grid_iter(parent, iter, length=None)`

Based on:

- `sage.combinat.words.word_infinite_datatypes.WordDatatype_iter`
- `sage.combinat.words.paths.FiniteWordPath_square_grid`
- `sage.combinat.words.finite_word.FiniteWord_class`

5.1. Comprehensive Module List
class sage.combinat.words.paths.FiniteWordPath_square_grid_iter_with_caching(parent, iter, length=None):

class sage.combinat.words.paths.FiniteWordPath_square_grid_list

class sage.combinat.words.paths.FiniteWordPath_square_grid_str

class sage.combinat.words.paths.FiniteWordPath_square_grid_tuple

class sage.combinat.words.paths.FiniteWordPath_triangle_grid

Bases: sage.combinat.words.paths.FiniteWordPath_2d

xmax()

Returns the maximum of the x-coordinates of the path.

EXAMPLES:

```
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.xmax()
4.50000000000000
```

xmin()

Returns the minimum of the x-coordinates of the path.

EXAMPLES:

```
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.xmin()
0.00000000000000
```

ymax()

Returns the maximum of the y-coordinates of the path.

EXAMPLES:

```
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.ymax()
2.59807621135332
```

ymin()

Returns the minimum of the y-coordinates of the path.

EXAMPLES:

```
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.ymin()
-3.00000000000000
```
EXAMPLES:

```python
sage: w = WordPaths('abcABC', steps='triangle')('ababcaABC')
sage: w.ymin()
0.000000000000000
sage: w = WordPaths('abcABC', steps='triangle')('ABAcacacabababcbcAC')
sage: w.ymin()
-0.866025403784439
```

class sage.combinat.words.paths.FiniteWordPath_triangle_grid_callable(parent, callable, length=None):

class sage.combinat.words.paths.FiniteWordPath_triangle_grid_callable_with_caching(parent, callable, length=None):

class sage.combinat.words.paths.FiniteWordPath_triangle_grid_iter(parent, iter, length=None):

class sage.combinat.words.paths.FiniteWordPath_triangle_grid_iter_with_caching(parent, iter, length=None):

class sage.combinat.words.paths.FiniteWordPath_triangle_grid_list:

class sage.combinat.words.paths.FiniteWordPath_triangle_grid_str:

class sage.combinat.words.paths.FiniteWordPath_triangle_grid_tuple:

sage.combinat.words.paths.WordPaths(alphabet, steps=None)
Returns the combinatorial class of paths of the given type of steps.

INPUT:

- alphabet - ordered alphabet
- steps - (default is None). It can be one of the following:
  - an iterable ordered container of as many vectors as there are letters in the alphabet. The vectors are
    associated to the letters according to their order in steps. The vectors can be a tuple or anything that
    can be passed to vector function.
  - an iterable ordered container of k vectors where k is half the size of alphabet. The vectors and their
    opposites are associated to the letters according to their order in steps (given vectors first, opposite
Combinatorics, Release 9.7

vectors after).

– None: In this case, the type of steps are guessed from the length of alphabet.
– ‘square_grid’ or ‘square’: (default when size of alphabet is 4) The order is: East, North, West, South.
– ‘triangle_grid’ or ‘triangle’:
– ‘hexagonal_grid’ or ‘hexagon’: (default when size of alphabet is 6)
– ‘cube_grid’ or ‘cube’:
– ‘north_east’, ‘ne’ or ‘NE’: (the default when size of alphabet is 2)
– ‘dyck’:

OUTPUT:

• The combinatorial class of all paths of the given type.

EXAMPLES:
The steps can be given explicitly:

```
sage: WordPaths('abc', steps=[(1,2), (-1,4), (0,-3)])
Word Paths over 3 steps
```

Different type of input alphabet:

```
sage: WordPaths(range(3), steps=[(1,2), (-1,4), (0,-3)])
Word Paths over 3 steps
sage: WordPaths(['cric','crac','croc'], steps=[(1,2), (1,4), (0,3)])
Word Paths over 3 steps
```

Directions can be in three dimensions as well:

```
sage: WordPaths('ab', steps=[(1,2,2),(-1,4,2)])
Word Paths over 2 steps
```

When the number of given steps is half the size of alphabet, the opposite of vectors are used:

```
sage: P = WordPaths('abcd', [(1,0), (0,1)])
sage: P
Word Paths over 4 steps
sage: sorted(P.letters_to_steps().items())
[('a', (1, 0)), ('b', (0, 1)), ('c', (-1, 0)), ('d', (0, -1))]
```

When no steps are given, default classes are returned:

```
sage: WordPaths('ab')
Word Paths in North and East steps
sage: WordPaths(range(4))
Word Paths on the square grid
sage: WordPaths(range(6))
Word Paths on the hexagonal grid
```

There are many type of built-in steps...

On a two letters alphabet:
Combinatorics, Release 9.7

```python
sage: WordPaths('ab', steps='north_east')
Word Paths in North and East steps
sage: WordPaths('', steps='dyck')
Finite Dyck paths
```

On a four letters alphabet:

```python
sage: WordPaths('ruld', steps='square_grid')
Word Paths on the square grid
```

On a six letters alphabet:

```python
sage: WordPaths('abcdef', steps='hexagonal_grid')
Word Paths on the hexagonal grid
sage: WordPaths('abcdef', steps='triangle_grid')
Word Paths on the triangle grid
sage: WordPaths('abcdef', steps='cube_grid')
Word Paths on the cube grid
```

```python
class sage.combinat.words.paths.WordPaths_all(alphabet, steps)
Bases: sage.combinat.words.words.FiniteWords

The combinatorial class of all paths, i.e of all words over an alphabet where each letter is mapped to a step (a vector).

letters_to_steps()
Returns the dictionary mapping letters to vectors (steps).

EXAMPLES:

```python
sage: d = WordPaths('ab').letters_to_steps()
sage: sorted(d.items())
[('a', (0, 1)), ('b', (1, 0))]
```

```python
sage: d = WordPaths('abcd').letters_to_steps()
sage: sorted(d.items())
[('a', (1, 0)), ('b', (0, 1)), ('c', (-1, 0)), ('d', (0, -1))]
```

```python
sage: d = WordPaths('abcdef').letters_to_steps()
sage: sorted(d.items())
[('a', (1, 0)), ('b', (1/2, 1/2*sqrt3)), ('c', (-1/2, 1/2*sqrt3)), ('d', (-1, 0)), ('e', (-1/2, -1/2*sqrt3)), ('f', (1/2, -1/2*sqrt3))]
```

vector_space()
Return the vector space over which the steps of the paths are defined.

EXAMPLES:

```python
sage: WordPaths('ab', steps='dyck').vector_space()
Ambient free module of rank 2 over the principal ideal domain Integer Ring
```

```
(continues on next page)
```
Ambient free module of rank 2 over the principal ideal domain Integer Ring
\[ \text{sage: WordPaths('abcdef', steps='hexagonal_grid').vector_space() \} \]
Vector space of dimension 2 over Number Field in sqrt3 with defining polynomial \[ \rightarrow x^2 - 3 \text{ with } \sqrt{3} = 1.732050807568878? \]
\[ \text{sage: WordPaths('abcdef', steps='cube_grid').vector_space() \} \]
Ambient free module of rank 3 over the principal ideal domain Integer Ring
\[ \text{sage: WordPaths('abcdef', steps='triangle_grid').vector_space() \} \]
Vector space of dimension 2 over Number Field in sqrt3 with defining polynomial \[ \rightarrow x^2 - 3 \text{ with } \sqrt{3} = 1.732050807568878? \]

5.1.359 Shuffle product of words

See also:
The module \texttt{sage.combinat.shuffle} contains a more general implementation of shuffle product.

\texttt{class sage.combinat.words.shuffle_product.ShuffleProduct_shifted(w1, w2, check=True) \}}
Shifted shuffle product of \(w1\) with \(w2\).
This is the shuffle product of \(w1\) with the word obtained by adding the length of \(w1\) to every letter of \(w2\).
Note that this class is meant to be used for words; it misbehaves when \(w1\) is a permutation or composition.

INPUT:

- \texttt{check} – boolean (default \texttt{True}) whether to check that all words in the shuffle product belong to the correct parent

EXAMPLES:
sage: from sage.combinat.words.shuffle_product import ShuffleProduct_shifted
sage: w, u = Word([1,2]), Word([3,4])
sage: S = ShuffleProduct_shifted(w,u)
sage: S == loads(dumps(S))
True

class sage.combinat.words.shuffle_product.ShuffleProduct_w1w2(w1, w2, check=True)

Bases: sage.structure.parent.Parent, sage.structure.unique_representation.UniqueRepresentation

The shuffle product of the two words w1 and w2.

If 𝑢 and 𝑣 are two words, then the shuffle product of 𝑢 and 𝑣 is a certain multiset of words defined as follows:

Let 𝑎 and 𝑏 be the lengths of 𝑢 and 𝑣, respectively. For every 𝑎-element subset 𝐼 of {1,2,⋯, 𝑎 + 𝑏}, let 𝑤(𝐼) be the length-𝑎 + 𝑏 word such that:

• for every 1 ≤ 𝑘 ≤ 𝑎, the 𝑖 𝑘-th letter of 𝑤(𝐼) is the 𝑘-th letter of 𝑢, where 𝑖 𝑘 is the 𝑘-th smallest element of 𝐼;

• for every 1 ≤ 𝑙 ≤ 𝑏, the 𝑗 𝑙-th letter of 𝑤(𝐼) is the 𝑙-th letter of 𝑣, where 𝑗 𝑙 is the 𝑙-th smallest element of \{1,2,⋯, 𝑎 + 𝑏\} \ 𝐼.

The shuffle product of 𝑢 and 𝑣 is then the multiset of all 𝑤(𝐼) with 𝐼 ranging over the 𝑎-element subsets of \{1,2,⋯, 𝑎 + 𝑏\}.

INPUT:

• check – boolean (default True) whether to check that all words in the shuffle product belong to the correct parent

EXAMPLES:

sage: from sage.combinat.words.shuffle_product import ShuffleProduct_w1w2
sage: W = Words([1,2,3,4])
sage: s = ShuffleProduct_w1w2(W([1,2]),W([3,4]))
sage: sorted(s)
[word: 1234, word: 1324, word: 1342, word: 3124, word: 3142, word: 3412]
sage: s == loads(dumps(s))
True
sage: TestSuite(s).run()

sage: s = ShuffleProduct_w1w2(W([1,4,3]),W([2]))
sage: sorted(s)
[word: 1243, word: 1423, word: 1432, word: 2143]

sage: s = ShuffleProduct_w1w2(W([1,4,3]),W([]))
sage: sorted(s)
[word: 143]

cardinality()

Return the number of words in the shuffle product of 𝑤1 and 𝑤2.

This is understood as a multiset cardinality, not as a set cardinality; it does not count the distinct words only.

It is given by 𝑙1 + 𝑙2 \choose 𝑙1, where 𝑙1 is the length of 𝑤1 and where 𝑙2 is the length of 𝑤2.

EXAMPLES:
5.1.360 Suffix Tries and Suffix Trees

class sage.combinat.words.suffix_trees.DecoratedSuffixTree(w)
     Bases: sage.combinat.words.suffix_trees.ImplicitSuffixTree

The decorated suffix tree of a word.

A decorated suffix tree of a word \( w \) is the suffix tree of \( w \) marked with the end point of all squares in the \( w \).

The symbol \( $ \) is appended to \( w \) to ensure that each final state is a leaf of the suffix tree.

INPUT:

* \( w \) – a finite word

EXAMPLES:

sage: from sage.combinat.words.suffix_trees import DecoratedSuffixTree
sage: w = Word('0011001')
sage: DecoratedSuffixTree(w)
Decoded suffix treet of : 0011001$
sage: w = Word('0011001', '01')
sage: DecoratedSuffixTree(w)
Decoded suffix treet of : 0011001$

ALGORITHM:

When using 'pair' as output, the squares are retrieved in linear time. The algorithm is an implementation of the one proposed in [DS2004].

square_vocabulary(output='pair')

Return the list of distinct squares of self.word.

Two types of outputs are available pair and word. The algorithm is only truly linear if output is set to pair. A pair is a tuple \((i, l)\) that indicates the factor self.word()[i:i+l]. The option 'word' return word objects.

INPUT:

* output – (default: "pair") either "pair" or "word"

EXAMPLES:

sage: from sage.combinat.words.suffix_trees import DecoratedSuffixTree
sage: w = Word('aabb')
sage: sorted(DecoratedSuffixTree(w).square_vocabulary())

(continues on next page)
class sage.combinat.words.suffix_trees.ImplicitSuffixTree(word)
Bases: sage.structure.sage_object.SageObject

Construct the implicit suffix tree of a word w.

The suffix tree of a word w is a compactification of the suffix trie for w. The compactification removes all nodes that have exactly one incoming edge and exactly one outgoing edge. It consists of two components: a tree and a word. Thus, instead of labelling the edges by factors of w, we can labelled them by indices of the occurrence of the factors in w.

The following is a straightforward implementation of Ukkonen’s on-line algorithm for constructing the implicit suffix tree [Ukko1995]. It constructs the suffix tree for w[:i] from that of w[:i-1].

**GENERAL IDEA.** The suffix tree of w[:i+1] can be obtained from that of w[:i] by visiting each node corresponding to a suffix of w[:i] and modifying the tree by applying one of two rules (either append a new node to the tree, or split an edge into two). The “active state” is the node where the algorithm begins and the “suffix link” carries us to the next node that needs to be dealt with.

**TREE.** The tree is modelled as an automaton, which is stored as a dictionary of dictionaries: it is keyed by the nodes of the tree, and the corresponding dictionary is keyed by pairs (i,j) of integers representing the word w[i-1:j]. This makes it faster to look up a particular transition beginning at a specific node.

**STATES/NODES.** The states will always be -1, 0, 1, ..., n. The state -1 is special and is only used for the purposes of the algorithm. All transitions map -1 to 0, so this information is not explicitly stored in the transition function.

**EXPLICIT/IMPLICIT NODES.** By definition, some of the nodes will not be states, but merely locations along an edge; these are called implicit nodes. A node r (implicit or explicit) is referenced as a pair (s,(k,p)) where s is an ancestor of r and w[k-1:p] is the word read by transitioning from s to r in the suffix trie. A reference pair is canonical if s is the closest ancestor of r.

**SUFFIX LINK.** The algorithm makes use of a map from (some) nodes to other nodes, called the suffix link. This is stored as a dictionary.

**ACTIVE STATE.** We store as ._active_state the active state of the tree, the state where the algorithm will begin when processing the next letter.

**RUNNING TIME.** The running time and storage space of the algorithm is linear in the length of the word w (whereas for a suffix tree it is quadratic).

REFERENCES:
- [Ukko1995]

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: w = Words("aco")("cacao")
sage: t = ImplicitSuffixTree(w); t
Implicit Suffix Tree of the word: cacao
sage: ababb = Words([0,1])([0,1,0,1,1])
sage: s = ImplicitSuffixTree(ababb); s
Implicit Suffix Tree of the word: 01011
```
**LZ_decomposition()**

Return a list of index of the beginning of the block of the Lempel-Ziv decomposition of `self.word`

The Lempel-Ziv decomposition is the factorisation $u_1\ldots u_k$ of a word $w = x_1\ldots x_n$ such that $u_i$ is the longest prefix of $u_i\ldots u_k$ that has an occurrence starting before $u_i$ or a letter if this prefix is empty.

**OUTPUT:**

Return a list `iB` of index such that the blocks of the decomposition are `self.word()[iB[k]:iB[k+1]]`

**EXAMPLES:**

```
sage: w = Word('abababb')
sage: T = w.suffix_tree()
sage: T.LZ_decomposition()
[0, 1, 2, 6, 7]
sage: w = Word('abaabacabba')
sage: T = w.suffix_tree()
sage: T.LZ_decomposition()
[0, 1, 2, 3, 6, 8, 9, 11, 13]
sage: w = Word([0, 0, 0, 1, 1, 0, 1])
sage: T = w.suffix_tree()
sage: T.LZ_decomposition()
[0, 1, 3, 4, 5, 7]
sage: w = Word('0000100101')
sage: T = w.suffix_tree()
sage: T.LZ_decomposition()
[0, 1, 4, 5, 9, 10]
```

**active_state()**

Returns the active state of the suffix tree.

**EXAMPLES:**

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.active_state()
(0, (6, 6))
```

**edge_iterator()**

Returns an iterator over the edges of the suffix tree. The edge from $u$ to $v$ labelled by $(i,j)$ is returned as the tuple $(u,v,(i,j))$.

**EXAMPLES:**

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: sorted( ImplicitSuffixTree(Word("aaaaa")) .edge_iterator() )
[(0, 1, (0, None))]
sage: sorted( ImplicitSuffixTree(Word([0,1,0,1])) .edge_iterator() )
[(0, 1, (0, None)), (0, 2, (1, None))]
sage: sorted( ImplicitSuffixTree(Word().edge_iterator() )
[]
```

**factor_iterator(n=None)**

Generate distinct factors of `self`.

**INPUT:**
COMBINATORICS, RELEASE 9.7

- \( n \) - an integer, or \( \text{None} \).

**OUTPUT:**

- If \( n \) is an integer, returns an iterator over all distinct factors of length \( n \). If \( n \) is \( \text{None} \), returns an iterator generating all distinct factors.

**EXAMPLES:**

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: sorted( ImplicitSuffixTree(Word("cacao")).factor_iterator() )
[word: , word: a, word: ac, word: aca, word: acao, word: ao, word: c, word: ca, ...
   ...word: cac, word: caca, word: cacao, word: cao, word: o]
sage: sorted( ImplicitSuffixTree(Word("cacao")).factor_iterator(1) )
[word: a, word: c, word: o]
sage: sorted( ImplicitSuffixTree(Word("cacao")).factor_iterator(2) )
[word: ac, word: ao, word: ca]
sage: sorted( ImplicitSuffixTree(Word([0,0,0])).factor_iterator() )
[word: , word: 0, word: 00, word: 000]
sage: sorted( ImplicitSuffixTree(Word([0,0,0])).factor_iterator(2) )
[word: 00]
sage: sorted( ImplicitSuffixTree(Word([0,0,0])).factor_iterator(0) )
[word: ]
sage: sorted( ImplicitSuffixTree(Word()).factor_iterator() )
[word: ]
sage: sorted( ImplicitSuffixTree(Word()).factor_iterator(2) )
[]
```

**leftmost_covering_set()**

Compute the leftmost covering set of square pairs in \( \text{self.word}() \). Return a square as a pair \((i, l)\) designating factor \( \text{self.word}()[i:i+l] \).

A leftmost covering set is a set such that the leftmost occurrence \((j, l)\) of a square in \( \text{self.word}() \) is covered by a pair \((i, l)\) in the set for all types of squares. We say that \((j, l)\) is covered by \((i, l)\) if \((i, l)\) \((i+1, l), \ldots, (j, l)\) are all squares.

The set is returned in the form of a list \( P \) such that \( P[i] \) contains all the lengths of squares starting at \( i \) in the set. The lists \( P[i] \) are sorted in decreasing order.

The algorithm used is described in [DS2004].

**EXAMPLES:**

```
sage: w = Word('abaabaabbaabaaba')
sage: T = w.suffix_tree()
sage: T.leftmost_covering_set()
[[6], [6], [2], [], [], [], [], [2], [], [], [], [6, 2], [], [], [], [], [], [], [], []]
sage: w = Word('abaca')
sage: T = w.suffix_tree()
sage: T.leftmost_covering_set()
[[], [], [], [], []]
sage: T = Word('aaaaa').suffix_tree()
sage: T.leftmost_covering_set()
[[4, 2], [], [], [], [], []]
```

**number_of_factors**

Count the number of distinct factors of \( \text{self.word}() \).

5.1. Comprehensive Module List 3609
INPUT:
• \( n \) - an integer, or None.

OUTPUT:
• If \( n \) is an integer, returns the number of distinct factors of length \( n \). If \( n \) is None, returns the total number of distinct factors.

EXAMPLES:
```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: t = ImplicitSuffixTree(Word([1,2,1,3,1,2,1]))
sage: t.number_of_factors()
22
sage: t.number_of_factors(1)
3
sage: t.number_of_factors(9)
0
sage: t.number_of_factors(0)
1

sage: t = ImplicitSuffixTree(Word("cacao"))

13
sage: list(map(t.number_of_factors, range(10)))
[1, 3, 3, 3, 2, 1, 0, 0, 0, 0]

sage: t = ImplicitSuffixTree(Word("c"*1000))

1001
sage: t.number_of_factors(17)
1
sage: t.number_of_factors(0)
1

sage: ImplicitSuffixTree(Word()).number_of_factors()
1

sage: blueberry = ImplicitSuffixTree(Word("blueberry"))

43
sage: list(map(blueberry.number_of_factors, range(10)))
[1, 6, 8, 7, 6, 5, 4, 3, 2, 1]
```

plot\( \text{\texttt{word\_labels=\texttt{False}, layout='tree', tree\_root=0, tree\_orientation='up', vertex\_colors=None, edge\_labels=True, *args, **kwds}} \)

Returns a Graphics object corresponding to the transition graph of the suffix tree.

INPUT:
• word_labels - boolean (default: False) if False, labels the edges by pairs \( (i, j) \); if True, labels the edges by word\( [i:j] \).
• layout - (default: 'tree')
• tree_root - (default: 0)
• tree_orientation - (default: 'up')
• vertex_colors - (default: None)
• edge_labels - (default: True)

**EXAMPLES:**

```python
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: ImplicitSuffixTree(Word('cacao')).plot(word_labels=True)
Graphics object consisting of 23 graphics primitives
sage: ImplicitSuffixTree(Word('cacao')).plot(word_labels=False)
Graphics object consisting of 23 graphics primitives
```

**process_letter**(letter)

Modifies the current implicit suffix tree producing the implicit suffix tree for self.word() + letter.

**EXAMPLES:**

```python
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: w = Words('aco')('cacao')
sage: t = ImplicitSuffixTree(w[:-1]); t
Implicit Suffix Tree of the word: caca
sage: t.process_letter(w[-1]); t
Implicit Suffix Tree of the word: cacao
sage: W = Words([0,1])
sage: s = ImplicitSuffixTree(W([0,1,0,1])); s
Implicit Suffix Tree of the word: 0101
sage: s.process_letter(W([1])[0]); s
Implicit Suffix Tree of the word: 01011
```

**show**(word_labels=None, *args, **kwds)

Displays the output of self.plot().

**INPUT:**

• word_labels - (default: None) if False, labels the edges by pairs \((i, j)\); if True, labels the edges by \(word[i:j]\).

**EXAMPLES:**

```python
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: w = Words('aco')('cacao')
sage: t = ImplicitSuffixTree(w)
sage: t.show(word_labels=True)
sage: t.show(word_labels=False)
```

**states()**

Returns the states (explicit nodes) of the suffix tree.

**EXAMPLES:**

```python
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.states()
[0, 1, 2, 3, 4, 5, 6, 7]
```
**suffix_link**(state)
Evaluates the suffix link map of the implicit suffix tree on state. Note that the suffix link is not defined for all states.

The suffix link of a state $x'$ that corresponds to the suffix $x$ is defined to be -1 if $x'$ is the root (0) and $y'$ otherwise, where $y'$ is the state corresponding to the suffix $x[1:]$.

**INPUT:**
- state - a state

**EXAMPLES:**

```python
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
gsage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.suffix_link(3)
5
sage: t.suffix_link(5)
0
sage: t.suffix_link(0)
-1
sage: t.suffix_link(-1)
Traceback (most recent call last):
  ...TypeError: there is no suffix link from -1
```

**suffix_walk**(edge, l)
Return the state of “w” if the input state is “aw”.

If the input state (edge, l) is path labeled “aw” with “a” a letter, the output is the state which is path labeled “w”.

**INPUT:**
- edge – the edge containing the state
- l – the string-depth of the state on edge (l>0)

**OUTPUT:**
Return "explicit", end_node) if the state of w is an explicit state and ("implicit", edge, d) is obtained by reading d letters on edge.

**EXAMPLES:**

```python
sage: T = Word('00110111011').suffix_tree()
sage: T.suffix_walk((0, 5), 1)
('explicit', 0)
sage: T.suffix_walk((7, 3), 1)
('implicit', (9, 4), 1)
```

**to_digraph**(word_labels=False)
Returns a DiGraph object of the transition graph of the suffix tree.

**INPUT:**
- word_labels - boolean (default: False) if False, labels the edges by pairs $(i, j)$; if True, labels the edges by word[i:j].

**EXAMPLES:**
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.to_digraph()
Digraph on 8 vertices

**to_explicit_suffix_tree()**

Converts self to an explicit suffix tree. It is obtained by processing an end of string letter as if it were a regular letter, except that no new leaf nodes are created (thus, the only thing that happens is that some implicit nodes become explicit).

**transition_function(word, node=0)**

Returns the node obtained by starting from node and following the edges labelled by the letters of word. Returns ("explicit", end_node) if we end at end_node, or ("implicit", edge, d) if we end d spots along an edge.

**transition_function_dictionary()**

Returns the transition function as a dictionary of dictionaries. The format is consistent with the input format for DiGraph.

(continues on next page)
### Combinatorics, Release 9.7

```python
sage: t.transition_function_dictionary()
{0: {1: (0, None), 2: (1, None)}

sage: W = Words([0,1])
sage: t = ImplicitSuffixTree(W([0,1,0]))
sage: t.transition_function_dictionary()
{0: {1: (0, None), 2: (1, None)}

trie_type_dict()
Returns a dictionary in a format compatible with that of the suffix trie transition function.

EXAMPLES:

```python
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree,
    SuffixTrie
sage: W = Words("ab")
sage: t = ImplicitSuffixTree(W("aba"))
sage: d = t.trie_type_dict()
sage: len(d)
5
sage: d
```

uncompactify()
Returns the tree obtained from self by splitting edges so that they are labelled by exactly one letter. The resulting tree is isomorphic to the suffix trie.

EXAMPLES:

```python
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree,
    SuffixTrie
sage: abbab = Words("ab")("abbab")
sage: s = SuffixTrie(abbab)
sage: t = ImplicitSuffixTree(abbab)
sage: t.uncompactify().is_isomorphic(s.to_digraph())
True
```

word()
Returns the word whose implicit suffix tree this is.

### sage.combinat.words.suffix_trees.SuffixTrie(word)

Bases: sage.structure.sage_object.SageObject

Construct the suffix trie of the word w.

The suffix trie of a finite word w is a data structure representing the factors of w. It is a tree whose edges are labelled with letters of w, and whose leaves correspond to suffixes of w.

This is a straightforward implementation of Algorithm 1 from [Ukko1995]. It constructs the suffix trie of w[:i] from that of w[:i-1].

A suffix trie is modelled as a deterministic finite-state automaton together with the suffix_link map. The set of states corresponds to factors of the word (below we write x’ for the state corresponding to x); these are always 0, 1, .... The state 0 is the initial state, and it corresponds to the empty word. For the purposes of the algorithm, there is also an auxiliary state -1. The transition function t is defined as:
\( t(-1,a) = 0 \) for all letters \( a \); and
\( t(x',a) = y' \) for all \( x', y' \in Q \) such that \( y = xa \),

and the suffix link function is defined as:

\[
\begin{align*}
\text{suffix_link}(0) &= -1; \\
\text{suffix_link}(x') &= y', \text{ if } x = ay \text{ for some letter } a.
\end{align*}
\]

REFERENCES:

- [Ukko1995]

EXAMPLES:

```python
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w); t
Suffix Trie of the word: cacao
```

```python
sage: e = Words("ab")()
sage: t = SuffixTrie(e); t
Suffix Trie of the word: 
```

```python
sage: t.process_letter("a"); t
Suffix Trie of the word: ab
```

```python
sage: t.process_letter("a"); t
Suffix Trie of the word: aba
```

active_state()  
Returns the active state of the suffix trie. This is the state corresponding to the word as a suffix of itself.

EXAMPLES:

```python
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w)
sage: t.active_state()
8
```

```python
sage: u = Words([0,1])([0,1,1,0,1,0,0,1])
sage: s = SuffixTrie(u)
sage: s.active_state()
22
```

final_states()  
Returns the set of final states of the suffix trie. These are the states corresponding to the suffixes of \( \text{self}. \text{word()} \). They are obtained by repeatedly following the suffix link from the active state until we reach 0.

EXAMPLES:

```python
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w)
```

(continues on next page)
Combinatorics, Release 9.7

sage: t.final_states() == Set([8, 9, 10, 11, 12, 0])
True

**has_suffix(word)**
  Return True if and only if word is a suffix of self.word().

EXAMPLES:

```sage
from sage.combinat.words.suffix_trees import SuffixTrie
w = Words("cao"("cacao")
t = SuffixTrie(w)
[t.has_suffix(w[i:]) for i in range(w.length()+1)]
[True, True, True, True, True, True]
[t.has_suffix(w[:i]) for i in range(w.length()+1)]
[True, False, False, False, False, True]
```

**node_to_word(state=0)**
  Returns the word obtained by reading the edge labels from 0 to state.

INPUT:

* state - (default: 0) a state

EXAMPLES:

```sage
from sage.combinat.words.suffix_trees import SuffixTrie
w = Words("abc"("abcba")
t = SuffixTrie(w)
t.node_to_word(10)
word: abcba
```

**plot(layout='tree', tree_root=0, tree_orientation='up', vertex_colors=None, edge_labels=True, \*args, **kwds)**
  Returns a Graphics object corresponding to the transition graph of the suffix trie.

EXAMPLES:

```sage
from sage.combinat.words.suffix_trees import SuffixTrie
SuffixTrie(Word("cacao")).plot()
```

**process_letter(letter)**
  Modify self to produce the suffix trie for self.word() + letter.

**Note:** letter must occur within the alphabet of the word.

EXAMPLES:

```sage
from sage.combinat.words.suffix_trees import SuffixTrie
w = Words("ab"("ababba")
t = SuffixTrie(w)
t
```

(continues on next page)
sage: t.process_letter("a"); t
Suffix Trie of the word: ababbaa

\textbf{show}(\texttt{*args, **kwds})

Displays the output of self.plot().

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.words.suffix_trees import SuffixTrie
def print_words(s):
    for word in s:
        print(word)
sage: words = ["foo", "bar", "baz", "qux"]
sage: print_words(words)
foo
bar
baz
qux
\end{verbatim}

\textbf{states}()

Returns the states of the automaton defined by the suffix trie.

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.words.suffix_trees import SuffixTrie
def print_words(s):
    for word in s:
        print(word)
sage: words = ["foo", "bar", "baz", "qux"]
sage: print_words(words)
foo
bar
baz
qux
\end{verbatim}

\textbf{suffix_link}(\texttt{state})

Evaluates the suffix link map of the suffix trie on \texttt{state}. Note that the suffix link map is not defined on -1.

INPUT:

- \texttt{state} - a state

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.words.suffix_trees import SuffixTrie
def print_words(s):
    for word in s:
        print(word)
sage: words = ["foo", "bar", "baz", "qux"]
sage: print_words(words)
foo
bar
baz
qux
\end{verbatim}

\textbf{to_digraph}()

Returns a \texttt{DiGraph} object of the transition graph of the suffix trie.

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.words.suffix_trees import SuffixTrie
def print_words(s):
    for word in s:
        print(word)
sage: words = ["foo", "bar", "baz", "qux"]
sage: print_words(words)
foo
bar
baz
qux
\end{verbatim}
Digraph on 6 vertices

\[
\begin{array}{cccccc}
0 & 1 & 0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
\end{array}
\]

\[\text{transition_function}(\text{node, word})\]

Returns the state reached by beginning at \text{node} and following the arrows in the transition graph labelled by the letters of \text{word}.

**INPUT:**

- \text{node} - a node
- \text{word} - a word

**EXAMPLES:**

```python
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words([0,1])([0,1,0,1,1])
```

```python
sage: t = SuffixTrie(w)
```

```python
sage: all(t.transition_function(u, letter) == v for (u, letter), v in t._transition_function.items())
True
```

\[\text{word}()\]

Returns the word whose suffix tree this is.

**EXAMPLES:**

```python
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("abc")("abcba")
```

```python
sage: t = SuffixTrie(w)
```

```python
sage: t.word()
word: abcba
```

```python
sage: t.word() == w
True
```

### 5.1.361 Word classes

**AUTHORS:**

- Arnaud Bergeron
- Amy Glen
- Sébastien Labbé
- Franco Saliola

**class** `sage.combinat.words.word.FiniteWord_callable` *(parent, callable, length=None)*

Bases: `sage.combinat.words.word_infinite_datatypes.WordDatatype_callable`, `sage.combinat.words.finite_word.FiniteWord_class`
Finite word represented by a callable.

For such word \( w \), type \( w \) and hit TAB key to see the list of functions defined on \( w \).

**EXAMPLES:**

```python
sage: f = lambda n : 3 if n > 8 else 6
sage: w = Word(f, length=30, caching=False)
sage: w
word: 666666666333333333333333333333
sage: w.is_symmetric()
True
```

**class** sage.combinat.words.word.FiniteWord_callable_with_caching

**Bases:** sage.combinat.words.word_infinite_datatypes.WordDatatype_callable_with_caching, sage.combinat.words.finite_word.FiniteWord_class

Finite word represented by a callable (with caching).

For such word \( w \), type \( w \) and hit TAB key to see the list of functions defined on \( w \).

**EXAMPLES:**

```python
sage: f = lambda n : n % 3
sage: w = Word(f, length=32)
sage: w
word: 01201201201201201201201201201201
sage: w.border()
word: 01201201201201201201201201201201
```

**class** sage.combinat.words.word.FiniteWord_char

**Bases:** sage.combinat.words.word_char.WordDatatype_char, sage.combinat.words.finite_word.FiniteWord_class

Finite word represented by an array unsigned char * (i.e. integers between 0 and 255).

For any word \( w \), type \( w \).<TAB> to see the functions that can be applied to \( w \).

**EXAMPLES:**

```python
sage: W = Words(range(20))
sage: w = W(list(range(1, 10)) * 2)
sage: type(w)
<class 'sage.combinat.words.word.FiniteWord_char'>
sage: w
word: 123456789123456789
sage: w.is_palindrome()
False
sage: (w*w[::-1]).is_palindrome()
True
sage: (w[:-1]*w[::-1]).is_palindrome()
True
sage: w.is_lyndon()
False
sage: W(list(range(10)) + [10, 10]).is_lyndon()
```

(continues on next page)
True

sage: w.is_square_free()
False
sage: w[:-1].is_square_free()
True

sage: u = W([randint(0,10) for i in range(10)])
sage: (u*u).is_square()
True
sage: (u*u*u).is_cube()
True

sage: len(w.factor_set())
127
sage: w.rauzy_graph(5)
Looped digraph on 9 vertices
sage: u = W([1,2,3])
sage: w.first_occurrence(u)
0
sage: w.first_occurrence(u, start=1)
9

class sage.combinat.words.word.FiniteWord_iter(parent, iter, length=None)
Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_iter, sage.combinat.words.finite_word.FiniteWord_class

Finite word represented by an iterator.

For such word \(w\), type \(w\). and hit TAB key to see the list of functions defined on \(w\).

EXAMPLES:

sage: w = Word(iter(range(10)), caching=False)
sage: w
word: 0123456789
sage: w.finite_differences()
word: 111111111

class sage.combinat.words.word.FiniteWord_iter_with_caching(parent, iter, length=None)
Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_iter_with_caching, sage.combinat.words.finite_word.FiniteWord_class

Finite word represented by an iterator (with caching).

For such word \(w\), type \(w\). and hit TAB key to see the list of functions defined on \(w\).

EXAMPLES:

sage: w = Word(iter('abcdef'))
sage: w.conjugate(2)
word: cdefab

class sage.combinat.words.word.FiniteWord_list
finite_word.FiniteWord_class

Finite word represented by a Python list.

For any word \( w \), type \( w \). and hit TAB key to see the list of functions defined on \( w \).

EXAMPLES:

```python
sage: w = Word(range(10))
sage: w.iterated_right_palindromic_closure()
word: 0102010301020104010201030102010501020103...
```

class sage.combinat.words.word.FiniteWord_morphic(parent, morphism, letter, coding=None, length=+Infinity)

Finite morphic word.

For such word \( w \), type \( w \). and hit TAB key to see the list of functions defined on \( w \).

EXAMPLES:

```python
sage: m = WordMorphism("a->ab,b->")
sage: w = m.fixed_point("a")
sage: w
word: ab
```

class sage.combinat.words.word.FiniteWord_str

Bases: sage.combinat.words.word_datatypes.WordDatatype_str, sage.combinat.words.finite_word.FiniteWord_class

Finite word represented by a Python str.

For such word \( w \), type \( w \). and hit TAB key to see the list of functions defined on \( w \).

EXAMPLES:

```python
sage: w = Word('abcdef')
sage: w.is_square()
False
```

class sage.combinat.words.word.FiniteWord_tuple

Bases: sage.combinat.words.word_datatypes.WordDatatype_tuple, sage.combinat.words.finite_word.FiniteWord_class

Finite word represented by a Python tuple.

For such word \( w \), type \( w \). and hit TAB key to see the list of functions defined on \( w \).

EXAMPLES:

```python
sage: w = Word(())
sage: w.is_empty()
True
```

class sage.combinat.words.word.InfiniteWord_callable(parent, callable, length=None)

Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_callable, sage.combinat.words.infinite_word.InfiniteWord_class

Infinite word represented by a callable.

5.1. Comprehensive Module List
For such word \( w \), type \( w \) and hit TAB key to see the list of functions defined on \( w \).

Infinite words behave like a Python list: they can be sliced using square brackets to define for example a prefix or a factor.

**EXAMPLES:**

```python
sage: w = Word(lambda n:n, caching=False)
sage: w
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,27,28, ...

sage: w.iterated_right_palindromic_closure()
word: 010201020102010301020102010301020103...
```

**class** sage.combinat.words.word.InfiniteWord_callable_with_caching

Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_callable_with_caching, sage.combinat.words.infinite_word.InfiniteWord_class

Infinite word represented by a callable (with caching).

For such word \( w \), type \( w \) and hit TAB key to see the list of functions defined on \( w \).

Infinite words behave like a Python list: they can be sliced using square brackets to define for example a prefix or a factor.

**EXAMPLES:**

```python
sage: w = Word(lambda n:n)
sage: factor = w[4:13]
sage: factor
word: 4,5,6,7,8,9,10,11,12
```

**class** sage.combinat.words.word.InfiniteWord_iter

Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_iter, sage.combinat.words.infinite_word.InfiniteWord_class

Infinite word represented by an iterable.

For such word \( w \), type \( w \) and hit TAB key to see the list of functions defined on \( w \).

Infinite words behave like a Python list: they can be sliced using square brackets to define for example a prefix or a factor.

**EXAMPLES:**

```python
sage: from itertools import chain, cycle
sage: w = Word(chain('letsgo', cycle('forever')), caching=False)
sage: w
word: letsgoforeverforeverforeverforeverforever...

sage: prefix = w[:100]
sage: prefix
word: letsgoforeverforeverforeverforever...

sage: prefix.is_lyndon()
False
```

**class** sage.combinat.words.word.InfiniteWord_iter_with_caching

Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_iter_with_caching, sage.combinat.words.infinite_word.InfiniteWord_class
Infinite word represented by an iterable (with caching).

For such word \( w \), type \( w \) and hit TAB key to see the list of functions defined on \( w \).

Infinite words behave like a Python list: they can be sliced using square brackets to define for example a prefix or a factor.

EXAMPLES:

```python
sage: from itertools import cycle
sage: w = Word(cycle([9,8,4]))
sage: w
word: 9849849849849849849849849849849849849849...

sage: prefix = w[:23]

sage: prefix
word: 98498498498498498498498

sage: prefix.minimal_period()
3
```

**class** sage.combinat.words.word.InfiniteWord_morphic

```
Bases: sage.combinat.words.morphic.WordDatatype_morphic, sage.combinat.words.infinite_word.InfiniteWord_class
```

Morphic word of infinite length.

For such word \( w \), type \( w \) and hit TAB key to see the list of functions defined on \( w \).

Infinite words behave like a Python list: they can be sliced using square brackets to define for example a prefix or a factor.

EXAMPLES:

```python
sage: m = WordMorphism('a->ab,b->a')

sage: w = m.fixed_point('a')

sage: w
word: abaababaabaababaabaababaabaababaabaababaabaababaabaababaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaababaabaab
• RSK_data – (Optional. Default: None) A semistandard and a standard Young tableau to run the inverse RSK bijection on.

**Note:** Be careful when defining words using callables and iterators. It appears that islice does not pickle correctly causing various errors when reloading. Also, most iterators do not support copying and should not support pickling by extension.

**EXAMPLES:**

**Empty word:**

```python
sage: Word()
word: 
```

**Word with string:**

```python
sage: Word("abbabaab")
word: abbabaab
```

**Word with string constructed from other types:**

```python
sage: Word((0,1,1,0,1,0,0,1), datatype="str")
word: 01101001
```

**Word with list:**

```python
sage: Word([0,1,1,0,1,0,0,1])
word: 01101001
```

**Word with list constructed from other types:**

```python
sage: Word("01101001", datatype="list")
word: 01101001
```

**Word with tuple:**

```python
sage: Word((0,1,1,0,1,0,0,1))
word: 01101001
```

**Word with tuple constructed from other types:**

```python
sage: Word("01101001", datatype="str")
word: 01101001
```

**Word with iterator:**

```python
sage: from itertools import count
sage: Word(count())
```

(continues on next page)
Word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,27,28,...
→ 29,30,31,32,33,34,35,36,37,38,39,...
sage: Word(iter("abbabaab")) # iterators default to infinite words
word: abbabaab
sage: Word(iter("abbabaab"), length="unknown")
word: abbabaab
sage: Word(iter("abbabaab"), length="finite")
word: abbabaab

Word with function (a 'callable'):

sage: f = lambda n : add(Integer(n).digits(2)) % 2
sage: Word(f)
word: 0110100110010110100101100110100110010110...
sage: Word(f, length=8)
word: 01101001

Word over a string with a parent:

sage: w = Word("abbabaab", alphabet="abc"); w
word: abbabaab
sage: w.parent()
Finite words over {'a', 'b', 'c'}

Word from a free monoid element:

sage: M.<x,y,z> = FreeMonoid(3)
sage: Word(x^3*y*x*z^2*x)
word: xxxyxzzx

The default parent is the combinatorial class of all words:

sage: w = Word("abbabaab"); w
word: abbabaab
sage: w.parent()
Finite words over Set of Python objects of class 'object'

We can also input a semistandard tableau and a standard tableau to obtain a word from the inverse RSK algorithm using the RSK_data option:

sage: p = Tableau([[1,2,2],[3]]); q = Tableau([[1,2,4],[3]])
sage: Word(RSK_data=[p, q])
word: 1322

class sage.combinat.words.word.Word_iter(parent, iter, length=None)
Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_iter, sage.combinat.words.abstract_word.Word_class

Word of unknown length (finite or infinite) represented by an iterable.

For such word \( w \), type \( w \) and hit TAB key to see the list of functions defined on \( w \).

Words behave like a Python list: they can be sliced using square brackets to define for example a prefix or a factor.

EXAMPLES:
Combinatorics, Release 9.7

```python
sage: w = Word(iter([1,1,4,9]*1000), length='unknown', caching=False)
sage: w
word: 1149114911491149114911491149114911491149...
sage: w.delta()
word: 2112112112112112112112112112112112112112...
```

class sage.combinat.words.word.Word_iter_with_caching(parent, iter, length=None)

Bases: `sage.combinat.words.word_infinite_datatypes.WordDatatype_iter_with_caching`, `sage.combinat.words.abstract_word.Word_class`

Word of unknown length (finite or infinite) represented by an iterable (with caching).

For such word \( w \), type `w. ` and hit TAB key to see the list of functions defined on \( w \).

Words behave like a Python list: they can be sliced using square braquets to define for example a prefix or a factor.

EXAMPLES:

```python
sage: w = Word(iter([1,2,3]*1000), length='unknown')
sage: w
word: 1231231231231231231231231231231231231231...
sage: w.finite_differences(mod=2)
word: 1101101101101101101101101101101101101101...
```

### 5.1.362 Fast word datatype using an array of unsigned char

class sage.combinat.words.word_char.WordDatatype_char

Bases: `sage.combinat.words.word_datatypes.WordDatatype`

A Fast class for words represented by an array unsigned char *.

Currently, only handles letters in [0,255].

**concatenate**(other)

Concatenation of self and other.

EXAMPLES:

```python
sage: W = Words([0,1,2])
sage: W([0,2,1]).concatenate([0,0,0])
word: 021000
```

**has_prefix**(other)

Test whether other is a prefix of self.

INPUT:

• other – a word or a sequence (e.g. tuple, list)

EXAMPLES:

```python
sage: W = Words([0,1,2])
sage: w = W([0,1,1,0,1,2,0])
sage: w.has_prefix([0,1,1])
True
sage: w.has_prefix([0,1,2])
```

(continues on next page)
False

\begin{verbatim}
sage: w.has_prefix(w)
True
sage: w.has_prefix(w[:1])
True
sage: w.has_prefix(w[1:])
False
\end{verbatim}

**is_empty()**

Return whether the word is empty.

**EXAMPLES:**

\begin{verbatim}
sage: W = Words([0,1,2])
sage: W([0,1,2,2]).is_empty()
False
sage: W([]).is_empty()
True
\end{verbatim}

**is_square()**

Return True if self is a square, and False otherwise.

**EXAMPLES:**

\begin{verbatim}
sage: w = Word([n % 4 for n in range(48)], alphabet=[0,1,2,3])
sage: w.is_square()
True
sage: w = Word([n % 4 for n in range(49)], alphabet=[0,1,2,3])
sage: w.is_square()
False
sage: (w*w).is_square()
True
\end{verbatim}

**length()**

Return the length of the word as a Sage integer.

**EXAMPLES:**

\begin{verbatim}
sage: W = Words([0,1,2,3,4])
sage: w = W([0,1,2,0,3,2,1])
sage: w.length()
7
sage: type(w.length())
<class 'sage.rings.integer.Integer'>
sage: type(len(w))
<class 'int'>
\end{verbatim}

**letters()**

Return the list of letters that appear in this word, listed in the order of first appearance.

**EXAMPLES:**
Combinatorics, Release 9.7

```sage
W = Words(5)
sage: W([1,3,1,2,2,3,1]).letters()
[1, 3, 2]
```

**longest_common_prefix(other)**

Return the longest common prefix of this word and other.

**EXAMPLES:**

```sage
W = Words([0,1,2])
sage: W([0,1,0,2]).longest_common_prefix([0,1])
word: 01
sage: u = W([0,1,0,0,1])
sage: v = W([0,1,0,2])
sage: u.longest_common_prefix(v)
word: 010
sage: v.longest_common_suffix(u)
word: 010
```

Using infinite words is also possible (and the return type is also a of the same type as self):

```sage
W([0,1,0,0]).longest_common_suffix(words.FibonacciWord())
word: 0100
sage: type(_)
<class 'sage.combinat.words.word.FiniteWord_char'>
```

An example of an intensive usage:

```sage
W = Words([0,1])
sage: w = words.FibonacciWord()
sage: w = W(list(w[:5000]))
sage: L = [len(w[n:].longest_common_prefix(w[n+fibonacci(i):]))
     for i in range(5,15) for n in range(1,1000)]
```

```python
for n,l in enumerate(L):
    if l.count(0) > 4:
        print("{} {}".format(n+1,l))
```

```
375 [0, 13, 0, 34, 0, 89, 0, 233, 0, 233]
376 [0, 12, 0, 33, 0, 88, 0, 232, 0, 232]
608 [8, 0, 21, 0, 55, 0, 144, 0, 377, 0]
609 [7, 0, 20, 0, 54, 0, 143, 0, 376, 0]
985 [0, 13, 0, 34, 0, 89, 0, 233, 0, 610]
986 [0, 12, 0, 33, 0, 88, 0, 232, 0, 609]
```

**longest_common_suffix(other)**

Return the longest common suffix between this word and other.

**EXAMPLES:**

```sage
W = Words([0,1,2])
sage: W([0,1,0,2]).longest_common_suffix([2,0,2])
word: 02
sage: u = W([0,1,0,0,1])
sage: v = W([1,2,0,0,1])
sage: u.longest_common_suffix(v)
```

(continues on next page)
sage.combinat.words.word_char.reversed_word_iterator(w)
This function exists only because it is not possible to use yield in the special method \_\_reversed\_\_.

EXAMPLES:

```python
sage: W = Words([0,1,2])
sage: w = W([0,1,0,0,1,2])
sage: list(reversed(w)) # indirect doctest
[2, 1, 0, 0, 1, 0]
```

### 5.1.363 Datatypes for finite words

**class** sage.combinat.words.word_datatypes.WordDatatype

Bases: object

The generic WordDatatype class.

Any word datatype must contain two attributes (at least):

- \_parent
- \_hash

They are automatically defined here and it’s not necessary (and forbidden) to define them anywhere else.

**class** sage.combinat.words.word_datatypes.WordDatatype_list

Bases: sage.combinat.words.word_datatypes.WordDatatype

Datatype class for words defined by lists.

**length()**

Return the length of the word.

EXAMPLES:

```python
sage: w = Word([0,1,1,0])
sage: w.length()
4
```

**number_of_letter_occurrences(a)**

Returns the number of occurrences of the letter a in the word self.

INPUT:

- a - a letter

OUTPUT:

- integer

EXAMPLES:
sage: w = Word([0,1,1,0,1])
sage: w.number_of_letter_occurrences(0)
2
sage: w.number_of_letter_occurrences(1)
3
sage: w.number_of_letter_occurrences(2)
0

See also:
sage.combinat.words.finite_word.FiniteWord_class.number_of_factor_occurrences()

class sage.combinat.words.word_datatypes.WordDatatype_str
Bases: sage.combinat.words.word_datatypes.WordDatatype

Datatype for words defined by strings.

find(sub, start=0, end=None)
Returns the index of the first occurrence of sub in self, such that sub is contained within self[start:end].
Returns -1 on failure.

INPUT:
• sub - string or word to search for.
• start - non negative integer (default: 0) specifying the position from which to start the search.
• end - non negative integer (default: None) specifying the position at which the search must stop. If
None, then the search is performed up to the end of the string.

OUTPUT:
non negative integer or -1

EXAMPLES:

sage: w = Word("abbabaabababa")
sage: w.find("a")
0
sage: w.find("a", 4)
5
sage: w.find("a", 4, 5)
-1

has_prefix(other)
Test whether self has other as a prefix.

INPUT:
• other - a word (an instance of Word_class) or a str.

OUTPUT:
• boolean

EXAMPLES:

sage: w = Word("abbabaabababa")
sage: u = Word("abbab")
sage: w.has_prefix(u)
True

(continues on next page)
sage: u.has_prefix(w)
False
sage: u.has_prefix("abbab")
True

**has_suffix**(other)
Test whether self has other as a suffix.

**INPUT:**
- other - a word (an instance of `Word_class`) or a str.

**OUTPUT:**
- boolean

**EXAMPLES:**

```python
sage: w = Word("abbabaabababa")
sage: u = Word("ababa")
sage: w.has_suffix(u)
True
sage: u.has_suffix(w)
False
sage: u.has_suffix("ababa")
True
```

**is_prefix**(other)
Test whether self is a prefix of other.

**INPUT:**
- other - a word (an instance of `Word_class`) or a str.

**OUTPUT:**
- boolean

**EXAMPLES:**

```python
sage: w = Word("abbabaabababa")
sage: u = Word("abab")
sage: w.is_prefix(u)
False
sage: u.is_prefix(w)
True
sage: u.is_prefix("abbabaabababa")
True
```

**is_suffix**(other)
Test whether self is a suffix of other.

**INPUT:**
- other - a word (an instance of `Word_class`) or a str.

**OUTPUT:**
- boolean

**EXAMPLES:**
Combinatorics, Release 9.7

```python
sage: w = Word("abbabaabababa")
sage: u = Word("ababa")
sage: w.is_suffix(u)
False
sage: u.is_suffix(w)
True
sage: u.is_suffix("abbabaabababa")
True
```

### length()

Return the length of the word.

**EXAMPLES:**

```python
sage: w = Word("abbabaabababa")
sage: w.length()
13
```

### number_of_letter_occurrences(letter)

Count the number of occurrences of `letter`.

**INPUT:**
- `letter` - a letter

**OUTPUT:**
- integer

**EXAMPLES:**

```python
sage: w = Word("abbabaabababa")
sage: w.number_of_letter_occurrences('a')
7
sage: w.number_of_letter_occurrences('b')
6
sage: w.number_of_letter_occurrences('c')
0
```

```python
sage: w.number_of_letter_occurrences('abb')
0
```

**See also:**

`sage.combinat.words.finite_word.FiniteWord_class.number_of_factor_occurrences()`

### partition(sep)

Search for the separator `sep` in `S`, and return the part before it, the separator itself, and the part after it. The concatenation of the terms in the list gives back the initial word.

See also the split method.

**Note:** This just wraps Python's built-in `str:partition()` for `str`.

**INPUT:**
- `sep` - string or word
EXAMPLES:

```python
sage: w = Word("MyTailorIsPoor")
sage: w.partition("Tailor")
[word: My, word: Tailor, word: IsPoor]

sage: w = Word("3230301032321233032321210121232121010")
sage: l = w.partition("323")
sage: print(l)
[word: , word: 323, word: 0301032321233032321210121232121010]
sage: sum(l, Word('')) == w
True
```

If the separator is not a string an error is raised:

```python
sage: w = Word("le papa du papa du papa etait un petit pioupiou")
sage: w.partition(Word(['p', 'a', 'p', 'a']))
Traceback (most recent call last):
  ... ValueError: the separator must be a string
```

rfind(sub, start=0, end=None)

Returns the index of the last occurrence of sub in self, such that sub is contained within self[start:end]. Returns -1 on failure.

INPUT:
- sub - string or word to search for.
- start - non negative integer (default: 0) specifying the position at which the search must stop.
- end - non negative integer (default: None) specifying the position from which to start the search. If None, then the search is performed up to the end of the string.

OUTPUT:
- non negative integer or -1

EXAMPLES:

```python
sage: w = Word("abbaabababa")
sage: w.rfind("a")
12
sage: w.rfind("a", 4, 8)
6
sage: w.rfind("a", 4, 5)
-1
```

split(sep=None, maxsplit=None)

Returns a list of words, using sep as a delimiter string. If maxsplit is given, at most maxsplit splits are done.

See also the partition method.

**Note:** This just wraps Python's builtin `str::split()` for `str`.

INPUT:
- sep - string or word (optional, default: None)
• `maxsplit` - positive integer (optional, default: None)

**OUTPUT:**

• a list of words

**EXAMPLES:**

You can split along white space to find words in a sentence:

```python
sage: w = Word("My tailor is poor")
sage: w.split(" ")
[word: My, word: tailor, word: is, word: poor]
```

The python behavior is kept when no argument is given:

```python
sage: w.split()
[word: My, word: tailor, word: is, word: poor]
```

You can split in two words letters to get the length of blocks in the other letter:

```python
sage: w = Word("ababbabaaba")
sage: w.split('a')
[word: , word: b, word: bb, word: b, word: , word: b, word: ]
sage: w.split('b')
[word: a, word: a, word: , word: a, word: aa, word: a]
```

You can split along words:

```python
sage: w = Word("3230301030323212323032321")
sage: w.split("32")
[word: , word: 30301030, word: , word: 12, word: 30, word: , word: 1]
```

If the separator is not a string a ValueError is raised:

```python
sage: w = Word("le papa du papa du papa etait un petit pioupiou")
sage: w.split(Word(['p','a','p','a']))
Traceback (most recent call last):
  ...
ValueError: the separator must be a string
```

```python
class sage.combinat.words.word_datatypes.WordDatatype_tuple
    Bases: sage.combinat.words.word_datatypes.WordDatatype

Datatype class for words defined by tuples.

    length()

    Return the length of the word.

**EXAMPLES:**

```python
sage: w = Word((0,1,1,0))
sage: w.length()
4
```
5.1.364 Common words

AUTHORS:
- Franco Saliola (2008-12-17): merged into sage
- Sebastien Labbe (2008-12-17): merged into sage
- Arnaud Bergeron (2008-12-17): merged into sage
- Amy Glen (2008-12-17): merged into sage
- Sébastien Labbé (2009-12-19): Added S-adic words (trac ticket #7543)

USE:
To see a list of all word constructors, type `words` and then press the tab key. The documentation for each constructor includes information about each word, which provides a useful reference.

REFERENCES:

EXAMPLES:
```
sage: t = words.ThueMorseWord(); t
word: 0110100110010110100101100110100110010110...
```

```python
class sage.combinat.words.word_generators.LowerChristoffelWord(p, q, alphabet=(0, 1), algorithm='cf')
```
Bases: `sage.combinat.words.word.FiniteWord_list`

Returns the lower Christoffel word of slope \(p/q\), where \(p\) and \(q\) are relatively prime non-negative integers, over the given two-letter alphabet.

The Christoffel word of slope \(p/q\) is obtained from the Cayley graph of \(\mathbb{Z}/(p + q)\mathbb{Z}\) with generator \(q\) as follows. If \(u \to v\) is an edge in the Cayley graph, then \(v = u + p \mod p + q\). Label the edge \(u \to v\) by \(alphabet[1]\) if \(u < v\) and \(alphabet[0]\) otherwise. The Christoffel word is the word obtained by reading the edge labels along the cycle beginning from 0.

EXAMPLES:
```
sage: words.LowerChristoffelWord(4,7)
word: 00100100101
```
```
sage: words.LowerChristoffelWord(4,7,alphabet='ab')
word: aabaabaabab
```

`markoff_number()`
Return the Markoff number associated to the Christoffel word \(self\).

The Markoff number of a Christoffel word \(w\) is \(\text{trace}(M(w))/3\), where \(M(w)\) is the \(2 \times 2\) matrix obtained by applying the morphism: 0 -> matrix(2,[2,1,1,1]) 1 -> matrix(2,[5,2,2,1])

EXAMPLES:
```
sage: w0 = words.LowerChristoffelWord(4,7)
```
```
sage: m0, m1 = (w.markoff_number() for w in (w0, w1, w2))
```
```
sage: m0**2 + m1**2 + m2**2 == 3*m0*m1*m2
True
```
**standard_factorization()**

Returns the standard factorization of the Christoffel word \texttt{self}.

The standard factorization of a Christoffel word \texttt{w} is the unique factorization of \texttt{w} into two Christoffel words.

**EXAMPLES:**

```python
sage: w = words.LowerChristoffelWord(5,9)
sage: w
word: 00100100100101
sage: w1, w2 = w.standard_factorization()
sage: w1
word: 001
sage: w2
word: 00100100101
```

```python
sage: w = words.LowerChristoffelWord(51,37)
sage: w1, w2 = w.standard_factorization()
sage: w1
word: 0101011010101101011
sage: w2
word: 0101011010101101011010101101010110101101...
sage: w1 * w2 == w
True
```

**class** 

`sage.combinat.words.word_generators.WordGenerator`

Bases: object

Constructor of several famous words.

**EXAMPLES:**

```python
sage: words.ThueMorseWord()
word: 0110100110010110100101100110100110010110...
```

```python
sage: words.FibonacciWord()
word: 0100101001001010010100100101001001010010...
```

```python
sage: words.ChristoffelWord(5, 8)
word: 00100100101
```

```python
sage: words.RandomWord(10, 4)  # not tested random
word: 1311131221
```

```python
sage: words.CodingOfRotationWord(alpha=0.618, beta=0.618)
word: 10101010101010101010101010101010101010101...
```

```python
sage: tm = WordMorphism('a->ab,b->ba')
sage: fib = WordMorphism('a->ab,b->a')
sage: tmword = words.ThueMorseWord([0, 1])
sage: from itertools import repeat
sage: words.s_adic(tmword, repeat('a'), {0:tm, 1:fib})
word: abbaababbaabbaabbaabbaababbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabba...
**Note:** To see a list of all word constructors, type `words` and then hit the TAB key. The documentation for each constructor includes information about each word, which provides a useful reference.

---

**BaumSweetWord()**

Returns the Baum-Sweet Word.

The Baum-Sweet Sequence is an infinite word over the alphabet \{0, 1\} defined by the following string substitution rules:

- `00` → `0000`
- `01` → `1001`
- `10` → `0100`
- `11` → `1101`

The substitution rule above can be considered as a morphism on the submonoid of \{0, 1\} generated by \{00, 01, 10, 11\} (which is a free monoid on these generators).

It is also defined as the concatenation of the terms from the Baum-Sweet Sequence:

\[
b_n = \begin{cases} 
0, & \text{if } n = 0 \\ 
1, & \text{if } m \text{ is even} \\ 
b_{m-1}, & \text{if } m \text{ is odd}
\end{cases}
\]

where \(n = m4^k\) and \(m\) is not divisible by 4 if \(m \neq 0\).

The individual terms of the Baum-Sweet Sequence are also given by:

\[
b_n = \begin{cases} 
1, & \text{if the binary representation of } n \text{ contains no block of consecutive 0's of odd length} \\ 
0, & \text{otherwise}
\end{cases}
\]

for \(n > 0\) with \(b_0 = 1\).

For more information see: [Wikipedia article Baum-Sweet_sequence](https://en.wikipedia.org/wiki/Baum%E2%80%93Sweet_sequence).

**EXAMPLES:**

Baum-Sweet Word:

```python
sage: w = words.BaumSweetWord(); w
word: 1101100101001001100100000100100101001001...
```

Block Definition:

```python
sage: w = words.BaumSweetWord()
sage: f = lambda n: '1' if all(len(x)%2==0 for x in bin(n)[2:].split('1')) else '0'
sage: all(f(i) == w[i] for i in range(1,100))
True
```

**CharacteristicSturmianWord(slope, alphabet=(0, 1), bits=None)**

Returns the characteristic Sturmian word (also called standard Sturmian word) of given slope.

Over a binary alphabet \{a, b\}, the characteristic Sturmian word \(c_\alpha\) of irrational slope \(\alpha\) is the infinite word satisfying \(s_{\alpha,0} = ac_\alpha\) and \(s'_{\alpha,0} = bc_\alpha\), where \(s_{\alpha,0}\) and \(s'_{\alpha,0}\) are respectively the lower and upper mechanical words with slope \(\alpha\) and intercept 0. Equivalently, for irrational \(\alpha\), \(c_\alpha = s_{\alpha,\alpha} = s'_{\alpha,\alpha}\).
Let $\alpha = [0, d_1 + 1, d_2, d_3, \ldots]$ be the continued fraction expansion of $\alpha$. It has been shown that the characteristic Sturmian word of slope $\alpha$ is also the limit of the sequence: $s_0 = b, s_1 = a, \ldots, s_{n+1} = s_n^d s_{n-1}$ for $n > 0$.

See Section 2.1 of [Loth02] for more details.

INPUT:

- **slope** - the slope of the word. It can be one of the following:
  - real number in $]0, 1[$
  - iterable over the continued fraction expansion of a real number in $]0, 1[$

- **alphabet** - any container of length two that is suitable to build an instance of OrderedAlphabet (list, tuple, str, ...)

- **bits** - integer (optional and considered only if slope is a real number) the number of bits to consider when computing the continued fraction.

OUTPUT:

word

ALGORITHM:

Let $[0, d_1 + 1, d_2, d_3, \ldots]$ be the continued fraction expansion of $\alpha$. Then, the characteristic Sturmian word of slope $\alpha$ is the limit of the sequence: $s_0 = b, s_1 = a$ and $s_{n+1} = s_n^d s_{n-1}$ for $n > 0$.

EXAMPLES:

From real slope:

```
sage: words.CharacteristicSturmianWord(1/golden_ratio^2)
word: 0100101001001010010100100101001001010010...
```

```
sage: words.CharacteristicSturmianWord(4/5)
word: 11110
```

```
sage: words.CharacteristicSturmianWord(5/14)
word: 01001001001001
```

```
sage: words.CharacteristicSturmianWord(pi-3)
word: 0000001000000100000010000001000000100000...
```

From an iterator of the continued fraction expansion of a real:

```
sage: def cf():
    ....: yield 0
    ....: yield 2
    ....: while True: yield 1
sage: F = words.CharacteristicSturmianWord(cf()); F
word: 010010010010010010010010010010010010010010...
```

```
sage: Fib = words.FibonacciWord(); Fib
word: 010010010010010010010010010010010010010010...
```

```
sage: F[:10000] == Fib[:10000]
True
```

The alphabet may be specified:

```
sage: words.CharacteristicSturmianWord(cf(), 'rs')
word: rsrrrsrrrsrrrsrrrsrrrsrrrsrrrsrrrsrrrsrrsr...
```

The characteristic sturmian word of slope $(\sqrt{3} - 1)/2$: 
sage: words.CharacteristicSturmianWord((sqrt(3)-1)/2)
word: 0100100101001001001010010010010100100101...

The same word defined from the continued fraction expansion of \((\sqrt{3} - 1)/2\):

sage: from itertools import cycle, chain
sage: it = chain([0], cycle([2, 1]))

sage: words.CharacteristicSturmianWord(it)
word: 0100100101001001001010010010010100100101...

The first terms of the standard sequence of the characteristic sturmian word of slope \((\sqrt{3} - 1)/2\):

sage: words.CharacteristicSturmianWord([0,2])
word: 01
sage: words.CharacteristicSturmianWord([0,2,1])
word: 010
sage: words.CharacteristicSturmianWord([0,2,1,2])
word: 01001001
sage: words.CharacteristicSturmianWord([0,2,1,2,1])
word: 01001001010
sage: words.CharacteristicSturmianWord([0,2,1,2,1,2])
word: 010010010100100100101001001001
sage: words.CharacteristicSturmianWord([0,2,1,2,1,2,1])
word: 0100100101001001001010010010010100100101...

ChristoffelWord

alias of LowerChristoffelWord

CodingOfRotationWord\((\alpha, \beta, x=0, \text{alphabet} =(0, 1))\)

Returns the infinite word obtained from the coding of rotation of parameters \((\alpha, \beta, x)\) over the given two-letter alphabet.

The coding of rotation corresponding to the parameters \((\alpha, \beta, x)\) is the symbolic sequence \(u = (u_n)_{n \geq 0}\) defined over the binary alphabet \(\{0, 1\}\) by \(u_n = 1\) if \(x + n\alpha \in [0, \beta]\) and \(u_n = 0\) otherwise. See [AC03].

EXAMPLES:

sage: alpha = 0.45
sage: beta = 0.48

sage: words.CodingOfRotationWord(0.45, 0.48)
word: 1101010101001010101011010101010010101010...

sage: words.CodingOfRotationWord(0.45, 0.48, alphabet='xy')
word: yyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxy...

FibonacciWord\((\text{alphabet}=(0, 1), \text{construction_method} = \text{‘recursive’})\)

Returns the Fibonacci word on the given two-letter alphabet.

INPUT:

- \text{alphabet} – any container of length two that is suitable to build an instance of OrderedAlphabet (list, tuple, str,...)
- \text{construction_method} – can be any of the following: “recursive”, “fixed point”, “function” (see below for definitions).
Recursive construction: the Fibonacci word is the limit of the following sequence of words: \( S_0 = 0, S_1 = 01, S_n = S_{n-1}S_{n-2} \) for \( n \geq 2 \).

Fixed point construction: the Fibonacci word is the fixed point of the morphism: \( 0 \mapsto 01 \) and \( 1 \mapsto 0 \).

Hence, it can be constructed by the following read-write process:

1. beginning at the first letter of 01,
2. if the next letter is 0, append 01 to the word;
3. if the next letter is 1, append 1 to the word;
4. move to the next letter of the word.

Function: Over the alphabet \( \{1, 2\} \), the \( n \)-th letter of the Fibonacci word is \( \lfloor (n + 2)\varphi \rfloor - \lfloor (n + 1)\varphi \rfloor \) where \( \varphi = (1 + \sqrt{5})/2 \) is the golden ratio.

EXAMPLES:

```sage
sage: w = words.FibonacciWord(construction_method="recursive"); w
word: 0100101001001010010100100101001001010010...
```

```sage
sage: v = words.FibonacciWord(construction_method="recursive", alphabet='ab'); v
word: abaabaababaababaababaababaababaababaababaabab...
```

```sage
sage: u = words.FibonacciWord(construction_method="fixed point"); u
word: 0100101001001010010100100101001001010010...
```

```sage
sage: words.FibonacciWord(construction_method="fixed point", alphabet=[4, 1])
word: 4144144144144144144144144144144144144141414...
```

```sage
sage: words.FibonacciWord([0,1], 'function')
word: 0100101001001010010100100101001001010010...
```

```sage
sage: words.FibonacciWord('ab', 'function')
word: abaabaababaababaababaababaabababababaabababab...
```

**FixedPointOfMorphism** *(morphism, first_letter)*

Returns the fixed point of the morphism beginning with \( \textit{first_letter} \).

A fixed point of a morphism \( \varphi \) is a word \( w \) such that \( \varphi(w) = w \).

INPUT:

- morphism – endomorphism prolongable on \( \textit{first_letter} \). It must be something that WordMorphism’s constructor understands (dict, str, ...).
- first_letter – the first letter of the fixed point

OUTPUT:

The fixed point of the morphism beginning with \( \textit{first_letter} \)

EXAMPLES:

```sage
sage: mu = {0:[0,1], 1:[1,0]}
sage: tm = words.FixedPointOfMorphism(mu,0); tm
word: 011010011011011001011100101100110011101101...
sage: TM = words.ThueMorseWord()
sage: tm[:1000] == TM[:1000]
True
```
Combinatorics, Release 9.7

\begin{verbatim}
sage: mu = {0:[0,1], 1:[0]}
sage: f = words.FixedPointOfMorphism(mu,0); f
word: 0100101001001010010100100101001001010010...
sage: F = words.FibonacciWord(); F
word: 0100101001001010010100100101001001010010...
sage: f[:1000] == F[:1000]
True

sage: fp = words.FixedPointOfMorphism('a->abc,b->,c->','a'); fp
word: abc

KolakoskiWord(alphabet=(1, 2))
Returns the Kolakoski word over the given alphabet and starting with the first letter of the alphabet.

Let \( A = \{a, b\} \) be an alphabet, where \( a \) and \( b \) are two distinct positive integers. The Kolakoski word \( K_{a,b} \)
over \( A \) and starting with \( a \) is the unique infinite word \( w \) such that \( w = \Delta(w) \), where \( \Delta(w) \) is the word
encoding the runs of \( w \) (see delta() method on words for more details).

Note that \( K_{a,b} \neq K_{b,a} \). On the other hand, the words \( K_{a,b} \) and \( K_{b,a} \) are the unique two words over \( A \) that
are fixed by \( \Delta \).

Also note that the Kolakoski word is also known as the Oldenburger word.

INPUT:
- alphabet - (default: (1,2)) an iterable of two positive integers

OUTPUT:
infinite word

EXAMPLES:
The usual Kolakoski word:

\begin{verbatim}
sage: w = words.KolakoskiWord()
sage: w
word: 122112221211221121121122122122121221221...
sage: w.delta()
word: 122112221211221121121122122122121221221...
\end{verbatim}

The other Kolakoski word on the same alphabet:

\begin{verbatim}
sage: w = words.KolakoskiWord(alphabet = (2,1))
sage: w
word: 221121221221121122121122112112212212211...
sage: w.delta()
word: 221121221221121122121122112112212212211...
\end{verbatim}

It is naturally generalized to any two integers alphabet:

\begin{verbatim}
sage: w = words.KolakoskiWord(alphabet = (2,5))
sage: w
word: 22552222555522552255552255552222555552...
sage: w.delta()
word: 22552222555522552255552255552222555552...
\end{verbatim}

REFERENCES:
\end{verbatim}
LowerChristoffelWord

alias of LowerChristoffelWord

LowerMechanicalWord(alpha, rho=0, alphabet=None)

Returns the lower mechanical word with slope α and intercept ρ

The lower mechanical word $s_{\alpha,\rho}$ with slope $\alpha$ and intercept $\rho$ is defined by $s_{\alpha,\rho}(n) = \lfloor \alpha(n+1) + \rho \rfloor - \lfloor \alpha n + \rho \rfloor$. [Loth02]

INPUT:

• alpha – real number such that $0 \leq \alpha \leq 1$
• rho – real number (optional, default: 0)
• alphabet – iterable of two elements or None (optional, default: None)

OUTPUT:
infinite word

EXAMPLES:

sage: words.LowerMechanicalWord(1/golden_ratio^2)
word: 00100101001001010010100100101001...

sage: words.LowerMechanicalWord(1/5)
word: 0000010000010000010000010000010000...

sage: words.LowerMechanicalWord(1/pi)
word: 0001001001001001001001000100100100100100...

MinimalSmoothPrefix(n)

This function finds and returns the minimal smooth prefix of length $n$.

See [BMP2007] for a definition.

INPUT:

• n – the desired length of the prefix

OUTPUT:

word – the prefix

Note: Be patient, this function can take a really long time if asked for a large prefix.

EXAMPLES:

sage: words.MinimalSmoothPrefix(10)
word: 1212212112

PalindromicDefectWord(k=1, alphabet='ab')

Return the finite word $w = ab^k ab^{k-1} ab^{k-1} ab^k a$.

As described by Brlek, Hamel, Nivat and Reutenauer in [BHN2004], this finite word $w$ is such that the infinite periodic word $w^\omega$ has palindromic defect $k$.

INPUT:

• k – positive integer (optional, default: 1)
• alphabet – iterable (optional, default: 'ab') of size two
## Palindromic Defect Words

**OUTPUT:**

finite word

**EXAMPLES:**

```python
sage: w = words.PalindromicDefectWord(10)
word: abbbbbbbbabbbbbbbbaabbbbbbbabbbbbbb...
```

```python
sage: w = words.PalindromicDefectWord(3)
sage: w
word: abbbabbaabbabba
sage: w.defect()
0
sage: (w^2).defect()
3
sage: (w^3).defect()
3
```

On other alphabets:

```python
sage: words.PalindromicDefectWord(3, alphabet='cd')
word: cdddcddccddcdcd
sage: words.PalindromicDefectWord(3, alphabet=['c', '3'])
word: c333c33cc33c333c
```

## Random Word

**RandomWord**(n, m=2, alphabet=None)

Return a random word of length **n** over the given **m**-letter alphabet.

**INPUT:**

- **n** - integer, the length of the word
- **m** - integer (default 2), the size of the output alphabet
- **alphabet** - (default is \{0, 1, ..., m-1\}) any container of length m that is suitable to build an instance of OrderedAlphabet (list, tuple, str, ...)

**EXAMPLES:**

```python
sage: words.RandomWord(10)  # random results
word: 0110100101
sage: words.RandomWord(10, 4)  # random results
word: 0322313320
sage: words.RandomWord(100, 7)  # random results
word: 2630644023642516442650025611300034413310...
```

```python
sage: words.RandomWord(100, 7, range(-3,4))  # random results
word: 1,3,-1,-1,3,2,2,0,1,-2,1,-1,-3,-2,2,0,3,0,-3,3,0,-2,-2,2,0,1,-3,2,-2,-2,-2,0,2,1,-2,-3,-2,-1,0,...
```

```python
sage: words.RandomWord(100, 5, "abcde")  # random results
word: acebeacdcbedbbdeadeebdddeebeaacaabadaac...
```

```python
sage: words.RandomWord(17, 5, "abcde")  # random results
word: dacabcbebddebaadd
```

## Episturmian Word

**StandardEpisturmianWord**(directive_word)

Returns the standard episturmian word (or epistandard word) directed by directive_word. Over a 2-letter alphabet, this function gives characteristic Sturmian words.
An infinite word \( w \) over a finite alphabet \( A \) is said to be **standard episturmian** (or **epistandard**) iff there exists an infinite word \( x_1x_2x_3 \cdots \) over \( A \) (called the **directive word** of \( w \)) such that \( w \) is the limit as \( n \) goes to infinity of \( \text{Pal}(x_1 \cdots x_n) \), where \( \text{Pal} \) is the iterated palindromic closure function.

Note that an infinite word is **episturmian** if it has the same set of factors as some epistandard word.

See for instance [DJP2001], [JP2002], and [GJ2007].

**INPUT:**
- **directive_word** - an infinite word or a period of a periodic infinite word

**EXAMPLES:**

```python
sage: Fibonacci = words.StandardEpisturmianWord(Words('ab')('ab')); Fibonacci
word: abaabaababaababaababaababaababaababaababaababaababaababaababaababaababa...  

sage: Tribonacci = words.StandardEpisturmianWord(Words('abc')('abc'));  
   ←Tribonacci
word: abacabaabacabacabacabacabacabacabacabacabacabacabacabacabacabacabacabacabacabacabacabacabacabac...  

sage: S = words.StandardEpisturmianWord(Words('abcd')('aabcdada')); S
word: aabaabcabaabaabcabaabaabcabaabaabcabaabaabcabaabaabcabaabaabcabaabaabcabaabaabcabaabaabcabaaba...  

sage: S[:25]
word: abaabaababaababaababaaba...  

sage: S = words.StandardEpisturmianWord(Tribonacci); S
word: abacabaabacabacabacabacabacabacabacabacabacabacabacabacabacabacabacabacabacabacabacabacabacabacabac...  

sage: words.StandardEpisturmianWord(123)
Traceback (most recent call last):
  ...  
TypeError: directive_word is not a word, so it cannot be used to build an episturmian word
```

**ThueMorseWord** \((alphabet=(0, 1), base=2)\)

Returns the (Generalized) Thue-Morse word over the given alphabet.

There are several ways to define the Thue-Morse word \( t \). We use the following definition: \( t[n] \) is the sum modulo \( m \) of the digits in the given base expansion of \( n \).

See [BmBGL07], [Blek89], and [MH38].

**INPUT:**
- **alphabet** - (default: \((0, 1)\)) any container that is suitable to build an instance of OrderedAlphabet (list, tuple, str, ...)
- **base** - an integer (default : 2) greater or equal to 2

**EXAMPLES:**

Thue-Morse word:

```python
sage: t = words.ThueMorseWord(); t
word: 011010011001011001011001011001011001011001011...  
```
Thue-Morse word on other alphabets:

```
sage: t = words.ThueMorseWord('ab'); t
word: abbabaabbaababbaabbaabbaabbaababba...
```

```
sage: t = words.ThueMorseWord(['L1', 'L2'])
sage: t[:8]
word: L1,L2,L2,L1,L2,L1,L1,L2
```

Generalized Thue Morse word:

```
sage: words.ThueMorseWord(alphabet=(0,1,2), base=2)
word: 0112122012202001122020012001011212202001...
```

```
sage: t = words.ThueMorseWord(alphabet=(0,1,2), base=5); t
word: 0120112012201200120112012120122012001201...
```

```
sage: t[100:130].critical_exponent()
10/3
```

REFERENCES:

**UpperChristoffelWord**\(p, q, \text{alphabet}=(0, 1)\)

Returns the upper Christoffel word of slope \(p/q\), where \(p\) and \(q\) are relatively prime non-negative integers, over the given alphabet.

The *upper Christoffel word of slope* \(p/q\) is equal to the reversal of the lower Christoffel word of slope \(p/q\). Equivalently, if \(xuy\) is the lower Christoffel word of slope \(p/q\), where \(x\) and \(y\) are letters, then \(yu\bar{x}\) is the upper Christoffel word of slope \(p/q\) (because \(u\) is a palindrome).

**INPUT:**

- alphabet - any container of length two that is suitable to build an instance of OrderedAlphabet (list, tuple, str, ...)

**EXAMPLES:**

```
sage: words.UpperChristoffelWord(1,0)
word: 1
```

```
sage: words.UpperChristoffelWord(0,1)
word: 0
```

```
sage: words.UpperChristoffelWord(1,1)
word: 10
```

```
sage: words.UpperChristoffelWord(4,7)
word: 10100100100
```

**UpperMechanicalWord**\(\alpha, \rho=0, \text{alphabet}=None\)

Returns the upper mechanical word with slope \(\alpha\) and intercept \(\rho\)

The upper mechanical word \(s'_{\alpha, \rho}\) with slope \(\alpha\) and intercept \(\rho\) is defined by \(s'_{\alpha, \rho}(n) = [\alpha(n + 1) + \rho] - [\alpha n + \rho]\). \([\text{Loth02}]\)

**INPUT:**

- alpha – real number such that \(0 \leq \alpha \leq 1\)
- rho – real number (optional, default: 0)
• alphabet – iterable of two elements or None (optional, default: None)

OUTPUT:
infinite word

EXAMPLES:

```python
sage: words.UpperMechanicalWord(1/golden_ratio^2)
word: 10100101001010010100101001010010100101001...

sage: words.UpperMechanicalWord(1/5)
word: 10000010000100001000010000100001000010000...

sage: words.UpperMechanicalWord(1/pi)
word: 1001001001001001001001000100100100100100...
```

dual_fibonacci_tile(n)

Returns the \( n \)-th dual Fibonacci Tile [BmBGL09].

EXAMPLES:

```python
sage: for i in range(4): words.dual_fibonacci_tile(i)
Path: 3210
Path: 32123032301030121012
Path: 3212303230103230321232101232123032123210...
Path: 3212303230103230321232101232123032123210...
```

fibonacci_tile(n)

Returns the \( n \)-th Fibonacci Tile [BmBGL09].

EXAMPLES:

```python
sage: for i in range(3): words.fibonacci_tile(i)
Path: 3210
Path: 323030101212
Path: 3230301030323212323032321210121232121010...
```

s_adic(sequence, letters, morphisms=None)

Returns the \( s \)-adic infinite word obtained from a sequence of morphisms applied on a letter.

DEFINITION (from [Fogg]):

Let \( w \) be a infinite word over an alphabet \( A = A_0 \). A standard representation of \( w \) is obtained from a sequence of substitutions \( \sigma_k : A_{k+1} \to A_k \) and a sequence of letters \( a_k \in A_k \) such that:

\[
\lim_{k\to\infty} \sigma_0 \circ \sigma_1 \circ \cdots \sigma_k(a_k).
\]

Given a set of substitutions \( S \), we say that the representation is \( S \)-adic standard if the substitutions are chosen in \( S \).

INPUT:

• sequence - An iterable sequence of indices or of morphisms. It may be finite or infinite. If sequence is infinite, the image of the \((i+1)\)-th letter under the \((i+1)\)-th morphism must start with the \(i\)-th letter.

• letters - A letter or a sequence of letters.

• morphisms - dict, list, callable or None (optional, default None) an object that maps indices to morphisms. If None, then sequence must consist of morphisms.

OUTPUT:
A word.

EXAMPLES:
Let us define three morphisms and compute the first nested successive prefixes of the \( s \)-adic word:

\[
\begin{align*}
\text{sage: } & \quad m1 = \text{WordMorphism}('e->gh,f->hg') \\
\text{sage: } & \quad m2 = \text{WordMorphism}('c->ef,d->e') \\
\text{sage: } & \quad m3 = \text{WordMorphism}('a->cd,b->dc') \\
\text{sage: } & \quad \text{s}\_\text{adic}([m1],'e') \\
\quad \text{word: } gh \\
\text{sage: } & \quad \text{s}\_\text{adic}([m1,m2],'ec') \\
\quad \text{word: } ghhg \\
\text{sage: } & \quad \text{s}\_\text{adic}([m1,m2,m3],'eca') \\
\quad \text{word: } ghhghg
\end{align*}
\]

When the given sequence of morphism is finite, one may simply give the last letter, i.e. \('a'\), instead of giving all of them, i.e. \('eca'\):

\[
\begin{align*}
\text{sage: } & \quad \text{s}\_\text{adic}([m1,m2,m3], 'a') \\
\quad \text{word: } ghhghg \\
\text{sage: } & \quad \text{s}\_\text{adic}([m1,m2,m3], 'b') \\
\quad \text{word: } gghhgh
\end{align*}
\]

If the letters don’t satisfy the hypothesis of the algorithm (nested prefixes), an error is raised:

\[
\begin{align*}
\text{sage: } & \quad \text{s}\_\text{adic}([m1,m2,m3], 'ecb') \\
\quad \text{Traceback (most recent call last):} \\
\quad \quad 
\text{ValueError: the hypothesis of the algorithm used is not satisfied; the image of \( \rightarrow \) the 3-th letter (=b) under the 3-th morphism (=a->cd, b->dc) should start \( \rightleftharpoons \) with the 2-th letter (=c)
\end{align*}
\]

Let’s define the Thue-Morse morphism and the Fibonacci morphism which will be used below to illustrate more examples and let’s import the `repeat` tool from the `itertools`:

\[
\begin{align*}
\text{sage: } & \quad \text{tm} = \text{WordMorphism}('a->ab,b->ba') \\
\text{sage: } & \quad \text{fib} = \text{WordMorphism}('a->ab,b->a') \\
\text{sage: } & \quad \text{from } \text{itertools } \text{import } \text{repeat}
\end{align*}
\]

Two trivial examples of infinite \( s \)-adic words:

\[
\begin{align*}
\text{sage: } & \quad \text{s}\_\text{adic}(\text{repeat}(\text{tm}),\text{repeat}(\text{'a'})) \\
\quad \text{word: } ababaabbaabababbaabbaababbaababbaababba... \\
\text{sage: } & \quad \text{s}\_\text{adic}(\text{repeat}(\text{fib}),\text{repeat}(\text{'a'})) \\
\quad \text{word: } abababaababaabababaabababaabababaababaabababa... \\
\end{align*}
\]

A less trivial infinite \( s \)-adic word:

\[
\begin{align*}
\text{sage: } & \quad D = \{4: \text{tm}, 5: \text{fib}\} \\
\text{sage: } & \quad \text{tmword} = \text{words.ThueMorseWord}([4, 5]) \\
\text{sage: } & \quad \text{it} = (D[a] \text{ for } a \text{ in tmword}) \\
\text{sage: } & \quad \text{s}\_\text{adic}(\text{it}, \text{repeat}(\text{'a'})) \\
\quad \text{word: } ababaabbaabbaabababbaabababbaabbaababbaababbaababbaababbaababbaababbaababbaababba... \\
\end{align*}
\]
Combinatorics, Release 9.7

The same thing using a sequence of indices:

```
sage: tmword = words.ThueMorseWord([0,1])
sage: words.s_adic(tmword, repeat('a'), [tm,fib])
word: abbaababbaababbaababbaababbaababbaababba...
```

The correspondence of the indices may be given as a dict:

```
sage: words.s_adic(tmword, repeat('a'), {0:tm,1:fib})
word: abbaababbaababbaababbaababbaababbaababba...
```

because dict are more versatile for indices:

```
sage: tmwordTF = words.ThueMorseWord('TF')
sage: words.s_adic(tmwordTF, repeat('a'), {'T':tm,'F':fib})
word: abbaababbaababbaababbaababbaababbaababba...
```

or by a callable:

```
sage: f = lambda n: tm if n == 0 else fib
sage: words.s_adic(words.ThueMorseWord(), repeat('a'), f)
word: abbaababbaababbaababbaababbaababbaababba...
```

Random infinite \(s\)-adic words:

```
sage: from sage.misc.prandom import randint
sage: def it():
    ....:   while True: yield randint(0,1)
sage: words.s_adic(it(), repeat('a'), [tm,fib]) # random
word: abbaababbaababbaababbaababbaababbaababba...
```

An example where the sequences cycle on two morphisms and two letters:

```
sage: G = WordMorphism('a->cd,b->dc')
sage: H = WordMorphism('c->ab,d->ba')
sage: from itertools import cycle
sage: words.s_adic([G,H], 'ac')
word: cddc
```

The morphism \(\sigma : a \mapsto ba, b \mapsto b\) can’t satisfy the hypothesis of the nested prefixes, but one may compute arbitrarily long finite words having the limit \(\sigma^\omega(a)\):

```
sage: sigma = WordMorphism('a->ba,b->b')
sage: words.s_adic(repeat(sigma), repeat('a'))
Traceback (most recent call last):
...
ValueError: the hypothesis of the algorithm used is not satisfied; the image of...
→ the 2-th letter (=a) under the 2-th morphism (=a->ba, b->b) should start with...
→ the 1-th letter (=a)
```
The following examples illustrates an $S$-adic word defined over an infinite set $S$ of morphisms $x_h$:

```
sage: x = lambda h:WordMorphism({1:[2], 2:[3]+[1]*(h+1), 3:[3]+[1]*h})
sage: for h in [0,1,2,3]:
    ....: print("{} {}\n".format(h, x(h)))
0 1->2, 2->31
1 1->2, 2->311
2 1->2, 2->3111
3 1->2, 2->31111
sage: w = Word(lambda n : valuation(n+1, 2)); w
word: 0102010301020104010201030102010501020103...
sage: s = words.s_adic(w, repeat(3), x); s
word: 323223222322232223222322232223222322232...
sage: prefixe = s[:10000]
sage: list(map(prefixe.number_of_factors, range(15)))
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15]
sage: [_[i+1] - _[i] for i in range(len(_)-1)]
[1, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15]
```

### 5.1.365 Datatypes for words defined by iterators and callables

```python
class sage.combinat.words.word_infinite_datatypes.WordDatatype_callable(parent, callable, length=None):
    Bases: sage.combinat.words.word_datatypes.WordDatatype
    Datatype for a word defined by a callable.

class sage.combinat.words.word_infinite_datatypes.WordDatatype_callable_with_caching(parent, callable, length=None):
    Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_callable
    Datatype for a word defined by a callable.
```

5.1. Comprehensive Module List 3649
**flush()**

Empty the associated cache of letters.

**EXAMPLES:**

The first 40 (by default) values are always cached:

```python
sage: w = words.ThueMorseWord()

sage: w._letter_cache
{0: 0, 1: 1, 2: 1, 3: 0, 4: 1, 5: 0, 6: 0, 7: 1, 8: 1, 9: 0, 10: 0, 11: 1, 12: 0, 13: 1, 14: 1, 15: 0, 16: 1, 17: 0, 18: 0, 19: 1, 20: 0, 21: 1, 22: 1, 23: 0, 24: 0, 25: 1, 26: 1, 27: 0, 28: 1, 29: 0, 30: 0, 31: 1, 32: 1, 33: 0, 34: 0, 35: 1, 36: 0, 37: 1, 38: 1, 39: 0}

sage: w[100]
1

sage: w._letter_cache
{0: 0, 1: 1, 2: 1, 3: 0, 4: 1, 5: 0, 6: 0, 7: 1, 8: 1, 9: 0, 10: 0, 11: 1, 12: 0, 13: 1, 14: 1, 15: 0, 16: 1, 17: 0, 18: 0, 19: 1, 20: 0, 21: 1, 22: 1, 23: 0, 24: 0, 25: 1, 26: 1, 27: 0, 28: 1, 29: 0, 30: 0, 31: 1, 32: 1, 33: 0, 34: 0, 35: 1, 36: 0, 37: 1, 38: 1, 39: 0, 100: 1}

sage: w.flush()

sage: w._letter_cache
{}
```

**class** sage.combinat.words.word_infinite_datatypes.WordDatatype_iter(parent, iter, length=None)

**Bases:** sage.combinat.words.word_datatypes.WordDatatype

**INPUT:**

- **parent** - a parent
- **iter** - an iterator
- **length** - (default: None) the length of the word

**EXAMPLES:**

```python
sage: w = Word(iter("abbabaab"), length="unknown", caching=False); w
word: abbabaab

sage: isinstance(w, sage.combinat.words.word_infinite_datatypes.WordDatatype_iter)
True

sage: w.length() is None
False

sage: w.length()
8

sage: s = "abbabaabbaababbaabbaabbaababbaabbaababbaababbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabbaabna
```

(continues on next page)
sage: w = Word(iter(" abbabaab"), length=8, caching=False); w
word: abbabaab
sage: isinstance(w, sage.combinat.words.word_infinite_datatypes.WordDatatype_iter)
True
sage: w.length()
8

class 
sage.combinat.words.word_infinite_datatypes.WordDatatype_iter_with_caching(parent, iter, length=None)

Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_iter

INPUT:

• parent - a parent
• iter - an iterator
• length - (default: None) the length of the word

EXAMPLES:

sage: import itertools
sage: w = Word(itertools.cycle(" abbabaab"))
word: abbabaababbabaababbabaababbabaababbabaababbabaababbabaab...
sage: w = Word(iter("abbabaab"), length="finite"); w
word: abbabaab
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length="unknown"); w
word: abbabaab
sage: w.length()
8
sage: list(w)
['a', 'b', 'b', 'a', 'b', 'a', 'a', 'b']
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length=8)
sage: w._len
8

flush()
Delete the cached values.

EXAMPLES:

sage: from itertools import count
sage: w = Word(count())
sage: w._last_index, len(w._list)
(39, 40)
sage: w[43]
43
sage: w._last_index, len(w._list)
(43, 44)
sage: w.flush()
5.1.366 User-customizable options for words

sage.combinat.words.word_options.WordOptions(**kwargs)
Sets the global options for elements of the word class. The defaults are for words to be displayed in list notation.

INPUT:
• display - ‘string’ (default), or ‘list’, words are displayed in string or list notation.
• truncate - boolean (default: True), whether to truncate the string output of long words (see truncate_length below).
• truncate_length - integer (default: 40), if the length of the word is greater than this integer, then the word is truncated.
• letter_separator - (string, default: “,“) if the string representation of letters have length greater than 1, then the letters are separated by this string in the string representation of the word.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:

```python
sage: w = Word([2,1,3,12])
sage: u = Word("abba")
sage: WordOptions(display='list')
sage: w
word: [2, 1, 3, 12]
sage: u
word: ['a', 'b', 'b', 'a']
sage: WordOptions(display='string')
sage: w
word: 2,1,3,12
sage: u
word: abba
```

5.1.367 Set of words

To define a new class of words, please refer to the documentation file: sage/combinat/words/notes/word_inheritance_howto.rst

AUTHORS:
• Franco Saliola (2008-12-17): merged into sage
• Sebastien Labbe (2008-12-17): merged into sage
• Arnaud Bergeron (2008-12-17): merged into sage
• Sebastien Labbe (2009-07-21): Improved morphism iterator (trac ticket #6571).
• Vincent Delecroix (2015): classes simplifications (trac ticket #19619)

EXAMPLES:
```
sage: Words()
Finite and infinite words over Set of Python objects of class 'object'
sage: Words(4)
Finite and infinite words over {1, 2, 3, 4}
sage: Words(4,5)
Words of length 5 over {1, 2, 3, 4}

sage: FiniteWords('ab')
Finite words over {'a', 'b'}
sage: InfiniteWords('natural numbers')
Infinite words over Non negative integers
```

```python
class sage.combinat.words.words.AbstractLanguage(alphabet=None, category=None):
    Bases: sage.structure.parent.Parent

    Abstract base class

    This is not to be used by any means. This class gather previous features of set of words (prior to trac ticket #19619). In the future that class might simply disappear or become a common base class for all languages. In the latter case, its name would possibly change to Language.

    **alphabet()**

    EXAMPLES:

    ```python
    sage: Words(NN).alphabet()
    Non negative integer semiring
    sage: InfiniteWords([1,2,3]).alphabet()
    {1, 2, 3}
    sage: InfiniteWords('ab').alphabet()
    {'a', 'b'}
    sage: FiniteWords([1,2,3]).alphabet()
    {1, 2, 3}
    sage: FiniteWords().alphabet()
    Set of Python objects of class 'object'
    ```

    **identity_morphism()**

    Returns the identity morphism from self to itself.

    EXAMPLES:

    ```python
    sage: W = Words('ab')
    sage: W.identity_morphism()
    WordMorphism: a->a, b->b
    
    sage: W = Words(range(3))
    sage: W.identity_morphism()
    WordMorphism: 0->0, 1->1, 2->2
    ```

    There is no support yet for infinite alphabet:

    ```python
    sage: W = Words(alphabet=Alphabet(name='NN'))
    sage: W
    Finite and infinite words over Non negative integers
    ```
```
Combinatorics, Release 9.7

```python
sage: W.identity_morphism()
Traceback (most recent call last):
...  
NotImplementedError: size of alphabet must be finite
```

class `sage.combinat.words.words.FiniteOrInfiniteWords`(*alphabet*)

**INPUT:**

- alphabet – the underlying alphabet

**cardinality()**

Return the cardinality of this set of words.

**EXAMPLES:**

```python
sage: Words('abcd').cardinality()
+Infinity
sage: Words('a').cardinality()
+Infinity
sage: Words('').cardinality()
1
```

**factors()**

Return the set of finite words.

**EXAMPLES:**

```python
sage: Words('ab').finite_words()
Finite words over {'a', 'b'}
```

**finite_words()**

Return the set of finite words.

**EXAMPLES:**

```python
sage: Words('ab').finite_words()
Finite words over {'a', 'b'}
```

**infinite_words()**

Return the set of infinite words.

**EXAMPLES:**

```python
sage: Words('ab').infinite_words()
Infinite words over {'a', 'b'}
```

**iterate_by_length(length)**

Return an iterator over the words of given length.

**EXAMPLES:**

```python
sage: [w.string_rep() for w in Words('ab').iterate_by_length(3)]
['aaa', 'aab', 'aba', 'abb', 'baa', 'bab', 'bba', 'bbb']
```

**shift()**

Return the set of infinite words.
EXAMPLES:

```python
sage: Words('ab').infinite_words()
Infinite words over {'a', 'b'}
```

```python
class sage.combinat.words.words.FiniteWords(alphabet=None, category=None)

The set of finite words over a fixed alphabet.

EXAMPLES:

```python
sage: W = FiniteWords('ab')
sage: W
Finite words over {'a', 'b'}
```

cardinality()

Return the cardinality of this set.

EXAMPLES:

```python
sage: FiniteWords('').cardinality()
1
sage: FiniteWords('a').cardinality()
+Infinity
```

factors()

Return itself.

EXAMPLES:

```python
sage: FiniteWords('ab').factors()
Finite words over {'a', 'b'}
```

iter_morphisms(arg=None, codomain=None, min_length=1)

Iterate over all morphisms with domain `self` and the given codomain.

INPUT:

- **arg** - (optional, default: None) It can be one of the following:
  - None - then the method iterates through all morphisms.
  - tuple `(a, b)` of two integers - It specifies the range `range(a, b)` of values to consider for the sum of the length of the image of each letter in the alphabet.
  - list of nonnegative integers - The length of the list must be equal to the size of the alphabet, and the `i`-th integer of `arg` determines the length of the word mapped to by the `i`-th letter of the (ordered) alphabet.

- **codomain** - (default: None) a combinatorial class of words. By default, codomain is `self`.

- **min_length** - (default: 1) nonnegative integer. If `arg` is not specified, then iterate through all the morphisms where the length of the images of each letter in the alphabet is at least `min_length`. This is ignored if `arg` is a list.

OUTPUT:

`iterator`

EXAMPLES:
Iterator over all non-erasing morphisms:

```sage
W = FiniteWords('ab')
sage: it = W.iter_morphisms()
sage: for _ in range(7): next(it)
WordMorphism: a->a, b->a
WordMorphism: a->a, b->b
WordMorphism: a->b, b->a
WordMorphism: a->b, b->b
WordMorphism: a->aa, b->a
WordMorphism: a->aa, b->b
WordMorphism: a->ab, b->a
```

Iterator over all morphisms including erasing morphisms:

```sage
W = FiniteWords('ab')
sage: it = W.iter_morphisms(min_length=0)
sage: for _ in range(7): next(it)
WordMorphism: a->, b->
WordMorphism: a->a, b->
WordMorphism: a->b, b->
WordMorphism: a->b, b->a
WordMorphism: a->b, b->b
WordMorphism: a->aa, b->
WordMorphism: a->ab, b->
```

Iterator over morphisms where the sum of the lengths of the images of the letters is in a specific range:

```sage
for m in W.iter_morphisms((0, 3), min_length=0): m
```

```sage
for m in W.iter_morphisms( (2, 4) ): m
```

(continues on next page)
WordMorphism: a->bb, b->a
WordMorphism: a->bb, b->b
WordMorphism: a->a, b->aa
WordMorphism: a->a, b->ab
WordMorphism: a->a, b->ba
WordMorphism: a->a, b->bb
WordMorphism: a->b, b->aa
WordMorphism: a->b, b->ab
WordMorphism: a->b, b->ba
WordMorphism: a->b, b->bb
WordMorphism: a->a, b->a
WordMorphism: a->b, b->a

Iterator over morphisms with specific image lengths:

```
sage: for m in W.iter_morphisms([0, 0]): m
WordMorphism: a->, b->
sage: for m in W.iter_morphisms([0, 1]): m
WordMorphism: a->, b->a
WordMorphism: a->, b->b
sage: for m in W.iter_morphisms([2, 1]): m
WordMorphism: a->aa, b->a
WordMorphism: a->aa, b->b
WordMorphism: a->ab, b->a
WordMorphism: a->ab, b->b
WordMorphism: a->ba, b->a
WordMorphism: a->ba, b->b
WordMorphism: a->bb, b->a
WordMorphism: a->bb, b->b
sage: for m in W.iter_morphisms([2, 2]): m
WordMorphism: a->aa, b->aa
WordMorphism: a->aa, b->ab
WordMorphism: a->aa, b->ba
WordMorphism: a->aa, b->bb
WordMorphism: a->ab, b->aa
WordMorphism: a->ab, b->ab
WordMorphism: a->ab, b->ba
WordMorphism: a->ab, b->bb
WordMorphism: a->ba, b->aa
WordMorphism: a->ba, b->ab
WordMorphism: a->ba, b->ba
WordMorphism: a->ba, b->bb
WordMorphism: a->bb, b->aa
WordMorphism: a->bb, b->ab
WordMorphism: a->bb, b->ba
WordMorphism: a->bb, b->bb
```

The codomain may be specified as well:

```
sage: Y = FiniteWords('xyz')
```
iterate_by_length($l=1$)

Returns an iterator over all the words of self of length $l$.

INPUT:

- $l$ - integer (default: 1), the length of the desired words

EXAMPLES:

```
sage: W = FiniteWords('ab')
sage: list(W.iterate_by_length(1))
[word: a, word: b]
sage: list(W.iterate_by_length(2))
[word: aa, word: ab, word: ba, word: bb]
sage: list(W.iterate_by_length(3))
[word: aaa, word: aab, word: aba, word: abb, word: baa, word: bab, word: bba,
```
Combinatorics, Release 9.7

(word: bbb]
sage: list(W.iterate_by_length('a'))
Traceback (most recent call last):
...
  TypeError: the parameter l (= 'a') must be an integer

random_element(length=None, *args, **kwds)
Returns a random finite word on the given alphabet.

INPUT:

• length – (optional) the length of the word. If not set, will use a uniformly random number between 0 and 10.
• all other argument are transmitted to the random generator of the alphabet

EXAMPLES:

sage: W = FiniteWords(5)
sage: W.random_element()  # random
word: 511432544523521544531411434451152142155...

sage: W = FiniteWords(ZZ)
sage: W.random_element()  # random
word: 5,-1,-1,-1,0,0,0,0,-3,-11

sage: W.random_element(length=4, x=0, y=4)  # random
word: 1003

shift()
Return the set of infinite words on the same alphabet.

EXAMPLES:

sage: FiniteWords('ab').shift()
Infinite words over {'a', 'b'}

class sage.combinat.words.words.InfiniteWords(alphabet=None, category=None)

cardinality()
Return the cardinality of this set

EXAMPLES:

sage: InfiniteWords('ab').cardinality()
+Infinity
sage: InfiniteWords('a').cardinality()
1
sage: InfiniteWords('').cardinality()
0

factors()
Return the set of finite words on the same alphabet.

EXAMPLES:
sage: InfiniteWords('ab').factors()
Finite words over {'a', 'b'}

random_element(*args, **kwds)
Return a random infinite word.

EXAMPLES:

sage: W = InfiniteWords('ab')
sage: W.random_element()  # random
word: abbbabbaabbbaabbaabababbbbbbbbaabbb...
sage: W = InfiniteWords(ZZ)
sage: W.random_element(x=2, y=4)  # random
word: 333322332232233332322332232232232332333...

shift()
Return itself.

EXAMPLES:

sage: InfiniteWords('ab').shift()
Finite words over {'a', 'b'}

sage.combinat.words.words.Words(alphabet=None, length=None, finite=True, infinite=True)
Returns the combinatorial class of words of length k over an alphabet.

EXAMPLES:

sage: Words()
Finite and infinite words over Set of Python objects of class 'object'
sage: Words(length=7)
Words of length 7 over Set of Python objects of class 'object'
sage: Words(5)
Finite and infinite words over {1, 2, 3, 4, 5}
sage: Words(5, 3)
Words of length 3 over {1, 2, 3, 4, 5}
sage: Words(5, infinite=False)
Finite words over {1, 2, 3, 4, 5}
sage: Words(5, finite=False)
Infinite words over {1, 2, 3, 4, 5}
sage: Words('ab')
Finite and infinite words over {'a', 'b'}
sage: Words('ab', 2)
Words of length 2 over {'a', 'b'}
sage: Words('ab', infinite=False)
Finite words over {'a', 'b'}
sage: Words('ab', finite=False)
Infinite words over {'a', 'b'}
sage: Words('positive integers', finite=False)
Infinite words over Positive integers
sage: Words('natural numbers')
Finite and infinite words over Non negative integers

class sage.combinat.words.words.Words_n(words, n)
Bases: sage.structure.parent.Parent
The set of words of fixed length on a given alphabet.

**alphabet()**
Return the underlying alphabet.

EXAMPLES:

```python
sage: Words([0,1], 4).alphabet()
{0, 1}
```

**cardinality()**
Returns the number of words of length $n$ from alphabet.

EXAMPLES:

```python
sage: Words(['a','b','c'], 4).cardinality()
81
sage: Words(3, 4).cardinality()
81
sage: Words(0,0).cardinality()
1
sage: Words(5,0).cardinality()
1
sage: Words(['a','b','c'],0).cardinality()
1
sage: Words(0,1).cardinality()
0
sage: Words(5,1).cardinality()
5
sage: Words(['a','b','c'],1).cardinality()
3
sage: Words(7,13).cardinality()
96889010407
sage: Words(['a','b','c','d','e','f','g'],13).cardinality()
96889010407
```

**iterate_by_length(length)**
All words in this class are of the same length, so use iterator instead.

**list()**
Returns a list of all the words contained in self.

EXAMPLES:

```python
sage: Words(0,0).list()
[ ]
sage: Words(5,0).list()
[ ]
sage: Words(['a','b','c'],0).list()
[ ]
sage: Words(5,1).list()
[1, 2, 3, 4, 5]
sage: Words(['a','b','c'],2).list()
[aa, ab, ac, ba, bb, bc, ca, cb, cc]
```
random_element(*args, **kwds)

Return a random word in this set.

EXAMPLES:

```python
sage: W = Words('ab', 4)
sage: W.random_element() # random
word: bbab
sage: W.random_element() in W
True
sage: W = Words(ZZ, 5)
sage: W.random_element() # random
word: 1,2,2,-1,12
sage: W.random_element() in W
True
```

### 5.1.368 Yang-Baxter Graphs

class sage.combinat.yang_baxter_graph.SwapIncreasingOperator(i)

Bases: sage.combinat.yang_baxter_graph.SwapOperator

The operator that swaps the items in positions \( i \) and \( i+1 \).

EXAMPLES:

```python
sage: from sage.combinat.yang_baxter_graph import SwapOperator
sage: s3 = SwapOperator(3)
sage: s3 == loads(dumps(s3))
True
```

position()

self is the operator that swaps positions \( i \) and \( i+1 \). This method returns \( i \).

EXAMPLES:

```python
sage: from sage.combinat.yang_baxter_graph import SwapOperator
sage: s3 = SwapOperator(3)
sage: s3.position()
3
```

sage.combinat.yang_baxter_graph.YangBaxterGraph(partition=None, root=None, operators=None)

Construct the Yang-Baxter graph from root by repeated application of operators, or the Yang-Baxter graph associated to partition.

INPUT:

The user needs to provide either partition or both root and operators, where

- partition – a partition of a positive integer
- root – the root vertex
- operator - a function that maps vertices \( u \) to a list of tuples of the form \((v, l)\) where \( v \) is a successor of \( u \) and \( l \) is the label of the edge from \( u \) to \( v \).
OUTPUT:

- Either:
  - `YangBaxterGraph_partition` - if partition is defined
  - `YangBaxterGraph_generic` - if partition is `None`

EXAMPLES:

The Yang-Baxter graph defined by a partition \([p_1, \ldots, p_k]\) is the labelled directed graph with vertex set obtained by bubble-sorting \((p_k - 1, p_k - 2, \ldots, 0, \ldots, p_1 - 1, p_1 - 2, \ldots, 0)\); there is an arrow from \(u\) to \(v\) labelled by \(i\) if \(v\) is obtained by swapping the \(i\)-th and \((i + 1)\)-th elements of \(u\). For example, if the partition is \([3, 1]\), then we begin with \((0, 2, 1, 0)\) and generate all tuples obtained from it by swapping two adjacent entries if they are increasing:

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: bubbleswaps = [SwapIncreasingOperator(i) for i in range(3)]
sage: Y = YangBaxterGraph(root=(0,2,1,0), operators=bubbleswaps); Y
Yang-Baxter graph with root vertex (0, 2, 1, 0)
sage: Y.vertices(sort=True)
[(0, 2, 1, 0), (2, 0, 1, 0), (2, 1, 0, 0)]
```

The `partition` keyword is a shorthand for the above construction:

```
sage: Y = YangBaxterGraph(partition=[3,1]); Y
Yang-Baxter graph of [3, 1], with top vertex (0, 2, 1, 0)
sage: Y.vertices(sort=True)
[(0, 2, 1, 0), (2, 0, 1, 0), (2, 1, 0, 0)]
```

The permutahedron can be realized as a Yang-Baxter graph:

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: swappers = [SwapIncreasingOperator(i) for i in range(3)]
sage: Y = YangBaxterGraph(root=(1,2,3,4), operators=swappers); Y
Yang-Baxter graph with root vertex (1, 2, 3, 4)
sage: Y.plot()
Graphics object consisting of 97 graphics primitives
```

The Cayley graph of a finite group can be realized as a Yang-Baxter graph:

```
sage: def left_multiplication_by(g):
    ...:     return lambda h : h*g
sage: G = CyclicPermutationGroup(4)
sage: operators = [ left_multiplication_by(gen) for gen in G.gens() ]
sage: Y = YangBaxterGraph(root=G.identity(), operators=operators); Y
Yang-Baxter graph with root vertex ()
sage: Y.plot(edge_labels=False)
Graphics object consisting of 9 graphics primitives
```

```
sage: G = SymmetricGroup(4)
sage: operators = [left_multiplication_by(gen) for gen in G.gens()]
sage: Y = YangBaxterGraph(root=G.identity(), operators=operators); Y
Yang-Baxter graph with root vertex ()
sage: Y.plot(edge_labels=False)
Graphics object consisting of 96 graphics primitives
```
AUTHORS:

• Franco Saliola (2009-04-23)

class sage.combinat.yang_baxter_graph.YangBaxterGraph_generic(root, operators)

Bases: sage.structure.sage_object.SageObject

A class to model the Yang-Baxter graph defined by root and operators.

INPUT:

• root – the root vertex of the graph
• operators – a list of callables that map vertices to (new) vertices.

Note: This is a lazy implementation: the digraph is only computed when it is needed.

EXAMPLES:

```python
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(4)]

sage: Y = YangBaxterGraph(root=(1,0,2,1,0), operators=ops); Y
Yang-Baxter graph with root vertex (1, 0, 2, 1, 0)

sage: loads(dumps(Y)) == Y
True
```

AUTHORS:

• Franco Saliola (2009-04-23)

edges()  
Return the (labelled) edges of self.

EXAMPLES:

```python
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator

sage: ops = [SwapIncreasingOperator(i) for i in range(3)]

sage: Y = YangBaxterGraph(root=(0,2,1,0), operators=ops)

sage: Y.edges()
[((0, 2, 1, 0), (2, 0, 1, 0), Swap-if-increasing at position 0), ((2, 0, 1, 0), ...
  \rightarrow (2, 1, 0, 0), Swap-if-increasing at position 1)]
```

plot(*args, **kwds)
Plot self as a digraph.

EXAMPLES:

```python
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator

sage: ops = [SwapIncreasingOperator(i) for i in range(4)]

sage: Y = YangBaxterGraph(root=(1,0,2,1,0), operators=ops)

sage: Y.plot()
Graphics object consisting of 16 graphics primitives

sage: Y.plot(edge_labels=False)
Graphics object consisting of 11 graphics primitives
```

relabel_edges(edge_dict, inplace=True)

Relabel the edges of self.

INPUT:
• edge_dict – a dictionary keyed by the (unlabelled) edges.

EXAMPLES:

```python
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(3)]

sage: Y = YangBaxterGraph(root=(0,2,1,0), operators=ops)

sage: def relabel_op(op, u):
    ....:     i = op.position()
    ....:     return u[:i] + u[i:i+2][::-1] + u[i+2:]

sage: Y.edges()
[((0, 2, 1, 0), (2, 0, 1, 0), Swap-if-increasing at position 0),
 (2, 0, 1, 0), (2, 1, 0, 0), Swap-if-increasing at position 1)]

sage: d = {((0,2,1,0),(2,0,1,0)):17, ((2,0,1,0),(2,1,0,0)):27}

sage: Y.relabel_edges(d, inplace=False).edges()
[((0, 2, 1, 0), (2, 0, 1, 0), 17),
 (2, 0, 1, 0), (2, 1, 0, 0), 27)]

sage: Y.relabel_edges(d, inplace=True).edges()
[((0, 2, 1, 0), (2, 0, 1, 0), 17),
 (2, 0, 1, 0), (2, 1, 0, 0), 27)]
```

relabel_vertices(v, relabel_operator, inplace=True)

Relabel the vertices u of self by the object obtained from u by applying the relabel_operator to v along a path from self.root() to u.

Note that the self.root() is paired with v.

INPUT:

• v – tuple, Permutation, ...

• inplace – if True, modifies self; otherwise returns a modified copy of self.

EXAMPLES:

```python
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(3)]

sage: Y = YangBaxterGraph(root=(0,2,1,0), operators=ops)

sage: def relabel_op(op, u):
    ....:     i = op.position()
    ....:     return u[:i] + u[i:i+2][::-1] + u[i+2:]

sage: d = Y.relabel_vertices((1,2,3,4), relabel_op, inplace=False); d
Yang-Baxter graph with root vertex (1, 2, 3, 4)

sage: Y.vertices(sort=True)
[(0, 2, 1, 0), (2, 0, 1, 0), (2, 1, 0, 0)]

sage: e = Y.relabel_vertices((1,2,3,4), relabel_op); e

sage: Y.vertices(sort=True)
[(1, 2, 3, 4), (2, 1, 3, 4), (2, 3, 1, 4)]
```

root()

Return the root vertex of self.

If self is the Yang-Baxter graph of the partition \([p_1, p_2, \ldots, p_k]\), then this is the vertex \((p_k - 1, p_k - 2, \ldots, 0, \ldots, p_1 - 1, p_1 - 2, \ldots, 0)\).

EXAMPLES:
.. code-block:: python

    sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
    sage: ops = [SwapIncreasingOperator(i) for i in range(4)]
    sage: Y = YangBaxterGraph(root=(1,0,2,1,0), operators=ops)
    sage: Y.root()
    (1, 0, 2, 1, 0)
    sage: Y = YangBaxterGraph(root=(0,1,0,2,1,0), operators=ops)
    sage: Y.root()
    (0, 1, 0, 2, 1, 0)
    sage: Y = YangBaxterGraph(root=(1,0,3,2,1,0), operators=ops)
    sage: Y.root()
    (1, 0, 3, 2, 1, 0)
    sage: Y = YangBaxterGraph(partition=[3,2])
    sage: Y.root()
    (1, 0, 2, 1, 0)

**successors**(v)

Return the successors of the vertex v.

**EXAMPLES:**

.. code-block:: python

    sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
    sage: ops = [SwapIncreasingOperator(i) for i in range(4)]
    sage: Y = YangBaxterGraph(root=(1,0,2,1,0), operators=ops)
    sage: Y.successors(Y.root())
    [(1, 2, 0, 1, 0)]
    sage: Y = YangBaxterGraph(root=(0,1,0,2,1,0), operators=ops)
    sage: Y.successors((1, 2, 0, 1, 0))
    [(1, 2, 1, 0, 0), (2, 1, 0, 1, 0)]

**vertex_relabelling_dict**(v, relabel_operator)

Return a dictionary pairing vertices u of self with the object obtained from v by applying the relabel_operator along a path from the root to u.

Note that the root is paired with v.

**INPUT:**

- v – an object
- relabel_operator – function mapping a vertex and a label to the image of the vertex

**OUTPUT:**

- dictionary pairing vertices with the corresponding image of v

**EXAMPLES:**

.. code-block:: python

    sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
    sage: ops = [SwapIncreasingOperator(i) for i in range(3)]
    sage: Y = YangBaxterGraph(root=(0,2,1,0), operators=ops)
    sage: def relabel_operator(op, u):
    ....:     i = op.position()
    ....:     return u[:i] + u[i:i+2][::-1] + u[i+2:]
    sage: Y.vertex_relabelling_dict((1,2,3,4), relabel_operator)
    {(0, 2, 1, 0): (1, 2, 3, 4),
     (2, 0, 1, 0): (2, 1, 3, 4),
     (2, 1, 0, 0): (2, 3, 1, 4)}
**vertices**($sort$=False)

Return the vertices of self.

**INPUT:**

- **sort** – boolean (default False) whether to sort the vertices

**EXAMPLES:**

```python
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(3)]
sage: Y = YangBaxterGraph(root=(0,2,1,0), operators=ops)
sage: Y.vertices(sort=True)
[(0, 2, 1, 0), (2, 0, 1, 0), (2, 1, 0, 0)]
```

### class sage.combinat.yang_baxter_graph.YangBaxterGraph_partition($partition$)

**Bases:** sage.combinat.yang_baxter_graph.YangBaxterGraph_generic

A class to model the Yang-Baxter graph of a partition.

The Yang-Baxter graph defined by a partition $[p_1, \ldots, p_k]$ is the labelled directed graph with vertex set obtained by bubble-sorting $(p_k-1, p_k-2, \ldots, 0, \ldots, p_1-1, p_1-2, \ldots, 0)$; there is an arrow from $u$ to $v$ labelled by $i$ if $v$ is obtained by swapping the $i$-th and $(i+1)$-th elements of $u$.

**Note:** This is a lazy implementation: the digraph is only computed when it is needed.

**EXAMPLES:**

```python
sage: Y = YangBaxterGraph(partition=[3,2,1]); Y
Yang-Baxter graph of [3, 2, 1], with top vertex (0, 1, 0, 2, 1, 0)
sage: loads(dumps(Y)) == Y
True
```

**AUTHORS:**
- Franco Saliola (2009-04-23)

### relabel_vertices($v$, inplace=True)

Relabel the vertices of self with the object obtained from $v$ by applying the transpositions corresponding to the edge labels along some path from the root to the vertex.

**INPUT:**

- **$v$** – tuple, Permutation, ...
- **inplace** – if True, modifies self; otherwise returns a modified copy of self.

**EXAMPLES:**

```python
sage: Y = YangBaxterGraph(partition=[3,1]); Y
Yang-Baxter graph of [3, 1], with top vertex (0, 1, 0, 2, 1, 0)
sage: d = Y.relabel_vertices((1,2,3,4), inplace=False);
d Digraph on 3 vertices
sage: Y.vertices(sort=True)
[(0, 2, 1, 0), (2, 0, 1, 0), (2, 1, 0, 0)]
sage: e = Y.relabel_vertices((1,2,3,4)); e
sage: Y.vertices(sort=True)
[(1, 2, 3, 4), (2, 1, 3, 4), (2, 3, 1, 4)]
```
**vertex_relabelling_dict(v)**

Return a dictionary pairing vertices \( u \) of self with the object obtained from \( v \) by applying transpositions corresponding to the edges labels along a path from the root to \( u \).

Note that the root is paired with \( v \).

**INPUT:**

- \( v \) – an object

**OUTPUT:**

- dictionary pairing vertices with the corresponding image of \( v \)

**EXAMPLES:**

```sage
sage: Y = YangBaxterGraph(partition=[3,1])
sage: Y.vertex_relabelling_dict((1,2,3,4))
{(0, 2, 1, 0): (1, 2, 3, 4),
 (2, 0, 1, 0): (2, 1, 3, 4),
 (2, 1, 0, 0): (2, 3, 1, 4)}
sage: Y.vertex_relabelling_dict((4,3,2,1))
{(0, 2, 1, 0): (4, 3, 2, 1),
 (2, 0, 1, 0): (3, 4, 2, 1),
 (2, 1, 0, 0): (3, 2, 4, 1)}
```

### 5.1.369 C-Finite Sequences

C-finite infinite sequences satisfy homogeneous linear recurrences with constant coefficients:

\[
a_{n+d} = c_0 a_n + c_1 a_{n+1} + \cdots + c_{d-1} a_{n+d-1}, \quad d > 0.
\]

CFiniteSequences are completely defined by their ordinary generating function (o.g.f., which is always a fraction of polynomials over \( \mathbb{Z} \) or \( \mathbb{Q} \)).

**EXAMPLES:**

```sage
sage: fibo = CFiniteSequence(x/(1-x-x^2)) # the Fibonacci sequence
sage: fibo
C-finite sequence, generated by -x/(x^2 + x - 1)
sage: fibo.parent()
The ring of C-Finite sequences in x over Rational Field
sage: fibo.parent().category()
Category of commutative rings
sage: C.<x> = CFiniteSequences(QQ)
sage: fibo.parent() == C
True
sage: C
The ring of C-Finite sequences in x over Rational Field
sage: C(x/(1-x-x^2))
C-finite sequence, generated by -x/(x^2 + x - 1)
sage: C(x/(1-x-x^2)) == fibo
True
sage: var('y')
y
sage: CFiniteSequence(y/(1-y-y^2))
```

(continues on next page)
C-finite sequence, generated by \(-y/(y^2 + y - 1)\)

\[ \text{sage: } \text{CFiniteSequence}(y/(1-y-y^2)) == \text{fibo} \]
\[ \text{False} \]

Finite subsets of the sequence are accessible via python slices:

\[ \text{sage: } \text{fibo}[137] \quad \text{#the 137th term of the Fibonacci sequence} \]
\[ 19134702400093278081449423917 \]

\[ \text{sage: } \text{fibo}[137] == \text{fibonacci}(137) \]
\[ \text{True} \]

\[ \text{sage: } \text{fibo}[0:12] \]
\[ [0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89] \]

\[ \text{sage: } \text{fibo}[14:4:-2] \]
\[ [377, 144, 55, 21, 8] \]

They can be created also from the coefficients and start values of a recurrence:

\[ \text{sage: } r = \text{C.from_recurrence}([1,1],[0,1]) \]
\[ \text{sage: } r == \text{fibo} \]
\[ \text{True} \]

Given enough values, the o.g.f. of a C-finite sequence can be guessed:

\[ \text{sage: } r = \text{C.guess}([0,1,1,2,3,5,8]) \]
\[ \text{sage: } r == \text{fibo} \]
\[ \text{True} \]

See also:

\[ \text{fibonacci()}, \text{BinaryRecurrenceSequence} \]

\textbf{class} \ \texttt{sage.rings.cfinite_sequence.CFiniteSequence}(parent, ogf)

\hspace*{1cm} Bases: \texttt{sage.structure.element.FieldElement}

Create a C-finite sequence given its ordinary generating function.

\textbf{INPUT:}

- \texttt{ogf} – a rational function, the ordinary generating function (can be an element from the symbolic ring, fraction field or polynomial ring)

\textbf{OUTPUT:}

- A \texttt{CFiniteSequence} object

\textbf{EXAMPLES:}
Polynomials are interpreted as finite sequences, or recurrences of degree 0:

```
sage: CFiniteSequence(x^2-4*x^5)
Finite sequence [1, 0, 0, -4], offset = 2
sage: CFiniteSequence(1)
Finite sequence [1], offset = 0
```

This implementation allows any polynomial fraction as o.g.f. by interpreting any power of \( x \) dividing the o.g.f. numerator or denominator as a right or left shift of the sequence offset:

```
sage: CFiniteSequence(x^2+3/x)
Finite sequence [3, 0, 0, 1], offset = -1
sage: CFiniteSequence(1/x+4/x^3)
Finite sequence [4, 0, 1], offset = -3
```

The o.g.f. is always normalized to get a denominator constant coefficient of +1:

```
sage: CFiniteSequence(1/(x-2))
C-finite sequence, generated by 1/(x - 2)
```

The given ogf is used to create an appropriate parent: it can be a symbolic expression, a polynomial, or a fraction field element as long as it can be coerced into a proper fraction field over the rationals:

```
sage: var('x')
x
sage: f1 = CFiniteSequence((2-x)/(1-x-x^2))
sage: P, <x> = QQ[]
sage: f2 = CFiniteSequence((2-x)/(1-x-x^2))
sage: f1 == f2
True
```

```
sage: f1.parent()
The ring of C-Finite sequences in x over Rational Field
sage: f1.ogf().parent()
Fraction Field of Univariate Polynomial Ring in x over Rational Field
sage: CFiniteSequence(log(x))
Traceback (most recent call last):
... TypeError: unable to convert log(x) to a rational
```

**closed_form**\((n=n')\)

Return a symbolic expression in \( n \), which equals the \( n \)-th term of the sequence.

It is a well-known property of C-finite sequences \( a_n \) that they have a closed form of the type:

\[
    a_n = \sum_{i=1}^{d} c_i(n) \cdot r_i^n,
\]
where \( r_i \) are the roots of the characteristic equation and \( c_i(n) \) is a polynomial (whose degree equals the multiplicity of \( r_i \) minus one). This is a natural generalization of Binet’s formula for Fibonacci numbers. See, for instance, [KP2011, Theorem 4.1].

Note that if the o.g.f. has a polynomial part, that is, if the numerator degree is not strictly less than the denominator degree, then this closed form holds only when \( n \) exceeds the degree of that polynomial part. In that case, the returned expression will differ from the sequence for small \( n \).

**EXAMPLES:**

```python
sage: CFiniteSequence(1/(1-x)).closed_form()
1
sage: CFiniteSequence(x^2/(1-x)).closed_form()
1
sage: CFiniteSequence(1/(1-x^2)).closed_form()
1/2*(-1)^n + 1/2
sage: CFiniteSequence(1/(1+x^3)).closed_form()
1/3*(-1)^n + 1/3*(1/2*I*sqrt(3) + 1/2)^n + 1/3*(-1/2*I*sqrt(3) + 1/2)^n
sage: CFiniteSequence(1/(1-x)/(1-2*x)/(1-3*x)).closed_form()
9/2*3^n - 4*2^n + 1/2

Binet’s formula for the Fibonacci numbers:

```python
sage: CFiniteSequence(x/(1-x-x^2)).closed_form()
sqrt(1/5)*(1/2*sqrt(5) + 1/2)^n - sqrt(1/5)*(-1/2*sqrt(5) + 1/2)^n
```

```python
0, 1, 1, 2, 3, 5
```

```python
sage: CFiniteSequence((4*x+3)/(1-2*x-5*x^2)).closed_form()
1/2*(sqrt(6) + 1)^n*(7*sqrt(1/6) + 3) - 1/2*(-sqrt(6) + 1)^n*(7*sqrt(1/6) - 3)
```

**Examples with multiple roots:**

```python
sage: CFiniteSequence(x*(x^2+4*x+1)/(1-x)^5).closed_form()
1/4*n^4 + 1/2*n^3 + 1/4*n^2
sage: CFiniteSequence((1+2*x-x^2)/(1-x)^4/(1+x)^2).closed_form()
1/12*n^3 - 1/8*(-1)*n*(n + 1) + 3/4*n^2 + 43/24*n + 9/8
sage: CFiniteSequence(1/(1-x)^3/(1-2*x)^4).closed_form()
4/3*(n^3 - 3*n^2 + 20*n - 36)*2^n + 1/2*n^2 + 19/2*n + 49
sage: CFiniteSequence((x/(1-x-x^2))^2).closed_form()
1/5*(n - sqrt(1/5))+(1/2*sqrt(5) + 1/2)^n + 1/5*(n + sqrt(1/5))+(1/2*sqrt(5) + 1/2)^n
```

**coefficients()**

Return the coefficients of the recurrence representation of the C-finite sequence.

**OUTPUT:**

- A list of values

**EXAMPLES:**

```python
sage: C.<x> = CFiniteSequences(QQ)
sage: lucas = C((2-x)/(1-x-x^2)) # the Lucas sequence
sage: lucas.coefficients()
[1, 1]
```
denominator()  
Return the numerator of the o.g.f of self.

EXAMPLES:

```
sage: f = CFiniteSequence((2-x)/(1-x-x^2)); f
C-finite sequence, generated by (x - 2)/(x^2 + x - 1)
sage: f.denominator()
x^2 + x - 1
```

time.sleep(1)

numerator()  
Return the numerator of the o.g.f of self.

EXAMPLES:

```
sage: f = CFiniteSequence((2-x)/(1-x-x^2)); f
C-finite sequence, generated by (x - 2)/(x^2 + x - 1)
sage: f.numerator()
x - 2
```

time.sleep(1)

ogf()  
Return the ordinary generating function associated with the CFiniteSequence.  
This is always a fraction of polynomials in the base ring.

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: r = C.from_recurrence([2],[1])
sage: r.ogf()
-1/2/(x - 1/2)
sage: C(0).ogf()
0
```

time.sleep(1)

recurrence_repr()  
Return a string with the recurrence representation of the C-finite sequence.

OUTPUT:
- A string

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: C((2-x)/(1-x-x^2)).recurrence_repr()
'homogeneous linear recurrence with constant coefficients of degree 2: a(n+2) = - 2*a(n+1) + a(n), starting a(0...) = [2, 1]'
sage: C(x/(1-x)^3).recurrence_repr()
'homogeneous linear recurrence with constant coefficients of degree 3: a(n+3) = 3*a(n+2) - 3*a(n+1) + a(n), starting a(1...) = [1, 3, 6]'
sage: C(1).recurrence_repr()
'Finite sequence [1], offset 0'
sage: r = C((-2*x^3 + x^2 - x + 1)/(2*x^2 - 3*x + 1))
sage: r.recurrence_repr()
'homogeneous linear recurrence with constant coefficients of degree 2: a(n+2) = -3*a(n+1) - 2*a(n), starting a(0...) = [1, 2, 5, 9]'
sage: r = CFiniteSequence(x^3/(1-x-x^2))
```
(continues on next page)
Continued from previous page:

```
sage: r.recurrence_repr()
'homogeneous linear recurrence with constant coefficients of degree 2: a(n+2) = a(n+1) + a(n), starting a(3...) = [1, 1, 2, 3]'
```

```
sage: series(n)
Return the Laurent power series associated with the CFiniteSequence, with precision n.

INPUT:

- n – a nonnegative integer

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: r = C.from_recurrence([-1,2],[0,1])
sage: s = r.series(4); s
x + 2*x^2 + 3*x^3 + 4*x^4 + O(x^5)
sage: type(s)
<class 'sage.rings.laurent_series_ring_element.LaurentSeries'>
```
```
sage.rings.cfinite_sequence.CFiniteSequences(base_ring=None, category=None)
Return the ring of C-Finite sequences.

The ring is defined over a base ring (\( \mathbb{Z} \) or \( \mathbb{Q} \)) and each element is represented by its ordinary generating function (ogf) which is a rational function over the base ring.

INPUT:

- base_ring – the base ring to construct the fraction field representing the C-Finite sequences
- names – (optional) the list of variables.

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: C
The ring of C-Finite sequences in x over Rational Field
sage: C.an_element()
C-finite sequence, generated by (x - 2)/(x^2 + x - 1)
sage: C.category()
Category of commutative rings
sage: C.one()
Finite sequence [1], offset = 0
sage: C.zero()
Constant infinite sequence \( \mathbb{Z} \).
sage: C(x)
Finite sequence [1], offset = 1
sage: C(1/x)
Finite sequence [1], offset = -1
sage: C((-x + 2)/(-x^2 - x + 1))
C-finite sequence, generated by (x - 2)/(x^2 + x - 1)
```
```
class sage.rings.cfinite_sequence.CFiniteSequences_generic(polynomial_ring, category)
Bases: sage.rings.ring.CommutativeRing, sage.structure.unique_representation.UniqueRepresentation

The class representing the ring of C-Finite Sequences
```
```
Element
alias of CFiniteSequence

an_element()
Return an element of C-Finite Sequences.

OUTPUT:
The Lucas sequence.

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: C.an_element()
C-finite sequence, generated by (x - 2)/(x^2 + x - 1)
```

fraction_field()
Return the fraction field used to represent the elements of self.

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: C.fraction_field()
Fraction Field of Univariate Polynomial Ring in x over Rational Field
```

from_recurrence(coefficients, values)
Create a C-finite sequence given the coefficients \( c \) and starting values \( a \) of a homogeneous linear recurrence.

\[
a_{n+d} = c_0 a_n + c_1 a_{n+1} + \cdots + c_{d-1} a_{n+d-1}, \quad d \geq 0.
\]

INPUT:
- coefficients – a list of rationals
- values – start values, a list of rationals

OUTPUT:
- A CFiniteSequence object

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: C.from_recurrence([1,1],[0,1])  # Fibonacci numbers
C-finite sequence, generated by -x/(x^2 + x - 1)
sage: C.from_recurrence([-1,2],[0,1])  # natural numbers
C-finite sequence, generated by x/(x^2 - 2*x + 1)
sage: r = C.from_recurrence([-1],[1])
sage: s = C.from_recurrence([-1],[1,1])
sage: r == s
True
sage: r = C(x^3/(1-x-x^2))
sage: s = C.from_recurrence([1,1],[0,0,0,1,1])
sage: r == s
True
sage: C.from_recurrence(1,1)
Traceback (most recent call last):
... ValueError: Wrong type for recurrence coefficient list.
```
\textbf{gen}(i=0)

Return the i-th generator of \texttt{self}.

INPUT:

\begin{itemize}
  \item \texttt{i} – an integer (default:0)
\end{itemize}

EXAMPLES:

\begin{verbatim}
sage: C.<x> = CFiniteSequences(QQ)
sage: C.gen()
x
sage: x == C.gen()
True
\end{verbatim}

\textbf{guess}(\texttt{sequence}, \texttt{algorithm}=\textquote{\texttt{sage}})

Return the minimal \texttt{CFiniteSequence} that generates the sequence.

Assume the first value has index 0.

INPUT:

\begin{itemize}
  \item \texttt{sequence} – list of integers
  \item \texttt{algorithm} – string
    \begin{itemize}
      \item \texttt{\textquote{sage}} - the default is to use Sage’s matrix kernel function
      \item \texttt{\textquote{pari}} - use Pari’s implementation of LLL
      \item \texttt{\textquote{bm}} - use Sage’s Berlekamp-Massey algorithm
    \end{itemize}
\end{itemize}

OUTPUT:

\begin{itemize}
  \item a \texttt{CFiniteSequence}, or 0 if none could be found
\end{itemize}

With the default kernel method, trailing zeroes are chopped off before a guessing attempt. This may reduce the data below the accepted length of six values.

EXAMPLES:

\begin{verbatim}
sage: C.<x> = CFiniteSequences(QQ)
sage: C.guess([1,2,4,8,16,32])
\text{C-finite sequence, generated by } -1/2/(x - 1/2)
sage: r = C.guess([1,2,3,4,5])
Traceback (most recent call last):
  ... ValueError: Sequence too short for guessing.
sage: r = C.guess([1,2,4,8,9], \textquote{\texttt{algorithm}}=\textquote{bm}); r
\text{C-finite sequence, generated by } -1/2/(x - 1/2)
sage: r[0:5]
[1, 2, 4, 8, 16]
\end{verbatim}

\textbf{ngens}()

Return the number of generators of \texttt{self}

EXAMPLES:
sage: from sage.rings.cfinite_sequence import CFiniteSequences
sage: C.<x> = CFiniteSequences(QQ)
sage: C.ngens()
1

polynomial_ring()

Return the polynomial ring used to represent the elements of self.

EXAMPLES:

sage: C.<x> = CFiniteSequences(QQ)
sage: C.polynomial_ring()
Univariate Polynomial Ring in x over Rational Field
