5.1 Comprehensive Module List

**Note:** This list is currently sorted in alphabetical order w.r.t. the module names. It can be updated semi-automatically by running in src/sage/combinat:

```
find -name "*.py*" | sed 's|\..pyx\?$||; s|\./| sage/combinat/|' | LANG=en_US.UTF-8 LC_COLLATE=C sort > /tmp/module_list.rst
```

and copy pasting the result back there.

**Todo:** See Issue #17421 for desirable improvements.

### 5.1.1 Abstract Recursive Trees

The purpose of this class is to help implement trees with a specific structure on the children of each node. For instance, one could want to define a tree in which each node sees its children as linearly (see the [Ordered Trees](#) module) or cyclically ordered.

**Tree structures**

Conceptually, one can define a tree structure from any object that can contain others. Indeed, a list can contain lists which contain lists which contain lists, and thus define a tree … The same can be done with sets, or any kind of iterable objects.

While any iterable is sufficient to encode trees, it can prove useful to have other methods available like isomorphism tests (see next section), conversions to DiGraphs objects (see `as_digraph()`) or computation of the number of automorphisms constrained by the structure on children. Providing such methods is the whole purpose of the `AbstractTree` class.

As a result, the `AbstractTree` class is not meant to be instantiated, but extended. It is expected that classes extending this one may also inherit from classes representing iterables, for instance `ClonableArray` or `ClonableList`.

**Constrained Trees**

The tree built from a specific container will reflect the properties of the container. Indeed, if `A` is an iterable class whose elements are linearly ordered, a class `B` extending both of `AbstractTree` and `A` will be such that the children of a node will be linearly ordered. If `A` behaves like a set (i.e. if there is no order on the elements it contains), then two trees will be considered as equal if one can be obtained from the other through permutations between the children of a same node (see next section).

**Paths and ID**
It is expected that each element of a set of children should be identified by its index in the container. This way, any node of the tree can be identified by a word describing a path from the root node.

**Canonical labellings**

Equality between instances of classes extending both `AbstractTree` and `A` is entirely defined by the equality defined on the elements of `A`. A canonical labelling of such a tree, however, should be such that two trees `a` and `b` satisfying `a == b` have the same canonical labellings. On the other hand, the canonical labellings of trees `a` and `b` satisfying `a != b` are expected to be different.

For this reason, the values returned by the `canonical_labelling` method heavily depend on the data structure used for a node’s children and **should be overridden** by most of the classes extending `AbstractTree` if it is incoherent with the data structure.

**Authors**

- Florent Hivert (2010-2011): initial revision
- Frédéric Chapoton (2011): contributed some methods

```python
class sage.combinat.abstract_tree(AbstractClonableTree

Bases: AbstractTree

Abstract Clonable Tree.

An abstract class for trees with clone protocol (see `list_clone`). It is expected that classes extending this one may also inherit from classes like `ClonableArray` or `ClonableList` depending whether one wants to build trees where adding a child is allowed.
```

**Note:** Due to the limitation of Cython inheritance, one cannot inherit here from `ClonableElement`, because it would prevent us from later inheriting from `ClonableArray` or `ClonableList`.

---

**How should this class be extended?**

A class extending `AbstractClonableTree` should satisfy the following assumptions:

- An instantiable class extending `AbstractClonableTree` should also extend the `ClonableElement` class or one of its subclasses generally, at least `ClonableArray`.
- To respect the Clone protocol, the `AbstractClonableTree.check()` method should be overridden by the new class.

See also the assumptions in `AbstractTree`.

```python
def check():
    Check that self is a correct tree.
```

This method does nothing. It is implemented here because many extensions of `AbstractClonableTree` also extend `sage.structure.list_clone.ClonableElement`, which requires it.

It should be overridden in subclasses in order to check that the characterizing property of the respective kind of tree holds (e.g. two children for binary trees).

**EXAMPLES:**

```python
sage: OrderedTree([[],[[]])].check()
sage: BinaryTree([[],[[],[]])].check()
```
class sage.combinat.abstract_tree.AbstractLabelledClonableTree

Bases: AbstractLabelledTree, AbstractClonableTree

Abstract Labelled Clonable Tree

This class takes care of modification for the label by the clone protocol.

Note: Due to the limitation of Cython inheritance, one cannot inherit here from ClonableArray, because it would prevent us to inherit later from ClonableList.

map_labels(f)

Apply the function f to the labels of self

This method returns a copy of self on which the function f has been applied on all labels (a label x is replaced by f(x)).

EXAMPLES:

```python
sage: LT = LabelledOrderedTree
sage: t = LT([LT([], label=1), LT([], label=7)], label=3); t
3[1[[], 7[]]]
sage: t.map_labels(lambda z:z+1)
4[2[[], 8[]]]
sage: LBT = LabelledBinaryTree
sage: bt = LBT([LBT([], label=1), LBT([], label=4)], label=2); bt
2[1[., .], 4[., .]]
sage: bt.map_labels(lambda z:z+1)
3[2[., .], 5[., .]]
```

set_label(path, label)

Change the label of subtree indexed by path to label.

INPUT:
• **path** — None (default) or a path (list or tuple of children index in the tree)

• **label** — any sage object

OUTPUT: Nothing. self is modified in place

**Note:** self must be in a mutable state. See `sage.structure.list_clone` for more details about mutability.

**EXAMPLES:**

```python
t = LabelledOrderedTree([[[]], [[]], [[]]])
sage: t.set_label((0,), 4)
Traceback (most recent call last):
... ValueError: object is immutable; please change a copy instead.
sage: with t.clone() as t:
.... t.set_label((0,), 4)
sage: t
None[4][, None[None][, None][]]
sage: with t.clone() as t:
.... t.set_label((1,0), label = 42)
sage: t
None[4][, None[42][, None][]]
```

```python
>>> from sage.all import *
>>> t = LabelledOrderedTree([[[]], [[]], [[]]])
>>> t.set_label((Integer(0),), Integer(4))
Traceback (most recent call last):
... ValueError: object is immutable; please change a copy instead.
>>> with t.clone() as t:
... t.set_label((Integer(0),), Integer(4))
>>> t
None[4][, None[None][, None][]]
>>> with t.clone() as t:
... t.set_label((Integer(1),Integer(0)), label = Integer(42))
>>> t
None[4][, None[42][, None][]]
```

**Todo:** Do we want to implement the following syntactic sugar:

```python
with t.clone() as tt:
    tt.labels[1,2] = 3 ?
```

**set_root_label** *(label)*

Set the label of the root of self.

**INPUT:** label — any Sage object

**OUTPUT:** None, self is modified in place

**Note:** self must be in a mutable state. See `sage.structure.list_clone` for more details about
mutability.

EXAMPLES:

```
sage: t = LabelledOrderedTree([[],[],[]])
sage: t.set_root_label(3)
Traceback (most recent call last):
...
ValueError: object is immutable; please change a copy instead.
sage: with t.clone() as t:
....:   t.set_root_label(3)
sage: t.label()
3
sage: t
3[None[], None[None[], None[]]]
```

```
>>> from sage.all import *
>>> t = LabelledOrderedTree([[],[],[]])
>>> t.set_root_label(Integer(3))
Traceback (most recent call last):
...
ValueError: object is immutable; please change a copy instead.
>>> with t.clone() as t:
...:   t.set_root_label(Integer(3))
>>> t.label()
3
>>> t
3[None[], None[None[], None[]]]
```

This also works for binary trees:

```
sage: bt = LabelledBinaryTree([[],[]])
sage: bt.set_root_label(3)
Traceback (most recent call last):
...
ValueError: object is immutable; please change a copy instead.
sage: with bt.clone() as bt:
....:   bt.set_root_label(3)
sage: bt.label()
3
sage: bt
3[None[., .], None[., .]]
```

```
>>> from sage.all import *
>>> bt = LabelledBinaryTree([[],[]])
>>> bt.set_root_label(Integer(3))
Traceback (most recent call last):
...
ValueError: object is immutable; please change a copy instead.
>>> with bt.clone() as bt:
...:   bt.set_root_label(Integer(3))
>>> bt.label()
3
>>> bt
3[None[., .], None[., .]]
```

class sage.combinat.abstract_tree.AbstractLabelledTree (parent, children, label=None, check=True)
Bases: AbstractTree
Abstract Labelled Tree.

Typically a class for labelled trees is constructed by inheriting from a class for unlabelled trees and AbstractLabelledTree.

How should this class be extended?

A class extending AbstractLabelledTree should respect the following assumptions:

- For a labelled tree $T$ the call $T.parent().unlabelled_trees()$ should return a parent for unlabelled trees of the same kind: for example,
  - if $T$ is a binary labelled tree, $T.parent()$ is LabelledBinaryTrees() and $T.parent().unlabelled_trees()$ is BinaryTrees()
  - if $T$ is an ordered labelled tree, $T.parent()$ is LabelledOrderedTrees() and $T.parent().unlabelled_trees()$ is OrderedTrees()

- In the same vein, the class of $T$ should contain an attribute _UnLabelled which should be the class for the corresponding unlabelled trees.

See also the assumptions in AbstractTree.

See also:
AbstractTree

as_digraph()

Return a directed graph version of self.

**Warning:** At this time, the output makes sense only if self is a labelled binary tree with no repeated labels and no None labels.

**EXAMPLES:**

```
sage: LT = LabelledOrderedTrees()
sage: t = LT([LT((),'label=6'),LT((),'label=1')],label=9)
sage: t1 = LT([LT((),'label=6'),LT((),'label=1')],label=9)
sage: t1.as_digraph()
Digraph on 3 vertices

sage: t = BinaryTree([[[None, None],[[],None]]])
sage: lt = t.canonical_labelling()
sage: lt.as_digraph()
Digraph on 4 vertices
```

```python
>>> from sage.all import *
>>> LT = LabelledOrderedTrees()
>>> t1 = LT([LT((),'label=Integer(6)'),LT((),'label=Integer(1)')],
         label=Integer(9))
>>> t1.as_digraph()
Digraph on 3 vertices
>>> t = BinaryTree([[[None, None],[[],None]]])
>>> lt = t.canonical_labelling()
```

(continues on next page)
**label** *(path=None)*

Return the label of *self*.

**INPUT:**

- path – None (default) or a path (list or tuple of children index in the tree)

**OUTPUT:** the label of the subtree indexed by *path*

**EXAMPLES:**

```sage
sage: t = LabelledOrderedTree([[], []], label = 3)
sage: t.label()
sage: t[0].label()
sage: t = LabelledOrderedTree([LabelledOrderedTree([], 5), []], label = 3)
sage: t.label()
sage: t[0].label()
sage: t[1].label()
sage: t.label([0])
```

```python
>>> from sage.all import *
```

```sage
sage: t = LabelledOrderedTree([[], []], label = Integer(3))
sage: t.label()
sage: t[Integer(0)].label()
sage: t = LabelledOrderedTree([LabelledOrderedTree([], Integer(5)), []], label = Integer(3))
sage: t.label()
sage: t[Integer(0)].label()
sage: t[Integer(1)].label()
sage: t.label([Integer(0)])
```

**labels()**

Return the list of labels of *self*.

**EXAMPLES:**

```sage
sage: LT = LabelledOrderedTree
sage: t = LT([LT([], label='b'), LT([], label='c')], label='a')
sage: t.labels()
['a', 'b', 'c']
```

```sage
sage: LBT = LabelledBinaryTree
sage: LBT([LBT([], label=1), LBT([], label=4)], label=2).labels()
[2, 1, 4]
```
leaf_labels()

Return the list of labels of the leaves of self.

In case of a labelled binary tree, these “leaves” are not actually the leaves of the binary trees, but the nodes whose both children are leaves!

EXAMPLES:

```python
sage: LT = LabelledOrderedTree
sage: t = LT([LT([], label='b'), LT([], label='c')], label='a')
sage: t.leaf_labels()
['b', 'c']
```

shape()

Return the unlabelled tree associated to self.

EXAMPLES:

```python
sage: t = LabelledOrderedTree([[[]],[[]]], label=25).shape(); t
[[[], [[]]]]
```
class sage.combinat.abstract_tree.AbstractTree

Bases: object

Abstract Tree.

There is no data structure defined here, as this class is meant to be extended, not instantiated.

How should this class be extended?

A class extending AbstractTree should respect several assumptions:

- For a tree $T$, the call $\text{iter}(T)$ should return an iterator on the children of the root $T$.
- The $\text{canonical_labelling}$ method should return the same value for trees that are considered equal (see the “canonical labellings” section in the documentation of the AbstractTree class).
- For a tree $T$ the call $T\text{.parent()}.\text{labelled_trees()}$ should return a parent for labelled trees of the same kind: for example,
  - if $T$ is a binary tree, $T\text{.parent()}$ is $\text{BinaryTrees()}$ and $T\text{.parent()}.\text{labelled_trees()}$ is $\text{LabelledBinaryTrees()}$
  - if $T$ is an ordered tree, $T\text{.parent()}$ is $\text{OrderedTrees()}$ and $T\text{.parent()}.\text{labelled_trees()}$ is $\text{LabelledOrderedTrees()}$

**breadth_first_order_traversal** ($\text{action=none}$)

Run the breadth-first post-order traversal algorithm and subject every node encountered to some procedure $\text{action}$. The algorithm is:

```python
queue <- [ root ];
while the queue is not empty:
  node <- pop( queue );
  manipulate the node;
  prepend to the queue the list of all subtrees of
  the node (from the rightmost to the leftmost).
```

**INPUT:**

- $\text{action}$ – (optional) a function which takes a node as input, and does something during the exploration
OUTPUT:

None. (This is not an iterator.)

EXAMPLES:

For example, on the following binary tree $b$:

```
          ___3____
         /     \
        1      7  
       / \   /   \
      2  5 8   4 6
```

the breadth-first order traversal algorithm explores $b$ in the following order of nodes: 3, 1, 7, 2, 5, 8, 4, 6.

**canonical_labelling** $(shift=1)$

Return a labelled version of `self`.

The actual canonical labelling is currently unspecified. However, it is guaranteed to have labels in 1...$n$ where $n$ is the number of nodes of the tree. Moreover, two (unlabelled) trees compare as equal if and only if their canonical labelled trees compare as equal.

EXAMPLES:

```
sage: t = OrderedTree([[], [], [[], []], [[], []], [], []])
sage: t.canonical_labelling()
1[2[4[], 5[6[], 7[]]], 8[9[], 10[]], 11[12[], 13[]]]
```

```
sage: BinaryTree([]).canonical_labelling()
1[., .]
```

```
sage: BinaryTree([[], [[]], []]).canonical_labelling()
2[1[3[., .], 4[., .]], 5[., .]]
```

```
>>> from sage.all import *
>>> t = OrderedTree([[], [], [[], []], [[], []], [], []])
>>> t.canonical_labelling()
1[2[4[], 5[6[], 7[]]], 8[9[], 10[]], 11[12[], 13[]]]
```

```
>>> BinaryTree([]).canonical_labelling()
1[., .]
```

```
>>> BinaryTree([[], [[]], []]).canonical_labelling()
2[1[3[., .], 4[., .]], 5[., .]]
```

depth()

Return the depth of `self`.

EXAMPLES:

```
sage: OrderedTree().depth()
1
```

```
sage: OrderedTree([]).depth()
1
```

```
sage: OrderedTree([[]]).depth()
2
```

```
sage: OrderedTree([[], []]).depth()
3
```

(continues on next page)
sage: OrderedTree([[], [], [[], []], [[], []]], [[], []]).depth()
4

sage: BinaryTree().depth()
0
sage: BinaryTree([[[], []]]).depth()
3

>>> from sage.all import *

>>> OrderedTree().depth()
1

>>> OrderedTree([]).depth()
1

>>> OrderedTree([[[]]]).depth()
2

>>> OrderedTree([[[], [[]]]]).depth()
3

>>> OrderedTree([[], [[]], [[], []], [[], []]], [[], []]).depth()
4

>>> BinaryTree().depth()
0

>>> BinaryTree([[], [[]]]).depth()
3

**iterative_post_order_traversal** (*action=None*)

Run the depth-first post-order traversal algorithm (iterative implementation) and subject every node encountered to some procedure *action*. The algorithm is:

explore each subtree (by the algorithm) from the leftmost one to the rightmost one;
then manipulate the root with function `action` (in the case of a binary tree, only if the root is not a leaf).

**INPUT:**

- *action*—(optional) a function which takes a node as input, and does something during the exploration

**OUTPUT:**

None. (This is *not* an iterator.)

**See also:**

- *post_order_traversal_iter()*

**iterative_pre_order_traversal** (*action=None*)

Run the depth-first pre-order traversal algorithm (iterative implementation) and subject every node encountered to some procedure *action*. The algorithm is:

manipulate the root with function `action` (in the case of a binary tree, only if the root is not a leaf);
then explore each subtree (by the algorithm) from the leftmost one to the rightmost one.

**INPUT:**

- *action*—(optional) a function which takes a node as input, and does something during the exploration
OUTPUT:

None. (This is not an iterator.)

See also:

- `pre_order_traversal_iter()`
- `pre_order_traversal()`

`node_number()`

Return the number of nodes of `self`.

See also:

`node_number_at_depth()`, `node_number_to_the_right()`

EXAMPLES:

```
sage: OrderedTree().node_number()
sage: OrderedTree([]).node_number()
sage: OrderedTree([[]]).node_number()
sage: OrderedTree([[[]]]).node_number()
sage: OrderedTree([[[]], [[]]]).node_number()
sage: OrderedTree([[[], [[]], [[]], [[]]], [[], []]]).node_number()
```

```text
>>> from sage.all import *
```

```text
>>> OrderedTree().node_number()
>>> OrderedTree([]).node_number()
>>> OrderedTree([[]]).node_number()
>>> OrderedTree([[[]]]).node_number()
>>> OrderedTree([[[]], [[]]]).node_number()
```

EXAMPLES:

```
sage: BinaryTree(None).node_number()
sage: BinaryTree([]).node_number()
sage: BinaryTree([[]], None).node_number()
sage: BinaryTree([[], None], None).node_number()
sage: BinaryTree([None, [[], []]], None).node_number()
```

```text
>>> from sage.all import *
```

```text
>>> BinaryTree(None).node_number()
>>> BinaryTree([]).node_number()
>>> BinaryTree([[]], None).node_number()
```
node_number_at_depth\textit{(depth)}

Return the number of nodes at a given depth.
This counts all nodes that are at the given depth.
Here the root is considered to have depth 0.

INPUT:

- \textit{depth} – an integer

See also:

\textit{node_number()}, \textit{node_number_to_the_right()}, \textit{paths_at_depth()}

EXAMPLES:

```python
sage: T = OrderedTree([[[], []], [], [[]]], [])
sage: ascii_art(T)
   ___o____
  / / /
 o_ _ _ o
 / / /
 o o o o
| | |
 o o
| |
 sagesage: [T.node_number_at_depth(i) for i in range(6)]
[1, 3, 4, 2, 1, 0]
```

```python
>>> from sage.all import *
>>> T = OrderedTree([[[], []], [], [[]]], [])
>>> ascii_art(T)
   ___o____
  / / /
 o_ _ _ o
 / / /
 o o o o
| | |
 o o
| |
>>> [T.node_number_at_depth(i) for i in range(Integer(6))]
[1, 3, 4, 2, 1, 0]
```

node_number_to_the_right\textit{(path)}

Return the number of nodes at the same depth and to the right of the node identified by \textit{path}.
This counts the nodes that are at the same depth as the given one, and strictly to its right.

See also:

\textit{node_number()}, \textit{node_number_at_depth()}, \textit{paths_to_the_right()}

EXAMPLES:
paths()

Return a generator for all paths to nodes of self.

OUTPUT:

This method returns a list of sequences of integers. Each of these sequences represents a path from the root node to some node. For instance, (1, 3, 2, 5, 0, 3) represents the node obtained by choosing the 1st child of the root node (in the ordering returned by `iter`), then the 3rd child of its child, then the 2nd child of the latter, etc. (where the labelling of the children is zero-based).
The root element is represented by the empty tuple ()

See also:

\textit{paths\_at\_depth()}, \textit{paths\_to\_the\_right()}

EXAMPLES:

\begin{verbatim}
sage: list(OrderedTree([]).paths()) [[]]
sage: list(OrderedTree([[], []]).paths())
[[], (0,), (1,), (1, 0)]
sage: list(BinaryTree([[], [], []]).paths())
[[], (0,), (1,), (1, 0), (1, 1)]

\texttt{paths\_at\_depth}(\texttt{depth}, \texttt{path}=[])
\end{verbatim}

Return a generator for all paths at a fixed depth.

This iterates over all paths for nodes that are at the given depth.

Here the root is considered to have depth 0.

INPUT:

\begin{itemize}
\item depth – an integer
\item path – optional given path (as a list) used in the recursion
\end{itemize}

\textbf{Warning:} The path option should not be used directly.

See also:

\textit{paths()}, \textit{paths\_to\_the\_right()}, \textit{node\_number\_at\_depth()}

EXAMPLES:

\begin{verbatim}
>>> from sage.all import *

>>> list(OrderedTree([]).paths()) [[]]

>>> list(OrderedTree([[], []]).paths())
[[], (0,), (1,), (1, 0)]

>>> list(BinaryTree([[], [], []]).paths())
[[], (0,), (1,), (1, 0), (1, 1)]

T = OrderedTree([[], [[], []]], [], [[], [], []])

>>> list(g)
[]

post_order_traversal (action=None)
Run the depth-first post-order traversal algorithm (recursive implementation) and subject every node encountered to some procedure action. The algorithm is:

```
explore each subtree (by the algorithm) from the leftmost one to the rightmost one;
then manipulate the root with function `action` (in the case of a binary tree, only if the root is not a leaf).
```

INPUT:

- **action** – (optional) a function which takes a node as input, and does something during the exploration

OUTPUT:

None. (This is *not* an iterator.)

See also:

- `post_order_traversal_iter()`
- `iterative_post_order_traversal()`

**post_order_traversal_iter()**

The depth-first post-order traversal iterator.

This method iters each node following the depth-first post-order traversal algorithm (recursive implementation). The algorithm is:

```
explore each subtree (by the algorithm) from the leftmost one to the rightmost one;
then yield the root (in the case of binary trees, only if it is not a leaf).
```

EXAMPLES:

For example on the following binary tree `b`:

```
|   ___3___ |
| /         |
| 1   _7_   |
| \
| 2 5 8 |
| / \ |
| 4 6 |
```

(only the nodes are shown), the depth-first post-order traversal algorithm explores `b` in the following order of nodes: 2, 1, 4, 6, 5, 8, 7, 3.

For another example, consider the labelled tree:

```
|   ___1___ |
| / / /     |
| 2 6 8_    |
| | | /     |
| 3_ 7 9 10 |
| / /       |
| 4 5 |
```

The algorithm explores this tree in the following order: 4, 5, 3, 2, 7, 6, 9, 10, 8, 1.
**pre_order_traversal** *(action=None)*  
Run the depth-first pre-order traversal algorithm (recursive implementation) and subject every node encountered to some procedure `action`. The algorithm is:

```plaintext
manipulate the root with function `action` (in the case of a binary tree, only if the root is not a leaf);  
then explore each subtree (by the algorithm) from the leftmost one to the rightmost one.
```

**INPUT:**

- `action` – (optional) a function which takes a node as input, and does something during the exploration

**OUTPUT:**

None. (This is not an iterator.)

**EXAMPLES:**

For example, on the following binary tree `b`:

```
        ___3___  
       /     \
      1  _7_  
     /   /  \
    2  5  8  
   /   /  \
  4  6  
```

the depth-first pre-order traversal algorithm explores `b` in the following order of nodes: 3, 1, 2, 7, 5, 4, 6, 8.

Another example:

```
     ___1___  
    /     /  \
   2  6  8_  
  /   / /  \
 3_ 7 9 10  
 / /  \
4 5  
```

The algorithm explores this tree in the following order: 1, 2, 3, 4, 5, 6, 7, 8, 9, 10.

**See also:**

- `pre_order_traversal_iter()`
- `iterative_pre_order_traversal()`

**pre_order_traversal_iter** ()

The depth-first pre-order traversal iterator.

This method iters each node following the depth-first pre-order traversal algorithm (recursive implementation). The algorithm is:

```plaintext
yield the root (in the case of binary trees, if it is not a leaf);  
then explore each subtree (by the algorithm) from the leftmost one to the rightmost one.
```
EXAMPLES:

For example, on the following binary tree $b$:

```
<table>
<thead>
<tr>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>2 5 8</td>
</tr>
<tr>
<td>4 6</td>
</tr>
</tbody>
</table>
```

(only the nodes shown), the depth-first pre-order traversal algorithm explores $b$ in the following order of nodes: 3, 1, 2, 7, 5, 4, 6, 8.

Another example:

```
<table>
<thead>
<tr>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>2 6 8</td>
</tr>
<tr>
<td>3 7 9 10</td>
</tr>
<tr>
<td>4 5</td>
</tr>
</tbody>
</table>
```

The algorithm explores this labelled tree in the following order: 1, 2, 3, 4, 5, 6, 7, 8, 9, 10.

```
sage: list(OrderedTree([]).subtrees())
[]
sage: list(OrderedTree([[[]], []]).subtrees())
[[[]], [], [[]], []]
sage: list(OrderedTree([[[]], [[]]]).canonical_labelling().subtrees())
[[1[2[]], 3[4[]]], 2[], 3[4[]], 4[]]
sage: list(BinaryTree([[[]], [[]]]).subtrees())
[[[., .], [[., .], [., .]]], [., .], [[., .], [., .]], [., .], [[., .], [., .]]]
sage: v = BinaryTree([[[]], []])
sage: list(v.canonical_labelling().subtrees())
[2[1[., .], 3[., .]], 1[., .], 3[., .]]
```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> list(BinaryTree([[],[],[]]).subtrees())
[[[., .], [., .], [., .]], [., .], [[., .], [., .], [., .]], [., .], [., .]]

>>> v = BinaryTree([[],[]])
>>> list(v.canonical_labelling().subtrees())
[2[1[., .], 3[., .]], 1[., .], 3[., .]]
```

to_hexacode()

Transform a tree into a hexadecimal string.

The definition of the hexacode is recursive. The first letter is the valence of the root as a hexadecimal (up to 15), followed by the concatenation of the hexacodes of the subtrees.

This method only works for trees where every vertex has valency at most 15.

See from_hexacode() for the reverse transformation.

EXAMPLES:

```python
sage: from sage.combinat.abstract_tree import from_hexacode
sage: LT = LabelledOrderedTrees()
sage: from_hexacode(2010, LT).to_hexacode()
'2010'
sage: LT.an_element().to_hexacode()
'3020010'
sage: t = from_hexacode('a0000000000000000', LT)
sage: t.to_hexacode()
'a0000000000'
sage: OrderedTrees(6).an_element().to_hexacode()
'500000'
```

```python
>>> from sage.all import *
>>> from sage.combinat.abstract_tree import from_hexacode

>>> LT = LabelledOrderedTrees()

>>> from_hexacode(2010, LT).to_hexacode()
'2010'

>>> LT.an_element().to_hexacode()
'3020010'

>>> t = from_hexacode('a0000000000000000', LT)

>>> t.to_hexacode()
'a0000000000'

>>> OrderedTrees(Integer(6)).an_element().to_hexacode()
'500000'
```

tree_factorial()

Return the tree-factorial of self.

Definition:

The tree-factorial $T!$ of a tree $T$ is the product $\prod_{v \in T} \#\text{children}(v)$.

EXAMPLES:

```python
sage: LT = LabelledOrderedTrees()
sage: t = LT([LT([],label=6),LT([],label=1)],label=9)
sage: t.tree_factorial()
```

(continues on next page)
sage.combinat.abstract_tree.from_hexacode (ch, parent=None, label=‘@’)

Transform a hexadecimal string into a tree.

INPUT:

• ch – a hexadecimal string
• parent – kind of trees to be produced. If None, this will be LabelledOrderedTrees
• label – a label (default: ‘@’) to be used for every vertex of the tree

See AbstractTree.to_hexacode() for the description of the encoding

See _from_hexacode_aux() for the actual code

EXAMPLES:

```python
sage: from sage.combinat.abstract_tree import from_hexacode
sage: from_hexacode('12000', LabelledOrderedTrees())
@
[@[@[[], []]]]
sage: from_hexacode('12000')
@
[@[@[[], []]]]
sage: from_hexacode('1200', LabelledOrderedTrees())
@
[@[@[[], []]]]
```

It can happen that only a prefix of the word is used:

```python
sage: from_hexacode('a' + '14*' + '0', LabelledOrderedTrees())
@
[@[], [], [], [], [], [], [], [], [], []]
```
One can choose the label:

```python
sage: from_hexacode('1200', LabelledOrderedTrees(), label='o')
o[o[o[], o[]]]
```

```python
>>> from sage.all import *

>>> from_hexacode('1200', LabelledOrderedTrees(), label='o')
o[o[o[], o[]]]
```

One can also create other kinds of trees:

```python
sage: from_hexacode('1200', OrderedTrees())
[[[], []]]
```

```python
>>> from sage.all import *

>>> from_hexacode('1200', OrderedTrees())
[[[], []]]
```

## 5.1.2 Affine Permutations

```python
class sage.combinat.affine_permutation.AffinePermutation (parent, lst, check=True)
Bases: ClonableArray
```

An affine permutation, represented in the window notation, and considered as a bijection from \( \mathbb{Z} \) to \( \mathbb{Z} \).

**EXAMPLES:**

```python
sage: A = AffinePermutationGroup(['A',7,1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9]
```

```python
>>> A = AffinePermutationGroup(['A',Integer(7),Integer(1)])
>>> p = A([Integer(3), -Integer(1), Integer(0), Integer(6), Integer(5), Integer(4), Integer(10), Integer(9)])
>>> p
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9]
```

**apply_simple_reflection** (**i, side='right'**)

Apply a simple reflection.

**INPUT:**

- **i** – an integer
- **side** – (default: 'right') determines whether to apply the reflection on the 'right' or 'left'

**EXAMPLES:**

```python
sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.apply_simple_reflection(3)
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9]
sage: p.apply_simple_reflection(11)
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9]
sage: p.apply_simple_reflection(3, 'left')
```

(continues on next page)
Type A affine permutation with window \([4, -1, 0, 6, 5, 3, 10, 9]\)

\[
\text{sage: } \text{p.apply_simple_reflection}(11, \text{\texttt{\textquotesingle}left\textquotesingle})
\]
Type A affine permutation with window \([4, -1, 0, 6, 5, 3, 10, 9]\)

```python
from sage.all import *
p = AffinePermutationGroup([A,Integer(7),Integer(1)])([Integer(3), -Integer(1), Integer(0), Integer(6), Integer(5), Integer(4), Integer(10), -Integer(3)])
p.apply_simple_reflection(Integer(3))
p.apply_simple_reflection(Integer(11))
p.apply_simple_reflection(Integer(3), \text{\texttt{\textquotesingle}left\textquotesingle})
p.apply_simple_reflection(Integer(11), \text{\texttt{\textquotesingle}left\textquotesingle})
```

\[
\text{grassmannian_quotient} \ (i=0, \ \text{\texttt{side='right'}})
\]

Return the Grassmannian quotient.

Factors self into a unique product of a Grassmannian and a finite-type element. Returns a tuple containing the Grassmannian and finite elements, in order according to side.

**INPUT:**

- \(i\) – (default: 0) an element of the index set; the descent checked for

**EXAMPLES:**

```python
A = AffinePermutationGroup(['A',7,1])
p=A([3, -1, 0, 6, 5, 4, 10, 9])
gq=p.grassmannian_quotient()
gq

(Type A affine permutation with window \([-1, 0, 3, 4, 5, 6, 9, 10]\),
Type A affine permutation with window \([3, 1, 2, 6, 5, 4, 8, 7]\))
gq[0].is_i_grassmannian()
True

gq[1].reduced_word()
True

gq[0].is_i_grassmannian()
True

gq[1].reduced_word()
True

gqLeft=p.grassmannian_quotient(side=\text{\texttt{\textquotesingle}left\textquotesingle})
gqLeft

(Type A affine permutation with window \([-1, 0, 3, 4, 5, 6, 9, 10]\),
Type A affine permutation with window \([3, 1, 2, 6, 5, 4, 8, 7]\))
gqLeft[0].is_i_grassmannian(side=\text{\texttt{\textquotesingle}left\textquotesingle})
True

gqLeft[1].is_i_grassmannian(side=\text{\texttt{\textquotesingle}left\textquotesingle})
True

```
Combinatorics, Release 10.4

Type A affine permutation with window [3, 1, 2, 6, 5, 4, 8, 7]

```python
>>> gq[Integer(0)].is_i_grassmannian()
True
>>> Integer(0) not in gq[Integer(1)].reduced_word()
True
>>> prod(gq)==p
True
>>> gqLeft=p.grassmannian_quotient(side=left)
>>> Integer(0) not in gqLeft[Integer(0)].reduced_word()
True
>>> gqLeft[Integer(1)].is_i_grassmannian(side='left')
True
>>> prod(gqLeft)==p
True
```

**index_set()**

Index set of the affine permutation group.

**EXAMPLES:**

```python
sage: A = AffinePermutationGroup([A,7,1])
sage: A.index_set()
(0, 1, 2, 3, 4, 5, 6, 7)
```

```python
>>> from sage.all import *
>>> A = AffinePermutationGroup([A,Integer(7),Integer(1)])
```

**is_i_grassmannian** *(i=0, side='right')*

Test whether self is i-grassmannian, i.e., either is the identity or has i as the sole descent.

**INPUT:**

- i – an element of the index set
- side – determines the side on which to check the descents

**EXAMPLES:**

```python
sage: A = AffinePermutationGroup([A,7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.is_i_grassmannian()
False
sage: q=A.from_word([3,2,1,0])
sage: q.is_i_grassmannian()
True
```

```python
>>> from sage.all import *
>>> A = AffinePermutationGroup([A,Integer(7),Integer(1)])
>>> p=A([Integer(3), -Integer(1), Integer(0), Integer(6), Integer(5),...
```
Integer(4), Integer(10), Integer(9))

>>> p.is_i_grassmannian()
False

>>> q=A.from_word([Integer(3),Integer(2),Integer(1),Integer(0)])

>>> q.is_i_grassmannian()
True

>>> q=A.from_word([Integer(2),Integer(3),Integer(4),Integer(5)])

>>> q.is_i_grassmannian(Integer(5))
True

>>> q.is_i_grassmannian(Integer(2), side='left')
True

**is_one()**

Tests whether the affine permutation is the identity.

**EXAMPLES:**

```python
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.is_one()
False

sage: q=A.one()
sage: q.is_one()
True
```

```python
>>> from sage.all import *

>>> A = AffinePermutationGroup(['A',Integer(7),Integer(1)])

>>> p=A([Integer(3), -Integer(1), Integer(0), Integer(6), Integer(5),
    →Integer(4), Integer(10), Integer(9)])

>>> p.is_one()
False

>>> q=A.one()

>>> q.is_one()
True
```

**lower_covers**(side='right')

Return lower covers of self.

The set of affine permutations of one less length related by multiplication by a simple transposition on the indicated side. These are the elements that self covers in weak order.

**EXAMPLES:**

```python
sage: A = AffinePermutationGroup(['A',7,1])

sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])

sage: p.lower_covers()
[Type A affine permutation with window [-1, 3, 0, 6, 5, 4, 10, 9],
 Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9],
 Type A affine permutation with window [3, -1, 0, 6, 4, 5, 10, 9],
 Type A affine permutation with window [3, -1, 0, 6, 5, 4, 9, 10]]
```

```python
>>> from sage.all import *

>>> A = AffinePermutationGroup(['A',Integer(7),Integer(1)])

>>> p=A([Integer(3), -Integer(1), Integer(0), Integer(6), Integer(5),
    →Integer(4), Integer(10), Integer(9)])

>>> p.lower_covers()
```
Type A affine permutation with window \([-1, 3, 0, 6, 5, 4, 10, 9]\),
Type A affine permutation with window \([3, -1, 0, 5, 6, 4, 10, 9]\),
Type A affine permutation with window \([3, -1, 0, 6, 4, 5, 10, 9]\),
Type A affine permutation with window \([3, -1, 0, 6, 5, 4, 9, 10]\)

reduced_word()  
Returns a reduced word for the affine permutation.

EXAMPLES:

```
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.reduced_word()
[0, 7, 4, 1, 0, 7, 5, 4, 2, 1]
```

signature()  
Signature of the affine permutation, \((-1)^l\), where \(l\) is the length of the permutation.

EXAMPLES:

```
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.signature()
1
```

to_weyl_group_element()  
The affine Weyl group element corresponding to the affine permutation.

EXAMPLES:

```
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.to_weyl_group_element()
[ 0 -1 0 1 0 0 1 0]
[ 1 -1 0 1 0 0 1 -1]
[ 1 -1 0 1 0 0 0 0]
[ 0 0 0 1 0 0 0 0]
[ 0 0 0 1 0 -1 1 0]
[ 0 0 0 1 -1 0 1 0]
[ 0 0 0 0 0 0 1 0]
[ 0 -1 1 0 0 0 1 0]
```
sage.combinat.affine_permutation.AffinePermutationGroup(cartan_type)

Wrapper function for specific affine permutation groups.

These are combinatorial implementations of the affine Weyl groups of types $A, B, C, D,$ and $G$ as permutations of the set of all integers. The basic algorithms are derived from [BB2005] and [Eri1995].

EXAMPLES:

```
sage: ct = CartanType(['A',7,1])
sage: A = AffinePermutationGroup(ct)
sage: A
The group of affine permutations of type ['A', 7, 1]
```

We define an element of $A$:

```
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9]
```

We find the value $p(1)$, considering $p$ as a bijection on the integers. This is the same as calling the `value()` method:

```
sage: p.value(1)
3
sage: p(1) == p.value(1)
True
```
We can also find the position of the integer 3 in \( p \) considered as a sequence, equivalent to finding \( p^{-1}(3) \):

```python
sage: p.position(3)
1
sage: (p^-1)(3)
1
```

Since the affine permutation group is a group, we demonstrate its group properties:

```python
sage: A.one()
Type A affine permutation with window [1, 2, 3, 4, 5, 6, 7, 8]
sage: q = A([0, 2, 3, 4, 5, 6, 7, 9])
sage: p * q
Type A affine permutation with window [1, -1, 0, 6, 5, 4, 10, 11]
sage: q * p
Type A affine permutation with window [3, -1, 1, 6, 5, 4, 10, 8]
sage: p^-1
Type A affine permutation with window [0, -1, 1, 6, 5, 4, 10, 11]
sage: p^-1 * p == A.one()
True
sage: p * p^-1 == A.one()
True
```

If we decide we prefer the Weyl Group implementation of the affine Weyl group, we can easily get it:

```python
sage: p.to_weyl_group_element()
[ 0 -1  0  1  0  0  1  0]
```
We can find a reduced word and do all of the other things one expects in a Coxeter group:

```
sage: p.has_right_descent(1)
True
sage: p.apply_simple_reflection(1)
Type A affine permutation with window [-1, 3, 0, 6, 5, 4, 10, 9]
sage: p.apply_simple_reflection(0)
Type A affine permutation with window [1, -1, 0, 6, 5, 4, 10, 11]
sage: p.reduced_word()
[0, 7, 4, 1, 0, 7, 5, 4, 2, 1]
sage: p.length()
10
```

The following methods are particular to type $A$. We can check if the element is fully commutative:

```
sage: p.is_fully_commutative()
False
sage: q.is_fully_commutative()
True
```

```
We can also compute the affine Lehmer code of the permutation, a weak composition with \( k + 1 \) entries:

```python
sage: p.to_lehmer_code()
[0, 3, 3, 0, 1, 2, 0, 1]
```

Once we have the Lehmer code, we can obtain a \( k \)-bounded partition by sorting the Lehmer code, and then reading the row lengths. There is a unique 0-Grassmanian (dominant) affine permutation associated to this \( k \)-bounded partition, and a \( k \)-core as well.

```python
sage: p.to_bounded_partition()
[5, 3, 2]
sage: p.to_dominant()
Type A affine permutation with window [-2, -1, 1, 3, 4, 8, 10, 13]
sage: p.to_core()
[5, 3, 2]
```

Finally, we can take a reduced word for \( p \) and insert it to find a standard composition tableau associated uniquely to that word:

```python
sage: p.tableau_of_word(p.reduced_word())
[]
```

We can also form affine permutation groups in types \( B, C, D, \) and \( G \):

```python
sage: B = AffinePermutationGroup(['B',4,1])
sage: B.an_element()
Type B affine permutation with window [-1, 3, 4, 11]
sage: C = AffinePermutationGroup(['C',4,1])
sage: C.an_element()
Type C affine permutation with window [2, 3, 4, 10]
sage: D = AffinePermutationGroup(['D',4,1])
sage: D.an_element()
Type D affine permutation with window [-1, 3, 11, 5]
sage: G = AffinePermutationGroup(['G',2,1])
sage: G.an_element()
Type G affine permutation with window [0, 4, -1, 8, 3, 7]
```
```python
>>> from sage.all import *
>>> B = AffinePermutationGroup(['B',Integer(4),Integer(1)])
>>> B.an_element()
Type B affine permutation with window [-1, 3, 4, 11]

>>> C = AffinePermutationGroup(['C',Integer(4),Integer(1)])
>>> C.an_element()
Type C affine permutation with window [2, 3, 4, 10]

>>> D = AffinePermutationGroup(['D',Integer(4),Integer(1)])
>>> D.an_element()
Type D affine permutation with window [-1, 3, 11, 5]

>>> G = AffinePermutationGroup(['G',Integer(2),Integer(1)])
>>> G.an_element()
Type G affine permutation with window [0, 4, -1, 8, 3, 7]
```

class **sage.combinat.affine_permutation.AffinePermutationGroupGeneric**(*cartan_type*)

**Bases:** *UniqueRepresentation, Parent*

The generic affine permutation group class, in which we define all type-free methods for the specific affine permutation groups.

**cartan_matrix()**

Returns the Cartan matrix of self.

**EXAMPLES:**

```
sage: AffinePermutationGroup(['A',7,1]).cartan_matrix()
[ 2 -1  0  0  0  0  0 -1]
[-1  2 -1  0  0  0  0  0]
[ 0 -1  2 -1  0  0  0  0]
[ 0  0 -1  2 -1  0  0  0]
[ 0  0  0 -1  2 -1  0  0]
[ 0  0  0  0 -1  2 -1  0]
[-1  0  0  0  0  0 -1  2]
```

```python
>>> from sage.all import *
>>> AffinePermutationGroup(['A',Integer(7),Integer(1)]).cartan_matrix()
[ 2 -1  0  0  0  0  0 -1]
[-1  2 -1  0  0  0  0  0]
[ 0 -1  2 -1  0  0  0  0]
[ 0  0 -1  2 -1  0  0  0]
[ 0  0  0 -1  2 -1  0  0]
[ 0  0  0  0 -1  2 -1  0]
[-1  0  0  0  0  0 -1  2]
```

cartan_type()  

Returns the Cartan type of self.

**EXAMPLES:**

```
sage: AffinePermutationGroup(['A',7,1]).cartan_type()
['A', 7, 1]
```

```python
>>> from sage.all import *
>>> AffinePermutationGroup(['A',Integer(7),Integer(1)]).cartan_type()
['A', 7, 1]
```
```python
>>> from sage.all import *
>>> AffinePermutationGroup(['A',Integer(7),Integer(1)]).cartan_type()
['A', 7, 1]
```

**classical()**

Returns the finite permutation group.

**EXAMPLES:**

```python
sage: A = AffinePermutationGroup(['A',7,1])  
sage: A.classical()  
Symmetric group of order 8! as a permutation group
```

```python
>>> from sage.all import *
>>> A = AffinePermutationGroup(['A',Integer(7),Integer(1)])
>>> A.classical()
Symmetric group of order 8! as a permutation group
```

**from_word**(w)

Builds an affine permutation from a given word. Note: Already in category as from_reduced_word, but this is less typing!

**EXAMPLES:**

```python
sage: A = AffinePermutationGroup(['A',7,1])
```

```python
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
```

```python
sage: A.from_word([0, 7, 4, 1, 0, 7, 5, 4, 2, 1])
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9]
```

```python
>>> from sage.all import *
>>> A = AffinePermutationGroup(['A',Integer(7),Integer(1)])
>>> p=A([Integer(3), -Integer(1), Integer(0), Integer(6), Integer(5), ˓→Integer(4), Integer(10), Integer(9)])
```

```python
>>> A.from_word([Integer(0), Integer(7), Integer(4), Integer(1), Integer(0), ˓→Integer(7), Integer(5), Integer(4), Integer(2), Integer(1)])
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9]
```

**index_set()**

**EXAMPLES:**

```python
sage: AffinePermutationGroup(['A',7,1]).index_set()
(0, 1, 2, 3, 4, 5, 6, 7)
```

```python
>>> from sage.all import *
>>> AffinePermutationGroup(['A',7,1]).index_set()
(0, 1, 2, 3, 4, 5, 6, 7)
```

**is_crystallographic()**

Tells whether the affine permutation group is crystallographic.

**EXAMPLES:**

```python
sage: AffinePermutationGroup(['A',7,1]).is_crystallographic()
True
```
```python
>>> from sage.all import *
>>> AffinePermutationGroup(['A',Integer(7),Integer(1)]).is_crystallographic()
True
```

**random_element** *(n=None)*

Return a random affine permutation of length \( n \).

If \( n \) is not specified, then \( n \) is chosen as a random non-negative integer in \([0, 1000]\).

Starts at the identity, then chooses an upper cover at random. Not very uniform: actually constructs a uniformly random reduced word of length \( n \). Thus we most likely get elements with lots of reduced words!

For the actual code, see `sage.categories.coxeter_group.random_element_of_length()`.

**EXAMPLES:**

```python
sage: A = AffinePermutationGroup(['A',7,1])
sage: A.random_element()  # random
Type A affine permutation with window [-12, 16, 19, -1, -2, 10, -3, 9]
sage: p = A.random_element(10)
sage: p.length() == 10
True
```

```python
>>> from sage.all import *
>>> A = AffinePermutationGroup(['A',Integer(7),Integer(1)])
>>> A.random_element()  # random
Type A affine permutation with window [-12, 16, 19, -1, -2, 10, -3, 9]
>>> p = A.random_element(Integer(10))
>>> p.length() == Integer(10)
True
```

**rank()**

Rank of the affine permutation group, equal to \( k + 1 \).

**EXAMPLES:**

```python
sage: AffinePermutationGroup(['A',7,1]).rank()
8
```

```python
>>> from sage.all import *
>>> AffinePermutationGroup(['A',7,1]).rank()
8
```

**reflection_index_set()**

**EXAMPLES:**

```python
sage: AffinePermutationGroup(['A',7,1]).reflection_index_set()
(0, 1, 2, 3, 4, 5, 6, 7)
```

```python
>>> from sage.all import *
>>> AffinePermutationGroup(['A',7,1]).reflection_index_set()
(0, 1, 2, 3, 4, 5, 6, 7)
```

**weyl_group()**

Returns the Weyl Group of the same type as `self`.

**EXAMPLES:**

```python
```
sage: A = AffinePermutationGroup(['A',7,1])
sage: A.weyl_group()
Weyl Group of type ['A', 7, 1] (as a matrix group acting on the root space)

>>> from sage.all import *
>>> A = AffinePermutationGroup(['A',Integer(7),Integer(1)])
>>> A.weyl_group()
Weyl Group of type ['A', 7, 1] (as a matrix group acting on the root space)

class sage.combinat.affine_permutation.AffinePermutationGroupTypeA(cartan_type)
    Bases: AffinePermutationGroupGeneric

Element
    alias of AffinePermutationGroupTypeA
    
    from_lehmer_code(C, typ='decreasing', side='right')
    
    Return the affine permutation with the supplied Lehmer code (a weak composition with \( k + 1 \) parts, at least one of which is 0).

    INPUT:
    
    - typ -- 'increasing' or 'decreasing' (default: 'decreasing'); type of product
    - side -- 'right' or 'left' (default: 'right'); whether the decomposition is from the right or left

    EXAMPLES:

sage: import itertools
sage: A = AffinePermutationGroup(['A',7,1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.to_lehmer_code()
[0, 3, 3, 0, 1, 2, 0, 1]
sage: A.from_lehmer_code(p.to_lehmer_code()) == p
True
sage: orders = ('increasing','decreasing')
sage: sides = ('left','right')
sage: all(A.from_lehmer_code(p.to_lehmer_code(o,s),o,s) == p
....: for o,s in itertools.product(orders,sides))
True

one()
    Return the identity element.
EXAMPLES:

```python
sage: AffinePermutationGroup(['A',7,1]).one()
Type A affine permutation with window [1, 2, 3, 4, 5, 6, 7, 8]
```

```python
>>> from sage.all import *
>>> AffinePermutationGroup(['A',Integer(7),Integer(1)]).one()
Type A affine permutation with window [1, 2, 3, 4, 5, 6, 7, 8]
```

class sage.combinat.affine_permutation.AffinePermutationGroupTypeB(cartan_type)

Bases: AffinePermutationGroupTypeC

Element

alias of AffinePermutationTypeB

class sage.combinat.affine_permutation.AffinePermutationGroupTypeC(cartan_type)

Bases: AffinePermutationGroupGeneric

Element

alias of AffinePermutationTypeC

one()

Return the identity element.

EXAMPLES:

```python
sage: ct=CartanType(['C',4,1])
sage: C = AffinePermutationGroup(ct)
sage: C.one()
Type C affine permutation with window [1, 2, 3, 4]
sage: C.one()*C.one()==C.one()
True
```

```python
>>> from sage.all import *
>>> ct=CartanType(['C',Integer(4),Integer(1)])
>>> C = AffinePermutationGroup(ct)
>>> C.one()
Type C affine permutation with window [1, 2, 3, 4]
>>> C.one()*C.one()==C.one()
True
```

class sage.combinat.affine_permutation.AffinePermutationGroupTypeD(cartan_type)

Bases: AffinePermutationGroupTypeC

Element

alias of AffinePermutationTypeD

class sage.combinat.affine_permutation.AffinePermutationGroupTypeG(cartan_type)

Bases: AffinePermutationGroupGeneric

Element

alias of AffinePermutationTypeG

one()

Return the identity element.

EXAMPLES:
```python
sage: AffinePermutationGroup(['G',2,1]).one()
Type G affine permutation with window [1, 2, 3, 4, 5, 6]
```

```python
>>> from sage.all import *
>>> AffinePermutationGroup(['G',Integer(2),Integer(1)]).one()
Type G affine permutation with window [1, 2, 3, 4, 5, 6]
```

class sage.combinat.affine_permutation.AffinePermutationTypeA (parent, lst, check=True)

Bases: AffinePermutation

apply_simple_reflection_left(i)
Apply the simple reflection to the values \(i, i + 1\).

EXAMPLES:

```python
sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.apply_simple_reflection_left(3)
Type A affine permutation with window [4, -1, 0, 6, 5, 3, 10, 9]
sage: p.apply_simple_reflection_left(11)
Type A affine permutation with window [4, -1, 0, 6, 5, 3, 10, 9]
```

apply_simple_reflection_right(i)
Apply the simple reflection to positions \(i, i + 1\).

INPUT:

- i – an integer

EXAMPLES:

```python
sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.apply_simple_reflection_right(3)
Type A affine permutation with window [3, -1, 6, 0, 5, 4, 10, 9]
sage: p.apply_simple_reflection_right(11)
Type A affine permutation with window [3, -1, 6, 0, 5, 4, 10, 9]
```

check()
Check that `self` is an affine permutation.

EXAMPLES:
sage: A = AffinePermutationGroup(['A',7,1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9]
sage: q = A([1,2,3]) # indirect doctest
Traceback (most recent call last):
... ValueError: length of list must be k+1=8
sage: q = A([1,2,3,4,5,6,7,0]) # indirect doctest
Traceback (most recent call last):
... ValueError: window does not sum to 36
sage: q = A([1,1,3,4,5,6,7,9]) # indirect doctest
Traceback (most recent call last):
... ValueError: entries must have distinct residues

>>> from sage.all import *
>>> A = AffinePermutationGroup(['A',Integer(7),Integer(1)])
>>> p = A([Integer(3), -Integer(1), Integer(0), Integer(6), Integer(5),
    Integer(4), Integer(10), Integer(9)])
>>> p
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9]
>>> q = A([Integer(1),Integer(2),Integer(3)]) # indirect doctest
Traceback (most recent call last):
... ValueError: length of list must be k+1=8
>>> q = A([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),Integer(6),
    Integer(7),Integer(0)]) # indirect doctest
Traceback (most recent call last):
... ValueError: window does not sum to 36
>>> q = A([Integer(1),Integer(1),Integer(3),Integer(4),Integer(5),Integer(6),
    Integer(7),Integer(9)]) # indirect doctest
Traceback (most recent call last):
... ValueError: entries must have distinct residues

flip_automorphism()

The Dynkin diagram automorphism which fixes $s_0$ and reverses all other indices.

EXAMPLES:

sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.flip_automorphism()
Type A affine permutation with window [0, -1, 5, 4, 3, 9, 10, 6]

>>> from sage.all import *
>>> A = AffinePermutationGroup(['A',Integer(7),Integer(1)])
>>> p=A([Integer(3), -Integer(1), Integer(0), Integer(6), Integer(5),
    Integer(4), Integer(10), Integer(9)])
>>> p.flip_automorphism()
Type A affine permutation with window [0, -1, 5, 4, 3, 9, 10, 6]

has_left_descent(i)

Determine whether there is a descent at $i$.  

46 Chapter 5. Comprehensive Module List
INPUT:

• \( i \) – an integer

EXAMPLES:

```python
sage: p = AffinePermutationGroup([A,7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.has_left_descent(1)
True
sage: p.has_left_descent(9)
True
sage: p.has_left_descent(0)
True
```

```python
>>> from sage.all import *
>>> p = AffinePermutationGroup(['A',Integer(7),Integer(1)])([Integer(3), Integer(-1), Integer(1), Integer(0), Integer(6), Integer(5), Integer(4), Integer(10), Integer(9)])
>>> p.has_left_descent(Integer(1))
True
>>> p.has_left_descent(Integer(9))
True
>>> p.has_left_descent(Integer(0))
True
```

\( \text{has_right_descent}(i) \)

Determine whether there is a descent at \( i \).

INPUT:

• \( i \) – an integer

EXAMPLES:

```python
sage: p = AffinePermutationGroup([A,7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.has_right_descent(1)
True
sage: p.has_right_descent(9)
True
sage: p.has_right_descent(0)
False
```

```python
>>> from sage.all import *
>>> p = AffinePermutationGroup(['A',Integer(7),Integer(1)])([Integer(3), Integer(-1), Integer(1), Integer(0), Integer(6), Integer(5), Integer(4), Integer(10), Integer(9)])
>>> p.has_right_descent(Integer(1))
True
>>> p.has_right_descent(Integer(9))
True
>>> p.has_right_descent(Integer(0))
False
```

\( \text{is_fully_commutative}() \)

Determine whether \( \text{self} \) is fully commutative.

This means that it has no reduced word with a braid.

This uses a specific algorithm.
EXAMPLES:

```python
sage: A = AffinePermutationGroup(['A',7,1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.is_fully_commutative()
False
sage: q = A([-3, -2, 0, 7, 9, 2, 11, 12])
sage: q.is_fully_commutative()
True
```

```python
>>> from sage.all import *
>>> A = AffinePermutationGroup(['A',Integer(7),Integer(1)])
>>> p = A([Integer(3), -Integer(1), Integer(0), Integer(6), Integer(5),
˓→Integer(4), Integer(10), Integer(9)])
>>> p.is_fully_commutative()
False
>>> q = A([-Integer(3), -Integer(2), Integer(0), Integer(7), Integer(9),
˓→Integer(2), Integer(11), Integer(12)])
>>> q.is_fully_commutative()
True
```

**maximal_cyclic_decomposition** *(typ='decreasing', side='right', verbose=False)*

Find the unique maximal decomposition of self into cyclically decreasing/increasing elements.

**INPUT:**

- **typ** - 'increasing' or 'decreasing' *(default: 'decreasing'); chooses whether to find increasing or decreasing sets*
- **side** - 'right' or 'left' *(default: 'right') chooses whether to find maximal sets starting from the left or the right*
- **verbose** - *(default: False)* print extra information while finding the decomposition

**EXAMPLES:**

```python
sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.maximal_cyclic_decomposition()
[[0, 7], [4, 1, 0], [7, 5, 4, 2, 1]]
sage: p.maximal_cyclic_decomposition(side=left)
[[1, 0, 7, 5, 4], [1, 0, 5], [2, 1]]
sage: p.maximal_cyclic_decomposition(typ=increasing, side=right)
[[1], [5, 0, 1, 2], [4, 5, 7, 0, 1]]
sage: p.maximal_cyclic_decomposition(typ=increasing, side=left)
[[0, 1, 2, 4, 5], [4, 7, 0, 1], [7]]
```

```python
>>> from sage.all import *
>>> p = AffinePermutationGroup(['A',Integer(7),Integer(1)])([Integer(3),-
˓→Integer(1), Integer(0), Integer(6), Integer(5),
˓→Integer(4), Integer(10), Integer(9)])
>>> p.maximal_cyclic_decomposition()
[[0, 7], [4, 1, 0], [7, 5, 4, 2, 1]]
>>> p.maximal_cyclic_decomposition(side=left)
[[1, 0, 7, 5, 4], [1, 0, 5], [2, 1]]
>>> p.maximal_cyclic_decomposition(typ=increasing, side=right)
[[1], [5, 0, 1, 2], [4, 5, 7, 0, 1]]
>>> p.maximal_cyclic_decomposition(typ=increasing, side=left)
[[0, 1, 2, 4, 5], [4, 7, 0, 1], [7]]
```
maximal_cyclic_factor (typ='decreasing', side='right', verbose=False)

For an affine permutation \( x \), find the unique maximal subset \( A \) of the index set such that \( x = yd_A \) is a reduced product.

INPUT:

- typ - 'increasing' or 'decreasing' (default: 'decreasing'); chooses whether to find increasing or decreasing sets
- side - 'right' or 'left' (default: 'right') chooses whether to find maximal sets starting from the left or the right
- verbose – True or False. If True, outputs information about how the cyclically increasing element was found.

EXAMPLES:

```sage
sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.maximal_cyclic_factor()
[7, 5, 4, 2, 1]
sage: p.maximal_cyclic_factor(side='left')
[1, 0, 7, 5, 4]
sage: p.maximal_cyclic_factor('increasing','right')
[4, 5, 7, 0, 1]
sage: p.maximal_cyclic_factor('increasing','left')
[0, 1, 2, 4, 5]
```

position (i)

Find the position \( j \) such that \( \text{self.value}(j) == i \).

EXAMPLES:

```sage
sage: A = AffinePermutationGroup(['A',7,1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.position(3)
1
sage: p.position(11)
9
```

```python
>>> from sage.all import *

>>> A = AffinePermutationGroup(['A',Integer(7),Integer(1)])
>>> p = A([Integer(3), -Integer(1), Integer(0), Integer(6), Integer(5), Integer(4), Integer(10), Integer(9)])
$$p . \text{position}(\text{Integer}(3))
1$$
```
The Dynkin diagram automorphism which sends $s_i$ to $s_i + 1$.

EXAMPLES:

```python
sage: A = AffinePermutationGroup(['A',7,1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.promotion()
Type A affine permutation with window [2, 4, 0, 1, 7, 6, 5, 11]
```

```python
from sage.all import *
A = AffinePermutationGroup(['A',Integer(7),Integer(1)])
p = A([Integer(3), -Integer(1), Integer(0), Integer(6), Integer(5), Integer(4), Integer(10), Integer(9)])
p.promotion()
Type A affine permutation with window [2, 4, 0, 1, 7, 6, 5, 11]
```

tableau_of_word (w, typ='decreasing', side='right', alpha=None)

Finds a tableau on the Lehmer code of self corresponding to the given reduced word.

For a full description of this algorithm, see [Den2012].

INPUT:

- $w$ – a reduced word for self
- typ = 'increasing' or 'decreasing'; the type of Lehmer code used
- side = 'right' or 'left'
- alpha – a content vector; $w$ should be of type alpha; specifying alpha produces semistandard tableaux

EXAMPLES:

```python
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.tableau_of_word(p.reduced_word())
[[], [1, 6, 9], [2, 7, 10], [], [3], [4, 8], [], [5]]
```

```python
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: w=p.reduced_word()
sage: w
[0, 7, 4, 1, 0, 7, 5, 4, 2, 1]
sage: alpha=[5,3,2]
sage: p.tableau_of_word(p.reduced_word(), alpha=alpha)
[[], [1, 2, 3], [1, 2, 3], [], [1], [1, 2], [], [1]]
sage: p.tableau_of_word(p.reduced_word(), side='left')
[[1, 4, 9], [6], [3, 7], [8], [], [2, 5, 10]]
```

```python
sage: p.tableau_of_word(p.reduced_word(), typ='increasing', side='right')
[[9, 10], [1, 2], [], [], [3, 4], [8], [], [5, 6, 7]]
```

```python
sage: p.tableau_of_word(p.reduced_word(), typ='increasing', side='left')
[[4, 2], [4, 5, 6], [9, 10], [], [3], [7, 8], [], []]
```
```python
>>> from sage.all import *
>>> A = AffinePermutationGroup(['A',Integer(7),Integer(1)])
>>> p=A([Integer(3), -Integer(1), Integer(0), Integer(6), Integer(5), Integer(4), Integer(10), Integer(9)])
>>> p.tableau_of_word(p.reduced_word())
[[], [1, 6, 9], [2, 7, 10], [], [3], [4, 8], [], [5]]
```

```python
>>> A = AffinePermutationGroup(['A',Integer(7),Integer(1)])
>>> p=A([Integer(3), -Integer(1), Integer(0), Integer(6), Integer(5), Integer(4), Integer(10), Integer(9)])
>>> w=p.reduced_word()
>>> w
[0, 7, 4, 1, 0, 7, 5, 4, 2, 1]
```

```python
>>> alpha=[Integer(5),Integer(3),Integer(2)]
>>> p.tableau_of_word(p.reduced_word(), alpha=alpha)
[[], [1, 2, 3], [1, 2, 3], [], [1], [1], [1, 2], [], [1]]
```

```python
>>> p.tableau_of_word(p.reduced_word(), side='left')
[[1, 4, 9], [6], [], [], [3, 7], [8], [], [2, 5, 10]]
```

```python
>>> p.tableau_of_word(p.reduced_word(), typ='increasing', side='right')
[[9, 10], [1, 2], [], [], [3,!4], [8], [], [5, 6, 7]]
```

```python
>>> p.tableau_of_word(p.reduced_word(), typ='increasing', side='left')
[[1, 2], [4, 5, 6], [9, 10], [], [3], [7, 8], [], [2, 5, 10]]
```

```python
>>> to_bounded_partition(typ='decreasing', side='right')
```

Return the $k$-bounded partition associated to the dominant element obtained by sorting the Lehmer code.

**INPUT:**

- **typ** - 'increasing' or 'decreasing' (default: 'decreasing'.) Chooses whether to find increasing or decreasing sets.
- **side** - 'right' or 'left' (default: 'right'.) Chooses whether to find maximal sets starting from the left or the right.

**EXAMPLES:**

```python
sage: A = AffinePermutationGroup(['A',2,1])
sage: p=A.from_lehmer_code([4,1,0])
sage: p.to_bounded_partition()
[2, 1, 1, 1]
```

```python
>>> to_core(typ='decreasing', side='right')
```

Returns the core associated to the dominant element obtained by sorting the Lehmer code.

**INPUT:**

- **typ** - 'increasing' or 'decreasing' (default: 'decreasing'.)
- **side** - 'right' or 'left' (default: 'right'.) Chooses whether to find maximal sets starting from the left or the right.

**EXAMPLES:**

```python
sage: A = AffinePermutationGroup(['A',2,1])
sage: p=A.from_lehmer_code([4,1,0])
sage: p.to_bounded_partition()
[2, 1, 1, 1]
```
sage: A = AffinePermutationGroup([A,2,1])

sage: p=A.from_lehmer_code([4,1,0])

sage: p.to_bounded_partition()
[2, 1, 1, 1]

sage: p.to_core()
[4, 2, 1, 1]

>>> from sage.all import *

>>> A = AffinePermutationGroup([A,Integer(2),Integer(1)])

>>> p=A.from_lehmer_code([Integer(4),Integer(1),Integer(0)])

>>> p.to_bounded_partition()
[2, 1, 1, 1]

>>> p.to_core()
[4, 2, 1, 1]

to_dominant (typ='decreasing', side='right')

Finds the Lehmer code and then sorts it. Returns the affine permutation with the given sorted Lehmer code; this element is 0-dominant.

INPUT:

• typ = 'increasing' or 'decreasing' (default: 'decreasing') chooses whether to find increasing or decreasing sets

• side = 'right' or 'left' (default: 'right') chooses whether to find maximal sets starting from the left or the right

EXAMPLES:

sage: A = AffinePermutationGroup([A,7,1])

sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])

sage: p.to_dominant()
Type A affine permutation with window [-2, -1, 1, 3, 4, 8, 10, 13]

sage: p.to_dominant(typ=increasing, side=left)
Type A affine permutation with window [3, 4, -1, 5, 0, 9, 6, 10]

>>> from sage.all import *

>>> A = AffinePermutationGroup([A,Integer(7),Integer(1)])

>>> p=A([Integer(3), -Integer(1), Integer(0), Integer(6), Integer(5), Integer(4), Integer(10), Integer(9)])

>>> p.to_dominant()
Type A affine permutation with window [-2, -1, 1, 3, 4, 8, 10, 13]

>>> p.to_dominant(typ=increasing, side=left)
Type A affine permutation with window [3, 4, -1, 5, 0, 9, 6, 10]

to_lehmer_code (typ='decreasing', side='right')

Return the affine Lehmer code.

There are four such codes; the options typ and side determine which code is generated. The codes generated are the shape of the maximal cyclic decompositions of self according to the given typ and side options.

INPUT:

• typ = 'increasing' or 'decreasing' (default: 'decreasing'); chooses whether to find increasing or decreasing sets

• side = 'right' or 'left' (default: 'right') chooses whether to find maximal sets starting from the left or the right
EXAMPLES:

```python
sage: import itertools
sage: A = AffinePermutationGroup(['A',7,1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: orders = ('increasing', 'decreasing')
sage: sides = ('left', 'right')
sage: for o, s in itertools.product(orders, sides):
    p.to_lehmer_code(o, s)
[2, 3, 2, 0, 1, 2, 0, 0]
[2, 2, 0, 0, 2, 1, 0, 3]
[3, 1, 0, 0, 2, 1, 0, 3]
[0, 3, 3, 0, 1, 2, 0, 1]
sage: for a in itertools.product(orders, sides):
    A.from_lehmer_code(p.to_lehmer_code(a[0], a[1]), a[0], a[1]) == p
True
True
True
True
```

```python
>>> from sage.all import *
>>> import itertools

>>> A = AffinePermutationGroup(['A', Integer(7), Integer(1)])
>>> p = A([Integer(3), -Integer(1), Integer(0), Integer(6), Integer(5), ...
        -> Integer(4), Integer(10), Integer(9)])
>>> orders = ('increasing', 'decreasing')
>>> sides = ('left', 'right')
>>> for o, s in itertools.product(orders, sides):
...     p.to_lehmer_code(o, s)
[2, 3, 2, 0, 1, 2, 0, 0]
[2, 2, 0, 0, 2, 1, 0, 3]
[3, 1, 0, 0, 2, 1, 0, 3]
[0, 3, 3, 0, 1, 2, 0, 1]
>>> for a in itertools.product(orders, sides):
...     A.from_lehmer_code(p.to_lehmer_code(a[Integer(0)], a[Integer(1)]), ...
        -> a[Integer(0)], a[Integer(1)]) == p
True
True
True
True
```

**to_type_a()**

Return an embedding of `self` into the affine permutation group of type $A$. (For type $A$, just returns `self`.)

EXAMPLES:

```python
sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.to_type_a() is p
True
```

```python
>>> from sage.all import *

>>> p = AffinePermutationGroup(['A', Integer(7), Integer(1)])([Integer(3), ...
        -> Integer(1), Integer(0), Integer(6), Integer(5), Integer(4), Integer(10),...
        -> Integer(9)])
>>> p.to_type_a() is p
True
```

**value** ($i$, `base_window=False`)
Return the image of the integer $i$ under this permutation.

**INPUT:**

- `base_window` – boolean; indicating whether $i$ is in the base window; if True, will run a bit faster, but the method will screw up if $i$ is not actually in the index set

**EXAMPLES:**

```python
sage: A = AffinePermutationGroup(['A',7,1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.value(1)
3
sage: p.value(9)
11
```

```python
>>> from sage.all import *

>>> A = AffinePermutationGroup(['A',Integer(7),Integer(1)])
>>> p = A([Integer(3), -Integer(1), Integer(0), Integer(6), Integer(5), Integer(4), Integer(10), Integer(9)])
>>> p.value(Integer(1))
3
>>> p.value(Integer(9))
11
```

```mermaid
class sage.combinat.affine_permutation.AffinePermutationTypeB
   Bases: AffinePermutationTypeC

apply_simple_reflection_left($i$)
   Apply the simple reflection indexed by $i$ on values.

**EXAMPLES:**

```python
sage: B = AffinePermutationGroup(['B',4,1])
sage: p=B([-5,1,6,-2])
sage: p.apply_simple_reflection_left(0)
Type B affine permutation with window [-5, -2, 6, 1]
sage: p.apply_simple_reflection_left(2)
Type B affine permutation with window [-5, 1, 7, -3]
sage: p.apply_simple_reflection_left(4)
Type B affine permutation with window [-4, 1, 6, -2]
```

```python
>>> from sage.all import *

>>> B = AffinePermutationGroup(['B',Integer(4),Integer(1)])
>>> p=B([-Integer(5),Integer(1),Integer(6),-Integer(2)])
>>> p.apply_simple_reflection_left(Integer(0))
Type B affine permutation with window [-5, -2, 6, 1]
>>> p.apply_simple_reflection_left(Integer(2))
Type B affine permutation with window [-5, 1, 7, -3]
>>> p.apply_simple_reflection_left(Integer(4))
Type B affine permutation with window [-4, 1, 6, -2]
```

apply_simple_reflection_right($i$)
   Apply the simple reflection indexed by $i$ on positions.

**EXAMPLES:**
sage: B = AffinePermutationGroup(['B',4,1])
sage: p=B([-5,1,6,-2])
sage: p.apply_simple_reflection_right(1)
Type B affine permutation with window [1, -5, 6, -2]
sage: p.apply_simple_reflection_right(0)
Type B affine permutation with window [-1, 5, 6, -2]
sage: p.apply_simple_reflection_right(4)
Type B affine permutation with window [-5, 1, 6, 11]

>>> from sage.all import *

>>> B = AffinePermutationGroup(['B',Integer(4),Integer(1)])
>>> p=B([-Integer(5),Integer(1),Integer(6),-Integer(2)])
>>> p.apply_simple_reflection_right(Integer(1))
Type B affine permutation with window [1, -5, 6, -2]
>>> p.apply_simple_reflection_right(Integer(0))
Type B affine permutation with window [-1, 5, 6, -2]
>>> p.apply_simple_reflection_right(Integer(4))
Type B affine permutation with window [-5, 1, 6, 11]

check()

Check that self is an affine permutation.

EXAMPLES:

sage: B = AffinePermutationGroup(['B',4,1])
sage: x = B([-5,1,6,-2])
sage: x
Type B affine permutation with window [-5, 1, 6, -2]

>>> from sage.all import *

>>> B = AffinePermutationGroup(['B',Integer(4),Integer(1)])

>>> x = B([-Integer(5),Integer(1),Integer(6),-Integer(2)])

>>> x
Type B affine permutation with window [-5, 1, 6, -2]

has_left_descent(i)

Determines whether there is a descent at i.

INPUT:

• i – an integer

EXAMPLES:

sage: B = AffinePermutationGroup(['B',4,1])
sage: p=B([-5,1,6,-2])
sage: [p.has_left_descent(i) for i in B.index_set()]
[True, True, False, False, True]

>>> from sage.all import *

>>> B = AffinePermutationGroup(['B',Integer(4),Integer(1)])

>>> p=B([-Integer(5),Integer(1),Integer(6),-Integer(2)])

>>> [p.has_left_descent(i) for i in B.index_set()]
[True, True, False, False, True]

has_right_descent(i)

Determines whether there is a descent at index i.
INPUT:
  • \(i\) – an integer

EXAMPLES:

```python
sage: B = AffinePermutationGroup(['B',4,1])
sage: p = B([-5,1,6,-2])
sage: [p.has_right_descent(i) for i in B.index_set()]
[True, False, False, True, False]
```

```python
>>> from sage.all import *
>>> B = AffinePermutationGroup(['B',Integer(4),Integer(1)])
>>> p = B([-Integer(5),Integer(1),Integer(6),-Integer(2)])
>>> [p.has_right_descent(i) for i in B.index_set()]
[True, False, False, True, False]
```

class sage.combinat.affine_permutation.AffinePermutationTypeC (parent, lst, check=True)

Bases: AffinePermutation

apply_simple_reflection_left\( (i)\)

Apply the simple reflection indexed by \(i\) on values.

EXAMPLES:

```python
sage: C = AffinePermutationGroup(['C',4,1])
sage: x = C([-1,5,3,7])
sage: for i in C.index_set(): x.apply_simple_reflection_left(i)
Type C affine permutation with window [1, 5, 3, 7]
Type C affine permutation with window [-2, 5, 3, 8]
Type C affine permutation with window [-1, 5, 2, 6]
Type C affine permutation with window [-1, 6, 4, 7]
Type C affine permutation with window [-1, 4, 3, 7]
```

```python
>>> from sage.all import *
>>> C = AffinePermutationGroup(['C',Integer(4),Integer(1)])
>>> x = C([-Integer(1),Integer(5),Integer(3),Integer(7)])
>>> for i in C.index_set(): x.apply_simple_reflection_left(i)
Type C affine permutation with window [1, 5, 3, 7]
Type C affine permutation with window [-2, 5, 3, 8]
Type C affine permutation with window [-1, 5, 2, 6]
Type C affine permutation with window [-1, 6, 4, 7]
Type C affine permutation with window [-1, 4, 3, 7]
```

apply_simple_reflection_right\( (i)\)

Apply the simple reflection indexed by \(i\) on positions.

EXAMPLES:

```python
sage: C = AffinePermutationGroup(['C',4,1])
sage: x = C([-1,5,3,7])
sage: for i in C.index_set(): x.apply_simple_reflection_right(i)
Type C affine permutation with window [1, 5, 3, 7]
Type C affine permutation with window [-2, 5, 3, 8]
Type C affine permutation with window [-1, 5, 2, 6]
Type C affine permutation with window [-1, 6, 4, 7]
Type C affine permutation with window [-1, 4, 3, 7]
```

```python
>>> from sage.all import *
>>> C = AffinePermutationGroup(['C',Integer(4),Integer(1)])
>>> x = C([-Integer(1),Integer(5),Integer(3),Integer(7)])
>>> for i in C.index_set(): x.apply_simple_reflection_right(i)
Type C affine permutation with window [1, 5, 3, 7]
Type C affine permutation with window [5, -1, 3, 7]
Type C affine permutation with window [-1, 3, 5, 7]
Type C affine permutation with window [-1, 5, 7, 3]
Type C affine permutation with window [-1, 5, 3, 2]
```
>>> from sage.all import *

>>> C = AffinePermutationGroup(['C', Integer(4), Integer(1)])

>>> x = C([-Integer(1), Integer(5), Integer(3), Integer(7)])

>>> for i in C.index_set(): x.apply_simple_reflection_right(i)

Type C affine permutation with window [1, 5, 3, 7]
Type C affine permutation with window [5, -1, 3, 7]
Type C affine permutation with window [-1, 3, 5, 7]
Type C affine permutation with window [-1, 5, 7, 3]
Type C affine permutation with window [-1, 5, 3, 2]

check()

Check that self is an affine permutation.

EXAMPLES:

sage: C = AffinePermutationGroup(['C', 4, 1])
sage: x = C([-1, 5, 3, 7])
sage: x
Type C affine permutation with window [-1, 5, 3, 7]

>>> from sage.all import *

>>> C = AffinePermutationGroup(['C', Integer(4), Integer(1)])

>>> x = C([-Integer(1), Integer(5), Integer(3), Integer(7)])

>>> x
Type C affine permutation with window [-1, 5, 3, 7]

has_left_descent(i)

Determine whether there is a descent at i.

INPUT:

• i -- an integer

EXAMPLES:

sage: C = AffinePermutationGroup(['C', 4, 1])
sage: x = C([-1, 5, 3, 7])
sage: for i in C.index_set(): x.has_left_descent(i)
True
False
True
False

has_right_descent(i)

Determine whether there is a descent at index i.

INPUT:
• $i$ – an integer

EXAMPLES:

```sage
sage: C = AffinePermutationGroup(['C',4,1])
sage: x = C([-1,5,3,7])
sage: for i in C.index_set(): x.has_right_descent(i)
True
False
True
False
True
```

```python
>>> from sage.all import *
>>> C = AffinePermutationGroup(['C',Integer(4),Integer(1)])
>>> x = C([-Integer(1),Integer(5),Integer(3),Integer(7)])
>>> for i in C.index_set(): x.has_right_descent(i)
True
False
True
False
```

`position(i)`

Find the position $j$ such that $\text{self.value}(j) = i$

EXAMPLES:

```sage
sage: C = AffinePermutationGroup(['C',4,1])
sage: x = C.one()
sage: [x.position(i) for i in range(-10,10)] == list(range(-10,10))
True
```

```python
>>> from sage.all import *
>>> C = AffinePermutationGroup(['C',Integer(4),Integer(1)])
>>> x = C.one()
>>> [x.position(i) for i in range(-Integer(10),Integer(10))] == list(range(-Integer(10),Integer(10)))
True
```

to_type_a()

Return an embedding of self into the affine permutation group of type $A$.

EXAMPLES:

```sage
sage: C = AffinePermutationGroup(['C',4,1])
sage: x = C([-1,5,3,7])
sage: x.to_type_a()
Type A affine permutation with window [-1, 5, 3, 7, 2, 6, 4, 10, 9]
```

```python
>>> from sage.all import *
>>> C = AffinePermutationGroup(['C',Integer(4),Integer(1)])
>>> x = C([-Integer(1),Integer(5),Integer(3),Integer(7)])
>>> x.to_type_a()
Type A affine permutation with window [-1, 5, 3, 7, 2, 6, 4, 10, 9]
```

`value(i)`

Return the image of the integer $i$ under this permutation.
EXAMPLES:

```python
sage: C = AffinePermutationGroup([C,4,1])
sage: x = C.one()
sage: [x.value(i) for i in range(-10,10)] == list(range(-10,10))
True
```

```python
>>> from sage.all import *
>>> C = AffinePermutationGroup([C,Integer(4),Integer(1)])
>>> x = C.one()
>>> [x.value(i) for i in range(-Integer(10),Integer(10))] == list(range(-Integer(10),Integer(10)))
True
```

```python
class sage.combinat.affine_permutation.AffinePermutationTypeD
    (parent, lst, check=True)
Bases: AffinePermutationTypeC

apply_simple_reflection_left(i)
Apply simple reflection indexed by i on values.

EXAMPLES:

```python
sage: D = AffinePermutationGroup([D,4,1])
sage: p=D([1,-6,5,-2])
sage: p.apply_simple_reflection_left(0)
Type D affine permutation with window [-2, -6, 5, 1]
sage: p.apply_simple_reflection_left(1)
Type D affine permutation with window [2, -6, 5, -1]
sage: p.apply_simple_reflection_left(4)
Type D affine permutation with window [1, -4, 3, -2]
```

```python
>>> from sage.all import *
>>> D = AffinePermutationGroup([D,Integer(4),Integer(1)])
>>> p=D([Integer(1),-Integer(6),Integer(5),-Integer(2)])
>>> p.apply_simple_reflection_left(Integer(0))
Type D affine permutation with window [-2, -6, 5, 1]
>>> p.apply_simple_reflection_left(Integer(1))
Type D affine permutation with window [2, -6, 5, -1]
>>> p.apply_simple_reflection_left(Integer(4))
Type D affine permutation with window [1, -4, 3, -2]
```

```python
apply_simple_reflection_right(i)
Apply the simple reflection indexed by i on positions.

EXAMPLES:

```python
sage: D = AffinePermutationGroup([D,4,1])
sage: p=D([1,-6,5,-2])
sage: p.apply_simple_reflection_right(0)
Type D affine permutation with window [6, -1, 5, -2]
sage: p.apply_simple_reflection_right(1)
Type D affine permutation with window [-6, 1, 5, -2]
sage: p.apply_simple_reflection_right(4)
Type D affine permutation with window [1, -6, 11, 4]
```

```python
>>> from sage.all import *
>>> D = AffinePermutationGroup([D,Integer(4),Integer(1)])
```

(continues on next page)
Combinatorics, Release 10.4

>>> p = D([Integer(1), -Integer(6), Integer(5), -Integer(2)])
>>> p.apply_simple_reflection_right(Integer(0))
Type D affine permutation with window [6, -1, 5, -2]

>>> p.apply_simple_reflection_right(Integer(1))
Type D affine permutation with window [-6, 1, 5, -2]

>>> p.apply_simple_reflection_right(Integer(4))
Type D affine permutation with window [1, -6, 11, 4]

check()

Check that self is an affine permutation.

EXAMPLES:

```sage
D = AffinePermutationGroup(['D', 4, 1])
p = D([1, -6, 5, -2])
p
```

```
Type D affine permutation with window [1, -6, 5, -2]
```

```sage
from sage.all import *

D = AffinePermutationGroup(['D', Integer(4), Integer(1)])
p = D([Integer(1), -Integer(6), Integer(5), -Integer(2)])
p
```

```
Type D affine permutation with window [1, -6, 5, -2]
```

has_left_descent(i)

Determine whether there is a descent at i.

INPUT:

- i – an integer

EXAMPLES:

```sage
D = AffinePermutationGroup(['D', 4, 1])
p = D([1, -6, 5, -2])
[p.has_left_descent(i) for i in D.index_set()]
```

```
[True, True, False, True, True]
```

```sage
from sage.all import *

D = AffinePermutationGroup(['D', Integer(4), Integer(1)])
p = D([Integer(1), -Integer(6), Integer(5), -Integer(2)])
[p.has_left_descent(i) for i in D.index_set()]
```

```
[True, True, False, True, True]
```

has_right_descent(i)

Determine whether there is a descent at index i.

INPUT:

- i – an integer

EXAMPLES:

```sage
D = AffinePermutationGroup(['D', 4, 1])
p = D([1, -6, 5, -2])
[p.has_right_descent(i) for i in D.index_set()]
```

```
[True, True, False, True, False]
```

```sage
from sage.all import *

D = AffinePermutationGroup(['D', Integer(4), Integer(1)])
p = D([Integer(1), -Integer(6), Integer(5), -Integer(2)])
[p.has_right_descent(i) for i in D.index_set()]
```

```
[True, True, False, True, False]
```
from sage.all import *
D = AffinePermutationGroup(['D', Integer(4), Integer(1)])
p = D([Integer(1), -Integer(6), Integer(5), -Integer(2)])
[p.has_right_descent(i) for i in D.index_set()]
[True, True, False, True, False]

class sage.combinat.affine_permutation.AffinePermutationTypeG (parent, lst,
check=True)
Bases: AffinePermutation

apply_simple_reflection_left(i)
Apply simple reflection indexed by i on values.
EXAMPLES:

code_snippet
sage: G = AffinePermutationGroup(['G',2,1])
sage: p = G([2, 10, -5, 12, -3, 5])
sage: p.apply_simple_reflection_left(0)
Type G affine permutation with window [0, 10, -7, 14, -3, 7]
sage: p.apply_simple_reflection_left(1)
Type G affine permutation with window [1, 9, -4, 11, -2, 6]
sage: p.apply_simple_reflection_left(2)
Type G affine permutation with window [3, 11, -5, 12, -4, 4]

apply_simple_reflection_right(i)
Apply the simple reflection indexed by i on positions.
EXAMPLES:

code_snippet
sage: G = AffinePermutationGroup(['G',2,1])
sage: p = G([2, 10, -5, 12, -3, 5])
sage: p.apply_simple_reflection_right(0)
Type G affine permutation with window [-9, -1, -5, 12, 8, 16]
sage: p.apply_simple_reflection_right(1)
Type G affine permutation with window [10, 2, 12, -5, 5, -3]
sage: p.apply_simple_reflection_right(2)
Type G affine permutation with window [2, -5, 10, -3, 12, 5]
>>> p.apply_simple_reflection_right(Integer(2))
Type G affine permutation with window [2, -5, 10, -3, 12, 5]

check()
Check that self is an affine permutation.

EXAMPLES:

```sage
g = AffinePermutationGroup(['G',2,1])
p = g([2, 10, -5, 12, -3, -5])
p
```
Type G affine permutation with window [2, 10, -5, 12, -3, 5]

```sage
from sage.all import *
g = AffinePermutationGroup(['G',Integer(2),Integer(1)])
p = g([Integer(2), Integer(10), -Integer(5), Integer(12), -Integer(3), -Integer(5)])
p
```
Type G affine permutation with window [2, 10, -5, 12, -3, 5]

has_left_descent(i)
Determines whether there is a descent at i.

INPUT:

- i – an integer

EXAMPLES:

```sage
g = AffinePermutationGroup(['G',2,1])
p = g([2, 10, -5, 12, -3, -5])
[p.has_left_descent(i) for i in g.index_set()]
```
[False, True, False]

```sage
from sage.all import *
g = AffinePermutationGroup(['G',Integer(2),Integer(1)])
p = g([Integer(2), Integer(10), -Integer(5), Integer(12), -Integer(3), -Integer(5)])
[p.has_left_descent(i) for i in g.index_set()]
```
[False, True, False]

has_right_descent(i)
Determines whether there is a descent at index i.

INPUT:

- i – an integer

EXAMPLES:

```sage
g = AffinePermutationGroup(['G',2,1])
p = g([2, 10, -5, 12, -3, -5])
[p.has_right_descent(i) for i in g.index_set()]
```
[False, False, True]

```sage
from sage.all import *
g = AffinePermutationGroup(['G',Integer(2),Integer(1)])
p = g([Integer(2), Integer(10), -Integer(5), Integer(12), -Integer(3), -Integer(5)])
[p.has_right_descent(i) for i in g.index_set()]
```
[False, False, True]
### position(i)

Find the position j such the self.value(j) == i.

**EXAMPLES:**

```
sage: G = AffinePermutationGroup(['G',2,1])
sage: p = G([2, 10, -5, 12, -3, 5])
sage: [p.position(i) for i in p]
[1, 2, 3, 4, 5, 6]
```

### to_type_a()

Return an embedding of self into the affine permutation group of type A.

**EXAMPLES:**

```
sage: G = AffinePermutationGroup(['G',2,1])
sage: p = G([2, 10, -5, 12, -3, 5])
sage: p.to_type_a()
Type A affine permutation with window [2, 10, -5, 12, -3, 5]
```

### value(i, base_window=False)

Return the image of the integer i under this permutation.

**INPUT:**

- `base_window` – boolean indicating whether i is between 1 and \( k + 1 \); if True, will run a bit faster, but the method will screw up if i is not actually in the index set

**EXAMPLES:**

```
sage: G = AffinePermutationGroup(['G',2,1])
sage: p = G([2, 10, -5, 12, -3, 5])
sage: [p.value(i) for i in range(1,13)]
[2, 10, -5, 12, -3, 5, 8, 16, 1, 18, 3, 11]
```
>>> from sage.all import *
>>> G = AffinePermutationGroup(['G', Integer(2), Integer(1)])
>>> p = G([Integer(2), Integer(10), -Integer(5), Integer(12), -Integer(3), -Integer(5)])
>>> [p.value(i) for i in (ellipsis_range(Integer(1), Ellipsis, Integer(12)))]
[2, 10, -5, 12, -3, 5, 8, 16, 1, 18, 3, 11]

5.1.5 Alternating Sign Matrices

AUTHORS:

- Mike Hansen (2007): Initial version
- Pierre Cange, Luis Serrano (2012): Added monotone triangles
- Travis Scrimshaw (2013-28-03): Added element class for ASM’s and made `MonotoneTriangles` inherit from `GelfandTsetlinPatterns`
- Jessica Striker (2013): Added additional methods
- Vincent Delecroix (2017): cleaning

```python
class sage.combinat.alternating_sign_matrix.AlternatingSignMatrices(n)
Bases: UniqueRepresentation, Parent
```

Class of all $n \times n$ alternating sign matrices.

An alternating sign matrix of size $n$ is an $n \times n$ matrix of 0’s, 1’s and $-1$’s such that the sum of each row and column is 1 and the non-zero entries in each row and column alternate in sign.

Alternating sign matrices of size $n$ are in bijection with `monotone triangles` with $n$ rows.

INPUT:

- $n$ – an integer, the size of the matrices.

EXAMPLES:

This will create an instance to manipulate the alternating sign matrices of size 3:
sage: A = AlternatingSignMatrices(3)
sage: A
Alternating sign matrices of size 3
sage: A.cardinality()
7

>>> from sage.all import *
>>> A = AlternatingSignMatrices(Integer(3))
>>> A
Alternating sign matrices of size 3
>>> A.cardinality()
7

Notably, this implementation allows to make a lattice of it:

sage: L = A.lattice()
sage: L
Finite lattice containing 7 elements
sage: L.category()
Category of facade finite enumerated lattice posets

>>> from sage.all import *
>>> L = A.lattice()
>>> L
Finite lattice containing 7 elements
>>> L.category()
Category of facade finite enumerated lattice posets

Element
alias of AlternatingSignMatrix
cardinality()

Return the cardinality of self.

The number of \( n \times n \) alternating sign matrices is equal to

\[
\prod_{k=0}^{n-1} \frac{(3k+1)!}{(n+k)!} = \frac{1!4!7!10! \cdots (3n-2)!}{n!(n+1)!(n+2)!(n+3)! \cdots (2n-1)!}
\]

EXAMPLES:

sage: [AlternatingSignMatrices(n).cardinality() for n in range(11)]
[1, 1, 2, 7, 42, 429, 7436, 218348, 10850216, 911835460, 129534272700]

>>> from sage.all import *
>>> [AlternatingSignMatrices(n).cardinality() for n in range(Integer(11))]
[1, 1, 2, 7, 42, 429, 7436, 218348, 10850216, 911835460, 129534272700]
cover_relations()

Iterate on the cover relations between the alternating sign matrices.

EXAMPLES:

sage: A = AlternatingSignMatrices(3)
sage: for (a,b) in A.cover_relations():
....:   eval('a, b')

(continues on next page)
>>> from sage.all import *
>>> A = AlternatingSignMatrices(Integer(3))
>>> for (a,b) in A.cover_relations():
...    eval('a, b')

>>> A = AlternatingSignMatrices(Integer(3))
>>> for (a,b) in A.cover_relations():
...    eval('a, b')

(continues on next page)
first()

Return the first alternating sign matrix.

EXAMPLES:

```sage
AlternatingSignMatrices(5).first()
```

```
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
```

```python
from sage.all import *

AlternatingSignMatrices(Integer(5)).first()
```

```
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
```

from_contre_tableau (comps)

Return an alternating sign matrix from a contre-tableau.

EXAMPLES:
from_corner_sum(\textit{corner})

Return an alternating sign matrix from a corner sum matrix.

EXAMPLES:

\begin{verbatim}
sage: A = AlternatingSignMatrices(3)
sage: A.from_corner_sum(matrix([[0,0,0,0],[0,1,1,1],[0,1,2,2],[0,1,2,3]]))
[1 0 0]
[0 1 0]
[0 0 1]
sage: A.from_corner_sum(matrix([[0,0,0,0],[0,0,1,1],[0,1,1,2],[0,1,2,3]]))
[ 0 1 0]
[ 1 -1 1]
[ 0 1 0]
\end{verbatim}

from_height_function(\textit{height})

Return an alternating sign matrix from a height function.

EXAMPLES:

\begin{verbatim}
>>> from sage.all import *
>>> A = AlternatingSignMatrices(Integer(3))
>>> A.from_corner_sum(matrix([[Integer(0),Integer(0),Integer(0),Integer(0)],[Integer(0),Integer(1),Integer(1),Integer(1)],[Integer(0),Integer(1),Integer(2),Integer(2)],[Integer(0),Integer(1),Integer(2),Integer(3)]]))
[ 1 0 0]
[ 0 1 0]
[ 0 0 1]
>>> A.from_corner_sum(matrix([[Integer(0),Integer(0),Integer(0),Integer(0)],[Integer(0),Integer(0),Integer(1),Integer(1)],[Integer(0),Integer(1),Integer(1),Integer(2)],[Integer(0),Integer(1),Integer(2),Integer(3)]]))
[ 0 1 0]
[ 1 -1 1]
[ 0 1 0]
\end{verbatim}
Combinatorics, Release 10.4

sage: A = AlternatingSignMatrices(3)
sage: A.from_height_function(matrix([[0,1,2,3],[1,2,1,2],[2,3,2,1],[3,2,1,0]]))
[0 0 1]
[1 0 0]
[0 1 0]
sage: A.from_height_function(matrix([[0,1,2,3],[1,2,1,2],[2,3,2,1],[3,2,1,0]]))
[0 1 0]
[1 -1 1]
[0 1 0]

from sage.all import *

>>> from sage.all import *
>>> A = AlternatingSignMatrices(Integer(3))

from monotone_triangle (triangle, check=True)

Return an alternating sign matrix from a monotone triangle.

EXAMPLES:

sage: A = AlternatingSignMatrices(3)
sage: A.from_monotone_triangle([[3, 2, 1], [2, 1]])
[1 0 0]
[0 1 0]
[0 0 1]
sage: A.from_monotone_triangle([[3, 2, 1], [2, 2]])
Traceback (most recent call last):
  ... ValueError: not a valid triangle

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

>>> A.from_monotone_triangle([[Integer(3), Integer(2), Integer(1)],␣
˓→[Integer(3), Integer(2)], [Integer(3)]])
[0 0 1]
[0 1 0]
[1 0 0]

>>> A.from_monotone_triangle([[Integer(3), Integer(2), Integer(1)],␣
˓→[Integer(2), Integer(2)], [Integer(1)]])
Traceback (most recent call last):
...
ValueError: not a valid triangle

gyration_orbit_sizes()
Return the sizes of gyration orbits of self.
EXAMPLES:
sage: AlternatingSignMatrices(3).gyration_orbit_sizes()
[3, 2, 2]
sage: AlternatingSignMatrices(4).gyration_orbit_sizes()
[4, 8, 2, 8, 8, 8, 2, 2]
sage:
sage:
....:
....:
sage:
True
>>>
>>>
[3,
>>>
[4,

A = AlternatingSignMatrices(5)
li = [5,10,10,10,10,10,2,5,10,10,10,10,10,10,10,10,10,10,10,10,
4,10,10,10,10,10,10,4,5,10,10,10,10,10,10,10,2,4,5,10,10,10,10,10,10,
4,5,10,10,2,2]
A.gyration_orbit_sizes() == li

from sage.all import *
AlternatingSignMatrices(Integer(3)).gyration_orbit_sizes()
2, 2]
AlternatingSignMatrices(Integer(4)).gyration_orbit_sizes()
8, 2, 8, 8, 8, 2, 2]

>>> A = AlternatingSignMatrices(Integer(5))
>>> li = [Integer(5),Integer(10),Integer(10),Integer(10),Integer(10),
˓→Integer(10),Integer(2),Integer(5),Integer(10),Integer(10),Integer(10),
˓→Integer(10),Integer(10),Integer(10),Integer(10),Integer(10),Integer(10),
˓→Integer(10),Integer(10),Integer(10),
... Integer(4),Integer(10),Integer(10),Integer(10),Integer(10),Integer(10),
˓→Integer(10),Integer(4),Integer(5),Integer(10),Integer(10),Integer(10),
˓→Integer(10),Integer(10),Integer(10),Integer(10),Integer(2),Integer(4),
˓→Integer(5),Integer(10),Integer(10),Integer(10),Integer(10),Integer(10),
˓→Integer(10),
... Integer(4),Integer(5),Integer(10),Integer(10),Integer(2),Integer(2)]
>>> A.gyration_orbit_sizes() == li
True

gyration_orbits()
Return the list of gyration orbits of self.
EXAMPLES:

72

Chapter 5. Comprehensive Module List


**sage**: AlternatingSignMatrices(3).gyration_orbits()
((
  [1 0 0] [0 0 1] [ 0 1 0]
  [0 1 0] [0 1 0] [ 1 -1 1]
  [0 0 1], [1 0 0], [ 0 1 0]
),
  (  
  [0 1 0] [1 0 0]  
  [1 0 0] [0 0 1]  
  [0 0 1], [0 1 0]  
  ),
  (  
  [0 0 1] [0 1 0]  
  [1 0 0] [0 0 1]  
  [0 1 0], [1 0 0]  
  ))

```python
>>> from sage.all import *
>>> AlternatingSignMatrices(Integer(3)).gyration_orbits()
((
  [1 0 0] [0 0 1] [ 0 1 0]
  [0 1 0] [0 1 0] [ 1 -1 1]
  [0 0 1], [1 0 0], [ 0 1 0]
),
  (  
  [0 1 0] [1 0 0]  
  [1 0 0] [0 0 1]  
  [0 0 1], [0 1 0]  
  ),
  (  
  [0 0 1] [0 1 0]  
  [1 0 0] [0 0 1]  
  [0 1 0], [1 0 0]  
  ))
```

**last**

Return the last alternating sign matrix.

**EXAMPLES:**

```python
sage: AlternatingSignMatrices(5).last()
[0 0 0 0 1]
[0 0 0 1 0]
[0 0 1 0 0]
[0 1 0 0 0]
[1 0 0 0 0]
```

```python
>>> from sage.all import *
>>> AlternatingSignMatrices(Integer(5)).last()
[0 0 0 0 1]
[0 0 0 1 0]
[0 0 1 0 0]
[0 1 0 0 0]
[1 0 0 0 0]
```

**lattice**

Return the lattice of the alternating sign matrices of size \(n\), created by `LatticePoset`.

5.1. Comprehensive Module List
EXAMPLES:

```sage
c A = AlternatingSignMatrices(3)
c L = A.lattice()
c L
Finite lattice containing 7 elements
```

```sage
c from sage.all import *
c A = AlternatingSignMatrices(Integer(3))
c L = A.lattice()
c L
Finite lattice containing 7 elements
```

**matrix_space()**

Return the underlying matrix space.

EXAMPLES:

```sage
c A = AlternatingSignMatrices(3)
c A.matrix_space()
c Full MatrixSpace of 3 by 3 dense matrices over Integer Ring
```

```sage
c from sage.all import *
c A = AlternatingSignMatrices(Integer(3))
c A.matrix_space()
c Full MatrixSpace of 3 by 3 dense matrices over Integer Ring
```

**random_element()**

Return a uniformly random alternating sign matrix.

EXAMPLES:

```sage
c AlternatingSignMatrices(7).random_element()  # random
[ 0 0 0 0 1 0 0]
[ 0 0 1 0 -1 0 1]
[ 0 0 0 0 1 0 0]
[ 0 1 -1 0 0 1 0]
[ 1 -1 1 0 0 0 0]
[ 0 0 0 1 0 0 0]
[ 0 1 0 0 0 0 0]
c A = AlternatingSignMatrices(5).random_element()
c bool(A.number_negative_ones()) or A.is_permutation()
True
```

```sage
c from sage.all import *
c AlternatingSignMatrices(Integer(7)).random_element()  # random
[ 0 0 0 0 1 0 0]
[ 0 0 1 0 -1 0 1]
[ 0 0 0 0 1 0 0]
[ 0 1 -1 0 0 1 0]
[ 1 -1 1 0 0 0 0]
[ 0 0 0 1 0 0 0]
[ 0 1 0 0 0 0 0]
c A = AlternatingSignMatrices(Integer(5)).random_element()
c bool(A.number_negative_ones()) or A.is_permutation()
True
```
This is done using a modified version of Propp and Wilson’s “coupling from the past” algorithm. It creates a uniformly random Gelfand-Tsetlin triangle with top row \([n, n - 1, \ldots, 2, 1]\), and then converts it to an alternating sign matrix.

**size()**

Return the size of the matrices in self.

```python
class sage.combinat.alternating_sign_matrix.AlternatingSignMatrix (parent, asm)
Bases: Element

An alternating sign matrix.

An alternating sign matrix is a square matrix of 0’s, 1’s and \(-1\)’s such that the sum of each row and column is 1 and the non-zero entries in each row and column alternate in sign.

These were introduced in [MRR1983].

**ASM_compatible(B)**

Return True if self and B are compatible alternating sign matrices in the sense of [EKLP1992]. (If self is of size \(n\), B must be of size \(n + 1\).

In [EKLP1992], there is a notion of a pair of ASM’s with sizes differing by 1 being compatible, in the sense that they can be combined to encode a tiling of the Aztec Diamond.

**EXAMPLES:**

```python
sage: A = AlternatingSignMatrix(matrix([[0, 0, 1, 0], [0, 1, -1, 1], [1, 0, 0, 0], [0, 0, 1, 0]]))
sage: B = AlternatingSignMatrix(matrix([[0, 0, 1, 0, 0], [0, 0, 0, 1, 0], [1, 0, 0, -1, 1], [0, 1, 0, 0, 0], [0, 0, 0, 1, 0]]))
sage: AASM_compatible(B)
True
sage: A = AlternatingSignMatrix(matrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]]))
```

```python
sage: B = AlternatingSignMatrix(matrix([[0, 0, 1, 0], [0, 0, 0, 1], [1, 0, 0, 0], [0, 1, 0, 0]]))
sage: AASM_compatible(B)
False
```
ASM_compatible_bigger()

Return all ASM’s compatible with self that are of size one greater than self.

Given an \( n \times n \) alternating sign matrix \( A \), there are as many ASM’s of size \( n + 1 \) compatible with \( A \) as 2 raised to the power of the number of 1’s in \( A \) [EKLP1992].

EXAMPLES:

```python
sage: A = AlternatingSignMatrix([[1,0],[0,1]])
 sage: A.ASM_compatible_bigger()
 [ [ 0 1 0 ] [ 1 0 0 ] [ 0 1 0 ] [ 1 0 0 ]
  [ 1 -1 1 ] [ 0 0 1 ] [ 1 0 0 ] [ 0 1 0 ]
  [ 0 1 0 ], [ 0 1 0 ], [ 0 0 1 ], [ 0 0 1 ] ]
 sage: B = AlternatingSignMatrix([[0,1],[1,0]])
 sage: B.ASM_compatible_bigger()
 [ [ 0 0 1 ] [ 0 0 1 ] [ 0 1 0 ] [ 1 0 0 ]
  [ 0 1 0 ] [ 0 0 1 ] [ 1 -1 1 ] [ 0 0 1 ]
  [ 1 0 0 ], [ 0 1 0 ], [ 1 0 0 ], [ 0 1 0 ] ]
 sage: B = AlternatingSignMatrix([[0,1,0],[1,-1,1],[0,1,0]])
 sage: len(B.ASM_compatible_bigger()) == 2**4
 True
```

```
>>> from sage.all import *
>>> A = AlternatingSignMatrix([[Integer(1),Integer(0)],[Integer(0),-Integer(1)]])
>>> A.ASM_compatible_bigger()
 [ [ 0 1 0 ] [ 1 0 0 ] [ 0 1 0 ] [ 1 0 0 ]
  [ 1 -1 1 ] [ 0 0 1 ] [ 1 0 0 ] [ 0 1 0 ]
  [ 0 1 0 ], [ 0 1 0 ], [ 0 0 1 ], [ 0 0 1 ] ]
>>> B = AlternatingSignMatrix([[Integer(0),Integer(1)],[Integer(1),-Integer(0)]])
>>> B.ASM_compatible_bigger()
 [ [ 0 0 1 ] [ 0 0 1 ] [ 0 1 0 ] [ 1 0 0 ]
  [ 0 1 0 ] [ 0 0 1 ] [ 1 -1 1 ] [ 0 0 1 ]
  [ 1 0 0 ], [ 0 1 0 ], [ 1 0 0 ], [ 0 1 0 ] ]
>>> B = AlternatingSignMatrix([[Integer(0),Integer(1),Integer(0)],[Integer(1),-Integer(1),Integer(1)],[Integer(0),Integer(1),Integer(0)]])
>>> len(B.ASM_compatible_bigger()) == Integer(2)**Integer(4)
 True
```

ASM_compatible_smaller()

Return the list of all ASMs compatible with self that are of size one smaller than self.

Given an alternating sign matrix \( A \) of size \( n \), there are as many ASM’s of size \( n - 1 \) compatible with it as 2 raised to the power of the number of \(-1\)’s in \( A \) [EKLP1992].

EXAMPLES:
sage: A = AlternatingSignMatrix(matrix([[0,0,1,0],[0,1,-1,1],[1,0,0,0],[0,0,1,-0]]))

sage: A.ASM_compatible_smaller()

[0 0 1 0 1 0]
[1 0 0 1 -1 1]
[0 1 0 0 1 0]

sage: B = AlternatingSignMatrix(matrix([[1,0,0],[0,0,1],[0,1,0]]))

sage: B.ASM_compatible_smaller()

[1 0]
[0 1]

>>> from sage.all import *

>>> A = AlternatingSignMatrix(matrix([[Integer(0),Integer(0),Integer(1)],
                                   [Integer(0),Integer(1),-Integer(1),Integer(1)],
                                   [Integer(0),Integer(0),Integer(0)],
                                   [Integer(0),Integer(0),Integer(0)]]))

>>> A.ASM_compatible_smaller()

[0 0 1 0 1 0]
[1 0 0 1 -1 1]
[0 1 0 0 1 0]

>>> B = AlternatingSignMatrix(matrix([[Integer(1),Integer(0),Integer(0)],
                                   [Integer(0),Integer(0),Integer(1)],
                                   [Integer(0),Integer(1),Integer(0)]]))

>>> B.ASM_compatible_smaller()

[1 0]
[0 1]

corner_sum_matrix()

Return the corner sum matrix of self.

EXAMPLES:

sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).corner_sum_matrix()

[0 0 0 0]
[0 1 1 1]
[0 1 2 2]
[0 1 2 3]

sage: asm = A([[0, 1, 0],[1, -1, 1],[0, 1, 0]])
sage: asm.corner_sum_matrix()

[0 0 0 0]
[0 0 1 1]
[0 1 2 2]
[0 1 2 3]

sage: asm = A([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: asm.corner_sum_matrix()

[0 0 0 0]
[0 0 1 1]
[0 1 1 2]
[0 1 2 3]
from sage.all import *

A = AlternatingSignMatrices(Integer(3))

A([[Integer(1), Integer(0), Integer(0)],[Integer(0), Integer(0), Integer(1)],
  [Integer(0)], [Integer(0), Integer(0), Integer(1)]]).corner_sum_matrix()

[0 0 0]
[0 1 1]
[0 1 2 2]
[0 1 2 3]

asm = A([[Integer(0), Integer(1), Integer(0)],[Integer(1), -Integer(1),
  Integer(1)], [Integer(0), Integer(1), Integer(0)]]

asm.corner_sum_matrix()

[0 0 0]
[0 0 1]
[0 1 2 2]
[0 1 2 3]

asm = A([[Integer(0), Integer(1), Integer(0)],[Integer(1), Integer(0),
  Integer(0)], [Integer(0), Integer(1), Integer(0)]]

asm.corner_sum_matrix()

[0 0 0]
[0 0 1]
[0 1 2 2]
[0 1 2 3]

asm = A([[Integer(0), Integer(1), Integer(0)],[Integer(1), Integer(0),
  Integer(0)], [Integer(0), Integer(1), Integer(0)]]

asm.corner_sum_matrix()

[0 0 0]
[0 0 1]
[0 1 2 2]
[0 1 2 3]

**gyration()**

Return the alternating sign matrix obtained by applying gyration to the height function in bijection with self.

Gyration acts on height functions as follows. Go through the entries of the matrix, first those for which the sum of the row and column indices is even, then for those for which it is odd, and increment or decrement the squares by 2 wherever possible such that the resulting matrix is still a height function. Gyration was first defined in [Wie2000] as an action on fully-packed loops.

**EXAMPLES:**

```python
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).gyration()

[0 1 0]
[0 0 1]
[1 0 0]
sage: asm = A([[0, 1, 0],[1, -1, 1],[0, 1, 0]])
sage: asm.gyration()

[1 0 0]
[0 1 0]
[0 0 1]
sage: asm = A([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: asm.gyration()

[0 1 0]
[0 0 1]
[1 0 0]
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).gyration().gyration()

[1 0 0]
[0 1 0]
[0 0 1]
```

(continues on next page)
sage: A = AlternatingSignMatrices(4)
sage: M = A([[0,0,1,0],[1,0,0,0],[0,1,-1,1],[0,0,1,0]])
sage: for i in range(5):
    M = M.gyration()
sage: M
[1 0 0 0]
[0 0 0 1]
[0 1 0 0]
[0 0 1 0]
sage: a0 = a = AlternatingSignMatrices(5).random_element()
sage: for i in range(20):
    a = a.gyration()
sage: a == a0
True

>>> from sage.all import *

>>> A = AlternatingSignMatrices(Integer(3))

>>> A([[Integer(1), Integer(0), Integer(0)],[Integer(0), Integer(1), Integer(0)],[Integer(0), Integer(0), Integer(1)]]).gyration()
[0 0 1]
[0 1 0]
[1 0 0]

>>> asm = A([[Integer(0), Integer(1), Integer(0)],[Integer(1), -Integer(1), Integer(0)],[Integer(0), Integer(1), Integer(0)]])

>>> asm.gyration()
[1 0 0]
[0 1 0]
[0 0 1]

>>> asm = A([[Integer(0), Integer(1), Integer(0)],[Integer(1), Integer(0), Integer(0)],[Integer(0), Integer(1), Integer(0)]])

>>> asm.gyration()
[0 1 0]
[0 0 1]
[1 0 0]

>>> A = AlternatingSignMatrices(Integer(3))

>>> A([[Integer(1), Integer(0), Integer(0)],[Integer(0), Integer(1), Integer(0)],[Integer(0), Integer(0), Integer(1)]]).gyration().gyration().gyration()
[0 0 1]
[0 1 0]
[1 0 0]

>>> A = AlternatingSignMatrices(Integer(4))

>>> M = A([[Integer(0),Integer(0),Integer(1),Integer(0)],[Integer(1), Integer(0), Integer(0), Integer(0)],[Integer(0),Integer(0),Integer(1),Integer(0)],[Integer(0),Integer(0),Integer(1),Integer(0)]]).gyration()

>>> for i in range(Integer(5)):
    ... M = M.gyration()
gyration_orbit()  
Return the gyration orbit of self (including self).

EXAMPLES:

```
sage: AlternatingSignMatrix([[0,1,0],[1,-1,1],[0,1,0]]).gyration_orbit()  
[ [ 0 1 0 ] [ 1 0 0 ] [ 0 0 1 ]  
 [ 1 -1 1 ] [ 0 1 0 ] [ 0 1 0 ]  
 [ 0 1 0 ] , [ 0 0 1 ] , [ 1 0 0 ] ]
sage: AlternatingSignMatrix([[0,1,0,0],[1,-1,1,0],[0,1,-1,1],[0,0,1,0]]).gyration_orbit()  
[ [ 0 1 0 0 ] [ 1 0 0 0 ] [ 0 0 1 0 ] [ 0 0 0 1 ]  
 [ 1 -1 1 0 ] [ 0 1 0 0 ] [ 0 1 -1 1 ] [ 0 0 1 0 ]  
 [ 0 1 -1 1 ] [ 0 0 1 0 ] [ 1 -1 1 0 ] [ 0 1 0 0 ]  
 [ 0 0 1 0 ] , [ 0 0 0 1 ] , [ 0 1 0 0 ] , [ 1 0 0 0 ] ]
sage: len(AlternatingSignMatrix([[0,1,0,0,0,0],[0,0,1,0,0,0],[1,-1,0,0,0,1],....: [0,1,0,0,0,0],[0,0,0,1,0,0],[0,0,0,0,1,0]]).gyration_orbit())  
12
```
height_function()

Return the height function from self.

A height function corresponding to an $n \times n$ ASM is an $(n + 1) \times (n + 1)$ matrix such that the first row is 0, 1, ..., $n$, the last row is $n, n - 1, ..., 1, 0$, and the difference between adjacent entries is 1.

EXAMPLES:

```python
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).height_function()
[0 1 2 3]
[1 0 1 2]
[2 1 0 1]
[3 2 1 0]
sage: asm = A([[0, 1, 0],[1, -1, 1],[0, 1, 0]])
sage: asm.height_function()
[0 1 2 3]
[1 2 1 2]
[2 1 2 1]
[3 2 1 0]
sage: asm = A([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: asm.height_function()
[0 1 2 3]
[1 2 1 2]
[2 3 2 1]
[3 2 1 0]
sage: A = AlternatingSignMatrices(4)
sage: all(A.from_height_function(a.height_function()) == a for a in A)
True
```

```python
>>> from sage.all import *
>>> A = AlternatingSignMatrices(Integer(3))
>>> A([[Integer(1), Integer(0), Integer(0)],[Integer(0), Integer(1),…
\[Integer(0)],[Integer(0), Integer(0), Integer(1)]]).height_function()
[0 1 2 3]
[1 0 1 2]
[2 1 0 1]
[3 2 1 0]
>>> asm = A([[Integer(0), Integer(1), Integer(0)],[Integer(1), -Integer(1),…
\[Integer(1)],[Integer(0), Integer(1), Integer(0)]])
>>> asm.height_function()
[0 1 2 3]
[1 2 1 2]
[2 1 2 1]
[3 2 1 0]
>>> asm = A([[Integer(0), Integer(0), Integer(1)],[Integer(1), Integer(0),…
\[Integer(0), [Integer(1), Integer(0)]])
>>> asm.height_function()
```

(continues on next page)
inversion_number()

Return the inversion number of self.

If we denote the entries of the alternating sign matrix as \( a_{i,j} \), the inversion number is defined as \( \sum_{i \leq k} \sum_{j \leq l} a_{i,j} a_{k,l} \). When restricted to permutation matrices, this gives the usual inversion number of the permutation.

This definition is equivalent to the one given in [MRR1983].

EXAMPLES:

```python
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).inversion_number()
0
sage: asm = A([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: asm.inversion_number()
2
sage: asm = A([[0, 1, 0],[1, -1, 1],[0, 1, 0]])
sage: asm.inversion_number()
2
sage: P = Permutations(5)
sage: all(p.number_of_inversions()==AlternatingSignMatrix(p.to_matrix()).inversion_number() for p in P)
True
```

is_permutation()

Return True if self is a permutation matrix and False otherwise.

EXAMPLES:

```python
>>> from sage.all import *
>>> A = AlternatingSignMatrices(Integer(3))
>>> A([[Integer(1), Integer(0), Integer(0)],[Integer(0), Integer(1), Integer(0)],[Integer(0), Integer(0), Integer(1)]]).inversion_number()
0
>>> asm = A([[Integer(0), Integer(0), Integer(1)],[Integer(1), Integer(0), Integer(0)],[Integer(0), Integer(0), Integer(1)]]
>>> asm.inversion_number()
2
>>> asm = A([[Integer(0), Integer(1), Integer(0)],[Integer(1), -Integer(1), Integer(1)],[Integer(0), Integer(1), Integer(0)]]
>>> asm.inversion_number()
2
>>> P = Permutations(Integer(5))
>>> all(p.number_of_inversions()==AlternatingSignMatrix(p.to_matrix()).inversion_number() for p in P)
True
```
left_key()

Return the left key of the alternating sign matrix self.

The left key of an alternating sign matrix was defined by Lascoux in [Lasc] and is obtained by successively removing all the $-1$'s until what remains is a permutation matrix. This notion corresponds to the notion of left key for semistandard tableaux. So our algorithm proceeds as follows: we map self to its corresponding monotone triangle, view that monotone triangle as a semistandard tableau, take its left key, and then map back through monotone triangles to the permutation matrix which is the left key.

See also [Ava2007].

EXAMPLES:

```python
sage: A = AlternatingSignMatrices(3)
sage: asm = A([[0,1,0],[1,0,0],[0,0,1]]).left_key()
[0 1 0]
[1 0 0]
[0 1 0]
sage: t = A([[0,1,0],[1,-1,1],[0,1,0]]).left_key(); t
[1 0 0]
[0 0 1]
[0 1 0]
sage: parent(t)
Alternating sign matrices of size 3
```
left_key_as_permutation()

Return the permutation of the left key of self.

See also:

• left_key()

EXAMPLES:

```
sage: A = AlternatingSignMatrices(3)
sage: A([[0,0,1],[1,0,0],[0,1,0]]).left_key_as_permutation()
[3, 1, 2]
sage: t = A([[0,1,0],[1,-1,1],[0,1,0]]).left_key_as_permutation(); t
[1, 3, 2]
sage: parent(t)
Standard permutations
```

link_pattern()

Return the link pattern corresponding to the fully packed loop corresponding to self.

EXAMPLES:

We can extract the underlying link pattern (a non-crossing partition) from a fully packed loop:

```
sage: A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: A.link_pattern()
[(1, 2), (3, 6), (4, 5)]
sage: B = AlternatingSignMatrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
sage: B.link_pattern()
[(1, 6), (2, 5), (3, 4)]
```

```python
>>> from sage.all import *
>>> A = AlternatingSignMatrix([[Integer(0), Integer(1), Integer(0)],
[Integer(1), -Integer(1), Integer(1)], [Integer(0), Integer(0), Integer(1)]])
>>> A.link_pattern()
[(1, 2), (3, 6), (4, 5)]
>>> B = AlternatingSignMatrix([[Integer(1), Integer(0), Integer(0)],
[Integer(0), Integer(1), Integer(0)], [Integer(0), Integer(0), Integer(1)]])
```
B.link_pattern()
[(1, 6), (2, 5), (3, 4)]

number_negative_ones()
Return the number of entries in self equal to -1.

EXAMPLES:

sage: A = AlternatingSignMatrices(3)
sage: asm = A([[0,1,0],[1,0,0],[0,0,1]])
sage: asm.number_negative_ones()
0
sage: asm = A([[0,1,0],[1,-1,1],[0,1,0]])
sage: asm.number_negative_ones()
1

>>> from sage.all import *
>>> A = AlternatingSignMatrices(Integer(3))
>>> asm = A([[Integer(0),Integer(1),Integer(0)],
   Integer(1),Integer(0),Integer(0),Integer(1)])
>>> asm.number_negative_ones()
0
>>> asm = A([[Integer(0),Integer(1),Integer(0)],
   Integer(1),-Integer(1),
   Integer(1),Integer(0),Integer(1),Integer(0)])
>>> asm.number_negative_ones()
1

rotate_ccw()
Return the counterclockwise quarter turn rotation of self.

EXAMPLES:

sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).rotate_ccw()
[0 0 1]
[0 1 0]
[1 0 0]
sage: asm = A([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: asm.rotate_ccw()
[1 0 0]
[0 0 1]
[0 1 0]

>>> from sage.all import *
>>> A = AlternatingSignMatrices(Integer(3))
>>> A([[Integer(1), Integer(0), Integer(0)],
   Integer(0), Integer(1),
   Integer(1),Integer(0),Integer(0),Integer(1)])
>>> A[[Integer(0),Integer(0),Integer(1)],
   Integer(1),Integer(0),
   Integer(1),Integer(0),Integer(1),Integer(0)])
>>> A.rotate_ccw()
[1 0 0]
[0 0 1]
[0 1 0]
\texttt{rotate\_cw()}

Return the clockwise quarter turn rotation of \texttt{self}.

**EXAMPLES:**

\begin{verbatim}
    sage: A = AlternatingSignMatrices(3)
    sage: A([[1, 0, 0], [0, 1, 0], [0, 0, 1]]).rotate\_cw()
    [0 0 1]
    [0 1 0]
    [1 0 0]
    sage: asm = A([[0, 0, 1], [1, 0, 0], [0, 1, 0]])
    sage: asm.rotate\_cw()
    [0 1 0]
    [1 0 0]
    [0 0 1]
\end{verbatim}

\texttt{to\_dyck\_word(algorithm)}

Return a Dyck word determined by the specified algorithm.

The algorithm ‘last\_diagonal’ uses the last diagonal of the monotone triangle corresponding to \texttt{self}. The algorithm ‘link\_pattern’ returns the Dyck word in bijection with the link pattern of the fully packed loop.

Note that these two algorithms in general yield different Dyck words for a given alternating sign matrix.

**INPUT:**

- \texttt{algorithm} -- either 'last\_diagonal' or 'link\_pattern'

**EXAMPLES:**

\begin{verbatim}
>>> from sage.all import *
>>> A = AlternatingSignMatrices(Integer(3))
>>> A([[Integer(1), Integer(0), Integer(0)], [Integer(0), Integer(1),
    -> Integer(0)], [Integer(0), Integer(0), Integer(1)]]).rotate\_cw()
    [0 0 1]
    [0 1 0]
    [1 0 0]
>>> asm = A([[Integer(0), Integer(0), Integer(1)], [Integer(1), Integer(0),
    -> Integer(0)], [Integer(0), Integer(1), Integer(0)]])
>>> asm.rotate\_cw()
    [0 1 0]
    [1 0 0]
    [0 0 1]
\end{verbatim}
sage: A = AlternatingSignMatrices(4)
sage: asm = A([[0,0,1,0],[1,0,0,0],[0,1,-1,1],[0,0,1,0]])
sage: asm.to_dyck_word(algorithm = 'link_pattern')
[1, 1, 1, 0, 1, 0, 0, 0]
sage: asm.to_dyck_word()
Traceback (most recent call last):
  ...
TypeError: ...to_dyck_word() ...argument...
sage: asm.to_dyck_word(algorithm = 'notamethod')
Traceback (most recent call last):
  ...
ValueError: unknown algorithm 'notamethod'

>>> from sage.all import *

>>>

from sage.all import *

>>>

A = AlternatingSignMatrices(Integer(3))

>>> A([[Integer(0),Integer(1),Integer(0)],[Integer(1),Integer(0),Integer(0)],
    →[Integer(0),Integer(0),Integer(1)]]).to_dyck_word(algorithm = 'last_diagonal',

TypeError: ...to_dyck_word() ...argument...

>>> asm.to_dyck_word(algorithm = 'notamethod')
Traceback (most recent call last):
  ...
ValueError: unknown algorithm 'notamethod'

to_fully_packed_loop()

Return the fully packed loop configuration from self.

See also:

FullyPackedLoop

EXAMPLES:
```python
sage: asm = AlternatingSignMatrix([[1,0,0],[0,1,0],[0,0,1]])
sage: fpl = asm.to_fully_packed_loop()
sage: fpl
+ + -- +
| |
| |
-- + + + --
| |
| |
+ -- + +
| |
| |
```

```python
>>> from sage.all import *
>>> asm = AlternatingSignMatrix([[Integer(1), Integer(0), Integer(0)],
→[Integer(0), Integer(1), Integer(0)],[Integer(0), Integer(0), Integer(1)]])
>>> fpl = asm.to_fully_packed_loop()
>>> fpl
+ + -- +
| |
| |
-- + + + --
| |
| |
+ -- + +
| |
| |
```

to_matrix()

Return self as a regular matrix.

EXAMPLES:

```python
sage: A = AlternatingSignMatrices(3)
sage: asm = A([[1, 0, 0],[0, 1, 0],[0, 0, 1]])
sage: m = asm.to_matrix(); m
[1 0 0]
[0 1 0]
[0 0 1]
sage: m.parent()
Full MatrixSpace of 3 by 3 dense matrices over Integer Ring

```
to_monotone_triangle()

Return a monotone triangle from self.

EXAMPLES:

```python
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0], [0, 1, 0], [0, 0, 1]]).to_monotone_triangle()
[[3, 2, 1], [2, 1], [1]]
sage: asm = A([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: asm.to_monotone_triangle()
[[3, 2, 1], [3, 1], [2]]
sage: A.from_monotone_triangle(asm.to_monotone_triangle()) == asm
True
```

to_permutation()

Return the corresponding permutation if self is a permutation matrix.

EXAMPLES:

```python
sage: A = AlternatingSignMatrices(3)
sage: asm = A([[0, 1, 0], [1, 0, 0], [0, 0, 1]])
sage: p = asm.to_permutation(); p
[2, 1, 3]
sage: parent(p)
Standard permutations
sage: asm = A([[1, 0, 0], [-1, 1], [0, 1, 0]])
sage: asm.to_permutation()
Traceback (most recent call last):
...
ValueError: not a permutation matrix
```

```python
>>> from sage.all import *
>>> A = AlternatingSignMatrices(Integer(3))
>>> asm = A([[Integer(0), Integer(1), Integer(0)], [Integer(1), Integer(0), 
˓→Integer(0)], [Integer(0), Integer(1), Integer(0)]]).to_monotone_triangle()
[[3, 2, 1], [3, 1], [2]]
>>> asm = A([[Integer(0), Integer(1), Integer(0)], [Integer(1), Integer(0), 
˓→Integer(0)], [Integer(0), Integer(1), Integer(0)]]).to_monotone_triangle()
[[3, 2, 1], [3, 1], [3]]
>>> A.from_monotone_triangle(asm.to_monotone_triangle()) == asm
True
```
Standard permutations
>>> asm = A([[Integer(0), Integer(1), Integer(0)], [Integer(1), -Integer(1), ~Integer(1)], [Integer(0), Integer(1), Integer(0)]]
>>> asm.to_permutation()
Traceback (most recent call last):
... ValueError: not a permutation matrix

\texttt{to\_semistandard\_tableau()} \hfill (continued on previous page)

Return the semistandard tableau corresponding the monotone triangle corresponding to \texttt{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: A = AlternatingSignMatrices(3)
sage: A([[0,0,1],[1,0,0],[0,1,0]]).to_semistandard_tableau()
[[1, 1, 3], [2, 3], [3]]
sage: t = A([[0,1,0],[1,-1,1],[0,1,0]]).to_semistandard_tableau(); t
[[1, 1, 2], [2, 3], [3]]
sage: parent(t)
Semistandard tableaux
\end{verbatim}

\texttt{to\_six\_vertex\_model()} \hfill (continued on next page)

Return the six vertex model configuration from \texttt{self}.

This method calls \textsf{sage.combinat.six_vertex_model.from_alternating_sign_matrix()}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: asm = AlternatingSignMatrix([[0,1,0],[1,-1,1],[0,1,0]])
>>> asm.to_six_vertex_model()
 ^ ^ ^
 | | |-> # -> # <- # <->
 ^ | ^ | | V | | V
-> # <-> # <-> # <->
 | | | | | | V | | V
-> # -> # <-> # <->
 | | | | | | | | V V V
>>> from sage.all import *
\end{verbatim}
transpose()

Return self transposed.

EXAMPLES:

```python
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0], [0, 1, 0], [0, 0, 1]]).transpose()
[1 0 0]
[0 1 0]
[0 0 1]
sage: asm = A([[0, 0, 1], [1, 0, 0], [0, 1, 0]])
sage: asm.transpose()
[0 1 0]
[0 0 1]
[1 0 0]
```

```python
>>> from sage.all import *
```
>>> from sage.all import *
>>> ct4 = ContreTableaux(Integer(4)); ct4
Contre tableaux of size 4
>>> ct4.cardinality()
42

class sage.combinat.alternating_sign_matrix.ContreTableaux_n(n)
Bases: ContreTableaux
cardinality()

EXAMPLES:

sage: [ContreTableaux(n).cardinality() for n in range(11)]
[1, 1, 2, 7, 42, 429, 7436, 218348, 10850216, 911835460, 129534272700]

>>> from sage.all import *

>>> [ContreTableaux(n).cardinality() for n in range(Integer(11))]
[1, 1, 2, 7, 42, 429, 7436, 218348, 10850216, 911835460, 129534272700]

class sage.combinat.alternating_sign_matrix.MonotoneTriangles(n)
Bases: GelfandTsetlinPatternsTopRow

Monotone triangles with n rows.
A monotone triangle is a number triangle \((a_{i,j})_{1 \leq i \leq n, 1 \leq j \leq i}\) on \(\{1, \ldots, n\}\) such that:

- \(a_{i,j} < a_{i,j+1}\)
- \(a_{i+1,j} < a_{i,j} \leq a_{i+1,j+1}\)

This notably requires that the bottom column is \([1, \ldots, n]\).
Alternatively a monotone triangle is a strict Gelfand-Tsetlin pattern with top row \((n, \ldots, 2, 1)\).

INPUT:

- \(n\) – The number of rows in the monotone triangles

EXAMPLES:

This represents the monotone triangles with base \([3, 2, 1]\):

sage: M = MonotoneTriangles(3)
sage: M
Monotone triangles with 3 rows
sage: M.cardinality()
7

>>> from sage.all import *

>>> M = MonotoneTriangles(Integer(3))

>>> M
Monotone triangles with 3 rows

>>> M.cardinality()
7

The monotone triangles are a lattice:

sage: M.lattice()
Finite lattice containing 7 elements
Monotone triangles can be converted to alternating sign matrices and back:

```python
sage: M = MonotoneTriangles(5)
sage: A = AlternatingSignMatrices(5)
sage: all(A.from_monotone_triangle(m).to_monotone_triangle() == m for m in M)
True
```

```python
sage: M = MonotoneTriangles(Integer(5))
>>> A = AlternatingSignMatrices(Integer(5))
>>>
all(A.from_monotone_triangle(m).to_monotone_triangle() == m for m in M)
True
```

cardinality()
Cardinality of self.

The number of monotone triangles with \(n\) rows is equal to

\[
\prod_{k=0}^{n-1} \frac{(3k + 1)!}{(n + k)!} = \frac{1! 4! 7! 10! \cdots (3n - 2)!}{n!(n+1)!(n+2)!(n+3)! \cdots (2n-1)!}
\]

EXAMPLES:

```python
sage: M = MonotoneTriangles(4)
sage: M.cardinality()
42
```

```python
>>> from sage.all import *
>>> M = MonotoneTriangles(Integer(4))
>>> M.cardinality()
42
```

cover_relations()
Iterate on the cover relations in the set of monotone triangles with \(n\) rows.

EXAMPLES:

```python
sage: M = MonotoneTriangles(3)
sage: for (a,b) in M.cover_relations():
....:     eval('a, b')
(([[3, 2, 1], [2, 1], [1]], [[3, 2, 1], [2, 1], [2]]))
(([[3, 2, 1], [2, 1], [1]], [[3, 2, 1], [3, 1], [1]]))
(([[3, 2, 1], [2, 1], [2]], [[3, 2, 1], [3, 1], [2]]))
(([[3, 2, 1], [3, 1], [1]], [[3, 2, 1], [3, 1], [2]]))
(([[3, 2, 1], [3, 1], [2]], [[3, 2, 1], [3, 1], [3]]))
(([[3, 2, 1], [3, 1], [2]], [[3, 2, 1], [3, 2], [2]]))
(([[3, 2, 1], [3, 1], [3]], [[3, 2, 1], [3, 2], [3]]))
(([[3, 2, 1], [3, 2], [2]], [[3, 2, 1], [3, 2], [3]]))
```

```python
>>> from sage.all import *
>>> M = MonotoneTriangles(Integer(3))
>>> for (a,b) in M.cover_relations():

(continues on next page)
... eval('a, b')

(
[[3, 2, 1], [2, 1], [1]],
[[3, 2, 1], [2, 1], [1]],
[[3, 2, 1], [3, 1], [1]])

(
[[3, 2, 1], [2, 1], [2]],
[[3, 2, 1], [3, 1], [2]],
[[3, 2, 1], [3, 1], [2]])

(
[[3, 2, 1], [3, 1], [1]],
[[3, 2, 1], [3, 1], [1]],
[[3, 2, 1], [3, 1], [2]])

(
[[3, 2, 1], [3, 1], [2]],
[[3, 2, 1], [3, 1], [3]],
[[3, 2, 1], [3, 2], [2]])

(
[[3, 2, 1], [3, 1], [2]],
[[3, 2, 1], [3, 2], [2]],
[[3, 2, 1], [3, 2], [3]])

(
[[3, 2, 1], [3, 1], [3]],
[[3, 2, 1], [3, 2], [2]],
[[3, 2, 1], [3, 2], [3]])

lattice()
Return the lattice of the monotone triangles with \( n \) rows.

EXAMPLES:

```python
sage: M = MonotoneTriangles(3)
sage: P = M.lattice()
sage: P
Finite lattice containing 7 elements
```

```python
sage: from sage.all import *
sage: M = MonotoneTriangles(Integer(3))
sage: P = M.lattice()
sage: P
Finite lattice containing 7 elements
```

class sage.combinat.alternating_sign_matrix.TruncatedStaircases
Bases: Parent

Factory class for the combinatorial class of truncated staircases of size \( n \) with last column \( \text{last_column} \).

EXAMPLES:

```python
sage: t4 = TruncatedStaircases(4, [2, 3]); t4
Truncated staircases of size 4 with last column [2, 3]
sage: t4.cardinality()
4
```

```python
sage: from sage.all import *
sage: t4 = TruncatedStaircases(Integer(4), [Integer(2),Integer(3)]); t4
Truncated staircases of size 4 with last column [2, 3]
sage: t4.cardinality()
4
```

class sage.combinat.alternating_sign_matrix.TruncatedStaircases_nlastcolumn
Bases: TruncatedStaircases

cardinality()

EXAMPLES:

```python
sage: T = TruncatedStaircases(4, [2, 3])
sage: T.cardinality()
4
```
5.1.6 Backtracking

This library contains a generic tool for constructing large sets whose elements can be enumerated by exploring a search space with a (lazy) tree or graph structure.

- **GenericBacktracker**: Depth first search through a tree described by a children function, with branch pruning, etc.

This module has mostly been superseded by `RecursivelyEnumeratedSet`.

```python
>>> from sage.all import *
>>> T = TruncatedStaircases(Integer(4), [Integer(2),Integer(3)])
>>> T.cardinality()
4
```

### Class `sage.combinat.backtrack.GenericBacktracker`

```python
class sage.combinat.backtrack.GenericBacktracker(initial_data, initial_state)
```

Bases: `object`

A generic backtrack tool for exploring a search space organized as a tree, with branch pruning, etc.

See also `RecursivelyEnumeratedSet_forest` for handling simple special cases.

### Class `sage.combinat.backtrack.PositiveIntegerSemigroup`

```python
class sage.combinat.backtrack.PositiveIntegerSemigroup
```

Bases: `UniqueRepresentation`, `RecursivelyEnumeratedSet_forest`

The commutative additive semigroup of positive integers.

This class provides an example of algebraic structure which inherits from `RecursivelyEnumeratedSet_forest`. It builds the positive integers a la Peano, and endows it with its natural commutative additive semigroup structure.

**EXAMPLES:**

```python
sage: from sage.combinat.backtrack import PositiveIntegerSemigroup
sage: PP = PositiveIntegerSemigroup()
sage: PP.category()
Join of Category of monoids and Category of commutative additive semigroups and...
∪ Category of infinite enumerated sets and Category of facade sets
sage: PP.cardinality()
+Infinity
sage: PP.one()
1
sage: PP.an_element()
1
sage: some_elements = list(PP.some_elements()); some_elements
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22,...
∪ 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42,...
∪ 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62,...
∪ 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82,...
∪ 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100]
```

(continues on next page)
children \(x\)

Return the single child \(x + 1\) of the integer \(x\)

EXAMPLES:

```
sage: from sage.combinat.backtrack import PositiveIntegerSemigroup
sage: PP = PositiveIntegerSemigroup()
sage: list(PP.children(1))
[2]
sage: list(PP.children(42))
[43]
```
5.1.7 Baxter permutations

class sage.combinat.baxter_permutations.BaxterPermutations

Bases: UniqueRepresentation, Parent

The combinatorial class of Baxter permutations.

A Baxter permutation is a permutation avoiding the generalized permutation patterns 2 \text{–} 41 \text{–} 3 and 3 \text{–} 14 \text{–} 2. In other words, a permutation \( \sigma \) is a Baxter permutation if for any subword \( u := u_1 u_2 u_3 u_4 \) of \( \sigma \) such that the letters \( u_2 \) and \( u_3 \) are adjacent in \( \sigma \), the standardized version of \( u \) is neither 2413 nor 3142.

INPUT:

* \( n \) – (default: None) a nonnegative integer, the size of the permutations.

OUTPUT:

Return the combinatorial class of the Baxter permutations of size \( n \) if \( n \) is not None. Otherwise, return the combinatorial class of all Baxter permutations.

EXAMPLES:

sage: BaxterPermutations(5)
Baxter permutations of size 5
sage: BaxterPermutations()
Baxter permutations

class sage.combinat.baxter_permutations.BaxterPermutations_all(n=None)

Bases: DisjointUnionEnumeratedSets, BaxterPermutations

The enumerated set of all Baxter permutations.

See BaxterPermutations for the definition of Baxter permutations.

EXAMPLES:

sage: from sage.combinat.baxter_permutations import BaxterPermutations_all
sage: BaxterPermutations_all()
**to_pair_of_twin_binary_trees**(\(p\))
Apply a bijection between Baxter permutations of size \(\texttt{self._n}\) and the set of pairs of twin binary trees with \(\texttt{self._n}\) nodes.

INPUT:

- \(p\) – a Baxter permutation.

OUTPUT:

The pair of twin binary trees \((T_L, T_R)\) where \(T_L\) (resp. \(T_R\)) is obtained by inserting the letters of \(p\) from left to right (resp. right to left) following the binary search tree insertion algorithm. This is called the *Baxter \(P\)-symbol* in [Gir2012] Definition 4.1.

**Note:** This method only works when \(p\) is a permutation. For words with repeated letters, it would return two “right binary search trees” (in the terminology of [Gir2012]), which conflicts with the definition in [Gir2012].

**EXAMPLES:**

```python
sage: BP = BaxterPermutations()
sage: BP.to_pair_of_twin_binary_trees(Permutation([]))  # needs sage.graphs
(., .)
```

```python
sage: BP = BaxterPermutations()
sage: BP.to_pair_of_twin_binary_trees(Permutation([1, 2, 3]))  # needs sage.graphs
(1[., 2[., 3[., .]]], 3[2[1[., .], .], .])
```

```python
sage: BP = BaxterPermutations()
sage: BP.to_pair_of_twin_binary_trees(Permutation([3, 4, 1, 2]))  # needs sage.graphs
(3[1[., 2[., .]], 4[., .]], 2[1[., .], 4[3[., .], .]])
```

**class** `sage.combinat.baxter_permutations.BaxterPermutations_size(n)`

**Bases:** `BaxterPermutations`

The enumerated set of Baxter permutations of a given size.

See `BaxterPermutations` for the definition of Baxter permutations.

**EXAMPLES:**
sage: from sage.combinat.baxter_permutations import BaxterPermutations_size
sage: BaxterPermutations_size(5)
Baxter permutations of size 5

>>> from sage.all import *
>>> from sage.combinat.baxter_permutations import BaxterPermutations_size
>>> BaxterPermutations_size(Integer(5))
Baxter permutations of size 5

cardinality()

Return the number of Baxter permutations of size self._n.

For any positive integer \( n \), the number of Baxter permutations of size \( n \) equals

\[
\sum_{k=1}^{n} \binom{n+1}{k} \binom{n+1}{k+1} \binom{n+1}{k+1+1} \binom{n+1}{k+1+1}.
\]

This is OEIS sequence A001181.

EXAMPLES:

sage: [BaxterPermutations(n).cardinality() for n in range(13)]
[1, 1, 2, 6, 22, 92, 422, 2074, 10754, 58202, 326240, 1882960, 11140560]
sage: BaxterPermutations(3r).cardinality()
6
sage: parent(_)
Integer Ring

>>> from sage.all import *
>>> [BaxterPermutations(n).cardinality() for n in range(Integer(13))]
[1, 1, 2, 6, 22, 92, 2074, 10754, 58202, 326240, 1882960, 11140560]

>>> BaxterPermutations(3).cardinality()
6
>>> parent(_)
Integer Ring

**A guided tour**

Consider the following combinatorial statistics on a permutation:

- \( wex \), the number of weak excedences,
- \( fix \), the number of fixed points,
- \( des \), the number of descents (after appending 0),
- \( adj \), the number of adjacencies (after appending 0), and
- \( llis \), the length of a longest increasing subsequence.

Moreover, let \( rot \) be action of rotation on a permutation, i.e., the conjugation with the long cycle.

It is known that there must exist a statistic \( s \) on permutations, which is equidistributed with \( llis \) but additionally invariant under \( rot \). However, at least very small cases do not contradict the possibility that one can even find a statistic \( s \), invariant under \( rot \) and such that \( (s, wex, fix) \sim (llis, des, adj) \). Let us check this for permutations of size at most 3:

```
sage: N = 3
sage: A = B = [pi for n in range(N+1) for pi in Permutations(n)]
sage: def alpha1(p): return len(p.weak_excedences())
sage: def alpha2(p): return len(p.fixed_points())
sage: def beta1(p): return len(p.descents(final_descent=True)) if p else 0
sage: def beta2(p): return len([e for (e, f) in zip(p, p[1:]+[0]) if e == f+1])
sage: tau = Permutation.longest_increasing_subsequence_length
sage: def rotate_permutation(p):
....:     cycle = Permutation(tuple(range(1, len(p)+1)))
```
....:     return Permutation([cycle.inverse()(p(cycle(i))) for i in range(1, ...

sage: bij = Bijectionist(A, B, tau)
sage: bij.set_statistics((len, len), (alpha1, beta1), (alpha2, beta2))
sage: a, b = bij.statistics_table()
sage: table(a, header_row=True, frame=True)

---
Code for the Strahler number can be obtained from FindStat. The following code is equivalent to `tau = findstat(397)`: 

```
sage: def tau(T):
    ....:     if len(T) == 0:
    ....:         return 1
    ....:     else:
    ....:         1 = [tau(S) for S in T]
    ....:         m = max(l)
    ....:         if 1.count(m) == 1:
    ....:             return m
    ....:         else:
    ....:             return m+1
sage: bij = Bijectionist(A, B, tau)
sage: bij.set_statistics((lambda a: a.size(), lambda b: b.node_number()-1))
sage: from sage.combinat.cyclic_sieving_phenomenon import orbit_decomposition
sage: bij.set_constant_blocks(orbit_decomposition(A, theta))
sage: list(bij.solutions_iterator())
[]
```

Next we demonstrate how to search for a bijection, instead An example identifying s and S:

```
sage: N = 4
sage: A = [dyck_word for n in range(1, N) for dyck_word in DyckWords(n)]
sage: B = [binary_tree for n in range(1, N) for binary_tree in BinaryTrees(n)]
sage: concat_path = lambda D1, D2: DyckWord(list(D1) + list(D2))
sage: concat_tree = lambda B1, B2: concat_path(B1.to_dyck_word(), B2.to_dyck_word()).to_binary_tree()
sage: bij = Bijectionist(A, B)
sage: bij.set_intertwining_relations((2, concat_path, concat_tree))
sage: bij.set_statistics((lambda d: d.semilength(), lambda t: t.node_number()))
sage: for D in sorted(bij.minimal_subdistributions_iterator(), key=lambda x: ...
(continues on next page)
>>> from sage.all import *

>>> N = Integer(4)

>>> A = [dyck_word for n in range(Integer(1), N) for dyck_word in DyckWords(n)]

>>> B = [binary_tree for n in range(Integer(1), N) for binary_tree in BinaryTrees(n)]

>>> concat_path = lambda D1, D2: DyckWord(list(D1) + list(D2))

>>> concat_tree = lambda B1, B2: concat_path(B1.to_dyck_word(), ...

... B2.to_dyck_word()).to_binary_tree()

>>> bij = Bijectionist(A, B)

>>> bij.set_intertwining_relations((Integer(2), concat_path, concat_tree))

>>> bij.set_statistics((

... lambda d: d.semilength(),

... lambda t: t.node_number()))

>>> for D in sorted(bij.minimal_subdistributions_iterator(), key=lambda x: ...

... len(x[Integer(0)][Integer(0)]), x):

... ascii_art(D)

(continues on next page)
The output is in a form suitable for FindStat:

```sage
sage: findmap(list(bij.minimal_subdistributions_iterator()))
# optional --

```

```python
>>> from sage.all import *

>>> findmap(list(bij.minimal_subdistributions_iterator()))
# optional --
˓→ internet
0: Mp00034 (quality [100])
1: Mp00061oMp00023 (quality [100])
2: Mp00018oMp00140 (quality [100])
```

```python
class sage.combinat.bijectionist.Bijectionist (A, B, tau=None, alpha_beta=(), P=None, pi_rho=(), phi_psi=(), Q=None, 
elements_distributions=(), value_restrictions=(), solver=None, key=None)

Bases: SageObject
```

A toolbox to list all possible bijections between two finite sets under various constraints.

**INPUT:**

- A, B – sets of equal size, given as a list
- tau – (optional) a function from B to \(\mathbb{Z}\), in case of None, the identity map \(\lambda x: x\) is used
- alpha_beta – (optional) a list of pairs of statistics alpha from A to \(\mathbb{W}\) and beta from B to \(\mathbb{W}\)
- P – (optional) a partition of A
- pi_rho – (optional) a list of triples \((k, p_i, r_i)\), where
  - \(p_i\) – a \(k\)-ary operation composing objects in A and
  - \(r_i\) – a \(k\)-ary function composing statistic values in \(\mathbb{Z}\)
- elements_distributions – (optional) a list of pairs \((tA, tZ)\), specifying the distributions of tA
- value_restrictions – (optional) a list of pairs \((a, tZ)\), restricting the possible values of a
- solver – (optional) the backend used to solve the mixed integer linear programs

\(\mathbb{W}\) and \(\mathbb{Z}\) can be arbitrary sets. As a natural example we may think of the natural numbers or tuples of integers.

We are looking for a statistic \(s: A \rightarrow \mathbb{Z}\) and a bijection \(S: A \rightarrow B\) such that

- \(s = \tau \circ S\): the statistics \(s\) and \(\tau\) are equidistributed and \(S\) is an intertwining bijection.
- \(\alpha = \beta \circ S\): the statistics \(\alpha\) and \(\beta\) are equidistributed and \(S\) is an intertwining bijection.
- \(s\) is constant on the blocks of \(P\).
- \(s(\pi(a_1, \ldots, a_k)) = \rho(s(a_1), \ldots, s(a_k))\).

Additionally, we may require that

- \(s(a) \in Z_a\) for specified sets \(Z_a \subseteq \mathbb{Z}\), and
• \( s|_{\tilde{A}} \) has a specified distribution for specified sets \( \tilde{A} \subset A \).

If \( \tau \) is the identity, the two unknown functions \( s \) and \( S \) coincide. Although we do not exclude other bijective choices for \( \tau \), they probably do not make sense.

If we want that \( S \) is graded, i.e. if elements of \( A \) and \( B \) have a notion of size and \( S \) should preserve this size, we can add grading statistics as \( \alpha \) and \( \beta \). Since \( \alpha \) and \( \beta \) will be equidistributed with \( S \) as an intertwining bijection, \( S \) will then also be graded.

In summary, we have the following two commutative diagrams, where \( s \) and \( S \) are unknown functions.

\[
\begin{array}{ccc}
A & \xrightarrow{s} & A^k \\
\downarrow{s^k} & & \downarrow{s} \\
Z & \xrightarrow{\varphi} & Z
\end{array}
\]

\[
\begin{array}{ccc}
\alpha \leftarrow W & \xrightarrow{S} & A \\
B & \xrightarrow{s} & Z \\
\beta \leftarrow Z & \xrightarrow{\varphi} & Z
\end{array}
\]

Note: If \( \tau \) is the identity map, the partition \( P \) of \( A \) necessarily consists only of singletons.

Note: The order of invocation of the methods with prefix set, i.e., set_statistics(), set_interwining_relations(), set_constant_blocks(), etc., is irrelevant. Calling any of these methods a second time overrides the previous specification.

**constant_blocks** *(singletons=False, optimal=False)*

Return the set partition \( P \) of \( A \) such that \( s : A \to Z \) is known to be constant on the blocks of \( P \).

INPUT:

- **singletons** – (default: False) whether or not to include singleton blocks in the output
- **optimal** – (default: False) whether or not to compute the coarsest possible partition

Note: computing the coarsest possible partition may be computationally expensive, but may speed up generating solutions.

**EXAMPLES:**

```
sage: A = B = ['a', 'b', 'c']
sage: bij = Bijectionist(A, B, lambda x: 0)
sage: bij.set_constant_blocks(['a', 'b'])
sage: bij.constant_blocks()
{{'a'}, {'b'}}
sage: bij.constant_blocks(singletons=True)
{{'a'}, {'b'}, {'c'}}
```

```
>>> from sage.all import *
>>> A = B = ['a', 'b', 'c']
>>> bij = Bijectionist(A, B, lambda x: Integer(0))
>>> bij.set_constant_blocks(['a', 'b'])
>>> bij.constant_blocks()
{{'a'}, {'b'}}
>>> bij.constant_blocks(singletons=True)
{{'a'}, {'b'}, {'c'}}
```
minimal_subdistributions_blocks_iterator()  
Return all representatives of minimal subsets $\tilde{P}$ of $P$ together with submultisets $\tilde{Z}$ with $s(\tilde{P}) = \tilde{Z}$ as multisets.

**Warning:** If there are several solutions with the same support (i.e., the sets of block representatives are the same), only one of these will be found, even if the distributions are different, see the doctest below. To find all solutions, use `minimal_subdistributions_iterator()`, which is, however, computationally more expensive.

**EXAMPLES:**

```python
sage: A = B = [permutation for n in range(3) for permutation in Permutations(n)]
sage: bij = Bijectionist(A, B, len)
sage: bij.set_statistics((len, len))
sage: for sol in bij.solutions_iterator():
    print(sol)
{[]} 0, [1] 1, [[1], [1]] 2, [[2], [1]] 2

sage: sorted(bij.minimal_subdistributions_blocks_iterator())
([[]], [0]), ([[1]], [1]), ([[1, 2]], [2]), ([[2, 1]], [2])
```

Another example:

```python
sage: N = 2; A = B = [dyck_word for n in range(N+1) for dyck_word in DyckWords(n)]
sage: def tau(D):
    return D.number_of_touch_points()
sage: bij = Bijectionist(A, B, tau)
sage: bij.set_statistics((lambda d: d.semilength(), lambda d: d.semilength()))
sage: for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    print(solution)
{[]} 0, [1, 0] 1, [[1, 0], [1]] 2,
[[[1, 0]], [1]], [[1, 0], [1]], [[1, 0], [1]], [[1, 0], [1]]

sage: for subdistribution in bij.minimal_subdistributions_blocks_iterator():
    print(subdistribution)
([[]], [0]),
([[], [1], [1], [1]], [1]),
([[1, 0, 1, 0], [1, 1, 0, 0]], [1, 2])
```

```python
>>> from sage.all import *

>>> N = Integer(2); A = B = [dyck_word for n in range(N+1) for dyck_word in DyckWords(n)]

>>> def tau(D):
    return D.number_of_touch_points()

>>> bij = Bijectionist(A, B, tau)
```

(continues on next page)
An example with two elements of the same block in a subdistribution:

```sage
A = B = ['a', 'b', 'c', 'd', 'e']
tau = {'a': 1, 'b': 1, 'c': 2, 'd': 2, 'e': 3}.get
bij = Bijectionist(A, B, tau)
```

```sage
bij.set_constant_blocks([['a', 'b']])
```

```sage
bij.set_value_restrictions(('a', [1, 2]))
```

```sage
bij.constant_blocks(optimal=True)
```

```sage
sorted(bij.solutions_iterator(), key=lambda d: tuple(sorted(d.items())))
```

```sage

{'a': 1, 'b': 2, 'c': 2, 'd': 3, 'e': 1},
{'a': 1, 'b': 2, 'c': 3, 'd': 2, 'e': 1},
{'a': 2, 'b': 1, 'c': 1, 'd': 3, 'e': 2},
{'a': 2, 'b': 1, 'c': 3, 'd': 1, 'e': 2}
```

```sage
bij.constant_blocks(optimal=True)
```

```sage
list(bij.minimal_subdistributions_blocks_iterator())
```

```sage
[(['b', 'b', 'c', 'd', 'e'], [1, 1, 2, 2, 3])]
```

An example with overlapping minimal subdistributions:

```sage
A = B = ['a', 'b', 'c', 'd', 'e']
tau = {'a': 1, 'b': 1, 'c': 2, 'd': 2, 'e': 3}.get
bij = Bijectionist(A, B, tau)
```

```sage
bij.set_distributions((['a', 'b'], [1, 2]), ('a', 'c', 'd'), [1, 2, 3])
```

```sage
sorted(bij.solutions_iterator(), key=lambda d: tuple(sorted(d.items())))
```

```sage

{'a': 1, 'b': 2, 'c': 2, 'd': 3, 'e': 1},
{'a': 1, 'b': 2, 'c': 3, 'd': 2, 'e': 1},
{'a': 2, 'b': 1, 'c': 1, 'd': 3, 'e': 2},
{'a': 2, 'b': 1, 'c': 3, 'd': 1, 'e': 2}
```

```sage
bij.constant_blocks(optimal=True)
```

```sage
list(bij.minimal_subdistributions_blocks_iterator())
```

```sage
[(['b', 'b'], [1, 2]), ('a', 'c', 'd'), [1, 2, 3])]
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> bij = Bijectionist(A, B, tau)
>>> bij.set_distributions((["a", "b"], [Integer(1), Integer(2)]), (["a", "c", "d"], [Integer(1), Integer(2), Integer(3)]))
>>> sorted(bij.solutions_iterator(), key=lambda d: tuple(sorted(d.items())))
[{a: 1, b: 2, c: 2, d: 3, e: 1},
 {a: 1, b: 2, c: 3, d: 2, e: 1},
 {a: 2, b: 1, c: 1, d: 3, e: 2},
 {a: 2, b: 1, c: 3, d: 1, e: 2}]
>>> bij.constant_blocks(optimal=True)
{{a, e}}
>>> list(bij.minimal_subdistributions_blocks_iterator())
[([a, b], [1, 2]), ([a, c, d], [1, 2, 3])]

Fedor Petrov’s example from https://mathoverflow.net/q/424187:

```python
sage: A = B = ["a"+str(i) for i in range(1, 9)] + ["b"+str(i) for i in range(3, 9)] + ["d"]
sage: tau = {b: Integer(0) if i < Integer(10) else Integer(1) for i, b in enumerate(B)}.get
sage: bij = Bijectionist(A, B, tau)
sage: bij.set_constant_blocks(["a"+str(i), "b"+str(i)] for i in range(1, 9) if "b"+str(i) in A)
sage: d = [0]*8+[1]*4
sage: sorted(bij.minimal_subdistributions_blocks_iterator())
((['a1', 'a2', 'a3', 'a4', 'a5', 'a6', 'a7', 'a8', 'a8'],
  [0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 1, 1, 1]),
 (["a1", 'a2', 'a3', 'a4', 'a5', 'a6', 'a7', 'a8', 'a8'],
  [0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 1, 1, 1]),
 (["a3", 'a4', 'd'], [0, 0, 1]))

(sage.solutions_iterator())
[0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 1, 1, 1])

>>> from sage.all import *

>>> A = B = ["a"+str(i) for i in range(Integer(1), Integer(9))] + ["b"+str(i) for i in range(3, 9)] + ["d"]
>>> tau = {b: Integer(0) if i < Integer(10) else Integer(1) for i, b in enumerate(B)}.get
>>> bij = Bijectionist(A, B, tau)
>>> bij.set_constant_blocks(["a"+str(i), "b"+str(i)] for i in range(Integer(1), Integer(9)) if "b"+str(i) in A)
>>> d = [Integer(0)]*Integer(8)+[Integer(1)]*Integer(4)
>>> sorted(bij.minimal_subdistributions_blocks_iterator())
([0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 1, 1, 1]),
 (["a7", 'a8', 'd'], [0, 0, 1])]
```

(continues on next page)
5.1. Comprehensive Module List

[0, 1, 0, 1, 0, 0, 0, 1, 0, 1, 0, 0, 0, 1, 0],
[0, 1, 0, 1, 0, 0, 0, 1, 0, 1, 0, 0, 0, 1, 0],
[0, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0, 0, 1, 0, 0],
[1, 0, 0, 1, 0, 0, 0, 1, 0, 1, 0, 0, 0, 1, 0],
[1, 0, 1, 0, 0, 0, 1, 0, 1, 0, 0, 0, 1, 0, 0],
[1, 1, 0, 0, 0, 1, 0, 0, 0, 0, 0, 1, 0, 0, 1],
[1, 1, 0, 0, 1, 0, 0, 0, 0, 0, 1, 0, 0, 0, 1],
[1, 1, 0, 0, 0, 1, 0, 0, 0, 0, 1, 0, 0, 0, 1],

>>> sorted(bij.minimal_subdistributions_blocks_iterator())  # random
[(['a1', 'a2', 'a3', 'a4', 'a5', 'a6', 'a7', 'a8', 'a8'],
  [0, 0, 0, 0, 0, 0, 0, 1, 1, 1, 1]),
(['a3', 'a4', 'd'], [0, 0, 1]),
(['a7', 'a8', 'd'], [0, 0, 1])]

The following solution is not found, because it happens to have the same support as the other:

```python
sage: D = set(A).difference(['b7', 'b8', 'd'])
sage: sorted(a.replace("b", "a") for a in D)
['a1', 'a2', 'a3', 'a3', 'a4', 'a4', 'a5', 'a5', 'a6', 'a6', 'a7', 'a8']
```

```python
sage: set(tuple(sorted(s[a] for a in D)) for s in bij.solutions_iterator())
{(0, 0, 0, 0, 0, 0, 0, 1, 1, 1, 1, 1)}
```

But it is, by design, included here:

```python
>>> from sage.all import *

>>> D = set(A).difference(['b7', 'b8', 'd'])
>>> sorted(a.replace("b", "a") for a in D)
(['a1', 'a2', 'a3', 'a3', 'a4', 'a4', 'a5', 'a5', 'a6', 'a6', 'a7', 'a8']
>>> set(tuple(sorted(s[a] for a in D)) for s in bij.solutions_iterator())
{(0, 0, 0, 0, 0, 0, 0, 1, 1, 1, 1, 1)}
```

minimal_subdistributions_iterator()

Return all minimal subsets \( \tilde{A} \) of \( A \) together with submultisets \( \tilde{Z} \) with \( s(\tilde{A}) = \tilde{Z} \) as multisets.

EXAMPLES:

```python
sage: A = B = [permutation for n in range(3) for permutation in Permutations(n)]
sage: bij = Bijectionist(A, B, len)
sage: bij.set_statistics((len, len))
sage: for sol in bij.solutions_iterator():
....:     print(sol)
([0], [1], [2], [1, 2])
```

```python
sage: sorted(bij.minimal_subdistributions_iterator())
[[[[[], []], [[[], []], [1, []]]], [1]], [1], [1, 2], [1, 2], [1, 2]], []]}}
```
```python
>>> from sage.all import *
>>> A = B = [permutation for n in range(Integer(3)) for permutation in Permutations(n)]
>>> bij = Bijectionist(A, B, len)
>>> bij.set_statistics((len, len))
>>> for sol in bij.solutions_iterator():
...   print(sol)
...
{[{}]: 0, [1]: 1, [1, 2]: 2, [2, 1]: 2}
>>> sorted(bij.minimal_subdistributions_iterator())
[([], [0]), ([1], [1]), ([1, 2], [2]), ([2, 1], [2])]

Another example:

```python
sage: N = 2; A = B = [dyck_word for n in range(N+1) for dyck_word in DyckWords(n)]
sage: def tau(D):
    return D.number_of_touch_points()
sage: bij = Bijectionist(A, B, tau)
sage: bij.set_statistics((lambda d: d.semilength(), lambda d: d.semilength()))
sage: for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    ...
    print(solution)
...
{[{}]: 0, [1, 0]: 1, [1, 0, 1, 0]: 1, [1, 1, 0, 0]: 2}
{[{}]: 0, [1, 0]: 1, [1, 0, 1, 0]: 2, [1, 1, 0, 0]: 1}
sage: for subdistribution in bij.minimal_subdistributions_iterator():
    ...
    print(subdistribution)
([[], [0])
([1, 0], [1])
([1, 0, 1, 0], [1, 1, 0, 0]), [1, 2])

```python
>>> from sage.all import *
>>> N = Integer(2); A = B = [dyck_word for n in range(N+Integer(1)) for dyck_word in DyckWords(n)]
>>> def tau(D):
    return D.number_of_touch_points()
>>> bij = Bijectionist(A, B, tau)
>>> bij.set_statistics((lambda d: d.semilength(), lambda d: d.semilength()))
>>> for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
...   print(solution)
...
{[{}]: 0, [1, 0]: 1, [1, 0, 1, 0]: 1, [1, 1, 0, 0]: 2}
{[{}]: 0, [1, 0]: 1, [1, 0, 1, 0]: 2, [1, 1, 0, 0]: 1}
>>> for subdistribution in bij.minimal_subdistributions_iterator():
...   print(subdistribution)
...
([[], [0])
([1, 0], [1])
([1, 0, 1, 0], [1, 1, 0, 0]), [1, 2])
```

An example with two elements of the same block in a subdistribution:

```python
sage: A = B = ["a", "b", "c", "d", "e"]
sage: tau = {"a": 1, "b": 1, "c": 2, "d": 2, "e": 3}.get
sage: bij = Bijectionist(A, B, tau)
sage: bij.set_constant_blocks(["a", "b",])
sage: bij.set_value_restrictions("a", [1, 2])
sage: bij.constant_blocks(optimal=True)
{{a, b}}
sage: list(bij.minimal_subdistributions_iterator())
[([], [1, 1, 2, 2, 3])]
```

An example with two elements of the same block in a subdistribution:
```python
>>> from sage.all import *
>>> A = B = ["a", "b", "c", "d", "e"]
>>> tau = {"a": Integer(1), "b": Integer(1), "c": Integer(2), "d": Integer(2), "e": Integer(3)}.get
>>> bij = Bijectionist(A, B, tau)
>>> bij.set_constant_blocks(["a", "b"])
>>> bij.set_value_restrictions("a", [Integer(1), Integer(2)])
>>> bij.constant_blocks(optimal=True)
{"a": {1}, "b": {1}, "c": {1, 2}, "d": {1, 2}}
```

### possible_values

**possible_values** \((p=None,\; optimal=False)\)

Return for each block the values of \(s\) compatible with the imposed restrictions.

**INPUT:**

- \(p\) – (optional) a block of \(P\), or an element of a block of \(P\), or a list of these
- \(optimal\) – (default: False) whether or not to compute the minimal possible set of statistic values

**Note:** Computing the minimal possible set of statistic values may be computationally expensive.

**Todo:** currently, calling this method with \(optimal=True\) does not update the internal dictionary, because this would interfere with the variables of the MILP.

**EXAMPLES:**

```python
sage: A = B = ["a", "b", "c", "d"]
sage: tau = {"a": 1, "b": 1, "c": 1, "d": 2}.get
sage: bij = Bijectionist(A, B, tau)
sage: bij.set_constant_blocks(["a", "b"])
sage: bij.possible_values(A)
{a: {1, 2}, b: {1, 2}, c: {1, 2}, d: {1, 2}}
sage: bij.possible_values(A, optimal=True)
{a: {1}, b: {1}, c: {1, 2}, d: {1, 2}}
```

```python
>>> from sage.all import *
>>> A = B = ["a", "b", "c", "d"]
>>> tau = {"a": Integer(1), "b": Integer(1), "c": Integer(1), "d": Integer(2)}.get
>>> bij = Bijectionist(A, B, tau)
>>> bij.set_constant_blocks(["a", "b"])
>>> bij.possible_values(A)
{a: {1, 2}, b: {1, 2}, c: {1, 2}, d: {1, 2}}
>>> bij.possible_values(A, optimal=True)
{a: {1}, b: {1}, c: {1, 2}, d: {1, 2}}
```

The internal dictionary is not updated:

```python
sage: bij.possible_values(A)
{a: {1, 2}, b: {1, 2}, c: {1, 2}, d: {1, 2}}
```
The function `bij.possible_values(A)` returns the possible values of `A`:

```
{'a': {1, 2}, 'b': {1, 2}, 'c': {1, 2}, 'd': {1, 2}}
```

The function `set_constant_blocks(P)` declares that $s : A \rightarrow Z$ is constant on each block of $P$.

**Warning:** Any restriction imposed by a previous invocation of `set_constant_blocks()` will be overwritten, including restrictions discovered by `set_intertwining_relations()` and `solutions_iterator()`!

A common example is to use the orbits of a bijection acting on $A$. This can be achieved using the function `orbit_decomposition()`.

**INPUT:**
- $P$ – a set partition of $A$, singletons may be omitted

**EXAMPLES:**
Initially the partitions are set to singleton blocks. The current partition can be reviewed using `constant_blocks()`:

```
sage: A = B = 'abcd'
sage: bij = Bijectionist(A, B, lambda x: B.index(x) % 2)
sage: bij.constant_blocks()
{}
sage: bij.set_constant_blocks([['a', 'c']])
sage: bij.constant_blocks()
{{'a', 'c'}}
```

We now add a map that combines some blocks:

```
sage: def pi(p1, p2): return 'abcdefgh'[A.index(p1) + A.index(p2)]
sage: def rho(s1, s2): return (s1 + s2) % Integer(2)
sage: bij.set_intertwining_relations((2, pi, rho))
sage: list(bij.solutions_iterator())
[{a: 0, b: 1, c: 0, d: 1}]
sage: bij.constant_blocks()
{{'a', 'c'}, {'b', 'd'}}
```

(continues on next page)
>>> bij.set_intertwining_relations((Integer(2), pi, rho))
>>> list(bij.solutions_iterator())
[{'a': 0, 'b': 1, 'c': 0, 'd': 1}]
>>> bij.constant_blocks()
{{'a', 'c'}, {'b', 'd'}}

Setting constant blocks overrides any previous assignment:

```
sage: bij.set_constant_blocks([[a, b]])
sage: bij.constant_blocks()
{{a, b}}
```

If there is no solution, and the coarsest partition is requested, an error is raised:

```
sage: bij.constant_blocks(optimal=True)
Traceback (most recent call last):
... StopIteration
```

**set_distributions** (*elements_distributions*)

Specify the distribution of $s$ for a subset of elements.

**Warning:** Any restriction imposed by a previous invocation of **set_distributions()** will be overwritten!

**INPUT:**

- one or more pairs of $(\hat{A}, \hat{Z})$, where $\hat{A} \subseteq A$ and $\hat{Z}$ is a list of values in $Z$ of the same size as $\hat{A}$

This method specifies that $\{s(a) | a \in \hat{A}\}$ equals $\hat{Z}$ as a multiset for each of the pairs.

When specifying several distributions, the subsets of $A$ do not have to be disjoint.

**ALGORITHM:**

We add

$$\sum_{a \in \hat{A}} x_{p(a), z} t^z = \sum_{z \in \hat{Z}} t^z,$$

where $p(a)$ is the block containing $a$, for each given distribution as a vector equation to the MILP.

**EXAMPLES:**
sage: A = B = [permutation for n in range(4) for permutation in Permutations(n)]

sage: tau = Permutation.longest_increasing_subsequence_length

sage: bij = Bijectionist(A, B, tau)

sage: bij.set_statistics((len, len))

sage: bij.set_distributions(([Permutation([1, 2, 3]), Permutation([1, 3, 2])], [1, 3]))

sage: for sol in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    print(sol)

>>> from sage.all import *

>>> A = B = [permutation for n in range(Integer(4)) for permutation in Permutations(n)]

>>> tau = Permutation.longest_increasing_subsequence_length

>>> bij = Bijectionist(A, B, tau)

>>> bij.set_statistics((len, len))

>>> bij.set_distributions(([Permutation([Integer(1), Integer(2), Integer(3)]), Permutation([Integer(1), Integer(3), Integer(2)])], [Integer(1), Integer(3)]))

>>> for sol in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    print(sol)

>>> bij.constant_blocks(optimal=True)

{{[2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]}}

>>> sorted(bij.minimal_subdistributions_blocks_iterator(), key=lambda d: (len(d[Integer(0)]), d[Integer(0)]))

[([], [0]), ([1], [1]), ([2, 1, 3], [2]), ([1, 2], [1, 2]), ([1, 2, 3], [1, 2, 3]), ([1, 3, 2], [1, 3, 2]), ([2, 1, 3], [2, 1, 3]), ([2, 3, 1], [2, 3, 1]), ([3, 1, 2], [3, 1, 2]), ([3, 2, 1], [3, 2, 1])]

(continues on next page)
We may also specify multiple, possibly overlapping distributions:

```python
sage: bij.set_distributions(((Permutation([1, 2, 3]), Permutation([1, 3, 2])), ...
...: (Permutation([3, 2, 1]), Permutation([3, 1, 2])), ...
...: (Permutation([2, 1, 3]), Permutation([2, 3, 1]), Permutation([1, 2, 3]))
```

```python
sage: for sol in sorted(list(bij.solutions_iterator()), key=lambda d:...
...: tuple(sorted(d.items()))):
...
...: print(sol)
```

```python
{{[1], [1, 3, 2]}, {[2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]}}
```

```python
sage: sorted(bij.minimal_subdistributions_blocks_iterator(), key=lambda d:...
...: (len(d[0]), d[0]))
```

```python
[(([], [0]), ([1], [1]), ([2, 1, 3], [3]), ([2, 3, 1], [2]), ([1, 2], [1, 2]), ([1, 2], [2, 1])]
```

```python
>>> from sage.all import *
```

```python
>>> bij.set_distributions(((Permutation([Integer(1), Integer(2), Integer(3)]),...
...: Permutation([Integer(1), Integer(3), Integer(2)])), [Integer(1),...
...: Integer(3)],...
...: (Permutation([Integer(1), Integer(3), Integer(2)]),...
...: Permutation([Integer(2), Integer(1), Integer(3)]),...
...: [Integer(1), Integer(2), Integer(2)]))
```

```python
>>> for sol in sorted(list(bij.solutions_iterator()), key=lambda d:...
...: tuple(sorted(d.items()))):
...
...: print(sol)
```

```python
{{[1], [1, 3, 2]}, {[2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]}}
```

```python
>>> sorted(bij.minimal_subdistributions_blocks_iterator(), key=lambda d:...
...: (len(d[Integer(0)]), d[Integer(0)]))
```

```python
[(([], [0]), ([1], [1]), ([1, 2, 3], [3]), ([2, 3, 1], [2]), ([1, 2], [1, 2]), ([1, 2], [2, 1])]
```

**set_homomesic**$(Q)$

Assert that the average of $s$ on each block of $Q$ is constant.

**INPUT:**

5.1. Comprehensive Module List
Combinatorics, Release 10.4

- $Q$ - a set partition of $A$

**EXAMPLES:**

```
sage: A = B = [1,2,3]
sage: bij = Bijectionist(A, B, lambda b: b % 3)
sage: bij.set_homomesic([[1,2], [3]])
sage: list(bij.solutions_iterator())
```

```
>>> from sage.all import *
>>> A = B = [Integer(1),Integer(2),Integer(3)]
>>> bij = Bijectionist(A, B, lambda b: b % Integer(3))
>>> bij.set_homomesic([[Integer(1),Integer(2)], [Integer(3)]]
>>> list(bij.solutions_iterator())
```

set_intertwining_relations(*pi_rho*)

Add restrictions of the form $s(\pi(a_1, \ldots, a_k)) = \rho(s(a_1), \ldots, s(a_k))$.

**Warning:** Any restriction imposed by a previous invocation of `set_intertwining_relations()` will be overwritten!

**INPUT:**
- `pi_rho` - one or more tuples $(k, \pi : A^k \to A, \rho : Z^k \to Z, \tilde{A})$ where $\tilde{A}$ (optional) is a k-ary function that returns true if and only if a k-tuple of objects in $A$ is in the domain of $\pi$

**ALGORITHM:**

The relation

$$s(\pi(a_1, \ldots, a_k)) = \rho(s(a_1), \ldots, s(a_k))$$

for each pair $(\pi, \rho)$ implies immediately that $s(\pi(a_1, \ldots, a_k))$ only depends on the blocks of $a_1, \ldots, a_k$.

The MILP formulation is as follows. Let $a_1, \ldots, a_k \in A$ and let $a = \pi(a_1, \ldots, a_k)$. Let $z_1, \ldots, z_k \in Z$ and let $z = \rho(z_1, \ldots, z_k)$. Suppose that $a_i \in p_i$ for all $i$ and that $a \in p$.

We then want to model the implication

$$x_{p_1, z_1} = 1, \ldots, x_{p_k, z_k} = 1 \Rightarrow x_{p, z} = 1.$$ 

We achieve this by requiring

$$x_{p, z} \geq 1 - k + \sum_{i=1}^{k} x_{p_i, z_i}.$$ 

Note that $z$ must be a possible value of $p$ and each $z_i$ must be a possible value of $p_i$.

**EXAMPLES:**

We can concatenate two permutations by increasing the values of the second permutation by the length of the first permutation:

```
sage: def concat(p1, p2): return Permutation(p1 + [i + len(p1) for i in p2])
```
We may be interested in statistics on permutations which are equidistributed with the number of fixed points, such that concatenating permutations corresponds to adding statistic values:

```python
>>> from sage.all import *

>>> def concat(p1, p2):
...     return Permutation(p1 + [i + len(p1) for i in p2])

>>> A = B = [permutation for n in range(4) for permutation in Permutations(n)]

>>> bij = Bijectionist(A, B, Permutation.number_of_fixed_points)
>>> bij.set_statistics((len, len))

>>> for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
...     print(solution)
...     ...
...     {[0]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 0, [2, 1, 3]: 0, [2, 3, 1]: 1, [3, 1, 2]: 0, [3, 2, 1]: 1}
...     ...

>>> bij.set_intertwining_relations((2, concat, lambda x, y: x + y))

>>> for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
...     print(solution)
...     ...
...     {[0]: 0, [1]: 1, [1, 2]: 2, [2, 1]: 0, [1, 2, 3]: 3, [1, 3, 2]: 1, [2, 1, 3]: 1, [2, 3, 1]: 0, [3, 1, 2]: 1, [3, 2, 1]: 0}
...     ...

(continues on next page)
```
The domain of the composition may be restricted. E.g., if we concatenate only permutations starting with a 1, we obtain fewer forced elements:

```python
sage: in_domain = lambda p1, p2: (not p1 or p1(1) == 1) and (not p2 or p2(1) == 1)
sage: bij.set_intertwining_relations((2, concat, lambda x, y: x + y, in_domain))
sage: for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    print(solution)
```

(continues on next page)
We can also restrict according to several composition functions. For example, we may additionally concatenate permutations by incrementing the elements of the first:

```python
sage: skew_concat = lambda p1, p2: Permutation([i + len(p2) for i in p1] + list(p2))

sage: bij.set_intertwining_relations((2, skew_concat, lambda x, y: x + y))

sage: for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    ...:     print(solution)
```
ALGORITHM:

We add

\[ x_{p(a), z} = x_{p(\psi(z)), \phi(a)} \]

for \( a \in A \) and \( z \in Z \) to the MILP, where \( \phi : A \to Z \) and \( \psi : Z \to A \). Note that, in particular, \( \phi \) must be constant on blocks.

EXAMPLES:

```python
sage: A = B = DyckWords(3)
sage: bij = Bijectionist(A, B)
sage: bij.set_statistics((lambda D: D.number_of_touch_points(), lambda D: D.number_of_initial_rises()))
sage: ascii_art(sorted(bij.minimal_subdistributions_iterator()))
```

```
[ ( [ / \ ] )
  ( [ / \ ] [ / \ ] [ / \ ] )
  ( [ / / \ ] [ / ] [ / ] ), ( [ / / \ ], [ / ] ), ( [ / / \ ], [ / ] )],

[ [ / / \ ] [ / \ ] [ / \ ] )
  ( [ / / \ ] [ / ] [ / ] )
  ( [ / / \ ] [ / ] )
  ( [ / ] [ / ] )
  ( [ / ] [ / ] )
]

```

```python
sage: bij.set_quadratic_relation((lambda D: D, lambda D: D))
sage: ascii_art(sorted(bij.minimal_subdistributions_iterator()))
```

```
[ ( [ / \ ] )
  ( [ / ] [ / ] ) [ / \ ] [ / \ ]
  ( [ / / \ ] [ / ] [ / ] )
  ( [ / / \ ] [ / ] )
  ( [ / ] [ / ] )
  ( [ / ] [ / ] )
]
```

```python
>>> from sage.all import *
>>> A = B = DyckWords(Integer(3))
>>> bij = Bijectionist(A, B)
>>> bij.set_statistics((lambda D: D.number_of_touch_points(), lambda D: D.number_of_initial_rises()))
>>> ascii_art(sorted(bij.minimal_subdistributions_iterator()))
```

```
[ ( [ / \ ] )
  ( [ / \ ] [ / \ ] [ / \ ] )
  ( [ / / \ ] [ / ] [ / ] )
  ( [ / / \ ] [ / ] )
  ( [ / ] [ / ] )
  ( [ / ] [ / ] )
]
```

```python
>>> bij.set_quadratic_relation((lambda D: D, lambda D: D))

```

```
[ ( [ / \ ] )
  ( [ / ] [ / ] ) [ / \ ] [ / \ ]
  ( [ / / \ ] [ / ] [ / ] )
  ( [ / / \ ] [ / ] )
  ( [ / ] [ / ] )
  ( [ / ] [ / ] )
]
```

(continues on next page)
**set_semi_conjugacy** (*pi_rho*)

Add restrictions of the form \( s(\pi(a_1, \ldots, a_k)) = \rho(s(a_1), \ldots, s(a_k)) \).

**Warning:** Any restriction imposed by a previous invocation of \( \text{set_intertwining_relations()} \) will be overwritten!

**INPUT:**

- \( \text{pi_rho} \) — one or more tuples \((k, \pi : A^k \to A, \rho : Z^k \to Z, \tilde{A} \) (optional)\) where \( \tilde{A} \) is a k-ary function that returns true if and only if a k-tuple of objects in \( A \) is in the domain of \( \pi \)

**ALGORITHM:**

The relation

\[
s(\pi(a_1, \ldots, a_k)) = \rho(s(a_1), \ldots, s(a_k))
\]

for each pair \((\pi, \rho)\) implies immediately that \( s(\pi(a_1, \ldots, a_k)) \) only depends on the blocks of \( a_1, \ldots, a_k \).

The MILP formulation is as follows. Let \( a_1, \ldots, a_k \in A \) and let \( a = \pi(a_1, \ldots, a_k) \). Let \( z_1, \ldots, z_k \in Z \) and let \( z = \rho(z_1, \ldots, z_k) \). Suppose that \( a_i \in p_i \) for all \( i \) and that \( a \in p \).

We then want to model the implication

\[
x_{p_1, z_1} = 1, \ldots, x_{p_k, z_k} = 1 \Rightarrow x_{p,z} = 1.
\]

We achieve this by requiring

\[
x_{p,z} \geq 1 - k + \sum_{i=1}^{k} x_{p_i,z_i}.
\]

Note that \( z \) must be a possible value of \( p \) and each \( z_i \) must be a possible value of \( p_i \).

**EXAMPLES:**

We can concatenate two permutations by increasing the values of the second permutation by the length of the first permutation:

```python
sage: def concat(p1, p2): return Permutation(p1 + [i + len(p1) for i in p2])
```

```python
>>> from sage.all import *
>>> def concat(p1, p2): return Permutation(p1 + [i + len(p1) for i in p2])
```

We may be interested in statistics on permutations which are equidistributed with the number of fixed points, such that concatenating permutations corresponds to adding statistic values:

```python
sage: A = B = [permutation for n in range(4) for permutation in Permutations(n)]
sage: bij = Bijectionist(A, B, Permutation.number_of_fixed_points)
```
sage: bij.set_statistics((len, len))
sage: for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    ...:
    print(solution)
    ...
{[ ]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 0, [2, 1, 3]: 0, [2, 3, 1]: 1, [3, 1, 2]: 1, [3, 2, 1]: 3}
...

sage: bij.set_intertwining_relations((2, concat, lambda x, y: x + y))
sage: for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    ...
    print(solution)
    ...
{[ ]: 0, [1]: 1, [1, 2]: 2, [2, 1]: 0, [1, 2, 3]: 3, [1, 3, 2]: 1, [2, 1, 3]: 1, [2, 3, 1]: 0, [3, 1, 2]: 0, [3, 2, 1]: 1}
...

>>> from sage.all import *
>>> A = B = [permutation for n in range(Integer(4)) for permutation in Permutations(n)]
>>> bij = Bijectionist(A, B, Permutation.number_of_fixed_points)
>>> bij.set_statistics((len, len))
>>> for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    ...
    print(solution)
    ...
{[ ]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 0, [2, 1, 3]: 0, [2, 3, 1]: 1, [3, 1, 2]: 1, [3, 2, 1]: 3}
...

>>> bij.set_intertwining_relations((2, concat, lambda x, y: x + y))
>>> for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    ...
    print(solution)
    ...
{[ ]: 0, [1]: 1, [1, 2]: 2, [2, 1]: 0, [1, 2, 3]: 3, [1, 3, 2]: 1, [2, 1, 3]: 1, [2, 3, 1]: 0, [3, 1, 2]: 0, [3, 2, 1]: 1}
...

The domain of the composition may be restricted. E.g., if we concatenate only permutations starting with a 1, we obtain fewer forced elements:

sage: in_domain = lambda p1, p2: (not p1 or p1(1) == 1) and (not p2 or p2(1) == 1)
sage: bij.set_intertwining_relations((2, concat, lambda x, y: x + y, in_domain))

(continues on next page)
We can also restrict according to several composition functions. For example, we may additionally concatenate permutations by incrementing the elements of the first:

```python
>>> from sage.all import *
>>> in_domain = lambda p1, p2: (not p1 or p1(Integer(1)) == Integer(1)) and
     (not p2 or p2(Integer(1)) == Integer(1))
>>> bij.set_intertwining_relations((Integer(2), concat, lambda x, y: x + y, in_domain))
```

```python
>>> for solution in sorted(list(bij.solutions_iterator()), key=lambda d:
     tuple(sorted(d.items()))):
     ...
     print(solution)
...
```
Combinatorics, Release 10.4

```python
sage: skew_concat = lambda p1, p2: Permutation([i + len(p2) for i in p1] + list(p2))
sage: bij.set_intertwining_relations((2, skew_concat, lambda x, y: x + y))
sage: for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    print(solution)
```

```
{[ ]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 0, [1, 3, 2]: 0, [2, 1, 3]: 1, [2, 3, 1]: 1, [3, 1, 2]: 1, [3, 2, 1]: 3}
{[ ]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 0, [1, 3, 2]: 1, [2, 1, 3]: 0, [2, 3, 1]: 1, [3, 1, 2]: 1, [3, 2, 1]: 3}
{[ ]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 0, [2, 1, 3]: 0, [2, 3, 1]: 1, [3, 1, 2]: 1, [3, 2, 1]: 3}
```

However, this yields no solution:

```python
sage: bij.set_intertwining_relations((Integer(2), concat, lambda x, y: x + y), (Integer(2), skew_concat, lambda x, y: x + y))
sage: list(bij.solutions_iterator())
[]
```

```
set_statistics(*alpha_beta)
Set constraints of the form $\alpha = \beta \circ S$.
```

**Warning:** Any restriction imposed by a previous invocation of `set_statistics()` will be overwritten!

**INPUT:**

- `alpha_beta` – one or more pairs ($\alpha : A \rightarrow W, \beta : B \rightarrow W$)

If the statistics $\alpha$ and $\beta$ are not equidistributed, an error is raised.

**ALGORITHM:**
We add
\[ \sum_{a \in A, z \in Z} x_{p(a), z} y(a) = \sum_{b \in B} s^\alpha(t(\beta(b))) \]
as a matrix equation to the MILP.

**EXAMPLES:**

We look for bijections \( S \) on permutations such that the number of weak exceedences of \( S(\pi) \) equals the number of descents of \( \pi \), and statistics \( s \), such that the number of fixed points of \( S(\pi) \) equals \( s(\pi) \):

```python
sage: N = 4; A = B = [permutation for n in range(N) for permutation in Permutations(n)]
sage: def wex(p): return len(p.weak_excedences())
sage: def fix(p): return len(p.fixed_points())
sage: def des(p): return len(p.descents(final_descent=True)) if p else 0
sage: def adj(p): return len([e for (e, f) in zip(p, p[1:]+[0]) if e == f+1])
sage: bij = Bijectionist(A, B, fix)
sage: bij.set_statistics((wex, des), (len, len))
sage: for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    print(solution)
{[\text{}]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 0, [2, 1, 3]: 1, [2, 3, 1]: 0, [3, 1, 2]: 3, [3, 2, 1]: 1}
{[\text{}]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 0, [2, 1, 3]: 0, [2, 3, 1]: 3, [3, 1, 2]: 1, [3, 2, 1]: 0}
{[\text{}]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 1, [2, 1, 3]: 1, [2, 3, 1]: 0, [3, 1, 2]: 3, [3, 2, 1]: 0}
{[\text{}]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 1, [2, 1, 3]: 0, [2, 3, 1]: 1, [3, 1, 2]: 3, [3, 2, 1]: 0}
{[\text{}]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 1, [2, 1, 3]: 0, [2, 3, 1]: 1, [3, 1, 2]: 3, [3, 2, 1]: 1}
```

```python
sage: bij = Bijectionist(A, B, fix)
> sage: bij.set_statistics((wex, des), (fix, adj), (len, len))
sage: for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    print(solution)
{[\text{}]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 1, [2, 1, 3]: 0, [2, 3, 1]: 0, [3, 1, 2]: 3, [3, 2, 1]: 0}
```

```python
>>> from sage.all import *
>>> N = Integer(4); A = B = [permutation for n in range(N) for permutation in Permutations(n)]
>>> def wex(p): return len(p.weak_excedences())
>>> def fix(p): return len(p.fixed_points())
>>> def des(p): return len(p.descents(final_descent=True)) if p else 0
>>> def adj(p): return len([e for (e, f) in zip(p, p[1:]+[0]) if e == f+1])
>>> bij = Bijectionist(A, B, fix)
>>> bij.set_statistics((wex, des), (fix, adj), (len, len))
```
for solution in sorted(list(bij.solutions_iterator()), key=lambda d:
    tuple(sorted(d.items()))):
    ...  print(solution)

Calling this with non-equidistributed statistics yields an error:

```python
sage: bij = Bijectionist(A, B, fix)
sage: bij.set_statistics((wex, fix))
Traceback (most recent call last):
  ...  ValueError: statistics alpha and beta are not equidistributed
```

```
>>> from sage.all import *
>>> bij = Bijectionist(A, B, fix)
>>> bij.set_statistics((wex, fix))
Traceback (most recent call last):
  ...  ValueError: statistics alpha and beta are not equidistributed
```

**set_value_restrictions** (*value_restrictions*)

Restrict the set of possible values $s(a)$ for a given element $a$.

**Warning:** Any restriction imposed by a previous invocation of `set_value_restrictions()` will be overwritten!

**INPUT:**

- value_restrictions – one or more pairs $(a \in A, \bar{Z} \subseteq \mathbb{Z})$

**EXAMPLES:**

We may want to restrict the value of a given element to a single or multiple values. We do not require that
the specified values are in the image of $\tau$. In some cases, the restriction may not be able to provide a better solution, as for size $3$ in the following example.

```python
sage: A = B = [permutation for n in range(4) for permutation in Permutations(n)]

sage: tau = Permutation.longest_increasing_subsequence_length

sage: bij = Bijectionist(A, B, tau)

sage: bij.set_statistics((len, len))

sage: bij.set_value_restrictions((Permutation([1, 2]), [1]),

....: (Permutation([3, 2, 1]), [2, 3, 4]))

sage: for sol in sorted(bij.solutions_iterator(), key=lambda d: sorted(d.items())):
   
   ....:   print(sol)

{[], 0, [1], 1, [1, 2]: 1, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 2, [2, 1, 3]: 3}

{[], 0, [1], 1, [1, 2]: 1, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 1, [2, 1, 3]: 3}

{[], 0, [1], 1, [1, 2]: 1, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 1, [2, 1, 3]: 2}

{[], 0, [1], 1, [1, 2]: 1, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 1, [2, 1, 3]: 2}

{[], 0, [1], 1, [1, 2]: 1, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 1, [2, 1, 3]: 2}

{[], 0, [1], 1, [1, 2]: 1, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 1, [2, 1, 3]: 2}

{[], 0, [1], 1, [1, 2]: 1, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 1, [2, 1, 3]: 2}

{[], 0, [1], 1, [1, 2]: 1, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 1, [2, 1, 3]: 2}

However, an error occurs if the set of possible values is empty. In this example, the image of \( \tau \) under any legal bijection is disjoint to the specified values.

\textbf{solutions\_iterator()}

An iterator over all solutions of the problem.

OUTPUT: An iterator overall possible mappings \( s : A \to Z \)

ALGORITHM:

We solve an integer linear program with a binary variable \( x_{p,z} \) for each partition block \( p \in P \) and each statistic value \( z \in Z \):

- \( x_{p,z} = 1 \) if and only if \( s(a) = z \) for all \( a \in p \).

Then we add the constraint \( \sum_{x \in V} x < |V| \), where \( V \) is the set containing all \( x \) with \( x = 1 \), that is, those indicator variables representing the current solution. Therefore, a solution of this new program must be different from all those previously obtained.

\textbf{INTEGER LINEAR PROGRAM:}

- Let \( m_w(p) \), for a block \( p \) of \( P \), be the multiplicity of the value \( w \) in \( W \) under \( \alpha \), that is, the number of elements \( a \in p \) with \( \alpha(a) = w \).

- Let \( n_w(z) \) be the number of elements \( b \in B \) with \( \beta(b) = w \) and \( \tau(b) = z \) for \( w \in W, z \in Z \).

- Let \( k \) be the arity of a pair \( (\pi, \rho) \) in an intertwining relation.

and the following constraints:

- because every block is assigned precisely one value, for all \( p \in P \),
  \[ \sum_z x_{p,z} = 1. \]

- because the statistics \( s \) and \( \tau \) and also \( \alpha \) and \( \beta \) are equidistributed, for all \( w \in W \) and \( z \in Z \),
  \[ \sum_p m_w(p) x_{p,z} = n_w(z). \]

- for each intertwining relation \( s(\pi(a_1, \ldots, a_k)) = \rho(s(a_1), \ldots, s(a_r)) \), and for all \( k \)-combinations of blocks \( p_i \in P \) such that there exist \( (a_1, \ldots, a_k) \in p_1 \times \cdots \times p_k \) with \( \pi(a_1, \ldots, a_k) \in W \) and \( z = \rho(z_1, \ldots, z_k) \),
  \[ x_{p,z} \geq 1 - k + \sum_{i=1}^k x_{p_i,z_i}. \]
• for each distribution restriction, i.e. a set of elements $\tilde{A}$ and a distribution of values given by integers $d_z$ representing the multiplicity of each $z \in \mathbb{Z}$, and $r_p = |p \cap \tilde{A}|$ indicating the relative size of block $p$ in the set of elements of the distribution,

$$\sum_p r_p x_{p,z} = d_z.$$  

**EXAMPLES:**

```python
sage: A = B = 'abc'
sage: bij = Bijectionist(A, B, lambda x: B.index(x) % 2, solver="GLPK")
sage: next(bij.solutions_iterator())
{'a': 0, 'b': 1, 'c': 0}
sage: list(bij.solutions_iterator())
[{'a': 0, 'b': 1, 'c': 0},
 {'a': 1, 'b': 0, 'c': 0},
 {'a': 0, 'b': 0, 'c': 1}]
sage: X = 4
sage: A = B = [permutation for n in range(X) for permutation in Permutations(n)]
```

Let $\tau$ be the number of non-left-to-right-maxima of a permutation:

```python
sage: def tau(pi):
    pi = list(pi)
    i = count = 0
    for j in range(len(pi)):
        if pi[j] > i:
            i = pi[j]
        else:
            count += 1
    return count
```

```python
>>> from sage.all import *
>>> def tau(pi):
...     pi = list(pi)
...     i = count = Integer(0)
...     for j in range(len(pi)):
...         if pi[j] > i:
...             i = pi[j]
...         else:
...             count += 1
...     return count
(continues on next page)
```
We look for a statistic which is constant on conjugacy classes:

```python
sage: P = [list(a) for n in range(N) for a in Permutations(n).conjugacy_classes()]
sage: bij = Bijectionist(A, B, tau, solver="GLPK")
sage: bij.set_statistics((len, len))
sage: bij.set_constant_blocks(P)
sage: for solution in bij.solutions_iterator():
    print(solution)
{[], [1]: 0, [1, 2]: 1, [2, 1]: 0, [1, 2, 3]: 0, [1, 3, 2]: 1, [2, 1, 3]: 1, [3, 2, 1]: 1, [2, 3, 1]: 2, [3, 1, 2]: 2}
{[], [1]: 0, [1, 2]: 0, [2, 1]: 1, [1, 2, 3]: 0, [1, 3, 2]: 1, [2, 1, 3]: 1, [3, 2, 1]: 1, [2, 3, 1]: 2, [3, 1, 2]: 2}
```

Changing or re-setting problem parameters clears the internal cache. Setting the verbosity prints the MILP which is solved:

```python
sage: set_verbose(2)
sage: bij.set_constant_blocks(P)
sage: _ = list(bij.solutions_iterator())

>>> set_verbose(Integer(0))

**statistics_fibers()**

Return a dictionary mapping statistic values in \( W \) to their preimages in \( A \) and \( B \).

This is a (computationally) fast way to obtain a first impression which objects in \( A \) should be mapped to which objects in \( B \).

EXAMPLES:

```
sage: A = B = [permutation for n in range(4) for permutation in...
    -->Permutations(n)]
sage: tau = Permutation.longest_increasing_subsequence_length
sage: def wex(p): return len(p.weak_excedences())
```
Combinatorics, Release 10.4

(continued from previous page)

\texttt{sage: bij.set_statistics((\text{len, len}), (wex, des), (fix, adj))}
\texttt{sage: table([[key, AB[0], AB[1]] for key, AB in bij.statistics_fibers().items()]})

\begin{tabular}{ll}
(0, 0, 0) & [[]] \\
(1, 1, 1) & [[1]] \\
(2, 2, 2) & [[1, 2]] \\
(2, 1, 0) & [[2, 1]] \\
(3, 3, 3) & [[1, 2, 3]] \\
(3, 2, 1) & [[1, 3, 2], [2, 1, 3], [3, 2, 1]] \\
(3, 2, 0) & [[2, 3, 1]] \\
(3, 1, 0) & [[3, 1, 2]] \\
\end{tabular}

\texttt{statistics_table(header=True)}

Provide information about all elements of \(A\) with corresponding \(\alpha\) values and all elements of \(B\) with corresponding \(\beta\) and \(\tau\) values.

\textbf{INPUT:}

- \texttt{header} – (default: True) whether to include a header with the standard Greek letters

\textbf{OUTPUT:}

A pair of lists suitable for \texttt{table}, where

- the first contains the elements of \(A\) together with the values of \(\alpha\)
- the second contains the elements of \(B\) together with the values of \(\tau\) and \(\beta\)

\textbf{EXAMPLES:}

\begin{verbatim}
>>> from sage.all import *
>>> A = B = [permutation for n in range(Integer(4)) for permutation in Permutations(n)]
>>> tau = Permutation.longest_increasing_subsequence_length

\textbf{5.1. Comprehensive Module List}

5.1.9 Binary Recurrence Sequences

This class implements several methods relating to general linear binary recurrence sequences, including a sieve to find perfect powers in integral linear binary recurrence sequences.

EXAMPLES:

```sage
sage: R = BinaryRecurrenceSequence(1,1)          #the Fibonacci sequence
sage: R(137) #the 137th term of the Fibonacci sequence
19134702400093278081449423917
sage: R(137) == fibonacci(137)
True
sage: [R(i) % 4 for i in range(12)]
[0, 1, 1, 2, 3, 1, 0, 1, 1, 2, 3, 1]

sage: R.period(4) #the period of the fibonacci sequence modulo 4
6

sage: R.pthpowers(2, 10**10) # long time (7 seconds) -- in fact these are all...squares, c.f. [BMS06]
[0, 1, 2, 12]

sage: S = BinaryRecurrenceSequence(8,1) #a Lucas sequence
sage: S.period(73)
148
sage: S(5) % 73 == S(5 +148) %73
True
sage: S.pthpowers(3, 10**10) # long time (3 seconds) -- provably finds the indices...of all 3rd powers less than 10^10
[0, 1, 2]

sage: T = BinaryRecurrenceSequence(2,0,1,2)
sage: [T(i) for i in range(10)]
[1, 2, 4, 8, 16, 32, 64, 128, 256, 512]
sage: T.is_degenerate()
True
sage: T.is_geometric()
True
sage: T.pthpowers(7, 10**30) #...needs sage.symbolic
Traceback (most recent call last):
... ValueError: the degenerate binary recurrence sequence is geometric or quasigeometric and has many pth powers
```

```python
>>> from sage.all import *
>>> R = BinaryRecurrenceSequence(Integer(1),Integer(1)) #the Fibonacci sequence
>>> R(Integer(137)) #the 137th term of the Fibonacci sequence
19134702400093278081449423917
>>> R(Integer(137)) == fibonacci(Integer(137))
True
>>> [R(i) % Integer(4) for i in range(Integer(12))]
```

(continues on next page)

ValueError: the degenerate binary recurrence sequence is geometric or quasigeometric and has many pth powers

AUTHORS:

• Isabel Vogt (2013): initial version

See [SV2013], [BMS2006], and [SS1983].

class sage.combinat.binary_recurrence_sequences.BinaryRecurrenceSequence(b, c,
u0=0,
u1=1)
Bases: sage.combinat.binary_recurrence_sequences.BinaryRecurrenceSequence.b, c,
u0=0,
u1=1)

Create a linear binary recurrence sequence defined by initial conditions u0 and u1 and recurrence relation \(u_{n+2} = b \cdot u_{n+1} + c \cdot u_n\).

INPUT:

• b – an integer (partially determining the recurrence relation)
• c – an integer (partially determining the recurrence relation)
• u0 – an integer (the 0th term of the binary recurrence sequence)
• u1 – an integer (the 1st term of the binary recurrence sequence)

OUTPUT:

• An integral linear binary recurrence sequence defined by \(u_0, u_1\), and \(u_{n+2} = b \cdot u_{n+1} + c \cdot u_n\)

See also:

fibonacci(), lucas_number1(), lucas_number2()
EXAMPLES:

```python
sage: R = BinaryRecurrenceSequence(3,3,2,1)
sage: R
Binary recurrence sequence defined by: u_n = 3 * u_{n-1} + 3 * u_{n-2};
With initial conditions: u_0 = 2, and u_1 = 1
>>> from sage.all import *
>>> R = BinaryRecurrenceSequence(Integer(3),Integer(3),Integer(2),Integer(1))
>>> R
Binary recurrence sequence defined by: u_n = 3 * u_{n-1} + 3 * u_{n-2};
With initial conditions: u_0 = 2, and u_1 = 1
```

```python
is_arithmetic()
Decide whether the sequence is degenerate and an arithmetic sequence.

The sequence is arithmetic if and only if u_1 - u_0 = u_2 - u_1 = u_3 - u_2.
This corresponds to the matrix F = [[0,1],[c,b]] being nondiagonalizable and \( \alpha/\beta = 1 \).

EXAMPLES:

```python
sage: S = BinaryRecurrenceSequence(2,-1)
sage: [S(i) for i in range(10)]
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
sage: S.is_arithmetic()
True
```

```python
is_degenerate()
Decide whether the binary recurrence sequence is degenerate.

Let \( \alpha \) and \( \beta \) denote the roots of the characteristic polynomial \( p(x) = x^2 - bx - c \). Let \( a = u_1 - u_0\beta/(\beta - \alpha) \) and \( b = u_1 - u_0\alpha/(\beta - \alpha) \). The sequence is, thus, given by \( u_n = a\alpha^n - b\beta^n \). Then we say that the sequence is nondegenerate if and only if \( a \times b \times \alpha \times \beta \neq 0 \) and \( \alpha/\beta \) is not a root of unity.

More concretely, there are 4 classes of degeneracy, that can all be formulated in terms of the matrix \( F = [[0,1],[c,b]] \).

- \( F \) is singular – this corresponds to \( c = 0 \), and thus \( \alpha \times \beta = 0 \). This sequence is geometric after term \( u_0 \) and so we call it quasigeometric.
- \( v = [u_0, u_1] \) is an eigenvector of \( F \) – this corresponds to a geometric sequence with \( a \times b = 0 \).
- \( F \) is nondiagonalizable – this corresponds to \( \alpha = \beta \). This sequence will be the point-wise product of an arithmetic and geometric sequence.
- \( F^k \) is scaler, for some \( k > 1 \) – this corresponds to \( \alpha/\beta \) a \( k \) th root of unity. This sequence is a union of several geometric sequences, and so we again call it quasigeometric.

EXAMPLES:
is_geometric()

Decide whether the binary recurrence sequence is geometric - i.e., a geometric sequence.

This is a subcase of a degenerate binary recurrence sequence, for which $a b = 0$, i.e., $u_n / u_{n-1} = r$ for some value of $r$.

See is_degenerate() for a description of degeneracy and definitions of $a$ and $b$.

EXAMPLES:

```python
sage: S = BinaryRecurrenceSequence(2,0,1,2)
sage: [S(i) for i in range(10)]
[1, 2, 4, 8, 16, 32, 64, 128, 256, 512]
sage: S.is_geometric()
True
```

```python
>>> from sage.all import *
>>> S = BinaryRecurrenceSequence(Integer(2),Integer(0),Integer(1),Integer(2))
>>> [S(i) for i in range(Integer(10))]
[1, 2, 4, 8, 16, 32, 64, 128, 256, 512]
```
is_quasigeometric()  
Decide whether the binary recurrence sequence is degenerate and similar to a geometric sequence, i.e. the  
union of multiple geometric sequences, or geometric after term $u_0$.  
If $\alpha/\beta$ is a $k$th root of unity, where $k > 1$, then necessarily $k = 2, 3, 4, 6$. Then $F = [[0, 1], [c, b]]$ is  
diagonalizable, and $F^k = [[\alpha^k, 0], [0, \beta^k]]$ is scalar matrix. Thus for all values of $j$ mod $k$, the $j$ mod $k$ terms  
of $u_n$ form a geometric series.  
If $\alpha$ or $\beta$ is zero, this implies that $c = 0$. This is the case when $F$ is singular. In this case, $u_1, u_2, u_3, ...$ is  
geometric.  
EXAMPLES:

```python
sage: S = BinaryRecurrenceSequence(0, 1)
sage: S.is_quasigeometric()
True
sage: R = BinaryRecurrenceSequence(3, 0)
sage: R.is_quasigeometric()
True
```

period($m$)  
Return the period of the binary recurrence sequence modulo an integer $m$.  
If $n_1$ is congruent to $n_2$ modulo period($m$), then $u_{n_1}$ is congruent to $u_{n_2}$ modulo $m$.  
INPUT:  
• $m$ – an integer (modulo which the period of the recurrence relation is calculated).  
OUTPUT:  
• The integer (the period of the sequence modulo $m$)  
EXAMPLES:  
If $p = \pm 1 \mod 5$, then the period of the Fibonacci sequence mod $p$ is $p-1$ (c.f. Lemma 3.3 of [BMS2006]).
### pthpowers \(p, \text{Bound}\)

Find the indices of proveably all \(p\)th powers in the recurrence sequence bounded by \(\text{Bound}\).

Let \(u_n\) be a binary recurrence sequence. A \(p\)th power in \(u_n\) is a solution to \(u_n = y^p\) for some integer \(y\). There are only finitely many \(p\)th powers in any recurrence sequence [SS1983].

**INPUT:**

- \(p\) – a rational prime integer (the fixed \(p\) in \(u_n = y^p\))
- \(\text{Bound}\) – a natural number (the maximum index \(n\) in \(u_n = y^p\) that is checked).

**OUTPUT:**
• A list of the indices of all $p$th powers less bounded by Bound. If the sequence is degenerate and there are many $p$th powers, raises ValueError.

**EXAMPLES:**

```python
sage: R = BinaryRecurrenceSequence(1,1)    #the Fibonacci sequence
sage: R.pthpowers(2, 10**10)                # long time (7 seconds) -- in fact these... are all squares, c.f. [BMS2006]_  
[0, 1, 2, 12]

sage: S = BinaryRecurrenceSequence(8,1)  #a Lucas sequence
sage: S.pthpowers(3,10**10)                # long time (3 seconds) -- provably finds the... indices of all 3rd powers less than 10^10
[0, 1, 2]

sage: Q = BinaryRecurrenceSequence(3,3,2,1)

sage: Q.pthpowers(11,10**10)              # long time (7.5 seconds)
[1]
```

If the sequence is degenerate, and there are no $p$th powers, returns[]. Otherwise, if there are many $p$th powers, raises ValueError.

```python
>>> from sage.all import *

>>> R = BinaryRecurrenceSequence(Integer(1),Integer(1))    #the Fibonacci sequence

>>> R.pthpowers(Integer(2), Integer(10)**Integer(10))     # long time (7... seconds) -- in fact these are all squares, c.f. [BMS2006]_  
[0, 1, 2, 12]

>>> S = BinaryRecurrenceSequence(Integer(8),Integer(1))  #a Lucas sequence

>>> S.pthpowers(Integer(3),Integer(10)**Integer(10))     # long time (3... seconds) -- provably finds the indices of all 3rd powers less than 10^10
[0, 1, 2]

>>> Q = BinaryRecurrenceSequence(Integer(3),Integer(3),Integer(2),Integer(1))

>>> Q.pthpowers(Integer(11),Integer(10)**Integer(10))    # long time (7.5 seconds)
[1]
```

(continues on next page)

ValueError: the degenerate binary recurrence sequence is geometric or quasigeometric and has many pth powers

>>> L = BinaryRecurrenceSequence(Integer(4), Integer(0), Integer(2), Integer(2))
[2, 2, 2^3, 2^5, 2^7, 2^9, 2^11, 2^13, 2^15, 2^17]
>>> L.is_quasigeometric()
True
>>> L.pthpowers(Integer(2), Integer(10)**Integer(30)) → # needs sage.symbolic
[]

Note: This function is primarily optimized in the range where Bound is much larger than p.

5.1.10 Binary Trees

This module deals with binary trees as mathematical (in particular immutable) objects.

Note: If you need the data-structure for example to represent sets or hash tables with AVL trees, you should have a look at sage.misc.sagex_ds.

AUTHORS:

• Florent Hivert (2010-2011): initial implementation.

class sage.combinat.binary_tree.BinaryTree(parent, children=None, check=True)
Bases: AbstractClonableTree, ClonableArray
Binary trees.

Binary trees here mean ordered (a.k.a. plane) finite binary trees, where “ordered” means that the children of each node are ordered.

Binary trees contain nodes and leaves, where each node has two children while each leaf has no children. The number of leaves of a binary tree always equals the number of nodes plus 1.

INPUT:

• children – None (default) or a list, tuple or iterable of length 2 of binary trees or convertible objects. This corresponds to the standard recursive definition of a binary tree as either a leaf or a pair of binary
trees. Syntactic sugar allows leaving out all but the outermost calls of the `BinaryTree()` constructor, so that, e.g., `BinaryTree([BinaryTree(None), BinaryTree(None)])` can be shortened to `BinaryTree([None, None]).` It is also allowed to abbreviate `[None, None]` by `[]`.

- **check** *(default: True)* whether check for binary should be performed or not.

**EXAMPLES:**

```python
sage: BinaryTree()
 .
sage: BinaryTree(None)
 .
sage: BinaryTree([[]])
[., .]
sage: BinaryTree([None, None])
[., .]
sage: BinaryTree([None, []])
[., [., .]]
sage: BinaryTree([[], None])
[[., .], .]
sage: BinaryTree([[], None])
[[., .], .]
sage: BinaryTree([None, BinaryTree([None, None])])
[., [., .]]
sage: BinaryTree([[], None, []])
[[., .], .]

Traceback (most recent call last):
 ... ValueError: this is not a binary tree
```

```bash
>>> from sage.all import *
>>> BinaryTree()
 .
>>> BinaryTree(None)
 .
>>> BinaryTree([[]])
[., .]
>>> BinaryTree([None, None])
[., .]
>>> BinaryTree([None, []])
[., [., .]]
>>> BinaryTree([[], None])
[[., .], .]
>>> BinaryTree([None, BinaryTree([None, None])])
[., [., .]]

Traceback (most recent call last):
 ... ValueError: this is not a binary tree
```

**as_ordered_tree** *(with_leaves=True)*

Return the same tree seen as an ordered tree. By default, leaves are transformed into actual nodes, but this can be avoided by setting the optional variable `with_leaves` to `False`.

**EXAMPLES:**
```python
sage: bt = BinaryTree([]); bt
[., .]
sage: bt.as_ordered_tree()
[[], []]
sage: bt.as_ordered_tree(with_leaves = False)
[]
sage: bt = bt.canonical_labelling(); bt
[., .]
sage: bt.as_ordered_tree()
1[[None], [None]]
sage: bt.as_ordered_tree(with_leaves=False)
1[]
```

```python
>>> from sage.all import *

>>>
```

**canonical_labelling**(shift=1)

Return a labelled version of `self`.

The canonical labelling of a binary tree is a certain labelling of the nodes (not the leaves) of the tree. The actual canonical labelling is currently unspecified. However, it is guaranteed to have labels in $1...n$ where $n$ is the number of nodes of the tree. Moreover, two (unlabelled) trees compare as equal if and only if their canonical labelled trees compare as equal.

**EXAMPLES:**

```python
sage: BinaryTree().canonical_labelling()
.
sage: BinaryTree([]).canonical_labelling()
[., .]
sage: BinaryTree([[], [[]], [None], [[], []]]).canonical_labelling()
5[2[1[., .], 4[3[., .], .]], 7[6[., .], 8[., .]]]
```

```python
>>> from sage.all import *

>>>
```

**canopee**()

Return the canopee of `self`.

The *canopee* of a non-empty binary tree $T$ with $n$ internal nodes is the list $l$ of 0 and 1 of length $n-1$ obtained by going along the leaves of $T$ from left to right except the two extremal ones, writing 0 if the leaf is a right
leaf and 1 if the leaf is a left leaf.

EXAMPLES:

```python
sage: BinaryTree([]).canopee()
[]
sage: BinaryTree([None, []]).canopee()
[1]
sage: BinaryTree([], None).canopee()
[0]
sage: BinaryTree([[], []]).canopee()
[0, 1]
sage: BinaryTree([[[], []], [], []]).canopee()
[0, 1, 0, 0, 1, 0, 1]
```

The number of pairs \((t_1, t_2)\) of binary trees of size \(n\) such that the canopee of \(t_1\) is the complementary of the canopee of \(t_2\) is also the number of Baxter permutations (see [DG1994], see also OEIS sequence A001181). We check this in small cases:

```python
sage: [len([(u,v) for u in BinaryTrees(n) for v in BinaryTrees(n) ...: if [1 - x for x in u.canopee()] == v.canopee()]) ...: for n in range(1, 5)]
[1, 2, 6, 22]
```

Here is a less trivial implementation of this:

```python
sage: from sage.all import *
>>> from sage.sets.finite_set_map_cy import fibers
sage: def baxter(n):
...:     f = fibers(lambda t: tuple(t.canopee()), BinaryTrees(n))
...:     return sum(len(f[i]) * len(f[tuple(1-x for x in i)])
...:         for i in f)
sage: [baxter(n) for n in range(1, 7)]
[1, 2, 6, 22, 92, 422]
```

(continues on next page)
... BinaryTrees(n))
... return sum(len(f[i])*len(f[tuple(Integer(1)-x for x in i)])
... for i in f)
>>> [baxter(n) for n in range(Integer(1), Integer(7))]
[1, 2, 6, 22, 92, 422]

check()

Check that self is a binary tree.

EXAMPLES:

```python
sage: BinaryTree([[], []])  # indirect doctest
[[., .], [., .]]
```

```python
sage: BinaryTree([[], [], []])  # indirect doctest
Traceback (most recent call last):
  ...
ValueError: this is not a binary tree
```
```
sage: BT = BinaryTree( '[.,]' )
sage: [BT.comb('left'), BT.comb('right')]
[[], []]

sage: BT = BinaryTree( '[[[.,], .], [., .]]' )
sage: BT.comb('left')
[., .]
sage: BT.comb('right')
[., .]
sage: BT = BinaryTree( '[[[., [., .]], .], [.], [[., .], [., .]], [., .]]' )
sage: ascii_art(BT)

```

dendriform_shuffle(other)

Return the list of terms in the dendriform product.

This is the list of all binary trees that can be obtained by identifying the rightmost path in self and the leftmost path in other. Every term corresponds to a shuffle of the vertices on the rightmost path in self and the vertices on the leftmost path in other.

EXAMPLES:

```python
sage: u = BinaryTree()
sage: g = BinaryTree([])
sage: l = BinaryTree([g, u])
sage: r = BinaryTree([u, g])

sage: list(g.dendriform_shuffle(g))
```

(continues from previous page)
\[\text{from sage.all import *} \]
\[\text{u = BinaryTree()} \]
\[\text{g = BinaryTree([]} \]
\[\text{l = BinaryTree([g, u])} \]
\[\text{r = BinaryTree([u, g])} \]

\[\text{list(g.dendriform_shuffle(g))} \]

\[\text{list(l.dendriform_shuffle(l))} \]

\[\text{list(l.dendriform_shuffle(r))} \]

\[\text{list(r.dendriform_shuffle(r))} \]

\[\text{graph(with_leaves=True)} \]

Convert self to a digraph.

By default, this graph contains both nodes and leaves, hence is never empty. To obtain a graph which contains only the nodes, the with_leaves optional keyword variable has to be set to False.

The resulting digraph is endowed with a combinatorial embedding, in order to be displayed correctly.

INPUT:

- with_leaves – (default: True) a Boolean, determining whether the resulting graph will be formed from the leaves and the nodes of self (if True), or only from the nodes of self (if False)

EXAMPLES:

\[\text{sage: t1 = BinaryTree([[], None])} \]
\[\text{sage: t1.graph()} \]

Digraph on 5 vertices

\[\text{sage: t1.graph(with_leaves=False)} \]

Digraph on 2 vertices

\[\text{sage: t1 = BinaryTree([[], [[], None]]}) \]
\[\text{sage: t1.graph()} \]

Digraph on 9 vertices

\[\text{sage: t1.graph().edges(sort=True)} \]

[(0, 1, None), (0, 4, None), (1, 2, None), (1, 3, None), (4, 5, None), (4, 8, None), (5, 6, None), (5, 7, None)]

\[\text{sage: t1.graph(with_leaves=False)} \]

Digraph on 4 vertices

\[\text{sage: t1.graph(with_leaves=False).edges(sort=True)} \]

[(0, 1, None), (0, 2, None), (2, 3, None)]
sage: t1 = BinaryTree()
sage: t1.graph()
Digraph on 1 vertex
sage: t1.graph(with_leaves=False)
Digraph on 0 vertices

sage: BinaryTree([]).graph()
Digraph on 3 vertices
sage: BinaryTree([]).graph(with_leaves=False)
Digraph on 1 vertex

sage: t1 = BinaryTree([[], [], []])
sage: t1.graph(with_leaves=False)
Digraph on 5 vertices
sage: t1.graph(with_leaves=False).edges(sort=True)
[(0, 1, None), (0, 2, None), (2, 3, None), (2, 4, None)]

>>> from sage.all import *
>>> t1 = BinaryTree([[], None])
>>> t1.graph()
Digraph on 5 vertices
>>> t1.graph(with_leaves=False)
Digraph on 2 vertices

>>> t1 = BinaryTree([[], [], None])
>>> t1.graph()
Digraph on 9 vertices
>>> t1.graph().edges(sort=True)
[(0, 1, None), (0, 4, None), (1, 2, None), (1, 3, None), (4, 5, None), (4, 8, None), (5, 6, None), (5, 7, None)]
>>> t1.graph(with_leaves=False)
Digraph on 4 vertices
>>> t1.graph(with_leaves=False).edges(sort=True)
[(0, 1, None), (0, 2, None), (2, 3, None)]

>>> t1 = BinaryTree()
>>> t1.graph()
Digraph on 1 vertex
>>> t1.graph(with_leaves=False)
Digraph on 0 vertices

>>> BinaryTree([]).graph()
Digraph on 3 vertices
>>> BinaryTree([]).graph(with_leaves=False)
Digraph on 1 vertex

>>> t1 = BinaryTree([[], [], []])
>>> t1.graph(with_leaves=False)
Digraph on 5 vertices
>>> t1.graph(with_leaves=False).edges(sort=True)
[(0, 1, None), (0, 2, None), (2, 3, None), (2, 4, None)]

**hook_number()**

Return the number of hooks.

Recalling that a branch is a path from a vertex of the tree to a leaf, the leftmost (resp. rightmost) branch of a
vertex $v$ is the branch from $v$ made only of left (resp. right) edges.

The hook of a vertex $v$ is a set of vertices formed by the union of $v$, and the vertices of its leftmost and rightmost branches.

There is a unique way to partition the set of vertices in hooks. The number of hooks in such a partition is the hook number of the tree.

We can obtain this partition recursively by extracting the root’s hook and iterating the processus on each tree of the remaining forest.

EXAMPLES:

```python
sage: BT = BinaryTree( '.' )
sage: BT.hook_number()
0
sage: BT = BinaryTree( '[.,]' )
sage: BT.hook_number()
1
sage: BT = BinaryTree( '[[[.,,], [,]], [,.,]]' )
; ascii_art(BT)
   /
  /  
 o  o
sage: BT.hook_number()
1
sage: BT = BinaryTree( '[[[.,, [,]], [,]], [[.,, [,]], [,.,]]], [,., [[[.,, [,]], [[.,, [,]], [,.,]], [,]], [,.,]]]' )
sage: ascii_art(BT)
   __o__________
  / \           
 o  _o_         
 / \           
 o  _o_         
 / \           
 o  _o_         
 / \           
 o  _o_         
 / \           
 o  _o_         
 / \           
 o  _o_         
 / \           
 o  _o_         
 / \           
 o  _o_         
 / \           
 o  _o_         
 sages: BT.hook_number()
6

>>> from sage.all import *
>>> BT = BinaryTree( '.' )
>>> BT.hook_number()
0
>>> BT = BinaryTree( '[.,]' )
>>> BT.hook_number()
1
>>> BT = BinaryTree( '[[[.,,], [,]], [,.,]]' )
; ascii_art(BT)
   /
  /  
 o  o
```
in_order_traversal( node_action=None, leaf_action=None)

Explore the binary tree self using the depth-first infix-order traversal algorithm, executing the node_action function whenever traversing a node and executing the leaf_action function whenever traversing a leaf.

In more detail, what this method does to a tree $T$ is the following:

```python
if the root of `T` is a node:
    apply in_order_traversal to the left subtree of `T`
    (with the same node_action and leaf_action);
    apply node_action to the root of `T`;
    apply in_order_traversal to the right subtree of `T`
    (with the same node_action and leaf_action);
else:
    apply leaf_action to the root of `T`.
```

For example on the following binary tree $T$, where we denote leaves by $a, b, c, \ldots$ and nodes by $1, 2, 3, \ldots$:

```
    ______3____
   /          /
  1          7
 /  \        /  \\
2    5      8
   /  \      /  \\
  a  b c  d  e  f  g
```

this method first applies leaf_action to $a$, then applies node_action to $1$, then leaf_action to $b$, then node_action to $2$, etc., with the vertices being traversed in the order $a, 1, b, 2, c, 3, d, 4, e, 5, f, 6, g, 7, h, 8, i$.

See in_order_traversal_iter() for a version of this algorithm which only iterates through the vertices rather than applying any function to them.

INPUT:
• **node_action** – (optional) a function which takes a node in input and does something during the exploration

• **leaf_action** – (optional) a function which takes a leaf in input and does something during the exploration

**in_order_traversal_iter()**

The depth-first infix-order traversal iterator for the binary tree `self`.

This method iterates each vertex (node and leaf alike) of the given binary tree following the depth-first infix order traversal algorithm.

The **depth-first infix order traversal algorithm** iterates through a binary tree as follows:

```
iterate through the left subtree (by the depth-first infix order traversal algorithm);
yield the root;
iterate through the right subtree (by the depth-first infix order traversal algorithm).
```

For example on the following binary tree $T$, where we denote leaves by $a, b, c, \ldots$ and nodes by $1, 2, 3, \ldots$:

```
  ____3____     ___7___
  / \  / \     / \  / \  
 a  2  _5_ 8 b c 4 6 h i
d e f g
```

the depth-first infix-order traversal algorithm iterates through the vertices of $T$ in the following order:

$a, 1, b, 2, c, 3, d, 4, e, 5, f, 6, g, 7, h, 8, i$.

See **in_order_traversal()** for a version of this algorithm which not only iterates through, but actually does something at the vertices of tree.

**is_complete()**

Return True if `self` is complete, else return False.

In a nutshell, a complete binary tree is a perfect binary tree except possibly in the last level, with all nodes in the last level “flush to the left”.

In more detail: A complete binary tree (also called binary heap) is a binary tree in which every level, except possibly the last one (the deepest), is completely filled. At depth $n$, all nodes must be as far left as possible.

For example:

```
  ___o___
 / \  / \  
 o  o o o
```

is not complete but the following ones are:
EXAMPLES:

```python
sage: def lst(i):
    ...:     return [bt for bt in BinaryTrees(i) if bt.is_complete()]

sage: for i in range(8): ascii_art(lst(i)) # long time

>>> from sage.all import *
>>> def lst(i):
...     return [bt for bt in BinaryTrees(i) if bt.is_complete()]

>>> for i in range(Integer(8)): ascii_art(lst(i)) # long time
```

(continues on next page)
is_empty()
Return whether self is empty.

The notion of emptiness employed here is the one which defines a binary tree to be empty if its root is a leaf. There is precisely one empty binary tree.

EXAMPLES:

```python
sage: BinaryTree().is_empty()
True
sage: BinaryTree([]).is_empty()
False
sage: BinaryTree([[], None]).is_empty()
False

>>> from sage.all import *
>>> BinaryTree().is_empty()
True
>>> BinaryTree([]).is_empty()
False
>>> BinaryTree([[], None]).is_empty()
False
```

is_full()
Return True if self is full, else return False.

A full binary tree is a tree in which every node either has two child nodes or has two child leaves.

This is also known as proper binary tree or 2-tree or strictly binary tree.

For example:

```
| ___o___ |
| / \    |
| o o    |
| / \    |
| o o    |
| / \    |
| o o    |
```
is not full but the next one is:

```
|  _o_  |
| / \  |
| o o  |
| / \ / |
| o o o |
```

EXAMPLES:

```python
sage: BinaryTree([[[], None], [None, []], []]).is_full()
False
sage: BinaryTree([[[], []], [[], []], []]).is_full()
True
sage: ascii_art([bt for bt in BinaryTrees(5) if bt.is_full()])
[  _o_  ,  _o_  ]
[ / \ / \ ]
[ o o o o ]
[ / \ / \ ]
[ o o o o ]
```

is_perfect()

Return True if self is perfect, else return False.

A perfect binary tree is a full tree in which all leaves are at the same depth.

For example:

```
|  _o_  |
| / \  |
| o o  |
| / \ / |
| o o o |
```

is not perfect but the next one is:

```
|  _o_  |
| / \  |
| o o  |
| / \ / |
| o o o |
```

EXAMPLES:
sage: def lst(i):
....  return [bt for bt in BinaryTrees(i) if bt.is_perfect()]
sage: for i in range(8): ascii_art(lst(i))  # long time

left_border_symmetry()

Return the tree where a symmetry has been applied recursively on all left borders. If a tree is made of
three trees \([T_1, T_2, T_3]\) on its left border, it becomes \([T_3', T_2', T_1']\) where same symmetry has been applied to
\(T_1, T_2, T_3\).

EXAMPLES:

sage: BinaryTree().left_border_symmetry()
.s
sage: BinaryTree([]).left_border_symmetry()
[., .]
sage: BinaryTree([[None, []], None]).left_border_symmetry()
[[., .], [., .]]
sage: BinaryTree([[None, [None, []]], None]).left_border_symmetry()
[[., .], [., [., .]]]
sage: bt = BinaryTree([[None, [None, []]], None]).canonical_labelling()
sage: bt
4[1[., 2[., 3[., .]]], .]
sage: bt.left_border_symmetry()
1[4[., .], 2[., 3[., .]]]
left_children_node_number (direction='left')

Return the number of nodes which are left children in self.

Every node (except the root) is either the left child or the right child of its parent node. The total number of nodes is 1 plus the number of left-children nodes plus the number of right-children nodes.

INPUT:

• direction – either 'left' (default) or 'right'; if set to 'right', instead count nodes that are right children

EXAMPLES:

sage: bt = BinaryTree([[[None,[]],[]],[[None,[]],None]])
sage: ascii_art(bt)
    __o__
   /   \
  o     o
 /\    /\ 
 o   o o   o
  \
 o   o
sage: bt.left_children_node_number('left')
3
sage: bt.left_children_node_number('right')
4
sage: all(5 == 1 + bt.left_children_node_number() + bt.left_children_node_number('right')
      for bt in BinaryTrees(5))
True

(continues on next page)
left_right_symmetry()

Return the left-right symmetrized tree of self.

EXAMPLES:

```python
sage: BinaryTree().left_right_symmetry()
```

```python
sage: BinaryTree([]).left_right_symmetry()
[., .]
```

```python
sage: BinaryTree([], []).left_right_symmetry()
[., [., .]]
```

```python
sage: BinaryTree([], []).left_right_symmetry()
[., [., .]]
```

```python
>>> from sage.all import *
```

```python
sage: BinaryTree().left_right_symmetry()
```

```python
sage: BinaryTree([]).left_right_symmetry()
[., .]
```

```python
sage: BinaryTree([], []).left_right_symmetry()
[., [., .], .]
```

left_rotate()

Return the result of left rotation applied to the binary tree self.

Left rotation on binary trees is defined as follows: Let $T$ be a binary tree such that the right child of the root of $T$ is a node. Let $A$ be the left child of the root of $T$, and let $B$ and $C$ be the left and right children of the right child of the root of $T$. (Keep in mind that nodes of trees are identified with the subtrees consisting of their descendants.) Then, the left rotation of $T$ is the binary tree in which the right child of the root is $C$, whereas the left child of the root is a node whose left and right children are $A$ and $B$. In pictures:

```
  *             *  
 / \          / \  
A   * left-rotate-> *   C 
 / \          / \  
B   C          A   B 
```

where asterisks signify a single node each (but $A$, $B$ and $C$ might be empty).

For example,

```
  *             *  
 / \          / \  
 o   o left-rotate-> o  
 / \          / \  
```

(continues on next page)
Left rotation is the inverse operation to right rotation (`right_rotate()`).

See also:

`right_rotate()`

EXAMPLES:

```sage
sage: b = BinaryTree([[],[],None]); ascii_art([b])
 [ _o_ ]
 [ / \
 [ o ]
 [ / ]
 [ o ]

sage: ascii_art([b.left_rotate()])
 [ o ]
 [ / ]
 [ o ]
 [ / \]
 [ o ]

sage: b.left_rotate().right_rotate() == b
True
```

```python
>>> from sage.all import *
>>> b = BinaryTree([[],[],None]); ascii_art([b])
 [ _o_ ]
 [ / \
 [ o ]
 [ / ]
 [ o ]

>>> ascii_art([b.left_rotate()])
 [ o ]
 [ / ]
 [ o ]
 [ / ]
 [ o ]

>>> b.left_rotate().right_rotate() == b
True
```

`make_leaf()`

Modify `self` so that it becomes a leaf (i.e., an empty tree).

**Note:** `self` must be in a mutable state.
make_node

Modify self so that it becomes a node with children child_list.

INPUT:

- child_list – a pair of binary trees (or objects convertible to)

Note: self must be in a mutable state.

See also:

make_leaf

EXAMPLES:

```python
sage: t = BinaryTree([None, None])
sage: t.make_node()
Traceback (most recent call last):
...
ValueError: object is immutable; please change a copy instead.
sage: with t.clone() as t1:
... t1.make_node([None, None])
sage: t, t1
([., .], .)
```

(continues on next page)
over (bt)

Return self over bt, where “over” is the over (/) operation.

If \( T \) and \( T' \) are two binary trees, then \( T \) over \( T' \) (written \( T/T' \)) is defined as the tree obtained by grafting \( T' \) on the rightmost leaf of \( T \). More precisely, \( T/T' \) is defined by identifying the root of the \( T' \) with the rightmost leaf of \( T \). See section 4.5 of [HNT2005].

If \( T \) is empty, then \( T/T' = T' \).

The definition of this “over” operation goes back to Loday-Ronco [LR012066] (Definition 2.2), but it is denoted by \( \backslash \) and called the “under” operation there. In fact, trees in Sage have their root at the top, contrary to the trees in [LR012066] which are growing upwards. For this reason, the names of the over and under operations are swapped, in order to keep a graphical meaning. (Our notation follows that of section 4.5 of [HNT2005].)

See also:

under ()

EXAMPLES:

Showing only the nodes of a binary tree, here is an example for the over operation:
A Sage example:

```python
sage: b1 = BinaryTree([[],[[[],[]]]])
sage: b2 = BinaryTree([[[None, []],[]]])

sage: ascii_art((b1, b2, b1/b2))
( o , o , o )
( / \
( o o o o o )
( / \
( o o o o )
( \ )
( o )
```

```python
>>> from sage.all import *

>>> b1 = BinaryTree([[],[[[],[]]]])

>>> b2 = BinaryTree([[[None, []],[]]])

>>> ascii_art((b1, b2, b1/b2))
( o , o , o )
( / \
( o o o o o )
( / \
( o o o o )
( \ )
( o )
```

`over_decomposition()`

Return the unique maximal decomposition as an over product.

This means that the tree is cut along all edges of its rightmost path.

Beware that the factors are ordered starting from the root.

See also:

`comb()`, `under_decomposition()`

EXAMPLES:

```python
sage: g = BinaryTree([])

sage: r = g.over(g); r
[., [., .]]

sage: l = g.under(g); l
[[., .], .]

sage: r.over_decomposition()
[[., .], [., .]]

sage: l.over_decomposition() == [l]
True
```
prune()

Return the binary tree obtained by deleting each leaf of self.

The operation of pruning is the left inverse of attaching as many leaves as possible to each node of a binary tree. That is to say, for all binary trees \( bt \), we have:

\[
bt == bt.to_full().prune()
\]

However, it is only a right inverse if and only if \( bt \) is a full binary tree:

\[
bt == bt.prune().to_full()
\]

OUTPUT:
A binary tree.

See also:
to_full()

EXAMPLES:

```python
sage: bt = BinaryTree([[[None, []], [[]], []], None])
```

(continues on next page)
We check the relationship with \texttt{to\_full()}: 

\begin{verbatim}
sage: bt = BinaryTree([[[], [[None, []], []], []], []])
sage: bt == bt.to_full().prune()
True
sage: bt == bt.prune().to_full()
False
sage: bt = BinaryTree([[[], []], [[[]], [], []]])
sage: bt.is_full()
True
sage: bt == bt.prune().to_full()
True
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> bt = BinaryTree([[[], [[None, []], []], []], []])
>>> bt == bt.to_full().prune()
True
>>> bt == bt.prune().to_full()
False
>>> bt = BinaryTree([[[], []], [[[]], [], []]])
>>> bt.is_full()
True
>>> bt == bt.prune().to_full()
True
\end{verbatim}
Pruning the empty tree is again the empty tree:

```python
sage: bt = BinaryTree(None)
sage: bt.prune()
```

```python
>>> from sage.all import *
```  
```python
>>> bt = BinaryTree(None)
```  
```python
>>> bt.prune()
```

```python
q_hook_length_fraction(q=None, q_factor=False)
```

Compute the $q$-hook length fraction of the binary tree `self`, with an additional “q-factor” if desired.

If $T$ is a (plane) binary tree and $q$ is a polynomial indeterminate over some ring, then the $q$-hook length fraction $h_q(T)$ of $T$ is defined by

$$h_q(T) = \left[ \frac{|T|!}{\prod_{t \in T} |T_t|_q} \right]_q,$$

where the product ranges over all nodes $t$ of $T$, where $T_t$ denotes the subtree of $T$ consisting of $t$ and its all descendants, and where for every tree $S$, we denote by $|S|$ the number of nodes of $S$. While this definition only shows that $h_q(T)$ is a rational function in $T$, it is in fact easy to show that $h_q(T)$ is actually a polynomial in $T$, and thus makes sense when any element of a commutative ring is substituted for $q$. This can also be explicitly seen from the following recursive formula for $h_q(T)$:

$$h_q(T) = \left[ \frac{|T|!}{|T_1|!} \right]_q h_q(T_1) h_q(T_2),$$

where $T$ is any nonempty binary tree, and $T_1$ and $T_2$ are the two child trees of the root of $T$, and where $\binom{a}{b}_q$ denotes a $q$-binomial coefficient.

A variation of the $q$-hook length fraction is the following “$q$-hook length fraction with $q$-factor”:

$$f_q(T) = h_q(T) \cdot \prod_{t \in T} q^{\text{right}(t)},$$

where for every node $t$, we denote by right($t$) the right child of $t$. This $f_q(T)$ differs from $h_q(T)$ only in a multiplicative factor, which is a power of $q$.

When $q = 1$, both $f_q(T)$ and $h_q(T)$ equal the number of permutations whose binary search tree (see [HNT2005] for the definition) is $T$ (after dropping the labels). For example, there are 20 permutations which give a binary tree of the following shape:

```
|   __o__ |
|   / \   |
|   o   o |
|   / \   |
|   o   o |
```

by the binary search insertion algorithm, in accordance with the fact that this tree satisfies $f_1(T) = 20$.

When $q$ is considered as a polynomial indeterminate, $f_q(T)$ is the generating function for all permutations whose binary search tree is $T$ (after dropping the labels) with respect to the number of inversions (i. e., the Coxeter length) of the permutations.

Objects similar to $h_q(T)$ also make sense for general ordered forests (rather than just binary trees), see e. g. [BW1988], Theorem 9.1.

INPUT:
• \(q\) – a ring element which is to be substituted as \(q\) into the \(q\)-hook length fraction (by default, this is set to be the indeterminate \(q\) in the polynomial ring \(\mathbb{Z}[q]\))

• \texttt{q_factor} – a Boolean (default: \texttt{False}) which determines whether to compute \(h_q(T)\) or to compute \(f_q(T)\) (namely, \(h_q(T)\) is obtained when \texttt{q_factor} == \texttt{False}, and \(f_q(T)\) is obtained when \texttt{q_factor} == \texttt{True})

**EXAMPLES:**

Let us start with a simple example. Actually, let us start with the easiest possible example – the binary tree with only one vertex (which is a leaf):

```python
sage: b = BinaryTree()
sage: b.q_hook_length_fraction() # needs sage.combinat
1
sage: b.q_hook_length_fraction(q_factor=True) # needs sage.combinat
1
```

Nothing different for a tree with one node and two leaves:

```python
sage: b = BinaryTree([]); b
[., .]
sage: b.q_hook_length_fraction() # needs sage.combinat
1
sage: b.q_hook_length_fraction(q_factor=True) # needs sage.combinat
1
```

Let us get to a more interesting tree:

```python
sage: b = BinaryTree([[[[]],[]],[[[]],None]]); b
[[[., .], [[., .], .]], [[., .], .]]
sage: b.q_hook_length_fraction((q=1)
20
sage: b.q_hook_length_fraction()
```

(continues on next page)
Let us check the fact that $f_q(T)$ is the generating function for all permutations whose binary search tree is $T$ (after dropping the labels) with respect to the number of inversions of the permutations:

```python
def q_hook_length_fraction_2(T):
    P = PolynomialRing(ZZ, 'q')
    q = P.gen()
    res = P.zero()
    for w in T.sylvester_class():
        res += q ** Permutation(w).length()
    return res
def test_genfun(i):
    return all( q_hook_length_fraction_2(T) == T.q_hook_length_fraction(q_factor=True) for T in BinaryTrees(i) )
sage: test_genfun(4) True
```
... \textbf{return all} \ (q\_hook\_length\_fraction\_2(T) \\
... \quad== T.q\_hook\_length\_fraction(q\_factor=True) \\
... \quadfor T in BinaryTrees(i) ) \\
>>> test_genfun(Integer(4)) \\
\textit{˓→ # needs sage.combinat} \\
True

\textbf{right\_rotate()} \\
Return the result of right rotation applied to the binary tree \texttt{self}.

Right rotation on binary trees is defined as follows: Let \( T \) be a binary tree such that the left child of the root of \( T \) is a node. Let \( C \) be the right child of the root of \( T \), and let \( A \) and \( B \) be the left and right children of the left child of the root of \( T \). (Keep in mind that nodes of trees are identified with the subtrees consisting of their descendants.) Then, the right rotation of \( T \) is the binary tree in which the left child of the root is \( A \), whereas the right child of the root is a node whose left and right children are \( B \) and \( C \). In pictures:

\begin{verbatim}
| *  * \\
| / \\
| *  C -right-rotate-> A  * \\
| / \\
| A  B  B  C \\
\end{verbatim}

where asterisks signify a single node each (but \( A \), \( B \) and \( C \) might be empty).

For example,

\begin{verbatim}
| o  _o_ \\
| / / \\
| o -right-rotate-> o  o \\
| / \\
| o  o  o  \\
<BLANKLINE>
| _o_  _o_ \\
| /  / \\
| o  o -right-rotate-> o  _o_ \\
| /  / \\
| o  o  o  o  \\
| /  \\
| o  o  o  \\
\end{verbatim}

Right rotation is the inverse operation to left rotation (\texttt{left\_rotate()}).

The right rotation operation introduced here is the one defined in Definition 2.1 of [CP2012].

See also:

\textit{left\_rotate()} \\
EXAMPLES:

\begin{verbatim}
sage: b = BinaryTree([[[],[]], None]); ascii_art([b]) \\
[ o ] \\
[ / ] \\
[ o ] \\
[ / ] \\
[ o  o ] \\
\end{verbatim}

\begin{verbatim}
sage: ascii_art([b.right_rotate()]) \\
[ _o_  ] \\
\end{verbatim}
sage: b = BinaryTree([[[],None],[None,[]], []]); ascii_art([b])
[    __o__    ]
[    / \    ]
[   _o_   ]
[   /   \   ]
[ _o_     ]
[   \     ]
sage: ascii_art([b.right_rotate()])
[    _o__    ]
[    / \    ]
[   _o_   ]
[   /   \   ]
[ _o_     ]
[   \     ]

>>> from sage.all import *

>>> b = BinaryTree([[[],[]], None]); ascii_art([b])
[    o    ]
[    /    ]
[ _o_    ]
[   /   ]
[ _o_    ]
[    \    ]

>>> ascii_art([b.right_rotate()])
[    _o_    ]
[    /   ]
[ _o_    ]
[   /   ]
[ _o_    ]
[    \    ]

>>> b = BinaryTree([[[],None],[None,[]], []]); ascii_art([b])
[    __o__    ]
[    / \    ]
[   _o_   ]
[   /   \   ]
[ _o_     ]
[   \     ]

>>> ascii_art([b.right_rotate()])
[    _o__    ]
[    / \    ]
[   _o_   ]
[   /   \   ]
[ _o_     ]
[   \     ]

>>> ascii_art([b.right_rotate()])
[    _o__    ]
[    / \    ]
[   _o_   ]
[   /   \   ]
[ _o_     ]
[   \     ]

show (with_leaves=False)

Show the binary tree show, with or without leaves depending on the Boolean keyword variable with_leaves.
**Warning:** For a labelled binary tree, the labels shown in the picture are not (in general) the ones given by the labelling!

Use `_latex_`, `view`, `_ascii_art_` or `pretty_print` for more faithful representations of the data of the tree.

### single_edge_cut.shapes()

Return the list of possible single-edge cut shapes for the binary tree.

This is used in `sage.combinat.interval_posets.TamariIntervalPoset.is_new()`.

**OUTPUT:**

a list of triples $(m, i, n)$ of integers

This is a list running over all inner edges (i.e., edges joining two non-leaf vertices) of the binary tree. The removal of each inner edge defines two binary trees (connected components), the root-tree and the sub-tree. Thus, to every inner edge, we can assign three positive integers: $m$ is the node number of the root-tree $R$, and $n$ is the node number of the sub-tree $S$. The integer $i$ is the index of the leaf of $R$ on which $S$ is grafted to obtain the original tree. The leaves of $R$ are numbered starting from 1 (from left to right), hence $1 \leq i \leq m + 1$.

In fact, each of $m$ and $n$ determines the other, as the total node number of $R$ and $S$ is the node number of `self`.

**EXAMPLES:**

```python
sage: BT = BinaryTrees(3)
sage: [t.single_edge_cut_shapes() for t in BT]
[[[2, 3, 1], [1, 2, 2]],
 [[2, 2, 1], [1, 2, 2]],
 [[2, 1, 1], [2, 3, 1]],
 [[2, 2, 1], [1, 1, 2]],
 [[2, 1, 1], [1, 1, 2]]]
sage: BT = BinaryTrees(2)
sage: [t.single_edge_cut_shapes() for t in BT]
[[[1, 2, 1]], [[1, 1, 1]]]
sage: BT = BinaryTrees(1)
sage: [t.single_edge_cut_shapes() for t in BT]
[[[]]]
```

```python
>>> from sage.all import *
>>> BT = BinaryTrees(Integer(3))
>>> [t.single_edge_cut_shapes() for t in BT]
[[[2, 3, 1], [1, 2, 2]],
 [[2, 2, 1], [1, 2, 2]],
 [[2, 1, 1], [2, 3, 1]],
 [[2, 2, 1], [1, 1, 2]],
 [[2, 1, 1], [1, 1, 2]]]
>>> BT = BinaryTrees(Integer(2))
>>> [t.single_edge_cut_shapes() for t in BT]
[[[1, 2, 1]], [[1, 1, 1]]]
>>> BT = BinaryTrees(Integer(1))
```

(continues on next page)
sylvester_class\(\) (**left_to_right**=**False**)  
Iterate over the sylvester class corresponding to the binary tree **self**.

The sylvester class of a tree \(T\) is the set of permutations \(\sigma\) whose right-to-left binary search tree (a notion defined in [HNT2005], Definition 7) is \(T\) after forgetting the labels. This is an equivalence class of the sylvester congruence (the congruence on words which holds two words \(uacbuv\) and \(ucuvb\) congruent whenever \(a, b, c\) are letters satisfying \(a \leq b < c\), and extends by transitivity) on the symmetric group.

For example the following tree’s sylvester class consists of the permutations \((1, 3, 2)\) and \((3, 1, 2)\):

```
   o
  / \  
 o o  
```

(only the nodes are drawn here).

The right-to-left binary search tree of a word is constructed by an RSK-like insertion algorithm which proceeds as follows: Start with an empty labelled binary tree, and read the word from right to left. Each time a letter is read from the word, insert this letter in the existing tree using binary search tree insertion (binary_search_insert()). This is what the binary_search_tree() method computes if it is given the keyword **left_to_right**=**False**.

Here are two more descriptions of the sylvester class of a binary search tree:

- The sylvester class of a binary search tree \(T\) is the set of all linear extensions of the poset corresponding to \(T\) (that is, of the poset whose Hasse diagram is \(T\), with the root on top), provided that the nodes of \(T\) are labelled with \(1, 2, \ldots, n\) in a binary-search-tree way (i.e., every left descendant of a node has a label smaller than that of the node, and every right descendant of a node has a label higher than that of the node).

- The sylvester class of a binary search tree \(T\) (with vertex labels \(1, 2, \ldots, n\)) is the interval \([u, v]\) in the right permutohedron order (permutohedron_lequal()), where \(u\) is the 312-avoiding permutation corresponding to \(T\) (to_312_avoiding_permutation()), and where \(v\) is the 132-avoiding permutation corresponding to \(T\) (to_132_avoiding_permutation()).

If the optional keyword variable **left_to_right** is set to **True**, then the left sylvester class of **self** is returned instead. This is the set of permutations \(\sigma\) whose left-to-right binary search tree (that is, the result of the binary_search_tree() with **left_to_right** set to **True**) is **self**. It is an equivalence class of the left sylvester congruence.

**Warning:** This method yields the elements of the sylvester class as raw lists, not as permutations!

**EXAMPLES:**

Verifying the claim that the right-to-left binary search trees of the permutations in the sylvester class of a tree \(t\) all equal \(t\):

```
sage: def test_bst_of_sc(n, left_to_right):
    ....:     for t in BinaryTrees(n):
    ....:         for p in t.sylvester_class(left_to_right=left_to_right):
    ....:             p_per = Permutation(p)
    ....:             tree = p_per.binary_search_tree(left_to_right=left_to_right)
    ....:             if not BinaryTree(tree) == t:
```

(continues on next page)
return False

return True

sage: test_bst_of_sc(4, False)  # needs sage.combinat
True

sage: test_bst_of_sc(5, False)  # long time  # needs sage.combinat
True

>>> from sage.all import *

>>> def test_bst_of_sc(n, left_to_right):
    ... for t in BinaryTrees(n):
        ... for p in t.sylvester_class(left_to_right=left_to_right):
            ... p_per = Permutation(p)
            ... tree = p_per.binary_search_tree(left_to_right=left_to_right)
            ... if not BinaryTree(tree) == t:
                ... return False
            ... return True

The same with the left-to-right version of binary search:

sage: test_bst_of_sc(4, True)  # needs sage.combinat
True

sage: test_bst_of_sc(5, True)  # long time  # needs sage.combinat
True

Checking that the sylvester class is the set of linear extensions of the poset of the tree:

sage: all(sorted(t.canonical_labelling().sylvester_class()) == sorted(list(v)
.....:  for v in t.canonical_labelling().to_poset().linear_
.....:      extensions()))
True

>>> from sage.all import *

>>> all(sorted(t.canonical_labelling().sylvester_class())  # needs sage.combinat
    ... == sorted(list(v)
    ... for v in t.canonical_labelling().to_poset().linear_
    ... extensions()))
True
... == sorted(list(v)
... for v in t.canonical_labelling().to_poset().linear_
˓→extensions())
... for t in BinaryTrees(Integer(4)))
True

tamari_greater()

The list of all trees greater or equal to self in the Tamari order.
This is the order filter of the Tamari order generated by self.
See tamari_lequal() for the definition of the Tamari poset.
See also:
tamari_smaller()

EXAMPLES:
For example, the tree:

```
| __o__ |
| / \ |
| o o |
| / \ / |
| o o o |
```

has these trees greater or equal to it:

```
| o , o , o , o , o , o , o , |
| \ \ \ \ \ \ \ \ \ \ \ |
| o o o o o o o o o |
```

tamari_interval (other)

Return the Tamari interval between self and other as a TamariIntervalPoset.
A “Tamari interval” is an interval in the Tamari poset. See `tamari_lequal()` for the definition of the Tamari poset.

**INPUT:**

- `other` – a binary tree greater or equal to `self` in the Tamari order

**EXAMPLES:**

```python
sage: bt = BinaryTree([[None, [], None], None])
sage: ip = bt.tamari_interval(BinaryTree([None, [None, [], None]])); ip
The Tamari interval of size 4 induced by relations [(2, 4), (3, 4), (3, 1), (2, 1)]

sage: ip.lower_binary_tree()
[[., [., [., .]]], .]
sage: ip.upper_binary_tree()
[., [[., [., .]], .]]
sage: ip.interval_cardinality()
4
sage: ip.number_of_tamari_inversions()
2
sage: list(ip.binary_trees())
[[., [., [., .]]], [., [., [., .]]], [., [[., .], .]], [[., .], .]]
sage: bt.tamari_interval(BinaryTree([None, [], []]))
Traceback (most recent call last):
...
ValueError: the two binary trees are not comparable on the Tamari lattice
```

```python
>>> from sage.all import *

>>> bt = BinaryTree([[None, [], None], None])

>>> ip = bt.tamari_interval(BinaryTree([None, [None, [], None]])); ip
The Tamari interval of size 4 induced by relations [(2, 4), (3, 4), (3, 1), (2, 1)]

>>> ip.lower_binary_tree()
[[., [., [., .]]], .]

>>> ip.upper_binary_tree()
[., [[., [., .]], .]]

>>> ip.interval_cardinality()
4

>>> ip.number_of_tamari_inversions()
2

>>> list(ip.binary_trees())
[[., [., [., .]]], [., [., [., .]]], [., [[., .], .]], [[., .], .]]

>>> bt.tamari_interval(BinaryTree([None, [], []]))
Traceback (most recent call last):
...
ValueError: the two binary trees are not comparable on the Tamari lattice
```

**tamari_join**(other)

Return the join of the binary trees `self` and `other` (of equal size) in the $n$-th Tamari poset (where $n$ is the size of these trees).

The $n$-th Tamari poset (defined in `tamari_lequal()`) is known to be a lattice, and the map from the $n$-th
symmetric group $S_n$ to the $n$-th Tamari poset defined by sending every permutation $p \in S_n$ to the binary search tree of $p$ (more precisely, to $p\.binary\.search\.tree\.shape()$) is a lattice homomorphism. (See Theorem 6.2 in [Rea2004].)

EXAMPLES:

```python
sage: a = BinaryTree([None, [None, []]])

sage: b = BinaryTree([None, [[], None]])

sage: c = BinaryTree([[None, []], None])

sage: d = BinaryTree([[[], None], None])

sage: e = BinaryTree([[], []])

sage: a.tamari_join(c) == a
True

sage: b.tamari_join(c) == b
True

sage: c.tamari_join(e) == a
True

sage: d.tamari_join(e) == e
True

sage: e.tamari_join(b) == a
True

sage: e.tamari_join(a) == a
True
```

```python
>>> from sage.all import *
>>> a = BinaryTree([None, [None, []]])

>>> b = BinaryTree([None, [[], None]])

>>> c = BinaryTree([[None, []], None])

>>> d = BinaryTree([[[], None], None])

>>> e = BinaryTree([[], []])

>>> a.tamari_join(c) == a
True

>>> b.tamari_join(c) == b
True

>>> c.tamari_join(e) == a
True

>>> d.tamari_join(e) == e
True

>>> e.tamari_join(b) == a
True

>>> e.tamari_join(a) == a
True
```

```python
sage: b1 = BinaryTree([[None, [[], None], None]])

sage: b2 = BinaryTree([[[], None], []])

sage: b1.tamari_join(b2)
[., [[., .], [., .]]]

sage: b3 = BinaryTree([[[], [], None]])

sage: b1.tamari_join(b3)
[., [., [[., .], .]]]
```

(continues on next page)
The universal property of the meet operation is satisfied:

```python
sage: def test_uni_join(p, q):
    j = p.tamari_join(q)
    if not p.tamari_lequal(j):
        return False
    if not q.tamari_lequal(j):
        return False
    for r in p.tamari_greater():
        if q.tamari_lequal(r) and not j.tamari_lequal(r):
            return False
    return True
```

```plaintext
sage: all( test_uni_join(p, q) for p in BinaryTrees(3) for q in BinaryTrees(3) )
True
```

```plaintext
sage: p = BinaryTrees(6).random_element()  # needs sage.combinat
sage: q = BinaryTrees(6).random_element()  # needs sage.combinat
sage: test_uni_join(p, q)  # needs sage.combinat
True
```

```plaintext
>>> from sage.all import *
>>> def test_uni_join(p, q):
...     j = p.tamari_join(q)
...     if not p.tamari_lequal(j):
...         return False
...     if not q.tamari_lequal(j):
...         return False
...     for r in p.tamari_greater():
...         if q.tamari_lequal(r) and not j.tamari_lequal(r):
...             return False
...     return True
```

```plaintext
>>> all( test_uni_join(p, q) for p in BinaryTrees(Integer(3)) for q in BinaryTrees(Integer(3)) )
True
```

```plaintext
>>> p = BinaryTrees(Integer(6)).random_element()  # needs sage.combinat
>>> q = BinaryTrees(Integer(6)).random_element()  # needs sage.combinat
>>> test_uni_join(p, q)  # needs sage.combinat
```
Border cases:

```python
sage: b = BinaryTree(Nonen)
sage: b.tamari_join(b)
```

```python
sage: b = BinaryTree([[]])
sage: b.tamari_join(b)
[., .]
```

```python
>>> from sage.all import *
>>> b = BinaryTree(Nonen)
>>> b.tamari_join(b)
[., .]
```

tamari_lequal(t2)

Return True if self is less or equal to another binary tree t2 (of the same size as self) in the Tamari order.

The Tamari order on binary trees of size n is the partial order on the set of all binary trees of size n generated by the following requirement: If a binary tree T' is obtained by right rotation (see right_rotate()) from a binary tree T, then T < T'. This not only is a well-defined partial order, but actually is a lattice structure on the set of binary trees of size n, and is a quotient of the weak order on the n-th symmetric group (also known as the right permutahedron order, see permutahedron_lequal()). See [CP2012]. The set of binary trees of size n equipped with the Tamari order is called the n-th Tamari poset.

The Tamari order can equivalently be defined as follows:

If T and S are two binary trees of size n, then the following four statements are equivalent:

- We have $T \leq S$ in the Tamari order.
- There exist elements t and s of the Sylvester classes (sylvester_class()) of T and S, respectively, such that $t \leq s$ in the weak order on the symmetric group.
- The 132-avoiding permutation corresponding to T (see to_132_avoiding_permutation()) is $\leq$ to the 132-avoiding permutation corresponding to S in the weak order on the symmetric group.
- The 312-avoiding permutation corresponding to T (see to_312_avoiding_permutation()) is $\leq$ to the 312-avoiding permutation corresponding to S in the weak order on the symmetric group.

See also:

tamari_smaller(), tamari_greater(), tamari_pred(), tamari_succ(), tamari_interval()

EXAMPLES:

This tree:

```
   o
  /|
 / |
 / o|
 /   |
```

(continues on next page)
is Tamari-≤ to the following tree:

Checking this:

```
sage: b = BinaryTree([[[[], []], None], []])
sage: c = BinaryTree([[[[], []], [None, []]]])
sage: b.tamari_lequal(c)
True

>>> from sage.all import *
>>> b = BinaryTree([[[[], []], None], []])
>>> c = BinaryTree([[[[], []], [None, []]]])
>>> b.tamari_lequal(c)
True
```

tamari_meet (other, side='right')

Return the meet of the binary trees self and other (of equal size) in the n-th Tamari poset (where n is the size of these trees).

The n-th Tamari poset (defined in tamari_lequal()) is known to be a lattice, and the map from the n-th symmetric group S_n to the n-th Tamari poset defined by sending every permutation p ∈ S_n to the binary search tree of p (more precisely, to p.binary_search_tree_shape()) is a lattice homomorphism. (See Theorem 6.2 in [Rea2004].)

Border cases:

sage: b = BinaryTree(None)
sage: b.tamari_meet(b)
.
sage: b = BinaryTree([])
sage: b.tamari_meet(b)[., .]

>>> from sage.all import *

>>> b = BinaryTree(None)

>>> b.tamari_meet(b)
.

>>> b = BinaryTree([])

>>> b.tamari_meet(b)[., .]

tamari_pred()

Compute the list of predecessors of self in the Tamari poset.

This list is computed by performing all left rotates possible on its nodes.

See tamari_lequal() for the definition of the Tamari poset.
EXAMPLES:

For this tree:

```
| __o__ |
| / \\ |
| o o |
```

the list is:

```
| o , _o_ |
| / / \\ |
| _o_ o o |
| / \\ / / |
| o o o o |
| / \\ |
| o o |
```

tamari_smaller()

The list of all trees smaller or equal to self in the Tamari order.
This is the order ideal of the Tamari order generated by self.
See tamari_lequal() for the definition of the Tamari poset.
See also:

tamari_greater()

EXAMPLES:

The tree:

```
| __o__ |
| / \\ |
| o o |
```

has these trees smaller or equal to it:

```
| __o__ , _o_ , o , o , o , o |
| / / \\ / / / / / / / / / |
| o o o _o_ o o o o o |
| / \ / / / / / / |
| o o o o o |
| / |
| o |
```

tamari_sorting_tuple(reverse=False)

Return the Tamari sorting tuple of self and the size of self.
This is a pair \((w,n)\), where \(n\) is the number of nodes of self, and \(w\) is an \(n\)-tuple whose \(i\)-th entry is the number of all nodes among the descendents of the right child of the \(i\)-th node of self. Here, the nodes of self are numbered from left to right.
INPUT:

- `reverse` - boolean (default False) if True, return instead the result for the left-right symmetric of the binary tree

OUTPUT:

a pair \((w, n)\), where \(w\) is a tuple of integers, and \(n\) the size

Two binary trees of the same size are comparable in the Tamari order if and only if the associated tuples \(w\) are componentwise comparable. (This is essentially the Theorem in [HT1972].) This is used in `tamari_lequal()`.

EXAMPLES:

```python
sage: [t.tamari_sorting_tuple() for t in BinaryTrees(3)]
[((2, 1, 0), 3),
 (2, 0, 1), 3),
 (0, 1, 0), 3),
 (1, 0, 0), 3),
 (0, 0, 0), 3)]
```

```python
sage: t = BinaryTrees(10).random_element()  # needs sage.combinat
sage: u = t.left_right_symmetry()  # needs sage.combinat
sage: t.tamari_sorting_tuple(True) == u.tamari_sorting_tuple()  # needs sage.combinat
```

REFERENCES:

- [HT1972]

`tamari_succ()`

Compute the list of successors of `self` in the Tamari poset.

This is the list of all trees obtained by a right rotate of one of its nodes.

See `tamari_lequal()` for the definition of the Tamari poset.

EXAMPLES:

The list of successors of:
to_132_avoiding_permutation()

Return a 132-avoiding permutation corresponding to the binary tree.

The linear extensions of a binary tree form an interval of the weak order called the sylvester class of the tree. This permutation is the maximal element of this sylvester class.

EXAMPLES:

```
sage: bt = BinaryTree([[],[]])
sage: bt.to_132_avoiding_permutation()
[3, 1, 2]
sage: bt = BinaryTree([[[], [[], None]], [], []])
sage: bt.to_132_avoiding_permutation()
[8, 6, 7, 3, 4, 1, 2, 5]
```

```
from sage.all import *
>>> bt = BinaryTree([[],[]])
>>> bt.to_132_avoiding_permutation()
[3, 1, 2]
>>> bt = BinaryTree([[[], [[], None]], [], []])
>>> bt.to_132_avoiding_permutation()
[8, 6, 7, 3, 4, 1, 2, 5]
```

to_312_avoiding_permutation()

Return a 312-avoiding permutation corresponding to the binary tree.

The linear extensions of a binary tree form an interval of the weak order called the sylvester class of the tree. This permutation is the minimal element of this sylvester class.

EXAMPLES:

```
sage: bt = BinaryTree([[],[]])
sage: bt.to_312_avoiding_permutation()
[1, 3, 2]
sage: bt = BinaryTree([[[], [[], None]], [], []])
sage: bt.to_312_avoiding_permutation()
[1, 3, 4, 2, 6, 8, 7, 5]
```

```
from sage.all import *
>>> bt = BinaryTree([[],[]])
>>> bt.to_312_avoiding_permutation()
[1, 3, 2]
>>> bt = BinaryTree([[[], [[], None]], [], []])
>>> bt.to_312_avoiding_permutation()
[1, 3, 4, 2, 6, 8, 7, 5]
```
Combinatorics, Release 10.4

[1, 3, 2]
>>> bt = BinaryTree([[], [[], None], [[]], []])
>>> bt.to_312_avoiding_permutation()
[1, 3, 4, 2, 6, 8, 7, 5]

to_dyck_word (usemap='1L0R')

Return the Dyck word associated with self using the given map.

INPUT:

- usemap – a string, either 1L0R, 1R0L, L1R0, R1L0

The bijection is defined recursively as follows:

- a leaf is associated to the empty Dyck Word
- a tree with children $l, r$ is associated with the Dyck word described by usemap where $L$ and $R$ are respectively the Dyck words associated with the trees $l$ and $r$.

EXAMPLES:

sage: # needs sage.combinat
sage: BinaryTree().to_dyck_word()
[]
sage: BinaryTree([]).to_dyck_word()
[1, 0]
sage: BinaryTree([[], [[]], None], [[]], []).to_dyck_word()
[1, 1, 1, 0, 0, 1, 1, 0, 0, 0, 1, 1, 0, 0, 1, 0]
sage: BinaryTree([[], None], None).to_dyck_word()
[1, 1, 0, 1, 0, 0]
sage: BinaryTree([None, []], None).to_dyck_word("1R0L")
[1, 0, 1, 0, 1, 0]
sage: BinaryTree([None, []], None).to_dyck_word("L1R0")
[1, 1, 0, 1, 0, 1]
sage: BinaryTree([None, []], None).to_dyck_word("R1L0")
[1, 1, 0, 1, 0, 0]
sage: BinaryTree([None, []], None).to_dyck_word("R10L")
Traceback (most recent call last):
... ValueError: R10L is not a correct map

>>> from sage.all import *
>>> # needs sage.combinat
>>> BinaryTree().to_dyck_word()
[]
>>> BinaryTree([]).to_dyck_word()
[1, 0]
>>> BinaryTree([[], [[]], None], [[]], []).to_dyck_word()
[1, 1, 1, 0, 0, 1, 1, 0, 0, 0, 1, 1, 0, 0, 1, 0]
>>> BinaryTree([[], None], None).to_dyck_word()
[1, 1, 0, 1, 0, 0]
>>> BinaryTree([None, []], None).to_dyck_word("1R0L")
[1, 0, 1, 0, 1, 0]
>>> BinaryTree([None, []], None).to_dyck_word("L1R0")
[1, 1, 0, 1, 0, 1]
>>> BinaryTree([None, []], None).to_dyck_word("R1L0")
[1, 1, 0, 1, 0, 0]
>>> BinaryTree([None, []], None).to_dyck_word("R10L")
(continues on next page)
Traceback (most recent call last):
...
ValueError: R10L is not a correct map
to_dyck_word_tamari()
Return the Dyck word associated with self in consistency with the Tamari order on Dyck words and binary trees.

The bijection is defined recursively as follows:

- a leaf is associated with an empty Dyck word;
- a tree with children \( l, r \) is associated with the Dyck word \( T(l)1T(r)0 \).

EXAMPLES:

```python
sage: BinaryTree().to_dyck_word_tamari()
[]
sage: BinaryTree([]).to_dyck_word_tamari()
[1, 0]
sage: BinaryTree([[None, []], None]).to_dyck_word_tamari()
[1, 1, 0, 0, 1, 0]
sage: BinaryTree([[[]], [[]], None]).to_dyck_word_tamari()
[1, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 1, 0, 0, 0]
```

to_full()
Return the full binary tree constructed from self.

Let \( T \) be a binary tree with \( n \) nodes. We construct a full binary tree \( F \) from \( T \) by attaching a leaf to each node of \( T \) which does not have 2 children. The resulting tree will have \( 2n + 1 \) nodes.

OUTPUT:
A full binary tree. See is_full() for the definition of full.

See also:
prune()

EXAMPLES:

```python
sage: bt = BinaryTree([[None, []], None])
sage: bt.to_full().is_full()
True
sage: ascii_art(bt)

```

(continues on next page)
sage: ascii_art(bt.to_full())
     __o___
    /     \
   o     o
   /     / \
  o     o   o

sage: bt = BinaryTree([[],[]])
sage: ascii_art(bt)
     o
    / \
   o   o

sage: ascii_art(bt.to_full())
     __o___
    /     \
   o     o
   /     / \
  o     o   o

sage: BinaryTree(\None).to_full()
[., .]

>>> from sage.all import *
>>> bt = BinaryTree([[\None,[]],\None])
>>> bt.to_full().is_full()
True

>>> ascii_art(bt)
     o
    / \
   o   o

>>> ascii_art(bt.to_full())
     __o___
    /     \
   o     o
   /     / \
  o     o   o

>>> bt = BinaryTree([[],[]])
>>> ascii_art(bt)
     o
    / \
   o   o

>>> ascii_art(bt.to_full())
     __o___
    /     \
   o     o
   /     / \
  o     o   o

(continues on next page)
to_ordered_tree_left_branch()

Return an ordered tree of size \( n + 1 \) by the following recursive rule:

- if \( x \) is the left child of \( y \), \( x \) becomes the left brother of \( y \)
- if \( x \) is the right child of \( y \), \( x \) becomes the last child of \( y \)

EXAMPLES:

```python
sage: bt = BinaryTree([[[], []]])
sage: bt.to_ordered_tree_left_branch()
[[[], []]]
```

>>> from sage.all import *
```python
>>> bt = BinaryTree([[[], None], [[], []]])
>>> bt.to_ordered_tree_left_branch()
[[[], [[None, []], []]], [[[], []]]]
```

to_ordered_tree_right_branch()

Return an ordered tree of size \( n + 1 \) by the following recursive rule:

- if \( x \) is the right child of \( y \), \( x \) becomes the right brother of \( y \)
- if \( x \) is the left child of \( y \), \( x \) becomes the first child of \( y \)

EXAMPLES:

```python
sage: bt = BinaryTree([[[], []]])
sage: bt.to_ordered_tree_right_branch()
[[[], []], [[]]]
```

```python
>>> from sage.all import *
```  
```python
>>> bt = BinaryTree([[], [[None, []], []]])
```  
```python
>>> bt.to_ordered_tree_right_branch()
[[[None, []], []], [[[], []]]]
```

to_poset (with_leaves=False, root_to_leaf=False)

Return the poset obtained by interpreting the tree as a Hasse diagram.

The default orientation is from leaves to root but you can pass root_to_leaf=True to obtain the inverse orientation.
Leaves are ignored by default, but one can set `with_leaves` to `True` to obtain the poset of the complete tree.

**INPUT:**

- `with_leaves` – (default: `False`) a Boolean, determining whether the resulting poset will be formed from the leaves and the nodes of `self` (if `True`), or only from the nodes of `self` (if `False`).
- `root_to_leaf` – (default: `False`) a Boolean, determining whether the poset orientation should be from root to leaves (if `True`) or from leaves to root (if `False`).

**EXAMPLES:**

```python
sage: bt = BinaryTree([])
sage: bt.to_poset()
Finite poset containing 1 elements
sage: bt.to_poset(with_leaves=True)
Finite poset containing 3 elements
sage: P1 = bt.to_poset(with_leaves=True)
sage: len(P1.maximal_elements())
1
sage: len(P1.minimal_elements())
2
sage: bt = BinaryTree([])
sage: P2 = bt.to_poset(with_leaves=True, root_to_leaf=True)
sage: len(P2.maximal_elements())
2
sage: len(P2.minimal_elements())
1
```

If the tree is labelled, we use its labelling to label the poset. Otherwise, we use the poset canonical labelling:

```python
sage: bt = BinaryTree([[None, []]]).canonical_labelling()
sage: bt
2[[1[., .], 3[., 4[., .]]]]
sage: bt.to_poset().cover_relations()
[[4, 3], [3, 2], [1, 2]]
```

```python
>>> from sage.all import *
>>> bt = BinaryTree([[None, []]]).canonical_labelling()
(continues on next page)
```
Let us check that the empty binary tree is correctly handled:

```python
sage: bt = BinaryTree()
sage: bt.to_poset()
Finite poset containing 0 elements
sage: bt.to_poset(with_leaves=True)
Finite poset containing 1 elements
```

**to_tilting()**

Transform a binary tree into a tilting object.

Let $t$ be a binary tree with $n$ nodes. There exists a unique depiction of $t$ (above the diagonal) such that all leaves are regularly distributed on the diagonal line from $(0, 0)$ to $(n, n)$ and all edges are either horizontal or vertical. This method provides the coordinates of this depiction, with the root as the top-left vertex.

**OUTPUT:**

a list of pairs of integers.

Every vertex of the binary tree is mapped to a pair of integers. The conventions are the following. The root has coordinates $(0, n)$ where $n$ is the node number. If a vertex is the left (right) son of another vertex, they share the first (second) coordinate.

**EXAMPLES:**

```python
sage: t = BinaryTrees(1)[0]
sage: t.to_tilting()
[(0, 1)]
```

```python
sage: for t in BinaryTrees(2):
    print(t.to_tilting())
[(1, 2), (0, 2)]
[(0, 1), (0, 2)]
```

```python
sage: from sage.combinat.abstract_tree import from_hexacode
sage: t = from_hexacode('202022002000', BinaryTrees())
```

```python
sage: len(t2.to_tilting()) == t2.node_number()
```

(continues on next page)

```python
>>> from sage.all import *
>>> t = BinaryTrees(Integer(1))[Integer(0)]
>>> t.to_tilting()
[(0, 1)]

>>> for t in BinaryTrees(Integer(2)):
...     print(t.to_tilting())
[(1, 2), (0, 2)]
[(0, 1), (0, 2)]

>>> from sage.combinat.abstract_tree import from_hexacode
>>> t = from_hexacode(2020222002000, BinaryTrees())
>>> print(t.to_tilting())
[(0, 1), (2, 3), (4, 5), (6, 7), (4, 7), (8, 9), (10, 11),
  (8, 11), (4, 11), (12, 13), (4, 13), (2, 13), (0, 13)]

>>> w = DyckWord([Integer(1), Integer(1), Integer(1), Integer(1), Integer(0),
  Integer(1), Integer(1), Integer(1), Integer(0), Integer(0), Integer(0), Integer(1),
  Integer(0), Integer(1), Integer(1), Integer(0), Integer(0), Integer(0),
  Integer(0), Integer(0), Integer(0)]) # needs sage.combinat
>>> t2 = w.to_binary_tree() # needs sage.combinat
>>> len(t2.to_tilting()) == t2.node_number() # needs sage.combinat
True
```

**to_undirected_graph** *(with_leaves=False)*

Return the undirected graph obtained from the tree nodes and edges.

Leaves are ignored by default, but one can set `with_leaves` to `True` to obtain the graph of the complete tree.

**INPUT:**

- `with_leaves` - (default: `False`) a Boolean, determining whether the resulting graph will be formed from the leaves and the nodes of `self` (if `True`), or only from the nodes of `self` (if `False`)

**EXAMPLES:**

```
sage: bt = BinaryTree([[]])
sage: bt.to_undirected_graph()
Graph on 1 vertex
sage: bt.to_undirected_graph(with_leaves=True)
Graph on 3 vertices

sage: bt = BinaryTree()
sage: bt.to_undirected_graph()
Graph on 0 vertices
sage: bt.to_undirected_graph(with_leaves=True)
Graph on 1 vertex
```

```python
>>> from sage.all import *
>>> bt = BinaryTree([])
(continues on next page)
```
Combinatorics, Release 10.4

If the tree is labelled, we use its labelling to label the graph. Otherwise, we use the graph canonical labelling which means that two different trees can have the same graph.

**EXAMPLES:**

```python
sage: bt = BinaryTree([[],[None,[]]])
sage: bt.canonical_labelling().to_undirected_graph() == bt.to_undirected_graph() False
sage: BinaryTree([[],[]]).to_undirected_graph() == BinaryTree([[],None,None]).to_undirected_graph() True
```

**twisting_number()**

Return a pair (number of maximal left branches, number of maximal right branches).

Recalling that a branch of a vertex $v$ is a path from a vertex of the tree to a leaf, a left (resp. right) branch is a branch made only of left (resp. right) edges. The length of a branch is the number of edges composing it. A left (resp. right) branch is maximal if it is not included in a strictly longer left (resp. right) branch.

**OUTPUT:**

A list of two integers

**EXAMPLES:**

```python
sage: BT = BinaryTree( '.' )
sage: BT.twisting_number() [0, 0]
sage: BT = BinaryTree( '[[,[,],[]]']
```

(continues on next page)
sage: BT.twisting_number()
[1, 1]
sage: BT = BinaryTree( '[[[., [., .]], .], [[., .], [[[., .], [., .]], [., .]]], [[., .], [[[., .], [., .]], [., .]]]]

sage: BT.twisting_number()
[5, 6]

sage: ascii_art(BT)

sage: BT = BinaryTree( '[[.,[[[.,.],[.]],.]]]' ); ascii_art(BT)

sage: BT.twisting_number()
[1, 1]
under \((bt)\)

Return \(self\ under\ bt\), where “under” is the \(\under\) operation.

If \(T\) and \(T'\) are two binary trees, then \(T\ under\ T'\) (written \(T \backslash T'\)) is defined as the tree obtained by grafting \(T\) on the leftmost leaf of \(T'\). More precisely, \(T \backslash T'\) is defined by identifying the root of \(T\) with the leftmost leaf of \(T'\).

If \(T'\) is empty, then \(T \backslash T' = T\).

The definition of this “under” operation goes back to Loday-Ronco [LR0102066] (Definition 2.2), but it is denoted by \(/\) and called the “over” operation there. In fact, trees in sage have their root at the top, contrary to the trees in [LR0102066] which are growing upwards. For this reason, the names of the over and under operations are swapped, in order to keep a graphical meaning. (Our notation follows that of section 4.5 of [HNT2005].)

See also:

\(over()\)

EXAMPLES:

Showing only the nodes of a binary tree, here is an example for the under operation:

code:
```python
sage: b1 = BinaryTree([[],[]])
sage: b2 = BinaryTree([None,[]])
sage: ascii_art((b1, b2, b1.under(b2)))
    ( o , o , _o_ )
    ( / \ / \ )
    ( o o o o )
    ( / )
    ( o )
```
under_decomposition()

Return the unique maximal decomposition as an under product.

This means that the tree is cut along all edges of its leftmost path.

Beware that the factors are ordered starting from the root.

See also:

comb(), over_decomposition()

EXAMPLES:

```python
sage: g = BinaryTree([])
sage: r = g.over(g); r
[., [., .]]
sage: l = g.under(g); l
[[., .], .]
sage: l.under_decomposition()
[[., .], [., .]]
sage: r.under_decomposition() == [r]
True
sage: x = r.under(g).under(r).under(g)
sage: ascii_art(x)
 o        
 /\      
 o o       
 o        
 /         
 
 o

sage: x.under_decomposition() == [g,r,g,r]
True
```

```python
>>> from sage.all import *
>>> g = BinaryTree([])
>>> r = g.over(g); r
[., [., .]]
>>> l = g.under(g); l
[[., .], .]
>>> l.under_decomposition()
[[., .], [., .]]
>>> r.under_decomposition() == [r]
True
>>> x = r.under(g).under(r).under(g)
>>> ascii_art(x)
 o        
 /\      
 o o       
 o        
 /         
 
 o
```

(continues on next page)
class sage.combinat.binary_tree.BinaryTrees
    Bases: UniqueRepresentation, Parent

Factory for binary trees.

A binary tree is a tree with at most 2 children. The binary trees considered here are also ordered (a.k.a. planar),
that is to say, their children are ordered.

A full binary tree is a binary tree with no nodes with 1 child.

INPUT:
    • size – (optional) an integer
    • full – (optional) a boolean

OUTPUT:
The set of all (full if full=True) binary trees (of the given size if specified).

See also:
    BinaryTree, BinaryTree.is_full()

EXAMPLES:

sage: BinaryTrees()
Binary trees

sage: BinaryTrees(2)
Binary trees of size 2

sage: BinaryTrees(full=True)
Full binary trees

sage: BinaryTrees(3, full=True)
Full binary trees of size 3

sage: BinaryTrees(4, full=True)
Traceback (most recent call last):
... ValueError: n must be 0 or odd

>>> from sage.all import *
>>> BinaryTrees()
Binary trees

>>> BinaryTrees(Integer(2))
Binary trees of size 2

>>> BinaryTrees(full=True)
Full binary trees

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> BinaryTrees(Integer(3), full=True)
Full binary trees of size 3
>>> BinaryTrees(Integer(4), full=True)
Traceback (most recent call last):
... ValueError: n must be 0 or odd
```

**Note:** This is a factory class whose constructor returns instances of subclasses.

**Note:** The fact that `BinaryTrees` is a class instead of a simple callable is an implementation detail. It could be changed in the future and one should not rely on it.

```python
def leaf()
    Return a leaf tree with self as parent.
    EXAMPLES:
    sage: BinaryTrees().leaf()
```

```python
>>> from sage.all import *
```

```python
>>> BinaryTrees().leaf()
```

```python
class sage.combinat.binary_tree.BinaryTrees_all
    Bases: DisjointUnionEnumeratedSets, BinaryTrees
    Element
    alias of BinaryTree

def labelled_trees()
    Return the set of labelled trees associated to self.
    EXAMPLES:
    sage: BinaryTrees().labelled_trees()
      Labelled binary trees
```

```python
>>> from sage.all import *
```

```python
>>> BinaryTrees().labelled_trees()
Labelled binary trees
```

```python
def unlabelled_trees()
    Return the set of unlabelled trees associated to self.
    EXAMPLES:
    sage: BinaryTrees().unlabelled_trees()
      Binary trees
```

202 Chapter 5. Comprehensive Module List
```python
from sage.all import *

BinaryTrees().unlabelled_trees()
```

```python
class sage.combinat.binary_tree.BinaryTrees_size(size):
    Bases: BinaryTrees
    
The enumerated sets of binary trees of given size.

cardinality()
    The cardinality of self
    This is a Catalan number.

class sage.combinat.binary_tree.FullBinaryTrees_all:
    Bases: DisjointUnionEnumeratedSets, BinaryTrees
    All full binary trees.

class sage.combinat.binary_tree.FullBinaryTrees_size(size):
    Bases: BinaryTrees
    Full binary trees of a fixed size (number of nodes).

cardinality()
    The cardinality of self
    This is a Catalan number.
```
random_element()

Return a random FullBinaryTree with uniform probability.

This method generates a random DyckWord of size \((s - 1)/2\), where \(s\) is the size of self, which uses a bijection between Dyck words and binary trees to get a binary tree, and convert it to a full binary tree.

EXAMPLES:

```python
sage: BinaryTrees(5, full=True).random_element()  # random
[[], [[], []]]

sage: BinaryTrees(0, full=True).random_element()  # needs sage.combinat

sage: BinaryTrees(1, full=True).random_element()  # needs sage.combinat
[., .]
```

```python
>>> from sage.all import *
>>> BinaryTrees(Integer(5), full=True).random_element()  # random
[[], [[], []]]

>>> BinaryTrees(Integer(0), full=True).random_element()  # needs sage.combinat

>>> BinaryTrees(Integer(1), full=True).random_element()  # needs sage.combinat
[., .]
```

class sage.combinat.binary_tree.LabelledBinaryTree(parent, children, label=None, check=True)

Labelled binary trees.

A labelled binary tree is a binary tree (see BinaryTree for the meaning of this) with a label assigned to each node. The labels need not be integers, nor are they required to be distinct. None can be used as a label.

**Warning:** While it is possible to assign values to leaves (not just nodes) using this class, these labels are disregarded by various methods such as `labels()`, `map_labels()`, and (ironically) `leaf_labels()`.

**INPUT:**

- `children` — None (default) or a list, tuple or iterable of length 2 of labelled binary trees or convertible objects. This corresponds to the standard recursive definition of a labelled binary tree as being either a leaf, or a pair of:
  - a pair of labelled binary trees,
  - and a label.

(The label is specified in the keyword variable `label`; see below.)

Syntactic sugar allows leaving out all but the outermost calls of the `LabelledBinaryTree()` constructor, so that, e. g., `LabelledBinaryTree([LabelledBinaryTree(None), LabelledBinaryTree(3)])` can be shortened to `LabelledBinaryTree([None, 3])`. However, using this shorthand, it is impossible to label any vertex of the tree other than the root (because there is no way to pass a `label` variable without calling `LabelledBinaryTree` explicitly).
It is also allowed to abbreviate `[None, None]` by `[]` if one does not want to label the leaves (which one should not do anyway!).

- **label** – (default: `None`) the label to be put on the root of this tree.
- **check** – (default: `True`) whether checks should be performed or not.

**Todo**: It is currently not possible to use `LabelledBinaryTree()` as a shorthand for `LabelledBinaryTree(None)` (in analogy to similar syntax in the `BinaryTree` class).

**EXAMPLES**:

```python
sage: LabelledBinaryTree(None)
.
sage: LabelledBinaryTree(None, label="ae")  # not well supported
'ae'
sage: LabelledBinaryTree([])
None[., .]
sage: LabelledBinaryTree([], label=3)  # not well supported
3[., .]
sage: LabelledBinaryTree([None, None])
None[., .]
sage: LabelledBinaryTree([None, None], label=5)
5[., .]
sage: LabelledBinaryTree([None, []])
None[., None[., .]]
sage: LabelledBinaryTree([None, []], label=4)
4[., None[., .]]
sage: LabelledBinaryTree([], [], label=False)
False[None[., .], .]
sage: LabelledBinaryTree([None, LabelledBinaryTree([None, None], label=4)],... →label=3)
3[., 4[., .]]
sage: LabelledBinaryTree([None, BinaryTree([None, None])], label=3)
3[., None[., .]]
sage: LabelledBinaryTree([], [], label=3)
Traceback (most recent call last):
...
ValueError: this is not a binary tree
```

```python
sage: LBT = LabelledBinaryTree
sage: t1 = LBT([[LBT([], label=2), None], None], label=4); t1
4[None[2[., .], .], .]
```

```python
>>> from sage.all import *
>>> LabelledBinaryTree(None)
.
>>> LabelledBinaryTree(None, label="ae")  # not well supported
'ae'
```
None[., .]

>>> LabelledBinaryTree([[None, None], label=Integer(5))
5[., .]

>>> LabelledBinaryTree([[None, []]])
None[., None[., .]]

>>> LabelledBinaryTree([[None, []], label=Integer(4))
4[., None[., .]]

>>> LabelledBinaryTree([[None], None])
None[None[., .], .]

>>> LabelledBinaryTree("[[], .]", label=False)
False[None[., .], .]

>>> LabelledBinaryTree([None, LabelledBinaryTree([None, None], label=Integer(4))], label=Integer(3))
3[., 4[., .]]

>>> LabelledBinaryTree([None, BinaryTree([None, None])], label=Integer(3))
3[., None[., .]]

>>> LabelledBinaryTree([None], None[., .]])

Traceback (most recent call last):
...
ValueError: this is not a binary tree

>>> LBT = LabelledBinaryTree
>>> t1 = LBT([[LBT([[label=Integer(2)], None], None], label=Integer(4))]; t1
4[None[2[., .], .], .]

**binary_search_insert**(letter)

Return the result of inserting a letter *letter* into the right strict binary search tree *self*.

**INPUT:**

- *letter*—any object comparable with the labels of *self*

**OUTPUT:**

The right strict binary search tree *self* with *letter* inserted into it according to the binary search insertion algorithm.

**Note:** *self* is supposed to be a binary search tree. This is not being checked!

A right strict binary search tree is defined to be a labelled binary tree such that for each node *n* with label *x*, every descendant of the left child of *n* has a label ≤ *x*, and every descendant of the right child of *n* has a label > *x*. (Here, only nodes count as descendants, and every node counts as its own descendant too.) Leaves are assumed to have no labels.

Given a right strict binary search tree *t* and a letter *i*, the result of inserting *i* into *t* (denoted *Ins(i, t)* in the following) is defined recursively as follows:

- If *t* is empty, then *Ins(i, t)* is the tree with one node only, and this node is labelled with *i*.
- Otherwise, let *j* be the label of the root of *t*. If *i* > *j*, then *Ins(i, t)* is obtained by replacing the right child of *t* by *Ins(i, r)* in *t*, where *r* denotes the right child of *t*. If *i* ≤ *j*, then *Ins(i, t)* is obtained by replacing the left child of *t* by *Ins(i, l)* in *t*, where *l* denotes the left child of *t*.

See, for example, [HNT2005] for properties of this algorithm.
**Warning:** If $t$ is nonempty, then inserting $i$ into $t$ does not change the root label of $t$. Hence, as opposed to algorithms like Robinson-Schensted-Knuth, binary search tree insertion involves no bumping.

**EXAMPLES:**

The example from Fig. 2 of [HNT2005]:

```python
sage: LBT = LabelledBinaryTree
sage: x = LBT(None)
sage: x

sage: x = x.binary_search_insert("b"); x
b[., .]
sage: x = x.binary_search_insert("d"); x
b[., d[., .]]
sage: x = x.binary_search_insert("e"); x
b[., d[., e[., .]]]
sage: x = x.binary_search_insert("a"); x
b[a[., .], d[., e[., .]]]
sage: x = x.binary_search_insert("b"); x
b[a[., b[., .]], d[., e[., .]]]
sage: x = x.binary_search_insert("d"); x
b[a[., b[., .]], d[., d[., .]], e[., .]]
sage: x = x.binary_search_insert("a"); x
b[a[., b[., .]], d[., d[., .]], e[., .]]
sage: x = x.binary_search_insert("c"); x
b[a[., b[., .]], d[., d[., .]], e[., .]]
```

```python
>>> from sage.all import *
>>> LBT = LabelledBinaryTree
>>> x = LBT(None)

sage: x

sage: x = x.binary_search_insert("b"); x
b[., .]
sage: x = x.binary_search_insert("d"); x
b[., d[., .]]
sage: x = x.binary_search_insert("e"); x
b[., d[., e[., .]]]
sage: x = x.binary_search_insert("a"); x
b[a[., .], d[., e[., .]]]
sage: x = x.binary_search_insert("b"); x
b[a[., b[., .]], d[., e[., .]]]
sage: x = x.binary_search_insert("d"); x
b[a[., b[., .]], d[., d[., .]], e[., .]]
sage: x = x.binary_search_insert("a"); x
b[a[., b[., .]], d[., d[., .]], e[., .]]
sage: x = x.binary_search_insert("c"); x
b[a[., b[., .]], d[., d[., .]], e[., .]]
```

Other examples:

```python
sage: LBT = LabelledBinaryTree
sage: LBT(None).binary_search_insert(3)
3[., .]
sage: LBT([], label = 1).binary_search_insert(3)
```

(continues on next page)
heap_insert (l)

Return the result of inserting a letter \( l \) into the binary heap (tree) \( \text{self} \).

A binary heap is a labelled complete binary tree such that for each node, the label at the node is greater or equal to the label of each of its child nodes. (More precisely, this is called a max-heap.)

For example:

```
|    7    |
| / \    |
| 5   6  |
| / \    |
| 3   4  |
```

is a binary heap.

See Wikipedia article Binary_heap#Insert for a description of how to insert a letter into a binary heap. The result is another binary heap.

INPUT:

- letter – any object comparable with the labels of \( \text{self} \)

Note: \( \text{self} \) is assumed to be a binary heap (tree). No check is performed.

left_rotate ()

Return the result of left rotation applied to the labelled binary tree \( \text{self} \).

Left rotation on labelled binary trees is defined as follows: Let \( T \) be a labelled binary tree such that the right child of the root of \( T \) is a node. Let \( A \) be the left child of the root of \( T \), and let \( B \) and \( C \) be the left and right children of the right child of the root of \( T \). (Keep in mind that nodes of trees are identified with the subtrees consisting of their descendants.) Furthermore, let \( x \) be the label at the root of \( T \), and \( y \) be the label at the
right child of the root of \( T \). Then, the left rotation of \( T \) is the labelled binary tree in which the root is labelled \( y \), the right child of the root is \( C \), whereas the left child of the root is a node labelled \( x \) whose left and right children are \( A \) and \( B \). In pictures:

<table>
<thead>
<tr>
<th>y</th>
<th>x</th>
</tr>
</thead>
<tbody>
<tr>
<td>/ \</td>
<td>/ \</td>
</tr>
<tr>
<td>x</td>
<td>C</td>
</tr>
<tr>
<td>/ \</td>
<td>/ \</td>
</tr>
<tr>
<td>A B</td>
<td>B C</td>
</tr>
</tbody>
</table>

Left rotation is the inverse operation to right rotation \((\text{right\_rotate})\).

right\_rotate()

Return the result of right rotation applied to the labelled binary tree \( self \).

Right rotation on labelled binary trees is defined as follows: Let \( T \) be a labelled binary tree such that the left child of the root of \( T \) is a node. Let \( C \) be the right child of the root of \( T \), and let \( A \) and \( B \) be the left and right children of the left child of the root of \( T \). (Keep in mind that nodes of trees are identified with the subtrees consisting of their descendants.) Furthermore, let \( y \) be the label at the root of \( T \), and \( x \) be the label at the left child of the root of \( T \). Then, the right rotation of \( T \) is the labelled binary tree in which the root is labelled \( x \), the left child of the root is \( A \), whereas the right child of the root is a node labelled \( y \) whose left and right children are \( B \) and \( C \). In pictures:

<table>
<thead>
<tr>
<th>y</th>
<th>x</th>
</tr>
</thead>
<tbody>
<tr>
<td>/ \</td>
<td>/ \</td>
</tr>
<tr>
<td>x</td>
<td>C</td>
</tr>
<tr>
<td>/ \</td>
<td>/ \</td>
</tr>
<tr>
<td>A B</td>
<td>B C</td>
</tr>
</tbody>
</table>

Right rotation is the inverse operation to left rotation \((\text{left\_rotate})\).

semistandard\_insert (letter)

Return the result of inserting a letter \( \text{letter} \) into the semistandard tree \( \text{self} \) using the bumping algorithm.

INPUT:

- \( \text{letter} \) – any object comparable with the labels of \( \text{self} \)

OUTPUT:

The semistandard tree \( \text{self} \) with \( \text{letter} \) inserted into it according to the bumping algorithm.

**Note:** \( \text{self} \) is supposed to be a semistandard tree. This is not being checked!

A semistandard tree is defined to be a labelled binary tree such that for each node \( n \) with label \( x \), every descendant of the left child of \( n \) has a label \( > x \), and every descendant of the right child of \( n \) has a label \( \geq x \). (Here, only nodes count as descendants, and every node counts as its own descendant too.) Leaves are assumed to have no labels.

Given a semistandard tree \( t \) and a letter \( i \), the result of inserting \( i \) into \( t \) (denoted \( \text{Ins}(i, t) \) in the following) is defined recursively as follows:

- If \( t \) is empty, then \( \text{Ins}(i, t) \) is the tree with one node only, and this node is labelled with \( i \).
- Otherwise, let \( j \) be the label of the root of \( t \). If \( i \geq j \), then \( \text{Ins}(i, t) \) is obtained by replacing the right child of \( t \) by \( \text{Ins}(i, r) \) in \( t \), where \( r \) denotes the right child of \( t \). If \( i < j \), then \( \text{Ins}(i, t) \) is obtained by replacing the label at the root of \( t \) by \( i \), and replacing the left child of \( t \) by \( \text{Ins}(j, l) \) in \( t \), where \( l \) denotes the left child of \( t \).
This algorithm is similar to the Robinson-Schensted-Knuth insertion algorithm for semistandard Young tableaux.

AUTHORS:

- Darij Grinberg (10 Nov 2013).

EXAMPLES:

```
sage: LBT = LabelledBinaryTree
sage: x = LBT(None)
sage: x.
sage: x = x.semistandard_insert("b"); x
b[., .]
sage: x = x.semistandard_insert("d"); x
b[., d[., .]]
sage: x = x.semistandard_insert("e"); x
b[., d[., e[., .]]]
sage: x = x.semistandard_insert("a"); x
a[b[., .], d[., e[., .]]]
sage: x = x.semistandard_insert("b"); x
a[b[., .], d[., e[., .]]]
sage: x = x.semistandard_insert("d"); x
a[b[., .], d[., e[., .]]]
sage: x = x.semistandard_insert("a"); x
a[b[., .], a[b[., .], e[., .]]]
sage: x = x.semistandard_insert("c"); x
a[b[., .], a[b[., .], c[., .]]]
```

Other examples:

```
sage: LBT = LabelledBinaryTree
sage: LBT(None).semistandard_insert(3)
3[., .]
sage: LBT([], label = 1).semistandard_insert(3)
1[., 3[., .]]
```
sage: LBT([], label = 3).semistandard_insert(1)
1[3[., .], .]
sage: res = LBT(None)
sage: for i in [3,1,5,2,4,6]:
    ....:     res = res.semistandard_insert(i)
sage: res
1[3[., .], 2[5[., .], 4[., 6[., .]]]]

>> from sage.all import *
>> LBT = LabelledBinaryTree
>> LBT(None).semistandard_insert(Integer(3))
3[., .]
>> LBT([], label = Integer(1)).semistandard_insert(Integer(3))
1[., 3[., .]]
>> LBT([], label = Integer(3)).semistandard_insert(Integer(1))
1[3[., .], .]
>> res = LBT(None)
>> for i in [Integer(3),Integer(1),Integer(5),Integer(2),Integer(4),
           Integer(6)]:
    ....:     res = res.semistandard_insert(i)
>> res
1[3[., .], 2[5[., .], 4[., 6[., .]]]]

class sage.combinat.binary_tree.LabelledBinaryTrees(category=None)
    Bases: LabelledOrderedTrees

This is a parent stub to serve as a factory class for trees with various labels constraints.

Element
    alias of LabelledBinaryTree

labelled_trees()
    Return the set of labelled trees associated to self.

    EXAMPLES:

    sage: LabelledBinaryTrees().labelled_trees()
    Labelled binary trees

    >>> from sage.all import *
    >>> LabelledBinaryTrees().labelled_trees()
    Labelled binary trees

unlabelled_trees()
    Return the set of unlabelled trees associated to self.

    EXAMPLES:

    sage: LabelledBinaryTrees().unlabelled_trees()
    Binary trees

    >>> from sage.all import *
    >>> LabelledBinaryTrees().unlabelled_trees()
    Binary trees

This is used to compute the shape:
sage: t = LabelledBinaryTrees().an_element().shape(); t
[[[., .], [., .]], [[., .], [., .]]]
sage: t.parent()
Binary trees

```python
>>> from sage.all import *
>>> t = LabelledBinaryTrees().an_element().shape(); t
[[[., .], [., .]], [[., .], [., .]]]
>>> t.parent()
Binary trees
```

```
sage.combinat.binary_tree.binary_search_tree_shape(w, left_to_right=True)
```

Direct computation of the binary search tree shape of a list of integers.

**INPUT:**
- w – a list of integers
- left_to_right – boolean (default True)

**OUTPUT:** a non labelled binary tree

This is used under the same name as a method for permutations.

**EXAMPLES:**

```python
sage: from sage.combinat.binary_tree import binary_search_tree_shape
sage: binary_search_tree_shape([1,4,3,2])
[[., [., .]], [., .]]
sage: binary_search_tree_shape([5,1,3,2])
[[., [., .]], [., .]]
```

By passing the option `left_to_right=False` one can have the insertion going from right to left:

```python
>>> from sage.all import *
>>> from sage.combinat.binary_tree import binary_search_tree_shape
>>> binary_search_tree_shape([Integer(1),Integer(4),Integer(3),Integer(2)])
[[., [., .]], [., .]]
>>> binary_search_tree_shape([Integer(5),Integer(1),Integer(3),Integer(2)])
[[., [., .]], [., .]]
```

```python
sage: binary_search_tree_shape([1,6,4,2], False)
[[., .], [[., .], [., .]]]
```

```python
>>> from sage.all import *
>>> binary_search_tree_shape([Integer(1),Integer(6),Integer(4),Integer(2)], False)
[[., .], [[., .], [., .]]]
```

```
sage.combinat.binary_tree.from_tamari_sorting_tuple(key)
```

Return a binary tree from its Tamari-sorting tuple.

See `tamari_sorting_tuple()`

**INPUT:**
- key – a tuple of integers

**EXAMPLES:**
```python
sage: from sage.combinat.binary_tree import from_tamari_sorting_tuple
sage: t = BinaryTrees(60).random_element()  # needs sage.combinat
sage: from_tamari_sorting_tuple(t.tamari_sorting_tuple()[0]) == t  # needs sage.combinat
True

>>> from sage.all import *
>>> from sage.combinat.binary_tree import from_tamari_sorting_tuple
>>> t = BinaryTrees(Integer(60)).random_element()  # needs sage.combinat
>>> from_tamari_sorting_tuple(t.tamari_sorting_tuple()[Integer(0)]) == t  # needs sage.combinat
True

5.1.11 Blob Algebras

AUTHORS:

- Travis Scrimshaw (2020-05-16): Initial version

class sage.combinat.blob_algebra.BlobAlgebra(k, q1, q2, q3, base_ring, prefix)

Bases: CombinatorialFreeModule

The blob algebra.

The blob algebra (also known as the Temperley-Lieb algebra of type $B$ in [ILZ2018], but is a quotient of the Temperley-Lieb algebra of type $B$ defined in [Graham1985]) is a diagram-type algebra introduced in [MS1994] whose basis consists of Temperley-Lieb diagrams, noncrossing perfect matchings, that may contain blobs on strands that can be deformed so that the blob touches the left side (which we can think of as a frozen pole).

The form we give here has 3 parameters, the natural one from the Temperley-Lieb algebra, one for the idempotent relation, and one for a loop with a blob.

INPUT:

- $k$ – the order
- $q_1$ – the loop parameter
- $q_2$ – the idempotent parameter
- $q_3$ – the blob loop parameter

EXAMPLES:

```python
sage: R.<q,r,s> = ZZ[]
sage: B4 = algebras.Blob(4, q, r, s)
sage: B = sorted(B4.basis())
sage: B[14]
B({{-4, -3}}, {{-2, -1}, {1, 2}, {3, 4}})
sage: B[40]
B({{3, 4}}, {{-4, -3}, {-2, -1}, {1, 2}})
sage: B[14] * B[40]
q*r*s*B({}, {{-4, -3}, {-2, -1}, {1, 2}, {3, 4}})
```
REFERENCES:

- [MS1994]
- [ILZ2018]

one_basis()
Return the index of the basis element 1.

EXAMPLES:

```sage
sage: R.<q,r,s> = ZZ[]
sage: B4 = algebras.Blob(4, q, r, s)
sage: B4.one_basis()
({}, {{-4, 4}, {-3, 3}, {-2, 2}, {-1, 1}})
```

order()
Return the order of self.

The order of a partition algebra is defined as half of the number of nodes in the diagrams.

EXAMPLES:

```sage
sage: R.<q,r,s> = ZZ[]
sage: B4 = algebras.Blob(4, q, r, s)
sage: B4.order()
4
```

product_on_basis(top, bot)
Return the product of the basis elements indexed by top and bot.

EXAMPLES:

```sage
sage: R.<q,r,s> = ZZ[]
sage: B4 = algebras.Blob(4, q, r, s)
```
(continues on next page)
sage: B = B4.basis()
sage: BD = sorted(B.keys())
sage: BD[14]
({{-4, -3}}, {{-2, -1}, {1, 2}, {3, 4}})
sage: BD[40]
({{3, 4}}, {{-4, -3}, {-2, -1}, {1, 2}})
sage: B4.product_on_basis(BD[14], BD[40])
q*r*s*B({}, {{-4, -3}, {-2, -1}, {1, 2}, {3, 4}})
sage: all(len((x*y).support()) == 1 for x in B for y in B)
True

>>> from sage.all import *
>>> R = ZZ['q, r, s']; (q, r, s,) = R._first_ngens(3)
>>> B4 = algebras.Blob(Integer(4), q, r, s)
>>> B = B4.basis()
>>> BD = sorted(B.keys())
>>> BD[14]
({{-4, -3}}, {{-2, -1}, {1, 2}, {3, 4}})
>>> BD[40]
({{3, 4}}, {{-4, -3}, {-2, -1}, {1, 2}})
>>> B4.product_on_basis(BD[14], BD[40])
q*r*s*B({}, {{-4, -3}, {-2, -1}, {1, 2}, {3, 4}})
>>> all(len((x*y).support()) == Integer(1) for x in B for y in B)
True

class sage.combinat.blob_algebra.BlobDiagram(parent, marked, unmarked)
  Bases: Element

A blob diagram.

A blob diagram consists of a perfect matching of the set \{1, \ldots, n\} \cup \{-1, \ldots, -n\} such that the result is a noncrossing matching (a Temperley-Lieb diagram), divided into two sets of pairs: one for the pairs with blobs and one for those without. The blobed pairs must either be either the leftmost propagating strand or to the left of it and not nested.

temperley_lieb_diagram()

Return the Temperley-Lieb diagram corresponding to self.

EXAMPLES:

sage: from sage.combinat.blob_algebra import BlobDiagrams
sage: BD4 = BlobDiagrams(Integer(4))
>>> B = BD4([[1, -3]], [[2, -4], [3, 4], [-1, -2]])
>>> B.temperley_lieb_diagram()
{{-4, 2}, {-3, 1}, {-2, -1}, (3, 4)}

sage: from sage.combinat.blob_algebra import BlobDiagrams
>>> BD4 = BlobDiagrams(Integer(4))
>>> B = BD4([[-1, 3], [2, -4], [3, 4], [-1, -2]])
>>> B.temperley_lieb_diagram()
{{-4, 2}, {-3, 1}, {-2, -1}, (3, 4)}

class sage.combinat.blob_algebra.BlobDiagrams(n)
  Bases: Parent, UniqueRepresentation
The set of all blob diagrams.

**Element**

alias of BlobDiagram

**base_set()**

Return the base set of self.

EXAMPLES:

```
sage: from sage.combinat.blob_algebra import BlobDiagrams
sage: BD4 = BlobDiagrams(4)
sage: sorted(BD4.base_set())
[-4, -3, -2, -1, 1, 2, 3, 4]
```

```
>>> from sage.all import *
>>> from sage.combinat.blob_algebra import BlobDiagrams
>>> BD4 = BlobDiagrams(Integer(4))
>>> sorted(BD4.base_set())
[-4, -3, -2, -1, 1, 2, 3, 4]
```

**cardinality()**

Return the cardinality of self.

EXAMPLES:

```
sage: from sage.combinat.blob_algebra import BlobDiagrams
sage: BD4 = BlobDiagrams(4)
sage: BD4.cardinality()
70
```

```
>>> from sage.all import *
>>> from sage.combinat.blob_algebra import BlobDiagrams
>>> BD4 = BlobDiagrams(Integer(4))
>>> BD4.cardinality()
70
```

**order()**

Return the order of self.

EXAMPLES:

```
sage: from sage.combinat.blob_algebra import BlobDiagrams
sage: BD4 = BlobDiagrams(4)
sage: BD4.order()
4
```

```
>>> from sage.all import *
>>> from sage.combinat.blob_algebra import BlobDiagrams
>>> BD4 = BlobDiagrams(Integer(4))
>>> BD4.order()
4
```
5.1.12 Cartesian Products

```python
class sage.combinat.cartesian_product.CartesianProduct_iters(*iters)
Bases: EnumeratedSetFromIterator

Cartesian product of finite sets.

This class will soon be deprecated (see Issue #18411 and Issue #19195). One should instead use the functorial construction `cartesian_product`. The main differences in behavior are:

- construction: `CartesianProduct` takes as many argument as there are factors whereas `cartesian_product` takes a single list (or iterable) of factors;
- representation of elements: elements are represented by plain Python list for `CartesianProduct` versus a custom element class for `cartesian_product`;
- membership testing: because of the above, plain Python lists are not considered as elements of a `cartesian_product`.

All of these is illustrated in the examples below.

EXAMPLES:
```
sage: F1 = ['a', 'b']
sage: F2 = [1, 2, 3, 4]
sage: F3 = Permutations(3)
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: C = CartesianProduct_iters(F1, F2, F3)
sage: c = cartesian_product([F1, F2, F3])
sage: type(C.an_element())
<class 'list'>
sage: type(c.an_element())
<class 'sage.sets.cartesian_product.CartesianProduct_with_category.element_class'>
sage: l = ['a', 1, Permutation([3,2,1])]
sage: l
['a', 1, [3, 2, 1]]
sage: l in C
True
sage: l in c
False
sage: elt = c(l)
sage: elt
('a', 1, [3, 2, 1])
sage: elt in c
True
sage: elt.parent() is c
True
```
```
```
```python
l = ['a', Integer(1), Permutation([Integer(3), Integer(2), Integer(1)])]
>>> l
['a', 1, [3, 2, 1]]
>>> l in C
True
>>> l in c
False
>>> elt = c(l)
>>> elt
('a', 1, [3, 2, 1])
>>> elt in c
True
>>> elt.parent() is c
True
```

### cardinality()

Returns the number of elements in the Cartesian product of everything in *iter*.  

**EXAMPLES:**

```python
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: CartesianProduct_iters(range(2), range(3)).cardinality()
6
sage: CartesianProduct_iters(range(2), range(3)).cardinality()
6
sage: CartesianProduct_iters(range(2), range(3), range(4)).cardinality()
24
```

This works correctly for infinite objects:

```python
sage: CartesianProduct_iters(ZZ, QQ).cardinality()
+Infinity
sage: CartesianProduct_iters(ZZ, []).cardinality()
0
```

### is_finite()

The Cartesian product is finite if all of its inputs are finite, or if any input is empty.  

**EXAMPLES:**

```python
```
Combinatorics, Release 10.4

```python
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: CartesianProduct_iters(ZZ, []).is_finite()
True
sage: CartesianProduct_iters(4, 4).is_finite()
Traceback (most recent call last):
  ... ValueError: unable to determine whether this product is finite

>>> from sage.all import *
>>> from sage.combinat.cartesian_product import CartesianProduct_iters
>>> CartesianProduct_iters(ZZ, []).is_finite()
True
>>> CartesianProduct_iters(Integer(4), Integer(4)).is_finite()
Traceback (most recent call last):
  ... ValueError: unable to determine whether this product is finite
```

**list()**

Returns

EXAMPLES:

```python
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: CartesianProduct_iters(range(3), range(3)).list()
[[0, 0], [0, 1], [0, 2], [1, 0], [1, 1], [1, 2], [2, 0], [2, 1], [2, 2]]
sage: CartesianProduct_iters('dog', 'cat').list()
[['d', 'c'], ['d', 'a'], ['d', 't'], ['o', 'c'], ['o', 'a'], ['o', 't'], ['g', 'c'], ['g', 'a'], ['g', 't']]
```

```python
>>> from sage.all import *
>>> from sage.combinat.cartesian_product import CartesianProduct_iters
>>> CartesianProduct_iters(range(Integer(3)), range(Integer(3))).list()
[[0, 0], [0, 1], [0, 2], [1, 0], [1, 1], [1, 2], [2, 0], [2, 1], [2, 2]]
>>> CartesianProduct_iters('dog', 'cat').list()
[['d', 'c'], ['d', 'a'], ['d', 't'], ['o', 'c'], ['o', 'a'], ['o', 't'], ['g', 'c'], ['g', 'a'], ['g', 't']]
```

**random_element()**

Return a random element from the Cartesian product of *iters.

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: c = CartesianProduct_iters('dog', 'cat').random_element()
True
```

unrank(x)

For finite Cartesian products, we can reduce unrank to the constituent iterators.

EXAMPLES:

```python
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: C = CartesianProduct_iters(range(1000), range(1000), range(1000))
sage: C[238792368]
[238, 792, 368]
```

Check for Issue #15919:

```python
sage: FF = IntegerModRing(29)
sage: C = CartesianProduct_iters(FF, FF, FF)
sage: C.unrank(0)
[0, 0, 0]
```

5.1.13 Enumerated sets of partitions, tableaux, ...

Partitions

- Integer partitions
- Skew Partitions
- Partition tuples
- Super Partitions
- Tableaux
- TableauTuples
• Skew Tableaux
• Ribbons
• Ribbon Tableaux
• Strong and weak tableaux
• Shifted primed tableaux
• Residue sequences of tableaux

RSK
• Robinson-Schensted-Knuth correspondence
• Growth diagrams and dual graded graphs

5.1.14 Combinatorial Hopf algebras
• Symmetric Functions
• Non-commutative symmetric functions and quasi-symmetric functions
• Symmetric functions in non-commuting variables
• Schubert Polynomials
• Poirier-Reutenauer Hopf algebra of standard tableaux
• Free Quasi-symmetric functions
• Grossman-Larson Hopf Algebras
• Word Quasi-symmetric functions

5.1.15 Poirier-Reutenauer Hopf algebra of standard tableaux

AUTHORS:
• Franco Saliola (2012): initial implementation
• Travis Scrimshaw (2018-04-11): added missing doctests and reorganization

class sage.combinat.chas.fsym.FSymBases(parent_with_realization)
Bases: Category_realization_of_parent

The category of graded bases of $FSym$ and $FSym^*$ indexed by standard tableaux.

class ElementMethods
Bases: object

duality_pairing(other)

    Compute the pairing between self and an element other of the dual.

EXAMPLES:
```python
sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: F = G.dual_basis()
sage: elt = G[[1,3],[2]] - 3*G[[1,2],[3]]
sage: elt.duality_pairing(F[[1,3],[2]])
1
sage: elt.duality_pairing(F[[1,2],[3]])
-3
sage: elt.duality_pairing(F[[1,2]])
0
```

```python
>>> from sage.all import *
>>> FSym = algebras.FSym(QQ)
>>> G = FSym.G()
>>> F = G.dual_basis()
>>> elt = G[[Integer(1),Integer(3)],[Integer(2)]] -
˓→Integer(3)*G[[Integer(1),Integer(2)],[Integer(3)]]
>>> elt.duality_pairing(F[[Integer(1),Integer(3)],[Integer(2)]]))
1
>>> elt.duality_pairing(F[[Integer(1),Integer(2)],[Integer(3)]]))
-3
>>> elt.duality_pairing(F[[Integer(1),Integer(2)]]))
0
```

```python
class ParentMethods
    Bases: object

    basis(degree=None)
    The basis elements (optionally: of the specified degree).
    OUTPUT: Family

    EXAMPLES:

    sage: FSym = algebras.FSym(QQ)
    sage: TG = FSym.G()
    sage: TG.basis()
    Lazy family (Term map from Standard tableaux to Hopf algebra of standard␣
    tableaux over the Rational Field in the Fundamental basis(i))_{i in Standard␣
    tableaux}
    sage: TG.basis().keys()
    Standard tableaux
    sage: TG.basis(degree=3).keys()
    Standard tableaux of size 3
    sage: TG.basis(degree=3).list()
    [G[123], G[13|2], G[12|3], G[1|2|3]]
```

```python
>>> from sage.all import *
>>> FSym = algebras.FSym(QQ)
>>> TG = FSym.G()
>>> TG.basis()
Lazy family (Term map from Standard tableaux to Hopf algebra of standard␣
    tableaux over the Rational Field in the Fundamental basis(i))_{i in Standard␣
    tableaux}
>>> TG.basis().keys()
```

(continues on next page)
Standard tableaux

```python
>>> TG.basis(degree=Integer(3)).keys()
Standard tableaux of size 3

>>> TG.basis(degree=Integer(3)).list()

\[G[123], G[13|2], G[12|3], G[1|2|3]\]
```

**degree_on_basis** \(t\)

Return the degree of a standard tableau in the algebra of free symmetric functions.

This is the size of the tableau \(t\).

**EXAMPLES:**

```python
sage: G = algebras.FSym(QQ).G()
sage: t = StandardTableau([[1, 3],[2]])
sage: G.degree_on_basis(t)
3
sage: u = StandardTableau([[1, 3, 4, 5],[2]])
sage: G.degree_on_basis(u)
5
```

**duality_pairing** \((x, y)\)

The canonical pairing between \(FSym\) and \(FSym^*\).

**EXAMPLES:**

```python
sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: F = G.dual_basis()
sage: t1 = StandardTableau([[1, 3, 5],[2, 4]])
sage: t2 = StandardTableau([[1, 3],[2, 5],[4]])
sage: G.duality_pairing(G[t1], F[t2])
0
sage: G.duality_pairing(G[t1], F[t1])
1
sage: G.duality_pairing(G[t2], F[t2])
1
sage: F.duality_pairing(F[t2], G[t2])
1
sage: z = G[[1, 3, 5],[2, 4]]
sage: all(F.duality_pairing(F[p1] * F[p2], z) == c
    ....:   for ((p1, p2), c) in z.coproduct())
True
```
duality_pairing_matrix(basis, degree)

The matrix of scalar products between elements of $FSym$ and elements of $FSym^*$. 

**INPUT:**
- `basis` - a basis of the dual Hopf algebra
- `degree` - a non-negative integer

**OUTPUT:**
- the matrix of scalar products between the basis `self` and the basis `basis` in the dual Hopf algebra of degree `degree`

**EXAMPLES:**

```python
sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: G.duality_pairing_matrix(G.dual_basis(), 3)

[ 1  0  0  0]
[ 0  1  0  0]
[ 0  0  1  0]
[ 0  0  0  1]
```

```python
>>> from sage.all import *
>>> FSym = algebras.FSym(QQ)
>>> G = FSym.G()
>>> G.duality_pairing_matrix(G.dual_basis(), Integer(3))

[ 1  0  0  0]
[ 0  1  0  0]
[ 0  0  1  0]
[ 0  0  0  1]
```

one_basis()

Return the basis index corresponding to 1.

**EXAMPLES:**

```python
sage: FSym = algebras.FSym(QQ)
sage: TG = FSym.G()
```

(continues on next page)
super_categories()

The super categories of self.

EXAMPLES:

```python
sage: from sage.combinat.chas.fsym import FSymBases
sage: FSym = algebras.FSym(ZZ)
sage: bases = FSymBases(FSym)
sage: bases.super_categories()
[Category of realizations of Hopf algebra of standard tableaux over the Integer Ring,
 Join of Category of realizations of Hopf algebras over Integer Ring
 and Category of graded algebras over Integer Ring
 and Category of graded coalgebras over Integer Ring,
 Category of graded connected Hopf algebras with basis over Integer Ring]
```

class sage.combinat.chas.fsym.FSymBasis_abstract (alg, graded=True)

Abstract base class for graded bases of \( FSym \) and of \( FSym^* \) indexed by standard tableaux.

This must define the following attributes:

* \_prefix – the basis prefix

some_elements()

Return some elements of self.

EXAMPLES:

```python
sage: G = algebras.FSym(QQ).G()
sage: G.some_elements()
```
class sage.combinat.chas.fsym.FreeSymmetricFunctions(base_ring)

Bases: UniqueRepresentation, Parent

The free symmetric functions.

The free symmetric functions is a combinatorial Hopf algebra defined using tableaux and denoted $FSym$.

Consider the Hopf algebra $FQSym(FreeQuasisymmetricFunctions)$ over a commutative ring $R$, and its bases $(F_w)$ and $(G_w)$ (where $w$, in both cases, ranges over all permutations in all symmetric groups $S_0, S_1, S_2, \ldots$). For each word $w$, let $P(w)$ be the P-tableau of $w$ (that is, the first of the two tableaux obtained by applying the RSK algorithm to $w$; see RSK()). If $t$ is a standard tableau of size $n$, then we define $G_t \in FQSym$ to be the sum of the $F_w$ with $w$ ranging over all permutations of $\{1, 2, \ldots, n\}$ satisfying $P(w) = t$. Equivalently, $G_t$ is the sum of the $G_w$ with $w$ ranging over all permutations of $\{1, 2, \ldots, n\}$ satisfying $Q(w) = t$ (where $Q(w)$ denotes the Q-tableau of $w$).

The $R$-linear span of the $G_t$ (for $t$ ranging over all standard tableaux) is a Hopf subalgebra of $FQSym$, denoted by $FSym$ and known as the free symmetric functions or the Poirier-Reutenauer Hopf algebra of tableaux. It has been introduced in [PoiReu95], where it was denoted by $(\bullet ; T, \ast, \delta)$. (What we call $G_t$ has just been called $t$ in [PoiReu95].) The family $(G_t)$ (with $t$ ranging over all standard tableaux) is a basis of $FSym$, called the Fundamental basis.

EXAMPLES:

As explained above, $FSym$ is constructed as a Hopf subalgebra of $FQSym$:

```python
sage: G = algebras.FSym(QQ).G()
sage: F = algebras.FQSym(QQ).F()
sage: G[[1,3],[2]]
G[13|2]
sage: G[[1,3],[2]].to_fqsym()
G[2, 1, 3] + G[3, 1, 2]
sage: F(G[[1,3],[2]])
F[2, 1, 3] + F[2, 3, 1]
```

This embedding is a Hopf algebra morphism:

```python
sage: all(F(G[t1] * G[t2]) == F(G[t1]) * F(G[t2])
....:    for t1 in StandardTableaux(2)
....:    for t2 in StandardTableaux(3))
True
sage: FF = F.tensor_square()
sage: all(FF(G[t].coproduct()) == F(G[t]).coproduct())
```

(continues on next page)
There is a Hopf algebra map from $FSym$ onto the Hopf algebra of symmetric functions, which maps a tableau $t$ to the Schur function indexed by the shape of $t$:

```python
sage: TG = algebras.FSym(QQ).G()
sage: t = StandardTableau([[1,3],[2,4],[5]])
sage: TG[t]
G[13|24|5]
sage: TG[t].to_symmetric_function()
s[2, 2, 1]
```

class `Fundamental`

Bases: `FSymBasis_abstract`

The Hopf algebra of tableaux on the Fundamental basis.

EXAMPLES:

```python
sage: FSym = algebras.FSym(QQ)
sage: TG = FSym.G()
sage: TG
Hopf algebra of standard tableaux over the Rational Field in the Fundamental basis
```
sage: TG.an_element()

```python
>>> from sage.all import *

>>> TG.an_element()
```

class Element

Bases: IndexedFreeModuleElement

to_fqsym()

Return the image of self under the natural inclusion map to $FQSym$.

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: t = StandardTableau([[1,3],[2,4],[5]])
sage: G[t].to_fqsym()
```

to_symmetric_function()

Return the image of self under the natural projection map to $Sym$.

The natural projection map $FSym \rightarrow Sym$ sends each standard tableau $t$ to the Schur function $s_{\lambda}$, where $\lambda$ is the shape of $t$. This map is a surjective Hopf algebra homomorphism.

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: t = StandardTableau([[Integer(1),Integer(3)],[Integer(2),Integer(4)],[Integer(5)]])
sage: G[t].to_symmetric_function()
s[2, 2, 1]
```

coproduct_on_basis(t)

Return the coproduct of the basis element indexed by $t$.

EXAMPLES:
sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: t = StandardTableau([[1,2,5], [3,4]])
sage: G.coproduct_on_basis(t)

>>> from sage.all import *
>>> FSym = algebras.FSym(QQ)
>>> G = FSym.G()
>>> t = StandardTableau([[Integer(1),Integer(2),Integer(5)], [Integer(3), Integer(4)]])
>>> G.coproduct_on_basis(t)

dual_basis()

Return the dual basis to self.

EXAMPLES:

sage: G = algebras.FSym(QQ).G()
sage: G.dual_basis()
Dual Hopf algebra of standard tableaux over the Rational Field in the FundamentalDual basis

>>> from sage.all import *
>>> G = algebras.FSym(QQ).G()
>>> G.dual_basis()
Dual Hopf algebra of standard tableaux over the Rational Field in the FundamentalDual basis

product_on_basis(t1, t2)

Return the product of basis elements indexed by t1 and t2.

EXAMPLES:

sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: t1 = StandardTableau([[1,2], [3]])
sage: t2 = StandardTableau([[1,2,3]])
sage: G.product_on_basis(t1, t2)

sage: t1 = StandardTableau([[1],[2]])
sage: t2 = StandardTableau([[1],[2]])
sage: G.product_on_basis(t1, t2)
G[134|2] + G[14|2|3]

sage: t1 = StandardTableau([[1],[2],[3]])
sage: t2 = StandardTableau([[1],[2]])
sage: G.product_on_basis(t1, t2)

```python
>>> from sage.all import *
>>> FSym = algebras.FSym(QQ)
>>> G = FSym.G()
>>> t1 = StandardTableau([[Integer(1),Integer(2)],[Integer(3)]])
>>> t2 = StandardTableau([[Integer(1),Integer(2)],[Integer(3)]]))
>>> G.product_on_basis(t1, t2)
>>> t1 = StandardTableau([[Integer(1)],[Integer(2)]]))
>>> t2 = StandardTableau([[Integer(1)],[Integer(2)]]))
>>> G.product_on_basis(t1, t2)
G[13|2|3]
>>> t1 = StandardTableau([[Integer(1)],[Integer(2)],[Integer(3)]]))
>>> t2 = StandardTableau([[Integer(1)],[Integer(2)]]))
>>> G.product_on_basis(t1, t2)
```

G

alias of Fundamental

_a_realization_

Return a particular realization of self (the Fundamental basis).

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: FSym.a_realization()
Hopf algebra of standard tableaux over the Rational Field
  in the Fundamental basis
```

dual()

Return the dual Hopf algebra of FSym.

EXAMPLES:

```
sage: algebras.FSym(QQ).dual()
Dual Hopf algebra of standard tableaux over the Rational Field
  in the Fundamental basis
```

class sage.combinat.chas.fsym.FreeSymmetricFunctions_Dual(base_ring)

Bases: UniqueRepresentation, Parent

The Hopf dual FSym\* of the free symmetric functions FSym.

See FreeSymmetricFunctions for the definition of the latter.

Recall that the fundamental basis of FSym consists of the elements G_t for t ranging over all standard tableaux. The dual basis of this is called the dual fundamental basis of FSym*, and is denoted by (G_t^*)*. The Hopf dual
\( \mathcal{F}\text{Sym}^* \) is isomorphic to the Hopf algebra \((\mathbb{Z}T, *, \delta')\) from [PoiReu95]; the isomorphism sends a basis element \(G^*_t\) to \(t\).

**EXAMPLES:**

```
sage: FSym = algebras.FSym(QQ)
sage: TF = FSym.dual().F()
sage: TF[[1,2]] * TF[[1],[2]]
sage: TF[[1,2],[3]].coproduct()
```

The Hopf algebra \( \mathcal{F}\text{Sym}^* \) is a Hopf quotient of \( \mathcal{F}\text{QSym} \); the canonical projection sends \( F_w \) (for a permutation \( w \)) to \( G^*_{Q(w)} \), where \( Q(w) \) is the \( Q \)-tableau of \( w \). This projection is implemented as a coercion:

```
sage: FQSym = algebras.FQSym(QQ)
sage: F = FQSym.F()
sage: TF(F[[1, 3, 2]])
F[12|3]
sage: TF(F[[5, 1, 4, 2, 3]])
F[135|2|4]
```

\( \mathcal{F} \)

alias of \textit{FundamentalDual}

**class FundamentalDual\((\text{alg}, \text{graded}=\text{True})\)**

**Bases:** \textit{FSymBasis_abstract}

The dual to the Hopf algebra of tableaux, on the fundamental dual basis.

**EXAMPLES:**

```
sage: FSym = algebras.FSym(QQ)
sage: TF = FSym.dual().F()
sage: TF
Dual Hopf algebra of standard tableaux over the Rational Field
in the FundamentalDual basis
```

(continues on next page)
Elements of the algebra look like:

```
sage: TF.an_element()
```

```
>>> from sage.all import *

>>> TF.an_element()
```

class Element

Bases: IndexedFreeModuleElement

```
to_quasisymmetric_function()

Return the image of self under the canonical projection $FSym^* \to QSym$ to the ring of quasi-symmetric functions.

This projection is the adjoint of the canonical injection $NSym \to FSym$ (see `to_fsym()`). It sends each tableau $t$ to the fundamental quasi-symmetric function $F_\alpha$, where $\alpha$ is the descent composition of $t$.

EXAMPLES:
```
sage: F = algebras.FSym(QQ).dual().F()
sage: F[[1,3,5],[2,4]].to_quasisymmetric_function()
F[1, 2, 2]
```
```
>>> from sage.all import *

>>> F = algebras.FSym(QQ).dual().F()

>>> F[[Integer(1),Integer(3),Integer(5)],[Integer(2),Integer(4)]].to_quasisymmetric_function()
F[1, 2, 2]
```

coproduct_on_basis($t$)

EXAMPLES:
```
sage: FSym = algebras.FSym(QQ)
sage: TF = FSym.dual().F()
sage: t = StandardTableau([[1,2,5], [3,4]])
sage: TF.coproduct_on_basis(t)
```
```
>>> from sage.all import *

>>> FSym = algebras.FSym(QQ)

>>> TF = FSym.dual().F()

>>> t = StandardTableau([[Integer(1),Integer(3),Integer(5)],[Integer(2),Integer(4)]]))

>>> TF.coproduct_on_basis(t)
```
**dual_basis()**

Return the dual basis to self.

**EXAMPLES:**

```
sage: F = algebras.FSym(QQ).dual().F()
sage: F.dual_basis()
Hopf algebra of standard tableaux over the Rational Field
in the Fundamental basis
```

```
>>> from sage.all import *
>>> F = algebras.FSym(QQ).dual().F()
>>> F.dual_basis()
Hopf algebra of standard tableaux over the Rational Field
in the Fundamental basis
```

**product_on_basis**(*t1, t2*)

**EXAMPLES:**

```
sage: FSym = algebras.FSym(QQ)
sage: TF = FSym.dual().F()
sage: t1 = StandardTableau([[1,2]])
sage: TF.product_on_basis(t1, t1)
sage: t0 = StandardTableau([])
sage: TF.product_on_basis(t1, t0) == TF[t1] == TF.product_on_basis(t0, t1)
True
```

```
>>> from sage.all import *
>>> FSym = algebras.FSym(QQ)
>>> FSym.a_realization()
Dual Hopf algebra of standard tableaux over the Rational Field
in the FundamentalDual basis
```

**a_realization()**

Return a particular realization of self (the Fundamental dual basis).

**EXAMPLES:**

```
sage: FSym = algebras.FSym(QQ).dual()
sage: FSym.a_realization()
Dual Hopf algebra of standard tableaux over the Rational Field
in the FundamentalDual basis
```

```
>>> from sage.all import *
>>> FSym = algebras.FSym(QQ).dual()
>>> FSym.a_realization()
Dual Hopf algebra of standard tableaux over the Rational Field
in the FundamentalDual basis
```

**dual()**

Return the dual Hopf algebra of self, which is $F_{Sym}$.

**EXAMPLES:**
sage: D = algebras.FSym(QQ).dual()
sage: D.dual()
Hopf algebra of standard tableaux over the Rational Field

>>> from sage.all import *
>>> D = algebras.FSym(QQ).dual()
>>> D.dual()
Hopf algebra of standard tableaux over the Rational Field

sage.combinat.chas.fsym.ascent_set(t)

Return the ascent set of a standard tableau \(t\) (encoded as a sorted list).

The ascent set of a standard tableau \(t\) is defined as the set of all entries \(i\) of \(t\) such that the number \(i + 1\) either appears to the right of \(i\) or appears in a row above \(i\) or does not appear in \(t\) at all.

EXAMPLES:

sage: from sage.combinat.chas.fsym import ascent_set
sage: t = StandardTableau([[1,3,4,7],[2,5,6],[8]])

sage: ascent_set(t)
[2, 3, 5, 6, 8]

sage: ascent_set(StandardTableau([]))
[]

sage: ascent_set(StandardTableau([[1, 2, 3]]))
[1, 2, 3]

sage: ascent_set(StandardTableau([[1, 2, 4], [3]]))
[1, 3, 4]

sage: ascent_set([[1, 3, 5], [2, 4]])
[2, 4, 5]

sage.combinat.chas.fsym.descent_composition(t)

Return the descent composition of a standard tableau \(t\).

This is the composition of the size of \(t\) whose partial sums are the elements of the descent set of \(t\) (see descent_set()).

EXAMPLES:

sage: from sage.combinat.chas.fsym import descent_composition
sage: t = StandardTableau([[1,3,4,7],[2,5,6],[8]])

sage: descent_composition(t)
(continues on next page)
sage: descent_composition([[1, 3, 5], [2, 4]])
[1, 2, 2]

sage.combinat.chas.fsym.descent_composition(t)
Return the descent composition of a standard tableau t (encoded as a sorted list).

The descent composition of a standard tableau t is defined as the set of all entries i of t such that the number i + 1 appears in a row below i in t.

EXAMPLES:

sage: t = StandardTableau([[1,3,4,7],[2,5,6],[8]])
sage: descent_composition(t)
[1, 3, 3, 1]
sage: descent_composition([[1,3,5],[2,4]])
[1, 2, 2]

sage.combinat.chas.fsym.descent_set(t)
Return the descent set of a standard tableau t (encoded as a sorted list).

The descent set of a standard tableau t is defined as the set of all entries i of t such that the number i + 1 appears in a row below i in t.

EXAMPLES:

sage: t = StandardTableau([[1,3,4,7],[2,5,6],[8]])
sage: descent_set(t)
[1, 3, 3, 1]
sage: descent_set(StandardTableau([]))
[]
sage: descent_set(StandardTableau([[1, 2, 3]]))
[]
sage: descent_set(StandardTableau([[1, 2, 4], [3]]))
[2]
sage: descent_set([[1, 3, 5], [2, 4]])
[1, 2, 2]

sage.combinat.chas.fsym.standardize(t)
Return the standard tableau corresponding to a given semistandard tableau t with no repeated entries.

Note: This is an optimized version of Tableau.standardization() for computations in \(F_{Sym}\) by using

5.1. Comprehensive Module List 235
the assumption of no repeated entries in \( t \).

**EXAMPLES:**

```python
sage: from sage.combinat.chas.fsym import standardize
sage: t = Tableau([[1,3,5,7],[2,4,8],[9]])
sage: standardize(t)
[[1, 3, 5, 6], [2, 4, 7], [8]]
sage: t = Tableau([[3,8,9,15],[5,10,12],[133]])
sage: standardize(t)
[[1, 3, 4, 7], [2, 5, 6], [8]]
```

```python
>>> from sage.all import *
>>> from sage.combinat.chas.fsym import standardize
>>> t = Tableau([[Integer(1),Integer(3),Integer(5),Integer(7)],[Integer(2),
Integer(4),Integer(8)],[Integer(9)]]
>>> standardize(t)
[[1, 3, 5, 6], [2, 4, 7], [8]]
>>> t = Tableau([[Integer(3),Integer(8),Integer(9),Integer(15)],[Integer(5),
Integer(10),Integer(12)],[Integer(133)]]
>>> standardize(t)
[[1, 3, 4, 7], [2, 5, 6], [8]]
```

### 5.1.16 Word Quasi-symmetric functions

**AUTHORS:**

- Travis Scrimshaw (2018-04-09): initial implementation
- Darij Grinberg and Amy Pang (2018-04-12): further bases and methods

**class** `sage.combinat.chas.wqsym.WQSymBases`(*base, graded*)

**Bases:** `Category_realization_of_parent`  

The category of bases of \( WQSym \).

**class** `ElementMethods`

**Bases:** `object`

**algebraic_complement**()

Return the image of the element `self` of \( WQSym \) under the algebraic complement involution.

If \( u = (u_1, u_2, \ldots, u_n) \) is a packed word that contains the letters 1, 2, \ldots, \( k \) and no others, then the *complement* of \( u \) is defined to be the packed word \( \overline{u} := (k + 1 - u_1, k + 1 - u_2, \ldots, k + 1 - u_n) \).

The algebraic complement involution is defined as the linear map \( WQSym \to WQSym \) that sends each basis element \( M_u \) of the monomial basis of \( WQSym \) to the basis element \( M_{\overline{u}} \). This is a graded algebra automorphism and a coalgebra anti-automorphism of \( WQSym \). Denoting by \( \overline{f} \) the image of an element \( f \in WQSym \) under the algebraic complement involution, it can be shown that every packed word \( u \) satisfies

\[
M_u = M_{\overline{u}}, \quad X_u = X_{\overline{u}},
\]

where standard notations for classical bases of \( WQSym \) are being used (that is, \( M \) for the monomial basis, and \( X \) for the characteristic basis).
This can be restated in terms of ordered set partitions: For any ordered set partition \( R = (R_1, R_2, \ldots, R_k) \), let \( R^r \) denote the ordered set partition \((R_k, R_{k-1}, \ldots, R_1)\); this is known as the reversal of \( R \). Then,

\[
\overline{M}_A = M_{A^r}, \quad \overline{X}_A = X_{A^r}
\]

for any ordered set partition \( A \).

The formula describing algebraic complements on the \( Q \) basis (WordQuasiSymmetricFunctions.StronglyCoarser) is more complicated, and requires some definitions. We define a partial order \( \leq \) on the set of all ordered set partitions as follows: \( A \leq B \) if and only if \( A \) is strongly finer than \( B \) (see is_strongly_finer() for a definition of this). The length \( \ell(R) \) of an ordered set partition \( R \) shall be defined as the number of parts of \( R \). Use the notation \( Q \) for the \( Q \) basis. For any ordered set partition \( A \) of \([n]\), we have

\[
\overline{Q}_A = \sum_P c_{A,P} Q_P,
\]

where the sum is over all ordered set partitions \( P \) of \([n]\), and where the coefficient \( c_{A,P} \) is defined as follows:

- If there exists an ordered set partition \( R \) satisfying \( R \leq P \) and \( A \leq R^r \), then this \( R \) is unique, and
  \[ c_{A,P} = (-1)^{\ell(R) - \ell(P)}. \]
- If there exists no such \( R \), then \( c_{A,P} = 0 \).

The formula describing algebraic complements on the \( \Phi \) basis (WordQuasiSymmetricFunctions.StronglyFiner) is identical to the above formula for the \( Q \) basis, except that the \( \leq \) sign has to be replaced by \( \geq \) in the definition of the coefficients \( c_{A,P} \).

In fact, both formulas are particular cases of a general formula for involutions: Assume that \( V \) is an (additive) abelian group, and that \( I \) is a poset. For each \( i \in I \), let \( M_i \) be an element of \( V \). Also, let \( \omega \) be an involution of the set \( I \) (not necessarily order-preserving or order-reversing), and let \( \omega' \) be an involutive group endomorphism of \( V \) such that each \( i \in I \) satisfies \( \omega'(M_i) = M_{\omega(i)} \). For each \( i \in I \), let \( F_i = \sum_{j \geq i} M_j \), where we assume that the sum is finite. Then, each \( i \in I \) satisfies

\[
\omega'(F_i) = \sum_{j \geq i} \sum_{k \leq j, \omega(k) \geq i} \mu(k, j) F_j,
\]

where \( \mu \) denotes the Möbius function. This formula becomes particularly useful when the \( k \) satisfying \( k \leq j \) and \( \omega(k) \geq i \) is unique (if it exists). In our situation, \( V \) is \( WQSym \), and \( I \) is the set of ordered set partitions equipped either with the \( \leq \) partial order defined above or with its opposite order. The \( M_i \) is the \( M_A \), whereas the \( F_i \) is either \( Q_i \) or \( \Phi_i \).

If we denote the star involution (star_involution()) of the quasisymmetric functions by \( f \mapsto f^* \), and if we let \( \pi \) be the canonical projection \( WQSym \to QSym \), then each \( f \in WQSym \) satisfies \( \pi(f^*) = (\pi(f))^* \).

See also:

coalgebraic_complement(), star_involution()

EXAMPLES:

Recall that the index set for the bases of \( WQSym \) is given by ordered set partitions, not packed words. Translated into the language of ordered set partitions, the algebraic complement involution acts on the Monomial basis by reversing the ordered set partition. In other words, we have

\[
\overline{M}(P_1, P_2, \ldots, P_k) = M(P_k, P_{k-1}, \ldots, P_1)
\]

for any standard ordered set partition \((P_1, P_2, \ldots, P_k)\). Let us check this in practice:
The algebraic complement involution intertwines the antipode and the inverse of the antipode:

```python
sage: all( M(I).antipode().algebraic_complement().antipode() == M(I).algebraic_complement() for I in OrderedSetPartitions(4) )
True
```

```python
>>> from sage.all import *
>>> WQSym = algebras.WQSym(ZZ)
>>> M = WQSym.M()
>>> M[[Integer(1),Integer(3)],[Integer(2)]].algebraic_complement()
M[[2], {1, 3}]
>>> M[[Integer(1),Integer(4)],[Integer(2),Integer(5)],[Integer(3), Integer(6)]] .algebraic_complement()
M[[3, 6], {2, 5}, {1, 4}]
>>> (Integer(3)*M[[Integer(1)]] - Integer(4)*M[[1]] +
 -Integer(5)*M[[Integer(1)],[Integer(2)]]).algebraic_complement()
-4*M[[1]] + 3*M[[1], {1, 2}] + 5*M[[1], {2}, {1}]
>>> X = WQSym.X()
>>> X[[Integer(1),Integer(3)],[Integer(2)]].algebraic_complement()
X[[2], {1, 3}]
>>> C = WQSym.C()
>>> C[[Integer(1),Integer(3)],[Integer(2)]].algebraic_complement()
-C[[1, 2, 3], {1}, {2}] + C[[2], {1, 3}]
>>> Q = WQSym.Q()
>>> Q[[Integer(1),Integer(2)],[Integer(5),Integer(6)],[Integer(3), Integer(4)]].algebraic_complement()
Q[[1, 2], {5, 6}, {1, 3}] - Q[[1, 2], {3, 4}, {5, 6}, {1, 2}] - Q[[3, 4, 5, 6], {1, 2}]
>>> Phi = WQSym.Phi()
>>> Phi[[Integer(2)], [Integer(1),Integer(3)]].algebraic_complement()
-Phi[[1], {3}, {2}] + Phi[[1, 3], {2}] + Phi[[3], {1}, {2}]
```
Testing the $\pi(f) = (\pi(f))^*$ relation:

```python
sage: all( M[I].algebraic_complement().to_quasisymmetric_function() == M[I].to_quasisymmetric_function().star_involution() for I in OrderedSetPartitions(Integer(4)) )
True

>>> from sage.all import *
>>> all( M[I].algebraic_complement().to_quasisymmetric_function() == M[I].to_quasisymmetric_function().star_involution() for I in OrderedSetPartitions(Integer(4)) )
True
```

Todo: Check further commutative squares.

calgebraic_complement()

Return the image of the element `self` of $WQSym$ under the coalgebraic complement involution.

If $u = (u_1, u_2, \ldots, u_n)$ is a packed word, then the reversal of $u$ is defined to be the packed word $(u_n, u_{n-1}, \ldots, u_1)$. This reversal is denoted by $u^r$.

The coalgebraic complement involution is defined as the linear map $WQSym \to WQSym$ that sends each basis element $M_u$ of the monomial basis of $WQSym$ to the basis element $M_{u^r}$. This is a graded coalgebra automorphism and an algebra anti-automorphism of $WQSym$. Denoting by $f^r$ the image of an element $f \in WQSym$ under the coalgebraic complement involution, it can be shown that every packed word $u$ satisfies

$$(M_u)^r = M_{u^r}, \quad (X_u)^r = X_{u^r},$$

where standard notations for classical bases of $WQSym$ are being used (that is, $M$ for the monomial basis, and $X$ for the characteristic basis).

This can be restated in terms of ordered set partitions: For any ordered set partition $R$ of $[n]$, let $\overline{R}$ denote the complement of $R$ (defined in `complement()`). Then,

$$(M_A)^r = M_{\overline{A}}, \quad (X_A)^r = X_{\overline{A}}$$

for any ordered set partition $A$.

Recall that $WQSym$ is a subring of the ring of all bounded-degree noncommutative power series in countably many indeterminates. The latter ring has an obvious continuous algebra anti-endomorphism which sends each letter $x_i$ to $x_i$ (and thus sends each monomial $x_{i_1}x_{i_2}\cdots x_{i_n}$ to $x_{i_n}x_{i_{n-1}}\cdots x_{i_1}$). This anti-endomorphism is actually an involution. The coalgebraic complement involution is simply the restriction of this involution to the subring $WQSym$.

The formula describing coalgebraic complements on the Q basis (`WordQuasiSymmetricFunctions.StronglyCoarser`) is more complicated, and requires some definitions. We define a partial order $\leq$ on the set of all ordered set partitions as follows: $A \leq B$ if and only if $A$ is strongly finer than $B$ (see `is_strongly_finer()` for a definition of this). The length $\ell(R)$ of an ordered set partition $R$ shall be defined as the number of parts of $R$. Use
the notation $Q$ for the $Q$ basis. For any ordered set partition $A$ of $[n]$, we have

$$(QA)^r = \sum_P c_{A,P} Q_P,$$

where the sum is over all ordered set partitions $P$ of $[n]$, and where the coefficient $c_{A,P}$ is defined as follows:

- If there exists an ordered set partition $R$ satisfying $R \leq P$ and $A \leq \overline{R}$, then this $R$ is unique, and $c_{A,P} = (-1)^{\ell(R) - \ell(P)}$.
- If there exists no such $R$, then $c_{A,P} = 0$.

The formula describing coalgebraic complements on the $\Phi$ basis is identical to the above formula for the $Q$ basis, except that the $\leq$ sign has to be replaced by $\geq$ in the definition of the coefficients $c_{A,P}$. In fact, both formulas are particular cases of the general formula for involutions described in the documentation of `algebraic_complement()`.

If we let $\pi$ be the canonical projection $WQSym \to QSym$, then each $f \in WQSym$ satisfies $\pi(f^r) = \pi(f)$.

See also:

-algebraic_complement(), star_involution()

EXAMPLES:

Recall that the index set for the bases of $WQSym$ is given by ordered set partitions, not packed words. Translated into the language of ordered set partitions, the coalgebraic complement involution acts on the Monomial basis by complementing the ordered set partition. In other words, we have

$$(M_A)^r = M_{\overline{A}}$$

for any standard ordered set partition $A$. Let us check this in practice:

```
sage: WQSym = algebras.WQSym(ZZ)
sage: M = WQSym.M()
sage: M[[1,3],[2]].coanalyic_complement()  
M[[1, 3], (2)]
sage: M[[1,2],[3]].coanalyic_complement()  
M[[2, 3], (1)]
sage: M[[1],[4],[2,3]].coanalyic_complement()  
M[[4], (1), (2, 3)]
sage: M[[1,4],[2,5],[3,6]].coanalyic_complement()  
M[[6, 3, 2], (2, 5), (1, 4)]
sage: (3*M[[1]] - 4*M[]) + 5*M[[1],[2]]).coanalyic_complement()  
-4*M[] + 3*M[[1]] + 5*M[[2], (1)]
sage: X = WQSym.X()
sage: X[[1,3],[2]].coanalyic_complement()  
X[[1, 3], (2)]
sage: C = WQSym.C()
sage: C[[1,3],[2]].coanalyic_complement()  
C[[1, 3], (2)]
sage: Q = WQSym.Q()
sage: Q[[1,2],[5,6],[3,4]].coanalyic_complement()  
Q[[5, 6], (1, 2), (3, 4)] + Q[[5, 6], (1, 2), (3, 4)] - Q[[5, 6], (1, 2, 3, -4)]
sage: Phi = WQSym.Phi()
sage: Phi[[2],[1,3]].coanalyic_complement()  
-Phi[[2], (1), (3)] + Phi[[2], (1, 3)] + Phi[[2], (3), (1)]
```
```python
>>> from sage.all import *
>>> WQSym = algebras.WQSym(ZZ)
>>> M = WQSym.M()
>>> M[[Integer(1),Integer(3)],[Integer(2)]]
M[{1, 3}, {2}]
>>> M[[Integer(1),Integer(2)],[Integer(3)]]
M[{2, 3}, {1}]
>>> M[[Integer(1)], [Integer(4)], [Integer(2),Integer(3)]]
M[{4}, {1}, {2, 3}]
>>> M[[Integer(1),Integer(4)],[Integer(2),Integer(5)],[Integer(3),Integer(6)]]
M[{3, 6}, {2, 5}, {1, 4}]
>>> (Integer(3)*M[[Integer(1)]] - Integer(4)*M[[]] +
  Integer(5)*M[[Integer(1)],[Integer(2)]]).coalgebraic_complement()
-4*M[[]] + 3*M[{1}] + 5*M[{2}, {1}]
>>> X = WQSym.X()
>>> X[[Integer(1),Integer(3)],[Integer(2)]]
X[{1, 3}, {2}]
>>> C = WQSym.C()
>>> C[[Integer(1),Integer(3)],[Integer(2)]]
C[{1, 3}, {2}]
>>> Q = WQSym.Q()
>>> Q[[Integer(1),Integer(2)],[Integer(5),Integer(6)],[Integer(3),Integer(4)]]
Q[{1, 2, 5, 6}, {3, 4}] + Q[{5, 6}, {1, 2}, {3, 4}] - Q[{5, 6}, {1, 2, 3, 4}]
>>> Phi = WQSym.Phi()
>>> Phi[[Integer(2), [Integer(1),Integer(3)]]
Phi[{2}, {1}, {3}] + Phi[{2}, {1, 3}] + Phi[{2}, {3}, {1}]
```

The coalgebraic complement involution intertwines the antipode and the inverse of the antipode:

```python
sage: all( M(I).antipode().coalgebraic_complement().antipode() # long time
  == M(I).coalgebraic_complement()
  for I in OrderedSetPartitions(4) )
True
```

Testing the $$\pi(f^r) = \pi(f)$$ relation above:

```python
sage: all( M[I].coalgebraic_complement().to_quasisymmetric_function()
   == M[I].to_quasisymmetric_function()
   for I in OrderedSetPartitions(4) )
True
```

```python
>>> from sage.all import *
>>> all( M[I].coalgebraic_complement().to_quasisymmetric_function()
 ... == M[I].to_quasisymmetric_function()
 ... for I in OrderedSetPartitions(Integer(4)) )
True
```
Todo: Check further commutative squares.

star_involution()

Return the image of the element self of \( WQSym \) under the star involution.

The star involution is the composition of the algebraic complement involution \( \text{algebraic_complement()} \) with the coalgebraic complement involution \( \text{coalgebraic_complement()} \). The composition can be performed in either order, as the involutions commute.

The star involution is a graded Hopf algebra anti-automorphism of \( WQSym \). Let \( f^* \) denote the image of an element \( f \in WQSym \) under the star involution. Let \( M, X, Q \) and \( \Phi \) stand for the monomial, characteristic, \( Q \) and \( \Phi \) bases of \( WQSym \). For any ordered set partition \( A \) of \( [n] \), we let \( A^* \) denote the complement \( \text{(complement())} \) of the reversal \( \text{(reversed())} \) of \( A \). Then, for any ordered set partition \( A \) of \( [n] \), we have:

\[
(M_A)^* = M_{A^*}, \quad (X_A)^* = X_{A^*}, \quad (Q_A)^* = Q_{A^*}, \quad (\Phi_A)^* = \Phi_{A^*}.
\]

The star involution \( \text{star_involution()} \) on the ring of noncommutative symmetric functions is a restriction of the star involution on \( WQSym \).

If we denote the star involution \( \text{star_involution()} \) of the quasisymmetric functions by \( f \mapsto f^* \), and if we let \( \pi \) be the canonical projection \( WQSym \rightarrow QSym \), then each \( f \in WQSym \) satisfies \( \pi(f^*) = (\pi(f))^* \).

Todo: More commutative diagrams? \( FQSym \) and \( FSym \) need their own \( \text{star_involution}() \) methods defined first.

See also:

\( \text{algebraic_complement()}, \text{coalgebraic_complement()} \)

EXAMPLES:

Keep in mind that the default input method for basis keys of \( WQSym \) is by entering an ordered set partition, not a packed word. Let us check the basis formulas for the star involution:

```python
sage: WQSym = algebras.WQSym(ZZ)
sage: M = WQSym.M()
sage: M[[1,3], [2,4,5]].star_involution()
M[{1, 2, 4}, {3, 5}]
sage: M[[1,3],[2]].star_involution()
M[{2}, {1, 3}]
sage: M[[1,4],[2,5],[3,6]].star_involution()
M[{1, 4}, {2, 5}, {3, 6}]
sage: (3*M[[1]] - 4*M[[]] + 5*M[[1],[2]]).star_involution()
-4*M[] + 3*M[{1}] + 5*M[{1}, {2}]
sage: X = WQSym.X()
sage: X[[1,3],[2]].star_involution()
X[{2}, {1, 3}]
sage: C = WQSym.C()
sage: C[[1,3],[2]].star_involution()
-C[{1, 2, 3}] - C[{1, 3}, {2}] + C[{2}, {1, 3}]
sage: Q = WQSym.Q()
sage: Q[[1,3],[2,4,5]].star_involution()
Q[{1, 2, 4}, {3, 5}]
sage: Phi = WQSym.Phi()
```

(continues on next page)
Testing the formulas for $(Q_A)^*$ and $(\Phi_A)^*$:

```python
sage: all(Q[A].star_involution() == Q[A.complement().reversed()] for A in OrderedSetPartitions(4))
True
```

```python
sage: all(Phi[A].star_involution() == Phi[A.complement().reversed()] for A in OrderedSetPartitions(4))
True
```

The star involution commutes with the antipode:

```python
sage: all( M(I).antipode().star_involution() == M(I).star_involution().antipode() for I in OrderedSetPartitions(4) )
True
```
Testing the $\pi(f^*) = (\pi(f))^*$ relation:

```python
sage: all( M[I].star_involution().to_quasisymmetric_function() == M[I].to_quasisymmetric_function().star_involution() for I in OrderedSetPartitions(4) )
True
```

Testing the fact that the star involution on the noncommutative symmetric functions is a restriction of the star involution on $WQSym$:

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: R = NCSF.R()
sage: all(R[I].star_involution().to_fqsym().to_wqsym() == R[I].to_fqsym().to_wqsym().star_involution() for I in Compositions(4))
True
```

Todo: Check further commutative squares.

---

to_quasisymmetric_function()

The projection of self to the ring $QSym$ of quasisymmetric functions.

There is a canonical projection $\pi : WQSym \to QSym$ that sends every element $M_P$ of the monomial basis of $WQSym$ to the monomial quasisymmetric function $M_c$, where $c$ is the composition whose parts are the sizes of the blocks of $P$. This $\pi$ is a ring homomorphism.

OUTPUT:

- an element of the quasisymmetric functions in the monomial basis

EXAMPLES:

```python
sage: M = algebras.WQSym(QQ).M()
sage: M[[[1,3],[2]]].to_quasisymmetric_function()
M[2, 1]
sage: (M[[[1,3],[2]]] + 3*M[[[2,3],[1]]] - M[[[1,2,3]]]).to_quasisymmetric_function()
```

(continues on next page)
\[4 \ast M[2, 1] - M[3]\]

\texttt{sage}: \(X, Y = M[[1, 3], [2]], M[[1, 2, 3]],\)

\texttt{sage}: \(X.to\_quasisymmetric\_function() \ast Y.to\_quasisymmetric\_function() == \)

\texttt{(X*Y).to\_quasisymmetric\_function()}

\texttt{True}

\texttt{sage}: \(C = \text{algebras.WQSym}(\mathbb{Q}).C()\)

\texttt{sage}: \(C[[2, 3], [1, 4]].to\_quasisymmetric\_function() == M(C[[2, 3], [1, 4]]).to\_\)

\texttt{quasisymmetric\_function()}

\texttt{True}

\texttt{sage}: \(C2 = \text{algebras.WQSym}(\mathbb{F}(2)).C()\)

\texttt{sage}: \(C2[[1, 2], [3, 4]].to\_quasisymmetric\_function() \equiv M[2, 2]\)

\texttt{sage}: \(C2[[2, 3], [1, 4]].to\_quasisymmetric\_function() \equiv M[4]\)

\[\begin{align*}
&\text{class ParentMethods} \\
&\text{Bases: object} \\
&\text{degree\_on\_basis (t)} \\
&\text{Return the degree of an ordered set partition in the algebra of word quasi-symmetric functions.}
&\text{This is the sum of the sizes of the blocks of the ordered set partition.}
\end{align*}\]

\texttt{EXAMPLES:}

\texttt{sage}: \(A = \text{algebras.WQSym}(\mathbb{Q}).M()\)

\texttt{sage}: \(u = \text{OrderedSetPartition}([[2, 1]],\)
Combinatorics, Release 10.4

```

class sage.combinat.chas.wqsym.WQSymBasis_abstract(alg, graded=True)

Bases: CombinatorialFreeModule, BindableClass

Abstract base class for bases of \textit{WQSym}.

This must define two attributes:

- \_prefix -- the basis prefix
- \_basis_name -- the name of the basis (must match one of the names that the basis can be constructed from \textit{WQSym})
an_element()

Return an element of self.

EXAMPLES:

```
sage: M = algebras.WQSym(QQ).M()
sage: M.an_element()
M[{1}] + 2*M[{1}, {2}]
```

options = Current options for WordQuasiSymmetricFunctions element -
display: normal - objects: compositions

some_elements()

Return some elements of the word quasi-symmetric functions.

EXAMPLES:

```
sage: M = algebras.WQSym(QQ).M()
sage: M.some_elements()
[M[], M[{1}], M[{1, 2}], M[{1}] + M[{1}, {2}], M[] + 1/2*M[{1}]]
```

```
>>> from sage.all import *

>>> M = algebras.WQSym(QQ).M()

>>> M.some_elements()

```

class sage.combinat.chas.wqsym.WordQuasiSymmetricFunctions(R)

Bases: UniqueRepresentation, Parent

The word quasi-symmetric functions.

The ring of word quasi-symmetric functions can be defined as a subring of the ring of all bounded-degree noncommutative power series in countably many indeterminates (i.e., elements in \( R \langle \langle x_1, x_2, x_3, \ldots \rangle \rangle \) of bounded degree). Namely, consider words over the alphabet \{1, 2, 3, \ldots\}; every noncommutative power series is an infinite \( R \)-linear combination of these words. For each such word \( w \), we define the packing of \( w \) to be the word \( \text{pack}(w) \) that is obtained from \( w \) by replacing the smallest letter that appears in \( w \) by 1, the second-smallest letter that appears in \( w \) by 2, etc. (for example, \( \text{pack}(4112774) = 3112443 \)). A word \( w \) is said to be \( \text{packed} \) if \( \text{pack}(w) = w \). For each packed word \( u \), we define the noncommutative power series \( M_u = \sum w \), where the sum ranges over all words \( w \) satisfying \( \text{pack}(w) = u \). The span of these power series \( M_u \) is a subring of the ring of all noncommutative power series; it is called the ring of word quasi-symmetric functions, and is denoted by \( WQSym \).

For each nonnegative integer \( n \), there is a bijection between packed words of length \( n \) and ordered set partitions of \{1, 2, \ldots, n\}. Under this bijection, a packed word \( u = (u_1, u_2, \ldots, u_n) \) of length \( n \) corresponds to the ordered set partition \( P = (P_1, P_2, \ldots, P_k) \) of \{1, 2, \ldots, n\} whose \( i \)-th part \( P_i \) (for each \( i \)) is the set of all \( j \in \{1, 2, \ldots, n\} \) such that \( u_j = i \).

The basis element \( M_u \) is also denoted as \( M_P \) in this situation. The basis \( (M_P)_P \) is called the Monomial basis and is implemented as \( \text{Monomial} \).
Other bases are the cone basis (aka C basis), the characteristic basis (aka X basis), the Q basis and the Phi basis.

Bases of \( WQSym \) are implemented (internally) using ordered set partitions. However, the user may access specific basis vectors using either packed words or ordered set partitions. See the examples below, noting especially the section on ambiguities.

\( WQSym \) is endowed with a connected graded Hopf algebra structure (see Section 2.2 of \([NoThWi08]\), Section 1.1 of \([FoiMal14]\) and Section 4.3.2 of \([MeNoTh11]\)) given by

\[
\Delta(M_{\{P_1,\ldots,P_\ell\}}) = \sum_{i=0}^{\ell} M_{\text{st}(P_1,\ldots,P_i)} \otimes M_{\text{st}(P_{i+1},\ldots,P_\ell)}.
\]

Here, for any ordered set partition \((Q_1,\ldots,Q_k)\) of a finite set \(Z\) of integers, we let \(\text{st}(Q_1,\ldots,Q_k)\) denote the set partition obtained from \(Z\) by replacing the smallest element appearing in it by 1, the second-smallest element by 2, and so on.

A rule for multiplying elements of the monomial basis relies on the quasi-shuffle product of two ordered set partitions. The quasi-shuffle product \(\square\) is given by \(\text{ShuffleProduct\_overlapping}\) with the + operation in the overlapping of the shuffles being the union of the sets. The product \(M_P M_Q\) for two ordered set partitions \(P\) and \(Q\) of \([n]\) and \([m]\) is then given by

\[
M_P M_Q = \sum_{R \in P \square Q^+} M_R,
\]

where \(Q^+\) means \(Q\) with all numbers shifted upwards by \(n\).

Sometimes, \( WQSym \) is also denoted as \( NQSym \).

REFERENCES:

• \([FoiMal14]\)
• \([MeNoTh11]\)
• \([NoThWi08]\)
• \([BerZab05]\)

EXAMPLES:

Constructing the algebra and its Monomial basis:

```
sage: WQSym = algebras.WQSym(ZZ)
sage: WQSym
Word Quasi-symmetric functions over Integer Ring
sage: M = WQSym.M()
sage: M
Word Quasi-symmetric functions over Integer Ring in the Monomial basis
sage: M[[]]
M[]
```

```bash
>>> from sage.all import *
>>> WQSym = algebras.WQSym(ZZ)
>>> WQSym
Word Quasi-symmetric functions over Integer Ring
>>> M = WQSym.M()
>>> M
Word Quasi-symmetric functions over Integer Ring in the Monomial basis
>>> M[[]]
M[]
```
Calling basis elements using packed words:

```
sage: x = M[1,2,1]; x
M([1, 3], {2})
sage: x == M[[1,2,1]] == M[Word([1,2,1])]  # True
sage: y = M[1,1,2] - M[1,2,2]; y
-M([1], {2, 3}) + M([1, 2], {3})
```

```python
>>> from sage.all import *
```

```
>>> x = M[Integer(1),Integer(2),Integer(1)]; x
M([1, 3], {2})
>>> x == M[[Integer(1),Integer(2),Integer(1)]] == M[Word([Integer(1),Integer(2), Integer(1)])]  # True
```

```
>>> y = M[Integer(1),Integer(1),Integer(2)] - M[Integer(1),Integer(2),Integer(2)]; y
-M([1], {2, 3}) + M([1, 2], {3})
```

Calling basis elements using ordered set partitions:

```
sage: z = M[[1,2,3]]; z
M([1, 2, 3])
sage: z == M[[[1,2,3]]] == M[OrderedSetPartition([[1,2,3]])]  # True
sage: M[[1,2],[3]]
M([1, 2], {3})
```

```python
>>> from sage.all import *
```

```
>>> z = M[[Integer(1),Integer(2),Integer(3)]]; z
M([1, 2, 3])
>>> z == M[[[Integer(1),Integer(2),Integer(3)]]] == M[OrderedSetPartition([[Integer(1),Integer(2),Integer(3)]]))]  # True
>>> M[[Integer(1),Integer(2)],[Integer(3)]]
M([1, 2], {3})
```

Note that expressions above are output in terms of ordered set partitions, even when input as packed words. Output as packed words can be achieved by modifying the global options. (See `OrderedSetPartitions.options()` for further details):

```
sage: M.options.objects = "words"
sage: y
-M([1, 2, 2]) + M([1, 1, 2])
sage: M.options.display = "compact"
sage: y
-M[122] + M[112]
sage: z
M[111]
```

```python
>>> from sage.all import *
```

```
>>> M.options.objects = "words"
>>> y
-M([1, 2, 2]) + M([1, 1, 2])
>>> M.options.display = "compact"
>>> y
-M[122] + M[112]
```

(continues on next page)
The options should be reset to display as ordered set partitions:

```python
sage: M.options._reset()
sage: z
M[{1, 2, 3}]
```

Illustration of the Hopf algebra structure:

```python
sage: M[[2, 3], [5], [6], [4], [1]].coproduct()
M[] # M[[2, 3], [5], [6], [4], [1]] + M[[1, 2]] # M[[3], [4], [2], [1]]
+ M[[1, 2], [3]] # M[[3], [2], [1]] + M[[1, 2], [4]] # M[[2], [1]]
+ M[[1, 2], [4], [5], [3]] # M[[1]] + M[[2, 3], [5], [6], [4], [1]] # M[]
sage: _ == M[[5], [1, 1, 4, 2, 3]].coproduct()
True
```

```python
sage: M[[1, 2, 3], [4, 5], [6]].antipode() # ordered set partition
-M[[1, 2, 3]]
sage: M[[1], [2], [3]].antipode()
-M[[1, 2, 3]] - M[[2, 3], [1]] - M[[3], [1, 2]] - M[[3], [2], [1]]
sage: x = M[[1], [2], [3]] + 3*M[[2], [1]]
sage: x.counit()
0
sage: x.antipode()
-M[[1, 2, 3]] - M[[2, 3], [1]] - M[[3], [1, 2]] - M[[3], [2], [1]]
```

```python
>>> from sage.all import *
>>> M[[Integer(2), Integer(3)], [Integer(5)], [Integer(6)], [Integer(4)], [1]].coproduct()
M[] # M[[2, 3], [5], [6], [4], [1]] + M[[1, 2]] # M[[3], [4], [2], [1]]
+ M[[1, 2], [3]] # M[[3], [2], [1]] + M[[1, 2], [4]] # M[[2], [1]]
+ M[[1, 2], [4], [5], [3]] # M[[1]] + M[[2, 3], [5], [6], [4], [1]] # M[]
```

```python
>>> M[[Integer(1), Integer(1), Integer(1)], [Integer(1), Integer(1), Integer(2)]].coproduct()
M[] # M[[1, 1, 1], [1, 1, 2]] + M[[1, 2, 3], [1], [2]] - M[[2, 3], [1]] + M[[3], [1, 2]] - M[[3], [2], [1]]
```

```python
>>> M[[Integer(1), Integer(1), Integer(1)], [Integer(1), Integer(1), Integer(2)]].antipode()
-M[[1, 2, 3]]
```

```python
>>> x = M[[Integer(1), Integer(2), Integer(3)], [Integer(5)]].antipode()
-3*M[[1, 2, 3]] + M[[1, 2, 3], [4, 5], [6]]
```

(continues on next page)
Ambiguities

Some ambiguity arises when accessing basis vectors with the dictionary syntax, i.e., $M[\ldots]$. A common example is when referencing an ordered set partition with one part. For example, in the expression $M[[1, 2]]$, does $[[1, 2]]$ refer to an ordered set partition or does $[1, 2]$ refer to a packed word? We choose the latter: if the received arguments do not behave like a tuple of iterables, then view them as describing a packed word. (In the running example, one argument is received, which behaves as a tuple of integers.) Here are a variety of ways to get the same basis vector:

```
sage: x = M[1,1]; x
M[[1, 2]]
sage: x == M[[1,1]]  # treated as word
True
sage: x == M[[1,2],] == M[[[1,2]]]  # treated as ordered set partitions
True
sage: M[[1,3],[2]]  # treat as ordered set partition
M[[1, 3], [2]]
sage: M[[1,3],[2]] == M[1,2,1]  # treat as word
True
```

```python
>>> from sage.all import *

>>> x = M[Integer(1),Integer(1)]; x
M[[1, 2]]
>>> x == M[[Integer(1),Integer(1)]]  # treated as word
True
>>> x == M[[Integer(1),Integer(2)],] == M[[[Integer(1),Integer(2)]]]  # treated as ordered set partitions
True

>>> M[[Integer(1),Integer(3)],[Integer(2)]]  # treat as ordered set partition
M[[1, 3], [2]]
>>> M[[Integer(1),Integer(3)],[Integer(2)]] == M[Integer(1),Integer(2), Integer(1)]  # treat as word
True
```

Todo:

- Dendriform structure.

C

alias of Cone

class Characteristic(alg)

Bases: WQSymBasis_abstract

The Characteristic basis of $WQSym$. 

252 Chapter 5. Comprehensive Module List
The Characteristic basis is a graded basis \((X_P)\) of \(WQSym\), indexed by ordered set partitions \(P\). It is defined by

\[
X_P = (-1)^{\ell(P)} M_P,
\]

where \((M_P)_P\) denotes the Monomial basis, and where \(\ell(P)\) denotes the number of blocks in an ordered set partition \(P\).

EXAMPLES:

```python
sage: WQSym = algebras.WQSym(QQ)
sage: X = WQSym.X(); X
Word Quasi-symmetric functions over Rational Field in the Characteristic basis

sage: X[[[1,2,3]]] * X[[1,2],[3]]
X[[1, 2, 3], {4, 5}, {6}] - X[{1, 2, 3, 4, 5}, {6}]
+ X[{4, 5}, {1, 2, 3}, {6}] - X[{4, 5}, {1, 2, 3, 6}]
+ X[{4, 5}, {6}, {1, 2, 3}]

sage: X[[1, 4], [3], [2]].coproduct()
X[1, 4] # X[{1, 2}] # X[1, 4] + X[{1, 2}] # X[{1, 4}] + X[{1, 4}] # X[1]

sage: M = WQSym.M()
sage: M(X[[1,2,3]])
-M([1, 2, 3])

sage: M(X[[1,3],[2]])
M([1, 3], [2])

sage: X(M[[1,2,3]])
-X[1, 2, 3]

sage: X(M[[1,3],[2]])
X[{1, 3}, {2}]
```

```python
>>> from sage.all import *

>>> WQSym = algebras.WQSym(QQ)
>>> X = WQSym.X(); X
Word Quasi-symmetric functions over Rational Field in the Characteristic basis

>>> X[[Integer(1), Integer(2), Integer(3)]] * X[[Integer(1), Integer(2)],
   \rightarrow [Integer(3)]]
X[[1, 2, 3], {4, 5}, {6}] - X[{1, 2, 3, 4, 5}, {6}]
+ X[{4, 5}, {1, 2, 3}, {6}] - X[{4, 5}, {1, 2, 3, 6}]
+ X[{4, 5}, {6}, {1, 2, 3}]

>>> X[[Integer(1), Integer(4)], [Integer(3)], [Integer(2)]].coproduct()
X[1, 4] # X[{1, 2}] # X[{1, 4}] + X[{1, 2}] # X[{1, 4}] + X[{1, 4}] # X[1]

>>> M = WQSym.M()
>>> M(X[[Integer(1), Integer(2), Integer(3)]]))
-M([1, 2, 3])

>>> M(X[[Integer(1), Integer(3)], [Integer(2)]])
M([1, 3], [2])

>>> X(M[[Integer(1), Integer(2), Integer(3)]]))
-X[{1, 2, 3}]

>>> X(M[[Integer(1), Integer(3)], [Integer(2)]]))
X[{1, 3}, {2}]
```
class Element

    Bases: IndexedFreeModuleElement

    algebraic_complement()

    Return the image of the element self of \(WQSym\) under the algebraic complement involution.

    See \(WQSymBases.ElementMethods.algebraic_complement()\) for a definition of the
    involution and for examples.

    See also:

    \(coalgebraic_complement()\), \(star_involution()\)

    EXAMPLES:

    >>> from sage.all import *
    >>> WQSym = algebras.WQSym(ZZ)
    >>> X = WQSym.X()
    >>> X[[Integer(1), Integer(2)], [Integer(5), Integer(6)], [Integer(3), Integer(4)]].algebraic_complement()
    X[[5, 6], [1, 2], [3, 4]]
    >>> X[[Integer(3)], [Integer(1), Integer(2)], [Integer(4)]].algebraic_complement()
    X[[2], [3, 4], [1]]

    coalgebraic_complement()

    Return the image of the element self of \(WQSym\) under the coalgebraic complement involution.

    See \(WQSymBases.ElementMethods.coalgebraic_complement()\) for a definition of
    the involution and for examples.

    See also:

    \(algebraic_complement()\), \(star_involution()\)

    EXAMPLES:

    >>> from sage.all import *
    >>> WQSym = algebras.WQSym(ZZ)
    >>> X = WQSym.X()
    >>> X[[Integer(1), Integer(2)], [Integer(5), Integer(6)], [Integer(3), Integer(4)]].coalgebraic_complement()
    X[[5, 6], [1, 2], [3, 4]]
    >>> X[[Integer(3)], [Integer(1), Integer(2)], [Integer(4)]].coalgebraic_complement()
    X[[2], [3, 4], [1]]
star_involution()

Return the image of the element self of $WQSym$ under the star involution.

See $WQSymBases.ElementMethods.star_involution()$ for a definition of the involution and for examples.

See also:

$algebraic_complement()$, $coalgebraic_complement()$

EXAMPLES:

```python
sage: WQSym = algebras.WQSym(ZZ)
sage: X = WQSym.X()
sage: X[[1,2],[5,6],[3,4]].star_involution()
X[[3, 4], [1, 2], [5, 6]]
sage: X[[3], [1, 2], [4]].star_involution()
X[{1}, {3, 4}, {2}]
```

```python
>>> from sage.all import *
>>> WQSym = algebras.WQSym(ZZ)
>>> X = WQSym.X()
>>> X[[Integer(1),Integer(2)],[Integer(5),Integer(6)],[Integer(3), Integer(4)]].star_involution()
X[(3, 4), (1, 2), (5, 6)]
>>> X[[Integer(3)],[Integer(1), Integer(2)], [Integer(4)]].star_involution()
X[{1}, {3, 4}, {2}]
```

class Cone(alg)

Bases: $WQSymBasis_abstract$

The Cone basis of $WQSym$.

Let $(X_P)_P$ denote the Characteristic basis of $WQSym$. Denote the quasi-shuffle of two ordered set partitions $A$ and $B$ by $A \vartriangleleft B$. For an ordered set partition $P = (P_1, \ldots, P_t)$, we form a list of ordered set partitions $[P] := (P'_1, \ldots, P'_k)$ as follows. Define a strictly decreasing sequence of integers $\ell + 1 = i_0 > i_1 > \cdots > i_k = 1$ recursively by requiring that $\min P_{i_j} \leq \min P_a$ for all $a < i_j - 1$. Set $P'_j = (P_{i_j}, \ldots, P_{i_{j-1}})$.

The Cone basis $(C_P)_P$ is defined by

\[
C_P = \sum_Q X_Q,
\]

where the sum is over all elements $Q$ of the quasi-shuffle product $P'_1 \vartriangleleft P'_2 \vartriangleleft \cdots \vartriangleleft P'_k$ with $[P] = (P'_1, \ldots, P'_k)$.

EXAMPLES:

```python
sage: WQSym = algebras.WQSym(QQ)
sage: C = WQSym.C()
sage: C
Word Quasi-symmetric functions over Rational Field in the Cone basis
sage: X = WQSym.X()
sage: X(C[[2,3],[1,4]])
X[{1, 2, 3, 4}] + X[{1, 4}, {2, 3}] + X[{2, 3}, {1, 4}]
sage: X(C[[1,4],[2,3]])
X[{1, 4}, {2, 3}]
sage: X(C[[2,3],[1],[4]])
```

Is this true? What is the formula?}
M

alias of Monomial
class Monomial(alg, graded=True)
    Bases: WQSymBasis_abstract

The Monomial basis of $WQSym$.

The family $(M_u)$, as defined in WordQuasiSymmetricFunctions with $u$ ranging over all packed words, is a basis for the free $R$-module $WQSym$ and called the Monomial basis. Here it is labelled using ordered set partitions.

EXAMPLES:

```python
sage: WQSym = algebras.WQSym(QQ)
sage: M = WQSym.M(); M
Word Quasi-symmetric functions over Rational Field in the Monomial basis
dsage: sorted(M.basis(2))
[M[{1}, {2}], M[{2}, {1}], M[{1, 2}]]
```

```python
>>> from sage.all import *
```

```python
M = algebras.WQSym(QQ).M(); M
Word Quasi-symmetric functions over Rational Field in the Monomial basis
>>> sorted(M.basis(Integer(2)))
[M[{1}, {2}], M[{2}, {1}], M[{1, 2}]]
```

coproduct_on_basis(x)

Return the coproduct of self on the basis element indexed by the ordered set partition $x$.

EXAMPLES:

```python
sage: M = algebras.WQSym(QQ).M()
sage: M.coproduct(M.one())  # indirect doctest
M[] # M[]
sage: M.coproduct( M([[1]]) )  # indirect doctest
M[] # M[[1]] + M[[1]] # M[]
sage: M.coproduct( M([[1,2]]) )
M[] # M[[1,2]] + M[[1,2]] # M[]
sage: M.coproduct( M([[1], [2]]) )
M[] # M[[1], {2}] + M[{1}] # M[[1]] + M[{1}, {2}] # M[]
```

```python
>>> from sage.all import *
```

```python
M = algebras.WQSym(QQ).M(); M
>>> M.coproduct(M.one())  # indirect doctest
M[] # M[]
>>> M.coproduct( M([[Integer(1)]]) )  # indirect doctest
M[] # M[[1]] + M[[1]] # M[]
>>> M.coproduct( M([[Integer(1),Integer(2)]]) )
M[] # M[[1,2]] + M[[1,2]] # M[]
>>> M.coproduct( M([[Integer(1)], [Integer(2)]]))
M[] # M[[1], {2}] + M[{1}] # M[[1]] + M[{1}, {2}] # M[]
```
product_on_basis (x, y)

Return the (associative) $\ast$ product of the basis elements of self indexed by the ordered set partitions $x$ and $y$.

This is the shifted quasi-shuffle product of $x$ and $y$.

EXAMPLES:

```python
sage: A = algebras.WQSym(QQ).M()
sage: x = OrderedSetPartition([[1], [2, 3]])
sage: y = OrderedSetPartition([[1, 2]])
sage: z = OrderedSetPartition([[1, 2], [3]])
sage: A.product_on_basis(x, y)
M[(1), (2, 3), (4, 5)] + M[(1), (2, 3, 4, 5)] + M[(1), (4, 5), {2, 3}] + M[(1, 4, 5), {2, 3}]
+ M[(4, 5), (1), {2, 3}]
sage: A.product_on_basis(x, z)
M[(1), (2, 3), (4, 5), (6)] + M[(1), (2, 3, 4, 5), (6)] + M[(1), (4, 5), {2, 3}, {6}] + M[(1), (4, 5), {2, 3}, {6}]
+ M[(1), (4, 5), {2, 3}, {6}] + M[(1, 4, 5), {2, 3}, {6}]
+ M[(4, 5), (1), {2, 3}, {6}] + M[(4, 5), (1), {6}, (2, 3)] + M[(4, 5), {1}, {6}, (2, 3)]
+ M[(4, 5), {6}, (1), (2, 3)]
sage: A.product_on_basis(y, y)
M[(1, 2), (3, 4)] + M[(1, 2, 3, 4)] + M[(3, 4), (1, 2)]
```

>>> from sage.all import *
>>> A = algebras.WQSym(QQ).M()
>>> x = OrderedSetPartition([[Integer(1)], [Integer(2), Integer(3)]]):
>>> y = OrderedSetPartition([[Integer(1), Integer(2)]]):
>>> z = OrderedSetPartition([[Integer(1), Integer(2)], [Integer(3)]]):
>>> A.product_on_basis(x, y)
M[(1), (2, 3), (4, 5)] + M[(1), (2, 3, 4, 5)] + M[(1), (4, 5), {2, 3}]
+ M[(4, 5), (1), {2, 3}]
>>> A.product_on_basis(x, z)
M[(1), (2, 3), (4, 5), (6)] + M[(1), (2, 3, 4, 5), (6)] + M[(1), (4, 5), {2, 3}, {6}]
+ M[(1), (4, 5), {2, 3}, {6}]
+ M[(1), (4, 5), {2, 3}, {6}]
+ M[(1, 4, 5), {2, 3}, {6}]
+ M[(4, 5), (1), {2, 3}, {6}] + M[(4, 5), (1), {6}, (2, 3)]
+ M[(4, 5), {1}, {6}, (2, 3)] + M[(4, 5), {1}, (2, 3)]
+ M[(4, 5), (6), (1), (2, 3)]
>>> A.product_on_basis(y, y)
M[(1, 2), (3, 4)] + M[(1, 2, 3, 4)] + M[(3, 4), (1, 2)]
```

**Phi**

alias of **StronglyFiner**

**Q**

alias of **StronglyCoarser**

class **StronglyCoarser**(alg)

    Bases: **WQSymBasis_abstract**

    The Q basis of WQSym.
We define a partial order $\leq$ on the set of all ordered set partitions as follows: $A \leq B$ if and only if $A$ is strongly finer than $B$ (see `is_strongly_finer()` for a definition of this).

The $Q$ basis $(Q_P)_P$ is a basis of $WQSym$ indexed by ordered set partitions, and is defined by

$$Q_P = \sum M_W,$$

where the sum is over ordered set partitions $W$ satisfying $P \leq W$.

**EXAMPLES:**

```python
sage: WQSym = algebras.WQSym(QQ)
sage: M = WQSym.M(); Q = WQSym.Q()
sage: Q
Word Quasi-symmetric functions over Rational Field in the Q basis

sage: Q(M[[2,3],[1,4]])
Q{[2, 3], [1, 4]}
sage: Q(M[[1,2],[3,4]])
Q{[1, 2], [3, 4]} - Q{[1, 2, 3, 4]}
sage: M(Q[[1,2],[3,4]])
M{[1, 2], [3, 4]} + M{[1, 2, 3, 4]}
sage: M(Q[[2,3],[1],[4]])
M{[2, 3], [1], [4]} + M{[2, 3], [1, 4]}
sage: M(Q[[3],[2,5],[1,4]])
M{[3], [2, 5], [1, 4]}
sage: M(Q[[1,4],[2,3],[5],[6]])
M{[1, 4], [2, 3], [5, 6]} + M{[1, 4], [2, 3, 5, 6]}
+ M{[1, 4], [2, 3, 5], 4} + M{[1, 4], [2, 3, 5, 6]}
sage: Q[[1,3],[2]] * Q[[1],[2]]
Q{[1, 3], [2]} + Q{[1, 2]} + Q{[1], [2]} + Q{[1]}
+ Q{[1]}
sage: Q[[1,3],[2]].coproduct()
Q{[1, 3], [2]} # Q{[1, 2]} # Q{[1]} + Q{[1, 3], [2]} # Q{[1]} + Q{[1, 3], [2]} # Q{[1]}
```

(continues on next page)
```python
>>> Q[[Integer(1), Integer(3)], [Integer(2)]] * Q[[Integer(1)], [Integer(2)]]
Q[[1, 3], {2}, {4}, {5}] + Q[[1, 3], {4}, {2}, {5}]
+ Q[[1, 3], {4}, {5}, {2}] + Q[{4}, {1, 3}, {2}, {5}]
+ Q[{4}, {1, 3}, {5}, {2}] + Q[{4}, {5}, {1, 3}, {2}]

>>> Q[[Integer(1), Integer(3)], [Integer(2)]] . coproduct()
Q[] # Q[[1, 3], {2}] + Q[[1, 2]] # Q[{1}] + Q[[1, 3], {2}] # Q[]
```

**class Element**

**Bases:** IndexedFreeModuleElement

**algebraic_complement()**

Return the image of the element self of \(WQSym\) under the algebraic complement involution.

See \(WQSymBases.ElementMethods.algebraic_complement()\) for a definition of the involution and for examples.

See also:

**coalgebraic_complement(), star_involution()**

**EXAMPLES:**

```python
sage: WQSym = algebras.WQSym(ZZ)
sage: Q = WQSym.Q()
sage: Q[[1,2],[5,6],[3,4]].algebraic_complement()
Q[{3, 4}, {1, 2, 5, 6}] + Q[{3, 4}, {5, 6}, {1, 2}]
- Q[{3, 4, 5, 6}, {1, 2}]
sage: Q[[3], [1, 2], [4]].algebraic_complement()
Q[{1, 2, 4}, {3}] + Q[{4}, {1, 2}, {3}] - Q[{4}, {1, 2, 3}]
```

```python
>>> from sage.all import *
```
Combinatorics, Release 10.4

```
sage: WQSym = algebras.WQSym(ZZ)
sage: Q = WQSym.Q()
sage: Q[[1,2],[5,6],[3,4]].coalgebraic_complement()
Q[[1, 2, 5, 6], {3, 4}] + Q[{5, 6}, {1, 2}, {3, 4}] - Q[{5, 6}, {1, 2, 3, 4}]
sage: Q[[3], [1, 2], [4]].coalgebraic_complement()
Q[{2}, {1, 3, 4}] + Q[{2}, {3, 4}, {1}] - Q[{2, 3, 4}, {1}]
```

from sage.all import *

```
>>> WQSym = algebras.WQSym(ZZ)
>>> Q = WQSym.Q()
>>> Q[[Integer(1),Integer(2)],[Integer(5),Integer(6)],[Integer(3),Integer(4)]].coalgebraic_complement()
Q[[1, 2, 5, 6], {3, 4}] + Q[{5, 6}, {1, 2}, {3, 4}] - Q[{5, 6}, {1, 2, 3, 4}]
>>> Q[[Integer(3)],[Integer(1), Integer(2)], [Integer(4)]].coalgebraic_complement()
Q[{2}, {1, 3, 4}] + Q[{2}, {3, 4}, {1}] - Q[{2, 3, 4}, {1}]
```

### star_involution()  
Return the image of the element self of $W_QSym$ under the star involution.

See WQSymBases.ElementMethods.star_involution() for a definition of the involution and for examples.

See also:  
`algebraic_complement()`, `coalgebraic_complement()`

**EXAMPLES:**

```
sage: WQSym = algebras.WQSym(ZZ)
sage: Q = WQSym.Q()
sage: Q[[1,2],[5,6],[3,4]].star_involution()
Q[{3, 4}, {1, 2}, {5, 6}]
sage: Q[[3], [1, 2], [4]].star_involution()
Q[{1}, {3, 4}, {2}]
```

from sage.all import *

```
>>> from sage.all import *
>>> WQSym = algebras.WQSym(ZZ)
>>> Q = WQSym.Q()
>>> Q[[Integer(1),Integer(2)],[Integer(5),Integer(6)],[Integer(3),Integer(4)]].star_involution()
Q[{3, 4}, {1, 2}, {5, 6}]
>>> Q[[Integer(3)],[Integer(1), Integer(2)], [Integer(4)]].star_involution()
Q[{1}, {3, 4}, {2}]
```

coproduct_on_basis(x)  
Return the coproduct of self on the basis element indexed by the ordered set partition x.

**EXAMPLES:**

```
sage: Q = algebras.WQSym(QQ).Q()
sage: Q.coproduct(Q.one())
# indirect doctest
Q[()] # Q[()]
sage: Q.coproduct( Q([[1]]) )
# indirect doctest
(continues on next page)
```

>>> from sage.all import *
>>>
```}

product_on_basis(x, y)

Return the (associative) * product of the basis elements of the Q basis `self` indexed by the ordered set partitions `x` and `y`.

This is the shifted shuffle product of `x` and `y`.

EXAMPLES:

```python
sage: A = algebras.WQSym(QQ).Q()
sage: x = OrderedSetPartition([[1],[2,3]])
sage: y = OrderedSetPartition([[1,2]])
sage: z = OrderedSetPartition([[1,2],[3]])
sage: A.product_on_basis(x, y)
Q[{1}, {2, 3}, {4, 5}] + Q[{1}, {4, 5}, {2, 3}] + Q[{4, 5}, {1}, {2, 3}]
sage: A.product_on_basis(x, z)
Q[{1}, {2, 3}, {4, 5}, {6}] + Q[{1}, {4, 5}, {2, 3}, {6}] + Q[{1}, {4, 5}, {6}, {1}, {2, 3}]
sage: A.product_on_basis(y, y)
Q[{1, 2}, {3, 4}] + Q[{3, 4}, {1, 2}]
>>> from sage.all import *
>>>
```
\[ + Q\{(1), (4, 5), (6), (2, 3)\} + Q\{(4, 5), (1), (2, 3), (6)\} \]
\[ + Q\{(4, 5), (1), (6), (2, 3)\} + Q\{(4, 5), (6), (1), (2, 3)\} \]

\[ \texttt{A.product_on_basis(y, y)} \]
\[ Q\{(1, 2), (3, 4)\} + Q\{(3, 4), (1, 2)\} \]

\section*{some\_elements()}

Return some elements of the word quasi-symmetric functions in the Q basis.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Q = algebras.WQSym(QQ).Q()
sage: Q.some_elements()
[Q[], Q[(1)], Q[(1, 2)], Q[] + 1/2*Q[(1)]]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> Q = algebras.WQSym(QQ).Q()

>>> Q.some_elements()
[Q[], Q[(1)], Q[(1, 2)], Q[] + 1/2*Q[(1)]]
\end{verbatim}

\section*{class StronglyFiner(alg)}

\textbf{Bases: WQSymBasis\_abstract}

The Phi basis of \( WQSym \).

We define a partial order \( \leq \) on the set of all ordered set partitions as follows: \( A \leq B \) if and only if \( A \) is strongly finer than \( B \) (see \texttt{is\_strongly\_finer()} for a definition of this).

The \textit{Phi basis} \((\Phi_P)_P\) is a basis of \( WQSym \) indexed by ordered set partitions, and is defined by

\[ \Phi_P = \sum W, \]

where the sum is over ordered set partitions \( W \) satisfying \( W \leq P \).

Novelli and Thibon introduced this basis in \cite{NovThi06} Section 2.7.2, and called it the quasi-ribbon basis. It later reappeared in \cite{MeNoTh11} Section 4.3.2.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: WQSym = algebras.WQSym(QQ)
sage: M = WQSym.M(); Phi = WQSym.Phi()
sage: Phi
Word Quasi-symmetric functions over Rational Field in the Phi basis

sage: Phi(M[[2, 3], [1, 4]])
Phi[[2], [3], [1], [4]] - Phi[[2], [3], [1, 4]]
- Phi[[2, 3], [1], [4]] + Phi[[2, 3], [1, 4]]

sage: M(Phi[[2, 3], [1], [4]])
M[[2, 3], [1], [4]] + M[[2, 3], [1, 4]]
+ M[[1, 2], [3], [4]] + M[[1, 2], [3, 4]]

\end{verbatim}

(continues on next page)
sage: M(Phi[[1, 4], [2, 3], [5], [6]])
M((1), (4), (2), (3), (5), (6)) + M((1), (4), (2, 3), (5), (6))
+ M((1, 4), (2), (3), (5), (6)) + M((1, 4), (2, 3), (5), (6))

sage: Phi[1] * Phi[1, 3, 2]
Phi((1, 2, 4), (1, 3)) + Phi((1, 2, 4), (2, 3))
+ Phi((2, 4), (1, 3)) + Phi((2, 3), (1, 3))

sage: Phi[[3, 5], [1, 4], [2]].coproduct()
Phi() # Phi[[3, 5], [1, 4], [2]]

- Section 2.7.2 of [NovThi06]

class Element
Bases: IndexedFreeModuleElement

algebraic_complement()

Return the image of the element self of \( WQSym \) under the algebraic complement involution. See \( WQSymBases.ElementMethods.algebraic_complement() \) for a definition of the involution and for examples.

See also:
coalgebraic_complement(), star_involution()

EXAMPLES:

```python
sage: WQSym = algebras.WQSym(ZZ)
sage: Phi = WQSym.Phi()
sage: Phi[[1],[2,4],[3]].algebraic_complement()
-Phi[{3}, {2}, {4}, {1}] + Phi[{3}, {2, 4}, {1}] + Phi[{3}, {4}, {2}, \rightarrow{1}]
sage: Phi[[1],[2,3],[4]].algebraic_complement()
-Phi[{4}, {2}, {3}, {1}] + Phi[{4}, {2, 3}, {1}] + Phi[{4}, {3}, {2}, \rightarrow{1}]
```

```python
>>> from sage.all import *

>>> WQSym = algebras.WQSym(ZZ)

>>> Phi = WQSym.Phi()

>>> Phi[[Integer(1)],[Integer(2)],[Integer(3),Integer(4)]].algebraic_complement()
-Phi[{4}, {3}, {1}, {2}] + Phi[{4}, {3}, {1, 2}] + Phi[{4}, {3}, {2}, \rightarrow{1}]

>>> Phi[[Integer(2)],[1,4],[3]].coalgebraic_complement()
-Phi[{3}, {1}, {4}, {2}] + Phi[{3}, {1, 4}, {2}] + Phi[{3}, {4}, {1}, \rightarrow{2}]
```

coalgebraic_complement()

Return the image of the element self of \( WQSym \) under the coalgebraic complement involution. See \( WQSymBases.ElementMethods.coalgebraic_complement() \) for a definition of the involution and for examples.

See also:
algebraic_complement(), star_involution()

EXAMPLES:

```
sage: WQSym = algebras.WQSym(ZZ)
sage: Phi = WQSym.Phi()
sage: Phi[[1],[2,4],[3]].coalgebraic_complement()
-Phi[{3}, {2}, {4}, {1}] + Phi[{3}, {2, 4}, {1}] + Phi[{3}, {4}, {2}, \rightarrow{1}]
sage: Phi[[1],[2,3],[4]].coalgebraic_complement()
-Phi[{4}, {2}, {3}, {1}] + Phi[{4}, {2, 3}, {1}] + Phi[{4}, {3}, {2}, \rightarrow{1}]
```

```python
>>> from sage.all import *

>>> WQSym = algebras.WQSym(ZZ)

>>> Phi = WQSym.Phi()

>>> Phi[[Integer(1)],[Integer(2)],[Integer(3),Integer(4)]].coalgebraic_complement()
-Phi[{4}, {3}, {1}, {2}] + Phi[{4}, {3}, {1, 2}] + Phi[{4}, {3}, {2}, \rightarrow{1}]
```
Combinatorics, Release 10.4

star_involution()

Return the image of the element self of $WQSym$ under the star involution.

See $WQSymBases.ElementMethods.star_involution()$ for a definition of the involution and for examples.

See also:

algebraic_complement(), coalgebraic_complement()

EXAMPLES:

```
sage: WQSym = algebras.WQSym(ZZ)
sage: Phi = WQSym.Phi()
sage: Phi[[1,2],[5,6],[3,4]].star_involution()
Phi[{3, 4}, {1, 2}, {5, 6}]
sage: Phi[[3], [1, 2], [4]].star_involution()
Phi[{1}, {3, 4}, {2}]
```

coproduct_on_basis$(x)$

Return the coproduct of self on the basis element indexed by the ordered set partition $x$.

The coproduct of the basis element $\Phi_x$ indexed by an ordered set partition $x$ of $[n]$ can be computed by the following formula ([NovThi06]):

$$\Delta \Phi_x = \sum \Phi_y \otimes \Phi_z,$$

where the sum ranges over all pairs $(y, z)$ of ordered set partitions $y$ and $z$ such that:

- $y$ and $z$ are ordered set partitions of two complementary subsets of $[n]$;
- $x$ is obtained either by concatenating $y$ and $z$, or by first concatenating $y$ and $z$ and then merging the two "middle blocks" (i.e., the last block of $y$ and the first block of $z$); in the latter case, the maximum of the last block of $y$ has to be smaller than the minimum of the first block of $z$ (so that when merging these blocks, their entries don't need to be sorted).

EXAMPLES:

```
sage: Phi = algebras.WQSym(QQ).Phi()
sage: Phi.coproduct(Phi.one())  # indirect doctest
```

(continues on previous page)
product_on_basis(\(x, y\))

Return the (associative) \(*\) product of the basis elements of the \(\Phi\) basis \(self\) indexed by the ordered set partitions \(x\) and \(y\).

This is obtained by the following algorithm (going back to [NovThi06]):

Let \(x\) be an ordered set partition of \([m]\), and \(y\) an ordered set partition of \([n]\). Transform \(x\) into a list \(u\) of all the \(m\) elements of \([m]\) by writing out each block of \(x\) (in increasing order) and putting bars between each two consecutive blocks; this is called a barred permutation. Do the same for \(y\), but also shift each entry of the resulting barred permutation by \(m\). Let \(v\) be the barred permutation of \([m+n]\) \(\setminus [m]\) thus obtained. Now, shuffle the two barred permutations \(u\) and \(v\) (ignoring the bars) in all the \(\binom{m+n}{m}\) possible ways. For each shuffle obtained, place bars between some entries of the shuffle, according to the following rule:

- If two consecutive entries of the shuffle both come from \(u\), then place a bar between them if the corresponding entries of \(u\) had a bar between them.
- If the first of two consecutive entries of the shuffle comes from \(v\) and the second from \(u\), then place a bar between them.

This results in a barred permutation of \([m+n]\). Transform it into an ordered set partition of \([m+n]\), by treating the bars as dividers separating consecutive blocks.

The product \(\Phi_x \Phi_y\) is the sum of \(\Phi_p\) with \(p\) ranging over all ordered set partitions obtained this way.

**EXAMPLES:**

```python
sage: from sage.all import *
sage: Phi = algebras.WQSym(QQ).Phi()
sage: Phi.coproduct(Phi.one())  # indirect doctest
Phi\[
\]
```

```python
>>> from sage.all import *
>>> Phi = algebras.WQSym(QQ).Phi()
```
sage: A.product_on_basis(x, y)
Phi[{1}, {2, 3, 4, 5}] + Phi[{1}, {2, 4}, {3, 5}]
+ Phi[{1}, {2, 4, 5}, {3}]
+ Phi[{1, 4}, {2, 3, 5}]
+ Phi[{1, 4, 5}, {2, 3}]
+ Phi[{1}, {2, 3, 5}, {6}]
+ Phi[{1}, {2, 4}, {3, 6}]
+ Phi[{1}, {2, 4, 5}, {6}]
+ Phi[{1, 4}, {2, 3, 5}]

sage: A.product_on_basis(x, z)
Phi[{1}, {2, 3, 4, 5}, {6}]
+ Phi[{1}, {2, 4}, {3, 5}, {6}]
+ Phi[{1, 4}, {2, 3, 5}]
+ Phi[{1, 4}, {2, 5}, {3, 6}]
+ Phi[{1, 4, 5}, {2, 3}]
+ Phi[{4}, {1}, {2, 3, 5}]
+ Phi[{4}, {1}, {2, 5}, {3}]
+ Phi[{4}, {1, 5}, {2, 3}]
+ Phi[{4, 5}, {1}, {2, 3}]

sage: A.product_on_basis(y, y)
Phi[{1, 2, 3, 4}]
+ Phi[{1, 3}, {2, 4}]
+ Phi[{1, 3, 4}, {2}]
+ Phi[{3}, {1, 2, 4}]
+ Phi[{3}, {1, 4}, {2}]
+ Phi[{3, 4}, {1, 2}]

>>> from sage.all import *

Return some elements of the word quasi-symmetric functions in the Phi basis.

EXAMPLES:
```python
sage: Phi = algebras.WQSym(QQ).Phi()
sage: Phi.some_elements()
[Phi[], Phi[{1}], Phi[{1, 2}], Phi[] + 1/2*Phi[{1}]]

>>> from sage.all import *

>>> Phi = algebras.WQSym(QQ).Phi()

| Phi[] | Phi[{1}] | Phi[{1, 2}] | Phi[] + 1/2*Phi[{1}] |
```

```
x

alias of Characteristic

a_realization()

Return a particular realization of self (the $M$-basis).

EXAMPLES:

```python
sage: WQSym = algebras.WQSym(QQ)
sage: WQSym.a_realization()

Word Quasi-symmetric functions over Rational Field in the Monomial basis

| Phi[] | Phi[{1}] | Phi[{1, 2}] | Phi[] + 1/2*Phi[{1}] |
```

5.1.17 Cluster algebras and quivers

- A compendium on the cluster algebra and quiver package in Sage [MS2011]

- Quiver mutation types
  - Quiver
  - ClusterSeed

5.1.18 ClusterSeed

A cluster seed is a pair $(B, x)$ with $B$ being a skew-symmetric $(n + m) \times n$-matrix and with $x$ being an $n$-tuple of independent elements in the field of rational functions in $n$ variables.

For the compendium on the cluster algebra and quiver package see [MS2011].

REFERENCES:
For mutation types of cluster seeds, see \texttt{sage.combinat.cluster_algebra_quiver.quiver_mutation_type.QuiverMutationType()}. Cluster seeds are closely related to \texttt{sage.combinat.cluster_algebra_quiver.quiver.ClusterQuiver}.

\begin{verbatim}
class sage.combinat.cluster_algebra_quiver.cluster_seed.ClusterSeed(
    data,
    frozen=None,
    is_principal=False,
    user_labels=None,
    user_labels_prefix='x')

Bases: sage.combinat.cluster_algebra_quiver.cluster_seed

The \textit{cluster seed} associated to an exchange matrix.

INPUT:

- \texttt{data} – can be any of the following:

\begin{itemize}
  \item \texttt{str} – a string representing a QuiverMutationType or a common quiver type (see Examples)
  \item \texttt{ClusterQuiver}
  \item \texttt{Matrix} – a skew-symmetrizable matrix
  \item \texttt{DiGraph} – must be the input data for a quiver
  \item List of edges – must be the edge list of a digraph for a quiver
\end{itemize}

EXAMPLES:

\begin{verbatim}
sage: S = ClusterSeed(['A', 5]); S
A seed for a cluster algebra of rank 5 of type ['A', 5]
sage: S = ClusterSeed(['A', [2, 5], 1]); S
A seed for a cluster algebra of rank 7 of type ['A', [2, 5], 1]
sage: T = ClusterSeed(S); T
A seed for a cluster algebra of rank 7 of type ['A', [2, 5], 1]
sage: T = ClusterSeed(S._M); T
A seed for a cluster algebra of rank 7
sage: T = ClusterSeed(S.quiver()._digraph); T
A seed for a cluster algebra of rank 7
sage: T = ClusterSeed(S.quiver()._digraph.edges(sort=True)); T
A seed for a cluster algebra of rank 7
sage: S = ClusterSeed(['B', 2]); S
\end{verbatim}

(continues on next page)
\end{verbatim}
A seed for a cluster algebra of rank 2 of type ['B', 2]
sage: S = ClusterSeed(['C', 2]); S
A seed for a cluster algebra of rank 2 of type ['B', 2]
sage: S = ClusterSeed(['A', [5,0],1]); S
A seed for a cluster algebra of rank 5 of type ['D', 5]
sage: S = ClusterSeed(['GR',[3,7]]); S
A seed for a cluster algebra of rank 6 of type ['E', 6]
sage: S = ClusterSeed(['F', 4, [2,1]]); S
A seed for a cluster algebra of rank 6 of type ['F', 4, [1, 2]]
sage: S = ClusterSeed(['A',4]); S._use_fpolys
True
sage: S._use_d_vec
True
sage: S._use_g_vec
True
sage: S._use_c_vec
True
sage: S = ClusterSeed(['A', 4]); S.use_fpolys(False); S._use_fpolys
False
sage: S = ClusterSeed(DiGraph([['a', 'b'], ['c', 'b'], ['c', 'd'], ['e', 'd']]),
....: frozen=['c']); S
A seed for a cluster algebra of rank 4 with 1 frozen variable
sage: S = ClusterSeed(['D', 4], user_labels=[-1, 0, 1, 2]); S
A seed for a cluster algebra of rank 4 of type ['D', 4]

>>> from sage.all import *

A seed for a cluster algebra of rank 5 of type ['A', 5]

>>> S = ClusterSeed(['A', Integer(5)]); S
A seed for a cluster algebra of rank 5 of type ['A', [5,0],1]

>>> T = ClusterSeed(S); T
A seed for a cluster algebra of rank 7 of type ['A', [2, 5, 1]]

>>> T = ClusterSeed(S._M); T
A seed for a cluster algebra of rank 7

True
>>> S._use_g_vec
True
>>> S._use_c_vec
True
```

A seed for a cluster algebra of rank 4 with 1 frozen variable

```python
>>> S = ClusterSeed(DiGraph([['a', 'b'], ['c', 'b'], ['c', 'd'], ['e', 'd']]), frozen=['c']); S
A seed for a cluster algebra of rank 4 with 1 frozen variable
```

A seed for a cluster algebra of rank 4 of type ['D', 4]

```python
>>> S = ClusterSeed(['D', Integer(4)], user_labels=[-Integer(1), Integer(0), Integer(1), Integer(2)]); S
A seed for a cluster algebra of rank 4 of type ['D', 4]
```

**LLM_gen_set** (*size_limit=*-1)

Produce a list of upper cluster algebra elements corresponding to all vectors in \{0, 1\}^n.

**INPUT:**

- B – a skew-symmetric matrix.
- size_limit – a limit on how many vectors you want the function to return.

**OUTPUT:**

An array of elements in the upper cluster algebra.

**EXAMPLES:**

```
sage: B = matrix([[0, 1, 0], [-1, 0, 1], [0, -1, 0], [1, 0, 0], [0, 1, 0], [0, 0, 1]])
sage: C = ClusterSeed(B)
sage: C.LLM_gen_set()
[1,
 (x1 + x3)/x0,
 (x0^2 + x2)/x1,
 (x0^3 + x1^2 + x2^2 + x3^2)/(x0*x1),
 (x1*x5 + 1)/x2,
 (x1^2 + x2 + x3^2 + x5)/x1, x1 + 3)/x2,
 (x0^2*x1^2 + x0^4 + x0^2 + x0*x4 + x2)/(x1^2)
]```
from sage.all import *
B = matrix([[Integer(0), Integer(1), Integer(0)], [-Integer(1), Integer(0), -Integer(1)], [Integer(0), Integer(1), Integer(0)], [Integer(1), Integer(0), Integer(0)], [Integer(0), Integer(0), -Integer(1)]])
C = ClusterSeed(B)
C.LLM_gen_set()

b_matrix()
Return the $B$-matrix of self.

EXAMPLES:

sage: ClusterSeed(['A',4]).b_matrix()
[ 0 1 0 0]
[-1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -1 0]

sage: ClusterSeed(['B',4]).b_matrix()
[ 0 1 0 0]
[-1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -2 0]

sage: ClusterSeed(['D',4]).b_matrix()
[ 0 1 0 0]
[-1 0 -1 -1]
[ 0 1 0 0]
[ 0 1 0 0]

sage: ClusterSeed(QuiverMutationType([[A,2],[B,2]])).b_matrix()
[ 0 1 0 0]
[-1 0 0 0]
[ 0 0 0 1]
[ 0 0 -2 0]

from sage.all import *
ClusterSeed(['A',Integer(4)]).b_matrix()
ClusterSeed(['B',Integer(4)]).b_matrix()
Combinatorics, Release 10.4

Continued from previous page

```
>>> ClusterSeed(['D', Integer(4)]).b_matrix()
[ 0 1 0 0]
[-1 0 -1 -1]
[ 0 1 0 0]
[ 0 1 0 0]

>>> ClusterSeed(QuiverMutationType([['A', Integer(2)],[['B', Integer(2)]])).b_matrix()
[ 0 1 0 0]
[-1 0 0 0]
[ 0 0 0 1]
[ 0 0 -2 0]
```

```
b_matrix_class (depth=+Infinity, up_to_equivalence=True)
Return all B-matrices in the mutation class of self.

INPUT:
• depth – (default: infinity) integer or infinity, only seeds with distance at most depth from self are returned
• up_to_equivalence – (default: True) if True, only B-matrices up to equivalence are considered.

EXAMPLES:
• for examples see b_matrix_class_iter()

b_matrix_class_iter (depth=+Infinity, up_to_equivalence=True)
Return an iterator through all B-matrices in the mutation class of self.

INPUT:
• depth – (default: infinity) integer or infinity, only seeds with distance at most depth from self are returned
• up_to_equivalence – (default: True) if True, only B-matrices up to equivalence are considered.

EXAMPLES:
A standard finite type example:
```
sage: S = ClusterSeed(['A',4])
sage: it = S.b_matrix_class_iter()
sage: for T in it: print(T)
[ 0 0 0 1]
[ 0 0 1 1]
[ 0 -1 0 0]
[-1 -1 0 0]
[ 0 0 0 1]
[ 0 0 1 0]
[ 0 -1 0 1]
[-1 0 -1 0]
[ 0 0 1 1]
[ 0 0 0 -1]
[-1 0 0 0]
[-1 1 0 0]
[ 0 0 0 1]
[ 0 0 -1 1]
[ 0 1 0 -1]
```
```
\[
\begin{bmatrix}
-1 & -1 & 1 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & -1 & 0 \\
0 & 1 & 0 & -1 \\
1 & 0 & 1 & 0 \\
0 & 0 & 0 & -1 \\
0 & 0 & -1 & 1 \\
0 & 1 & 0 & -1 \\
0 & 1 & 0 & -1 \\
1 & 1 & 0 & 0 \\
\end{bmatrix}
\]

```python
>>> from sage.all import *
>>> S = ClusterSeed(['\Lambda', Integer(4)])
>>> it = S.b_matrix_class_iter()
>>> for T in it: print(T)
```

```
\[
\begin{bmatrix}
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 1 \\
0 & -1 & 0 & 0 \\
-1 & -1 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 \\
0 & -1 & 0 & 1 \\
-1 & 0 & -1 & 0 \\
0 & 0 & 1 & 1 \\
0 & 0 & 0 & -1 \\
-1 & 0 & 0 & 0 \\
-1 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & -1 & 1 \\
0 & 1 & 0 & -1 \\
-1 & -1 & 1 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & -1 & 0 \\
0 & 1 & 0 & -1 \\
-1 & 0 & 1 & 0 \\
0 & 0 & 0 & -1 \\
0 & 0 & -1 & 1 \\
0 & 1 & 0 & -1 \\
1 & 1 & 1 & 0 \\
\end{bmatrix}
```

A finite type example with given depth:

```python
sage: it = S.b_matrix_class_iter(depth=1)
sage: for T in it: print(T)
```

```
\[
\begin{bmatrix}

```

5.1. Comprehensive Module List 275
```python
>>> from sage.all import *
>>> it = S.b_matrix_class_iter(depth=Integer(1))
>>> for T in it: print(T)
[ 0 0 0 1]
[ 0 0 1 1]
[ 0 -1 0 0]
[-1 -1 0 0]
[ 0 0 0 1]
[ 0 0 1 0]
[ 0 -1 0 1]
[-1 0 -1 0]
[ 0 0 1 1]
[ 0 0 0 -1]
[-1 0 0 0]
[-1 1 0 0]
```

Finite type example not considered up to equivalence:

```python
sage: S = ClusterSeed(['A',3])
sage: it = S.b_matrix_class_iter(up_to_equivalence=False)
sage: b_matrix_class = list(it)
sage: len(b_matrix_class)
14
sage: b_matrix_class[0]
[ 0 1 0]
[-1 0 -1]
[ 0 1 0]
```

Infinite (but finite mutation) type example:

```python
sage: S = ClusterSeed(['A',[1,2],1])
sage: it = S.b_matrix_class_iter()
sage: for T in it: print(T)
[ 0 1 1]
[-1 0 1]
[-1 -1 0]
[ 0 -2 1]
[ 2 0 -1]
[-1 1 0]
```

(continues on next page)
Infinite mutation type example:

```python
sage: S = ClusterSeed(['E',10])
sage: it = S.b_matrix_class_iter(depth=3)
sage: len ([T for T in it])
266
```

For a cluster seed from an arbitrarily labelled digraph:

```python
sage: dg = DiGraph([['a', 'b'], ['b', 'c']], format="list_of_edges")
sage: S = ClusterSeed(dg, frozen=['b'])
sage: S.b_matrix_class()
```

```
[ 0 0 0]
[ 0 0 0]
[-1 1, -1 -1, 1 1]
```

```python
>>> from sage.all import *

>>> dg = DiGraph([['a', 'b'], ['b', 'c']], format="list_of_edges")

>>> S = ClusterSeed(dg, frozen=['b'])

>>> S.b_matrix_class()
```

```
[ 0 0 0]
[ 0 0 0]
[-1 1, -1 -1, 1 1]
```

```python
c_matrix (show_warnings=True)
Return all c-vectors of self.
```

**Warning:** This method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

**EXAMPLES:**

```python
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: S.c_matrix()
```

```
[ 1 0 0]
[ 0 0 -1]
[ 0 -1 0]
```

(continues on next page)
sage: S = ClusterSeed(["A",4])
sage: S.use_g_vectors(False); S.use_fpolys(False)
sage: S.use_c_vectors(False); S.use_d_vectors(False); S.track_mutations(False)
sage: S.c_matrix()
Traceback (most recent call last):
...
ValueError: Unable to calculate c-vectors. Need to use c vectors.

>>> from sage.all import *
>>> S = ClusterSeed(['A',Integer(3)]).principal_extension()
>>> S.mutate([Integer(2),Integer(1),Integer(2)])
>>> S.c_matrix()
[ 1  0  0]
[ 0  0 -1]
[ 0 -1  0]

>>> S = ClusterSeed(['A',Integer(4)])
>>> S.use_g_vectors(False); S.use_fpolys(False)
>>> S.use_c_vectors(False); S.use_d_vectors(False); S.track_mutations(False)
>>> S.c_matrix()
Traceback (most recent call last):
...
ValueError: Unable to calculate c-vectors. Need to use c vectors.

c_vector (k)
Return the k-th c-vector of self. It is obtained as the k-th column vector of the bottom part of the B-matrix of self.

Warning: This method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

EXAMPLES:

sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: [S.c_vector(k) for k in range(3)]
[(1, 0, 0), (0, 0, -1), (0, -1, 0)]

sage: S = ClusterSeed(Matrix([[0,1],[-1,0],[1,0],[-1,1]])); S
A seed for a cluster algebra of rank 2 with 2 frozen variables
sage: S.c_vector(0)
(1, 0)

sage: S = ClusterSeed(Matrix([[0,1],[-1,0],[1,0],[-1,1]]))
sage: S.use_c_vectors(bot_is_c=True); S
A seed for a cluster algebra of rank 2 with 2 frozen variables
sage: S.c_vector(0)
(1, -1)
Combinatorics, Release 10.4

(continued from previous page)

\[(1, 0, 0), (0, 0, -1), (0, -1, 0)\]

```python
>>> S = ClusterSeed(Matrix([[Integer(0), Integer(1)], [-Integer(1), Integer(0)], [-Integer(1), Integer(1)]])); S
A seed for a cluster algebra of rank 2 with 2 frozen variables
>>> S.c_vector(Integer(0))
(1, 0)
```

```python
>>> S = ClusterSeed(Matrix([[Integer(0), Integer(1)], [-Integer(1), Integer(0)], [-Integer(1), Integer(1)]])); S
A seed for a cluster algebra of rank 2 with 2 frozen variables
>>> S.c_vector(Integer(0))
(1, -1)
```

**cluster()**

Return a copy of the *cluster* of *self*.

**EXAMPLES:**

```python
sage: S = ClusterSeed([A,3])
sage: S.cluster()
[x0, x1, x2]
sage: S.mutate(1)
sage: S.cluster()
[x0, (x0*x2 + 1)/x1, x2]
sage: S.mutate(2)
sage: S.cluster()
[x0, (x0*x2 + 1)/x1, (x0*x2 + x1 + 1)/(x1*x2)]
sage: S.mutate([2,1])
sage: S.cluster()
[x0, x1, x2]
```

```python
>>> from sage.all import *
>>> S = ClusterSeed(['A', Integer(3)])
>>> S.cluster()
[x0, x1, x2]
>>> S.mutate(Integer(1))
>>> S.cluster()
[x0, (x0*x2 + 1)/x1, x2]
>>> S.mutate(Integer(2))
>>> S.cluster()
[x0, (x0*x2 + 1)/x1, (x0*x2 + x1 + 1)/(x1*x2)]
>>> S.mutate([Integer(2), Integer(1)])
>>> S.cluster()
[x0, x1, x2]
```

**cluster_class**(depth=+Infinity, show_depth=False, up_to_equivalence=True)

Return the cluster class of *self* with respect to certain constraints.

**INPUT:**
• depth – (default: infinity) integer, only seeds with distance at most depth from self are returned
• return_depth – (default: False); if True, ignored if depth is set; returns the depth of the mutation class, i.e., the maximal distance from self of an element in the mutation class
• up_to_equivalence – (default: True); if True, only clusters up to equivalence are considered.

EXAMPLES:
• for examples see cluster_class_iter()

cluster_class_iter (depth=+Infinity, show_depth=False, up_to_equivalence=True)
Return an iterator through all clusters in the mutation class of self.

INPUT:
• depth – (default: infinity) integer or infinity, only seeds with distance at most depth from self are returned
• show_depth – (default: False) if True, ignored if depth is set; returns the depth of the mutation class, i.e., the maximal distance from self of an element in the mutation class
• up_to_equivalence – (default: True) if True, only clusters up to equivalence are considered.

EXAMPLES:
A standard finite type example:

```python
sage: S = ClusterSeed(['A', 3])
sage: it = S.cluster_class_iter()
sage: cluster_class = list(it)
sage: len(cluster_class)
14
sage: cluster_class[0]
[x0, x1, x2]
```

```python
>>> from sage.all import *

```
A finite type example with given depth:

```python
sage: it = S.cluster_class_iter(depth=1)
sage: for T in it: print(T)
[x0, x1, x2]
[x0, x1, (x1 + 1)/x2]
[x0, (x0*x2 + 1)/x1, x2]
[(x1 + 1)/x0, x1, x2]
```

```python
>>> from sage.all import *

```
A finite type example where the depth is returned while computing:

```python
sage: it = S.cluster_class_iter(show_depth=True)
sage: _ = list(it)
Depth: 0 found: 1 Time: ... s
Depth: 1 found: 4 Time: ... s
Depth: 2 found: 9 Time: ... s
Depth: 3 found: 13 Time: ... s
Depth: 4 found: 14 Time: ... s

>>> from sage.all import *
>>> it = S.cluster_class_iter(show_depth=True)
>>> _ = list(it)
Depth: 0 found: 1 Time: ... s
Depth: 1 found: 4 Time: ... s
Depth: 2 found: 9 Time: ... s
Depth: 3 found: 13 Time: ... s
Depth: 4 found: 14 Time: ... s
```

Finite type examples not considered up to equivalence:

```python
sage: it = S.cluster_class_iter(up_to_equivalence=False)
sage: len([T for T in it])
84

sage: it = ClusterSeed([A,2]).cluster_class_iter(up_to_equivalence=False)
sage: cluster_class = list(it)
sage: len(cluster_class)
10
sage: cluster_class[0]
[x0, x1]
sage: cluster_class[-1]
[x1, x0]
```

```python
>>> from sage.all import *
>>> it = S.cluster_class_iter(up_to_equivalence=False)
>>> len([T for T in it])
84

>>> it = ClusterSeed(['A',Integer(2)]).cluster_class_iter(up_to_equivalence=False)
>>> cluster_class = list(it)
>>> len(cluster_class)
10
>>> cluster_class[Integer(0)]
[x0, x1]
>>> cluster_class[-Integer(1)]
[x1, x0]
```

Infinite type examples:

```python
sage: S = ClusterSeed(['A', [1,1], 1])
sage: it = S.cluster_class_iter()
sage: next(it)
[x0, x1]
sage: next(it)
[x0, (x0^2 + 1)/x1]
```

(continues on next page)
sage: next(it)
[(x1^2 + 1)/x0, x1]
sage: next(it)
[(x0^4 + 2*x0^2 + x1^2 + 1)/(x0*x1^2), (x0^2 + 1)/x1]
sage: next(it)
[(x1^2 + 1)/x0, (x1^4 + x0^2 + 2*x1^2 + 1)/(x0^2*x1)]

sage: it = S.cluster_class_iter(depth=3)
sage: for T in it: print(T)
[x0, x1]
[x0, (x0^2 + 1)/x1]
[(x1^2 + 1)/x0, x1]
[(x0^4 + 2*x0^2 + x1^2 + 1)/(x0*x1^2), (x0^2 + 1)/x1]
[(x1^2 + 1)/x0, (x1^4 + x0^2 + 2*x1^2 + 1)/(x0^2*x1)]
[(x0^4 + 2*x0^2 + x1^2 + 1)/(x0*x1^2), (x0^6 + 3*x0^4 + 2*x0^2*x1^2 + x1^4 +...
→3*x0^2 + 2*x1^2 + 1)/(x0^2*x1^3)]
[(x1^6 + x0^4 + 2*x0^2*x1^2 + 3*x1^4 + 2*x0^2 + 3*x1^2 + 1)/(x0^3*x1^2), (x1^4 +
→4 + x0^2 + 2*x1^2 + 1)/(x0^2*x1)]

>>> from sage.all import *
>>> S = ClusterSeed(['A'], [Integer(1), Integer(1)], Integer(1))
>>> it = S.cluster_class_iter()
>>> next(it)
[x0, x1]
>>> next(it)
[x0, (x0^2 + 1)/x1]
>>> next(it)
[(x1^2 + 1)/x0, x1]
>>> next(it)
[(x0^4 + 2*x0^2 + x1^2 + 1)/(x0*x1^2), (x0^2 + 1)/x1]

>>> for T in it: print(T)
[x0, x1]
[x0, (x0^2 + 1)/x1]
[(x1^2 + 1)/x0, x1]
[(x0^4 + 2*x0^2 + x1^2 + 1)/(x0*x1^2), (x0^2 + 1)/x1]
[(x1^2 + 1)/x0, (x1^4 + x0^2 + 2*x1^2 + 1)/(x0^2*x1)]
[(x0^4 + 2*x0^2 + x1^2 + 1)/(x0*x1^2), (x0^6 + 3*x0^4 + 2*x0^2*x1^2 + x1^4 +...
→3*x0^2 + 2*x1^2 + 1)/(x0^2*x1^3)]
[(x1^6 + x0^4 + 2*x0^2*x1^2 + 3*x1^4 + 2*x0^2 + 3*x1^2 + 1)/(x0^3*x1^2), (x1^4 +
→4 + x0^2 + 2*x1^2 + 1)/(x0^2*x1)]

For a cluster seed from an arbitrarily labelled digraph:

sage: dg = DiGraph([['a', 'b'], ['b', 'c']], format="list_of_edges")
sage: S = ClusterSeed(dg, frozen=['b'])
sage: S.cluster_class()
[[a, c], [a, (b + 1)/c], [(b + 1)/a, c], [(b + 1)/a, (b + 1)/c]]

sage: S2 = ClusterSeed(dg, frozen=[])  
sage: S2.cluster_class()[0][a, b, c]
```python
>>> from sage.all import *
>>> dg = DiGraph([['a', 'b'], ['b', 'c']], format="list_of_edges")
>>> S = ClusterSeed(dg, frozen=['b'])
>>> S.cluster_class()
[[a, c], [a, (b + 1)/c], [(b + 1)/a, c], [(b + 1)/a, (b + 1)/c]]
>>> S2 = ClusterSeed(dg, frozen=[])  
>>> S2.cluster_class()[Integer(0)]
[a, b, c]
```

### cluster_index(cluster_str)

Return the index of a cluster if `use_fpolys` is on.

**INPUT:**

- `cluster_str` – the string to look for in the cluster

**OUTPUT:**

An integer or `None` if the string is not a cluster variable

**EXAMPLES:**

```python
sage: S = ClusterSeed(['A', 4], user_labels=['x', 'y', 'z', 'w']); S.mutate('x → ')
sage: S.cluster_index('x')
sage: S.cluster_index('(y+1)/x')
0
```

### cluster_variable(k)

Generates a cluster variable using F-polynomials

**EXAMPLES:**

```python
sage: S = ClusterSeed(['A',3])
sage: S.mutate([0,1])
sage: S.cluster_variable(0)
(x1 + 1)/x0
sage: S.cluster_variable(1)
(x0*x2 + x1 + 1)/(x0*x1)
```

### coefficient(k)

Return the coefficient of `self` at index k, or vertex k if k is not an index.
EXAMPLES:

```python
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: [S.coefficient(k) for k in range(3)]
[y0, 1/y2, 1/y1]
```

```python
>>> from sage.all import *
>>> S = ClusterSeed(['A',Integer(3)]).principal_extension()
>>> S.mutate([Integer(2),Integer(1),Integer(2)])
>>> [S.coefficient(k) for k in range(Integer(3))]
[y0, 1/y2, 1/y1]
```

coefficients()

Return all coefficients of self.

EXAMPLES:

```python
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: S.coefficients()
[y0, 1/y2, 1/y1]
```

```python
>>> from sage.all import *
>>> S = ClusterSeed(['A',Integer(3)]).principal_extension()
>>> S.mutate([Integer(2),Integer(1),Integer(2)])
>>> S.coefficients()
[y0, 1/y2, 1/y1]
```

d_matrix(show_warnings=True)

Return the matrix of d-vectors of self.

EXAMPLES:

```python
sage: S = ClusterSeed(['A',4]); S.d_matrix()
[-1 0 0 0]
[ 0 -1 0 0]
[ 0 0 -1 0]
[ 0 0 0 -1]
sage: S.mutate([1,2,1,0,1,3]); S.d_matrix()
[1 1 0 1]
[1 1 1 1]
[1 0 1 1]
[0 0 0 1]
```

```python
>>> from sage.all import *
>>> S = ClusterSeed(['A',Integer(4)]); S.d_matrix()
[-1 0 0 0]
[ 0 -1 0 0]
[ 0 0 -1 0]
[ 0 0 0 -1]
>>> S.mutate([Integer(1),Integer(2),Integer(1),Integer(0),Integer(1),
-Integer(3)]); S.d_matrix()
[1 1 0 1]
[1 1 1 1]
[1 0 1 1]
[0 0 0 1]
```
**d_vector** \((k)\)

Return the \(k\)-th \textit{d-vector} of \texttt{self}. This is the exponent vector of the denominator of the \(k\)-th cluster variable.

**EXAMPLES:**

```
sage: S = ClusterSeed(['A',3])
sage: S.mutate([2,1,2])
sage: [S.d_vector(k) for k in range(3)]
[(-1, 0, 0), (0, 1, 1), (0, 1, 0)]
```

**exchangeable_part()**

Return the restriction to the principal part (i.e. the exchangeable variables) of \texttt{self}.

**EXAMPLES:**

```
sage: S = ClusterSeed(['A',4])
sage: T = ClusterSeed(S.quiver().digraph().edges(sort=True), frozen=[3])
sage: T.quiver().digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1)), (2, 3, (1, -1))]
sage: T.exchangeable_part().quiver().digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1))]
```

**f_polynomial** \((k)\)

Return the \(k\)-th \textit{F-polynomial} of \texttt{self}. It is obtained from the \(k\)-th cluster variable by setting all \(x_i\) to 1.

**Warning:** This method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

**EXAMPLES:**

```
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: [S.f_polynomial(k) for k in range(3)]
[1, y1*y2 + y2 + 1, y1 + 1]
sage: S = ClusterSeed(Matrix([[0,1],[1,0],[0,0]]))
sage: S.use_c_vectors(bot_is_c=True); S
A seed for a cluster algebra of rank 2 with 2 frozen variables
```
sage: T = ClusterSeed(Matrix([[0,1],[-1,0]])).principal_extension(); T
A seed for a cluster algebra of rank 2 with principal coefficients
sage: S.mutate(0)
sage: T.mutate(0)
sage: S.f_polynomials()
[y0 + y1, 1]
sage: T.f_polynomials()
[y0 + 1, 1]

>> from sage.all import *
>> S = ClusterSeed(['A',Integer(3)]).principal_extension()
>> S.mutate([Integer(2),Integer(1),Integer(2)])
>> [S.f_polynomial(k) for k in range(Integer(3))]
[1, y1*y2 + y2 + 1, y1 + 1]
>> S = ClusterSeed(Matrix([[Integer(0),Integer(1)],[[-Integer(1),Integer(0)]]])
A seed for a cluster algebra of rank 2 with 2 frozen variables
>> T = ClusterSeed(Matrix([[Integer(0),Integer(1)],[[-Integer(1),Integer(1)]]])).principal_extension(); T
A seed for a cluster algebra of rank 2 with principal coefficients
>> S.mutate(Integer(0))
>> T.mutate(Integer(0))
>> S.f_polynomials()
[y0 + y1, 1]
>> T.f_polynomials()
[y0 + 1, 1]

f_polynomials()
Return all F-polynomials of self. These are obtained from the cluster variables by setting all $x_i$'s to 1.

Warning: This method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

EXAMPLES:

sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: S.f_polynomials()
[1, y1*y2 + y2 + 1, y1 + 1]

>>> from sage.all import *
>>> S = ClusterSeed(['A',Integer(3)]).principal_extension()
>>> S.mutate([Integer(2),Integer(1),Integer(2)])
>>> S.f_polynomials()
[1, y1*y2 + y2 + 1, y1 + 1]

find_upper_bound (verbose=False)
Return the upper bound of the given cluster algebra as a quotient ring.

The upper bound is the intersection of the Laurent polynomial rings of the initial cluster and its neighboring clusters. As such, it always contains both the cluster algebra and the upper cluster algebra. This function uses the algorithm from [MM2015].
When the initial seed is totally coprime (for example, when the unfrozen part of the exchange matrix has full rank), the upper bound is equal to the upper cluster algebra by [BFZ2005].

**Warning:** The computation time grows rapidly with the size of the seed and the number of steps. For most seeds larger than four vertices, the algorithm may take an infeasible amount of time. Additionally, it will run forever without terminating whenever the upper bound is infinitely-generated (such as the example in [Spe2013]).

**INPUT:**

- **verbose** — (default: False) if True, prints output during the computation.

**EXAMPLES:**

- **finite type:**
  ```sage
  sage: S = ClusterSeed(['A',3])
  sage: S.find_upper_bound()
  Quotient of Multivariate Polynomial Ring in x0, x1, x2, x0p, x1p, x2p, z0
  over Rational Field
  by the ideal (x0*x0p - x1 - 1, x1*x1p - x0*x2 - 1, x2*x2p - x1 - 1,
  x0*z0 - x2p, x1*z0 + z0 - x0p*x2p, x2*z0 - x0p,
  x1p*z0 + z0 - x0p*x1p*x2p + x1 + 1)
  ```

- **Markov:**
  ```sage
  sage: B = matrix([[0,2,-2],[-2,0,2],[2,-2,0]])
  sage: S = ClusterSeed(B)
  sage: S.find_upper_bound()
  Quotient of Multivariate Polynomial Ring in x0, x1, x2, x0p, x1p, x2p, z0
  over Rational Field
  by the ideal (x0*x0p - x1 - 1, x1*x1p - x0*x2 - 1, x2*x2p - x1 - 1,
  x0*z0 - x2p, x1*z0 + z0 - x0p*x2p, x2*z0 - x0p,
  x1p*z0 + z0 - x0p*x1p*x2p + x1 + 1)
  >>> from sage.all import *
  >>> S = ClusterSeed(['A',Integer(3)])
  >>> S.find_upper_bound()
  Quotient of Multivariate Polynomial Ring in x0, x1, x2, x0p, x1p, x2p, z0
  over Rational Field
  by the ideal (x0*x0p - x1 - 1, x1*x1p - x0*x2 - 1, x2*x2p - x1 - 1,
  x0*z0 - x2p, x1*z0 + z0 - x0p*x2p, x2*z0 - x0p,
  x1p*z0 + z0 - x0p*x1p*x2p + x1 + 1)
  ```

- **Markov:**
  ```sage
  sage: B = matrix([[Integer(0),Integer(2),-Integer(2)],[Integer(-2),Integer(0),Integer(2)],[Integer(2),-Integer(2),Integer(0)]]
  sage: S = ClusterSeed(B)
  sage: S.find_upper_bound()
  Quotient of Multivariate Polynomial Ring in x0, x1, x2, x0p, x1p, x2p, z0
  over Rational Field
  by the ideal (x0*x0p - x2^2 - x1^2, x1*x1p - x2^2 - x0^2, x2*x2p - x1^2 -
  x0^2, x0*p*x1p*x2p - x0*x1*x2p - x0*x2*x1p - x1*x2*x0p -...
  >>> from sage.all import *
  >>> S = ClusterSeed(B)

\end{align*} \]

**first_green_vertex()**

Return the first green vertex of self.

A vertex is defined to be green if its c-vector has all non-positive entries. More information on green vertices can be found at [BDP2013]

**EXAMPLES:**

```python
sage: ClusterSeed(['A', 3]).principal_extension().first_green_vertex()
0

sage: ClusterSeed(['A', [3, 3], 1]).principal_extension().first_green_vertex()
0
```

```python
>>> from sage.all import *
```

```python
>>> ClusterSeed(['A', Integer(3)]).principal_extension().first_green_vertex()
0
```

**first_red_vertex()**

Return the first red vertex of self.

A vertex is defined to be red if its c-vector has all non-negative entries. More information on red vertices can be found at [BDP2013].

**EXAMPLES:**

```python
sage: ClusterSeed(['A', 3]).principal_extension().first_red_vertex()
```

```python
sage: ClusterSeed(['A', [3, 3], 1]).principal_extension().first_red_vertex()
1
```

```python
sage: Q = ClusterSeed(['A', [3, 3], 1]).principal_extension()
sage: Q.mutate(1)
sage: Q.first_red_vertex()
1
```

```python
>>> from sage.all import *
```

```python
>>> ClusterSeed(['A', Integer(3)]).principal_extension().first_red_vertex()
```

```python
>>> ClusterSeed(['A', [Integer(3), Integer(3)], Integer(1)]).principal_extension().first_red_vertex()
```

```python
>>> Q = ClusterSeed(['A', [Integer(3), Integer(3)], Integer(1)]).principal_extension()
>>> Q.mutate(Integer(1))
>>> Q.first_red_vertex()
1
```
first_urban_renewal()

Return the first urban renewal vertex.

An urban renewal vertex is one in which there are two arrows pointing toward the vertex and two arrows
pointing away.

EXAMPLES:

```
sage: G = ClusterSeed(['GR', [4, 9]]); G.first_urban_renewal()

5
```

```
>>> from sage.all import *

>>> G = ClusterSeed(['GR', [Integer(4), Integer(9)]]); G.first_urban_renewal()

5
```

free_vertices()

Return the list of exchangeable vertices of self.

EXAMPLES:

```
sage: S = ClusterSeed(DiGraph([('a', 'b'), ('c', 'b'), ('c', 'd'), ('e', 'd')]),
    frozen=['b', 'd'])
sage: S.free_vertices()
['a', 'c', 'e']
```

```
sage: S = ClusterSeed(DiGraph([5, 'b'])))
sage: S.free_vertices()
[5, 'b']
```

```
>>> from sage.all import *

>>> S = ClusterSeed(DiGraph([['a', 'b'], ['c', 'b'], ['c', 'd'], ['e', 'd']])),
    frozen=['b', 'd'])
>>> S.free_vertices()
['a', 'c', 'e']
```

```
>>> S = ClusterSeed(DiGraph([['Integer(5)', 'b']]))
>>> S.free_vertices()
[5, 'b']
```

frozen_vertices()

Return the list of frozen vertices of self.

EXAMPLES:

```
sage: S = ClusterSeed(DiGraph([['a', 'b'], ['c', 'b'], ['c', 'd'], ['e', 'd']]),
    frozen=['b', 'd'])
sage: sorted(S.frozen_vertices())
['b', 'd']
```

```
>>> S = ClusterSeed(DiGraph([['a', 'b'], ['c', 'b'], ['c', 'd'], ['e', 'd']])),
    frozen=['b', 'd'])
>>> sorted(S.frozen_vertices())
['b', 'd']
```

```
>>> S = ClusterSeed(DiGraph([['Integer(5)', 'b']]))
>>> sorted(S.frozen_vertices())
['b', 'd']
```
**g_matrix** *(show_warnings=True)*

Return the matrix of all g-vectors of *self*. These are the degree vectors of the cluster variables after setting all \(y_i\)'s to 0.

**Warning:** This method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

**EXAMPLES:**

```python
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: S.g_matrix()
[ 1 0 0]
[ 0 0 -1]
[ 0 -1 0]

sage: S = ClusterSeed(['A',3])
sage: S.mutate([0,1])
sage: S.g_matrix()
[-1 -1 0]
[ 1 0 0]
[ 0 0 1]

sage: S = ClusterSeed(['A',4])
sage: S.use_g_vectors(False); S.use_fpolys(False); S.g_matrix()
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]

sage: S = ClusterSeed(['A',4])
sage: S.use_g_vectors(False); S.use_c_vectors(False); S.use_fpolys(False)
sage: S.track_mutations(False); S.g_matrix()
Traceback (most recent call last):
...
ValueError: Unable to calculate g-vectors. Need to use g vectors.
```

```python
>>> from sage.all import *
>>> S = ClusterSeed(['A',Integer(3)]).principal_extension()
>>> S.mutate([Integer(2),Integer(1),Integer(2)])
>>> S.g_matrix()
[ 1 0 0]
[ 0 0 -1]
[ 0 -1 0]

>>> S = ClusterSeed(['A',Integer(3)])
>>> S.mutate([Integer(0),Integer(1)])
>>> S.g_matrix()
[-1 -1 0]
[ 1 0 0]
[ 0 0 1]

>>> S = ClusterSeed(['A',Integer(4)])
>>> S.use_g_vectors(False); S.use_fpolys(False); S.g_matrix()
[1 0 0 0]
```
Combinatorics, Release 10.4

(continued from previous page)

\[
\begin{bmatrix}
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}
\]

```python
>>> S = ClusterSeed(['A',Integer(4)])
>>> S.use_g_vectors(False); S.use_c_vectors(False); S.use_fpolys(False)
>>> S.track_mutations(False); S.g_matrix()
Traceback (most recent call last):
... ValueErro
```

\texttt{g\_vector}(k)

Return the \texttt{k-th g-vector} of \texttt{self}. This is the degree vector of the \texttt{k-th} cluster variable after setting all \(y_i\)'s to 0.

\textbf{Warning:} This method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

\textbf{EXAMPLES:}

```python
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: [S.g_vector(k) for k in range(3)]
[(1, 0, 0), (0, 0, -1), (0, -1, 0)]
```

```python
>>> from sage.all import *
>>> S = ClusterSeed(['A',Integer(3)]).principal_extension()
>>> S.mutate([Integer(2),Integer(1),Integer(2)])
>>> [S.g_vector(k) for k in range(Integer(3))]
[(1, 0, 0), (0, 0, -1), (0, -1, 0)]
```

\texttt{get\_upper\_cluster\_algebra\_element}(a)

Compute an element in the upper cluster algebra of \(B\) corresponding to the vector \(a \in \mathbb{Z}^n\).

See [LLM2014] for more details.

\textbf{INPUT:}

- \(B\) – a skew-symmetric matrix. Must have the same number of columns as the length of the vectors in \(vd\).
- \(a\) – a vector in \(\mathbb{Z}^n\) where \(n\) is the number of columns in \(B\).

\textbf{OUTPUT:}

Return an element in the upper cluster algebra. Depending on the input it may or may not be irreducible.

\textbf{EXAMPLES:}

```python
sage: B = matrix([[0,3,-3],[-3,0,3],[3,-3,0], [1,0,0], [0,1,0], [0,0,1]])
sage: C = ClusterSeed(B)
sage: C.get_upper_cluster_algebra_element([1,1,0])
(x0^3*x2^3*x3*x4 + x2^6*x3 + x1^3*x2^3)/(x0*x1)
sage: C.get_upper_cluster_algebra_element([1,1,1])
x0^2*x1^2*x2^2*x3*x4*x5 + x0^2*x1^2*x2^2
```

(continues on next page)
sage: B = matrix([[0, 3, 0], [-3, 0, 3], [0, -3, 0]])
sage: C = ClusterSeed(B)
sage: C.get_upper_cluster_algebra_element([1, 1, 0])
\((x_1^3 x_2^3 + x_0^3 + x_2^3)/(x_0 x_1)\)
sage: C.get_upper_cluster_algebra_element([1, 1, 1])
\((x_0^3 x_1^3 + x_1^3 x_2^3 + x_0^3 + x_2^3)/(x_0 x_1 x_2)\)
sage: B = matrix([[0, 2], [-3, 0], [4, -5]])
sage: C = ClusterSeed(B)
sage: C.get_upper_cluster_algebra_element([1, 1])
\((x_2^9 + x_1^3 x_2^5 + x_0^2 x_2^4)/(x_0 x_1)\)

from sage.all import *

>>> B = matrix([[Integer(0), Integer(3), -Integer(3)], [-Integer(3), Integer(0), Integer(3)], [Integer(3), -Integer(3), Integer(0)]])
>>> C = ClusterSeed(B)
>>> C.get_upper_cluster_algebra_element([Integer(1), Integer(1), Integer(0)])
\((x_1^3 x_2^3 x_3 x_4 + x_2^6 x_3 + x_1^3)/(x_0 x_1)\)

EXAMPLES:

```python
sage: greedy(a1, a2, algorithm='by_recursion')
```

Return the greedy element \(x[a_1, a_2]\) assuming that self is rank two.

The third input can be 'by_recursion', 'by_combinators', or 'just_numbers' to specify if the user wants the element computed by the recurrence, combinatorial formula, or wants to set \(x_1\) and \(x_2\) to be one.

See [LLZ2014] for more details.
### green_vertices()

Return the list of green vertices of self.

A vertex is defined to be green if its c-vector has all non-positive entries. More information on green vertices can be found at [BDP2013]

**OUTPUT:**

The green vertices as a list of integers.

**EXAMPLES:**

```python
sage: S = ClusterSeed(['R2', [3, 3]]).principal_extension().green_vertices()
sage: S = ClusterSeed(['R2', [2, 2]]).principal_extension().green_vertices()
```

### ground_field()

5.1. Comprehensive Module List 293
Return the ground field of the cluster of self.

EXAMPLES:

```python
sage: S = ClusterSeed(['A',3])
sage: S.ground_field()
Multivariate Polynomial Ring in x0, x1, x2, y0, y1, y2 over Rational Field
```

```python
>>> from sage.all import *
>>> S = ClusterSeed(['A',Integer(3)])
>>> S.ground_field()
Multivariate Polynomial Ring in x0, x1, x2, y0, y1, y2 over Rational Field
```

**highest_degree_denominator**(filter=None)

Return the vertex of the cluster polynomial with highest degree in the denominator.

INPUT:

- filter — a list or iterable

OUTPUT:

An integer.

EXAMPLES:

```python
sage: B = matrix([[0,-1,0,-1,1,1], [1,0,1,0,-1,-1], [0,-1,0,-1,1,1], ...
   ....: [1,0,1,0,-1,-1], [-1,1,-1,1,0,0], [-1,1,-1,1,0,0]])
sage: C = ClusterSeed(B).principal_extension(); C.mutate([0,1,2,4,3,2,5,4,3])
sage: C.highest_degree_denominator()
5
```

```python
>>> from sage.all import *
>>> B = matrix([[Integer(0),-Integer(1),Integer(0),-Integer(1),Integer(1),
   ⭕ Integer(1)], [Integer(1),Integer(0),Integer(1),Integer(0),-Integer(1),-
   ⭕ Integer(1)], [Integer(0),-Integer(1),Integer(1),Integer(0),-Integer(1),Integer(1),
   ⭕ Integer(1)], ...
   ....: [Integer(1),Integer(0),Integer(1),Integer(0),-Integer(1),-
   ⭕ Integer(1)], [-Integer(1),Integer(1),-Integer(1),Integer(1),Integer(1),Integer(0),
   ⭕ Integer(0)], [-Integer(1),Integer(1),-Integer(1),Integer(1),Integer(1),Integer(0),
   ⭕ Integer(0)]])
>>> C = ClusterSeed(B).principal_extension(); C.mutate([Integer(0),Integer(1),
   ⭕ Integer(2),Integer(4),Integer(3),Integer(2),Integer(5),Integer(4),
   ⭕ Integer(3)])
>>> C.highest_degree_denominator()
5
```

**interact**(fig_size=1, circular=True)

Start an interactive window for cluster seed mutations.

Only in Jupyter notebook mode.

INPUT:

- fig_size — (default: 1) factor by which the size of the plot is multiplied.
- circular — (default: True) if True, the circular plot is chosen, otherwise `>>spring<<` is used.
is_acyclic()
Return True iff self is acyclic (i.e., if the underlying quiver is acyclic).

EXAMPLES:

```
sage: ClusterSeed(['A',4]).is_acyclic()
True
sage: ClusterSeed(['A',[2,1],1]).is_acyclic()
True
sage: ClusterSeed([[0,1],[1,2],[2,0]]).is_acyclic()
False
```

is_bipartite(return_bipartition=False)
Return True iff self is bipartite (i.e., if the underlying quiver is bipartite).

INPUT:
- return_bipartition – (default: False) if True, the bipartition is returned in the case of self being bipartite.

EXAMPLES:

```
sage: ClusterSeed(['A',[3,3],1]).is_bipartite()
True
sage: ClusterSeed(['A',[4,3],1]).is_bipartite()
False
```

is_finite()
Return True if self is of finite type.

EXAMPLES:

```
sage: S = ClusterSeed(['A',3])
sage: S.is_finite()
True
sage: S = ClusterSeed(['A',[2,2],1])
```

(continues on next page)
Combinatorics, Release 10.4

sage: S.is_finite()
False

>>> from sage.all import *

>>> S = ClusterSeed(['A', Integer(3)])

>>> S.is_finite()
True

>>> S = ClusterSeed(['A', [Integer(2), Integer(2)], Integer(1)])

>>> S.is_finite()
False

\texttt{is\_mutation\_finite}(\texttt{nr\_of\_checks}=\texttt{None}, \texttt{return\_path}=\texttt{False})

Return True if \texttt{self} is of finite mutation type.

INPUT:

\begin{itemize}
  \item \texttt{nr\_of\_checks} – (default: \texttt{None}) number of mutations applied. Standard is 500 times the number of vertices of \texttt{self}.
  \item \texttt{return\_path} – (default: \texttt{False}) if True, in case of \texttt{self} not being mutation finite, a path from \texttt{self} to a quiver with an edge label \((a, -b)\) and \(a \times b > 4\) is returned.
\end{itemize}

ALGORITHM:

\begin{itemize}
  \item A cluster seed is mutation infinite if and only if every \(b_{ij} \times b_{ji} > -4\). Thus, we apply random mutations in random directions
\end{itemize}

Warning:

\begin{itemize}
  \item Uses a non-deterministic method by random mutations in various directions.
  \item In theory, it can return a wrong True.
\end{itemize}

EXAMPLES:

sage: S = ClusterSeed(['A', 10])
sage: S._mutation_type = None
sage: S.is_mutation_finite()
True

sage: S = ClusterSeed([(0,1), (1,2), (2,3), (3,4), (4,5), (5,6), (6,7), (7,8), (2,9)])
sage: S.is_mutation_finite()
False

>>> from sage.all import *

>>> S = ClusterSeed(['A', Integer(10)])

>>> S._mutation_type = None

>>> S.is_mutation_finite()
True

>>> S = ClusterSeed([(Integer(0), Integer(1)), (Integer(1), Integer(2)),
  → (Integer(2), Integer(3)), (Integer(3), Integer(4)), (Integer(4), Integer(5)),
  → (Integer(5), Integer(6)), (Integer(6), Integer(7)), (Integer(7), Integer(8)),
  → (Integer(2), Integer(9))])

(continues on next page)
**m()**

Return the number of *frozen variables* of `self`.

**EXAMPLES:**

```python
sage: S = ClusterSeed(['A',3])
sage: S.n()
3
sage: S.m()
0
sage: S = S.principal_extension()
sage: S.m()
3
```

```python
>>> from sage.all import *
```

```python
>>> S = ClusterSeed(['A',Integer(3)])
```

```python
>>> S.n()
3
```

```python
>>> S.m()
0
```

```python
>>> S = S.principal_extension()
```

```python
>>> S.m()
3
```

**most_decreased_denominator_after_mutation()**

Return the vertex that will produce the most decrease in denominator degrees after mutation

**EXAMPLES:**

```python
sage: S = ClusterSeed(['A',5])
sage: S.mutate([0,2,3,1,2,3,1,2,0,2,3])
sage: S.most_decreased_denominator_after_mutation()
2
```

```python
>>> from sage.all import *
```

```python
>>> S = ClusterSeed(['A',Integer(5)])
```

```python
>>> S.mutate([Integer(0),Integer(2),Integer(3),Integer(1),Integer(2),
Integer(3),Integer(1),Integer(2),Integer(0),Integer(2),Integer(3)])
```

```python
>>> S.most_decreased_denominator_after_mutation()
2
```

**most_decreased_edge_after_mutation()**

Return the vertex that will produce the least degrees after mutation

**EXAMPLES:**

```python
sage: S = ClusterSeed(['A',5])
```

```python
>>> S.mutate([0,2,3,1,2,3,1,2,0,2,3])
```

```python
>>> from sage.all import *
```

```python
>>> S = ClusterSeed(['A',Integer(5)])
```

```python
>>> S.mutate([Integer(0),Integer(2),Integer(3),Integer(1),Integer(2),
Integer(3),Integer(1),Integer(2),Integer(0),Integer(2),Integer(3)])
```

```
```
sage: S.most_decreased_edge_after_mutation()
2

>>> from sage.all import *

>>> S = ClusterSeed(['A',Integer(5)])

>>> S.mutate([Integer(0),Integer(2),Integer(3),Integer(1),Integer(2),Integer(3),Integer(1),Integer(2),Integer(0),Integer(2),Integer(3)])

>>> S.most_decreased_edge_after_mutation()
2

mutate (sequence, inplace=True, input_type=None)

Mutate self at a vertex or a sequence of vertices.

INPUT:

- sequence -- a vertex of self, an iterator of vertices of self, a function which takes in the ClusterSeed and returns a vertex or an iterator of vertices, or a string representing a type of vertices to mutate
- inplace -- (default: True) if False, the result is returned, otherwise self is modified
- input_type -- (default: None) indicates the type of data contained in the sequence

Possible values for vertex types in sequence are:

- "first_source": mutates at first found source vertex,
- "sources": mutates at all sources,
- "first_sink": mutates at first sink,
- "sinks": mutates at all sink vertices,
- "green": mutates at the first green vertex,
- "red": mutates at the first red vertex,
- "urban_renewal" or "urban": mutates at first urban renewal vertex,
- "all_urban_renewals" or "all_urban": mutates at all urban renewal vertices.

For input_type, if no value is given, preference will be given to vertex names, then indices, then cluster variables. If all input is not of the same type, an error is given. Possible values for input_type are:

- "vertices": interprets the input sequence as vertices
- "indices": interprets the input sequence as indices
- "cluster_vars": interprets the input sequence as cluster variables this must be selected if inputting a sequence of cluster variables.

EXAMPLES:

sage: S = ClusterSeed(['A',4]); S.b_matrix()
[ 0 1 0 0]
[-1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -1 0]

sage: S.mutate(0); S.b_matrix()
[ 0 -1 0 0]
[ 1 0 -1 0]
sage: T = S.mutate(0, inplace=False); T
A seed for a cluster algebra of rank 4 of type ['A', 4]

sage: S.mutate(0)
sage: S == T
True

sage: S.mutate([0,1,0])
sage: S.b_matrix()

True

sage: S.cluster() == T.cluster()
True

sage: S._mut_path
[0, 1, 0, 1, 0, 2, 1]
Input can be ambiguously interpreted as both vertices and indices. Mutating at vertices by default.

```python
sage: S = ClusterSeed(DiGraph([[1, 2], [2, 'c']]))
sage: S.mutate(1)
```

```python
sage: S.mutate([a, b, a, b, a])
sage: S.cluster()
```

```python
sage: S.mutate(0, input_type=vertices);S.cluster()
```

Input can be ambiguously interpreted as both vertices and cluster variables. Mutating at vertices by default.

```python
sage: S = ClusterSeed(DiGraph([[-1, 0], [0, 1]]))
sage: S.mutate(-1);S.cluster()
```

```python
sage: S.mutate(0, input_type='vertices');S.cluster()
```

>>> from sage.all import *

```python
>>> S = ClusterSeed([A,Integer(4)]); S.b_matrix()
```
Continuing from the previous page...

[(b + 1)/x5, b]

>>> S = ClusterSeed(DiGraph([[Integer(1), Integer(2)]]))

>>> S.cluster()
[x1, x2]

>>> S.mutate(Integer(1))
Input can be ambiguously interpreted as both vertices and indices.
Mutating at vertices by default.
mutation_analysis (options=['all'], filter=None)

Runs an analysis of all potential mutation options. Note that this might take a long time on large seeds.

**Note:** Edges are only returned if we have a non-valued quiver. Green and red vertices are only returned if the cluster is principal.

**INPUT:**
- options – (default: ['all']) a list of mutation options.
- filter – (default: None) A vertex or interval of vertices to limit our search to

Possible options are:
- "all" – All options below
- "edges" – Number of edges (works with skew-symmetric quivers)
- "edge_diff" – Edges added/deleted (works with skew-symmetric quivers)
- "green_vertices" – List of green vertices (works with principals)
- "green_vertices_diff" – Green vertices added/removed (works with principals)
- "red_vertices" – List of red vertices (works with principals)
- "red_vertices_diff" – Red vertices added/removed (works with principals)
- "urban_renewals" – List of urban renewal vertices
- "urban_renewals_diff" – Urban renewal vertices added/removed
- "sources" – List of source vertices
- "sources_diff" – Source vertices added/removed
- "sinks" – List of sink vertices
- "sinks_diff" – Sink vertices added/removed
- "denominators" – List of all denominators of the cluster variables

**OUTPUT:**

Outputs a dictionary indexed by the vertex numbers. Each vertex will itself also be a dictionary with each desired option included as a key in the dictionary. As an example you would get something similar to: {0: {'edges': 1}, 1: {'edges': 2}}. This represents that if you were to do a mutation at the current seed then mutating at vertex 0 would result in a quiver with 1 edge and mutating at vertex 0 would result in a quiver with 2 edges.

**EXAMPLES:**
sage: B = [[0, 4, 0, -1], [-4, 0, 3, 0], [0, -3, 0, 1], [1, 0, -1, 0]]

5.1. Comprehensive Module List
mutation_class

The method `mutation_class` returns the mutation class of `self` with respect to certain constraints.

**Note:** Vertex labels are not tracked in this method.

**See also:** `mutation_class_iter()`

**INPUT:**

- `depth` = (default: `infinity`) integer, only seeds with distance at most `depth` from `self` are returned.
- `show_depth` = (default: `False`) if `True`, the actual depth of the mutation is shown.
- `return_paths` = (default: `False`) if `True`, a shortest path of mutation sequences from `self` to the given quiver is returned as well.
- `up_to_equivalence` = (default: `True`) if `True`, only seeds up to equivalence are considered.
- `sink_source` = (default: `False`) if `True`, only mutations at sinks and sources are applied.

**EXAMPLES:**

- For examples see `mutation_class_iter()`

*mutation_class_iter*

The method `mutation_class_iter` returns an iterator for the mutation class of `self` with respect to certain constraints.

**INPUT:**

- `depth` = (default: `infinity`) integer or `infinity`, only seeds with distance at most `depth` from `self` are returned.
- `show_depth` = (default: `False`) if `True`, the current depth of the mutation is shown while computing.
- `return_paths` = (default: `False`) if `True`, a shortest path of mutations from `self` to the given quiver is returned as well.
- `up_to_equivalence` = (default: `True`) if `True`, only one seed up to simultaneous permutation of rows and columns of the exchange matrix is recorded.
- `sink_source` = (default: `False`) if `True`, only mutations at sinks and sources are applied.
EXAMPLES:

A standard finite type example:

```sage
S = ClusterSeed(['A',3])
sage: it = S.mutation_class_iter()
sage: for T in it: print(T)
```

A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]

```sage
>>> from sage.all import *
>>> S = ClusterSeed(['A',Integer(3)])
>>> it = S.mutation_class_iter()
>>> for T in it: print(T)
```

A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]

A finite type example with given depth:

```sage
sage: it = S.mutation_class_iter(depth=1)
sage: for T in it: print(T)
```

A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]

```sage
>>> from sage.all import *
>>> it = S.mutation_class_iter(depth=Integer(1))
>>> for T in it: print(T)
```

A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A finite type example where the depth is shown while computing:

```python
sage: it = S.mutation_class_iter(show_depth=True)
sage: for T in it: pass
Depth: 0  found: 1  Time: ... s
Depth: 1  found: 4  Time: ... s
Depth: 2  found: 9  Time: ... s
Depth: 3  found: 13 Time: ... s
Depth: 4  found: 14 Time: ... s
```

A finite type example with shortest paths returned:

```python
sage: it = S.mutation_class_iter(return_paths=True)
sage: mutation_class = list(it)
sage: len(mutation_class)
14

(A seed for a cluster algebra of rank 3 of type ['A', 3], [])
```

Finite type examples not considered up to equivalence:

```python
sage: it = S.mutation_class_iter(up_to_equivalence=False)
sage: len([T for T in it])
84

sage: it = ClusterSeed(['A',2]).mutation_class_iter(return_paths=True,
....: up_to_equivalence=False)
sage: mutation_class = list(it)
sage: len(mutation_class)
10

(A seed for a cluster algebra of rank 2 of type ['A', 2], [])
```

(continues on next page)
```
mutation_class = list(it)
len(mutation_class)
10
mutation_class[Integer(0)]
(A seed for a cluster algebra of rank 2 of type ['A', 2], [])
```

Check that Issue #14638 is fixed:

```
sage: S = ClusterSeed(['E', 6])
sage: MC = S.mutation_class(depth=7); len(MC)  # long time
534
```

```
from sage.all import *
S = ClusterSeed(['E', Integer(6)])
MC = S.mutation_class(depth=Integer(7)); len(MC)  # long time
534
```

Infinite type examples:

```
sage: S = ClusterSeed(['A', [1, 1], 1])
sage: it = S.mutation_class_iter()
sage: next(it)

```

(continues on next page)
(continued from previous page)

(A seed for a cluster algebra of rank 2 of type [‘A’, [1, 1], 1], [0])
(A seed for a cluster algebra of rank 2 of type [‘A’, [1, 1], 1], [1, 0])
(A seed for a cluster algebra of rank 2 of type [‘A’, [1, 1], 1], [0, 1])
(A seed for a cluster algebra of rank 2 of type [‘A’, [1, 1], 1], [1, 0, 1])
(A seed for a cluster algebra of rank 2 of type [‘A’, [1, 1], 1], [0, 1, 0])

mutation_sequence (sequence, show_sequence=False, fig_size=1.2, return_output=’seed’)  
Return the seeds obtained by mutating self at all vertices in sequence.

INPUT:

• sequence – an iterable of vertices of self.
• show_sequence – (default: False) if True, a png containing the associated quivers is shown.
• fig_size – (default: 1.2) factor by which the size of the plot is multiplied.
• return_output – (default: ’seed’) determines what output is to be returned:
  – if ’seed’, outputs all the cluster seeds obtained by the sequence of mutations.
  – if ’matrix’, outputs a list of exchange matrices.
  – if ’var’, outputs a list of new cluster variables obtained at each step.

EXAMPLES:

```python
sage: S = ClusterSeed([‘A’,2])
sage: for T in S.mutation_sequence([0,1,0]):
    print(T.b_matrix())
[ 0 -1]
[ 1 0]
[ 0 1]
[-1 0]
[ 0 -1]
[ 1 0]
sage: S = ClusterSeed([‘A’,2])
sage: S.mutation_sequence([0,1,0,1], return_output=’var’)  
[(x1 + 1)/x0, (x0 + x1 + 1)/(x0*x1), (x0 + 1)/x1, x0]
```

```python
>>> from sage.all import *
>>> S = ClusterSeed([‘A’,Integer(2)])
>>> for T in S.mutation_sequence([Integer(0),Integer(1),Integer(0)]):
...   print(T.b_matrix())
[ 0 -1]
[ 1 0]
[ 0 1]
[-1 0]
[ 0 -1]
[ 1 0]

>>> S = ClusterSeed([‘A’,Integer(2)])
>>> S.mutation_sequence([Integer(0),Integer(1),Integer(0),Integer(1)], return_output=’var’)  
[(x1 + 1)/x0, (x0 + x1 + 1)/(x0*x1), (x0 + 1)/x1, x0]
```

mutation_type ()

Return the mutation type of each connected component of self, if it can be determined.
Otherwise, the mutation type of this component is set to be unknown.

The mutation types of the components are ordered by vertex labels.

**Warning:**

- All finite types can be detected,
- All affine types can be detected, except affine type $D$ (the algorithm is not yet implemented)
- All exceptional types can be detected.
- Might fail to work if it is used within different Sage processes simultaneously (that happened in the doctesting).

**EXAMPLES:**

- **finite types:**

  ```sage
  sage: S = ClusterSeed(['A',5])
  sage: S._mutation_type = S._quiver._mutation_type = None
  sage: S.mutation_type()
  ['A', 5]
  sage: S = ClusterSeed([(0,1),(1,2),(2,3),(3,4)])
  sage: S.mutation_type()
  ['A', 5]
  sage: S = ClusterSeed(DiGraph([['a','b'],['c','b'],['c','d'],['e','d']]),
  ....:    frozen=['c'])
  sage: S.mutation_type()
  [ ['A', 2], ['A', 2] ]
  >>> from sage.all import *
  >>> S = ClusterSeed(['A',Integer(5)])
  >>> S._mutation_type = S._quiver._mutation_type = None
  >>> S.mutation_type()
  ['A', 5]
  >>> S = ClusterSeed([(Integer(0),Integer(1)),(Integer(1),Integer(2)),
  ....:    (Integer(2),Integer(3)),(Integer(3),Integer(4))])
  >>> S.mutation_type()
  ['A', 5]
  >>> S = ClusterSeed(DiGraph([['a','b'],['c','b'],['c','d'],['e','d']]),
  ....:    frozen=['c'])
  >>> S.mutation_type()
  [ ['A', 2], ['A', 2] ]
  ```

- **affine types:**

  ```sage
  sage: S = ClusterSeed(['E',8,[1,1]]); S
  A seed for a cluster algebra of rank 10 of type ['E', 8, [1, 1]]
  sage: S._mutation_type = S._quiver._mutation_type = None; S
  A seed for a cluster algebra of rank 10
  sage: S.mutation_type()  # long time
  ['E', 8, [1, 1]]
  ```
Combinatorics, Release 10.4

>>> from sage.all import *
>>> S = ClusterSeed(['E', Integer(8), [Integer(1), Integer(1)]]); S
A seed for a cluster algebra of rank 10 of type ['E', 8, [1, 1]]
>>> S._mutation_type = S._quiver._mutation_type = None; S
A seed for a cluster algebra of rank 10
>>> S.mutation_type() # long time
['E', 8, [1, 1]]

• the not yet working affine type D:

    sage: S = ClusterSeed(['D', 4, 1])
    sage: S._mutation_type = S._quiver._mutation_type = None
    sage: S.mutation_type() # todo: not implemented
    ['D', 4, 1]

    >>> from sage.all import *
    >>> S = ClusterSeed(['D', Integer(4), Integer(1)])
    >>> S._mutation_type = S._quiver._mutation_type = None
    >>> S.mutation_type() # todo: not implemented
    ['D', 4, 1]

• the exceptional types:

    sage: S = ClusterSeed(['X', 6])
    sage: S._mutation_type = S._quiver._mutation_type = None
    sage: S.mutation_type() # long time
    ['X', 6]

    >>> from sage.all import *
    >>> S = ClusterSeed(['X', Integer(6)])
    >>> S._mutation_type = S._quiver._mutation_type = None
    >>> S.mutation_type() # long time
    ['X', 6]

• infinite types:

    sage: S = ClusterSeed(['GR', [4, 9]])
    sage: S._mutation_type = S._quiver._mutation_type = None
    sage: S.mutation_type() 'undetermined infinite mutation type'

    >>> from sage.all import *
    >>> S = ClusterSeed(['GR', [Integer(4), Integer(9)]]):
    >>> S._mutation_type = S._quiver._mutation_type = None
    >>> S.mutation_type() # undetermined infinite mutation type'

mutations()
Return the list of mutations self has undergone if they are being tracked.

EXAMPLES:

    sage: S = ClusterSeed(['A', 3])
    sage: S.mutations()
    []

(continues on next page)
sage: S.mutate([0, 1, 0, 2])
sage: S.mutations()
[0, 1, 0, 2]

sage: S.track_mutations(False)
sage: S.mutations()
Traceback (most recent call last):
...
ValueError: Not recording mutation sequence. Need to track mutations.

>>> from sage.all import *
>>> S = ClusterSeed(['A', Integer(3)])
>>> S.mutations()
[]

>>> S.mutate([Integer(0), Integer(1), Integer(0), Integer(2)])
>>> S.mutations()
[0, 1, 0, 2]

>>> S.track_mutations(False)
>>> S.mutations()
Traceback (most recent call last):
...
ValueError: Not recording mutation sequence. Need to track mutations.

n()

Return the number of *exchangeable variables* of *self*.

EXAMPLES:

sage: S = ClusterSeed(['A', 3])
sage: S.n()
3

>>> from sage.all import *
>>> S = ClusterSeed(['A', Integer(3)])
>>> S.n()
3

oriented_exchange_graph()

Return the oriented exchange graph of *self* as a directed graph.

The seed must be a cluster seed for a cluster algebra of finite type with principal coefficients (the corresponding quiver must have mutable vertices 0, 1, ..., \(n - 1\)).

EXAMPLES:

sage: S = ClusterSeed(['A', 2]).principal_extension()
sage: G = S.oriented_exchange_graph(); G
Digraph on 5 vertices
sage: G.out_degree_sequence()
[2, 1, 1, 1, 0]

sage: S = ClusterSeed(['B', 2]).principal_extension()
sage: G = S.oriented_exchange_graph(); G
Digraph on 6 vertices

(continues on next page)
sage: G.out_degree_sequence()
[2, 1, 1, 1, 1, 0]

```python
>>> from sage.all import *
>>> S = ClusterSeed(['A', Integer(2)]).principal_extension()
>>> G = S.oriented_exchange_graph(); G
Digraph on 5 vertices
>>> G.out_degree_sequence()
[2, 1, 1, 1, 0]

>>> S = ClusterSeed(['B', Integer(2)]).principal_extension()
>>> G = S.oriented_exchange_graph(); G
Digraph on 6 vertices
>>> G.out_degree_sequence()
[2, 1, 1, 1, 1, 0]
```

plot (circular=False, mark=None, save_pos=False, force_c=False, with_greens=False, add_labels=False)

Return the plot of the quiver of self.

INPUT:

- circular – (default: False) if True, the circular plot is chosen, otherwise <<spring>> is used.
- mark – (default: None) if set to i, the vertex i is highlighted.
- save_pos – (default: False) if True, the positions of the vertices are saved.
- force_c – (default: False) if True, will show the frozen vertices even if they were never initialized
- with_greens – (default: False) if True, will display the green vertices in green
- add_labels – (default: False) if True, will use the initial variables as labels

EXAMPLES:

```python
sage: S = ClusterSeed(['A', 5])
sage: S.plot()
# needs sage.plot sage.symbolic
Graphics object consisting of 15 graphics primitives
sage: S.plot(circular=True)
# needs sage.plot sage.symbolic
Graphics object consisting of 15 graphics primitives
sage: S.plot(circular=True, mark=1)
# needs sage.plot sage.symbolic
Graphics object consisting of 15 graphics primitives
```

```python
>>> from sage.all import *
>>> S = ClusterSeed(['A', Integer(5)])
>>> S.plot()
# needs sage.plot sage.symbolic
Graphics object consisting of 15 graphics primitives
>>> S.plot(circular=True)
# needs sage.plot sage.symbolic
Graphics object consisting of 15 graphics primitives
```
principal_extension()

Return the principal extension of self, yielding a $2n \times n$ matrix.

Raises an error if the input seed has a non-square exchange matrix. In this case, the method instead adds $n$ frozen variables to any previously frozen variables. I.e., the seed obtained by adding a frozen variable to every exchangeable variable of self.

EXAMPLES:

```
sage: S = ClusterSeed([[0,1],[1,2],[2,3],[2,4]]); S
A seed for a cluster algebra of rank 5

sage: T = S.principal_extension(); T
A seed for a cluster algebra of rank 5 with principal coefficients

sage: T.b_matrix()
[ 0 1 0 0 0]
[-1 0 1 0 0]
[ 0 -1 0 1 1]
[ 0 0 -1 0 0]
[ 1 0 0 0 0]
[ 0 1 0 0 0]
[ 0 0 0 1 0]
[ 0 0 0 0 1]
```

```
sage: S = ClusterSeed(['A', 4], user_labels=['a', 'b', 'c', 'd'])
sage: T = S.principal_extension()
sage: T.cluster()
[a, b, c, d]

```

```
sage: T.b_matrix()
[ 0 1 0 0 0]
[-1 0 1 0 0]
[ 0 -1 0 1 1]
[ 0 0 -1 0 0]
[ 1 0 0 0 0]
[ 0 1 0 0 0]
[ 0 0 0 1 0]
[ 0 0 0 0 1]
```

```python
>>> from sage.all import *

>>> S = ClusterSeed([[Integer(0),Integer(1)],[Integer(1),Integer(2)],[Integer(2),Integer(3)],[Integer(2),Integer(4)]]); S
A seed for a cluster algebra of rank 5

>>> T = S.principal_extension(); T
A seed for a cluster algebra of rank 5 with principal coefficients

>>> T.b_matrix()
[ 0 1 0 0 0]
[-1 0 1 0 0]
[ 0 -1 0 1 1]
[ 0 0 -1 0 0]
[ 1 0 0 0 0]
[ 0 1 0 0 0]
[ 0 0 1 0 0]
[ 0 0 0 1 0]
```

(continues on next page)
```python
>>> S = ClusterSeed(['A', Integer(4)], user_labels=['a', 'b', 'c', 'd'])
>>> T = S.principal_extension()
>>> T.cluster()
[a, b, c, d]
>>> T.coefficients()
[y0, y1, y2, y3]
>>> S2 = ClusterSeed(['A', Integer(4)], user_labels={Integer(0):'a',
    Integer(1):'b', Integer(2):'c', Integer(3):'d'})
>>> S2 == S
True
>>> T2 = S2.principal_extension()
>>> T2 == T
True
```

**quiver()**

Return the quiver associated to self.

**EXAMPLES:**

```python
sage: S = ClusterSeed(['A',3])
sage: S.quiver()
Quiver on 3 vertices of type ['A', 3]
```

```python
sage: from sage.all import *
>>> S = ClusterSeed(['A',Integer(3)])
>>> S.quiver()
Quiver on 3 vertices of type ['A', 3]
```

**red_vertices()**

Return the list of red vertices of self.

A vertex is defined to be red if its c-vector has all non-negative entries. More information on red vertices can be found at [BDP2013].

**OUTPUT:**

The red vertices as a list of integers.

**EXAMPLES:**

```python
sage: ClusterSeed(['A',3]).principal_extension().red_vertices()
[]
sage: ClusterSeed(['A',[3,3],1]).principal_extension().red_vertices()
[]
sage: Q = ClusterSeed(['A',[3,3],1]).principal_extension()
sage: Q.mutate(1)
sage: Q.red_vertices()
[1]
```

```python
>>> from sage.all import *
>>> ClusterSeed(['A',Integer(3)]).principal_extension().red_vertices()
[]
```
>>> ClusterSeed(['A', [Integer(3), Integer(3)], Integer(1)]).principal_extension().red_vertices()
[]

>>> Q = ClusterSeed(['A', [Integer(3), Integer(3)], Integer(1)]).principal_extension()
>>> Q.mutate(Integer(1))
>>> Q.red_vertices()
[1]

\texttt{reorient} (\texttt{data})

Reorients \texttt{self} with respect to the given total order, or with respect to an iterator of ordered pairs.

\textbf{Warning:}

- This operation might change the mutation type of \texttt{self}.
- Ignores ordered pairs \((i, j)\) for which neither \((i, j)\) nor \((j, i)\) is an edge of \texttt{self}.

\textbf{INPUT:}

- \texttt{data} – an iterator defining a total order on \texttt{self.vertices()}, or an iterator of ordered pairs in \texttt{self} defining the new orientation of these edges.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: S = ClusterSeed(['A', [2, 3], 1])
sage: S.mutation_type()
['A', [2, 3], 1]
sage: S.reorient([(0,1),(2,3)])
sage: S.mutation_type()
['D', 5]
sage: S.reorient([(1,0),(2,3)])
sage: S.mutation_type()
['A', [1, 4], 1]
sage: S.reorient([0,1,2,3,4])
sage: S.mutation_type()
['A', [1, 4], 1]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> S = ClusterSeed(['A', [Integer(2), Integer(3)], Integer(1)])
>>> S.mutation_type()
['A', [2, 3], 1]
>>> S.reorient([(Integer(0),Integer(1)),(Integer(2),Integer(3))])
>>> S.mutation_type()
['D', 5]
>>> S.reorient([(Integer(1),Integer(0)),(Integer(2),Integer(3))])
>>> S.mutation_type()
['A', [1, 4], 1]
\end{verbatim}
reset_cluster()

Reset the cluster of self to the initial cluster.

EXAMPLES:

```python
sage: S = ClusterSeed(['A',3])
sage: S.mutate([1,2,1])
[\(x_0, (x_1 + 1)/x_2, (x_0 \times x_2 + x_1 + 1)/(x_1 \times x_2)\)]
sage: S.reset_cluster()
```

```python
sage: T = S.principal_extension()
sage: T.cluster()
```

```python
[\(x_0, x_1, x_2\)]
sage: S = ClusterSeed(['B',3], user_labels=[[1,2],[2,3],[3,4]],
.....: user_labels_prefix='p')
sage: S.mutate([0,1])
sage: S.cluster()
[\((p_{2_3} + 1)/p_{1_2}, (p_{1_2} \times p_{3_4}^2 + p_{2_3} + 1)/(p_{1_2} \times p_{2_3}), p_{3_4}\)]
sage: S.reset_cluster()
sage: S.cluster()
[p_{1_2}, p_{2_3}, p_{3_4}]
sage: S.g_matrix()
[1 0 0]
[0 1 0]
[0 0 1]
sage: S.f_polynomials()
[1, 1, 1]
```

```python
>>> from sage.all import *
```
```python
>>> T.cluster()
[x0, x1, x2]
>>> T.mutate([Integer(1), Integer(2), Integer(1)])
>>> T.cluster()
[x0, (x1*y2 + x0)/x2, (x1*y1*y2 + x0*y1 + x2)/(x1*x2)]
>>> T.reset_cluster()
>>> T.cluster()
[x0, x1, x2]
```

```python
>>> S = ClusterSeed(['B', Integer(3)], user_labels=[[Integer(1), Integer(2)],
  [Integer(2), Integer(3)], [Integer(3), Integer(4)],
  user_labels_prefix='p')
>>> S.mutate([Integer(0), Integer(1)])
>>> S.cluster()
[(p_2_3 + 1)/p_1_2, (p_1_2*p_3_4^2 + p_2_3 + 1)/(p_1_2*p_2_3), p_3_4]
>>> S.reset_cluster()
>>> S.cluster()
[p_1_2, p_2_3, p_3_4]
>>> S.g_matrix()
[1 0 0]
[0 1 0]
[0 0 1]
>>> S.f_polynomials()
[1, 1, 1]
```

**reset_coefficients()**

Reset the coefficients of self to the frozen variables but keep the current cluster.

This raises an error if the number of frozen variables is different from the number of exchangeable variables.

**Warning:** This command to be phased out since `use_c_vectors()` does this more effectively.

**EXAMPLES:**

```python
sage: S = ClusterSeed(['A', 3]).principal_extension()
sage: S.b_matrix()
[ 0 1 0]
[-1 0 -1]
[ 0 1 0]
[ 1 0 0]
[ 0 1 0]
[ 0 0 1]
sage: S.mutate([1, 2, 1])
sage: S.b_matrix()
[ 0 1 -1]
[-1 0 1]
[ 1 -1 0]
[ 1 0 0]
[ 0 1 -1]
[ 0 0 -1]
sage: S.reset_coefficients()
sage: S.b_matrix()
[ 0 1 -1]
```
save_image (filename, circular=False, mark=None, save_pos=False)

Save the plot of the underlying digraph of the quiver of self.

INPUT:

- filename – the filename the image is saved to.
- circular – (default: False) if True, the circular plot is chosen, otherwise >>spring<< is used.
- mark – (default: None) if set to i, the vertex i is highlighted.
- save_pos – (default: False) if True, the positions of the vertices are saved.

EXAMPLES:

>> from sage.all import *
>> S = ClusterSeed(['A',Integer(3)]).principal_extension()
>> S.b_matrix()
[ 0 1 0]
[ -1 0 -1]
[ 0 1 0]
[ 0 0 1]
>> S.mutate([Integer(1),Integer(2),Integer(1)])
>> S.b_matrix()
[ 0 1 -1]
[ -1 0 1]
[ 1 -1 0]
[ 1 0 0]
[ 0 1 -1]
[ 0 0 -1]
>> S.reset_coefficients()
>> S.b_matrix()
[ 0 1 -1]
[ -1 0 1]
[ 1 -1 0]
[ 1 0 0]
[ 0 1 0]
[ 0 0 1]
set_c_matrix\(\text{data}\)
Will force set the c-matrix according to a matrix, a quiver, or a seed.

INPUT:

- data – The matrix to set the c-matrix to. Also allowed to be a quiver or cluster seed, in which case the b-matrix is used.

EXAMPLES:

```python
sage: S = ClusterSeed(['A',3])
sage: X = matrix([[0,0,1],[0,1,0],[1,0,0]])
sage: S.set_c_matrix(X)
sage: S.c_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
```

```python
sage: Y = matrix([[-1,0,1],[0,1,0],[1,0,0]])
sage: S.set_c_matrix(Y)
C matrix does not look to be valid - there exists a column containing positive and negative entries. Continuing...
```

```python
sage: Z = matrix([[1,0,1],[0,1,0],[2,0,2]])
sage: S.set_c_matrix(Z)
C matrix does not look to be valid - not a linearly independent set. Continuing...
```

```python
>>> from sage.all import *
>>> S = ClusterSeed(['A',Integer(3)])
>>> X = matrix([[Integer(0),Integer(0),Integer(1)],[Integer(0),Integer(1),
-Integer(0)],[Integer(1),Integer(0),Integer(0)]])
>>> S.set_c_matrix(X)
```

```python
>>> Y = matrix([[-Integer(1),Integer(0),Integer(1)],[Integer(0),Integer(1),
-Integer(0)],[Integer(1),Integer(0),Integer(0)]])
>>> S.set_c_matrix(Y)
C matrix does not look to be valid - there exists a column containing positive and negative entries. Continuing...
```

```python
>>> Z = matrix([[Integer(1),Integer(0),Integer(1)],[Integer(0),Integer(1),
-Integer(0)],[Integer(2),Integer(0),Integer(2)]])
>>> S.set_c_matrix(Z)
C matrix does not look to be valid - not a linearly independent set. Continuing...
```

set_cluster\(\text{cluster, force=False}\)
Sets the cluster for self to cluster.
**Warning:** Initialization may lead to inconsistent data.

**INPUT:**

- `cluster` – an iterable defining a cluster for `self`.

**EXAMPLES:**

```python
sage: S = ClusterSeed([A,3])
sage: cluster = S.cluster()
sage: S.mutate([1,2,1])
sage: S.cluster()
[x0, (x1 + 1)/x2, (x0*x2 + x1 + 1)/(x1*x2)]
sage: cluster2 = S.cluster()
sage: S.set_cluster(cluster)
Warning: using set_cluster at this point could lead to inconsistent seed data.
sage: S.set_cluster(cluster, force=True)
sage: S.cluster()
[x0, x1, x2]
sage: S.set_cluster(cluster2, force=True)
sage: S.cluster()
[x0, (x1 + 1)/x2, (x0*x2 + x1 + 1)/(x1*x2)]
sage: S = ClusterSeed([A,3]); S.use_fpolys(False)
sage: S.set_cluster([1,1,1])
Warning: clusters not being tracked so this command is ignored.
```

```python
>>> from sage.all import *

>>> S = ClusterSeed(['A',Integer(3)])
>>> cluster = S.cluster()
>>> S.mutate([Integer(1),Integer(2),Integer(1)])
>>> S.cluster()
[x0, (x1 + 1)/x2, (x0*x2 + x1 + 1)/(x1*x2)]
>>> cluster2 = S.cluster()

>>> S.set_cluster(cluster)
Warning: using set_cluster at this point could lead to inconsistent seed data.

>>> S.set_cluster(cluster, force=True)

```
• **circular** – (default: False) if True, the circular plot is chosen, otherwise `spring` is used.
• **mark** – (default: None) if set to `i`, the vertex `i` is highlighted.
• **save_pos** – (default: False) if True, the positions of the vertices are saved.
• **force_c** – (default: False) if True, will show the frozen vertices even if they were never initialized
• **with_greens** – (default: False) if True, will display the green vertices in green
• **add_labels** – (default: False) if True, will use the initial variables as labels

**smallest_c_vector()**
Return the vertex with the smallest c-vector.

**OUTPUT:** An integer.

**EXAMPLES:**

```sage
sage: B = matrix([[0,2], [-2,0]])
sage: C = ClusterSeed(B).principal_extension()
sage: C.mutate(0)
sage: C.smallest_c_vector()
0
```

```sage
>>> from sage.all import *
>>> B = matrix([[Integer(0),Integer(2)], [-Integer(2),Integer(0)]]))
>>> C = ClusterSeed(B).principal_extension()
>>> C.mutate(Integer(0))
>>> C.smallest_c_vector()
0
```

**track_mutations**(use=True)
Begin tracking the mutation path.

**Warning:** May initialize all other data to ensure that all c-, d-, and g-vectors agree on the start of mutations.

**INPUT:**

• **use** – (default: True) If True, will begin filling the mutation path

**EXAMPLES:**

```sage
sage: S = ClusterSeed(['A',4]); S.track_mutations(False)
sage: S.mutate(0)
sage: S.mutations()
Traceback (most recent call last):
  ...
ValueError: Not recording mutation sequence. Need to track mutations.
sage: S.track_mutations(True)
sage: S.g_matrix()
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: S.mutate([0,1])
```

(continues on next page)
sage: S.mutations()
[0, 1]

>>> from sage.all import *

>>> S = ClusterSeed(['A',Integer(4)]); S.track_mutations(False)

>>> S.mutate(Integer(0))

>>> S.mutations()
Traceback (most recent call last):
...
ValueError: Not recording mutation sequence. Need to track mutations.

>>> S.track_mutations(True)

>>> S.g_matrix()

\[
\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
\end{bmatrix}
\]

>>> S.mutate([Integer(0),Integer(1)])

>>> S.mutations()
[0, 1]

universal_extension()

Return the universal extension of self.

This is the initial seed of the associated cluster algebra with universal coefficients, as defined in section 12 of [FZ2007].

This method works only if self is a bipartite, finite-type seed.

Due to some limitations in the current implementation of CartanType, we need to construct the set of almost positive coroots by hand. As a consequence their ordering is not the standard one (the rows of the bottom part of the exchange matrix might be a shuffling of those you would expect).

EXAMPLES:

\[
\begin{align*}
\text{sage: } & S = \text{ClusterSeed(['A',2])} \\
\text{sage: } & T = S.\text{universal_extension()} \\
\text{sage: } & T.b_matrix() \\
& \begin{bmatrix}
0 & 1 \\
-1 & 0 \\
-1 & 0 \\
1 & 0 \\
1 & -1 \\
0 & 1 \\
0 & -1 \\
\end{bmatrix}
\end{align*}
\]

\[
\begin{align*}
\text{sage: } & S = \text{ClusterSeed(['A',3])} \\
\text{sage: } & T = S.\text{universal_extension()} \\
\text{sage: } & T.b_matrix() \\
& \begin{bmatrix}
0 & 1 & 0 \\
-1 & 0 & -1 \\
0 & 1 & 0 \\
-1 & 0 & 0 \\
1 & 0 & 0 \\
1 & -1 & 0 \\
1 & -1 & 1 \\
0 & 1 & 0 \\
\end{bmatrix}
\end{align*}
\]

(continues on next page)
\[ \begin{bmatrix} 0 & -1 & 0 \\ 0 & -1 & 1 \\ 0 & 0 & -1 \\ 0 & 0 & 1 \end{bmatrix} \]

\texttt{sage: } S = ClusterSeed(['B', 2])
\texttt{sage: } T = S.universal_extension()
\texttt{sage: } T.b_matrix()
\[ \begin{bmatrix} 0 & 1 \\ -2 & 0 \\ -1 & 0 \\ 1 & 0 \\ 1 & -1 \\ 2 & -1 \\ 0 & 1 \\ 0 & -1 \end{bmatrix} \]

\texttt{sage: } S = ClusterSeed(['A', 5], user_labels=[-2, -1, 0, 1, 2])
\texttt{sage: } U = S.universal_extension()
\texttt{sage: } U.b_matrix() == ClusterSeed(['A', 5]).universal_extension().b_matrix()
\texttt{True}

\texttt{>>> from sage.all import *}
\texttt{>>> S = ClusterSeed(['A', Integer(2)])}
\texttt{>>> T = S.universal_extension()}
\texttt{>>> T.b_matrix()}
\[ \begin{bmatrix} 0 & 1 \\ -1 & 0 \\ -1 & 0 \\ 1 & 0 \\ 1 & -1 \\ 0 & 1 \\ 0 & -1 \end{bmatrix} \]

\texttt{>>> S = ClusterSeed(['A', Integer(3)])}
\texttt{>>> T = S.universal_extension()}
\texttt{>>> T.b_matrix()}
\[ \begin{bmatrix} 0 & 1 & 0 \\ -1 & 0 & -1 \\ 0 & 1 & 0 \\ -1 & 0 & 0 \\ 1 & 0 & 0 \\ 1 & -1 & 0 \\ 1 & -1 & 1 \\ 0 & 1 & 0 \\ 0 & -1 & 0 \\ 0 & -1 & 1 \\ 0 & 0 & -1 \\ 0 & 0 & 1 \end{bmatrix} \]

\texttt{>>> S = ClusterSeed(['B', Integer(2)])}
\texttt{>>> T = S.universal_extension()}
\texttt{>>> T.b_matrix()}
\[ \begin{bmatrix} 0 & 1 \\ -2 & 0 \\ -1 & 0 \end{bmatrix} \]
urban_renewals (return_first=False)

Return the list of the urban renewal vertices of self.

An urban renewal vertex is one in which there are two arrows pointing toward the vertex and two arrows pointing away.

INPUT:

• return_first – (default: False) if True, will return the first urban renewal

OUTPUT:

A list of vertices (as integers)

EXAMPLES:

sage: G = ClusterSeed(['GR', [4, 9]]); G.urban_renewals()
[5, 6]

sage: from sage.all import *

sage: G = ClusterSeed(['GR', [Integer(4), Integer(9)]]); G.urban_renewals()
[5, 6]

use_c_vectors (use=True, bot_is_c=False, force=False)

Reconstruct c-vectors from other data or initialize if no usable data exists.

Warning: Initialization may lead to inconsistent data.

INPUT:

• use – (default: True) If True, will use c-vectors

• bot_is_c – (default: False) If True and ClusterSeed self has self._m == self._n, then will assume bottom half of the extended exchange matrix is the c-matrix. If True, lets the ClusterSeed know c-vectors can be calculated.

EXAMPLES:

sage: S = ClusterSeed(['A', 4])
sage: S.use_c_vectors(False); S.use_g_vectors(False)
sage: S.use_fpolys(False); S.track_mutations(False)
sage: S.use_c_vectors(True)
Warning: Initializing c-vectors at this point could lead to inconsistent seed data.

sage: S.use_c_vectors(True, force=True)
$\texttt{sage: S.c_matrix()}$

\[
\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
\end{bmatrix}
\]

$\texttt{sage: S = ClusterSeed(['A',4])}$

$\texttt{sage: S.use_c_vectors(False); S.use_g_vectors(False)}$

$\texttt{sage: S.use_fpolys(False); S.track_mutations(False)}$

$\texttt{sage: S.mutate(1)}$

$\texttt{sage: S.use_c_vectors(True, force=True)}$

$\texttt{sage: S.c_matrix()}$

\[
\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
\end{bmatrix}
\]

$\texttt{>>> from sage.all import *}$

$\texttt{>>> S = ClusterSeed(['A',Integer(4)])}$

$\texttt{>>> S.use_c_vectors(False); S.use_g_vectors(False)}$

$\texttt{>>> S.use_fpolys(False); S.track_mutations(False)}$

$\texttt{>>> S.use_c_vectors(True)}$

\begin{Verbatim}
Warning: Initializing c-vectors at this point could lead to inconsistent seed data.
\end{Verbatim}

$\texttt{>>> S.use_c_vectors(True, force=True)}$

$\texttt{>>> S.c_matrix()}$

\[
\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
\end{bmatrix}
\]

$\texttt{>>> S = ClusterSeed(['A',Integer(4)])}$

$\texttt{>>> S.use_c_vectors(False); S.use_g_vectors(False)}$

$\texttt{>>> S.use_fpolys(False); S.track_mutations(False)}$

$\texttt{>>> S.mutate(Integer(1))}$

$\texttt{>>> S.use_c_vectors(True, force=True)}$

$\texttt{>>> S.c_matrix()}$

\[
\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
\end{bmatrix}
\]

\textbf{use\_d\_vectors (use=True, force=False)}

Reconstruct d-vectors from other data or initialize if no usable data exists.

\begin{Verbatim}
Warning: Initialization may lead to inconsistent data.
\end{Verbatim}

\textbf{INPUT:}

\begin{itemize}
  \item \texttt{use} – (default: True) If True, will use d-vectors
\end{itemize}

\textbf{EXAMPLES:}
```python
sage: S = ClusterSeed(['A',4])
sage: S.use_d_vectors(True)
sage: S.d_matrix()
[-1 0 0 0]
[0 -1 0 0]
[0 0 -1 0]
[0 0 0 -1]

sage: S = ClusterSeed(['A',4]); S.use_d_vectors(False)
sage: S.track_mutations(False); S.mutate(1); S.d_matrix()
[-1 0 0 0]
[0 1 0 0]
[0 0 -1 0]
[0 0 0 -1]

sage: S.use_fpolys(False)
sage: S.d_matrix()
Traceback (most recent call last):
  ...
ValueError: Unable to calculate d-vectors. Need to use d vectors.

sage: S = ClusterSeed(['A',4]); S.use_d_vectors(False)
sage: S.track_mutations(False); S.mutate(1); S.d_matrix()
[-1 0 0 0]
[0 1 0 0]
[0 0 -1 0]
[0 0 0 -1]

sage: S.use_fpolys(False)
sage: S.use_d_vectors(True)
Warning: Initializing d-vectors at this point could lead to inconsistent seed data.
sage: S.use_d_vectors(True, force=True)
sage: S.d_matrix()
[-1 0 0 0]
[0 -1 0 0]

>>> S.d_matrix()
\[-1 0 0 0
1 0 0 0
0 1 0 0
0 0 -1 0
0 0 0 -1\]
```

**use_fpolys** (*use=True, user_labels=None, user_labels_prefix=None*)

Use F-polynomials in our Cluster Seed

Note: This will automatically try to recompute the cluster variables if possible

**INPUT:**

- **use** *(default: True)* If True, will use F-polynomials
- **user_labels** *(default: None)* If set, will overwrite the default cluster variable labels
- **user_labels_prefix** *(default: None)* If set, will overwrite the default

**EXAMPLES:**

5.1. Comprehensive Module List
```python
sage: S = ClusterSeed([\'A\',4]); S.use_fpolys(False); S._cluster
sage: S.use_fpolys(True)
sage: S.cluster()
[x0, x1, x2, x3]
```

```python
sage: S = ClusterSeed([\'A\',4]); S.use_fpolys(False); S.track_mutations(False)
sage: S.mutate(1)
sage: S.use_fpolys(True)
Traceback (most recent call last):
... ...
ValueError: F-polynomials and Cluster Variables cannot be reconstructed from given data.
sage: S.cluster()
Traceback (most recent call last):
... ...
ValueError: Clusters not being tracked
```

```python
>>> from sage.all import *
>>> S = ClusterSeed([\'A\',Integer(4)]); S.use_fpolys(False); S._cluster
>>> S.use_fpolys(True)
>>> S.cluster()
[x0, x1, x2, x3]
```

```python

>>> S.mutate(Integer(1))
>>> S.use_fpolys(True)
Traceback (most recent call last):
... ...
ValueError: F-polynomials and Cluster Variables cannot be reconstructed from given data.
>>> S.cluster()
Traceback (most recent call last):
... ...
ValueError: Clusters not being tracked
```

**use_g_vectors** *(use=True, force=False)*

Reconstruct g-vectors from other data or initialize if no usable data exists.

**Warning:** Initialization may lead to inconsistent data.

**INPUT:**

- **use** — (default: True) If True, will use g-vectors

**EXAMPLES:**

```python
sage: S = ClusterSeed([\'A\',4])
sage: S.use_g_vectors(False); S.use_fpolys(False)
sage: S.use_g_vectors(True)
sage: S.g_matrix()
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```
sage: S = ClusterSeed(['A', 4])
sage: S.use_g_vectors(False); S.use_fpolys(False)
sage: S.mutate(1)
sage: S.use_g_vectors(True)

Warning: Initializing g-vectors at this point could lead to inconsistent seed data.
>>> S.use_g_vectors(True, force=True)
>>> S.g_matrix()
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]

variable_class (depth=+Infinity, ignore_bipartite_belt=False)
Return all cluster variables in the mutation class of self.

INPUT:
- depth – (default: infinity) integer, only seeds with distance at most depth from self are returned
- ignore_bipartite_belt – (default: False) if True, the algorithm does not use the bipartite belt

EXAMPLES:
- for examples see variable_class_iter()

variable_class_iter (depth=+Infinity, ignore_bipartite_belt=False)
Return an iterator for all cluster variables in the mutation class of self.

INPUT:
- depth – (default: infinity) integer, only seeds with distance at most depth from self are returned
- ignore_bipartite_belt – (default: False) if True, the algorithm does not use the bipartite belt

EXAMPLES:
A standard finite type example:

```
sage: S = ClusterSeed(['A',3])
sage: it = S.variable_class_iter()
sage: for T in it: print(T)
x0
x1
x2
(x1 + 1)/x0
(x1^2 + x0*x2 + 2*x1 + 1)/(x0*x1*x2)
(x1 + 1)/x2
```
(continued from previous page)

```python
>>> from sage.all import *

```Combinatorics, Release 10.4

Finite type examples with given depth:

```python
sage: it = S.variable_class_iter(depth=1)
sage: for T in it: print(T)
Found a bipartite seed - restarting the depth counter at zero and constructing the variable class using its bipartite belt.
x0
x1
x2
(\(x_1 + 1\))/x0
(\(x_1^2 + x_0*x_2 + 2*x_1 + 1\))/(x_0*x_1*x_2)
(\(x_1 + 1\))/x2
(\(x_0*x_2 + x_1 + 1\))/(x_0*x_1)
(\(x_0*x_2 + 1\))/x1
(\(x_0*x_2 + x_1 + 1\))/(x_1*x_2)
```

Note that the notion of `depth` depends on whether a bipartite seed is found or not, or if it is manually ignored:

```python
sage: it = S.variable_class_iter(depth=1, ignore_bipartite_belt=True)
sage: for T in it: print(T)
```

(continues on next page)

\]
\[
\text{>>> S = ClusterSeed(['A',[Integer(1),Integer(1)],Integer(1)])}
\]
```python
>>> it = S.variable_class_iter(depth=Integer(2))
>>> for T in it: print(T)
Found a bipartite seed - restarting the depth counter at zero and constructing the variable class using its bipartite belt.
x0
x1
(x1^2 + 1)/x0
(x1^4 + x0^2 + 2*x1^2 + 1)/(x0^2*x1)
(x0^4 + 2*x0^2 + x1^2 + 1)/(x0*x1^2)
(x0^2 + 1)/x1
(x1^6 + x0^4 + 2*x0^2*x1^2 + 3*x1^4 + 2*x0^2 + 3*x1^2 + 1)/(x0^3*x1^2)
(x1^8 + x0^6 + 2*x0^4*x1^2 + 3*x0^2*x1^4 + 4*x1^6 + 3*x0^4 + 6*x0^2*x1^2 +
-6*x1^4 + 3*x0^2 + 4*x1^2 + 1)/(x0^4*x1^3)
(x0^8 + 4*x0^6 + 3*x0^4*x1^2 + 2*x0^2*x1^4 + x1^6 + 6*x0^4 + 6*x0^2*x1^2 +
-3*x1^4 + 4*x0^2 + 3*x1^2 + 1)/(x0^3*x1^4)
(x0^6 + 3*x0^4 + 2*x0^2*x1^2 + x1^4 + 3*x0^2 + 2*x1^2 + 1)/(x0^2*x1^3)
```

\(x(k)\)

Return the \(k\)-th initial cluster variable for the associated cluster seed, or the cluster variable of the corresponding vertex in \texttt{self.quiver}.

**EXAMPLES:**

```python
sage: S = ClusterSeed(['A', 3])
sage: S.mutate([2, 1])
sage: S.x(0)
x0
sage: S.x(1)
x1
sage: S.x(2)
x2
sage: dg = DiGraph([['a', 'b'], ['b', 'c']], format="list_of_edges")
sage: S = ClusterSeed(dg, frozen=['c'])
sage: S.x(0)
a
sage: S.x('a')
a
```

```python
>>> from sage.all import *
>>> S = ClusterSeed(['A', Integer(3)])
>>> S.mutate([Integer(2), Integer(1)])
>>> S.x(Integer(0))
x0
>>> S.x(Integer(1))
x1
>>> S.x(Integer(2))
x2
>>> dg = DiGraph([['a', 'b'], ['b', 'c']], format="list_of_edges")
>>> S = ClusterSeed(dg, frozen=['c'])
>>> S.x(Integer(0))
```

(continues on next page)
\texttt{y(k)}

Return the $k$-th initial coefficient (frozen variable) for the associated cluster seed, or the cluster variable of the corresponding vertex in \texttt{self.quiver}.

EXAMPLES:

\begin{verbatim}
sage: S = ClusterSeed(['A', 3]).principal_extension()
sage: S.mutate([2, 1])
sage: S.y(0)
y0
sage: S.y(1)
y1
sage: S.y(2)
y2
sage: dg = DiGraph([['a', 'b'], ['b', 'c']], format="list_of_edges")
sage: S = ClusterSeed(dg, frozen=['c'])
sage: S.y(0)
c
sage: S.y('c')
c
>>> from sage.all import *
>>> S = ClusterSeed(['A', Integer(3)]).principal_extension()
>>> S.mutate([Integer(2), Integer(1)])
>>> S.y(Integer(0))
y0

>>> S.y(Integer(1))
y1

>>> S.y(Integer(2))
y2

>>> dg = DiGraph([['a', 'b'], ['b', 'c']], format="list_of_edges")
>>> S = ClusterSeed(dg, frozen=['c'])
>>> S.y(Integer(0))
c
>>> S.y('c')
c
\end{verbatim}
class sage.combinat.cluster_algebra_quiver.cluster_seed.ClusterVariable(parent, numerator, denominator, coerce=True, reduce=True, mutation_type=None, variable_type=None, xdim=0)

Bases: FractionFieldElement

This class is a thin wrapper for cluster variables in cluster seeds.

It provides the extra feature to store if a variable is frozen or not.

• the associated positive root:

```python
sage: S = ClusterSeed(['A',3])
sage: for T in S.variable_class_iter():
    ....:     print("{} {}\n".format(T, T.almost_positive_root()))
x0 -alpha[1]
x1 -alpha[2]
x2 -alpha[3]
  (x1 + 1)/x0 alpha[1]
(x1^2 + x0*x2 + 2*x1 + 1)/(x0*x1*x2) alpha[1] + alpha[2] + alpha[3]
  (x1 + 1)/x2 alpha[3]
(x0*x2 + x1 + 1)/(x0*x1) alpha[1] + alpha[2]
  (x0*x2 + 1)/x1 alpha[2]
(x0*x2 + x1 + 1)/(x1*x2) alpha[2] + alpha[3]
```

```python
>>> from sage.all import *
>>> S = ClusterSeed(['A',Integer(3)])
>>> for T in S.variable_class_iter():
    ...
    print("{} {}\n".format(T, T.almost_positive_root()))
x0 -alpha[1]
x1 -alpha[2]
x2 -alpha[3]
  (x1 + 1)/x0 alpha[1]
(x1^2 + x0*x2 + 2*x1 + 1)/(x0*x1*x2) alpha[1] + alpha[2] + alpha[3]
  (x1 + 1)/x2 alpha[3]
(x0*x2 + x1 + 1)/(x0*x1) alpha[1] + alpha[2]
  (x0*x2 + 1)/x1 alpha[2]
(x0*x2 + x1 + 1)/(x1*x2) alpha[2] + alpha[3]
```

almost_positive_root()

Return the almost positive root associated to self if self is of finite type.

EXAMPLES:
x0 - alpha[1]
x1 - alpha[2]
x2 - alpha[3]
(x1 + 1)/x0 alpha[1]
(x1^2 + x0*x2 + 2*x1 + 1)/(x0*x1*x2) alpha[1] + alpha[2] + alpha[3]
(x1 + 1)/x2 alpha[3]
(x0*x2 + x1 + 1)/(x0*x1) alpha[1] + alpha[2]
(x0*x2 + 1)/x1 alpha[2]
(x0*x2 + x1 + 1)/(x1*x2) alpha[2] + alpha[3]

sage.combinat.cluster_algebra_quiver.cluster_seed.PathSubset(n, m)

Encode a maximal Dyck path from (0, 0) to (n, m) (for n ≥ m ≥ 0) as a subset of {0, 1, 2, ..., 2n − 1}.

The encoding is given by indexing horizontal edges by odd numbers and vertical edges by evens.

The horizontal between (i, j) and (i + 1, j) is indexed by the odd number 2i + 1. The vertical between (i, j) and (i, j + 1) is indexed by the even number 2j.

EXAMPLES:
sage.combinat.cluster_algebra_quiver.cluster_seed.SetToPath(T)

Rearrange the encoding for a maximal Dyck path (as a set) so that it is a list in the proper order of the edges.

EXAMPLES:

```python
sage: from sage.combinat.cluster_algebra_quiver.cluster_seed import PathSubset
sage: SetToPath(PathSubset(4,0))
[1, 3, 5, 7]
sage: SetToPath(PathSubset(4,1))
[1, 3, 5, 7, 6]
sage: SetToPath(PathSubset(4,2))
[1, 3, 2, 5, 7, 6]
sage: SetToPath(PathSubset(4,3))
[1, 3, 2, 5, 4, 7, 6]
sage: SetToPath(PathSubset(4,4))
[1, 0, 3, 2, 5, 4, 7, 6]
```

sage.combinat.cluster_algebra_quiver.cluster_seed.coeff_recurs(p, q, a1, a2, b, c)

Coefficients in Laurent expansion of greedy element, as defined by recursion.

EXAMPLES:

```python
sage: coeff_recurs(1, 1, 5, 5, 3, 3)
10
```

sage.combinat.cluster_algebra_quiver.cluster_seed.get_green_vertices(C)

Get the green vertices from a matrix.

Will go through each column and return the ones where no entry is greater than 0.

INPUT:
• \( \text{C} \) – The \( \text{C} \)-matrix to check

**EXAMPLES:**

```python
go to sage.combinat.cluster_algebra_quiver.cluster_seed
get_green_vertices(C)
```

Get the green vertices from a matrix.

Will go through each column and return the ones where no entry is less than 0.

**INPUT:**

• \( \text{C} \) – The \( \text{C} \)-matrix to check

**EXAMPLES:**

```python
go to sage.combinat.cluster_algebra_quiver.cluster_seed
get_red_vertices(C)
```

Get the red vertices from a matrix.

Will go through each column and return the ones where no entry is less than 0.

**INPUT:**

• \( \text{C} \) – The \( \text{C} \)-matrix to check

**EXAMPLES:**

```python
go to sage.combinat.cluster_algebra_quiver.cluster_seed
is_LeeLiZel_allowable(T, n, m, b, c)
```

Check if the subset \( T \) contributes to the computation of the greedy element \( x[m, n] \) in the rank two \((b, c)\)-cluster algebra.

This uses the conditions of Lee-Li-Zelevinsky's paper [LLZ2014].

**EXAMPLES:**

```python
go to sage.combinat.cluster_algebra_quiver.cluster_seed
is_LeeLiZel_allowable()
go to sage.combinat.cluster_algebra_quiver.cluster_seed
is_LeeLiZel_allowable({1, 3, 2, 5, 7, 6}, 4, 2, 6, 6)
```

False
```

```python
go to sage.combinat.cluster_algebra_quiver.cluster_seed
is_LeeLiZel_allowable({1, 2, 5}, 3, 3, 1, 1)
```

True
5.1.19 mutation_class

This file contains helper functions for computing the mutation class of a cluster algebra or quiver.

For the compendium on the cluster algebra and quiver package see [MS2011]

AUTHORS:

• Gregg Musiker
• Christian Stump

5.1.20 Helper functions for mutation types of quivers

This file contains helper functions for detecting the mutation type of a cluster algebra or quiver.

For the compendium on the cluster algebra and quiver package see [MS2011]

AUTHORS:

• Gregg Musiker
• Christian Stump

sage.combinat.cluster_algebra_quiver.mutation_type.is_mutation_finite(M, nr_of_checks=None)

Use a non-deterministic method by random mutations in various directions. Can result in a wrong answer.

**Warning:** This method modifies the input matrix M!

INPUT:

• **nr_of_checks** – (default: None) number of mutations applied. Standard is 500*number of vertices of self.

ALGORITHM:

A quiver is mutation infinite if and only if every edge label (a, -b) satisfy a*b > 4. Thus, we apply random mutations in random directions

EXAMPLES:

sage: from sage.combinat.cluster_algebra_quiver.mutation_type import is_mutation_finite
sage: Q = ClusterQuiver([['A',10]])
from sage.all import *
from sage.combinat.cluster_algebra_quiver.mutation_type import is_mutation_finite

Q = ClusterQuiver([('A',Integer(10))])
# needs sage.modules
M = Q.b_matrix()
# needs sage.modules
is_mutation_finite(M)  # random
(False, [9, 6, 9, 8, 9, 4, 0, 4, 5, 2, 1, 0, 1, 0, 7, 1, 9, 2, 5, 7, 8, 6, 3, 0,...
→2, 5, 4, 2, 6, 9, 2, 7, 3, 5, 3, 7, 9, 5, 9, 0, 2, 7, 9, 2, 4, 2, 1, 6, 9, 4, 3,...
→5, 0, 8, 2, 9, 5, 3, 7, 0, 1, 8, 3, 7, 2, 7, 3, 4, 8, 0, 4, 9, 5, 2, 8, 4, 8,...
→1, 7, 8, 9, 1, 5, 0, 8, 7, 4, 8, 9, 8, 0, 7, 4, 7, 1, 2, 8, 6, 1, 3, 9, 3, 9, 1,...
→3, 2, 4, 9, 5, 1, 2, 9, 4, 8, 5, 3, 4, 6, 8, 9, 2, 5, 9, 4, 6, 2, 1, 4, 9, 6,...
→0, 9, 8, 0, 4, 7, 9, 2, 1, 6])
A seed for a cluster algebra of rank 1

```python
>>> S.is_mutation_finite()
# needs sage.modules
True
```

`sage.combinat.cluster_algebra_quiver.mutation_type.load_data(user=True)`

Load a dict with keys being tuples representing exceptional QuiverMutationTypes, and with values being lists or sets containing all mutation equivalent quivers as dig6 data.

We check

• the data stored by the user (unless `user=False` was given)
• and the data installed by the optional package `database_mutation_class`.

INPUT:

• `user` – boolean (default: `True`) whether to look at user data. If not, only consider the optional package.

EXAMPLES:

```python
sage: from sage.combinat.cluster_algebra_quiver.mutation_type import load_data
sage: load_data(2) # random - depends on the data the user has stored
{('G', 2): [('AO', (((0, 1), (1, -3)),)), ('AO', (((0, 1), (3, -1)),))],}
```

```python
>>> from sage.all import *
>>> from sage.combinat.cluster_algebra_quiver.mutation_type import load_data
>>> load_data(Integer(2)) # random - depends on the data the user has stored
{('G', 2): [('AO', (((0, 1), (1, -3)),)), ('AO', (((0, 1), (3, -1)),))],}
```

### 5.1.21 Quiver

A *quiver* is an oriented graph without loops, two-cycles, or multiple edges. The edges are labelled by pairs \((i, -j)\) (with \(i\) and \(j\) being positive integers) such that the matrix \(M = (m_{ab})\) with \(m_{ab} = i, m_{ba} = -j\) for an edge \((i, -j)\) between vertices \(a\) and \(b\) is skew-symmetrizable.

**Warning:** This is not the standard definition of a quiver. Normally, in cluster algebra theory, a quiver is defined as an oriented graph without loops and two-cycles but with multiple edges allowed; the edges are unlabelled. This notion of quivers, however, can be seen as a particular case of our notion of quivers. Namely, if we have a quiver (in the regular sense of this word) with \(i\) edges from \(a\) to \(b\), then we represent it by a quiver (in our sense of this word) with an edge from \(a\) to \(b\) labelled by the pair \((i, -i)\).

For the compendium on the cluster algebra and quiver package see [MS2011]

**AUTHORS:**

• Gregg Musiker
• Christian Stump

**See also:**

For mutation types of combinatorial quivers, see `QuiverMutationType()`. Cluster seeds are closely related to `ClusterSeed()`.
class sage.combinat.cluster_algebra_quiver.quiver.ClusterQuiver(data, frozen=None, user_labels=None)

Bases: SageObject

The quiver associated to an exchange matrix.

INPUT:

- **data** – can be any of the following:
  
  - :class:`QuiverMutationType`
  - :class:`str` – a string representing a :class:`QuiverMutationType` or a common quiver type (see Examples)
  - :class:`ClusterQuiver`
  - :class:`Matrix` – a skew-symmetrizable matrix
  - :class:`DiGraph` – must be the input data for a quiver
  - List of edges – must be the edge list of a digraph for a quiver

- **frozen** – (default: None) sets the list of frozen variables if the input type is a :class:`DiGraph`, it is ignored otherwise

- **user_labels** – (default: None) sets the names of the labels for the vertices of the quiver if the input type is not a :class:`DiGraph`; otherwise it is ignored

EXAMPLES:

From a :class:`QuiverMutationType`:

```
sage: Q = ClusterQuiver(['A',5]); Q
Quiver on 5 vertices of type ['A', 5]
sage: Q = ClusterQuiver(['B',2]); Q
Quiver on 2 vertices of type ['B', 2]
sage: Q2 = ClusterQuiver(['C',2]); Q2
Quiver on 2 vertices of type ['B', 2]
sage: MT = Q.mutation_type(); MT.standard_quiver() == Q
True
sage: MT = Q2.mutation_type(); MT.standard_quiver() == Q2
False
sage: Q = ClusterQuiver(['A', [2,5],1]); Q
Quiver on 7 vertices of type ['A', [2, 5], 1]
sage: Q = ClusterQuiver(['A', [5,0],1]); Q
Quiver on 5 vertices of type ['D', 5]
sage: Q.is_finite()
True
sage: Q.is_acyclic()
False
sage: Q = ClusterQuiver(['F', 4, [2,1]]); Q
Quiver on 6 vertices of type ['F', 4, [1, 2]]
sage: MT = Q.mutation_type(); MT.standard_quiver() == Q
False
sage: dg = Q.digraph(); Q.mutate([2,1,4,0,5,3])
sage: dg2 = Q.digraph(); dg2.is_isomorphic(dg, edge_labels=True)
False
sage: dg2.is_isomorphic(MT.standard_quiver().digraph(), edge_labels=True)
True
```

(continues on next page)
sage: Q = ClusterQuiver(['G', 2, (3, 1)]); Q
Quiver on 4 vertices of type ['G', 2, [1, 3]]
sage: MT = Q.mutation_type(); MT.standard_quiver() == Q
False

sage: Q = ClusterQuiver(['GR', [3, 6]]); Q
Quiver on 4 vertices of type ['D', 4]
sage: MT = Q.mutation_type(); MT.standard_quiver() == Q
False

sage: Q = ClusterQuiver(['GR', [3, 7]]); Q
Quiver on 6 vertices of type ['E', 6]
sage: Q = ClusterQuiver(['TR', 2]); Q
Quiver on 3 vertices of type ['A', 3]
sage: MT = Q.mutation_type(); MT.standard_quiver() == Q
False
sage: Q.mutate([1, 0]); MT.standard_quiver() == Q
True

sage: Q = ClusterQuiver(['TR', 3]); Q
Quiver on 6 vertices of type ['D', 6]

>>> from sage.all import *

>>> Q = ClusterQuiver(['A', Integer(5)]); Q
Quiver on 5 vertices of type ['A', 5]

>>> Q = ClusterQuiver(['B', Integer(2)]); Q
Quiver on 2 vertices of type ['B', 2]

>>> Q2 = ClusterQuiver(['C', Integer(2)]); Q2
Quiver on 2 vertices of type ['B', 2]

>>> MT = Q.mutation_type(); MT.standard_quiver() == Q
True

>>> MT = Q2.mutation_type(); MT.standard_quiver() == Q2
False

>>> Q = ClusterQuiver(['A', [Integer(2), Integer(5)], Integer(1)]); Q
Quiver on 7 vertices of type ['A', [2, 5], 1]

>>> Q = ClusterQuiver(['A', [Integer(5), Integer(0)], Integer(1)]); Q
Quiver on 5 vertices of type ['D', 5]

>>> Q.is_finite()
True

>>> Q.is_acyclic()
False

>>> Q = ClusterQuiver(['F', Integer(4), [Integer(2), Integer(1)]]); Q
Quiver on 6 vertices of type ['F', 4, [1, 2]]

>>> MT = Q.mutation_type(); MT.standard_quiver() == Q
False

>>> dg = Q.digraph(); Q.mutate([Integer(2), Integer(1), Integer(4), Integer(0),
    Integer(5), Integer(3)]

>>> dg2 = Q.digraph(); dg2.is_isomorphic(dg, edge_labels=True)

(continues on next page)
False
>>> dg2.is_isomorphic(MT.standard_quiver().digraph(), edge_labels=True)
True

>>> Q = ClusterQuiver(['G', Integer(2), {Integer(3), Integer(1)}]); Q
Quiver on 4 vertices of type ['G', 2, [1, 3]]
>>> MT = Q.mutation_type(); MT.standard_quiver() == Q
False

>>> Q = ClusterQuiver(['GR', [Integer(3), Integer(6)]]); Q
Quiver on 4 vertices of type ['D', 4]
>>> MT = Q.mutation_type(); MT.standard_quiver() == Q
False

>>> Q = ClusterQuiver(['GR', [Integer(3), Integer(7)]]); Q
Quiver on 6 vertices of type ['E', 6]

>>> Q = ClusterQuiver(['TR', Integer(2)]); Q
Quiver on 3 vertices of type ['A', 3]
>>> MT = Q.mutation_type(); MT.standard_quiver() == Q
False

>>> Q.mutate([Integer(1), Integer(0)]); MT.standard_quiver() == Q
True

>>> Q = ClusterQuiver(['TR', Integer(3)]); Q
Quiver on 6 vertices of type ['D', 6]
>>> MT = Q.mutation_type(); MT.standard_quiver() == Q
False

From a \texttt{ClusterQuiver}:

\begin{sage}
\texttt{Q = ClusterQuiver(['A', [2, 5], 1]); Q}
\texttt{Quiver on 7 vertices of type ['A', [2, 5], 1]}
\texttt{Q = ClusterQuiver( Q ); T}
\texttt{Quiver on 7 vertices of type ['A', [2, 5], 1]}
\end{sage}

\begin{sage}
\texttt{from \texttt{sage.all import *}}
\texttt{Q = ClusterQuiver(['A', [Integer(2), Integer(5)], Integer(1)]); Q}
\texttt{Quiver on 7 vertices of type ['A', [2, 5], 1]}
\texttt{T = ClusterQuiver( Q ); T}
\texttt{Quiver on 7 vertices of type ['A', [2, 5], 1]}
\end{sage}

From a Matrix:

\begin{sage}
\texttt{Q = ClusterQuiver(['A', [2, 5], 1]); Q}
\texttt{Quiver on 7 vertices of type ['A', [2, 5], 1]}
\texttt{T = ClusterQuiver( Q._M ); T}
\texttt{Quiver on 7 vertices}
\end{sage}

\begin{sage}
\texttt{Q = ClusterQuiver( matrix([[0, 1, -1], [-1, 0, 1], [1, -1, 0], [1, 2, 3]]) ); Q}
\texttt{Quiver on 4 vertices with 1 frozen vertex}
\texttt{Q = ClusterQuiver( matrix([]) ); Q}
\texttt{Quiver without vertices}
\end{sage}
```python
>>> from sage.all import *
>>> Q = ClusterQuiver(['A', [Integer(2), Integer(5)], Integer(1)]); Q
Quiver on 7 vertices of type ['A', [2, 5], 1]
>>> T = ClusterQuiver( Q._M ); T
Quiver on 7 vertices

>>> Q = ClusterQuiver( matrix([[Integer(0), Integer(1), -Integer(1)],
    [-Integer(1), Integer(0), Integer(1)],
    [Integer(1), -Integer(1), -Integer(1), Integer(0)],
    [Integer(1), -Integer(1), Integer(0)]]) ); Q
Quiver on 4 vertices with 1 frozen vertex

>>> Q = ClusterQuiver( matrix([]) ); Q
Quiver without vertices

From a DiGraph:
sage: Q = ClusterQuiver(['A', [2,5],1]); Q
Quiver on 7 vertices of type ['A', [2, 5], 1]
sage: T = ClusterQuiver( Q._digraph ); T
Quiver on 7 vertices

sage: Q = ClusterQuiver( DiGraph([[1,2],[2,3],[3,4],[4,1]])); Q
Quiver on 4 vertices

sage: Q = ClusterQuiver(DiGraph([[a, b], [b, c], [c, d], [d, e]],
    ... frozen=[c])); Q
Quiver on 5 vertices with 1 frozen vertex

sage: Q.mutation_type()
[ [\text{A}, 2], [\text{A}, 2] ]
sage: Q
Quiver on 5 vertices of type [ ['A', 2], ['A', 2] ] with 1 frozen vertex

From a List of edges:
sage: Q = ClusterQuiver(['A', [2,5],1]); Q
Quiver on 7 vertices of type ['A', [2, 5], 1]
sage: T = ClusterQuiver( Q._digraph.edges(sort=True) ); T
Quiver on 7 vertices

(continues on next page)
```

5.1. Comprehensive Module List

351
```python
sage: Q = ClusterQuiver([[1, 2], [2, 3], [3, 4], [4, 1]]); Q
Quiver on 4 vertices

>>> from sage.all import *
>>> Q = ClusterQuiver(['A', [Integer(2), Integer(5)], Integer(1)]); Q
Quiver on 7 vertices of type ['A', [2, 5], 1]
>>> T = ClusterQuiver(Q._digraph.edges(sort=True)); T
Quiver on 7 vertices

>>> Q = ClusterQuiver([[Integer(1), Integer(2)], [Integer(2), Integer(3)],
             [Integer(3), Integer(4)], [Integer(4), Integer(1)]]); Q
Quiver on 4 vertices
```

**b_matrix()**

Return the b-matrix of self.

**EXAMPLES:**

```python
sage: ClusterQuiver(['A',4]).b_matrix()
[ 0 1 0 0]
[-1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -1 0]

sage: ClusterQuiver(['B',4]).b_matrix()
[ 0 1 0 0]
[-1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -2 0]

sage: ClusterQuiver(['D',4]).b_matrix()
[ 0 1 0 0]
[-1 0 -1 -1]
[ 0 1 0 0]
[ 0 1 0 0]

sage: ClusterQuiver(QuiverMutationType([[ 'A',2],['B',2]])).b_matrix()
[ 0 1 0 0]
[-1 0 0 0]
[ 0 0 0 1]
[ 0 0 -2 0]
```

```python
>>> from sage.all import *
>>> ClusterQuiver(['A',Integer(4)]).b_matrix()
[ 0 1 0 0]
[-1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -1 0]

>>> ClusterQuiver(['B',Integer(4)]).b_matrix()
[ 0 1 0 0]
[-1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -2 0]

>>> ClusterQuiver(['D',Integer(4)]).b_matrix()
```

(continues on next page)
canonical_label (certificate=False)

Return the canonical labelling of self.

See sage.graphs.generic_graph.GenericGraph.canonical_label().

INPUT:

• certificate – boolean (default: False) if True, the dictionary from self.vertices() to the vertices of the returned quiver is returned as well.

EXAMPLES:

sage: Q = ClusterQuiver(['A', 4]); Q.digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1)), (2, 3, (1, -1))]

sage: T = Q.canonical_label(); T.digraph().edges(sort=True)
[(0, 3, (1, -1)), (1, 2, (1, -1)), (1, 3, (1, -1))]

sage: T, iso = Q.canonical_label(certificate=True)

sage: T.digraph().edges(sort=True); iso
[(0, 3, (1, -1)), (1, 2, (1, -1)), (1, 3, (1, -1))]
{0: 0, 1: 3, 2: 1, 3: 2}

sage: Q = ClusterQuiver(QuiverMutationType([['B', 2], ['A', 1]])); Q
Quiver on 3 vertices of type [ ['B', 2], ['A', 1] ]

sage: Q.canonical_label()
Quiver on 3 vertices of type [ ['A', 1], ['B', 2] ]

sage: Q.canonical_label(certificate=True)
(Quiver on 3 vertices of type [ ['A', 1], ['B', 2] ], {0: 1, 1: 2, 2: 0})

>>> from sage.all import *

>>> Q = ClusterQuiver(['A', Integer(4)]); Q.digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1)), (2, 3, (1, -1))]

>>> T = Q.canonical_label(); T.digraph().edges(sort=True)
[(0, 3, (1, -1)), (1, 2, (1, -1)), (1, 3, (1, -1))]

>>> T, iso = Q.canonical_label(certificate=True)

>>> T.digraph().edges(sort=True); iso
[(0, 3, (1, -1)), (1, 2, (1, -1)), (1, 3, (1, -1))]
{0: 0, 1: 3, 2: 1, 3: 2}

>>> Q = ClusterQuiver(QuiverMutationType([['B', Integer(2)], ['A', 5]])

(continues on next page)
Quiver on 3 vertices of type [ ['B', 2], ['A', 1] ]

>>> Q.canonical_label()
Quiver on 3 vertices of type [ ['A', 1], ['B', 2] ]

>>> Q.canonical_label(certificate=True)
(Quiver on 3 vertices of type [ ['A', 1], ['B', 2] ], {0: 1, 1: 2, 2: 0})

d_vector_fan()

Return the d-vector fan associated with the quiver.

It is the fan whose maximal cones are generated by the d-matrices of the clusters.

This is a complete simplicial fan (and even smooth when the initial quiver is acyclic). It only makes sense for quivers of finite type.

EXAMPLES:

```python
sage: # needs sage.geometry.polyhedron sage.libs.singular
sage: Fd = ClusterQuiver([[1,2]]).d_vector_fan(); Fd
Rational polyhedral fan in 2-d lattice N
sage: Fd.ngenerating_cones()
5
sage: Fd = ClusterQuiver([[1,2],[2,3]]).d_vector_fan(); Fd
Rational polyhedral fan in 3-d lattice N
sage: Fd.ngenerating_cones()
14
sage: Fd.is_smooth()
True
sage: Fd = ClusterQuiver([[1,2],[2,3],[3,1]]).d_vector_fan(); Fd
Rational polyhedral fan in 3-d lattice N
sage: Fd.ngenerating_cones()
14
sage: Fd.is_smooth()
False
```

```python
>>> from sage.all import *
>>> # needs sage.geometry.polyhedron sage.libs.singular
>>> Fd = ClusterQuiver([[Integer(1),Integer(2)]]).d_vector_fan(); Fd
Rational polyhedral fan in 2-d lattice N
>>> Fd.ngenerating_cones()
5
>>> Fd = ClusterQuiver([[Integer(1),Integer(2)],[Integer(2),Integer(3)]]).d_vector_fan(); Fd
Rational polyhedral fan in 3-d lattice N
>>> Fd.ngenerating_cones()
14
>>> Fd.is_smooth()
True
>>> Fd = ClusterQuiver([[Integer(1),Integer(2)],[Integer(2),Integer(3)],[Integer(3),Integer(1)]]).d_vector_fan(); Fd
Rational polyhedral fan in 3-d lattice N
>>> Fd.ngenerating_cones()
14
>>> Fd.is_smooth()
False
```
digraph()

Return the underlying digraph of self.

EXAMPLES:

```python
sage: ClusterQuiver(['A',1]).digraph()
Digraph on 1 vertex
sage: list(ClusterQuiver(['A',1]).digraph())
[0]
sage: ClusterQuiver(['A',1]).digraph().edges(sort=True)
[]

sage: ClusterQuiver(['A',4]).digraph()
Digraph on 4 vertices
sage: ClusterQuiver(['A',4]).digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1)), (2, 3, (1, -1))]

sage: ClusterQuiver(['B',4]).digraph()
Digraph on 4 vertices
sage: ClusterQuiver(['A',4]).digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1)), (2, 3, (1, -1))]

sage: ClusterQuiver(QuiverMutationType([['A',2],['B',2]])).digraph()
Digraph on 4 vertices
sage: ClusterQuiver(QuiverMutationType([['A',2],['B',2]])).digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 3, (1, -2))]

sage: ClusterQuiver([C, 4], user_labels = ['x', 'y', 'z', 'w']).digraph().edges(sort=True)
[('x', 'y', (1, -1)), ('z', 'w', (2, -1)), ('z', 'y', (1, -1))]
```

(continues on next page)
exchangeable_part()

Return the restriction to the principal part (i.e., exchangeable part) of self, the subquiver obtained by deleting the frozen vertices of self.

EXAMPLES:

```python
sage: Q = ClusterQuiver(['A', 4])
sage: T = ClusterQuiver(Q.digraph().edges(sort=True), frozen=[3])
sage: T.digraph().edges(sort=True)
[[(0, 1, (1, -1)), (2, 1, (1, -1)), (2, 3, (1, -1))]]
sage: T.exchangeable_part().digraph().edges(sort=True)
[[(0, 1, (1, -1)), (2, 1, (1, -1))]]
sage: Q2 = Q.principal_extension()
sage: Q3 = Q2.principal_extension()
sage: Q2.exchangeable_part() == Q3.exchangeable_part()
True
```

first_sink()

Return the first vertex of self that is a sink.

EXAMPLES:

```python
sage: Q = ClusterQuiver(['A', 5])
sage: Q.mutate([1,2,4,3,2])
sage: Q.first_sink()
0
```
EXAMPLES:

```python
sage: Q = ClusterQuiver(['A', 5])
sage: Q.mutate([2, 1, 3, 4, 2])
sage: Q.first_source()
1
```

```python
>>> from sage.all import *

>>> Q = ClusterQuiver(['A', Integer(5)])
>>> Q.mutate([Integer(2), Integer(1), Integer(3), Integer(4), Integer(2)])
>>> Q.first_source()
```

### free_vertices()

Return the list of free vertices of self.

**EXAMPLES:**

```python
sage: Q = ClusterQuiver(DiGraph([['a', 'b'], ['c', 'b'], ['c', 'd'], ['e', 'd →']]),
....:   frozen=['b', 'd'])
sage: Q.free_vertices()
['a', 'c', 'e']
```

```python
>>> from sage.all import *

>>> Q = ClusterQuiver(DiGraph([['a', 'b'], ['c', 'b'], ['c', 'd'], ['e', 'd →']]),
...   frozen=['b', 'd'])
>>> Q.free_vertices()
['a', 'c', 'e']
```

### frozen_vertices()

Return the list of frozen vertices of self.

**EXAMPLES:**

```python
sage: Q = ClusterQuiver(DiGraph([['a', 'b'], ['c', 'b'], ['c', 'd'], ['e', 'd →']]),
....:   frozen=['b', 'd'])
sage: sorted(Q.frozen_vertices())
['b', 'd']
```

```python
>>> from sage.all import *

>>> Q = ClusterQuiver(DiGraph([['a', 'b'], ['c', 'b'], ['c', 'd'], ['e', 'd →']]),
...   frozen=['b', 'd'])
>>> sorted(Q.frozen_vertices())
['b', 'd']
```

### g_vector_fan()

Return the g-vector fan associated with the quiver.

It is the fan whose maximal cones are generated by the g-matrices of the clusters.

This is a complete simplicial fan. It is only supported for quivers of finite type.

**EXAMPLES:**

5.1. Comprehensive Module List
sage: Fg = ClusterQuiver([[1,2]]).g_vector_fan(); Fg
Rational polyhedral fan in 2-d lattice N
sage: Fg.ngenerating_cones()
5

sage: Fg = ClusterQuiver([[1,2],[2,3]]).g_vector_fan(); Fg
Rational polyhedral fan in 3-d lattice N
sage: Fg.ngenerating_cones()
14
sage: Fg.is_smooth()
True

sage: Fg = ClusterQuiver([[1,2],[2,3],[3,1]]).g_vector_fan(); Fg
Rational polyhedral fan in 3-d lattice N
sage: Fg.ngenerating_cones()
14
sage: Fg.is_smooth()
True

>>> from sage.all import *

>>> Fg = ClusterQuiver([[Integer(1),Integer(2)]]).g_vector_fan(); Fg
Rational polyhedral fan in 2-d lattice N
>>> Fg.ngenerating_cones()
5

>>> Fg = ClusterQuiver([[Integer(1),Integer(2)],[Integer(2),Integer(3)]]).g_vector_fan(); Fg
Rational polyhedral fan in 3-d lattice N
>>> Fg.ngenerating_cones()
14
>>> Fg.is_smooth()
True

>>> Fg = ClusterQuiver([[Integer(1),Integer(2)],[Integer(2),Integer(3)],[Integer(3),Integer(1)]]).g_vector_fan(); Fg
Rational polyhedral fan in 3-d lattice N
>>> Fg.ngenerating_cones()
14
>>> Fg.is_smooth()
True

interact(fig_size=1, circular=True)

Start an interactive window for cluster quiver mutations.

Only in Jupyter notebook mode.

INPUT:

- **fig_size** – (default: 1) factor by which the size of the plot is multiplied.
- **circular** – (default: True) if True, the circular plot is chosen, otherwise >>spring<< is used.

is_acyclic()

Return true if self is acyclic.

EXAMPLES:
sage: ClusterQuiver(['A',4]).is_acyclic()
True
sage: ClusterQuiver(['A',2,1,1]).is_acyclic()
True
sage: ClusterQuiver([[0,1],[1,2],[2,0]]).is_acyclic()
False

>>> from sage.all import *

>>> ClusterQuiver(['A',Integer(4)]).is_acyclic()
True

>>> ClusterQuiver(['A',[Integer(2),Integer(1)],Integer(1)]).is_acyclic()
True

>>> ClusterQuiver([[Integer(0),Integer(1)], [Integer(1),Integer(2)],
    [Integer(2),Integer(0)]]).is_acyclic()
False

is_bipartite (return_bipartition=False)
Return True if self is bipartite.

EXAMPLES:

sage: ClusterQuiver(['A',3,1]).is_bipartite()
True

sage: ClusterQuiver(['A',4,1]).is_bipartite()
False

>>> from sage.all import *

>>> ClusterQuiver(['A',Integer(3),Integer(3)]).is_bipartite()
True

>>> ClusterQuiver(['A',Integer(4),Integer(3)]).is_bipartite()
False

is_finite ()
Return True if self is of finite type.

EXAMPLES:

sage: Q = ClusterQuiver(['A',3])
sage: Q.is_finite()
True
sage: Q = ClusterQuiver(['A',2,1])
sage: Q.is_finite()
False
sage: Q = ClusterQuiver(['A',3,['B',3]])
sage: Q.is_finite()
True
sage: Q = ClusterQuiver(['T',4,4,4])
sage: Q.is_finite()
False
sage: Q = ClusterQuiver(['A',3,['T',4,4,4]])
sage: Q.is_finite()
False
sage: Q = ClusterQuiver([['A',3],['T',[2,2,3]]])
sage: Q.is_finite()
True
sage: Q = ClusterQuiver([['A',3],['D',5]])
sage: Q.is_finite()
True
sage: Q = ClusterQuiver([['A',3],['D',5,1]])
sage: Q.is_finite()
False
sage: Q = ClusterQuiver([0,1,2],[1,2,2],[2,0,2])
sage: Q.is_finite()
False
sage: Q = ClusterQuiver([0,1,2],[1,2,2],[2,0,2],[3,4,1],[4,5,1])
sage: Q.is_finite()
False

>>> from sage.all import *
>>> Q = ClusterQuiver(['A',Integer(3)])
>>> Q.is_finite()
True
>>> Q = ClusterQuiver(['A',[Integer(2),Integer(2)],Integer(1)])
>>> Q.is_finite()
False
>>> Q = ClusterQuiver(['A',Integer(3)],[B,Integer(3)])
>>> Q.is_finite()
True
>>> Q = ClusterQuiver(['T',[Integer(4),Integer(4),Integer(4)]]
>>> Q.is_finite()
False
>>> Q = ClusterQuiver(['A',Integer(3)],[T,[Integer(2),Integer(2),Integer(3)]]
>>> Q.is_finite()
True
>>> Q = ClusterQuiver(['A',Integer(3)],[D,Integer(5)])
>>> Q.is_finite()
True
>>> Q = ClusterQuiver(['A',Integer(3)],[T,[Integer(2),Integer(2),Integer(3)]]
>>> Q.is_finite()
True

Chapter 5. Comprehensive Module List
is_mutation_finite(nr_of_checks=None, return_path=False)

Uses a non-deterministic method by random mutations in various directions. Can result in a wrong answer.

INPUT:

- **nr_of_checks** – (default: None) number of mutations applied. Standard is 500*(number of vertices of self).
- **return_path** – (default: False) if True, in case of self not being mutation finite, a path from self to a quiver with an edge label (a,-b) and a*b > 4 is returned.

ALGORITHM:

A quiver is mutation infinite if and only if every edge label (a,-b) satisfy a*b > 4. Thus, we apply random mutations in random directions.

EXAMPLES:

```sage
def Q = ClusterQuiver(['A',10])
def Q._mutation_type = None
def Q.is_mutation_finite()
    True

def Q = ClusterQuiver([(0,1),(1,2),(2,3),(3,4),(4,5),(5,6),(6,7),(7,8),(2,9)])
def Q.is_mutation_finite()
    False
```

```
>>> from sage.all import *

>>> Q = ClusterQuiver(['A',Integer(10)])
>>> Q._mutation_type = None
>>> Q.is_mutation_finite()
    True

>>> Q = ClusterQuiver([(Integer(0),Integer(1)),(Integer(1),Integer(2)),(Integer(2),Integer(3)),(Integer(3),Integer(4)),(Integer(4),Integer(5)),(Integer(5),Integer(6)),(Integer(6),Integer(7)),(Integer(7),Integer(8)),(Integer(9),Integer(9))])
>>> Q.is_mutation_finite()
    False
```

**m()**

Return the number of frozen vertices of self.

EXAMPLES:

```sage
def Q = ClusterQuiver(['A',4])
def Q.m()
    0

def T = ClusterQuiver(Q.digraph().edges(sort=True), frozen=[3])
def T.m()
    3

def T.m()
    1
```

```sage
def Q = ClusterQuiver(['A',Integer(4)])
def Q.m()
```

(continues on next page)
\begin{verbatim}
>>> T = ClusterQuiver(Q.digraph().edges(sort=True), frozen=[Integer(3)])
>>> T.n()
3
>>> T.m()
1
\end{verbatim}

\textbf{mutate} \textit{(data, inplace=True)}

Mutates \textit{self} at a sequence of vertices.

INPUT:

- \textit{sequence} – a vertex of \textit{self}, an iterator of vertices of \textit{self}, a function which takes in the ClusterQuiver and returns a vertex or an iterator of vertices, or a string of the parameter wanting to be called on ClusterQuiver that will return a vertex or an iterator of vertices.

- \textit{inplace} – (default: True) if False, the result is returned, otherwise \textit{self} is modified.

EXAMPLES:

\begin{verbatim}
sage: Q = ClusterQuiver(['A',4]); Q.b_matrix()
[ 0 1 0 0]
[-1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -1 0]

sage: Q.mutate(0); Q.b_matrix()
[ 0 -1 0 0]
[ 1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -1 0]

sage: T = Q.mutate(0, inplace=False); T
Quiver on 4 vertices of type ['A', 4]

sage: Q.mutate(0)
sage: Q == T
True

sage: Q.mutate([0,1,0])
sage: Q.b_matrix()
[ 0 -1 1 0]
[ 1 0 0 0]
[-1 0 0 1]
[ 0 0 -1 0]

sage: Q = ClusterQuiver(QuiverMutationType([[A',1],[A',3]]))
sage: Q.b_matrix()
[ 0 0 0 0]
[ 0 0 1 0]
[ 0 -1 0 -1]
[ 0 0 1 0]

sage: T = Q.mutate(0,inplace=False)
sage: Q == T
True
\end{verbatim}

(continues on next page)
sage: Q = ClusterQuiver(['A',3]); Q.b_matrix()
[ 0 1 0]
[-1 0 -1]
[ 0 1 0]
sage: Q.mutate('first_sink'); Q.b_matrix()
[ 0 -1 0]
[ 1 0 1]
[ 0 -1 0]
sage: Q.mutate('first_source'); Q.b_matrix()
[ 0 1 0]
[-1 0 -1]
[ 0 1 0]

sage: dg = DiGraph()
sage: dg.add_vertices(['a','b','c','d','e'])
sage: dg.add_edges([['a','b'], ['b','c'], ['c','d'], ['d','e']])
sage: Q2 = ClusterQuiver(dg, frozen=['c']); Q2.b_matrix()
[ 0 1 0 0]
[-1 0 0 0]
[ 0 0 0 1]
[ 0 0 -1 0]
[ 0 -1 1 0]
sage: Q2.mutate('a'); Q2.b_matrix()
[ 0 -1 0 0]
[ 1 0 0 0]
[ 0 0 0 1]
[ 0 0 -1 0]
[ 0 -1 1 0]

sage: from sage.all import *

>>> Q = ClusterQuiver(['A',Integer(4)]); Q.b_matrix()
[ 0 1 0 0]

[ 0 1 0 1]
[ 0 0 -1 0]

>>> Q.mutate(Integer(0)); Q.b_matrix()
[ 0 -1 0 0]
[ 1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -1 0]

>>> T = Q.mutate(Integer(0), inplace=False); T
Quiver on 4 vertices of type ['A', 4]

>>> Q.mutate(Integer(0))

>>> Q == T
True

>>> Q.mutate([Integer(0),Integer(1),Integer(0)])
>>> Q.b_matrix()
[ 0 -1  1  0]
[ 1  0  0  0]
[-1  0  0  1]
[ 0  0 -1  0]

>>> Q = ClusterQuiver(QuiverMutationType([['A',Integer(1)],[A,Integer(3)]]))
>>> Q.b_matrix()
[ 0  0  0  0]
[ 0  0  1  0]
[ 0 -1  0 -1]
[ 0  0  1  0]

>>> T = Q.mutate(Integer(0),inplace=False)
>>> Q == T
True

>>> Q = ClusterQuiver([A,Integer(3)]); Q.b_matrix()
[ 0  1  0]
[-1  0 -1]
[ 0  1  0]

>>> Q.mutate('first_sink'); Q.b_matrix()
[ 0 -1  0]
[ 1  0  1]
[ 0 -1  0]

>>> Q.mutate('first_source'); Q.b_matrix()
[ 0  1  0]
[-1  0 -1]
[ 0  1  0]

>>> dg = DiGraph()
>>> dg.add_vertices(['a','b','c','d','e'])
>>> dg.add_edges(['a','b','c','d','e'])
>>> Q2 = ClusterQuiver(dg, frozen=['c']); Q2.b_matrix()
[ 0  1  0  0  0]
[ 0  0  0  1  0]
[ 0 -1  1  0  0]

>>> Q2.mutate('a'); Q2.b_matrix()
[ 0 -1  0  0  0]
[ 1  0  0  0  0]
[ 0  0  1  0  0]
[ 0  0 -1  0  0]
[ 0 -1  1  0  0]

>>> dg = DiGraph([('a', 'b'), ('b', 'c'), format='list_of_edges')
>>> Q = ClusterQuiver(dg); Q
Quiver on 3 vertices
>>> Q.mutate(['a', 'b'],inplace=False).digraph().edges(sort=True)
[('a', 'b', (1, -1)), ('c', 'b', (1, -1))]

**mutation_class** (depth=+Infinity, show_depth=False, return_paths=False, data_type='quiver', up_to_equivalence=True, sink_source=False)

Return the mutation class of self together with certain constraints.

**INPUT:**
• depth – (default: infinity') integer, only seeds with distance at most
    depth from `self` are returned
• show_depth – (default: False) if True, the actual depth of the mutation is shown
• return_paths – (default: False) if True, a shortest path of mutation sequences from self to the
given quiver is returned as well
• data_type – (default: "quiver") can be one of the following:
  – "quiver" – the quiver is returned
  – "dig6" – the dig6-data is returned
  – "path" – shortest paths of mutation sequences from self are returned
• sink_source – (default: False) if True, only mutations at sinks and sources are applied

EXAMPLES:

```python
sage: Q = ClusterQuiver(["A", 3])
sage: Ts = Q.mutation_class()
sage: for T in Ts: print(T)
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
sage: Ts = Q.mutation_class(depth=1)
sage: for T in Ts: print(T)
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]

Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
```

(continues on next page)
Quiver on 3 vertices of type ['A', 3]

```python
sage: Ts = Q.mutation_class(return_paths=\texttt{True}, up_to_equivalence=\texttt{False})
sage: len(Ts)
14
sage: Ts[0]
(Quiver on 3 vertices of type ['A', 3], [])
```

```python
sage: Ts = Q.mutation_class(show_depth=\texttt{True})
Depth: 0 found: 1 Time: ... s
Depth: 1 found: 3 Time: ... s
Depth: 2 found: 4 Time: ... s
```

```python
sage: Ts = Q.mutation_class(show_depth=\texttt{True}, up_to_equivalence=\texttt{False})
Depth: 0 found: 1 Time: ... s
Depth: 1 found: 4 Time: ... s
Depth: 2 found: 6 Time: ... s
Depth: 3 found: 10 Time: ... s
Depth: 4 found: 14 Time: ... s
```

```python
>>> from sage.all import *
>>> Q = ClusterQuiver(['A', Integer(3)])
>>> Ts = Q.mutation_class()
```
mutation_class_iter (depth=+$\infty$, show_depth=False, return_paths=False, data_type='quiver', up_to_equivalence=True, sink_source=False)

Return an iterator for the mutation class of self together with certain constraints.

INPUT:

- depth – (default: infinity) integer, only quivers with distance at most depth from self are returned.
- show_depth – (default: False) if True, the actual depth of the mutation is shown.
- return_paths – (default: False) if True, a shortest path of mutation sequences from self to the given quiver is returned as well.
- data_type – (default: “quiver”) can be one of the following:
  - "quiver"
  - "matrix"
  - "digraph"
  - "dig6"
  - "path"
- up_to_equivalence – (default: True) if True, only one quiver for each graph-isomorphism class is recorded.
- sink_source – (default: False) if True, only mutations at sinks and sources are applied.

EXAMPLES:

```
sage: Q = ClusterQuiver(['A', 3])
sage: it = Q.mutation_class_iter()
sage: for T in it: print(T)
Quiver on 3 vertices of type ['A', 3]
```

(continues on next page)
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]

sage: it = Q.mutation_class_iter(depth=1)

sage: for T in it: print(T)

Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]

sage: it = Q.mutation_class_iter(show_depth=True)

sage: for T in it: pass

Depth: 0  found: 1  Time: ... s
Depth: 1  found: 3  Time: ... s

>>> it = Q.mutation_class_iter(return_paths=True, data_type='matrix')
>>> next(it)
(([-1 0 -1 0] [-1 0 -1 0] [ 0 1 0 1]), [])
```

```python
dg = DiGraph([['a', 'b'], ['b', 'c']], format=list_of_edges)
S = ClusterQuiver(dg, frozen=['b'])
S.mutation_class()
```

**mutation_sequence** *(sequence, show_sequence=False, fig_size=1.2)*

Return a list containing the sequence of quivers obtained from `self` by a sequence of mutations on vertices.

**INPUT:**

- `sequence` – a list or tuple of vertices of `self`.
- `show_sequence` – (default: False) if True, a png containing the mutation sequence is shown.
- `fig_size` – (default: 1.2) factor by which the size of the sequence is expanded.

**EXAMPLES:**

```python
sage: Q = ClusterQuiver(['A', 4])
sage: seq = Q.mutation_sequence([0,1]); seq
[Quiver on 4 vertices of type ['A', 4],
 Quiver on 4 vertices of type ['A', 4],
 Quiver on 4 vertices of type ['A', 4]]
sage: [T.b_matrix() for T in seq]
[[ 0 0 -1 0]
 [ 0 0 -1 0]
 [ 0 0 -1 0]
 [ 0 0 -1 0]],
[[ 0 0 0 -1]
 [ 0 -1 0 -1]
 [ 0 0 0 0]
 [ 0 0 0 0]],
[[ 0 0 0 0]
 [ 0 0 0 0]
 [ 0 0 0 0]
 [ 0 0 0 0]]
```

(continues on next page)
>>> from sage.all import *
>>> Q = ClusterQuiver(['A',Integer(4)])
>>> seq = Q.mutation_sequence([Integer(0),Integer(1)]); seq
[Quiver on 4 vertices of type ['A', 4],
 Quiver on 4 vertices of type ['A', 4],
 Quiver on 4 vertices of type ['A', 4]]
>>> [T.b_matrix() for T in seq]
[
 [ 0 1 0 0] [ 0 -1 0 0] [ 0 1 -1 0]
[-1 0 -1 0] [ 1 0 -1 0] [-1 0 1 0]
 [ 0 1 0 1] [ 0 1 0 1] [ 1 -1 0 1]
[ 0 0 -1 0], [ 0 0 -1 0], [ 0 0 -1 0]
]

mutation_type()

Return the mutation type of self.

Return the mutation type of each connected component of self if it can be determined, otherwise, the mutation type of this component is set to be unknown.

The mutation types of the components are ordered by vertex labels.

If you do many type recognitions, you should consider to save exceptional mutation types using save_quiver_data()

WARNING:

- All finite types can be detected,
- All affine types can be detected, EXCEPT affine type D (the algorithm is not yet implemented)
- All exceptional types can be detected.

EXAMPLES:

```python
sage: ClusterQuiver(['A',4]).mutation_type()
['A', 4]
sage: ClusterQuiver(['A', (3,1),1]).mutation_type()
['A', [1, 3], 1]
sage: ClusterQuiver(['C',2]).mutation_type()
['B', 2]
sage: ClusterQuiver(['B',4,1]).mutation_type()
['BD', 4, 1]
```

>> from sage.all import *
>> ClusterQuiver(['A',Integer(4)]).mutation_type()
['A', 4]
>> ClusterQuiver(['A', (Integer(3),Integer(1)),Integer(1)]).mutation_type()
['A', [1, 3], 1]
>> ClusterQuiver(['C',Integer(2)]).mutation_type()
['B', 2]
>> ClusterQuiver(['B',Integer(4),Integer(1)]).mutation_type()
['BD', 4, 1]

finite types:
Combinatorics, Release 10.4

```plaintext
sage: Q = ClusterQuiver(["A",5])
sage: Q._mutation_type = None
sage: Q.mutation_type()
["A", 5]

sage: Q = ClusterQuiver([(0,1),(1,2),(2,3),(3,4)])

    → Integer(4), Integer(1)], [Integer(4), Integer(5), Integer(1)]]
>>> Q.mutation_type()
['undetermined finite mutation type', ['A', 3]]

n()
Return the number of free vertices of self.

EXAMPLES:

```python
sage: ClusterQuiver(['A',4]).n()
4
sage: ClusterQuiver(['A',(3,1),1]).n()
4
sage: ClusterQuiver(['B',4]).n()
4
sage: ClusterQuiver(['B',4,1]).n()
5
```

number_of_edges()
Return the total number of edges on the quiver

Note: This only works with non-valued quivers. If used on a non-valued quiver then the positive value is taken to be the number of edges added

OUTPUT:
An integer of the number of edges.

EXAMPLES:

```python
>>> from sage.all import *
>>> ClusterQuiver(['A',Integer(4)]).n()
3
>>> ClusterQuiver(['A',(Integer(3),Integer(1)),Integer(1)]).n()
3
>>> ClusterQuiver(['B',Integer(4)]).n()
3
>>> ClusterQuiver(['B',Integer(4),Integer(1)]).n()
5
```

plot (circular=True, center=(0, 0), directed=True, mark=None, save_pos=False, greens=[])
Return the plot of the underlying digraph of self.
INPUT:

- `circular` – (default: `True`) if `True`, the circular plot is chosen, otherwise `spring` is used.
- `center` – (default: `(0,0)`) sets the center of the circular plot, otherwise it is ignored.
- `directed` – (default: `True`) if `True`, the directed version is shown, otherwise the undirected.
- `mark` – (default: `None`) if set to `i`, the vertex `i` is highlighted.
- `save_pos` – (default: `False`) if `True`, the positions of the vertices are saved.
- `greens` – (default: `[]`) if set to a list, will display the green vertices as green

EXAMPLES:

```python
sage: Q = ClusterQuiver(['A',5])
sage: Q.plot()  # needs sage.plot sage.symbolic
Graphics object consisting of 15 graphics primitives
sage: Q.plot(circular=True)  # needs sage.plot sage.symbolic
Graphics object consisting of 15 graphics primitives
sage: Q.plot(circular=True, mark=1)  # needs sage.plot sage.symbolic
Graphics object consisting of 15 graphics primitives
```

```python
>>> from sage.all import *
>>> Q = ClusterQuiver(['A',Integer(5)])
```

poincare_semistable `(theta, d)`

Return the Poincaré polynomial of the moduli space of semi-stable representations of dimension vector `d`.

INPUT:

- `theta` – stability weight, as list or vector of rationals
- `d` – dimension vector, as list or vector of coprime integers

The semi-stability is taken with respect to the slope function

\[ \mu(d) = \theta(d) / \text{dim}(d) \]

where `d` is a dimension vector.

This uses the matrix-inversion algorithm from [Rei2002].

EXAMPLES:

```python
sage: Q = ClusterQuiver(['A',2])
sage: Q.poincare_semistable([1,0],[1,0])
1
```

```python
sage: Q.poincare_semistable([1,0],[1,1])
```

(continues on next page)
```python
sage: K2 = ClusterQuiver(matrix([[0,2],[-2,0]]))
sage: theta = (1, 0)
sage: K2.poincare_semistable(theta, [1,0])
1
sage: K2.poincare_semistable(theta, [1,1])
v^2 + 1
sage: K2.poincare_semistable(theta, [1,2])
1
sage: K2.poincare_semistable(theta, [1,3])
0
sage: K3 = ClusterQuiver(matrix([[0,3],[-3,0]]))
sage: theta = (1, 0)
sage: K3.poincare_semistable(theta, (2,3))
v^12 + v^10 + 3*v^8 + 3*v^6 + 3*v^4 + v^2 + 1
sage: K3.poincare_semistable(theta, (3,4))(1)
68
```
sage: T = Q.principal_extension(); T
Quiver on 4 vertices of type ['A', 2] with 2 frozen vertices
sage: T2 = T.principal_extension(); T2
Quiver on 6 vertices of type ['A', 2] with 4 frozen vertices
sage: Q.digraph().edges(sort=True)
[(0, 1, (1, -1))]

sage: T.digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 0, (1, -1)), (3, 1, (1, -1))]

sage: T2.digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 0, (1, -1)), (3, 1, (1, -1)), (4, 0, (1, -1)), (5, 1, -\rightarrow (1, -1))]

>>> from sage.all import *
>>> Q = ClusterQuiver(['A',Integer(2)]); Q
Quiver on 2 vertices of type ['A', 2]

>>> T = Q.principal_extension(); T
Quiver on 4 vertices of type ['A', 2] with 2 frozen vertices

>>> T2 = T.principal_extension(); T2
Quiver on 6 vertices of type ['A', 2] with 4 frozen vertices

>>> Q.digraph().edges(sort=True)
[(0, 1, (1, -1))]

>>> T.digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 0, (1, -1)), (3, 1, (1, -1))]

>>> T2.digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 0, (1, -1)), (3, 1, (1, -1)), (4, 0, (1, -1)), (5, 1, -\rightarrow (1, -1))]

\texttt{qmu\_save} (filename=None)

Save self in a .qmu file.

This file can then be opened in Bernhard Keller’s Quiver Applet.

See https://webusers.imj-prg.fr/~bernhard.keller/quivermutation/

INPUT:

• filename – the filename the image is saved to.

If a filename is not specified, the default name is from\_sage.qmu in the current sage directory.

EXAMPLES:

sage: Q = ClusterQuiver(['F',4,[1,2]])
sage: import tempfile
sage: with tempfile.NamedTemporaryFile(suffix=".qmu") as f:
....:     Q.qmu_save(f.name)

Make sure we can save quivers with \(m! = n\) frozen variables, see Issue #14851:
sage: S = ClusterSeed(['A',3])
sage: T1 = S.principal_extension()
sage: Q = T1.quiver()
sage: import tempfile
sage: with tempfile.NamedTemporaryFile(suffix='.qmu') as f:
    # needs sage.plot sage.symbolic
    Q.qmu_save(f.name)

>>> from sage.all import *
>>> S = ClusterSeed(['A',Integer(3)])
>>> T1 = S.principal_extension()
>>> Q = T1.quiver()
>>> import tempfile
>>> with tempfile.NamedTemporaryFile(suffix='.qmu') as f:
    # needs sage.plot sage.symbolic
    Q.qmu_save(f.name)

relabel (relabelling, inplace=True)

Return the quiver after doing a relabelling

Will relabel the vertices of the quiver

INPUT:

• relabelling – Dictionary of labels to move around

• inplace – (default: True) if True, will return a duplicate of the quiver

EXAMPLES:

sage: S = ClusterQuiver(['A',4]).relabel({1:5,2:go})

>>> from sage.all import *
>>> S = ClusterQuiver(['A',Integer(4)]).relabel({Integer(1):5,Integer(2):'go'})

reorient (data)

Reorient self with respect to the given total order, or with respect to an iterator of edges in self to be reverted.

Warning: This operation might change the mutation type of self.

INPUT:

• data – an iterator defining a total order on self.vertices(), or an iterator of edges in self to be reoriented.

EXAMPLES:

sage: Q = ClusterQuiver(['A', (2,3), 1])

sage: Q.mutation_type()
['A', [2, 3], 1]

sage: Q.reorient([(0,1),(1,2),(2,3),(3,4)])

sage: Q.mutation_type()
['D', 5]

(continues on next page)
 sage: Q.reorient([0,1,2,3,4])
 sage: Q.mutation_type()
 ['A', [1, 4], 1]

>>> from sage.all import *

>>> Q = ClusterQuiver(['A', (Integer(2), Integer(3)), Integer(1)])

>>> Q.mutation_type()
['A', [2, 3], 1]

>>> Q.reorient([(Integer(0), Integer(1)), (Integer(1), Integer(2)), (Integer(2), Integer(3)), (Integer(3), Integer(4))])

>>> Q.mutation_type()
['D', 5]

>>> Q.reorient([Integer(0), Integer(1), Integer(2), Integer(3), Integer(4)])

>>> Q.mutation_type()
['A', [1, 4], 1]

**save_image** (filename, circular=False)

Save the plot of the underlying digraph of self.

INPUT:

- filename – the filename the image is saved to.
- circular – (default: False) if True, the circular plot is chosen, otherwise >>spring<< is used.

EXAMPLES:

 sage: Q = ClusterQuiver(['F', 4, [1, 2]])
 sage: import tempfile
 sage: with tempfile.NamedTemporaryFile(suffix='.png') as f:
     # needs sage.plot sage.symbolic
     ....:     Q.save_image(f.name)

>>> from sage.all import *

>>> Q = ClusterQuiver(['F', Integer(4), [Integer(1), Integer(2)]])

>>> import tempfile

>>> with tempfile.NamedTemporaryFile(suffix='.png') as f:
     # needs sage.plot sage.symbolic
     ....:     Q.save_image(f.name)

**show** (fig_size=1, circular=False, directed=True, mark=None, save_pos=False, greens=[])  

Show the plot of the underlying digraph of self.

INPUT:

- fig_size – (default: 1) factor by which the size of the plot is multiplied.
- circular – (default: False) if True, the circular plot is chosen, otherwise >>spring<< is used.
- directed – (default: True) if True, the directed version is shown, otherwise the undirected.
- mark – (default: None) if set to i, the vertex i is highlighted.
- save_pos – (default: False) if True, the positions of the vertices are saved.
- greens – (default:[]) if set to a list, will display the green vertices as green
sinks()

Return all vertices of self that are sinks.

EXAMPLES:

```
sage: Q = ClusterQuiver(['A',5])
sage: Q.mutate([1,2,4,3,2])
sage: Q.sinks()  
[0, 2]

sage: Q = ClusterQuiver(['A',5])
sage: Q.mutate([2,1,3,4,2])
sage: Q.sinks()  
[3]
```

```
>>> from sage.all import *

>>> Q = ClusterQuiver(['A','Integer(5)'])
>>> Q.mutate([Integer(1),Integer(2),Integer(4),Integer(3),Integer(2)])
>>> Q.sinks()  
[0, 2]

>>> Q = ClusterQuiver(['A','Integer(5)'])
>>> Q.mutate([Integer(2),Integer(1),Integer(3),Integer(4),Integer(2)])
>>> Q.sinks()  
[3]
```

sources()

Return all vertices of self that are sources.

EXAMPLES:

```
sage: Q = ClusterQuiver(['A',5])
sage: Q.mutate([1,2,4,3,2])
sage: Q.sources()  
[]

sage: Q = ClusterQuiver(['A',5])
sage: Q.mutate([2,1,3,4,2])
sage: Q.sources()  
[]
```

```
>>> from sage.all import *

>>> Q = ClusterQuiver(['A','Integer(5)'])
>>> Q.mutate([Integer(1),Integer(2),Integer(4),Integer(3),Integer(2)])
>>> Q.sources()  
[]

>>> Q = ClusterQuiver(['A','Integer(5)'])
>>> Q.mutate([Integer(2),Integer(1),Integer(3),Integer(4),Integer(2)])
>>> Q.sources()  
[1]
```
5.1.22 Quiver mutation types

AUTHORS:

• Gregg Musiker (2012, initial version)
• Christian Stump (2012, initial version)
• Hugh Thomas (2012, initial version)

sage.combinat.cluster_algebra_quiver.quiver_mutation_type.QuiverMutationType(*args)

Quiver mutation types can be seen as a slight generalization of generalized Cartan types.

Background on generalized Cartan types can be found at Wikipedia article Generalized_Cartan_matrix

For the compendium on the cluster algebra and quiver package in Sage see [MS2011]

A $B$-matrix is a skew-symmetrizable $(n \times n)$-matrix $M$. I.e., there exists an invertible diagonal matrix $D$ such that $DM$ is skew-symmetric. $M$ can be encoded as a quiver by having a directed edge from vertex $i$ to vertex $j$ with label $(a, b)$ if $a = M_{i,j} > 0$ and $b = M_{j,i} < 0$. We consider quivers up to mutation equivalence.

To a quiver mutation type we can associate a generalized Cartan type by sending $M$ to the generalized Cartan matrix $C(M)$ obtained by replacing all positive entries by their negatives and adding 2's on the main diagonal.

QuiverMutationType constructs a quiver mutation type object. For more detail on the possible different types, please see the compendium.

INPUT:

The input consists either of a quiver mutation type, or of a letter (a string), a rank (one integer or a list/tuple of integers), and an optional twist (an integer or a list of integers). There are several different naming conventions for quiver mutation types.

• Finite type – letter is a Dynkin type (A-G), and rank is the rank.
• Affine type – there is more than one convention for naming affine types.
  – Kac’s notation: letter is a Dynkin type, rank is the rank of the associated finite Dynkin diagram, and twist is the twist, which could be 1, 2, or 3. In the special case of affine type A, there is more than one quiver mutation type associated to the Cartan type. In this case only, rank is a pair of integers (i,j), giving the number of edges pointing clockwise and the number of edges pointing counter-clockwise. The total number of vertices is given by i+j in this case.
  – Naive notation: letter is one of ‘BB’, ‘BC’, ‘BD’, ‘CC’, ‘CD’. The name specifies the two ends of the diagram, which are joined by a path. The total number of vertices is given by rank +1 (to match the indexing people expect because these are affine types). In general, rank must be large enough for the picture to make sense, but we accept letter is BC and rank=1.
  – Macdonald notation: for the dual of an untwisted affine type (such as ['C', 6, 1]), we accept a twist of -1 (i.e., ['C',6,-1]).
• Elliptic type – letter is a Dynkin type, rank is the rank of the finite Dynkin diagram, and twist is a tuple of two integers. We follow Saito’s notation.
• Other shapes:
  – Rank 2: letter is ‘R2’, and rank is a pair of integers specifying the label on the unique edge.
  – Triangle: letter is TR, and rank is the number of vertices along a side.
- T: This defines a quiver shaped like a T. letter is ‘T’, and the rank is a triple, whose entries specify the number of vertices along each path from the branch point (counting the branch point).

- Grassmannian: This defines the cluster algebra (without coefficients) corresponding to the cluster algebra with coefficients which is the coordinate ring of a Grassmannian. letter is ‘GR’. rank is a pair of integers \((k, n)\) with \(k < n\) specifying the Grassmannian of \(k\)-planes in \(n\)-space. This defines a quiver given by a \((k-1) \times (n-k-1)\) grid where each square is cyclically oriented.

- Exceptional mutation finite quivers: The two exceptional mutation finite quivers, found by Derksen-Owen, have letter as ‘X’ and rank 6 or 7, equal to the number of vertices.

- AE, BE, CE, DE: Quivers are built of one end which looks like type (affine A), B, C, or D, and the other end which looks like type E (i.e., it consists of two antennae, one of length one, and one of length two). letter is ‘AE’, ‘BE’, ‘CE’, or ‘DE’, and rank is the total number of vertices. Note that ‘AE’ is of a slightly different form and requires rank to be a pair of integers \((i, j)\) just as in the case of affine type A. See Exercise 4.3 in Kac’s book Infinite Dimensional Lie Algebras for more details.

- Infinite type E: It is also possible to obtain infinite-type E quivers by specifying letter as ‘E’ and rank as the number of vertices.

REFERENCES:

- A good reference for finite and affine Dynkin diagrams, including Kac’s notation, is the Wikipedia article Dynkin_diagram.

- A good reference for the skew-symmetrizable elliptic diagrams is “Cluster algebras of finite mutation type via unfolding” by A. Felikson, M. Shapiro, and P. Tumarkin, [FST2012].

EXAMPLES:

Finite types:

```
sage: QuiverMutationType('A', 1)
['A', 1]
sage: QuiverMutationType('A', 5)
['A', 5]
sage: QuiverMutationType('B', 2)
['B', 2]
sage: QuiverMutationType('B', 5)
['B', 5]
sage: QuiverMutationType('C', 2)
['C', 2]
sage: QuiverMutationType('C', 5)
['C', 5]
sage: QuiverMutationType('D', 2)
[['A', 1], ['A', 1]]
sage: QuiverMutationType('D', 3)
['A', 3]
sage: QuiverMutationType('D', 4)
['D', 4]
sage: QuiverMutationType('E', 6)
['E', 6]
sage: QuiverMutationType('G', 2)
['G', 2]
```
```
sage: QuiverMutationType('A', (1, 0), 1)
['A', 1]

sage: QuiverMutationType('A', (2, 0), 1)
[ ['A', 1], ['A', 1] ]

sage: QuiverMutationType('A', (7, 0), 1)
['D', 7]
```

```
>>> from sage.all import *

>>> QuiverMutationType('A', Integer(1))
['A', 1]

>>> QuiverMutationType('A', Integer(5))
['A', 5]

>>> QuiverMutationType('B', Integer(2))
['B', 2]

>>> QuiverMutationType('C', Integer(2))
['C', 2]

>>> QuiverMutationType('D', Integer(2))
[ ['A', 1], ['A', 1] ]

>>> QuiverMutationType('E', Integer(6))
['E', 6]

>>> QuiverMutationType('G', Integer(2))
['G', 2]

>>> QuiverMutationType('A', (Integer(1), Integer(0)), Integer(1))
['A', 1]

>>> QuiverMutationType('A', (Integer(2), Integer(0)), Integer(1))
[ ['A', 1], ['A', 1] ]

>>> QuiverMutationType('A', (Integer(7), Integer(0)), Integer(1))
['D', 7]
```

**Affine types:**

```
sage: QuiverMutationType('A', (1, 1), 1)
['A', [1, 1], 1]

sage: QuiverMutationType('A', (2, 4), 1)
['A', [2, 4], 1]
```

```
sage: QuiverMutationType('BB', 2, 1)
['BB', 2, 1]
```
sage: QuiverMutationType('BB', 4, 1)
['BB', 4, 1]
sage: QuiverMutationType('CC', 2, 1)
['CC', 2, 1]
sage: QuiverMutationType('CC', 4, 1)
['CC', 4, 1]
sage: QuiverMutationType('BC', 1, 1)
['BC', 1, 1]
sage: QuiverMutationType('BC', 5, 1)
['BC', 5, 1]
sage: QuiverMutationType('BD', 3, 1)
['BD', 3, 1]
sage: QuiverMutationType('BD', 5, 1)
['BD', 5, 1]
sage: QuiverMutationType('CD', 3, 1)
['CD', 3, 1]
sage: QuiverMutationType('CD', 5, 1)
['CD', 5, 1]
sage: QuiverMutationType('D', 4, 1)
['D', 4, 1]
sage: QuiverMutationType('D', 6, 1)
['D', 6, 1]
sage: QuiverMutationType('E', 6, 1)
['E', 6, 1]
sage: QuiverMutationType('E', 7, 1)
['E', 7, 1]
sage: QuiverMutationType('E', 8, 1)
['E', 8, 1]
sage: QuiverMutationType('F', 4, 1)
['F', 4, 1]
sage: QuiverMutationType('F', 4, -1)
['F', 4, -1]
sage: QuiverMutationType('G', 2, 1)
['G', 2, 1]
sage: QuiverMutationType('G', 2, -1)
['G', 2, -1]
sage: QuiverMutationType('A', 3, 2) == QuiverMutationType('D', 3, 2)
True

>>> from sage.all import *
>>> QuiverMutationType('A', Integer(1), Integer(1))
['A', [1, 1], 1]
>>> QuiverMutationType('A', Integer(2), Integer(4)), Integer(1))
['A', [2, 4], 1]

>>> QuiverMutationType('BB', Integer(2), Integer(1))
['BB', 2, 1]
>>> QuiverMutationType('BB', Integer(4), Integer(1))
Combinatorics, Release 10.4

```python
>>> QuiverMutationType('CC', Integer(2), Integer(1))
['CC', 2, 1]
>>> QuiverMutationType('CC', Integer(4), Integer(1))
['CC', 4, 1]

>>> QuiverMutationType('BC', Integer(1), Integer(1))
['BC', 1, 1]
>>> QuiverMutationType('BC', Integer(5), Integer(1))
['BC', 5, 1]

['D', 6, 1]

>>> QuiverMutationType('E', Integer(6), Integer(1))
['E', 6, 1]
>>> QuiverMutationType('E', Integer(7), Integer(1))
['E', 7, 1]
>>> QuiverMutationType('E', Integer(8), Integer(1))
['E', 8, 1]

>>> QuiverMutationType('F', Integer(4), Integer(1))
['F', 4, 1]
>>> QuiverMutationType('F', Integer(4), -Integer(1))
['F', 4, -1]

>>> QuiverMutationType('G', Integer(2), Integer(1))
['G', 2, 1]
>>> QuiverMutationType('G', Integer(2), -Integer(1))
['G', 2, -1]

>>> QuiverMutationType('A', Integer(3), Integer(2)) == QuiverMutationType('D', -Integer(3), Integer(2))
True
```

Affine types using Kac’s Notation:

```python
sage: QuiverMutationType('A', 1, 1)
['A', [1, 1], 1]
sage: QuiverMutationType('B', 5, 1)
['BD', 5, 1]
sage: QuiverMutationType('C', 5, 1)
['CC', 5, 1]
sage: QuiverMutationType('A', 2, 2)
['BC', 1, 1]
```

(continues on next page)
sage: QuiverMutationType('A', 7, 2)
['CD', 4, 1]
sage: QuiverMutationType('A', 8, 2)
['BC', 4, 1]
sage: QuiverMutationType('B', 6, 2)
['BB', 5, 1]
sage: QuiverMutationType('E', 6, 2)
['F', 4, -1]
sage: QuiverMutationType('D', 4, 3)
['G', 2, -1]

>>> from sage.all import *

>>> QuiverMutationType('A', Integer(1), Integer(1))
['A', [1, 1], 1]
>>> QuiverMutationType('B', Integer(5), Integer(1))
['BD', 5, 1]
>>> QuiverMutationType('C', Integer(5), Integer(1))
['CC', 5, 1]

Elliptic types:

sage: QuiverMutationType('E', 6, [1, 1])
['E', 6, [1, 1]]
sage: QuiverMutationType('F', 4, [2, 1])
['F', 4, [1, 2]]
sage: QuiverMutationType('G', 2, [3, 3])
['G', 2, [3, 3]]

>>> from sage.all import *

>>> QuiverMutationType('E', Integer(6), [Integer(1), Integer(1)])
['E', 6, [1, 1]]
>>> QuiverMutationType('F', Integer(4), [Integer(2), Integer(1)])
['F', 4, [1, 2]]

Mutation finite types:

Rank 2 cases:

sage: QuiverMutationType('R2', (1, 1))
['A', 2]
sage: QuiverMutationType('R2', (1, 2))
['B', 2]
sage: QuiverMutationType('R2', (1, 3))
['G', 2]
sage: QuiverMutationType('R2', (1, 4))
['BC', 1, 1]
sage: QuiverMutationType('R2', (1, 5))
['R2', [1, 5]]
sage: QuiverMutationType('R2', (2, 2))
['A', [1, 1], 1]
sage: QuiverMutationType('R2', (3, 5))
['R2', [3, 5]]

```python
>>> from sage.all import *
>>> QuiverMutationType(R2,(Integer(1), Integer(1)))
[A, 2]
>>> QuiverMutationType(R2,(Integer(1), Integer(2)))
[B, 2]
>>> QuiverMutationType(R2,(Integer(1), Integer(3)))
['G', 2]
>>> QuiverMutationType(R2,(Integer(1), Integer(4)))
['BC', 1, 1]
>>> QuiverMutationType(R2,(Integer(1), Integer(5)))
['R2', [1, 5]]
>>> QuiverMutationType(R2,(Integer(2), Integer(2)))
['A', [1, 1], 1]
>>> QuiverMutationType(R2,(Integer(3), Integer(5)))
['R2', [3, 5]]
```

Exceptional Derksen-Owen quivers:

sage: QuiverMutationType('X', 6)
['X', 6]

```python
>>> from sage.all import *
>>> QuiverMutationType('X', Integer(6))
['X', 6]
```

(Mainly) mutation infinite types:

Infinite type E:

sage: QuiverMutationType('E', 9)
['E', 8, 1]
sage: QuiverMutationType('E', 10)
['E', 10]
sage: QuiverMutationType('E', 12)
['E', 12]
sage: QuiverMutationType('AE', (2, 3))
['AE', [2, 3]]
sage: QuiverMutationType('BE', 5)
['BE', 5]
sage: QuiverMutationType('CE', 5)
['CE', 5]
sage: QuiverMutationType('DE', 6)
['DE', 6]
Grassmannian types:

```python
sage: QuiverMutationType('GR', (2, 4))
['A', 1]
sage: QuiverMutationType('GR', (2, 6))
['A', 3]
sage: QuiverMutationType('GR', (3, 6))
['D', 4]
sage: QuiverMutationType('GR', (3, 7))
['E', 6]
sage: QuiverMutationType('GR', (3, 8))
['E', 8]
sage: QuiverMutationType('GR', (3, 10))
['GR', [3, 10]]
```

```python
>>> from sage.all import *
```
```python
>>> from sage.all import *
>>> QuiverMutationType('TR', Integer(2))
['A', 3]
>>> QuiverMutationType('TR', Integer(3))
['D', 6]
>>> QuiverMutationType('TR', Integer(4))
['E', 8, [1, 1]]
>>> QuiverMutationType('TR', Integer(5))
['TR', 5]
```

**Types:**

```

(continues on next page)
Reducible types:

```
sage: QuiverMutationType(['A',3],['B',4])
[['A', 3], ['B', 4]]
```

```python
from sage.all import *
```

```
sage: QuiverMutationType(['A',Integer(3)],['B',Integer(4)])
[['A', 3], ['B', 4]]
```

```python
class sage.combinat.cluster_algebra_quiver.quiver_mutation_type.
QuiverMutationTypeFactory
    bases: SageObject

    samples (finite=None, affine=None, elliptic=None, mutation_finite=None)

    Return a sample of the available quiver mutations types.

    INPUT:

    • finite
    • affine
    • elliptic
    • mutation_finite

    All four input keywords default values are None. If set to True or False, only these samples are returned.

    EXAMPLES:

```
sage: QuiverMutationType.samples()
[['A', 1], ['A', 5], ['B', 2], ['B', 5], ['C', 3], ['C', 5], ['A', 1], ['A', 1], ['D', 5], ['E', 6], ['E', 7], ['E', 8], ['F', 4], ['G', 2], ['A', 1], ['A', 4], ['B', 4, 1], ['BB', 5, 1], ['E', 6], ['E', 7], ['E', 11], ['E', 11], ['R2', 1], ['R2', 3], ['E', 10], ['BE', 5], ['GR', 3], ['T', 3, 3, 4]]
```

```
sage: QuiverMutationType.samples(finite=True)
[['A', 1], ['A', 5], ['B', 2], ['B', 5], ['C', 3], ['C', 5], ['A', 1], ['A', 1], ['D', 5], ['E', 6], ['E', 7], ['E', 8], ['F', 4], ['G', 2]]
```

```
sage: QuiverMutationType.samples(affine=True)
[['A', 1], ['A', 4], ['B', 4, 1], ['BB', 5, 1]]
```

```
sage: QuiverMutationType.samples(elliptic=True)
[['E', 6], ['E', 7], ['E', 11], ['E', 11]]
```

```
sage: QuiverMutationType.samples(mutation_finite=False)
[['R2', 1], ['R2', 3], ['E', 10], ['BE', 5], ['GR', 3], ['T', 3, 3, 4]]
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> QuiverMutationType.samples()
[['A', 1], ['A', 5], ['B', 2], ['B', 5], ['C', 3],

 ['GR', [3, 10]], ['T', [3, 3, 4]]]
```

```python
class sage.combinat.cluster_algebra_quiver.quiver_mutation_type.QuiverMutationType_Irreducible

Bases: QuiverMutationType_abstract

The mutation type for a cluster algebra or a quiver. Should not be called directly, but through QuiverMutationType.

class_size()

If it is known, the size of the mutation class of all quivers which are mutation equivalent to the standard quiver of self (up to isomorphism) is returned.

Otherwise, NotImplemented is returned.

Formula for finite type A is taken from Torkildsen - Counting cluster-tilted algebras of type \(A_n\). Formulas for affine type A and finite type D are taken from Bastian, Prellberg, Rubey, Stump - Counting the number of elements in the mutation classes of \(\tilde{A}_n\) quivers. Formulas for finite and affine types B and C are proven but not yet published. Conjectural formulas for several other non-simply-laced affine types are implemented. Exceptional Types (finite, affine, and elliptic) E, F, G, and X are hardcoded.

EXAMPLES:

```
sage: mut_type = QuiverMutationType( ['A',5] ); mut_type
['A', 5]
sage: mut_type.class_size()
19

sage: mut_type = QuiverMutationType( ['A',[10,3], 1] ); mut_type
['A', [10, 3], 1]
sage: mut_type.class_size()
142120
```

(continues on next page)
sage: mut_type = QuiverMutationType( ['B', 6] ); mut_type
['B', 6]
sage: mut_type.class_size()
132

sage: mut_type = QuiverMutationType( ['BD', 6, 1] ); mut_type
['BD', 6, 1]
sage: mut_type.class_size()
Warning: This method uses a formula which has not been proved correct.
504

sage: from sage.all import *

sage: mut_type = QuiverMutationType( ['A', 5] ); mut_type
['A', 5]
sage: mut_type.class_size()
19

sage: mut_type = QuiverMutationType( ['A', [10, 3], 1] ); mut_type
['A', [3, 10], 1]
sage: mut_type.class_size()
142120

sage: mut_type = QuiverMutationType( ['B', 6] ); mut_type
['B', 6]
sage: mut_type.class_size()
132

sage: mut_type = QuiverMutationType( ['BD', 6, 1] ); mut_type
['BD', 6, 1]
sage: mut_type.class_size()
Warning: This method uses a formula which has not been proved correct.
504

Check that Issue #14048 is fixed:

sage: mut_type = QuiverMutationType( ['F', 4, (2, 1)] )
sage: mut_type.class_size()
90

sage: from sage.all import *

sage: mut_type = QuiverMutationType( ['F', 4, (2, 1)] )
sage: mut_type.class_size()
90

dual()

Return the QuiverMutationType which is dual to self.

EXAMPLES:

sage: mut_type = QuiverMutationType('A', 5); mut_type
['A', 5]
sage: mut_type.dual()
['A', 5]
sage: mut_type = QuiverMutationType('B', 5); mut_type
(continues on next page)
irreducible_components()  
Return a list of all irreducible components of self.

EXAMPLES:

```python
sage: mut_type = QuiverMutationType(['A', 3]); mut_type
['A', 3]
sage: mut_type.irreducible_components()
(['A', 3],)
```

```python
>>> from sage.all import *

sage: mut_type = QuiverMutationType(['A', 3]); mut_type
['A', 3]
sage: mut_type.irreducible_components()
(['A', 3],)
```

```
irreducible_components()  
Return a list of all irreducible components of self.

EXAMPLES:

```python
sage: mut_type = QuiverMutationType(['A', 3]); mut_type
['A', 3]
sage: mut_type.irreducible_components()
(['A', 3],)
```

```python
>>> from sage.all import *

sage: mut_type = QuiverMutationType(['A', 3]); mut_type
['A', 3]
sage: mut_type.irreducible_components()
(['A', 3],)
```
Combinatorics, Release 10.4

20

```python
sage: mut_type = QuiverMutationType(['A',3],['B',3],['X',6])
sage: mut_type
['A', 3], ['B', 3], ['X', 6]
sage: mut_type.class_size()
100
```

```python
>>> from sage.all import *

```  

```python
>>> mut_type = QuiverMutationType(['A',Integer(3)],[B,Integer(3)]); mut_type
['A', 3], ['B', 3]
```

```python
>>> mut_type.class_size()
20
```

```python
>>> mut_type = QuiverMutationType(['A',Integer(3)],[B,Integer(3)],['X',
˓→Integer(6)])
```

```python
>>> mut_type
['A', 3], ['B', 3], ['X', 6]
```

```python
>>> mut_type.class_size()
100
```

dual()

Return the `QuiverMutationType` which is dual to `self`.

EXAMPLES:

```python
sage: mut_type = QuiverMutationType(['A',5],[B,6],[C,5],[D,4]); mut_type
['A', 5], ['B', 6], ['C', 5], ['D', 4]
```

```python
sage: mut_type.dual()
['A', 5], ['C', 6], ['B', 5], ['D', 4]
```

```python
>>> from sage.all import *

```  

```python
>>> mut_type = QuiverMutationType(['A',Integer(5)],[B,Integer(6)],[C,
˓→Integer(5)],[D,Integer(4)]); mut_type
['A', 5], ['B', 6], ['C', 5], ['D', 4]
```

```python
>>> mut_type.dual()
['A', 5], ['C', 6], ['B', 5], ['D', 4]
```

irreducible_components()

Return a list of all irreducible components of `self`.

EXAMPLES:

```python
sage: mut_type = QuiverMutationType('A',3); mut_type
['A', 3]
```

```python
sage: mut_type.irreducible_components()
(['A', 3],)
```

```python
sage: mut_type = QuiverMutationType(['A',3],[B,3]); mut_type
[['A', 3], ['B', 3]]
```

```python
sage: mut_type.irreducible_components()
(['A', 3], ['B', 3])
```

```python
sage: mut_type = QuiverMutationType(['A',3],[B,3],['X',6])
```

```python
sage: mut_type
['A', 3], ['B', 3], ['X', 6]
```

```python
>>> from sage.all import *
```

```python
>>> mut_type = QuiverMutationType(['A',Integer(3)],[B,Integer(3)],['X',
˓→Integer(6)])
```

```python
```

(continues on next page)
Combinatorics, Release 10.4

```python
sage: mut_type.irreducible_components()
(['A', 3], ['B', 3], ['X', 6])

>>> from sage.all import *

>>> mut_type = QuiverMutationType('A', Integer(3)); mut_type
['A', 3]

>>> mut_type.irreducible_components()
(['A', 3],)

>>> mut_type = QuiverMutationType(['A', Integer(3)], ['B', Integer(3)]); mut_type
['A', 3], ['B', 3]

>>> mut_type.irreducible_components()
(['A', 3], ['B', 3])

>>> mut_type = QuiverMutationType(['A', Integer(3)], ['B', Integer(3)], ['X', Integer(6)]);

>>> mut_type
['A', 3], ['B', 3], ['X', 6]

>>> mut_type.irreducible_components()
(['A', 3], ['B', 3], ['X', 6])
```

class sage.combinat.cluster_algebra_quiver.quiver_mutation_type.
QuiverMutationType_abstract

Bases: UniqueRepresentation, SageObject

EXAMPLES:

```python
sage: mut_type1 = QuiverMutationType('A',5)
sage: mut_type2 = QuiverMutationType('A',5)
sage: mut_type3 = QuiverMutationType('A',6)
sage: mut_type1 == mut_type2
True
sage: mut_type1 == mut_type3
False
```

```python
>>> from sage.all import *

>>> mut_type1 = QuiverMutationType('A',Integer(5))

>>> mut_type2 = QuiverMutationType('A',Integer(5))

>>> mut_type3 = QuiverMutationType('A',Integer(6))

>>> mut_type1 == mut_type2
True

>>> mut_type1 == mut_type3
False
```

b_matrix()

Return the B-matrix of the standard quiver of self.

The conventions for B-matrices agree with Fomin-Zelevinsky (up to a reordering of the simple roots).

EXAMPLES:

```python
sage: mut_type = QuiverMutationType(['A',5]); mut_type
['A', 5]
sage: mut_type.b_matrix()  # needs sage.modules
[ 0 1 0 0 0]
```

(continues on next page)
cartan_matrix()  
Return the Cartan matrix of self.

Note that (up to a reordering of the simple roots) the convention for the definition of Cartan matrix, used here and elsewhere in Sage, agrees with the conventions of Kac, Fulton-Harris, and Fomin-Zelevinsky, but disagrees with the convention of Bourbaki. The \((i, j)\) entry is \(2(\alpha_i, \alpha_j)/(\alpha_i, \alpha_i)\).

EXAMPLES:
sage: mut_type = QuiverMutationType(['A', 3], ['B', 3]); mut_type
[ ['A', 3], ['B', 3] ]
sage: mut_type.cartan_matrix()  #...
needs sage.modules
[ 2 -1 0 0 0 0]
[-1 2 -1 0 0 0]
[ 0 -1 2 0 0 0]
[ 0 0 0 2 -1 0]
[ 0 0 0 -1 2 -1]
[ 0 0 0 0 -2 2]

>>> from sage.all import *
>>> mut_type = QuiverMutationType(['A', Integer(5)]); mut_type
['A', 5]
>>> mut_type.cartan_matrix()  #...
needs sage.modules
[ 2 -1 0 0 0]
[-1 2 -1 0 0]
[ 0 -1 2 -1 0]
[ 0 0 -1 2 -1]
[ 0 0 0 -1 2]

>>> mut_type = QuiverMutationType(['A', Integer(3), ['B', Integer(3)]]; mut_type
['A', 3], ['B', 3] ]
>>> mut_type.cartan_matrix()  #...
needs sage.modules
[ 2 -1 0 0 0 0]
[-1 2 -1 0 0 0]
[ 0 -1 2 0 0 0]
[ 0 0 0 2 -1 0]
[ 0 0 0 -1 2 -1]
[ 0 0 0 0 -2 2]

is_affine()
Return True if self is of affine type.

EXAMPLES:
sage: mt = QuiverMutationType(['A', 2])
sage: mt.is_affine()
False
sage: mt = QuiverMutationType(['A', [4, 2], 1])
sage: mt.is_affine()
True

>>> from sage.all import *
>>> mt = QuiverMutationType(['A', Integer(2)])
>>> mt.is_affine()
False
>>> mt = QuiverMutationType(['A', [Integer(4), Integer(2)], Integer(1)])
>>> mt.is_affine()
True

is_elliptic()
Return `True` if `self` is of elliptic type.

EXAMPLES:

```python
sage: mt = QuiverMutationType(['A', 2])
sage: mt.is_elliptic()
False

type: mt = QuiverMutationType(['E', 6, [1, 1]])
sage: mt.is_elliptic()
True

>>> from sage.all import *

>>> mt = QuiverMutationType(['A', Integer(2)])
>>> mt.is_elliptic()
True

```
is_mutation_finite()

Return True if self is of finite mutation type.

This means that its mutation class has only finitely many different B-matrices.

EXAMPLES:

```
sage: mt = QuiverMutationType([D, 5, 1])
sage: mt.is_mutation_finite()
True
```

```
>>> from sage.all import *
>>> mt = QuiverMutationType([D, Integer(5), Integer(1)])
>>> mt.is_mutation_finite()
True
```

is_simply_laced()

Return True if self is simply laced.

This means that the only arrows that appear in the quiver of self are single unlabelled arrows.

EXAMPLES:

```
sage: mt = QuiverMutationType([A, 2])
sage: mt.is_simply_laced()
True
```

```
sage: mt = QuiverMutationType([B, 2])
sage: mt.is_simply_laced()
False
```

```
sage: mt = QuiverMutationType([A, (1, 1), 1])
sage: mt.is_simply_laced()
False
```

```
>>> from sage.all import *
>>> mt = QuiverMutationType([A, Integer(2)])
>>> mt.is_simply_laced()
True
```

```
>>> mt = QuiverMutationType([B, Integer(2)])
>>> mt.is_simply_laced()
False
```

```
>>> mt = QuiverMutationType([A, (Integer(1), Integer(1)), Integer(1)])
>>> mt.is_simply_laced()
False
```

is_skew_symmetric()

Return True if the B-matrix of self is skew-symmetric.

EXAMPLES:

```
sage: mt = QuiverMutationType([A, 2])
sage: mt.is_skew_symmetric()
True
```

```
sage: mt = QuiverMutationType([B, 2])
```

(continues on next page)
Combinatorics, Release 10.4

sage: mt.is_skew_symmetric()
False

sage: mt = QuiverMutationType(['A', (1, 1), 1])
sage: mt.is_skew_symmetric()
True

>>> from sage.all import *

>>> m = QuiverMutationType(['A', Integer(2)])
>>> m.is_skew_symmetric()
True

>>> m = QuiverMutationType(['B', Integer(2)])
>>> m.is_skew_symmetric()
False

>>> m = QuiverMutationType(['A', (Integer(1), Integer(1)), Integer(1)])

Return the classification letter of self.

EXAMPLES:

sage: mut_type = QuiverMutationType(['A', 5]); mut_type
['A', 5]
sage: mut_type.letter()
'A'

sage: mut_type = QuiverMutationType(['BC', 5, 1]); mut_type
['BC', 5, 1]
sage: mut_type.letter()
'BC'

sage: mut_type = QuiverMutationType(['A', 3], ['B', 3]); mut_type
['A', 3], ['B', 3]

sage: mut_type.letter()
'A x B'

sage: mut_type = QuiverMutationType(['A', 3], ['B', 3], ['X', 6]); mut_type
['A', 3], ['B', 3], ['X', 6]

sage: mut_type.letter()
'A x B x X'

>>> from sage.all import *

>>> m = QuiverMutationType(['A', Integer(5)])

>>> m = QuiverMutationType(['BC', Integer(5), Integer(1)])

(continues from previous page)
Combinatorics, Release 10.4

>>> mut_type = QuiverMutationType(['A',Integer(3)],[['A',3],['B',3]]); mut_type
[ ['A', 3], ['B', 3] ]
>>> mut_type.letter()
'A x B'

>>> mut_type = QuiverMutationType(['A',Integer(3)],[['A',3],['B',3],['X',Integer(6)]]); mut_type
[ ['A', 3], ['B', 3], ['X', 6] ]
>>> mut_type.letter()
'A x B x X'

plot (circular=False, directed=True)

Return the plot of the underlying graph or digraph of self.

INPUT:

- circular – (default: False) if True, the circular plot is chosen, otherwise >>spring<< is used.
- directed – (default: True) if True, the directed version is shown, otherwise the undirected.

EXAMPLES:

sage: QMT = QuiverMutationType(['A',5])

sage: pl = QMT.plot()   # needs sage.plot sage.symbolic

sage: pl = QMT.plot(circular=True)   # needs sage.plot sage.symbolic

>>> from sage.all import *

>>> QMT = QuiverMutationType(['A',Integer(5)])

>>> pl = QMT.plot()   # needs sage.plot sage.symbolic

>>> pl = QMT.plot(circular=True)   # needs sage.plot sage.symbolic

properties()

Print a scheme of all properties of self.

Most properties have natural definitions for either irreducible or reducible types. affine and elliptic
are only defined for irreducible types.

EXAMPLES:

sage: mut_type = QuiverMutationType(['A',3]); mut_type
['A', 3]

sage: mut_type.properties()
['A', 3] has rank 3 and the following properties:
 - irreducible: True
 - mutation finite: True
 - simply-laced: True
 - skew-symmetric: True
 - finite: True
 - affine: False
 - elliptic: False

sage: mut_type = QuiverMutationType(['B',3]); mut_type
['B', 3]

sage: mut_type.properties()
[['B', 3] has rank 3 and the following properties:
- irreducible: True
- mutation finite: True
- simply-laced: False
- skew-symmetric: False
- finite: True
- affine: False
- elliptic: False

```
sage: mut_type = QuiverMutationType(['B',3, 1]); mut_type
['BD', 3, 1]
sage: mut_type.properties()
['BD', 3, 1] has rank 4 and the following properties:
- irreducible: True
- mutation finite: True
- simply-laced: False
- skew-symmetric: False
- finite: False
- affine: True
- elliptic: False
```

```
sage: mut_type = QuiverMutationType(['E',6,[1, 1]]); mut_type
['E', 6, [1, 1]]
sage: mut_type.properties()
['E', 6, [1, 1]] has rank 8 and the following properties:
- irreducible: True
- mutation finite: True
- simply-laced: False
- skew-symmetric: True
- finite: False
- affine: False
- elliptic: True
```

```
sage: mut_type = QuiverMutationType(['A',3],['B',3]); mut_type
[['A', 3], ['B', 3]]
sage: mut_type.properties()
[['A', 3], ['B', 3]] has rank 6 and the following properties:
- irreducible: False
- mutation finite: True
- simply-laced: False
- skew-symmetric: False
- finite: True
- affine: False
- elliptic: False
```

```
sage: mut_type = QuiverMutationType('GR',[4,9]); mut_type
['GR', [4, 9]]
sage: mut_type.properties()
['GR', [4, 9]] has rank 12 and the following properties:
- irreducible: True
- mutation finite: False
- simply-laced: True
- skew-symmetric: True
- finite: False
- affine: False
- elliptic: False
```

```python
>>> from sage.all import *
```
```python
>>> mut_type = QuiverMutationType([\'A\', Integer(3)]); mut_type
[\'A\', 3]
>>> mut_type.properties()
[\'A\', 3] has rank 3 and the following properties:
  - irreducible: True
  - mutation finite: True
  - simply-laced: True
  - skew-symmetric: True
  - finite: True
  - affine: False
  - elliptic: False

>>> mut_type = QuiverMutationType([\'B\', Integer(3)]); mut_type
[\'B\', 3]
>>> mut_type.properties()
[\'B\', 3] has rank 3 and the following properties:
  - irreducible: True
  - mutation finite: True
  - simply-laced: False
  - skew-symmetric: False
  - finite: True
  - affine: False
  - elliptic: False

>>> mut_type = QuiverMutationType([\'B\', Integer(3), Integer(1)]); mut_type
[\'BD\', 3, 1]
>>> mut_type.properties()
[\'BD\', 3, 1] has rank 4 and the following properties:
  - irreducible: True
  - mutation finite: True
  - simply-laced: False
  - skew-symmetric: False
  - finite: False
  - affine: True
  - elliptic: False

>>> mut_type = QuiverMutationType([\'E\', Integer(6), [Integer(1), Integer(1)]]); mut_type
[\'E\', 6, [1, 1]]
>>> mut_type.properties()
[\'E\', 6, [1, 1]] has rank 8 and the following properties:
  - irreducible: True
  - mutation finite: True
  - simply-laced: False
  - skew-symmetric: True
  - finite: False
  - affine: False
  - elliptic: True

>>> mut_type = QuiverMutationType([\'A\', Integer(3)], [\'B\', Integer(3)]); mut_type
[[\'A\', 3], [\'B\', 3]]
>>> mut_type.properties()
[[\'A\', 3], [\'B\', 3]] has rank 6 and the following properties:
  - irreducible: False
  - mutation finite: True
  - simply-laced: False
  - skew-symmetric: False
```

(continues on next page)
- finite: True

```python
>>> mut_type = QuiverMutationType('GR', [Integer(4), Integer(9)]); mut_type
['GR', [4, 9]]
```

```python
>>> mut_type.properties()
['GR', [4, 9]] has rank 12 and the following properties:
- irreducible: True
- mutation finite: False
- simply-laced: True
- skew-symmetric: True
- finite: False
- affine: False
- elliptic: False
```

**rank()**

Return the rank in the standard quiver of `self`.

The rank is the number of vertices.

**EXAMPLES:**

```python
sage: mut_type = QuiverMutationType(['A', 5]); mut_type
['A', 5]
sage: mut_type.rank()
5
```

```python
sage: mut_type = QuiverMutationType(['A', [4, 5], 1]); mut_type
['A', [4, 5], 1]
sage: mut_type.rank()
9
```

```python
sage: mut_type = QuiverMutationType(['BC', 5, 1]); mut_type
['BC', 5, 1]
sage: mut_type.rank()
6
```

```python
sage: mut_type = QuiverMutationType(['A', 3], ['B', 3]); mut_type
[['A', 3], ['B', 3]]
sage: mut_type.rank()
6
```

```python
sage: mut_type = QuiverMutationType(['A', 3], ['B', 3], ['X', 6]); mut_type
[['A', 3], ['B', 3], ['X', 6]]
sage: mut_type.rank()
12
```

```python
>>> from sage.all import *
```

```python
>>> mut_type = QuiverMutationType(['A', Integer(5)]); mut_type
['A', 5]
```

```python
>>> mut_type.rank()
5
```

```python
>>> mut_type = QuiverMutationType(['A', [Integer(4), Integer(5)], Integer(1)]);
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> mut_type = QuiverMutationType( ['BC','Integer(5), Integer(1)] ); mut_type
['BC', 5, 1]
>>> mut_type.rank()
6

>>> mut_type = QuiverMutationType( ['A',Integer(3)], ['B',Integer(3)] ); mut_type
['A', 3], [ 'B', 3 ]
>>> mut_type.rank()
6

>>> mut_type = QuiverMutationType( ['A',Integer(3)], ['B',Integer(3)], ['X',
Integer(6)] ); mut_type
['A', 3], [ 'B', 3], ['X', 6 ]
>>> mut_type.rank()
12
```

```python
show(circular=False, directed=True)
```

Show the plot of the underlying digraph of self.

INPUT:

- `circular` – (default: False) if True, the circular plot is chosen, otherwise spring is used.
- `directed` – (default: True) if True, the directed version is shown, otherwise the undirected.

```python
standard_quiver()
```

Return the standard quiver of self.

EXAMPLES:

```python
sage: mut_type = QuiverMutationType( ['A',5] ); mut_type
['A', 5]
sage: mut_type.standard_quiver()
# needs sage.modules
Quiver on 5 vertices of type ['A', 5]

sage: mut_type = QuiverMutationType( ['A',[5,3], 1] ); mut_type
['A', [3, 5], 1]
sage: mut_type.standard_quiver()
# needs sage.modules
Quiver on 8 vertices of type ['A', [3, 5], 1]

sage: mut_type = QuiverMutationType( ['A',3],[ 'B',3]); mut_type
[ ['A', 3], ['B', 3] ]
sage: mut_type.standard_quiver()
# needs sage.modules
Quiver on 6 vertices of type [ ['A', 3], ['B', 3] ]

sage: mut_type = QuiverMutationType( ['A',3],[ 'B',3],[ 'X',6]); mut_type
[ ['A', 3], ['B', 3], ['X', 6] ]
sage: mut_type.standard_quiver()
# needs sage.modules
Quiver on 12 vertices of type [ ['A', 3], ['B', 3], ['X', 6] ]
```

```python
>>> from sage.all import *

```
\begin{verbatim}
['A', 5]
>>> mut_type.standard_quiver()
→needs sage.modules
Quiver on 5 vertices of type ['A', 5]

>>> mut_type = QuiverMutationType( ['A',Integer(5),Integer(3)], Integer(1)])
→)
['A', [3, 5], 1]
>>> mut_type.standard_quiver()
→needs sage.modules
Quiver on 8 vertices of type ['A', [3, 5], 1]

>>> mut_type = QuiverMutationType(["A",Integer(3)],["B",Integer(3)])
; mut_type
[['A', 3], ['B', 3] ]

>>> mut_type.standard_quiver()
→needs sage.modules
Quiver on 6 vertices of type [ ['A', 3], ['B', 3] ]

>>> mut_type = QuiverMutationType(["A",Integer(3)],["B",Integer(3)],["X",
→Integer(6)])
; mut_type
[['A', 3], ['B', 3], ['X', 6] ]

>>> mut_type.standard_quiver()
→needs sage.modules
Quiver on 12 vertices of type [ ['A', 3], ['B', 3], ['X', 6] ]
\end{verbatim}

sage.combinat.cluster_algebra_quiver.quiver_mutation_type.save_quiver_data(n,
up_to=True,
types='ClassicalExceptional',
verbose=True)

Save mutation classes of certain quivers of ranks up to and equal to \( n \) or equal to \( n \) to \texttt{DOT_SAGE/cluster_algebra_quiver/mutation_classes_n.dig6}.

This data will then be used to determine quiver mutation types.

\textbf{INPUT:}

- \( n \) – the rank (or the upper limit on the rank) of the mutation classes that are being saved.
- \( \text{up\_to} \) – (default:True) if True, saves data for ranks smaller than or equal to \( n \). If False, saves data for rank exactly \( n \).
- \( \text{types} \) – (default:’ClassicalExceptional’) if all, saves data for both exceptional mutation-finite quivers and for classical quiver. The input ‘Exceptional’ or ‘Classical’ is also allowed to save only part of this data.
5.1.23 Cluster complex (or generalized dual associahedron)

EXAMPIES:

A first example of a cluster complex:

```
sage: C = ClusterComplex([A, 2]); C
Cluster complex of type [A, 2] with 5 vertices and 5 facets
```

```
>>> from sage.all import *

>>> C = ClusterComplex([A, Integer(2)]); C
Cluster complex of type [A', 2] with 5 vertices and 5 facets
```

Its vertices, facets, and minimal non-faces:

```
sage: C.vertices()
(0, 1, 2, 3, 4)

sage: C.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]

sage: for F in C.facets(): F.cluster()
[(-1, 0), (0, -1)]
[(-1, 0), (0, 1)]
[(0, -1), (1, 0)]
[(1, 0), (1, 1)]
[(1, 1), (0, 1)]

sage: C.minimal_nonfaces()
[[0, 2], [0, 3], [1, 3], [1, 4], [2, 4]]
```

We can do everything we can do on simplicial complexes, e.g. computing its homology:

```
sage: C.homology()
{0: 0, 1: Z}
```

```
>>> from sage.all import *

>>> C.homology()
{0: 0, 1: Z}
```

AUTHORS:
A cluster complex (or generalized dual associahedron).

The cluster complex (or generalized dual associahedron) is a simplicial complex constructed from a cluster algebra. Its vertices are the cluster variables and its facets are the clusters, i.e., maximal subsets of compatible cluster variables.

The cluster complex of type $A_n$ is the simplicial complex with vertices being (proper) diagonals in a convex $(n + 3)$-gon and with facets being triangulations.

The implementation of the cluster complex depends on its connection to subword complexes, see [CLS2014]. Let $c$ be a Coxeter element with reduced word $c$ in a finite Coxeter group $W$, and let $w_0$ be the $c$-sorting word for the longest element $w_0 \in W$.

The multi-cluster complex $\Delta(W, k)$ has vertices in one-to-one correspondence with letters in the word $Q = c^k w_0$ and with facets being complements in $Q$ of reduced expressions for $w_0$.

For $k = 1$, the multi-cluster complex is isomorphic to the cluster complex as defined above.

**EXAMPLES:**

A first example of a cluster complex:

```python
sage: C = ClusterComplex(['A', 2]); C
Cluster complex of type ['A', 2] with 5 vertices and 5 facets
```

```python
>>> from sage.all import *
>>> C = ClusterComplex(['A', Integer(2)]); C
Cluster complex of type ['A', 2] with 5 vertices and 5 facets
```

Its vertices, facets, and minimal non-faces:

```python
sage: C.vertices()
(0, 1, 2, 3, 4)
sage: C.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
sage: C.minimal_nonfaces()
[[0, 2], [0, 3], [1, 3], [1, 4], [2, 4]]
```

```python
>>> from sage.all import *
>>> C.vertices()
(0, 1, 2, 3, 4)
>>> C.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
>>> C.minimal_nonfaces()
[[0, 2], [0, 3], [1, 3], [1, 4], [2, 4]]
```

We can do everything we can do on simplicial complexes, e.g. computing its homology:

```python
sage: C.homology()
{0: 0, 1: Z}
```
We can also create a multi-cluster complex:

```python
>>> from sage.all import *
>>> C.homology()
(0: 0, 1: Z)
```

REFERENCES:

- [CLS2014]

Element

alias of `ClusterComplexFacet`

cyclic_rotation()

Return the operation on the facets of self obtained by the cyclic rotation as defined in [CLS2014].

EXAMPLES:

```python
>>> from sage.all import *
>>> ClusterComplex(['A', Integer(2)]).cyclic_rotation()
<function ...act at ...>
```

k()

Return the index $k$ of self.

EXAMPLES:

```python
>>> from sage.all import *
>>> ClusterComplex(['A', Integer(2)]).k()
1
```

minimal_nonfaces()

Return the minimal non-faces of self.

EXAMPLES:

```python
>>> from sage.all import *
>>> ClusterComplex(['A', Integer(2)]).minimal_nonfaces()
[[0, 2], [0, 3], [1, 3], [1, 4], [2, 4]]
```
class sage.combinat.cluster_complex.ClusterComplexFacet (parent, positions, facet_test=True)

Bases: SubwordComplexFacet

A cluster (i.e., a facet) of a cluster complex.

cluster()

Return this cluster as a set of almost positive roots.

EXAMPLES:

```
sage: C = ClusterComplex(['A', 2])
sage: F = C((0, 1))
sage: F.cluster()
[(-1, 0), (0, -1)]
```

```
>>> from sage.all import *
>>> C = ClusterComplex(['A', Integer(2)])
>>> F = C((Integer(0), Integer(1)))
>>> F.cluster()
[(-1, 0), (0, -1)]
```

product_of_upper_cluster()

Return the product of the upper cluster in reversed order.

EXAMPLES:

```
sage: C = ClusterComplex(['A', 2])
sage: for F in C: F.product_of_upper_cluster().reduced_word()
[]
[2]
[1]
[1, 2]
[1, 2]
```

```
>>> from sage.all import *
>>> C = ClusterComplex(['A', Integer(2)])
>>> for F in C: F.product_of_upper_cluster().reduced_word()
[]
[2]
[1]
[1, 2]
[1, 2]
```

upper_cluster()

Return the part of the cluster that contains positive roots

EXAMPLES:

```
sage: C = ClusterComplex(['A', 2])
sage: F = C((0, 1))
sage: F.upper_cluster()
[]
```

```
>>> from sage.all import *
>>> C = ClusterComplex(['A', Integer(2)])
>>> F = C((Integer(0), Integer(1)))
>>> F.upper_cluster()
[]
```

(continues on next page)
5.1.24 Colored Permutations

Todo: Much of the colored permutations (and element) class can be generalized to $G \wr S_n$

```python
>>> F.upper_cluster()
[]
```

```python
class sage.combinat.colored_permutations.ColoredPermutation(parent, colors, perm)
    Bases: MultiplicativeGroupElement

A colored permutation.

colors()
    Return the colors of self.

    EXAMPLES:

    sage: C = ColoredPermutations(4, 3)
    sage: s1,s2,t = C.gens()
    sage: x = s1*s2*t
    sage: x.colors()
    [1, 0, 0]

    >>> from sage.all import *
    >>> C = ColoredPermutations(Integer(4), Integer(3))
    >>> s1,s2,t = C.gens()
    >>> x = s1*s2*t
    >>> x.colors()
    [1, 0, 0]
```

```python
has_left_descent(i)
    Return True if i is a left descent of self.

    Let $p = (s_1, \ldots, s_n, \sigma)$ be a colored permutation. We say $p$ has a left $n$-descent if $s_n > 0$. If $i < n$, then we say $p$ has a left $i$-descent if either
    • $s_i \neq 0, s_{i+1} = 0$ and $\sigma_i < \sigma_{i+1}$ or
    • $s_i = s_{i+1}$ and $\sigma_i > \sigma_{i+1}$.

    This notion of a left $i$-descent is done in order to recursively construct $w(p) = \sigma_i w(\sigma_i^{-1}p)$, where $w(p)$ denotes a reduced word of $p$.

    EXAMPLES:

    sage: C = ColoredPermutations(2, 4)
    sage: s1,s2,s3,s4 = C.gens()
    sage: x = s4*s1*s2*s3*s4
    sage: x.has_left_descent(i) for i in C.index_set()
    [True, False, False, True]
```

(continues on next page)
sage: [x.has_left_descent(i) for i in C.index_set()]  
[True, False, False, True]

sage: C = ColoredPermutations(3, 3)  
sage: x = C([[2,1,0],[3,1,2]])  
sage: [x.has_left_descent(i) for i in C.index_set()]  
[False, True, False]

length()  

Return the length of self in generating reflections.  
This is the minimal numbers of generating reflections needed to obtain self.

EXAMPLES:

sage: C = ColoredPermutations(3, 3)  
sage: x = C([[2,1,0],[3,1,2]])  
sage: x.length()  
7

sage: C = ColoredPermutations(4, 4)  
sage: x = C([[2,1,0,1],[3,2,4,1]])  
sage: x.length()  
12

>>> from sage.all import *  
(continues on next page)
Combinatorics, Release 10.4

>>> C = ColoredPermutations(Integer(3), Integer(3))
>>> x = C([[Integer(2), Integer(1), Integer(0)], [Integer(3), Integer(1), Integer(2)])
>>> x.length()
7

>>> C = ColoredPermutations(Integer(4), Integer(4))
>>> x = C([[Integer(2), Integer(1), Integer(0), Integer(1)], [Integer(3), Integer(2), Integer(4), Integer(1)])
>>> x.length()
12

one_line_form()

Return the one line form of self.

EXAMPLES:

sage: C = ColoredPermutations(4, 3)
sage: s1, s2, t = C.gens()
sage: x = s1*s2*t
sage: x
[[1, 0, 0], [3, 1, 2]]
sage: x.one_line_form()
[(1, 3), (0, 1), (0, 2)]

permutation()

Return the permutation of self.

This is obtained by forgetting the colors.

EXAMPLES:

sage: C = ColoredPermutations(4, 3)
sage: s1, s2, t = C.gens()
sage: x = s1*s2*t
sage: x
[[1, 0, 0], [3, 1, 2]]
sage: x.permutation()
[3, 1, 2]

reduced_word()

Return a word in the simple reflections to obtain self.
EXAMPLES:

```
sage: C = ColoredPermutations(3, 3)
sage: x = C([[2,1,0],[3,1,2]])
sage: x.reduced_word()
[2, 1, 3, 2, 1, 3, 3]
sage: C = ColoredPermutations(4, 4)
sage: x = C([[2,1,0,1],[3,2,4,1]])
sage: x.reduced_word()
[2, 1, 4, 3, 2, 1, 4, 3, 2, 4, 4, 3]
```

```
>>> from sage.all import *
>>> C = ColoredPermutations(Integer(3), Integer(3))
>>> x = C([[Integer(2),Integer(1),Integer(0)],[Integer(3),Integer(1),Integer(2)])
>>> x.reduced_word()
[2, 1, 3, 2, 1, 3, 3]
>>> C = ColoredPermutations(Integer(4), Integer(4))
>>> x = C([[Integer(2),Integer(1),Integer(0),Integer(1)],[Integer(3),Integer(2),Integer(4),Integer(1)])
>>> x.reduced_word()
[2, 1, 4, 3, 2, 1, 4, 3, 2, 4, 4, 3]
```

to_matrix()

Return a matrix of self.

The colors are mapped to roots of unity.

EXAMPLES:

```
sage: C = ColoredPermutations(4, 3)
sage: s1,s2,t = C.gens()
sage: x = s1*s2*t*s2; x.one_line_form()
[(1, 2), (0, 1), (0, 3)]
sage: M = x.to_matrix(); M

# needs sage.rings.number_field
[ 0 1 0]
[zeta4 0 0]
[ 0 0 1]
```

```
>>> from sage.all import *
>>> C = ColoredPermutations(Integer(4), Integer(3))
>>> s1,s2,t = C.gens()
>>> x = s1*s2*t*s2; x.one_line_form()
[(1, 2), (0, 1), (0, 3)]
>>> M = x.to_matrix(); M

# needs sage.rings.number_field
[ 0 1 0]
[zeta4 0 0]
[ 0 0 1]
```

The matrix multiplication is in the opposite order:

```
sage: M == s2.to_matrix()*t.to_matrix()*s2.to_matrix()*s1.to_matrix()  # needs sage.rings.number_field
True
```
class sage.combinat.colored_permutations.ColoredPermutations(m, n)

Bases: ShephardToddFamilyGroup

The group of \( m \)-colored permutations on \( \{1, 2, \ldots, n\} \).

Let \( S_n \) be the symmetric group on \( n \) letters and \( C_m \) be the cyclic group of order \( m \). The \( m \)-colored permutation group on \( n \) letters is given by \( P_m^n = C_m \wr S_n \). This is also the complex reflection group \( G(m, 1, n) \).

We define our multiplication by

\[
((s_1, \ldots, s_n), \sigma) \cdot ((t_1, \ldots, t_n), \tau) = ((s_1 t_{\sigma(1)}, \ldots, s_n t_{\sigma(n)}), \tau \sigma).
\]

EXAMPLES:

\[
\text{sage: } C = \text{ColoredPermutations}(4, 3); C
\]
4-colored permutations of size 3
\[
\text{sage: } s1, s2, t = C.gens()
\]
\[
\text{sage: } (s1, s2, t)
\]
\[
([[[0, 0, 0], [2, 1, 3]], [[0, 0, 0], [1, 3, 2]], [[0, 0, 1], [1, 2, 3]])
\]
\[
\text{sage: } s1*\text{s2}
\]
\[
[[0, 0, 0], [3, 1, 2]]
\]
\[
\text{sage: } (s1*\text{s2})*s1 == s2*s1*s2
\]
True
\[
\text{sage: } t^4 == C.\text{one()}
\]
True
\[
\text{sage: } s2*t*s2
\]
\[
[[0, 1, 0], [1, 2, 3]]
\]

We can also create a colored permutation by passing an iterable consisting of tuples consisting of (color, element):

\[
\text{sage: } x = C([(2, 1), (3, 3), (3, 2)]); x
\]
\[
[[2, 3, 3], [1, 3, 2]]
\]

\[
\text{>>> from sage.all import *}
\]
\[
\text{>>> C = ColoredPermutations(Integer(4), Integer(3)); C}
\]
4-colored permutations of size 3
\[
\text{>>> } s1, s2, t = C.gens()
\]
\[
\text{>>> } (s1, s2, t)
\]
\[
([[[0, 0, 0], [2, 1, 3]], [[0, 0, 0], [1, 3, 2]], [[0, 0, 1], [1, 2, 3]])
\]
\[
\text{>>> } s1*\text{s2}
\]
\[
[[0, 0, 0], [3, 1, 2]]
\]
\[
\text{>>> } (s1*\text{s2})*s1 == s2*s1*s2
\]
True
\[
\text{>>> } t**\text{Integer}(4) == C.\text{one()}
\]
True
\[
\text{>>> } s2*t*s2
\]
\[
[[0, 1, 0], [1, 2, 3]]
\]
or a list of colors and a permutation:

```python
from sage.all import *

C([[Integer(3),Integer(3),Integer(1)], [Integer(1),Integer(3),Integer(2)])

C(P.an_element())
```

There is also the natural lift from permutations:

```python
C(C.an_element()) == C.an_element()
```

A colored permutation:

```python
C(C.an_element()) == C.an_element()
```

REFERENCES:

- Wikipedia article Generalized_symmetric_group
- Wikipedia article Complex_reflection_group

```python
class sage.combinat.colored_permutations.ShephardToddFamilyGroup(m, p, n)
```

The Shephard-Todd family complex reflection group $G(m, p, n)$ realized as a subgroup of colored permutations.

A general complex reflection group is a subgroup of $GL(V)$, where $V$ is a C vector space, that is generated by reflections, diagonalizable matrices with at most one eigenvalue not equal to 1. The group of colored permutations $G(m, 1, n)$ are the generalized permutation matrices whose entries are $m$-th roots of unity. For $p|m$, the group $G(m, p, n)$ is the index $p$ subgroup such that the product of the entries is a $m/p$-th root of unity.

By the (Chevalley-)Shephard-Todd classification of irreducible finite complex reflection groups, the groups $G(m, p, n)$ (with $G(2, 2, 2)$ being exceptionally reducible since it is the Klein four group) form the only infinite family with an additional 34 exceptional groups $G_k$, where $4 \leq k \leq 37$. To avoid ambiguities, we refer to $G(m, p, n)$ as the Shephard-Todd family complex reflection group.

INPUT:

- $m$ – positive integer
- $p$ – positive integer dividing $m$
• n – positive integer

• Wikipedia article Complex_reflection_group

EXAMPLES:

```sage
sage: groups.misc.ShephardToddFamily(6, 1, 4)
6-colored permutations of size 4
sage: groups.misc.ShephardToddFamily(6, 2, 4)
Complex reflection group G(6, 2, 4)
sage: groups.misc.ShephardToddFamily(6, 3, 4)
Complex reflection group G(6, 3, 4)
sage: groups.misc.ShephardToddFamily(6, 6, 4)
Complex reflection group G(6, 6, 4)
```

```python
>>> from sage.all import *

>>> groups.misc.ShephardToddFamily(Integer(6), Integer(1), Integer(4))
6-colored permutations of size 4
```

```python
>>> groups.misc.ShephardToddFamily(Integer(6), Integer(2), Integer(4))
Complex reflection group G(6, 2, 4)
```

```python
>>> groups.misc.ShephardToddFamily(Integer(6), Integer(3), Integer(4))
Complex reflection group G(6, 3, 4)
```

```python
>>> groups.misc.ShephardToddFamily(Integer(6), Integer(6), Integer(4))
Complex reflection group G(6, 6, 4)
```

Element

alias of ColoredPermutation

as_permutation_group()

Return the permutation group corresponding to self.

EXAMPLES:

```sage
sage: C = ColoredPermutations(4, 3)
sage: C.as_permutation_group() # needs sage.groups
Complex reflection group G(4, 1, 3) as a permutation group
```

```python
>>> from sage.all import *

>>> C = ColoredPermutations(Integer(4), Integer(3))

>>> C.as_permutation_group() # needs sage.groups
Complex reflection group G(4, 1, 3) as a permutation group
```

cardinality()

Return the cardinality of self.

EXAMPLES:

```sage
sage: C = ColoredPermutations(4, 3)
sage: C.cardinality()  # needs sage.groups
384
sage: C.cardinality() == 4**3 * factorial(3)
True
```
```python
>>> from sage.all import *

>>> C = ColoredPermutations(Integer(4), Integer(3))
>>> C.cardinality()
384

>>> C.cardinality() == Integer(4)**Integer(3) * factorial(Integer(3))
True
```

codegrees()

Return the codegrees of self.

Let $G$ be a complex reflection group. The codegrees $d_1 \leq d_2 \leq \cdots \leq d_\ell$ of $G$ can be defined by:

$$
\prod_{i=1}^{\ell} (q - d_i^*) - 1 = \sum_{g \in G} \det(g) q^{\dim(V^g)} ,
$$

where $V$ is the natural complex vector space that $G$ acts on and $\ell$ is the rank()

If $m = 1$, then we are in the special case of the symmetric group and the codegrees are $(n-2, n-3, \ldots, 1, 0)$. Otherwise the degrees are $((n-1)m, (n-2)m, \ldots, m, 0)$.

EXAMPLES:

```python
sage: C = ColoredPermutations(4, 3)
sage: C.codegrees()
(8, 4, 0)
sage: S = ColoredPermutations(1, 3)
sage: S.codegrees()
(1, 0)
sage: G = groups.misc.ShephardToddFamily(6, 2, 3)
sage: G.codegrees()
(12, 6, 0)
```

coxeter_matrix()

Return the Coxeter matrix of self.

When the group is imprimitive and not a Coxeter group, this returns None.

EXAMPLES:

```python
>>> from sage.all import *

>>> C = ColoredPermutations(Integer(4), Integer(3))

>>> C.coxeter_matrix()
# needs sage.modules

[1 3 2 2]
[3 1 3 2]
[2 3 1 4]
[2 2 4 1]
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: C = ColoredPermutations(Integer(1), Integer(4))

[4 1]

>>> G = groups.misc.ShephardToddFamily(Integer(7), Integer(7), Integer(2))

[1 7]
[7 1]

>>> G = groups.misc.ShephardToddFamily(Integer(6), Integer(3), Integer(1))

is None

True

>>> G = groups.misc.ShephardToddFamily(Integer(6), Integer(3), Integer(4))

is None

True

degrees()

Return the degrees of self.

The degrees of a complex reflection group are the degrees of the fundamental invariants of the ring of polynomial invariants.

If \( m = 1 \), then we are in the special case of the symmetric group and the degrees are \((2, 3, \ldots, n, n+1)\).

Otherwise the degrees are \((m, 2m, \ldots, nm)\).

EXAMPLES:

```
sage: C = ColoredPermutations(4, 3)
sage: C.degrees()
(4, 8, 12)
sage: S = ColoredPermutations(1, 3)
sage: S.degrees()
(2, 3)
```
We now check that the product of the degrees is equal to the cardinality of self:

```python
sage: prod(C.degrees()) == C.cardinality()
True
sage: prod(S.degrees()) == S.cardinality()
True
sage: prod(G.degrees()) == G.cardinality()
True
```

**fixed_point_polynomial** *(q=None)*

The fixed point polynomial of self.

The fixed point polynomial $f_G$ of a complex reflection group $G$ is counting the dimensions of fixed points subspaces:

$$f_G(q) = \sum_{w \in W} q^{\dim V^w}.$$

Furthermore, let $d_1, d_2, \ldots, d_\ell$ be the degrees of $G$, where $\ell$ is the *rank()*. Then the fixed point polynomial is given by

$$f_G(q) = \prod_{i=1}^\ell (q + d_i - 1).$$

INPUT:

- `q` – (default: the generator of `ZZ['q']`) the parameter $q$

EXAMPLES:

```python
sage: C = ColoredPermutations(4, 3)
sage: C.fixed_point_polynomial()
q^3 + 21*q^2 + 131*q + 231
```
sage: S = ColoredPermutations(1, 3)
sage: S.fixed_point_polynomial()
q^2 + 3*q + 2

>>> from sage.all import *

>>> C = ColoredPermutations(Integer(4), Integer(3))
>>> C.fixed_point_polynomial()
q^3 + 21*q^2 + 131*q + 231

>>> S = ColoredPermutations(Integer(1), Integer(3))
>>> S.fixed_point_polynomial()
q^2 + 3*q + 2

gens()
Return the generators of self.

EXAMPLES:

sage: C = ColoredPermutations(4, 3)
sage: C.gens()
([[[0, 0, 0], [2, 1, 3]],
  [[0, 0, 0], [1, 3, 2]],
  [[0, 0, 1], [1, 2, 3]]],

sage: S = SignedPermutations(4)
sage: S.gens()
([2, 1, 3, 4], [1, 3, 2, 4], [1, 2, 4, 3], [1, 2, 3, -4])

>>> from sage.all import *

>>> C = ColoredPermutations(Integer(4), Integer(3))

>>> C.gens()
([[[0, 0, 0], [2, 1, 3]],
  [[0, 0, 0], [1, 3, 2]],
  [[0, 0, 1], [1, 2, 3]]],

>>> S = SignedPermutations(Integer(4))

>>> S.gens()
([2, 1, 3, 4], [1, 3, 2, 4], [1, 2, 4, 3], [1, 2, 3, -4])

index_set()
Return the index set of self.

EXAMPLES:

sage: C = ColoredPermutations(3, 4)
sage: C.index_set()
(1, 2, 3, 4)

sage: C = ColoredPermutations(1, 4)
sage: C.index_set()
(1, 2, 3)

sage: G = groups.misc.ShephardToddFamily(6, 6, 4)
sage: G.index_set()
(1, 2, 3)
```python
sage: G = groups.misc.ShephardToddFamily(6, 2, 4)
sage: G.index_set()
(1, 2, 3, 4, 5)

sage: G = groups.misc.ShephardToddFamily(6, 6, 1)
sage: G.index_set()
()

sage: G = groups.misc.ShephardToddFamily(6, 2, 1)
sage: G.index_set()
(1,

>>> from sage.all import *

>>> C = ColoredPermutations(Integer(3), Integer(4))

>>> C.is_well_generated()
True

>>> C = ColoredPermutations(Integer(1), Integer(4))

>>> C.is_well_generated()
True

>>> G = groups.misc.ShephardToddFamily(Integer(6), Integer(6), Integer(4))

>>> G.is_well_generated()
True

is_well_generated()

Return if self is a well-generated complex reflection group.

A complex reflection group \( G \) is well-generated if it is generated by \( \ell \) reflections. Equivalently, \( G \) is well-generated if \( d_i + d_i^* = d_\ell \) for all \( 1 \leq i \leq \ell \).

EXAMPLES:
```
```python
>>> from sage.all import *
>>> C = ColoredPermutations(Integer(4), Integer(3))
>>> C.is_well_generated()
True
>>> C = ColoredPermutations(Integer(2), Integer(8))
>>> C.is_well_generated()
True
>>> C = ColoredPermutations(Integer(1), Integer(4))
>>> C.is_well_generated()
True
```

**matrix_group()**

Return the matrix group corresponding to self.

**EXAMPLES:**

```python
sage: C = ColoredPermutations(4, 3)
sage: C.matrix_group()  #←needs sage.modules
Matrix group over Cyclotomic Field of order 4 and degree 2 with 3 generators

```

```python
[0 1 0] [1 0 0] [1 0 0]
[1 0 0] [0 0 1] [0 1 0]
[0 0 1] [0 1 0] [0 0 zeta4]
```

```python
>>> from sage.all import *
>>> C = ColoredPermutations(Integer(4), Integer(3))
>>> C.matrix_group()
#←needs sage.modules
Matrix group over Cyclotomic Field of order 4 and degree 2 with 3 generators

```

```python
[0 1 0] [1 0 0] [1 0 0]
[1 0 0] [0 0 1] [0 1 0]
[0 0 1] [0 1 0] [0 0 zeta4]
```

**number_of_reflection_hyperplanes()**

Return the number of reflection hyperplanes of self.

The number of reflection hyperplanes of a complex reflection group is equal to the sum of the codegrees plus the rank.

**EXAMPLES:**

```python
sage: C = ColoredPermutations(1, 2)
sage: C.number_of_reflection_hyperplanes()
1
sage: C = ColoredPermutations(1, 3)
sage: C.number_of_reflection_hyperplanes()
3
sage: C = ColoredPermutations(4, 12)
sage: C.number_of_reflection_hyperplanes()
276
```

```python
>>> from sage.all import *
>>> C = ColoredPermutations(Integer(1), Integer(2))
>>> C.number_of_reflection_hyperplanes()
1
```
```python
>>> C = ColoredPermutations(Integer(1), Integer(3))
>>> C.number_of_reflection_hyperplanes()
3
>>> C = ColoredPermutations(Integer(4), Integer(12))
>>> C.number_of_reflection_hyperplanes()
276

one()

Return the identity element of self.

EXAMPLES:

```python
sage: C = ColoredPermutations(4, 3)
sage: C.one()
[[0, 0, 0], [1, 2, 3]]
```

```python
>>> from sage.all import *

```python
>>> C = ColoredPermutations(Integer(4), Integer(3))
>>> C.one()
[[0, 0, 0], [1, 2, 3]]

order()

Return the cardinality of self.

EXAMPLES:

```python
sage: C = ColoredPermutations(4, 3)
sage: C.cardinality()
384
sage: C.cardinality() == 4**3 * factorial(3)
True
```

```python
>>> from sage.all import *

```python
>>> C = ColoredPermutations(Integer(4), Integer(3))
>>> C.cardinality()
384
>>> C.cardinality() == Integer(4)**Integer(3) * factorial(Integer(3))
True

random_element()

Return an element of self at random.

EXAMPLES:

```python
sage: C = ColoredPermutations(4, 3)
sage: s = C.random_element(); s  # random
[[0, 2, 1], [2, 1, 3]]
sage: s in C
True
```

```python
>>> from sage.all import *

```python
>>> C = ColoredPermutations(Integer(4), Integer(3))
>>> s = C.random_element(); s  # random
[[0, 2, 1], [2, 1, 3]]
>>> s in C
True
```
**rank()**

Return the rank of `self`.

The rank of a complex reflection group is equal to the dimension of the complex vector space the group acts on.

**EXAMPLES:**

```python
sage: C = ColoredPermutations(4, 12)
sage: C.rank()
12
sage: C = ColoredPermutations(7, 4)
sage: C.rank()
4
sage: C = ColoredPermutations(1, 4)
sage: C.rank()
3
```

```python
>>> from sage.all import *
>>> C = ColoredPermutations(Integer(4), Integer(12))
>>> C.rank()
12
>>> C = ColoredPermutations(Integer(7), Integer(4))
>>> C.rank()
4
>>> C = ColoredPermutations(Integer(1), Integer(4))
>>> C.rank()
3
```

**simple_reflection(i)**

Return the `i`-th simple reflection of `self`.

**EXAMPLES:**

```python
sage: C = ColoredPermutations(4, 3)
sage: C.gens()
([[0, 0, 0], [2, 1, 3]], [[0, 0, 0], [1, 3, 2]], [[0, 0, 1], [1, 2, 3]])
sage: C.simple_reflection(2)
[[0, 0, 0], [1, 3, 2]]
sage: C.simple_reflection(3)
[[0, 0, 1], [1, 2, 3]]

sage: S = SignedPermutations(4)
sage: S.simple_reflection(1)
[2, 1, 3, 4]
sage: S.simple_reflection(4)
[1, 2, 3, -4]
```

```python
sage: G = groups.misc.ShephardToddFamily(4, 2, 3)
sage: list(G.simple_reflections())
[[[0, 0, 0], [2, 1, 3]],
 [[0, 0, 0], [1, 3, 2]],
 [[0, 1, 3], [1, 3, 2]],
 [[0, 0, 2], [1, 2, 3]]]
```

```python
sage: G = groups.misc.ShephardToddFamily(8, 4, 1)
sage: G.simple_reflections()
Finite family {1: [[4], [1]]}
```

(continues on next page)
```python
sage: G = groups.misc.ShephardToddFamily(8, 8, 1)
sage: G.simple_reflections()
Finite family {}
```

```python
>>> from sage.all import *

>>> C = ColoredPermutations(Integer(4), Integer(3))

>>> C.gens()
([[[0, 0, 0], [2, 1, 3]], [[0, 0, 0], [1, 3, 2]], [[0, 0, 1], [1, 2, 3]]])

>>> C.simple_reflection(Integer(2))
([[0, 0, 0], [1, 3, 2]])

>>> C.simple_reflection(Integer(3))
([[0, 0, 1], [1, 2, 3]])

>>> S = SignedPermutations(Integer(4))

>>> S.simple_reflection(Integer(1))
([2, 1, 3, 4])

>>> S.simple_reflection(Integer(4))
([1, 2, 3, -4])

>>> G = groups.misc.ShephardToddFamily(Integer(4), Integer(2), Integer(3))

>>> list(G.simple_reflections())
([[[0, 0, 0], [2, 1, 3]],
  [[0, 0, 0], [1, 3, 2]],
  [[0, 1, 3], [1, 3, 2]],
  [[0, 0, 2], [1, 2, 3]]])

>>> G = groups.misc.ShephardToddFamily(Integer(8), Integer(4), Integer(1))

>>> G.simple_reflections()
Finite family {1: [[[4], [1]]]}

>>> G = groups.misc.ShephardToddFamily(Integer(8), Integer(8), Integer(1))

>>> G.simple_reflections()
Finite family {}  
```

```python
class sage.combinat.colored_permutations.SignedPermutation (parent, colors, perm)

Bases: ColoredPermutation

A signed permutation.

cycle_type()

Return a pair of partitions of \text{len} (\text{self}) corresponding to the signed cycle type of \text{self}.

A cycle is a tuple \( C = (c_0, \ldots, c_{k-1}) \) with \( \pi(c_i) = c_{i+1} \) for \( 0 \leq i < k \) and \( \pi(c_{k-1}) = c_0 \). If \( C \) is a cycle, \( \overline{C} = (-c_0, \ldots, -c_{k-1}) \) is also a cycle. A cycle is negative, if \( C = \overline{C} \) up to cyclic reordering. In this case, \( k \) is necessarily even and the length of \( C \) is \( k/2 \). A positive cycle is a pair \( C\overline{C} \), its length is \( k \).

Let \( \alpha \) be the partition whose parts are the lengths of the positive cycles and let \( \beta \) be the partition whose parts are the lengths of the negative cycles. Then \( (\alpha, \beta) \) is the cycle type of \( \pi \).

EXAMPLES:

```python
sage: G = SignedPermutations(7)
sage: pi = G([2, -1, 4, -6, -5, -3, 7])
sage: pi.cycle_type()
([3, 1], [2, 1])
```
```
Continued from previous page

```python
sage: G = SignedPermutations(5)
sage: all(pi.cycle_type().size() == 5 for pi in G)
True
sage: set(pi.cycle_type() for pi in G) == set(PartitionTuples(2, 5))
True
```

```python
>>> from sage.all import *
>>> G = SignedPermutations(Integer(7))
>>> pi = G([Integer(2), -Integer(1), Integer(4), -Integer(6), -Integer(5), - Integer(3), Integer(7)])
>>> pi.cycle_type()
([3, 1], [2, 1])

>>> G = SignedPermutations(Integer(5))
>>> all(pi.cycle_type().size() == Integer(5) for pi in G)
True
>>> set(pi.cycle_type() for pi in G) == set(PartitionTuples(Integer(2), Integer(5)))
True
```

**has_left_descent**(i)
Return True if i is a left descent of self.

**EXAMPLES:**

```python
sage: S = SignedPermutations(4)
sage: s1, s2, s3, s4 = S.gens()
sage: x = s4*s1*s2*s3*s4
sage: [x.has_left_descent(i) for i in S.index_set()]
[True, False, False, True]
```

```python
>>> from sage.all import *
>>> S = SignedPermutations(Integer(4))
>>> s1, s2, s3, s4 = S.gens()
>>> x = s4*s1*s2*s3*s4
>>> [x.has_left_descent(i) for i in S.index_set()]
[True, False, False, True]
```

**order()**
Return the multiplicative order of the signed permutation.

**EXAMPLES:**

```python
sage: pi = SignedPermutations(7)([2,-1,4,-6,-5,-3,7])
sage: pi.to_cycles(singletons=False)
[(1, 2, -1, -2), (3, 4, -6), (-3, -4, 6), (5, -5)]
sage: pi.order()
12
```

```python
>>> from sage.all import *
>>> pi = SignedPermutations(Integer(7))([Integer(2),-Integer(1),Integer(4),- Integer(6),-Integer(5),-Integer(3),Integer(7)])
>>> pi.to_cycles(singletons=False)
[(1, 2, -1, -2), (3, 4, -6), (-3, -4, 6), (5, -5)]
>>> pi.order()
12
```
to_cycles \( (\text{singletons}=\text{True}, \text{use}\_\text{min}=\text{True}, \text{negative}\_\text{cycles}=\text{True}) \)

Return the signed permutation \( \text{self} \) as a list of disjoint cycles.

The cycles are returned in the order of increasing smallest elements, and each cycle is returned as a tuple which starts with its smallest positive element.

INPUT:

- \( \text{singletons} \) – (default: \text{True}) whether to include singleton cycles or not
- \( \text{use}\_\text{min} \) – (default: \text{True}) if False, the cycles are returned in the order of increasing largest (not smallest) elements, and each cycle starts with its largest element
- \( \text{negative}\_\text{cycles} \) – (default: \text{True}) if False, for any two cycles \( C^+ = \{\pm c_1, \ldots, \pm c_k\} \) such that \( C^+ \neq C^- \), this does not include the cycle \( C^- \)

**Warning:** The argument \( \text{negative}\_\text{cycles} \) does not refer to the usual definition of a negative cycle; see \( \text{cycle}\_\text{type}() \).

**EXAMPLES:**

```python
sage: pi = SignedPermutations(7)([2,-1,4,-6,-5,-3,7])
sage: pi.to_cycles()
[(1, 2, -1, -2), (3, 4, -6), (-3, -4, 6), (5, -5), (7,), (-7,)]
sage: pi.to_cycles(singletons=False)
[(1, 2, -1, -2), (3, 4, -6), (-3, -4, 6), (5, -5)]
sage: pi.to_cycles(negative_cycles=False)
[(1, 2, -1, -2), (3, 4, -6), (5, -5)]
sage: pi.to_cycles(singletons=False, negative_cycles=False)
[(1, 2, -1, -2), (3, 4, -6), (5, -5)]
sage: pi.to_cycles(use_min=False)
[(7,), (-7,), (6, -3, -4), (-6, 3, 4), (5, -5), (2, -1, -2, 1)]
sage: pi.to_cycles(singletons=False, use_min=False)
[(6, -3, -4), (-6, 3, 4), (5, -5), (2, -1, -2, 1)]
```

```python
>>> from sage.all import *
>>> pi = SignedPermutations(Integer(7))([Integer(2),-Integer(1),Integer(4),-Integer(6),-Integer(5),-Integer(3),Integer(7)])
>>> pi.to_cycles()
[(1, 2, -1, -2), (3, 4, -6), (-3, -4, 6), (5, -5), (7,), (-7,)]
>>> pi.to_cycles(singletons=False)
[(1, 2, -1, -2), (3, 4, -6), (-3, -4, 6), (5, -5)]
>>> pi.to_cycles(negative_cycles=False)
[(1, 2, -1, -2), (3, 4, -6), (5, -5)]
>>> pi.to_cycles(singletons=False, negative_cycles=False)
[(1, 2, -1, -2), (3, 4, -6), (5, -5)]
>>> pi.to_cycles(use_min=False)
[(7,), (-7,), (6, -3, -4), (-6, 3, 4), (5, -5), (2, -1, -2, 1)]
>>> pi.to_cycles(singletons=False, use_min=False)
[(6, -3, -4), (-6, 3, 4), (5, -5), (2, -1, -2, 1)]
```

to_matrix()

Return a matrix of \( \text{self} \).

**EXAMPLES:**

```python
The matrix multiplication is in the opposite order:

```
sage: m1,m2,m3,m4 = [g.to_matrix() for g in S.gens()]  # needs sage.modules
sage: M == m4 * m3 * m2 * m1 * m4  # needs sage.modules
True
```

### class `sage.combinat.colored_permutations.SignedPermutations(n)`

**Bases:** `ColoredPermutations`

Group of signed permutations.

The group of signed permutations is also known as the hyperoctahedral group, the Coxeter group of type $B_n$, and the 2-colored permutation group. Thus it can be constructed as the wreath product $S_2 \wr S_n$.

**EXAMPLES:**

```
sage: S = SignedPermutations(4)
sage: s1,s2,s3,s4 = S.gens()
sage: x = s4*s1*s2*s3*s4
sage: M = x.to_matrix(); M  # needs sage.modules
[ 0 1 0 0]
[ 0 0 1 0]
[ 0 0 0 -1]
[-1 0 0 0]
```

```
>>> from sage.all import *

>>> S = SignedPermutations(Integer(4))

>>> s1,s2,s3,s4 = S.gens()

>>> x = s4*s1*s2*s3*s4

>>> M = x.to_matrix(); M  # needs sage.modules

>>> from sage.all import *

>>> m1,m2,m3,m4 = [g.to_matrix() for g in S.gens()]

>>> M == m4 * m3 * m2 * m1 * m4  # needs sage.modules
True
```
This is a finite Coxeter group of type $B_n$:

```python
sage: S.canonical_representation()  #...
˓→needs sage.modules
Finite Coxeter group over Number Field in a with defining polynomial $x^2 - 2$
  with a = 1.414213562373095? with Coxeter matrix:
  [1 3 2 2]
  [3 1 3 2]
  [2 3 1 4]
  [2 2 4 1]
sage: S.long_element()  
[-1, -2, -3, -4]
sage: S.long_element().reduced_word()  
[1, 2, 1, 3, 2, 1, 4, 3, 2, 1, 4, 3, 2, 4, 3, 4]
```

We can also go between the 2-colored permutation group:

```python
sage: C = ColoredPermutations(2, 3)
sage: S = SignedPermutations(3)
sage: S.an_element()  
[-3, 1, 2]
sage: C(S.an_element())  
[[1, 0, 0], [3, 1, 2]]
sage: S(C(S.an_element())) == S.an_element()  
True
```

(continues on next page)
There is also the natural lift from permutations:

```python
sage: P = Permutations(3)
sage: x = S(P.an_element()); x
[3, 1, 2]
sage: x.parent()
Signed permutations of 3
```

REFERENCES:

- Wikipedia article Hyperoctahedral_group

**Element**

alias of `SignedPermutation`

**conjugacy_class_representative** (*nu*)

Return a permutation with (signed) cycle type *nu*.

**EXAMPLES:**

```python
sage: G = SignedPermutations(4)
sage: for nu in PartitionTuples(2, 4):
    ....:     print(nu, G.conjugacy_class_representative(nu))
    ....:     assert nu == G.conjugacy_class_representative(nu).cycle_type(), nu

([], [2, 2]) [2, -1, 4, -3]
([], [2, 1, 1]) [2, -1, -3, -4]
([], [1, 1, 1, 1]) [-1, -2, -3, -4]

**long_element** *(index_set=None)*

Return the longest element of `self`, or of the parabolic subgroup corresponding to the given `index_set`.

**INPUT:**

- *index_set* – (optional) a subset (as a list or iterable) of the nodes of the indexing set

**EXAMPLES:**

```python
sage: S = SignedPermutations(4)
sage: S.long_element()
[-1, -2, -3, -4]

```

```python
>>> from sage.all import *

```

```python
>>> S = SignedPermutations(Integer(4))

```

```python
>>> S.long_element()
[-1, -2, -3, -4]
```

**one()**

Return the identity element of `self`.

**EXAMPLES:**

```python
sage: S = SignedPermutations(4)
sage: S.one()
[1, 2, 3, 4]

```

```python
>>> from sage.all import *

```

```python
>>> S = SignedPermutations(Integer(4))

```

```python
>>> S.one()
[1, 2, 3, 4]
```

**random_element()**

Return an element drawn uniformly at random.
EXAMPLES:

```python
sage: C = SignedPermutations(7)
sage: s = C.random_element(); s # random
[7, 6, -4, -5, 2, 3, -1]
sage: s in C
True
```

```python
>>> from sage.all import *
>>> C = SignedPermutations(Integer(7))
>>> s = C.random_element(); s # random
[7, 6, -4, -5, 2, 3, -1]
>>> s in C
True
```

```python
simple_reflection(i)
```

Return the i-th simple reflection of self.

EXAMPLES:

```python
sage: S = SignedPermutations(4)
sage: S.simple_reflection(1)
[2, 1, 3, 4]
sage: S.simple_reflection(4)
[1, 2, 3, -4]
```

```python
>>> from sage.all import *
>>> S = SignedPermutations(Integer(4))
>>> S.simple_reflection(Integer(1))
[2, 1, 3, 4]
>>> S.simple_reflection(Integer(4))
[1, 2, 3, -4]
```

### 5.1.25 Combinatorial Functions

This module implements some combinatorial functions, as listed below. For a more detailed description, see the relevant docstrings.

**Sequences:**

- Bell numbers, `bell_number()`
- Catalan numbers, `catalan_number()` (not to be confused with the Catalan constant)
- Narayana numbers, `narayana_number()`
- Euler numbers, `euler_number()` (Maxima)
- Eulerian numbers, `eulerian_number()`
- Eulerian polynomial, `eulerian_polynomial()`
- Lucas numbers, `lucas_number1()`, `lucas_number2()`.
- Stirling numbers, `stirling_number1()`, `stirling_number2()`.
- Polygonal numbers, `polygonal_number()`
Set-theoretic constructions:

- Derangements of a multiset, `derangements()` and `number_of_derangements()`.
- Tuples of a multiset, `tuples()` and `number_of_tuples()`. An ordered tuple of length k of set S is an ordered selection with repetitions of S and is represented by a sorted list of length k containing elements from S.
- Unordered tuples of a set, `unordered_tuples()` and `number_of_unordered_tuples()`. An unordered tuple of length k of set S is an unordered selection with repetitions of S and is represented by a sorted list of length k containing elements from S.

**Warning:** The following function is deprecated and will soon be removed.

- Permutations of a multiset, `permutations()`, `permutations_iterator()`, `number_of_permutations()`. A permutation is a list that contains exactly the same elements but possibly in different order.

Related functions:

- Bernoulli polynomials, `bernoulli_polynomial()`

**Implemented in other modules (listed for completeness):**

The package `sage.arith` contains the following combinatorial functions:

- `binomial()` the binomial coefficient (wrapped from PARI)
- `factorial()` (wrapped from PARI)
- `falling_factorial()` Definition: for integer \( a \geq 0 \) we have \( x(x-1)\cdots(x-a+1) \). In all other cases we use the GAMMA-function: \( \frac{\Gamma(x+1)}{\Gamma(x-a+1)} \).
- `rising_factorial()` Definition: for integer \( a \geq 0 \) we have \( x(x+1)\cdots(x+a-1) \). In all other cases we use the GAMMA-function: \( \frac{\Gamma(x+a)}{\Gamma(x)} \).

From other modules:

- `number_of_partitions()` (wrapped from PARI) the `number` of partitions:
- `sage.combinat.q_analogues.gaussian_binomial()` the Gaussian binomial

\[
\binom{n}{k}_q = \frac{(1 - q^m)(1 - q^{m-1})\cdots(1 - q^{m-r+1})}{(1 - q)(1 - q^2)\cdots(1 - q^r)}.
\]

The `sage.groups.perm_gps.permgroup_elements` contains the following combinatorial functions:

- matrix method of `PermutationGroupElement` yielding the permutation matrix of the group element.

**Todo:**

**GUAVA commands:**

- VandermondeMat
- GrayMat returns a list of all different vectors of length n over the field F, using Gray ordering.

**Not in GAP:**

- Rencontres numbers (Wikipedia article Rencontres_number)

Functions and classes

class sage.combinat.combinat.CombinatorialElement (parent, *args, **kwds)

Bases: CombinatorialObject, Element

CombinatorialElement is both a CombinatorialObject and an Element. So it represents a list which is an element of some parent.

A CombinatorialElement subclass also automatically supports the __classcall__ mechanism.

Warning: This class is slowly being deprecated. Use ClonableList instead.

INPUT:

- parent – the Parent class for this element.
- lst – a list or any object that can be converted to a list by calling list().

EXAMPLES:

```
sage: from sage.combinat.combinat import CombinatorialElement
sage: e = CombinatorialElement(Partitions(6), [3,2,1])
True
sage: parent(e)
Partitions of the integer 6
sage: list(e)
[3, 2, 1]
```

```
>>> from sage.all import *
>>> from sage.combinat.combinat import CombinatorialElement
>>> e = CombinatorialElement(Partitions(Integer(6)), [Integer(3),Integer(2),
                                 -Integer(1)])
>>> e == loads(dumps(e))
True
>>> parent(e)
Partitions of the integer 6
>>> list(e)
[3, 2, 1]
```
Check class calls:

```python
sage: class Foo(CombinatorialElement):
    # needs sage.combinat
    @staticmethod
    def __classcall__(cls, x):
        return x
sage: Foo(17)  # needs sage.combinat
17
```

```python
>>> from sage.all import *
>>> class Foo(CombinatorialElement):
    # needs sage.combinat
    @staticmethod
    def __classcall__(cls, x):
        return x
>>> Foo(Integer(17))  # needs sage.combinat
17
```

class `sage.combinat.combinat.CombinatorialObject` *(l, copy=True)*

Bases: `SageObject`

CombinatorialObject provides a thin wrapper around a list. The main differences are that `__setitem__` is disabled so that CombinatorialObjects are shallowly immutable, and the intention is that they are semantically immutable.

Because of this, CombinatorialObjects provide a `__hash__` function which computes the hash of the string representation of a list and the hash of its parent’s class. Thus, each CombinatorialObject should have a unique string representation.

**See also:**

`CombinatorialElement` if you want a combinatorial object which is an element of a parent.

**Warning:** This class is slowly being deprecated. Use `ClonableList` instead.

**INPUT:**

- `l` — a list or any object that can be converted to a list by calling `list()`.
- `copy` — (boolean, default `True`) if `False`, then `l` must be a list, which is assigned to `self._list` without copying.

**EXAMPLES:**

```python
sage: c = CombinatorialObject([1,2,3])
sage: c == loads(dumps(c))
True
sage: c._list
[1, 2, 3]
sage: c._hash is None
True
```

```python
>>> from sage.all import *
>>> c = CombinatorialObject([Integer(1),Integer(2),Integer(3)])
>>> c == loads(dumps(c))
```
For efficiency, you can specify `copy=False` if you know what you are doing:

```python
sage: from sage.combinat.combinat import CombinatorialObject
sage: x = [3, 2, 1]
>>> C = CombinatorialObject(x, copy=False)
>>> C
[3, 2, 1]
>>> x[0] = 5
>>> C
[5, 2, 1]
```

**index**(key)

EXAMPLES:

```python
sage: c = CombinatorialObject([1,2,3])
sage: c.index(1)
0
sage: c.index(3)
2
```

```python
>>> from sage.all import *
>>> from sage.combinat.combinat import CombinatorialObject
>>> x = [Integer(3), Integer(2), Integer(1)]
>>> C = CombinatorialObject(x, copy=False)
>>> C
[3, 2, 1]
>>> x[Integer(0)] = Integer(5)
>>> C
[5, 2, 1]
```

```
sage.combinat.combinat.bell_number(n, algorithm='flint', **options)
```

Return the $n$-th Bell number.

This is the number of ways to partition a set of $n$ elements into pairwise disjoint nonempty subsets.

**INPUT:**

- $n$ – a positive integer
- `algorithm` – (Default: 'flint') any one of the following:
  - 'dobinski' – Use Dobinski's formula implemented in Sage
  - 'flint' – Wrap FLINT's `arith_bell_number`
Let $B_n$ denote the $n$-th Bell number. Dobinski’s formula is:

$$B_n = e^{-1} \sum_{k=0}^{\infty} \frac{k^n}{k!}.$$ 

To show our implementation of Dobinski’s method works, suppose that $n \geq 5$ and let $k_0$ be the smallest positive integer such that $\frac{k_0^n}{k_0!} < 1$. Note that $k_0 > n$ and $k_0 \leq 2n$ because we can prove that $\frac{(2n)^n}{(2n)!} < 1$ by Stirling.

If $k > k_0$, then we have $\frac{c_{k+1}}{c_k} = \frac{(1+k^{-1})^n}{k+1} < \frac{(1+n^{-1})^n}{n} < \frac{1}{2}$.

Using this, we can see that $\frac{c_k}{k_0^n} < \frac{1}{2^{k-k_0}}$ for $k > k_0 > n$. So summing this it gives that $\sum_{k=k_0+1}^{\infty} \frac{k^n}{k!} < 1$, and hence

$$B_n = e^{-1} \left( \sum_{k=0}^{k_0} \frac{k^n}{k!} + E_1 \right) = e^{-1} \sum_{k=0}^{k_0} \frac{k^n}{k!} + E_2,$$

where $0 < E_1 < 1$ and $0 < E_2 < e^{-1}$. Next we have for any $q > 0$

$$\sum_{k=0}^{k_0} \frac{k^n}{k!} = \frac{1}{q} \sum_{k=0}^{k_0} \left\lfloor \frac{qk^n}{k!} \right\rfloor + \frac{E_3}{q}$$

where $0 \leq E_3 \leq k_0 + 1 \leq 2n + 1$. Let $E_4 = \frac{E_3}{q}$ and let $q = 2n + 1$. We find $0 \leq E_4 \leq 1$. These two bounds give:

$$B_n = \frac{e^{-1}}{q} \sum_{k=0}^{k_0} \left\lfloor \frac{qk^n}{k!} \right\rfloor + e^{-1} E_4 + E_2$$

$$= \frac{e^{-1}}{q} \sum_{k=0}^{k_0} \frac{qk^n}{k!} + E_5$$

where

$$0 < E_5 = e^{-1} E_4 + E_2 \leq e^{-1} + e^{-1} < \frac{3}{4}.$$ 

It follows that

$$B_n = \left\lceil e^{-1} \sum_{k=0}^{k_0} \frac{qk^n}{k!} \right\rceil.$$ 

Now define

$$b = \sum_{k=0}^{k_0} \left\lfloor \frac{qk^n}{k!} \right\rfloor.$$
This \( b \) can be computed exactly using integer arithmetic. To avoid the costly integer division by \( k! \), we collect more terms and do only one division, for example with 3 terms:

\[
\frac{k^n}{k!} + \frac{(k + 1)^n}{(k + 1)!} + \frac{(k + 2)^n}{(k + 2)!} = \frac{k^n(k + 1)(k + 2)}{(k + 2)!} + \frac{(k + 1)^n(k + 2) + (k + 2)^n}{(k + 2)!}
\]

In the implementation, we collect \( \sqrt{n}/2 \) terms.

To actually compute \( B_n \) from \( b \), we let \( p = \left\lceil \log_2(b) \right\rceil + 1 \) such that \( b < 2^p \) and we compute with \( p \) bits of precision. This implies that \( b \) (and \( q < b \) can be represented exactly.

We compute \( \frac{e^{-1}b}{q} \), rounding down, and we must have an absolute error of at most \( 1/4 \) (given that \( E_5 < 3/4 \)). This means that we need a relative error of at most

\[
eq \frac{eq}{4b} < \frac{(eq)/4}{2^p} = \frac{7}{2^p}
\]

(assuming \( n \geq 5 \)). With a precision of \( p \) bits and rounding down, every rounding has a relative error of at most \( 2^{-p} = 2/2^p \). Since we do 3 roundings (\( b \) and \( q \) do not require rounding), we get a relative error of at most \( 6/2^p \). All this implies that the precision of \( p \) bits is sufficient.

**EXAMPLES:**

```python
sage: # needs sage.libs.flint
sage: bell_number(10)
115975
sage: bell_number(2)
2
sage: bell_number(-10)
Traceback (most recent call last):
  ... ArithmeticError: Bell numbers not defined for negative indices
sage: bell_number(1)
1
sage: bell_number(1/3)
Traceback (most recent call last):
  ... TypeError: no conversion of this rational to integer

>>> from sage.all import *
>>> # needs sage.libs.flint
>>> bell_number(Integer(10))
115975
>>> bell_number(Integer(2))
2
>>> bell_number(-Integer(10))
Traceback (most recent call last):
  ... ArithmeticError: Bell numbers not defined for negative indices
>>> bell_number(Integer(1))
1
>>> bell_number(Integer(1)/Integer(3))
Traceback (most recent call last):
  ... TypeError: no conversion of this rational to integer
```

When using the mpmath algorithm, we are required have mpmath’s precision set to at least \( \log_2(B_n) \) bits. If upon computing the Bell number the first time, we deem the precision too low, we use our guess to (temporarily) raise mpmath’s precision and the Bell number is recomputed.

### 5.1. Comprehensive Module List

441
If you know what precision is necessary before computing the Bell number, you can use the `prec` option:

```
sage: k2 = bell_number(30, 'mpmath', prec=30); k2
   # needs mpmath
846749014511809332450147
sage: k == k2
   # needs mpmath
True
```

**Warning:** Running `mpmath` with the precision set too low can result in incorrect results:

```
sage: k = bell_number(30, 'mpmath', prec=15); k
   # needs mpmath
846749014511809388871680
sage: k == bell_number(30)
   # needs mpmath sage.libs.flint
False
```

sage.combinat.combinat.bell_polynomial(n, k=None, ordinary=False)

Return the (partial) (exponential/ordinary) bell Polynomial.

The partial (exponential) Bell polynomial is defined by the formula

\[ B_{n,k}(x_0, x_1, \ldots, x_{n-k}) = \sum_{j_0 + \ldots + j_{n-k} = k} \frac{n!}{j_0! j_1! \cdots j_{n-k}!} \left( \frac{x_0}{(0+1)!} \right)^{j_0} \left( \frac{x_1}{(1+1)!} \right)^{j_1} \cdots \left( \frac{x_{n-k}}{(n-k+1)!} \right)^{j_{n-k}}. \]

The complete (exponential) Bell Polynomial is defined as

\[ B_n(x_0, x_1, \ldots, x_{n-k}) = \sum_{k=0}^{n} B_{n,k}(x_0, x_1, \ldots, x_{n-k}). \]

The ordinary variant of the partial Bell polynomial is defined by

\[ \hat{B}_{n,k}(x_0, x_1, \ldots, x_{n-k}) = \sum_{j_0 + \ldots + j_{n-k} = k} \binom{k}{j_0, j_1, \ldots, j_{n-k}} x_0^{j_0} x_1^{j_1} \cdots x_{n-k}^{j_{n-k}}, \]

where we have used the multinomial coefficient. The complete version has the same definition as its exponential counterpart.

If we define \( f(z) = \sum_{n=1}^{\infty} x_{n-1} z^n / n! \) then these are alternative definitions for exponential Bell polynomials

\[ \exp(f(z)) = \sum_{n=0}^{\infty} B_n(x_0, \ldots, x_{n-1}) \frac{z^n}{n!}, \]
\[ \frac{f(z)^k}{k!} = \sum_{n=k}^{\infty} B_{n,k}(x_0, \ldots, x_{n-k}) \frac{z^n}{n!}. \]

Defining \( g(z) = \sum_{n=1}^{\infty} x_{n-1} z^n, \) we have the analogous alternative definitions

\[ \frac{1}{1 - f(z)} = \sum_{n=0}^{\infty} \hat{B}_n(x_0, \ldots, x_{n-1}) z^n, \]
\[ f(z)^k = \sum_{n=k}^{\infty} \hat{B}_{n,k}(x_0, \ldots, x_{n-k}) z^n, \]

(see reference).

INPUT:
• \( k \) – (optional) if specified, returns the partial Bell polynomial, otherwise returns the complete Bell polynomial
• \( \text{ordinary} \) – (default: False) if True, returns the (partial) ordinary Bell polynomial, otherwise returns the (partial) exponential Bell polynomial

EXAMPLES:

The complete and partial Bell polynomials:
The ordinary variants are:

```
sage: # needs sage.combinat sage.arith
sage: bell_polynomial(3, ordinary=True)
x0^3 + 2*x0*x1 + x2
sage: bell_polynomial(4, ordinary=True)
x0^4 + 3*x0^2*x1 + x1^2 + 2*x0*x2 + x3
sage: bell_polynomial(6, Integer(3), True)
x1^3 + 6*x0*x1*x2 + 3*x0^2*x3
sage: bell_polynomial(6, Integer(6), True)
x0^6
```

We verify the alternative definition of the different Bell polynomials using the functions \( f \) and \( g \) given above:

```
sage: # needs sage.combinat sage.arith
sage: n = 6 # positive integer
sage: k = 4 # positive integer
sage: R.<x> = InfinitePolynomialRing(QQ)
sage: PR = PolynomialRing(QQ, 'x', n)
sage: d = {x[i]: PR.gen(i) for i in range(n)} # substitution dictionnary
sage: L.<z> = LazyPowerSeriesRing(R)
sage: f = lambda i: x[i-1]/factorial(i), valuation=1
sage: all(exp(f)[i].subs(d) * factorial(i) == bell_polynomial(i) for i in range(n+1))
True
```
sage: all((f^k/factorial(k))[i].subs(d) * factorial(i) == bell_polynomial(i, k) for i in range(k, n+k))
True
sage: g = L(lambda i: x[i-1], valuation=1)
sage: all((1/(1-g))[i].subs(d) == bell_polynomial(i, ordinary=True) for i in range(n+1))
True
sage: all((g^k)[i].subs(d) == bell_polynomial(i, k, True) for i in range(k, n+k))
True

>>> from sage.all import *
>>> # needs sage.combinat sage.arith
>>> n = Integer(6) # positive integer
>>> k = Integer(4) # positive integer
>>> R = InfinitePolynomialRing(QQ, names=('x',)); (x,) = R._first_ngens(1)
>>> PR = PolynomialRing(QQ, x, n)
>>> d = {x[i]: PR.gen(i) for i in range(n)} #substitution dictionnary
>>> L = LazyPowerSeriesRing(R, names=('z',)); (z,) = L._first_ngens(1)
>>> f = L(lambda i: x[i-Integer(1)]/factorial(i), valuation=Integer(1))
>>> all(exp(f)[i].subs(d) * factorial(i) == bell_polynomial(i) for i in range(n+Integer(1)))
True
>>> all((f**k/factorial(k))[i].subs(d) * factorial(i) == bell_polynomial(i, k) for i in range(k, n+k))
True
>>> g = L(lambda i: x[i-Integer(1)], valuation=Integer(1))
>>> all((Integer(1)/(1-g))[i].subs(d) == bell_polynomial(i, ordinary=True) for i in range(n+Integer(1)))
True
>>> all((g**k)[i].subs(d) == bell_polynomial(i, k, True) for i in range(k, n+k))
True

REFERENCES:

AUTHORS:
• Blair Sutton (2009-01-26)
• Thierry Monteil (2015-09-29): the result must always be a polynomial.
• Kei Beauduin (2024-04-06): when univariate, the polynomial is in variable x0. extended to complete exponential, partial ordinary and complete ordinary Bell polynomials.

sage.combinat.combinat.bernoulli_polynomial(x, n)
Return the n-th Bernoulli polynomial evaluated at x.

The generating function for the Bernoulli polynomials is
\[
\frac{te^{xt}}{e^t-1} = \sum_{n=0}^{\infty} B_n(x) \frac{t^n}{n!},
\]
and they are given directly by
\[
B_n(x) = \sum_{i=0}^{n} \binom{n}{i} B_{n-i}x^i.
\]

5.1. Comprehensive Module List
One has $B_n(x) = -n\zeta(1-n, x)$, where $\zeta(s, x)$ is the Hurwitz zeta function. Thus, in a certain sense, the Hurwitz zeta function generalizes the Bernoulli polynomials to non-integer values of $n$.

**EXAMPLES:**

```python
sage: # needs sage.libs.flint
sage: y = QQ['y'].0
sage: bernoulli_polynomial(y, 5)
y^5 - 5/2*y^4 + 5/3*y^3 - 1/6*y
sage: bernoulli_polynomial(y, 5)(12)
199870
sage: bernoulli_polynomial(12, 5)
199870
sage: bernoulli_polynomial(y^2 + 1, 5)
y^10 + 5/2*y^8 + 5/3*y^6 - 1/6*y^2
sage: P.<t> = ZZ[]
sage: p = bernoulli_polynomial(t, 6)
sage: p.parent()
Univariate Polynomial Ring in t over Rational Field
```

We verify an instance of the formula which is the origin of the Bernoulli polynomials (and numbers):

```python
sage: power_sum = sum(k^4 for k in range(10))
sage: 5*power_sum == bernoulli_polynomial(10, 5) - bernoulli(5)  # needs sage.libs.flint
True
```

**REFERENCES:**

- Wikipedia article Bernoulli polynomials

`sage.combinat.combinat.catalan_number(n)`

Return the $n$-th Catalan number.

The $n$-th Catalan number is given directly in terms of binomial coefficients by

$$C_n = \frac{1}{n+1} \binom{2n}{n} = \frac{(2n)!}{(n+1)!n!} \quad \text{for} \quad n \geq 0.$$
Consider the set $S = \{1, \ldots, n\}$. A noncrossing partition of $S$ is a partition in which no two blocks "cross" each other, i.e., if $a$ and $b$ belong to one block and $x$ and $y$ to another, they are not arranged in the order $axby$. $C_n$ is the number of noncrossing partitions of the set $S$. There are many other interpretations (see REFERENCES).

When $n = -1$, this function returns the limit value $-1/2$. For other $n < 0$ it returns 0.

INPUT:

- $n$ – integer

OUTPUT:

integer

EXAMPLES:

```
sage: [catalan_number(i) for i in range(7)]
[1, 1, 2, 5, 14, 42, 132]
sage: x = (QQ['x'].0).O(8)
sage: (-1/2)*sqrt(1 - 4*x)
-1/2 + x + x^2 + 2*x^3 + 5*x^4 + 14*x^5 + 42*x^6 + 132*x^7 + O(x^8)
sage: [catalan_number(i) for i in range(-7,7)]
[0, 0, 0, 0, 0, -1/2, 1, 1, 2, 5, 14, 42, 132]
sage: [catalan_number(n).mod(2) for n in range(16)]
[1, 1, 0, 1, 0, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 1]
```

REFERENCES:

- Wikipedia article Catalan_number
- http://www-history.mcs.st-andrews.ac.uk/~history/Miscellaneous/CatalanNumbers/catalan.html

sage.combinat.combinat.euler_number($n$, algorithm='flint')

Return the $n$-th Euler number.

INPUT:

- $n$ – a positive integer
- algorithm – (Default: 'flint') any one of the following:
  - 'maxima' – Wraps Maxima’s euler.
  - 'flint' – Wrap FLINT’s arith_euler_number

EXAMPLES:

```
sage: [euler_number(i) for i in range(10)]
[1, 0, -1, 0, 5, 0, -61, 0, 1385, 0]
sage: x = PowerSeriesRing(QQ, 'x').gen().O(10)
```

(continues on next page)
sage: 2/(exp(x)+exp(-x))
1 - 1/2*x^2 + 5/24*x^4 - 61/720*x^6 + 277/8064*x^8 + O(x^10)
sage: [euler_number(i)/factorial(i) for i in range(11)]
# needs sage.libs.flint
[1, 0, -1/2, 0, 5/24, 0, -61/720, 0, 277/8064, 0, -50521/3628800]
sage: euler_number(-1)
Traceback (most recent call last):
... ValueError: n (=1) must be a nonnegative integer

>>> from sage.all import *
>>> [euler_number(i) for i in range(Integer(10))]
# needs sage.libs.flint
[1, 0, -1/2, 0, 5/24, 0, -61/720, 0, 277/8064, 0, -50521/3628800]

REFERENCES:

• Wikipedia article Euler_number

sage.combinat.combinat.eulerian_number(k, algorithm='recursive')

Return the Eulerian number of index (n, k).

This is the coefficient of t^k in the Eulerian polynomial A_n(t).

INPUT:

• n – integer

• k – integer between 0 and n - 1

• algorithm = "recursive" (default) or "formula"

OUTPUT:

an integer

See also:

eulerian_polynomial()
sage.combinat.combinat.eulerian_polynomial(algorithm='derivative')

Return the Eulerian polynomial of index \( n \).

This is the generating polynomial counting permutations in the symmetric group \( S_n \) according to their number of descents.

**INPUT:**
- \( n \) – an integer
- algorithm – "derivative" (default) or "coeffs"

**OUTPUT:**
polynomial in one variable \( t \)

**See also:**
eulerian_number()

**EXAMPLES:**

```
sage: from sage.combinat.combinat import eulerian_polynomial
sage: eulerian_polynomial(5)
t^4 + 26*t^3 + 66*t^2 + 26*t + 1
```

```
>>> from sage.all import *
>>> from sage.combinat.combinat import eulerian_polynomial
>>> eulerian_polynomial(Integer(5))
t^4 + 26*t^3 + 66*t^2 + 26*t + 1
```

**REFERENCES:**
- Wikipedia article Eulerian_number

sage.combinat.combinat.fibonacci(n, algorithm='pari')

Return the \( n \)-th Fibonacci number.

The Fibonacci sequence \( F_n \) is defined by the initial conditions \( F_1 = F_2 = 1 \) and the recurrence relation \( F_{n+2} = F_{n+1} + F_n \). For negative \( n \) we define \( F_n = (-1)^{n+1}F_{-n} \), which is consistent with the recurrence relation.

**INPUT:**
- algorithm – a string:
  - "pari" – (default) use the PARI C library's pari: fibo function
  - "gap" – use GAP's Fibonacci function

**Note:** PARI is tens to hundreds of times faster than GAP here. Moreover, PARI works for every large input whereas GAP does not.

**EXAMPLES:**

```
sage: fibonacci(10)  # needs sage.libs.pari
55
sage: fibonacci(10, algorithm='gap')  # needs sage.libs.gap
55
```
>>> from sage.all import *
>>> fibonacci(Integer(10))

sage.combinat.combinat.fibonacci_sequence (start, stop=None, algorithm=None)
Return an iterator over the Fibonacci sequence, for all fibonacci numbers \( f_n \) from \( n = \text{start} \) up to (but not including) \( n = \text{stop} \)

INPUT:

• start – starting value
• stop – stopping value
• algorithm – (default: None) passed on to fibonacci function (or not passed on if None, i.e., use the default)

EXAMPLES:

sage: fibs = [i for i in fibonacci_sequence(10, 20)]; fibs
˓→ needs sage.libs.pari
[55, 89, 144, 233, 377, 610, 987, 1597, 2584, 4181]
```python
>>> from sage.all import *
>>> fibs = [i for i in fibonacci_sequence(Integer(10), Integer(20))]; fibs
[55, 89, 144, 233, 377, 610, 987, 1597, 2584, 4181]
```

```
sage: sum([i for i in fibonacci_sequence(100, 110)])  # needs sage.libs.pari
69919376923075308730013
```

```
>>> from sage.all import *
>>> sum([i for i in fibonacci_sequence(Integer(100), Integer(110))])  # needs sage.libs.pari
69919376923075308730013
```

- `fibonacci_xrange()`

AUTHORS:

- Bobby Moretti

`sage.combinat.combinat.fibonacci_xrange` (`start, stop=None, algorithm='pari'`)

Return an iterator over all of the Fibonacci numbers in the given range, including $f_n = start$ up to, but not including, $f_n = stop$.

EXAMPLES:

```
sage: fibs_in_some_range = [i for i in fibonacci_xrange(10**7, 10**8)]  # needs sage.libs.pari
4
sage: fibs_in_some_range
[14930352, 24157817, 39088169, 63245986]
```

```
>>> from sage.all import *
>>> fibs_in_some_range = [i for i in fibonacci_xrange(Integer(10)**Integer(7), Integer(10)**Integer(8))]
4
>>> fibs_in_some_range
[14930352, 24157817, 39088169, 63245986]
```

```
sage: fibs = [i for i in fibonacci_xrange(10, 100)]; fibs  # needs sage.libs.pari
[13, 21, 34, 55, 89]
```

```
>>> from sage.all import *
>>> fibs = [i for i in fibonacci_xrange(Integer(10), Integer(100))]; fibs  # needs sage.libs.pari
[13, 21, 34, 55, 89]
```
A solution to the second Project Euler problem:

```
sage: sum([i for i in fibonacci_xrange(10^6) if is_even(i)])  # ...
1089154
```

```
sage.combinat.combinat.lucas_number1(n, P, Q)
```

Return the \( n \)-th Lucas number “of the first kind” (this is not standard terminology). The Lucas sequence \( L^{(1)}(n) \) is defined by the initial conditions \( L^{(1)}(1) = 0, L^{(1)}(2) = 1 \) and the recurrence relation \( L^{(1)}(n+2) = P \cdot L^{(1)}(n+1) - Q \cdot L^{(1)}(n) \).

Wraps GAP’s Lucas(...) [1].

\( P = 1, Q = -1 \) gives the Fibonacci sequence.

INPUT:

- \( n \) – integer
- \( P, Q \) – integer or rational numbers

OUTPUT: integer or rational number

EXAMPLES:

```
sage: lucas_number1(5,1,-1)
5
sage: lucas_number1(6,1,-1)
8
sage: lucas_number1(7,1,-1)
13
sage: lucas_number1(7,1,-2)
43
sage: lucas_number1(5,2,3/5)
229/25
sage: lucas_number1(5,2,1.5)
1/4
```
There was a conjecture that the sequence \( L_n \) defined by \( L_{n+2} = L_{n+1} + L_n \), \( L_1 = 1, L_2 = 3 \), has the property that \( n \) prime implies that \( L_n \) is prime.

```python
sage: def lucas(n):
    ....:     return Integer((5/2)*lucas_number1(n,1,-1) + (1/2)*lucas_number2(n,1,-1))
sage: [[lucas(n), is_prime(lucas(n)), n+1, is_prime(n+1)] for n in range(15)]  # needs sage.libs.gap
[[1, False, 1, False],
 [3, True, 2, True],
 [4, False, 3, True],
 [7, True, 4, False],
 [11, True, 5, True],
 [18, False, 6, False],
 [29, True, 7, True],
 [47, True, 8, False],
 [76, False, 9, False],
 [123, False, 10, False],
 [199, True, 11, True],
 [322, False, 12, False],
 [521, True, 13, True],
 [843, False, 14, False],
 [1364, False, 15, False]]
```
Can you use Sage to find a counterexample to the conjecture?

`sage.combinat.combinat.lucas_number2(n, P, Q)`

Return the \( n \)-th Lucas number “of the second kind” (this is not standard terminology). The Lucas sequence \( L_n^{(2)} \) is defined by the initial conditions \( L_1^{(2)} = 2, L_2^{(2)} = P \) and the recurrence relation \( L_{n+2}^{(2)} = P \cdot L_{n+1}^{(2)} - Q \cdot L_n^{(2)} \).

Wraps GAP’s Lucas(...)[2].

**INPUT:**
- \( n \) – integer
- \( P, Q \) – integer or rational numbers

**OUTPUT:** integer or rational number

**EXAMPLES:**

```sage
sage: [lucas_number2(i,1,-1) for i in range(10)]  # needs sage.libs.gap
[2, 1, 3, 4, 7, 11, 18, 29, 47, 76]
sage: [fibonacci(i-1)+fibonacci(i+1) for i in range(10)]  # needs sage.libs.pari
[2, 1, 3, 4, 7, 11, 18, 29, 47, 76]
```

```python
>>> from sage.all import *

>>> n = lucas_number2(Integer(5),Integer(2),Integer(3)); n
2
>>> type(n)
<class 'sage.rings.integer.Integer'>

>>> n = lucas_number2(Integer(5),Integer(2),-Integer(3)/Integer(9)); n
418/9
>>> type(n)
<class 'sage.rings.rational.Rational'>
```

454 Chapter 5. Comprehensive Module List
The case \( P = 1, Q = -1 \) is the Lucas sequence in Brualdi’s Introductory Combinatorics, 4th ed., Prentice-Hall, 2004:

```
sage: [lucas_number2(n,1,-1) for n in range(10)]  # needs sage.libs.gap
[2, 1, 3, 4, 7, 11, 18, 29, 47, 76]
```

```
>>> from sage.all import *
>>> [lucas_number2(n,Integer(1),-Integer(1)) for n in range(Integer(10))]  # needs sage.libs.gap
[2, 1, 3, 4, 7, 11, 18, 29, 47, 76]
```

```
sage.combinat.combinat.narayana_number(n, k)
Return the Narayana number of index \((n, k)\).

For every integer \( n \geq 1 \), the sum of Narayana numbers \( \sum_k N_{n,k} \) is the Catalan number \( C_n \).

INPUT:
- \( n \) – an integer
- \( k \) – an integer between 0 and \( n - 1 \)

OUTPUT:
an integer

EXAMPLES:
```
sage: from sage.combinat.combinat import narayana_number
sage: [narayana_number(3, i) for i in range(3)]
[1, 3, 1]
sage: sum(narayana_number(7,i) for i in range(7)) == catalan_number(7)
True
```

REFERENCES:
- Wikipedia article Narayana_number

```
sage.combinat.combinat.number_of_tuples(S, k, algorithm='naive')
Return the size of tuples \((S, k)\) when \( S \) is a set. More generally, return the size of tuples \((\text{set}(S), k)\).
(So, unlike tuples(), this method removes redundant entries from \( S \)).

INPUT:
- \( S \) – the base set
- \( k \) – the length of the tuples
- algorithm – can be one of the following:
  - 'naive' – (default) use the naive counting \(|S|^k\)
  - 'gap' – wraps GAP’s NrTuples
```

5.1. Comprehensive Module List 455
Warning: When using algorithm='gap', S must be a list of objects that have string representations that can be interpreted by the GAP interpreter. If S consists of at all complicated Sage objects, this function might not do what you expect.

EXAMPLES:

```
sage: S = [1,2,3,4,5]
sage: number_of_tuples(S,2)
25
sage: number_of_tuples(S,2, algorithm="gap")
# needs sage.libs.gap
25
sage: S = [1,1,2,3,4,5]
sage: number_of_tuples(S,2)
25
sage: number_of_tuples(S,2, algorithm="gap")
# needs sage.libs.gap
25
sage: number_of_tuples(S,0)
1
sage: number_of_tuples(S,0, algorithm="gap")
# needs sage.libs.gap
1
```

```python
>>> from sage.all import *
>>> S = [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)]
>>> number_of_tuples(S,Integer(2))
25
>>> number_of_tuples(S,Integer(2), algorithm="gap")
# needs sage.libs.gap
25
>>> S = [Integer(1),Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)]
>>> number_of_tuples(S,Integer(2))
25
>>> number_of_tuples(S,Integer(2), algorithm="gap")
# needs sage.libs.gap
25
>>> number_of_tuples(S,Integer(0))
1
>>> number_of_tuples(S,Integer(0), algorithm="gap")
# needs sage.libs.gap
1
```

```
sage.combinat.combinat.number_of_unordered_tuples(S, k, algorithm='naive')
```

Return the size of unordered_tuples(S, k) when S is a set.

INPUT:

- S – the base set
- k – the length of the tuples
- algorithm – can be one of the following:
  - 'naive' – (default) use the naive counting \(|S|+k-1\)
  - 'gap' – wraps GAP's NrUnorderedTuples
**Warning:** When using `algorithm='gap'`, `S` must be a list of objects that have string representations that can be interpreted by the GAP interpreter. If `S` consists of all complicated Sage objects, this function might not do what you expect.

**EXAMPLES:**

```python
sage: S = [1,2,3,4,5]
sage: number_of_unordered_tuples(S,2) 15
sage: number_of_unordered_tuples(S,2, algorithm="gap") # needs sage.libs.gap 15
sage: S = [1,1,2,3,4,5]
sage: number_of_unordered_tuples(S,2) 15
sage: number_of_unordered_tuples(S,2, algorithm="gap") # needs sage.libs.gap 15
sage: S = [1,1,2,3,4,5]
sage: number_of_unordered_tuples(S,0) 1
sage: number_of_unordered_tuples(S,0, algorithm="gap") # needs sage.libs.gap 1

>>> from sage.all import *
>>> S = [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)]
>>> number_of_unordered_tuples(S,Integer(2)) 15
>>> number_of_unordered_tuples(S,Integer(2), algorithm="gap") # needs sage.libs.gap 15
>>> S = [Integer(1),Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)]
>>> number_of_unordered_tuples(S,Integer(2)) 15
>>> number_of_unordered_tuples(S,Integer(2), algorithm="gap") # needs sage.libs.gap 15
>>> number_of_unordered_tuples(S,Integer(0)) 1
>>> number_of_unordered_tuples(S,Integer(0), algorithm="gap") # needs sage.libs.gap 1
```

`sage.combinat.combinat.polygonal_number(s, n)`

Return the `n`-th `s`-gonal number.

Polygonal sequences are represented by dots forming a regular polygon. Two famous sequences are the triangular numbers (3rd column of Pascal’s Triangle) and the square numbers. The `n`-th term in a polygonal sequence is defined by

\[ P(s, n) = \frac{n^2(s - 2) - n(s - 4)}{2} \]

where `s` is the number of sides of the polygon.

**INPUT:**

- `s` – integer greater than 1; the number of sides of the polygon

---

**5.1. Comprehensive Module List**
- \( n \) – integer; the index of the returned \( s \)-gonal number

OUTPUT: an integer

EXAMPLES:

The triangular numbers:

```sage
sage: [polygonal_number(3, n) for n in range(10)]
[0, 1, 3, 6, 10, 15, 21, 28, 36, 45]
sage: [polygonal_number(3, n) for n in range(-10, 0)]
[45, 36, 28, 21, 15, 10, 6, 3, 1, 0]
```

```python
>>> from sage.all import *
>>> [polygonal_number(Integer(3), n) for n in range(Integer(10))]
[0, 1, 3, 6, 10, 15, 21, 28, 36, 45]
>>> [polygonal_number(Integer(3), n) for n in range(-Integer(10), Integer(0))]
[45, 36, 28, 21, 15, 10, 6, 3, 1, 0]
```

The square numbers:

```sage
sage: [polygonal_number(4, n) for n in range(10)]
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
```

```python
>>> from sage.all import *
>>> [polygonal_number(Integer(4), n) for n in range(Integer(10))]
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
```

The pentagonal numbers:

```sage
sage: [polygonal_number(5, n) for n in range(10)]
[0, 1, 5, 12, 22, 35, 51, 70, 92, 117]
```

```python
>>> from sage.all import *
>>> [polygonal_number(Integer(5), n) for n in range(Integer(10))]
[0, 1, 5, 12, 22, 35, 51, 70, 92, 117]
```

The hexagonal numbers:

```sage
sage: [polygonal_number(6, n) for n in range(10)]
[0, 1, 6, 15, 28, 45, 66, 91, 120, 153]
```

```python
>>> from sage.all import *
>>> [polygonal_number(Integer(6), n) for n in range(Integer(10))]
[0, 1, 6, 15, 28, 45, 66, 91, 120, 153]
```

The input is converted into an integer:

```sage
sage: polygonal_number(3.0, 2.0)
3
```

```python
>>> from sage.all import *
>>> polygonal_number(RealNumber(3.0), RealNumber('2.0'))
3
```

A non-integer input returns an error:
sage: polygonal_number(3.5, 1)  # needs sage.rings.real_mpfr
Traceback (most recent call last):
... TypeError: Attempt to coerce non-integral RealNumber to Integer

>>> from sage.all import *
>>> polygonal_number(RealNumber('3.5'), Integer(1))  # needs sage.rings.real_mpfr
Traceback (most recent call last):
... TypeError: Attempt to coerce non-integral RealNumber to Integer

s must be greater than 1:

sage: polygonal_number(1, 4)
Traceback (most recent call last):
... ValueError: s (=1) must be greater than 1

>>> from sage.all import *
>>> polygonal_number(Integer(1), Integer(4))
Traceback (most recent call last):
... ValueError: s (=1) must be greater than 1

REFERENCES:

- Wikipedia article Polygonal_number

sage.combinat.combinat.stirling_number1(n, k, algorithm='gap')

Return the \( n \)-th Stirling number \( S_1(n, k) \) of the first kind.

This is the number of permutations of \( n \) points with \( k \) cycles.

See Wikipedia article Stirling_numbers_of_the_first_kind.

INPUT:

- \( n \) – nonnegative machine-size integer
- \( k \) – nonnegative machine-size integer
- algorithm:
  - "gap" (default) – use GAP's Stirling1 function
  - "flint" – use flint's arith_stirling_number_1u function

EXAMPLES:

sage: # needs sage.libs.gap
sage: stirling_number1(3,2)
3
sage: stirling_number1(5,2)
50
sage: 9*stirling_number1(9,5) + stirling_number1(9,4)
269325
sage: stirling_number1(10,5)
269325
```python
>>> from sage.all import *
>>> # needs sage.libs.gap
>>> stirling_number1(Integer(3),Integer(2))
3
>>> stirling_number1(Integer(5),Integer(2))
50
>>> Integer(9)*stirling_number1(Integer(9),Integer(5)) + stirling_number1(Integer(9),Integer(4))
269325
>>> stirling_number1(Integer(10),Integer(5))
269325
```

Indeed, $S_1(n, k) = S_1(n-1, k-1) + (n-1)S_1(n-1, k)$.

`sage.combinat.combinat.stirling_number2(n, k, algorithm=None)`

Return the $n$-th Stirling number $S_2(n, k)$ of the second kind.

This is the number of ways to partition a set of $n$ elements into $k$ pairwise disjoint nonempty subsets. The $n$-th Bell number is the sum of the $S_2(n, k)$'s, $k = 0, ..., n$.

See [Wikipedia article Stirling_numbers_of_the_second_kind](https://en.wikipedia.org/wiki/Stirling_numbers_of_the_second_kind).

**INPUT:**

- $n$ – nonnegative machine-size integer
- $k$ – nonnegative machine-size integer
- algorithm:
  - None (default) – use native implementation
  - "flint" – use flint's arith_stirling_number_2 function
  - "gap" – use GAP's Stirling2 function
  - "maxima" – use Maxima's stirling2 function

**EXAMPLES:**

Print a table of the first several Stirling numbers of the second kind:

```python
sage: for n in range(10):
    ... for k in range(10):
    ...     print(str(stirling_number2(n,k)).rjust(k and 6))
1 0 0 0 0 0 0 0 0 0
0 1 0 0 0 0 0 0 0 0
0 1 1 0 0 0 0 0 0 0
0 1 3 1 0 0 0 0 0 0
0 1 7 6 1 0 0 0 0 0
0 1 15 25 10 1 0 0 0 0
0 1 31 90 65 15 1 0 0 0
0 1 63 301 350 140 21 1 0 0
0 1 127 966 1701 1050 266 28 1 0
0 1 255 3025 7770 6951 2646 462 36 1
```

```python
>>> from sage.all import *
>>> for n in range(Integer(10)):
...     for k in range(Integer(10)):
...         print(str(stirling_number2(n,k)).rjust(k and Integer(6)))
1 0 0 0 0 0 0 0 0 0
0 1 0 0 0 0 0 0 0 0
0 1 1 0 0 0 0 0 0 0
0 1 3 1 0 0 0 0 0 0
0 1 7 6 1 0 0 0 0 0
0 1 15 25 10 1 0 0 0 0
0 1 31 90 65 15 1 0 0 0
0 1 63 301 350 140 21 1 0 0
0 1 127 966 1701 1050 266 28 1 0
0 1 255 3025 7770 6951 2646 462 36 1
```

(continues on next page)
Stirling numbers satisfy $S_2(n, k) = S_2(n - 1, k - 1) + kS_2(n - 1, k)$:

```
sage: 5*stirling_number2(9, 5) + stirling_number2(9, 4)
42525
sage: stirling_number2(10, 5)
42525
```

```
>>> from sage.all import *
>>> Integer(5)*stirling_number2(Integer(9),Integer(5)) + stirling_number2(Integer(9),Integer(4))
42525
>>> stirling_number2(Integer(10),Integer(5))
42525
```

sage.combinat.combinat.tuples($S, k, algorithm='itertools$)

Return a list of all $k$-tuples of elements of a given set $S$.

This function accepts the set $S$ in the form of any iterable (list, tuple or iterator), and returns a list of $k$-tuples. If $S$ contains duplicate entries, then you should expect the method to return tuples multiple times!

Recall that $k$-tuples are ordered (in the sense that two $k$-tuples differing in the order of their entries count as different) and can have repeated entries (even if $S$ is a list with no repetition).

INPUT:

- $S$ – the base set
- $k$ – the length of the tuples
- algorithm – can be one of the following:
  - 'itertools' – (default) use python's itertools
  - 'native' – use a native Sage implementation

Note: The ordering of the list of tuples depends on the algorithm.

EXAMPLES:

```
sage: S = [1,2]
sage: tuples(S,3)
[(1, 1, 1), (1, 1, 2), (1, 2, 1), (1, 2, 2),
 (2, 1, 1), (2, 1, 2), (2, 2, 1), (2, 2, 2)]
sage: mset = ['s','t','e','i','n']
sage: tuples(mset, 2)
[('s', 's'), ('s', 't'), ('s', 'e'), ('s', 'i'), ('s', 'n'),
 ('t', 's'), ('t', 't'), ('t', 'e'), ('t', 'i'), ('t', 'n'),
```
\[(e, s), (e, t), (e, e), (e, i), (e, n),
(i, s), (i, t), (i, e), (i, i), (i, n),
(n, s), (n, t), (n, e), (n, i), (n, n)]

>>> from sage.all import *

>>> S = [Integer(1), Integer(2)]

>>> tuples(S, Integer(3))

\[(1, 1, 1), (1, 1, 2), (1, 2, 1), (1, 2, 2),
(2, 1, 1), (2, 1, 2), (2, 2, 1), (2, 2, 2)]

>>> mset = ['s', 't', 'e', 'i', 'n']

>>> tuples(mset, Integer(2))

\[(s, s), (s, t), (s, e), (s, i), (s, n),
(t, s), (t, t), (t, e), (t, i), (t, n),
(e, s), (e, t), (e, e), (e, i), (e, n),
(i, s), (i, t), (i, e), (i, i), (i, n),
(n, s), (n, t), (n, e), (n, i), (n, n)]

sage: K.<a> = GF(4, 'a')

# needs sage.rings.finite_rings

sage: mset = [x for x in K if x != 0]

# needs sage.rings.finite_rings

sage: tuples(mset, 2)

\[(a, a), (a, a + 1), (a, 1), (a + 1, a), (a + 1, a + 1),
(a + 1, 1), (1, a), (1, a + 1), (1, 1)]

We check that the implementations agree (up to ordering):

sage: tuples(S, 3, 'native')
\[(1, 1, 1), (2, 1, 1), (2, 2, 1), (2, 2, 2),
(1, 1, 2), (2, 1, 2), (1, 2, 1), (1, 2, 2), (2, 2, 2)]

Lastly we check on a multiset:

sage: S = [1, 1, 2]
sage: sorted(tuples(S, 3)) == sorted(tuples(S, 3, 'native'))
True

- Jon Hanke (2006-08)

\[ \text{sage.combinat.combinat.unordered_tuples} (S, k, \text{algorithm}='\text{itertools}') \]

Return a list of all unordered tuples of length \( k \) of the set \( S \).

An unordered tuple of length \( k \) of set \( S \) is an unordered selection with repetitions of \( S \) and is represented by a sorted list of length \( k \) containing elements from \( S \).

Unlike \text{tuples}(), the result of this method does not depend on how often an element appears in \( S \); only the set \( S \) is being used. For example, \text{unordered_tuples}([1, 1, 1], 2) will return \([(1, 1)]\). If you want it to return \([(1, 1), (1, 1), (1, 1)]\), use Python’s \text{itertools.combinations_withReplacement} instead.

INPUT:

- \( S \) – the base set
- \( k \) – the length of the tuples
- \text{algorithm} – can be one of the following:
  - ‘\text{itertools}’ – (default) use python’s \text{itertools}
  - ‘\text{gap}’ – wraps GAP’s \text{UnorderedTuples}

**Warning:** When using \text{algorithm}='\text{gap}', \( S \) must be a list of objects that have string representations that can be interpreted by the GAP interpreter. If \( S \) consists of all complicated Sage objects, this function might not do what you expect.

EXAMPLES:

\[ \text{sage: S = [1,2]} \]
\[ \text{sage: unordered_tuples(S, 3)} \]
\[ [(1, 1, 1), (1, 1, 2), (1, 2, 2), (2, 2, 2)] \]

\[ \text{>>> from sage.all import *} \]
\[ \text{>>> S = [Integer(1),Integer(2)]} \]
\[ \text{>>> unordered_tuples(S, Integer(3))} \]
\[ [(1, 1, 1), (1, 1, 2), (1, 2, 2), (2, 2, 2)] \]

We check that this agrees with GAP:

\[ \text{sage: unordered_tuples(S, 3, algorithm='gap')} \]
\[ \text{# needs sage.libs.gap} \]
\[ [(1, 1, 1), (1, 1, 2), (1, 2, 2), (2, 2, 2)] \]

\[ \text{>>> from sage.all import *} \]
\[ \text{>>> unordered_tuples(S, Integer(3), algorithm='gap')} \]
\[ \text{# needs sage.libs.gap} \]
\[ [(1, 1, 1), (1, 1, 2), (1, 2, 2), (2, 2, 2)] \]

We check the result on strings:
sage: S = ['a', 'b', 'c']
sage: unordered_tuples(S, 2)
[('a', 'a'), ('a', 'b'), ('a', 'c'), ('b', 'b'), ('b', 'c'), ('c', 'c')]
sage: unordered_tuples(S, 2, algorithm='gap')  # needs sage.libs.gap
[('a', 'a'), ('a', 'b'), ('a', 'c'), ('b', 'b'), ('b', 'c'), ('c', 'c')]

Lastly we check on a multiset:

sage: S = [1,1,2]
sage: unordered_tuples(S, 3) == unordered_tuples(S, 3, gap)
True

sage: unordered_tuples(S, 3)
[(1, 1, 1), (1, 1, 2), (1, 2, 2), (2, 2, 2)]

sage.combinat.combinat.unshuffle_iterator(a, one=1)

Iterate over the unshuffles of a list (or tuple) a, also yielding the signs of the respective permutations.

If \( n \) and \( k \) are integers satisfying \( 0 \leq k \leq n \), then a \((k, n - k)\)-unshuffle means a permutation \( \pi \in S_n \) such that \( \pi(1) < \pi(2) < \cdots < \pi(k) \) and \( \pi(k + 1) < \pi(k + 2) < \cdots < \pi(n) \). This method provides, for a list \( a = (a_1, a_2, \ldots, a_n) \) of length \( n \), an iterator yielding all pairs:

\[
\left( (a_{\pi(1)}, a_{\pi(2)}, \ldots, a_{\pi(k)}), (a_{\pi(k+1)}, a_{\pi(k+2)}, \ldots, a_{\pi(n)}) \right), (-1)^{\pi}
\]

for all \( k \in \{0, 1, \ldots, n\} \) and all \((k, n - k)\)-unshuffles \( \pi \). The optional variable \( one \) can be set to a different value which results in the \((-1)^{\pi}\) component being multiplied by said value.

The iterator does not yield these in order of increasing \( k \).

EXAMPLES:

sage: from sage.combinat.combinat import unshuffle_iterator
sage: list(unshuffle_iterator([1,3,4]))
[(((1, 2), (3, 4)), (1, -1)), (((1, 3), (4, 2)), (1, -1)), (((1, 4), (3, 2)), (1, -1)), (((3, 2), (1, 4)), (1, 1)), (((4, 2), (1, 3)), (1, 1))]
sage: list(unshuffle_iterator([3,1]))
[(((1, 2), (3, 1)), (1, -1)), (((3, 2), (1, 1)), (1, -1)), (((4, 2), (1, 1)), (1, 1))]
sage: list(unshuffle_iterator([8]))
5.1.26 Fast computation of combinatorial functions (Cython + mpz)

Currently implemented:

- Stirling numbers of the second kind
- iterators for set partitions
- iterator for Lyndon words
- iterator for perfect matchings
- conjugate of partitions

AUTHORS:

- Fredrik Johansson (2010-10): Stirling numbers of second kind
- Martin Rubey and Travis Scrimshaw (2018): iterators for set partitions, Lyndon words, and perfect matchings

sage.combinat.combinat_cython.conjugate(p)

Return the conjugate partition associated to the partition $p$ as a list.

EXAMPLES:

```python
sage: from sage.combinat.combinat_cython import conjugate
sage: conjugate([2,2])
[2, 2]
sage: conjugate([6,3,1])
[3, 2, 2, 1, 1, 1]
```

(continues on next page)
sage.combinat.combinat_cython.lyndon_word_iterator \((n, k)\)

Generate the Lyndon words of fixed length \(k\) with \(n\) letters.

The resulting Lyndon words will be words represented as lists whose alphabet is \(\text{range}(n) = \{0, 1, \ldots, n-1\}\).

**ALGORITHM:**

The iterative FKM Algorithm 7.2 from [Rus2003].

**EXAMPLES:**

```python
sage: from sage.combinat.combinat_cython import lyndon_word_iterator
doctest:...: 3 warnings

sage: list(lyndon_word_iterator(4, 2))
[[0, 1], [0, 2], [0, 3], [1, 2], [1, 3], [2, 3]]

sage: list(lyndon_word_iterator(2, 4))
[[0, 0, 0, 1], [0, 0, 1, 1], [0, 1, 1, 1]]
```

sage.combinat.combinat_cython.perfect_matchings_iterator \((n)\)

Iterate over all perfect matchings with \(n\) parts.

This iterates over all perfect matchings of \(\{0, 1, \ldots, 2n - 1\}\) using a Gray code for fixed-point-free involutions due to Walsh [Wal2001].

**EXAMPLES:**

```python
sage: from sage.combinat.combinat_cython import perfect_matchings_iterator

doctest:...: 3 warnings

sage: list(perfect_matchings_iterator(1))
[[[0, 1]]]

sage: list(perfect_matchings_iterator(2))
[[[0, 1], [2, 3]], [[0, 2], [1, 3]], [[0, 3], [1, 2]]]

sage: list(perfect_matchings_iterator(0))
[[[]]]
```

**REFERENCES:**
Combinatorics, Release 10.4

• [Wal2001]

`sage.combinat.combinat_cython.set_partition_composition(sp1, sp2)`

Return a tuple consisting of the composition of the set partitions `sp1` and `sp2` and the number of components removed from the middle rows of the graph.

EXAMPLES:

```python
sage: from sage.combinat.combinat_cython import set_partition_composition
sage: sp1 = ((1,-2),(2,-1))
sp2 = ((1,-2),(2,-1))
sage: p, c = set_partition_composition(sp1, sp2)
sage: (SetPartition(p), c) == (SetPartition([[1,-1],[2,-2]]), 0)  # needs sage.combinat
True
```

It is possible to take combinations of Sage objects:

```python
sage: Combinations([vector([1,1]), vector([2,2]), vector([3,3])], 2).list() # needs sage.modules
[[(1, 1), (2, 2)], [(1, 1), (3, 3)], [(2, 2), (3, 3)]]
```

```python
>>> from sage.all import *
>>>
Combinations([vector([Integer(1),Integer(1)]), vector([Integer(2),
Integer(2)]), vector([Integer(3),Integer(3)])], Integer(2)).list() # needs...
[[(1, 1), (2, 2)], [(1, 1), (3, 3)], [(2, 2), (3, 3)]]
```

### class `sage.combinat.combination.Combinations_mset(mset)`

**Bases:** `Parent`

**cardinality()**

Return the size of combinations(mset).

**IMPLEMENTATION:** Wraps GAP’s NrCombinations.

**EXAMPLES:**

```python
sage: mset = [1,1,2,3,4,4,5]
sage: Combinations(mset,2).cardinality() # needs sage.libs.gap
12
```

```python
>>> from sage.all import *
>>>
mset = [Integer(1),Integer(1),Integer(2),Integer(3),Integer(4),Integer(4),
Integer(5)]
>>> Combinations(mset,Integer(2)).cardinality() # needs sage.libs.gap
12
```

### class `sage.combinat.combination.Combinations_msetk(mset, k)`

**Bases:** `Parent`

**cardinality()**

Return the size of combinations(mset, k).

**EXAMPLES:**

```python
sage: Combinations(range(16000)).cardinality() == 2^16000
True
```

```python
>>> from sage.all import *
>>>
Combinations(range(Integer(16000))).cardinality() == Integer(2)**Integer(16000)
True
```

### class `sage.combinat.combination.Combinations_set(mset)`

**Bases:** `Combinations_mset`

**cardinality()**

Return the size of Combinations(set).

**EXAMPLES:**

```python
sage: Combinations(range(16000)).cardinality() == 2^16000
True
```

```python
>>> from sage.all import *
>>>
Combinations(range(Integer(16000))).cardinality() == Integer(2)**Integer(16000)
True
```
**rank**($x$)

**EXAMPLES:**

```python
sage: c = Combinations([1,2,3])
sage: list(range(c.cardinality())) == list(map(c.rank, c))
```

```python
True
```

```python
>>> from sage.all import *

>>> c = Combinations([Integer(1),Integer(2),Integer(3)])

>>> list(range(c.cardinality())) == list(map(c.rank, c))
```

```python
True
```

**unrank**($r$)

**EXAMPLES:**

```python
sage: c = Combinations([1,2,3])

sage: c.list() == list(map(c.unrank, range(c.cardinality())))
```

```python
True
```

```python
>>> from sage.all import *

>>> c = Combinations([Integer(1),Integer(2),Integer(3)])

>>> c.list() == list(map(c.unrank, range(c.cardinality())))
```

```python
True
```

class `sage.combinat.combination.Combinations_setk`(mset, $k$)

**Bases:** `Combinations_msetk`

**cardinality**()

Return the size of combinations($s$, $k$).

**EXAMPLES:**

```python
sage: Combinations(range(16000), 5).cardinality()
```

```python
8732673194560003200
```

```python
>>> from sage.all import *

>>> Combinations(range(Integer(16000)), Integer(5)).cardinality()
```

```python
8732673194560003200
```

**list**()

**EXAMPLES:**

```python
sage: Combinations([1,2,3,4,5],3).list()
```

```python
[[[1, 2, 3], [1, 2, 4], [1, 2, 5], [1, 3, 4], [1, 3, 5], [1, 4, 5], [2, 3, 4], [2, 3, 5], [2, 4, 5], [3, 4, 5]]
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *

>>> Combinations([Integer(1), Integer(2), Integer(3), Integer(4), Integer(5)],
                Integer(3)).list()
[[1, 2, 3],
 [1, 2, 4],
 [1, 2, 5],
 [1, 3, 4],
 [1, 3, 5],
 [1, 4, 5],
 [2, 3, 4],
 [2, 3, 5],
 [2, 4, 5],
 [3, 4, 5]]
```

rank \(x\)

**EXAMPLES:**

```python
sage: c = Combinations([1, 2, 3], 2)
sage: list(range(c.cardinality())) == list(map(c.rank, c.list()))
True
```

unrank \(r\)

**EXAMPLES:**

```python
sage: c = Combinations([1, 2, 3], 2)
sage: c.list() == list(map(c.unrank, range(c.cardinality())))
True
```

```
sage.combinat.combination.from_rank(r, n, k)

Return the combination of rank \(r\) in the subsets of \(\text{range}(n)\) of size \(k\) when listed in lexicographic order.

The algorithm used is based on factoradics and presented in [DGH2020]. It is there compared to the other from the literature.

**EXAMPLES:**

```python
sage: import sage.combinat.combination as combination
sage: combination.from_rank(0, 3, 0)
()  
sage: combination.from_rank(0, 3, 1)
(0,)  
sage: combination.from_rank(1, 3, 1)
(1,)  
sage: combination.from_rank(2, 3, 1)
(2,)  
sage: combination.from_rank(0, 3, 2)
```

(continues on next page)
sage: combination.from_rank(1,3,2)
(0, 2)
sage: combination.from_rank(2,3,2)
(1, 2)
sage: combination.from_rank(0,3,3)
(0, 1, 2)

>>> from sage.all import *
>>> import sage.combinat.combination as combination

>>> combination.from_rank(Integer(0),Integer(3),Integer(0))
()

>>> combination.from_rank(Integer(0),Integer(3),Integer(1))
(0,)

>>> combination.from_rank(Integer(1),Integer(3),Integer(1))
(1,)

>>> combination.from_rank(Integer(2),Integer(3),Integer(1))
(2,)

>>> combination.from_rank(Integer(0),Integer(3),Integer(2))
(0, 1)

>>> combination.from_rank(Integer(1),Integer(3),Integer(2))
(0, 2)

>>> combination.from_rank(Integer(2),Integer(3),Integer(2))
(1, 2)

>>> combination.from_rank(Integer(0),Integer(3),Integer(3))
(0, 1, 2)

sage.combinat.combination.rank(comb, n, check=True)

Return the rank of comb in the subsets of range(n) of size k where k is the length of comb.

The algorithm used is based on combinadics and James McCaffrey's MSDN article. See: Wikipedia article Combinadic.

EXAMPLES:

sage: import sage.combinat.combination as combination

sage: combination.rank([], 3)
0
sage: combination.rank([0], 3)
0
sage: combination.rank([1], 3)
1
sage: combination.rank([2], 3)
2
sage: combination.rank([0,1], 3)
0
sage: combination.rank([0,2], 3)
1
sage: combination.rank([1,2], 3)
2
sage: combination.rank([0,1,2], 3)
0
sage: combination.rank([0,1,2,3], 3)
Traceback (most recent call last):

5.1.28 Combinatorial maps

This module provides a decorator that can be used to add semantic to a Python method by marking it as implementing a combinatorial map, that is a map between two enumerated sets:

```python
sage: from sage.combinat.combinatorial_map import combinatorial_map
sage: class MyPermutation():
    ....:     @combinatorial_map()
    ....:     def reverse(self):
    ....:         """
    ....:         Reverse the permutation
    ....:     
```

(continues on next page)
By default, this decorator is a no-op: it returns the decorated method as is:

```python
sage: MyPermutation.reverse
<function MyPermutation.reverse at ...>
```

See `combinatorial_map_wrapper()` for the various options this decorator can take.

Projects built on top of Sage are welcome to customize locally this hook to instrument the Sage code and exploit this semantic information. Typically, the decorator could be used to populate a database of maps. For a real-life application, see the project `FindStat < http://findstat.org/ >`. As a basic example, a variant of the decorator is provided as `combinatorial_maps_in_class()`; it wraps the decorated method, so that one can later use `combinatorial_maps_in_class()` to query an object, or class thereof, for all the combinatorial maps that apply to it.

Note: Since decorators are evaluated upon loading Python modules, customizing `combinatorial_map` needs to be done before the modules using it are loaded. In the examples below, where we illustrate the customized `combinatorial_map` decorator on the `sage.combinat.permutation` module, we resort to force a reload of this module after dynamically changing `sage.combinat.combinatorial_map.combinatorial_map`. This is good enough for those doctests, but remains fragile.

For real use cases, it is probably best to just edit this source file statically (see below).

```python
class sage.combinat.combinatorial_map.CombinatorialMap(f, order=None, name=None)
    Bases: object

    This is a wrapper class for methods that are combinatorial maps.

    For further details and doctests, see `Combinatorial maps` and `combinatorial_map_wrapper()`.

    name()
        Returns the name of a combinatorial map. This is used for the string representation of self.

    EXAMPLES:
```

(continues on next page)
order()  
Returns the order of self, or None if the order is not known.

EXAMPLES:

```python
sage: from sage.combinat.combinatorial_map import combinatorial_map
class CombinatorialClass:
    ....: @combinatorial_map(order=2)
    ....: def to_self_1(): pass
    ....: def to_self_2(): pass
sage: CombinatorialClass.to_self_1.order() 2
sage: CombinatorialClass.to_self_2.order() is None True
```

unbounded_map()  
Return the unbounded version of self.

You can use this method to return a function which takes as input an element in the domain of the combinatorial map. See the example below.

EXAMPLES:

```python
sage: sage.combinat.combinatorial_map.combinatorial_map = sage.combinat.
combinat.combinatorial_map.combinatorial_map_wrapper
```
**Combinatorics, Release 10.4**

```python
sage: from importlib import reload
sage: _ = reload(sage.combinat.permutation)
sage: from sage.combinat.permutation import Permutation
sage: pi = Permutation([1,3,2])
sage: f = pi.reverse
sage: F = f.unbounded_map()
sage: F(pi)
[2, 3, 1]
```

```python
>>> from sage.all import *
>>> sage.combinat.combinatorial_map.combinatorial_map = sage.combinat.combinatorial_map.combinatorial_map_wrapper
>>> from importlib import reload
>>> _ = reload(sage.combinat.permutation)
>>> from sage.combinat.permutation import Permutation
>>> pi = Permutation([Integer(1),Integer(3),Integer(2)])
>>> f = pi.reverse
>>> F = f.unbounded_map()
>>> F(pi)
[2, 3, 1]
```

`sage.combinat.combinatorial_map.combinatorial_map`(f=None, order=None, name=None)

Combinatorial map decorator

See *Combinatorial maps* for a description of this decorator and its purpose. This default implementation does nothing.

**INPUT:**

- `f` – (default: None, if `combinatorial_map` is used as a decorator) a function
- `name` – (default: None) the name for nicer outputs on combinatorial maps
- `order` – (default: None) the order of the combinatorial map, if it is known. Is not used, but might be helpful later

**OUTPUT:**

- `f` unchanged

**EXAMPLES:**

```python
sage: from sage.combinat.combinatorial_map import combinatorial_map_trivial as...
←combinatorial_map
sage: class MyPermutation():
    ....:     @combinatorial_map
    ....:     def reverse(self):
    ....:         
    ....:             Reverse the permutation
    ....:         
    ....:         # ... code ...
    ....:     @combinatorial_map(name='descent set of permutation')
    ....:     def descent_set(self):
    ....:         
    ....:             The descent set of the permutation
    ....:         
    ....:         # ... code ...

sage: MyPermutation.reverse
```

(continues on next page)
Combinatorial map decorator

See *Combinatorial maps* for a description of this decorator and its purpose. This default implementation does nothing.

**INPUT:**

- \( f \) – (default: None, if \( \text{combinatorial\_map} \) is used as a decorator) a function
- \( \text{name} \) – (default: None) the name for nicer outputs on combinatorial maps
- \( \text{order} \) – (default: None) the order of the combinatorial map, if it is known. Is not used, but might be helpful later

**OUTPUT:**

- \( f \) unchanged

**EXAMPLES:**

```python
sage: from sage.combinat.combinatorial_map import combinatorial_map_trivial
sage: class MyPermutation():
    def reverse(self):
        Reverse the permutation
        # ... code ...
        @combinatorial_map(name='descent set of permutation')
        def descent_set(self):
            The descent set of the permutation
            # ... code ...
```
The descent set of the permutation

# ... code ...

Combinatorial map decorator (basic example).

See Combinatorial maps for a description of the combinatorial_map decorator and its purpose. This implementation, together with combinatorial_maps_in_class() illustrates how to use this decorator as a hook to instrument the Sage code.

**INPUT:**

- \( f \) – (default: None, if combinatorial_map is used as a decorator) a function
- \( \text{name} \) – (default: None) the name for nicer outputs on combinatorial maps
- \( \text{order} \) – (default: None) the order of the combinatorial map, if it is known. Is not used, but might be helpful later

**OUTPUT:**

- A combinatorial map. This is an instance of the CombinatorialMap.

**EXAMPLES:**
We define a class illustrating the use of this implementation of the `combinatorial_map` decorator with its various arguments:

```python
sage: from sage.combinat.combinatorial_map import combinatorial_map_wrapper as...
  →combinatorial_map
sage: class MyPermutation():
  ....: @combinatorial_map()
  ....: def reverse(self):
  ....:     ""
  ....:     Reverse the permutation
  ....:     ""
  ....:     pass
  ....: @combinatorial_map(order=2)
  ....: def inverse(self):
  ....:     ""
  ....:     The inverse of the permutation
  ....:     ""
  ....:     pass
  ....: @combinatorial_map(name='descent set of permutation')
  ....: def descent_set(self):
  ....:     ""
  ....:     The descent set of the permutation
  ....:     ""
  ....:     pass
  ....: def major_index(self):
  ....:     ""
  ....:     The major index of the permutation
  ....:     ""
  ....:     pass
sage: MyPermutation.reverse
Combinatorial map: reverse
sage: MyPermutation.descent_set
Combinatorial map: descent set
sage: MyPermutation.inverse
Combinatorial map: inverse
```

```python
>>> from sage.all import *
  →from sage.combinat.combinatorial_map import combinatorial_map_wrapper as...
  →combinatorial_map
  →combinatorial_map
>>> class MyPermutation():
...    @combinatorial_map()
...    def reverse(self):
...        ""
...        Reverse the permutation
...        ""
...        pass
...    @combinatorial_map(order=Integer(2))
...    def inverse(self):
...        ""
...        The inverse of the permutation
...        ""
...        pass
...    @combinatorial_map(name='descent set of permutation')
...    def descent_set(self):
...        ""
...        The descent set of the permutation
...        ""
...        pass
```
The major index of the permutation...

>>> MyPermutation.reverse
Combinatorial map: reverse
>>> MyPermutation.descent_set
Combinatorial map: descent set of permutation
>>> MyPermutation.inverse
Combinatorial map: inverse

One can now determine all the combinatorial maps associated with a given object as follows:

```
sage: from sage.combinat.combinatorial_map import combinatorial_maps_in_class
sage: X = combinatorial_maps_in_class(MyPermutation); X
[Combinatorial map: reverse,
 Combinatorial map: descent set of permutation,
 Combinatorial map: inverse]
```

The method `major_index` defined about is not a combinatorial map:

```
sage: MyPermutation.major_index
<function MyPermutation.major_index at ...>
```

But one can define a function that turns `major_index` into a combinatorial map:

```
sage: def major_index(p):
     return p.major_index()
sage: major_index
<function major_index at ...>
```

```
sage.combinat.combinatorial_map.combinatorial_maps_in_class(dcls)
Return the combinatorial maps of the class as a list of combinatorial maps.
```
For further details and doctests, see *Combinatorial maps* and *combinatorial_map_wrapper()*.

**EXAMPLES:**

```python
sage: sage.combinat.combinatorial_map.combinatorial_map = sage.combinat.
    →combinatorial_map.combinatorial_map_wrapper
sage: from importlib import reload
sage: _ = reload(sage.combinat.permutation)

sage: from sage.combinat.combinatorial_map import combinatorial_maps_in_class
sage: p = Permutation([1,3,2,4])
sage: cmaps = combinatorial_maps_in_class(p)
sage: cmaps
# random
[Combinatorial map: Robinson-Schensted insertion tableau,
 Combinatorial map: Robinson-Schensted recording tableau,
 Combinatorial map: Robinson-Schensted tableau shape,
 Combinatorial map: complement,
 Combinatorial map: descent composition,
 Combinatorial map: inverse, ...]
sage: p.left_tableau in cmaps
True
sage: p.right_tableau in cmaps
True
sage: p.complement in cmaps
True
```

```python
>>> from sage.all import *

>>> sage.combinat.combinatorial_map.combinatorial_map = sage.combinat.
    →combinatorial_map.combinatorial_map_wrapper

>>> from importlib import reload

>>> from sage.combinat.combinatorial_map import combinatorial_maps_in_class

>>> p = Permutation([Integer(1),Integer(3),Integer(2),Integer(4)])

>>> cmaps = combinatorial_maps_in_class(p)

>>> cmaps
# random
[Combinatorial map: Robinson-Schensted insertion tableau,
 Combinatorial map: Robinson-Schensted recording tableau,
 Combinatorial map: Robinson-Schensted tableau shape,
 Combinatorial map: complement,
 Combinatorial map: descent composition,
 Combinatorial map: inverse, ...]

>>> p.left_tableau in cmaps
True

>>> p.right_tableau in cmaps
True

>>> p.complement in cmaps
True
```
5.1.29 Integer compositions

A composition \( c \) of a nonnegative integer \( n \) is a list of positive integers (the parts of the composition) with total sum \( n \).

This module provides tools for manipulating compositions and enumerated sets of compositions.

EXAMPLES:

```plaintext
sage: Composition([5, 3, 1, 3])
[5, 3, 1, 3]
```

```plaintext
sage: list(Compositions(4))
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1], [4]]
```

```plaintext
>>> from sage.all import *

>>> Composition([Integer(5), Integer(3), Integer(1), Integer(3)])
[5, 3, 1, 3]

>>> list(Compositions(Integer(4)))
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1], [4]]
```

AUTHORS:

- Mike Hansen, Nicolas M. Thiéry
- MuPAD-Combinat developers (algorithms and design inspiration)
- Travis Scrimshaw (2013-02-03): Removed CombinatorialClass

class sage.combinat.composition.Composition(parent, *args, **kwds)

Integer compositions

A composition of a nonnegative integer \( n \) is a list \((i_1, \ldots, i_k)\) of positive integers with total sum \( n \).

EXAMPLES:

The simplest way to create a composition is by specifying its entries as a list, tuple (or other iterable):

```plaintext
sage: Composition([3,1,2])
[3, 1, 2]
```

```plaintext
sage: Composition((3,1,2))
[3, 1, 2]
```

```plaintext
sage: Composition(i for i in range(2,5))
[2, 3, 4]
```

```plaintext
>>> from sage.all import *

>>> Composition([Integer(3),Integer(1),Integer(2)])
[3, 1, 2]

>>> Composition((Integer(3),Integer(1),Integer(2)))
[3, 1, 2]

>>> Composition(i for i in range(Integer(2),Integer(5)))
[2, 3, 4]
```

You can also create a composition from its code. The code of a composition \((i_1, i_2, \ldots, i_k)\) of \( n \) is a list of length \( n \) that consists of a 1 followed by \( i_1 - 1 \) zeros, then a 1 followed by \( i_2 - 1 \) zeros, and so on.

```plaintext
sage: Composition([4,1,2,3,5]).to_code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
```

```plaintext
sage: Composition(code=_)
[4, 1, 2, 3, 5]
```

(continues on next page)
You can also create the composition of $n$ corresponding to a subset of $\{1,2,\ldots,n-1\}$ under the bijection that maps the composition $(i_1,i_2,\ldots,i_k)$ of $n$ to the subset $\{i_1,i_1+i_2,i_1+i_2+i_3,\ldots,i_1+\cdots+i_{k-1}\}$ (see to_subset()):

```python
sage: Composition(from_subset={1, 2, 4}, 5)
[1, 2, 1]
sage: Composition([1, 1, 2, 1]).to_subset()
[1, 2, 1]
```

The following notation equivalently specifies the composition from the set $\{i_1-1,i_1+i_2-1,i_1+i_2+i_3-1,\ldots,i_1+\cdots+i_{k-1}-1,n-1\}$ or $\{i_1-1,i_1+i_2-1,i_1+i_2+i_3-1,\ldots,i_1+\cdots+i_{k-1}-1\}$ and $n$. This provides compatibility with Python's 0-indexing.

```python
sage: Composition(descents=[1,0,4,8,11])
[1, 1, 3, 4, 3]
sage: Composition(descents=[0,1,3,4])
[1, 1, 2, 1]
sage: Composition(descents=(Integer(1), Integer(4)))
[1, 1, 2, 1]
```
An integer composition may be regarded as a sequence. Thus it is an instance of the Python abstract base class `Sequence` allows us to check if objects behave “like” sequences based on implemented methods. Note that `collections.abc.Sequence` is not the same as `sage.structure.sequence.Sequence`:

```python
sage: import collections.abc
sage: C = Composition([3,2,3])
sage: isinstance(C, collections.abc.Sequence)
True
sage: issubclass(C.__class__, collections.abc.Sequence)
True
```

Typically, instances of `collections.abc.Sequence` have a `count` method. `Composition.count` counts the number of parts of a specified size:

```python
sage: C.count(3)
2
```

EXAMPLES:

```python
sage: C = Composition([3,1,2])
sage: TestSuite(C).run()
```

```
>>> from sage.all import *
>>> import collections.abc
>>> C = Composition([Integer(3),Integer(2),Integer(3)])
>>> isinstance(C, collections.abc.Sequence)
True
>>> issubclass(C.__class__, collections.abc.Sequence)
True

complement ()

Return the complement of the composition self.

The complement of a composition \( I \) is defined as follows:

If \( I \) is the empty composition, then the complement is the empty composition as well. Otherwise, let \( S \) be the descent set of \( I \) (that is, the subset \( \{i_1, i_1 + i_2, \ldots, i_1 + i_2 + \cdots + i_{k-1}\} \) of \( \{1, 2, \ldots, |I| - 1\} \), where \( I \) is written as \( (i_1, i_2, \ldots, i_k) \)). Then, the complement of \( I \) is defined as the composition of size \( |I| \) whose descent set is \( \{1, 2, \ldots, |I| - 1\} \setminus S \).

The complement of a composition \( I \) also is the reverse composition (\( \text{reversed()} \)) of the conjugate (\( \text{conjugate()} \)) of \( I \).

EXAMPLES:

```python
sage: Composition([1, 1, 3, 1, 2, 1, 3]).conjugate() [1, 1, 3, 3, 1, 3]
sage: Composition([1, 1, 3, 1, 2, 1, 3]).complement() [3, 1, 3, 3, 1, 1]
```
>>> from sage.all import *
>>> Composition([Integer(1), Integer(1), Integer(3), Integer(1), Integer(2),
   ← Integer(1), Integer(3)]).conjugate()
[1, 1, 3, 3, 1, 3]
>>> Composition([Integer(1), Integer(1), Integer(3), Integer(1), Integer(2),
   ← Integer(1), Integer(3)]).complement()
[3, 1, 3, 3, 1, 1]

conjugate()

Return the conjugate of the composition self.

The conjugate of a composition $I$ is defined as the complement (see complement()) of the reverse composition (see reversed()) of $I$.

An equivalent definition of the conjugate goes by saying that the ribbon shape of the conjugate of a composition $I$ is the conjugate of the ribbon shape of $I$. (The ribbon shape of a composition is returned by to_skew_partition().)

This implementation uses the algorithm from mupad-combinat.

EXAMPLES:

```
sage: Composition([1, 1, 3, 1, 2, 1, 3]).conjugate()
[1, 1, 3, 3, 1, 3]
```

The ribbon shape of the conjugate of $I$ is the conjugate of the ribbon shape of $I$:

```
sage: all( I.conjugate().to_skew_partition() == I.to_skew_partition().conjugate()
for I in Compositions(4) )
True
```

count ($n$)

Return the number of parts of size $n$.

EXAMPLES:

```
sage: C = Composition([3, 2, 3])
sage: C.count(3)
2
sage: C.count(2)
1
sage: C.count(1)
0
```
```python
>>> from sage.all import *
>>> C = Composition([Integer(3),Integer(2),Integer(3)])
>>> C.count(Integer(3))
2
>>> C.count(Integer(2))
1
>>> C.count(Integer(1))
0
```

**descents** *(final_descent=False)*

This gives one fewer than the partial sums of the composition.

This is here to maintain some sort of backward compatibility, even through the original implementation was broken (it gave the wrong answer). The same information can be found in `partial_sums()`.

**See also:**

`partial_sums()`

**INPUT:**

- `final_descent` – *(Default: False)* a boolean integer

**OUTPUT:**

- the list of partial sums of `self` with each part decremented by 1. This includes the sum of all entries when `final_descent` is True.

**EXAMPLES:**

```python
sage: c = Composition([2,1,3,2])
sage: c.descents()
[1, 2, 5]
sage: c.descents(final_descent=True)
[1, 2, 5, 7]
```

**fatten** *(grouping)*

Return the composition fatter than `self`, obtained by grouping together consecutive parts according to `grouping`.

**INPUT:**

- `grouping` – a composition whose sum is the length of `self`

**EXAMPLES:**

Let us start with the composition:

```python
sage: c = Composition([4,5,2,7,1])
```

```python
>>> from sage.all import *
>>> c = Composition([Integer(4),Integer(5),Integer(2),Integer(7),Integer(1)])
```

With `grouping` equal to `(1,...,1), c` is left unchanged:
Combinatorics, Release 10.4

```
sage: c.fatten(Composition([1,1,1,1]))
[4, 5, 2, 7, 1]

>>> from sage.all import *

>>> c.fatten(Composition([[Integer(1),Integer(1),Integer(1),Integer(1),
                        Integer(1)]]))
[4, 5, 2, 7, 1]
```

With grouping equal to (ℓ) where ℓ is the length of c, this yields the coarsest composition above c:

```
sage: c.fatten(Composition([5]))
[19]

>>> from sage.all import *

>>> c.fatten(Composition([Integer(5)]))
[19]
```

Other values for grouping yield (all the) other compositions coarser than c:

```
sage: c.fatten(Composition([2,1,2]))
[9, 2, 8]
sage: c.fatten(Composition([3,1,1]))
[11, 7, 1]

>>> from sage.all import *

>>> c.fatten(Composition([Integer(2),Integer(1),Integer(2)]))
[9, 2, 8]
>>> c.fatten(Composition([Integer(3),Integer(1),Integer(1)]))
[11, 7, 1]
```

**fatter()**

Return the set of compositions which are fatter than self.

Complexity for generation: $O(|c|)$ memory, $O(|r|)$ time where $|c|$ is the size of self and $r$ is the result.

**EXAMPLES:**

```
sage: C = Composition([4,5,2]).fatter()
sage: C.cardinality()
4
sage: list(C)
[[4, 5, 2], [4, 7], [9, 2], [11]]

>>> from sage.all import *

>>> C = Composition([Integer(4),Integer(5),Integer(2)]).fatter()
>>> C.cardinality()
4
>>> list(C)
[[4, 5, 2], [4, 7], [9, 2], [11]]
```

Some extreme cases:

```
sage: list(Composition([5]).fatter())
[[5]]
sage: list(Composition([]).fatter())
[]
```

(continues on next page)
sage: list(Composition([1,1,1,1]).fatter()) == list(Compositions(4))
True

>>> from sage.all import *
>>> list(Composition([Integer(5)]).fatter())
[[5]]
>>> list(Composition([]).fatter())
[]
>>> list(Composition([Integer(1),Integer(1),Integer(1),Integer(1)]).fatter())
[[], [1], [2], [3], [4], [5]]

 finer()

Return the set of compositions which are finer than self.

EXAMPLES:

sage: C = Composition([3,2]).finer()
sage: C.cardinality()
8
sage: C.list()
[[1, 1, 1, 1, 1], [1, 1, 1, 2], [1, 2, 1, 1], [1, 2, 2], [2, 1, 1, 1], [2, 1, 2], [3, 1, 1], [3, 2]]

sage: Composition([]).finer()
[]

>>> from sage.all import *
>>> C = Composition([Integer(3),Integer(2)]).finer()
>>> C.cardinality()
8
>>> C.list()
[[1, 1, 1, 1, 1], [1, 1, 1, 2], [1, 2, 1, 1], [1, 2, 2], [2, 1, 1, 1], [2, 1, 2], [3, 1, 1], [3, 2]]

inf (other, check=True)

Return the meet of self with a composition other of the same size.

The meet of two compositions I and J of size n is the finest composition of n which is coarser than each of I and J. It can be described as the composition whose descent set is the intersection of the descent sets of I and J.

INPUT:

• other – composition of same size as self
• check = (default: True) a Boolean determining whether to check the input compositions for having the same size

OUTPUT:

• the meet of the compositions self and other

EXAMPLES:
Let us verify on small examples that the meet of $I$ and $J$ is coarser than both of $I$ and $J$:

```python
sage: all( all( I.is_finer(I.meet(J)) and
....: J.is_finer(I.meet(J))
....: for J in Compositions(4) )
....: for I in Compositions(4) )
True
```

and is the finest composition to do so:

```python
sage: all( all( all( I.meet(J).is_finer(K)
....: for K in I.fatter() )
....: if J.is_finer(K) )
....: for J in Compositions(3) )
```
\begin{verbatim}
True

>>> from sage.all import *
>>> all( all( all( I.meet(J).is_finer(K)
... for K in I.fatter() )
... if J.is_finer(K) )
... for J in Compositions(Integer(3)) )
... for I in Compositions(Integer(3)) )
True

The descent set of the meet of \( I \) and \( J \) is the intersection of the descent sets of \( I \) and \( J \):

\begin{verbatim}
sage: def test_meet(n):
....: return all( all( I.to_subset().intersection(J.to_subset())
....: == I.meet(J).to_subset() for J in Compositions(n) )
....: for I in Compositions(n) )
sage: all( test_meet(n) for n in range(1, 5) )
True
\end{verbatim}

See also:

\texttt{join()}

AUTHORS:

• Darij Grinberg (2013-09-05)

\texttt{is_finer(co2)}

Return \texttt{True} if the composition \texttt{self} is finer than the composition \texttt{co2}; otherwise, return \texttt{False}.

EXAMPLES:

\begin{verbatim}
sage: Composition([4,1,2]).is_finer([3,1,3])
False
sage: Composition([3,1,3]).is_finer([4,1,2])
False
sage: Composition([1,2,2,1,1,2]).is_finer([5,1,3])
True
sage: Composition([2,2,2]).is_finer([4,2])
True

>>> from sage.all import *
>>> Composition([Integer(4),Integer(1),Integer(2)]).is_finer([Integer(3),
˓→Integer(1),Integer(3)])
False
>>> Composition([Integer(3),Integer(1),Integer(3)]).is_finer([Integer(4),
˓→
\end{verbatim}

(continues on next page)
join(\(other, check=True\))
Return the join of \(self\) with a composition \(other\) of the same size.

The join of two compositions \(I\) and \(J\) of size \(n\) is the coarsest composition of \(n\) which refines each of \(I\) and \(J\). It can be described as the composition whose descent set is the union of the descent sets of \(I\) and \(J\). It is also the concatenation of \(I_1, I_2, \ldots, I_m\), where \(I = I_1 \cdot I_2 \cdot \ldots \cdot I_m\) is the ribbon decomposition of \(I\) with respect to \(J\) (see \(ribbon\_decomposition()\)).

**INPUT:**

- \(other\) – composition of same size as \(self\)
- \(check\) – (default: True) a Boolean determining whether to check the input compositions for having the same size

**OUTPUT:**

- the join of the compositions \(self\) and \(other\)

**EXAMPLES:**

```python
sage: Composition([3, 1, 1, 3, 1]).join([4, 3, 2])
[3, 1, 1, 2, 1, 1]
sage: Composition([9, 6]).join([1, 3, 6, 3, 2])
[1, 3, 5, 1, 3, 2]
sage: Composition([9, 6]).join([1, 3, 5, 1, 3, 2])
[1, 3, 5, 1, 3, 2]
sage: Composition([1, 1, 1, 1, 1]).join([3, 2])
[1, 1, 1, 1, 1]
sage: Composition([4, 2]).join([3, 3])
[3, 1, 2]
sage: Composition([]).join([])
[]
```

```python
>>> from sage.all import *
>>> Composition([Integer(3), Integer(1), Integer(1), Integer(3), Integer(1)]).join([Integer(4), Integer(3), Integer(2)])
[3, 1, 1, 2, 1, 1]
>>> Composition([Integer(9), Integer(6)]).join([Integer(1), Integer(3), Integer(5), Integer(1)])
[1, 3, 5, 1, 3, 2]
>>> Composition([Integer(9), Integer(6)]).join([Integer(1), Integer(3), Integer(5), Integer(1)])
[1, 3, 5, 1, 3, 2]
>>> Composition([Integer(1), Integer(1), Integer(1), Integer(1), Integer(1)]).join([Integer(3), Integer(2)])
[1, 1, 1, 1, 1]
>>> Composition([Integer(4), Integer(2)]).join([Integer(3), Integer(3)])
[3, 1, 2]
```
Composition([]).join([])

Let us verify on small examples that the join of $I$ and $J$ refines both of $I$ and $J$:

```python
sage: all( all( I.join(J).is_finer(I) and
......: I.join(J).is_finer(J)
......: for J in Compositions(4) )
......: for I in Compositions(4) )
True
```

```python
>>> from sage.all import *
```

```python
sage: all( all( I.join(J).is_finer(I) and
......: I.join(J).is_finer(J)
......: for J in Compositions(Integer(4)) )
......: for I in Compositions(Integer(4)) )
True
```

and is the coarsest composition to do so:

```python
sage: all( all( K.is_finer(I.join(J))
......: for K in I.finer() 
......: if K.is_finer(J) 
......: for J in Compositions(3) )
......: for I in Compositions(3) )
True
```

```python
>>> from sage.all import *
```

```python
sage: all( all( K.is_finer(I.join(J))
......: for K in I.finer() 
......: if K.is_finer(J) 
......: for J in Compositions(Integer(3)) )
......: for I in Compositions(Integer(3)) )
True
```

Let us check that the join of $I$ and $J$ is indeed the concatenation of $I_1, I_2, \ldots, I_m$, where $I = I_1 \bullet I_2 \bullet \ldots \bullet I_m$ is the ribbon decomposition of $I$ with respect to $J$:

```python
sage: all( Composition.sum(I.ribbon_decomposition(J)[0])
......: == I.join(J) for J in Compositions(4) )
......: for I in Compositions(4) )
True
```

```python
>>> from sage.all import *
```

```python
sage: all( Composition.sum(I.ribbon_decomposition(J)[Integer(0)])
......: == I.join(J) for J in Compositions(Integer(4)) )
......: for I in Compositions(Integer(4)) )
True
```

Also, the descent set of the join of $I$ and $J$ is the union of the descent sets of $I$ and $J$:

```python
sage: all( I.to_subset().union(J.to_subset())
......: == I.join(J).to_subset()
......: for J in Compositions(4) )
......: for I in Compositions(4) )
True
```
```python
>>> from sage.all import *
>>> all( all( I.to_subset().union(J.to_subset())
...        == I.join(J).to_subset() 
...          for J in Compositions(Integer(4)) )
...        for I in Compositions(Integer(4)) )
True
```

See also:

`meet()`, `ribbon_decomposition()`

AUTHORS:

- Darij Grinberg (2013-09-05)

```python
def major_index()
    Return the major index of self. The major index is defined as the sum of the descents.

    EXAMPLES:

    >>> Composition([1, 1, 3, 1, 2, 1, 3]).major_index()
    31
```

```python
>>> from sage.all import *
>>> Composition([Integer(1), Integer(1), Integer(3), Integer(1), Integer(2),
...               Integer(1), Integer(3)]).major_index()
31
```

```python
def meet(other, check=True)
    Return the meet of self with a composition other of the same size.

    The meet of two compositions \( I \) and \( J \) of size \( n \) is the finest composition of \( n \) which is coarser than each of \( I \) and \( J \). It can be described as the composition whose descent set is the intersection of the descent sets of \( I \) and \( J \).

    INPUT:

    - other – composition of same size as self
    - check – (default: True) a Boolean determining whether to check the input compositions for having the same size

    OUTPUT:

    - the meet of the compositions self and other

    EXAMPLES:

    >>> Composition([3, 1, 1, 3, 1]).meet([4, 3, 2])
    [4, 5]
    >>> Composition([9, 6]).meet([1, 3, 6, 3, 2])
    [15]
    >>> Composition([9, 6]).meet([1, 3, 5, 1, 3, 2])
    [9, 6]
    >>> Composition([1, 1, 1, 1, 1]).meet([3, 2])
    [3, 2]
    >>> Composition([4, 2]).meet([3, 3])
    [6]
    >>> Composition([]).meet([])
    []
```
(continues on next page)
Let us verify on small examples that the meet of \( I \) and \( J \) is coarser than both of \( I \) and \( J \):

```python
sage: all( all( I.is_finer(I.meet(J)) and
.....: J.is_finer(I.meet(J))
.....: for J in Compositions(4) )
.....: for I in Compositions(4) )
True
```

and is the finest composition to do so:

```python
sage: all( all( all( I.meet(J).is_finer(K)
.....: for K in I.fatter() )
.....: if J.is_finer(K) )
.....: for J in Compositions(3) )
.....: for I in Compositions(3) )
True
```

The descent set of the meet of \( I \) and \( J \) is the intersection of the descent sets of \( I \) and \( J \):
sage: def test_meet(n):
    ....:     return all( all( I.to_subset().intersection(J.to_subset())
    ....:                     == I.meet(J).to_subset()  
    ....:                        for J in Compositions(n) )
    ....:                        for I in Compositions(n) )

sage: all( test_meet(n) for n in range(1, 5) )
True

>>> from sage.all import *

>>> def test_meet(n):
...    return all( all( I.to_subset().intersection(J.to_subset())
...                     == I.meet(J).to_subset()  
...                        for J in Compositions(n) )
...                        for I in Compositions(n) )

>>> all( test_meet(n) for n in range(Integer(1), Integer(5)) )
True

See also:

join()

AUTHORS:

• Darij Grinberg (2013-09-05)

near_concatenation(other)

Return the near-concatenation of two nonempty compositions self and other.

The near-concatenation \( I \odot J \) of two nonempty compositions \( I \) and \( J \) is defined as the composition

\[
(i_1, i_2, \ldots, i_{n-1}, i_n + j_1, j_2, j_3, \ldots, j_m),
\]

where \((i_1, i_2, \ldots, i_n) = I \) and \((j_1, j_2, \ldots, j_m) = J \).

This method returns None if one of the two input compositions is empty.

EXAMPLES:

sage: Composition([1, 1, 3]).near_concatenation(Composition([4, 1, 2]))
[1, 1, 7, 1, 2]

sage: Composition([6]).near_concatenation(Composition([1, 5]))
[7, 5]

sage: Composition([1, 5]).near_concatenation(Composition([6]))
[1, 11]

>>> from sage.all import *

>>> Composition([Integer(1), Integer(1), Integer(3)]).near_concatenation(Composition([Integer(4), Integer(1), Integer(2)]))
[1, 1, 7, 1, 2]

>>> Composition([Integer(6)]).near_concatenation(Composition([Integer(1), Integer(5)]))
[7, 5]

>>> Composition([Integer(1), Integer(5)]).near_concatenation(Composition([Integer(6)]))
[1, 11]

partial_sums(final=True)

The partial sums of the sequence defined by the entries of the composition.

If \( I = (i_1, \ldots, i_m) \) is a composition, then the partial sums of the entries of the composition are \([i_1, i_1 + i_2, \ldots, i_1 + i_2 + \cdots + i_m] \).

INPUT:
• `final` — (default: `True`) whether or not to include the final partial sum, which is always the size of the composition.

See also:

to_subset()

EXAMPLES:

```
sage: Composition([1,1,3,1,2,1,3]).partial_sums()
[1, 2, 5, 6, 8, 9, 12]

>>> from sage.all import *
>>> Composition([Integer(1),Integer(1),Integer(3),Integer(1),Integer(2),Integer(1),Integer(3)]).partial_sums()
[1, 2, 5, 6, 8, 9, 12]
```

With `final = False`, the last partial sum is not included:

```
sage: Composition([1,1,3,1,2,1,3]).partial_sums(final=False)
[1, 2, 5, 6, 8, 9]

>>> from sage.all import *
>>> Composition([Integer(1),Integer(1),Integer(3),Integer(1),Integer(2),Integer(1),Integer(3)]).partial_sums(final=False)
[1, 2, 5, 6, 8, 9]
```

peaks()

Return a list of the peaks of the composition `self`.

The peaks of a composition are the descents which do not immediately follow another descent.

EXAMPLES:

```
sage: Composition([1, 1, 3, 1, 2, 1, 3]).peaks()
[4, 7]

>>> from sage.all import *
>>> Composition([Integer(1), Integer(1), Integer(3), Integer(1), Integer(2), Integer(1), Integer(3)]).peaks()
[4, 7]
```

refinement_splitting(J)

Return the refinement splitting of `self` according to `J`.

INPUT:

• `J` — A composition such that `self` is finer than `J`

OUTPUT:

• the unique list of compositions \( \{I^{(p)}\}_{p=1,\ldots,m} \), obtained by splitting `I`, such that \( |I^{(p)}| = J_p \) for all \( p = 1,\ldots,m \).

See also:

`refinement_splitting_lengths()`

EXAMPLES:
refinement_splitting_lengths(J)

Return the lengths of the compositions in the refinement splitting of self according to J.

See also:

refinement_splitting() for the definition of refinement splitting

EXAMPLES:

>>> Composition([Integer(1),Integer(2),Integer(2),Integer(1),Integer(1),
                 Integer(2)]).refinement_splitting_lengths([Integer(5),Integer(1),
                                                           Integer(3)])
[3, 1, 2]
>>> Composition([]).refinement_splitting_lengths([])
[]
Composition([Integer(3)]).refinement_splitting_lengths([Integer(2)])
Traceback (most recent call last):
...
ValueError: compositions self (= [3]) and J (= [2]) must be of the same size

Composition([Integer(2),Integer(1)]).refinement_splitting_lengths([Integer(1),Integer(2)])
Traceback (most recent call last):
...
ValueError: composition J (= [2, 1]) does not refine self (= [1, 2])

reversed()
Return the reverse composition of self.

The reverse composition of a composition \((i_1, i_2, \ldots, i_k)\) is defined as the composition \((i_k, i_{k-1}, \ldots, i_1)\).

EXAMPLES:

```sage
Composition([1, 1, 3, 1, 2, 1, 3]).reversed()
[3, 1, 2, 1, 3, 1, 1]
```

ribbon_decomposition(other, check=True)
Return a pair describing the ribbon decomposition of a composition self with respect to a composition other of the same size.

If \(I\) and \(J\) are two compositions of the same nonzero size, then the ribbon decomposition of \(I\) with respect to \(J\) is defined as follows: Write \(I\) and \(J\) as \(I = (i_1, i_2, \ldots, i_n)\) and \(J = (j_1, j_2, \ldots, j_m)\). Then, the equality \(I = I_1 \bullet I_2 \bullet \ldots \bullet I_m\) holds for a unique \(m\)-tuple \((I_1, I_2, \ldots, I_m)\) of compositions such that each \(I_k\) has size \(j_k\) and for a unique choice of \(m - 1\) signs \(\bullet\) each of which is either the concatenation sign \(\cdot\) or the near-concatenation sign \(\odot\) (see \_add\(_\) and near_concatenation() for the definitions of these two signs). This \(m\)-tuple and this choice of signs together are said to form the ribbon decomposition of \(I\) with respect to \(J\). If \(I\) and \(J\) are empty, then the same definition applies, except that there are 0 rather than \(m - 1\) signs.

See Section 4.8 of [NCSF1].

INPUT:

- other – composition of same size as self
- check – (default: True) a Boolean determining whether to check the input compositions for having the same size

OUTPUT:

- a pair \((u, v)\), where \(u\) is a tuple of compositions (corresponding to the \(m\)-tuple \((I_1, I_2, \ldots, I_m)\) in the above definition), and \(v\) is a tuple of 0's and 1's (encoding the choice of signs \(\bullet\) in the above definition, with a 0 standing for \(\cdot\) and a 1 standing for \(\odot\)).

EXAMPLES:

```sage
Composition([3, 1, 1, 3, 1]).ribbon_decomposition([4, 3, 2])
(((3, 1), [1, 2], [1, 1]), (0, 1))
```
Let us check that the defining property $I = I_1 \cdot I_2 \cdot \ldots \cdot I_m$ is satisfied:

```python
sage: def compose_back(u, v):
    comp = u[0]
    r = len(v)
    if len(u) != r + 1:
        raise ValueError("something is wrong")
    for i in range(r):
        if v[i] == 0:
            comp += u[i + 1]
        else:
            comp = comp.near_concatenation(u[i + 1])
    return comp
sage: all( all( all( compose_back(*I.ribbon_decomposition(J)) == I
                      for J in Compositions(n) )
                  for I in Compositions(n) )
          for n in range(1, 5) )
True
```

(continues on next page)

• Darij Grinberg (2013-08-29)

**shuffle_product** *(other, overlap=False)*

The (overlapping) shuffles of *self* and *other*.

Suppose $I = (i_1, \ldots, i_k)$ and $J = (j_1, \ldots, j_l)$ are two compositions. A *shuffle* of $I$ and $J$ is a composition of length $k + l$ that contains both $I$ and $J$ as subsequences.

More generally, an *overlapping shuffle* of $I$ and $J$ is obtained by distributing the elements of $I$ and $J$ (preserving the relative ordering of these elements) among the positions of an empty list; an element of $I$ and an element of $J$ are permitted to share the same position, in which case they are replaced by their sum. In particular, a shuffle of $I$ and $J$ is an overlapping shuffle of $I$ and $J$.

**INPUT:**

• *other* – composition

• *overlap* – boolean (default: False); if True, the overlapping shuffle product is returned.

**OUTPUT:**

An enumerated set (allowing for multiplicities)

**EXAMPLES:**

The shuffle product of $[2, 2]$ and $[1, 1, 3]$:

```
sage: alph = Composition([2, 2])
sage: beta = Composition([1, 1, 3])
sage: S = alph.shuffle_product(beta); S
Shuffle product of [2, 2] and [1, 1, 3]
sage: S.list()  # needs sage.combinat
[[2, 2, 1, 1, 3], [2, 1, 2, 1, 3], [2, 1, 1, 2, 3], [2, 1, 1, 3, 2],
 [1, 2, 2, 1, 3], [1, 2, 1, 2, 3], [1, 2, 1, 3, 2], [1, 1, 2, 2, 3],
 [1, 1, 2, 3, 2], [1, 1, 3, 2, 2]]
```

```
>>> from sage.all import *
>>> alph = Composition([Integer(2), Integer(2)])
>>> beta = Composition([Integer(1), Integer(1), Integer(3)])
>>> S = alph.shuffle_product(beta); S  # needs sage.combinat
Shuffle product of [2, 2] and [1, 1, 3]
>>> S.list()  # needs sage.combinat
[[2, 2, 1, 1, 3], [2, 1, 2, 1, 3], [2, 1, 1, 2, 3], [2, 1, 1, 3, 2],
 [1, 2, 2, 1, 3], [1, 2, 1, 2, 3], [1, 2, 1, 3, 2], [1, 1, 2, 2, 3],
 [1, 1, 2, 3, 2], [1, 1, 3, 2, 2]]
```
The *overlapping* shuffle product of \([2, 2]\) and \([1, 1, 3]\):

```python
sage: alph = Composition([2, 2])
sage: beta = Composition([1, 1, 3])
sage: O = alph.shuffle_product(beta, overlap=True); O
Overlapping shuffle product of \([2, 2]\) and \([1, 1, 3]\)
sage: O.list()
```

```python
[[2, 2, 1, 1, 3], [2, 1, 2, 1, 3], [2, 1, 1, 2, 3], [2, 1, 1, 3, 2],
 [1, 2, 2, 1, 3], [1, 2, 1, 2, 3], [1, 2, 1, 3, 2], [1, 1, 2, 2, 3],
 [1, 1, 2, 3, 2], [1, 1, 3, 2, 2],
 [3, 2, 1, 3], [2, 3, 1, 3], [3, 1, 2, 3], [2, 1, 3, 3], [3, 1, 3, 2],
 [2, 1, 1, 5], [1, 3, 2, 3], [1, 2, 3, 3], [1, 3, 3, 2], [1, 2, 1, 5],
 [1, 1, 5, 2], [1, 1, 2, 5],
 [3, 3, 3], [3, 1, 5], [1, 3, 5]]
```

Note that the shuffle product of two compositions can include the same composition more than once since a composition can be a shuffle of two compositions in several ways. For example:

```python
sage: # needs sage.combinat
sage: w1 = Composition([1])
sage: S = w1.shuffle_product(w1); S
Shuffle product of \([1]\) and \([1]\)
sage: S.list()
```

```python
[[[1, 1], [1, 1]],
 [1, 1, 5, 2], [1, 1, 2, 5],
 [3, 3, 3], [3, 1, 5], [1, 3, 5]]
```

```python
>>> from sage.all import *
>>> alph = Composition([Integer(2), Integer(2)])
>>> beta = Composition([Integer(1), Integer(1), Integer(3)])
>>> O = alph.shuffle_product(beta, overlap=True); O
Overlapping shuffle product of \([2, 2]\) and \([1, 1, 3]\)
>>> O.list()
```

```python
[[[2, 2, 1, 1, 3], [2, 1, 2, 1, 3], [2, 1, 1, 2, 3], [2, 1, 1, 3, 2],
 [1, 2, 2, 1, 3], [1, 2, 1, 2, 3], [1, 2, 1, 3, 2], [1, 1, 2, 2, 3],
 [1, 1, 2, 3, 2], [1, 1, 3, 2, 2],
 [3, 2, 1, 3], [2, 3, 1, 3], [3, 1, 2, 3], [2, 1, 3, 3], [3, 1, 3, 2],
 [2, 1, 1, 5], [1, 3, 2, 3], [1, 2, 3, 3], [1, 3, 3, 2], [1, 2, 1, 5],
 [1, 1, 5, 2], [1, 1, 2, 5],
 [3, 3, 3], [3, 1, 5], [1, 3, 5]]
```

---

5.1. Comprehensive Module List
size()

Return the size of self, that is the sum of its parts.

EXAMPLES:

```python
sage: Composition([7, 1, 3]).size()
11
```

specht_module(base_ring=None)

Return the Specht module corresponding to self.

EXAMPLES:

```python
sage: SM = Composition([1, 2, 2]).specht_module(QQ); SM
Specht module of [(0, 0), (1, 0), (1, 1), (2, 0), (2, 1)] over Rational Field
```

```python
s = SymmetricFunctions(QQ).s()
s(SM.frobenius_image())
s[2, 2, 1]
```

specht_module_dimension(base_ring=None)

Return the dimension of the Specht module corresponding to self.

INPUT:

- base_ring – (default: QQ) the base ring

EXAMPLES:

```python
sage: Composition([1, 2, 2]).specht_module_dimension()   # needs sage.combinat sage.modules
5
```

```python
sage: Composition([1, 2, 2]).specht_module_dimension(GF(2))   # needs sage.combinat sage.modules sage.rings.finite_rings
5
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *

>>> Composition([Integer(1), Integer(2), Integer(2)]).specht_module_dimension()
5

>>> Composition([Integer(1), Integer(2), Integer(2)]).specht_module_dimension(GF(Integer(2)))
# needs sage.combinat sage.modules sage.rings.finite_rings
5
```

**static sum** *(compositions)*

Return the concatenation of the given compositions.

**INPUT:**

- compositions – a list (or iterable) of compositions

**EXAMPLES:**

```python
sage: Composition.sum([Composition([1, 1, 3]), Composition([4, 1, 2]),
                      Composition([3, 1])])
[1, 1, 3, 4, 1, 2, 3, 1]

>>> from sage.all import *

>>> Composition.sum([Composition([Integer(1), Integer(1), Integer(3)]),
                    Composition([Integer(4), Integer(1), Integer(2)]),
                    Composition([Integer(3),
                    Integer(1)])])
[1, 1, 3, 4, 1, 2, 3, 1]
```

Any iterable can be provided as input:

```python
sage: Composition.sum([Composition([i,i]) for i in [4,1,3]])
[4, 4, 1, 1, 3, 3]

>>> from sage.all import *

>>> Composition.sum([Composition([i,i]) for i in [Integer(4),Integer(1),
                                              Integer(3)])])
[4, 4, 1, 1, 3, 3]
```

Empty inputs are handled gracefully:

```python
sage: Composition.sum([]) == Composition([])
True

>>> from sage.all import *

>>> Composition.sum([]) == Composition([])
True
```

**sup**(other, check=True)

Return the join of self with a composition other of the same size.

The join of two compositions \( I \) and \( J \) of size \( n \) is the coarsest composition of \( n \) which refines each of \( I \) and \( J \). It can be described as the composition whose descent set is the union of the descent sets of \( I \) and \( J \). It is also the concatenation of \( I_1, I_2, \ldots, I_m \), where \( I = I_1 \bullet I_2 \bullet \ldots \bullet I_m \) is the ribbon decomposition of \( I \) with respect to \( J \) (see ribbon_decomposition()).

**INPUT:**

- other – composition of same size as self
• check – (default: True) a Boolean determining whether to check the input compositions for having the same size

OUTPUT:

• the join of the compositions self and other

EXAMPLES:

```python
sage: Composition([3, 1, 1, 3, 1]).join([4, 3, 2])
[3, 1, 1, 2, 1, 1]
sage: Composition([9, 6]).join([1, 3, 6, 3, 2])
[1, 3, 5, 1, 3, 2]
sage: Composition([9, 6]).join([1, 3, 5, 1, 3, 2])
[1, 3, 5, 1, 3, 2]
sage: Composition([1, 1, 1, 1, 1]).join([3, 2])
[1, 1, 1, 1, 1]
sage: Composition([4, 2]).join([3, 3])
[3, 1, 2]
sage: Composition([]).join([])
[]
```

Let us verify on small examples that the join of $I$ and $J$ refines both of $I$ and $J$:

```python
call( all( I.join(J).is_finer(I) and
.....: I.join(J).is_finer(J)
.....: for J in Compositions(4) )
.....: for I in Compositions(4) )
True
```

```python
>>> from sage.all import *
>>> call( all( I.join(J).is_finer(I) and
.....: I.join(J).is_finer(J)
.....: for J in Compositions(Integer(4)) )
.....: for I in Compositions(Integer(4)) )
True
```

and is the coarsest composition to do so:
Let us check that the join of $I$ and $J$ is indeed the concatenation of $I_1, I_2, \ldots, I_m$, where $I = I_1 \cdot I_2 \cdot \cdots \cdot I_m$ is the ribbon decomposition of $I$ with respect to $J$:

```
sage: all( all( Composition.sum(I.ribbon_decomposition(J)[0]) == I.join(J) for J in Compositions(4) ) for I in Compositions(4) )
True
```

Also, the descent set of the join of $I$ and $J$ is the union of the descent sets of $I$ and $J$:

```
sage: all( I.to_subset().union(J.to_subset()) == I.join(J).to_subset() for J in Compositions(Integer(4)) )
True
```

See also:

- `meet()`, `ribbon_decomposition()`

AUTHORS:

- Darij Grinberg (2013-09-05)

`to_code()`

Return the code of the composition `self`.

The code of a composition $I$ is a list of length size($I$) of 1s and 0s such that there is a 1 wherever a new part starts. (Exceptional case: When the composition is empty, the code is [0].)
Combinatorics, Release 10.4

```python
sage: Composition([4,1,2,3,5]).to_code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]

>>> from sage.all import *
>>> Composition([Integer(4),Integer(1),Integer(2),Integer(3),Integer(5)]).to_code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
```

to_partition()

Return the partition obtained by sorting self into decreasing order.

**EXAMPLES:**

```python
sage: Composition([2,1,3]).to_partition()  # needs sage.combinat
[3, 2, 1]

sage: Composition([4,2,2]).to_partition()  # needs sage.combinat
[4, 2, 2]

sage: Composition([]).to_partition()  # needs sage.combinat
[]
```

to_skew_partition (overlap=1)

Return the skew partition obtained from self.

This is a skew partition whose rows have the entries of self as their length, taken in reverse order (so the first entry of self is the length of the lowermost row, etc.). The parameter overlap indicates the number of cells on each row that are directly below cells of the previous row. When it is set to 1 (its default value), the result is the ribbon shape of self.

**EXAMPLES:**

```python
sage: Composition([3,4,1]).to_skew_partition()  # needs sage.combinat
[6, 6, 3] / [5, 2]

sage: Composition([3,4,1]).to_skew_partition(overlap=0)
[8, 7, 3] / [7, 3]

sage: Composition([]).to_skew_partition()  # needs sage.combinat
[] / []

sage: Composition([1,2]).to_skew_partition()  # needs sage.combinat
[2, 1] / []

sage: Composition([2,1]).to_skew_partition()  # needs sage.combinat
[2, 2] / [1]
```
to_subtract (final=False)

The subset corresponding to self under the bijection (see below) between compositions of \( n \) and subsets of \{1, 2, ..., n - 1\}.

The bijection maps a composition \((i_1, ..., i_k)\) of \( n \) to \{\( i_1 \), \( i_1 + i_2 \), \( i_1 + i_2 + i_3 \), ..., \( i_1 + \cdots + i_{k-1} \}\}.

INPUT:

- final = (default: False) whether or not to include the final partial sum, which is always the size of the composition.

See also:

partial_sums()

EXAMPLES:

sage: Composition([1,1,3,1,2,1,3]).to_subtract()
\{1, 2, 5, 6, 8, 9\}
sage: for I in Compositions(3): print(I.to_subtract())
\{1, 2\}
\{1\}
\{2\}
\{\}\n
With final=True, the sum of all the elements of the composition is included in the subset:

sage: Composition([1,1,3,1,2,1,3]).to_subtract(final=True)
\{1, 2, 5, 6, 8, 9, 12\}
**wll_gt** *(co2)*

Return `True` if the composition `self` is greater than the composition `co2` with respect to the wll-ordering; otherwise, return `False`.

The wll-ordering is a total order on the set of all compositions defined as follows: A composition `I` is greater than a composition `J` if and only if one of the following conditions holds:

- The size of `I` is greater than the size of `J`.
- The size of `I` equals the size of `J`, but the length of `I` is greater than the length of `J`.
- The size of `I` equals the size of `J`, and the length of `I` equals the length of `J`, but `I` is lexicographically greater than `J`.

(“wll-ordering” is short for “weight, length, lexicographic ordering”.)

**EXAMPLES:**

```python
sage: Composition([4,1,2]).wll_gt([3,1,3])
True
sage: Composition([7]).wll_gt([4,1,2])
False
sage: Composition([8]).wll_gt([4,1,2])
True
sage: Composition([3,2,2,2]).wll_gt([5,2])
True
sage: Composition([]).wll_gt([3])
False
sage: Composition([2,1]).wll_gt([2,1])
False
sage: Composition([2,2,2]).wll_gt([4,2])
True
sage: Composition([4,2]).wll_gt([2,2,2])
False
sage: Composition([1,1,2]).wll_gt([2,2])
True
sage: Composition([2,2]).wll_gt([1,3])
True
sage: Composition([2,1,2]).wll_gt([])
True
```

```python
>>> from sage.all import *
>>> Composition([Integer(4),Integer(1),Integer(2)]).wll_gt([Integer(3),
 →Integer(1),Integer(3)])
True
>>> Composition([Integer(7)]).wll_gt([Integer(4),Integer(1),Integer(2)])
False
>>> Composition([Integer(8)]).wll_gt([Integer(4),Integer(1),Integer(2)])
True
>>> Composition([Integer(3),Integer(2),Integer(2),Integer(2)]).wll_ →gt([Integer(5),Integer(2)])
True
>>> Composition([]).wll_gt([Integer(3)])
False
>>> Composition([Integer(2),Integer(1)]).wll_gt([Integer(2),Integer(1)])
False
>>> Composition([Integer(2),Integer(2),Integer(2)]).wll_gt([Integer(4),
 →Integer(2)])
True
```

(continues on next page)
Composition([Integer(4), Integer(2)]).wll_gt([Integer(2), Integer(2), Integer(2)])
False
Composition([Integer(1), Integer(1), Integer(2)]).wll_gt([Integer(2), Integer(2), Integer(2)])
True
Composition([Integer(2), Integer(2)]).wll_gt([Integer(1), Integer(3)])
True
Composition([Integer(2), Integer(1), Integer(2)]).wll_gt([])
True

class sage.combinat.composition.Compositions(is_infinite=False, category=None)
Bases: UniqueRepresentation, Parent

Set of integer compositions.

A composition $c$ of a nonnegative integer $n$ is a list of positive integers with total sum $n$.

See also:

- Composition
- Partitions
- IntegerVectors

EXAMPLES:

There are 8 compositions of 4:

\[
\text{sage: Compositions(4).cardinality()}
8
\]

\[
\text{Compositions(Integer(4)).cardinality()}
8
\]

Here is the list of them:

\[
\text{sage: Compositions(4).list()}
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1], [4]]
\]

\[
\text{Compositions(Integer(4)).list()}
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1], [4]]
\]

You can use the .first() method to get the ‘first’ composition of a number:

\[
\text{sage: Compositions(4).first()}
[1, 1, 1, 1]
\]

\[
\text{Compositions(Integer(4)).first()}
[1, 1, 1, 1]
\]

You can also calculate the ‘next’ composition given the current one:
Compositions(4).next([1,1,2])
[1, 2, 1]

```python
from sage.all import *
Compositions(Integer(4)).next([Integer(1),Integer(1),Integer(2)])
[1, 2, 1]
```

If $n$ is not specified, this returns the combinatorial class of all (non-negative) integer compositions:

```python
Compositions()  # Compositions of non-negative integers
[] in Compositions()  # True
[2,3,1] in Compositions()  # True
[-2,3,1] in Compositions()  # False
```

```python
from sage.all import *
Compositions()  # Compositions of non-negative integers
[] in Compositions()  # True
[Integer(2),Integer(3),Integer(1)] in Compositions()  # True
[-Integer(2),Integer(3),Integer(1)] in Compositions()  # False
```

If $n$ is specified, it returns the class of compositions of $n$:

```python
Compositions(3)  # Compositions of 3
list(Compositions(3))
[[1, 1, 1], [1, 2], [2, 1], [3]]
Compositions(3).cardinality()
4
```

```python
from sage.all import *
Compositions(Integer(3))  # Compositions of 3
list(Compositions(Integer(3)))
[[1, 1, 1], [1, 2], [2, 1], [3]]
Compositions(Integer(3)).cardinality()
4
```

The following examples show how to test whether or not an object is a composition:

```python
[3,4] in Compositions()
True
[3,4] in Compositions(7)
True
[3,4] in Compositions(5)
False
```

```python
from sage.all import *
[Integer(3),Integer(4)] in Compositions()
```
Similarly, one can check whether or not an object is a composition which satisfies further constraints:

```
sage: [4,2] in Compositions(6, inner=[2,2])
True
sage: [4,2] in Compositions(6, inner=[2,3])
False
sage: [4,1] in Compositions(5, inner=[2,1], max_slope = 0)
True
```

An example with incompatible constraints:

```
sage: [4,2] in Compositions(6, inner=[2,2], min_part=3)
False
```

The options `length`, `min_length`, and `max_length` can be used to set length constraints on the compositions. For example, the compositions of `4` of length equal to, at least, and at most `2` are given by:

```
sage: Compositions(4, length=2).list()
[[3, 1], [2, 2], [1, 3]]
sage: Compositions(4, min_length=2).list()
[[3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
sage: Compositions(4, max_length=2).list()
[[4], [3, 1], [2, 2], [1, 3]]
```

Setting both `min_length` and `max_length` to the same value is equivalent to setting `length` to this value:
Compositions(4, min_length=2, max_length=2).list()
[[[3, 1], [2, 2], [1, 3]]

```python
>>> from sage.all import *
>>> Compositions(Integer(4), min_length=Integer(2), max_length=Integer(2)).list()
[[[3, 1], [2, 2], [1, 3]]
```

The options `inner` and `outer` can be used to set part-by-part containment constraints. The list of compositions of 4 bounded above by [3,1,2] is given by:

```python
sage: list(Compositions(4, outer=[3,1,2]))
[[[3, 1], [2, 1, 1], [1, 1, 2]]
```

```python
>>> from sage.all import *
>>> list(Compositions(Integer(4), outer=[Integer(3),Integer(1),Integer(2)]))
[[[3, 1], [2, 1, 1], [1, 1, 2]]
```

`outer` sets `max_length` to the length of its argument. Moreover, the parts of `outer` may be infinite to clear the constraint on specific parts. This is the list of compositions of 4 of length at most 3 such that the first and third parts are at most 1:

```python
sage: Compositions(4, outer=[1,oo,1]).list()
[[[1, 3], [1, 2, 1]]
```

```python
>>> from sage.all import *
>>> Compositions(Integer(4), outer=[Integer(1),oo,Integer(1)]).list()
[[[1, 3], [1, 2, 1]]
```

This is the list of compositions of 4 bounded below by [1,1,1]:

```python
sage: Compositions(4, inner=[1,1,1]).list()
[[[2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

```python
>>> from sage.all import *
>>> Compositions(Integer(4), inner=[Integer(1),Integer(1),Integer(1)]).list()
[[[2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

The options `min_slope` and `max_slope` can be used to set constraints on the slope, that is the difference $p[i+1]-p[i]$ of two consecutive parts. The following is the list of weakly increasing compositions of 4:

```python
sage: Compositions(4, min_slope=0).list()
[[[4], [2, 2], [1, 3], [1, 1, 2], [1, 1, 1, 1]]
```

```python
>>> from sage.all import *
>>> Compositions(Integer(4), min_slope=Integer(0)).list()
[[[4], [2, 2], [1, 3], [1, 1, 2], [1, 1, 1, 1]]
```

Here are the weakly decreasing ones:

```python
sage: Compositions(4, max_slope=0).list()
[[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

```python
>>> from sage.all import *
>>> Compositions(Integer(4), max_slope=Integer(0)).list()
[[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```
The following is the list of compositions of 4 such that two consecutive parts differ by at most one:

```
sage: Compositions(4, min_slope=-1, max_slope=1).list()
[[4], [2, 2], [2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

The constraints can be combined together in all reasonable ways. This is the list of compositions of 5 of length between 2 and 4 such that the difference between consecutive parts is between -2 and 1:

```
sage: Compositions(5, max_slope=1, min_slope=-2, min_length=2, max_length=4).list()
[[3, 2], [3, 1, 1], [2, 3], [2, 2, 1], [2, 1, 2], [2, 1, 1, 1], [1, 2, 2], [1, 2, 1, 1], [1, 1, 2, 1], [1, 1, 1, 2]]
```

We can do the same thing with an outer constraint:

```
sage: Compositions(5, max_slope=1, min_slope=-2, min_length=2, max_length=4, outer=[2, 5, 2]).list()
[[2, 3], [2, 2, 1], [2, 1, 2], [1, 2, 2]]
```

However, providing incoherent constraints may yield strange results. It is up to the user to ensure that the inner and outer compositions themselves satisfy the parts and slope constraints.

Note that setting min_part=0 is not allowed:

```
sage: Compositions(2, length=3, min_part=0)
Traceback (most recent call last):
... ValueError: setting min_part=0 is not allowed for Compositions
```

Instead you must use IntegerVectors:

```
sage: list(IntegerVectors(2, 3))
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```
The generation algorithm is constant amortized time, and handled by the generic tool `IntegerListsLex`.

### Element

**from_code** *(code)*

Return the composition from its code. The code of a composition \( I \) is a list of length \( \text{size}(I) \) consisting of 1s and 0s such that there is a 1 wherever a new part starts. (Exceptional case: When the composition is empty, the code is \([0]\).)

**EXAMPLES:**

```python
sage: Composition([4,1,2,3,5]).to_code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: Compositions().from_code(_)  # output will be the same as the input
[4, 1, 2, 3, 5]
sage: Composition([3,1,2,3,5]).to_code()
[1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: Compositions().from_code(_)  # output will be the same as the input
[3, 1, 2, 3, 5]
```

**from_descents** *(descents, nps=None)*

Return a composition from the list of descents.

**INPUT:**

- **descents** – an iterable
- **nps** – (default: None) an integer or None

**OUTPUT:**

- The composition of nps whose descents are listed in descents, assuming that nps is not None (otherwise, the last element of descents is removed from descents, and nps is set to be this last element plus 1).

**EXAMPLES:**

```python
sage: [x-1 for x in Composition([1, 1, 3, 4, 3]).to_subset()]
[0, 1, 4, 8]
sage: Compositions().from_descents([1,0,4,8],12)  # Output will be the same as the input
[1, 1, 3, 4, 3]
```
sage: Compositions().from_descents([1,0,4,8,11])
[1, 1, 3, 4, 3]

from sage.all import *

>>> Compositions().from_descents([Integer(1),Integer(0),Integer(4),
                                   Integer(8),Integer(12)])
[1, 1, 3, 4, 3]

from_subset (S, n)

The composition of \( n \) corresponding to the subset \( S \) of \{1,2,...,n-1\} under the bijection that maps the composition \((i_1,i_2,...,i_k)\) of \( n \) to the subset \( \{i_1,i_1+i_2,i_1+i_2+i_3,...,i_1+\cdots+i_{k-1}\} \) (see `Composition.to_subset()`).

INPUT:

- \( S \) – an iterable, a subset of \{1,2,...,n-1\}
- \( n \) – an integer

EXAMPLES:

sage: Compositions().from_subset([2,1,5,9], 12)
[1, 1, 3, 4, 3]
sage: Compositions().from_subset({2,1,5,9}, 12)
[1, 1, 3, 4, 3]
sage: Compositions().from_subset([], 12)
[12]
sage: Compositions().from_subset([], 0)
[]

from sage.all import *

>>> Compositions().from_subset([Integer(2),Integer(1),Integer(5),Integer(9)],
                              Integer(12))
[1, 1, 3, 4, 3]

class sage.combinat.composition.Compositions_all

Bases: Compositions

Class of all compositions.

subset (size=None)

Return the set of compositions of the given size.
EXAMPLES:

```python
sage: C = Compositions()
sage: C.subset(4)
Compositions of 4
sage: C.subset(size=3)
Compositions of 3
```

```python
>>> from sage.all import *
>>> C = Compositions()
>>> C.subset(Integer(4))
Compositions of 4
>>> C.subset(size=Integer(3))
Compositions of 3
```

`zero()`

Return the zero of the additive monoid.

This is the empty composition.

EXAMPLES:

```python
sage: C = Compositions()
sage: C.zero()
[]
```

```python
>>> from sage.all import *
>>> C = Compositions()
>>> C.zero()
[]
```

class `sage.combinat.composition.Compositions_constraints`(*args, **kwds)

Bases: `IntegerListsLex`

class `sage.combinat.composition.Compositions_n(n)`

Bases: `Compositions`

Class of compositions of a fixed $n$.

cardinality()

Return the number of compositions of $n$.

random_element()

Return a random Composition with uniform probability.

This method generates a random binary word starting with a 1 and then uses the bijection between compositions and their code.

EXAMPLES:

```python
sage: Compositions(5).random_element()  # random
[2, 1, 1, 1]
sage: Compositions(0).random_element()
[]
sage: Compositions(1).random_element()
[1]
```
>>> from sage.all import *

```
>>> Compositions(Integer(5)).random_element() # random
[2, 1, 1, 1]
>>> Compositions(Integer(0)).random_element()
[]
>>> Compositions(Integer(1)).random_element()
[1]
```

sage.combinat.composition.composition_iterator_fast(n)

Iterator over compositions of \( n \) yielded as lists.

### 5.1.30 Signed Compositions

class sage.combinat.composition_signed.SignedCompositions(n)

Bases: Compositions\_n

The class of signed compositions of \( n \).

**EXAMPLES:**

```
sage: SC3 = SignedCompositions(3); SC3
Signed compositions of 3
sage: SC3.cardinality()
18
sage: len(SC3.list())
18
sage: SC3.first()
[1, 1, 1]
```

```sage
sage: SC3.last()
[-3]
sage: SC3.random_element() # random
[1, -1, 1]
sage: SC3.list()
[[1, 1, 1],
 [1, 1, -1],
 [1, -1, 1],
 [1, -1, -1],
 [-1, 1, 1],
 [-1, 1, -1],
 [-1, -1, 1],
 [-1, -1, -1],
 [1, 2],
 [1, -2],
 [-1, 2],
 [-1, -2],
 [2, 1],
 [2, -1],
 [-2, 1],
 [-2, -1],
 [3],
 [-3]]
```

```sage
>>> from sage.all import *

```sage
```
```sage
```
```sage
```sage
```sage
```
```sage
```sage
```sage
```sage
```sage
```sage
```sage
(continues on next page)
```python
>>> SC3.cardinality()
18
>>> len(SC3.list())
18
>>> SC3.first()
[1, 1, 1]
>>> SC3.last()
[-3]
>>> SC3.random_element()  # random
[1, -1, 1]
>>> SC3.list()
[[1, 1, 1],
 [1, 1, -1],
 [1, -1, 1],
 [1, -1, -1],
 [-1, 1, 1],
 [-1, 1, -1],
 [-1, -1, 1],
 [-1, -1, -1],
 [1, 2],
 [1, -2],
 [-1, 2],
 [-1, -2],
 [2, 1],
 [2, -1],
 [-2, 1],
 [-2, -1],
 [3],
 [-3]]
```

**cardinality()**

Return the number of elements in `self`.

The number of signed compositions of \( n \) is equal to

\[
\sum_{i=1}^{n+1} \binom{n-1}{i-1} 2^i
\]

**EXAMPLES:**

```python
sage: SC4 = SignedCompositions(4)
sage: SC4.cardinality() == len(SC4.list())
True
sage: SignedCompositions(3).cardinality()
18
```

```python
>>> from sage.all import *
>>> SC4 = SignedCompositions(Integer(4))
>>> SC4.cardinality() == len(SC4.list())
True
>>> SignedCompositions(Integer(3)).cardinality()
18
```
5.1.31 Composition Tableaux

AUTHORS:

• Chris Berg, Jeff Ferreira (2012-9): Initial version

```python
class sage.combinat.composition_tableau.CompositionTableau(parent, t)

Bases: CombinatorialElement

A composition tableau.

A composition tableau \( t \) of shape \( I = (I_1, \ldots, I_\ell) \) is an array of boxes in rows, \( I_i \) boxes in row \( i \), filled with positive integers such that:

1) the entries in the rows of \( t \) weakly decrease from left to right,
2) the left-most column of \( t \) strictly increase from top to bottom.
3) Add zero entries to the rows of \( t \) until the resulting array is rectangular of shape \( \ell \times m \). For \( 1 \leq i < j \leq \ell, 2 \leq k \leq m \) and \( t(j, k) \neq 0 \), and also if \( t(j, k) \geq t(i, k) \) implies \( t(j, k) > t(i, k - 1) \).

INPUT:

• \( t \) – A list of lists

EXAMPLES:

```python
sage: CompositionTableau([[1], [2, 2]])
[[1], [2, 2]]

sage: CompositionTableau([[1], [3, 2], [4, 4]])
[[1], [3, 2], [4, 4]]

sage: CompositionTableau([])
[]
```

```
>>> from sage.all import *

>>> CompositionTableau([[Integer(1)], [Integer(3), Integer(2)], [Integer(4), Integer(4)]])
[[1], [3, 2], [4, 4]]

>>> CompositionTableau([])
[]
```

descent_composition()  
Return the composition corresponding to the set of all \( i \) that do not have \( i + 1 \) appearing strictly to the left of \( i \) in self.

EXAMPLES:

```python
sage: CompositionTableau([[1], [3, 2], [4, 4]]).descent_composition()
[1, 2, 2]
```

```python
>>> from sage.all import *

>>> CompositionTableau([[Integer(1)], [Integer(3), Integer(2)], [Integer(4), Integer(4)]]).descent_composition()
[1, 2, 2]
```

descent_set()  
Return the set of all \( i \) that do not have \( i + 1 \) appearing strictly to the left of \( i \) in self.

EXAMPLES:
CompositionTableau([[1], [3, 2], [4, 4]]).descent_set()
[1, 3]

>>> from sage.all import *
>>> CompositionTableau([[Integer(1), Integer(3), Integer(2)], [Integer(4), Integer(4)]]).descent_set()
[1, 3]

is_standard()  
Return True if self is a standard composition tableau and False otherwise.

EXAMPLES:

sage: CompositionTableau([[1, 1], [3, 2], [4, 4, 3]]).is_standard()
False
sage: CompositionTableau([[2, 1], [3], [4]]).is_standard()
True

>>> from sage.all import *
>>> CompositionTableau([[Integer(1), Integer(3), Integer(2)], [Integer(4), Integer(4)]]).is_standard()
False
>>> CompositionTableau([[Integer(2), Integer(1)], [Integer(3)], [Integer(4)]]).is_standard()
True

pp()  
Return a pretty print string of self.

EXAMPLES:

sage: CompositionTableau([[1], [3, 2], [4, 4]]).pp()
1
3 2
4 4

>>> from sage.all import *
>>> CompositionTableau([[Integer(1), Integer(3), Integer(2)], [Integer(4), Integer(4)]]).pp()
1
3 2
4 4

shape_composition()  
Return a Composition object which is the shape of self.

EXAMPLES:

sage: CompositionTableau([[1, 1], [3, 2], [4, 4, 3]]).shape_composition()
[2, 2, 3]
sage: CompositionTableau([[2, 1], [3], [4]]).shape_composition()
[2, 1, 1]
CompositionTableau([[Integer(2), Integer(1)], [Integer(3)], [Integer(4)]]).shape_composition()  
[2, 1, 1]

**shape_partition()**

Return a partition which is the shape of self sorted into weakly decreasing order.

**EXAMPLES:**

```sage
CompositionTableau([[1, 1], [3, 2], [4, 4, 3]]).shape_partition()
[3, 2, 2]
CompositionTableau([[2, 1], [3], [4]]).shape_partition()
[2, 1, 1]
```

**size()**

Return the number of boxes in self.

**EXAMPLES:**

```sage
CompositionTableau([[1], [3, 2], [4, 4]]).size()
5
```

**weight()**

Return a composition where entry $i$ is the number of times that $i$ appears in self.

**EXAMPLES:**

```sage
CompositionTableau([[1], [3, 2], [4, 4]]).weight()
[1, 1, 1, 2, 0]
```

```python
>>> from sage.all import *
>>> CompositionTableau([[1], [3, 2], [4, 4]]).weight()
[1, 1, 1, 2, 0]
```

```python
>>> CompositionTableau([[1, 1], [3, 2], [4, 4, 3]]).shape_partition()
[3, 2, 2]
```

```python
>>> CompositionTableau([[2, 1], [3], [4]]).shape_partition()
[2, 1, 1]
```

```python
>>> from sage.all import *
>>> CompositionTableau([[1, 1], [3, 2], [4, 4, 3]]).shape_partition()
[3, 2, 2]
```

```python
>>> CompositionTableau([[2, 1], [3], [4]]).shape_partition()
[2, 1, 1]
```

```python
>>> from sage.all import *
>>> CompositionTableau([[1, 1], [3, 2], [4, 4, 3]]).shape_partition()
[3, 2, 2]
```

```python
>>> CompositionTableau([[2, 1], [3], [4]]).shape_partition()
[2, 1, 1]
```

```python
>>> from sage.all import *
>>> CompositionTableau([[1, 1], [3, 2], [4, 4, 3]]).shape_partition()
[3, 2, 2]
```

```python
>>> CompositionTableau([[2, 1], [3], [4]]).shape_partition()
[2, 1, 1]
```

```python
>>> from sage.all import *
>>> CompositionTableau([[1, 1], [3, 2], [4, 4, 3]]).shape_partition()
[3, 2, 2]
```

```python
>>> CompositionTableau([[2, 1], [3], [4]]).shape_partition()
[2, 1, 1]
```
• size – the size of the composition tableaux
• shape – the shape of the composition tableaux
• max_entry – the maximum entry for the composition tableaux

Positional arguments:

• The first argument is interpreted as size or shape depending on whether it is an integer or a composition.

EXAMPLES:

```
sage: CT = CompositionTableaux(3); CT
Composition Tableaux of size 3 and maximum entry 3
sage: list(CT)
[[[1], [2], [3]],
 [[[1], [2, 2]],
 [[[1], [3, 2]],
 [[[1], [3, 3]],
 [[[2], [3, 3]],
 [[[1, 1], [2]],
 [[[1, 1], [3]],
 [[[2, 1], [3]],
 [[[2, 2], [3]],
 [[[1, 1, 1]],
 [[[2, 1, 1]],
 [[[2, 2, 1]],
 [[[3, 1, 1]],
 [[[3, 2, 1]],
 [[[3, 2, 2]],
 [[[3, 3, 1]],
 [[[3, 3, 2]],
 [[[3, 3, 3]]]

sage: CT = CompositionTableaux([1,2,1]); CT
Composition tableaux of shape [1, 2, 1] and maximum entry 4
sage: list(CT)
[[[1], [2, 2], [3]],
 [[[1], [2, 2], [4]],
 [[[1], [3, 2], [4]],
 [[[1], [3, 3], [4]],
 [[[2], [3, 3], [4]]]

sage: CT = CompositionTableaux(shape=[1,2,1],max_entry=3); CT
Composition tableaux of shape [1, 2, 1] and maximum entry 3
sage: list(CT)
[[[1], [2, 2], [3]]]

sage: CT = CompositionTableaux(2,max_entry=3); CT
Composition Tableaux of size 2 and maximum entry 3
sage: list(CT)
[[[1], [2]],
 [[[1], [3]],
 [[[2], [3]],
 [[[1, 1]],
 [[[2, 1]],
 [[[2, 2]],
 [[[3, 1]],
 [[[3, 2]],
 [[[3, 3]],
 [[[3, 2]],
 [[[3, 3]],
 [[[3, 3]],

(continues on next page)
sage: CT = CompositionTableaux(0); CT
Composition Tableaux of size 0 and maximum entry 0
sage: list(CT)
[[[]]]

>>> from sage.all import *

>>> CT = CompositionTableaux(Integer(3)); CT
Composition Tableaux of size 3 and maximum entry 3

[[[]]]
```

**Element**

alias of :class:`CompositionTableau`

**class** \texttt{sage.combinat.composition\_tableau.CompositionTableaux\_Backtracker}\((\text{shape}, \text{max\_entry}=\text{None})\)

**Bases:** \texttt{GenericBacktracker}

A backtracker class for generating sets of composition tableaux.

**get\_next\_pos**(\textit{ii, jj})

**EXAMPLES:**

```
sage: from sage.combinat.composition_tableau import...
    -> CompositionTableauxBacktracker
sage: T = CompositionTableau([[2,1],[5,4,3,2],[6],[7,7,6]])
sage: n = CompositionTableauxBacktracker(T.shape_composition())
sage: n.get_next_pos(1,1)
(1, 2)
```

```
>>> from sage.all import *
    
>>> from sage.combinat.composition_tableau import...
    -> CompositionTableauxBacktracker
>>> T = CompositionTableau([[Integer(2),Integer(1)],[Integer(5),Integer(4),
    -> Integer(3),Integer(2)],[Integer(6)],[Integer(7),Integer(7),Integer(6)]])
>>> n = CompositionTableauxBacktracker(T.shape_composition())
>>> n.get_next_pos(Integer(1),Integer(1))
(1, 2)
```

**class** \texttt{sage.combinat.composition\_tableau.CompositionTableaux\_all}\((\text{max\_entry}=\text{None})\)

**Bases:** \texttt{CompositionTableaux, DisjointUnionEnumeratedSets}

All composition tableaux.

**an\_element**()

Return a particular element of \texttt{self}.

**EXAMPLES:**

```
sage: CT = CompositionTableaux()
sage: CT.an_element()
[[1, 1], [2]]
```

```
>>> from sage.all import *
    
>>> CT = CompositionTableaux()
>>> CT.an_element()
[[1, 1], [2]]
```
class sage.combinat.composition_tableau.CompositionTableaux_shape(comp, max_entry=None)

Bases: CompositionTableaux

Composition tableaux of a fixed shape \( \text{comp} \) with a given max entry.

INPUT:

- \( \text{comp} \) – a composition.
- \( \text{max_entry} \) – a nonnegative integer. This keyword argument defaults to the size of \( \text{comp} \).

\text{an_element}()

Return a particular element of \( \text{CompositionTableaux\_shape} \).

EXAMPLES:

\[
\begin{align*}
\text{sage:}& \ CT = \text{CompositionTableaux}([1, 2, 1]) \\
\text{sage:}& \ CT.\text{an\_element}() \\
\text{[[1], [2, 2], [3]]}
\end{align*}
\]

\[
\begin{align*}
\text{sage:}& \ \text{from sage.all import *} \\
\text{sage:}& \ CT = \text{CompositionTableaux}([[\text{Integer}(1), \text{Integer}(2), \text{Integer}(1)]]) \\
\text{sage:}& \ CT.\text{an\_element}() \\
\text{[[1], [2, 2], [3]]}
\end{align*}
\]

class sage.combinat.composition_tableau.CompositionTableaux_size(n, max_entry=None)

Bases: CompositionTableaux

Composition tableaux of a fixed size \( n \).

INPUT:

- \( n \) – a nonnegative integer.
- \( \text{max\_entry} \) – a nonnegative integer. This keyword argument defaults to \( n \).

OUTPUT:

- The class of composition tableaux of size \( n \).

5.1.32 Constellations

A constellation is a tuple \( (g_0, g_1, \ldots, g_k) \) of permutations such that the product \( g_0 g_1 \ldots g_k \) is the identity. One often assumes that the group generated by \( g_0, g_1, \ldots, g_k \) acts transitively ([LZ2004] definition 1). Geometrically, it corresponds to a covering of the 2-sphere ramified over \( k \) points (the transitivity condition corresponds to the connectivity of the covering).

EXAMPLES:

\[
\begin{align*}
\text{sage:}& \ c = \text{Constellation}(['_{(1,2)}', '_{(1,3)}', \text{None}]) \\
\text{sage:}& \ c \\
\text{constellation of length 3 and degree 3} \\
g0 \ (1,2)(3) \\
g1 \ (1,3)(2) \\
g2 \ (1,3,2) \\
\text{sage:}& \ C = \text{Constellations}(3,4); C \\
\text{connected constellations of length 3 and degree 4 on \{1, 2, 3, 4\}}
\end{align*}
\]
sage: C.cardinality()  # long time
426

sage: C = Constellations(3, 4, domain=('a', 'b', 'c', 'd'))
sage: C
Connected constellations of length 3 and degree 4 on {'a', 'b', 'c', 'd'}
sage: c = C(('a', 'c'), ('b', 'c'), ('a', 'd'), None)
sage: c
Constellation of length 3 and degree 4
g0 ('a', 'c') (b') (d')
g1 ('a', 'd') (b', 'c')
g2 ('a', 'd', 'c', 'b')
sage: c.is_connected()
True
sage: c.euler_characteristic()
2
sage: TestSuite(C).run()

>>> from sage.all import *
>>> c = Constellation(['(1,2)', '(1,3)', None])
>>> c
Constellation of length 3 and degree 3
g0 (1,2)(3)
g1 (1,3)(2)
g2 (1,3,2)
>>> C = Constellations(Integer(3), Integer(4)); C
Connected constellations of length 3 and degree 4 on {1, 2, 3, 4}
>>> C.cardinality()  # long time
426

>>> C = Constellations(Integer(3), Integer(4), domain=('a', 'b', 'c', 'd'))
>>> C
Connected constellations of length 3 and degree 4 on {'a', 'b', 'c', 'd'}
>>> c = C(('a', 'c'), ('b', 'c'), ('a', 'd'), None)
>>> c
Constellation of length 3 and degree 4
g0 ('a', 'c') (b') (d')
g1 ('a', 'd') (b', 'c')
g2 ('a', 'd', 'c', 'b')
>>> c.is_connected()
True
>>> c.euler_characteristic()
2
>>> TestSuite(C).run()

sage.combinat.constellation.Constellation(g=None, mutable=False, connected=True, check=True)

**INPUT:**

- **g** – a list of permutations
- **mutable** – whether the result is mutable or not. Default is False.
- **connected** – whether the result should be connected. Default is True.
- **check** – whether or not to check. If it is True, then the list g must contains no None.

**EXAMPLES:**
Simple initialization:

```python
sage: Constellation([(0,1), (0,3)(1,2), (0,3,1,2)])
Constellation of length 3 and degree 4
g0 (0,1)(2)(3)
g1 (0,3)(1,2)
g2 (0,3,1,2)
```

```python
>>> from sage.all import *

>>> Constellation([(0,1), (0,3)(1,2), (0,3,1,2)])
Constellation of length 3 and degree 4
g0 (0,1)(2)(3)
g1 (0,3)(1,2)
g2 (0,3,1,2)
```

One of the permutation can be omitted:

```python
sage: Constellation([(0,1), None, (0,4)(1,2,3)])
Constellation of length 3 and degree 5
g0 (0,1)(2)(3)(4)
g1 (0,3,2,1,4)
g2 (0,4)(1,2,3)
```

```python
>>> from sage.all import *

>>> Constellation([(0,1), None, (0,4)(1,2,3)])
Constellation of length 3 and degree 5
g0 (0,1)(2)(3)(4)
g1 (0,3,2,1,4)
g2 (0,4)(1,2,3)
```

One can define mutable constellations:

```python
sage: Constellation([[0,2,1], [2,1,0], [1,2,0]], mutable=True)
Constellation of length 3 and degree 3
g0 (0)(1,2)
g1 (0,2)(1)
g2 (0,1,2)
```

```python
>>> from sage.all import *

>>> Constellation([[0,2,1], [2,1,0], [1,2,0]], mutable=True)
Constellation of length 3 and degree 3
g0 (0)(1,2)
g1 (0,2)(1)
g2 (0,1,2)
```

class `sage.combinat.constellation.Constellation_class` (parent, g, connected, mutable, check)

Bases: `Element`

**Constellation**

A constellation or a tuple of permutations \((g_0, g_1, ..., g_k)\) such that the product \(g_0g_1...g_k\) is the identity.

**braid_group_action** \((i)\)

Act on `self` as the braid group generator that exchanges position \(i\) and \(i + 1\).

**INPUT:**
• $i$ – integer in $[0, n - 1]$ where $n$ is the length of self

EXAMPLES:

```python
sage: sigma = lambda c, i: c.braid_group_action(i)
sage: c = Constellation(['(0,1)(2,3,4)', '(1,4)', 'None']); c
Constellation of length 3 and degree 5
  g0 (0,1)(2,3,4)
  g1 (0)(1,4)(2)(3)
  g2 (0,1,3,2,4)
sage: sigma(c, 1)
Constellation of length 3 and degree 5
  g0 (0,1)(2,3,4)
  g1 (0,1,3,2,4)
  g2 (0,3)(1)(2)(4)
```

Check the commutation relation:

```python
sage: c = Constellation(['(0,1)(2,3,4)', '(1,4)', 'None'])
sage: d = Constellation(['(0,1,3,5)', '(2,3,4)', '(0,3,5)', 'None'])
sage: c13 = sigma(sigma(c, 0), 2)
sage: c31 = sigma(sigma(c, 2), 0)
sage: c13 == c31
True
sage: d13 = sigma(sigma(d, 0), 2)
sage: d31 = sigma(sigma(d, 2), 0)
sage: d13 == d31
True
```

Check the braid relation:

```python
>>> from sage.all import *
>>> sigma = lambda c, i: c.braid_group_action(i)

>>> c = Constellation(['(0,1)(2,3,4)', '(1,4)', 'None'])
>>> d = Constellation(['(0,1,3,5)', '(2,3,4)', '(0,3,5)', 'None'])
>>> c13 = sigma(sigma(c, Integer(0)), Integer(2))
>>> c31 = sigma(sigma(c, Integer(2)), Integer(0))
>>> c13 == c31
True
>>> d13 = sigma(sigma(d, Integer(0)), Integer(2))
>>> d31 = sigma(sigma(d, Integer(2)), Integer(0))
>>> d13 == d31
True
```
sage: c121 = sigma(sigma(sigma(c, 1), 2), 1)
sage: c212 = sigma(sigma(sigma(c, 2), 1), 2)
sage: c121 == c212
True
sage: d121 = sigma(sigma(sigma(d, 1), 2), 1)
sage: d212 = sigma(sigma(sigma(d, 2), 1), 2)
sage: d121 == d212
True

```python
>>> from sage.all import *
>>> c121 = sigma(sigma(sigma(c, Integer(1)), Integer(2)), Integer(1))
>>> c212 = sigma(sigma(sigma(c, Integer(2)), Integer(1)), Integer(2))
>>> c121 == c212
True
>>> d121 = sigma(sigma(sigma(d, Integer(1)), Integer(2)), Integer(1))
>>> d212 = sigma(sigma(sigma(d, Integer(2)), Integer(1)), Integer(2))
>>> d121 == d212
True
```

**braid_group_orbit()**

Return the graph of the action of the braid group.

The action is considered up to isomorphism of constellation.

**EXAMPLES:**

```python
sage: c = Constellation(["(0,1)(2,3,4),'(1,4)',None"]); c
Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0)(1,4)(2)(3)
g2 (0,1,3,2,4)
sage: G = c.braid_group_orbit()
sage: G.num_verts()
4
sage: G.num_edges()
12
```

```python
>>> from sage.all import *
>>> c = Constellation(["(0,1)(2,3,4),'(1,4)',None"]); c
Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0)(1,4)(2)(3)
g2 (0,1,3,2,4)
>>> G = c.braid_group_orbit()
>>> G.num_verts()
4
>>> G.num_edges()
12
```

**connected_components()**

Return the connected components.

**OUTPUT:**

A list of connected constellations.

**EXAMPLES:**

5.1. Comprehensive Module List
sage: c = Constellation(["(0,1)(2)", None, "(0,1)(2)"], connected=False)
sage: cc = c.connected_components(); cc
[Constellation of length 3 and degree 2
  g0 (0,1)
g1 (0)(1)
g2 (0,1),
Constellation of length 3 and degree 1
  g0 (0)
g1 (0)
g2 (0)]
sage: all(c2.is_connected() for c2 in cc)
True

sage: c = Constellation(["(0,1,2)", None], connected=False)
sage: c.connected_components()
[Constellation of length 2 and degree 3
  g0 (0,1,2)
g1 (0,2,1)]

>>> from sage.all import *
>>> c = Constellation(["(0,1)(2)", None, "(0,1)(2)"], connected=False)
>>> cc = c.connected_components(); cc
[Constellation of length 3 and degree 2
  g0 (0,1)
g1 (0)(1)
g2 (0,1),
Constellation of length 3 and degree 1
  g0 (0)
g1 (0)
g2 (0)]
>>> all(c2.is_connected() for c2 in cc)
True

>>> c = Constellation(["(0,1,2)", None], connected=False)
>>> c.connected_components()
[Constellation of length 2 and degree 3
  g0 (0,1,2)
g1 (0,2,1)]

**copy()**

Return a copy of self.

**degree()**

Return the degree of the constellation.

The degree of a constellation is the number $n$ that corresponds to the symmetric group $S(n)$ in which the permutations of the constellation are defined.

**EXAMPLES:**

sage: c = Constellation([])
sage: c.degree()
0
sage: c = Constellation(["(0,1)"],None)
sage: c.degree()
2
sage: c = Constellation(["(0,1)"’,"(0,3,2)(1,5)"’,None,’(4,3,2,1)’])

(continues on next page)
sage: c.degree()
6

>>> from sage.all import *
>>> c = Constellation([])
>>> c.degree()
0
>>> c = Constellation(['(0,1)',None])
>>> c.degree()
2
>>> c = Constellation(['(0,1)','(0,3,2)(1,5)',None,'(4,3,2,1)'])
>>> c.degree()
6

**euler_characteristic()**

Return the Euler characteristic of the surface.

ALGORITHM:
Hurwitz formula

EXAMPLES:

sage: c = Constellation(['(0,1)', '(0,2)', None])
sage: c.euler_characteristic()
2
sage: c = Constellation(['(0,1,2,3)', '(1,3,0,2)', '(0,3,1,2)', None])
sage: c.euler_characteristic()
-4

**g(i=None)**

Return the permutation $g_i$ of the constellation.

INPUT:

- $i$ – integer or None (default)

If None, return instead the list of all $g_i$.

EXAMPLES:

sage: c = Constellation(['(0,1,2)(3,4)', '(0,3)', None])
sage: c.g(0)
(0,1,2) (3,4)
sage: c.g(1)
(0,3)
sage: c.g(2)
(0,4,3,2,1)
genus()

Return the genus of the surface.

EXAMPLES:

```
sage: c = Constellation([('0', '1'), ('0', '2'), None])
sage: c.genus()
0
sage: c = Constellation([('0', '1'), ('0', '2', '3'), None], connected=False)
sage: c.genus()
1
```

is_connected()

Test of connectedness.

EXAMPLES:

```
sage: c = Constellation([('0', '1'), None, ('0', '1')], connected=False)
sage: c.is_connected()
False
sage: c = Constellation([('0', '1'), None, ('0', '1')], connected=False)
sage: c.is_connected()
True
```

```
is_isomorphic \(\text{(other, return\_map=False)}\)

Test of isomorphism.

Return True if the constellations are isomorphic (i.e. related by a common conjugacy) and return the permutation that conjugate the two permutations if return\_map is True in such a way that self. relabel(m) == other.

ALGORITHM:
uses canonical labels obtained from the method relabel().

EXAMPLES:

```
sage: c = Constellation([[1,0,2],[2,1,0],[0,2,1],None])
sage: d = Constellation([[2,1,0],[0,2,1],[1,0,2],None])
sage: answer, mapping = c.is_isomorphic(d,return_map=True)
sage: answer
True
sage: c.relabel(mapping) == d
True
```

```bash
>>> from sage.all import *
```

```bash
>>> c = Constellation([[(Integer(1), Integer(0), Integer(2))], [Integer(2),
← Integer(1), Integer(0)], [Integer(0), Integer(2), Integer(1)], None])
```

```bash
>>> d = Constellation([[(Integer(2), Integer(1), Integer(0))], [Integer(0),
← Integer(2), Integer(1)], [Integer(1), Integer(0), Integer(2)], None])
```

```bash
>>> answer, mapping = c.is_isomorphic(d,return_map=True)
```

```bash
>>> answer
True
>>> c.relabel(mapping) == d
True
```

is_mutable()

Return False as self is immutable.

EXAMPLES:

```
sage: c = Constellation([(0,1),(0,2),(0,3),None], mutable=False)
sage: c.is_mutable()
False
```

```bash
>>> from sage.all import *
```

```bash
>>> c = Constellation([(Integer(0), Integer(2), Integer(1)), [Integer(2),
← Integer(1), Integer(0)], [Integer(1), Integer(2), Integer(0)]), mutable=False)
```

```bash
>>> c.is_mutable()
False
```

length()

Return the number of permutations.

EXAMPLES:

```
sage: c = Constellation(['(0,1)', '(0,2)', '(0,3)', None])
sage: c.length()
4
```

```
sage: c = Constellation(['(0,1,3)', None, '(1,2)'])
sage: c.length()
3
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *

>>> c = Constellation(["(0,1)"','(0,2)',"(0,3)",None])
4

>>> c = Constellation(["(0,1,3)",None,"(1,2)"])
3
```

**mutable_copy()**

Return a mutable copy of self.

EXAMPLES:

```python
sage: c = Constellation([(0,2,1),(2,1,0),(1,2,0)], mutable=False)
sage: d = c.mutable_copy()  # mutable=False
sage: d.is_mutable()
True
```

```python
sage: c = Constellation([(0,1,2)(3,4),(0,3),None])

>>> c.profile()
([3, 2], [2, 1, 1, 1], [5])
```

**passport**(i=None)

Return the profile of self.

The profile of a constellation is the tuple of partitions associated to the conjugacy classes of the permutations of the constellation.

This is also called the passport.

EXAMPLES:

```python
sage: c = Constellation([(0,1,2)(3,4),(0,3),None])

>>> c.profile()
([3, 2], [2, 1, 1, 1], [5])
```

**profile**(i=None)

Return the profile of self.

The profile of a constellation is the tuple of partitions associated to the conjugacy classes of the permutations of the constellation.

This is also called the passport.

EXAMPLES:

```python
sage: c = Constellation([(0,1,2)(3,4),None])

>>> c.profile()
([3, 2], [2, 1, 1, 1], [5])
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> c = Constellation([(0,1,2)(3,4),'(0,3)',None])
>>> c.profile()
([3, 2], [2, 1, 1, 1], [5])
```

**relabel** *(perm=None, return_map=False)*

Relabel self.

If `perm` is provided then relabel with respect to `perm`. Otherwise use canonical labels. In that case, if `return_map` is provided, the return also the map used for canonical labels.

**Algorithm:**

the cycle for `g(0)` are adjacent and the cycle are joined with respect to the other permutations. The minimum is taken for all possible renerrotations.

**EXAMPLES:**

```python
sage: c = Constellation([('0,1')(2,3,4)','(1,4)',None]); c
Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0)(1,4)(2)(3)
g2 (0,1,3,2,4)
sage: c2 = c.relabel(); c2
Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0)(1,2)(3)(4)
g2 (0,1,4,3,2)
```

The map returned when the option `return_map` is set to `True` can be used to set the relabelling:

```python
sage: c3, perm = c.relabel(return_map=True)
sage: c3 == c2 and c3 == c.relabel(perm=perm)
True
```

```python
sage: S5 = SymmetricGroup(range(5))
sage: d = c.relabel(S5([4,3,1,0,2])); d
Constellation of length 3 and degree 5
g0 (0,2,1)(3,4)
g1 (0)(1)(2,3)(4)
g2 (0,1,2,4,3)
sage: d.is_isomorphic(c)
True
```

```python
>>> from sage.all import *
>>> c3, perm = c.relabel(return_map=True)
(continues on next page)
```
We check that after a random relabelling the new constellation is isomorphic to the initial one:

```python
sage: c = Constellation(['(0,1)(2,3,4)','(1,4)','None'])
sage: p = S5.random_element()
sage: cc = c.relabel(perm=p)
sage: cc.is_isomorphic(c)
True
```

Check that it works for “non standard” labels:

```python
sage: c = Constellation(((a,b),(c,d,e)),(b,d),None)
sage: c.relabel()
Constellation of length 3 and degree 5
g0 (a,b)(c,d,e)
g1 (a)(b,c)(d)(e)
g2 (a,b,e,d,c)
```

```python
>>> from sage.all import *
```

```python
>>> c = Constellation(((a,b),(c,d,e)),(b,d),None)
>>> c.relabel()
```

```python
set_immutable()
```

Do nothing, as self is already immutable.

**EXAMPLES:**

```python
sage: c = Constellation(([0,2,1],[2,1,0],[1,2,0]),mutable=False)
sage: c.set_immutable()
sage: c.is_mutable()
False
```
switch \((i, j_0, j_1)\)

Perform the multiplication by the transposition \((j_0, j_1)\) between the permutations \(g_i\) and \(g_{i+1}\).

The modification is local in the sense that it modifies \(g_i\) and \(g_{i+1}\) but does not modify the product \(g_ig_{i+1}\).

The new constellation is

\[
(g_0, \ldots, g_{i-1}, g_i(j_0j_1), (j_0j_1)g_{i+1}, g_{i+2}, \ldots, g_k)
\]

EXAMPLES:

```python
sage: c = Constellation([(0,1)(2,3,4),'(1,4)',None], mutable=True); c
Constellation of length 3 and degree 5
  g0  (0,1)(2,3,4)
  g1  (0)(1,4)(2)(3)
  g2  (0,1,3,2,4)

sage: c.is_mutable()
True
sage: c.switch(1,2,3); c
Constellation of length 3 and degree 5
  g0  (0,1)(2,3,4)
  g1  (0)(1,4)(2,3)
  g2  (0,1,3,4)(2)

sage: c._check()
```

```python
sage: from sage.all import *

>>> c = Constellation([[(Integer(0),Integer(2),Integer(1)),[Integer(2),
˓→Integer(1),Integer(0)],[Integer(1),Integer(2),Integer(0)]], mutable=False)

>>> c.set_immutable()

>>> c.is_mutable()
False
```
Combinatorics, Release 10.4

>>> c.switch(Integer(2), Integer(1), Integer(3)); c
Constellation of length 3 and degree 5
g0 (0, 1, 4, 2, 3)
g1 (0)(1, 4)(2, 3)
g2 (0, 3, 4)(1)(2)

>>> c._check()

>>> c.switch(Integer(0), Integer(0), Integer(1)); c
Constellation of length 3 and degree 5
g0 (0)(1, 4, 2, 3)
g1 (0, 4, 1)(2, 3)
g2 (0, 3, 4)(1)(2)

>>> c._check()

sage.combinat.constellation.Constellations(*data, **options)
Build a set of constellations.

INPUT:

- profile – an optional profile
- length – an optional length
- degree – an optional degree
- connected – an optional boolean

EXAMPLES:

sage: Constellations(4, 2)
Connected constellations of length 4 and degree 2 on {1, 2}

sage: Constellations([3, 2, 1], [3, 3], [3, 3])
Connected constellations with profile ([3, 2, 1], [3, 3], [3, 3]) on {1, 2, 3, 4, 5, 6}

>>> from sage.all import *

>>> Constellations(Integer(4), Integer(2))
Connected constellations of length 4 and degree 2 on {1, 2}

>>> Constellations([[Integer(3), Integer(2), Integer(1)], [Integer(3), Integer(3)], [Integer(3), Integer(3)]])
Connected constellations with profile ([3, 2, 1], [3, 3], [3, 3]) on {1, 2, 3, 4, 5, 6}

class sage.combinat.constellation.Constellations_ld(length, degree, sym=None, connected=True)

Bases: UniqueRepresentation, Parent

Constellations of given length and degree.

EXAMPLES:

sage: C = Constellations(2, 3); C
Connected constellations of length 2 and degree 3 on {1, 2, 3}
sage: C([(2, 3, 1), [3, 1, 2]])
Constellation of length 2 and degree 3
g0 (1, 2, 3)
g1 (1, 3, 2)

(continues on next page)
```
sage: C.cardinality()
2
sage: Constellations(2,3,connected=False).cardinality()
6
```

```
>>> from sage.all import *
>>> C = Constellations(Integer(2),Integer(3)); C
Connected constellations of length 2 and degree 3 on {1, 2, 3}
>>> C([[Integer(2),Integer(3),Integer(1)],[Integer(3),Integer(1),Integer(2)]])
Constellation of length 2 and degree 3
g0 (1,2,3)
g1 (1,3,2)
>>> C.cardinality()
2
>>> Constellations(Integer(2),Integer(3),connected=False).cardinality()
6
```

**Element**

alias of `Constellation_class`

**braid_group_action()**

Return a list of graphs that corresponds to the braid group action on self up to isomorphism.

**OUTPUT:**

- list of graphs

**EXAMPLES:**

```
sage: C = Constellations(3,3)
sage: C.braid_group_action()
[Looped multi-digraph on 3 vertices,
 Looped multi-digraph on 1 vertex,
 Looped multi-digraph on 3 vertices]
```

```
>>> from sage.all import *
>>> C = Constellations(Integer(3),Integer(3))

>>> C.braid_group_action()
[Looped multi-digraph on 3 vertices,
 Looped multi-digraph on 1 vertex,
 Looped multi-digraph on 3 vertices]
```

**braid_group_orbits()**

Return the orbits under the action of the braid group.

**EXAMPLES:**

```
sage: C = Constellations(3,3)
sage: O = C.braid_group_orbits()
sage: len(O)
3
sage: [x.profile() for x in O[0]]

[[[1, 1, 1], [3], [3]],
 [[3], [1, 1, 1], [3]],
 [[3], [3], [1, 1, 1]]]
sage: [x.profile() for x in O[1]]

[[[3], [3], [3]]]

sage: [x.profile() for x in O[2]]

[[[2, 1], [2, 1], [3]],
 [[2, 1], [3], [2, 1]],
 [[3], [2, 1], [2, 1]]]
```

5.1. Comprehensive Module List
```python
>>> from sage.all import *
>>> C = Constellations(Integer(3), Integer(3))
>>> O = C.braid_group_orbits()
>>> len(O)
3
>>> [x.profile() for x in O[Integer(0)]]
[(\[1, 1, 1\], \[3\], \[3\]), (\[3\], \[1, 1, 1\], \[3\]), (\[3\], \[3\], \[1, 1, 1\])]
>>> [x.profile() for x in O[Integer(1)]]
[(\[3\], \[3\], \[3\])]
>>> [x.profile() for x in O[Integer(2)]]
[(\[2, 1\], \[2, 1\], \[3\]), (\[2, 1\], \[3\], \[2, 1\]), (\[3\], \[2, 1\], \[2, 1\])]
```

### is_empty()

Return whether this set of constellations is empty.

**EXAMPLES:**

```python
sage: Constellations(2, 3).is_empty()
False
sage: Constellations(1, 2).is_empty()
True
sage: Constellations(1, 2, connected=False).is_empty()
False
```

### random_element (mutable=False)

Return a random element.

This is found by trial and rejection, starting from a random list of permutations.

**EXAMPLES:**

```python
sage: const = Constellations(3, 3)
sage: const.random_element()
Constellation of length 3 and degree 3
...
...
...
sage: c = const.random_element()
sage: c.degree() == 3 and c.length() == 3
True
```
class sage.combinat.constellation.Constellations_p(profile, domain=None, connected=True)
Bases: UniqueRepresentation, Parent

Constellations with fixed profile.

EXAMPLES:

```python
sage: C = Constellations([[3,1],[3,1],[2,2]]); C
Connected constellations with profile ([3, 1], [3, 1], [2, 2]) on {1, 2, 3, 4}
sage: C.cardinality()
24
sage: C.first()
Constellation of length 3 and degree 4
g0 (1)(2,3,4)
g1 (1,2,3)(4)
g2 (1,2)(3,4)
sage: C.last()
Constellation of length 3 and degree 4
g0 (1,4,3)(2)
g1 (1,4,2)(3)
g2 (1,2)(3,4)
```

```python
>>> from sage.all import *
```
The number obtained above is up to isomorphism. And we can check:

```
sage: len(C.isomorphism_representatives())
1
```

**isomorphism_representatives()**

Return a set of isomorphism representative of self.

**EXAMPLES:**

```
sage: C = Constellations([[5], [4,1], [3,2]])
sage: C.cardinality()
240
sage: ir = sorted(C.isomorphism_representatives())
sage: len(ir)
2
sage: ir[0]
Constellation of length 3 and degree 5
g0 (1,2,3,4,5)
g1 (1)(2,3,4,5)
g2 (1,5,3)(2,4)
sage: ir[1]
Constellation of length 3 and degree 5
g0 (1,2,3,4,5)
g1 (1)(2,5,3,4)
g2 (1,5)(2,3,4)
```
sage.combinat.constellation.perm_conjugate(p,s)

Return the conjugate of the permutation \( p \) by the permutation \( s \).

INPUT:

two permutations of \( \{0,...,n-1\} \) given by lists of values

OUTPUT:

a permutation of \( \{0,...,n-1\} \) given by a list of values

EXAMPLES:

```python
sage: from sage.combinat.constellation import perm_conjugate
sage: perm_conjugate([3,1,2,0], [3,2,0,1])
[0, 3, 2, 1]
```

sage.combinat.constellation.perm_invert(p)

Return the inverse of the permutation \( p \).

INPUT:

a permutation of \( \{0,...,n-1\} \) given by a list of values

OUTPUT:

a permutation of \( \{0,...,n-1\} \) given by a list of values

EXAMPLES:

```python
sage: from sage.combinat.constellation import perm_invert
sage: perm_invert([3,2,0,1])
[2, 3, 1, 0]
```
```python
>>> from sage.all import *
>>> from sage.combinat.constellation import perm_invert
>>> perm_invert([Integer(3),Integer(2),Integer(0),Integer(1)])
[2, 3, 1, 0]
```

```
sage.combinat.constellation.perm_sym_domain(g)

Return the domain of a single permutation (before initialization).

EXAMPLES:

```python
sage: from sage.combinat.constellation import perm_sym_domain
sage: perm_sym_domain([1,2,3,4])
{1, 2, 3, 4}
sage: perm_sym_domain(((1,2),(0,4)))
{0, 1, 2, 4}
sage: sorted(perm_sym_domain((1,2,0,5)))
[0, 1, 2, 5]
```

```
sage.combinat.constellation_perms_are_connected(g, n)

Checks that the action of the generated group is transitive

INPUT:

- a list of permutations of \([0, n - 1]\) (in a SymmetricGroup)
- an integer \(n\)

EXAMPLES:

```python
sage: from sage.combinat.constellation import perms_are_connected
sage: S = SymmetricGroup(range(3))
sage: perms_are_connected([S([0,1,2]),S([0,2,1])],3)
False
sage: perms_are_connected([S([0,1,2]),S([1,2,0])],3)
True
```

```
sage.combinat.constellation_perms_canonical_labels(p, e=None)

Relabel a list with a common conjugation such that two conjugated lists are relabeled the same way.

INPUT:
```
• \( p \) is a list of at least 2 permutations
• \( e \) is None or a list of integer in the domain of the permutations. If provided, then the renumbering algorithm is only performed from the elements of \( e \).

OUTPUT:
• a pair made of a list of permutations (as a list of lists) and a list that corresponds to the conjugacy used.

EXAMPLES:
```python
sage: from sage.combinat.constellation import perms_canonical_labels
sage: l0 = [[2,0,3,1], [3,1,2,0], [0,2,1,3]]

sage: l, m = perms_canonical_labels(l0); l
[[1, 2, 3, 0], [0, 3, 2, 1], [2, 1, 0, 3]]

sage: S = SymmetricGroup(range(4))

sage: [~S(m) * S(u) * S(m) for u in l0] == list(map(S, l))
True

sage: perms_canonical_labels([])
Traceback (most recent call last):
 ...
ValueError: input must have length >= 2
```

sage.combinat.constellation.perms_canonical_labels_from \( (x, y, j0, verbose=False) \)

Return canonical labels for \( x \), \( y \) that starts at \( j0 \)

**Warning:** The group generated by \( x \) and the elements of \( y \) should be transitive.

INPUT:
• \( x \) – list; a permutation of \([0, \ldots, n]\) as a list
• \( y \) – list of permutations of \([0, \ldots, n]\) as a list of lists
• \( j0 \) – an index in \([0, \ldots, n]\)

OUTPUT:
mapping: a permutation that specify the new labels

EXAMPLES:
sage: from sage.combinat.constellation import perms_canonical_labels_from
sage: perms_canonical_labels_from([0,1,2], [[1,2,0]], 0)
[0, 1, 2]
sage: perms_canonical_labels_from([1,0,2], [[2,0,1]], 0)
[0, 1, 2]
sage: perms_canonical_labels_from([1,0,2], [[2,0,1]], 1)
[1, 0, 2]
sage: perms_canonical_labels_from([1,0,2], [[2,0,1]], 2)
[2, 1, 0]

sage.combinat.constellation.perms_sym_init(g, sym=None)

Initialize a list of permutations (in the same symmetric group).

OUTPUT:

- sym – a symmetric group
- gg – a list of permutations

EXAMPLES:

sage: from sage.combinat.constellation import perms_sym_init
sage: S, g = perms_sym_init([[0,2,1,3], [1,3,2,0]])
sage: S.domain()
{0, 1, 2, 3}
sage: g
[(1,2), (0,1,3)]

sage: S, g = perms_sym_init([(2,1), (0,3)])
sage: S.domain()
{0, 1, 2, 3}
sage: g
[(1,2), (0,3)]

sage: S, g = perms_sym_init([(1,0), (2,1)])
sage: S.domain()
{0, 1, 2}
sage: g
[(0,1), (1,2)]

sage: S, g = perms_sym_init([[(1,0),(2,3)], (0,1,4)])

(continues on next page)
5.1.33 Cores

A $k$-core is a partition from which no rim hook of size $k$ can be removed. Alternatively, a $k$-core is an integer partition such that the Ferrers diagram for the partition contains no cells with a hook of size (a multiple of) $k$.

Authors:

- Anne Schilling and Mike Zabrocki (2011): initial version
- Travis Scrimshaw (2012): Added latex output for Core class

```python
class sage.combinat.core.Core(parent, core):
    Bases: CombinatorialElement

    A $k$-core is an integer partition from which no rim hook of size $k$ can be removed.

    EXAMPLES:

    sage: c = Core([2,1],4); c
    [2, 1]
    sage: c = Core([3,1],4); c
    Traceback (most recent call last):
    ... ValueError: [3, 1] is not a 4-core
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> c = Core([Integer(2),Integer(1)],Integer(4)); c
[2, 1]
>>> c = Core([Integer(3),Integer(1)],Integer(4)); c
Traceback (most recent call last):
... ValueError: [3, 1] is not a 4-core
```

**affine_symmetric_group_action**(w, transposition=False)

Return the (left) action of the affine symmetric group on self.

**INPUT:**

- w is a tuple of integers \([w_1, \ldots, w_m]\) with \(0 \leq w_j < k\). If transposition is set to be True, then \(w = [w_0, w_1]\) is interpreted as a transposition \(t_{w_0, w_1}\) (see \_transposition_to_reduced_word()).

The output is the (left) action of the product of the corresponding simple transpositions on self, that is \(s_{w_1} \cdots s_{w_m}(self)\). See \texttt{affine_symmetric_group_simple_action()}.

**EXAMPLES:**

```python
sage: c = Core([4,2],3)
sage: c.affine_symmetric_group_action([0,1,0,2,1])
[8, 6, 4, 2]
sage: c.affine_symmetric_group_action([0,2], transposition=True)
[4, 2, 1, 1]
sage: c = Core([11,8,5,5,3,3,1,1,1],4)
sage: c.affine_symmetric_group_action([2,5], transposition=True)
[11, 8, 7, 6, 5, 4, 3, 2, 1]
```

```python
>>> from sage.all import *
>>> c = Core([Integer(4),Integer(2),Integer(3)])
>>> c.affine_symmetric_group_action([Integer(0),Integer(1),Integer(0),
\_Integer(2),Integer(1)])
[8, 6, 4, 2]
>>> c.affine_symmetric_group_action([Integer(0),Integer(2)],
\_transposition=True)
[4, 2, 1, 1]
>>> c = Core([Integer(11),Integer(8),Integer(5),Integer(5),Integer(3),
\_Integer(3),Integer(1),Integer(1),Integer(1),Integer(1)],Integer(4))
>>> c.affine_symmetric_group_action([Integer(2),Integer(5)],
\_transposition=True)
[11, 8, 7, 6, 5, 4, 3, 2, 1]
```

**affine_symmetric_group_simple_action**(i)

Return the action of the simple transposition \(s_i\) of the affine symmetric group on self.

This gives the action of the affine symmetric group of type \(A_k^{(1)}\) on the \(k\)-core self. If self has outside (resp. inside) corners of content \(i\) modulo \(k\), then these corners are added (resp. removed). Otherwise the action is trivial.

**EXAMPLES:**

```python
sage: c = Core([4,2],3)
sage: c.affine_symmetric_group_simple_action(0)  #...
needs sage.modules
```
This action corresponds to the left action by the $i$-th simple reflection in the affine symmetric group:

```
sage: c = Core([4,2],3)
sage: W = c.to_grassmannian().parent() #...
needs sage.modules
sage: i = 0
sage: (c.affine_symmetric_group_simple_action(i).to_grassmannian() #...
needs sage.modules
.....: == W.simple_reflection(i)*c.to_grassmannian())
True
sage: i = 1
sage: (c.affine_symmetric_group_simple_action(i).to_grassmannian() #...
needs sage.modules
.....: == W.simple_reflection(i)*c.to_grassmannian())
True
```

### contains (other)
Checks whether self contains other.

**INPUT:**

- other – another $k$-core or a list

---

5.1. Comprehensive Module List
OUTPUT: a boolean

This returns True if the Ferrers diagram of self contains the Ferrers diagram of other.

EXAMPLES:

```python
sage: c = Core([4,2],3)
sage: x = Core([4,2,2,1,1],3)
sage: x.contains(c)
True
sage: c.contains(x)
False
```

```python
>>> from sage.all import *
>>> c = Core([Integer(4),Integer(2)],Integer(3))
>>> x = Core([Integer(4),Integer(2),Integer(2),Integer(1),Integer(1)],
          →Integer(3))
>>> x.contains(c)
True
>>> c.contains(x)
False
```

**k()**

Return $k$ of the $k$-core self.

EXAMPLES:

```python
sage: c = Core([2,1],4)
sage: c.k()
4
```

```python
>>> from sage.all import *
>>> c = Core([Integer(2),Integer(1)],Integer(4))
>>> c.k()
4
```

**length()**

Return the length of self.

The length of a $k$-core is the size of the corresponding $(k-1)$-bounded partition which agrees with the length of the corresponding Grassmannian element, see to_grassmannian().

EXAMPLES:

```python
sage: c = Core([4,2],3); c.length()
4
sage: c.to_grassmannian().length()  #˓→needs sage.modules
4
```

```python
sage: Core([9,5,3,2,1,1], 5).length()
13
```

```python
>>> from sage.all import *
>>> c = Core([Integer(4),Integer(2)],Integer(3)); c.length()
4
>>> c.to_grassmannian().length()  #˓→needs sage.modules
```

(continues on next page)
size()

Return the size of self as a partition.

EXAMPLES:

```python
sage: Core([2,1],4).size()
3
sage: Core([4,2],3).size()
6
```

strong_covers()

Return a list of all elements that cover self in strong order.

EXAMPLES:

```python
sage: c = Core([1],3)
sage: c.strong_covers()
[[2], [1, 1]]
sage: c = Core([4,2],3)
sage: c.strong_covers()
[[5, 3, 1], [4, 2, 1, 1]]
```

strong_down_list()

Return a list of all elements that are covered by self in strong order.

EXAMPLES:

```python
sage: c = Core([1],3)
sage: c.strong_down_list()
[]
sage: c = Core([5,3,1],3)
sage: c.strong_down_list()
[[4, 2], [3, 1, 1]]
```
strong_le(other)
Strong order (Bruhat) comparison on cores.

INPUT:
• other — another k-core

OUTPUT: a boolean
This returns whether self <= other in Bruhat (or strong) order.

EXAMPLES:
```python
sage: c = Core([4,2], 3)
sage: x = Core([4,2,2,1,1], 3)
sage: c.strong_le(x)
True
sage: c.strong_le([4,2,2,1,1])
True
sage: x = Core([4,1], 4)
sage: c.strong_le(x)
Traceback (most recent call last):
  ... ValueError: the two cores do not have the same k
```
sage: gamma = Core([9,5,3,2,1,1], 5)
sage: gamma.to_bounded_partition()
[4, 3, 2, 2, 1, 1]

>>> from sage.all import *
>>> gamma = Core([Integer(9),Integer(5),Integer(3),Integer(2),Integer(1),
→Integer(1)], Integer(5))
>>> gamma.to_bounded_partition()
[4, 3, 2, 2, 1, 1]

to_grassmannian()

Bijection between $k$-cores and Grassmannian elements in the affine Weyl group of type $A_{k-1}^{(1)}$.

For further details, see the documentation of the method from_kbounded_to_reduced_word() and from_kbounded_to_grassmannian().

EXAMPLES:

sage: c = Core([3,1,1],3)
sage: w = c.to_grassmannian(); w
[[-1 1 1]
 [ -2 2 1]
 [ -2 1 2]]
sage: c.parent()
3-Cores of length 4
sage: w.parent()
Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root space)

sage: c = Core([],3)
sage: c.to_grassmannian()
[1 0 0]
[0 1 0]
[0 0 1]

>>> from sage.all import *

>>> c = Core([Integer(3),Integer(1),Integer(1)],Integer(3))
>>> w = c.to_grassmannian(); w
[[-1 1 1]
 [ -2 2 1]
 [ -2 1 2]]
>>> c.parent()
3-Cores of length 4
>>> w.parent()
Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root space)

>>> c = Core([],Integer(3))
>>> c.to_grassmannian()
[1 0 0]
[0 1 0]
[0 0 1]

5.1. Comprehensive Module List 555
to_partition()

Turn the core self into the partition identical to self.

EXAMPLES:

```python
sage: mu = Core([2,1,1],3)
sage: mu.to_partition()
[2, 1, 1]
```

```python
>>> from sage.all import *

>>> mu = Core([Integer(2),Integer(1),Integer(1)],Integer(3))

>>> mu.to_partition()
[2, 1, 1]
```

weak_covers()

Return a list of all elements that cover self in weak order.

EXAMPLES:

```python
sage: c = Core([1],3)
sage: c.weak_covers()
[[1, 1], [2]]
```

```python
sage: c = Core([4,2],3)
sage: c.weak_covers()
[[5, 3, 1]]
```

```python
>>> from sage.all import *

>>> c = Core([Integer(1)],Integer(3))

>>> c.weak_covers()
[[1, 1], [2]]
```

```python
>>> c = Core([Integer(4),Integer(2)],Integer(3))

>>> c.weak_covers()
[[5, 3, 1]]
```

weak_le(other)

Weak order comparison on cores.

INPUT:

• other — another k-core

OUTPUT: a boolean

This returns whether self <= other in weak order.

EXAMPLES:

```python
sage: c = Core([4,2],3)
sage: x = Core([5,3,1],3)
sage: c.weak_le(x)
# True
```

```python
sage: c = Core([5,3,1],3)
sage: c.weak_le(x)
# True
```

(continues on next page)
sage.combinat.core.Cores \( (k, \text{length=\text{None}}, **\text{kwargs}) \)

A \( k \)-core is a partition from which no rim hook of size \( k \) can be removed. Alternatively, a \( k \)-core is an integer partition such that the Ferrers diagram for the partition contains no cells with a hook of size (a multiple of) \( k \).

The \( k \)-cores generally have two notions of size which are useful for different applications. One is the number of cells in the Ferrers diagram with hook less than \( k \), the other is the total number of cells of the Ferrers diagram. In the implementation in Sage, the first of notion is referred to as the length of the \( k \)-core and the second is the size of the \( k \)-core. The class of Cores requires that either the size or the length of the elements in the class is specified.

EXAMPLES:

We create the set of the 4-cores of length 6. Here the length of a \( k \)-core is the size of the corresponding \( (k-1) \)-bounded partition, see also \texttt{length()}:

```python
sage: C = Cores(4, 6); C
4-Cores of length 6
sage: C.list()
[[[6, 3], [5, 2, 1], [4, 1, 1, 1], [4, 2, 2]], [[3, 3, 1, 1], [3, 2, 1, 1, 1], [2, 2, 2, 1, 1, 1]]
```
We may also list the set of 4-cores of size 6, where the size is the number of boxes in the core, see also \texttt{size()}:

\begin{verbatim}
sage: C = Cores(4, size=6); C 4-Cores of size 6 sage: C.list() [[4, 1, 1], [3, 2, 1], [3, 1, 1, 1]] sage: C.cardinality() 3 sage: C.an_element() [4, 1, 1]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> C = Cores(Integer(4), size=Integer(6)); C 4-Cores of size 6 >>> C.list() [[4, 1, 1], [3, 2, 1], [3, 1, 1, 1]] >>> C.cardinality() 3 >>> C.an_element() [4, 1, 1]
\end{verbatim}

\texttt{class sage.combinat.core.Cores_length}(k,n)

\texttt{Bases: UniqueRepresentation, Parent}

The class of \(k\)-cores of length \(n\).

\texttt{Element alias of Core}

\texttt{from\_partition}(part)

Converts the partition \texttt{part} into a core (as the identity map).

This is the inverse method to \texttt{to\_partition()}.

EXEMPLES:

\begin{verbatim}
sage: C = Cores(3,4) sage: c = C.from_partition([4,2]); c [4, 2] sage: mu = Partition([2,1,1])\end{verbatim}
sage: C = Cores(3,3)
sage: C.from_partition(mu).to_partition() == mu
  True

sage: mu = Partition([])
sage: C = Cores(3,0)
sage: C.from_partition(mu).to_partition() == mu
  True

>>> from sage.all import *
>>> C = Cores(Integer(3),Integer(4))
>>> c = C.from_partition([Integer(4),Integer(2)]); c
  [4, 2]

>>> mu = Partition([Integer(2),Integer(1),Integer(1)])
>>> C = Cores(Integer(3),Integer(3))
>>> C.from_partition(mu).to_partition() == mu
  True

list()

Return the list of all \( k \)-cores of length \( n \).

EXAMPLES:

sage: C = Cores(3,4)
sage: C.list()
  [[4, 2], [3, 1, 1], [2, 2, 1, 1]]

class sage.combinat.core.Cores_size\(k,n\)
  Bases: UniqueRepresentation, Parent

The class of \( k \)-cores of size \( n \).

Element
  alias of Core

from_partition\(\text{part}\)

Convert the partition \( \text{part} \) into a core (as the identity map).

This is the inverse method to to_partition().

EXAMPLES:
sage: mu = Partition([2,1,1])
sage: C = Cores(3, size=4)
sage: C.from_partition(mu).to_partition() == mu
True

sage: mu = Partition([])
sage: C = Cores(3, size=0)
sage: C.from_partition(mu).to_partition() == mu
True

list()

Return the list of all \( k \)-cores of size \( n \).

EXAMPLES:

sage: C = Cores(3, size = 4)
sage: C.list()
[[3, 1], [2, 1, 1]]

5.1.34 Counting

- The On-Line Encyclopedia of Integer Sequences (OEIS)
- Functions that compute some of the sequences in Sloane’s tables
- Compute Bell and Uppuluri-Carpenter numbers
- \( q \)-Analogues, \( q \)-Bernoulli Numbers and Polynomials
- Binary Recurrence Sequences
- C-Finite Sequences
- Combinatorial Functions
Todo: Mention `sage/combinat/degree_sequences`?

5.1.35 Affine Crystals

```python
class sage.combinat.crystals.affine.AffineCrystalFromClassical(cartan_type, classical_crystal, category=None):
```

Bases: `UniqueRepresentation`, `Parent`

This abstract class can be used for affine crystals that are constructed from a classical crystal. The zero arrows can be implemented using different methods (for example using a Dynkin diagram automorphisms or virtual crystals).

This is a helper class, mostly used to implement Kirillov-Reshetikhin crystals (see: `KirillovReshetikhinCrystal()`).

For general information about crystals see `sage.combinat.crystals`.

INPUT:

- `cartan_type` – the Cartan type of the resulting affine crystal
- `classical_crystal` – instance of a classical crystal

EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: A.list()
[[[1]], [[2]], [[3]]]
sage: A.cartan_type()
['A', 2, 1]
sage: A.index_set()
(0, 1, 2)
sage: b = A(rows=[[1]])
sage: b.weight()
-Lambda[0] + Lambda[1]
sage: b.classical_weight()
(1, 0, 0)
sage: [x.s(0) for x in A.list()]
[[[3]], [[2]], [[1]]]
sage: [x.s(1) for x in A.list()]
[[[2]], [[1]], [[3]]]

>>> from sage.all import *
>>> n = Integer(2)
>>> C = crystals.Tableaux(['A',n],shape=Integer(1))
>>> pr = attrcall("promotion")
>>> pr_inverse = attrcall("promotion_inverse")
>>> A = crystals.AffineFromClassicalAndPromotion(['A',n,Integer(1)],C,pr,pr_inverse,Integer(1))
>>> A.list()
[[[1]], [[2]], [[3]]]
>>> A.cartan_type()
```

(continues on next page)
Element alias of `AffineCrystalFromClassicalElement`  

`cardinality()`  

Return the cardinality of `self`.  

**EXAMPLES:**

```python  
sage: C = crystals.Tableaux(['A',3],shape=[1])  
sage: pr = attrcall("promotion")  
sage: pr_inverse = attrcall("promotion_inverse")  
sage: A = crystals.AffineFromClassicalAndPromotion(['A',3,1],C,pr,pr_inverse,→1)  
sage: A.cardinality() == C.cardinality()  
True
```

`lift(affine_elt)`  

Lift an affine crystal element to the corresponding classical crystal element.  

**EXAMPLES:**

```python  
sage: n = 2  
sage: C = crystals.Tableaux(['A',n],shape=[1])  
sage: pr = attrcall("promotion")  
sage: pr_inverse = attrcall("promotion_inverse")  
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,→1)  
sage: b = A.list()[0]  
sage: A.lift(b)  
[[1]]  
sage: A.lift(b).parent()  
The crystal of tableaux of type ['A', 2] and shape(s) [[1]]
```
```python
>>> from sage.all import *
>>> n = Integer(2)
>>> C = crystals.Tableaux(['A',n],shape=[Integer(1)])
>>> pr = attrcall("promotion")
>>> pr_inverse = attrcall("promotion_inverse")
>>> A = crystals.AffineFromClassicalAndPromotion(['A',n,Integer(1)],C,pr,pr_inverse,Integer(1))
>>> b = A.list()[Integer(0)]
>>> A.lift(b)
[[1]]
>>> A.lift(b).parent()
The crystal of tableaux of type ['A', 2] and shape(s) [[1]]
```

**retract** *(classical_elt)*

Transform a classical crystal element to the corresponding affine crystal element.

**EXAMPLES:**

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: t = C(rows=[[1]])
sage: t.parent()
The crystal of tableaux of type ['A', 2] and shape(s) [[1]]
sage: A.retract(t)
[[1]]
sage: A.retract(t).parent() is A
True
```
class sage.combinat.crystals.affine.AffineCrystalFromClassicalAndPromotion(car\-tan_type, clas-
sical_crys-
tal, p au-
to-
mor-
phism, p_in-
verse_auto-
mor-
phism, dynkin_node, cate-
gory=None)

Bases: AffineCrystalFromClassical

Crystals that are constructed from a classical crystal and a Dynkin diagram automorphism $\sigma$. In type $A_n$, the
Dynkin diagram automorphism is $i \rightarrow i+1 \text{ (mod } n)+1$ and the corresponding map on the crystal is the promotion
operation $pr$ on tableaux. The affine crystal operators are given by $f_0 = pr^{-1} f_{\sigma(0)} pr$.

INPUT:

- cartan_type – the Cartan type of the resulting affine crystal
- classical_crystal – instance of a classical crystal
- automorphism, inverse_automorphism – a function on the elements of the classi-
cal_crystal
- dynkin_node – an integer specifying the classical node in the image of the zero node under the automor-
phism $\sigma$

EXAMPLES:

```sage
c = crystals.TypeA(nolución, shape=[1])
p = attrcall("promotion")
pr_inverse = attrcall("promotion_inverse")
A = crystals.AffineFromClassicalAndPromotion([\A,n,1], C, pr, pr_inverse, 1)
A.list()
```

```
[[[1]], [[2]], [[3]]]
```

```sage
A.cartan_type()
```

```
['A', 2, 1]
```

```sage
A.index_set()
```

```
(0, 1, 2)
```

```sage
b = A(rows=[[1]])
b.weight()
```

```
-Lambda[0] + Lambda[1]
```

```sage
b.classical_weight()
```

```
(1, 0, 0)
```

```sage
[x.s(0) for x in A.list()]
```

```
[[[3]], [[2]], [[1]]]
```

```sage
[x.s(1) for x in A.list()]
```

```
[[2]], [[1]], [[3]]
```
```python
>>> from sage.all import *
>>> n = Integer(2)
>>> C = crystals.Tableaux(['A',n],shape=[Integer(1)])
>>> pr = attrcall("promotion")
>>> pr_inverse = attrcall("promotion_inverse")
>>> A = crystals.AffineFromClassicalAndPromotion(['A',n,Integer(1)],C,pr,pr_inverse)
>>> A.list()
[[[1]], [[2]], [[3]]]
>>> A.cartan_type()
['A', 2, 1]
>>> A.index_set()
(0, 1, 2)
>>> b = A(rows=[[Integer(1)])
>>> b.weight()
-Lambda[0] + Lambda[1]
>>> b.classical_weight()
(1, 0, 0)
```

**Element**

alias of *AffineCrystalFromClassicalAndPromotionElement*

**automorphism**(x)

Give the analogue of the affine Dynkin diagram automorphism on the level of crystals.

**EXAMPLES:**

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
```

**inverse_automorphism**(x)

Give the analogue of the inverse of the affine Dynkin diagram automorphism on the level of crystals.

**EXAMPLES:**
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])

sage: pr = attrcall("promotion")

sage: pr_inverse = attrcall("promotion_inverse")

sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)

sage: b = A.list()[0]

sage: A.inverse_automorphism(b)
[[3]]

>>> from sage.all import *

>>> n = Integer(2)

>>> C = crystals.Tableaux(['A',n],shape=[Integer(1)])

>>> pr = attrcall("promotion")

>>> pr_inverse = attrcall("promotion_inverse")

>>> A = crystals.AffineFromClassicalAndPromotion(['A',n,Integer(1)],C,pr,pr_inverse,Integer(1))

>>> b = A.list()[Integer(0)]

>>> A.inverse_automorphism(b)
[[3]]

class

sage.combinat.crystals.affine.AffineCrystalFromClassicalAndPromotionElement

Bases: AffineCrystalFromClassicalElement

Elements of crystals that are constructed from a classical crystal and a Dynkin diagram automorphism. In type $A$, the automorphism is the promotion operation on tableaux.

This class is not instantiated directly but rather __call__-ed from AffineCrystalFromClassicalAndPromotion. The syntax of this is governed by the (classical) crystal.

Since this class inherits from AffineCrystalFromClassicalElement, the methods that need to be implemented are $e_0()$, $f_0()$ and possibly $\epsilon_0()$ and $\phi_0()$ if more efficient algorithms exist.

EXAMPLES:

sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])

sage: pr = attrcall("promotion")

sage: pr_inverse = attrcall("promotion_inverse")

sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)

sage: b = A(rows=[[1]])

sage: b._repr_()
'[1]'

>>> from sage.all import *

>>> n = Integer(2)

>>> C = crystals.Tableaux(['A',n],shape=[Integer(1)])

>>> pr = attrcall("promotion")

>>> pr_inverse = attrcall("promotion_inverse")

>>> A = crystals.AffineFromClassicalAndPromotion(['A',n,Integer(1)],C,pr,pr_inverse,Integer(1))

>>> b = A(rows=[[Integer(1)]])

>>> b._repr_()
'[[1]]'

e0()

Implement $e_0$ using the automorphism as $e_0 = pr^{-1}e_{\text{Dynkin}}e_{\text{Ode}}pr$.
EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,
                                          -1)
sage: b = A(rows=[[1]])
sage: b.e0()
[[3]]
```

```python
>>> from sage.all import *
>>> n = Integer(2)
>>> C = crystals.Tableaux(['A',n],shape=[Integer(1)])
>>> pr = attrcall("promotion")
>>> pr_inverse = attrcall("promotion_inverse")
>>> A = crystals.AffineFromClassicalAndPromotion(['A',n,Integer(1)],C,pr,pr_ ˓→inverse,Integer(1))
>>> b = A(rows=[[Integer(1)]])
>>> b.e0()
[[3]]
```

`epsilon0()`

Implement `epsilon_0` using the automorphism.

EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,
                                          -1)
```

```python
>>> from sage.all import *
>>> n = Integer(2)
>>> C = crystals.Tableaux(['A',n],shape=[Integer(1)])
>>> pr = attrcall("promotion")
>>> pr_inverse = attrcall("promotion_inverse")
>>> A = crystals.AffineFromClassicalAndPromotion(['A',n,Integer(1)],C,pr,pr_ ˓→inverse,Integer(1))
```

```python
[x.epsilon0() for x in A.list()]
[1, 0, 0]
```

`f0()`

Implement `f_0` using the automorphism as `f_0 = pr^{-1} f_{dynkin,ode} pr`

EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,
                                          -1)
```

(continues on next page)
\[ \phi_0 \]

Implement \( \phi_0 \) using the automorphism.

EXAMPLES:

\begin{verbatim}
from sage.all import *
n = Integer(2)
C = crystals.Tableaux(['A',n],shape=[1])
pr = attrcall("promotion")
pr_inverse = attrcall("promotion_inverse")
A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse)
b = A(rows=[[Integer(3)]])
b.phi0()
\end{verbatim}

\[ 0, 0, 1 \]

\begin{verbatim}
from sage.all import *
n = Integer(1)
C = crystals.Tableaux(['A',n],shape=[1])
pr = attrcall("promotion")
pr_inverse = attrcall("promotion_inverse")
A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
[x.phi0() for x in A.list()]
\end{verbatim}

\[ 0, 0, 1 \]
sage: b = A(rows=[[1]])
sage: b._repr_()
'[[1]]'

>>> from sage.all import *
>>> n = Integer(2)
>>> C = crystals.Tableaux(['A',n],shape=[Integer(1)])
>>> pr = attrcall("promotion")
>>> pr_inverse = attrcall("promotion_inverse")
>>> A = crystals.AffineFromClassicalAndPromotion(['A',n,Integer(1)],C,pr,pr_inverse,Integer(1))
>>> b = A(rows=[[Integer(1)]])
>>> b._repr_()
'[[1]]'

classical_weight()

Return the classical weight corresponding to self.

EXAMPLES:

sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,Integer(1))
sage: b = A(rows=[[1]])
sage: b.classical_weight()
(1, 0, 0)

>>> from sage.all import *
>>> n = Integer(2)
>>> C = crystals.Tableaux(['A',n],shape=[Integer(1)])
>>> pr = attrcall("promotion")
>>> pr_inverse = attrcall("promotion_inverse")
>>> A = crystals.AffineFromClassicalAndPromotion(['A',n,Integer(1)],C,pr,pr_inverse,Integer(1))
>>> b = A(rows=[[Integer(1)]])
>>> b.classical_weight()
(1, 0, 0)

e(i)

Return the action of e_i on self.

EXAMPLES:

sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,Integer(1))
sage: b = A(rows=[[1]])
sage: b.e(0)
[[3]]
sage: b.e(1)
from sage.all import *

n = Integer(2)
C = crystals.Tableaux(['A',n],shape=[Integer(1)])
pr = attrcall("promotion")
pr_inverse = attrcall("promotion_inverse")
A = crystals.AffineFromClassicalAndPromotion(['A',n,Integer(1)],C,pr,pr_inverse)
b = A(rows=[[Integer(1)]])
b.e(Integer(0))
[Integer(3)]
b.e(Integer(1))
[Integer(1)]
e0()
Assumes that \( e_0 \) is implemented separately.

epsilon(i)
Return the maximal time the crystal operator \( e_i \) can be applied to self.

EXAMPLES:

```sage
n = 2
C = crystals.Tableaux(['A',n],shape=[1])
pr = attrcall("promotion")
pr_inverse = attrcall("promotion_inverse")
A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse)
[x.epsilon(0) for x in A.list()]
[1, 0, 0]
[x.epsilon(1) for x in A.list()]
[0, 1, 0]
```

epsilon0()
Uses \( \epsilon_0 \) from the super class, but should be implemented if a faster implementation exists.

EXAMPLES:

```sage
n = 2
C = crystals.Tableaux(['A',n],shape=[1])
pr = attrcall("promotion")
pr_inverse = attrcall("promotion_inverse")
A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse)
[x.epsilon0() for x in A.list()]
[1, 0, 0]
```

570 Chapter 5. Comprehensive Module List
```python
>>> from sage.all import *
>>> n = Integer(2)
>>> C = crystals.Tableaux(['A',n],shape=[Integer(1)])
>>> pr = attrcall("promotion")
>>> pr_inverse = attrcall("promotion_inverse")
>>> A = crystals.AffineFromClassicalAndPromotion(['A',n,Integer(1)],C,pr,pr_inverse,Integer(1))
>>> [x.epsilon0() for x in A.list()]
[1, 0, 0]
```

**f**(<i>i</i>)

Return the action of <i>f_0</i> on self.

**EXAMPLES:**

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: b = A(rows=[[3]])
sage: b.f(0)
[[1]]
sage: b.f(2)
```

**f0()**

Assumes that <i>f_0</i> is implemented separately.

**lift()**

Lift an affine crystal element to the corresponding classical crystal element.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> n = Integer(2)
>>> C = crystals.Tableaux(['A',n],shape=[Integer(1)])
>>> pr = attrcall("promotion")
>>> pr_inverse = attrcall("promotion_inverse")
>>> A = crystals.AffineFromClassicalAndPromotion(['A',n,Integer(1)],C,pr,pr_inverse,Integer(1))
>>> b = A(rows=[[Integer(3)]])
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> n = Integer(2)
>>> C = crystals.Tableaux(['A',n],shape=[Integer(1)])
>>> pr = attrcall("promotion")
>>> pr_inverse = attrcall("promotion_inverse")
>>> A = crystals.AffineFromClassicalAndPromotion(['A',n,Integer(1)],C,pr,pr_inverse,Integer(1))
>>> b = A.list()[Integer(0)]
>>> b.lift()
[[1]]
>>> b.lift().parent()
The crystal of tableaux of type ['A', 2] and shape(s) [[1]]
```

\(\phi(i)\)

Returns the maximal time the crystal operator \(f_i\) can be applied to self.

EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
```

```python
sage: [x.phi(0) for x in A.list()]
[0, 0, 1]
```

```python
sage: [x.phi(1) for x in A.list()]
[1, 0, 0]
```

\(\phi0()\)

Uses \(\phi_0\) from the super class, but should be implemented if a faster implementation exists.

EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
```

```python
sage: [x.phi0() for x in A.list()]
[0, 0, 1]
```

(continues on next page)
```python
>>> C = crystals.Tableaux(['A',n],shape=[Integer(1)])
>>> pr = attrcall("promotion")
>>> pr_inverse = attrcall("promotion_inverse")
>>> A = crystals.AffineFromClassicalAndPromotion(['A',n,Integer(1)],C,pr,pr_inverse,Integer(1))
>>> [x.phi0() for x in A.list()]
[0, 0, 1]
```

**pp** ()

Method for pretty printing.

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['D',3,2],1,1)
sage: t=K(rows=[[1]])
sage: t.pp()
1
```

```python
>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['D',Integer(3),Integer(2)],Integer(1),Integer(1))

```

5.1. Comprehensive Module List 573

### 5.1.36 Affine factorization crystal of type $A$

```python
class sage.combinat.crystals.affine_factorization.AffineFactorizationCrystal(w, n, x=None):
    Bases: UniqueRepresentation, Parent

The crystal on affine factorizations with a cut-point, as introduced by [MS2015].

**INPUT:**

- $w$ – an element in an (affine) Weyl group or a skew shape of $k$-bounded partitions (if $k$ was specified)
- $n$ – the number of factors in the factorization
- $x$ – (default: None) the cut point; if not specified it is determined as the minimal missing residue in $w$
- $k$ – (default: None) positive integer, specifies that $w$ is $k$-bounded or a $k + 1$-core when specified

**EXAMPLES:**

```python
sage: W = WeylGroup(['A',3,1], prefix='s')
sage: w = W.from_reduced_word([2,3,2,1])
sage: B = crystals.AffineFactorization(w,3); B
Crystal on affine factorizations of type A2 associated to s2*s3*s2*s1
sage: B.list()
[(1, s2, s3*s2*s1),
 (1, s3*s2, s3*s1),
 (1, s3*s2*s1, s3),
 (s3, s2, s3*s1),
 (s3, s2*s1, s3),
```
Combinatorics, Release 10.4

(s3*s2, s1, s3),
(s3*s2*s1, 1, s3),
(s3*s2*s1, s3, 1),
(s3*s2, 1, s3*s1),
(s3*s2, s3, s1),
(s3*s2, s3*s1, 1),
(s2, 1, s3*s2*s1),
(s2, s3, s2*s1),
(s2, s3*s2, s1),
(s2, s3*s2*s1, 1)]

>>> from sage.all import *

>>> W = WeylGroup(['A', Integer(3), Integer(1)], prefix='s')
>>> w = W.from_reduced_word([Integer(2), Integer(3), Integer(2), Integer(1)])
>>> B = crystals.AffineFactorization(w, Integer(3)); B
Crystal on affine factorizations of type A2 associated to s2*s3*s2*s1

>>> B.list()
[(1, s2, s3*s2*s1),
 (1, s3*s2, s3*s1),
 (1, s3*s2*s1, s3),
 (s3, s2, s3*s1),
 (s3, s2*s1, s3),
 (s3*s2, s1, s3),
 (s3*s2*s1, 1, s3),
 (s3*s2*s1, s3, 1),
 (s3*s2, 1, s3*s1),
 (s3*s2, s3, s1),
 (s3*s2, s3*s1, 1),
 (s2, 1, s3*s2*s1),
 (s2, s3, s2*s1),
 (s2, s3*s2, s1),
 (s2, s3*s2*s1, 1)]

We can also access the crystal by specifying a skew shape in terms of $k$-bounded partitions:

```
sage: crystals.AffineFactorization([[3,1,1],[1]], 3, k=3)
Crystal on affine factorizations of type A2 associated to s2*s3*s2*s1
```

```sage
>>> from sage.all import *

>>> crystals.AffineFactorization([[Integer(3),Integer(1),Integer(1)],
       →[Integer(1)]], Integer(3), k=Integer(3))
Crystal on affine factorizations of type A2 associated to s2*s3*s2*s1
```

We can compute the highest weight elements:

```
sage: hw = [w for w in B if w.is_highest_weight()]
sage: hw
[(1, s2, s3*s2*s1)]
sage: hw[0].weight()
(3, 1, 0)
```

```sage
>>> from sage.all import *

>>> hw = [w for w in B if w.is_highest_weight()]
>>> hw
[(1, s2, s3*s2*s1)]
```
And show that this crystal is isomorphic to the tableau model of the same weight:

```python
sage: C = crystals.Tableaux(['A',2],shape=[3,1])
sage: GC = C.digraph()
sage: GB = B.digraph()
sage: GC.is_isomorphic(GB, edge_labels=True)
True
```

The crystal operators themselves move elements between adjacent factors:

```python
sage: b = hw[0];b
(1, s2, s3*s2*s1)
sage: b.f(1)
(1, s3*s2, s3*s1)
```

The cut point $x$ is not supposed to occur in the reduced words for $w$:

```python
sage: B = crystals.AffineFactorization([3,2],[2],4,x=0,k=3)
Traceback (most recent call last):
  ...
ValueError: x cannot be in reduced word of s0*s3*s2
```

```python
sage: B = crystals.AffineFactorization([Integer(3),Integer(2)],[Integer(2)],
                                            Integer(4),x=Integer(0),k=Integer(3))
Traceback (most recent call last):
  ...
ValueError: x cannot be in reduced word of s0*s3*s2
```

```python
class Element
    Bases: ElementWrapper

bracketing(i)

    Removes all bracketed letters between i-th and i + 1-th entry.

    EXAMPLES:

    sage: B = crystals.AffineFactorization([[3,1],[1]], 3, k=3, x=4)
sage: W = B.w.parent()
```
sage: t = B((W.one(), W.from_reduced_word([3]), W.from_reduced_word([2, 1]))); t
(1, s3, s2*s1)
sage: t.bracketing(1)
[[3], [2, 1]]

>>> from sage.all import *

>>> B = crystals.AffineFactorization([[Integer(3), Integer(1)],
    [Integer(1)]], Integer(3), k=Integer(3), x=Integer(4))
>>> W = B.w.parent()
>>> t = B((W.one(), W.from_reduced_word([Integer(3)]), W.from_reduced_-
    word([Integer(2), Integer(1)])); t
(1, s3, s2*s1)
>>> t.bracketing(Integer(1))
[[3], [2, 1]]

e(i)

Return the action of \(e_i\) on \(self\).

EXAMPLES:

sage: B = crystals.AffineFactorization([[3,1],[1]], 4, k=3)
sage: W = B.w.parent()
sage: t = B((W.one(), W.one(), W.from_reduced_word([3]), W.from_reduced_-
    word([2,1]))); t
(1, 1, s3, s2*s1)
sage: t.e(1)
(1, 1, 1, s3*s2*s1)

>>> from sage.all import *

>>> B = crystals.AffineFactorization([[Integer(3), Integer(1)],
    [Integer(1)]], Integer(4), k=Integer(3))
>>> W = B.w.parent()
>>> t = B((W.one(), W.one(), W.from_reduced_word([Integer(3)]), W.from_-
    reduced_word([Integer(2), Integer(1)])); t
(1, 1, s3, s2*s1)
>>> t.e(Integer(1))
(1, 1, 1, s3*s2*s1)

f(i)

Return the action of \(f_i\) on \(self\).

EXAMPLES:

sage: B = crystals.AffineFactorization([[3,1],[1]], 4, k=3)
sage: W = B.w.parent()
sage: t = B((W.one(), W.one(), W.from_reduced_word([3]), W.from_reduced_-
    word([2,1]))); t
(1, 1, s3, s2*s1)
sage: t.f(2)
(1, s3, 1, s2*s1)
sage: t.f(1)
(1, s3*s2, s1)

>>> from sage.all import *

>>> B = crystals.AffineFactorization([[Integer(3), Integer(1)]],
    [Integer(1)]), Integer(4), k=Integer(3))
    [Integer(1)]), Integer(4), k=Integer(3))
>>> W = B.w.parent()
>>> t = B((W.one(), W.one(), W.from_reduced_word([Integer(3)]), W.from_-
    reduced_word([Integer(2), Integer(1)])); t
(1, 1, s3, s2*s1)
>>> t.e(Integer(1))
(1, 1, 1, s3*s2*s1)
```python
>>> W = B.w.parent()
>>> t = B((W.one(),W.one(),W.from_reduced_word([Integer(3)]),W.from_reduced_word([Integer(2),Integer(1)]))); t
(1, 1, s3, s2*s1)
>>> t.f(Integer(2))
(1, s3, 1, s2*s1)
>>> t.f(Integer(1))
(1, 1, s3*s2, s1)
```

### to_tableau()

Return the tableau representation of self.

Uses the recording tableau of a minor variation of Edelman-Greene insertion. See Theorem 4.11 in [MS2015].

**EXAMPLES:**

```python
sage: W = WeylGroup(['A',3,1], prefix='s')
sage: w = W.from_reduced_word([2,1,3,2])
sage: B = crystals.AffineFactorization(w,3)
sage: for x in B:
    ...:    x.to_tableau().pp()
    (1, s2*s1, s3*s2)
    1
    2
    (s2, s1, s3*s2)
    1
    2
    (s2, s3*s1, s2)
    1
    2
    3
    (s2*s1, 1, s3*s2)
    1
    3
    (s2*s1, s3, s2)
    1
    3
    3
    (s2*s1, s3*s2, 1)
    2
    3
    3
```

```python
>>> from sage.all import *
>>> W = WeylGroup(['A',3,1], prefix='s')
>>> w = W.from_reduced_word([Integer(2),Integer(1),Integer(3),Integer(2)])
>>> B = crystals.AffineFactorization(w,3)
>>> for x in B:
    ...:    x.to_tableau().pp()
    (1, s2*s1, s3*s2)
    1
    2
    (s2, s1, s3*s2)
    1
    2
    3
    (s2*s1, 1, s3*s2)
    1
    3
    (s2*s1, s3, s2)
    1
    3
    (s2*s1, s3*s2, 1)
    2
    3
    3
```

(continues on next page)
class sage.combinat.crystals.affine_factorization.FactorizationToTableaux(parent, cartan_type=None, virtualization=None, scaling_factors=None)

Bases: CrystalMorphism

is_embedding()

Return True as this is an isomorphism.

EXAMPLES:

```
sage: W = WeylGroup(['A',3,1], prefix='s')
sage: w = W.from_reduced_word([2,1,3,2])
sage: B = crystals.AffineFactorization(w,3)
sage: phi = B._tableaux_isomorphism
sage: phi.is_isomorphism()
```

```
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(3),Integer(1)], prefix='s')
>>> w = W.from_reduced_word([Integer(2),Integer(1),Integer(3),Integer(2)])
>>> B = crystals.AffineFactorization(w,Integer(3))
>>> phi = B._tableaux_isomorphism
>>> phi.is_isomorphism()
```

is_isomorphism()

Return True as this is an isomorphism.

EXAMPLES:

```
sage: W = WeylGroup(['A',3,1], prefix='s')
sage: w = W.from_reduced_word([2,1,3,2])
sage: B = crystals.AffineFactorization(w,3)
sage: phi = B._tableaux_isomorphism
sage: phi.is_isomorphism()
```
Combinatorics, Release 10.4

>>> from sage.all import *

>>> W = WeylGroup(['A', Integer(3), Integer(1)], prefix='s')
>>> w = W.from_reduced_word([Integer(2), Integer(1), Integer(3), Integer(2)])
>>> B = crystals.AffineFactorization(w, Integer(3))
>>> phi = B._tableaux_isomorphism
>>> phi.is_isomorphism()
True

\textbf{is_surjective}()

Return \textbf{True} as this is an isomorphism.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: W = WeylGroup(['A',3,1], prefix='s')
sage: w = W.from_reduced_word([2,1,3,2])
sage: B = crystals.AffineFactorization(w,3)

sage: phi = B._tableaux_isomorphism
sage: phi.is_isomorphism()
True
\end{verbatim}

\textbf{sage.combinat.crystals.affine_factorization.affine_factorizations} (w, l, weight=None)

Return all factorizations of $w$ into $l$ factors or of weight weight.

\textbf{INPUT:}

- $w$ – an (affine) permutation or element of the (affine) Weyl group
- $l$ – nonnegative integer
- weight – (default: None) tuple of nonnegative integers specifying the length of the factors

\textbf{EXAMPLES:}

\begin{verbatim}
sage: W = WeylGroup(['A',3,1], prefix='s')
sage: w = W.from_reduced_word([3,2,3,1,0,1])

sage: from sage.combinat.crystals.affine_factorization import affine_factorizations

sage: affine_factorizations(w,4)

5.1.37 Affinization Crystals

class sage.combinat.crystals.affinization.AffinizationOfCrystal(B)

    Bases: UniqueRepresentation, Parent

    An affinization of a crystal.

    Let g be a Kac-Moody algebra of affine type. The affinization of a finite $U'_q(g)$-crystal $B$ is the (infinite) $U_q(g)$-crystal with underlying set:

    $$B^{aff} = \{ b(m) \mid b \in B, m \in \mathbb{Z} \}$$
and crystal structure determined by:

\[
e_i(b(m)) = \begin{cases} 
(e_0 b)(m + 1) & i = 0, \\
(e_i b)(m) & i \neq 0,
\end{cases}
\]

\[
f_i(b(m)) = \begin{cases} 
(f_0 b)(m - 1) & i = 0, \\
(f_i b)(m) & i \neq 0,
\end{cases}
\]

\[
\text{wt}(b(m)) = \text{wt}(b) + m\delta.
\]

EXAMPLES:
We first construct a Kirillov-Reshetikhin crystal and then take it’s corresponding affinization:

```
sage: K = crystals.KirillovReshetikhin(['A',2,1], 2, 2)
sage: A = K.affinization()
```

Next we construct an affinization crystal from a tensor product of KR crystals:

```
sage: KT = crystals.TensorProductOfKirillovReshetikhinTableaux(['C',2,1], [[1,2], [2,1]])
sage: A = crystals.AffinizationOf(KT)
```

REFERENCES:
- [HK2002] Chapter 10

**class Element** *(parent, b, m)*

Bases: `Element`

An element in an affinization crystal.

**e(i)**

Return the action of \(e_i\) on `self`.

**INPUT:**
- `i` – an element of the index set

**EXAMPLES:**

```
sage: A = crystals.KirillovReshetikhin(['A',2,1], 2,2).affinization()
sage: mg = A.module_generators[0]
sage: mg.e(0)
[[1, 2], [2, 3]](1)
sage: mg.e(1)
sage: mg.e(0).e(1)
[[1, 1], [2, 3]](1)
```
epsilon \( (i) \)

Return \( \varepsilon_i \) of self.

**INPUT:**

• \( i \) – an element of the index set

**EXAMPLES:**

```python
sage: A = crystals.KirillovReshetikhin(['A', 2, 1], 2, 2).affinization()
sage: mg = A.module_generators[0]
sage: mg.epsilon(0)
2
sage: mg.epsilon(1)
0
```

\( f(i) \)

Return the action of \( f_i \) on self.

**INPUT:**

• \( i \) – an element of the index set

**EXAMPLES:**

```python
sage: A = crystals.KirillovReshetikhin(['A', 2, 1], 2, 2).affinization()
sage: mg = A.module_generators[0]
sage: mg.f(2)
[[1, 1], [2, 3]](0)
sage: mg.f(2).f(2).f(0)
[[], [2, 2]](-1)
```

```python
>>> from sage.all import *

>>> A = crystals.KirillovReshetikhin(['A', Integer(2), Integer(1)],
   Integer(2), Integer(2)).affinization()
>>> mg = A.module_generators[Integer(0)]
>>> mg.e(Integer(0))
[[[1, 2], [2, 3]], (1)
>>> mg.e(Integer(1))
>>> mg.e(Integer(0)).e(Integer(1))
[[[1, 1], [2, 3]], (1)
```

5.1. Comprehensive Module List
\[
[[1, 1], [2, 3]](0)
\]
\[
\ggg \text{mg.f(Integer(2)).f(Integer(2)).f(Integer(0))}
\ggg \text{mg.f_string([Integer(2),Integer(1),Integer(1)])}
[[1, 2], [2, 3]](0)
\ggg \text{mg.f_string([Integer(2),Integer(1),Integer(0)])}
[[1, 1], [2, 2]](-1)
\]

**phi** \(i\)

Return \(\varphi_i\) of self.

**INPUT:**
- \(i\) – an element of the index set

**EXAMPLES:**

```python
sage: A = crystals.KirillovReshetikhin(['A',2,1], 2,2).affinization()
sage: mg = A.module_generators[0]
sage: mg.phi(0)
0
sage: mg.phi(2)
2
```

```python
>>> from sage.all import *
>>> A = crystals.KirillovReshetikhin(['A',Integer(2),Integer(1)],...
-Integer(2),Integer(2)).affinization()
>>> mg = A.module_generators[Integer(0)]
>>> mg.phi(Integer(0))
0
>>> mg.phi(Integer(2))
2
```

**weight** ()

Return the weight of self.

The weight \(w_t\) of an element is:

\[
wt(b(m)) = wt(b) + m\delta,
\]

where \(\delta\) is the null root.

**EXAMPLES:**

```python
sage: A = crystals.KirillovReshetikhin(['A',2,1], 2,2).affinization()
sage: mg = A.module_generators[0]
sage: mg.weight()
-2*Lambda[0] + 2*Lambda[2]
sage: mg.e(0).weight()
sage: mg.e(0).e(0).weight()
2*Lambda[0] - 2*Lambda[1] + 2*delta
```

```python
>>> from sage.all import *
>>> A = crystals.KirillovReshetikhin(['A',Integer(2),Integer(1)],...
-Integer(2),Integer(2)).affinization()
>>> mg = A.module_generators[Integer(0)]
>>> mg.weight()
```

5.1.38 Alcove paths

AUTHORS:
- Brant Jones (2008): initial version
- Arthur Lubovsky (2013-03-07): rewritten to implement affine type
- Travis Scrimshaw (2016-06-23): implemented \( \mathcal{B}(\infty) \)

Special thanks to: Nicolas Borie, Anne Schilling, Travis Scrimshaw, and Nicolas Thiéry.

```python
>>> mg.e(Integer(0)).weight()
>>> mg.e(Integer(0)).e(Integer(0)).weight()
2*Lambda[0] - 2*Lambda[1] + 2*delta
```

Alcove path crystals are a discrete version of Littelmann paths. We verify that the alcove path crystal is isomorphic to the LS path crystal:

```
sage: C1 = crystals.AlcovePaths(['C',3],[2,1,0])
sage: g1 = C1.digraph()  #long time
sage: C2 = crystals.LSPaths(['C',3],[2,1,0])
sage: g2 = C2.digraph()  #long time
sage: g1.is_isomorphic(g2, edge_labels=True)  #long time
True
```

The preferred initialization method is via explicit weights rather than a Cartan type and the coefficients of the fundamental weights:

```
sage: R = RootSystem(['C',3])
sage: P = R.weight_lattice()
sage: La = P.fundamental_weights()
sage: C1==C
True
```

```
sage: R = RootSystem(['C','Integer(3)'])
sage: P = R.weight_lattice()
sage: La = P.fundamental_weights()
sage: C = crystals.AlcovePaths(Integer(2)*La[Integer(1)]+La[Integer(2)]); C
Highest weight crystal of alcove paths of type ['C', 3] and weight 2*Integer(2)*Lambda[1] +...
```
We now explain the data structure:

```python
sage: C = crystals.AlcovePaths([['A',2], [2,0]]) ; C
Highest weight crystal of alcove paths of type ['A', 2] and weight 2*Lambda[1]
sage: C._R.lambda_chain()
[(alpha[1], 0), (alpha[1] + alpha[2], 0), (alpha[1], 1), (alpha[1] + alpha[2], 1)]
```

The previous list gives the initial “straight line” path from the fundamental alcove $A_0$ to its translation $A_0 - \lambda$ where $\lambda = 2\omega_1$ in this example. The initial path for weight $\lambda$ is called the $\lambda$-chain. This path is constructed from the ordered pairs $(\beta, k)$, by crossing the hyperplane orthogonal to $\beta$ at height $-k$. We can view a plot of this path as follows:

```python
sage: x = C( () )
sage: x.plot()  # not tested - outputs a pdf
```

An element of the crystal is given by a subset of the $\lambda$-chain. This subset indicates the hyperplanes where the initial path should be folded. The highest weight element is given by the empty subset.

```python
sage: x
()
sage: x.f(1).f(2)
((alpha[1], 1), (alpha[1] + alpha[2], 1))
sage: x.f(1).f(2).integer_sequence()
[2, 3]
sage: C([2,3])
((alpha[1], 1), (alpha[1] + alpha[2], 1))
sage: C([2,3]).is_admissible()  # check if a valid vertex
True
sage: C([1,3]).is_admissible()  # check if a valid vertex
False
```

```python
>>> from sage.all import *

>>> x = C( () )

>>> x.f(Integer(1)).f(Integer(2))
((alpha[1], 1), (alpha[1] + alpha[2], 1))

>>> x.f(Integer(1)).f(Integer(2)).integer_sequence()
[2, 3]

>>> C([Integer(2), Integer(3)])
((alpha[1], 1), (alpha[1] + alpha[2], 1))

>>> C([Integer(2), Integer(3)]).is_admissible()  # check if a valid vertex
```
True
>>> C([Integer(1),Integer(3)]).is_admissible() #check if a valid vertex
False

Alcove path crystals now works in affine type (Issue #14143):

```
sage: C = crystals.AlcovePaths(['A',2,1],[1,0,0]) ; C
Highest weight crystal of alcove paths of type ['A', 2, 1] and weight Lambda[0]
sage: x=C( () )
sage: x.f(0)
((alpha[0], 0),)
sage: C.R
Root system of type ['A', 2, 1]
sage: C.weight
Lambda[0]
```

```
from sage.all import *
```

```
>>> C = crystals.AlcovePaths(['A',Integer(2),Integer(1)],[Integer(1),Integer(0),-
˓→Integer(0)]) ; C
Highest weight crystal of alcove paths of type ['A', 2, 1] and weight Lambda[0]
>>> x=C( () )
>>> x.f(Integer(0))
((alpha[0], 0),)
>>> C.R
Root system of type ['A', 2, 1]
>>> C.weight
Lambda[0]
```

```
Test that the tensor products of Kirillov-Reshetikhin crystals minus non-pseudo-Demazure arrows is in bijection with alcove path construction:
```
```
sage: K = crystals.KirillovReshetikhin(['B',3,1],2,1)
sage: T = crystals.TensorProduct(K,K)
sage: g = T.digraph() #long time
sage: for e in g.edges(sort=False): #long time
....:     if e[0].phi(0) == 1 and e[2] == 0:
....:         g.delete_edge(e)
```
```
sage: C = crystals.AlcovePaths(['B',3,1],[0,2,0], highest_weight_crystal=False)
sage: g2 = C.digraph() #long time
sage: g.is_isomorphic(g2, edge_labels = True) #long time
True
```
```
from sage.all import *
```

```
>>> K = crystals.KirillovReshetikhin(['B',Integer(3),Integer(1)],Integer(2),-
˓→Integer(1))
>>> T = crystals.TensorProduct(K,K)
>>> g = T.digraph() #long time
>>> for e in g.edges(sort=False): #long time
...     if e[Integer(0)].phi(Integer(0)) == Integer(1) and e[Integer(2)] ==-
˓→Integer(0):
...         g.delete_edge(e)
```
```
>>> C = crystals.AlcovePaths(['B',Integer(3),Integer(1)], [Integer(0),Integer(2),-
˓→Integer(0)], highest_weight_crystal=False)
```
```
>>> g2 = C.digraph() #long time
```
```
In type $C_n^{(1)}$, the Kirillov-Reshetikhin crystal is not connected when restricted to pseudo-Demazure arrows, hence the previous example will fail for type $C_n^{(1)}$ crystals.

---

**Warning:** Weights from finite root systems index non-highest weight crystals.

**Element vertexes()**

Return a list of all the vertices of the crystal.

The vertices are represented as lists of integers recording the folding positions.

One can compute all vertices of the crystal by finding all the admissible subsets of the $\lambda$-chain (see method is_admissible, for definition). We use the breadth first search algorithm.

**Warning:** This method is (currently) only useful for the case when highest_weight_crystal = False, where you cannot always reach all vertices of the crystal using crystal operators, starting from the highest weight vertex. This method is typically slower than generating the crystal graph using crystal operators.

---

**EXAMPLES:**

```python
g.is_isomorphic(g2, edge_labels = True) # long time
True
```
The number of elements reachable using the crystal operators from the module generator:

```python
sage: len(list(C))
55
```

```
class sage.combinat.crystals.alcove_path.CrystalOfAlcovePathsElement
Bases: ElementWrapper

Crystal of alcove paths element.

INPUT:

• data – a list of folding positions in the lambda chain (indexing starts at 0) or a tuple of `RootsWithHeight` giving folding positions in the lambda chain.

EXAMPLES:

```python
sage: C = crystals.AlcovePaths(['A',2],[3,2])
sage: x = C ( () )
sage: x.f(1).f(2)
((alpha[1], 2), (alpha[1] + alpha[2], 4))
sage: x.f(1).f(2).integer_sequence()
[8, 9]
sage: C([8,9])
((alpha[1], 2), (alpha[1] + alpha[2], 4))
```
```
```
>>> from sage.all import *
>>> C = crystals.AlcovePaths(['A',Integer(2)], [Integer(3),Integer(2)])
>>> x = C ( () )
>>> x.f(Integer(1)).f(Integer(2))
((alpha[1], 2), (alpha[1] + alpha[2], 4))
>>> x.f(Integer(1)).f(Integer(2)).integer_sequence()
[8, 9]
>>> C([Integer(8),Integer(9)])
((alpha[1], 2), (alpha[1] + alpha[2], 4))
```
```
e(i)

Return the \( i \)-th crystal raising operator on \texttt{self}.

INPUT:

• \( i \) – element of the index set of the underlying root system.

EXAMPLES:
sage: C = crystals.AlcovePaths(['A',2],[2,0]); C
Highest weight crystal of alcove paths of type ['A', 2] and weight 2*Lambda[1]
sage: x = C( () )
sage: x.e(1)
sage: x.f(1) == x.f(1).f(2).e(2)
True

>>> from sage.all import *
>>> C = crystals.AlcovePaths(['A',Integer(2)],[Integer(2),Integer(0)]); C
Highest weight crystal of alcove paths of type ['A', 2] and weight 2*Lambda[1]
>>> x = C( () )
>>> x.e(Integer(1))
>>> x.f(Integer(1)) == x.f(Integer(1)).f(Integer(2)).e(Integer(2))
True

epsilon(i)
Return the distance to the start of the i-string.

EXAMPLES:

sage: C = crystals.AlcovePaths(['A',2],[1,1])
sage: [c.epsilon(1) for c in C]
[0, 1, 0, 0, 1, 0, 1, 2]
sage: [c.epsilon(2) for c in C]
[0, 0, 1, 2, 1, 1, 0, 0]

>>> from sage.all import *
>>> C = crystals.AlcovePaths(['A',Integer(2)],[Integer(1),Integer(1)])
>>> [c.epsilon(Integer(1)) for c in C]
[0, 1, 0, 0, 1, 0, 1, 2]
>>> [c.epsilon(Integer(2)) for c in C]
[0, 0, 1, 2, 1, 1, 0, 0]

f(i)
Returns the i-th crystal lowering operator on self.

INPUT:

• i – element of the index_set of the underlying root_system.

EXAMPLES:

sage: C = crystals.AlcovePaths(['B',2],[1,1])
sage: x=C( () )
sage: x.f(1)
((alpha[1], 0),)
sage: x.f(1).f(2)
((alpha[1], 0), (alpha[1] + alpha[2], 2))

>>> from sage.all import *
>>> C = crystals.AlcovePaths(['B',Integer(2)],[Integer(1),Integer(1)])
>>> x=C( () )
>>> x.f(Integer(1))
((alpha[1], 0),)
>>> x.f(Integer(1)).f(Integer(2))
((alpha[1], 0), (alpha[1] + alpha[2], 2))
integer_sequence()

Return a list of integers corresponding to positions in the \( \lambda \)-chain where it is folded.

Todo: Incorporate this method into the \_repr\_ for finite Cartan type.

Note: Only works for finite Cartan types and indexing starts at 0.

EXAMPLES:

```python
sage: C = crystals.AlcovePaths(['A',2],[3,2])
sage: x = C( () )
sage: x.f(1).f(2).integer_sequence()
[8, 9]
```

```python
>>> from sage.all import *
>>> C = crystals.AlcovePaths(['A',Integer(2)],[Integer(3),Integer(2)])
>>> x = C( ()
>>> x.f(Integer(1)).f(Integer(2)).integer_sequence()
[8, 9]
```

is_admissible()

Diagnostic test to check if self is a valid element of the crystal.

If self.value is given by

\[(\beta_1, i_1), (\beta_2, i_2), \ldots, (\beta_k, i_k),\]

for highest weight crystals this checks if the sequence

\[1 \rightarrow s_{\beta_1} \rightarrow s_{\beta_1} s_{\beta_2} \rightarrow \cdots \rightarrow s_{\beta_1} s_{\beta_2} \cdots s_{\beta_k}\]

is a path in the Bruhat graph. If highest_weight_crystal=False, then the method checks if the above sequence is a path in the quantum Bruhat graph.

EXAMPLES:

```python
sage: C = crystals.AlcovePaths(['A',2],[1,1]); C
Highest weight crystal of alcove paths of type ['A', 2] and weight Lambda[1] → Lambda[2]
sage: roots = sorted(C._R._root_lattice.positive_roots()); roots
[alpha[1], alpha[1] + alpha[2], alpha[2]]
sage: r1 = C._R(roots[0],0); r1
(alpha[1], 0)
sage: r2 = C._R(roots[2],0); r2
(alpha[2], 0)
sage: r3 = C._R(roots[1],1); r3
(alpha[1] + alpha[2], 1)
sage: x = C( (r3,) )
sage: x.is_admissible()  
True
```

```python
sage: x = C( (r3, ) ); x
((alpha[1] + alpha[2], 1),)
sage: x.is_admissible()  
False
```

(continues on next page)
Todo: Better doctest

path()

Return the path in the (quantum) Bruhat graph corresponding to self.

EXAMPLES:

```python
sage: C = crystals.AlcovePaths(['C', 2, 1], [2, 1], False)
sage: C([7, 8]).is_admissible()
True
sage: C = crystals.AlcovePaths(['A', 2], [3, 2])
sage: C([2, 3]).is_admissible()
True
```
>>> b = C.highest_weight_vector().f_string([Integer(1), Integer(3), Integer(2), Integer(1)])

```
[1, s1, s3*s1, s2*s3*s1, s3*s2*s3*s1]
```

```
>>> b.path()
[1, s2, s3*s2, s2*s3*s2]
```

```
>>> b = C.highest_weight_vector().f_string([Integer(2), Integer(3), Integer(3), Integer(2)])

```

```
>>> b.path()
[1, s2, s3*s2, s2*s3*s2]
```

```
>>> b = C.highest_weight_vector().f_string([Integer(2), Integer(3), Integer(3), Integer(2), Integer(1)])

```

```
>>> b.path()
[1, s2, s3*s2, s2*s3*s2, s1*s2*s3*s2]
```

\phi(i)

Return the distance to the end of the i-string.

This method overrides the generic implementation in the category of crystals since this computation is more efficient.

**EXAMPLES:**

```
sage: C = crystals.AlcovePaths(['A', 2], [1, 1])
sage: [c.phi(1) for c in C]
[1, 0, 0, 1, 0, 2, 1, 0]
sage: [c.phi(2) for c in C]
[1, 2, 1, 0, 0, 0, 0, 1]
```

```
>>> from sage.all import *
>>> C = crystals.AlcovePaths(['A', Integer(2)], [Integer(1), Integer(1)])
>>> [c.phi(Integer(1)) for c in C]
[1, 0, 0, 1, 0, 2, 1, 0]
>>> [c.phi(Integer(2)) for c in C]
[1, 2, 1, 0, 0, 0, 0, 1]
```

**plot()**

Return a plot of self.

**Note:** Currently only implemented for types $A_2$, $B_2$, and $C_2$.

**EXAMPLES:**

```
sage: C = crystals.AlcovePaths(['A', 2], [2, 0])
sage: x = C(()).f(1).f(2)
sage: x.plot() # Not tested - creates a pdf
```

```
>>> from sage.all import *
>>> C = crystals.AlcovePaths(['A', Integer(2)], [Integer(2), Integer(0)])
>>> x = C(()).f(Integer(1)).f(Integer(2))
>>> x.plot() # Not tested - creates a pdf
```

**weight()**

Return the weight of self.

**EXAMPLES:**

```
```python
sage: C = crystals.AlcovePaths(['A',2],[2,0])
sage: for i in C: i.weight()
  (2, 0, 0)
  (1, 1, 0)
  (0, 2, 0)
  (0, -1, 0)
  (-1, 0, 0)
  (-2, -2, 0)
sage: B = crystals.AlcovePaths(['A',2,1],[1,0,0])
sage: p = B.module_generators[0].f_string([0,1,2])
sage: p.weight()
Lambda[0] - delta
```

```python
>>> from sage.all import *

>>> C = crystals.AlcovePaths(['A',Integer(2)],[Integer(2),Integer(0)])
>>> for i in C: i.weight()
  (2, 0, 0)
  (1, 1, 0)
  (0, 2, 0)
  (0, -1, 0)
  (-1, 0, 0)
  (-2, -2, 0)

>>> B = crystals.AlcovePaths(['A',Integer(2),Integer(1)],[Integer(1),-
\rightarrow Integer(0),Integer(0)])
>>> p = B.module_generators[Integer(0)].f_string([Integer(0),Integer(1),-
\rightarrow Integer(2)])
>>> p.weight()
Lambda[0] - delta
```

```python
class sage.combinat.crystals.alcove_path.InfinityCrystalOfAlcovePaths(car-
tan_type)

Bases: UniqueRepresentation, Parent

B(\infty) crystal of alcove paths.

class Element (parent, elt, shift)

Bases: ElementWrapper

Initialize self.

EXAMPLES:

```python
sage: A = crystals.infinity.AlcovePaths(['F',4])
sage: mg = A.highest_weight_vector()
sage: x = mg.f_string([2,3,1,4,4,2,3,1])
sage: TestSuite(x).run()
```

```python
>>> from sage.all import *

>>> A = crystals.infinity.AlcovePaths(['F',Integer(4)])
>>> mg = A.highest_weight_vector()
>>> x = mg.f_string([Integer(2),Integer(3),Integer(1),Integer(4),Integer(4),-
\rightarrow Integer(2),Integer(3),Integer(1)])
>>> TestSuite(x).run()
```

\(e(i)\)

Return the action of \(e_i\) on self.

INPUT:

• \( i \) – an element of the index set

EXAMPLES:

```python
sage: A = crystals.infinity.AlcovePaths(['D', 5, 1])
sage: mg = A.highest_weight_vector()
sage: x = mg.f_string([1, 3, 4, 2, 5, 4, 5, 5])
sage: x.f(4).e(5) == x.e(5).f(4)
True
```

```python
>>> from sage.all import *

>>> A = crystals.infinity.AlcovePaths(['D', Integer(5), Integer(1)])

>>> mg = A.highest_weight_vector()

>>> x = mg.f_string([Integer(1), Integer(3), Integer(4), Integer(2),
  
  Integer(5), Integer(4), Integer(5), Integer(5)])

>>> x.f(Integer(4)).e(Integer(5)) == x.e(Integer(5)).f(Integer(4))
True
```

epsilon(\( i \))

Return \( \epsilon_i \) of self.

INPUT:
• \( i \) – an element of the index set

EXAMPLES:

```python
sage: A = crystals.infinity.AlcovePaths(['A', 7, 2])
sage: mg = A.highest_weight_vector()
sage: x = mg.f_string([1, 0, 2, 3, 4, 4, 4, 2, 3, 3, 3])

[x.epsilon(i) for i in A.index_set()]
[0, 0, 0, 3, 0]

sage: x = mg.f_string([2, 2, 1, 1, 0, 1, 0, 2, 3, 3, 3, 4])

[x.epsilon(i) for i in A.index_set()]
[1, 2, 0, 1, 1]
```

```python
>>> from sage.all import *

>>> A = crystals.infinity.AlcovePaths(['A', Integer(7), Integer(2)])

>>> mg = A.highest_weight_vector()

>>> x = mg.f_string([Integer(1), Integer(0), Integer(2), Integer(3),
  
  Integer(4), Integer(4), Integer(4), Integer(2), Integer(3), Integer(3),
  
  Integer(3)])

>>> x.epsilon(i) for i in A.index_set()]
[0, 0, 0, 3, 0]

>>> x = mg.f_string([Integer(2), Integer(2), Integer(1), Integer(1),
  
  Integer(0), Integer(1), Integer(0), Integer(2), Integer(3), Integer(3),
  
  Integer(3), Integer(4)])

>>> [x.epsilon(i) for i in A.index_set()]
[1, 2, 0, 1, 1]
```

\( f(\( i \))\)

Return the action of \( f_i \) on self.

INPUT:
• \( i \) – an element of the index set

EXAMPLES:

```python
sage: A = crystals.infinity.AlcovePaths(['E', 7, 1])
sage: mg = A.highest_weight_vector()
sage: mg.f_string([1, 3, 5, 6, 4, 2, 0, 2, 1, 0, 2, 4, 7, 4, 2])
```
Combinatorics, Release 10.4

Continued from previous page

((alpha[2], -3), (alpha[5], -1), (alpha[1], -1),
(alpha[0] + alpha[1], -2),
(alpha[5] + alpha[6], -1), (alpha[1] + alpha[3], -1),
(alpha[0] + alpha[1] + alpha[3], -1),

```python
from sage.all import *

A = crystals.infinity.AlcovePaths(['E', Integer(7), Integer(1)])
mg = A.highest_weight_vector()
f_string = mg.f_string([Integer(1), Integer(3), Integer(5), Integer(6), Integer(4),
                        Integer(2), Integer(0), Integer(2), Integer(1), Integer(0), Integer(2),
                        Integer(4), Integer(7), Integer(4), Integer(2)])

(alpha[0] + alpha[1], -2),
(alpha[5] + alpha[6], -1), (alpha[1] + alpha[3], -1),
(alpha[0] + alpha[1] + alpha[3], -1),
```

\[\phi(i)\]

Return \(\phi_i\) of self.

Let \(A \in B(\infty)\) Define \(\phi_i(A) := \varepsilon_i(A) + \langle h_i, wt(A) \rangle\), where \(h_i\) is the \(i\)-th simple coroot and \(wt(A)\) is the weight() of \(A\).

INPUT:
- \(i\) – an element of the index set

EXAMPLES:

```python
sage: A = crystals.infinity.AlcovePaths(['A', 8, 2])
sage: mg = A.highest_weight_vector()
sage: x = mg.f_string([1, 0, 2, 3, 4, 4, 4, 2, 3, 3, 3])
sage: [x.phi(i) for i in A.index_set()]
[1, 1, 1, 3, -2]
sage: x = mg.f_string([2, 2, 1, 1, 0, 1, 0, 2, 3, 3, 3, 4])
sage: [x.phi(i) for i in A.index_set()]
[4, -1, 0, 0, 2]
```

```python
>>> from sage.all import *

>>> A = crystals.infinity.AlcovePaths(['A', Integer(8), Integer(2)])
>>> mg = A.highest_weight_vector()
>>> x = mg.f_string([Integer(1), Integer(0), Integer(2), Integer(1),
                   Integer(0), Integer(4), Integer(4), Integer(2), Integer(3), Integer(3),
                   Integer(3)])

>>> [x.phi(i) for i in A.index_set()]
[1, 1, 1, 3, -2]
>>> x = mg.f_string([Integer(2), Integer(1), Integer(0), Integer(2), Integer(1),
                   Integer(0), Integer(4), Integer(4), Integer(2), Integer(3), Integer(3),
                   Integer(3), Integer(4)])

>>> [x.phi(i) for i in A.index_set()]
[4, -1, 0, 0, 2]
```

projection \((k=\text{None})\)

Return the projection self onto \(B(kp)\).
INPUT:

- \( k \) – (optional) if not given, defaults to the smallest value such that \( \text{self} \) is not None under the projection

EXAMPLES:

```python
sage: A = crystals.infinity.AlcovePaths(['G',2])
sage: mg = A.highest_weight_vector()
sage: x = mg.f_string([2,1,2,2,1,1]); x
((\alpha[2], -3), (\alpha[1] + \alpha[2], -3),
(3*\alpha[1] + 2*\alpha[2], -1), (2*\alpha[1] + \alpha[2], -1))
sage: x.projection()
((\alpha[2], 0), (\alpha[1] + \alpha[2], 9),
(3*\alpha[1] + 2*\alpha[2], 8), (2*\alpha[1] + \alpha[2], 14))
sage: x.projection().parent()
Highest weight crystal of alcove paths of type ['G', 2]

sage: mg.projection().parent()
Highest weight crystal of alcove paths of type ['G', 2]
and weight 0

sage: mg.f(1).projection().parent()
Highest weight crystal of alcove paths of type ['G', 2]
and weight \Lambda[1] + \Lambda[2]

sage: b = mg.f_string([1,2,2,1,2])
sage: b.projection().parent()
Highest weight crystal of alcove paths of type ['G', 2]
and weight 2*\Lambda[1] + 2*\Lambda[2]

>>> from sage.all import *
>>> A = crystals.infinity.AlcovePaths(['G',Integer(2)])
>>> mg = A.highest_weight_vector()
>>> x = mg.f_string([Integer(2),Integer(1),Integer(1),Integer(2),
Integer(2),Integer(1),Integer(1)]); x
((\alpha[2], -3), (\alpha[1] + \alpha[2], -3),
(3*\alpha[1] + 2*\alpha[2], -1), (2*\alpha[1] + \alpha[2], -1))
>>> x.projection()
((\alpha[2], 0), (\alpha[1] + \alpha[2], 9),
(3*\alpha[1] + 2*\alpha[2], 8), (2*\alpha[1] + \alpha[2], 14))
>>> x.projection().parent()
Highest weight crystal of alcove paths of type ['G', 2]

>>> mg.projection().parent()
Highest weight crystal of alcove paths of type ['G', 2]
and weight 0

>>> mg.f(Integer(1)).projection().parent()
Highest weight crystal of alcove paths of type ['G', 2]
and weight \Lambda[1] + \Lambda[2]

>>> mg.f(Integer(1)).f(Integer(2)).projection().parent()
Highest weight crystal of alcove paths of type ['G', 2]
```

(continues on next page)
and weight $\Lambda[1] + \Lambda[2]$

```python
>>> b = mg.f_string([Integer(1), Integer(2), Integer(2), Integer(1),
                   Integer(2)])
>>> b.projection().parent()
Highest weight crystal of alcove paths of type ['G', 2]
and weight $2\Lambda[1] + 2\Lambda[2]$
```

```python
>>> b.projection(Integer(3)).parent()
Highest weight crystal of alcove paths of type ['G', 2]
and weight $3\Lambda[1] + 3\Lambda[2]$
```

```python
>>> b.projection(Integer(1))
```

weight()

Return the weight of self.

EXAMPLES:

```python
sage: A = crystals.infinity.AlcovePaths(['E', 6])
sage: mg = A.highest_weight_vector()
sage: fstr = [1,3,4,2,1,2,3,6,5,3,2,6,2]
sage: x = mg.f_string(fstr)
sage: al = A.weight_lattice_realization().simple_roots()
sage: x.weight() == -sum(al[i]*fstr.count(i) for i in A.index_set())
True
```

```python
>>> from sage.all import *
>>> A = crystals.infinity.AlcovePaths(['E', Integer(6)])
>>> mg = A.highest_weight_vector()
>>> fstr = [Integer(1), Integer(3), Integer(4), Integer(2), Integer(1),
          Integer(2), Integer(3), Integer(6), Integer(5), Integer(3),
          Integer(2), Integer(6), Integer(2)]
>>> x = mg.f_string(fstr)
>>> al = A.weight_lattice_realization().simple_roots()
>>> x.weight() == -sum(al[i]*fstr.count(i) for i in A.index_set())
True
```

**class** `sage.combinat.crystals.alcove_path.RootsWithHeight(weight)`

**Bases:** `UniqueRepresentation`, `Parent`

Data structure of the ordered pairs $(\beta, k)$, where $\beta$ is a positive root and $k$ is a non-negative integer. A total order is implemented on this set, and depends on the weight.

**INPUT:**

- `cartan_type` – Cartan type of a finite or affine untwisted root system
- `weight` – dominant weight as a list of (integral) coefficients of the fundamental weights

**EXAMPLES:**

```python
sage: from sage.combinat.crystals.alcove_path import RootsWithHeight
sage: R = RootsWithHeight(['A', 2], [1, 1]); R
Roots with height of Cartan type ['A', 2] and dominant weight $\Lambda[1] + \Lambda[2]$
```

```python
sage: r1 = R._root_lattice.from_vector(vector([1, 0])); r1
alpha[1]
sage: r2 = R._root_lattice.from_vector(vector([1, 1])); r2
```
sage: x = R(r1,0); x
(alpha[1], 0)
sage: y = R(r2,1); y
(alpha[1] + alpha[2], 1)
sage: x < y
True

>>> from sage.all import *
>>> from sage.combinat.crystals.alcove_path import RootsWithHeight
>>> R = RootsWithHeight(['A',Integer(2)],[Integer(1),Integer(1)]); R
Roots with height of Cartan type ['A', 2] and dominant weight Lambda[1] +-
→Lambda[2]

>>> r1 = R._root_lattice.from_vector(vector([Integer(1),Integer(0)])); r1
alpha[1]

>>> r2 = R._root_lattice.from_vector(vector([Integer(1),Integer(1)])); r2

>>> x = R(r1,Integer(0)); x
(alpha[1], 0)

>>> y = R(r2,Integer(1)); y
(alpha[1] + alpha[2], 1)

>>> x < y
True

\textbf{Element}

\textit{alias of \texttt{RootsWithHeightElement}}

\texttt{lambda\_chain()}

Return the unfolded \(\lambda\)-chain.

\textbf{Note:} Only works in root systems of finite type.

\textbf{EXAMPLES:}

\texttt{sage: from sage.combinat.crystals.alcove_path import RootsWithHeight}

\texttt{sage: R = RootsWithHeight(['A',2],[1,1]); R}
Roots with height of Cartan type ['A', 2] and dominant weight Lambda[1] +-
→Lambda[2]

\texttt{sage: R.lambda\_chain()}
[(alpha[2], 0), (alpha[1] + alpha[2], 0), (alpha[1], 0), (alpha[1] + alpha[2],
→1)]

\texttt{word()}

\textbf{Gives the initial alcove path (\(\lambda\)-chain) in terms of simple roots. Used for plotting the path.}
Note: Currently only implemented for finite Cartan types.

EXAMPLES:

```
sage: from sage.combinat.crystals.alcove_path import RootsWithHeight
sage: R = RootsWithHeight(['A',2],[3,2])
sage: R.word()
[2, 1, 2, 0, 1, 2, 1, 0, 1, 2]
```

```
>>> from sage.all import *
>>> from sage.combinat.crystals.alcove_path import RootsWithHeight
>>> R = RootsWithHeight(['A',Integer(2)],[Integer(3),Integer(2)])
>>> R.word()
[2, 1, 2, 0, 1, 2, 1, 0, 1, 2]
```

class sage.combinat.crystals.alcove_path.RootsWithHeightElement (parent, root, height)

Bases: Element

Element of RootsWithHeight.

INPUT:

- root – A positive root \( \beta \) in our root system
- height – Is an integer, such that \( 0 \leq l \leq \langle \lambda, \beta^\vee \rangle \)

EXAMPLES:

```
sage: from sage.combinat.crystals.alcove_path import RootsWithHeight
sage: rl = RootSystem(['A',2]).root_lattice()
sage: x = rl.from_vector(vector([1,1])); x
sage: R = RootsWithHeight(['A',2],[1,1]); R
Roots with height of Cartan type ['A', 2] and dominant weight Lambda[1] +␣
˓→Lambda[2]
sage: y = R(x, 1); y
(alpha[1] + alpha[2], 1)
```

```
>>> from sage.all import *
>>> from sage.combinat.crystals.alcove_path import RootsWithHeight
>>> rl = RootSystem(['A',Integer(2)]).root_lattice()
>>> x = rl.from_vector(vector([Integer(1),Integer(1)])); x
>>> R = RootsWithHeight(['A',Integer(2)],[Integer(1),Integer(1)]); R
Roots with height of Cartan type ['A', 2] and dominant weight Lambda[1] +␣
˓→Lambda[2]
>>> y = R(x, Integer(1)); y
(alpha[1] + alpha[2], 1)
```

```
sage.combinat.crystals.alcove_path.compare_graphs (g1, g2, node1, node2)
```

Compare two edge-labeled graphs obtained from Crystal.digraph(), starting from the root nodes of each graph.

- g1 – graphs, first digraph
- g2 – graphs, second digraph
- node1 – element of g1
\textbullet\ node2 – element of $g_2$

Traverse $g_1$ starting at node1 and compare this graph with the one obtained by traversing $g_2$ starting with node2. If the graphs match (including labels) then return True. Return False otherwise.

**EXAMPLES:**

```python
sage: from sage.combinat.crystals.alcove_path import compare_graphs
sage: G1 = crystals.Tableaux(['A',3], shape=[1,1]).digraph()
sage: C = crystals.AlcovePaths(['A',3],[0,1,0])
sage: G2 = C.digraph()
sage: compare_graphs(G1, G2, C( () ), G2.vertices(sort=True)[0])
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.crystals.alcove_path import compare_graphs
>>> G1 = crystals.Tableaux(['A',Integer(3)], shape=[Integer(1),Integer(1)]).→digraph()
>>> C = crystals.AlcovePaths(['A',Integer(3)],[Integer(0),Integer(1),Integer(0)])
>>> G2 = C.digraph()
>>> compare_graphs(G1, G2, C( () ), G2.vertices(sort=True)[Integer(0)])
True
```

5.1.40 Benkart-Kang-Kashiwara crystals for the general-linear Lie superalgebra

```python
class sage.combinat.crystals.bkk_crystals.CrystalOfBKKTableaux(ct, shape)
Bases: CrystalOfWords
```

Crystal of tableaux for type $A(m|n)$.

This is an implementation of the tableaux model of the Benkart-Kang-Kashiwara crystal [BKK2000] for the Lie superalgebra $\mathfrak{gl}(m + 1, n + 1)$.

**INPUT:**

- \texttt{ct} – a super Lie Cartan type of type $A(m|n)$
- **shape** – shape specifying the highest weight; this should be a partition contained in a hook of height \( n + 1 \) and width \( m + 1 \)

**EXAMPLES:**

```python
sage: T = crystals.Tableaux(['A', [1,1]], shape = [2,1])
sage: T.cardinality()
20
```

```python
>>> from sage.all import *
>>> T = crystals.Tableaux(['A', [Integer(1),Integer(1)]], shape = [Integer(2), Integer(1)])
>>> T.cardinality()
20
```

```python
class Element
    Bases: CrystalOfBKKTableauxElement

genuine_highest_weight_vectors(index_set=None)
    Return a tuple of genuine highest weight elements.

    A *fake highest weight vector* is one which is annihilated by \( e_i \) for all \( i \) in the index set, but whose weight is not bigger in dominance order than all other elements in the crystal. A *genuine highest weight vector* is a highest weight element that is not fake.

**EXAMPLES:**

```python
sage: B = crystals.Tableaux(['A', [1,1]], shape=[3,2,1])
sage: B.genuine_highest_weight_vectors()
([[-2, -2, -2], [-1, -1], [1]],)
```

```python
>>> from sage.all import *
>>> B = crystals.Tableaux(['A', [Integer(1),Integer(1)]], shape=[Integer(3), Integer(2),Integer(1)])
```

```python
shape()
    Return the shape of self.

**EXAMPLES:**

```python
sage: T = crystals.Tableaux(['A', [2,1]], shape=[2,1])
sage: T.shape()
[2, 1]
```

```python
>>> from sage.all import *
>>> T = crystals.Tableaux(['A', [Integer(1), Integer(2)]], shape=[Integer(2), Integer(1)])
```
5.1.41 Catalog Of Crystals

Let \( I \) be an index set and let \((A, \Pi, \Pi^\vee, P, P^\vee)\) be a Cartan datum associated with generalized Cartan matrix \( A = (a_{ij})_{i,j \in I} \). An abstract crystal associated to this Cartan datum is a set \( B \) together with maps

\[
\begin{align*}
e_i, f_i : & B \to B \cup \{0\}, & \varepsilon_i, \varphi_i : & B \to \mathbb{Z} \cup \{-\infty\}, & \text{wt} : & B \to P,
\end{align*}
\]

subject to the following conditions:

1. \( \varphi_i(b) = \varepsilon_i(b) + \langle h_i, \text{wt}(b) \rangle \) for all \( b \in B \) and \( i \in I \);
2. \( \text{wt}(e_i b) = \text{wt}(b) + \alpha_i \) if \( e_i b \in B \);
3. \( \text{wt}(f_i b) = \text{wt}(b) - \alpha_i \) if \( f_i b \in B \);
4. \( \varepsilon_i(e_i b) = \varepsilon_i(b) - 1, \varphi_i(e_i b) = \varphi_i(b) + 1 \) if \( e_i b \in B \);
5. \( \varepsilon_i(f_i b) = \varepsilon_i(b) + 1, \varphi_i(f_i b) = \varphi_i(b) - 1 \) if \( f_i b \in B \);
6. \( f_i b = b' \) if and only if \( b = e_i b' \) for \( b, b' \in B \) and \( i \in I \);
7. if \( \varphi_i(b) = -\infty \) for \( b \in B \), then \( e_i b = f_i b = 0 \).

- LSPaths
- RiggedConfigurations

5.1.45 An introduction to crystals

Informally, a crystal $\mathcal{B}$ is an oriented graph with edges colored in some set $I$ such that, for each $i \in I$, each node $x$ has:

- at most one $i$-successor, denoted $f_i x$;
- at most one $i$-predecessor, denoted $e_i x$.

By convention, one writes $f_i x = \emptyset$ and $e_i x = \emptyset$ when $x$ has no successor resp. predecessor.

One may think of $\mathcal{B}$ as essentially a deterministic automaton whose dual is also deterministic; in this context, the $f_i$’s and $e_i$’s are respectively the transition functions of the automaton and of its dual, and $\emptyset$ is the sink.

A crystal comes further endowed with a weight function $\text{wt} : \mathcal{B} \to L$ which satisfies appropriate conditions.

In combinatorial representation theory, crystals are used as combinatorial data to model representations of Lie algebra.

Axiomatic definition

Let $C$ be a Cartan type (CartanType) with index set $I$, and $L$ be a realization of the weight lattice of the type $C$. Let $\alpha_i$ and $\alpha'_i$ denote the simple roots and coroots respectively.

A type $C$ crystal is a non-empty set $\mathcal{B}$ endowed with maps $\text{wt} : \mathcal{B} \to L, e_i, f_i : \mathcal{B} \to \mathcal{B} \cup \{\emptyset\}$, and $\varepsilon_i, \varphi_i : \mathcal{B} \to \mathbb{Z} \cup \{-\infty\}$ for $i \in I$ satisfying the following properties for all $i \in I$:

- for $b, b' \in \mathcal{B}$, we have $f_i b' = b$ if and only if $e_i b = b'$;
- if $e_i b \in \mathcal{B}$, then:
  - $\text{wt}(e_i b) = \text{wt}(b) + \alpha_i$,
  - $\varepsilon_i(e_i b) = \varepsilon_i(b) - 1$,
  - $\varphi_i(e_i b) = \varphi_i(b) + 1$;
- if $f_i b \in \mathcal{B}$, then:
  - $\text{wt}(f_i b) = \text{wt}(b) - \alpha_i$,
  - $\varepsilon_i(f_i b) = \varepsilon_i(b) + 1$. 

5.1. Comprehensive Module List
\[ \phi_i(f_ib) = \phi_i(b) - 1; \]

- \[ \phi_i(b) = \varepsilon_i(b) + (\alpha_i^\vee, \text{wt}(b)), \]
- \[ \text{if } \phi_i(b) = -\infty \text{ for } b \in B, \text{ then } e_ib = f_ib = \emptyset. \]

Some further conditions are required to guarantee that this data indeed models a representation of a Lie algebra. For finite simply laced types a complete characterization is given by Stembridge's local axioms [Ste2003].

**EXAMPLES:**

We construct the type \( A_5 \) crystal on letters (or in representation theoretic terms, the highest weight crystal of type \( A_5 \) corresponding to the highest weight \( \Lambda_1 \)):

```sage
C = crystals.Letters(['A', 5]); C
```

The crystal of letters for type ['A', 5]

```sage
>>> from sage.all import *
>>> C = crystals.Letters(['A', Integer(5)]); C
The crystal of letters for type ['A', 5]
```

It has a single highest weight element:

```sage
C.highest_weight_vectors()
```

(1,)

```sage
>>> from sage.all import *
>>> C = crystals.Letters(['A', Integer(5)]); C
The crystal of letters for type ['A', 5]
```

```sage
C.highest_weight_vectors()
```

(1,)

A crystal is an enumerated set (see `EnumeratedSets`); and we can count and list its elements in the usual way:

```sage
C.cardinality()
```

6

```sage
C.list()
```

[1, 2, 3, 4, 5, 6]

```sage
>>> from sage.all import *
>>> C = crystals.Letters(['A', Integer(5)]); C
The crystal of letters for type ['A', 5]
```

```sage
C.cardinality()
```

6

```sage
C.list()
```

[1, 2, 3, 4, 5, 6]

as well as use it in for loops:

```sage
[x for x in C]
```

[1, 2, 3, 4, 5, 6]

```sage
>>> from sage.all import *
>>> C = crystals.Letters(['A', Integer(5)]); C
The crystal of letters for type ['A', 5]
```

```sage
[x for x in C]
```

[1, 2, 3, 4, 5, 6]

Here are some more elaborate crystals (see their respective documentations):

```sage
Tens = crystals.TensorProduct(C, C)
sage: Spin = crystals.Spins(['B', 3])
sage: Tab = crystals.Tableaux(['A', 3], shape = [2,1,1])
sage: Fast = crystals.FastRankTwo(['B', 2], shape = [3/2, 1/2])
sage: KR = crystals.KirillovReshetikhin(['A',2,1],1,1)
```
One can get (currently) crude plotting via:

```python
sage: Tab.plot()
# needs sage.plot
```

If dot2tex is installed, one can obtain nice latex pictures via:

```python
sage: K = crystals.KirillovReshetikhin(['A',3,1], 1,1)
sage: view(K, pdflatex=True) # optional - dot2tex graphviz, not tested (opens external window)
```

or with colored edges:

```python
sage: G = K.digraph()
sage: G.set_latex_options(color_by_label={0:"black", 1:"red", 2:"blue", 3:"green"})
sage: view(G, pdflatex=True) # optional - dot2tex graphviz, not tested (opens external window)
```

For rank two crystals, there is an alternative method of getting metapost pictures. For more information see `C.metapost`.

* The overview of crystal features in Sage*
The crystals library in Sage grew up from an initial implementation in MuPAD-Combinat (see `<MuPAD-Combinat>/lib/COMBINAT/crystals.mu`).

```python
class sage.combinat.crystals.crystals.CrystalBacktracker (crystal, index_set=None)

Bases: GenericBacktracker

Time complexity: \( O(nF) \) amortized for each produced element, where \( n \) is the size of the index set, and \( F \) is the cost of computing \( e \) and \( f \) operators.

Memory complexity: \( O(D) \) where \( D \) is the depth of the crystal.

Principle of the algorithm:

Let \( C \) be a classical crystal. It’s an acyclic graph where each connected component has a unique element without predecessors (the highest weight element for this component). Let’s assume for simplicity that \( C \) is irreducible (i.e. connected) with highest weight element \( u \).

One can define a natural spanning tree of \( C \) by taking \( u \) as the root of the tree, and for any other element \( y \) taking as ancestor the element \( x \) such that there is an \( i \)-arrow from \( x \) to \( y \) with \( i \) minimal. Then, a path from \( u \) to \( y \) describes the lexicographically smallest sequence \( i_1, \ldots, i_k \) such that \((f_{i_k} \circ f_{i_{k-1}}) (u) = y\).

Morally, the iterator implemented below just does a depth first search walk through this spanning tree. In practice, this can be achieved recursively as follows: take an element \( x \), and consider in turn each successor \( y = f_i(x) \), ignoring those such that \( y = f_j(x') \) for some \( x' \) and \( j < i \) (this can be tested by computing \( e_j(y) \) for \( j < i \)).

EXAMPLES:

```
5.1.46 Direct Sum of Crystals

**class** sage.combinat.crystals.direct_sum.DirectSumOfCrystals *(crystals, facade, keepkey, category, **options)*

**Bases:** DisjointUnionEnumeratedSets

Direct sum of crystals.

Given a list of crystals $B_0, \ldots, B_k$ of the same Cartan type, one can form the direct sum $B_0 \oplus \cdots \oplus B_k$.

**INPUT:**

- **crystals** – a list of crystals of the same Cartan type
- **keepkey** – a boolean

The option `keepkey` is by default set to `False`, assuming that the crystals are all distinct. In this case the elements of the direct sum are just represented by the elements in the crystals $B_i$. If the crystals are not all distinct, one should set the `keepkey` option to `True`. In this case, the elements of the direct sum are represented as tuples $(i, b)$ where $b \in B_i$.

**EXAMPLES:**

```
sage: C = crystals.Letters(['A',2])
sage: C1 = crystals.Tableaux(['A',2],shape=[1,1])
sage: B = crystals.DirectSum([C,C1])
sage: B.list()
[1, 2, 3, [[1], [2]], [[1], [3]], [[2], [3]]]
sage: [b.f(1) for b in B]
[2, None, None, None, [[2], [3]], None]
sage: B.module_generators
(1, [[1], [2]])
```

```
>>> from sage.all import *
>>> C = crystals.Letters(['A',Integer(2)])
>>> C1 = crystals.Tableaux(['A',Integer(2)],shape=[Integer(1),Integer(1)])
>>> B = crystals.DirectSum([C,C1])
>>> B.list()
[1, 2, 3, [[1], [2]], [[1], [3]], [[2], [3]]]
>>> [b.f(Integer(1)) for b in B]
[2, None, None, None, [[2], [3]], None]
>>> B.module_generators
(1, [[1], [2]])
```

```
sage: B = crystals.DirectSum([C,C], keepkey=True)
sage: B.list()
[(0, 1), (0, 2), (0, 3), (1, 1), (1, 2), (1, 3)]
sage: B.module_generators
((0, 1), (1, 1))
sage: b = B( tuple([0,C(1)]) )
sage: b
(0, 1)
sage: b.weight()
(1, 0, 0)
```

```
>>> from sage.all import *
>>> B = crystals.DirectSum([C,C], keepkey=True)
>>> B.list()
```

(continues on next page)
The following is required, because `DirectSumOfCrystals` takes the same arguments as `DisjointUnionEnumeratedSets` (which see for details).

```python
class Element
    Bases: ElementWrapper

    A class for elements of direct sums of crystals.

e(i)
    Return the action of \(e_i\) on \(self\).

    EXAMPLES:

    sage: C = crystals.Letters(['A',2])
    sage: B = crystals.DirectSum([C,C], keepkey=True)
    sage: [[b, b.e(2)] for b in B]
    [[(0, 1), None], [(0, 2), None], [(0, 3), (0, 2)], [(1, 1), None], [(1, 2), None], [(1, 3), (1, 2)]]

>>> from sage.all import *
>>> C = crystals.Letters(['A',Integer(2)])
>>> B = crystals.DirectSum([C,C], keepkey=True)
>>> [[b, b.e(Integer(2))] for b in B]
[[[0, 1], None], [[0, 2], None], [[0, 3], (0, 2)], [[1, 1], None], [[1, 2], None], [[1, 3], (1, 2)]]

epsilon(i)
    EXAMPLES:

sage: C = crystals.Letters(['A',2])
    sage: B = crystals.DirectSum([C,C], keepkey=True)
    sage: b = B( tuple([Integer(0),C(Integer(1))]) )
    sage: b.epsilon(2)
    0

>>> from sage.all import *
>>> C = crystals.Letters(['A',Integer(2)])
>>> B = crystals.DirectSum([C,C], keepkey=True)
>>> b = B( tuple([Integer(0),C(Integer(2))]) )
>>> b.epsilon(Integer(2))
0

f(i)
    Return the action of \(f_i\) on \(self\).

    EXAMPLES:
```
Combinatorics, Release 10.4

```python
sage: C = crystals.Letters(['A',2])
sage: B = crystals.DirectSum([C,C], keepkey=True)

sage: [(b,b.f(1)) for b in B]
[(0, 1), (0, 2), (0, 2), None], [(0, 3), None], [(1, 1), (1, 2)], [(1, -2), None], [(1, 3), None]
```

```python
>>> from sage.all import *

>>> C = crystals.Letters(['A',Integer(2)])
>>> B = crystals.DirectSum([C,C], keepkey=True)

>>> [(b,b.f(Integer(1))) for b in B]
[(0, 1), (0, 2), (0, 2), None], [(0, 3), None], [(1, 1), (1, 2)], [(1, -2), None], [(1, 3), None]
```

\(\phi (i)\)

EXAMPLES:

```python
sage: C = crystals.Letters(['A',2])
sage: B = crystals.DirectSum([C,C], keepkey=True)

sage: b = B( tuple([0,C(2)]) )
sage: b.phi(2)
1
```

```python
>>> from sage.all import *

>>> C = crystals.Letters(['A',Integer(2)])

>>> b = B( tuple([Integer(0),C(Integer(2))])

>>> b.phi(Integer(2))
1
```

weight()

Return the weight of self.

EXAMPLES:

```python
sage: C = crystals.Letters(['A',2])
sage: B = crystals.DirectSum([C,C], keepkey=True)

sage: b = B( tuple([0,C(2)]) )
sage: b
(0, 2)

sage: b.weight()
(0, 1, 0)
```

```python
>>> from sage.all import *

>>> C = crystals.Letters(['A',Integer(2)])

>>> b = B( tuple([Integer(0),C(Integer(2))])

>>> b
(0, 2)

>>> b.weight()
(0, 1, 0)
```

weight_lattice_realization()

Return the weight lattice realization used to express weights.

The weight lattice realization is the common parent which all weight lattice realizations of the crystals of self coerce into.
EXAMPLES:

```python
sage: LaZ = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: LaQ = RootSystem(['A',2,1]).weight_space(extended=True).fundamental_weights()
sage: B = crystals.LSPaths(LaQ[1])
sage: B.weight_lattice_realization()
Extended weight space over the Rational Field of the Root system of type ['A', 2, 1]
sage: C = crystals.AlcovePaths(LaZ[1])
sage: C.weight_lattice_realization()
Extended weight lattice of the Root system of type ['A', 2, 1]
sage: D = crystals.DirectSum([B,C])
sage: D.weight_lattice_realization()
Extended weight space over the Rational Field of the Root system of type ['A', 2, 1]
```

```python
>>> from sage.all import *
>>> LaZ = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice(extended=True).fundamental_weights()
>>> LaQ = RootSystem(['A',Integer(2),Integer(1)]).weight_space(extended=True).fundamental_weights()
>>> B = crystals.LSPaths(LaQ[Integer(1)])
>>> B.weight_lattice_realization()
Extended weight space over the Rational Field of the Root system of type ['A', 2, 1]
>>> C = crystals.AlcovePaths(LaZ[Integer(1)])
>>> C.weight_lattice_realization()
Extended weight lattice of the Root system of type ['A', 2, 1]
>>> D = crystals.DirectSum([B,C])
>>> D.weight_lattice_realization()
Extended weight space over the Rational Field of the Root system of type ['A', 2, 1]
```

5.1.47 Elementary Crystals

Let $\lambda$ be a weight. The crystals $T_\lambda$, $R_\lambda$, $B_\lambda$, and $C$ are important objects in the tensor category of crystals. For example, the crystal $T_0$ is the neutral object in this category; i.e., $T_0 \otimes B \cong B \otimes T_0 \cong B$ for any crystal $B$. We list some other properties of these crystals:

- The crystal $T_\lambda \otimes B(\infty)$ is the crystal of the Verma module with highest weight $\lambda$, where $\lambda$ is a dominant integral weight.
- Let $u_\infty$ be the highest weight vector of $B(\infty)$ and $\lambda$ be a dominant integral weight. There is an embedding of crystals $B(\lambda) \rightarrow T_\lambda \otimes B(\infty)$ sending $u_\lambda \mapsto t_\lambda \otimes u_\infty$ which is not strict, but the embedding $B(\lambda) \rightarrow C \otimes T_\lambda \otimes B(\infty)$ by $u_\lambda \mapsto c \otimes t_\lambda \otimes u_\infty$ is a strict embedding.
- For any integral weight $\lambda$, there is a surjective crystal morphism $\Psi_\lambda: R_\lambda \otimes B(\infty) \rightarrow B(\lambda)$. More precisely, if $B = \{r_\lambda \otimes b \in R_\lambda \otimes B(\infty) : \Psi_\lambda(r_\lambda \otimes b) \neq 0\}$, then $B \cong B(\lambda)$ as crystals.
- For all Cartan types and all weights $\lambda$, we have $R_\lambda \cong C \otimes T_\lambda$ as crystals.
- For each $i$, there is a strict crystal morphism $\Psi_i: B(\infty) \rightarrow B_i \otimes B(\infty)$ defined by $u_\infty \mapsto b_i(0) \otimes u_\infty$, where $u_\infty$ is the highest weight vector of $B(\infty)$.

For more information on $B(\infty)$, see `InfinityCrystalOfTableaux`.

614  Chapter 5. Comprehensive Module List
Note: As with *TensorProductOfCrystals*, we are using the opposite of Kashiwara’s convention.

- [NZ1997]

class *sage.combinat.crystals.elementary_crystals.AbstractSingleCrystalElement*

Bases: `Element`

Abstract base class for elements in crystals with a single element.

```
e(i)
Return $\epsilon_i$ of `self`, which is None for all $i$.
INPUT:
- `i` – An element of the index set

EXAMPLES:
```
sage: ct = CartanType(["A",2])
sage: la = RootSystem(ct).weight_lattice().fundamental_weights()
sage: T = crystals.elementary.T(ct,la[1])
sage: t = T.highest_weight_vector()
sage: t.e(1)
sage: t.e(2)
```

```
>>> from sage.all import *

>>> ct = CartanType(["A",Integer(2)])
>>> la = RootSystem(ct).weight_lattice().fundamental_weights()
>>> T = crystals.elementary.T(ct,la[Integer(1)])
>>> t = T.highest_weight_vector()
>>> t.e(Integer(1))
>>> t.e(Integer(2))
```

```
f(i)
Return $f_i$ of `self`, which is None for all $i$.
INPUT:
- `i` – An element of the index set

EXAMPLES:
```
sage: ct = CartanType(["A",2])
sage: la = RootSystem(ct).weight_lattice().fundamental_weights()
sage: T = crystals.elementary.T(ct,la[1])
sage: t = T.highest_weight_vector()
sage: t.f(1)
sage: t.f(2)
```

5.1. Comprehensive Module List
```python
>>> from sage.all import *
>>> ct = CartanType(['A',Integer(2)])
>>> la = RootSystem(ct).weight_lattice().fundamental_weights()
>>> T = crystals.elementary.T(ct,la[Integer(1)])
>>> t = T.highest_weight_vector()
>>> t.f(Integer(1))
```

```python
class sage.combinat.crystals.elementary_crystals.ComponentCrystal(cartan_type, P)
    Bases: UniqueRepresentation, Parent

The component crystal.

Defined in [Ka1993], the component crystal $C = \{c\}$ is the single element crystal whose crystal structure is defined
by

$$\text{wt}(c) = 0, \quad e_i c = f_i c = 0, \quad \varepsilon_i(c) = \varphi_i(c) = 0.$$  

Note $C \cong B(0)$, where $B(0)$ is the highest weight crystal of highest weight 0.

INPUT:

- `cartan_type` – a Cartan type

class Element
    Bases: AbstractSingleCrystalElement

Element of a component crystal.

epsilon(i)
    Return $\varepsilon_i$ of self, which is 0 for all $i$.

INPUT:

- `i` – An element of the index set

EXAMPLES:

```python
sage: C = crystals.elementary.Component("C5")
sage: c = C.highest_weight_vector()
sage: [c.epsilon(i) for i in C.index_set()]
[0, 0, 0, 0, 0]
```

```python
>>> from sage.all import *
>>> C = crystals.elementary.Component("C5")
>>> c = C.highest_weight_vector()
>>> [c.epsilon(i) for i in C.index_set()]
[0, 0, 0, 0, 0]
```

phi(i)
    Return $\varphi_i$ of self, which is 0 for all $i$.

INPUT:

- `i` – An element of the index set

EXAMPLES:

```python
sage: C = crystals.elementary.Component("C5")
sage: c = C.highest_weight_vector()
sage: [c.phi(i) for i in C.index_set()]
[0, 0, 0, 0, 0]
```

```python
>>> from sage.all import *
>>> C = crystals.elementary.Component("C5")
>>> c = C.highest_weight_vector()
>>> [c.phi(i) for i in C.index_set()]
[0, 0, 0, 0, 0]
```
weight()

Return the weight of self, which is always 0.

EXAMPLES:

```python
sage: C = crystals.elementary.Component("F4")
sage: c = C.highest_weight_vector()
sage: c.weight()
(0, 0, 0, 0)
```

cardinality()

Return the cardinality of self, which is always 1.

EXAMPLES:

```python
sage: C = crystals.elementary.Component("E6")
sage: c = C.highest_weight_vector()
sage: C.cardinality()
1
```

weight_lattice_realization()

Return the weight lattice realization of self.

EXAMPLES:

```python
sage: C = crystals.elementary.Component("A2")
sage: C.weight_lattice_realization()
Ambient space of the Root system of type ['A', 2]
sage: P = RootSystem(['A',2]).weight_lattice()
sage: C = crystals.elementary.Component(P)
sage: C.weight_lattice_realization() is P
True
```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> P = RootSystem(['A',Integer(2)]).weight_lattice()
>>> C = crystals.elementary.Component(P)
>>> C.weight_lattice_realization() is P
True
```

```python
class sage.combinat.crystals.elementary_crystals.ElementaryCrystal(cartan_type, i)
    Bases: UniqueRepresentation, Parent

    The elementary crystal \( B_i \).

    For \( i \) an element of the index set of type \( X \), the crystal \( B_i \) of type \( X \) is the set
    
    \[
    B_i = \{ b_i(m) : m \in \mathbb{Z} \},
    \]

    where the crystal structure is given by

    \[
    \begin{align*}
    wt(b_i(m)) &= m\alpha_i \\
    \varphi_j(b_i(m)) &= \begin{cases} 
    m & \text{if } j = i, \\
    -\infty & \text{if } j \neq i,
    \end{cases} \\
    \varepsilon_j(b_i(m)) &= \begin{cases} 
    -m & \text{if } j = i, \\
    -\infty & \text{if } j \neq i,
    \end{cases} \\
    e_j b_i(m) &= \begin{cases} 
    b_i(m+1) & \text{if } j = i, \\
    0 & \text{if } j \neq i,
    \end{cases} \\
    f_j b_i(m) &= \begin{cases} 
    b_i(m-1) & \text{if } j = i, \\
    0 & \text{if } j \neq i.
    \end{cases}
    \end{align*}
    \]

    The Kashiwara embedding theorem asserts there is a unique strict crystal embedding of crystals
    
    \[
    B(\infty) \hookrightarrow B_i \otimes B(\infty),
    \]

    satisfying certain properties (see [Ka1993]). The above embedding may be iterated to obtain a new embedding
    
    \[
    B(\infty) \hookrightarrow B_{i_N} \otimes B_{i_{N-1}} \otimes \cdots \otimes B_{i_2} \otimes B_{i_1} \otimes B(\infty),
    \]

    which is a foundational object in the study of polyhedral realizations of crystals (see, for example, [NZ1997]).

    class Element (parent, m)
        Bases: Element

        Element of a \( B_i \) crystal.

        e(i)
            Return the action of \( e_i \) on self.

            INPUT:
            • \( i \) – An element of the index set

            EXAMPLES:

            sage: B = crystals.elementary.Elementary(['E',7],1)
            sage: B(3).e(1)
            4
            sage: B(172).e_string([1]*171)
            343
            sage: B(0).e(2)
```

618 Chapter 5. Comprehensive Module List
epsilon(i)

Return $\varepsilon_i$ of self.

INPUT:

• i – An element of the index set

EXAMPLES:

```python
sage: B = crystals.elementary.Elementary(['E',4], 3)
sage: [[B(j).epsilon(i) for i in B.index_set()] for j in range(5)]
[[[-inf, -inf, 0, -inf],
  [-inf, -inf, -1, -inf],
  [-inf, -inf, -2, -inf],
  [-inf, -inf, -3, -inf],
  [-inf, -inf, -4, -inf]]
```

f(i)

Return the action of $f_i$ on self.

INPUT:

• i – An element of the index set

EXAMPLES:

```python
sage: B = crystals.elementary.Elementary(['E',7], 1)
sage: B(3).f(1)
2
sage: B(172).f_string([1]*171)
1
```

phi(i)

Return $\phi_i$ of self.
INPUT:
- $i$ – An element of the index set

EXAMPLES:

```python
sage: B = crystals.elementary.Elementary(['E', 8, 1], 4)
sage: [[B(m).phi(j) for j in B.index_set()] for m in range(44, 49)]
[[-inf, -inf, -inf, -inf, 44, -inf, -inf, -inf, -inf],
 [-inf, -inf, -inf, -inf, 45, -inf, -inf, -inf, -inf],
 [-inf, -inf, -inf, -inf, 46, -inf, -inf, -inf, -inf],
 [-inf, -inf, -inf, -inf, 47, -inf, -inf, -inf, -inf],
```

```python
>>> from sage.all import *
>>> B = crystals.elementary.Elementary(['E', Integer(8), Integer(1)], Integer(4))
>>> [[B(m).phi(j) for j in B.index_set()] for m in range(Integer(44), Integer(49))]
[[-inf, -inf, -inf, -inf, 44, -inf, -inf, -inf, -inf],
 [-inf, -inf, -inf, -inf, 45, -inf, -inf, -inf, -inf],
 [-inf, -inf, -inf, -inf, 46, -inf, -inf, -inf, -inf],
 [-inf, -inf, -inf, -inf, 47, -inf, -inf, -inf, -inf],
```

`weight()`

Return the weight of self.

EXAMPLES:

```python
sage: B = crystals.elementary.Elementary(['C', 14], 12)
sage: B(-385).weight()
-385*alpha[12]
```

```python
>>> from sage.all import *
>>> B = crystals.elementary.Elementary(['C', Integer(14)], Integer(12))
>>> B(-Integer(385)).weight()
-385*alpha[12]
```

`weight_lattice_realization()`

Return a realization of the lattice containing the weights of self.

EXAMPLES:

```python
sage: B = crystals.elementary.Elementary(['A', 4, 1], 2)
sage: B.weight_lattice_realization()
Root lattice of the Root system of type ['A', 4, 1]
```

```python
>>> from sage.all import *
>>> B = crystals.elementary.Elementary(['A', Integer(4), Integer(1)], ...
 Integer(2))
>>> B.weight_lattice_realization()
Root lattice of the Root system of type ['A', 4, 1]
```

`sage.combinat.crystals.elementary_crystals.RCrystal(cartan_type, weight, dual)`

Bases: `UniqueRepresentation`, `Parent`  
The crystal $R_\Lambda$. 
For a fixed weight $\lambda$, the crystal $R_\lambda = \{r_\lambda\}$ is a single element crystal with the crystal structure defined by

$$\mathrm{wt}(r_\lambda) = \lambda, \quad e_ir_\lambda = f_ir_\lambda = 0, \quad \varepsilon_i(r_\lambda) = -\langle h_i, \lambda \rangle, \quad \varphi_i(r_\lambda) = 0,$$

where $\{h_i\}$ are the simple coroots.

Tensoring $R_\lambda$ with a crystal $B$ results in shifting the weights of the vertices in $B$ by $\lambda$ and may also cut a subset out of the original graph of $B$. That is, $\mathrm{wt}(r_\lambda \otimes b) = \mathrm{wt}(b) + \lambda$, where $b \in B$, provided $r_\lambda \otimes b \neq 0$. For example, the crystal graph of $B(\lambda)$ is the same as the crystal graph of $R_\lambda \otimes B(\infty)$ generated from the component $r_\lambda \otimes u_\infty$.

There is also a dual version of this crystal given by $R_\lambda^\vee = \{r_\lambda^\vee\}$ with the crystal structure defined by

$$\mathrm{wt}(r_\lambda^\vee) = \lambda, \quad e_ir_\lambda^\vee = f_ir_\lambda^\vee = 0, \quad \varepsilon_i(r_\lambda^\vee) = 0, \quad \varphi_i(r_\lambda^\vee) = \langle h_i, \lambda \rangle.$$

INPUT:

- `cartan_type` – a Cartan type
- `weight` – an element of the weight lattice of type `cartan_type`
- `dual` – (default: `False`) boolean

EXAMPLES:

We check by tensoring $R_\lambda$ with $B(\infty)$ results in a component of $B(\lambda)$:

```python
sage: B = crystals.infinity.Tableaux("A2")
sage: R = crystals.elementary.R("A2", B.Lambda()[1]+B.Lambda()[2])
sage: T = crystals.TensorProduct(R, B)
sage: mg = T(R.highest_weight_vector(), B.highest_weight_vector())
sage: S = T.subcrystal(generators=[mg])
sage: sorted([x.weight() for x in S], key=str)
[(0, 1, 2), (0, 2, 1), (1, 0, 2), (1, 1, 1),
 (1, 1, 1), (1, 2, 0), (2, 0, 1), (2, 1, 0)]
sage: C = crystals.Tableaux("A2", shape=[2,1])
sage: sorted([x.weight() for x in C], key=str)
[(0, 1, 2), (0, 2, 1), (1, 0, 2), (1, 1, 1),
 (1, 1, 1), (1, 2, 0), (2, 0, 1), (2, 1, 0)]
sage: GT = T.digraph(subset=S)
sage: GC = C.digraph()
sage: GT.is_isomorphic(GC, edge_labels=True)
True
```

```bash
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux("A2")
>>> R = crystals.elementary.R("A2", B.Lambda()[1]+B.Lambda()[2])
>>> T = crystals.TensorProduct(R, B)
>>> mg = T(R.highest_weight_vector(), B.highest_weight_vector())
>>> S = T.subcrystal(generators=[mg])
>>> sorted([x.weight() for x in S], key=str)
[(0, 1, 2), (0, 2, 1), (1, 0, 2), (1, 1, 1),
 (1, 1, 1), (1, 2, 0), (2, 0, 1), (2, 1, 0)]
>>> C = crystals.Tableaux("A2", shape=[2,1])
>>> sorted([x.weight() for x in C], key=str)
[(0, 1, 2), (0, 2, 1), (1, 0, 2), (1, 1, 1),
 (1, 1, 1), (1, 2, 0), (2, 0, 1), (2, 1, 0)]
>>> GT = T.digraph(subset=S)
>>> GC = C.digraph()
>>> GT.is_isomorphic(GC, edge_labels=True)
True
```
class Element
    Bases: AbstractSingleCrystalElement

Element of a $R_\lambda$ crystal.

epsilon(i)
    Return $\varepsilon_i$ of self.
    We have $\varepsilon_i(r_\lambda) = -\langle h_i, \lambda \rangle$ for all $i$, where $h_i$ is a simple coroot.

INPUT:
    • $i$ – An element of the index set

EXAMPLES:

sage: la = RootSystem(['A',2]).weight_lattice().fundamental_weights()
sage: R = crystals.elementary.R("A2", la[1])
sage: r = R.highest_weight_vector()
sage: [r.epsilon(i) for i in R.index_set()]
[-1, 0]

sage: R = crystals.elementary.R("A2", la[1], dual=True)
sage: r = R.highest_weight_vector()
sage: [r.epsilon(i) for i in R.index_set()]
[0, 0]

>>> from sage.all import *
>>> la = RootSystem(['A','2']).weight_lattice().fundamental_weights()
>>> R = crystals.elementary.R("A2", la[1])
>>> r = R.highest_weight_vector()
>>> [r.epsilon(i) for i in R.index_set()]
[-1, 0]

>>> R = crystals.elementary.R("A2", la[1], dual=True)
>>> r = R.highest_weight_vector()
>>> [r.epsilon(i) for i in R.index_set()]
[0, 0]

phi(i)
    Return $\varphi_i$ of self, which is 0 for all $i$.

INPUT:
    • $i$ – An element of the index set

EXAMPLES:

sage: la = RootSystem("C5").weight_lattice().fundamental_weights()
 sage: r = R.highest_weight_vector()
 sage: [r.phi(i) for i in R.index_set()]
[0, 0, 0, 0, 0]

 sage: r = R.highest_weight_vector()
 sage: [r.phi(i) for i in R.index_set()]
[0, 0, 0, 1, 1]

>>> from sage.all import *
>>> la = RootSystem("C5").weight_lattice().fundamental_weights()

(continues on next page)
>>> R = crystals.elementary.R("C5", la[Integer(4)]+la[Integer(5)])
>>> r = R.highest_weight_vector()
>>> [r.phi(i) for i in R.index_set()]
[0, 0, 0, 0, 0]

>>> R = crystals.elementary.R("C5", la[Integer(4)]+la[Integer(5)],
˓→dual=True)
>>> r = R.highest_weight_vector()
>>> [r.phi(i) for i in R.index_set()]
[0, 0, 0, 1, 1]

weight()

Return the weight of self, which is always λ.

EXAMPLES:

```python
sage: ct = CartanType(['C',5])
sage: la = RootSystem(ct).weight_lattice().fundamental_weights()
sage: t = T.highest_weight_vector()
sage: t.weight()
```

```python
>>> from sage.all import *

>>> ct = CartanType(['C',Integer(5)])
>>> la = RootSystem(ct).weight_lattice().fundamental_weights()
>>> T = crystals.elementary.T(ct,la[Integer(4)]+la[Integer(5)]-
˓→la[Integer(1)]-la[Integer(2)])
>>> t = T.highest_weight_vector()
>>> t.weight()
```

cardinality()

Return the cardinality of self, which is always 1.

EXAMPLES:

```python
sage: La = RootSystem(['C',12]).weight_lattice().fundamental_weights()
sage: R = crystals.elementary.R(['C',12],La[9])
sage: R.cardinality()
1

>>> from sage.all import *

>>> La = RootSystem(['C',Integer(12)]).weight_lattice().fundamental_weights()
>>> R = crystals.elementary.R(['C',Integer(12)],La[Integer(9)])
>>> R.cardinality()
1
```

weight_lattice_realization()

Return a realization of the lattice containing the weights of self.

EXAMPLES:

```python
sage: La = RootSystem(['C',12]).weight_lattice().fundamental_weights()
sage: R = crystals.elementary.R(['C',12], La[9])
sage: R.weight_lattice_realization()
```

(continues on next page)
Weight lattice of the Root system of type ['C', 12]
sage: ct = CartanMatrix([[2, -4], [-5, 2]])
sage: La = RootSystem(ct).weight_lattice().fundamental_weights()
sage: R = crystals.elementary.R(ct, La[1])
sage: R.weight_lattice_realization()
Weight lattice of the Root system of type
[ 2 -4]
[-5  2]

>>> from sage.all import *
>>> La = RootSystem(['C',Integer(12)]).weight_lattice().fundamental_weights()
>>> R = crystals.elementary.R(['C',Integer(12)], La[Integer(9)])
>>> R.weight_lattice_realization()
Weight lattice of the Root system of type ['C', 12]

>>> ct = CartanMatrix([[Integer(2), -Integer(4)], [-Integer(5), Integer(2)]])
>>> La = RootSystem(ct).weight_lattice().fundamental_weights()
>>> R = crystals.elementary.R(ct, La[Integer(1)])
>>> R.weight_lattice_realization()
Weight lattice of the Root system of type
[ 2 -4]
[-5  2]

class sage.combinat.crystals.elementary_crystals.TCrystal(cartan_type, weight)
Bases: UniqueRepresentation, Parent

The crystal $T_\lambda$.

Let $\lambda$ be a weight. As defined in [Ka1993] the crystal $T_\lambda = \{ t_\lambda \}$ is a single element crystal with the crystal structure defined by

$$\text{wt}(t_\lambda) = \lambda, \quad e_i t_\lambda = f_i t_\lambda = 0, \quad \varepsilon_i(t_\lambda) = \varphi_i(t_\lambda) = -\infty.$$  

The crystal $T_\lambda$ shifts the weights of the vertices in a crystal $B$ by $\lambda$ when tensored with $B$, but leaves the graph structure of $B$ unchanged. That is to say, for all $b \in B$, we have $\text{wt}(b \otimes t_\lambda) = \text{wt}(b) + \lambda$.

INPUT:

- cartan_type – A Cartan type
- weight – An element of the weight lattice of type cartan_type

EXAMPLES:

sage: ct = CartanType(['A',2])
sage: C = crystals.Tableaux(ct, shape=[1])
sage: for x in C: x.weight()
(1, 0, 0)
(0, 1, 0)
(0, 0, 1)
sage: La = RootSystem(ct).ambient_space().fundamental_weights()
sage: TLa = crystals.elementary.T(ct, 3*(La[1] + La[2]))
sage: TP = crystals.TensorProduct(TLa, C)
sage: for x in TP: x.weight()
(7, 3, 0)
(6, 4, 0)
(6, 3, 1)
sage: G = C.digraph()
sage: H = TP.digraph()
sage: G.is_isomorphic(H, edge_labels=True)
True

>>> from sage.all import *
>>> ct = CartanType(['A', Integer(2)])
>>> C = crystals.Tableaux(ct, shape=[Integer(1)])
>>> for x in C: x.weight()
(1, 0, 0)
(0, 1, 0)
(0, 0, 1)

>>> La = RootSystem(ct).ambient_space().fundamental_weights()
>>> TL = crystals.elementary.T(ct, Integer(3)*(La[Integer(1)] + La[Integer(2)]))
>>> TP = crystals.TensorProduct(TL, C)
>>> for x in TP: x.weight()
(7, 3, 0)
(6, 4, 0)
(6, 3, 1)

class Element
Bases: AbstractSingleCrystalElement

Element of a $T_\lambda$ crystal.

epsilon(i)

Return $\varepsilon_i$ of self, which is $-\infty$ for all $i$.

INPUT:
• $i$ – An element of the index set

EXAMPLES:

sage: ct = CartanType(['C', 5])
sage: la = RootSystem(ct).weight_lattice().fundamental_weights()
sage: t = T.highest_weight_vector()
[sage: [t.epsilon(i) for i in T.index_set()]
[-inf, -inf, -inf, -inf, -inf]

phi(i)

Return $\varphi_i$ of self, which is $-\infty$ for all $i$.

INPUT:
• $i$ – An element of the index set
EXAMPLES:

```python
c sage: ct = CartanType(['C',5])
c sage: la = RootSystem(ct).weight_lattice().fundamental_weights()
c sage: t = T.highest_weight_vector()
c sage: [t.phi(i) for i in T.index_set()]
[-inf, -inf, -inf, -inf, -inf]
```

```python
c sage: ct = CartanType(['C',Integer(5)])
c sage: la = RootSystem(ct).weight_lattice().fundamental_weights()
c sage: T = crystals.elementary.T(ct,la[Integer(4)]+la[Integer(5)]-la[Integer(1)]-la[Integer(2)])
c sage: t = T.highest_weight_vector()
c sage: [t.phi(i) for i in T.index_set()]
[-inf, -inf, -inf, -inf, -inf]
```

weight()  
Return the weight of self, which is always $\lambda$.

EXAMPLES:

```python
c sage: ct = CartanType(['C',5])
c sage: la = RootSystem(ct).weight_lattice().fundamental_weights()
c sage: t = T.highest_weight_vector()
c sage: t.weight()
```

```python
c sage: ct = CartanType(['C',Integer(5)])
c sage: la = RootSystem(ct).weight_lattice().fundamental_weights()
c sage: T = crystals.elementary.T(ct,la[Integer(4)]+la[Integer(5)]-la[Integer(1)]-la[Integer(2)])
c sage: t = T.highest_weight_vector()
c sage: t.weight()
```

cardinality()  
Return the cardinality of self, which is always 1.

EXAMPLES:

```python
c sage: La = RootSystem(['C',12]).weight_lattice().fundamental_weights()
c sage: T = crystals.elementary.T(['C',12], La[9])
c sage: T.cardinality()
1
```

```python
c sage: La = RootSystem(['C',Integer(12)]).weight_lattice().fundamental_weights()
c sage: T = crystals.elementary.T(['C',Integer(12)], La[Integer(9)])
c sage: T.cardinality()
1
```

weight_lattice_realization()  
Return a realization of the lattice containing the weights of self.
EXAMPLES:

```python
sage: La = RootSystem(['C',12]).weight_lattice().fundamental_weights()
sage: T = crystals.elementary.T(['C',12], La[9])
sage: T.weight_lattice_realization()
Weight lattice of the Root system of type ['C', 12]
sage: ct = CartanMatrix([[2, -4], [-5, 2]])
sage: La = RootSystem(ct).weight_lattice().fundamental_weights()
sage: T = crystals.elementary.T(ct, La[1])
sage: T.weight_lattice_realization()
Weight lattice of the Root system of type
[ 2 -4]
[-5  2]
```

```python
>>> from sage.all import *

>>> La = RootSystem(['C',Integer(12)]).weight_lattice().fundamental_weights()
>>> T = crystals.elementary.T(['C',Integer(12)], La[Integer(9)])
>>> T.weight_lattice_realization()
Weight lattice of the Root system of type ['C', 12]

>>> ct = CartanMatrix([[Integer(2), -Integer(4)], [-Integer(5), Integer(2)]])
>>> La = RootSystem(ct).weight_lattice().fundamental_weights()
>>> T = crystals.elementary.T(ct, La[Integer(1)])
>>> T.weight_lattice_realization()
Weight lattice of the Root system of type
[ 2 -4]
[-5  2]
```

### 5.1.48 Fast Rank Two Crystals

**class** `sage.combinat.crystals.fast_crystals.FastCrystal(ct, shape, format)`

**Bases:** `UniqueRepresentation`, `Parent`

An alternative implementation of rank 2 crystals. The root operators are implemented in memory by table lookup. This means that in comparison with the `CrystalsOfTableaux`, these crystals are slow to instantiate but faster for computation. Implemented for types $A_2$, $B_2$, and $C_2$.

**INPUT:**

- `cartan_type` – the Cartan type and must be either type $A_2$, $B_2$, or $C_2$
- `shape` – A shape is of the form $[11, 12]$ where 11 and 12 are either integers or (in type $B_2$) half integers such that $11 - 12$ is integral. It is assumed that $11 >= 12 >= 0$. If 11 and 12 are integers, this will produce a crystal isomorphic to the one obtained by `sage.combinat.crystals.Tableaux(type, shape=[11,12])`. Furthermore `sage.combinat.crystals.FastRankTwo(["B", 2], 11+1/2, 12+1/2)` produces a crystal isomorphic to the following crystal T:

```python
sage: C = crystals.Tableaux(['B',2], shape=[11,12])
# not tested
sage: D = crystals.Spins(['B',2])
# not tested
sage: T = crystals.TensorProduct(C, D, C.list()[0], D.list()[0])
# not tested
```

```python
>>> from sage.all import *

>>> C = crystals.Tableaux(['B',Integer(2)], shape=[Integer(11),Integer(12)])
... # not tested

>>> D = crystals.Spins(['B',Integer(2)])
... # not tested
```

(continues on next page)
• format – (default: 'string') the default representation of elements is in term of the Berenstein-Zelevinsky-Littelmann (BZL) strings \([a_1, a_2, \ldots]\) described under metapost in `crystals`. Alternative representations may be obtained by the options 'dual_string' or 'simple'. In the 'simple' format, the element is represented by and integer, and in the 'dual_string' format, it is represented by the BZL string, but the underlying decomposition of the long Weyl group element into simple reflections is changed.

**class Element (parent, value, format)**

Bases: Element

EXAMPLES:

```python
sage: C = crystals.FastRankTwo(['A',2],shape=[2,1])
sage: c = C(0); c
[0, 0, 0]
sage: C[0].parent()
The fast crystal for A2 with shape [2,1]
sage: TestSuite(c).run()

>>> from sage.all import *

>>> C = crystals.FastRankTwo(['A',Integer(2)],shape=[Integer(2),Integer(1)])

>>> c = C(Integer(0)); c
[0, 0, 0]

>>> C[Integer(0)].parent()
The fast crystal for A2 with shape [2,1]

>>> TestSuite(c).run()
```

\(e(i)\)

Return the action of \(e_i\) on self.

EXAMPLES:

```python
sage: C = crystals.FastRankTwo(['A',2],shape=[2,1])
sage: C(1).e(1)
[0, 0, 0]
sage: C(0).e(1) is None
True

>>> from sage.all import *

>>> C = crystals.FastRankTwo(['A',Integer(2)],shape=[Integer(2),Integer(1)])

>>> C(Integer(1)).e(Integer(1))
[0, 0, 0]

>>> C(Integer(0)).e(Integer(1)) is None
True
```

\(f(i)\)

Return the action of \(f_i\) on self.

EXAMPLES:
sage: C = crystals.FastRankTwo(['A',2],shape=[2,1])
sage: C(6).f(1)
[1, 2, 1]
sage: C(7).f(1) is None
True

weight()
Return the weight of self.

EXAMPLES:

sage: [v.weight() for v in crystals.FastRankTwo(['A',2], shape=[2,1])]
[(2, 1, 0), (1, 2, 0), (1, 1, 1), (1, 0, 2), (0, 1, 2), (2, 0, 1), (1, 1, -1), (0, 2, 1)]
sage: [v.weight() for v in crystals.FastRankTwo(['B',2], shape=[1,0])]
[(1, 0), (0, 1), (0, 0), (0, -1), (-1, 0)]
sage: [v.weight() for v in crystals.FastRankTwo(['B',2], shape=[1/2,1/2])]
[(1/2, 1/2), (1/2, -1/2), (-1/2, 1/2), (-1/2, -1/2)]
sage: [v.weight() for v in crystals.FastRankTwo(['C',2], shape=[1,0])]
[(1, 0), (0, 1), (0, -1), (-1, 0)]
sage: [v.weight() for v in crystals.FastRankTwo(['C',2], shape=[1,1])]
[(1, 1), (1, -1), (0, 0), (-1, 1), (-1, -1)]

>>> from sage.all import *

>>> [v.weight() for v in crystals.FastRankTwo(['A',Integer(2)],
                                          shape=[Integer(2),
                                          -Integer(1)])]
[(2, 1, 0), (1, 2, 0), (1, 1, 1), (1, 0, 2), (0, 1, 2), (2, 0, 1), (1, 1, -1), (0, 2, 1)]

>>> [v.weight() for v in crystals.FastRankTwo(['B',Integer(2)],
                                          shape=[Integer(1),Integer(0)])]
[(1, 0), (0, 1), (0, -1), (-1, 0)]

>>> [v.weight() for v in crystals.FastRankTwo(['B',Integer(2)],
                                          shape=[Integer(1)/Integer(2),Integer(1)/Integer(2)])]
[(1/2, 1/2), (1/2, -1/2), (-1/2, 1/2), (-1/2, -1/2)]

>>> [v.weight() for v in crystals.FastRankTwo(['C',Integer(2)],
                                          shape=[Integer(1),Integer(0)])]
[(1, 0), (0, 1), (0, -1), (-1, 0)]

>>> [v.weight() for v in crystals.FastRankTwo(['C',Integer(2)],
                                          shape=[Integer(1),Integer(1)])]
[(1, 1), (1, -1), (0, 0), (-1, 1), (-1, -1)]

cmp_elements(x, y)
Return True if and only if there is a path from x to y in the crystal graph.

Because the crystal graph is classical, it is a directed acyclic graph which can be interpreted as a poset. This function implements the comparison function of this poset.

EXAMPLES:
```python
sage: C = crystals.FastRankTwo(['A', 2], shape=[2, 1])
sage: x = C(0)
sage: y = C(1)
sage: C.cmp_elements(x, y)
-1
sage: C.cmp_elements(y, x)
1
sage: C.cmp_elements(x, x)
0
```

```python
>>> from sage.all import *
>>> C = crystals.FastRankTwo(['A', Integer(2)], shape=[Integer(2), Integer(1)])
>>> x = C(Integer(0))
>>> y = C(Integer(1))
>>> C.cmp_elements(x, y)
-1
>>> C.cmp_elements(y, x)
1
>>> C.cmp_elements(x, x)
0
```

digraph()

Return the digraph associated to self.

EXAMPLES:

```python
sage: C = crystals.FastRankTwo(['A', 2], shape=[2, 1])
sage: C.digraph()
Digraph on 8 vertices
```

```python
>>> from sage.all import *
>>> C = crystals.FastRankTwo(['A', Integer(2)], shape=[Integer(2), Integer(1)])
>>> C.digraph()
Digraph on 8 vertices
```

5.1.49 Fully commutative stable Grothendieck crystal

AUTHORS:

- Jianping Pan (2020-08-31): initial version
- Wencin Poh (2020-08-31): initial version
- Anne Schilling (2020-08-31): initial version

class sage.combinat.crystals.fully_commutative_stable_grothendieck.DiminishingHeckeFactorization

Bases: Element

Class of decreasing factorizations in the 0-Hecke monoid.

INPUT:

- `t` – decreasing factorization inputted as list of lists
- `max_value` – maximal value of entries
EXAMPLES:

```python
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorization
sage: t = [[3, 2], [], [2, 1]]
sage: h = DecreasingHeckeFactorization(t, 3); h
(3, 2)()(2, 1)
sage: h.excess
1
sage: h.factors
3
sage: h.max_value
3
sage: h.value
((3, 2), (), (2, 1))
```

```python
sage: u = [[3, 2, 1], [3], [2, 1]]
sage: h = DecreasingHeckeFactorization(u); h
(3, 2, 1)(3)(2, 1)
sage: h.weight()
(2, 1, 3)
sage: h.parent()
Decreasing Hecke factorizations with 3 factors associated to [2, 1, 3, 2, 1] with excess 1
```

```python
>>> from sage.all import *
>>> from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorization
>>> t = [[Integer(3), Integer(2)], [], [Integer(2), Integer(1)]]
>>> h = DecreasingHeckeFactorization(t, Integer(3)); h
(3, 2)()(2, 1)
>>> h.excess
1
>>> h.factors
3
>>> h.max_value
3
>>> h.value
((3, 2), (), (2, 1))
```

```python
>>> u = [[Integer(3), Integer(2), Integer(1)], [Integer(3)], [Integer(2), Integer(1)]]
>>> h = DecreasingHeckeFactorization(u); h
(3, 2, 1)(3)(2, 1)
>>> h.weight()
(2, 1, 3)
>>> h.parent()
Decreasing Hecke factorizations with 3 factors associated to [2, 1, 3, 2, 1] with excess 1
```

to_increasing_hecke_biword()

Return the associated increasing Hecke biword of self.

EXAMPLES:

```python
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorization
sage: t = [[2], [], [2, 1], [4, 3, 1]]
(continues on next page)
```
sage: h = DecreasingHeckeFactorization(t, 4)
sage: h.to_increasing_hecke_biword()
[[1, 1, 1, 2, 2, 4], [1, 3, 4, 1, 2, 2]]

```
>> from sage.all import *
>> from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorization
>> t = [[Integer(2)], [], [Integer(2), Integer(1)], [Integer(4), Integer(3), Integer(1)]]
>> h = DecreasingHeckeFactorization(t, Integer(4))
>> h.to_increasing_hecke_biword()
[[1, 1, 1, 2, 2, 4], [1, 3, 4, 1, 2, 2]]
```

to_word()  
Return the word associated to self in the 0-Hecke monoid.

EXAMPLES:
```
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorization
sage: t = [[2], [2, 1], [], [4, 3, 1]]
sage: h = DecreasingHeckeFactorization(t)
sage: h.to_word()
[2, 2, 1, 4, 3, 1]
```

weight()  
Return the weight of self.

EXAMPLES:
```
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorization
sage: t = [[2], [2, 1], [], [4, 3, 1]]
sage: h = DecreasingHeckeFactorization(t, 6)
sage: h.weight()
(3, 0, 2, 1)
```
class sage.combinat.crystals.fully_commutative_stable_grothendieck.DecreasingHeckeFactorizations

Bases: UniqueRepresentation, Parent

Set of decreasing factorizations in the 0-Hecke monoid.

INPUT:

- \( w \) – an element in the symmetric group
- \( \text{factors} \) – the number of factors in the factorization
- \( \text{excess} \) – the total number of letters in the factorization minus the length of a reduced word for \( w \)

EXAMPLES:

```python
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorizations
sage: S = SymmetricGroup(3+1)
sage: w = S.from_reduced_word([1, 3, 2, 1])
sage: F = DecreasingHeckeFactorizations(w, 3, 3); F
Decreasing Hecke factorizations with 3 factors associated to [1, 3, 2, 1] with excess 3
sage: F.list()
[(3, 1)(3, 1)(3, 2, 1), (3, 1)(3, 2, 1)(2, 1), (3, 2, 1)(2, 1)(2, 1)]
```

```
>>> from sage.all import *
>>> from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorizations
>>> S = SymmetricGroup(Integer(3)+Integer(1))
>>> w = S.from_reduced_word([Integer(1), Integer(3), Integer(2), Integer(1)])
>>> F = DecreasingHeckeFactorizations(w, Integer(3), Integer(3)); F
Decreasing Hecke factorizations with 3 factors associated to [1, 3, 2, 1] with excess 3
>>> F.list()
[(3, 1)(3, 1)(3, 2, 1), (3, 1)(3, 2, 1)(2, 1), (3, 2, 1)(2, 1)(2, 1)]
```

Element

alias of DecreasingHeckeFactorization

list()

Return list of all elements of self.

EXAMPLES:

```python
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorizations
sage: S = SymmetricGroup(3+1)
sage: w = S.from_reduced_word([1, 3, 2, 1])
sage: F = DecreasingHeckeFactorizations(w, 3, 3)
sage: F.list()
[(3, 1)(3, 1)(3, 2, 1), (3, 1)(3, 2, 1)(2, 1), (3, 2, 1)(2, 1)(2, 1)]
```

```python
>>> from sage.all import *
>>> from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorizations
>>> S = SymmetricGroup(Integer(3)+Integer(1))
>>> w = S.from_reduced_word([Integer(1), Integer(3), Integer(2), Integer(1)])
>>> F = DecreasingHeckeFactorizations(w, Integer(3), Integer(3)); F
>>> F.list()
[(3, 1)(3, 1)(3, 2, 1), (3, 1)(3, 2, 1)(2, 1), (3, 2, 1)(2, 1)(2, 1)]
```

(continues on next page)
Bases: UniqueRepresentation, Parent

The crystal on fully commutative decreasing factorizations in the 0-Hecke monoid, as introduced by [MPPS2020].

INPUT:

- **w** – an element in the symmetric group or a (skew) shape
- **factors** – the number of factors in the factorization
- **excess** – the total number of letters in the factorization minus the length of a reduced word for \(w\)
- **shape** – (default: False) indicator for input \(w\), True if \(w\) is entered as a (skew) shape and False otherwise.

EXAMPLES:

```
sage: S = SymmetricGroup(3+1)
sage: w = S.from_reduced_word([1, 3, 2])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 3, 2); B
Fully commutative stable Grothendieck crystal of type A_2 associated to [1, 3, 2] → with excess 2
 sage: B.list()
[(1)(3, 1)(3, 2),
 (3, 1)(1)(3, 2),
 (3, 1)(3, 1)(2),
 (3)(3, 1)(3, 2),
 (3, 1)(3)(3, 2),
 (3, 1)(3, 2)(2)]
```

We can also access the crystal by specifying a skew shape:
sage: crystals.FullyCommutativeStableGrothendieck([[2, 2], [1]], 4, 1, shape=True)
Fully commutative stable Grothendieck crystal of type A_3 associated to [2, 1, 3]→ with excess 1

>>> from sage.all import *
>>> crystals.FullyCommutativeStableGrothendieck([[Integer(2), Integer(2)],
→ [Integer(1)]], Integer(4), Integer(1), shape=True)
Fully commutative stable Grothendieck crystal of type A_3 associated to [2, 1, 3]→ with excess 1

We can compute the highest weight elements:

```sage
sage: hw = [w for w in B if w.is_highest_weight()]
sage: hw
[(1)(3, 1)(3, 2), (3)(3, 1)(3, 2)]
sage: hw[0].weight()
(2, 2, 1)
```

```sage
>>> from sage.all import *
>>> hw = [w for w in B if w.is_highest_weight()]
>>> hw
[(1)(3, 1)(3, 2), (3)(3, 1)(3, 2)]
>>> hw[Integer(0)].weight()
(2, 2, 1)
```

The crystal operators themselves move elements between adjacent factors:

```sage
sage: b = hw[0]; b
(1)(3, 1)(3, 2)
sage: b.f(2)
(3, 1)(1)(3, 2)
```

```sage
>>> from sage.all import *
>>> b = hw[Integer(0)]; b
(1)(3, 1)(3, 2)
>>> b.f(Integer(2))
(3, 1)(1)(3, 2)
```

class Element (parent, t)
Bases: DecreasingHeckeFactorization

Create an instance self of element t.

This method takes into account the constraints on the word, the number of factors, and excess statistic associated to the parent class.

EXAMPLES:

```sage
sage: S = SymmetricGroup(3+1)
sage: w = S.from_reduced_word([1, 3, 2])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 3, 2)
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck.
→ import DecreasingHeckeFactorization
sage: h = DecreasingHeckeFactorization([[3, 1], [3], [3, 2]], 4)
sage: u = B(h); u.value
((3, 1), (3,), (3, 2))
```
(continues on next page)
sage: v = B([[3, 1], [3], [3, 2]]); v.value
((3, 1), (3,), (3, 2))

```python
>>> from sage.all import *

>>> S = SymmetricGroup(Integer(3)+Integer(1))
>>> w = S.from_reduced_word([Integer(1), Integer(3), Integer(2)])
>>> B = crystals.FullyCommutativeStableGrothendieck(w, Integer(3), Integer(2))
>>> from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorization

>>> h = DecreasingHeckeFactorization([[Integer(3), Integer(1)], [Integer(3)], [Integer(3), Integer(2)]], Integer(4))

```

```
>>> u = B(h); u.value
((3, 1), (3,), (3, 2))

>>> v = B([[Integer(3), Integer(1)], [Integer(3)], [Integer(3), Integer(2)]]); v.value
((3, 1), (3,), (3, 2))
```

bracketing(i)

Remove all bracketed letters between i-th and (i + 1)-th entry.

EXAMPLES:

```python
sage: S = SymmetricGroup(4+1)
sage: w = S.from_reduced_word([3, 2, 1, 4, 3])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 3, 2)
sage: h = B([[3], [4, 2, 1], [4, 3, 1]])
sage: h.bracketing(1)
[[], [1]]
sage: h.bracketing(2)
[[], [2, 1]]

```

```python
>>> from sage.all import *

>>> S = SymmetricGroup(Integer(4)+Integer(1))

>>> w = S.from_reduced_word([Integer(3), Integer(2), Integer(1), Integer(4), Integer(3)])

>>> B = crystals.FullyCommutativeStableGrothendieck(w, Integer(3), Integer(2))

>>> h = B([[Integer(3)], [Integer(4), Integer(2), Integer(1)], [Integer(4), Integer(3), Integer(1)]])

>>> h.bracketing(Integer(1))
[[], [1]]

>>> h.bracketing(Integer(2))
[[], [2, 1]]
```

e(i)

Return the action of $e_i$ on self using the rules described in [MPPS2020].

EXAMPLES:

```
sage: S = SymmetricGroup(4+1)
sage: w = S.from_reduced_word([2, 1, 4, 3, 2])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 4, 3)
sage: h = B([[4, 2], [4, 2, 1], [3, 2], [2]]); h
(4, 2)(4, 2, 1)(3, 2)

>>> h.e(1)
(4, 2)(4, 2, 1)(3)(3, 2)
```

(continues on next page)
sage: h.e(2)
(4, 2)(2, 1)(4, 3, 2)(2)
sage: h.e(3)

>>> from sage.all import *
>>> S = SymmetricGroup(Integer(4)+Integer(1))
>>> w = S.from_reduced_word([Integer(2), Integer(1), Integer(4),
Integer(3), Integer(2)])
>>> B = crystals.FullyCommutativeStableGrothendieck(w, Integer(4),
Integer(3))
>>> h = B([[Integer(4), Integer(2)], [Integer(4), Integer(2), Integer(1)],
[Integer(3), Integer(2)], [Integer(2)]]); h
(4, 2)(4, 2, 1)(3, 2)(2)
>>> h.e(Integer(1))
(4, 2)(4, 2, 1)(3)(3, 2)
>>> h.e(Integer(2))
(4, 2)(2, 1)(4, 3, 2)(2)
>>> h.e(Integer(3))

f(i)

Return the action of $f_i$ on self using the rules described in [MPPS2020].

EXAMPLES:

sage: S = SymmetricGroup(4+1)
sage: w = S.from_reduced_word([3, 2, 1, 4, 3])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 4, 3)
sage: h = B([[3, 2], [2, 1], [4, 3], [3, 1]]); h
(3, 2)(2, 1)(4, 3)(3, 1)
sage: h.f(1)
(3, 2)(2, 1)(4, 3, 1)(3)
sage: h.f(2)
sage: h.f(3)
(3, 2, 1)(1)(4, 3)(3, 1)

module_generators()

Return generators for self as a crystal.

EXAMPLES:
sage: S = SymmetricGroup(3+1)
sage: w = S.from_reduced_word([1, 3, 2])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 3, 2)
sage: B.module_generators
((1)(3, 1)(3, 2), (3)(3, 1)(3, 2))
sage: C = crystals.FullyCommutativeStableGrothendieck(w, 4, 2)
sage: C.module_generators
(()(1)(3, 1)(3, 2),
(3)(3, 1)(3, 2),
(1)(1)(1)(3, 2),
(1)(1)(3)(3, 2),
(1)(3)(3)(3, 2))

>>> from sage.all import *
>>> S = SymmetricGroup(Integer(3)+Integer(1))
>>> w = S.from_reduced_word([Integer(1), Integer(3), Integer(2)])
>>> B = crystals.FullyCommutativeStableGrothendieck(w, Integer(3), Integer(2))
>>> B.module_generators
((1)(3, 1)(3, 2),
(3)(3, 1)(3, 2),
(1)(1)(1)(3, 2),
(1)(1)(3)(3, 2),
(1)(3)(3)(3, 2))

5.1.50 Crystals of Generalized Young Walls

AUTHORS:

• Lucas David-Roesler: Initial version
• Ben Salisbury: Initial version
• Travis Scrimshaw: Initial version

Generalized Young walls are certain generalizations of Young tableaux introduced in [KS2010] and designed to be a realization of the crystals $B(\infty)$ and $B(\lambda)$ in type $A_n^{(1)}$.

REFERENCES:

• [KLRS2016]
• [KS2010]

class sage.combinat.crystals.generalized_young_walls.CrystalOfGeneralizedYoungWalls(n, La)

Bases: InfinityCrystalOfGeneralizedYoungWalls

The crystal $\mathcal{Y}(\lambda)$ of generalized Young walls of the given type with highest weight $\lambda$.

These were characterized in Theorem 4.1 of [KS2010]. See GeneralizedYoungWall.

in_highest_weight_crystal().

INPUT:

• n – type $A_n^{(1)}$
• weight – dominant integral weight
EXAMPLES:

```
sage: La = RootSystem(['A', 3, 1]).weight_lattice(extended=True).fundamental_weights()[1]
sage: YLa = crystals.GeneralizedYoungWalls(3, La)
sage: y = YLa([[0], [1, 0, 3, 2, 1], [2, 1, 0], [3]])
sage: y.pp()
 3|
 0|1|2|
1|2|3|0|1|
 0|
sage: y.weight()
sage: y.in_highest_weight_crystal(La)
True
sage: y.f(1)
[[0], [1, 0, 3, 2, 1], [2, 1, 0], [3], [], [1]]
sage: yy = crystals.infinity.GeneralizedYoungWalls(3)(
    [[0], [1, 0, 3, 2, 1], [2, 1, 0], [3], [], [1], [], [], [], [1]])
sage: yy.f(1)
[[0], [1, 0, 3, 2, 1], [2, 1, 0], [3], [], [1], [], [], [], [1]]
sage: yyy.in_highest_weight_crystal(La)
False
```

```
>>> from sage.all import *
>>> La = RootSystem(['A', Integer(3), Integer(1)]).weight_lattice(extended=True).
  fundamental_weights()[Integer(1)]
>>> YLa = crystals.GeneralizedYoungWalls(Integer(3), La)
>>> y = YLa([[Integer(0)], [Integer(1), Integer(0), Integer(3), Integer(2),
  Integer(1)], [Integer(2), Integer(1), Integer(0), Integer(0),
  Integer(3)]]))
>>> y.pp()
 3|
 0|1|2|
1|2|3|0|1|
 0|
>>> y.weight()
>>> y.in_highest_weight_crystal(La)
True
>>> y.f(Integer(1))
[[0], [1, 0, 3, 2, 1], [2, 1, 0], [3], [], [1]]
>>> yy = crystals.infinity.GeneralizedYoungWalls(Integer(3))([[Integer(0)],
  Integer(1), Integer(0), Integer(3), Integer(2), Integer(1)], [Integer(2),
  Integer(1), Integer(0), Integer(3), [], [1], [Integer(1)]]))
```
Combinatorics, Release 10.4

(continued from previous page)

```
>>> yy.f(Integer(1))
[[0], [1, 0, 3, 2, 1], [2, 1, 0], [3], [], [1], [1], [1], [1], [1]]
>>> yyy = yy.f(Integer(1))
>>> yyy.in_highest_weight_crystal(La)
False
>>> LS = crystals.LSPaths(['A', Integer(3), Integer(1)], [Integer(1), Integer(0),
                        Integer(0), Integer(0)])
>>> C = LS.subcrystal(max_depth=Integer(4))
>>> G = LS.digraph(subset=C)
>>> P = RootSystem(['A', Integer(3), Integer(1)]).weight_lattice(extended=True)
>>> La = P.fundamental_weights()
>>> YW = crystals.GeneralizedYoungWalls(Integer(3), La[Integer(0)])
>>> CW = YW.subcrystal(max_depth=Integer(4))
>>> GW = YW.digraph(subset=CW)
>>> GW.is_isomorphic(G, edge_labels=True)
True
```

To display the crystal down to a specified depth:

```
sage: S = YLa.subcrystal(max_depth=4)
sage: G = YLa.digraph(subset=S)
sage: view(G)  # not tested
```

```
>>> from sage.all import *
```  
```
>>> S = YLa.subcrystal(max_depth=Integer(4))
>>> G = YLa.digraph(subset=S)
>>> view(G)  # not tested
```

Element

alias of `CrystalOfGeneralizedYoungWallsElement`

```
class sage.combinat.crystals.generalized_young_walls.CrystalOfGeneralizedYoungWallsElement
```

Bases: `GeneralizedYoungWall`

Element of the highest weight crystal of generalized Young walls.

```
e(i)
```

Compute the action of $e_i$ restricted to the highest weight crystal.

**EXAMPLES:**

```
sage: La = RootSystem(['A', 2, 1]).weight_lattice(extended=True).fundamental_weights()[1]
sage: hwy = crystals.GeneralizedYoungWalls(2, La)([[], [1, 0, 0], [2, 1]])
sage: hwy.e(1)
[[], [1, 0], [2]]
sage: hwy.e(2)
sage: hwy.e(3)
```

```
>>> from sage.all import *
```  
```
>>> La = RootSystem(['A', Integer(2), Integer(1)]).weight_lattice(extended=True).fundamental_weights()[Integer(1)]
>>> hwy = crystals.GeneralizedYoungWalls(Integer(2), La)([[], [1, 0], [2, 1]])
```
f \(i\)

Compute the action of \(f_i\) restricted to the highest weight crystal.

EXAMPLES:

```python
sage: La = RootSystem(['A', 2, 1]).weight_lattice(extended=True).fundamental_weights()

sage: Y = crystals.infinity.GeneralizedYoungWalls(2)

sage: y = Y([[[]], [[1, 0], [2, 1]]])

sage: y.f(1)

[[[]], [[1, 0], [2, 1]], [[], [1]]]

sage: hwy = crystals.GeneralizedYoungWalls(2, La)([[[]], [[1, 0], [2, 1]]])

sage: hwy.f(1)
```

phi \(i\)

Return the value \(\varepsilon_i(Y) + \langle h_i, \text{wt}(Y) \rangle\), where \(h_i\) is the \(i\)-th simple coroot and \(Y\) is self.

EXAMPLES:

```python
sage: La = RootSystem(['A', 3, 1]).weight_lattice(extended=True).fundamental_weights()

sage: y = crystals.GeneralizedYoungWalls(3, La[0])([])

sage: y.phi(1)

0

sage: y.phi(2)

0
```

weight()

Return the weight of self in the highest weight crystal as an element of the weight lattice \(\bigoplus_{i=0}^{n} \mathbb{Z} \Lambda_i\).

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()[1]
sage: hwy = crystals.GeneralizedYoungWalls(2,La)([[], [1,0], [2,1]])
sage: hwy.weight()
```

```python
>>> from sage.all import *

>>> La = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice(extended=True).fundamental_weights()[Integer(1)]

>>> hwy = crystals.GeneralizedYoungWalls(Integer(2),La)([[], [Integer(1),Integer(0)], [Integer(2),Integer(1)]])

>>> hwy.weight()
```

class `sage.combinat.crystals.generalized_young_walls.GeneralizedYoungWall` (parent, data)

Bases: `CombinatorialElement`

A generalized Young wall.

For more information, see `InfinityCrystalOfGeneralizedYoungWalls`.

**EXAMPLES:**

```python
sage: Y = crystals.infinity.GeneralizedYoungWalls(4)
sage: mg = Y.module_generators[0]; mg.pp()
0

sage: mg.f_string([1,2,0,1]).pp()
1|2|
0|1|
```

```python
>>> from sage.all import *

>>> Y = crystals.infinity.GeneralizedYoungWalls(Integer(4))

>>> mg = Y.module_generators[Integer(0)]; mg.pp()
0

>>> mg.f_string([Integer(1),Integer(2),Integer(0),Integer(1)]).pp()
1|2|
0|1|
```

**Epsilon()**

Return $\sum_{i=0}^{n} \varepsilon_i(Y)\Lambda_i$ where $Y$ is self.

**EXAMPLES:**

```python
sage: y = crystals.infinity.GeneralizedYoungWalls(3)([[0], [1,0,3,2], [2,1], [3, 2,1,0,3,2], [0], [], [2]])
sage: y.Epsilon()
Lambda[0] + 3*Lambda[2]
```

```python
>>> from sage.all import *

>>> y = crystals.infinity.GeneralizedYoungWalls(Integer(3))([[Integer(0)], [Integer(1), Integer(0), Integer(3)], [Integer(2)], [Integer(3), Integer(2), Integer(1), Integer(0), Integer(3), Integer(2)], [Integer(0)], [], [Integer(2)]])
```
Combinatorics, Release 10.4

>>> y.Epsilon()
Lambda[0] + 3*Lambda[2]

**Phi()**

Return $\sum_{i=0}^{n} \varphi_i(Y)\Lambda_i$ where $Y$ is self.

**EXAMPLES:**

```python
sage: y = crystals.infinity.GeneralizedYoungWalls(3)([[0], [1, 0, 3, 2], [2, 1], [3, 2, 1, 0, 3, 2], [0], [], [2]])
sage: y.Phi()
sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[], [1, 0, 3, 2], [2, 1], [3, 2, 1, 0, 3, 2], [0], [], [2]])
sage: x.Phi()
```

```python
>>> from sage.all import *

>>> y = crystals.infinity.GeneralizedYoungWalls(Integer(3))([[0], [1, 0, 3, 2], [2, 1], [3, 2, 1, 0, 3, 2], [0], [], [2]])
>>> y.Phi()

>>> x = crystals.infinity.GeneralizedYoungWalls(Integer(3))([[], [1, 0, 3, 2], [2, 1], [3, 2, 1, 0, 3, 2], [0], [], [2]])
>>> x.Phi()
```

**a(i,k)**

Return the number $a_i(k)$ of $i$-colored boxes in the $k$-th column of self.

**EXAMPLES:**

```python
sage: y = crystals.infinity.GeneralizedYoungWalls(3)([[0], [1, 0, 3, 2], [2, 1], [3, 2, 1, 0, 3, 2], [0], [], [2]])
sage: y.a(1,2)
1
sage: y.a(0,2)
1
sage: y.a(3,2)
0
```

```python
>>> from sage.all import *

>>> y = crystals.infinity.GeneralizedYoungWalls(Integer(3))([[0], [1, 0, 3, 2], [2, 1], [3, 2, 1, 0, 3, 2], [0], [], [2]])

```

(continues on next page)
column \( (k) \)

Return the list of boxes from the \( k \)-th column of \( \text{self} \).

**EXAMPLES:**

```
sage: y = crystals.infinity.GeneralizedYoungWalls(3)([[0],[1,0,3,2],[2,1],[3, 2,1,0,3,2],[0],[0],[2]])
sage: y.column(2)
[None, 0, 1, 2, None, None, None]
sage: hw = crystals.infinity.GeneralizedYoungWalls(5)([])
sage: hw.column(1)
[]
```

content()

Return total number of blocks in \( \text{self} \).

**EXAMPLES:**

```
sage: y = crystals.infinity.GeneralizedYoungWalls(2)([[0],[1,0],[2,1,0,2],[1]])
sage: y.content()
8
sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[],[1,0,3,2],[2,1],[3,2, 1,0,3,2],[0],[0],[2]])
sage: x.content()
13
```

```
\( e(i) \)

Return the application of the Kashiwara raising operator \( e_i \) on \( \text{self} \).

This will remove the \( i \)-colored box corresponding to the rightmost \( + \) in \( \text{self}.\text{signature}(i) \).

EXAMPLES:

```python
sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[], [1, 0, 3, 2], [2, 1], [3, 2, 1, 0, 3, 2], [], [], [2]])
sage: x.e(2)
[[], [1, 0, 3, 2], [2, 1], [3, 2, 1, 0, 3, 2]]
sage: _.e(2)
[[], [1, 0, 3], [2, 1], [3, 2, 1, 0, 3, 2]]
sage: _.e(2)
[[], [1, 0, 3], [2, 1], [3, 2, 1, 0, 3]]
sage: _.e(2)
```

\( \epsilon(i) \)

Return the number of \( i \)-colored arrows in the \( i \)-string above \( \text{self} \) in the crystal graph.

EXAMPLES:

```python
sage: y = crystals.infinity.GeneralizedYoungWalls(3)([[], [1, 0, 3, 2], [2, 1], [3, 2, 1, 0, 3, 2], [], [], [2]])
sage: y.\epsilon(1)
0
sage: y.\epsilon(2)
3
sage: y.\epsilon(0)
0
```

\( f(i) \)

Return the application of the Kashiwara lowering operator \( f_i \) on \( \text{self} \).

This will add an \( i \)-colored colored box to the site corresponding to the leftmost plus in \( \text{self}.\text{signature}(i) \).
EXAMPLES:

```python
sage: hw = crystals.infinity.GeneralizedYoungWalls(2)([])

sage: hw.f(1)
[[], [1]]

sage: __.f(2)
[[], [1, 2]]

sage: __.f(0)
[[0], [1, 0], [2]]
```

```python
>>> from sage.all import *

>>> hw = crystals.infinity.GeneralizedYoungWalls(Integer(2))([])

>>> hw.f(Integer(1))
[[], [1]]

>>> __.f(Integer(2))
[[], [1, 2]]

>>> __.f(Integer(0))
[[0], [1, 0], [2]]
```

**generate_signature**(i)

The i-signature of self (with whitespace where cancellation occurs) together with the unreduced sequence from \{+, −\}. The result also records to the row and column position of the sign.

EXAMPLES:

```python
sage: y = crystals.infinity.GeneralizedYoungWalls(2)([[0], [1, 0], [2, 1, 0, 2], [], →[1]])

sage: y.generate_signature(1)
([[‘+’, 2, 5], [‘-’, 4, 1]], ‘’)

>>> from sage.all import *

>>> y = crystals.infinity.GeneralizedYoungWalls(Integer(2))([[Integer(0)], →[Integer(1), Integer(0)], [Integer(2), Integer(1), Integer(0), Integer(2)], [], →[Integer(1)]]))

>>> y.generate_signature(Integer(1))
([[‘+’, 2, 5], [‘-’, 4, 1]], ‘’)
```

**in_highest_weight_crystal**(La)

Return a boolean indicating if the generalized Young wall element is in the highest weight crystal cut out by the given highest weight La.

By Theorem 4.1 of [KS2010], a generalized Young wall Y represents a vertex in the highest weight crystal $Y(\lambda)$, with $\lambda = \Lambda_1 + \Lambda_2 + \cdots + \Lambda_i$, a dominant integral weight of level $\ell > 0$, if it satisfies the following condition. For each positive integer k, if there exists $j \in I$ such that $a_j(k) - a_{j-1}(k) > 0$, then for some $p = 1, \ldots, \ell$,

$$j + k \equiv i_p + 1 \mod n + 1 \quad \text{and} \quad a_j(k) - a_{j-1}(k) \leq \lambda(h_{i_p}),$$

where \{h_0, h_1, \ldots, h_n\} is the set of simple coroots attached to $A_n^{(1)}$.

EXAMPLES:
sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()[1]
sage: GYW = crystals.infinity.GeneralizedYoungWalls(2)
sage: y = GYW([[],[1,0],[2,1]])
sage: y.in_highest_weight_crystal(La)
True
sage: x = GYW([[],[1],[2],[1],[2],[1],[2],[2]])
sage: x.in_highest_weight_crystal(La)
False

latex_large()

Generate LaTeX code for self but the output is larger. Requires TikZ.

EXAMPLES:

sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[],[1,0,3,2],[2,1],[3,2,1,0,3,2],[[],[],[2]])
sage: x.latex_large()
'\begin{tikzpicture}[baseline=5,scale=.45] \n \foreach \x [count=\s from 0] in {\n{},{1,0,3,2},{2,1},{3,2,1,0,3,2},{},{},\n}\foreach \y [count=\t from 0] in \x { \node[font=\scriptsize] at (-\t,\s) {$\y$}; \n \draw (-\t+.5,\s+.5) to (-\t-.5,\s+.5); \n \draw (-\t+.5,\s-.5) to (-\t-.5,\s-.5); \n \draw (-\t-.5,\s-.5) to (-\t-.5,\s+.5); } \n \draw[->,thick] (.5,\s+1) to (.5,-.5) to (-\t-1,-.5); }\n\end{tikzpicture} \n'

number_of_parts()

Return the value of $\mathcal{N}$ on self.

In [KLRS2016], the statistic $\mathcal{N}$ was defined on elements in $\mathcal{Y}(\infty)$ which counts how many parts are in the corresponding Kostant partition. Specifically, the computation of $\mathcal{N}(Y)$ is done using the following algorithm:
• If $Y$ has no rows whose right-most box is colored $n$ and such that the length of this row is a multiple of $n + 1$, then $\mathcal{N}(Y)$ is the total number of distinct rows in $Y$, not counting multiplicity.

• Otherwise, search $Y$ for the longest row such that the right-most box is colored $n$ and such that the total number of boxes in the row is $k(n + 1)$ for some $k \geq 1$. Replace this row by $n + 1$ distinct rows of length $k$, reordering all rows, if necessary, so that the result is a proper wall. (Note that the resulting wall may no longer be reduced.) Repeat the search and replace process for all other rows of the above form for each $k' < k$. Then $\mathcal{N}(Y)$ is the number of distinct rows, not counting multiplicity, in the wall resulting from this process.

EXAMPLES:

```python
sage: Y = crystals.infinity.GeneralizedYoungWalls(3)
sage: y = Y([[0],[],[],[],[0],[],[],[],[0]])
sage: y.number_of_parts()
1

sage: Y = crystals.infinity.GeneralizedYoungWalls(3)
sage: y = Y([[0,3,2],[1,0],[],[],[0,3],[1,0],[],[],[0]])
sage: y.number_of_parts()
4

sage: Y = crystals.infinity.GeneralizedYoungWalls(2)
sage: y = Y([[0,2,1],[1,0],[],[],[0,2,1,0,2,1,0],[],[2,1,0,2,1,0]])
sage: y.number_of_parts()
8
```

```python
>>> from sage.all import *
>>> Y = crystals.infinity.GeneralizedYoungWalls(Integer(3))
>>> y = Y([[Integer(0),],[[],[],[Integer(0)],[],[],[Integer(0)]]])
>>> y.number_of_parts()
1

>>> Y = crystals.infinity.GeneralizedYoungWalls(Integer(3))
>>> y = Y([[Integer(0),Integer(3),Integer(2)],[Integer(1),Integer(0)],[[],[],[Integer(0),Integer(3)],[Integer(1),Integer(0)],[[],[],[Integer(0)]]])
>>> y.number_of_parts()
4

>>> Y = crystals.infinity.GeneralizedYoungWalls(Integer(2))
>>> y = Y([[Integer(0),Integer(2),Integer(1)],[Integer(1),Integer(0)],[[],[],[Integer(2),Integer(1),Integer(0)],[Integer(2),Integer(1),Integer(0)],[[],[],[Integer(2),Integer(1),Integer(0)]]])
>>> y.number_of_parts()
8
```

$\phi_i(i)$

Return the value $\varepsilon_i(Y) + \langle h_i, \text{wt}(Y) \rangle$, where $h_i$ is the $i$-th simple coroot and $Y$ is self.

EXAMPLES:

```python
sage: y = crystals.infinity.GeneralizedYoungWalls(3)([[0],[1,0,3,2],[2,1],[3,2,1,0,3,2],[0],[[],[2,1,0,3,2]])
sage: y.phi(1)
3

sage: y.phi(2)
-1
```
```python
>>> from sage.all import *
>>> y = crystals.infinity.GeneralizedYoungWalls(Integer(3))([[Integer(0)],
    ->[Integer(1),Integer(0),Integer(3),Integer(2)],[Integer(2),Integer(1)],
    ->[Integer(3),Integer(2),Integer(1),Integer(0),Integer(3),Integer(2)],
    ->[Integer(0)],[],[Integer(2)]]))
>>> y.phi(Integer(1))
3
>>> y.phi(Integer(2))
-1
```

**PP()**

Pretty print self.

**EXAMPLES:**

```
sage: y = crystals.infinity.GeneralizedYoungWalls(2)([[0,2,1],[1,0,2,1,0],[],
    ->[0],[1,0,2],[],[],[],])
sage: y.pp()
1|
   |
2|0|1|
   0|
   |
0|1|2|0|1|
   1|2|0|
```

```python
>>> from sage.all import *
>>> x = crystals.infinity.GeneralizedYoungWalls(Integer(3))([[],[],[],[],[],[],[]])
```

**raw_signature(i)**

Return the sequence from \{+, -\} obtained from all \textit{i}\textunderscore admissible slots and removable \textit{i}\textunderscore boxes without canceling any \textit{(+, -)}\textunderscore pairs. The result also notes the row and column of the sign.

**EXAMPLES:**

```
sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[],[],[],[],[],[],[]])
sage: x.raw_signature(2)
[['-', 3, 6], ['-', 1, 4], ['-', 6, 1]]
```

```python
>>> from sage.all import *
>>> x = crystals.infinity.GeneralizedYoungWalls(Integer(3))([[],[],[],[],[],[],[]])
```

(continues on next page)
signature \(i \) 
Return the \(i\)-signature of \texttt{self}.

The signature is obtained by reading \texttt{self} in columns bottom to top starting from the left. Then add a \(-\) at every \(i\)-box which may be removed from \texttt{self} and still obtain a legal generalized Young wall, and add a \(+\) at each site for which an \(i\)-box may be added and still obtain a valid generalized Young wall. Then successively cancel any \((+, -)\)-pair to obtain a sequence of the form \(-\cdots - +\cdots +\). This resulting sequence is the output.

EXAMPLES:

```
sage: y = crystals.infinity.GeneralizedYoungWalls(2)([[0], [1, 0], [2, 1, 0, 2], [], [1]])
sage: y.signature(1)
```

```
sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[], [1, 0, 3, 2], [2, 1], [3, 2, 1, 0, 3, 2], [], [], [2]])
sage: x.signature(2)
```

sum_of_weighted_row_lengths() 
Return the value of \(M\) on \texttt{self}.

Let \(\mathcal{Y}_0 \subset \mathcal{Y}(\infty)\) be the set of generalized Young walls which have no rows whose right-most box is colored \(n\). For \(Y \in \mathcal{Y}_0\),

\[
M(Y) = \sum_{i=1}^{n} (i + 1)M_i(Y),
\]

where \(M_i(Y)\) is the number of nonempty rows in \(Y\) whose right-most box is colored \(i - 1\).

EXAMPLES:

```
sage: Y = crystals.infinity.GeneralizedYoungWalls(2)
sage: y = Y([[0, 2, 1, 0, 2], [1, 0, 2], [], [], [0, 2], [1, 0], [], [0], [1, 0]])
sage: y.sum_of_weighted_row_lengths()
```
**from sage.all import**

```python
>>> Y = crystals.infinity.GeneralizedYoungWalls(Integer(2))
>>> y = Y([[Integer(0),Integer(2),Integer(1),Integer(0),Integer(2)],
        [Integer(1),Integer(0),Integer(2)],[],[Integer(0),Integer(2)],
        [Integer(1),Integer(0)]])
>>> y.sum_of_weighted_row_lengths()
15
```

**weight (root_lattice=False)**

Return the weight of self.

**INPUT:**

- **root_lattice** – boolean determining whether weight should appear in root lattice or not in extended affine weight lattice.

**EXAMPLES:**

```python
sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[], [1, 0, 3, 2], [2, 1], [3, 2, 
   →1, 0, 3, 2], [1, [1], [2]])
sage: x.weight()
sage: x.weight(root_lattice=True)
```

**class sage.combinat.crystals.generalized_young_walls.InfinityCrystalOfGeneralizedYoungWalls**

The crystal $\mathcal{Y}(\infty)$ of generalized Young walls of type $A_n^{(1)}$ as defined in [KS2010].

A generalized Young wall is a collection of boxes stacked on a fixed board, such that color of the box at the site located in the $j$-th row from the bottom and the $i$-th column from the right is $j - 1 \mod n + 1$. There are several growth conditions on elements in $Y \in \mathcal{Y}(\infty)$:

- Walls grow in rows from right to left. That is, for every box $y \in Y$ that is not in the rightmost column, there must be a box immediately to the right of $y$.
- For all $p > q$ such that $p - q \equiv 0 \mod n + 1$, the $p$-th row has most as many boxes as the $q$-th row.
- There does not exist a column in the wall such that if one $i$-colored box, for every $i = 0, 1, \ldots, n$, is removed from that column, then the result satisfies the above conditions.

There is a crystal structure on $\mathcal{Y}(\infty)$ defined as follows. Define maps

\[
\epsilon_i, f_i: \mathcal{Y}(\infty) \rightarrow \mathcal{Y}(\infty) \sqcup \{0\}, \quad \epsilon_i, \varphi_i: \mathcal{Y}(\infty) \rightarrow \mathbb{Z}, \quad \text{wt}: \mathcal{Y}(\infty) \rightarrow \bigoplus_{i=0}^n \mathbb{Z}A_i \oplus \mathbb{Z}\delta,
\]
by

\[ \text{wt}(Y) = - \sum_{i=0}^{n} m_i(Y) \alpha_i, \]

where \( m_i(Y) \) is the number of \( i \)-boxes in \( Y \), \( \varepsilon_i(Y) \) is the number of \( - \) in the \( i \)-signature of \( Y \), and

\[ \varphi_i(Y) = \varepsilon_i(Y) + \langle h_i, \text{wt}(Y) \rangle. \]

See \( \text{GeneralizedYoungWall.e()} \), \( \text{GeneralizedYoungWall.f()} \), and \( \text{GeneralizedYoungWall.signature()} \) for more about \( e_i, f_i, \) and \( i \)-signatures.

INPUT:

* \( n \) – type \( A_n^{(1)} \)

EXAMPLES:

\begin{verbatim}
>>> from sage.all import *

>>> Yinf = crystals.infinity.GeneralizedYoungWalls(Integer(3))

>>> y = Yinf([[Integer(0)], [Integer(1), Integer(0), Integer(3), Integer(2)], [], [Integer(3), Integer(2), Integer(1)], [Integer(0)], [Integer(1), Integer(0)]])

>>> y.pp()

 0|1|
 0|
 1|2|3|        0|1|
 |   1|2|3| 2|3|0|1|        0|
 |   2|3|0|1|
 |   0|

>>> y.weight(root_lattice=True)

>>> y.f(Integer(0))

[[0], [1, 0, 3, 2], [], [3, 2, 1], [0], [1, 0]]

>>> y.e(Integer(0)).pp()

 0|1|
 0|
 1|2|3|
 |   1|2|3| 2|3|0|1|        0|
 |   2|3|0|1|
 |   0|

(continues on next page)
\end{verbatim}
To display the crystal down to depth 3:

```sage
sage: S = Yinf.subcrystal(max_depth=3)
sage: G = Yinf.digraph(subset=S)  # long time
sage: view(G)  # not tested
```

```python
>>> from sage.all import *
>>> S = Yinf.subcrystal(max_depth=Integer(3))
>>> G = Yinf.digraph(subset=S)  # long time
>>> view(G)  # not tested
```

**Element**

alias of `GeneralizedYoungWall`

### 5.1.51 Highest weight crystals

```python
class sage.combinat.crystals.highest_weight_crystals.FiniteDimensionalHighestWeightCrystal(...)
```

**Bases:** `TensorProductOfCrystals`

Commonalities for all finite dimensional type $E$ highest weight crystals.

Subclasses should setup an attribute `column_crystal` in their `__init__` method before calling the `__init__` method of this class.

**Element**

alias of `TensorProductOfRegularCrystalsElement`

**module_generator()**

This yields the module generator (or highest weight element) of the classical crystal of given dominant weight in self.

**EXAMPLES:**

```sage
c = CartanType(['E', 6])
c = La = C.root_system().weight_lattice().fundamental_weights()
c = T = crystals.HighestWeight(La[2])
c = T.module_generator()
[[[2, -1], (1,)]]
c = T = crystals.HighestWeight(0*La[2])
c = T.module_generator()
[]
c = c = CartanType(['E', 7])
c = La = C.root_system().weight_lattice().fundamental_weights()
c = T = crystals.HighestWeight(La[1])
c = T.module_generator()
[[[-7, 1], (7,)]]
```
```python
>>> from sage.all import *
>>> C=CartanType(['E',Integer(6)])
>>> La=C.root_system().weight_lattice().fundamental_weights()
>>> T = crystals.HighestWeight(La[Integer(2)])
>>> T.module_generator()
[((2, -1), (1,))]
>>> T = crystals.HighestWeight(Integer(0)*La[Integer(2)])
>>> T.module_generator()
[]
>>> C=CartanType(['E',Integer(7)])
>>> La=C.root_system().weight_lattice().fundamental_weights()
>>> T = crystals.HighestWeight(La[Integer(1)])
>>> T.module_generator()
[(-7, 1), (7,)]
```

```python

class sage.combinat.crystals.highest_weight_crystals.FiniteDimensionalHighestWeightCrystal_TypeE

Bases: FiniteDimensionalHighestWeightCrystal_TypeE

Class of finite dimensional highest weight crystals of type $E_6$.

EXAMPLES:

```python
sage: C=CartanType(['E',6])
sage: La=C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[2]); T
Finite dimensional highest weight crystal of type ['E', 6] and highest weight→Lambda[2]
sage: B1 = T.column_crystal[1]; B1
The crystal of letters for type ['E', 6]
sage: B6 = T.column_crystal[6]; B6
The crystal of letters for type ['E', 6] (dual)
sage: t = T(B6([-1]),B1([-1,3])); t
[(-1,), (-1, 3)]
sage: [t.epsilon(i) for i in T.index_set()]
[2, 0, 0, 0, 0, 0]
sage: [t.phi(i) for i in T.index_set()]
[0, 0, 1, 0, 0, 0]
sage: TestSuite(t).run()
```
(continues on next page)
class sage.combinat.crystals.highest_weight_crystals.FiniteDimensionalHighestWeightCrystal_TypeE

Bases: \texttt{FiniteDimensionalHighestWeightCrystal\_TypeE}

Class of finite dimensional highest weight crystals of type $E_7$.

\textbf{EXAMPLES:}

```
sage: C=CartanType(['E',7])
sage: La=C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[1])
sage: T.cardinality()
133
sage: B7 = T.column_crystal[7]; B7
The crystal of letters for type ['E', 7]
sage: t = T(B7([-5, 6]), B7([-2, 3])); t
[(-5, 6), (-2, 3)]
sage: [t.epsilon(i) for i in T.index_set()]
[0, 1, 0, 0, 1, 0, 0]
sage: [t.phi(i) for i in T.index_set()]
[0, 0, 1, 0, 0, 1, 0]
sage: TestSuite(t).run()
```

```
>>> from sage.all import *

```

```
sage: C=CartanType(['E',Integer(7)])
>>> La=C.root_system().weight_lattice().fundamental_weights()
>>> T = crystals.HighestWeight(La[Integer(1)])
>>> T.cardinality()
133
>>> B7 = T.column_crystal[Integer(7)]; B7
The crystal of letters for type ['E', 7]
>>> t = T(B7([-Integer(5), Integer(6)]), B7([-Integer(2), Integer(3)])); t
[(-5, 6), (-2, 3)]
>>> [t.epsilon(i) for i in T.index_set()]
[0, 1, 0, 0, 1, 0, 0]
>>> [t.phi(i) for i in T.index_set()]
[0, 0, 1, 0, 0, 1, 0]
>>> TestSuite(t).run()
```

sage.combinat.crystals.highest_weight_crystals.HighestWeightCrystal\(\text{dominant\_weight,}\)\model=\text{None}\)

Return the highest weight crystal of highest weight \texttt{dominant\_weight} of the given \texttt{model}.

\textbf{INPUT:}

- \texttt{dominant\_weight} -- a dominant weight
- \texttt{model} -- (optional) if not specified, then we have the following default models:
  - types $A_n$, $B_n$, $C_n$, $D_n$, $G_2$ - \texttt{tableaux}
  - types $E_{6,7}$ - \texttt{type E finite dimensional crystal}
  - all other types - \texttt{LS paths}
otherwise can be one of the following:

- 'Tableaux' - KN tableaux
- 'TypeE' - type E finite dimensional crystal
- 'NakajimaMonomials' - Nakajima monomials
- 'LSPaths' - LS paths
- 'AlcovePaths' - alcove paths
- 'GeneralizedYoungWalls' - generalized Young walls
- 'RiggedConfigurations' - rigged configurations

EXAMPLES:

```plaintext
sage: La = RootSystem(['A',2]).weight_lattice().fundamental_weights()
sage: wt = La[1] + La[2]
sage: crystals.HighestWeight(wt)
The crystal of tableaux of type ['A', 2] and shape(s) [[2, 1]]

sage: La = RootSystem(['C',2]).weight_lattice().fundamental_weights()
sage: wt = 5*La[1] + La[2]
sage: crystals.HighestWeight(wt)
The crystal of tableaux of type ['C', 2] and shape(s) [[6, 1]]

sage: La = RootSystem(['B',2]).weight_lattice().fundamental_weights()
sage: wt = La[1] + La[2]
sage: crystals.HighestWeight(wt)
The crystal of tableaux of type ['B', 2] and shape(s) [[3/2, 1/2]]
```

>>> from sage.all import *

```plaintext
>>> La = RootSystem(['A',Integer(2)]).weight_lattice().fundamental_weights()
>>> wt = La[Integer(1)] + La[Integer(2)]
>>> crystals.HighestWeight(wt)
The crystal of tableaux of type ['A', 2] and shape(s) [[2, 1]]

>>> La = RootSystem(['C',Integer(2)]).weight_lattice().fundamental_weights()
>>> wt = Integer(5)*La[Integer(1)] + La[Integer(2)]
>>> crystals.HighestWeight(wt)
The crystal of tableaux of type ['C', 2] and shape(s) [[6, 1]]

>>> La = RootSystem(['B',Integer(2)]).weight_lattice().fundamental_weights()
>>> wt = La[Integer(1)] + La[Integer(2)]
>>> crystals.HighestWeight(wt)
The crystal of tableaux of type ['B', 2] and shape(s) [[3/2, 1/2]]
```

Some type $E$ examples:

```plaintext
sage: C = CartanType(['E',6])
sage: La = C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[1])
sage: T.cardinality()
27
sage: T = crystals.HighestWeight(La[6])
sage: T.cardinality()
27
sage: T = crystals.HighestWeight(La[2])
```

(continues on next page)
```python
sage: T.cardinality()
78
sage: T = crystals.HighestWeight(La[4])
sage: T.cardinality()
2925
sage: T = crystals.HighestWeight(La[3])
sage: T.cardinality()
351
sage: T = crystals.HighestWeight(La[5])
sage: T.cardinality()
351

sage: C = CartanType(['E',7])
sage: La = C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[1])
sage: T.cardinality()
133
sage: T = crystals.HighestWeight(La[2])
sage: T.cardinality()
912
sage: T = crystals.HighestWeight(La[3])
sage: T.cardinality()
8645
sage: T = crystals.HighestWeight(La[4])
sage: T.cardinality()
365750
sage: T = crystals.HighestWeight(La[5])
sage: T.cardinality()
27664
sage: T = crystals.HighestWeight(La[6])
sage: T.cardinality()
1539
sage: T = crystals.HighestWeight(La[7])
sage: T.cardinality()
56
```

```python
>>> from sage.all import *

>>> C = CartanType(['E',6])

>>> La = C.root_system().weight_lattice().fundamental_weights()

>>> T = crystals.HighestWeight(La[1])

>>> T.cardinality()
27

>>> T = crystals.HighestWeight(La[6])

>>> T.cardinality()
27

>>> T = crystals.HighestWeight(La[2])

>>> T.cardinality()
78

>>> T = crystals.HighestWeight(La[4])

>>> T.cardinality()
2925

>>> T = crystals.HighestWeight(La[3])

>>> T.cardinality()
351

>>> T = crystals.HighestWeight(La[5])

>>> T.cardinality()
```

(continues on next page)
An example with an affine type:

```python
sage: C = CartanType(['C',2,1])
sage: La = C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[1])
sage: sorted(T.subcrystal(max_depth=3), key=str)
 (-Lambda[0] + Lambda[1] + Lambda[2] - delta,),
 (2*Lambda[0] - Lambda[1],),
 (Lambda[0] + Lambda[1] - Lambda[2],),
 (Lambda[0] - Lambda[1] + Lambda[2],),
 (Lambda[1],)]
```

Using the various models:

```python
sage: La = RootSystem(['F',4]).weight_lattice().fundamental_weights()
```
sage: crystals.HighestWeight(wt)
The crystal of LS paths of type ['F', 4] and weight Lambda[1] + Lambda[4]

sage: crystals.HighestWeight(wt, model='NakajimaMonomials')

sage: crystals.HighestWeight(wt, model='AlcovePaths')

sage: crystals.HighestWeight(wt, model='RiggedConfigurations')

>>> from sage.all import *
>>> La = RootSystem(['A',3,1]).weight_lattice().fundamental_weights()
>>> wt = La[0] + La[2]
>>> crystals.HighestWeight(wt, model='GeneralizedYoungWalls')
Highest weight crystal of generalized Young walls of Cartan type ['A', 3, 1] and highest weight Lambda[0] + Lambda[2]

5.1.52 Induced Crystals

We construct a crystal structure on a set induced by a bijection $\Phi$.

AUTHORS:

```python
class sage.combinat.crystals.induced_structure.InducedCrystal (X, phi, inverse)
Bases: UniqueRepresentation, Parent

A crystal induced from an injection.

Let $X$ be a set and let $C$ be crystal and consider any injection $\Phi : X \rightarrow C$. We induce a crystal structure on $X$ by considering $\Phi$ to be a crystal morphism.

Alternatively we can induce a crystal structure on some (sub)set of $X$ by considering an injection $\Phi : C \rightarrow X$ considered as a crystal morphism. This form is also useful when the set $X$ is not explicitly known.

INPUT:
Combinatorics, Release 10.4

- $X$ – the base set
- $\phi$ – the map $\Phi$
- inverse – (optional) the inverse map $\Phi^{-1}$
- from$\_crystal$ – (default: False) if the induced structure is of the second type $\Phi : C \to X$

**EXAMPLES:**

We construct a crystal structure of Gelfand-Tsetlin patterns by going through their bijection with semistandard tableaux:

```python
sage: D = crystals.Tableaux(['A', 3], shapes=PartitionsInBox(4, 3))
sage: G = GelfandTsetlinPatterns(4, 3)
sage: phi = lambda x: D(x.to_tableau())
sage: phi_inv = lambda x: G(x.to_tableau())
sage: I = crystals.Induced(G, phi, phi_inv)
sage: I.digraph().is_isomorphic(D.digraph(), edge_labels=True)
```

Now we construct the above example but inducing the structure going the other way (from tableaux to Gelfand-Tsetlin patterns). This can also give us more information coming from the crystal.

```python
sage: D2 = crystals.Tableaux(['A', 3], shapes=PartitionsInBox(4, 1))
sage: G2 = GelfandTsetlinPatterns(4, 1)
sage: phi2 = lambda x: D2(x.to_tableau())
sage: phi2_inv = lambda x: G2(x.to_tableau())
sage: I2 = crystals.Induced(D2, phi2_inv, phi2, from$\_crystal$=True)
sage: I2.module$\_generators$
```

```python
True
```
We check an example when the codomain is larger than the domain (although here the crystal structure is trivial):

```python
sage: P = Permutations(4)
sage: D = crystals.Tableaux(['A',3], shapes=Partitions(4))
sage: T = crystals.TensorProduct(D, D)
sage: phi = lambda p: T(D(RSK(p)[0]), D(RSK(p)[1]))
sage: phi_inv = lambda d: RSK_inverse(d[0].to_tableau(), d[1].to_tableau(), output='permutation')
sage: all(phi_inv(phi(p)) == p for p in P) # Check it really is the inverse
True
sage: I = crystals.Induced(P, phi, phi_inv)
sage: I.digraph()
Digraph on 24 vertices
```

We construct an example without a specified inverse map:

```python
sage: X = Words(2,4)
sage: L = crystals.Letters(['A',1])
sage: T = crystals.TensorProduct(*[L]*4)
sage: Phi = lambda x : T(*[L(i) for i in x])
sage: I = crystals.Induced(X, Phi)
sage: I.digraph()
Digraph on 16 vertices
```

```python
>>> from sage.all import *
>>> P = Permutations(Integer(4))
>>> D = crystals.Tableaux(['A',Integer(3)], shapes=Partitions(Integer(4)))
>>> T = crystals.TensorProduct(D, D)
>>> phi = lambda p: T(D(RSK(p)[0]), D(RSK(p)[1]))
>>> phi_inv = lambda d: RSK_inverse(d[0].to_tableau(), d[1].to_tableau(), output='permutation')
>>> all(phi_inv(phi(p)) == p for p in P) # Check it really is the inverse
True
>>> I = crystals.Induced(P, phi, phi_inv)
>>> I.digraph()
Digraph on 24 vertices
```

```python
class Element
    Bases: ElementWrapper

An element of an induced crystal.

    e(i)

        Return e_i of self.

EXAMPLES:
```
```
```
```
sage: phi = lambda x: D(x.to_tableau())
sage: phi_inv = lambda x: G(x.to_tableau())
sage: I = crystals.Induced(G, phi, phi_inv)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: elt.e(1)
[[1, 1, 0, 0], [1, 1, 0], [1, 1], [1]]
sage: elt.e(2)
[[1, 1, 0, 0], [1, 1, 0], [1, 1], [1]]
sage: elt.e(3)

epsilon(i)
Return $\varepsilon_i$ of self.

EXAMPLES:

sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,3))
sage: G = GelfandTsetlinPatterns(4, 3)
sage: phi = lambda x: D(x.to_tableau())
sage: phi_inv = lambda x: G(x.to_tableau())
sage: I = crystals.Induced(G, phi, phi_inv)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])

>>> [elt.epsilon(i) for i in I.index_set()]
[0, 1, 0]

f(i)
Return $f_i$ of self.

EXAMPLES:
sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,3))
sage: G = GelfandTsetlinPatterns(4, 3)
sage: phi = lambda x: D(x.to_tableau())
sage: phi_inv = lambda x: G(x.to_tableau())
sage: I = crystals.Induced(G, phi, phi_inv)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: elt.f(1)
[[1, 1, 0, 0], [1, 1, 0], [1, 0], [0]]
sage: elt.f(2)
sage: elt.f(3)
[[1, 1, 0, 0], [1, 0, 0], [1, 0], [1]]

>>> from sage.all import *
>>> D = crystals.Tableaux(['A',Integer(3)],
    shapes=PartitionsInBox(Integer(4),Integer(3)))
>>> G = GelfandTsetlinPatterns(Integer(4), Integer(3))
>>> phi = lambda x: D(x.to_tableau())
>>> phi_inv = lambda x: G(x.to_tableau())
>>> I = crystals.Induced(G, phi, phi_inv)
>>> elt = I([[Integer(1), Integer(1), Integer(0), Integer(0)],
    [Integer(1), Integer(1), Integer(0)], [Integer(1), Integer(0)],
    [Integer(1)]])
>>> elt.f(Integer(1))
[[1, 1, 0, 0], [1, 1, 0], [1, 0], [0]]
>>> elt.f(Integer(2))
>>> elt.f(Integer(3))
[[1, 1, 0, 0], [1, 0, 0], [1, 0], [1]]

phi(i)

Return $\varphi_i$ of self.

EXAMPLES:

>>> from sage.all import *
>>> D = crystals.Tableaux(['A',Integer(3)],
    shapes=PartitionsInBox(Integer(4),Integer(3)))
>>> G = GelfandTsetlinPatterns(Integer(4), Integer(3))
>>> phi = lambda x: D(x.to_tableau())
>>> phi_inv = lambda x: G(x.to_tableau())
>>> I = crystals.Induced(G, phi, phi_inv)
>>> elt = I([[Integer(1), Integer(1), Integer(0), Integer(0)],
    [Integer(1), Integer(1), Integer(0)], [Integer(1), Integer(0)],
    [Integer(1)]]))
>>> [elt.phi(i) for i in I.index_set()]
[1, 0, 1]

weight()

Return the weight of self.
EXAMPLES:

```python
sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,3))
sage: G = GelfandTsetlinPatterns(4, 3)
sage: phi = lambda x: D(x.to_tableau())
sage: phi_inv = lambda x: G(x.to_tableau())
sage: I = crystals.Induced(G, phi, phi_inv)
sage: elt = I([[[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]],
          [1, 0, 1, 0]])
sage: elt.weight()
(1, 0, 1, 0)
```

```python
>>> from sage.all import *
```  
```python
>>> D = crystals.Tableaux(['A',Integer(3)],
                        shapes=Partitions(Integer(4),Integer(3)))
```  
```python
>>> G = GelfandTsetlinPatterns(Integer(4), Integer(3))
```  
```python
>>> phi = lambda x: D(x.to_tableau())
```  
```python
>>> phi_inv = lambda x: G(x.to_tableau())
```  
```python
>>> I = crystals.Induced(G, phi, phi_inv)
>>> elt = I([[[Integer(1), Integer(1), Integer(0), Integer(0)],
           [Integer(1), Integer(1), Integer(0)],
           [Integer(1), Integer(0)],
           [Integer(1)]],
           [Integer(1), Integer(0), 1, 0]])
>>> elt.weight()
(1, 0, 1, 0)
```

cardinality()

Return the cardinality of self.

EXAMPLES:

```python
sage: P = Permutations(4)
sage: D = crystals.Tableaux(['A',3], shapes=Partitions(4))
sage: T = crystals.TensorProduct(D, D)
sage: phi = lambda p: T(D(RSK(p)[0]), D(RSK(p)[1]))
```  
```python
>>> phi_inv = lambda d: RSK_inverse(d[0].to_tableau(), d[1].to_tableau(),
output='permutation')
```  
```python
>>> I = crystals.Induced(P, phi, phi_inv)
```  
```python
>>> I.cardinality() == factorial(4)
True
```  
```python
>>> from sage.all import *
```  
```python
>>> P = Permutations(Integer(4))
```  
```python
>>> D = crystals.Tableaux(['A',Integer(3)], shapes=Partitions(Integer(4)))
```  
```python
>>> T = crystals.TensorProduct(D, D)
```  
```python
>>> phi = lambda p: T(D(RSK(p)[Integer(0)]), D(RSK(p)[Integer(1)]))
```  
```python
>>> phi_inv = lambda d: RSK_inverse(d[Integer(0)].to_tableau(), d[Integer(1)].
to_tableau(), output='permutation')
```  
```python
>>> I = crystals.Induced(P, phi, phi_inv)
```  
```python
>>> I.cardinality() == factorial(Integer(4))
True
```

class sage.combinat.crystals.induced_structure.InducedFromCrystal (X, phi, inverse)

Bases: UniqueRepresentation, Parent

A crystal induced from an injection.

Alternatively we can induce a crystal structure on some (sub)set of $X$ by considering an injection $\Phi : C \rightarrow X$ considered as a crystal morphism.
See also:

*InducedCrystal*

**INPUT:**

- \( X \) – the base set
- \( \phi \) – the map \( \Phi \)
- \( \text{inverse} \) – (optional) the inverse map \( \Phi^{-1} \)

**EXAMPLES:**

We construct a crystal structure on generalized permutations with a fixed first row by using RSK:

```python
sage: C = crystals.Tableaux(['A',3], shape=[2,1])
sage: def psi(x):
    ...:    ret = RSK_inverse(x.to_tableau(), Tableau([[1,1],[2]]))
    ...:    return (tuple(ret[0]), tuple(ret[1]))
sage: I = crystals.Induced(C, psi, psi_inv, from_crystal=True)
```

```python
>>> sage.all import *
>>> C = crystals.Tableaux(['A',Integer(3)], shape=[Integer(2),Integer(1)])
>>> def psi(x):
...    ret = RSK_inverse(x.to_tableau(), Tableau([Integer(1),Integer(1),
...    Integer(2)]))
...    return (tuple(ret[0]), tuple(ret[1]))
>>> I = crystals.Induced(C, psi, psi_inv, from_crystal=True)
```

**class Element**

**Bases:** ElementWrapper

An element of an induced crystal.

\(e_i\)

Return \(e_i\) of \self\.

**EXAMPLES:**

```python
sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,1))
sage: G = GelfandTsetlinPatterns(4, 1)
sage: def phi(x): return G(x.to_tableau())
```

```python
>>> from sage.all import *
>>> D = crystals.Tableaux(['A',Integer(3)], shapes=PartitionsInBox(Integer(4),Integer(1)))
>>> G = GelfandTsetlinPatterns(Integer(4), Integer(1))
>>> def phi(x): return G(x.to_tableau())
```

(continues on next page)
elt.e(Integer(1))
elt.e(Integer(2))
elt.e(Integer(3))

epsilon(i)
Return \( \varepsilon_i \) of self.

EXAMPLES:

```
sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,1))
sage: G = GelfandTsetlinPatterns(4, 1)
sage: def phi(x): return G(x.to_tableau())
sage: def phi_inv(x): return D(G(x).to_tableau())
sage: I = crystals.Induced(D, phi, phi_inv, from_crystal=True)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: [elt.epsilon(i) for i in I.index_set()]
[0, 1, 0]
```

```
>>> from sage.all import *
>>> D = crystals.Tableaux(['A',Integer(3)], shapes=PartitionsInBox(Integer(4),Integer(1)))
>>> G = GelfandTsetlinPatterns(Integer(4), Integer(1))
>>> def phi(x): return G(x.to_tableau())
>>> def phi_inv(x): return D(G(x).to_tableau())
>>> I = crystals.Induced(D, phi, phi_inv, from_crystal=True)
>>> elt = I([[Integer(1), Integer(1), Integer(0), Integer(0)],...
        [Integer(1), Integer(1), Integer(0)], [Integer(1), Integer(0)],...
        [Integer(1)]]))
>>> [elt.epsilon(i) for i in I.index_set()]
[0, 1, 0]
```

```
f(i)
Return \( f_i \) of self.

EXAMPLES:

```
sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,1))
sage: G = GelfandTsetlinPatterns(4, 1)
sage: def phi(x): return G(x.to_tableau())
sage: def phi_inv(x): return D(G(x).to_tableau())
sage: I = crystals.Induced(D, phi, phi_inv, from_crystal=True)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: elt.f(1)
[[1, 1, 0, 0], [1, 1, 0], [1, 0], [0]]
sage: elt.f(2)
sage: elt.f(3)
[[1, 1, 0, 0], [1, 0, 0], [1, 0], [1]]
```

```
>>> from sage.all import *
>>> D = crystals.Tableaux(['A',Integer(3)], shapes=PartitionsInBox(Integer(4),Integer(1)))
>>> G = GelfandTsetlinPatterns(Integer(4), Integer(1))
```

def phi(x):
    return G(x.to_tableau())

def phi_inv(x):
    return D(G(x).to_tableau())

I = crystals.Induced(D, phi, phi_inv, from_crystal=True)
elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
elt.f(Integer(1))
elt.f(Integer(2))
elt.f(Integer(3))

weight()

>>> from sage.all import *
>>> D = crystals.Tableaux(['A', 3], shapes=PartitionsInBox(4, 1))
>>> G = GelfandTsetlinPatterns(4, 1)
>>> def phi(x):
...     return G(x.to_tableau())
... def phi_inv(x):
...     return D(G(x).to_tableau())
... I = crystals.Induced(D, phi, phi_inv, from_crystal=True)
... elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
... elt.weight()
(1, 0, 1, 0)

(continues on next page)
```python
G = GelfandTsetlinPatterns(Integer(4), Integer(1))
def phi(x): return G(x.to_tableau())
def phi_inv(x): return D(G(x).to_tableau())
I = crystals.Induced(D, phi, phi_inv, from_crystal=True)
elt = I([[Integer(1), Integer(1), Integer(0), Integer(0)],
    [Integer(1), Integer(1), Integer(0)], [Integer(1), Integer(0)],
    [Integer(1)]])
elt.weight()
(1, 0, 1, 0)
```

**cardinality()**

Return the cardinality of self.

**EXAMPLES:**

```python
sage: C = crystals.Tableaux(['A',3], shape=[2,1])
sage: def psi(x):
    ....:     ret = RSK_inverse(x.to_tableau(), Tableau([[1,1],[2]]))
    ....:     return (tuple(ret[0]), tuple(ret[1]))
sage: psi_inv = lambda x: C(RSK(*x)[0])
sage: I = crystals.Induced(C, psi, psi_inv, from_crystal=True)
sage: I.cardinality() == C.cardinality()
True
```

### 5.1.53 $B(\infty)$ Crystals of Tableaux in Nonexceptional Types and $G_2$

A tableau model for $B(\infty)$. For more information, see `InfinityCrystalOfTableaux`.

**AUTHORS:**

- Ben Salisbury: Initial version
- Travis Scrimshaw: Initial version

```python
class sage.combinat.crystals.infinity_crystals.DualInfinityQueerCrystalOfTableaux(car-
tan_type)
Bases: CrystalOfWords
Initialize self.

**EXAMPLES:**

```
```python
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux(['A', Integer(2)])
>>> TestSuite(B).run() # long time
```

**class Element**

Bases: `InfinityQueerCrystalOfTableauxElement`

**index_set()**

Return the index set of self.

EXAMPLES:

```python
sage: B = crystals.infinity.Tableaux(['Q',3])
sage: B.index_set()
(1, 2, -1)
```

```python
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux(['Q',Integer(3)])
>>> B.index_set()
(1, 2, -1)
```

**module_generator()**

Return the module generator (or highest weight element) of self.

The module generator is the unique semistandard hook tableau of shape \((n, n-1, \ldots, 2, 1)\) with weight 0.

EXAMPLES:

```python
sage: B = crystals.infinity.Tableaux(['Q',5])
sage: B.module_generator()
[[5, 5, 5, 5, 5], [4, 4, 4, 4], [3, 3, 3], [2, 2], [1]]
```

```python
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux(['Q',Integer(5)])
>>> B.module_generator()
[[5, 5, 5, 5, 5], [4, 4, 4, 4], [3, 3, 3], [2, 2], [1]]
```

**class sage.combinat.crystals.infinity_crystals.InfinityCrystalOfTableaux**

Bases: `CrystalOfWords`

`B(\infty)` crystal of tableaux.

A tableaux model \(T(\infty)\) for the crystal \(B(\infty)\) is introduced by Hong and Lee in [HL2008]. This model is currently valid for types \(A_n, B_n, C_n, D_n,\) and \(G_2\), and builds on the tableaux model given by Kashiwara and Nakashima [KN1994] in types \(A_n, B_n, C_n,\) and \(D_n,\) and by Kang and Misra [KM1994] in type \(G_2.\)

**Note:** We are using the English convention for our tableaux.

We say a tableau \(T\) is *marginally large* if:

- for each \(1 \leq i \leq n\), the leftmost box in the \(i\)-th row from the top in \(T\) is an \(i\)-box,
- for each \(1 \leq i \leq n\), the number of \(i\)-boxes in the \(i\)-th row from the top in \(T\) is greater than the total number of boxes in the \((i+1)\)-th row by exactly one.

We now will describe this tableaux model type-by-type.
Type $A_n$

$\mathcal{T}(\infty)$ is the set of marginally large semistandard tableaux with exactly $n$ rows over the alphabet $\{1 \prec 2 \prec \cdots \prec n+1\}$.

Type $B_n$

$\mathcal{T}(\infty)$ is the set of marginally large semistandard tableaux with exactly $n$ rows over the alphabet $\{1 \prec \cdots \prec n \prec 0 \prec \pi \prec \cdots \prec \bar{T}\}$ and subject to the following constraints:

- for each $1 \leq i \leq n$, the contents of the boxes in the $i$-th row are $\leq \bar{i}$,
- the entry 0 can appear at most once in a single row.

Type $C_n$

$\mathcal{T}(\infty)$ is the set of marginally large semistandard tableaux with exactly $n$ rows over the alphabet $\{1 \prec \cdots \prec n \prec \pi \prec \cdots \prec \bar{T}\}$ and for each $1 \leq i \leq n$, the contents of the boxes in the $i$-th row are $\leq \bar{i}$.

Type $D_n$

$\mathcal{T}(\infty)$ is the set of marginally large semistandard tableaux with exactly $n-1$ rows over the alphabet $\{1 \prec \cdots \prec n, \pi \prec \cdots \prec \bar{T}\}$ and subject to the following constraints:

- for each $1 \leq i \leq n$, the contents of the boxes in the $i$-th row are $\leq \bar{i}$,
- the entries $n$ and $\pi$ may not appear simultaneously in a single row.

Type $G_2$

$\mathcal{T}(\infty)$ is the set of marginally large semistandard tableaux with exactly 2 rows over the ordered alphabet $\{1 \prec 2 \prec 3 \prec 0 \prec 3 \prec 2 \prec \bar{T}\}$ and subject to the following constraints:

- the contents of the boxes in the first row are $\leq \bar{i}$,
- the contents of the boxes in the second row are $\leq 3$,
- the entry 0 can appear at most once in the first row and not at all in the second row.

In particular, the shape of the tableaux is not fixed in any instance of $\mathcal{T}(\infty)$; the row lengths of a tableau can be arbitrarily long.

INPUT:

- `cartan_type` - One of ['A', $n$], ['B', $n$], ['C', $n$], ['D', $n$], or ['G', 2], where $n$ is a positive integer

EXAMPLES:

```sage
sage: B = crystals.infinity.Tableaux(['A',2])
sage: b = B.highest_weight_vector(); b.pp()
1 1
2
sage: b.f_string([2,1,1,2,2,2]).pp()
1 1 1 1 1 2 3
2 3 3 3
```

(continues on next page)
We check that a few classical crystals embed into $T(\infty)$:

```python
sage: def crystal_test(B, C):
    ...:     T = crystals.elementary.T(C.cartan_type(), C.module_generators[0].weight())
    ...:     TP = crystals.TensorProduct(T, B)
    ...:     mg = TP(T[0], B.module_generators[0])
    ...:     g = {C.module_generators[0]: mg}
    ...:     f = C.crystal_morphism(g, category=HighestWeightCrystals())
    ...:     G = B.digraph(subset=[f(x) for x in C])
    ...:     return G.is_isomorphic(C.digraph(), edge_labels=True)
sage: B = crystals.infinity.Tableaux(['A',2])
sage: C = crystals.Tableaux(['A',2], shape=[2,1])
sage: crystal_test(B, C)
True
sage: C = crystals.Tableaux(['A',2], shape=[6,2])
sage: crystal_test(B, C)
True
sage: B = crystals.infinity.Tableaux(['B',2])
sage: C = crystals.Tableaux(['B',2], shape=[3])
sage: crystal_test(B, C)
True
sage: C = crystals.Tableaux(['B',2], shape=[2,1])
sage: crystal_test(B, C)
True
sage: B = crystals.infinity.Tableaux(['C',3])
sage: C = crystals.Tableaux(['C',3], shape=[2,1])
```

(continues on next page)
sage: crystal_test(B, C)
True
sage: B = crystals.infinity.Tableaux(['D',4])
sage: C = crystals.Tableaux(['D',4], shape=[2])
sage: crystal_test(B, C)
True
sage: C = crystals.Tableaux(['D',4], shape=[1,1,1,1])
sage: crystal_test(B, C)
True
sage: B = crystals.infinity.Tableaux(['G',2])
sage: C = crystals.Tableaux(['G',2], shape=[3])
sage: crystal_test(B, C)
True

```python
>>> from sage.all import *
>>> def crystal_test(B, C):
...     T = crystals.elementary.T(C.cartan_type(), C.module_generators[Integer(0)].weight())
...     TP = crystals.TensorProduct(T, B)
...     mg = TP(T[Integer(0)], B.module_generators[Integer(0)])
...     g = {C.module_generators[Integer(0)]: mg}
...     f = C.crystal_morphism(g, category=HighestWeightCrystals())
...     G = B.digraph(subset=[f(x) for x in C])
...     return G.is_isomorphic(C.digraph(), edge_labels=True)

>>> B = crystals.infinity.Tableaux(['A',Integer(2)])
>>> C = crystals.Tableaux(['A',Integer(2)], shape=[Integer(2),Integer(1)])
>>> crystal_test(B, C)
True
>>> C = crystals.Tableaux(['A',Integer(2)], shape=[Integer(6),Integer(2)])
>>> crystal_test(B, C)
True
>>> B = crystals.infinity.Tableaux(['B',Integer(2)])
>>> C = crystals.Tableaux(['B',Integer(2)], shape=[Integer(3)])
>>> crystal_test(B, C)
True
>>> C = crystals.Tableaux(['B',Integer(2)], shape=[Integer(2),Integer(1)])
>>> crystal_test(B, C)
True
>>> B = crystals.infinity.Tableaux(['C',Integer(3)])
>>> C = crystals.Tableaux(['C',Integer(3)], shape=[Integer(2),Integer(1)])
>>> crystal_test(B, C)
True
>>> B = crystals.infinity.Tableaux(['D',Integer(4)])
>>> C = crystals.Tableaux(['D',Integer(4)], shape=[Integer(2)])
>>> crystal_test(B, C)
True
>>> C = crystals.Tableaux(['D',Integer(4)], shape=[Integer(1),Integer(1),Integer(1),Integer(1)])
>>> crystal_test(B, C)
True
>>> B = crystals.infinity.Tableaux(['G',Integer(2)])
>>> C = crystals.Tableaux(['G',Integer(2)], shape=[Integer(3)])
>>> crystal_test(B, C)
True
```

class Element

    Bases: InfinityCrystalOfTableauxElement
Elements in $B(\infty)$ crystal of tableaux.

\textbf{content()}

Return the content of \texttt{self}.

The content $|T|$ of $T \in B(\infty)$ is the number of blocks added to the highest weight to obtain $T$ with any $\tau$-boxes in the $i$-th row counted with multiplicity 2 provided the underlying Cartan type is of type $B$, $D$, or $G$.

\textbf{EXAMPLES:}

```python
sage: B = crystals.infinity.Tableaux("D5")
sage: b = B.highest_weight_vector().f_string([5, 4, 3, 1, 1, 3, 4, 5, 3, 4, 5, 1, 4, 5, 2, 3, 5, 3, 5, 1, 4, 5, 2, 3, 5, 3, 2, 4])
sage: b.content()
13

sage: B = crystals.infinity.Tableaux("B2")
sage: b = B(rows=[[1,1,1,1,1,1,2,2,2,-2,-2], [2,0,-2,-2,-2]])
sage: b.content()
12

sage: B = crystals.infinity.Tableaux("C2")
sage: b = B(rows=[[1,1,1,1,1,1,2,2,2,-2,-2], [2,-2,-2,-2]])
sage: b.content()
8
```

\textbf{phi (i)}

Return $\varphi_i$ of \texttt{self}.

Let $T \in B(\infty)$ Define $\varphi_i(T) := \varepsilon_i(T) + \langle h_i, \text{wt}(T) \rangle$, where $h_i$ is the $i$-th simple coroot and $\text{wt}(T)$ is the \texttt{weight()} of $T$.

\textbf{INPUT:}
- $i$ – An element of the index set

\textbf{EXAMPLES:}
reduced_form()

Return the reduced form of self.

The reduced form of a tableau \( T \in \mathcal{T}(\infty) \) is the (not necessarily semistandard) tableaux obtained from \( T \) by removing all \( i \)-boxes in the \( i \)-th row, subject to the condition that if the row is empty, a \( * \) is put as a placeholder. This is described in [BN2010] and [LS2012].

EXAMPLES:

```python
sage: B = crystals.infinity.Tableaux(['A',3])
sage: b = B.highest_weight_vector().f_string([2,2,2,3,3,3,3,3])
sage: b.pp()
1 1 1 1 1 1 1
2 2 2 4 4 4
3 4 4
sage: b.reduced_form()
[['*'], [4, 4, 4], [4, 4]]
```

seg()

Returns the statistic seg of self.

More precisely, following [LS2012], define a \( k \)-segment of a tableau \( T \) in \( \mathcal{B}(\infty) \) to be a maximal string of \( k \)-boxes in a single row of \( T \). Set \( \text{seg}'(T) \) to be the number of \( k \)-segments in \( T \), as \( k \) varies over all possible values. Then \( \text{seg}(T) \) is determined type-by-type.
• In types $A_n$ and $C_n$, define $\text{seg}(T) := \text{seg}'(T)$.
• In types $B_n$ and $G_2$, set $\varepsilon(T)$ to be the number of rows in $T$ which contain both a 0-box and an $\tau$-box. Define $\text{seg}(T) := \text{seg}'(T) - \varepsilon(T)$.
• In type $D_n$, set $\delta(T)$ to be the number of rows in $T$ which contain an $\tau$-box, but no $n$-box nor $\pi\tau$-box. Define $\text{seg}(T) := \text{seg}'(T) + \delta(T)$.

EXEMPLARY:

```python
sage: B = crystals.infinity.Tableaux(['A',3])
sage: b = B.highest_weight_vector().f_string([1,3,2,2,3,1,1,3])
sage: b.pp()
1 1 1 1 1 2 2 4
2 2 2 2 3
3 4 4
sage: b.seg()
4

sage: B = crystals.infinity.Tableaux(['D',4])
sage: b = B(rows=[[1,1,1,1,1,1,3,-2,-1],[2,2,2,4,-2],[3,3],[4]])
sage: b.pp()
1 1 1 1 1 1 3 -2 -1
2 2 2 4 -2
3 3
4
sage: b.seg()
6

sage: B = crystals.infinity.Tableaux(['G',2])
sage: b = B.highest_weight_vector().f_string([2,1,1,1,2,1,2,2,1,2,2,2,1,2,˓→2,1])
sage: b.pp()
1 1 1 1 1 1 1 2 3 0 -3
2 3 3 3 3 3
sage: b.seg()
5

>>> from sage.all import *
>>> B = crystals.infinity.Tableaux(['A',Integer(3)])
>>> b = B(rows=[[1,1,1,1,1,1,3,-2,-1],[2,2,2,4,-2],[3,3],[4]])
>>> b.pp()
1 1 1 1 1 1 3 -2 -1
2 2 2 4 -2
3 3
4
>>> b.seg()
4

>>> B = crystals.infinity.Tableaux(['D',Integer(4)])
>>> b = B(rows=[[1,1,1,1,1,1,3,-2,-1],[2,2,2,4,-2],[3,3],[4]])
>>> b.pp()
1 1 1 1 1 1 3 -2 -1
2 2 2 4 -2
3 3
4
>>> b.seg()
```
weight()

Return the weight of self.

From the definition of a crystal and that the highest weight element $b_\infty$ of $B(\infty)$ is 0, the weight of $T \in B(\infty)$ can be defined as $\text{wt}(T) := -\sum_i \alpha_i$ where $\bar{e}_i \cdots \bar{e}_i T = b_\infty$ and $\{\alpha_i\}$ is the set of simple roots. (Note that the weight is independent of the path chosen to get to the highest weight.)

However we can also take advantage of the fact that $\rho: R_\lambda \otimes B(\infty) \longrightarrow B(\lambda)$, where $\lambda$ is the shape of $T$, preserves the tableau representation of $T$. Therefore

$$\text{wt}(T) = \text{wt}(\rho(T)) - \lambda$$

where $\text{wt}(\rho(T))$ is just the usual weight of the tableau $T$.

Let $\Lambda_i$ be the $i$-th fundamental weight. In type $D$, the height $n - 1$ columns corresponds to $\Lambda_{n - 1} + \Lambda_n$ and in type $B$, the height $n$ columns corresponds to $2\Lambda_n$.

**EXAMPLES:**

```python
sage: B = crystals.infinity.Tableaux("C7")
sage: b = B.highest_weight_vector().f_string([1,6,4,7,4,2,4,6,2,4,6,7,1,2,4,7])
sage: b.weight()
(-2, -1, 3, -5, 5, -3, -3)
```

Check that the definitions agree:

```python
sage: P = B.weight_lattice_realization()
sage: alpha = P.simple_roots()
True
```
>>> from sage.all import *
>>> P = B.weight_lattice_realization()
>>> alpha = P.simple_roots()
>>> b.weight() == -Integer(2)*alpha[Integer(1)]
˓→-Integer(3)*alpha[Integer(2)] - Integer(5)*alpha[Integer(4)]
˓→-Integer(3)*alpha[Integer(6)] - Integer(3)*alpha[Integer(7)]
True

Check that it works for type $B$:

```python
sage: B = crystals.infinity.Tableaux("B2")
```

```python
sage: B.highest_weight_vector().weight()
(0, 0)
```

```python
sage: b = B.highest_weight_vector().f_string([1,2,2,1,2])
```

```python
True
```

```python
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux("B2")
```

```python
>>> B.highest_weight_vector().weight()
(0, 0)
```

```python
>>> b = B.highest_weight_vector().f_string([Integer(1),Integer(2),
˓→Integer(2),Integer(2),Integer(1),Integer(2)])
```

```python
>>> b.weight() == -Integer(2)*alpha[Integer(1)]
˓→-Integer(4)*alpha[Integer(2)]
True
```

Check that it works for type $D$:

```python
sage: B = crystals.infinity.Tableaux("D4")
```

```python
sage: B.highest_weight_vector().weight()
(0, 0, 0, 0)
```

```python
sage: b = B.highest_weight_vector().f_string([1,4,4,2,4,1,3,2,4])
```

```python
True
```

```python
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux("D4")
```

```python
>>> B.highest_weight_vector().weight()
(0, 0, 0, 0)
```

```python
>>> b = B.highest_weight_vector().f_string([Integer(1),Integer(4),
˓→Integer(4),Integer(2),Integer(4),Integer(3),Integer(2),Integer(4),
˓→Integer(1),Integer(3),Integer(2),Integer(4)])
```

```python
>>> b.weight() == -Integer(2)*alpha[Integer(1)]
˓→-Integer(3)*alpha[Integer(2)]
˓→-Integer(3)*alpha[Integer(6)]
˓→-Integer(5)*alpha[Integer(4)]
True
```
Return the module generator (or highest weight element) of self.

The module generator is the unique tableau of shape \((n, n - 1, \ldots, 2, 1)\) with weight 0.

EXAMPLES:

```
sage: T = crystals.infinity.Tableaux(['A',3])
sage: T.module_generator()
[[1, 1, 1], [2, 2], [3]]
```

```
>>> from sage.all import *

>>> T = crystals.infinity.Tableaux(['A',Integer(3)])

>>> T.module_generator()
[[1, 1, 1], [2, 2], [3]]
```

class sage.combinat.crystals.infinity_crystals.InfinityCrystalOfTableauxTypeD(c.cartan_type)

Bases: InfinityCrystalOfTableaux

\(B(\infty)\) crystal of tableaux for type \(D_n\).

This is the set \(\mathcal{T}(\infty)\) of marginally large semistandard tableaux with exactly \(n - 1\) rows over the alphabet \(\{1 < \cdots < n, \pi < \cdots < \bar{\pi}\}\) and subject to the following constraints:

- for each \(1 \leq i \leq n\), the contents of the boxes in the \(i\)-th row are \(\leq i\),
- the entries \(n\) and \(\pi\) may not appear simultaneously in a single row.

For more information, see InfinityCrystalOfTableaux.

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux("D4")
sage: b = B.highest_weight_vector().f_string([4,3,2,1,4])
sage: b.pp()
  1 1 1 1 1 1 2
  2 2 2 2 3
  3 -4 -3

sage: b.weight()
(-1, 0, -2, -1)
```

```
>>> from sage.all import *

>>> B = crystals.infinity.Tableaux("D4")

>>> b = B.highest_weight_vector().f_string([Integer(4),Integer(3),Integer(2),
                                           Integer(1),Integer(4)])

>>> b.pp()
  1 1 1 1 1 2
  2 2 2 2 3
  3 -4 -3

>>> b.weight()
(-1, 0, -2, -1)
```

class Element

Bases: InfinityCrystalOfTableauxElementTypeD, Element

Elements in \(B(\infty)\) crystal of tableaux for type \(D_n\).
module_generator()

Return the module generator (or highest weight element) of self.

The module generator is the unique tableau of shape \((n-1, \ldots, 2, 1)\) with weight 0.

EXAMPLES:

```
sage: T = crystals.infinity.Tableaux(['D',4])
sage: T.module_generator()
[[1, 1, 1], [2, 2], [3]]

>>> from sage.all import *
>>> T = crystals.infinity.Tableaux(['D',Integer(4)])
>>> T.module_generator()
[[1, 1, 1], [2, 2], [3]]
```

5.1.54 Crystals of Kac modules of the general-linear Lie superalgebra

class sage.combinat.crystals.kac_modules.CrystalOfKacModule(cartan_type, la, mu)

Bases: UniqueRepresentation, Parent

Crystal of a Kac module.

Let \( \mathfrak{g} \) be the general linear Lie superalgebra \( \mathfrak{gl}(m|n) \). Let \( \lambda \) and \( \mu \) be dominant weights for \( \mathfrak{gl}_m \) and \( \mathfrak{gl}_n \), respectively. Let \( K \) be the module \( K = \{f_\alpha\} \), where \( \alpha \) ranges over all odd positive roots. A Kac module is the \( U_q(\mathfrak{g}) \)-module constructed from the highest weight \( U_q(\mathfrak{gl}_m \oplus \mathfrak{gl}_n) \)-module \( V(\lambda, \mu) \) (induced to a \( U_q(\mathfrak{g}) \)-module in the natural way) by

\[
K(\lambda, \mu) := K \otimes_L V(\lambda, \mu),
\]

where \( L \) is the subalgebra generated by \( e_0 \) and \( U_q(\mathfrak{gl}_m \oplus \mathfrak{gl}_n) \).

The Kac module admits a \( U_q(\mathfrak{g}) \)-crystal structure by taking the crystal structure of \( K \) as given by \texttt{CrystalOfOddNegativeRoots} and the crystal \( B(\lambda, \mu) \) (the natural crystal structure of \( V(\lambda, \mu) \)).

Note: Our notation differs slightly from [Kwon2012] in that our last tableau is transposed.

EXAMPLES:

```
sage: K = crystals.KacModule(['A', [1,2]], [2], [1,1])
sage: K.cardinality()
576
sage: K.cardinality().factor()
2^6 * 3^2
sage: len(K.cartan_type().root_system().ambient_space().positive_odd_roots())
6
sage: mg = K.module_generator()
sage: mg
{}, [[-2, -2]], [[1], [2]])
sage: mg.weight()
(2, 0, 1, 1, 0)
sage: mg.f(-1)
({}, [[-2, -1]], [[1], [2]])
sage: mg.f(0)
({-e[-1]+e[1]}, [[-2, -2]], [[1], [2]])
```
sage: mg.f(1)
({}, [-2, -2], [[1], [3]])

sage: mg.f(2)

sage: sorted(K.highest_weight_vectors(), key=str)
[([-e[-1]+e[3]], [-2, -1], [[1], [2]]),
 ([-e[-1]+e[3]], [-2, -2], [[1], [2]]),
 ((), [-2, -2], [[1], [2]])]

>>> from sage.all import *

>>> K = crystals.KacModule(['A', [Integer(1), Integer(2)]], [Integer(2)],
 \rightarrow [Integer(1), Integer(1)])

>>> K.cardinality()
576

>>> K.cardinality().factor()
2^6 * 3^2

>>> len(K.cartan_type().root_system().ambient_space().positive_odd_roots())
6

>>> mg = K.module_generator()

>>> mg.weight()
(2, 0, 1, 1, 0)

>>> mg.f(-Integer(1))

>>> mg.f(Integer(0))

>>> mg.f(Integer(1))

>>> mg.f(Integer(2))

>>> sorted(K.highest_weight_vectors(), key=str)
[([-e[-1]+e[3]], [-2, -1], [[1], [2]]),
 ([-e[-1]+e[3]], [-2, -2], [[1], [2]]),
 ((), [-2, -2], [[1], [2]])]

sage: K = crystals.KacModule(['A', [1,1]], [2], [1])

sage: K.cardinality()
96

sage: K.cardinality().factor()
2^5 * 3

sage: len(K.cartan_type().root_system().ambient_space().positive_odd_roots())
4

sage: sorted(K.highest_weight_vectors(), key=str)
[([-e[-1]+e[1]], [-1], [[2]]),
 ([-e[-1]+e[2]], [-1], [[2]]),
 ((), [-1, -1], [[1]])]
>>> from sage.all import *
>>> K = crystals.KacModule(['A', [Integer(1), Integer(1)]], [Integer(2)],
                         [Integer(1)])
>>> K.cardinality()
96
>>> K.cardinality().factor()
2^5 * 3
>>> len(K.cartan_type().root_system().ambient_space().positive_odd_roots())
4

REFERENCES:

• [Kwon2012]

class Element
Bases: ElementWrapper

An element of a Kac module crystal.

\(e(i)\)

Return the action of the crystal operator \(e_i\) on \(self\).

EXAMPLES:

```
sage: K = crystals.KacModule(['A', [2,2]], [2,1], [1])
sage: mg = K.module_generator()
sage: mg.e(0)
sage: mg.e(1)
sage: mg.e(-1)
```

(continues on next page)
Return the action of the crystal operator $f_i$ on $self$.

EXAMPLES:

```python
sage: K = crystals.KacModule(['A', [2, 2]], [2, 1], [1])
sage: mg = K.module_generator()
sage: mg.f(-2)
({}, [[-3, -2], [-2]], [[1]])
sage: mg.f(-1)
({}, [[-3, -3], [-1]], [[1]])
sage: mg.f(0)
({-e[-1]+e[1]}, [[-3, -3], [-2]], [[1]])
sage: mg.f(1)
({}, [[-3, -3], [-2]], [[2]])
sage: mg.f(2)
sage: b = mg.f_string([1, 0, 1, -1, -2, 0, 1, 2, 0, -2, -1, 2, 0]); b
({-e[-3]+e[3], -e[-2]+e[1], -e[-1]+e[1], -e[-1]+e[2]},
  [[-3, -2], [-2]], [[3]])
```
```python
sage: K = crystals.KacModule(['A', [3,2]], [2,1], [5,1])
sage: mg = K.module_generator()
sage: mg.weight()
(2, 1, 0, 0, 5, 1, 0)
sage: mg.weight().is_dominant()
True
sage: mg.f(0).weight()
(2, 1, 0, -1, 6, 1, 0)
sage: b = mg.f_string([2,1,-3,-2,-1,1,1,0,-2,-1,2,1,1,0,2,-3,-2,-1])
sage: b.weight()
(0, 0, 1, 1, 4, 3)
```

```python
>>> from sage.all import *

>>> K = crystals.KacModule(['A', [Integer(3),Integer(2)]], [Integer(2),
Integer(1)], [Integer(5),Integer(1)])

>>> mg = K.module_generator()

>>> mg.weight()
(2, 1, 0, 0, 5, 1, 0)

>>> mg.weight().is_dominant()
True

>>> mg.f(Integer(0)).weight()
(2, 1, 0, -1, 6, 1, 0)

>>> b = mg.f_string([Integer(2),Integer(1),-Integer(3),-Integer(2),-
Integer(1),Integer(1),Integer(1),Integer(0),-Integer(2),-Integer(1),
Integer(2),Integer(1),Integer(1),Integer(0),Integer(2),-
Integer(3),-Integer(2),-Integer(1)])

>>> b.weight()
(0, 0, 1, 1, 4, 3)
```

---

```python
module_generator()
Return the module generator of self.

EXAMPLES:

```python
sage: K = crystals.KacModule(['A', [2,1]], [2,1], [1])
sage: K.module_generator()
({}, [[-3, -3], [-2]], [1])
```

```python
>>> from sage.all import *

>>> K = crystals.KacModule(['A', [Integer(2),Integer(1)]], [Integer(2),
Integer(1)], [1])

>>> K.module_generator()
({}, [[-3, -3], [-2]], [1])
```

---

```python
class sage.combinat.crystals.kac_modules.CrystalOfOddNegativeRoots(cartan_type)
Bases: UniqueRepresentation, Parent

Crystal of the set of odd negative roots.

Let $g$ be the general-linear Lie superalgebra $\mathfrak{gl}(m|n)$. This is the crystal structure on the set of negative roots as given by [Kwon2012].

More specifically, this is the crystal basis of the subalgebra of $U_q^{-}(\mathfrak{g})$ generated by $f_\alpha$, where $\alpha$ ranges over all odd positive roots. As $\mathbb{Q}(q)$-modules, we have

$$U_q^{-}(\mathfrak{g}) \cong K \otimes U_q^{-}(\mathfrak{gl}_m \oplus \mathfrak{gl}_n).$$

EXAMPLES:
```
class Element
    
    Bases: ElementWrapper
    
    An element of the crystal of odd negative roots.

    e(i)
    
    Return the action of the crystal operator e_i on self.

    EXAMPLES:

    sage: S = crystals.OddNegativeRoots(['A', [2,1]])
    sage: mg = S.module_generator(); mg
    ()
    sage: mg.f(0)
    (-e[-1]+e[1])
    sage: mg.f_string([0,-1,0,1,2,1,0])
    (-e[-2]+e[3], -e[-1]+e[1], -e[-1]+e[2])

    >>> from sage.all import *
    >>> S = crystals.OddNegativeRoots(['A', [Integer(2),Integer(1)]]))
    >>> mg = S.module_generator(); mg
    ()
    >>> mg.f(Integer(0))
    (-e[-1]+e[1])
    >>> mg.f_string([Integer(0),-Integer(1),Integer(0),Integer(1),Integer(2),
    -Integer(1),Integer(0)])
    (-e[-2]+e[3], -e[-1]+e[1], -e[-1]+e[2])

    >>> from sage.all import *
    >>> S = crystals.OddNegativeRoots(['A', [Integer(2),Integer(2)]]))
    >>> mg = S.module_generator()
    >>> mg.e(Integer(0))
    >>> mg.e(Integer(1))
    >>> b = mg.f_string([Integer(0),-Integer(1),Integer(0),Integer(1),Integer(2),
    -Integer(1),Integer(0)])
    >>> b.e(-Integer(1))
    >>> b.e(Integer(0))
    (-e[-2]+e[3], -e[-1]+e[1])
    >>> b.e(Integer(1))
    >>> b.e(Integer(2))
    (-e[-2]+e[2], -e[-1]+e[1])
    >>> b.e_string([Integer(2),Integer(1),Integer(0),-Integer(1),Integer(0)])
    ()
**epsilon(i)**

Return $\varepsilon_i$ of self.

**EXAMPLES:**

```
sage: S = crystals.OddNegativeRoots(['A', [2,2]])
sage: mg = S.module_generator()
sage: [mg.epsilon(i) for i in S.index_set()]
[0, 0, 0, 0, 0]
sage: b = mg.f_string([0,1,0,-1,0,-1,-2,-2,0]); b
{-e[-3]+e[1], -e[-3]+e[2], -e[-1]+e[1]}
sage: [b.epsilon(i) for i in S.index_set()]
[2, 0, 1, 0, 0]
sage: b = mg.f_string([0,1,0,-1,0,-1,-2,2,-1,0]); b
{-e[-3]+e[1], -e[-3]+e[3], -e[-2]+e[1], -e[-1]+e[1]}
sage: [b.epsilon(i) for i in S.index_set()]
[1, 0, 1, 0, 1]
```

**f(i)**

Return the action of the crystal operator $f_i$ on self.

**EXAMPLES:**

```
sage: S = crystals.OddNegativeRoots(['A', [2,2]])
sage: mg = S.module_generator()
sage: mg.f(0)
{-e[-1]+e[1]}
sage: mg.f(1)
sage: b = mg.f_string([0,1,0,-1,0]); b
{-e[-2]+e[3], -e[-1]+e[1]}
sage: b.f(-2)
{-e[-3]+e[3], -e[-1]+e[1]}
sage: b.f(-1)
sage: b.f(0)
sage: b.f(1)
{-e[-2]+e[3], -e[-1]+e[2]}
```

```python
>>> from sage.all import *
>>> S = crystals.OddNegativeRoots(['A', [Integer(2),Integer(2)]])
>>> mg = S.module_generator()
```
Combinatorics, Release 10.4

>>> mg.f(Integer(0))
{-e[-1]+e[1]}
>>> mg.f(Integer(1))

>>> b = mg.f_string([Integer(0),Integer(1),Integer(2),-Integer(1),
˓→Integer(0)]); b
{-e[-2]+e[3], -e[-1]+e[1]}
>>> b.f(-Integer(2))
{-e[-3]+e[3], -e[-1]+e[1]}
>>> b.f(-Integer(1))
>>> b.f(Integer(0))
>>> b.f(Integer(1))
{-e[-2]+e[3], -e[-1]+e[2]}

\(\phi(i)\)

Return \(\phi_i\) of self.

EXAMPLES:

```
sage: S = crystals.OddNegativeRoots(['A', [2,2]])
sage: mg = S.module_generator()
sage: [mg.phi(i) for i in S.index_set()]
[0, 0, 1, 0, 0]
sage: b = mg.f(0)
sage: [b.phi(i) for i in S.index_set()]
[0, 1, 0, 1, 0]
sage: b = mg.f_string([0,1,0,-1,0,-1]); b
{-e[-2]+e[1], -e[-2]+e[2], -e[-1]+e[1]}
sage: [b.phi(i) for i in S.index_set()]
[2, 0, 0, 1, 1]
```

```
>>> from sage.all import *
>>> S = crystals.OddNegativeRoots(['A', [Integer(2),Integer(2)]])
>>> mg = S.module_generator()
>>> [mg.phi(i) for i in S.index_set()]
[0, 0, 1, 0, 0]
>>> b = mg.f(Integer(0))
>>> [b.phi(i) for i in S.index_set()]
[0, 1, 0, 1, 0]
>>> b = mg.f_string([Integer(0),Integer(1),Integer(0),-Integer(1),
˓→Integer(0),-Integer(1)]); b
{-e[-2]+e[1], -e[-2]+e[2], -e[-1]+e[1]}
>>> [b.phi(i) for i in S.index_set()]
[2, 0, 0, 1, 1]
```

weight ()

Return the weight of self.

EXAMPLES:

```
sage: S = crystals.OddNegativeRoots(['A', [2,2]])
sage: mg = S.module_generator()
sage: mg.weight()
(0, 0, 0, 0, 0, 0)
sage: mg.weight([0,1,2,-1,-2]).weight()
(-1, 0, 0, 0, 1)
sage: mg.f_string([0,1,2,-1,-2,0,1,0,2]).weight()
(-1, 0, -2, 1, 0, 2)
```
```
>>> from sage.all import *
>>> S = crystals.OddNegativeRoots(['A', [Integer(2), Integer(2)]])
>>> mg = S.module_generator()
>>> mg.weight()
(0, 0, 0, 0, 0, 0)
>>> mg.f_string([Integer(0), Integer(1), Integer(2), -Integer(1), -Integer(2)]).weight()
(-1, 0, 0, 0, 1)
>>> mg.f_string([Integer(0), Integer(1), Integer(2), -Integer(1), -Integer(2), -Integer(0), Integer(1), Integer(0), Integer(2)]).weight()
(-1, 0, -2, 1, 0, 2)
```

```python
module_generator()

Return the module generator of self.

EXAMPLES:

```
sage: S = crystals.OddNegativeRoots(['A', [2,1]])
sage: S.module_generator()
{}
```

```
>>> from sage.all import *
>>> S = crystals.OddNegativeRoots(['A', [Integer(2), Integer(1)]])
>>> S.module_generator()
{}
```

```
sage.combinat.crystals.kac_modules.latex_dual(elt)

Return a latex representation of a type $A_n$ crystal tableau elt expressed in terms of dual letters.

The dual letter of $k$ is expressed as $n + 2 - k$.

EXAMPLES:

```
sage: from sage.combinat.crystals.kac_modules import latex_dual
sage: T = crystals.Tableaux(['A',2], shape=[2,1])
sage: print(latex_dual(T[0]))
\begin{array}{|c|c|}
\cline{1-2}
\lr{\overline{3}}&\lr{\overline{3}}\\
\cline{1-2}
\lr{\overline{2}}\\
\cline{1-1}
\end{array}
```
```
```
>>> from sage.all import *
>>> from sage.combinat.crystals.kac_modules import latex_dual
>>> T = crystals.Tableaux(['A',Integer(2)], shape=[Integer(2),Integer(1)])
```

```
sage.combinat.crystals.kac_modules.to_dual_tableau(elt)
```

5.1. Comprehensive Module List 687
Return a type $A_n$ crystal tableau $\text{elt}$ as a tableau expressed in terms of dual letters.

The dual letter of $k$ is expressed as $\overline{n + 2 - k}$ represented as $-(n + 2 - k)$.

EXAMPLES:

```python
sage: from sage.combinat.crystals.kac_modules import to_dual_tableau
sage: T = crystals.Tableaux(['A',2], shape=[2,1])
sage: ascii_art([to_dual_tableau(t) for t in T])
[ -3 -3 -3 -2 -3 -1 -3 -1 -2 -1 -3 -3 -3 -2 -2 -2 ]
[ -2 , -2 , -2 , -1 , -1 , -1 , -1 , -1 ]
```

```python
>>> from sage.all import *
>>> from sage.combinat.crystals.kac_modules import to_dual_tableau
>>> T = crystals.Tableaux(['A',Integer(2)], shape=[Integer(2),Integer(1)])
>>> ascii_art([to_dual_tableau(t) for t in T])
[ -3 -3 -3 -2 -3 -1 -3 -1 -2 -1 -3 -3 -3 -2 -2 -2 ]
[ -2 , -2 , -2 , -1 , -1 , -1 , -1 , -1 ]
```

5.1.55 Kirillov-Reshetikhin Crystals

```
class sage.combinat.crystals.kirillov_reshetikhin.AmbientRetractMap(base, ambient, pdict_inv, index_set, similarity_factor_domain=None, automorphism=None)
```

Bases: `Map`

The retraction map from the ambient crystal.

Consider a crystal embedding $\phi : X \rightarrow Y$, then the elements $X$ can be considered as a subcrystal of the ambient crystal $Y$. The ambient retraction is the partial map $\phi : Y \rightarrow X$ such that $\phi \circ \phi$ is the identity on $X$.

```
class sage.combinat.crystals.kirillov_reshetikhin.CrystalDiagramAutomorphism(C, on_hw, index_set=None, automorphism=None, cache=True)
```

Bases: `CrystalMorphism`

The crystal automorphism induced from the diagram automorphism.

For example, in type $A_n^{(1)}$ this is the promotion operator and in type $D_n^{(1)}$, this corresponds to the automorphism induced from interchanging the 0 and 1 nodes in the Dynkin diagram.

INPUT:

- $C$ – a crystal
• **on_hw** – a function for the images of the **index_set**-highest weight elements
• **index_set** – (default: the empty set) the index set
• **automorphism** – (default: the identity) the twisting automorphism
• **cache** – (default: True) cache the result

**is_embedding()**

Return **True** as **self** is a crystal isomorphism.

**EXAMPLES:**
```
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: K.promotion().is_isomorphism()
True
```
```
>>> from sage.all import *

K = crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
                             →Integer(2))
>>> K.promotion().is_isomorphism()
True
```

**is_isomorphism()**

Return **True** as **self** is a crystal isomorphism.

**EXAMPLES:**
```
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: K.promotion().is_isomorphism()
True
```
```
>>> from sage.all import *

K = crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
                             →Integer(2))
>>> K.promotion().is_isomorphism()
True
```

**is_strict()**

Return **True** as **self** is a crystal isomorphism.

**EXAMPLES:**
```
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: K.promotion().is_isomorphism()
True
```
```
>>> from sage.all import *

K = crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
                             →Integer(2))
>>> K.promotion().is_isomorphism()
True
```

**is_surjective()**

Return **True** as **self** is a crystal isomorphism.

**EXAMPLES:**
```python
crystals.KirillovReshetikhin(['A',3,1], 2,2)
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
```

class sage.combinat.crystals.kirillov_reshetikhin.CrystalOfTableaux_E7(car-
tan_type, shapes)

Bases: CrystalOfTableaux

The type $E_7$ crystal $B(s\Lambda_7)$.

This is a helper class for the corresponding class `$KR_{crystal} < sage.combinat.crystals.kirillov_reshetikhin.KR_{type,E7} > B^{s\lambda}$`.

module_generator (shape)

Return the module generator of self with shape shape.

Note: Only implemented for single rows (i.e., highest weight $s\Lambda_7$).

EXAMPLES:

```python
crystals.KirillovReshetikhin(['A',3,1], 2,2)
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystal: sage.combinat.crystals.kirillov_reshetikhin.KR_type_A(cartan_type, r, s)

Class of Kirillov-Reshetikhin crystals of type $A_n^{(1)}$.

EXAMPLES:

```python
crystals.KirillovReshetikhin(['A',3,1], 2,2)
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
  →Integer(2))
```
classical_decomposition()

Specifies the classical crystal underlying the KR crystal of type A.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['A', 3] and shape(s) [[2, 2]]
```

```python
>>> from sage.all import *

```  

```python
>> K = crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
Integer(2))
>> K.classical_decomposition()
The crystal of tableaux of type ['A', 3] and shape(s) [[2, 2]]
```

dynkin_diagram_automorphism(i)

Specifies the Dynkin diagram automorphism underlying the promotion action on the crystal elements. The automorphism needs to map node 0 to some other Dynkin node.

For type $A$ we use the Dynkin diagram automorphism which $i \mapsto i + 1 \mod n + 1$, where $n$ is the rank.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: K.dynkin_diagram_automorphism(0)
1
sage: K.dynkin_diagram_automorphism(3)
0
```

```python
>>> from sage.all import *

```  

```python
>> K = crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
Integer(2))
>> K.dynkin_diagram_automorphism(Integer(0))
1
>> K.dynkin_diagram_automorphism(Integer(3))
0
```

promotion()

Specifies the promotion operator used to construct the affine type $A$ crystal.

For type $A$ this corresponds to the Dynkin diagram automorphism which $i \mapsto i + 1 \mod n + 1$, where $n$ is the rank.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: b = K.classical_decomposition()(rows=[[1,2],[3,4]])
sage: K.promotion()(b)
[[1, 3], [2, 4]]
```
```python
>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2),
˓→Integer(2))
>>> b = K.classical_decomposition()(rows=[[Integer(1),Integer(2)],[Integer(3),
˓→Integer(4)])
>>> K.promotion()(b)
[[1, 3], [2, 4]]
>>> b = K.classical_decomposition()(rows=[[Integer(1),Integer(2)],
˓→[Integer(3), Integer(4)])
>>> K.promotion_inverse()(b)
[[1, 2], [3, 4]]
>>> b = K.classical_decomposition()(rows=[[Integer(1), Integer(2)],
˓→[Integer(3), Integer(3)])
>>> K.promotion_inverse()(K.promotion()(b))
[[1, 2], [3, 3]]
```

**promotion_inverse()**

Specifies the inverse promotion operator used to construct the affine type \(A\) crystal.

For type \(A\) this corresponds to the Dynkin diagram automorphism which \(i \mapsto i - 1 \mod n + 1\), where \(n\) is the rank.

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: b = K.classical_decomposition()(rows=[[1,3],[2,4]])
sage: K.promotion_inverse()(b)
[[1, 2], [3, 4]]
sage: b = K.classical_decomposition()(rows=[[1,2],[3,3]])
sage: K.promotion_inverse()(K.promotion()(b))
[[1, 2], [3, 3]]
```

```python
class sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(cartan_type, r, s, dual=None)
```

Bases: `KirillovReshetikhinGenericCrystal`

Class of Kirillov-Reshetikhin crystals \(B^{r,s}\) of type \(A^{(2)}_{2n}\) for \(1 \leq r \leq n\) in the realization with classical subalgebra \(B_n\). The Cartan type in this case is inputted as the dual of \(A^{(2)}_{2n}\).

This is an alternative implementation to `KR_type_box` that uses the classical decomposition into type \(C_n\) crystals.

**EXAMPLES:**

```python
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: K
Kirillov-Reshetikhin crystal of type ['BC', 2, 2]^* with (r,s)=(1,1)
sage: B = K(rows=[[[-1]])
sage: B.f(0)
[[1]]
sage: B.e(0)
```
We can now check whether the two KR crystals of type $A_4^{(2)}$ (namely the KR crystal and its dual construction) are isomorphic up to relabelling of the edges:

```
sage: C = CartanType(['A',4,2])
sage: K = crystals.KirillovReshetikhin(C,1,1)
sage: Kdual = crystals.KirillovReshetikhin(C.dual(),1,1)
sage: G = K.digraph()
sage: Gdual = Kdual.digraph()
sage: f = {0:2, 1:1, 2:0}
sage: Gnew = DiGraph(); Gnew.add_vertices(Gdual.vertices(sort=True)); Gnew.add_edges([(u,v,f[i]) for (u,v,i) in Gdual.edges(sort=True)])
sage: G.is_isomorphic(Gnew, edge_labels = True)
True
```
ambient_dict_pm_diagrams()  

Return a dictionary of all self-dual ± diagrams for the ambient crystal whose keys are their inner shape.

EXAMPLES:

```python
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: K.ambient_dict_pm_diagrams()
{{1: [[0, 0], [1]]},
 [2]: [[0, 0], [2]])
```

ambient_highest_weight_dict()  

Return a dictionary of all \{2, ... , n + 1\}-highest weight vectors in the ambient crystal. The key is the inner shape of their corresponding ± diagram, or equivalently, their \{2, ... , n + 1\} weight.

EXAMPLES:

```python
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 2)
sage: K.ambient_highest_weight_dict()
{{1: [[0, 0], [0]],
 [2]: [[0, 0], [1, 1], [0]],
 [2, 2]: [[0, 0], [0, 0], [2]])
```
classical_decomposition()

Return the classical crystal underlying the Kirillov-Reshetikhin crystal of type $A^{(2)}_{2n}$ with $B_n$ as classical subdiagram.

It is given by $B^{r,s} \cong \bigoplus_{\Lambda} B(\Lambda)$, where $B(\Lambda)$ is a highest weight crystal of type $B_n$ of highest weight $\Lambda$. The sum is over all weights $\Lambda$ obtained from a rectangle of width $s$ and height $r$ by removing horizontal dominoes. Here we identify the fundamental weight $\Lambda_i$ with a column of height $i$.

EXAMPLES:

```python
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 2, 2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['B', 2] and shape(s) [[], [2], [2, 2]]
```

from_ambient_crystal()

Return a map from the ambient crystal of type $B^{(1)}_{n+1}$ to the Kirillov-Reshetikhin crystal of type $A^{(2)}_{2n}$.

Note that this map is only well-defined on type $A^{(2)}_{2n}$ elements that are in the image under to_ambient_crystal().

EXAMPLES:

```python
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 2)
sage: b = K.ambient_crystal()(rows=[[2,2]])
sage: K.from_ambient_crystal()(b)
[[1, 1]]
```

highest_weight_dict()

Return a dictionary of the classical highest weight vectors of self whose keys are their shape.

EXAMPLES:

```python
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 2)
sage: K.highest_weight_dict()
{[]} : [], [2] : [[1, 1]]
```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, Integer(1),
                        Integer(2))
>>> K.highest_weight_dict()
{{}: [1], [2]: [[1, 1]]}
```

to_ambient_crystal()

Return a map from the Kirillov-Reshetikhin crystal of type $A_2^{(2)}$ to the ambient crystal of type $B_2^{(1)}$.

EXAMPLES:

```python
>>> from sage.all import *
>>> C = CartanType(['A',4,2]).dual()
>>> K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 2)
>>> b=K(rows=[[1,1]])
>>> K.to_ambient_crystal()(b)
[[2, 2]]
>>> K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 2, 2)
>>> b=K(rows=[[1,1]])
>>> K.to_ambient_crystal()(b)
[[1, 2], [2, -1]]
>>> K.to_ambient_crystal()(b).parent()
Kirillov-Reshetikhin crystal of type ['B', 3, 1] with (r,s)=(2,2)
```

class `sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2Element`

Bases: `KirillovReshetikhinGenericCrystalElement`
Class for the elements in the Kirillov-Reshetikhin crystals $B^{r,s}$ of type $A_{2n}^{(2)}$ for $r < n$ with underlying classical algebra $B_n$.

EXAMPLES:

```python
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 2)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2_with_category.element_class'>
```

```python
>>> from sage.all import *

>>> C = CartanType(['A',Integer(4),Integer(2)]).dual()

>>> K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, Integer(1), Integer(2))

>>> type(K.module_generators[Integer(0)])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2_with_category.element_class'>
```

**e0()**

Return $e_0$ on `self` by mapping `self` to the ambient crystal, calculating $e_1e_0$ there and pulling the element back.

EXAMPLES:

```python
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: b = K(rows=[[1]])
sage: b.e(0)  # indirect doctest
[[[-1]]]
```

```python
>>> from sage.all import *

>>> C = CartanType(['A',Integer(4),Integer(2)]).dual()

>>> K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, Integer(1), Integer(1))

>>> b = K(rows=[[Integer(1)]])

>>> b.e(Integer(0))  # indirect doctest
[[[-1]]]
```

**epsilon0()**

Calculate $\varepsilon_0$ of `self` by mapping the element to the ambient crystal and calculating $\varepsilon_1$ there.

EXAMPLES:

```python
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: b = K(rows=[[1]])

>>> b.epsilon(0)  # indirect doctest
1
```

```python
>>> from sage.all import *

>>> C = CartanType(['A',Integer(4),Integer(2)]).dual()

>>> K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, Integer(1), Integer(1))

>>> b = K(rows=[[Integer(1)]])

(continues on next page)```
b.epsilon(Integer(0))  # indirect doctest
1

Return $f_0$ on self by mapping self to the ambient crystal, calculating $f_1f_0$ there and pulling the element back.

EXAMPLES:

```python
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: b = K(rows=[[-1]])
sage: b.f(0)  # indirect doctest
[[1]]
```

phi0()

Calculate $\varphi_0$ of self by mapping the element to the ambient crystal and calculating $\varphi_1$ there.

EXAMPLES:

```python
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: b = K(rows=[[-1]])
sage: b.phi(0)  # indirect doctest
1
```

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_Bn(cartan_type, r, s, dual=None)

Bases: KirillovReshetikhinGenericCrystal

Class of Kirillov-Reshetikhin crystals $B_{n-s}$ of type $B_n^{(1)}$.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,2)
sage: K
Kirillov-Reshetikhin crystal of type ['B', 3, 1] with (r,s)=(3,2)
sage: b = K(rows=[[1],[2],[3]])
sage: b.f(0)
sage: b.e(0)
```
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,2)
sage: [b.weight() for b in K if b.is_highest_weight([1,2,3])]
[-Lambda[0] + Lambda[1], -2*Lambda[0] + 2*Lambda[3]]
sage: [b.weight() for b in K if b.is_highest_weight([0,2,3])]
\[
\rightarrow [3, 3])
\]

\[
sage: K = crystals.KirillovReshetikhin(['B', 3, 1], 3, 3)
\]

\[
sage: K.ambient_highest_weight_dict()
\]

\[
\{(3,): [[1, 1, 1]],
    (3, 1, 1): [[1, 1, 1], [2], [3]],
    (3, 2, 2): [[1, 1, 1], [2, 2], [3, 3]],
    (3, 3, 3): [[1, 1, 1], [2, 2, 2], [3, 3, 3]]
\]

from sage.all import *

\[
K = crystals.KirillovReshetikhin(['B', Integer(3), Integer(1)], Integer(3),
    \rightarrow [3, 3])
\]

\[
K.ambient_highest_weight_dict()
\]

\[
\{(2,): [[1, 1]], (2, 1, 1): [[1, 1], [2], [3]], (2, 2, 2): [[1, 1], [2, 2], \rightarrow [3, 3])
\]

\[
K = crystals.KirillovReshetikhin(['B', Integer(3), Integer(1)], Integer(3),
    \rightarrow [3, 3])
\]

\[
K.ambient_highest_weight_dict()
\]

\[
\{(3,): [[1, 1, 1]],
    (3, 1, 1): [[1, 1, 1], [2], [3]],
    (3, 2, 2): [[1, 1, 1], [2, 2], [3, 3]],
    (3, 3, 3): [[1, 1, 1], [2, 2, 2], [3, 3, 3]]
\]

classical_decomposition()

Return the classical crystal underlying the Kirillov-Reshetikhin crystal \(B_{n,s}^{\text{c}}\) of type \(B_{n}^{(1)}\).

It is the same as for \(r < n\), given by \(B_{n,s}^{\text{c}} \cong \bigoplus_{\Lambda} B(\Lambda)\), where \(\Lambda\) are weights obtained from a rectangle of width \(s/2\) and height \(n\) by removing horizontal dominoes. Here we identify the fundamental weight \(\Lambda_i\) with a column of height \(i\) for \(i < n\) and a column of width \(1/2\) for \(i = n\).

EXAMPLES:

\[
sage: K = crystals.KirillovReshetikhin(['B', 3, 1], 3, 2)
\]

\[
sage: K.classical_decomposition()
\]

The crystal of tableaux of type ['B', 3] and shape(s) [[1], [1, 1, 1]]

\[
sage: K = crystals.KirillovReshetikhin(['B', 3, 1], 3, 3)
\]

\[
sage: K.classical_decomposition()
\]

The crystal of tableaux of type ['B', 3] and shape(s) [[3/2, 1/2, 1/2], [3/2, \rightarrow 3/2, 3/2]]

from sage.all import *

\[
K = crystals.KirillovReshetikhin(['B', Integer(3), Integer(1)], Integer(3),
    \rightarrow Integer(2))
\]

\[
K.classical_decomposition()
\]

The crystal of tableaux of type ['B', 3] and shape(s) [[1], [1, 1, 1]]

\[
K = crystals.KirillovReshetikhin(['B', Integer(3), Integer(1)], Integer(3),
    \rightarrow Integer(3))
\]

\[
K.classical_decomposition()
\]

The crystal of tableaux of type ['B', 3] and shape(s) [[3/2, 1/2, 1/2], [3/2, \rightarrow 3/2, 3/2]]

from_ambient_crystal()

Return a map from the ambient crystal of type \(A_{2n-1}^{(2)}\) to the Kirillov-Reshetikhin crystal self.

Note that this map is only well-defined on elements that are in the image under to_ambient_crystal().
EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,1)
sage: [b == K.from_ambient_crystal()(K.to_ambient_crystal()(b)) for b in K]
[True, True, True, True, True, True, True, True]
sage: b = K.ambient_crystal()(rows=[[1],[2],[-3]])
sage: K.from_ambient_crystal()(b)
[++-, []]
```

```python
>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['B',Integer(3),Integer(1)],Integer(3),
˓→Integer(1))

>>> [b == K.from_ambient_crystal()(K.to_ambient_crystal()(b)) for b in K]
[True, True, True, True, True, True, True, True]

>>> b = K.ambient_crystal()(rows=[[Integer(1)], [Integer(2)], [-Integer(3)]])

>>> K.from_ambient_crystal()(b)
[++-, []]
```

**highest_weight_dict()**

Return a dictionary of the classical highest weight vectors of `self` whose keys are 2 times their shape.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,2)
sage: K.highest_weight_dict()
{(2,): [[1]], (2, 2, 2): [[1], [2], [3]]}
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,3)
sage: K.highest_weight_dict()
{(3, 1, 1): [+++, [[1]]], (3, 3, 3): [+++, [[1], [2], [3]]]}
```

```python
>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['B',Integer(3),Integer(1)],Integer(3),
˓→Integer(2))

>>> K.highest_weight_dict()
{(2,): [[1]], (2, 2, 2): [[1], [2], [3]]}

>>> K = crystals.KirillovReshetikhin(['B',Integer(3),Integer(1)],Integer(3),
˓→Integer(3))

>>> K.highest_weight_dict()
{(3, 1, 1): [+++, [[1]]], (3, 3, 3): [+++, [[1], [2], [3]]]}
```

**similarity_factor()**

Sets the similarity factor used to map to the ambient crystal.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,2)
sage: K.similarity_factor()
{1: 2, 2: 2, 3: 1}
```

```python
>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['B',Integer(3),Integer(1)],Integer(3),
˓→Integer(2))

>>> K.similarity_factor()
{1: 2, 2: 2, 3: 1}
```

**to_ambient_crystal()**

Return a map from `self` to the ambient crystal of type $A_{2n-1}^{(2)}$.  

5.1. Comprehensive Module List 701
EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,1)
sage: [K.to_ambient_crystal()(b) for b in K]
[[[1], [2], [3]], [[1], [2], [-3]], [[1], [3], [-2]], [[2], [3], [-1]], [[1], [-3], [-2]], [[2], [-3], [-1]], [[3], [-2], [-1]], [[-3], [-2], [-1]]
```

```python
>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['B',Integer(3),Integer(1)],Integer(3),-Integer(1))
```

```python
>>> [K.to_ambient_crystal()(b) for b in K]
[[[1], [2], [3]], [[1], [2], [-3]], [[1], [3], [-2]], [[2], [3], [-1]], [[1], [-3], [-2]], [[2], [-3], [-1]], [[3], [-2], [-1]], [[-3], [-2], [-1]]
```

### class `sage.combinat.crystals.kirillov_reshetikhin.KR_type_BnElement`

Class for the elements in the Kirillov-Reshetikhin crystals $B_n^\alpha$ of type $B_n^{(1)}$.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,2)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_Bn_with_category.element_class'>
```

```python
>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['B',Integer(3),Integer(1)],Integer(3),-Integer(1))
```

```python
>>> b = K.module_generators[Integer(0)]
```

```python
e0()  
Return $e_0$ on self by mapping self to the ambient crystal, calculating $e_0$ there and pulling the element back.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,1)  
sage: b = K.module_generators[0]  
sage: b.e(0)  
# indirect doctest
[---, []]
```

```python
>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['B',Integer(3),Integer(1)],Integer(3),-Integer(1))
```

```python
>>> b = K.module_generators[Integer(0)]
```

```python
epsilon0()  
Calculate $\varepsilon_0$ of self by mapping the element to the ambient crystal and calculating $\varepsilon_0$ there.

EXAMPLES:

```python
```
sage: K=crystals.KirillovReshetikhin(['B',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.epsilon(0) # indirect doctest
1

>>> from sage.all import *
>>> K=crystals.KirillovReshetikhin(['B',Integer(3),Integer(1)],Integer(3),
→Integer(1))
>>> b = K.module_generators[Integer(0)]
>>> b.epsilon(Integer(0)) # indirect doctest
1

f0()  
Return \( f_0 \) on \( self \) by mapping \( self \) to the ambient crystal, calculating \( f_0 \) there and pulling the element back.

EXAMPLES:

sage: K=crystals.KirillovReshetikhin(['B',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.f(0) # indirect doctest

>>> from sage.all import *
>>> K=crystals.KirillovReshetikhin(['B',Integer(3),Integer(1)],Integer(3),
→Integer(1))
>>> b = K.module_generators[Integer(0)]
>>> b.f(Integer(0)) # indirect doctest

phi0()  
Calculate \( \phi_0 \) of \( self \) by mapping the element to the ambient crystal and calculating \( \phi_0 \) there.

EXAMPLES:

sage: K=crystals.KirillovReshetikhin(['B',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.phi(0) # indirect doctest
0

>>> from sage.all import *
>>> K=crystals.KirillovReshetikhin(['B',Integer(3),Integer(1)],Integer(3),
→Integer(1))
>>> b = K.module_generators[Integer(0)]
>>> b.phi(Integer(0)) # indirect doctest
0

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_C(cartan_type, r, s, dual=None)

Bases: KirillovReshetikhinGenericCrystal

Class of Kirillov-Reshetikhin crystals \( B^r.s \) of type \( C^{(1)}_n \) for \( r < n \).

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['C',2,1], 1,2)
sage: K
Kirillov-Reshetikhin crystal of type ['C', 2, 1] with (r,s)=(1,2)

(continues on next page)
sage: b = K(rows=[])  
| sage: b.f(0)  
| \[
| [[1, 1]]  
| sage: b.e(0)  
| \[
| [[-1, -1]]  

```python  
>>> from sage.all import *  
>>> K = crystals.KirillovReshetikhin(['C',Integer(2),Integer(1)], Integer(1),  
\rightarrow Integer(2))  
>>> K  
Kirillov-Reshetikhin crystal of type ['C', 2, 1] with (r,s)=(1,2)  
>>> b = K(rows=[])  
>>> b.f(Integer(0))  
| \[
| [[1, 1]]  
| >>> b.e(Integer(0))  
| \[
| [[-1, -1]]  

**Element**

alias of KR_type_CElement

**ambient_crystal()**

Return the ambient crystal $B_{r,s}^{A_{2n+1}^{(2)}}$ of type $A_{2n+1}^{(2)}$ associated to the Kirillov-Reshetikhin crystal of type $C_n^{(1)}$.

This ambient crystal is used to construct the zero arrows.

**EXAMPLES:**

```python  
sage: K = crystals.KirillovReshetikhin(['C',3,1], 2,3)  
sage: K.ambient_crystal()  
Kirillov-Reshetikhin crystal of type ['B', 4, 1]^* with (r,s)=(2,3)  
>>> from sage.all import *  
>>> K = crystals.KirillovReshetikhin(['C',Integer(3),Integer(1)], Integer(2),  
\rightarrow Integer(3))  
>>> K.ambient_crystal()  
Kirillov-Reshetikhin crystal of type ['B', 4, 1]^* with (r,s)=(2,3)
```

**ambient_dict_pm_diagrams()**

Return a dictionary of all self-dual $\pm$ diagrams for the ambient crystal whose keys are their inner shape.

**EXAMPLES:**

```python  
sage: K = crystals.KirillovReshetikhin(['C',2,1], 1,2)  
sage: K.ambient_dict_pm_diagrams()  
{[1]: [[1, 1], [0]], [2]: [[0, 0], [2]]}  
sage: K = crystals.KirillovReshetikhin(['C',3,1], 2,2)  
sage: K.ambient_dict_pm_diagrams()  
{[1]: [[1, 1], [0, 0], [0]],  
[2]: [[0, 0], [1, 1], [0]],  
[2, 2]: [[0, 0], [0, 0], [2]]}  
sage: K = crystals.KirillovReshetikhin(['C',3,1], 2,3)  
sage: K.ambient_dict_pm_diagrams()  
{[1, 1]: [[1, 1], [0, 0], [1]],  
[3, 1]: [[0, 0], [1, 1], [1]],  
[3, 3]: [[0, 0], [0, 0], [3]]}  
```
ambient_highest_weight_dict()

Return a dictionary of all \(\{2, \ldots, n+1\}\)-highest weight vectors in the ambient crystal.

The key is the inner shape of their corresponding \(\pm\) diagram, or equivalently, their \(\{2, \ldots, n+1\}\) weight.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['C',3,1], 2,2)
sage: K.ambient_highest_weight_dict()
{[1]: [[2], [-2]], [2]: [[1, 2], [2, -1]], [2, 2]: [[2, 2], [3, 3]]}
```

classical_decomposition()

Return the classical crystal underlying the Kirillov-Reshetikhin crystal of type \(C_n^{(1)}\).

It is given by \(B_{t,s} \cong \bigoplus \Lambda \in B(\Lambda)\), where \(\Lambda\) are weights obtained from a rectangle of width \(s\) and height \(r\) by removing horizontal dominoes. Here we identify the fundamental weight \(\Lambda_i\) with a column of height \(i\).

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['C',3,1], 2,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['C', 3] and shape(s) [[], [1], [1]]
```

from_ambient_crystal()

Return a map from the ambient crystal of type \(A_{2n+1}^{(2)}\) to the Kirillov-Reshetikhin crystal of type \(C_n^{(1)}\).
Note that this map is only well-defined on type $C_n^{(1)}$ elements that are in the image under `to_ambient_crystal()`.

**EXAMPLES:**

```
sage: K = crystals.KirillovReshetikhin(['C',3,1], 2,2)
sage: b = K.ambient_crystal()(rows=[[2,2],[3,3]])
sage: K.from_ambient_crystal()(b)
[[1, 1], [2, 2]]
```

**highest_weight_dict()**

Return a dictionary of the classical highest weight vectors of `self` whose keys are their shape.

**EXAMPLES:**

```
sage: K = crystals.KirillovReshetikhin(['C',3,1], 2,2)
sage: K.highest_weight_dict()
```

**to_ambient_crystal()**

Return a map from the Kirillov-Reshetikhin crystal of type $C_n^{(1)}$ to the ambient crystal of type $A_{2n+1}^{(2)}$.

**EXAMPLES:**

```
sage: K = crystals.KirillovReshetikhin(['C',3,1], 2,2)
sage: b=K(rows=[[1,1]])
sage: K.to_ambient_crystal()(b)
[[1, 2], [2, -1]]
sage: b=K(rows=[])
sage: K.to_ambient_crystal()(b)
[[-2]]
sage: K.to_ambient_crystal()(b).parent()
Kirillov-Reshetikhin crystal of type ['B', 4, 1]^* with (r,s)=(2,2)
```

(continues on next page)
class sage.combinat.crystals.kirillov_reshetikhin.KR_type_CElement

Bases: KirillovReshetikhinGenericCrystalElement

Class for the elements in the Kirillov-Reshetikhin crystals $B^{r,s}$ of type $C_n^{(1)}$ for $r < n$.

EXAMPLES:

```python
sage: K=crystals.KirillovReshetikhin(['C',3,1],1,2)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_C_with_category.element_class'>
```

>>> from sage.all import *
```

```python
sage: K=crystals.KirillovReshetikhin(['C',Integer(3),Integer(1)],Integer(1), Integer(2))
sage: type(K.module_generators[Integer(0)])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_C_with_category.element_class'>
```

```python
>>> from sage.all import *
```

```python
e0()  

Return $e_0$ on self by mapping self to the ambient crystal, calculating $e_1e_0$ there and pulling the element back.

EXAMPLES:

```python
sage: K=crystals.KirillovReshetikhin(['C',3,1],1,2)
sage: b = K(rows=[])  
sage: b.e(0)  
# indirect doctest  
[[-1, -1]]
```

```python
>>> from sage.all import *
```

```python
sage: K=crystals.KirillovReshetikhin(['C',Integer(3),Integer(1)],Integer(1), Integer(2))
sage: b=K(rows=[Integer(1),Integer(1)])
```

```python
epsilon0()  

Calculate $\varepsilon_0$ of self by mapping the element to the ambient crystal and calculating $\varepsilon_1$ there.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['C',2,1], 1,2)
sage: b=K(rows=[[1,1]])  
sage: b.epsilon(0)  
# indirect doctest  
2
```

```python
>>> from sage.all import *
```

```python
sage: K = crystals.KirillovReshetikhin(['C',Integer(2),Integer(1)], Integer(1), Integer(2))
sage: b=K(rows=[[Integer(1),Integer(1)]])
```

```python
Return $f_0$ on `self` by mapping `self` to the ambient crystal, calculating $f_1f_0$ there and pulling the element back.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['C',3,1],1,2)
sage: b = K(rows=[])
sage: b.f(0) # indirect doctest
[[1, 1]]
```

Calculate $ϕ_0$ of `self` by mapping the element to the ambient crystal and calculating $ϕ_1$ there.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['C',2,1], 1,2)
sage: b=K(rows=[[-1,-1]])
sage: b.phi(0) # indirect doctest
2
```

Bases: `KirillovReshetikhinGenericCrystal`

Class of Kirillov-Reshetikhin crystals $B_n^r$ of type $C_n^{(1)}$.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['C',3,1],3,1)
sage: for b in K:
    print([b, b.f(0)])
```

```python
class sage.combinat.crystals.kirillov_reshetikhin.KR_type_Cn(cartan_type, r, s, dual=None)
```

(continues on next page)
Element alias of \texttt{KR\_type\_CnElement} \par
\textbf{classical\_decomposition()} \par
Specifies the classical crystal underlying the Kirillov-Reshetikhin crystal $B^{n,s}$ of type $C^{(1)}_n$.

The classical decomposition is given by $B^{n,s} \cong B(s\Lambda_n)$.

\textbf{EXAMPLES:} \par
\begin{verbatim}
sage: K = crystals.KirillovReshetikhin(['C',3,1],3,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['C', 3] and shape(s) [[2, 2, 2]]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['C',Integer(3),Integer(1)],Integer(3), Integer(2))

>>> K.classical_decomposition()
The crystal of tableaux of type ['C', 3] and shape(s) [[2, 2, 2]]
\end{verbatim}

\textbf{from\_highest\_weight\_vector\_to\_pm\_diagram(b)} \par
This gives the bijection between an element $b$ in the classical decomposition of the KR crystal that is $2, 3, \ldots, n$-highest weight and $\pm$ diagrams.

\textbf{EXAMPLES:} \par
\begin{verbatim}
sage: K = crystals.KirillovReshetikhin(['C',3,1],3,2)
sage: T = K.classical_decomposition()
sage: b = T(rows=[[2, 2], [3, 3], [-3, -1]])
sage: pm = K.from_highest_weight_vector_to_pm_diagram(b); pm
[[0, 0], [1, 0], [0, 1], [0]]
sage: pm.pp()
 . .
 . +
 _ _
sage: hw = [ b for b in T if all(b.epsilon(i)==0 for i in [2,3]) ]
sage: all(K.from_pm_diagram_to_highest_weight_vector(K.from_highest_weight_vector_to_pm_diagram(b)) == b for b in hw)
True
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['C',Integer(3),Integer(1)],Integer(3), Integer(2))

>>> T = K.classical_decomposition()

>>> b = T(rows=[[Integer(2), Integer(2)], [Integer(3), Integer(3)], [-
\end{verbatim}
from sage.combinat.crystals.kirillov_reshetikhin.PMDiagram(
    \[\[0, 0\], \[1, 0\], \[0, 1\], \[0\]\]
)

>>> pm = K.from_highest_weight_vector_to_pm_diagram(b); pm
\[\[0, 0\], \[1, 0\], \[0, 1\], \[0\]\]

>>> pm.pp()
. . + - -

>>> hw = [b for b in T if all(b.epsilon(i)==Integer(0) for i in [Integer(2), Integer(3)])]
>>> all(K.from_pm_diagram_to_highest_weight_vector(K.from_highest_weight_vector_to_pm_diagram(b)) == b for b in hw)
True

\textbf{from_pm_diagram_to_highest_weight_vector}(pm)

This gives the bijection between a ± diagram and an element \(b\) in the classical decomposition of the KR crystal that is \(\{2, 3, \ldots, n\}\)-highest weight.

\textbf{EXAMPLES:}

```python
sage: K = crystals.KirillovReshetikhin(['C',3,1],3,2)
sage: pm = sage.combinat.crystals.kirillov_reshetikhin.PMDiagram([[0, 0], [1, -0], [0, 1], [0]])
sage: K.from_pm_diagram_to_highest_weight_vector(pm)
[[2, 2], [3, 3], [-3, -1]]
```

```python
>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['C',Integer(3),Integer(1)],Integer(3), Integer(2))

>>> pm = sage.combinat.crystals.kirillov_reshetikhin.PMDiagram([[Integer(0), -Integer(0)], [Integer(1), Integer(0)], [Integer(0), Integer(1)], [-Integer(0)]])

>>> K.from_pm_diagram_to_highest_weight_vector(pm)
[[2, 2], [3, 3], [-3, -1]]
```

class \texttt{sage.combinat.crystals.kirillov_reshetikhin.KR\_type\_CnElement}

Bases: \texttt{KirillovReshetikhinGenericCrystalElement}

Class for the elements in the Kirillov-Reshetikhin crystals \(B^{n,s}\) of type \(C_n^{(1)}\).

\textbf{EXAMPLES:}

```python
sage: K=crystals.KirillovReshetikhin(['C',3,1],3,2)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_Cn_with_category.element_class'>
```

```python
>>> from sage.all import *

>>> K=crystals.KirillovReshetikhin(['C',Integer(3),Integer(1)],Integer(3), Integer(2))

>>> type(K.module_generators[Integer(0)])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_Cn_with_category.element_class'>
```

e0()

Return \(e_0\) on \texttt{self} by going to the ±-diagram corresponding to the \(\{2, \ldots, n\}\)-highest weight vector in the component of \texttt{self}, then applying [Definition 6.1, 4], and pulling back from ±-diagrams.
Combinatorics, Release 10.4

EXAMPLES:

```python
sage: K=crystals.KirillovReshetikhin(['C',3,1],3,2)
sage: b = K.module_generators[0]
sage: b.e(0) # indirect doctest
[[1, 2], [2, 3], [3, -1]]
sage: b = K(rows=[[1,2],[2,3],[3,-1]])
sage: b.e(0)
[[2, 2], [3, 3], [-1, -1]]
sage: b=K(rows=[[1,-3],[3,-2],[-3,-1]])
sage: b.e(0)
[[3, -3], [-3, -2], [-1, -1]]
```

```python
>>> from sage.all import *

>>> K=crystals.KirillovReshetikhin(['C',Integer(3),Integer(1)],Integer(3),-Integer(2))

>>> b = K.module_generators[Integer(0)]

>>> b.e(Integer(0)) # indirect doctest
[[1, 2], [2, 3], [3, -1]]

>>> b=K(rows=[[Integer(1),Integer(2)],[Integer(2),Integer(3)],[Integer(3),-Integer(1)]]))

>>> b.e(Integer(0))
[[2, 2], [3, 3], [-1, -1]]

>>> b=K(rows=[[Integer(1),-Integer(3)],[Integer(3),-Integer(2)],[-Integer(3),-Integer(1)]]))

>>> b.e(Integer(0))
[[3, -3], [-3, -2], [-1, -1]]
```

epsilon0()  
Calculate \( \varepsilon_0 \) of self using Lemma 6.1 of [4].

EXAMPLES:

```python
sage: K=crystals.KirillovReshetikhin(['C',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.epsilon(0) # indirect doctest
1
```

```python
>>> from sage.all import *

>>> K=crystals.KirillovReshetikhin(['C',Integer(3),Integer(1)],Integer(3),-Integer(1))

>>> b = K.module_generators[Integer(0)]

>>> b.epsilon(Integer(0)) # indirect doctest
1
```

f0()  
Return \( e_0 \) on self by going to the \( \pm \)-diagram corresponding to the \( \{2, ..., n\} \)-highest weight vector in the component of self, then applying [Definition 6.1, 4], and pulling back from \( \pm \)-diagrams.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['C',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.f(0) # indirect doctest
```

```python
>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['C',Integer(3),Integer(1)],Integer(3),-Integer(1))

>>> b = K.module_generators[Integer(0)]

>>> b.f(Integer(0)) # indirect doctest
```

(continues on next page)
Combinatorics, Release 10.4

```python
>>> Integer(1))
>>> b = K.module_generators[Integer(0)]
>>> b.f(Integer(0)) # indirect doctest
```

phi0()

Calculate $\varphi_0$ of self.

EXAMPLES:

```python
sage: K=crystals.KirillovReshetikhin(['C',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.phi(0) # indirect doctest
0
```

```python
>>> from sage.all import *
```
from sage.all import *
K = crystals.KirillovReshetikhin(['D', Integer(4), Integer(3)],
    -Integer(1), Integer(1))
[x.e0() for x in K]

epsilon0()

Return $\epsilon_0$ of self.

EXAMPLES:
sage: K = crystals.KirillovReshetikhin(['D',4,3], 1, 5)
sage: [mg.epsilon0() for mg in K.module_generators]
[5, 6, 7, 8, 9, 10]

f0()

Return the action of $f_0$ on self.

EXAMPLES:
sage: K = crystals.KirillovReshetikhin(['D',4,3], 1,1)
sage: [x.f0() for x in K]
[[[1]], None, None, None, None, [[2]], [[3]], []]

phi0()

Return $\phi_0$ of self.

EXAMPLES:
sage: K = crystals.KirillovReshetikhin(['D',4,3], 1, 5)
sage: [mg.phi0() for mg in K.module_generators]
[5, 4, 3, 2, 1, 0]

classical_decomposition()

Return the classical decomposition of self.

EXAMPLES:
sage: K = crystals.KirillovReshetikhin(['D',4,3], 1, 5)
sage: K.classical_decomposition()
The crystal of tableaux of type ['G', 2]
   and shape(s) [[], [1], [2], [3], [4], [5]]

>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['D',Integer(4),Integer(3)], Integer(1),
   →Integer(5))
>>> K.classical_decomposition()
The crystal of tableaux of type ['G', 2]
   and shape(s) [[], [1], [2], [3], [4], [5]]

from_coordinates (coords)
Return an element of self from the coordinates coords.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',4,3], 1, 5)
sage: K.from_coordinates((0, 2, 3, 1, 0, 1))
[[2, 2, 3, 0, -1]]

>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['D',Integer(4),Integer(3)], Integer(1),
   →Integer(5))
>>> K.from_coordinates((Integer(0), Integer(2), Integer(3), Integer(1),
   →Integer(0), Integer(1)))
[[2, 2, 3, 0, -1]]
The classical decomposition is given by $B^{n,s} \cong B(s\Lambda_n)$.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['D',4,2],3,1)
sage: K.classical_decomposition()
The crystal of tableaux of type ['B', 3] and shape(s) [[1/2, 1/2, 1/2]]

sage: K = crystals.KirillovReshetikhin(['D',4,2],3,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['B', 3] and shape(s) [[1, 1, 1]]
```

```python
from sage.all import *

>>> K = crystals.KirillovReshetikhin(['D',Integer(4),Integer(2)],Integer(3),
˓→Integer(1))
>>> K.classical_decomposition()
The crystal of tableaux of type ['B', 3] and shape(s) [[1/2, 1/2, 1/2]]

>>> K = crystals.KirillovReshetikhin(['D',Integer(4),Integer(2)],Integer(3),
˓→Integer(2))
>>> K.classical_decomposition()
The crystal of tableaux of type ['B', 3] and shape(s) [[1, 1, 1]]
```

fromHighestWeightVectorToPmDiagram($b$)

This gives the bijection between an element $b$ in the classical decomposition of the KR crystal that is \{2,3,...,n\}-highest weight and ± diagrams.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['D',4,2],3,1)
sage: T = K.classical_decomposition()
sage: hw = [ b for b in T if all(b.epsilon(i)==0 for i in [2,3]) ]
sage: [K.from_highest_weight_vector_to_pm_diagram(b) for b in hw]
[[[0, 0], [0, 0], [1, 0], [0]], [[0, 0], [0, 0], [0, 1], [0]]]

sage: K = crystals.KirillovReshetikhin(['D',4,2],3,2)
sage: T = K.classical_decomposition()
sage: hw = [ b for b in T if all(b.epsilon(i)==0 for i in [2,3]) ]
sage: [K.from_highest_weight_vector_to_pm_diagram(b) for b in hw]
[[[0, 0], [0, 0], [2, 0], [0]],
[[0, 0], [0, 0], [0, 0], [2]],
[[0, 0], [2, 0], [0, 0], [0]],
[[0, 0], [0, 0], [0, 2], [0]]]
```

```python
>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['D',Integer(4),Integer(2)],Integer(3),
˓→Integer(1))

>>> T = K.classical_decomposition()

>>> hw = [ b for b in T if all(b.epsilon(i)==Integer(0) for i in [2,3]) ]

>>> [K.from_highest_weight_vector_to_pm_diagram(b) for b in hw]
[[[0, 0], [0, 0], [1, 0], [0]], [[0, 0], [0, 0], [0, 1], [0]]]

>>> K = crystals.KirillovReshetikhin(['D',Integer(4),Integer(2)],Integer(3),
˓→Integer(2))

>>> T = K.classical_decomposition()

>>> hw = [ b for b in T if all(b.epsilon(i)==Integer(0) for i in [2,3]) ]

>>> [K.from_highest_weight_vector_to_pm_diagram(b) for b in hw]
[[[0, 0], [0, 0], [2, 0], [0]],
[[0, 0], [0, 0], [0, 0], [2]],
[[0, 0], [2, 0], [0, 0], [0]],
[[0, 0], [0, 0], [0, 2], [0]]]
```
Note that, since the classical decomposition of this crystal is of type $B_n$, there can be (at most one) entry 0 in the $\{2, 3, \ldots, n\}$-highest weight elements at height $n$. In the following implementation this is realized as an empty column of height $n$ since this uniquely specifies the existence of the 0.

**EXAMPLES:**

```python
sage: b = hw[1]
sage: pm = K.from_highest_weight_vector_to_pm_diagram(b)
sage: pm.pp()
. .
. .
. .
```

```python
>> from sage.all import *
>> b = hw[Integer(1)]
>> pm = K.from_highest_weight_vector_to_pm_diagram(b)
>> pm.pp()
. .
. .
```

**from_pm_diagram_to_highest_weight_vector** ($pm$)

This gives the bijection between a ± diagram and an element $b$ in the classical decomposition of the KR crystal that is $\{2, 3, \ldots, n\}$-highest weight.

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['D',4,2],3,2)
sage: pm = sage.combinat.crystals.kirillov_reshetikhin.PMDiagram([ [0,0], [0,0], [2] ])
sage: K.from_pm_diagram_to_highest_weight_vector(pm)
[ [2], [3], [0] ]
```

```python
>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['D',Integer(4),Integer(2)],Integer(3),
Integer(2))
>>> pm = sage.combinat.crystals.kirillov_reshetikhin.PMDiagram([ [Integer(0),
Integer(0), Integer(0), Integer(0)], [Integer(0), Integer(0), Integer(0)],
[Integer(2)] ])
>>> K.from_pm_diagram_to_highest_weight_vector(pm)
[ [2], [3], [0] ]
```

**class** `sage.combinat.crystals.kirillov_reshetikhin.KR_type_Dn_twistedElement`

**Bases:** KirillovReshetikhinGenericCrystalElement

Class for the elements in the Kirillov-Reshetikhin crystals $B_n^\ast$ of type $D_n^{(2)}$.  

**EXAMPLES:**

```python
sage: K=crystals.KirillovReshetikhin(['D',4,2],3,2)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_Dn_twisted_with_
category.element_class'>
```

```python
>>> from sage.all import *
>>> K=crystals.KirillovReshetikhin(['D',Integer(4),Integer(2)],Integer(3),
Integer(2))
```
Return \( e_0 \) on \( \text{self} \) by going to the \( \pm \)-diagram corresponding to the \( \{2, \ldots, n\} \)-highest weight vector in the component of \( \text{self} \), then applying [Definition 6.2, 4], and pulling back from \( \pm \)-diagrams.

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['D', 4, 2], 3, 3)
sage: b = K.module_generators[0]
sage: b.e(0) # indirect doctest
[++, [[2], [3], [0]]]
```

Calculate \( \epsilon_0 \) of \( \text{self} \) using Lemma 6.2 of [4].

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['D', 4, 2], 3, 1)
sage: b = K.module_generators[0]
sage: b.epsilon(0) # indirect doctest
1
```

Return \( f_0 \) on \( \text{self} \) by going to the \( \pm \)-diagram corresponding to the \( \{2, \ldots, n\} \)-highest weight vector in the component of \( \text{self} \), then applying [Definition 6.2, 4], and pulling back from \( \pm \)-diagrams.

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['D', 4, 2], 3, 2)
sage: b = K.module_generators[0]
sage: b.f(0) # indirect doctest
```
Calculate $\varphi_0$ of self.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['D',4,2],3,1)
sage: b = K.module_generators[0]
sage: b.phi(0) # indirect doctest
0
```

```python
>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['D',Integer(4),Integer(2)],Integer(3),
   \rightarrow Integer(1))
>>> b = K.module_generators[Integer(0)]
>>> b.phi(Integer(0)) # indirect doctest
0
```

```python
class sage.combinat.crystals.kirillov_reshetikhin.KR_type_E6(cartan_type, r, s)
Bases: KirillovReshetikhinCrystalFromPromotion

Class of Kirillov-Reshetikhin crystals of type $E_6^{(1)}$ for $r = 1, 2, 6$.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: K.module_generator().e(0)
[]
sage: K.module_generator().e(0).f(0)
[[(-2, -1), (1,)]]
sage: K = crystals.KirillovReshetikhin(['E',6,1], 1,1)
sage: b = K.module_generator()
sage: b
[(1,)]
sage: b.e(0)
[(-2, 1)]
sage: b = [t for t in K if t.epsilon(1) == 1 and t.phi(3) == 1 and t.phi(2) == 0...
   \rightarrow and t.epsilon(2) == 0][0]
sage: b
[(-1, 3)]
sage: b.e(0)
[(-1, -2, 3)]
```

```python
>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['E',Integer(6),Integer(1)],Integer(2),
   \rightarrow Integer(1))
>>> K.module_generator().e(Integer(0))
[]
>>> K.module_generator().e(Integer(0)).f(Integer(0))
[[(-2, -1), (1,)]]
>>> K = crystals.KirillovReshetikhin(['E',Integer(6),Integer(1)], Integer(1),
   \rightarrow Integer(1))
>>> b = K.module_generator()
>>> b
[(1,)]
>>> b.e(Integer(0))
[(-2, 1)]
>>> b = [t for t in K if t.epsilon(Integer(1)) == Integer(1) and t.
   \rightarrow phi(Integer(3)) == Integer(1) and t.
   \rightarrow phi(Integer(3)) == Integer(1) and t.phi(Integer(2)) == Integer(0) and t.
   \rightarrow (continues on next page)
The elements of the Kirillov-Reshetikhin crystals can be constructed from a classical crystal element using `retract()`.

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: La = K.cartan_type().classical().root_system().weight_lattice().fundamental_weights()
sage: H = crystals.HighestWeight(La[2])
sage: t = H.module_generator()
sage: t
[(2, -1), (1,)]
sage: type(K.retract(t))
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_E6_with_category.element_class'>
sage: K.retract(t).e(0)
[]
```

**affine_weight(b)**

Return the affine level zero weight corresponding to the element \( b \) of the classical crystal underlying \( \text{self} \).

For the coefficients to calculate the level, see Table Aff 1 in [Ka1990].

**EXAMPLES:**

```python
>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['E',6,1],Integer(2),Integer(1))
>>> La = K.cartan_type().classical().root_system().weight_lattice().fundamental_weights()
>>> H = crystals.HighestWeight(La[Integer(2)])
>>> t = H.module_generator()
>>> t
([[2, -1], (1,)])
>>> type(K.retract(t))
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_E6_with_category.element_class'>
>>> K.retract(t).e(Integer(0))
[]
```
automorphism_on_affine_weight(weight)

Act with the Dynkin diagram automorphism on affine weights as outputted by the affine_weight method.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: sorted([x[0], K.automorphism_on_affine_weight(x[0])]  
          ... for x in K.highest_weight_dict().values())
```

```plaintext
[(0, 0, 0, 0, 0, 0, 0),  
 (0, -2, 0, 1, 0, 0, 0)]
```
weight Lambda[2],
Finite dimensional highest weight crystal of type ['E', 6] and highest_
weight 2*Lambda[2])
sage: K = crystals.KirillovReshetikhin(['E',6,1], 1,2)
sage: K.classical_decomposition()
Direct sum of the crystals Family
(Finite dimensional highest weight crystal of type ['E', 6] and highest_
weight 2*Lambda[1],)

>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['E',Integer(6),Integer(1)], Integer(2),
 Integer(2))
>>> K.classical_decomposition()
Direct sum of the crystals Family
(Finite dimensional highest weight crystal of type ['E', 6] and highest_
weight 0,
Finite dimensional highest weight crystal of type ['E', 6] and highest_
weight Lambda[2],
Finite dimensional highest weight crystal of type ['E', 6] and highest_
weight 2*Lambda[2])

>>> K = crystals.KirillovReshetikhin(['E',Integer(6),Integer(1)], Integer(1),
 Integer(2))
>>> K.classical_decomposition()
Direct sum of the crystals Family
(Finite dimensional highest weight crystal of type ['E', 6] and highest_
weight 2*Lambda[1],)

dynkin_diagram_automorphism(i)

Specifies the Dynkin diagram automorphism underlying the promotion action on the crystal elements.

Here we use the Dynkin diagram automorphism of order 3 which maps node 0 to node 1.

EXAMPLES:
sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: [K.dynkin_diagram_automorphism(i) for i in K.index_set()]
[1, 6, 3, 5, 4, 2, 0]

>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['E',Integer(6),Integer(1)],Integer(2),
 Integer(1))
>>> [K.dynkin_diagram_automorphism(i) for i in K.index_set()]
[1, 6, 3, 5, 4, 2, 0]

highest_weight_dict()

Return a dictionary between \{1, 2, 3, 4, 5\}-highest weight elements, and a tuple of affine weights and its
classical component.

EXAMPLES:
sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: sorted(K.highest_weight_dict().items(), key=str)
[([(2, -1), (1,)], ((-2, 0, 1, 0, 0, 0, 0, 0), 1)),
 ([(3, -1, -6), (1,)], ((-1, 0, 0, 1, 0, 0, -1, 1),
 ([(5, -2, -6), (-6, 2)]), ((0, 0, 0, 0, 0, 1, -2, 1),
 ([(6, -2), (-6, 2)]), ((0, 0, 0, 0, 0, 0, 0, 0), 1)),
 ([(2, -1), (1,)], ((-2, 0, 1, 0, 0, 0, 0, 0), 1)),
 ([(3, -1, -6), (1,)], ((-1, 0, 0, 1, 0, 0, -1, 1),
 ([(5, -2, -6), (-6, 2)]), ((0, 0, 0, 0, 0, 1, -2, 1),
 ([(6, -2), (-6, 2)]), ((0, 0, 0, 0, 0, 0, 0, 0), 1))]

5.1. Comprehensive Module List
>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['E',Integer(6),Integer(1)],Integer(2),
       Integer(1))
>>> sorted(K.highest_weight_dict().items(), key=str)
[(([(2, -1), (1,)]), ((-2, 0, 1, 0, 0, 0, 0), 1)),
(([(3, -1, -6), (1,)]), ((-1, 0, 0, 1, 0, 0, -1), 1)),
(([(5, -2, -6), (-6, 2)]), (0, 0, 0, 0, 1, -2), 1)),
(([(6, -2), (-6, 2)]), (0, 0, 0, 0, 0, 0), 1)),
([], (0, 0, 0, 0, 0, 0), 0))]

highest_weight_dict_inv()
Return a dictionary between a tuple of affine weights and a classical component, and \{2, 3, 4, 5, 6\}-highest weight elements.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: K.highest_weight_dict_inv()
{((-2, 0, 1, 0, 0, 0, 0), 1): [(2, -1), (1,)],
((-1, -1, 0, 0, 0, 1, 0), 1): [(5, -3), (-1, 3)],
((0, -2, 0, 1, 0, 0, 0), 1): [(-1,), (-1, 3)],
((0, 0, 0, 0, 0, 0, 0), 0): [],
((0, 0, 0, 0, 0, 0, 0), 1): [(1, -3), (-1, 3)]}

hw_auxiliary()
Return the 2, 3, 4, 5 highest weight elements of self.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: K.hw_auxiliary()
([], [(2, -1), (1,)], [(5, -3), (-1, 3)], [(6, -2), (-6, 2)],
[(-1,), (-6, 2)], [(3, -1, -6), (1,)], [(4, -3, -6), (-1, 3)],
[(1, -3), (-1, 3)], [(-1,), (-1, 3)])
**promotion()**

Specifies the promotion operator used to construct the affine type $E_n^{(1)}$ crystal.

**EXAMPLES:**

```
sage: K = crystals.KirillovReshetikhin(['E',6,1], 2,1)
sage: promotion = K.promotion()
sage: all(promotion(promotion(promotion(b))) == b for b in K.classical_decomposition())
True
```

```
>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['E','6','1'], Integer(2), Integer(1))
>>> promotion = K.promotion()
>>> all(promotion(promotion(promotion(b))) == b for b in K.classical_decomposition())
True
```

**promotion_inverse()**

Return the inverse promotion. Since promotion is of order 3, the inverse promotion is the same as promotion applied twice.

**EXAMPLES:**

```
sage: K = crystals.KirillovReshetikhin(['E',6,1], 2,1)
sage: p = K.promotion()
sage: p_inv = K.promotion_inverse()
sage: all(p_inv(p(b)) == b for b in K.classical_decomposition())
True
```

```
>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['E','6','1'], Integer(2), Integer(1))
>>> p = K.promotion()
```
>>> p_inv = K.promotion_inverse()
>>> all(p_inv(p(b)) == b for b in K.classical_decomposition())
True

**promotion_on_highest_weight_vectors()**

Return a dictionary of the promotion map on \( \{1, 2, 3, 4, 5\} \)-highest weight elements to \( \{2, 3, 4, 5, 6\} \)-highest weight elements in \self{}.

**EXAMPLES:**

```
sage: K = crystals.KirillovReshetikhin(['E',6,1], 2, 1)
sage: dic = K.promotion_on_highest_weight_vectors()
sage: sorted(dic.items(), key=str)
[([(2, -1), (1,)], [(1, -3), (-1, 3)]),
 ([(3, -1, -6), (1,)], [(5, -3), (-1, 3)]),
 ([(5, -2, -6), (-6, 2)], [(2, -1), (1,)]),
 ([(6, -2), (-6, 2)], []),
 ([(1, -3), (-1, 3)]),]
```

```
>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['E',Integer(6),Integer(1)], Integer(2), Integer(1))
>>> dic = K.promotion_on_highest_weight_vectors()
>>> sorted(dic.items(), key=str)
[([(2, -1), (1,)], [(1, -3), (-1, 3)]),
 ([(3, -1, -6), (1,)], [(5, -3), (-1, 3)]),
 ([(5, -2, -6), (-6, 2)], [(2, -1), (1,)]),
 ([(6, -2), (-6, 2)], []),
 ([(1, -3), (-1, 3)]),]
```

**promotion_on_highest_weight_vectors_function()**

Return a lambda function on \x{} defined by \self.promotion_on_highest_weight_vectors()[x].

**EXAMPLES:**

```
sage: K = crystals.KirillovReshetikhin(['E',6,1], 2, 1)
sage: f = K.promotion_on_highest_weight_vectors_function()
sage: f(K.module_generator().lift())
[(-1,), (-1, 3)]
```

```
>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['E',Integer(6),Integer(1)], Integer(2), Integer(1))
>>> f = K.promotion_on_highest_weight_vectors_function()
>>> f(K.module_generator().lift())
[(-1,), (-1, 3)]
```

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_E7(ct, r, s)

Bases: KirillovReshetikhinGenericCrystal

The Kirillov-Reshetikhin crystal \( B_7^{s} \) of type \( E_7^{(1)} \).

**A7_decomposition()**

Return the decomposition of \self{} into \( A_7 \) highest weight crystals.

The \( A_7 \) decomposition of \( B_7^{s} \) is given by the parameters \( m_4, m_5, m_6, m_7 \geq 0 \) such that \( m_4 + m_5 \leq m_7 \) and \( s = m_4 + m_5 + m_6 + m_7 \). The corresponding \( A_7 \) highest weight crystal has highest weight \( \lambda = \ldots \)
\[(m_7 - m_4 - m_5)\Lambda_6 + m_5\Lambda_4 + m_6\Lambda_2.\]

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['E',7,1], 7, 3)
sage: K.A7_decomposition()
The crystal of tableaux of type ['A', 7] and shape(s)
[[3, 3, 3, 3, 3, 3], [3, 3, 2, 2, 2, 2], [3, 3, 1, 1, 1, 1], [3, 3],
 [2, 2, 2, 2, 1, 1], [2, 2, 1, 1], [1, 1, 1, 1, 1, 1], [1, 1]]
```

```python
>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['E',Integer(7),Integer(1)], Integer(7),-
integer(3))
>>> K.A7_decomposition()
The crystal of tableaux of type ['A', 7] and shape(s)
[[3, 3, 3, 3, 3, 3], [3, 3, 2, 2, 2, 2], [3, 3, 1, 1, 1, 1], [3, 3],
 [2, 2, 2, 2, 1, 1], [2, 2, 1, 1], [1, 1, 1, 1, 1, 1], [1, 1]]
```

class Element
Bases: KirillovReshetikhinGenericCrystalElement
e0()

Return the action of \(e_0\) on self.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['E',7,1], 7, 2)
sage: mg = K.module_generator()
sage: mg.e0()
[[[7], (-1, 7)]]
sage: mg.e0().e0()
[[(-1, 7), (-1, 7)]]
sage: mg.e_string([0,0,0]) is None
True
```

```python
>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['E',Integer(7),Integer(1)],-
integer(7), Integer(2))
>>> mg = K.module_generator()
>>> mg.e0()
[[[7], (-1, 7)]]
>>> mg.e0().e0()
[[(-1, 7), (-1, 7)]]
>>> mg.e_string([Integer(0),Integer(0),Integer(0)]) is None
True
```

f0()

Return the action of \(f_0\) on self.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['E',7,1], 7, 2)
sage: mg = K.module_generator()
sage: x = mg.f_string([7,6,5,4,3,2,4,5,6,1,3,4,5,2,4,3,1])
sage: x.f0()
[[[7], (7)]]
sage: mg.f0() is None
True
```

5.1. Comprehensive Module List
classical_decomposition()

Return the classical decomposition of self.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['E', 7, 1], 7, 4)
sage: K.classical_decomposition()
The crystal of tableaux of type ['E', 7] and shape(s) [[4]]
```

from_A7_crystal()

Return the inclusion of the KR crystal $B_{7,s}^{E(1)}$ of type $E_7^{(1)}$ into type $A_7$ highest weight crystals.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['E', 7, 1], 7, 2)
sage: K.from_A7_crystal()
['A', 6] -> ['E', 7, 1] Virtual Crystal morphism:
  From: The crystal of tableaux of type ['A', 7] and shape(s)
  [[2, 2, 2, 2, 2, 2], [2, 2, 1, 1, 1, 1], [2, 2], [1, 1, 1, 1], []]
  To: Kirillov-Reshetikhin crystal of type ['E', 7, 1] with (r,s)=(7,2)
  Defn: ...
```

to_A7_crystal()

Return the map decomposing the KR crystal $B_{7,s}^{E(1)}$ of type $E_7^{(1)}$ into type $A_7$ highest weight crystals.

EXAMPLES:
```python
sage: K = crystals.KirillovReshetikhin(['E',7,1], 7, 2)
sage: K.to_A7_crystal()

Virtual Crystal morphism:
    From: Kirillov-Reshetikhin crystal of type ['E', 7, 1] with (r,s)=(7,2)
    To:   The crystal of tableaux of type ['A', 7] and shape(s)
           [[2, 2, 2, 2, 2, 2], [2, 2, 1, 1, 1, 1], [2, 2], [1, 1, 1, 1], []]
Defn: ...

>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['E','Integer(7)','Integer(1)'], Integer(7),
                                           Integer(2))
>>> K.to_A7_crystal()

Virtual Crystal morphism:
    From: Kirillov-Reshetikhin crystal of type ['E', 7, 1] with (r,s)=(7,2)
    To:   The crystal of tableaux of type ['A', 7] and shape(s)
           [[2, 2, 2, 2, 2, 2], [2, 2, 1, 1, 1, 1], [2, 2], [1, 1, 1, 1], []]
Defn: ...
```

```python
class sage.combinat.crystals.kirillov_reshetikhin.KR_type_box(cartan_type, r, s)
    Bases: KirillovReshetikhinGenericCrystal, AffineCrystalFromClassical

Class of Kirillov-Reshetikhin crystals $B^{r,s}$ of type $A_{2n}^{(2)}$ for $r \leq n$ and type $D_{n+1}^{(2)}$ for $r < n$.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['A',4,2], 1,1)
sage: K
Kirillov-Reshetikhin crystal of type ['BC', 2, 2] with (r,s)=(1,1)
sage: b = K(rows=[])  # Create a crystal
sage: b.f(0)
[[1]]
sage: b.e(0)
[[[-1]]]

>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['A','Integer(4)','Integer(2)'], Integer(1),
                                           Integer(1))
>>> K
Kirillov-Reshetikhin crystal of type ['BC', 2, 2] with (r,s)=(1,1)
>>> b = K(rows=[])  # Create a crystal
>>> b.f(Integer(0))
[[1]]
>>> b.e(Integer(0))
[[[-1]]]

Element
    alias of KR_type_boxElement

ambient_crystal()

    Return the ambient crystal $B^{r,2s}$ of type $C_n^{(1)}$ associated to the Kirillov-Reshetikhin crystal.

    The ambient crystal is used to construct the zero arrows.

    EXAMPLES:
```
sage: K = crystals.KirillovReshetikhin(['A',4,2], 2,2)
sage: K.ambient_crystal()
Kirillov-Reshetikhin crystal of type ['C', 2, 1] with (r,s)=(2,4)

>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['A',Integer(4),Integer(2)], Integer(2),
          Integer(2))

>>> K.ambient_crystal()
Kirillov-Reshetikhin crystal of type ['C', 2, 1] with (r,s)=(2,4)

ambient_highest_weight_dict()

Return a dictionary of the classical highest weight vectors of the ambient crystal of self whose keys are their shape.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['A',6,2], 2,2)
sage: K.ambient_highest_weight_dict()
{[], [1], [2], [1, 1], [2, 1], [2, 2], [1, 1, 1], [2, 2, 2], [2, 2, 2, 2]}

>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['A',Integer(6),Integer(2)], Integer(2),
          Integer(2))

>>> K.ambient_highest_weight_dict()
{[], [1], [2], [1, 1], [2, 1], [2, 2], [1, 1, 1], [2, 2, 2], [2, 2, 2, 2]}

classical_decomposition()

Return the classical crystal underlying the Kirillov-Reshetikhin crystal of type $A^{(2)}_{2n}$ and $D^{(2)}_{n+1}$.

It is given by $B^{r,s} \cong \bigoplus_{\Lambda} B(\Lambda)$, where $\Lambda$ are weights obtained from a rectangle of width $s$ and height $r$ by removing boxes. Here we identify the fundamental weight $\Lambda_i$ with a column of height $i$.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['A',4,2], 2,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['C', 2] and shape(s) [[], [1], [2], [1, 1],
          [2, 1], [2, 2], [1, 1, 1], [2, 2, 2], [2, 2, 2, 2]]

sage: K = crystals.KirillovReshetikhin(['D',4,2], 2,3)
sage: K.classical_decomposition()
The crystal of tableaux of type ['B', 3] and shape(s) [[], [1], [2], [1, 1],
          [2, 1], [2, 2], [3, 2], [3, 3]]

>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['A',Integer(4),Integer(2)], Integer(2),
          Integer(2))

(continues on next page)
from sage.all import *

K = crystals.KirillovReshetikhin(['A',6,2], 2,2)
K.highest_weight_dict()

>>> from sage.all import *

K = crystals.KirillovReshetikhin(['A',Integer(6),Integer(2)], Integer(2),
   ->Integer(2))
K.highest_weight_dict()

(continues on next page)
similarity_factor()

Sets the similarity factor used to map to the ambient crystal.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['A', 6, 2], 2, 2)
sage: K.similarity_factor()
{1: 2, 2: 2}
sage: K = crystals.KirillovReshetikhin(['D', 5, 2], 1, 1)
sage: K.similarity_factor()
{1: 2, 2: 2, 3: 2, 4: 1}

>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['A', Integer(6), Integer(2)], Integer(2),
˓→ Integer(2))
>>> K.similarity_factor()
{1: 2, 2: 2, 3: 2}
>>> K = crystals.KirillovReshetikhin(['D', Integer(5), Integer(2)], Integer(1),
˓→ Integer(1))
>>> K.similarity_factor()
{1: 2, 2: 2, 3: 2, 4: 1}

to_ambient_crystal()

Return a map from self to the ambient crystal of type $C_n^{(1)}$.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D', 4, 2], 1, 1)
sage: [K.to_ambient_crystal()(b) for b in K]
[[], [[1, 1]], [[2, 2]], [[3, 3]], [[3, -3]], [[-3, -3]], [[-2, -2]], [[-1, -1]]]

sage: K = crystals.KirillovReshetikhin(['A', 4, 2], 1, 1)
sage: [K.to_ambient_crystal()(b) for b in K]
[[], [[1, 1]], [[2, 2]], [[-2, -2]], [[-1, -1]]]

>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['D', Integer(4), Integer(2)], Integer(1),
˓→ Integer(1))

>>> [K.to_ambient_crystal()(b) for b in K]
[[], [[1, 1]], [[2, 2]], [[3, 3]], [[3, -3]], [[-3, -3]], [[-2, -2]], [[-1, -1]]]

>>> K = crystals.KirillovReshetikhin(['A', Integer(4), Integer(2)], Integer(1),
˓→ Integer(1))

>>> [K.to_ambient_crystal()(b) for b in K]
[[], [[1, 1]], [[2, 2]], [[-2, -2]], [[-1, -1]]]

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_boxElement

Bases: KirillovReshetikhinGenericCrystalElement

Class for the elements in the Kirillov-Reshetikhin crystals $B_{r-s}^r$ of type $A_{2n+2}$ for $r \leq n$ and type $D_{n+1}$ for $r < n$. 
EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['A', 4, 2], 1, 2)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_box_with_category.element_class'>
```

```python
>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['A', Integer(4), Integer(2)], Integer(1), Integer(2))

>>> type(K.module_generators[Integer(0)])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_box_with_category.element_class'>
```

```python
e0()

Return $e_0$ on self by mapping self to the ambient crystal, calculating $e_0$ there and pulling the element back.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['A', 4, 2], 1, 1)
sage: b = K(rows=[])  
sage: b.e(0)  # indirect doctest
[[-1]]
```

```python
>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['A', Integer(4), Integer(2)], Integer(1), Integer(2))

>>> b = K(rows=[])  

>>> b.e(Integer(0))  # indirect doctest
[[-1]]
```

```python
epsilon0()

Return $\varepsilon_0$ of self by mapping the element to the ambient crystal and calculating $\varepsilon_0$ there.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['A', 4, 2], 1, 1)

sage: b = K(rows=[[1]])  

sage: b.epsilon(0)  # indirect doctest
2
```

```python
>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['A', Integer(4), Integer(2)], Integer(1), Integer(2))

>>> b = K(rows=[[Integer(1)]])  

>>> b.epsilon(Integer(0))  # indirect doctest
2
```

```python
f0()

Return $f_0$ on self by mapping self to the ambient crystal, calculating $f_0$ there and pulling the element back.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['A', 4, 2], 1, 1)

sage: b = K(rows=[])  
```

(continues on next page)
sage: b.f(0)  # indirect doctest
[[1]]

>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['A',Integer(4),Integer(2)],Integer(1),
           →Integer(1))

>>> b = K(rows=[])  

>>> b.f(Integer(0))  # indirect doctest
[[1]]

phi0()

Return $\varphi_0$ of self by mapping the element to the ambient crystal and calculating $\varphi_0$ there.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',3,2], 1,1)
sage: b = K(rows=[[-1]])
sage: b.phi(0)  # indirect doctest
2

>>> from sage.all import *

>>> K = crystals.KirillovReshetikhin(['D',Integer(3),Integer(2)], Integer(1),
           →Integer(1))

>>> b = K(rows=[[-Integer(1)]])

>>> b.phi(Integer(0))  # indirect doctest
2

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_spin(cartan_type, r, s)

Bases: KirillovReshetikhinCrystalFromPromotion

Class of Kirillov–Reshetikhin crystals $B_{m,s}^n$ of type $D_1^n$.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',4,1],4,1); K
Kirillov–Reshetikhin crystal of type ['D', 4, 1] with (r,s)=(4,1)
sage: [b,b.f(0)] for b in K
[[[[++++, []]], None], [[++--, []], None], [[+--+, []], None],
 [[-++-, []], None], [[+-+-, []], None], [[++-+, []], None],
 [[-+++], [], [++++, []]], [[------, []], [++++, []]]]

sage: K = crystals.KirillovReshetikhin(['D',4,1],4,2); K
Kirillov–Reshetikhin crystal of type ['D', 4, 1] with (r,s)=(4,2)
sage: [b,b.f(0)] for b in K
[[[[1], [2], [3], [4]], None], [[1], [2], [-4], [4]], None],
 [[1], [3], [-4], [4]], None], [[2], [3], [-4], [4]], None],
 [[1], [4], [-4], [4]], None], [[2], [4], [-4], [4]], None],
 [[3], [4], [-4], [4]], [[1], [2], [3], [4]],
 [[-4], [4], [-4], [4]], [[1], [2], [-4], [4]],
 [[-4], [4], [-4], [-3]], [[1], [2], [-4], [-3]],
 [[-4], [4], [-4], [-2]], [[1], [3], [-4], [-3]],
 [[-4], [4], [-4], [-1]], [[2], [3], [-4], [-3]],
 [[-4], [4], [-3], [-2]], [[1], [4], [-4], [-3]],
 [[-4], [4], [-3], [-1]], [[2], [4], [-4], [-3]],
 [[-4], [4], [-2], [-1]], [[-4], [4], [-4], [-3]],
 [[-4], [-3], [-2], [-1]], [[-4], [4], [-4], [-3]],

(continues on next page)
classical_decomposition()

Return the classical crystal underlying the Kirillov-Reshetikhin crystal $B^{r,s}$ of type $D_n^{(1)}$ for $r = n - 1, n$.

The classical decomposition is given by $B^{r,s} \cong B(s\Lambda_r)$.
EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['D',4,1],4,1)
sage: K.classical_decomposition()
The crystal of tableaux of type ['D', 4] and shape(s) [[1/2, 1/2, 1/2, 1/2]]
sage: K = crystals.KirillovReshetikhin(['D',4,1],3,1)
sage: K.classical_decomposition()
The crystal of tableaux of type ['D', 4] and shape(s) [[1/2, 1/2, 1/2, -1/2]]
sage: K = crystals.KirillovReshetikhin(['D',4,1],3,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['D', 4] and shape(s) [[1, 1, 1, -1]]
```

`dynkin_diagram_automorphism(i)`

Specifies the Dynkin diagram automorphism underlying the promotion action on the crystal elements.

Here we use the Dynkin diagram automorphism which interchanges nodes 0 and 1 and leaves all other nodes unchanged.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['D',4,1],4,1)
sage: K.dynkin_diagram_automorphism(0)
1
sage: K.dynkin_diagram_automorphism(1)
0
sage: K.dynkin_diagram_automorphism(4)
4
```

`promotion()`

Return the promotion operator on $B^{r,s}$ of type $D^{(1)}_n$ for $r = n - 1, n$.

EXAMPLES:
sage: K = crystals.KirillovReshetikhin(['D',4,1],3,1)
sage: T = K.classical_decomposition()
sage: promotion = K.promotion()
sage: for t in T:
    print("{} {}").format(t, promotion(t))

[+++-, []] [-++-, []]
[+--+], [], [-++-, []]
[---+, []] [+-++, []]
[-----, []] [+---, []]
[--+-, []] [+-+-, []]
[---+, []] [+--+, []]
[---+, []] [+-++, []]

>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['D',Integer(4),Integer(1)],Integer(3),
                   Integer(1))
>>> T = K.classical_decomposition()
>>> promotion = K.promotion()
>>> for t in T:
    print("{} {}").format(t, promotion(t))

[+++-, []] [-++-, []]
[+--+], [], [-++-, []]
[---+, []] [+-++, []]
[-----, []] [+---, []]
[--+-, []] [+-+-, []]
[---+, []] [+--+, []]
[---+, []] [+-++, []]

promotion_inverse()

Return the inverse promotion operator on $B_{r,s}^{r,s}$ of type $D_n^{(1)}$ for $r = n-1, n$. EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',4,1],3,1)
sage: T = K.classical_decomposition()
sage: promotion = K.promotion()
sage: promotion_inverse = K.promotion_inverse()
sage: all(promotion_inverse(promotion(t)) == t for t in T)
True

>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['D',Integer(4),Integer(1)],Integer(3),
                   Integer(1))
>>> T = K.classical_decomposition()
>>> promotion = K.promotion()
>>> promotion_inverse = K.promotion_inverse()
>>> all(promotion_inverse(promotion(t)) == t for t in T)
True

promotion_on_highest_weight_vectors()

Return the promotion operator on $\{2,3,\ldots,n\}$-highest weight vectors.

A $\{2,3,\ldots,n\}$-highest weight vector in $B(s\Lambda_n)$ of weight $w = (w_1,\ldots,w_n)$ is mapped to a $\{2,3,\ldots,n\}$-highest weight vector in $B(s\Lambda_{n-1})$ of weight $(-w_1,w_2,\ldots,w_n)$ and vice versa.

See also:
promotion_on_highest_weight_vectors_inverse()

Return the inverse promotion operator on \{2, 3, \ldots, n\}-highest weight vectors.

See also:

- promotion_on_highest_weight_vectors()
- promotion_inverse()

EXAMPLES:
```python
sage: KR = crystals.KirillovReshetikhin(['D',4,1],3,2)
sage: prom = KR.promotion_on_highest_weight_vectors()
sage: prom_inv = KR.promotion_on_highest_weight_vectors_inverse()
sage: T = KR.classical_decomposition()
sage: HW = [t for t in T if t.is_highest_weight([2,3,4])]
sage: all(prom_inv[prom[t]] == t for t in HW)
True
```

```python
from sage.all import *
KR = crystals.KirillovReshetikhin(['D',Integer(4),Integer(1)],Integer(2))
prom = KR.promotion_on_highest_weight_vectors()
prom_inv = KR.promotion_on_highest_weight_vectors_inverse()
T = KR.classical_decomposition()
HW = [t for t in T if t.is_highest_weight([Integer(2),Integer(3),Integer(4)])]
all(prom_inv[prom[t]] == t for t in HW)
```

```python
class sage.combinat.crystals.kirillov_reshetikhin.KR_type_vertical(cartan_type, r, s):
    Bases: KirillovReshetikhinCrystalFromPromotion

Class of Kirillov-Reshetikhin crystals $B^{r,s}$ of type $D_n^{(1)}$ for $r \leq n - 2$, $B_n^{(1)}$ for $r < n$, and $A_{2n-1}^{(2)}$ for $r \leq n$.

EXAMPLES:
```
sage: K = crystals.KirillovReshetikhin(['D',4,1], 2,2)
sage: b = K(rows=[])
sage: b.f(0)
[[1], [2]]
sage: b.f(0).f(0)
[[1, 1], [2, 2]]
sage: b.e(0)
[[-2], [-1]]
sage: b.e(0).e(0)
[[2, -2], [-1, -1]]
sage: K = crystals.KirillovReshetikhin(['D',5,1], 3,1)
sage: b = K(rows=[[1]])
sage: b.e(0)
[[3], [-3], [-2]]
sage: K = crystals.KirillovReshetikhin(['B',3,1], 1,1)
sage: [b,b.f(0)] for b in K
[[[]], [[1]], None, [[2]], None, [[3]], None, [[0]], None, [[-3]], None, [[-2]], [[1]], [[-1]], [[2]]]
sage: K = crystals.KirillovReshetikhin(['A',5,2], 1,1)
sage: [b,b.f(0)] for b in K
[[[]], [[1]], None, [[2]], None, [[3]], None, [[-3]], None, [[-2]], [[1]], [[-1]], [[2]]]
```
```
Combinatorics, Release 10.4

```python
>>> b.f(Integer(0))
[[1], [2]]
>>> b.f(Integer(0)).f(Integer(0))
[[1, 1], [2, 2]]
>>> b.e(Integer(0))
[[-2], [-1]]
>>> b.e(Integer(0)).e(Integer(0))
[[-2, -2], [-1, -1]]

``` classical_decomposition()

Specifies the classical crystal underlying the Kirillov-Reshetikhin crystal of type $D_n^{(1)}$, $B_n^{(1)}$, and $A_{2n-1}^{(2)}$.

It is given by $B^{s,r} \cong \bigoplus_{\Lambda} B(\Lambda)$, where $\Lambda$ are weights obtained from a rectangle of width $s$ and height $r$ by removing vertical dominoes. Here we identify the fundamental weight $\Lambda_i$ with a column of height $i$.

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['D',4,1], 2,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['D', 4] and shape(s) [[], [1, 1], [2, 2]]
```

dynkin_diagram_automorphism(i)

Specifies the Dynkin diagram automorphism underlying the promotion action on the crystal elements. The automorphism needs to map node 0 to some other Dynkin node.

Here we use the Dynkin diagram automorphism which interchanges nodes 0 and 1 and leaves all other nodes unchanged.

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['D',4,1],1,1)
sage: K.dynkin_diagram_automorphism(0)
```
from highest_weight_vector_to_pm_diagram(b)

This gives the bijection between an element \( b \) in the classical decomposition of the KR crystal that is 2, 3, ..., \( n \)-highest weight and \( \pm \) diagrams.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['D',4,1], 2,2)
sage: T = K.classical_decomposition()
sage: b = T(rows=[[2],[-2]])
sage: pm = K.from_highest_weight_vector_to_pm_diagram(b); pm
[[1, 1], [0, 0], [0]]
sage: pm.pp()
+
-

sage: hw = [ b for b in T if all(b.epsilon(i)==0 for i in [2,3,4]) ]
sage: all(K.from_pm_diagram_to_highest_weight_vector(K.from_highest_weight_vector_to_pm_diagram(b)) == b for b in hw)
True
```
from pm_diagram_to_highest_weight_vector (pm)

This gives the bijection between a \( \pm \) diagram and an element \( b \) in the classical decomposition of the KR crystal that is \( 2, 3, \ldots, n \)-highest weight.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2)
sage: pm = sage.combinat.crystals.kirillov_reshetikhin.PMDiagram([[1, 1], [0, -1], [0]])
sage: K.from_pm_diagram_to_highest_weight_vector(pm)
[[2], [-2]]
```

promotion()

Specifies the promotion operator used to construct the affine type \( D_n^{(1)} \) etc. crystal. This corresponds to the Dynkin diagram automorphism which interchanges nodes 0 and 1, and leaves all other nodes unchanged. On the level of crystals it is constructed using \( \pm \) diagrams.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2)
sage: promotion = K.promotion()
sage: b = K.classical_decomposition()(rows=[])  
sage: promotion(b)
[[1, 2], [-2, -1]]
```
promote_inverse()

Return inverse of promotion.

In this case promotion is an involution, so promotion inverse equals promotion.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2)
sage: promotion = K.promotion()
sage: promotion_inverse = K.promotion_inverse()
sage: all( promotion_inverse(promotion(b.lift())) == b.lift() for b in K )
True
```

promotion_on_highest_weight_vector(b)

Calculates promotion on a $2, 3, ..., n$ highest weight vector $b$.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2)
sage: T = K.classical_decomposition()
sage: hw = [ b for b in T if all(b.epsilon(i)==0 for i in [2, 3, 4]) ]
sage: [K.promotion_on_highest_weight_vector(b) for b in hw]
[[[1, 2], [-2, -1]], [[2, 2], [-2, -1]], [[1, 2], [3, -1]],
[[2], [-2]], [[1, 2], [2, -2]], [[2, 2], [-1, -1]],
[[2, 2], [3, -1]], [[2, 2], [3, 3]], [], [[1], [2]],
[[1, 1], [2, 2]], [[2], [-1]], [[1, 2], [2, -1]],
[[2], [3]], [[1, 2], [2, 3]]]
```

sage.combinat.crystals.kirillov_reshetikhin.KashiwaraNakashimaTableaux(car-
tan_type, r, s)

Return the Kashiwara-Nakashima model for the Kirillov-Reshetikhin crystal $B_{r,s}$ in the given type.
The Kashiwara-Nakashima (KN) model constructs the KR crystal from the KN tableaux model for the corresponding classical crystals. This model is named for the underlying KN tableaux.

Many Kirillov-Reshetikhin crystals are constructed from a classical crystal together with an automorphism \( p \) on the level of crystals which corresponds to a Dynkin diagram automorphism mapping node 0 to some other node \( i \). The action of \( f_0 \) and \( e_0 \) is then constructed using \( f_0 = p^{-1} \circ f_i \circ p \).

For example, for type \( A_n^{(1)} \) the Kirillov-Reshetikhin crystal \( B^{r,s} \) is obtained from the classical crystal \( B(s\omega_r) \) using the promotion operator. For other types, see [Shi2002], [Sch2008], and [JS2010].

Other Kirillov-Reshetikhin crystals are constructed using similarity methods. See Section 4 of [FOS2009].

For more information on Kirillov-Reshetikhin crystals, see KirillovReshetikhinCrystal().

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2, 1)
sage: K2 = crystals.kirillov_reshetikhin.KashiwaraNakashimaTableaux(['A',3,1], 2, 1)
sage: K is K2
True
```

```python
>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(2), Integer(1))
>>> K2 = crystals.kirillov_reshetikhin.KashiwaraNakashimaTableaux(['A',Integer(3), Integer(1)], Integer(2), Integer(1))
>>> K is K2
True
```

Return the Kirillov-Reshetikhin crystal \( B^{r,s} \) of the given type in the given model.

For more information about general crystals see sage.combinat.crystals.crystals.

There are a variety of models for Kirillov-Reshetikhin crystals. There is one using the classical crystal with Kashiwara-Nakashima tableaux. There is one using rigged configurations. Another tableau model comes from the bijection between rigged configurations and tensor products of tableaux called Kirillov-Reshetikhin tableaux. Lastly there is a model of Kirillov-Reshetikhin crystals for \( s = 1 \) from crystals of LS paths.

INPUT:

- `cartan_type` – an affine Cartan type
- `r` – a label of finite Dynkin diagram
- `s` – a positive integer
- `model` – (default: 'KN') can be one of the following:
  - 'KN' or 'KashiwaraNakashimaTableaux' – use the Kashiwara-Nakashima tableaux model
  - 'KR' or 'KirillovReshetikhinTableaux' – use the Kirillov-Reshetikhin tableaux model
  - 'RC' or 'RiggedConfiguration' – use the rigged configuration model
  - 'LSPaths' – use the LS path model

EXAMPLES:
```python
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2, 1)
sage: K.index_set()
(0, 1, 2, 3)
sage: K.list()
([[[1], [2]], [[1], [3]], [[2], [3]], [[1], [4]], [[2], [4]], [[3], [4]]])
sage: b=K(rows=[[1],[2]])
sage: b.weight()
-Lambda[0] + Lambda[2]
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2, 2)
```

```python
sage: K.automorphism(K.module_generators[0])
[[[2, 2], [3, 3]]
sage: K.module_generators[0].e(0)
[[[1, 2], [2, 4]]
sage: K.module_generators[0].f(2)
[[[1, 1], [2, 3]]
sage: K.module_generators[0].f(1)

0
sage: K.module_generators[0].phi(0)
0
sage: K.module_generators[0].phi(1)
2
sage: K.module_generators[0].epsilon(0)
2
sage: K.module_generators[0].epsilon(1)
0
sage: K.module_generators[0].epsilon(2)
0
```

```python
sage: b = K(rows=[[1,2],[2,3]])
sage: b
[[1, 2], [2, 3]]
sage: b.f(2)
[[1, 2], [3, 3]]
```

```python
sage: K = crystals.KirillovReshetikhin(['D',4,1], 2, 1)
sage: K.cartan_type()
['D', 4, 1]
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_vertical_with_
˓
category.element_class'>
```

```python
>>> from sage.all import *

sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinCrystalFromLSPaths(car-
tan_type, r, s=1)

Single column Kirillov-Reshetikhin crystals.

This yields the single column Kirillov-Reshetikhin crystals from the projected level zero LS paths, see CrystalOfLSPaths. This works for all types (even exceptional types). The weight of the canonical element in this crystal is $\Lambda_r$. For other implementation see KirillovReshetikhinCrystal().

EXAMPLES:
sage: K = crystals.kirillov_reshetikhin.LSPaths(['A',2,1],2) # indirect doctest
sage: KR = crystals.KirillovReshetikhin(['A',2,1],2)

(continues on next page)
sage: G = K.digraph()
sage: GR = KR.digraph()
sage: G.is_isomorphic(GR, edge_labels = True)  # doctest: +NORMALIZE_WHITESPACE
True

sage: K = crystals.kirillov_reshetikhin.LSPaths(['C', 3, 1], 2)
sage: KR = crystals.KirillovReshetikhin(['C', 3, 1], 2, 1)
sage: G = K.digraph()
sage: GR = KR.digraph()
sage: G.is_isomorphic(GR, edge_labels = True)  # doctest: +NORMALIZE_WHIT
True

sage: K = crystals.kirillov_reshetikhin.LSPaths(['E', 6, 1], 1)
sage: KR = crystals.KirillovReshetikhin(['E', 6, 1], 1, 1)
sage: G = K.digraph()
sage: GR = KR.digraph()
sage: G.is_isomorphic(GR, edge_labels = True)  # doctest: +NORMALIZE_WHITESPACE

```python
class sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinCrystalFromPromotion:
    def __init__(self, classical_type, r, s):
        pass

class sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinCrystalFromPromotionElement:
    def __init__(self, *args, **kwargs):
        pass
```

**class sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinCrystalFromPromotion**

**Bases:**  
*KirillovReshetikhinGenericCrystal, AffineCrystalFromClassicalAndpromotion*

This generic class assumes that the Kirillov-Reshetikhin crystal is constructed from a classical crystal using the classical_decomposition and an automorphism promotion and its inverse, which corresponds to a Dynkin diagram automorphism dynkin_diagram_automorphism.

Each instance using this class needs to implement the methods:

- classical_decomposition
- promotion
- promotion_inverse
- dynkin_diagram_automorphism

**Element**

alias of *KirillovReshetikhinCrystalFromPromotionElement*

**class sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinCrystalFromPromotionElement**

**Bases:**  
*AffineCrystalFromClassicalAndpromotionElement, KirillovReshetikhinGenericCrystalElement*

Element for a Kirillov-Reshetikhin crystal from promotion.
class sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystal(cartan_type, r, s, dual=None):

    Bases: AffineCrystalFromClassical

    Generic class for Kirillov-Reshetikhin crystal $B^{r,s}$ of the given type.
    Input is a Dynkin node $r$, a positive integer $s$, and a Cartan type cartan_type.

    Element
        alias of KirillovReshetikhinGenericCrystalElement

classically_highest_weight_vectors()
    Return the classically highest weight vectors of self.

    EXAMPLES:

    sage: K = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2)
    sage: K.classically_highest_weight_vectors()
    ([], [[1], [2]], [[1, 1], [2, 2]])

    kirillov_reshetikhin_tableaux()
    Return the corresponding set of KirillovReshetikhinTableaux.

    EXAMPLES:

    sage: KRC = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2)
    sage: KRC.kirillov_reshetikhin_tableaux()
    Kirillov-Reshetikhin tableaux of type ['D', 4, 1] and shape (2, 2)

    module_generator()
    Return the unique module generator of classical weight $s\Lambda_r$ of a Kirillov-Reshetikhin crystal $B^{r,s}$

    EXAMPLES:

    sage: K = crystals.KirillovReshetikhin(['C', 2, 1], 1, 2)
    sage: K.module_generator()
    [[1, 1]]
    sage: K = crystals.KirillovReshetikhin(['E', 6, 1], 1, 1)
    sage: K.module_generator()
    [(1,)]
    sage: K = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2)

(continues on next page)
sage: K.module_generator()
[[1], [2]]

>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['C',Integer(2),Integer(1)],Integer(1),
    →Integer(2))
>>> K.module_generator()
[[1], [1]]
>>> K = crystals.KirillovReshetikhin(['E',Integer(6),Integer(1)],Integer(1),
    →Integer(1))
>>> K.module_generator()
[(1,)]
>>> K = crystals.KirillovReshetikhin(['D',Integer(4),Integer(1)],Integer(2),
    →Integer(1))
>>> K.module_generator()
[[1], [2]]

r()

Return r of the underlying Kirillov-Reshetikhin crystal $B^{r,s}$.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',4,1], 2, 1)
sage: K.r()
2

>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['D',4,1], 2, 1)
>>> K.r()
2

s()

Return s of the underlying Kirillov-Reshetikhin crystal $B^{r,s}$.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',4,1], 2, 1)
sage: K.s()
1

>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['D',4,1], 2, 1)
>>> K.s()
1

class sage.combinat.crystals.kirillov_reshetikhin.
KirillovReshetikhinGenericCrystalElement

Bases: AffineCrystalFromClassicalElement

Abstract class for all Kirillov-Reshetikhin crystal elements.

lusztig_involution()

Return the classical Lusztig involution on self.
EXAMPLES:

```python
sage: KRC = crystals.KirillovReshetikhin(['D',4,1], 2,2)
sage: elt = KRC(-1,2); elt
[[2], [-1]]
sage: elt.lusztig_involution()
[[1], [-2]]
```

```python
>>> from sage.all import *
>>> KRC = crystals.KirillovReshetikhin(['D',Integer(4),Integer(1)],...
˓→Integer(2),Integer(2))
>>> elt = KRC(-Integer(1),Integer(2)); elt
[[2], [-1]]
>>> elt.lusztig_involution()
[[1], [-2]]
```

```python
pp()  
Pretty print self.
```

EXAMPLES:

```python
sage: C = crystals.KirillovReshetikhin(['D',4,1], 2,1)
sage: C(2,1).pp()
  1
  2
sage: C = crystals.KirillovReshetikhin(['B',3,1], 3,3)
sage: C.module_generators[0].pp()
+ (X) 1
+
```

```python
>>> from sage.all import *
>>> C = crystals.KirillovReshetikhin(['D',Integer(4),Integer(1)], Integer(2),...
˓→Integer(1))
>>> C(Integer(2),Integer(1)).pp()
  1
  2
>>> C = crystals.KirillovReshetikhin(['B',Integer(3),Integer(1)], Integer(3),...
˓→Integer(3))
>>> C.module_generators[Integer(0)].pp()
+ (X) 1
+
```

to_kirillov_reshetikhin_tableau()

Construct the corresponding KirillovReshetikhinTableauxElement from self.

We construct the Kirillov-Reshetikhin tableau element as follows:

1. Let $\lambda$ be the shape of self.
2. Determine a path $\epsilon_i \epsilon_{i_2} \cdots \epsilon_{i_k}$ to the highest weight.
3. Apply $f_{i_k} \cdots f_{i_2} f_{i_1}$ to a highest weight KR tableau from filling the shape $\lambda$.

EXAMPLES:

```python
sage: KRC = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1)
sage: KRC(columns=[[2,1]]).to_kirillov_reshetikhin_tableau()
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: KRC = crystals.KirillovReshetikhin(['D', 4, 1], 2, 1)
sage: KRC(rows=[]).to_kirillov_reshetikhin_tableau()
[[[1], [-1]]
```

```
>>> from sage.all import *

>>> KRC = crystals.KirillovReshetikhin(['A', Integer(4), Integer(1)],
                                            →Integer(2), Integer(1))

>>> KRC(columns=[[Integer(2),Integer(1)]]).to_kirillov_reshetikhin_tableau()
[[[1], [2]]
```

```python
to_tableau()

Return the Tableau corresponding to self.

EXAMPLES:

sage: C = crystals.KirillovReshetikhin(['D',4,1], 2,1)
sage: t = C(2,1).to_tableau(); t
[[[1], [2]]
sage: type(t)
<class 'sage.combinat.tableau.Tableaux_all_with_category.element_class'>
```

```
>>> from sage.all import *

>>> C = crystals.KirillovReshetikhin(['D',Integer(4),Integer(1)], Integer(2),
                                            →Integer(1))

>>> t = C(Integer(2),Integer(1)).to_tableau(); t
[[[1], [2]]
```

```python
class sage.combinat.crystals.kirillov_reshetikhin.PMDiagram(pm_diagram,
                                                        from_shapes=None)

Bases: CombinatorialObject

Class of ± diagrams. These diagrams are in one-to-one bijection with \( X_{n-1} \) highest weight vectors in an \( X_n \) highest weight crystal \( X = B, C, D \). See Section 4.1 of [Sch2008].

The input is a list \( pm = [([a_0, b_0], [a_1, b_1], ..., [a_{n-1}, b_{n-1}], [b_n]) \) of pairs and a last 1-tuple (or list of length 1). The pair \([a_i, b_i]\) specifies the number of \( a_i \) + and \( b_i \) − in the \( i \)-th row of the ± diagram if \( n - i \) is odd and the number of \( a_i \) ± pairs above row \( i \) and \( b_i \) columns of height \( i \) not containing any + or − if \( n - i \) is even.

Setting the option from_shapes = True one can also input a ± diagram in terms of its outer, intermediate, and inner shape by specifying a list \([n, s, outer, intermediate, inner] \) where \( s \) is the width of the ± diagram, and outer, intermediate, and inner are the outer, intermediate, and inner shapes, respectively.

EXAMPLES:

sage: from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram

sage: pm = PMDiagram([[0,1],[1,2],[1]])
sage: pm.pm_diagram

[[0, 1], [1, 2], [1]]
sage: pm._list
```
sage: pm.n
2
sage: pm.width
5
sage: pm.pp()
. . .
 . + - -

sage: PMDiagram([2, 5, [4, 4], [4, 2], [4, 1]], from_shapes=True)
[[0, 1], [1, 2], [1]]

heights_of_addable_plus()  
Return a list with the heights of all addable plus in the $\pm$ diagram.

EXAMPLES:

sage: from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram
sage: pm = PMDiagram([[[0], [1], [2]], [Integer(1), Integer(2)], [Integer(1)]])
>>> pm.heights_of_addable_plus()
[1, 2, 3, 4, 5]

sage: pm = PMDiagram([[[1], [2]], [Integer(1), Integer(2)], [Integer(1)]])
>>> pm.heights_of_addable_plus()
[1, 2, 3, 4]

heights_of_minus()  
Return a list with the heights of all minus in the $\pm$ diagram.
EXAMPLES:

```
sage: from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram
sage: pm = PMDiagram([[1,2],[1,2],[1,1],[1,1],[1,1],[1]])
sage: pm.heights_of_minus()
[5, 3, 3, 1, 1]
sage: pm = PMDiagram([[1,2],[1,1],[1,1],[1,1],[1]])

```

```
inner_shape()  
Return the inner shape of the pm diagram

EXAMPLES:

```
sage: from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram
sage: pm = PMDiagram([[0,1],[1,2],[1]])
sage: pm.inner_shape()
[4, 1]
sage: pm = PMDiagram([[1,2],[1,1],[1,1],[1,1],[1]])

```

```
intermediate_shape()  
Return the intermediate shape of the pm diagram (inner shape plus positions of plusses)

EXAMPLES:

```
```
### `outer_shape()`

Return the outer shape of the ± diagram

**EXAMPLES:**

```
sage: from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram
sage: pm = PMDiagram([[0, 1], [1, 2], [1]])
sage: pm.outer_shape()
[4, 4]
sage: pm = PMDiagram([[1, 2], [1, 1], [1, 1], [1, 1], [1]])
sage: pm.outer_shape()
[8, 8, 4, 4]
sage: pm = PMDiagram([[1, 2], [1, 2], [1, 1], [1, 1], [1, 1], [1]])
sage: pm.outer_shape()
[13, 8, 8, 4, 4]
```
>>> from sage.all import *
>>> from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram

>>> pm = PMDiagram([[Integer(0),Integer(1)],[Integer(1),Integer(2)],
                  →[Integer(1)]])
>>> pm.outer_shape()
[4, 4]

>>> pm = PMDiagram([[Integer(1),Integer(2)],[Integer(1),Integer(1)],
                  →[Integer(1),Integer(1)],[Integer(1),Integer(1)],
                  →[Integer(1)]]))
>>> pm.outer_shape()
[8, 8, 4, 4]

>>> pm = PMDiagram([[Integer(1),Integer(0)],[Integer(0),Integer(1)],
                  →[Integer(2),Integer(0)],[Integer(0),Integer(0)],
                  →[Integer(0)]]))
>>> pm.pp()

sigma()

Return sigma on pm diagrams as needed for the analogue of the Dynkin diagram automorphism that interchanges nodes 0 and 1 for type $D_n(1)$, $B_n(1)$, $A_{2n-1}(2)$ for Kirillov-Reshetikhin crystals.

EXAMPLES:

sage: pm = sage.combinat.crystals.kirillov_reshetikhin.PMDiagram([[0,1],[1,2],
                  →[1]])
sage: pm.sigma()
[[1, 0], [2, 1], [1]]
sage.combinat.crystals.kirillov_reshetikhin.horizontal_dominoes_removed(r, s)

Returns all partitions obtained from a rectangle of width $s$ and height $r$ by removing horizontal dominoes.

EXAMPLES:

```
sage: sage.combinat.crystals.kirillov_reshetikhin.horizontal_dominoes_removed(2, 2)
[[], [2], [2, 2]]
sage: sage.combinat.crystals.kirillov_reshetikhin.horizontal_dominoes_removed(3, 2)
[[], [2], [2, 2], [2, 2, 2]]
```

```
>>> from sage.all import *

>>> sage.combinat.crystals.kirillov_reshetikhin.horizontal_dominoes_removed(Integer(2), Integer(2))

>>> sage.combinat.crystals.kirillov_reshetikhin.horizontal_dominoes_removed(Integer(3), Integer(2))
```

sage.combinat.crystals.kirillov_reshetikhin.partitions_in_box(r, s)

Returns all partitions in a box of width $r$ and height $s$.

EXAMPLES:

```
sage: sage.combinat.crystals.kirillov_reshetikhin.partitions_in_box(3, 2)

```

```
>>> from sage.all import *

>>> sage.combinat.crystals.kirillov_reshetikhin.partitions_in_box(Integer(3), Integer(2))
```

sage.combinat.crystals.kirillov_reshetikhin.vertical_dominoes_removed(r, s)

Returns all partitions obtained from a rectangle of width $s$ and height $r$ by removing vertical dominoes.

EXAMPLES:

```
sage: sage.combinat.crystals.kirillov_reshetikhin.vertical_dominoes_removed(2, 2)

```

```
>>> from sage.all import *

>>> sage.combinat.crystals.kirillov_reshetikhin.vertical_dominoes_removed(Integer(2), Integer(2))
```

(continues on next page)
Consider a Kac–Moody algebra \( g \) of affine Cartan type \( X \), and we want to model the \( U'_q(g) \)-crystal \( B(\lambda) \). First we consider the set of fundamental weights \( \{\Lambda_i\} \in \mathfrak{g} \) and let \( \{\overline{\Lambda}_i\} \in \mathfrak{I}_0 \) be the corresponding fundamental weights of the corresponding classical Lie algebra \( \mathfrak{g}_0 \). To model \( B(\lambda) \), we start with a sequence of perfect \( U'_q(g) \)-crystals \( (B^{(i)})_i \) of level \( l \) such that

\[
\lambda \in \overline{P}_l^+ = \left\{ \mu \in \overline{P}^+ \mid (c, \mu) = l \right\}
\]

where \( c \) is the canonical central element of \( U'_q(g) \) and \( \overline{P}^+ \) is the nonnegative weight lattice spanned by \( \{\overline{\Lambda}_i \mid i \in I\} \).

Next we consider the crystal isomorphism \( \Phi_0 : B(\lambda_0) \to B^{(0)} \otimes B(\lambda_1) \) defined by \( u_{\lambda_0} \to b^{(0)}_{\lambda_0} \otimes u_{\lambda_1} \) where \( b^{(0)}_{\lambda_0} \) is the unique element in \( B^{(0)} \) such that \( \varphi_b(b^{(0)}_{\lambda_0}) = \lambda_0 \) and \( \lambda_1 = \varepsilon(b^{(0)}_{\lambda_0}) \) and \( u_\mu \) is the highest weight element in \( B(\mu) \). Iterating this, we obtain the following isomorphism:

\[
\Phi_n : B(\lambda) \to B^{(0)} \otimes B^{(1)} \otimes \cdots \otimes B^{(N)} \otimes B(\lambda_{N+1})
\]

We note by Lemma 10.6.2 in [HK2002] that for any \( b \in B(\lambda) \) there exists a finite \( N \) such that

\[
\Phi_N(b) = \left( \bigotimes_{k=0}^{N-1} b^{(k)} \right) \otimes u_{\lambda_N}.
\]

Therefore we can model elements \( b \in B(\lambda) \) as a \( U'_q(g) \)-crystal by considering an infinite list of elements \( b^{(k)} \in B^{(k)} \) and defining the crystal structure by:

\[
\overline{wt}(b) = \lambda_N + \sum_{k=0}^{N-1} \overline{wt}(b^{(k)})
\]

\[
e_i(b) = e_i \left( b^{(k)} \otimes b^{(N)} \right) \otimes u_{\lambda_N},
\]

\[
f_i(b) = f_i \left( b^{(k)} \otimes b^{(N)} \right) \otimes u_{\lambda_N},
\]

\[
\varepsilon_i(b) = \max (\varepsilon_i(b'), -\varphi_i(b^{(N)}), 0),
\]

\[
\varphi_i(b) = \varphi_i(b') + \max \left( \varphi_i(b^{(N)}), -\varepsilon_i(b'), 0 \right),
\]

where \( b' = b^{(0)} \otimes \cdots \otimes b^{(N-1)} \). To translate this into a finite list, we consider a finite sequence \( b^{(0)} \otimes \cdots \otimes b^{(N-1)} \otimes b^{(N)} \) and if

\[
f_i \left( b^{(0)} \otimes \cdots \otimes b^{(N-1)} \otimes b^{(N)} \right) = b_0 \otimes \cdots \otimes b^{(N-1)} \otimes f_i \left( b^{(N)} \right),
\]
then we take the image as \( b^{(0)} \otimes \cdots \otimes f_i \left( b^{(N)}_{\lambda_N} \right) \otimes b^{(N+1)}_{\lambda_{N+1}} \). Similarly we remove \( b^{(N)}_{\lambda_N} \) if we have \( b_0 \otimes \cdots \otimes b^{(N-1)}_{\lambda_{N-1}} \otimes b^{(N)}_{\lambda_N} \). Additionally if 

\[
e_i \left( b^{(0)} \otimes \cdots \otimes b^{(N-1)}_{\lambda_{N-1}} \otimes b^{(N)}_{\lambda_N} \right) = b^{(0)} \otimes \cdots \otimes b^{(N-1)}_{\lambda_{N-1}} \otimes e_i \left( b^{(N)}_{\lambda_N} \right),
\]

then we consider this to be \( 0 \).

We can then lift the \( \mathcal{U}_q'(\mathfrak{g}) \)-crystal structure to a \( \mathcal{U}_q(\mathfrak{g}) \)-crystal structure by using a tensor product of the affinization of the of crystals \( B^{(i)} \) for all \( i \).

**INPUT:**

- \( B \) – a single or list of \( \mathcal{U}_q' \) perfect crystal(s) of level \( l \)
- \( \text{weight} \) – a weight in \( \mathcal{P}_l^+ \)

**EXAMPLES:**

```sage
sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]; mg
[[[3]]]

sage: mg.f_string([0,1,2,2])
[[[3]], [[3]], [[1]]]

sage: x = mg.f_string([0,1,2]); x
[[[2]], [[3]], [[1]]]

sage: x.weight()
Lambda[0]
```

```python
>>> from sage.all import *
>>> B = crystals.KirillovReshetikhin(['A',Integer(2),Integer(1)], Integer(1),
˓→Integer(1))

>>> La = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice().fundamental_ ˓→weights()

>>> C = crystals.KyotoPathModel(B, La[Integer(0)])

>>> mg = C.module_generators[Integer(0)]; mg
[[[3]]]

>>> mg.f_string([Integer(0),Integer(1),Integer(2),Integer(2)])
[[[3]], [[3]], [[1]]]

>>> x = mg.f_string([Integer(0),Integer(1),Integer(2)]); x
[[[2]], [[3]], [[1]]]

>>> x.weight()
Lambda[0]
```

An example of type \( A_5^{(2)} \):

```sage
sage: B = crystals.KirillovReshetikhin(['A',5,2], 1,1)
sage: La = RootSystem(['A',5,2]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]; mg
[[[-1]]]

sage: mg.f_string([0,2,1,3])
[[[-3]], [[2]], [[-1]]]

sage: mg.f_string([0,2,3,1])
[[[-3]], [[2]], [[-1]]]
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> B = crystals.KirillovReshetikhin(['A',Integer(5),Integer(2)], Integer(1),
... Integer(1))
>>> La = RootSystem(['A',Integer(5),Integer(2)]).weight_lattice().fundamental_weights()
>>> C = crystals.KyotoPathModel(B, La[Integer(0)])
>>> mg = C.module_generators[Integer(0)]; mg
[[[-1]]]
>>> mg.f_string([Integer(0),Integer(2),Integer(1),Integer(3)])
[[[-3]], [[2]], [[-1]]]
>>> mg.f_string([Integer(0),Integer(2),Integer(3),Integer(1)])
[[[-3]], [[2]], [[-1]]]
```

An example of type $D_3^{(2)}$:

```python
sage: B = crystals.KirillovReshetikhin(['D',3,2], 1,1)
sage: La = RootSystem(['D',3,2]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]; mg
[[[]]]
sage: mg.f_string([0,1,2,0])
[[[0]], [[1]], [[]]]
```

An example using multiple crystals of the same level:

```python
sage: B1 = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: B2 = crystals.KirillovReshetikhin(['A',2,1], 2,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel([B1, B2, B1], La[0])
sage: mg = C.module_generators[0]; mg
[[[3]]]
sage: mg.f_string([0,1,2,2])
[[[3]], [[1]], [[3]], [[3]]]
sage: mg.f_string([0,1,2,2])
[[[3]], [[1]], [[3]], [[3]]]
sage: mg.f_string([0,1,2,2])
[[[3]], [[2]], [[3]], [[1]], [[2]]]
sage: mg.f_string([0,1,2,1,0,2])
[[[3]], [[1]], [[2]], [[1]], [[3]], [[1]], [[3]]]
```

```python
>>> from sage.all import *
>>> B1 = crystals.KirillovReshetikhin(['A',Integer(2),Integer(1)], Integer(1),
... Integer(1))
>>> B2 = crystals.KirillovReshetikhin(['A',Integer(2),Integer(1)], Integer(2),
... Integer(1))
>>> La = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice().fundamental_weights()
```

(continues on next page)
By using the extended weight lattice, the Kyoto path model lifts the perfect crystals to their affinizations:

```
sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: P = RootSystem(['A',2,1]).weight_lattice(extended=True)
sage: La = P.fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]; mg
[[[3]](0)]
sage: x = mg.f_string([0,1,2]); x
[[[2]](-1), [[3]](0), [[1]](0)]
sage: x.weight()
Lambda[0] - delta
```

class Element

Bases: `TensorProductOfRegularCrystalsElement`

An element in the Kyoto path model.

```
e(i)
    Return the action of e_i on self.

    EXAMPLES:
```

```
Combinatorics, Release 10.4

```python
>>> from sage.all import *

>>> B = crystals.KirillovReshetikhin(['A', Integer(2), Integer(1)],
   ... Integer(1), Integer(1))

>>> La = RootSystem(['A', Integer(2), Integer(1)]).weight_lattice().
   ... fundamental_weights()

>>> C = crystals.KyotoPathModel(B, La[Integer(0)])

>>> mg = C.module_generators[Integer(0)]

>>> all(mg.e(i) is None for i in C.index_set())
True

>>> mg.f(Integer(0)).e(Integer(0)) == mg
True

epsilon(i)

Return $\varepsilon_i$ of self.

EXAMPLES:

```python
sage: B = crystals.KirillovReshetikhin(['A', 2, 1], 1, 1)
sage: La = RootSystem(['A', 2, 1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]
sage: [mg.epsilon(i) for i in C.index_set()]
[0, 0, 0]
sage: elt = mg.f(0)
sage: [elt.epsilon(i) for i in C.index_set()]
[1, 0, 0]
sage: elt = mg.f_string([0, 1, 2])
sage: [elt.epsilon(i) for i in C.index_set()]
[0, 0, 1]
sage: elt = mg.f_string([0, 1, 2, 2])
sage: [elt.epsilon(i) for i in C.index_set()]
[0, 0, 2]

f(i)

Return the action of $f_i$ on self.

EXAMPLES:

```
sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]
sage: mg.f(2)
sage: mg.f(0)
[[[1]], [[2]]]
sage: mg.f_string([0,1,2])
[[[2]], [[3]], [[1]]]

>>> from sage.all import *

>>> B = crystals.KirillovReshetikhin(['A',Integer(2),Integer(1)],-
Integer(1),Integer(1))
>>> La = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice().-
fundamental_weights()
>>> C = crystals.KyotoPathModel(B, La[Integer(0)])
>>> mg = C.module_generators[Integer(0)]
>>> mg.f(Integer(2))
>>> mg.f(Integer(0))
[[[1]], [[2]]]
>>> mg.f_string([Integer(0),Integer(1),Integer(2)])
[[[2]], [[3]], [[1]]]

\phi_i

Return $\phi_i$ of self.

EXAMPLES:

sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]
sage: [mg.phi(i) for i in C.index_set()]
[1, 0, 0]
sage: elt = mg.f(0)
sage: [elt.phi(i) for i in C.index_set()]
[0, 1, 1]
sage: elt = mg.f_string([0,1])
sage: [elt.phi(i) for i in C.index_set()]
[0, 0, 2]

>>> from sage.all import *

>>> B = crystals.KirillovReshetikhin(['A',Integer(2),Integer(1)],-
Integer(1),Integer(1))
>>> La = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice().-
fundamental_weights()
>>> C = crystals.KyotoPathModel(B, La[Integer(0)])
>>> mg = C.module_generators[Integer(0)]
>>> [mg.phi(i) for i in C.index_set()]
[1, 0, 0]
>>> elt = mg.f(Integer(0))
>>> [elt.phi(i) for i in C.index_set()]
[0, 1, 1]
>>> elt = mg.f_string([Integer(0),Integer(1)])
>>> [elt.phi(i) for i in C.index_set()]
[0, 0, 2]
**truncates** $k=\text{None}$

Truncate self to have length $k$ and return as an element in a (finite) tensor product of crystals.

**INPUT:**
- $k$ – (optional) the length to truncate to; if not specified, then returns one more than the current non-ground-state elements (i.e. the current list in self)

**EXAMPLES:**

```python
sage: B1 = crystals.KirillovReshetikhin(['A','2',1], 1,1)
sage: B2 = crystals.KirillovReshetikhin(['A','2',1], 2,1)
sage: La = RootSystem(['A','2',1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel([B1,B2,B1], La[0])
sage: mg = C.highest_weight_vector()
sage: elt = mg.f_string([0,1,2,2,1,0]); elt
[[[3]], [[2], [3]], [[1]], [[2]]]
sage: t = elt.truncate(); t
[[[3]], [[2], [3]], [[1]], [[2]]]
sage: t.parent() is C.finite_tensor_product(4)
True
sage: elt.truncate(2)
[[[3]], [[2], [3]]]
sage: elt.truncate(10)
[[[3]], [[2], [3]], [[1]], [[2]], [[1], [3]],
[[2]], [[1]], [[2], [3]], [[1]], [[3]]]
```

**weight()**

Return the weight of self.

**EXAMPLES:**

```python
sage: B = crystals.KirillovReshetikhin(['A','2',1], 1,1)
sage: P = RootSystem(['A','2',1]).weight_lattice(extended=True)
sage: La = P.fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: mg.weight()
Lambda[0]
sage: mg.f_string([0,1,2]).weight()
Lambda[0] - delta
```

```python
>>> from sage.all import *
>>> B = crystals.KirillovReshetikhin(['A',Integer(2),Integer(1)],-
Integer(1),Integer(1))
>>> P = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice(extended=True)
>>> La = P.fundamental_weights()
>>> C = crystals.KyotoPathModel(B, La[0])
>>> mg = C.module_generators[Integer(0)]
>>> mg.weight()
Lambda[0]
>>> mg.f_string([Integer(0),Integer(1),Integer(2)]).weight()
Lambda[0] - delta
```

**finite_tensor_product** *(k)*

Return the finite tensor product of crystals of length *k* from truncating `self`.

**EXAMPLES:**

```python
sage: B1 = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: B2 = crystals.KirillovReshetikhin(['A',2,1], 2,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel([B1,B2,B1], La[0])
sage: C.finite_tensor_product(Integer(5))
```

```
Full tensor product of the crystals
[Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(1,1),
 Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(2,1),
 Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(1,1),
 Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(1,1),
 Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(2,1)]
```

```python
>>> from sage.all import *
>>> B1 = crystals.KirillovReshetikhin(['A',Integer(2),Integer(1)], Integer(1),-
Integer(1))
>>> B2 = crystals.KirillovReshetikhin(['A',Integer(2),Integer(1)], Integer(2),-
Integer(1))
>>> La = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice().fundamental_-
weights()
>>> C = crystals.KyotoPathModel([B1,B2,B1], La[Integer(0)])
>>> C.finite_tensor_product(Integer(5))
```

```
Full tensor product of the crystals
[Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(1,1),
 Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(2,1),
 Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(1,1),
 Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(1,1),
 Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(2,1)]
```

**weight_lattice_realization** ()

Return the weight lattice realization used to express weights.

**EXAMPLES:**

```python
```
```python
sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: C.weight_lattice_realization()
Weight lattice of the Root system of type ['A', 2, 1]
sage: P = RootSystem(['A',2,1]).weight_lattice(extended=True)
sage: C = crystals.KyotoPathModel(B, P.fundamental_weight(0))
sage: C.weight_lattice_realization()
Extended weight lattice of the Root system of type ['A', 2, 1]
```

5.1.57 Crystals of letters

```python
class sage.combinat.crystals.letters.BKKLetter
    Bases: Letter

    e(i)

    Return the action of $e_i$ on self.

    EXAMPLES:
```
```python
sage: C = crystals.Letters(['A', [2, 1]])
sage: c = C(-2)
sage: c.e(-2)
-3
sage: c = C(1)
sage: c.e(0)
-1
sage: c = C(2)
sage: c.e(1)
1
sage: c.e(-2)
```

```python
>>> from sage.all import *
>>> B = crystals.KirillovReshetikhin(['A',Integer(2),Integer(1)], Integer(1), Integer(1))
>>> La = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice().fundamental_weights()
>>> C = crystals.KyotoPathModel(B, La[Integer(0)])
>>> C.weight_lattice_realization()
Weight lattice of the Root system of type ['A', 2, 1]
```
\begin{Verbatim}
>>> c = C(Integer(2))
>>> c.e(Integer(1))
1
>>> c.e(-Integer(2))
\end{Verbatim}

\section*{f(i)}
Return the action of \( f_i \) on \texttt{self}.

\section*{EXAMPLES:}
\begin{Verbatim}
\begin{verbatim}
sage: C = crystals.Letters(['A', [2, 1]])
sage: c = C.an_element()
sage: c.f(-2)
-2
sage: c = C(-1)
sage: c.f(0)
1
sage: c = C(1)
sage: c.f(1)
2
sage: c.f(-2)
\end{verbatim}
\end{Verbatim}

\begin{Verbatim}
\begin{verbatim}
>>> from sage.all import *
>>> C = crystals.Letters(['A', [Integer(2), Integer(1)]]
>>> c = C.an_element()
>>> c.f(-Integer(2))
-2
>>> c = C(-Integer(1))
>>> c.f(Integer(0))
1
>>> c = C(Integer(1))
>>> c.f(Integer(1))
2
>>> c.f(-Integer(2))
\end{verbatim}
\end{Verbatim}

\section*{weight()}
Return weight of \texttt{self}.

\section*{EXAMPLES:}
\begin{Verbatim}
\begin{verbatim}
sage: C = crystals.Letters(['A', [2, 1]])
sage: c = C(-1)
sage: c.weight()
(0, 0, 1, 0, 0)
sage: c = C(2)
sage: c.weight()
(0, 0, 0, 0, 1)
\end{verbatim}
\end{Verbatim}

\begin{Verbatim}
\begin{verbatim}
>>> from sage.all import *
>>> C = crystals.Letters(['A', [Integer(2), Integer(1)]]
>>> c = C(-Integer(1))
>>> c.weight()
(0, 0, 1, 0, 0)
>>> c = C(Integer(2))
>>> c.weight()
(0, 0, 0, 0, 1)
\end{verbatim}
\end{Verbatim}
class sage.combinat.crystals.letters.ClassicalCrystalOfLetters(cartan_type, element_class, element_print_style=None, dual=None)

Bases: UniqueRepresentation, Parent

A generic class for classical crystals of letters.

All classical crystals of letters should be instances of this class or of subclasses. To define a new crystal of letters, one only needs to implement a class for the elements (which subclasses Letter), with appropriate $e_i$ and $f_i$ operations. If the module generator is not 1, one also needs to define the subclass ClassicalCrystalOfLetters for the crystal itself.

The basic assumption is that crystals of letters are small, but used intensively as building blocks. Therefore, we explicitly build in memory the list of all elements, the crystal graph and its transitive closure, so as to make the following operations constant time: list, cmp, (todo: phi, epsilon, e, and f with caching)

list()

Return a list of the elements of self.

EXAMPLES:

```python
sage: C = crystals.Letters(['A', 5])
sage: C.list()
[1, 2, 3, 4, 5, 6]

>>> from sage.all import *
>>> C = crystals.Letters(['A', Integer(5)])
>>> C.list()
[1, 2, 3, 4, 5, 6]
```

lt_elements(x, y)

Return True if and only if there is a path from $x$ to $y$ in the crystal graph, when $x$ is not equal to $y$.

Because the crystal graph is classical, it is a directed acyclic graph which can be interpreted as a poset. This function implements the comparison function of this poset.

EXAMPLES:

```python
sage: C = crystals.Letters(['A', 5])
sage: x = C(1)
sage: y = C(2)
sage: C.lt_elements(x, y)
True
sage: C.lt_elements(y, x)
False
sage: C.lt_elements(x, x)
False
```

```python
>>> from sage.all import *
>>> C = crystals.Letters(['A', Integer(5)])
>>> x = C(Integer(1))
>>> y = C(Integer(2))
>>> (continues on next page)```
>>> C.lt_elements(x,y)
True
>>> C.lt_elements(y,x)
False
>>> C.lt_elements(x,x)
False
>>> C = crystals.Letters(['D', Integer(4)])
>>> C.lt_elements(C(Integer(4)),C(-Integer(4)))
False
>>> C.lt_elements(C(-Integer(4)),C(Integer(4)))
False

class sage.combinat.crystals.letters.ClassicalCrystalOfLettersWrapped(cartan_type)

Bases: ClassicalCrystalOfLetters

Crystal of letters by wrapping another crystal.

This is used for a crystal of letters of type $E_8$ and $F_4$.

This class follows the same output as the other crystal of letters, where $b$ is represented by the “letter” with $\varphi_i(b)$ (resp., $\varepsilon_i$) number of $i$'s (resp., $-i$'s or $\bar{i}$'s). However, this uses an auxiliary crystal to construct these letters to avoid hardcoding the crystal elements and the corresponding edges; in particular, the 248 nodes of $E_8$.

class sage.combinat.crystals.letters.CrystalOfBKKLetters(cost, dual)

Bases: ClassicalCrystalOfLetters

Crystal of letters for Benkart-Kang-Kashiwara supercrystals.

This implements the $\mathfrak{gl}(m|n)$ crystal of Benkart, Kang and Kashiwara [BKK2000].

EXAMPLES:

```
sage: C = crystals.Letters(['A', [1, 1]]); C
The crystal of letters for type ['A', [1, 1]]
sage: C = crystals.Letters(['A', [2,4]], dual=True); C
The crystal of letters for type ['A', [2, 4]] (dual)
```

```
>>> from sage.all import *

>>> C = crystals.Letters(['A', [Integer(1), Integer(1)]]); C
The crystal of letters for type ['A', [1, 1]]

>>> C = crystals.Letters(['A', [Integer(2),Integer(4)]], dual=True); C
The crystal of letters for type ['A', [2, 4]] (dual)
```

Element

alias of BKKLetter

sage.combinat.crystals.letters.CrystalOfLetters(cartan_type, element_print_style=None, dual=None)

Return the crystal of letters of the given type.

For classical types, this is a combinatorial model for the crystal with highest weight $\Lambda_1$ (the first fundamental weight).

Any irreducible classical crystal appears as the irreducible component of the tensor product of several copies of this crystal (plus possibly one copy of the spin crystal, see CrystalOfSpins). See [KN1994]. Elements of this
irreducible component have a fixed shape, and can be fit inside a tableau shape. Otherwise said, any irreducible classical crystal is isomorphic to a crystal of tableaux with cells filled by elements of the crystal of letters (possibly tensored with the crystal of spins).

We also have the crystal of fundamental representation of the general linear Lie superalgebra, which are used as letters inside of tableaux following [BKK2000]. Similarly, all of these crystals appear as a subcrystal of a sufficiently large tensor power of this crystal.

INPUT:
• T—a Cartan type

EXAMPLES:

```
sage: C = crystals.Letters(['A',5])
sage: C.list()
[1, 2, 3, 4, 5, 6]
sage: C.cartan_type()
['A', 5]
```

For type $E_6$, one can also specify how elements are printed. This option is usually set to None and the default representation is used. If one chooses the option ‘compact’, the elements are printed in the more compact convention with 27 letters +abcdefghijklmnopqrstuvwxyz and the 27 letters –ABCDEFGHIJKLMNOPQRSTUVWXYZ for the dual crystal.

EXAMPLES:

```
sage: C = crystals.Letters(['E',6], element_print_style = 'compact')

sage: C
The crystal of letters for type ['E', 6]

sage: C.list()
[+, a, b, c, d, e, f, g, h, i, j, k, l, m, n, o, p, q, r, s, t, u, v, w, x, y, z]

sage: C = crystals.Letters(['E',6], element_print_style = 'compact', dual = True)

sage: C
The crystal of letters for type ['E', 6] (dual)

sage: C.list()
```

```
class sage.combinat.crystals.letters.CrystalOfQueerLetters(ct)

Bases: ClassicalCrystalOfLetters

Queer crystal of letters elements.

The index set is of the form \{-n, \ldots, -1, 1, \ldots, n\}. For \(1 < i \leq n\), the operators \(e_i\) and \(f_i\) are defined as

\[
\begin{align*}
\hat{f}_i &= s_{w_i^{-1}} f_{w_i}, \\
\hat{e}_i &= s_{w_i^{-1}} e_{w_i},
\end{align*}
\]

where \(w_i = s_2 \cdots s_i s_{i+1} \cdots s_n\) and \(s_i\) is the reflection along the \(i\)-string in the crystal. See [GJK+2014].

Element

\index_set()  
Return index set of self.

EXAMPLES:

```
sage: Q = crystals.Letters(['Q',3])
sage: Q.index_set()
(1, 2, -2, -1)

>>> from sage.all import *
>>> Q = crystals.Letters(['Q','Integer(3)'])
>>> Q.index_set()
(1, 2, -2, -1)
```

class sage.combinat.crystals.letters.Crystal_of_letters_type_A_element

Bases: Letter

Type A crystal of letters elements.

e(i)  
Return the action of \(e_i\) on self.

EXAMPLES:

```
sage: C = crystals.Letters(['A',4])
sage: [(c,i,c.e(i)) for i in C.index_set() for c in C if c.e(i) is not None]
[(2, 1, 1), (3, 2, 2), (4, 3, 3), (5, 4, 4)]

>>> from sage.all import *
>>> C = crystals.Letters(['A','Integer(4)'])
>>> [(c,i,c.e(i)) for i in C.index_set() for c in C if c.e(i) is not None]
[(2, 1, 1), (3, 2, 2), (4, 3, 3), (5, 4, 4)]
```

epsilon(i)  
Return \(\epsilon_i\) of self.

EXAMPLES:

```
sage: C = crystals.Letters(['A',4])
sage: [(c,i) for i in C.index_set() for c in C if c.epsilon(i) != 0]
[(2, 1), (3, 2), (4, 3), (5, 4)]
```
\begin{Verbatim}
>>> from sage.all import *

>>> C = crystals.Letters(['A',Integer(4)])

>>> [(c,i) for i in C.index_set() for c in C if c.epsilon(i) != Integer(0)]
[(2, 1), (3, 2), (4, 3), (5, 4)]
\end{Verbatim}

\textbf{f}(i)

Return the action of $f_i$ on \texttt{self}.

\textbf{EXAMPLES:}

\begin{Verbatim}
sage: C = crystals.Letters(['A',4])
sage: [(c,i,c.f(i)) for i in C.index_set() for c in C if c.f(i) is not None]
[(1, 1, 2), (2, 2, 3), (3, 3, 4), (4, 4, 5)]
\end{Verbatim}

\begin{Verbatim}
>>> from sage.all import *

>>> C = crystals.Letters(['A',Integer(4)])

>>> [(c,i,c.f(i)) for i in C.index_set() for c in C if c.f(i) is not None]
[(1, 1, 2), (2, 2, 3), (3, 3, 4), (4, 4, 5)]
\end{Verbatim}

\begin{Verbatim}
\textbf{phi}(i)

Return $\varphi_i$ of \texttt{self}.

\textbf{EXAMPLES:}

\begin{Verbatim}
sage: C = crystals.Letters(['A',4])
sage: [(c,i) for i in C.index_set() for c in C if c.phi(i) != 0]
[(1, 1), (2, 2), (3, 3), (4, 4)]
\end{Verbatim}

\begin{Verbatim}
>>> from sage.all import *

>>> C = crystals.Letters(['A',Integer(4)])

>>> [(c,i) for i in C.index_set() for c in C if c.phi(i) != Integer(0)]
[(1, 1), (2, 2), (3, 3), (4, 4)]
\end{Verbatim}

\begin{Verbatim}
\textbf{weight}()

Return the weight of \texttt{self}.

\textbf{EXAMPLES:}

\begin{Verbatim}
sage: [v.weight() for v in crystals.Letters(['A',3])]
[(1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1)]
\end{Verbatim}

\begin{Verbatim}
>>> from sage.all import *

>>> [v.weight() for v in crystals.Letters(['A',Integer(3)])]
[(1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1)]
\end{Verbatim}

\textbf{class} \texttt{sage.combinat.crystals.letters.Crystal_of_letters_type_B_element}

\textbf{Bases:} \texttt{Letter}

Type $B$ crystal of letters elements.

\begin{Verbatim}
\textbf{e}(i)

Return the action of $e_i$ on \texttt{self}.

\textbf{EXAMPLES:}

\end{Verbatim}
sage: C = crystals.Letters(['B',4])
sage: [(c,i,c.e(i)) for i in C.index_set() for c in C if c.e(i) is not None]
[(2, 1, 1),
 (-1, 1, -2),
 (3, 2, 2),
 (-2, 2, -3),
 (4, 3, 3),
 (-3, 3, -4),
 (0, 4, 4),
 (-4, 4, 0)]

>>> from sage.all import *
>>> C = crystals.Letters(['B',Integer(4)])
>>> [(c,i,c.e(i)) for i in C.index_set() for c in C if c.e(i) is not None]
[(2, 1, 1),
 (-1, 1, -2),
 (3, 2, 2),
 (-2, 2, -3),
 (4, 3, 3),
 (-3, 3, -4),
 (0, 4, 4),
 (-4, 4, 0)]

epsilon(i)

Return \(\varepsilon_i\) of self.

EXAMPLES:

sage: C = crystals.Letters(['B',3])
sage: [(c,i) for i in C.index_set() for c in C if c.epsilon(i) != 0]
[(2, 1), (-1, 1), (3, 2), (-2, 2), (0, 3), (-3, 3)]

>>> from sage.all import *
>>> C = crystals.Letters(['B',Integer(3)])
>>> [(c,i) for i in C.index_set() for c in C if c.epsilon(i) != Integer(0)]
[(2, 1), (-1, 1), (3, 2), (-2, 2), (0, 3), (-3, 3)]

f(i)

Return the actions of \(f_i\) on self.

EXAMPLES:

sage: C = crystals.Letters(['B',4])
sage: [(c,i,c.f(i)) for i in C.index_set() for c in C if c.f(i) is not None]
[(1, 1, 2),
 (-2, 1, -1),
 (2, 2, 3),
 (-3, 2, -2),
 (3, 3, 4),
 (-4, 3, -3),
 (4, 4, 0),
 (0, 4, -4)]

>>> from sage.all import *
>>> C = crystals.Letters(['B',Integer(4)])
>>> [(c,i,c.f(i)) for i in C.index_set() for c in C if c.f(i) is not None]
(continues on next page)
\[(1, 1, 2),\]
\[(-2, 1, -1),\]
\[(2, 2, 3),\]
\[(-3, 2, -2),\]
\[(3, 3, 4),\]
\[(-4, 3, -3),\]
\[(4, 4, 0),\]
\[(0, 4, -4)\]

\[\text{phi}(i)\]

Return \(\varphi_i\) of self.

EXAMPLES:

```
sage: C = crystals.Letters(['B',3])
sage: [(c,i) for i in C.index_set() for c in C if c.phi(i) != 0]
[(1, 1), (-2, 1), (2, 2), (-3, 2), (3, 3), (0, 3)]
```

```python
>>> from sage.all import *
>>> C = crystals.Letters(['B',Integer(3)])
>>> [(c,i) for i in C.index_set() for c in C if c.phi(i) != Integer(0)]
[(1, 1), (-2, 1), (2, 2), (-3, 2), (3, 3), (0, 3)]
```

\[\text{weight}()\]

Return the weight of self.

EXAMPLES:

```
sage: [v.weight() for v in crystals.Letters(['B',3])]
[(1, 0, 0),
 (0, 1, 0),
 (0, 0, 1),
 (0, 0, 0),
 (0, 0, -1),
 (0, -1, 0),
 (-1, 0, 0)]
```

```python
>>> from sage.all import *
>>> [v.weight() for v in crystals.Letters(['B',Integer(3)])]
[(1, 0, 0),
 (0, 1, 0),
 (0, 0, 1),
 (0, 0, 0),
 (0, 0, -1),
 (0, -1, 0),
 (-1, 0, 0)]
```

class sage.combinat.crystals.letters.Crystal_of_letters_type_C_element

Bases: Letter

Type \(C\) crystal of letters elements.

\[e(i)\]

Return the action of \(e_i\) on self.

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: C = crystals.Letters(['C',4])
sage: [(c,i,c.e(i)) for i in C.index_set() for c in C if c.e(i) is not None]
[(2, 1, 1),
 (-1, 1, -2),
 (3, 2, 2),
 (-2, 2, -3),
 (4, 3, 3),
 (-3, 3, -4),
 (-4, 4, 4)]
```

```python
>>> from sage.all import *
>>> C = crystals.Letters(['C',Integer(4)])
>>> [(c,i,c.e(i)) for i in C.index_set() for c in C if c.e(i) is not None]
[(2, 1, 1),
 (-1, 1, -2),
 (3, 2, 2),
 (-2, 2, -3),
 (4, 3, 3),
 (-3, 3, -4),
 (-4, 4, 4)]
```

epsilon(i)

Return $\varepsilon_i$ of self.

EXAMPLES:

```python
sage: C = crystals.Letters(['C',3])
sage: [(c,i) for i in C.index_set() for c in C if c.epsilon(i) != 0]
[(2, 1), (-1, 1), (3, 2), (-2, 2), (-3, 3)]
```

```python
>>> from sage.all import *
>>> C = crystals.Letters(['C',Integer(3)])
>>> [(c,i) for i in C.index_set() for c in C if c.epsilon(i) != Integer(0)]
[(2, 1), (-1, 1), (3, 2), (-2, 2), (-3, 3)]
```

f(i)

Return the action of $f_i$ on self.

EXAMPLES:

```python
sage: C = crystals.Letters(['C',4])
sage: [(c,i,c.f(i)) for i in C.index_set() for c in C if c.f(i) is not None]
[(1, 1, 2), (-2, 1, -1), (2, 2, 3),
 (-3, 2, -2), (3, 3, 4), (-4, 3, -3), (4, 4, -4)]
```

```python
>>> from sage.all import *
>>> C = crystals.Letters(['C',Integer(4)])
>>> [(c,i,c.f(i)) for i in C.index_set() for c in C if c.f(i) is not None]
[(1, 1, 2), (-2, 1, -1), (2, 2, 3),
 (-3, 2, -2), (3, 3, 4), (-4, 3, -3), (4, 4, -4)]
```

phi(i)

Return $\varphi_i$ of self.

EXAMPLES:
sage: C = crystals.Letters(['C',3])
sage: [(c,i) for i in C.index_set() for c in C if c.phi(i) != 0]
[(1, 1), (-2, 1), (2, 2), (-3, 2), (3, 3)]

>>> from sage.all import *
>>> C = crystals.Letters(['C',Integer(3)])
>>> [(c,i) for i in C.index_set() for c in C if c.phi(i) != Integer(0)]
[(1, 1), (-2, 1), (2, 2), (-3, 2), (3, 3)]

weight()
Return the weight of self.

EXAMPLES:

sage: [v.weight() for v in crystals.Letters(['C',3])]
[(1, 0, 0), (0, 1, 0), (0, 0, 1), (0, 0, -1), (0, -1, 0), (-1, 0, 0)]

>>> from sage.all import *
>>> [v.weight() for v in crystals.Letters(['C',Integer(3)])]
[(1, 0, 0), (0, 1, 0), (0, 0, 1), (0, 0, -1), (0, -1, 0), (-1, 0, 0)]

class sage.combinat.crystals.letters.Crystal_of_letters_type_D_element
Bases: Letter

Type $D$ crystal of letters elements.

\(e_i\)

Return the action of \(e_i\) on \(self\).

EXAMPLES:

sage: C = crystals.Letters(['D',5])
sage: [(c,i,c.e(i)) for i in C.index_set() for c in C if c.e(i) is not None]
[(2, 1, 1),
 (-1, 1, -2),
 (3, 2, 2),
 (-2, 2, -3),
 (4, 3, 3),
 (-3, 3, -4),
 (5, 4, 4),
 (-4, 4, -5),
 (-5, 5, 4),
 (-4, 5, 5)]

>>> from sage.all import *
>>> C = crystals.Letters(['D',Integer(5)])
>>> [(c,i,c.e(i)) for i in C.index_set() for c in C if c.e(i) is not None]
[(2, 1, 1),
 (-1, 1, -2),
 (3, 2, 2),
 (-2, 2, -3),
 (4, 3, 3),
 (-3, 3, -4),
 (5, 4, 4),
 (-4, 4, -5),
 (-5, 5, 4),
 (-4, 5, 5)]
\textbf{epsilon} \((i)\)

Return \(\varepsilon_i\) of \texttt{self}.

**EXAMPLES:**

```
sage: C = crystals.Letters(['D',4])
sage: [(c,i) for i in C.index_set() for c in C if c.epsilon(i) != 0]
[(2, 1), (-1, 1), (3, 2), (-2, 2), (4, 3), (-3, 3), (-4, 4), (-3, 4)]
```

\textbf{f} \((i)\)

Return the action of \(f_i\) on \texttt{self}.

**EXAMPLES:**

```
sage: C = crystals.Letters(['D',5])
sage: [(c,i,c.f(i)) for i in C.index_set() for c in C if c.f(i) is not None]
[(1, 1, 2),
 (-2, 1, -1),
 (2, 2, 3),
 (-3, 2, -2),
 (3, 3, 4),
 (-4, 3, -3),
 (4, 4, 5),
 (-5, 4, -4),
 (4, 5, -5),
 (5, 5, -4)]
```

\textbf{phi} \((i)\)

Return \(\varphi_i\) of \texttt{self}.

**EXAMPLES:**

```
sage: C = crystals.Letters(['D',4])
sage: [(c,i) for i in C.index_set() for c in C if c.phi(i) != 0]
[(1, 1), (-2, 1), (2, 2), (-3, 2), (3, 3), (-4, 3), (3, 4), (4, 4)]
```

```
weight()

Return the weight of self.

EXAMPLES:

```python
def weight():
    return self.weight()
```

```python
sage: [(v.weight() for v in crystals.Letters(['D',4]))
[(1, 0, 0, 0),
 (0, 1, 0, 0),
 (0, 0, 1, 0),
 (0, 0, 0, 1),
 (0, 0, 0, 0),
 (0, 0, 0, -1),
 (0, 0, -1, 0),
 (0, -1, 0, 0),
 (-1, 0, 0, 0)]
```

```python
>>> from sage.all import *
>>> [(v.weight() for v in crystals.Letters(['D',Integer(4)]))
[(1, 0, 0, 0),
 (0, 1, 0, 0),
 (0, 0, 1, 0),
 (0, 0, 0, 1),
 (0, 0, 0, 0),
 (0, 0, 0, -1),
 (0, 0, -1, 0),
 (0, -1, 0, 0),
 (-1, 0, 0, 0)]
```

class sage.combinat.crystals.letters.Crystal_of_letters_type_E6_element

Bases: LetterTuple

Type $E_6$ crystal of letters elements. This crystal corresponds to the highest weight crystal $B(\Lambda_1)$.

\[ e(i) \]

Return the action of $e_i$ on self.

EXAMPLES:

```python
def e(i):
    return self.e(i)
```

```python
sage: C = crystals.Letters(['E',6])
sage: C((-1,3)).e(1)
(1,)
sage: C((-2,-3,4)).e(2)
(-3, 2)
sage: C((1,)).e(1)
```

```python
>>> from sage.all import *
>>> C = crystals.Letters(['E',Integer(6)])
>>> C((-Integer(1),Integer(3))).e(Integer(1))
(1,)
>>> C((-Integer(2),-Integer(3),Integer(4))).e(Integer(2))
(-3, 2)
>>> C((Integer(1),)).e(Integer(1))
```

\[ f(i) \]

Return the action of $f_i$ on self.

```python
def f(i):
    return self.f(i)
```
EXAMPLES:

```python
sage: C = crystals.Letters(['E',6])
sage: C((1,)).f(1)
(-1, 3)
sage: C((-6,)).f(1)
```

```python
>>> from sage.all import *

>>> C = crystals.Letters(['E',Integer(6)])
>>> C((Integer(1),)).f(Integer(1))
(-1, 3)
```

```
weight()
```

Return the weight of self.

EXAMPLES:

```python
sage: [v.weight() for v in crystals.Letters(['E',6])]
[(0, 0, 0, 0, -2/3, -2/3, 2/3),
 (-1/2, 1/2, 1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, -1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, 1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
 (-1/2, -1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, 1/2, 1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
 (-1/2, -1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, -1/2, 1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, 1/2, 1/2, 1/2, -1/3, 1/3, -1/3),
 (-1/2, 1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
 (-1/2, -1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (-1/2, 1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
 (-1/2, -1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (0, 0, 0, 0, 1, 1/3, 1/3, -1/3),
 (0, 0, 0, 1, 1, 1/3, 1/3, -1/3),
 (-1/2, -1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
 (1/2, -1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
 (1/2, 1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
 (1/2, 1/2, 1/2, 1/2, 1/3, 1/3, -1/3),
 (-1/2, -1/2, -1/2, -1/2, -1/6, -1/6, 1/6),
 (-1/2, 1/2, 1/2, 1/2, 1/3, 1/3, -1/3),
 (-1/2, 1/2, -1/2, 1/2, 1/3, 1/3, -1/3),
 (1, 0, 0, 0, 0, 1/3, 1/3, -1/3),
 (0, -1, 0, 0, 1/3, 1/3, -1/3),
 (0, 0, -1, 0, 1/3, 1/3, -1/3),
 (0, 0, 0, -1, 1/3, 1/3, -1/3),
 (-1/2, -1/2, 1/2, 1/2, 1/3, 1/3, -1/3),
 (-1, 0, 0, 0, 1, 1/3, 1/3, -1/3)]
```

```python
>>> from sage.all import *

>>> [v.weight() for v in crystals.Letters(['E',Integer(6)])]
[(0, 0, 0, 0, -2/3, -2/3, 2/3),
 (-1/2, 1/2, 1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, -1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, 1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
 (-1/2, -1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, 1/2, 1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
 (-1/2, -1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, -1/2, 1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, 1/2, 1/2, 1/2, -1/3, 1/3, -1/3),
 (-1/2, -1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
 (1/2, -1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
 (1/2, 1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
 (1/2, 1/2, 1/2, 1/2, 1/3, 1/3, -1/3),
 (-1/2, -1/2, -1/2, -1/2, -1/6, -1/6, 1/6),

```

(continues on next page)
class sage.combinat.crystals.letters.Crystal_of_letters_type_E6_element_dual

Bases: LetterTuple

Type $E_6$ crystal of letters elements. This crystal corresponds to the highest weight crystal $B(\Lambda_6)$. This crystal is dual to $B(\Lambda_1)$ of type $E_6$.

e(i)

Return the action of $e_i$ on self.

EXAMPLES:

```
sage: C = crystals.Letters(['E',6], dual = True)
sage: C((-1,)).e(1)
(1, -3)
```

```
>>> from sage.all import *
>>> C = crystals.Letters(['E',Integer(6)], dual = True)
>>> C((Integer(-1),)).e(Integer(1))
(1, -3)
```

f(i)

Return the action of $f_i$ on self.

EXAMPLES:

```
sage: C = crystals.Letters(['E',6], dual = True)
sage: C((6,)).f(6)
(5, -6)
sage: C((6,)).f(1)
```

```
>>> from sage.all import *
>>> C = crystals.Letters(['E',Integer(6)], dual = True)
>>> C((Integer(6),)).f(Integer(6))
(5, -6)
>>> C((Integer(6),)).f(Integer(1))
```
lift()
Lift an element of self to the crystal of letters crystals.Letters(['E',6]) by taking its inverse weight.

EXAMPLES:

```
sage: C = crystals.Letters(['E',6], dual = True)
sage: b = C.module_generators[0]
sage: b.lift()
(-6,)
```

```python
>>> from sage.all import *
>>> C = crystals.Letters(['E',Integer(6)], dual = True)
>>> b = C.module_generators[Integer(0)]
>>> b.lift()
(-6,)
```

retract(p)
Retract element p, which is an element in crystals.Letters(['E',6]) to an element in crystals.Letters(['E',6], dual=True) by taking its inverse weight.

EXAMPLES:

```
sage: C = crystals.Letters(['E',6])
sage: Cd = crystals.Letters(['E',6], dual = True)
sage: b = Cd.module_generators[0]
sage: p = C((-1,3))
sage: b.retract(p)
(1, -3)
sage: b.retract(None)
```

```python
>>> from sage.all import *
>>> C = crystals.Letters(['E','Integer(6)'])
>>> Cd = crystals.Letters(['E','Integer(6)'], dual = True)
>>> b = Cd.module_generators['Integer(0)']
>>> p = C((-Integer(1),Integer(3)))
>>> b.retract(p)
(1, -3)
>>> b.retract(None)
```

weight()
Return the weight of self.

EXAMPLES:

```
sage: C = crystals.Letters(['E',6], dual = True)
sage: b=C.module_generators[0]
sage: b.weight()
(0, 0, 0, 0, 1, -1/3, -1/3, 1/3)
sage: [v.weight() for v in C]
[(0, 0, 0, 0, 1, -1/3, -1/3, 1/3),
 (0, 0, 0, 1, 0, -1/3, -1/3, 1/3),
 (0, 0, 1, 0, 0, -1/3, -1/3, 1/3),
 (0, 1, 0, 0, 0, -1/3, -1/3, 1/3),
 (0, 0, 0, 1, -1/3, -1/3, 1/3),
 (-1, 0, 0, 0, 0, -1/3, -1/3, 1/3),
 (1, 0, 0, 0, 0, -1/3, -1/3, 1/3),
 (1/2, 1/2, 1/2, 1/2, 1/2, 1/2, 1/6, 1/6, -1/6),
```
(0, -1, 0, 0, -1/3, -1/3, 1/3),
(-1/2, -1/2, 1/2, 1/2, 1/2, 1/6, 1/6, -1/6),
(0, 0, -1, 0, 0, -1/3, -1/3, 1/3),

class sage.combinat.crystals.letters.Crystal_of_letters_type_E7_element
Bases: LetterTuple
Type $E_7$ crystal of letters elements. This crystal corresponds to the highest weight crystal $B(\Lambda_7)$.

**e** $(i)$

Return the action of $e_i$ on self.

**EXAMPLES:**

```
sage: C = crystals.Letters(['E',7])
sage: C((7,)).e(7)
(7,)
```

```
>>> from sage.all import *
>>> C = crystals.Letters(['E',Integer(7)])
>>> C((Integer(7),)).e(Integer(7))
>>> C((-Integer(7),Integer(6))).e(Integer(7))
(7,)
```

**f** $(i)$

Return the action of $f_i$ on self.

**EXAMPLES:**

```
sage: C = crystals.Letters(['E',7])
sage: C((-7,)).f(7)
sage: C((7,)).f(7)
(-7, 6)
```

```
>>> from sage.all import *
>>> C = crystals.Letters(['E',Integer(7)])
>>> C((-Integer(7),)).f(Integer(7))
>>> C((Integer(7),)).f(Integer(7))
(-7, 6)
```

**weight** ()

Return the weight of self.

**EXAMPLES:**

```
sage: [v.weight() for v in crystals.Letters(['E',7])]
[(0, 0, 0, 0, 0, 0, 0, -1/2, 1/2), (0, 0, 0, 0, 1, 0, -1/2, 1/2), (0, 0, 0, 0, 1, 0, 0, 1, 0),

[(1, 1, 1), (3, 1, 2), (0, 1, 1), (-2, 1, 1), (2, 2, 1), (-3, 2, 1)]
\]

\textbf{weight}()

Return the weight of self.

\textbf{EXAMPLES:}

\[
sage: [v.weight() for v in crystals.Letters(['G', 2])]
[(1, 0, -1), (1, -1, 0), (0, 1, -1), (0, 0, 0), (0, -1, 1), (-1, 1, 0), (-1,\rightarrow 0, 1)]
\]

\[
>>> from sage.all import *
>>> [v.weight() for v in crystals.Letters(['G', Integer(2)])]
[(1, 0, -1), (1, -1, 0), (0, 1, -1), (0, 0, 0), (0, -1, 1), (-1, 1, 0), (-1,\rightarrow 0, 1)]
\]

\textbf{class} \texttt{sage.combinat.crystals.letters.EmptyLetter}

\textbf{Bases:} \texttt{Element}

The affine letter \(\emptyset\) thought of as a classical crystal letter in classical type \(B_n\) and \(C_n\).

\textbf{Warning:} This is not a classical letter.

Used in the rigged configuration bijections.

\textbf{e} \(i\)

Return \(e_i\) of self which is None.

\textbf{EXAMPLES:}

\[
sage: C = crystals.Letters(['C', 3])
sage: C('E').e(1)
\]

\[
>>> from sage.all import *
>>> C = crystals.Letters(['C', Integer(3)])
>>> C('E').e(Integer(1))
\]
\textbf{epsilon}(i)

Return $\varepsilon_i$ of \texttt{self}.

**EXAMPLES:**

\begin{verbatim}
sage: C = crystals.Letters(['C', 3])
sage: C('E').epsilon(1)
0

>>> from sage.all import *
>>> C = crystals.Letters(['C', Integer(3)])
>>> C('E').epsilon(Integer(1))
0
\end{verbatim}

\textbf{f}(i)

Return $f_i$ of \texttt{self} which is \texttt{None}.

**EXAMPLES:**

\begin{verbatim}
sage: C = crystals.Letters(['C', 3])
sage: C('E').f(1)

>>> from sage.all import *
>>> C = crystals.Letters(['C', Integer(3)])
>>> C('E').f(Integer(1))

\end{verbatim}

\textbf{phi}(i)

Return $\varphi_i$ of \texttt{self}.

**EXAMPLES:**

\begin{verbatim}
sage: C = crystals.Letters(['C', 3])
sage: C('E').phi(1)
0

>>> from sage.all import *
>>> C = crystals.Letters(['C', Integer(3)])
>>> C('E').phi(Integer(1))
0
\end{verbatim}

\textbf{value}

\textbf{weight()}

Return the weight of \texttt{self}.

**EXAMPLES:**

\begin{verbatim}
sage: C = crystals.Letters(['C', 3])
sage: C('E').weight()
(0, 0, 0)

>>> from sage.all import *
>>> C = crystals.Letters(['C', Integer(3)])
>>> C('E').weight()
(0, 0, 0)
\end{verbatim}
class sage.combinat.crystals.letters.Letter

Bases: Element

A class for letters.

Like ElementWrapper, plus delegates __lt__ (comparison) to the parent.

EXAMPLES:

```
sage: from sage.combinat.crystals.letters import Letter
sage: a = Letter(ZZ, 1)
sage: Letter(ZZ, 1).parent()
Integer Ring
sage: Letter(ZZ, 1)._repr_()
'1'

sage: parent1 = ZZ  # Any fake value ...
sage: parent2 = QQ  # Any fake value ...
sage: l11 = Letter(parent1, 1)
sage: l12 = Letter(parent1, 2)
sage: l21 = Letter(parent2, 1)
sage: l22 = Letter(parent2, 2)
sage: l11 == l11
True
sage: l11 == l12
False
sage: l11 == l21  # not tested
False

sage: C = crystals.Letters(['B', 3])
sage: C(0) != C(0)
False
sage: C(1) != C(-1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.crystals.letters import Letter

>>> a = Letter(ZZ, Integer(1))
>>> Letter(ZZ, Integer(1)).parent()
Integer Ring

>>> Letter(ZZ, Integer(1))._repr_()
'1'

>>> parent1 = ZZ  # Any fake value ...
>>> parent2 = QQ  # Any fake value ...
>>> l11 = Letter(parent1, Integer(1))
>>> l12 = Letter(parent1, Integer(2))
>>> l21 = Letter(parent2, Integer(1))
>>> l22 = Letter(parent2, Integer(2))
>>> l11 == l11
True
>>> l11 == l12
False
>>> l11 == l21  # not tested
False

(continues on next page)
>>> C = crystals.Letters(['B', Integer(3)])
>>> C(Integer(0)) != C(Integer(0))
False
>>> C(Integer(1)) != C(-Integer(1))
True

**value**

class sage.combinat.crystals.letters.LetterTuple

    Bases: Element

    Abstract class for type $E$ letters.

    epsilon($i$)

    Return $\epsilon_i$ of self.

    EXAMPLES:

    ```python
    sage: C = crystals.Letters(['E',6])
    sage: C((-6,)).epsilon(1)
    0
    sage: C((-6,)).epsilon(6)
    1
    ```

    >>> from sage.all import *
    >>> C = crystals.Letters(['E',Integer(6)])
    >>> C((-Integer(6),)).epsilon(Integer(1))
    0
    >>> C((-Integer(6),)).epsilon(Integer(6))
    1

    phi($i$)

    Return $\varphi_i$ of self.

    EXAMPLES:

    ```python
    sage: C = crystals.Letters(['E',6])
    sage: C((1,)).phi(1)
    1
    sage: C((1,)).phi(6)
    0
    ```

    >>> from sage.all import *
    >>> C = crystals.Letters(['E',Integer(6)])
    >>> C((Integer(1),)).phi(Integer(1))
    1
    >>> C((Integer(1),)).phi(Integer(6))
    0

**value**

class sage.combinat.crystals.letters.LetterWrapped

    Bases: Element

    Element which uses another crystal implementation and converts those elements to a tuple with $\pm i$.  

5.1. Comprehensive Module List

787
Return $e_i$ of self.

EXAMPLES:

```python
sage: C = crystals.Letters(['E', 8])
sage: C((-8,)).e(1)
(-7, 8)
sage: C((-8,)).e(8)
(-7, 8)
```

Return $\epsilon_i$ of self.

```python
sage: C = crystals.Letters(['E', 8])
sage: C((-8,)).epsilon(1)
0
sage: C((-8,)).epsilon(8)
1
```

Return $f_i$ of self.

```python
sage: C = crystals.Letters(['E', 8])
sage: C((8,)).f(6)
(7, -8)
sage: C((8,)).f(8)
(7, -8)
```

Return $\varphi_i$ of self.

```python
sage: C = crystals.Letters(['E', 8])
sage: C((8,)).phi(8)
```

(continues on next page)
Combinatorics, Release 10.4

1
sage: C((8,)).phi(6)
0

>>> from sage.all import *
>>>
C = crystals.Letters(['E', Integer(8)])
>>> C((Integer(8),)).phi(Integer(8))
1
>>> C((Integer(8),)).phi(Integer(6))
0

value

class sage.combinat.crystals.letters.QueerLetter_element

Bases: Letter

Queer supercrystal letters elements.

e(i)

Return the action of $e_i$ on self.

EXAMPLES:

```
sage: Q = crystals.Letters(['Q',3])
sage: [(c,i,c.e(i)) for i in Q.index_set() for c in Q if c.e(i) is not None]
[(2, 1, 1), (3, 2, 2), (3, -2, 2), (2, -1, 1)]
```

epsilon(i)

Return $\varepsilon_i$ of self.

EXAMPLES:

```
sage: Q = crystals.Letters(['Q',3])
sage: [(c,i) for i in Q.index_set() for c in Q if c.epsilon(i) != 0]
[(2, 1), (3, 2), (3, -2), (2, -1)]
```

f(i)

Return the action of $f_i$ on self.

EXAMPLES:

```
sage: Q = crystals.Letters(['Q',3])
sage: [(c,i,c.f(i)) for i in Q.index_set() for c in Q if c.f(i) is not None]
[(1, 1, 2), (2, 2, 3), (2, -2, 3), (1, -1, 2)]
```
Combinatorics, Release 10.4

>>> from sage.all import *
>>> Q = crystals.Letters(['Q',Integer(3)])
>>> [(c,i,c.f(i)) for i in Q.index_set() for c in Q if c.f(i) is not None]
[(1, 1, 2), (2, 2, 3), (2, -2, 3), (1, -1, 2)]

phi(i)
Return \( \varphi_i \) of self.

EXAMPLES:

sage: Q = crystals.Letters(['Q',3])
sage: [(c,i) for i in Q.index_set() for c in Q if c.phi(i) != 0]
[(1, 1), (2, 2), (2, -2), (1, -1)]

weight()
Return the weight of self.

EXAMPLES:

sage: [v.weight() for v in crystals.Letters(['Q',4])]
[(1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1)]

>>> from sage.all import *
>>> [v.weight() for v in crystals.Letters(['Q',Integer(4)])]
[(1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1)]

5.1.58 Littelmann paths

AUTHORS:

• Mark Shimozono, Anne Schilling (2012): Initial version
• Anne Schilling (2013): Implemented CrystalOfProjectedLevelZeroLSPaths
• Travis Scrimshaw (2016): Implemented InfinityCrystalOfLSPaths

class sage.combinat.crystals.littelmann_path.CrystalOfLSPaths(starting_weight, starting_weight_parent)

Bases: UniqueRepresentation, Parent

Crystal graph of LS paths generated from the straight-line path to a given weight.

INPUT:

• cartan_type – (optional) the Cartan type

• starting_weight – a weight; if cartan_type is given, then the weight should be given as a list of coefficients of the fundamental weights, otherwise it should be given in the weight_space basis; for affine highest weight crystals, one needs to use the extended weight space

The crystal class of piecewise linear paths in the weight space, generated from a straight-line path from the origin to a given element of the weight lattice.

EXAMPLES:
sage: R = RootSystem(['A',2,1])
sage: La = R.weight_space(extended = True).basis()
sage: B = crystals.LSPaths(La[2]-La[0]); B
The crystal of LS paths of type ['A', 2, 1] and weight -Lambda[0] + Lambda[2]

sage: C = crystals.LSPaths(['A',2,1],[1,0,1]); C
The crystal of LS paths of type ['A', 2, 1] and weight -Lambda[0] + Lambda[2]

sage: B == C
True

sage: c = C.module_generators[0]; c
(-Lambda[0] + Lambda[2],)

sage: [c.f(i) for i in C.index_set()]
[None, None, (Lambda[1] - Lambda[2],)]

sage: R = C.R; R
Root system of type ['A', 2, 1]

sage: Lambda = R.weight_space().basis(); Lambda
Finite family {0: Lambda[0], 1: Lambda[1], 2: Lambda[2]}

sage: b=C(tuple([-Lambda[0]+Lambda[2]]))

sage: b==c
True

sage: b.f(2)
(Lambda[1] - Lambda[2],)

>>> from sage.all import *
>>> R = RootSystem(['A','Integer(2)','Integer(1)'])
>>> La = R.weight_space(extended = True).basis()
>>> B = crystals.LSPaths(La['Integer(2)']-La['Integer(0)']); B
The crystal of LS paths of type ['A', 2, 1] and weight -Lambda[0] + Lambda[2]

>>> C = crystals.LSPaths(['A','Integer(2)','Integer(1)'],['-Integer(1)'],'Integer(0),
->Integer(1))]; C
The crystal of LS paths of type ['A', 2, 1] and weight -Lambda[0] + Lambda[2]

>>> B == C
True

>>> c = C.module_generators['Integer(0)']; c
(-Lambda[0] + Lambda[2],)

>>> [c.f(i) for i in C.index_set()]
[None, None, (Lambda[1] - Lambda[2],)]

>>> R = C.R; R
Root system of type ['A', 2, 1]

>>> Lambda = R.weight_space().basis(); Lambda
Finite family {0: Lambda[0], 1: Lambda[1], 2: Lambda[2]}

>>> b=C(tuple([-Lambda['Integer(0)']+Lambda['Integer(2)]]))

>>> b==c
True

>>> b.f('Integer(2)')
(Lambda[1] - Lambda[2],)

For classical highest weight crystals, we can also compare the results with the tableaux implementation:

sage: C = crystals.LSPaths(['A',2],[1,1])
sage: sorted(C, key=str)
→2*Lambda[2]),
(continued from previous page)

```python
sage: C.cardinality()
8
sage: B = crystals.Tableaux(['A',2],shape=[2,1])
sage: B.cardinality()
8
sage: B.digraph().is_isomorphic(C.digraph())
True
```

>>> from sage.all import *

```python
>>> C = crystals.LSPaths(['A',Integer(2)],[Integer(1),Integer(1)])
>>> sorted(C, key=str)
2*Lambda[2]),
->Lambda[2]),
```

```python
>>> B = crystals.LSPaths([A,Integer(2)],shape=[Integer(2),Integer(1)])
>>> B.cardinality()
8
>>> B.digraph().is_isomorphic(C.digraph())
True
```

Make sure you use the weight space and not the weight lattice for your weights:

```python
sage: R = RootSystem(['A',2,1])
sage: La = R.weight_lattice(extended = True).basis()
sage: B = crystals.LSPaths(La[2]); B
Traceback (most recent call last):
...
ValueError: use the weight space, rather than weight lattice for your weights
```

```python
>>> from sage.all import *

>>> R = RootSystem(['A',Integer(2),Integer(1)])
>>> La = R.weight_lattice(extended = True).basis()
>>> B = crystals.LSPaths(La[Integer(2)]); B
Traceback (most recent call last):
...
ValueError: use the weight space, rather than weight lattice for your weights
```

REFERENCES:

- [Li1995b]

**class Element**

Bases: `ElementWrapper`

A Littelmann path (crystal element).

**compress()**

Merge consecutive positively parallel steps present in `self`.

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: C = crystals.LSPaths(['A',2],[1,1])
sage: Lambda = C.R.weight_space().fundamental_weights(); Lambda
Finite family {1: Lambda[1], 2: Lambda[2]}
sage: c.compress()
(Lambda[1] + Lambda[2],)

>>> from sage.all import *
>>> C = crystals.LSPaths(['A',Integer(2)],[Integer(1),Integer(1)])
>>> Lambda = C.R.weight_space().fundamental_weights(); Lambda
Finite family {1: Lambda[1], 2: Lambda[2]}
>>> c = C(tuple([Integer(1)/Integer(2)*Lambda[Integer(1)]+Integer(1)/Integer(2)*Lambda[Integer(2)], Integer(1)/Integer(2)*Lambda[Integer(1)]+Integer(1)/Integer(2)*Lambda[Integer(2)]]))
>>> c.compress()
(Lambda[1] + Lambda[2],)
```

dualize()

Return the dualized path of self.

EXAMPLES:

```python
sage: C = crystals.LSPaths(['A',2],[1,1])
sage: for c in C:
    ...:     print("{} {}\n".format(c, c.dualize()))
```

e(i, power=1, to_string_end=False, length_only=False)

Return the i-th crystal raising operator on self.

INPUT:
Combinatorics, Release 10.4

• \( i \) – element of the index set of the underlying root system
• \( \text{power} \) – positive integer (default: 1); specifies the power of the raising operator to be applied
• \( \text{to_string_end} \) – boolean (default: False); if True, returns the dominant end of the \( i \)-string of self
• \( \text{length_only} \) – boolean; if True, returns the distance to the dominant end of the \( i \)-string of self

EXAMPLES:

```python
sage: C = crystals.LSPaths(['A',2],[1,1])
sage: c = C[2]; c
sage: c.e(1)
sage: c.e(2)
(-Lambda[1] + 2*Lambda[2],)
sage: c.e(2, to_string_end=True)
(-Lambda[1] + 2*Lambda[2],)
sage: c.e(1, to_string_end=True)
sage: c.e(1, length_only=True)
0
```

```python
>>> from sage.all import *
>>> C = crystals.LSPaths(['A',Integer(2)],[Integer(1),Integer(1)])
>>> c = C[Integer(2)]; c
>>> c.e(Integer(1))
>>> c.e(Integer(2))
(-Lambda[1] + 2*Lambda[2],)
>>> c.e(Integer(1), to_string_end=True)
(-Lambda[1] + 2*Lambda[2],)
>>> c.e(Integer(1), to_string_end=True)
>>> c.e(Integer(1), length_only=True)
0
```

`endpoint()`

Compute the endpoint of self.

EXAMPLES:

```python
sage: C = crystals.LSPaths(['A',2],[1,1])
sage: b = C.module_generators[0]
sage: b.endpoint()
sage: b.f_string([1,2,2,1])
(-Lambda[1] - Lambda[2],)
sage: b.f_string([1,2,2,1]).endpoint()
sage: b.f_string([1,2])
sage: b.f_string([1,2]).endpoint()
0
sage: b = C([])
sage: b.endpoint()
0
```
>>> from sage.all import *
>>> C = crystals.LSPaths(['A',Integer(2)],[Integer(1),Integer(1)])
>>> b = C.module_generators[Integer(0)]
>>> b.endpoint()
>>> b.f_string([Integer(1),Integer(2),Integer(2),Integer(1)])
(-Lambda[1] - Lambda[2],)
>>> b.f_string([Integer(1),Integer(2),Integer(2),Integer(1)]).endpoint()
>>> b.f_string([Integer(1),Integer(2)])
>>> b.f_string([Integer(1),Integer(2)]).endpoint()
0
>>> b = C([])
>>> b.endpoint()
0

epsilon(i)
Return the distance to the beginning of the i-string.
This method overrides the generic implementation in the category of crystals since this computation is more efficient.
EXAMPLES:

sage: C = crystals.LSPaths(['A',2],[1,1])
sage: [c.epsilon(1) for c in C]
[0, 1, 0, 0, 1, 0, 1, 2]
sage: [c.epsilon(2) for c in C]
[0, 0, 1, 2, 1, 1, 0, 0]

f(i, power=1, to_string_end=False, length_only=False)
Return the i-th crystal lowering operator on self.
INPUT:
- i – element of the index set of the underlying root system
- power – positive integer (default: 1); specifies the power of the lowering operator to be applied
- to_string_end – boolean (default: False); if True, returns the anti-dominant end of the i-string of self
- length_only – boolean; if True, returns the distance to the anti-dominant end of the i-string of self
EXAMPLES:

sage: C = crystals.LSPaths(['A',2],[1,1])
sage: c = C.module_generators[0]
sage: c.f(1)
(-Lambda[1] + 2*Lambda[2],)
sage: c.f(1, power=2)
sage: c.f(2)
sage: c.f(2, to_string_end=True)
sage: c.f(2, length_only=True)
1

sage: C = crystals.LSPaths(['A', '2', '1'], [-1, -1, 2])
sage: c = C.module_generators[0]
sage: c.f(2, power=2)
(Lambda[0] + Lambda[1] - 2*Lambda[2],)

>>> from sage.all import *
>>> C = crystals.LSPaths(['A', Integer(2)], [Integer(1), Integer(1)])
>>> c = C.module_generators[Integer(0)]
>>> c.f(Integer(1))
(-Lambda[1] + 2*Lambda[2],)
>>> c.f(Integer(1), power=Integer(2))
>>> c.f(Integer(2))
>>> c.f(Integer(2), to_string_end=True)
>>> c.f(Integer(2), length_only=True)
1

>>> C = crystals.LSPaths(['A', Integer(2), Integer(1)], [-Integer(1), -Integer(1), Integer(1)])
>>> c = C.module_generators[Integer(0)]
>>> c.f(Integer(2), power=Integer(2))
(Lambda[0] + Lambda[1] - 2*Lambda[2],)

\(\phi(i)\)

Return the distance to the end of the \(i\)-string.

This method overrides the generic implementation in the category of crystals since this computation is more efficient.

EXAMPLES:

```
sage: C = crystals.LSPaths(['A', '2'], [1, 1])
sage: [c.phi(1) for c in C]
[1, 0, 0, 1, 0, 2, 1, 0]
sage: [c.phi(2) for c in C]
[1, 2, 1, 0, 0, 0, 0, 1]
```

```
>>> from sage.all import *
>>> C = crystals.LSPaths(['A', Integer(2)], [Integer(1), Integer(1)])
>>> [c.phi(Integer(1)) for c in C]
[1, 0, 0, 1, 0, 2, 1, 0]
>>> [c.phi(Integer(2)) for c in C]
[1, 2, 1, 0, 0, 0, 0, 1]
```

\(\text{reflect\_step}(which\_step, i)\)

Apply the \(i\)-th simple reflection to the indicated step in self.

EXAMPLES:
```
sage: C = crystals.LSPaths(["A", 2], [1, 1])
sage: b = C.module_generators[0]
sage: b.reflect_step(0, 1)
(-Lambda[1] + 2*Lambda[2],)
sage: b.reflect_step(0, 2)
```

```>>> from sage.all import *
>>> C = crystals.LSPaths(["A", Integer(2)], [Integer(1), Integer(1)])
>>> b = C.module_generators[Integer(0)]
>>> b.reflect_step(Integer(0), Integer(1))
(-Lambda[1] + 2*Lambda[2],)
>>> b.reflect_step(Integer(0), Integer(2))
```

$s(i)$

Compute the reflection of self along the $i$-string.

This method is more efficient than the generic implementation since it uses powers of $e$ and $f$ in the Littelmann model directly.

EXAMPLES:

```
sage: C = crystals.LSPaths(["A", 2], [1, 1])
sage: c = C.module_generators[0]
sage: c.s(1)
(-Lambda[1] + 2*Lambda[2],)
sage: c.s(2)
sage: C = crystals.LSPaths(["A", 2, 1], [-1, 0, 1])
sage: c = C.module_generators[0]; c
(-Lambda[0] + Lambda[2],)
sage: c.s(2)
(Lambda[1] - Lambda[2],)
sage: c.s(1)
(-Lambda[0] + Lambda[2],)
sage: c.f(2).s(1)
(Lambda[0] - Lambda[1],)
```

```>>> from sage.all import *
>>> C = crystals.LSPaths(["A", Integer(2)], [Integer(1), Integer(1)])
>>> c = C.module_generators[Integer(0)]
>>> c.s(Integer(1))
(-Lambda[1] + 2*Lambda[2],)
>>> c.s(Integer(2))
>>> C = crystals.LSPaths(["A", Integer(2), Integer(1)], [-Integer(1), \rightarrow Integer(0), Integer(1)])
>>> c = C.module_generators[Integer(0)]; c
(-Lambda[0] + Lambda[2],)
>>> c.s(Integer(2))
(Lambda[1] - Lambda[2],)
>>> c.s(Integer(1))
(-Lambda[0] + Lambda[2],)
>>> c.f(Integer(2)).s(Integer(1))
```

(continues on next page)
split_step(\textit{which\_step}, r)

Split the indicated step into two parallel steps of relative lengths \( r \) and \( 1 - r \).

\textbf{INPUT:}

- \textit{which\_step} – a position in the tuple \textit{self}
- \textit{r} – a rational number between 0 and 1

\textbf{EXAMPLES:}

```python
sage: C = crystals.LSPaths(['A', 2], [1, 1])
sage: b = C.module_generators[0]
sage: b.split_step(0, 1/3)
```

weight()

Return the weight of \textit{self}.

\textbf{EXAMPLES:}

```python
sage: B = crystals.LSPaths(['A', 1, 1], [1, 0])
sage: b = B.highest_weight_vector()
sage: b.f(0).weight() -Lambda[0] + 2*Lambda[1] - delta
```

weight_lattice_realization()

Return weight lattice realization of \textit{self}.

\textbf{EXAMPLES:}

```python
sage: B = crystals.LSPaths(['B', 3], [1, 1, 0])
```

(continues on next page)
>> B = crystals.LSPaths(["B", Integer(3), Integer(1)], [Integer(1), Integer(1), Integer(0)])
>> B.weight_lattice_realization()

Extended weight space over the Rational Field of the Root system of type ['B', → 3, 1]

**class** sage.combinat.crystals.littelmann_path.CrystalOfProjectedLevelZeroLSPaths(*starting_weight*, *starting_weight_parent*)

**Bases:** CrystalOfLSPaths

Crystal of projected level zero LS paths.

**INPUT:**

- *weight* – a dominant weight of the weight space of an affine Kac-Moody root system

When *weight* is just a single fundamental weight \( \Lambda_r \), this crystal is isomorphic to a Kirillov-Reshetikhin (KR) crystal, see also sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinFromLSPaths(). For general weights, it is isomorphic to a tensor product of single-column KR crystals.

**EXAMPLES:**

```python
sage: R = RootSystem(['C',3,1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(La[1]+La[3])
sage: LS.cardinality()
84
sage: GLS = LS.digraph()
```

```python
sage: K1 = crystals.KirillovReshetikhin(['C',3,1],1,1)
sage: K3 = crystals.KirillovReshetikhin(['C',3,1],3,1)
sage: T = crystals.TensorProduct(K3,K1)
sage: T.cardinality()
84
sage: GT = T.digraph() # long time
sage: GLS.is_isomorphic(GT, edge_labels = True) # long time
True
```

```python
>>> from sage.all import *
>>> R = RootSystem(['C','3',1])
>>> La = R.weight_space().basis()
>>> LS = crystals.ProjectedLevelZeroLSPaths(La[Integer(1)]+La[Integer(3)])
>>> LS.cardinality()
84
>>> GLS = LS.digraph()
```

```python
>>> K1 = crystals.KirillovReshetikhin(['C','3',1],1,1)
>>> K3 = crystals.KirillovReshetikhin(['C','3',1],3,1)
>>> T = crystals.TensorProduct(K3,K1)
>>> T.cardinality()
84
```

5.1. Comprehensive Module List
class Element

    Bases: Element

    Element of a crystal of projected level zero LS paths.

    energy_function()

    Return the energy function of self.

    The energy function $D(\pi)$ of the level zero LS path $\pi \in B_{\text{cl}}(\lambda)$ requires a series of definitions; for simplicity the root system is assumed to be untwisted affine.

    The LS path $\pi$ is a piecewise linear map from the unit interval $[0, 1]$ to the weight lattice. It is specified by “times” $0 = \sigma_0 < \sigma_1 < \cdots < \sigma_s = 1$ and “direction vectors” $x_u \lambda$ where $x_u \in W/W_J$ for $1 \leq u \leq s$, and $W_J$ is the stabilizer of $\lambda$ in the finite Weyl group $W$. Precisely,

    $$
    \pi(t) = \sum_{u=1}^{u-1} (\sigma_{u'} - \sigma_{u'-1})x_{u'}\lambda + (t - \sigma_{u-1})x_u\lambda
    $$

    for $1 \leq u \leq s$ and $\sigma_{u-1} \leq t \leq \sigma_u$.

    For any $x, y \in W/W_J$, let

    $$
    d : x = w_0 \beta_1 \leftrightarrow w_1 \beta_2 \cdots \leftrightarrow w_{n} = y
    $$

    be a shortest directed path in the parabolic quantum Bruhat graph. Define

    $$
    \text{wt}(d) := \sum_{1 \leq k \leq n} \beta_k^\vee
    $$

    for $\ell(w_{k-1}) < \ell(w_k)$. It can be shown that $\text{wt}(d)$ depends only on $x, y$; call its value $\text{wt}(x, y)$. The energy function $D(\pi)$ is defined by

    $$
    D(\pi) = -\sum_{u=1}^{s-1} (1 - \sigma_u)\langle \lambda, \text{wt}(x_u, x_{u+1}) \rangle
    $$

    For more information, see [LNSSS2013].

    Note: In the dual-of-untwisted case the parabolic quantum Bruhat graph that is used is obtained by exchanging the roles of roots and coroots. Moreover, in the computation of the pairing the short roots must be doubled (or tripled for type $G$). This factor is determined by the translation factor of the corresponding root. Type $BC$ is viewed as untwisted type, whereas the dual of $BC$ is viewed as twisted. Except for the untwisted cases, these formulas are currently still conjectural.

    EXAMPLES:

    sage: R = RootSystem(['C',3,1])
    sage: La = R.weight_space().basis()
    sage: LS = crystals.ProjectedLevelZeroLSPaths(La[1]+La[3])
    sage: b = LS.module_generators[0]
    sage: c = b.f(1).f(3).f(2)
from sage.all import *

R = RootSystem(['C',Integer(3),Integer(1)])
La = R.weight_space().basis()
LS = crystals.ProjectedLevelZeroLSPaths(La[Integer(1)]+La[Integer(3)])
b = LS.module_generators[Integer(0)]
c = b.f(Integer(1)).f(Integer(3)).f(Integer(2))
c.energy_function()
0
c=b.e(Integer(0))
c.energy_function()
1

R = RootSystem(['A',Integer(2),Integer(1)])
La = R.weight_space().basis()
LS = crystals.ProjectedLevelZeroLSPaths(Integer(2)*La[Integer(1)])
b = LS.module_generators[Integer(0)]
c = b.e(Integer(0))
c.energy_function()
1

for c in sorted(LS, key=str):
  print("{} {}\n").format(c,c.energy_function()))

(-2*Lambda[0] + 2*Lambda[1],) 0
(-2*Lambda[1] + 2*Lambda[2],) 0
(-Lambda[0] + Lambda[1], -Lambda[1] + Lambda[2]) 1
(-Lambda[0] + Lambda[1], Lambda[0] - Lambda[2]) 1
(2*Lambda[0] - 2*Lambda[2],) 0
(Lambda[0] - Lambda[2], -Lambda[0] + Lambda[1]) 0

The next test checks that the energy function is constant on classically connected components:
sage: R = RootSystem(['A',2,1])
sage: La = R.weight_space().basis()
sage: G = LS.digraph(index_set=[1,2])
sage: C = G.connected_components(sort=False)
sage: [all(c[0].energy_function()==a.energy_function() for a in c) for c in C]
[True, True, True, True]

sage: R = RootSystem(['D',4,2])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(La[2])
sage: J = R.cartan_type().classical().index_set()
sage: hw = [x for x in LS if x.is_highest_weight(J)]
sage: [(x.weight(), x.energy_function()) for x in hw]
[(-2*Lambda[0] + Lambda[2], 0), (-2*Lambda[0] + Lambda[1], 1), (0, 2)]

sage: G = LS.digraph(index_set=J)
sage: C = G.connected_components(sort=False)

sage: [all(c[0].energy_function()==a.energy_function() for a in c) for c in C]
[True, True, True]

sage: R = RootSystem(CartanType(['G',2,1]).dual())
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(La[1]+La[2])
sage: G = LS.digraph(index_set=R.cartan_type().classical().index_set())
sage: C = G.connected_components(sort=False)

sage: [all(c[0].energy_function()==a.energy_function() for a in c) for c in C]
# long time
[True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True]
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> LS = crystals.ProjectedLevelZeroLSPaths(Integer(2)*La[Integer(1)]+La[Integer(2)])
>>> G = LS.digraph(index_set=[Integer(1), Integer(2)])
>>> C = G.connected_components(sort=False)
>>> [all(c[Integer(0)].energy_function()==a.energy_function() for a in c) for c in C]
[True, True, True, True]
>>> R = RootSystem(['D', Integer(4), Integer(2)])
>>> La = R.weight_space().basis()
>>> LS = crystals.ProjectedLevelZeroLSPaths(La[Integer(1)])

[True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True]
```

Scalar Factors

Return the scalar factors for `self`.  

5.1. Comprehensive Module List 803
Each LS path (or self) can be written as a piecewise linear map
\[ \pi(t) = \sum_{u'=1}^{u-1} (\sigma_{u'} - \sigma_{u'-1})\nu_{u'} + (t - \sigma_{u-1})\nu_u \]
for \(0 < \sigma_1 < \sigma_2 < \cdots < \sigma_s = 1\) and \(\sigma_{u-1} \leq t \leq \sigma_u\) and \(1 \leq u \leq s\). This method returns the tuple of \((\sigma_1, \ldots, \sigma_s)\).

**EXAMPLES:**

```python
sage: R = RootSystem(['C', 3, 1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(La[1]+La[3])
sage: b = LS.module_generators[0]
sage: b.scalar_factors()
[1]
sage: c = b.f(1).f(3).f(2)
sage: c.scalar_factors()
[1/3, 1]
```

**weyl_group_representation()**

Transform the weights in the LS path self to elements in the Weyl group.

Each LS path can be written as the piecewise linear map:
\[ \pi(t) = \sum_{u'=1}^{u-1} (\sigma_{u'} - \sigma_{u'-1})\nu_{u'} + (t - \sigma_{u-1})\nu_u \]
for \(0 < \sigma_1 < \sigma_2 < \cdots < \sigma_s = 1\) and \(\sigma_{u-1} \leq t \leq \sigma_u\) and \(1 \leq u \leq s\). Each weight \(\nu_u\) is also associated to a Weyl group element. This method returns the list of Weyl group elements associated to the \(\nu_u\) for \(1 \leq u \leq s\).

**EXAMPLES:**

```python
sage: R = RootSystem(['C', 3, 1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(La[1]+La[3])
sage: b = LS.module_generators[0]
sage: b.weyl_group_representation()
[s2*s1*s3, s1*s3]
```

```python
>>> from sage.all import *
>>> R = RootSystem(['C', Integer(3), Integer(1)])
>>> La = R.weight_space().basis()
>>> LS = crystals.ProjectedLevelZeroLSPaths(La[Integer(1)]+La[Integer(3)])
>>> b = LS.module_generators[Integer(0)]
>>> b.weyl_group_representation()
[s2*s1*s3, s1*s3]
```
```python
>>> b = LS.module_generators[Integer(0)]
>>> c = b.f(Integer(1)).f(Integer(3)).f(Integer(2))
>>> c.weyl_group_representation()
[s2*s1*s3, s1*s3]
```

**classically_highest_weight_vectors()**

Return the classically highest weight vectors of *self*.

**EXAMPLES:**

```python
sage: R = RootSystem(['A',2,1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(2*La[1])
sage: LS.classically_highest_weight_vectors()
((-2*Lambda[0] + 2*Lambda[1],),
 (-Lambda[0] + Lambda[1], -Lambda[1] + Lambda[2]))
```

```python
>>> from sage.all import *
>>> R = RootSystem(['A',Integer(2),Integer(1)])
>>> La = R.weight_space().basis()
>>> LS = crystals.ProjectedLevelZeroLSPaths(Integer(2)*La[Integer(1)])
>>> LS.classically_highest_weight_vectors()
((-2*Lambda[0] + 2*Lambda[1],),
 (-Lambda[0] + Lambda[1], -Lambda[1] + Lambda[2]))
```

**is_perfect**(level=1)

Check whether the crystal *self* is perfect (of level *level*).

**INPUT:**

- level – (default: 1) positive integer

A crystal *B* is perfect of level *ℓ* if:

1. *B* is isomorphic to the crystal graph of a finite-dimensional $U'_q(g)$-module.
2. *B* ⊗ *B* is connected.
3. There exists a $\lambda \in X$, such that $\text{wt}(B) \subset \lambda + \sum_{i \in I} Z_{\leq 0} \alpha_i$ and there is a unique element in *B* of classical weight $\lambda$.
4. For all $b \in B$, $\text{level}(\varepsilon(b)) \geq \ell$.
5. For all $\Lambda$ dominant weights of level $\ell$, there exist unique elements $b_\Lambda, b^\Lambda \in B$, such that $\varepsilon(b_\Lambda) = \Lambda = \varphi(b^\Lambda)$.

Points (1)-(3) are known to hold. This method checks points (4) and (5).

**EXAMPLES:**

```python
sage: C = CartanType(['C',2,1])
sage: R = RootSystem(C)
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(La[1])
sage: LS.is_perfect()
False
sage: LS = crystals.ProjectedLevelZeroLSPaths(La[2])
sage: LS.is_perfect()
True
```

(continues on next page)
sage: C = CartanType(['E', 6, 1])
sage: R = RootSystem(C)
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(La[1])
sage: LS.is_perfect()
True
sage: LS.is_perfect(2)
False
sage: C = CartanType(['D', 4, 1])
sage: R = RootSystem(C)
sage: La = R.weight_space().basis()
sage: all(crystals.ProjectedLevelZeroLSPaths(La[i]).is_perfect() for i in [1, 2, 3, 4])
True
sage: C = CartanType(['A', 6, 2])
sage: R = RootSystem(C)
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(La[1]+La[2])
sage: LS.is_perfect()
True
sage: LS.is_perfect(2)
False

>>> from sage.all import *

>>> C = CartanType(['C', Integer(2), Integer(1)])
>>> R = RootSystem(C)
>>> La = R.weight_space().basis()
>>> LS = crystals.ProjectedLevelZeroLSPaths(La[Integer(1)])
>>> LS.is_perfect()
False
>>> LS = crystals.ProjectedLevelZeroLSPaths(La[Integer(2)])
>>> LS.is_perfect()
True

>>> C = CartanType(['E', Integer(6), Integer(1)])
>>> R = RootSystem(C)
>>> La = R.weight_space().basis()
>>> LS = crystals.ProjectedLevelZeroLSPaths(La[Integer(1)])
>>> LS.is_perfect()
True
>>> LS.is_perfect(Integer(2))
False

>>> C = CartanType(['D', Integer(4), Integer(1)])
>>> R = RootSystem(C)
>>> La = R.weight_space().basis()
>>> all(crystals.ProjectedLevelZeroLSPaths(La[i]).is_perfect() for i in [Integer(1), Integer(2), Integer(3), Integer(4)])
True

>>> C = CartanType(['A', Integer(6), Integer(2)])
>>> R = RootSystem(C)
>>> La = R.weight_space().basis()
LS = crystals.ProjectedLevelZeroLSPaths(La[Integer(1)]+La[Integer(2)])
LS.is_perfect()
True
LS.is_perfect(Integer(2))
False

maximal_vector()
Return the maximal vector of self.
EXAMPLES:
sage: R = RootSystem(['A',2,1])
sage: La = R.weight_space().basis()
sage: LS.maximal_vector()
(-3*Lambda[0] + 2*Lambda[1] + Lambda[2],)

from sage.all import *

R = RootSystem(['A',Integer(2),Integer(1)])
La = R.weight_space().basis()
LS = crystals.ProjectedLevelZeroLSPaths(Integer(2)*La[Integer(1)]+La[Integer(2)])
LS.maximal_vector()
(-3*Lambda[0] + 2*Lambda[1] + Lambda[2],)

one_dimensional_configuration_sum(q=None, group_components=True)
Compute the one-dimensional configuration sum.
INPUT:
• q – (default: None) a variable or None; if None, a variable q is set in the code
• group_components – (default: True) boolean; if True, then the terms are grouped by classical component
The one-dimensional configuration sum is the sum of the weights of all elements in the crystal weighted by the energy function. For untwisted types it uses the parabolic quantum Bruhat graph, see [LNSSS2013]. In the dual-of-untwisted case, the parabolic quantum Bruhat graph is defined by exchanging the roles of roots and coroots (which is still conjectural at this point).
EXAMPLES:
sage: R = RootSystem(['A',2,1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(2*La[1])
sage: LS.one_dimensional_configuration_sum() # long time
B[-2*Lambda[1] + 2*Lambda[2]] + (q+1)*B[-Lambda[1]]
+ B[-2*Lambda[2]] + (q+1)*B[Lambda[2]]
sage: R.<t> = ZZ[]
sage: LS.one_dimensional_configuration_sum(t, False) # long time
B[-2*Lambda[1] + 2*Lambda[2]] + (t+1)*B[-Lambda[1]]
+ B[-2*Lambda[2]] + (t+1)*B[Lambda[2]]

from sage.all import *
R = RootSystem(['A',Integer(2),Integer(1)])
Combinatorics, Release 10.4

(continued from previous page)

>>>
La = R.weight_space().basis()
>>> LS = crystals.ProjectedLevelZeroLSPaths(Integer(2)*La[Integer(1)])
>>> LS.one_dimensional_configuration_sum() # long time
B[-2*Lambda[1] + 2*Lambda[2]] + (q+1)*B[-Lambda[1]]
+ B[-2*Lambda[2]] + (q+1)*B[Lambda[2]]

>>> R = ZZ[t]; (t,) = R._first_ngens(1)
>>> LS.one_dimensional_configuration_sum(t, False) # long time
B[-2*Lambda[1] + 2*Lambda[2]] + (t+1)*B[-Lambda[1]]
+ B[-2*Lambda[2]] + (t+1)*B[Lambda[2]]

class sage.combinat.crystals.littelmann_path.InfinityCrystalOfLSPaths(car-
tan_type)

Bases: UniqueRepresentation, Parent

LS path model for $B(\infty)$.

Elements of $B(\infty)$ are equivalence classes of paths $[\pi]$ in $B(k\rho)$ for $k \gg 0$, where $\rho$ is the Weyl vector. A canonical representative for an element of $B(\infty)$ is chosen by taking $k$ to be minimal such that the endpoint of $\pi$ is strictly dominant but its representative in $B((k-1)\rho)$ is on the wall of the dominant chamber.

REFERENCES:
  • [LZ2011]

class Element

Bases: Element

e(i, power=1, length_only=False)

Return the $i$-th crystal raising operator on self.

INPUT:
  • i – element of the index set
  • power – (default: 1) positive integer; specifies the power of the lowering operator to be applied
  • length_only – (default: False) boolean; if True, then return the distance to the anti-dominant end of the $i$-string of self

EXAMPLES:

sage: B = crystals.infinity.LSPaths(['B',3,1])
sage: mg = B.module_generator()
sage: mg.e(0)
sage: mg.e(1)
sage: mg.e(2)
sage: x = mg.f_string([1,0,2,1,0,2,1,1,0])
sage: all(x.f(i).e(i) == x for i in B.index_set())
True
sage: all(x.e(i).f(i) == x for i in B.index_set() if x.epsilon(i) > 0)
True

>>> from sage.all import *

>>> B = crystals.infinity.LSPaths(['B',Integer(3),Integer(1)])
>>> mg = B.module_generator()
>>> mg.e(Integer(0))
>>> mg.e(Integer(1))
>>> mg.e(Integer(2))
>>> x = mg.f_string([Integer(1),Integer(0),Integer(2),Integer(1),Integer(0)],
(continues on next page)
\[ \textbf{f}(i, \text{power}=1, \text{length_only}=\text{False}) \]

Return the \(i\)-th crystal lowering operator on \(\text{self}\).

\textbf{INPUT:}

\begin{itemize}
  \item \(i\) – element of the index set
  \item \text{power} – (default: 1) positive integer; specifies the power of the lowering operator to be applied
  \item \text{length_only} – (default: False) boolean; if True, then return the distance to the anti-dominant end of the \(i\)-string of \(\text{self}\)
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: B = crystals.infinity.LSPaths(['D',3,2])
sage: mg = B.highest_weight_vector()
sage: mg.f(1)
(3*Lambda[0] - Lambda[1] + 3*Lambda[2],
sage: mg.f(2)
(Lambda[0] + 2*Lambda[1] - Lambda[2],
sage: mg.f(0)
(-Lambda[0] + 2*Lambda[1] + Lambda[2] - delta,
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> B = crystals.infinity.LSPaths(['D',Integer(3),Integer(2)])

>>> mg = B.highest_weight_vector()

>>> mg.f(Integer(1))
(3*Lambda[0] - Lambda[1] + 3*Lambda[2],

>>> mg.f(Integer(2))
(Lambda[0] + 2*Lambda[1] - Lambda[2],

>>> mg.f(Integer(0))
(-Lambda[0] + 2*Lambda[1] + Lambda[2] - delta,
\end{verbatim}

\textbf{phi}(i)

Return \(\varphi_i\) of \(\text{self}\).

Let \(\pi \in \mathcal{B}(\infty)\). Define

\[ \varphi_i(\pi) := \varepsilon_i(\pi) + \langle h_i, \text{wt}(\pi) \rangle, \]

where \(h_i\) is the \(i\)-th simple coroot and \(\text{wt}(\pi)\) is the \textit{weight} of \(\pi\).

\textbf{INPUT:}

\begin{itemize}
  \item \(i\) – element of the index set
\end{itemize}

\textbf{EXAMPLES:}
weight()
Return the weight of self.

Todo: This is a generic algorithm. We should find a better description and implement it.

EXAMPLES:

```
sage: B = crystals.infinity.LSPaths(['E',6])
sage: mg = B.highest_weight_vector()
sage: f_seq = [1,4,2,6,4,2,3,1,5,5]
sage: x = mg.f_string(f_seq)
sage: x.weight()
sage: al = B.cartan_type().root_system().weight_space().simple_roots()
sage: x.weight() == -sum(al[i] for i in f_seq)
True
```

module_generator()
Return the module generator (or highest weight element) of self.

The module generator is the unique path \( \pi_\infty: t \mapsto t \rho \), for \( t \in [0, \infty) \).

EXAMPLES:

```
sage: B = crystals.infinity.LSPaths(['A',6,2])
sage: mg = B.module_generator(); mg
(Lambda[0] + Lambda[1] + Lambda[2] + Lambda[3],)
```

(continues on next page)
sage: mg.weight()
0

>>> from sage.all import *
>>> B = crystals.infinity.LSPaths(['A',Integer(6),Integer(2)])
>>> mg = B.module_generator(); mg
(Lambda[0] + Lambda[1] + Lambda[2] + Lambda[3],)
>>> mg.weight()
0

weight_lattice_realization()

Return the weight lattice realization of self.

EXAMPLES:

sage: B = crystals.infinity.LSPaths(['C',4])
sage: B.weight_lattice_realization()
Weight space over the Rational Field of the Root system of type ['C', 4]

sage.combinat.crystals.littelmann_path.positively_parallel_weights(v, w)

Check whether the vectors v and w are positive scalar multiples of each other.

EXAMPLES:

sage: from sage.combinat.crystals.littelmann_path import positively_parallel_weights
sage: La = RootSystem(['A',5,2]).weight_space(extended=True).fundamental_weights()
sage: rho = sum(La)
sage: positively_parallel_weights(rho, 4*rho)
True
sage: positively_parallel_weights(4*rho, rho)
True
sage: positively_parallel_weights(rho, -rho)
False
sage: positively_parallel_weights(rho, La[1] + La[2])
False

>>> from sage.all import *
>>> from sage.combinat.crystals.littelmann_path import positively_parallel_weights
>>> La = RootSystem(['A',Integer(5),Integer(2)]).weight_space(extended=True).fundamental_weights()
>>> rho = sum(La)
>>> positively_parallel_weights(rho, Integer(4)*rho)
True
>>> positively_parallel_weights(Integer(4)*rho, rho)
True
>>> positively_parallel_weights(rho, -rho)
False
>>> positively_parallel_weights(rho, La[Integer(1)] + La[Integer(2)])
False
5.1.59 Crystals of Modified Nakajima Monomials

AUTHORS:

• Arthur Lubovsky: Initial version
• Ben Salisbury: Initial version

Let $Y_{i,k}$, for $i \in I$ and $k \in \mathbb{Z}$, be a commuting set of variables, and let $1$ be a new variable which commutes with each $Y_{i,k}$. (Here, $I$ represents the index set of a Cartan datum.) One may endow the structure of a crystal on the set $\mathcal{M}$ of monomials of the form

$$M = \prod_{(i,k) \in I \times \mathbb{Z}_{\geq 0}} Y_{i,k}^{y_i(k)} 1.$$

Elements of $\mathcal{M}$ are called modified Nakajima monomials. We will omit the $1$ from the end of a monomial if there exists at least one $y_i(k) \neq 0$. The crystal structure on this set is defined by

$$\text{wt}(M) = \sum_{i \in I} \left( \sum_{k \geq 0} y_i(k) \right) \Lambda_i,$$

$$\varphi_i(M) = \max \left\{ \sum_{0 \leq j \leq k} y_i(j) : k \geq 0 \right\},$$

$$\varepsilon_i(M) = \varphi_i(M) - (h_i, \text{wt}(M)),$$

$$k_f = k_f(M) = \min \left\{ k \geq 0 : \varphi_i(M) = \sum_{0 \leq j \leq k} y_i(j) \right\},$$

$$k_e = k_e(M) = \max \left\{ k \geq 0 : \varphi_i(M) = \sum_{0 \leq j \leq k} y_i(j) \right\},$$

where $\{h_i : i \in I\}$ and $\{\Lambda_i : i \in I\}$ are the simple coroots and fundamental weights, respectively. With a chosen set of integers $C = (c_{ij})_{i \neq j}$ such that $c_{ij} + c_{ji} = 1$, one defines

$$A_{i,k} = Y_{i,k} Y_{i,k+1} \prod_{j \neq i} Y_{j,k+c_{ij}},$$

where $(a_{ij})$ is a Cartan matrix. Then

$$e_i M = \begin{cases} 0 & \text{if } \varepsilon_i(M) = 0, \\ A_{i,k} M & \text{if } \varepsilon_i(M) > 0, \end{cases}$$

$$f_i M = A_{i,k}^{-1} M.$$

It is shown in [KKS2007] that the connected component of $\mathcal{M}$ containing the element $1$, which we denote by $\mathcal{M}(\infty)$, is crystal isomorphic to the crystal $B(\infty)$.

Let $\mathcal{\tilde{M}}$ be $\mathcal{M}$ as a set, and with crystal structure defined as on $\mathcal{M}$ with the exception that

$$f_i M = \begin{cases} 0 & \text{if } \varphi_i(M) = 0, \\ A_{i,k}^{-1} M & \text{if } \varphi_i(M) > 0. \end{cases}$$

Then Kashiwara [Ka2003] showed that the connected component in $\mathcal{\tilde{M}}$ containing a monomial $M$ such that $e_i M = 0$, for all $i \in I$, is crystal isomorphic to the irreducible highest weight crystal $B(\text{wt}(M))$.

WARNING:

Monomial crystals depend on the choice of positive integers $C = (c_{ij})_{i \neq j}$ satisfying the condition $c_{ij} + c_{ji} = 1$. We have chosen such integers uniformly such that $c_{ij} = 1$ if $i < j$ and $c_{ij} = 0$ if $i > j$. 

812 Chapter 5. Comprehensive Module List
class \texttt{sage.combinat.crystals.monomial\_crystals.CrystalOfNakajimaMonomials}(ct, La, c)

Bases: \texttt{InfinityCrystalOfNakajimaMonomials}

Let $\tilde{\mathcal{M}}$ be $\tilde{\mathcal{M}}$ as a set, and with crystal structure defined as on $\twiddle{\mathcal{M}}$ with the exception that

$$f_i M = \begin{cases} 
0 & \text{if } \varphi_i(M) = 0, \\
A_{i,j}^{-1} M & \text{if } \varphi_i(M) > 0.
\end{cases}$$

Then Kashiwara [Ka2003] showed that the connected component in $\twiddle{\mathcal{M}}$ containing a monomial $M$ such that $e_i M = 0$, for all $i \in I$, is crystal isomorphic to the irreducible highest weight crystal $B(\text{wt}(M))$.

INPUT:

- ct – a Cartan type
- La – an element of the weight lattice

EXAMPLES:

```python
sage: La = RootSystem("A2").weight_lattice().fundamental_weights()
sage: B = crystals.Tableaux("A2",shape=[2,1])
sage: GM = M.digraph()
sage: GB = B.digraph()
sage: GM.is_isomorphic(GB,edge_labels=True)
True
```

(continues on next page)
sage: B = crystals.LSPaths(3*LA[0])
sage: SM = M.subcrystal(max_depth=4)
sage: SB = B.subcrystal(max_depth=4)
sage: GM = M.digraph(subset=SM)
sage: GB = B.digraph(subset=SB)
sage: GM.is_isomorphic(GB, edge_labels=True)

True

sage: c = matrix([[0,1,0],[0,0,1],[1,0,0]])

Class sage.combinat.crystals.monomial_crystals.CrystalOfNakajimaMonomialsElement (parent, Y, A)

Bases: NakajimaMonomial

Element class for CrystalOfNakajimaMonomials.

The $f_i$ operators need to be modified from the version in monomial_crystalsNakajimaMonomial in order to create irreducible highest weight realizations. This modified $f_i$ is defined as

$$f_i M = \begin{cases} 
0 & \text{if } \varphi_i(M) = 0, \\
A_{i,k} M & \text{if } \varphi_i(M) > 0.
\end{cases}$$

EXAMPLES:

```
sage: La = RootSystem(['A', 5, 2]).weight_lattice(extended=True).fundamental_weights()
sage: M = crystals.NakajimaMonomials(['A', 5, 2], 3*La[0])
sage: m = M.module_generators[0].f(0); m
Y(0,0)^2 Y(0,1)^{-1} Y(2,0)
sage: TestSuite(m).run()
```
```python
>>> from sage.all import *

>>> La = RootSystem(['A', Integer(5), Integer(2)]).weight_lattice(extended=True).fundamental_weights()

>>> M = crystals.NakajimaMonomials(['A', Integer(5), Integer(2)], -Integer(3)*La[Integer(0)])

>>> m = M.module_generators[Integer(0)]

>>> [m.f(i) for i in M.index_set()]
[(Y(0,0)^2 Y(0,1)^-1 Y(2,0), None, None, None)]

sage: M = crystals.infinity.NakajimaMonomials("E8")

sage: M.set_variables(A)

sage: m = M.module_generators[0].f_string([Integer(4), Integer(2), Integer(3), Integer(8)])

sage: m
A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(8,0)^-1

sage: [m.f(i) for i in M.index_set()]
[A(1,2)^-1 A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(8,0)^-1,
 A(2,0)^-1 A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(8,0)^-1,
 A(2,1)^-1 A(3,0)^-1 A(3,1)^-1 A(4,0)^-1 A(8,0)^-1,
 A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(4,1)^-1 A(8,0)^-1,
 A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(5,0)^-1 A(8,0)^-1,
 A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(6,0)^-1 A(8,0)^-1,
 A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(7,1)^-1 A(8,0)^-1,
 A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(8,0)^-2]

sage: M.set_variables(Y)

```

weight()

Return the weight of self as an element of the weight lattice.

EXAMPLES:

```python
sage: La = RootSystem("A2").weight_lattice().fundamental_weights()

sage: M.module_generators[0].weight()
(2, 1, 0)

>>> from sage.all import *

>>> La = RootSystem("A2").weight_lattice().fundamental_weights()

>>> M = crystals.NakajimaMonomials("A2",La[Integer(1)]+La[Integer(2)])

(continues on next page)
>>>
M.module_generators[Integer(0)].weight()
(2, 1, 0)

class sage.combinat.crystals.monomial_crystals.InfinityCrystalOfNakajimaMonomials (ct,
category=None)

Bases: UniqueRepresentation, Parent

Crystal \(B(\infty)\) in terms of (modified) Nakajima monomials.

Let \(Y_{i,k}\), for \(i \in I\) and \(k \in \mathbb{Z}\), be a commuting set of variables, and let \(1\) be a new variable which commutes with each \(Y_{i,k}\). (Here, \(I\) represents the index set of a Cartan datum.) One may endow the structure of a crystal on the set \(\widehat{\mathcal{M}}\) of monomials of the form

\[
M = \prod_{(i,k) \in I \times \mathbb{Z}_{\geq 0}} Y_{i,k}^{y_i(k)} 1.
\]

Elements of \(\widehat{\mathcal{M}}\) are called modified Nakajima monomials. We will omit the 1 from the end of a monomial if there exists at least one \(y_i(k) \neq 0\). The crystal structure on this set is defined by

\[
\text{wt}(M) = \sum_{i \in I} \left( \sum_{k \geq 0} y_i(k) \right) \Lambda_i,
\]
\[
\varphi_i(M) = \max \left\{ \sum_{0 \leq j \leq k} y_i(j) : k \geq 0 \right\},
\]
\[
\varepsilon_i(M) = \varphi_i(M) - (h_i, \text{wt}(M)),
\]
\[
k_f = k_f(M) = \min \left\{ k \geq 0 : \varphi_i(M) = \sum_{0 \leq j \leq k} y_i(j) \right\},
\]
\[
k_e = k_e(M) = \max \left\{ k \geq 0 : \varphi_i(M) = \sum_{0 \leq j \leq k} y_i(j) \right\},
\]

where \(\{h_i : i \in I\}\) and \(\{\Lambda_i : i \in I\}\) are the simple coroots and fundamental weights, respectively. With a chosen set of non-negative integers \(C = (c_{ij})_{i \neq j}\) such that \(c_{ii} = 0\) for all \(i \in I\), \(c_{ij} \in \mathbb{Z}_{>0}\) for all \(i, j \in I\), and \(c_{ij} + c_{ji} = 1\) for all \(i \neq j\); the default is \(c_{ij} = 0\) if \(i < j\) and 0 otherwise.

It is shown in [KKS2007] that the connected component of \(\widehat{\mathcal{M}}\) containing the element 1, which we denote by \(\mathcal{M}(\infty)\), is crystal isomorphic to the crystal \(B(\infty)\).

INPUT:

- **cartan_type** – a Cartan type
- **c** – (optional) the matrix \((c_{ij})_{i,j \in I}\) such that \(c_{ii} = 0\) for all \(i \in I\), \(c_{ij} \in \mathbb{Z}_{>0}\) for all \(i, j \in I\), and \(c_{ij} + c_{ji} = 1\) for all \(i \neq j\); the default is \(c_{ij} = 0\) if \(i < j\) and 0 otherwise
EXAMPLES:

```python
sage: B = crystals.infinity.Tableaux("C3")
sage: S = B.subcrystal(max_depth=4)
sage: G = B.digraph(subset=S) # long time
sage: M = crystals.infinity.NakajimaMonomials("C3") # long time
sage: T = M.subcrystal(max_depth=4) # long time
sage: H = M.digraph(subset=T) # long time
sage: G.is_isomorphic(H, edge_labels=True) # long time
True

sage: M = crystals.infinity.NakajimaMonomials(['A',2,1])
sage: T = M.subcrystal(max_depth=3)
sage: H = M.digraph(subset=T) # long time
sage: Y = crystals.infinity.GeneralizedYoungWalls(2)
sage: YS = Y.subcrystal(max_depth=3)
sage: YG = Y.digraph(subset=YS) # long time
sage: YG.is_isomorphic(H, edge_labels=True) # long time
True

sage: M = crystals.infinity.NakajimaMonomials("D4")
sage: B = crystals.infinity.Tableaux("D4")
sage: MS = M.subcrystal(max_depth=3)
sage: BS = B.subcrystal(max_depth=3)
sage: MG = M.digraph(subset=MS) # long time
sage: BG = B.digraph(subset=BS) # long time
sage: BG.is_isomorphic(MG, edge_labels=True) # long time
True
```

>>> from sage.all import *
>>> B = crystals.infinity.Tableaux("C3")
>>> S = B.subcrystal(max_depth=Integer(4))
>>> G = B.digraph(subset=S) # long time
>>> M = crystals.infinity.NakajimaMonomials("C3") # long time
>>> T = M.subcrystal(max_depth=Integer(4)) # long time
>>> H = M.digraph(subset=T) # long time
>>> G.is_isomorphic(H, edge_labels=True) # long time
True

>>> M = crystals.infinity.NakajimaMonomials(['A',Integer(2),Integer(1)])
>>> T = M.subcrystal(max_depth=Integer(3))
>>> H = M.digraph(subset=T) # long time
>>> Y = crystals.infinity.GeneralizedYoungWalls(Integer(2))
>>> YS = Y.subcrystal(max_depth=Integer(3))
>>> YG = Y.digraph(subset=YS) # long time
>>> YG.is_isomorphic(H, edge_labels=True) # long time
True

>>> M = crystals.infinity.NakajimaMonomials("D4")
>>> B = crystals.infinity.Tableaux("D4")
>>> MS = M.subcrystal(max_depth=Integer(3))
>>> BS = B.subcrystal(max_depth=Integer(3))
>>> MG = M.digraph(subset=MS) # long time
>>> BG = B.digraph(subset=BS) # long time
>>> BG.is_isomorphic(MG, edge_labels=True) # long time
True
alias of `NakajimaMonomial`

\( \text{c()} \)
Return the matrix \( c_{ij} \) of self.

**EXAMPLES:**
```
sage: La = RootSystem(['B',3]).weight_lattice().fundamental_weights()
sage: M = crystals.NakajimaMonomials(La[1]+La[2])
sage: M.c()
[0 1 1]
[0 0 1]
[0 0 0]
sage: c = Matrix([[0,0,1],[1,0,0],[0,1,0]])
sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: M = crystals.NakajimaMonomials(2*La[1], c=c)
sage: M.c() == c
True
```

\( \text{cardinality()} \)
Return the cardinality of self, which is always \( \infty \).

**EXAMPLES:**
```
sage: M = crystals.infinity.NakajimaMonomials(['A',5,2])
sage: M.cardinality()
+Infinity
```

\( \text{get_variables()} \)
Return the type of monomials to use for the element output.

**EXAMPLES:**
Combinatorics, Release 10.4

sage: M = crystals.infinity.NakajimaMonomials(['A', 4])
sage: M.get_variables()
'Y'

>>> from sage.all import *
>>> M = crystals.infinity.NakajimaMonomials(['A', Integer(4)])
>>> M.get_variables()
'Y'

set_variables(letter)

Set the type of monomials to use for the element output.

If the $A$ variables are used, the output is written as $\prod_{i \in I} Y_i^{\lambda_i} \prod_{i,k} A_{i,k}^{c_{i,k}}$, where $\sum_{i \in I} \lambda_i \Lambda_i$ is the corresponding dominant weight.

INPUT:

- letter – can be one of the following:
  - 'Y' – use $Y_{i,k}$, corresponds to fundamental weights
  - 'A' – use $A_{i,k}$, corresponds to simple roots

EXAMPLES:

sage: M = crystals.infinity.NakajimaMonomials(['A', 4])
sage: elt = M.highest_weight_vector().f_string([2,1,3,2,3,2,4,3])
sage: elt
Y(1,2) Y(2,0)^-1 Y(2,2)^-1 Y(3,0)^-1 Y(3,2)^-1 Y(4,0)
sage: M.set_variables('A')
sage: elt
A(1,1)^-1 A(2,0)^-1 A(2,1)^-2 A(3,0)^-2 A(3,1)^-1 A(4,0)^-1
sage: M.set_variables('Y')

>>> from sage.all import *
>>> M = crystals.infinity.NakajimaMonomials(['A', Integer(4)])
>>> elt = M.highest_weight_vector().f_string([Integer(2),Integer(1),
→ Integer(3),Integer(2),Integer(3),Integer(2),Integer(4),Integer(3)])
>>> elt
Y(1,2) Y(2,0)^-1 Y(2,2)^-1 Y(3,0)^-1 Y(3,2)^-1 Y(4,0)
>>> M.set_variables('A')
>>> elt
A(1,1)^-1 A(2,0)^-1 A(2,1)^-2 A(3,0)^-2 A(3,1)^-1 A(4,0)^-1
>>> M.set_variables('Y')

sage: La = RootSystem(['A',2]).weight_lattice().fundamental_weights()
sage: M = crystals.NakajimaMonomials(La[1]+La[2])
sage: lw = M.lowest_weight_vectors()[0]
sage: lw
Y(1,2)^-1 Y(2,1)^-1
sage: M.set_variables('A')
sage: lw
Y(1,0) Y(2,0) A(1,0)^-1 A(1,1)^-1 A(2,0)^-2
sage: M.set_variables('Y')

>>> from sage.all import *
>>> La = RootSystem(['A',Integer(2)]).weight_lattice().fundamental_weights()

(continues on next page)
>>> M = crystals.NakajimaMonomials(La[Integer(1)]+La[Integer(2)])
>>> lw = M.lowest_weight_vectors()[Integer(0)]
>>> lw
Y(1,2)^{-1} Y(2,1)^{-1}
>>> M.set_variables('A')
>>> lw
Y(1,0) Y(2,0) A(1,0)^{-1} A(1,1)^{-1} A(2,0)^{-2}
>>> M.set_variables('Y')
e(i)

Return the action of $e_i$ on self.

INPUT:

- $i$ – an element of the index set

EXAMPLES:

```
sage: M = crystals.infinity.NakajimaMonomials(['E',7,1])
sage: m = M.module_generators[0].f_string([0,1,4,3])
sage: [m.e(i) for i in M.index_set()]
[None, None, None, Y(0,0)^-1 Y(1,1)^-1 Y(2,1) Y(3,0) Y(3,1) Y(4,0)^-1 Y(4,1)^-1 Y(5,0),
  None, None, None, None]
sage: M = crystals.infinity.NakajimaMonomials("C5")
sage: m = M.module_generators[0].f_string([1,3])
sage: [m.e(i) for i in M.index_set()]
[Y(2,1) Y(3,0)^-1 Y(3,1)^-1 Y(4,0),
  None, Y(1,0)^-1 Y(1,1)^-1 Y(2,0),
  None, None]
sage: M = crystals.infinity.NakajimaMonomials(['D',4,1])
sage: M.set_variables(A)
sage: m = M.module_generators[0].f_string([4,2,3,0])
sage: [m.e(i) for i in M.index_set()]
[A(2,1)^-1 A(3,1)^-1 A(4,0)^-1,
  None, None, None,
  A(0,2)^-1 A(2,1)^-1 A(4,0)^-1,
  None]
sage: M.set_variables('Y')
```

```python
>>> from sage.all import *

>>> M = crystals.infinity.NakajimaMonomials(['E',Integer(7),Integer(1)])
>>> m = M.module_generators[Integer(0)].f_string([Integer(0),Integer(1),
  Integer(4),Integer(3)])

>>> [m.e(i) for i in M.index_set()]
[None, None, None, Y(0,0)^-1 Y(1,1)^-1 Y(2,1) Y(3,0) Y(3,1) Y(4,0)^-1 Y(4,1)^-1 Y(5,0),
  None, None, None, None]
```

```python
>>> M = crystals.infinity.NakajimaMonomials("C5")
>>> m = M.module_generators[Integer(0)].f_string([Integer(1),Integer(3)])

>>> [m.e(i) for i in M.index_set()]
```

(continues on next page)
\[ Y(2,1) Y(3,0)^{-1} Y(3,1)^{-1} Y(4,0), \]
\[ Y(1,0)^{-1} Y(1,1)^{-1} Y(2,0), \]
\[ None, \]
\[ None, \]
\[ None \]

>>> M = crystals.infinity.NakajimaMonomials(['D',Integer(4),Integer(1)])
>>> M.set_variables('A')
>>> m = M.module_generators[0].f_string([Integer(4),Integer(2),
   Integer(3),Integer(0)])

... [m.e(i) for i in M.index_set()]
[A(2,1)^{-1} A(3,1)^{-1} A(4,0)^{-1},
None,
None,
A(0,2)^{-1} A(2,1)^{-1} A(4,0)^{-1},
None]

>>> M.set_variables('Y')

epsilon(i)
Return the value of \( \varepsilon_i \) on self.

INPUT:

\[ i \] – an element of the index set

EXAMPLES:

\[\text{sage}: M = \text{crystals.infinity.NakajimaMonomials(['G',2,1])} \]
\[\text{sage}: m = M.module_generators[0].f(2) \]
\[\text{sage}: [m.epsilon(i) \text{ for i in M.index_set()}] \]
[0, 0, 1]  

\[\text{sage}: M = \text{crystals.infinity.NakajimaMonomials(['C',4,1])} \]
\[\text{sage}: m = M.module_generators[0].f_string([4,2,3]) \]
\[\text{sage}: [m.epsilon(i) \text{ for i in M.index_set()}] \]
[0, 0, 0, 1, 0]  

\[\text{from sage.all import } * \]
\[\text{sage}: M = \text{crystals.infinity.NakajimaMonomials(['G',Integer(2),Integer(1)])} \]
\[\text{sage}: m = M.module_generators[Integer(0)].f(Integer(2)) \]
\[\text{sage}: [m.epsilon(i) \text{ for i in M.index_set()}] \]
[0, 0, 1]  

\[\text{sage}: M = \text{crystals.infinity.NakajimaMonomials(['C',Integer(4),Integer(1)])} \]
\[\text{sage}: m = M.module_generators[Integer(0)].f_string([Integer(4),Integer(2),
   Integer(3)]) \]
\[\text{sage}: [m.epsilon(i) \text{ for i in M.index_set()}] \]
[0, 0, 0, 1, 0]  

\( f(i) \)
Return the action of \( f_i \) on self.

INPUT:

\[ i \] – an element of the index set

EXAMPLES:
sage: M = crystals.infinity.NakajimaMonomials("B4")
sage: m = M.module_generators[0].f_string([1,3,4])
sage: [m.f(i) for i in M.index_set()]
[1]

>>> from sage.all import *
>>> M = crystals.infinity.NakajimaMonomials("B4")
>>> m = M.module_generators[0].f_string([1,3,4])
>>> [m.f(i) for i in M.index_set()]
[1]

phi(i)

Return the value of $\varphi_i$ on self.

INPUT:
- i – an element of the index set

EXAMPLES:

sage: M = crystals.infinity.NakajimaMonomials([D,4,3])
sage: m = M.module_generators[0].f(1)
sage: [m.phi(i) for i in M.index_set()]
[1, -1, 1]

sage: M = crystals.infinity.NakajimaMonomials([C,4,1])
sage: m = M.module_generators[0].f_string([4,2,3])
sage: [m.phi(i) for i in M.index_set()]
[0, 1, -1, 2, -1]

weight()

Return the weight of self as an element of the weight lattice.

EXAMPLES:
```python
sage: C = crystals.infinity.NakajimaMonomials(['A',1,1])
sage: v = C.highest_weight_vector()
sage: v.f(1).weight() + v.f(0).weight()
-delta

sage: M = crystals.infinity.NakajimaMonomials(['A',4,2])
sage: m = M.highest_weight_vector().f_string([1,2,0,1])
sage: m.weight()
2*Lambda[0] - Lambda[1] - delta
```

```python
>>> from sage.all import *
>>> C = crystals.infinity.NakajimaMonomials(['A',Integer(1),Integer(1)])
>>> v = C.highest_weight_vector()
>>> v.f(Integer(1)).weight() + v.f(Integer(0)).weight()
-delta

>>> M = crystals.infinity.NakajimaMonomials(['A',Integer(4),Integer(2)])
>>> m = M.highest_weight_vector().f_string([Integer(1),Integer(2),Integer(0),
    Integer(1)])
>>> m.weight()
2*Lambda[0] - Lambda[1] - delta
```

### weight_in_root_lattice()

Return the weight of `self` as an element of the root lattice.

EXAMPLES:

```python
sage: M = crystals.infinity.NakajimaMonomials(['F',4])
sage: m = M.module_generators[0].f_string([3,3,1,2,4])
sage: m.weight_in_root_lattice()

sage: M = crystals.infinity.NakajimaMonomials(['B',3,1])
sage: mg = M.module_generators[0]
sage: m = mg.f_string([1,3,2,0,1,2,3,0,0,1])
sage: m.weight_in_root_lattice()

sage: M = crystals.infinity.NakajimaMonomials(['C',3,1])
sage: m = M.module_generators[0].f_string([3,0,1,2,0])
sage: m.weight_in_root_lattice()
```

```python
>>> from sage.all import *

>>> M = crystals.infinity.NakajimaMonomials(['F',Integer(4)])
>>> m = M.module_generators[Integer(0)].f_string([Integer(3),Integer(3),
    Integer(1),Integer(2),Integer(4)])
>>> m.weight_in_root_lattice()

>>> M = crystals.infinity.NakajimaMonomials(['B',Integer(3),Integer(1)])
>>> mg = M.module_generators[Integer(0)]
>>> m = mg.f_string([Integer(1),Integer(3),Integer(2),Integer(0),Integer(1),
    Integer(2),Integer(3),Integer(0),Integer(0),Integer(1)])
>>> m.weight_in_root_lattice()
```

(continues on next page)
class sage.combinat.crystals.multisegments.InfinityCrystalOfMultisegments(n)

Bases: Parent, UniqueRepresentation

The type $A_n^{(1)}$ crystal $B(\infty)$ realized using Bernstein-Zelevinsky (BZ) multisegments.

Using (a modified version of the) notation from [JL2009], for $\ell \in \mathbb{Z}_{>0}$ and $i \in \mathbb{Z}/(n+1)\mathbb{Z}$, a segment of length $\ell$ and head $i$ is the sequence of consecutive residues $[i, i+1, \ldots, i+\ell-1]$. The notation for a segment of length $\ell$ and head $i$ is simplified to $[i; \ell]$. Similarly, a segment of length $\ell$ and tail $i$ is the sequence of consecutive residues $[i-\ell+1, \ldots, i-1, i]$. The latter is denoted simply by $([\ell]; i)$. Finally, a multisegment is a formal linear combination of segments, usually written in the form

$$\psi = \sum_{i \in \mathbb{Z}/(n+1)\mathbb{Z}} \sum_{\ell \in \mathbb{Z}_{>0}} m_{[\ell]; i}(\ell; i).$$

Such a multisegment is called aperiodic if, for every $\ell > 0$, there exists some $i \in \mathbb{Z}/(n+1)\mathbb{Z}$ such that $([\ell]; i)$ does not appear in $\psi$. Denote the set of all periodic multisegments, together with the empty multisegment $\emptyset$, by $\Psi$. We define a crystal structure on multisegments as follows. Set $S_{[\ell], i} = \sum_{k \geq \ell} (m_{[k]; i} - m_{[k+1]; i})$ and let $\ell_f$ be the minimal $\ell$ that attains the value $\min_{\ell > 0} S_{[\ell], i}$. Then we have

$$f_i \psi = \begin{cases} 
\psi + (1; i) & \text{if } \ell_f = 1, \\
\psi + (\ell_f; i) - (\ell_f - 1; i - 1) & \text{if } \ell_f > 1.
\end{cases}$$

Similarly, let $\ell_c$ be the maximal $\ell$ that attains the value $\min_{\ell > 0} S_{[\ell], i}$. Then we have

$$e_i \psi = \begin{cases} 
0 & \text{if } \min_{\ell > 0} S_{[\ell], i} = 0, \\
\psi + (1; i) & \text{if } \ell_c = 1, \\
\psi - (\ell_c; i) + (\ell_c - 1; i - 1) & \text{if } \ell_c > 1.
\end{cases}$$

Alternatively, the crystal operators may be defined using a signature rule, as detailed in Section 4 of [JL2009] (following [AJL2011]). For $\psi \in \Psi$ and $i \in \mathbb{Z}/(n+1)\mathbb{Z}$, encode all segments in $\psi$ with tail $i$ by the symbol $R$ and all segments in $\psi$ with tail $i-1$ by $A$. For $\ell > 0$, set $w_{[\ell], i} = R^{m_{[\ell], i}} A^{m_{[\ell+1], i-1}}$ and $w_i = \prod_{\ell \geq 1} w_{[\ell], i}$. By successively canceling out as many $RA$ factors as possible, set $\tilde{w}_i = A^{a_i(\psi)} R^{r_i(\psi)}$. If $a_i(\psi) > 0$, denote by $\ell_f > 0$ the length of the rightmost segment $A$ in $\tilde{w}_i$. If $a_i(\psi) = 0$, set $\ell_f = 0$. Then

$$f_i \psi = \begin{cases} 
\psi + (1; i) & \text{if } a_i(\psi) = 0, \\
\psi + (\ell_f; i) - (\ell_f - 1; i - 1) & \text{if } a_i(\psi) > 0.
\end{cases}$$

The rule for computing $e_i \psi$ is similar.

INPUT:

* $n$ — for type $A_n^{(1)}$

EXAMPLES:
sage: B = crystals.infinity.Multisegments(2)
sage: x = B([(8,1), (6,0), (5,1), (5,0), (4,0), (4,1), (3,0), (3,1), (3,1), (1, 0), (1,2), (1,2)]); x
(8; 1] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1] 
+ 2 * (3; 0] + 2 * (3; 1] + (1; 0] + 2 * (1; 2]
sage: x.f(1)
(8; 1] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1] 
+ 2 * (3; 0] + 2 * (3; 1] + (2; 1] + (1; 1] + 2 * (1; 2]
sage: x.e(1)
(7; 0] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1] 
+ 2 * (3; 0] + 2 * (3; 1] + (1; 0] + 2 * (1; 2]
sage: x.e(1).e(1)
sage: x.f(0)
(8; 1] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1] 
+ 2 * (3; 0] + 2 * (3; 1] + (2; 0] + (1; 0] + (1; 2]

>>> from sage.all import *
>>> B = crystals.infinity.Multisegments(Integer(2))
>>> x = B([(Integer(8),Integer(1)), (Integer(6),Integer(0)), (Integer(5), Integer(1)), (Integer(5),Integer(0)), (Integer(4),Integer(0)), (Integer(4), Integer(1)), (Integer(4),Integer(0)), (Integer(4),Integer(0)), (Integer(3),Integer(1)), (Integer(3),Integer(0)), (Integer(3),Integer(0)), (Integer(2),Integer(1)), (Integer(2),Integer(0))]); x
(8; 1] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1] 
+ 2 * (3; 0] + 2 * (3; 1] + (1; 0] + 2 * (1; 2]
>>> x.f(Integer(1))
(8; 1] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1] 
+ 2 * (3; 0] + 2 * (3; 1] + (2; 1] + 2 * (1; 2]
>>> x.f(Integer(1)).f(Integer(1))
(8; 1] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1] 
+ 2 * (3; 0] + 2 * (3; 1] + (2; 1] + (1; 1] + 2 * (1; 2]
>>> x.e(Integer(1))
(7; 0] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1] 
+ 2 * (3; 0] + 2 * (3; 1] + (1; 0] + 2 * (1; 2]
>>> x.e(Integer(1)).e(Integer(1))
>>> x.f(Integer(0))
(8; 1] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1] 
+ 2 * (3; 0] + 2 * (3; 1] + (2; 0] + (1; 0] + (1; 2]

We check an sl̂ 2 example against the generalized Young walls:

sage: B = crystals.infinity.Multisegments(1)
sage: G = B.subcrystal(max_depth=4).digraph()
sage: C = crystals.infinity.GeneralizedYoungWalls(1)
sage: GC = C.subcrystal(max_depth=4).digraph()
sage: G.is_isomorphic(GC, edge_labels=True)
True

>>> from sage.all import *
>>> B = crystals.infinity.Multisegments(Integer(1))
>>> G = B.subcrystal(max_depth=Integer(4)).digraph()
>>> C = crystals.infinity.GeneralizedYoungWalls(Integer(1))
>>> GC = C.subcrystal(max_depth=Integer(4)).digraph()
>>> G.is_isomorphic(GC, edge_labels=True)
(continues on next page)
True

REFERENCES:
• [AJL2011]
• [JL2009]
• [LTV1999]

class Element (parent, value)

Bases: ElementWrapper

An element in a BZ multisegments crystal.

e(i)

Return the action of $e_i$ on self.

INPUT:
• $i$ – an element of the index set

EXAMPLES:

```python
sage: B = crystals.infinity.Multisegments(2)
sage: b = B([(4,2), (3,0), (3,1), (1,1), (1,0)])
sage: b.e(0)
(4; 2] + (3; 0] + (3; 1] + (1; 1]
sage: b.e(1)
sage: b.e(2)
(3; 0] + 2 * (3; 1] + (1; 0] + (1; 1]
```

epsilon(i)

Return $\varepsilon_i$ of self.

INPUT:
• $i$ – an element of the index set

EXAMPLES:

```python
>>> from sage.all import *
>>> B = crystals.infinity.Multisegments(Integer(2))
>>> b = B([(Integer(4),Integer(2)), (Integer(3),Integer(0)), (Integer(3),
          Integer(1)), (Integer(1),Integer(1)), (Integer(1),Integer(0))])
>>> b.e(Integer(0))
(4; 2] + (3; 0] + (3; 1] + (1; 1]
>>> b.e(Integer(1))
>>> b.e(Integer(2))
(3; 0] + 2 * (3; 1] + (1; 0] + (1; 1]
```
```python
>>> from sage.all import *
>>> B = crystals.infinity.Multisegments(Integer(2))
>>> b = B([(Integer(4),Integer(2)), (Integer(3),Integer(0)), (Integer(3),
→Integer(1)), (Integer(1),Integer(1)), (Integer(1),Integer(0))])
>>> b.epsilon(Integer(0))
1
>>> b.epsilon(Integer(1))
0
>>> b.epsilon(Integer(2))
1
```

\( f(i) \)

Return the action of \( f_i \) on \( \text{self} \).

**INPUT:**

- \( i \) – an element of the index set

**EXAMPLES:**

```python
sage: B = crystals.infinity.Multisegments(2)
sage: b = B([(4,2), (3,0), (3,1), (1,1), (1,0)])
sage: b.f(0)
(4; 2] + (3; 0] + (3; 1] + 2 * (1; 0] + (1; 1]
sage: b.f(1)
(4; 2] + (3; 0] + (3; 1] + (1; 0] + 2 * (1; 1]
sage: b.f(2)
2 * (4; 2] + (3; 0] + (1; 0] + (1; 1]
```

```python
>>> from sage.all import *
>>> B = crystals.infinity.Multisegments(Integer(2))
>>> b = B([(Integer(4),Integer(2)), (Integer(3),Integer(0)), (Integer(3),
→Integer(1)), (Integer(1),Integer(1)), (Integer(1),Integer(0))])
>>> b.f(Integer(0))
(4; 2] + (3; 0] + (3; 1] + 2 * (1; 0] + (1; 1]
>>> b.f(Integer(1))
(4; 2] + (3; 0] + (3; 1] + (1; 0] + 2 * (1; 1]
>>> b.f(Integer(2))
2 * (4; 2] + (3; 0] + (1; 0] + (1; 1]
```

\( \phi(i) \)

Return \( \varphi_i \) of \( \text{self} \).

Let \( \psi \in \Psi \). Define \( \varphi_i(\psi) := \varepsilon_i(\psi) + \langle h_i, \text{wt}(\psi) \rangle \), where \( h_i \) is the \( i \)-th simple coroot and \( \text{wt}(\psi) \) is the weight() of \( \psi \).

**INPUT:**

- \( i \) – an element of the index set

**EXAMPLES:**

```python
sage: B = crystals.infinity.Multisegments(2)
sage: b = B([(4,2), (3,0), (3,1), (1,1), (1,0)])
sage: b.phi(0)
1
sage: b.phi(1)
0
sage: mg = B.highest_weight_vector()
sage: mg.f(1).phi(0)
1
```

>>> from sage.all import *
>>> B = crystals.infinity.Multisegments(Integer(2))
>>> b = B([(Integer(4),Integer(2)), (Integer(3),Integer(0)), (Integer(3),
        Integer(1)), (Integer(1),Integer(1)), (Integer(1),Integer(0))])
>>> b.phi(Integer(0))
1
>>> b.phi(Integer(1))
0
>>> mg = B.highest_weight_vector()
>>> mg.f(Integer(1)).phi(Integer(0))
1

weight()  
Return the weight of self.

EXAMPLES:

sage: B = crystals.infinity.Multisegments(2)  
sage: b = B([(4,2), (3,0), (3,1), (1,1), (1,0)])  
sage: b.weight()  
-4*delta

highest_weight_vector()  
Return the highest weight vector of self.

EXAMPLES:

sage: B = crystals.infinity.Multisegments(2)  
sage: B.highest_weight_vector()  
0

weight_lattice_realization()  
Return a realization of the weight lattice of self.

EXAMPLES:

sage: B = crystals.infinity.Multisegments(2)  
sage: B.weight_lattice_realization()  
Extended weight lattice of the Root system of type ['A', 2, 1]
5.1.61 Crystal Of Mirković-Vilonen (MV) Polytopes

AUTHORS:
- Dinakar Muthiah, Travis Scrimshaw (2015-05-11): initial version

```python
class sage.combinat.crystals.mv_polytopes.MVPolytope(parent, lusztig_datum, long_word=None):
    Bases: PBWCrystalElement

A Mirković-Vilonen (MV) polytope.

EXAMPLES:

We can create an animation showing how the MV polytope changes under a string of crystal operators:
```
sage: MV = crystals.infinity.MVPolytopes(['C', 2])
sage: u = MV.highest_weight_vector()
sage: L = RootSystem(['C', 2, 1]).ambient_space()
sage: s = [1, 2, 1, 2, 2, 2, 1, 1, 1, 2, 1, 2, 1, 2, 1, 2]
sage: BB = [[-9, 2], [-10, 2]]
sage: p = L.plot(reflection_hyperplanes=False, bounding_box=BB)  # long time

sage: frames = [p + L.plot_mv_polytope(u.f_string(s[:i]), circle_size=0.1, wireframe='green', fill='purple', bounding_box=BB) for i in range(len(s))]
sage: animation(frames).show(delay=60)  # optional -- ImageMagick # long time
```

```python
>>> from sage.all import *
>>> MV = crystals.infinity.MVPolytopes(['C', Integer(2)])
>>> u = MV.highest_weight_vector()
>>> L = RootSystem(['C', Integer(2), Integer(1)]).ambient_space()
>>> s = [Integer(1), Integer(2), Integer(1), Integer(2), Integer(2), Integer(2), Integer(1), Integer(1), Integer(1), Integer(1), Integer(2), Integer(1), Integer(2), Integer(2), Integer(1), Integer(2)]
>>> BB = [[-Integer(9), Integer(2)], [-Integer(10), Integer(2)]]
>>> p = L.plot(reflection_hyperplanes=False, bounding_box=BB)  # long time

>>> frames = [p + L.plot_mv_polytope(u.f_string(s[:i]), circle_size=RealNumber('0.1'), wireframe='green', fill='purple', bounding_box=BB) for i in range(len(s))]
>>> animation(frames).show(delay=Integer(60))  # optional -- ImageMagick # long time
```

```
plot (P=None, **options)
Plot self.

INPUT:
- P -- (optional) a space to realize the polytope; default is the weight lattice realization of the crystal

See also:
plot_mv_polytope()
```
EXAMPLES:

```python
sage: MV = crystals.infinity.MVPolytopes(['C', 2])
sage: b = MV.highest_weight_vector().f_string([1, 2, 1, 2, 2, 1, 1, 1, 1, 2, 1])
sage: b.plot()  # needs sage.plot
Graphics object consisting of 12 graphics primitives
```

```python
>>> from sage.all import *

MV = crystals.infinity.MVPolytopes(['C', Integer(2)])
b = MV.highest_weight_vector().f_string([Integer(1), Integer(2), Integer(1),
Integer(2), Integer(2), Integer(2), Integer(1), Integer(1), Integer(1),
Integer(1), Integer(2), Integer(1)])

b.plot()  # needs sage.plot
Graphics object consisting of 12 graphics primitives
```

Here is the above example placed inside the ambient space of type $C_2$:

![Polytope](image)

**polytope** *(P=None)*

Return a polytope of self.

**INPUT:**

- `P` – (optional) a space to realize the polytope; default is the weight lattice realization of the crystal

**EXAMPLES:**

```python
sage: MV = crystals.infinity.MVPolytopes(['C', 3])
sage: b = MV.module_generators[0].f_string([3, 2, 3, 2, 1])
sage: P = b.polytope(); P
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 6 vertices

sage: P.vertices()
(A vertex at (0, 0, 0),
 A vertex at (0, 1, -1),
 A vertex at (0, 1, 1),
 A vertex at (1, -1, 0),
 A vertex at (1, 1, -2),
 A vertex at (1, 1, 2))
```

---

**5.1. Comprehensive Module List**

833
>>> from sage.all import *
>>> MV = crystals.infinity.MVPolytopes(['C', Integer(3)])
>>> b = MV.module_generators[Integer(0)].f_string([Integer(3),Integer(2),
  →Integer(3),Integer(2),Integer(1)])
>>> P = b.polytope(); P
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 6 vertices
>>> P.vertices()
(A vertex at (0, 0, 0),
 A vertex at (0, 1, -1),
 A vertex at (0, 1, 1),
 A vertex at (1, -1, 0),
 A vertex at (1, 1, -2),
 A vertex at (1, 1, 2))

class sage.combinat.crystals.mv_polytopes.MVPolytopes(cartan_type)
Bases: PBWCrystal
The crystal of Mirković-Vilonen (MV) polytopes.

Let $W$ denote the corresponding Weyl group and $P_\mathbb{R} = \mathbb{R} \otimes P$. Let $\Gamma = \{ w \Lambda_i \mid w \in W, i \in I \}$. Consider $M = (M_\gamma \in \mathbb{Z})_{\gamma \in \Gamma}$ that satisfy the tropical Plücker relations (see Proposition 7.1 of [BZ01]). The MV polytope is defined as

$$P(M) = \{ \alpha \in P_\mathbb{R} \mid \langle \alpha, \gamma \rangle \geq M_\gamma \text{ for all } \gamma \in \Gamma \}.$$ 

The vertices $\{ \mu_w \}_{w \in W}$ are given by

$$\langle \mu_w, \gamma \rangle = M_\gamma$$

and are known as the GGMS datum of the MV polytope.

Each path from $\mu_e$ to $\mu_{w_0}$ corresponds to a reduced expression $i = (i_1, \ldots, i_m)$ for $w_0$ and the corresponding edge lengths $(n_k)_{k=1}^m$ from the Lusztig datum with respect to $i$. Explicitly, we have

$$n_k = -M_{w_{k-1}}\Lambda_i - M_{w_k}\Lambda_i - \sum_{j \neq i} a_{ji} M_{w_k}\Lambda_j,$$

$$\mu_{w_k} - \mu_{w_{k-1}} = n_k w_{k-1} \alpha_{i_k},$$

where $w_k = s_{i_1} \cdots s_{i_k}$ and $(a_{ji})$ is the Cartan matrix.

MV polytopes have a crystal structure that corresponds to the crystal structure, which is isomorphic to $B(\infty)$ with $\mu_{w_0} = 0$, on PBW data. Specifically, we have $f_j P(M)$ as being the unique MV polytope given by shifting $\mu_e$ by $-\alpha_j$ and fixing the vertices $\mu_w$ when $s_j w < w$ (in Bruhat order) and the weight is given by $\mu_e$. Furthermore, the $*$-involution is given by negating $P(M)$.

INPUT:

- cartan_type -- a Cartan type

EXAMPLES:

```
sage: MV = crystals.infinity.MVPolytopes(['B', 3])
sage: hw = MV.highest_weight_vector()
sage: x = hw.f_string([1,2,2,3,3,1,3,3,2,3,2,1,3,1,2,3,1,2,1,3,2]); x
MV polytope with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)
```
Elements are expressed in terms of Lusztig datum for a fixed reduced expression of $w_0$:

```
sage: MV.default_long_word()
[1, 3, 2, 3, 1, 2, 3, 1, 2]
sage: MV.set_default_long_word([2, 1, 3, 2, 1, 3, 2, 3, 1])
sage: x
MV polytope with Lusztig datum (3, 1, 1, 0, 1, 0, 1, 3, 4)
sage: MV.set_default_long_word([1, 3, 2, 3, 1, 2, 3, 1, 2])
```

We can construct elements by giving it Lusztig data (with respect to the default long word reduced expression):

```
sage: MV([1, 1, 1, 3, 1, 0, 0, 1, 1])
MV polytope with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)
```

We can also construct elements by passing in a reduced expression for a long word:

```
sage: x = MV([1, 1, 1, 3, 1, 0, 0, 1, 1], [3, 2, 1, 3, 2, 3, 2, 1, 2]); x
MV polytope with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)
sage: x.to_highest_weight()[1]
[1, 2, 2, 2, 2, 2, 1, 3, 3, 3, 3, 2, 3, 2, 3, 3, 2, 3, 2, 1, 3]
```

The highest weight crystal $B(\lambda) \subseteq B(\infty)$ is characterized by the MV polytopes that sit inside of $W\lambda$ (translating $\mu_{w_0} \mapsto \lambda$):

```
>>> from sage.all import *
>>> MV = crystals.infinity.MVPolytopes(['B', Integer(3)])
>>> hw = MV.highest_weight_vector()
>>> x = hw.f_string([Integer(1),Integer(2),Integer(2),Integer(3),Integer(3),
      → Integer(1),Integer(3),Integer(3),Integer(2),Integer(3),Integer(2),Integer(1),
      → Integer(3),Integer(1),Integer(2),Integer(3),Integer(1),Integer(2),Integer(1),
      → Integer(3),Integer(2)]); x
MV polytope with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)
```

sage: MV = crystals.infinity.MVPolytopes(['A',2])

REFERENCES:
• [Kam2007]
• [Kam2010]

Element
alias of MVPolytope
latex_options()
Return the latex options of self.
EXAMPLES:

```
sage: MV = crystals.infinity.MVPolytopes(['F', 4])
sage: MV.latex_options()
{'P': Ambient space of the Root system of type ['F', 4],
 'circle_size': 0.1,
 'mark_endpoints': True,
 'projection': True}
```

```
>>> from sage.all import *
>>> MV = crystals.infinity.MVPolytopes(['F', Integer(4)])
>>> MV.latex_options()
{'P': Ambient space of the Root system of type ['F', 4],
 'circle_size': 0.1,
 'mark_endpoints': True,
 'projection': True}
```

```latex
set_latex_options(**kwds)
```

Set the latex options for the elements of self.

INPUT:

- `projection` – the projection; set to True to use the default projection of the specified weight lattice realization (initial: True)
- `P` – the weight lattice realization to use (initial: the weight lattice realization of self)
- `mark_endpoints` – whether to mark the endpoints (initial: True)
- `circle_size` – the size of the endpoint circles (initial: 0.1)

EXAMPLES:

```
sage: MV = crystals.infinity.MVPolytopes(['C', 2])
sage: P = RootSystem(['C', 2]).weight_lattice()
sage: b = MV.highest_weight_vector().f_string([1,2,1,2])
sage: latex(b)
\begin{tikzpicture}
\draw (0, 0) -- (0, -2) -- (-1, -3) -- (-1, -3) -- (-2, -2);
\draw (0, 0) -- (-1, 1) -- (-1, 1) -- (-2, 0) -- (-2, -2);
\draw[fill=black] (0, 0) circle (0.1);
\draw[fill=black] (-2, -2) circle (0.1);
\end{tikzpicture}
sage: MV.set_latex_options(P=P, circle_size=float(0.2))
sage: latex(b)
\begin{tikzpicture}
\draw (0, 0) -- (2, -2) -- (2, -3) -- (2, -3) -- (0, -2);
\draw (0, 0) -- (-2, 1) -- (-2, 1) -- (-2, 0) -- (0, -2);
\draw[fill=black] (0, 0) circle (0.2);
\draw[fill=black] (0, -2) circle (0.2);
\end{tikzpicture}
sage: MV.set_latex_options(mark_endpoints=False)
sage: latex(b)
\begin{tikzpicture}
\draw (0, 0) -- (2, -2) -- (2, -3) -- (2, -3) -- (0, -2);
\draw (0, 0) -- (-2, 1) -- (-2, 1) -- (-2, 0) -- (0, -2);
\draw[fill=black] (0, 0) circle (0.2);
\end{tikzpicture}
sage: MV.set_latex_options(P=MV.weight_lattice_realization(),
.....: circle_size=0.2,
.....: mark_endpoints=True)
```

5.1. Comprehensive Module List
5.1.62 $\mathcal{B}(\infty)$ Crystal Of PBW Monomials

AUTHORS:

- Dinakar Muthiah (2015-05-11): initial version

See also:

For information on PBW datum, see PBW Data.

class sage.combinat.crystals.pbw_crystal.PBWCrystal(cartan_type)
Bases: Parent, UniqueRepresentation

Crystal of $\mathcal{B}(\infty)$ given by PBW monomials.

A model of the crystal $\mathcal{B}(\infty)$ whose elements are PBW datum up to equivalence by the tropical Plücker relations. The crystal structure on Lusztig data $x = (x_1, \ldots, x_m)$ for the reduced word $s_{i_1} \cdots s_{i_m} = w_0$ is given as follows. Suppose $i_1 = j$, then $f_j x = (x_1 + 1, x_2, \ldots, x_m)$. If $i_1 \neq j$, then we use the tropical Plücker relations to change the reduced expression such that $i_1' = j$ and then we change back to the original word.

EXAMPLES:

```
sage: PBW = crystals.infinity.PBW(['B', 3])
sage: hw = PBW.highest_weight_vector()
sage: x = hw.f_string((1,2,2,3,3,1,3,3,3,2,3,3,2,1,3,1,2,3,1,2,1,3,2)); x
PBW monomial with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)
```
Elements are expressed in terms of Lusztig datum for a fixed reduced expression of $w_0$:

```python
sage: PBW.default_long_word()
[1, 3, 2, 3, 1, 2, 3, 1, 2]
sage: PBW.set_default_long_word([2,1,3,2,1,3,2,3,1])
sage: x
PBW monomial with Lusztig datum (3, 1, 1, 0, 1, 0, 1, 3, 4)
sage: PBW.set_default_long_word([1, 3, 2, 3, 1, 2, 3, 1, 2])
```

We can construct elements by giving it Lusztig data (with respect to the default long word):

```python
sage: PBW([1,1,1,3,1,0,0,1,1])
PBW monomial with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)
```

We can also construct elements by passing in a reduced expression for a long word:

```python
sage: x = PBW([1,1,1,3,1,0,0,1,1], [3,2,1,3,2,3,2,1,2]); x
PBW monomial with Lusztig datum (1, 1, 1, 0, 1, 0, 5, 1, 1)
sage: x.to_highest_weight()[1]
[1, 2, 2, 2, 2, 1, 3, 3, 3, 3, 2, 3, 2, 3, 3, 2, 3, 2, 1, 3]
```

```
>>> from sage.all import *
>>> PBW = crystals.infinity.PBW(['B', Integer(3)])
>>> hw = PBW.highest_weight_vector()
>>> x = hw.f_string([Integer(1),Integer(2),Integer(2),Integer(3),Integer(3),
˓→Integer(1),Integer(3),Integer(3),Integer(2),Integer(3),Integer(1),Integer(1),
˓→Integer(3),Integer(2),Integer(2),Integer(3),Integer(1),Integer(2),Integer(2),Integer(1),
˓→Integer(3),Integer(2)]); x
PBW monomial with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)
```

Element

alias of `PBWCrystalElement`

5.1. Comprehensive Module List
default_long_word()
Return the default long word used to express elements of self.

EXAMPLES:

```python
sage: B = crystals.infinity.PBW(['E', 6])
sage: B.default_long_word()
[1, 3, 4, 5, 6, 2, 4, 5, 3, 4, 1, 3, 2, 4, 5, 6, 2, 4,
  5, 3, 4, 1, 3, 2, 4, 5, 3, 4, 1, 3, 2, 4, 1, 3, 2, 1]
```

```python
>>> from sage.all import *
>>> B = crystals.infinity.PBW(['E', Integer(6)])
>>> B.default_long_word()
[1, 3, 4, 5, 6, 2, 4, 5, 3, 4, 1, 3, 2, 4, 5, 6, 2, 4,
  5, 3, 4, 1, 3, 2, 4, 5, 3, 4, 1, 3, 2, 4, 1, 3, 2, 1]
```

set_default_long_word(word)
Set the default long word used to express elements of self.

EXAMPLES:

```python
sage: B = crystals.infinity.PBW(['C', 3])
sage: B.default_long_word()
[1, 3, 2, 3, 1, 2, 3, 1, 2]
sage: x = B.highest_weight_vector().f_string([2,1,3,2,3,1])
sage: x
PBW monomial with Lusztig datum (1, 2, 2, 0, 0, 0, 0, 0, 1)
sage: B.set_default_long_word([2,1,3,2,1,3,2,3,1])
sage: B.default_long_word()
[2, 1, 3, 2, 1, 3, 2, 3, 1]
sage: x
PBW monomial with Lusztig datum (2, 0, 0, 0, 0, 0, 1, 3, 2)
```

```python
>>> from sage.all import *
>>> B = crystals.infinity.PBW(['C', Integer(3)])
>>> B.default_long_word()
[1, 3, 2, 3, 1, 2, 3, 1, 2]
>>> x = B.highest_weight_vector().f_string([Integer(2),Integer(1),Integer(3),
  →Integer(2),Integer(3),Integer(1),Integer(2),Integer(3),Integer(3),
  →Integer(1)])
>>> x
PBW monomial with Lusztig datum (1, 2, 2, 0, 0, 0, 0, 0, 1)
>>> B.set_default_long_word([Integer(2),Integer(1),Integer(3),Integer(2),
  →Integer(1),Integer(3),Integer(2),Integer(3),Integer(3),Integer(1)])
>>> B.default_long_word()
[2, 1, 3, 2, 1, 3, 2, 3, 1]
>>> x
PBW monomial with Lusztig datum (2, 0, 0, 0, 0, 0, 1, 3, 2)
```

class sage.combinat.crystals.pbw_crystal.PBWCrystalElement (parent, lusztig_datum, CrystalElement) (parent, lusztig_datum, long_word=None)

Bases: Element

A crystal element in the PBW model.

\(e(i)\)
Return the action of \(e_i\) on self.

EXAMPLES:
\[
\text{sage: } B = \text{crystals.infinity.PBW(['B', 3])} \\
\text{sage: } b = B.\text{highest_weight_vector()} \\
\text{sage: } c = b.\text{f_string([2,1,3,2,1,3,2,2])}; c \\
\text{PBW monomial with Lusztig datum (0, 1, 0, 1, 0, 0, 0, 1, 2)} \\
\text{sage: } c.\text{e(2)} \\
\text{PBW monomial with Lusztig datum (0, 1, 0, 1, 0, 0, 0, 1, 1)} \\
\text{sage: } c.\text{e_string([2,2,1,3,2,1,3,2,2])} == b \\
\text{True}
\]

```python
>>> from sage.all import *

>>> B = crystals.infinity.PBW(['B', Integer(3)])

>>> b = B.\text{highest_weight_vector()}

>>> c = b.\text{f_string([Integer(2), Integer(1), Integer(3), Integer(2), Integer(1), Integer(3), Integer(2)])}; c

PBW monomial with Lusztig datum (0, 1, 0, 1, 0, 0, 0, 1, 2)

>>> c.\text{e(Integer(2))}

PBW monomial with Lusztig datum (0, 1, 0, 1, 0, 0, 0, 1, 1)

>>> c.\text{e_string([Integer(2), Integer(2), Integer(1), Integer(3), Integer(2), Integer(1), Integer(3), Integer(2)])} == b

True
```

\[\epsilon(i)\]

Return \(\epsilon_i\) of self.

**EXAMPLES:**

```python
\]
```

\[f(i)\]

Return the action of \(f_i\) on self.

**EXAMPLES:**

```python
```

(continues on next page)
Combinatorics, Release 10.4

```
>>> b = B.highest_weight_vector()
>>> c = b.f_string([Integer(1), Integer(2), Integer(3), Integer(1), Integer(2),
                  Integer(3), Integer(4)]); c
PBW monomial with Lusztig datum (0, 1, 0, 0, 0, 2, 0, 0)
>>> c == b.f_string([Integer(1), Integer(2), Integer(4), Integer(1), Integer(2),
                   Integer(3), Integer(3)])
True
```

**lusztig_datum**(\(\text{word}=\text{None} \))

Return the Lusztig datum of \(\text{self} \) with respect to the reduced expression of the long word \(\text{word} \).

**EXAMPLES:**

```
sage: B = crystals.infinity.PBW(['A', 2])
sage: u = B.highest_weight_vector()
sage: b = u.f_string([2,1,2,2,2,2,1,1,2,1,2,1,2,1,2,2])
sage: b.lusztig_datum()
(6, 0, 10)
sage: b.lusztig_datum(word=[2,1,2])
(4, 6, 0)
```

**phi**(\(i \))

Return \(\phi_i \) of \(\text{self} \).

**EXAMPLES:**

```
sage: B = crystals.infinity.PBW(['A', Integer(2)])
sage: s = B((3,0,0), (1,2,1))
sage: s.phi(Integer(1))
-3
>>> from sage.all import *
>>> B = crystals.infinity.PBW(['A', Integer(2)])
>>> s = B((Integer(3), Integer(0), Integer(0)), (Integer(1), Integer(1), Integer(1)))
>>> s.phi(Integer(1))
-3
>>> s.phi(Integer(2))
3
```

**star**(\())

Return the starred crystal element corresponding to \(\text{self} \).
Let $b$ be an element of $\text{self}$ with Lusztig datum $(b_1, \ldots, b_N)$ with respect to $w_0 = s_{i_1} \cdots s_{i_N}$. Then $b^*$ is the element with Lusztig datum $(b_N, \ldots, b_1)$ with respect to $w_0 = s_{i_N^*} \cdots s_{i_1^*}$, where $i_j^* = \omega(i_j)$ with $\omega$ being the automorphism given by the action of $w_0$ on the simple roots.

**EXAMPLES:**

```python
sage: P = crystals.infinity.PBW(['A', 2])
sage: P((1,2,3), (1,2,1)).star() == P((3,2,1), (2,1,2))
True

sage: B = crystals.infinity.PBW(['E', 6])
sage: b = B.highest_weight_vector()
sage: c = b.f_string([1,2,6,3,4,2,5,2,3,4,1,6])
sage: c == c.star().star()
True
```

```python
>>> from sage.all import *

>>> P = crystals.infinity.PBW(['A', Integer(2)])
>>> P((Integer(1),Integer(2),Integer(3)), (Integer(1),Integer(2),Integer(1))).star() == P((Integer(3),Integer(2),Integer(1)), (Integer(2),Integer(1),Integer(2)))
True

>>> B = crystals.infinity.PBW(['E', Integer(6)])
>>> b = B.highest_weight_vector()
>>> c = b.f_string([Integer(1),Integer(2),Integer(6),Integer(3),Integer(4),Integer(2),Integer(5),Integer(2),Integer(3),Integer(4),Integer(1),Integer(6)])
>>> c == c.star().star()
True
```

**weight()**

Return weight of $\text{self}$.

**EXAMPLES:**

```python
sage: B = crystals.infinity.PBW(['A', 2])
sage: s = B((2,2,2), (1,2,1))
sage: s.weight()
(-4, 0, 4)
```

```python
>>> from sage.all import *

>>> B = crystals.infinity.PBW(['A', Integer(2)])
>>> s = B((Integer(2),Integer(2),Integer(2)), (Integer(1),Integer(2),Integer(2)), (Integer(1),Integer(1))
>>> s.weight()
(-4, 0, 4)
```
5.1.63 PBW Data

This contains helper classes and functions which encode PBW data in finite type.

AUTHORS:

- Dinakar Muthiah (2015-05): initial version
- Travis Scrimshaw (2016-06): simplified code and converted to Cython

class sage.combinat.crystals.pbw_datum.PBWData(cartan_type)

Bases: object

Helper class for the set of PBW data.

class sage.combinat.crystals.pbw_datum.PBWDatum(parent, long_word, lusztig_datum)

Bases: object

Helper class which represents a PBW datum.

convert_to_new_long_word(pbw_datum, new_long_word)

Convert the PBW datum pbw_datum from its long word to new_long_word.

convert_to_long_word_with_first_letter(i)

Return a new PBWDatum equivalent to self whose long word begins with i.

(continues on next page)
>>> from sage.all import *
>>> from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
>>> P = PBWData("A3")
>>> datum = PBWDatum(P, (1, 2, 1, 3, 2), (1, 0, 1, 3, 2))
>>> datum.convert_to_long_word_with_first_letter(1)
PBW Datum element of type ['A', 3] with long word (1, 2, 3, 1, 2, 1)
and Lusztig datum (1, 0, 4, 1, 2, 3)
>>> datum.convert_to_long_word_with_first_letter(2)
PBW Datum element of type ['A', 3] with long word (2, 1, 2, 3, 2, 1)
and Lusztig datum (0, 1, 0, 4, 2, 3)
>>> datum.convert_to_long_word_with_first_letter(3)
PBW Datum element of type ['A', 3] with long word (3, 1, 2, 3, 1, 2)
and Lusztig datum (8, 1, 0, 4, 1, 2)

**convert_to_new_long_word** *(new_long_word)*

Return a new PBWDatum equivalent to *self* whose long word is *new_long_word*.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
>>> P = PBWData("A2")
>>> datum = PBWDatum(P, (1, 2), (1, 0))
>>> new_datum = datum.convert_to_new_long_word((2, 1))
>>> new_datum.long_word
(2, 1)
>>> new_datum.lusztig_datum
(0, 1)
```

**is_equivalent_to** *(other_pbw_datum)*

Return whether *self* is equivalent to *other_pbw_datum* modulo the tropical Plücker relations.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
>>> P = PBWData("A2")
>>> datum = PBWDatum(P, (1, 2, 1), (1, 0, 1))
>>> new_datum = datum.convert_to_new_long_word((2, 1, 2))
>>> new_datum.long_word
(2, 1, 2)
>>> new_datum.lusztig_datum
(0, 1, 0)
```
sage: from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
sage: P = PBWData("A2")
1
sage: L1 = PBWDatum(P, (1, 2, 1), (1, 0, 1))
1
sage: L2 = PBWDatum(P, (2, 1, 2), (0, 1, 0))
1
sage: L1.is_equivalent_to(L2)
True
sage: L1 == L2
False

>>> from sage.all import *
>>> from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
>>>
>>> P = PBWData("A2")
1
>>> L1 = PBWDatum(P, (Integer(1), Integer(2), Integer(1)), (Integer(1),
...
Integer(2), Integer(1)))
1
>>> L2 = PBWDatum(P, (Integer(2), Integer(1), Integer(2)), (Integer(0),
...
Integer(1), Integer(0)))
1
>>> L1.is_equivalent_to(L2)
True
>>> L1 == L2
False

star()  
Return the starred version of self, i.e., with reversed long_word and lusztigdatum.

EXAMPLES:

sage: from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
sage: P = PBWData("A2")
1
sage: L = PBWDatum(P, (1, 2, 1), (1, 1, 1))
1
sage: L.weight() == PBWDatum(P, (2, 1, 2), (3, 2, 1))
True

weight()  
Return the weight of self.

EXAMPLES:

sage: from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
sage: P = PBWData("A2")
1
sage: L = PBWDatum(P, (1, 2, 1), (1, 1, 1))
1
sage: L.weight() == PBWDatum(P, (2, 1, 2), (3, 2, 1))
True
\[
\text{Combinatorics, Release 10.4}
\]

(continued from previous page)

\[
\text{sage.combinat.crystals.pbw_datum. compute_new_lusztig_datum(enhanced_braid_chain, initial_lusztig_datum)}
\]

Return the Lusztig datum obtained by applying tropical Plücker relations along `enhanced_braid_chain` starting with `initial_lusztig_datum`.

EXAMPLES:

```python
>>> from sage.combinat.root_system.braid_move_calculator import BraidMoveCalculator
>>> from sage.combinat.crystals.pbw_datum import enhance_braid_move_chain
>>> from sage.combinat.crystals.pbw_datum import compute_new_lusztig_datum
>>> ct = CartanType(['A', 2])
>>> W = CoxeterGroup(ct)
>>> B = BraidMoveCalculator(W)
>>> chain = B.chain_of_reduced_words((1,2,1),(2,1,2))
>>> enhanced_braid_chain = enhance_braid_move_chain(chain, ct)
>>> compute_new_lusztig_datum(enhanced_braid_chain,(1,0,1))
(0, 1, 0)
```

```python
>>> from sage.all import *
>>> from sage.combinat.root_system.braid_move_calculator import BraidMoveCalculator
>>> from sage.combinat.crystals.pbw_datum import enhance_braid_move_chain
>>> from sage.combinat.crystals.pbw_datum import compute_new_lusztig_datum
>>> ct = CartanType(['A', Integer(2)])
>>> W = CoxeterGroup(ct)
>>> B = BraidMoveCalculator(W)
>>> chain = B.chain_of_reduced_words((Integer(1),Integer(2),Integer(1)), ...
... (Integer(2),Integer(1),Integer(2)))
>>> enhanced_braid_chain = enhance_braid_move_chain(chain, ct)
>>> compute_new_lusztig_datum(enhanced_braid_chain,(Integer(1),Integer(0), ...
... Integer(1)))
(0, 1, 0)
```

\[
\text{sage.combinat.crystals.pbw_datum. enhance_braid_move_chain(braid_move_chain, cartan_type)}
\]

Return a list of tuples that records the data of the long words in `braid_move_chain` plus the data of the intervals where the braid moves occur and the data of the off-diagonal entries of the 2 × 2 Cartan submatrices of each braid move.

INPUT:

- `braid_move_chain` – a chain of reduced words in the Weyl group of `cartan_type`
- `cartan_type` – a finite Cartan type

OUTPUT:

A list of 2-tuples (interval_of_change, cartan_sub_matrix) where

- `interval_of_change` is the (half-open) interval of indices where the braid move occurs; this is `None` for the first tuple
- `cartan_sub_matrix` is the off-diagonal entries of the 2×2 submatrix of the Cartan matrix corresponding to the braid move; this is `None` for the first tuple
For a matrix:

\[
\begin{bmatrix}
2 & a \\
b & 2
\end{bmatrix}
\]

the cartan_sub_matrix is the pair \((a, b)\).

sage.combinat.crystals.pbw_datum.tropical_plucker_relation\((a, lusztig_datum)\)

Apply the tropical Plücker relation of type \(a\) to \(lusztig_datum\).

The relations are obtained by tropicalizing the relations in Proposition 7.1 of [BZ01].

INPUT:

- \(a\) – a pair \((x, y)\) of the off-diagonal entries of a \(2 \times 2\) Cartan matrix

EXAMPLES:

sage: from sage.combinat.crystals.pbw_datum import tropical_plucker_relation
sage: tropical_plucker_relation((0,0), (2,3))
(3, 2)

sage: tropical_plucker_relation((-1,-1), (1,2,3))
(4, 1, 2)

sage: tropical_plucker_relation((-1,-2), (1,2,3,4))
(8, 1, 2, 3)

sage: tropical_plucker_relation((-2,-1), (1,2,3,4))
(6, 1, 2, 3)

5.1.64 Polyhedral Realization of \(B(\infty)\)

class sage.combinat.crystals.polyhedral_realization.InfinityCrystalAsPolyhedralRealization

Bases: TensorProductOfCrystals

The polyhedral realization of \(B(\infty)\).

Note: Here we are using anti-Kashiwara notation and might differ from some of the literature.

Consider a Kac-Moody algebra \(g\) of Cartan type \(X\) with index set \(I\), and consider a finite sequence \(J = (j_1, j_2, \ldots, j_m)\) whose support equals \(I\). We extend this to an infinite sequence by taking \(\bar{J} = J \cdot J \cdot J \cdots\).
where \( \cdot \) denotes concatenation of sequences. Let

\[ B_J = B_{j_n} \otimes \cdots \otimes B_{j_2} \otimes B_{j_1}, \]

where \( B_i \) is an ElementaryCrystal.

As given in Theorem 2.1.1 of [Ka1993], there exists a strict crystal embedding \( \Psi_i : B(\infty) \to B_i \otimes B(\infty) \) defined by \( u_\infty \mapsto b_i(0) \otimes u_\infty \), where \( b_i(0) \in B_i \) and \( u_\infty \) is the (unique) highest weight element in \( B(\infty) \). This is sometimes known as the Kashiwara embedding [NZ1997] (though, in [NZ1997], the target of this map is denoted by \( Z^J_f \)). By iterating this embedding by taking \( \Psi_J = \Psi_j^n \circ \Psi_{j_{n-1}} \circ \cdots \circ \Psi_j \), we obtain the following strict crystal embedding:

\[ \Psi^n_J : B(\infty) \to B_j^\otimes \otimes B(\infty). \]

We note there is a natural analog of Lemma 10.6.2 in [HK2002] that for any \( b \in B(\infty) \), there exists a positive integer \( N \) such that

\[ \Psi^n_J (b) = \left( \bigotimes_{k=1}^N b^{(k)} \right) \otimes u_\infty. \]

Therefore we can model elements \( b \in B(\infty) \) by considering an infinite list of elements \( b^{(k)} \in B_J \) and defining the crystal structure by:

\[
\begin{align*}
\text{wt}(b) &= \sum_{k=1}^N \text{wt}(b^{(k)}) \\
\varepsilon_i(b) &= e_i \left( \bigotimes_{k=1}^N b^{(k)} \right) \otimes u_\infty, \\
f_i(b) &= f_i \left( \bigotimes_{k=1}^N b^{(k)} \right) \otimes u_\infty, \\
\varphi_i(b) &= \varepsilon_i(b) - \langle \text{wt}(b), h^\vee_i \rangle.
\end{align*}
\]

To translate this into a finite list, we consider a finite sequence \( b_1 \otimes \cdots \otimes b_N \) and if

\[ f_i \left( b^{(1)} \otimes \cdots \otimes b^{(N-1)} \otimes b^{(N)} \right) = b^{(1)} \otimes \cdots \otimes b^{(N-1)} \otimes f_i \left( b^{(N)} \right), \]

then we take the image as \( b^{(1)} \otimes \cdots \otimes f_i \left( b^{(N)} \right) \otimes b^{(N+1)} \). Similarly we remove \( b^{(N)} \) if we have \( b^{(N)} = \bigotimes_{k=1}^m b_{j_k}(0) \). Additionally if

\[ e_i \left( b^{(1)} \otimes \cdots \otimes b^{(N-1)} \otimes b^{(N)} \right) = b^{(1)} \otimes \cdots \otimes b^{(N-1)} \otimes e_i \left( b^{(N)} \right), \]

then we consider this to be 0.

**INPUT:**
- cartan_type – a Cartan type
- seq – (default: None) a finite sequence whose support equals the index set of the Cartan type; if None, then this is the index set

**EXAMPLES:**
sage: B = crystals.infinity.PolyhedralRealization(['A',2])
sage: mg = B.module_generators[0]; mg
[0, 0]
sage: mg.f_string([2,1,2,2])
[0, -3, -1, 0, 0, 0]

>>> from sage.all import *
>>> B = crystals.infinity.PolyhedralRealization(['A',Integer(2)])
>>> mg = B.module_generators[Integer(0)]; mg
[0, 0]
>>> mg.f_string([Integer(2),Integer(1),Integer(2),Integer(2)])
[0, -3, -1, 0, 0, 0]

An example of type $B_2$:

sage: B = crystals.infinity.PolyhedralRealization(['B',2])
sage: mg = B.module_generators[0]; mg
[0, 0]
sage: mg.f_string([2,1,2,2])
[0, -2, -1, -1, 0, 0]

>>> from sage.all import *
>>> B = crystals.infinity.PolyhedralRealization(['B',Integer(2)])
>>> mg = B.module_generators[Integer(0)]; mg
[0, 0]
>>> mg.f_string([Integer(2),Integer(1),Integer(2),Integer(2)])
[0, -2, -1, -1, 0, 0]

An example of type $G_2$:

sage: B = crystals.infinity.PolyhedralRealization(['G',2])
sage: mg = B.module_generators[0]; mg
[0, 0]
sage: mg.f_string([2,1,2,2])
[0, -3, -1, 0, 0, 0]

>>> from sage.all import *
>>> B = crystals.infinity.PolyhedralRealization(['G',Integer(2)])
>>> mg = B.module_generators[Integer(0)]; mg
[0, 0]
>>> mg.f_string([Integer(2),Integer(1),Integer(2),Integer(2)])
[0, -3, -1, 0, 0, 0]

class Element

Bases: TensorProductOfCrystalsElement

An element in the polyhedral realization of $B(\infty)$.

$e(i)$

Return the action of $e_i$ on self.

EXAMPLES:

sage: B = crystals.infinity.PolyhedralRealization(['A',2])
sage: mg = B.module_generators[0]
sage: all(mg.e(i) is None for i in B.index_set())
True

```
sage: mg.f(1).e(1) == mg
True
```

```python
>>> from sage.all import *

>>> B = crystals.infinity.PolyhedralRealization(['A',Integer(2)])
>>> mg = B.module_generators[Integer(0)]
>>> all(mg.e(i) is None for i in B.index_set())
True
>>> mg.f(Integer(1)).e(Integer(1)) == mg
True
```

**epsilon**(*i*)

Return $\epsilon_i$ of self.

**EXAMPLES:**

```
sage: B = crystals.infinity.PolyhedralRealization(['A',2,1])
sage: mg = B.module_generators[0]
sage: [mg.epsilon(i) for i in B.index_set()]
[0, 0, 0]
sage: elt = mg.f(0)
sage: [elt.epsilon(i) for i in B.index_set()]
[1, 0, 0]
sage: elt = mg.f_string([0,1,2])
sage: [elt.epsilon(i) for i in B.index_set()]
[0, 0, 1]
sage: elt = mg.f_string([0,1,2,2])
sage: [elt.epsilon(i) for i in B.index_set()]
[0, 0, 2]
```

```
>>> from sage.all import *

>>> B = crystals.infinity.PolyhedralRealization(['A',Integer(2), Integer(1)])
>>> mg = B.module_generators[Integer(0)]
>>> [mg.epsilon(i) for i in B.index_set()]
[0, 0, 0]
```

```
>>> elt = mg.f(Integer(0))
>>> [elt.epsilon(i) for i in B.index_set()]
[1, 0, 0]
```

```
>>> elt = mg.f_string([Integer(0),Integer(1),Integer(2)])
>>> [elt.epsilon(i) for i in B.index_set()]
[0, 0, 1]
```

```
>>> elt = mg.f_string([Integer(0),Integer(1),Integer(2),Integer(2)])
>>> [elt.epsilon(i) for i in B.index_set()]
[0, 0, 2]
```

**f**(*i*)

Return the action of $f_i$ on self.

**EXAMPLES:**

```
sage: B = crystals.infinity.PolyhedralRealization(['A',2])
sage: mg = B.module_generators[0]
sage: mg.f(1)
[-1, 0, 0, 0]
```

(continues on next page)
>>> from sage.all import *
>>> B = crystals.infinity.PolyhedralRealization(['A', Integer(2)])
>>> mg = B.module_generators[Integer(0)]
>>> mg.f(Integer(1))
[-1, 0, 0, 0]
>>> mg.f_string([Integer(1), Integer(2), Integer(2), Integer(1)])
[-1, -2, -1, 0, 0, 0]

\phi (i)

Return $\phi_i$ of self.

EXAMPLES:

sage: B = crystals.infinity.PolyhedralRealization(['A', Z, 1])
sage: mg = B.module_generators[0]
sage: [mg.phi(i) for i in B.index_set()]
[0, 0, 0]
sage: elt = mg.f(0)
sage: [elt.phi(i) for i in B.index_set()]
[-1, 1, 1]
sage: elt = mg.f_string([0,1])
sage: [elt.phi(i) for i in B.index_set()]
[-1, 0, 2]
sage: elt = mg.f_string([0,1,2,2])
sage: [elt.phi(i) for i in B.index_set()]
[1, 1, 0]

truncate ($k=None$)

Truncate self to have length $k$ and return as an element in a (finite) tensor product of crystals.

INPUT:

- $k$ – (optional) the length of the truncation; if not specified, then returns one more than the current non-ground-state elements (i.e. the current list in self)

EXAMPLES:

sage: B = crystals.infinity.PolyhedralRealization(['A', 2])
sage: mg = B.module_generators[0]
sage: elt = mg.f_string([1,2,2,1]); elt
[-1, -2, -1, 0, 0, 0]
sage: t = elt.truncate(); t
[-1, -2, -1, 0, 0, 0]
sage: t.parent() is B.finite_tensor_product(6)
True
sage: elt.truncate(2)
[-1, -2]
sage: elt.truncate(10)
[-1, -2, -1, 0, 0, 0, 0, 0, 0, 0]

>>> from sage.all import *
>>> B = crystals.infinity.PolyhedralRealization(['A',Integer(2)])
>>> mg = B.module_generators[Integer(0)]
>>> elt = mg.f_string([Integer(1),Integer(2),Integer(2),Integer(1)]); elt
[-1, -2, -1, 0, 0, 0]
>>> t = elt.truncate(); t
[-1, -2, -1, 0, 0, 0]
>>> t.parent() is B.finite_tensor_product(Integer(6))
True
>>> elt.truncate(Integer(2))
[-1, -2]
>>> elt.truncate(Integer(10))
[-1, -2, -1, 0, 0, 0, 0, 0, 0, 0]

finite_tensor_product($k$)

Return the finite tensor product of crystals of length $k$ by truncating self.

EXAMPLES:

sage: B = crystals.infinity.PolyhedralRealization(['A',2])
sage: B.finite_tensor_product(5)
Full tensor product of the crystals
[The 1-elementary crystal of type ['A', 2],
The 2-elementary crystal of type ['A', 2],
The 1-elementary crystal of type ['A', 2],
The 2-elementary crystal of type ['A', 2],
The 1-elementary crystal of type ['A', 2]]

>>> from sage.all import *
>>> B = crystals.infinity.PolyhedralRealization(['A',Integer(2)])
>>> B.finite_tensor_product(Integer(5))
Full tensor product of the crystals
[The 1-elementary crystal of type ['A', 2],
The 2-elementary crystal of type ['A', 2],
The 1-elementary crystal of type ['A', 2],
The 2-elementary crystal of type ['A', 2],
The 1-elementary crystal of type ['A', 2]]
5.1.65 Spin Crystals

These are the crystals associated with the three spin representations: the spin representations of odd orthogonal groups (or rather their double covers); and the $+$ and $-$ spin representations of the even orthogonal groups.

We follow Kashiwara and Nakashima (Journal of Algebra 165, 1994) in representing the elements of the spin crystal by sequences of signs $\pm$.

`sage.combinat.crystals.spins.CrystalOfSpins(ct)`

Return the spin crystal of the given type $B$.

This is a combinatorial model for the crystal with highest weight $\Lambda_n$ (the $n$-th fundamental weight). It has $2^n$ elements, here called Spins. See also `CrystalOfLetters()`, `CrystalOfSpinsPlus()`, and `CrystalOfSpinsMinus()`.

**INPUT:**
- ['B', $n$] – A Cartan type $B_n$.

**EXAMPLES:**

```python
sage: C = crystals.Spins(['B',3])
sage: C.list()
[+++ , ++- , +-+ , -++ , +-- , -+- , --+
```

```python
>>> from sage.all import *
>>> C = crystals.Spins(['B',Integer(3)])
>>> C.list()
[+++ , ++- , +-+ , -++ , +-- , -+- , --+
```

```python
sage: [x.signature() for x in C]
['+++ ', '+-+ ', '+-+ ', '-++ ', '-++ ', '+-- ', '-+- ', '--+ ', '--- ']
```

`sage.combinat.crystals.spins.CrystalOfSpinsMinus(ct)`

Return the minus spin crystal of the given type $D$.

This is the crystal with highest weight $\Lambda_n-1$ (the $(n-1)$-st fundamental weight).

**INPUT:**
- ['D', $n$] – A Cartan type $D_n$.

**EXAMPLES:**

```python
sage: E = crystals.SpinsMinus(['D',4])
sage: E.list()
[+++ -, ++-+, +++-, --+, +++-, ++-, ++-, ++-, ++-,
```

```python
>>> from sage.all import *
>>> E = crystals.SpinsMinus(['D',4])
>>> E.list()
[+++ -, ++-+, +++-, --+, +++-, ++-, ++-, ++-, ++-,
```

```python
sage: [x.signature() for x in E]
['+++-', '+-+-', '+-+-', '-+++', '-++-', '-+-', '-+-', '-+-', '-+-']
```
```python
>>> from sage.all import *
>>> E = crystals.SpinsMinus(['D', Integer(4)])
>>> E.list()
[+--+,-+-+,+-++,-+++,----,-++,---+,-+-++]
>>> [x.signature() for x in E]
[+--+,-+-+,+-++,-+++,----,-++,---+,-+-++]

sage.combinat.crystals.spins.CrystalOfSpinsPlus(ct)

Return the plus spin crystal of the given type D.

This is the crystal with highest weight \(\Lambda_n\) (the \(n\)-th fundamental weight).

INPUT:

- \(['D', n]\) – A Cartan type \(D_n\).

EXAMPLES:

```python
sage: D = crystals.SpinsPlus(['D',4])
sage: D.list()
[++++, ++--, +-+-, -++-, +--+, -+-+, --++, ----]
```
class sage.combinat.crystals.spins.Spin

Bases: Element

A spin letter in the crystal of spins.

EXAMPLES:

```python
sage: C = crystals.Spins(['B',3])
sage: c = C([1,1,1])
sage: c
+++
sage: c.parent()
The crystal of spins for type ['B', 3]
```

```python
sage: D = crystals.Spins(['B',4])
sage: a = C([1,1,1])
sage: b = C([-1,-1,-1])
sage: c = D([1,1,1,1])
sage: a == a
True
sage: a == b
False
sage: b == c
False
```

```python
>>> from sage.all import *

>>> C = crystals.Spins(['B',Integer(3)])

>>> x = C([Integer(1),Integer(1),Integer(1)])

>>> y = C([-Integer(1),-Integer(1),-Integer(1)])

>>> C.lt_elements(x, y)
True

>>> C.lt_elements(y, x)
False

>>> C.lt_elements(x, x)
False

pp()

Pretty print self as a column.
EXAMPLES:

```python
sage: C = crystals.Spins(['B',3])
sage: b = C([1,1,-1])
sage: b.pp() + + -
```

```python
>>> from sage.all import *
>>> C = crystals.Spins(['B',Integer(3)])
>>> b = C([Integer(1),Integer(1),-Integer(1)])
>>> b.pp() + + -
```

**signature()**
Return the signature of self.

EXAMPLES:

```python
sage: C = crystals.Spins(['B',3])
sage: C([1,1,1]).signature() '+++'
sage: C([1,1,-1]).signature() '++-
```

```python
>>> from sage.all import *
>>> C = crystals.Spins(['B',Integer(3)])
>>> C([Integer(1),Integer(1),Integer(1)]).signature() '+++'
>>> C([Integer(1),Integer(1),-Integer(1)]).signature() '++-
```

**value**
Return self as a tuple with +1 and -1.

EXAMPLES:

```python
sage: C = crystals.Spins(['B',3])
sage: C([1,1,1]).value (1, 1, 1)
sage: C([1,1,-1]).value (1, 1, -1)
```

```python
>>> from sage.all import *
>>> C = crystals.Spins(['B',Integer(3)])
>>> C([Integer(1),Integer(1),Integer(1)]).value (1, 1, 1)
>>> C([Integer(1),Integer(1),-Integer(1)]).value (1, 1, -1)
```

**weight()**
Return the weight of self.

EXAMPLES:
class sage.combinat.crystals.spins.Spin_crystal_type_B_element

Bases: Spin

Type B spin representation crystal element

\( e(i) \)

Return the action of \( e_i \) on self.

EXAMPLES:

```python
sage: C = crystals.Spins(['B',3])
sage: [[C[m].e(i) for i in range(1,4)] for m in range(8)]
[[None, None, None], [None, None, +++], [None, ++-, None], [+--, None, None], [None, None, ++-], [None, -+-, None], [None, None, --+], [None, None, None]]
```

\( \epsilon(i) \)

Return \( \epsilon_i \) of self.

EXAMPLES:

```python
sage: C = crystals.Spins(['B',3])
sage: [[C[m].epsilon(i) for i in range(1,4)] for m in range(8)]
[[0, 0, 0], [0, 0, 1], [0, 1, 0], [1, 0, 0], [0, 0, 1], [1, 0, 1], [0, 1, 0], [0, 0, 1]]
```

\( f(i) \)

Return the action of \( f_i \) on self.

EXAMPLES:
sage: C = crystals.Spins(['B',3])
sage: [[C[m].f(i) for i in range(1,4)] for m in range(8)]
[[None, None, ++-], [None, ++-, None], [---, None, +--], [None, None, --+, [None, None, None]]

>>> from sage.all import *
>>> C = crystals.Spins(['B',Integer(3)])
>>> [[C[m].f(i) for i in range(Integer(1),Integer(4))] for m in range(Integer(8))]
[[None, None, ++-], [None, ++-, None], [---, None, +--], [None, None, --+, [None, None, None]]

phi(i)
Return $\varphi_i$ of self.

EXAMPLES:

sage: C = crystals.Spins(['B',3])
sage: [[C[m].phi(i) for i in range(1,4)] for m in range(8)]
[[0, 0, 1], [0, 1, 0], [1, 0, 1], [0, 0, 1], [1, 0, 0], [0, 1, 0], [0, 0, 1], [0, 0, 0]]

>>> from sage.all import *
>>> C = crystals.Spins(['B',Integer(3)])
>>> [[C[m].phi(i) for i in range(Integer(1),Integer(4))] for m in range(Integer(8))]
[[0, 0, 1], [0, 1, 0], [1, 0, 1], [0, 0, 1], [1, 0, 0], [0, 1, 0], [0, 0, 1], [0, 0, 0]]

class sage.combinat.crystals.spins.Spin_crystal_type_D_element
Bases: Spin

Type D spin representation crystal element $e(i)$

Return the action of $e_i$ on self.

EXAMPLES:

sage: D = crystals.SpinsPlus(['D',4])
sage: [[D.list()[m].e(i) for i in range(1,4)] for m in range(8)]
[[None, None, None], [None, None, None], [None, ++-, None], [+-+, None, None], [-++, None, None], [None, None, None], [None, None, None], [None, None, None]]

>>> from sage.all import *
>>> D = crystals.SpinsPlus(['D',Integer(4)])
>>> [[D.list()[m].e(i) for i in range(Integer(1),Integer(4))] for m in range(Integer(8))]
[[None, None, None], [None, None, None], [None, ++-, None], [+-+, None, None], [-++, None, None], [None, None, None], [None, None, None], [None, None, None]]
sage: E = crystals.SpinsMinus(['D',4])
sage: [[E[m].e(i) for i in range(1,4)] for m in range(8)]
[[None, None, None], [None, None, +++-], [None, ++-+, None], [+--+, None, None],
[None, None, None], [+---, None, None], [None, -+--, None], [None, None, --+-]]

>>> from sage.all import *
>>> E = crystals.SpinsMinus(['D',Integer(4)])
>>> [[E[m].e(i) for i in range(Integer(1),Integer(4))] for m in range(Integer(8))]
[[None, None, None], [None, None, +++-], [None, ++-+, None], [+--+, None, None],
[None, None, None], [+---, None, None], [None, -+--, None], [None, None, --+-]]

epsilon(i)

Return $\epsilon_i$ of self.

EXAMPLES:

sage: C = crystals.SpinsMinus(['D',4])
sage: [[C[m].epsilon(i) for i in C.index_set()] for m in range(8)]
[[0, 0, 0, 0], [0, 0, 1, 0], [0, 1, 0, 0], [1, 0, 0, 0],
[0, 0, 0, 1], [1, 0, 1, 0], [1, 1, 1, 0], [0, 0, 1, 0]]

>>> from sage.all import *
>>> C = crystals.SpinsMinus(['D',Integer(4)])
>>> [[C[m].epsilon(i) for i in C.index_set()] for m in range(Integer(8))]
[[0, 0, 0, 0], [0, 0, 1, 0], [0, 1, 0, 0], [1, 0, 0, 0],
[0, 0, 0, 1], [1, 0, 1, 0], [1, 1, 1, 0], [0, 0, 1, 0]]

f(i)

Return the action of $f_i$ on self.

EXAMPLES:

sage: D = crystals.SpinsPlus(['D',4])
sage: [[D.list()[m].f(i) for i in range(1,4)] for m in range(8)]
[[None, None, None], [None, +-+-, None], [;++-, None, +--+], [None, None, None],
[None, None, None], [None, +--+, None], [None, None, None], [None, None, None]]

>>> from sage.all import *
>>> D = crystals.SpinsPlus(['D',Integer(4)])
>>> [[D.list()[m].f(i) for i in range(Integer(1),Integer(4))] for m in range(Integer(8))]
[[None, None, None], [None, +-+-, None], [;++-, None, +--+], [None, None, None],
[None, None, None], [None, +--+, None], [None, None, None], [None, None, None]]

sage: E = crystals.SpinsMinus(['D',4])
sage: [[E[m].f(i) for i in range(1,4)] for m in range(8)]
[[None, None, ++-+], [None, +-++, None], [+--+, None, None], [None, None, None],
[None, None, ++-+], [None, +-++, None], [+--+, None, None], [None, None, None]]

(continues on next page)
from sage.all import *

E = crystals.SpinsMinus(['D',Integer(4)])

>>> ([E[m].f(i) for i in range(Integer(1),Integer(4))] for m in range(Integer(8))
  [[None, None, ++-+], [None, ++++, None], [-+++, None, None], [None, None, None],
   [-+--, None, None], [None, --+-, None], [None, None, ---+], [None, None, None]])

phi(i)

Return \( \varphi_i \) of self.

EXAMPLES:

sage: C = crystals.SpinsPlus(['D',4])

sage: [[C[m].phi(i) for i in C.index_set()] for m in range(8)]

[[0, 0, 0, 1], [0, 1, 0, 0], [1, 0, 1, 0], [0, 0, 1, 0],
 [1, 0, 0, 0], [0, 1, 0, 0], [0, 0, 0, 1], [0, 0, 0, 0]]

5.1.66 Star-Crystal Structure On \( B(\infty) \)

AUTHORS:

- Ben Salisbury: Initial version
- Travis Scrimshaw: Initial version

class sage.combinat.crystals.star_crystal.StarCrystal(Binf)

Bases: UniqueRepresentation, Parent

The star-crystal or \(*\)-crystal version of a highest weight crystal.

The \(*\)-crystal structure on \( B(\infty) \) is the structure induced by the algebra antiautomorphism \( *: U_q(g) \to U_q(g) \) that stabilizes the negative half \( U_q^-\). It is defined by

\[
E_i^* = E_i, \quad F_i^* = F_i, \quad q^* = q, \quad (q^h)^* = q^{-h},
\]

where \( E_i \) and \( F_i \) are the Chevalley generators of \( U_q(g) \) and \( h \) is an element of the Cartan subalgebra.

The induced operation on the crystal \( B(\infty) \) is called the Kashiwara involution. Its implementation here is based on the recursive algorithm from Theorem 2.2.1 of [Ka1993], which states that for any \( i \in I \) there is a unique strict crystal embedding

\[
\Psi_i: B(\infty) \to B_i \otimes B(\infty)
\]

such that
• \( u_\infty \mapsto b_i(0) \otimes u_\infty \), where \( u_\infty \) is the highest weight vector in \( B(\infty) \);

• if \( \Psi_i(b) = f_i^m b_i(0) \otimes b_0 \), then \( \Psi_i(f_i^m b_i(0) \otimes b_0) = m \);

• the image of \( \Psi_i \) is \( \{ f_i^m b_i(0) \otimes b : \epsilon_i(b^*) = 0, m \geq 0 \} \).

Here, \( B_i \) is the \( i \)-th elementary crystal. See \texttt{ElementaryCrystal} for more information.

**INPUT:**

• \( B_{\text{inf}} \) – a crystal from \texttt{catalog\_infinity\_crystals}

**EXAMPLES:**

```python
sage: B = crystals.infinity.Tableaux(['A',2])
sage: Bstar = crystals.infinity.Star(B)
sage: mg = Bstar.highest_weight_vector()
sage: mg
[[1, 1], [2]]
sage: mg.f_string([1,2,1,2,2])
[[1, 1, 1, 1, 1, 2, 2], [2, 3, 3, 3]]
```

```python
>>> from sage.all import *

```
Combinatorics, Release 10.4

>>> ascii_art(nuJ.e(Integer(1)))
-1[ ]-1 ( /) 0[ ] 1 ( /) -1[ ]-1 ( /) -2[ ]-1

>>> M = crystals.infinity.NakajimaMonomials(['B', Integer(2), Integer(1)])
>>> Mstar = crystals.infinity.Star(M)
>>> m = Mstar.module_generators[Integer(0)].f_string([Integer(0),
    -Integer(1), Integer(2), Integer(2), Integer(1), Integer(0)])
>>> m.e(Integer(1))
Y(0,0)^-1 Y(0,2)^-1 Y(1,1) Y(1,2)^-1 Y(2,1)^2

epsilon (i)

Return $\varepsilon^*_i$ of self.

INPUT:

• $i$ -- an element of the index set

EXAMPLES:

sage: Y = crystals.infinity.GeneralizedYoungWalls(3)
sage: Ystar = crystals.infinity.Star(Y)
sage: y = Ystar.module_generators[0].f_string([0,1,3,2,1,0])
sage: [y.epsilon(i) for i in y.index_set()]
[1, 0, 1, 0]

sage: RC = crystals.infinity.RiggedConfigurations(['E', 6, 1])
sage: RCstar = crystals.infinity.Star(RC)
sage: nuJ = RCstar.module_generators[0].f_string([0,4,6,1,2])
sage: [nuJ.epsilon(i) for i in nuJ.index_set()]
[0, 1, 1, 0, 0, 0, 1]

>>> from sage.all import *

>>> Y = crystals.infinity.GeneralizedYoungWalls(Integer(3))
>>> Ystar = crystals.infinity.Star(Y)
>>> y = Ystar.module_generators[Integer(0)].f_string([Integer(0),
    -Integer(1), Integer(3), Integer(2), Integer(1), Integer(0)])
>>> [y.epsilon(i) for i in y.index_set()]
[1, 0, 1, 0]

>>> RC = crystals.infinity.RiggedConfigurations(['E', Integer(6),
    -Integer(1)])
>>> RCstar = crystals.infinity.Star(RC)
>>> nuJ = RCstar.module_generators[Integer(0)].f_string([Integer(0),
    -Integer(4), Integer(6), Integer(1), Integer(2)])
>>> [nuJ.epsilon(i) for i in nuJ.index_set()]
[0, 1, 1, 0, 0, 0, 1]

f (i)

Return the action of $f^*_i$ on self.

INPUT:

• $i$ -- an element of the index set

EXAMPLES:

sage: T = crystals.infinity.Tableaux("G2")
sage: Tstar = crystals.infinity.Star(T)
sage: t = Tstar.module_generators[0].f_string([1,2,1,1,2])
sage: t
Jump \((i)\)

Return the \(i\)-jump of \(self\).

For \(b \in B(\infty)\),

\[
\text{jump}_i(b) = \varepsilon_i(b) + \varepsilon^*_i(b) + \langle h_i, \text{wt}(b) \rangle,
\]

where \(h_i\) is a simple coroot.

**INPUT:**

- \(i\) - an element of the index set

**EXAMPLES:**

```python
sage: RC = crystals.infinity.RiggedConfigurations("D4")
sage: RCstar = crystals.infinity.Star(RC)
sage: nu0star = RCstar.module_generators[0]
sage: nustar = nu0star.f_string([2,1,3,4,2])
>> [nustar.jump(i) for i in RC.index_set()]
[0, 1, 0, 0]
sage: nustar = nu0star.f_string([2,1,3,4,2,1,3,2]) # long time
>> [nustar.jump(i) for i in RC.index_set()] # long time
[1, 0, 1, 2]
```

```python
>>> from sage.all import *
>>> RC = crystals.infinity.RiggedConfigurations("D4")
>>> RCstar = crystals.infinity.Star(RC)
>>> nu0star = RCstar.module_generators[0]
>>> nustar = nu0star.f_string([Integer(2),Integer(1),Integer(3),Integer(4),Integer(2)])
>>> [nustar.jump(i) for i in RC.index_set()]
[0, 1, 0, 0]
>>> nustar = nu0star.f_string([Integer(2),Integer(1),Integer(3),Integer(4),Integer(2),Integer(1),Integer(3),Integer(2)]) # long time
>> [nustar.jump(i) for i in RC.index_set()]
[0, 1, 0, 0]
```

(continues on next page)
\[
\phi_i^n(b) = \varepsilon_i^n(b) + \langle h_i, \text{wt}(b) \rangle,
\]

where \(h_i\) is a simple coroot.

**INPUT:**
- \(i\) – an element of the index set

**EXAMPLES:**

```python
sage: T = crystals.infinity.Tableaux("A2")
sage: Tstar = crystals.infinity.Star(T)
sage: t = Tstar.module_generators[0].f_string([1,2,1,1,2])
sage: [t.phi(i) for i in t.index_set()]
[-3, 1]

sage: M = crystals.infinity.NakajimaMonomials([B,2,1])
sage: Mstar = crystals.infinity.Star(M)
sage: m = Mstar.module_generators[0].f_string([0,1,2,2,1,0])
sage: [m.phi(i) for i in m.index_set()]
[-1, -1, 4]
```

**weight()**

Return the weight of self.

**EXAMPLES:**

```python
sage: RC = crystals.infinity.RiggedConfigurations([E,6,1])
sage: RCstar = crystals.infinity.Star(RC)
sage: nuJ = RCstar.module_generators[0].f_string([0,4,6,1,2])
sage: nuJ.weight()
```
5.1.67 Tensor Products of Crystals

Main entry points:

• TensorProductOfCrystals
• CrystalOfTableaux

AUTHORS:

• Anne Schilling, Nicolas Thiery (2007): Initial version
• Ben Salisbury, Travis Scrimshaw (2013): Refactored tensor products to handle non-regular crystals and created new subclass to take advantage of the regularity
• Travis Scrimshaw (2020): Added queer crystal

class sage.combinat.crystals.tensor_product.CrystalOfQueerTableaux(cartan_type, shape)

Bases: CrystalOfWords, QueerSuperCrystalsMixin

A queer crystal of the semistandard decomposition tableaux of a given shape.

INPUT:

• cartan_type – a Cartan type
• shape – a shape

class Element

Bases: TensorProductOfQueerSuperCrystalsElement

rows()

Return the list of rows of self.

EXAMPLES:

sage: B = crystals.Tableaux(['Q',3], shape=[3,2,1])
sage: t = B.an_element()
sage: t.rows()
[[3, 3, 3], [2, 2], [1]]
class sage.combinat.crystals.tensor_product.CrystalOfTableaux(cartan_type, shapes)

Bases: CrystalOfWords

A class for crystals of tableaux with integer valued shapes

INPUT:

- cartan_type – a Cartan type
- shape – a partition of length at most cartan_type.rank()
- shapes – a list of such partitions

This constructs a classical crystal with the given Cartan type and highest weight(s) corresponding to the given shape(s).

If the type is $D_r$, the shape is permitted to have a negative value in the $r$-th position. Thus if the shape equals $[s_1, \ldots, s_r]$, then $s_r$ may be negative but in any case $s_1 \geq \cdots \geq s_{r-1} \geq |s_r|$. This crystal is related to that of shape $[s_1, \ldots, |s_r|]$ by the outer automorphism of $SO(2r)$.

If the type is $D_r$ or $B_r$, the shape is permitted to be of length $r$ with all parts of half integer value. This corresponds to having one spin column at the beginning of the tableau. If several shapes are provided, they currently should all or none have this property.

Crystals of tableaux are constructed using an embedding into tensor products following Kashiwara and Nakashima [KN1994]. Sage’s tensor product rule for crystals differs from that of Kashiwara and Nakashima by reversing the order of the tensor factors. Sage produces the same crystals of tableaux as Kashiwara and Nakashima. With Sage’s convention, the tensor product of crystals is the same as the monoid operation on tableaux and hence the plactic monoid.

See also:

sage.combinat.crystals.crystals for general help on crystals, and in particular plotting and \LaTeX output.

EXAMPLES:

We create the crystal of tableaux for type $A_2$, with highest weight given by the partition $[2, 1, 1]$:

```
sage: T = crystals.Tableaux(['A',3], shape = [2,1,1])
```

```
>>> from sage.all import *
>>> T = crystals.Tableaux(['A',Integer(3)], shape = [Integer(2),Integer(1),
˓→Integer(1)])
```

Here is the list of its elements:

```
sage: T.list()

[[[1, 1], [2], [3]], [[1, 2], [2], [3]], [[1, 3], [2], [3]],
     [[1, 4], [2], [3]], [[1, 4], [2], [4]],
     [[1, 4], [3], [4]],
     [[1, 1], [2], [4]], [[1, 2], [2], [4]],
     [[1, 3], [2], [4]],
     [[1, 1], [3], [4]],
     [[1, 2], [3], [4]],
     [[2, 2], [3], [4]]]
```

```
>>> from sage.all import *
>>> T.list()

[[[1, 1], [2], [3]], [[1, 2], [2], [3]], [[1, 3], [2], [3]],
     [[1, 4], [2], [3]],
     [[1, 4], [2], [4]],
     [[1, 4], [3], [4]],
     [[1, 1], [2], [4]],
     [[1, 2], [2], [4]],
     [[1, 3], [2], [4]],
     [[1, 1], [3], [4]],
```

5.1. Comprehensive Module List 867
Internally, a tableau of a given Cartan type is represented as a tensor product of letters of the same type. The order in which the tensor factors appear is by reading the columns of the tableaux left to right, top to bottom (in French notation). As an example:

```sage
t = crystals.Tableaux(['A',2], shape = [3,2])
t.module_generators[0]
[[1, 1, 1], [2, 2]]
t.list(t.module_generators[0])
[2, 1, 2, 1, 1]
```

```sage
>>> from sage.all import *

>>> t = crystals.Tableaux(['A',Integer(2)], shape = [Integer(3),Integer(2)])

>>> t.module_generators[Integer(0)]
[[1, 1, 1], [2, 2]]

>>> t.list(t.module_generators[Integer(0)])
[2, 1, 2, 1, 1]
```

To create a tableau, one can use:

```sage
tab = crystals.Tableaux(['A',3], shape = [2,2])
tab(rows=[[1,2],[3,4]])
[[1, 2], [3, 4]]

>>> from sage.all import *

>>> tab = crystals.Tableaux(['A',Integer(3)], shape = [Integer(2),Integer(2)])

>>> tab(rows=[[Integer(1),Integer(2)],[Integer(3),Integer(4)])
[[1, 2], [3, 4]]
```

Todo: FIXME:

- Do we want to specify the columns increasingly or decreasingly? That is, should this be `Tab(columns = [[1,3],[2,4]])`?
- Make this fully consistent with `Tableau()`!

We illustrate the use of a shape with a negative last entry in type $D$:

```sage
t = crystals.Tableaux(['D',4], shape=[1,1,1,-1])
t.cardinality()
35
t.list(T.module_generators[0])
```

```sage
>>> from sage.all import *

>>> t = crystals.Tableaux(['D',Integer(4)], shape=[Integer(1),Integer(1),
,Integer(1),-Integer(1)])

>>> t.cardinality()
35
```

We illustrate the construction of crystals of spin tableaux when the partitions have half integer values in type $B$ and $D$:
We can also construct the tableaux for $\mathfrak{gl}(m|n)$ as given by [BKK2000]:

```
sage: T = crystals.Tableaux(['A', [1,2]], shape=[4,2,1,1,1])
sage: T.cardinality()
1392
```

We can also construct the tableaux for $q(n)$ as given by [GJK+2014]:

```
sage: T = crystals.Tableaux(['Q', 3], shape=[3,1])
sage: T.cardinality()
24
```
class Element
Bases: CrystalOfTableauxElement
cartan_type()
Returns the Cartan type of the associated crystal

EXAMPLES:

sage: T = crystals.Tableaux(['A',3], shape = [2,2])
sage: T.cartan_type()
['A', 3]

>>> from sage.all import *
>>> T = crystals.Tableaux(['A',Integer(3)], shape = [Integer(2),Integer(2)])
>>> T.cartan_type()
['A', 3]

module_generator(shape)
This yields the module generator (or highest weight element) of a classical crystal of given shape. The module
generator is the unique tableau with equal shape and content.

EXAMPLES:

sage: T = crystals.Tableaux(['D',3], shape = [1,1])
sage: T.module_generator([1,1])
[[1], [2]]

sage: T = crystals.Tableaux(['D',4], shape = [2,2,2,-2])
sage: T.module_generator(tuple([2,2,2,-2]))
[[1, 1], [2, 2], [3, 3], [-4, -4]]
sage: T.cardinality()
294

sage: T = crystals.Tableaux(['D',4], shape = [2,2,2,2])
sage: T.module_generator(tuple([2,2,2,2]))
[[1, 1], [2, 2], [3, 3], [4, 4]]

sage: from sage.all import *
>>> T = crystals.Tableaux(['D',Integer(3)], shape = [Integer(1),Integer(1)])

>>> from sage.all import *
>>> T = crystals.Tableaux(['D',Integer(4)], shape = [Integer(2),Integer(2), Integer(2),-Integer(2)])

class sage.combinat.crystals.tensor_product.CrystalOfWords
Bases: UniqueRepresentation, Parent
Auxiliary class to provide a call method to create tensor product elements. This class is shared with several tensor product classes and is also used in CrystalOfTableaux to allow tableaux of different tensor product structures in column-reading (and hence different shapes) to be considered elements in the same crystal.

**class Element**

Bases: TensorProductOfCrystalsElement

class sage.combinat.crystals.tensor_product.FullTensorProductOfCrystals (crystals, **options)

Bases: TensorProductOfCrystals

Full tensor product of crystals.

**Todo:** Merge this into TensorProductOfCrystals.

c**ardinality()**

Return the cardinality of self.

**EXAMPLES:**

```python
sage: C = crystals.Letters(['A',2])
sage: T = crystals.TensorProduct(C,C)
sage: T.cardinality()
9
```

```python
>>> from sage.all import *

>>> C = crystals.Letters(['A',Integer(2)])
>>> T = crystals.TensorProduct(C,C)
>>> T.cardinality()
9
```

**weight_lattice_realization()**

Return the weight lattice realization used to express weights.

The weight lattice realization is the common parent which all weight lattice realizations of the crystals of self coerce into.

**EXAMPLES:**

```python
sage: B = crystals.elementary.B(['A',4], 2)
sage: B.weight_lattice_realization()
Root lattice of the Root system of type ['A', 4]
sage: T = crystals.infinity.Tableaux(['A',4])
sage: T.weight_lattice_realization()
Ambient space of the Root system of type ['A', 4]
sage: TP = crystals.TensorProduct(B, T)
sage: TP.weight_lattice_realization()
Ambient space of the Root system of type ['A', 4]
```

```python
>>> from sage.all import *

>>> B = crystals.elementary.B(['A',Integer(4)], Integer(2))
>>> B.weight_lattice_realization()
Root lattice of the Root system of type ['A', 4]
>>> T = crystals.infinity.Tableaux(['A',Integer(4)])
>>> T.weight_lattice_realization()
```

(continues on next page)
Ambient space of the Root system of type ['A', 4]

```python
>>> TP = crystals.TensorProduct(B, T)
>>> TP.weight_lattice_realization()
Ambient space of the Root system of type ['A', 4]
```

```python
class sage.combinat.crystals.tensor_product.FullTensorProductOfQueerSuperCrystals(crystals, **options)
```

Bases: `FullTensorProductOfCrystals, QueerSuperCrystalsMixin`

Tensor product of queer super crystals.

class `Element`

Bases: `TensorProductOfQueerSuperCrystalsElement`

```python
class sage.combinat.crystals.tensor_product.FullTensorProductOfRegularCrystals(crystals, **options)
```

Bases: `FullTensorProductOfCrystals`

Full tensor product of regular crystals.

class `Element`

Bases: `TensorProductOfRegularCrystalsElement`

```python
class sage.combinat.crystals.tensor_product.FullTensorProductOfSuperCrystals(crystals, **options)
```

Bases: `FullTensorProductOfCrystals`

Tensor product of super crystals.

EXAMPLES:

```python
sage: L = crystals.Letters(['A', [1,1]])
sage: T = tensor([L,L,L])
sage: T.cardinality()
64

>>> from sage.all import *
>>> L = crystals.Letters(['A', [Integer(1),Integer(1)])
>>> T = tensor([L,L,L])
>>> T.cardinality()
64
```

class `Element`

Bases: `TensorProductOfSuperCrystalsElement`

class sage.combinat.crystals.tensor_product.QueerSuperCrystalsMixin

Bases: object

Mixin class with methods for a finite queer supercrystal.
index_set()

Return the enlarged index set.

EXAMPLES:

```python
sage: Q = crystals.Letters(['Q', 3])
sage: T = tensor([Q, Q])
sage: T.index_set()
(-4, -3, -2, -1, 1, 2)
```

```python
>>> from sage.all import *

>>> Q = crystals.Letters(['Q', Integer(3)])

>>> T = tensor([Q, Q])

>>> T.index_set()
(-4, -3, -2, -1, 1, 2)
```

class sage.combinat.crystals.tensor_product.TensorProductOfCrystals

Bases: CrystalOfWords

Tensor product of crystals.

Given two crystals $B$ and $B'$ of the same Cartan type, one can form the tensor product $B \otimes B'$. As a set $B \otimes B'$ is the Cartesian product $B \times B'$. The crystal operators $f_i$ and $e_i$ act on $b \otimes b' \in B \otimes B'$ as follows:

\[
f_i(b \otimes b') = \begin{cases} 
    f_i(b) \otimes b' & \text{if } \varepsilon_i(b) \geq \varphi_i(b') \\
    b \otimes f_i(b') & \text{otherwise}
\end{cases}
\]

and

\[
e_i(b \otimes b') = \begin{cases} 
    e_i(b) \otimes b' & \text{if } \varepsilon_i(b) > \varphi_i(b') \\
    b \otimes e_i(b') & \text{otherwise.}
\end{cases}
\]

We also define:

\[
\varphi_i(b \otimes b') = \max(\varphi_i(b), \varphi_i(b') + \langle \alpha_i^\vee, \operatorname{wt}(b) \rangle),
\]

\[
\varepsilon_i(b \otimes b') = \max(\varepsilon_i(b'), \varepsilon_i(b) - \langle \alpha_i^\vee, \operatorname{wt}(b') \rangle).
\]

Note: This is the opposite of Kashiwara's convention for tensor products of crystals.

Since tensor products are associative $(B \otimes C) \otimes D \cong B \otimes (C \otimes D)$ via the natural isomorphism $(b \otimes c) \otimes d \mapsto b \otimes (c \otimes d)$, we can generalizing this to arbitrary tensor products. Thus consider $B_N \otimes \cdots \otimes B_1$, where each $B_k$ is an abstract crystal. The underlying set of the tensor product is $B_N \times \cdots \times B_1$, while the crystal structure is given as follows. Let $I$ be the index set, and fix some $i \in I$ and $b_N \otimes \cdots \otimes b_1 \in B_N \otimes \cdots \otimes B_1$. Define

\[
a_i(k) := \varepsilon_i(b_k) - \sum_{j=1}^{k-1} (\alpha_i^\vee, \operatorname{wt}(b_j)).
\]
Then
\[ \text{wt}(b_N \otimes \cdots \otimes b_1) = \text{wt}(b_N) + \cdots + \text{wt}(b_1), \]
\[ \varepsilon_i(b_N \otimes \cdots \otimes b_1) = \max_{1 \leq k \leq N} \left( \sum_{j=1}^{k} \varepsilon_i(b_j) - \sum_{j=1}^{k-1} \varphi_i(b_j) \right) = \max_{1 \leq k \leq N} \left( \varepsilon_i(b_N) + \sum_{j=k}^{N-1} \left( \varphi_i(b_j) - \varepsilon_i(b_{j+1}) \right) \right) = \max_{1 \leq k \leq N} \left( \lambda_i + a_i(k) \right) \]
where \( \lambda_i = \langle \alpha_i^\vee, \text{wt}(b_N \otimes \cdots \otimes b_1) \rangle \). Then for \( k = 1, \ldots, N \) the action of the Kashiwara operators is determined as follows.

- If \( a_i(k) > a_i(j) \) for \( 1 \leq j < k \) and \( a_i(k) \geq a_i(j) \) for \( k < j \leq N \):
  \[ e_i(b_N \otimes \cdots \otimes b_1) = b_N \otimes \cdots \otimes e_i b_k \otimes \cdots \otimes b_1. \]
- If \( a_i(k) \geq a_i(j) \) for \( 1 \leq j < k \) and \( a_i(k) > a_i(j) \) for \( k < j \leq N \):
  \[ f_i(b_N \otimes \cdots \otimes b_1) = b_N \otimes \cdots \otimes f_i b_k \otimes \cdots \otimes b_1. \]

Note that this is just recursively applying the definition of the tensor product on two crystals. Recall that \( \langle \alpha_i^\vee, \text{wt}(b_j) \rangle = \varphi_i(b_j) - \varepsilon_i(b_j) \) by the definition of a crystal.

**Regular crystals**

Now if all crystals \( B_k \) are regular crystals, all \( \varepsilon_i \) and \( \varphi_i \) are non-negative and we can define tensor product by the *signature rule*. We start by writing a word in \( + \) and \( - \) as follows:

\[ \underbrace{\cdots}_{\varphi_i(b_N) \text{ times}} \underbrace{\cdots + \cdots + \cdots + \cdots +}_{\varepsilon_i(b_N) \text{ times}} \underbrace{\cdots}_{\varphi_i(b_2) \text{ times}} \underbrace{\cdots + \cdots + \cdots + \cdots +}_{\varepsilon_i(b_1) \text{ times}} \]

and then canceling ordered pairs of \( + - \) until the word is in the reduced form:

\[ \overbrace{\cdots }^{\varphi_i \text{ times}} \underbrace{\cdots + \cdots + \cdots + \cdots +}_{\varepsilon_i \text{ times}} \]

Here \( e_i \) acts on the factor corresponding to the leftmost \( + \) and \( f_i \) on the factor corresponding to the rightmost \( - \). If there is no \( + \) or \( - \) respectively, then the result is 0 (None).

**EXAMPLES:**

We construct the type \( A_2 \)-crystal generated by \( 2 \otimes 1 \otimes 1 \):

```python
sage: C = crystals.Letters(['A', 2])
sage: T = crystals.TensorProduct(C, C, C, generators=[[C(2), C(1), C(1)]])
```

```python
>>> from sage.all import *
>>> C = crystals.Letters(['A', Integer(2)])
>>> T = crystals.TensorProduct(C, C, C, generators=[[C(Integer(2)), C(Integer(1)),
                                 -C(Integer(1))]])]
```

It has 8 elements:
One can also check the Cartan type of the crystal:

```python
sage: T.cartan_type()
['A', 2]
```

Other examples include crystals of tableaux (which internally are represented as tensor products obtained by reading the tableaux columnwise):

```python
sage: C = crystals.Tableaux(['A',3], shape=[1,1,0])
sage: D = crystals.Tableaux(['A',3], shape=[1,0,0])
sage: T = crystals.TensorProduct(C,D, generators=[[C(rows=[1], [2]), D(rows=[1])], [C(rows=[2], [3]), D(rows=[1])]])
sage: T.cardinality()
24
sage: T.module_generators
([[1], [2]], [[1]])
```

If no module generators are specified, we obtain the full tensor product:

```python
sage: C = crystals.Letters(['A',2])
sage: T = crystals.TensorProduct(C,C)
sage: T.list()
[[1, 1], [1, 2], [1, 3], [2, 1], [2, 2], [2, 3], [3, 1], [3, 2], [3, 3]]
```

---

5.1. Comprehensive Module List
For a tensor product of crystals without module generators, the default implementation of `module_generators` contains all elements in the tensor product of the crystals. If there is a subset of elements in the tensor product that still generates the crystal, this needs to be implemented for the specific crystal separately:

```python
sage: T.module_generators.list()
[[1, 1], [1, 2], [1, 3], [2, 1], [2, 2], [2, 3], [3, 1], [3, 2], [3, 3]]
```

For classical highest weight crystals, it is also possible to list all highest weight elements:

```python
sage: C = crystals.Letters(['A',2])
sage: T = crystals.TensorProduct(C,C,C,generators=[[C(2),C(1),C(1)],[C(1),C(2),C(1)]]
```

Examples with non-regular and infinite crystals (these did not work before Issue #14402):

```python
sage: B = crystals.infinity.Tableaux(['D',10])
sage: T = crystals.TensorProduct(B,B)
sage: T
Full tensor product of the crystals
[The infinity crystal of tableaux of type ['D', 10],
The infinity crystal of tableaux of type ['D', 10]]
```

```python
sage: B = crystals.infinity.GeneralizedYoungWalls(15)
sage: T = crystals.TensorProduct(B,B)
sage: T
Full tensor product of the crystals
[Crystal of generalized Young walls of type ['A', 15, 1],
Crystal of generalized Young walls of type ['A', 15, 1],
Crystal of generalized Young walls of type ['A', 15, 1]]
```
Combinatorics, Release 10.4

(weights())
sage: B = crystals.GeneralizedYoungWalls(2, La[0] + La[1])
sage: C = crystals.GeneralizedYoungWalls(2, 2*La[2])
sage: D = crystals.GeneralizedYoungWalls(2, 3*La[0] + La[2])
sage: T = crystals.TensorProduct(B, C, D)
sage: T

Full tensor product of the crystals

(Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and...
Highest weight Lambda[0] + Lambda[1],
Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and...
Highest weight 2*Lambda[2],
Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and...
Highest weight 3*Lambda[0] + Lambda[2])

from sage.all import *
>>> B = crystals.infinity.Tableaux(['D', Integer(10)])
>>> T = crystals.TensorProduct(B, B)
>>> T

Full tensor product of the crystals

(The infinity crystal of tableaux of type ['D', 10],
The infinity crystal of tableaux of type ['D', 10])

>>> B = crystals.infinity.GeneralizedYoungWalls(Integer(15))
>>> T = crystals.TensorProduct(B, B, B)
>>> T

Full tensor product of the crystals

(Crystal of generalized Young walls of type ['A', 15, 1],
Crystal of generalized Young walls of type ['A', 15, 1],
Crystal of generalized Young walls of type ['A', 15, 1])

>>> La = RootSystem(['A', Integer(2), Integer(1)]).weight_lattice(extended=True).
fundamental_weights()
>>> B = crystals.GeneralizedYoungWalls(Integer(2), La[Integer(0)] + La[Integer(1)])
>>> C = crystals.GeneralizedYoungWalls(Integer(2), Integer(2)*La[Integer(2)])
>>> D = crystals.GeneralizedYoungWalls(Integer(2),
Integer(3)*La[Integer(0)] + La[Integer(2)])
>>> T = crystals.TensorProduct(B, C, D)
>>> T

Full tensor product of the crystals

(Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and...
Highest weight Lambda[0] + Lambda[1],
Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and...
Highest weight 2*Lambda[2],
Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and...
Highest weight 3*Lambda[0] + Lambda[2])

There is also a global option for setting the convention (by default Sage uses anti-Kashiwara):

sage: C = crystals.Letters(['A', 2])
sage: T = crystals.TensorProduct(C, C)
sage: elt = T(C(1), C(2)); elt
[1, 2]
sage: crystals.TensorProduct.options.convention = "Kashiwara"
sage: elt
[2, 1]
sage: crystals.TensorProduct.options._reset()
```python
>>> from sage.all import *
>>> C = crystals.Letters(['A',Integer(2)])
>>> T = crystals.TensorProduct(C,C)
>>> elt = T(C(Integer(1)), C(Integer(2))); elt
[1, 2]
>>> crystals.TensorProduct.options.convention = "Kashiwara"
>>> elt
[2, 1]
>>> crystals.TensorProduct.options._reset()
```

```python
defn = Current options for TensorProductOfCrystals - convention: antiKashiwara
class sage.combinat.crystals.tensor_product.TensorProductOfCrystalsWithGenerators(crystals, generators, cartan_type):
    Bases: TensorProductOfCrystals
    Tensor product of crystals with a generating set.
    
    Todo: Deprecate this class in favor of using subcrystal().

class sage.combinat.crystals.tensor_product.TensorProductOfRegularCrystalsWithGenerators(crystals, generators, cartan_type):
    Bases: TensorProductOfCrystalsWithGenerators
    Tensor product of regular crystals with a generating set.
    
class Element
        Bases: TensorProductOfRegularCrystalsElement
```

**5.1.68 Tensor Products of Crystal Elements**

**AUTHORS:**

- Anne Schilling, Nicolas Thiery (2007): Initial version
- Ben Salisbury, Travis Scrimshaw (2013): Refactored tensor products to handle non-regular crystals and created new subclass to take advantage of the regularity
- Travis Scrimshaw (2017): Cythonized element classes
- Franco Saliola (2017): Tensor products for crystal of super algebras
- Anne Schilling (2018): Tensor products for crystals of queer super algebras
class sage.combinat.crystals.tensor_product_element.CrystalOfBKKTableauxElement

    Bases: TensorProductOfSuperCrystalsElement

    Element class for the crystal of tableaux for Lie superalgebras of [BKK2000].

PP()

    Pretty print self.

    EXAMPLES:

    sage: C = crystals.Tableaux(['A', [1, 2]], shape=[1, 1])
    sage: c = C.an_element()
    sage: c.pp()
    -2
    -1

    >>> from sage.all import *
    >>> C = crystals.Tableaux(['A', [Integer(1), Integer(2)]], shape=[Integer(1), Integer(1)])
    >>> c = C.an_element()
    >>> c.pp()
    -2
    -1

to_tableau()

    Return the Tableau object corresponding to self.

    EXAMPLES:

    sage: C = crystals.Tableaux(['A', [1, 2]], shape=[1, 1])
    sage: c = C.an_element()
    sage: c.to_tableau()
    [[-2], [-1]]
    sage: type(c.to_tableau())
    <class 'sage.combinat.tableau.Tableaux_all_with_category.element_class'>
    sage: type(c)
    <class 'sage.combinat.crystals.bkk_crystals.CrystalOfBKKTableaux_with_category.element_class'>

    >>> from sage.all import *
    >>> C = crystals.Tableaux(['A', [Integer(1), Integer(2)]], shape=[Integer(1), Integer(1)])
    >>> c = C.an_element()
    >>> c.to_tableau()
    [[-2], [-1]]
    >>> type(c.to_tableau())
    <class 'sage.combinat.tableau.Tableaux_all_with_category.element_class'>
    >>> type(c)
    <class 'sage.combinat.crystals.bkk_crystals.CrystalOfBKKTableaux_with_category.element_class'>

class sage.combinat.crystals.tensor_product_element.CrystalOfTableauxElement

    Bases: TensorProductOfRegularCrystalsElement

    Element in a crystal of tableaux.
PP()

EXAMPLES:

```python
sage: T = crystals.Tableaux(['A',3], shape = [2,2])
sage: t = T(rows=[[1,2],[3,4]])
sage: t.pp()
 1 2
 3 4
```

```python
>>> from sage.all import *

>>> T = crystals.Tableaux(['A',Integer(3)], shape = [Integer(2),Integer(2)])
>>> t = T(rows=[[Integer(1),Integer(2)],[Integer(3),Integer(4)]])
>>> t.pp()
 1 2
 3 4
```

promotion()

Return the result of applying promotion on self.

Promotion for type A crystals of tableaux of rectangular shape. This method only makes sense in type A with rectangular shapes.

EXAMPLES:

```python
sage: C = crystals.Tableaux(['A',3], shape = [3,3,3])
sage: t = C(Tableau([[1,1,1],[2,2,3],[3,4,4]]))
sage: t
[[1, 1, 1], [2, 2, 3], [3, 4, 4]]
sage: t.promotion()
[[1, 1, 2], [2, 2, 3], [3, 4, 4]]
sage: t.promotion().parent()
The crystal of tableaux of type ['A', 3] and shape(s) [[3, 3, 3]]
```

```python
>>> from sage.all import *

>>> C = crystals.Tableaux(['A',Integer(3)], shape = [Integer(3),Integer(3), Integer(3)])
>>> t = C(Tableau([[Integer(1),Integer(1),Integer(1)],[Integer(2),Integer(2), Integer(3)],[Integer(3),Integer(4),Integer(4)]]))
>>> t
[[1, 1, 1], [2, 2, 3], [3, 4, 4]]
>>> t.promotion()
[[1, 1, 2], [2, 2, 3], [3, 4, 4]]
>>> t.promotion().parent()
The crystal of tableaux of type ['A', 3] and shape(s) [[3, 3, 3]]
```

promotion_inverse()

Return the result of applying inverse promotion on self.

Inverse promotion for type A crystals of tableaux of rectangular shape. This method only makes sense in type A with rectangular shapes.

EXAMPLES:

```python
sage: C = crystals.Tableaux(['A',3], shape = [3,3,3])
sage: t = C(Tableau([[1,1,1],[2,2,3],[3,4,4]]))
sage: t
[[1, 1, 1], [2, 2, 3], [3, 4, 4]]
```

(continues on next page)
Continued from previous page

```python
sage: t.promotion_inverse()
[[1, 1, 2], [2, 3, 3], [4, 4, 4]]
sage: t.promotion_inverse().parent()
The crystal of tableaux of type ['A', 3] and shape(s) [[3, 3, 3]]
```

```python
>>> from sage.all import *
>>> C = crystals.Tableaux(['A', Integer(3)], shape = [Integer(3), Integer(3),
--> Integer(3)])
>>> t = C([1, 1, 1], [2, 2, 3], [3, 4, 4])
>>> t
[[1, 1, 1], [2, 2, 3], [3, 4, 4]]
>>> t.promotion_inverse()
[[1, 1, 2], [2, 3, 3], [4, 4, 4]]
>>> t.promotion_inverse().parent()
The crystal of tableaux of type ['A', 3] and shape(s) [[3, 3, 3]]
```

**shape()**

Return the shape of the tableau corresponding to self.

**OUTPUT:** an instance of *Partition*

**See also:**

to_tableau()

**EXAMPLES:**

```python
sage: C = crystals.Tableaux(['A', 2], shape=[2, 1])
sage: x = C.an_element()
sage: x.to_tableau().shape()
[2, 1]
sage: x.shape()
[2, 1]
```

```python
>>> from sage.all import *
>>> C = crystals.Tableaux(['A', Integer(2)], shape=[Integer(2), Integer(1)])
>>> x = C.an_element()
>>> x.to_tableau().shape()
[2, 1]
>>> x.shape()
[2, 1]
```

**to_tableau()**

Return the Tableau object corresponding to self.

**EXAMPLES:**

```python
sage: T = crystals.Tableaux(['A', 3], shape = [2, 2])
sage: t = T(rows=[[1, 2], [3, 4]]).to_tableau(); t
[[1, 2], [3, 4]]
sage: type(t)
<class 'sage.combinat.tableau.Tableaux_all_with_category.element_class'>
sage: type(t[0][0])
<class 'int'>
sage: T = crystals.Tableaux(['D', 3], shape = [1, 1])
sage: t = T(rows=[[-3], [3]]).to_tableau(); t
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
[[[-3], [3]]
sage: t = T(rows=[[3], [-3]]).to_tableau(); t
[[3], [-3]]
sage: T = crystals.Tableaux(['B', 2], shape=[1, 1])
sage: t = T(rows=[[0], [0]]).to_tableau(); t
[[0], [0]]
```

```python
>>> from sage.all import *
>>> T = crystals.Tableaux(['A', Integer(3)], shape=[Integer(2), Integer(2)])
>>> t = T(rows=[[Integer(1), Integer(2), Integer(3), Integer(4)]]).to_tableau(); t
[[1, 2], [3, 4]]
>>> type(t)
<class 'sage.combinat.tableau.Tableaux_all_with_category.element_class'>
>>> type(t[Integer(0)][Integer(0)])
<class 'int'>
>>> T = crystals.Tableaux(['D', Integer(3)], shape=[Integer(1), Integer(1)])
>>> t = T(rows=[[Integer(3), Integer(4), Integer(5), Integer(6)]]).to_tableau(); t
[[3], [-3]]
```

```python
class sage.combinat.crystals.tensor_product_element.ImmutableListWithParent
Bases: ClonableArray

A class for lists having a parent

Specification: any subclass C should implement __init__ which accepts the following form C(parent, list=list)
```

```python
class sage.combinat.crystals.tensor_product_element.InfinityCrystalOfTableauxElement
Bases: CrystalOfTableauxElement

• (i)
  Return the action of \( \tilde{e}_i \) on self.

INPUT:
  • i – an element of the index set

EXAMPLES:
```
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *

>>> B = crystals.infinity.Tableaux(['B',Integer(3)])

>>> b = B(rows=[
    [Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),
    -Integer(1),Integer(1),Integer(2),Integer(0),-Integer(3),
    -Integer(1),-Integer(1),-Integer(1)],
    [Integer(2),Integer(2),Integer(2),
    -Integer(2),-Integer(2)],
    [Integer(3),-Integer(3),-Integer(3)]])

>>> b.e(Integer(3)).pp()
1 1 1 1 1 1 2 0 -3 -1 -1 -1 -1
2 2 2 2 -2 -2
3 0 -3

>>> b.e(Integer(1)).pp()
1 1 1 1 1 1 1 0 -3 -1 -1 -1 -1
2 2 2 2 -2 -2
3 -3 -3
```

\( f(i) \)

Return the action of \( \tilde{f}_i \) on \self\.

**INPUT:**

- \( i \) – an element of the index set

**EXAMPLES:**

```python
sage: B = crystals.infinity.Tableaux(['C',4])
sage: b = B.highest_weight_vector()
sage: b.f(1).pp()
1 1 1 1
2 2 2
3 3
4

sage: b.f(3).pp()
1 1 1 1
2 2 2 2
3 3 4
4

sage: b.f(3).f(4).pp()
1 1 1 1
2 2 2 2
3 3 -4
4
```

```python
>>> from sage.all import *

>>> B = crystals.infinity.Tableaux(['C',Integer(4)])

>>> b = B.highest_weight_vector()

>>> b.f(Integer(1)).pp()
1 1 1 1
2 2 2
3 3
4

>>> b.f(Integer(3)).pp()
1 1 1 1
2 2 2 2
3 3 4
4

>>> b.f(Integer(3)).f(Integer(4)).pp()
1 1 1 1
2 2 2
3 -3 -3
```

(continues on next page)
class sage.combinat.crystals.tensor_product_element.
InfinityCrystalOfTableauxElementTypeD

    Bases: InfinityCrystalOfTableauxElement

    e(i)
    
    Return the action of $\tilde{e}_i$ on self.
    
    INPUT:
    
    • i – an element of the index set
    
    EXAMPLES:

    sage: B = crystals.infinity.Tableaux(['D',4])
    sage: b = B.highest_weight_vector().f_string([1,4,3,1,2]); b.pp()
    1 1 1 2 3
    2 2 2
    3 -3
    sage: b.e(2).pp()
    1 1 1 2 2
    2 2 2
    3 -3

>>> from sage.all import *
>>> B = crystals.infinity.Tableaux(['D',Integer(4)])
>>> b = B.highest_weight_vector().f_string([Integer(1),Integer(4),Integer(3),
→Integer(1),Integer(2)]); b.pp()
1 1 1 2 3
2 2 2
3 -3
>>> b.e(Integer(2)).pp()
1 1 1 2 2
2 2 2
3 -3

f(i)
    
    Return the action of $\tilde{f}_i$ on self.
    
    INPUT:
    
    • i – an element of the index set
    
    EXAMPLES:

    sage: B = crystals.infinity.Tableaux(['D',5])
    sage: b = B.highest_weight_vector().f_string([1,4,3,1,5]); b.pp()
    1 1 1 1 1 2 2
    2 2 2 2 2
    3 3 3 -5
    4 5
    sage: b.f(1).pp()
    1 1 1 1 1 1 2 2
    2 2 2 2 2
    3 3 3 -5

(continues on next page)
5.1. Comprehensive Module List

```python
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux(['D', Integer(5)])
>>> b = B.highest_weight_vector().f_string([Integer(1), Integer(4), Integer(3), Integer(1), Integer(5)]); b.pp()
1 1 1 1 1 1 2 2
2 2 2 2 2
3 3 3 -5
4 5
>>> b.f(Integer(1)).pp()
1 1 1 1 1 1 2 2 2
2 2 2 2 2
3 3 3 -5
4 5
>>> b.f(Integer(5)).pp()
1 1 1 1 1 1 2 2
2 2 2 2 2
3 3 3 -5
4 -4
```

class sage.combinat.crystals.tensor_product_element.
InfinityQueerCrystalOfTableauxElement

Bases: TensorProductOfQueerSuperCrystalsElement

Initialize self.

EXAMPLES:

```python
sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([[4,4,4,4,2,1],[3,3,3],[2,2],[1]])
sage: t
[[4, 4, 4, 4, 2, 1], [3, 3, 3], [2, 2], [1]]
sage: TestSuite(t).run()
```

```python
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux(['Q',Integer(4)])
>>> t = B([[Integer(4), Integer(4), Integer(4), Integer(4), Integer(2), Integer(1)],
    [Integer(3), Integer(3), Integer(3)], [Integer(2), Integer(2)], [Integer(1)]])
>>> t
[[4, 4, 4, 4, 2, 1], [3, 3, 3], [2, 2], [1]]
>>> TestSuite(t).run()
```

\( e(i) \)

Return the action of \( e_i \) on \( \text{self} \).

INPUT:

- \( i \) – an element of the index set

EXAMPLES:
sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([[4,4,4,4,4,2,1],[3,3,3,3],[2,2,1],[1]])
sage: t.e(1)
[[4, 4, 4, 4, 4, 2, 1], [3, 3, 3, 3], [2, 2, 1], [1]]
sage: t.e(3)
[[4, 4, 4, 4, 4, 3, 2, 1], [3, 3, 3, 3], [2, 2, 1], [1]]
sage: t.e(-1)

>>> from sage.all import *
>>>
>>> B = crystals.infinity.Tableaux(['Q','Integer(4)'])
>>> t = B([[Integer(4),Integer(4),Integer(4),Integer(4),Integer(4),Integer(2),
         -Integer(1)], [Integer(3),Integer(3),Integer(3),Integer(3),Integer(3)], [Integer(2),
         -Integer(2),Integer(1)], [Integer(1)]])
>>> t.e(Integer(1))
[[4, 4, 4, 4, 4, 4, 2, 1], [3, 3, 3, 3], [2, 2, 1], [1]]
>>> t.e(Integer(3))
[[4, 4, 4, 4, 4, 3, 2, 1], [3, 3, 3, 3], [2, 2, 1], [1]]
>>> t.e(-Integer(1))

epsilon(i)

Return \( \epsilon_i \) of self.

INPUT:

* i – an element of the index set

EXAMPLES:

sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([[4,4,4,4,4,2,1],[3,3,3,3],[2,2,1],[1]])
sage: [t.epsilon(i) for i in B.index_set()]
[-1, 1, -2, 0]

>>> from sage.all import *
>>> B = crystals.infinity.Tableaux(['Q','Integer(4)'])
>>> t = B([[Integer(4),Integer(4),Integer(4),Integer(4),Integer(4),Integer(2),
         -Integer(1)], [Integer(3),Integer(3),Integer(3),Integer(3),Integer(3)], [Integer(2),
         -Integer(2),Integer(1)], [Integer(1)]])
>>> [t.epsilon(i) for i in B.index_set()]
[-1, 1, -2, 0]

f(i)

Return the action of \( f_i \) on self.

INPUT:

* i – an element of the index set

EXAMPLES:

sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([[4,4,4,4,4,2,1],[3,3,3,3],[2,2,1],[1]])
sage: t.f(1)
[[4, 4, 4, 4, 4, 2, 2], [3, 3, 3, 3], [2, 2, 1], [1]]
sage: t.f(3)
sage: t.f(-1)
[[4, 4, 4, 4, 4, 2, 2], [3, 3, 3, 3], [2, 2, 1], [1]]
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux(['Q',Integer(4)])
>>> t = B([[Integer(4),Integer(4),Integer(4),Integer(4),Integer(4),Integer(2),
       Integer(1)],[Integer(3),Integer(3),Integer(3),Integer(3),Integer(3),Integer(3)],
       [Integer(2),Integer(1)],[Integer(1)])
>>> t.f(Integer(1))
[[4, 4, 4, 4, 4, 2, 2], [3, 3, 3, 3], [2, 2, 1], [1]]
>>> t.f(Integer(3))
>>> t.f(-Integer(1))
[[4, 4, 4, 4, 4, 2, 2], [3, 3, 3, 3], [2, 2, 1], [1]]

rows()

Return the list of rows of self.

EXAMPLES:

sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([[4,4,4,4,4,2,1],[3,3,3,3],[2,2,1],[1]])
sage: t.rows()
[[1, 2, 4, 4, 4, 4, 4], [3, 3, 3, 3], [1, 2, 2], [1]]

weight()

Return the weight of self.

EXAMPLES:

sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([[4,4,4,4,4,2,1],[3,3,3,3],[2,2,1],[1]])
sage: t.weight()
(4, 2, 2, 0)

class

sage.combinat.crystals.tensor_product_element.TensorProductOfCrystalsElement

Bases: ImmutableListWithParent

A class for elements of tensor products of crystals.

e(i)

Return the action of eᵢ on self.

INPUT:
• \(i\) – an element of the index set

EXAMPLES:

```python
sage: B = crystals.infinity.Tableaux("D4")
sage: T = crystals.TensorProduct(B,B)
sage: b1 = B.highest_weight_vector().f_string([1, 4, 3])
sage: b2 = B.highest_weight_vector().f_string([2, 3, 1, 4])
sage: t = T(b2, b1)
sage: t.e(1)
[[[1, 1, 1, 1, 1], [2, 2, 3, -3], [3]], [[1, 1, 1, 1, 2], [2, 2, 2], [3, -3]]]
sage: t.e(2)
sage: t.e(3)
[[[1, 1, 1, 1, 2], [2, 2, 3, -4], [3]], [[1, 1, 1, 1, 2], [2, 2, 2], [3, -3]]]
sage: t.e(4)
[[[1, 1, 1, 1, 2], [2, 2, 3, 4], [3]], [[1, 1, 1, 1, 2], [2, 2, 2], [3, -3]]]
```

```python
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux("D4")
>>> T = crystals.TensorProduct(B,B)
>>> b1 = B.highest_weight_vector().f(2)
>>> b2 = B.highest_weight_vector().f_string([2, 2, 1])
>>> t = T(b2, b1)
>>> for i in B.index_set():
...     print(t.epsilon(i))
[0, 3]
```

epsilon\((i)\)

Return \(\epsilon_i\) of self.

INPUT:

• \(i\) – an element of the index set

EXAMPLES:

```python
sage: B = crystals.infinity.Tableaux("G2")
sage: T = crystals.TensorProduct(B,B)
sage: b1 = B.highest_weight_vector().f(2)
sage: b2 = B.highest_weight_vector().f_string([2, 2, 1])
sage: t = T(b2, b1)
sage: [t.epsilon(i) for i in B.index_set()]
[0, 3]
```

```python
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux("G2")
>>> T = crystals.TensorProduct(B,B)
>>> b1 = B.highest_weight_vector().f(Integer(2))
```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> b2 = B.highest_weight_vector().f_string([Integer(2), Integer(2),
                                            Integer(1)])
>>> t = T(b2, b1)
>>> [t.epsilon(i) for i in B.index_set()]
[0, 3]
```

\( f(i) \)

Return the action of \( f_i \) on \( \text{self} \).

INPUT:

- \( i \) – an element of the index set

EXAMPLES:

```python
sage: La = RootSystem(['A', 3, 1]).weight_lattice(extended=True).fundamental_weights()
sage: B = crystals.GeneralizedYoungWalls(3, La[0])
sage: T = crystals.TensorProduct(B, B, B)
sage: b1 = B.highest_weight_vector().f_string([0, 3])
sage: b2 = B.highest_weight_vector().f_string([0])
sage: b3 = B.highest_weight_vector()
sage: t = T(b3, b2, b1)
sage: t.f(0)
[[[0]], [[0]], [[0, 3]]]
sage: t.f(1)
[[], [[0]], [[0, 3], [1]]]
sage: t.f(2)
[[], [[0]], [[0, 3, 1]]]
sage: t.f(3)
[[], [[0, 3]], [[0, 3]]]
```

```python
>>> from sage.all import *
```

```python
>>> La = RootSystem(['A', Integer(3), Integer(1)]).weight_lattice(extended=True).fundamental_weights()
>>> B = crystals.GeneralizedYoungWalls(Integer(3), La[Integer(0)])
>>> T = crystals.TensorProduct(B, B, B)
>>> b1 = B.highest_weight_vector().f_string([Integer(0), Integer(3)])
>>> b2 = B.highest_weight_vector().f_string([Integer(0)])
>>> b3 = B.highest_weight_vector()
>>> t = T(b3, b2, b1)
>>> t.f(Integer(0))
[[[0]], [[0]], [[0, 3]]]
>>> t.f(Integer(1))
[[], [[0]], [[0, 3], [1]]]
>>> t.f(Integer(2))
[[], [[0]], [[0, 3, 1]]]
>>> t.f(Integer(3))
[[], [[0, 3]], [[0, 3]]]
```

\( \phi(i) \)

Return \( \phi_i \) of \( \text{self} \).

INPUT:

- \( i \) – an element of the index set

EXAMPLES:
sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: B = crystals.GeneralizedYoungWalls(2,La[0]+La[1])
sage: T = crystals.TensorProduct(B,B)
sage: b1 = B.highest_weight_vector().f_string([1,0])
sage: b2 = B.highest_weight_vector().f_string([0,1])
sage: t = T(b2, b1)
sage: [t.phi(i) for i in B.index_set()]
[1, 1, 4]

from sage.all import *

La = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice(extended=True).fundamental_weights()
B = crystals.GeneralizedYoungWalls(Integer(2),La[Integer(0)]+La[Integer(1)])
T = crystals.TensorProduct(B,B)
b1 = B.highest_weight_vector().f_string([Integer(1),Integer(0)])
b2 = B.highest_weight_vector().f_string([Integer(0),Integer(1)])
t = T(b2, b1)
[t.phi(i) for i in B.index_set()]
[1, 1, 4]

pp()

Pretty print self.

EXAMPLES:

sage: C = crystals.Tableaux(['A',3], shape=[3,1])
sage: D = crystals.Tableaux(['A',3], shape=[1])
sage: E = crystals.Tableaux(['A',3], shape=[2,2,2])
sage: T = crystals.TensorProduct(C,D,E)
sage: T.module_generators[0].pp()
 1 1 1 (X) 1 (X) 1 1
 2 2 2
 3 3

from sage.all import *

C = crystals.Tableaux(['A',3], shape=[3,1])
D = crystals.Tableaux(['A',3], shape=[1])
E = crystals.Tableaux(['A',3], shape=[2,2,2])
T = crystals.TensorProduct(C,D,E)
T.module_generators[Integer(0)].pp()
 1 1 1 (X) 1 (X) 1 1
 2 2 2
 3 3

weight()

Return the weight of self.

EXAMPLES:

sage: B = crystals.infinity.Tableaux("A3")
sage: T = crystals.TensorProduct(B,B)
sage: b1 = B.highest_weight_vector().f_string([2,1,3])
sage: b2 = B.highest_weight_vector().f(1)
sage: t = T(b2, b1)
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: t
[[[1, 1, 1, 2], [2, 2], [3]], [[1, 1, 1, 1, 2], [2, 2, 4], [3]]]
sage: t.weight()
(-2, 1, 0, 1)
```

```python
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux("A3")
>>> T = crystals.TensorProduct(B,B)
>>> b1 = B.highest_weight_vector().f_string([Integer(2),Integer(1), Integer(3)])
>>> b2 = B.highest_weight_vector().f(Integer(1))
>>> t = T(b2, b1)
```

```python
t
[[[1, 1, 1, 2], [2, 2], [3]], [[1, 1, 1, 1, 2], [2, 2, 4], [3]]
>>> t.weight()
(-2, 1, 0, 1)
```

```python
sage: C = crystals.Letters(['A',3])
sage: T = crystals.TensorProduct(C,C)
sage: T(C(1),C(2)).weight()
(1, 1, 0, 0)
sage: T = crystals.Tableaux(['D',4],shape=[])  
sage: T.list()[0].weight()
(0, 0, 0, 0)
```

```python
>>> from sage.all import *
>>> C = crystals.Letters(['A',Integer(3)])
>>> T = crystals.TensorProduct(C,C)
>>> T(C(Integer(1)),C(Integer(2))).weight()
(1, 1, 0, 0)
>>> T = crystals.Tableaux(['D',Integer(4)],shape=[])  
>>> T.list()[Integer(0)].weight()
(0, 0, 0, 0)
```

**class** `sage.combinat.crystals.tensor_product_element.TensorProductOfQueerSuperCrystalsElement`  

**Bases:** `TensorProductOfRegularCrystalsElement`  

Element class for a tensor product of crystals for queer Lie superalgebras.  

This implements the tensor product rule for crystals of Grantcharov et al. [GJK+2014]. Given crystals $B_1$ and $B_2$ of type $q_{n+1}$, we define the tensor product $b_1 \otimes b_2 \in B_1 \otimes B_2$, where $b_1 \in B_1$ and $b_2 \in B_2$, as the following:

In addition to the tensor product rule for type $A_n$, the tensor product rule for $e_{-1}$ and $f_{-1}$ on $b_1 \otimes b_2$ are given by

$$e_{-1}(b_1 \otimes b_2) = \begin{cases} 
    b_1 \otimes e_{-1} b_2 & \text{if } \text{wt}(b_1)_1 = \text{wt}(b_1)_2 = 0, \\
    e_{-1} b_1 \otimes b_2 & \text{otherwise},
\end{cases}$$

$$f_{-1}(b_1 \otimes b_2) = \begin{cases} 
    b_1 \otimes f_{-1} b_2 & \text{if } \text{wt}(b_1)_1 = \text{wt}(b_1)_2 = 0, \\
    f_{-1} b_1 \otimes b_2 & \text{otherwise}.
\end{cases}$$

For $1 < i \leq n$, the operators $e_{-i}$ and $f_{-i}$ are defined as

$$e_{-i} = s_{w_i}^{-1} e_{-1} s_{w_i}, \quad f_{-i} = s_{w_i}^{-1} f_{-1} s_{w_i}.$$  

5.1. Comprehensive Module List
Here, \(w_i = s_2 \cdots s_is_{i-1}\) and \(s_i\) is the reflection along the \(i\)-string in the crystal. Moreover, for \(1 < i \leq n\), we define the operators \(e_{-i'}\) and \(f_{-i'}\) as

\[
e_{-i'} = s_{w_0}f_{-(n+1-i)}s_{w_0}, \quad f_{-i'} = s_{w_0}e_{-(n+1-i)}s_{w_0},
\]

where \(w_0\) is the longest element in the symmetric group \(S_{n+1}\) generated by \(s_1, \ldots, s_n\). In this implementation, we use the integers \(-2n, \ldots, -(n+1)\) to respectively denote the indices \(-n', \ldots, -1'\).

e(i)

Return \(e_i\) on self.

**EXAMPLES:**

```python
sage: Q = crystals.Letters(['Q', 3])
sage: T = tensor([Q, Q])
sage: t = T(Q(1), Q(1))
sage: t.e(-1)
sage: t = T(Q(2), Q(1))
sage: t.e(-1)
[1, 1]

sage: T = tensor([Q, Q, Q])
sage: t = T(Q(1), Q(3), Q(2), Q(1))
sage: t.e(-2)
[2, 2, 1, 1]
```

\(\epsilon(i)\)

Return \(\epsilon_i\) on self.

**EXAMPLES:**

```python
>>> from sage.all import *

\[\text{sage: Q = crystals.Letters(['Q', Integer(3)])}\]
\[\text{sage: T = tensor([Q, Q, Q, Q])}\]
\[\text{sage: t = T(Q(Integer(1)), Q(Integer(3)), Q(Integer(2)), Q(Integer(1)))}\]
\[\text{sage: t.epsilon(-Integer(2))}\]
\[1\]
```

892 Chapter 5. Comprehensive Module List
\( f(i) \)

Return \( f_i \) on self.

EXAMPLES:

```python
 sage: Q = crystals.Letters(['Q', 3])
sage: T = tensor([Q, Q])
sage: t = T(Q(1), Q(1))
sage: t.f(-1)
[2, 1]
```

>>> from sage.all import *

```python
 sage: Q = crystals.Letters(['Q', Integer(3)])
sage: T = tensor([Q, Q])
sage: t = T(Q(Integer(1)), Q(Integer(1)))
sage: t.f(-Integer(1))
[2, 1]
```

\( \phi(i) \)

Return \( \phi_i \) on self.

EXAMPLES:

```python
 sage: Q = crystals.Letters(['Q', 3])
sage: T = tensor([Q, Q, Q, Q])
sage: t = T(Q(1), Q(3), Q(2), Q(1))
sage: t.phi(-2)
0
 sage: t.phi(-1)
1
```

```python
 sage: Q = crystals.Letters(['Q', Integer(3)])
sage: T = tensor([Q, Q, Q, Q])
sage: t = T(Q(Integer(1)), Q(Integer(3)), Q(Integer(2)), Q(Integer(1)))
sage: t.phi(-Integer(2))
0
 sage: t.phi(-Integer(1))
1
```

class sage.combinat.crystals.tensor_product_element.TensorProductOfRegularCrystalsElement

Bases: TensorProductOfCrystalsElement

Element class for a tensor product of regular crystals.

\( e(i) \)

Return the action of \( e_i \) on self.

EXAMPLES:

```python
 sage: C = crystals.Letters(['A', 5])
sage: T = crystals.TensorProduct(C, C)
sage: T(C(1), C(2)).e(1) == T(C(1), C(1))
True
 sage: T(C(2), C(1)).e(1) is None
True
```

(continues on next page)
Combinatorics, Release 10.4

>>> from sage.all import *
>>> C = crystals.Letters(['A',Integer(5)])
>>> T = crystals.TensorProduct(C,C)
>>> T(C(Integer(1)),C(Integer(1))).epsilon(Integer(1))
0
>>> T(C(Integer(1)),C(Integer(2))).epsilon(Integer(1))
1
>>> T(C(Integer(2)),C(Integer(1))).epsilon(Integer(1))
0

epsilone(i)

Return $\varepsilon_i$ of self.

EXAMPLES:

```python
sage: C = crystals.Letters(['A',5])
sage: T = crystals.TensorProduct(C,C)
sage: T(C(1),C(1)).epsilon(1)
0
sage: T(C(1),C(2)).epsilon(1)
1
sage: T(C(2),C(1)).epsilon(1)
0
```

f (i)

Return the action of $f_i$ on self.

EXAMPLES:

```python
sage: C = crystals.Letters(['A',5])
sage: T = crystals.TensorProduct(C,C)
sage: T(C(1),C(1)).f(1)
[1, 2]
sage: T(C(1),C(2)).f(1)
[2, 2]
sage: T(C(2),C(1)).f(1) is None
True
```

(continues on previous page)
phi (i)

Return $\varphi_i$ of self.

EXAMPLES:

```sage
c = crystals.Letters(['A',5])
t = crystals.TensorProduct(c,c)
t(c(1),c(1)).phi(1)
2
t(c(1),c(2)).phi(1)
1
t(c(2),c(1)).phi(1)
0
```

position_of_first_unmatched_plus (i)

Return the position of the first unmatched $+$ or None if there is no unmatched $+$.  

EXAMPLES:

```sage
c = crystals.Letters(['A',5])
t = crystals.TensorProduct(c,c)
t(c(2),c(1)).position_of_first_unmatched_plus(1)
1
t(c(1),c(2)).position_of_first_unmatched_plus(1)
```

```sage
c = crystals.Letters(['A',Integer(5)])
t = crystals.TensorProduct(c,c)
t(c(2),c(1)).position_of_first_unmatched_plus(1)
1
t(c(1),c(2)).position_of_first_unmatched_plus(1)
```

position_of_last_unmatched_minus (i)

Return the position of the last unmatched $-$ or None if there is no unmatched $-$.  

EXAMPLES:
sage: C = crystals.Letters(['A',5])
sage: T = crystals.TensorProduct(C,C)
sage: T(C(2),C(1)).position_of_last_unmatched_minus(1)
0
sage: T(C(1),C(2)).position_of_last_unmatched_minus(1)
0

>>> from sage.all import *
>>> C = crystals.Letters(['A',Integer(5)])
>>> T = crystals.TensorProduct(C,C)
>>> T(C(Integer(2)),C(Integer(1))).position_of_last_unmatched_minus(Integer(1))
0
>>> T(C(Integer(1)),C(Integer(2))).position_of_last_unmatched_minus(Integer(1))
0

positions_of_unmatched_minus \(i\), dual=False, reverse=False

EXAMPLES:

sage: C = crystals.Letters(['A',5])
sage: T = crystals.TensorProduct(C,C)
sage: T(C(2),C(1)).positions_of_unmatched_minus(1)
[]
sage: T(C(1),C(2)).positions_of_unmatched_minus(1)
[0]

>>> from sage.all import *
>>> C = crystals.Letters(['A',Integer(5)])
>>> T = crystals.TensorProduct(C,C)
>>> T(C(Integer(2)),C(Integer(1))).positions_of_unmatched_minus(Integer(1))
[]
>>> T(C(Integer(1)),C(Integer(2))).positions_of_unmatched_minus(Integer(1))
[0]

positions_of_unmatched_plus \(i\)

EXAMPLES:

sage: C = crystals.Letters(['A',5])
sage: T = crystals.TensorProduct(C,C)
sage: T(C(2),C(1)).positions_of_unmatched_plus(1)
[]
sage: T(C(1),C(2)).positions_of_unmatched_plus(1)
[1]

>>> from sage.all import *
>>> C = crystals.Letters(['A',Integer(5)])
>>> T = crystals.TensorProduct(C,C)
>>> T(C(Integer(2)),C(Integer(1))).positions_of_unmatched_plus(Integer(1))
[]
>>> T(C(Integer(1)),C(Integer(2))).positions_of_unmatched_plus(Integer(1))
[1]

class sage.combinat.crystals.tensor_product_element.TensorProductOfSuperCrystalsElement

Bases: TensorProductOfRegularCrystalsElement

Element class for a tensor product of crystals for Lie superalgebras.
This implements the tensor product rule for crystals of Lie superalgebras of [BKK2000].

\( e(i) \)
Return \( e_i \) on self.

**EXAMPLES:**

```python
sage: C = crystals.Letters(['A', [2, 1]])
sage: T = tensor([C,C])
sage: t = T(C(1),C(1))
sage: t.e(0)
[-1, 1]
```

```python
>>> from sage.all import *

>>> C = crystals.Letters(['A', [Integer(2), Integer(1)]]))
>>> T = tensor([C,C])
>>> t = T(C(Integer(1)),C(Integer(1)))
>>> t.e(Integer(0))
[-1, 1]
```

\( \epsilon(i) \)
Return \( \epsilon_i \) on self.

**EXAMPLES:**

```python
sage: C = crystals.Letters(['A', [2, 1]])
sage: T = tensor([C,C])
sage: t = T(C(1),C(1))
sage: t.epsilon(0)
1
```

```python
>>> from sage.all import *

>>> C = crystals.Letters(['A', [Integer(2), Integer(1)]]))
>>> T = tensor([C,C])
>>> t = T(C(Integer(1)),C(Integer(1)))
>>> t.epsilon(Integer(0))
1
```

\( f(i) \)
Return \( f_i \) on self.

**EXAMPLES:**

```python
sage: C = crystals.Letters(['A', [2, 1]])
sage: T = tensor([C,C])
sage: t = T(C(1),C(1))
sage: t.f(0)
sage: t.f(1)
[1, 2]
```

```python
>>> from sage.all import *

>>> C = crystals.Letters(['A', [Integer(2), Integer(1)]]))
>>> T = tensor([C,C])
>>> t = T(C(Integer(1)),C(Integer(1)))
>>> t.f(Integer(0))
>>> t.f(Integer(1))
[1, 2]
```
\phi(i)

Return \varphi, on self.

**EXAMPLES:**

```python
sage: C = crystals.Letters(['A', [2, 1]])
sage: T = tensor([C,C])
sage: t = T(C(1),C(1))
sage: t.phi(0)
0
```

```python
>>> from sage.all import *
>>> C = crystals.Letters(['A', [Integer(2), Integer(1)]]
>>> T = tensor([C,C])
>>> t = T(C(Integer(1)),C(Integer(1)))
>>> t.phi(Integer(0))
0
```

### 5.1.69 Cyclic sieving phenomenon

Implementation of the Cyclic Sieving Phenomenon as described by Reiner, Stanton, and White in [RSW2004].

We define the `CyclicSievingPolynomial()` of a finite set \( S \) together with cyclic action `cyc_act` (of order \( n \)) to be the unique polynomial \( P(q) \) of order \( < n \) such that the triple \( (S, \text{cyc_act}, P(q)) \) exhibits the cyclic sieving phenomenon.

**AUTHORS:**

- Christian Stump

**REFERENCES:**

`sage.combinat.cyclic_sieving_phenomenon.CyclicSievingCheck(L, cyc_act, f, order=None)`

Return whether the triple \( (L, \text{cyc_act}, f) \) exhibits the cyclic sieving phenomenon.

If `cyc_act` is `None`, \( L \) is expected to contain the orbit lengths.

**INPUT:**

- `L` - if `cyc_act` is `None`: list of orbit sizes, otherwise list of objects
- `cyc_act` - (default:`None`) bijective function from \( L \) to \( L \)
- `order` - (default:`None`) if set to an integer, this cyclic order of `cyc_act` is used (must be an integer multiple of the order of `cyc_act`) otherwise, the order of `cyc_action` is used

**EXAMPLES:**

```python
sage: from sage.combinat.cyclic_sieving_phenomenon import *

sage: S42 = Subsets([1,2,3,4], 2)

sage: def cyc_act(S):
        return Set(i.mod(4) + 1 for i in S)

sage: cyc_act([1,3])
{2, 4}

sage: cyc_act([1,4])
{1, 2}

sage: p = q_binomial(4,2); p
q^4 + q^3 + 2*q^2 + q + 1
```

(continues on next page)
The `CyclicSievingPolynomial` function in SageMath is used to determine if a given action exhibits the cyclic sieving phenomenon. The function takes a list of objects or orbit sizes and a bijective function from this list to itself. It returns the unique polynomial of degree smaller than a specified order such that the triple (L, cyc_act, p) exhibits the Cyclic Sieving Phenomenon.

**INPUT:**
- L – if cyc_act is None: list of orbit sizes, otherwise list of objects
- cyc_act – (default=None) bijective function from L to L
- order – (default=None) if set to an integer, this cyclic order of cyc_act is used (must be an integer multiple of the order of cyc_act) otherwise, the order of cyc_act is used
- get_order – (default=False) if True, a tuple [p, n] is returned where p is as above, and n is the order

**EXAMPLES:**

```python
sage: from sage.combinat.cyclic_sieving_phenomenon import CyclicSievingPolynomial
sage: S42 = Subsets([1,2,3,4], 2)
sage: def cyc_act(S): return Set(i.mod(4) + 1 for i in S)
sage: cyc_act([1,3])
{2, 4}
sage: cyc_act([1,4])
{1, 2}
sage: CyclicSievingPolynomial(S42, cyc_act)
q^3 + 2*q^2 + q + 2
sage: CyclicSievingPolynomial(S42, cyc_act, get_order=True)
[q^3 + 2*q^2 + q + 2, 4]
sage: CyclicSievingPolynomial(S42, cyc_act, order=8)
q^6 + 2*q^4 + q^2 + 2
sage: CyclicSievingPolynomial([4,2])
q^3 + 2*q^2 + q + 2
```
```python
>>> from sage.all import *
>>> from sage.combinat.cyclic_sieving_phenomenon import CyclicSievingPolynomial

```sage.combinat.cyclic_sieving_phenomenon.orbit_decomposition\((L, \text{cyc\_act})\)

Return the orbit decomposition of \(L\) by the action of \text{cyc\_act}.

**INPUT:**

- \(L\) – list
- \text{cyc\_act} – bijective function from \(L\) to \(L\)

**OUTPUT:**

- a list of lists, the orbits under the \text{cyc\_act} acting on \(L\)

**EXAMPLES:**

```python
>>> from sage.combinat.cyclic_sieving_phenomenon import *

```sage: S42 = Subsets([1, 2, 3, 4], 2); S42
Subsets of {1, 2, 3, 4} of size 2
```sage: def cyc_act(S):
    return Set(i.mod(4) + 1 for i in S)
```sage: cyc_act([1, 3])
\{2, 4\}
```sage: cyc_act([1, 4])
\{1, 2\}
```sage: orbits = orbit_decomposition(S42, cyc_act)
```sage: sorted([sorted(orb, key=sorted) for orb in orbits], key=len)
[[\{1, 3\}, \{2, 4\}], [[\{1, 2\}, \{1, 4\}, \{2, 3\}, \{3, 4\}]]
```
5.1.70 De Bruijn sequences

A De Bruijn sequence is defined as the shortest cyclic sequence that incorporates all substrings of a certain length of an alphabet.

For instance, the $2^3 = 8$ binary strings of length 3 are all included in the following string:

```python
sage: DeBruijnSequences(2,3).an_element()
[0, 0, 0, 1, 0, 1, 1, 1]
```

They can be obtained as a subsequence of the cyclic De Bruijn sequence of parameters $k = 2$ and $n = 3$:

```python
sage: seq = DeBruijnSequences(2,3).an_element()
sage: print(Word(seq).string_rep())
00010111
```

This sequence is of length $k^n$, which is best possible as it is the number of $k$-ary strings of length $n$. One can equivalently define a De Bruijn sequence of parameters $k$ and $n$ as a cyclic sequence of length $k^n$ in which all substring of length $n$ are different.

See also Wikipedia article De_Bruijn_sequence.

AUTHOR:
- Eviatar Bach (2011): initial version
• Nathann Cohen (2011): Some work on the documentation and defined the `__contain__` method

```python
class sage.combinat.debruijn_sequence.DeBruijnSequences(k, n):
    Bases: UniqueRepresentation, Parent
    
    Represents the De Bruijn sequences of given parameters $k$ and $n$.
    
    A De Bruijn sequence of parameters $k$ and $n$ is defined as the shortest cyclic sequence that incorporates all substrings of length $n$ a $k$-ary alphabet.
    
    This class can be used to generate the lexicographically smallest De Bruijn sequence, to count the number of existing De Bruijn sequences or to test whether a given sequence is De Bruijn.
    
    INPUT:
    
    • $k$ – A natural number to define arity. The letters used are the integers $0..k - 1$.
    
    • $n$ – A natural number that defines the length of the substring.
    
    EXAMPLES:
    
    Obtaining a De Bruijn sequence:
    ```
    sage: seq = DeBruijnSequences(2, 3).an_element()
    sage: seq
    [0, 0, 0, 1, 0, 1, 1, 1]
    ```
    ```
    >>> from sage.all import *
    >>> seq = DeBruijnSequences(Integer(2), Integer(3)).an_element()
    >>> seq
    [0, 0, 0, 1, 0, 1, 1, 1]
    ```
    
    Testing whether it is indeed one:
    ```
    sage: seq in DeBruijnSequences(2, 3)
    True
    ```
    ```
    >>> from sage.all import *
    >>> seq in DeBruijnSequences(Integer(2), Integer(3))
    True
    ```
    
    The total number for these parameters:
    ```
    sage: DeBruijnSequences(2, 3).cardinality()
    2
    ```
    ```
    >>> from sage.all import *
    >>> DeBruijnSequences(Integer(2), Integer(3)).cardinality()
    2
    ```
    
    **Note:** This function only generates one De Bruijn sequence (the smallest lexicographically). Support for generating all possible ones may be added in the future.
    
    `an_element`:
    
    Returns the lexicographically smallest De Bruijn sequence with the given parameters.
    
    **ALGORITHM:**
    ```
The algorithm is described in the book “Combinatorial Generation” by Frank Ruskey. This program is based on a Ruby implementation by Jonas Elfström, which is based on the C program by Joe Sadawa.

EXAMPLES:

```python
sage: DeBruijnSequences(2, 3).an_element()
[0, 0, 0, 1, 0, 1, 1, 1]
```

```python
>>> from sage.all import *
>>> DeBruijnSequences(Integer(2), Integer(3)).an_element()
[0, 0, 0, 1, 0, 1, 1, 1]
```

cardinality()

Returns the number of distinct De Bruijn sequences for the object’s parameters.

EXAMPLES:

```python
sage: DeBruijnSequences(2, 5).cardinality()
2048
```

```python
>>> from sage.all import *
>>> DeBruijnSequences(Integer(2), Integer(5)).cardinality()
2048
```

ALGORITHM:

The formula for cardinality is \( k! k^{n-1} / k^n \) [Ros2002].

```python
sage.combinat.debruijn_sequence.debruijn_sequence(k, n)
```

The generating function for De Bruijn sequences. This avoids the object creation, so is significantly faster than accessing from DeBruijnSequence. For more information, see the documentation there. The algorithm used is from Frank Ruskey’s “Combinatorial Generation”.

INPUT:

- \( k \) – Arity. Must be an integer.
- \( n \) – Substring length. Must be an integer.

EXAMPLES:

```python
sage: from sage.combinat.debruijn_sequence import debruijn_sequence
sage: debruijn_sequence(3, 1)
[0, 1, 2]
```

```python
>>> from sage.all import *
>>> from sage.combinat.debruijn_sequence import debruijn_sequence
>>>
```

```python
sage.combinat.debruijn_sequence.is_debruijn_sequence(seq, k, n)
```

Given a sequence of integer elements in \( 0..k-1 \), tests whether it corresponds to a De Bruijn sequence of parameters \( k \) and \( n \).

INPUT:

- \( \text{seq} \) – Sequence of elements in \( 0..k-1 \).
- \( n, k \) – Integers.
EXAMPLES:

```python
sage: from sage.combinat.debruijn_sequence import is_debruijn_sequence
sage: s = DeBruijnSequences(2, 3).an_element()
True
sage: is_debruijn_sequence(s, 2, 3)
False
sage: is_debruijn_sequence([1] + s[1:], 2, 3)
False
```

```python
>>> from sage.all import *
>>> from sage.combinat.debruijn_sequence import is_debruijn_sequence
>>> s = DeBruijnSequences(Integer(2), Integer(3)).an_element()
>>> is_debruijn_sequence(s, Integer(2), Integer(3))
True
>>> is_debruijn_sequence(s + [Integer(0)], Integer(2), Integer(3))
False
>>> is_debruijn_sequence([Integer(1)] + s[Integer(1):], Integer(2), Integer(3))
False
```

5.1.71 Degree sequences

The present module implements the `DegreeSequences` class, whose instances represent the integer sequences of length `n`:

```python
sage: DegreeSequences(6)
Degree sequences on 6 elements

>>> from sage.all import *
>>> DegreeSequences(Integer(6))
Degree sequences on 6 elements
```

With the object `DegreeSequences(n)`, one can:

- Check whether a sequence is indeed a degree sequence:

  ```python
  sage: DS = DegreeSequences(5)
  sage: [4, 3, 3, 3, 3] in DS
  True
  sage: [4, 4, 0, 0, 0] in DS
  False
  >>> from sage.all import *
  >>> DS = DegreeSequences(Integer(5))
  >>> [Integer(4), Integer(3), Integer(3), Integer(3), Integer(3)] in DS
  True
  >>> [Integer(4), Integer(4), Integer(0), Integer(0), Integer(0)] in DS
  False
  ```

- List all the possible degree sequences of length `n`:

  ```python
  sage: for seq in DegreeSequences(4):
  ....:     print(seq)
  [0, 0, 0, 0]
  ```

<td></td>
</tr>
<tr>
<td>[3, 3, 3, 3]</td>
<td></td>
</tr>
</tbody>
</table>

```python
>>> from sage.all import *
>>> for seq in DegreeSequences(Integer(4)):
...     print(seq)
[0, 0, 0, 0]
[1, 1, 0, 0]
[2, 1, 1, 0]
[3, 1, 1, 1]
[1, 1, 1, 1]
[2, 2, 1, 1]
[2, 2, 2, 0]
[3, 2, 2, 1]
[2, 2, 2, 2]
[3, 3, 2, 2]
[3, 3, 3, 3]
```

**Note:** Given a degree sequence, one can obtain a graph realizing it by using `DegreeSequence()`. For instance:

```python
sage: ds = [3, 3, 2, 2, 2, 2, 2, 1, 1, 0]
sage: g = graphs.DegreeSequence(ds)  # needs networkx sage.graphs
sage: g.degree_sequence()  # needs networkx sage.graphs
[3, 3, 2, 2, 2, 2, 2, 1, 1, 0]
```

```python
>>> from sage.all import *
>>> ds = [Integer(3), Integer(3), Integer(2), Integer(2), Integer(2), Integer(2),
       Integer(2), Integer(1), Integer(1), Integer(0)]
>>> g = graphs.DegreeSequence(ds)  # needs networkx sage.graphs
>>> g.degree_sequence()           # needs networkx sage.graphs
[3, 3, 2, 2, 2, 2, 2, 1, 1, 0]
```

5.1. Comprehensive Module List
Definitions

A sequence of integers $d_1, ..., d_n$ is said to be a degree sequence (or graphic sequence) if there exists a graph in which vertex $i$ is of degree $d_i$. It is often required to be non-increasing, i.e. that $d_1 \geq ... \geq d_n$. Finding a graph with given degree sequence is known as graph realization problem.

An integer sequence need not necessarily be a degree sequence. Indeed, in a degree sequence of length $n$ no integer can be larger than $n - 1$ – the degree of a vertex is at most $n - 1$ – and the sum of them is at most $n(n - 1)$.

Degree sequences are completely characterized by a result from Erdős and Gallai:

\begin{align*}
\text{Erdős and Gallai:} & \quad \text{The sequence of integers } d_1 \geq \cdots \geq d_n \text{ is a degree sequence if and only if } \\
& \sum_{i} d_i \text{ is even and } \forall i \\
& \sum_{j \leq i} d_j \leq j(j - 1) + \sum_{j > i} \min(d_j, i).
\end{align*}

Alternatively, a degree sequence can be defined recursively:

\begin{align*}
\text{Havel and Hakimi:} & \quad \text{The sequence of integers } d_1 \geq \cdots \geq d_n \text{ is a degree sequence if and only if } d_2 - 1, ..., d_{d_1 + 1} - 1, d_{d_1 + 2}, ..., d_n \text{ is also a degree sequence.}
\end{align*}

Or equivalently:

\begin{align*}
\text{Havel and Hakimi (bis):} & \quad \text{If there is a realization of an integer sequence as a graph (i.e. if the sequence is a degree sequence), then it can be realized in such a way that the vertex of maximum degree } \Delta \text{ is adjacent to the } \Delta \text{ vertices of highest degree (except itself, of course).}
\end{align*}

Algorithms

Checking whether a given sequence is a degree sequence

This is tested using Erdős and Gallai’s criterion. It is also checked that the given sequence is non-increasing and has length $n$.

Iterating through the sequences of length $n$

From Havel and Hakimi’s recursive definition of a degree sequence, one can build an enumeration algorithm as done in [RCES1994]. It consists in trying to extend a current degree sequence on $n$ elements into a degree sequence on $n + 1$ elements by adding a vertex of degree larger than those already present in the sequence. This can be seen as reversing the reduction operation described in Havel and Hakimi’s characterization. This operation can appear in several different ways:

- Extensions of a degree sequence that do not change the value of the maximum element
  - If the maximum element of a given degree sequence is 0, then one can remove it to reduce the sequence, following Havel and Hakimi’s rule. Conversely, if the maximum element of the (current) sequence is 0, then one can always extend it by adding a new element of degree 0 to the sequence.
    \[ 0, 0, 0 \xrightarrow{\text{Extension}} 0, 0, 0 \xrightarrow{\text{Extension}} 0, 0, 0, ..., 0, 0, 0 \xrightarrow{\text{Reduction}} 0, 0, 0 \xrightarrow{\text{Reduction}} 0, 0, 0 \]
  - If there are at least $\Delta + 1$ elements of (maximum) degree $\Delta$ in a given degree sequence, then one can reduce it by removing a vertex of degree $\Delta$ and decreasing the values of $\Delta$ elements of value $\Delta$ to $\Delta - 1$. Conversely, if the maximum element of the (current) sequence is $d > 0$, then one can add a new element of degree $d$ to the sequence if it can be linked to $d$ elements of (current) degree $d - 1$. Those $d$ vertices of degree $d - 1$ hence become vertices of degree $d$, and so $d$ elements of degree $d - 1$ are removed from the sequence while $d + 1$ elements of degree $d$ are added to it.
    \[ 3, 2, 2, 1 \xrightarrow{\text{Extension}} 3, 3, (2 + 1), (2 + 1), (2 + 1), 1 = 3, 3, 3, 3, 3, 1 \xrightarrow{\text{Reduction}} 3, 2, 2, 1 \]
• Extension of a degree sequence that changes the value of the maximum element:
  
  - In the general case, i.e. when the number of elements of value Δ, Δ − 1 is small compared to Δ (i.e. the maximum element of a given degree sequence), reducing a sequence strictly decreases the value of the maximum element. According to Havel and Hakimi’s characterization there is only one way to reduce a sequence, but reversing this operation is more complicated than in the previous cases. Indeed, the following extensions are perfectly valid according to the reduction rule.

  \[
  2, 1, 1, 0, 0 \xrightarrow{\text{Extension}} 3, (2 + 1), (1 + 1), (1 + 1), 0, 0 = 3, 3, 2, 2, 0, 0 \xrightarrow{\text{Reduction}} 2, 1, 1, 0, 0
  \]

  \[
  2, 1, 1, 0, 0 \xrightarrow{\text{Extension}} 3, (2 + 1), (1 + 1), 1, (0 + 1), 0 = 3, 3, 2, 1, 1, 0 \xrightarrow{\text{Reduction}} 2, 1, 1, 0, 0
  \]

  \[
  2, 1, 1, 0, 0 \xrightarrow{\text{Extension}} 3, (2 + 1), 1, 1, (0 + 1), (0 + 1) = 3, 3, 1, 1, 1, 1 \xrightarrow{\text{Reduction}} 2, 1, 1, 0, 0
  \]

  \[
  \ldots
  \]

  In order to extend a current degree sequence while strictly increasing its maximum degree, it is equivalent to pick a set \( I \) of elements of the degree sequence with \( |I| > \Delta \) in such a way that the \( (d_i + 1)_{i \in I} \) are the \( |I| \) maximum elements of the sequence \( (d_i + 1)_{0 \leq i \leq n} \), and to add to this new sequence an element of value \( |I| \). The non-increasing sequence containing the elements \( |I| \) and \( (d_i + 1)_{0 \leq i \leq n} \) can be reduced to \( (d_i)_{1 \leq i \leq n} \) by Havel and Hakimi’s rule.

  \[
  \ldots 1, 1, 2, 2, 2, 2, 3, 3, 3, 4, 4, 6, \ldots \xrightarrow{\text{Extension}} \ldots 1, 1, 2, 2, 2, 3, 3, 3, 3, 4, 4, 5, 7, \ldots
  \]

  The number of possible sets \( I \) having this property (i.e. the number of possible extensions of a sequence) is smaller than it seems. Indeed, by definition, if \( j \not\in I \) then for all \( i \in I \) the inequality \( d_i \leq d_i + 1 \) holds. Hence, each set \( I \) is entirely determined by the largest element \( d_k \) of the sequence that it does not contain (hence \( I \) contains \( \{1, \ldots, k - 1\} \)), and by the cardinalities of \( \{i \in I : d_i = d_k\} \) and \( \{i \in I : d_i = d_k - 1\} \).

  \[
  I = \{i \in I : d_i = d_k\} \cup \{i \in I : d_i = d_k - 1\} \cup \{i : d_i > d_k\}
  \]

  The number of possible extensions is hence at most cubic, and is easily enumerated.

**About the implementation**

In the actual implementation of the enumeration algorithm, the degree sequence is stored differently for reasons of efficiency.

Indeed, when enumerating all the degree sequences of length \( n \), Sage first allocates an array \( \text{seq} \) of \( n + 1 \) integers where \( \text{seq}[i] \) is the number of elements of value \( i \) in the current sequence. Obviously, \( \text{seq}[n]=0 \) holds in permanence: it is useful to allocate a larger array than necessary to simplify the code. The \( \text{seq} \) array is a global variable.

The recursive function \( \text{enum}(\text{depth}, \text{maximum}) \) is the one building the list of sequences. It builds the list of degree sequences of length \( n \) which \( \text{extend} \) the sequence currently stored in \( \text{seq}[0] \ldots \text{seq}[\text{depth}-1] \). When it is called, \( \text{maximum} \) must be set to the maximum value of an element in the partial sequence \( \text{seq}[0] \ldots \text{seq}[\text{depth}-1] \).

If during its run the function \( \text{enum} \) heavily works on the content of the \( \text{seq} \) array, the value of \( \text{seq} \) is the same before and after the run of \( \text{enum} \).

**Extending the current partial sequence**

The two cases for which the maximum degree of the partial sequence does not change are easy to detect. It is (slightly) harder to enumerate all the sets \( I \) corresponding to possible extensions of the partial sequence. As said previously, to extend them one can associate an integer \( \text{current\_box} \) such that \( I \) contains all the \( i \) satisfying \( d_i > \text{current\_box} \). The variable \( \text{taken} \) represents the number of all such elements \( i \), so that when enumerating all possible sets \( I \) in the algorithm we have the equality

\[
I = \text{taken} + \text{number of elements of value} \text{ current\_box} + \text{number of elements of value} \text{ current\_box} - 1.
\]

**REFERENCES:**
Warning: For the moment, iterating over all degree sequences involves building the list of them first, then iterate on this list. This is obviously bad, as it requires uselessly a lot of memory for large values of \(n\). This should be changed. Updating the code does not require more than a couple of minutes.

```python
class sage.combinat.degree_sequences.DegreeSequences(n)
    Bases: object
    DegreeSequences
    An instance of this class represents the degree sequences of graphs on a given number \(n\) of vertices. It can be used to list and count them, as well as to test whether a sequence is a degree sequence. For more information, please refer to the documentation of the DegreeSequence module.
    EXAMPLES:
    sage: DegreeSequences(8)
    Degree sequences on 8 elements
    sage: [3,3,2,2,2,2,2,2] in DegreeSequences(8)
    True
    >>> from sage.all import *
    >>> DegreeSequences(Integer(8))
    Degree sequences on 8 elements
    >>> [Integer(3),Integer(3),Integer(2),Integer(2),Integer(2),Integer(2),Integer(2),Integer(2)] in DegreeSequences(Integer(8))
    True
```

### 5.1.72 Derangements

AUTHORS:

- Alasdair McAndrew (2010-05): Initial version
- Travis Scrimshaw (2013-03-30): Put derangements into category framework

```python
class sage.combinat.derangements.Derangement(parent, *args, **kwds)
    Bases: CombinatorialElement
    A derangement.
    A derangement on a set \(S\) is a permutation \(\sigma\) such that \(\sigma(x) \neq x\) for all \(x \in S\), i.e. \(\sigma\) is a permutation of \(S\) with no fixed points.
    EXAMPLES:
    sage: D = Derangements(4)
    sage: elt = D([4,3,2,1])
    sage: TestSuite(elt).run()
```
To implement the above code:

```python
>>> from sage.all import *
>>> D = Derangements(Integer(4))
>>> elt = D([Integer(4),Integer(3),Integer(2),Integer(1)])
>>> TestSuite(elt).run()
```

**to_permutation()**

Return the permutation corresponding to self.

**EXAMPLES:**

```python
sage: D = Derangements(4)
sage: p = D([4,3,2,1]).to_permutation(); p
[4, 3, 2, 1]
sage: type(p)
<class 'sage.combinat.permutation.StandardPermutations_all_with_category.element_class'>
sage: D = Derangements([1, 3, 3, 4])
sage: D[0].to_permutation()
Traceback (most recent call last):
  ... ValueError: can only convert to a permutation for derangements of [1, 2, ..., \rightarrow n]
```

**class sage.combinat.derangements.Derangements(x)**

**Bases:** UniqueRepresentation, Parent

The class of all derangements of a set or multiset.

A derangement on a set \( S \) is a permutation \( \sigma \) such that \( \sigma(x) \neq x \) for all \( x \in S \), i.e. \( \sigma \) is a permutation of \( S \) with no fixed points.

For an integer, or a list or string with all elements distinct, the derangements are obtained by a standard result described in [BV2004]. For a list or string with repeated elements, the derangements are formed by computing all permutations of the input and discarding all non-derangements.

**INPUT:**

- \( x \) – Can be an integer which corresponds to derangements of \( \{1, 2, 3, \ldots, x\} \), a list, or a string

**REFERENCES:**

- [BV2004]
- Wikipedia article Derangement

**EXAMPLES:**

D2.random_element()  # random
[2, 3, 1, 3, 1, 2]

(continues on next page)
Element

alias of Derangement
cardinality()

Counts the number of derangements of a positive integer, a list, or a string. The list or string may contain repeated elements. If an integer \( n \) is given, the value returned is the number of derangements of \([1, 2, 3, \ldots, n]\).

For an integer, or a list or string with all elements distinct, the value is obtained by the standard result \( D_2 = 1, D_3 = 2, D_n = (n-1)(D_{n-1} + D_{n-2}) \).

For a list or string with repeated elements, the number of derangements is computed by Macmahon’s theorem. If the numbers of repeated elements are \( a_1, a_2, \ldots, a_k \) then the number of derangements is given by the coefficient of \( x_1x_2 \cdots x_k \) in the expansion of \( \prod_{i=0}^{k} (S - s_i)^{a_i} \), where \( S = x_1 + x_2 + \cdots + x_k \).

EXAMPLES:

```
sage: D = Derangements(5)
sage: D.cardinality()
44
sage: D = Derangements([1, 44, 918, 67, 254])
sage: D.cardinality()
44
sage: D = Derangements(['A', 'AT', 'CAT', 'CATS', 'CARTS'])
sage: D.cardinality()
44
sage: D = Derangements('UNCOPYRIGHTABLE')
sage: D.cardinality()
48106515734
sage: D = Derangements([1, 1, 2, 2, 3, 3])
sage: D.cardinality()
10
sage: D = Derangements('SATTAS')
sage: D.cardinality()
10
sage: D = Derangements([1, 1, 2, 2, 2])
sage: D.cardinality()
0
```

```python
>>> from sage.all import *
```

```
>>> D = Derangements(Integer(5))
>>> D.cardinality()
44
>>> D = Derangements([Integer(1), Integer(44), Integer(918), Integer(67), Integer(254)])
>>> D.cardinality()
44
>>> D = Derangements(['A', 'AT', 'CAT', 'CATS', 'CARTS'])
>>> D.cardinality()
```

(continues on next page)
random_element()

Produce all derangements of a positive integer, a list, or a string. The list or string may contain repeated
elements. If an integer $n$ is given, then a random derangements of $[1, 2, 3, \ldots, n]$ is returned

For an integer, or a list or string with all elements distinct, the value is obtained by an algorithm described in
[MPP2008]. For a list or string with repeated elements the derangement is formed by choosing an element
at random from the list of all possible derangements.

OUTPUT:

A single list or string containing a derangement, or an empty list if there are no derangements.

EXAMPLES:

```plaintext
sage: D = Derangements(4)
sage: D.random_element() # random
[2, 3, 4, 1]
sage: D = Derangements(['A', 'AT', 'CAT', 'CARTS', 'CARETS'])
sage: D.random_element() # random
['AT', 'CARTS', 'A', 'CAT', 'CARETS', 'CATS']
sage: D = Derangements('UNCOPYRIGHTABLE')
sage: D.random_element() # random
sage: D = Derangements([1,1,1,1,2,2,2,2,3,3,3,3])
sage: D.random_element() # random
[3, 2, 2, 3, 1, 3, 1, 3, 2, 1, 1, 2]
sage: D = Derangements('ESSENCES')
sage: D.random_element() # random
sage: D = Derangements([1,1,2,2,2])
sage: D.random_element() []
```
Combinatorics, Release 10.4

(continued from previous page)

>>> D = Derangements([Integer(1),Integer(1),Integer(1),Integer(1),Integer(2),
                   →Integer(2),Integer(2),Integer(2),Integer(3),Integer(3),Integer(3),
                   →Integer(3),Integer(3),Integer(3)])
>>> D.random_element() # random
[3, 2, 2, 3, 1, 3, 1, 3, 2, 1, 1, 2]

>>> D = Derangements('ESSENCES')
>>> D.random_element() # random
['N', 'E', 'E', 'C', 'S', 'S', 'S', 'E']

>>> D = Derangements([Integer(1),Integer(1),Integer(2),Integer(2),Integer(2)])
>>> D.random_element()
[]

5.1.73 Descent Algebras

AUTHORS:

• Travis Scrimshaw (2013-07-28): Initial version

class sage.combinat.descent_algebra.DescentAlgebra(R, n)

Bases: UniqueRepresentation, Parent

Solomon’s descent algebra.

The descent algebra \(\Sigma_n\) over a ring \(R\) is a subalgebra of the symmetric group algebra \(RS_n\). (The product in the latter algebra is defined by \((pq)(i) = q(p(i))\) for any two permutations \(p\) and \(q\) in \(S_n\) and every \(i \in \{1, 2, \ldots, n\}\). The algebra \(\Sigma_n\) inherits this product.)

There are three bases currently implemented for \(\Sigma_n\):

• the standard basis \(D_S\) of (sums of) descent classes, indexed by subsets \(S\) of \(\{1, 2, \ldots, n-1\}\),

• the subset basis \(B_p\), indexed by compositions \(p\) of \(n\),

• the idempotent basis \(I_p\), indexed by compositions \(p\) of \(n\), which is used to construct the mutually orthogonal idempotents of the symmetric group algebra.

The idempotent basis is only defined when \(R\) is a \(Q\)-algebra.

We follow the notations and conventions in [GR1989], apart from the order of multiplication being different from the one used in that article. Schocker’s exposition [Sch2004], in turn, uses the same order of multiplication as we are, but has different notations for the bases.

INPUT:

• \(R\) – the base ring

• \(n\) – a nonnegative integer

REFERENCES:

• [GR1989]

• [MR1995]

• [Sch2004]

EXAMPLES:
Combinatorics, Release 10.4

```
sage: DA = DescentAlgebra(QQ, 4)
sage: D = DA.D(); D
Descent algebra of 4 over Rational Field in the standard basis
sage: B = DA.B(); B
Descent algebra of 4 over Rational Field in the subset basis
sage: I = DA.I(); I
Descent algebra of 4 over Rational Field in the idempotent basis
sage: basis_B = B.basis()
sage: elt = basis_B[Composition([1,2,1])] + 4*basis_B[Composition([1,3])]; elt
B[1, 2, 1] + 4*B[1, 3]
sage: D(elt)
5*D{} + 5*D{1} + D{1, 3} + D{3}
sage: I(elt)
7/6*I[1, 1, 1, 1] + 2*I[1, 1, 2] + 3*I[1, 2, 1] + 4*I[1, 3]
```
The subset basis \( (B_S)_{S \subseteq \{1, 2, \ldots, n-1\}} \) of \( \Sigma_n \) is formed by

\[
B_S = \sum_{T \subseteq S} D_T,
\]

where \( (D_S)_{S \subseteq \{1, 2, \ldots, n-1\}} \) is the standard basis. However it is more natural to index the subset basis by compositions of \( n \) under the bijection \( \{i_1, i_2, \ldots, i_k\} \mapsto (i_1, i_2 - i_1, i_3 - i_2, \ldots, i_k - i_{k-1}, n - i_k) \) (where \( i_1 < i_2 < \cdots < i_k \)), which is what Sage uses to index the basis.

The basis element \( B_p \) is denoted \( \Xi^p \) in [Sch2004].

By using compositions of \( n \), the product \( B_p B_q \) becomes a sum over the non-negative-integer matrices \( M \) with row sum \( p \) and column sum \( q \). The summand corresponding to \( M \) is \( B_c \), where \( c \) is the composition obtained by reading \( M \) row-by-row from left-to-right and top-to-bottom and removing all zeroes. This multiplication rule is commonly called “Solomon’s Mackey formula”.

**EXAMPLES:**

```python
sage: DA = DescentAlgebra(QQ, 4)
sage: B = DA.B()
sage: list(B.basis())
[\( B[1, 1, 1, 1], B[1, 1, 2], B[1, 2, 1], B[1, 3], B[2, 1, 1], B[2, 2], B[3, 1], B[4] \)]
```

```python
>>> from sage.all import *
>>> DA = DescentAlgebra(QQ, Integer(4))
>>> B = DA.B()
>>> list(B.basis())
[\( B[1, 1, 1, 1], B[1, 1, 2], B[1, 2, 1], B[1, 3], B[2, 1, 1], B[2, 2], B[3, 1], B[4] \)]
```

**one_basis()**

Return the identity element which is the composition \([n] \), as per AlgebrasWithBasis. ParentMethods.one_basis.

**EXAMPLES:**

```python
sage: DA = DescentAlgebra(QQ, 4).B().one_basis()
[4]
sage: DA = DescentAlgebra(QQ, 0).B().one_basis()
[]
sage: all( U * DA(QQ, 3).B().one() == U
... for U in DA(QQ, 3).B().basis() )
True
```

```python
>>> from sage.all import *
>>> DA = DescentAlgebra(QQ, Integer(4)).B().one_basis()
[4]
>>> DA = DescentAlgebra(QQ, Integer(0)).B().one_basis()
[]
>>> all( U * DA(QQ, Integer(3)).B().one() == U
... for U in DA(QQ, Integer(3)).B().basis() )
True
```

**product_on_basis\( (p, q) \)**

Return \( B_p B_q \), where \( p \) and \( q \) are compositions of \( n \).
EXAMPLES:

```python
sage: DA = DescentAlgebra(QQ, 4)
sage: B = DA.B()
sage: p = Composition([1,2,1])
sage: q = Composition([3,1])
sage: B.product_on_basis(p, q)
B[1, 1, 1, 1] + 2*B[1, 2, 1]
```

```python
>>> from sage.all import *
>>> DA = DescentAlgebra(QQ, Integer(4))
>>> B = DA.B()
>>> p = Composition([Integer(1),Integer(2),Integer(1)])
>>> q = Composition([Integer(3),Integer(1)])
>>> B.product_on_basis(p, q)
B[1, 1, 1, 1] + 2*B[1, 2, 1]
```

to_D_basis (p)

Return $B_p$ as a linear combination of $D$-basis elements.

EXAMPLES:

```python
sage: DA = DescentAlgebra(QQ, 4)
sage: B = DA.B()
sage: D = DA.D()
sage: list(map(D, B.basis()))  # indirect doctest
[D{} + D{1} + D{1, 2} + D{1, 2, 3} + D{1, 3} + D{2} + D{2, 3} + D{3},
 D{} + D{1} + D{1, 2} + D{2},
 D{} + D{1} + D{1, 3} + D{3},
 D{} + D{1},
 D{} + D{2} + D{2, 3} + D{3},
 D{} + D{2},
 D{} + D{3},
 D{3}]
```

```python
>>> from sage.all import *
>>> DA = DescentAlgebra(QQ, Integer(4))
>>> B = DA.B()
>>> D = DA.D()
>>> list(map(D, B.basis()))  # indirect doctest
[D{} + D{1} + D{1, 2} + D{1, 2, 3} + D{1, 3} + D{2} + D{2, 3} + D{3},
 D{} + D{1} + D{1, 2} + D{2},
 D{} + D{1} + D{1, 3} + D{3},
 D{} + D{1},
 D{} + D{2} + D{2, 3} + D{3},
 D{} + D{2},
 D{} + D{3},
 D{3}]
```

to_I_basis (p)

Return $B_p$ as a linear combination of $I$-basis elements.

This is done using the formula

$$B_p = \sum_{q \leq p} \frac{1}{k!(q, p)} I_q,$$
where $\leq$ is the refinement order and $k!(q,p)$ is defined as follows: When $q \leq p$, we can write $q$ as a concatenation $q_1 q_2 \cdots q_k$ with each $q_i$ being a composition of the $i$-th entry of $p$, and then we set $k!(q,p)$ to be $l(q_1)! l(q_2)! \cdots l(q_k)!$, where $l(r)$ denotes the number of parts of any composition $r$.

EXAMPLES:

```python
sage: DA = DescentAlgebra(QQ, 4)
sage: B = DA.B()
sage: I = DA.I()
sage: list(map(I, B.basis())) # indirect doctest
[I[1, 1, 1, 1],
1/2*I[1, 1, 1, 1] + I[1, 1, 2],
1/2*I[1, 1, 1, 1] + I[1, 2, 1],
1/6*I[1, 1, 1, 1] + 1/2*I[1, 1, 2] + 1/2*I[1, 2, 1] + I[1, 3],
1/2*I[1, 1, 1, 1] + I[2, 1, 1],
1/4*I[1, 1, 1, 1] + 1/2*I[1, 1, 2] + 1/2*I[2, 1, 1] + I[3, 1],
1/6*I[1, 1, 1, 1] + 1/2*I[1, 2, 1] + 1/2*I[2, 1, 1] + I[3, 1],
```

```python
>>> from sage.all import *
>>> B = DescentAlgebra(QQ, Integer(4)).B()
>>> I = DA.I()
>>> list(map(I, B.basis())) # indirect doctest
[I[1, 1, 1, 1],
1/2*I[1, 1, 1, 1] + I[1, 1, 2],
1/2*I[1, 1, 1, 1] + I[1, 2, 1],
1/6*I[1, 1, 1, 1] + 1/2*I[1, 1, 2] + 1/2*I[1, 2, 1] + I[1, 3],
1/2*I[1, 1, 1, 1] + I[2, 1, 1],
1/4*I[1, 1, 1, 1] + 1/2*I[1, 1, 2] + 1/2*I[2, 1, 1] + I[3, 1],
1/6*I[1, 1, 1, 1] + 1/2*I[1, 2, 1] + 1/2*I[2, 1, 1] + I[3, 1],
```

to_nsym($p$)

Return $B_p$ as an element in $NSym$, the non-commutative symmetric functions.

This maps $B_p$ to $S_p$ where $S$ denotes the Complete basis of $NSym$.

EXAMPLES:

```python
sage: B = DescentAlgebra(QQ, 4).B()
sage: S = NonCommutativeSymmetricFunctions(QQ).Complete()
sage: list(map(S, B.basis())) # indirect doctest
[S[1, 1, 1, 1],
S[1, 1, 2],
S[1, 2, 1],
S[1, 3],
S[2, 1, 1],
S[2, 2],
S[3, 1],
S[4]]
```

```python
>>> from sage.all import *
>>> B = DescentAlgebra(QQ, Integer(4)).B()
>>> S = NonCommutativeSymmetricFunctions(QQ).Complete()
>>> list(map(S, B.basis())) # indirect doctest
[S[1, 1, 1, 1],
S[1, 1, 2],
S[1, 2, 1],
S[1, 3],
S[2, 1, 1],
S[2, 2],
S[3, 1],
S[4]]
```

(continues on next page)
class D (alg, prefix='D')

Bases: CombinatorialFreeModule, BindableClass

The standard basis of a descent algebra.

This basis is indexed by $S \subseteq \{1, 2, \ldots, n-1\}$, and the basis vector indexed by $S$ is the sum of all permutations, taken in the symmetric group algebra $RS_n$, whose descent set is $S$. We denote this basis vector by $D_S$.

Occasionally this basis appears in literature but indexed by compositions of $n$ rather than subsets of $\{1, 2, \ldots, n-1\}$. The equivalence between these two indexings is owed to the bijection from the power set of $\{1, 2, \ldots, n-1\}$ to the set of all compositions of $n$ which sends every subset $\{i_1, i_2, \ldots, i_k\}$ of $\{1, 2, \ldots, n-1\}$ (with $i_1 < i_2 < \cdots < i_k$) to the composition $(i_1, i_2 - i_1, \ldots, i_k - i_{k-1}, n - i_k)$.

The basis element corresponding to a composition $p$ (or to the subset of $\{1, 2, \ldots, n-1\}$) is denoted $\Delta^p$ in [Sch2004].

EXAMPLES:

```python
sage: DA = DescentAlgebra(QQ, 4)
sage: D = DA.D()
sage: list(D.basis())
[D{}, D{1}, D{2}, D{3}, D{1, 2}, D{1, 3}, D{2, 3}, D{1, 2, 3}]

sage: DA = DescentAlgebra(QQ, 0)
sage: D = DA.D()
sage: list(D.basis())
[D{}]
```

```python
>>> from sage.all import *
>>> DA = DescentAlgebra(QQ, Integer(4))
>>> D = DA.D()
>>> list(D.basis())
[D{}, D{1}, D{2}, D{3}, D{1, 2}, D{1, 3}, D{2, 3}, D{1, 2, 3}]

>>> DA = DescentAlgebra(QQ, Integer(0))
>>> D = DA.D()
>>> list(D.basis())
[D{}]
```

one_basis()

Return the identity element, as per `AlgebrasWithBasis.ParentMethods.one_basis`.

EXAMPLES:

```python
sage: DescentAlgebra(QQ, 4).D().one_basis()
()  
sage: DescentAlgebra(QQ, 0).D().one_basis()
(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

sage: all( U * DescentAlgebra(QQ, 3).D().one() == U 
    ....:     for U in DescentAlgebra(QQ, 3).D().basis() )
True

>>> from sage.all import *
>>> DescentAlgebra(QQ, Integer(4)).D().one_basis()

>>> DescentAlgebra(QQ, Integer(0)).D().one_basis()

>>> all( U * DescentAlgebra(QQ, Integer(3)).D().one() == U 
    ...     for U in DescentAlgebra(QQ, Integer(3)).D().basis() )
True

**product_on_basis** \((S, T)\)

Return \(D_SD_T\), where \(S\) and \(T\) are subsets of \([n - 1]\).

**EXAMPLES:**

sage: DA = DescentAlgebra(QQ, 4)
sage: D = DA.D()
sage: D.product_on_basis((1, 3), (2,))
\(D\{\} + D\{1\} + D\{1, 2\} + 2*D\{1, 2, 3\} + D\{1, 3\} + D\{2\} + D\{2, 3\} + D\{3\}\)

>>> from sage.all import *
>>> DA = DescentAlgebra(QQ, Integer(4))
>>> D = DA.D()
>>> D.product_on_basis((Integer(1), Integer(3)), (Integer(2),))
\(D\{\} + D\{1\} + D\{1, 2\} + 2*D\{1, 2, 3\} + D\{1, 3\} + D\{2\} + D\{2, 3\} + D\{3\}\)

**to_B_basis** \((S)\)

Return \(D_S\) as a linear combination of \(B_p\)-basis elements.

**EXAMPLES:**

sage: DA = DescentAlgebra(QQ, 4)
sage: D = DA.D()
sage: B = DA.B()
sage: list(map(B, D.basis()))  # indirect doctest
[\([4]\),
 \(B\{1, 3\} - B\{4\},
 B\{2, 2\} - B\{4\},
 B\{3, 1\} - B\{4\},
 B\{1, 1, 2\} - B\{1, 3\} - B\{2, 2\} + B\{4\},
 B\{1, 2, 1\} - B\{1, 3\} - B\{3, 1\} + B\{4\},
 B\{2, 1, 1\} - B\{2, 2\} - B\{3, 1\} + B\{4\},
 B\{1, 1, 1, 1\} - B\{1, 1, 2\} - B\{1, 2, 1\} + B\{1, 3\} - B\{2, 1, 1\} + B\{2, 2\} + B\{3, 1\} - B\{4\}\)]

>>> from sage.all import *
>>> DA = DescentAlgebra(QQ, Integer(4))
>>> D = DA.D()
>>> B = DA.B()
To compute the idempotent basis of a descent algebra, one can use the following formula:

\[ I_p = \sum_{q \leq p} \frac{(-1)^{l(q) - l(p)}}{k(q, p)} B_q, \]

where \( \leq \) is the refinement order and \( l(r) \) denotes the number of parts of any composition \( r \), and where \( k(q, p) \)
Combinatorics, Release 10.4

is defined as follows: When \( q \leq p \), we can write \( q \) as a concatenation \( q(1)q(2)\cdots q(k) \) with each \( q(i) \) being a composition of the \( i \)-th entry of \( p \), and then we set \( k(q, p) \) to be the product \( l(q(1))l(q(2))\cdots l(q(k)) \).

Let \( \lambda(p) \) denote the partition obtained from a composition \( p \) by sorting. This basis is called the idempotent basis since for any \( q \) such that \( \lambda(p) = \lambda(q) \), we have:

\[
I_p I_q = s(\lambda)I_p
\]

where \( \lambda \) denotes \( \lambda(p) = \lambda(q) \), and where \( s(\lambda) \) is the stabilizer of \( \lambda \) in \( S_n \). (This is part of Theorem 4.2 in [GR1989].)

It is also straightforward to compute the idempotents \( E_\lambda \) for the symmetric group algebra by the formula (Theorem 3.2 in [GR1989]):

\[
E_\lambda = \frac{1}{k!} \sum_{\lambda(p) = \lambda} I_p.
\]

**Note:** The basis elements are not orthogonal idempotents.

**EXAMPLES:**

```python
sage: DA = DescentAlgebra(QQ, 4)
sage: I = DA.I()
sage: list(I.basis())
[I[1, 1, 1, 1], I[1, 1, 2], I[1, 2, 1], I[1, 3], I[2, 1, 1], I[2, 2], I[3, 1], ...
→ I[4]]
```

```python
>>> from sage.all import *

>>> DA = DescentAlgebra(QQ, Integer(4))

>>> I = DA.I()

>>> list(I.basis())
[I[1, 1, 1, 1], I[1, 1, 2], I[1, 2, 1], I[1, 3], I[2, 1, 1], I[2, 2], I[3, 1], ...
→ I[4]]
```

**idempotent** (la)

Return the idempotent corresponding to the partition \( \lambda \) of \( n \).

**EXAMPLES:**

```python
sage: I = DescentAlgebra(QQ, 4).I()
sage: E = I.idempotent([3, 1]); E
1/2*I[1, 3] + 1/2*I[3, 1]
sage: E*E == E
True

sage: E2 = I.idempotent([2, 1, 1]); E2
1/6*I[1, 1, 2] + 1/6*I[1, 2, 1] + 1/6*I[2, 1, 1]
sage: E2*E2 == E2
True

sage: E*E2 == I.zero()
True
```

```python
>>> from sage.all import *

>>> I = DescentAlgebra(QQ, Integer(4)).I()

>>> E = I.idempotent([Integer(3), Integer(1)]); E
1/2*I[1, 3] + 1/2*I[3, 1]
```

(continues on next page)
 Combinatorics, Release 10.4

>>> E*E == E
True
>>> E2 = I.idempotent([Integer(2),Integer(1),Integer(1)]); E2
1/6*I[1, 1, 2] + 1/6*I[1, 2, 1] + 1/6*I[2, 1, 1]
>>> E2*E2 == E2
True
>>> E*E2 == I.zero()
True

one()

Return the identity element, which is \( B_n \), in the \( I \) basis.

**EXAMPLES:**

```
sage: DescentAlgebra(QQ, 4).I().one()
```

>>> from sage.all import *

```sage: DescentAlgebra(QQ, Integer(4)).I().one()
I[
```

one_basis()

The element 1 is not (generally) a basis vector in the \( I \) basis, thus this raises a **TypeError**.

**EXAMPLES:**

```
sage: DescentAlgebra(QQ, 4).I().one_basis()
Traceback (most recent call last):
  ... 
TypeError: 1 is not a basis element in the I basis
```

```
>>> from sage.all import *

```sage: DescentAlgebra(QQ, Integer(4)).I().one_basis()
Traceback (most recent call last):
  ... 
TypeError: 1 is not a basis element in the I basis
```

product_on_basis (p, q)

Return \( I_pI_q \), where \( p \) and \( q \) are compositions of \( n \).

**EXAMPLES:**

```
sage: DA = DescentAlgebra(QQ, 4)
sage: I = DA.I()
sage: p = Composition([1,2,1])
sage: q = Composition([3,1])
sage: I.product_on_basis(p, q)
0
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```
sage: I.product_on_basis(p, p)
2*I[1, 2, 1]
```

```
>>> from sage.all import *
>>>
>>> DA = DescentAlgebra(QQ, Integer(4))
>>>
>>> I = DA.I()
>>>
>>> p = Composition([Integer(1), Integer(2), Integer(1)])
>>>
>>> q = Composition([Integer(3), Integer(1)])
>>>
>>> I.product_on_basis(p, q)
0
>>> I.product_on_basis(p, p)
2*I[1, 2, 1]
```

**to_B_basis** *(p)*

Return $I_p$ as a linear combination of $B$-basis elements.

This is computed using the formula (Theorem 3.3 in [GR1989])

$$I_p = \sum_{q \leq p} (-1)^{|q|-|p|} k(q, p) B_q,$$

where $\leq$ is the refinement order and $l(r)$ denotes the number of parts of any composition $r$, and where $k(q, p)$ is defined as follows: When $q \leq p$, we can write $q$ as a concatenation $q(1)q(2)\cdots q(k)$ with each $q(i)$ being a composition of the $i$-th entry of $p$, and then we set $k(q, p)$ to be $l(q(1))l(q(2))\cdots l(q(k))$.

**EXAMPLES:**

```
sage: DA = DescentAlgebra(QQ, 4)
sage: B = DA.B()
sage: I = DA.I()
sage: list(map(B, I.basis()))  # indirect doctest
[B[1, 1, 1, 1],
 -1/2*B[1, 1, 1, 1] + B[1, 1, 2],
 -1/2*B[1, 1, 1, 1] + B[1, 2, 1],
 1/3*B[1, 1, 1, 1] - 1/2*B[1, 1, 2] - 1/2*B[1, 2, 1] + B[1, 3],
 -1/2*B[1, 1, 1, 1] + B[2, 1, 1],
 1/4*B[1, 1, 1, 1] - 1/2*B[1, 1, 2] - 1/2*B[2, 1, 1] + B[2, 2],
 1/3*B[1, 1, 1, 1] - 1/2*B[1, 2, 1] + B[2, 1, 1]
```

```
>>> from sage.all import *
>>>
>>> DA = DescentAlgebra(QQ, Integer(4))
>>>
>>> B = DA.B()
>>>
>>> I = DA.I()
>>>
>>> list(map(B, I.basis()))  # indirect doctest
[B[1, 1, 1, 1],
 -1/2*B[1, 1, 1, 1] + B[1, 1, 2],
 -1/2*B[1, 1, 1, 1] + B[1, 2, 1],
 1/3*B[1, 1, 1, 1] - 1/2*B[1, 1, 2] - 1/2*B[1, 2, 1] + B[1, 3],
 -1/2*B[1, 1, 1, 1] + B[2, 1, 1],
 1/4*B[1, 1, 1, 1] - 1/2*B[1, 1, 2] - 1/2*B[2, 1, 1] + B[2, 2],
 1/3*B[1, 1, 1, 1] - 1/2*B[1, 2, 1] + B[2, 1, 1]
```

5.1. Comprehensive Module List 923
Combinatorics, Release 10.4

a_realization()

Return a particular realization of self (the \(B\)-basis).

EXAMPLES:

\begin{verbatim}
sage: DA = DescentAlgebra(QQ, 4)
sage: DA.a_realization()
Descent algebra of 4 over Rational Field in the subset basis
\end{verbatim}

idempotent

alias of \(I\)

standard

alias of \(D\)

subset

alias of \(B\)

class sage.combinat.descent_algebra.DescentAlgebraBases(base)

Bases: Category_realization_of_parent

The category of bases of a descent algebra.

class ElementMethods

Bases: object

to_symmetric_group_algebra()

Return self in the symmetric group algebra.

EXAMPLES:

\begin{verbatim}
sage: B = DescentAlgebra(QQ, 4).B()
sage: B[1,3].to_symmetric_group_algebra()
[1, 2, 3, 4] + [2, 1, 3, 4] + [3, 1, 2, 4] + [4, 1, 2, 3]
sage: I = DescentAlgebra(QQ, 4).I()
sage: elt = I(B[1,3])
sage: elt.to_symmetric_group_algebra()
[1, 2, 3, 4] + [2, 1, 3, 4] + [3, 1, 2, 4] + [4, 1, 2, 3]
\end{verbatim}

class ParentMethods

Bases: object
to_symmetric_group_algebra()

Morphism from self to the symmetric group algebra.

EXAMPLES:

```
sage: D = DescentAlgebra(QQ, 4).D()
sage: D.to_symmetric_group_algebra(D[1,3])
[2, 1, 4, 3] + [3, 1, 4, 2] + [3, 2, 4, 1] + [4, 1, 3, 2] + [4, 2, 3, 1]
sage: B = DescentAlgebra(QQ, 4).B()
sage: B.to_symmetric_group_algebra(B[1,2,1])
[1, 2, 3, 4] + [1, 2, 4, 3] + [1, 3, 4, 2] + [2, 1, 3, 4]
+ [2, 1, 4, 3] + [2, 3, 4, 1] + [3, 1, 2, 4] + [3, 1, 4, 2]
+ [3, 2, 4, 1] + [4, 1, 2, 3] + [4, 1, 3, 2] + [4, 2, 3, 1]
```

from sage.all import *

```
>>> B = DescentAlgebra(QQ, Integer(4)).B()
>>> B.to_symmetric_group_algebra_on_basis(c)
[[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1],
 [1, 2, 3] + [2, 1, 3] + [3, 1, 2],
 [1, 2, 3] + [1, 3, 2] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1],
 [1, 2, 3] + [2, 1, 3] + [3, 1, 2] + [2, 3, 1] + [3, 1, 2],
 [1, 2, 3] + [2, 1, 3] + [3, 1, 2] + [2, 3, 1] + [3, 1, 2],
 [1, 2, 3] + [2, 1, 3] + [3, 1, 2] + [2, 3, 1] + [3, 1, 2],
```

(continues on next page)
Combinatorics, Release 10.4

[1, 2, 3] + [1, 3, 2] + [2, 3, 1],
[1, 2, 3]]

```python
>>> I = DescentAlgebra(QQ, Integer(3)).I()
>>> [I.to_symmetric_group_algebra_on_basis(c)
...   for c in Compositions(Integer(3))]
[[[1, 2, 3] + [1, 3, 2] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1],
  1/2*[1, 2, 3] - 1/2*[1, 3, 2] + 1/2*[2, 3, 1] + 1/2*[2, 1, 3] - 1/2*[3, 1, 2] - 1/2*[3, 2, 1],
  1/2*[1, 2, 3] + 1/2*[1, 3, 2] - 1/2*[2, 3, 1] - 1/2*[2, 1, 3] + 1/2*[3, 1, 2] - 1/2*[3, 2, 1],
  1/3*[1, 2, 3] - 1/6*[1, 3, 2] - 1/6*[2, 3, 1] + 1/3*[3, 1, 2] - 1/6*[3, 2, 1]])
```

**super_categories()**

The super categories of self.

**EXAMPLES:**

```python
sage: from sage.combinat.descent_algebra import DescentAlgebraBases
sage: DA = DescentAlgebra(QQ, Integer(4))
sage: bases = DescentAlgebraBases(DA)
sage: bases.super_categories()
[Category of finite dimensional algebras with basis over Rational Field, Category of realizations of Descent algebra of 4 over Rational Field]
```

```python
>>> from sage.all import *
>>> from sage.combinat.descent_algebra import DescentAlgebraBases
>>> DA = DescentAlgebra(QQ, Integer(4))
>>> bases = DescentAlgebraBases(DA)
>>> bases.super_categories()
[Category of finite dimensional algebras with basis over Rational Field, Category of realizations of Descent algebra of 4 over Rational Field]
```

### 5.1.74 Combinatorial designs and incidence structures

All designs can be accessed by `designs.<tab>` and are listed in the design catalog:

- **Catalog of designs**

**Design-related classes**

- **Incidence structures** *(i.e. hypergraphs, i.e. set systems)*
- **Covering designs**: coverings of t-element subsets of a v-set by k-sets

**Constructions**

- **Block designs**
- **Balanced Incomplete Block Designs (BIBD)**
- **Resolvable Balanced Incomplete Block Design (RBIBD)**
- **Group-Divisible Designs (GDD)**
- **Mutually Orthogonal Latin Squares (MOLS)**
- **Orthogonal arrays (OA)**
• Orthogonal arrays (build recursive constructions)
• Orthogonal arrays (find recursive constructions)
• Difference families
• Difference Matrices
• Steiner Quadruple Systems
• Two-graphs
• Database of small combinatorial designs
• Database of generalised quadrangles with spread

Technical things
• External Representations of Block Designs
• Cython functions for combinatorial designs
• Hypergraph isomorphic copy search
• Evenly distributed sets in finite fields

5.1.75 Balanced Incomplete Block Designs (BIBD)

This module gathers everything related to Balanced Incomplete Block Designs. One can build a BIBD (or check that it can be built) with `balanced_incomplete_block_design()`:

```sage
sage: BIBD = designs.balanced_incomplete_block_design(7,3,1) # needs sage.schemes
```

```python
>>> from sage.all import *
>>> BIBD = designs.balanced_incomplete_block_design(Integer(7),Integer(3),Integer(1)) # needs sage.schemes
```

In particular, Sage can build a \((v, k, 1)\)-BIBD when one exists for all \(k \leq 5\). The following functions are available:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>balanced_incomplete_block_design()</code></td>
<td>Return a BIBD of parameters (v, k, \lambda).</td>
</tr>
<tr>
<td><code>BIBD_from_TD()</code></td>
<td>Return a BIBD through TD-based constructions.</td>
</tr>
<tr>
<td><code>BIBD_from_difference_family()</code></td>
<td>Return the BIBD associated to the difference family (D) on the group (G).</td>
</tr>
<tr>
<td><code>BIBD_from_PBD()</code></td>
<td>Return a ((v, k, 1))-BIBD from a ((r, K))-PBD where (r = (v - 1)/(k - 1)).</td>
</tr>
<tr>
<td><code>PBD_from_TD()</code></td>
<td>Return a ((kt, {k, t}))-PBD if (u = 0) and a ((kt + u, {k, k + 1, t, u}))-PBD otherwise.</td>
</tr>
<tr>
<td><code>steiner_triple_system()</code></td>
<td>Return a Steiner Triple System.</td>
</tr>
<tr>
<td><code>v_5_1_BIBD()</code></td>
<td>Return a ((v, 5, 1))-BIBD.</td>
</tr>
<tr>
<td><code>v_4_1_BIBD()</code></td>
<td>Return a ((v, 4, 1))-BIBD.</td>
</tr>
<tr>
<td><code>PBD_4_5_8_9_12()</code></td>
<td>Return a ((v, {4, 5, 8, 9, 12}))-PBD on (v) elements.</td>
</tr>
<tr>
<td><code>BIBD_5q_5_for_q_prime_j()</code></td>
<td>Return a ((5q, 5, 1))-BIBD with (q \equiv 1 \pmod{4}) a prime power.</td>
</tr>
</tbody>
</table>

Construction of BIBD when \(k = 4\)

Decompositions of \(K_v\) into \(K_4\) (i.e. \((v, 4, 1)\)-BIBD) are built following Douglas Stinson’s construction as presented in [Stinson2004] page 167. It is based upon the construction of \((v\{4, 5, 8, 9, 12\})\)-PBD (see the doc of
Combining, Release 10.4

Knowing that a \( (v\{4, 5, 8, 9, 12\})\)-PBD on \( v \) points can always be transformed into a \((k - 1)v + 1, 4, 1\)-BIBD, which covers all possible cases of \((v, 4, 1)\)-BIBD.

**Construction of BIBD when \( k = 5 \)**

Decompositions of \( K_v \) into \( K_4 \) (i.e. \((v, 4, 1)\)-BIBD) are built following Clayton Smith’s construction [ClaytonSmith].

**Functions**

`sage.combinat.designs.bibd.BIBD`
alias of `BalancedIncompleteBlockDesign`

`sage.combinat.designs.bibd.BIBD_5q_5_for_q_prime_power(q)`
Return a \((5q, 5, 1)\)-BIBD with \( q \equiv 1 \pmod{4} \) a prime power.

See Theorem 24 [ClaytonSmith].

**INPUT:**

- \( q \) (integer) – a prime power such that \( q \equiv 1 \pmod{4} \).

**EXAMPLES:**

```python
sage: from sage.combinat.designs.bibd import BIBD_5q_5_for_q_prime_power
sage: for q in [25, 45, 65, 85, 125, 145, 185, 205, 305, 405, 605]:  # long time
....:     _ = BIBD_5q_5_for_q_prime_power(q/5)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.bibd import BIBD_5q_5_for_q_prime_power
>>> for q in [Integer(25), Integer(45), Integer(65), Integer(85), Integer(125),
... Integer(145), Integer(185), Integer(205), Integer(305), Integer(405),
... Integer(605)]:  # long time
...     _ = BIBD_5q_5_for_q_prime_power(q/Integer(5))
```

`sage.combinat.designs.bibd.BIBD_from_PBD(PBD, v, k, check=True, base_cases=None)`

Return a \((v, k, 1)\)-BIBD from a \((r, K)\)-PBD where \( r = (v - 1)/(k - 1) \).

This is Theorem 7.20 from [Stinson2004].

**INPUT:**

- \( v, k \) – integers.
- \( PBD \) – A PBD on \( r = (v - 1)/(k - 1) \) points, such that for any block of PBD of size \( s \) there must exist a \((k - 1)s + 1, k, 1\)-BIBD.
- \( check \) (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.
- \( base\_cases \) – caching system, for internal use.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.bibd import PBD_4_5_8_9_12
sage: from sage.combinat.designs.bibd import BIBD_from_PBD
sage: from sage.combinat.designs.bibd import is_pairwise_balanced_design
sage: PBD = PBD_4_5_8_9_12(17)  # needs sage.schemes
sage: bibd = is_pairwise_balanced_design(BIBD_from_PBD(PBD, 52, 4), 52, [4])  # needs sage.schemes
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> from sage.combinat.designs.bibd import PBD_4_5_8_9_12
>>> from sage.combinat.designs.bibd import BIBD_from_PBD
>>> from sage.combinat.designs.bibd import is_pairwise_balanced_design

PBD = PBD_4_5_8_9_12(Integer(17)) # needs sage.schemes

bibd = is_pairwise_balanced_design(BIBD_from_PBD(PBD,Integer(52),Integer(4)),
Integer(52),[Integer(4)]) # needs sage.schemes
```

sage.combinat.designs.bibd.BIBD_from_TD \( (v, k, existence=False) \)

Return a BIBD through TD-based constructions.

**INPUT:**

- \( v, k \) – (integers) computes a \( (v, k, 1) \)-BIBD.
- existence – (boolean) instead of building the design, return:
  - True – meaning that Sage knows how to build the design
  - Unknown – meaning that Sage does not know how to build the design, but that the design may exist (see sage.misc.unknown)
  - False – meaning that the design does not exist

This method implements three constructions:

- If there exists a \( TD(k, v) \) and a \( (v, k, 1) \)-BIBD then there exists a \( (kv, k, 1) \)-BIBD.
  The BIBD is obtained from all blocks of the \( TD \), and from the blocks of the \( (v, k, 1) \)-BIBDs defined over the \( k \) groups of the \( TD \).

- If there exists a \( TD(k, v) \) and a \( (v + 1, k, 1) \)-BIBD then there exists a \( (kv + 1, k, 1) \)-BIBD.
  The BIBD is obtained from all blocks of the \( TD \), and from the blocks of the \( (v + 1, k, 1) \)-BIBDs defined over the sets \( V_1 \cup \infty, ..., V_k \cup \infty \) where the \( V_1, ..., V_k \) are the groups of the TD.

- If there exists a \( TD(k, v) \) and a \( (v + k, k, 1) \)-BIBD then there exists a \( (kv + k, k, 1) \)-BIBD.
  The BIBD is obtained from all blocks of the \( TD \), and from the blocks of the \( (v + k, k, 1) \)-BIBDs defined over the sets \( V_1 \cup \{\infty_1, ..., \infty_k\}, ..., V_k \cup \{\infty_1, ..., \infty_k\} \) where the \( V_1, ..., V_k \) are the groups of the TD.
By making sure that all copies of the \( (v + k, k, 1) \)-BIBD contain the block \( \{\infty_1, ..., \infty_k\} \), the result is also a BIBD.

These constructions can be found in [http://www.argilo.net/files/bibd.pdf](http://www.argilo.net/files/bibd.pdf).

**EXAMPLES:**

First construction:

```python
sage: from sage.combinat.designs.bibd import BIBD_from_TD
sage: BIBD_from_TD(25,5,existence=True) # needs sage.schemes
True
sage: _ = BlockDesign(25,BIBD_from_TD(25,5)) # needs sage.schemes
```

(continues on next page)
Second construction:

```python
sage: from sage.combinat.designs.bibd import BIBD_from_TD
sage: BIBD_from_TD(21,5,existence=True)  # needs sage.schemes
True
sage: _ = BlockDesign(21,BIBD_from_TD(21,5))  # needs sage.schemes
```

Third construction:

```python
sage: from sage.combinat.designs.bibd import BIBD_from_TD
sage: BIBD_from_TD(85,5,existence=True)  # needs sage.schemes
True
sage: _ = BlockDesign(85,BIBD_from_TD(85,5))  # needs sage.schemes
```

No idea:

```python
sage: from sage.combinat.designs.bibd import BIBD_from_TD
sage: BIBD_from_TD(20,5,existence=True)  # needs sage.schemes
Unknown
sage: BIBD_from_TD(20,5)
Traceback (most recent call last):
  ...
NotImplementedError: I do not know how to build a (20,5,1)-BIBD!
```
sage.combinat.designs.bibd.BIBD_from_arc_in_desarguesian_projective_plane\((n, k, \\
existence=False)\)

Return a \((n, k, 1)\)-BIBD from a maximal arc in a projective plane.

This function implements a construction from Denniston [Denniston69], who describes a maximal arc in a Desarguesian Projective Plane of order \(2^k\). From two powers of two \(n, q\) with \(n < q\), it produces a \(((n - 1)(q + 1) + 1, n, 1)\)-BIBD.

**INPUT:**

- \(n, k\) (integers) – must be powers of two (among other restrictions).
- \(existence\) (boolean) – whether to return the BIBD obtained through this construction (default), or to merely indicate with a boolean return value whether this method can build the requested BIBD.

**EXAMPLES:**

A \((232, 8, 1)\)-BIBD:

```python
sage: from sage.combinat.designs.bibd import BIBD_from_arc_in_desarguesian_projective_plane
sage: D = BIBD_from_arc_in_desarguesian_projective_plane(232, 8)
sage: BalancedIncompleteBlockDesign(232, D)
(232, 8, 1)-Balanced Incomplete Block Design
```

A \((120, 8, 1)\)-BIBD:

```python
sage: D = BIBD_from_arc_in_desarguesian_projective_plane(120, 8)
sage: BalancedIncompleteBlockDesign(120, D)
(120, 8, 1)-Balanced Incomplete Block Design
```

Other parameters:

```python
sage: all(BIBD_from_arc_in_desarguesian_projective_plane(n, k, existence=True) \\
....: for n, k in
```

(continues on next page)
\[ \begin{array}{l}
\text{[(120, 8), (232, 8), (456, 8), (904, 8), (496, 16),}
\text{ (976, 16), (1936, 16), (2016, 32), (4000, 32), (8128, 64)]} \\
\text{True}
\end{array} \]

\[
\begin{align*}
\text{>>> from sage.all import *}
\text{>>> all(BIBD_from_arc_in_desarguesian_projective_plane(n,k,existence=True}
\text{... for n,k in ...}
\text{... [(Integer(120), Integer(8)), (Integer(232), Integer(8)), (Integer(456),}
\text{ ... (Integer(8)), (Integer(904), Integer(8)), (Integer(496), Integer(16)),}
\text{ ... (Integer(976), Integer(16)), (Integer(1936), Integer(16)), ...}
\text{ ... (Integer(2016), Integer(32)), (Integer(4000), Integer(32)), (Integer(8128), ...}
\text{ ... (Integer(64))])}
\text{True}
\end{align*}
\]

Of course, not all can be built this way:

\[
\begin{align*}
sage: BIBD_from_arc_in_desarguesian_projective_plane(7,3,existence=True)
\text{False}
\text{sage: BIBD_from_arc_in_desarguesian_projective_plane(7,3)}
\text{Traceback (most recent call last):}
\text{...}
\text{ValueError: This function cannot produce a (7,3,1)-BIBD}
\end{align*}
\]

\[
\begin{align*}
>>> from sage.all import *
\text{>>> BIBD_from_arc_in_desarguesian_projective_plane(Integer(7),Integer(3),}
\text{ ... existence=True)}
\text{False}
\text{>>> BIBD_from_arc_in_desarguesian_projective_plane(Integer(7),Integer(3))}
\text{Traceback (most recent call last):}
\text{...}
\text{ValueError: This function cannot produce a (7,3,1)-BIBD}
\end{align*}
\]

REFERENCE:

\text{sage.combinat.designs.bibd.BIBD_from_difference_family} \((G, D, \lambda={}, \text{check=True})\)

Return the BIBD associated to the difference family \(D\) on the group \(G\).

Let \(G\) be a group. A \((G, k, \lambda)\)-difference family is a family \(B = \{B_1, B_2, \ldots, B_b\}\) of \(k\)-subsets of \(G\) such that for each element of \(G \setminus \{0\}\) there exists exactly \(\lambda\) pairs of elements \((x, y)\), \(x\) and \(y\) belonging to the same block, such that \(x - y = g\) (or \(xy^{-1} = g\) in multiplicative notation).

If \(\{B_1, B_2, \ldots, B_b\}\) is a \((G, k, \lambda)\)-difference family then its set of translates \(\{B_i \cdot g; i \in \{1, \ldots, b\}, g \in G\}\) is a \((v, k, \lambda)\)-BIBD where \(v\) is the cardinality of \(G\).

\text{INPUT:}

- \(G\) – a finite additive Abelian group
- \(D\) – a difference family on \(G\) (short blocks are allowed).
- \(\lambda\) – the \(\lambda\) parameter (optional, only used if \text{check} is \text{True})
- \text{check} – whether or not we check the output (default: \text{True})

\text{EXAMPLES:}

\[
\begin{align*}
sage: G = \text{Zmod}(21)
sage: D = [[0,1,4,14,16]]
\end{align*}
\]
sage: sorted(G(x-y) for x in D[0] for y in D[0] if x != y)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20]

sage: from sage.combinat.designs.bibd import BIBD_from_difference_family

sage: BIBD_from_difference_family(G, D)
[[0, 1, 4, 14, 16],
 [1, 2, 5, 15, 17],

 [17, 18, 0, 10, 12],
 [18, 19, 1, 11, 13],
 [19, 20, 2, 12, 14],
 [20, 0, 3, 13, 15]]
class sage.combinat.designs.bibd.BalancedIncompleteBlockDesign(points, blocks, k=None, lambd=1, check=True, copy=True, **kwds)

Bases: PairwiseBalancedDesign

Balanced Incomplete Block Design (BIBD)

INPUT:

- points -- the underlying set. If points is an integer \( v \), then the set is considered to be \{0, ..., v - 1\}.
- blocks -- collection of blocks
- \( k \) (integer) -- size of the blocks. Set to None (automatic guess) by default.
- \( \lambda \) (integer) -- value of \( \lambda \), set to 1 by default.
- check (boolean) -- whether to check that the design is a \( PBD \) with the right parameters.
- copy -- (use with caution) if set to False then blocks must be a list of lists of integers. The list will not be copied but will be modified in place (each block is sorted, and the whole list is sorted). Your blocks object will become the instance's internal data.

EXAMPLES:

```python
sage: b=designs.balanced_incomplete_block_design(9,3); b
(9,3,1)-Balanced Incomplete Block Design

>>> from sage.all import *

>>> b=designs.balanced_incomplete_block_design(Integer(9),Integer(3)); b
(9,3,1)-Balanced Incomplete Block Design
```

arc(s, solver=2, verbose=None, integrality_tolerance=0)

Return the \( s \)-arc with maximum cardinality.

A \( s \)-arc is a subset of points in a BIBD that intersects each block on at most \( s \) points. It is one possible generalization of independent set for graphs.

A simple counting shows that the cardinality of a \( s \)-arc is at most \((s - 1) \times r + 1\) where \( r \) is the number of blocks incident to any point. A \( s \)-arc in a BIBD with cardinality \((s - 1) \times r + 1\) is called maximal and is characterized by the following property: it is not empty and each block either contains 0 or \( s \) points of this arc. Equivalently, the trace of the BIBD on these points is again a BIBD (with block size \( s \)).

For more informations, see Wikipedia article Arc_(projective_geometry).

INPUT:

- \( s \) -- (default to 2) the maximum number of points from the arc in each block
- solver -- (default: None) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to None, the default one is used. For more information on MILP solvers and which default solver is used, see the method solve of the class MixedIntegerLinearProgram.
- verbose -- integer (default: 0). Sets the level of verbosity. Set to 0 by default, which means quiet.
- integrality_tolerance -- parameter for use with MILP solvers over an inexact base ring; see MixedIntegerLinearProgram.get_values().

EXAMPLES:
```python
sage: # needs sage.schemes
sage: B = designs.balanced_incomplete_block_design(21, 5)
sage: a2 = B.arc(); a2  # random
[5, 9, 10, 12, 15, 20]
sage: len(a2)
6
sage: a4 = B.arc(4); a4  # random
[0, 1, 2, 5, 6, 8, 9, 10, 11, 12, 13, 14, 15, 16, 18, 20]
sage: len(a4)
16
```

The 2-arc and 4-arc above are maximal. One can check that they intersect the blocks in either 0 or \(s\) points. Or equivalently that the traces are again BIBD:

```python
sage: r = (21-1)//(5-1)
sage: 1 + r*1
6
sage: 1 + r*3
16

sage: B.trace(a2).is_t_design(2, return_parameters=True)  # needs sage.schemes
(True, (2, 6, 2, 1))
sage: B.trace(a4).is_t_design(2, return_parameters=True)  # needs sage.schemes
(True, (2, 16, 4, 1))
```

Some other examples which are not maximal:

```python
sage: # needs sage.numerical.mip
sage: B = designs.balanced_incomplete_block_design(25, 4)
```
sage: a2 = B.arc(2)
sage: r = (25-1)//(4-1)
sage: len(a2), 1 + r
(8, 9)
sage: sa2 = set(a2)
sage: set(len(sa2.intersection(b)) for b in B.blocks())
{0, 1, 2}
sage: B.trace(a2).is_t_design(2)
False

sage: # needs sage.numerical.mip
sage: a3 = B.arc(3)
sage: len(a3), 1 + 2*r
(15, 17)
sage: sa3 = set(a3)
sage: set(len(sa3.intersection(b)) for b in B.blocks()) == set([0,3])
False
sage: B.trace(a3).is_t_design(3)
False

>>> from sage.all import *
>>> # needs sage.numerical.mip
>>> B = designs.balanced_incomplete_block_design(Integer(25), Integer(4))
>>> a2 = B.arc(Integer(2))
>>> r = (Integer(25)-Integer(1))//(Integer(4)-Integer(1))
>>> len(a2), Integer(1) + r
(8, 9)
>>> sa2 = set(a2)
>>> set(len(sa2.intersection(b)) for b in B.blocks())
{0, 1, 2}
>>> B.trace(a2).is_t_design(Integer(2))
False

>>> # needs sage.numerical.mip
>>> a3 = B.arc(Integer(3))
>>> len(a3), Integer(1) + Integer(2)*r
(15, 17)
>>> sa3 = set(a3)
>>> set(len(sa3.intersection(b)) for b in B.blocks()) == set([Integer(0),
-Integer(3)])
False
>>> B.trace(a3).is_t_design(Integer(3))
False

sage.combinat.designs.bibd.BruckRyserChowla_check(v, k, lambda)
Check whether the parameters passed satisfy the Bruck-Ryser-Chowla theorem.
For more information on the theorem, see the corresponding Wikipedia entry.

INPUT:

• v, k, lambda – integers; parameters to check

OUTPUT:

• True – the parameters satisfy the theorem
• False – the theorem fails for the given parameters
• Unknown – the preconditions of the theorem are not met

EXAMPLES:
sage: from sage.combinat.designs.bibd import BruckRyserChowla_check sage: BruckRyserChowla_check(22,7,2) False
Nonexistence of projective planes of order 6 and 14
sage: from sage.combinat.designs.bibd import BruckRyserChowla_check sage: BruckRyserChowla_check(43,7,1)# needs sage.schemes False sage: BruckRyserChowla_check(211,15,1)# needs sage.schemes False
Existence of symmetric BIBDs with parameters (79, 13, 2) and (56, 11, 2)
sage: from sage.combinat.designs.bibd import BruckRyserChowla_check sage: BruckRyserChowla_check(79,13,2)# needssage.schemes Truesage: BruckRyserChowla_check(56,11,2) True

combatant.d designs.bibd.PBD_4_5_8_9_12(v, check=True)
Returna\( (v, \{4, 5, 8, 9, 12\})\)-PBD on \(v\) elements.
A \( (v, \{4, 5, 8, 9, 12\})\)-PBD exists if and only if \(v \equiv 0, 1 \pmod{4}\). The construction implemented here appears page 168 in [Stinson2004].

INPUT:
• \(v\) – an integer congruent to 0 or 1 modulo 4.
• check (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

EXAMPLES:
sage: designs.balanced_incomplete_block_design(40,4).blocks() # indirect doctest...
  # needs sage.schemes
[[0, 1, 2, 12], [0, 3, 6, 9], [0, 4, 8, 10],
 [0, 5, 7, 11], [0, 13, 26, 39], [0, 14, 25, 28],
 [0, 15, 27, 38], [0, 16, 22, 32], [0, 17, 23, 34], ...

>>> from sage.all import *
>>> designs.balanced_incomplete_block_design(Integer(40),Integer(4)).blocks() #...
  # indirect doctest # needs sage.schemes
[[0, 1, 2, 12], [0, 3, 6, 9], [0, 4, 8, 10],
 [0, 5, 7, 11], [0, 13, 26, 39], [0, 14, 25, 28],
 [0, 15, 27, 38], [0, 16, 22, 32], [0, 17, 23, 34], ...

Check that Issue #16476 is fixed:
sage: from sage.combinat.designs.bibd import PBD_4_5_8_9_12
sage: for v in (0,1,4,5,8,9,12,13,16,17,20,21,24,25): #...
  # needs sage.schemes
  ....: _ = PBD_4_5_8_9_12(v)

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
from sage.combinat.designs.bibd import PBD_from_TD

PBD_from_TD(k, t, u)
```

Return a \((k, \{k, t\})\)-PBD if \(u = 0\) and a \((kt + u, \{k, k + 1, t, u\})\)-PBD otherwise.

This is theorem 23 from [ClaytonSmith]. The PBD is obtained from the blocks a truncated \(TD(k + 1, t)\), to which are added the blocks corresponding to the groups of the TD. When \(u = 0\), a \(TD(k, t)\) is used instead.

**INPUT:**

- \(k, t, u\) – integers such that \(0 \leq u \leq t\).

**EXAMPLES:**

```python
sage: from sage.combinat.designs.bibd import PBD_from_TD
sage: PBD = PBD_from_TD(2, 2, 1); PBD
[[0, 2, 4], [0, 3], [1, 2], [1, 3, 4], [0, 1], [2, 3]]
sage: is_pairwise_balanced_design(PBD, 2*2+1, [2, 3])
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.bibd import PBD_from_TD
>>> PBD = PBD_from_TD(Integer(2), Integer(2), Integer(1)); PBD
[[0, 2, 4], [0, 3], [1, 2], [1, 3, 4], [0, 1], [2, 3]]
>>> is_pairwise_balanced_design(PBD, Integer(2)*Integer(2)+Integer(1), [Integer(2), Integer(3)])
True
```

class sage.combinat.designs.bibd.PairwiseBalancedDesign

```
PairwiseBalancedDesign(points, blocks, K=None, lambd=1, check=True, copy=True, **kwds)
```

**Bases:** `GroupDivisibleDesign`

**Pairwise Balanced Design (PBD)**

A Pairwise Balanced Design, or \((v, K, \lambda)\)-PBD, is a collection \(\mathcal{B}\) of blocks defined on a set \(X\) of size \(v\), such that any block pair of points \(p_1, p_2 \in X\) occurs in exactly \(\lambda\) blocks of \(\mathcal{B}\). Besides, for every block \(B \in \mathcal{B}\) we must have \(|B| \in K\).

**INPUT:**

- **points** – the underlying set. If **points** is an integer \(v\), then the set is considered to be \(\{0, \ldots, v - 1\}\).
- **blocks** – collection of blocks
- **K** – list of integers of which the sizes of the blocks must be elements. Set to None (automatic guess) by default.
- **lambd** (integer) – value of \(\lambda\), set to 1 by default.
- **check** (boolean) – whether to check that the design is a PBD with the right parameters.
- **copy** (use with caution) if set to False then **blocks** must be a list of lists of integers. The list will not be copied but will be modified in place (each block is sorted, and the whole list is sorted). Your **blocks** object will become the instance's internal data.
Return a BIBD of parameters \(v, k, \lambda\).

A Balanced Incomplete Block Design of parameters \(v, k, \lambda\) is a collection \(\mathcal{C}\) of \(k\)-subsets of \(V = \{0, \ldots, v-1\}\) such that for any two distinct elements \(x, y \in V\) there are \(\lambda\) elements \(S \in \mathcal{C}\) such that \(x, y \in S\).

For more information on BIBD, see the corresponding Wikipedia entry.

INPUT:

- \(v, k, \lambda\) – integers
- \(\text{existence} \) (boolean) – instead of building the design, return:
  - True – meaning that Sage knows how to build the design
  - Unknown – meaning that Sage does not know how to build the design, but that the design may exist (see sage.misc.unknown).
  - False – meaning that the design does not exist.
- \(\text{use\_LJCR} \) (boolean) – whether to query the La Jolla Covering Repository for the design when Sage does not know how to build it (see best_known_covering_design_www()). This requires internet.

See also:

- steiner_triple_system()
- v_4_1_BIBD()
- v_5_1_BIBD()

Todo: Implement other constructions from the Handbook of Combinatorial Designs.

EXAMPLES:

```python
sage: designs.balanced_incomplete_block_design(7, 3, 1).blocks()  # needs sage.schemes
[[0, 1, 3], [0, 2, 4], [0, 5, 6], [1, 2, 6], [1, 4, 5], [2, 3, 5], [3, 4, 6]]
```

```python
sage: B = designs.balanced_incomplete_block_design(66, 6, 1, use_LJCR=True)  # optional -= internet
sage: B  # optional -= internet
(66,6,1)-Balanced Incomplete Block Design
sage: B.blocks()  # optional -= internet
[[0, 1, 2, 3, 4, 65], [0, 5, 22, 32, 38, 58], [0, 6, 21, 30, 43, 48], ...]
```

```python
sage: designs.balanced_incomplete_block_design(216, 6, 1)  # optional -= internet
Traceback (most recent call last):
  ... Not Implemented Error: I don't know how to build a (216,6,1)-BIBD!
```

```python
>>> from sage.all import *
>>> designs.balanced_incomplete_block_design(Integer(7), Integer(3), Integer(1)).blocks()  # needs sage.schemes
[[0, 1, 3], [0, 2, 4], [0, 5, 6], [1, 2, 6], [1, 4, 5], [2, 3, 5], [3, 4, 6]]
```

sage.combinat.designs.bibd.biplane(n, existence=False)

Return a biplane of order $n$.

A biplane of order $n$ is a symmetric $(1 + \frac{(n+1)(n+2)}{2}, n+2, 2)$-BIBD. A symmetric (or square) $(v, k, \lambda)$-BIBD is a $(v, k, \lambda)$-BIBD with $v$ blocks.

INPUT:

- $n$ – (integer) order of the biplane
- existence (boolean) – instead of building the design, return:
  - True – meaning that Sage knows how to build the design
  - Unknown – meaning that Sage does not know how to build the design, but that the design may exist (see sage.misc.unknown).
  - False – meaning that the design does not exist.

See also:

- balanced_incomplete_block_design()

EXAMPLES:

```python
sage: designs.biplane(4)  # needs sage.rings.finite_rings
(16,6,2)-Balanced Incomplete Block Design
sage: designs.biplane(7, existence=True)  # needs sage.schemes
True
sage: designs.biplane(11)  # needs sage.schemes
(79,13,2)-Balanced Incomplete Block Design
```
A Steiner Triple System (STS) of a set \( \{0, \ldots, n-1\} \) is a family \( S \) of 3-sets such that for any \( i \neq j \) there exists exactly one set of \( S \) in which they are both contained.

It can alternatively be thought of as a factorization of the complete graph \( K_n \) with triangles.

A Steiner Triple System of a \( n \)-set exists if and only if \( n \equiv 1 \pmod{6} \) or \( n \equiv 3 \pmod{6} \), in which case one can be found through Bose's and Skolem's constructions, respectively [AndHonk97].

**INPUT:**

- \( n \) return a Steiner Triple System of \( \{0, \ldots, n-1\} \)

**EXAMPLES:**

A Steiner Triple System on 9 elements

\[
\text{sage: } \text{sts} = \text{designs.steiner_triple_system}(9) \\
\text{sage: } \text{sts} \\
(9,3,1)-\text{Balanced Incomplete Block Design} \\
\text{sage: } \text{list(sts)} \\
[[0, 1, 5], [0, 2, 4], [0, 3, 6], [0, 7, 8], [1, 2, 3], [1, 4, 7], [1, 6, 8], [2, 5, 8], [2, 6, 7], [3, 4, 8], [3, 5, 7], [4, 5, 6]]
\]

As any pair of vertices is covered once, its parameters are

\[
\text{sage: } \text{sts.is_t_design(return_parameters=True)} \\
(\text{True}, (2, 9, 3, 1))
\]

An exception is raised for invalid values of \( n \)

\[
\text{sage: } \text{designs.steiner_triple_system(10)} \\
\text{Traceback (most recent call last):} \\
\text{...} \\
\text{EmptySetError: } \text{Steiner triple systems only exist for } n = 1 \text{ mod } 6 \text{ or } n = 3 \text{ mod } 6
\]

\[
\text{>>> from sage.all import *} \\
\text{>>> sts = designs.steiner_triple_system(Integer(10))} \\
\text{Traceback (most recent call last):} \\
\text{...} \\
\text{EmptySetError: } \text{Steiner triple systems only exist for } n = 1 \text{ mod } 6 \text{ or } n = 3 \text{ mod } 6
\]
EmptySetError: Steiner triple systems only exist for n = 1 mod 6 or n = 3 mod 6

REFERENCE:
sage.combinat.designs.bibd.v_4_1_BIBD(v, check=True)

Return a \((v, 4, 1)\)-BIBD.

A \((v, 4, 1)\)-BIBD is an edge-decomposition of the complete graph \(K_v\) into copies of \(K_4\). For more information, see balanced_incomplete_block_design(). It exists if and only if \(v \equiv 1, 4 \pmod{12}\).

See page 167 of [Stinson2004] for the construction details.

See also:

- balanced_incomplete_block_design()

INPUT:

- \(v\) (integer) – number of points.
- check (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

EXAMPLES:

```python
sage: from sage.combinat.designs.bibd import v_4_1_BIBD # long time
sage: for n in range(13,100): # long time
....:   if n%12 in [1,4]:
....:     _ = v_4_1_BIBD(n, check = True)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.bibd import v_4_1_BIBD # long time
>>> for n in range(Integer(13),Integer(100)):
    # long...
  if n%Integer(12) in [Integer(1),Integer(4)]:
    _ = v_4_1_BIBD(n, check = True)
```

sage.combinat.designs.bibd.v_5_1_BIBD(v, check=True)

Return a \((v, 5, 1)\)-BIBD.

This method follows the construction from [ClaytonSmith].

INPUT:

- \(v\) (integer)

See also:

- balanced_incomplete_block_design()

EXAMPLES:

```python
sage: from sage.combinat.designs.bibd import v_5_1_BIBD
sage: i = 0
sage: while i<200:
    #...
```
5.1.76 Resolvable Balanced Incomplete Block Design (RBIBD)

This module contains everything related to resolvable Balanced Incomplete Block Designs. The constructions implemented here can be obtained through the `designs.<tab>` object:

```python
from sage.combinat.designs.resolvable_bibd import v_5_1_BIBD
```

For Balanced Incomplete Block Design (BIBD) see the module `bibd`. A BIBD is said to be resolvable if its blocks can be partitioned into parallel classes, i.e. partitions of its ground set.

The main function of this module is `resolvable_balanced_incomplete_block_design()`, which calls all others.

```python
resolvable_balanced_incomplete_block_design()  # Return a resolvable BIBD of parameters v, k.
kirkman_triplet_system()  # Return a Kirkman Triple System on v points.
v_4_1_rbibd()  # Return a (v, 4, 1)-RBIBD
PBD_4_7()  # Return a (v, {4, 7})-PBD
PBD_4_7_from_Y()  # Return a (3v + 1, {4, 7})-PBD from a (v, {4, 5, 7}, N = {3, 6, 10})-GDD.
```

References:

Functions

```python
sage.combinat.designs.resolvable_bibd.PBD_4_7(v, check=True, existence=False)
```

Return a (v, {4, 7})-PBD

For all \( v \) such that \( n \equiv 1 \pmod{3} \) and \( n \neq 10, 19, 31 \) there exists a \((v, \{4, 7\})\)-PBD. This is proved in Proposition IX.4.5 from [BJL99], which this method implements.

This construction of PBD is used by the construction of Kirkman Triple Systems.

EXAMPLES:

```python
sage: from sage.combinat.designs.resolvable_bibd import PBD_4_7
sage: PBD_4_7(22)
```
Pairwise Balanced Design on 22 points with sets of sizes in \([4, 7]\).
```python
>>> from sage.all import *
>>> from sage.combinat.designs.resolvable_bibd import PBD_4_7
>>> PBD_4_7(Integer(22))
Pairwise Balanced Design on 22 points with sets of sizes in [4, 7]
```

`sage.combinat.designs.resolvable_bibd.PBD_4_7_from_Y(gdd, check=True)`

Return a \((3v+1, \{4,7\})\)-PBD from a \((v, \{4,5,7\}, N-\{3,6,10\})\)-GDD.

This implements Lemma IX.3.11 from [BJL99] (p.625). All points of the GDD are tripled, and a \(+\infty\) point is added to the design.

- A group of size \(s \in Y = N-\{3,6,10\}\) becomes a set of size \(3s\). Adding \(+\infty\) to it gives it size \(3s+1\), and this set is then replaced by a \((3s+1, \{4,7\})\)-PBD.

- A block of size \(s \in \{4,5,7\}\) becomes a \((3s, \{4,7\}, \{3\})\)-GDD.

This lemma is part of the existence proof of \((v, \{4,7\})\)-PBD as explained in IX.4.5 from [BJL99]).

**INPUT:**

- `gdd` – a \((v, \{4,5,7\}, Y)\)-GDD where \(Y = N-\{3,6,10\}\).

- `check` – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.resolvable_bibd import PBD_4_7_from_Y
sage: PBD_4_7_from_Y(designs.transversal_design(7,8)) # needs sage.schemes
Pairwise Balanced Design on 169 points with sets of sizes in [4, 7]
```

`sage.combinat.designs.resolvable_bibd.kirkman_triple_system(v, existence=False)`

Return a Kirkman Triple System \(KTS(v)\) on \(v\) points.

A Kirkman Triple System \(KTS(v)\) is a resolvable Steiner Triple System. It exists if and only if \(v \equiv 3 \pmod{6}\).

**INPUT:**

- `n` (integer)

- `existence` (boolean; False by default) – whether to build the \(KTS(n)\) or only answer whether it exists.

**See also:**

`IncidenceStructure.is_resolvable()`

**EXAMPLES:**

A solution to Kirkman’s original problem:

```python
sage: kts = designs.kirkman_triple_system(15)
sage: classes = kts.is_resolvable(1)[1]
sage: names = '0123456789abcdef'
sage: def to_name(r_s_t):
```
....: r, s, t = r_s_t
....: return ' ' + names[r] + names[s] + names[t] + ' '
sage: rows = [' '.join((Day{}.format(i) for i in range(1, 8)))
for i in range(1, 8))]
sage: rows.extend(' '.join(map(to_name, row)) for i in range(1, 8))
sage: print('
'.join(rows))
Day 1  Day 2  Day 3  Day 4  Day 5  Day 6  Day 7
07e  18e  29e  3ae  4be  5ce  6de
139  24a  35b  46c  05d  167  028
26b  03c  14d  257  368  049  15a
458  569  06a  01b  12c  23d  347
acd  7bd  78c  89d  79a  8ab  9bc

>>> from sage.all import *
>>> kts = designs.kirkman_triple_system(Integer(15))
>>> classes = kts.is_resolvable(Integer(1))[Integer(1)]
>>> names = '0123456789abcdef'
>>> def to_name(r_s_t):
>>> r, s, t = r_s_t
>>> return ' ' + names[r] + names[s] + names[t] + ' '
>>> rows = [' '.join((Day{}.format(i) for i in range(1, 8)))
for i in range(1, 8))]
>>> rows.extend(' '.join(map(to_name, row)) for i in range(1, 8))
>>> print('
'.join(rows))
Day 1  Day 2  Day 3  Day 4  Day 5  Day 6  Day 7
07e  18e  29e  3ae  4be  5ce  6de

458  569  06a  01b  12c  23d  347
acd  7bd  78c  89d  79a  8ab  9bc

sage.combinat.designs.resolvable_bibd.resolvable_balanced_incomplete_block_design(v, k, existence=False)

Return a resolvable BIBD of parameters v, k.

A BIBD is said to be resolvable if its blocks can be partitioned into parallel classes, i.e. partitions of the ground set.

INPUT:

• v, k (integers)
• existence (boolean) – instead of building the design, return:
  • True – meaning that Sage knows how to build the design
  • Unknown – meaning that Sage does not know how to build the design, but that the design may exist (see sage.misc.unknown).
  • False – meaning that the design does not exist.

See also:

• IncidenceStructure.is_resolvable()
• balanced_incomplete_block_design()
EXAMPLES:

```python
sage: KTS15 = designs.resolvable_balanced_incomplete_block_design(15,3); KTS15
(15,3,1)-Balanced Incomplete Block Design
sage: KTS15.is_resolvable()
True
```

```python
>>> from sage.all import *
>>> KTS15 = designs.resolvable_balanced_incomplete_block_design(Integer(15),
Integer(3)); KTS15
(15,3,1)-Balanced Incomplete Block Design
>>> KTS15.is_resolvable()
True
```

```python
sage.combinat.designs.resolvable_bibd.v_4_1_rbibd(v, existence=False)
Return a \((v,4,1)\)-RBIBD.

INPUT:

- \(n\) (integer)
- \(existence\) (boolean; False by default) – whether to build the design or only answer whether it exists.

See also:

- `IncidenceStructure.is_resolvable()`
- `resolvable_balanced_incomplete_block_design()`

Note: A resolvable \((v,4,1)\)-BIBD exists whenever \(1 \equiv 4 \pmod{12}\). This function, however, only implements a construction of \((v,4,1)\)-BIBD such that \(v = 3q + 1 \equiv 1 \pmod{3}\) where \(q\) is a prime power (see VII.7.5.a from [BIL99]).

EXAMPLES:

```python
sage: rBIBD = designs.resolvable_balanced_incomplete_block_design(28,4)
sage: rBIBD.is_resolvable()
True
sage: rBIBD.is_t_design(return_parameters=True)
(True, (2, 28, 4, 1))
```

```python
>>> from sage.all import *
>>> rBIBD = designs.resolvable_balanced_incomplete_block_design(Integer(28),
Integer(4))
>>> rBIBD.is_resolvable()
True
>>> rBIBD.is_t_design(return_parameters=True)
(True, (2, 28, 4, 1))
```
5.1.77 Group-Divisible Designs (GDD)

This module gathers everything related to Group-Divisible Designs. The constructions defined here can be accessed through `designs`:

```
sage: designs.group_divisible_design(14, {4}, {2})
Group Divisible Design on 14 points of type 2^7
```

The main function implemented here is `group_divisible_design()` (which calls all others) and the main class is `GroupDivisibleDesign`. The following functions are available:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>group_divisible_design()</code></td>
<td>Return a $(v, K, G)$-Group Divisible Design.</td>
</tr>
<tr>
<td><code>GDD_4_2()</code></td>
<td>Return a $(2q, {4}, {2})$-GDD for $q$ a prime power with $q \equiv 1 \pmod{6}$.</td>
</tr>
</tbody>
</table>

**Functions**

```
sage.combinat.designs.group_divisible_designs.GDD_4_2(q, existence=False, check=True)
```

Return a $(2q, \{4\}, \{2\})$-GDD for $q$ a prime power with $q \equiv 1 \pmod{6}$.

This method implements Lemma VII.5.17 from [BJL99] (p.495).

**INPUT:**

- $q$ (integer)
- `existence` (boolean) – instead of building the design, return:
  - `True` – meaning that Sage knows how to build the design
  - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`).
  - `False` – meaning that the design does not exist.
- `check` (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `True` by default.

**EXAMPLES:**

```
sage: from sage.combinat.designs.group_divisible_designs import GDD_4_2
sage: GDD_4_2(7, existence=True)
True
sage: GDD_4_2(7)
Group Divisible Design on 14 points of type 2^7
sage: GDD_4_2(8, existence=True)
Unknown
sage: GDD_4_2(8)
Traceback (most recent call last):

NotImplementedError
```

class sage.combinat.designs.group_divisible_designs.GroupDivisibleDesign(points, groups, blocks, G=None, K=None, lambda=1, check=True, copy=True, **kwds)

Bases: IncidenceStructure

Group Divisible Design (GDD)

Let $K$ and $G$ be sets of positive integers and let $\lambda$ be a positive integer. A Group Divisible Design of index $\lambda$ and order $v$ is a triple $(V, G, B)$ where:

- $V$ is a set of cardinality $v$
- $G$ is a partition of $V$ into groups whose size belongs to $G$
- $B$ is a family of subsets of $V$ whose size belongs to $K$ such that any two points $p_1, p_2 \in V$ from different groups appear simultaneously in exactly $\lambda$ elements of $B$. Besides, a group and a block intersect on at most one point.

If $K = \{k_1, \ldots, k_l\}$ and $G$ has exactly $m_i$ groups of cardinality $k_i$, then $G$ is said to have type $k_1^{m_1} \ldots k_l^{m_l}$.

INPUT:

- **points** – the underlying set. If **points** is an integer $v$, then the set is considered to be $\{0, \ldots, v - 1\}$.
- **groups** – the groups of the design. Set to **None** for an automatic guess (this triggers **check=True** and can thus cost some time).
- **blocks** – collection of blocks
- **G** – list of integers of which the sizes of the groups must be elements. Set to **None** (automatic guess) by default.
- **K** – list of integers of which the sizes of the blocks must be elements. Set to **None** (automatic guess) by default.
- **lambda** (integer) – value of $\lambda$, set to 1 by default.
- **check** (boolean) – whether to check that the design is indeed a $GDD$ with the right parameters. Set to **True** by default.
- **copy** – (use with caution) if set to **False** then **blocks** must be a list of lists of integers. The list will not be copied but will be modified in place (each block is sorted, and the whole list is sorted). Your **blocks** object will become the instance’s internal data.
EXAMPLES:

```python
sage: from sage.combinat.designs.group_divisible_designs import GroupDivisibleDesign
sage: TD = designs.transversal_design(4,10)
```

```python
sage: groups = [list(range(i*10,(i+1)*10)) for i in range(4)]
sage: GDD = GroupDivisibleDesign(40,groups,TD); GDD
Group Divisible Design on 40 points of type 10^4
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.group_divisible_designs import GroupDivisibleDesign
>>>
>>> TD = designs.transversal_design(Integer(4),Integer(10))
```n
```python
>>> groups = [list(range(i*Integer(10),(i+Integer(1))*Integer(10))) for i in range(Integer(4))]
```n
```python
>>> GDD = GroupDivisibleDesign(Integer(40),groups,TD); GDD
Group Divisible Design on 40 points of type 10^4
```

With unspecified groups:

```python
sage: # needs sage.schemes
sage: D = designs.transversal_design(4,3).relabel(list('abcdefghiklm'), inplace=False).blocks()
```

```python
sage: GDD = GroupDivisibleDesign('abcdefghiklm',None,D)
sage: sorted(GDD.groups())
[['a', 'b', 'c'], ['d', 'e', 'f'], ['g', 'h', 'i'], ['k', 'l', 'm']]
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.group_divisible_designs import GroupDivisibleDesign
```n
```python
>>> TD = designs.transversal_design(Integer(4),Integer(3)).relabel(list('abcdefghiklm'),inplace=False).blocks()
```n
```python
>>> GDD = GroupDivisibleDesign('abcdefghiklm',None,D)
```n
```python
>>> sorted(GDD.groups())
[['a', 'b', 'c'], ['d', 'e', 'f'], ['g', 'h', 'i'], ['k', 'l', 'm']]
```

`groups()`

Return the groups of the Group-Divisible Design.

EXAMPLES:

```python
sage: from sage.combinat.designs.group_divisible_designs import GroupDivisibleDesign
sage: TD = designs.transversal_design(4,10)
```

```python
sage: groups = [list(range(i*10,(i+1)*10)) for i in range(4)]
sage: GDD = GroupDivisibleDesign(40,groups,TD); GDD
Group Divisible Design on 40 points of type 10^4
```

```python
sage: GDD.groups()
[[0, 1, 2, 3, 4, 5, 6, 7, 8, 9],
 [10, 11, 12, 13, 14, 15, 16, 17, 18, 19],
 [20, 21, 22, 23, 24, 25, 26, 27, 28, 29],
 [30, 31, 32, 33, 34, 35, 36, 37, 38, 39]]
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.group_divisible_designs import GroupDivisibleDesign
>>> TD = designs.transversal_design(Integer(4),Integer(10))
```n
```python
>>> groups = [list(range(i*Integer(10),(i+Integer(1))*Integer(10))) for i in range(Integer(4))]
```
GDD = GroupDivisibleDesign(Integer(40), groups, TD); GDD
Group Divisible Design on 40 points of type 10^4
>>>
GDD.groups()
[[0, 1, 2, 3, 4, 5, 6, 7, 8, 9],
 [10, 11, 12, 13, 14, 15, 16, 17, 18, 19],
 [20, 21, 22, 23, 24, 25, 26, 27, 28, 29],
 [30, 31, 32, 33, 34, 35, 36, 37, 38, 39]]

sage.combinat.designs.group_divisible_designs.group_divisible_design(v, K, G, existence=False, check=False)

Return a \((v, K, G)\)-Group Divisible Design.

A \((v, K, G)\)-GDD is a pair \((\mathcal{G}, \mathcal{B})\) where:
- \(\mathcal{G}\) is a partition of \(X = \bigcup \mathcal{G}\) where \(|X| = v\)
- \(\forall S \in \mathcal{G}, |S| \in G\)
- \(\forall S \in \mathcal{B}, |S| \in K\)
- \(\mathcal{G} \cup \mathcal{B}\) is a \((v, K \cup G)\)-PBD

For more information, see the documentation of GroupDivisibleDesign or PairwiseBalancedDesign.

INPUT:
- \(v\) (integer)
- \(K, G\) (sets of integers)
- \(existence\) (boolean) – instead of building the design, return:
  - \(True\) – meaning that Sage knows how to build the design
  - \(Unknown\) – meaning that Sage does not know how to build the design, but that the design may exist (see sage.misc.unknown).
  - \(False\) – meaning that the design does not exist.
- \(check\) – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

Note: The GDD returned by this function are defined on \(\text{range}(v)\), and its groups are sets of consecutive integers.

EXAMPLES:

sage: designs.group_divisible_design(14, {4}, {2})
Group Divisible Design on 14 points of type 2^7

>>> from sage.all import *
>>> designs.group_divisible_design(Integer(14), {Integer(4)}, {Integer(2)})
Group Divisible Design on 14 points of type 2^7
## 5.1.78 Block designs

A block design is a set together with a family of subsets (repeated subsets are allowed) whose members are chosen to satisfy some set of properties that are deemed useful for a particular application. See Wikipedia article Block_design.

- Vincent Delecroix (2014): rewrite the part on projective planes Issue #16281
- Peter Dobcsanyi and David Joyner (2007-2008)

This is a significantly modified form of the module block_design.py (version 0.6) written by Peter Dobcsanyi peter@designtheory.org. Thanks go to Robert Miller for lots of good design suggestions.

### Todo:
Implement more finite non-Desarguesian plane as in [We07] and Wikipedia article Non-Desarguesian_plan.

### Functions and methods

**sage.combinat.designs.block_design.AffineGeometryDesign** (*n, d, F, point_coordinates=True, check=True*)

Return an affine geometry design.

The affine geometry design $AG_d(n,q)$ is the 2-design whose blocks are the $d$-vector subspaces in $F^n_q$. It has parameters

$$v = q^n, \quad k = q^d, \quad \lambda = \binom{n-1}{d-1}_q$$

where the $q$-binomial coefficient $\binom{m}{r}_q$ is defined by

$$\binom{m}{r}_q = \frac{(q^m - 1)(q^{m-1} - 1)\cdots(q^{m-r+1} - 1)}{(q^r - 1)(q^{r-1} - 1)\cdots(q - 1)}$$

**See also:**

**ProjectiveGeometryDesign()**

**INPUT:**
- *n* (integer) – the Euclidean dimension. The number of points of the design is $v = |F^n_q|$.
- *d* (integer) – the dimension of the (affine) subspaces of $F^n_q$ which make up the blocks.
- *F* – a finite field or a prime power.
- *point_coordinates* – (default: True) whether we use coordinates in $F^n_q$ or plain integers for the points of the design.
- *check* – (default: True) whether to check the output.

**EXAMPLES:**
Combinatorics, Release 10.4

```
sage: # needs sage.combinat
sage: BD = designs.AffineGeometryDesign(3, 1, GF(2))
sage: BD.is_t_design(return_parameters=True)
(True, (2, 8, 2, 1))
sage: BD = designs.AffineGeometryDesign(3, 2, GF(4))
sage: BD.is_t_design(return_parameters=True)
(True, (2, 64, 16, 5))
sage: BD = designs.AffineGeometryDesign(4, 2, GF(3))
sage: BD.is_t_design(return_parameters=True)
(True, (2, 81, 9, 13))
```

With $F$ an integer instead of a finite field:

```
sage: BD = designs.AffineGeometryDesign(Integer(3), Integer(1), GF(Integer(2)))
sage: BD.is_t_design(return_parameters=True)
(True, (2, 8, 2, 1))
sage: BD = designs.AffineGeometryDesign(Integer(3), Integer(2), GF(Integer(4)))
sage: BD.is_t_design(return_parameters=True)
(True, (2, 64, 16, 5))
```

Testing the option `point_coordinates`:

```
sage: designs.AffineGeometryDesign(3, 1, GF(2),
.....:    point_coordinates=True).blocks()[0]
[(0, 0, 0), (0, 0, 1)]
sage: designs.AffineGeometryDesign(3, 1, GF(2),
.....:    point_coordinates=False).blocks()[0]
[0, 1]
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> BD = designs.AffineGeometryDesign(Integer(3), Integer(1), GF(Integer(2))
...:    point_coordinates=True).blocks()[Integer(0)]
>>> BD = designs.AffineGeometryDesign(Integer(3), Integer(2), GF(Integer(4))
...:    point_coordinates=True).blocks()[Integer(0)]
```

```
sage.combinat.designs.block_design.CremonaRichmondConfiguration()
Return the Cremona-Richmond configuration.
```

The Cremona-Richmond configuration is a set system whose incidence graph is equal to the `TutteCoxeterGraph()`. It is a generalized quadrangle of parameters $(2, 2)$. 

952 Chapter 5. Comprehensive Module List
For more information, see the Wikipedia article Cremona-Richmond_configuration.

EXAMPLES:

```python
sage: H = designs.CremonaRichmondConfiguration(); H
#...
needs networkx
Incidence structure with 15 points and 15 blocks
sage: g = graphs.TutteCoxeterGraph()
#...
needs networkx
sage: H.incidence_graph().is_isomorphic(g)
#...
needs networkx
True
```

```python
>>> from sage.all import *

>>> H = designs.CremonaRichmondConfiguration(); H
#...
needs networkx
Incidence structure with 15 points and 15 blocks
>>> g = graphs.TutteCoxeterGraph()
#...
needs networkx
>>> H.incidence_graph().is_isomorphic(g)
#...
needs networkx
True
```

sage.combinat.designs.block_design.DesarguesianProjectivePlaneDesign(n, point_coordinates=True, check=True)

Return the Desarguesian projective plane of order $n$ as a 2-design.

The Desarguesian projective plane of order $n$ can also be defined as the projective plane over a field of order $n$.

For more information, have a look at Wikipedia article Projective_plane.

INPUT:

- $n$ – an integer which must be a power of a prime number
- point_coordinates – (boolean) whether to label the points with their homogeneous coordinates (default) or with integers.
- check – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

ProjectiveGeometryDesign()

EXAMPLES:

```python
sage: designs.DesarguesianProjectivePlaneDesign(2)
(7,3,1)-Balanced Incomplete Block Design
sage: designs.DesarguesianProjectivePlaneDesign(3)
(13,4,1)-Balanced Incomplete Block Design
sage: designs.DesarguesianProjectivePlaneDesign(4)
(21,5,1)-Balanced Incomplete Block Design
sage: designs.DesarguesianProjectivePlaneDesign(5)
(31,6,1)-Balanced Incomplete Block Design
sage: designs.DesarguesianProjectivePlaneDesign(6)
Traceback (most recent call last):
... ValueError: the order of a finite field must be a prime power
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> designs.DesarguesianProjectivePlaneDesign(Integer(2))
(7,3,1)-Balanced Incomplete Block Design
>>> designs.DesarguesianProjectivePlaneDesign(Integer(3))
(13,4,1)-Balanced Incomplete Block Design
>>> designs.DesarguesianProjectivePlaneDesign(Integer(4))
(21,5,1)-Balanced Incomplete Block Design
>>> designs.DesarguesianProjectivePlaneDesign(Integer(5))
(31,6,1)-Balanced Incomplete Block Design
>>> designs.DesarguesianProjectivePlaneDesign(Integer(6))
Traceback (most recent call last):
  ... ValueError: the order of a finite field must be a prime power
```

sage.combinat.designs.block_design.Hadamard3Design(n)

Return the Hadamard 3-design with parameters \(3 - (n, \frac{n}{2}, \frac{n}{4} - 1)\).

This is the unique extension of the Hadamard 2-design (see HadamardDesign()). We implement the description from pp. 12 in [CvL].

INPUT:

- \(n\) (integer) – a multiple of \(4\) such that \(n > 4\).

EXAMPLES:

```python
sage: # needs sage.combinat sage.modules
sage: designs.Hadamard3Design(12)
Incidence structure with 12 points and 22 blocks

>>> from sage.all import *
>>> # needs sage.combinat sage.modules
>>> designs.Hadamard3Design(Integer(12))
Incidence structure with 12 points and 22 blocks
```

We verify that any two blocks of the Hadamard 3-design \(3 - (8, 4, 1)\) design meet in 0 or 2 points. More generally, it is true that any two blocks of a Hadamard 3-design meet in 0 or \(\frac{n}{4}\) points (for \(n > 4\)).

```python
sage: # needs sage.combinat sage.modules
sage: D = designs.Hadamard3Design(8)
sage: N = D.incidence_matrix()
sage: N.transpose()*N
[4 2 2 2 2 2 2 2 2 2 2 2 2 2 0]
[2 4 2 2 2 2 2 2 2 2 2 2 2 2 0 2]
[2 2 4 2 2 2 2 2 2 2 2 2 2 2 0 2 2]
[2 2 2 4 2 2 2 2 2 2 2 2 2 2 0 2 2 2]
[2 2 2 2 4 2 2 2 2 2 2 2 2 2 0 2 2 2 2]
[2 2 2 2 2 4 2 2 2 2 2 2 2 2 0 2 2 2 2 2]
[2 2 2 2 2 2 4 2 2 2 2 2 2 2 0 2 2 2 2 2 2]
[2 2 2 2 2 2 2 4 2 2 2 2 2 2 0 2 2 2 2 2 2 2]
[2 2 2 2 2 2 2 2 4 2 2 2 2 2 0 2 2 2 2 2 2 2 2]
[2 2 2 2 2 2 2 2 2 4 2 2 2 2 0 2 2 2 2 2 2 2 2 2]
[2 2 2 2 2 2 2 2 2 2 4 2 2 2 0 2 2 2 2 2 2 2 2 2 2]
[2 2 2 2 2 2 2 2 2 2 2 4 2 2 0 2 2 2 2 2 2 2 2 2 2 2]
[2 2 2 2 2 2 2 2 2 2 2 2 4 2 0 2 2 2 2 2 2 2 2 2 2 2 2]
[2 2 2 2 2 2 2 2 2 2 2 2 2 4 2 0 2 2 2 2 2 2 2 2 2 2 2 2]

2 2 2 2 2 2 2 2 2 2 2 2 4 2
0 2 2 2 2 2 2 2 2 2 2 2 2 4]
```

REFERENCES:
sage.combinat.designs.block_design.HadamardDesign(n)

As described in Section 1, p. 10, in [CvL]. The input n must have the property that there is a Hadamard matrix of order \(n + 1\) (and that a construction of that Hadamard matrix has been implemented…).

EXAMPLES:

```python
sage: # needs sage.combinat sage.modules
ds = designs.HadamardDesign(7)

sage: print(ds)
Incidence structure with 7 points and 7 blocks

sage: J = matrix(ZZ, 11, 11, [1]*11*11); N*J
[5 5 5 5 5 5 5 5 5 5 5
5 5 5 5 5 5 5 5 5 5 5
5 5 5 5 5 5 5 5 5 5 5
5 5 5 5 5 5 5 5 5 5 5
5 5 5 5 5 5 5 5 5 5 5
5 5 5 5 5 5 5 5 5 5 5
5 5 5 5 5 5 5 5 5 5 5
5 5 5 5 5 5 5 5 5 5 5
5 5 5 5 5 5 5 5 5 5 5
5 5 5 5 5 5 5 5 5 5 5
5 5 5 5 5 5 5 5 5 5 5]
```

For example, the Hadamard 2-design with \(n = 11\) is a design whose parameters are \(2 - (11, 5, 2)\). We verify that \(N.J = 5.J\) for this design.
REFERENCES:

sage.combinat.designs.block_design.HughesPlane(q2, check=True)

Return the Hughes projective plane of order \( q^2 \).

Let \( q \) be an odd prime, the Hughes plane of order \( q^2 \) is a finite projective plane of order \( q^2 \) introduced by D. Hughes in [Hu57]. Its construction is as follows.

Let \( K = GF(q^2) \) be a finite field with \( q^2 \) elements and \( F = GF(q) \subset K \) be its unique subfield with \( q \) elements.

We define a twisted multiplication on \( K \) as

\[
x \circ y = \begin{cases} 
  x y & \text{if } y \text{ is a square in } K \\
  x^q y & \text{otherwise}
\end{cases}
\]

The points of the Hughes plane are the triples \((x, y, z)\) of points in \( K^3 \setminus \{0, 0, 0\} \) up to the equivalence relation \((x, y, z) \sim (x \circ k, y \circ k, z \circ k)\) where \( k \in K \).

For \( a = 1 \) or \( a \in (K \setminus F) \) we define a block \( L(a) \) as the set of triples \((x, y, z)\) so that \( x + a \circ y + z = 0 \). The rest of the blocks are obtained by letting act the group \( GL(3, F) \) by its standard action.

For more information, see Wikipedia article Hughes plane and [We07].

See also:

DesarguesianProjectivePlaneDesign() to build the Desarguesian projective planes

INPUT:

- \( q^2 \) – an even power of an odd prime number
- check – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

EXAMPLES:

sage: H = designs.HughesPlane(9); H
(91,10,1)-Balanced Incomplete Block Design

```python
>>> from sage.all import *
>>> D = designs.HadamardDesign(Integer(11)); N = D.incidence_matrix()
>>> J = matrix(ZZ, Integer(11), Integer(11),
˓→[Integer(1)]*Integer(11)*Integer(11)); N*J

[5 5 5 5 5 5 5 5 5 5 5]
```
We prove in the following computations that the Desarguesian plane $H$ is not Desarguesian. Let us consider the two triangles $(0, 1, 10)$ and $(57, 70, 59)$. We show that the intersection points $D_{0, 1} \cap D_{57, 70}$, $D_{1, 10} \cap D_{70, 59}$ and $D_{10, 0} \cap D_{59, 57}$ are on the same line while $D_{0, 70}$, $D_{1, 59}$ and $D_{10, 57}$ are not concurrent:

```python
sage: blocks = H.blocks()
sage: line = lambda p, q: next(b for b in blocks if p in b and q in b)

sage: b_0_1 = line(0, 1)
sage: b_1_10 = line(1, 10)
sage: b_10_0 = line(10, 0)
sage: b_57_70 = line(57, 70)
sage: b_70_59 = line(70, 59)

>>> p == q
False
```

sage.combinat.designs.block_design.

ProjectiveGeometryDesign(n, d, F, algorithm=None,
point_coordinates=True,
check=True)

Return a projective geometry design.

The projective geometry design $PG_d(n, q)$ has for points the lines of $\mathbb{F}_q^{n+1}$, and for blocks the $(d+1)$-dimensional subspaces of $\mathbb{F}_q^{n+1}$, each of which contains $\frac{\mathbb{F}_q^{d+1}-1}{\mathbb{F}_q-1}$ lines. It is a 2-design with parameters

$$v = \binom{n+1}{1}, \quad k = \binom{d+1}{1}, \quad \lambda = \binom{n-1}{d-1}$$

where the $q$-binomial coefficient $\binom{m}{r}_q$ is defined by

$$\binom{m}{r}_q = \frac{(q^m-1)(q^{m-1}-1)\cdots(q^{m-r+1}-1)}{(q^r-1)(q^{r-1}-1)\cdots(q-1)}$$

See also:

AffineGeometryDesign()

INPUT:

- n – the projective dimension
- d – the dimension of the subspaces which make up the blocks.
- F – a finite field or a prime power.
- algorithm – set to None by default, which results in using Sage’s own implementation. In order to use GAP’s implementation instead (i.e. its PGPointFlatBlockDesign function) set algorithm="gap". Note that GAP’s “design” package must be available in this case, and that it can be installed with the gap_packages spkg.
- point_coordinates – True by default. Ignored and assumed to be False if algorithm="gap". If True, the ground set is indexed by coordinates in $\mathbb{F}_q^{n+1}$. Otherwise the ground set is indexed by integers.
- check – (default: True) whether to check the output.

EXAMPLES:

The set of $d$-dimensional subspaces in a $n$-dimensional projective space forms 2-designs (or balanced incomplete block designs):

```python
sage: PG = designs.ProjectiveGeometryDesign(4, 2, GF(2)); PG
_incidence structure with 31 points and 155 blocks
sage: PG.is_t_design(return_parameters=True)
(True, (2, 31, 7, 7))

sage: PG = designs.ProjectiveGeometryDesign(3, 1, GF(4))
```

(continues on next page)
sage: PG.is_t_design(return_parameters=True)  
needs sage.combinat
(True, (2, 85, 5, 1))

>>> from sage.all import *
>>> PG = designs.ProjectiveGeometryDesign(Integer(4), Integer(2), GF(Integer(2)))
Incidence structure with 31 points and 155 blocks
>>> PG.is_t_design(return_parameters=True)  
needs sage.combinat
(True, (2, 31, 7, 7))

>>> PG = designs.ProjectiveGeometryDesign(Integer(3), Integer(1), GF(Integer(4)))
Incidence structure with 85 points and 85 blocks
>>> PG.is_t_design(return_parameters=True)  
needs sage.combinat
(True, (2, 85, 5, 1))

Check with F being a prime power:

sage: PG = designs.ProjectiveGeometryDesign(3, 2, 4); PG
Incidence structure with 85 points and 85 blocks

>>> from sage.all import *
>>> PG = designs.ProjectiveGeometryDesign(Integer(3), Integer(2), Integer(4)); PG
Incidence structure with 85 points and 85 blocks

Use coordinates:

sage: PG = designs.ProjectiveGeometryDesign(2, 1, GF(3))
sage: PG.blocks()[0]
[(1, 0, 0), (1, 0, 1), (1, 0, 2), (0, 0, 1)]

>>> from sage.all import *
>>> PG = designs.ProjectiveGeometryDesign(Integer(2), Integer(1), GF(Integer(3)))
>>> PG.blocks()[Integer(0)]
[(1, 0, 0), (1, 0, 1), (1, 0, 2), (0, 0, 1)]

Use indexing by integers:

sage: PG = designs.ProjectiveGeometryDesign(2, 1, GF(3), point_coordinates=0)
sage: PG.blocks()[0]
[0, 1, 2, 12]

>>> from sage.all import *
>>> PG = designs.ProjectiveGeometryDesign(Integer(2), Integer(1), GF(Integer(3)),
point_coordinates=Integer(0))
>>> PG.blocks()[Integer(0)]
[0, 1, 2, 12]

Check that the constructor using gap also works:

sage: BD = designs.ProjectiveGeometryDesign(2, 1, GF(2), algorithm="gap")  
optional - gap_package_design
sage: BD.is_t_design(return_parameters=True)  
(continues on next page)
>>> from sage.all import *
>>> BD = designs.ProjectiveGeometryDesign(Integer(2), Integer(1), GF(Integer(2)),
       algorithm="gap")  # optional - gap_package_design
>>> BD.is_t_design(return_parameters=True)  # optional - gap_package_design
(True, (2, 7, 3, 1))

sage.combinat.designs.block_design.WittDesign(n)

INPUT:

* n is in 9, 10, 11, 12, 21, 22, 23, 24.

Wraps GAP Design's WittDesign. If n=24 then this function returns the large Witt design W_{24}, the unique (up to isomorphism) 5 - (24, 8, 1) design. If n=12 then this function returns the small Witt design W_{12}, the unique (up to isomorphism) 5 - (12, 6, 1) design. The other values of n return a block design derived from these.

Note: Requires GAP's Design package (included in the gap_packages Sage spkg).

EXAMPLES:

sage: # optional - gap_package_design
sage: BD = designs.WittDesign(9)
sage: BD.is_t_design(return_parameters=True)
(True, (2, 9, 3, 1))
sage: BD
Incidence structure with 9 points and 12 blocks
sage: print(BD)
Incidence structure with 9 points and 12 blocks

sage.combinat.designs.block_design.are_hyperplanes_in_projective_geometry_parameters(v, k, lmbda, return_parameters=False)

Return True if the parameters (v,k,lmbda) are the one of hyperplanes in a (finite Desarguesian) projective space.

In other words, test whether there exists a prime power q and an integer d greater than two such that:
\[ v = \frac{q^d + 1}{q - 1} = q^d + q^{d-1} + \ldots + 1 \]
\[ k = \frac{q^d - 1}{q - 1} = q^{d-1} + q^{d-2} + \ldots + 1 \]
\[ \lambda = \frac{q^d - 1}{(q - 1)} = q^{d-2} + q^{d-3} + \ldots + 1 \]

If it exists, such a pair \((q, d)\) is unique.

**INPUT:**
- \(v, k, \lambda\) – integers

**OUTPUT:**
- a boolean or, if `return_parameters` is set to True a pair \((True, (q, d))\) or \((False, (None, None))\).

**EXAMPLES:**

```python
sage: from sage.combinat.designs.block_design import are_hyperplanes_in_projective_geometry_parameters

sage: are_hyperplanes_in_projective_geometry_parameters(40, 13, 4)
True

sage: are_hyperplanes_in_projective_geometry_parameters(40, 13, 4,...)
(True, (3, 3))

sage: PG = designs.ProjectiveGeometryDesign(3, 2, GF(3))  # needs sage.combinat
sage: PG.is_t_design(return_parameters=True)  # needs sage.combinat
(True, (2, 40, 13, 4))

sage: are_hyperplanes_in_projective_geometry_parameters(15, 3, 1)
False

sage: are_hyperplanes_in_projective_geometry_parameters(15, 3, 1,...)
(False, (None, None))
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.block_design import are_hyperplanes_in_projective_geometry_parameters

>>> are_hyperplanes_in_projective_geometry_parameters(Integer(40), Integer(13), Integer(4))
True

>>> are_hyperplanes_in_projective_geometry_parameters(Integer(40), Integer(13), Integer(4),...
(True, (3, 3))

>>> PG = designs.ProjectiveGeometryDesign(Integer(3), Integer(2), GF(Integer(3)))  # needs sage.combinat
>>> PG.is_t_design(return_parameters=True)  # needs sage.combinat
(True, (2, 40, 13, 4))

>>> are_hyperplanes_in_projective_geometry_parameters(Integer(15), Integer(3), Integer(1))
False

>>> are_hyperplanes_in_projective_geometry_parameters(Integer(15), Integer(3), Integer(1),...
(False, (None, None))
```

5.1. Comprehensive Module List
sage.combinat.designs.block_design.normalize_hughes_plane_point(p, q)

Return the normalized form of point $p$ as a 3-tuple.

In the Hughes projective plane over the finite field $K$, all triples $(xk, yk, zk)$ with $k \in K$ represent the same point (where the multiplication is over the nearfield built from $K$). This function chooses a canonical representative among them.

This function is used in `HughesPlane()`.

INPUT:

- $p$ – point with the coordinates $(x, y, z)$ (a list, a vector, a tuple…)
- $q$ – cardinality of the underlying finite field

EXAMPLES:

```python
sage: from sage.combinat.designs.block_design import normalize_hughes_plane_point
sage: K = FiniteField(9,'x')
sage: x = K.gen()
sage: normalize_hughes_plane_point((x, x + 1, x), 9)
(1, x, 1)
sage: normalize_hughes_plane_point(vector((x,x,x)), 9)
(1, 1, 1)
sage: zero = K.zero()
sage: normalize_hughes_plane_point((2*x + 2, zero, zero), 9)
(1, 0, 0)
sage: one = K.one()
sage: normalize_hughes_plane_point((2*x, one, zero), 9)
(2*x, 1, 0)
```

sage.combinat.designs.block_design.projective_plane(n, check=True, existence=False)

Return a projective plane of order $n$ as a 2-design.

A finite projective plane is a 2-design with $n^2 + n + 1$ lines (or blocks) and $n^2 + n + 1$ points. For more information on finite projective planes, see the Wikipedia article Projective_plane#Finite_projective_planes.

If no construction is possible, then the function raises a `EmptySetError`, whereas if no construction is available, the function raises a `NotImplementedError`.

INPUT:

- $n$ – the finite projective plane’s order

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: # needs sage.schemes

```

(continues on next page)
EmptySetError: By the Bruck-Ryser theorem, no projective plane of order 14 exists.

```
sage.combinat.designs.block_design.projective_plane_to_OA(pplane, pt=None, check=True)
```

Return the orthogonal array built from the projective plane $pplane$.

The orthogonal array $OA(n + 1, n, 2)$ is obtained from the projective plane $pplane$ by removing the point $pt$ and the $n + 1$ lines that pass through it. These $n + 1$ lines form the $n + 1$ groups while the remaining $n^2 + n$ lines form the transversals.

**INPUT:**

- $pplane$ – a projective plane as a 2-design
- $pt$ – a point in the projective plane $pplane$. If it is not provided, then it is set to $n^2 + n$.
- $check$ – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

**EXAMPLES:**

```
sage: from sage.combinat.designs.block_design import projective_plane_to_OA
sage: p2 = designs.DesarguesianProjectivePlaneDesign(2, point_coordinates=False)
sage: projective_plane_to_OA(p2)
[[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 0]]
sage: p3 = designs.DesarguesianProjectivePlaneDesign(3, point_coordinates=False)
sage: projective_plane_to_OA(p3)
[[0, 0, 0, 0],
 [0, 1, 2, 1],
 [0, 2, 1, 2],
 [1, 0, 2, 2],
 [1, 1, 1, 0],
 [1, 2, 0, 1],
 [2, 0, 1, 1],
 [2, 1, 0, 2],
 [2, 2, 2, 0]]
sage: pp = designs.DesarguesianProjectivePlaneDesign(16, point_coordinates=False)
sage: _ = projective_plane_to_OA(pp, pt=0)
sage: _ = projective_plane_to_OA(pp, pt=3)
sage: _ = projective_plane_to_OA(pp, pt=7)
```
sage.combinat.designs.block_design.q3_minus_one_matrix($K$)

Return a companion matrix in $GL(3, K)$ whose multiplicative order is $q^3 - 1$.

This function is used in $HughesPlane()$.

EXAMPLES:

```python
sage: from sage.combinat.designs.block_design import q3_minus_one_matrix
sage: m = q3_minus_one_matrix(GF(3))
sage: m.multiplicative_order() == 3**3 - 1
True
sage: m = q3_minus_one_matrix(GF(4, 'a'))
sage: m.multiplicative_order() == 4**3 - 1
True
sage: m = q3_minus_one_matrix(GF(5))
sage: m.multiplicative_order() == 5**3 - 1
True
sage: m = q3_minus_one_matrix(GF(9, 'a'))
sage: m.multiplicative_order() == 9**3 - 1
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.block_design import q3_minus_one_matrix
>>> m = q3_minus_one_matrix(GF(Integer(3)))
>>> m.multiplicative_order() == Integer(3)**Integer(3) - Integer(1)
True
>>> m = q3_minus_one_matrix(GF(Integer(4), 'a'))
>>> m.multiplicative_order() == Integer(4)**Integer(3) - Integer(1)
True
>>> m = q3_minus_one_matrix(GF(Integer(5)))
>>> m.multiplicative_order() == Integer(5)**Integer(3) - Integer(1)
True
>>> m = q3_minus_one_matrix(GF(Integer(9), 'a'))
>>> m.multiplicative_order() == Integer(9)**Integer(3) - Integer(1)
True
```

sage.combinat.designs.block_design.tdesign_params($t, v, k, L$)

Return the design’s parameters: $(t, v, b, k, L)$. Note that $t$ must be given.

EXAMPLES:
sage: BD = BlockDesign(7, [[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]])
sage: from sage.combinat.designs.block_design import tdesign_params
sage: tdesign_params(2,7,3,1)
(2, 7, 7, 3, 3, 1)

>>> from sage.all import *
>>> BD = BlockDesign(Integer(7), [[Integer(0),Integer(1),Integer(2)],
                                [Integer(0),Integer(3),Integer(4)],
                                [Integer(0),Integer(5),Integer(6)],
                                [Integer(1),Integer(3),Integer(5)],
                                [Integer(1),Integer(4),Integer(6)],
                                [Integer(2),Integer(3),Integer(6)],
                                [Integer(2),Integer(4),Integer(5)]])
>>> from sage.combinat.designs.block_design import tdesign_params
>>> tdesign_params(Integer(2),Integer(7),Integer(3),Integer(1))
(2, 7, 7, 3, 3, 1)

5.1.79 Covering Arrays (CA)

A Covering Array, denoted $CA(N; t, k, v)$, is an $N$ by $k$ array with entries from a set of $v$ elements with the property that in every selection of $t$ columns, every sequence of $t$ elements appears in at least one row.

An Orthogonal Array, denoted $OA(N; t, k, v)$ is a covering array with the property that every sequence of $t$-elements appears in exactly one row. (See sage.combinat.designs.orthogonal_arrays).

This module collects methods relating to covering arrays, some of which are inherited from orthogonal array methods. This module defines the following functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>is_covering_array()</td>
<td>Check that an input list of lists is a $CA(N; t, k, v)$.</td>
</tr>
<tr>
<td>CA_relabel()</td>
<td>Return a relabelled version of the CA.</td>
</tr>
<tr>
<td>CA_standard_label()</td>
<td>Return a version of the CA relabelled to symbols $(0, \ldots, n-1)$.</td>
</tr>
</tbody>
</table>

5.1.80 Covering designs: coverings of $t$-element subsets of a $v$-set by $k$-sets

A $(v, k, t)$ covering design $C$ is an incidence structure consisting of a set of points $P$ of order $v$, and a set of blocks $B$, where each block contains $k$ points of $P$. Every $t$-element subset of $P$ must be contained in at least one block.

If every $t$-set is contained in exactly one block of $C$, then we have a block design. Following the block design implementation, the standard representation of a covering design uses $P = [0, 1, \ldots, v-1]$.

In addition to the parameters and incidence structure for a covering design from this database, we include extra information:

- Best known lower bound on the size of a $(v, k, t)$-covering design
- Name of the person(s) who produced the design
• Method of construction used
• Date when the design was added to the database

REFERENCES:

AUTHORS:
• Daniel M. Gordon (2008-12-22): initial version

Classes and methods

class sage.combinat.designs.covering_design.CoveringDesign(v=0, k=0, t=0, size=0, 
points=None, blocks=None, 
low_bd=0, method='', 
creator='', timestamp='')

Bases: SageObject

Covering design.

INPUT:
• v, k, t – integer parameters of the covering design
• size (integer)
• points – list of points (default points are [0, ..., v − 1])
• blocks
• low_bd (integer) – lower bound for such a design
• method, creator, timestamp – database information

def creator()

Return the creator of the covering design

This field is optional, and is used in a database to give attribution for the covering design It can refer to the 
person who submitted it, or who originally gave a construction

EXAMPLES:

sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), 
[[0, 1, 2], 
...: [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6], 
...: [2, 4, 5]],0, 'Projective Plane', 'Gino Fano')
sage: C.creator()
'Gino Fano'

>>> from sage.all import *
>>> from sage.combinat.designs.covering_design import CoveringDesign
>>> C = CoveringDesign(Integer(7), Integer(3), Integer(2), Integer(7),
˓→range(Integer(7)), [[Integer(0), Integer(1), Integer(2)],
˓→[Integer(0), Integer(3), Integer(4)], [Integer(0), Integer(5),
˓→Integer(6)], [Integer(1), Integer(3), Integer(5)], [Integer(1), Integer(4),
˓→Integer(6)], [Integer(2), Integer(3), Integer(6)],
˓→[Integer(2), Integer(4), Integer(5)]],Integer(0), 'Projective Plane',
˓→'Gino Fano')
>>> C.creator()
'Gino Fano'
incidence_structure()

Return the incidence structure of this design, without extra parameters.

EXAMPLES:

```python
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [(0, 1, 2),
.....: (0, 3, 4), (0, 5, 6), (1, 3, 5), (1, 4, 6),
.....: (2, 3, 6), (2, 4, 5)], 0, 'Projective Plane')
sage: D = C.incidence_structure()
sage: D.ground_set()
[0, 1, 2, 3, 4, 5, 6]
sage: D.blocks()
[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5],
[1, 4, 6], [2, 3, 6], [2, 4, 5]]
```

is_covering()

Check all \( t \)-sets are in fact covered by the blocks of self.

Note:  This is very slow and wasteful of memory.

EXAMPLES:

```python
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [(0, 1, 2),
.....: (0, 3, 4), (0, 5, 6), (1, 3, 5), (1, 4, 6),
.....: (2, 3, 6), (2, 4, 6)], 0, 'Projective Plane')
sage: C.is_covering()
True
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [(0, 1, 2),
.....: (0, 3, 4), (0, 5, 6), (1, 3, 5), (1, 4, 6),
.....: (2, 4, 6)], 0, 'not a covering')  # last block altered
sage: C.is_covering()
False
```
Combinatorics, Release 10.4

(continued from previous page)

>>> C = CoveringDesign(Integer(7), Integer(3), Integer(2), Integer(7),
                      range(Integer(7)), [[Integer(0), Integer(1), Integer(2)],
                       ..., [Integer(0), Integer(3), Integer(4)], [Integer(0), Integer(5),
                       ... [Integer(2), Integer(3), Integer(6)], [Integer(2), Integer(4), Integer(5)],
                      ... [Integer(2), Integer(3), Integer(6)], [Integer(2), Integer(4), Integer(5)]],
                      0, 'not a covering')
>>> C.is_covering()
False

k()
Return \( k \), the size of blocks of the covering design

EXAMPLES:

sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
.....: [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
.....: [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.k()
3

>>> from sage.all import *
>>> from sage.combinat.designs.covering_design import CoveringDesign
>>> C = CoveringDesign(Integer(7), Integer(3), Integer(2), Integer(7),
.....: range(Integer(7)), [[Integer(0), Integer(1), Integer(2)],
.....: [Integer(0), Integer(3), Integer(4)], [Integer(0), Integer(5),
.....: Integer(6)], [Integer(1), Integer(3), Integer(5)], [Integer(1), Integer(4),
.....: Integer(6)], [Integer(2), Integer(3), Integer(6)], [Integer(2), Integer(4),
.....: Integer(5)]], Integer(0), 'Projective Plane')
>>> C.k()
3

low_bd()
Return a lower bound for the number of blocks a covering design with these parameters could have.

Typically this is the Schönheim bound, but for some parameters better bounds have been shown.

EXAMPLES:

sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
.....: [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
.....: [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.low_bd()
7

>>> from sage.all import *
>>> from sage.combinat.designs.covering_design import CoveringDesign
>>> C = CoveringDesign(Integer(7), Integer(3), Integer(2), Integer(7),
.....: range(Integer(7)), [[Integer(0), Integer(1), Integer(2)],
.....: [Integer(0), Integer(3), Integer(4)], [Integer(0), Integer(5),
.....: Integer(6)], [Integer(1), Integer(3), Integer(5)], [Integer(1), Integer(4),
.....: Integer(6)], [Integer(2), Integer(3), Integer(6)], [Integer(2), Integer(4),
.....: Integer(5)]], Integer(0), 'Projective Plane')

(continues on next page)
method()

Return the method used to create the covering design.

This field is optional, and is used in a database to give information about how coverings were constructed.

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
design: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2], 
.....: [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], 
.....: [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.method() 
'Projective Plane'
```

size()

Return the number of blocks in the covering design

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
design: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2], 
.....: [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], 
.....: [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.size() 
7
```

```

C.size()
7

\texttt{t()}

Return $t$, the size of sets which must be covered by the blocks of the covering design.

\textbf{EXAMPLES:}

\begin{verbatim}
>>> from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
>>> C.t()
2

>>> from sage.all import *
>>> from sage.combinat.designs.covering_design import CoveringDesign

>>> C = CoveringDesign(Integer(7), Integer(3), Integer(2), Integer(7), range(Integer(7)), [[Integer(0), Integer(1), Integer(2)], [Integer(0), Integer(3), Integer(4)], [Integer(0), Integer(5), Integer(6)], [Integer(1), Integer(3), Integer(5)], [Integer(1), Integer(4), Integer(6)], [Integer(2), Integer(3), Integer(6)], [Integer(2), Integer(4), Integer(5)]], Integer(0), 'Projective Plane', Gino Fano, 1892-01-01 00:00:00)
>>> C.t()
2

\end{verbatim}

\texttt{timestamp()}

Return the time that the covering was submitted to the database.

\textbf{EXAMPLES:}

\begin{verbatim}
>>> from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane', 'Gino Fano', 1892-01-01 00:00:00)
sage: C.timestamp() # No exact date known; in Fano's 1892 article
'1892-01-01 00:00:00'

>>> from sage.all import *
>>> from sage.combinat.designs.covering_design import CoveringDesign

>>> C = CoveringDesign(Integer(7), Integer(3), Integer(2), Integer(7), range(Integer(7)), [[Integer(0), Integer(1), Integer(2)], [Integer(0), Integer(3), Integer(4)], [Integer(0), Integer(5), Integer(6)], [Integer(1), Integer(3), Integer(5)], [Integer(1), Integer(4), Integer(6)], [Integer(2), Integer(3), Integer(6)], [Integer(2), Integer(4), Integer(5)]], Integer(0), 'Projective Plane', 'Gino Fano', 1892-01-01 00:00:00)
>>> C.timestamp() # No exact date known; in Fano's 1892 article
'1892-01-01 00:00:00'

\end{verbatim}

\texttt{v()}

Return $v$, the number of points in the covering design.

\textbf{EXAMPLES:}

\begin{verbatim}
5.1. Comprehensive Module List
Return the best known \((v, k, t)\) covering design from an online database.

This uses the La Jolla Covering Repository, a database available at https://ljcr.dmgordon.org/cover.html

**INPUT:**

- \(v\) – integer, the size of the point set for the design
- \(k\) – integer, the number of points per block
- \(t\) – integer, the size of sets covered by the blocks
- \(\text{verbose}\) – bool (default: False), print verbose message

**OUTPUT:**

A `CoveringDesign` object representing the \((v, k, t)\)-covering design with smallest number of blocks available in the database.

**EXAMPLES:**

```sage
cfrom sage.combinat.designs.covering_design import ( # optional - internet
c    best_known_covering_design_www)
cC = best_known_covering_design_www(7, 3, 2) # optional - internet
cprint(C) # optional - internet
C(7, 3, 2) = 7
Method: lex covering
Submitted on: 1996-12-01 00:00:00
0 1 2
0 3 4
0 5 6
1 3 5
1 4 6
2 3 6
2 4 5
```
A `ValueError` is raised if the \((v, k, t)\) parameters are not found in the database.

The Schonheim lower bound for such a covering design’s size: \(C(v, k, t) \leq \left\lceil \frac{v}{k} \right\rceil \cdots \left\lceil \frac{v-t+1}{k-t+1} \right\rceil \cdots \)

**EXAMPLES:**

```python
sage: from sage.combinat.designs.covering_design import schonheim
dsage: schonheim(10, 3, 2)
17
dsage: schonheim(32, 16, 8)
930
```

Construct a trivial covering design.

**INPUT:**

- \(v\) – integer, size of point set
- \(k\) – integer, cardinality of each block
- \(t\) – integer, cardinality of sets being covered

**OUTPUT:**

A trivial \((v, k, t)\) covering design
EXAMPLES:

```python
sage: C = trivial_covering_design(8, 3, 1)
sage: print(C)
C(8, 3, 1) = 3
Method: Trivial
0 1 2
0 6 7
3 4 5
sage: C = trivial_covering_design(5, 3, 2)
sage: print(C)
4 <= C(5, 3, 2) <= 10
Method: Trivial
0 1 2
0 1 3
0 1 4
0 2 3
0 2 4
0 3 4
1 2 3
1 2 4
1 3 4
2 3 4
```

```python
>>> from sage.all import *

>>> C = trivial_covering_design(Integer(8), Integer(3), Integer(1))

>>> print(C)
C(8, 3, 1) = 3
Method: Trivial
0 1 2
0 6 7
3 4 5

>>> C = trivial_covering_design(Integer(5), Integer(3), Integer(2))

>>> print(C)
4 <= C(5, 3, 2) <= 10
Method: Trivial
0 1 2
0 1 3
0 1 4
0 2 3
0 2 4
0 3 4
1 2 3
1 2 4
1 3 4
2 3 4
```

Note: Cases are:

- \( t = 0 \): This could be empty, but it's a useful convention to have one block (which is empty if \( k = 0 \)).
- \( t = 1 \): This contains \( \lceil v/k \rceil \) blocks: \([0, ..., k - 1], [k, ..., 2k - 1], ..., \). The last block wraps around if \( k \) does not divide \( v \).
- anything else: Just use every \( k \)-subset of \([0, 1, ..., v - 1]\).
5.1.81 Database of small combinatorial designs

This module implements combinatorial designs that cannot be obtained by more general constructions. Most of them come from the Handbook of Combinatorial Designs [DesignHandbook].

All this would only be a dream without the mathematical knowledge and help of Julian R. Abel.

These functions can all be obtained through the designs.<tab> functions.

This module implements:

- $\text{OA}(7,18)$, $\text{OA}(9,40)$, $\text{OA}(7,66)$, $\text{OA}(7,68)$, $\text{OA}(8,69)$, $\text{OA}(7,74)$, $\text{OA}(8,76)$, $\text{OA}(11,80)$, $\text{OA}(15,112)$, $\text{OA}(9,120)$, $\text{OA}(9,135)$, $\text{OA}(11,160)$, $\text{OA}(16,176)$, $\text{OA}(11,185)$, $\text{OA}(10,205)$, $\text{OA}(16,208)$, $\text{OA}(15,224)$, $\text{OA}(11,254)$, $\text{OA}(20,352)$, $\text{OA}(20,416)$, $\text{OA}(10,469)$, $\text{OA}(10,520)$, $\text{OA}(12,522)$, $\text{OA}(14,524)$, $\text{OA}(20,544)$, $\text{OA}(17,560)$, $\text{OA}(11,640)$, $\text{OA}(10,796)$, $\text{OA}(15,896)$, $\text{OA}(9,1078)$, $\text{OA}(25,1262)$, $\text{OA}(9,1612)$, $\text{OA}(10,1620)$

- 2 MOLS of order 10, 5 MOLS of order 12, 4 MOLS of order 14, 4 MOLS of order 15, 3 MOLS of order 18

- $V(m,t)$ vectors:
  - $m = 3$ and $t = 2, 4, 6, 10, 12, 14, 20, 24, 26, 32, 34$
  - $m = 4$ and $t = 3, 7, 9, 13, 15, 25$
  - $m = 5$ and $t = 6, 8, 12, 14, 20, 26$
  - $m = 6$ and $t = 5, 7, 11, 13, 17, 21$
  - $m = 7$ and $t = 6, 10, 16, 18$
  - $m = 8$ and $t = 9, 11, 17, 29, 57$
  - $m = 9$ and $t = 12, 14, 18, 20, 22, 30, 34, 42, 44$
  - $m = 10$ and $t = 13, 15, 19, 21, 25, 27, 31, 33, 43, 49, 81, 97, 103, 181, 187, 259, 273, 319, 391, 409$

- $\text{RBIBD}(120, 8, 1)$

- $(v,k,\lambda)$-BIBD:
  - $\lambda = 1:n (66, 6, 1)$, $(76, 6, 1)$, $(96, 6, 1)$, $(106, 6, 1)$, $(111, 6, 1)$, $(120, 8, 1)$, $(126, 6, 1)$, $(136, 6, 1)$, $(141, 6, 1)$, $(171, 6, 1)$, $(196, 6, 1)$, $(201, 6, 1)$
  - $\lambda = 2:n (56, 11, 2)$, $(79, 13, 2)$
  - $\lambda = 8:n (45, 9, 8)$
  - $\lambda = 14:n (176, 50, 14)$

- $(v,k,\lambda)$-difference families:
  - $\lambda = 1:n (15, 3, 1)$, $(21, 3, 1)$, $(21, 5, 1)$, $(25, 3, 1)$, $(25, 4, 1)$, $(27, 3, 1)$, $(33, 3, 1)$, $(37, 4, 1)$, $(39, 3, 1)$, $(40, 4, 1)$, $(45, 3, 1)$, $(45, 5, 1)$, $(49, 3, 1)$, $(49, 4, 1)$, $(51, 3, 1)$, $(52, 4, 1)$, $(55, 3, 1)$, $(57, 3, 1)$, $(63, 3, 1)$, $(64, 4, 1)$, $(65, 5, 1)$, $(69, 3, 1)$, $(75, 3, 1)$, $(76, 4, 1)$, $(81, 3, 1)$, $(81, 5, 1)$, $(85, 4, 1)$, $(85, 4, 1)$
(91, 6, 1), (91, 7, 1), (121, 5, 1), (121, 6, 1), (141, 5, 1), (161, 5, 1), (175, 7, 1), (201, 5, 1), (217, 7, 1), (221, 5, 1), (259, 7, 1)

- $\lambda = 2: n = (16, 3, 2), (19, 4, 2), (22, 4, 2), (28, 3, 2), (31, 4, 2), (31, 5, 2), (34, 4, 2), (35, 5, 2), (40, 3, 2), (43, 4, 2), (43, 7, 2), (46, 4, 2), (46, 6, 2), (51, 5, 2), (61, 6, 2), (64, 7, 2), (71, 5, 2), (75, 5, 2), (85, 7, 2), (85, 8, 2), (153, 9, 2), (181, 10, 2)

- $\lambda = 3: n = (21, 4, 3), (21, 6, 3), (29, 7, 3), (41, 6, 3), (43, 7, 3), (45, 12, 3), (49, 9, 3), (51, 6, 3), (57, 7, 3), (61, 6, 3), (61, 10, 3), (71, 7, 3), (85, 7, 3), (97, 9, 3), (121, 10, 3)

- $\lambda = 4: n = (22, 7, 4), (29, 8, 4), (43, 8, 4), (46, 10, 4), (55, 9, 4), (67, 12, 4), (71, 8, 4)

- $\lambda = 5: n = (13, 5, 5), (17, 5, 5), (21, 6, 5), (22, 6, 5), (28, 6, 5), (33, 5, 5), (33, 6, 5), (37, 10, 5), (39, 6, 5), (45, 11, 5), (46, 10, 5), (55, 10, 5), (67, 11, 5), (73, 10, 5)

- $\lambda = 6: n = (11, 4, 6), (15, 4, 6), (15, 5, 6), (29, 8, 6), (46, 10, 6), (53, 13, 6), (67, 12, 6)

- $\lambda = 7: n = (25, 7, 7), (53, 14, 7), (61, 15, 7)

- $\lambda = 8: n = (22, 8, 8), (34, 12, 8), (133, 33, 8)

- $\lambda = 9: n = (21, 10, 9)

- $\lambda = 10: n = (34, 12, 10), (43, 15, 10), (49, 21, 10)

- $\lambda = 12: n = (22, 8, 12)

- $\lambda = 14: n = (21, 8, 14)

- $\lambda = 56: n = (901, 225, 56)$

- $(v, k, \lambda)$-difference matrices:
  - $\lambda = 1: n = (12, 6, 1), (21, 6, 1), (24, 8, 1), (28, 6, 1), (33, 6, 1), (35, 6, 1), (36, 9, 1), (39, 6, 1), (44, 6, 1), (45, 7, 1), (48, 9, 1), (51, 6, 1), (52, 6, 1), (55, 7, 1), (56, 8, 1), (57, 8, 1), (60, 6, 1), (75, 8, 1), (273, 17, 1), (993, 32, 1)

- $(n, k; \lambda, \mu; u)$-quasi-difference matrices:
  - $(19, 6; 1, 1; 1), (21, 5; 1, 1; 1), (21, 6; 1, 1; 5), (25, 6; 1, 1; 5), (33, 6; 1, 1; 1), (35, 7; 1, 1; 7), (37, 6; 1, 1; 1), (45, 7; 1, 1; 9), (54, 7; 1, 1; 8), (57, 9; 1, 1; 8)

- $(q, k)$ even distributed sets
  - $k = 5$: 41, 61, 101, 121, 181, 241, 281, 361, 401, 421, 461, 521, 541, 601, 641, 661, 701, 761, 821, 841, 881, 941, 961, 1021, 1061, 1181, 1201, 1301, 1321, 1361, 1381, 1481, 1601, 1621, 1681, 1721, 1741, 1801, 1861, 1901
  - $k = 8$: 449, 617, 673, 729, 841, 953, 1009, 1289, 1681, 1849
  - $k = 9$: 73, 433, 937, 1009, 1153, 1297, 1369, 1657, 1801, 1873
- $k = 10$: 1171, 1531, 1621, 1801

Functions

sage.combinat.designs.database.BIBD_106_6_1()

Return a (106,6,1)-BIBD.

This construction appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```python
sage: from sage.combinat.designs.database import BIBD_106_6_1
sage: BalancedIncompleteBlockDesign(106, BIBD_106_6_1())
(106,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.BIBD_111_6_1()

Return a (111,6,1)-BIBD.

This construction appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```python
sage: from sage.combinat.designs.database import BIBD_111_6_1
sage: BalancedIncompleteBlockDesign(111, BIBD_111_6_1())
(111,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.BIBD_126_6_1()

Return a (126,6,1)-BIBD.

This construction appears in VI.16.92 from [DesignHandbook].

EXAMPLES:

```python
sage: from sage.combinat.designs.database import BIBD_126_6_1
sage: BalancedIncompleteBlockDesign(126, BIBD_126_6_1())
(126,6,1)-Balanced Incomplete Block Design
```
Combinatorics, Release 10.4

>>> BalancedIncompleteBlockDesign(Integer(126), BIBD_126_6_1())
(126,6,1)-Balanced Incomplete Block Design

sage.combinat.designs.database.BIBD_136_6_1()
Return a (136,6,1)-BIBD.
This construction appears in II.3.32 from [DesignHandbook].
EXAMPLES:
sage: from sage.combinat.designs.database import BIBD_136_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(136, BIBD_136_6_1())
(136,6,1)-Balanced Incomplete Block Design

>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_136_6_1
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>> BalancedIncompleteBlockDesign(Integer(136), BIBD_136_6_1())
(136,6,1)-Balanced Incomplete Block Design

sage.combinat.designs.database.BIBD_141_6_1()
Return a (141,6,1)-BIBD.
This construction appears in II.3.32 from [DesignHandbook].
EXAMPLES:
sage: from sage.combinat.designs.database import BIBD_141_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(141, BIBD_141_6_1())
(141,6,1)-Balanced Incomplete Block Design

>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_141_6_1
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>> BalancedIncompleteBlockDesign(Integer(141), BIBD_141_6_1())
(141,6,1)-Balanced Incomplete Block Design

sage.combinat.designs.database.BIBD_171_6_1()
Return a (171,6,1)-BIBD.
This construction appears in II.3.32 from [DesignHandbook].
EXAMPLES:
sage: from sage.combinat.designs.database import BIBD_171_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(171, BIBD_171_6_1())
(171,6,1)-Balanced Incomplete Block Design

>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_171_6_1
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>> BalancedIncompleteBlockDesign(Integer(171), BIBD_171_6_1())
(171,6,1)-Balanced Incomplete Block Design
Return a (196,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_196_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(196, BIBD_196_6_1())
(196,6,1)-Balanced Incomplete Block Design
>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_196_6_1
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>>
BalancedIncompleteBlockDesign(Integer(196), BIBD_196_6_1())
(196,6,1)-Balanced Incomplete Block Design
```

Return a (201,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_201_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(201, BIBD_201_6_1())
(201,6,1)-Balanced Incomplete Block Design
>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_201_6_1
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>>
BalancedIncompleteBlockDesign(Integer(201), BIBD_201_6_1())
(201,6,1)-Balanced Incomplete Block Design
```

Return a (45,9,1)-BIBD.

This BIBD is obtained from the codewords of minimal weight in the ExtendedQuadraticResidueCode() of length 48. This construction appears in VII.11.2 from [DesignHandbook], which cites [HT95].

INPUT:

- from_code (boolean) – whether to build the design from hardcoded data (default) or from the code object (much longer).

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_45_9_8
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: B = BalancedIncompleteBlockDesign(45, BIBD_45_9_8(), lambd=8); B
(45,9,8)-Balanced Incomplete Block Design
>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_45_9_8
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>>
>>> B = BalancedIncompleteBlockDesign(Integer(45), BIBD_45_9_8(),
(continues on next page)
\[ \lambda = \text{Integer}(8) \] \; B
(45,9,8)-Balanced Incomplete Block Design

REFERENCE:

sage.combinat.designs.database.BIBD_56_11_2()
Return a symmetric (56, 11, 2)-BIBD.
The construction implemented is given in [Hall71].

Note: A symmetric \((v, k, \lambda)\) BIBD is a \((v, k, \lambda)\) BIBD with \(v\) blocks.

EXAMPLES:
sage: from sage.combinat.designs.database import BIBD_56_11_2 sage: D = IncidenceStructure(BIBD_56_11_2()) # needs sage.libs.gap sage: D.is_t_design(t=2, v=56, k=11, l=2) # needs sage.libs.gap True

sage.combinat.designs.database.BIBD_66_6_1()
Return a (66,6,1)-BIBD.

This BIBD was obtained from La Jolla covering repository (https://math.ccrwest.org/cover.html) where it is attributed to Colin Barker.

EXAMPLES:

sage: from sage.combinat.designs.database import BIBD_66_6_1 sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign sage: BalancedIncompleteBlockDesign(66, BIBD_66_6_1()) (66,6,1)-Balanced Incomplete Block Design

sage.combinat.designs.database.BIBD_76_6_1()
Return a (76,6,1)-BIBD.

This BIBD was obtained from La Jolla covering repository (https://math.ccrwest.org/cover.html) where it is attributed to Colin Barker.

EXAMPLES:

sage: from sage.combinat.designs.database import BIBD_76_6_1 sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign sage: BalancedIncompleteBlockDesign(76, BIBD_76_6_1()) (76,6,1)-Balanced Incomplete Block Design
Combinatorics, Release 10.4

sage.combinat.designs.database.BIBD_79_13_2()

Return a symmetric \((79, 13, 2)\)-BIBD.

The construction implemented is the one described in [Aschbacher71]. A typo in that paper was corrected in [Hall71].

**Note:** A symmetric \((v, k, \lambda)\) BIBD is a \((v, k, \lambda)\) BIBD with \(v\) blocks.

**EXAMPLES:**

```
sage: from sage.combinat.designs.database import BIBD_79_13_2
sage: D = IncidenceStructure(BIBD_79_13_2())  # needs sage.libs.gap
sage: D.is_t_design(t=2, v=79, k=13, l=2)  # needs sage.libs.gap
True
```

sage.combinat.designs.database.BIBD_96_6_1()

Return a \((96, 6, 1)\)-BIBD.

This BIBD was obtained from La Jolla covering repository (https://math.ccrwest.org/cover.html) where it is attributed to Colin Barker.

**EXAMPLES:**

```
sage: from sage.combinat.designs.database import BIBD_96_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(96, BIBD_96_6_1())
(96,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.DM_12_6_1()

Return a \((12, 6, 1)\)-difference matrix as built in [Hanani75].

This design is Lemma 3.21 from [Hanani75].

**EXAMPLES:**

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_12_6_1
sage: G, M = DM_12_6_1()
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(12, 6)
```
```python
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(12),Integer(6))
```

**REFERENCES:**

sage.combinat.designs.database.DM_21_6_1()

Return a \((21, 6, 1)\)-difference matrix.

As explained in the Handbook III.3.50 [DesignHandbook].

**EXAMPLES:**

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_21_6_1
sage: G,M = DM_21_6_1()

sage: is_difference_matrix(M,G,6,1)
True
```

Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(21,6)  # needs sage.rings.finite_rings
```

sage.combinat.designs.database.DM_24_8_1()

Return a \((24, 8, 1)\)-difference matrix.

As explained in the Handbook III.3.52 [DesignHandbook].

**EXAMPLES:**

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_24_8_1
sage: G,M = DM_24_8_1()

sage: is_difference_matrix(M,G,8,1)
True
```

Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(24,8)
```
sage.combinat.designs.database.DM_273_17_1()

Return a (273, 17, 1)-difference matrix.

Given by Julian R. Abel.

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_273_17_1
sage: G, M = DM_273_17_1()
          # needs sage.schemes
sage: is_difference_matrix(M, G, 17, 1)  # needs sage.schemes
True
```

Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(273, 17)
          # needs sage.schemes
```

```
>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(273), Integer(17))  # needs sage.schemes
```

sage.combinat.designs.database.DM_28_6_1()

Return a (28, 6, 1)-difference matrix.

As explained in the Handbook III.3.54 [DesignHandbook].

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_28_6_1
sage: G, M = DM_28_6_1()
          # needs sage.modules
sage: is_difference_matrix(M, G, Integer(6), Integer(1))  # needs sage.modules
True
```

(continues on next page)
Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(28, 6)  # needs sage.modules
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(28), Integer(6))  # needs sage.modules
```

```
sage.combinat.designs.database.DM_33_6_1()
Return a \((33, 6, 1)\)-difference matrix.

As explained in the Handbook III.3.56 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_33_6_1
sage: G, M = DM_33_6_1()
```

```
sage: is_difference_matrix(M, G, 6, 1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_33_6_1
>>> G, M = DM_33_6_1()
```

```
>>> is_difference_matrix(M, G, Integer(6), Integer(1))
True
```

```
sage: _ = designs.difference_matrix(33, 6)  # needs sage.rings.finite_rings
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(33), Integer(6))  # needs sage.rings.finite_rings
```

sage.combinat.designs.database.DM_35_6_1()
Return a \((35, 6, 1)\)-difference matrix.

As explained in the Handbook III.3.58 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_35_6_1
sage: G, M = DM_35_6_1()
```

```
sage: is_difference_matrix(M, G, 6, 1)
True
```

```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_35_6_1

>>> G,M = DM_35_6_1()
>>> is_difference_matrix(M,G,Integer(6),Integer(1))
True
```

Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(35, 6)
# needs sage.rings.finite_rings
```

```python
>>> from sage.all import *

>>> _ = designs.difference_matrix(Integer(35), Integer(6))
˓→ # needs sage.rings.finite_rings
```

```python
sage.combinat.designs.database.DM_36_9_1()
Return a (36, 9, 1)-difference matrix.
As explained in the Handbook III.3.59 [DesignHandbook].
EXAMPLES:
```

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_36_9_1
sage: G,M = DM_36_9_1()
˓→ # needs sage.modules
sage: is_difference_matrix(M,G,Integer(9),Integer(1))
˓→ # needs sage.modules
True
```

Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(36, 9)
˓→ # needs sage.modules
```

```python
>>> from sage.all import *

>>> _ = designs.difference_matrix(Integer(36), Integer(9))
˓→ # needs sage.modules
```

```python
sage.combinat.designs.database.DM_39_6_1()
Return a (39, 6, 1)-difference matrix.
As explained in the Handbook III.3.61 [DesignHandbook].
EXAMPLES:
```
Combinatorics, Release 10.4

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_39_6_1
sage: G, M = DM_39_6_1()
sage: is_difference_matrix(M, G, 6, 1)
True
```

Thedesignisavailablefromthegeneralconstructor:

```python
sage: designs.difference_matrix(39, 6, existence=True)  # needs sage.rings.finite_rings
True
```

```python
sage: designs.difference_matrix(Integer(39), Integer(6), existence=True)  # needs sage.rings.finite_rings
True
```

```
sage.combinat.designs.database.DM_44_6_1()

Returna (44, 6, 1)-differencematrix.

As explained in the Handbook III.3.64 [DesignHandbook].

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_44_6_1
sage: G, M = DM_44_6_1()
sage: is_difference_matrix(M, G, 6, 1)
True
```

Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(44, 6)
```

```
sage.combinat.designs.database.DM_45_7_1()

Returna (45, 7, 1)-differencematrix.

As explained in the Handbook III.3.65 [DesignHandbook].

... whose description contained a very deadly typo, kindly fixed by Julian R. Abel.
```
EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_45_7_1
sage: G,M = DM_45_7_1()
sage: is_difference_matrix(M,G,7,1)
True

>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_45_7_1
>>>
G,M = DM_45_7_1()
>>>
is_difference_matrix(M,G,Integer(7),Integer(1))
True
```

Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(45,7)  #...
   # needs sage.rings.finite_rings

>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_48_9_1
>>>
G,M = DM_48_9_1()
>>>
is_difference_matrix(M,G,Integer(9),Integer(1))  # needs sage.rings.finite_rings
```

sage.combinat.designs.database.DM_48_9_1()

Return a \((48,9,1)\)-difference matrix.

As explained in the Handbook III.3.67 [DesignHandbook].

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_48_9_1
sage: G,M = DM_48_9_1()
   # needs sage.rings.finite_rings
sage: is_difference_matrix(M,G,9,1)
True

>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_48_9_1
>>>
G,M = DM_48_9_1()
>>>
is_difference_matrix(M,G,Integer(9),Integer(1))  # needs sage.rings.finite_rings
```

Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(48,9)  #...
   # needs sage.rings.finite_rings

>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_48_9_1
>>>
G,M = DM_48_9_1()
>>>
is_difference_matrix(M,G,Integer(9),Integer(1))  # needs sage.rings.finite_rings
```
Combinatorics, Release 10.4

sage.combinat.designs.database.DM_51_6_1()

Return a $(51, 6, 1)$-difference matrix.

As explained in the Handbook III.3.69 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_51_6_1
sage: G,M = DM_51_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(51,6)
```  

sage.combinat.designs.database.DM_52_6_1()

Return a $(52, 6, 1)$-difference matrix.

As explained in the Handbook III.3.70 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_52_6_1
sage: G,M = DM_52_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(52,6)
```
sage.combinat.designs.database.DM_55_7_1()
Return a (55, 7, 1)-difference matrix.
As explained in the Handbook III.3.72 [DesignHandbook].
EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_55_7_1
sage: G,M = DM_55_7_1()
sage: is_difference_matrix(M,G,7,1)
True
```
Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(55,7)
```

sage.combinat.designs.database.DM_56_8_1()
Return a (56, 8, 1)-difference matrix.
As explained in the Handbook III.3.73 [DesignHandbook].
EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_56_8_1
sage: G,M = DM_56_8_1()
sage: is_difference_matrix(M,G,8,1)
True
```
Can be obtained from the constructor:
Combinatorics, Release 10.4

```python
sage: _ = designs.difference_matrix(56,8)  # needs sage.rings.finite_rings

>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(56),Integer(8))  # needs sage.rings.finite_rings
```

```
sage.combinat.designs.database.DM_57_8_1()
Return a \((57, 8, 1)\)-difference matrix.

Given by Julian R. Abel.

EXAMPLES:
```
```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_57_8_1
sage: G,M = DM_57_8_1()
# needs sage.rings.finite_rings sage.schemes
sage: is_difference_matrix(M,G,8,1)  # needs sage.rings.finite_rings sage.schemes
True
```
```
Can be obtained from the constructor:
```
```
sage: _ = designs.difference_matrix(57,8)  # needs sage.rings.finite_rings sage.schemes

>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(57),Integer(8))  # needs sage.rings.finite_rings sage.schemes
```
```
sage.combinat.designs.database.DM_60_6_1()
Return a \((60, 6, 1)\)-difference matrix.

As explained in [JulianAbel13].

REFERENCES:

EXAMPLES:
```
```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_60_6_1
sage: G,M = DM_60_6_1()
```
```
```
Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(60, 6)
```

```python
sage: _ = designs.difference_matrix(Integer(60), Integer(6))
```

`sage.combinat.designs.database.DM_75_8_1()`

Return a \((75, 8, 1)\)-difference matrix.

As explained in the Handbook III.3.75 [DesignHandbook].

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_75_8_1
sage: G, M = DM_75_8_1()
sage: is_difference_matrix(M, G, Integer(8), Integer(1))
True
```

Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(75, 8)
```

```python
sage: _ = designs.difference_matrix(Integer(75), Integer(8))  # needs sage.rings.finite_rings
```

`sage.combinat.designs.database.DM_993_32_1()`

Return a \((993, 32, 1)\)-difference matrix.

Given by Julian R. Abel.

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_993_32_1
sage: G, M = DM_993_32_1()
sage: is_difference_matrix(M, G, Integer(32), Integer(1))
True
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_993_32_1

G,M = DM_993_32_1()

is_difference_matrix(M,G,Integer(32),Integer(1)) # needs sage.schemes

True

Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(993,32) # needs sage.schemes

>>> from sage.all import *

>>> _ = designs.difference_matrix(Integer(993),Integer(32)) # needs sage.schemes

sage.combinat.designs.database.HigmanSimsDesign()

Return the Higman-Sims designs, which is a \((176, 50, 14)\)-BIBD.

This design is built from a from the WittDesign \(W\) on 24 points. We define two points \(a, b\), and consider:

- The collection \(W_a\) of all blocks of \(W\) containing \(a\) but not containing \(b\).
- The collection \(W_b\) of all blocks of \(W\) containing \(b\) but not containing \(a\).

The design is then obtained from the incidence structure produced by the blocks \(A \in W_a\) and \(B \in W_b\) whose intersection has cardinality 2. This construction, due to M.Smith, can be found in [KY04] or in 10.A.(v) of [BL1984].

EXAMPLES:

```python
sage: H = designs.HigmanSimsDesign(); H # optional - gap_
Incidence structure with 176 points and 176 blocks

sage: H.is_t_design(return_parameters=1) # optional - gap_
(True, (2, 176, 50, 14))

>>> from sage.all import *

>>> H = designs.HigmanSimsDesign(); H # optional - gap_
Incidence structure with 176 points and 176 blocks

>>> H.is_t_design(return_parameters=Integer(1)) # optional - gap_
(True, (2, 176, 50, 14))

Make sure that the automorphism group of this designs is isomorphic to the automorphism group of the HigmanSimsGraph(). Note that the first of those permutation groups acts on 176 points, while the second acts on 100:

```python
sage: gH = H.automorphism_group() # optional - gap_

sage: gG = graphs.HigmanSimsGraph().automorphism_group() # optional - gap_

sage: gG.is_isomorphic(gG) # long time, optional - gap_
True
```
>>> from sage.all import *
>>> gH = H.automorphism_group()  # optional - gap_src
>>> gG = graphs.HigmanSimsGraph().automorphism_group()  # optional - gap_src
>>> gG.is_isomorphic(gG)  # long time, optional - gap_src
True

REFERENCE:
sage.combinat.designs.database.MOLS_10_2()

Return a pair of MOLS of order 10

EXAMPLES:

sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_squares
sage: from sage.combinat.designs.database import MOLS_10_2
sage: MOLS = MOLS_10_2()  #...
# needs sage.modules
sage: print(are_mutually_orthogonal_latin_squares(MOLS))  #...
# needs sage.modules
True

The design is available from the general constructor:

sage: designs.orthogonal_arrays.is_available(2,10)
True

sage: designs.orthogonal_arrays.is_available(Integer(2),Integer(10))
True

sage.combinat.designs.database.MOLS_12_5()

Return 5 MOLS of order 12

These MOLS have been found by Brendan McKay.

EXAMPLES:

sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_squares
sage: from sage.combinat.designs.database import MOLS_12_5
sage: MOLS = MOLS_12_5()  #...
# needs sage.modules
(continues on next page)
sage: print(are_mutually_orthogonal_latin_squares(MOLS))
True

>>> from sage.all import *
>>> from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_squares
>>> from sage.combinat.designs.database import MOLS_12_5
>>> MOLS = MOLS_12_5()
# needs sage.modules
>>> print(are_mutually_orthogonal_latin_squares(MOLS))
# needs sage.modules
True

sage.combinat.designs.database.MOLS_14_4()
Return four MOLS of order 14.
These MOLS were shared by Ian Wanless. The first proof of existence was given in [Todorov12].

EXAMPLES:

sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_squares
sage: from sage.combinat.designs.database import MOLS_14_4
sage: MOLS = MOLS_14_4()
# needs sage.modules
sage: print(are_mutually_orthogonal_latin_squares(MOLS))
# needs sage.modules
True

>>> from sage.all import *
>>> from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_squares
>>> from sage.combinat.designs.database import MOLS_14_4
>>> MOLS = MOLS_14_4()
# needs sage.modules
>>> print(are_mutually_orthogonal_latin_squares(MOLS))
# needs sage.modules
True

The design is available from the general constructor:

sage: designs.orthogonal_arrays.is_available(4,14)
# needs sage.schemes
True

>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(4),Integer(14))
# needs sage.schemes
True

REFERENCE:

sage.combinat.designs.database.MOLS_15_4()
Return 4 MOLS of order 15.
These MOLS were shared by Ian Wanless.
EXAMPLES:

```python
sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_squares
sage: from sage.combinat.designs.database import MOLS_15_4
sage: MOLS = MOLS_15_4()
# needs sage.modules
sage: print(are_mutually_orthogonal_latin_squares(MOLS))
# needs sage.modules
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_squares
>>> from sage.combinat.designs.database import MOLS_15_4
>>>
MOLS = MOLS_15_4()
# needs sage.modules
>>> print(are_mutually_orthogonal_latin_squares(MOLS))
# needs sage.modules
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(4,15)
# needs sage.schemes
True
```

```python
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(4),Integer(15))
# needs sage.schemes
True
```

sage.combinat.designs.database.MOLS_18_3()

Return 3 MOLS of order 18.

These MOLS were shared by Ian Wanless.

EXAMPLES:

```python
sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_squares
sage: from sage.combinat.designs.database import MOLS_18_3
sage: MOLS = MOLS_18_3()
# needs sage.modules
sage: print(are_mutually_orthogonal_latin_squares(MOLS))
# needs sage.modules
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_squares
>>> from sage.combinat.designs.database import MOLS_18_3
>>> MOLS = MOLS_18_3()
# needs sage.modules
>>> print(are_mutually_orthogonal_latin_squares(MOLS))
# needs sage.modules
True
```
The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(3,18)
True
```

```python
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(3),Integer(18))
True
```

`sage.combinat.designs.database.OA_10_1620()`

Returns an OA(10,1620)

This is obtained through the generalized Brouwer-van Rees construction. Indeed, 1620 = 144.11 + (36 = 4.9) and there exists an $OA(10, 153) - OA(10, 9)$.

**Note:** This function should be removed once `find_brouwer_van_rees_with_one_truncated_column()` can handle all incomplete orthogonal arrays obtained through `incomplete_orthogonal_array()`.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_1620
sage: OA = OA_10_1620()  # not tested -- ~7s
sage: is_orthogonal_array(OA,10,1620,2)  # not tested -- ~7s
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_10_1620
>>> OA = OA_10_1620()  # not tested -- ~7s
>>> is_orthogonal_array(OA,Integer(10),Integer(1620),Integer(2))  # not tested -- ~7s
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(10,1620)  # not tested -- needs sage.schemes
True
```

```python
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(10),Integer(1620))  # not tested -- needs sage.schemes
True
```

`sage.combinat.designs.database.OA_10_205()`

Returns an $OA(10, 205)$.

Julian R. Abel shared the following construction, which originally appeared in Theorem 8.7 of [Greig99], and can in Lemmas 5.14–5.16 of [ColDin01]:

Consider a $PG(2, 4^2)$ containing a Baer subplane (i.e. a $PG(2, 4)$) $B$ and a point $p \in B$. Among the $4^2 + 1 = 17$ lines of $PG(2, 4^2)$ containing $p$:

- $4 + 1 = 5$ lines intersect $B$ on 5 points
• $4^2 - 4 = 12$ lines intersect $B$ on 1 point

As those lines are disjoint outside of $B$ we can use them as groups to build a GDD on $16^2 + 16 + 1 - (4^4 + 4 + 1) = 252$ points. By keeping only 9 lines of the second kind, however, we obtain a $(204, \{9, 13, 17\})$-GDD of type $12^5.16^9$.

We complete it into a PBD by adding a block $g \cup \{204\}$ for each group $g$. We then build an OA from this PBD using the fact that all blocks of size 9 are disjoint.

See also:

`sage.combinat.designs.orthogonal_arrays.OA_from_PBD()`

**EXAMPLES:**

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_205
sage: OA = OA_10_205()  # needs sage.schemes
sage: is_orthogonal_array(OA, 10, 205, 2)  # needs sage.schemes
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(10, 205)  # needs sage.schemes
True
```

```python
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(10), Integer(205))  # needs sage.schemes
True
```

`sage.combinat.designs.database.OA_10_469()`

Return an OA(10,469).

This construction appears in [Brouwer80]. It is based on the same technique used in `brouwer_separable_design()`

Julian R. Abel’s instructions:

Brouwer notes that a cyclic $PG(2,37)$ (or $(1407, 38, 1)$-BIBD) can be obtained with a base block containing 13, 9, and 16 points in each residue class mod 3. Thus, by reducing the $PG(2,37)$ to its points congruent to 0 (mod 3) one obtains a $(469, \{9, 13, 16\})$-PBD which consists in 3 symmetric designs, i.e. 469 blocks of size 9, 469 blocks of size 13, and 469 blocks of size 16.

For each block size $s$, one can build a matrix with size $s \times 469$ in which each block is a row, and such that each point of the PBD appears once per column. By multiplying a row of an $OA(9,s) - s.OA(9,1)$ with the rows of the matrix one obtains a parallel class of a resolvable $OA(9,469)$.
Add to this the parallel class of all blocks \((0,0,...),(1,1,...),...\) to obtain a resolvable \(OA(9,469)\) equivalent to an \(OA(10,469)\).

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_469
sage: OA = OA_10_469()  # long time
    # needs sage.schemes
sage: is_orthogonal_array(OA, 10, 469, 2)  # long time
    # needs sage.schemes
True

>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_10_469
>>> OA = OA_10_469()  # long time
    # needs sage.schemes
>>> is_orthogonal_array(OA, Integer(10), Integer(469), Integer(2))  # long time
    # needs sage.schemes
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(10, 469)  # long time
    # needs sage.schemes
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_10_520
>>> OA = OA_10_520()  # long time
    # needs sage.schemes
>>> is_orthogonal_array(OA, Integer(10), Integer(520), Integer(2))  # long time
    # needs sage.schemes
True
```

```python
sage.combinat.designs.database.OA_10_520()
```

Return an \(OA(10,520)\).

This design is built by the slightly more general construction \(OA_{520\text{ plus }x}(10)\).

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_520
sage: OA = OA_10_520()  # long time
    # needs sage.schemes
sage: is_orthogonal_array(OA, 10, 520, 2)  # long time
    # needs sage.schemes
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_10_520
>>> OA = OA_10_520()  # long time
    # needs sage.schemes
>>> is_orthogonal_array(OA, Integer(10), Integer(520), Integer(2))  # long time
    # needs sage.schemes
True
```

The design is available from the general constructor:
sage: designs.orthogonal_arrays.is_available(10,520)  # needs sage.schemes
True

>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(10),Integer(520)) ...
# needs sage.schemes
True

sage.combinat.designs.database.OA_10_796()

Returns an OA(10,796)

Construction shared by Julian R. Abel, from [AC07]:

Truncate one block of a $TD(17,47)$ to size 13, then add an extra point. Form a block on each group plus the extra point: we obtain a \((796,\{13, 16, 17, 47, 48\})\)-PBD in which only the extra point lies in more than one block of size 48 (and each other point lies in exactly 1 such block).

For each block $B$ (of size $k$ say) not containing the extra point, construct a $TD(10, k) - k.TD(k, 1)$ on $I(10).X.B$. For each block $B$ (of size $k = 47$ or 48) containing the extra point, construct a $TD(10, k) - TD(k, 1)$ on $I(10).X.B$, the size 1 hole being on $I(10).X.P$ where $P$ is the extra point. Finally form 1 extra block of size 10 on $I(10).X.P$.

EXAMPLES:

sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_796
sage: OA = OA_10_796()  # needs sage.schemes
sage: is_orthogonal_array(OA,10,796,2)  # needs sage.schemes
True

The design is available from the general constructor:

sage: designs.orthogonal_arrays.is_available(10,796)  # needs sage.schemes
True

sage.combinat.designs.database.OA_11_160()

Returns an OA(11,160)

Published by Julian R. Abel in [Ab1995]. Uses the fact that $160 = 2^5 \times 5$ is a product of a power of 2 and a prime number.
See also:

`sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()`

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_160
sage: OA = OA_11_160()
# needs sage.rings.finite_rings
sage: is_orthogonal_array(OA, 11, 160, 2)
# needs sage.rings.finite_rings
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_11_160
>>> OA = OA_11_160()
# needs sage.rings.finite_rings
>>> is_orthogonal_array(OA, Integer(11), Integer(160), Integer(2))
# needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(11, 160)  # needs sage.schemes
True
```

```python
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(11), Integer(160))  # needs sage.schemes
True
```

`sage.combinat.designs.database.OA_11_185()`

Returns an OA(11, 185)

The construction is given in [Greig99]. In Julian R. Abel's words:

Start with a $PG(2,16)$ with 7 points Fano subplane; outside this plane there are 7(17 − 3) = 98 points on a line of the subplane and 273 − 98 − 7 = 168 other points. Greig notes that the subdesign consisting of these 168 points is a $(168, \{10, 12\})$-PBD. Now add the 17 points of a line disjoint from this subdesign (e.g. a line of the Fano subplane). This line will intersect every line of the 168 point subdesign in 1 point. Thus the new line sizes are 11 and 13, plus a unique line of size 17, giving a $(185, \{11, 13, 17\})$-PBD and an OA(11, 185).

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_185
sage: OA = OA_11_185()
# needs sage.rings.finite_rings
sage: is_orthogonal_array(OA, 11, 185, 2)
# needs sage.rings.finite_rings
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> OA = OA_11_185()
# needs sage.rings.finite_rings
>>> is_orthogonal_array(OA, Integer(11), Integer(185), Integer(2))
# needs sage.rings.finite_rings
True
```
The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(11,185)  #...
    needs sage.schemes
True
```

```python
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(11),Integer(185))  # ...
    # needs sage.schemes
True
```

```
```

```python
sage.combinat.designs.database.OA_11_254()
```

Return an OA(11,254)

This construction appears in [Greig99].

From a cyclic \( PG(2,19) \) whose base blocks contains 7, 9, and 4 points in the congruence classes mod 3, build a \( (254,11,13,16) - PBD \) by ignoring the points of a congruence class. There exist \( OA(12,11), OA(12,13), OA(12,16), \) which gives the \( OA(11,254) \).

See also:

```
sage.combinat.designs.orthogonal_arrays.OA_from_PBD()
```

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_254
sage: OA = OA_11_254()  #...
    needs sage.schemes
sage: is_orthogonal_array(OA,11,254,2)  #...
    needs sage.schemes
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_11_254
>>>
OA = OA_11_254()  #...
    needs sage.schemes
>>> is_orthogonal_array(OA,Integer(11),Integer(254),Integer(2))  #...
    # needs sage.schemes
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(11,254)  #...
    needs sage.schemes
True
```

```python
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(11),Integer(254))  # ...
    # needs sage.schemes
True
```

```python
```
sage.combinat.designs.database.OA_11_640()

Returns an OA(11,640)

Published by Julian R. Abel in [Ab1995] (uses the fact that 640 = 2^7 \times 5 is the product of a power of 2 and a prime number).

See also:
sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_640
sage: OA = OA_11_640()  # not tested (too long)  # needs sage.rings.finite_rings
sage: is_orthogonal_array(OA, Integer(11), Integer(640), Integer(2))  # not tested (too long)  # needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(11, 640)  # needs sage.schemes
True
```

sage.combinat.designs.database.OA_11_80()

Return an OA(11,80)

As explained in the Handbook III.3.76 [DesignHandbook]. Uses the fact that 80 = 2^4 \times 5 and that 5 is prime.

See also:
sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:
sage: OA = OA_11_80()  # needs sage.rings.finite_rings sage.schemes
sage: is_orthogonal_array(OA,11,80,2)  # needs sage.rings.finite_rings sage.schemes
True

>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_11_80
>>> OA = OA_11_80()  # needs sage.rings.finite_rings sage.schemes
>>> is_orthogonal_array(OA,Integer(11),Integer(80),Integer(2))  # needs sage.rings.finite_rings sage.schemes
True

The design is available from the general constructor:

sage: designs.orthogonal_arrays.is_available(11,80)  # needs sage.rings.finite_rings sage.schemes
True

>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(11),Integer(80))  # needs sage.rings.finite_rings sage.schemes
True

sage.combinat.designs.database.OA_12_522()

Return an OA(12,522)

This design is built by the slightly more general construction OA_520_plus_x().

EXAMPLES:

sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_12_522
sage: OA = OA_12_522()  # needs sage.schemes
sage: is_orthogonal_array(OA,12,522,2)  # needs sage.schemes
True

>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_12_522
>>> OA = OA_12_522()  # needs sage.schemes
>>> is_orthogonal_array(OA,Integer(12),Integer(522),Integer(2))  # needs sage.schemes
True

The design is available from the general constructor:

sage: designs.orthogonal_arrays.is_available(12,522)  # needs sage.schemes
True
```python
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(12), Integer(522))
# needs sage.schemes
True
```
sage.combinat.designs.database.OA_14_524()

Return an OA(14,524)

This design is built by the slightly more general construction OA_520_plus_x().

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_14_524
sage: OA = OA_14_524()
# needs sage.schemes
sage: is_orthogonal_array(OA, 14, 524, 2)
# needs sage.schemes
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_14_524
>>> OA = OA_14_524()
# needs sage.schemes
>>> is_orthogonal_array(OA, Integer(14), Integer(524), Integer(2))
# needs sage.schemes
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(14, 524)
# needs sage.schemes
True
```

```python
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(14), Integer(524))
# needs sage.schemes
True
```
sage.combinat.designs.database.OA_15_112()

Returns an OA(15,112)

Published by Julian R. Abelin [Ab1995]. Uses the fact that 112 = 2^4 × 7 and that 7 is prime.

See also:

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_15_112
sage: OA = OA_15_112()
# needs sage.rings.finite_rings sage.schemes
sage: is_orthogonal_array(OA, 15, 112, 2)
# needs sage.rings.finite_rings sage.schemes
True
```
from sage.all import *
from sage.combinat.designs.designs_pyx import is_orthogonal_array
from sage.combinat.designs.database import OA_15_112
OA = OA_15_112()
# needs sage.rings.finite_rings sage.schemes
is_orthogonal_array(OA,Integer(15),Integer(112),Integer(2))
# needs sage.rings.finite_rings sage.schemes
True

OA = OA_15_224()
Returns an OA(15,224)
Published by Julian R. Abel in [Ab1995] (uses the fact that 224 = 2^5 \times 7 is a product of a power of 2 and a prime number).

See also:
sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

is_orthogonal_array(OA,15,224,2)
# not tested (too long)
True

The design is available from the general constructor:

sage: designs.orthogonal_arrays.is_available(15,224)
# needs sage.schemes
True

sage: designs.orthogonal_arrays.is_available(Integer(15),Integer(224))
(continues on next page)
sage.combinat.designs.database.OA_15_896()

Returns an OA(15,896)

Uses the fact that $896 = 2^7 \times 7$ is the product of a power of 2 and a prime number.

See also:

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_15_896
sage: OA = OA_15_896()  # not tested (too long, ~2min)
               # needs sage.rings.finite_rings
sage: is_orthogonal_array(OA, 15, 896, 2)  # not tested (too long)
               # needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(15, 896)  # needs sage.schemes
True
```

sage.combinat.designs.database.OA_16_176()

Returns an OA(16,176)

Published by Julian R. Abel in [Ab1995]. Uses the fact that $176 = 2^4 \times 11$ is a product of a power of 2 and a prime number.

See also:

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_16_176
sage: OA = OA_16_176()  # needs sage.rings.finite_rings
```

(continues on next page)
The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(16,176)  # needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(16),Integer(176))  # needs sage.schemes
True
```

```python
sage.combinat.designs.database.OA_16_208()
```

Returns an OA(16,208)

Published by Julian R. Abel in [Ab1995]. Uses the fact that 208 = 2^4 \times 13 is a product of 2 and a prime number.

See also:

```
sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()
```

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_16_208
sage: OA = OA_16_208()  # not tested (too long)  # needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,16,208,2)  # not tested (too long)  # needs sage.rings.finite_rings
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_16_208
>>> OA = OA_16_208()  # not tested (too long)  # needs sage.rings.finite_rings
>>> is_orthogonal_array(OA,Integer(16),Integer(176),Integer(2))  # needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(16,208)  # needs sage.schemes
True
```
sage.combinat.designs.database.OA_17_560()

Returns an OA(17,560)

This OA is built in Corollary 2.2 of [Thwarts].

EXAMPLES:

```python
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_17_560
>>> OA = OA_17_560()
# not tested (~25s)
```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_20_352
>>> OA = OA_20_352()       # not tested (~25s)

True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(20,352)  #..

True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_20_416
>>> OA = OA_20_416()       # not tested (~35s)

True
```

sage.combinat.designs.database.OA_20_416()

Returns an OA(20,416)

Published by Julian R. Abel in [Ab1995] (uses the fact that 416 = $2^5 \times 13$ is the product of a power of 2 and a prime number).

**See also:**

`sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()`

**EXAMPLES:**

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_20_416
sage: OA = OA_20_416()       # not tested (~35s)

True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(20,416)  #..

True
```

5.1. Comprehensive Module List 1009
"Combinatorics, Release 10.4"

```python
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(20),Integer(416))
... # needs sage.schemes
True
```

```
sage.combinat.designs.database.OA_20_544()

Returns an OA(20,544)

Published by Julian R. Abel in [Ab1995] (uses the fact that 544 = 2^5 × 17 is the product of a power of 2 and a prime number).

See also:

`sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()`

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_20_544
sage: OA = OA_20_544()  # not tested (too long ~1mn)  # needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,20,544,2)  # not tested  # needs sage.rings.finite_rings
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_20_544

OA = OA_20_544()  # not tested (too long ~1mn)  # needs sage.rings.finite_rings
is_orthogonal_array(OA,Integer(20),Integer(544),Integer(2))  # not tested  # needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(20,544)  # needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(20),Integer(544))  ...
# needs sage.schemes
True
```

```
sage.combinat.designs.database.OA_25_1262()

Returns an OA(25,1262)

The construction is given in [Greig99]. In Julian R. Abel’s words:

Start with a cyclic PG(2, 43) or (1893, 44, 1)-BIBD whose base block contains respectively 12, 13 and 19 point in the residue classes mod 3. In the resulting BIBD, remove one of the three classes: the result is a (1262, {25, 31, 32})-PBD, from which the OA(25, 1262) is obtained.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_25_1262
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: OA = OA_25_1262()  # not tested -- too long
sage: is_orthogonal_array(OA, 25, 1262, 2)  # not tested -- too long
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_25_1262

>>> OA = OA_25_1262()  # not tested -- too long

>>> is_orthogonal_array(OA, Integer(25), Integer(1262), Integer(2))  # not tested -- too long
True
```

Thedesignisavailablefromthegeneralconstructor:

```python
sage: designs.orthogonal_arrays.is_available(25, 1262)  # needs sage.schemes
True
```

```
>>> from sage.all import *

>>> designs.orthogonal_arrays.is_available(Integer(25), Integer(1262))  # needs sage.schemes
True
```

sage.combinat.designs.database.OA_520_plus_x(x)

Return an $OA(10 + x, 520 + x)$.

The construction shared by Julian R. Abel works for $OA(10, 520), OA(12, 522),$ and $OA(14, 524)$.

Let $n = 520 + x$ and $k = 10 + x$. Build a $TD(17, 31)$. Remove $8 - x$ points contained in a common block, add a new point $p$ and create a block $g_i \cup \{p\}$ for every (possibly truncated) group $g_i$. The result is a $(520 + x, 9 + x, 16, 17, 31, 32) - PBD$. Note that all blocks of size $\geq 30$ only intersect on $p$, and that the unique block $B_9$ of size 9 intersects all blocks of size 32 on one point. Now:

- Build an $OA(k, 16) - 16.OA(k, 16)$ for each block of size 16
- Build an $OA(k, 17) - 17.OA(k, 17)$ for each block of size 17
- Build an $OA(k, 31) - OA(k, 1)$ for each block of size 31 (with the hole on $p$).
- Build an $OA(k, 32) - 2.OA(k, 1)$ for each block $B$ of size 32 (with the holes on $p$ and $B \cap B_9$).
- Build an $OA(k, 9)$ on $B_9$.

Only a row $[p, p, ...]$ is missing from the $OA(10 + x, 520 + x)$

This construction is used in $OA(10, 520), OA(12, 522),$ and $OA(14, 524)$.

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_520_plus_x

sage: OA = OA_520_plus_x(0)  # not tested (already tested in OA_10_520)

sage: is_orthogonal_array(OA, 10, 520, 2)  # not tested (already tested in OA_10_520)
True
```

```
>>> from sage.all import *

>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array

>>> designs.orthogonal_arrays.is_available(OA, 10, 520, 2)  # not tested (already tested in OA_10_520)
True
```

(continues on next page)
sage.combinat.designs.database.OA_7_18()

Return an OA(7,18)

Proved in [JulianAbel13].

See also:

sage.combinat.designs.orthogonal_arrays.OA_from_quasi_difference_matrix()

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_7_18
sage: OA = OA_7_18()
sage: is_orthogonal_array(OA,7,18,2)
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(7,18)  # needs sage.schemes
True
```

sage.combinat.designs.database.OA_7_66()

Return an OA(7,66)

Construction shared by Julian R. Abel.

See also:

sage.combinat.designs.orthogonal_arrays.OA_from_PBD()

EXAMPLES:

```python
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_7_66
sage: OA = OA_7_66()
sage: is_orthogonal_array(OA,7,66,2)  # needs sage.schemes
```

(continues on next page)
The design is available from the general constructor:

```python
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(7,66)  # needs sage.schemes
True
```

```python
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(7),Integer(66))  # needs sage.schemes
True
```

```
sage.combinat.designs.database.OA_7_68()
```

Return an OA(7,68)

Construction shared by Julian R. Abel.

See also:
```
sage.combinat.designs.orthogonal_arrays.OA_from_PBD()
```

EXAMPLES:

```python
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
```

```
sage: OA = OA_7_68()  # needs sage.schemes
```

```
sage: is_orthogonal_array(OA,7,68,2)  # needs sage.schemes
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(7,68)  # needs sage.schemes
True
```
sage.combinat.designs.database.OA_7_74()

Return an OA(7,74)

Construction shared by Julian R. Abel.

See also:

\texttt{sage.combinat.designs.orthogonal_arrays.OA\_from\_PBD()}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_7_74
sage: OA = OA_7_74()
# needs sage.schemes
sage: is_orthogonal_array(OA,7,74,2) # needs sage.schemes
True
\end{verbatim}

The design is available from the general constructor:

\begin{verbatim}
sage: designs.orthogonal_arrays.is_available(7,74) # needs sage.schemes
True
\end{verbatim}

sage.combinat.designs.database.OA_8_69()

Return an OA(8,69)

Construction shared by Julian R. Abel.

See also:

\texttt{sage.combinat.designs.orthogonal_arrays.OA\_from\_PBD()}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_8_69
sage: OA = OA_8_69()
# needs sage.schemes
sage: is_orthogonal_array(OA,Integer(7),Integer(74),Integer(2))
# needs sage.schemes
True
\end{verbatim}

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```
sage: is_orthogonal_array(OA, 8, 69, 2)  # needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_8_69
>>> OA = OA_8_69()  # needs sage.schemes
>>> is_orthogonal_array(OA, Integer(8), Integer(69), Integer(2))  # needs sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(8, 69)  # needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_8_76
>>> OA = OA_8_76()  # needs sage.schemes
>>> is_orthogonal_array(OA, Integer(8), Integer(76), Integer(2))  # needs sage.schemes
True
```

sage.combinat.designs.database.OA_8_76()

Return an OA(8,76)

Construction shared by Julian R. Abel.

See also:

`sage.combinat.designs.orthogonal_arrays.OA_from_PBD()`

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_8_76
sage: OA = OA_8_76()  # needs sage.schemes
sage: is_orthogonal_array(OA, 8, 76, 2)  # needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_8_76
>>> OA = OA_8_76()  # needs sage.schemes
>>> is_orthogonal_array(OA, Integer(8), Integer(76), Integer(2))  # needs sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(8, 76)  # needs sage.schemes
True
```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(8), Integer(76))
... False  # needs sage.schemes
True

sage.combinat.designs.database.OA_9_1078()

Returns an OA(9,1078)

This is obtained through the generalized Brouwer-van Rees construction. Indeed, 1078 = 89.11 + (99 = 9.11) and there exists an OA(9, 100) − OA(9, 11).

Note: This function should be removed once find_brouwer_van_rees_with_one_truncated_column() can handle all incomplete orthogonal arrays obtained through incomplete_orthogonal_array().

EXAMPLES:

sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_1078
sage: OA = OA_9_1078()
# not tested -- ~3s
sage: is_orthogonal_array(OA, 9, 1078, 2)  # not tested -- ~3s
True

>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_9_1078
>>> OA = OA_9_1078()
# not tested -- ~3s
>>> is_orthogonal_array(OA, Integer(9), Integer(1078), Integer(2))  # not tested -- ~3s
True

The design is available from the general constructor:

sage: designs.orthogonal_arrays.is_available(9, 1078)  # needs sage.schemes
True

sage.combinat.designs.database.OA_9_120()

Return an OA(9,120)

Construction shared by Julian R. Abel:

From a resolvable (120, 8, 1) − BIBD, one can obtain 7 MOLS(120) or a resolvable TD(8, 120) by forming a resolvable TD(8, 8) − 8.TD(8, 1) on $I_8 \times B$ for each block $B$ in the BIBD. This gives a TD(8, 120) − 120.TD(8, 1) (which is resolvable as the BIBD is resolvable).

See also:

RBIBD_120_8_1()

EXAMPLES:
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_120
sage: OA = OA_9_120()  # needs sage.modules sage.schemes
sage: is_orthogonal_array(OA,9,120,2)  # needs sage.modules sage.schemes
True

>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_9_135
>>> OA = OA_9_135()  # needs sage.rings.finite_rings sage.schemes
>>> is_orthogonal_array(OA,Integer(9),Integer(135),Integer(2)) (continues on next page)

The design is available from the general constructor:

sage: designs.orthogonal_arrays.is_available(9,120)  # needs sage.schemes
True

>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(9),Integer(120))  # needs sage.schemes
True

sage.combinat.designs.database.OA_9_135()
Return an OA(9,135)

Construction shared by Julian R. Abel:

This design can be built by Wilson’s method (135 = 8.16 + 7) applied to an Orthogonal Array OA(9 + 7, 16) with 7 groups truncated to size 1 in such a way that a block contain 0, 1 or 3 points of the truncated groups.

This is possible, because PG(2, 2) (the projective plane over GF(2)) is a subdesign in PG(2, 16) (the projective plane over GF(16)); in a cyclic PG(2, 16) or BIBD(273, 17, 1) the points ≡ 0 (mod 39) form such a subdesign (note that 273 = 16^2 + 16 + 1 and 273 = 39 × 7 and 7 = 2^2 + 2 + 1).

EXAMPLES:

sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_135
sage: OA = OA_9_135()  # needs sage.rings.finite_rings sage.schemes
sage: is_orthogonal_array(OA,9,135,2)  # needs sage.rings.finite_rings sage.schemes
True

>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_9_135
>>> OA = OA_9_135()  # needs sage.rings.finite_rings sage.schemes
>>> is_orthogonal_array(OA,Integer(9),Integer(135),Integer(2)) (continues on next page)
The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(9,135)  # needs sage.rings.finite_rings sage.schemes
True
```

As this orthogonal array requires a \((273, 17, 1)\) cyclic difference set, we check that it is available:

```
sage: G,D = designs.difference_family(273,17,1); G  # needs sage.libs.pari
Ring of integers modulo 273
```

```
from sage.all import *

>>> designs.orthogonal_arrays.is_available(Integer(9),Integer(135))  # needs sage.schemes
True
```

```
from sage.all import *

>>> G,D = designs.difference_family(Integer(273),Integer(17),Integer(1)); G  # needs sage.libs.pari
Ring of integers modulo 273
```

```
sage.combinat.designs.database.OA_9_1612()
```

Returns an OA(9,1612)

This is obtained through the generalized Brouwer-van Rees construction. Indeed, \(1612 = 89.17 + 99 = 9.11\) and there exists an \(O_A(9,100) - O_A(9,11)\).

**Note:** This function should be removed once `find_brouwer_van_rees_with_one_truncated_column()` can handle all incomplete orthogonal arrays obtained through `incomplete_orthogonal_array()`.

**EXAMPLES:**

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_1612
sage: OA = OA_9_1612()  # not tested -- ~6s
sage: is_orthogonal_array(OA,9,1612,2)  # not tested -- ~6s
True
```

```
from sage.all import *

>>> from sage.all import *

>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array

>>> from sage.combinat.designs.database import OA_9_1612

>>> OA = OA_9_1612()  # not tested -- ~6s

>>> is_orthogonal_array(OA,Integer(9),Integer(1612),Integer(2))  # not tested -- ~6s
True
```

The design is available from the general constructor:
sage: designs.orthogonal_arrays.is_available(9,1612)  
# needs sage.schemes  
True

>>> from sage.all import *  
>>> designs.orthogonal_arrays.is_available(Integer(9),Integer(1612))  
# needs sage.schemes  
True

sage.combinat.designs.database.OA_9_40()

Return an OA(9,40)

As explained in the Handbook III.3.62 [DesignHandbook]. Uses the fact that 40 = 2³ × 5 and that 5 is prime.

See also:

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array  
sage: from sage.combinat.designs.database import OA_9_40  
sage: OA = OA_9_40()  
# needs sage.rings.finite_rings  
>>> is_orthogonal_array(OA,Integer(9),Integer(40),Integer(2))  
# needs sage.rings.finite_rings  
True

The design is available from the general constructor:

sage: designs.orthogonal_arrays.is_available(9,40)  
# needs sage.schemes  
True

>>> from sage.all import *  
>>> designs.orthogonal_arrays.is_available(Integer(9),Integer(40))  
# needs sage.schemes  
True

sage.combinat.designs.database.QDM_19_6_1_1_1_1()

Return a (19, 6; 1, 1; 1)-quasi-difference matrix.

Used to build an OA(6, 20)

EXAMPLES:
sage: from sage.combinat.designs.database import QDM_19_6_1_1_1
sage: G,M = QDM_19_6_1_1_1()
sage: is_quasi_difference_matrix(M,G,6,1,1,1)
True

>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_19_6_1_1_1
>>> G,M = QDM_19_6_1_1_1()

sage.combinat.designs.database.QDM_21_5_1_1_1()
Return a (21; 5; 1; 1; 1)-quasi-difference matrix.
Used to build an OA(5, 22)

EXAMPLES:
sage: from sage.combinat.designs.database import QDM_21_5_1_1_1
sage: G,M = QDM_21_5_1_1_1()
sage: is_quasi_difference_matrix(M,G,5,1,1,1)
True

>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_21_5_1_1_1

sage.combinat.designs.database.QDM_21_6_1_1_5()
Return a (21; 6; 1; 1; 5)-quasi-difference matrix.
Used to build an OA(6, 26)

EXAMPLES:
sage: from sage.combinat.designs.database import QDM_21_6_1_1_5
sage: G,M = QDM_21_6_1_1_5()
sage: is_quasi_difference_matrix(M,G,6,1,1,5)
True

>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_21_6_1_1_5

sage.combinat.designs.database.QDM_21_5_1_1_1()
Return a (21; 5; 1; 1; 1)-quasi-difference matrix.
Used to build an OA(5, 22)

EXAMPLES:
sage: from sage.combinat.designs.database import QDM_21_5_1_1_1
sage: G,M = QDM_21_5_1_1_1()
sage: is_quasi_difference_matrix(M,G,5,1,1,1)
True

>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_21_5_1_1_1

sage.combinat.designs.database.QDM_21_6_1_1_5()
Return a (21; 6; 1; 1; 5)-quasi-difference matrix.
Used to build an OA(6, 26)

EXAMPLES:
sage: from sage.combinat.designs.database import QDM_21_6_1_1_5
sage: G,M = QDM_21_6_1_1_5()
sage: is_quasi_difference_matrix(M,G,6,1,1,5)
True

>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_21_6_1_1_5

Chapter 5. Comprehensive Module List
sage.combinat.designs.database.QDM_25_6_1_1_5()

Return a \((25, 6; 1, 1; 5)\)-quasi-difference matrix.

Used to build an \(OA(6, 30)\)

EXAMPLES:

```python
sage: from sage.combinat.designs.database import QDM_25_6_1_1_5
sage: G, M = QDM_25_6_1_1_5()  # needs sage.modules
sage: is_quasi_difference_matrix(M, G, 6, 1, 1, 5)  # needs sage.modules
True
```

sage.combinat.designs.database.QDM_33_6_1_1_1_1()

Return a \((33, 6; 1, 1; 1)\)-quasi-difference matrix.

Used to build an \(OA(6, 34)\)

EXAMPLES:

```python
sage: from sage.combinat.designs.database import QDM_33_6_1_1_1_1
sage: G, M = QDM_33_6_1_1_1_1()  # needs sage.modules
sage: is_quasi_difference_matrix(M, G, 6, 1, 1, 1)  # needs sage.modules
True
```

sage.combinat.designs.database.QDM_35_7_1_1_1_7()

Return a \((35, 7; 1, 1; 7)\)-quasi-difference matrix.

Used to build an \(OA(7, 42)\)

As explained in the Handbook III.3.63 [DesignHandbook].

EXAMPLES:

```python
sage: from sage.combinat.designs.database import QDM_35_7_1_1_1_7
sage: G, M = QDM_35_7_1_1_1_7()  # needs sage.modules
```

(continues on next page)
sage: G,M = QDM_35_7_1_1_1_7()
sage: is_quasi_difference_matrix(M,G,7,1,1,7)
True

>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_35_7_1_1_1_7
>>> from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
>>>
G,M = QDM_35_7_1_1_1_7()
>>> is_quasi_difference_matrix(M,G,Integer(7),Integer(1),Integer(1),Integer(7))
True

sage.combinat.designs.database.QDM_37_6_1_1_1_1()
Return a (37, 6; 1, 1; 1)-quasi-difference matrix.
Used to build an OA(6, 38)
Given in the Handbook III.3.60 [DesignHandbook].
EXAMPLES:
sage: from sage.combinat.designs.database import QDM_37_6_1_1_1_1
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_37_6_1_1_1_1()
sage: is_quasi_difference_matrix(M,G,6,1,1,1)
True

>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_37_6_1_1_1_1
>>> from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
>>>
G,M = QDM_37_6_1_1_1_1()
>>> is_quasi_difference_matrix(M,G,Integer(6),Integer(1),Integer(1),Integer(1))
True

sage.combinat.designs.database.QDM_45_7_1_1_1_9()
Return a (45, 7; 1, 1; 9)-quasi-difference matrix.
Used to build an OA(7, 54)
As explained in the Handbook III.3.71 [DesignHandbook].
EXAMPLES:
sage: from sage.combinat.designs.database import QDM_45_7_1_1_1_9
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_45_7_1_1_1_9()
sage: is_quasi_difference_matrix(M,G,7,1,1,9)
True

>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_45_7_1_1_1_9
>>> from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
>>>
G,M = QDM_45_7_1_1_1_9()
>>> is_quasi_difference_matrix(M,G,Integer(7),Integer(1),Integer(1),Integer(9))
True

sage.combinat.designs.database.QDM_54_7_1_1_1_8()
Return a (54, 7; 1, 1; 8)-quasi-difference matrix.
Used to build an $OA(7, 62)$

As explained in the Handbook III.3.74 [DesignHandbook].

EXAMPLES:

```python
sage: from sage.combinat.designs.database import QDM_54_7_1_1_8
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G, M = QDM_54_7_1_1_8()
sage: is_quasi_difference_matrix(M, G, 7, 1, 1, 8)
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_54_7_1_1_8
>>> from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
>>> G, M = QDM_54_7_1_1_8()
>>> is_quasi_difference_matrix(M, G, Integer(7), Integer(1), Integer(1), Integer(8))
True
```

`sage.combinat.designs.database.QDM_57_9_1_1_8()`

Return a $(57, 9; 1, 1; 8)$-quasi-difference matrix.

Used to build an $OA(9, 65)$

Construction shared by Julian R. Abel

EXAMPLES:

```python
sage: from sage.combinat.designs.database import QDM_57_9_1_1_8
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G, M = QDM_57_9_1_1_8()
# → needs sage.schemes
sage: is_quasi_difference_matrix(M, G, 9, 1, 1, 8)
# → needs sage.schemes
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_57_9_1_1_8
>>> from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
>>> G, M = QDM_57_9_1_1_8()
# → needs sage.schemes
>>> is_quasi_difference_matrix(M, G, Integer(9), Integer(1), Integer(1), Integer(8))
# → needs sage.schemes
True
```

`sage.combinat.designs.database.RBIBD_120_8_1()`

Return a resolvable $BIBD(120, 8, 1)$

This function output a list $L$ of $17 \times 15$ blocks such that $L[i*15:(i+1)*15]$ is a partition of 120.

Construction shared by Julian R. Abel:

Seiden’s method: Start with a cyclic $(273, 17, 1) = BIBD$ and let $B$ be an hyperoval, i.e. a set of 18 points which intersects any block of the BIBD in either 0 points (153 blocks) or 2 points (120 blocks). Dualise this design and take these last 120 blocks as points in the design; blocks in the design will correspond to the $273 - 18 = 255$ non-hyperoval points.

The design is also resolvable. In the original $PG(2, 16)$ take any point $T$ in the hyperoval and consider a block $B1$ containing $T$. The 15 points in $B1$ that do not belong to the hyperoval correspond to 15
blocks forming a parallel class in the dualised design. The other 16 parallel classes come in a similar way, by using point \( T \) and the other 16 blocks containing \( T \).

See also:

\[ \text{OA}_9_{120}(\)\]

EXAMPLES:

```python
sage: from sage.combinat.designs.database import RBIBD_120_8_1
sage: RBIBD = RBIBD_120_8_1()
# needs sage.modules
sage: is_pairwise_balanced_design(RBIBD,120,[8])
# needs sage.modules
True
```

It is indeed resolvable, and the parallel classes are given by 17 slices of consecutive 15 blocks:

```python
sage: for i in range(17):
    # needs sage.modules
    assert len(set(sum(RBIBD[i*15:(i+1)*15],[]))) == 120
```

The BIBD is available from the constructor:

```python
sage: _ = designs.balanced_incomplete_block_design(120,8)
# needs sage.modules
>>> from sage.all import *
>>> _ = designs.balanced_incomplete_block_design(Integer(120),Integer(8))
# needs sage.modules
```

\[ \text{sage.combinat.designs.database.cyclic_shift}(l,i)\]

\[ \text{sage.combinat.designs.database.f}()\]

Return a \((57,9;1,1;8)\)-quasi-difference matrix.

Used to build an \(OA(9,65)\)

Construction shared by Julian R. Abel

EXAMPLES:
Combinatorics, Release 10.4

5.1.82 Catalog of designs

This module gathers all designs that can be reached through designs.<tab>. Example with the Witt design on 24 points:

```
sage: designs.WittDesign(24)  # optional - gap_package_design
Incidence structure with 24 points and 759 blocks
```

Or a Steiner Triple System on 19 points:

```
sage: designs.steiner_triple_system(19)  # optional - gap_package_design
(19,3,1)-Balanced Incomplete Block Design
```

La Jolla Covering Repository

The La Jolla Covering Repository (LJCR, see\(^1\)) is an online database of covering designs. As it is frequently updated, it is not included in Sage, but one can query it through designs.best_known_covering_design_from_LJCR:

```
sage: C = designs.best_known_covering_design_from_LJCR(7, 3, 2)  # optional - internet
sage: C  # optional - internet
(7, 3, 2)-covering design of size 7
Lower bound: 7
Method: lex covering
Submitted on: 1996-12-01 00:00:00
```

\(^1\) La Jolla Covering Repository, [https://math.ccrwest.org/cover.html](https://math.ccrwest.org/cover.html)
sage: C.incidence_structure()  # optional - internet
Incidence structure with 7 points and 7 blocks

>>> from sage.all import *
>>> C = designs.best_known_covering_design_from_LJCR(Integer(7), Integer(3),
       Integer(2))  # optional - internet
>>> C  # optional - internet
(7, 3, 2)-covering design of size 7
Lower bound: 7
Method: lex covering
Submitted on: 1996-12-01 00:00:00
>>> C.incidence_structure()  # optional - internet
Incidence structure with 7 points and 7 blocks

Design constructors

This module gathers the following designs:

- ProjectiveGeometryDesign()
- DesarguesianProjectivePlaneDesign()
- HughesPlane()
- HigmanSimsDesign()
- balanced_incomplete_block_design()
- resolvable_balanced_incomplete_block_design()
- kirkman_triple_system()
- AffineGeometryDesign()
- CremonaRichmondConfiguration()
- WittDesign()
- HadamardDesign()
- Hadamard3Design()
- mutually_orthogonal_latin_squares()
- transversal_design()
- orthogonal_array()
- incomplete_orthogonal_array()
- difference_family()
- difference_matrix()
- steiner_triple_system()
- steiner_quadruple_system()
- projective_plane()
- biplane()
- gen_quadrangles_with_spread()

And the designs.best_known_covering_design_from_LJCR function which queries the LJCR.

Todo: Implement DerivedDesign and ComplementaryDesign.

REFERENCES:
5.1.83 Cython functions for combinatorial designs

This module implements the design methods that need to be somewhat efficient.

Functions

sage.combinat.designs.designs_pyx.is_covering_array(array, strength=None, levels=None, verbose=False, parameters=False)

Check if the input is a covering array with given strength.

See sage.combinat.designs.covering_array for a definition.

INPUT:

• array – the Covering Array to be tested.
• strength (integer) – the parameter \( t \) of the covering array, such that in any selection of \( t \) columns of the array, every \( t \)-tuple appears at least once. If set to None then all \( t > 0 \) are tested to and the maximal strength is used.
• levels – the number of symbols that appear in array. If set to None, then each unique entry in array is counted.
• verbose (boolean) – whether to display some information about the covering array.
• parameters (boolean) – whether to return the parameters of the Covering Array. If set to True, the function returns a pair (boolean_answer, \( (N, t, k, v) \)).

EXAMPLES:

sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: C = [[1, 1, 1, 0],
.....: [1, 1, 0, 0],
.....: [0, 0, 0]]

sage: is_covering_array(C)
Traceback (most recent call last):
... ValueError: Not all rows are the same length, row 2 is not the same length as row...

sage: C = [[0, 1, 1],
.....: [1, 1, 0],
.....: [1, 0, 1],
.....: [0, 0, 0]]

sage: is_covering_array(C, strength=4)
Traceback (most recent call last):
... ValueError: Strength must be equal or less than number of columns

sage: C = [[0, 1, 1],
.....: [1, 1, 1],
.....: [1, 0, 1]]

sage: is_covering_array(C, verbose=True)
A 3 by 3 Covering Array with strength 0 with entries from a symbol set of size 2
True

sage: C = [[0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
.....: [0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
.....: [0, 1, 1, 1, 0, 0, 0, 1, 1, 1],
.....: [0, 1, 1, 0, 0, 1, 1, 1, 1, 1],

(continues on next page)
### A Matrix is a \((G, k, \lambda)\)-Difference Matrix

A matrix \(M\) is a \((G, k, \lambda)\)-difference matrix if its entries are element of \(G\), and if for any two rows \(R, R'\) of \(M\) and \(x \in G\) there are exactly \(\lambda\) values \(i\) such that \(R_i - R'_i = x\).

**INPUT:**

- \(M\) – a matrix with entries from \(G\)
- \(G\) – a group
- \(k\) – integer
- \(\lambda\) (integer) – set to 1 by default.
- \(\text{verbose}\) (boolean) – whether to print some information when the answer is False.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: q = 3**3
sage: F = GF(q, 'x')
sage: M = [[x*y for y in F] for x in F]
sage: is_difference_matrix(M, F, q, verbose=1)
True
```

```python
sage: B = [[0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
       [0, 1, 2, 3, 4, 2, 3, 4, 0, 1],
       [0, 2, 4, 1, 3, 3, 0, 2, 4, 1]]
```

```python
sage: G = GF(5)
sage: B = [[G(b) for b in R] for R in B]
sage: is_difference_matrix(list(zip(*B)), G, 3, 2)
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> q = Integer(3)**Integer(3)
>>> F = GF(q, 'x')
>>> is_difference_matrix(list(zip(*B)), G, 3, 2)
True
```

...
Bad input:

```python
sage: for R in M: R.append(None)
sage: is_difference_matrix(M,F,q,verbose=1)
The matrix has 28 columns but k=27
False
sage: for R in M: _=R.pop(-1)
sage: M.append([None]*3**3)
sage: is_difference_matrix(M,F,q,verbose=1)
The matrix has 28 rows instead of \lambda(|G|-1+2u)+\mu=1(27-1+2.0)+1=27
False
sage: _= M.pop(-1)
sage: for R in M: R[-1] = 0
sage: is_difference_matrix(M,F,q,verbose=1)
Columns 0 and 26 do not generate all elements of G exactly \lambda(=1) times. The element x appeared 0 times as a difference.
False
```

```python
def from sage.all import *
def # needs sage.rings.finite_rings
def for R in M: R.append(None)
def is_difference_matrix(M,F,q,verbose=Integer(1))
The matrix has 28 columns but k=27
False
def for R in M: _=R.pop(-Integer(1))
def M.append([None]*Integer(3)**Integer(3))
def is_difference_matrix(M,F,q,verbose=Integer(1))
The matrix has 28 rows instead of \lambda(|G|-1+2u)+\mu=1(27-1+2.0)+1=27
False
def _= M.pop(-Integer(1))
def for R in M: R[-Integer(1)] = Integer(0)
def is_difference_matrix(M,F,q,verbose=Integer(1))
Columns 0 and 26 do not generate 0 exactly 27 times instead of the expected \mu(=1)
False
```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> for R in M: R[-Integer(1)] = Integer(1)
>>> M[-Integer(1)][-Integer(1)] = Integer(0)
>>> is_difference_matrix(M,F,q,verbose=Integer(1))
Columns 0 and 26 do not generate all elements of G exactly lambda(=1) times.
The element x appeared 0 times as a difference.
False
```

```python
sage.combinat.designs.designs_pyx.is_group_divisible_design(groups, blocks, v, G=None, K=None, lambd=1, verbose=False)
```

Checks that input is a Group Divisible Design on \{0, ..., v - 1\}

For more information on Group Divisible Designs, see `GroupDivisibleDesign`

**INPUT:**

- `groups` – a partition of \(X\). If set to `None` the groups are guessed automatically, and the function returns `(True, guessed_groups)` instead of `True`
- `blocks` – collection of blocks
- `v` (integers) – size of the ground set assumed to be \(X = \{0, ..., v - 1\}\).
- `G` – list of integers of which the sizes of the groups must be elements. Set to `None` (automatic guess) by default.
- `K` – list of integers of which the sizes of the blocks must be elements. Set to `None` (automatic guess) by default.
- `lambd` – value of \(\lambda\). Set to 1 by default.
- `verbose` (boolean) – whether to display some information when the design is not a GDD.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.designs_pyx import is_group_divisible_design
sage: TD = designs.transversal_design(4,10) # needs sage.modules
sage: groups = [list(range(i*10,(i+1)*10)) for i in range(4)]
```

```python
sage: is_group_divisible_design(groups,TD,40,lambd=1) # needs sage.modules
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_group_divisible_design
>>> TD = designs.transversal_design(Integer(4),Integer(10)) # needs sage.modules
>>> groups = [list(range(i*Integer(10),(i+Integer(1))*Integer(10))) for i in range(Integer(4))]
```

```python
>>> is_group_divisible_design(groups,TD,Integer(40),lambd=Integer(1)) # needs sage.modules
True
```

```python
sage.combinat.designs.designs_pyx.is_orthogonal_array(OA, k, n, t=2, verbose=False, terminology='OA')
```

Check that the integer matrix \(OA\) is an \(OA(k,n,t)\).

See `orthogonal_array()` for a definition.
INPUT:

• OA – the Orthogonal Array to be tested
• k, n, t (integers) – only implemented for t = 2.
• verbose (boolean) – whether to display some information when OA is not an orthogonal array \( OA(k,n) \).
• terminology (string) – how to phrase the information when verbose = True. Possible values are "OA", "MOLS".

EXAMPLES:

```
sage: # needs sage.schemes
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: OA = designs.orthogonal_arrays.build(8,9)
sage: is_orthogonal_array(OA,8,9)
True
sage: is_orthogonal_array(OA,8,10)
False
sage: OA[4][3] = 1
sage: is_orthogonal_array(OA,8,9)
False
sage: is_orthogonal_array(OA,8,9,verbose=True)
Columns 0 and 3 are not orthogonal
False
sage: is_orthogonal_array(OA,8,9,verbose=True, terminology="MOLS")
Squares 0 and 3 are not orthogonal
False
```

```
>>> from sage.all import *

>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array

>>> OA = designs.orthogonal_arrays.build(Integer(8),Integer(9))

>>> is_orthogonal_array(OA,Integer(8),Integer(9))
True

>>> is_orthogonal_array(OA,Integer(8),Integer(10))
False

>>> OA[Integer(4)][Integer(3)] = Integer(1)

>>> is_orthogonal_array(OA,Integer(8),Integer(9))
False

>>> is_orthogonal_array(OA,Integer(8),Integer(9),verbose=True)
Columns 0 and 3 are not orthogonal
False

>>> is_orthogonal_array(OA,Integer(8),Integer(9), verbose=True, terminology="MOLS")
Squares 0 and 3 are not orthogonal
False
```

```
sage.combinat.designs.designs_pyx.is_pairwise_balanced_design(blocks, v, K=None, lambd=1, verbose=False)
```

Checks that input is a Pairwise Balanced Design (PBD) on \( \{0, ..., v - 1\} \).

For more information on Pairwise Balanced Designs (PBD), see PairwiseBalancedDesign.

INPUT:

• blocks – collection of blocks
• v (integers) – size of the ground set assumed to be \( X = \{0, ..., v - 1\} \).
• K – list of integers of which the sizes of the blocks must be elements. Set to None (automatic guess) by default.
• lambda – value of \( \lambda \). Set to 1 by default.
• verbose (boolean) – whether to display some information when the design is not a PBD.

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_pairwise_balanced_design
sage: sts = designs.steiner_triple_system(9)
sage: is_pairwise_balanced_design(sts, 9, [3], 1)
True
sage: TD = designs.transversal_design(4, 10).blocks()
# needs sage.modules
sage: groups = [list(range(i*10,(i+1)*10)) for i in range(4)]
sage: is_pairwise_balanced_design(TD + groups, 40, [4, 10], 1, verbose=True)  # needs sage.modules
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_pairwise_balanced_design
>>> p = designs.projective_plane(4)
# needs sage.schemes
>>> b = p.blocks()
# needs sage.schemes
```

sage.combinat.designs.designs_pyx.is_projective_plane(blocks, verbose=False)

Test whether the blocks form a projective plane on \( \{0, \ldots, v - 1\} \)

A projective plane is an incidence structure that has the following properties:

1. Given any two distinct points, there is exactly one line incident with both of them.
2. Given any two distinct lines, there is exactly one point incident with both of them.
3. There are four points such that no line is incident with more than two of them.

For more informations, see Wikipedia article Projective_plane.

is_t_design() can also check if an incidence structure is a projective plane with the parameters \( v = k^2 + k + 1 \), \( t = 2 \) and \( l = 1 \).

INPUT:

• blocks – collection of blocks
• verbose – whether to print additional information

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_projective_plane
sage: p = designs.projective_plane(4)  # needs sage.schemes
sage: b = p.blocks()  # needs sage.schemes
```
sage: is_projective_plane(b, verbose=True)  # needs sage.schemes
True

sage: # needs sage.schemes
sage: p = designs.projective_plane(2)
sage: b = p.blocks()
sage: is_projective_plane(b)  # needs sage.schemes
True

sage: b[0][2] = 5
sage: is_projective_plane(b, verbose=True)  # needs sage.schemes
the pair (0,5) has been seen 2 times but lambda=1
False

sage: is_projective_plane([[0,1,2],[1,2,4]], verbose=True)  # needs sage.schemes
the pair (0,3) has been seen 0 times but lambda=1
False

sage: is_projective_plane([[1]], verbose=True)  # needs sage.schemes
First block has less than 3 points.
False

# needs sage.schemes
sage: p = designs.projective_plane(2)
sage: b = p.blocks()
is_projective_plane(b, verbose=True)  # needs sage.schemes
True

>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_projective_plane
>>> p = designs.projective_plane(Integer(4))  # needs sage.schemes
>>> b = p.blocks()  # needs sage.schemes
>>> is_projective_plane(b, verbose=True)  # needs sage.schemes
True

>>> # needs sage.schemes
>>> p = designs.projective_plane(Integer(2))
>>> b = p.blocks()
>>> is_projective_plane(b)  # needs sage.schemes
True

>>> b[Integer(0)][Integer(2)] = Integer(5)
>>> is_projective_plane(b, verbose=True)  # needs sage.schemes
the pair (0,5) has been seen 2 times but lambda=1
False

>>> is_projective_plane([[Integer(0),Integer(1),Integer(2)],[Integer(1),
Integer(2),Integer(4)]], verbose=True)  # needs sage.schemes
the pair (0,3) has been seen 0 times but lambda=1
False

>>> is_projective_plane([[Integer(1)]], verbose=True)
First block has less than 3 points.
False

```
>>> # needs sage.schemes
>>> p = designs.projective_plane(Integer(2))
>>> b = p.blocks()
>>> b[Integer(2)].append(Integer(4))
>>> is_projective_plane(b, verbose=True)
a block has size 4 while K=[3]
False
```

```
sage.combinat.designs.designs_pyx.is_quasi_difference_matrix(M, G, k, lmbda, mu, u,
              verbose=False)
```

Test if the matrix is a \((G, k; \lambda, \mu; u)\)-quasi-difference matrix

Let \(G\) be an abelian group of order \(n\). A \((n, k; \lambda, \mu; u)\)-quasi-difference matrix (QDM) is a matrix \(Q_{ij}\) with
\(\lambda(n - 1 + 2u) + \mu\) rows and \(k\) columns, with each entry either equal to None (i.e. the ‘missing entries’) or to an element of \(G\). Each column contains exactly \(\lambda u\) empty entries, and each row contains at most one None. Furthermore, for each \(1 \leq i < j \leq k\), the multiset
\[
\{q_{i1} - q_{lj} : 1 \leq l \leq \lambda(n - 1 + 2u) + \mu, \text{ with } q_{i1} \text{ and } q_{lj} \text{ not empty}\}
\]
contains \(\lambda\) times every nonzero element of \(G\) and contains \(\mu\) times 0.

INPUT:

- \(M\) – a matrix with entries from \(G\) (or equal to None for missing entries)
- \(G\) – a group
- \(k, \lambda, \mu, u\) – integers
- \(\text{verbose}\) (boolean) – whether to print some information when the answer is False.

EXAMPLES:

Differences matrices:

```
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: q = 3**3
sage: F = GF(q, 'x')
    # needs sage.rings.finite_rings
    sage: M = [[x*y for y in F] for x in F]
    # needs sage.rings.finite_rings
    sage: is_quasi_difference_matrix(M,F,q,1,1,0,verbose=1)
    True
sage: B = [[0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
    ....: [0, 1, 2, 3, 4, 2, 3, 4, 0, 1],
    ....: [0, 2, 4, 1, 3, 3, 0, 2, 4, 1]]
    sage: G = GF(5)
    sage: B = [G(b) for b in B]
    sage: is_quasi_difference_matrix(list(zip(*B)),G,3,2,2,0)
    True
```
\[ q = \text{Integer}(3)^*\text{Integer}(3) \]\n
\[ F = \text{GF}(q, 'x') \]

\[ M = [[x^y \text{ for } y \text{ in } F] \text{ for } x \text{ in } F] \]

\[ \text{is_quasi_difference_matrix}(M,F,q,\text{Integer}(1),\text{Integer}(1),\text{Integer}(0),\]

\[ \text{verbose=\text{Integer}(1)}) \]

\[ \text{True} \]

\[ B = [[\text{Integer}(0), \text{Integer}(0), \text{Integer}(0), \text{Integer}(0), \text{Integer}(0),\]

\[ \text{Integer}(0), \text{Integer}(0), \text{Integer}(0)],\]

\[ \text{... \text{for } R \text{ in } B} \]

\[ \text{is_quasi_difference_matrix}(\text{list}(*B),\text{G},\text{Integer}(3),\text{Integer}(2),\text{Integer}(2),\]

\[ \text{verbose=\text{Integer}(1)}) \]

\[ \text{True} \]

A quasi-difference matrix from the database:

\[ \text{sage: from sage.combinat.designs.database import QDM} \]

\[ \text{sage: G,M = QDM[38,1][37,1,1,1][1]}() \]

\[ \text{sage: is_quasi_difference_matrix}(M,G,k=6,\text{lambda}=1,\text{mu}=1,\text{u}=1) \]

\[ \text{True} \]

Bad input:

\[ \text{sage: is_quasi_difference_matrix}(M,G,k=6,\text{lambda}=1,\text{mu}=1,\text{u}=3,\text{verbose}=1) \]

The matrix has 39 rows instead of \( \lambda(|G|-1+2u)+\mu=1(37-1+2.3)+1=43 \)

False

\[ \text{sage: is_quasi_difference_matrix}(M,G,k=6,\text{lambda}=1,\text{mu}=2,\text{u}=1,\text{verbose}=1) \]

The matrix has 39 rows instead of \( \lambda(|G|-1+2u)+\mu=1(37-1+2.1)+2=40 \)

False

\[ \text{sage: M[3][1] = None} \]

Row 3 contains more than one empty entry

False

\[ \text{sage: M[3][1] = 1} \]

\[ \text{sage: M[6][1] = None} \]

Column 1 contains 2 empty entries instead of the expected \( \lambda.\text{u}=1.1=1 \)

False

\[ \text{sage: from sage.all import *} \]

\[ \text{sage: is_quasi_difference_matrix}(M,G,k=\text{Integer}(6),\text{lambda}=\text{Integer}(1),\text{mu}=\text{Integer}(1),\]

\[ \text{verbose=\text{Integer}(1)}) \]

\[ \text{(continues on next page)} \]
→ u=Integer(3), verbose=Integer(1))
The matrix has 39 rows instead of lambda(|G|-1+2u)+mu=1(37-1+2.3)+1=43 False
>>> is_quasi_difference_matrix(M,G,k=Integer(6),lmbda=Integer(1),mu=Integer(2),
→ u=Integer(1), verbose=Integer(1))
The matrix has 39 rows instead of lambda(|G|-1+2u)+mu=1(37-1+2.1)+2=40 False
>>> M[Integer(3)][Integer(1)] = None
>>> is_quasi_difference_matrix(M,G,k=Integer(6),lmbda=Integer(1),mu=Integer(1),
→ u=Integer(1), verbose=Integer(1))
Row 3 contains more than one empty entry False
>>> M[Integer(3)][Integer(1)] = Integer(1)

>>> is_quasi_difference_matrix(M,G,k=Integer(6),lmbda=Integer(1),mu=Integer(1),
→ u=Integer(1), verbose=Integer(1))
Column 1 contains 2 empty entries instead of the expected lambda.u=1.1=1 False

5.1.84 Difference families

This module gathers everything related to difference families. One can build a difference family (or check that it can be built) with \texttt{difference-family}():

\begin{verbatim}
sage: G,F = designs.difference_family(13,4,1) # needs sage.libs.pari sage.modules

>>> from sage.all import *
>>> G,F = designs.difference_family(Integer(13),Integer(4),Integer(1)) # needs sage.libs.pari sage.modules
\end{verbatim}

It defines the following functions:

\begin{verbatim}
are_complementary_difference_sets() Check if A and B are complementary difference sets over the group G.
are_hadamard_difference_set_parameters() Check whether \((v,k,lmbda)\) is of the form \((4N^2, 2N^2 - N, N^2 - N)\).
are_mcfarland_1973_parameters() Test whether \((v,k,lmbda)\) is a triple that can be obtained from the construction from [McF1973].
block_stabilizer() Compute the left stabilizer of the block \(B\) under the action of \(G\).
complementary_difference_sets() Compute complementary difference sets over a group of order \(n = 2m + 1\).
complementary_difference_setsI() Construct complementary difference sets in a group of order \(n \equiv 3 \mod 4, n\) a prime power.
complementary_difference_setsII() Construct complementary difference sets in a group of order \(n = p^4, \) where \(p \equiv 5 \mod 8\) and \(t \equiv 1, 2, 3 \mod 4\).
complementary_difference_setsIII() Construct complementary difference sets in a group of order \(n = 2m + 1, \) where \(4m + 3\) is a prime power.
df_q_6_1() Return a \((q, 6, 1)\)-difference family over the finite field \(K\).
difference_family() Return a \((k, 1)\)-difference family on an Abelian group of cardinality \(v\).
\end{verbatim}

REFERENCES:

Functions

`sage.combinat.designs.difference_family.are_complementary_difference_sets(G, A, B, verbose=False)`

Check if $A$ and $B$ are complementary difference sets over the group $G$.

According to [Sze1971], two sets $A, B$ of size $m$ are complementary difference sets over a group $G$ of size $2m + 1$ if:

1. they are $2 - \{2m + 1; m, m; m - 1\}$ supplementary difference sets
2. $A$ is skew, i.e. $a \in A$ implies $-a \notin A$

INPUT:

- $G$ – a group of odd order
- $A$ – a set of elements of $G$
- $B$ – a set of elements of $G$
- verbose – boolean (default: False); if True the function will be verbose when the sets do not satisfy the constraints

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import are_complementary_difference_sets
sage: are_complementary_difference_sets(Zmod(7), [1, 2, 4], [1, 2, 4])
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import are_complementary_difference_sets
>>> are_complementary_difference_sets(Zmod(Integer(7)), [Integer(1), Integer(2), Integer(4)], [Integer(1), Integer(2), Integer(4)])
True
```

If verbose=True, the function will be verbose:

```python
sage: are_complementary_difference_sets(Zmod(7), [1, 2, 5], [1, 2, 4], verbose=True)
The sets are not supplementary difference sets with lambda = 2
False
```
Combinatorics, Release 10.4

>>> from sage.all import *
>>> are_complementary_difference_sets(Zmod(Integer(7)), [Integer(1), Integer(2), ... Integer(5)], [Integer(1), Integer(2), Integer(4)], verbose=True)
The sets are not supplementary difference sets with lambda = 2
False

See also:

is_supplementary_difference_set()
sage.combinat.designs.difference_family.are_hadamard_difference_set_parameters(v, k, lambda)

Check whether \((v, k, \lambda)\) is of the form \((4N^2, 2N^2 - N, N^2 - N)\).

INPUT:

• \((v, k, \lambda)\) – parameters of a difference set

EXAMPLES:

sage: from sage.combinat.designs.difference_family import are_hadamard_difference_set_parameters
sage: are_hadamard_difference_set_parameters(36, 15, 6)
True
sage: are_hadamard_difference_set_parameters(60, 13, 5)
False

>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import are_hadamard_difference_set_parameters
>>> are_hadamard_difference_set_parameters(Integer(36), Integer(15), Integer(6))
True
>>> are_hadamard_difference_set_parameters(Integer(60), Integer(13), Integer(5))
False

sage.combinat.designs.difference_family.are_mcfarland_1973_parameters(v, k, lambda, return_parameters=False)

Test whether \((v, k, \lambda)\) is a triple that can be obtained from the construction from \[\text{McF1973}\].

See mcfarland_1973_construction().

INPUT:

• \(v, k, \lambda\) – integers; parameters of the difference family

• return_parameters – boolean (default False); if True, return a pair \((\text{True}, (q, s))\) so that \((q, s)\) can be used in the function mcfarland_1973_construction() to actually build a \((v, k, \lambda)\)-difference family. Or \((\text{False}, \text{None})\) if the construction is not possible

EXAMPLES:

sage: # needs sage.rings.finite_rings
sage: from sage.combinat.designs.difference_family import are_mcfarland_1973_parameters
sage: are_mcfarland_1973_parameters(64, 28, 12)

            assert answer is True
Combinatorics, Release 10.4

(continued from previous page)

```python
... assert designs.difference_family(v, k, l, existence=True) is True
...
G, D = designs.difference_family(v, k, l)
```

sage.combinat.designs.difference_family.block_stabilizer(G, B)

Compute the left stabilizer of the block $B$ under the action of $G$.

This function return the list of all $x \in G$ such that $x \cdot B = B$ (as a set).

**INPUT:**

- $G$ – a group (additive or multiplicative)
- $B$ – a subset of $G$

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_family import block_stabilizer
sage: Z8 = Zmod(8)
sage: block_stabilizer(Z8, [Z8(0), Z8(2), Z8(4), Z8(6)])
[0, 2, 4, 6]
sage: block_stabilizer(Z8, [Z8(0), Z8(2)])
[0]
sage: C = cartesian_product([Zmod(4), Zmod(3)])
sage: block_stabilizer(C, [C((0, 0)), C((2, 0)), C((0, 1)), C((2, 1))])
[(0, 0), (2, 0)]
sage: b = list(map(Zmod(45), [1, 3, 7, 10, 22, 25, 30, 35, 37, 38, 44]))
sage: block_stabilizer(Zmod(45), b)
[0]
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import block_stabilizer

>>> Z8 = Zmod(Integer(8))

>>> block_stabilizer(Z8, [Z8(Integer(0)), Z8(Integer(2)), Z8(Integer(4)),
Z8(Integer(6))])
[0, 2, 4, 6]

>>> block_stabilizer(Z8, [Z8(Integer(0)), Z8(Integer(2))])
[0]

>>> C = cartesian_product([Zmod(Integer(4)), Zmod(Integer(3))])

>>> block_stabilizer(C, [C((Integer(0), Integer(0))), C((Integer(2), Integer(0))),
C((Integer(0), Integer(1))), C((Integer(2), Integer(1)))]
[(0, 0), (2, 0)]

>>> b = list(map(Zmod(Integer(45)), [Integer(1), Integer(3), Integer(7),
Integer(10), Integer(22), Integer(25), Integer(30), Integer(35), Integer(37),
Integer(38), Integer(44)]))

>>> block_stabilizer(Zmod(Integer(45)), b)
[0]
```
Compute complementary difference sets over a group of order \( n = 2m + 1 \).

According to [Sze1971], two sets \( A, B \) of size \( m \) are complementary difference sets over a group \( G \) of size \( n = 2m + 1 \) if:

1. they are \( 2^{-\{2m+1; m, m-1\}} \) supplementary difference sets
2. \( A \) is skew, i.e. \( a \in A \) implies \( -a \notin A \)

This method tries to call \( \text{complementary_difference_setsI()} \), \( \text{complementary_difference_setsII()} \) or \( \text{complementary_difference_setsIII()} \) if the parameter \( n \) satisfies the requirements of one of these functions.

**INPUT:**

- \( n \) – integer; the order of the group over which the sets are constructed
- \( \text{existence} \) – boolean (default: False); if True, only check whether the supplementary difference sets can be constructed
- \( \text{check} \) – boolean (default: True); if True, check that the sets are complementary difference sets before returning them; setting this to False might speed up the computation for large values of \( n \)

**OUTPUT:**

If \( \text{existence} = \text{False} \), the function returns group \( G \) and two complementary difference sets, or raises an error if data for the given \( n \) is not available. If \( \text{existence} = \text{True} \), the function returns a boolean representing whether complementary difference sets can be constructed for the given \( n \).

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_family import complementary_difference_sets
sage: complementary_difference_sets(15)  # needs sage.libs.pari
(Ring of integers modulo 15, [1, 2, 4, 6, 7, 10, 12], [0, 1, 2, 6, 9, 13, 14])
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import complementary_difference_sets
>>> complementary_difference_sets(Integer(15))  # needs sage.libs.pari
(Ring of integers modulo 15, [1, 2, 4, 6, 7, 10, 12], [0, 1, 2, 6, 9, 13, 14])
```

If \( \text{existence} = \text{True} \), the function returns a boolean:

```python
sage: complementary_difference_sets(15, existence=True)  # needs sage.libs.pari
True
sage: complementary_difference_sets(16, existence=True)
False
```

```python
>>> from sage.all import *
>>> complementary_difference_sets(Integer(15), existence=True)  # needs sage.libs.pari
True
```

(continues on next page)
See also:

are_complementary_difference_sets()

Construct complementary difference sets in a group of order $n \equiv 3 \pmod{4}$, $n$ a prime power.

Let $G$ be a Galois Field of order $n$, where $n$ satisfies the requirements above. Let $A$ be the set of non-zero quadratic elements in $G$, and $B = A$. Then $A$ and $B$ are complementary difference sets over a group of order $n$. This construction is described in [Sze1971].

INPUT:

• $n$ – integer; the order of the group $G$

• check – boolean (default: True); if True, check that the sets are complementary difference sets before returning them

OUTPUT:

The function returns the Galois field of order $n$ and the two sets, or raises an error if $n$ does not satisfy the requirements of this construction.

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import complementary_difference_setsI
sage: complementary_difference_setsI(19)
(Finite Field of size 19,
 [1, 4, 5, 6, 7, 9, 11, 16, 17],
 [1, 4, 5, 6, 7, 9, 11, 16, 17])
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import complementary_difference_setsI
>>> complementary_difference_setsI(Integer(19))
(Finite Field of size 19,
 [1, 4, 5, 6, 7, 9, 11, 16, 17],
 [1, 4, 5, 6, 7, 9, 11, 16, 17])
```

Construct complementary difference sets in a group of order $n = p^t$, where $p \equiv 5 \pmod{8}$ and $t \equiv 1, 2, 3 \pmod{4}$.

Consider a finite field $G$ of order $n$ and let $\rho$ be the generator of the corresponding multiplicative group. Then, there are two different constructions, depending on whether $t$ is even or odd.

If $t \equiv 2 \pmod{4}$, let $C_0$ be the set of non-zero octic residues in $G$, and let $C_i = \rho^i C_0$ for $1 \leq i \leq 7$. Then, $A = C_0 \cup C_1 \cup C_2 \cup C_3$ and $B = C_0 \cup C_1 \cup C_6 \cup C_7$.

If $t$ is odd, let $C_0$ be the set of non-zero fourth powers in $G$, and let $C_i = \rho^i C_0$ for $1 \leq i \leq 3$. Then, $A = C_0 \cup C_1$ and $B = C_0 \cup C_3$. 
For more details on this construction, see [Sze1971].

INPUT:

• \( n \) – integer; the order of the group \( G \)

• check – boolean (default: True); if True, check that the sets are complementary difference sets before returning them; setting this to False might speed up the computation for large values of \( n \)

OUTPUT:

The function returns the Galois field of order \( n \) and the two sets, or raises an error if \( n \) does not satisfy the requirements of this construction.

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import complementary_difference_setsII
sage: complementary_difference_setsII(5)  # needs sage.libs.pari
(Finite Field of size 5, [1, 2], [1, 3])
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import complementary_difference_setsII
>>> complementary_difference_setsII(Integer(5))  # needs sage.libs.pari
(Finite Field of size 5, [1, 2], [1, 3])
```

See also:

`are_complementary_difference_sets()` `complementary_difference_sets()`

sage.combinat.designs.difference_family.complementary_difference_setsIII(\( n \), check=True)

Construct complementary difference sets in a group of order \( n = 2m + 1 \), where \( 4m + 3 \) is a prime power.

Consider a finite field \( G \) of order \( n \) and let \( \rho \) be a primitive element of this group. Now let \( Q \) be the set of non zero quadratic residues in \( G \), and let \( A = \{ a | \rho^{2a} - 1 \in Q \} \), \( B' = \{ b | - (\rho^{2b} + 1) \in Q \} \). Then \( A \) and \( B = Q \setminus B' \) are complementary difference sets over the ring of integers modulo \( n \). For more details, see [Sz1969].

INPUT:

• \( n \) – integer; the order of the group over which the sets are constructed

• check – boolean (default: True); if True, check that the sets are complementary difference sets before returning them; setting this to False might speed up the computation for large values of \( n \)

OUTPUT:

The function returns the Galois field of order \( n \) and the two sets, or raises an error if \( n \) does not satisfy the requirements of this construction.

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import complementary_difference_setsIII
sage: complementary_difference_setsIII(11)  # needs sage.libs.pari
(Ring of integers modulo 11, [1, 2, 5, 7, 8], [0, 1, 3, 8, 10])
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import complementary_difference_setsIII
>>> complementary_difference_setsIII(Integer(11))  # needs sage.libs.pari
(Ring of integers modulo 11, [1, 2, 5, 7, 8], [0, 1, 3, 8, 10])
```

See also:

are_complementary_difference_sets() complementary_difference_sets()

sage.combinat.designs.difference_family.df_q_6_1(K, existence=False, check=True)

Return a \((q, 6, 1)\)-difference family over the finite field \(K\).

The construction uses Theorem 11 of [Wi72].

EXAMPLES:

```python
sage: # needs sage.rings.finite_rings
sage: from sage.combinat.designs.difference_family import is_difference_family, df_q_6_1
sage: prime_powers = [v for v in range(31,500,30) if is_prime_power(v)]
[31, 151, 181, 211, 241, 271, 331, 361, 421]
```

```python
sage: for v in prime_powers:
...:     K = GF(v, 'a')
...:     df = df_q_6_1(K, check=True)
...:     assert is_difference_family(K, df, v, 6, 1)
```

Todo: Do improvements due to Zhen and Wu 1999.

sage.combinat.designs.difference_family.difference_family(v, k, l=1, existence=False, explain_construction=False, check=True)

Return a \((k, 1)\)-difference family on an Abelian group of cardinality \(v\).

Let \(G\) be a finite Abelian group. For a given subset \(D\) of \(G\), we define \(\Delta D\) to be the multi-set of differences \(\Delta D = \{x - y; x \in D, y \in D, x \neq y\}\). A \((G, k, \lambda)\)-difference family is a collection of \(k\)-subsets of \(G\), \(D = \{D_1, D_2, \ldots, D_b\}\) such that the union of the difference sets \(\Delta D_i\) for \(i = 1, \ldots, b\), seen as a multi-set, contains each element of \(G \setminus \{0\}\) exactly \(\lambda\)-times.
When there is only one block, i.e. $\lambda(v-1) = k(k-1)$, then a $(G, k, \lambda)$-difference family is also called a *difference set*.

See also Wikipedia article Difference_set.

If there is no such difference family, an EmptySetError is raised and if there is no construction at the moment NotImplementedError is raised.

**INPUT:**

- $v, k, 1$ – parameters of the difference family. If 1 is not provided it is assumed to be 1
- existence – if True, then return either True if Sage knows how to build such design, Unknown if it does not and False if it knows that the design does not exist
- explain_construction – instead of returning a difference family, returns a string that explains the construction used
- check – boolean (default: True); if True, then the result of the computation is checked before being returned. This should not be needed but ensures that the output is correct

**OUTPUT:**

A pair $(G, D)$ made of a group $G$ and a difference family $D$ on that group. Or, if existence=True a boolean or if explain_construction=True a string.

**EXAMPLES:**

```python
sage: G, D = designs.difference_family(73, 4)  # needs sage.libs.pari
sage: G  # needs sage.libs.pari
Finite Field of size 73
sage: D  # needs sage.libs.pari
[[0, 1, 5, 18],
 [0, 3, 15, 54],
 [0, 9, 45, 16],
 [0, 27, 62, 48],
 [0, 8, 40, 71],
 [0, 24, 47, 67]]

sage: print(designs.difference_family(73, 4, explain_construction=True))
The database contains a (73,4)-evenly distributed set

sage: G, D = designs.difference_family(15, 7, 3)  # needs sage.libs.pari
sage: G  # needs sage.libs.pari
Ring of integers modulo 15
sage: D
[[0, 1, 2, 4, 5, 8, 10]]

sage: print(designs.difference_family(15, 7, 3, explain_construction=True))
Singer difference set

sage: print(designs.difference_family(91, 10, 1, explain_construction=True))
Singer difference set

sage: print(designs.difference_family(64, 28, 12, explain_construction=True))
McFarland 1973 construction

sage: print(designs.difference_family(576, 276, 132, explain_construction=True))
Hadamard difference set product from N1=2 and N2=3
```
For \( k = 6, 7 \), we look at the set of small prime powers for which a construction is available:

```python
sage: def prime_power_mod(r, m):
    k = m + r
    while True:
        if is_prime_power(k):
            yield k
        k += m

sage: # needs sage.libs.pari
sage: from itertools import islice
sage: l6 = {True: [], False: [], Unknown: []}

sage: for q in islice(prime_power_mod(1, 30), int(60)):
    l6[designs.difference_family(q, 6, existence=True)].append(q)

sage: l6[True]
[31, 121, 151, 181, 211, ..., 3061, 3121, 3181]
```

Todo: Implement recursive constructions from Buratti “Recursive for difference matrices and relative difference families” (1998) and Jungnickel “Composition theorems for difference families and regular planes” (1978)

sage.combinat.designs.difference_family.get_fixed_relative_difference_set(G, rel_diff_set, as_elements=False)

Construct an equivalent relative difference set fixed by the size of the set.

Given a relative difference set $R(q+1, q-1, q, 1)$, it is possible to find a translation of this set fixed by $q$ (see Section 3 of [Spe1975]). We say that a set is fixed by $t$ if $\{td|d \in R\} = R$.

In addition, the set returned by this function will contain the element 0. This is needed in the construction of supplementary difference sets (see supplementary_difference_set_from_rel_diff_set()).

INPUT:

- G – a group, of which rel_diff_set is a subset
- rel_diff_set – the relative difference set
- as_elements – boolean (default: False); if True, the list returned will contain elements of the abelian group (this may slow down the computation considerably)

OUTPUT:

By default, this function returns the set as a list of integers. However, if as_elements=True it will return the set as a list containing elements of the abelian group. If no such set can be found, the function will raise an error.

EXAMPLES:

sage: from sage.combinat.designs.difference_family import relative_difference_set_from_m_sequence, get_fixed_relative_difference_set
g, s1 = relative_difference_set_from_m_sequence(5, 2, return_group=True) #..
needs sage.libs.pari sage.modules
sage: get_fixed_relative_difference_set(G, s1) # random
[2, 10, 19, 23, 0]

>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import relative_difference_set_from_m_sequence

G, s1 = relative_difference_set_from_m_sequence(Integer(5), Integer(2),
return_group=True) # needs sage.libs.pari sage.modules

get_fixed_relative_difference_set(G, s1) # random
[2, 10, 19, 23, 0]

If as_elements=True, the result will contain elements of the group:

sage: get_fixed_relative_difference_set(G, s1, as_elements=True) # random
[(2), (10), (19), (23), (0)]

sage.combinat.designs.difference_family.group_law(G)
Return a triple (identity, operation, inverse) that define the operations on the group G.

EXAMPLES:

sage: from sage.combinat.designs.difference_family import group_law
group_law(Zmod(3))
(0, <built-in function add>, <built-in function neg>)
group_law(SymmetricGroup(5))
(()), <built-in function mul>, <built-in function inv>)
group_law(VectorSpace(QQ, 3))
((0, 0, 0), <built-in function add>, <built-in function neg>)

sage.combinat.designs.difference_family.hadamard_difference_set_product(G1, D1, G2, D2)
Make a product of two Hadamard difference sets.
This product construction appears in [Tu1984].
INPUT:
• G1, D1, G2, D2 – two Hadamard difference sets

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import hadamard_difference_set_product
sage: from sage.combinat.designs.difference_family import is_difference_family
sage: G1, D1 = designs.difference_family(16, 6, 2)  # needs sage.rings.finite_rings
sage: G2, D2 = designs.difference_family(36, 15, 6)  # needs sage.rings.finite_rings
sage: G11, D11 = hadamard_difference_set_product(G1, D1, G1, D1)  # needs sage.rings.finite_rings
sage: assert is_difference_family(G11, D11, 256, 120, 56)  # needs sage.rings.finite_rings
sage: assert designs.difference_family(256, 120, 56, existence=True) is True  # needs sage.rings.finite_rings
sage: G12, D12 = hadamard_difference_set_product(G1, D1, G2, D2)  # needs sage.rings.finite_rings
sage: assert is_difference_family(G12, D12, 576, 276, 132)  # needs sage.rings.finite_rings
sage: assert designs.difference_family(576, 276, 132, existence=True) is True  # needs sage.rings.finite_rings
```
INPUT:

- \( N \) – positive integer

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import hadamard_difference_set_
    \rightarrow product_parameters
sage: hadamard_difference_set_product_parameters(8)  # needs sage.rings.finite_rings
(2, 2)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import hadamard_difference_set_
    \rightarrow product_parameters
>>> hadamard_difference_set_product_parameters(Integer(8))  # needs sage.rings.finite_rings
(2, 2)
```

\( \text{sage.combinat.designs.difference_family.is_difference_family} \) (\( G, D, v=\text{None}, k=\text{None}, \\
l=\text{None}, \text{verbose}=\text{False} \))

Check whether \( D \) forms a difference family in the group \( G \).

INPUT:

- \( G \) – group of cardinality \( v \)
- \( D \) – a set of \( k \)-subsets of \( G \)
- \( v, k \) and \( l \) – optional parameters of the difference family
- \( \text{verbose} \) – boolean (default: False); whether to print additional information

See also:
\( \text{difference_family()} \)

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import is_difference_family
sage: G = Zmod(21)
sage: D = [[0,1,4,14,16]]
sage: is_difference_family(G, D, 21, 5)
True

sage: G = Zmod(41)
sage: D = [[0,1,4,11,29],[0,2,8,17,21]]
sage: is_difference_family(G, D, verbose=True)
Too few:
  5 is obtained 0 times in blocks []
  14 is obtained 0 times in blocks []
  27 is obtained 0 times in blocks []
  36 is obtained 0 times in blocks []
Too much:
  4 is obtained 2 times in blocks [0, 1]
  13 is obtained 2 times in blocks [0, 1]
  28 is obtained 2 times in blocks [0, 1]
  37 is obtained 2 times in blocks [0, 1]
False
sage: D = [[0,1,4,11,29],[0,2,8,17,22]]
sage: is_difference_family(G, D)
(continues on next page)
True

```
sage: G = Zmod(61)
sage: D = [[0, 1, 3, 13, 34], [0, 4, 9, 23, 45], [0, 6, 17, 24, 32]]
sage: is_difference_family(G, D)
True

sage: # needs sage.modules
sage: G = AdditiveAbelianGroup([3]*4)
sage: a, b, c, d = G.gens()
sage: D = [[d, -a+d, -c+d, a-b-d, b+c+d],
       [c, a+b-d, -b+c, a-b+d, a+b+c],
       [-a-b+c+d, a-b-c-d, -a+c-d, b-c+d, a+b],
       [-b-d, a+b+d, a-b+c-d, a-b+c, -b+c+d]]
sage: is_difference_family(G, D)
True
```
... [-a-b+c+d, a-b-c-d, -a+c-d, b-c+d, a+b],
... [-b-d, a+b+d, a-b+c-d, a-b+c, -b+c+d]]

>>> is_difference_family(G, D)
True

The following example has a third block with a non-trivial stabilizer:

```
sage: G = Zmod(15)
sage: D = [[0,1,4],[0,2,9],[0,5,10]]
sage: is_difference_family(G,D,verbose=True)
It is a (15,3,1)-difference family
True
```

```
>>> from sage.all import *
>>> G = Zmod(Integer(15))
>>> D = [[Integer(0),Integer(1),Integer(4)],
      [Integer(0),Integer(2),Integer(9)],
      [Integer(0),Integer(5),Integer(10)]]
>>> is_difference_family(G,D,verbose=True)
It is a (15,3,1)-difference family
True
```

The function also supports multiplicative groups (non necessarily Abelian):

```
sage: # needs sage.groups
sage: G = DihedralGroup(8)
sage: x,y = G.gens()
sage: i = G.one()
sage: D1 = [[i,x,x^4], [i,x^2, y*x], [i,x^5,y], [i,x^6,y*x^2], [i,x^7,y*x^5]]
sage: is_difference_family(G, D1, 16, 3, 2)
True
```

```
>>> from sage.all import *
>>> # needs sage.groups
>>> G = DihedralGroup(Integer(8))
>>> x,y = G.gens()
>>> i = G.one()
>>> D1 = [[i,x,x**Integer(4)], [i,x**Integer(2), y*x], [i,x**Integer(5),y], [i,
     x**Integer(6),y*x**Integer(2)], [i,x**Integer(7),y*x**Integer(5)]]
>>> is_difference_family(G, D1, Integer(16), Integer(3), Integer(2))
True
```

```
>>> from sage.combinat.designs.bibd import BIBD_from_difference_family
>>> bibd = BIBD_from_difference_family(G, D1, lambd=2)
```

```
from sage.combinat.designs.difference_family import is_fixed_relative_difference_set
```

Check if the relative difference set $R$ is fixed by $q$.

A relative difference set $R$ is fixed by $q$ if $\{qd|d \in R\} = R$ (see Section 3 of [Spe1975]).

INPUT:

- $R$ – a list containing elements of an abelian group; the relative difference set
- $q$ – an integer

EXAMPLES:
If the relative difference set does not contain elements of the group, the method returns false:

```sage
sage: G, s1 = relative_difference_set_from_m_sequence(7, 2, return_group=True) # needs sage.libs.pari
sage: s2 = get_fixed_relative_difference_set(G, s1, as_elements=False) # needs sage.libs.pari
sage: is_fixed_relative_difference_set(s2, len(s2)) # needs sage.libs.pari
False
```

Check if \( R \) is a difference set of \( G \) relative to \( H \), with the given parameters.

This function checks that \( G, H \) and \( R \) have the orders specified in the parameters, and that \( R \) satisfies the definition
of relative difference set (from [EB1966]): the collection of differences \( r - s, r, s \in R, r \neq s \) contains only elements of \( G \) which are not in \( H \), and contains every such element exactly \( d \) times.

**INPUT:**

- \( R \) – list; the relative difference set of length \( k \)
- \( G \) – an additive abelian group of order \( mn \)
- \( H \) – list; a submodule of \( G \) of order \( n \)
- \( \text{params} \) – a tuple in the form \((m, n, k, d)\)
- \( \text{verbose} \) – boolean (default: False); if True, the function will be verbose when the sequences do not satisfy the contraints

**EXAMPLES:**

```sage
define from sage.combinat.designs.difference_family import _get_submodule_of_order, relative_difference_set_from_m_sequence, is_relative_difference_set

sage: q, N = 5, 2
sage: params = ((q**N-1) // (q-1), q - 1, q**(N-1), q**(N-2))
sage: G, R = relative_difference_set_from_m_sequence(q, N, return_group=True) #
    # needs sage.libs.pari sage.modules
sage: H = _get_submodule_of_order(G, q - 1) #
    # needs sage.libs.pari sage.modules
sage: is_relative_difference_set(R, G, H, params) #
    # needs sage.libs.pari sage.modules
True
```

If we pass the `verbose` argument, the function will explain why it failed:

```sage
define from sage.all import *
define from sage.combinat.designs.difference_family import _get_submodule_of_order, relative_difference_set_from_m_sequence, is_relative_difference_set
def

>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import _get_submodule_of_order, relative_difference_set_from_m_sequence, is_relative_difference_set
>>> q, N = Integer(5), Integer(2)
>>> params = ((q**N-Integer(1)) // (q-Integer(1)), q - Integer(1), q**(N-Integer(1)), q**(N-Integer(2)))
>>> G, R = relative_difference_set_from_m_sequence(q, N, return_group=True) #
    # needs sage.libs.pari sage.modules
>>> H = _get_submodule_of_order(G, q - Integer(1)) #
    # needs sage.libs.pari sage.modules
>>> is_relative_difference_set(R, G, H, params) #
    # needs sage.libs.pari sage.modules
True
```

(continues on next page)
There is a value in the difference set which is not repeated d times
False

sage.combinat.designs.difference_family.is_supplementary_difference_set(Ks, v=None, lmbda=None, G=None, verbose=False)

Check that the sets in Ks are \( n - \{ v; k_1, ..., k_n; \lambda \} \) supplementary difference sets over group \( G \) of order \( v \).

From the definition in [Spe1975]: let \( S_1, S_2, ..., S_n \) be \( n \) subsets of a group \( G \) of order \( v \) such that \( |S_i| = k_i \). If, for each \( g \in G, g \neq 0 \), the total number of solutions of \( a_i - a'_i = g \), with \( a_i, a'_i \in S_i \) is \( \lambda \), then \( S_1, S_2, ..., S_n \) are \( n - \{ v; k_1, ..., k_n; \lambda \} \) supplementary difference sets.

One of the parameters \( v \) or \( G \) must always be specified. If \( G \) is not given, the function will use an Additive-AbelianGroup of order \( v \).

**INPUT:**
- \( Ks \) – a list of sets to be checked
- \( v \) – integer; the parameter \( v \) of the supplementary difference sets
- \( lmbda \) – integer; the parameter \( \lambda \) of the supplementary difference sets
- \( G \) – a group of order \( v \)
- \( verbose \) – boolean (default: False); if True, the function will be verbose when the sets do not satisfy the contraints

**EXAMPLES:**

```sage
sage: from sage.combinat.designs.difference_family import supplementary_difference_set_from_rel_diff_set, is_supplementary_difference_set
sage: G, [S1, S2, S3, S4] = supplementary_difference_set_from_rel_diff_set(17)  # needs sage.modules sage.rings.finite_rings
sage: is_supplementary_difference_set([S1, S2, S3, S4], lmbda=16, G=G)  # needs sage.modules sage.rings.finite_rings
True
```

```sage
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import supplementary_difference_set_from_rel_diff_set, is_supplementary_difference_set
... G, [S1, S2, S3, S4] = supplementary_difference_set_from_rel_diff_set(Integer(17))  # needs sage.modules sage.rings.finite_rings
... is_supplementary_difference_set([S1, S2, S3, S4], lmbda=Integer(16), G=G)  # needs sage.modules sage.rings.finite_rings
True
```

The parameter \( v \) can be given instead of \( G \):

```sage
sage: is_supplementary_difference_set([S1, S2, S3, S4], v=16, lmbda=16)  # needs sage.modules sage.rings.finite_rings
True
sage: is_supplementary_difference_set([S1, S2, S3, S4], v=20, lmbda=16)  # needs sage.modules sage.rings.finite_rings
False
```
>>> from sage.all import *
>>> is_supplementary_difference_set([S1, S2, S3, S4], v=Integer(16),
→   lmbda=Integer(16))  # needs sage.modules sage.rings.finite_rings
True
>>> is_supplementary_difference_set([S1, S2, S3, S4], v=Integer(20),
→   lmbda=Integer(16))  # needs sage.modules sage.rings.finite_rings
False

If verbose=True, the function will be verbose:

sage: is_supplementary_difference_set([S1, S2, S3, S4], lmbda=14, G=G,  
→   # needs sage.modules sage.rings.finite_rings
...   verbose=True)
Number of pairs with difference (1) is 16, but lambda is 14
False

>>> from sage.all import *
>>> is_supplementary_difference_set([S1, S2, S3, S4], lmbda=Integer(14), G=G,  
→   # needs sage.modules sage.rings.finite_rings
...   verbose=True)
Number of pairs with difference (1) is 16, but lambda is 14
False

See also:

supplementary_difference_set_from_rel_diff_set()
sage.combinat.designs.difference_family.mcfarland_1973_construction(q,s)

Return a difference set.

The difference set returned has the following parameters

\[ v = \frac{q^{s+1}(q^{s+1} + q - 2)}{q - 1}, k = \frac{q^s(q^{s+1} - 1)}{q - 1}, \lambda = \frac{q^s(q^s - 1)}{q - 1} \]

This construction is due to [McF1973].

INPUT:

• q, s – integers; parameters for the difference set (see the above formulas for the expression of v, k, l in terms of q and s)

See also:

The function are_mcfarland_1973_parameters() makes the translation between the parameters (q, s) corresponding to a given triple (v, k, l).

ALGORITHM:

Uses dancing links sage.combinat.dlx

sage.combinat.designs.difference_family.one_radical_difference_family(K, k)

Search for a radical difference family on $K$ using dancing links algorithm.

For the definition of radical difference family, see radical_difference_family(). Here, we consider only radical difference family with $\lambda = 1$.

INPUT:

- $K$ – a finite field of cardinality $q$
- $k$ – a positive integer so that $k(k-1)$ divides $q-1$

OUTPUT:

Either a difference family or None if it does not exist.

ALGORITHM:

The existence of a radical difference family is equivalent to a one dimensional tiling (or packing) problem in a cyclic group. This subsequent problem is solved by a call to the function one_cyclic_tiling().
Let $K^*$ be the multiplicative group of the finite field $K$. A radical family has the form $B = \{x_1 B, \ldots, x_k B\}$, where $B = \{x : x^k = 1\}$ (for $k$ odd) or $B = \{x : x^{k-1} = 1\} \cup \{0\}$ (for $k$ even). Equivalently, $K^*$ decomposes as:

$$K^* = \Delta(x_1 B) \cup \cdots \cup \Delta(x_k B) = x_1 \Delta B \cup \cdots \cup x_k \Delta B.$$ 

We observe that $C = B \backslash 0$ is a subgroup of the (cyclic) group $K^*$, that can thus be generated by some element $r$. Furthermore, we observe that $\Delta B$ is always a union of cosets of $\pm C$ (which is twice larger than $C$).

$$\begin{align*}
(k \text{ odd}) & \quad \Delta B = \{r^i - r^j : r^i \neq r^j\} = \pm C \cdot \{r^i - 1 : 0 < i \leq m\} \\
(k \text{ even}) & \quad \Delta B = \{r^i - r^j : r^i \neq r^j\} \cup C = \pm C \cdot \{r^i - 1 : 0 < i < m\} \cup \pm C
\end{align*}$$

where

$$(k \text{ odd}) \quad m = (k - 1)/2 \quad \text{and} \quad (k \text{ even}) \quad m = k/2.$$ 

Consequently, $B = \{x_1 B, \ldots, x_k B\}$ is a radical difference family if and only if $\{x_1(\Delta B/(\pm C)), \ldots, x_k(\Delta B/(\pm C))\}$ is a partition of the cyclic group $K^*/(\pm C)$.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_family import...
....: one_radical_difference_family,
....: is_difference_family)
sage: one_radical_difference_family(GF(13), 4) # needs sage.rings.finite_rings
[[0, 1, 3, 9]]
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import...
...: one_radical_difference_family,
...: is_difference_family)
>>> one_radical_difference_family(GF(Integer(13)), Integer(4)) # needs sage.rings.finite_rings
[[0, 1, 3, 9]]
```

The parameters that appear in [Bu95]:

```python
sage: df = one_radical_difference_family(GF(449), 8); df # needs sage.rings.finite_rings
[[0, 1, 18, 25, 176, 324, 359, 444],
 [0, 9, 88, 162, 222, 225, 237, 404],
 [0, 11, 140, 198, 275, 357, 394, 421],
 [0, 40, 102, 249, 271, 305, 388, 441],
 [0, 49, 80, 93, 161, 204, 327, 433],
 [0, 70, 99, 197, 230, 362, 403, 435],
 [0, 121, 141, 193, 293, 331, 335, 382],
 [0, 191, 285, 295, 321, 371, 390, 392]]
sage: is_difference_family(GF(449), df, 449, 8, 1) # needs sage.rings.finite_rings
True
```

```python
>>> from sage.all import *
>>> df = one_radical_difference_family(GF(Integer(449)), Integer(8)); df ...
(continues on next page)
```
sage.combinat.designs.difference_family.radical_difference_family(K, k, l=1, existence=False, check=True)

Return a \((v, k, l)\)-radical difference family.

Let fix an integer \(k\) and a prime power \(q = tk(k-1) + 1\). Let \(K\) be a field of cardinality \(q\). A \((q, k, 1)\)-difference family is radical if its base blocks are either: a coset of the \(k\)-th root of unity for \(k\) odd or a coset of \(k - 1\)-th root of unity and 0 if \(k\) is even (the number \(t\) is the number of blocks of that difference family).

The terminology comes from M. Buratti article [Bu95] but the first constructions go back to R. Wilson [Wi72].

INPUT:

- \(K\) – a finite field
- \(k\) – positive integer; the size of the blocks
- \(l\) – integer (default: 1); the \(\lambda\) parameter
- \(\text{existence}\) – if True, then return either True if Sage knows how to build such design, Unknown if it does not and False if it knows that the design does not exist
- \(\text{check}\) – boolean (default: True); if True then the result of the computation is checked before being returned. This should not be needed but ensures that the output is correct

EXAMPLES:

sage: from sage.combinat.designs.difference_family import radical_difference_family

sage: radical_difference_family(GF(73), 9) # needs sage.rings.finite_rings
[[[1, 2, 4, 8, 16, 32, 37, 55, 64]]]

sage: radical_difference_family(GF(281), 5) # needs sage.rings.finite_rings
[[[1, 86, 90, 153, 232],
  [4, 50, 63, 79, 85],
  [5, 36, 149, 169, 203],
  [7, 40, 68, 219, 228],
  [9, 121, 212, 248, 253],
  [29, 81, 222, 246, 265],
  [31, 137, 167, 247, 261],
  [32, 70, 118, 119, 223],
  [39, 56, 66, 138, 263],
  [43, 45, 116, 141, 217],
sage: for k in range(5,10):
    # needs sage.rings.finite_rings
    print("k = ",format(k))
    list_q = []
    for q in range(k*(k-1)+1, 2000, k*(k-1)):
        if is_prime_power(q):
            K = GF(q,'a')
            if radical_difference_family(K, k, existence=True) is True:
                list_q.append(q)
                _ = radical_difference_family(K,k)
    print(" ".join(str(p) for p in list_q))

Return a difference set made of a cyclotomic coset in the finite field \( K \) and with parameters \( k \) and \( l=1 \).

Most of these difference sets appear in chapter VI.18.48 of the Handbook of combinatorial designs.

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import radical_difference_set
sage: D = radical_difference_set(GF(7), 3, 1); D
[[1, 2, 4]]  # needs sage.rings.finite_rings
c sage: sorted(x-y for x in D[0] for y in D[0] if x != y)
[1, 2, 3, 4, 5, 6]  # needs sage.rings.finite_rings
sage: D = radical_difference_set(GF(16,'a'), 6, 2)  # needs sage.rings.finite_rings
sage: sorted(x-y for x in D[0] for y in D[0] if x != y)
[1, 2, 3, 4, 5, 6]
```

```python
sage: for k in range(2,50):
.....:     for l in reversed(divisors(k*(k-1))):
```
v = k*(k-1)//l + 1
if is_prime_power(v) and radical_difference_set(GF(v,'a'),k,l,
existence=True) is True:

_ = radical_difference_set(GF(v,'a'),k,l)
print("{:3} {:3} {:3}".format(v,k,l))

sage.combinat.designs.difference_family.relative_difference_set_from_homomorphism(q, N, d, check=True, return_group=False)

5.1. Comprehensive Module List 1073
Construct $R((q^N - 1)/(q - 1), n, q^{N-1}, q^{N-2}d)$ where $nd = q - 1$.

Given a prime power $q$, a number $N \geq 2$ and integers $d$ such that $d|q - 1$ we create the relative difference set using the construction from Corollary 5.1.1 of [EB1966].

INPUT:

- $q$ – a prime power
- $N$ – an integer greater than 1
- $d$ – an integer which divides $q - 1$
- `check` – boolean (default: True); if True, check that the result is a relative difference set before returning it
- `return_group` – boolean (default: False); if True, the function will also return the group from which the set is created

OUTPUT:

If `return_group=False`, the function return only the relative difference set. Otherwise, it returns a tuple containing the group and the set.

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import relative_difference_set_from_homomorphism
sage: relative_difference_set_from_homomorphism(7, 2, 3) # random
[(0), (3), (4), (2), (13), (7), (14)]

sage: relative_difference_set_from_homomorphism(9, 2, 4, # random
....:           check=False, return_group=True)
(Additive abelian group isomorphic to Z/80,
 [(0), (4), (6), (13), (7), (12), (15), (8), (9)])

sage: relative_difference_set_from_homomorphism(9, 2, 5) #...
 Traceback (most recent call last):
 ... ValueError: q-1 must be a multiple of d
```
Combinatorics, Release 10.4

sage.combinat.designs.difference_family.relative_difference_set_from_m_sequence(q, N, check=True, return_group=False)

Construct $R((q^N - 1)/(q - 1), q - 1, q^{N-1}, q^{N-2})$ where $q$ is a prime power and $N \geq 2$.

The relative difference set is constructed over the set of additive integers modulo $q^N - 1$, as described in Theorem 5.1 of [EB1966]. Given an m-sequence $(a_i)$ of period $q^N - 1$, the set is: $R = \{i|0 \leq i \leq q^{N-1}, a_i = 1\}$.

**INPUT:**

- $q$ – a prime power
- $N$ – a nonnegative number
- `check` – boolean (default: True); if True, check that the result is a relative difference set before returning it
- `return_group` – boolean (default: False); if True, the function will also return the group from which the set is created

**OUTPUT:**

If `return_group=False`, the function return only the relative difference set. Otherwise, it returns a tuple containing the group and the set.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_family import relative_difference_set_from_m_sequence
sage: relative_difference_set_from_m_sequence(2, 4, check=True, return_group=True)
(Additive abelian group isomorphic to Z/15, [(0), (4), (5), (6), (7), (9), (11), (12)])
```

```python
sage: relative_difference_set_from_m_sequence(8, 2, check=False)
[(0), (6), (30), (40), (41), (44), (56), (61)]
```

```python
sage: relative_difference_set_from_m_sequence(6, 2)
Traceback (most recent call last):
  ... ValueError: q must be a prime power
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import relative_difference_set_from_m_sequence
>>> relative_difference_set_from_m_sequence(Integer(2), Integer(4), check=True, return_group=True)
(Additive abelian group isomorphic to Z/15, [(0), (4), (5), (6), (7), (9), (11), (12)])
```

```python
>>> relative_difference_set_from_m_sequence(Integer(8), Integer(2), check=False)
[(0), (6), (30), (40), (41), (44), (56), (61)]
```

```python
>>> relative_difference_set_from_m_sequence(Integer(6), Integer(2))
Traceback (most recent call last):
  ... ValueError: q must be a prime power
```

(continues on next page)
sage.combinat.designs.difference_family.singer_difference_set \((q, d)\)

Return a difference set associated to the set of hyperplanes in a projective space of dimension \(d\) over \(GF(q)\).

A Singer difference set has parameters:

\[
v = \frac{q^{d+1} - 1}{q - 1}, \quad k = \frac{q^d - 1}{q - 1}, \quad \lambda = \frac{q^{d-1} - 1}{q - 1}.
\]

The idea of the construction is as follows. One consider the finite field \(GF(q^{d+1})\) as a vector space of dimension \(d + 1\) over \(GF(q)\). The set of \(GF(q)\)-lines in \(GF(q^{d+1})\) is a projective plane and its set of hyperplanes form a balanced incomplete block design.

Now, considering a multiplicative generator \(z\) of \(GF(q^{d+1})\), we get a transitive action of a cyclic group on our projective plane from which it is possible to build a difference set.

The construction is given in details in [Stinson2004], section 3.3.

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import singer_difference_set
sage: G,D = singer_difference_set(3,2)
# needs sage.rings.finite_rings
sage: is_difference_family(G, D, verbose=True)
# needs sage.rings.finite_rings
It is a (13,4,1)-difference family
True

sage: G,D = singer_difference_set(4,2)
# needs sage.rings.finite_rings
sage: is_difference_family(G, D, verbose=True)
# needs sage.rings.finite_rings
It is a (21,5,1)-difference family
True

sage: G,D = singer_difference_set(3,3)
# needs sage.rings.finite_rings
sage: is_difference_family(G, D, verbose=True)
# needs sage.rings.finite_rings
It is a (40,13,4)-difference family
True

sage: G,D = singer_difference_set(9,3)
# needs sage.rings.finite_rings
sage: is_difference_family(G, D, verbose=True)
# needs sage.rings.finite_rings
It is a (820,91,10)-difference family
True

>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import singer_difference_set, is_difference_family
>>> G,D = singer_difference_set(Integer(3),Integer(2)) # needs sage.rings.finite_rings
```

(continues on next page)
sage.combinat.designs.difference_family.skew_spin_goethals_seidel_difference_family(n, existence=False, check=True)

Construct skew spin type Goethals-Seidel difference family with parameters \((n; k_1, k_2, k_3, k_4; \lambda)\).

The construction is described in [Djo2024]. This function contains, for each value of \(n\), either a full representation of \(S_1, S_2\) together with the multiplier \(\mu\), or a subgroup \(H\), two sets of representatives, and the multiplier.

This data is used to construct the difference family using the functions _construct_gs_difference_family_from_full() and _construct_gs_difference_family_from_compact().

INPUT:

- \(n\) – integer; the parameter of the GS difference family
- \(existence\) – boolean (default: False); if True, only check whether the skew difference family can be constructed
- \(check\) – boolean (default: True); if True, check that the sets are a skew difference family before returning them; setting this parameter to False may speed up the computation considerably

OUTPUT:

If \(existence=False\), the function returns the group \(G\) of integers modulo \(n\) and a list containing 4 sets, or raises an error if data for the given \(n\) is not available. If \(existence=True\), the function returns a boolean representing whether the skew difference family can be constructed.

EXAMPLES:
sage: from sage.combinat.designs.difference_family import skew_spin_goethals_seidel_difference_family
sage: G, [S1, S2, S3, S4] = skew_spin_goethals_seidel_difference_family(61)

>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import skew_spin_goethals_seidel_difference_family

>>> G, [S1, S2, S3, S4] = skew_spin_goethals_seidel_difference_family(Integer(61))

If existence is True, the function returns a boolean:

sage: skew_spin_goethals_seidel_difference_family(61, existence=True)
True
sage: skew_spin_goethals_seidel_difference_family(5, existence=True)
False

sage.combinat.designs.difference_family.skew_supplementary_difference_set(n, existence=False, check=True, return_group=False)

Construct $4 - \{n; n_1, n_2, n_3, n_4; \lambda\}$ supplementary difference sets, where $S_1$ is skew and $n_1 + n_2 + n_3 + n_4 = n + \lambda$.

These sets are constructed from available data, as described in [Djo1994a]. The set $S_1 \subset G$ is always skew, i.e. $S_1 \cap (-S_1) = \emptyset$ and $S_1 \cup (-S_1) = G \setminus \{0\}$.

The data is taken from:

- $n = 103, 151$: [Djo1994a]
- $n = 67, 113, 127, 157, 163, 181, 241$: [Djo1992a]
- $n = 37, 43$: [Djo1992b]
- $n = 39, 49, 65, 93, 121, 129, 133, 217, 219, 267$: [Djo1992c]
- $n = 97$: [Djo2008a]
- $n = 109, 145, 247$: [Djo2008b]
- $n = 73$: [Djo2023b]
- $n = 213, 631$: [DGK2014]
- $n = 331$: [DK2016]

Additional skew Supplementary difference sets are built using the function skew_supplementary_difference_set_over_polynomial_ring(), and skew_supplementary_difference_set_with_paley_todd().

INPUT:

- $n$ – integer; the parameter of the supplementary difference set
• **existence** – boolean (default: False); if True, only check whether the supplementary difference sets can be constructed

• **check** – boolean (default: True); if True, check that the sets are supplementary difference sets with $S_1$ skew before returning them; setting this parameter to False may speed up the computation considerably

• **return_group** – boolean (default: False); if True, the function will also return the group from which the sets are created

**OUTPUT:**

If **existence=False**, the function returns a list containing 4 sets, or raises an error if data for the given $n$ is not available. If **return_group=True** the function will additionally return the group from which the sets are created. If **existence=True**, the function returns a boolean representing whether skew supplementary difference sets can be constructed.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_family import skew_supplementary_difference_set
sage: [S1, S2, S3, S4] = skew_supplementary_difference_set(39)

>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import skew_supplementary_difference_set
>>> [S1, S2, S3, S4] = skew_supplementary_difference_set(Integer(39))

If **return_group=True**, the function will also return the group:

```python
sage: G, [S1, S2, S3, S4] = skew_supplementary_difference_set(103, return_group=True)

```python

>>> from sage.all import *
>>> G, [S1, S2, S3, S4] = skew_supplementary_difference_set(Integer(103), return_group=True)

If **existence=True**, the function returns a boolean:

```python
sage: skew_supplementary_difference_set(103, existence=True)
True
sage: skew_supplementary_difference_set(17, existence=True)
False

```python

```python
>>> from sage.all import *
>>> skew_supplementary_difference_set(Integer(103), existence=True)
True
>>> skew_supplementary_difference_set(Integer(17), existence=True)
False
```

**Note:** The data for $n = 247$ in [Djo2008b] contains a typo: the set $\alpha_2$ should contain 223 instead of 233. This can be verified by checking the resulting sets, which are given explicitly in the paper.
Construct skew supplementary difference sets over a polynomial ring of order \( n \).
The skew supplementary difference sets for \( n = 81, 169 \) are taken from [Djo1994a].

INPUT:
- \( n \) – integer; the parameter of the supplementary difference sets
- \( \text{existence} \) – boolean (default: False); if True, only check whether the supplementary difference sets can be constructed
- \( \text{check} \) – boolean (default: True); if True, check that the sets are supplementary difference sets with \( S_1 \) skew before returning them; setting this parameter to False may speed up the computation considerably

OUTPUT:
If \( \text{existence}=\text{False} \), the function returns a Polynomial Ring of order \( n \) and a list containing 4 sets, or raises an error if data for the given \( n \) is not available. If \( \text{existence}=\text{True} \), the function returns a boolean representing whether skew supplementary difference sets can be constructed.

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import skew_supplementary_difference_set_over_polynomial_ring
sage: G, [S1, S2, S3, S4] = skew_supplementary_difference_set_over_polynomial_ring(81)  # needs sage.libs.pari

>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import skew_supplementary_difference_set_over_polynomial_ring
>>> G, [S1, S2, S3, S4] = skew_supplementary_difference_set_over_polynomial_ring(Integer(81))  # needs sage.libs.pari
```

If \( \text{existence}=\text{True} \), the function returns a boolean:

```python
sage: skew_supplementary_difference_set_over_polynomial_ring(81, existence=True)
True
sage: skew_supplementary_difference_set_over_polynomial_ring(17, existence=True)
False
```

Construct \( 4 - \{ n; n_1, n_2, n_3, n_4; \lambda \} \) skew supplementary difference sets where \( S_1 \) is the Paley-Todd difference set.
The skew SDS returned have the property that \( n_1 + n_2 + n_3 + n_4 = n + \lambda \).
This construction is described in [DK2016]. The function contains, for each value of \( n \), a set \( H \) containing integers modulo \( n \), and four sets \( J, K, L \). Then, these are used to construct \( (n; k_2, k_3, k_4; \lambda_2) \) difference family, with
\[ \lambda_2 = k_2 + k_3 + k_4 + \frac{(3n - 1)}{4} \]. Finally, these sets together with the Paley-Todd difference set form a skew supplementary difference set.

**INPUT:**

- \( n \) – integer; the parameter of the supplementary difference set
- \( \text{existence} \) – boolean (default: False); if True, only check whether the supplementary difference sets can be constructed
- \( \text{check} \) – boolean (default: True); if True, check that the sets are supplementary difference sets with \( S_1 \) skew before returning them; setting this parameter to False may speed up the computation considerably

**OUTPUT:**

If \( \text{existence} = \) False, the function returns the group \( G \) of integers modulo \( n \) and a list containing 4 sets, or raises an error if data for the given \( n \) is not available. If \( \text{existence} = \) True, the function returns a boolean representing whether skew supplementary difference sets can be constructed.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_family import skew_supplementary_difference_set_with_paley_todd
sage: G, [S1, S2, S3, S4] = skew_supplementary_difference_set_with_paley_todd(239)
```

If \( \text{existence} \) is \( \) True, the function returns a boolean:

```python
sage: skew_supplementary_difference_set_with_paley_todd(239, existence=True) # True
sage: skew_supplementary_difference_set_with_paley_todd(17, existence=True) # False
```

**sage.combinat.designs.difference_family.spin_goethals_seidel_difference_family** \((n, \text{existence}=False, \text{check}=True)\)

Construct a spin type Goethals-Seidel difference family with parameters \( (n; k_1, k_2, k_3, k_4; \lambda) \).

The construction is described in [Djo2024]. This function contains, for each value of \( n \), either a full representation of \( S_1, S_2 \) together with the multiplier \( \mu \), or a subgroup \( H \), two sets of representatives, and the multiplier. This data is used to construct the difference family using the functions \_construct_gs_difference_family_from_full() and \_construct_gs_difference_family_from_compact().

Additionally, this function also checks if a (skew) difference family can be constructed using \texttt{ske...seidel_difference_family()}.  

5.1. Comprehensive Module List 1081
INPUT:

- \( n \) – integer; the parameter of the GS difference family
- \( \text{existence} \) – boolean (default: False); if True, only check whether the difference family can be constructed
- \( \text{check} \) – boolean (default: True); if True, check that the sets are a difference family before returning them; setting this parameter to False may speed up the computation considerably

OUTPUT:

If \( \text{existence}=\text{False} \), the function returns the group \( G \) of integers modulo \( n \) and a list containing 4 sets, or raises an error if data for the given \( n \) is not available. If \( \text{existence}=\text{True} \), the function returns a boolean representing whether the difference family can be constructed.

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import spin_goethals_seidel_difference_family
sage: G, [S1, S2, S3, S4] = spin_goethals_seidel_difference_family(73)
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import spin_goethals_seidel_difference_family
>>> G, [S1, S2, S3, S4] = spin_goethals_seidel_difference_family(Integer(73))
```

If \( \text{existence} \) is True, the function returns a boolean:

```python
sage: spin_goethals_seidel_difference_family(73, existence=True)
True
sage: spin_goethals_seidel_difference_family(5, existence=True)
False
```

```python
>>> from sage.all import *
>>> spin_goethals_seidel_difference_family(Integer(73), existence=True)
True
>>> spin_goethals_seidel_difference_family(Integer(5), existence=True)
False
```

Construct \( 4 - \{2v; v, v+1, v, 2v\} \) supplementary difference sets where \( q = 2v + 1 \).

This is a deprecated version of `supplementary_difference_set_from_rel_diff_set()`, please use that instead.

Construct \( 4 - \{2v; v, v+1, v, 2v\} \) supplementary difference sets where \( q = 2v + 1 \).

The sets are created from relative difference sets as detailed in Theorem 3.3 of [Spe1975]. This construction requires that \( q \) is an odd prime power and that there exists \( s \geq 0 \) such that \( (q - (2^{s+1} + 1))/2^{s+1} \) is an odd prime power.
Note that the construction from [Spe1975] states that the resulting sets are $4 - \{2v; v+1, v, v; 2v\}$ supplementary difference sets. However, the implementation of that construction returns $4 - \{2v; v+1, v, v; 2v\}$ supplementary difference sets. This is not important, since the supplementary difference sets are not ordered.

**INPUT:**

- $q$ – an odd prime power
- `existence` – boolean (default: `False`); If `True`, only check whether the supplementary difference sets can be constructed
- `check` – boolean (default: `True`); If `True`, check that the sets are supplementary difference sets before returning them

**OUTPUT:**

If `existence=False`, the function returns the 4 sets (containing integers), or raises an error if $q$ does not satisfy the constraints. If `existence=True`, the function returns a boolean representing whether supplementary difference sets can be constructed.

**EXAMPLES:**

```sage
from sage.combinat.designs.difference_family import supplementary_difference_set

sage: supplementary_difference_set_from_rel_diff_set(17) #random
(Additive abelian group isomorphic to Z/16, 
[(1), (5), (6), (7), (9), (13), (14), (15)],
[(0), (2), (3), (5), (6), (10), (11), (13), (14)],
[(0), (1), (2), (3), (5), (6), (7), (12)],
[(0), (2), (3), (5), (6), (7), (9), (12)])
```

If `existence=True`, the function returns a boolean:

```sage
sage: supplementary_difference_set_from_rel_diff_set(7, existence=True)
False
sage: supplementary_difference_set_from_rel_diff_set(17, existence=True)
True
```

See also:

`is_supplementary_difference_set()`
Construct $4 - \{n; n_1, n_2, n_3, n_4; \lambda\}$ supplementary difference sets, where $n_1 + n_2 + n_3 + n_4 = n + \lambda$.

These sets are constructed from available data, as described in [Djo1994a]. The data is taken from:

- $n = 191$: [Djo2008c]
- $n = 239$: [Djo1994b]
- $n = 251$: [DGK2014]

Additional SDS are constructed using $\text{skew_supplementary_difference_set}()$.

**INPUT:**

- $n$ – integer; the parameter of the supplementary difference set
- $\text{existence}$ – boolean (default: False); if True, only check whether the supplementary difference sets can be constructed
- $\text{check}$ – boolean (default: True); if True, check that the sets are supplementary difference sets before returning them; Setting this parameter to False may speed up the computation considerably

**OUTPUT:**

If $\text{existence}=\text{False}$, the function returns the ring of integers modulo $n$ and a list containing the 4 sets, or raises an error if data for the given $n$ is not available. If $\text{existence}=\text{True}$, the function returns a boolean representing whether skew supplementary difference sets can be constructed.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_family import supplementary_difference_set_hadamard
sage: G, [S1, S2, S3, S4] = supplementary_difference_set_hadamard(191)
```

If $\text{existence}=\text{True}$, the function returns a boolean:

```python
sage: supplementary_difference_set_hadamard(191, existence=True) True
sage: supplementary_difference_set_hadamard(17, existence=True) False
```

```python
sage: from sage.all import *

>>> supplementary_difference_set_hadamard(Integer(191), existence=True) True
>>> supplementary_difference_set_hadamard(Integer(17), existence=True) False
```

**sage.combinat.designs.difference_family.turyn_1965_3x3xK** ($k=4$)

Return a difference set in either $C_3 \times C_3 \times C_4$ or $C_3 \times C_3 \times C_2 \times C_2$ with parameters $v = 36$, $k = 15$, $\lambda = 6$.

This example appears in [Tu1965].
INPUT:

- \( k \) – either 2 (to get a difference set in \( C_3 \times C_3 \times C_2 \times C_2 \)) or 4 (to get a difference set in \( C_3 \times C_3 \times C_3 \times C_4 \))

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import turyn_1965_3x3xK
sage: from sage.combinat.designs.difference_family import is_difference_family
sage: G, D = turyn_1965_3x3xK(4)
sage: assert is_difference_family(G, D, 36, 15, 6)
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import turyn_1965_3x3xK
>>> G, D = turyn_1965_3x3xK(Integer(4))
>>> assert is_difference_family(G, D, Integer(36), Integer(15), Integer(6))
```

sage.combinat.designs.difference_family.twin_prime_powers_difference_set \((p, check=True)\)

Return a difference set on \( GF(p) \times GF(p+2) \).

The difference set is built from the following element of the Cartesian product of finite fields \( GF(p) \times GF(p+2) \):

- \((x,0)\) with any \(x\)
- \((x,y)\) with \(x\) and \(y\) squares
- \((x,y)\) with \(x\) and \(y\) non-squares

For more information see Wikipedia article Difference_set.

INPUT:

- check – boolean (default: True); if True, then the result of the computation is checked before being returned. This should not be needed but ensures that the output is correct

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import twin_prime_powers_difference_set
sage: G, D = twin_prime_powers_difference_set(3)
```

```python
The Cartesian product of (Finite Field of size 3, Finite Field of size 5)
```

```python
d
[[[1, 1), (1, 4), (2, 2), (2, 3), (0, 0), (1, 0), (2, 0)]]
```
5.1.85 Difference Matrices

This module gathers code related to difference matrices. One can build those objects (or know if they can be built) with \texttt{difference_matrix()}: 

\begin{verbatim}
sage: G,DM = designs.difference_matrix(9,5,1)
>>> from sage.all import *
>>> G,DM = designs.difference_matrix(Integer(9),Integer(5),Integer(1))
\end{verbatim}

Functions

\texttt{sage.combinat.designs.difference_matrices.difference_matrix}(g, k, lmbda=1, existence=False, check=True)

Return a \((g, k, \lambda)\)-difference matrix

A matrix \(M\) is a \((g, k, \lambda)\)-difference matrix if it has size \(\lambda g \times k\), its entries belong to the group \(G\) of cardinality \(g\), and for any two rows \(R, R'\) of \(M\) and \(x \in G\) there are exactly \(\lambda\) values \(i\) such that \(R_i - R'_i = x\).

INPUT:

- \(k\) – (integer) number of columns. If \(k=None\) it is set to the largest value available.
- \(g\) – (integer) cardinality of the group \(G\)
- \(\lambda\) – (integer; default: 1) – number of times each element of \(G\) appears as a difference.
- \(check\) – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to \texttt{True} by default.
- \(existence\) (boolean) – instead of building the design, return:
  - \texttt{True} – meaning that Sage knows how to build the design
  - \texttt{Unknown} – meaning that Sage does not know how to build the design, but that the design may exist (see \texttt{sage.misc.unknown}).
  - \texttt{False} – meaning that the design does not exist.

Note: When \(k=None\) and \(existence=True\) the function returns an integer, i.e. the largest \(k\) such that we can build a \((g, k, \lambda)\)-DM.

EXAMPLES:

\begin{verbatim}
sage: G,M = designs.difference_matrix(25,10); G
Finite Field in x of size 5^2
sage: designs.difference_matrix(993,None,existence=1)
32
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> G,M = designs.difference_matrix(Integer(25),Integer(10)); G
Finite Field in x of size 5^2
>>> designs.difference_matrix(Integer(993),None,existence=Integer(1))
32
\end{verbatim}
Here we print for each $g$ the maximum possible $k$ for which Sage knows how to build a $(g, k, 1)$-difference matrix:

```python
sage: for g in range(2, 30):
    ...:     k_max = designs.difference_matrix(g=g, k=None, existence=True)
    ...:     print("{:2} {}").format(g, k_max)
    ...:
    2 2
    3 3
    4 4
    5 5
    6 2
    7 7
    8 8
    9 9
    10 2
    11 11
    12 6
    13 13
    14 2
    15 3
    16 16
    17 17
    18 2
    19 19
    20 4
    21 6
    22 2
    23 23
    24 8
    25 25
    26 2
    27 27
    28 6
    29 29
```

```python
>>> from sage.all import *
>>> for g in range(Integer(2), Integer(30)):
...     k_max = designs.difference_matrix(g=g, k=None, existence=True)
...     print("{:2} {}").format(g, k_max)
... _ = designs.difference_matrix(g, k_max)
```

(continues on next page)
Return the product of the \((G_1, k, \lambda_1)\) and \((G_2, k, \lambda_2)\) difference matrices \(M_1\) and \(M_2\).

The result is a \((G_1 \times G_2, k, \lambda_1 \lambda_2)\)-difference matrix.

**INPUT:**
- \(k, \lambda_1, \lambda_2\) – positive integers
- \(G_1, G_2\) – groups
- \(M_1, M_2\) – \((G_1, k, \lambda_1)\) and \((G_2, k, \lambda_2)\) difference matrices
- \(\text{check}\) – boolean (default: True); whether to check the output before it is returned

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_matrices import difference_matrix_product
   difference_matrix_product(k, M1, G1, \lambda_1, M2, G2, \lambda_2, check=True)

sage: G1,M1 = designs.difference_matrix(11,6)
sage: G2,M2 = designs.difference_matrix(7,6)
sage: G,M = difference_matrix_product(6,M1,G1,1,M2,G2,1)
sage: G1
Finite Field of size 11
sage: G2
Finite Field of size 7
sage: G
The Cartesian product of (Finite Field of size 11, Finite Field of size 7)
sage: is_difference_matrix(M,G,6,1)
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.difference_matrices import difference_matrix_product
   difference_matrix_product
>>> G1,M1 = designs.difference_matrix(Integer(11),Integer(6))
>>> G2,M2 = designs.difference_matrix(Integer(7),Integer(6))
>>> G,M = difference_matrix_product(Integer(6),M1,G1,Integer(1),M2,G2,Integer(1))
>>> G1
Finite Field of size 11
>>> G2
Finite Field of size 7
>>> G
```

(continues on next page)
The Cartesian product of (Finite Field of size 11, Finite Field of size 7)

```python
>>> is_difference_matrix(M, G, Integer(6), Integer(1))
True
```

```python
sage.combinat.designs.difference_matrices.find_product_decomposition(k, lmbda=1)
```

Try to find a product decomposition construction for difference matrices.

**INPUT:**

- `g, k, lmbda` – integers, parameters of the difference matrix

**OUTPUT:**

A pair of pairs `(g1, lmbda1), (g2, lmbda2)` if Sage knows how to build `(g1, k, lmbda1)` and `(g2, k, lmbda2)` difference matrices and `False` otherwise.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_matrices import find_product_decomposition
sage: find_product_decomposition(77, 6)
((7, 1), (11, 1))
```

```python
sage: find_product_decomposition(616, 7)
((7, 1), (88, 1))
```

```python
sage: find_product_decomposition(24, 10)
False
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.difference_matrices import find_product_decomposition
```

```python
>>> find_product_decomposition(Integer(77), Integer(6))
((7, 1), (11, 1))
```

```python
>>> find_product_decomposition(Integer(616), Integer(7))
((7, 1), (88, 1))
```

```python
>>> find_product_decomposition(Integer(24), Integer(10))
False
```

### 5.1.86 Evenly distributed sets in finite fields

This module consists of a simple class `EvenlyDistributedSetsBacktracker`. Its main purpose is to iterate through the evenly distributed sets of a given finite field.

The naive backtracker implemented here is not directly used to generate difference family as even for small parameters it already takes time to run. Instead, its output has been stored into a database `sage.combinat.designs.database`. If the backtracker is improved, then one might want to update this database with more values.
Classes and methods

class sage.combinat.designs.evenly_distributed_sets.EvenlyDistributedSetsBacktracker
    Bases: object

Set of evenly distributed subsets in finite fields.

Definition: Let $K$ be a finite field of cardinality $q$ and $k$ an integer so that $k(k - 1)$ divides $q - 1$. Let $H = K^*$ be the multiplicative group of invertible elements in $K$. A $k$-evenly distributed set in $K$ is a set $B = \{b_1, b_2, \ldots, b_k\}$ of $k$ elements of $K$ so that the $k(k - 1)$ differences $\Delta B = \{b_i - b_j; i \neq j\}$ hit each coset modulo $H^{2(q-1)/(k(k-1))}$ exactly twice.

Evenly distributed sets were introduced by Wilson [Wi72] (see also [BJL99-1], Chapter VII.6). He proved that for any $k$, and for any prime power $q$ large enough such that $k(k - 1)$ divides $k$ there exists a $k$-evenly distributed set in the field of cardinality $q$. This existence result based on a counting argument (using Dirichlet theorem) does not provide a simple method to generate them.

From a $k$-evenly distributed set, it is straightforward to build a $(q, k, 1)$-difference family (see to_difference_family()). Another approach to generate a difference family, somehow dual to this one, is via radical difference family (see in particular radical_difference_family() from the module difference_family).

By default, this backtracker only considers evenly distributed sets up to affine automorphisms, i.e. $B$ is considered equivalent to $sB + t$ for any invertible element $s$ and any element $t$ in the field $K$. Note that the set of differences is just multiplicatively translated by $s$ as $\Delta(sB + t) = s\Delta B$, and so that $B$ is an evenly distributed set if and only if $sB$ is one too. This behaviour can be modified via the argument up_to_isomorphism (see the input section and the examples below).

INPUT:

- $K$ – a finite field of cardinality $q$
- $k$ – a positive integer such that $k(k - 1)$ divides $q - 1$
- up_to_isomorphism – (boolean, default True) whether only consider evenly distributed sets up to automorphisms of the field of the form $x \mapsto ax + b$. If set to False then the iteration is over all evenly distributed sets that contain 0 and 1.
- check – boolean (default is False). Whether you want to check intermediate steps of the iterator. This is mainly intended for debugging purpose. Setting it to True will considerably slow the iteration.

EXAMPLES:

The main part of the code is contained in the iterator. To get one evenly distributed set just do:

```python
sage: from sage.combinat.designs.evenly_distributed_sets import...
    →EvenlyDistributedSetsBacktracker
sage: E = EvenlyDistributedSetsBacktracker(Zmod(151),6)
sage: B = E.an_element()
sage: B
[0, 1, 69, 36, 57, 89]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.evenly_distributed_sets import...
    →EvenlyDistributedSetsBacktracker
>>> E = EvenlyDistributedSetsBacktracker(Zmod(Integer(151)),Integer(6))
>>> B = E.an_element()
>>> B
[0, 1, 69, 36, 57, 89]
```
The class has a method to convert it to a difference family:

```python
sage: E.to_difference_family(B)
[[0, 1, 69, 36, 57, 89],
 [0, 132, 48, 71, 125, 121],
 [0, 59, 145, 10, 41, 117],
 [0, 87, 114, 112, 127, 42],
 [0, 8, 99, 137, 3, 108]]
```

It is also possible to run over all evenly distributed sets:

```python
>>> from sage.all import *

>>> E.to_difference_family(B)
[[0, 1, 69, 36, 57, 89],
 [0, 132, 48, 71, 125, 121],
 [0, 59, 145, 10, 41, 117],
 [0, 87, 114, 112, 127, 42],
 [0, 8, 99, 137, 3, 108]]
```

Or only count them:

```python
sage: for k in range(13, 200, 12):
    if is_prime_power(k):
        K = GF(k, 'a')
        E1 = EvenlyDistributedSetsBacktracker(K, 4, False)
        E2 = EvenlyDistributedSetsBacktracker(K, 4, True)
        print("{:3} {:3} {:3}".format(k, E1.cardinality(), E2.cardinality()))
```

(continues on next page)
Note that by definition, the number of evenly distributed sets up to isomorphisms is at most \(k(k-1)\) times smaller than without isomorphisms. But it might not be exactly \(k(k-1)\) as some of them might have symmetries:

```python
sage: B = EvenlyDistributedSetsBacktracker(Zmod(13), 4).an_element()
sage: B
[0, 1, 11, 5]
sage: [9*x + 5 for x in B]
[5, 1, 0, 11]
sage: [3*x + 11 for x in B]
[11, 1, 5, 0]
```

```python
>>> from sage.all import *
>>> B = EvenlyDistributedSetsBacktracker(Zmod(Integer(13)), Integer(4)).an_element()
>>> B
[0, 1, 11, 5]
>>> [Integer(9)*x + Integer(5) for x in B]
[5, 1, 0, 11]
>>> [Integer(3)*x + Integer(11) for x in B]
[11, 1, 5, 0]
```

`an_element()`

Return an evenly distributed set.

If there is no such subset raise an `EmptySetError`.

---

EXAMPLES:

```python
sage: from sage.combinat.designs.evenly_distributed_sets import EvenlyDistributedSetsBacktracker
sage: E = EvenlyDistributedSetsBacktracker(Zmod(41), 5)
```

```python
sage: E.an_element()
[0, 1, 13, 38, 31]
```

```python
sage: E = EvenlyDistributedSetsBacktracker(Zmod(61), 6)
```

```python
sage: E.an_element()
Traceback (most recent call last):
... EmptySetError: no 6-evenly distributed set in Ring of integers modulo 61
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.evenly_distributed_sets import EvenlyDistributedSetsBacktracker
>>> E = EvenlyDistributedSetsBacktracker(Zmod(Integer(41)), Integer(5))
```

```python
>>> E.an_element()
[0, 1, 13, 38, 31]
```

```python
>>> E = EvenlyDistributedSetsBacktracker(Zmod(Integer(61)), Integer(6))
```

```python
>>> E.an_element()
Traceback (most recent call last):
... EmptySetError: no 6-evenly distributed set in Ring of integers modulo 61
```

cardinality()

Return the number of evenly distributed sets.

Use with precaution as there can be a lot of such sets and this method might be very long to answer!

EXAMPLES:

```python
sage: from sage.combinat.designs.evenly_distributed_sets import EvenlyDistributedSetsBacktracker
sage: E = EvenlyDistributedSetsBacktracker(GF(25, 'a'), 4); E
4-evenly distributed sets (up to isomorphism) in Finite Field in a of size 5^2
```

```python
sage: E.cardinality()
4
```

```python
sage: E = EvenlyDistributedSetsBacktracker(GF(25, 'a'), 4, up_to_isomorphism=False)
```

```python
sage: E.cardinality()
40
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.evenly_distributed_sets import EvenlyDistributedSetsBacktracker
```

```python
>>> E = EvenlyDistributedSetsBacktracker(GF(Integer(25), 'a'), Integer(4)); E
4-evenly distributed sets (up to isomorphism) in Finite Field in a of size 5^2
```

```python
>>> E.cardinality()
```

(continues on next page)
\texttt{E = EvenlyDistributedSetsBacktracker(GF(Integer(25), 'a'), Integer(4), 
\hspace{1cm} \text{up_to_isomorphism=False})}

\begin{verbatim}
>>> E = EvenlyDistributedSetsBacktracker(GF(Integer(25), 'a'), Integer(4), 
... \hspace{1cm} \text{up_to_isomorphism=False})

\end{verbatim}

**to\_difference\_family** \texttt{(B, check=True)}

Given an evenly distributed set \( B \) convert it to a difference family.

As for any \( x \in K^* = H \) we have \( |\Delta B \cap xH^{2(q-1)/(k(k-1))}| = 2 \) (see \texttt{EvenlyDistributedSets-Backtracker}), the difference family is produced as \( \{xB : x \in H^{2(q-1)/(k(k-1))}\} \)

This method is useful if you want to obtain the difference family from the output of the iterator.

**INPUT:**

- \( B \) - an evenly distributed set
- \( \text{check} \) - (boolean, default True) whether to check the result

**EXAMPLES:**

\begin{verbatim}
sage: from sage.combinat.designs.evenly_distributed_sets import *

\hline
\text{->} \text{EvenlyDistributedSetsBacktracker} \\
\text{sage: E = EvenlyDistributedSetsBacktracker(Zmod(41), 5)} \\
\text{sage: B = E.an_element(); B} \\
\hspace{1cm} [0, 1, 13, 38, 31] \\
\text{sage: D = E.to_difference_family(B); D} \\
\hspace{1cm} [[0, 1, 13, 38, 31], [0, 32, 6, 27, 8]] \\
\text{sage: from sage.combinat.designs.difference_family import is_difference_family} \\
\text{sage: is_difference_family(Zmod(41), D, 41, 5, 1)} \\
\hspace{1cm} True \\
\text{\hline}
\end{verbatim}

\begin{verbatim}
>>> from sage.all import * 
>>> from sage.combinat.designs.evenly_distributed_sets import *

\hline
\text{->} \text{EvenlyDistributedSetsBacktracker} \\
\text{>>> E = EvenlyDistributedSetsBacktracker(Zmod(Integer(41)), Integer(5))} \\
\text{>>> B = E.an_element(); B} \\
\hspace{1cm} [0, 1, 13, 38, 31] \\
\text{>>> D = E.to_difference_family(B); D} \\
\hspace{1cm} [[0, 1, 13, 38, 31], [0, 32, 6, 27, 8]] \\
\text{>>> from sage.combinat.designs.difference_family import is_difference_family} \\
\text{>>> is_difference_family(Zmod(Integer(41)), D, Integer(41), Integer(5), 
\hspace{1cm} \text{Integer(1)})} \\
\hspace{1cm} True \\
\text{\hline}
\end{verbatim}

Setting \text{check} \text{ to False} is much faster:

\begin{verbatim}
sage: timeit("df = E.to_difference_family(B, check=True)") \# random
625 loops, best of 3: 117 µs per loop \\
sage: timeit("df = E.to_difference_family(B, check=False)") \# random
625 loops, best of 3: 1.83 µs per loop \\
\end{verbatim}
>>> from sage.all import *
>>> timeit("df = E.to_difference_family(B, check=True)")  # random
625 loops, best of 3: 117 µs per loop
>>> timeit("df = E.to_difference_family(B, check=False)")  # random
625 loops, best of 3: 1.83 µs per loop

5.1.87 External Representations of Block Designs

The “ext_rep” module is an API to the abstract tree represented by an XML document containing the External Representation of a list of block designs. The module also provides the related I/O operations for reading/writing ext-rep files or data. The parsing is based on expat.

This is a modified form of the module ext_rep.py (version 0.8) written by Peter Dobcsanyi [Do2009] peter@designtheory.org.

**Todo:** The XML data from the designtheory.org database contains a wealth of information about things like automorphism groups, transitivity, cycle type representatives, etc, but none of this data is made available through the current implementation.

**Functions**

```python
class sage.combinat.designs.ext_rep.XTree(node)

    Bases: object

    A lazy class to wrap a rooted tree representing an XML document. The tree’s nodes are tuples of the structure:
        (name, {dictionary of attributes}, [list of children])

    Methods and services of an XTree object t:
        • t.attribute – attribute named
        • t.child – first child named
        • t[i] – i-th child
        • for child in t: – iterate over t’s children
        • len(t) – number of t’s children

    If child is not an empty subtree, return the subtree as an XTree object. If child is an empty subtree, return _name
    of the subtree. Otherwise return the child itself.

    The lazy tree idea originated from a utility class of the pyRXP 0.9 package by Robin Becker at ReportLab.
```

```python
class sage.combinat.designs.ext_rep.XTreeProcessor

    Bases: object

    An incremental event-driven parser for ext-rep documents. The processing stages:
        • <list_of_designs ...> opening element. call-back: list_of_designs_proc
        • <list_definition> subtree. call-back: list_definition_proc
        • <info> subtree. call-back: info_proc
```

5.1. Comprehensive Module List
• iterating over `<designs>` processing each `<block_design>` separately. call-back: `block_design_proc`
• finishing with closing `</designs>` and `</list_of_designs>`.

`parse(xml_source)`

The main parsing function. Given an XML source (either a file handle or a string), parse the entire XML source.

**EXAMPLES:**

```python
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: proc = ext_rep.XTreeProcessor()
sage: proc.save_designs = True
sage: f = ext_rep.open_extrep_file(file_loc)
sage: proc.parse(f)
sage: f.close()
sage: os.remove(file_loc)
sage: proc.list_of_designs[0]
(2, [[0, 1], [0, 1]])
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
>>> proc = ext_rep.XTreeProcessor()
>>> proc.save_designs = True
>>> f = ext_rep.open_extrep_file(file_loc)
>>> proc.parse(f)
>>> f.close()
>>> os.remove(file_loc)
>>> proc.list_of_designs[Integer(0)]
(2, [[0, 1], [0, 1]])
```

`sage.combinat.designs.ext_rep.check_dtrs_protocols(input_name, input_pv)`

Check that the XML data is in a valid format. We can currently handle version 2.0. For more information see [http://designtheory.org/library/extrep/](http://designtheory.org/library/extrep/)

**EXAMPLES:**

```python
sage: from sage.combinat.designs import ext_rep
sage: ext_rep.check_dtrs_protocols(source, 2.0)
sage: ext_rep.check_dtrs_protocols(source, 3.0)
Traceback (most recent call last):
  ... RuntimeException: Incompatible dtrs_protocols: program: 2.0 source: 3.0
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> ext_rep.check_dtrs_protocols('source', '2.0')
>>> ext_rep.check_dtrs_protocols('source', '3.0')
Traceback (most recent call last):
  ... RuntimeException: Incompatible dtrs_protocols: program: 2.0 source: 3.0
```

`sage.combinat.designs.ext_rep.designs_from_XML(fname)`

Return a list of designs contained in an XML file `fname`. The list contains tuples of the form `(v, bs)` where `v` is the number of points of the design and `bs` is the list of blocks.
EXAMPLES:

```python
def from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: ext_rep.designs_from_XML(file_loc)[0]
(2, [[0, 1], [0, 1]])
sage: os.remove(file_loc)

sage: from sage.combinat.designs import BlockDesign
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: v, blocks = ext_rep.designs_from_XML(file_loc)[0]
sage: d = BlockDesign(v, blocks)
sage: d.blocks()
[[0, 1], [0, 1]]
sage: d.is_t_design(t=2)
True
sage: d.is_t_design(return_parameters=True)
(True, (2, 2, 2, 2))
```

```python
def from sage.all import *
def from sage.combinat.designs import ext_rep
def ext_rep.designs_from_XML_url(url)
Return a list of designs contained in an XML file named by a URL. The list contains tuples of the form (v, bs)
where v is the number of points of the design and bs is the list of blocks.

EXAMPLES:

```python
def sage.combinat.designs.ext_rep.designs_from_XML_url(url)
def from sage.combinat.designs import BlockDesign
def from sage.combinat.designs import ext_rep
def ext_rep.designs_from_XML_url("file:/// + file_loc")
(2, [[0, 1], [0, 1]])
def os.remove(file_loc)
```
(3, [[0, 1], [0, 1], [0, 1], [0, 2], [0, 2], [1, 2]]),
(3, [[0, 1], [0, 1], [0, 2], [0, 2], [1, 2], [1, 2]])

```python
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> import os

file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)

ext_rep.designs_from_XML_url("file://" + file_loc)[Integer(0)]

>>> os.remove(file_loc)

file_loc = ext_rep.dump_to_tmpfile("boo")

ext_rep.designs_from_XML_url("http://designtheory.org/database/v-b-k/v3-b6-k2.icgsa.txt.bz2")

[(3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 1], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 2], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 2], [1, 2]]),
 (3, [[0, 1], [0, 1], [0, 2], [0, 2], [0, 2], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 2], [0, 2], [1, 2], [1, 2]]),
 (3, [[0, 1], [0, 1], [0, 2], [0, 2], [1, 2], [1, 2]])]
```

sage.combinat.designs.ext_rep.dump_to_tmpfile(x)

Utility function to dump a string to a temporary file.

EXAMPLES:

```python
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile("boo")
sage: os.remove(file_loc)
```

sage.combinat.designs.ext_rep.open_extrep_file(fname)

Try to guess the compression type from extension and open the extrep file.

EXAMPLES:

```python
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: proc = ext_rep.XTreeProcessor()
sage: f = ext_rep.open_extrep_file(file_loc)
sage: proc.parse(f)
sage: f.close()
sage: os.remove(file_loc)
```
sage.combinat.designs.ext_rep.open_extrep_url(url)

Try to guess the compression type from extension and open the extrep file pointed to by the url. This function (unlike open_extrep_file) returns the uncompressed text contained in the file.

EXAMPLES:

```python
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: proc = ext_rep.XTreeProcessor()
sage: s = ext_rep.open_extrep_url("file://" + file_loc)
sage: proc.parse(s)
sage: os.remove(file_loc)

sage: from sage.combinat.designs import ext_rep
sage: s = ext_rep.designs_from_XML_url("http://designtheory.org/database/v-b-k/v3-b6-k2.icgsa.txt.bz2")
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
>>> proc = ext_rep.XTreeProcessor()
>>> s = ext_rep.open_extrep_url("file://" + file_loc)
>>> proc.parse(s)
>>> os.remove(file_loc)

>>> from sage.combinat.designs import ext_rep
>>> s = ext_rep.designs_from_XML_url("http://designtheory.org/database/v-b-k/v3-b6-k2.icgsa.txt.bz2")
```

5.1.88 Database of generalised quadrangles with spread

This module implements some construction of generalised quadrangles with spread.

EXAMPLES:

```python
sage: GQ, S = designs.generalised_quadrangle_with_spread(4, 16, check=False)
sage: GQ
Incidence structure with 325 points and 1105 blocks
sage: GQ2, O = designs.generalised_quadrangle_hermitian_with_ovoid(4)
sage: GQ2
Incidence structure with 1105 points and 325 blocks
sage: GQ3 = GQ.dual()
sage: set(GQ3._points) == set(GQ2._points)
True
sage: GQ2.is_isomorphic(GQ3) # long time
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
>>> proc = ext_rep.XTreeProcessor()
>>> s = ext_rep.open_extrep_url("file://" + file_loc)
>>> proc.parse(s)
>>> os.remove(file_loc)

>>> from sage.combinat.designs import ext_rep
>>> s = ext_rep.designs_from_XML_url("http://designtheory.org/database/v-b-k/v3-b6-k2.icgsa.txt.bz2")
```

```
>>> from sage.all import *
>>> GQ, S = designs.generalised_quadrangle_with_spread(Integer(4), Integer(16), check=False)
>>> GQ
Incidence structure with 325 points and 1105 blocks
>>> GQ2, O = designs.generalised_quadrangle_hermitian_with_ovoid(Integer(4))
>>> GQ2
Incidence structure with 1105 points and 325 blocks
>>> GQ3 = GQ.dual()
```

(continues on next page)
>>> set(GQ3._points) == set(GQ2._points)
True
>>> GQ2.is_isomorphic(GQ3)  # long time
True

sage.combinat.designs.gen_quadrangles_with_spread.dual_GQ_ovoid(GQ, O)

Compute the dual incidence structure of GQ and return the image of O under the dual map

INPUT:
• GQ – IncidenceStructure; the generalised quadrangle we want the dual of
• O – iterable; the iterable of blocks we want to compute the dual

OUTPUT:
A pair (D, S) where D is the dual of GQ and S is the dual of O

EXAMPLES:

```sage
from sage.combinat.designs.gen_quadrangles_with_spread import *
....: dual_GQ_ovoid
sage: t = designs.generalised_quadrangle_hermitian_with_ovoid(3)
sage: t[0].is_generalized_quadrangle(parameters=True)
(9, 3)
sage: t = dual_GQ_ovoid(*t)
sage: t[0].is_generalized_quadrangle(parameters=True)
(3, 9)
sage: all([x in t[0] for x in t[1]])
True
```

```sage
from sage.all import *
from sage.combinat.designs.gen_quadrangles_with_spread import dual_GQ_ovoid
sage: t = designs.generalised_quadrangle_hermitian_with_ovoid(Integer(3))
sage: t[Integer(0)].is_generalized_quadrangle(parameters=True)
(9, 3)
sage: t = dual_GQ_ovoid(*t)
sage: t[Integer(0)].is_generalized_quadrangle(parameters=True)
(3, 9)
sage: all([x in t[Integer(0)] for x in t[Integer(1)]])
True
```

sage.combinat.designs.gen_quadrangles_with_spread.generalised_quadrangle_hermitian_with_ovoid(q)

Construct the generalised quadrangle $H(3, q^2)$ with an ovoid.

The GQ has order $(q^2, q)$.

INPUT:
• q – integer; a prime power
OUTPUT:

A pair \((D, O)\) where \(D\) is an IncidenceStructure representing the generalised quadrangle and \(O\) is a list of points of \(D\) which constitute an ovoid of \(D\).

EXAMPLES:

```python
sage: t = designs.generalised_quadrangle_hermitian_with_ovoid(4)
sage: t[0]
Incidence structure with 1105 points and 325 blocks
sage: len(t[1])
65
sage: G = t[0].intersection_graph([1])  # line graph
sage: G.is_strongly_regular(True)
(325, 68, 3, 17)
sage: set(t[0].block_sizes())
{17}
```

REFERENCES:

For more on \(H(3, q^2)\) and the construction implemented here see [PT2009] or [TP1994].

sage.combinat.designs.gen_quadrangles_with_spread.generalised_quadrangle_with_spread

Construct a generalised quadrangle \(GQ\) of order \((s, t)\) with a spread \(S\).

INPUT:

- \(s, t\) – integers; order of the generalised quadrangle
- \(existence\) – boolean;
- \(check\) – boolean; if True, then Sage checks that the object built is correct. (default: True)

OUTPUT:

A pair \((GQ, S)\) where \(GQ\) is a IncidenceStructure representing the generalised quadrangle and \(S\) is a list of blocks of \(GQ\) representing the spread of \(GQ\).

EXAMPLES:

```python
sage: t = designs.generalised_quadrangle_with_spread(3, 9)
sage: t[0]
Incidence structure with 112 points and 280 blocks
```
Combinatorics, Release 10.4

sage: designs.generalised_quadrangle_with_spread(5, 25, existence=True)
True
sage: (designs.generalised_quadrangle_with_spread(4, 16, check=False))[0]
Incidence structure with 325 points and 1105 blocks
sage: designs.generalised_quadrangle_with_spread(0, 2, existence=True)
False

sage: from sage.all import *
sage: t = designs.generalised_quadrangle_with_spread(Integer(3), Integer(9))
sage: t[Integer(0)]
Incidence structure with 112 points and 280 blocks
sage: designs.generalised_quadrangle_with_spread(Integer(5), Integer(25), existence=True)
True
sage: (designs.generalised_quadrangle_with_spread(Integer(4), Integer(16), check=False))[Integer(0)]
Incidence structure with 325 points and 1105 blocks
sage: designs.generalised_quadrangle_with_spread(Integer(0), Integer(2), existence=True)
False

REFERENCES:
For more on generalised quadrangles and their spread see [PT2009] or [TP1994].
sage.combinat.designs.gen_quadrangles_with_spread.is_GQ_with_spread(GQ, S, s=None, t=None)
Check if GQ is a generalised quadrangle of order \((s, t)\) and check that \(S\) is a spread of GQ

INPUT:
• \(GQ\) – IncidenceStructure; the incidence structure that is supposed to be a generalised quadrangle
• \(S\) – iterable; the spread of \(GQ\) as an iterable of the blocks of \(GQ\)
• \(s, t\) – integers (optional); if \((s, t)\) are given, then we check that \(GQ\) has order \((s, t)\)

EXAMPLES:

sage: from sage.combinat.designs.gen_quadrangles_with_spread import *
sage: t = designs.generalised_quadrangle_hermitian_with_ovoid(3)
sage: is_GQ_with_spread(*t)
Traceback (most recent call last):
  ... TypeError: 'int' object is not iterable
sage: t = dual_GQ_ovoid(*t)
sage: is_GQ_with_spread(*t)
True
sage: is_GQ_with_spread(*t, s=3)
True

>>> from sage.all import *
>>> from sage.combinat.designs.gen_quadrangles_with_spread import *
>>> t = designs.generalised_quadrangle_hermitian_with_ovoid(Integer(3))
>>> is_GQ_with_spread(*t)
Traceback (most recent call last):
... TypeError: 'int' object is not iterable

5.1.89 Incidence structures (i.e. hypergraphs, i.e. set systems)

An incidence structure is specified by a list of points, blocks, or an incidence matrix \((1^2)\). IncidenceStructure instances have the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>automorphism_group()</td>
<td>Return the subgroup of the automorphism group of the incidence graph which respects the P B partition. It is (isomorphic to) the automorphism group of the block design, although the degrees differ.</td>
</tr>
<tr>
<td>block_sizes()</td>
<td>Return the set of block sizes.</td>
</tr>
<tr>
<td>blocks()</td>
<td>Return the list of blocks.</td>
</tr>
<tr>
<td>canonical_label()</td>
<td>Return a canonical label for the incidence structure.</td>
</tr>
<tr>
<td>coloring()</td>
<td>Compute a (weak) (k)-coloring of the hypergraph</td>
</tr>
<tr>
<td>complement()</td>
<td>Return the complement of the incidence structure.</td>
</tr>
<tr>
<td>copy()</td>
<td>Return a copy of the incidence structure.</td>
</tr>
<tr>
<td>degree()</td>
<td>Return the degree of a point (p) (or a set of points).</td>
</tr>
<tr>
<td>degrees()</td>
<td>Return the degree of all sets of given size, or the degree of all points.</td>
</tr>
<tr>
<td>dual()</td>
<td>Return the dual of the incidence structure.</td>
</tr>
<tr>
<td>edge_coloring()</td>
<td>Compute a proper edge-coloring.</td>
</tr>
<tr>
<td>ground_set()</td>
<td>Return the ground set (i.e. the list of points).</td>
</tr>
<tr>
<td>incidence_graph()</td>
<td>Return the incidence graph of the incidence structure</td>
</tr>
<tr>
<td>incidence_matrix()</td>
<td>Return the incidence matrix (A) of the design. (A) is a ((v \times b)) matrix defined by: (A[i,j] = 1) if (i) is in block (B_j) and (0) otherwise.</td>
</tr>
<tr>
<td>induced_substructure()</td>
<td>Return the substructure induced by a set of points.</td>
</tr>
<tr>
<td>intersection_graph()</td>
<td>Return the intersection graph of the incidence structure.</td>
</tr>
<tr>
<td>is_berge_cyclic()</td>
<td>Check whether self is a Berge-Cyclic uniform hypergraph.</td>
</tr>
<tr>
<td>is_connected()</td>
<td>Test whether the design is connected.</td>
</tr>
<tr>
<td>is_generalized_quadrangle()</td>
<td>Test if the incidence structure is a generalized quadrangle.</td>
</tr>
<tr>
<td>is_isomorphic()</td>
<td>Return whether the two incidence structures are isomorphic.</td>
</tr>
<tr>
<td>is_regular()</td>
<td>Test whether the incidence structure is (r)-regular.</td>
</tr>
<tr>
<td>is_resolvable()</td>
<td>Test whether the hypergraph is resolvable</td>
</tr>
<tr>
<td>is_simple()</td>
<td>Test whether this design is simple (i.e. no repeated block).</td>
</tr>
<tr>
<td>is_spread()</td>
<td>Check whether the input is a spread for self.</td>
</tr>
<tr>
<td>is_t_design()</td>
<td>Test whether self is a (t-(v,k,l)) design.</td>
</tr>
<tr>
<td>is_uniform()</td>
<td>Test whether the incidence structure is (k)-uniform</td>
</tr>
<tr>
<td>isomorphic_substructures_iter-</td>
<td>Iterates over all copies of (H_2) contained in self.</td>
</tr>
<tr>
<td>ture()</td>
<td></td>
</tr>
<tr>
<td>num_blocks()</td>
<td>Return the number of blocks.</td>
</tr>
<tr>
<td>num_points()</td>
<td>Return the size of the ground set.</td>
</tr>
<tr>
<td>packing()</td>
<td>Return a maximum packing</td>
</tr>
<tr>
<td>rank()</td>
<td>Return the rank of the hypergraph (the maximum size of a block).</td>
</tr>
</tbody>
</table>

---

Table 2 – continued from previous page

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relabel()</td>
<td>Relabel the ground set</td>
</tr>
<tr>
<td>trace()</td>
<td>Return the trace of a set of points.</td>
</tr>
</tbody>
</table>

AUTHORS:

- Peter Dobcsanyi and David Joyner (2007-2008)
  
  This is a significantly modified form of part of the module block_design.py (version 0.6) written by Peter Dobcsanyi peter@designtheory.org.

- Vincent Delecroix (2014): major rewrite

Methods

class sage.combinat.designs.incidence_structures.IncidenceStructure (points=None, blocks=None, incidence_matrix=None, name=None, check=True, copy=True)

Bases: object

A base class for incidence structures (i.e. hypergraphs, i.e. set systems)

An incidence structure (i.e. hypergraph, i.e. set system) can be defined from a collection of blocks (i.e. sets, i.e. edges), optionally with an explicit ground set (i.e. point set, i.e. vertex set). Alternatively they can be defined from a binary incidence matrix.

INPUT:

- points – (i.e. ground set, i.e. vertex set) the underlying set. If points is an integer \( v \), then the set is considered to be \( \{0, \ldots, v - 1\} \).

  Note: The following syntax, where points is omitted, automatically defines the ground set as the union of the blocks:

```python
sage: H = IncidenceStructure([[\'a\', \'b\', \'c\'], [\'c\', \'d\', \'e\']])
sage: sorted(H.ground_set())
[\'a\', \'b\', \'c\', \'d\', \'e\']
```

```python
>>> from sage.all import *

>>> H = IncidenceStructure([[\'a\', \'b\', \'c\'], [\'c\', \'d\', \'e\']])
>>> sorted(H.ground_set())
[\'a\', \'b\', \'c\', \'d\', \'e\']
```

- blocks – (i.e. edges, i.e. sets) the blocks defining the incidence structure. Can be any iterable.
- incidence_matrix – a binary incidence matrix. Each column represents a set.
- name (a string, such as “Fano plane”).
- check – whether to check the input
- copy – (use with caution) if set to False then blocks must be a list of lists of integers. The list will not be copied but will be modified in place (each block is sorted, and the whole list is sorted). Your blocks object will become the IncidenceStructure instance’s internal data.

EXAMPLES:

An incidence structure can be constructed by giving the number of points and the list of blocks:

```
sage: IncidenceStructure(7, [[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]])
```

Incidence structure with 7 points and 7 blocks

```
>>> from sage.all import *
```  

```
>>> IncidenceStructure(Integer(7), [[Integer(0),Integer(1),Integer(2)],
                                 [Integer(0),Integer(3),Integer(4)],
                                 [Integer(0),Integer(5),Integer(6)],
                                 [Integer(1),Integer(3),Integer(5)],
                                 [Integer(1),Integer(4),Integer(6)],
                                 [Integer(2),Integer(3),Integer(6)],
                                 [Integer(2),Integer(4),Integer(5)]])
```

Incidence structure with 7 points and 7 blocks

Only providing the set of blocks is sufficient. In this case, the ground set is defined as the union of the blocks:

```
sage: IncidenceStructure([[1,2,3],[2,3,4]])
```

Incidence structure with 4 points and 2 blocks

```
>>> from sage.all import *
```  

```
>>> IncidenceStructure([[Integer(1),Integer(2),Integer(3)],
                      [Integer(2),Integer(3),Integer(4)]])
```

Incidence structure with 4 points and 2 blocks

Or by its adjacency matrix (a \{0, 1\}-matrix in which rows are indexed by points and columns by blocks):

```
sage: m = matrix([[0,1,0],[0,0,1],[1,0,1],[1,1,1]])
```

Incidence structure with 4 points and 3 blocks

```
# needs sage.modules
```  

```
>>> m = matrix([[Integer(0),Integer(1),Integer(0)],[Integer(0),Integer(0),Integer(1)],[Integer(1),Integer(0),Integer(1)],[Integer(1),Integer(1),Integer(1)]]
```

Incidence structure with 4 points and 3 blocks

The points can be any (hashable) object:

```
sage: V = [(0,'a'),(0,'b'),(1,'a'),(1,'b')]
sage: B = [(V[0],V[1],V[2]), (V[1],V[2]), (V[0],V[2])]
sage: I = IncidenceStructure(V, B)
sage: I.ground_set()  
[(0, 'a'), (0, 'b'), (1, 'a'), (1, 'b')]  
sage: I.blocks()  
[[(0, 'a'), (0, 'b'), (1, 'a')], [(0, 'a'), (1, 'a')], [(0, 'b'), (1, 'a')]]
```  

```
>>> from sage.all import *
```  

```
>>> V = [(Integer(0),'a'),(Integer(0),'b'),(Integer(1),'a'),(Integer(1),'b')]
```

(continues on next page)
B = [(V[0], V[1], V[2]), (V[1], V[2]), (V[0], V[2])]

I = IncidenceStructure(V, B)

I.ground_set()
[(0, 'a'), (0, 'b'), (1, 'a'), (1, 'b')]

I.blocks()
[((0, 'a'), (0, 'b'), (1, 'a')), [(0, 'a'), (1, 'a')], [(0, 'b'), (1, 'a')]]

The order of the points and blocks does not matter as they are sorted on input (see Issue #1133):

```sage
sage: A = IncidenceStructure([0,1,2], [[0],[0,2]])
sage: B = IncidenceStructure([1,0,2], [[0],[2,0]])
sage: B == A
True
```

```sage
sage: C = BlockDesign(2, [[0], [1,0]])
sage: D = BlockDesign(2, [[0,1], [0]])
sage: C == D
True
```

```sage
>>> from sage.all import *

```

```sage
A = IncidenceStructure([Integer(0), Integer(1), Integer(2)], [[Integer(0)],
    [Integer(0), Integer(2)])
B = IncidenceStructure([Integer(1), Integer(0), Integer(2)], [[Integer(0)],
    [Integer(2), Integer(0)])
B == A
True
```

```sage
C = BlockDesign(Integer(2), [[Integer(0)], [Integer(1),Integer(0)])
D = BlockDesign(Integer(2), [[Integer(0),Integer(1)], [Integer(0)])
C == D
True
```

If you care for speed, you can set `copy` to `False`, but in that case, your input must be a list of lists and the ground set must be 0, ..., 𝑣 − 1:

```sage
blocks = [[0,1],[2,0],[1,2]]  # a list of lists of integers
I = IncidenceStructure(3, blocks, copy=False)
I._blocks is blocks
True
```

```sage
>>> from sage.all import *

```

```sage
blocks = [[Integer(0),Integer(1),Integer(2)], [Integer(0),Integer(2),Integer(0)],
    [Integer(0),Integer(1)])  # a list of lists of integers
I = IncidenceStructure(Integer(3), blocks, copy=False)
I._blocks is blocks
True
```

`automorphism_group()`

Return the subgroup of the automorphism group of the incidence graph which respects the P B partition. It is (isomorphic to) the automorphism group of the block design, although the degrees differ.

EXAMPLES:
(7,3,1)-Balanced Incomplete Block Design
sage: G = P.automorphism_group()
sage: G.is_isomorphic(PGL(3,2))
True
sage: G
Permutation Group with generators [...]  
sage: G.cardinality()
168

A non self-dual example:

sage: IS = IncidenceStructure(list(range(4)), [[0,1,2,3],[1,2,3]])
sage: IS.automorphism_group().cardinality()  # needs sage.groups
6
sage: IS.dual().automorphism_group().cardinality()  # needs sage.groups sage.modules
1

Examples with non-integer points:

sage: I = IncidenceStructure('abc', ('ab','ac','bc'))
sage: I.automorphism_group()  # needs sage.groups
Permutation Group with generators [('b','c'), ('a','b')]
sage: IncidenceStructure(((1,2),(3,4))).automorphism_group()  # needs sage.groups
Permutation Group with generators [(1,2),(3,4)]
Permutation Group with generators [('b','c'), ('a','b')]

```python
>>> IncidenceStructure(((Integer(1),Integer(2)),(Integer(3),Integer(4)))).
automorphism_group()  # needs sage.groups
Permutation Group with generators [(1,2),(3,4)]
```

## block_sizes()

Return the set of block sizes.

**EXAMPLES:**

```python
sage: BD = IncidenceStructure(8, [[0,1,3],[1,4,5,6],[1,2],[5,6,7]])
sage: BD.block_sizes()
[3, 2, 4, 3]
sage: BD = IncidenceStructure(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]])
sage: BD.block_sizes()
[3, 3, 3, 3, 3, 3]
```

```python
>>> from sage.all import *

>>> BD = IncidenceStructure(Integer(8), [[Integer(0),Integer(1),Integer(3)],
  [Integer(1),Integer(4),Integer(5),Integer(6)],[Integer(1),Integer(2)],
  [Integer(5),Integer(6),Integer(7)]])
>>> BD.block_sizes()
[3, 2, 4, 3]
>>> BD = IncidenceStructure(Integer(7),[[Integer(0),Integer(1),Integer(2)],
  [Integer(0),Integer(3),Integer(4)],[Integer(0),Integer(5),Integer(6)],
  [Integer(1),Integer(3),Integer(5)],[Integer(1),Integer(4),Integer(6)],
  [Integer(2),Integer(3),Integer(6)],[Integer(2),Integer(4),Integer(5)]])
>>> BD.block_sizes()
[3, 3, 3, 3, 3, 3]
```

## blocks()

Return the list of blocks.

**EXAMPLES:**

```python
sage: BD = IncidenceStructure(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]])
sage: BD.blocks()
[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6], [2, 4, 5]]
```

```python
>>> from sage.all import *

>>> BD = IncidenceStructure(Integer(7),[[Integer(0),Integer(1),Integer(2)],
  [Integer(0),Integer(3),Integer(4)],[Integer(0),Integer(5),Integer(6)],
  [Integer(1),Integer(3),Integer(5)],[Integer(1),Integer(4),Integer(6)],
  [Integer(2),Integer(3),Integer(6)],[Integer(2),Integer(4),Integer(5)]])
>>> BD.blocks()
[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6], [2, 4, 5]]
```

## canonical_label()

Return a canonical label for the incidence structure.

A canonical label is relabeling of the points into integers \(\{0, \ldots, n-1\}\) such that isomorphic incidence structures are relabelled to equal objects.

**EXAMPLES:**
```python
sage: # needs sage.schemes
sage: fano1 = designs.balanced_incomplete_block_design(7,3)
sage: fano2 = designs.projective_plane(2)
sage: fano1 == fano2
False
sage: fano1.relabel(fano1.canonical_label())
sage: fano2.relabel(fano2.canonical_label())
sage: fano1 == fano2
True
```

```python
>>> from sage.all import *
>>> # needs sage.schemes
>>> fano1 = designs.balanced_incomplete_block_design(Integer(7),Integer(3))
>>> fano2 = designs.projective_plane(Integer(2))
>>> fano1 == fano2
False
>>> fano1.relabel(fano1.canonical_label())
>>> fano2.relabel(fano2.canonical_label())
>>> fano1 == fano2
True
```

**coloring** *(k, solver=None, verbose=None, integrality_tolerance=0)*

Compute a (weak) *k*-coloring of the hypergraph

A weak coloring of a hypergraph $\mathcal{H}$ is an assignment of colors to its vertices such that no set is monochromatic.

**INPUT:**

- *k* (integer) – compute a coloring with *k* colors if an integer is provided, otherwise returns an optimal coloring (i.e. with the minimum possible number of colors).
- *solver* – (default: None) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to None, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- *verbose* – non-negative integer (default: 0). Set the level of verbosity you want from the linear program solver. Since the problem is *NP*-complete, its solving may take some time depending on the graph. A value of 0 means that there will be no message printed by the solver.
- *integrality_tolerance* – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

**EXAMPLES:**

The Fano plane has chromatic number 3:

```python
sage: len(designs.steiner_triple_system(7).coloring())  # needs sage.numerical.mip
3
```

```python
>>> from sage.all import *
>>> # needs sage.numerical.mip
>>> len(designs.steiner_triple_system(Integer(7)).coloring())  # needs sage.numerical.mip
3
```

One admissible 3-coloring:
The chromatic number of a graph is equal to the chromatic number of its 2-uniform corresponding hypergraph:

```python
sage: g = graphs.PetersenGraph()
sage: H = IncidenceStructure(g.edges(sort=True, labels=False))
sage: len(g.coloring())  # needs sage.numerical.mip
3
sage: len(H.coloring())  # needs sage.numerical.mip
3
>>> from sage.all import *
>>> g = graphs.PetersenGraph()
>>> H = IncidenceStructure(g.edges(sort=True, labels=False))
>>> len(g.coloring())  # needs sage.numerical.mip
3
>>> len(H.coloring())  # needs sage.numerical.mip
3
```

**complement**(uniform=False)

Return the complement of the incidence structure.

Two different definitions of "complement" are made available, according to the value of uniform.

**INPUT:**

- uniform (boolean) –
  - if set to False (default), returns the incidence structure whose blocks are the complements of all blocks of the incidence structure.
  - If set to True and the incidence structure is $k$-uniform, returns the incidence structure whose blocks are all $k$-sets of the ground set that do not appear in self.

**EXAMPLES:**

The complement of a BalancedIncompleteBlockDesign is also a 2-design:

```python
sage: bibd = designs.balanced_incomplete_block_design(13,4)  # needs sage.schemes
sage: bibd.is_t_design(return_parameters=True)  # needs sage.schemes
(True, (2, 13, 4, 1))
sage: bibd.complement().is_t_design(return_parameters=True)  # needs sage.schemes
(True, (2, 13, 9, 6))
```
>>> from sage.all import *

>>> bibd = designs.balanced_incomplete_block_design(Integer(13),Integer(4))  
"# needs sage.schemes"

>>> bibd.is_t_design(return_parameters=True)  
# needs sage.schemes
(True, (2, 13, 4, 1))

>>> bibd.complement().is_t_design(return_parameters=True)  
# needs sage.schemes
(True, (2, 13, 9, 6))

The “uniform” complement of a graph is a graph:

sage: g = graphs.PetersenGraph()
sage: G = IncidenceStructure(g.edges(sort=True, labels=False))
sage: H = G.complement(uniform=True)
sage: h = Graph(H.blocks())
sage: g == h
False
sage: g == h.complement()
True

```python
>>> from sage.all import *

>>> g = graphs.PetersenGraph()

>>> G = IncidenceStructure(g.edges(sort=True, labels=False))

>>> H = G.complement(uniform=True)

>>> h = Graph(H.blocks())

>>> g == h
False

>>> g == h.complement()
True
```

`copy()`

Return a copy of the incidence structure.

**EXAMPLES:**

sage: IS = IncidenceStructure([[1,2,3,"e"],],name="Test")

sage: IS
Incidence structure with 4 points and 1 blocks

sage: copy(IS)
Incidence structure with 4 points and 1 blocks

sage: [1, 2, 3, 'e'] in copy(IS)
True

sage: copy(IS)._name
'Test'

```python
>>> from sage.all import *

>>> IS = IncidenceStructure([[Integer(1),Integer(2),Integer(3),"e"],],name=
"Test")

>>> IS
Incidence structure with 4 points and 1 blocks

>>> copy(IS)
Incidence structure with 4 points and 1 blocks

>>> [Integer(1), Integer(2), Integer(3), 'e'] in copy(IS)
True

>>> copy(IS)._name
'Test'
```
degree \((p=None,\ \text{subset}=\text{False})\)

Return the degree of a point \(p\) (or a set of points).

The degree of a point (or set of points) is the number of blocks that contain it.

INPUT:

- \(p\) – a point (or a set of points) of the incidence structure.
- \(\text{subset}\) (boolean) – whether to interpret the argument as a set of point (\(\text{subset}=\text{True}\)) or as a point (\(\text{subset}=\text{False}\), default).

EXAMPLES:

```python
sage: designs.steiner_triple_system(9).degree(3)
4
sage: designs.steiner_triple_system(9).degree({1,2},subset=True)
1
```

degrees \((size=None)\)

Return the degree of all sets of given size, or the degree of all points.

The degree of a point (or set of point) is the number of blocks that contain it.

INPUT:

- \(size\) (integer) – return the degree of all subsets of points of cardinality \(size\). When \(size=\text{None}\), the function outputs the degree of all points.

OUTPUT:

A dictionary whose values are degrees and keys are either:

- the points of the incidence structure if \(size=\text{None}\) (default)
- the subsets of size \(size\) of the points stored as tuples

EXAMPLES:

```python
sage: IncidenceStructure([[1,2,3],[1,4]]).degrees(2)
{(1, 2): 1, (1, 3): 1, (1, 4): 1, (2, 3): 1, (2, 4): 0, (3, 4): 0}
```

```python
>>> from sage.all import *
>>> IncidenceStructure([[Integer(1),Integer(2),Integer(3)],[Integer(1),Integer(4)]]).degrees(Integer(2))
{(1, 2): 1, (1, 3): 1, (1, 4): 1, (2, 3): 1, (2, 4): 0, (3, 4): 0}
```

In a Steiner triple system, all pairs have degree 1:
\begin{verbatim}
sage: S13 = designs.steiner_triple_system(13)
sage: all(v == 1 for v in S13.degrees(2).values())
True

>>> from sage.all import *
>>> S13 = designs.steiner_triple_system(Integer(13))
>>> all(v == Integer(1) for v in S13.degrees(Integer(2)).values())
True
\end{verbatim}

\textbf{dual (algorithm=None)}

Return the dual of the incidence structure.

**INPUT:**

- \texttt{algorithm} – whether to use Sage's implementation (\texttt{algorithm=None}, default) or use GAP's (\texttt{algorithm="gap"}).

**Note:** The \texttt{algorithm="gap"} option requires GAP's Design package (included in the gap_packages Sage spkg).

**EXAMPLES:**

The dual of a projective plane is a projective plane:

\begin{verbatim}
sage: PP = designs.DesarguesianProjectivePlaneDesign(4)  # needs sage.rings.finite_rings
sage: PP.dual().is_t_design(return_parameters=True)  # needs sage.modules sage.rings.finite_rings
(True, (2, 21, 5, 1))

>>> from sage.all import *
>>> PP = designs.DesarguesianProjectivePlaneDesign(Integer(4))  # needs sage.rings.finite_rings
>>> PP.dual().is_t_design(return_parameters=True)  # needs sage.modules sage.rings.finite_rings
(True, (2, 21, 5, 1))
\end{verbatim}

**REFERENCE:**

- Leonard Soicher, Design package manual

\textbf{edge_coloring()}

Compute a proper edge-coloring.

A proper edge-coloring is an assignment of colors to the sets of the incidence structure such that two sets with non-empty intersection receive different colors. The coloring returned minimizes the number of colors.

**OUTPUT:**

A partition of the sets into color classes.

**EXAMPLES:**

\begin{verbatim}
sage: H = Hypergraph([{{1,2,3},{2,3,4},{3,4,5},{4,5,6}}]; H
Incidence structure with 6 points and 4 blocks
sage: C = H.edge_coloring()
sage: C  # random
\end{verbatim}
from sage.all import *

H = Hypergraph([(1, 2, 3), (2, 3, 4), (3, 4, 5), (4, 5, 6)]);
H

Incidence structure with 6 points and 4 blocks

C = H.edge_coloring()

C

# random
[[[3, 4, 5]], [[2, 3, 4]], [[4, 5, 6], [1, 2, 3]]]

Set(map(Set, sum(C, []))) == Set(map(Set, H.blocks()))

True

ground_set()

Return the ground set (i.e. the list of points).

EXAMPLES:

sage: BD = IncidenceStructure(7, [[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6], [2, 4, 5]])

sage: BD.incidence_graph()

Bipartite graph on 14 vertices

sage: A = BD.incidence_matrix()

Graph block_matrix([[[A^0, A],

(continues on next page)
....: [A.transpose(),A*0]) == BD.incidence_graph() True

>>> from sage.all import *
>>> BD = IncidenceStructure(Integer(7), [[Integer(0),Integer(1),Integer(2)],
   ->[Integer(0),Integer(3),Integer(4)],[Integer(0),Integer(5),Integer(6)],
   ->[Integer(1),Integer(3),Integer(5)],
   ...
   ->[Integer(2),Integer(3),Integer(6)],[Integer(2),Integer(4),Integer(5)]]
>>> BD.incidence_graph() #... needs sage.modules
Bipartite graph on 14 vertices
>>> A = BD.incidence_matrix() #... needs sage.modules
>>> Graph(block_matrix([[A*Integer(0), A],
   -># needs sage.modules
   ...
   ->graph() [A.transpose(),A*Integer(0)]]) == BD.incidence_ graph() True

incidence_matrix()
Return the incidence matrix $A$ of the design. $A$ is a $(v \times b)$ matrix defined by: $A[i, j] = 1$ if $i$ is in block $B_j$ and 0 otherwise.

EXAMPLES:

sage: BD = IncidenceStructure(7, [[0,1,2],[0,3,4],[0,5,6],[1,3,5],
   ....: [1,4,6],[2,3,6],[2,4,5]])
sage: BD.block_sizes()
[3, 3, 3, 3, 3, 3, 3]

sage: BD.incidence_matrix() #... needs sage.modules
[1 1 0 0 0 0 0]
[1 0 1 1 0 0]
[1 0 0 0 0 1 1]
[0 1 0 1 0 1 0]
[0 1 0 0 1 0 1]
[0 0 1 1 0 0 1]
[0 0 1 0 1 1 0]
sage: I = IncidenceStructure('abc', {'ab','abc','ac','c'})

sage: I.incidence_matrix() #... needs sage.modules
[1 1 0]
[1 1 0]
[0 1 1]

>>> from sage.all import *
>>> BD = IncidenceStructure(Integer(7), [[Integer(0),Integer(1),Integer(2)],
   ->[Integer(0),Integer(3),Integer(4)],[Integer(0),Integer(5),Integer(6)],
   ->[Integer(1),Integer(3),Integer(5)],
   ...
   ->[Integer(2),Integer(3),Integer(6)],[Integer(2),Integer(4),Integer(5)]]
>>> BD.block_sizes()
[3, 3, 3, 3, 3, 3]
>>> BD.incidence_matrix() #... (continues on next page)
induced_substructure(points)

Return the substructure induced by a set of points.

The substructure induced in $\mathcal{H}$ by a set $X \subseteq V(\mathcal{H})$ of points is the incidence structure $\mathcal{H}_X$ defined on $X$ whose sets are all $S \in \mathcal{H}$ such that $S \subseteq X$.

INPUT:

• points — a set of points.

Note: This method goes over all sets of self before building a new IncidenceStructure (which involves some relabelling and sorting). It probably should not be called in a performance-critical code.

EXAMPLES:

A Fano plane with one point removed:

```python
sage: F = designs.steiner_triple_system(7)
sage: F.induced_substructure([0..5])
Incidence structure with 6 points and 4 blocks
```

intersection_graph(sizes=None)

Return the intersection graph of the incidence structure.

The vertices of this graph are the blocks() of the incidence structure. Two of them are adjacent if the size of their intersection belongs to the set sizes.

INPUT:

• sizes — a list/set of integers. For convenience, setting sizes to 5 has the same effect as sizes=[5]. When set to None (default), behaves as sizes=PositiveIntegers().

EXAMPLES:

The intersection graph of a balanced_incomplete_block_design() is a strongly regular graph (when it is not trivial):
sage: BIBD = designs.balanced_incomplete_block_design(19,3)
sage: G = BIBD.intersection_graph(1)
sage: G.is_strongly_regular(parameters=True)
(57, 24, 11, 9)

>>> from sage.all import *
>>> BIBD = designs.balanced_incomplete_block_design(Integer(19),Integer(3))
>>> G = BIBD.intersection_graph(Integer(1))
>>> G.is_strongly_regular(parameters=True)
(57, 24, 11, 9)

is_berge_cyclic()

Check whether self is a Berge-Cyclic uniform hypergraph.

A k-uniform Berge cycle (named after Claude Berge) of length \( \ell \) is a cyclic list of distinct \( k \)-sets \( F_1, \ldots, F_\ell \), \( \ell > 1 \), and distinct vertices \( C = \{v_1, \ldots, v_\ell\} \) such that for each \( 1 \leq i \leq \ell \), \( F_i \) contains \( v_i \) and \( v_{i+1} \) (where \( v_{\ell+1} = v_1 \)).

A uniform hypergraph is Berge-cyclic if its incidence graph is cyclic. It is called “Berge-acyclic” otherwise.

For more information, see [Fag1983] and Wikipedia article Hypergraph.

EXAMPLES:

sage: Hypergraph(5, [[1, 2, 3], [2, 3, 4]]).is_berge_cyclic()  # needs sage.modules
True
sage: Hypergraph(6, [[1, 2, 3], [3, 4, 5]]).is_berge_cyclic()  # needs sage.modules
False

>>> from sage.all import *
>>> Hypergraph(Integer(5), [[Integer(1), Integer(2), Integer(3)], [Integer(2), Integer(3), Integer(4)]]).is_berge_cyclic()  # needs sage.modules
True
>>> Hypergraph(Integer(6), [[Integer(1), Integer(2), Integer(3)], [Integer(3), Integer(4), Integer(5)]]).is_berge_cyclic()  # needs sage.modules
False

is_connected()

Test whether the design is connected.

EXAMPLES:

sage: IncidenceStructure(3, [[0,1],[0,2]]).is_connected()
True
sage: IncidenceStructure(4, [[0,1],[2,3]]).is_connected()
False

>>> from sage.all import *
>>> IncidenceStructure(Integer(3), [[Integer(0),Integer(1)],[Integer(0), Integer(2)]]).is_connected()
True
>>> IncidenceStructure(Integer(4), [[Integer(0),Integer(1)],[Integer(2), Integer(3)]]).is_connected()
False
is_generalized_quadrangle (verbose=False, parameters=False)

Test if the incidence structure is a generalized quadrangle.

An incidence structure is a generalized quadrangle iff (see [BH2012], section 9.6):

• two blocks intersect on at most one point.
• For every point $p$ not in a block $B$, there is a unique block $B'$ intersecting both $\{p\}$ and $B$

It is a regular generalized quadrangle if furthermore:

• it is $s + 1$-uniform for some positive integer $s$.
• it is $t + 1$-regular for some positive integer $t$.

For more information, see the Wikipedia article Generalized_quadrangle.

Note: Some references (e.g. [PT2009] or Wikipedia article Generalized_quadrangle) only allow regular generalized quadrangles. To use such a definition, see the parameters optional argument described below, or the methods is_regular() and is_uniform().

INPUT:

• verbose (boolean) – whether to print an explanation when the instance is not a generalized quadrangle.
• parameters (boolean; False) – if set to True, the function returns a pair $(s, t)$ instead of True answers. In this case, $s$ and $t$ are the integers defined above if they exist (each can be set to False otherwise).

EXAMPLES:

```plaintext
sage: h = designs.CremonaRichmondConfiguration()  # needs networkx
sage: h.is_generalized_quadrangle()  # needs networkx
True

>>> from sage.all import *
>>> h = designs.CremonaRichmondConfiguration()  # needs networkx
>>> h.is_generalized_quadrangle()  # needs networkx
True

This is actually a regular generalized quadrangle:

```plaintext
sage: h.is_generalized_quadrangle(parameters=True)  # needs networkx
(2, 2)

>>> from sage.all import *
>>> h.is_generalized_quadrangle(parameters=True)  # needs networkx
(2, 2)
```

is_isomorphic (other, certificate=False)

Return whether the two incidence structures are isomorphic.

INPUT:
other – an incidence structure.

- certificate (boolean) – whether to return an isomorphism from self to other instead of a boolean answer.

### EXAMPLES:

```python
sage: # needs sage.schemes
sage: fano1 = designs.balanced_incomplete_block_design(7,3)
sage: fano2 = designs.projective_plane(2)
sage: fano1.is_isomorphic(fano2)
True
sage: fano1.is_isomorphic(fano2,certificate=True)
{0: 0, 1: 1, 2: 2, 3: 6, 4: 4, 5: 3, 6: 5}
```

### is_regular (r=None)
Test whether the incidence structure is r-regular.

An incidence structure is said to be r-regular if all its points are incident with exactly r blocks.

**INPUT:**

- r (integer)

**OUTPUT:**

If r is defined, a boolean is returned. If r is set to None (default), the method returns either False or the integer r such that the incidence structure is r-regular.

**Warning:** In case of 0-regular incidence structure, beware that if not H.is_regular() is a satisfied condition.

### EXAMPLES:

```python
sage: designs.balanced_incomplete_block_design(7,3).is_regular()  # needs sage.schemes
3
sage: designs.balanced_incomplete_block_design(7,3).is_regular(r=3)  # needs sage.schemes
True
sage: designs.balanced_incomplete_block_design(7,3).is_regular(r=4)  # needs sage.schemes
False
```

(continues on next page)
is_resolvable (certificate, solver=False, verbose=None, check=0, integrality_tolerance=True)

Test whether the hypergraph is resolvable

A hypergraph is said to be resolvable if its sets can be partitionned into classes, each of which is a partition of the ground set.

Note: This problem is solved using an Integer Linear Program, and GLPK (the default LP solver) has been reported to be very slow on some instances. If you hit this wall, consider installing a more powerful MILP solver (CPLEX, Gurobi, …).

INPUT:

- certificate (boolean) – whether to return the classes along with the binary answer (see examples below).
- solver – (default: None) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to None, the default one is used. For more information on MILP solvers and which default solver is used, see the method solve of the class MixedIntegerLinearProgram.
- verbose – integer (default: 0). Sets the level of verbosity. Set to 0 by default, which means quiet.
- check (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.
- integrality_tolerance – parameter for use with MILP solvers over an inexact base ring; see MixedIntegerLinearProgram.get_values().

EXAMPLES:

Some resolvable designs:

```
sage: TD = designs.transversal_design(2,2,resolvable=True)
sage: TD.is_resolvable()  # needs sage.combinat
True

sage: AG = designs.AffineGeometryDesign(3,1,GF(2))  # needs sage.combinat
sage: AG.is_resolvable()  # needs sage.combinat
True
```

```python
>>> from sage.all import *
>>> TD = designs.transversal_design(Integer(2),Integer(2),resolvable=True)
>>> TD.is_resolvable()
True

>>> AG = designs.AffineGeometryDesign(Integer(3),Integer(1),GF(Integer(2)))  # needs sage.combinat
```
Combinatorics, Release 10.4

(continued from previous page)

>>> AG.is_resolvable()
# needs sage.combinat
True

Their classes:

```
sage: b, cls = TD.is_resolvable(True)
sage: b
True
sage: cls # random
[[[0, 3], [1, 2]], [[1, 3], [0, 2]]]

sage: # needs sage.combinat
sage: b, cls = AG.is_resolvable(True)
sage: b
True
sage: cls # random
[[[6, 7], [4, 5], [0, 1], [2, 3]],
 [[5, 7], [0, 4], [3, 6], [1, 2]],
 [[0, 2], [4, 7], [1, 3], [5, 6]],
 [[3, 4], [0, 7], [1, 5], [2, 6]],
 [[3, 7], [1, 6], [0, 5], [2, 4]],
 [[0, 6], [2, 7], [1, 4], [3, 5]],
 [[4, 6], [0, 3], [2, 5], [1, 7]]]
```

>>> from sage.all import *

```
>>> b, cls = TD.is_resolvable(True)
      
>>> b
True

>>> cls # random
[[[0, 3], [1, 2]], [[1, 3], [0, 2]]]

>>> # needs sage.combinat

>>> b, cls = AG.is_resolvable(True)

>>> b
True

>>> cls # random
[[[6, 7], [4, 5], [0, 1], [2, 3]],
 [[5, 7], [0, 4], [3, 6], [1, 2]],
 [[0, 2], [4, 7], [1, 3], [5, 6]],
 [[3, 4], [0, 7], [1, 5], [2, 6]],
 [[3, 7], [1, 6], [0, 5], [2, 4]],
 [[0, 6], [2, 7], [1, 4], [3, 5]],
 [[4, 6], [0, 3], [2, 5], [1, 7]]]
```

A non-resolvable design:

```
sage: Fano = designs.balanced_incomplete_block_design(7,3) # needs sage.schemes

sage: Fano.is_resolvable()
# needs sage.schemes
False

sage: Fano.is_resolvable(True) # needs sage.schemes (False, [])
```

5.1. Comprehensive Module List 1121
is_simple()

Test whether this design is simple (i.e. no repeated block).

EXAMPLES:

```python
sage: IncidenceStructure(3, [[0,1],[1,2],[0,2]]).is_simple()
True
sage: IncidenceStructure(3, [[0],[0]]).is_simple()
False
sage: V = [(0,'a'),(0,'b'),(1,'a'),(1,'b')]
sage: B = [[V[0],V[1]], [V[1],V[2]]]
sage: I = IncidenceStructure(V, B)
sage: I.is_simple()
True
sage: I2 = IncidenceStructure(V, B*2)
sage: I2.is_simple()
False
```

is_spread(spread)

Check whether the input is a spread for self.

A spread of an incidence structure \((P, B)\) is a subset of \(B\) which forms a partition of \(P\).

INPUT:

- spread – iterable; defines the spread

EXAMPLES:

```python
sage: E = IncidenceStructure([[1, 2, 3], [4, 5, 6], [1, 5, 6]])
sage: E.is_spread([[1, 2, 3], [4, 5, 6]])
(continues on next page)```
True

```python
sage: E.is_spread([1, 2, 3, 4, 5, 6])
Traceback (most recent call last):
...
TypeError: 'sage.rings.integer.Integer' object is not iterable
```
sage: E.is_spread([[1, 2, 3, 4], [5, 6]])
False

```python
>>> from sage.all import *

>>> E = IncidenceStructure([[Integer(1), Integer(2), Integer(3)], [Integer(4), Integer(5), Integer(6)]])
>>> E.is_spread([[Integer(1), Integer(2), Integer(3)], [Integer(4), Integer(5), Integer(6)]])
True
>>> E.is_spread([[Integer(1), Integer(2), Integer(3), Integer(4), Integer(5), Integer(6)]])
Traceback (most recent call last):
...
TypeError: 'sage.rings.integer.Integer' object is not iterable
```

Order of blocks or of points within each block doesn’t matter:

```python
sage: E = IncidenceStructure([[1, 2, 3], [4, 5, 6], [1, 5, 6]])
sage: E.is_spread([[5, 6, 4], [3, 1, 2]])
True
```

```python
>>> from sage.all import *

>>> E = IncidenceStructure([[Integer(1), Integer(2), Integer(3)], [Integer(4), Integer(5), Integer(6)]])
>>> E.is_spread([[Integer(5), Integer(6), Integer(4)], [Integer(3), Integer(1), Integer(2)]])
True
```

**is_t_design**(t=None, v=None, k=None, l=None, return_parameters=False)

Test whether self is a \( t - (v, k, l) \) design.

A \( t - (v, k, \lambda) \) (sometimes called \( t \)-design for short) is a block design in which:

- the underlying set has cardinality \( v \)
- the blocks have size \( k \)
- each \( t \)-subset of points is covered by \( \lambda \) blocks

**INPUT:**

- \( t, v, k, l \) (integers) – their value is set to None by default. The function tests whether the design is a \( t - (v, k, l) \) design using the provided values and guesses the others. Note that \( l \) cannot be specified if \( t \) is not.
- return_parameters (boolean)– whether to return the parameters of the \( t \)-design. If set to True, the function returns a pair (boolean_answer, \( (t, v, k, l) \)).

**EXAMPLES:**
Steiner triple and quadruple systems are other names for 2 - (v, 3, 1) and 3 - (v, 4, 1) designs:
```python
sage: S3_9 = designs.steiner_triple_system(9)
sage: S3_9.is_t_design(2,9,3,1)
True
sage: blocks = designs.steiner_quadruple_system(8)
sage: S4_8 = IncidenceStructure(8, blocks)
sage: S4_8.is_t_design(3,8,4,1)
True
sage: blocks = designs.steiner_quadruple_system(14)
sage: S4_14 = IncidenceStructure(14, blocks)
sage: S4_14.is_t_design(3,14,4,1)
True
```

Some examples of Witt designs that need the gap database:

```python
sage: # optional - gap_package_design
sage: BD = designs.WittDesign(9)
sage: BD.is_t_design(2,9,3,1)
True
sage: W12 = designs.WittDesign(12)
sage: W12.is_t_design(5,12,6,1)
True
```

Further examples:

```python
sage: D = IncidenceStructure(4,[[],[]])
sage: D.is_t_design(return_parameters=True)
(True, (0, 4, 0, 2))
```
is_uniform\(k=None\)

Test whether the incidence structure is \(k\)-uniform

An incidence structure is said to be \(k\)-uniform if all its blocks have size \(k\).

**INPUT:**

- \(k\) (integer)

**OUTPUT:**

If \(k\) is defined, a boolean is returned. If \(k\) is set to None (default), the method returns either \(False\) or the integer \(k\) such that the incidence structure is \(k\)-uniform.

**Warning:** In case of 0-uniform incidence structure, beware that if not \(H.is_uniform()\) is a satisfied condition.
EXAMPLES:

```python
sage: designs.balanced_incomplete_block_design(7,3).is_uniform()  # needs sage.schemes
3
sage: designs.balanced_incomplete_block_design(7,3).is_uniform(k=3)  # needs sage.schemes
True
sage: designs.balanced_incomplete_block_design(7,3).is_uniform(k=4)  # needs sage.schemes
False
```

```python
>>> from sage.all import *
>>> designs.balanced_incomplete_block_design(Integer(7),Integer(3)).is_uniform()  # needs sage.schemes
3
>>> designs.balanced_incomplete_block_design(Integer(7),Integer(3)).is_uniform(k=Integer(3))  # needs sage.schemes
True
>>> designs.balanced_incomplete_block_design(Integer(7),Integer(3)).is_uniform(k=Integer(4))  # needs sage.schemes
False
```

isomorphic_substructures_iterator(H2, induced=False)

Iterates over all copies of \( H2 \) contained in \( \text{self} \).

A hypergraph \( H_1 \) contains an isomorphic copy of a hypergraph \( H_2 \) if there exists an injection \( f : V(H_2) \mapsto V(H_1) \) such that for any set \( S_2 \in E(H_2) \) the set \( S_1 = f(S_2) \) belongs to \( E(H_1) \).

It is an induced copy if no other set of \( E(H_1) \) is contained in \( f(V(H_2)) \), i.e. \( |E(H_2)| = \{ S : S \in E(H_1) \text{ and } f(V(H_2)) \} \).

This function lists all such injections. In particular, the number of copies of \( H \) in itself is equal to the size of its automorphism group.

See subhypergraph_search for more information.

INPUT:

- \( H2 \) an \texttt{IncidenceStructure} object.
- \texttt{induced} (boolean) – whether to require the copies to be induced. Set to \texttt{False} by default.

EXAMPLES:

How many distinct \( C_5 \) in Petersen’s graph?

```python
sage: P = graphs.PetersenGraph()
sage: C = graphs.CycleGraph(5)
sage: IP = IncidenceStructure(P.edges(sort=True, labels=False))
sage: IC = IncidenceStructure(C.edges(sort=True, labels=False))
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC))
120
```
As the automorphism group of $C_5$ has size 10, the number of distinct unlabelled copies is 12. Let us check that all functions returned correspond to an actual $C_5$ subgraph:

```
sage: for f in IP.isomorphic_substructures_iterator(IC):
    ....: assert all(P.has_edge(f[x],f[y]) for x,y in C.edges(sort=True, labels=False))
```

The number of induced copies, in this case, is the same:

```
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC, induced=True))
120
```

They begin to differ if we make one vertex universal:

```
sage: P.add_edges([(0,x) for x in P], loops=False)
sage: IP = IncidenceStructure(P.edges(sort=True, labels=False))
sage: IC = IncidenceStructure(C.edges(sort=True, labels=False))
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC))
420
```

```
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC, induced=True))
60
```

The number of copies of $H$ in itself is the size of its automorphism group:

```
sage: H = designs.projective_plane(3)  # needs sage.schemes
sage: sum(1 for _ in H.isomorphic_substructures_iterator(H))  # needs sage.schemes
5616
```

```
sage: H.automorphism_group().cardinality()  # needs sage.groups sage.schemes
5616
```
```
>>> from sage.all import *

>>> H = designs.projective_plane(Integer(3))
...
# needs sage.schemes

>>> sum(Integer(1) for _ in H.isomorphic_substructures_iterator(H))
...
# needs sage.schemes
5616

>>> H.automorphism_group().cardinality()
...
# needs sage.groups sage.schemes
5616
```

### num_blocks()

Return the number of blocks.

**EXAMPLES:**

```
sage: designs.DesarguesianProjectivePlaneDesign(2).num_blocks()
7
sage: B = IncidenceStructure(4, [[0,1],[0,2],[0,3],[1,2],[1,2,3]])
sage: B.num_blocks()
5
```

### num_points()

Return the size of the ground set.

**EXAMPLES:**

```
sage: designs.DesarguesianProjectivePlaneDesign(2).num_points()
7
sage: B = IncidenceStructure(4, [[0,1],[0,2],[0,3],[1,2],[1,2,3]])
sage: B.num_points()
4
```

### packing(solver, verbose=None, integrality_tolerance=0)

Return a maximum packing

A maximum packing in a hypergraph is collection of disjoint sets/blocks of maximal cardinality. This problem is NP-complete in general, and in particular on 3-uniform hypergraphs. It is solved here with an Integer Linear Program.

For more information, see the Wikipedia article Packing in a hypergraph.
Combinatorics, Release 10.4

INPUT:

- **solver** – (default: None) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to None, the default one is used. For more information on LP solvers and which default solver is used, see the method `solve` of the class *MixedIntegerLinearProgram*.

- **verbose** – integer (default: 0). Sets the level of verbosity. Set to 0 by default, which means quiet.

- **integrality_tolerance** – parameter for use with MILP solvers over an inexact base ring; see *MixedIntegerLinearProgram.get_values()*.

EXAMPLES:

```python
sage: P = IncidenceStructure([[1,2],[3,4],[2,3]]).packing()  # needs sage.numerical.mip
sage: sorted(sorted(b) for b in P)  # needs sage.numerical.mip
[[1, 2], [3, 4]]
sage: len(designs.steiner_triple_system(9).packing())  # needs sage.numerical.mip
3
```

```python
>>> from sage.all import *
>>> P = IncidenceStructure([[Integer(1),Integer(2)],[Integer(3),Integer(4)], [Integer(2),Integer(3)]]).packing()  # needs sage.numerical.mip
>>> sorted(sorted(b) for b in P)  # needs sage.numerical.mip
[[1, 2], [3, 4]]
>>> len(designs.steiner_triple_system(Integer(9)).packing())  # needs sage.numerical.mip
3
```

rank()

Return the rank of the hypergraph (the maximum size of a block).

EXAMPLES:

```python
sage: h = Hypergraph(8, [[0,1,3],[1,4,5,6],[1,2]])
sage: h.rank()
4
```

```python
>>> from sage.all import *
>>> h = Hypergraph(Integer(8), [[Integer(0),Integer(1),Integer(3)],[Integer(1),Integer(4),Integer(5),Integer(6)],[Integer(1),Integer(2)]])
>>> h.rank()
4
```

relabel *(perm=None, inplace=True)*

Relabel the ground set

INPUT:

- **perm** – can be one of
  
  - a dictionary – then each point \(p\) (which should be a key of \(d\)) is relabeled to \(d[p]\)
  
  - a list or a tuple of length \(n\) – the first point returned by `ground_set()` is relabeled to \(l[0]\), the second to \(l[1]\), etc.
– None – the incidence structure is relabeled to be on \( \{0, 1, \ldots, n - 1\} \) in the ordering given by `ground_set()`.

* inplace – If True then return a relabeled graph and does not touch `self` (default is False).

**EXAMPLES:**

```python
sage: # needs sage.schemes
sage: TD = designs.transversal_design(5,5)
sage: TD.relabel({i: chr(97+i) for i in range(25)})
sage: TD.ground_set()
['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k', 'l', 'm', 'n', 'o', 'p', 'q', 'r', 's', 't', 'u', 'v', 'w', 'x', 'y']
sage: TD.blocks()[:3]
[['a', 'f', 'k', 'p', 'u'], ['a', 'g', 'm', 's', 'y'], ['a', 'h', 'o', 'q', 'x']]
```

Relabel to integer points:

```python
>>> from sage.all import *
>>> # needs sage.schemes
>>> TD = designs.transversal_design(Integer(5),Integer(5))
>>> TD.relabel({i: chr(Integer(97)+i) for i in range(Integer(25)))
>>> TD.ground_set()
[[0, 5, 10, 15, 20], [0, 6, 12, 18, 24], [0, 7, 14, 16, 23]]
>>> TD.blocks()[:Integer(3)]
[[[0, 5, 10, 15, 20], [0, 6, 12, 18, 24], [0, 7, 14, 16, 23]]
```

**trace** *(points, min_size=1, multiset=True)*

Return the trace of a set of points.

Given an hypergraph \( \mathcal{H} \), the *trace* of a set \( X \) of points in \( \mathcal{H} \) is the hypergraph whose blocks are all non-empty \( S \cap X \) where \( S \in \mathcal{H} \).

**INPUT:**

* points – a set of points.

* min_size (integer; default 1) – minimum size of the sets to keep. By default all empty sets are discarded, i.e. min_size=1.

* multiset (boolean; default True) – whether to keep multiple copies of the same set.
Note: This method goes over all sets of self before building a new IncidenceStructure (which involves some relabelling and sorting). It probably should not be called in a performance-critical code.

EXAMPLES:
A Baer subplane of order 2 (i.e. a Fano plane) in a projective plane of order 4:

```
# needs sage.schemes
P4 = designs.projective_plane(4)
F = designs.projective_plane(2)
for x in Subsets(P4.ground_set(),7):
    if P4.trace(x,min_size=2).is_isomorphic(F):
        break
subplane = P4.trace(x,min_size=2); subplane
Incidence structure with 7 points and 7 blocks
subplane.is_isomorphic(F)
True
```

```
from sage.all import *
# needs sage.schemes
P4 = designs.projective_plane(Integer(4))
F = designs.projective_plane(Integer(2))
for x in Subsets(P4.ground_set(),Integer(7)):
    if P4.trace(x,min_size=Integer(2)).is_isomorphic(F):
        break
subplane = P4.trace(x,min_size=Integer(2)); subplane
Incidence structure with 7 points and 7 blocks
subplane.is_isomorphic(F)
True
```

5.1.90 Mutually Orthogonal Latin Squares (MOLS)
The main function of this module is mutually_orthogonal_latin_squares() and can be used to generate MOLS (or check that they exist):

```
mOLS = designs.mutually_orthogonal_latin_squares(4,8)  # needs sage.schemes
```

```
from sage.all import *
MOLS = designs.mutually_orthogonal_latin_squares(Integer(4),Integer(8))   # needs sage.schemes
```

For more information on MOLS, see the Wikipedia entry on MOLS. If you are only interested by latin squares, see latin.

The functions defined here are

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mutually_orthogonal_latin_squares()</td>
<td>Return $k$ Mutually Orthogonal $n \times n$ Latin Squares.</td>
</tr>
<tr>
<td>are_mutually_orthogonal_latin_squares()</td>
<td>Check that the list $l$ of matrices in are MOLS.</td>
</tr>
<tr>
<td>latin_square_product()</td>
<td>Return the product of two (or more) latin squares.</td>
</tr>
<tr>
<td>MOLS_table()</td>
<td>Prints the MOLS table.</td>
</tr>
</tbody>
</table>
Table of MOLS

Sage can produce a table of MOLS similar to the one from the Handbook of Combinatorial Designs [DesignHandbook](available here).

```
sage: from sage.combinat.designs.latin_squares import MOLS_table

sage: MOLS_table(600)  # long time
```

Functions

```python
def MOLS_table(start, stop=None, compare=False, width=None):
    # Prints the MOLS table that Sage can produce.
    pass
```

**INPUT:**

- `start, stop` (integers) – print the table of MOLS for value of `n` such that `start <= n < stop`. If only one integer is given as input, it is interpreted as the value of `stop` with `start=0` (same behaviour as `range`).

- `compare` (boolean) – if sets to `True` the MOLS displays with `+` and `−` entries its difference with the table from the Handbook of Combinatorial Designs (2ed).

- `width` (integer) – the width of each column of the table. By default, it is computed from range of values determined by the parameters `start` and `stop`.

**EXAMPLES:**
```python
sage: # needs sage.schemes
sage: from sage.combinat.designs.latin_squares import MOLS_table
sage: MOLS_table(100)
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 ...

```

(continues on next page)
Check whether the list of matrices in \( l \) form mutually orthogonal latin squares.

INPUT:

- `verbose` – if True then print why the list of matrices provided are not mutually orthogonal latin squares

EXAMPLES:

```python
sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_squares

sage.combinat.designs.latin_squares.are_mutually_orthogonal_latin_squares(l, verbose=False)
```

(continues on next page)
sage: m1 = matrix([[0,1,2],[2,0,1],[1,2,0]])
sage: m2 = matrix([[0,1,2],[1,2,0],[2,0,1]])
sage: m3 = matrix([[0,1,2],[2,0,1],[1,2,0]])
sage: are_mutually_orthogonal_latin_squares([m1,m2])
True
sage: are_mutually_orthogonal_latin_squares([m1,m3])
False
sage: are_mutually_orthogonal_latin_squares([m2,m3])
True
sage: are_mutually_orthogonal_latin_squares([m1,m2,m3], verbose=True)
Squares 0 and 2 are not orthogonal
False
sage: m = designs.mutually_orthogonal_latin_squares(7,8) # needs sage.schemes
sage: are_mutually_orthogonal_latin_squares(m) # needs sage.schemes
True

sage.combinat.designs.latin_squares.latin_square_product(M, N, *others)

Return the product of two (or more) latin squares.

Given two Latin Squares \(M, N\) of respective sizes \(m, n\), the direct product \(M \times N\) of size \(mn\) is defined by
\( (M \times N)((i_1, i_2), (j_1, j_2)) = (M(i_1, j_1), N(i_2, j_2)) \) where \(i_1, j_1 \in [m], i_2, j_2 \in [n]\)

Each pair of values \((i, j) \in [m] \times [n]\) is then relabeled to \(i n + j\).

This is Lemma 6.25 of [Stinson2004].

INPUT:
An arbitrary number of latin squares (greater than 2).
EXAMPLES:

```python
sage: from sage.combinat.designs.latin_squares import latin_square_product
sage: m=designs.mutually_orthogonal_latin_squares(3,4)[0] # needs sage.schemes
sage: latin_square_product(m,m,m) # needs sage.schemes
64 x 64 sparse matrix over Integer Ring (use the '.str()' method to see the entries)
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.latin_squares import latin_square_product
>>> m=designs.mutually_orthogonal_latin_squares(Integer(3), Integer(4))[Integer(0)] # needs sage.schemes
>>> latin_square_product(m,m,m) # needs sage.schemes
64 x 64 sparse matrix over Integer Ring (use the '.str()' method to see the entries)
```

`sage.combinat.designs.latin_squares.mutually_orthogonal_latin_squares`(k, n, partitions=False, check=True)

Return \(k\) Mutually Orthogonal \(n \times n\) Latin Squares (MOLS).

For more information on Mutually Orthogonal Latin Squares, see `latin_squares`.

INPUT:

- \(k\) (integer) – number of MOLS. If \(k=None\) it is set to the largest value available.
- \(n\) (integer) – size of the latin square.
- \(partitions\) (boolean) – a Latin Square can be seen as 3 partitions of the \(n^2\) cells of the array into \(n\) sets of size \(n\), respectively:
  - The partition of rows
  - The partition of columns
  - The partition of number (cells numbered with 0, cells numbered with 1, \ldots)

These partitions have the additional property that any two sets from different partitions intersect on exactly one element.

When \(partitions\) is set to \(True\), this function returns a list of \(k+2\) partitions satisfying this intersection property instead of the \(k+2\) MOLS (though the data is exactly the same in both cases).

- \(check\) – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to \(True\) by default.

EXAMPLES:
sage: designs.mutually_orthogonal_latin_squares(3,7)  #...

]
What is the maximum number of MOLS of size 8 that Sage knows how to build?:

```
sage: designs.orthogonal_arrays.largest_available_k(8)-2
7
```

If you only want to know if Sage is able to build a given set of MOLS, query the `orthogonal_arrays.*` functions:

```
sage: designs.orthogonal_arrays.is_available(5+2, 5) # 5 MOLS of order 5
False
sage: designs.orthogonal_arrays.is_available(4+2, 6) # 4 MOLS of order 6
False
```

Sage, however, is not able to prove that the second MOLS do not exist:
sage: designs.orthogonal_arrays.exists(4+2, 6)  # 4 MOLS of order 6
# needs sage.schemes
Unknown

>>> from sage.all import *

sage: designs.orthogonal_arrays.exists(Integer(4)+Integer(2), Integer(6))  # 4 MOLS of order 6
# needs sage.schemes
Unknown

If you ask for such a MOLS then you will respectively get an informative `EmptySetError` or `NotImplementedError`:

sage: designs.mutually_orthogonal_latin_squares(5, 5)
Traceback (most recent call last):
...
EmptySetError: there exist at most n-1 MOLS of size n if n>=2
sage: designs.mutually_orthogonal_latin_squares(4, 6)  #
# needs sage.schemes
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build 4 MOLS of order 6

5.1.91 Orthogonal arrays (OA)

This module gathers some construction related to orthogonal arrays (or transversal designs). One can build an $OA(k, n)$ (or check that it can be built) from the Sage console with `designs.orthogonal_arrays.build`:

sage: OA = designs.orthogonal_arrays.build(4, 8)

See also the modules `orthogonal_arrays_build_recursive` or `orthogonal_arrays_find_recursive` for recursive constructions.

This module defines the following functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>orthogonal_array()</code></td>
<td>Return an orthogonal array of parameters $k, n, t$.</td>
</tr>
<tr>
<td><code>transversal_design()</code></td>
<td>Return a transversal design of parameters $k, n$.</td>
</tr>
<tr>
<td><code>incomplete_orthogonal_array()</code></td>
<td>Return an $OA(k, n) - \sum_{1 \leq i \leq r} OA(k, s_i)$.</td>
</tr>
</tbody>
</table>
Check that a given set of blocks $B$ is a transversal design.

Check that the integer matrix $OA$ is an $OA(k, n, t)$.

Return an $OA(k, rm + u)$ from a truncated $OA(k + s, r)$ by Wilson’s construction.

Return the product of two transversal designs.

Return $x$ disjoint blocks contained in a given $OA(k, n)$.

Return a relabelled version of the OA.

Return a version of the OA relabelled to symbols $(0, \ldots, n-1)$.

Return an Orthogonal Array from a Quasi-Difference matrix

Return an Orthogonal Array from a $V(m, t)$

Return an $OA(k, n)$ from a PBD

Return an $OA(k, |G| \cdot 2^c)$ from a constrained $(G, k - 1, 2)$-difference matrix.

Return the first $k$ columns of $OA$.

Return a QDM a $V(m, t)$

REFERENCES:
– [CD1996]

Functions

class sage.combinat.designs.orthogonal_arrays.OAMainFunctions(*args, **kwds)

Bases: object

Functions related to orthogonal arrays.

An orthogonal array of parameters $k, n, t$ is a matrix with $k$ columns filled with integers from $[n]$ in such a way that for any $t$ columns, each of the $n^t$ possible rows occurs exactly once. In particular, the matrix has $n^t$ rows.

For more information on orthogonal arrays, see Wikipedia article Orthogonal_array.

From here you have access to:

- $\text{build}(k, n, t=2)$: return an orthogonal array with the given parameters.
- $\text{is_available}(k, n, t=2)$: answer whether there is a construction available in Sage for a given set of parameters.
- $\text{exists}(k, n, t=2)$: answer whether an orthogonal array with these parameters exist.
- $\text{largest_available_k}(n, t=2)$: return the largest integer $k$ such that Sage knows how to build an $OA(k, n)$.
- $\text{explain_construction}(k, n, t=2)$: return a string that explains the construction that Sage uses to build an $OA(k, n)$.

EXAMPLES:

```python
sage: designs.orthogonal_arrays.build(3, 2)
[[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 0]]

sage: designs.orthogonal_arrays.build(5, 5)
[[0, 0, 0, 0, 0], [0, 1, 2, 3, 4], [0, 2, 4, 1, 3],
[0, 3, 1, 4, 2], [0, 4, 3, 2, 1], [1, 0, 4, 3, 2],
(continues on next page)```
Combinatorics, Release 10.4

(continued from previous page)

[4, 0, 1, 2, 3], [4, 1, 3, 0, 2], [4, 2, 0, 3, 1],
[4, 3, 2, 1, 0], [4, 4, 4, 4, 4]]
```

What is the largest value of \( k \) for which Sage knows how to compute a \( OA(k, 14) \)?:

```
sage: designs.orthogonal_arrays.largest_available_k(14)
6
```

If you ask for an orthogonal array that does not exist, then you will either obtain an EmptySetError (if it knows that such an orthogonal array does not exist) or a Not Implemented Error:

```
sage: designs.orthogonal_arrays.build(4,2)
Traceback (most recent call last):
...
EmptySetError: There exists no OA(4,2) as k(=4)>n+t-1=3
```

```
sage: designs.orthogonal_arrays.build(12,20)
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build an OA(12,20)!
```

```
sage: designs.orthogonal_arrays.build(Integer(4),Integer(2))
Traceback (most recent call last):
...
EmptySetError: There exists no OA(4,2) as k(=4)>n+t-1=3
```

```
sage: designs.orthogonal_arrays.build(Integer(12),Integer(20))
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build an OA(12,20)!
```

```
static build(k, n, t=2, resolvable=False)
    Return an OA(k, n) of strength t
```
An orthogonal array of parameters $k, n, t$ is a matrix with $k$ columns filled with integers from $[n]$ in such a way that for any $t$ columns, each of the $n^t$ possible rows occurs exactly once. In particular, the matrix has $n^t$ rows.

More general definitions sometimes involve a $\lambda$ parameter, and we assume here that $\lambda = 1$.

For more information on orthogonal arrays, see Wikipedia article Orthogonal_array.

**INPUT:**

- $k, n, t$ (integers) – parameters of the orthogonal array.
- `resolvable` (boolean) – set to `True` if you want the design to be resolvable. The $n$ classes of the resolvable design are obtained as the first $n$ blocks, then the next $n$ blocks, etc … Set to `False` by default.

**EXAMPLES:**

```python
sage: designs.orthogonal_arrays.build(3,3,resolvable=True) # indirect doctest
[[0, 0, 0],
 [1, 2, 1],
 [2, 1, 2],
 [0, 2, 2],
 [1, 1, 0],
 [2, 0, 1],
 [0, 1, 1],
 [1, 0, 2],
 [2, 2, 0]]
```

```python
OA_7_50 = designs.orthogonal_arrays.build(7,50) # indirect doctest
```

```python
from sage.all import *
>>> from sage.all import *
>>> designs.orthogonal_arrays.build(Integer(3),Integer(3),resolvable=True) # indirect doctest
[[0, 0, 0],
 [1, 2, 1],
 [2, 1, 2],
 [0, 2, 2],
 [1, 1, 0],
 [2, 0, 1],
 [0, 1, 1],
 [1, 0, 2],
 [2, 2, 0]]
>>> OA_7_50 = designs.orthogonal_arrays.build(Integer(7),Integer(50)) # indirect doctest
```

**static exists**($k,n,t=2$)

Return the existence status of an $OA(k,n)$

**INPUT:**

- $k, n, t$ (integers) – parameters of the orthogonal array.

**Warning:** The function does not only return booleans, but True, False, or Unknown.

**See also:**

`is_available()`

**EXAMPLES:**
static explain_construction\( (k, n, t=2) \)

Return a string describing how to build an \( OA(k, n) \)

INPUT:

- \( k, n, t \) (integers) – parameters of the orthogonal array.

EXAMPLES:

```
sage: designs.orthogonal_arrays.explain_construction(9,565)
"Wilson's construction n=23.24+13 with master design OA(9+1,23)"
sage: designs.orthogonal_arrays.explain_construction(10,154)
'the database contains a (137,10;1,0;17)-quasi difference matrix'
```

static is_available\( (k, n, t=2) \)

Return whether Sage can build an \( OA(k, n) \).

INPUT:

- \( k, n, t \) (integers) – parameters of the orthogonal array.

See also:

exists()

EXAMPLES:

```
sage: designs.orthogonal_arrays.is_available(3,6) # indirect doctest
True
sage: designs.orthogonal_arrays.is_available(4,6) # indirect doctest
False
```

(continues on next page)
static largest_available_k(n, t=2)

Return the largest \( k \) such that Sage can build an \( OA(k, n) \).

INPUT:

- \( n \) (integer)
- \( t \) – (integer; default: 2) – strength of the array

EXAMPLES:

```python
sage: designs.orthogonal_arrays.largest_available_k(0)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(1)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(10)
4
sage: designs.orthogonal_arrays.largest_available_k(27)
28
sage: designs.orthogonal_arrays.largest_available_k(100)
10
sage: designs.orthogonal_arrays.largest_available_k(-1)
Traceback (most recent call last):
...
ValueError: n(=-1) was expected to be >=0
```

```python
>>> from sage.all import *

>>> designs.orthogonal_arrays.largest_available_k(Integer(0))
+Infinity
>>> designs.orthogonal_arrays.largest_available_k(Integer(1))
+Infinity
>>> designs.orthogonal_arrays.largest_available_k(Integer(10))
4
>>> designs.orthogonal_arrays.largest_available_k(Integer(27))
28
>>> designs.orthogonal_arrays.largest_available_k(Integer(100))
10
>>> designs.orthogonal_arrays.largest_available_k(-Integer(1))
Traceback (most recent call last):
...
ValueError: n(=-1) was expected to be >=0
```

```

sage.combinat.designs.orthogonal_arrays.OA_find_disjoint_blocks(OA, k, n, x, solver, integrality_tolerance)

Return \( x \) disjoint blocks contained in a given \( OA(k, n) \).

\( x \) blocks of an \( OA \) are said to be disjoint if they all have different values for a every given index, i.e. if they correspond to disjoint blocks in the \( TD \) associated with the \( OA \).

INPUT:

- \( OA \) – an orthogonal array
- \( k, n, x \) (integers)
• **solver** – (default: None) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to None, the default one is used. For more information on MILP solvers and which default solver is used, see the method solve of the class MixedIntegerLinearProgram.

• **integrality_tolerance** – parameter for use with MILP solvers over an inexact base ring; see MixedIntegerLinearProgram.get_values().

See also:

`incomplete_orthogonal_array()`

**EXAMPLES:**

```python
sage: from sage.combinat.designs.orthogonal_arrays import OA_find_disjoint_blocks
sage: k=3; n=4; x=3
sage: Bs = OA_find_disjoint_blocks(designs.orthogonal_arrays.build(k,n),k,n,x)
sage: assert len(Bs) == x
sage: for i in range(k):
    ....:     assert len(set([B[i] for B in Bs])) == x
sage: OA_find_disjoint_blocks(designs.orthogonal_arrays.build(k,n),k,n,5)
Traceback (most recent call last):
... ValueError: There does not exist 5 disjoint blocks in this OA(3,4)
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import OA_find_disjoint_blocks
>>> k=Integer(3); n=Integer(4); x=Integer(3)
>>> Bs = OA_find_disjoint_blocks(designs.orthogonal_arrays.build(k,n),k,n,x)
>>> assert len(Bs) == x
>>> for i in range(k):
    ...     assert len(set([B[i] for B in Bs])) == x
>>> OA_find_disjoint_blocks(designs.orthogonal_arrays.build(k,n),k,n,Integer(5))
Traceback (most recent call last):
... ValueError: There does not exist 5 disjoint blocks in this OA(3,4)
```

```
```

`sage.combinat.designs.orthogonal_arrays.OA_from_PBD(k, n, PBD, check=True)`

Return an $OA(k, n)$ from a PBD

**Construction**

Let $B$ be a $(n, K, 1)$-PBD. If there exists for every $i \in K$ a $TD(k, i) - i \times TD(k, 1)$ (i.e. if there exist $k$ idempotent MOLS), then one can obtain a $OA(k, n)$ by concatenating:

- A $TD(k, i) - i \times TD(k, 1)$ defined over the elements of $B$ for every $B \in B$.
- The rows $(i, ..., i)$ of length $k$ for every $i \in [n]$.

**Note:** This function raises an exception when Sage is unable to build the necessary designs.

**INPUT:**

- $k, n$ (integers)
- $PBD$ – a PBD on $0, ..., n - 1$.

**EXAMPLES:**

We start from the example VI.1.2 from the [DesignHandbook] to build an $OA(3, 10)$:
**sage:** from sage.combinat.designs.orthogonal_arrays import OA_from_PBD
**sage:** from sage.combinat.designs.designs_pyx import is_orthogonal_array
**sage:**
```
pbd = [[0,1,2,3], [0,4,5,6], [0,7,8,9], [1,4,7], [1,5,8],
       ...  [1,6,9], [2,4,9], [2,5,7], [2,6,8], [3,4,8], [3,5,9], [3,6,7]]
```
**sage:**
```
oa = OA_from_PBD(3,10,pbd)
```
**sage:** is_orthogonal_array(oa, 3, 10)
```
True
```
**sage:** from sage.all import *
**sage:** from sage.combinat.designs.orthogonal_arrays import OA_from_PBD
**sage:** from sage.combinat.designs.designs_pyx import is_orthogonal_array
**sage:**
```
pbd = [[Integer(0),Integer(1),Integer(2),Integer(3)], [Integer(0),Integer(4),
       ...  [Integer(1),Integer(4),Integer(7)], [Integer(1),Integer(5),Integer(8)],
       ...  [Integer(3),Integer(4),Integer(8)], [Integer(3),Integer(5),Integer(9)],
       ...  [Integer(3),Integer(6),Integer(7)]]
```
**sage:**
```
oa = OA_from_PBD(Integer(3),Integer(10),pbd)
```
**sage:** is_orthogonal_array(oa, Integer(3), Integer(10))
```
True
```
But we cannot build an $OA(4, 10)$ for this PBD (although there exists an $OA(4, 10)$):

**sage:** OA_from_PBD(4,10,pbd)
```
Traceback (most recent call last):
...
EmptySetError: There is no OA(n+1,n) - 3.OA(n+1,1)
as all blocks intersect in a projective plane.
```

**sage:** from sage.all import *
**sage:** OA_from_PBD(Integer(4),Integer(10),pbd)
```
Traceback (most recent call last):
...
EmptySetError: There is no OA(n+1,n) - 3.OA(n+1,1)
as all blocks intersect in a projective plane.
```

Or an $OA(3, 6)$ (as the PBD has 10 points):

**sage:** _ = OA_from_PBD(3,6,pbd)
```
Traceback (most recent call last):
...
RuntimeError: PBD is not a valid Pairwise Balanced Design on [0,...,5]
```

**sage:** from sage.all import *
**sage:** _ = OA_from_PBD(Integer(3),Integer(6),pbd)
```
Traceback (most recent call last):
...
RuntimeError: PBD is not a valid Pairwise Balanced Design on [0,...,5]
```

sage.combinat.designs.orthogonal_arrays.OA_from_Vmt($m, t, V$)

Return an Orthogonal Array from a $V(m, t)$

INPUT:

- $m, t$ (integers)
- $V$ – the vector $V(m, t)$. 

5.1. Comprehensive Module List 1149
Combinatorics, Release 10.4

See also:

- QDM_from_Vmt()
- OA_from_quasi_difference_matrix()

EXAMPLES:

```
sage: _ = designs.orthogonal_arrays.build(6,46) # indirect doctest
>>> from sage.all import *
>>> _ = designs.orthogonal_arrays.build(Integer(6),Integer(46)) # indirect doctest
```

Return an Orthogonal Array from a Quasi-Difference matrix

**Difference Matrices**

Let $G$ be a group of order $g$. A *difference matrix* $M$ is a $g \times k$ matrix with entries from $G$ such that for any $1 \leq i < j < k$ the set $\{d_{ll} - d_{lj} : 1 \leq l \leq g\}$ is equal to $G$.

By concatenating the $g$ matrices $M + x$ (where $x \in G$), one obtains a matrix of size $g^2 \times x$ which is also an $OA(k,g)$.

**Quasi-difference Matrices**

A quasi-difference matrix is a difference matrix with missing entries. The construction above can be applied again in this case, where the missing entries in each column of $M$ are replaced by unique values on which $G$ has a trivial action.

This produces an incomplete orthogonal array with a “hole” (i.e. missing rows) of size 'u' (i.e. the number of missing values per column of $M$). If there exists an $OA(k,u)$, then adding the rows of this $OA(k,u)$ to the incomplete orthogonal array should lead to an OA…

**Formal definition** (from the Handbook of Combinatorial Designs [DesignHandbook])

Let $G$ be an abelian group of order $n$. A $(n,k;\lambda,\mu;u)$-quasi-difference matrix (QDM) is a matrix $Q = (q_{ij})$ with $\lambda(n^2+2nu) + \mu$ rows and $k$ columns, with each entry either empty or containing an element of $G$. Each column contains exactly $\lambda u$ entries, and each row contains at most one empty entry. Furthermore, for each $1 \leq i < j \leq k$ the multiset

$$\{q_{ll} - q_{lj} : 1 \leq l \leq \lambda(n-1+2u) + \mu, \text{ with } q_{ii} \text{ and } q_{ij} \text{ not empty}\}$$

contains every nonzero element of $G$ exactly $\lambda$ times, and contains 0 exactly $\mu$ times.

**Construction**

If a $(n,k;\lambda,\mu;u)$-QDM exists and $\mu \leq \lambda$, then an $ITD_{\lambda}(k,n+u;u)$ exists. Start with a $(n,k;\lambda,\mu;u)$-QDM $A$ over the group $G$. Append $\lambda - \mu$ rows of zeroes. Then select $u$ elements $\infty_1, \ldots, \infty_u$ not in $G$, and replace the empty entries, each by one of these infinite symbols, so that $\infty_i$ appears exactly once in each column. Develop the resulting matrix over the group $G$ (leaving infinite symbols fixed), to obtain a $\lambda(n^2+2nu) \times k$ matrix $T$. Then $T$ is an orthogonal array with $k$ columns and index $\lambda$, having $n + u$ symbols and one hole of size $u$.

Adding to $T$ an $OA(k,u)$ with elements $\infty_1, \ldots, \infty_u$ yields the $ITD_{\lambda}(k,n+u;u)$.

INPUT:
• M – the difference matrix whose entries belong to G
• G – a group
• add_col (boolean) – whether to add a column to the final OA equal to \((x_1, \ldots, x_g, x_1, \ldots, x_g, \ldots)\) where \(G = \{x_1, \ldots, x_g\}\).
• fill_hole (boolean) – whether to return the incomplete orthogonal array, or complete it with the \(OA(k, u)\) (default). When fill_hole is None, no block of the incomplete OA contains more than one value \(\geq |G|\).

EXAMPLES:

```sage```
sage: _ = designs.orthogonal_arrays.build(6,20) # indirect doctest
```sage```

```
>>> from sage.all import *
>>> _ = designs.orthogonal_arrays.build(Integer(6),Integer(20)) # indirect doctest
sage.combinat.designs.orthogonal_arrays.OA_from_wider_OA(OA,k)
```

Return the first \(k\) columns of OA.

If OA has \(k\) columns, this function returns OA immediately.

INPUT:

• OA – an orthogonal array.
• k (integer)

EXAMPLES:

```sage```
sage: from sage.combinat.designs.orthogonal_arrays import OA_from_wider_OA
sage: OA_from_wider_OA(designs.orthogonal_arrays.build(6,20,2),1)[:5]

```sage```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import OA_from_wider_OA

```sage```

```sage```

```
sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix(k, c, G, A, Y, check=True)

```

Return an \(OA(k, |G| \cdot 2^c)\) from a constrained \((G, k – 1, 2)\)-difference matrix.

This construction appears in [AC1994] and [Ab1995].

Let \(G\) be an additive Abelian group. We denote by \(H\) a \(GF(2)\)-hyperplane in \(GF(2^c)\).

Let \(A\) be a \((k – 1) \times 2|G|\) array with entries in \(G \times GF(2^c)\) and \(Y\) be a vector with \(k – 1\) entries in \(GF(2^c)\). Let \(B\) and \(C\) be respectively the part of the array that belong to \(G\) and \(GF(2^c)\).

The input \(A\) and \(Y\) must satisfy the following conditions. For any \(i \neq j\) and \(g \in G\):
• there are exactly two values of \(s\) such that \(B_{i,s} - B_{j,s} = g\) (i.e. \(B\) is a \((G, k – 1, 2)\)-difference matrix),
• let \(s_1\) and \(s_2\) denote the two values of \(s\) given above, then exactly one of \(C_{i,s_1} - C_{j,s_1}\) and \(C_{i,s_2} - C_{j,s_2}\) belongs to the \(GF(2)\)-hyperplane \((Y_i - Y_j) \cdot H\) (we implicitly assumed that \(Y_i \neq Y_j\)).
Under these conditions, it is easy to check that the array whose \( k - 1 \) rows of length \(|G| \cdot 2^c\) indexed by \( 1 \leq i \leq k - 1 \) given by \( A_{i,s} + (0, Y_i \cdot v) \) where \( 1 \leq s \leq 2|G|, v \in H \) is a \((G \times GF(2^c), k - 1, 1)\)-difference matrix.

**INPUT:**

- \( k, c \) – integers
- \( G \) – an additive Abelian group
- \( A \) – a matrix with entries in \( G \times GF(2^c) \)
- \( Y \) – a vector with entries in \( GF(2^c) \)
- \( \text{check} \) – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to \text{True} by default.

**Note:** By convention, a multiplicative generator \( w \) of \( GF(2^c)^* \) is fixed (inside the function). The hyperplane \( H \) is the one spanned by \( w^0, w^1, \ldots, w^{c-1} \). The \( GF(2^c) \) part of the input matrix \( A \) and vector \( Y \) are given in the following form: the integer \( i \) corresponds to the element \( w^i \) and \text{None} corresponds to 0.

**See also:**

Several examples use this construction:

- \text{OA\_9\_40()}

sage.combinat.designs.orthogonal_arrays.OA_relabel(OA, k, n, blocks=(), matrix=None, symbol_list=None)

Return a relabelled version of the OA.

INPUT:

• OA – an OA, or rather a list of blocks of length \(k\), each of which contains integers from 0 to \(n - 1\).
• \(k, n\) (integers)
• blocks (list of blocks) – relabels the integers of the OA from [0..n − 1] into [0..n − 1] in such a way that the \(i\) blocks from block are respectively relabeled as \([n-i,...,n-i]\), …, \([n-1,...,n-1]\). Thus, the blocks from this list are expected to have disjoint values for each coordinate.

If set to the empty list (default) no such relabelling is performed.
• matrix – a matrix of dimensions \(k, n\) such that if the \(i\)th coordinate of a block is \(x\), this \(x\) will be relabelled with matrix\([i]\)[x]. This is not necessarily an integer between 0 and \(n - 1\), and it is not necessarily an integer either. This is performed after the previous relabelling.

If set to None (default) no such relabelling is performed.
• symbol_list – a list of the desired symbols for the relabelled OA. If this is not None, the same relabelling is done on all blocks such that the index of an element in symbol_list is its preimage in the relabelling map.

Note: A None coordinate in one block remains a None coordinate in the final block.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import OA_relabel
sage: OA = designs.orthogonal_arrays.build(3,2)

sage: OA_relabel(OA, 3, 2, matrix=[["A","B"],["C","D"],["E","F"]])

sage: TD = OA_relabel(OA, 3, 2, matrix=[[0,1],[2,3],[4,5]]); TD
[ [0, 2, 4], [0, 3, 5], [1, 2, 5], [1, 3, 4] ]
```

```
sage: TD = OA_relabel(OA, 3, 2, symbol_list=['A', 'B'])
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import OA_relabel

>>> OA = designs.orthogonal_arrays.build(Integer(3),Integer(2))

>>> OA_relabel(OA,Integer(3),Integer(2),matrix=[["A","B"],["C","D"],["E","F"]])

>>> TD = OA_relabel(OA,Integer(3),Integer(2),matrix=[[Integer(0),Integer(1)],
    [Integer(2),Integer(3)],[Integer(4),Integer(5)]]); TD
[ [0, 2, 4], [0, 3, 5], [1, 2, 5], [1, 3, 4] ]
```
>>> from sage.combinat.designs.orthogonal_arrays import is_transversal_design
>>> is_transversal_design(TD, Integer(3), Integer(2))
True

>>> OA = designs.orthogonal_arrays.build(Integer(3), Integer(2))
>>> OA_relabel(OA, Integer(3), Integer(2), symbol_list=['A', 'B'])

Making sure that $[2, 2, 2, 2]$ is a block of $OA(4, 3)$. We do this by relabelling block $[0, 0, 0, 0]$ which belongs to the design:

```
sage: designs.orthogonal_arrays.build(4, 3)
[[0, 0, 0, 0], [0, 1, 2, 1], [0, 2, 1, 2], [1, 0, 2, 2], [1, 1, 1, 0], [1, 2, 0,
  ->1], [2, 0, 1, 1], [2, 1, 0, 2], [2, 2, 2, 0]]
sage: OA_relabel(designs.orthogonal_arrays.build(4, 3), 4, 3, blocks=[[0, 0, 0, 0]])
[[2, 2, 2, 2], [2, 0, 1, 0], [2, 1, 0, 1], [0, 2, 1, 1], [0, 0, 0, 2], [0, 1, 2,
  ->0], [1, 2, 0, 0], [1, 0, 2, 1], [1, 1, 1, 2]]
```

```
sage.combinat.designs.orthogonal_arrays.OA_standard_label(OA)
Return the inputted OA with entries relabelled as integers [0,...,n-1].

INPUT:
• OA – a list of lists with symbols as entries that are not necessarily integers.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import OA_standard_label
sage: C = [['a', 'a', 'a', 'b'],
       ['a', 'a', 'b', 'a'],
       ['a', 'b', 'a', 'a'],
       ['b', 'a', 'a', 'a'],
       ['b', 'b', 'b', 'b']]
```

```
sage: OA_standard_label(C)
[['0', '0', '0', '1'], ['0', '0', '1', '0'], ['0', '1', '0', '0'], ['1', '0', '0',
  '0'], ['1', '1', '1', '1']]
```

```
sage.combinat.designs.orthogonal_arrays.QDM_from_Vmt(m, t, V)
Return a QDM from a $V(m, t)$
```
Definition

Let $q$ be a prime power and let $q = mt + 1$ for $m, t$ integers. Let $\omega$ be a primitive element of $\mathbb{F}_q$. A $V(m, t)$ vector is a vector $(a_1, \ldots, a_{m+1})$ for which, for each $1 \leq k < m$, the differences

$$\{a_{i+k} - a_i : 1 \leq i \leq m + 1, i + k \neq m + 2\}$$

represent the $m$ cyclotomic classes of $\mathbb{F}_{mt+1}$ (compute subscripts modulo $m + 2$). In other words, for fixed $k$, is $a_{i+k} - a_i = \omega^{mx+\alpha}$ and $a_{j+k} - a_j = \omega^{my+\beta}$ then $\alpha \not\equiv \beta \mod m$.

Construction of a quasi-difference matrix from a $V(m, t)$ vector

Starting with a $V(m, t)$ vector $(a_1, \ldots, a_{m+1})$, form a single row of length $m + 2$ whose first entry is empty, and whose remaining entries are $(a_1, \ldots, a_{m+1})$. Form $t$ rows by multiplying this row by the $t$ th roots, i.e. the powers of $\omega^m$. From each of these $t$ rows, form $m + 2$ rows by taking the $m + 2$ cyclic shifts of the row. The result is a $(a, m + 2; 1, 0; t) - QDM$.

For more information, refer to the Handbook of Combinatorial Designs [DesignHandbook].

INPUT:

- $m, t$ (integers)
- $V$ – the vector $V(m, t)$.

See also:

OA_from_quasi_difference_matrix()

EXAMPLES:

```python
sage: _ = designs.orthogonal_arrays.build(6,46) # indirect doctest
```

```python
>>> from sage.all import *

>>> _ = designs.orthogonal_arrays.build(Integer(6),Integer(46)) # indirect doctest
```

```
sage.combinat.designs.orthogonal_arrays.TD_product (k, TD1, n1, TD2, n2, check=True)
```

Return the product of two transversal designs.

From a transversal design $TD_1$ of parameters $k, n_1$ and a transversal design $TD_2$ of parameters $k, n_2$, this function returns a transversal design of parameters $k, n$ where $n = n_1 \times n_2$.

Formally, if the groups of $TD_1$ are $V_1^1, \ldots, V_k^1$ and the groups of $TD_2$ are $V_1^2, \ldots, V_k^2$, the groups of the product design are $V_1^1 \times V_1^2, \ldots, V_k^1 \times V_k^2$ and its blocks are the \{(x_1, x_2), \ldots, (x_k, x_k)\} where \{x_1, \ldots, x_k\} is a block of $TD_1$ and \{x_1^2, \ldots, x_k^2\} is a block of $TD_2$.

INPUT:

- $TD1, TD2$ – transversal designs
- $k, n1, n2$ – integers
- $check$ – boolean (default: True); whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed.

**Note:** This function uses transversal designs with $V_1 = \{0, \ldots, n - 1\}, \ldots, V_k = \{(k - 1)n, \ldots, kn - 1\}$ both as input and output.

**EXAMPLES:**
sage: from sage.combinat.designs.orthogonal_arrays import TD_product
sage: TD1 = designs.transversal_design(6,7)
sage: TD2 = designs.transversal_design(6,12)
sage: TD6_84 = TD_product(6,TD1,7,TD2,12)

>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import TD_product
>>> TD1 = designs.transversal_design(Integer(6),Integer(7))
>>> TD2 = designs.transversal_design(Integer(6),Integer(12))
>>> TD6_84 = TD_product(Integer(6),TD1,Integer(7),TD2,Integer(12))

class sage.combinat.designs.orthogonal_arrays.TransversalDesign

Bases: GroupDivisibleDesign

Class for Transversal Designs

INPUT:

• blocks – collection of blocks
• k, n (integers) – parameters of the transversal design. They can be set to None (default) in which case their value is determined by the blocks.
• check (boolean) – whether to check that the design is indeed a transversal design with the right parameters. Set to True by default.

EXAMPLES:

sage: designs.transversal_design(None,5)
Transversal Design TD(6,5)
sage: designs.transversal_design(None,30)
Transversal Design TD(6,30)
sage: designs.transversal_design(None,36)
Transversal Design TD(10,36)

>>> from sage.all import *
>>> designs.transversal_design(None,Integer(5))
Transversal Design TD(6,5)
>>> designs.transversal_design(None,Integer(30))
Transversal Design TD(6,30)
>>> designs.transversal_design(None,Integer(36))
Transversal Design TD(10,36)

sage.combinat.designs.orthogonal_arrays.incomplete_orthogonal_array

Return an $OA(k,n) - \sum_{1 \leq i \leq x} OA(k,s_i)$.

An $OA(k,n) - \sum_{1 \leq i \leq x} OA(k,s_i)$ is an orthogonal array from which have been removed disjoint $OA(k,s_1), ..., OA(k,s_x)$. If there exist $OA(k,s_1), ..., OA(k,s_x)$ they can be used to fill the holes and give rise to an $OA(k,n)$.

A very useful particular case (see e.g. the Wilson construction in $wilson_construction()$) is when all $s_i = 1$. In that case the incomplete design is a $OA(k,n) - x.OA(k,1)$. Such design is equivalent to transversal
design $TD(k, n)$ from which has been removed $x$ disjoint blocks.

INPUT:

- $k$, $n$ (integers)
- `holes` (list of integers) – respective sizes of the holes to be found.
- `resolvable` (boolean) – set to `True` if you want the design to be resolvable. The classes of the resolvable design are obtained as the first $n$ blocks, then the next $n$ blocks, etc ... Set to `False` by default.
- `existence` (boolean) – instead of building the design, return:
  - `True` – meaning that Sage knows how to build the design
  - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`).
  - `False` – meaning that the design does not exist.

Note: By convention, the ground set is always $V = \{0, \ldots, n-1\}$.

If all holes have size 1, in the incomplete orthogonal array returned by this function the holes are $\{n-1, \ldots, n-s_1\}^k$, $\{n-s_1-1, \ldots, n-s_1-s_2\}^k$, etc.

More generally, if `holes` is equal to $u_1, \ldots, u_k$, the $i$-th hole is the set of points $\{n - \sum_{j \geq i} u_j, \ldots, n - \sum_{j \geq i+1} u_j\}^k$.

See also:

`OA_find_disjoint_blocks()`

EXAMPLES:

```python
sage: IOA = designs.incomplete_orthogonal_array(3, 3, [1, 1, 1])
sage: IOA
[[0, 1, 2], [0, 2, 1], [1, 0, 2], [1, 2, 0], [2, 0, 1], [2, 1, 0]]
sage: missing_blocks = [[0, 0, 0], [1, 1, 1], [2, 2, 2]]
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: is_orthogonal_array(IOA + missing_blocks, 3, 3, 2)
True
```

```python
>>> from sage.all import *
>>> IOA = designs.incomplete_orthogonal_array(Integer(3), Integer(3), [Integer(1), Integer(1), Integer(1)])
>>> IOA
[[0, 1, 2], [0, 2, 1], [1, 0, 2], [1, 2, 0], [2, 0, 1], [2, 1, 0]]
>>> missing_blocks = [[Integer(0), Integer(0), Integer(0)], [Integer(1), Integer(1), Integer(1)], [Integer(2), Integer(2), Integer(2)]]
>>> from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
>>> is_orthogonal_array(IOA + missing_blocks, Integer(3), Integer(3), Integer(2))
True
```

`sage.combinat.designs.orthogonal_arrays.is_transversal_design(B, k, n, verbose=False)`

Check that a given set of blocks $B$ is a transversal design.

See `transversal_design()` for a definition.

INPUT:

- `B` – the list of blocks
• $k, n$ – integers
• verbose – boolean; whether to display information about what is going wrong

**Note:** The transversal design must have $\{0, \ldots, kn-1\}$ as a ground set, partitioned as $k$ sets of size $n$: $\{0, \ldots, k-1\} \cup \{k, \ldots, 2k-1\} \cup \cdots \cup \{k(n-1), \ldots, kn-1\}$.

**EXAMPLES:**

```python
sage: TD = designs.transversal_design(5, 5, check=True) # indirect doctest
sage: from sage.combinat.designs.orthogonal_arrays import is_transversal_design
sage: is_transversal_design(TD, 5, 5)
True
sage: is_transversal_design(TD, 4, 4)
False
```

```python
>>> from sage.all import *
>>> TD = designs.transversal_design(Integer(5), Integer(5), check=True) # indirect doctest
>>> from sage.combinat.designs.orthogonal_arrays import is_transversal_design
>>> is_transversal_design(TD, Integer(5), Integer(5))
True
>>> is_transversal_design(TD, Integer(4), Integer(4))
False
```

`sage.combinat.designs.orthogonal_arrays.largest_available_k(n, t=2)`

Return the largest $k$ such that Sage can build an $OA(k, n)$.

**INPUT:**

• $n$ (integer)
• $t$ – (integer; default: 2) – strength of the array

**EXAMPLES:**

```python
sage: designs.orthogonal_arrays.largest_available_k(0)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(1)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(10)
4
sage: designs.orthogonal_arrays.largest_available_k(27)
28
sage: designs.orthogonal_arrays.largest_available_k(100)
10
sage: designs.orthogonal_arrays.largest_available_k(-1)
Traceback (most recent call last):
  ...
ValueError: n=(-1) was expected to be >=0
```

```python
>>> from sage.all import *
>>> designs.orthogonal_arrays.largest_available_k(Integer(0))
+Infinity
>>> designs.orthogonal_arrays.largest_available_k(Integer(1))
+Infinity
>>> designs.orthogonal_arrays.largest_available_k(Integer(10))
```

(continues on next page)
sage.combinat.designs.orthogonal_arrays.orthogonal_array\( (k, n, t=2, \text{resolvable}=False, \text{check}=True, \text{existence}=False, \text{explain\_construction}=False)\)

Return an orthogonal array of parameters \(k, n, t\).

An orthogonal array of parameters \(k, n, t\) is a matrix with \(k\) columns filled with integers from \([n]\) in such a way that for any \(t\) columns, each of the \(n^t\) possible rows occurs exactly once. In particular, the matrix has \(n^t\) rows.

More general definitions sometimes involve a \(\lambda\) parameter, and we assume here that \(\lambda = 1\).

An orthogonal array is said to be *resolvable* if it corresponds to a resolvable transversal design (see `sage.combinat.designs.incidence_structures.IncidenceStructure.is_resolvable()`).

For more information on orthogonal arrays, see Wikipedia article Orthogonal_array.

**INPUT:**

- \(k\) – (integer) number of columns. If \(k=None\) it is set to the largest value available.
- \(n\) – (integer) number of symbols
- \(t\) – (integer; default: 2) – strength of the array
- \(\text{resolvable}\) (boolean) – set to True if you want the design to be resolvable. The \(n\) classes of the resolvable design are obtained as the first \(n\) blocks, then the next \(n\) blocks, etc ... Set to False by default.
- \(\text{check}\) – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.
- \(\text{existence}\) (boolean) – instead of building the design, return:
  - True – meaning that Sage knows how to build the design
  - Unknown – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`).
  - False – meaning that the design does not exist.

**Note:** When \(k=None\) and \(\text{existence}=True\) the function returns an integer, i.e. the largest \(k\) such that we can build a \(OA(k, n)\).

- \(\text{explain\_construction}\) (boolean) – return a string describing the construction.

**OUTPUT:**

The kind of output depends on the input:

- if \(\text{existence}=False\) (the default) then the output is a list of lists that represent an orthogonal array with parameters \(k\) and \(n\)
• if `existence=True` and `k` is an integer, then the function returns a boolean: either `True, Unknown` or `False`.

• if `existence=True` and `k=None` then the output is the largest value of `k` for which Sage knows how to compute a $TD(k,n)$.

**Note:** This method implements theorems from [Stinson2004]. See the code’s documentation for details.

**See also:**

When $t = 2$ an orthogonal array is also a transversal design (see `transversal_design()`) and a family of mutually orthogonal latin squares (see `mutually_orthogonal_latin_squares()`).

```python
sage.combinat.designs.orthogonal_arrays.transversal_design(k, n, resolvable=False, check=True, existence=False)
```

Return a transversal design of parameters $k, n$.

A transversal design of parameters $k, n$ is a collection $\mathcal{S}$ of subsets of $V = V_1 \cup \cdots \cup V_k$ (where the groups $V_i$ are disjoint and have cardinality $n$) such that:

• Any $S \in \mathcal{S}$ has cardinality $k$ and intersects each group on exactly one element.

• Any two elements from distinct groups are contained in exactly one element of $\mathcal{S}$.

More general definitions sometimes involve a $\lambda$ parameter, and we assume here that $\lambda = 1$.

For more information on transversal designs, see [http://mathworld.wolfram.com/TransversalDesign.html](http://mathworld.wolfram.com/TransversalDesign.html).

**INPUT:**

• $n, k$ – integers. If `k` is `None` it is set to the largest value available.

• `resolvable` (boolean) – set to `True` if you want the design to be resolvable (see `sage.combinat.designs.incidence_structures.IncidenceStructure.is_resolvable()`). The $n$ classes of the resolvable design are obtained as the first $n$ blocks, then the next $n$ blocks, etc ... Set to `False` by default.

• `check` – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `False` by default.

• `existence` (boolean) – instead of building the design, return:

  - `True` – meaning that Sage knows how to build the design
  - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`).
  - `False` – meaning that the design does not exist.

**Note:** When `k=None` and `existence=True` the function returns an integer, i.e. the largest $k$ such that we can build a $TD(k,n)$.

**OUTPUT:**

The kind of output depends on the input:

• if `existence=False` (the default) then the output is a list of lists that represent a $TD(k,n)$ with $V_1 = \{0, \ldots, n - 1\}, \ldots, V_k = \{(k-1)n, \ldots, kn - 1\}$
• if `existence=True` and `k` is an integer, then the function returns a boolean: either `True`, `Unknown` or `False`.
• if `existence=True` and `k=None` then the output is the largest value of `k` for which Sage knows how to compute a $TD(k, n)$.

See also:
* orthogonal_array() – a transversal design $TD(k, n)$ is equivalent to an orthogonal array $OA(k, n, 2)$.

**EXAMPLES:**

```python
sage: TD = designs.transversal_design(5,5); TD
Transversal Design TD(5,5)
sage: TD.blocks()
[[0, 5, 10, 15, 20], [0, 6, 12, 18, 24], [0, 7, 14, 16, 23],
 [0, 8, 11, 19, 22], [0, 9, 13, 17, 21], [1, 5, 14, 18, 22],
 [1, 6, 11, 16, 21], [1, 7, 13, 19, 20], [1, 8, 10, 17, 24],
 [1, 9, 12, 15, 23], [2, 5, 13, 16, 24], [2, 6, 10, 19, 23],
 [2, 7, 12, 17, 22], [2, 8, 14, 15, 21], [2, 9, 11, 18, 20],
 [3, 5, 12, 19, 21], [3, 6, 14, 17, 20], [3, 7, 11, 15, 24],
 [3, 8, 13, 18, 23], [3, 9, 10, 16, 22], [4, 5, 11, 17, 23],
 [4, 6, 13, 15, 22], [4, 7, 10, 18, 21], [4, 8, 12, 16, 20],
 [4, 9, 14, 19, 24]]
```

```python
>>> from sage.all import *
>>> TD = designs.transversal_design(Integer(5),Integer(5)); TD
Transversal Design TD(5,5)
>>> TD.blocks()
[[0, 5, 10, 15, 20], [0, 6, 12, 18, 24], [0, 7, 14, 16, 23],

```

Some examples of the maximal number of transversal Sage is able to build:

```python
sage: TD_4_10 = designs.transversal_design(4,10)
sage: designs.transversal_design(5,10,existence=True)
Unknown
```

```python
>>> from sage.all import *
>>> TD_4_10 = designs.transversal_design(Integer(4),Integer(10))
>>> designs.transversal_design(Integer(5),Integer(10),existence=True)
Unknown
```

For prime powers, there is an explicit construction which gives a $TD(n + 1, n)$:

```python
sage: designs.transversal_design(4, 3, existence=True)
True
sage: designs.transversal_design(674, 673, existence=True)
True
```
>>> from sage.all import *
>>> designs.transversal_design(Integer(4), Integer(3), existence=True)
True
>>> designs.transversal_design(Integer(674), Integer(673), existence=True)
True

For other values of $n$ it depends:

```
sage: designs.transversal_design(7, 6, existence=True)
False
sage: designs.transversal_design(4, 6, existence=True)
Unknown
sage: designs.transversal_design(3, 6, existence=True)
True
sage: designs.transversal_design(11, 10, existence=True)
False
sage: designs.transversal_design(4, 10, existence=True)
True
sage: designs.transversal_design(5, 10, existence=True)
Unknown
sage: designs.transversal_design(7, 20, existence=True)
Unknown
sage: designs.transversal_design(6, 12, existence=True)
True
sage: designs.transversal_design(7, 12, existence=True)
True
sage: designs.transversal_design(8, 12, existence=True)
Unknown
sage: designs.transversal_design(6, 20, existence=True)
Unknown
sage: designs.transversal_design(7, 20, existence=True)
Unknown
```

>>> from sage.all import *
>>> designs.transversal_design(Integer(7), Integer(6), existence=True)
False
>>> designs.transversal_design(Integer(4), Integer(6), existence=True)
Unknown
>>> designs.transversal_design(Integer(3), Integer(6), existence=True)
True

(continues on next page)
If you ask for a transversal design that Sage is not able to build then an EmptySetError or a NotImplementedError is raised:

```python
sage: designs.transversal_design(47, 100)
Traceback (most recent call last):
... NotImplementedError: I don't know how to build a TD(47,100)!
sage: designs.transversal_design(55, 54)
Traceback (most recent call last):
... EmptySetError: There exists no TD(55,54)!
```

Those two errors correspond respectively to the cases where Sage answer Unknown or False when the parameter existence is set to True:

```python
sage: designs.transversal_design(47, 100, existence=True)
Unknown
sage: designs.transversal_design(55, 54, existence=True)
False
```

If for a given $n$ you want to know the largest $k$ for which Sage is able to build a $TD(k, n)$ just call the function with $k$ set to None and existence set to True as follows:

```python
sage: designs.transversal_design(None, 6, existence=True)
3
sage: designs.transversal_design(None, 20, existence=True)
6
sage: designs.transversal_design(None, 30, existence=True)
6
sage: designs.transversal_design(None, 120, existence=True)
9
```
sage.combinat.designs.orthogonal_arrays.wilson_construction(OA, k, r, m, u, check=True, explain_construction=False)

Returns a $OA(k, rm + \sum_i u_i)$ from a truncated $OA(k + s, r)$ by Wilson’s construction.

**Simple form:**

Let $OA$ be a truncated $OA(k + s, r)$ with $s$ truncated columns of sizes $u_1, ..., u_s$, whose blocks have sizes in \{ $k + b_1, ..., k + b_t$ \}. If there exist:

- An $OA(k, m + b_i) - b_i.OA(k, 1)$ for every $1 \leq i \leq t$
- An $OA(k, u_i)$ for every $1 \leq i \leq s$

Then there exists an $OA(k, rm + \sum u_i)$. The construction is a generalization of Lemma 3.16 in [HananiBIBD].

**Brouwer-Van Rees form:**

Let $OA$ be a truncated $OA(k + s, r)$ with $s$ truncated columns of sizes $u_1, ..., u_s$. Let the set $H_i$ of the $u_i$ points of column $k + i$ be partitioned into $\sum_j H_{ij}$. Let $m_{ij}$ be integers such that:

- For $0 \leq i < l$ there exists an $OA(k, \sum_j m_{ij}\vert H_{ij}\vert)$
- For any block $B \in OA$ intersecting the sets $H_{ij(i)}$ there exists an $OA(k, m + \sum_i m_{ij}) - \sum_i OA(k, m_{ij(j)})$.

Then there exists an $OA(k, rm + \sum_{i,j} m_{ij})$. This construction appears in [BvR1982].

**INPUT:**

- $OA$ – an incomplete orthogonal array with $k + s$ columns. The elements of a column of size $c$ must belong to $\{0, ..., c\}$. The missing entries of a block are represented by None values. If $OA=None$, it is defined as a truncated orthogonal arrays with $k + s$ columns.
- $k$, $r$, $m$ (integers)
- $u$ (list) – two cases depending on the form to use:
  - Simple form: a list of length $s$ such that column $k+i$ has size $u[i]$. The untruncated points of column $k+i$ are assumed to be $[0, \ldots, u[i]-1]$.
  - Brouwer-Van Rees form: a list of length $s$ such that $u[i]$ is the list of pairs $(m_{i0}, \vert H_{i0}\vert), ..., (m_{ip}, \vert H_{ip}\vert))$. The untruncated points of column $k+i$ are assumed to be $[0, \ldots, u_i-1]$ where $u_i = \sum_j \vert H_{ip}\vert$. Besides, the first $\vert H_{i0}\vert$ points represent $H_{i0}$, the next $\vert H_{i1}\vert$ points represent $H_{i1}$, etc...
- $explain\_construction$ (boolean) – return a string describing the construction.
- $check$ (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

 for R in OA]

>>> OAb = wilson_construction(OA,Integer(5),Integer(11),Integer(21),
[(Integer(5),Integer(5))])

>>> is_orthogonal_array(OAb,Integer(5),Integer(256))
True

5.1.92 Orthogonal arrays (build recursive constructions)

This module implements several constructions of Orthogonal Arrays. As their input can be complex, they all have a counterpart in the orthogonal_arrays_find_recursive module that automatically computes it.

All these constructions are automatically queried when the orthogonal_array() function is called.

Functions

sage.combinat.designs.orthogonal_arrays_build_recursive.OA_and_oval(q, solver, integrity_tolerance)

Return a OA(q + 1, q) whose blocks contains ≤ 2 zeroes in the last q columns.

This OA is build from a projective plane of order q, in which there exists an oval O of size q + 1 (i.e. a set of q + 1 points no three of which are [colinear/contained in a common set of the projective plane]).

Removing an element x ∈ O and all sets that contain it, we obtain a TD(q + 1, q) in which O intersects all columns except one. As O is an oval, no block of the TD intersects it more than twice.

INPUT:

- q – a prime power
• **solver** – (default: None) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to None, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.

• **integrality_tolerance** – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

**Note:** This function is called by `construction_3_6()`, an implementation of Construction 3.6 from [AC07].

**EXAMPLES:**

```python
sage: from sage.combinat.designs.orthogonal_arrays_build_recursive import OA_and_oval
sage: _ = OA_and_oval
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_build_recursive import OA_and_oval
>>> _ = OA_and_oval
```

`sage.combinat.designs.orthogonal_arrays_build_recursive.brouwer_separable_design(k, t, q, x, check=False, verbose=False, explain_construction=False)`

Returns a $OA(k, t(q^2 + q + 1) + x)$ using Brouwer’s result on separable designs.

This method is an implementation of Brouwer’s construction presented in [Brouwer80]. It consists in a systematic application of the usual transformation from PBD to OA, applied to a specific PBD.

**Baer subplanes**

When $q$ is a prime power, the projective plane $PG(2, q^2)$ can be partitioned into subplanes $PG(2, q)$ (called Baer subplanes), giving $PG(2, q^2) = B_1 \cup \cdots \cup B_{q^2-q+1}$. As a result, every line of the $PG(2, q^2)$ intersects one of the subplane on $q + 1$ points and all others on 1 point.

The $OA$ are built by considering $B_1 \cup \cdots \cup B_t$, for a total of $t(q^2 + q + 1)$ points (to which $x$ new points are then added). The blocks of this subdesign belong to two categories:

- The blocks of size $t$: they come from the lines which intersect a $B_i$ on $q + 1$ points for some $i > t$. The blocks of size $t$ can be partitioned into $q^2 - q + t - 1$ parallel classes according to their associated subplane $B_i$ with $i > t$.
- The blocks of size $q + t$: those blocks form a symmetric design, as every point is incident with $q + t$ of them.

**Constructions**

In the following, we write $N = t(q^2 + q + 1) + x$. The code is also heavily commented, and will clear any doubt.

- i) $x = 0$: in that case we build a resolvable $OA(k - 1, N)$ that will then be completed into an $OA(k, N)$.
  - **Sets of size $t$**
We take the product of each parallel class with the parallel classes of a resolvable $OA(k - 1, t) - t.OA(k - 1, t)$, yielding new parallel classes.

- **Sets of size $q + t$**

  A $N \times (q + t)$ array is built whose rows are the sets of size $q + t$ such that every value appears once per column. For each block of a $OA(k - 1, q + t) - (q + t).OA(k - 1, t)$, the product with the rows of the matrix yields a parallel class.

- **Sets of size $t$**

  Each set of size $t$ gives a $OA(k, t) - t.OA(k, 1)$, except if there is only one parallel class in which case a $OA(k, t)$ is sufficient.

- **Sets of size $q + t$**

  A $(N - x) \times (q + t)$ array $M$ is built whose $N - x$ rows are the sets of size $q + t$ such that every value appears once per column. For each of the new $x = q + t$ points $p_1, \ldots, p_{q+t}$, we build a matrix $M_i$ obtained from $M$ by adding a column equal to $(p_1, p_2, \ldots)$. We add to the OA the product of all rows of the $M_i$ with the block of the $x = q + t$ parallel classes of a resolvable $OA(k, t + q + 1) - (t + q + 1).OA(k, 1)$.

- **Set of size $x$) An $OA(k, x)$**

  - **ii) $x = q + t$**

    - **Sets of size $t$**

      Each set of size $t$ gives a $OA(k, t) - t.OA(k, 1)$, except if there is only one parallel class in which case a $OA(k, t)$ is sufficient.

    - **Sets of size $q + t$**

      A $(N - x) \times (q + t)$ array $M$ is built whose $N - x$ rows are the sets of size $q + t$ such that every value appears once per column. For each of the new $x = q + t$ points $p_1, \ldots, p_{q+t}$, we build a matrix $M_i$ obtained from $M$ by adding a column equal to $(p_1, p_2, \ldots)$. We add to the OA the product of all rows of the $M_i$ with the block of the $x = q + t$ parallel classes of a resolvable $OA(k, t + q + 1) - (t + q + 1).OA(k, 1)$.

    - **Set of size $x$) An $OA(k, x)$**

  - **iii) $x = q^2 - q + 1 - t$**

    - **Sets of size $t$**

      All blocks of the $i$-th parallel class are extended with the $i$-th new point. The blocks are then replaced by a $OA(k, t + 1) - (t + 1).OA(k, 1)$ or, if there is only one parallel class (i.e. $x = 1$) by a $OA(k, t + 1) - OA(k, 1)$.

    - **Set of size $q + t$**

      They are replaced by $OA(k, q + t) - (q + t).OA(k, 1)$.

    - **Set of size $x$) An $OA(k, x)$**

  - **iv) $x = q^2 + 1$**

    - **Sets of size $t$**

      All blocks of the $i$-th parallel class are extended with the $i$-th new point (the other $x - q - t$ new points are not touched at this step). The blocks are then replaced by a $OA(k, t + 1) - (t + 1).OA(k, 1)$ or, if there is only one parallel class (i.e. $x = 1$) by a $OA(k, t + 1) - OA(k, 1)$.

    - **Set of size $q + t$) Same as for ii)**

    - **Set of size $x$) An $OA(k, x)$**

  - **v) $0 < x < q^2 - q + 1 - t$**

    - **Sets of size $t$**

      The blocks of the first $x$ parallel class are extended with the $x$ new points, and replaced with $OA(k, t + 1) - (t + 1).OA(k, 1)$ or, if $x = 1$, by $OA(k, t + 1) - OA(k, 1)$

      The blocks of the other parallel classes are replaced by $OA(k, t) - t.OA(k, t)$ or, if there is only one class left, by $OA(k, t) - OA(k, t)$
Sets of size $q + t$  
They are replaced with $OA(k, q + t) - (q + t).OA(k, 1)$.

Set of size $x$) An $OA(k, x)$

- vi)  $t + q < x < q^2 + 1$

Sets of size $t$) Same as in vi) with an $x$ equal to $x - q + t$.

Sets of size $t$) Same as in vii)

Set of size $x$) An $OA(k, x)$

INPUT:

- $k, t, q, x$ (integers)
- check – (boolean) Whether to check that output is correct before returning it. Set to False by default.
- verbose (boolean) – whether to print some information on the construction and parameters being used.
- explain_construction (boolean) – return a string describing the construction.

→Integer(189)))
Brouwer's separable design construction with t=9,q=4,x=0 from:
  Andries E. Brouwer,
  A series of separable designs with application to pairwise orthogonal Latin...
  Vol. 1, n. 1, pp. 39-41,
  European Journal of Combinatorics, 1980
```

Return an $OA(k, nm + i)$. This is Wilson’s construction with $i$ truncated columns of size 1 and such that a block $B_0$ of the incomplete OA intersects all truncated columns. As a consequence, all other blocks intersect only 0 or 1 of the last $i$ columns. This allow to consider the block $B_0$ only up to its first $k$ coordinates and then use a $OA(k, i)$ instead of a $OA(k, m + i) - i.OA(k, 1)$.

This is construction 3.3 from [AC07].

**INPUT:**
- $k, n, m, i$ (integers) such that the following designs are available: $OA(k, n), OA(k, m), OA(k, m + 1), OA(k, r)$.
- `explain_construction` (boolean) – return a string describing the construction.

**See also:**
- `find_construction_3_3()`

**EXAMPLES:**

```python
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_...
→construction_3_3
sage: from sage.combinat.designs.orthogonal_arrays_build_recursive import...
→construction_3_3
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: k = 11; n = 177
sage: is_orthogonal_array(construction_3_3(*find_construction_3_3(k,n)[1]),k,n,2)... → # needs sage.schemes
True
sage: print(designs.orthogonal_arrays.explain_construction(9,91))

  Vol. 15, n.3, pp. 255-261,
  Journal of Combinatorial Designs, 2007
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_...
```

(continues on next page)
Return a \( OA(k, nm + rs) \).

This is Wilson’s construction applied to a truncated \( OA(k + r + 1, n) \) with \( r \) columns of size 1 and one column of size \( s \).

The unique elements of the \( r \) truncated columns are picked so that a block \( B_0 \) contains them all.

- If there exists an \( OA(k, m + r + 1) \) the column of size \( s \) is truncated in order to intersect \( B_0 \).
- Otherwise, if there exists an \( OA(k, m + r) \), the last column must not intersect \( B_0 \)

This is construction 3.4 from [AC07].

**INPUT:**

- \( k, n, m, r, s \) – integers; we assume that \( s < n \) and \( 1 \leq r, s \)
  
  The following designs must be available: \( OA(k, n), OA(k, m), OA(k, m + 1), OA(k, m + 2), OA(k, s) \). Additionally, it requires either a \( OA(k, m + r) \) or a \( OA(k, m + r + 1) \).
- \( \text{explain}\_\text{construction} \) (boolean) – return a string describing the construction.

**See also:**

\( \text{find}\_\text{construction}\_3\_4() \)

**EXAMPLES:**

```python
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_construction_3_4
sage: from sage.combinat.designs.orthogonal_arrays_build_recursive import construction_3_4
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: k = 8; n = 196
sage: is_orthogonal_array(construction_3_4(*find_construction_3_4(k,n)[1]),k,n,2) # needs sage.schemes
True
```

sage.combinat.designs.orthogonal_arrays_build_recursive.construction_3_5(k, n, m, r, s, t,
  explain_construction=False)

Return an \( OA(k, nm + r + s + t) \).

This is exactly Wilson’s construction with three truncated groups except we make sure that all blocks have size \( > k \), so we don’t need a \( OA(k, m + 0) \) but only \( OA(k, m + 1), OA(k, m + 2) \) \( ‘OA(k, m+3)’ \).

This is construction 3.5 from [AC07].

INPUT:

- \( k, n, m \) (integers)
- \( r, s, t \) (integers) – sizes of the three truncated groups, such that \( r \leq s \) and \( (q - r - 1)(q - s) \geq (q - s - 1)(q - r) \).
- `explain_construction` (boolean) – return a string describing the construction.

The following designs must be available: \( OA(k, n), OA(k, r), OA(k, s), OA(k, t), OA(k, m+1), OA(k, m+2), OA(k, m + 3) \).

    Journal of Combinatorial Designs, 2007
```

sage.combinat.designs.orthogonal_arrays_build_recursive.construction_3_6(k, n, m, 
    i, explain_construction=False)

Return a \( OA(k, nm + i) \)

This is Wilson’s construction with \( r \) columns of order 1, in which each block intersects at most two truncated columns. Such a design exists when \( n \) is a prime power and is returned by \( OA_{\text{and}}_{\text{oval}}() \).

INPUT:

- \( k, n, m, i \) (integers) – \( n \) must be a prime power. The following designs must be available: \( OA(k + r, q) \), \( OA(k, m), OA(k, m + 1), OA(k, m + 2) \).

- explain_construction (boolean) – return a string describing the construction.

This is construction 3.6 from [AC07].

See also:

- find_construction_3_6()
- OA_and_oval()

EXAMPLES:

5.1. Comprehensive Module List 1175
Return an $OA(k, (q - 1) \ast (q - x) + x + 2)$ using the $q - x$ construction.

Let $v = (q - 1) \ast (q - x) + x + 2$. If there exists a projective plane of order $q$ (e.g. when $q$ is a prime power) and $0 < x < q$ then there exists a $(v - 1, \{q - x - 1, q - x + 1\})$-GDD of type $(q - 1)^{q-x}(x+1)^3$ (see [Greig99] or Theorem 2.50, section IV.2.3 of [DesignHandbook]). By adding to the ground set one point contained in all groups of the GDD, one obtains a $(v, \{q - x - 1, q - x + 1, q + x + 2\})$-PBD with exactly one set of size $x + 2$.

Thus, assuming that we have the following:

- $OA(k, q - x - 1) - (q - x - 1).OA(k, 1)$
- $OA(k, q - x + 1) - (q - x + 1).OA(k, 1)$
- $OA(k, q) - q.OA(k, 1)$
- $OA(k, x + 2)$
Then we can build from the PBD an $OA(k, v)$.

Construction of the PBD (shared by Julian R. Abel):

Start with a resolvable $(q^2, q, 1)$-BIBD and put the points into a $q \times q$ array so that rows form a parallel class and columns form another.

Now delete:

- All $(q - 1)$ points from the first $x$ columns and not in the first row
- All $q - x$ points in the last $q - x$ columns AND the first row.

Then add a point $p_1$ to the blocks that are rows. Add a second point $p_2$ to the $q - x$ blocks that are columns of size $q - 1$, plus the first row of size $x + 1$.

INPUT:

- $k, q, x$ – integers such that $0 < x < q$ and such that Sage can build:
  - A projective plane of order $q$
  - $OA(k, q - x - 1) - (q - x - 1).OA(k, 1)$
  - $OA(k, q - x + 1) - (q - x + 1).OA(k, 1)$
  - $OA(k, q) - q.OA(k, 1)$
  - $OA(k, x + 2)$
- **check** – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.
- **explain_construction** (boolean) – return a string describing the construction.

Journal of Combinatorial Designs, 1999

REFERENCES:
sage.combinat.designs.orthogonal_arrays_build_recursive.three_factor_product (k, n1, n2, n3, check=False, explain_construction=False)

Returns an OA(k + 1, n1n2n3)

The three factor product construction from [DukesLing14] does the following:

If n1 ≤ n2 ≤ n3 are such that there exists an OA(k, n1), OA(k + 1, n2) and OA(k + 1, n3), then there exists a OA(k + 1, n1n2n3).

It works with a modified product of orthogonal arrays ([Rees93], [Rees00]) which keeps track of parallel classes in the OA (the definition is given for transversal designs).

A subset of blocks in an TD(k, n) is called a c-parallel class if every point is covered exactly c times.
A 1-parallel class is a parallel class.

The modified product:

If there exists an OA(k, n1), and if there exists an OA(k, n2) whose blocks are partitionned into s n1-parallel classes and n2 − sn1 parallel classes, then there exists an OA(k, n1n2) whose blocks can be partitionned into sn12 parallel classes and (n1n2 − sn12)/n1 = n2 − sn1 n1-parallel classes.

Proof:

• The product of the blocks of a parallel class with an OA(k, n1) yields an n1-parallel class of an OA(k, n1n2).

• The product of the blocks of a n1-parallel class of OA(k, n2) with an OA(k, n1) can be done in such a way that it yields n1n2 parallel classes of OA(k, n1n2). Those classes cover exactly the pairs that would have been covered with the usual product.

This can be achieved by simple cyclic permutations. Let us build the product of the n1-parallel class \( P \subseteq OA(k, n2) \) with \( OA(k, n1) \): when computing the product of \( P \in P \) with \( B1 \in OA(k, n1) \) the i-th coordinate should not be \( (B1_i, P_i) \) but \( (B1_i + r, P_i) \) (the sum is mod n1) where r is the number of blocks of \( P \) we have already processed whose i-th coordinate is equal to \( P_i \) (note that r < n1 as \( P \) is n1-parallel).

With these tools, one can obtain the designs promised by the three factors construction applied to k, n1, n2, n3 (thanks to Julian R. Abel's help):

1) Let s be the largest integer \( \leq n3/n1 \). Apply the product construction to \( OA(k, n3) \) and a resolvable OA(k, n3) whose blocks are partitionned into s n1-parallel classes and n3 − sn1 parallel classes. It re-
Combinatorics, Release 10.4

sults in a $OA(k, n_1 n_3)$ partitioned into $s n_1^2$ parallel classes plus $(n_1 n_3 - s n_1^2) / n_1 = n_3 - s n_1$ parallel classes.

2) Add $n_3 - n_1$ parallel classes to every $n_1$-parallel class to turn them into $n_3$-parallel classes. Apply the product construction to this partitioned $OA(k, n_1 n_3)$ with a resolvable $OA(k, n_2)$.

3) As $OA(k, n_2)$ is resolvable, the $n_2$-parallel classes of $OA(k, n_1 n_2 n_3)$ are actually the union of $n_2$ parallel classes, thus the $OA(k, n_1 n_2 n_3)$ is resolvable and can be turned into an $OA(k + 1, n_1 n_2 n_3)$

INPUT:

- $k, n_1, n_2, n_3$ (integers)
- check – (boolean) Whether to check that everything is going smoothly while the design is being built. It is disabled by default, as the constructor of orthogonal arrays checks the final design anyway.
- explain_construction (boolean) – return a string describing the construction.

Three-factor product with \( n=8 \cdot 9 \cdot 9 \) from:
Peter J. Dukes, Alan C.H. Ling,
A three-factor product construction for mutually orthogonal latin squares,

REFERENCE:
sage.combinat.designs.orthogonal_arrays_build_recursive.thwart_lemma_3_5
    \((k, n, m, a, b, c, d=0, complement=False, explain_construction=False)\)

Returns an \( OA(k, nm + a + b + c + d) \)

(When \( d=0 \))

According to [Thwats] when \( n \) is a prime power and \( a + b + c \leq n + 1 \), one can build an \( OA(k + 3, n) \) with three truncated columns of sizes \( a, b, c \) in such a way that all blocks have size \( \leq k + 2 \).

(in order to build a \( OA(k, nm + a + b + c) \) the following designs must also exist: \( OA(k, a), OA(k, b), OA(k, c), OA(k, m + 0), OA(k, m + 1), OA(k, m + 2) \))

Considering the complement of each truncated column, it is also possible to build an \( OA(k + 3, n) \) with three truncated columns of sizes \( a, b, c \) in such a way that all blocks have size \( > k \) whenever \((n-a)+(n-b)+(n-c) \leq n + 1\).

(in order to build a \( OA(k, nm + a + b + c) \) the following designs must also exist: \( OA(k, a), OA(k, b), OA(k, c), OA(k, m + 1), OA(k, m + 2), OA(k, m + 3) \))

Here is the proof of Lemma 3.5 from [Thwats] enriched with explanations from Julian R. Abel:

For any prime power \( n \) one can build \( k - 1 \) MOLS by associating to every nonzero \( x \in \mathbb{F}_n \) the latin square:

\[
M_x(i, j) = i + x \cdot j \quad \text{where} \quad i, j \in \mathbb{F}_n
\]

In particular \( M_1(i, j) = i + j \), whose \( n \) columns and lines are indexed by the elements of \( \mathbb{F}_n \). If we order the elements of \( \mathbb{F}_n \) as \( 0, 1, ..., n-1, x+0, ..., x+n-1, x^2+0, ... \) and reorder the columns and lines of \( M_1 \) accordingly, the top-left \( a \times b \) squares contains at most \( a + b - 1 \) distinct symbols.

(When \( d \neq 0 \))

If there exists an \( OA(k + 3, n) \) with three truncated columns of sizes \( a, b, c \) in such a way that all blocks have size \( \leq k + 2 \), by truncating arbitrarily another column to size \( d \) one obtains an \( OA \) with 4 truncated columns whose blocks miss at least one value. Thus, following the proof again one can build an \( OA(k + 4) \) with four truncated columns of sizes \( a, b, c, d \) with blocks of size \( \leq k + 3 \).

1180 Chapter 5. Comprehensive Module List
(in order to build a $OA(k, nm + a + b + c + d)$ the following designs must also exist: $OA(k, a)$, $OA(k, b)$, $OA(k, c)$, $OA(k, d)$, $OA(k, m + 0)$, $OA(k, m + 1)$, $OA(k, m + 2)$, $OA(k, m + 3)$)

As before, this also shows that one can build an $OA(k + 4, n)$ with four truncated columns of sizes $a, b, c, d$ in such a way that all blocks have size $> k$ whenever $(n - a) + (n - b) + (n - c) \leq n + 1$

(in order to build a $OA(k, nm + a + b + c + d)$ the following designs must also exist: $OA(k, n - a)$, $OA(k, n - b)$, $OA(k, n - c)$, $OA(k, d)$, $OA(k, m + 1)$, $OA(k, m + 2)$, $OA(k, m + 3)$, $OA(k, m + 4)$)

INPUT:

- $k, n, m, a, b, c, d$ – integers which must satisfy the constraints above. In particular, $a + b + c \leq n + 1$ must hold. By default, $d = 0$.
- complement (boolean) – whether to complement the sets, i.e. follow the $n - a, n - b, n - c$ variant described above.
- explain_construction (boolean) – return a string describing the construction.

    Thwarts in transversal designs,
```

REFERENCE:

sage.combinat.designs.orthogonal_arrays_build_recursive.thwart_lemma_4_1

Returns an $OA(k, nm + 4(n - 2))$.

Implements Lemma 4.1 from [Thwarts].

If $n \equiv 0, 1 \pmod{3}$ is a prime power, then there exists a truncated $OA(n + 1, n)$ whose last four columns have size $n - 2$ and intersect every block on 1, 3 or 4 values. Consequently, if there exists an $OA(k, m + 1)$, $OA(k, m + 3)$, $OA(k, m + 4)$ and a $OA(k, n - 2)$ then there exists an $OA(k, nm + 4(n - 2))$.
Proof: form the transversal design by removing one point of the $AG(2,3)$ (Affine Geometry) contained in the Desarguesian Projective Plane $PG(2,n)$.

The affine geometry on 9 points contained in the projective geometry $PG(2,n)$ is given explicitly in [OS64] (Thanks to Julian R. Abel for finding the reference!).

**INPUT:**

- $k$, $n$, $m$ (integers)
- `explain_construction` (boolean) – return a string describing the construction.

**See also:**

- `find_thwart_lemma_4_1()`

**EXAMPLES:**

```sage
def print(designs.orthogonal_arrays.explain_construction(10,408))
  print(designs.orthogonal_arrays.explain_construction(10,408))

Lemma 4.1 with $n=13$, $m=28$ from:

5.1.93 Orthogonal arrays (find recursive constructions)

This module implements several functions to find recursive constructions of Orthogonal Arrays.

The main function of this module, i.e. `find_recursive_construction()`, queries all implemented recursive constructions of designs implemented in `orthogonal_arrays_build_recursive` in order to obtain an $OA(k,n)$.

`find_recursive_construction()` is called by the `orthogonal_array()` function.
<table>

**REFERENCES:**

**Functions**

`sage.combinat.designs.orthogonal_arrays_find_recursive.find_brouwer_separable_design(k, n)`

Find $t(q^2 + q + 1) + x = n$ to obtain an $OA(k, n)$ by Brouwer's separable design construction.

**INPUT:**

- $k, n$ – integers

The assumptions made on the parameters $t, q, x$ are explained in the documentation of `brouwer_separable_design()`.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_brouwer_separable_design
sage: find_brouwer_separable_design(5, 13)[1]
(5, 1, 3, 0)
sage: find_brouwer_separable_design(5, 14)
False
```
Find \( rm + x_1 + \ldots + x_c = n \) such that the Brouwer-van Rees constructions yields a \( OA(k, n) \).

Let \( n = rm + \sum_{1 \leq i \leq c} u_i \) such that \( c \leq r \). The generalization of Wilson's construction found by Brouwer and van Rees (with one truncated column) ensures that an \( OA(k, n) \) exists if the following designs exist: \( OA(k+1, r) \), \( OA(k, m) \), \( OA(k, \sum_{1 \leq i \leq c} u_i) \), \( OA(k, m + x_1) - OA(k, x_1) \), \ldots , \( OA(k, m + x_c) - OA(k, x_c) \).

For more information, see the documentation of \( \text{wilson_construction}() \).

**INPUT:**

- \( k, n \) – integers

**EXAMPLES:**

```python
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_brouwer_van_rees_with_one_truncated_column
sage: find_brouwer_van_rees_with_one_truncated_column(5, 53)
(None, 5, 7, 7, [(2, 1), (2, 1)])
sage: find_brouwer_van_rees_with_one_truncated_column(6, 96)
(None, 6, 7, 13, [(3, 1), (1, 1), (1, 1)])
```

Find a decomposition for construction 3.3 from [AC07]

**INPUT:**

- \( k, n \) – integers

**See also:**

\( \text{construction} \_3 \_3() \)

**OUTPUT:**

A pair \( f, \text{args} \) such that \( f(\text{args}) \) returns the requested OA.

**EXAMPLES:**
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_construction_3_3
sage: find_construction_3_3(11, 177)[1]
(11, 11, 16, 1)
sage: find_construction_3_3(12, 11)

sage.combinat.designs.orthogonal_arrays_find_recursive.find_construction_3_4(k, n)

Find a decomposition for construction 3.4 from [AC07]

INPUT:

• k, n – integers

See also:

construction_3_4()

OUTPUT:

A pair f, args such that f(*args) returns the requested OA.

EXAMPLES:

sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_construction_3_4
sage: find_construction_3_4(8, 196)[1]
(8, 25, 7, 12, 9)
sage: find_construction_3_4(9, 24)

sage.combinat.designs.orthogonal_arrays_find_recursive.find_construction_3_5(k, n)

Find a decomposition for construction 3.5 from [AC07]

INPUT:

• k, n – integers

See also:

construction_3_5()

OUTPUT:

A pair f, args such that f(*args) returns the requested OA.

EXAMPLES:
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_ ˓→construction_3_5
sage: find_construction_3_5(8,111)[1]
(8, 13, 6, 9, 11, 13)
sage: find_construction_3_5(9,24)

>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_ ˓→construction_3_5
>>> find_construction_3_5(Integer(8),Integer(111))[Integer(1)]
(8, 13, 7, 4)
>>> find_construction_3_5(Integer(8),Integer(98))

sage.combinat.designs.orthogonal_arrays_find_recursive.find_construction_3_6(k, n)

Find a decomposition for construction 3.6 from [AC07]

INPUT:
• k, n – integers

See also:
construction_3_6()

OUTPUT:
A pair $f, args$ such that $f(*args)$ returns the requested OA.

EXAMPLES:

sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_ ˓→construction_3_6
sage: find_construction_3_6(8,95)[1]
(8, 13, 7, 4)

sage.combinat.designs.orthogonal_arrays_find_recursive.find_product_decomposition(k, n)

Find $n_1 n_2 = n$ to obtain an $OA(k, n)$ by the product construction.

If Sage can build an $OA(k, n_1)$ and an $OA(k, n_2)$ such that $n = n_1 \times n_2$ then an $OA(k, n)$ can be built by a product construction (which correspond to Wilson's construction with no truncated column). This function look for a pair of integers $(n_1, n_2)$ with $n_1 \leq n_2$, $n_1 \times n_2 = n$ and such that both an $OA(k, n_1)$ and an $OA(k, n_2)$ are available.

INPUT:
• k, n – integers

OUTPUT:
A pair $f, args$ such that $f(*args)$ is an $OA(k, n)$ or False if no product decomposition was found.

EXAMPLES:
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_product_decomposition
sage: f, args = find_product_decomposition(6, 84)

sage: args
(6, 7, 12, False)

>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_product_decomposition
>>> f, args = find_product_decomposition(Integer(6), Integer(84))

sage.combinat.designs.orthogonal_arrays_find_recursive.find_q_x(k, n)

Find integers \(q, x\) such that the \(q - x\) construction yields an OA\((k, n)\).

See the documentation of \(\text{construction}_q_x()\) to find out what hypotheses the integers \(q, x\) must satisfy.

**Warning:** For efficiency reasons, this function checks that Sage can build an OA\((k + 1, q - x - 1)\) and an OA\((k + 1, q - x + 1)\), which is stronger than checking that Sage can build a OA\((k, q - x - 1) - (q - x - 1)\).OA\((k, 1)\) and a OA\((k, q - x + 1) - (q - x + 1)\).OA\((k, 1)\). The latter would trigger a lot of independent set computations in sage.combinat.designs.orthogonal_arrays.incomplete_orthogonal_array().

**INPUT:**

* k, n – integers

**See also:**

\(\text{construction}_q_x()\)

**EXAMPLES:**

sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_q_x
sage: find_q_x(10, 9)
False
sage: find_q_x(9, 158)
(9, 16, 6)

sage.combinat.designs.orthogonal_arrays_find_recursive.find_recursive_construction(n)

Find a recursive construction of an OA\((k, n)\) (calls all others find_* functions)

This determines whether an OA\((k, n)\) can be built through the following constructions:

* \(\text{wilson_construction}()\)
* \(\text{construction}_3_3()\)
• construction_3_4()
• construction_3_5()
• construction_3_6()
• construction_q_x()
• thwart_lemma_3_5()
• thwart_lemma_4_1()
• three_factor_product()
• brouwer_separable_design()

INPUT:
* k, n – integers

OUTPUT:
Return a pair f, args such that f(*args) returns the requested OA if possible, and False otherwise.

EXAMPLES:

```python
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_recursive_construction
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: count = 0
sage: for n in range(10, 150):
...     k = designs.orthogonal_arrays.largest_available_k(n)
...     if find_recursive_construction(k, n):
...         count = count + 1
...         f, args = find_recursive_construction(k, n)
...         OA = f(*args)
...         assert is_orthogonal_array(OA, k, n, 2, verbose=True)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_recursive_construction
>>> from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
>>> count = Integer(0)
>>> for n in range(Integer(10), Integer(150)):
...     k = designs.orthogonal_arrays.largest_available_k(n)
...     if find_recursive_construction(k, n):
...         count = count + Integer(1)
...         f, args = find_recursive_construction(k, n)
...         OA = f(*args)
...         assert is_orthogonal_array(OA, k, n, Integer(2), verbose=True)
```

```
56
```

Find $n_1 n_2 n_3 = n$ to obtain an OA$(k, n)$ by the three-factor product from [DukesLing14]

INPUT:
* k, n – integers
See also:

three_factor_product()

OUTPUT:

A pair \( f, \text{args} \) such that \( f(*\text{args}) \) returns the requested OA.

EXAMPLES:

```python
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_three_factor_product
sage: find_three_factor_product(10, 648)[1]
(9, 8, 9, 9)
sage: find_three_factor_product(10, 50)
False
```

Find the values on which Lemma 3.5 from [Thwarts] applies.

OUTPUT:

A pair \((f, \text{args})\) such that \(f(*\text{args})\) returns an OA\((k, n)\) or False if the construction is not available.

See also:

thwart_lemma_3_5()

EXAMPLES:

```python
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_thwart_lemma_3_5
sage: find_thwart_lemma_3_5(7, 66)
(7, 9, 7, 1, 1, 0, False)
sage: is_orthogonal_array(find_thwart_lemma_3_5(7, 66), 7, 66, 2)
True
sage: find_thwart_lemma_3_5(6, 100)
(6, 8, 10, 7, 5, 0, True)
sage: is_orthogonal_array(find_thwart_lemma_3_5(6, 100), 6, 100, 2)
True
```

(continues on next page)
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array

>>> f, args = find_thwart_lemma_3_5(Integer(7), Integer(66))

>>> args
(7, 9, 7, 1, 1, 0, False)

>>> OA = f(*args)

>>> is_orthogonal_array(OA, Integer(7), Integer(66), Integer(2))
True

>>> f, args = find_thwart_lemma_3_5(Integer(6), Integer(100))

>>> args
(6, 8, 10, 7, 5, True)

>>> OA = f(*args)

>>> is_orthogonal_array(OA, Integer(6), Integer(100), Integer(2))
True

Some values from [Thwarts]:

sage.combinat.designs.orthogonal_arrays_find_recursive.find_thwart_lemma_4_1(k, n)
Find a decomposition for Lemma 4.1 from [Thwarts].

INPUT:

• \( k, n \) – integers

See also:
thwart_lemma_4_1()

OUTPUT:

A pair \( f, \text{args} \) such that \( f(*\text{args}) \) returns the requested OA.

EXAMPLES:

```python
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_thwart_lemma_4_1
sage: find_thwart_lemma_4_1(10, 408)[1]
(10, 13, 28)
sage: find_thwart_lemma_4_1(10, 50)
False
```

Find \( rm + u = n \) to obtain an \( OA(k, n) \) by Wilson’s construction with one truncated column.

This function looks for possible integers \( m, t, u \) satisfying that \( mt + u = n \) and such that Sage knows how to build a \( OA(k, m) \), \( OA(k, m + 1) \), \( OA(k + 1, t) \) and a \( OA(k, u) \).

INPUT:

• \( k, n \) – integers

OUTPUT:

A pair \( f, \text{args} \) such that \( f(*\text{args}) \) is an \( OA(k, n) \) or False if no decomposition with one truncated block was found.

EXAMPLES:

```python
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_wilson_decomposition_with_one_truncated_group
sage: f, args = find_wilson_decomposition_with_one_truncated_group(4, 38)
sage: args
(None, 4, 5, 7, (3,), False)
sage: _ = f(*args)
sage: find_wilson_decomposition_with_one_truncated_group(4, 20)
False
```
Find \( rm + r_1 + r_2 = n \) to obtain an \( OA(k, n) \) by Wilson’s construction with two truncated columns.

Look for integers \( r, m, r_1, r_2 \) satisfying \( n = rm + r_1 + r_2 \) and \( 1 \leq r_1, r_2 < r \) and such that the following designs exist: \( OA(k + 2, r), OA(k, r_1), OA(k, r_2), OA(k, m), OA(k, m + 1), OA(k, m + 2) \).

**INPUT:**
- \( k, n \) – integers

**OUTPUT:**
A pair \( f, args \) such that \( f(*args) \) is an \( OA(k, n) \) or False if no decomposition with two truncated blocks was found.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_wilson_decomposition_with_two_truncated_groups
sage: f, args = find_wilson_decomposition_with_two_truncated_groups(5, 58)
sage: args
(3, 5, 5, (4, 5), False)
sage: _ = f(*args)
```

```python
code
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_wilson_decomposition_with_two_truncated_groups
>>> f, args = find_wilson_decomposition_with_two_truncated_groups(Integer(5), Integer(58))
>>> args
(3, 5, 5, (4, 5), False)
```

sage.combinat.designs.orthogonal_arrays_find_recursive.int_as_sum(value, S, k_max)

Return a tuple \( (s_1, s_2, \ldots, s_k) \) of less than \( k_max \) elements of \( S \) such that \( value = s_1 + s_2 + \ldots + s_k \). If there is no such tuples then the function returns None.

**INPUT:**
- \( value \) (integer)
- \( S \) – a list of integers
- \( k_max \) (integer)

**EXAMPLES:**
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import int_as_sum
sage: D = int_as_sum(21, [5, 12], 100)
sage: for k in range(20, 40):
    ....:     print("{} {}").format(k, int_as_sum(k, [5, 12], 100))
20 (5, 5, 5, 5)
21 None

5.1.94 Steiner Quadruple Systems

A Steiner Quadruple System on \( n \) points is a family \( SQS_n \subset \binom{[n]}{4} \) of 4-sets, such that any set \( S \subset [n] \) of size three is a subset of exactly one member of \( SQS_n \).

This module implements Haim Hanani’s constructive proof that a Steiner Quadruple System exists if and only if \( n \equiv 2, 4 \pmod{6} \). Hanani’s proof consists in 6 different constructions that build a large Steiner Quadruple System from a smaller one, and though it does not give a very clear understanding of why it works (to say the least)… it does!

The constructions have been implemented while reading two papers simultaneously, for one of them sometimes provides the informations that the other one does not. The first one is Haim Hanani’s original paper [Han1960], and the other one is a paper from Horan and Hurlbert which goes through all constructions [HH2012].

It can be used through the `designs` object:

```sage
from sage.all import *

designs.steiner_quadruple_system(8)
```

Incidence structure with 8 points and 14 blocks

AUTHORS:

- Nathann Cohen (May 2013, while listening to “Le Blues Du Pauvre Delahaye”)

Index

This module’s main function is the following:

```plaintext
steiner_quadruple_system()  Return a Steiner Quadruple System on \( n \) points
```

This function redistributes its work among 6 constructions:

<table>
<thead>
<tr>
<th>Construction</th>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>two_n()</code></td>
<td>Return a Steiner Quadruple System on ( 2n ) points</td>
</tr>
<tr>
<td>2</td>
<td><code>three_n_minus_two()</code></td>
<td>Return a Steiner Quadruple System on ( 3n - 2 ) points</td>
</tr>
<tr>
<td>3</td>
<td><code>three_n_minus_eight()</code></td>
<td>Return a Steiner Quadruple System on ( 3n - 8 ) points</td>
</tr>
<tr>
<td>4</td>
<td><code>three_n_minus_four()</code></td>
<td>Return a Steiner Quadruple System on ( 3n - 4 ) points</td>
</tr>
<tr>
<td>5</td>
<td><code>four_n_minus_six()</code></td>
<td>Return a Steiner Quadruple System on ( 4n - 6 ) points</td>
</tr>
<tr>
<td>6</td>
<td><code>twelve_n_minus_ten()</code></td>
<td>Return a Steiner Quadruple System on ( 12n - 10 ) points</td>
</tr>
</tbody>
</table>

It also defines two specific Steiner Quadruple Systems that the constructions require, i.e. \( SQS_{14} \) and \( SQS_{38} \) as well as the systems of pairs \( P_\alpha(m) \) and \( P_\alpha(m) \) (see [Han1960]).
Functions

sage.combinat.designs.steiner_quadruple_systems.P(\(alpha, m\))

Return the collection of pairs \(P_{\alpha}(m)\)

For more information on this system, see [Han1960].

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import P
sage: P(3,4)
[(0, 5), (2, 7), (4, 1), (6, 3)]
```

sage.combinat.designs.steiner_quadruple_systems.barP(\(eps, m\))

Return the collection of pairs \(\bar{P}_{\alpha}(m)\)

For more information on this system, see [Han1960].

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import barP
sage: barP(3,4)
[(0, 4), (3, 5), (1, 2)]
```

sage.combinat.designs.steiner_quadruple_systems.barP_system()

Return the 1-factorization of \(K_{2m, \bar{P}}(m)\)

For more information on this system, see [Han1960].

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import barP_system
sage: barP_system(3)
[[[4, 3], (2, 5)],
 [[0, 5], (4, 1)],
 [[0, 2], (1, 3)],
 [[1, 5], (4, 2), (0, 3)],
 [[0, 4], (2, 5), (1, 2)],
 [[0, 1], (2, 3), (4, 5)]]
```

(continues on next page)
sage.combinat.designs.steiner_quadruple_systems.four_n_minus_six(*B*)

Return a Steiner Quadruple System on $4n - 6$ points.

**INPUT:**

- $B$ – A Steiner Quadruple System on $n$ points.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.steiner_quadruple_systems import four_n_minus_six
sage: for n in range(4, 20):
....:     if (n % 6) in [2, 4]:
....:         sqs = designs.steiner_quadruple_system(n)
....:         if not four_n_minus_six(sqs).is_t_design(3, 4*n-6, 4, 1):
....:             print("Something is wrong !")
```

sage.combinat.designs.steiner_quadruple_systems.relabel_system(*B*)

Relabels the set so that \{n - 4, n - 3, n - 2, n - 1\} is in $B$.

**INPUT:**

- $B$ – a list of 4-uples on 0, ..., $n - 1$.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.steiner_quadruple_systems import relabel_system
sage: SQS8 = designs.steiner_quadruple_system(8)
sage: relabel_system(SQS8)
Incidence structure with 8 points and 14 blocks
```

sage.combinat.designs.steiner_quadruple_systems.steiner_quadruple_system(*check=False*)

Return a Steiner Quadruple System on $n$ points.

**INPUT:**

- $n$ – an integer such that $n \equiv 2, 4 \pmod{6}$
- $check$ (boolean) – whether to check that the system is a Steiner Quadruple System before returning it (False by default)

**EXAMPLES:**
sage: sqs4 = designs.steiner_quadruple_system(4)
sage: sqs4
Incidence structure with 4 points and 1 blocks
sage: sqs4.is_t_design(3,4,4,1)
True
sage: sqs8 = designs.steiner_quadruple_system(8)
sage: sqs8
Incidence structure with 8 points and 14 blocks
sage: sqs8.is_t_design(3,8,4,1)
True

>>> from sage.all import *

>>> sqs4 = designs.steiner_quadruple_system(Integer(4))

>>> sqs4
Incidence structure with 4 points and 1 blocks

>>> sqs4.is_t_design(Integer(3),Integer(4),Integer(4),Integer(1))
True

>>> sqs8 = designs.steiner_quadruple_system(Integer(8))

>>> sqs8
Incidence structure with 8 points and 14 blocks

>>> sqs8.is_t_design(Integer(3),Integer(8),Integer(4),Integer(1))
True

sage.combinat.designs.steiner_quadruple_systems.three_n_minus_eight(B)

Return a Steiner Quadruple System on $3n - 8$ points.

INPUT:

- $B$ – A Steiner Quadruple System on $n$ points.

EXAMPLES:

sage: from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_eight

sage: for n in range(4, 30):
....:     if (n%12) == 2:
....:         sqs = designs.steiner_quadruple_system(n)
....:         if not three_n_minus_eight(sqs).is_t_design(3,3*n-8,4,1):
....:             print("Something is wrong !")

>>> from sage.all import *

>>> from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_eight

>>> for n in range(Integer(4), Integer(30)):
...     if (n%Integer(12)) == Integer(2):
...         sqs = designs.steiner_quadruple_system(n)
...         if not three_n_minus_eight(sqs).is_t_design(Integer(3),Integer(3)*n-
...             Integer(8),Integer(4),Integer(1)):
...             print("Something is wrong !")

sage.combinat.designs.steiner_quadruple_systems.three_n_minus_four(B)

Return a Steiner Quadruple System on $3n - 4$ points.

INPUT:

- $B$ – A Steiner Quadruple System on $n$ points where $n \equiv 10 \pmod{12}$. 
**EXAMPLES:**

```python
sage: from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_four

sage: for n in range(4, 30):
    ....:     if n%12 == 10:
    ....:         sqs = designs.steiner_quadruple_system(n)
    ....:         if not three_n_minus_four(sqs).is_t_design(3,3*n-4,4,1):
    ....:             print("Something is wrong !")
```

```python
>>> from sage.all import *

>>> from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_four

>>> for n in range(Integer(4), Integer(30)):
    ...     if n%Integer(12) == Integer(10):
    ...         sqs = designs.steiner_quadruple_system(n)
    ...         if not three_n_minus_four(sqs).is_t_design(Integer(3),Integer(3)*n-Integer(4),Integer(4),Integer(1)):
    ...             print("Something is wrong !")
```

**sage.combinat.designs.steiner_quadruple_systems.three_n_minus_two**(B)

Return a Steiner Quadruple System on \(3n - 2\) points.

**INPUT:**

- **B** – A Steiner Quadruple System on \(n\) points.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_two

sage: for n in range(4, 30):
    ....:     if (n%6) in [2,4]:
    ....:         sqs = designs.steiner_quadruple_system(n)
    ....:         if not three_n_minus_two(sqs).is_t_design(3,3*n-2,4,1):
    ....:             print("Something is wrong !")
```

```python
>>> from sage.all import *

>>> from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_two

>>> for n in range(Integer(4), Integer(30)):
    ...     if (n%Integer(6)) in [Integer(2),Integer(4)]:
    ...         sqs = designs.steiner_quadruple_system(n)
    ...         if not three_n_minus_two(sqs).is_t_design(Integer(3),Integer(3)*n-Integer(4),Integer(4),Integer(1)):
    ...             print("Something is wrong !")
```

**sage.combinat.designs.steiner_quadruple_systems.twelve_n_minus_ten**(B)

Return a Steiner Quadruple System on \(12n - 6\) points.

**INPUT:**

- **B** – A Steiner Quadruple System on \(n\) points.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.steiner_quadruple_systems import twelve_n_minus_ten

sage: for n in range(4, 15):
    ....:     if (n%6) in [2,4]:
    ....:         sqs = designs.steiner_quadruple_system(n)
```
if not twelve_n_minus_ten(sqs).is_t_design(3,12*n-10,4,1):
    print("Something is wrong !")

sage.combinat.designs.steiner_quadruple_systems.two_n(B)

Return a Steiner Quadruple System on 2n points.

INPUT:

• B – A Steiner Quadruple System on n points.

EXAMPLES:

5.1.95 Hypergraph isomorphic copy search

This module implements a code for the following problem:

INPUT: two hypergraphs $H_1, H_2$

OUTPUT: a copy of $H_2$ in $H_1$

It is also possible to enumerate all such copies, and to require that such copies be induced copies. More formally:

A copy of $H_2$ in $H_1$ is an injection $f : V(H_2) \rightarrow V(H_1)$ such that for any set $S_2 \in E(H_2)$ we have $f(S_2) \in E(H_1)$.

It is an induced copy if no other set of $E(H_1)$ is contained in $f(V(H_2))$, i.e. $|E(H_2)| = \{S : S \in E(H_1) \text{ and } S \subseteq f(V(H_2))\}$.

The functions implemented here lists all such injections. In particular, the number of copies of $H$ in itself is equal to $|\text{Aut}(H)|$.

The feature is available through `IncidenceStructure.isomorphic_substructures_iterator()`. 
Implementation

A hypergraph is stored as a list of edges, each of which is a “dense” bitset over $|V(H_1)|$ points. In particular, two sets of distinct cardinalities require the same memory space. A hypergraph is a C struct with the following fields:

- $n, m$ (int) – number of points and edges.
- $limbs$ (int) – number of 64-bits blocks per set.
- $set_space$ (uint64_t*) – address of the memory used to store the sets.
- $sets$ (uint64_t**) – sets[$i$] points toward the limbs blocks encoding set $i$. Note also that sets[$i$][limbs] is equal to the cardinality of set[$i$], so that sets has length $m*(\text{limbs+1})*\text{sizeof(uint64_t)}$.
- $names$ (int*) – associates an integer ‘name’ to each of the $n$ points.

The operations used on this data structure are:

- void permute(hypergraph * h, int n1, int n2) – exchanges points $n1$ and $n2$ in the data structure. Note that their names are also exchanged so that we still know which is which.
- int induced_hypergraph(hypergraph * h1, int n, hypergraph * tmp1) – stores in tmp1 the hypergraph induced by the first $n$ points, i.e. all sets $S$ such that $S \subseteq \{0, \ldots, n-1\}$. The function returns the number of such sets.
- void trace_hypergraph64(hypergraph * h, int n, hypergraph * tmp) – stores in tmp1 the trace of $h$ on the first $n$ points, i.e. all sets of the form $S \cap \{0, \ldots, n-1\}$.

Algorithm

We try all possible assignments of a representant $r_i \in H_1$ for every $i \in H_2$. When we have picked a representant for the first $n < \text{points} \{0, \ldots, n-1\} \subseteq V(H_2)$, we check that:

- The hypergraph induced by the (ordered) list $0, \ldots, n-1$ in $H_2$ is equal to the one induced by $r_0, \ldots, r_{n-1}$ in $H_1$.
- If $S \subseteq \{0, \ldots, n-1\}$ is contained in $c$ sets of size $k$ in $H_2$, then $\{r_i : i \in S\}$ is contained in $\geq c$ sets of size $k$ in $H_1$. This is done by comparing the trace of the hypergraphs while remembering the original size of each set.

As we very often need to build the hypergraph obtained by the trace of the first $n$ points (for all possible $n$), those hypergraphs are cached. The hypergraphs induced by the same points are handled similarly.

Limitations

Number of points For efficiency reason the implementation assumes that $H_2$ has $\leq 64$ points. Making this work for larger values means that calls to qsort have to be replaced by calls to qsort_r (i.e. to sort the edges you need to know the number of limbs per edge) and that induces a big slowdown for small cases (~50% when this code was implemented). Also, 64 points for $H_2$ is already very very big considering the problem at hand. Even $|V(H_1)| > 64$ seems too much.

Vertex ordering The order of vertices in $H_2$ has a huge influence on the performance of the algorithm. If no set of $H_2$ contains more that one of the first $k < n$ points, then almost all partial assignments of representants are possible for the first $k$ points (though the degree of the vertices is taken into account). For this reason it is best to pick an ordering such that the first vertices are contained in as many sets as possible together. A heuristic is implemented at relabel_heuristic().

AUTHORS:
- Nathann Cohen (November 2014, written in various airports between Nice and Chennai).
Methods

class sage.combinat.designs.subhypergraph_search.SubHypergraphSearch
Bases: object

relabel_heuristic()

Relabels $H_2$ in order to make the algorithm faster.

Objective: we try to pick an ordering $p_1, \ldots, p_k$ of the points of $H_2$ that maximizes the number of sets involving the first points in the ordering. One way to formalize the problems indicates that it may be NP-Hard (generalizes the max clique problem for graphs) so we do not try to solve it exactly: we just need a sufficiently good heuristic.

Assuming that the first points are $p_1, \ldots, p_k$, we determine $p_{k+1}$ as the point $x$ such that the number of sets $S$ with $x \in S$ and $S \cap \{p_1, \ldots, p_k\} \neq \emptyset$ is maximal. In case of ties, we take a point with maximum degree.

This function is called when an instance of SubHypergraphSearch is created.

EXAMPLES:

```python
sage: d = designs.projective_plane(3)  # needs sage.schemes

sage: d.isomorphic_substructures_iterator(d).relabel_heuristic()  # needs sage.schemes

>>> from sage.all import *
>>> d = designs.projective_plane(Integer(3))  # needs sage.schemes
>>> d.isomorphic_substructures_iterator(d).relabel_heuristic()  # needs sage.schemes
```

5.1.96 Two-graphs

A two-graph on $n$ points is a family $T \subset \binom{[n]}{3}$ of 3-sets, such that any 4-set $S \subset [n]$ of size four contains an even number of elements of $T$. Any graph $([n], E)$ gives rise to a two-graph $T(E) = \{ t \in \binom{[n]}{3} : |\{t\} \cap E| \text{ odd} \}$, and any two graphs with the same two-graph can be obtained one from the other by Seidel switching. This defines an equivalence relation on the graphs on $[n]$, called Seidel switching equivalence. Conversely, given a two-graph $T$, one can construct a graph $\Gamma$ in the corresponding Seidel switching class with an isolated vertex $w$. The graph $\Gamma \setminus w$ is called the descendant of $T$ w.r.t. $v$.

$T$ is called regular if each two-subset of $[n]$ is contained in the same number $\alpha$ of triples of $T$.

This module implements a direct construction of a two-graph from a list of triples, construction of descendant graphs, regularity checking, and other things such as constructing the complement two-graph, cf. [BH2012].

Methods

class `sage.combinat.designs.twographs.TwoGraph` (points=None, blocks=None, incidence_matrix=None, name=None, check=False, copy=True)

Bases: `IncidenceStructure`

Two-graphs class.

A two-graph on $n$ points is a 3-uniform hypergraph, i.e. a family $T \subset \binom{[n]}{3}$ of 3-sets, such that any 4-set $S \subset [n]$ of size four contains an even number of elements of $T$. For more information, see the documentation of the `twographs` module.

`complement()`

The two-graph which is the complement of self

That is, the two-graph consisting exactly of triples not in self. Note that this is different from complement of the parent class.

EXAMPLES:

```python
sage: p = graphs.CompleteGraph(8).line_graph().twograph()
# needs sage.modules
sage: pc = p.complement(); pc
# needs sage.modules
Incidence structure with 28 points and 1260 blocks
```

```python
>> from sage.all import *
>> p = graphs.CompleteGraph(Integer(8)).line_graph().twograph()
# needs sage.modules
>> pc = p.complement(); pc
# needs sage.modules
Incidence structure with 28 points and 1260 blocks
```

`descendant(v)`

The descendant graph at v

The switching class of graphs corresponding to self contains a graph $D$ with $v$ its own connected component; removing $v$ from $D$, one obtains the descendant graph of self at v, which is constructed by this method.
Combinatorics, Release 10.4

INPUT:

• v – an element of ground_set()

EXAMPLES:

```python
sage: p = graphs.PetersenGraph().twograph().descendant(0)  # needs sage.modules
sage: p.is_strongly_regular(parameters=True)  # needs sage.modules
(9, 4, 1, 2)
```

```python
>>> from sage.all import *

>>> p = graphs.PetersenGraph().twograph().descendant(Integer(0))  # needs sage.modules

>>> p.is_strongly_regular(parameters=True)  # needs sage.modules
(9, 4, 1, 2)
```

```python
sage.combinat.designs.twographs.is_twograph(T)
```

Check whether the incidence system $T$ is a two-graph.

INPUT:
• \(T\) — an incidence structure

**EXAMPLES:**

a two-graph from a graph:

```python
sage: from sage.combinat.designs.twographs import (is_twograph, TwoGraph)
sage: p = graphs.PetersenGraph().twograph()  # needs sage.modules
sage: is_twograph(p)  # needs sage.modules
True
```

a non-regular 2-uniform hypergraph which is a two-graph:

```python
sage: is_twograph(TwoGraph([[1, 2, 3], [1, 2, 4]]))
True
```

`sage.combinat.designs.twographs.taylor_twograph(q)` constructing Taylor's two-graph for \(U_3(q)\), \(q\) odd prime power

The Taylor's two-graph \(T\) has the \(q^3 + 1\) points of the projective plane over \(F_{q^2}\) singular w.r.t. the non-degenerate Hermitean form \(S\) preserved by \(U_3(q)\) as its ground set; the triples are \(\{x, y, z\}\) satisfying the condition that \(S(x, y)S(y, z)S(z, x)\) is square (respectively non-square) if \(q \equiv 1 \mod 4\) (respectively if \(q \equiv 3 \mod 4\)). See §7E of [BL1984].

There is also a \(2 - (q^3 + 1, q + 1, 1)\)-design on these \(q^3 + 1\) points, known as the unital of order \(q\), also invariant under \(U_3(q)\).

**INPUT:**

• \(q\) — a power of an odd prime

**EXAMPLES:**

```python
sage: from sage.combinat.designs.twographs import taylor_twograph
sage: T = taylor_twograph(3); T  # needs sage.rings.finite_rings
Incidence structure with 28 points and 1260 blocks
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.twographs import taylor_twograph
>>> T = taylor_twograph(Integer(3)); T
# needs sage.rings.finite_rings
Incidence structure with 28 points and 1260 blocks
```
sage.combinat.designs.twographs.twograph_descendant \((G, v, name=None)\)

Return the descendant graph w.r.t. vertex \(v\) of the two-graph of \(G\)

In the switching class of \(G\), construct a graph \(\Delta\) with \(v\) an isolated vertex, and return the subgraph \(\Delta \setminus v\).

It is equivalent to, although much faster than, computing the `TwoGraph.descendant()` of two-graph of \(G\), as the intermediate two-graph is not constructed.

**INPUT:**
- \(G\) – a graph
- \(v\) – a vertex of \(G\)
- \(name\) – (default: None); no name, otherwise derive from the construction

**EXAMPLES:**

one of s.r.g.’s from the database:

```python
sage: from sage.combinat.designs.twographs import twograph_descendant
sage: A = graphs.strongly_regular_graph(280, 135, 70)  # optional - gap_package_design internet
sage: twograph_descendant(A, 0).is_strongly_regular(parameters=True)  # optional - gap_package_design internet
(279, 150, 85, 75)
```

```python
>>> from sage.all import *
>>> from sage.combinat.designs.twographs import twograph_descendant
>>> A = graphs.strongly_regular_graph(Integer(280), Integer(135), Integer(70))  # optional - gap_package_design internet
>>> twograph_descendant(A, Integer(0)).is_strongly_regular(parameters=True)  # optional - gap_package_design internet
(279, 150, 85, 75)
```

### 5.1.97 Combinatorial diagrams

A combinatorial diagram is a collection of cells \((i, j)\) indexed by pairs of natural numbers.

For arbitrary diagrams, see `Diagram`. There are also two other specific types of diagrams implemented here. They are northwest diagrams (`NorthwestDiagram`) and Rothe diagrams (`RotheDiagram()`, a special kind of northwest diagram).

**AUTHORS:**
- Trevor K. Karn (2022-08-01): initial version

```python
class sage.combinat.diagram.Diagram (parent, cells, n_rows=None, n_cols=None, check=True)
```

Bases: `ClonableArray`

Combinatorial diagrams with positions indexed by rows and columns.

The positions are indexed by rows and columns as in a matrix. For example, a Ferrers diagram is a diagram obtained from a partition \(\lambda = (\lambda_0, \lambda_1, \ldots, \lambda_\ell)\), where the cells are in rows \(i\) for \(0 \leq i \leq \ell\) and the cells in row \(i\) consist of \((i, j)\) for \(0 \leq j < \lambda_i\). In English notation, the indices are read from top left to bottom right as in a matrix.

Indexing conventions are the same as `Partition`. Printing the diagram of a partition, however, will always be in English notation.

**EXAMPLES:**

To create an arbitrary diagram, pass a list of all cells:
```python
sage: from sage.combinat.diagram import Diagram
sage: cells = [(0,0), (0,1), (1,0), (1,1), (4,4), (4,5), (4,6), (5,4), (7, 6)]
```
```python
sage: D = Diagram(cells); D
```
```python
[(0, 0), (0, 1), (1, 0), (1, 1), (4, 4), (4, 5), (4, 6), (5, 4), (7, 6)]
```
```python
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>>
cells = [(Integer(0),Integer(0)), (Integer(0),Integer(1)), (Integer(1),
  Integer(0)), (Integer(1),Integer(1)), (Integer(4),Integer(4)), (Integer(4),
  Integer(5)), (Integer(4),Integer(6)), (Integer(5),Integer(4)), (Integer(7),
  Integer(6))]
>>> D = Diagram(cells); D
[(0, 0), (0, 1), (1, 0), (1, 1), (4, 4), (4, 5), (4, 6), (5, 4), (7, 6)]
```
We can visualize the diagram by printing O's and .'. O's are present in the cells which are present in the diagram and a . represents the absence of a cell in the diagram:
```python
sage: D.pp()
O O . . . . .
O O . . . . .
. . . . . . .
. . . . . . .
. . . O O O
. . . O . .
. . . . . . .
. . . . . . O
```
```python
>>> from sage.all import *
>>>
D.pp()
O O . . . . .
O O . . . . .
. . . . . . .
. . . . . . .
. . . O O O
. . . O . .
. . . . . . .
. . . . . . O
```
We can also check if certain cells are contained in a given diagram:
```python
sage: (1, 0) in D
True
```
```python
sage: (2, 2) in D
False
```
```python
>>> from sage.all import *
>>> (Integer(1), Integer(0)) in D
True
>>> (Integer(2), Integer(2)) in D
False
```
If you know that there are entire empty rows or columns at the end of the diagram, you can manually pass them with keyword arguments n_rows= or n_cols=:
```python
sage: Diagram([(0,0), (0,3), (2,2), (2,4)]).pp()  
```
(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

.. . . . .
.. O O O
```
sage: Diagram([(Integer(0), Integer(0)), (Integer(0), Integer(3)), (Integer(2), Integer(2)), (Integer(2), Integer(4))]).pp()
```

```
O O . . .
. . . . .
. O O . O
. . . . .
. . . . .
. . . . .
```

```
>>> from sage.all import *
```

```
>>> Diagram([(Integer(0), Integer(0)), (Integer(0), Integer(3)), (Integer(2), Integer(2)), (Integer(2), Integer(4))]).pp()
```

```
O O O O .
. . . . .
. O O . .
. . . . .
. . . . .
. . . . .
```

```
>>> Diagram([(Integer(0), Integer(0)), (Integer(0), Integer(3)), (Integer(2), Integer(2)), (Integer(2), Integer(4))], n_rows=Integer(6), n_cols=Integer(6)).pp()
```

```
O O O O O
. . . . .
. O O . .
. . . . .
. . . . .
. . . . .
```

cells()

Return a list of the cells contained in the diagram self.

EXAMPLES:

```
sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D1.cells()
[(0, 2), (0, 3), (1, 1), (3, 2)]
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram

>>> D1 = Diagram([(Integer(0),Integer(0)), (Integer(0),Integer(3)), (Integer(2), Integer(2)), (Integer(2), Integer(4))])

>>> D1.cells()
[(0, 2), (0, 3), (1, 1), (3, 2)]
```

cell

Check that this is a valid diagram.

EXAMPLES:

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,0), (0,3), (2,2), (2,4)])

sage: D.check()
```

```
>>> from sage.all import *

>>> from sage.combinat.diagram import Diagram

>>> D = Diagram([(Integer(0),Integer(0)), (Integer(0),Integer(3)), (Integer(0),Integer(3))])
```

(continues on next page)
In the next two examples, a bad diagram is passed. The first example fails because one cell is indexed by negative integers:

```
sage: D = Diagram([(0,0), (0,-3), (2,2), (2,4)])
Traceback (most recent call last):
...
ValueError: diagrams must be indexed by non-negative integers
```

The next example fails because one cell is indexed by rational numbers:

```
sage: D = Diagram([(0,0), (0,3), (2/3,2), (2,4)])
Traceback (most recent call last):
...
ValueError: diagrams must be indexed by non-negative integers
```

**n_cells()**

Return the total number of cells contained in the diagram `self`.

**EXAMPLES:**

```
sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D1.number_of_cells()  
4
sage: D1.n_cells()  
4
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram

>>> D1 = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1),Integer(1)),(Integer(3),Integer(2))])

>>> D1.number_of_cells()  
4
>>> D1.n_cells()  
4
```

**ncols()**

Return the total number of rows of `self`. 
EXAMPLES:
The following example has three columns which are filled, but they are contained in rows 0 to 3 (for a total of four):

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D.number_of_cols()
4
sage: D.ncols()
4
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram

>>> D = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1),
˓→Integer(1)),(Integer(3),Integer(2))])

>>> D.number_of_cols()
4

>>> D.ncols()
4
```

We can also include empty columns at the end:

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,2),(0,3),(1,1),(3,2)], n_cols=6)
sage: D.number_of_cols()
6
sage: D.pp()
. . O O . .
. O . . . .
. . . . . .
. . O . . .
```

```
>>> from sage.all import *

>>> from sage.combinat.diagram import Diagram

>>> D = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1),
˓→Integer(1)),(Integer(3),Integer(2))], n_cols=Integer(6))

>>> D.number_of_cols()
6

>>> D.pp()
. . O O . .
. O . . . .
. . . . . .
. . O . . .
```

`nrows()`

Return the total number of rows of `self`.

EXAMPLES:
The following example has three rows which are filled, but they are contained in rows 0 to 3 (for a total of four):

```
sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D1.number_of_rows()
4
```

(continues on next page)
The total number of rows includes including those which are empty. We can also include empty rows at the end:

```
sage: from sage.combinat.diagram import Diagram
dsage: D = Diagram([(0,2),(0,3),(1,1),(3,2)], n_rows=6)
dsage: D.number_of_rows()
6
dsage: D.pp()
 . . O O
  . O .
  . . .
  . . O .
  . . . .
  . . . .
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1), Integer(1)),(Integer(3),Integer(2))], n_rows=Integer(6))
>>> D.number_of_rows()
6
>>> D.pp()
 . . O O
  . O .
  . . .
  . . O .
  . . . .
  . . . .
```

```
number_of_cells()
```

Return the total number of cells contained in the diagram self.

EXAMPLES:

```
sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D1.number_of_cells()
4
sage: D1.n_cells()
4
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
```
D1 = Diagram([(Integer(0), Integer(2)), (Integer(0), Integer(3)), (Integer(1), Integer(1)), (Integer(3), Integer(2))])

D1.number_of_cells()
4

D1.n_cells()
4

**number_of_cols()**

Return the total number of rows of self.

**EXAMPLES:**

The following example has three columns which are filled, but they are contained in rows 0 to 3 (for a total of four):

```python
def main():
    from sage.combinat.diagram import Diagram
    D = Diagram([(0, 2), (0, 3), (1, 1), (3, 2)])
    D.number_of_cols()
    4
    D.ncols()
    4

if __name__ == '__main__':
    main()
```

We can also include empty columns at the end:

```python
def main():
    from sage.all import *
    from sage.combinat.diagram import Diagram
    D = Diagram([(0, 2), (0, 3), (1, 1), (3, 2), (n_cols=Integer(6))]
    D.number_of_cols()
    6
    D.pp()
    . . O O . .
    . O . . . .
    . . . . . .
    . . O . . .

if __name__ == '__main__':
    main()
```
EXAMPLES:

The following example has three rows which are filled, but they are contained in rows 0 to 3 (for a total of four):

```python
sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D1.number_of_rows()
4
sage: D1.nrows()
4
```

```python
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D1 = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1), Integer(1)),(Integer(3),Integer(2))])
>>> D1.number_of_rows()
4
>>> D1.nrows()
4
```

The total number of rows includes including those which are empty. We can also include empty rows at the end:

```python
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,2),(0,3),(1,1),(3,2)], n_rows=6)
sage: D.number_of_rows()
6
sage: D.pp()
.. O O
  . O ..
  . . .
  . O .
  . . .
  . . .

>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1), Integer(1)),(Integer(3),Integer(2))], n_rows=Integer(6))
>>> D.number_of_rows()
6
>>> D.pp()
.. O O
  . O ..
  . . .
  . O .
  . . .
  . . .
```

`pp()`

Return a visualization of the diagram.

Cells which are present in the diagram are filled with a O. Cells which are not present in the diagram are filled with a .

EXAMPLES:
sage: from sage.combinat.diagram import Diagram
sage: Diagram([(0,0), (0,3), (2,2), (2,4)]).pp()
O . . O .
. . . . .
. . . . .

sage: Diagram([(0,0), (0,3), (2,2), (2,4)], n_rows=6, n_cols=6).pp()
O . . O . .
. . . . . .
. . . . . .
. . . . . .
. . . . . .

sage: Diagram([]).pp()

size()

Return the total number of cells contained in the diagram self.

EXAMPLES:

sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D1.number_of_cells()
4
sage: D1.n_cells()
4

>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram

>>> D1 = Diagram([(Integer(0),Integer(0)), (Integer(0),Integer(3)), (Integer(2), Integer(2)), (Integer(2),Integer(4))]).pp()
O . . O .
. . . . .
. . . . .

>>> D1 = Diagram([(Integer(0),Integer(0)), (Integer(0),Integer(3)), (Integer(2), Integer(2)), (Integer(2),Integer(4))], n_rows=Integer(6), n_cols=Integer(6)).pp()
O . . O . .
. . . . . .
. . . . . .
. . . . . .
. . . . . .

>>> Diagram([]).pp()

specht_module (base_ring=None)

Return the Specht module corresponding to self.
EXAMPLES:

```python
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,0), (1,1), (2,2), (2,3)])
sage: SM = D.specht_module(QQ)  # needs sage.modules
sage: s = SymmetricFunctions(QQ).s()  # needs sage.modules
sage: s(SM.frobenius_image())  # needs sage.modules
```

```python
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D = Diagram([(Integer(0),Integer(0)), (Integer(1),Integer(1)), (Integer(2),Integer(2)), (Integer(2),Integer(3))])
>>> SM = D.specht_module(QQ)  # needs sage.modules
>>> s = SymmetricFunctions(QQ).s()  # needs sage.modules
>>> s(SM.frobenius_image())  # needs sage.modules
```

**specht_module_dimension** *(base_ring=None)*

Return the dimension of the Specht module corresponding to self.

**INPUT:**

- base_ring – (default: QQ) the base ring

**EXAMPLES:**

```python
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,0), (1,1), (2,2), (2,3)])
```

```python
sage: D.specht_module_dimension()  # needs sage.modules
12
```

```python
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D = Diagram([(Integer(0),Integer(0)), (Integer(1),Integer(1)), (Integer(2),Integer(2)), (Integer(2),Integer(3))])
```

```python
>>> D.specht_module_dimension()  # needs sage.modules
12
```

**class** `sage.combinat.diagram.Diagrams` *(category=None)*

**Bases:** `UniqueRepresentation`, `Parent`

The class of combinatorial diagrams.

5.1. Comprehensive Module List
A *combinatorial diagram* is a set of cells indexed by pairs of natural numbers. Calling an instance of `Diagrams` is one way to construct diagrams.

**EXAMPLES:**

```python
sage: from sage.combinat.diagram import Diagrams
sage: Dgms = Diagrams()

sage: D = Dgms([(0,0), (0,3), (2,2), (2,4)])

sage: D.parent()
Combinatorial diagrams
```

**Element**

alias of `Diagram`

`from_composition(alpha)`

Create the diagram corresponding to a weak composition \( \alpha \vdash n \).

**EXAMPLES:**

```python
sage: alpha = Composition([3,0,2,1,4,4])
sage: from sage.combinat.diagram import Diagrams

sage: Diagrams()(alpha).pp()
O O O .
. . . .
O O . .
O O O O
O O O O

sage: Diagrams().from_composition(alpha).pp()
O O O .
. . . .
```

(continues on next page)
from\_polyomino(p)

Create the diagram corresponding to a 2d Polyomino

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
    # needs sage.modules
sage: p = Polyomino([(0,0),(1,0),(1,1),(1,2)])
    # needs sage.modules
sage: from sage.combinat.diagram import Diagrams
sage: Diagrams()(p).pp()  # needs sage.modules
  o .
  o o o
```

```
>>> from sage.all import *
>>> from sage.combinat.tiling import Polyomino
    # needs sage.modules
>>> p = Polyomino([(Integer(0),Integer(0)),(Integer(1),Integer(0)),
  (Integer(1),Integer(1)),(Integer(1),Integer(2))]) # needs sage.modules
>>> from sage.combinat.diagram import Diagrams
>>> Diagrams()(p).pp()  # needs sage.modules
      o .
      o o o
```

We can also call this method directly:

```
sage: Diagrams().from\_polyomino(p).pp()  # needs sage.modules
      o .
      o o o
```

```
>>> from sage.all import *
>>> Diagrams().from\_polyomino(p).pp()  # needs sage.modules
      o .
      o o o
```

This only works for a 2d Polyomino:

```
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')  # needs sage.modules
sage: Diagrams().from\_polyomino(p)  # needs sage.modules
Traceback (most recent call last):
  ... ValueError: the polyomino must be 2 dimensional
```
from sage.all import *

p = Polyomino([(Integer(0),Integer(0),Integer(0)), (Integer(0),Integer(1),
    Integer(0)), (Integer(1),Integer(1),Integer(0)), (Integer(1),Integer(1),
    Integer(1))], color='blue')  # needs sage.modules

Diagrams().from_polyomino(p)  # needs sage.modules

Traceback (most recent call last):
...
ValueError: the polyomino must be 2 dimensional

from_zero_one_matrix(M, check=True)

Get a diagram from a matrix with entries in \{0, 1\}, where positions of cells are indicated by the 1's.

EXAMPLES:

sage: M = matrix([[1,0,1,1],[0,1,1,0]])
...

sage: M = matrix([[1, 0, 0], [1, 0, 0], [0, 0, 0]])
...

sage: M = matrix([[Integer(1), Integer(0), Integer(0)], [Integer(1), Integer(0),
    Integer(0)]])  # needs sage.modules

sage: M = matrix([[Integer(1), Integer(0), Integer(0)], [Integer(1), Integer(0),
    Integer(0)]])  # needs sage.modules
class sage.combinat.diagram.NorthwestDiagram(parent, cells, n_rows=None, n_cols=None, check=True)

Bases: Diagram

Diagrams with the northwest property.

A diagram is a set of cells indexed by natural numbers. Such a diagram has the northwest property if the presence of cells \((i_1, j_1)\) and \((i_2, j_2)\) implies the presence of the cell \((\min(i_1, i_2), \min(j_1, j_2))\). Diagrams with the northwest property are called northwest diagrams.

For general diagrams see Diagram.

EXAMPLES:

```
sage: from sage.combinat.diagram import NorthwestDiagram
sage: N = NorthwestDiagram([(0,0), (0, 2), (2,0)])
>>> from sage.all import *
>>> from sage.combinat.diagram import NorthwestDiagram
>>> N = NorthwestDiagram([(Integer(0),Integer(0)), (Integer(0), Integer(3)), (Integer(3),Integer(0))])
```

To visualize them, use the .pp() method:

```
sage: N.pp()
 . .
 . .
```

```
>> from sage.all import *
>>> N.pp()
 . .
 . .
```

check()

A diagram has the northwest property if the presence of cells \((i_1, j_1)\) and \((i_2, j_2)\) implies the presence of the cell \((\min(i_1, i_2), \min(j_1, j_2))\). This method checks if the northwest property is satisfied for self.

EXAMPLES:

```
sage: from sage.combinat.diagram import NorthwestDiagram
sage: N = NorthwestDiagram([(0,0), (0,3), (3,0)])
sage: N.check()
>>> from sage.all import *
>>> from sage.combinat.diagram import NorthwestDiagram
>>>
```

Here is a non-example:

```
sage: notN = NorthwestDiagram([(0,1), (1,0)]) #.check() is implicit
Traceback (most recent call last):
...
ValueError: diagram is not northwest
```
peelable_tableaux()

Return the set of peelable tableaux whose diagram is self.

For a fixed northwest diagram $D$, we say that a Young tableau $T$ is $D$-peelable if:

1. the row indices of the cells in the first column of $D$ are the entries in an initial segment in the first column of $T$ and
2. the tableau $Q$ obtained by removing those cells from $T$ and playing jeu de taquin is $(D - C)$-peelable, where $D - C$ is the diagram formed by forgetting the first column of $D$.

Reiner and Shimozono [RS1995] showed that the number $\text{red}(w)$ of reduced words of a permutation $w$ may be computed using the peelable tableaux of the Rothe diagram $D(w)$. Explicitly,

$$\text{red}(w) = \sum_T f_{\text{shape } T},$$

where the sum runs over the $D(w)$-peelable tableaux $T$ and $f_\lambda$ is the number of standard Young tableaux of shape $\lambda$ (which may be computed using the hook-length formula).

EXAMPLES:

We can compute the $D$-peelable diagrams for a northwest diagram $D$:

```python
sage: from sage.combinat.diagram import NorthwestDiagram
sage: cells = [(0,0), (0,1), (0,2), (1,0), (2,0), (2,2), (2,4),
           ..., (4,0), (4,2)]
 sage: D = NorthwestDiagram(cells); D.pp()
    O O O . .
    O . . . .
    O . O . O
    . . . . .
    O . O . .

sage: D.peelable_tableaux()
    {[[1, 1, 1], [2, 3, 3], [3, 5], [5]],
     [[1, 1, 1, 3], [2, 3], [3, 5], [5]]}
```
EXAMPLES:

If the diagram is only one column, there is only one peelable tableau:

```
sage: from sage.combinat.diagram import NorthwestDiagram
sage: NWD = NorthwestDiagram([(0,0), (2,0)])
sage: NWD.peelable_tableaux()
{[[1], [3]]}
```

```
>>> from sage.all import *

D = NorthwestDiagram([(Integer(0), Integer(0)), (Integer(2), Integer(0))])

D.peelable_tableaux()
{[[1], [3]]}
```

From [RS1995], we know that there is only one peelable tableau for the Rothe diagram of the permutation (in one-line notation) 251643:

```
sage: D = NorthwestDiagram([(Integer(1), Integer(2)), (Integer(1), Integer(3)),
                          (Integer(3), Integer(2)), (Integer(3), Integer(3)),
                          (Integer(4), Integer(2))])

D.peelable_tableaux()
{[[2, 2], [4, 4], [5]]}
```

Here are all the intermediate steps to compute the peelables for the Rothe diagram of (in one-line notation) 64817235. They are listed from deepest in the recursion to the final step. The recursion has depth five in this case so we will label the intermediate tableaux by $D_i$ where $i$ is the step in the recursion at which they appear.

Start with the one that has a single column:

```
sage: D5 = NorthwestDiagram([(2,0)]); D5.pp()
.

sage: D5.peelable_tableaux()
{[[3]]}
```

5.1. Comprehensive Module List
>>> from sage.all import *
>>> D5 = NorthwestDiagram([(Integer(2), Integer(0))]); D5.pp()
   .
   O
>>> D5.peelable_tableaux()
{[[3]]}

Now we know all of the $D_5$ peelables, so we can compute the $D_4$ peelables:

```
sage: D4 = NorthwestDiagram([(0, 0), (2,0), (4, 0), (2, 2)])
sage: D4.pp()
O . .
 . .
O . O
 . .
O . .
sage: D4.peelable_tableaux()
{[[1, 3], [3], [5]]}
```

```
>>> D4 = NorthwestDiagram([(Integer(0), Integer(0)), (Integer(2),Integer(0)),
                          (Integer(4), Integer(0)), (Integer(2), Integer(2))])
>>> D4.pp()
O . .
 . .
O . O
 . .
O . .
>>> D4.peelable_tableaux()
{[[1, 3], [3], [5]]}
```

There is only one $D_4$ peelable, so we can compute the $D_3$ peelables:

```
sage: D3 = NorthwestDiagram([(0,0), (0,1), (2, 1), (2, 3), (4,1)])
sage: D3.pp()
O O . .
 . . .
. O . O
 . . .
. O . .
sage: D3.peelable_tableaux()
{[[1, 1], [3, 3], [5]], [[1, 1, 3], [3], [5]]}
```

```
>>> D3 = NorthwestDiagram([(Integer(0),Integer(0)), (Integer(0),Integer(1)),
                          (Integer(2), Integer(1)), (Integer(2), Integer(3)), (Integer(4),
                          Integer(1))])
>>> D3.pp()
O O . .
 . . .
. O . O
 . . .
. O . .
```

(continues on next page)
D3.peelable_tableaux()
{[[1, 1], [3, 3], [5]], [[1, 1], [3], [5]]}

Now compute the $D_2$ peelables:

```
sage: cells = [(0,0), (0,1), (0,2), (1,0), (2,0), (2,2), (2,4),
            (4,0), (4,2)]

sage: D2 = NorthwestDiagram(cells); D2.pp()
  O O O . .
  O . . . .
  O . O . O
  . . . . .
  O . O . .

sage: D2.peelable_tableaux()
{[[1, 1, 1], [2, 3, 3], [3, 5], [5]],
 [[1, 1, 1, 3], [2, 3], [3, 5], [5]]}
```

And the $D_1$ peelables:

```
sage: cells = [(0,0), (0,1), (0,2), (0,3), (1,0), (1,1), (2,0),
            (2,1), (2,3), (2,5), (4,0), (4,1), (4,3)]

sage: D1 = NorthwestDiagram(cells); D1.pp()
  O O O . .
  O . . . .
  O . O . .
  . . . . .
  O . O . .

sage: D1.peelable_tableaux()
{[[1, 1, 1, 1], [2, 2, 3, 3], [3, 3, 5], [5, 5]],
 [[1, 1, 1, 1, 3], [2, 2, 3], [3, 3, 5], [5, 5]]}
```

```
>>> from sage.all import *

>>> cells = [(Integer(0),Integer(0)), (Integer(0),Integer(1)), (Integer(0),
            Integer(2)), (Integer(1),Integer(0)), (Integer(2),Integer(0)), (Integer(2),
            Integer(2)), (Integer(2),Integer(4)),
            (Integer(4),Integer(0)), (Integer(4),Integer(2))]

>>> D2 = NorthwestDiagram(cells); D2.pp()
  O O O . .
  O . . . .
  O . O . .
  . . . . .
  O . O . .

>>> D2.peelable_tableaux()
{[[1, 1, 1], [2, 3, 3], [3, 5], [5]],
 [[1, 1, 1, 3], [2, 3], [3, 5], [5]]}
```

```
>>> from sage.all import *

>>> cells = [(Integer(0),Integer(0)), (Integer(0),Integer(1)), (Integer(0),
            Integer(2)), (Integer(1),Integer(0)), (Integer(2),Integer(0)), (Integer(2),
            Integer(1)), (Integer(2),Integer(0)), (Integer(2),Integer(3)), (Integer(2),
            Integer(5)), (Integer(4),Integer(0)), (Integer(4),Integer(1)), (Integer(4),
            Integer(2)), (Integer(4),Integer(3))]

>>> D2 = NorthwestDiagram(cells); D2.pp()
  O O O . .
  O . . . .
  O . . . .
  . . . . .
  O . O . .

>>> D2.peelable_tableaux()
{[[1, 1, 1], [2, 3, 3], [3, 5], [5]],
 [[1, 1, 1, 3], [2, 3], [3, 5], [5]]}
```

(continues on next page)
Which we can use to get the $D$ peelables:

```
sage: cells = [(0,0), (0,1), (0,2), (0,3), (0,4),
            ....: (1,0), (1,1), (1,2),
            ....: (2,0), (2,1), (2,2), (2,4), (2,6),
            ....: (4,1), (4,2), (4,4)]
sage: D = NorthwestDiagram(cells); D.pp()
O O O O O . .
O O O . . . .
O O O . O . O
. . . . . . . .
sage: D.peelable_tableaux()
{[[1, 1, 1, 1, 1], [2, 2, 2, 3, 3], [3, 3, 3], [5, 5, 5]],
[[1, 1, 1, 1, 1], [2, 2, 2, 3, 3], [3, 3, 3, 5], [5, 5]],
[[1, 1, 1, 1, 1, 3], [2, 2, 2, 3], [3, 3, 3], [5, 5, 5]],
[[1, 1, 1, 1, 1, 3], [2, 2, 2, 3], [3, 3, 3, 5], [5, 5]]}
```

ALGORITHM:

This implementation uses the algorithm suggested in Remark 25 of [RS1995].
Diagrams satisfying the northwest property.

A diagram $D$ is a **northwest diagram** if for every two cells $(i_1, j_1)$ and $(i_2, j_2)$ in $D$ then there exists the cell $(\min(i_1, i_2), \min(j_1, j_2)) \in D$.

**EXAMPLES:**

```python
sage: from sage.combinat.diagram import NorthwestDiagram
sage: N = NorthwestDiagram([(0,0), (0, 10), (5,0)]); N.pp()
O . . . . . . . . O
. . . . . . . . . .
. . . . . . . . . .
. . . . . . . . . .
O . . . . . . . . .

>>> from sage.all import *
>>> from sage.combinat.diagram import NorthwestDiagram

>>> N = NorthwestDiagram([(Integer(0), Integer(0)), (Integer(0), Integer(10)),
\rightarrow (Integer(5), Integer(0))]); N.pp()
O . . . . . . . . O
. . . . . . . . . .
. . . . . . . . . .
. . . . . . . . . .
O . . . . . . . . .

Note that checking whether or not the northwest property is satisfied is automatically checked. The diagram found by adding the cell $(1, 1)$ to the diagram above is **not** a northwest diagram. The cell $(1, 0)$ should be present due to the presence of $(5, 0)$ and $(1, 1)$:

```python
sage: from sage.combinat.diagram import Diagram
sage: Diagram([(0, 0), (0, 10), (5, 0), (1, 1)]).pp()
O . . . . . . . . O
. O . . . . . . . .
. . . . . . . . . .
. . . . . . . . . .
O . . . . . . . . .

sage: NorthwestDiagram([(0, 0), (0, 10), (5, 0), (1, 1)])
Traceback (most recent call last):
...
ValueError: diagram is not northwest
```

```python
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram

>>> Diagram([(Integer(0), Integer(0)), (Integer(0), Integer(10)),
\rightarrow (Integer(5), Integer(0)), (Integer(1), Integer(1))]).pp()
O . . . . . . . . O
. O . . . . . . . .
. . . . . . . . . .
. . . . . . . . . .
O . . . . . . . . .

>>> NorthwestDiagram([(Integer(0), Integer(0)), (Integer(0), Integer(10)),
\rightarrow (Integer(5), Integer(0)), (Integer(1), Integer(1))])
Traceback (most recent call last):
...
ValueError: diagram is not northwest
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

ValueError: diagram is not northwest

However, this behavior can be turned off if you are confident that you are providing a northwest diagram:

```python
sage: N = NorthwestDiagram([(0, 0), (0, 10), (5, 0),
                        (1, 1), (0, 1), (1, 0)],
                        check=False)
```

```python
sage: N.pp()
  O O . . . . . . . O
  O O . . . . . . .  
    . . . . . . . . .
    . . . . . . . . .
  O . . . . . . . .  
```

```python
>>> from sage.all import *

>>> N = NorthwestDiagram([ (Integer(0), Integer(0)), (Integer(0), Integer(10)),
                        (Integer(5), Integer(0)),
                        (Integer(1), Integer(1)), (Integer(0), Integer(1)),
                        (Integer(1), Integer(0))],
                        check=False)
```

```python
>>> N.pp()
  O O . . . . . . . O
  O O . . . . . . .  
    . . . . . . . . .
    . . . . . . . . .
  O . . . . . . . .  
```

Note that arbitrary diagrams which happen to be northwest diagrams only live in the parent of `Diagrams`:

```python
sage: D = Diagram([(0, 0), (0, 10), (5, 0), (1, 1), (0, 1), (1, 0)])
sage: D.pp()
  O O . . . . . . . O
  O O . . . . . . .  
    . . . . . . . . .
    . . . . . . . . .
  O . . . . . . . .  
```

```python
sage: from sage.combinat.diagram import NorthwestDiagrams
sage: D in NorthwestDiagrams()
False
```

```python
>>> from sage.all import *

>>> D = Diagram([ (Integer(0), Integer(0)), (Integer(0), Integer(10)), (Integer(5),
                        Integer(0)), (Integer(1), Integer(1)), (Integer(0), Integer(1)),
                        (Integer(1), Integer(0))])
```

```python
>>> D.pp()
  O O . . . . . . . O
  O O . . . . . . .  
    . . . . . . . . .
    . . . . . . . . .
  O . . . . . . . .  
```

```python
>>> from sage.combinat.diagram import NorthwestDiagrams
```

(continues on next page)
Here are some more examples:

```python
sage: from sage.combinat.diagram import NorthwestDiagram, NorthwestDiagrams
sage: D = NorthwestDiagram([(0,1), (0,2), (1,1)]); D.pp()
 . O O
 . O .
sage: NWDgms = NorthwestDiagrams()
sage: D = NWDgms([(1,1), (1,2), (2,1)]); D.pp()
 . . .
 . O O
 . O .
sage: D.parent()
Combinatorial northwest diagrams
```

Additionally, there are natural constructions of a northwest diagram given the data of a permutation (Rothe diagrams are the prototypical example of northwest diagrams), or the data of a partition of an integer, or a skew partition.

The Rothe diagram $D(\omega)$ of a permutation $\omega$ is specified by the cells

$$D(\omega) = \{(\omega_j, i) : i < j, \omega_i > \omega_j\}.$$  

We can construct one by calling `rothe_diagram()` method on the set of all `NorthwestDiagrams`:

```python
sage: w = Permutations(4)([4,3,2,1])
sage: NorthwestDiagrams().rothe_diagram(w).pp()
 O O O .
 O O . .
 O . . .
 . . . .
```

```python
>>> from sage.all import *
>>>
>>> w = Permutations(Integer(4))([Integer(4),Integer(3),Integer(2),Integer(1)])
>>> NorthwestDiagrams().rothe_diagram(w).pp()
 O O O .
 O O . .
 O . . .
 . . . .
```
To turn a Ferrers diagram into a northwest diagram, we may call \texttt{from\_partition()}. This will return a Ferrer's diagram in the set of all northwest diagrams. For many use-cases it is probably better to get Ferrer's diagrams by the corresponding method on partitions, namely \texttt{sage.combinat.partitions.Partitions.ferrers\_diagram():}

```
sage: mu = Partition([7,3,1,1])
sage: mu.pp()
******
***
*
```

```sage
NorthwestDiagrams().from\_partition(mu).pp()
```

```
o o o o o o o
o o o . . .
o . . . . . .
o . . . . . .
o . . . . . .
```

```
>>> from sage.all import *

>>> mu = Partition([Integer(7),Integer(3),Integer(1),Integer(1)])

>>> mu.pp()
******
***
*
```

```sage
NorthwestDiagrams().from\_partition(mu).pp()
```

```
o o o o o o o
o o o . . .
o . . . . . .
o . . . . . .
o . . . . . .
```

It is also possible to turn a Ferrers diagram of a skew partition into a northwest diagram, although it is more subtle than just using the skew diagram itself. One must first reflect the partition about a vertical axis so that the skew partition looks “backwards”:

```
sage: mu, nu = Partition([5,4,3,2,1]), Partition([3,2,1])
sage: s = mu/nu; s.pp()
**
**
**
*
```

```sage
NorthwestDiagrams().from\_skew\_partition(s).pp()
```

```
o . .
. o .
. . o o
. . . o
. . . o
```

```
>>> from sage.all import *

>>> mu, nu = Partition([Integer(5),Integer(4),Integer(3),Integer(2),Integer(1)]), Partition([Integer(3),Integer(2),Integer(1)])

>>> s = mu/nu; s.pp()
**
**
**
*
```

Combinatorics, Release 10.4

Element

alias of NorthwestDiagram

from_parallelogram_polyomino(p)

Create the diagram corresponding to a ParallelogramPolyomino.

EXAMPLES:

```python
sage: p = ParallelogramPolyomino([[0, 0, 1, 0, 0, 0, 1, 1],
                                 [1, 1, 0, 1, 0, 0, 0, 0]])
```

```python
sage: from sage.combinat.diagram import NorthwestDiagrams
```

```python
sage: NorthwestDiagrams().from_parallelogram_polyomino(p).pp()  # needs sage.modules
```

```python
O O .
```

```python
O O O
```

```python

. . O O
```

```python
. . . O O
```

```python
. . . . O
```

```python
. . . . .
```

```python
from_partition(mu)

Return the Ferrer’s diagram of mu as a northwest diagram.

EXAMPLES:

```python
sage: mu = Partition([5,2,1]); mu.pp()
```

```python
******
```

```python
**
```

```python
*
```

```python
sage: mu.parent()
```

Partitions

```python
sage: from sage.combinat.diagram import NorthwestDiagrams
```

```python
sage: D = NorthwestDiagrams().from_partition(mu)
```

```python
sage: D.pp()
```

from_permutation(w)

Return the Rothe diagram of \( w \).

We construct a northwest diagram from a permutation by constructing its Rothe diagram. Formally, if \( \omega \) is a Permutation then the Rothe diagram \( D(\omega) \) is the diagram whose cells are

\[
D(\omega) = \{ (\omega_j, i) : i < j, \omega_i > \omega_j \}.
\]

Informally, one can construct the Rothe diagram by starting with all \( n^2 \) possible cells, and then deleting the cells \( (i, \omega(i)) \) as well as all cells to the right and below. (These are sometimes called “death rays”.)
See also:

RotheDiagram()

EXAMPLES:

```
sage: from sage.combinat.diagram import NorthwestDiagrams
sage: w = Permutations(3)([2,1,3])
sage: NorthwestDiagrams().rothe_diagram(w).pp()
\ O \ . 
\ . \ . 
\ . \ . 

sage: NorthwestDiagrams().from_permutation(w).pp()
\ O \ . 
\ . \ . 
\ . \ . 

sage: w = Permutations(8)([2,5,4,1,3,6,7,8])
sage: NorthwestDiagrams().rothe_diagram(w).pp()

. . .
>>> w = Permutations(Integer(8))([Integer(2), Integer(5), Integer(4), Integer(1),
Integer(3), Integer(6), Integer(7), Integer(8)])
>>> NorthwestDiagrams().rothe_diagram(w).pp()
O . . . . . . .
O . O O . . . .
O . O . . . . .
```

```python
sage.combinat.diagram.RotheDiagram(w)
The Rothe diagram of a permutation w.
```

EXAMPLES:

```python
sage: w = Permutations(9)([1, 7, 4, 5, 9, 3, 2, 8, 6])
```

(continues on next page)
O O O . . . .
O O . . . . .
O . O . . . .
. . . . . . . .
. . . . O . . .
. . . . . . . .
. . . . . . . .
. . . . . . . .
. . . . . . . .
. . . . . . . .

>>> from sage.all import *

>>> w = Permutations(Integer(9))([Integer(1), Integer(7), Integer(4), Integer(5),
˓→Integer(9), Integer(3), Integer(2), Integer(8), Integer(6)])

>>> from sage.combinat.diagram import RotheDiagram

>>> D = RotheDiagram(w); D.pp()
O O O . . . .
O O . . . . .
O O . . . . .
O O . . O . O.
O . . . . . . .
. . . . . . . .
. . . . O . . .
. . . . . . . .
. . . . . . . .
. . . . . . . .

The Rothe diagram is a northwest diagram:

sage: D.parent()
Combinatorial northwest diagrams

>>> from sage.all import *

>>> D.parent()
Combinatorial northwest diagrams

Some other examples:

sage: RotheDiagram([2, 1, 4, 3]).pp()
O . . .
. . . .
. . O .
. . . .

sage: RotheDiagram([4, 1, 3, 2]).pp()
O O O .
. . . .
. O . .
. . . .

>>> from sage.all import *

>>> RotheDiagram([Integer(2), Integer(1), Integer(4), Integer(3)]).pp()
O . . .
. . . .
. . O .
. . . .

>>> RotheDiagram([Integer(4), Integer(1), Integer(3), Integer(2)]).pp()
O O O .
Currently, only elements of the set of `sage.combinat.permutations.Permutations` are supported. In particular, elements of permutation groups are not supported:

```python
sage: w = SymmetricGroup(9).an_element()  # needs sage.groups
sage: RotheDiagram(w)  # needs sage.groups
Traceback (most recent call last):
... ValueError: w must be a permutation
```

```python
>>> from sage.all import *
>>> w = SymmetricGroup(Integer(9)).an_element()  # needs sage.groups
>>> RotheDiagram(w)  # needs sage.groups
Traceback (most recent call last):
... ValueError: w must be a permutation
```

5.1.98 Diagram and Partition Algebras

AUTHORS:

- Mike Hansen (2007): Initial version
- Mike Zabrocki (2018): Implementation of individual element diagram classes
- Travis Scrimshaw (2024): Implemented the Potts representation of the partition algebra.

```python
class sage.combinat.diagram_algebras.AbstractPartitionDiagram(parent, d, check=True)
```

Abstract base class for partition diagrams.

This class represents a single partition diagram, that is used as a basis key for a diagram algebra element. A partition diagram should be a partition of the set \{1, \ldots, k, -1, \ldots, -k\}. Each such set partition is regarded as a graph on nodes \{1, \ldots, k, -1, \ldots, -k\} arranged in two rows, with nodes 1, \ldots, k in the top row from left to right and with nodes -1, \ldots, -k in the bottom row from left to right, and an edge connecting two nodes if and only if the nodes lie in the same subset of the set partition.

EXAMPLES:
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: pd1 = da.AbstractPartitionDiagram(pd, [[1,2],[-1,-2]])
sage: pd2 = da.AbstractPartitionDiagram(pd, [[1,2],[-1,-2]])

sage: pd1
{{-2, -1}, {1, 2}}

sage: pd1 == pd2
True

sage: pd1 == [[1,2],[-1,-2]]
True

sage: pd1 == ((-2,-1),(2,1))
True

sage: pd1 == SetPartition([[1,2],[-1,-2]])
True

sage: pd3 = da.AbstractPartitionDiagram(pd, [[1,-2],[-1,2]])
sage: pd1 == pd3
False

sage: pd4 = da.AbstractPartitionDiagram(pd, [[1,2],[3,4]])
Traceback (most recent call last):
  ... ValueError: {{1, 2}, {3, 4}} does not represent two rows of vertices of order 2

---

base_diagram()

Return the underlying implementation of the diagram.

OUTPUT:

* tuple of tuples of integers

EXAMPLES:
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: pd([[1,2],[-1,-2]]).base_diagram() == ((-2,-1),(1,2))
True

check()
Check the validity of the input for the diagram.

compose(other, check=True)
Compose self with other.
The composition of two diagrams \(X\) and \(Y\) is given by placing \(X\) on top of \(Y\) and removing all loops.

OUTPUT:
A tuple where the first entry is the composite diagram and the second entry is how many loop were removed.

Note: This is not really meant to be called directly, but it works to call it this way if desired.

EXAMPLES:

sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: pd([[1,2],[-1,-2]]).compose(pd([[1,2],[-1,-2]]))
({{-2, -1}, {1, 2}}, 1)

count_blocks_of_size(n)
Count the number of blocks of a given size.

INPUT:

• \(n\) – a positive integer

EXAMPLES:
```python
>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import PartitionDiagram
>>> pd = PartitionDiagram([[-1,3,5],[2,4],[3,1,2],[5],[-4]])
>>> pd.count_blocks_of_size(Integer(1))
2
>>> pd.count_blocks_of_size(Integer(2))
1
>>> pd.count_blocks_of_size(Integer(3))
2
```

**diagram()**

Return the underlying implementation of the diagram.

**OUTPUT:**

- tuple of tuples of integers

**EXAMPLES:**

```python
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: pd([[1,2],[-1,-2]]).base_diagram() == ((-2,-1),(1,2))
True
```

```python
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>>
pd = da.AbstractPartitionDiagrams(Integer(2))
>>> pd([[1,2],[2,2,3],[3]]).base_diagram() ==
((-2,2,3),(-1,1))
True
```

**dual()**

Return the dual diagram of self by flipping it top-to-bottom.

**EXAMPLES:**

```python
sage: from sage.combinat.diagram_algebras import PartitionDiagram
sage: D = PartitionDiagram([[1,-1],[2,-2,-3],[3]])
2
```

```python
>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import PartitionDiagram
>>>
D = PartitionDiagram([[1,-1],[2,-2,-3],[3]])
>>> D.dual()
((-3), (-2, 2, 3), (-1, 1))
```

**is_planar()**

Test if the diagram self is planar.

A diagram element is planar if the graph of the nodes is planar.

**EXAMPLES:**
```python
sage: from sage.combinat.diagram_algebras import BrauerDiagram
sage: BrauerDiagram([[1,-2],[2,-1]]).is_planar()
False
sage: BrauerDiagram([[1,-1],[2,-2]]).is_planar()
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import BrauerDiagram
>>>
BrauerDiagram([[Integer(1),-Integer(2)],[Integer(2),-Integer(1)]]).is_planar()
False
BrauerDiagram([[Integer(1),-Integer(1)],[Integer(2),-Integer(2)]]).is_planar()
True
```

**order()**

Return the maximum entry in the diagram element.

A diagram element will be a partition of the set \{-1, -2, \ldots, -k, 1, 2, \ldots, k\}. The order of the diagram element is the value \(k\).

**EXAMPLES:**

```python
sage: from sage.combinat.diagram_algebras import PartitionDiagram
sage: PartitionDiagram([[1,-1],[2,-2,-3],[3]]).order()
3
sage: PartitionDiagram([[1,-1]]).order()
1
sage: PartitionDiagram([[1,-3,-5],[2,4],[3,-1,-2],[5],[-4]]).order()
5
```

```python
>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import PartitionDiagram
>>>
PartitionDiagram([[Integer(1),-Integer(1)],[Integer(2),-Integer(2),-Integer(3)], [Integer(3)]]).order()
3
PartitionDiagram([[Integer(1),-Integer(1)]].order()
1
PartitionDiagram([[Integer(1),-Integer(3),-Integer(5)],[Integer(2),-Integer(4)],[Integer(3),-Integer(1),-Integer(2)],[Integer(5)],[Integer(4)]]).order()
5
```

**propagating_number()**

Return the propagating number of the diagram.

The propagating number is the number of blocks with both a positive and negative number.

**EXAMPLES:**

```python
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: d1 = pd([[1,-2],[2,-1]])
sage: d1.propagating_number()
2
sage: d2 = pd([[1,2],[-2,-1]])
sage: d2.propagating_number()
0
```
```python
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> pd = da.AbstractPartitionDiagrams(Integer(2))
>>> d1 = pd([[Integer(1),-Integer(2)], [Integer(2),-Integer(1)]]).
>>> d1.propagating_number()
2
>>> d2 = pd([[Integer(1),Integer(2)], [-Integer(2),-Integer(1)]]).
>>> d2.propagating_number()
0
```

**set_partition()**

Return the underlying implementation of the diagram as a set of sets.

**EXAMPLES:**

```python
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: X = pd([[1,2],[1,-2]]).set_partition(); X
{{-2, -1}, {1, 2}}
sage: X.parent()
Set partitions
```

class sage.combinat.diagram_algebras.AbstractPartitionDiagrams(order, category=None)

Bases: Parent, UniqueRepresentation

This is an abstract base class for partition diagrams.

The primary use of this class is to serve as basis keys for diagram algebras, but diagrams also have properties in their own right. Furthermore, this class is meant to be extended to create more efficient contains methods.

**INPUT:**

- `order` – integer or integer +1/2; the order of the diagrams
- `category` – (default: FiniteEnumeratedSets()); the category

All concrete classes should implement attributes

- `_name` – the name of the class
- `_diagram_func` – an iterator function that takes the order as its only input

**EXAMPLES:**

```python
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
```
(continues on next page)
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> pd = da.PartitionDiagrams(Integer(2))
>>> pd
Partition diagrams of order 2
>>> pd.an_element() in pd
True
>>> elm = pd([[Integer(1),Integer(2)],[Integer(-1),Integer(-2)]])
>>> elm in pd
True

Element
alias of AbstractPartitionDiagram
class sage.combinat.diagram_algebras.BrauerAlgebra(k, q, base_ring, prefix)
Bases: SubPartitionAlgebra, UnitDiagramMixin
A Brauer algebra.
The Brauer algebra of rank $k$ is an algebra with basis indexed by the collection of set partitions of
$\{1, \ldots, k, -1, \ldots, -k\}$ with block size 2.
This algebra is a subalgebra of the partition algebra. For more information, see PartitionAlgebra.

INPUT:

- $k$ – rank of the algebra
- $q$ – the deformation parameter $q$

OPTIONAL ARGUMENTS:

- `base_ring` – (default None) a ring containing q; if None then just takes the parent of q
- `prefix` – (default "B") a label for the basis elements

EXAMPLES:
We now define the Brauer algebra of rank 2 with parameter $x$ over $\mathbb{Z}$:

```python
sage: R.<x> = ZZ[]
sage: B = BrauerAlgebra(2, x, R)
sage: B
Brauer Algebra of rank 2 with parameter x
over Univariate Polynomial Ring in x over Integer Ring
sage: B.basis()
Lazy family (Term map from Brauer diagrams of order 2 to Brauer Algebra of rank 2 with parameter x
over Univariate Polynomial Ring in x over Integer Ring(i))_{i in Brauer diagrams of order 2}
sage: B.basis().keys()
Brauer diagrams of order 2
sage: B.basis().keys()([-2, 1], [2, -1])
((-2, 1), (-1, 2))
sage: b = B.basis().list(); b
[B([-2, -1], (1, 2)), B([-2, 1], (-1, 2)), B([-2, 2], (-1, 1))]
sage: b[0]
B([-2, -1], (1, 2))
```

(re continued on next page)
jucys_murphy ($j$)

Return the $j$-th generalized Jucys-Murphy element of self.

The $j$-th Jucys-Murphy element of a Brauer algebra is simply the $j$-th Jucys-Murphy element of the symmetric group algebra with an extra $(z - 1)/2$ term, where $z$ is the parameter of the Brauer algebra.

REFERENCES:

EXAMPLES:
```
sage: # needs sage.symbolic
sage: z = var('z')
sage: B = BrauerAlgebra(3,z)
sage: B.jucys_murphy(1)
(1/2*z-1/2)*B{{-3, 3}, {-2, 2}, {-1, 1}}
sage: B.jucys_murphy(3)
-B{{-3, -2}, {-1, 1}, {2, 3}} - B{{-3, -1}, {-2, 2}, {1, 3}}
+ B{{-3, 1}, {-2, 2}, {-1, 3}} + B{{-3, 2}, {-2, 3}, {-1, 1}}
+ (1/2*z-1/2)*B{{-3, 3}, {-2, 2}, {-1, 1}}
```

```python
>>> from sage.all import *
>>> # needs sage.symbolic
>>> z = var('z')
>>> B = BrauerAlgebra(Integer(3),z)
>>> B.jucys_murphy(Integer(1))
(1/2*z-1/2)*B{{-3, 3}, {-2, 2}, {-1, 1}}
>>> B.jucys_murphy(Integer(3))
-B{{-3, -2}, {-1, 1}, {2, 3}} - B{{-3, -1}, {-2, 2}, {1, 3}}
+ B{{-3, 1}, {-2, 2}, {-1, 3}} + B{{-3, 2}, {-2, 3}, {-1, 1}}
+ (1/2*z-1/2)*B{{-3, 3}, {-2, 2}, {-1, 1}}
```

```
options = Current options for Brauer diagram - display: normal

class sage.combinat.diagram_algebras.BrauerDiagram(parent, d, check=True)

    Bases: AbstractPartitionDiagram

    A Brauer diagram.
    
    A Brauer diagram for an integer \( k \) is a partition of the set \( \{1, \ldots, k, -1, \ldots, -k\} \) with block size 2.

    EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(2)
sage: bd1 = bd([[1,2],[-1,-2]])
Traceback (most recent call last):
...
ValueError: all blocks of \{\{-2, -1, 1, 2\}\} must be of size 2
```

```python
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
...
>>> bd1 = bd([[Integer(1),Integer(2)],[Integer(-1),Integer(-2)]])
>>> bd2 = bd([[Integer(1),Integer(2)],[Integer(-1),Integer(-2)]])
...
ValueError: all blocks of \{\{-2, -1, 1, 2\}\} must be of size 2
```

```
// Return the induced bijection - as a list of \((x, f(x))\) values - from the free nodes on the top at the Brauer
diagram to the free nodes at the bottom of \( \text{self} \).

    OUTPUT:
    
    If \( \text{two_line} \) is True, then the output is the induced bijection as a two-row list \((\text{inputs}, \text{outputs})\).

    EXAMPLES:
```

5.1. Comprehensive Module List 1243
Combinatorics, Release 10.4

```python
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
sage: elm = bd([[1,2],[-2,-3],[3,-1]])
sage: elm.bijection_on_free_nodes()
[[3, -1]]
sage: elm2 = bd([[1,-2],[2,-3],[3,-1]])
sage: elm2.bijection_on_free_nodes(two_line=True)
[[1, 2, 3], [-2, -3, -1]]
```

```python
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> bd = da.BrauerDiagrams(Integer(3))
>>> elm = bd([[Integer(1),Integer(2)],[Integer(2),-Integer(3)],[Integer(3),-Integer(1)]])
>>> elm.bijection_on_free_nodes()
[[3, -1]]
>>> elm2 = bd([[Integer(1),-Integer(2)],[Integer(2),-Integer(3)],[Integer(3),-Integer(1)]])
>>> elm2.bijection_on_free_nodes(two_line=True)
[[1, 2, 3], [-2, -3, -1]]
```

check()
Check the validity of the input for self.

involution_permutation_triple (curt=True)
Return the involution permutation triple of self.

From Graham-Lehrer (see BrauerDiagrams), a Brauer diagram is a triple \((D_1, D_2, \pi)\), where:

- \(D_1\) is a partition of the top nodes;
- \(D_2\) is a partition of the bottom nodes;
- \(\pi\) is the induced permutation on the free nodes.

INPUT:
- curt – (default: True) if True, then return bijection on free nodes as a one-line notation (standardized to look like a permutation), else, return the honest mapping, a list of pairs \((i, -j)\) describing the bijection on free nodes.

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
sage: elm = bd([[1,2],[-2,-3],[3,-1]])
sage: elm.involution_permutation_triple()
((1, 2), (-3, -2), [1])
sage: elm.involution_permutation_triple(curt=False)
(((1, 2)), (-3, -2), [[3, -1]])
```

```python
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> bd = da.BrauerDiagrams(Integer(3))
>>> elm = bd([[Integer(1),Integer(2)],[Integer(2),-Integer(3)],[Integer(3),-Integer(1)]])
>>> elm.involution_permutation_triple()
(((1, 2)), (-3, -2), [[3, -1]])
```

(continues on next page)
is_elementary_symmetric()
Check if is elementary symmetric.

Let \((D_1, D_2, \pi)\) be the Graham-Lehrer representation of the Brauer diagram \(d\). We say \(d\) is elementary symmetric if \(D_1 = D_2\) and \(\pi\) is the identity.

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
>>> elm = bd([[1,2],[-1,-2],[3,-3]])
sage: elm.is_elementary_symmetric()
True
sage: elm2 = bd([[1,2],[-1,-3],[3,-2]])
sage: elm2.is_elementary_symmetric()
False
```

```python
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> bd = da.BrauerDiagrams(Integer(3))
>>> elm = bd([[Integer(1),Integer(2)],[Integer(1),-Integer(2)],[Integer(3),-Integer(3)]])
>>> elm.is_elementary_symmetric()
True
>>> elm2 = bd([[Integer(1),Integer(2)],[Integer(1),-Integer(3)],[Integer(3),-Integer(2)]])
>>> elm2.is_elementary_symmetric()
False
```

options = Current options for Brauer diagram - display: normal

perm()
Return the induced bijection on the free nodes of self in one-line notation, re-indexed and treated as a permutation.

See also:
bijection_on_free_nodes()

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
>>> elm = bd([[1,2],[-2,-3],[3,-1]])
sage: elm.perm()
[1]
```

```python
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> bd = da.BrauerDiagrams(Integer(3))
>>> elm = bd([[Integer(1),Integer(2)],[Integer(2),-Integer(3)],[Integer(3),-Integer(1)]])
>>> elm.perm()
[1]
```
class sage.combinat.diagram_algebras.BrauerDiagrams(order, category=None)

Bases: AbstractPartitionDiagrams

This class represents all Brauer diagrams of integer or integer +1/2 order. For more information on Brauer diagrams, see `BrauerAlgebra`.

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(2); bd
Brauer diagrams of order 2
sage: bd.list()
[{{-2, -1}, {1, 2}}, {{-2, 1}, {-1, 2}}, {{-2, 2}, {-1, 1}}]

sage: bd = da.BrauerDiagrams(5/2); bd
Brauer diagrams of order 5/2
sage: bd.list()
[{{-3, 3}, {-2, -1}, {1, 2}}, {{-3, 3}, {-2, 1}, {-1, 2}}, {{-3, 3}, {-2, 2}, {-1, 1}}]
```

>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> bd = da.BrauerDiagrams(Integer(2)); bd
Brauer diagrams of order 2
>>> bd.list()
[{{-2, -1}, {1, 2}}, {{-2, 1}, {-1, 2}}, {{-2, 2}, {-1, 1}}]

```python
Element

alias of `BrauerDiagram`

cardinality()

Return the cardinality of `self`.

The number of Brauer diagrams of integer order \( k \) is \((2k - 1)!!\).

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
sage: bd.cardinality()
15

sage: bd = da.BrauerDiagrams(7/2)
sage: bd.cardinality()
15
```

```python
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> bd = da.BrauerDiagrams(Integer(3))
>>> bd.cardinality()
```

(continues on next page)
\texttt{from\_involution\_permutation\_triple(D1\_D2\_pi)}

Construct a Brauer diagram of \texttt{self} from an involution permutation triple.

A Brauer diagram can be represented as a triple where the first entry is a list of arcs on the top row of the diagram, the second entry is a list of arcs on the bottom row of the diagram, and the third entry is a permutation on the remaining nodes. This triple is called the \textit{involution permutation triple}. For more information, see [GL1996].

\textbf{INPUT:}

- \texttt{D1\_D2\_pi} – a list or tuple where the first entry is a list of arcs on the top of the diagram, the second entry is a list of arcs on the bottom of the diagram, and the third entry is a permutation on the free nodes.

\textbf{REFERENCES:}

\textbf{EXAMPLES:}

\begin{verbatim}
from sage.all import *
import sage.combinat.diagram_algebras as da
da.BrauerDiagrams(4)
d.from_involution_permutation_triple([[1,2], [3,4], [2,1]])
{{-4, -3}, {-2, 3}, {-1, 4}, {1, 2}}
\end{verbatim}

\textbf{options = Current options for Brauer diagram – display: normal}

\textbf{symmetric\_diagrams(l=None, perm=None)}

Return the list of Brauer diagrams with symmetric placement of \texttt{l} arcs, and with free nodes permuted according to \texttt{perm}.

\textbf{EXAMPLES:}

\begin{verbatim}
from sage.all import *
import sage.combinat.diagram_algebras as da
da.BrauerDiagrams(4)
da.symmetric_diagrams(l=1, perm=[2,1])
[{{-4, -2}, {-3, 1}, {-1, 3}, {2, 4}},
 {4, -1}, {-3, 2}, {-2, 3}, {1, 4}},
 {4, 2}, {-3, 1}, {-2, 4}, {1, 3}},
 {4, 3}, {-3, 4}, {-2, -1}, {1, 2}},
 {4, 1}, {-3, -2}, {-1, 4}, {2, 3}}
\end{verbatim}
class sage.combinat.diagram_algebras.DiagramAlgebra(k, q, base_ring, prefix, diagrams, category=None)

Bases: CombinatorialFreeModule

Abstract class for diagram algebras and is not designed to be used directly.

class Element
Bases: IndexedFreeModuleElement

An element of a diagram algebra.

This subclass provides a few additional methods for partition algebra elements. Most element methods are already implemented elsewhere.

diagram()

Return the underlying diagram of self if self is a basis element. Raises an error if self is not a basis element.

EXAMPLES:

```python
sage: R.<x> = ZZ[]
sage: P = PartitionAlgebra(2, x, R)
sage: elt = 3*P([[-1, 2], [-2, -1]])
sage: elt.diagram()
{{-2, -1}, {1, 2}}
```

```python
>>> from sage.all import *
>>> R = ZZ['x']; (x,) = R._first_ngens(1)
>>> P = PartitionAlgebra(Integer(2), x, R)
>>> elt = Integer(3)*P([[-Integer(1), Integer(2)], [-Integer(2),-Integer(1)]])
>>> elt.diagram()
{{-2, -1}, {1, 2}}
```

diagrams()

Return the diagrams in the support of self.

EXAMPLES:

```python
sage: R.<x> = ZZ[]
sage: P = PartitionAlgebra(2, x, R)
sage: elt = 3*P([[-1, 2], [-2, -1]]) + P([[-1, 2], [-2, -1]])
sage: sorted(elt.diagrams(), key=str)
[{{-2, -1}, {1, 2}}, {{-2}, {-1}, {1, 2}}]
```

```python
>>> from sage.all import *
>>> R = ZZ['x']; (x,) = R._first_ngens(1)
>>> P = PartitionAlgebra(Integer(2), x, R)
>>> elt = Integer(3)*P([[-Integer(1), Integer(2)], [-Integer(2),-Integer(1)]]) + P([[-Integer(1), Integer(2)], [-Integer(2),-Integer(1)]])
>>> elt.diagrams()
[{{-2, -1}, {1, 2}}, {{-2}, {-1}, {1, 2}}]
```
order()

Return the order of self.

The order of a partition algebra is defined as half of the number of nodes in the diagrams.

EXAMPLES:

```python
sage: q = var('q')  # needs sage.symbolic
sage: PA = PartitionAlgebra(2, q)  # needs sage.symbolic
sage: PA.order()  # needs sage.symbolic
2
```

set_partitions()

Return the collection of underlying set partitions indexing the basis elements of a given diagram algebra.

Todo: Is this really necessary? deprecate?

```python
class sage.combinat.diagram_algebras.DiagramBasis(k, q, base_ring, prefix, diagrams, category=None)
Bases: DiagramAlgebra

Abstract base class for diagram algebras in the diagram basis.

product_on_basis(d1, d2)

Return the product $D_{d_1}D_{d_2}$ by two basis diagrams.

class sage.combinat.diagram_algebras.HalfTemperleyLiebDiagrams(order, defects)
Bases: UniqueRepresentation, Parent

Half diagrams for the Temperley-Lieb algebra cell modules.

class Element (parent, d, check=True)
Bases: AbstractPartitionDiagram

check()

Check the validity of the input of self.

EXAMPLES:
sage: import sage.combinat.diagram_algebras as da
sage: htdl = da.HalfTemperleyLiebDiagrams(7, 3)
sage: htdl([[1,2], [3,4]]) # indirect doctest
{{1, 2}, {3, 4}}
Traceback (most recent call last):
...
ValueError: {{-2, -1}, {1, 2}} does not represent a half TL diagram of order 7
sage: htdl([[1,2,3], [4,5]]) # indirect doctest
Traceback (most recent call last):
...
ValueError: all blocks of {{1, 2, 3}, {4, 5}} must be of size 2
sage: htdl([[1,2], [3,4], [5,6]]) # indirect doctest
Traceback (most recent call last):
...
ValueError: {{1, 2}, {3, 4}, {5, 6}} does not have 3 defects
sage: htdl([[1,3], [2,4]]) # indirect doctest
Traceback (most recent call last):
...
ValueError: {{1, 3}, {2, 4}} is not planar

>> from sage.all import *
>> import sage.combinat.diagram_algebras as da
>> htdl = da.HalfTemperleyLiebDiagrams(Integer(7), Integer(3))
>> htdl([[Integer(1),Integer(2)], [Integer(3),Integer(4)]]) # indirect doctest
{{1, 2}, {3, 4}}
>> htdl([[Integer(1),Integer(2)], [-Integer(1), -Integer(2)]]) # indirect doctest
Traceback (most recent call last):
...
ValueError: {{-2, -1}, {1, 2}} does not represent a half TL diagram of order 7
>> htdl([[Integer(1),Integer(2),Integer(3)], [Integer(4),Integer(5)]]) # indirect doctest
Traceback (most recent call last):
...
ValueError: all blocks of {{1, 2, 3}, {4, 5}} must be of size 2
>> htdl([[Integer(1),Integer(2),Integer(3)], [Integer(4),Integer(5), Integer(6)]]) # indirect doctest
Traceback (most recent call last):
...
ValueError: {{1, 2}, {3, 4}, {5, 6}} does not have 3 defects
>> htdl([[Integer(1),Integer(3)], [Integer(2),Integer(4)]]) # indirect doctest
Traceback (most recent call last):
...
ValueError: {{1, 3}, {2, 4}} is not planar

defects()

Return the defects of self.

EXAMPLES:

sage: import sage.combinat.diagram_algebras as da
sage: htdl = da.HalfTemperleyLiebDiagrams(7, 3)
```python
sage: d = htld([[1, 2], [4, 5]])
sage: d.defects()
frozenset({3, 6, 7})
```

This code snippet demonstrates the use of a combinatorial object `d` from the `IdealDiagram` class. The `defects` method is called on `d` to return a set of defects, which is a frozenset containing the values `{3, 6, 7}`.

### cardinality()

Return the cardinality of `self`.

**EXAMPLES:**

```python
sage: import sage.combinat.diagram_algebras as da
sage: htld = da.HalfTemperleyLiebDiagrams(7, 3)
sage: htld.cardinality()
14
```

### class sage.combinat.diagram_algebras.IdealDiagram(parent, d, check=True)

Bases: AbstractPartitionDiagram

The element class for an ideal diagram.

An ideal diagram for an integer $k$ is a partition of the set \{1, \ldots, k, -1, \ldots, -k\} where the propagating number is strictly smaller than the order.

**EXAMPLES:**

```python
sage: from sage.combinat.diagram_algebras import IdealDiagrams as IDs
sage: IDs(2)
Ideal diagrams of order 2
sage: IDs(2).list()
[[(−2, −1, 1, 2),
  (−2, 1, 2), (−1)],
 (−2), (−1, 1, 2),
 (−2, −1), (1, 2),
 (−2), (−1), (1, 2)],
 (−2, −1, 1), (2),
 (−2, 1), (−1), (2),
 (−2, −1, 2), (1),
 (−2, 2), (−1), (1),
 (−2), (−1, 1), (2),
 (−2), (−1, 2), (1),
 (−2, −1), (1), (2),
 (−2), (−1), (1), (2)]
```

This is an excerpt from a comprehensive module list, indicating the classes and methods available in the combinatorics module.
sage: PDs(4).cardinality() == factorial(4) + IDs(4).cardinality()
True

>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import IdealDiagrams as IDs
>>> IDs(Integer(2))
Ideal diagrams of order 2
>>> IDs(Integer(2)).list()
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2}, {-1, 1, 2}},
 {{-2, -1}, {1, 2}},
 {{-2}, {-1}, {1, 2}},
 {{-2, -1}, {1}, {2}},
 {{-2}, {-1, 1}, {2}},
 {{-2, 1}, {-1}, {2}},
 {{-2}, {-1}, {2}},
 {{-2, -1}, {1}},
 {{-2, 1}, {-1}},
 {{-2, 2}, {-1}},
 {{-2, -1}, {1}},
 {{-2, -1}, {2}},
 {{-2, -1}, {1}, {2}},
 {{-2}, {-1}, {1}, {2}}]

>>> from sage.combinat.diagram_algebras import PartitionDiagrams as PDs
>>> PDs(Integer(4)).cardinality() == factorial(Integer(4)) + IDs(Integer(4)).cardinality()
True

check()

Check the validity of the input for self.

class sage.combinat.diagram_algebras.IdealDiagrams(order, category=None)

    Bases: AbstractPartitionDiagrams

    All "ideal" diagrams of integer or integer +1/2 order.

    If k is an integer then an ideal diagram of order k is a partition diagram of order k with propagating number less than k.

    EXAMPLES:

sage: import sage.combinat.diagram_algebras as da
sage: id = da.IdealDiagrams(3)
sage: id.an_element() in id
True
sage: id.cardinality() == len(id.list())
True
sage: da.IdealDiagrams(3/2).list()
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2}, {-1, 1, 2}},
 {{-2, -1}, {1, 2}},
 {{-2}, {-1, 1, 2}},
 {{-2, 1}, {-1, 2}},
 {{-2}, {-1}, {1, 2}},
 {{-2}, {-1}, {1}, {2}}]

>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> id = da.IdealDiagrams(Integer(3))
>>> id.an_element() in id
True

(continues on next page)
Element
    alias of IdealDiagram
class sage.combinat.diagram_algebras.OrbitBasis(alg)
    Bases: DiagramAlgebra
    The orbit basis of the partition algebra.
    Let $D_\pi$ represent the diagram basis element indexed by the partition $\pi$, then (see equations (2.14), (2.17) and (2.18) of [BH2017])
    $D_\pi = \sum_{\tau \geq \pi} O_\tau,$
    where the sum is over all partitions $\tau$ which are coarser than $\pi$ and $O_\tau$ is the orbit basis element indexed by the partition $\tau$.
    If $\mu_{2k}(\pi, \tau)$ represents the Moebius function of the partition lattice, then
    $O_\pi = \sum_{\tau \geq \pi} \mu_{2k}(\pi, \tau)D_\tau.$
    If $\tau$ is a partition of $\ell$ blocks and the $i^{th}$ block of $\tau$ is a union of $b_i$ blocks of $\pi$, then
    $\mu_{2k}(\pi, \tau) = \ell \prod_{i=1}^{\ell} (-1)^{b_i-1}(b_i-1)!.$

EXAMPLES:

```python
sage: R.<x> = QQ[

sage: P2 = PartitionAlgebra(2, x, R)
sage: O2 = P2.orbit_basis(); O2
Orbit basis of Partition Algebra of rank 2 with parameter x over
Univariate Polynomial Ring in x over Rational Field
sage: oa = O2([[1],[-1],[2,-2]]); ob = O2([[-1,-2,2],[1]]); oa, ob
(O{{-2, 2}, {-1}, {1}}, O{{-2, -1, 2}, {1}})
sage: oa * ob
(x-2)*O{{-2, -1, 2}, {1}}
```

```python
>>> from sage.all import *

>>> R = QQ['x']; (x,) = R._first_ngens(1)

>>> P2 = PartitionAlgebra(Integer(2), x, R)

>>> O2 = P2.orbit_basis(); O2
Orbit basis of Partition Algebra of rank 2 with parameter x over
Univariate Polynomial Ring in x over Rational Field

>>> oa = O2([[Integer(1)],[Integer(-1)],[Integer(2),-Integer(2)]]); ob = O2([[Integer(-1)-Integer(2),Integer(2)], [Integer(1)]]); oa, ob
(O{{-2, 2}, {-1}, {1}}, O{{-2, -1, 2}, {1}})

>>> oa * ob
(x-2)*O{{-2, -1, 2}, {1}}
```

5.1. Comprehensive Module List 1253
We can convert between the two bases:

```python
sage: pa = P2(oa); pa
2*P{{-2, -1, 1, 2}} - P{{-2, -1, 2}, {1}} - P{{-2, 1, 2}, {-1}}
  + P{{-2, 2}, {-1}, {1}} - P{{-2, 2}, {-1, 1}}

sage: pa * ob
(-x+2)*P{{-2, -1, 1, 2}} + (x-2)*P{{-2, -1, 2}, {1}}

sage: _ == pa * P2(ob)
True

sage: O2(pa * ob)
(x-2)*O{{-2, -1, 2}, {1}}
```

Note that the unit in the orbit basis is not a single diagram, in contrast to the natural diagram basis:

```python
sage: P2.one()
P{{-2, 2}, {-1, 1}}

sage: O2.one()
O{{-2, -1, 1, 2}} + O{{-2, 2}, {-1, 1}}

sage: O2.one() == P2.one()
True
```

```python
>>> from sage.all import *

>>> pa = P2(oa); pa
2*P{{-2, -1, 1, 2}} - P{{-2, -1, 2}, {1}} - P{{-2, 1, 2}, {-1}}
  + P{{-2, 2}, {-1}, {1}} - P{{-2, 2}, {-1, 1}}

>>> pa * ob
(-x+2)*P{{-2, -1, 1, 2}} + (x-2)*P{{-2, -1, 2}, {1}}

>>> _ == pa * P2(ob)
True

>>> O2(pa * ob)
(x-2)*O{{-2, -1, 2}, {1}}
```

```python
>>> from sage.all import *

>>> P2.one()
P{{-2, 2}, {-1, 1}}

>>> O2.one()
O{{-2, -1, 1, 2}} + O{{-2, 2}, {-1, 1}}

>>> O2.one() == P2.one()
True
```

```python
class Element
    Bases: Element
to_diagram_basis()
    Expand self in the natural diagram basis of the partition algebra.

EXAMPLES:

sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(2, x, R)
sage: O = P.orbit_basis()
sage: elt = O.an_element(); elt
3*O{{-2}, {-1, 1, 2}} + 2*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}

sage: elt.to_diagram_basis()
3*P{{-2}, {-1, 1, 2}} - 3*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}

sage: pp = P.an_element(); pp
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
```

Combinatorics, Release 10.4

```
sage: op = pp.to_orbit_basis(); op
3*O{{-2}, {-1, 1, 2}} + 7*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
sage: pp == op.to_diagram_basis()
True
```

```
from sage.all import *
R = QQ['x']; (x,) = R._first_ngens(1)
P = PartitionAlgebra(Integer(2), x, R)
O = P.orbit_basis()
ext = O.an_element(); elt
3*O{{-2}, {-1, 1, 2}} + 2*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
ext.to_diagram_basis()
3*P{{-2}, {-1, 1, 2}} - 3*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
pp = P.an_element(); pp
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
op = pp.to_orbit_basis(); op
3*O{{-2}, {-1, 1, 2}} + 7*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
pp == op.to_diagram_basis()
True
```

```
diagram_basis()

Return the associated partition algebra of self in the diagram basis.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: O2 = PartitionAlgebra(2, x, R).orbit_basis()
sage: P2 = O2.diagram_basis(); P2
Partition Algebra of rank 2 with parameter x over Univariate Polynomial Ring in x over Rational Field
sage: o2 = O2.an_element(); o2
3*O{{-2}, {-1, 1, 2}} + 2*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
sage: P2(o2)
3*P{{-2}, {-1, 1, 2}} - 3*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
```

```
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> O2 = PartitionAlgebra(Integer(2), x, R).orbit_basis()
>>> P2 = O2.diagram_basis(); P2
Partition Algebra of rank 2 with parameter x over Univariate Polynomial Ring in x over Rational Field
>>> o2 = O2.an_element(); o2
3*O{{-2}, {-1, 1, 2}} + 2*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
>>> P2(o2)
3*P{{-2}, {-1, 1, 2}} - 3*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
```
```
one()

Return the element 1 of the partition algebra in the orbit basis.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: P2 = PartitionAlgebra(2, x, R)
sage: O2 = P2.orbit_basis()
sage: O2.one()
O{{-2, -1, 1, 2}} + O{{-2, 2}, {-1, 1}}
```

```
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> O2 = PartitionAlgebra(Integer(2), x, R).orbit_basis()
>>> P2 = O2.diagram_basis(); P2
Partition Algebra of rank 2 with parameter x over Univariate Polynomial Ring in x over Rational Field
>>> o2 = O2.an_element(); o2
3*O{{-2}, {-1, 1, 2}} + 2*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
>>> P2(o2)
3*P{{-2}, {-1, 1, 2}} - 3*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
```
product_on_basis $(d_1, d_2)$

Return the product $O_{d_1}O_{d_2}$ of two elements in the orbit basis self.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: OP = PartitionAlgebra(2, x, R).orbit_basis()
sage: SP = OP.basis().keys(); sp = SP([-2, -1, 1, 2])
sage: OP.product_on_basis(sp, sp)
O{-2, -1, 1, 2}
sage: o1 = OP.one(); o2 = OP([]); o3 = OP.an_element()
sage: o2 == o1
False
sage: o1 * o1 == o1
True
sage: o3 * o1 == o3 * o1 == o3
True
sage: o4 = (3*OP([-2, -1, 1, 2]) + 2*OP([-2, -1, 1, 2]))
    + 2*OP([-2, -1, 2, [1]]))
    + 2*OP([-2, -1, 2, [1]]))
sage: o4 * o4
6*O{-2, -1, 1, 2} + 4*O{-2, -1, 1, 2} + 4*O{-2, -1, 2, [1]}
```

We compute Examples 4.5 in [BH2017]:

```
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(3, x); O = P.orbit_basis()
sage: O([1, 2, 3], [-1, -2, -3]) * O([1, 2, 3], [-1, -2, -3])
(x-2)*O{-3, -2, -1} + (x-1)*O{-3, -2, -1, 1, 2, 3} + (x-1)*O{-3, -2, -1, 1, 2, 3}
```
sage: P = PartitionAlgebra(4,x); O = P.orbit_basis()
sage: O[[1],[-1],[2,3],[4,-2],[-3,-4]] * O[[1],[2,-2],[3,4],[-1,-3],[-4]]
(x^2-11*x+30)*O(4,-1,-2,4,1,2,3)
+ (x^2-9*x+20)*O(4,-1,-2,4,1,2,3)
+ (x^2-9*x+20)*O(4,-1,-2,4,1,2,3)
+ (x^2-7*x+12)*O(4,-1,-2,4,1,2,3)
+ (x^2-9*x+20)*O(4,-1,-2,4,1,2,3)
+ (x^2-7*x+12)*O(4,-1,-2,4,1,2,3)

sage: O[[1],[-1],[2,-2],[3,4],[-1,-3],[4]] * O[[1],[-2],[2,3],[-4],[4],[5]]
(x^2-11*x+30)*O(4,-1,-2,4,1,2,3)
+ (x^2-9*x+20)*O(4,-1,-2,4,1,2,3)
+ (x^2-9*x+20)*O(4,-1,-2,4,1,2,3)
+ (x^2-7*x+12)*O(4,-1,-2,4,1,2,3)
+ (x^2-9*x+20)*O(4,-1,-2,4,1,2,3)
+ (x^2-7*x+12)*O(4,-1,-2,4,1,2,3)

sage: P = PartitionAlgebra(6,x); O = P.orbit_basis()
sage: O[[1,-2,-3],[2,4],[3,5,-6],[6],[-1],[-4,-5]]
(...)
0

sage: P = PartitionAlgebra(6,x); O = P.orbit_basis()

>>> from sage.all import *
>>> R = QQ[x]; (x,) = R._first_ngens(1)
>>> P = PartitionAlgebra(Integer(3),x); O = P.orbit_basis()

5.1. Comprehensive Module List

1257
class sage.combinat.diagram_algebras.PartitionAlgebra(k, q, base_ring, prefix)

Bases: DiagramBasis, UnitDiagramMixin

A partition algebra.

A partition algebra of rank \( k \) over a given ground ring \( R \) is an algebra with \((R\text{-module})\) basis indexed by the collection of set partitions of \{1, \ldots, k, -1, \ldots, -k\}. Each such set partition can be represented by a graph on nodes \{1, \ldots, k\} arranged in two rows, with nodes \{1, \ldots, k\} in the top row from left to right and with nodes \{-1, \ldots, -k\} in the bottom row from left to right, and edges drawn such that the connected components of the graph are precisely the parts of the set partition. (This choice of edges is often not unique, and so there are often many graphs representing one and the same set partition; the representation nevertheless is useful and vivid. We often speak of “diagrams” to mean graphs up to such equivalence of choices of edges; of course, we could just as well speak of set partitions.)

There is not just one partition algebra of given rank over a given ground ring, but rather a whole family of them, indexed by the elements of \( R \). More precisely, for every \( q \in R \), the partition algebra of rank \( k \) over \( R \) with parameter \( q \) is defined to be the \( R \)-algebra with basis the collection of all set partitions of \{1, \ldots, k, -1, \ldots, -k\}, where the product of two basis elements is given by the rule

\[
a \cdot b = q^N(a \circ b),
\]

where \( a \circ b \) is the composite set partition obtained by placing the diagram (i.e., graph) of \( a \) above the diagram of \( b \), identifying the bottom row nodes of \( a \) with the top row nodes of \( b \), and omitting any closed “loops” in the middle. The number \( N \) is the number of connected components formed by the omitted loops.

The parameter \( q \) is a deformation parameter. Taking \( q = 1 \) produces the semigroup algebra (over the base ring) of the partition monoid, in which the product of two set partitions is simply given by their composition.

The partition algebra is regarded as an example of a “diagram algebra” due to the fact that its natural basis is given by certain graphs often called diagrams.

There are a number of predefined elements for the partition algebra. We define the cup/cap pair by \( a() \). The simple transpositions are denoted \( s() \). Finally, we define elements \( e() \), where if \( i = (2r + 1)/2 \), then \( e(i) \) contains the blocks \{\( r + 1 \)\} and \{-\( r - 1 \)\} and if \( i \in \mathbb{Z} \), then \( e(i) \) contains the block \{-\( i \), \(-i - 1 \), \( i \), \( i + 1 \)\}, with all other blocks being \{-\( j \), \( j \)\}. So we have:

\[
\begin{align*}
sage: & P = \text{PartitionAlgebra}(4, 0) \\
sage: & P.a(2) \\
& P\{(-4, 4), (-3, -2), (-1, 1), (2, 3)\} \\
sage: & P.e(3/2)
\end{align*}
\]

REFERENCES:

• [BH2017]
An excellent reference for partition algebras and their various subalgebras (Brauer algebra, Temperley–Lieb algebra, etc) is the paper [HR2005].

INPUT:

- $k$ – rank of the algebra
- $q$ – the deformation parameter $q$

OPTIONAL ARGUMENTS:

- `base_ring` – (default None) a ring containing $q$; if None, then Sage automatically chooses the parent of $q$
- `prefix` – (default "P") a label for the basis elements

EXAMPLES:

The following shorthand simultaneously defines the univariate polynomial ring over the rationals as well as the variable $x$:

```python
sage: R.<x> = PolynomialRing(QQ)
sage: R
Univariate Polynomial Ring in x over Rational Field
sage: x
```

```python
sage: x.parent() is R
True
```

```python
>>> from sage.all import *
>>> R = PolynomialRing(QQ, names=('x',)); (x,) = R._first_ngens(1)
>>> R
Univariate Polynomial Ring in x over Rational Field
>>> x
```

```python
>>> x.parent() is R
True
```
We now define the partition algebra of rank 2 with parameter x over \( \mathbb{Z} \) in the usual (diagram) basis:

```python
sage: R.<x> = ZZ[

sage: A2 = PartitionAlgebra(2, x, R)

sage: A2
Partition Algebra of rank 2 with parameter x
over Univariate Polynomial Ring in x over Integer Ring

sage: A2.basis().keys()
Partition diagrams of order 2

sage: A2.basis().keys()([[[-2, 1, 2], [-1]]])
{(−2, 1, 2), (−1)}

sage: A2.basis().list()

sage: E = A2([[1,2],[-2,-1]]); E
P{−2, −1}, (1, 2)

sage: E in A2.basis().list()
True

sage: E

sage: E^2
x*P{−2, −1}, (1, 2)

sage: E^5
x^4*P{−2, −1}, (1, 2)

sage: (A2([[2,-2],[-1,1]]) - 2*A2([[1,2],[-1,-2]]))^2
(4*x-4)*P{−2, −1}, (1, 2) + P{−2, 2}, (−1, 1)

>>> from sage.all import *

>>> R = ZZ['x']; (x,) = R._first_ngens(1)

>>> A2 = PartitionAlgebra(Integer(2), x, R)

>>> A2
Partition Algebra of rank 2 with parameter x
over Univariate Polynomial Ring in x over Integer Ring

>>> A2.basis().keys()
Partition diagrams of order 2

>>> A2.basis().keys()([[-Integer(2), Integer(1), Integer(2)], [-Integer(1)]]))
{(−2, 1, 2), (−1)}

>>> A2.basis().list()

>>> E = A2([[Integer(1),Integer(2)],[-Integer(2),-Integer(1)]]); E
P{−2, −1}, (1, 2)

>>> E in A2.basis().list()
True

>>> E=Integer(2)

>>> E*Integer(2)

>>> E=Integer(5)

>>> E^4*P{−2, −1}, (1, 2)
```
Next, we construct an element:

```
sage: a2 = A2.an_element(); a2
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
```

There is a natural embedding into partition algebras on more elements, by adding identity strands:

```
sage: A4 = PartitionAlgebra(4, x, R)
sage: A4(a2)
3*P{{-4, 4}, {-3, 3}, {-2}, {-1, 1, 2}}
+ 2*P{{-4, 4}, {-3, 3}, {-2, -1, 1, 2}}
+ 2*P{{-4, 4}, {-3, 3}, {-2, 1, 2}, {-1}}
```

Thus, the empty partition corresponds to the identity:

```
sage: A4([])
P{{-4, 4}, {-3, 1}, {-2, 3}, {-1, 2}}
```

The group algebra of the symmetric group is a subalgebra:

```
sage: S3 = SymmetricGroupAlgebra(ZZ, 3)
sage: s3 = S3.an_element(); s3
[1, 2, 3] + 2*[1, 3, 2] + 3*[2, 1, 3] + [3, 1, 2]
sage: A4(s3)
P{{-4, 4}, {-3, 3}, {-2, 2}, {-1, 1}}
```
**Combinatorics, Release 10.4**

```
>>> from sage.all import *

>>> S3 = SymmetricGroupAlgebra(ZZ, Integer(3))
>>> s3 = S3.an_element(); s3
[1, 2, 3] + 2*[1, 3, 2] + 3*[2, 1, 3] + [3, 1, 2]

```  

```python
A4(s3)
P{{-4, 4}, {-3, 1}, {-2, 3}, {-1, 2}} + 2*P{{-4, 4}, {-3, 2}, {-2, 3}, {-1, 1}} + 3*P{{-4, 4}, {-3, 3}, {-2, 1}, {-1, 2}} + P{{-4, 4}, {-3, 3}, {-2, 2}, {-1, 1}}
```

```python
A4([Integer(2),Integer(1)])
P{{-4, 4}, {-3, 3}, (-2, 1), (-1, 2)}
```  

Be careful not to confuse the embedding of the group algebra of the symmetric group with the embedding of partial set partitions. The latter are embedded by adding the parts \{i, -i\} if possible, and singleton sets for the remaining parts:

```python
sage: A4([[2,1]])
P{{-4, 4}, {-3, 3}, (-2), (-1), {1, 2}}
```

```python
sage: A4([[-Integer(1),Integer(3)],[Integer(2),-Integer(3),Integer(1)]])
P{{-4, 4}, {-3, -2, 1}, (-1, 3), {2}}
```  

Another subalgebra is the Brauer algebra, which has perfect matchings as basis elements. The group algebra of the symmetric group is in fact a subalgebra of the Brauer algebra:

```python
sage: B3 = BrauerAlgebra(3, x, R)
sage: b3 = B3(s3); b3
B{{-3, 1}, {-2, 3}, {-1, 2}} + 2*B{{-3, 2}, {-2, 3}, {-1, 1}} + 3*B{{-3, 3}, {-2, 1}, {-1, 2}} + B{{-3, 3}, {-2, 2}, {-1, 1}}
```

```python
sage: B3 = BrauerAlgebra(Integer(3), x, R)
sage: b3 = B3(s3); b3
B{{-3, 1}, {-2, 3}, {-1, 2}} + 2*B{{-3, 2}, {-2, 3}, {-1, 1}} + 3*B{{-3, 3}, {-2, 1}, {-1, 2}} + B{{-3, 3}, {-2, 2}, {-1, 1}}
```

An important basis of the partition algebra is the **orbit basis**:

```python
sage: O2 = A2.orbit_basis()
sage: o2 = O2([[1,2],[-1,-2]]); o2
O{{-2, -1}, {1, 2}} + O{{-2, -1, 1, 2}}
```

```python
sage: O2 = A2.orbit_basis()
sage: o2 = O2([[Integer(1),Integer(2)],[Integer(1),-Integer(2)]]); o2
O{{-2, -1}, {1, 2}} + O{{-2, -1, 1, 2}}
```

The diagram basis element corresponds to the sum of all orbit basis elements indexed by coarser set partitions:
We can convert back from the orbit basis to the diagram basis:

```
sage: o2 = O2.an_element(); o2
3*O{{-2}, {-1, 1, 2}} + 2*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
sage: A2(o2)
3*P{{-2}, {-1, 1, 2}} - 3*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
```

One can work with partition algebras using a symbol for the parameter, leaving the base ring unspecified. This implies that the underlying base ring is Sage’s symbolic ring.

```
sage: # needs sage.symbolic
sage: q = var('q')
sage: PA = PartitionAlgebra(2, q); PA
Partition Algebra of rank 2 with parameter q over Symbolic Ring
sage: PA([[1,2],[-2,-1]])^2 == q*PA([[1,2],[-2,-1]])
True
sage: ((PA([[2, -2], [1, -1]]) - 2*PA([[1, 2], [2, -1]]))^2
....: == (4*q-4)*PA([[1, 2], [2, -1]]) + PA([[2, -2], [1, -1]])
True
```

The identity element of the partition algebra is the set partition \{\{1, -1\}, \{2, -2\}, \ldots, \{k, -k\}\}:

```
sage: # needs sage.symbolic
sage: P = PA.basis().list()
sage: PA.one()
P{{-2, 2}, {-1, 1}}
True
```

(continues on next page)
We now give some further examples of the use of the other arguments. One may wish to “specialize” the parameter to a chosen element of the base ring:

```python
sage: R.<q> = RR[]
sage: PA = PartitionAlgebra(2, q, R, prefix='B')
sage: PA
Partition Algebra of rank 2 with parameter q over
Univariate Polynomial Ring in q over Real Field with 53 bits of precision
1.00000000000000*B((-2, -1), (1, 2))
sage: PA = PartitionAlgebra(2, 5, base_ring=IntegerRing(), prefix='B')
sage: PA
Partition Algebra of rank 2 with parameter 5 over Integer Ring
((PA([[2, -2], [1, -1]]) - 2*PA([[[-2, -1], [1, 2]]]))^2
... == 16*PA([[[-2, -1], [1, 2]]) + PA([[2, -2], [1, -1]])
True
```

Symmetric group algebra elements and elements from other subalgebras of the partition algebra (e.g., Brauer-Algebra and TemperleyLiebAlgebra) can also be coerced into the partition algebra:

```python
sage: # needs sage.symbolic
sage: S = SymmetricGroupAlgebra(SR, 2)
sage: B = BrauerAlgebra(2, x, SR)
sage: A = PartitionAlgebra(2, x, SR)
sage: S([2,1]) * A([[1,-1],[2,-2]])
```
\[ P\{ -2, 1 \}, \{ -1, 2 \} \]
\[
\text{sage: } B([-1,-2],[2,1]) * A([[1],[-1],[2,-2]])
\]
\[
P\{ -2, -1 \}, \{ 1, 2 \} \]
\[
\text{sage: } A([[1],[-1],[2,-2]]) * B([-1,-2],[2,1])
\]
\[
P\{ -2, -1 \}, \{ 1, 2 \} \]

The same is true if the elements come from a subalgebra of a partition algebra of smaller order, or if they are defined over a different base ring:

\[
\text{sage: } R = \text{FractionField}(\text{ZZ}'q')); q = R\text{.gen()}
\]
\[
\text{sage: } S = \text{SymmetricGroupAlgebra}(\text{ZZ}, 2)
\]
\[
\text{sage: } B = \text{BrauerAlgebra}(2, q, \text{ZZ}'q')
\]
\[
\text{sage: } A = \text{PartitionAlgebra}(3, q, R)
\]
\[
\text{sage: } S([2,1]) * A([[1,-1],[2,-3],[3,-2]])
\]
\[
P\{ -3, 1 \}, \{ -2, 3 \}, \{ -1, 2 \} \]

\[
\text{sage: } A(B([-1,-2],[2,1]))
\]
\[
P\{ -3, 3 \}, \{ -2, -1 \}, \{ 1, 2 \} \]

```python
>>> from sage.all import *

R = FractionField(ZZ['q']); q = R.gen()
S = SymmetricGroupAlgebra(ZZ, 2)
B = BrauerAlgebra(2, q, ZZ[q])
A = PartitionAlgebra(Integer(3), q, R)
S([2,1]) * A([[1,-1],[2,-3],[3,-2]])
P{(-3, 1), (-2, 3), (-1, 2)}
A(B([-1,-2],[2,1]))
P{(-3, 3), (-2, -1), (1, 2)}
```

### class Element

**Bases:** `Element`

```
def dual()
    Return the dual of self.
```

The dual of an element in the partition algebra is formed by taking the dual of each diagram in the support.

**EXAMPLES:**
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(2, x, R)
sage: elt = P.an_element(); elt
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
sage: elt.dual()
3*P{{-2, -1, 1}, {2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, -1, 2}, {1}}

>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> P = PartitionAlgebra(Integer(2), x, R)
>>> elt = P.an_element(); elt
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
>>> elt.dual()
3*P{{-2, -1, 1}, {2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, -1, 2}, {1}}

to_orbit_basis()

Return self in the orbit basis of the associated partition algebra.

EXAMPLES:

sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(2, x, R)
sage: pp = P.an_element();
sage: pp.to_orbit_basis()
3*O{{-2}, {-1, 1, 2}} + 7*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
sage: pp = (3*P([[-2], [-1, 1, 2]]) + 2*P([[-2, -1, 1, 2]])
.... + 2*P([[-2, 1, 2], [-1]])); pp
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, -1, 2}, {-1}}
>>> pp.to_orbit_basis()
3*O{{-2}, {-1, 1, 2}} + 7*O{{-2, -1, 1, 2}} + 2*O{{-2, -1, 2}, {-1}}

>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> P = PartitionAlgebra(Integer(2), x, R)
>>> pp = P.an_element();
>>> pp.to_orbit_basis()
3*O{{-2}, {-1, 1, 2}} + 7*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
>>> pp = (Integer(3)*P([[-Integer(2), [-Integer(1), Integer(2)]
... + Integer(2)*P([[-Integer(2), -Integer(1), Integer(2)]
... -Integer(2)])) + Integer(2)*P([[-Integer(2), -Integer(1), Integer(2)]
... -Integer(2)])); pp
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, -1, 2}, {-1}}
>>> pp.to_orbit_basis()
3*O{{-2}, {-1, 1, 2}} + 7*O{{-2, -1, 1, 2}} + 2*O{{-2, -1, 2}, {-1}}

L(i)

Return the i-th Jucys-Murphy element $L_i$ from [Eny2012].

INPUT:

- i – a half integer between 1/2 and $k$

ALGORITHM:

We use the recursive definition for $L_{2i}$ given in [Cre2020]. See also [Eny2012] and [Eny2013].
Note: $L_{1/2}$ and $L_1$ differs from [HR2005].

EXAMPLES:

```python
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.jucys_murphy_element(1/2)
0
sage: P3.jucys_murphy_element(1)
P{(-3, 3), (-2, 2), (-1), (1)}
sage: P3.jucys_murphy_element(2)
P{(-3, 3), (-2), (-1, 1), (2)} - P{(-3, 3), (-2), (-1, 1, 2)}
+ P{(-3, 3), (-2, -1), (1, 2)} - P{(-3, 3), (-2, -1, 1), (2)}
+ P{(-3, 3), (-2), (-1, 2)}
sage: P3.jucys_murphy_element(3/2)
n*P{(-3, 3), (-2, -1, 1, 2)} - P{(-3, 3), (-2, -1, 2), (1)}
- P{(-3, 3), (-2, 1, 2), (1)} + P{(-3, 3), (-2, 2), (-1, 1)}
True
```

We test the relations in Lemma 2.2.3(2) in [Cre2020] (v1):

```python
sage: k = 4
sage: R.<n> = QQ[]
sage: P = PartitionAlgebra(k, n)
sage: L = [P.L(i/2) for i in range(1,2*k+1)]
sage: all(x.dual() == x for x in L)
True
sage: all(x * y == y * x for x in L for y in L)  # long time
True
sage: Lsum = sum(L)
sage: gens = [P.s(i) for i in range(1,k)]
sage: gens += [P.e(i/2) for i in range(1,2*k)]
sage: all(x * Lsum == Lsum * x for x in gens)
True
```

```python
>>> from sage.all import *
"""
```

(continues on next page)
Combinatorics, Release 10.4

>>> k = Integer(4)
>>> R = QQ['n']; (n,) = R._first_ngens(1)
>>> P = PartitionAlgebra(k, n)
>>> L = [P.L(i/Integer(2)) for i in range(Integer(1),Integer(2)*k+Integer(1))]
>>> all(x.dual() == x for x in L)
True

>>> all(x * y == y * x for x in L for y in L)  # long time
True

>>> Lsum = sum(L)
>>> gens = [P.s(i) for i in range(Integer(1),k)]
>>> gens += [P.e(i/Integer(2)) for i in range(Integer(1),Integer(2)*k)]
>>> all(x * Lsum == Lsum * x for x in gens)
True

Also the relations in Lemma 2.2.3(3) in [Cre2020] (v1):

```
sage: all(P.e((2*i+1)/2) * P.sigma(2*i/2) * P.e((2*i+1)/2)
....:   == (n - P.L((2*i-1)/2)) * P.e((2*i+1)/2) for i in range(1,k))
True

sage: all(P.e(i/2) * (P.L(i/2) + P.L((i+1)/2))
....:   == (P.L(i/2) + P.L((i+1)/2)) * P.e(i/2)
....:   == n * P.e(i/2) for i in range(1,2*k))
True

sage: all(P.sigma((2*i+1)/2) * P.e((2*i+1)/2) * P.e(2*i/2)
....:   == P.L(2*i/2) * P.e(2*i/2) for i in range(1,k))
True
```

Also (continues on next page)
The same tests for a half integer partition algebra:

```
sage: k = 9/2
sage: R.<n> = QQ[]
```

```
sage: P = PartitionAlgebra(k, n)
```

```
sage: L = [P.L(i/2) for i in range(1,2*k+1)]
```

```
sage: all(x.dual() == x for x in L)
True
```

```
sage: all(x * y == y * x for x in L for y in L)
# long time
True
```

```
sage: Lsum = sum(L)
sage: gens = [P.s(i) for i in range(1,k-1/2)]
```

```
sage: gens += [P.e(i/2) for i in range(1,2*k)]
```

```
sage: all(x * Lsum == Lsum * x for x in gens)
True
```

```
sage: all(P.e((2*i+1)/2) * P.sigma(2*i/2) * P.e((2*i+1)/2) ==
    (n - P.L((2*i-1)/2)) * P.e((2*i+1)/2) for i in range(1,floor(k)))
True
```

```
sage: all(P.e(i/2) * (P.L(i/2) + P.L((i+1)/2)) ==
    (P.L(i/2) + P.L((i+1)/2)) * P.e(i/2) ==
    n * P.e(i/2) for i in range(1,2*k))
True
```

```
sage: all(P.sigma(2*i/2) * P.e((2*i-1)/2) * P.e(2*i/2) ==
    P.L(2*i/2) * P.e(2*i/2) for i in range(1,ceil(k))
True
```

```
sage: all(P.e(2*i/2) * P.e((2*i+1)/2) * P.sigma((2*i+1)/2) ==
    P.e(2*i/2) * P.L(2*i/2) for i in range(1,floor(k))
True
```

```
sage: all(P.e(2*i/2) * P.e((2*i+1)/2) * P.sigma((2*i+1)/2) ==
    P.e(2*i/2) * P.L(2*i/2) for i in range(1,floor(k))
True
```

```
from sage.all import *
```

```
k = Integer(9)/Integer(2)
R = QQ['n']; (n,) = R._first_ngens(1)
P = PartitionAlgebra(k, n)
L = [P.L(i/Integer(2)) for i in range(Integer(1),Integer(2)*k+Integer(1))]
all(x.dual() == x for x in L)
True
```

```
all(x * y == y * x for x in L for y in L)  # long time
(continues on next page)
True
>>> Lsum = sum(L)

>>> gens = [P.s(i) for i in range(Integer(1), k-Integer(1)/Integer(2))]
>>> gens += [P.e(i/Integer(2)) for i in range(Integer(1), Integer(2)*k)]
>>> all(x * Lsum == Lsum * x for x in gens)
True

>>> all(P.e((Integer(2)*i+Integer(1))/Integer(2)) * P.sigma((Integer(2)*i-Integer(1))/Integer(2))
... == (n - P.L((Integer(2)*i-Integer(1))/Integer(2))) * P.e((Integer(2)*i+Integer(1))/Integer(2)) for i in range(Integer(1), floor(k)))
True

>>> all(P.e(i/Integer(2)) * (P.L(i/Integer(2)) + P.L((i+Integer(1))/Integer(2))) * P.e(i/Integer(2))
... == n * P.e(i/Integer(2)) for i in range(Integer(1), Integer(2)*k))
True

>>> all(P.s((Integer(2)*i+Integer(1))/Integer(2)) * P.e((Integer(2)*i-Integer(1))/Integer(2)) * P.e((Integer(2)*i+Integer(1))/Integer(2))
... == P.L((Integer(2)*i+Integer(1))/Integer(2)) * P.e((Integer(2)*i+Integer(1))/Integer(2)) for i in range(Integer(1), ceil(k)))
True

>>> all(P.e((Integer(2)*i+Integer(1))/Integer(2)) * P.e((Integer(2)*i+Integer(1))/Integer(2))
... == P.L((Integer(2)*i+Integer(1))/Integer(2)) for i in range(Integer(1), floor(k)))
True

>>> all(P.e((Integer(2)*i+Integer(1))/Integer(2)) * P.e((Integer(2)*i+Integer(1))/Integer(2))
... == P.L((Integer(2)*i+Integer(1))/Integer(2)) for i in range(Integer(1), floor(k)))
True

>>> all(P.e((Integer(2)*i+Integer(1))/Integer(2)) * P.e((Integer(2)*i+Integer(1))/Integer(2))
... == P.L((Integer(2)*i+Integer(1))/Integer(2)) for i in range(Integer(1), floor(k)))
True

a(i)

Return the element \(a_i\) in self.

The element \(a_i\) is the cap and cup at \((i, i + 1)\), so it contains the blocks \(\{i, i + 1\}, \{-i, -i + 1\}\). Other blocks are of the form \(\{-j, j\}\).

INPUT:

* \(i\) – an integer between 1 and \(k - 1\)

EXAMPLES:

```
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.a(1)
P{{-3, 3}, {-2, -1}, {1, 2}}
sage: P3.a(2)
P{{-3, -2}, {-1, 1}, {2, 3}}
sage: P3 = PartitionAlgebra(5/2, n)
```
Return the element $e_i$ in self.

If $i = (2r + 1)/2$, then $e_i$ contains the blocks $\{r + 1\}$ and $\{-r - 1\}$. If $i \in \mathbb{Z}$, then $e_i$ contains the block $\{-i, -i - 1, i, i + 1\}$. Other blocks are of the form $\{-j, j\}$.

**INPUT:**

- $i$ – a half integer between 1/2 and $k - 1/2$

**EXAMPLES:**

```python
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.e(1)
P(..., {1, 2}, {1, 2})
sage: P3.e(2)
P(..., {1, 2}, {1, 2})
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> from sage.all import *
>>> R = QQ['n']; (n,) = R._first_ngens(1)
>>> P3 = PartitionAlgebra(Integer(3), n)
>>> P3.e(Integer(1))
P{{-3, 3}, {-2, -1, 1, 2}}
>>> P3.e(Integer(2))
P{{-3, 3}, {-2, 2}, {-1}, {1}}
>>> P3.e(Integer(3))
Traceback (most recent call last):
  ... ValueError: i must be an (half) integer between 1/2 and 5/2
>>> P3.e(Integer(3))
Traceback (most recent call last):
  ... ValueError: i must be an (half) integer between 1/2 and 5/2
>>> P2h = PartitionAlgebra(Integer(5)/Integer(2), n)
>>> for k in range(Integer(1), Integer(5)):
P{{-3, 3}, {-2, 2}, {-1, 1}, {2}},
```

**generator_a (i)**

Return the element $a_i$ in self.

The element $a_i$ is the cap and cup at $(i, i+1)$, so it contains the blocks $\{i, i+1\}$, $\{-i, -i-1\}$. Other blocks are of the form $\{-j, j\}$.

**INPUT:**

- $i$ – an integer between 1 and $k-1$

**EXAMPLES:**

```python
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.a(1)
P{{-3, 3}, {-2, -1, 1, 2}}
sage: P3.a(2)
P{{-3, -2}, {-1, 1}, {2, 3}}
sage: P3 = PartitionAlgebra(5/2, n)
sage: P3.a(1)
P{{-3, 3}, {-2, -1, 1, 2}}
sage: P3.a(2)
Traceback (most recent call last):
  ... ValueError: i must be an integer between 1 and 1
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> R = QQ['n']; (n,) = R._first_ngens(1)
>>> P3 = PartitionAlgebra(Integer(3), n)
```

```python
>>> P3.a(Integer(1))
P\{{-3, 3}, {-2, -1}, \{1, 2\}}
```

```python
>>> P3.a(Integer(2))
P\{{-3, -2}, \{-1, 1\}, \{2, 3\}}
```

```python
>>> P3 = PartitionAlgebra(Integer(5)/Integer(2), n)
>>> P3.a(Integer(1))
P\{{-3, 3}, {-2, -1}, \{1, 2\}}
```

```python
>>> P3.a(Integer(2))
Traceback (most recent call last):
...  
ValueError: i must be an integer between 1 and 1
```

---

**generator_e**

Return the element \(e_i\) in self.

If \(i = (2r + 1)/2\), then \(e_i\) contains the blocks \(\{r + 1\}\) and \(\{-r - 1\}\). If \(i \in \mathbb{Z}\), then \(e_i\) contains the block \(\{-i, -i - 1, i, i + 1\}\). Other blocks are of the form \(\{-j, j\}\).

**INPUT:**

- \(i\) – a half integer between 1/2 and \(k - 1/2\)

**EXAMPLES:**

```python
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.e(1)
P\{{-3, 3}, {-2, -1, 1, 2}}
sage: P3.e(2)
P\{{-3, -2, 2, 3}, \{-1, 1\}}
sage: P3.e(1/2)
P\{{-3, 3}, \{-2, 2\}, \{-1, 1\}}
sage: P3.e(5/2)
P\{{-3, \{-2, 2\}, \{-1, 1\}, \{3\}}
sage: P3.e(0)
Traceback (most recent call last):
...  
ValueError: i must be an (half) integer between 1/2 and 5/2
```

```python
sage: P3.e(3)
Traceback (most recent call last):
...  
ValueError: i must be an (half) integer between 1/2 and 5/2
```

```python
sage: P2h = PartitionAlgebra(5/2,n)
sage: [P2h.e(k/2) for k in range(1,5)]
[P\{{-3, 3}, \{-2, 2\}, \{-1, \{1\}\}, \{3\}}
```

```python
>>> from sage.all import *
>>> R = QQ['n']; (n,) = R._first_ngens(1)
>>> P3 = PartitionAlgebra(Integer(3), n)
>>> P3.e(Integer(1))
```

(continues on next page)
generator_s(i)

Return the i-th simple transposition s_i in self.

Borrowing the notation from the symmetric group, the i-th simple transposition s_i has blocks of the form \{-i, i+1\}, \{-i-1, i\}. Other blocks are of the form \{-j, j\}.

INPUT:

• i – an integer between 1 and \(k-1\)

EXAMPLES:

```python
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.s(1)
P{(-3, 3), {-2, 1}, {-1, 2}}
sage: P3.s(2)
P{(-3, 2), {-2, 3}, {-1, 1}}

sage: R.<n> = ZZ[]
sage: P2h = PartitionAlgebra(Integer(5)/Integer(2), n)
sage: P2h.s(1)
P{(-3, 3), {-2, 1}, {-1, 2}}
```

```python
>>> from sage.all import *
>>> R = QQ['n']; (n,) = R._first_ngens(1)
>>> P3 = PartitionAlgebra(Integer(3), n)
>>> P3.s(Integer(1))
P{(-3, 3), {-2, 1}, {-1, 2}}
>>> P3.s(Integer(2))
P{(-3, 2), {-2, 3}, {-1, 1}}
>>> R = ZZ['n']; (n,) = R._first_ngens(1)
>>> P2h = PartitionAlgebra(Integer(5)/Integer(2), n)
```

(continues on next page)
\textbf{\texttt{jucys_murphy_element}} \textit{(i)}

Return the \textit{i}-th Jucys-Murphy element $L_i$ from [Eny2012].

\textbf{INPUT:}

\begin{itemize}
  \item $i$ – a half integer between 1/2 and $k$
\end{itemize}

\textbf{ALGORITHM:}

We use the recursive definition for $L_{2i}$ given in [Cre2020]. See also [Eny2012] and [Eny2013].

\textbf{Note:} $L_{1/2}$ and $L_1$ differs from [HR2005].

\textbf{EXAMPLES:}

\begin{verbatim}
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.jucys_murphy_element(1/2)
0
sage: P3.jucys_murphy_element(1)
P{(-3, 3), (-2, 2), (-1), (1)}
sage: P3.jucys_murphy_element(2)
P{(-3, 3), (-2), (-1, 1), (2)} - P{(-3, 3), (-2), (-1, 1, 2)} + P{(-3, 3), (-2, -1, 1), (2)} + P{(-3, 3), (-2, 1), (-1, 2)}
sage: P3.jucys_murphy_element(3/2)
n*P{(-3, 3), (-2, -1, 1, 2)} - P{(-3, 3), (-2, -1, 2), (1)} - P{(-3, 3), (-2, 1, 2), (1)} + P{(-3, 3), (-2, 2), (-1, 1)}
True
\end{verbatim}

We test the relations in Lemma 2.2.3(2) in [Cre2020] (v1):

\begin{verbatim}
sage: k = 4
sage: R.<n> = QQ[]
\end{verbatim}
sage: P = PartitionAlgebra(k, n)
sage: L = [P.L(i/2) for i in range(1,2*k+1)]
sage: all(x.dual() == x for x in L)
True
sage: all(x * y == y * x for x in L for y in L)
# long time
True
sage: Lsum = sum(L)
sage: gens = [P.s(i) for i in range(1,k)]
sage: gens += [P.e(i/2) for i in range(1,2*k)]
sage: all(x * Lsum == Lsum * x for x in gens)
True

Also the relations in Lemma 2.2.3(3) in [Cre2020] (v1):

sage: all(P.e((2*i+1)/2) * P.sigma(2*i/2) * P.e((2*i+1)/2)
....:  == (n - P.L((2*i-1)/2)) * P.e((2*i+1)/2) for i in range(1,k))
True
sage: all(P.e(i/2) * (P.L(i/2) + P.L((i+1)/2))
....:  == (P.L(i/2) + P.L((i+1)/2)) * P.e(i/2)
....:  == n * P.e(i/2) for i in range(1,2*k))
True
sage: all(P.sigma(2*i/2) * P.e((2*i-1)/2) * P.e(2*i/2)
....:  == P.L(2*i/2) * P.e(2*i/2) for i in range(1,k))
True
sage: all(P.e(2*i/2) * P.e((2*i-1)/2) * P.sigma(2*i/2)
....:  == P.e(2*i/2) * P.L(2*i/2) for i in range(1,k))
True
sage: all(P.sigma((2*i+1)/2) * P.e((2*i+1)/2) * P.e(2*i/2)
....:  == P.e(2*i/2) * P.L(2*i/2) for i in range(1,k))
True
sage: all(P.e(2*i/2) * P.e((2*i+1)/2) * P.sigma((2*i+1)/2)
....:  == P.e(2*i/2) * P.L(2*i/2) for i in range(1,k))
True

>>> from sage.all import *
>>> k = Integer(4)
>>> R = QQ['n']; (n,) = R._first_ngens(1)
>>> P = PartitionAlgebra(k, n)
>>> L = [P.L(i/Integer(2)) for i in range(Integer(1),Integer(2)*k+Integer(1))]
>>> all(x.dual() == x for x in L)
True
>>> all(x * y == y * x for x in L for y in L)
# long time
True
>>> Lsum = sum(L)
>>> gens = [P.s(i) for i in range(Integer(1),k)]
>>> gens += [P.e(i/Integer(2)) for i in range(Integer(1),Integer(2)*k)]
>>> all(x * Lsum == Lsum * x for x in gens)
True

(continues on next page)
The same tests for a half integer partition algebra:

```python
sage: k = 9/2
sage: R.<n> = QQ[]
sage: P = PartitionAlgebra(k, n)
sage: L = [P.L((i/2)) for i in range(1,2*k+1)]
sage: all(x.dual() == x for x in L)  # long time
True
sage: all(x * y == y * x for x in L for y in L)
True
sage: Lsum = sum(L)
sage: gens = [P.e(i/2) for i in range(1,2*k)]
sage: gens += [P.e((2*i+1)/2) for i in range(1,floor(k))]
sage: all(x * Lsum == Lsum * x for x in gens)
True
sage: all(P.e((2*i+1)/2) * P.sigma(2*i/2) * P.e((2*i+1)/2) ==
    (n - P.L((2*i-1)/2)) * P.e((2*i+1)/2) for i in range(1,floor(k)))
True
sage: all(P.e(i/2) * (P.L(i/2) + P.L((i+1)/2)) * P.e(i/2) ==
    n * P.e(i/2) for i in range(1,2*k))
True
sage: all(P.sigma(2*i/2) * P.e((2*i-1)/2) * P.e(2*i/2) ==
    P.L(2*i/2) * P.e(2*i/2) for i in range(1,ceil(k)))
True
sage: all(P.e(2*i/2) * P.e(2*i-1/2) * P.sigma(2*i/2) ==
    P.e(2*i/2) * P.L(2*i/2) for i in range(1,ceil(k)))
True
sage: all(P.sigma((2*i+1)/2) * P.e(2*i+1/2) * P.e(2*i/2) ==
    P.L(2*i/2) * P.e(2*i/2) for i in range(1,floor(k))}
True
```
sage: all(P.e(2*i/2) * P.e((2*i+1)/2) * P.sigma((2*i+1)/2) == P.e(2*i/2) * P.L(2*i/2) for i in range(1,floor(k)))
True

>>> from sage.all import *
>>> k = Integer(9)/Integer(2)
>>> R = QQ['n']; (n,) = R._first_ngens(1)
>>> P = PartitionAlgebra(k, n)
>>> L = [P.L(i/Integer(2)) for i in range(Integer(1),Integer(2)*k+Integer(1))]
>>> all(x.dual() == x for x in L)
True
>>> all(x * y == y * x for x in L for y in L)  # long time
True
>>> Lsum = sum(L)
>>> gens = [P.s(i) for i in range(Integer(1),k-Integer(1)/Integer(2))]
>>> gens += [P.e(i/Integer(2)) for i in range(Integer(1),Integer(2)*k)]
>>> all(x * Lsum == Lsum * x for x in gens)
True
>>> all(P.e((Integer(2)*i+Integer(1))/Integer(2)) * P.sigma(Integer(2)*i/Integer(2)) * P.e((Integer(2)*i+Integer(1))/Integer(2)) == (n - P.L((Integer(2)*i-Integer(1))/Integer(2))) * P.e((Integer(2)*i+Integer(1))/Integer(2)) for i in range(Integer(1),ceil(k)))
True

orbit_basis()

Return the orbit basis of self.

EXAMPLES:

sage: R.<x> = QQ[]
Combinatorics, Release 10.4

```python
sage: P2 = PartitionAlgebra(2, x, R)
sage: O2 = P2.orbit_basis(); O2
Orbit basis of Partition Algebra of rank 2 with parameter x over
Univariate Polynomial Ring in x over Rational Field
sage: pp = 7 * P2[{-1}, {-2, 1, 2}] - 2 * P2[{-2}, {-1, 1}, {2}]; pp
-2*P{{-2}, {-1, 1}, {2}} + 7*P{{-2, 1, 2}, {-1}}
```

```python
sage: op = pp.to_orbit_basis(); op
-2*O{{-2}, {-1, 1}, {2}} - 2*O{{-2}, {-1, 1, 2}}
- 2*O{{-2, -1, 1}, {2}} + 5*O{{-2, -1, 1, 2}}
+ 7*O{{-2, 1, 2}, {-1}} - 2*O{{-2, 2}, {-1, 1}}
sage: op == O2(op)
True
```

```python
sage: pp * op.leading_term()
4*P{{-2}, {-1, 1}, {2}} - 4*P{{-2, -1, 1}, {2}}
+ 14*P{{-2, -1, 1, 2}} - 14*P{{-2, 1, 2}, {-1}}
```

```python
>>> from sage.all import *

>>> R = QQ['x']; (x,) = R._first_ngens(1)

>>> P2 = PartitionAlgebra(Integer(2), x, R)

>>> O2 = P2.orbit_basis(); O2
Orbit basis of Partition Algebra of rank 2 with parameter x over
Univariate Polynomial Ring in x over Rational Field

>>> pp = Integer(7) * P2[{-Integer(1)}, {-Integer(2), Integer(1), Integer(2)}]; pp
-2*P{{-2}, {-1, 1}, {2}} + 7*P{{-2, 1, 2}, {-1}}

>>> op = pp.to_orbit_basis(); op
-2*O{{-2}, {-1, 1}, {2}} - 2*O{{-2}, {-1, 1, 2}}
- 2*O{{-2, -1, 1}, {2}} + 5*O{{-2, -1, 1, 2}}
+ 7*O{{-2, 1, 2}, {-1}} - 2*O{{-2, 2}, {-1, 1}}

>>> op == O2(op)
True

>>> pp * op.leading_term()
4*P{{-2}, {-1, 1}, {2}} - 4*P{{-2, -1, 1}, {2}}
+ 14*P{{-2, -1, 1, 2}} - 14*P{{-2, 1, 2}, {-1}}
```

**potts_representation** *(y=None)*

Return the *PottsRepresentation* with magnetic field direction *y* of *self*.

**Note:** The deformation parameter *d* of *self* must be a positive integer.

**INPUT:**

- *y* – (option) an integer between 1 and *d*; ignored if the order of *self* is an integer, otherwise the default is 1

**EXAMPLES:**

```python
sage: PA = algebras.Partition(5/2, QQ(4))
sage: PR = PA.potts_representation()
sage: PA = algebras.Partition(5/2, 3/2)
sage: PA.potts_representation()
Traceback (most recent call last):
...`
ValueError: the partition algebra deformation parameter must be a positive integer

```python
>>> from sage.all import *
>>> PA = algebras.Partition(Integer(5)/Integer(2), QQ(Integer(4)))
>>> PA.potts_representation()
Traceback (most recent call last):
... ValueError: the partition algebra deformation parameter must be a positive integer
```

\( s(i) \)

Return the \( i \)-th simple transposition \( s_i \) in \( \text{self} \).

Borrowing the notation from the symmetric group, the \( i \)-th simple transposition \( s_i \) has blocks of the form \( \{-i, i+1\}, \{-i-1, i\} \). Other blocks are of the form \( \{-j, j\} \).

**INPUT:**

\[ \bullet \ i \text{ – an integer between } 1 \text{ and } k - 1 \]

**EXAMPLES:**

```python
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.s(1)
P\{\{-3, 3\}, \{-2, 1\}, \{-1, 2\}\}
sage: P3.s(2)
P\{\{-3, 2\}, \{-2, 3\}, \{-1, 1\}\}

sage: R.<n> = ZZ[]
sage: P2h = PartitionAlgebra(5/2,n)
sage: P2h.s(Integer(1))
P\{\{-3, 3\}, \{-2, 1\}, \{-1, 2\}\}
```

\( \sigma(i) \)

Return the element \( \sigma_i \) from [Eny2012] of \( \text{self} \).

**INPUT:**

\[ \bullet \ i \text{ – a half integer between } 1/2 \text{ and } k - 1/2 \]
Note: In [Cre2020] and [Eny2013], these are the elements $\sigma_{2i}$.

EXAMPLES:

```python
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.sigma(1)
P{(-3, 3), (-2, 2), (-1, 1)}
sage: P3.sigma(3/2)
P{(-3, 3), (-2, 1), (-1, 2)}
sage: P3.sigma(2)
-P{(-3, -1, 1, 3), (-2, 2)} + P{(-3, -1, 3), (-2, 1, 2)}
+ P{(-3, 1, 3), (-2, -1, 2)} - P{(-3, 3), (-2, -1, 1, 2)}
+ P{(-3, 3), (-2, 2), (-1, 1)}
sage: P3.sigma(5/2)
-P{(-3, -1, 1, 2), (-2, 3)} + P{(-3, -1, 2), (-2, 1, 3)}
+ P{(-3, 1, 2), (-2, -1, 3)} - P{(-3, 2), (-2, -1, 1, 3)}
+ P{(-3, 2), (-2, 3), (-1, 1)}
```

We test the relations in Lemma 2.2.3(1) in [Cre2020] (v1):

```python
sage: k = 4
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(k, x)
sage: all(P.sigma(i/2).dual() == P.sigma(i/2)  
...: for i in range(1,2*k))
True
sage: all(P.sigma(i)*P.sigma(i+1/2) == P.sigma(i+1/2)*P.sigma(i) == P.s(i)  
...: for i in range(1,floor(k)))
True
sage: all(P.sigma(i)*P.e(i) == P.e(i)*P.sigma(i) == P.e(i)  
...: for i in range(1,floor(k)))
True
```

sage: k = 9/2
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(k, x)
```

(continues on next page)
class sage.combinat.diagram_algebras.PartitionDiagram(parent, d, check=True)

Bases: AbstractPartitionDiagram

The element class for a partition diagram.

A partition diagram for an integer \( k \) is a partition of the set \( \{1, \ldots, k, -1, \ldots, -k\} \)

EXAMPLES:
```python
sage: from sage.combinat.diagram_algebras import PartitionDiagram,
    PartitionDiagrams
sage: PartitionDiagrams(1)
Partition diagrams of order 1
sage: PartitionDiagrams(1).list()
[[(1, -1), (1, 1)], [(1, -1), (1)]]
```

```python
sage: PartitionDiagram(((1,-2),(2,-1))).parent()
Partition diagrams of order 2
```

```python
>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import PartitionDiagram, PartitionDiagrams
>>> PartitionDiagrams(Integer(1)).list()
[{{-1, 1}}, {{-1}, {1}}]
```

```python
class sage.combinat.diagram_algebras.PartitionDiagrams(order, category=None)
Bases: AbstractPartitionDiagrams
This class represents all partition diagrams of integer or integer +1/2 order.
EXAMPLES:
```
```python
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.PartitionDiagrams(1); pd
Partition diagrams of order 1
sage: pd.list()
[{{-1, 1}}, {{-1}, {1}}]
```

```python
sage: pd = da.PartitionDiagrams(3/2); pd
Partition diagrams of order 3/2
sage: pd.list()
[{{-2, -1, 1, 2}}, {{-2, 1, 2}, {-1}}, {{-2, 2}, {-1, 1}}, {{-2, -1, 2}, {1}}, {{-2, 2}, {-1}, {1}}]
```

```python
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> pd = da.PartitionDiagrams(Integer(1)); pd
>>> pd.list()
[{{-1, 1}}, {{-1}, {1}}]
```

```python
>>> pd = da.PartitionDiagrams(Integer(3)/Integer(2)); pd
>>> pd.list()
[{{-2, -1, 1, 2}}, {{-2, 1, 2}, {-1}}, {{-2, 2}, {-1, 1}}, {{-2, -1, 2}, {1}}, {{-2, 2}, {-1}, {1}}]
```
```
```
Element

    alias of PartitionDiagram

cardinality()

    The cardinality of partition diagrams of half-integer order \( n \) is the \( 2^n \)-th Bell number.

    EXAMPLES:

    sage: import sage.combinat.diagram_algebras as da
    sage: pd = da.PartitionDiagrams(3)
    sage: pd.cardinality()
    203
    sage: pd = da.PartitionDiagrams(7/2)
    sage: pd.cardinality()
    877

>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> pd = da.PartitionDiagrams(Integer(3))
>>> pd.cardinality()
203
>>> pd = da.PartitionDiagrams(Integer(7)/Integer(2))
>>> pd.cardinality()
877

class sage.combinat.diagram_algebras.PlanarAlgebra(k, q, base_ring, prefix)

    Bases: SubPartitionAlgebra, UnitDiagramMixin

    A planar algebra.

    The planar algebra of rank \( k \) is an algebra with basis indexed by the collection of all planar set partitions of \( \{1, \ldots, k, -1, \ldots, -k\} \).

    This algebra is thus a subalgebra of the partition algebra. For more information, see PartitionAlgebra.

    INPUT:

    - \( k \) – rank of the algebra
    - \( q \) – the deformation parameter \( q \)

    OPTIONAL ARGUMENTS:

    - \( \text{base\_ring} \) – (default None) a ring containing \( q \); if None then just takes the parent of \( q \)
    - \( \text{prefix} \) – (default "Pl") a label for the basis elements

    EXAMPLES:

    We define the planar algebra of rank 2 with parameter \( x \) over \( \mathbb{Z} \):

    sage: R.<x> = ZZ[]
    sage: Pl = PlanarAlgebra(2, x, R); Pl
    Planar Algebra of rank 2 with parameter x over Univariate Polynomial Ring in x over Integer Ring
    (continues on next page)
sage: Pl.basis().keys()
Planar diagrams of order 2
sage: Pl.basis().keys()([[[-1, 1], [2, -2]]])
{{-2, 2}, {-1, 1}}

sage: Pl.basis().list()
[Pl{{-2}, {-1}, {1, 2}},
Pl{{-2}, {-1}, {1}, {2}},
Pl{{-2, 1}, {-1}, {2}},
Pl{{-2, 2}, {-1}, {1}},
Pl{{-2, 1, 2}, {-1}},
Pl{{-2, 2}, {-1, 1}},
Pl{{-2}, {-1, 1}, {2}},
Pl{{-2}, {-1, 2}, {1}},
Pl{{-2}, {-1, 1, 2}},
Pl{{-2, -1}, {1, 2}},
Pl{{-2, -1}, {1}, {2}},
Pl{{-2, -1, 1}, {2}},
Pl{{-2, -1, 2}, {1}},
Pl{{-2, -1, 1, 2}}]

sage: E = Pl([[1,2],[-1,-2]])

sage: E^2 == x*E
True
sage: E^5 == x^4*E
True

```python
>>> from sage.all import *
>>> R = ZZ['x']; (x,) = R._first_ngens(1)
>>> P1 = PlanarAlgebra(Integer(2), x, R); P1
Planar Algebra of rank 2 with parameter x over Univariate Polynomial Ring in x
˓→ over Integer Ring

>>> P1.basis().keys()
Planar diagrams of order 2

>>> P1.basis().keys()([[[-Integer(1), Integer(1)], [Integer(2), -Integer(2)]]])
{{-2, 2}, {-1, 1}}

>>> P1.basis().list()
[Pl{{-2}, {-1}, {1, 2}},
Pl{{-2}, {-1}, {1}, {2}},
Pl{{-2, 1}, {-1}, {2}},
Pl{{-2, 2}, {-1}, {1}},
Pl{{-2, 1, 2}, {-1}},
Pl{{-2, 2}, {-1, 1}},
Pl{{-2}, {-1, 1}, {2}},
Pl{{-2}, {-1, 2}, {1}},
Pl{{-2}, {-1, 1, 2}},
Pl{{-2, -1}, {1, 2}},
Pl{{-2, -1}, {1}, {2}},
Pl{{-2, -1, 1}, {2}},
Pl{{-2, -1, 2}, {1}},
Pl{{-2, -1, 1, 2}}]

>>> E = Pl([[Integer(1),Integer(2)],[Integer(1),-Integer(2)]]))

>>> E**Integer(2) == x*E
True

>>> E**Integer(5) == x**Integer(4)*E
True
```

class sage.combinat.diagram_algebras.PlanarDiagram(parent, d, check=True)

Bases: AbstractPartitionDiagram
The element class for a planar diagram.

A planar diagram for an integer \( k \) is a partition of the set \( \{1, \ldots, k, -1, \ldots, -k\} \) so that the diagram is non-crossing.

EXAMPLES:

```python
sage: from sage.combinat.diagram_algebras import PlanarDiagrams
sage: PlanarDiagrams(2)
Planar diagrams of order 2
sage: PlanarDiagrams(2).list()
[[{-2}, {-1}, {1, 2}],
 {{-2}, {-1}, {1}, {2}},
 {{-2}, 1, {-1}, {2}},
 {{-2}, 2, {-1}, {1}},
 {{-2, 1, 2}, {-1}},
 {{-2, 1, 2}, {-1}},
 {{-2}, {-1, 1}, {2}},
 {{-2}, {-1, 2}, {1}},
 {{-2}, {-1, 1, 2}},
 {{-2, -1}, {1, 2}},
 {{-2, -1}, {1}, {2}},
 {{-2, -1, 1}, {2}},
 {{-2, -1, 2}, {1}},
 {{-2, -1, 1, 2}}
]
```

```python
>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import PlanarDiagrams
>>> PlanarDiagrams(Integer(2))
Planar diagrams of order 2
>>> PlanarDiagrams(Integer(2)).list()
[[{-2}, {-1}, {1, 2}],
 {{-2}, {-1}, {1}, {2}},
 {{-2, 1}, {-1}, {2}},
 {{-2, 2}, {-1}, {1}},
 {{-2, -1}, {1, 2}},
 {{-2, -1}, {1}, {2}},
 {{-2, -1, 1}, {2}},
 {{-2, -1, 2}, {1}},
 {{-2, -1, 1, 2}}
]
```

```
check()
```

Check the validity of the input for self.

```
class sage.combinat.diagram_algebras.PlanarDiagrams(order, category=None)

Bases: AbstractPartitionDiagrams

All planar diagrams of integer or integer +1/2 order.

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: pld = da.PlanarDiagrams(1); pld
Planar diagrams of order 1
```

(continues on next page)
Element

alias of PlanarDiagram
cardinality()

Return the cardinality of self.

The number of all planar diagrams of order \(k\) is the \(2k\)-th Catalan number.

EXAMPLES:

```sage
sage: import sage.combinat.diagram_algebras as da
dsage: pld = da.PlanarDiagrams(3)
sage: pld.cardinality()
132
```

class sage.combinat.diagram_algebras.PottsRepresentation(PA, y)

Bases: CombinatorialFreeModule

The Potts representation of the partition algebra.

Let \(P_n(d)\) be the PartitionAlgebra over \(R\) with the deformation parameter \(d \in \mathbb{Z}_{>0}\) being a positive integer. Recall the multiplication convention of diagrams in \(P_n(d)\) computing \(DD'\) by placing \(D\) above \(D'\).
The Potts representation is the right $P_n(d)$-module on $M = V^\otimes n$, with $V = R^d$, with the action given as follows. We identify the natural basis vectors in $M$ with words of length $n$ in the alphabet $\{1, \ldots, d\}$ (which we call colors). For a basis vector $w$ and diagram $D$, define $w \cdot D$ as the sum over all $v$ such that every part in $wDv$ (consider this as coloring the nodes of $D$) is given by the same color.

If $n$ is a half integer, then there is an extra fixed color for the node $\lceil n \rceil$, which is called the magnetic field direction from the physics interpretation of this representation.

EXAMPLES:

In this example, we consider $R = Q$ and use the Potts representation to construct the centralizer algebra of the left $S_{d-1}$-action on $V^\otimes n$ with $V = Q^d$ being the permutation action.

```python
sage: PA = algebras.Partition(5/2, QQ(2))
sage: PR = PA.potts_representation(2)
sage: mats = [PR.representation_matrix(x) for x in PA.basis()]
sage: MS = mats[0].parent()
sage: CM = MS.submodule(mats)
sage: CM.dimension()
16
```

We check that this commutes with the $S_{d-1}$-action:

```python
sage: all((g * v) * x == g * (v * x) for g in PR.symmetric_group() for v in PR.basis() for x in PA.basis())
True
```

Next, we see that the centralizer of the $S_d$-action is smaller than the semisimple quotient of the partition algebra:

```python
sage: PA.dimension()
52
sage: len(PA.radical_basis())
9
sage: SQ = PA.semisimple_quotient()
sage: SQ.dimension()
43
```

(continues on next page)
Next, we get orthogonal idempotents that project onto the central orthogonal idempotents in the semisimple quotient and construct the corresponding Peirce summands $e_iP_n(d)e_i$:

```python
sage: # long time
sage: orth_idems = PA.orthogonal_idempotents_central_mod_radical()

sage: algs = [PA.peirce_summand(idm, idm) for idm in orth_idems]

sage: [A.dimension() for A in algs]
[16, 2, 1, 25]
```

We saw that we obtain the entire endomorphism algebra since $d = 2$ and $S_{d-1}$ is the trivial group. Hence, the 16 dimensional Peirce summand computed above is isomorphic to this endomorphism algebra (both are $4 \times 4$ matrix algebras over $\mathbb{Q}$). Hence, we have a natural quotient construction of the centralizer algebra from the partition algebra.

Next, we consider a case with a nontrivial $S_d$-action (now it is $S_d$ since the partition algebra has integer rank). We perform the same computations as before:

```python
sage: PA = algebras.Partition(2, QQ(2))

sage: PA.dimension()
15

sage: PA.semisimple_quotient().dimension()
10

sage: orth_idems = PA.orthogonal_idempotents_central_mod_radical()

sage: algs = [PA.peirce_summand(idm, idm) for idm in orth_idems]

sage: [A.dimension() for A in algs]
[4, 2, 4, 1]
```

We perform the same computations as before:

```python
sage: PA = algebras.Partition(Integer(2), QQ(Integer(2)))

sage: PA.dimension()
15

sage: PA.semisimple_quotient().dimension()
10

sage: orth_idems = PA.orthogonal_idempotents_central_mod_radical()

sage: algs = [PA.peirce_summand(idm, idm) for idm in orth_idems]

sage: [A.dimension() for A in algs]
[4, 2, 4, 1]
```
To do the remainder of the computation, we need to monkey patch a \texttt{product\_on\_basis} method:

\begin{verbatim}
sage: CM.product_on_basis
NotImplemented
sage: CM.product_on_basis = lambda x,y: CM.retract(CM.basis()[x].lift() * CM.basis()[y].lift())
sage: CM.orthogonal_idempotents_central_mod_radical()
((Free module generated by \{0, 1, 2, 3\} over Rational Field,
  Free module generated by \{\} over Rational Field),
  (Free module generated by \{\} over Rational Field,
  Free module generated by \{0, 1, 2, 3\} over Rational Field))

sage: CM.peirce_decomposition()
[[Free module generated by \{0, 1, 2, 3\} over Rational Field,
  Free module generated by \{\} over Rational Field],
  [Free module generated by \{\} over Rational Field,
  Free module generated by \{0, 1, 2, 3\} over Rational Field]]
\end{verbatim}

Hence, we see that the centralizer algebra is isomorphic to a product of two $2 \times 2$ matrix algebras (over $\mathbb{Q}$), which are naturally a part of the partition algebra decomposition.

Lastly, we verify the commuting actions:

\begin{verbatim}
sage: all((g * v) * x == g * (v * x) for g in PR.symmetric_group() for v in PR.basis() for x in PA.basis())
True

>>> from sage.all import *

>>> all((g * v) * x == g * (v * x) for g in PR.symmetric_group() for v in PR.basis() for x in PA.basis())
True
\end{verbatim}

REFERENCES:

- [MR1998]
**magnetic_field_direction()**

Return the magnetic field direction defining self.

**EXAMPLES:**

```python
sage: PA = algebras.Partition(7/2, QQ(4))
sage: PR = PA.potts_representation(2)
sage: PR.magnetic_field_direction()
2
```

```python
>>> from sage.all import *

>>> PA = algebras.Partition(Integer(7)/Integer(2), QQ(Integer(4)))

>>> PR = PA.potts_representation(Integer(2))

>>> PR.magnetic_field_direction()
2
```

**number_of_colors()**

Return the number of colors defining self.

**EXAMPLES:**

```python
sage: PA = algebras.Partition(3, QQ(4))
sage: PR = PA.potts_representation()
sage: PR.number_of_colors()
4
```

```python
>>> from sage.all import *

>>> PA = algebras.Partition(Integer(3), QQ(Integer(4)))

>>> PR = PA.potts_representation()

>>> PR.number_of_colors()
4
```

**number_of_factors()**

Return the number of factors defining self.

**EXAMPLES:**

```python
sage: PA = algebras.Partition(7/2, QQ(4))
sage: PR = PA.potts_representation()
sage: PR.number_of_factors()
3
```

```python
>>> from sage.all import *

>>> PA = algebras.Partition(Integer(7)/Integer(2), QQ(Integer(4)))

>>> PR = PA.potts_representation()

>>> PR.number_of_factors()
3
```

**partition_algebra()**

Return the partition algebra that self is a representation of.

**EXAMPLES:**

```python
sage: PA = algebras.Partition(3, QQ(4))
sage: PR = PA.potts_representation()
sage: PR.partition_algebra() is PA
True
```
```python
>>> from sage.all import *

>>> PA = algebras.Partition(Integer(3), QQ(Integer(4)))

>>> PR = PA.potts_representation()

>>> PR.partition_algebra()
True

representation_matrix(elt)

Return the representation matrix of self in self.

EXAMPLES:

```
sage: PA = algebras.Partition(7/2, QQ(2))
sage: PR = PA.potts_representation()
sage: PR.representation_matrix(PA.an_element())

[[7 0 3 0 2 0 0 0]

```

```
symmetric_group()

Return the symmetric group that naturally acts on self.

EXAMPLES:

```python
sage: PA = algebras.Partition(3, QQ(4))
sage: PR = PA.potts_representation()
sage: PR.symmetric_group()
Symmetric group of order 4! as a permutation group
sage: PA = algebras.Partition(7/2, QQ(4))
sage: PR = PA.potts_representation()
{2, 3, 4}
sage: PR = PA.potts_representation(2)
{1, 3, 4}
sage: PR = PA.potts_representation(4)
{1, 2, 3}
```

```python
>>> from sage.all import *
>>> PA = algebras.Partition(Integer(3), QQ(Integer(4)))
>>> PR = PA.potts_representation()
>>> PR.symmetric_group()
Symmetric group of order 4! as a permutation group
>>> PA = algebras.Partition(Integer(7)/Integer(2), QQ(Integer(4)))
>>> PR = PA.potts_representation()
>>> PR.symmetric_group().domain()
{2, 3, 4}
>>> PR = PA.potts_representation(Integer(2))
>>> PR.symmetric_group().domain()
{1, 3, 4}
>>> PR = PA.potts_representation(Integer(4))
>>> PR.symmetric_group().domain()
{1, 2, 3}
```

```python
class sage.combinat.diagram_algebras.PropagatingIdeal(k, q, base_ring, prefix)

Bases: SubPartitionAlgebra

A propagating ideal.

The propagating ideal of rank $k$ is a non-unital algebra with basis indexed by the collection of ideal set partitions of \{1, \ldots, k, -1, \ldots, -k\}. We say a set partition is ideal if its propagating number is less than $k$.

This algebra is a non-unital subalgebra and an ideal of the partition algebra. For more information, see PartitionAlgebra.

EXAMPLES:

We now define the propagating ideal of rank 2 with parameter $x$ over $\mathbb{Z}$:

```python
sage: R.<x> = QQ[]
sage: I = PropagatingIdeal(2, x, R); I
Propagating Ideal of rank 2 with parameter $x$ over Univariate Polynomial Ring in $x$ over Rational Field
sage: I.basis().keys()
Ideal diagrams of order 2
```
sage: I.basis().list()
[I{{-2, -1, 1, 2}},
 I{{-2, 1, 2}, {-1}},
 I{{-2}, {-1, 1, 2}},
 I{{-2, -1}, {1, 2}},
 I{{-2, -1, 1}, {2}},
 I{{-2, 1}, {-1}, {2}},
 I{{-2, -1, 2}, {1}},
 I{{-2}, {-1, 2}, {1}},
 I{{-2}, {-1}, {1}, {2}}]
sage: E = I([[-1,-2],[1,2]])
sage: E^2 == x*E
True
sage: E^5 == x^4*E
True

```python
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> I = PropagatingIdeal(Integer(2), x, R); I
Propagating Ideal of rank 2 with parameter x
over Univariate Polynomial Ring in x over Rational Field
>>> I.basis().keys()
Ideal diagrams of order 2
>>> I.basis().list()
[I{{-2, -1, 1, 2}},
 I{{-2, 1, 2}, {-1}},
 I{{-2}, {-1, 1, 2}},
 I{{-2, -1}, {1, 2}},
 I{{-2, -1, 1}, {2}},
 I{{-2, 1}, {-1}, {2}},
 I{{-2, -1, 2}, {1}},
 I{{-2}, {-1, 2}, {1}},
 I{{-2}, {-1}, {1}, {2}}]
```

```python
>>> E = I([[1,2],[-1,-2]])
>>> E**Integer(2) == x*E
True
>>> E**Integer(5) == x**Integer(4)*E
True
```

class Element

    Bases: Element

    An element of a propagating ideal.

    We need to take care of exponents since we are not unital.

class sage.combinat.diagram_algebras.SubPartitionAlgebra (k, q, base_ring, prefix, diagrams, category=None)

    Bases: DiagramBasis

5.1. Comprehensive Module List
A subalgebra of the partition algebra in the diagram basis indexed by a subset of the diagrams.

```
class Element
    Bases: Element
    to_orbit_basis()
        Return self in the orbit basis of the associated ambient partition algebra.

    EXAMPLES:
    sage: R.<x> = QQ[]
    sage: B = BrauerAlgebra(2, x, R)
    sage: bb = B([[[-2, -1], [1, 2]]]); bb
    B{-2, -1}, {1, 2})
    sage: bb.to_orbit_basis()
    O{-2, -1}, {1, 2}) + O{-2, -1, 1, 2})
```

```
ambient()
    Return the partition algebra self is a sub-algebra of.

    EXAMPLES:
    sage: x = var('x')  # needs sage.symbolic
    sage: BA = BrauerAlgebra(2, x)  # needs sage.symbolic
    sage: BA.ambient()  # needs sage.symbolic
    Partition Algebra of rank 2 with parameter x over Symbolic Ring

>>> from sage.all import *
>>> x = var('x')  # needs sage.symbolic
>>> BA = BrauerAlgebra(Integer(2), x)  # needs sage.symbolic
>>> BA.ambient()  # needs sage.symbolic
Partition Algebra of rank 2 with parameter x over Symbolic Ring
```

```
lift()
    Return the lift map from diagram subalgebra to the ambient space.

    EXAMPLES:
    sage: R.<x> = QQ[]
    sage: BA = BrauerAlgebra(2, x, R)
    sage: E = BA([[1, 2], [-1, -2]])
    sage: lifted = BA.lift(E); lifted
    B{-2, -1}, {1, 2})
```
sage: lifted.parent() is BA.ambient()
True

```python
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> BA = BrauerAlgebra(Integer(2), x, R)
>>> E = BA([[Integer(1),Integer(2)],[Integer(-1),Integer(-2)]]
>>> lifted = BA.lift(E); lifted
B((-2, -1), (1, 2))
>>> lifted.parent() is BA.ambient()
True
```

**retract** $(x)$
Retract an appropriate partition algebra element to the corresponding element in the partition subalgebra.

**EXAMPLES:**

```python
sage: R.<x> = QQ[]
sage: BA = BrauerAlgebra(2, x, R)
sage: PA = BA.ambient()
sage: E = PA([[-1,2], [-1,-2]])
sage: BA.retract(E) in BA
True
```

```
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> BA = BrauerAlgebra(Integer(2), x, R)
>>> PA = BA.ambient()
>>> E = PA([[Integer(1),Integer(2)],[Integer(-1),Integer(-2)]]
>>> BA.retract(E) in BA
True
```

```python
sage.combinat.diagram_algebras.TL_diagram_ascii_art(diagram, use_unicode=False, blobs=[])  
```
Return ascii art for a Temperley-Lieb diagram diagram.

**INPUT:**

- diagram – a list of pairs of matchings of the set $\{-1, \ldots, -n, 1, \ldots, n\}$
- use_unicode – (default: False): whether or not to use unicode art instead of ascii art
- blobs – (optional) a list of matchings with blobs on them

**EXAMPLES:**

```python
sage: from sage.combinat.diagram_algebras import TL_diagram_ascii_art
sage: TL = 
[(-15,-12), (-14,-13), (-11,15), (-10,14), (-9,-6),
 ...:  (-8,-7), (-5,-4), (-3,1), (-2,-1), (2,3), (4,5),
 ...:  (6,11), (7, 8), (9,10), (12,13)]
sage: TL_diagram_ascii_art(TL, use_unicode=False)
```

(continues on next page)
sage: TL_diagram_ascii_art(TL, use_unicode=True)

sage: TL = [(-15, -12), (-14, -13), (-11, -8), (-10, -7), (-9, -6), (-8, -5), (-7, -4), (-6, -3), (-5, 1), (-4, 2), (-3, 3), (-2, 4), (1, 5), (2, 6), (3, 7), (4, 8), (5, 9), (6, 10), (7, 11), (8, 12), (9, 13), (10, 14), (11, 15), (12, 16), (13, 17), (14, 18), (15, 19), (16, 20), (17, 18), (18, 19)]

sage: TL_diagram_ascii_art(TL, use_unicode=False, blobs=[(-2, -1), (-5, 1)])

>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import TL_diagram_ascii_art

>>> TL = [(-15, -12), (-14, -13), (-11, -8), (-10, -7), (-9, -6), (-8, -5), (-7, -4), (-6, -3), (-5, 1), (-4, 2), (-3, 3), (-2, 4), (1, 5), (2, 6), (3, 7), (4, 8), (5, 9), (6, 10), (7, 11), (8, 12), (9, 13), (10, 14), (11, 15), (12, 16), (13, 17), (14, 18), (15, 19), (16, 20), (17, 18), (18, 19)]

>>> TL_diagram_ascii_art(TL, use_unicode=False, blobs=[(-2, -1), (-5, 1)])
class sage.combinat.diagram_algebras.TemperleyLiebAlgebra(k, q, base_ring, prefix)

Bases: SubPartitionAlgebra, UnitDiagramMixin

A Temperley–Lieb algebra.

The Temperley–Lieb algebra of rank $k$ is an algebra with basis indexed by the collection of planar set partitions of \{1, \ldots, k, -1, \ldots, -k\} with block size 2.

This algebra is thus a subalgebra of the partition algebra. For more information, see PartitionAlgebra.

INPUT:
• k – rank of the algebra
• q – the deformation parameter $q$

OPTIONAL ARGUMENTS:
• base_ring – (default None) a ring containing $q$; if None then just takes the parent of $q$
• prefix – (default "T") a label for the basis elements

EXAMPLES:
We define the Temperley–Lieb algebra of rank $2$ with parameter $x$ over $\mathbb{Z}$:

```python
sage: R.<x> = ZZ[]
sage: T = TemperleyLiebAlgebra(2, x, R); T
Temperley-Lieb Algebra of rank 2 with parameter x
over Univariate Polynomial Ring in x over Integer Ring
sage: T.basis()
Lazy family (Term map from Temperley Lieb diagrams of order 2
to Temperley-Lieb Algebra of rank 2 with parameter x over
Univariate Polynomial Ring in x over Integer
Ring(i))_{i in Temperley Lieb diagrams of order 2}
sage: T.basis().keys()
Temperley Lieb diagrams of order 2
doubly_clamped_universal
sage: T.basis().keys()([[[-1, 1], [2, -2]]]
{|-2, 2}, {-1, 1}]
sage: b = T.basis().list(); b
[T{{{-2, -1}, {1, 2}}, T{{{2, 2}, {-1, 1}}}
  T{(-2, -1), (1, 2)}, T{(-2, 2), {-1, 1}}]
sage: b[0]
T{{-2, -1}, {1, 2}}
sage: b[0]**2 == x*b[0]
True
sage: b[0]**5 == x^4*b[0]
True

>>> from sage.all import *
>>> R = ZZ["x"]; (x,) = R._first_ngens(1)
>>> T = TemperleyLiebAlgebra(Integer(2), x, R); T
Temperley-Lieb Algebra of rank 2 with parameter x
over Univariate Polynomial Ring in x over Integer Ring
>>> T.basis()
Lazy family (Term map from Temperley Lieb diagrams of order 2
to Temperley-Lieb Algebra of rank 2 with parameter x over
Univariate Polynomial Ring in x over Integer
Ring(i))_{i in Temperley Lieb diagrams of order 2}
>>> T.basis().keys()

True
```

The Temperley-Lieb algebra is a cellular algebra, and we verify that the dimensions of the simple modules at $q = 0$.
is given by OEIS sequence A050166:

```python
sage: for k in range(1,5):
    ....:    TL = TemperleyLiebAlgebra(2*k, 0, QQ)
    ....:    print("\"\{}
    ....:        for la in reversed(TL.cell_poset()) if la != 0))
    ....:        TL = TemperleyLiebAlgebra(2*k, 0, QQ)
    ....:        print("\"\{}
    ....:        for la in reversed(TL.cell_poset()) if la != 0))
    ....:        TL = TemperleyLiebAlgebra(2*k+1, 0, QQ)
    ....:        print("\"\{}
    ....:        for la in reversed(TL.cell_poset()) if la != 0))
    ....:        from sage.all import *
    ....:        for k in range(Integer(1),Integer(5)):
    ....:            TL = TemperleyLiebAlgebra(Integer(2)*k, Integer(0), QQ)
    ....:            print("\"\{}
    ....:            for la in reversed(TL.cell_poset()) if la != Integer(0)))
    ....:            TL = TemperleyLiebAlgebra(Integer(2)*k+Integer(1), Integer(0), QQ)
    ....:            print("\"\{}
    ....:            for la in reversed(TL.cell_poset()) if la != Integer(0)))
    ....:            TL = TemperleyLiebAlgebra(8, -1, QQ)
    ....:            for la in TL.cell_poset():
    ....:                CM = TL.cell_module(la)
    ....:                if not CM.nonzero_bilinear_form():
    ....:                    continue
    ....:                print(la, CM.dimension(), CM.simple_module().dimension())
    ....:                TL = TemperleyLiebAlgebra(2*k, -1, QQ)
    ....:                print("\"\{}
    ....:                for la in reversed(TL.cell_poset())
```

Additional examples when the Temperley-Lieb algebra is not semisimple:

```python
sage: TL = TemperleyLiebAlgebra(8, -1, QQ)
sage: for la in TL.cell_poset():
    ....:    CM = TL.cell_module(la)
    ....:    if not CM.nonzero_bilinear_form():
    ....:        continue
    ....:    print(la, CM.dimension(), CM.simple_module().dimension())
    ....:    TL = TemperleyLiebAlgebra(2*k, -1, QQ)
    ....:    print("\"\{}
    ....:    for la in reversed(TL.cell_poset())
```

cell_module_indices (la)
Return the indices of the cell module of self indexed by la.
This is the finite set \( M(\lambda) \).
EXAMPLES:

```python
sage: R.<q> = QQ[]
sage: TL = TemperleyLiebAlgebra(8, q, R)
sage: TL.cell_module_indices(4)
Half Temperley-Lieb diagrams of order 8 with 4 defects
```

```python
>>> from sage.all import *

>>> R = QQ['q']; (q,) = R._first_ngens(1)

>>> TL = TemperleyLiebAlgebra(Integer(8), q, R)

>>> TL.cell_module_indices(Integer(4))
Half Temperley-Lieb diagrams of order 8 with 4 defects
```

cell_poset()

Return the cell poset of self.

EXAMPLES:

```python
sage: R.<q> = QQ[]
sage: TL = TemperleyLiebAlgebra(7, q, R)
sage: TL.cell_poset().cover_relations()
[[1, 3], [3, 5], [5, 7]]

sage: TL = TemperleyLiebAlgebra(8, q, R)
sage: TL.cell_poset().cover_relations()
[[0, 2], [2, 4], [4, 6], [6, 8]]
```

```python
>>> from sage.all import *

>>> R = QQ['q']; (q,) = R._first_ngens(1)

>>> TL = TemperleyLiebAlgebra(Integer(7), q, R)

>>> TL.cell_poset().cover_relations()
[[1, 3], [3, 5], [5, 7]]

>>> TL = TemperleyLiebAlgebra(Integer(8), q, R)

>>> TL.cell_poset().cover_relations()
[[0, 2], [2, 4], [4, 6], [6, 8]]
```

cellular_involution(x)

Return the cellular involution of x in self.

EXAMPLES:

```python
sage: TL = TemperleyLiebAlgebra(4, QQ.zero(), QQ)
sage: ascii_art(TL.cellular_involution(TL.an_element()))
  o o o o 
  o o o o  |  `-`  |  |  `-`  |  |  `-`  |
  `-` `-`  | `-` `-` | | `-` `-` |
  o o o o  | `-` `-` | | `-` `-` |
  o o o o  o o o o  o o o o

sage: ascii_art(TL.cellular_involution(TL.an_element()))
  o o o o 
  o o o o  |  `-`  |  |  `-`  |  |  `-`  |
  `-` `-`  | `-` `-` | | `-` `-` |
  o o o o  | `-` `-` | | `-` `-` |
  o o o o  o o o o  o o o o
```

5.1. Comprehensive Module List 1303
>>> from sage.all import *
>>> TL = TemperleyLiebAlgebra(Integer(4), QQ.zero(), QQ)
>>> ascii_art(TL.an_element())
        o o o o o o o o
          o o o       | `-` |   | `-` |
 2* `-` `-` + 2* `------` + 3* `---` |
   .- .-   .- .-   .- |   |

>>> ascii_art(TL.cellular_involution(TL.an_element()))
        o o o o o o o o
          o o o       | A-A |   | A-A |
 2* A-A A-A + 2* A-----A + 3* A---A |
   .-. .-. .-. .-. |   |

class sage.combinat.diagram_algebras.TemperleyLiebDiagram (parent, d, check=True)
Bases: AbstractPartitionDiagram
The element class for a Temperley-Lieb diagram.
A Temperley-Lieb diagram for an integer \( k \) is a partition of the set \( \{1, \ldots, k, -1, \ldots, -k\} \) so that the blocks are all of size 2 and the diagram is planar.

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import TemperleyLiebDiagrams
sage: TemperleyLiebDiagrams(2)
Temperley Lieb diagrams of order 2
sage: TemperleyLiebDiagrams(2).list()
[{{-2, -1}, {1, 2}}, {{-2, 2}, {-1, 1}}]
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import TemperleyLiebDiagrams

>>> TemperleyLiebDiagrams(Integer(2))
Temperley Lieb diagrams of order 2
>>> TemperleyLiebDiagrams(Integer(2)).list()
[{{-2, -1}, {1, 2}}, {{-2, 2}, {-1, 1}}]
```

class sage.combinat.diagram_algebras.TemperleyLiebDiagrams (order, category=None)
Bases: AbstractPartitionDiagrams
All Temperley-Lieb diagrams of integer or integer +1/2 order.

For more information on Temperley-Lieb diagrams, see TemperleyLiebAlgebra.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: td = da.TemperleyLiebDiagrams(3); td
Temperley Lieb diagrams of order 3
sage: td.list()
[{{-3, 3}, {-2, -1}, {1, 2}},
 {{-3, 1}, {-2, -1}, {2, 3}},
 {{-3, -2}, {-1, 1}, {2, 3}},
 {{-3, -2}, {-1, -3}, {1, 2}}]
```

(continues on next page)
Element

alias of TemperleyLiebDiagram
cardinality()

Return the cardinality of self.

The number of Temperley–Lieb diagrams of integer order \( k \) is the \( k \)-th Catalan number.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
dsage: td = da.TemperleyLiebDiagrams(Integer(3))
dsage: td.cardinality()
5
```
Combinatorics, Release 10.4

sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(2, x, R)
sage: P.one_basis()
{(−2, 2), (−1, 1)}

>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> P = PartitionAlgebra(Integer(2), x, R)
>>> P.one_basis()
{(−2, 2), (−1, 1)}

sage.combinat.diagram_algebras.brauer_diagrams(k)

Return a generator of all Brauer diagrams of order k.

A Brauer diagram of order \( k \) is a partition diagram of order \( k \) with block size 2.

INPUT:

- \( k \) – the order of the Brauer diagrams

EXAMPLES:

sage: import sage.combinat.diagram_algebras as da
sage: [SetPartition(p) for p in da.brauer_diagrams(2)]

[{{{−2, −1}, {1, 2}}}, {{{−2, 1}, {−1, 2}}}, {{{−2, 2}, {−1, 1}}},
  {{−3, 3}, {−2, −1}, {1, 2}}, {{−3, 3}, {−2, 1}, {−1, 2}},
  {{−3, 3}, {−2, 2}, {−1, 1}}]

sage.combinat.diagram_algebras.diagram_latex(diagram, fill=False, edge_options=None, edge_additions=None)

Return latex code for the diagram \( \text{diagram} \) using tikz.

EXAMPLES:

sage: from sage.combinat.diagram_algebras import PartitionDiagrams, diagram_latex
sage: P = PartitionDiagrams(2)
sage: D = P([[-1, 2], [−2, −1]])
sage: print(diagram_latex(D)) # indirect doctest
\begin{tikzpicture}[scale=0.5, thick, baseline={(0,-1ex/2)}]
\tikzstyle{vertex} = [shape = circle, minimum size = 7pt, inner sep = 1pt]
\node[vertex] (G--2) at (1.5, -1) [shape = circle, draw] {};
\node[vertex] (G--1) at (0.0, -1) [shape = circle, draw] {};
\node[vertex] (G-1) at (0.0, 1) [shape = circle, draw] {};
\node[vertex] (G-2) at (1.5, 1) [shape = circle, draw] {};
\draw[] (G--2) .. controls +(-0.5, 0.5) and +(0.5, 0.5) .. (G--1);
\draw[] (G--1) .. controls +(0.5, −0.5) and +(−0.5, 0.5) .. (G-2);
\end{tikzpicture}
>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import PartitionDiagrams, diagram_latex
>>> P = PartitionDiagrams(Integer(2))
>>> D = P([[Integer(1), Integer(2)], [-Integer(2), -Integer(1)]])
>>> print(diagram_latex(D))
\begin{tikzpicture}[scale = 0.5, thick, baseline={(0,-1ex/2)}]
\tikzstyle{vertex} = [shape = circle, minimum size = 7pt, inner sep = 1pt]
\node[vertex] (G--2) at (1.5, -1) [shape = circle, draw] {}; \\
\node[vertex] (G--1) at (0.0, -1) [shape = circle, draw] {}; \\
\node[vertex] (G-1) at (0.0, 1) [shape = circle, draw] {}; \\
\node[vertex] (G-2) at (1.5, 1) [shape = circle, draw] {}; \\
\draw[] (G--2) .. controls +(-0.5, 0.5) and +(0.5, 0.5) .. (G--1);
\draw[] (G-1) .. controls +(0.5, -0.5) and +(-0.5, -0.5) .. (G-2);
\end{tikzpicture}

sage.combinat.diagram_algebras.ideal_diagrams(k)
Return a generator of all “ideal” diagrams of order k.
An ideal diagram of order k is a partition diagram of order k with propagating number less than k.

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: all_diagrams = da.partition_diagrams(2)
sage: [SetPartition(p) for p in all_diagrams if p not in da.ideal_diagrams(2)]
[[{-2, 1}, {-1, 2}], {[{-2, 2}, {-1, 1}]]
```

```python
sage: all_diagrams = da.partition_diagrams(3/2)
sage: [SetPartition(p) for p in all_diagrams if p not in da.ideal_diagrams(3/2)]
[[{-2, 2}, {-1, 1}]]
```

sage.combinat.diagram_algebras.identity_set_partition(k)
Return the identity set partition \{\{1, -1\}, \ldots, \{k, -k\}\}.

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: SetPartition(da.identity_set_partition(2))
\{\{-2, 2\}, \{-1, 1\}\}
```

```python
sage: SetPartition(da.identity_set_partition(Integer(2)))
\{\{-2, 2\}, \{-1, 1\}\}
```
sage.combinat.diagram_algebras.is_planar(sp)

Return True if the diagram corresponding to the set partition sp is planar; otherwise, return False.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
dsage: da.is_planar( da.to_set_partition([[1,-2],[2,-1]]))
False
dsage: da.is_planar( da.to_set_partition([[1,-1],[2,-2]]))
True
```
sage: sp3 = da.to_set_partition([[1, -1], [2], [-2]])
sage: sp4 = da.to_set_partition([[1], [-1], [2], [-2]])
sage: g = da.pair_to_graph( sp3, sp4 ); g
Graph on 8 vertices
sage: g.vertices(sort=True)
[(-2, 1), (-2, 2), (-1, 1), (-1, 2), (1, 1), (1, 2), (2, 1), (2, 2)]
sage: g.edges(sort=True)
[((-2, 1), (2, 2), None), ((-1, 1), (1, 1), None), ((-1, 1), (1, 2), None)]

>>> from sage.all import *

>>> sp3 = da.to_set_partition([[Integer(1), -Integer(1)], [Integer(2)], [-Integer(2)]])
>>> sp4 = da.to_set_partition([[Integer(1)], [-Integer(1)], [Integer(2)], [-Integer(2)]])
>>> g = da.pair_to_graph( sp3, sp4 ); g
Graph on 8 vertices

>>> g.vertices(sort=True)
[(-2, 1), (-2, 2), (-1, 1), (-1, 2), (1, 1), (1, 2), (2, 1), (2, 2)]

sage.combinat.diagram_algebras.partition_diagrams(k)

Return a generator of all partition diagrams of order k.

A partition diagram of order $k \in \mathbb{Z}$ is a set partition of \{1, \ldots, k, -1, \ldots, -k\}. If we have $k - 1/2 \in \mathbb{Z}$, then a partition diagram of order $k \in 1/2\mathbb{Z}$ is a set partition of \{1, \ldots, k + 1/2, -1, \ldots, -(k + 1/2)\} with $k + 1/2$ and $-(k + 1/2)$ in the same block. See [HR2005].

INPUT:

- $k$ – the order of the partition diagrams

EXAMPLES:

sage: import sage.combinat.diagram_algebras as da
sage: [SetPartition(p) for p in da.partition_diagrams(2)]

[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2}, {-1, 1, 2}},
 {{-2}, {-1}, {1, 2}},
 {{-2}, {-1}, {1, 2}},
 {{-2, -1, 1}, {2}},
 {{-2, 1}, {-1, 2}},
 {{-2, 1}, {-1}, {2}},
 {{-2, 1}, {-1, 2}},
 {{-2}, {-1, 1}, {2}},
 {{-2, -1}, {1, 2}},
 {{-2}, {-1}, {1, 2}},
 {{-2}, {-1, 1}, {2}},
]
\begin{verbatim}
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da

>>> [SetPartition(p) for p in da.partition_diagrams(Integer(2))]

>>> [SetPartition(p) for p in da.partition_diagrams(Integer(3)/Integer(2))]

sage.combinat.diagram_algebras.planar_diagrams(k)

Return a generator of all planar diagrams of order k.

A planar diagram of order k is a partition diagram of order k that has no crossings.

EXAMPLES:

\begin{verbatim}
sage: import sage.combinat.diagram_algebras as da
given_diagrams = [SetPartition(p) for p in da.partition_diagrams(2)]
sage: da2 = [SetPartition(p) for p in da.planar_diagrams(2)]
sage: [p for p in given_diagrams if p not in da2]

sage: given_diagrams = [SetPartition(p) for p in da.partition_diagrams(5/2)]
sage: da5o2 = [SetPartition(p) for p in da.planar_diagrams(5/2)]
sage: [p for p in given_diagrams if p not in da5o2]
\end{verbatim}
\end{verbatim}

sage.combinat.diagram_algebras.planar_partitions_rec(X) Iterate over all planar set partitions of X by using a recursive algorithm.

ALGORITHM:
To construct the set partition \( \rho = \{ \rho_1, \ldots, \rho_k \} \) of \([n]\), we remove the part of the set partition containing the last element of \( X \), which, we consider to be \( \rho_k = \{i_1, \ldots, i_m\} \) without loss of generality. The remaining parts come from the planar set partitions of \( \{1, \ldots, i_1 - 1\}, \{i_1 + 1, \ldots, i_2 - 1\}, \ldots, \{i_m + 1, \ldots, n\} \).

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: list(da.planar_partitions_rec([1,2,3]))
[([1, 2], [3]), ([1], [2], [3]), ([2], [1, 3]), ([1], [2, 3]), ([1, 2, 3],)]
```
sage.combinat.diagram_algebras.temperley_lieb_diagrams\(k\)

Return a generator of all Temperley–Lieb diagrams of order \(k\).

A Temperley–Lieb diagram of order \(k\) is a partition diagram of order \(k\) with block size 2 and is planar.

**INPUT:**
- \(k\) – the order of the Temperley–Lieb diagrams

**EXAMPLES:**

```python
sage: import sage.combinat.diagram_algebras as da
dsage: [SetPartition(p) for p in da.temperley_lieb_diagrams(2)]
[{{-2, -1}, {1, 2}}, {{-2, 2}, {-1, 1}}]
sage: [SetPartition(p) for p in da.temperley_lieb_diagrams(5/2)]
[{{-3, 3}, {-2, -1}, {1, 2}}, {{-3, 3}, {-2, 2}, {-1, 1}}]
```

sage.combinat.diagram_algebras.to_Brauer_partition\((l, k=None)\)

Same as `to_set_partition()` but assumes omitted elements are connected straight through.

**EXAMPLES:**

```python
sage: import sage.combinat.diagram_algebras as da
df = lambda sp: SetPartition(da.to_Brauer_partition(sp))
df([[1,2],[-1,-2]]) == SetPartition([[1,2],[-1,-2]])
True
df([[1,3],[-1,-3]]) == SetPartition([[1,3],[-3,-1],[2,-2]])
True
df([[1,-4],[-3,-1],[3,4]]) == SetPartition([[3,-1],[2,-2],[1,-4],[3,4]])
True
df(p = SetPartition([[1,2],[-1,-2],[3,-3],[4,-4]]))
SetPartition(da.to_Brauer_partition([[1,2],[-1,-2]], k=4)) == p
True
```
True
>>> f([[Integer(1),-Integer(4)],[-Integer(3),-Integer(1)],[Integer(3),
    →Integer(4)]]) == SetPartition([[Integer(3),-Integer(1)],[Integer(2),-
    →Integer(2)],[Integer(1),-Integer(4)],[Integer(3),Integer(4)]])
True
>>> p = SetPartition([[Integer(1),Integer(2)],[Integer(2),-Integer(1)],
    →[Integer(3),-Integer(3)],[Integer(4),-Integer(4)]])
>>> SetPartition(da.to_Brauer_partition([[Integer(1),Integer(2)],[Integer(2),-
    →Integer(1)]], k=Integer(4))) == p
True

sage.combinat.diagram_algebras.to_graph(sp)

Return a graph representing the set partition sp.

EXAMPLES:

sage: import sage.combinat.diagram_algebras as da
sage: g = da.to_graph( da.to_set_partition([[1,-2],[2,-1]])); g
Graph on 4 vertices
sage: g.vertices(sort=True)
[-2, -1, 1, 2]
sage: g.edges(sort=True)
[(-2, 1, None), (-1, 2, None)]

>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da

sage.combinat.diagram_algebras.to_set_partition(l, k=None)

Convert input to a set partition of \{1, \ldots, k, -1, \ldots, -k\}

Convert a list of a list of numbers to a set partitions. Each list of numbers
in the outer list specifies the numbers contained in one of the blocks in the set partition.

If k is specified, then the set partition will be a set partition of \{1, \ldots, k, -1, \ldots, -k\}. Otherwise, k will default
to the minimum number needed to contain all of the specified numbers.

INPUT:

- l – a list of lists of integers
- k – integer (default: None)

OUTPUT:

- a list of sets

EXAMPLES:
sage: import sage.combinat.diagram_algebras as da
sage: f = lambda sp: SetPartition(da.to_set_partition(sp))
True
sage: da.to_set_partition([[1]])
[({1}, {-1})]
sage: da.to_set_partition([[1,-1],[2,-2]],9/2)
[({-1, 1}, {-2, 3}, {2}, {-4, 4}, {-5, 5}, {-3})]

>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da

5.1.99 Exact Cover Problem via Dancing Links

sage.combinat.dlx.AllExactCovers(M)

Use A. Ajanki’s DLXMatrix class to solve the exact cover problem on the matrix M (treated as a dense binary
matrix).

EXAMPLES:

sage: # needs sage.modules
sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]]) # no exact covers
sage: for cover in AllExactCovers(M):
...
    print(cover)
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]]) # two exact covers
sage: for cover in AllExactCovers(M):
...
    print(cover)
[(1, 1, 0), (0, 0, 1)]
[(1, 0, 1), (0, 1, 0)]

class sage.combinat.dlx.DLXMatrix(ones, initialsolution=None)

    Bases: object
Solve the Exact Cover problem by using the Dancing Links algorithm described by Knuth.

Consider a matrix $M$ with entries of 0 and 1, and compute a subset of the rows of this matrix which sum to the vector of all 1's.

The dancing links algorithm works particularly well for sparse matrices, so the input is a list of lists of the form: (note the 1-index!):

```
[ [1, [i_11, i_12, ..., i_1r]]
  ...
  [m, [i_m1, i_m2, ..., i_ms]]
]
```

where $M[j][i_jk] = 1$.

The first example below corresponds to the matrix:

```
1110
1010
0100
0001
```

which is exactly covered by:

```
1110
0001
```

and

```
1010
0100
0001
```

EXAMPLES:

```python
sage: from sage.combinat.dlx import *
sage: ones = [[1, [1, 2, 3]]]
sage: ones += [[2, [1, 3]]]
sage: ones += [[3, [2]]]
sage: ones += [[4, [4]]]
sage: DLXM = DLXMatrix(ones, [4])
sage: for C in DLXM:
    ...:     print(C)
[4, 1]
[4, 2, 3]
```

```python
>>> from sage.all import *
>>> from sage.combinat.dlx import *
>>> ones = [[Integer(1), [Integer(1), Integer(2), Integer(3)]]]
>>> ones += [[Integer(2), [Integer(1), Integer(3)]]]
>>> ones += [[Integer(3), [Integer(2)]]]
>>> ones += [[Integer(4), [Integer(4)]]]
>>> DLXM = DLXMatrix(ones, [Integer(4)])
>>> for C in DLXM:
...     print(C)
[4, 1]
[4, 2, 3]
```
Note: The 0 entry is reserved internally for headers in the sparse representation, so rows and columns begin their indexing with 1. Apologies for any heartache this causes. Blame the original author, or fix it yourself.

next ()

Search for the first solution we can find, and return it.

Knuth describes the Dancing Links algorithm recursively, though actually implementing it as a recursive algorithm is permissible only for highly restricted problems. (for example, the original author implemented this for Sudoku, and it works beautifully there)

What follows is an iterative description of DLX:

```python
stack <- [(NULL)]
level <- 0
while level >= 0:
    cur <- stack[level]
    if cur = NULL:
        if R[h] = h:
            level <- level - 1
            yield solution
        else:
            cover(best_column)
            stack[level] = best_column
    else if D[cur] != C[cur]:
        if cur != C[cur]:
            delete solution[level]
            for j in L[cur], L[L[cur]], ... , while j != cur:
                uncover(C[j])
            cur <- D[cur]
            solution[level] <- cur
            stack[level] <- cur
            for j in R[cur], R[R[cur]], ... , while j != cur:
                cover(C[j])
            level <- level + 1
            stack[level] <- (NULL)
        else:
            if C[cur] != cur:
                delete solution[level]
                for j in L[cur], L[L[cur]], ... , while j != cur:
                    uncover(C[j])
                uncover(cur)
                level <- level - 1
```

sage.combinat.dlx. OneExactCover (M)

Use A. Ajanki’s DLXMatrix class to solve the exact cover problem on the matrix M (treated as a dense binary matrix).

EXAMPLES:

```
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]]) # no exact covers
```

(continues on next page)
5.1.100 Dyck Words

A class of an object enumerated by the Catalan numbers, see [Sta-EC2], [StaCat98] for details.

AUTHORS:

• Mike Hansen
• Dan Drake (2008-05-30): DyckWordBacktracker support
• Florent Hivert (2009-02-01): Bijections with NonDecreasingParkingFunctions
• Christian Stump (2011-12): added combinatorial maps and statistics
• Mike Zabrocki:
  – (2012-10): added pretty print, characteristic function, more functions
  – (2013-01): added inverse of area/dinv, bounce/area map
• Jean–Baptiste Priez, Travis Scrimshaw (2013-05-17): Added ASCII art
• Travis Scrimshaw (2013-07-09): Removed CombinatorialClass and added global options.

REFERENCES:

class sage.combinat.dyck_word.CompleteDyckWords

Bases: DyckWords

Abstract base class for all complete Dyck words.

Element

alias of DyckWord_complete

from Catalan_code (code)

Return the Dyck word associated to the given Catalan code code.

A Catalan code of length n is a sequence \( (a_1, a_2, \ldots, a_n) \) of \( n \) integers \( a_i \) such that:

• \( 0 \leq a_i \leq n - i \) for every \( i \);
• if \( i < j \) and \( a_i > 0 \) and \( a_j > 0 \) and \( a_{i+1} = a_{i+2} = \cdots = a_{j-1} = 0 \), then \( a_i - a_j < j - i \).
It turns out that the Catalan codes of length $n$ are in bijection with Dyck words.

The Catalan code of a Dyck word is example (x) in Richard Stanley’s exercises on combinatorial interpretations for Catalan objects. The code in this example is the reverse of the description provided there. See [Sta-EC2] and [StaCat98].

EXAMPLES:

```python
sage: DyckWords().from_Catalan_code([])
[]
sage: DyckWords().from_Catalan_code([0])
[1, 0]
sage: DyckWords().from_Catalan_code([0, 1])
[1, 1, 0, 0]
sage: DyckWords().from_Catalan_code([0, 0])
[1, 0, 1, 0]
```

```
>>> from sage.all import *
>>> DyckWords().from_Catalan_code([])
[]
>>> DyckWords().from_Catalan_code([Integer(0)])
[1, 0]
>>> DyckWords().from_Catalan_code([Integer(0), Integer(1)])
[1, 1, 0, 0]
>>> DyckWords().from_Catalan_code([Integer(0), Integer(0)])
[1, 0, 1, 0]
```

```python
from_area_sequence(code)
```

Return the Dyck word associated to the given area sequence `code`.

See `to_area_sequence()` for a definition of the area sequence of a Dyck word.

See also:

`area()`, `to_area_sequence()`.

INPUT:

- `code` – a list of integers satisfying code[0] == 0 and 0 <= code[i+1] <= code[i]+1.

EXAMPLES:

```python
sage: DyckWords().from_area_sequence([])
[]
sage: DyckWords().from_area_sequence([0])
[1, 0]
sage: DyckWords().from_area_sequence([0, 1])
[1, 1, 0, 0]
sage: DyckWords().from_area_sequence([0, 0])
[1, 0, 1, 0]
```

```
>>> from sage.all import *
>>> DyckWords().from_area_sequence([])
[]
>>> DyckWords().from_area_sequence([Integer(0)])
[1, 0]
>>> DyckWords().from_area_sequence([Integer(0), Integer(1)])
[1, 1, 0, 0]
>>> DyckWords().from_area_sequence([Integer(0), Integer(0)])
[1, 0, 1, 0]
```
from_non_decreasing_parking_function (pf)

Bijection from non-decreasing parking functions.

See there the method to_dyck_word() for more information.

EXAMPLES:

```python
sage: D = DyckWords()
sage: D.from_non_decreasing_parking_function([])
[]
sage: D.from_non_decreasing_parking_function([1])
[1, 0]
sage: D.from_non_decreasing_parking_function([1, 1])
[1, 1, 0, 0]
sage: D.from_non_decreasing_parking_function([1, 2])
[1, 1, 1, 0, 1, 0]
sage: D.from_non_decreasing_parking_function([1, 1, 1])
[1, 1, 1, 0, 0, 0]
sage: D.from_non_decreasing_parking_function([1, 1, 3, 4, 6, 6])
[1, 1, 1, 3, 3, 4, 6, 6]
```

from_noncrossing_partition (ncp)

Convert a noncrossing partition ncp to a Dyck word.

EXAMPLES:

```python
>>> from sage.all import *
>>> D = DyckWords()
>>> D.from_non_decreasing_parking_function([])
[]
>>> D.from_non_decreasing_parking_function([Integer(1)])
[1, 0]
>>> D.from_non_decreasing_parking_function([Integer(1), Integer(1)])
[1, 1, 0, 0]
>>> D.from_non_decreasing_parking_function([Integer(1), Integer(2)])
[1, 1, 1, 0, 1, 0]
>>> D.from_non_decreasing_parking_function([Integer(1), Integer(1), Integer(1)])
[1, 1, 1, 0, 0, 0]
>>> D.from_non_decreasing_parking_function([Integer(1), Integer(1), Integer(3), Integer(3), Integer(4), Integer(6), Integer(6)])
[1, 1, 1, 0, 0, 1, 0, 1, 0, 0, 1, 1, 0, 0]
```
>>> from sage.all import *
>>> DyckWord(noncrossing_partition=[[Integer(1),Integer(2)]]) # indirect...
˓→doctest
[1, 1, 0, 0]
>>> DyckWord(noncrossing_partition=[[Integer(1)],[Integer(2)]])
[1, 0, 1, 0]

>>> dws = DyckWords(Integer(5)).list()
>>> ncps = [x.to_noncrossing_partition() for x in dws]
>>> dws2 = [DyckWord(noncrossing_partition=x) for x in ncps]
>>> dws == dws2
True

class sage.combinat.dyck_word.CompleteDyckWords_all
Bases: CompleteDyckWords, DyckWords_all

All complete Dyck words.

class height_poset
Bases: UniqueRepresentation, Parent

The poset of complete Dyck words compared componentwise by heights.
This is, D is smaller than or equal to D' if it is weakly below D'.
This is implemented by comparison of area sequences.

le (dw1, dw2)

Compare two Dyck words of equal size, and return True if all of the heights of dw1 are less than or equal to the respective heights of dw2.

See also:

to_area_sequence()

EXAMPLES:

sage: poset = DyckWords().height_poset()
sage: poset.le(DyckWord([]), DyckWord([]))
True
sage: poset.le(DyckWord([1,0]), DyckWord([1,0]))
True
sage: poset.le(DyckWord([1,0,1,0]), DyckWord([1,1,0,0]))
True
sage: poset.le(DyckWord([1,1,0,0]), DyckWord([1,0,1,0]))
False
sage: [poset.le(dw1, dw2)
˓→for dw1 in DyckWords(3) for dw2 in DyckWords(3)]
[True, True, True, True, False, True, False, True, False, False, True, True, True, False, True, False, False, False, False, True]

(continues on next page)
>>> poset.le(DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]),... DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]))
True
>>> poset.le(DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]),... DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]))
False
>>> [poset.le(dw1, dw2)
... for dw1 in DyckWords(Integer(3)) for dw2 in DyckWords(Integer(3))]
[True, True, True, False, False, False, True, True, True, True, True, False, False, False, False, True]

class sage.combinat.dyck_word.CompleteDyckWords_size(k)

Bases: CompleteDyckWords, DyckWords_size

All complete Dyck words of a given size.

cardinality()

Return the number of complete Dyck words of semilength \( n \), i.e. the \( n \)-th Catalan number.

EXAMPLES:

sage: DyckWords(4).cardinality()
14
sage: ns = list(range(9))

sage: dws = [DyckWords(n) for n in ns]
sage: all(dw.cardinality() == len(dw.list()) for dw in dws)
True

>>> from sage.all import *

>>> DyckWords(Integer(4)).cardinality()
14
>>> ns = list(range(Integer(9)))
>>> dws = [DyckWords(n) for n in ns]
>>> all(dw.cardinality() == len(dw.list()) for dw in dws)
True

random_element()

Return a random complete Dyck word of semilength \( n \).

The algorithm is based on a classical combinatorial fact. One chooses at random a word with \( n \) 0's and \( n + 1 \) 1's. One then considers every 1 as an ascending step and every 0 as a descending step, and one finds the lowest point of the path (with respect to a slightly tilted slope). One then cuts the path at this point and builds a Dyck word by exchanging the two parts of the word and removing the initial step.

Todo: extend this to m-Dyck words

EXAMPLES:

sage: dw = DyckWords(8)
sage: dw.random_element()  # random
[1, 1, 1, 1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 1, 0, 1, 0]
sage: D = DyckWords(8)

(continues on next page)
A Dyck word is a sequence of open and close symbols such that every close symbol has a corresponding open symbol preceding it. That is to say, a Dyck word of length \( n \) is a list with \( k \) entries 1 and \( n - k \) entries 0 such that the first \( i \) entries always have at least as many 1s among them as 0s. (Here, the 1 serves as the open symbol and the 0 as the close symbol.) Alternatively, the alphabet 1 and 0 can be replaced by other characters such as '(' and ')'.

A Dyck word is complete if every open symbol moreover has a corresponding close symbol.

A Dyck word may also be specified by either a noncrossing partition or by an area sequence or the sequence of heights.

A Dyck word may also be thought of as a lattice path in the \( \mathbb{Z}^2 \) grid, starting at the origin \((0, 0)\), and with steps in the North \( N = (0, 1) \) and east \( E = (1, 0) \) directions such that it does not pass below the \( x = y \) diagonal. The diagonal is referred to as the “main diagonal” in the documentation. A North step is represented by a 1 in the list and an East step is represented by a 0.

Equivalently, the path may be represented with steps in the \( NE = (1, 1) \) and the \( SE = (1, -1) \) direction such that it does not pass below the horizontal axis.

A path representing a Dyck word (either using \( N \) and \( E \) steps, or using \( NE \) and \( SE \) steps) is called a Dyck path.
EXAMPLES:

```python
sage: dw = DyckWord([1, 0, 1, 0]); dw
[1, 0, 1, 0]
sage: print(dw)
()()
sage: dw.height()
1
sage: dw.to_noncrossing_partition()
{{1}, {2}}
```

```python
>>> from sage.all import *

>>> dw = DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]); dw
[1, 0, 1, 0]

>>> print(dw)
()()

>>> dw.height()
1

>>> dw.to_noncrossing_partition()
{{1}, {2}}
```

```python
sage: DyckWord('()()')
[1, 0, 1, 0]
sage: DyckWord('(()())')
[1, 1, 0, 0]
sage: DyckWord('(())')
[1, 1]
sage: DyckWord('()')
[]
```

```python
>>> from sage.all import *

>>> DyckWord('()()')
[1, 0, 1, 0]

>>> DyckWord('(()())')
[1, 1, 0, 0]

>>> DyckWord('(())')
[1, 1]

>>> DyckWord('()')
[]
```

```python
sage: DyckWord(noncrossing_partition=[[1], [2]])
[1, 0, 1, 0]

sage: DyckWord(noncrossing_partition=[[1, 2]])
[1, 1, 0, 0]

sage: DyckWord(noncrossing_partition=[])  
[]
```

```python
>>> from sage.all import *

>>> DyckWord(noncrossing_partition=[[1], [2]])
[1, 0, 1, 0]

>>> DyckWord(noncrossing_partition=[[1, 2]])
[1, 1, 0, 0]

>>> DyckWord(noncrossing_partition=[])  
[]
```

(continues on next page)
ascent_prime_decomposition()

Decompose this Dyck word into a sequence of ascents and prime Dyck paths.

A Dyck word is prime if it is complete and has precisely one return - the final step. In particular, the empty Dyck path is not prime. Thus, the factorization is unique.

This decomposition yields a sequence of odd length: the words with even indices consist of up steps only, the words with odd indices are prime Dyck paths. The concatenation of the result is the original word.

EXAMPLES:

\[
\text{sage: D = DyckWord([1,1,1,0,1,0,1,1,1,1,0,1])}
\]
\[
\text{sage: D.ascent_prime_decomposition()}
\]
\[
[[1, 1], [1, 0], [], [1, 0], [1, 1, 1], [1, 0], [1]]
\]
\[
\text{sage: DyckWord([]).ascent_prime_decomposition()}
\]
\[
[[[]]]
\]
\[
\text{sage: DyckWord([1,1]).ascent_prime_decomposition()}
\]
\[
[[[1, 1]]]
\]
\[
\text{sage: DyckWord([1,0,1,0]).ascent_prime_decomposition()}
\]
\[
[[], [1, 0], [], [1, 0], []]
\]

>>> from sage.all import *

>>>

associated_parenthesis(pos)

Report the position for the parenthesis in self that matches the one at position pos.

The positions in self are counted from 0.

INPUT:

• pos – the index of the parenthesis in the list

OUTPUT:

• Integer representing the index of the matching parenthesis. If no parenthesis matches, return None.

EXAMPLES:
Combinatorics, Release 10.4

sage: DyckWord([1, 0]).associated_parenthesis(0)
1
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(0)
1
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(1)
0
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(2)
3
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(3)
2
sage: DyckWord([1, 1, 0, 0]).associated_parenthesis(0)
3
sage: DyckWord([1, 1, 0, 0]).associated_parenthesis(2)
1
sage: DyckWord([1, 1, 0]).associated_parenthesis(1)
2
sage: DyckWord([1, 1]).associated_parenthesis(0)

>>> from sage.all import *

>>> DyckWord([Integer(1), Integer(0)]).associated_parenthesis(Integer(0))
1
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).associated_parenthesis(Integer(0))
1
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).associated_parenthesis(Integer(1))
0
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).associated_parenthesis(Integer(2))
3
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).associated_parenthesis(Integer(3))
2
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).associated_parenthesis(Integer(0))
3
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).associated_parenthesis(Integer(2))
1
>>> DyckWord([Integer(1), Integer(1), Integer(0)]).associated_parenthesis(Integer(1))
2
>>> DyckWord([Integer(1), Integer(1)]).associated_parenthesis(Integer(0))

catalan_factorization()
Decompose this Dyck word into a sequence of complete Dyck words.

Each element of the list returned is a (possibly empty) complete Dyck word. The original word is obtained
by placing an up step between each of these complete Dyck words. Thus, the number of words returned is
one more than the final height.

See Section 1.2 of [CC1982] or Lemma 9.1.1 of [Lot2005].

EXAMPLES:

sage: D = DyckWord([1, 1, 1, 0, 1, 0, 1, 1, 1, 1, 0, 1])
sage: D.catalan_factorization()
[[[[], [], [1, 0, 1, 0], [], [], [1, 0], []]]]
Combinatorics, Release 10.4

Continued from previous page

```python
sage: DyckWord([]).catalan_factorization()
[[[]]]
sage: DyckWord([1,1]).catalan_factorization()
[[[]], [[[]]]]
sage: DyckWord([1,0,1,0]).catalan_factorization()
[[[1, 0, 1, 0]]]
```

```python
>>> from sage.all import *

>>> D = DyckWord([Integer(1), Integer(1), Integer(1), Integer(0), Integer(1),
                  Integer(0), Integer(1), Integer(1), Integer(1), Integer(1), Integer(0),
                  Integer(1)])

>>> D.catalan_factorization()
[[[]], [[[]]], [[], [1, 0, 1, 0]], [], [[], [1, 0], []]]

>>> DyckWord([]).catalan_factorization()
[[[]]]

>>> DyckWord([Integer(1), Integer(1)]).catalan_factorization()
[[], [1, 0]]

>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).catalan_factorization()
[[[1, 0, 1, 0]]]
```

**height()**

Return the height of self.

We view the Dyck word as a Dyck path from \((0, 0)\) to \((2n, 0)\) in the first quadrant by letting 1’s represent steps in the direction \((1, 1)\) and 0’s represent steps in the direction \((1, −1)\).

The height is the maximum \(y\)-coordinate reached.

See also:

heights()

**EXAMPLES:**

```python
sage: DyckWord([]).height()
0
sage: DyckWord([1,0]).height()
1
sage: DyckWord([1, 1, 0, 0]).height()
2
sage: DyckWord([1, 1, 0, 1, 0]).height()
2
sage: DyckWord([1, 1, 0, 0, 1, 0]).height()
2
sage: DyckWord([1, 0, 1, 0]).height()
1
sage: DyckWord([1, 1, 0, 0, 1, 1, 0, 0, 0]).height()
3
```
>>> from sage.all import *
>>> DyckWord([]).height()
0
>>> DyckWord([Integer(1), Integer(0)]).height()
1
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).height()
2
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(0)]).height()
2
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).height()
1
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1), Integer(1), Integer(0), Integer(0), Integer(1), Integer(1), Integer(0), Integer(0)]).height()
3

heights()

Return the heights of self.

We view the Dyck word as a Dyck path from (0, 0) to (2n, 0) in the first quadrant by letting 1’s represent steps in the direction (1, 1) and 0’s represent steps in the direction (1, -1).

The heights is the sequence of the y-coordinates of all 2n + 1 lattice points along the path.

See also:

from_heights(), min_from_heights()

EXAMPLES:

sage: DyckWord([]).heights()
(0,)
sage: DyckWord([1, 0]).heights()
(0, 1, 0)
sage: DyckWord([1, 1, 0, 0]).heights()
(0, 1, 2, 1, 0)
sage: DyckWord([1, 1, 0, 1, 0]).heights()
(0, 1, 2, 1, 2, 1)
sage: DyckWord([1, 1, 0, 0, 1, 0]).heights()
(0, 1, 2, 1, 0, 1, 0)
sage: DyckWord([1, 0, 1, 0]).heights()
(0, 1, 2, 1, 0, 1, 0)
sage: DyckWord([1, 1, 0, 0, 1, 1, 1, 0, 0, 0]).heights()
(0, 1, 2, 1, 0, 1, 2, 3, 2, 1, 0)
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),
→Integer(0)]).heights()
(0, 1, 2, 1, 0, 1, 0)
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).heights()
(0, 0, 1, 0)
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),
→Integer(1), Integer(1), Integer(0), Integer(0), Integer(0)]).heights()
(0, 1, 2, 1, 0, 1, 2, 3, 2, 1, 0)

is_complete()

Return True if self is complete.

A Dyck word \(d\) is complete if \(d\) contains as many closers as openers.

EXAMPLES:

sage: DyckWord([1, 0, 1, 0]).is_complete()
True
sage: DyckWord([1, 0, 1, 1, 0]).is_complete()
False

>>> from sage.all import *

sage: DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).is_complete()
True
sage: DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0)]).is_complete()
False

latex_options()

Return the latex options for use in the _latex_ function as a dictionary.

The default values are set using the options.

- **tikz_scale** – (default: 1) scale for use with the tikz package.
- **diagonal** – (default: False) boolean value to draw the diagonal or not.
- **line width** – (default: \(2^\text{tikz_scale}\)) value representing the line width.
- **color** – (default: black) the line color.
- **bounce path** – (default: False) boolean value to indicate if the bounce path should be drawn.
- **peaks** – (default: False) boolean value to indicate if the peaks should be displayed.
- **valleys** – (default: False) boolean value to indicate if the valleys should be displayed.

EXAMPLES:

sage: D = DyckWord([1, 0, 1, 0, 1, 0])

sage: D.latex_options()
{'bounce path': False, 'color': 'black', 'diagonal': False, 'line width': 2, 'peaks': False, 'tikz_scale': 1, 'valleys': False}
Todo: This should probably be merged into DyckWord.options.

length()
Return the length of self.

EXAMPLES:

```sage
DyckWord([1, 0, 1, 0]).length()
4
sage: DyckWord([1, 0, 1, 1, 0]).length()
5
```

number_of_close_symbols()
Return the number of close symbols in self.

EXAMPLES:

```sage
DyckWord([1, 0, 1, 0]).number_of_close_symbols()
2
sage: DyckWord([1, 0, 1, 1, 0]).number_of_close_symbols()
2
```

number_of_double_rises()
Return a the number of positions in self where there are two consecutive 1’s.

EXAMPLES:
\begin{verbatim}
sage: DyckWord([1, 0, 1, 1, 0, 1, 0, 1, 0, 1, 0]).number_of_double_rises()
sage: DyckWord([1, 1, 0, 0]).number_of_double_rises()
sage: DyckWord([1, 0, 1, 0]).number_of_double_rises()

>>> from sage.all import *

>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0), Integer(0), Integer(1), Integer(1), Integer(0), Integer(0), Integer(1), Integer(0), Integer(0), Integer(1), Integer(0)]).number_of_double_rises()

>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).number_of_double_rises()

>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).number_of_double_rises()

number_of_initial_rises()

Return the length of the initial run of self.

OUTPUT:

- a non-negative integer indicating the length of the initial rise

EXAMPLES:

\begin{verbatim}
sage: DyckWord([1, 0, 1, 0]).number_of_initial_rises()
sage: DyckWord([1, 1, 0, 0]).number_of_initial_rises()
sage: DyckWord([1, 1, 0, 0, 1, 0]).number_of_initial_rises()
sage: DyckWord([1, 0, 1, 1, 0, 0]).number_of_initial_rises()

>>> from sage.all import *

>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).number_of_initial_rises()

>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).number_of_initial_rises()

>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1), Integer(0)]).number_of_initial_rises()

>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0), Integer(0)]).number_of_initial_rises()

number_of_open_symbols()

Return the number of open symbols in self.

EXAMPLES:
\end{verbatim}
number_of_open_symbols()

Return the number of open symbols of the Dyck path associated to self.

EXAMPLES:

```python
sage: DyckWord([1, 0, 1, 0]).number_of_open_symbols()
2
sage: DyckWord([1, 0, 1, 1, 0]).number_of_open_symbols()
3
```

number_of_peaks()

Return the number of peaks of the Dyck path associated to self.

See also:

peaks(), number_of_valleys()

EXAMPLES:

```python
sage: DyckWord([1, 0, 1, 0]).number_of_peaks()
2
sage: DyckWord([1, 1, 0, 0]).number_of_peaks()
1
sage: DyckWord([1,1,0,1,0,1,0,0]).number_of_peaks()
3
sage: DyckWord([]).number_of_peaks()
0
```

number_of_touch_points()

Return the number of touches of self at the main diagonal.

OUTPUT:

- a non-negative integer

EXAMPLES:

```python
>>> from sage.all import *
>>> DyckWord([1, 0, 1, 0]).number_of_touch_points()
2
>>> DyckWord([1, 1, 0, 0]).number_of_touch_points()
1
>>> DyckWord([1,1,0,1,0,1,0,0]).number_of_touch_points()
3
>>> DyckWord([]).number_of_touch_points()
0
```
number_of_valleys()

Return the number of valleys of self.

See also:

number_of_peaks(), valleys()

EXAMPLES:

>>> from sage.all import *

>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).number_of_valleys()
1
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).number_of_valleys()
0
>>> DyckWord([Integer(1), Integer(0), Integer(0), 1, 0]).number_of_valleys()
1
>>> DyckWord([Integer(0), 1, 0, 1, 0]).number_of_valleys()
1

peaks()

Return a list of the positions of the peaks of a Dyck word.

A peak is 1 followed by a 0. Note that this does not agree with the definition given in [Hag2008].

See also:

valleys(), number_of_peaks()
EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).peaks()
[0, 2]
sage: DyckWord([1, 1, 0, 0]).peaks()
[1]
sage: DyckWord([1, 1, 0, 1, 0, 1, 0, 0]).peaks() # Haglund's def gives 2
[1, 3, 5]
```

```
>>> from sage.all import *

>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).peaks()
[0, 2]

>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).peaks()
[1]

>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(0), Integer(0), Integer(1), Integer(0), Integer(0), Integer(1), Integer(0), Integer(0)]).peaks() # Haglund's def gives 2
[1, 3, 5]
```

```
plot(**kwds)

Plot a Dyck word as a continuous path.

EXAMPLES:

```
sage: w = DyckWords(100).random_element()
sage: w.plot()
# needs sage.plot
Graphics object consisting of 1 graphics primitive
```

```
>>> from sage.all import *

>>> w = DyckWords(Integer(100)).random_element()

>>> w.plot()
# needs sage.plot
Graphics object consisting of 1 graphics primitive
```

```
position_of_first_return()

Return the number of vertical steps before the Dyck path returns to the main diagonal.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0, 1, 0]).position_of_first_return()
1

sage: DyckWord([1, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0, 1, 0, 0]).position_of_first_return()
7

sage: DyckWord([1, 1, 0, 0]).position_of_first_return()
2

sage: DyckWord([1, 0, 1, 0]).position_of_first_return()
1

sage: DyckWord([]).position_of_first_return()
0
```

```
>>> from sage.all import *

>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0), Integer(1), Integer(0), Integer(1), Integer(0), Integer(0), Integer(1), Integer(0), Integer(0)]).position_of_first_return()
1
```

(continues on next page)
positions_of_double_rises()  
Return a list of positions in self where there are two consecutive 1’s.

EXAMPLES:

sage: DyckWord([1, 0, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0, 1, 0]).positions_of_double_rises()  
[2, 5]  
sage: DyckWord([1, 1, 0, 0]).positions_of_double_rises()  
[0]  
sage: DyckWord([1, 0, 1, 0]).positions_of_double_rises()  
[]

>>> from sage.all import *

pp(type=None, labelling=None, underpath=True)
Display a DyckWord as a lattice path in the $\mathbb{Z}^2$ grid.

If the type is “N-E”, then a cell below the diagonal is indicated by a period, whereas a cell below the path but above the diagonal is indicated by an x. If a list of labels is included, they are displayed along the vertical edges of the Dyck path.

If the type is “NE-SE”, then the path is simply printed as up steps and down steps.

INPUT:

- type – (default: None) can either be:
  - None to use the option default
  - “N-E” to show self as a path of north and east steps, or
  - “NE-SE” to show self as a path of north-east and south-east steps.
- labelling – (if type is “N-E”) a list of labels assigned to the up steps in self.
• underpath – (if type is “N-E”, default: True) If True, the labelling is shown under the path; otherwise, it is shown to the right of the path.

EXAMPLES:

```
sage: for D in DyckWords(3): D.pretty_print()
|   |
|   |
| ..|
|   |
| x |
| ..|

>>> from sage.all import *

```
>>> from sage.all import *
>>> D in DyckWords(Integer(3)): D.pretty_print(type="NE-SE")
