>>> is_difference_matrix(M,G,Integer(6),Integer(1))
True
```

sage.combinat.designs.difference_matrices.**find_product_decomposition**(*k*, *lmbda=1*)

Try to find a product decomposition construction for difference matrices.

INPUT:

- g, k, lmbda – integers, parameters of the difference matrix

OUTPUT:

A pair of pairs (g1,lmbda),(g2,lmbda2) if Sage knows how to build $(g1, k, lmbda1)$ and $(g2, k, lmbda2)$ difference matrices and False otherwise.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_matrices import find_product_
↪decomposition
sage: find_product_decomposition(77,6)
((7, 1), (11, 1))
sage: find_product_decomposition(616,7)
((7, 1), (88, 1))
sage: find_product_decomposition(24,10)
False
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_matrices import find_product_
↪decomposition
>>> find_product_decomposition(Integer(77),Integer(6))
((7, 1), (11, 1))
>>> find_product_decomposition(Integer(616),Integer(7))
((7, 1), (88, 1))
>>> find_product_decomposition(Integer(24),Integer(10))
False
```

5.1.86 Evenly distributed sets in finite fields

This module consists of a simple class *EvenlyDistributedSetsBacktracker*. Its main purpose is to iterate through the evenly distributed sets of a given finite field.

The naive backtracker implemented here is not directly used to generate difference family as even for small parameters it already takes time to run. Instead, its output has been stored into a database *sage.combinat.designs.database*. If the backtracker is improved, then one might want to update this database with more values.

Classes and methods

class sage.combinat.designs.evenly_distributed_sets.**EvenlyDistributedSetsBacktracker**

Bases: object

Set of evenly distributed subsets in finite fields.

> **Definition:** Let K be a finite field of cardinality q and k an integer so that $k(k-1)$ divides $q-1$. Let $H = K^*$ be the multiplicative group of invertible elements in K. A *k-evenly distributed set* in K is a set $B = \{b_1, b_2, \ldots, b_k\}$ of k elements of K so that the $k(k-1)$ differences $\Delta B = \{b_i - b_j; i \neq j\}$ hit each coset modulo $H^{2(q-1)/(k(k-1))}$ exactly twice.

Evenly distributed sets were introduced by Wilson [Wi72] (see also [BJL99-1], Chapter VII.6). He proved that for any k, and for any prime power q large enough such that $k(k-1)$ divides k there exists a k-evenly distributed set in the field of cardinality q. This existence result based on a counting argument (using Dirichlet theorem) does not provide a simple method to generate them.

From a k-evenly distributed set, it is straightforward to build a $(q, k, 1)$-difference family (see `to_difference_family()`). Another approach to generate a difference family, somehow dual to this one, is via radical difference family (see in particular `radical_difference_family()` from the module `difference_family`).

By default, this backtracker only considers evenly distributed sets up to affine automorphisms, i.e. B is considered equivalent to $sB + t$ for any invertible element s and any element t in the field K. Note that the set of differences is just multiplicatively translated by s as $\Delta(sB + t) = s(\Delta B)$, and so that B is an evenly distributed set if and only if sB is one too. This behaviour can be modified via the argument `up_to_isomorphism` (see the input section and the examples below).

INPUT:

- `K` – a finite field of cardinality q
- `k` – positive integer such that $k(k-1)$ divides $q-1$
- `up_to_isomorphism` – boolean (default: `True`); whether only consider evenly distributed sets up to automorphisms of the field of the form $x \mapsto ax + b$. If set to `False` then the iteration is over all evenly distributed sets that contain `0` and `1`.
- `check` – boolean (default: `False`); whether you want to check intermediate steps of the iterator. This is mainly intended for debugging purpose. Setting it to `True` will considerably slow the iteration.

EXAMPLES:

The main part of the code is contained in the iterator. To get one evenly distributed set just do:

```
sage: from sage.combinat.designs.evenly_distributed_sets import␣
↪EvenlyDistributedSetsBacktracker
sage: E = EvenlyDistributedSetsBacktracker(Zmod(151),6)
sage: B = E.an_element()
sage: B
[0, 1, 69, 36, 57, 89]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.evenly_distributed_sets import␣
↪EvenlyDistributedSetsBacktracker
>>> E = EvenlyDistributedSetsBacktracker(Zmod(Integer(151)),Integer(6))
>>> B = E.an_element()
>>> B
[0, 1, 69, 36, 57, 89]
```

The class has a method to convert it to a difference family:

```
sage: E.to_difference_family(B)
[[0, 1, 69, 36, 57, 89],
 [0, 132, 48, 71, 125, 121],
 [0, 59, 145, 10, 41, 117],
 [0, 87, 114, 112, 127, 42],
 [0, 8, 99, 137, 3, 108]]
```

```
>>> from sage.all import *
>>> E.to_difference_family(B)
[[0, 1, 69, 36, 57, 89],
 [0, 132, 48, 71, 125, 121],
 [0, 59, 145, 10, 41, 117],
 [0, 87, 114, 112, 127, 42],
 [0, 8, 99, 137, 3, 108]]
```

It is also possible to run over all evenly distributed sets:

```
sage: E = EvenlyDistributedSetsBacktracker(Zmod(13), 4, up_to_isomorphism=False)
sage: for B in E: print(B)
[0, 1, 11, 5]
[0, 1, 4, 6]
[0, 1, 9, 3]
[0, 1, 8, 10]

sage: E = EvenlyDistributedSetsBacktracker(Zmod(13), 4, up_to_isomorphism=True)
sage: for B in E: print(B)
[0, 1, 11, 5]
```

```
>>> from sage.all import *
>>> E = EvenlyDistributedSetsBacktracker(Zmod(Integer(13)), Integer(4), up_to_
↪isomorphism=False)
>>> for B in E: print(B)
[0, 1, 11, 5]
[0, 1, 4, 6]
[0, 1, 9, 3]
[0, 1, 8, 10]

>>> E = EvenlyDistributedSetsBacktracker(Zmod(Integer(13)), Integer(4), up_to_
↪isomorphism=True)
>>> for B in E: print(B)
[0, 1, 11, 5]
```

Or only count them:

```
sage: for k in range(13, 200, 12):
....:     if is_prime_power(k):
....:         K = GF(k,'a')
....:         E1 = EvenlyDistributedSetsBacktracker(K, 4, False)
....:         E2 = EvenlyDistributedSetsBacktracker(K, 4, True)
....:         print("{:3} {:3} {:3}".format(k, E1.cardinality(), E2.
↪cardinality()))
 13   4   1
 25  40   4
 37  12   1
 49  24   2
 61  12   1
 73  48   4
 97  64   6
109  72   6
121 240  20
```

(continues on next page)

(continued from previous page)

```
157  96   8
169 240  20
181 204  17
193 336  28
```

```
>>> from sage.all import *
>>> for k in range(Integer(13), Integer(200), Integer(12)):
...     if is_prime_power(k):
...         K = GF(k,'a')
...         E1 = EvenlyDistributedSetsBacktracker(K, Integer(4), False)
...         E2 = EvenlyDistributedSetsBacktracker(K, Integer(4), True)
...         print("{:3} {:3} {:3}".format(k, E1.cardinality(), E2.cardinality()))
 13   4   1
 25  40   4
 37  12   1
 49  24   2
 61  12   1
 73  48   4
 97  64   6
109  72   6
121 240  20
157  96   8
169 240  20
181 204  17
193 336  28
```

Note that by definition, the number of evenly distributed sets up to isomorphisms is at most $k(k-1)$ times smaller than without isomorphisms. But it might not be exactly $k(k-1)$ as some of them might have symmetries:

```
sage: B = EvenlyDistributedSetsBacktracker(Zmod(13), 4).an_element()
sage: B
[0, 1, 11, 5]
sage: [9*x + 5 for x in B]
[5, 1, 0, 11]
sage: [3*x + 11 for x in B]
[11, 1, 5, 0]
```

```
>>> from sage.all import *
>>> B = EvenlyDistributedSetsBacktracker(Zmod(Integer(13)), Integer(4)).an_
↪element()
>>> B
[0, 1, 11, 5]
>>> [Integer(9)*x + Integer(5) for x in B]
[5, 1, 0, 11]
>>> [Integer(3)*x + Integer(11) for x in B]
[11, 1, 5, 0]
```

an_element()

Return an evenly distributed set.

If there is no such subset raise an EmptySetError.

EXAMPLES:

```
sage: from sage.combinat.designs.evenly_distributed_sets import EvenlyDistributedSetsBacktracker

sage: E = EvenlyDistributedSetsBacktracker(Zmod(41),5)
sage: E.an_element()
[0, 1, 13, 38, 31]

sage: E = EvenlyDistributedSetsBacktracker(Zmod(61),6)
sage: E.an_element()
Traceback (most recent call last):
...
EmptySetError: no 6-evenly distributed set in Ring of integers modulo 61
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.evenly_distributed_sets import EvenlyDistributedSetsBacktracker

>>> E = EvenlyDistributedSetsBacktracker(Zmod(Integer(41)),Integer(5))
>>> E.an_element()
[0, 1, 13, 38, 31]

>>> E = EvenlyDistributedSetsBacktracker(Zmod(Integer(61)),Integer(6))
>>> E.an_element()
Traceback (most recent call last):
...
EmptySetError: no 6-evenly distributed set in Ring of integers modulo 61
```

cardinality()

Return the number of evenly distributed sets.

Use with precaution as there can be a lot of such sets and this method might be very long to answer!

EXAMPLES:

```
sage: from sage.combinat.designs.evenly_distributed_sets import EvenlyDistributedSetsBacktracker

sage: E = EvenlyDistributedSetsBacktracker(GF(25,'a'), 4); E
4-evenly distributed sets (up to isomorphism)
 in Finite Field in a of size 5^2
sage: E.cardinality()
4

sage: E = EvenlyDistributedSetsBacktracker(GF(25,'a'), 4,
....:                                      up_to_isomorphism=False)
sage: E.cardinality()
40
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.evenly_distributed_sets import EvenlyDistributedSetsBacktracker

>>> E = EvenlyDistributedSetsBacktracker(GF(Integer(25),'a'), Integer(4)); E
```

(continues on next page)

(continued from previous page)

```
4-evenly distributed sets (up to isomorphism)
 in Finite Field in a of size 5^2
>>> E.cardinality()
4

>>> E = EvenlyDistributedSetsBacktracker(GF(Integer(25),'a'), Integer(4),
...                                      up_to_isomorphism=False)
>>> E.cardinality()
40
```

to_difference_family(*B*, *check=True*)

Given an evenly distributed set `B` convert it to a difference family.

As for any $x \in K^* = H$ we have $|\Delta B \cap x H^{2(q-1)/(k(k-1))}| = 2$ (see *EvenlyDistributedSetsBacktracker*), the difference family is produced as $\{xB : x \in H^{2(q-1)/(k(k-1))}\}$

This method is useful if you want to obtain the difference family from the output of the iterator.

INPUT:

- `B` – an evenly distributed set
- `check` – boolean (default: `True`); whether to check the result

EXAMPLES:

```
sage: from sage.combinat.designs.evenly_distributed_sets import␣
↪EvenlyDistributedSetsBacktracker
sage: E = EvenlyDistributedSetsBacktracker(Zmod(41),5)
sage: B = E.an_element(); B
[0, 1, 13, 38, 31]
sage: D = E.to_difference_family(B); D
[[0, 1, 13, 38, 31], [0, 32, 6, 27, 8]]

sage: from sage.combinat.designs.difference_family import is_difference_family
sage: is_difference_family(Zmod(41),D,41,5,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.evenly_distributed_sets import␣
↪EvenlyDistributedSetsBacktracker
>>> E = EvenlyDistributedSetsBacktracker(Zmod(Integer(41)),Integer(5))
>>> B = E.an_element(); B
[0, 1, 13, 38, 31]
>>> D = E.to_difference_family(B); D
[[0, 1, 13, 38, 31], [0, 32, 6, 27, 8]]

>>> from sage.combinat.designs.difference_family import is_difference_family
>>> is_difference_family(Zmod(Integer(41)),D,Integer(41),Integer(5),
↪Integer(1))
True
```

Setting `check` to `False` is much faster:

```
sage: timeit("df = E.to_difference_family(B, check=True)") # random
625 loops, best of 3: 117 µs per loop

sage: timeit("df = E.to_difference_family(B, check=False)")  # random
625 loops, best of 3: 1.83 µs per loop
```

```
>>> from sage.all import *
>>> timeit("df = E.to_difference_family(B, check=True)") # random
625 loops, best of 3: 117 µs per loop

>>> timeit("df = E.to_difference_family(B, check=False)")  # random
625 loops, best of 3: 1.83 µs per loop
```

5.1.87 External Representations of Block Designs

The "ext_rep" module is an API to the abstract tree represented by an XML document containing the External Representation of a list of block designs. The module also provides the related I/O operations for reading/writing ext-rep files or data. The parsing is based on expat.

This is a modified form of the module ext_rep.py (version 0.8) written by Peter Dobcsanyi [Do2009] peter@designtheory.org.

Todo

The XML data from the designtheory.org database contains a wealth of information about things like automorphism groups, transitivity, cycle type representatives, etc, but none of this data is made available through the current implementation.

Functions

class sage.combinat.designs.ext_rep.**XTree**(*node*)

Bases: object

A lazy class to wrap a rooted tree representing an XML document. The tree's nodes are tuples of the structure:

(name, {dictionary of attributes}, [list of children])

Methods and services of an XTree object t:

- t.attribute – attribute named
- t.child – first child named
- t[i] – i-th child
- for child in t: – iterate over t's children
- len(t) – number of t's children

If child is not an empty subtree, return the subtree as an XTree object. If child is an empty subtree, return _name of the subtree. Otherwise return the child itself.

The lazy tree idea originated from a utility class of the pyRXP 0.9 package by Robin Becker at ReportLab.

class sage.combinat.designs.ext_rep.**XTreeProcessor**

Bases: object

An incremental event-driven parser for ext-rep documents. The processing stages:

- `<list_of_designs ...>` opening element. call-back: `list_of_designs_proc`
- `<list_definition>` subtree. call-back: `list_definition_proc`
- `<info>` subtree. call-back: `info_proc`
- iterating over `<designs>` processing each `<block_design>` separately. call-back: `block_design_proc`
- finishing with closing `</designs>` and `</list_of_designs>`.

parse(*xml_source*)

The main parsing function. Given an XML source (either a file handle or a string), parse the entire XML source.

EXAMPLES:

```
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: proc = ext_rep.XTreeProcessor()
sage: proc.save_designs = True
sage: f = ext_rep.open_extrep_file(file_loc)
sage: proc.parse(f)
sage: f.close()
sage: os.remove(file_loc)
sage: proc.list_of_designs[0]
(2, [[0, 1], [0, 1]])
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
>>> proc = ext_rep.XTreeProcessor()
>>> proc.save_designs = True
>>> f = ext_rep.open_extrep_file(file_loc)
>>> proc.parse(f)
>>> f.close()
>>> os.remove(file_loc)
>>> proc.list_of_designs[Integer(0)]
(2, [[0, 1], [0, 1]])
```

sage.combinat.designs.ext_rep.**check_dtrs_protocols**(*input_name*, *input_pv*)

Check that the XML data is in a valid format. We can currently handle version 2.0. For more information see http://designtheory.org/library/extrep/

EXAMPLES:

```
sage: from sage.combinat.designs import ext_rep
sage: ext_rep.check_dtrs_protocols('source', '2.0')
sage: ext_rep.check_dtrs_protocols('source', '3.0')
Traceback (most recent call last):
...
RuntimeError: Incompatible dtrs_protocols: program: 2.0 source: 3.0
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> ext_rep.check_dtrs_protocols('source', '2.0')
>>> ext_rep.check_dtrs_protocols('source', '3.0')
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
RuntimeError: Incompatible dtrs_protocols: program: 2.0 source: 3.0
```

sage.combinat.designs.ext_rep.**designs_from_XML**(*fname*)

Return a list of designs contained in an XML file fname. The list contains tuples of the form (v, bs) where v is the number of points of the design and bs is the list of blocks.

EXAMPLES:

```
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: ext_rep.designs_from_XML(file_loc)[0]
(2, [[0, 1], [0, 1]])
sage: os.remove(file_loc)

sage: from sage.combinat.designs import ext_rep
sage: from sage.combinat.designs.block_design import BlockDesign
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: v, blocks = ext_rep.designs_from_XML(file_loc)[0]
sage: d = BlockDesign(v, blocks)
sage: d.blocks()
[[0, 1], [0, 1]]
sage: d.is_t_design(t=2)
True
sage: d.is_t_design(return_parameters=True)
(True, (2, 2, 2, 2))
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
>>> ext_rep.designs_from_XML(file_loc)[Integer(0)]
(2, [[0, 1], [0, 1]])
>>> os.remove(file_loc)

>>> from sage.combinat.designs import ext_rep
>>> from sage.combinat.designs.block_design import BlockDesign
>>> file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
>>> v, blocks = ext_rep.designs_from_XML(file_loc)[Integer(0)]
>>> d = BlockDesign(v, blocks)
>>> d.blocks()
[[0, 1], [0, 1]]
>>> d.is_t_design(t=Integer(2))
True
>>> d.is_t_design(return_parameters=True)
(True, (2, 2, 2, 2))
```

sage.combinat.designs.ext_rep.**designs_from_XML_url**(*url*)

Return a list of designs contained in an XML file named by a URL. The list contains tuples of the form (v, bs) where v is the number of points of the design and bs is the list of blocks.

EXAMPLES:

```
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: ext_rep.designs_from_XML_url("file://" + file_loc)[0]
(2, [[0, 1], [0, 1]])
sage: os.remove(file_loc)

sage: from sage.combinat.designs import ext_rep
sage: ext_rep.designs_from_XML_url("http://designtheory.org/database/v-b-k/v3-b6-
↪k2.icgsa.txt.bz2") # optional - internet
[(3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 1], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 2], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 2], [1, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 2], [0, 2], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 2], [0, 2], [1, 2]]),
 (3, [[0, 1], [0, 1], [0, 2], [0, 2], [1, 2], [1, 2]])]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
>>> ext_rep.designs_from_XML_url("file://" + file_loc)[Integer(0)]
(2, [[0, 1], [0, 1]])
>>> os.remove(file_loc)

>>> from sage.combinat.designs import ext_rep
>>> ext_rep.designs_from_XML_url("http://designtheory.org/database/v-b-k/v3-b6-k2.
↪icgsa.txt.bz2") # optional - internet
[(3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 1], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 2], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 2], [1, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 2], [0, 2], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 2], [0, 2], [1, 2]]),
 (3, [[0, 1], [0, 1], [0, 2], [0, 2], [1, 2], [1, 2]])]
```

sage.combinat.designs.ext_rep.**dump_to_tmpfile**(*s*)

Utility function to dump a string to a temporary file.

EXAMPLES:

```
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile("boo")
sage: os.remove(file_loc)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> file_loc = ext_rep.dump_to_tmpfile("boo")
>>> os.remove(file_loc)
```

sage.combinat.designs.ext_rep.**open_extrep_file**(*fname*)

Try to guess the compression type from extension and open the extrep file.

EXAMPLES:

```
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: proc = ext_rep.XTreeProcessor()
sage: f = ext_rep.open_extrep_file(file_loc)
sage: proc.parse(f)
sage: f.close()
sage: os.remove(file_loc)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
>>> proc = ext_rep.XTreeProcessor()
>>> f = ext_rep.open_extrep_file(file_loc)
>>> proc.parse(f)
>>> f.close()
>>> os.remove(file_loc)
```

sage.combinat.designs.ext_rep.**open_extrep_url**(*url*)

Try to guess the compression type from extension and open the extrep file pointed to by the url. This function (unlike open_extrep_file) returns the uncompressed text contained in the file.

EXAMPLES:

```
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: proc = ext_rep.XTreeProcessor()
sage: s = ext_rep.open_extrep_url("file://" + file_loc)
sage: proc.parse(s)
sage: os.remove(file_loc)

sage: from sage.combinat.designs import ext_rep
sage: s = ext_rep.designs_from_XML_url("http://designtheory.org/database/v-b-k/v3-
↪b6-k2.icgsa.txt.bz2") # optional - internet
```

```

5.1.88 Database of generalised quadrangles with spread

This module implements some construction of generalised quadrangles with spread.

EXAMPLES:

```
sage: GQ, S = designs.generalised_quadrangle_with_spread(4, 16, check=False)
sage: GQ
Incidence structure with 325 points and 1105 blocks
sage: GQ2, O = designs.generalised_quadrangle_hermitian_with_ovoid(4)
sage: GQ2
Incidence structure with 1105 points and 325 blocks
sage: GQ3 = GQ.dual()
sage: set(GQ3._points) == set(GQ2._points)
True
sage: GQ2.is_isomorphic(GQ3) # long time
True
```

```
>>> from sage.all import *
>>> GQ, S = designs.generalised_quadrangle_with_spread(Integer(4), Integer(16),␣
↪check=False)
>>> GQ
Incidence structure with 325 points and 1105 blocks
>>> GQ2, O = designs.generalised_quadrangle_hermitian_with_ovoid(Integer(4))
>>> GQ2
Incidence structure with 1105 points and 325 blocks
>>> GQ3 = GQ.dual()
>>> set(GQ3._points) == set(GQ2._points)
True
>>> GQ2.is_isomorphic(GQ3) # long time
True
```

sage.combinat.designs.gen_quadrangles_with_spread.**dual_GQ_ovoid**(GQ, O)

Compute the dual incidence structure of GQ and return the image of O under the dual map

INPUT:

- `GQ` – IncidenceStructure; the generalised quadrangle we want the dual of
- `O` – iterable; the iterable of blocks we want to compute the dual

OUTPUT: a pair `(D, S)` where `D` is the dual of `GQ` and `S` is the dual of `O`

EXAMPLES:

```
sage: from sage.combinat.designs.gen_quadrangles_with_spread import \
....: dual_GQ_ovoid
sage: t = designs.generalised_quadrangle_hermitian_with_ovoid(3)
sage: t[0].is_generalized_quadrangle(parameters=True)
(9, 3)
sage: t = dual_GQ_ovoid(*t)
sage: t[0].is_generalized_quadrangle(parameters=True)
```

(continues on next page)

(continued from previous page)

```
(3, 9)
sage: all([x in t[0] for x in t[1]])
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.gen_quadrangles_with_spread import dual_GQ_ovoid
>>> t = designs.generalised_quadrangle_hermitian_with_ovoid(Integer(3))
>>> t[Integer(0)].is_generalized_quadrangle(parameters=True)
(9, 3)
>>> t = dual_GQ_ovoid(*t)
>>> t[Integer(0)].is_generalized_quadrangle(parameters=True)
(3, 9)
>>> all([x in t[Integer(0)] for x in t[Integer(1)]])
True
```

sage.combinat.designs.gen_quadrangles_with_spread.**generalised_quadrangle_hermitian_with_ovoid**(q)

Construct the generalised quadrangle $H(3, q^2)$ with an ovoid.

The GQ has order (q^2, q).

INPUT:

- `q` – integer; a prime power

OUTPUT:

A pair `(D, O)` where `D` is an IncidenceStructure representing the generalised quadrangle and `O` is a list of points of `D` which constitute an ovoid of `D`.

EXAMPLES:

```
sage: t = designs.generalised_quadrangle_hermitian_with_ovoid(4)
sage: t[0]
Incidence structure with 1105 points and 325 blocks
sage: len(t[1])
65
sage: G = t[0].intersection_graph([1])  # line graph
sage: G.is_strongly_regular(True)
(325, 68, 3, 17)
sage: set(t[0].block_sizes())
{17}
```

```
>>> from sage.all import *
>>> t = designs.generalised_quadrangle_hermitian_with_ovoid(Integer(4))
>>> t[Integer(0)]
Incidence structure with 1105 points and 325 blocks
>>> len(t[Integer(1)])
65
>>> G = t[Integer(0)].intersection_graph([Integer(1)])  # line graph
>>> G.is_strongly_regular(True)
(325, 68, 3, 17)
>>> set(t[Integer(0)].block_sizes())
{17}
```

REFERENCES:

For more on $H(3, q^2)$ and the construction implemented here see [PT2009] or [TP1994].

sage.combinat.designs.gen_quadrangles_with_spread.**generalised_quadrangle_with_spread**(*s*, *t*, *existence=False*, *check=True*)

Construct a generalised quadrangle GQ of order (s, t) with a spread S.

INPUT:

- `s`, `t` – integers; order of the generalised quadrangle
- `existence` – boolean;
- `check` – boolean; if `True`, then Sage checks that the object built is correct. (default: `True`)

OUTPUT:

A pair (GQ, S) where GQ is a `IncidenceStructure` representing the generalised quadrangle and S is a list of blocks of GQ representing the spread of GQ.

EXAMPLES:

```
sage: t = designs.generalised_quadrangle_with_spread(3, 9)
sage: t[0]
Incidence structure with 112 points and 280 blocks
sage: designs.generalised_quadrangle_with_spread(5, 25, existence=True)
True
sage: (designs.generalised_quadrangle_with_spread(4, 16, check=False))[0]
Incidence structure with 325 points and 1105 blocks
sage: designs.generalised_quadrangle_with_spread(0, 2, existence=True)
False
```

```
>>> from sage.all import *
>>> t = designs.generalised_quadrangle_with_spread(Integer(3), Integer(9))
>>> t[Integer(0)]
Incidence structure with 112 points and 280 blocks
>>> designs.generalised_quadrangle_with_spread(Integer(5), Integer(25),␣
↪existence=True)
True
>>> (designs.generalised_quadrangle_with_spread(Integer(4), Integer(16),␣
↪check=False))[Integer(0)]
Incidence structure with 325 points and 1105 blocks
>>> designs.generalised_quadrangle_with_spread(Integer(0), Integer(2),␣
↪existence=True)
False
```

REFERENCES:

For more on generalised quadrangles and their spread see [PT2009] or [TP1994].

sage.combinat.designs.gen_quadrangles_with_spread.**is_GQ_with_spread**(*GQ*, *S*, *s=None*, *t=None*)

Check if GQ is a generalised quadrangle of order (s, t) and check that S is a spread of GQ

INPUT:

- `GQ` – IncidenceStructure; the incidence structure that is supposed to be a generalised quadrangle

- `S` – iterable; the spread of `GQ` as an iterable of the blocks of `GQ`
- `s`, `t` – integers (optional); if (s,t) are given, then we check that `GQ` has order (s,t)

EXAMPLES:

```
sage: from sage.combinat.designs.gen_quadrangles_with_spread import *
sage: t = generalised_quadrangle_hermitian_with_ovoid(3)
sage: is_GQ_with_spread(*t)
Traceback (most recent call last):
...
TypeError: 'int' object is not iterable
sage: t = dual_GQ_ovoid(*t)
sage: is_GQ_with_spread(*t)
True
sage: is_GQ_with_spread(*t, s=3)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.gen_quadrangles_with_spread import *
>>> t = generalised_quadrangle_hermitian_with_ovoid(Integer(3))
>>> is_GQ_with_spread(*t)
Traceback (most recent call last):
...
TypeError: 'int' object is not iterable
>>> t = dual_GQ_ovoid(*t)
>>> is_GQ_with_spread(*t)
True
>>> is_GQ_with_spread(*t, s=Integer(3))
True
```

5.1.89 Incidence structures (i.e. hypergraphs, i.e. set systems)

An incidence structure is specified by a list of points, blocks, or an incidence matrix ([1],[2]). *IncidenceStructure* instances have the following methods:

automorphism_group()	Return the subgroup of the automorphism group of the incidence graph which respects the P B partition. It is (isomorphic to) the automorphism group of the block design, although the degrees differ.
block_sizes()	Return the set of block sizes.
blocks()	Return the list of blocks.
canonical_label()	Return a canonical label for the incidence structure.
coloring()	Compute a (weak) k-coloring of the hypergraph.
complement()	Return the complement of the incidence structure.
copy()	Return a copy of the incidence structure.
degree()	Return the degree of a point `p` (or a set of points).
degrees()	Return the degree of all sets of given size, or the degree of all points.
dual()	Return the dual of the incidence structure.
edge_coloring()	Compute a proper edge-coloring.
ground_set()	Return the ground set (i.e the list of points).

continues on next page

[1] Block designs and incidence structures from wikipedia, Wikipedia article Block_design Wikipedia article Incidence_structure
[2] E. Assmus, J. Key, Designs and their codes, CUP, 1992.

Table 2 – continued from previous page

`incidence_graph()`	Return the incidence graph of the incidence structure.
`incidence_matrix()`	Return the incidence matrix A of the design. A is a $(v \times b)$ matrix defined by: `A[i,j] = 1` if `i` is in block `B_j` and 0 otherwise.
`induced_substructure()`	Return the substructure induced by a set of points.
`intersection_graph()`	Return the intersection graph of the incidence structure.
`is_berge_cyclic()`	Check whether `self` is a Berge-Cyclic uniform hypergraph.
`is_connected()`	Test whether the design is connected.
`is_generalized_quadrangle()`	Test if the incidence structure is a generalized quadrangle.
`is_isomorphic()`	Return whether the two incidence structures are isomorphic.
`is_regular()`	Test whether the incidence structure is r-regular.
`is_resolvable()`	Test whether the hypergraph is resolvable.
`is_simple()`	Test whether this design is simple (i.e. no repeated block).
`is_spread()`	Check whether the input is a spread for `self`.
`is_t_design()`	Test whether `self` is a $t-(v,k,l)$ design.
`is_uniform()`	Test whether the incidence structure is k-uniform
`isomorphic_substructures_iterator()`	Iterate over all copies of `H2` contained in `self`.
`num_blocks()`	Return the number of blocks.
`num_points()`	Return the size of the ground set.
`packing()`	Return a maximum packing.
`rank()`	Return the rank of the hypergraph (the maximum size of a block).
`relabel()`	Relabel the ground set.
`trace()`	Return the trace of a set of points.

AUTHORS:

- Peter Dobcsanyi and David Joyner (2007-2008)

  This is a significantly modified form of part of the module block_design.py (version 0.6) written by Peter Dobcsanyi peter@designtheory.org.

- Vincent Delecroix (2014): major rewrite

Methods

class sage.combinat.designs.incidence_structures.**IncidenceStructure**(*points=None*, *blocks=None*, *incidence_matrix=None*, *name=None*, *check=True*, *copy=True*)

Bases: `object`

A base class for incidence structures (i.e. hypergraphs, i.e. set systems)

An incidence structure (i.e. hypergraph, i.e. set system) can be defined from a collection of blocks (i.e. sets, i.e. edges), optionally with an explicit ground set (i.e. point set, i.e. vertex set). Alternatively they can be defined from a binary incidence matrix.

INPUT:

- `points` – (i.e. ground set, i.e. vertex set) the underlying set. If `points` is an integer v, then the set is considered to be $\{0, ..., v-1\}$.

Note

The following syntax, where `points` is omitted, automatically defines the ground set as the union of the blocks:

```
sage: H = IncidenceStructure([['a','b','c'],['c','d','e']])
sage: sorted(H.ground_set())
['a', 'b', 'c', 'd', 'e']
```

```
>>> from sage.all import *
>>> H = IncidenceStructure([['a','b','c'],['c','d','e']])
>>> sorted(H.ground_set())
['a', 'b', 'c', 'd', 'e']
```

- `blocks` – (i.e. edges, i.e. sets) the blocks defining the incidence structure; can be any iterable
- `incidence_matrix` – a binary incidence matrix; each column represents a set
- `name` – string (such as "Fano plane")
- `check` – whether to check the input
- `copy` – (use with caution) if set to `False` then `blocks` must be a list of lists of integers. The list will not be copied but will be modified in place (each block is sorted, and the whole list is sorted). Your `blocks` object will become the `IncidenceStructure` instance's internal data.

EXAMPLES:

An incidence structure can be constructed by giving the number of points and the list of blocks:

```
sage: IncidenceStructure(7, [[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,
↪5]])
Incidence structure with 7 points and 7 blocks
```

```
>>> from sage.all import *
>>> IncidenceStructure(Integer(7), [[Integer(0),Integer(1),Integer(2)],
↪[Integer(0),Integer(3),Integer(4)],[Integer(0),Integer(5),Integer(6)],
↪[Integer(1),Integer(3),Integer(5)],[Integer(1),Integer(4),Integer(6)],
↪[Integer(2),Integer(3),Integer(6)],[Integer(2),Integer(4),Integer(5)]])
Incidence structure with 7 points and 7 blocks
```

Only providing the set of blocks is sufficient. In this case, the ground set is defined as the union of the blocks:

```
sage: IncidenceStructure([[1,2,3],[2,3,4]])
Incidence structure with 4 points and 2 blocks
```

```
>>> from sage.all import *
>>> IncidenceStructure([[Integer(1),Integer(2),Integer(3)],[Integer(2),Integer(3),
↪Integer(4)]])
Incidence structure with 4 points and 2 blocks
```

Or by its adjacency matrix (a $\{0,1\}$-matrix in which rows are indexed by points and columns by blocks):

```
sage: m = matrix([[0,1,0],[0,0,1],[1,0,1],[1,1,1]])                          #␣
↪needs sage.modules
sage: IncidenceStructure(m)                                                  #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.modules
Incidence structure with 4 points and 3 blocks
```

```
>>> from sage.all import *
>>> m = matrix([[Integer(0),Integer(1),Integer(0)],[Integer(0),Integer(0),
↪Integer(1)],[Integer(1),Integer(0),Integer(1)],[Integer(1),Integer(1),
↪Integer(1)]])                                    # needs sage.modules
>>> IncidenceStructure(m)                                                    #␣
↪needs sage.modules
Incidence structure with 4 points and 3 blocks
```

The points can be any (hashable) object:

```
sage: V = [(0,'a'),(0,'b'),(1,'a'),(1,'b')]
sage: B = [(V[0],V[1],V[2]), (V[1],V[2]), (V[0],V[2])]
sage: I = IncidenceStructure(V, B)
sage: I.ground_set()
[(0, 'a'), (0, 'b'), (1, 'a'), (1, 'b')]
sage: I.blocks()
[[(0, 'a'), (0, 'b'), (1, 'a')], [(0, 'a'), (1, 'a')], [(0, 'b'), (1, 'a')]]
```

```
>>> from sage.all import *
>>> V = [(Integer(0),'a'),(Integer(0),'b'),(Integer(1),'a'),(Integer(1),'b')]
>>> B = [(V[Integer(0)],V[Integer(1)],V[Integer(2)]), (V[Integer(1)],
↪V[Integer(2)]), (V[Integer(0)],V[Integer(2)])]
>>> I = IncidenceStructure(V, B)
>>> I.ground_set()
[(0, 'a'), (0, 'b'), (1, 'a'), (1, 'b')]
>>> I.blocks()
[[(0, 'a'), (0, 'b'), (1, 'a')], [(0, 'a'), (1, 'a')], [(0, 'b'), (1, 'a')]]
```

The order of the points and blocks does not matter as they are sorted on input (see Issue #11333):

```
sage: A = IncidenceStructure([0,1,2], [[0],[0,2]])
sage: B = IncidenceStructure([1,0,2], [[0],[2,0]])
sage: B == A
True

sage: C = BlockDesign(2, [[0], [1,0]])
sage: D = BlockDesign(2, [[0,1], [0]])
sage: C == D
True
```

```
>>> from sage.all import *
>>> A = IncidenceStructure([Integer(0),Integer(1),Integer(2)], [[Integer(0)],
↪[Integer(0),Integer(2)]])
>>> B = IncidenceStructure([Integer(1),Integer(0),Integer(2)], [[Integer(0)],
↪[Integer(2),Integer(0)]])
>>> B == A
True

>>> C = BlockDesign(Integer(2), [[Integer(0)], [Integer(1),Integer(0)]])
```

(continues on next page)

(continued from previous page)

```
>>> D = BlockDesign(Integer(2), [[Integer(0),Integer(1)], [Integer(0)]])
>>> C == D
True
```

If you care for speed, you can set `copy` to `False`, but in that case, your input must be a list of lists and the ground set must be $0, ..., v-1$:

```
sage: blocks = [[0,1],[2,0],[1,2]]  # a list of lists of integers
sage: I = IncidenceStructure(3, blocks, copy=False)
sage: I._blocks is blocks
True
```

```
>>> from sage.all import *
>>> blocks = [[Integer(0),Integer(1)],[Integer(2),Integer(0)],[Integer(1),
↪Integer(2)]]  # a list of lists of integers
>>> I = IncidenceStructure(Integer(3), blocks, copy=False)
>>> I._blocks is blocks
True
```

automorphism_group()

Return the subgroup of the automorphism group of the incidence graph which respects the P B partition. It is (isomorphic to) the automorphism group of the block design, although the degrees differ.

EXAMPLES:

```
sage: # needs sage.groups sage.rings.finite_rings
sage: P = designs.DesarguesianProjectivePlaneDesign(2); P
(7,3,1)-Balanced Incomplete Block Design
sage: G = P.automorphism_group()
sage: G.is_isomorphic(PGL(3,2))
True
sage: G
Permutation Group with generators [...]
sage: G.cardinality()
168
```

```
>>> from sage.all import *
>>> # needs sage.groups sage.rings.finite_rings
>>> P = designs.DesarguesianProjectivePlaneDesign(Integer(2)); P
(7,3,1)-Balanced Incomplete Block Design
>>> G = P.automorphism_group()
>>> G.is_isomorphic(PGL(Integer(3),Integer(2)))
True
>>> G
Permutation Group with generators [...]
>>> G.cardinality()
168
```

A non self-dual example:

```
sage: IS = IncidenceStructure(list(range(4)), [[0,1,2,3],[1,2,3]])
sage: IS.automorphism_group().cardinality()                                    #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.groups
6
sage: IS.dual().automorphism_group().cardinality()                          #␣
↪needs sage.groups sage.modules
1
```

```
>>> from sage.all import *
>>> IS = IncidenceStructure(list(range(Integer(4))), [[Integer(0),Integer(1),
↪Integer(2),Integer(3)],[Integer(1),Integer(2),Integer(3)]])
>>> IS.automorphism_group().cardinality()                                   #␣
↪needs sage.groups
6
>>> IS.dual().automorphism_group().cardinality()                            #␣
↪needs sage.groups sage.modules
1
```

Examples with non-integer points:

```
sage: I = IncidenceStructure('abc', ('ab','ac','bc'))
sage: I.automorphism_group()                                                #␣
↪needs sage.groups
Permutation Group with generators [('b','c'), ('a','b')]
sage: IncidenceStructure([[(1,2),(3,4)]]).automorphism_group()              #␣
↪needs sage.groups
Permutation Group with generators [((1,2),(3,4))]
```

```
>>> from sage.all import *
>>> I = IncidenceStructure('abc', ('ab','ac','bc'))
>>> I.automorphism_group()                                                  #␣
↪needs sage.groups
Permutation Group with generators [('b','c'), ('a','b')]
>>> IncidenceStructure([[(Integer(1),Integer(2)),(Integer(3),Integer(4))]]).
↪automorphism_group()                 # needs sage.groups
Permutation Group with generators [((1,2),(3,4))]
```

block_sizes()

Return the set of block sizes.

EXAMPLES:

```
sage: BD = IncidenceStructure(8, [[0,1,3],[1,4,5,6],[1,2],[5,6,7]])
sage: BD.block_sizes()
[3, 2, 4, 3]
sage: BD = IncidenceStructure(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,
↪6],[2,4,5]])
sage: BD.block_sizes()
[3, 3, 3, 3, 3, 3, 3]
```

```
>>> from sage.all import *
>>> BD = IncidenceStructure(Integer(8), [[Integer(0),Integer(1),Integer(3)],
↪[Integer(1),Integer(4),Integer(5),Integer(6)],[Integer(1),Integer(2)],
↪[Integer(5),Integer(6),Integer(7)]])
```

(continues on next page)

(continued from previous page)

```
>>> BD.block_sizes()
[3, 2, 4, 3]
>>> BD = IncidenceStructure(Integer(7),[[Integer(0),Integer(1),Integer(2)],
↪[Integer(0),Integer(3),Integer(4)],[Integer(0),Integer(5),Integer(6)],
↪[Integer(1),Integer(3),Integer(5)],[Integer(1),Integer(4),Integer(6)],
↪[Integer(2),Integer(3),Integer(6)],[Integer(2),Integer(4),Integer(5)]])
>>> BD.block_sizes()
[3, 3, 3, 3, 3, 3, 3]
```

blocks()

Return the list of blocks.

EXAMPLES:

```
sage: BD = IncidenceStructure(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,
↪6],[2,4,5]])
sage: BD.blocks()
[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6], [2, 4, 5]]
```

```
>>> from sage.all import *
>>> BD = IncidenceStructure(Integer(7),[[Integer(0),Integer(1),Integer(2)],
↪[Integer(0),Integer(3),Integer(4)],[Integer(0),Integer(5),Integer(6)],
↪[Integer(1),Integer(3),Integer(5)],[Integer(1),Integer(4),Integer(6)],
↪[Integer(2),Integer(3),Integer(6)],[Integer(2),Integer(4),Integer(5)]])
>>> BD.blocks()
[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6], [2, 4, 5]]
```

canonical_label()

Return a canonical label for the incidence structure.

A canonical label is relabeling of the points into integers $\{0, ..., n-1\}$ such that isomorphic incidence structures are relabelled to equal objects.

EXAMPLES:

```
sage: # needs sage.schemes
sage: fano1 = designs.balanced_incomplete_block_design(7,3)
sage: fano2 = designs.projective_plane(2)
sage: fano1 == fano2
False
sage: fano1.relabel(fano1.canonical_label())
sage: fano2.relabel(fano2.canonical_label())
sage: fano1 == fano2
True
```

```
>>> from sage.all import *
>>> # needs sage.schemes
>>> fano1 = designs.balanced_incomplete_block_design(Integer(7),Integer(3))
>>> fano2 = designs.projective_plane(Integer(2))
>>> fano1 == fano2
False
>>> fano1.relabel(fano1.canonical_label())
>>> fano2.relabel(fano2.canonical_label())
```

(continues on next page)

(continued from previous page)

```
>>> fano1 == fano2
True
```

coloring(*k*, *solver=None*, *verbose=None*, *integrality_tolerance=0*)

Compute a (weak) k-coloring of the hypergraph.

A weak coloring of a hypergraph $\mathcal{H}$ is an assignment of colors to its vertices such that no set is monochromatic.

INPUT:

- `k` – integer; compute a coloring with k colors if an integer is provided, otherwise returns an optimal coloring (i.e. with the minimum possible number of colors).
- `solver` – (default: `None`) specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `verbose` – nonnegative integer (default: 0); set the level of verbosity you want from the linear program solver. Since the problem is NP-complete, its solving may take some time depending on the graph. A value of 0 means that there will be no message printed by the solver.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`

EXAMPLES:

The Fano plane has chromatic number 3:

```
sage: len(designs.steiner_triple_system(7).coloring())                         #␣
↪needs sage.numerical.mip
3
```

```
>>> from sage.all import *
>>> len(designs.steiner_triple_system(Integer(7)).coloring())                  ␣
↪     # needs sage.numerical.mip
3
```

One admissible 3-coloring:

```
sage: designs.steiner_triple_system(7).coloring()    # not tested             #␣
↪needs sage.numerical.mip
[[0, 2, 5, 1], [4, 3], [6]]
```

```
>>> from sage.all import *
>>> designs.steiner_triple_system(Integer(7)).coloring()    # not tested      ␣
↪     # needs sage.numerical.mip
[[0, 2, 5, 1], [4, 3], [6]]
```

The chromatic number of a graph is equal to the chromatic number of its 2-uniform corresponding hypergraph:

```
sage: g = graphs.PetersenGraph()
sage: H = IncidenceStructure(g.edges(sort=True, labels=False))
sage: len(g.coloring())
3
sage: len(H.coloring())                                                        #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.numerical.mip
3
```

```
>>> from sage.all import *
>>> g = graphs.PetersenGraph()
>>> H = IncidenceStructure(g.edges(sort=True, labels=False))
>>> len(g.coloring())
3
>>> len(H.coloring())                                                    #␣
↪needs sage.numerical.mip
3
```

complement(*uniform=False*)

Return the complement of the incidence structure.

Two different definitions of "complement" are made available, according to the value of `uniform`.

INPUT:

- `uniform` – boolean
  - if set to `False` (default), returns the incidence structure whose blocks are the complements of all blocks of the incidence structure.
  - If set to `True` and the incidence structure is k-uniform, returns the incidence structure whose blocks are all k-sets of the ground set that do not appear in `self`.

EXAMPLES:

The complement of a *BalancedIncompleteBlockDesign* is also a 2-design:

```
sage: bibd = designs.balanced_incomplete_block_design(13,4)               #␣
↪needs sage.schemes
sage: bibd.is_t_design(return_parameters=True)                            #␣
↪needs sage.schemes
(True, (2, 13, 4, 1))
sage: bibd.complement().is_t_design(return_parameters=True)               #␣
↪needs sage.schemes
(True, (2, 13, 9, 6))
```

```
>>> from sage.all import *
>>> bibd = designs.balanced_incomplete_block_design(Integer(13),Integer(4))  ␣
↪              # needs sage.schemes
>>> bibd.is_t_design(return_parameters=True)                              #␣
↪needs sage.schemes
(True, (2, 13, 4, 1))
>>> bibd.complement().is_t_design(return_parameters=True)                 #␣
↪needs sage.schemes
(True, (2, 13, 9, 6))
```

The "uniform" complement of a graph is a graph:

```
sage: g = graphs.PetersenGraph()
sage: G = IncidenceStructure(g.edges(sort=True, labels=False))
sage: H = G.complement(uniform=True)
```

(continues on next page)

(continued from previous page)

```
sage: h = Graph(H.blocks())
sage: g == h
False
sage: g == h.complement()
True
```

```
>>> from sage.all import *
>>> g = graphs.PetersenGraph()
>>> G = IncidenceStructure(g.edges(sort=True, labels=False))
>>> H = G.complement(uniform=True)
>>> h = Graph(H.blocks())
>>> g == h
False
>>> g == h.complement()
True
```

copy()

Return a copy of the incidence structure.

EXAMPLES:

```
sage: IS = IncidenceStructure([[1,2,3,"e"]], name='Test')
sage: IS
Incidence structure with 4 points and 1 blocks
sage: copy(IS)
Incidence structure with 4 points and 1 blocks
sage: [1, 2, 3, 'e'] in copy(IS)
True
sage: copy(IS)._name
'Test'
```

```
>>> from sage.all import *
>>> IS = IncidenceStructure([[Integer(1),Integer(2),Integer(3),"e"]], name=
↪'Test')
>>> IS
Incidence structure with 4 points and 1 blocks
>>> copy(IS)
Incidence structure with 4 points and 1 blocks
>>> [Integer(1), Integer(2), Integer(3), 'e'] in copy(IS)
True
>>> copy(IS)._name
'Test'
```

degree(*p=None*, *subset=False*)

Return the degree of a point `p` (or a set of points).

The degree of a point (or set of points) is the number of blocks that contain it.

INPUT:

- `p` – a point (or a set of points) of the incidence structure
- `subset` – boolean (default: `False`); whether to interpret the argument as a set of point or as a point (default)

EXAMPLES:

```
sage: designs.steiner_triple_system(9).degree(3)
4
sage: designs.steiner_triple_system(9).degree({1,2},subset=True)
1
```

```
>>> from sage.all import *
>>> designs.steiner_triple_system(Integer(9)).degree(Integer(3))
4
>>> designs.steiner_triple_system(Integer(9)).degree({Integer(1),Integer(2)},
↪subset=True)
1
```

degrees(*size=None*)

Return the degree of all sets of given size, or the degree of all points.

The degree of a point (or set of point) is the number of blocks that contain it.

INPUT:

- `size` – integer; return the degree of all subsets of points of cardinality `size`. When `size=None`, the function outputs the degree of all points.

> **Note**
>
> When `size=None` the output is indexed by the points. When `size=1` it is indexed by tuples of size 1. This is the same information, stored slightly differently.

OUTPUT: a dictionary whose values are degrees and keys are either:

- the points of the incidence structure if `size=None` (default)
- the subsets of size `size` of the points stored as tuples

EXAMPLES:

```
sage: IncidenceStructure([[1,2,3],[1,4]]).degrees(2)
{(1, 2): 1, (1, 3): 1, (1, 4): 1, (2, 3): 1, (2, 4): 0, (3, 4): 0}
```

```
>>> from sage.all import *
>>> IncidenceStructure([[Integer(1),Integer(2),Integer(3)],[Integer(1),
↪Integer(4)]]).degrees(Integer(2))
{(1, 2): 1, (1, 3): 1, (1, 4): 1, (2, 3): 1, (2, 4): 0, (3, 4): 0}
```

In a Steiner triple system, all pairs have degree 1:

```
sage: S13 = designs.steiner_triple_system(13)
sage: all(v == 1 for v in S13.degrees(2).values())
True
```

```
>>> from sage.all import *
>>> S13 = designs.steiner_triple_system(Integer(13))
>>> all(v == Integer(1) for v in S13.degrees(Integer(2)).values())
True
```

dual(*algorithm=None*)

Return the dual of the incidence structure.

INPUT:

- algorithm – whether to use Sage's implementation (algorithm=None, default) or use GAP's (algorithm='gap')

> **Note**
>
> The algorithm='gap' option requires GAP's Design package (included in the gap_packages Sage spkg).

EXAMPLES:

The dual of a projective plane is a projective plane:

```
sage: PP = designs.DesarguesianProjectivePlaneDesign(4)                    #␣
↪needs sage.rings.finite_rings
sage: PP.dual().is_t_design(return_parameters=True)                        #␣
↪needs sage.modules sage.rings.finite_rings
(True, (2, 21, 5, 1))
```

```
>>> from sage.all import *
>>> PP = designs.DesarguesianProjectivePlaneDesign(Integer(4))              ␣
↪     # needs sage.rings.finite_rings
>>> PP.dual().is_t_design(return_parameters=True)                        #␣
↪needs sage.modules sage.rings.finite_rings
(True, (2, 21, 5, 1))
```

REFERENCE:

- Leonard Soicher, Design package manual

edge_coloring()

Compute a proper edge-coloring.

A proper edge-coloring is an assignment of colors to the sets of the incidence structure such that two sets with non-empty intersection receive different colors. The coloring returned minimizes the number of colors.

OUTPUT: a partition of the sets into color classes

EXAMPLES:

```
sage: H = Hypergraph([{1,2,3},{2,3,4},{3,4,5},{4,5,6}]); H
Incidence structure with 6 points and 4 blocks
sage: C = H.edge_coloring()
sage: C # random
[[[3, 4, 5]], [[2, 3, 4]], [[4, 5, 6], [1, 2, 3]]]
sage: Set(map(Set,sum(C,[]))) == Set(map(Set,H.blocks()))
True
```

```
>>> from sage.all import *
>>> H = Hypergraph([{Integer(1),Integer(2),Integer(3)},{Integer(2),Integer(3),
↪Integer(4)},{Integer(3),Integer(4),Integer(5)},{Integer(4),Integer(5),
```

(continues on next page)

(continued from previous page)

```
↪Integer(6)}]); H
Incidence structure with 6 points and 4 blocks
>>> C = H.edge_coloring()
>>> C # random
[[[3, 4, 5]], [[2, 3, 4]], [[4, 5, 6], [1, 2, 3]]]
>>> Set(map(Set,sum(C,[]))) == Set(map(Set,H.blocks()))
True
```

ground_set()

Return the ground set (i.e the list of points).

EXAMPLES:

```
sage: IncidenceStructure(3, [[0,1],[0,2]]).ground_set()
[0, 1, 2]
```

```
>>> from sage.all import *
>>> IncidenceStructure(Integer(3), [[Integer(0),Integer(1)],[Integer(0),
↪Integer(2)]]).ground_set()
[0, 1, 2]
```

incidence_graph(*labels=False*)

Return the incidence graph of the incidence structure.

A point and a block are adjacent in this graph whenever they are incident.

INPUT:

- `labels` – boolean; whether to return a graph whose vertices are integers, or labelled elements
  - `labels is False` – default; in this case the first vertices of the graphs are the elements of `ground_set()`, and appear in the same order. Similarly, the following vertices represent the elements of `blocks()`, and appear in the same order.
  - `labels is True`, the points keep their original labels, and the blocks are `Set` objects.

    Note that the labelled incidence graph can be incorrect when blocks are repeated, and on some (rare) occasions when the elements of `ground_set()` mix `Set()` and non-`Set` objects.

EXAMPLES:

```
sage: BD = IncidenceStructure(7, [[0,1,2],[0,3,4],[0,5,6],[1,3,5],
....:                             [1,4,6],[2,3,6],[2,4,5]])
sage: BD.incidence_graph()                                              #␣
↪needs sage.modules
Bipartite graph on 14 vertices
sage: A = BD.incidence_matrix()                                         #␣
↪needs sage.modules
sage: Graph(block_matrix([[A*0, A],                                     #␣
↪needs sage.modules
....:                     [A.transpose(),A*0]])) == BD.incidence_graph()
True
```

```
>>> from sage.all import *
>>> BD = IncidenceStructure(Integer(7), [[Integer(0),Integer(1),Integer(2)],
```

(continues on next page)

(continued from previous page)

```
↪[Integer(0),Integer(3),Integer(4)],[Integer(0),Integer(5),Integer(6)],
↪[Integer(1),Integer(3),Integer(5)],
...                              [Integer(1),Integer(4),Integer(6)],
↪[Integer(2),Integer(3),Integer(6)],[Integer(2),Integer(4),Integer(5)]])
>>> BD.incidence_graph()                                                  #␣
↪needs sage.modules
Bipartite graph on 14 vertices
>>> A = BD.incidence_matrix()                                             #␣
↪needs sage.modules
>>> Graph(block_matrix([[A*Integer(0), A],                                 ␣
↪     # needs sage.modules
...                     [A.transpose(),A*Integer(0)]])) == BD.incidence_
↪graph()
True
```

incidence_matrix()

Return the incidence matrix A of the design. A is a $(v \times b)$ matrix defined by: `A[i,j] = 1` if `i` is in block `B_j` and 0 otherwise.

EXAMPLES:

```
sage: BD = IncidenceStructure(7, [[0,1,2],[0,3,4],[0,5,6],[1,3,5],
....:                              [1,4,6],[2,3,6],[2,4,5]])
sage: BD.block_sizes()
[3, 3, 3, 3, 3, 3, 3]
sage: BD.incidence_matrix()                                               #␣
↪needs sage.modules
[1 1 1 0 0 0 0]
[1 0 0 1 1 0 0]
[1 0 0 0 0 1 1]
[0 1 0 1 0 1 0]
[0 1 0 0 1 0 1]
[0 0 1 1 0 0 1]
[0 0 1 0 1 1 0]

sage: I = IncidenceStructure('abc', ('ab','abc','ac','c'))
sage: I.incidence_matrix()                                                #␣
↪needs sage.modules
[1 1 1 0]
[1 1 0 0]
[0 1 1 1]
```

```
>>> from sage.all import *
>>> BD = IncidenceStructure(Integer(7), [[Integer(0),Integer(1),Integer(2)],
↪[Integer(0),Integer(3),Integer(4)],[Integer(0),Integer(5),Integer(6)],
↪[Integer(1),Integer(3),Integer(5)],
...                              [Integer(1),Integer(4),Integer(6)],
↪[Integer(2),Integer(3),Integer(6)],[Integer(2),Integer(4),Integer(5)]])
>>> BD.block_sizes()
[3, 3, 3, 3, 3, 3, 3]
>>> BD.incidence_matrix()                                                 #␣
↪needs sage.modules
```

(continues on next page)

(continued from previous page)

```
[1 1 1 0 0 0 0]
[1 0 0 1 1 0 0]
[1 0 0 0 0 1 1]
[0 1 0 1 0 1 0]
[0 1 0 0 1 0 1]
[0 0 1 1 0 0 1]
[0 0 1 0 1 1 0]

>>> I = IncidenceStructure('abc', ('ab','abc','ac','c'))
>>> I.incidence_matrix()                                                    #␣
↪needs sage.modules
[1 1 1 0]
[1 1 0 0]
[0 1 1 1]
```

induced_substructure(*points*)

Return the substructure induced by a set of points.

The substructure induced in $\mathcal{H}$ by a set $X \subseteq V(\mathcal{H})$ of points is the incidence structure $\mathcal{H}_X$ defined on X whose sets are all $S \in \mathcal{H}$ such that $S \subseteq X$.

INPUT:

- `points` – set of points

Note: This method goes over all sets of `self` before building a new *IncidenceStructure* (which involves some relabelling and sorting). It probably should not be called in a performance-critical code.

EXAMPLES:

A Fano plane with one point removed:

```
sage: F = designs.steiner_triple_system(7)
sage: F.induced_substructure([0..5])
Incidence structure with 6 points and 4 blocks
```

```
>>> from sage.all import *
>>> F = designs.steiner_triple_system(Integer(7))
>>> F.induced_substructure((ellipsis_range(Integer(0),Ellipsis,Integer(5))))
Incidence structure with 6 points and 4 blocks
```

intersection_graph(*sizes=None*)

Return the intersection graph of the incidence structure.

The vertices of this graph are the *blocks()* of the incidence structure. Two of them are adjacent if the size of their intersection belongs to the set `sizes`.

INPUT:

- `sizes` – list/set of integers; for convenience, setting `sizes` to `5` has the same effect as `sizes=[5]`. When set to `None` (default), behaves as `sizes=PositiveIntegers()`.

EXAMPLES:

The intersection graph of a *balanced_incomplete_block_design()* is a strongly regular graph (when it is not trivial):

```
sage: BIBD =  designs.balanced_incomplete_block_design(19,3)
sage: G = BIBD.intersection_graph(1)
sage: G.is_strongly_regular(parameters=True)
(57, 24, 11, 9)
```

```
>>> from sage.all import *
>>> BIBD =  designs.balanced_incomplete_block_design(Integer(19),Integer(3))
>>> G = BIBD.intersection_graph(Integer(1))
>>> G.is_strongly_regular(parameters=True)
(57, 24, 11, 9)
```

is_berge_cyclic()

Check whether `self` is a Berge-Cyclic uniform hypergraph.

A k-uniform Berge cycle (named after Claude Berge) of length ℓ is a cyclic list of distinct k-sets $F_1, \ldots, F_\ell$, $\ell > 1$, and distinct vertices $C = \{v_1, \ldots, v_\ell\}$ such that for each $1 \leq i \leq \ell$, F_i contains v_i and v_{i+1} (where $v_{l+1} = v_1$).

A uniform hypergraph is Berge-cyclic if its incidence graph is cyclic. It is called "Berge-acyclic" otherwise.

For more information, see [Fag1983] and Wikipedia article Hypergraph.

EXAMPLES:

```
sage: Hypergraph(5, [[1, 2, 3], [2, 3, 4]]).is_berge_cyclic()              #␣
↪needs sage.modules
True
sage: Hypergraph(6, [[1, 2, 3], [3, 4, 5]]).is_berge_cyclic()              #␣
↪needs sage.modules
False
```

```
>>> from sage.all import *
>>> Hypergraph(Integer(5), [[Integer(1), Integer(2), Integer(3)], [Integer(2),
↪ Integer(3), Integer(4)]]).is_berge_cyclic()              # needs sage.
↪modules
True
>>> Hypergraph(Integer(6), [[Integer(1), Integer(2), Integer(3)], [Integer(3),
↪ Integer(4), Integer(5)]]).is_berge_cyclic()              # needs sage.
↪modules
False
```

is_connected()

Test whether the design is connected.

EXAMPLES:

```
sage: IncidenceStructure(3, [[0,1],[0,2]]).is_connected()
True
sage: IncidenceStructure(4, [[0,1],[2,3]]).is_connected()
False
```

```
>>> from sage.all import *
>>> IncidenceStructure(Integer(3), [[Integer(0),Integer(1)],[Integer(0),
↪Integer(2)]]).is_connected()
True
>>> IncidenceStructure(Integer(4), [[Integer(0),Integer(1)],[Integer(2),
↪Integer(3)]]).is_connected()
False
```

is_generalized_quadrangle(*verbose=False*, *parameters=False*)

Test if the incidence structure is a generalized quadrangle.

An incidence structure is a generalized quadrangle iff (see [BH2012], section 9.6):

- two blocks intersect on at most one point.
- For every point p not in a block B, there is a unique block B' intersecting both $\{p\}$ and B

It is a *regular* generalized quadrangle if furthermore:

- it is $s+1$-`uniform` for some positive integer s.
- it is $t+1$-`regular` for some positive integer t.

For more information, see the Wikipedia article Generalized_quadrangle.

Note

Some references (e.g. [PT2009] or Wikipedia article Generalized_quadrangle) only allow *regular* generalized quadrangles. To use such a definition, see the `parameters` optional argument described below, or the methods `is_regular()` and `is_uniform()`.

INPUT:

- `verbose` – boolean; whether to print an explanation when the instance is not a generalized quadrangle
- `parameters` – (boolean; `False`); if set to `True`, the function returns a pair `(s,t)` instead of `True` answers. In this case, s and t are the integers defined above if they exist (each can be set to `False` otherwise).

EXAMPLES:

```
sage: h = designs.CremonaRichmondConfiguration()                              #␣
↪needs networkx
sage: h.is_generalized_quadrangle()                                           #␣
↪needs networkx
True
```

```
>>> from sage.all import *
>>> h = designs.CremonaRichmondConfiguration()                              #␣
↪needs networkx
>>> h.is_generalized_quadrangle()                                           #␣
↪needs networkx
True
```

This is actually a *regular* generalized quadrangle:

```
sage: h.is_generalized_quadrangle(parameters=True)                    #␣
↪needs networkx
(2, 2)
```

```
>>> from sage.all import *
>>> h.is_generalized_quadrangle(parameters=True)                    #␣
↪needs networkx
(2, 2)
```

is_isomorphic(*other*, *certificate=False*)

Return whether the two incidence structures are isomorphic.

INPUT:

- `other` – an incidence structure
- `certificate` – boolean (default: `False`); whether to return an isomorphism from `self` to `other` instead of a boolean answer

EXAMPLES:

```
sage: # needs sage.schemes
sage: fano1 = designs.balanced_incomplete_block_design(7,3)
sage: fano2 = designs.projective_plane(2)
sage: fano1.is_isomorphic(fano2)
True
sage: fano1.is_isomorphic(fano2,certificate=True)
{0: 0, 1: 1, 2: 2, 3: 6, 4: 4, 5: 3, 6: 5}
```

```
>>> from sage.all import *
>>> # needs sage.schemes
>>> fano1 = designs.balanced_incomplete_block_design(Integer(7),Integer(3))
>>> fano2 = designs.projective_plane(Integer(2))
>>> fano1.is_isomorphic(fano2)
True
>>> fano1.is_isomorphic(fano2,certificate=True)
{0: 0, 1: 1, 2: 2, 3: 6, 4: 4, 5: 3, 6: 5}
```

is_regular(*r=None*)

Test whether the incidence structure is r-regular.

An incidence structure is said to be r-regular if all its points are incident with exactly r blocks.

INPUT:

- `r` – integer

OUTPUT:

If `r` is defined, a boolean is returned. If `r` is set to `None` (default), the method returns either `False` or the integer `r` such that the incidence structure is r-regular.

Warning

In case of 0-regular incidence structure, beware that `if not H.is_regular()` is a satisfied condition.

EXAMPLES:

```
sage: designs.balanced_incomplete_block_design(7,3).is_regular()              #␣
↪needs sage.schemes
3
sage: designs.balanced_incomplete_block_design(7,3).is_regular(r=3)           #␣
↪needs sage.schemes
True
sage: designs.balanced_incomplete_block_design(7,3).is_regular(r=4)           #␣
↪needs sage.schemes
False
```

```
>>> from sage.all import *
>>> designs.balanced_incomplete_block_design(Integer(7),Integer(3)).is_
↪regular()             # needs sage.schemes
3
>>> designs.balanced_incomplete_block_design(Integer(7),Integer(3)).is_
↪regular(r=Integer(3))         # needs sage.schemes
True
>>> designs.balanced_incomplete_block_design(Integer(7),Integer(3)).is_
↪regular(r=Integer(4))         # needs sage.schemes
False
```

is_resolvable(*certificate*, *solver=False*, *verbose=None*, *check=0*, *integrality_tolerance=True*)

Test whether the hypergraph is resolvable.

A hypergraph is said to be resolvable if its sets can be partitionned into classes, each of which is a partition of the ground set.

Note

This problem is solved using an Integer Linear Program, and GLPK (the default LP solver) has been reported to be very slow on some instances. If you hit this wall, consider installing a more powerful MILP solver (CPLEX, Gurobi, …).

INPUT:

- `certificate` – boolean; whether to return the classes along with the binary answer (see examples below)
- `solver` – (default: `None`) specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `verbose` – integer (default: 0); sets the level of verbosity. Set to 0 by default, which means quiet.
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`

EXAMPLES:

Some resolvable designs:

```
sage: TD = designs.transversal_design(2,2,resolvable=True)
sage: TD.is_resolvable()
True

sage: AG = designs.AffineGeometryDesign(3,1,GF(2))                          #␣
↪needs sage.combinat
sage: AG.is_resolvable()                                                     #␣
↪needs sage.combinat
True
```

```
>>> from sage.all import *
>>> TD = designs.transversal_design(Integer(2),Integer(2),resolvable=True)
>>> TD.is_resolvable()
True

>>> AG = designs.AffineGeometryDesign(Integer(3),Integer(1),GF(Integer(2)))  ␣
↪                       # needs sage.combinat
>>> AG.is_resolvable()                                                      #␣
↪needs sage.combinat
True
```

Their classes:

```
sage: b, cls = TD.is_resolvable(True)
sage: b
True
sage: cls # random
[[[0, 3], [1, 2]], [[1, 3], [0, 2]]]

sage: # needs sage.combinat
sage: b, cls = AG.is_resolvable(True)
sage: b
True
sage: cls  # random
[[[6, 7], [4, 5], [0, 1], [2, 3]],
 [[5, 7], [0, 4], [3, 6], [1, 2]],
 [[0, 2], [4, 7], [1, 3], [5, 6]],
 [[3, 4], [0, 7], [1, 5], [2, 6]],
 [[3, 7], [1, 6], [0, 5], [2, 4]],
 [[0, 6], [2, 7], [1, 4], [3, 5]],
 [[4, 6], [0, 3], [2, 5], [1, 7]]]
```

```
>>> from sage.all import *
>>> b, cls = TD.is_resolvable(True)
>>> b
True
>>> cls # random
[[[0, 3], [1, 2]], [[1, 3], [0, 2]]]

>>> # needs sage.combinat
>>> b, cls = AG.is_resolvable(True)
>>> b
```

(continues on next page)

(continued from previous page)

```
True
>>> cls  # random
[[[6, 7], [4, 5], [0, 1], [2, 3]],
 [[5, 7], [0, 4], [3, 6], [1, 2]],
 [[0, 2], [4, 7], [1, 3], [5, 6]],
 [[3, 4], [0, 7], [1, 5], [2, 6]],
 [[3, 7], [1, 6], [0, 5], [2, 4]],
 [[0, 6], [2, 7], [1, 4], [3, 5]],
 [[4, 6], [0, 3], [2, 5], [1, 7]]]
```

A non-resolvable design:

```
sage: Fano = designs.balanced_incomplete_block_design(7,3)                      #␣
↪needs sage.schemes
sage: Fano.is_resolvable()                                                       #␣
↪needs sage.schemes
False
sage: Fano.is_resolvable(True)                                                   #␣
↪needs sage.schemes
(False, [])
```

```
>>> from sage.all import *
>>> Fano = designs.balanced_incomplete_block_design(Integer(7),Integer(3))     ␣
↪              # needs sage.schemes
>>> Fano.is_resolvable()                                                       #␣
↪needs sage.schemes
False
>>> Fano.is_resolvable(True)                                                   #␣
↪needs sage.schemes
(False, [])
```

is_simple()

Test whether this design is simple (i.e. no repeated block).

EXAMPLES:

```
sage: IncidenceStructure(3, [[0,1],[1,2],[0,2]]).is_simple()
True
sage: IncidenceStructure(3, [[0],[0]]).is_simple()
False

sage: V = [(0,'a'),(0,'b'),(1,'a'),(1,'b')]
sage: B = [[V[0],V[1]], [V[1],V[2]]]
sage: I = IncidenceStructure(V, B)
sage: I.is_simple()
True
sage: I2 = IncidenceStructure(V, B*2)
sage: I2.is_simple()
False
```

```
>>> from sage.all import *
>>> IncidenceStructure(Integer(3), [[Integer(0),Integer(1)],[Integer(1),
```

(continues on next page)

(continued from previous page)

```
↪Integer(2)],[Integer(0),Integer(2)]]).is_simple()
True
>>> IncidenceStructure(Integer(3), [[Integer(0)],[Integer(0)]]).is_simple()
False

>>> V = [(Integer(0),'a'),(Integer(0),'b'),(Integer(1),'a'),(Integer(1),'b')]
>>> B = [[V[Integer(0)],V[Integer(1)]], [V[Integer(1)],V[Integer(2)]]]
>>> I = IncidenceStructure(V, B)
>>> I.is_simple()
True
>>> I2 = IncidenceStructure(V, B*Integer(2))
>>> I2.is_simple()
False
```

is_spread(*spread*)

Check whether the input is a spread for `self`.

A spread of an incidence structure (P, B) is a subset of B which forms a partition of P.

INPUT:

- `spread` – iterable; defines the spread

EXAMPLES:

```
sage: E = IncidenceStructure([[1, 2, 3], [4, 5, 6], [1, 5, 6]])
sage: E.is_spread([[1, 2, 3], [4, 5, 6]])
True
sage: E.is_spread([1, 2, 3, 4, 5, 6])
Traceback (most recent call last):
...
TypeError: 'sage.rings.integer.Integer' object is not iterable
sage: E.is_spread([[1, 2, 3, 4], [5, 6]])
False
```

```
>>> from sage.all import *
>>> E = IncidenceStructure([[Integer(1), Integer(2), Integer(3)], [Integer(4),
↪ Integer(5), Integer(6)], [Integer(1), Integer(5), Integer(6)]])
>>> E.is_spread([[Integer(1), Integer(2), Integer(3)], [Integer(4),␣
↪Integer(5), Integer(6)]])
True
>>> E.is_spread([Integer(1), Integer(2), Integer(3), Integer(4), Integer(5),␣
↪Integer(6)])
Traceback (most recent call last):
...
TypeError: 'sage.rings.integer.Integer' object is not iterable
>>> E.is_spread([[Integer(1), Integer(2), Integer(3), Integer(4)],␣
↪[Integer(5), Integer(6)]])
False
```

Order of blocks or of points within each block doesn't matter:

```
sage: E = IncidenceStructure([[1, 2, 3], [4, 5, 6], [1, 5, 6]])
sage: E.is_spread([[5, 6, 4], [3, 1, 2]])
```

(continues on next page)

(continued from previous page)

```
True
```

```
>>> from sage.all import *
>>> E = IncidenceStructure([[Integer(1), Integer(2), Integer(3)], [Integer(4),
↪ Integer(5), Integer(6)], [Integer(1), Integer(5), Integer(6)]])
>>> E.is_spread([[Integer(5), Integer(6), Integer(4)], [Integer(3),␣
↪Integer(1), Integer(2)]])
True
```

is_t_design(*t=None*, *v=None*, *k=None*, *l=None*, *return_parameters=False*)

Test whether `self` is a $t-(v,k,l)$ design.

A $t-(v,k,\lambda)$ (sometimes called t-design for short) is a block design in which:

- the underlying set has cardinality v
- the blocks have size k
- each t-subset of points is covered by λ blocks

INPUT:

- `t`, `v`, `k`, `l` – integers; their value is set to `None` by default. The function tests whether the design is a $t-(v,k,l)$ design using the provided values and guesses the others. Note that `l` cannot be specified if `t` is not.
- `return_parameters` – boolean; whether to return the parameters of the t-design. If set to `True`, the function returns a pair `(boolean_answer, (t,v,k,l))`.

EXAMPLES:

```
sage: fano_blocks = [[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]]
sage: BD = IncidenceStructure(7, fano_blocks)
sage: BD.is_t_design()
True
sage: BD.is_t_design(return_parameters=True)
(True, (2, 7, 3, 1))
sage: BD.is_t_design(2, 7, 3, 1)
True
sage: BD.is_t_design(1, 7, 3, 3)
True
sage: BD.is_t_design(0, 7, 3, 7)
True

sage: BD.is_t_design(0,6,3,7) or BD.is_t_design(0,7,4,7) or BD.is_t_design(0,
↪7,3,8)
False

sage: BD = designs.AffineGeometryDesign(3, 1, GF(2))                        #␣
↪needs sage.combinat
sage: BD.is_t_design(1)                                                     #␣
↪needs sage.combinat
True
sage: BD.is_t_design(2)                                                     #␣
↪needs sage.combinat
True
```

```
>>> from sage.all import *
>>> fano_blocks = [[Integer(0),Integer(1),Integer(2)],[Integer(0),Integer(3),
↪Integer(4)],[Integer(0),Integer(5),Integer(6)],[Integer(1),Integer(3),
↪Integer(5)],[Integer(1),Integer(4),Integer(6)],[Integer(2),Integer(3),
↪Integer(6)],[Integer(2),Integer(4),Integer(5)]]
>>> BD = IncidenceStructure(Integer(7), fano_blocks)
>>> BD.is_t_design()
True
>>> BD.is_t_design(return_parameters=True)
(True, (2, 7, 3, 1))
>>> BD.is_t_design(Integer(2), Integer(7), Integer(3), Integer(1))
True
>>> BD.is_t_design(Integer(1), Integer(7), Integer(3), Integer(3))
True
>>> BD.is_t_design(Integer(0), Integer(7), Integer(3), Integer(7))
True

>>> BD.is_t_design(Integer(0),Integer(6),Integer(3),Integer(7)) or BD.is_t_
↪design(Integer(0),Integer(7),Integer(4),Integer(7)) or BD.is_t_
↪design(Integer(0),Integer(7),Integer(3),Integer(8))
False

>>> BD = designs.AffineGeometryDesign(Integer(3), Integer(1), GF(Integer(2)))␣
↪                         # needs sage.combinat
>>> BD.is_t_design(Integer(1))                                               ␣
↪     # needs sage.combinat
True
>>> BD.is_t_design(Integer(2))                                               ␣
↪     # needs sage.combinat
True
```

Steiner triple and quadruple systems are other names for $2-(v,3,1)$ and $3-(v,4,1)$ designs:

```
sage: S3_9 = designs.steiner_triple_system(9)
sage: S3_9.is_t_design(2,9,3,1)
True

sage: blocks = designs.steiner_quadruple_system(8)
sage: S4_8 = IncidenceStructure(8, blocks)
sage: S4_8.is_t_design(3,8,4,1)
True

sage: blocks = designs.steiner_quadruple_system(14)
sage: S4_14 = IncidenceStructure(14, blocks)
sage: S4_14.is_t_design(3,14,4,1)
True
```

```
>>> from sage.all import *
>>> S3_9 = designs.steiner_triple_system(Integer(9))
>>> S3_9.is_t_design(Integer(2),Integer(9),Integer(3),Integer(1))
True

>>> blocks = designs.steiner_quadruple_system(Integer(8))
```

(continues on next page)

(continued from previous page)

```
>>> S4_8 = IncidenceStructure(Integer(8), blocks)
>>> S4_8.is_t_design(Integer(3),Integer(8),Integer(4),Integer(1))
True

>>> blocks = designs.steiner_quadruple_system(Integer(14))
>>> S4_14 = IncidenceStructure(Integer(14), blocks)
>>> S4_14.is_t_design(Integer(3),Integer(14),Integer(4),Integer(1))
True
```

Some examples of Witt designs that need the gap database:

```
sage: # optional - gap_package_design
sage: BD = designs.WittDesign(9)
sage: BD.is_t_design(2,9,3,1)
True
sage: W12 = designs.WittDesign(12)
sage: W12.is_t_design(5,12,6,1)
True
sage: W12.is_t_design(4)
True
```

```
>>> from sage.all import *
>>> # optional - gap_package_design
>>> BD = designs.WittDesign(Integer(9))
>>> BD.is_t_design(Integer(2),Integer(9),Integer(3),Integer(1))
True
>>> W12 = designs.WittDesign(Integer(12))
>>> W12.is_t_design(Integer(5),Integer(12),Integer(6),Integer(1))
True
>>> W12.is_t_design(Integer(4))
True
```

Further examples:

```
sage: D = IncidenceStructure(4,[[],[]])
sage: D.is_t_design(return_parameters=True)
(True,  (0, 4, 0, 2))

sage: D = IncidenceStructure(4, [[0,1],[0,2],[0,3]])
sage: D.is_t_design(return_parameters=True)
(True, (0, 4, 2, 3))

sage: D = IncidenceStructure(4, [[0],[1],[2],[3]])
sage: D.is_t_design(return_parameters=True)
(True, (1, 4, 1, 1))

sage: D = IncidenceStructure(4,[[0,1],[2,3]])
sage: D.is_t_design(return_parameters=True)
(True, (1, 4, 2, 1))

sage: D = IncidenceStructure(4, [list(range(4))])
sage: D.is_t_design(return_parameters=True)
```

(continues on next page)

(continued from previous page)

```
(True, (4, 4, 4, 1))
```

```
>>> from sage.all import *
>>> D = IncidenceStructure(Integer(4),[[],[]])
>>> D.is_t_design(return_parameters=True)
(True,  (0, 4, 0, 2))

>>> D = IncidenceStructure(Integer(4), [[Integer(0),Integer(1)],[Integer(0),
↪Integer(2)],[Integer(0),Integer(3)]])
>>> D.is_t_design(return_parameters=True)
(True, (0, 4, 2, 3))

>>> D = IncidenceStructure(Integer(4), [[Integer(0)],[Integer(1)],
↪[Integer(2)],[Integer(3)]])
>>> D.is_t_design(return_parameters=True)
(True, (1, 4, 1, 1))

>>> D = IncidenceStructure(Integer(4),[[Integer(0),Integer(1)],[Integer(2),
↪Integer(3)]])
>>> D.is_t_design(return_parameters=True)
(True, (1, 4, 2, 1))

>>> D = IncidenceStructure(Integer(4), [list(range(Integer(4)))])
>>> D.is_t_design(return_parameters=True)
(True, (4, 4, 4, 1))
```

is_uniform(*k=None*)

Test whether the incidence structure is k-uniform

An incidence structure is said to be k-uniform if all its blocks have size k.

INPUT:

- `k` – integer

OUTPUT:

If `k` is defined, a boolean is returned. If `k` is set to `None` (default), the method returns either `False` or the integer `k` such that the incidence structure is k-uniform.

> **Warning**
>
> In case of 0-uniform incidence structure, beware that `if not H.is_uniform()` is a satisfied condition.

EXAMPLES:

```
sage: designs.balanced_incomplete_block_design(7,3).is_uniform()              #␣
↪needs sage.schemes
3
sage: designs.balanced_incomplete_block_design(7,3).is_uniform(k=3)           #␣
↪needs sage.schemes
True
sage: designs.balanced_incomplete_block_design(7,3).is_uniform(k=4)           #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.schemes
False
```

```
>>> from sage.all import *
>>> designs.balanced_incomplete_block_design(Integer(7),Integer(3)).is_
↪uniform()            # needs sage.schemes
3
>>> designs.balanced_incomplete_block_design(Integer(7),Integer(3)).is_
↪uniform(k=Integer(3))          # needs sage.schemes
True
>>> designs.balanced_incomplete_block_design(Integer(7),Integer(3)).is_
↪uniform(k=Integer(4))          # needs sage.schemes
False
```

isomorphic_substructures_iterator(*H2*, *induced=False*)

Iterate over all copies of `H2` contained in `self`.

A hypergraph H_1 contains an isomorphic copy of a hypergraph H_2 if there exists an injection $f : V(H_2) \mapsto V(H_1)$ such that for any set $S_2 \in E(H_2)$ the set $S_1 = f(S2)$ belongs to $E(H_1)$.

It is an *induced* copy if no other set of $E(H_1)$ is contained in $f(V(H_2))$, i.e. $|E(H_2)| = \{S : S \in E(H_1)$ and $f(V(H_2))\}$.

This function lists all such injections. In particular, the number of copies of H in itself is equal to *the size of its automorphism group*.

See *subhypergraph_search* for more information.

INPUT:

- `H2` – an *IncidenceStructure* object
- `induced` – boolean (default: `False`); whether to require the copies to be induced

EXAMPLES:

How many distinct C_5 in Petersen's graph ?

```
sage: P = graphs.PetersenGraph()
sage: C = graphs.CycleGraph(5)
sage: IP = IncidenceStructure(P.edges(sort=True, labels=False))
sage: IC = IncidenceStructure(C.edges(sort=True, labels=False))
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC))
120
```

```
>>> from sage.all import *
>>> P = graphs.PetersenGraph()
>>> C = graphs.CycleGraph(Integer(5))
>>> IP = IncidenceStructure(P.edges(sort=True, labels=False))
>>> IC = IncidenceStructure(C.edges(sort=True, labels=False))
>>> sum(Integer(1) for _ in IP.isomorphic_substructures_iterator(IC))
120
```

As the automorphism group of C_5 has size 10, the number of distinct unlabelled copies is 12. Let us check that all functions returned correspond to an actual C_5 subgraph:

```
sage: for f in IP.isomorphic_substructures_iterator(IC):
....:     assert all(P.has_edge(f[x],f[y]) for x,y in C.edges(sort=True,␣
↪labels=False))
```

```
>>> from sage.all import *
>>> for f in IP.isomorphic_substructures_iterator(IC):
...     assert all(P.has_edge(f[x],f[y]) for x,y in C.edges(sort=True,␣
↪labels=False))
```

The number of induced copies, in this case, is the same:

```
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC,induced=True))
120
```

```
>>> from sage.all import *
>>> sum(Integer(1) for _ in IP.isomorphic_substructures_iterator(IC,
↪induced=True))
120
```

They begin to differ if we make one vertex universal:

```
sage: P.add_edges([(0,x) for x in P], loops=False)
sage: IP = IncidenceStructure(P.edges(sort=True, labels=False))
sage: IC = IncidenceStructure(C.edges(sort=True, labels=False))
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC))
420
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC,induced=True))
60
```

```
>>> from sage.all import *
>>> P.add_edges([(Integer(0),x) for x in P], loops=False)
>>> IP = IncidenceStructure(P.edges(sort=True, labels=False))
>>> IC = IncidenceStructure(C.edges(sort=True, labels=False))
>>> sum(Integer(1) for _ in IP.isomorphic_substructures_iterator(IC))
420
>>> sum(Integer(1) for _ in IP.isomorphic_substructures_iterator(IC,
↪induced=True))
60
```

The number of copies of H in itself is the size of its automorphism group:

```
sage: H = designs.projective_plane(3)                                   #␣
↪needs sage.schemes
sage: sum(1 for _ in H.isomorphic_substructures_iterator(H))            #␣
↪needs sage.schemes
5616
sage: H.automorphism_group().cardinality()                              #␣
↪needs sage.groups sage.schemes
5616
```

```
>>> from sage.all import *
>>> H = designs.projective_plane(Integer(3))                            ␣
```

(continues on next page)

(continued from previous page)

```
↪     # needs sage.schemes
>>> sum(Integer(1) for _ in H.isomorphic_substructures_iterator(H))          ␣
↪     # needs sage.schemes
5616
>>> H.automorphism_group().cardinality()                                    #␣
↪needs sage.groups sage.schemes
5616
```

num_blocks()

Return the number of blocks.

EXAMPLES:

```
sage: designs.DesarguesianProjectivePlaneDesign(2).num_blocks()
7
sage: B = IncidenceStructure(4, [[0,1],[0,2],[0,3],[1,2], [1,2,3]])
sage: B.num_blocks()
5
```

```
>>> from sage.all import *
>>> designs.DesarguesianProjectivePlaneDesign(Integer(2)).num_blocks()
7
>>> B = IncidenceStructure(Integer(4), [[Integer(0),Integer(1)],[Integer(0),
↪Integer(2)],[Integer(0),Integer(3)],[Integer(1),Integer(2)], [Integer(1),
↪Integer(2),Integer(3)]])
>>> B.num_blocks()
5
```

num_points()

Return the size of the ground set.

EXAMPLES:

```
sage: designs.DesarguesianProjectivePlaneDesign(2).num_points()
7
sage: B = IncidenceStructure(4, [[0,1],[0,2],[0,3],[1,2], [1,2,3]])
sage: B.num_points()
4
```

```
>>> from sage.all import *
>>> designs.DesarguesianProjectivePlaneDesign(Integer(2)).num_points()
7
>>> B = IncidenceStructure(Integer(4), [[Integer(0),Integer(1)],[Integer(0),
↪Integer(2)],[Integer(0),Integer(3)],[Integer(1),Integer(2)], [Integer(1),
↪Integer(2),Integer(3)]])
>>> B.num_points()
4
```

packing(*solver*, *verbose=None*, *integrality_tolerance=0*)

Return a maximum packing.

A maximum packing in a hypergraph is collection of disjoint sets/blocks of maximal cardinality. This problem is NP-complete in general, and in particular on 3-uniform hypergraphs. It is solved here with an Integer Linear Program.

For more information, see the Wikipedia article Packing_in_a_hypergraph.

INPUT:

- `solver` – (default: `None`) specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on LP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `verbose` – integer (default: 0); sets the level of verbosity. Set to 0 by default, which means quiet.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

EXAMPLES:

```
sage: P = IncidenceStructure([[1,2],[3,4],[2,3]]).packing()                    #␣
↪needs sage.numerical.mip
sage: sorted(sorted(b) for b in P)                                             #␣
↪needs sage.numerical.mip
[[1, 2], [3, 4]]
sage: len(designs.steiner_triple_system(9).packing())                          #␣
↪needs sage.numerical.mip
3
```

```
>>> from sage.all import *
>>> P = IncidenceStructure([[Integer(1),Integer(2)],[Integer(3),Integer(4)],
↪[Integer(2),Integer(3)]]).packing()                    # needs sage.numerical.
↪mip
>>> sorted(sorted(b) for b in P)                                             #␣
↪needs sage.numerical.mip
[[1, 2], [3, 4]]
>>> len(designs.steiner_triple_system(Integer(9)).packing())                   ␣
↪      # needs sage.numerical.mip
3
```

rank()

Return the rank of the hypergraph (the maximum size of a block).

EXAMPLES:

```
sage: h = Hypergraph(8, [[0,1,3],[1,4,5,6],[1,2]])
sage: h.rank()
4
```

```
>>> from sage.all import *
>>> h = Hypergraph(Integer(8), [[Integer(0),Integer(1),Integer(3)],
↪[Integer(1),Integer(4),Integer(5),Integer(6)],[Integer(1),Integer(2)]])
>>> h.rank()
4
```

relabel(*perm=None*, *inplace=True*)

Relabel the ground set.

INPUT:

- `perm` – can be one of
  - a dictionary – then each point `p` (which should be a key of `d`) is relabeled to `d[p]`

  – a list or a tuple of length n – the first point returned by `ground_set()` is relabeled to l[0], the second to l[1], ...
  – None – the incidence structure is relabeled to be on $\{0, 1, ..., n - 1\}$ in the ordering given by `ground_set()`

- inplace – boolean (default: False); if True then return a relabeled graph and does not touch self

EXAMPLES:

```
sage: # needs sage.schemes
sage: TD = designs.transversal_design(5,5)
sage: TD.relabel({i: chr(97+i) for i in range(25)})
sage: TD.ground_set()
['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k', 'l', 'm',
 'n', 'o', 'p', 'q', 'r', 's', 't', 'u', 'v', 'w', 'x', 'y']
sage: TD.blocks()[:3]
[['a', 'f', 'k', 'p', 'u'], ['a', 'g', 'm', 's', 'y'], ['a', 'h', 'o', 'q', 'x
↪']]
```

```
>>> from sage.all import *
>>> # needs sage.schemes
>>> TD = designs.transversal_design(Integer(5),Integer(5))
>>> TD.relabel({i: chr(Integer(97)+i) for i in range(Integer(25))})
>>> TD.ground_set()
['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k', 'l', 'm',
 'n', 'o', 'p', 'q', 'r', 's', 't', 'u', 'v', 'w', 'x', 'y']
>>> TD.blocks()[:Integer(3)]
[['a', 'f', 'k', 'p', 'u'], ['a', 'g', 'm', 's', 'y'], ['a', 'h', 'o', 'q', 'x
↪']]
```

Relabel to integer points:

```
sage: TD.relabel()                                                      #␣
↪needs sage.schemes
sage: TD.blocks()[:3]                                                   #␣
↪needs sage.schemes
[[0, 5, 10, 15, 20], [0, 6, 12, 18, 24], [0, 7, 14, 16, 23]]
```

```
>>> from sage.all import *
>>> TD.relabel()                                                      #␣
↪needs sage.schemes
>>> TD.blocks()[:Integer(3)]                                            ␣
↪     # needs sage.schemes
[[0, 5, 10, 15, 20], [0, 6, 12, 18, 24], [0, 7, 14, 16, 23]]
```

trace(*points*, *min_size=1*, *multiset=True*)

Return the trace of a set of points.

Given an hypergraph $\mathcal{H}$, the *trace* of a set X of points in $\mathcal{H}$ is the hypergraph whose blocks are all non-empty $S \cap X$ where $S \in \mathcal{H}$.

INPUT:

- points – set of points

- `min_size` – integer (default: 1); minimum size of the sets to keep. By default all empty sets are discarded, i.e. `min_size=1`
- `multiset` – boolean (default: `True`); whether to keep multiple copies of the same set

Note: This method goes over all sets of `self` before building a new `IncidenceStructure` (which involves some relabelling and sorting). It probably should not be called in a performance-critical code.

EXAMPLES:

A Baer subplane of order 2 (i.e. a Fano plane) in a projective plane of order 4:

```
sage: # needs sage.schemes
sage: P4 = designs.projective_plane(4)
sage: F = designs.projective_plane(2)
sage: for x in Subsets(P4.ground_set(),7):
....:     if P4.trace(x,min_size=2).is_isomorphic(F):
....:         break
sage: subplane = P4.trace(x,min_size=2); subplane
Incidence structure with 7 points and 7 blocks
sage: subplane.is_isomorphic(F)
True
```

```
>>> from sage.all import *
>>> # needs sage.schemes
>>> P4 = designs.projective_plane(Integer(4))
>>> F = designs.projective_plane(Integer(2))
>>> for x in Subsets(P4.ground_set(),Integer(7)):
...     if P4.trace(x,min_size=Integer(2)).is_isomorphic(F):
...         break
>>> subplane = P4.trace(x,min_size=Integer(2)); subplane
Incidence structure with 7 points and 7 blocks
>>> subplane.is_isomorphic(F)
True
```

5.1.90 Mutually Orthogonal Latin Squares (MOLS)

The main function of this module is `mutually_orthogonal_latin_squares()` and can be can be used to generate MOLS (or check that they exist):

```
sage: MOLS = designs.mutually_orthogonal_latin_squares(4,8)                  #␣
↪needs sage.schemes
```

```
>>> from sage.all import *
>>> MOLS = designs.mutually_orthogonal_latin_squares(Integer(4),Integer(8))         ␣
↪            # needs sage.schemes
```

For more information on MOLS, see the Wikipedia entry on MOLS. If you are only interested by latin squares, see `latin`.

The functions defined here are

mutually_orthogonal_latin_squares()	Return k Mutually Orthogonal $n \times n$ Latin Squares.
are_mutually_orthogonal_latin_squares()	Check that the list `l` of matrices in are MOLS.
latin_square_product()	Return the product of two (or more) latin squares.
MOLS_table()	Print the MOLS table.

Table of MOLS

Sage can produce a table of MOLS similar to the one from the Handbook of Combinatorial Designs [DesignHandbook] (available here).

```
sage: from sage.combinat.designs.latin_squares import MOLS_table
sage: MOLS_table(600) # long time
       0   1   2   3   4   5   6   7   8   9  10  11  12  13  14  15  16  17  18  19
    ________________________________________________________________________________
  0| +oo +oo   1   2   3   4   1   6   7   8   2  10   5  12   4   4  15  16   5  18
 20|   4   5   3  22   7  24   4  26   5  28   4  30  31   5   4   5   8  36   4   5
 40|   7  40   5  42   5   6   4  46   8  48   6   5   5  52   5   6   7   7   5  58

Functions

`sage.combinat.designs.latin_squares.MOLS_table(start, stop=None, compare=False, width=None)`

Print the MOLS table that Sage can produce.

INPUT:

- `start`, `stop` – integers; print the table of MOLS for value of n such that `start<=n<stop`. If only one integer is given as input, it is interpreted as the value of `stop` with `start=0` (same behaviour as `range`).
- `compare` – boolean; if sets to `True` the MOLS displays with $+$ and $-$ entries its difference with the table from the Handbook of Combinatorial Designs (2ed).
- `width` – integer; the width of each column of the table. By default, it is computed from range of values determined by the parameters `start` and `stop`.

EXAMPLES:

```
sage: # needs sage.schemes
sage: from sage.combinat.designs.latin_squares import MOLS_table
sage: MOLS_table(100)
       0   1   2   3   4   5   6   7   8   9  10  11  12  13  14  15  16  17  18 ␣

sage.combinat.designs.latin_squares.**are_mutually_orthogonal_latin_squares**(*l*, *verbose=False*)

Check whether the list of matrices in `l` form mutually orthogonal latin squares.

INPUT:

- `verbose` – if `True` then print why the list of matrices provided are not mutually orthogonal latin squares

EXAMPLES:

```
sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_
↪latin_squares
sage: m1 = matrix([[0,1,2],[2,0,1],[1,2,0]])
sage: m2 = matrix([[0,1,2],[1,2,0],[2,0,1]])
sage: m3 = matrix([[0,1,2],[2,0,1],[1,2,0]])
sage: are_mutually_orthogonal_latin_squares([m1,m2])
True
sage: are_mutually_orthogonal_latin_squares([m1,m3])
False
sage: are_mutually_orthogonal_latin_squares([m2,m3])
True
sage: are_mutually_orthogonal_latin_squares([m1,m2,m3], verbose=True)
Squares 0 and 2 are not orthogonal
False

sage: m = designs.mutually_orthogonal_latin_squares(7,8)                        #␣
↪needs sage.schemes
sage: are_mutually_orthogonal_latin_squares(m)                                  #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_
↪squares
```

(continues on next page)

(continued from previous page)

```
>>> m1 = matrix([[Integer(0),Integer(1),Integer(2)],[Integer(2),Integer(0),
↪Integer(1)],[Integer(1),Integer(2),Integer(0)]])
>>> m2 = matrix([[Integer(0),Integer(1),Integer(2)],[Integer(1),Integer(2),
↪Integer(0)],[Integer(2),Integer(0),Integer(1)]])
>>> m3 = matrix([[Integer(0),Integer(1),Integer(2)],[Integer(2),Integer(0),
↪Integer(1)],[Integer(1),Integer(2),Integer(0)]])
>>> are_mutually_orthogonal_latin_squares([m1,m2])
True
>>> are_mutually_orthogonal_latin_squares([m1,m3])
False
>>> are_mutually_orthogonal_latin_squares([m2,m3])
True
>>> are_mutually_orthogonal_latin_squares([m1,m2,m3], verbose=True)
Squares 0 and 2 are not orthogonal
False

>>> m = designs.mutually_orthogonal_latin_squares(Integer(7),Integer(8))
↪               # needs sage.schemes
>>> are_mutually_orthogonal_latin_squares(m)                                #
↪needs sage.schemes
True
```

sage.combinat.designs.latin_squares.**latin_square_product**(*M*, *N*, **others*)

Return the product of two (or more) latin squares.

Given two Latin Squares M, N of respective sizes m, n, the direct product $M \times N$ of size mn is defined by $(M \times N)((i_1, i_2), (j_1, j_2)) = (M(i_1, j_1), N(i_2, j_2))$ where $i_1, j_1 \in [m], i_2, j_2 \in [n]$

Each pair of values $(i, j) \in [m] \times [n]$ is then relabeled to $in + j$.

This is Lemma 6.25 of [Stinson2004].

INPUT:

- `M`, `N`, `*others` – an arbitrary number of latin squares (greater than or equal to 2)

EXAMPLES:

```
sage: from sage.combinat.designs.latin_squares import latin_square_product
sage: m=designs.mutually_orthogonal_latin_squares(3,4)[0]                     #
↪needs sage.schemes
sage: latin_square_product(m,m,m)                                             #
↪needs sage.schemes
64 x 64 sparse matrix over Integer Ring (use the '.str()' method to see the
↪entries)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.latin_squares import latin_square_product
>>> m=designs.mutually_orthogonal_latin_squares(Integer(3),
↪Integer(4))[Integer(0)]                         # needs sage.schemes
>>> latin_square_product(m,m,m)                                             #
↪needs sage.schemes
64 x 64 sparse matrix over Integer Ring (use the '.str()' method to see the
↪entries)
```

sage.combinat.designs.latin_squares.**mutually_orthogonal_latin_squares**(*k*, *n*, *partitions=False*, *check=True*)

Return k Mutually Orthogonal $n \times n$ Latin Squares (MOLS).

For more information on Mutually Orthogonal Latin Squares, see `latin_squares`.

INPUT:

- `k` – integer; number of MOLS. If `k` is `None` it is set to the largest value available
- `n` – integer; size of the latin square
- `partitions` – boolean; a Latin Square can be seen as 3 partitions of the n^2 cells of the array into n sets of size n, respectively:
  - The partition of rows
  - The partition of columns
  - The partition of number (cells numbered with 0, cells numbered with 1, …)

  These partitions have the additional property that any two sets from different partitions intersect on exactly one element.

  When `partitions` is set to `True`, this function returns a list of $k + 2$ partitions satisfying this intersection property instead of the $k + 2$ MOLS (though the data is exactly the same in both cases).
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.

EXAMPLES:

```
sage: designs.mutually_orthogonal_latin_squares(4,5)                        #␣
↪needs sage.schemes

```

What is the maximum number of MOLS of size 8 that Sage knows how to build?:

```
sage: designs.orthogonal_arrays.largest_available_k(8)-2                      #␣
↪needs sage.schemes
7
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.largest_available_k(Integer(8))-Integer(2)        ␣
↪              # needs sage.schemes
7
```

If you only want to know if Sage is able to build a given set of MOLS, query the `orthogonal_arrays.*` functions:

```
sage: designs.orthogonal_arrays.is_available(5+2, 5) # 5 MOLS of order 5
False
sage: designs.orthogonal_arrays.is_available(4+2,6)  # 4 MOLS of order 6        #␣
↪needs sage.schemes
False
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(5)+Integer(2), Integer(5)) # 5␣
↪MOLS of order 5
False
>>> designs.orthogonal_arrays.is_available(Integer(4)+Integer(2),Integer(6))  # 4␣
↪MOLS of order 6        # needs sage.schemes
False
```

Sage, however, is not able to prove that the second MOLS do not exist:

```
sage: designs.orthogonal_arrays.exists(4+2,6)  # 4 MOLS of order 6              #␣
↪needs sage.schemes
Unknown
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.exists(Integer(4)+Integer(2),Integer(6))  # 4 MOLS␣
↪of order 6              # needs sage.schemes
Unknown
```

If you ask for such a MOLS then you will respectively get an informative `EmptySetError` or `NotImplementedError`:

```
sage: designs.mutually_orthogonal_latin_squares(5, 5)
Traceback (most recent call last):
...
EmptySetError: there exist at most n-1 MOLS of size n if n>=2
sage: designs.mutually_orthogonal_latin_squares(4,6)                          #␣
↪needs sage.schemes
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build 4 MOLS of order 6
```

```
>>> from sage.all import *
>>> designs.mutually_orthogonal_latin_squares(Integer(5), Integer(5))
Traceback (most recent call last):
...
EmptySetError: there exist at most n-1 MOLS of size n if n>=2
>>> designs.mutually_orthogonal_latin_squares(Integer(4),Integer(6))           ␣
↪              # needs sage.schemes
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build 4 MOLS of order 6
```

5.1.91 Orthogonal arrays (OA)

This module gathers some construction related to orthogonal arrays (or transversal designs). One can build an $OA(k, n)$ (or check that it can be built) from the Sage console with `designs.orthogonal_arrays.build`:

```
sage: OA = designs.orthogonal_arrays.build(4,8)
```

```
>>> from sage.all import *
>>> OA = designs.orthogonal_arrays.build(Integer(4),Integer(8))
```

See also the modules *orthogonal_arrays_build_recursive* or *orthogonal_arrays_find_recursive* for recursive constructions.

This module defines the following functions:

orthogonal_array()	Return an orthogonal array of parameters k, n, t.
transversal_design()	Return a transversal design of parameters k, n.
incomplete_orthogonal_array()	Return an $OA(k, n) - \sum_{1 \leq i \leq x} OA(k, s_i)$.

is_transversal_design()	Check that a given set of blocks B is a transversal design.
is_orthogonal_array()	Check that the integer matrix OA is an $OA(k, n, t)$.
wilson_construction()	Return a $OA(k, rm+u)$ from a truncated $OA(k+s, r)$ by Wilson's construction.
TD_product()	Return the product of two transversal designs.
OA_find_disjoint_blocks()	Return x disjoint blocks contained in a given $OA(k, n)$.
OA_relabel()	Return a relabelled version of the OA.
OA_standard_label()	Return a version of the OA relabelled to symbols $(0, \dots, n-1)$.
OA_from_quasi_difference_matrix()	Return an Orthogonal Array from a Quasi-Difference matrix
OA_from_Vmt()	Return an Orthogonal Array from a $V(m, t)$
OA_from_PBD()	Return an $OA(k, n)$ from a PBD
OA_n_times_2_pow_c_from_matrix()	Return an $OA(k, \|G\| \cdot 2^c)$ from a constrained $(G, k-1, 2)$-difference matrix.
OA_from_wider_OA()	Return the first k columns of OA.
QDM_from_Vmt()	Return a QDM a $V(m, t)$

Functions

class sage.combinat.designs.orthogonal_arrays.**OAMainFunctions**(**args*, ***kwds*)

Bases: object

Functions related to orthogonal arrays.

An orthogonal array of parameters k, n, t is a matrix with k columns filled with integers from $[n]$ in such a way that for any t columns, each of the n^t possible rows occurs exactly once. In particular, the matrix has n^t rows.

For more information on orthogonal arrays, see Wikipedia article Orthogonal_array.

From here you have access to:

- build(k,n,t=2): return an orthogonal array with the given parameters.
- is_available(k,n,t=2): answer whether there is a construction available in Sage for a given set of parameters.
- exists(k,n,t=2): answer whether an orthogonal array with these parameters exist.
- largest_available_k(n,t=2): return the largest integer k such that Sage knows how to build an $OA(k, n)$.
- explain_construction(k,n,t=2): return a string that explains the construction that Sage uses to build an $OA(k, n)$.

EXAMPLES:

```
sage: designs.orthogonal_arrays.build(3,2)
[[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 0]]

sage: designs.orthogonal_arrays.build(5,5)
[[0, 0, 0, 0, 0], [0, 1, 2, 3, 4], [0, 2, 4, 1, 3],
 [0, 3, 1, 4, 2], [0, 4, 3, 2, 1], [1, 0, 4, 3, 2],
 [1, 1, 1, 1, 1], [1, 2, 3, 4, 0], [1, 3, 0, 2, 4],
```

(continues on next page)

 [3, 3, 3, 3, 3], [3, 4, 0, 1, 2], [4, 0, 1, 2, 3],
 [4, 1, 3, 0, 2], [4, 2, 0, 3, 1], [4, 3, 2, 1, 0],
 [4, 4, 4, 4, 4]]
```

What is the largest value of k for which Sage knows how to compute a $OA(k, 14, 2)$?:

```
sage: designs.orthogonal_arrays.largest_available_k(14)
6
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.largest_available_k(Integer(14))
6
```

If you ask for an orthogonal array that does not exist, then you will either obtain an `EmptySetError` (if it knows that such an orthogonal array does not exist) or a `NotImplementedError`:

```
sage: designs.orthogonal_arrays.build(4,2)
Traceback (most recent call last):
...
EmptySetError: There exists no OA(4,2) as k(=4)>n+t-1=3
sage: designs.orthogonal_arrays.build(12,20)
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build an OA(12,20)!
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.build(Integer(4),Integer(2))
Traceback (most recent call last):
...
EmptySetError: There exists no OA(4,2) as k(=4)>n+t-1=3
>>> designs.orthogonal_arrays.build(Integer(12),Integer(20))
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build an OA(12,20)!
```

static build(*k*, *n*, *t=2*, *resolvable=False*)

Return an $OA(k, n)$ of strength t.

An orthogonal array of parameters k, n, t is a matrix with k columns filled with integers from $[n]$ in such a way that for any t columns, each of the n^t possible rows occurs exactly once. In particular, the matrix has n^t rows.

More general definitions sometimes involve a λ parameter, and we assume here that $\lambda = 1$.

For more information on orthogonal arrays, see Wikipedia article Orthogonal_array.

INPUT:

- `k`, `n`, `t` – integers; parameters of the orthogonal array
- `resolvable` – boolean (default: `False`); set to `True` if you want the design to be resolvable. The n classes of the resolvable design are obtained as the first n blocks, then the next n blocks, etc.

EXAMPLES:

```
sage: designs.orthogonal_arrays.build(3,3,resolvable=True) # indirect doctest
[[0, 0, 0],
 [1, 2, 1],
 [2, 1, 2],
 [0, 2, 2],
 [1, 1, 0],
 [2, 0, 1],
 [0, 1, 1],
 [1, 0, 2],
 [2, 2, 0]]
sage: OA_7_50 = designs.orthogonal_arrays.build(7,50)        # indirect doctest
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.build(Integer(3),Integer(3),resolvable=True) #␣
↪indirect doctest
[[0, 0, 0],
 [1, 2, 1],
 [2, 1, 2],
 [0, 2, 2],
 [1, 1, 0],
 [2, 0, 1],
 [0, 1, 1],
 [1, 0, 2],
 [2, 2, 0]]
>>> OA_7_50 = designs.orthogonal_arrays.build(Integer(7),Integer(50))        #␣
↪indirect doctest
```

static exists(*k*, *n*, *t=2*)

Return the existence status of an $OA(k, n)$.

INPUT:

- `k`, `n`, `t` – integers; parameters of the orthogonal array

Warning

The function does not only return booleans, but `True`, `False`, or `Unknown`.

See also

is_available()

EXAMPLES:

```
sage: designs.orthogonal_arrays.exists(3,6) # indirect doctest
True
sage: designs.orthogonal_arrays.exists(4,6) # indirect doctest
Unknown
sage: designs.orthogonal_arrays.exists(7,6) # indirect doctest
False
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.exists(Integer(3),Integer(6)) # indirect doctest
True
>>> designs.orthogonal_arrays.exists(Integer(4),Integer(6)) # indirect doctest
Unknown
>>> designs.orthogonal_arrays.exists(Integer(7),Integer(6)) # indirect doctest
False
```

static explain_construction(*k*, *n*, *t=2*)

Return a string describing how to builds an $OA(k, n)$.

INPUT:

- `k`, `n`, `t` – integers; parameters of the orthogonal array

EXAMPLES:

```
sage: designs.orthogonal_arrays.explain_construction(9,565)
"Wilson's construction n=23.24+13 with master design OA(9+1,23)"
sage: designs.orthogonal_arrays.explain_construction(10,154)
'the database contains a (137,10;1,0;17)-quasi difference matrix'
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.explain_construction(Integer(9),Integer(565))
"Wilson's construction n=23.24+13 with master design OA(9+1,23)"
>>> designs.orthogonal_arrays.explain_construction(Integer(10),Integer(154))
'the database contains a (137,10;1,0;17)-quasi difference matrix'
```

static is_available(*k*, *n*, *t=2*)

Return whether Sage can build an $OA(k, n)$.

INPUT:

- `k`, `n`, `t` – integers; parameters of the orthogonal array

See also

exists()

EXAMPLES:

```
sage: designs.orthogonal_arrays.is_available(3,6) # indirect doctest
True
sage: designs.orthogonal_arrays.is_available(4,6) # indirect doctest
False
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(3),Integer(6)) # indirect␣
→doctest
True
>>> designs.orthogonal_arrays.is_available(Integer(4),Integer(6)) # indirect␣
→doctest
False
```

static largest_available_k(*n*, *t=2*)

Return the largest k such that Sage can build an $OA(k, n)$.

INPUT:

- `n` – integer
- `t` – integer (default: 2); strength of the array

EXAMPLES:

```
sage: designs.orthogonal_arrays.largest_available_k(0)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(1)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(10)
4
sage: designs.orthogonal_arrays.largest_available_k(27)
28
sage: designs.orthogonal_arrays.largest_available_k(100)
10
sage: designs.orthogonal_arrays.largest_available_k(-1)
Traceback (most recent call last):
...
ValueError: n(=-1) was expected to be >=0
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.largest_available_k(Integer(0))
+Infinity
>>> designs.orthogonal_arrays.largest_available_k(Integer(1))
+Infinity
>>> designs.orthogonal_arrays.largest_available_k(Integer(10))
4
>>> designs.orthogonal_arrays.largest_available_k(Integer(27))
28
>>> designs.orthogonal_arrays.largest_available_k(Integer(100))
10
>>> designs.orthogonal_arrays.largest_available_k(-Integer(1))
Traceback (most recent call last):
...
ValueError: n(=-1) was expected to be >=0
```

sage.combinat.designs.orthogonal_arrays.**OA_find_disjoint_blocks**(*OA*, *k*, *n*, *x*, *solver*, *integrality_tolerance*)

Return x disjoint blocks contained in a given $OA(k, n)$.

x blocks of an OA are said to be disjoint if they all have different values for a every given index, i.e. if they correspond to disjoint blocks in the TD associated with the OA.

INPUT:

- `OA` – an orthogonal array
- `k`, `n`, `x` – integers
- `solver` – (default: `None`) specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`

See also

`incomplete_orthogonal_array()`

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import OA_find_disjoint_blocks
sage: k=3;n=4;x=3
sage: Bs = OA_find_disjoint_blocks(designs.orthogonal_arrays.build(k,n),k,n,x)
sage: assert len(Bs) == x
sage: for i in range(k):
....:     assert len(set([B[i] for B in Bs])) == x
sage: OA_find_disjoint_blocks(designs.orthogonal_arrays.build(k,n),k,n,5)
Traceback (most recent call last):
...
ValueError: There does not exist 5 disjoint blocks in this OA(3,4)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import OA_find_disjoint_blocks
>>> k=Integer(3);n=Integer(4);x=Integer(3)
>>> Bs = OA_find_disjoint_blocks(designs.orthogonal_arrays.build(k,n),k,n,x)
>>> assert len(Bs) == x
>>> for i in range(k):
...     assert len(set([B[i] for B in Bs])) == x
>>> OA_find_disjoint_blocks(designs.orthogonal_arrays.build(k,n),k,n,Integer(5))
Traceback (most recent call last):
...
ValueError: There does not exist 5 disjoint blocks in this OA(3,4)
```

sage.combinat.designs.orthogonal_arrays.**OA_from_PBD**(*k*, *n*, *PBD*, *check=True*)

Return an $OA(k, n)$ from a PBD.

Construction

Let $\mathcal{B}$ be a $(n, K, 1)$-PBD. If there exists for every $i \in K$ a $TD(k, i) - i \times TD(k, 1)$ (i.e. if there exist k idempotent MOLS), then one can obtain a $OA(k, n)$ by concatenating:

- A $TD(k, i) - i \times TD(k, 1)$ defined over the elements of B for every $B \in \mathcal{B}$.
- The rows $(i, ..., i)$ of length k for every $i \in [n]$.

Note

This function raises an exception when Sage is unable to build the necessary designs.

INPUT:

- k, n – integers
- PBD – a PBD on $0, \ldots, n - 1$

EXAMPLES:

We start from the example VI.1.2 from the [DesignHandbook] to build an $OA(3, 10)$:

```
sage: from sage.combinat.designs.orthogonal_arrays import OA_from_PBD
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: pbd = [[0,1,2,3],[0,4,5,6],[0,7,8,9],[1,4,7],[1,5,8],
....: [1,6,9],[2,4,9],[2,5,7],[2,6,8],[3,4,8],[3,5,9],[3,6,7]]
sage: oa = OA_from_PBD(3,10,pbd)
sage: is_orthogonal_array(oa, 3, 10)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import OA_from_PBD
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> pbd = [[Integer(0),Integer(1),Integer(2),Integer(3)],[Integer(0),Integer(4),
↪Integer(5),Integer(6)],[Integer(0),Integer(7),Integer(8),Integer(9)],
↪[Integer(1),Integer(4),Integer(7)],[Integer(1),Integer(5),Integer(8)],
... [Integer(1),Integer(6),Integer(9)],[Integer(2),Integer(4),Integer(9)],
↪[Integer(2),Integer(5),Integer(7)],[Integer(2),Integer(6),Integer(8)],
↪[Integer(3),Integer(4),Integer(8)],[Integer(3),Integer(5),Integer(9)],
↪[Integer(3),Integer(6),Integer(7)]]
>>> oa = OA_from_PBD(Integer(3),Integer(10),pbd)
>>> is_orthogonal_array(oa, Integer(3), Integer(10))
True
```

But we cannot build an $OA(4, 10)$ for this PBD (although there exists an $OA(4, 10)$:

```
sage: OA_from_PBD(4,10,pbd)
Traceback (most recent call last):
...
EmptySetError: There is no OA(n+1,n) - 3.OA(n+1,1)
as all blocks intersect in a projective plane.
```

```
>>> from sage.all import *
>>> OA_from_PBD(Integer(4),Integer(10),pbd)
Traceback (most recent call last):
...
EmptySetError: There is no OA(n+1,n) - 3.OA(n+1,1)
as all blocks intersect in a projective plane.
```

Or an $OA(3, 6)$ (as the PBD has 10 points):

```
sage: _ = OA_from_PBD(3,6,pbd)
Traceback (most recent call last):
...
RuntimeError: PBD is not a valid Pairwise Balanced Design on [0,...,5]
```

```
>>> from sage.all import *
>>> _ = OA_from_PBD(Integer(3),Integer(6),pbd)
Traceback (most recent call last):
...
RuntimeError: PBD is not a valid Pairwise Balanced Design on [0,...,5]
```

sage.combinat.designs.orthogonal_arrays.**OA_from_Vmt**(*m*, *t*, *V*)

Return an Orthogonal Array from a $V(m, t)$.

INPUT:

- m, t – integers
- V – the vector $V(m, t)$

See also

- *QDM_from_Vmt()*
- *OA_from_quasi_difference_matrix()*

EXAMPLES:

```
sage: _ = designs.orthogonal_arrays.build(6,46) # indirect doctest
```

```
>>> from sage.all import *
>>> _ = designs.orthogonal_arrays.build(Integer(6),Integer(46)) # indirect doctest
```

sage.combinat.designs.orthogonal_arrays.**OA_from_quasi_difference_matrix**(*M*, *G*, *add_col=True*, *fill_hole=True*)

Return an Orthogonal Array from a Quasi-Difference matrix.

Difference Matrices

Let G be a group of order g. A *difference matrix* M is a $g \times k$ matrix with entries from G such that for any $1 \leq i < j < k$ the set $\{d_{li} - d_{lj} : 1 \leq l \leq g\}$ is equal to G.

By concatenating the g matrices $M + x$ (where $x \in G$), one obtains a matrix of size $g^2 \times x$ which is also an $OA(k, g)$.

Quasi-difference Matrices

A quasi-difference matrix is a difference matrix with missing entries. The construction above can be applied again in this case, where the missing entries in each column of M are replaced by unique values on which G has a trivial action.

This produces an incomplete orthogonal array with a "hole" (i.e. missing rows) of size 'u' (i.e. the number of missing values per column of M). If there exists an $OA(k, u)$, then adding the rows of this $OA(k, u)$ to the incomplete orthogonal array should lead to an OA…

Formal definition (from the Handbook of Combinatorial Designs [DesignHandbook])

Let G be an abelian group of order n. A $(n, k; \lambda, \mu; u)$-quasi-difference matrix (QDM) is a matrix $Q = (q_{ij})$ with $\lambda(n-1+2u)+\mu$ rows and k columns, with each entry either empty or containing an element of G. Each column contains exactly λu entries, and each row contains at most one empty entry. Furthermore, for each $1 \leq i < j \leq k$ the multiset

$$\{q_{li} - q_{lj} : 1 \leq l \leq \lambda(n-1+2u)+\mu, \text{ with } q_{li} \text{ and } q_{lj} \text{ not empty}\}$$

contains every nonzero element of G exactly λ times, and contains 0 exactly μ times.

Construction

If a $(n, k; \lambda, \mu; u)$-QDM exists and $\mu \leq \lambda$, then an $ITD_\lambda(k, n+u; u)$ exists. Start with a $(n, k; \lambda, \mu; u)$-QDM A over the group G. Append $\lambda - \mu$ rows of zeroes. Then select u elements $\infty_1, \dots, \infty_u$ not in G, and replace the empty entries, each by one of these infinite symbols, so that ∞_i appears exactly once in each column. Develop the resulting matrix over the group G (leaving infinite symbols fixed), to obtain a $\lambda(n^2+2nu) \times k$ matrix T. Then T is an orthogonal array with k columns and index λ, having $n+u$ symbols and one hole of size u.

Adding to T an $OA(k, u)$ with elements $\infty_1, \dots, \infty_u$ yields the $ITD_\lambda(k, n+u; u)$.

For more information, see the Handbook of Combinatorial Designs [DesignHandbook] or http://web.cs.du.edu/~petr/milehigh/2013/Colbourn.pdf.

INPUT:

- `M` – the difference matrix whose entries belong to `G`
- `G` – a group
- `add_col` – boolean; whether to add a column to the final OA equal to $(x_1, \dots, x_g, x_1, \dots, x_g, \dots)$ where $G = \{x_1, \dots, x_g\}$
- `fill_hole` – boolean; whether to return the incomplete orthogonal array, or complete it with the $OA(k, u)$ (default). When `fill_hole is None`, no block of the incomplete OA contains more than one value $\geq |G|$.

EXAMPLES:

```
sage: _ = designs.orthogonal_arrays.build(6,20) # indirect doctest
```

```
>>> from sage.all import *
>>> _ = designs.orthogonal_arrays.build(Integer(6),Integer(20)) # indirect doctest
```

sage.combinat.designs.orthogonal_arrays.**OA_from_wider_OA**(*OA*, *k*)

Return the first k columns of OA.

If OA has k columns, this function returns OA immediately.

INPUT:

- `OA` – an orthogonal array
- `k` – integer

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import OA_from_wider_OA
sage: OA_from_wider_OA(designs.orthogonal_arrays.build(6,20,2),1)[:5]
[(19,), (19,), (19,), (19,), (19,)]
sage: _ = designs.orthogonal_arrays.build(5,46) # indirect doctest
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import OA_from_wider_OA
>>> OA_from_wider_OA(designs.orthogonal_arrays.build(Integer(6),Integer(20),
↪Integer(2)),Integer(1))[:Integer(5)]
[(19,), (19,), (19,), (19,), (19,)]
>>> _ = designs.orthogonal_arrays.build(Integer(5),Integer(46)) # indirect doctest
```

sage.combinat.designs.orthogonal_arrays.**OA_n_times_2_pow_c_from_matrix**(*k*, *c*, *G*, *A*, *Y*, *check=True*)

Return an $OA(k, |G| \cdot 2^c)$ from a constrained $(G, k-1, 2)$-difference matrix.

This construction appears in [AC1994] and [Ab1995].

Let G be an additive Abelian group. We denote by H a $GF(2)$-hyperplane in $GF(2^c)$.

Let A be a $(k-1) \times 2|G|$ array with entries in $G \times GF(2^c)$ and Y be a vector with $k-1$ entries in $GF(2^c)$. Let B and C be respectively the part of the array that belong to G and $GF(2^c)$.

The input A and Y must satisfy the following conditions. For any $i \neq j$ and $g \in G$:

- there are exactly two values of s such that $B_{i,s} - B_{j,s} = g$ (i.e. B is a $(G, k-1, 2)$-difference matrix),
- let s_1 and s_2 denote the two values of s given above, then exactly one of $C_{i,s_1} - C_{j,s_1}$ and $C_{i,s_2} - C_{j,s_2}$ belongs to the $GF(2)$-hyperplane $(Y_i - Y_j) \cdot H$ (we implicitly assumed that $Y_i \neq Y_j$).

Under these conditions, it is easy to check that the array whose $k-1$ rows of length $|G| \cdot 2^c$ indexed by $1 \leq i \leq k-1$ given by $A_{i,s} + (0, Y_i \cdot v)$ where $1 \leq s \leq 2|G|, v \in H$ is a $(G \times GF(2^c), k-1, 1)$-difference matrix.

INPUT:

- `k`, `c` – integers
- `G` – an additive Abelian group
- `A` – a matrix with entries in $G \times GF(2^c)$
- `Y` – a vector with entries in $GF(2^c)$
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.

Note

By convention, a multiplicative generator w of $GF(2^c)^*$ is fixed (inside the function). The hyperplane H is the one spanned by $w^0, w^1, \ldots, w^{c-1}$. The $GF(2^c)$ part of the input matrix A and vector Y are given in the following form: the integer i corresponds to the element w^i and `None` corresponds to 0.

```

sage.combinat.designs.orthogonal_arrays.**OA_relabel**(*OA*, *k*, *n*, *blocks=()*, *matrix=None*, *symbol_list=None*)

Return a relabelled version of the OA.

INPUT:

- `OA` – an OA, or rather a list of blocks of length k, each of which contains integers from 0 to $n-1$
- `k`, `n` – integers
- `blocks` – list of blocks; relabels the integers of the OA from $[0..n-1]$ into $[0..n-1]$ in such a way that the i blocks from `block` are respectively relabeled as `[n-i,...,n-i]`, ..., `[n-1,...,n-1]`. Thus, the blocks from this list are expected to have disjoint values for each coordinate.

  If set to the empty list (default) no such relabelling is performed.
- `matrix` – a matrix of dimensions k, n such that if the i th coordinate of a block is x, this x will be relabelled with `matrix[i][x]`. This is not necessarily an integer between 0 and $n-1$, and it is not necessarily an integer either. This is performed *after* the previous relabelling.

  If set to `None` (default) no such relabelling is performed.
- `symbol_list` – list of the desired symbols for the relabelled OA. If this is not `None`, the same relabelling

is done on all blocks such that the index of an element in symbol_list is its preimage in the relabelling map.

Note: A `None` coordinate in one block remains a `None` coordinate in the final block.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import OA_relabel
sage: OA = designs.orthogonal_arrays.build(3,2)
sage: OA_relabel(OA,3,2,matrix=[["A","B"],["C","D"],["E","F"]])
[['A', 'C', 'E'], ['A', 'D', 'F'], ['B', 'C', 'F'], ['B', 'D', 'E']]

sage: TD = OA_relabel(OA,3,2,matrix=[[0,1],[2,3],[4,5]]); TD
[[0, 2, 4], [0, 3, 5], [1, 2, 5], [1, 3, 4]]
sage: from sage.combinat.designs.orthogonal_arrays import is_transversal_design
sage: is_transversal_design(TD,3,2)
True

sage: OA = designs.orthogonal_arrays.build(3,2)
sage: OA_relabel(OA, 3, 2, symbol_list=['A', 'B'])
[['A', 'A', 'A'], ['A', 'B', 'B'], ['B', 'A', 'B'], ['B', 'B', 'A']]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import OA_relabel
>>> OA = designs.orthogonal_arrays.build(Integer(3),Integer(2))
>>> OA_relabel(OA,Integer(3),Integer(2),matrix=[["A","B"],["C","D"],["E","F"]])
[['A', 'C', 'E'], ['A', 'D', 'F'], ['B', 'C', 'F'], ['B', 'D', 'E']]

>>> TD = OA_relabel(OA,Integer(3),Integer(2),matrix=[[Integer(0),Integer(1)],
↪[Integer(2),Integer(3)],[Integer(4),Integer(5)]]); TD
[[0, 2, 4], [0, 3, 5], [1, 2, 5], [1, 3, 4]]
>>> from sage.combinat.designs.orthogonal_arrays import is_transversal_design
>>> is_transversal_design(TD,Integer(3),Integer(2))
True

>>> OA = designs.orthogonal_arrays.build(Integer(3),Integer(2))
>>> OA_relabel(OA, Integer(3), Integer(2), symbol_list=['A', 'B'])
[['A', 'A', 'A'], ['A', 'B', 'B'], ['B', 'A', 'B'], ['B', 'B', 'A']]
```

Making sure that `[2,2,2,2]` is a block of $OA(4, 3)$. We do this by relabelling block `[0,0,0,0]` which belongs to the design:

```
sage: designs.orthogonal_arrays.build(4,3)
[[0, 0, 0, 0], [0, 1, 2, 1], [0, 2, 1, 2], [1, 0, 2, 2], [1, 1, 1, 0], [1, 2, 0,␣
↪1], [2, 0, 1, 1], [2, 1, 0, 2], [2, 2, 2, 0]]
sage: OA_relabel(designs.orthogonal_arrays.build(4,3),4,3,blocks=[[0,0,0,0]])
[[2, 2, 2, 2], [2, 0, 1, 0], [2, 1, 0, 1], [0, 2, 1, 1], [0, 0, 0, 2], [0, 1, 2,␣
↪0], [1, 2, 0, 0], [1, 0, 2, 1], [1, 1, 1, 2]]
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.build(Integer(4),Integer(3))
```

(continues on next page)

(continued from previous page)

```
[[0, 0, 0, 0], [0, 1, 2, 1], [0, 2, 1, 2], [1, 0, 2, 2], [1, 1, 1, 0], [1, 2, 0,␣
↪1], [2, 0, 1, 1], [2, 1, 0, 2], [2, 2, 2, 0]]
>>> OA_relabel(designs.orthogonal_arrays.build(Integer(4),Integer(3)),Integer(4),
↪Integer(3),blocks=[[Integer(0),Integer(0),Integer(0),Integer(0)]])
[[2, 2, 2, 2], [2, 0, 1, 0], [2, 1, 0, 1], [0, 2, 1, 1], [0, 0, 0, 2], [0, 1, 2,␣
↪0], [1, 2, 0, 0], [1, 0, 2, 1], [1, 1, 1, 2]]
```

sage.combinat.designs.orthogonal_arrays.**OA_standard_label**(*OA*)

Return the inputted OA with entries relabelled as integers [0,…,n-1].

INPUT:

- `OA` – list of lists with symbols as entries that are not necessarily integers

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import OA_standard_label
sage: C = [['a', 'a', 'a', 'b'],
....:      ['a', 'a', 'b', 'a'],
....:      ['a', 'b', 'a', 'a'],
....:      ['b', 'a', 'a', 'a'],
....:      ['b', 'b', 'b', 'b']]
sage: OA_standard_label(C)
[[0, 0, 0, 1], [0, 0, 1, 0], [0, 1, 0, 0], [1, 0, 0, 0], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import OA_standard_label
>>> C = [['a', 'a', 'a', 'b'],
...      ['a', 'a', 'b', 'a'],
...      ['a', 'b', 'a', 'a'],
...      ['b', 'a', 'a', 'a'],
...      ['b', 'b', 'b', 'b']]
>>> OA_standard_label(C)
[[0, 0, 0, 1], [0, 0, 1, 0], [0, 1, 0, 0], [1, 0, 0, 0], [1, 1, 1, 1]]
```

sage.combinat.designs.orthogonal_arrays.**QDM_from_Vmt**(*m*, *t*, *V*)

Return a QDM from a $V(m,t)$.

Definition

Let q be a prime power and let $q = mt + 1$ for m, t integers. Let ω be a primitive element of $\mathbf{F}_q$. A $V(m,t)$ vector is a vector $(a_1, \dots, a_{m+1}$ for which, for each $1 \leq k < m$, the differences

$$\{a_{i+k} - a_i : 1 \leq i \leq m+1, i+k \neq m+2\}$$

represent the m cyclotomic classes of $\mathbf{F}_{mt+1}$ (compute subscripts modulo $m+2$). In other words, for fixed k, is $a_{i+k} - a_i = \omega^{mx+\alpha}$ and $a_{j+k} - a_j = \omega^{my+\beta}$ then $\alpha \not\equiv \beta \mod m$

Construction of a quasi-difference matrix from a `V(m,t)` vector

Starting with a $V(m,t)$ vector $(a_1, \dots, a_{m+1})$, form a single row of length $m+2$ whose first entry is empty, and whose remaining entries are $(a_1, \dots, a_{m+1})$. Form t rows by multiplying this row by the t th roots, i.e. the powers of ω^m. From each of these t rows, form $m+2$ rows by taking the $m+2$ cyclic shifts of the row. The result is a $(a, m+2; 1, 0; t) - QDM$.

For more information, refer to the Handbook of Combinatorial Designs [DesignHandbook].

INPUT:

- m, t – integers
- V – the vector $V(m, t)$

See also

OA_from_quasi_difference_matrix()

EXAMPLES:

```
sage: _ = designs.orthogonal_arrays.build(6,46) # indirect doctest
```

```
>>> from sage.all import *
>>> _ = designs.orthogonal_arrays.build(Integer(6),Integer(46)) # indirect doctest
```

sage.combinat.designs.orthogonal_arrays.**TD_product**(*k*, *TD1*, *n1*, *TD2*, *n2*, *check=True*)

Return the product of two transversal designs.

From a transversal design TD_1 of parameters k, n_1 and a transversal design TD_2 of parameters k, n_2, this function returns a transversal design of parameters k, n where $n = n_1 \times n_2$.

Formally, if the groups of TD_1 are $V^1_1, \dots, V^1_k$ and the groups of TD_2 are $V^2_1, \dots, V^2_k$, the groups of the product design are $V^1_1 \times V^2_1, \dots, V^1_k \times V^2_k$ and its blocks are the $\{(x^1_1, x^2_1), \dots, (x^1_k, x^2_k)\}$ where $\{x^1_1, \dots, x^1_k\}$ is a block of TD_1 and $\{x^2_1, \dots, x^2_k\}$ is a block of TD_2.

INPUT:

- TD1, TD2 – transversal designs
- k, n1, n2 – integers
- check – boolean (default: True); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.

Note

This function uses transversal designs with $V_1 = \{0, \dots, n-1\}, \dots, V_k = \{(k-1)n, \dots, kn-1\}$ both as input and output.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import TD_product
sage: TD1 = designs.transversal_design(6,7)
sage: TD2 = designs.transversal_design(6,12)
sage: TD6_84 = TD_product(6,TD1,7,TD2,12)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import TD_product
>>> TD1 = designs.transversal_design(Integer(6),Integer(7))
>>> TD2 = designs.transversal_design(Integer(6),Integer(12))
>>> TD6_84 = TD_product(Integer(6),TD1,Integer(7),TD2,Integer(12))
```

class sage.combinat.designs.orthogonal_arrays.**TransversalDesign**(*blocks*, *k=None*, *n=None*, *check=True*, ***kwds*)

Bases: *GroupDivisibleDesign*

Class for Transversal Designs.

INPUT:

- `blocks` – collection of blocks
- `k`, `n` – integers; parameters of the transversal design. They can be set to `None` (default) in which case their value is determined by the blocks.
- `check` – boolean (default: `True`); whether to check that the design is indeed a transversal design with the right parameters

EXAMPLES:

```
sage: designs.transversal_design(None,5)
Transversal Design TD(6,5)
sage: designs.transversal_design(None,30)
Transversal Design TD(6,30)
sage: designs.transversal_design(None,36)
Transversal Design TD(10,36)
```

```
>>> from sage.all import *
>>> designs.transversal_design(None,Integer(5))
Transversal Design TD(6,5)
>>> designs.transversal_design(None,Integer(30))
Transversal Design TD(6,30)
>>> designs.transversal_design(None,Integer(36))
Transversal Design TD(10,36)
```

`sage.combinat.designs.orthogonal_arrays.`**`incomplete_orthogonal_array`**`(`*k*, *n*, *holes*, *resolvable=False*, *existence=False*`)`

Return an $OA(k,n) - \sum_{1\leq i\leq x} OA(k,s_i)$.

An $OA(k,n) - \sum_{1\leq i\leq x} OA(k,s_i)$ is an orthogonal array from which have been removed disjoint $OA(k,s_1),...,OA(k,s_x)$. If there exist $OA(k,s_1),...,OA(k,s_x)$ they can be used to fill the holes and give rise to an $OA(k,n)$.

A very useful particular case (see e.g. the Wilson construction in `wilson_construction()`) is when all $s_i = 1$. In that case the incomplete design is a $OA(k,n) - x.OA(k,1)$. Such design is equivalent to transversal design $TD(k,n)$ from which has been removed x disjoint blocks.

INPUT:

- `k`, `n` – integers
- `holes` – list of integers respective sizes of the holes to be found
- `resolvable` – boolean (default: `False`); set to `True` if you want the design to be resolvable. The classes of the resolvable design are obtained as the first n blocks, then the next n blocks, etc.
- `existence` – boolean; instead of building the design, return:
  - `True` – meaning that Sage knows how to build the design
  - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`)
  - `False` – meaning that the design does not exist

Note

By convention, the ground set is always $V = \{0, ..., n-1\}$.

If all holes have size 1, in the incomplete orthogonal array returned by this function the holes are $\{n-1, ..., n-s_1\}^k$, $\{n-s_1-1, ..., n-s_1-s_2\}^k$, etc.

More generally, if `holes` is equal to $u1, ..., uk$, the i-th hole is the set of points $\{n-\sum_{j\geq i} u_j, ..., n-\sum_{j\geq i+1} u_j\}^k$.

EXAMPLES:

```
sage: IOA = designs.incomplete_orthogonal_array(3,3,[1,1,1])
sage: IOA
[[0, 1, 2], [0, 2, 1], [1, 0, 2], [1, 2, 0], [2, 0, 1], [2, 1, 0]]
sage: missing_blocks = [[0,0,0],[1,1,1],[2,2,2]]
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: is_orthogonal_array(IOA + missing_blocks,3,3,2)
True
```

```
>>> from sage.all import *
>>> IOA = designs.incomplete_orthogonal_array(Integer(3),Integer(3),[Integer(1),
↪Integer(1),Integer(1)])
>>> IOA
[[0, 1, 2], [0, 2, 1], [1, 0, 2], [1, 2, 0], [2, 0, 1], [2, 1, 0]]
>>> missing_blocks = [[Integer(0),Integer(0),Integer(0)],[Integer(1),Integer(1),
↪Integer(1)],[Integer(2),Integer(2),Integer(2)]]
>>> from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
>>> is_orthogonal_array(IOA + missing_blocks,Integer(3),Integer(3),Integer(2))
True
```

`sage.combinat.designs.orthogonal_arrays.`**`is_transversal_design`**(*B*, *k*, *n*, *verbose=False*)

Check that a given set of blocks `B` is a transversal design.

See *transversal_design()* for a definition.

INPUT:

- `B` – the list of blocks
- `k`, `n` – integers
- `verbose` – boolean; whether to display information about what is going wrong

Note

The transversal design must have $\{0, \ldots, kn-1\}$ as a ground set, partitioned as k sets of size n: $\{0, \ldots, k-1\} \sqcup \{k, \ldots, 2k-1\} \sqcup \cdots \sqcup \{k(n-1), \ldots, kn-1\}$.

EXAMPLES:

```
sage: TD = designs.transversal_design(5, 5, check=True) # indirect doctest
sage: from sage.combinat.designs.orthogonal_arrays import is_transversal_design
sage: is_transversal_design(TD, 5, 5)
True
sage: is_transversal_design(TD, 4, 4)
False
```

```
>>> from sage.all import *
>>> TD = designs.transversal_design(Integer(5), Integer(5), check=True) #␣
↪indirect doctest
>>> from sage.combinat.designs.orthogonal_arrays import is_transversal_design
>>> is_transversal_design(TD, Integer(5), Integer(5))
True
>>> is_transversal_design(TD, Integer(4), Integer(4))
False
```

sage.combinat.designs.orthogonal_arrays.**largest_available_k**(*n*, *t=2*)

Return the largest k such that Sage can build an $OA(k, n)$.

INPUT:

- n – integer
- t – integer (default: 2); strength of the array

EXAMPLES:

```
sage: designs.orthogonal_arrays.largest_available_k(0)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(1)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(10)
4
sage: designs.orthogonal_arrays.largest_available_k(27)
28
sage: designs.orthogonal_arrays.largest_available_k(100)
10
sage: designs.orthogonal_arrays.largest_available_k(-1)
Traceback (most recent call last):
...
ValueError: n(=-1) was expected to be >=0
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.largest_available_k(Integer(0))
+Infinity
>>> designs.orthogonal_arrays.largest_available_k(Integer(1))
+Infinity
>>> designs.orthogonal_arrays.largest_available_k(Integer(10))
4
>>> designs.orthogonal_arrays.largest_available_k(Integer(27))
28
>>> designs.orthogonal_arrays.largest_available_k(Integer(100))
10
```

(continues on next page)

(continued from previous page)

```
>>> designs.orthogonal_arrays.largest_available_k(-Integer(1))
Traceback (most recent call last):
...
ValueError: n(=-1) was expected to be >=0
```

sage.combinat.designs.orthogonal_arrays.**orthogonal_array**(*k*, *n*, *t=2*, *resolvable=False*, *check=True*, *existence=False*, *explain_construction=False*)

Return an orthogonal array of parameters k, n, t.

An orthogonal array of parameters k, n, t is a matrix with k columns filled with integers from $[n]$ in such a way that for any t columns, each of the n^t possible rows occurs exactly once. In particular, the matrix has n^t rows.

More general definitions sometimes involve a λ parameter, and we assume here that $\lambda = 1$.

An orthogonal array is said to be *resolvable* if it corresponds to a resolvable transversal design (see `sage.combinat.designs.incidence_structures.IncidenceStructure.is_resolvable()`).

For more information on orthogonal arrays, see Wikipedia article Orthogonal_array.

INPUT:

- `k` – integer; number of columns. If `k` is `None` it is set to the largest value available.
- `n` – integer; number of symbols
- `t` – integer (default: 2); strength of the array
- `resolvable` – boolean (default: `False`); set to `True` if you want the design to be resolvable. The n classes of the resolvable design are obtained as the first n blocks, then the next n blocks, etc.
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.
- `existence` – boolean; instead of building the design, return:
  - `True` – meaning that Sage knows how to build the design
  - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`)
  - `False` – meaning that the design does not exist

  Note

  When `k=None` and `existence=True` the function returns an integer, i.e. the largest k such that we can build a $OA(k, n)$.

- `explain_construction` – boolean; return a string describing the construction

OUTPUT: the kind of output depends on the input:

- if `existence=False` (the default) then the output is a list of lists that represent an orthogonal array with parameters `k` and `n`
- if `existence=True` and `k` is an integer, then the function returns a troolean: either `True`, `Unknown` or `False`
- if `existence=True` and `k=None` then the output is the largest value of `k` for which Sage knows how to compute a $TD(k, n)$.

Note

This method implements theorems from [Stinson2004]. See the code's documentation for details.

See also

When $t = 2$ an orthogonal array is also a transversal design (see *transversal_design()*) and a family of mutually orthogonal latin squares (see *mutually_orthogonal_latin_squares()*).

`sage.combinat.designs.orthogonal_arrays.`**`transversal_design`**(*k*, *n*, *resolvable=False*, *check=True*, *existence=False*)

Return a transversal design of parameters k, n.

A transversal design of parameters k, n is a collection $\mathcal{S}$ of subsets of $V = V_1 \cup \cdots \cup V_k$ (where the *groups* V_i are disjoint and have cardinality n) such that:

- Any $S \in \mathcal{S}$ has cardinality k and intersects each group on exactly one element.
- Any two elements from distincts groups are contained in exactly one element of $\mathcal{S}$.

More general definitions sometimes involve a λ parameter, and we assume here that $\lambda = 1$.

For more information on transversal designs, see http://mathworld.wolfram.com/TransversalDesign.html.

INPUT:

- `n`, `k` – integers; if `k is None` it is set to the largest value available
- `resolvable` – boolean; set to `True` if you want the design to be resolvable (see *sage.combinat.designs.incidence_structures.IncidenceStructure.is_resolvable()*). The n classes of the resolvable design are obtained as the first n blocks, then the next n blocks, etc … Set to `False` by default.
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.
- `existence` – boolean; instead of building the design, return:
  - `True` – meaning that Sage knows how to build the design
  - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`)
  - `False` – meaning that the design does not exist

Note

When `k=None` and `existence=True` the function returns an integer, i.e. the largest k such that we can build a $TD(k, n)$.

OUTPUT: the kind of output depends on the input:

- if `existence=False` (the default) then the output is a list of lists that represent a $TD(k, n)$ with $V_1 = \{0, \dots, n-1\}, \dots, V_k = \{(k-1)n, \dots, kn-1\}$
- if `existence=True` and `k` is an integer, then the function returns a troolean: either `True`, `Unknown` or `False`

- if `existence=True` and `k=None` then the output is the largest value of `k` for which Sage knows how to compute a $TD(k, n)$.

See also

`orthogonal_array()` – a transversal design $TD(k, n)$ is equivalent to an orthogonal array $OA(k, n, 2)$.

EXAMPLES:

```
sage: TD = designs.transversal_design(5,5); TD
Transversal Design TD(5,5)
sage: TD.blocks()
[[0, 5, 10, 15, 20], [0, 6, 12, 18, 24], [0, 7, 14, 16, 23],
 [0, 8, 11, 19, 22], [0, 9, 13, 17, 21], [1, 5, 14, 18, 22],
 [1, 6, 11, 16, 21], [1, 7, 13, 19, 20], [1, 8, 10, 17, 24],
 [1, 9, 12, 15, 23], [2, 5, 13, 16, 24], [2, 6, 10, 19, 23],
 [2, 7, 12, 17, 22], [2, 8, 14, 15, 21], [2, 9, 11, 18, 20],
 [3, 5, 12, 19, 21], [3, 6, 14, 17, 20], [3, 7, 11, 15, 24],
 [3, 8, 13, 18, 23], [3, 9, 10, 16, 22], [4, 5, 11, 17, 23],
 [4, 6, 13, 15, 22], [4, 7, 10, 18, 21], [4, 8, 12, 16, 20],
 [4, 9, 14, 19, 24]]
```

```
>>> from sage.all import *
>>> TD = designs.transversal_design(Integer(5),Integer(5)); TD
Transversal Design TD(5,5)
>>> TD.blocks()
[[0, 5, 10, 15, 20], [0, 6, 12, 18, 24], [0, 7, 14, 16, 23],
 [0, 8, 11, 19, 22], [0, 9, 13, 17, 21], [1, 5, 14, 18, 22],
 [1, 6, 11, 16, 21], [1, 7, 13, 19, 20], [1, 8, 10, 17, 24],
 [1, 9, 12, 15, 23], [2, 5, 13, 16, 24], [2, 6, 10, 19, 23],
 [2, 7, 12, 17, 22], [2, 8, 14, 15, 21], [2, 9, 11, 18, 20],
 [3, 5, 12, 19, 21], [3, 6, 14, 17, 20], [3, 7, 11, 15, 24],
 [3, 8, 13, 18, 23], [3, 9, 10, 16, 22], [4, 5, 11, 17, 23],
 [4, 6, 13, 15, 22], [4, 7, 10, 18, 21], [4, 8, 12, 16, 20],
 [4, 9, 14, 19, 24]]
```

Some examples of the maximal number of transversal Sage is able to build:

```
sage: TD_4_10 = designs.transversal_design(4,10)
sage: designs.transversal_design(5,10,existence=True)
Unknown
```

```
>>> from sage.all import *
>>> TD_4_10 = designs.transversal_design(Integer(4),Integer(10))
>>> designs.transversal_design(Integer(5),Integer(10),existence=True)
Unknown
```

For prime powers, there is an explicit construction which gives a $TD(n + 1, n)$:

```
sage: designs.transversal_design(4, 3, existence=True)
True
sage: designs.transversal_design(674, 673, existence=True)
True
```

```
>>> from sage.all import *
>>> designs.transversal_design(Integer(4), Integer(3), existence=True)
True
>>> designs.transversal_design(Integer(674), Integer(673), existence=True)
True
```

For other values of `n` it depends:

```
sage: designs.transversal_design(7, 6, existence=True)
False
sage: designs.transversal_design(4, 6, existence=True)
Unknown
sage: designs.transversal_design(3, 6, existence=True)
True

sage: designs.transversal_design(11, 10, existence=True)
False
sage: designs.transversal_design(4, 10, existence=True)
True
sage: designs.transversal_design(5, 10, existence=True)
Unknown

sage: designs.transversal_design(7, 20, existence=True)
Unknown
sage: designs.transversal_design(6, 12, existence=True)
True
sage: designs.transversal_design(7, 12, existence=True)
True
sage: designs.transversal_design(8, 12, existence=True)
Unknown

sage: designs.transversal_design(6, 20, existence = True)
True
sage: designs.transversal_design(7, 20, existence = True)
Unknown
```

```
>>> from sage.all import *
>>> designs.transversal_design(Integer(7), Integer(6), existence=True)
False
>>> designs.transversal_design(Integer(4), Integer(6), existence=True)
Unknown
>>> designs.transversal_design(Integer(3), Integer(6), existence=True)
True

>>> designs.transversal_design(Integer(11), Integer(10), existence=True)
False
>>> designs.transversal_design(Integer(4), Integer(10), existence=True)
True
>>> designs.transversal_design(Integer(5), Integer(10), existence=True)
Unknown

>>> designs.transversal_design(Integer(7), Integer(20), existence=True)
Unknown
```

(continues on next page)

(continued from previous page)

```
>>> designs.transversal_design(Integer(6), Integer(12), existence=True)
True
>>> designs.transversal_design(Integer(7), Integer(12), existence=True)
True
>>> designs.transversal_design(Integer(8), Integer(12), existence=True)
Unknown

>>> designs.transversal_design(Integer(6), Integer(20), existence = True)
True
>>> designs.transversal_design(Integer(7), Integer(20), existence = True)
Unknown
```

If you ask for a transversal design that Sage is not able to build then an `EmptySetError` or a `NotImplementedError` is raised:

```
sage: designs.transversal_design(47, 100)
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build a TD(47,100)!
sage: designs.transversal_design(55, 54)
Traceback (most recent call last):
...
EmptySetError: There exists no TD(55,54)!
```

```
>>> from sage.all import *
>>> designs.transversal_design(Integer(47), Integer(100))
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build a TD(47,100)!
>>> designs.transversal_design(Integer(55), Integer(54))
Traceback (most recent call last):
...
EmptySetError: There exists no TD(55,54)!
```

Those two errors correspond respectively to the cases where Sage answer `Unknown` or `False` when the parameter `existence` is set to `True`:

```
sage: designs.transversal_design(47, 100, existence=True)
Unknown
sage: designs.transversal_design(55, 54, existence=True)
False
```

```
>>> from sage.all import *
>>> designs.transversal_design(Integer(47), Integer(100), existence=True)
Unknown
>>> designs.transversal_design(Integer(55), Integer(54), existence=True)
False
```

If for a given n you want to know the largest k for which Sage is able to build a $TD(k, n)$ just call the function with k set to `None` and `existence` set to `True` as follows:

```
sage: designs.transversal_design(None, 6, existence=True)
3
sage: designs.transversal_design(None, 20, existence=True)
6
sage: designs.transversal_design(None, 30, existence=True)
6
sage: designs.transversal_design(None, 120, existence=True)
9
```

```
>>> from sage.all import *
>>> designs.transversal_design(None, Integer(6), existence=True)
3
>>> designs.transversal_design(None, Integer(20), existence=True)
6
>>> designs.transversal_design(None, Integer(30), existence=True)
6
>>> designs.transversal_design(None, Integer(120), existence=True)
9
```

sage.combinat.designs.orthogonal_arrays.**wilson_construction**(*OA*, *k*, *r*, *m*, *u*, *check=True*, *explain_construction=False*)

Return a $OA(k, rm + \sum_i u_i)$ from a truncated $OA(k + s, r)$ by Wilson's construction.

Simple form:

Let OA be a truncated $OA(k + s, r)$ with s truncated columns of sizes $u_1, ..., u_s$, whose blocks have sizes in $\{k + b_1, ..., k + b_t\}$. If there exist:

- An $OA(k, m + b_i) - b_i.OA(k, 1)$ for every $1 \leq i \leq t$
- An $OA(k, u_i)$ for every $1 \leq i \leq s$

Then there exists an $OA(k, rm + \sum u_i)$. The construction is a generalization of Lemma 3.16 in [HananiBIBD].

Brouwer-Van Rees form:

Let OA be a truncated $OA(k + s, r)$ with s truncated columns of sizes $u_1, ..., u_s$. Let the set H_i of the u_i points of column $k + i$ be partitionned into $\sum_j H_{ij}$. Let m_{ij} be integers such that:

- For $0 \leq i < l$ there exists an $OA(k, \sum_j m_{ij}|H_{ij}|)$
- For any block $B \in OA$ intersecting the sets $H_{ij(i)}$ there exists an $OA(k, m + \sum_i m_{ij}) - \sum_i OA(k, m_{ij(j)})$.

Then there exists an $OA(k, rm + \sum_{i,j} m_{ij})$. This construction appears in [BvR1982].

INPUT:

- `OA` – an incomplete orthogonal array with $k + s$ columns. The elements of a column of size c must belong to $\{0, ..., c\}$. The missing entries of a block are represented by `None` values. If `OA=None`, it is defined as a truncated orthogonal arrays with $k + s$ columns.
- `k`, `r`, `m` – integers
- `u` – list; two cases depending on the form to use:
  - Simple form: a list of length s such that column `k+i` has size `u[i]`. The untruncated points of column `k+i` are assumed to be `[0,...,u[i]-1]`.
  - Brouwer-Van Rees form: a list of length s such that `u[i]` is the list of pairs $(m_{i0}, |H_{i0}|), ..., (m_{ip_i}, |H_{ip_i}|)$. The untruncated points of column `k+i` are assumed to be $[0, ..., u_i - 1]$

where $u_i = \sum_j |H_{ip_i}|$. Besides, the first $|H_{i0}|$ points represent H_{i0}, the next $|H_{i1}|$ points represent H_{i1}, etc...

- `explain_construction` – boolean; return a string describing the construction
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.

↪Integer(5))]])
>>> is_orthogonal_array(OAb,Integer(5),Integer(256))
True
```

5.1.92 Orthogonal arrays (build recursive constructions)

This module implements several constructions of *Orthogonal Arrays*. As their input can be complex, they all have a counterpart in the *orthogonal_arrays_find_recursive* module that automatically computes it.

All these constructions are automatically queried when the *orthogonal_array()* function is called.

construction_3_3()	Return an $OA(k, nm + i)$.
construction_3_4()	Return a $OA(k, nm + rs)$.
construction_3_5()	Return an $OA(k, nm + r + s + t)$.
construction_3_6()	Return a $OA(k, nm + i)$.
construction_q_x()	Return an $OA(k, (q-1) * (q-x) + x + 2)$ using the $q - x$ construction.
OA_and_oval()	Return a $OA(q + 1, q)$ whose blocks contains ≤ 2 zeroes in the last q columns.
thwart_lemma_3_5()	Return an $OA(k, nm + a + b + c + d)$.
thwart_lemma_4_1()	Return an $OA(k, nm + 4(n - 2))$.
three_factor_product()	Return an $OA(k + 1, n_1 n_2 n_3)$.
brouwer_separable_design()	Return a $OA(k, t(q^2 + q + 1) + x)$ using Brouwer's result on separable designs.

Functions

sage.combinat.designs.orthogonal_arrays_build_recursive.**OA_and_oval**(*q*, *solver*, *integrality_tolerance*)

Return a $OA(q+1,q)$ whose blocks contains ≤ 2 zeroes in the last q columns.

This OA is build from a projective plane of order q, in which there exists an oval O of size $q+1$ (i.e. a set of $q+1$ points no three of which are [colinear/contained in a common set of the projective plane]).

Removing an element $x\in O$ and all sets that contain it, we obtain a $TD(q+1,q)$ in which O intersects all columns except one. As O is an oval, no block of the TD intersects it more than twice.

INPUT:

- `q` – a prime power
- `solver` – (default: `None`) specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`

Note: This function is called by *construction_3_6()*, an implementation of Construction 3.6 from [AC07].

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_build_recursive import OA_and_
↪oval
sage: _ = OA_and_oval
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_build_recursive import OA_and_
↪oval
>>> _ = OA_and_oval
```

sage.combinat.designs.orthogonal_arrays_build_recursive.**brouwer_separable_design**(*k*, *t*, *q*, *x*, *check=False*, *verbose=False*, *explain_construction=False*)

Return a $OA(k,t(q^2+q+1)+x)$ using Brouwer's result on separable designs.

This method is an implementation of Brouwer's construction presented in [Brouwer80]. It consists in a systematic application of the usual transformation from PBD to OA, applied to a specific PBD.

Baer subplanes

When q is a prime power, the projective plane $PG(2,q^2)$ can be partitionned into subplanes $PG(2,q)$ (called Baer subplanes), giving $PG(2,q^2)=B_1\cup\cdots\cup B_{q^2-q+1}$. As a result, every line of the $PG(2,q^2)$ intersects one of the subplane on $q+1$ points and all others on 1 point.

The OA are built by considering $B_1 \cup \dots \cup B_t$, for a total of $t(q^2+q+1)$ points (to which x new points are then added). The blocks of this subdesign belong to two categories:

- The blocks of size t: they come from the lines which intersect a B_i on $q+1$ points for some $i > t$. The blocks of size t can be partitionned into $q^2-q+t-1$ parallel classes according to their associated subplane B_i with $i > t$.
- The blocks of size $q+t$: those blocks form a symmetric design, as every point is incident with $q+t$ of them.

Constructions

In the following, we write $N = t(q^2+q+1)+x$. The code is also heavily commented, and will clear any doubt.

- i) $x = 0$: in that case we build a resolvable $OA(k-1, N)$ that will then be completed into an $OA(k, N)$.
  - *Sets of size* t)

    We take the product of each parallel class with the parallel classes of a resolvable $OA(k-1,t) - t.OA(k-1,t)$, yielding new parallel classes.
  - *Sets of size* $q+t$)

    A $N \times (q+t)$ array is built whose rows are the sets of size $q+t$ such that every value appears once per column. For each block of a $OA(k-1, q+t) - (q+t).OA(k-1,t)$, the product with the rows of the matrix yields a parallel class.
- ii) $x = q + t$
  - *Sets of size* t)

    Each set of size t gives a $OA(k,t) - t.OA(k,1)$, except if there is only one parallel class in which case a $OA(k,t)$ is sufficient.
  - *Sets of size* $q+t$)

    A $(N-x) \times (q+t)$ array M is built whose $N-x$ rows are the sets of size $q+t$ such that every value appears once per column. For each of the new $x = q+t$ points $p_1, \dots, p_{q+t}$ we build a matrix M_i obtained from M by adding a column equal to $(p_i, p_i, p_i \dots)$. We add to the OA the product of all rows of the M_i with the block of the $x = q+t$ parallel classes of a resolvable $OA(k, t+q+1) - (t+q+1).OA(k,1)$.
  - *Set of size* x) An $OA(k,x)$
- iii) $x = q^2 - q + 1 - t$
  - *Sets of size* t)

    All blocks of the i-th parallel class are extended with the i-th new point. The blocks are then replaced by a $OA(k,t+1) - (t+1).OA(k,1)$ or, if there is only one parallel class (i.e. $x=1$) by a $OA(k,t+1) - OA(k,1)$.
  - *Set of size* $q+t$)

    They are replaced by $OA(k, q+t) - (q+t).OA(k,1)$.
  - *Set of size* x) An $OA(k,x)$
- iv) $x = q^2 + 1$
  - *Sets of size* t)

All blocks of the i-th parallel class are extended with the i-th new point (the other $x - q - t$ new points are not touched at this step). The blocks are then replaced by a $OA(k, t + 1) - (t + 1).OA(k, 1)$ or, if there is only one parallel class (i.e. $x = 1$) by a $OA(k, t + 1) - OA(k, 1)$.

- *Sets of size* $q + t$) Same as for ii)
- *Set of size* x) An $OA(k, x)$

- v) $0 < x < q^2 - q + 1 - t$
  - *Sets of size* t)

    The blocks of the first x parallel class are extended with the x new points, and replaced with $OA(k.t + 1) - (t + 1).OA(k, 1)$ or, if $x = 1$, by $OA(k.t + 1) - .OA(k, 1)$

    The blocks of the other parallel classes are replaced by $OA(k, t) - t.OA(k, t)$ or, if there is only one class left, by $OA(k, t) - OA(k, t)$
  - *Sets of size* $q + t$)

    They are replaced with $OA(k, q + t) - (q + t).OA(k, 1)$.
  - *Set of size* x) An $OA(k, x)$

- vi) $t + q < x < q^2 + 1$
  - *Sets of size* t) Same as in v) with an x equal to $x - q + t$.
  - *Sets of size* t) Same as in vii)
  - *Set of size* x) An $OA(k, x)$

INPUT:

- `k`, `t`, `q`, `x` – integers
- `check` – boolean (default: `False`); whether to check that output is correct before returning it
- `verbose` – boolean; whether to print some information on the construction and parameters being used
- `explain_construction` – boolean; return a string describing the construction

sage.combinat.designs.orthogonal_arrays_build_recursive.**construction_3_3**(*k*, *n*, *m*, *i*, *explain_construction=False*)

Return an $OA(k, nm + i)$.

This is Wilson's construction with i truncated columns of size 1 and such that a block B_0 of the incomplete OA intersects all truncated columns. As a consequence, all other blocks intersect only 0 or 1 of the last i columns. This allow to consider the block B_0 only up to its first k coordinates and then use a $OA(k, i)$ instead of a $OA(k, m + i) - i.OA(k, 1)$.

This is construction 3.3 from [AC07].

INPUT:

- `k, n, m, i` – integers such that the following designs are available: $OA(k, n)$, $OA(k, m)$, $OA(k, m + 1)$, $OA(k, r)$
- `explain_construction` – boolean; return a string describing the construction

```

sage.combinat.designs.orthogonal_arrays_build_recursive.**construction_3_4**(*k*, *n*, *m*, *r*, *s*, *explain_construction=False*)

Return a $OA(k, nm + rs)$.

This is Wilson's construction applied to a truncated $OA(k + r + 1, n)$ with r columns of size 1 and one column of size s.

The unique elements of the r truncated columns are picked so that a block B_0 contains them all.

- If there exists an $OA(k, m + r + 1)$ the column of size s is truncated in order to intersect B_0.
- Otherwise, if there exists an $OA(k, m + r)$, the last column must not intersect B_0

This is construction 3.4 from [AC07].

INPUT:

- k, n, m, r, s – integers; we assume that $s < n$ and $1 \leq r, s$

  The following designs must be available: $OA(k, n)$, $OA(k, m)$, $OA(k, m + 1)$, $OA(k, m + 2)$, $OA(k, s)$. Additionally, it requires either a $OA(k, m + r)$ or a $OA(k, m + r + 1)$.

- explain_construction – boolean; return a string describing the construction

```

sage.combinat.designs.orthogonal_arrays_build_recursive.**construction_3_5**(*k*, *n*, *m*, *r*, *s*, *t*, *explain_construction=False*)

Return an $OA(k, nm + r + s + t)$.

This is exactly Wilson's construction with three truncated groups except we make sure that all blocks have size $> k$, so we don't need a $OA(k, m + 0)$ but only $OA(k, m + 1)$, $OA(k, m + 2)$,`OA(k,m+3)`.

This is construction 3.5 from [AC07].

INPUT:

- `k`, `n`, `m` – integers
- `r`, `s`, `t` – integers; sizes of the three truncated groups, such that $r \leq s$ and $(q - r - 1)(q - s) \geq (q - s - 1) * (q - r)$
- `explain_construction` – boolean; return a string describing the construction

The following designs must be available : $OA(k, n)$, $OA(k, r)$, $OA(k, s)$, $OA(k, t)$, $OA(k, m+1)$, $OA(k, m+2)$, $OA(k, m + 3)$.

   Journal of Combinatorial Designs, 2007
```

sage.combinat.designs.orthogonal_arrays_build_recursive.**construction_q_x**(*k*, *q*, *x*, *check=True*, *explain_construction=False*)

Return an $OA(k,(q-1)*(q-x)+x+2)$ using the $q-x$ construction.

Let $v=(q-1)*(q-x)+x+2$. If there exists a projective plane of order q (e.g. when q is a prime power) and $0<x<q$ then there exists a $(v-1,\{q-x-1,q-x+1\})$-GDD of type $(q-1)^{q-x}(x+1)^1$ (see [Greig99] or Theorem 2.50, section IV.2.3 of [DesignHandbook]). By adding to the ground set one point contained in all groups of the GDD, one obtains a $(v,\{q-x-1,q-x+1,q,x+2\})$-PBD with exactly one set of size $x+2$.

Thus, assuming that we have the following:

- $OA(k,q-x-1)-(q-x-1).OA(k,1)$
- $OA(k,q-x+1)-(q-x+1).OA(k,1)$
- $OA(k,q)-q.OA(k,1)$
- $OA(k,x+2)$

Then we can build from the PBD an $OA(k,v)$.

Construction of the PBD (shared by Julian R. Abel):

> Start with a resolvable $(q^2,q,1)$-BIBD and put the points into a $q\times q$ array so that rows form a parallel class and columns form another.
>
> Now delete:
>
> - All $x(q-1)$ points from the first x columns and not in the first row
> - All $q-x$ points in the last $q-x$ columns AND the first row.
>
> Then add a point p_1 to the blocks that are rows. Add a second point p_2 to the $q-x$ blocks that are columns of size $q-1$, plus the first row of size $x+1$.

INPUT:

- `k`, `q`, `x` – integers such that $0<x<q$ and such that Sage can build:
  - A projective plane of order q
  - $OA(k,q-x-1)-(q-x-1).OA(k,1)$
  - $OA(k,q-x+1)-(q-x+1).OA(k,1)$
  - $OA(k,q)-q.OA(k,1)$

- $OA(k, x+2)$

- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.
- `explain_construction` – boolean; return a string describing the construction

REFERENCES:

`sage.combinat.designs.orthogonal_arrays_build_recursive.`**`three_factor_product`**(*k*, *n1*, *n2*, *n3*, *check=False*, *explain_construction=False*)

Return an $OA(k+1, n_1 n_2 n_3)$.

The three factor product construction from [DukesLing14] does the following:

> If $n_1 \leq n_2 \leq n_3$ are such that there exists an $OA(k, n_1)$, $OA(k+1, n_2)$ and $OA(k+1, n_3)$, then there exists a $OA(k+1, n_1n_2n_3)$.

It works with a modified product of orthogonal arrays ([Rees93], [Rees00]) which keeps track of parallel classes in the OA (the definition is given for transversal designs).

> A subset of blocks in an $TD(k, n)$ is called a c-parallel class if every point is covered exactly c times. A 1-parallel class is a parallel class.

The modified product:

> If there exists an $OA(k, n_1)$, and if there exists an $OA(k, n_2)$ whose blocks are partitionned into s n_1-parallel classes and $n_2 - sn_1$ parallel classes, then there exists an $OA(k, n_1n_2)$ whose blocks can be partitionned into sn_1^2 parallel classes and $(n_1n_2 - sn_1^2)/n_1 = n_2 - sn_1$ n_1-parallel classes.
>
> Proof:
>
> - The product of the blocks of a parallel class with an $OA(k, n_1)$ yields an n_1-parallel class of an $OA(k, n_1n_2)$.
> - The product of the blocks of a n_1-parallel class of $OA(k, n_2)$ with an $OA(k, n_1)$ can be done in such a way that it yields n_1n_2 parallel classes of $OA(k, n_1n_2)$. Those classes cover exactly the pairs that would have been covered with the usual product.
>
>   This can be achieved by simple cyclic permutations. Let us build the product of the n_1-parallel class $\mathcal{P} \subseteq OA(k, n_2)$ with $OA(k, n_1)$: when computing the product of $P \in \mathcal{P}$ with $B^1 \in OA(k, n_1)$ the i-th coordinate should not be (B_i^1, P_i) but $(B_i^1 + r, P_i)$ (the sum is mod n_1) where r is the number of blocks of $\mathcal{P}$ we have already processed whose i-th coordinate is equal to P_i (note that $r < n_1$ as $\mathcal{P}$ is n_1-parallel).

With these tools, one can obtain the designs promised by the three factors construction applied to k, n_1, n_2, n_3 (thanks to Julian R. Abel's help):

1) Let s be the largest integer $\leq n_3/n_1$. Apply the product construction to $OA(k, n_1)$ and a resolvable $OA(k, n_3)$ whose blocks are partitionned into s n_1-parallel classes and $n_3 - sn_1$ parallel classes. It results in a $OA(k, n_1n_3)$ partitionned into sn_1^2 parallel classes plus $(n_1n_3 - sn_1^2)/n_1 = n_3 - sn_1$ n_1-parallel classes.
2) Add $n_3 - n_1$ parallel classes to every n_1-parallel class to turn them into n_3-parallel classes. Apply the product construction to this partitionned $OA(k, n_1n_3)$ with a resolvable $OA(k, n_2)$.
3) As $OA(k, n_2)$ is resolvable, the n_2-parallel classes of $OA(k, n_1n_2n_3)$ are actually the union of n_2 parallel classes, thus the $OA(k, n_1n_2n_3)$ is resolvable and can be turned into an $OA(k+1, n_1n_2n_3)$

INPUT:

- `k`, `n1`, `n2`, `n3` – integers
- `check` – boolean; whether to check that everything is going smoothly while the design is being built. It is disabled by default, as the constructor of orthogonal arrays checks the final design anyway.
- `explain_construction` – boolean; return a string describing the construction

sage.combinat.designs.orthogonal_arrays_build_recursive.**thwart_lemma_3_5**(*k*, *n*, *m*, *a*, *b*, *c*, *d=0*, *complement=False*, *explain_construction=False*)

Return an $OA(k, nm + a + b + c + d)$.

(When `d=0`)

According to [Thwarts] when n is a prime power and $a + b + c \leq n + 1$, one can build an $OA(k + 3, n)$ with three truncated columns of sizes a, b, c in such a way that all blocks have size $\leq k + 2$.

(in order to build a $OA(k, nm + a + b + c)$ the following designs must also exist: $OA(k, a)$, $OA(k, b)$, $OA(k, c)$, $OA(k, m + 0)$, $OA(k, m + 1)$, $OA(k, m + 2)$)

Considering the complement of each truncated column, it is also possible to build an $OA(k + 3, n)$ with three truncated columns of sizes a, b, c in such a way that all blocks have size $> k$ whenever $(n-a)+(n-b)+(n-c) \leq n + 1$.

(in order to build a $OA(k, nm + a + b + c)$ the following designs must also exist: $OA(k, a)$, $OA(k, b)$, $OA(k, c)$, $OA(k, m + 1)$, $OA(k, m + 2)$, $OA(k, m + 3)$)

Here is the proof of Lemma 3.5 from [Thwarts] enriched with explanations from Julian R. Abel:

> For any prime power n one can build $k - 1$ MOLS by associating to every nonzero $x \in \mathbb{F}_n$ the latin square:
>
> $$M_x(i, j) = i + x * j \text{ where } i, j \in \mathbb{F}_n$$
>
> In particular $M_1(i, j) = i + j$, whose n columns and lines are indexed by the elements of $\mathbb{F}_n$. If we order the elements of $\mathbb{F}_n$ as $0, 1, ..., n-1, x+0, ..., x+n-1, x^2+0, ...$ and reorder the columns and lines of M_1 accordingly, the top-left $a \times b$ squares contains at most $a + b - 1$ distinct symbols.

(When $d \neq 0$)

If there exists an $OA(k + 3, n)$ with three truncated columns of sizes a, b, c in such a way that all blocks have size $\leq k + 2$, by truncating arbitrarily another column to size d one obtains an OA with 4 truncated columns whose blocks miss at least one value. Thus, following the proof again one can build an $OA(k + 4)$ with four truncated columns of sizes a, b, c, d with blocks of size $\leq k + 3$.

(in order to build a $OA(k, nm + a + b + c + d)$ the following designs must also exist: $OA(k, a)$, $OA(k, b)$, $OA(k, c)$, $OA(k, d)$, $OA(k, m + 0)$, $OA(k, m + 1)$, $OA(k, m + 2)$, $OA(k, m + 3)$)

As before, this also shows that one can build an $OA(k + 4, n)$ with four truncated columns of sizes a, b, c, d in such a way that all blocks have size $> k$ whenever $(n - a) + (n - b) + (n - c) \leq n + 1$

(in order to build a $OA(k, nm+a+b+c+d)$ the following designs must also exist: $OA(k, n-a)$, $OA(k, n-b)$, $OA(k, n - c)$, $OA(k, d)$, $OA(k, m + 1)$, $OA(k, m + 2)$, $OA(k, m + 3)$, $OA(k, m + 4)$)

INPUT:

- `k`, `n`, `m`, `a`, `b`, `c`, `d` – integers which must satisfy the constraints above. In particular, $a + b + c \leq n + 1$ must hold By default, $d = 0$.
- `complement` – boolean; whether to complement the sets, i.e. follow the $n - a, n - b, n - c$ variant described above
- `explain_construction` – boolean; return a string describing the construction

5.1.93 Orthogonal arrays (find recursive constructions)

This module implements several functions to find recursive constructions of *Orthogonal Arrays*.

The main function of this module, i.e. *find_recursive_construction()*, queries all implemented recursive constructions of designs implemented in *orthogonal_arrays_build_recursive* in order to obtain an $OA(k, n)$.

find_recursive_construction() is called by the *orthogonal_array()* function.

find_recursive_construction()	Find a recursive construction of an $OA(k, n)$ (calls all others `find_*` functions)
find_product_decomposition()	Find $n_1 n_2 = n$ to obtain an $OA(k, n)$ by the product construction
find_wilson_decomposition_with_one_truncated_group()	Find $rm + u = n$ to obtain an $OA(k, n)$ by Wilson's construction with one truncated column.
find_wilson_decomposition_with_two_truncated_groups()	Find $rm + r_1 + r_2 = n$ to obtain an $OA(k, n)$ by Wilson's construction with two truncated columns.
find_construction_3_3()	Find a decomposition for construction 3.3 from [AC07].
find_construction_3_4()	Find a decomposition for construction 3.4 from [AC07].
find_construction_3_5()	Find a decomposition for construction 3.5 from [AC07].
find_construction_3_6()	Find a decomposition for construction 3.6 from [AC07].
find_q_x()	Find integers q, x such that the $q - x$ construction yields an $OA(k, n)$.
find_thwart_lemma_3_5()	Find the values on which Lemma 3.5 from [Thwarts] applies.
find_thwart_lemma_4_1()	Find a decomposition for Lemma 4.1 from [Thwarts].
find_three_factor_product()	Find $n_1 n_2 n_3 = n$ to obtain an $OA(k, n)$ by the three-factor product from [DukesLing14]
find_brouwer_separable_design()	Find $t(q^2 + q + 1) + x = n$ to obtain an $OA(k, n)$ by Brouwer's separable design construction.
find_brouwer_van_rees_with_one_truncated_column()	Find $rm + x_1 + ... + x_c = n$ such that the Brouwer-van Rees constructions yields a $OA(k, n)$.

REFERENCES:

Functions

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_brouwer_separable_design**(*k*, *n*)

Find $t(q^2 + q + 1) + x = n$ to obtain an $OA(k, n)$ by Brouwer's separable design construction.

INPUT:

- `k`, `n` – integers

The assumptions made on the parameters t, q, x are explained in the documentation of *brouwer_separable_design()*.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪brouwer_separable_design
sage: find_brouwer_separable_design(5,13)[1]
(5, 1, 3, 0)
sage: find_brouwer_separable_design(5,14)
False
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪brouwer_separable_design
>>> find_brouwer_separable_design(Integer(5),Integer(13))[Integer(1)]
(5, 1, 3, 0)
```

(continues on next page)

(continued from previous page)

```
>>> find_brouwer_separable_design(Integer(5),Integer(14))
False
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_brouwer_van_rees_with_one_truncated_colu**

Find $rm + x_1 + ... + x_c = n$ such that the Brouwer-van Rees constructions yields a $OA(k, n)$.

Let $n = rm + \sum_{1 \leq i \leq c}$ such that $c \leq r$. The generalization of Wilson's construction found by Brouwer and van Rees (with one truncated column) ensures that an $OA(k, n)$ exists if the following designs exist: $OA(k+1, r)$, $OA(k, m)$, $OA(k, \sum_{1 \leq i \leq c} u_i)$, $OA(k, m+x_1) - OA(k, x_1)$, ..., $OA(k, m+x_c) - OA(k, x_c)$.

For more information, see the documentation of `wilson_construction()`.

INPUT:

- `k`, `n` – integers

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪brouwer_van_rees_with_one_truncated_column
sage: find_brouwer_van_rees_with_one_truncated_column(5,53)[1]
(None, 5, 7, 7, [[(2, 1), (2, 1)]])
sage: find_brouwer_van_rees_with_one_truncated_column(6,96)[1]
(None, 6, 7, 13, [[(3, 1), (1, 1), (1, 1)]])
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪brouwer_van_rees_with_one_truncated_column
>>> find_brouwer_van_rees_with_one_truncated_column(Integer(5),
↪Integer(53))[Integer(1)]
(None, 5, 7, 7, [[(2, 1), (2, 1)]])
>>> find_brouwer_van_rees_with_one_truncated_column(Integer(6),
↪Integer(96))[Integer(1)]
(None, 6, 7, 13, [[(3, 1), (1, 1), (1, 1)]])
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_construction_3_3**(*k*, *n*)

Find a decomposition for construction 3.3 from [AC07].

INPUT:

- `k`, `n` – integers

See also

`construction_3_3()`

OUTPUT:

A pair `f,args` such that `f(*args)` returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_3
```

(continues on next page)

(continued from previous page)

```
sage: find_construction_3_3(11,177)[1]
(11, 11, 16, 1)
sage: find_construction_3_3(12,11)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_3
>>> find_construction_3_3(Integer(11),Integer(177))[Integer(1)]
(11, 11, 16, 1)
>>> find_construction_3_3(Integer(12),Integer(11))
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_construction_3_4**(k, n)

Find a decomposition for construction 3.4 from [AC07].

INPUT:

- k, n – integers

See also

construction_3_4()

OUTPUT:

A pair f,args such that f(*args) returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_4
sage: find_construction_3_4(8,196)[1]
(8, 25, 7, 12, 9)
sage: find_construction_3_4(9,24)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_4
>>> find_construction_3_4(Integer(8),Integer(196))[Integer(1)]
(8, 25, 7, 12, 9)
>>> find_construction_3_4(Integer(9),Integer(24))
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_construction_3_5**(k, n)

Find a decomposition for construction 3.5 from [AC07].

INPUT:

- k, n – integers

See also

construction_3_5()

OUTPUT:

A pair `f,args` such that `f(*args)` returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_5
sage: find_construction_3_5(8,111)[1]
(8, 13, 6, 9, 11, 13)
sage: find_construction_3_5(9,24)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_5
>>> find_construction_3_5(Integer(8),Integer(111))[Integer(1)]
(8, 13, 6, 9, 11, 13)
>>> find_construction_3_5(Integer(9),Integer(24))
```

`sage.combinat.designs.orthogonal_arrays_find_recursive.`**`find_construction_3_6`**`(k, n)`

Find a decomposition for construction 3.6 from [AC07].

INPUT:

- `k`, `n` – integers

See also

`construction_3_6()`

OUTPUT:

A pair `f,args` such that `f(*args)` returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_6
sage: find_construction_3_6(8,95)[1]
(8, 13, 7, 4)
sage: find_construction_3_6(8,98)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_6
>>> find_construction_3_6(Integer(8),Integer(95))[Integer(1)]
(8, 13, 7, 4)
>>> find_construction_3_6(Integer(8),Integer(98))
```

`sage.combinat.designs.orthogonal_arrays_find_recursive.`**`find_product_decomposition`**`(k, n)`

Find $n_1 n_2 = n$ to obtain an $OA(k, n)$ by the product construction.

If Sage can build a $OA(k, n_1)$ and a $OA(k, n_2)$ such that $n = n_1 \times n_2$ then a $OA(k, n)$ can be built by a product construction (which correspond to Wilson's construction with no truncated column). This function look for a pair of integers (n_1, n_2) with $n1 \leq n_2, n_1 \times n_2 = n$ and such that both an $OA(k, n_1)$ and an $OA(k, n_2)$ are available.

INPUT:

- `k`, `n` – integers

OUTPUT:

A pair `f,args` such that `f(*args)` is an $OA(k, n)$ or `False` if no product decomposition was found.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪product_decomposition
sage: f,args = find_product_decomposition(6, 84)
sage: args
(None, 6, 7, 12, (), False)
sage: _ = f(*args)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪product_decomposition
>>> f,args = find_product_decomposition(Integer(6), Integer(84))
>>> args
(None, 6, 7, 12, (), False)
>>> _ = f(*args)
```

`sage.combinat.designs.orthogonal_arrays_find_recursive.`**`find_q_x`**`(k, n)`

Find integers q, x such that the $q - x$ construction yields an $OA(k, n)$.

See the documentation of `construction_q_x()` to find out what hypotheses the integers q, x must satisfy.

> **Warning**
>
> For efficiency reasons, this function checks that Sage can build an $OA(k+1, q-x-1)$ and an $OA(k+1, q-x+1)$, which is stronger than checking that Sage can build a $OA(k, q-x-1)-(q-x-1).OA(k, 1)$ and a $OA(k, q-x+1)-(q-x+1).OA(k, 1)$. The latter would trigger a lot of independent set computations in `sage.combinat.designs.orthogonal_arrays.incomplete_orthogonal_array()`.

INPUT:

- `k`, `n` – integers

> **See also**
>
> `construction_q_x()`

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_q_x
sage: find_q_x(10,9)
False
sage: find_q_x(9,158)[1]
(9, 16, 6)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_q_x
>>> find_q_x(Integer(10),Integer(9))
False
```

(continues on next page)

(continued from previous page)

```
>>> find_q_x(Integer(9),Integer(158))[Integer(1)]
(9, 16, 6)
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_recursive_construction**(n)

Find a recursive construction of an $OA(k, n)$ (calls all others `find_*` functions).

This determines whether an $OA(k, n)$ can be built through the following constructions:

- *wilson_construction()*
- *construction_3_3()*
- *construction_3_4()*
- *construction_3_5()*
- *construction_3_6()*
- *construction_q_x()*
- *thwart_lemma_3_5()*
- *thwart_lemma_4_1()*
- *three_factor_product()*
- *brouwer_separable_design()*

INPUT:

- `k`, `n` – integers

OUTPUT:

Return a pair `f,args` such that `f(*args)` returns the requested OA if possible, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪recursive_construction
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: count = 0
sage: for n in range(10,150):
....:     k = designs.orthogonal_arrays.largest_available_k(n)
....:     if find_recursive_construction(k,n):
....:         count = count + 1
....:         f,args = find_recursive_construction(k,n)
....:         OA = f(*args)
....:         assert is_orthogonal_array(OA,k,n,2,verbose=True)
sage: count
56
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪recursive_construction
>>> from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
>>> count = Integer(0)
>>> for n in range(Integer(10),Integer(150)):
...     k = designs.orthogonal_arrays.largest_available_k(n)
...     if find_recursive_construction(k,n):
```

(continues on next page)

(continued from previous page)

```
...         count = count + Integer(1)
...         f,args = find_recursive_construction(k,n)
...         OA = f(*args)
...         assert is_orthogonal_array(OA,k,n,Integer(2),verbose=True)
>>> count
56
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_three_factor_product**(k, n)

Find $n_1 n_2 n_3 = n$ to obtain an $OA(k, n)$ by the three-factor product from [DukesLing14].

INPUT:

- k, n – integers

See also

three_factor_product()

OUTPUT:

A pair f,args such that f(*args) returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪three_factor_product
sage: find_three_factor_product(10,648)[1]
(9, 8, 9, 9)
sage: find_three_factor_product(10,50)
False
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_three_
↪factor_product
>>> find_three_factor_product(Integer(10),Integer(648))[Integer(1)]
(9, 8, 9, 9)
>>> find_three_factor_product(Integer(10),Integer(50))
False
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_thwart_lemma_3_5**(k, N)

Find the values on which Lemma 3.5 from [Thwarts] applies.

OUTPUT:

A pair (f,args) such that f(*args) returns an $OA(k, n)$ or False if the construction is not available.

See also

thwart_lemma_3_5()

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪thwart_lemma_3_5
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array

sage: f,args = find_thwart_lemma_3_5(7,66)
sage: args
(7, 9, 7, 1, 1, 1, 0, False)
sage: OA = f(*args)
sage: is_orthogonal_array(OA,7,66,2)
True

sage: f,args = find_thwart_lemma_3_5(6,100)
sage: args
(6, 8, 10, 8, 7, 5, 0, True)
sage: OA = f(*args)
sage: is_orthogonal_array(OA,6,100,2)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪thwart_lemma_3_5
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array

>>> f,args = find_thwart_lemma_3_5(Integer(7),Integer(66))
>>> args
(7, 9, 7, 1, 1, 1, 0, False)
>>> OA = f(*args)
>>> is_orthogonal_array(OA,Integer(7),Integer(66),Integer(2))
True

>>> f,args = find_thwart_lemma_3_5(Integer(6),Integer(100))
>>> args
(6, 8, 10, 8, 7, 5, 0, True)
>>> OA = f(*args)
>>> is_orthogonal_array(OA,Integer(6),Integer(100),Integer(2))
True
```

Some values from [Thwarts]:

```
sage: kn = ((10,1046), (10,1048), (10,1059), (11,1524),
....:       (11,2164), (12,3362), (12,3992),  (12,3994))
sage: for k,n in kn:

↪tested -- too long
...     assert designs.orthogonal_array(k,n,existence=True) is True
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_thwart_lemma_4_1**(*k*, *n*)

Find a decomposition for Lemma 4.1 from [Thwarts].

INPUT:

- k, n – integers

See also

thwart_lemma_4_1()

OUTPUT:

A pair f,args such that f(*args) returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪thwart_lemma_4_1
sage: find_thwart_lemma_4_1(10,408)[1]
(10, 13, 28)
sage: find_thwart_lemma_4_1(10,50)
False
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪thwart_lemma_4_1
>>> find_thwart_lemma_4_1(Integer(10),Integer(408))[Integer(1)]
(10, 13, 28)
```

(continues on next page)

(continued from previous page)

```
>>> find_thwart_lemma_4_1(Integer(10),Integer(50))
False
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_wilson_decomposition_with_one_truncated_g**

Find $rm + u = n$ to obtain an $OA(k, n)$ by Wilson's construction with one truncated column.

This function looks for possible integers m, t, u satisfying that $mt + u = n$ and such that Sage knows how to build a $OA(k, m)$, $OA(k, m + 1)$, $OA(k + 1, t)$ and a $OA(k, u)$.

INPUT:

- `k`, `n` – integers

OUTPUT:

A pair `f,args` such that `f(*args)` is an $OA(k, n)$ or `False` if no decomposition with one truncated block was found.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪wilson_decomposition_with_one_truncated_group
sage: f,args = find_wilson_decomposition_with_one_truncated_group(4,38)
sage: args
(None, 4, 5, 7, (3,), False)
sage: _ = f(*args)

sage: find_wilson_decomposition_with_one_truncated_group(4,20)
False
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪wilson_decomposition_with_one_truncated_group
>>> f,args = find_wilson_decomposition_with_one_truncated_group(Integer(4),
↪Integer(38))
>>> args
(None, 4, 5, 7, (3,), False)
>>> _ = f(*args)

>>> find_wilson_decomposition_with_one_truncated_group(Integer(4),Integer(20))
False
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_wilson_decomposition_with_two_truncated_g**

Find $rm + r_1 + r_2 = n$ to obtain an $OA(k, n)$ by Wilson's construction with two truncated columns.

Look for integers r, m, r_1, r_2 satisfying $n = rm + r_1 + r_2$ and $1 \leq r_1, r_2 < r$ and such that the following designs exist : $OA(k + 2, r)$, $OA(k, r1)$, $OA(k, r2)$, $OA(k, m)$, $OA(k, m + 1)$, $OA(k, m + 2)$.

INPUT:

- `k`, `n` – integers

OUTPUT:

A pair `f,args` such that `f(*args)` is an $OA(k, n)$ or `False` if no decomposition with two truncated blocks was found.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪wilson_decomposition_with_two_truncated_groups
sage: f,args = find_wilson_decomposition_with_two_truncated_groups(5,58)
sage: args
(None, 5, 7, 7, (4, 5), False)
sage: _ = f(*args)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪wilson_decomposition_with_two_truncated_groups
>>> f,args = find_wilson_decomposition_with_two_truncated_groups(Integer(5),
↪Integer(58))
>>> args
(None, 5, 7, 7, (4, 5), False)
>>> _ = f(*args)
```

`sage.combinat.designs.orthogonal_arrays_find_recursive.`**`int_as_sum`**`(`*value*, *S*, *k_max*`)`

Return a tuple $(s_1, s_2, \ldots, s_k)$ of less then k_max elements of S such that $value = s_1 + s_2 + \ldots + s_k$. If there is no such tuples then the function returns `None`.

INPUT:

- `value` – integer
- `S` – list of integers
- `k_max` – integer

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import int_as_
↪sum
sage: D = int_as_sum(21,[5,12],100)
sage: for k in range(20,40):
....:     print("{} {}".format(k, int_as_sum(k,[5,12],100)))
20 (5, 5, 5, 5)
21 None
22 (12, 5, 5)
23 None
24 (12, 12)
25 (5, 5, 5, 5, 5)
26 None
27 (12, 5, 5, 5)
28 None
29 (12, 12, 5)

38 None
39 (12, 12, 5, 5, 5)
```

5.1.94 Steiner Quadruple Systems

A Steiner Quadruple System on n points is a family $SQS_n \subset \binom{[n]}{4}$ of 4-sets, such that any set $S \subset [n]$ of size three is a subset of exactly one member of SQS_n.

This module implements Haim Hanani's constructive proof that a Steiner Quadruple System exists if and only if $n \equiv 2, 4 \pmod 6$. Hanani's proof consists in 6 different constructions that build a large Steiner Quadruple System from a smaller one, and though it does not give a very clear understanding of why it works (to say the least)… it does !

The constructions have been implemented while reading two papers simultaneously, for one of them sometimes provides the informations that the other one does not. The first one is Haim Hanani's original paper [Han1960], and the other one is a paper from Horan and Hurlbert which goes through all constructions [HH2012].

It can be used through the `designs` object:

```
sage: designs.steiner_quadruple_system(8)
Incidence structure with 8 points and 14 blocks
```

```
>>> from sage.all import *
>>> designs.steiner_quadruple_system(Integer(8))
Incidence structure with 8 points and 14 blocks
```

AUTHORS:

- Nathann Cohen (May 2013, while listening to "*Le Blues Du Pauvre Delahaye*")

Index

This module's main function is the following:

steiner_quadruple_system()	Return a Steiner Quadruple System on n points

This function redistributes its work among 6 constructions:

Construction 1	*two_n()*	Return a Steiner Quadruple System on $2n$ points
Construction 2	*three_n_minus_two()*	Return a Steiner Quadruple System on $3n-2$ points
Construction 3	*three_n_minus_eight()*	Return a Steiner Quadruple System on $3n-8$ points
Construction 4	*three_n_minus_four()*	Return a Steiner Quadruple System on $3n-4$ points
Construction 5	*four_n_minus_six()*	Return a Steiner Quadruple System on $4n-6$ points
Construction 6	*twelve_n_minus_ten()*	Return a Steiner Quadruple System on $12n-10$ points

It also defines two specific Steiner Quadruple Systems that the constructions require, i.e. SQS_{14} and SQS_{38} as well as the systems of pairs $P_\alpha(m)$ and $\overline{P}_\alpha(m)$ (see [Han1960]).

Functions

`sage.combinat.designs.steiner_quadruple_systems.P(alpha, m)`

Return the collection of pairs $P_\alpha(m)$.

For more information on this system, see [Han1960].

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import P
sage: P(3,4)
[(0, 5), (2, 7), (4, 1), (6, 3)]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import P
>>> P(Integer(3),Integer(4))
[(0, 5), (2, 7), (4, 1), (6, 3)]
```

`sage.combinat.designs.steiner_quadruple_systems.barP(eps, m)`

Return the collection of pairs $\overline{P}_\alpha(m)$.

For more information on this system, see [Han1960].

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import barP
sage: barP(3,4)
[(0, 4), (3, 5), (1, 2)]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import barP
>>> barP(Integer(3),Integer(4))
[(0, 4), (3, 5), (1, 2)]
```

sage.combinat.designs.steiner_quadruple_systems.**barP_system**()

Return the 1-factorization of K_{2m} $\overline{P}(m)$.

For more information on this system, see [Han1960].

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import barP_system
sage: barP_system(3)
[[(4, 3), (2, 5)],
[(0, 5), (4, 1)],
[(0, 2), (1, 3)],
[(1, 5), (4, 2), (0, 3)],
[(0, 4), (3, 5), (1, 2)],
[(0, 1), (2, 3), (4, 5)]]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import barP_system
>>> barP_system(Integer(3))
[[(4, 3), (2, 5)],
[(0, 5), (4, 1)],
[(0, 2), (1, 3)],

[(0, 1), (2, 3), (4, 5)]]
```

sage.combinat.designs.steiner_quadruple_systems.**four_n_minus_six**(B)

Return a Steiner Quadruple System on $4n - 6$ points.

INPUT:

- B – a Steiner Quadruple System on n points

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import four_n_minus_six
sage: for n in range(4, 20):
....:     if (n%6) in [2,4]:
....:         sqs = designs.steiner_quadruple_system(n)
....:         if not four_n_minus_six(sqs).is_t_design(3,4*n-6,4,1):
....:             print("Something is wrong !")
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import four_n_minus_six
>>> for n in range(Integer(4), Integer(20)):
...     if (n%Integer(6)) in [Integer(2),Integer(4)]:
...         sqs = designs.steiner_quadruple_system(n)
...         if not four_n_minus_six(sqs).is_t_design(Integer(3),Integer(4)*n-
↪Integer(6),Integer(4),Integer(1)):
...             print("Something is wrong !")
```

sage.combinat.designs.steiner_quadruple_systems.**relabel_system**(*B*)

Relabel the set so that $\{n-4, n-3, n-2, n-1\}$ is in B.

INPUT:

- B – list of 4-uples on $0, ..., n-1$

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import relabel_system
sage: SQS8 = designs.steiner_quadruple_system(8)
sage: relabel_system(SQS8)
Incidence structure with 8 points and 14 blocks
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import relabel_system
>>> SQS8 = designs.steiner_quadruple_system(Integer(8))
>>> relabel_system(SQS8)
Incidence structure with 8 points and 14 blocks
```

sage.combinat.designs.steiner_quadruple_systems.**steiner_quadruple_system**(*check=False*)

Return a Steiner Quadruple System on n points.

INPUT:

- n – integer such that $n \equiv 2, 4 \pmod 6$
- check – boolean (default: False); whether to check that the system is a Steiner Quadruple System before returning it

EXAMPLES:

```
sage: sqs4 = designs.steiner_quadruple_system(4)
sage: sqs4
Incidence structure with 4 points and 1 blocks
sage: sqs4.is_t_design(3,4,4,1)
True

sage: sqs8 = designs.steiner_quadruple_system(8)
sage: sqs8
Incidence structure with 8 points and 14 blocks
sage: sqs8.is_t_design(3,8,4,1)
True
```

```
>>> from sage.all import *
>>> sqs4 = designs.steiner_quadruple_system(Integer(4))
>>> sqs4
Incidence structure with 4 points and 1 blocks
>>> sqs4.is_t_design(Integer(3),Integer(4),Integer(4),Integer(1))
True

>>> sqs8 = designs.steiner_quadruple_system(Integer(8))
>>> sqs8
Incidence structure with 8 points and 14 blocks
>>> sqs8.is_t_design(Integer(3),Integer(8),Integer(4),Integer(1))
True
```

sage.combinat.designs.steiner_quadruple_systems.**three_n_minus_eight**(B)

Return a Steiner Quadruple System on $3n - 8$ points.

INPUT:

- B – a Steiner Quadruple System on n points

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_
↪eight
sage: for n in range(4, 30):
....:     if (n%12) == 2:
....:         sqs = designs.steiner_quadruple_system(n)
....:         if not three_n_minus_eight(sqs).is_t_design(3,3*n-8,4,1):
....:             print("Something is wrong !")
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_
↪eight
>>> for n in range(Integer(4), Integer(30)):
...     if (n%Integer(12)) == Integer(2):
...         sqs = designs.steiner_quadruple_system(n)
...         if not three_n_minus_eight(sqs).is_t_design(Integer(3),Integer(3)*n-
↪Integer(8),Integer(4),Integer(1)):
...             print("Something is wrong !")
```

sage.combinat.designs.steiner_quadruple_systems.**three_n_minus_four**(B)

Return a Steiner Quadruple System on $3n - 4$ points.

INPUT:

- B – a Steiner Quadruple System on n points where $n \equiv 10 \pmod{12}$

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_
↪four
sage: for n in range(4, 30):
....:     if n%12 == 10:
....:         sqs = designs.steiner_quadruple_system(n)
....:         if not three_n_minus_four(sqs).is_t_design(3,3*n-4,4,1):
....:             print("Something is wrong !")
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_four
>>> for n in range(Integer(4), Integer(30)):
...     if n%Integer(12) == Integer(10):
...         sqs = designs.steiner_quadruple_system(n)
...         if not three_n_minus_four(sqs).is_t_design(Integer(3),Integer(3)*n-
↪Integer(4),Integer(4),Integer(1)):
...             print("Something is wrong !")
```

sage.combinat.designs.steiner_quadruple_systems.**three_n_minus_two**(B)

Return a Steiner Quadruple System on $3n - 2$ points.

INPUT:

- B – a Steiner Quadruple System on n points

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_
↪two
sage: for n in range(4, 30):
....:     if (n%6) in [2,4]:
....:         sqs = designs.steiner_quadruple_system(n)
....:         if not three_n_minus_two(sqs).is_t_design(3,3*n-2,4,1):
....:             print("Something is wrong !")
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_two
>>> for n in range(Integer(4), Integer(30)):
...     if (n%Integer(6)) in [Integer(2),Integer(4)]:
...         sqs = designs.steiner_quadruple_system(n)
...         if not three_n_minus_two(sqs).is_t_design(Integer(3),Integer(3)*n-
↪Integer(2),Integer(4),Integer(1)):
...             print("Something is wrong !")
```

sage.combinat.designs.steiner_quadruple_systems.**twelve_n_minus_ten**(B)

Return a Steiner Quadruple System on $12n - 6$ points.

INPUT:

- B – a Steiner Quadruple System on n points

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import twelve_n_minus_
↪ten
sage: for n in range(4, 15):
....:     if (n%6) in [2,4]:
....:         sqs = designs.steiner_quadruple_system(n)
....:         if not twelve_n_minus_ten(sqs).is_t_design(3,12*n-10,4,1):
....:             print("Something is wrong !")
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import twelve_n_minus_ten
>>> for n in range(Integer(4), Integer(15)):
...     if (n%Integer(6)) in [Integer(2),Integer(4)]:
...         sqs = designs.steiner_quadruple_system(n)
...         if not twelve_n_minus_ten(sqs).is_t_design(Integer(3),Integer(12)*n-
↪Integer(10),Integer(4),Integer(1)):
...             print("Something is wrong !")
```

sage.combinat.designs.steiner_quadruple_systems.**two_n**(B)

Return a Steiner Quadruple System on $2n$ points.

INPUT:

- B – a Steiner Quadruple System on n points

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import two_n
sage: for n in range(4, 30):
....:     if (n%6) in [2,4]:
....:         sqs = designs.steiner_quadruple_system(n)
....:         if not two_n(sqs).is_t_design(3,2*n,4,1):
....:             print("Something is wrong !")
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import two_n
>>> for n in range(Integer(4), Integer(30)):
...     if (n%Integer(6)) in [Integer(2),Integer(4)]:
...         sqs = designs.steiner_quadruple_system(n)
...         if not two_n(sqs).is_t_design(Integer(3),Integer(2)*n,Integer(4),
↪Integer(1)):
...             print("Something is wrong !")
```

5.1.95 Hypergraph isomorphic copy search

This module implements a code for the following problem:

> **INPUT:** two hypergraphs H_1, H_2
>
> **OUTPUT:** a copy of H_2 in H_1

It is also possible to enumerate all such copies, and to require that such copies be induced copies. More formally:

> A copy of H_2 in H_1 is an injection $f : V(H_2) \mapsto V(H_1)$ such that for any set $S_2 \in E(H_2)$ we have $f(S_2) \in E(H_1)$.
>
> It is an *induced* copy if no other set of $E(H_1)$ is contained in $f(V(H_2))$, i.e. $|E(H_2)| = \{S : S \in E(H_1)$ and $S \subseteq f(V(H_2))\}$.

The functions implemented here lists all such injections. In particular, the number of copies of H in itself is equal to $|Aut(H)|$.

The feature is available through `IncidenceStructure.isomorphic_substructures_iterator()`.

Implementation

A hypergraph is stored as a list of edges, each of which is a "dense" bitset over $|V(H_1)|$ points. In particular, two sets of distinct cardinalities require the same memory space. A hypergraph is a C struct with the following fields:

- `n`, `m` – (`int`) number of points and edges
- `limbs` – (`int`) number of 64-bits blocks per set
- `set_space` – (`uint64_t *`) address of the memory used to store the sets
- `sets` – (`uint64_t **`) `sets[i]` points toward the `limbs` blocks encoding set i. Note also that `sets[i][limbs]` is equal to the cardinality of `set[i]`, so that `sets` has length `m*(limbs+1)*sizeof(uint64_t)`.
- `names` – (`int *`) associates an integer 'name' to each of the `n` points

The operations used on this data structure are:

- `void permute(hypergraph * h, int n1, int n2)` – exchanges points $n1$ and $n2$ in the data structure. Note that their names are also exchanged so that we still know which is which.

- `int induced_hypergraph(hypergraph * h1, int n, hypergraph * tmp1)` – stores in `tmp1` the hypergraph induced by the first n points, i.e. all sets S such that $S \subseteq \{0, ..., n-1\}$. The function returns the number of such sets.
- `void trace_hypergraph64(hypergraph * h, int n, hypergraph * tmp)` – stores in `tmp1` the trace of h on the first n points, i.e. all sets of the form $S \cap \{0, \ldots, n-1\}$.

Algorithm

We try all possible assignments of a representant $r_i \in H_1$ for every $i \in H_2$. When we have picked a representant for the first $n <$ points $\{0, \ldots, n-1\} \subsetneq V(H_2)$, we check that:

- The hypergraph induced by the (ordered) list $0, \ldots, n-1$ in H_2 is equal to the one induced by $r_0, \ldots, r_{n-1}$ in H_1.
- If $S \subseteq \{0, ..., n-1\}$ is contained in c sets of size k in H_2, then $\{r_i : i \in S\}$ is contained in $\geq c$ sets of size k in H_1. This is done by comparing the trace of the hypergraphs while remembering the original size of each set.

As we very often need to build the hypergraph obtained by the trace of the first n points (for all possible n), those hypergraphs are cached. The hypergraphs induced by the same points are handled similarly.

Limitations

Number of points For efficiency reason the implementation assumes that H_2 has ≤ 64 points. Making this work for larger values means that calls to `qsort` have to be replaced by calls to `qsort_r` (i.e. to sort the edges you need to know the number of limbs per edge) and that induces a big slowdown for small cases (~50% when this code was implemented). Also, 64 points for H_2 is already very very big considering the problem at hand. Even $|V(H_1)| > 64$ seems too much.

Vertex ordering The order of vertices in H_2 has a huge influence on the performance of the algorithm. If no set of H_2 contains more that one of the first $k < n$ points, then almost all partial assignments of representants are possible for the first k points (though the degree of the vertices is taken into account). For this reason it is best to pick an ordering such that the first vertices are contained in as many sets as possible together. A heuristic is implemented at *relabel_heuristic()*.

AUTHORS:

- Nathann Cohen (November 2014, written in various airports between Nice and Chennai).

Methods

class `sage.combinat.designs.subhypergraph_search.`**SubHypergraphSearch**

Bases: `object`

relabel_heuristic()

Relabel H_2 in order to make the algorithm faster.

Objective: we try to pick an ordering $p_1, ..., p_k$ of the points of H_2 that maximizes the number of sets involving the first points in the ordering. One way to formalize the problems indicates that it may be NP-Hard (generalizes the max clique problem for graphs) so we do not try to solve it exactly: we just need a sufficiently good heuristic.

Assuming that the first points are $p_1, ..., p_k$, we determine p_{k+1} as the point x such that the number of sets S with $x \in S$ and $S \cap \{p_1, ..., p_k\} \neq \emptyset$ is maximal. In case of ties, we take a point with maximum degree.

This function is called when an instance of *SubHypergraphSearch* is created.

EXAMPLES:

```
sage: d = designs.projective_plane(3)                                    #␣
↪needs sage.schemes
```

(continues on next page)

(continued from previous page)

```
sage: d.isomorphic_substructures_iterator(d).relabel_heuristic()          #␣
↪needs sage.schemes
```

```
>>> from sage.all import *
>>> d = designs.projective_plane(Integer(3))                                 ␣
↪     # needs sage.schemes
>>> d.isomorphic_substructures_iterator(d).relabel_heuristic()          #␣
↪needs sage.schemes
```

5.1.96 Two-graphs

A two-graph on n points is a family $T \subset \binom{[n]}{3}$ of 3-sets, such that any 4-set $S \subset [n]$ of size four contains an even number of elements of T. Any graph $([n], E)$ gives rise to a two-graph $T(E) = \{t \in \binom{[n]}{3} : \left|\binom{t}{2} \cap E\right| \ odd\}$, and any two graphs with the same two-graph can be obtained one from the other by `Seidel switching`. This defines an equivalence relation on the graphs on $[n]$, called Seidel switching equivalence. Conversely, given a two-graph T, one can construct a graph Γ in the corresponding Seidel switching class with an isolated vertex w. The graph $\Gamma \setminus w$ is called the *descendant* of T w.r.t. v.

T is called regular if each two-subset of $[n]$ is contained in the same number alpha of triples of T.

This module implements a direct construction of a two-graph from a list of triples, construction of descendant graphs, regularity checking, and other things such as constructing the complement two-graph, cf. [BH2012].

AUTHORS:

- Dima Pasechnik (Aug 2015)

Index

This module's methods are the following:

is_regular_twograph()	Test if `self` is a regular two-graph, i.e. a 2-design
complement()	Return the complement of `self`
descendant()	Return the descendant graph at w

This module's functions are the following:

taylor_twograph()	Construct Taylor's two-graph for $U_3(q)$
is_twograph()	Check that the incidence system is a two-graph
twograph_descendant()	Return the descendant graph w.r.t. a given vertex of the two-graph of a given graph

Methods

class sage.combinat.designs.twographs.**TwoGraph**(*points=None*, *blocks=None*, *incidence_matrix=None*, *name=None*, *check=False*, *copy=True*)

Bases: *IncidenceStructure*

Two-graphs class.

A two-graph on n points is a 3-uniform hypergraph, i.e. a family $T \subset \binom{[n]}{3}$ of 3-sets, such that any 4-set $S \subset [n]$ of size four contains an even number of elements of T. For more information, see the documentation of the *twographs* module.

complement()

The two-graph which is the complement of `self`.

That is, the two-graph consisting exactly of triples not in `self`. Note that this is different from *complement* of the *parent class*.

EXAMPLES:

```
sage: p = graphs.CompleteGraph(8).line_graph().twograph()                    #␣
↪needs sage.modules
sage: pc = p.complement(); pc                                                #␣
↪needs sage.modules
Incidence structure with 28 points and 1260 blocks
```

```
>>> from sage.all import *
>>> p = graphs.CompleteGraph(Integer(8)).line_graph().twograph()              ␣
↪     # needs sage.modules
>>> pc = p.complement(); pc                                                 #␣
↪needs sage.modules
Incidence structure with 28 points and 1260 blocks
```

descendant(*v*)

The descendant `graph` at `v`.

The *switching class of graphs* corresponding to `self` contains a graph `D` with `v` its own connected component; removing `v` from `D`, one obtains the descendant graph of `self` at `v`, which is constructed by this method.

INPUT:

- `v` – an element of `ground_set()`

EXAMPLES:

```
sage: p = graphs.PetersenGraph().twograph().descendant(0)                    #␣
↪needs sage.modules
sage: p.is_strongly_regular(parameters=True)                                 #␣
↪needs sage.modules
(9, 4, 1, 2)
```

```
>>> from sage.all import *
>>> p = graphs.PetersenGraph().twograph().descendant(Integer(0))              ␣
↪     # needs sage.modules
>>> p.is_strongly_regular(parameters=True)                                  #␣
↪needs sage.modules
(9, 4, 1, 2)
```

is_regular_twograph(*alpha=False*)

Test if the *TwoGraph* is regular, i.e. is a 2-design.

Namely, each pair of elements of `ground_set()` is contained in exactly `alpha` triples.

INPUT:

- `alpha` – boolean (default: `False`); return the value of `alpha`, if possible

EXAMPLES:

```
sage: # needs sage.modules
sage: p = graphs.PetersenGraph().twograph()
sage: p.is_regular_twograph(alpha=True)
4
sage: p.is_regular_twograph()
True
sage: p = graphs.PathGraph(5).twograph()
sage: p.is_regular_twograph(alpha=True)
False
sage: p.is_regular_twograph()
False
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> p = graphs.PetersenGraph().twograph()
>>> p.is_regular_twograph(alpha=True)
4
>>> p.is_regular_twograph()
True
>>> p = graphs.PathGraph(Integer(5)).twograph()
>>> p.is_regular_twograph(alpha=True)
False
>>> p.is_regular_twograph()
False
```

sage.combinat.designs.twographs.**is_twograph**(T)

Check whether the incidence system T is a two-graph.

INPUT:

- `T` – an `incidence structure`

EXAMPLES:

a two-graph from a graph:

```
sage: from sage.combinat.designs.twographs import (is_twograph, TwoGraph)
sage: p = graphs.PetersenGraph().twograph()                                    #␣
↪needs sage.modules
sage: is_twograph(p)                                                            #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.twographs import (is_twograph, TwoGraph)
>>> p = graphs.PetersenGraph().twograph()                                   #␣
↪needs sage.modules
>>> is_twograph(p)                                                           #␣
↪needs sage.modules
True
```

a non-regular 2-uniform hypergraph which is a two-graph:

```
sage: is_twograph(TwoGraph([[1,2,3],[1,2,4]]))
True
```

```
>>> from sage.all import *
>>> is_twograph(TwoGraph([[Integer(1),Integer(2),Integer(3)],[Integer(1),
↪Integer(2),Integer(4)]]))
True
```

sage.combinat.designs.twographs.**taylor_twograph**(*q*)

Constructing Taylor's two-graph for $U_3(q)$, q odd prime power.

The Taylor's two-graph T has the q^3+1 points of the projective plane over F_{q^2} singular w.r.t. the non-degenerate Hermitean form S preserved by $U_3(q)$ as its ground set; the triples are $\{x,y,z\}$ satisfying the condition that $S(x,y)S(y,z)S(z,x)$ is square (respectively non-square) if $q \cong 1 \mod 4$ (respectively if $q \cong 3 \mod 4$). See §7E of [BL1984].

There is also a $2-(q^3+1,q+1,1)$-design on these q^3+1 points, known as the unital of order q, also invariant under $U_3(q)$.

INPUT:

- `q` – a power of an odd prime

EXAMPLES:

```
sage: from sage.combinat.designs.twographs import taylor_twograph
sage: T = taylor_twograph(3); T                                         #␣
↪needs sage.rings.finite_rings
Incidence structure with 28 points and 1260 blocks
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.twographs import taylor_twograph
>>> T = taylor_twograph(Integer(3)); T                                  ␣
↪     # needs sage.rings.finite_rings
Incidence structure with 28 points and 1260 blocks
```

sage.combinat.designs.twographs.**twograph_descendant**(*G*, *v*, *name=None*)

Return the descendant graph w.r.t. vertex v of the two-graph of G.

In the *switching class* of G, construct a graph Δ with v an isolated vertex, and return the subgraph $\Delta \setminus v$. It is equivalent to, although much faster than, computing the *TwoGraph.descendant()* of two-graph of G, as the intermediate two-graph is not constructed.

INPUT:

- `G` – a graph
- `v` – a vertex of `G`
- `name` – (default: `None`) no name, otherwise derive from the construction

EXAMPLES:

one of s.r.g.'s from the database:

```
sage: from sage.combinat.designs.twographs import twograph_descendant
sage: A = graphs.strongly_regular_graph(280,135,70)                 # optional -
↪ gap_package_design internet
sage: twograph_descendant(A, 0).is_strongly_regular(parameters=True)   # optional -
↪ gap_package_design internet
(279, 150, 85, 75)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.twographs import twograph_descendant
>>> A = graphs.strongly_regular_graph(Integer(280),Integer(135),Integer(70))       ␣
↪            # optional - gap_package_design internet
>>> twograph_descendant(A, Integer(0)).is_strongly_regular(parameters=True)   #␣
↪optional - gap_package_design internet
(279, 150, 85, 75)
```

5.1.97 Combinatorial diagrams

A combinatorial diagram is a collection of cells (i, j) indexed by pairs of natural numbers.

For arbitrary diagrams, see `Diagram`. There are also two other specific types of diagrams implemented here. They are northwest diagrams (`NorthwestDiagram`) and Rothe diagrams (`RotheDiagram()`, a special kind of northwest diagram).

AUTHORS:

- Trevor K. Karn (2022-08-01): initial version

class sage.combinat.diagram.**Diagram**(*parent*, *cells*, *n_rows=None*, *n_cols=None*, *check=True*)

Bases: `ClonableArray`

Combinatorial diagrams with positions indexed by rows and columns.

The positions are indexed by rows and columns as in a matrix. For example, a Ferrers diagram is a diagram obtained from a partition $\lambda = (\lambda_0, \lambda_1, \ldots, \lambda_\ell)$, where the cells are in rows i for $0 \leq i \leq \ell$ and the cells in row i consist of (i, j) for $0 \leq j < \lambda_i$. In English notation, the indices are read from top left to bottom right as in a matrix.

Indexing conventions are the same as `Partition`. Printing the diagram of a partition, however, will always be in English notation.

EXAMPLES:

To create an arbitrary diagram, pass a list of all cells:

```
sage: from sage.combinat.diagram import Diagram
sage: cells = [(0,0), (0,1), (1,0), (1,1), (4,4), (4,5), (4,6), (5,4), (7, 6)]
sage: D = Diagram(cells); D
[(0, 0), (0, 1), (1, 0), (1, 1), (4, 4), (4, 5), (4, 6), (5, 4), (7, 6)]
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> cells = [(Integer(0),Integer(0)), (Integer(0),Integer(1)), (Integer(1),
↪Integer(0)), (Integer(1),Integer(1)), (Integer(4),Integer(4)), (Integer(4),
↪Integer(5)), (Integer(4),Integer(6)), (Integer(5),Integer(4)), (Integer(7),␣
↪Integer(6))]
>>> D = Diagram(cells); D
[(0, 0), (0, 1), (1, 0), (1, 1), (4, 4), (4, 5), (4, 6), (5, 4), (7, 6)]
```

We can visualize the diagram by printing `O`'s and `.`'s. `O`'s are present in the cells which are present in the diagram and a `.` represents the absence of a cell in the diagram:

```
sage: D.pp()
O O . . . . .
O O . . . . .
. . . . . . .
```

(continues on next page)

(continued from previous page)

```
. . . . . . .
. . . . O O O
. . . . O . .
. . . . . . .
. . . . . . O
```

```
>>> from sage.all import *
>>> D.pp()
O O . . . . .
O O . . . . .
. . . . . . .
. . . . . . .
. . . . O O O
. . . . O . .
. . . . . . .
. . . . . . O
```

We can also check if certain cells are contained in a given diagram:

```
sage: (1, 0) in D
True
sage: (2, 2) in D
False
```

```
>>> from sage.all import *
>>> (Integer(1), Integer(0)) in D
True
>>> (Integer(2), Integer(2)) in D
False
```

If you know that there are entire empty rows or columns at the end of the diagram, you can manually pass them with keyword arguments `n_rows=` or `n_cols=`:

```
sage: Diagram([(0,0), (0,3), (2,2), (2,4)]).pp()
O . . O .
. . . . .
. . O . O
sage: Diagram([(0,0), (0,3), (2,2), (2,4)], n_rows=6, n_cols=6).pp()
O . . O . .
. . . . . .
. . O . O .
. . . . . .
. . . . . .
. . . . . .
```

```
>>> from sage.all import *
>>> Diagram([(Integer(0),Integer(0)), (Integer(0),Integer(3)), (Integer(2),
↪Integer(2)), (Integer(2),Integer(4))]).pp()
O . . O .
. . . . .
. . O . O
>>> Diagram([(Integer(0),Integer(0)), (Integer(0),Integer(3)), (Integer(2),
```

(continues on next page)

(continued from previous page)

```
↪Integer(2)), (Integer(2),Integer(4))], n_rows=Integer(6), n_cols=Integer(6)).
↪pp()
O . . O . .
. . . . . .
. . O . O .
. . . . . .
. . . . . .
. . . . . .
```

cells()

Return a list of the cells contained in the diagram self.

EXAMPLES:

```
sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D1.cells()
[(0, 2), (0, 3), (1, 1), (3, 2)]
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D1 = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1),
↪Integer(1)),(Integer(3),Integer(2))])
>>> D1.cells()
[(0, 2), (0, 3), (1, 1), (3, 2)]
```

check()

Check that this is a valid diagram.

EXAMPLES:

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,0), (0,3), (2,2), (2,4)])
sage: D.check()
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D = Diagram([(Integer(0),Integer(0)), (Integer(0),Integer(3)),␣
↪(Integer(2),Integer(2)), (Integer(2),Integer(4))])
>>> D.check()
```

In the next two examples, a bad diagram is passed. The first example fails because one cell is indexed by negative integers:

```
sage: D = Diagram([(0,0), (0,-3), (2,2), (2,4)])
Traceback (most recent call last):
...
ValueError: diagrams must be indexed by nonnegative integers
```

```
>>> from sage.all import *
>>> D = Diagram([(Integer(0),Integer(0)), (Integer(0),-Integer(3)),␣
↪(Integer(2),Integer(2)), (Integer(2),Integer(4))])
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
ValueError: diagrams must be indexed by nonnegative integers
```

The next example fails because one cell is indexed by rational numbers:

```
sage: D = Diagram([(0,0), (0,3), (2/3,2), (2,4)])
Traceback (most recent call last):
...
ValueError: diagrams must be indexed by nonnegative integers
```

```
>>> from sage.all import *
>>> D = Diagram([(Integer(0),Integer(0)), (Integer(0),Integer(3)),
→(Integer(2)/Integer(3),Integer(2)), (Integer(2),Integer(4))])
Traceback (most recent call last):
...
ValueError: diagrams must be indexed by nonnegative integers
```

essential_set()

Return the essential set of `self` as defined by Fulton.

Let D be a diagram. Then the *essential set* of D are the cells $(i, j) \in D$ such that $(i + 1, j) \notin D$ and $(i, j + 1) \notin D$; that is, the maximally southwest elements in each connected component of D.

EXAMPLES:

```
sage: w = Permutation([2, 1, 5, 4, 3])
sage: D = w.rothe_diagram()
sage: D.essential_set()
((0, 0), (2, 3), (3, 2))
```

```
>>> from sage.all import *
>>> w = Permutation([Integer(2), Integer(1), Integer(5), Integer(4),
→Integer(3)])
>>> D = w.rothe_diagram()
>>> D.essential_set()
((0, 0), (2, 3), (3, 2))
```

n_cells()

Return the total number of cells contained in the diagram `self`.

EXAMPLES:

```
sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D1.number_of_cells()
4
sage: D1.n_cells()
4
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D1 = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1),
```

(continues on next page)

(continued from previous page)

```
↪Integer(1)),(Integer(3),Integer(2))])
>>> D1.number_of_cells()
4
>>> D1.n_cells()
4
```

ncols()

Return the total number of rows of `self`.

EXAMPLES:

The following example has three columns which are filled, but they are contained in rows 0 to 3 (for a total of four):

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D.number_of_cols()
4
sage: D.ncols()
4
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1),
↪Integer(1)),(Integer(3),Integer(2))])
>>> D.number_of_cols()
4
>>> D.ncols()
4
```

We can also include empty columns at the end:

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,2),(0,3),(1,1),(3,2)], n_cols=6)
sage: D.number_of_cols()
6
sage: D.pp()
. . O O . .
. O . . . .
. . . . . .
. . O . . .
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1),
↪Integer(1)),(Integer(3),Integer(2))], n_cols=Integer(6))
>>> D.number_of_cols()
6
>>> D.pp()
. . O O . .
. O . . . .
. . . . . .
. . O . . .
```

nrows()

Return the total number of rows of `self`.

EXAMPLES:

The following example has three rows which are filled, but they are contained in rows 0 to 3 (for a total of four):

```
sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D1.number_of_rows()
4
sage: D1.nrows()
4
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D1 = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1),
↪Integer(1)),(Integer(3),Integer(2))])
>>> D1.number_of_rows()
4
>>> D1.nrows()
4
```

The total number of rows includes including those which are empty. We can also include empty rows at the end:

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,2),(0,3),(1,1),(3,2)], n_rows=6)
sage: D.number_of_rows()
6
sage: D.pp()
. . O O
. O . .
. . . .
. . O .
. . . .
. . . .
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1),
↪Integer(1)),(Integer(3),Integer(2))], n_rows=Integer(6))
>>> D.number_of_rows()
6
>>> D.pp()
. . O O
. O . .
. . . .
. . O .
. . . .
. . . .
```

number_of_cells()

Return the total number of cells contained in the diagram `self`.

EXAMPLES:

```
sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D1.number_of_cells()
4
sage: D1.n_cells()
4
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D1 = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1),
↪Integer(1)),(Integer(3),Integer(2))])
>>> D1.number_of_cells()
4
>>> D1.n_cells()
4
```

number_of_cols()

Return the total number of rows of `self`.

EXAMPLES:

The following example has three columns which are filled, but they are contained in rows 0 to 3 (for a total of four):

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D.number_of_cols()
4
sage: D.ncols()
4
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1),
↪Integer(1)),(Integer(3),Integer(2))])
>>> D.number_of_cols()
4
>>> D.ncols()
4
```

We can also include empty columns at the end:

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,2),(0,3),(1,1),(3,2)], n_cols=6)
sage: D.number_of_cols()
6
sage: D.pp()
. . O O . .
. O . . . .
. . . . . .
. . O . . .
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1),
↪Integer(1)),(Integer(3),Integer(2))], n_cols=Integer(6))
>>> D.number_of_cols()
6
>>> D.pp()
. . O O . .
. O . . . .
. . . . . .
. . O . . .
```

number_of_rows()

Return the total number of rows of `self`.

EXAMPLES:

The following example has three rows which are filled, but they are contained in rows 0 to 3 (for a total of four):

```
sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D1.number_of_rows()
4
sage: D1.nrows()
4
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D1 = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1),
↪Integer(1)),(Integer(3),Integer(2))])
>>> D1.number_of_rows()
4
>>> D1.nrows()
4
```

The total number of rows includes including those which are empty. We can also include empty rows at the end:

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,2),(0,3),(1,1),(3,2)], n_rows=6)
sage: D.number_of_rows()
6
sage: D.pp()
. . O O
. O . .
. . . .
. . O .
. . . .
. . . .
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
```

(continues on next page)

(continued from previous page)

```
>>> D = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1),
↪Integer(1)),(Integer(3),Integer(2))], n_rows=Integer(6))
>>> D.number_of_rows()
6
>>> D.pp()
. . O O
. O . .
. . . .
. . O .
. . . .
. . . .
```

pp()

Return a visualization of the diagram.

Cells which are present in the diagram are filled with a `O`. Cells which are not present in the diagram are filled with a `.`.

EXAMPLES:

```
sage: from sage.combinat.diagram import Diagram
sage: Diagram([(0,0), (0,3), (2,2), (2,4)]).pp()
O . . O .
. . . . .
. . O . O
sage: Diagram([(0,0), (0,3), (2,2), (2,4)], n_rows=6, n_cols=6).pp()
O . . O . .
. . . . . .
. . O . O .
. . . . . .
. . . . . .
. . . . . .
sage: Diagram([]).pp()
-
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> Diagram([(Integer(0),Integer(0)), (Integer(0),Integer(3)), (Integer(2),
↪Integer(2)), (Integer(2),Integer(4))]).pp()
O . . O .
. . . . .
. . O . O
>>> Diagram([(Integer(0),Integer(0)), (Integer(0),Integer(3)), (Integer(2),
↪Integer(2)), (Integer(2),Integer(4))], n_rows=Integer(6), n_
↪cols=Integer(6)).pp()
O . . O . .
. . . . . .
. . O . O .
. . . . . .
. . . . . .
. . . . . .
>>> Diagram([]).pp()
-
```

size()

Return the total number of cells contained in the diagram `self`.

EXAMPLES:

```
sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D1.number_of_cells()
4
sage: D1.n_cells()
4
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D1 = Diagram([(Integer(0),Integer(2)),(Integer(0),Integer(3)),(Integer(1),
↪Integer(1)),(Integer(3),Integer(2))])
>>> D1.number_of_cells()
4
>>> D1.n_cells()
4
```

specht_module(*base_ring=None*)

Return the Specht module corresponding to `self`.

EXAMPLES:

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,0), (1,1), (2,2), (2,3)])
sage: SM = D.specht_module(QQ)                                          #␣
↪needs sage.modules
sage: s = SymmetricFunctions(QQ).s()                                    #␣
↪needs sage.modules
sage: s(SM.frobenius_image())                                           #␣
↪needs sage.modules
s[2, 1, 1] + s[2, 2] + 2*s[3, 1] + s[4]
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D = Diagram([(Integer(0),Integer(0)), (Integer(1),Integer(1)),␣
↪(Integer(2),Integer(2)), (Integer(2),Integer(3))])
>>> SM = D.specht_module(QQ)                                            #␣
↪needs sage.modules
>>> s = SymmetricFunctions(QQ).s()                                      #␣
↪needs sage.modules
>>> s(SM.frobenius_image())                                             #␣
↪needs sage.modules
s[2, 1, 1] + s[2, 2] + 2*s[3, 1] + s[4]
```

specht_module_dimension(*base_ring=None*)

Return the dimension of the Specht module corresponding to `self`.

INPUT:

- `base_ring` – (default: **Q**) the base ring

EXAMPLES:

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,0), (1,1), (2,2), (2,3)])
sage: D.specht_module_dimension()                                          #␣
↪needs sage.modules
12
sage: D.specht_module(QQ).dimension()                                      #␣
↪needs sage.modules
12
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D = Diagram([(Integer(0),Integer(0)), (Integer(1),Integer(1)),␣
↪(Integer(2),Integer(2)), (Integer(2),Integer(3))])
>>> D.specht_module_dimension()                                          #␣
↪needs sage.modules
12
>>> D.specht_module(QQ).dimension()                                      #␣
↪needs sage.modules
12
```

class sage.combinat.diagram.**Diagrams**(*category=None*)

Bases: UniqueRepresentation, Parent

The class of combinatorial diagrams.

A *combinatorial diagram* is a set of cells indexed by pairs of natural numbers. Calling an instance of *Diagrams* is one way to construct diagrams.

EXAMPLES:

```
sage: from sage.combinat.diagram import Diagrams
sage: Dgms = Diagrams()
sage: D = Dgms([(0,0), (0,3), (2,2), (2,4)])
sage: D.parent()
Combinatorial diagrams
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagrams
>>> Dgms = Diagrams()
>>> D = Dgms([(Integer(0),Integer(0)), (Integer(0),Integer(3)), (Integer(2),
↪Integer(2)), (Integer(2),Integer(4))])
>>> D.parent()
Combinatorial diagrams
```

Element

alias of *Diagram*

from_composition(*alpha*)

Create the diagram corresponding to a weak composition $\alpha \vDash n$.

EXAMPLES:

```
sage: alpha = Composition([3,0,2,1,4,4])
sage: from sage.combinat.diagram import Diagrams
```

(continues on next page)

(continued from previous page)

```
sage: Diagrams()(alpha).pp()
O O O .
. . . .
O O . .
O . . .
O O O O
O O O O
sage: Diagrams().from_composition(alpha).pp()
O O O .
. . . .
O O . .
O . . .
O O O O
O O O O
```

```
>>> from sage.all import *
>>> alpha = Composition([Integer(3),Integer(0),Integer(2),Integer(1),
↪Integer(4),Integer(4)])
>>> from sage.combinat.diagram import Diagrams
>>> Diagrams()(alpha).pp()
O O O .
. . . .
O O . .
O . . .
O O O O
O O O O
>>> Diagrams().from_composition(alpha).pp()
O O O .
. . . .
O O . .
O . . .
O O O O
O O O O
```

from_polyomino(*p*)

Create the diagram corresponding to a 2d `Polyomino`

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino                              #␣
↪needs sage.modules
sage: p = Polyomino([(0,0),(1,0),(1,1),(1,2)])                               #␣
↪needs sage.modules
sage: from sage.combinat.diagram import Diagrams
sage: Diagrams()(p).pp()                                                      #␣
↪needs sage.modules
O . .
O O O
```

```
>>> from sage.all import *
>>> from sage.combinat.tiling import Polyomino                              #␣
↪needs sage.modules
```

(continues on next page)

(continued from previous page)

```
>>> p = Polyomino([(Integer(0),Integer(0)),(Integer(1),Integer(0)),
↪(Integer(1),Integer(1)),(Integer(1),Integer(2))])                    ␣
↪   # needs sage.modules
>>> from sage.combinat.diagram import Diagrams
>>> Diagrams()(p).pp()                                                #␣
↪needs sage.modules
O . .
O O O
```

We can also call this method directly:

```
sage: Diagrams().from_polyomino(p).pp()                               #␣
↪needs sage.modules
O . .
O O O
```

```
>>> from sage.all import *
>>> Diagrams().from_polyomino(p).pp()                                 #␣
↪needs sage.modules
O . .
O O O
```

This only works for a 2d `Polyomino`:

```
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')     #␣
↪needs sage.modules
sage: Diagrams().from_polyomino(p)                                    #␣
↪needs sage.modules
Traceback (most recent call last):
...
ValueError: the polyomino must be 2 dimensional
```

```
>>> from sage.all import *
>>> p = Polyomino([(Integer(0),Integer(0),Integer(0)), (Integer(0),Integer(1),
↪Integer(0)), (Integer(1),Integer(1),Integer(0)), (Integer(1),Integer(1),
↪Integer(1))], color='blue')      # needs sage.modules
>>> Diagrams().from_polyomino(p)                                      #␣
↪needs sage.modules
Traceback (most recent call last):
...
ValueError: the polyomino must be 2 dimensional
```

from_zero_one_matrix(*M*, *check=True*)

Get a diagram from a matrix with entries in $\{0, 1\}$, where positions of cells are indicated by the 1's.

EXAMPLES:

```

O . .
O . .
. . .
```

class sage.combinat.diagram.**NorthwestDiagram**(*parent*, *cells*, *n_rows=None*, *n_cols=None*, *check=True*)

Bases: `Diagram`

Diagrams with the northwest property.

A diagram is a set of cells indexed by natural numbers. Such a diagram has the *northwest property* if the presence of cells $(i1, j1)$ and $(i2, j2)$ implies the presence of the cell $(\min(i1, i2), \min(j1, j2))$. Diagrams with the northwest property are called *northwest diagrams*.

For general diagrams see `Diagram`.

EXAMPLES:

```
sage: from sage.combinat.diagram import NorthwestDiagram
sage: N = NorthwestDiagram([(0,0), (0, 2), (2,0)])
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import NorthwestDiagram
>>> N = NorthwestDiagram([(Integer(0),Integer(0)), (Integer(0), Integer(2)),␣
↪(Integer(2),Integer(0))])
```

To visualize them, use the `.pp()` method:

```
sage: N.pp()
O . O
. . .
O . .
```

```
>>> from sage.all import *
>>> N.pp()
O . O
. . .
O . .
```

check()

A diagram has the northwest property if the presence of cells $(i1, j1)$ and $(i2, j2)$ implies the presence of the cell $(min(i1, i2), min(j1, j2))$. This method checks if the northwest property is satisfied for `self`

EXAMPLES:

```
sage: from sage.combinat.diagram import NorthwestDiagram
sage: N = NorthwestDiagram([(0,0), (0,3), (3,0)])
sage: N.check()
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import NorthwestDiagram
>>> N = NorthwestDiagram([(Integer(0),Integer(0)), (Integer(0),Integer(3)),␣
↪(Integer(3),Integer(0))])
>>> N.check()
```

Here is a non-example:

```
sage: notN = NorthwestDiagram([(0,1), (1,0)])  #.check() is implicit
Traceback (most recent call last):
...
ValueError: diagram is not northwest
```

```
>>> from sage.all import *
>>> notN = NorthwestDiagram([(Integer(0),Integer(1)), (Integer(1),
↪Integer(0))])  #.check() is implicit
Traceback (most recent call last):
...
ValueError: diagram is not northwest
```

peelable_tableaux()

Return the set of peelable tableaux whose diagram is `self`.

For a fixed northwest diagram D, we say that a Young tableau T is D-peelable if:

1. the row indices of the cells in the first column of D are the entries in an initial segment in the first column of T and

2. the tableau Q obtained by removing those cells from T and playing jeu de taquin is $(D - C)$-peelable, where $D - C$ is the diagram formed by forgetting the first column of D.

Reiner and Shimozono [RS1995] showed that the number $\mathrm{red}(w)$ of reduced words of a permutation w may be computed using the peelable tableaux of the Rothe diagram $D(w)$. Explicitly,

$$\mathrm{red}(w) = \sum_T f_{\mathrm{shape}\, T},$$

where the sum runs over the $D(w)$-peelable tableaux T and f_λ is the number of standard Young tableaux of shape λ (which may be computed using the hook-length formula).

EXAMPLES:

We can compute the D-peelable diagrams for a northwest diagram D:

```
sage: from sage.combinat.diagram import NorthwestDiagram
sage: cells = [(0,0), (0,1), (0,2), (1,0), (2,0), (2,2), (2,4),
....:          (4,0), (4,2)]
sage: D = NorthwestDiagram(cells); D.pp()
O O O . .
O . . . .
O . O . O
. . . . .
O . O . .
sage: D.peelable_tableaux()
{[[1, 1, 1], [2, 3, 3], [3, 5], [5]],
[[1, 1, 1, 3], [2, 3], [3, 5], [5]]}
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import NorthwestDiagram
>>> cells = [(Integer(0),Integer(0)), (Integer(0),Integer(1)), (Integer(0),
↪Integer(2)), (Integer(1),Integer(0)), (Integer(2),Integer(0)), (Integer(2),
↪Integer(2)), (Integer(2),Integer(4)),
...          (Integer(4),Integer(0)), (Integer(4),Integer(2))]
>>> D = NorthwestDiagram(cells); D.pp()
O O O . .
O . . . .
O . O . O
. . . . .
O . O . .
>>> D.peelable_tableaux()
{[[1, 1, 1], [2, 3, 3], [3, 5], [5]],
[[1, 1, 1, 3], [2, 3], [3, 5], [5]]}
```

EXAMPLES:

If the diagram is only one column, there is only one peelable tableau:

```
sage: from sage.combinat.diagram import NorthwestDiagram
sage: NWD = NorthwestDiagram([(0,0), (2,0)])
sage: NWD.peelable_tableaux()
{[[1], [3]]}
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import NorthwestDiagram
```

(continues on next page)

(continued from previous page)

```
>>> NWD = NorthwestDiagram([(Integer(0),Integer(0)), (Integer(2),Integer(0))])
>>> NWD.peelable_tableaux()
{[[1], [3]]}
```

From [RS1995], we know that there is only one peelable tableau for the Rothe diagram of the permutation (in one line notation) 251643:

```
sage: D = NorthwestDiagram([(1, 2), (1, 3), (3, 2), (3, 3), (4, 2)])
sage: D.pp()
. . . .
. . O O
. . . .
. . O O
. . O .

sage: D.peelable_tableaux()
{[[2, 2], [4, 4], [5]]}
```

```
>>> from sage.all import *
>>> D = NorthwestDiagram([(Integer(1), Integer(2)), (Integer(1), Integer(3)),␣
↪(Integer(3), Integer(2)), (Integer(3), Integer(3)), (Integer(4),␣
↪Integer(2))])
>>> D.pp()
. . . .
. . O O
. . . .
. . O O
. . O .

>>> D.peelable_tableaux()
{[[2, 2], [4, 4], [5]]}
```

Here are all the intermediate steps to compute the peelables for the Rothe diagram of (in one-line notation) 64817235. They are listed from deepest in the recursion to the final step. The recursion has depth five in this case so we will label the intermediate tableaux by D_i where i is the step in the recursion at which they appear.

Start with the one that has a single column:

```
sage: D5 = NorthwestDiagram([(2,0)]); D5.pp()
.
.
O
sage: D5.peelable_tableaux()
{[[3]]}
```

```
>>> from sage.all import *
>>> D5 = NorthwestDiagram([(Integer(2),Integer(0))]); D5.pp()
.
.
O
>>> D5.peelable_tableaux()
{[[3]]}
```

Now we know all of the D_5 peelables, so we can compute the D_4 peelables:

```
sage: D4 = NorthwestDiagram([(0, 0), (2,0), (4, 0), (2, 2)])
sage: D4.pp()
O . .
. . .
O . O
. . .
O . .

sage: D4.peelable_tableaux()
{[[1, 3], [3], [5]]}
```

```
>>> from sage.all import *
>>> D4 = NorthwestDiagram([(Integer(0), Integer(0)), (Integer(2),Integer(0)),␣
↪(Integer(4), Integer(0)), (Integer(2), Integer(2))])
>>> D4.pp()
O . .
. . .
O . O
. . .
O . .

>>> D4.peelable_tableaux()
{[[1, 3], [3], [5]]}
```

There is only one D_4 peelable, so we can compute the D_3 peelables:

```
sage: D3 = NorthwestDiagram([(0,0), (0,1), (2, 1), (2, 3), (4,1)])
sage: D3.pp()
O O . .
. . . .
. O . O
. . . .
. O . .

sage: D3.peelable_tableaux()
{[[1, 1], [3, 3], [5]], [[1, 1, 3], [3], [5]]}
```

```
>>> from sage.all import *
>>> D3 = NorthwestDiagram([(Integer(0),Integer(0)), (Integer(0),Integer(1)),␣
↪(Integer(2), Integer(1)), (Integer(2), Integer(3)), (Integer(4),
↪Integer(1))])
>>> D3.pp()
O O . .
. . . .
. O . O
. . . .
. O . .

>>> D3.peelable_tableaux()
{[[1, 1], [3, 3], [5]], [[1, 1, 3], [3], [5]]}
```

Now compute the D_2 peelables:

```
sage: cells = [(0,0), (0,1), (0,2), (1,0), (2,0), (2,2), (2,4),
....:           (4,0), (4,2)]
sage: D2 = NorthwestDiagram(cells); D2.pp()
O O O . .
O . . . .
O . O . O
. . . . .
O . O . .

sage: D2.peelable_tableaux()
{[[1, 1, 1], [2, 3, 3], [3, 5], [5]],
[[1, 1, 1, 3], [2, 3], [3, 5], [5]]}
```

```
>>> from sage.all import *
>>> cells = [(Integer(0),Integer(0)), (Integer(0),Integer(1)), (Integer(0),
↪Integer(2)), (Integer(1),Integer(0)), (Integer(2),Integer(0)), (Integer(2),
↪Integer(2)), (Integer(2),Integer(4)),
...           (Integer(4),Integer(0)), (Integer(4),Integer(2))]
>>> D2 = NorthwestDiagram(cells); D2.pp()
O O O . .
O . . . .
O . O . O
. . . . .
O . O . .

>>> D2.peelable_tableaux()
{[[1, 1, 1], [2, 3, 3], [3, 5], [5]],
[[1, 1, 1, 3], [2, 3], [3, 5], [5]]}
```

And the D_1 peelables:

```
sage: cells = [(0,0), (0,1), (0,2), (0,3), (1,0), (1,1), (2,0),
....:           (2,1), (2,3), (2,5), (4,0), (4,1), (4,3)]
sage: D1 = NorthwestDiagram(cells); D1.pp()
O O O O . .
O O . . . .
O O . O . O
. . . . . .
O O . O . .

sage: D1.peelable_tableaux()
{[[1, 1, 1, 1], [2, 2, 3, 3], [3, 3, 5], [5, 5]],
[[1, 1, 1, 1, 3], [2, 2, 3], [3, 3, 5], [5, 5]]}
```

```
>>> from sage.all import *
>>> cells = [(Integer(0),Integer(0)), (Integer(0),Integer(1)), (Integer(0),
↪Integer(2)), (Integer(0),Integer(3)), (Integer(1),Integer(0)), (Integer(1),
↪Integer(1)), (Integer(2),Integer(0)),
...           (Integer(2),Integer(1)), (Integer(2),Integer(3)), (Integer(2),
↪Integer(5)), (Integer(4),Integer(0)), (Integer(4),Integer(1)), (Integer(4),
↪Integer(3))]
>>> D1 = NorthwestDiagram(cells); D1.pp()
```

(continues on next page)

(continued from previous page)

```
O O O O . .
O O . . . .
O O . O . O
. . . . . .
O O . O . .

>>> D1.peelable_tableaux()
{[[1, 1, 1, 1], [2, 2, 3, 3], [3, 3, 5], [5, 5]],
[[1, 1, 1, 1, 3], [2, 2, 3], [3, 3, 5], [5, 5]]}
```

Which we can use to get the D peelables:

```
sage: cells = [(0,0), (0,1), (0,2), (0,3), (0,4),
....:           (1,0), (1,1), (1,2),
....:           (2,0), (2,1), (2,2), (2,4), (2,6),
....:                  (4,1), (4,2), (4,4)]
sage: D = NorthwestDiagram(cells); D.pp()
O O O O O . .
O O O . . . .
O O O . O . O
. . . . . . .
. O O . O . .
sage: D.peelable_tableaux()
{[[1, 1, 1, 1, 1], [2, 2, 2, 3, 3], [3, 3, 3], [5, 5, 5]],
 [[1, 1, 1, 1, 1], [2, 2, 2, 3, 3], [3, 3, 3, 5], [5, 5]],
 [[1, 1, 1, 1, 1, 3], [2, 2, 2, 3], [3, 3, 3], [5, 5, 5]],
 [[1, 1, 1, 1, 1, 3], [2, 2, 2, 3], [3, 3, 3, 5], [5, 5]]}
```

```
>>> from sage.all import *
>>> cells = [(Integer(0),Integer(0)), (Integer(0),Integer(1)), (Integer(0),
↪Integer(2)), (Integer(0),Integer(3)), (Integer(0),Integer(4)),
...           (Integer(1),Integer(0)), (Integer(1),Integer(1)), (Integer(1),
↪Integer(2)),
...           (Integer(2),Integer(0)), (Integer(2),Integer(1)), (Integer(2),
↪Integer(2)), (Integer(2),Integer(4)), (Integer(2),Integer(6)),
...                  (Integer(4),Integer(1)), (Integer(4),Integer(2)),␣
↪(Integer(4),Integer(4))]
>>> D = NorthwestDiagram(cells); D.pp()
O O O O O . .
O O O . . . .
O O O . O . O
. . . . . . .
. O O . O . .
>>> D.peelable_tableaux()
{[[1, 1, 1, 1, 1], [2, 2, 2, 3, 3], [3, 3, 3], [5, 5, 5]],
 [[1, 1, 1, 1, 1], [2, 2, 2, 3, 3], [3, 3, 3, 5], [5, 5]],
 [[1, 1, 1, 1, 1, 3], [2, 2, 2, 3], [3, 3, 3], [5, 5, 5]],
 [[1, 1, 1, 1, 1, 3], [2, 2, 2, 3], [3, 3, 3, 5], [5, 5]]}
```

ALGORITHM:

This implementation uses the algorithm suggested in Remark 25 of [RS1995].

class sage.combinat.diagram.**NorthwestDiagrams**(*category=None*)

Bases: *Diagrams*

Diagrams satisfying the northwest property.

A diagram D is a *northwest diagram* if for every two cells (i_1, j_1) and (i_2, j_2) in D then there exists the cell $(\min(i_1, i_2), \min(j_1, j_2)) \in D$.

EXAMPLES:

```
sage: from sage.combinat.diagram import NorthwestDiagram
sage: N = NorthwestDiagram([(0,0), (0, 10), (5,0)]); N.pp()
O . . . . . . . . . O
. . . . . . . . . . .
. . . . . . . . . . .
. . . . . . . . . . .
. . . . . . . . . . .
O . . . . . . . . . .
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import NorthwestDiagram
>>> N = NorthwestDiagram([(Integer(0),Integer(0)), (Integer(0), Integer(10)),␣
↪(Integer(5),Integer(0))]); N.pp()
O . . . . . . . . . O
. . . . . . . . . . .
. . . . . . . . . . .
. . . . . . . . . . .
. . . . . . . . . . .
O . . . . . . . . . .
```

Note that checking whether or not the northwest property is satisfied is automatically checked. The diagram found by adding the cell $(1, 1)$ to the diagram above is *not* a northwest diagram. The cell $(1, 0)$ should be present due to the presence of $(5, 0)$ and $(1, 1)$:

```
sage: from sage.combinat.diagram import Diagram
sage: Diagram([(0, 0), (0, 10), (5, 0), (1, 1)]).pp()
O . . . . . . . . . O
. O . . . . . . . . .
. . . . . . . . . . .
. . . . . . . . . . .
. . . . . . . . . . .
O . . . . . . . . . .
sage: NorthwestDiagram([(0, 0), (0, 10), (5, 0), (1, 1)])
Traceback (most recent call last):
...
ValueError: diagram is not northwest
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> Diagram([(Integer(0), Integer(0)), (Integer(0), Integer(10)), (Integer(5),␣
↪Integer(0)), (Integer(1), Integer(1))]).pp()
O . . . . . . . . . O
. O . . . . . . . . .
. . . . . . . . . . .
```

(continues on next page)

(continued from previous page)

```
. . . . . . . . . . . .
. . . . . . . . . . . .
O . . . . . . . . . . .
>>> NorthwestDiagram([(Integer(0), Integer(0)), (Integer(0), Integer(10)),␣
↪(Integer(5), Integer(0)), (Integer(1), Integer(1))])
Traceback (most recent call last):
...
ValueError: diagram is not northwest
```

However, this behavior can be turned off if you are confident that you are providing a northwest diagram:

```
sage: N = NorthwestDiagram([(0, 0), (0, 10), (5, 0),
....:                       (1, 1), (0, 1), (1, 0)],
....:                       check=False)
sage: N.pp()
O O . . . . . . . . . O
O O . . . . . . . . . .
. . . . . . . . . . . .
. . . . . . . . . . . .
. . . . . . . . . . . .
O . . . . . . . . . . .
```

```
>>> from sage.all import *
>>> N = NorthwestDiagram([(Integer(0), Integer(0)), (Integer(0), Integer(10)),␣
↪(Integer(5), Integer(0)),
...                       (Integer(1), Integer(1)), (Integer(0), Integer(1)),␣
↪(Integer(1), Integer(0))],
...                       check=False)
>>> N.pp()
O O . . . . . . . . . O
O O . . . . . . . . . .
. . . . . . . . . . . .
. . . . . . . . . . . .
. . . . . . . . . . . .
O . . . . . . . . . . .
```

Note that arbitrary diagrams which happen to be northwest diagrams only live in the parent of `Diagrams`:

```
sage: D = Diagram([(0, 0), (0, 10), (5, 0), (1, 1), (0, 1), (1, 0)])
sage: D.pp()
O O . . . . . . . . . O
O O . . . . . . . . . .
. . . . . . . . . . . .
. . . . . . . . . . . .
. . . . . . . . . . . .
O . . . . . . . . . . .
sage: from sage.combinat.diagram import NorthwestDiagrams
sage: D in NorthwestDiagrams()
False
```

```
>>> from sage.all import *
>>> D = Diagram([(Integer(0), Integer(0)), (Integer(0), Integer(10)), (Integer(5),
```

(continues on next page)

(continued from previous page)

```
↪ Integer(0)), (Integer(1), Integer(1)), (Integer(0), Integer(1)), (Integer(1),␣
↪Integer(0))])
>>> D.pp()
O O . . . . . . . . . O
O O . . . . . . . . . .
. . . . . . . . . . . .
. . . . . . . . . . . .
. . . . . . . . . . . .
O . . . . . . . . . . .
>>> from sage.combinat.diagram import NorthwestDiagrams
>>> D in NorthwestDiagrams()
False
```

Here are some more examples:

```
sage: from sage.combinat.diagram import NorthwestDiagram, NorthwestDiagrams
sage: D = NorthwestDiagram([(0,1), (0,2), (1,1)]); D.pp()
. O O
. O .
sage: NWDgms = NorthwestDiagrams()
sage: D = NWDgms([(1,1), (1,2), (2,1)]); D.pp()
. . .
. O O
. O .
sage: D.parent()
Combinatorial northwest diagrams
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import NorthwestDiagram, NorthwestDiagrams
>>> D = NorthwestDiagram([(Integer(0),Integer(1)), (Integer(0),Integer(2)),␣
↪(Integer(1),Integer(1))]); D.pp()
. O O
. O .
>>> NWDgms = NorthwestDiagrams()
>>> D = NWDgms([(Integer(1),Integer(1)), (Integer(1),Integer(2)), (Integer(2),
↪Integer(1))]); D.pp()
. . .
. O O
. O .
>>> D.parent()
Combinatorial northwest diagrams
```

Additionally, there are natural constructions of a northwest diagram given the data of a permutation (Rothe diagrams are the prototypical example of northwest diagrams), or the data of a partition of an integer, or a skew partition.

The Rothe diagram $D(\omega)$ of a permutation ω is specified by the cells

$$D(\omega) = \{(\omega_j, i) : i < j,\, \omega_i > \omega_j\}.$$

We can construct one by calling *rothe_diagram()* method on the set of all *NorthwestDiagrams*:

```
sage: w = Permutations(4)([4,3,2,1])
sage: NorthwestDiagrams().rothe_diagram(w).pp()
```

(continues on next page)

(continued from previous page)

```
O O O .
O O . .
O . . .
. . . .
```

```
>>> from sage.all import *
>>> w = Permutations(Integer(4))([Integer(4),Integer(3),Integer(2),Integer(1)])
>>> NorthwestDiagrams().rothe_diagram(w).pp()
O O O .
O O . .
O . . .
. . . .
```

To turn a Ferrers diagram into a northwest diagram, we may call *from_partition()*. This will return a Ferrer's diagram in the set of all northwest diagrams. For many use-cases it is probably better to get Ferrer's diagrams by the corresponding method on partitions, namely `sage.combinat.partitions.Partitions.ferrers_diagram()`:

```
sage: mu = Partition([7,3,1,1])
sage: mu.pp()
*******
***
*
*
sage: NorthwestDiagrams().from_partition(mu).pp()
O O O O O O O
O O O . . . .
O . . . . . .
O . . . . . .
```

```
>>> from sage.all import *
>>> mu = Partition([Integer(7),Integer(3),Integer(1),Integer(1)])
>>> mu.pp()
*******
***
*
*
>>> NorthwestDiagrams().from_partition(mu).pp()
O O O O O O O
O O O . . . .
O . . . . . .
O . . . . . .
```

It is also possible to turn a Ferrers diagram of a skew partition into a northwest diagram, altough it is more subtle than just using the skew diagram itself. One must first reflect the partition about a vertical axis so that the skew partition looks "backwards":

```
sage: mu, nu = Partition([5,4,3,2,1]), Partition([3,2,1])
sage: s = mu/nu; s.pp()
   **
  **
 **
```

(continues on next page)

(continued from previous page)

```
**
*
sage: NorthwestDiagrams().from_skew_partition(s).pp()
O O . . .
. O O . .
. . O O .
. . . O O
. . . . O
```

```
>>> from sage.all import *
>>> mu, nu = Partition([Integer(5),Integer(4),Integer(3),Integer(2),Integer(1)]),␣
↪Partition([Integer(3),Integer(2),Integer(1)])
>>> s = mu/nu; s.pp()
   **
  **
 **
**
*
>>> NorthwestDiagrams().from_skew_partition(s).pp()
O O . . .
. O O . .
. . O O .
. . . O O
. . . . O
```

Element

alias of *NorthwestDiagram*

from_parallelogram_polyomino(*p*)

Create the diagram corresponding to a *ParallelogramPolyomino*.

EXAMPLES:

```
sage: p = ParallelogramPolyomino([[0, 0, 1, 0, 0, 0, 1, 1],                    #␣
↪needs sage.modules
....:                             [1, 1, 0, 1, 0, 0, 0, 0]])
sage: from sage.combinat.diagram import NorthwestDiagrams
sage: NorthwestDiagrams().from_parallelogram_polyomino(p).pp()                 #␣
↪needs sage.modules
O O .
O O O
. O O
. O O
. O O
```

```
>>> from sage.all import *
>>> p = ParallelogramPolyomino([[Integer(0), Integer(0), Integer(1),␣
↪Integer(0), Integer(0), Integer(0), Integer(1), Integer(1)],                  ␣
↪ # needs sage.modules
...                             [Integer(1), Integer(1), Integer(0),␣
↪Integer(1), Integer(0), Integer(0), Integer(0), Integer(0)]])
>>> from sage.combinat.diagram import NorthwestDiagrams
```

(continues on next page)

(continued from previous page)

```
>>> NorthwestDiagrams().from_parallelogram_polyomino(p).pp()              #␣
↪needs sage.modules
O O .
O O O
. O O
. O O
. O O
```

from_partition(*mu*)

Return the Ferrer's diagram of `mu` as a northwest diagram.

EXAMPLES:

```
sage: mu = Partition([5,2,1]); mu.pp()
*****
**
*
sage: mu.parent()
Partitions
sage: from sage.combinat.diagram import NorthwestDiagrams
sage: D = NorthwestDiagrams().from_partition(mu)
sage: D.pp()
O O O O O
O O . . .
O . . . .
sage: D.parent()
Combinatorial northwest diagrams
```

```
>>> from sage.all import *
>>> mu = Partition([Integer(5),Integer(2),Integer(1)]); mu.pp()
*****
**
*
>>> mu.parent()
Partitions
>>> from sage.combinat.diagram import NorthwestDiagrams
>>> D = NorthwestDiagrams().from_partition(mu)
>>> D.pp()
O O O O O
O O . . .
O . . . .
>>> D.parent()
Combinatorial northwest diagrams
```

This will print in English notation even if the notation is set to French for the partition:

```
sage: Partitions.options.convention="french"
sage: mu.pp()
*
**
*****
sage: D.pp()
```

(continues on next page)

(continued from previous page)

```
O O O O O
O O . . .
O . . . .
```

```
>>> from sage.all import *
>>> Partitions.options.convention="french"
>>> mu.pp()
*
**
*****
>>> D.pp()
O O O O O
O O . . .
O . . . .
```

from_permutation(*w*)

Return the Rothe diagram of `w`.

We construct a northwest diagram from a permutation by constructing its Rothe diagram. Formally, if ω is a *Permutation* then the Rothe diagram $D(\omega)$ is the diagram whose cells are

$$D(\omega) = \{(\omega_j, i) : i < j,\, \omega_i > \omega_j\}.$$

Informally, one can construct the Rothe diagram by starting with all n^2 possible cells, and then deleting the cells $(i, \omega(i))$ as well as all cells to the right and below. (These are sometimes called "death rays".)

RotheDiagram()

EXAMPLES:

```
sage: from sage.combinat.diagram import NorthwestDiagrams
sage: w = Permutations(3)([2,1,3])
sage: NorthwestDiagrams().rothe_diagram(w).pp()
O . .
. . .
. . .
sage: NorthwestDiagrams().from_permutation(w).pp()
O . .
. . .
. . .

sage: w = Permutations(8)([2,5,4,1,3,6,7,8])
sage: NorthwestDiagrams().rothe_diagram(w).pp()
O . . . . . . .
O . O O . . . .
O . O . . . . .
. . . . . . . .
. . . . . . . .
. . . . . . . .
```

(continues on next page)

(continued from previous page)

```
. . . . . . . .
. . . . . . . .
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import NorthwestDiagrams
>>> w = Permutations(Integer(3))([Integer(2),Integer(1),Integer(3)])
>>> NorthwestDiagrams().rothe_diagram(w).pp()
O . .
. . .
. . .
>>> NorthwestDiagrams().from_permutation(w).pp()
O . .
. . .
. . .

>>> w = Permutations(Integer(8))([Integer(2),Integer(5),Integer(4),Integer(1),
→Integer(3),Integer(6),Integer(7),Integer(8)])
>>> NorthwestDiagrams().rothe_diagram(w).pp()
O . . . . . . .
O . O O . . . .
O . O . . . . .
. . . . . . . .
. . . . . . . .
. . . . . . . .
. . . . . . . .
. . . . . . . .
```

from_skew_partition(*s*)

Get the northwest diagram found by reflecting a skew shape across a vertical plane.

EXAMPLES:

```
sage: mu, nu = Partition([3,2,1]), Partition([2,1])
sage: s = mu/nu; s.pp()
  *
 *
*
sage: from sage.combinat.diagram import NorthwestDiagrams
sage: D = NorthwestDiagrams().from_skew_partition(s)
sage: D.pp()
O . .
. O .
. . O

sage: mu, nu = Partition([3,3,2]), Partition([2,2,2])
sage: s = mu/nu; s.pp()
  *
  *
sage: NorthwestDiagrams().from_skew_partition(s).pp()
O . .
O . .
. . .
```

```
>>> from sage.all import *
>>> mu, nu = Partition([Integer(3),Integer(2),Integer(1)]),␣
↪Partition([Integer(2),Integer(1)])
>>> s = mu/nu; s.pp()
  *
 *
*
>>> from sage.combinat.diagram import NorthwestDiagrams
>>> D = NorthwestDiagrams().from_skew_partition(s)
>>> D.pp()
O . .
. O .
. . O

>>> mu, nu = Partition([Integer(3),Integer(3),Integer(2)]),␣
↪Partition([Integer(2),Integer(2),Integer(2)])
>>> s = mu/nu; s.pp()
  *
  *
>>> NorthwestDiagrams().from_skew_partition(s).pp()
O . .
O . .
. . .
```

rothe_diagram(*w*)

Return the Rothe diagram of `w`.

We construct a northwest diagram from a permutation by constructing its Rothe diagram. Formally, if ω is a `Permutation` then the Rothe diagram $D(\omega)$ is the diagram whose cells are

$$D(\omega) = \{(\omega_j, i) : i < j,\, \omega_i > \omega_j\}.$$

Informally, one can construct the Rothe diagram by starting with all n^2 possible cells, and then deleting the cells $(i, \omega(i))$ as well as all cells to the right and below. (These are sometimes called "death rays".)

O . . . . . . .
O . O O . . . .
O . O . . . . .
. . . . . . . .
. . . . . . . .
. . . . . . . .
. . . . . . . .
. . . . . . . .
```

sage.combinat.diagram.**RotheDiagram**(*w*)

The Rothe diagram of a permutation `w`.

EXAMPLES:

```
sage: w = Permutations(9)([1, 7, 4, 5, 9, 3, 2, 8, 6])
sage: from sage.combinat.diagram import RotheDiagram
sage: D = RotheDiagram(w); D.pp()
. . . . . . . . .
. O O O O O . . .
. O O . . . . . .
. O O . . . . . .
. O O . . O . O .
. O . . . . . . .
. . . . . . . . .
. . . . . O . . .
. . . . . . . . .
```

```
>>> from sage.all import *
>>> w = Permutations(Integer(9))([Integer(1), Integer(7), Integer(4), Integer(5),␣
↪Integer(9), Integer(3), Integer(2), Integer(8), Integer(6)])
>>> from sage.combinat.diagram import RotheDiagram
>>> D = RotheDiagram(w); D.pp()
. . . . . . . . .
. O O O O O . . .
. O O . . . . . .
. O O . . . . . .
. O O . . O . O .
. O . . . . . . .
. . . . . . . . .
. . . . . O . . .
. . . . . . . . .
```

The Rothe diagram is a northwest diagram:

```
sage: D.parent()
Combinatorial northwest diagrams
```

```
>>> from sage.all import *
>>> D.parent()
Combinatorial northwest diagrams
```

Some other examples:

```
sage: RotheDiagram([2, 1, 4, 3]).pp()
O . . .
. . . .
. . O .
. . . .

sage: RotheDiagram([4, 1, 3, 2]).pp()
O O O .
. . . .
. O . .
. . . .
```

```
>>> from sage.all import *
>>> RotheDiagram([Integer(2), Integer(1), Integer(4), Integer(3)]).pp()
O . . .
. . . .
. . O .
. . . .

>>> RotheDiagram([Integer(4), Integer(1), Integer(3), Integer(2)]).pp()
O O O .
. . . .
. O . .
. . . .
```

Currently, only elements of the set of `sage.combinat.permutations.Permutations` are supported. In particular, elements of permutation groups are not supported:

```
sage: w = SymmetricGroup(9).an_element()                                    #␣
↪needs sage.groups
sage: RotheDiagram(w)                                                       #␣
↪needs sage.groups
Traceback (most recent call last):
...
ValueError: w must be a permutation
```

```
>>> from sage.all import *
>>> w = SymmetricGroup(Integer(9)).an_element()                             ␣
↪     # needs sage.groups
>>> RotheDiagram(w)                                                       #␣
↪needs sage.groups
Traceback (most recent call last):
...
ValueError: w must be a permutation
```

class sage.combinat.diagram_algebras.**AbstractPartitionDiagram**(*parent*, *d*, *check=True*)

Bases: *AbstractSetPartition*

Abstract base class for partition diagrams.

This class represents a single partition diagram, that is used as a basis key for a diagram algebra element. A partition diagram should be a partition of the set $\{1, \ldots, k, -1, \ldots, -k\}$. Each such set partition is regarded as a graph on nodes $\{1, \ldots, k, -1, \ldots, -k\}$ arranged in two rows, with nodes $1, \ldots, k$ in the top row from left to right and with nodes $-1, \ldots, -k$ in the bottom row from left to right, and an edge connecting two nodes if and only if the nodes lie in the same subset of the set partition.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: pd1 = da.AbstractPartitionDiagram(pd, [[1,2],[-1,-2]])
sage: pd2 = da.AbstractPartitionDiagram(pd, [[1,2],[-1,-2]])
sage: pd1
{{-2, -1}, {1, 2}}
sage: pd1 == pd2
True
sage: pd1 == [[1,2],[-1,-2]]
```

(continues on next page)

(continued from previous page)

```
True
sage: pd1 == ((-2,-1),(2,1))
True
sage: pd1 == SetPartition([[1,2],[-1,-2]])
True
sage: pd3 = da.AbstractPartitionDiagram(pd, [[1,-2],[-1,2]])
sage: pd1 == pd3
False
sage: pd4 = da.AbstractPartitionDiagram(pd, [[1,2],[3,4]])
Traceback (most recent call last):
...
ValueError: {{1, 2}, {3, 4}} does not represent two rows of vertices of order 2
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> pd = da.AbstractPartitionDiagrams(Integer(2))
>>> pd1 = da.AbstractPartitionDiagram(pd, [[Integer(1),Integer(2)],[-Integer(1),-
↪Integer(2)]])
>>> pd2 = da.AbstractPartitionDiagram(pd, [[Integer(1),Integer(2)],[-Integer(1),-
↪Integer(2)]])
>>> pd1
{{-2, -1}, {1, 2}}
>>> pd1 == pd2
True
>>> pd1 == [[Integer(1),Integer(2)],[-Integer(1),-Integer(2)]]
True
>>> pd1 == ((-Integer(2),-Integer(1)),(Integer(2),Integer(1)))
True
>>> pd1 == SetPartition([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)]])
True
>>> pd3 = da.AbstractPartitionDiagram(pd, [[Integer(1),-Integer(2)],[-Integer(1),
↪Integer(2)]])
>>> pd1 == pd3
False
>>> pd4 = da.AbstractPartitionDiagram(pd, [[Integer(1),Integer(2)],[Integer(3),
↪Integer(4)]])
Traceback (most recent call last):
...
ValueError: {{1, 2}, {3, 4}} does not represent two rows of vertices of order 2
```

base_diagram()

Return the underlying implementation of the diagram.

OUTPUT: tuple of tuples of integers

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: pd([[1,2],[-1,-2]]).base_diagram() == ((-2,-1),(1,2))
True
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> pd = da.AbstractPartitionDiagrams(Integer(2))
>>> pd([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)]]).base_diagram() ==␣
↪((-Integer(2),-Integer(1)),(Integer(1),Integer(2)))
True
```

check()

Check the validity of the input for the diagram.

compose(*other*, *check=True*)

Compose `self` with `other`.

The composition of two diagrams X and Y is given by placing X on top of Y and removing all loops.

OUTPUT:

A tuple where the first entry is the composite diagram and the second entry is how many loop were removed.

> **Note**
>
> This is not really meant to be called directly, but it works to call it this way if desired.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: pd([[1,2],[-1,-2]]).compose(pd([[1,2],[-1,-2]]))
({{-2, -1}, {1, 2}}, 1)
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> pd = da.AbstractPartitionDiagrams(Integer(2))
>>> pd([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)]]).
↪compose(pd([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)]]))
({{-2, -1}, {1, 2}}, 1)
```

count_blocks_of_size(*n*)

Count the number of blocks of a given size.

INPUT:

- `n` – positive integer

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import PartitionDiagram
sage: pd = PartitionDiagram([[1,-3,-5],[2,4],[3,-1,-2],[5],[-4]])
sage: pd.count_blocks_of_size(1)
2
sage: pd.count_blocks_of_size(2)
1
sage: pd.count_blocks_of_size(3)
2
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import PartitionDiagram
>>> pd = PartitionDiagram([[Integer(1),-Integer(3),-Integer(5)],[Integer(2),
↪Integer(4)],[Integer(3),-Integer(1),-Integer(2)],[Integer(5)],[-
↪Integer(4)]])
>>> pd.count_blocks_of_size(Integer(1))
2
>>> pd.count_blocks_of_size(Integer(2))
1
>>> pd.count_blocks_of_size(Integer(3))
2
```

diagram()

Return the underlying implementation of the diagram.

OUTPUT: tuple of tuples of integers

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: pd([[1,2],[-1,-2]]).base_diagram() == ((-2,-1),(1,2))
True
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> pd = da.AbstractPartitionDiagrams(Integer(2))
>>> pd([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)]]).base_diagram() ==␣
↪((-Integer(2),-Integer(1)),(Integer(1),Integer(2)))
True
```

dual()

Return the dual diagram of `self` by flipping it top-to-bottom.

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import PartitionDiagram
sage: D = PartitionDiagram([[1,-1],[2,-2,-3],[3]])
sage: D.dual()
{{-3}, {-2, 2, 3}, {-1, 1}}
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import PartitionDiagram
>>> D = PartitionDiagram([[Integer(1),-Integer(1)],[Integer(2),-Integer(2),-
↪Integer(3)],[Integer(3)]])
>>> D.dual()
{{-3}, {-2, 2, 3}, {-1, 1}}
```

is_planar()

Test if the diagram `self` is planar.

A diagram element is planar if the graph of the nodes is planar.

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import BrauerDiagram
sage: BrauerDiagram([[1,-2],[2,-1]]).is_planar()
False
sage: BrauerDiagram([[1,-1],[2,-2]]).is_planar()
True
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import BrauerDiagram
>>> BrauerDiagram([[Integer(1),-Integer(2)],[Integer(2),-Integer(1)]]).is_
→planar()
False
>>> BrauerDiagram([[Integer(1),-Integer(1)],[Integer(2),-Integer(2)]]).is_
→planar()
True
```

order()

Return the maximum entry in the diagram element.

A diagram element will be a partition of the set $\{-1, -2, \ldots, -k, 1, 2, \ldots, k\}$. The order of the diagram element is the value k.

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import PartitionDiagram
sage: PartitionDiagram([[1,-1],[2,-2,-3],[3]]).order()
3
sage: PartitionDiagram([[1,-1]]).order()
1
sage: PartitionDiagram([[1,-3,-5],[2,4],[3,-1,-2],[5],[-4]]).order()
5
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import PartitionDiagram
>>> PartitionDiagram([[Integer(1),-Integer(1)],[Integer(2),-Integer(2),-
→Integer(3)],[Integer(3)]]).order()
3
>>> PartitionDiagram([[Integer(1),-Integer(1)]]).order()
1
>>> PartitionDiagram([[Integer(1),-Integer(3),-Integer(5)],[Integer(2),
→Integer(4)],[Integer(3),-Integer(1),-Integer(2)],[Integer(5)],[-
→Integer(4)]]).order()
5
```

propagating_number()

Return the propagating number of the diagram.

The propagating number is the number of blocks with both a positive and negative number.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: d1 = pd([[1,-2],[2,-1]])
sage: d1.propagating_number()
```

(continues on next page)

(continued from previous page)

```
2
sage: d2 = pd([[1,2],[-2,-1]])
sage: d2.propagating_number()
0
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> pd = da.AbstractPartitionDiagrams(Integer(2))
>>> d1 = pd([[Integer(1),-Integer(2)],[Integer(2),-Integer(1)]])
>>> d1.propagating_number()
2
>>> d2 = pd([[Integer(1),Integer(2)],[-Integer(2),-Integer(1)]])
>>> d2.propagating_number()
0
```

set_partition()

Return the underlying implementation of the diagram as a set of sets.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: X = pd([[1,2],[-1,-2]]).set_partition(); X
{{-2, -1}, {1, 2}}
sage: X.parent()
Set partitions
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> pd = da.AbstractPartitionDiagrams(Integer(2))
>>> X = pd([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)]]).set_
↪partition(); X
{{-2, -1}, {1, 2}}
>>> X.parent()
Set partitions
```

class sage.combinat.diagram_algebras.**AbstractPartitionDiagrams**(*order*, *category=None*)

Bases: `Parent`, `UniqueRepresentation`

This is an abstract base class for partition diagrams.

The primary use of this class is to serve as basis keys for diagram algebras, but diagrams also have properties in their own right. Furthermore, this class is meant to be extended to create more efficient contains methods.

INPUT:

- `order` – integer or integer $+1/2$; the order of the diagrams
- `category` – (default: `FiniteEnumeratedSets()`) the category

All concrete classes should implement attributes

- `_name` – the name of the class
- `_diagram_func` – an iterator function that takes the order as its only input

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.PartitionDiagrams(2)
sage: pd
Partition diagrams of order 2
sage: pd.an_element() in pd
True
sage: elm = pd([[1,2],[-1,-2]])
sage: elm in pd
True
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> pd = da.PartitionDiagrams(Integer(2))
>>> pd
Partition diagrams of order 2
>>> pd.an_element() in pd
True
>>> elm = pd([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)]])
>>> elm in pd
True
```

Element

alias of *AbstractPartitionDiagram*

class sage.combinat.diagram_algebras.**BrauerAlgebra**(*k*, *q*, *base_ring*, *prefix*)

Bases: *SubPartitionAlgebra*, *UnitDiagramMixin*

A Brauer algebra.

The Brauer algebra of rank k is an algebra with basis indexed by the collection of set partitions of $\{1, \ldots, k, -1, \ldots, -k\}$ with block size 2.

This algebra is a subalgebra of the partition algebra. For more information, see *PartitionAlgebra*.

INPUT:

- `k` – rank of the algebra
- `q` – the deformation parameter q
- `base_ring` – (default: `None`) a ring containing `q`; if `None` then just takes the parent of `q`
- `prefix` – (default: `'B'`) a label for the basis elements

EXAMPLES:

We now define the Brauer algebra of rank 2 with parameter `x` over $\mathbf{Z}$:

```
sage: R.<x> = ZZ[]
sage: B = BrauerAlgebra(2, x, R)
sage: B
Brauer Algebra of rank 2 with parameter x
 over Univariate Polynomial Ring in x over Integer Ring
sage: B.basis()
Lazy family (Term map from Brauer diagrams of order 2 to Brauer Algebra
 of rank 2 with parameter x over Univariate Polynomial Ring in x
 over Integer Ring(i))_{i in Brauer diagrams of order 2}
sage: B.basis().keys()
```

{{-2, 1}, {-1, 2}}
sage: b = B.basis().list(); b
[B{{-2, -1}, {1, 2}}, B{{-2, 1}, {-1, 2}}, B{{-2, 2}, {-1, 1}}]
sage: b[0]
B{{-2, -1}, {1, 2}}
sage: b[0]^2
x*B{{-2, -1}, {1, 2}}
sage: b[0]^5
x^4*B{{-2, -1}, {1, 2}}
```

```
>>> from sage.all import *
>>> R = ZZ['x']; (x,) = R._first_ngens(1)
>>> B = BrauerAlgebra(Integer(2), x, R)
>>> B
Brauer Algebra of rank 2 with parameter x
 over Univariate Polynomial Ring in x over Integer Ring
>>> B.basis()
Lazy family (Term map from Brauer diagrams of order 2 to Brauer Algebra
 of rank 2 with parameter x over Univariate Polynomial Ring in x
 over Integer Ring(i))_{i in Brauer diagrams of order 2}
>>> B.basis().keys()
Brauer diagrams of order 2
>>> B.basis().keys()([[-Integer(2), Integer(1)], [Integer(2), -Integer(1)]])
{{-2, 1}, {-1, 2}}
>>> b = B.basis().list(); b
[B{{-2, -1}, {1, 2}}, B{{-2, 1}, {-1, 2}}, B{{-2, 2}, {-1, 1}}]
>>> b[Integer(0)]
B{{-2, -1}, {1, 2}}
>>> b[Integer(0)]**Integer(2)
x*B{{-2, -1}, {1, 2}}
>>> b[Integer(0)]**Integer(5)
x^4*B{{-2, -1}, {1, 2}}
```

Note, also that since the symmetric group algebra is contained in the Brauer algebra, there is also a conversion between the two.

```
sage: R.<x> = ZZ[]
sage: B = BrauerAlgebra(2, x, R)
sage: S = SymmetricGroupAlgebra(R, 2)
sage: S([2,1])*B([[1,-1],[2,-2]])
B{{-2, 1}, {-1, 2}}
```

```
>>> from sage.all import *
>>> R = ZZ['x']; (x,) = R._first_ngens(1)
>>> B = BrauerAlgebra(Integer(2), x, R)
>>> S = SymmetricGroupAlgebra(R, Integer(2))
>>> S([Integer(2),Integer(1)])*B([[Integer(1),-Integer(1)],[Integer(2),-
↪Integer(2)]])
B{{-2, 1}, {-1, 2}}
```

jucys_murphy(*j*)

Return the j-th generalized Jucys-Murphy element of `self`.

The j-th Jucys-Murphy element of a Brauer algebra is simply the j-th Jucys-Murphy element of the symmetric group algebra with an extra $(z-1)/2$ term, where `z` is the parameter of the Brauer algebra.

REFERENCES:

EXAMPLES:

```
sage: # needs sage.symbolic
sage: z = var('z')
sage: B = BrauerAlgebra(3,z)
sage: B.jucys_murphy(1)
(1/2*z-1/2)*B{{-3, 3}, {-2, 2}, {-1, 1}}
sage: B.jucys_murphy(3)
-B{{-3, -2}, {-1, 1}, {2, 3}} - B{{-3, -1}, {-2, 2}, {1, 3}}
 + B{{-3, 1}, {-2, 2}, {-1, 3}} + B{{-3, 2}, {-2, 3}, {-1, 1}}
 + (1/2*z-1/2)*B{{-3, 3}, {-2, 2}, {-1, 1}}
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> z = var('z')
>>> B = BrauerAlgebra(Integer(3),z)
>>> B.jucys_murphy(Integer(1))
(1/2*z-1/2)*B{{-3, 3}, {-2, 2}, {-1, 1}}
>>> B.jucys_murphy(Integer(3))
-B{{-3, -2}, {-1, 1}, {2, 3}} - B{{-3, -1}, {-2, 2}, {1, 3}}
 + B{{-3, 1}, {-2, 2}, {-1, 3}} + B{{-3, 2}, {-2, 3}, {-1, 1}}
 + (1/2*z-1/2)*B{{-3, 3}, {-2, 2}, {-1, 1}}
```

options = Current options for Brauer diagram - display: normal

class sage.combinat.diagram_algebras.**BrauerDiagram**(*parent*, *d*, *check=True*)

Bases: *AbstractPartitionDiagram*

A Brauer diagram.

A Brauer diagram for an integer k is a partition of the set $\{1,\ldots,k,-1,\ldots,-k\}$ with block size 2.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(2)
sage: bd1 = bd([[1,2],[-1,-2]])
sage: bd2 = bd([[1,2,-1,-2]])
Traceback (most recent call last):
...
ValueError: all blocks of {{-2, -1, 1, 2}} must be of size 2
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> bd = da.BrauerDiagrams(Integer(2))
>>> bd1 = bd([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)]])
>>> bd2 = bd([[Integer(1),Integer(2),-Integer(1),-Integer(2)]])
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
ValueError: all blocks of {{-2, -1, 1, 2}} must be of size 2
```

bijection_on_free_nodes(*two_line=False*)

Return the induced bijection - as a list of $(x, f(x))$ values - from the free nodes on the top at the Brauer diagram to the free nodes at the bottom of `self`.

OUTPUT:

If `two_line` is `True`, then the output is the induced bijection as a two-row list `(inputs, outputs)`.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
sage: elm = bd([[1,2],[-2,-3],[3,-1]])
sage: elm.bijection_on_free_nodes()
[[3, -1]]
sage: elm2 = bd([[1,-2],[2,-3],[3,-1]])
sage: elm2.bijection_on_free_nodes(two_line=True)
[[1, 2, 3], [-2, -3, -1]]
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> bd = da.BrauerDiagrams(Integer(3))
>>> elm = bd([[Integer(1),Integer(2)],[-Integer(2),-Integer(3)],[Integer(3),-
→Integer(1)]])
>>> elm.bijection_on_free_nodes()
[[3, -1]]
>>> elm2 = bd([[Integer(1),-Integer(2)],[Integer(2),-Integer(3)],[Integer(3),-
→Integer(1)]])
>>> elm2.bijection_on_free_nodes(two_line=True)
[[1, 2, 3], [-2, -3, -1]]
```

check()

Check the validity of the input for `self`.

involution_permutation_triple(*curt=True*)

Return the involution permutation triple of `self`.

From Graham-Lehrer (see `BrauerDiagrams`), a Brauer diagram is a triple (D_1, D_2, π), where:

- D_1 is a partition of the top nodes;
- D_2 is a partition of the bottom nodes;
- π is the induced permutation on the free nodes.

INPUT:

- `curt` – boolean (default: `True`); if `True`, then return bijection on free nodes as a one-line notation (standardized to look like a permutation), else, return the honest mapping, a list of pairs $(i, -j)$ describing the bijection on free nodes

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
sage: elm = bd([[1,2],[-2,-3],[3,-1]])
sage: elm.involution_permutation_triple()
([(1, 2)], [(-3, -2)], [1])
sage: elm.involution_permutation_triple(curt=False)
([(1, 2)], [(-3, -2)], [[3, -1]])
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> bd = da.BrauerDiagrams(Integer(3))
>>> elm = bd([[Integer(1),Integer(2)],[-Integer(2),-Integer(3)],[Integer(3),-
↪Integer(1)]])
>>> elm.involution_permutation_triple()
([(1, 2)], [(-3, -2)], [1])
>>> elm.involution_permutation_triple(curt=False)
([(1, 2)], [(-3, -2)], [[3, -1]])
```

is_elementary_symmetric()

Check if is elementary symmetric.

Let (D_1, D_2, π) be the Graham-Lehrer representation of the Brauer diagram d. We say d is *elementary symmetric* if $D_1 = D_2$ and π is the identity.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
sage: elm = bd([[1,2],[-1,-2],[3,-3]])
sage: elm.is_elementary_symmetric()
True
sage: elm2 = bd([[1,2],[-1,-3],[3,-2]])
sage: elm2.is_elementary_symmetric()
False
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> bd = da.BrauerDiagrams(Integer(3))
>>> elm = bd([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)],[Integer(3),-
↪Integer(3)]])
>>> elm.is_elementary_symmetric()
True
>>> elm2 = bd([[Integer(1),Integer(2)],[-Integer(1),-Integer(3)],[Integer(3),-
↪Integer(2)]])
>>> elm2.is_elementary_symmetric()
False
```

options = Current options for Brauer diagram - display: normal

perm()

Return the induced bijection on the free nodes of `self` in one-line notation, re-indexed and treated as a permutation.

See also

bijection_on_free_nodes()

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
sage: elm = bd([[1,2],[-2,-3],[3,-1]])
sage: elm.perm()
[1]
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> bd = da.BrauerDiagrams(Integer(3))
>>> elm = bd([[Integer(1),Integer(2)],[-Integer(2),-Integer(3)],[Integer(3),-
↪Integer(1)]])
>>> elm.perm()
[1]
```

class sage.combinat.diagram_algebras.**BrauerDiagrams**(*order*, *category=None*)

Bases: *AbstractPartitionDiagrams*

This class represents all Brauer diagrams of integer or integer $+1/2$ order. For more information on Brauer diagrams, see *BrauerAlgebra*.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(2); bd
Brauer diagrams of order 2
sage: bd.list()
[{{-2, -1}, {1, 2}}, {{-2, 1}, {-1, 2}}, {{-2, 2}, {-1, 1}}]

sage: bd = da.BrauerDiagrams(5/2); bd
Brauer diagrams of order 5/2
sage: bd.list()
[{{-3, 3}, {-2, -1}, {1, 2}},
 {{-3, 3}, {-2, 1}, {-1, 2}},
 {{-3, 3}, {-2, 2}, {-1, 1}}]
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> bd = da.BrauerDiagrams(Integer(2)); bd
Brauer diagrams of order 2
>>> bd.list()
[{{-2, -1}, {1, 2}}, {{-2, 1}, {-1, 2}}, {{-2, 2}, {-1, 1}}]

>>> bd = da.BrauerDiagrams(Integer(5)/Integer(2)); bd
Brauer diagrams of order 5/2
>>> bd.list()
[{{-3, 3}, {-2, -1}, {1, 2}},
 {{-3, 3}, {-2, 1}, {-1, 2}},
```

(continues on next page)

(continued from previous page)

```
{{-3, 3}, {-2, 2}, {-1, 1}}]
```

Element

alias of *BrauerDiagram*

cardinality()

Return the cardinality of `self`.

The number of Brauer diagrams of integer order k is $(2k-1)!!$.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
sage: bd.cardinality()
15

sage: bd = da.BrauerDiagrams(7/2)
sage: bd.cardinality()
15
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> bd = da.BrauerDiagrams(Integer(3))
>>> bd.cardinality()
15

>>> bd = da.BrauerDiagrams(Integer(7)/Integer(2))
>>> bd.cardinality()
15
```

from_involution_permutation_triple(*D1_D2_pi*)

Construct a Brauer diagram of `self` from an involution permutation triple.

A Brauer diagram can be represented as a triple where the first entry is a list of arcs on the top row of the diagram, the second entry is a list of arcs on the bottom row of the diagram, and the third entry is a permutation on the remaining nodes. This triple is called the *involution permutation triple*. For more information, see [GL1996].

INPUT:

- `D1_D2_pi` – list or tuple where the first entry is a list of arcs on the top of the diagram, the second entry is a list of arcs on the bottom of the diagram, and the third entry is a permutation on the free nodes.

REFERENCES:

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(4)
sage: bd.from_involution_permutation_triple([[[1,2]],[[3,4]],[2,1]])
{{-4, -3}, {-2, 3}, {-1, 4}, {1, 2}}
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
```

(continues on next page)

(continued from previous page)

```
>>> bd = da.BrauerDiagrams(Integer(4))
>>> bd.from_involution_permutation_triple([[[Integer(1),Integer(2)]],
→[[Integer(3),Integer(4)]],[Integer(2),Integer(1)]])
{{-4, -3}, {-2, 3}, {-1, 4}, {1, 2}}
```

options = Current options for Brauer diagram - display: normal

symmetric_diagrams(*l=None*, *perm=None*)

Return the list of Brauer diagrams with symmetric placement of l arcs, and with free nodes permuted according to $perm$.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(4)
sage: bd.symmetric_diagrams(l=1, perm=[2,1])
[{{-4, -2}, {-3, 1}, {-1, 3}, {2, 4}},
 {{-4, -3}, {-2, 1}, {-1, 2}, {3, 4}},
 {{-4, -1}, {-3, 2}, {-2, 3}, {1, 4}},
 {{-4, 2}, {-3, -1}, {-2, 4}, {1, 3}},
 {{-4, 3}, {-3, 4}, {-2, -1}, {1, 2}},
 {{-4, 1}, {-3, -2}, {-1, 4}, {2, 3}}]
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> bd = da.BrauerDiagrams(Integer(4))
>>> bd.symmetric_diagrams(l=Integer(1), perm=[Integer(2),Integer(1)])
[{{-4, -2}, {-3, 1}, {-1, 3}, {2, 4}},
 {{-4, -3}, {-2, 1}, {-1, 2}, {3, 4}},
 {{-4, -1}, {-3, 2}, {-2, 3}, {1, 4}},
 {{-4, 2}, {-3, -1}, {-2, 4}, {1, 3}},
 {{-4, 3}, {-3, 4}, {-2, -1}, {1, 2}},
 {{-4, 1}, {-3, -2}, {-1, 4}, {2, 3}}]
```

class sage.combinat.diagram_algebras.**DiagramAlgebra**(*k*, *q*, *base_ring*, *prefix*, *diagrams*, *category=None*)

Bases: `CombinatorialFreeModule`

Abstract class for diagram algebras and is not designed to be used directly.

class Element

Bases: `IndexedFreeModuleElement`

An element of a diagram algebra.

This subclass provides a few additional methods for partition algebra elements. Most element methods are already implemented elsewhere.

diagram()

Return the underlying diagram of `self` if `self` is a basis element. Raises an error if `self` is not a basis element.

EXAMPLES:

```
sage: R.<x> = ZZ[]
sage: P = PartitionAlgebra(2, x, R)
sage: elt = 3*P([[1,2],[-2,-1]])
sage: elt.diagram()
{{-2, -1}, {1, 2}}
```

```
>>> from sage.all import *
>>> R = ZZ['x']; (x,) = R._first_ngens(1)
>>> P = PartitionAlgebra(Integer(2), x, R)
>>> elt = Integer(3)*P([[Integer(1),Integer(2)],[-Integer(2),-
↪Integer(1)]])
>>> elt.diagram()
{{-2, -1}, {1, 2}}
```

diagrams()

Return the diagrams in the support of `self`.

EXAMPLES:

```
sage: R.<x> = ZZ[]
sage: P = PartitionAlgebra(2, x, R)
sage: elt = 3*P([[1,2],[-2,-1]]) + P([[1,2],[-2], [-1]])
sage: sorted(elt.diagrams(), key=str)
[{{-2, -1}, {1, 2}}, {{-2}, {-1}, {1, 2}}]
```

```
>>> from sage.all import *
>>> R = ZZ['x']; (x,) = R._first_ngens(1)
>>> P = PartitionAlgebra(Integer(2), x, R)
>>> elt = Integer(3)*P([[Integer(1),Integer(2)],[-Integer(2),-
↪Integer(1)]]) + P([[Integer(1),Integer(2)],[-Integer(2)], [-
↪Integer(1)]])
>>> sorted(elt.diagrams(), key=str)
[{{-2, -1}, {1, 2}}, {{-2}, {-1}, {1, 2}}]
```

order()

Return the order of `self`.

The order of a partition algebra is defined as half of the number of nodes in the diagrams.

EXAMPLES:

```
sage: q = var('q')                                                      #␣
↪needs sage.symbolic
sage: PA = PartitionAlgebra(2, q)                                       #␣
↪needs sage.symbolic
sage: PA.order()                                                        #␣
↪needs sage.symbolic
2
```

```
>>> from sage.all import *
>>> q = var('q')                                                      #␣
↪needs sage.symbolic
>>> PA = PartitionAlgebra(Integer(2), q)                               ␣
```

(continues on next page)

(continued from previous page)

```
↪     # needs sage.symbolic
>>> PA.order()                                                           #␣
↪needs sage.symbolic
2
```

set_partitions()

Return the collection of underlying set partitions indexing the basis elements of a given diagram algebra.

Todo

Is this really necessary? deprecate?

class sage.combinat.diagram_algebras.**DiagramBasis**(*k*, *q*, *base_ring*, *prefix*, *diagrams*, *category=None*)

Bases: *DiagramAlgebra*

Abstract base class for diagram algebras in the diagram basis.

product_on_basis(*d1*, *d2*)

Return the product $D_{d_1} D_{d_2}$ by two basis diagrams.

class sage.combinat.diagram_algebras.**HalfTemperleyLiebDiagrams**(*order*, *defects*)

Bases: UniqueRepresentation, Parent

Half diagrams for the Temperley-Lieb algebra cell modules.

class Element(*parent*, *d*, *check=True*)

Bases: *AbstractPartitionDiagram*

check()

Check the validity of the input of `self`.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: htld = da.HalfTemperleyLiebDiagrams(7, 3)
sage: htld([[1,2], [3,4]])  # indirect doctest
{{1, 2}, {3, 4}}
sage: htld([[1,2], [-1, -2]])  # indirect doctest
Traceback (most recent call last):
...
ValueError: {{-2, -1}, {1, 2}} does not represent a half TL diagram of␣
↪order 7
sage: htld([[1,2,3], [4,5]])  # indirect doctest
Traceback (most recent call last):
...
ValueError: all blocks of {{1, 2, 3}, {4, 5}} must be of size 2
sage: htld([[1,2], [3,4], [5,6]])  # indirect doctest
Traceback (most recent call last):
...
ValueError: {{1, 2}, {3, 4}, {5, 6}} does not have 3 defects
sage: htld([[1,3], [2,4]])  # indirect doctest
Traceback (most recent call last):
...
ValueError: {{1, 3}, {2, 4}} is not planar
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> htld = da.HalfTemperleyLiebDiagrams(Integer(7), Integer(3))
>>> htld([[Integer(1),Integer(2)], [Integer(3),Integer(4)]])  # indirect␣
↪doctest
{{1, 2}, {3, 4}}
>>> htld([[Integer(1),Integer(2)], [-Integer(1), -Integer(2)]])  #␣
↪indirect doctest
Traceback (most recent call last):
...
ValueError: {{-2, -1}, {1, 2}} does not represent a half TL diagram of␣
↪order 7
>>> htld([[Integer(1),Integer(2),Integer(3)], [Integer(4),Integer(5)]])
↪# indirect doctest
Traceback (most recent call last):
...
ValueError: all blocks of {{1, 2, 3}, {4, 5}} must be of size 2
>>> htld([[Integer(1),Integer(2)], [Integer(3),Integer(4)], [Integer(5),
↪Integer(6)]])  # indirect doctest
Traceback (most recent call last):
...
ValueError: {{1, 2}, {3, 4}, {5, 6}} does not have 3 defects
>>> htld([[Integer(1),Integer(3)], [Integer(2),Integer(4)]])  # indirect␣
↪doctest
Traceback (most recent call last):
...
ValueError: {{1, 3}, {2, 4}} is not planar
```

defects()

Return the defects of `self`.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: htld = da.HalfTemperleyLiebDiagrams(7, 3)
sage: d = htld([[1, 2], [4, 5]])
sage: d.defects()
frozenset({3, 6, 7})
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> htld = da.HalfTemperleyLiebDiagrams(Integer(7), Integer(3))
>>> d = htld([[Integer(1), Integer(2)], [Integer(4), Integer(5)]])
>>> d.defects()
frozenset({3, 6, 7})
```

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: htld = da.HalfTemperleyLiebDiagrams(7, 3)
```

(continues on next page)

(continued from previous page)

```
sage: htld.cardinality()
14
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> htld = da.HalfTemperleyLiebDiagrams(Integer(7), Integer(3))
>>> htld.cardinality()
14
```

class sage.combinat.diagram_algebras.**IdealDiagram**(*parent*, *d*, *check=True*)

Bases: *AbstractPartitionDiagram*

The element class for a ideal diagram.

An ideal diagram for an integer k is a partition of the set $\{1, \ldots, k, -1, \ldots, -k\}$ where the propagating number is strictly smaller than the order.

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import IdealDiagrams as IDs
sage: IDs(2)
Ideal diagrams of order 2
sage: IDs(2).list()
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2}, {-1, 1, 2}},
 {{-2, -1}, {1, 2}},
 {{-2}, {-1}, {1, 2}},
 {{-2, -1, 1}, {2}},
 {{-2, 1}, {-1}, {2}},
 {{-2, -1, 2}, {1}},
 {{-2, 2}, {-1}, {1}},
 {{-2}, {-1, 1}, {2}},
 {{-2}, {-1, 2}, {1}},
 {{-2, -1}, {1}, {2}},
 {{-2}, {-1}, {1}, {2}}]

sage: from sage.combinat.diagram_algebras import PartitionDiagrams as PDs
sage: PDs(4).cardinality() == factorial(4) + IDs(4).cardinality()
True
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import IdealDiagrams as IDs
>>> IDs(Integer(2))
Ideal diagrams of order 2
>>> IDs(Integer(2)).list()
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2}, {-1, 1, 2}},
 {{-2, -1}, {1, 2}},
 {{-2}, {-1}, {1, 2}},
 {{-2, -1, 1}, {2}},
 {{-2, 1}, {-1}, {2}},
```

(continues on next page)

(continued from previous page)

```
 {{-2, -1, 2}, {1}},
 {{-2, 2}, {-1}, {1}},
 {{-2}, {-1, 1}, {2}},
 {{-2}, {-1, 2}, {1}},
 {{-2, -1}, {1}, {2}},
 {{-2}, {-1}, {1}, {2}}]

>>> from sage.combinat.diagram_algebras import PartitionDiagrams as PDs
>>> PDs(Integer(4)).cardinality() == factorial(Integer(4)) + IDs(Integer(4)).
↪cardinality()
True
```

check()

Check the validity of the input for `self`.

class sage.combinat.diagram_algebras.**IdealDiagrams**(*order*, *category=None*)

Bases: *AbstractPartitionDiagrams*

All "ideal" diagrams of integer or integer $+1/2$ order.

If k is an integer then an ideal diagram of order k is a partition diagram of order k with propagating number less than k.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: id = da.IdealDiagrams(3)
sage: id.an_element() in id
True
sage: id.cardinality() == len(id.list())
True
sage: da.IdealDiagrams(3/2).list()
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2, -1, 2}, {1}},
 {{-2, 2}, {-1}, {1}}]
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> id = da.IdealDiagrams(Integer(3))
>>> id.an_element() in id
True
>>> id.cardinality() == len(id.list())
True
>>> da.IdealDiagrams(Integer(3)/Integer(2)).list()
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2, -1, 2}, {1}},
 {{-2, 2}, {-1}, {1}}]
```

Element

alias of *IdealDiagram*

class sage.combinat.diagram_algebras.**OrbitBasis**(*alg*)

Bases: *DiagramAlgebra*

The orbit basis of the partition algebra.

Let D_π represent the diagram basis element indexed by the partition π, then (see equations (2.14), (2.17) and (2.18) of [BH2017])

$$D_\pi = \sum_{\tau \geq \pi} O_\tau,$$

where the sum is over all partitions τ which are coarser than π and O_τ is the orbit basis element indexed by the partition τ.

If $\mu_{2k}(\pi, \tau)$ represents the Moebius function of the partition lattice, then

$$O_\pi = \sum_{\tau \geq \pi} \mu_{2k}(\pi, \tau) D_\tau.$$

If τ is a partition of ℓ blocks and the i-th block of τ is a union of b_i blocks of π, then

$$\mu_{2k}(\pi, \tau) = \prod_{i=1}^{\ell} (-1)^{b_i - 1} (b_i - 1)!.$$

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: P2 = PartitionAlgebra(2, x, R)
sage: O2 = P2.orbit_basis(); O2
Orbit basis of Partition Algebra of rank 2 with parameter x over
 Univariate Polynomial Ring in x over Rational Field
sage: oa = O2([[1],[-1],[2,-2]]); ob = O2([[-1,-2,2],[1]]); oa, ob
(O{{-2, 2}, {-1}, {1}}, O{{-2, -1, 2}, {1}})
sage: oa * ob
(x-2)*O{{-2, -1, 2}, {1}}
```

```
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> P2 = PartitionAlgebra(Integer(2), x, R)
>>> O2 = P2.orbit_basis(); O2
Orbit basis of Partition Algebra of rank 2 with parameter x over
 Univariate Polynomial Ring in x over Rational Field
>>> oa = O2([[Integer(1)],[-Integer(1)],[Integer(2),-Integer(2)]]); ob = O2([[-
↪Integer(1),-Integer(2),Integer(2)],[Integer(1)]]); oa, ob
(O{{-2, 2}, {-1}, {1}}, O{{-2, -1, 2}, {1}})
>>> oa * ob
(x-2)*O{{-2, -1, 2}, {1}}
```

We can convert between the two bases:

```
sage: pa = P2(oa); pa
2*P{{-2, -1, 1, 2}} - P{{-2, -1, 2}, {1}} - P{{-2, 1, 2}, {-1}}
 + P{{-2, 2}, {-1}, {1}} - P{{-2, 2}, {-1, 1}}
sage: pa * ob
(-x+2)*P{{-2, -1, 1, 2}} + (x-2)*P{{-2, -1, 2}, {1}}
```

(continues on next page)

(continued from previous page)

```
sage: _ == pa * P2(ob)
True
sage: O2(pa * ob)
(x-2)*O{{-2, -1, 2}, {1}}
```

```
>>> from sage.all import *
>>> pa = P2(oa); pa
2*P{{-2, -1, 1, 2}} - P{{-2, -1, 2}, {1}} - P{{-2, 1, 2}, {-1}}
 + P{{-2, 2}, {-1}, {1}} - P{{-2, 2}, {-1, 1}}
>>> pa * ob
(-x+2)*P{{-2, -1, 1, 2}} + (x-2)*P{{-2, -1, 2}, {1}}
>>> _ == pa * P2(ob)
True
>>> O2(pa * ob)
(x-2)*O{{-2, -1, 2}, {1}}
```

Note that the unit in the orbit basis is not a single diagram, in contrast to the natural diagram basis:

```
sage: P2.one()
P{{-2, 2}, {-1, 1}}
sage: O2.one()
O{{-2, -1, 1, 2}} + O{{-2, 2}, {-1, 1}}
sage: O2.one() == P2.one()
True
```

```
>>> from sage.all import *
>>> P2.one()
P{{-2, 2}, {-1, 1}}
>>> O2.one()
O{{-2, -1, 1, 2}} + O{{-2, 2}, {-1, 1}}
>>> O2.one() == P2.one()
True
```

class Element

Bases: *Element*

to_diagram_basis()

Expand `self` in the natural diagram basis of the partition algebra.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(2, x, R)
sage: O = P.orbit_basis()
sage: elt = O.an_element(); elt
3*O{{-2}, {-1, 1, 2}} + 2*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
sage: elt.to_diagram_basis()
3*P{{-2}, {-1, 1, 2}} - 3*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
sage: pp = P.an_element(); pp
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
sage: op = pp.to_orbit_basis(); op
3*O{{-2}, {-1, 1, 2}} + 7*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
```

(continues on next page)

(continued from previous page)

```
sage: pp == op.to_diagram_basis()
True
```

```
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> P = PartitionAlgebra(Integer(2), x, R)
>>> O = P.orbit_basis()
>>> elt = O.an_element(); elt
3*O{{-2}, {-1, 1, 2}} + 2*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
>>> elt.to_diagram_basis()
3*P{{-2}, {-1, 1, 2}} - 3*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
>>> pp = P.an_element(); pp
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
>>> op = pp.to_orbit_basis(); op
3*O{{-2}, {-1, 1, 2}} + 7*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
>>> pp == op.to_diagram_basis()
True
```

diagram_basis()

Return the associated partition algebra of `self` in the diagram basis.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: O2 = PartitionAlgebra(2, x, R).orbit_basis()
sage: P2 = O2.diagram_basis(); P2
Partition Algebra of rank 2 with parameter x over Univariate
Polynomial Ring in x over Rational Field
sage: o2 = O2.an_element(); o2
3*O{{-2}, {-1, 1, 2}} + 2*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
sage: P2(o2)
3*P{{-2}, {-1, 1, 2}} - 3*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
```

```
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> O2 = PartitionAlgebra(Integer(2), x, R).orbit_basis()
>>> P2 = O2.diagram_basis(); P2
Partition Algebra of rank 2 with parameter x over Univariate
Polynomial Ring in x over Rational Field
>>> o2 = O2.an_element(); o2
3*O{{-2}, {-1, 1, 2}} + 2*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
>>> P2(o2)
3*P{{-2}, {-1, 1, 2}} - 3*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
```

one()

Return the element 1 of the partition algebra in the orbit basis.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: P2 = PartitionAlgebra(2, x, R)
sage: O2 = P2.orbit_basis()
```

(continues on next page)

(continued from previous page)

```
sage: O2.one()
O{{-2, -1, 1, 2}} + O{{-2, 2}, {-1, 1}}
```

```
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> P2 = PartitionAlgebra(Integer(2), x, R)
>>> O2 = P2.orbit_basis()
>>> O2.one()
O{{-2, -1, 1, 2}} + O{{-2, 2}, {-1, 1}}
```

product_on_basis(*d1*, *d2*)

Return the product $O_{d_1} O_{d_2}$ of two elements in the orbit basis `self`.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: OP = PartitionAlgebra(2, x, R).orbit_basis()
sage: SP = OP.basis().keys(); sp = SP([[-2, -1, 1, 2]])
sage: OP.product_on_basis(sp, sp)
O{{-2, -1, 1, 2}}
sage: o1 = OP.one(); o2 = OP([]); o3 = OP.an_element()
sage: o2 == o1
False
sage: o1 * o1 == o1
True
sage: o3 * o1 == o1 * o3 and o3 * o1 == o3
True
sage: o4 = (3*OP([[-2, -1, 1], [2]]) + 2*OP([[-2, -1, 1, 2]])
....:       + 2*OP([[-2, -1, 2], [1]]))
sage: o4 * o4
6*O{{-2, -1, 1}, {2}} + 4*O{{-2, -1, 1, 2}} + 4*O{{-2, -1, 2}, {1}}
```

```
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> OP = PartitionAlgebra(Integer(2), x, R).orbit_basis()
>>> SP = OP.basis().keys(); sp = SP([[-Integer(2), -Integer(1), Integer(1),␣
↪Integer(2)]])
>>> OP.product_on_basis(sp, sp)
O{{-2, -1, 1, 2}}
>>> o1 = OP.one(); o2 = OP([]); o3 = OP.an_element()
>>> o2 == o1
False
>>> o1 * o1 == o1
True
>>> o3 * o1 == o1 * o3 and o3 * o1 == o3
True
>>> o4 = (Integer(3)*OP([[-Integer(2), -Integer(1), Integer(1)],␣
↪[Integer(2)]]) + Integer(2)*OP([[-Integer(2), -Integer(1), Integer(1),␣
↪Integer(2)]])
...       + Integer(2)*OP([[-Integer(2), -Integer(1), Integer(2)],␣
↪[Integer(1)]]))
>>> o4 * o4
```

(continues on next page)

(continued from previous page)

```
6*O{{-2, -1, 1}, {2}} + 4*O{{-2, -1, 1, 2}} + 4*O{{-2, -1, 2}, {1}}
```

We compute Examples 4.5 in [BH2017]:

```
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(3,x); O = P.orbit_basis()
sage: O[[1,2,3],[-1,-2,-3]] * O[[1,2,3],[-1,-2,-3]]
(x-2)*O{{-3, -2, -1}, {1, 2, 3}} + (x-1)*O{{-3, -2, -1, 1, 2, 3}}

sage: P = PartitionAlgebra(4,x); O = P.orbit_basis()
sage: O[[1],[-1],[2,3],[4,-2],[-3,-4]] * O[[1],[2,-2],[3,4],[-1,-3],[-4]]
(x^2-11*x+30)*O{{-4}, {-3, -1}, {-2, 4}, {1}, {2, 3}}
 + (x^2-9*x+20)*O{{-4}, {-3, -1, 1}, {-2, 4}, {2, 3}}
 + (x^2-9*x+20)*O{{-4}, {-3, -1, 2, 3}, {-2, 4}, {1}}
 + (x^2-9*x+20)*O{{-4, 1}, {-3, -1}, {-2, 4}, {2, 3}}
 + (x^2-7*x+12)*O{{-4, 1}, {-3, -1, 2, 3}, {-2, 4}}
 + (x^2-9*x+20)*O{{-4, 2, 3}, {-3, -1}, {-2, 4}, {1}}
 + (x^2-7*x+12)*O{{-4, 2, 3}, {-3, -1, 1}, {-2, 4}}

sage: O[[1,-1],[2,-2],[3],[4,-3],[-4]] * O[[1,-2],[2],[3,-1],[4],[-3],[-4]]
(x-6)*O{{-4}, {-3}, {-2, 1}, {-1, 4}, {2}, {3}}
 + (x-5)*O{{-4}, {-3, 3}, {-2, 1}, {-1, 4}, {2}}
 + (x-5)*O{{-4, 3}, {-3}, {-2, 1}, {-1, 4}, {2}}

sage: P = PartitionAlgebra(6,x); O = P.orbit_basis()
sage: (O[[1,-2,-3],[2,4],[3,5,-6],[6],[-1],[-4,-5]]
....:  * O[[1,-2],[2,3],[4],[5],[6,-4,-5,-6],[-1,-3]])
0

sage: (O[[1,-2],[2,-3],[3,5],[4,-5],[6,-4],[-1],[-6]]
....:  * O[[1,-2],[2,-1],[3,-4],[4,-6],[5,-3],[6,-5]])
O{{-6, 6}, {-5}, {-4, 2}, {-3, 4}, {-2}, {-1, 1}, {3, 5}}
```

```
>>> from sage.all import *

class sage.combinat.diagram_algebras.**PartitionAlgebra**(*k*, *q*, *base_ring*, *prefix*)

Bases: *DiagramBasis*, *UnitDiagramMixin*

A partition algebra.

A partition algebra of rank k over a given ground ring R is an algebra with (R-module) basis indexed by the collection of set partitions of $\{1,\ldots,k,-1,\ldots,-k\}$. Each such set partition can be represented by a graph on nodes $\{1,\ldots,k,-1,\ldots,-k\}$ arranged in two rows, with nodes $1,\ldots,k$ in the top row from left to right and with nodes $-1,\ldots,-k$ in the bottom row from left to right, and edges drawn such that the connected components of the graph are precisely the parts of the set partition. (This choice of edges is often not unique, and so there are often many graphs representing one and the same set partition; the representation nevertheless is useful and vivid. We often speak of "diagrams" to mean graphs up to such equivalence of choices of edges; of course, we could just as well speak of set partitions.)

There is not just one partition algebra of given rank over a given ground ring, but rather a whole family of them, indexed by the elements of R. More precisely, for every $q\in R$, the partition algebra of rank k over R with parameter q is defined to be the R-algebra with basis the collection of all set partitions of $\{1,\ldots,k,-1,\ldots,-k\}$, where the product of two basis elements is given by the rule

$$a\cdot b=q^N(a\circ b),$$

where $a\circ b$ is the composite set partition obtained by placing the diagram (i.e., graph) of a above the diagram of b, identifying the bottom row nodes of a with the top row nodes of b, and omitting any closed "loops" in the middle. The number N is the number of connected components formed by the omitted loops.

The parameter q is a deformation parameter. Taking $q = 1$ produces the semigroup algebra (over the base ring) of the partition monoid, in which the product of two set partitions is simply given by their composition.

The partition algebra is regarded as an example of a "diagram algebra" due to the fact that its natural basis is given by certain graphs often called diagrams.

There are a number of predefined elements for the partition algebra. We define the cup/cap pair by `a()`. The simple transpositions are denoted `s()`. Finally, we define elements `e()`, where if $i = (2r + 1)/2$, then `e(i)` contains the blocks $\{r + 1\}$ and $\{-r - 1\}$ and if $i \in \mathbf{Z}$, then e_i contains the block $\{-i, -i - 1, i, i + 1\}$, with all other blocks being $\{-j, j\}$. So we have:

```
sage: P = PartitionAlgebra(4, 0)
sage: P.a(2)
P{{-4, 4}, {-3, -2}, {-1, 1}, {2, 3}}
sage: P.e(3/2)
P{{-4, 4}, {-3, 3}, {-2}, {-1, 1}, {2}}
sage: P.e(2)
P{{-4, 4}, {-3, -2, 2, 3}, {-1, 1}}
sage: P.e(5/2)
P{{-4, 4}, {-3}, {-2, 2}, {-1, 1}, {3}}
sage: P.s(2)
P{{-4, 4}, {-3, 2}, {-2, 3}, {-1, 1}}
```

```
>>> from sage.all import *
>>> P = PartitionAlgebra(Integer(4), Integer(0))
>>> P.a(Integer(2))
P{{-4, 4}, {-3, -2}, {-1, 1}, {2, 3}}
>>> P.e(Integer(3)/Integer(2))
P{{-4, 4}, {-3, 3}, {-2}, {-1, 1}, {2}}
>>> P.e(Integer(2))
P{{-4, 4}, {-3, -2, 2, 3}, {-1, 1}}
>>> P.e(Integer(5)/Integer(2))
P{{-4, 4}, {-3}, {-2, 2}, {-1, 1}, {3}}
>>> P.s(Integer(2))
P{{-4, 4}, {-3, 2}, {-2, 3}, {-1, 1}}
```

An excellent reference for partition algebras and their various subalgebras (Brauer algebra, Temperley–Lieb algebra, etc) is the paper [HR2005].

INPUT:

- `k` – rank of the algebra
- `q` – the deformation parameter q
- `base_ring` – (default: `None`) a ring containing `q`; if `None`, then Sage automatically chooses the parent of `q`
- `prefix` – (default: `'P'`) a label for the basis elements

EXAMPLES:

The following shorthand simultaneously defines the univariate polynomial ring over the rationals as well as the variable `x`:

```
sage: R.<x> = PolynomialRing(QQ)
sage: R
Univariate Polynomial Ring in x over Rational Field
sage: x
```

(continues on next page)

(continued from previous page)

```
x
sage: x.parent() is R
True
```

```
>>> from sage.all import *
>>> R = PolynomialRing(QQ, names=('x',)); (x,) = R._first_ngens(1)
>>> R
Univariate Polynomial Ring in x over Rational Field
>>> x
x
>>> x.parent() is R
True
```

We now define the partition algebra of rank 2 with parameter x over **Z** in the usual (diagram) basis:

```
sage: R.<x> = ZZ[]
sage: A2 = PartitionAlgebra(2, x, R)
sage: A2
Partition Algebra of rank 2 with parameter x
 over Univariate Polynomial Ring in x over Integer Ring
sage: A2.basis().keys()
Partition diagrams of order 2
sage: A2.basis().keys()([[-2, 1, 2], [-1]])
{{-2, 1, 2}, {-1}}
sage: A2.basis().list()
[P{{-2, -1, 1, 2}}, P{{-2, 1, 2}, {-1}},
 P{{-2}, {-1, 1, 2}}, P{{-2, -1}, {1, 2}},
 P{{-2}, {-1}, {1, 2}}, P{{-2, -1, 1}, {2}},
 P{{-2, 1}, {-1, 2}}, P{{-2, 1}, {-1}, {2}},
 P{{-2, 2}, {-1, 1}}, P{{-2, -1, 2}, {1}},
 P{{-2, 2}, {-1}, {1}}, P{{-2}, {-1, 1}, {2}},
 P{{-2}, {-1, 2}, {1}}, P{{-2, -1}, {1}, {2}},
 P{{-2}, {-1}, {1}, {2}}]
sage: E = A2([[1,2],[-2,-1]]); E
P{{-2, -1}, {1, 2}}
sage: E in A2.basis().list()
True
sage: E^2
x*P{{-2, -1}, {1, 2}}
sage: E^5
x^4*P{{-2, -1}, {1, 2}}
sage: (A2([[2,-2],[-1,1]]) - 2*A2([[1,2],[-1,-2]]))^2
(4*x-4)*P{{-2, -1}, {1, 2}} + P{{-2, 2}, {-1, 1}}
```

```
>>> from sage.all import *
>>> R = ZZ['x']; (x,) = R._first_ngens(1)
>>> A2 = PartitionAlgebra(Integer(2), x, R)
>>> A2
Partition Algebra of rank 2 with parameter x
 over Univariate Polynomial Ring in x over Integer Ring
>>> A2.basis().keys()
Partition diagrams of order 2
```

(continues on next page)

(continued from previous page)

```
>>> A2.basis().keys()([[-Integer(2), Integer(1), Integer(2)], [-Integer(1)]])
{{-2, 1, 2}, {-1}}
>>> A2.basis().list()
[P{{-2, -1, 1, 2}}, P{{-2, 1, 2}, {-1}},
 P{{-2}, {-1, 1, 2}}, P{{-2, -1}, {1, 2}},
 P{{-2}, {-1}, {1, 2}}, P{{-2, -1, 1}, {2}},
 P{{-2, 1}, {-1, 2}}, P{{-2, 1}, {-1}, {2}},
 P{{-2, 2}, {-1, 1}}, P{{-2, -1, 2}, {1}},
 P{{-2, 2}, {-1}, {1}}, P{{-2}, {-1, 1}, {2}},
 P{{-2}, {-1, 2}, {1}}, P{{-2, -1}, {1}, {2}},
 P{{-2}, {-1}, {1}, {2}}]
>>> E = A2([[Integer(1),Integer(2)],[-Integer(2),-Integer(1)]]); E
P{{-2, -1}, {1, 2}}
>>> E in A2.basis().list()
True
>>> E**Integer(2)
x*P{{-2, -1}, {1, 2}}
>>> E**Integer(5)
x^4*P{{-2, -1}, {1, 2}}
>>> (A2([[Integer(2),-Integer(2)],[-Integer(1),Integer(1)]]) -␣
↪Integer(2)*A2([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)]]))**Integer(2)
(4*x-4)*P{{-2, -1}, {1, 2}} + P{{-2, 2}, {-1, 1}}
```

Next, we construct an element:

```
sage: a2 = A2.an_element(); a2
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
```

```
>>> from sage.all import *
>>> a2 = A2.an_element(); a2
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
```

There is a natural embedding into partition algebras on more elements, by adding identity strands:

```
sage: A4 = PartitionAlgebra(4, x, R)
sage: A4(a2)
3*P{{-4, 4}, {-3, 3}, {-2}, {-1, 1, 2}}
 + 2*P{{-4, 4}, {-3, 3}, {-2, -1, 1, 2}}
 + 2*P{{-4, 4}, {-3, 3}, {-2, 1, 2}, {-1}}
```

```
>>> from sage.all import *
>>> A4 = PartitionAlgebra(Integer(4), x, R)
>>> A4(a2)
3*P{{-4, 4}, {-3, 3}, {-2}, {-1, 1, 2}}
 + 2*P{{-4, 4}, {-3, 3}, {-2, -1, 1, 2}}
 + 2*P{{-4, 4}, {-3, 3}, {-2, 1, 2}, {-1}}
```

Thus, the empty partition corresponds to the identity:

```
sage: A4([])
P{{-4, 4}, {-3, 3}, {-2, 2}, {-1, 1}}
sage: A4(5)
```

(continues on next page)

(continued from previous page)

```
5*P{{-4, 4}, {-3, 3}, {-2, 2}, {-1, 1}}
```

```
>>> from sage.all import *
>>> A4([])
P{{-4, 4}, {-3, 3}, {-2, 2}, {-1, 1}}
>>> A4(Integer(5))
5*P{{-4, 4}, {-3, 3}, {-2, 2}, {-1, 1}}
```

The group algebra of the symmetric group is a subalgebra:

```
sage: S3 = SymmetricGroupAlgebra(ZZ, 3)
sage: s3 = S3.an_element(); s3
[1, 2, 3] + 2*[1, 3, 2] + 3*[2, 1, 3] + [3, 1, 2]
sage: A4(s3)
P{{-4, 4}, {-3, 1}, {-2, 3}, {-1, 2}}
 + 2*P{{-4, 4}, {-3, 2}, {-2, 3}, {-1, 1}}
 + 3*P{{-4, 4}, {-3, 3}, {-2, 1}, {-1, 2}}
 + P{{-4, 4}, {-3, 3}, {-2, 2}, {-1, 1}}
sage: A4([2,1])
P{{-4, 4}, {-3, 3}, {-2, 1}, {-1, 2}}
```

```
>>> from sage.all import *
>>> S3 = SymmetricGroupAlgebra(ZZ, Integer(3))
>>> s3 = S3.an_element(); s3
[1, 2, 3] + 2*[1, 3, 2] + 3*[2, 1, 3] + [3, 1, 2]
>>> A4(s3)
P{{-4, 4}, {-3, 1}, {-2, 3}, {-1, 2}}
 + 2*P{{-4, 4}, {-3, 2}, {-2, 3}, {-1, 1}}
 + 3*P{{-4, 4}, {-3, 3}, {-2, 1}, {-1, 2}}
 + P{{-4, 4}, {-3, 3}, {-2, 2}, {-1, 1}}
>>> A4([Integer(2),Integer(1)])
P{{-4, 4}, {-3, 3}, {-2, 1}, {-1, 2}}
```

Be careful not to confuse the embedding of the group algebra of the symmetric group with the embedding of partial set partitions. The latter are embedded by adding the parts $\{i, -i\}$ if possible, and singletons sets for the remaining parts:

```
sage: A4([[2,1]])
P{{-4, 4}, {-3, 3}, {-2}, {-1}, {1, 2}}
sage: A4([[-1,3],[-2,-3,1]])
P{{-4, 4}, {-3, -2, 1}, {-1, 3}, {2}}
```

```
>>> from sage.all import *
>>> A4([[Integer(2),Integer(1)]])
P{{-4, 4}, {-3, 3}, {-2}, {-1}, {1, 2}}
>>> A4([[-Integer(1),Integer(3)],[-Integer(2),-Integer(3),Integer(1)]])
P{{-4, 4}, {-3, -2, 1}, {-1, 3}, {2}}
```

Another subalgebra is the Brauer algebra, which has perfect matchings as basis elements. The group algebra of the symmetric group is in fact a subalgebra of the Brauer algebra:

```
sage: B3 = BrauerAlgebra(3, x, R)
sage: b3 = B3(s3); b3
B{{-3, 1}, {-2, 3}, {-1, 2}} + 2*B{{-3, 2}, {-2, 3}, {-1, 1}}
 + 3*B{{-3, 3}, {-2, 1}, {-1, 2}} + B{{-3, 3}, {-2, 2}, {-1, 1}}
```

```
>>> from sage.all import *
>>> B3 = BrauerAlgebra(Integer(3), x, R)
>>> b3 = B3(s3); b3
B{{-3, 1}, {-2, 3}, {-1, 2}} + 2*B{{-3, 2}, {-2, 3}, {-1, 1}}
 + 3*B{{-3, 3}, {-2, 1}, {-1, 2}} + B{{-3, 3}, {-2, 2}, {-1, 1}}
```

An important basis of the partition algebra is the `orbit basis`:

```
sage: O2 = A2.orbit_basis()
sage: o2 = O2([[1,2],[-1,-2]]) + O2([[1,2,-1,-2]]); o2
O{{-2, -1}, {1, 2}} + O{{-2, -1, 1, 2}}
```

```
>>> from sage.all import *
>>> O2 = A2.orbit_basis()
>>> o2 = O2([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)]]) +␣
→O2([[Integer(1),Integer(2),-Integer(1),-Integer(2)]]); o2
O{{-2, -1}, {1, 2}} + O{{-2, -1, 1, 2}}
```

The diagram basis element corresponds to the sum of all orbit basis elements indexed by coarser set partitions:

```
sage: A2(o2)
P{{-2, -1}, {1, 2}}
```

```
>>> from sage.all import *
>>> A2(o2)
P{{-2, -1}, {1, 2}}
```

We can convert back from the orbit basis to the diagram basis:

```
sage: o2 = O2.an_element(); o2
3*O{{-2}, {-1, 1, 2}} + 2*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
sage: A2(o2)
3*P{{-2}, {-1, 1, 2}} - 3*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
```

```
>>> from sage.all import *
>>> o2 = O2.an_element(); o2
3*O{{-2}, {-1, 1, 2}} + 2*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
>>> A2(o2)
3*P{{-2}, {-1, 1, 2}} - 3*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
```

One can work with partition algebras using a symbol for the parameter, leaving the base ring unspecified. This implies that the underlying base ring is Sage's symbolic ring.

```
sage: # needs sage.symbolic
sage: q = var('q')
sage: PA = PartitionAlgebra(2, q); PA
Partition Algebra of rank 2 with parameter q over Symbolic Ring
```

(continues on next page)

(continued from previous page)

```
sage: PA([[1,2],[-2,-1]])^2 == q*PA([[1,2],[-2,-1]])
True
sage: ((PA([[2, -2], [1, -1]]) - 2*PA([[-2, -1], [1, 2]]))^2
....:    == (4*q-4)*PA([[1, 2], [-2, -1]]) + PA([[2, -2], [1, -1]]))
True
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> q = var('q')
>>> PA = PartitionAlgebra(Integer(2), q); PA
Partition Algebra of rank 2 with parameter q over Symbolic Ring
>>> PA([[Integer(1),Integer(2)],[-Integer(2),-Integer(1)]])**Integer(2) ==␣
↪q*PA([[Integer(1),Integer(2)],[-Integer(2),-Integer(1)]])
True
>>> ((PA([[Integer(2), -Integer(2)], [Integer(1), -Integer(1)]]) -␣
↪Integer(2)*PA([[-Integer(2), -Integer(1)], [Integer(1),␣
↪Integer(2)]]))**Integer(2)
...    == (Integer(4)*q-Integer(4))*PA([[Integer(1), Integer(2)], [-Integer(2), -
↪Integer(1)]]) + PA([[Integer(2), -Integer(2)], [Integer(1), -Integer(1)]]))
True
```

The identity element of the partition algebra is the set partition $\{\{1,-1\},\{2,-2\},\ldots,\{k,-k\}\}$:

```
sage: # needs sage.symbolic
sage: P = PA.basis().list()
sage: PA.one()
P{{-2, 2}, {-1, 1}}
sage: PA.one() * P[7] == P[7]
True
sage: P[7] * PA.one() == P[7]
True
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> P = PA.basis().list()
>>> PA.one()
P{{-2, 2}, {-1, 1}}
>>> PA.one() * P[Integer(7)] == P[Integer(7)]
True
>>> P[Integer(7)] * PA.one() == P[Integer(7)]
True
```

We now give some further examples of the use of the other arguments. One may wish to "specialize" the parameter to a chosen element of the base ring:

```
sage: R.<q> = RR[]
sage: PA = PartitionAlgebra(2, q, R, prefix='B')
sage: PA
Partition Algebra of rank 2 with parameter q over
 Univariate Polynomial Ring in q over Real Field with 53 bits of precision
sage: PA([[1,2],[-1,-2]])
1.00000000000000*B{{-2, -1}, {1, 2}}
```

(continues on next page)

(continued from previous page)

```
sage: PA = PartitionAlgebra(2, 5, base_ring=ZZ, prefix='B')
sage: PA
Partition Algebra of rank 2 with parameter 5 over Integer Ring
sage: ((PA([[2, -2], [1, -1]]) - 2*PA([[-2, -1], [1, 2]]))^2
....:   == 16*PA([[-2, -1], [1, 2]]) + PA([[2, -2], [1, -1]]))
True
```

```
>>> from sage.all import *
>>> R = RR['q']; (q,) = R._first_ngens(1)
>>> PA = PartitionAlgebra(Integer(2), q, R, prefix='B')
>>> PA
Partition Algebra of rank 2 with parameter q over
 Univariate Polynomial Ring in q over Real Field with 53 bits of precision
>>> PA([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)]])
1.00000000000000*B{{-2, -1}, {1, 2}}
>>> PA = PartitionAlgebra(Integer(2), Integer(5), base_ring=ZZ, prefix='B')
>>> PA
Partition Algebra of rank 2 with parameter 5 over Integer Ring
>>> ((PA([[Integer(2), -Integer(2)], [Integer(1), -Integer(1)]]) -␣
↪Integer(2)*PA([[-Integer(2), -Integer(1)], [Integer(1),␣
↪Integer(2)]]))**Integer(2)
...   == Integer(16)*PA([[-Integer(2), -Integer(1)], [Integer(1), Integer(2)]]) +␣
↪PA([[Integer(2), -Integer(2)], [Integer(1), -Integer(1)]]))
True
```

Symmetric group algebra elements and elements from other subalgebras of the partition algebra (e.g., `BrauerAlgebra` and `TemperleyLiebAlgebra`) can also be coerced into the partition algebra:

```
sage: # needs sage.symbolic
sage: S = SymmetricGroupAlgebra(SR, 2)
sage: B = BrauerAlgebra(2, x, SR)
sage: A = PartitionAlgebra(2, x, SR)
sage: S([2,1]) * A([[1,-1],[2,-2]])
P{{-2, 1}, {-1, 2}}
sage: B([[-1,-2],[2,1]]) * A([[1],[-1],[2,-2]])
P{{-2}, {-1}, {1, 2}}
sage: A([[1],[-1],[2,-2]]) * B([[-1,-2],[2,1]])
P{{-2, -1}, {1}, {2}}
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> S = SymmetricGroupAlgebra(SR, Integer(2))
>>> B = BrauerAlgebra(Integer(2), x, SR)
>>> A = PartitionAlgebra(Integer(2), x, SR)
>>> S([Integer(2),Integer(1)]) * A([[Integer(1),-Integer(1)],[Integer(2),-
↪Integer(2)]])
P{{-2, 1}, {-1, 2}}
>>> B([[-Integer(1),-Integer(2)],[Integer(2),Integer(1)]]) * A([[Integer(1)],[-
↪Integer(1)],[Integer(2),-Integer(2)]])
P{{-2}, {-1}, {1, 2}}
>>> A([[Integer(1)],[-Integer(1)],[Integer(2),-Integer(2)]]) * B([[-Integer(1),-
↪Integer(2)],[Integer(2),Integer(1)]])
```

(continues on next page)

(continued from previous page)

```
P{{-2, -1}, {1}, {2}}
```

The same is true if the elements come from a subalgebra of a partition algebra of smaller order, or if they are defined over a different base ring:

```
sage: R = FractionField(ZZ['q']); q = R.gen()
sage: S = SymmetricGroupAlgebra(ZZ, 2)
sage: B = BrauerAlgebra(2, q, ZZ[q])
sage: A = PartitionAlgebra(3, q, R)
sage: S([2,1]) * A([[1,-1],[2,-3],[3,-2]])
P{{-3, 1}, {-2, 3}, {-1, 2}}
sage: A(B([[-1,-2],[2,1]]))
P{{-3, 3}, {-2, -1}, {1, 2}}
```

```
>>> from sage.all import *
>>> R = FractionField(ZZ['q']); q = R.gen()
>>> S = SymmetricGroupAlgebra(ZZ, Integer(2))
>>> B = BrauerAlgebra(Integer(2), q, ZZ[q])
>>> A = PartitionAlgebra(Integer(3), q, R)
>>> S([Integer(2),Integer(1)]) * A([[Integer(1),-Integer(1)],[Integer(2),-
→Integer(3)],[Integer(3),-Integer(2)]])
P{{-3, 1}, {-2, 3}, {-1, 2}}
>>> A(B([[-Integer(1),-Integer(2)],[Integer(2),Integer(1)]]))
P{{-3, 3}, {-2, -1}, {1, 2}}
```

class Element

Bases: *Element*

dual()

Return the dual of `self`.

The dual of an element in the partition algebra is formed by taking the dual of each diagram in the support.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(2, x, R)
sage: elt = P.an_element(); elt
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
sage: elt.dual()
3*P{{-2, -1, 1}, {2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, -1, 2}, {1}}
```

```
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> P = PartitionAlgebra(Integer(2), x, R)
>>> elt = P.an_element(); elt
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
>>> elt.dual()
3*P{{-2, -1, 1}, {2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, -1, 2}, {1}}
```

to_orbit_basis()

Return `self` in the orbit basis of the associated partition algebra.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(2, x, R)
sage: pp = P.an_element();
sage: pp.to_orbit_basis()
3*O{{-2}, {-1, 1, 2}} + 7*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
sage: pp = (3*P([[-2], [-1, 1, 2]]) + 2*P([[-2, -1, 1, 2]])
....:       + 2*P([[-2, 1, 2], [-1]])); pp
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
sage: pp.to_orbit_basis()
3*O{{-2}, {-1, 1, 2}} + 7*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
```

```
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> P = PartitionAlgebra(Integer(2), x, R)
>>> pp = P.an_element();
>>> pp.to_orbit_basis()
3*O{{-2}, {-1, 1, 2}} + 7*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
>>> pp = (Integer(3)*P([[-Integer(2)], [-Integer(1), Integer(1),␣
↪Integer(2)]]) + Integer(2)*P([[-Integer(2), -Integer(1), Integer(1),␣
↪Integer(2)]])
...       + Integer(2)*P([[-Integer(2), Integer(1), Integer(2)], [-
↪Integer(1)]])); pp
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
>>> pp.to_orbit_basis()
3*O{{-2}, {-1, 1, 2}} + 7*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
```

L(i)

Return the `i`-th Jucys-Murphy element L_i from [Eny2012].

INPUT:

- `i` – half integer between $1/2$ and k

ALGORITHM:

We use the recursive definition for L_{2i} given in [Cre2020]. See also [Eny2012] and [Eny2013].

Note

$L_{1/2}$ and L_1 differs from [HR2005].

EXAMPLES:

```
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.jucys_murphy_element(1/2)
0
sage: P3.jucys_murphy_element(1)
P{{-3, 3}, {-2, 2}, {-1}, {1}}
sage: P3.jucys_murphy_element(2)
P{{-3, 3}, {-2}, {-1, 1}, {2}} - P{{-3, 3}, {-2}, {-1, 1, 2}}
 + P{{-3, 3}, {-2, -1}, {1, 2}} - P{{-3, 3}, {-2, -1, 1}, {2}}
```

(continues on next page)

(continued from previous page)

```
 + P{{-3, 3}, {-2, 1}, {-1, 2}}
sage: P3.jucys_murphy_element(3/2)
n*P{{-3, 3}, {-2, -1, 1, 2}} - P{{-3, 3}, {-2, -1, 2}, {1}}
 - P{{-3, 3}, {-2, 1, 2}, {-1}} + P{{-3, 3}, {-2, 2}, {-1, 1}}
sage: P3.L(3/2) * P3.L(2) == P3.L(2) * P3.L(3/2)
True
```

```
>>> from sage.all import *
>>> R = QQ['n']; (n,) = R._first_ngens(1)
>>> P3 = PartitionAlgebra(Integer(3), n)
>>> P3.jucys_murphy_element(Integer(1)/Integer(2))
0
>>> P3.jucys_murphy_element(Integer(1))
P{{-3, 3}, {-2, 2}, {-1}, {1}}
>>> P3.jucys_murphy_element(Integer(2))
P{{-3, 3}, {-2}, {-1, 1}, {2}} - P{{-3, 3}, {-2}, {-1, 1, 2}}
 + P{{-3, 3}, {-2, -1}, {1, 2}} - P{{-3, 3}, {-2, -1, 1}, {2}}
 + P{{-3, 3}, {-2, 1}, {-1, 2}}
>>> P3.jucys_murphy_element(Integer(3)/Integer(2))
n*P{{-3, 3}, {-2, -1, 1, 2}} - P{{-3, 3}, {-2, -1, 2}, {1}}
 - P{{-3, 3}, {-2, 1, 2}, {-1}} + P{{-3, 3}, {-2, 2}, {-1, 1}}
>>> P3.L(Integer(3)/Integer(2)) * P3.L(Integer(2)) == P3.L(Integer(2)) * P3.
↪L(Integer(3)/Integer(2))
True
```

We test the relations in Lemma 2.2.3(2) in [Cre2020] (v1):

```
sage: k = 4
sage: R.<n> = QQ[]
sage: P = PartitionAlgebra(k, n)
sage: L = [P.L(i/2) for i in range(1,2*k+1)]
sage: all(x.dual() == x for x in L)
True
sage: all(x * y == y * x for x, y in Subsets(L, 2))  # long time
True
sage: Lsum = sum(L)
sage: gens = [P.s(i) for i in range(1,k)]
sage: gens += [P.e(i/2) for i in range(1,2*k)]
sage: all(x * Lsum == Lsum * x for x in gens)
True
```

```
>>> from sage.all import *
>>> k = Integer(4)
>>> R = QQ['n']; (n,) = R._first_ngens(1)
>>> P = PartitionAlgebra(k, n)
>>> L = [P.L(i/Integer(2)) for i in range(Integer(1),Integer(2)*k+Integer(1))]
>>> all(x.dual() == x for x in L)
True
>>> all(x * y == y * x for x, y in Subsets(L, Integer(2)))  # long time
True
>>> Lsum = sum(L)
>>> gens = [P.s(i) for i in range(Integer(1),k)]
```

(continues on next page)

(continued from previous page)

```
>>> gens += [P.e(i/Integer(2)) for i in range(Integer(1),Integer(2)*k)]
>>> all(x * Lsum == Lsum * x for x in gens)
True
```

Also the relations in Lemma 2.2.3(3) in [Cre2020] (v1):

```
sage: all(P.e((2*i+1)/2) * P.sigma(2*i/2) * P.e((2*i+1)/2)
....:     == (n - P.L((2*i-1)/2)) * P.e((2*i+1)/2) for i in range(1,k))
True
sage: all(P.e(i/2) * (P.L(i/2) + P.L((i+1)/2))
....:     == (P.L(i/2) + P.L((i+1)/2)) * P.e(i/2)
....:     == n * P.e(i/2) for i in range(1,2*k))
True
sage: all(P.sigma(2*i/2) * P.e((2*i-1)/2) * P.e(2*i/2)
....:     == P.L(2*i/2) * P.e(2*i/2) for i in range(1,k))
True
sage: all(P.e(2*i/2) * P.e((2*i-1)/2) * P.sigma(2*i/2)
....:     == P.e(2*i/2) * P.L(2*i/2) for i in range(1,k))
True
sage: all(P.sigma((2*i+1)/2) * P.e((2*i+1)/2) * P.e(2*i/2)
....:     == P.L(2*i/2) * P.e(2*i/2) for i in range(1,k))
True
sage: all(P.e(2*i/2) * P.e((2*i+1)/2) * P.sigma((2*i+1)/2)
....:     == P.e(2*i/2) * P.L(2*i/2) for i in range(1,k))
True
```

```
>>> from sage.all import *
>>> all(P.e((Integer(2)*i+Integer(1))/Integer(2)) * P.sigma(Integer(2)*i/
↪Integer(2)) * P.e((Integer(2)*i+Integer(1))/Integer(2))
...     == (n - P.L((Integer(2)*i-Integer(1))/Integer(2))) * P.
↪e((Integer(2)*i+Integer(1))/Integer(2)) for i in range(Integer(1),k))
True
>>> all(P.e(i/Integer(2)) * (P.L(i/Integer(2)) + P.L((i+Integer(1))/
↪Integer(2)))
...     == (P.L(i/Integer(2)) + P.L((i+Integer(1))/Integer(2))) * P.e(i/
↪Integer(2))
...     == n * P.e(i/Integer(2)) for i in range(Integer(1),Integer(2)*k))
True
>>> all(P.sigma(Integer(2)*i/Integer(2)) * P.e((Integer(2)*i-Integer(1))/
↪Integer(2)) * P.e(Integer(2)*i/Integer(2))
...     == P.L(Integer(2)*i/Integer(2)) * P.e(Integer(2)*i/Integer(2)) for i␣
↪in range(Integer(1),k))
True
>>> all(P.e(Integer(2)*i/Integer(2)) * P.e((Integer(2)*i-Integer(1))/
↪Integer(2)) * P.sigma(Integer(2)*i/Integer(2))

True
```

a(i)

Return the element a_i in `self`.

The element a_i is the cap and cup at $(i, i+1)$, so it contains the blocks $\{i, i+1\}$, $\{-i, -i-1\}$. Other blocks are of the form $\{-j, j\}$.

INPUT:

- `i` – integer between 1 and $k-1$

EXAMPLES:

```
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.a(1)
P{{-3, 3}, {-2, -1}, {1, 2}}
sage: P3.a(2)
P{{-3, -2}, {-1, 1}, {2, 3}}
```

(continues on next page)

(continued from previous page)

```
sage: P3 = PartitionAlgebra(5/2, n)
sage: P3.a(1)
P{{-3, 3}, {-2, -1}, {1, 2}}
sage: P3.a(2)
Traceback (most recent call last):
...
ValueError: i must be an integer between 1 and 1
```

```
>>> from sage.all import *
>>> R = QQ['n']; (n,) = R._first_ngens(1)
>>> P3 = PartitionAlgebra(Integer(3), n)
>>> P3.a(Integer(1))
P{{-3, 3}, {-2, -1}, {1, 2}}
>>> P3.a(Integer(2))
P{{-3, -2}, {-1, 1}, {2, 3}}

>>> P3 = PartitionAlgebra(Integer(5)/Integer(2), n)
>>> P3.a(Integer(1))
P{{-3, 3}, {-2, -1}, {1, 2}}
>>> P3.a(Integer(2))
Traceback (most recent call last):
...
ValueError: i must be an integer between 1 and 1
```

e(*i*)

Return the element e_i in `self`.

If $i = (2r+1)/2$, then e_i contains the blocks $\{r+1\}$ and $\{-r-1\}$. If $i \in \mathbf{Z}$, then e_i contains the block $\{-i, -i-1, i, i+1\}$. Other blocks are of the form $\{-j, j\}$.

INPUT:

- `i` – half integer between $1/2$ and $k - 1/2$

EXAMPLES:

```
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.e(1)
P{{-3, 3}, {-2, -1, 1, 2}}
sage: P3.e(2)
P{{-3, -2, 2, 3}, {-1, 1}}
sage: P3.e(1/2)
P{{-3, 3}, {-2, 2}, {-1}, {1}}
sage: P3.e(5/2)
P{{-3}, {-2, 2}, {-1, 1}, {3}}
sage: P3.e(0)
Traceback (most recent call last):
...
ValueError: i must be an (half) integer between 1/2 and 5/2
sage: P3.e(3)
Traceback (most recent call last):

 P{{-3, -2, 2, 3}, {-1, 1}}]
```

generator_s(i)

Return the i-th simple transposition s_i in self.

Borrowing the notation from the symmetric group, the i-th simple transposition s_i has blocks of the form $\{-i, i+1\}$, $\{-i-1, i\}$. Other blocks are of the form $\{-j, j\}$.

INPUT:

- i – integer between 1 and $k-1$

EXAMPLES:

```
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.s(1)
P{{-3, 3}, {-2, 1}, {-1, 2}}
sage: P3.s(2)
P{{-3, 2}, {-2, 3}, {-1, 1}}
```

(continues on next page)

(continued from previous page)

```
sage: R.<n> = ZZ[]
sage: P2h = PartitionAlgebra(5/2,n)
sage: P2h.s(1)
P{{-3, 3}, {-2, 1}, {-1, 2}}
```

```
>>> from sage.all import *
>>> R = QQ['n']; (n,) = R._first_ngens(1)
>>> P3 = PartitionAlgebra(Integer(3), n)
>>> P3.s(Integer(1))
P{{-3, 3}, {-2, 1}, {-1, 2}}
>>> P3.s(Integer(2))
P{{-3, 2}, {-2, 3}, {-1, 1}}

>>> R = ZZ['n']; (n,) = R._first_ngens(1)
>>> P2h = PartitionAlgebra(Integer(5)/Integer(2),n)
>>> P2h.s(Integer(1))
P{{-3, 3}, {-2, 1}, {-1, 2}}
```

jucys_murphy_element (i)

Return the `i`-th Jucys-Murphy element L_i from [Eny2012].

INPUT:

- `i` – half integer between $1/2$ and k

ALGORITHM:

We use the recursive definition for L_{2i} given in [Cre2020]. See also [Eny2012] and [Eny2013].

> **Note**
>
> $L_{1/2}$ and L_1 differs from [HR2005].

EXAMPLES:

```
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.jucys_murphy_element(1/2)
0
sage: P3.jucys_murphy_element(1)
P{{-3, 3}, {-2, 2}, {-1}, {1}}
sage: P3.jucys_murphy_element(2)
P{{-3, 3}, {-2}, {-1, 1}, {2}} - P{{-3, 3}, {-2}, {-1, 1, 2}}
 + P{{-3, 3}, {-2, -1}, {1, 2}} - P{{-3, 3}, {-2, -1, 1}, {2}}
 + P{{-3, 3}, {-2, 1}, {-1, 2}}
sage: P3.jucys_murphy_element(3/2)
n*P{{-3, 3}, {-2, -1, 1, 2}} - P{{-3, 3}, {-2, -1, 2}, {1}}
 - P{{-3, 3}, {-2, 1, 2}, {-1}} + P{{-3, 3}, {-2, 2}, {-1, 1}}
sage: P3.L(3/2) * P3.L(2) == P3.L(2) * P3.L(3/2)
True
```

```
>>> from sage.all import *
>>> R = QQ['n']; (n,) = R._first_ngens(1)
>>> P3 = PartitionAlgebra(Integer(3), n)
>>> P3.jucys_murphy_element(Integer(1)/Integer(2))
0
>>> P3.jucys_murphy_element(Integer(1))
P{{-3, 3}, {-2, 2}, {-1}, {1}}
>>> P3.jucys_murphy_element(Integer(2))
P{{-3, 3}, {-2}, {-1, 1}, {2}} - P{{-3, 3}, {-2}, {-1, 1, 2}}
 + P{{-3, 3}, {-2, -1}, {1, 2}} - P{{-3, 3}, {-2, -1, 1}, {2}}
 + P{{-3, 3}, {-2, 1}, {-1, 2}}
>>> P3.jucys_murphy_element(Integer(3)/Integer(2))
n*P{{-3, 3}, {-2, -1, 1, 2}} - P{{-3, 3}, {-2, -1, 2}, {1}}
 - P{{-3, 3}, {-2, 1, 2}, {-1}} + P{{-3, 3}, {-2, 2}, {-1, 1}}
>>> P3.L(Integer(3)/Integer(2)) * P3.L(Integer(2)) == P3.L(Integer(2)) * P3.
↪L(Integer(3)/Integer(2))
True
```

We test the relations in Lemma 2.2.3(2) in [Cre2020] (v1):

```
sage: k = 4
sage: R.<n> = QQ[]
sage: P = PartitionAlgebra(k, n)
sage: L = [P.L(i/2) for i in range(1,2*k+1)]
sage: all(x.dual() == x for x in L)
True
sage: all(x * y == y * x for x, y in Subsets(L, 2))  # long time
True
sage: Lsum = sum(L)
sage: gens = [P.s(i) for i in range(1,k)]
sage: gens += [P.e(i/2) for i in range(1,2*k)]
sage: all(x * Lsum == Lsum * x for x in gens)
True
```

```
>>> from sage.all import *
>>> k = Integer(4)
>>> R = QQ['n']; (n,) = R._first_ngens(1)
>>> P = PartitionAlgebra(k, n)
>>> L = [P.L(i/Integer(2)) for i in range(Integer(1),Integer(2)*k+Integer(1))]
>>> all(x.dual() == x for x in L)
True
>>> all(x * y == y * x for x, y in Subsets(L, Integer(2)))  # long time
True
>>> Lsum = sum(L)
>>> gens = [P.s(i) for i in range(Integer(1),k)]
>>> gens += [P.e(i/Integer(2)) for i in range(Integer(1),Integer(2)*k)]
>>> all(x * Lsum == Lsum * x for x in gens)
True
```

Also the relations in Lemma 2.2.3(3) in [Cre2020] (v1):

```
sage: all(P.e((2*i+1)/2) * P.sigma(2*i/2) * P.e((2*i+1)/2)

True
```

orbit_basis()

Return the orbit basis of `self`.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: P2 = PartitionAlgebra(2, x, R)
sage: O2 = P2.orbit_basis(); O2
Orbit basis of Partition Algebra of rank 2 with parameter x over
 Univariate Polynomial Ring in x over Rational Field
sage: pp = 7 * P2[{-1}, {-2, 1, 2}] - 2 * P2[{-2}, {-1, 1}, {2}]; pp
-2*P{{-2}, {-1, 1}, {2}} + 7*P{{-2, 1, 2}, {-1}}
sage: op = pp.to_orbit_basis(); op
-2*O{{-2}, {-1, 1}, {2}} - 2*O{{-2}, {-1, 1, 2}}
 - 2*O{{-2, -1, 1}, {2}} + 5*O{{-2, -1, 1, 2}}
 + 7*O{{-2, 1, 2}, {-1}} - 2*O{{-2, 2}, {-1, 1}}
sage: op == O2(op)
True
sage: pp * op.leading_term()
4*P{{-2}, {-1, 1}, {2}} - 4*P{{-2, -1, 1}, {2}}
 + 14*P{{-2, -1, 1, 2}} - 14*P{{-2, 1, 2}, {-1}}
```

```
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> P2 = PartitionAlgebra(Integer(2), x, R)
```

(continues on next page)

(continued from previous page)

```
>>> O2 = P2.orbit_basis(); O2
Orbit basis of Partition Algebra of rank 2 with parameter x over
 Univariate Polynomial Ring in x over Rational Field
>>> pp = Integer(7) * P2[{-Integer(1)}, {-Integer(2), Integer(1), Integer(2)}
↪] - Integer(2) * P2[{-Integer(2)}, {-Integer(1), Integer(1)}, {Integer(2)}];
↪ pp
-2*P{{-2}, {-1, 1}, {2}} + 7*P{{-2, 1, 2}, {-1}}
>>> op = pp.to_orbit_basis(); op
-2*O{{-2}, {-1, 1}, {2}} - 2*O{{-2}, {-1, 1, 2}}
 - 2*O{{-2, -1, 1}, {2}} + 5*O{{-2, -1, 1, 2}}
 + 7*O{{-2, 1, 2}, {-1}} - 2*O{{-2, 2}, {-1, 1}}
>>> op == O2(op)
True
>>> pp * op.leading_term()
4*P{{-2}, {-1, 1}, {2}} - 4*P{{-2, -1, 1}, {2}}
 + 14*P{{-2, -1, 1, 2}} - 14*P{{-2, 1, 2}, {-1}}
```

potts_representation(*y=None*)

Return the *PottsRepresentation* with magnetic field direction `y` of `self`.

Note

The deformation parameter d of `self` must be a positive integer.

INPUT:

- `y` – (optional) an integer between 1 and d; ignored if the order of `self` is an integer, otherwise the default is 1

EXAMPLES:

```
sage: PA = algebras.Partition(5/2, QQ(4))
sage: PR = PA.potts_representation()

sage: PA = algebras.Partition(5/2, 3/2)
sage: PA.potts_representation()
Traceback (most recent call last):
...
ValueError: the partition algebra deformation parameter must
 be a positive integer
```

```
>>> from sage.all import *
>>> PA = algebras.Partition(Integer(5)/Integer(2), QQ(Integer(4)))
>>> PR = PA.potts_representation()

>>> PA = algebras.Partition(Integer(5)/Integer(2), Integer(3)/Integer(2))
>>> PA.potts_representation()
Traceback (most recent call last):
...
ValueError: the partition algebra deformation parameter must
 be a positive integer
```

s(i)

Return the i-th simple transposition s_i in self.

Borrowing the notation from the symmetric group, the i-th simple transposition s_i has blocks of the form $\{-i, i+1\}$, $\{-i-1, i\}$. Other blocks are of the form $\{-j, j\}$.

INPUT:

- i – integer between 1 and $k-1$

EXAMPLES:

```
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.s(1)
P{{-3, 3}, {-2, 1}, {-1, 2}}
sage: P3.s(2)
P{{-3, 2}, {-2, 3}, {-1, 1}}

sage: R.<n> = ZZ[]
sage: P2h = PartitionAlgebra(5/2,n)
sage: P2h.s(1)
P{{-3, 3}, {-2, 1}, {-1, 2}}
```

```
>>> from sage.all import *
>>> R = QQ['n']; (n,) = R._first_ngens(1)
>>> P3 = PartitionAlgebra(Integer(3), n)
>>> P3.s(Integer(1))
P{{-3, 3}, {-2, 1}, {-1, 2}}
>>> P3.s(Integer(2))
P{{-3, 2}, {-2, 3}, {-1, 1}}

>>> R = ZZ['n']; (n,) = R._first_ngens(1)
>>> P2h = PartitionAlgebra(Integer(5)/Integer(2),n)
>>> P2h.s(Integer(1))
P{{-3, 3}, {-2, 1}, {-1, 2}}
```

sigma(i)

Return the element σ_i from [Eny2012] of self.

INPUT:

- i – half integer between $1/2$ and $k-1/2$

Note

In [Cre2020] and [Eny2013], these are the elements σ_{2i}.

EXAMPLES:

```
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.sigma(1)
P{{-3, 3}, {-2, 2}, {-1, 1}}
sage: P3.sigma(3/2)
```

(continues on next page)

(continued from previous page)

```
P{{-3, 3}, {-2, 1}, {-1, 2}}
sage: P3.sigma(2)
-P{{-3, -1, 1, 3}, {-2, 2}} + P{{-3, -1, 3}, {-2, 1, 2}}
 + P{{-3, 1, 3}, {-2, -1, 2}} - P{{-3, 3}, {-2, -1, 1, 2}}
 + P{{-3, 3}, {-2, 2}, {-1, 1}}
sage: P3.sigma(5/2)
-P{{-3, -1, 1, 2}, {-2, 3}} + P{{-3, -1, 2}, {-2, 1, 3}}
 + P{{-3, 1, 2}, {-2, -1, 3}} - P{{-3, 2}, {-2, -1, 1, 3}}
 + P{{-3, 2}, {-2, 3}, {-1, 1}}
```

```
>>> from sage.all import *
>>> R = QQ['n']; (n,) = R._first_ngens(1)
>>> P3 = PartitionAlgebra(Integer(3), n)
>>> P3.sigma(Integer(1))
P{{-3, 3}, {-2, 2}, {-1, 1}}
>>> P3.sigma(Integer(3)/Integer(2))
P{{-3, 3}, {-2, 1}, {-1, 2}}
>>> P3.sigma(Integer(2))
-P{{-3, -1, 1, 3}, {-2, 2}} + P{{-3, -1, 3}, {-2, 1, 2}}
 + P{{-3, 1, 3}, {-2, -1, 2}} - P{{-3, 3}, {-2, -1, 1, 2}}
 + P{{-3, 3}, {-2, 2}, {-1, 1}}
>>> P3.sigma(Integer(5)/Integer(2))
-P{{-3, -1, 1, 2}, {-2, 3}} + P{{-3, -1, 2}, {-2, 1, 3}}
 + P{{-3, 1, 2}, {-2, -1, 3}} - P{{-3, 2}, {-2, -1, 1, 3}}
 + P{{-3, 2}, {-2, 3}, {-1, 1}}
```

We test the relations in Lemma 2.2.3(1) in [Cre2020] (v1):

```
sage: k = 4
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(k, x)
sage: all(P.sigma(i/2).dual() == P.sigma(i/2)
....:     for i in range(1,2*k))
True
sage: all(P.sigma(i)*P.sigma(i+1/2) == P.sigma(i+1/2)*P.sigma(i) == P.s(i)
....:     for i in range(1,floor(k)))

...     for i in range(Integer(1),floor(k)))
True
>>> all(P.sigma(i+Integer(1)/Integer(2))*P.e(i) == P.e(i)*P.
↪sigma(i+Integer(1)/Integer(2)) == P.e(i)
...     for i in range(Integer(1),floor(k)))
True
```

class sage.combinat.diagram_algebras.**PartitionDiagram**(*parent*, *d*, *check=True*)

Bases: *AbstractPartitionDiagram*

The element class for a partition diagram.

A partition diagram for an integer k is a partition of the set $\{1, \ldots, k, -1, \ldots, -k\}$

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import PartitionDiagram,␣
↪PartitionDiagrams
sage: PartitionDiagrams(1)
Partition diagrams of order 1
sage: PartitionDiagrams(1).list()
[{{-1, 1}}, {{-1}, {1}}]
sage: PartitionDiagram([[1,-1]])
{{-1, 1}}
sage: PartitionDiagram(((1,-2),(2,-1))).parent()
Partition diagrams of order 2
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import PartitionDiagram, PartitionDiagrams
>>> PartitionDiagrams(Integer(1))
Partition diagrams of order 1
>>> PartitionDiagrams(Integer(1)).list()
[{{-1, 1}}, {{-1}, {1}}]
>>> PartitionDiagram([[Integer(1),-Integer(1)]])
{{-1, 1}}
>>> PartitionDiagram(((Integer(1),-Integer(2)),(Integer(2),-Integer(1)))).parent()
Partition diagrams of order 2
```

class sage.combinat.diagram_algebras.**PartitionDiagrams**(*order*, *category=None*)

Bases: *AbstractPartitionDiagrams*

This class represents all partition diagrams of integer or integer $+1/2$ order.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.PartitionDiagrams(1); pd
Partition diagrams of order 1
sage: pd.list()
[{{-1, 1}}, {{-1}, {1}}]

sage: pd = da.PartitionDiagrams(3/2); pd
Partition diagrams of order 3/2
sage: pd.list()
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2, 2}, {-1, 1}},
 {{-2, -1, 2}, {1}},
 {{-2, 2}, {-1}, {1}}]
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> pd = da.PartitionDiagrams(Integer(1)); pd
Partition diagrams of order 1
>>> pd.list()
[{{-1, 1}}, {{-1}, {1}}]

>>> pd = da.PartitionDiagrams(Integer(3)/Integer(2)); pd
Partition diagrams of order 3/2
```

(continues on next page)

(continued from previous page)

```
>>> pd.list()
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2, 2}, {-1, 1}},
 {{-2, -1, 2}, {1}},
 {{-2, 2}, {-1}, {1}}]
```

Element

alias of *PartitionDiagram*

cardinality()

The cardinality of partition diagrams of half-integer order n is the $2n$-th Bell number.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.PartitionDiagrams(3)
sage: pd.cardinality()
203

sage: pd = da.PartitionDiagrams(7/2)
sage: pd.cardinality()
877
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> pd = da.PartitionDiagrams(Integer(3))
>>> pd.cardinality()
203

>>> pd = da.PartitionDiagrams(Integer(7)/Integer(2))
>>> pd.cardinality()
877
```

class sage.combinat.diagram_algebras.**PlanarAlgebra**(*k*, *q*, *base_ring*, *prefix*)

Bases: *SubPartitionAlgebra*, *UnitDiagramMixin*

A planar algebra.

The planar algebra of rank k is an algebra with basis indexed by the collection of all planar set partitions of $\{1, \ldots, k, -1, \ldots, -k\}$.

This algebra is thus a subalgebra of the partition algebra. For more information, see *PartitionAlgebra*.

INPUT:

- `k` – rank of the algebra
- `q` – the deformation parameter q
- `base_ring` – (default: `None`) a ring containing `q`; if `None` then just takes the parent of `q`
- `prefix` – (default: `'Pl'`) a label for the basis elements

EXAMPLES:

We define the planar algebra of rank 2 with parameter x over $\mathbf{Z}$:

```
sage: R.<x> = ZZ[]
sage: Pl = PlanarAlgebra(2, x, R); Pl
Planar Algebra of rank 2 with parameter x over Univariate Polynomial Ring in x␣
↪over Integer Ring
sage: Pl.basis().keys()
Planar diagrams of order 2
sage: Pl.basis().keys()([[-1, 1], [2, -2]])
{{-2, 2}, {-1, 1}}
sage: Pl.basis().list()
[Pl{{-2}, {-1}, {1, 2}},
 Pl{{-2}, {-1}, {1}, {2}},
 Pl{{-2, 1}, {-1}, {2}},
 Pl{{-2, 2}, {-1}, {1}},
 Pl{{-2, 1, 2}, {-1}},
 Pl{{-2, 2}, {-1, 1}},
 Pl{{-2}, {-1, 1}, {2}},
 Pl{{-2}, {-1, 2}, {1}},
 Pl{{-2}, {-1, 1, 2}},
 Pl{{-2, -1}, {1, 2}},
 Pl{{-2, -1}, {1}, {2}},
 Pl{{-2, -1, 1}, {2}},
 Pl{{-2, -1, 2}, {1}},
 Pl{{-2, -1, 1, 2}}]
sage: E = Pl([[1,2],[-1,-2]])
sage: E^2 == x*E
True
sage: E^5 == x^4*E
True
```

```
>>> from sage.all import *
>>> R = ZZ['x']; (x,) = R._first_ngens(1)
>>> Pl = PlanarAlgebra(Integer(2), x, R); Pl
Planar Algebra of rank 2 with parameter x over Univariate Polynomial Ring in x␣
↪over Integer Ring
>>> Pl.basis().keys()
Planar diagrams of order 2
>>> Pl.basis().keys()([[-Integer(1), Integer(1)], [Integer(2), -Integer(2)]])
{{-2, 2}, {-1, 1}}
>>> Pl.basis().list()
[Pl{{-2}, {-1}, {1, 2}},
 Pl{{-2}, {-1}, {1}, {2}},
 Pl{{-2, 1}, {-1}, {2}},
 Pl{{-2, 2}, {-1}, {1}},
 Pl{{-2, 1, 2}, {-1}},
 Pl{{-2, 2}, {-1, 1}},
 Pl{{-2}, {-1, 1}, {2}},
 Pl{{-2}, {-1, 2}, {1}},
 Pl{{-2}, {-1, 1, 2}},
 Pl{{-2, -1}, {1, 2}},
 Pl{{-2, -1}, {1}, {2}},
 Pl{{-2, -1, 1}, {2}},
 Pl{{-2, -1, 2}, {1}},
```

(continues on next page)

(continued from previous page)

```
 Pl{{-2, -1, 1, 2}}]
>>> E = Pl([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)]])
>>> E**Integer(2) == x*E
True
>>> E**Integer(5) == x**Integer(4)*E
True
```

class sage.combinat.diagram_algebras.**PlanarDiagram**(*parent*, *d*, *check=True*)

Bases: *AbstractPartitionDiagram*

The element class for a planar diagram.

A planar diagram for an integer k is a partition of the set $\{1, \ldots, k, -1, \ldots, -k\}$ so that the diagram is non-crossing.

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import PlanarDiagrams
sage: PlanarDiagrams(2)
Planar diagrams of order 2
sage: PlanarDiagrams(2).list()
[{{-2}, {-1}, {1, 2}},
 {{-2}, {-1}, {1}, {2}},
 {{-2, 1}, {-1}, {2}},
 {{-2, 2}, {-1}, {1}},
 {{-2, 1, 2}, {-1}},
 {{-2, 2}, {-1, 1}},
 {{-2}, {-1, 1}, {2}},
 {{-2}, {-1, 2}, {1}},
 {{-2}, {-1, 1, 2}},
 {{-2, -1}, {1, 2}},
 {{-2, -1}, {1}, {2}},
 {{-2, -1, 1}, {2}},
 {{-2, -1, 2}, {1}},
 {{-2, -1, 1, 2}}]
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import PlanarDiagrams
>>> PlanarDiagrams(Integer(2))
Planar diagrams of order 2
>>> PlanarDiagrams(Integer(2)).list()
[{{-2}, {-1}, {1, 2}},
 {{-2}, {-1}, {1}, {2}},
 {{-2, 1}, {-1}, {2}},
 {{-2, 2}, {-1}, {1}},
 {{-2, 1, 2}, {-1}},
 {{-2, 2}, {-1, 1}},
 {{-2}, {-1, 1}, {2}},
 {{-2}, {-1, 2}, {1}},
 {{-2}, {-1, 1, 2}},
 {{-2, -1}, {1, 2}},
 {{-2, -1}, {1}, {2}},
 {{-2, -1, 1}, {2}},
```

(continues on next page)

(continued from previous page)

```
 {{-2, -1, 2}, {1}},
 {{-2, -1, 1, 2}}]
```

check()

Check the validity of the input for `self`.

class sage.combinat.diagram_algebras.**PlanarDiagrams**(*order*, *category=None*)

Bases: *AbstractPartitionDiagrams*

All planar diagrams of integer or integer $+1/2$ order.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pld = da.PlanarDiagrams(1); pld
Planar diagrams of order 1
sage: pld.list()
[{{-1, 1}}, {{-1}, {1}}]

sage: pld = da.PlanarDiagrams(3/2); pld
Planar diagrams of order 3/2
sage: pld.list()
[{{-2, 1, 2}, {-1}},
 {{-2, 2}, {-1}, {1}},
 {{-2, 2}, {-1, 1}},
 {{-2, -1, 2}, {1}},
 {{-2, -1, 1, 2}}]
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> pld = da.PlanarDiagrams(Integer(1)); pld
Planar diagrams of order 1
>>> pld.list()
[{{-1, 1}}, {{-1}, {1}}]

>>> pld = da.PlanarDiagrams(Integer(3)/Integer(2)); pld
Planar diagrams of order 3/2
>>> pld.list()
[{{-2, 1, 2}, {-1}},
 {{-2, 2}, {-1}, {1}},
 {{-2, 2}, {-1, 1}},
 {{-2, -1, 2}, {1}},
 {{-2, -1, 1, 2}}]
```

Element

alias of *PlanarDiagram*

cardinality()

Return the cardinality of `self`.

The number of all planar diagrams of order k is the $2k$-th Catalan number.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pld = da.PlanarDiagrams(3)
sage: pld.cardinality()
132
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> pld = da.PlanarDiagrams(Integer(3))
>>> pld.cardinality()
132
```

class sage.combinat.diagram_algebras.**PottsRepresentation**(*PA*, *y*)

Bases: *CombinatorialFreeModule*

The Potts representation of the partition algebra.

Let $P_n(d)$ be the *PartitionAlgebra* over R with the deformation parameter $d \in \mathbf{Z}_{>0}$ being a positive integer. Recall the multiplication convention of diagrams in $P_n(d)$ computing DD' by placing D above D'.

The *Potts representation* is the right $P_n(d)$-module on $M = V^{\otimes n}$, with $V = R^d$, with the action given as follows. We identify the natural basis vectors in M with words of length n in the alphabet $\{1, \ldots, d\}$ (which we call colors). For a basis vector w and diagram D, define $w \cdot D$ as the sum over all v such that every part in wDv (consider this as coloring the nodes of D) is given by the same color.

If n is a half integer, then there is an extra fixed color for the node $\lceil n \rceil$, which is called the *magnetic field direction* from the physics interpretation of this representation.

EXAMPLES:

In this example, we consider $R = \mathbf{Q}$ and use the Potts representation to construct the centralizer algebra of the left S_{d-1}-action on $V^{\otimes n}$ with $V = \mathbf{Q}^d$ being the permutation action.

```
sage: PA = algebras.Partition(5/2, QQ(2))
sage: PR = PA.potts_representation(2)
sage: mats = [PR.representation_matrix(x) for x in PA.basis()]
sage: MS = mats[0].parent()
sage: CM = MS.submodule(mats)
sage: CM.dimension()
16
```

```
>>> from sage.all import *
>>> PA = algebras.Partition(Integer(5)/Integer(2), QQ(Integer(2)))
>>> PR = PA.potts_representation(Integer(2))
>>> mats = [PR.representation_matrix(x) for x in PA.basis()]
>>> MS = mats[Integer(0)].parent()
>>> CM = MS.submodule(mats)
>>> CM.dimension()
16
```

We check that this commutes with the S_{d-1}-action:

```
sage: all((g * v) * x == g * (v * x) for g in PR.symmetric_group()
....:     for v in PR.basis() for x in PA.basis())
True
```

```
>>> from sage.all import *
>>> all((g * v) * x == g * (v * x) for g in PR.symmetric_group()
...     for v in PR.basis() for x in PA.basis())
True
```

Next, we see that the centralizer of the S_d-action is smaller than the semisimple quotient of the partition algebra:

```
sage: PA.dimension()
52
sage: len(PA.radical_basis())
9
sage: SQ = PA.semisimple_quotient()
sage: SQ.dimension()
43
```

```
>>> from sage.all import *
>>> PA.dimension()
52
>>> len(PA.radical_basis())
9
>>> SQ = PA.semisimple_quotient()
>>> SQ.dimension()
43
```

Next, we get orthogonal idempotents that project onto the central orthogonal idempotents in the semisimple quotient and construct the corresponding Peirce summands $e_i P_n(d) e_i$:

```
sage: # long time
sage: orth_idems = PA.orthogonal_idempotents_central_mod_radical()
sage: algs = [PA.peirce_summand(idm, idm) for idm in orth_idems]
sage: [A.dimension() for A in algs]
[16, 2, 1, 25]
```

```
>>> from sage.all import *
>>> # long time
>>> orth_idems = PA.orthogonal_idempotents_central_mod_radical()
>>> algs = [PA.peirce_summand(idm, idm) for idm in orth_idems]
>>> [A.dimension() for A in algs]
[16, 2, 1, 25]
```

We saw that we obtain the entire endomorphism algebra since $d = 2$ and S_{d-1} is the trivial group. Hence, the 16 dimensional Peirce summand computed above is isomorphic to this endomorphism algebra (both are 4×4 matrix algebras over $\mathbf{Q}$). Hence, we have a natural quotient construction of the centralizer algebra from the partition algebra.

Next, we consider a case with a nontrivial S_d-action (now it is S_d since the partition algebra has integer rank). We perform the same computations as before:

```
sage: PA = algebras.Partition(2, QQ(2))
sage: PA.dimension()
15
sage: PA.semisimple_quotient().dimension()
10
```

(continues on next page)

(continued from previous page)

```
sage: orth_idems = PA.orthogonal_idempotents_central_mod_radical()
sage: algs = [PA.peirce_summand(idm, idm) for idm in orth_idems]
sage: [A.dimension() for A in algs]
[4, 2, 4, 1]

sage: PR = PA.potts_representation()
sage: mats = [PR.representation_matrix(x) for x in PA.basis()]
sage: MS = mats[0].parent()
sage: cat = Algebras(QQ).WithBasis().Subobjects()
sage: CM = MS.submodule(mats, category=cat)
sage: CM.dimension()
8
```

```
>>> from sage.all import *
>>> PA = algebras.Partition(Integer(2), QQ(Integer(2)))
>>> PA.dimension()
15
>>> PA.semisimple_quotient().dimension()
10
>>> orth_idems = PA.orthogonal_idempotents_central_mod_radical()
>>> algs = [PA.peirce_summand(idm, idm) for idm in orth_idems]
>>> [A.dimension() for A in algs]
[4, 2, 4, 1]

>>> PR = PA.potts_representation()
>>> mats = [PR.representation_matrix(x) for x in PA.basis()]
>>> MS = mats[Integer(0)].parent()
>>> cat = Algebras(QQ).WithBasis().Subobjects()
>>> CM = MS.submodule(mats, category=cat)
>>> CM.dimension()
8
```

To do the remainder of the computation, we need to monkey patch a `product_on_basis` method:

```
sage: CM.product_on_basis
NotImplemented
sage: CM.product_on_basis = lambda x,y: CM.retract(CM.basis()[x].lift() * CM.
↪basis()[y].lift())
sage: CM.orthogonal_idempotents_central_mod_radical()
(1/2*B[0] + 1/2*B[3] + 1/2*B[5] + 1/2*B[6],
 1/2*B[0] - 1/2*B[3] + 1/2*B[5] - 1/2*B[6])
sage: CM.peirce_decomposition()
[[Free module generated by {0, 1, 2, 3} over Rational Field,
  Free module generated by {} over Rational Field],
 [Free module generated by {} over Rational Field,
  Free module generated by {0, 1, 2, 3} over Rational Field]]
```

```
>>> from sage.all import *
>>> CM.product_on_basis
NotImplemented
>>> CM.product_on_basis = lambda x,y: CM.retract(CM.basis()[x].lift() * CM.
↪basis()[y].lift())
```

(continues on next page)

(continued from previous page)

```
>>> CM.orthogonal_idempotents_central_mod_radical()
(1/2*B[0] + 1/2*B[3] + 1/2*B[5] + 1/2*B[6],
 1/2*B[0] - 1/2*B[3] + 1/2*B[5] - 1/2*B[6])
>>> CM.peirce_decomposition()
[[Free module generated by {0, 1, 2, 3} over Rational Field,
  Free module generated by {} over Rational Field],
 [Free module generated by {} over Rational Field,
  Free module generated by {0, 1, 2, 3} over Rational Field]]
```

Hence, we see that the centralizer algebra is isomorphic to a product of two 2×2 matrix algebras (over $\mathbf{Q}$), which are naturally a part of the partition algebra decomposition.

Lastly, we verify the commuting actions:

```
sage: all((g * v) * x == g * (v * x) for g in PR.symmetric_group()
....:     for v in PR.basis() for x in PA.basis())
True
```

```
>>> from sage.all import *
>>> all((g * v) * x == g * (v * x) for g in PR.symmetric_group()
...     for v in PR.basis() for x in PA.basis())
True
```

REFERENCES:

- [MR1998]

class Element

Bases: `IndexedFreeModuleElement`

magnetic_field_direction()

Return the magnetic field direction defining `self`.

EXAMPLES:

```
sage: PA = algebras.Partition(7/2, QQ(4))
sage: PR = PA.potts_representation(2)
sage: PR.magnetic_field_direction()
2
```

```
>>> from sage.all import *
>>> PA = algebras.Partition(Integer(7)/Integer(2), QQ(Integer(4)))
>>> PR = PA.potts_representation(Integer(2))
>>> PR.magnetic_field_direction()
2
```

number_of_colors()

Return the number of colors defining `self`.

EXAMPLES:

```
sage: PA = algebras.Partition(3, QQ(4))
sage: PR = PA.potts_representation()
sage: PR.number_of_colors()
4
```

```
>>> from sage.all import *
>>> PA = algebras.Partition(Integer(3), QQ(Integer(4)))
>>> PR = PA.potts_representation()
>>> PR.number_of_colors()
4
```

number_of_factors()

Return the number of factors defining `self`.

EXAMPLES:

```
sage: PA = algebras.Partition(7/2, QQ(4))
sage: PR = PA.potts_representation()
sage: PR.number_of_factors()
3
```

```
>>> from sage.all import *
>>> PA = algebras.Partition(Integer(7)/Integer(2), QQ(Integer(4)))
>>> PR = PA.potts_representation()
>>> PR.number_of_factors()
3
```

partition_algebra()

Return the partition algebra that `self` is a representation of.

EXAMPLES:

```
sage: PA = algebras.Partition(3, QQ(4))
sage: PR = PA.potts_representation()
sage: PR.partition_algebra() is PA
True
```

```
>>> from sage.all import *
>>> PA = algebras.Partition(Integer(3), QQ(Integer(4)))
>>> PR = PA.potts_representation()
>>> PR.partition_algebra() is PA
True
```

representation_matrix(*elt*)

Return the representation matrix of `self` in `self`.

EXAMPLES:

```
sage: PA = algebras.Partition(7/2, QQ(2))
sage: PR = PA.potts_representation()
sage: PR.representation_matrix(PA.an_element())
[7 0 3 0 2 0 0 0]

True
```

symmetric_group()

Return the symmetric group that naturally acts on `self`.

EXAMPLES:

```
sage: PA = algebras.Partition(3, QQ(4))
sage: PR = PA.potts_representation()
sage: PR.symmetric_group()
Symmetric group of order 4! as a permutation group
```

(continues on next page)

(continued from previous page)

```
sage: PA = algebras.Partition(7/2, QQ(4))
sage: PR = PA.potts_representation()
sage: PR.symmetric_group().domain()
{2, 3, 4}
sage: PR = PA.potts_representation(2)
sage: PR.symmetric_group().domain()
{1, 3, 4}
sage: PR = PA.potts_representation(4)
sage: PR.symmetric_group().domain()
{1, 2, 3}
```

```
>>> from sage.all import *

>>> PR = PA.potts_representation()
>>> PR.symmetric_group().domain()
{2, 3, 4}
>>> PR = PA.potts_representation(Integer(2))
>>> PR.symmetric_group().domain()
{1, 3, 4}
>>> PR = PA.potts_representation(Integer(4))
>>> PR.symmetric_group().domain()
{1, 2, 3}
```

class sage.combinat.diagram_algebras.**PropagatingIdeal**(*k*, *q*, *base_ring*, *prefix*)

Bases: *SubPartitionAlgebra*

A propagating ideal.

The propagating ideal of rank k is a non-unital algebra with basis indexed by the collection of ideal set partitions of $\{1, \ldots, k, -1, \ldots, -k\}$. We say a set partition is *ideal* if its propagating number is less than k.

This algebra is a non-unital subalgebra and an ideal of the partition algebra. For more information, see *PartitionAlgebra*.

EXAMPLES:

We now define the propagating ideal of rank 2 with parameter x over $\mathbf{Z}$:

```
sage: R.<x> = QQ[]
sage: I = PropagatingIdeal(2, x, R); I
Propagating Ideal of rank 2 with parameter x
 over Univariate Polynomial Ring in x over Rational Field
sage: I.basis().keys()
Ideal diagrams of order 2
sage: I.basis().list()
[I{{-2, -1, 1, 2}},
 I{{-2, 1, 2}, {-1}},
 I{{-2}, {-1, 1, 2}},
 I{{-2, -1}, {1, 2}},
```

(continues on next page)

(continued from previous page)

```
 I{{-2}, {-1}, {1, 2}},
 I{{-2, -1, 1}, {2}},
 I{{-2, 1}, {-1}, {2}},
 I{{-2, -1, 2}, {1}},
 I{{-2, 2}, {-1}, {1}},
 I{{-2}, {-1, 1}, {2}},
 I{{-2}, {-1, 2}, {1}},
 I{{-2, -1}, {1}, {2}},
 I{{-2}, {-1}, {1}, {2}}]
sage: E = I([[1,2],[-1,-2]])
sage: E^2 == x*E
True
sage: E^5 == x^4*E
True
```

```
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> I = PropagatingIdeal(Integer(2), x, R); I
Propagating Ideal of rank 2 with parameter x
 over Univariate Polynomial Ring in x over Rational Field
>>> I.basis().keys()
Ideal diagrams of order 2
>>> I.basis().list()
[I{{-2, -1, 1, 2}},
 I{{-2, 1, 2}, {-1}},
 I{{-2}, {-1, 1, 2}},
 I{{-2, -1}, {1, 2}},
 I{{-2}, {-1}, {1, 2}},
 I{{-2, -1, 1}, {2}},
 I{{-2, 1}, {-1}, {2}},
 I{{-2, -1, 2}, {1}},
 I{{-2, 2}, {-1}, {1}},
 I{{-2}, {-1, 1}, {2}},
 I{{-2}, {-1, 2}, {1}},
 I{{-2, -1}, {1}, {2}},
 I{{-2}, {-1}, {1}, {2}}]
>>> E = I([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)]])
>>> E**Integer(2) == x*E
True
>>> E**Integer(5) == x**Integer(4)*E
True
```

class Element

Bases: *Element*

An element of a propagating ideal.

We need to take care of exponents since we are not unital.

class sage.combinat.diagram_algebras.**SubPartitionAlgebra**(*k*, *q*, *base_ring*, *prefix*, *diagrams*, *category=None*)

Bases: *DiagramBasis*

A subalgebra of the partition algebra in the diagram basis indexed by a subset of the diagrams.

class Element

Bases: `Element`

to_orbit_basis()

Return `self` in the orbit basis of the associated ambient partition algebra.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: B = BrauerAlgebra(2, x, R)
sage: bb = B([[-2, -1], [1, 2]]); bb
B{{-2, -1}, {1, 2}}
sage: bb.to_orbit_basis()
O{{-2, -1}, {1, 2}} + O{{-2, -1, 1, 2}}
```

```
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> B = BrauerAlgebra(Integer(2), x, R)
>>> bb = B([[-Integer(2), -Integer(1)], [Integer(1), Integer(2)]]); bb
B{{-2, -1}, {1, 2}}
>>> bb.to_orbit_basis()
O{{-2, -1}, {1, 2}} + O{{-2, -1, 1, 2}}
```

ambient()

Return the partition algebra `self` is a sub-algebra of.

EXAMPLES:

```
sage: x = var('x')                                                    #␣
↪needs sage.symbolic
sage: BA = BrauerAlgebra(2, x)                                        #␣
↪needs sage.symbolic
sage: BA.ambient()                                                    #␣
↪needs sage.symbolic
Partition Algebra of rank 2 with parameter x over Symbolic Ring
```

```
>>> from sage.all import *
>>> x = var('x')                                                    #␣
↪needs sage.symbolic
>>> BA = BrauerAlgebra(Integer(2), x)                                ␣
↪      # needs sage.symbolic
>>> BA.ambient()                                                    #␣
↪needs sage.symbolic
Partition Algebra of rank 2 with parameter x over Symbolic Ring
```

lift()

Return the lift map from diagram subalgebra to the ambient space.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: BA = BrauerAlgebra(2, x, R)
sage: E = BA([[1,2],[-1,-2]])
sage: lifted = BA.lift(E); lifted
```

(continues on next page)

(continued from previous page)

```
B{{-2, -1}, {1, 2}}
sage: lifted.parent() is BA.ambient()
True
```

```
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> BA = BrauerAlgebra(Integer(2), x, R)
>>> E = BA([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)]])
>>> lifted = BA.lift(E); lifted
B{{-2, -1}, {1, 2}}
>>> lifted.parent() is BA.ambient()
True
```

retract(*x*)

Retract an appropriate partition algebra element to the corresponding element in the partition subalgebra.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: BA = BrauerAlgebra(2, x, R)
sage: PA = BA.ambient()
sage: E = PA([[1,2], [-1,-2]])
sage: BA.retract(E) in BA
True
```

```
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> BA = BrauerAlgebra(Integer(2), x, R)
>>> PA = BA.ambient()
>>> E = PA([[Integer(1),Integer(2)], [-Integer(1),-Integer(2)]])
>>> BA.retract(E) in BA
True
```

sage.combinat.diagram_algebras.**TL_diagram_ascii_art**(*diagram*, *use_unicode=False*, *blobs=[]*)

Return ascii art for a Temperley-Lieb diagram `diagram`.

INPUT:

- `diagram` – list of pairs of matchings of the set $\{-1, \ldots, -n, 1, \ldots, n\}$
- `use_unicode` – boolean (default: `False`); whether or not to use unicode art instead of ascii art
- `blobs` – (optional) a list of matchings with blobs on them

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import TL_diagram_ascii_art
sage: TL = [(-15,-12), (-14,-13), (-11,15), (-10,14), (-9,-6),
....:       (-8,-7), (-5,-4), (-3,1), (-2,-1), (2,3), (4,5),
....:       (6,11), (7, 8), (9,10), (12,13)]
sage: TL_diagram_ascii_art(TL, use_unicode=False)
 o o o o o o o o o o o o o o o
 | `-` `-` | `-` `-` | `-` | |

class sage.combinat.diagram_algebras.**TemperleyLiebAlgebra**(*k*, *q*, *base_ring*, *prefix*)

Bases: *SubPartitionAlgebra*, *UnitDiagramMixin*

A Temperley–Lieb algebra.

The Temperley–Lieb algebra of rank k is an algebra with basis indexed by the collection of planar set partitions of $\{1, \ldots, k, -1, \ldots, -k\}$ with block size 2.

This algebra is thus a subalgebra of the partition algebra. For more information, see *PartitionAlgebra*.

INPUT:

- `k` – rank of the algebra
- `q` – the deformation parameter q
- `base_ring` – (default: `None`) a ring containing `q`; if `None` then just takes the parent of `q`
- `prefix` – (default: `'T'`) a label for the basis elements

EXAMPLES:

We define the Temperley–Lieb algebra of rank 2 with parameter x over $\mathbf{Z}$:

```
sage: R.<x> = ZZ[]
sage: T = TemperleyLiebAlgebra(2, x, R); T
Temperley-Lieb Algebra of rank 2 with parameter x
 over Univariate Polynomial Ring in x over Integer Ring
sage: T.basis()
Lazy family (Term map from Temperley Lieb diagrams of order 2
 to Temperley-Lieb Algebra of rank 2 with parameter x over
 Univariate Polynomial Ring in x over Integer
 Ring(i))_{i in Temperley Lieb diagrams of order 2}
sage: T.basis().keys()
Temperley Lieb diagrams of order 2
sage: T.basis().keys()([[-1, 1], [2, -2]])
{{-2, 2}, {-1, 1}}
sage: b = T.basis().list(); b
[T{{-2, -1}, {1, 2}}, T{{-2, 2}, {-1, 1}}]
sage: b[0]
T{{-2, -1}, {1, 2}}
sage: b[0]^2 == x*b[0]
True
sage: b[0]^5 == x^4*b[0]
True
```

```
>>> from sage.all import *
>>> R = ZZ['x']; (x,) = R._first_ngens(1)
>>> T = TemperleyLiebAlgebra(Integer(2), x, R); T
Temperley-Lieb Algebra of rank 2 with parameter x
 over Univariate Polynomial Ring in x over Integer Ring
>>> T.basis()
Lazy family (Term map from Temperley Lieb diagrams of order 2
 to Temperley-Lieb Algebra of rank 2 with parameter x over
```

(continues on next page)

(continued from previous page)

```
 Univariate Polynomial Ring in x over Integer
 Ring(i))_{i in Temperley Lieb diagrams of order 2}
>>> T.basis().keys()
Temperley Lieb diagrams of order 2
>>> T.basis().keys()([[-Integer(1), Integer(1)], [Integer(2), -Integer(2)]])
{{-2, 2}, {-1, 1}}
>>> b = T.basis().list(); b
[T{{-2, -1}, {1, 2}}, T{{-2, 2}, {-1, 1}}]
>>> b[Integer(0)]
T{{-2, -1}, {1, 2}}
>>> b[Integer(0)]**Integer(2) == x*b[Integer(0)]
True
>>> b[Integer(0)]**Integer(5) == x**Integer(4)*b[Integer(0)]
True
```

The Temperley-Lieb algebra is a cellular algebra, and we verify that the dimensions of the simple modules at $q = 0$ is given by OEIS sequence A050166:

```
sage: for k in range(1,5):
....:     TL = TemperleyLiebAlgebra(2*k, 0, QQ)
....:     print("".join("{:3}".format(TL.cell_module(la).simple_module().
↪dimension())
....:                   for la in reversed(TL.cell_poset()) if la != 0))
  1
  1  2
  1  4  5
  1  6 14 14
sage: for k in range(1,4):
....:     TL = TemperleyLiebAlgebra(2*k+1, 0, QQ)
....:     print("".join("{:3}".format(TL.cell_module(la).simple_module().
↪dimension())
....:                   for la in reversed(TL.cell_poset()) if la != 0))
  1  2
  1  4  5
  1  6 14 14
```

```
>>> from sage.all import *
>>> for k in range(Integer(1),Integer(5)):
...     TL = TemperleyLiebAlgebra(Integer(2)*k, Integer(0), QQ)
...     print("".join("{:3}".format(TL.cell_module(la).simple_module().
↪dimension())
...                   for la in reversed(TL.cell_poset()) if la != Integer(0)))
  1
  1  2
  1  4  5
  1  6 14 14
>>> for k in range(Integer(1),Integer(4)):
...     TL = TemperleyLiebAlgebra(Integer(2)*k+Integer(1), Integer(0), QQ)
...     print("".join("{:3}".format(TL.cell_module(la).simple_module().
↪dimension())
...                   for la in reversed(TL.cell_poset()) if la != Integer(0)))
  1  2
```

(continues on next page)

(continued from previous page)

  1  1
  1  3  2
  1  5  8  5
  1  7 20 21 13
```

cell_module_indices(*la*)

Return the indices of the cell module of `self` indexed by `la` .

This is the finite set $M(\lambda)$.

EXAMPLES:

```
sage: R.<q> = QQ[]
sage: TL = TemperleyLiebAlgebra(8, q, R)
sage: TL.cell_module_indices(4)
Half Temperley-Lieb diagrams of order 8 with 4 defects
```

```
>>> from sage.all import *
>>> R = QQ['q']; (q,) = R._first_ngens(1)
>>> TL = TemperleyLiebAlgebra(Integer(8), q, R)
>>> TL.cell_module_indices(Integer(4))
Half Temperley-Lieb diagrams of order 8 with 4 defects
```

cell_poset()

Return the cell poset of `self`.

EXAMPLES:

```
sage: R.<q> = QQ[]
sage: TL = TemperleyLiebAlgebra(7, q, R)
sage: TL.cell_poset().cover_relations()
[[1, 3], [3, 5], [5, 7]]

sage: TL = TemperleyLiebAlgebra(8, q, R)
sage: TL.cell_poset().cover_relations()
[[0, 2], [2, 4], [4, 6], [6, 8]]
```

```
>>> from sage.all import *
>>> R = QQ['q']; (q,) = R._first_ngens(1)
>>> TL = TemperleyLiebAlgebra(Integer(7), q, R)
>>> TL.cell_poset().cover_relations()
[[1, 3], [3, 5], [5, 7]]

>>> TL = TemperleyLiebAlgebra(Integer(8), q, R)
>>> TL.cell_poset().cover_relations()
[[0, 2], [2, 4], [4, 6], [6, 8]]
```

cellular_involution(*x*)

Return the cellular involution of `x` in `self`.

EXAMPLES:

```
sage: TL = TemperleyLiebAlgebra(4, QQ.zero(), QQ)
sage: ascii_art(TL.an_element())
                o o o o       o o o o
   o o o o      | `-` |       | `-` |
2* `-` `-` + 2* `-----`  + 3* `---. |
   .-. .-.      .-. .-.       .-. | |
   o o o o      o o o o       o o o o
sage: ascii_art(TL.cellular_involution(TL.an_element()))
                o o o o       o o o o
   o o o o      `-` `-`       `-` | |
2* `-` `-` + 2* .-----.  + 3* .---` |
   .-. .-.      | .-. |       | .-. |
   o o o o      o o o o       o o o o
```

```
>>> from sage.all import *
>>> TL = TemperleyLiebAlgebra(Integer(4), QQ.zero(), QQ)
>>> ascii_art(TL.an_element())
                o o o o       o o o o
   o o o o      | `-` |       | `-` |
2* `-` `-` + 2* `-----`  + 3* `---. |
   .-. .-.      .-. .-.       .-. | |
   o o o o      o o o o       o o o o
>>> ascii_art(TL.cellular_involution(TL.an_element()))
                o o o o       o o o o
   o o o o      `-` `-`       `-` | |
2* `-` `-` + 2* .-----.  + 3* .---` |
   .-. .-.      | .-. |       | .-. |
   o o o o      o o o o       o o o o
```

class sage.combinat.diagram_algebras.**TemperleyLiebDiagram**(*parent*, *d*, *check=True*)

Bases: *AbstractPartitionDiagram*

The element class for a Temperley-Lieb diagram.

A Temperley-Lieb diagram for an integer k is a partition of the set $\{1, \ldots, k, -1, \ldots, -k\}$ so that the blocks are all of size 2 and the diagram is planar.

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import TemperleyLiebDiagrams
sage: TemperleyLiebDiagrams(2)
Temperley Lieb diagrams of order 2
sage: TemperleyLiebDiagrams(2).list()
[{{-2, -1}, {1, 2}}, {{-2, 2}, {-1, 1}}]
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import TemperleyLiebDiagrams
>>> TemperleyLiebDiagrams(Integer(2))
Temperley Lieb diagrams of order 2
>>> TemperleyLiebDiagrams(Integer(2)).list()
[{{-2, -1}, {1, 2}}, {{-2, 2}, {-1, 1}}]
```

check()

Check the validity of the input for `self`.

class sage.combinat.diagram_algebras.**TemperleyLiebDiagrams**(*order*, *category=None*)

Bases: *AbstractPartitionDiagrams*

All Temperley-Lieb diagrams of integer or integer $+1/2$ order.

For more information on Temperley-Lieb diagrams, see *TemperleyLiebAlgebra*.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: td = da.TemperleyLiebDiagrams(3); td
Temperley Lieb diagrams of order 3
sage: td.list()
[{{-3, 3}, {-2, -1}, {1, 2}},
 {{-3, 1}, {-2, -1}, {2, 3}},
 {{-3, -2}, {-1, 1}, {2, 3}},
 {{-3, -2}, {-1, 3}, {1, 2}},
 {{-3, 3}, {-2, 2}, {-1, 1}}]

sage: td = da.TemperleyLiebDiagrams(5/2); td
Temperley Lieb diagrams of order 5/2
sage: td.list()
[{{-3, 3}, {-2, -1}, {1, 2}}, {{-3, 3}, {-2, 2}, {-1, 1}}]
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> td = da.TemperleyLiebDiagrams(Integer(3)); td
Temperley Lieb diagrams of order 3
>>> td.list()
[{{-3, 3}, {-2, -1}, {1, 2}},
 {{-3, 1}, {-2, -1}, {2, 3}},
 {{-3, -2}, {-1, 1}, {2, 3}},
 {{-3, -2}, {-1, 3}, {1, 2}},
 {{-3, 3}, {-2, 2}, {-1, 1}}]

>>> td = da.TemperleyLiebDiagrams(Integer(5)/Integer(2)); td
Temperley Lieb diagrams of order 5/2
```

(continues on next page)

(continued from previous page)

```
>>> td.list()
[{{-3, 3}, {-2, -1}, {1, 2}}, {{-3, 3}, {-2, 2}, {-1, 1}}]
```

Element

alias of *TemperleyLiebDiagram*

cardinality()

Return the cardinality of `self`.

The number of Temperley–Lieb diagrams of integer order k is the k-th Catalan number.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: td = da.TemperleyLiebDiagrams(3)
sage: td.cardinality()
5
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> td = da.TemperleyLiebDiagrams(Integer(3))
>>> td.cardinality()
5
```

class sage.combinat.diagram_algebras.**UnitDiagramMixin**

Bases: `object`

Mixin class for diagram algebras that have the unit indexed by the *identity_set_partition()*.

one_basis()

The following constructs the identity element of `self`.

It is not called directly; instead one should use `DA.one()` if `DA` is a defined diagram algebra.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(2, x, R)
sage: P.one_basis()
{{-2, 2}, {-1, 1}}
```

```
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> P = PartitionAlgebra(Integer(2), x, R)
>>> P.one_basis()
{{-2, 2}, {-1, 1}}
```

sage.combinat.diagram_algebras.**brauer_diagrams**(k)

Return a generator of all Brauer diagrams of order `k`.

A Brauer diagram of order k is a partition diagram of order k with block size 2.

INPUT:

- `k` – the order of the Brauer diagrams

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: [SetPartition(p) for p in da.brauer_diagrams(2)]
[{{-2, -1}, {1, 2}}, {{-2, 1}, {-1, 2}}, {{-2, 2}, {-1, 1}}]
sage: [SetPartition(p) for p in da.brauer_diagrams(5/2)]
[{{-3, 3}, {-2, -1}, {1, 2}},
 {{-3, 3}, {-2, 1}, {-1, 2}},
 {{-3, 3}, {-2, 2}, {-1, 1}}]
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> [SetPartition(p) for p in da.brauer_diagrams(Integer(2))]
[{{-2, -1}, {1, 2}}, {{-2, 1}, {-1, 2}}, {{-2, 2}, {-1, 1}}]
>>> [SetPartition(p) for p in da.brauer_diagrams(Integer(5)/Integer(2))]
[{{-3, 3}, {-2, -1}, {1, 2}},
 {{-3, 3}, {-2, 1}, {-1, 2}},
 {{-3, 3}, {-2, 2}, {-1, 1}}]
```

sage.combinat.diagram_algebras.**diagram_latex**(*diagram*, *fill=False*, *edge_options=None*, *edge_additions=None*)

Return latex code for the diagram `diagram` using tikz.

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import PartitionDiagrams, diagram_latex
sage: P = PartitionDiagrams(2)
sage: D = P([[1,2],[-2,-1]])
sage: print(diagram_latex(D)) # indirect doctest
\begin{tikzpicture}[scale = 0.5,thick, baseline={(0,-1ex/2)}]
\tikzstyle{vertex} = [shape = circle, minimum size = 7pt, inner sep = 1pt]
\node[vertex] (G--2) at (1.5, -1) [shape = circle, draw] {};
\node[vertex] (G--1) at (0.0, -1) [shape = circle, draw] {};
\node[vertex] (G-1) at (0.0, 1) [shape = circle, draw] {};
\node[vertex] (G-2) at (1.5, 1) [shape = circle, draw] {};
\draw[] (G--2) .. controls +(-0.5, 0.5) and +(0.5, 0.5) .. (G--1);
\draw[] (G-1) .. controls +(0.5, -0.5) and +(-0.5, -0.5) .. (G-2);
\end{tikzpicture}
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram_algebras import PartitionDiagrams, diagram_latex
>>> P = PartitionDiagrams(Integer(2))
>>> D = P([[Integer(1),Integer(2)],[-Integer(2),-Integer(1)]])
>>> print(diagram_latex(D)) # indirect doctest
\begin{tikzpicture}[scale = 0.5,thick, baseline={(0,-1ex/2)}]
\tikzstyle{vertex} = [shape = circle, minimum size = 7pt, inner sep = 1pt]
\node[vertex] (G--2) at (1.5, -1) [shape = circle, draw] {};
\node[vertex] (G--1) at (0.0, -1) [shape = circle, draw] {};
\node[vertex] (G-1) at (0.0, 1) [shape = circle, draw] {};
\node[vertex] (G-2) at (1.5, 1) [shape = circle, draw] {};
\draw[] (G--2) .. controls +(-0.5, 0.5) and +(0.5, 0.5) .. (G--1);
\draw[] (G-1) .. controls +(0.5, -0.5) and +(-0.5, -0.5) .. (G-2);
\end{tikzpicture}
```

sage.combinat.diagram_algebras.**ideal_diagrams**(*k*)

Return a generator of all "ideal" diagrams of order k.

An ideal diagram of order k is a partition diagram of order k with propagating number less than k.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: all_diagrams = da.partition_diagrams(2)
sage: [SetPartition(p) for p in all_diagrams if p not in da.ideal_diagrams(2)]
[{{-2, 1}, {-1, 2}}, {{-2, 2}, {-1, 1}}]

sage: all_diagrams = da.partition_diagrams(3/2)
sage: [SetPartition(p) for p in all_diagrams if p not in da.ideal_diagrams(3/2)]
[{{-2, 2}, {-1, 1}}]
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> all_diagrams = da.partition_diagrams(Integer(2))
>>> [SetPartition(p) for p in all_diagrams if p not in da.ideal_
↪diagrams(Integer(2))]
[{{-2, 1}, {-1, 2}}, {{-2, 2}, {-1, 1}}]

>>> all_diagrams = da.partition_diagrams(Integer(3)/Integer(2))
>>> [SetPartition(p) for p in all_diagrams if p not in da.ideal_
↪diagrams(Integer(3)/Integer(2))]
[{{-2, 2}, {-1, 1}}]
```

sage.combinat.diagram_algebras.**identity_set_partition**(*k*)

Return the identity set partition $\{\{1,-1\},\ldots,\{k,-k\}\}$.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: SetPartition(da.identity_set_partition(2))
{{-2, 2}, {-1, 1}}
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> SetPartition(da.identity_set_partition(Integer(2)))
{{-2, 2}, {-1, 1}}
```

sage.combinat.diagram_algebras.**is_planar**(*sp*)

Return True if the diagram corresponding to the set partition sp is planar; otherwise, return False.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: da.is_planar( da.to_set_partition([[1,-2],[2,-1]]))
False
sage: da.is_planar( da.to_set_partition([[1,-1],[2,-2]]))
True
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
```

(continues on next page)

(continued from previous page)

```
>>> da.is_planar( da.to_set_partition([[Integer(1),-Integer(2)],[Integer(2),-
↪Integer(1)]]))
False
>>> da.is_planar( da.to_set_partition([[Integer(1),-Integer(1)],[Integer(2),-
↪Integer(2)]]))
True
```

sage.combinat.diagram_algebras.**pair_to_graph**(*sp1*, *sp2*)

Return a graph consisting of the disjoint union of the graphs of set partitions `sp1` and `sp2` along with edges joining the bottom row (negative numbers) of `sp1` to the top row (positive numbers) of `sp2`.

The vertices of the graph `sp1` appear in the result as pairs `(k, 1)`, whereas the vertices of the graph `sp2` appear as pairs `(k, 2)`.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: sp1 = da.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = da.to_set_partition([[1,-2],[2,-1]])
sage: g = da.pair_to_graph( sp1, sp2 ); g
Graph on 8 vertices

sage: g.vertices(sort=True)
[(-2, 1), (-2, 2), (-1, 1), (-1, 2), (1, 1), (1, 2), (2, 1), (2, 2)]
sage: g.edges(sort=True)
[((-2, 1), (1, 1), None), ((-2, 1), (2, 2), None),
 ((-2, 2), (1, 2), None), ((-1, 1), (1, 2), None),
 ((-1, 1), (2, 1), None), ((-1, 2), (2, 2), None)]
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> sp1 = da.to_set_partition([[Integer(1),-Integer(2)],[Integer(2),-Integer(1)]])
>>> sp2 = da.to_set_partition([[Integer(1),-Integer(2)],[Integer(2),-Integer(1)]])
>>> g = da.pair_to_graph( sp1, sp2 ); g
Graph on 8 vertices

>>> g.vertices(sort=True)
[(-2, 1), (-2, 2), (-1, 1), (-1, 2), (1, 1), (1, 2), (2, 1), (2, 2)]
>>> g.edges(sort=True)
[((-2, 1), (1, 1), None), ((-2, 1), (2, 2), None),
 ((-2, 2), (1, 2), None), ((-1, 1), (1, 2), None),
 ((-1, 1), (2, 1), None), ((-1, 2), (2, 2), None)]
```

Another example which used to be wrong until Issue #15958:

```
sage: sp3 = da.to_set_partition([[1, -1], [2], [-2]])
sage: sp4 = da.to_set_partition([[1], [-1], [2], [-2]])
sage: g = da.pair_to_graph( sp3, sp4 ); g
Graph on 8 vertices

sage: g.vertices(sort=True)
[(-2, 1), (-2, 2), (-1, 1), (-1, 2), (1, 1), (1, 2), (2, 1), (2, 2)]
sage: g.edges(sort=True)
```

(continues on next page)

(continued from previous page)

```
[((-2, 1), (2, 2), None), ((-1, 1), (1, 1), None),
 ((-1, 1), (1, 2), None)]
```

```
>>> from sage.all import *
>>> sp3 = da.to_set_partition([[Integer(1), -Integer(1)], [Integer(2)], [-
↪Integer(2)]])
>>> sp4 = da.to_set_partition([[Integer(1)], [-Integer(1)], [Integer(2)], [-
↪Integer(2)]])
>>> g = da.pair_to_graph( sp3, sp4 ); g
Graph on 8 vertices

>>> g.vertices(sort=True)
[(-2, 1), (-2, 2), (-1, 1), (-1, 2), (1, 1), (1, 2), (2, 1), (2, 2)]
>>> g.edges(sort=True)
[((-2, 1), (2, 2), None), ((-1, 1), (1, 1), None),
 ((-1, 1), (1, 2), None)]
```

sage.combinat.diagram_algebras.**partition_diagrams**(k)

Return a generator of all partition diagrams of order `k`.

A partition diagram of order $k \in \mathbf{Z}$ to is a set partition of $\{1, \ldots, k, -1, \ldots, -k\}$. If we have $k - 1/2 \in ZZ$, then a partition diagram of order $k \in 1/2\mathbf{Z}$ is a set partition of $\{1, \ldots, k + 1/2, -1, \ldots, -(k + 1/2)\}$ with $k + 1/2$ and $-(k + 1/2)$ in the same block. See [HR2005].

INPUT:

- `k` – the order of the partition diagrams

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: [SetPartition(p) for p in da.partition_diagrams(2)]
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2}, {-1, 1, 2}},
 {{-2, -1}, {1, 2}},
 {{-2}, {-1}, {1, 2}},
 {{-2, -1, 1}, {2}},
 {{-2, 1}, {-1, 2}},
 {{-2, 1}, {-1}, {2}},
 {{-2, 2}, {-1, 1}},
 {{-2, -1, 2}, {1}},
 {{-2, 2}, {-1}, {1}},
 {{-2}, {-1, 1}, {2}},
 {{-2}, {-1, 2}, {1}},
 {{-2, -1}, {1}, {2}},
 {{-2}, {-1}, {1}, {2}}]
sage: [SetPartition(p) for p in da.partition_diagrams(3/2)]
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2, 2}, {-1, 1}},
 {{-2, -1, 2}, {1}},
 {{-2, 2}, {-1}, {1}}]
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> [SetPartition(p) for p in da.partition_diagrams(Integer(2))]
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2}, {-1, 1, 2}},
 {{-2, -1}, {1, 2}},
 {{-2}, {-1}, {1, 2}},
 {{-2, -1, 1}, {2}},
 {{-2, 1}, {-1, 2}},
 {{-2, 1}, {-1}, {2}},
 {{-2, 2}, {-1, 1}},
 {{-2, -1, 2}, {1}},
 {{-2, 2}, {-1}, {1}},
 {{-2}, {-1, 1}, {2}},
 {{-2}, {-1, 2}, {1}},
 {{-2, -1}, {1}, {2}},
 {{-2}, {-1}, {1}, {2}}]
>>> [SetPartition(p) for p in da.partition_diagrams(Integer(3)/Integer(2))]
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2, 2}, {-1, 1}},
 {{-2, -1, 2}, {1}},
 {{-2, 2}, {-1}, {1}}]
```

sage.combinat.diagram_algebras.**planar_diagrams**(k)

Return a generator of all planar diagrams of order `k`.

A planar diagram of order k is a partition diagram of order k that has no crossings.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: all_diagrams = [SetPartition(p) for p in da.partition_diagrams(2)]
sage: da2 = [SetPartition(p) for p in da.planar_diagrams(2)]
sage: [p for p in all_diagrams if p not in da2]
[{{-2, 1}, {-1, 2}}]
sage: all_diagrams = [SetPartition(p) for p in da.partition_diagrams(5/2)]
sage: da5o2 = [SetPartition(p) for p in da.planar_diagrams(5/2)]
sage: [p for p in all_diagrams if p not in da5o2]
[{{-3, -1, 3}, {-2, 1, 2}},
 {{-3, -2, 1, 3}, {-1, 2}},
 {{-3, -1, 1, 3}, {-2, 2}},
 {{-3, 1, 3}, {-2, -1, 2}},
 {{-3, 1, 3}, {-2, 2}, {-1}},
 {{-3, 1, 3}, {-2}, {-1, 2}},
 {{-3, -1, 2, 3}, {-2, 1}},
 {{-3, 3}, {-2, 1}, {-1, 2}},
 {{-3, -1, 3}, {-2, 1}, {2}},
 {{-3, -1, 3}, {-2, 2}, {1}}]
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
```

(continues on next page)

(continued from previous page)

```
>>> all_diagrams = [SetPartition(p) for p in da.partition_diagrams(Integer(2))]
>>> da2 = [SetPartition(p) for p in da.planar_diagrams(Integer(2))]
>>> [p for p in all_diagrams if p not in da2]
[{{-2, 1}, {-1, 2}}]
>>> all_diagrams = [SetPartition(p) for p in da.partition_diagrams(Integer(5)/
↪Integer(2))]
>>> da5o2 = [SetPartition(p) for p in da.planar_diagrams(Integer(5)/Integer(2))]
>>> [p for p in all_diagrams if p not in da5o2]
[{{-3, -1, 3}, {-2, 1, 2}},
 {{-3, -2, 1, 3}, {-1, 2}},
 {{-3, -1, 1, 3}, {-2, 2}},
 {{-3, 1, 3}, {-2, -1, 2}},
 {{-3, 1, 3}, {-2, 2}, {-1}},
 {{-3, 1, 3}, {-2}, {-1, 2}},
 {{-3, -1, 2, 3}, {-2, 1}},
 {{-3, 3}, {-2, 1}, {-1, 2}},
 {{-3, -1, 3}, {-2, 1}, {2}},
 {{-3, -1, 3}, {-2, 2}, {1}}]
```

sage.combinat.diagram_algebras.**planar_partitions_rec**(*X*)

Iterate over all planar set partitions of X by using a recursive algorithm.

ALGORITHM:

To construct the set partition $\rho = \{\rho_1, \ldots, \rho_k\}$ of $[n]$, we remove the part of the set partition containing the last element of X, which, we consider to be $\rho_k = \{i_1, \ldots, i_m\}$ without loss of generality. The remaining parts come from the planar set partitions of $\{1, \ldots, i_1 - 1\}, \{i_1 + 1, \ldots, i_2 - 1\}, \ldots, \{i_m + 1, \ldots, n\}$.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: list(da.planar_partitions_rec([1,2,3]))
[([1, 2], [3]), ([1], [2], [3]), ([2], [1, 3]), ([1], [2, 3]), ([1, 2, 3],)]
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> list(da.planar_partitions_rec([Integer(1),Integer(2),Integer(3)]))
[([1, 2], [3]), ([1], [2], [3]), ([2], [1, 3]), ([1], [2, 3]), ([1, 2, 3],)]
```

sage.combinat.diagram_algebras.**propagating_number**(*sp*)

Return the propagating number of the set partition sp.

The propagating number is the number of blocks with both a positive and negative number.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: sp1 = da.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = da.to_set_partition([[1,2],[-2,-1]])
sage: da.propagating_number(sp1)
2
sage: da.propagating_number(sp2)
0
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> sp1 = da.to_set_partition([[Integer(1),-Integer(2)],[Integer(2),-Integer(1)]])
>>> sp2 = da.to_set_partition([[Integer(1),Integer(2)],[-Integer(2),-Integer(1)]])
>>> da.propagating_number(sp1)
2
>>> da.propagating_number(sp2)
0
```

sage.combinat.diagram_algebras.**temperley_lieb_diagrams**(*k*)

Return a generator of all Temperley–Lieb diagrams of order k.

A Temperley–Lieb diagram of order k is a partition diagram of order k with block size 2 and is planar.

INPUT:

- k – the order of the Temperley–Lieb diagrams

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: [SetPartition(p) for p in da.temperley_lieb_diagrams(2)]
[{{-2, -1}, {1, 2}}, {{-2, 2}, {-1, 1}}]
sage: [SetPartition(p) for p in da.temperley_lieb_diagrams(5/2)]
[{{-3, 3}, {-2, -1}, {1, 2}}, {{-3, 3}, {-2, 2}, {-1, 1}}]
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> [SetPartition(p) for p in da.temperley_lieb_diagrams(Integer(2))]
[{{-2, -1}, {1, 2}}, {{-2, 2}, {-1, 1}}]
>>> [SetPartition(p) for p in da.temperley_lieb_diagrams(Integer(5)/Integer(2))]
[{{-3, 3}, {-2, -1}, {1, 2}}, {{-3, 3}, {-2, 2}, {-1, 1}}]
```

sage.combinat.diagram_algebras.**to_Brauer_partition**(*l*, *k=None*)

Same as *to_set_partition()* but assumes omitted elements are connected straight through.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: f = lambda sp: SetPartition(da.to_Brauer_partition(sp))
sage: f([[1,2],[-1,-2]]) == SetPartition([[1,2],[-1,-2]])
True
sage: f([[1,3],[-1,-3]]) == SetPartition([[1,3],[-3,-1],[2,-2]])
True
sage: f([[1,-4],[-3,-1],[3,4]]) == SetPartition([[-3,-1],[2,-2],[1,-4],[3,4]])
True
sage: p = SetPartition([[1,2],[-1,-2],[3,-3],[4,-4]])
sage: SetPartition(da.to_Brauer_partition([[1,2],[-1,-2]], k=4)) == p
True
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> f = lambda sp: SetPartition(da.to_Brauer_partition(sp))
>>> f([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)]]) ==␣
```

(continues on next page)

(continued from previous page)

```
↪SetPartition([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)]])
True
>>> f([[Integer(1),Integer(3)],[-Integer(1),-Integer(3)]]) ==␣
↪SetPartition([[Integer(1),Integer(3)],[-Integer(3),-Integer(1)],[Integer(2),-
↪Integer(2)]])
True
>>> f([[Integer(1),-Integer(4)],[-Integer(3),-Integer(1)],[Integer(3),
↪Integer(4)]]) == SetPartition([[-Integer(3),-Integer(1)],[Integer(2),-
↪Integer(2)],[Integer(1),-Integer(4)],[Integer(3),Integer(4)]])
True
>>> p = SetPartition([[Integer(1),Integer(2)],[-Integer(1),-Integer(2)],
↪[Integer(3),-Integer(3)],[Integer(4),-Integer(4)]])
>>> SetPartition(da.to_Brauer_partition([[Integer(1),Integer(2)],[-Integer(1),-
↪Integer(2)]], k=Integer(4))) == p
True
```

`sage.combinat.diagram_algebras.`**`to_graph`**`(`*sp*`)`

Return a graph representing the set partition `sp`.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: g = da.to_graph( da.to_set_partition([[1,-2],[2,-1]])); g
Graph on 4 vertices

sage: g.vertices(sort=True)
[-2, -1, 1, 2]
sage: g.edges(sort=True)
[(-2, 1, None), (-1, 2, None)]
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> g = da.to_graph( da.to_set_partition([[Integer(1),-Integer(2)],[Integer(2),-
↪Integer(1)]])); g
Graph on 4 vertices

>>> g.vertices(sort=True)
[-2, -1, 1, 2]
>>> g.edges(sort=True)
[(-2, 1, None), (-1, 2, None)]
```

`sage.combinat.diagram_algebras.`**`to_set_partition`**`(`*l*, *k=None*`)`

Convert input to a set partition of $\{1, \ldots, k, -1, \ldots, -k\}$.

Convert a list of a list of numbers to a set partitions. Each list of numbers in the outer list specifies the numbers contained in one of the blocks in the set partition.

If k is specified, then the set partition will be a set partition of $\{1, \ldots, k, -1, \ldots, -k\}$. Otherwise, k will default to the minimum number needed to contain all of the specified numbers.

INPUT:

- `l` – list of lists of integers
- `k` – integer (default: `None`)

OUTPUT: list of sets

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: f = lambda sp: SetPartition(da.to_set_partition(sp))
sage: f([[1,-1],[2,-2]]) == SetPartition(da.identity_set_partition(2))
True
sage: da.to_set_partition([[1]])
[{1}, {-1}]
sage: da.to_set_partition([[1,-1],[-2,3]],9/2)
[{-1, 1}, {-2, 3}, {2}, {-4, 4}, {-5, 5}, {-3}]
```

```
>>> from sage.all import *
>>> import sage.combinat.diagram_algebras as da
>>> f = lambda sp: SetPartition(da.to_set_partition(sp))
>>> f([[Integer(1),-Integer(1)],[Integer(2),-Integer(2)]]) == SetPartition(da.
↪identity_set_partition(Integer(2)))
True
>>> da.to_set_partition([[Integer(1)]])
[{1}, {-1}]
>>> da.to_set_partition([[Integer(1),-Integer(1)],[-Integer(2),Integer(3)]],
↪Integer(9)/Integer(2))
[{-1, 1}, {-2, 3}, {2}, {-4, 4}, {-5, 5}, {-3}]
```

5.1.99 Exact Cover Problem via Dancing Links

sage.combinat.dlx.**AllExactCovers**(M)

Use A. Ajanki's DLXMatrix class to solve the exact cover problem on the matrix M (treated as a dense binary matrix).

EXAMPLES:

```
sage: # needs sage.modules
sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]])  # no exact covers
sage: for cover in AllExactCovers(M):
....:     print(cover)
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]]) # two exact covers
sage: for cover in AllExactCovers(M):
....:     print(cover)
[(1, 1, 0), (0, 0, 1)]
[(1, 0, 1), (0, 1, 0)]
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> M = Matrix([[Integer(1),Integer(1),Integer(0)],[Integer(1),Integer(0),
↪Integer(1)],[Integer(0),Integer(1),Integer(1)]])  # no exact covers
>>> for cover in AllExactCovers(M):
...     print(cover)
>>> M = Matrix([[Integer(1),Integer(1),Integer(0)],[Integer(1),Integer(0),
↪Integer(1)],[Integer(0),Integer(0),Integer(1)],[Integer(0),Integer(1),
↪Integer(0)]]) # two exact covers
>>> for cover in AllExactCovers(M):
```

(continues on next page)

(continued from previous page)

```
...     print(cover)
[(1, 1, 0), (0, 0, 1)]
[(1, 0, 1), (0, 1, 0)]
```

class sage.combinat.dlx.**DLXMatrix**(*ones*, *initialsolution=None*)

Bases: object

Solve the Exact Cover problem by using the Dancing Links algorithm described by Knuth.

Consider a matrix M with entries of 0 and 1, and compute a subset of the rows of this matrix which sum to the vector of all 1s.

The dancing links algorithm works particularly well for sparse matrices, so the input is a list of lists of the form: (note the 1-index!):

```
[
 [1, [i_11,i_12,...,i_1r]]
 ...
 [m,[i_m1,i_m2,...,i_ms]]
]
```

where M[j][i_jk] = 1.

The first example below corresponds to the matrix:

```
1110
1010
0100
0001
```

which is exactly covered by:

```
1110
0001
```

and

```
1010
0100
0001
```

EXAMPLES:

```
sage: from sage.combinat.dlx import *
sage: ones = [[1,[1,2,3]]]
sage: ones+= [[2,[1,3]]]
sage: ones+= [[3,[2]]]
sage: ones+= [[4,[4]]]
sage: DLXM = DLXMatrix(ones,[4])
sage: for C in DLXM:
....:     print(C)
[4, 1]
[4, 2, 3]
```

```
>>> from sage.all import *
>>> from sage.combinat.dlx import *
>>> ones = [[Integer(1),[Integer(1),Integer(2),Integer(3)]]]
>>> ones+= [[Integer(2),[Integer(1),Integer(3)]]]
>>> ones+= [[Integer(3),[Integer(2)]]]
>>> ones+= [[Integer(4),[Integer(4)]]]
>>> DLXM = DLXMatrix(ones,[Integer(4)])
>>> for C in DLXM:
...     print(C)
[4, 1]
[4, 2, 3]
```

Note

The 0 entry is reserved internally for headers in the sparse representation, so rows and columns begin their indexing with 1. Apologies for any heartache this causes. Blame the original author, or fix it yourself.

next()

Search for the first solution we can find, and return it.

Knuth describes the Dancing Links algorithm recursively, though actually implementing it as a recursive algorithm is permissible only for highly restricted problems. (for example, the original author implemented this for Sudoku, and it works beautifully there)

What follows is an iterative description of DLX:

```
stack <- [(NULL)]
level <- 0
while level >= 0:
    cur <- stack[level]
    if cur = NULL:
        if R[h] = h:
            level <- level - 1
            yield solution
        else:
            cover(best_column)
            stack[level] = best_column
    else if D[cur] != C[cur]:
        if cur != C[cur]:
            delete solution[level]
            for j in L[cur], L[L[cur]], ... , while j != cur:
                uncover(C[j])
        cur <- D[cur]
        solution[level] <- cur
        stack[level] <- cur
        for j in R[cur], R[R[cur]], ... , while j != cur:
            cover(C[j])
        level <- level + 1
        stack[level] <- (NULL)
    else:
        if C[cur] != cur:
            delete solution[level]
```

(continues on next page)

(continued from previous page)

```
            for j in L[cur], L[L[cur]], ... , while j != cur:
                uncover(C[j])
        uncover(cur)
        level <- level - 1
```

sage.combinat.dlx.**OneExactCover**(*M*)

Use A. Ajanki's DLXMatrix class to solve the exact cover problem on the matrix M (treated as a dense binary matrix).

EXAMPLES:

```
sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]])  # no exact covers              #␣
↪needs sage.modules
sage: OneExactCover(M)                                                       #␣
↪needs sage.modules

sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]])  # two exact covers      #␣
↪needs sage.modules
sage: OneExactCover(M)                                                       #␣
↪needs sage.modules
[(1, 1, 0), (0, 0, 1)]
```

```
>>> from sage.all import *
>>> M = Matrix([[Integer(1),Integer(1),Integer(0)],[Integer(1),Integer(0),
↪Integer(1)],[Integer(0),Integer(1),Integer(1)]])  # no exact covers          ␣
↪      # needs sage.modules
>>> OneExactCover(M)                                                         #␣
↪needs sage.modules

>>> M = Matrix([[Integer(1),Integer(1),Integer(0)],[Integer(1),Integer(0),
↪Integer(1)],[Integer(0),Integer(0),Integer(1)],[Integer(0),Integer(1),
↪Integer(0)]])  # two exact covers         # needs sage.modules
>>> OneExactCover(M)                                                         #␣
↪needs sage.modules
[(1, 1, 0), (0, 0, 1)]
```

5.1.100 Dyck Words

A class of an object enumerated by the `Catalan numbers`, see [Sta-EC2], [StaCat98] for details.

AUTHORS:

- Mike Hansen
- Dan Drake (2008-05-30): DyckWordBacktracker support
- Florent Hivert (2009-02-01): Bijections with NonDecreasingParkingFunctions
- Christian Stump (2011-12): added combinatorial maps and statistics
- Mike Zabrocki:
  - (2012-10): added pretty print, characteristic function, more functions
  - (2013-01): added inverse of area/dinv, bounce/area map
- Jean–Baptiste Priez, Travis Scrimshaw (2013-05-17): Added ASCII art

- Travis Scrimshaw (2013-07-09): Removed `CombinatorialClass` and added global options.

REFERENCES:

class sage.combinat.dyck_word.**CompleteDyckWords**

Bases: *DyckWords*

Abstract base class for all complete Dyck words.

Element

alias of *DyckWord_complete*

from_Catalan_code(*code*)

Return the Dyck word associated to the given Catalan code `code`.

A Catalan code of length n is a sequence $(a_1, a_2, \ldots, a_n)$ of n integers a_i such that:

- $0 \leq a_i \leq n - i$ for every i;
- if $i < j$ and $a_i > 0$ and $a_j > 0$ and $a_{i+1} = a_{i+2} = \cdots = a_{j-1} = 0$, then $a_i - a_j < j - i$.

It turns out that the Catalan codes of length n are in bijection with Dyck words.

The Catalan code of a Dyck word is example (x) in Richard Stanley's exercises on combinatorial interpretations for Catalan objects. The code in this example is the reverse of the description provided there. See [Sta-EC2] and [StaCat98].

EXAMPLES:

```
sage: DyckWords().from_Catalan_code([])
[]
sage: DyckWords().from_Catalan_code([0])
[1, 0]
sage: DyckWords().from_Catalan_code([0, 1])
[1, 1, 0, 0]
sage: DyckWords().from_Catalan_code([0, 0])
[1, 0, 1, 0]
```

```
>>> from sage.all import *
>>> DyckWords().from_Catalan_code([])
[]
>>> DyckWords().from_Catalan_code([Integer(0)])
[1, 0]
>>> DyckWords().from_Catalan_code([Integer(0), Integer(1)])
[1, 1, 0, 0]
>>> DyckWords().from_Catalan_code([Integer(0), Integer(0)])
[1, 0, 1, 0]
```

from_area_sequence(*code*)

Return the Dyck word associated to the given area sequence `code`.

See *to_area_sequence()* for a definition of the area sequence of a Dyck word.

See also

area(), *to_area_sequence()*.

INPUT:

- `code` – list of integers satisfying `code[0] == 0` and `0 <= code[i+1] <= code[i]+1`

EXAMPLES:

```
sage: DyckWords().from_area_sequence([])
[]
sage: DyckWords().from_area_sequence([0])
[1, 0]
sage: DyckWords().from_area_sequence([0, 1])
[1, 1, 0, 0]
sage: DyckWords().from_area_sequence([0, 0])
[1, 0, 1, 0]
```

```
>>> from sage.all import *
>>> DyckWords().from_area_sequence([])
[]
>>> DyckWords().from_area_sequence([Integer(0)])
[1, 0]
>>> DyckWords().from_area_sequence([Integer(0), Integer(1)])
[1, 1, 0, 0]
>>> DyckWords().from_area_sequence([Integer(0), Integer(0)])
[1, 0, 1, 0]
```

from_non_decreasing_parking_function(*pf*)

Bijection from *non-decreasing parking functions*.

See there the method *to_dyck_word()* for more information.

EXAMPLES:

```
sage: D = DyckWords()
sage: D.from_non_decreasing_parking_function([])
[]
sage: D.from_non_decreasing_parking_function([1])
[1, 0]
sage: D.from_non_decreasing_parking_function([1,1])
[1, 1, 0, 0]
sage: D.from_non_decreasing_parking_function([1,2])
[1, 0, 1, 0]
sage: D.from_non_decreasing_parking_function([1,1,1])
[1, 1, 1, 0, 0, 0]
sage: D.from_non_decreasing_parking_function([1,2,3])
[1, 0, 1, 0, 1, 0]
sage: D.from_non_decreasing_parking_function([1,1,3,3,4,6,6])
[1, 1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 0]
```

```
>>> from sage.all import *
>>> D = DyckWords()
>>> D.from_non_decreasing_parking_function([])
[]
>>> D.from_non_decreasing_parking_function([Integer(1)])
[1, 0]
>>> D.from_non_decreasing_parking_function([Integer(1),Integer(1)])
[1, 1, 0, 0]
```

(continues on next page)

(continued from previous page)

```
>>> D.from_non_decreasing_parking_function([Integer(1),Integer(2)])
[1, 0, 1, 0]
>>> D.from_non_decreasing_parking_function([Integer(1),Integer(1),Integer(1)])
[1, 1, 1, 0, 0, 0]
>>> D.from_non_decreasing_parking_function([Integer(1),Integer(2),Integer(3)])
[1, 0, 1, 0, 1, 0]
>>> D.from_non_decreasing_parking_function([Integer(1),Integer(1),Integer(3),
↪Integer(3),Integer(4),Integer(6),Integer(6)])
[1, 1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 0]
```

from_noncrossing_partition(*ncp*)

Convert a noncrossing partition `ncp` to a Dyck word.

EXAMPLES:

```
sage: DyckWord(noncrossing_partition=[[1,2]]) # indirect doctest
[1, 1, 0, 0]
sage: DyckWord(noncrossing_partition=[[1],[2]])
[1, 0, 1, 0]

sage: dws = DyckWords(5).list()
sage: ncps = [x.to_noncrossing_partition() for x in dws]
sage: dws2 = [DyckWord(noncrossing_partition=x) for x in ncps]
sage: dws == dws2
True
```

```
>>> from sage.all import *
>>> DyckWord(noncrossing_partition=[[Integer(1),Integer(2)]]) # indirect␣
↪doctest
[1, 1, 0, 0]
>>> DyckWord(noncrossing_partition=[[Integer(1)],[Integer(2)]])
[1, 0, 1, 0]

>>> dws = DyckWords(Integer(5)).list()
>>> ncps = [x.to_noncrossing_partition() for x in dws]
>>> dws2 = [DyckWord(noncrossing_partition=x) for x in ncps]
>>> dws == dws2
True
```

class sage.combinat.dyck_word.**CompleteDyckWords_all**

Bases: *CompleteDyckWords*, *DyckWords_all*

All complete Dyck words.

class height_poset

Bases: `UniqueRepresentation`, `Parent`

The poset of complete Dyck words compared componentwise by `heights`.

This is, `D` is smaller than or equal to `D'` if it is weakly below `D'`.

This is implemented by comparison of area sequences.

le(*dw1*, *dw2*)

Compare two Dyck words of equal size, and return `True` if all of the heights of `dw1` are less than or equal to the respective heights of `dw2` .

See also

to_area_sequence()

EXAMPLES:

```
sage: poset = DyckWords().height_poset()
sage: poset.le(DyckWord([]), DyckWord([]))
True
sage: poset.le(DyckWord([1,0]), DyckWord([1,0]))
True
sage: poset.le(DyckWord([1,0,1,0]), DyckWord([1,1,0,0]))
True
sage: poset.le(DyckWord([1,1,0,0]), DyckWord([1,0,1,0]))
False
sage: [poset.le(dw1, dw2)
....:     for dw1 in DyckWords(3) for dw2 in DyckWords(3)]
[True, True, True, True, True, False, True, False, True, True,
False, False, True, True, True, False, False, False, True,
True, False, False, False, False, True]
```

```
>>> from sage.all import *
>>> poset = DyckWords().height_poset()
>>> poset.le(DyckWord([]), DyckWord([]))
True
>>> poset.le(DyckWord([Integer(1),Integer(0)]), DyckWord([Integer(1),
→Integer(0)]))
True
>>> poset.le(DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]),␣
→DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]))
True
>>> poset.le(DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]),␣
→DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]))
False
>>> [poset.le(dw1, dw2)
...     for dw1 in DyckWords(Integer(3)) for dw2 in DyckWords(Integer(3))]
[True, True, True, True, True, False, True, False, True, True,
False, False, True, True, True, False, False, False, True,
True, False, False, False, False, True]
```

class sage.combinat.dyck_word.**CompleteDyckWords_size**(*k*)

Bases: *CompleteDyckWords*, *DyckWords_size*

All complete Dyck words of a given size.

cardinality()

Return the number of complete Dyck words of semilength n, i.e. the n-th *Catalan number*.

EXAMPLES:

```
sage: DyckWords(4).cardinality()
14
sage: ns = list(range(9))
sage: dws = [DyckWords(n) for n in ns]
```

(continues on next page)

(continued from previous page)

```
sage: all(dw.cardinality() == len(dw.list()) for dw in dws)
True
```

```
>>> from sage.all import *
>>> DyckWords(Integer(4)).cardinality()
14
>>> ns = list(range(Integer(9)))
>>> dws = [DyckWords(n) for n in ns]
>>> all(dw.cardinality() == len(dw.list()) for dw in dws)
True
```

random_element()

Return a random complete Dyck word of semilength n.

The algorithm is based on a classical combinatorial fact. One chooses at random a word with n 0s and $n+1$ 1s. One then considers every 1 as an ascending step and every 0 as a descending step, and one finds the lowest point of the path (with respect to a slightly tilted slope). One then cuts the path at this point and builds a Dyck word by exchanging the two parts of the word and removing the initial step.

Todo

extend this to m-Dyck words

EXAMPLES:

```
sage: dw = DyckWords(8)
sage: dw.random_element()  # random
[1, 1, 1, 1, 1, 0, 0, 0, 0, 0, 1, 0, 1, 0, 1, 0]

sage: D = DyckWords(8)
sage: D.random_element() in D
True
```

```
>>> from sage.all import *
>>> dw = DyckWords(Integer(8))
>>> dw.random_element()  # random
[1, 1, 1, 1, 1, 0, 0, 0, 0, 0, 1, 0, 1, 0, 1, 0]

>>> D = DyckWords(Integer(8))
>>> D.random_element() in D
True
```

class sage.combinat.dyck_word.**DyckWord**(*parent*, *l*, *latex_options={}*)

Bases: *CombinatorialElement*

A Dyck word.

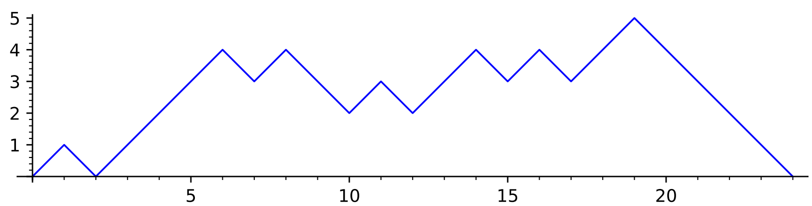
A Dyck word is a sequence of open and close symbols such that every close symbol has a corresponding open symbol preceding it. That is to say, a Dyck word of length n is a list with k entries 1 and $n-k$ entries 0 such that the first i entries always have at least as many 1s among them as 0s. (Here, the 1 serves as the open symbol and the 0 as the close symbol.) Alternatively, the alphabet 1 and 0 can be replaced by other characters such as '(' and ')'.

A Dyck word is *complete* if every open symbol moreover has a corresponding close symbol.

A Dyck word may also be specified by either a noncrossing partition or by an area sequence or the sequence of heights.

A Dyck word may also be thought of as a lattice path in the $\mathbf{Z}^2$ grid, starting at the origin $(0, 0)$, and with steps in the North $N = (0, 1)$ and east $E = (1, 0)$ directions such that it does not pass below the $x = y$ diagonal. The diagonal is referred to as the "main diagonal" in the documentation. A North step is represented by a 1 in the list and an East step is represented by a 0.

Equivalently, the path may be represented with steps in the $NE = (1, 1)$ and the $SE = (1, -1)$ direction such that it does not pass below the horizontal axis.



A path representing a Dyck word (either using N and E steps, or using NE and SE steps) is called a Dyck path.

EXAMPLES:

```
sage: dw = DyckWord([1, 0, 1, 0]); dw
[1, 0, 1, 0]
sage: print(dw)
()()
sage: dw.height()
1
sage: dw.to_noncrossing_partition()
{{1}, {2}}
```

```
>>> from sage.all import *
>>> dw = DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]); dw
[1, 0, 1, 0]
>>> print(dw)
()()
>>> dw.height()
1
>>> dw.to_noncrossing_partition()
{{1}, {2}}
```

```
sage: DyckWord('()()')
[1, 0, 1, 0]
sage: DyckWord('(())')
[1, 1, 0, 0]
sage: DyckWord('((')
[1, 1]
sage: DyckWord('')
[]
```

```
>>> from sage.all import *
>>> DyckWord('()()')
[1, 0, 1, 0]
>>> DyckWord('(())')
[1, 1, 0, 0]
>>> DyckWord('((')
[1, 1]
>>> DyckWord('')
[]
```

```
sage: DyckWord(noncrossing_partition=[[1],[2]])
[1, 0, 1, 0]
sage: DyckWord(noncrossing_partition=[[1,2]])
[1, 1, 0, 0]
sage: DyckWord(noncrossing_partition=[])
[]
```

```
>>> from sage.all import *
>>> DyckWord(noncrossing_partition=[[Integer(1)],[Integer(2)]])
[1, 0, 1, 0]
>>> DyckWord(noncrossing_partition=[[Integer(1),Integer(2)]])
[1, 1, 0, 0]
>>> DyckWord(noncrossing_partition=[])
[]
```

```
sage: DyckWord(area_sequence=[0,0])
[1, 0, 1, 0]
sage: DyckWord(area_sequence=[0,1])
[1, 1, 0, 0]
sage: DyckWord(area_sequence=[0,1,2,2,0,1,1,2])
[1, 1, 1, 0, 1, 0, 0, 0, 1, 1, 0, 1, 1, 0, 0, 0]
sage: DyckWord(area_sequence=[])
[]
```

```
>>> from sage.all import *
>>> DyckWord(area_sequence=[Integer(0),Integer(0)])
[1, 0, 1, 0]
>>> DyckWord(area_sequence=[Integer(0),Integer(1)])
[1, 1, 0, 0]
>>> DyckWord(area_sequence=[Integer(0),Integer(1),Integer(2),Integer(2),
↪Integer(0),Integer(1),Integer(1),Integer(2)])
[1, 1, 1, 0, 1, 0, 0, 0, 1, 1, 0, 1, 1, 0, 0, 0]
```

(continues on next page)

(continued from previous page)

```
>>> DyckWord(area_sequence=[])
[]
```

```
sage: DyckWord(heights_sequence=(0,1,0,1,0))
[1, 0, 1, 0]
sage: DyckWord(heights_sequence=(0,1,2,1,0))
[1, 1, 0, 0]
sage: DyckWord(heights_sequence=(0,))
[]
```

```
>>> from sage.all import *
>>> DyckWord(heights_sequence=(Integer(0),Integer(1),Integer(0),Integer(1),
↪Integer(0)))
[1, 0, 1, 0]
>>> DyckWord(heights_sequence=(Integer(0),Integer(1),Integer(2),Integer(1),
↪Integer(0)))
[1, 1, 0, 0]
>>> DyckWord(heights_sequence=(Integer(0),))
[]
```

```
sage: print(DyckWord([1,0,1,1,0,0]).to_path_string())
   /\
/\/  \
sage: DyckWord([1,0,1,1,0,0]).pretty_print()
   ___
  | x
 _|  .
|  . .
```

```
>>> from sage.all import *
>>> print(DyckWord([Integer(1),Integer(0),Integer(1),Integer(1),Integer(0),
↪Integer(0)]).to_path_string())
   /\
/\/  \
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(1),Integer(0),Integer(0)]).
↪pretty_print()
   ___
  | x
 _|  .
|  . .
```

ascent_prime_decomposition()

Decompose this Dyck word into a sequence of ascents and prime Dyck paths.

A Dyck word is *prime* if it is complete and has precisely one return - the final step. In particular, the empty Dyck path is not prime. Thus, the factorization is unique.

This decomposition yields a sequence of odd length: the words with even indices consist of up steps only, the words with odd indices are prime Dyck paths. The concatenation of the result is the original word.

EXAMPLES:

```
sage: D = DyckWord([1,1,1,0,1,0,1,1,1,1,0,1])
sage: D.ascent_prime_decomposition()
[[1, 1], [1, 0], [], [1, 0], [1, 1, 1], [1, 0], [1]]

sage: DyckWord([]).ascent_prime_decomposition()
[[]]

sage: DyckWord([1,1]).ascent_prime_decomposition()
[[1, 1]]

sage: DyckWord([1,0,1,0]).ascent_prime_decomposition()
[[], [1, 0], [], [1, 0], []]
```

```

>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).ascent_prime_
↪decomposition()
[[], [1, 0], [], [1, 0], []]
```

associated_parenthesis(*pos*)

Report the position for the parenthesis in `self` that matches the one at position `pos`.

The positions in `self` are counted from 0.

INPUT:

- `pos` – the index of the parenthesis in the list

OUTPUT:

- Integer representing the index of the matching parenthesis. If no parenthesis matches, return `None`.

EXAMPLES:

```
sage: DyckWord([1, 0]).associated_parenthesis(0)
1
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(0)
1
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(1)
0
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(2)
3
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(3)
2
```

(continues on next page)

(continued from previous page)

```
sage: DyckWord([1, 1, 0, 0]).associated_parenthesis(0)
3
sage: DyckWord([1, 1, 0, 0]).associated_parenthesis(2)
1
sage: DyckWord([1, 1, 0]).associated_parenthesis(1)
2
sage: DyckWord([1, 1]).associated_parenthesis(0)
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0)]).associated_parenthesis(Integer(0))
1
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).associated_
↪parenthesis(Integer(0))
1
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).associated_
↪parenthesis(Integer(1))
0
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).associated_
↪parenthesis(Integer(2))
3
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).associated_
↪parenthesis(Integer(3))
2
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).associated_
↪parenthesis(Integer(0))
3
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).associated_
↪parenthesis(Integer(2))
1
>>> DyckWord([Integer(1), Integer(1), Integer(0)]).associated_
↪parenthesis(Integer(1))
2
>>> DyckWord([Integer(1), Integer(1)]).associated_parenthesis(Integer(0))
```

catalan_factorization()

Decompose this Dyck word into a sequence of complete Dyck words.

Each element of the list returned is a (possibly empty) complete Dyck word. The original word is obtained by placing an up step between each of these complete Dyck words. Thus, the number of words returned is one more than the final height.

See Section 1.2 of [CC1982] or Lemma 9.1.1 of [Lot2005].

EXAMPLES:

```
sage: D = DyckWord([1,1,1,0,1,0,1,1,1,1,0,1])
sage: D.catalan_factorization()
[[], [], [1, 0, 1, 0], [], [], [1, 0], []]

sage: DyckWord([]).catalan_factorization()
[[]]

sage: DyckWord([1,1]).catalan_factorization()
```

(continues on next page)

(continued from previous page)

```
[[], [], []]

sage: DyckWord([1,0,1,0]).catalan_factorization()
[[1, 0, 1, 0]]
```

```
>>> from sage.all import *
>>> D = DyckWord([Integer(1),Integer(1),Integer(1),Integer(0),Integer(1),
↪Integer(0),Integer(1),Integer(1),Integer(1),Integer(1),Integer(0),
↪Integer(1)])
>>> D.catalan_factorization()
[[], [], [1, 0, 1, 0], [], [], [1, 0], []]

>>> DyckWord([]).catalan_factorization()
[[]]

>>> DyckWord([Integer(1),Integer(1)]).catalan_factorization()
[[], [], []]

>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).catalan_
↪factorization()
[[1, 0, 1, 0]]
```

height()

Return the height of `self`.

We view the Dyck word as a Dyck path from $(0, 0)$ to $(2n, 0)$ in the first quadrant by letting `1`'s represent steps in the direction $(1, 1)$ and `0`'s represent steps in the direction $(1, -1)$.

The height is the maximum y-coordinate reached.

See also

heights()

EXAMPLES:

```
sage: DyckWord([]).height()
0
sage: DyckWord([1,0]).height()
1
sage: DyckWord([1, 1, 0, 0]).height()
2
sage: DyckWord([1, 1, 0, 1, 0]).height()
2
sage: DyckWord([1, 1, 0, 0, 1, 0]).height()
2
sage: DyckWord([1, 0, 1, 0]).height()
1
sage: DyckWord([1, 1, 0, 0, 1, 1, 1, 0, 0, 0]).height()
3
```

```
>>> from sage.all import *
>>> DyckWord([]).height()
0
>>> DyckWord([Integer(1),Integer(0)]).height()
1
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).height()
2
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(0)]).
↪height()
2
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(0)]).height()
2
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).height()
1
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(1), Integer(1), Integer(0), Integer(0), Integer(0)]).height()
3
```

heights()

Return the heights of `self`.

We view the Dyck word as a Dyck path from $(0,0)$ to $(2n,0)$ in the first quadrant by letting `1`'s represent steps in the direction $(1,1)$ and `0`'s represent steps in the direction $(1,-1)$.

The heights is the sequence of the y-coordinates of all $2n+1$ lattice points along the path.

See also

from_heights(), *min_from_heights()*

EXAMPLES:

```
sage: DyckWord([]).heights()
(0,)
sage: DyckWord([1,0]).heights()
(0, 1, 0)
sage: DyckWord([1, 1, 0, 0]).heights()
(0, 1, 2, 1, 0)
sage: DyckWord([1, 1, 0, 1, 0]).heights()
(0, 1, 2, 1, 2, 1)
sage: DyckWord([1, 1, 0, 0, 1, 0]).heights()
(0, 1, 2, 1, 0, 1, 0)
sage: DyckWord([1, 0, 1, 0]).heights()
(0, 1, 0, 1, 0)
sage: DyckWord([1, 1, 0, 0, 1, 1, 1, 0, 0, 0]).heights()
(0, 1, 2, 1, 0, 1, 2, 3, 2, 1, 0)
```

```
>>> from sage.all import *
>>> DyckWord([]).heights()
(0,)
>>> DyckWord([Integer(1),Integer(0)]).heights()
```

(continues on next page)

(continued from previous page)

```
(0, 1, 0)
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).heights()
(0, 1, 2, 1, 0)
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(0)]).
↪heights()
(0, 1, 2, 1, 2, 1)
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(0)]).heights()
(0, 1, 2, 1, 0, 1, 0)
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).heights()
(0, 1, 0, 1, 0)
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(1), Integer(1), Integer(0), Integer(0), Integer(0)]).heights()
(0, 1, 2, 1, 0, 1, 2, 3, 2, 1, 0)
```

is_complete()

Return `True` if `self` is complete.

A Dyck word d is complete if d contains as many closers as openers.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).is_complete()
True
sage: DyckWord([1, 0, 1, 1, 0]).is_complete()
False
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).is_complete()
True
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0)]).is_
↪complete()
False
```

latex_options()

Return the latex options for use in the `_latex_` function as a dictionary.

The default values are set using the options.

- `tikz_scale` – (default: 1) scale for use with the tikz package
- `diagonal` – boolean (default: `False`); value to draw the diagonal or not
- `line width` – (default: `2*tikz_scale`) value representing the line width
- `color` – (default: black) the line color
- `bounce path` – boolean (default: `False`); value to indicate if the bounce path should be drawn
- `peaks` – boolean (default: `False`); value to indicate if the peaks should be displayed
- `valleys` – boolean (default: `False`); value to indicate if the valleys should be displayed

EXAMPLES:

```
sage: D = DyckWord([1,0,1,0,1,0])
sage: D.latex_options()
```

(continues on next page)

(continued from previous page)

```
{'bounce path': False,
 'color': black,
 'diagonal': False,
 'line width': 2,
 'peaks': False,
 'tikz_scale': 1,
 'valleys': False}
```

```
>>> from sage.all import *
>>> D = DyckWord([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
↪Integer(0)])
>>> D.latex_options()
{'bounce path': False,
 'color': black,
 'diagonal': False,
 'line width': 2,
 'peaks': False,
 'tikz_scale': 1,
 'valleys': False}
```

Todo

This should probably be merged into DyckWord.options.

length()

Return the length of `self`.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).length()
4
sage: DyckWord([1, 0, 1, 1, 0]).length()
5
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).length()
4
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0)]).
↪length()
5
```

number_of_close_symbols()

Return the number of close symbols in `self`.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).number_of_close_symbols()
2
sage: DyckWord([1, 0, 1, 1, 0]).number_of_close_symbols()
2
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).number_of_
↪close_symbols()
2
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0)]).
↪number_of_close_symbols()
2
```

number_of_double_rises()

Return a the number of positions in `self` where there are two consecutive 1's.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0, 1, 0]).number_of_double_
↪rises()
2
sage: DyckWord([1, 1, 0, 0]).number_of_double_rises()
1
sage: DyckWord([1, 0, 1, 0]).number_of_double_rises()
0
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),
↪Integer(1), Integer(1), Integer(0), Integer(0), Integer(1), Integer(0),
↪Integer(0), Integer(1), Integer(0)]).number_of_double_rises()
2
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).number_of_
↪double_rises()
1
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).number_of_
↪double_rises()
0
```

number_of_initial_rises()

Return the length of the initial run of `self`.

OUTPUT: nonnegative integer indicating the length of the initial rise

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).number_of_initial_rises()
1
sage: DyckWord([1, 1, 0, 0]).number_of_initial_rises()
2
sage: DyckWord([1, 1, 0, 0, 1, 0]).number_of_initial_rises()
2
sage: DyckWord([1, 0, 1, 1, 0, 0]).number_of_initial_rises()
1
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).number_of_
↪initial_rises()
1
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).number_of_
```

(continues on next page)

(continued from previous page)

```
↪initial_rises()
2
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(0)]).number_of_initial_rises()
2
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(0)]).number_of_initial_rises()
1
```

number_of_open_symbols()

Return the number of open symbols in `self`.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).number_of_open_symbols()
2
sage: DyckWord([1, 0, 1, 1, 0]).number_of_open_symbols()
3
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).number_of_open_
↪symbols()
2
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0)]).
↪number_of_open_symbols()
3
```

number_of_peaks()

Return the number of peaks of the Dyck path associated to `self` .

See also

peaks(), *number_of_valleys()*

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).number_of_peaks()
2
sage: DyckWord([1, 1, 0, 0]).number_of_peaks()
1
sage: DyckWord([1,1,0,1,0,1,0,0]).number_of_peaks()
3
sage: DyckWord([]).number_of_peaks()
0
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).number_of_
↪peaks()
2
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).number_of_
↪peaks()
```

(continues on next page)

(continued from previous page)

```
1
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)]).number_of_peaks()
3
>>> DyckWord([]).number_of_peaks()
0
```

number_of_touch_points()

Return the number of touches of `self` at the main diagonal.

OUTPUT: nonnegative integer

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).number_of_touch_points()
2
sage: DyckWord([1, 1, 0, 0]).number_of_touch_points()
1
sage: DyckWord([1, 1, 0, 0, 1, 0]).number_of_touch_points()
2
sage: DyckWord([1, 0, 1, 1, 0, 0]).number_of_touch_points()
2
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).number_of_
↪touch_points()
2
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).number_of_
↪touch_points()
1
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(0)]).number_of_touch_points()
2
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(0)]).number_of_touch_points()
2
```

number_of_valleys()

Return the number of valleys of `self`.

> **See also**
>
> *number_of_peaks()*, *valleys()*

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).number_of_valleys()
1
sage: DyckWord([1, 1, 0, 0]).number_of_valleys()
0
sage: DyckWord([1, 1, 0, 0, 1, 0]).number_of_valleys()
1
```

(continues on next page)

(continued from previous page)

```
sage: DyckWord([1, 0, 1, 1, 0, 0]).number_of_valleys()
1
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).number_of_
↪valleys()
1
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).number_of_
↪valleys()
0
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(0)]).number_of_valleys()
1
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(0)]).number_of_valleys()
1
```

peaks()

Return a list of the positions of the peaks of a Dyck word.

A peak is 1 followed by a 0. Note that this does not agree with the definition given in [Hag2008].

See also

valleys(), *number_of_peaks()*

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).peaks()
[0, 2]
sage: DyckWord([1, 1, 0, 0]).peaks()
[1]
sage: DyckWord([1,1,0,1,0,1,0,0]).peaks() # Haglund's def gives 2
[1, 3, 5]
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).peaks()
[0, 2]
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).peaks()
[1]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)]).peaks() # Haglund's def gives 2
[1, 3, 5]
```

plot(***kwds*)

Plot a Dyck word as a continuous path.

EXAMPLES:

```
sage: w = DyckWords(100).random_element()
sage: w.plot()                                                          #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.plot
Graphics object consisting of 1 graphics primitive
```

```
>>> from sage.all import *
>>> w = DyckWords(Integer(100)).random_element()
>>> w.plot()                                                            #␣
↪needs sage.plot
Graphics object consisting of 1 graphics primitive
```

position_of_first_return()

Return the number of vertical steps before the Dyck path returns to the main diagonal.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0, 1, 0]).position_of_first_
↪return()
1
sage: DyckWord([1, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0, 1, 0, 0]).position_of_first_
↪return()
7
sage: DyckWord([1, 1, 0, 0]).position_of_first_return()
2
sage: DyckWord([1, 0, 1, 0]).position_of_first_return()
1
sage: DyckWord([]).position_of_first_return()
0
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(1), Integer(1), Integer(0), Integer(0), Integer(1), Integer(0),␣
↪Integer(0), Integer(1), Integer(0)]).position_of_first_return()
1
>>> DyckWord([Integer(1), Integer(1), Integer(1), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(0), Integer(1), Integer(0), Integer(0),␣
↪Integer(1), Integer(0), Integer(0)]).position_of_first_return()
7
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).position_of_
↪first_return()
2
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).position_of_
↪first_return()
1
>>> DyckWord([]).position_of_first_return()
0
```

positions_of_double_rises()

Return a list of positions in `self` where there are two consecutive 1's.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0, 1, 0]).positions_of_
↪double_rises()
```

(continues on next page)

(continued from previous page)

```
[2, 5]
sage: DyckWord([1, 1, 0, 0]).positions_of_double_rises()
[0]
sage: DyckWord([1, 0, 1, 0]).positions_of_double_rises()
[]
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(1), Integer(1), Integer(0), Integer(0), Integer(1), Integer(0),␣
↪Integer(0), Integer(1), Integer(0)]).positions_of_double_rises()
[2, 5]
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).positions_of_
↪double_rises()
[0]
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).positions_of_
↪double_rises()
[]
```

pp(*type=None*, *labelling=None*, *underpath=True*)

Display a DyckWord as a lattice path in the $\mathbf{Z}^2$ grid.

If the `type` is “N-E”, then a cell below the diagonal is indicated by a period, whereas a cell below the path but above the diagonal is indicated by an x. If a list of labels is included, they are displayed along the vertical edges of the Dyck path.

If the `type` is “NE-SE”, then the path is simply printed as up steps and down steps.

INPUT:

- `type` – (default: `None`) can either be:
  - `None` to use the option default
  - “N-E” to show `self` as a path of north and east steps, or
  - “NE-SE” to show `self` as a path of north-east and south-east steps.
- `labelling` – (if type is “N-E”) a list of labels assigned to the up steps in `self`
- `underpath` – (if type is “N-E”, default: `True`) if `True`, the labelling is shown under the path; otherwise, it is shown to the right of the path

EXAMPLES:

```
sage: for D in DyckWords(3): D.pretty_print()
     _
   _|

>>> from sage.all import *
>>> DyckWord([]).pretty_print()
.
```

pretty_print(*type=None*, *labelling=None*, *underpath=True*)

Display a DyckWord as a lattice path in the $\mathbf{Z}^2$ grid.

If the `type` is "N-E", then a cell below the diagonal is indicated by a period, whereas a cell below the path but above the diagonal is indicated by an x. If a list of labels is included, they are displayed along the vertical edges of the Dyck path.

If the `type` is "NE-SE", then the path is simply printed as up steps and down steps.

INPUT:

- `type` – (default: `None`) can either be:
  - `None` to use the option default
  - "N-E" to show `self` as a path of north and east steps, or

    – "NE-SE" to show `self` as a path of north-east and south-east steps.

- `labelling` – (if type is "N-E") a list of labels assigned to the up steps in `self`
- `underpath` – (if type is "N-E", default: `True`) if `True`, the labelling is shown under the path; otherwise, it is shown to the right of the path

EXAMPLES:

```

```

```
sage: DyckWord([]).pretty_print()
.
```

```
>>> from sage.all import *
>>> DyckWord([]).pretty_print()
.
```

returns_to_zero()

Return a list of positions where `self` has height 0, excluding the position 0.

EXAMPLES:

```
sage: DyckWord([]).returns_to_zero()
[]
sage: DyckWord([1, 0]).returns_to_zero()
[2]
sage: DyckWord([1, 0, 1, 0]).returns_to_zero()
[2, 4]
sage: DyckWord([1, 1, 0, 0]).returns_to_zero()
[4]
```

```
>>> from sage.all import *
>>> DyckWord([]).returns_to_zero()
[]
>>> DyckWord([Integer(1), Integer(0)]).returns_to_zero()
[2]
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).returns_to_
↪zero()
[2, 4]
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).returns_to_
↪zero()
[4]
```

rise_composition()

The sequences of lengths of runs of 1's in `self`. Also equal to the sequence of lengths of vertical segments in the Dyck path.

EXAMPLES:

```
sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).pretty_print()
           ___
          | x
   _______|  .
  | x x x  . .
  | x x  . . .
 _| x  . . . .
| x  . . . . .
|  . . . . . .

sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).rise_composition()
[2, 3, 2]
sage: DyckWord([1,1,0,0]).rise_composition()
[2]
sage: DyckWord([1,0,1,0]).rise_composition()
[1, 1]
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(1),␣
↪Integer(1), Integer(0), Integer(0), Integer(0), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(0)]).pretty_print()
           ___
          | x
   _______|  .
  | x x x  . .
  | x x  . . .
 _| x  . . . .
| x  . . . . .
|  . . . . . .

>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(1),␣
↪Integer(1), Integer(0), Integer(0), Integer(0), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(0)]).rise_composition()
[2, 3, 2]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]).rise_composition()
[2]
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).rise_composition()
[1, 1]
```

set_latex_options(*D*)

Set the latex options for use in the `_latex_` function.

The default values are set in the `__init__` function.

- `tikz_scale` – (default: 1) scale for use with the tikz package
- `diagonal` – boolean (default: `False`); value to draw the diagonal or not
- `line width` – (default: `2*tikz_scale`) value representing the line width
- `color` – (default: black) the line color
- `bounce path` – boolean (default: `False`); value to indicate if the bounce path should be drawn
- `peaks` – boolean (default: `False`); value to indicate if the peaks should be displayed
- `valleys` – boolean (default: `False`); value to indicate if the valleys should be displayed

INPUT:

- `D` – dictionary with a list of latex parameters to change

EXAMPLES:

```
sage: D = DyckWord([1,0,1,0,1,0])
sage: D.set_latex_options({"tikz_scale":2})
sage: D.set_latex_options({"valleys":True, "color":"blue"})
```

```
>>> from sage.all import *
>>> D = DyckWord([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
↪Integer(0)])
>>> D.set_latex_options({"tikz_scale":Integer(2)})
>>> D.set_latex_options({"valleys":True, "color":"blue"})
```

Todo

This should probably be merged into DyckWord.options.

tamari_interval(*other*)

Return the Tamari interval between `self` and `other` as a *TamariIntervalPoset*.

A "Tamari interval" means an interval in the Tamari order. The Tamari order on the set of Dyck words of size n is the partial order obtained from the Tamari order on the set of binary trees of size n (see `tamari_lequal()`) by means of the Tamari bijection between Dyck words and binary trees (`to_dyck_word_tamari()`).

INPUT:

- `other` – a Dyck word greater or equal to `self` in the Tamari order

EXAMPLES:

```
sage: # needs sage.graphs
sage: dw = DyckWord([1, 1, 0, 1, 0, 0, 1, 0])
sage: ip = dw.tamari_interval(DyckWord([1, 1, 1, 0, 0, 1, 0, 0])); ip
The Tamari interval of size 4 induced by relations [(2, 4), (3, 4), (3, 1),␣
↪(2, 1)]
sage: ip.lower_dyck_word()
[1, 1, 0, 1, 0, 0, 1, 0]
sage: ip.upper_dyck_word()
[1, 1, 1, 0, 0, 1, 0, 0]
sage: ip.interval_cardinality()
4
sage: ip.number_of_tamari_inversions()

ValueError: the two Dyck words are not comparable on the Tamari lattice
```

to_area_sequence()

Return the area sequence of the Dyck word `self`.

The area sequence of a Dyck word w is defined as follows: Representing the Dyck word w as a Dyck path from $(0, 0)$ to (n, n) using N and E steps (this involves padding w by E steps until w reaches the main diagonal if w is not already a complete Dyck path), the area sequence of w is the sequence $(a_1, a_2, \ldots, a_n)$, where a_i is the number of full cells in the i-th row of the rectangle $[0, n] \times [0, n]$ which lie completely above the diagonal. (The cells are the regions into which the rectangle is subdivided by the lines $x = i$ with i integer and the lines $y = j$ with j integer. The i-th row consists of all the cells between the lines $y = i - 1$ and $y = i$.)

An alternative definition: Representing the Dyck word w as a Dyck path consisting of NE and SE steps, the area sequence is the sequence of ordinates of all lattice points on the path which are starting points of NE steps.

A list of integers l is the area sequence of some Dyck path if and only if it satisfies $l_0 = 0$ and $0 \leq l_{i+1} \leq l_i + 1$ for $i > 0$.

EXAMPLES:

```
sage: DyckWord([]).to_area_sequence()
[]
sage: DyckWord([1, 0]).to_area_sequence()
[0]
sage: DyckWord([1, 1, 0, 0]).to_area_sequence()
[0, 1]
sage: DyckWord([1, 0, 1, 0]).to_area_sequence()
[0, 0]
sage: all(dw ==
....:     DyckWords().from_area_sequence(dw.to_area_sequence())
....:     for i in range(6) for dw in DyckWords(i))
True
sage: DyckWord([1,0,1,0,1,0,1,0,1,0]).to_area_sequence()
[0, 0, 0, 0, 0]
sage: DyckWord([1,1,1,1,1,0,0,0,0,0]).to_area_sequence()
[0, 1, 2, 3, 4]
sage: DyckWord([1,1,1,1,0,1,0,0,0,0]).to_area_sequence()
[0, 1, 2, 3, 3]
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).to_area_sequence()
[0, 1, 1, 0, 1, 1, 1]
```

```
>>> from sage.all import *
>>> DyckWord([]).to_area_sequence()
[]
>>> DyckWord([Integer(1), Integer(0)]).to_area_sequence()
[0]
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).to_area_
↪sequence()
[0, 1]
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).to_area_
↪sequence()
[0, 0]
>>> all(dw ==
...     DyckWords().from_area_sequence(dw.to_area_sequence())
...     for i in range(Integer(6)) for dw in DyckWords(i))
True
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
↪Integer(0),Integer(1),Integer(0),Integer(1),Integer(0)]).to_area_sequence()
[0, 0, 0, 0, 0]
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),
↪Integer(0),Integer(0),Integer(0),Integer(0),Integer(0)]).to_area_sequence()
[0, 1, 2, 3, 4]
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(1),Integer(0),

↪Integer(1),Integer(0),Integer(0)]).to_area_sequence()
[0, 1, 1, 0, 1, 1, 1]
```

to_binary_tree(*usemap='1L0R'*)

Return a binary tree recursively constructed from the Dyck path `self` by the map `usemap`. The default `usemap` is `'1L0R'` which means:

- an empty Dyck word is a leaf,
- a non empty Dyck word reads $1L0R$ where L and R correspond to respectively its left and right subtrees.

INPUT:

- `usemap` – string, either `'1L0R'`, `'1R0L'`, `'L1R0'`, `'R1L0'`

Other valid `usemap` are `'1R0L'`, `'L1R0'`, and `'R1L0'`. These correspond to different maps from Dyck paths to binary trees, whose recursive definitions are hopefully clear from the names.

EXAMPLES:

```
sage: # needs sage.graphs
sage: dw = DyckWord([1,0])
sage: dw.to_binary_tree()
[., .]
sage: dw = DyckWord([])
sage: dw.to_binary_tree()
.
sage: dw = DyckWord([1,0,1,1,0,0])
sage: dw.to_binary_tree()
[., [[., .], .]]
```

(continues on next page)

(continued from previous page)

```
sage: dw.to_binary_tree("L1R0")
[[., .], [., .]]
sage: dw = DyckWord([1,0,1,1,0,0,1,1,1,0,1,0,0,0])
sage: dw.to_binary_tree() == dw.to_binary_tree("1R0L").left_right_symmetry()
True
sage: dw.to_binary_tree() == dw.to_binary_tree("L1R0").left_border_symmetry()
False
sage: dw.to_binary_tree("1R0L") == dw.to_binary_tree("L1R0").left_border_
↪symmetry()
True
sage: dw.to_binary_tree("R1L0") == dw.to_binary_tree("L1R0").left_right_
↪symmetry()
True
sage: dw.to_binary_tree("R10L")
Traceback (most recent call last):
...
ValueError: R10L is not a correct map
```

```
>>> from sage.all import *
>>> # needs sage.graphs
>>> dw = DyckWord([Integer(1),Integer(0)])
>>> dw.to_binary_tree()
[., .]
>>> dw = DyckWord([])
>>> dw.to_binary_tree()
.
>>> dw = DyckWord([Integer(1),Integer(0),Integer(1),Integer(1),Integer(0),
↪Integer(0)])
>>> dw.to_binary_tree()
[., [[., .], .]]
>>> dw.to_binary_tree("L1R0")
[[., .], [., .]]
>>> dw = DyckWord([Integer(1),Integer(0),Integer(1),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(1),Integer(0),Integer(1),
↪Integer(0),Integer(0),Integer(0)])
>>> dw.to_binary_tree() == dw.to_binary_tree("1R0L").left_right_symmetry()
True
>>> dw.to_binary_tree() == dw.to_binary_tree("L1R0").left_border_symmetry()
False
>>> dw.to_binary_tree("1R0L") == dw.to_binary_tree("L1R0").left_border_
↪symmetry()
True
>>> dw.to_binary_tree("R1L0") == dw.to_binary_tree("L1R0").left_right_
↪symmetry()
True
>>> dw.to_binary_tree("R10L")
Traceback (most recent call last):
...
ValueError: R10L is not a correct map
```

to_binary_tree_tamari()

Return the binary tree corresponding to `self` in a way which is consistent with the Tamari orders on the set of Dyck paths and on the set of binary trees.

This is the 'L1R0' map documented in *to_binary_tree()*.

EXAMPLES:

```
sage: DyckWord([1,0]).to_binary_tree_tamari()                                #␣
↪needs sage.graphs
[., .]
sage: DyckWord([1,0,1,1,0,0]).to_binary_tree_tamari()                        #␣
↪needs sage.graphs
[[., .], [., .]]
sage: DyckWord([1,0,1,0,1,0]).to_binary_tree_tamari()                        #␣
↪needs sage.graphs
[[[., .], .], .]
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(0)]).to_binary_tree_tamari()                ␣
↪               # needs sage.graphs
[., .]
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(1),Integer(0),
↪Integer(0)]).to_binary_tree_tamari()                         # needs sage.
↪graphs
[[., .], [., .]]
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
↪Integer(0)]).to_binary_tree_tamari()                         # needs sage.
↪graphs
[[[., .], .], .]
```

to_path_string(*unicode=False*)

Return a path representation of the Dyck word consisting of steps / and \ .

INPUT:

- unicode – boolean (default: False); whether to use unicode

EXAMPLES:

```
sage: print(DyckWord([1, 0, 1, 0]).to_path_string())
/\/\
sage: print(DyckWord([1, 1, 0, 0]).to_path_string())
 /\
/  \
sage: print(DyckWord([1,1,0,1,1,0,0,1,0,1,0,0]).to_path_string())
    /\
 /\/  \/\/\
/          \
```

```
>>> from sage.all import *
>>> print(DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).to_path_
↪string())
/\/\
>>> print(DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).to_path_
↪string())
 /\
```

(continues on next page)

(continued from previous page)

```
/   \
>>> print(DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(1),
↪Integer(0),Integer(0),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0)]).to_path_string())
    /\
 /\/  \/\/\
/          \
```

to_standard_tableau()

Return a standard tableau of shape (a, b) where a is the number of open symbols and b is the number of close symbols in `self`.

EXAMPLES:

```
sage: DyckWord([]).to_standard_tableau()
[]
sage: DyckWord([1, 0]).to_standard_tableau()
[[1], [2]]
sage: DyckWord([1, 1, 0, 0]).to_standard_tableau()
[[1, 2], [3, 4]]
sage: DyckWord([1, 0, 1, 0]).to_standard_tableau()
[[1, 3], [2, 4]]
sage: DyckWord([1]).to_standard_tableau()
[[1]]
sage: DyckWord([1, 0, 1]).to_standard_tableau()
[[1, 3], [2]]
```

```
>>> from sage.all import *
>>> DyckWord([]).to_standard_tableau()
[]
>>> DyckWord([Integer(1), Integer(0)]).to_standard_tableau()
[[1], [2]]
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).to_standard_
↪tableau()
[[1, 2], [3, 4]]
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).to_standard_
↪tableau()
[[1, 3], [2, 4]]
>>> DyckWord([Integer(1)]).to_standard_tableau()
[[1]]
>>> DyckWord([Integer(1), Integer(0), Integer(1)]).to_standard_tableau()
[[1, 3], [2]]
```

to_tamari_sorting_tuple()

Convert a Dyck word to a Tamari sorting tuple.

The result is a list of integers, one for every up-step from left to right. To each up-step is associated the distance to the corresponding down step in the Dyck word.

This is useful for a faster conversion to binary trees.

EXAMPLES:

```
sage: DyckWord([]).to_tamari_sorting_tuple()
[]
sage: DyckWord([1, 0]).to_tamari_sorting_tuple()
[0]
sage: DyckWord([1, 1, 0, 0]).to_tamari_sorting_tuple()
[1, 0]
sage: DyckWord([1, 0, 1, 0]).to_tamari_sorting_tuple()
[0, 0]
sage: DyckWord([1, 1, 0, 1, 0, 0]).to_tamari_sorting_tuple()
[2, 0, 0]
```

```
>>> from sage.all import *
>>> DyckWord([]).to_tamari_sorting_tuple()
[]
>>> DyckWord([Integer(1), Integer(0)]).to_tamari_sorting_tuple()
[0]
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).to_tamari_
↪sorting_tuple()
[1, 0]
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).to_tamari_
↪sorting_tuple()
[0, 0]
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(0),␣
↪Integer(0)]).to_tamari_sorting_tuple()
[2, 0, 0]
```

See also

to_Catalan_code()

touch_composition()

Return a composition which indicates the positions where `self` returns to the diagonal.

This assumes `self` to be a complete Dyck word.

OUTPUT: a composition of length equal to the length of the Dyck word

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).touch_composition()
[1, 1]
sage: DyckWord([1, 1, 0, 0]).touch_composition()
[2]
sage: DyckWord([1, 1, 0, 0, 1, 0]).touch_composition()
[2, 1]
sage: DyckWord([1, 0, 1, 1, 0, 0]).touch_composition()
[1, 2]
sage: DyckWord([]).touch_composition()
[]
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).touch_
```

(continues on next page)

(continued from previous page)

```
↪composition()
[1, 1]
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).touch_
↪composition()
[2]
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(0)]).touch_composition()
[2, 1]
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(0)]).touch_composition()
[1, 2]
>>> DyckWord([]).touch_composition()
[]
```

touch_points()

Return the abscissae (or, equivalently, ordinates) of the points where the Dyck path corresponding to `self` (comprising NE and SE steps) touches the main diagonal. This includes the last point (if it is on the main diagonal) but excludes the beginning point.

Note that these abscissae are precisely the entries of *returns_to_zero()* divided by 2.

OUTPUT: list of integers indicating where the path touches the diagonal

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).touch_points()
[1, 2]
sage: DyckWord([1, 1, 0, 0]).touch_points()
[2]
sage: DyckWord([1, 1, 0, 0, 1, 0]).touch_points()
[2, 3]
sage: DyckWord([1, 0, 1, 1, 0, 0]).touch_points()
[1, 3]
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).touch_points()
[1, 2]
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).touch_points()
[2]
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(0)]).touch_points()
[2, 3]
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(0)]).touch_points()
[1, 3]
```

valleys()

Return a list of the positions of the valleys of a Dyck word.

A valley is 0 followed by a 1.

See also

peaks(), *number_of_valleys()*

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).valleys()
[1]
sage: DyckWord([1, 1, 0, 0]).valleys()
[]
sage: DyckWord([1,1,0,1,0,1,0,0]).valleys()
[2, 4]
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).valleys()
[1]
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).valleys()
[]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)]).valleys()
[2, 4]
```

class sage.combinat.dyck_word.**DyckWordBacktracker**(*k1*, *k2*)

Bases: *GenericBacktracker*

This class is an iterator for all Dyck words with n opening parentheses and $n - k$ closing parentheses using the backtracker class. It is used by the *DyckWords_size* class.

This is not really meant to be called directly, partially because it fails in a couple corner cases: `DWB(0)` yields `[0]`, not the empty word, and `DWB(k, k+1)` yields something (it shouldn't yield anything). This could be fixed with a sanity check in `_rec()`, but then we'd be doing the sanity check *every time* we generate new objects; instead, we do *one* sanity check in *DyckWords* and assume here that the sanity check has already been made.

AUTHOR:

- Dan Drake (2008-05-30)

class sage.combinat.dyck_word.**DyckWord_complete**(*parent*, *l*, *latex_options={}*)

Bases: *DyckWord*

The class of complete *Dyck words*. A Dyck word is complete, if it contains as many closers as openers.

For further information on Dyck words, see *DyckWords_class*.

area()

Return the area for `self` corresponding to the area of the Dyck path.

One can view a balanced Dyck word as a lattice path from $(0, 0)$ to (n, n) in the first quadrant by letting '1's represent steps in the direction $(1, 0)$ and '0's represent steps in the direction $(0, 1)$. The resulting path will remain weakly above the diagonal $y = x$.

The area statistic is the number of complete squares in the integer lattice which are below the path and above the line $y = x$. The 'half-squares' directly above the line $y = x$ do not contribute to this statistic.

EXAMPLES:

```
sage: dw = DyckWord([1,0,1,0])
sage: dw.area() # 2 half-squares, 0 complete squares
0
```

```
>>> from sage.all import *
>>> dw = DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)])
>>> dw.area() # 2 half-squares, 0 complete squares
0
```

```
sage: dw = DyckWord([1,1,1,0,1,1,1,0,0,0,1,1,0,0,1,0,0,0])
sage: dw.area()
19
```

```
>>> from sage.all import *
>>> dw = DyckWord([Integer(1),Integer(1),Integer(1),Integer(0),Integer(1),
↪Integer(1),Integer(1),Integer(0),Integer(0),Integer(0),Integer(1),
↪Integer(1),Integer(0),Integer(0),Integer(1),Integer(0),Integer(0),
↪Integer(0)])
>>> dw.area()
19
```

```
sage: DyckWord([1,1,1,1,0,0,0,0]).area()
6
sage: DyckWord([1,1,1,0,1,0,0,0]).area()
5
sage: DyckWord([1,1,1,0,0,1,0,0]).area()

```

area_dinv_to_bounce_area_map()

Return the image of `self` under the map which sends a Dyck word with `area` equal to r and `dinv` equal to s to a Dyck word with `bounce` equal to r and `area` equal to s .

The inverse of this map is *bounce_area_to_area_dinv_map()*.

For a definition of this map, see [Hag2008] p. 50 where it is called ζ. However, this map differs from Haglund's map by an application of *reverse()* (as does the definition of the *bounce()* statistic).

EXAMPLES:

```
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).area_dinv_to_bounce_area_map()
[1, 1, 1, 1, 1, 0, 0, 0, 1, 0, 0, 1, 0, 0]
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).area()
5
```

(continues on next page)

(continued from previous page)

```
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).dinv()
13
sage: DyckWord([1,1,1,1,1,0,0,0,1,0,0,1,0,0]).area()
13
sage: DyckWord([1,1,1,1,1,0,0,0,1,0,0,1,0,0]).bounce()
5
sage: DyckWord([1,1,1,1,1,0,0,0,1,0,0,1,0,0]).area_dinv_to_bounce_area_map()
[1, 0, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0, 1, 0]
sage: DyckWord([1,1,0,0]).area_dinv_to_bounce_area_map()
[1, 0, 1, 0]
sage: DyckWord([1,0,1,0]).area_dinv_to_bounce_area_map()
[1, 1, 0, 0]
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)]).area_dinv_to_bounce_area_map()

↪bounce_area_map()
[1, 1, 0, 0]
```

bounce()

Return the bounce statistic of `self` due to J. Haglund, see [Hag2008].

One can view a balanced Dyck word as a lattice path from $(0,0)$ to (n,n) in the first quadrant by letting '1's represent steps in the direction $(0,1)$ and '0's represent steps in the direction $(1,0)$. The resulting path will remain weakly above the diagonal $y=x$.

We describe the bounce statistic of such a path in terms of what is known as the "bounce path".

We can think of our bounce path as describing the trail of a billiard ball shot West from (n, n), which "bounces" down whenever it encounters a vertical step and "bounces" left when it encounters the line $y = x$.

The bouncing ball will strike the diagonal at the places

$$(0, 0), (j_1, j_1), (j_2, j_2), \ldots, (j_r - 1, j_r - 1), (j_r, j_r) = (n, n).$$

We define the bounce to be the sum $\sum_{i=1}^{r-1} j_i$.

EXAMPLES:

```
sage: DyckWord([1,1,1,0,1,1,1,0,0,0,1,1,0,0,1,0,0,0]).bounce()
7
sage: DyckWord([1,1,1,1,0,0,0,0]).bounce()
0
sage: DyckWord([1,1,1,0,1,0,0,0]).bounce()
1
sage: DyckWord([1,1,1,0,0,1,0,0]).bounce()
2
sage: DyckWord([1,1,1,0,0,0,1,0]).bounce()
3
sage: DyckWord([1,0,1,1,0,1,0,0]).bounce()
3
sage: DyckWord([1,1,0,1,1,0,0,0]).bounce()
1
sage: DyckWord([1,1,0,0,1,1,0,0]).bounce()
2
sage: DyckWord([1,0,1,1,1,0,0,0]).bounce()
1
sage: DyckWord([1,0,1,1,0,0,1,0]).bounce()
4
sage: DyckWord([1,0,1,0,1,1,0,0]).bounce()
3
sage: DyckWord([1,1,0,0,1,0,1,0]).bounce()
5
sage: DyckWord([1,1,0,1,0,0,1,0]).bounce()
4
sage: DyckWord([1,1,0,1,0,1,0,0]).bounce()
2
sage: DyckWord([1,0,1,0,1,0,1,0]).bounce()
6
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(0),Integer(1),
↪Integer(1),Integer(1),Integer(0),Integer(0),Integer(0),Integer(1),
↪Integer(1),Integer(0),Integer(0),Integer(1),Integer(0),Integer(0),
↪Integer(0)]).bounce()
7
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(1),Integer(0),
↪Integer(0),Integer(0),Integer(0)]).bounce()
0
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(0),Integer(1),
↪Integer(0),Integer(0),Integer(0)]).bounce()
1
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(0),Integer(0),
```

(continues on next page)

(continued from previous page)

```
↪Integer(1),Integer(0),Integer(0)]).bounce()
2
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(0),Integer(0),
↪Integer(0),Integer(1),Integer(0)]).bounce()
3
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)]).bounce()
3
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(1),

1
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0),Integer(1),
↪Integer(1),Integer(0),Integer(0)]).bounce()
2
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(1),Integer(1),
↪Integer(0),Integer(0),Integer(0)]).bounce()
1
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(0)]).bounce()
4
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
↪Integer(1),Integer(0),Integer(0)]).bounce()
3
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0),Integer(1),
↪Integer(0),Integer(1),Integer(0)]).bounce()
5
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(0)]).bounce()
4
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)]).bounce()
2
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
↪Integer(0),Integer(1),Integer(0)]).bounce()
6
```

bounce_area_to_area_dinv_map()

Return the image of the Dyck word under the map which sends a Dyck word with `bounce` equal to r and `area` equal to s to a Dyck word with `area` equal to r and `dinv` equal to s .

This implementation uses a recursive method by saying that the last entry in the area sequence of the Dyck word `self` is equal to the number of touch points of the Dyck path minus 1 of the image of this map.

The inverse of this map is *area_dinv_to_bounce_area_map()*.

For a definition of this map, see [Hag2008] p. 50 where it is called ζ^{-1}. However, this map differs from Haglund's map by an application of *reverse()* (as does the definition of the *bounce()* statistic).

EXAMPLES:

```
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).bounce_area_to_area_dinv_map()
[1, 1, 0, 0, 1, 1, 1, 1, 0, 0, 1, 0, 0, 0]
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).area()
5
```

(continues on next page)

(continued from previous page)

```
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).bounce()
9
sage: DyckWord([1,1,0,0,1,1,1,1,0,0,1,0,0,0]).area()
9
sage: DyckWord([1,1,0,0,1,1,1,1,0,0,1,0,0,0]).dinv()
5
sage: all(D==D.bounce_area_to_area_dinv_map().area_dinv_to_bounce_area_map()␣
↪for D in DyckWords(6))
True
sage: DyckWord([1,1,0,0]).bounce_area_to_area_dinv_map()
[1, 0, 1, 0]
sage: DyckWord([1,0,1,0]).bounce_area_to_area_dinv_map()
[1, 1, 0, 0]
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)]).bounce_area_to_area_dinv_map()

>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).bounce_area_to_
↪area_dinv_map()
[1, 1, 0, 0]
```

bounce_path()

Return the bounce path of `self` formed by starting at (n, n) and traveling West until encountering the first vertical step of `self`, then South until encountering the diagonal, then West again to hit the path, etc. until the $(0, 0)$ point is reached. The path followed by this walk is the bounce path.

See also

`bounce()`

EXAMPLES:

```
sage: DyckWord([1,1,0,1,0,0]).bounce_path()
[1, 0, 1, 1, 0, 0]
sage: DyckWord([1,1,1,0,0,0]).bounce_path()
[1, 1, 1, 0, 0, 0]
sage: DyckWord([1,0,1,0,1,0]).bounce_path()
[1, 0, 1, 0, 1, 0]
sage: DyckWord([1,1,1,1,0,0,1,0,0,0]).bounce_path()
[1, 1, 0, 0, 1, 1, 1, 0, 0, 0]
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0)]).bounce_path()
[1, 0, 1, 1, 0, 0]
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(0),Integer(0),
↪Integer(0)]).bounce_path()
[1, 1, 1, 0, 0, 0]
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
↪Integer(0)]).bounce_path()
[1, 0, 1, 0, 1, 0]
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(0),Integer(0),Integer(0)]).bounce_path()
[1, 1, 0, 0, 1, 1, 1, 0, 0, 0]
```

characteristic_symmetric_function(*q=None*, *R=Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field*)

The characteristic function of `self` is the sum of $q^{dinv(D,F)}Q_{ides(read(D,F))}$ over all permutation fillings of the Dyck path representing `self`, where $ides(read(D,F))$ is the descent composition of the inverse of the reading word of the filling.

INPUT:

- `q` – (default: `q = R('q')`) a parameter for the generating function power
- `R` – (default: `R = QQ['q','t'].fraction_field()`) the base ring to do the calculations over

OUTPUT:

- an element of the symmetric functions over the ring `R` (in the Schur basis).

EXAMPLES:

```
sage: R = QQ['q','t'].fraction_field()
sage: (q,t) = R.gens()
sage: f = sum(t**D.area() * D.characteristic_symmetric_function()            #␣
↪needs sage.modules
....:          for D in DyckWords(3)); f
(q^3+q^2*t+q*t^2+t^3+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q+t)*s[2, 1] + s[3]
sage: f.nabla(power=-1)                                                        #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.modules
s[1, 1, 1]
```

```
>>> from sage.all import *
>>> R = QQ['q','t'].fraction_field()
>>> (q,t) = R.gens()
>>> f = sum(t**D.area() * D.characteristic_symmetric_function()          #␣
↪needs sage.modules
...         for D in DyckWords(Integer(3))); f
(q^3+q^2*t+q*t^2+t^3+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q+t)*s[2, 1] + s[3]
>>> f.nabla(power=-Integer(1))                                              ␣
↪     # needs sage.modules
s[1, 1, 1]
```

decomposition_reverse()

Return the involution of `self` with a recursive definition.

If a Dyck word D decomposes as $1D_1 0D_2$ where D_1 and D_2 are complete Dyck words then the decomposition reverse is $1\phi(D_2)0\phi(D_1)$.

EXAMPLES:

```
sage: DyckWord([1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 0, 1, 0, 0]).decomposition_
↪reverse()
[1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]
sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).decomposition_
↪reverse()
[1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 0, 1, 0, 0]
sage: DyckWord([1,1,0,0]).decomposition_reverse()
[1, 0, 1, 0]
sage: DyckWord([1,0,1,0]).decomposition_reverse()
[1, 1, 0, 0]
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(0),␣
↪Integer(0), Integer(1), Integer(1), Integer(0), Integer(1), Integer(0),␣
↪Integer(1), Integer(0), Integer(0)]).decomposition_reverse()
[1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(1),␣
↪Integer(1), Integer(0), Integer(0), Integer(0), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(0)]).decomposition_reverse()
[1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 0, 1, 0, 0]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]).decomposition_
↪reverse()
[1, 0, 1, 0]
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).decomposition_
↪reverse()
[1, 1, 0, 0]
```

dinv(*labeling=None*)

Return the dinv statistic of `self` due to M. Haiman, see [Hag2008].

If a labeling is provided then this function returns the dinv of the labeled Dyck word.

INPUT:

- `labeling` – an optional argument to be viewed as the labelings of the vertical edges of the Dyck path

OUTPUT:

- an integer representing the `dinv` statistic of the Dyck path or the labelled Dyck path.

EXAMPLES:

```
sage: DyckWord([1,0,1,0,1,0,1,0,1,0]).dinv()
10
sage: DyckWord([1,1,1,1,1,0,0,0,0,0]).dinv()
0
sage: DyckWord([1,1,1,1,0,1,0,0,0,0]).dinv()
1
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).dinv()
13
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).dinv([1,2,3,4,5,6,7])
11
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).dinv([6,7,5,3,4,2,1])
2
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
↪Integer(0),Integer(1),Integer(0),Integer(1),Integer(0)]).dinv()
10
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),
↪Integer(0),Integer(0),Integer(0),Integer(0),Integer(0)]).dinv()
0
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0),Integer(0),Integer(0)]).dinv()
1
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)]).dinv()
13
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)]).dinv([Integer(1),Integer(2),Integer(3),
↪Integer(4),Integer(5),Integer(6),Integer(7)])
11
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)]).dinv([Integer(6),Integer(7),Integer(5),
↪Integer(3),Integer(4),Integer(2),Integer(1)])
2
```

first_return_decomposition()

Decompose a Dyck word into a pair of Dyck words (potentially empty) where the first word consists of the word after the first up step and the corresponding matching closing parenthesis.

EXAMPLES:

```
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).first_return_decomposition()
([1, 0, 1, 0], [1, 1, 0, 1, 0, 1, 0, 0])
```

(continues on next page)

(continued from previous page)

```
sage: DyckWord([1,1,0,0]).first_return_decomposition()
([1, 0], [])
sage: DyckWord([1,0,1,0]).first_return_decomposition()
([], [1, 0])
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)]).first_return_decomposition()
([1, 0, 1, 0], [1, 1, 0, 1, 0, 1, 0, 0])
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]).first_return_
↪decomposition()
([1, 0], [])
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).first_return_
↪decomposition()
([], [1, 0])
```

list_parking_functions()

Return all parking functions whose supporting Dyck path is `self`.

EXAMPLES:

```
sage: DyckWord([1,1,0,0,1,0]).list_parking_functions()
[[1, 1, 3], [1, 3, 1], [3, 1, 1]]
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0),Integer(1),
↪Integer(0)]).list_parking_functions()
[[1, 1, 3], [1, 3, 1], [3, 1, 1]]
```

major_index()

Return the major index of `self` .

The major index of a Dyck word D is the sum of the positions of the valleys of D (when started counting at position `1`).

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).major_index()
2
sage: DyckWord([1, 1, 0, 0]).major_index()
0
sage: DyckWord([1, 1, 0, 0, 1, 0]).major_index()
4
sage: DyckWord([1, 0, 1, 1, 0, 0]).major_index()
2
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).major_index()
2
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).major_index()
0
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(0)]).major_index()
4
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(0)]).major_index()
2
```

number_of_parking_functions()

Return the number of parking functions with `self` as the supporting Dyck path.

One representation of a parking function is as a pair consisting of a Dyck path and a permutation π such that if $[a_0, a_1, \ldots, a_{n-1}]$ is the area_sequence of the Dyck path (see `to_area_sequence`) then the permutation π satisfies $\pi_i < \pi_{i+1}$ whenever $a_i < a_{i+1}$. This function counts the number of permutations π which satisfy this condition.

EXAMPLES:

```
sage: DyckWord(area_sequence=[0,1,2]).number_of_parking_functions()
1
sage: DyckWord(area_sequence=[0,1,1]).number_of_parking_functions()
3
sage: DyckWord(area_sequence=[0,1,0]).number_of_parking_functions()
3
sage: DyckWord(area_sequence=[0,0,0]).number_of_parking_functions()
6
```

```
>>> from sage.all import *
>>> DyckWord(area_sequence=[Integer(0),Integer(1),Integer(2)]).number_of_
↪parking_functions()
1
>>> DyckWord(area_sequence=[Integer(0),Integer(1),Integer(1)]).number_of_
↪parking_functions()
3
>>> DyckWord(area_sequence=[Integer(0),Integer(1),Integer(0)]).number_of_
↪parking_functions()
3
>>> DyckWord(area_sequence=[Integer(0),Integer(0),Integer(0)]).number_of_
↪parking_functions()
6
```

number_of_tunnels(*tunnel_type='centered'*)

Return the number of tunnels of `self` of type `tunnel_type`.

A tunnel is a pair (a, b) where `a` is the position of an open parenthesis and `b` is the position of the matching close parenthesis. If $a + b = n$ then the tunnel is called *centered* . If $a + b < n$ then the tunnel is called *left* and if $a + b > n$, then the tunnel is called *right*.

INPUT:

- `tunnel_type` – (default: `'centered'`) can be one of the following: `'left'`, `'right'`, `'centered'`, or `'all'`

EXAMPLES:

```
sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).number_of_tunnels()
0
```

(continues on next page)

(continued from previous page)

```
sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).number_of_tunnels(
↪'left')
5
sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).number_of_tunnels(
↪'right')
2
sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).number_of_tunnels(
↪'all')
7
sage: DyckWord([1, 1, 0, 0]).number_of_tunnels('centered')
2
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(1),␣
↪Integer(1), Integer(0), Integer(0), Integer(0), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(0)]).number_of_tunnels()
0
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(1),␣
↪Integer(1), Integer(0), Integer(0), Integer(0), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(0)]).number_of_tunnels('left')
5
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(1),␣
↪Integer(1), Integer(0), Integer(0), Integer(0), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(0)]).number_of_tunnels('right')
2
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(1),␣
↪Integer(1), Integer(0), Integer(0), Integer(0), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(0)]).number_of_tunnels('all')
7
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).number_of_
↪tunnels('centered')
2
```

parking_functions()

Iterate over parking functions whose supporting Dyck path is `self`.

EXAMPLES:

```
sage: list(DyckWord([1,1,0,1,0,0]).parking_functions())
[[1, 1, 2], [1, 2, 1], [2, 1, 1]]
```

```
>>> from sage.all import *
>>> list(DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0)]).parking_functions())
[[1, 1, 2], [1, 2, 1], [2, 1, 1]]
```

pyramid_weight()

Return the pyramid weight of `self`.

A pyramid of `self` is a subsequence of the form $1^h 0^h$. A pyramid is maximal if it is neither preceded by a 1 nor followed by a 0.

The pyramid weight of a Dyck path is the sum of the lengths of the maximal pyramids and was defined in [DS1992].

EXAMPLES:

```
sage: DyckWord([1,1,0,1,1,1,0,0,1,0,0,0,1,1,0,0]).pyramid_weight()
6
sage: DyckWord([1,1,1,0,0,0]).pyramid_weight()
3
sage: DyckWord([1,0,1,0,1,0]).pyramid_weight()
3
sage: DyckWord([1,1,0,1,0,0]).pyramid_weight()
2
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(1),
↪Integer(1),Integer(0),Integer(0),Integer(1),Integer(0),Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(0),Integer(0)]).pyramid_weight()
6
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(0),Integer(0),
↪Integer(0)]).pyramid_weight()
3
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
↪Integer(0)]).pyramid_weight()
3
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0)]).pyramid_weight()
2
```

reading_permutation()

Return the reading permutation of `self`.

This is the permutation formed by taking the reading word of the Dyck path representing `self` (with N and E steps) if the vertical edges of the Dyck path are labeled from bottom to top with 1 through n and the diagonals are read from top to bottom starting with the diagonal furthest from the main diagonal.

EXAMPLES:

```
sage: DyckWord([1,0,1,0]).reading_permutation()
[2, 1]
sage: DyckWord([1,1,0,0]).reading_permutation()
[2, 1]
sage: DyckWord([1,1,0,1,0,0]).reading_permutation()
[3, 2, 1]
sage: DyckWord([1,1,0,0,1,0]).reading_permutation()
[2, 3, 1]
sage: DyckWord([1,0,1,1,0,0,1,0]).reading_permutation()
[3, 4, 2, 1]
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).reading_
↪permutation()
[2, 1]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]).reading_
↪permutation()
[2, 1]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
```

(continues on next page)

(continued from previous page)

```
↪Integer(0)]).reading_permutation()
[3, 2, 1]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0),Integer(1),
↪Integer(0)]).reading_permutation()
[2, 3, 1]
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(0)]).reading_permutation()
[3, 4, 2, 1]
```

reverse()

Return the reverse and complement of `self`.

This operation corresponds to flipping the Dyck path across the $y = -x$ line.

EXAMPLES:

```
sage: DyckWord([1,1,0,0,1,0]).reverse()
[1, 0, 1, 1, 0, 0]
sage: DyckWord([1,1,1,0,0,0]).reverse()
[1, 1, 1, 0, 0, 0]
sage: len([D for D in DyckWords(5) if D.reverse() == D])
10
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0),Integer(1),
↪Integer(0)]).reverse()
[1, 0, 1, 1, 0, 0]
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(0),Integer(0),
↪Integer(0)]).reverse()
[1, 1, 1, 0, 0, 0]
>>> len([D for D in DyckWords(Integer(5)) if D.reverse() == D])
10
```

semilength()

Return the semilength of `self`.

The semilength of a complete Dyck word d is the number of openers and the number of closers.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).semilength()
2
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).semilength()
2
```

to_132_avoiding_permutation()

Use the bijection by C. Krattenthaler in [Kra2001] to send `self` to a 132-avoiding permutation.

EXAMPLES:

```
sage: DyckWord([1,1,0,0]).to_132_avoiding_permutation()
[1, 2]
```

(continues on next page)

(continued from previous page)

```
sage: DyckWord([1,0,1,0]).to_132_avoiding_permutation()
[2, 1]
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).to_132_avoiding_permutation()
[6, 5, 4, 7, 2, 1, 3]
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]).to_132_avoiding_
↪permutation()
[1, 2]
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).to_132_avoiding_
↪permutation()
[2, 1]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)]).to_132_avoiding_permutation()
[6, 5, 4, 7, 2, 1, 3]
```

to_312_avoiding_permutation()

Convert `self` to a 312-avoiding permutation using the bijection by Bandlow and Killpatrick in [BK2001].

This sends the area to the inversion number.

EXAMPLES:

```
sage: DyckWord([1,1,0,0]).to_312_avoiding_permutation()
[2, 1]
sage: DyckWord([1,0,1,0]).to_312_avoiding_permutation()
[1, 2]
sage: p = DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).to_312_avoiding_
↪permutation(); p
[2, 3, 1, 5, 6, 7, 4]
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).area()
5
sage: p.length()
5
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]).to_312_avoiding_
↪permutation()
[2, 1]
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).to_312_avoiding_
↪permutation()
[1, 2]
>>> p = DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)]).to_312_avoiding_permutation(); p
[2, 3, 1, 5, 6, 7, 4]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)]).area()
5
>>> p.length()
5
```

to_321_avoiding_permutation()

Use the bijection (pp. 60-61 of [Knu1973] or section 3.1 of [CK2008]) to send `self` to a 321-avoiding permutation.

It is shown in [EP2004] that it sends the number of centered tunnels to the number of fixed points, the number of right tunnels to the number of excedences, and the semilength plus the height of the middle point to 2 times the length of the longest increasing subsequence.

EXAMPLES:

```
sage: DyckWord([1,0,1,0]).to_321_avoiding_permutation()
[2, 1]
sage: DyckWord([1,1,0,0]).to_321_avoiding_permutation()
[1, 2]
sage: D = DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0])
sage: p = D.to_321_avoiding_permutation()
sage: p
[3, 5, 1, 6, 2, 7, 4]
sage: D.number_of_tunnels()
0
sage: p.number_of_fixed_points()
0
sage: D.number_of_tunnels('right')
4
sage: len(p.weak_excedences())-p.number_of_fixed_points()
4
sage: n = D.semilength()
sage: D.heights()[n] + n
8
sage: 2*p.longest_increasing_subsequence_length()
8
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).to_321_avoiding_
↪permutation()
[2, 1]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]).to_321_avoiding_
↪permutation()
[1, 2]
>>> D = DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)])
>>> p = D.to_321_avoiding_permutation()
>>> p
[3, 5, 1, 6, 2, 7, 4]
>>> D.number_of_tunnels()
0
>>> p.number_of_fixed_points()
0
>>> D.number_of_tunnels('right')
4
>>> len(p.weak_excedences())-p.number_of_fixed_points()
4
>>> n = D.semilength()
```

(continues on next page)

(continued from previous page)

```
>>> D.heights()[n] + n
8
>>> Integer(2)*p.longest_increasing_subsequence_length()
8
```

to_Catalan_code()

Return the Catalan code associated to `self`.

A Catalan code of length n is a sequence $(a_1, a_2, \ldots, a_n)$ of n integers a_i such that:

- $0 \leq a_i \leq n - i$ for every i;
- if $i < j$ and $a_i > 0$ and $a_j > 0$ and $a_{i+1} = a_{i+2} = \cdots = a_{j-1} = 0$, then $a_i - a_j < j - i$.

It turns out that the Catalan codes of length n are in bijection with Dyck words.

The Catalan code of a Dyck word is example (x) in Richard Stanley's exercises on combinatorial interpretations for Catalan objects. The code in this example is the reverse of the description provided there. See [Sta-EC2] and [StaCat98].

EXAMPLES:

```
sage: DyckWord([]).to_Catalan_code()
[]
sage: DyckWord([1, 0]).to_Catalan_code()
[0]
sage: DyckWord([1, 1, 0, 0]).to_Catalan_code()
[0, 1]
sage: DyckWord([1, 0, 1, 0]).to_Catalan_code()
[0, 0]
sage: all(dw ==
....:     DyckWords().from_Catalan_code(dw.to_Catalan_code())
....:     for i in range(6) for dw in DyckWords(i))
True
```

```
>>> from sage.all import *
>>> DyckWord([]).to_Catalan_code()
[]
>>> DyckWord([Integer(1), Integer(0)]).to_Catalan_code()
[0]
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).to_Catalan_
↪code()
[0, 1]
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).to_Catalan_
↪code()
[0, 0]
>>> all(dw ==
...     DyckWords().from_Catalan_code(dw.to_Catalan_code())
...     for i in range(Integer(6)) for dw in DyckWords(i))
True
```

See also

`to_tamari_sorting_tuple()`

to_alternating_sign_matrix()

Return self as an alternating sign matrix.

This is an inclusion map from Dyck words of length $2n$ to certain $n \times n$ alternating sign matrices.

EXAMPLES:

```
sage: DyckWord([1,1,1,0,1,0,0,0]).to_alternating_sign_matrix()              #␣
↪needs sage.modules
[ 0  0  1  0]
[ 1  0 -1  1]
[ 0  1  0  0]
[ 0  0  1  0]
sage: DyckWord([1,0,1,0,1,1,0,0]).to_alternating_sign_matrix()              #␣
↪needs sage.modules
[1 0 0 0]
[0 1 0 0]
[0 0 0 1]
[0 0 1 0]
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(0),Integer(1),
↪Integer(0),Integer(0),Integer(0)]).to_alternating_sign_matrix()              ␣
↪ # needs sage.modules
[ 0  0  1  0]
[ 1  0 -1  1]
[ 0  1  0  0]
[ 0  0  1  0]
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
↪Integer(1),Integer(0),Integer(0)]).to_alternating_sign_matrix()              ␣
↪ # needs sage.modules
[1 0 0 0]
[0 1 0 0]
[0 0 0 1]
[0 0 1 0]
```

to_non_decreasing_parking_function()

Bijection to *non-decreasing parking functions*.

See there the method *to_dyck_word()* for more information.

EXAMPLES:

```
sage: DyckWord([]).to_non_decreasing_parking_function()
[]
sage: DyckWord([1,0]).to_non_decreasing_parking_function()
[1]
sage: DyckWord([1,1,0,0]).to_non_decreasing_parking_function()
[1, 1]
sage: DyckWord([1,0,1,0]).to_non_decreasing_parking_function()
[1, 2]
sage: DyckWord([1,0,1,1,0,1,0,0,1,0]).to_non_decreasing_parking_function()
[1, 2, 2, 3, 5]
```

```
>>> from sage.all import *
>>> DyckWord([]).to_non_decreasing_parking_function()
[]
>>> DyckWord([Integer(1),Integer(0)]).to_non_decreasing_parking_function()
[1]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]).to_non_decreasing_
↪parking_function()
[1, 1]
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).to_non_decreasing_
↪parking_function()
[1, 2]
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0),Integer(1),Integer(0)]).to_non_decreasing_
↪parking_function()
[1, 2, 2, 3, 5]
```

to_noncrossing_partition(*bijection=None*)

Bijection of Biane from `self` to a noncrossing partition.

There is an optional parameter `bijection` that indicates if a different bijection from Dyck words to non-crossing partitions should be used (since there are potentially many).

If the parameter `bijection` is "Stump" then the bijection used is from [Stu2008], see also the method *to_noncrossing_permutation()*.

Thanks to Mathieu Dutour for describing the bijection. See also *from_noncrossing_partition()*.

EXAMPLES:

```
sage: DyckWord([]).to_noncrossing_partition()
{}
sage: DyckWord([1, 0]).to_noncrossing_partition()
{{1}}
sage: DyckWord([1, 1, 0, 0]).to_noncrossing_partition()
{{1, 2}}
sage: DyckWord([1, 1, 1, 0, 0, 0]).to_noncrossing_partition()
{{1, 2, 3}}
sage: DyckWord([1, 0, 1, 0, 1, 0]).to_noncrossing_partition()
{{1}, {2}, {3}}
sage: DyckWord([1, 1, 0, 1, 0, 0]).to_noncrossing_partition()
{{1, 3}, {2}}
sage: DyckWord([]).to_noncrossing_partition("Stump")
{}
sage: DyckWord([1, 0]).to_noncrossing_partition("Stump")
{{1}}
sage: DyckWord([1, 1, 0, 0]).to_noncrossing_partition("Stump")
{{1, 2}}
sage: DyckWord([1, 1, 1, 0, 0, 0]).to_noncrossing_partition("Stump")
{{1, 3}, {2}}
sage: DyckWord([1, 0, 1, 0, 1, 0]).to_noncrossing_partition("Stump")
{{1}, {2}, {3}}
sage: DyckWord([1, 1, 0, 1, 0, 0]).to_noncrossing_partition("Stump")
{{1, 2, 3}}
```

```
>>> from sage.all import *
>>> DyckWord([]).to_noncrossing_partition()
{}
>>> DyckWord([Integer(1), Integer(0)]).to_noncrossing_partition()
{{1}}
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).to_noncrossing_
→partition()
{{1, 2}}
>>> DyckWord([Integer(1), Integer(1), Integer(1), Integer(0), Integer(0),␣
→Integer(0)]).to_noncrossing_partition()
{{1, 2, 3}}
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0), Integer(1),␣
→Integer(0)]).to_noncrossing_partition()
{{1}, {2}, {3}}
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(0),␣
→Integer(0)]).to_noncrossing_partition()
{{1, 3}, {2}}
>>> DyckWord([]).to_noncrossing_partition("Stump")
{}
>>> DyckWord([Integer(1), Integer(0)]).to_noncrossing_partition("Stump")
{{1}}
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).to_noncrossing_
→partition("Stump")
{{1, 2}}
>>> DyckWord([Integer(1), Integer(1), Integer(1), Integer(0), Integer(0),␣
→Integer(0)]).to_noncrossing_partition("Stump")
{{1, 3}, {2}}
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0), Integer(1),␣
→Integer(0)]).to_noncrossing_partition("Stump")
{{1}, {2}, {3}}
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(0),␣
→Integer(0)]).to_noncrossing_partition("Stump")
{{1, 2, 3}}
```

to_noncrossing_permutation()

Use the bijection by C. Stump in [Stu2008] to send `self` to a non-crossing permutation.

A non-crossing permutation when written in cyclic notation has cycles which are strictly increasing. Sends the area to the inversion number and `self.major_index()` to $n(n-1) - maj(\sigma) - maj(\sigma^{-1})$. Uses the function *pealing()*

EXAMPLES:

```
sage: DyckWord([1,1,0,0]).to_noncrossing_permutation()
[2, 1]
sage: DyckWord([1,0,1,0]).to_noncrossing_permutation()
[1, 2]
sage: p = DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).to_noncrossing_
→permutation(); p
[2, 3, 1, 5, 6, 7, 4]
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).area()
5
sage: p.length()
5
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]).to_noncrossing_
↪permutation()
[2, 1]
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).to_noncrossing_
↪permutation()
[1, 2]
>>> p = DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)]).to_noncrossing_permutation(); p
[2, 3, 1, 5, 6, 7, 4]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)]).area()
5
>>> p.length()
5
```

to_ordered_tree()

Return the ordered tree corresponding to `self` where the depth of the tree is the maximal height of `self`.

EXAMPLES:

```
sage: # needs sage.graphs
sage: D = DyckWord([1,1,0,0])
sage: D.to_ordered_tree()
[[[]]]
sage: D = DyckWord([1,0,1,0])
sage: D.to_ordered_tree()
[[], []]
sage: D = DyckWord([1, 0, 1, 1, 0, 0])
sage: D.to_ordered_tree()
[[], [[]]]
sage: D = DyckWord([1, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 1, 0, 0, 0])
sage: D.to_ordered_tree()
[[], [[], []], [[], [[]]]]
```

```
>>> from sage.all import *
>>> # needs sage.graphs
>>> D = DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)])
>>> D.to_ordered_tree()
[[[]]]
>>> D = DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)])
>>> D.to_ordered_tree()
[[], []]
>>> D = DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(0)])
>>> D.to_ordered_tree()
[[], [[]]]
>>> D = DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(1), Integer(0), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(1), Integer(1), Integer(0), Integer(0), Integer(0)])
>>> D.to_ordered_tree()
```

(continues on next page)

(continued from previous page)

```
[[], [[], []], [[], [[]]]]
```

to_pair_of_standard_tableaux()

Convert `self` to a pair of standard tableaux of the same shape and of length less than or equal to two.

EXAMPLES:

```
sage: DyckWord([1,0,1,0]).to_pair_of_standard_tableaux()
([[1], [2]], [[1], [2]])
sage: DyckWord([1,1,0,0]).to_pair_of_standard_tableaux()
([[1, 2]], [[1, 2]])
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).to_pair_of_standard_tableaux()
([[1, 2, 4, 7], [3, 5, 6]], [[1, 2, 4, 6], [3, 5, 7]])
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).to_pair_of_
↪standard_tableaux()
([[1], [2]], [[1], [2]])
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]).to_pair_of_
↪standard_tableaux()
([[1, 2]], [[1, 2]])
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(0)]).to_pair_of_standard_tableaux()
([[1, 2, 4, 7], [3, 5, 6]], [[1, 2, 4, 6], [3, 5, 7]])
```

to_partition()

Return the partition associated to `self`.

This partition is determined by thinking of `self` as a lattice path and considering the cells which are above the path but within the $n \times n$ grid and the partition is formed by reading the sequence of the number of cells in this collection in each row.

OUTPUT:

- a partition representing the rows of cells in the square lattice and above the path

EXAMPLES:

```
sage: DyckWord([]).to_partition()
[]
sage: DyckWord([1,0]).to_partition()
[]
sage: DyckWord([1,1,0,0]).to_partition()
[]
sage: DyckWord([1,0,1,0]).to_partition()
[1]
sage: DyckWord([1,0,1,0,1,0]).to_partition()
[2, 1]
sage: DyckWord([1,1,0,0,1,0]).to_partition()
[2]
sage: DyckWord([1,0,1,1,0,0]).to_partition()
[1, 1]
```

```
>>> from sage.all import *
>>> DyckWord([]).to_partition()
[]
>>> DyckWord([Integer(1),Integer(0)]).to_partition()
[]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]).to_partition()
[]
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).to_partition()
[1]
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
↪Integer(0)]).to_partition()
[2, 1]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0),Integer(1),
↪Integer(0)]).to_partition()
[2]
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(1),Integer(0),
↪Integer(0)]).to_partition()
[1, 1]
```

to_permutation(*map*)

This is simply a method collecting all implemented maps from Dyck words to permutations.

INPUT:

- `map` – defines the map from Dyck words to permutations. These are currently:
  - `Bandlow-Killpatrick`: *to_312_avoiding_permutation()*
  - `Knuth`: *to_321_avoiding_permutation()*
  - `Krattenthaler`: *to_132_avoiding_permutation()*
  - `Stump`: *to_noncrossing_permutation()*

EXAMPLES:

```
sage: D = DyckWord([1,1,1,0,1,0,0,0])
sage: D.pretty_print()
   _____
 _| x x
| x x  .
| x  . .
|  . . .

sage: D.to_permutation(map='Bandlow-Killpatrick')
[3, 4, 2, 1]
sage: D.to_permutation(map='Stump')
[4, 2, 3, 1]
sage: D.to_permutation(map='Knuth')
[1, 2, 4, 3]
sage: D.to_permutation(map='Krattenthaler')
[2, 1, 3, 4]
```

```
>>> from sage.all import *
>>> D = DyckWord([Integer(1),Integer(1),Integer(1),Integer(0),Integer(1),
↪Integer(0),Integer(0),Integer(0)])
```

(continues on next page)

(continued from previous page)

```
>>> D.pretty_print()
   _____
 _| x x
| x x  .
| x  . .
|  . . .

>>> D.to_permutation(map='Bandlow-Killpatrick')
[3, 4, 2, 1]
>>> D.to_permutation(map='Stump')
[4, 2, 3, 1]
>>> D.to_permutation(map='Knuth')
[1, 2, 4, 3]
>>> D.to_permutation(map='Krattenthaler')
[2, 1, 3, 4]
```

to_triangulation()

Map `self` to a triangulation.

The map from complete Dyck words of length $2n$ to triangulations of $n + 2$-gon given by this function is a bijection that can be described as follows.

Consider the Dyck word as a path from $(0, 0)$ to (n, n) staying above the diagonal, where 1 is an up step and 0 is a right step. Then each horizontal step has a co-height (0 at the top and $n - 1$ at most at the bottom). One reads the Dyck word from left to right. At the beginning, all vertices from 0 to $n + 1$ are available. For each horizontal step, one creates an edge from the vertex indexed by the co-height to the next available vertex. This chops out a triangle from the polygon and one removes the middle vertex of this triangle from the list of available vertices.

This bijection has the property that the set of smallest vertices of the edges in a triangulation is an encoding of the co-heights, from which the Dyck word can be easily recovered.

OUTPUT:

a list of pairs (i, j) that are the edges of the triangulations.

EXAMPLES:

```
sage: DyckWord([1, 1, 0, 0]).to_triangulation()
[(0, 2)]

sage: [t.to_triangulation() for t in DyckWords(3)]
[[(2, 4), (1, 4)],
[(2, 4), (0, 2)],
[(1, 3), (1, 4)],
[(1, 3), (0, 3)],
[(0, 2), (0, 3)]]
```

```
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).to_
↪triangulation()
[(0, 2)]

>>> [t.to_triangulation() for t in DyckWords(Integer(3))]
[[(2, 4), (1, 4)],
```

(continues on next page)

(continued from previous page)

```
[(2, 4), (0, 2)],
[(1, 3), (1, 4)],
[(1, 3), (0, 3)],
[(0, 2), (0, 3)]]
```

REFERENCES:

- [Cha2005]

to_triangulation_as_graph()

Map `self` to a triangulation and return the result as a graph.

See *to_triangulation()* for the bijection used to map complete Dyck words to triangulations.

OUTPUT:

- a graph containing both the perimeter edges and the inner edges of a triangulation of a regular polygon.

EXAMPLES:

```
sage: g = DyckWord([1, 1, 0, 0, 1, 0]).to_triangulation_as_graph(); g        #␣
↪needs sage.graphs
Graph on 5 vertices
sage: g.edges(sort=True, labels=False)                                       #␣
↪needs sage.graphs
[(0, 1), (0, 4), (1, 2), (1, 3), (1, 4), (2, 3), (3, 4)]
sage: g.show()                          # not tested                         #␣
↪needs sage.graphs
```

```
>>> from sage.all import *
>>> g = DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(0)]).to_triangulation_as_graph(); g        # needs sage.graphs
Graph on 5 vertices
>>> g.edges(sort=True, labels=False)                                       #␣
↪needs sage.graphs
[(0, 1), (0, 4), (1, 2), (1, 3), (1, 4), (2, 3), (3, 4)]
>>> g.show()                          # not tested                         #␣
↪needs sage.graphs
```

tunnels()

Return an iterator of ranges of the matching parentheses in the Dyck word `self`.

That is, if `(a,b)` is in `self.tunnels()`, then the matching parenthesis to `self[a]` is `self[b-1]`.

EXAMPLES:

```
sage: list(DyckWord([1, 1, 0, 1, 1, 0, 0, 1, 0, 0]).tunnels())
[(0, 10), (1, 3), (3, 7), (4, 6), (7, 9)]
```

```
>>> from sage.all import *
>>> list(DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(1),
↪ Integer(0), Integer(0), Integer(1), Integer(0), Integer(0)]).tunnels())
[(0, 10), (1, 3), (3, 7), (4, 6), (7, 9)]
```

class sage.combinat.dyck_word.**DyckWords**

Bases: `UniqueRepresentation`, `Parent`

Dyck words.

A Dyck word is a sequence $(w_1, \ldots, w_n)$ consisting of 1 s and 0 s, with the property that for any i with $1 \leq i \leq n$, the sequence $(w_1, \ldots, w_i)$ contains at least as many 1 s as 0 s.

A Dyck word is balanced if the total number of 1 s is equal to the total number of 0 s. The number of balanced Dyck words of length $2k$ is given by the `Catalan number` C_k.

EXAMPLES:

This class can be called with three keyword parameters `k1`, `k2` and `complete`.

If neither `k1` nor `k2` are specified, then `DyckWords` returns the combinatorial class of all balanced (=complete) Dyck words, unless the keyword `complete` is set to False (in which case it returns the class of all Dyck words).

```
sage: DW = DyckWords(); DW
Complete Dyck words
sage: [] in DW
True
sage: [1, 0, 1, 0] in DW
True
sage: [1, 1, 0] in DW
False
sage: ADW = DyckWords(complete=False); ADW
Dyck words
sage: [] in ADW
True
sage: [1, 0, 1, 0] in ADW
True
sage: [1, 1, 0] in ADW
True
sage: [1, 0, 0] in ADW
False
```

```
>>> from sage.all import *
>>> DW = DyckWords(); DW
Complete Dyck words
>>> [] in DW
True
>>> [Integer(1), Integer(0), Integer(1), Integer(0)] in DW
True
>>> [Integer(1), Integer(1), Integer(0)] in DW
False
>>> ADW = DyckWords(complete=False); ADW
Dyck words
>>> [] in ADW
True
>>> [Integer(1), Integer(0), Integer(1), Integer(0)] in ADW
True
>>> [Integer(1), Integer(1), Integer(0)] in ADW
True
>>> [Integer(1), Integer(0), Integer(0)] in ADW
False
```

If just `k1` is specified, then it returns the balanced Dyck words with `k1` opening parentheses and `k1` closing parentheses.

```
sage: DW2 = DyckWords(2); DW2
Dyck words with 2 opening parentheses and 2 closing parentheses
sage: DW2.first()
[1, 0, 1, 0]
sage: DW2.last()
[1, 1, 0, 0]
sage: DW2.cardinality()
2
sage: DyckWords(100).cardinality() == catalan_number(100)
True
```

```
>>> from sage.all import *
>>> DW2 = DyckWords(Integer(2)); DW2
Dyck words with 2 opening parentheses and 2 closing parentheses
>>> DW2.first()
[1, 0, 1, 0]
>>> DW2.last()
[1, 1, 0, 0]
>>> DW2.cardinality()
2
>>> DyckWords(Integer(100)).cardinality() == catalan_number(Integer(100))
True
```

If `k2` is specified in addition to `k1`, then it returns the Dyck words with `k1` opening parentheses and `k2` closing parentheses.

```
sage: DW32 = DyckWords(3,2); DW32
Dyck words with 3 opening parentheses and 2 closing parentheses
sage: DW32.list()
[[1, 0, 1, 0, 1],
 [1, 0, 1, 1, 0],
 [1, 1, 0, 0, 1],
 [1, 1, 0, 1, 0],
 [1, 1, 1, 0, 0]]
```

```
>>> from sage.all import *
>>> DW32 = DyckWords(Integer(3),Integer(2)); DW32
Dyck words with 3 opening parentheses and 2 closing parentheses
>>> DW32.list()
[[1, 0, 1, 0, 1],
 [1, 0, 1, 1, 0],
 [1, 1, 0, 0, 1],
 [1, 1, 0, 1, 0],
 [1, 1, 1, 0, 0]]
```

Element

alias of *DyckWord*

from_heights(*heights*)

Compute a Dyck word knowing its heights.

We view the Dyck word as a Dyck path from $(0, 0)$ to $(2n, 0)$ in the first quadrant by letting `1`'s represent steps in the direction $(1, 1)$ and `0`'s represent steps in the direction $(1, -1)$.

The `heights()` is the sequence of the y-coordinates of the $2n + 1$ lattice points along this path.

EXAMPLES:

```
sage: from sage.combinat.dyck_word import DyckWord
sage: D = DyckWords(complete=False)
sage: D.from_heights((0,))
[]
sage: D.from_heights((0, 1, 0))
[1, 0]
sage: D.from_heights((0, 1, 2, 1, 0))
[1, 1, 0, 0]
```

```
>>> from sage.all import *
>>> from sage.combinat.dyck_word import DyckWord
>>> D = DyckWords(complete=False)
>>> D.from_heights((Integer(0),))
[]
>>> D.from_heights((Integer(0), Integer(1), Integer(0)))
[1, 0]
>>> D.from_heights((Integer(0), Integer(1), Integer(2), Integer(1),␣
↪Integer(0)))
[1, 1, 0, 0]
```

This also works for incomplete Dyck words:

```
sage: D.from_heights((0, 1, 2, 1, 2, 1))
[1, 1, 0, 1, 0]
sage: D.from_heights((0, 1, 2, 1))
[1, 1, 0]
```

```
>>> from sage.all import *
>>> D.from_heights((Integer(0), Integer(1), Integer(2), Integer(1),␣
↪Integer(2), Integer(1)))
[1, 1, 0, 1, 0]
>>> D.from_heights((Integer(0), Integer(1), Integer(2), Integer(1)))
[1, 1, 0]
```

See also:

heights(), *min_from_heights()*

min_from_heights(*heights*)

Compute the smallest Dyck word which achieves or surpasses a given sequence of heights.

INPUT:

- `heights` – a nonempty list or iterable consisting of nonnegative integers, the first of which is 0

OUTPUT:

- The smallest Dyck word whose sequence of heights is componentwise higher-or-equal to `heights`. Here, "smaller" can be understood both in the sense of lexicographic order on the Dyck words, and in the sense of every vertex of the path having the smallest possible height.

See also

- *heights()*
- *from_heights()*

EXAMPLES:

```
sage: D = DyckWords(complete=False)
sage: D.min_from_heights((0,))
[]
sage: D.min_from_heights((0, 1, 0))
[1, 0]
sage: D.min_from_heights((0, 0, 2, 0, 0))
[1, 1, 0, 0]
sage: D.min_from_heights((0, 0, 2, 0, 2, 0))
[1, 1, 0, 1, 0]
sage: D.min_from_heights((0, 0, 1, 0, 1, 0))
[1, 1, 0, 1, 0]
```

```
>>> from sage.all import *
>>> D = DyckWords(complete=False)
>>> D.min_from_heights((Integer(0),))
[]
>>> D.min_from_heights((Integer(0), Integer(1), Integer(0)))
[1, 0]
>>> D.min_from_heights((Integer(0), Integer(0), Integer(2), Integer(0),␣
↪Integer(0)))
[1, 1, 0, 0]
>>> D.min_from_heights((Integer(0), Integer(0), Integer(2), Integer(0),␣
↪Integer(2), Integer(0)))
[1, 1, 0, 1, 0]
>>> D.min_from_heights((Integer(0), Integer(0), Integer(1), Integer(0),␣
↪Integer(1), Integer(0)))
[1, 1, 0, 1, 0]
```

options = Current options for DyckWords - ascii_art: path - diagram_style: grid - display: list - latex_bounce_path: False - latex_color: black - latex_diagonal: False - latex_line_width_scalar: 2 - latex_peaks: False - latex_tikz_scale: 1 - latex_valleys: False

class sage.combinat.dyck_word.**DyckWords_all**

Bases: *DyckWords*

All Dyck words.

class sage.combinat.dyck_word.**DyckWords_size**(*k1*, *k2*)

Bases: *DyckWords*

Dyck words with k_1 openers and k_2 closers.

cardinality()

Return the number of Dyck words with k_1 openers and k_2 closers.

This number is

$$\frac{k_1 - k_2 + 1}{k_1 + 1} \binom{k_1 + k_2}{k_2} = \binom{k_1 + k_2}{k_2} - \binom{k_1 + k_2}{k_2 - 1}$$

if $k_2 \leq k_1 + 1$, and 0 if $k_2 > k_1$ (these numbers are the same if $k_2 = k_1 + 1$).

EXAMPLES:

```
sage: DyckWords(3, 2).cardinality()
5
sage: all(all(DyckWords(p, q).cardinality()
....:             == len(DyckWords(p, q).list()) for q in range(p + 1))
....:       for p in range(7))
True
```

```
>>> from sage.all import *
>>> DyckWords(Integer(3), Integer(2)).cardinality()
5
>>> all(all(DyckWords(p, q).cardinality()
...             == len(DyckWords(p, q).list()) for q in range(p + Integer(1)))
...       for p in range(Integer(7)))
True
```

sage.combinat.dyck_word.**is_a**(*obj*, *k1=None*, *k2=None*)

Test if `obj` is a Dyck word with exactly `k1` open symbols and exactly `k2` close symbols.

If `k1` is not specified, then the number of open symbols can be arbitrary. If `k1` is specified but `k2` is not, then `k2` is set to be `k1`.

EXAMPLES:

```
sage: from sage.combinat.dyck_word import is_a
sage: is_a([1,1,0,0])
True
sage: is_a([1,0,1,0])
True
sage: is_a([1,1,0,0], 2)
True
sage: is_a([1,1,0,0], 3)
False
sage: is_a([1,1,0,0], 3, 2)
False
sage: is_a([1,1,0])
True
sage: is_a([0,1,0])
False
sage: is_a([1,0,0])
False
sage: is_a([1,1,0],2,1)
True
sage: is_a([1,1,0],2)
False
sage: is_a([1,1,0],1,1)
False
```

```
>>> from sage.all import *
>>> from sage.combinat.dyck_word import is_a
>>> is_a([Integer(1),Integer(1),Integer(0),Integer(0)])
True
>>> is_a([Integer(1),Integer(0),Integer(1),Integer(0)])
True
>>> is_a([Integer(1),Integer(1),Integer(0),Integer(0)], Integer(2))
True
>>> is_a([Integer(1),Integer(1),Integer(0),Integer(0)], Integer(3))
False
>>> is_a([Integer(1),Integer(1),Integer(0),Integer(0)], Integer(3), Integer(2))
False
>>> is_a([Integer(1),Integer(1),Integer(0)])
True
>>> is_a([Integer(0),Integer(1),Integer(0)])
False
>>> is_a([Integer(1),Integer(0),Integer(0)])
False
>>> is_a([Integer(1),Integer(1),Integer(0)],Integer(2),Integer(1))
True
>>> is_a([Integer(1),Integer(1),Integer(0)],Integer(2))
False
>>> is_a([Integer(1),Integer(1),Integer(0)],Integer(1),Integer(1))
False
```

sage.combinat.dyck_word.**is_area_sequence**(*seq*)

Test if a sequence l of integers satisfies $l_0 = 0$ and $0 \leq l_{i+1} \leq l_i + 1$ for $i > 0$.

EXAMPLES:

```
sage: from sage.combinat.dyck_word import is_area_sequence
sage: is_area_sequence([0,2,0])
False
sage: is_area_sequence([1,2,3])
False
sage: is_area_sequence([0,1,0])
True
sage: is_area_sequence([0,1,2])
True
sage: is_area_sequence([])
True
```

```
>>> from sage.all import *
>>> from sage.combinat.dyck_word import is_area_sequence
>>> is_area_sequence([Integer(0),Integer(2),Integer(0)])
False
>>> is_area_sequence([Integer(1),Integer(2),Integer(3)])
False
>>> is_area_sequence([Integer(0),Integer(1),Integer(0)])
True
>>> is_area_sequence([Integer(0),Integer(1),Integer(2)])
True
>>> is_area_sequence([])
```

(continues on next page)

(continued from previous page)

```
True
```

sage.combinat.dyck_word.**pealing**(*D*, *return_touches=False*)

A helper function for computing the bijection from a Dyck word to a 231-avoiding permutation using the bijection "Stump". For details see [Stu2008].

See also

to_noncrossing_partition()

EXAMPLES:

```
sage: from sage.combinat.dyck_word import pealing
sage: pealing(DyckWord([1,1,0,0]))
[1, 0, 1, 0]
sage: pealing(DyckWord([1,0,1,0]))
[1, 0, 1, 0]
sage: pealing(DyckWord([1, 1, 0, 0, 1, 1, 1, 0, 0, 0]))
[1, 0, 1, 0, 1, 0, 1, 0, 1, 0]
sage: pealing(DyckWord([1,1,0,0]),return_touches=True)
([1, 0, 1, 0], [[1, 2]])
sage: pealing(DyckWord([1,0,1,0]),return_touches=True)
([1, 0, 1, 0], [])
sage: pealing(DyckWord([1, 1, 0, 0, 1, 1, 1, 0, 0, 0]),return_touches=True)
([1, 0, 1, 0, 1, 0, 1, 0, 1, 0], [[1, 2], [3, 5]])
```

```
>>> from sage.all import *
>>> from sage.combinat.dyck_word import pealing
>>> pealing(DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]))
[1, 0, 1, 0]
>>> pealing(DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]))
[1, 0, 1, 0]
>>> pealing(DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(1), Integer(1), Integer(0), Integer(0), Integer(0)]))
[1, 0, 1, 0, 1, 0, 1, 0, 1, 0]
>>> pealing(DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]),return_
↪touches=True)
([1, 0, 1, 0], [[1, 2]])
>>> pealing(DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]),return_
↪touches=True)
([1, 0, 1, 0], [])
>>> pealing(DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(1), Integer(1), Integer(0), Integer(0), Integer(0)]),return_

```

sage.combinat.dyck_word.**replace_parens**(*x*)

A map sending `'('` to `open_symbol` and `')'` to `close_symbol`, and raising an error on any input other than `'('` and `')'`. The values of the constants `open_symbol` and `close_symbol` are subject to change.

This is the inverse map of *replace_symbols()*.

INPUT:

- x – either an opening or closing parenthesis

OUTPUT:

- If x is an opening parenthesis, replace x with the constant open_symbol.
- If x is a closing parenthesis, replace x with the constant close_symbol.
- Raise a ValueError if x is neither an opening nor a closing parenthesis.

See also

replace_symbols()

EXAMPLES:

```
sage: from sage.combinat.dyck_word import replace_parens
sage: replace_parens('(')
1
sage: replace_parens(')')
0
sage: replace_parens(1)
Traceback (most recent call last):
...
ValueError
```

```
>>> from sage.all import *
>>> from sage.combinat.dyck_word import replace_parens
>>> replace_parens('(')
1
>>> replace_parens(')')
0
>>> replace_parens(Integer(1))
Traceback (most recent call last):
...
ValueError
```

sage.combinat.dyck_word.**replace_symbols**(*x*)

A map sending open_symbol to '(' and close_symbol to ')', and raising an error on any input other than open_symbol and close_symbol. The values of the constants open_symbol and close_symbol are subject to change.

This is the inverse map of *replace_parens()*.

INPUT:

- x – either open_symbol or close_symbol

OUTPUT:

- If x is open_symbol, replace x with '('.
- If x is close_symbol, replace x with ')'.
- If x is neither open_symbol nor close_symbol, a ValueError is raised.

See also

replace_parens()

EXAMPLES:

```
sage: from sage.combinat.dyck_word import replace_symbols
sage: replace_symbols(1)
'('
sage: replace_symbols(0)
')'
sage: replace_symbols(3)
Traceback (most recent call last):
...
ValueError
```

```
>>> from sage.all import *
>>> from sage.combinat.dyck_word import replace_symbols
>>> replace_symbols(Integer(1))
'('
>>> replace_symbols(Integer(0))
')'
>>> replace_symbols(Integer(3))
Traceback (most recent call last):
...
ValueError
```

5.1.101 Substitutions over unit cube faces (Rauzy fractals)

This module implements the $E_1^*(\sigma)$ substitution associated with a one-dimensional substitution σ, that acts on unit faces of dimension $(d-1)$ in $\mathbf{R}^d$.

This module defines the following classes and functions:

- `Face` – a class to model a face
- `Patch` – a class to model a finite set of faces
- `E1Star` – a class to model the $E_1^*(\sigma)$ application defined by the substitution sigma

See the documentation of these objects for more information.

The convention for the choice of the unit faces and the definition of $E_1^*(\sigma)$ varies from article to article. Here, unit faces are defined by

$$\begin{array}{rcl} [x,1]^* & = & \{x+\lambda e_2+\mu e_3 : \lambda,\mu\in[0,1]\} \\ [x,2]^* & = & \{x+\lambda e_1+\mu e_3 : \lambda,\mu\in[0,1]\} \\ [x,3]^* & = & \{x+\lambda e_1+\mu e_2 : \lambda,\mu\in[0,1]\} \end{array}$$

and the dual substitution $E_1^*(\sigma)$ is defined by

$$E_1^*(\sigma)([x,i]^*) = \bigcup_{k=1,2,3} \quad \bigcup_{s|\sigma(k)=pis} [M^{-1}(x+\ell(s)),k]^*,$$

where $\ell(s)$ is the abelianized of s, and M is the matrix of σ.

EXAMPLES:

We start by drawing a simple three-face patch:

```
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: x = [Face((0,0,0),1), Face((0,0,0),2), Face((0,0,0),3)]
sage: P = Patch(x)
sage: P
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*]
sage: P.plot()                          #not tested
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import E1Star, Face, Patch
>>> x = [Face((Integer(0),Integer(0),Integer(0)),Integer(1)), Face((Integer(0),
↪Integer(0),Integer(0)),Integer(2)), Face((Integer(0),Integer(0),Integer(0)),
↪Integer(3))]
>>> P = Patch(x)
>>> P
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*]
>>> P.plot()                          #not tested
```

We apply a substitution to this patch, and draw the result:

```
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 1, -1), 2]*, [(1, 0, -
↪1), 1]*]
sage: E(P).plot()                          #not tested
```

```
>>> from sage.all import *
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)], Integer(2):[Integer(1),
↪Integer(3)], Integer(3):[Integer(1)]})
>>> E = E1Star(sigma)
>>> E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 1, -1), 2]*, [(1, 0, -
↪1), 1]*]
>>> E(P).plot()                          #not tested
```

Note

- The type of a face is given by an integer in `[1, ..., d]` where `d` is the length of the vector of the face.
- The alphabet of the domain and the codomain of σ must be equal, and they must be of the form `[1, ..., d]`, where `d` is a positive integer corresponding to the length of the vectors of the faces on which $E_1^*(\sigma)$ will act.

```
sage: P = Patch([Face((0,0,0),1), Face((0,0,0),2), Face((0,0,0),3)])
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 1, -1), 2]*, [(1, 0, -
↪1), 1]*]
```

```
>>> from sage.all import *
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),Integer(1)), Face((Integer(0),
↪Integer(0),Integer(0)),Integer(2)), Face((Integer(0),Integer(0),Integer(0)),
↪Integer(3))])
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)], Integer(2):[Integer(1),
↪Integer(3)], Integer(3):[Integer(1)]})
>>> E = E1Star(sigma)
>>> E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 1, -1), 2]*, [(1, 0, -
↪1), 1]*]
```

The application of an `E1Star` substitution assigns to each new face the color of its preimage. The `repaint` method allows us to repaint the faces of a patch. A single color can also be assigned to every face, by specifying a list of a single color:

```
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P = E(P, 5)
sage: P.repaint(['green'])
sage: P.plot()                    #not tested
```

```
>>> from sage.all import *
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in [Integer(1),
↪Integer(2),Integer(3)]])
>>> P = E(P, Integer(5))
>>> P.repaint(['green'])
>>> P.plot()                    #not tested
```

A list of colors allows us to color the faces sequentially:

```
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P = E(P)
sage: P.repaint(['red', 'yellow', 'green', 'blue', 'black'])
sage: P = E(P, 3)
sage: P.plot()                    #not tested
```

```
>>> from sage.all import *
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in [Integer(1),
↪Integer(2),Integer(3)]])
>>> P = E(P)
>>> P.repaint(['red', 'yellow', 'green', 'blue', 'black'])
>>> P = E(P, Integer(3))
>>> P.plot()                    #not tested
```

All the color schemes from `list(matplotlib.cm.datad)` can be used:

```
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.repaint(cmap='summer')
sage: P = E(P, 3)
sage: P.plot()                    #not tested
sage: P.repaint(cmap='hsv')
sage: P = E(P, 2)
sage: P.plot()                    #not tested
```

```
>>> from sage.all import *
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in [Integer(1),
↪Integer(2),Integer(3)]])
>>> P.repaint(cmap='summer')
>>> P = E(P, Integer(3))
>>> P.plot()                    #not tested
>>> P.repaint(cmap='hsv')
>>> P = E(P, Integer(2))
>>> P.plot()                    #not tested
```

It is also possible to specify a dictionary to color the faces according to their type:

```
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P = E(P, 5)
sage: P.repaint({1:(0.7, 0.7, 0.7), 2:(0.5,0.5,0.5), 3:(0.3,0.3,0.3)})
sage: P.plot()                    #not tested
sage: P.repaint({1:'red', 2:'yellow', 3:'green'})
sage: P.plot()                    #not tested
```

```
>>> from sage.all import *
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in [Integer(1),
↪Integer(2),Integer(3)]])
>>> P = E(P, Integer(5))
>>> P.repaint({Integer(1):(RealNumber('0.7'), RealNumber('0.7'), RealNumber('0.7')),␣
↪Integer(2):(RealNumber('0.5'),RealNumber('0.5'),RealNumber('0.5')),␣
↪Integer(3):(RealNumber('0.3'),RealNumber('0.3'),RealNumber('0.3'))})
>>> P.plot()                    #not tested
>>> P.repaint({Integer(1):'red', Integer(2):'yellow', Integer(3):'green'})
>>> P.plot()                    #not tested
```

Let us look at a nice big patch in 3D:

```
sage: sigma = WordMorphism({1:[1,2], 2:[3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P = P + P.translate([-1,1,0])
sage: P = E(P, 11)
sage: P.plot3d()                    #not tested
```

```
>>> from sage.all import *
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)], Integer(2):[Integer(3)],
↪ Integer(3):[Integer(1)]})
>>> E = E1Star(sigma)
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in [Integer(1),
```

(continues on next page)

(continued from previous page)

```
↪Integer(2),Integer(3)]])
>>> P = P + P.translate([-Integer(1),Integer(1),Integer(0)])
>>> P = E(P, Integer(11))
>>> P.plot3d()                    #not tested
```

Plotting with TikZ pictures is possible:

```
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: s = P.plot_tikz()
sage: print(s)                        #not tested
\begin{tikzpicture}
[x={(-0.216506cm,-0.125000cm)}, y={(0.216506cm,-0.125000cm)}, z={(0.000000cm,0.
↪250000cm)}]
\definecolor{facecolor}{rgb}{0.000,1.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 0, 1) -- (1, 0, 1) -- (1, 0, 0) -- cycle;
\definecolor{facecolor}{rgb}{1.000,0.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 1, 0) -- (0, 1, 1) -- (0, 0, 1) -- cycle;
\definecolor{facecolor}{rgb}{0.000,0.000,1.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (1, 0, 0) -- (1, 1, 0) -- (0, 1, 0) -- cycle;
\end{tikzpicture}
```

```
>>> from sage.all import *
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in [Integer(1),
↪Integer(2),Integer(3)]])
>>> s = P.plot_tikz()
>>> print(s)                    #not tested
\begin{tikzpicture}
[x={(-0.216506cm,-0.125000cm)}, y={(0.216506cm,-0.125000cm)}, z={(0.000000cm,0.
↪250000cm)}]
\definecolor{facecolor}{rgb}{0.000,1.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 0, 1) -- (1, 0, 1) -- (1, 0, 0) -- cycle;
\definecolor{facecolor}{rgb}{1.000,0.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 1, 0) -- (0, 1, 1) -- (0, 0, 1) -- cycle;
\definecolor{facecolor}{rgb}{0.000,0.000,1.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (1, 0, 0) -- (1, 1, 0) -- (0, 1, 0) -- cycle;
\end{tikzpicture}
```

Plotting patches made of unit segments instead of unit faces:

```
sage: P = Patch([Face([0,0], 1), Face([0,0], 2)])
sage: E = E1Star(WordMorphism({1:[1,2],2:[1]}))
sage: F = E1Star(WordMorphism({1:[1,1,2],2:[2,1]}))
sage: E(P,5).plot()                                                          #␣
↪needs sage.plot
Graphics object consisting of 21 graphics primitives
sage: F(P,3).plot()                                                          #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.plot
Graphics object consisting of 34 graphics primitives
```

```
>>> from sage.all import *
>>> P = Patch([Face([Integer(0),Integer(0)], Integer(1)), Face([Integer(0),
↪Integer(0)], Integer(2))])
>>> E = E1Star(WordMorphism({Integer(1):[Integer(1),Integer(2)],
↪Integer(2):[Integer(1)]}))
>>> F = E1Star(WordMorphism({Integer(1):[Integer(1),Integer(1),Integer(2)],
↪Integer(2):[Integer(2),Integer(1)]}))
>>> E(P,Integer(5)).plot()                                                    ␣
↪     # needs sage.plot
Graphics object consisting of 21 graphics primitives
>>> F(P,Integer(3)).plot()                                                    ␣
↪     # needs sage.plot
Graphics object consisting of 34 graphics primitives
```

Everything works in any dimension (except for the plotting features which only work in dimension two or three):

```
sage: P = Patch([Face((0,0,0,0),1), Face((0,0,0,0),4)])
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1,4], 4:[1]})
sage: E = E1Star(sigma)
sage: E(P)
Patch: [[(0, 0, 0, 0), 3]*, [(0, 0, 0, 0), 4]*, [(0, 0, 1, -1), 3]*, [(0, 1, 0, -1),␣
↪2]*, [(1, 0, 0, -1), 1]*]
```

```
>>> from sage.all import *
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0),Integer(0)),Integer(1)),␣
↪Face((Integer(0),Integer(0),Integer(0),Integer(0)),Integer(4))])
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)], Integer(2):[Integer(1),
↪Integer(3)], Integer(3):[Integer(1),Integer(4)], Integer(4):[Integer(1)]})
>>> E = E1Star(sigma)
>>> E(P)
Patch: [[(0, 0, 0, 0), 3]*, [(0, 0, 0, 0), 4]*, [(0, 0, 1, -1), 3]*, [(0, 1, 0, -1),␣
↪2]*, [(1, 0, 0, -1), 1]*]
```

```
sage: sigma = WordMorphism({1:[1,2],2:[1,3],3:[1,4],4:[1,5],5:[1,6],6:[1,7],7:[1,8],
↪8:[1,9],9:[1,10],10:[1,11],11:[1,12],12:[1]})
sage: E = E1Star(sigma)

```

class `sage.combinat.e_one_star.`**E1Star**(*sigma*, *method='suffix'*)

Bases: `SageObject`

A class to model the $E_1^*(\sigma)$ map associated with a unimodular substitution σ.

INPUT:

- `sigma` – unimodular `WordMorphism`, i.e. such that its incidence matrix has determinant ± 1
- `method` – 'prefix' or 'suffix' (default: `'suffix'`); enables to use an alternative definition $E_1^*(\sigma)$ substitutions, where the abelianized of the prefix` is used instead of the suffix

Note

The alphabet of the domain and the codomain of σ must be equal, and they must be of the form `[1, ...,` d], where d is a positive integer corresponding to the length of the vectors of the faces on which $E_1^*(\sigma)$ will act.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 1, -1), 2]*, [(1,␣
↪0, -1), 1]*]
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import E1Star, Face, Patch
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in [Integer(1),
↪Integer(2),Integer(3)]])
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)],␣
↪Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1)]})
>>> E = E1Star(sigma)
>>> E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 1, -1), 2]*, [(1,␣
↪0, -1), 1]*]
```

```
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma, method='prefix')
sage: E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 0, 1), 1]*, [(0,␣
↪0, 1), 2]*]
```

```
>>> from sage.all import *
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in [Integer(1),
↪Integer(2),Integer(3)]])
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)],␣
↪Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1)]})
>>> E = E1Star(sigma, method='prefix')
>>> E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 0, 1), 1]*, [(0,␣
↪0, 1), 2]*]
```

```
sage: x = [Face((0,0,0,0),1), Face((0,0,0,0),4)]
sage: P = Patch(x)
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1,4], 4:[1]})
sage: E = E1Star(sigma)
sage: E(P)
Patch: [[(0, 0, 0, 0), 3]*, [(0, 0, 0, 0), 4]*, [(0, 0, 1, -1), 3]*, [(0, 1, 0, -
↪1), 2]*, [(1, 0, 0, -1), 1]*]
```

```
>>> from sage.all import *
>>> x = [Face((Integer(0),Integer(0),Integer(0),Integer(0)),Integer(1)),␣
```

(continues on next page)

(continued from previous page)

```
↪Face((Integer(0),Integer(0),Integer(0),Integer(0)),Integer(4))]
>>> P = Patch(x)
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)],␣
↪Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1),Integer(4)],␣
↪Integer(4):[Integer(1)]})
>>> E = E1Star(sigma)
>>> E(P)
Patch: [[(0, 0, 0, 0), 3]*, [(0, 0, 0, 0), 4]*, [(0, 0, 1, -1), 3]*, [(0, 1, 0, -
↪1), 2]*, [(1, 0, 0, -1), 1]*]
```

inverse_matrix()

Return the inverse of the matrix associated with `self`.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E.inverse_matrix()
[ 0  1  0]
[ 0  0  1]
[ 1 -1 -1]
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import E1Star, Face, Patch
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)],␣
↪Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1)]})
>>> E = E1Star(sigma)
>>> E.inverse_matrix()
[ 0  1  0]
[ 0  0  1]
[ 1 -1 -1]
```

matrix()

Return the matrix associated with `self`.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E.matrix()
[1 1 1]
[1 0 0]
[0 1 0]
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import E1Star, Face, Patch
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)],␣
↪Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1)]})
>>> E = E1Star(sigma)
>>> E.matrix()
```

(continues on next page)

(continued from previous page)

```
[1 1 1]
[1 0 0]
[0 1 0]
```

sigma()

Return the WordMorphism associated with self.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E.sigma()
WordMorphism: 1->12, 2->13, 3->1
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import E1Star, Face, Patch
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)],␣
↪Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1)]})
>>> E = E1Star(sigma)
>>> E.sigma()
WordMorphism: 1->12, 2->13, 3->1
```

class sage.combinat.e_one_star.**Face**(*v*, *t*, *color=None*)

Bases: SageObject

A class to model a unit face of arbitrary dimension.

A unit face in dimension d is represented by a d-dimensional vector v and a type t in $\{1, \ldots, d\}$. The type of the face corresponds to the canonical unit vector to which the face is orthogonal. The optional color argument is used in plotting functions.

INPUT:

- v – tuple of integers
- t – integer in [1, ..., len(v)], type of the face. The face of type i is orthogonal to the canonical vector e_i.
- color – color (default: None); color of the face, used for plotting only. If None, its value is guessed from the face type.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face
sage: f = Face((0,2,0), 3)
sage: f.vector()
(0, 2, 0)
sage: f.type()
3
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face
>>> f = Face((Integer(0),Integer(2),Integer(0)), Integer(3))
>>> f.vector()
```

(continues on next page)

(continued from previous page)

```
(0, 2, 0)
>>> f.type()
3
```

```
sage: f = Face((0,2,0), 3, color=(0.5, 0.5, 0.5))
sage: f.color()
RGB color (0.5, 0.5, 0.5)
```

```
>>> from sage.all import *
>>> f = Face((Integer(0),Integer(2),Integer(0)), Integer(3), color=(RealNumber('0.
→5'), RealNumber('0.5'), RealNumber('0.5')))
>>> f.color()
RGB color (0.5, 0.5, 0.5)
```

color (*color=None*)

Return or change the color of the face.

INPUT:

- `color` – string, rgb tuple, color (default: `None`) the new color to assign to the face. If `None`, it returns the color of the face.

OUTPUT: color or None

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face
sage: f = Face((0,2,0), 3)
sage: f.color()
RGB color (0.0, 0.0, 1.0)
sage: f.color('red')
sage: f.color()
RGB color (1.0, 0.0, 0.0)
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face
>>> f = Face((Integer(0),Integer(2),Integer(0)), Integer(3))
>>> f.color()
RGB color (0.0, 0.0, 1.0)
>>> f.color('red')
>>> f.color()
RGB color (1.0, 0.0, 0.0)
```

type ()

Return the type of the face.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face
sage: f = Face((0,2,0), 3)
sage: f.type()
3
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face
>>> f = Face((Integer(0),Integer(2),Integer(0)), Integer(3))
>>> f.type()
3
```

```
sage: f = Face((0,2,0), 3)
sage: f.type()
3
```

```
>>> from sage.all import *
>>> f = Face((Integer(0),Integer(2),Integer(0)), Integer(3))
>>> f.type()
3
```

vector()

Return the vector of the face.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face
sage: f = Face((0,2,0), 3)
sage: f.vector()
(0, 2, 0)
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face
>>> f = Face((Integer(0),Integer(2),Integer(0)), Integer(3))
>>> f.vector()
(0, 2, 0)
```

class sage.combinat.e_one_star.**Patch**(*faces*, *face_contour=None*)

Bases: `SageObject`

A class to model a collection of faces. A patch is represented by an immutable set of Faces.

Note

The dimension of a patch is the length of the vectors of the faces in the patch, which is assumed to be the same for every face in the patch.

Note

Since version 4.7.1, Patches are immutable, except for the colors of the faces, which are not taken into account for equality tests and hash functions.

INPUT:

- `faces` – finite iterable of faces
- `face_contour` – dictionary (default: `None`); maps the face type to vectors describing the contour of unit faces. If `None`, defaults contour are assumed for faces of type 1, 2, 3 or 1, 2, 3. Used in plotting methods

only.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*]
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face, Patch
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in [Integer(1),
↪Integer(2),Integer(3)]])
>>> P
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*]
```

```
sage: face_contour = {}
sage: face_contour[1] = map(vector, [(0,0,0),(0,1,0),(0,1,1),(0,0,1)])
sage: face_contour[2] = map(vector, [(0,0,0),(0,0,1),(1,0,1),(1,0,0)])
sage: face_contour[3] = map(vector, [(0,0,0),(1,0,0),(1,1,0),(0,1,0)])
sage: Patch([Face((0,0,0),t) for t in [1,2,3]], face_contour=face_contour)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*]
```

```
>>> from sage.all import *
>>> face_contour = {}
>>> face_contour[Integer(1)] = map(vector, [(Integer(0),Integer(0),Integer(0)),
↪(Integer(0),Integer(1),Integer(0)),(Integer(0),Integer(1),Integer(1)),
↪(Integer(0),Integer(0),Integer(1))])
>>> face_contour[Integer(2)] = map(vector, [(Integer(0),Integer(0),Integer(0)),
↪(Integer(0),Integer(0),Integer(1)),(Integer(1),Integer(0),Integer(1)),
↪(Integer(1),Integer(0),Integer(0))])
>>> face_contour[Integer(3)] = map(vector, [(Integer(0),Integer(0),Integer(0)),
↪(Integer(1),Integer(0),Integer(0)),(Integer(1),Integer(1),Integer(0)),
↪(Integer(0),Integer(1),Integer(0))])
>>> Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in [Integer(1),
↪Integer(2),Integer(3)]], face_contour=face_contour)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*]
```

difference(*other*)

Return the difference of `self` and `other`.

INPUT:

- `other` – a finite iterable of faces or a single face

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.difference(Face([0,0,0],2))
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 3]*]
sage: P.difference(P)
Patch: []
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face, Patch
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in␣
↪[Integer(1),Integer(2),Integer(3)]])
>>> P.difference(Face([Integer(0),Integer(0),Integer(0)],Integer(2)))
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 3]*]
>>> P.difference(P)
Patch: []
```

dimension()

Return the dimension of the vectors of the faces of `self`.

It returns `None` if `self` is the empty patch.

The dimension of a patch is the length of the vectors of the faces in the patch, which is assumed to be the same for every face in the patch.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.dimension()
3
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face, Patch
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in␣
↪[Integer(1),Integer(2),Integer(3)]])
>>> P.dimension()
3
```

faces_of_color(*color*)

Return a list of the faces that have the given color.

INPUT:

- `color` – color

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1, 'red'), Face((1,2,0),3, 'blue'), Face((1,2,
↪0),1, 'red')])
sage: sorted(P.faces_of_color('red'))
[[(0, 0, 0), 1]*, [(1, 2, 0), 1]*]
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face, Patch
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),Integer(1), 'red'),␣
↪Face((Integer(1),Integer(2),Integer(0)),Integer(3), 'blue'),␣
↪Face((Integer(1),Integer(2),Integer(0)),Integer(1), 'red')])
>>> sorted(P.faces_of_color('red'))
[[(0, 0, 0), 1]*, [(1, 2, 0), 1]*]
```

faces_of_type(*t*)

Return a list of the faces that have type `t`.

INPUT:

- `t` – integer or any other type

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1), Face((1,2,0),3), Face((1,2,0),1)])
sage: sorted(P.faces_of_type(1))
[[(0, 0, 0), 1]*, [(1, 2, 0), 1]*]
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face, Patch
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),Integer(1)),␣
↪Face((Integer(1),Integer(2),Integer(0)),Integer(3)), Face((Integer(1),
↪Integer(2),Integer(0)),Integer(1))])
>>> sorted(P.faces_of_type(Integer(1)))
[[(0, 0, 0), 1]*, [(1, 2, 0), 1]*]
```

faces_of_vector(*v*)

Return a list of the faces whose vector is `v`.

INPUT:

- `v` – a vector

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1), Face((1,2,0),3), Face((1,2,0),1)])
sage: sorted(P.faces_of_vector([1,2,0]))
[[(1, 2, 0), 1]*, [(1, 2, 0), 3]*]
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face, Patch
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),Integer(1)),␣
↪Face((Integer(1),Integer(2),Integer(0)),Integer(3)), Face((Integer(1),
↪Integer(2),Integer(0)),Integer(1))])
>>> sorted(P.faces_of_vector([Integer(1),Integer(2),Integer(0)]))
[[(1, 2, 0), 1]*, [(1, 2, 0), 3]*]
```

occurrences_of(*other*)

Return all positions at which other appears in self, that is, all vectors v such that `set(other.translate(v)) <= set(self)`.

INPUT:

- `other` – a Patch

OUTPUT: list of vectors

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch, E1Star
sage: P = Patch([Face([0,0,0], 1), Face([0,0,0], 2), Face([0,0,0], 3)])
sage: Q = Patch([Face([0,0,0], 1), Face([0,0,0], 2)])
sage: P.occurrences_of(Q)
```

(continues on next page)

(continued from previous page)

```
[(0, 0, 0)]
sage: Q = Q.translate([1,2,3])
sage: P.occurrences_of(Q)
[(-1, -2, -3)]
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face, Patch, E1Star
>>> P = Patch([Face([Integer(0),Integer(0),Integer(0)], Integer(1)),␣
↪Face([Integer(0),Integer(0),Integer(0)], Integer(2)), Face([Integer(0),
↪Integer(0),Integer(0)], Integer(3))])
>>> Q = Patch([Face([Integer(0),Integer(0),Integer(0)], Integer(1)),␣
↪Face([Integer(0),Integer(0),Integer(0)], Integer(2))])
>>> P.occurrences_of(Q)
[(0, 0, 0)]
>>> Q = Q.translate([Integer(1),Integer(2),Integer(3)])
>>> P.occurrences_of(Q)
[(-1, -2, -3)]
```

```
sage: E = E1Star(WordMorphism({1:[1,2], 2:[1,3], 3:[1]}))
sage: P = Patch([Face([0,0,0], 1), Face([0,0,0], 2), Face([0,0,0], 3)])
sage: P = E(P,4)
sage: Q = Patch([Face([0,0,0], 1), Face([0,0,0], 2)])
sage: L = P.occurrences_of(Q)
sage: sorted(L)
[(0, 0, 0), (0, 0, 1), (0, 1, -1), (1, 0, -1), (1, 1, -3), (1, 1, -2)]
```

```
>>> from sage.all import *
>>> E = E1Star(WordMorphism({Integer(1):[Integer(1),Integer(2)],␣
↪Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1)]}))
>>> P = Patch([Face([Integer(0),Integer(0),Integer(0)], Integer(1)),␣
↪Face([Integer(0),Integer(0),Integer(0)], Integer(2)), Face([Integer(0),
↪Integer(0),Integer(0)], Integer(3))])
>>> P = E(P,Integer(4))
>>> Q = Patch([Face([Integer(0),Integer(0),Integer(0)], Integer(1)),␣
↪Face([Integer(0),Integer(0),Integer(0)], Integer(2))])
>>> L = P.occurrences_of(Q)
>>> sorted(L)
[(0, 0, 0), (0, 0, 1), (0, 1, -1), (1, 0, -1), (1, 1, -3), (1, 1, -2)]
```

plot(*projmat=None*, *opacity=0.75*)

Return a 2D graphic object depicting the patch.

INPUT:

- `projmat` – matrix (default: `None`); the projection matrix. Its number of lines must be two. Its number of columns must equal the dimension of the ambient space of the faces. If `None`, the isometric projection is used by default.
- `opacity` – float between `0` and `1` (default: `0.75`) opacity of the face

Warning

Plotting is implemented only for patches in two or three dimensions.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.plot()                                                           #␣
↪needs sage.plot
Graphics object consisting of 3 graphics primitives
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import E1Star, Face, Patch
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in␣
↪[Integer(1),Integer(2),Integer(3)]])
>>> P.plot()                                                           #␣
↪needs sage.plot
Graphics object consisting of 3 graphics primitives
```

```
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P = E(P, 5)
sage: P.plot()                                                           #␣
↪needs sage.plot
Graphics object consisting of 57 graphics primitives
```

```
>>> from sage.all import *
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)],␣
↪Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1)]})
>>> E = E1Star(sigma)
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in␣
↪[Integer(1),Integer(2),Integer(3)]])
>>> P = E(P, Integer(5))
>>> P.plot()                                                           #␣
↪needs sage.plot
Graphics object consisting of 57 graphics primitives
```

Plot with a different projection matrix:

```
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: M = matrix(2, 3, [1,0,-1,0.3,1,-3])
sage: P = E(P, 3)
sage: P.plot(projmat=M)                                                  #␣
↪needs sage.plot
Graphics object consisting of 17 graphics primitives
```

```
>>> from sage.all import *
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)],␣
↪Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1)]})
```

(continues on next page)

(continued from previous page)

```
>>> E = E1Star(sigma)
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in␣
↪[Integer(1),Integer(2),Integer(3)]])
>>> M = matrix(Integer(2), Integer(3), [Integer(1),Integer(0),-Integer(1),
↪RealNumber('0.3'),Integer(1),-Integer(3)])
>>> P = E(P, Integer(3))
>>> P.plot(projmat=M)                                                    #␣
↪needs sage.plot
Graphics object consisting of 17 graphics primitives
```

Plot patches made of unit segments:

```
sage: P = Patch([Face([0,0], 1), Face([0,0], 2)])
sage: E = E1Star(WordMorphism({1:[1,2],2:[1]}))
sage: F = E1Star(WordMorphism({1:[1,1,2],2:[2,1]}))
sage: E(P,5).plot()                                                       #␣
↪needs sage.plot
Graphics object consisting of 21 graphics primitives
sage: F(P,3).plot()                                                       #␣
↪needs sage.plot
Graphics object consisting of 34 graphics primitives
```

```
>>> from sage.all import *
>>> P = Patch([Face([Integer(0),Integer(0)], Integer(1)), Face([Integer(0),
↪Integer(0)], Integer(2))])
>>> E = E1Star(WordMorphism({Integer(1):[Integer(1),Integer(2)],
↪Integer(2):[Integer(1)]}))
>>> F = E1Star(WordMorphism({Integer(1):[Integer(1),Integer(1),Integer(2)],
↪Integer(2):[Integer(2),Integer(1)]}))
>>> E(P,Integer(5)).plot()                                                 ␣
↪     # needs sage.plot
Graphics object consisting of 21 graphics primitives
>>> F(P,Integer(3)).plot()                                                 ␣
↪     # needs sage.plot
Graphics object consisting of 34 graphics primitives
```

plot3d()

Return a 3D graphics object depicting the patch.

> **Warning**
>
> 3D plotting is implemented only for patches in three dimensions.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.plot3d()                              #not tested
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import E1Star, Face, Patch
```

(continues on next page)

(continued from previous page)

```
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in␣
↪[Integer(1),Integer(2),Integer(3)]])
>>> P.plot3d()                  #not tested
```

```
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P = E(P, 5)
sage: P.repaint()
sage: P.plot3d()                  #not tested
```

```
>>> from sage.all import *
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)],␣
↪Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1)]})
>>> E = E1Star(sigma)
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in␣
↪[Integer(1),Integer(2),Integer(3)]])
>>> P = E(P, Integer(5))
>>> P.repaint()
>>> P.plot3d()                  #not tested
```

plot_tikz(*projmat=None*, *print_tikz_env=True*, *edgecolor='black'*, *scale=0.25*, *drawzero=False*, *extra_code_before=''*, *extra_code_after=''*)

Return a string containing some TikZ code to be included into a LaTeX document, depicting the patch.

> **Warning**
>
> Tikz Plotting is implemented only for patches in three dimensions.

INPUT:

- `projmat` – matrix (default: `None`); the projection matrix. Its number of lines must be two. Its number of columns must equal the dimension of the ambient space of the faces. If `None`, the isometric projection is used by default.
- `print_tikz_env` – boolean (default: `True`); if `True`, the tikzpicture environment are printed
- `edgecolor` – string (default: `'black'`); either `'black'` or `'facecolor'` (color of unit face edges)
- `scale` – real number (default: `0.25`) scaling constant for the whole figure
- `drawzero` – boolean (default: `False`); if `True`, mark the origin by a black dot
- `extra_code_before` – string (default: `''`); extra code to include in the tikz picture
- `extra_code_after` – string (default: `''`); extra code to include in the tikz picture

EXAMPLES:

```
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: s = P.plot_tikz()
sage: len(s)
602
```

(continues on next page)

(continued from previous page)

```
sage: print(s)       #not tested
\begin{tikzpicture}
[x={(-0.216506cm,-0.125000cm)}, y={(0.216506cm,-0.125000cm)}, z={(0.000000cm,
↪0.250000cm)}]
\definecolor{facecolor}{rgb}{0.000,1.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 0, 1) -- (1, 0, 1) -- (1, 0, 0) -- cycle;

\end{tikzpicture}
```

```
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P = E(P, 4)
sage: from sage.misc.latex import latex              #not tested
sage: latex.add_to_preamble('\\usepackage{tikz}')    #not tested
sage: view(P)                              #not tested
```

```
>>> from sage.all import *
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)],␣
↪Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1)]})
>>> E = E1Star(sigma)
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in␣
↪[Integer(1),Integer(2),Integer(3)]])
```

(continues on next page)

(continued from previous page)

```
>>> P = E(P, Integer(4))
>>> from sage.misc.latex import latex              #not tested
>>> latex.add_to_preamble('\\usepackage{tikz}')    #not tested
>>> view(P)                            #not tested
```

Plot using shades of gray (useful for article figures):

```
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.repaint([(0.9, 0.9, 0.9), (0.65,0.65,0.65), (0.4,0.4,0.4)])
sage: P = E(P, 4)
sage: s = P.plot_tikz()
```

```
>>> from sage.all import *
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)],␣
↪Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1)]})
>>> E = E1Star(sigma)
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in␣
↪[Integer(1),Integer(2),Integer(3)]])
>>> P.repaint([(RealNumber('0.9'), RealNumber('0.9'), RealNumber('0.9')),␣
↪(RealNumber('0.65'),RealNumber('0.65'),RealNumber('0.65')), (RealNumber('0.4
↪'),RealNumber('0.4'),RealNumber('0.4'))])
>>> P = E(P, Integer(4))
>>> s = P.plot_tikz()
```

Plotting with various options:

```
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: M = matrix(2,3,[float(u) for u in [1,0,-0.7071,0,1,-0.7071]])
sage: P = E(P, 3)
sage: s = P.plot_tikz(projmat=M, edgecolor='facecolor', scale=0.6,␣
↪drawzero=True)
```

```
>>> from sage.all import *
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)],␣
↪Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1)]})
>>> E = E1Star(sigma)
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in␣
↪[Integer(1),Integer(2),Integer(3)]])
>>> M = matrix(Integer(2),Integer(3),[float(u) for u in [Integer(1),
↪Integer(0),-RealNumber('0.7071'),Integer(0),Integer(1),-RealNumber('0.7071
↪')]])
>>> P = E(P, Integer(3))
>>> s = P.plot_tikz(projmat=M, edgecolor='facecolor', scale=RealNumber('0.6'),
↪ drawzero=True)
```

Adding X, Y, Z axes using the extra code feature:

```
sage: length = 1.5
sage: space = 0.3
sage: axes = ''
sage: axes += "\\draw[->, thick, black] (0,0,0) -- (%s, 0, 0);\n" % length
sage: axes += "\\draw[->, thick, black] (0,0,0) -- (0, %s, 0);\n" % length
sage: axes += "\\node at (%s,0,0) {$x$};\n" % (length + space)
sage: axes += "\\node at (0,%s,0) {$y$};\n" % (length + space)
sage: axes += "\\node at (0,0,%s) {$z$};\n" % (length + space)
sage: axes += "\\draw[->, thick, black] (0,0,0) -- (0, 0, %s);\n" % length
sage: cube = Patch([Face((0,0,0),1), Face((0,0,0),2), Face((0,0,0),3)])
sage: options = dict(scale=0.5,drawzero=True,extra_code_before=axes)
sage: s = cube.plot_tikz(**options)
sage: len(s)
986
sage: print(s)    #not tested
\begin{tikzpicture}
[x={(-0.433013cm,-0.250000cm)}, y={(0.433013cm,-0.250000cm)}, z={(0.000000cm,
↪0.500000cm)}]
\draw[->, thick, black] (0,0,0) -- (1.50000000000000, 0, 0);

\definecolor{facecolor}{rgb}{0.000,0.000,1.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (1, 0, 0) -- (1, 1, 0) -- (0, 1, 0) -- cycle;
\node[circle,fill=black,draw=black,minimum size=1.5mm,inner sep=0pt] at (0,0,
↪0) {};
\end{tikzpicture}
```

repaint(*cmap='Set1'*)

Repaint all the faces of `self` from the given color map.

This only changes the colors of the faces of `self`.

INPUT:

- `cmap` – color map (default: `'Set1'`). It can be one of the following:
  - `string` – a coloring map; for available coloring map names type: `sorted(colormaps)`
  - `list` – list of colors to assign cyclically to the faces A list of a single color colors all the faces with the same color
  - `dict` – dictionary of face types mapped to colors, to color the faces according to their type
  - `{}`, the empty dict – shortcut for `{1:'red', 2:'green', 3:'blue'}`

EXAMPLES:

Using a color map:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: color = (0, 0, 0)
sage: P = Patch([Face((0,0,0),t,color) for t in [1,2,3]])
sage: for f in P: f.color()
RGB color (0.0, 0.0, 0.0)
RGB color (0.0, 0.0, 0.0)
RGB color (0.0, 0.0, 0.0)
sage: P.repaint()
```

(continues on next page)

(continued from previous page)

```
sage: next(iter(P)).color()     #random
RGB color (0.498..., 0.432..., 0.522...)
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face, Patch
>>> color = (Integer(0), Integer(0), Integer(0))
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t,color) for t in␣
↪[Integer(1),Integer(2),Integer(3)]])
>>> for f in P: f.color()
RGB color (0.0, 0.0, 0.0)
RGB color (0.0, 0.0, 0.0)
RGB color (0.0, 0.0, 0.0)
>>> P.repaint()
>>> next(iter(P)).color()     #random
RGB color (0.498..., 0.432..., 0.522...)
```

Using a list of colors:

```
sage: P = Patch([Face((0,0,0),t,color) for t in [1,2,3]])
sage: P.repaint([(0.9, 0.9, 0.9), (0.65,0.65,0.65), (0.4,0.4,0.4)])
sage: for f in P: f.color()
RGB color (0.9, 0.9, 0.9)
RGB color (0.65, 0.65, 0.65)
RGB color (0.4, 0.4, 0.4)
```

```
>>> from sage.all import *
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t,color) for t in␣
↪[Integer(1),Integer(2),Integer(3)]])
>>> P.repaint([(RealNumber('0.9'), RealNumber('0.9'), RealNumber('0.9')),␣
↪(RealNumber('0.65'),RealNumber('0.65'),RealNumber('0.65')), (RealNumber('0.4
↪'),RealNumber('0.4'),RealNumber('0.4'))])
>>> for f in P: f.color()
RGB color (0.9, 0.9, 0.9)
RGB color (0.65, 0.65, 0.65)
RGB color (0.4, 0.4, 0.4)
```

Using a dictionary to color faces according to their type:

```
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.repaint({1:'black', 2:'yellow', 3:'green'})
sage: P.plot()                    #not tested
sage: P.repaint({})
sage: P.plot()                    #not tested
```

```
>>> from sage.all import *
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in␣
↪[Integer(1),Integer(2),Integer(3)]])
>>> P.repaint({Integer(1):'black', Integer(2):'yellow', Integer(3):'green'})
>>> P.plot()                    #not tested
>>> P.repaint({})
>>> P.plot()                    #not tested
```

translate(*v*)

Return a translated copy of `self` by vector v.

INPUT:

- `v` – vector or tuple

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1), Face((1,2,0),3), Face((1,2,0),1)])
sage: P.translate([-1,-2,0])
Patch: [[(-1, -2, 0), 1]*, [(0, 0, 0), 1]*, [(0, 0, 0), 3]*]
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face, Patch
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),Integer(1)),␣
↪Face((Integer(1),Integer(2),Integer(0)),Integer(3)), Face((Integer(1),
↪Integer(2),Integer(0)),Integer(1))])
>>> P.translate([-Integer(1),-Integer(2),Integer(0)])
Patch: [[(-1, -2, 0), 1]*, [(0, 0, 0), 1]*, [(0, 0, 0), 3]*]
```

union(*other*)

Return a Patch consisting of the union of `self` and `other`.

INPUT:

- `other` – a Patch or a Face or a finite iterable of faces

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1), Face((0,0,0),2)])
sage: P.union(Face((1,2,3), 3))
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(1, 2, 3), 3]*]
sage: P.union([Face((1,2,3), 3), Face((2,3,3), 2)])
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(1, 2, 3), 3]*, [(2, 3, 3), 2]*]
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face, Patch
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),Integer(1)),␣
↪Face((Integer(0),Integer(0),Integer(0)),Integer(2))])
>>> P.union(Face((Integer(1),Integer(2),Integer(3)), Integer(3)))
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(1, 2, 3), 3]*]
>>> P.union([Face((Integer(1),Integer(2),Integer(3)), Integer(3)),␣
↪Face((Integer(2),Integer(3),Integer(3)), Integer(2))])
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(1, 2, 3), 3]*, [(2, 3, 3), 2]*]
```

5.1.102 Enumerated sets and combinatorial objects

Todo

Proofread / point to the main classes rather than the modules

Categories

- `EnumeratedSets`, `FiniteEnumeratedSets`

Basic enumerated sets

5.1.103 Tools for enumeration modulo the action of a permutation group

`sage.combinat.enumeration_mod_permgroup.`**`all_children`**`(`*v*, *max_part*`)`

Return all the children of an integer vector (`ClonableIntArray`) `v` in the tree of enumeration by lexicographic order. The children of an integer vector `v` whose entries have the sum n are all integer vectors of sum $n + 1$ which follow `v` in the lexicographic order.

That means this function adds 1 on the last nonzero entries and the following ones. For an integer vector v such that

$$v = [\dots, a, 0, 0] \text{ with } a \neq 0,$$

then, the list of children is

$$[[\dots, a+1, 0, 0], [\dots, a, 1, 0], [\dots, a, 0, 1]].$$

EXAMPLES:

```
sage: from sage.combinat.enumeration_mod_permgroup import all_children
sage: from sage.structure.list_clone_demo import IncreasingIntArrays
sage: v = IncreasingIntArrays()([1,2,3,4])
sage: all_children(v, -1)
[[1, 2, 3, 5]]
```

```
>>> from sage.all import *
>>> from sage.combinat.enumeration_mod_permgroup import all_children
>>> from sage.structure.list_clone_demo import IncreasingIntArrays
>>> v = IncreasingIntArrays()([Integer(1),Integer(2),Integer(3),Integer(4)])
>>> all_children(v, -Integer(1))
[[1, 2, 3, 5]]
```

sage.combinat.enumeration_mod_permgroup.**canonical_children**(*sgs*, *v*, *max_part*)

Return the canonical children of the integer vector `v`. This function computes all children of the integer vector `v` via the function *all_children()* and returns from this list only these which are canonicals identified via the function *is_canonical()*.

EXAMPLES:

```
sage: from sage.combinat.enumeration_mod_permgroup import canonical_children
sage: G = PermutationGroup([[(1,2,3,4)]])
sage: sgs = G.strong_generating_system()
sage: from sage.structure.list_clone_demo import IncreasingIntArrays
sage: IA = IncreasingIntArrays()
sage: canonical_children(sgs, IA([1,2,3,5]), -1)
[]
```

```
>>> from sage.all import *
>>> from sage.combinat.enumeration_mod_permgroup import canonical_children
>>> G = PermutationGroup([[(Integer(1),Integer(2),Integer(3),Integer(4))]])
>>> sgs = G.strong_generating_system()
>>> from sage.structure.list_clone_demo import IncreasingIntArrays
>>> IA = IncreasingIntArrays()
>>> canonical_children(sgs, IA([Integer(1),Integer(2),Integer(3),Integer(5)]), -
↪Integer(1))
[]
```

sage.combinat.enumeration_mod_permgroup.**canonical_representative_of_orbit_of**(*sgs*, *v*)

Return the maximal vector for the lexicographic order living in the orbit of v under the action of the permutation group whose strong generating system is `sgs`. The maximal vector is also called "canonical". Hence, this method returns the canonical vector inside the orbit of v. If v is already canonical, the method returns v.

Let G to be the permutation group which admits `sgs` as a strong generating system. An integer vector v is said to be canonical under the action of G if and only if:

$$v = \max_{\text{lex order}} \{g \cdot v | g \in G\}$$

EXAMPLES:

```
sage: from sage.combinat.enumeration_mod_permgroup import canonical_
↪representative_of_orbit_of
sage: G = PermutationGroup([[(1,2,3,4)]])
sage: sgs = G.strong_generating_system()
sage: from sage.structure.list_clone_demo import IncreasingIntArrays
sage: IA = IncreasingIntArrays()
sage: canonical_representative_of_orbit_of(sgs, IA([1,2,3,5]))
[5, 1, 2, 3]
```

```
>>> from sage.all import *
>>> from sage.combinat.enumeration_mod_permgroup import canonical_representative_
↪of_orbit_of
>>> G = PermutationGroup([[(Integer(1),Integer(2),Integer(3),Integer(4))]])
>>> sgs = G.strong_generating_system()
>>> from sage.structure.list_clone_demo import IncreasingIntArrays
>>> IA = IncreasingIntArrays()
>>> canonical_representative_of_orbit_of(sgs, IA([Integer(1),Integer(2),
↪Integer(3),Integer(5)]))
[5, 1, 2, 3]
```

`sage.combinat.enumeration_mod_permgroup.`**`is_canonical`**`(`*sgs*, *v*`)`

Return `True` if the integer vector v is maximal with respect to the lexicographic order in its orbit under the action of the permutation group whose strong generating system is `sgs`. Such vectors are said to be canonical.

Let G to be the permutation group which admit `sgs` as a strong generating system. An integer vector v is said to be canonical under the action of G if and only if:

$$v = \max_{\text{lex order}} \{g \cdot v | g \in G\}$$

EXAMPLES:

```
sage: from sage.combinat.enumeration_mod_permgroup import is_canonical
sage: G = PermutationGroup([[(1,2,3,4)]])
sage: sgs = G.strong_generating_system()
sage: from sage.structure.list_clone_demo import IncreasingIntArrays
sage: IA = IncreasingIntArrays()
sage: is_canonical(sgs, IA([1,2,3,6]))
False
```

```
>>> from sage.all import *
>>> from sage.combinat.enumeration_mod_permgroup import is_canonical
>>> G = PermutationGroup([[(Integer(1),Integer(2),Integer(3),Integer(4))]])
>>> sgs = G.strong_generating_system()
>>> from sage.structure.list_clone_demo import IncreasingIntArrays
>>> IA = IncreasingIntArrays()
>>> is_canonical(sgs, IA([Integer(1),Integer(2),Integer(3),Integer(6)]))
False
```

sage.combinat.enumeration_mod_permgroup.**lex_cmp**(*v1*, *v2*)

Lexicographic comparison of `ClonableIntArray`.

INPUT:

- `v1`, `v2` – two instances of `ClonableIntArray`

OUTPUT:

`-1,0,1`, depending on whether v_1 is lexicographically smaller, equal, or greater than v_2.

EXAMPLES:

```
sage: I =  IntegerVectorsModPermutationGroup(SymmetricGroup(5),5)
sage: I =  IntegerVectorsModPermutationGroup(SymmetricGroup(5))
sage: J =  IntegerVectorsModPermutationGroup(SymmetricGroup(6))
sage: v1 = I([2,3,1,2,3], check=False)
sage: v2 = I([2,3,2,3,2], check=False)
sage: v3 = J([2,3,1,2,3,1], check=False)
sage: from sage.combinat.enumeration_mod_permgroup import lex_cmp
sage: lex_cmp(v1, v1)
0
sage: lex_cmp(v1, v2)
-1
sage: lex_cmp(v2, v1)
1
sage: lex_cmp(v1, v3)
-1
sage: lex_cmp(v3, v1)
1
```

```
>>> from sage.all import *
>>> I =  IntegerVectorsModPermutationGroup(SymmetricGroup(Integer(5)),Integer(5))
>>> I =  IntegerVectorsModPermutationGroup(SymmetricGroup(Integer(5)))
>>> J =  IntegerVectorsModPermutationGroup(SymmetricGroup(Integer(6)))
>>> v1 = I([Integer(2),Integer(3),Integer(1),Integer(2),Integer(3)], check=False)
>>> v2 = I([Integer(2),Integer(3),Integer(2),Integer(3),Integer(2)], check=False)
>>> v3 = J([Integer(2),Integer(3),Integer(1),Integer(2),Integer(3),Integer(1)],␣
↪check=False)
>>> from sage.combinat.enumeration_mod_permgroup import lex_cmp
>>> lex_cmp(v1, v1)
0
>>> lex_cmp(v1, v2)
-1
>>> lex_cmp(v2, v1)
1
>>> lex_cmp(v1, v3)
-1
>>> lex_cmp(v3, v1)
1
```

sage.combinat.enumeration_mod_permgroup.**lex_cmp_partial**(*v1*, *v2*, *step*)

Partial comparison of the two lists according the lexicographic order. It compares the `step`-th first entries.

EXAMPLES:

```
sage: from sage.combinat.enumeration_mod_permgroup import lex_cmp_partial
sage: from sage.structure.list_clone_demo import IncreasingIntArrays
sage: IA = IncreasingIntArrays()
sage: lex_cmp_partial(IA([0,1,2,3]),IA([0,1,2,4]),3)
0
sage: lex_cmp_partial(IA([0,1,2,3]),IA([0,1,2,4]),4)
-1
```

```
>>> from sage.all import *
>>> from sage.combinat.enumeration_mod_permgroup import lex_cmp_partial
>>> from sage.structure.list_clone_demo import IncreasingIntArrays
>>> IA = IncreasingIntArrays()
>>> lex_cmp_partial(IA([Integer(0),Integer(1),Integer(2),Integer(3)]),
↪IA([Integer(0),Integer(1),Integer(2),Integer(4)]),Integer(3))
0
>>> lex_cmp_partial(IA([Integer(0),Integer(1),Integer(2),Integer(3)]),
↪IA([Integer(0),Integer(1),Integer(2),Integer(4)]),Integer(4))
-1
```

sage.combinat.enumeration_mod_permgroup.**orbit**(*sgs*, *v*)

Return the orbit of the integer vector `v` under the action of the permutation group whose strong generating system is `sgs`.

NOTE:

The returned orbit is a set. In the doctests, we convert it into a sorted list.

EXAMPLES:

```
sage: from sage.combinat.enumeration_mod_permgroup import orbit
sage: G = PermutationGroup([[(1,2,3,4)]])
sage: sgs = G.strong_generating_system()
sage: from sage.structure.list_clone_demo import IncreasingIntArrays
sage: IA = IncreasingIntArrays()
sage: sorted(orbit(sgs, IA([1,2,3,4])))
[[1, 2, 3, 4], [2, 3, 4, 1], [3, 4, 1, 2], [4, 1, 2, 3]]
```

```
>>> from sage.all import *
>>> from sage.combinat.enumeration_mod_permgroup import orbit
>>> G = PermutationGroup([[(Integer(1),Integer(2),Integer(3),Integer(4))]])
>>> sgs = G.strong_generating_system()
>>> from sage.structure.list_clone_demo import IncreasingIntArrays
>>> IA = IncreasingIntArrays()
>>> sorted(orbit(sgs, IA([Integer(1),Integer(2),Integer(3),Integer(4)])))
[[1, 2, 3, 4], [2, 3, 4, 1], [3, 4, 1, 2], [4, 1, 2, 3]]
```

5.1.104 Compute Bell and Uppuluri-Carpenter numbers

AUTHORS:

- Nick Alexander

sage.combinat.expnums.**expnums**(*n*, *aa*)

Compute the first n exponential numbers around aa, starting with the zero-th.

INPUT:

- `n` – C machine int
- `aa` – C machine int

OUTPUT: list of length n

ALGORITHM: We use the same integer addition algorithm as GAP. This is an extension of Bell's triangle to the general case of exponential numbers. The recursion performs $O(n^2)$ additions, but the running time is dominated by the cost of the last integer addition, because the growth of the integer results of partial computations is exponential in n. The algorithm stores $O(n)$ integers, but each is exponential in n.

EXAMPLES:

```
sage: expnums(10, 1)
[1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147]
```

```
>>> from sage.all import *
>>> expnums(Integer(10), Integer(1))
[1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147]
```

```
sage: expnums(10, -1)
[1, -1, 0, 1, 1, -2, -9, -9, 50, 267]
```

```
>>> from sage.all import *
>>> expnums(Integer(10), -Integer(1))
[1, -1, 0, 1, 1, -2, -9, -9, 50, 267]
```

```
sage: expnums(1, 1)
[1]
sage: expnums(0, 1)
[]
sage: expnums(-1, 0)
[]
```

```
>>> from sage.all import *
>>> expnums(Integer(1), Integer(1))
[1]
>>> expnums(Integer(0), Integer(1))
[]
>>> expnums(-Integer(1), Integer(0))
[]
```

AUTHORS:

- Nick Alexander

`sage.combinat.expnums.`**`expnums2`**`(`*n*, *aa*`)`

A vanilla python (but compiled via Cython) implementation of expnums.

We Compute the first n exponential numbers around aa, starting with the zero-th.

EXAMPLES:

```
sage: from sage.combinat.expnums import expnums2
sage: expnums2(10, 1)
[1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147]
```

```
>>> from sage.all import *
>>> from sage.combinat.expnums import expnums2
>>> expnums2(Integer(10), Integer(1))
[1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147]
```

5.1.105 Families

This is a backward compatibility stub. Use `sage.sets.family` instead.

5.1.106 Brent Yorgey's fast algorithm for integer vector (multiset) partitions.

ALGORITHM:

Brent Yorgey, Generating Multiset Partitions, The Monad Reader, Issue 8, September 2007, p. 5.

https://wiki.haskell.org/The_Monad.Reader/Previous_issues

AUTHORS:

- D. K. Sunko (2020-02-19): initial version
- F. Chapoton (2020-02-22): conversion to iterators and shorter doctests and doc tweaks
- T. Scrimshaw (2020-03-06): Cython optimizations and doc tweaks

`sage.combinat.fast_vector_partitions.`**`fast_vector_partitions`**`(`*v*, *min_vals=None*`)`

Brent Yorgey's fast algorithm for integer vector (multiset) partitions.

INPUT:

- `v` – list of nonnegative integers, understood as the vector to be partitioned
- `min_vals` – (optional) list of nonnegative integers, of same length as `v`

OUTPUT: list of lists, each representing a vector partition of `v`

If `min_vals` is given, only partitions with parts `p >= min_vals` in the lexicographic ordering will appear.

If `min_vals` is given and `len(min_vals) != len(v)`, an error is raised.

EXAMPLES:

The older the computer, the more impressive the comparison:

```
sage: from sage.combinat.fast_vector_partitions import fast_vector_partitions
sage: fastvparts = list(fast_vector_partitions([3, 3, 3]))
sage: vparts = list(VectorPartitions([3, 3, 3]))
sage: vparts == fastvparts[::-1]
True
sage: len(fastvparts)
686
sage: list(fast_vector_partitions([1, 2, 3], min_vals=[0, 1, 1]))
[[[1, 2, 3]],
 [[0, 2, 3], [1, 0, 0]],
 [[0, 2, 2], [1, 0, 1]],
```

(continues on next page)

(continued from previous page)

```
 [[0, 2, 1], [1, 0, 2]],
 [[0, 2, 0], [1, 0, 3]],
 [[0, 1, 3], [1, 1, 0]],
 [[0, 1, 2], [1, 1, 1]],
 [[0, 1, 1], [1, 1, 2]],
 [[0, 1, 1], [0, 1, 2], [1, 0, 0]],
 [[0, 1, 1], [0, 1, 1], [1, 0, 1]]]
sage: L1 = list(fast_vector_partitions([5, 7, 6], min_vals=[1, 3, 2]))
sage: L1 == list(VectorPartitions([5, 7, 6], min=[1, 3, 2]))[::-1]
True
```

```
>>> from sage.all import *
>>> from sage.combinat.fast_vector_partitions import fast_vector_partitions
>>> fastvparts = list(fast_vector_partitions([Integer(3), Integer(3),␣
↪Integer(3)]))
>>> vparts = list(VectorPartitions([Integer(3), Integer(3), Integer(3)]))
>>> vparts == fastvparts[::-Integer(1)]
True
>>> len(fastvparts)
686
>>> list(fast_vector_partitions([Integer(1), Integer(2), Integer(3)], min_
↪vals=[Integer(0), Integer(1), Integer(1)]))
[[[1, 2, 3]],
 [[0, 2, 3], [1, 0, 0]],
 [[0, 2, 2], [1, 0, 1]],
 [[0, 2, 1], [1, 0, 2]],
 [[0, 2, 0], [1, 0, 3]],
 [[0, 1, 3], [1, 1, 0]],
 [[0, 1, 2], [1, 1, 1]],
 [[0, 1, 1], [1, 1, 2]],
 [[0, 1, 1], [0, 1, 2], [1, 0, 0]],
 [[0, 1, 1], [0, 1, 1], [1, 0, 1]]]
>>> L1 = list(fast_vector_partitions([Integer(5), Integer(7), Integer(6)], min_
↪vals=[Integer(1), Integer(3), Integer(2)]))
>>> L1 == list(VectorPartitions([Integer(5), Integer(7), Integer(6)],␣
↪min=[Integer(1), Integer(3), Integer(2)]))[::-Integer(1)]
True
```

Note

The partitions are returned as an iterator.

In this documentation, `a <|= b` means `a[i] <= b[i]` for all `i` (notation following B. Yorgey's paper). It is the monomial partial ordering in Dickson's lemma: `a <|= b` iff `x^a` divides `x^b` as monomials.

Warning

The ordering of the partitions is reversed with respect to the output of Sage class *VectorPartitions*.

`sage.combinat.fast_vector_partitions.`**`recursive_vector_partitions`**`(v, vL)`

Iterate over a lexicographically ordered list of lists, each list representing a vector partition of `v`, such that no part of any partition is lexicographically smaller than `vL`.

Internal part of *fast_vector_partitions()*.

INPUT:

- `v` – list of nonnegative integers, understood as a vector
- `vL` – list of nonnegative integers, understood as a vector

EXAMPLES:

```
sage: from sage.combinat.fast_vector_partitions import recursive_vector_partitions
sage: list(recursive_vector_partitions([2, 2, 2],[1, 1, 1]))
[[[2, 2, 2]], [[1, 1, 1], [1, 1, 1]]]
sage: list(recursive_vector_partitions([2, 2, 2],[1, 1, 0]))
[[[2, 2, 2]], [[1, 1, 1], [1, 1, 1]], [[1, 1, 0], [1, 1, 2]]]
sage: list(recursive_vector_partitions([2, 2, 2],[1, 0, 1]))
[[[2, 2, 2]],
 [[1, 1, 1], [1, 1, 1]],
 [[1, 1, 0], [1, 1, 2]],
 [[1, 0, 2], [1, 2, 0]],
 [[1, 0, 1], [1, 2, 1]]]
```

```
>>> from sage.all import *
>>> from sage.combinat.fast_vector_partitions import recursive_vector_partitions
>>> list(recursive_vector_partitions([Integer(2), Integer(2), Integer(2)],
↪[Integer(1), Integer(1), Integer(1)]))
[[[2, 2, 2]], [[1, 1, 1], [1, 1, 1]]]
>>> list(recursive_vector_partitions([Integer(2), Integer(2), Integer(2)],
↪[Integer(1), Integer(1), Integer(0)]))
[[[2, 2, 2]], [[1, 1, 1], [1, 1, 1]], [[1, 1, 0], [1, 1, 2]]]
>>> list(recursive_vector_partitions([Integer(2), Integer(2), Integer(2)],
↪[Integer(1), Integer(0), Integer(1)]))
[[[2, 2, 2]],
 [[1, 1, 1], [1, 1, 1]],
 [[1, 1, 0], [1, 1, 2]],
 [[1, 0, 2], [1, 2, 0]],
 [[1, 0, 1], [1, 2, 1]]]
```

`sage.combinat.fast_vector_partitions.`**`recursive_within_from_to`**(*m*, *s*, *e*, *useS*, *useE*)

Iterate over a lexicographically ordered list of lists `v` satisfying `e <= v <= s` and `v <|= m` as vectors.

Internal part of *fast_vector_partitions()*.

INPUT:

- `m` – list of nonnegative integers, understood as a vector
- `s` – list of nonnegative integers, understood as a vector
- `e` – list of nonnegative integers, understood as a vector
- `useS` – boolean
- `useE` – boolean

EXAMPLES:

```
sage: from sage.combinat.fast_vector_partitions import recursive_within_from_to
sage: list(recursive_within_from_to([1, 2, 3],[1, 2, 2],[1, 1, 1],True,True))
[[1, 2, 2], [1, 2, 1], [1, 2, 0], [1, 1, 3], [1, 1, 2], [1, 1, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.fast_vector_partitions import recursive_within_from_to
>>> list(recursive_within_from_to([Integer(1), Integer(2), Integer(3)],
↪[Integer(1), Integer(2), Integer(2)],[Integer(1), Integer(1), Integer(1)],True,
↪True))
[[1, 2, 2], [1, 2, 1], [1, 2, 0], [1, 1, 3], [1, 1, 2], [1, 1, 1]]
```

Note: The flags `useS` and `useE` are used to implement the condition efficiently. Because testing it loops over the vector, re-testing at each step as the vector is parsed is inefficient: all but the last comparison have been done cumulatively already. This code tests only for the last one, using the flags to accumulate information from previous calls.

Warning: Expects to be called with `s <|= m`.

Expects to be called first with `useS == useE == True`.

`sage.combinat.fast_vector_partitions.`**`within_from_to`**`(m, s, e)`

Iterate over a lexicographically ordered list of lists `v` satisfying `e <= v <= s` and `v <|= m` as vectors.

Internal part of `fast_vector_partitions()`.

INPUT:

- `m` – list of nonnegative integers, understood as a vector
- `s` – list of nonnegative integers, understood as a vector
- `e` – list of nonnegative integers, understood as a vector

EXAMPLES:

```
sage: from sage.combinat.fast_vector_partitions import within_from_to
sage: list(within_from_to([1, 2, 3], [1, 2, 2], [1, 1, 1]))
[[1, 2, 2], [1, 2, 1], [1, 2, 0], [1, 1, 3], [1, 1, 2], [1, 1, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.fast_vector_partitions import within_from_to
>>> list(within_from_to([Integer(1), Integer(2), Integer(3)], [Integer(1),
↪Integer(2), Integer(2)], [Integer(1), Integer(1), Integer(1)]))
[[1, 2, 2], [1, 2, 1], [1, 2, 0], [1, 1, 3], [1, 1, 2], [1, 1, 1]]
```

Note: The input `s` will be "clipped" internally if it does not satisfy the condition `s <|= m`.

To understand the input check, some line art is helpful. Assume that `(a,b)` are the two least significant coordinates of some vector. Say:

```
e = (2,3), s = (7,6), m = (9,8).
```

In the figure, these values are denoted by `E`, `S`, and `M`, while the letter `X` stands for all other allowed values of `v = (a,b)`:

```
b ^
  |
8 --------X---X---X---X---X-----------M
  |                                   |
7 -       X   X   X   X   X           |
  |                                   |
6 -       X   X   X   X   X   S       |
  |                                   |
5 -       X   X   X   X   X   X       |

```

If `S` moves horizontally, the full-height columns fill the box in until `S` reaches `M`, at which point it remains the limit in the b-direction as it moves out of the box, while M takes over as the limit in the a-direction, so the `M`-column remains filled only up to `S`, no matter how much `S` moves further to the right.

If `S` moves vertically, its column will be filled to the top of the box, but it remains the relevant limit in the a-direction, while `M` takes over in the b-direction as `S` goes out of the box upwards.

Both behaviors are captured by using the smaller coordinate of `S` and `M`, whenever `S` is outside the box defined by M. The input will be "clipped" accordingly in that case.

Warning

The "clipping" behavior is transparent to the user, but may be puzzling when comparing outputs with the function *recursive_within_from_to()* which has no input protection.

5.1.107 Fully commutative elements of Coxeter groups

An element w in a Coxeter system (W,S) is fully commutative (FC) if every two reduced words of w can be related by a sequence of only commutation relations, i.e., relations of the form $st = ts$ where s, t are commuting generators in S. See [Ste1996].

A draft of this code was written during an REU project at University of Colorado Boulder. We thank Rachel Castro, Joel Courtney, Thomas Magnuson and Natalie Schoenhals for their contribution to the project and the code.

class sage.combinat.fully_commutative_elements.**FullyCommutativeElement**

Bases: NormalizedClonableList

A fully commutative (FC) element in a Coxeter system.

An element w in a Coxeter system (W,S) is fully commutative (FC) if every two reduced word of w can be related by a sequence of only commutation relations, i.e., relations of the form $st = ts$ where s, t are commuting generators in S.

Every FC element has a canonical reduced word called its Cartier–Foata form. See [Gre2006]. We will normalize each FC element to this form.

check()

Called automatically when an element is created.

EXAMPLES:

```
sage: CoxeterGroup(['A', 3]).fully_commutative_elements()([1, 2]) # indirect␣
↪doctest
[1, 2]
sage: CoxeterGroup(['A', 3]).fully_commutative_elements()([1, 2, 1]) #␣
↪indirect doctest
Traceback (most recent call last):
...
ValueError: the input is not a reduced word of a fully commutative element
```

```
>>> from sage.all import *
>>> CoxeterGroup(['A', Integer(3)]).fully_commutative_elements()([Integer(1),␣
↪Integer(2)]) # indirect doctest
[1, 2]
>>> CoxeterGroup(['A', Integer(3)]).fully_commutative_elements()([Integer(1),␣
↪Integer(2), Integer(1)]) # indirect doctest
Traceback (most recent call last):
...
ValueError: the input is not a reduced word of a fully commutative element
```

coset_decomposition(*J*, *side='left'*)

Return the coset decomposition of `self` with respect to the parabolic subgroup generated by `J`.

INPUT:

- `J` – subset of the generating set S of the Coxeter system
- `side` – string (default: `'left'`); if the value is set to 'right', then the function returns the tuple (w'^J, w'_J) from the coset decomposition $w = w'^J \cdot w'_J$ of w with respect to J

OUTPUT:

The tuple of elements (w_J, w^J) such that $w = w_J \cdot w^J$, w_J is generated by the elements in J, and w^J has no left descent from J. This tuple is unique and satisfies the equation $\ell(w) = \ell(w_J) + \ell(w^J)$, where ℓ denotes Coxeter length, by general theory; see Proposition 2.4.4 of [BB2005].

EXAMPLES:

```
sage: FC = CoxeterGroup(['B', 6]).fully_commutative_elements()
sage: w = FC([1, 6, 2, 5, 4, 6, 5])
sage: w.coset_decomposition({1})
([1], [6, 2, 5, 4, 6, 5])
sage: w.coset_decomposition({1}, side = 'right')
([1, 6, 2, 5, 4, 6, 5], [])
sage: w.coset_decomposition({5, 6})
([6, 5, 6], [1, 2, 4, 5])
sage: w.coset_decomposition({5, 6}, side='right')
([1, 6, 2, 5, 4], [6, 5])
```

```
>>> from sage.all import *
>>> FC = CoxeterGroup(['B', Integer(6)]).fully_commutative_elements()
>>> w = FC([Integer(1), Integer(6), Integer(2), Integer(5), Integer(4),␣
→Integer(6), Integer(5)])
>>> w.coset_decomposition({Integer(1)})
([1], [6, 2, 5, 4, 6, 5])
>>> w.coset_decomposition({Integer(1)}, side = 'right')
([1, 6, 2, 5, 4, 6, 5], [])
>>> w.coset_decomposition({Integer(5), Integer(6)})
([6, 5, 6], [1, 2, 4, 5])
>>> w.coset_decomposition({Integer(5), Integer(6)}, side='right')
([1, 6, 2, 5, 4], [6, 5])
```

Note

The factor w_J of the coset decomposition $w = w_J \cdot w^J$ can be obtained by greedily "pulling left descents of w that are in J to the left"; see the proof of [BB2005]. This greedy algorithm works for all elements in Coxeter group, but it becomes especially simple for FC elements because descents are easier to find for FC elements.

descents(*side='left'*)

Obtain the set of descents on the appropriate side of `self`.

INPUT:

- `side` – string (default: `'left'`); if set to 'right', find the right descents

A generator s is called a left or right descent of an element w if $l(sw)$ or $l(ws)$ is smaller than $l(w)$, respectively. If w is FC, then s is a left descent of w if and only if s appears to in the word and every generator to the left of the leftmost s in the word commutes with s. A similar characterization exists for right descents of FC elements.

EXAMPLES:

```
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: w = FC([1, 4, 3, 5, 2, 4, 3])
sage: sorted(w.descents())
[1, 4]
sage: w.descents(side='right')
{3}
sage: FC = CoxeterGroup(['A', 5]).fully_commutative_elements()
```

(continues on next page)

(continued from previous page)

```
sage: sorted(FC([1, 4, 3, 5, 2, 4, 3]).descents())
[1, 4]
```

```
>>> from sage.all import *
>>> FC = CoxeterGroup(['B', Integer(5)]).fully_commutative_elements()
>>> w = FC([Integer(1), Integer(4), Integer(3), Integer(5), Integer(2),␣
↪Integer(4), Integer(3)])
>>> sorted(w.descents())
[1, 4]
>>> w.descents(side='right')
{3}
>>> FC = CoxeterGroup(['A', Integer(5)]).fully_commutative_elements()
>>> sorted(FC([Integer(1), Integer(4), Integer(3), Integer(5), Integer(2),␣
↪Integer(4), Integer(3)]).descents())
[1, 4]
```

See also

find_descent()

find_descent(*s*, *side='left'*)

Check if s is a descent of self and find its position if so.

A generator s is called a left or right descent of an element w if $l(sw)$ or $l(ws)$ is smaller than $l(w)$, respectively. If w is FC, then s is a left descent of w if and only if s appears to in the word and every generator to the left of the leftmost s in the word commutes with s. A similar characterization exists for right descents of FC elements.

INPUT:

- s – integer representing a generator of the Coxeter system
- side – string (default: 'left'); if the argument is set to 'right', the function checks if s is a right descent of self and finds the index of the rightmost occurrence of s if so

OUTPUT:

Determine if the generator s is a left descent of self; return the index of the leftmost occurrence of s in self if so and return None if not.

EXAMPLES:

```
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: w = FC([1, 4, 3, 5, 2, 4, 3])
sage: w.find_descent(1)
0
sage: w.find_descent(1, side='right')

sage: w.find_descent(4)
1
sage: w.find_descent(4, side='right')

sage: w.find_descent(3)
```

```
>>> from sage.all import *
>>> FC = CoxeterGroup(['B', Integer(5)]).fully_commutative_elements()
>>> w = FC([Integer(1), Integer(4), Integer(3), Integer(5), Integer(2),␣
→Integer(4), Integer(3)])
>>> w.find_descent(Integer(1))
0
>>> w.find_descent(Integer(1), side='right')
<BLANKLINE>
>>> w.find_descent(Integer(4))
1
>>> w.find_descent(Integer(4), side='right')
<BLANKLINE>
>>> w.find_descent(Integer(3))
<BLANKLINE>
```

group_element()

Get the actual element of the Coxeter group associated with `self.parent()` corresponding to `self`.

EXAMPLES:

```
sage: W = CoxeterGroup(['A', 3])
sage: FC = W.fully_commutative_elements()
sage: x = FC([1, 2])
sage: x.group_element()
[ 0 -1  1]
[ 1 -1  1]
[ 0  0  1]
sage: x.group_element() in W
True
```

```
>>> from sage.all import *
>>> W = CoxeterGroup(['A', Integer(3)])
>>> FC = W.fully_commutative_elements()
>>> x = FC([Integer(1), Integer(2)])
>>> x.group_element()
[ 0 -1  1]
[ 1 -1  1]
[ 0  0  1]
>>> x.group_element() in W
True
```

has_descent(*s*, *side='left'*)

Determine if `s` is a descent on the appropriate side of `self`.

INPUT:

- `side` – string (default: `'left'`); if set to ‘right’, determine if `self` has `s` as a right descent

OUTPUT: boolean

EXAMPLES:

```
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: w = FC([1, 4, 3, 5, 2, 4, 3])
sage: w.has_descent(1)
```

(continues on next page)

(continued from previous page)

```
True
sage: w.has_descent(1, side='right')
False
sage: w.has_descent(4)
True
sage: w.has_descent(4, side='right')
False
```

```
>>> from sage.all import *
>>> FC = CoxeterGroup(['B', Integer(5)]).fully_commutative_elements()
>>> w = FC([Integer(1), Integer(4), Integer(3), Integer(5), Integer(2),␣
↪Integer(4), Integer(3)])
>>> w.has_descent(Integer(1))
True
>>> w.has_descent(Integer(1), side='right')
False
>>> w.has_descent(Integer(4))
True
>>> w.has_descent(Integer(4), side='right')
False
```

See also

find_descent()

heap(***kargs*)

Create the heap poset of `self`.

The heap of an FC element w is a labeled poset that can be defined from any reduced word of w. Different reduced words yield isomorphic labeled posets, so the heap is well defined.

Heaps are very useful for visualizing and studying FC elements; see, for example, [Ste1996] and [GX2020].

INPUT:

- `self` – list; a reduced word $w = s_0 ... s_{k-1}$ of an FC element
- `one_index` – boolean (default: `False`); setting the value to True will change the underlying set of the poset to $\{1, 2, \dots, n\}$
- `display_labeling` – boolean (default: `False`); setting the value to `True` will display the label s_i for each element i of the poset

OUTPUT:

A labeled poset where the underlying set is $\{0, 1, ..., k - 1\}$ and where each element i carries s_i as its label. The partial order $\prec$ on the poset is defined by declaring $i \prec j$ if $i < j$ and $m(s_i, s_j) \neq 2$.

EXAMPLES:

```
sage: FC = CoxeterGroup(['A', 5]).fully_commutative_elements()
sage: FC([1, 4, 3, 5, 2, 4]).heap().cover_relations()
[[1, 2], [1, 3], [2, 5], [2, 4], [3, 5], [0, 4]]
sage: FC([1, 4, 3, 5, 4, 2]).heap(one_index=True).cover_relations()
[[2, 3], [2, 4], [3, 6], [3, 5], [4, 6], [1, 5]]
```

```
>>> from sage.all import *
>>> FC = CoxeterGroup(['A', Integer(5)]).fully_commutative_elements()
>>> FC([Integer(1), Integer(4), Integer(3), Integer(5), Integer(2),␣
→Integer(4)]).heap().cover_relations()
[[1, 2], [1, 3], [2, 5], [2, 4], [3, 5], [0, 4]]
>>> FC([Integer(1), Integer(4), Integer(3), Integer(5), Integer(4),␣
→Integer(2)]).heap(one_index=True).cover_relations()
[[2, 3], [2, 4], [3, 6], [3, 5], [4, 6], [1, 5]]
```

is_fully_commutative()

Check if `self` is the reduced word of an FC element.

To check if `self` is FC, we use the well-known characterization that an element w in a Coxeter system (W, S) is FC if and only if for every pair of generators $s, t \in S$ for which $m(s, t) > 2$, no reduced word of w contains the 'braid' word $sts...$ of length $m(s, t)$ as a contiguous subword. See [Ste1996].

`check()` is an alias of this method, and is called automatically when an element is created.

EXAMPLES:

```
sage: FC = CoxeterGroup(['A', 3]).fully_commutative_elements()
sage: x = FC([1, 2]); x.is_fully_commutative()
True
sage: x = FC.element_class(FC, [1, 2, 1], check=False); x.is_fully_
→commutative()
False
```

```
>>> from sage.all import *
>>> FC = CoxeterGroup(['A', Integer(3)]).fully_commutative_elements()
>>> x = FC([Integer(1), Integer(2)]); x.is_fully_commutative()
True
>>> x = FC.element_class(FC, [Integer(1), Integer(2), Integer(1)],␣
→check=False); x.is_fully_commutative()
False
```

n_value()

Calculate the n-value of `self`.

The *n-value* of a fully commutative element is the *width* (length of any longest antichain) of its heap. The n-value is important as it coincides with Lusztig's a-value for FC elements in all Weyl and affine Weyl groups as well as so-called star-reducible groups; see [GX2020].

EXAMPLES:

```
sage: FC = CoxeterGroup(['A', 5]).fully_commutative_elements()
sage: FC([1,3]).n_value()
2
sage: FC([1,2,3]).n_value()
1
sage: FC([1,3,2]).n_value()
2
sage: FC([1,3,2,5]).n_value()
3
```

```
>>> from sage.all import *
>>> FC = CoxeterGroup(['A', Integer(5)]).fully_commutative_elements()
>>> FC([Integer(1),Integer(3)]).n_value()
2
>>> FC([Integer(1),Integer(2),Integer(3)]).n_value()
1
>>> FC([Integer(1),Integer(3),Integer(2)]).n_value()
2
>>> FC([Integer(1),Integer(3),Integer(2),Integer(5)]).n_value()
3
```

normalize()

Mutate `self` into Cartier-Foata normal form.

EXAMPLES:

The following reduced words express the same FC elements in B_5:

```
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: FC([1, 4, 3, 5, 2, 4, 3]) # indirect doctest
[1, 4, 3, 5, 2, 4, 3]
sage: FC([4, 1, 3, 5, 2, 4, 3]) # indirect doctest
[1, 4, 3, 5, 2, 4, 3]
sage: FC([4, 3, 1, 5, 4, 2, 3]) # indirect doctest
[1, 4, 3, 5, 2, 4, 3]
```

```
>>> from sage.all import *
>>> FC = CoxeterGroup(['B', Integer(5)]).fully_commutative_elements()
>>> FC([Integer(1), Integer(4), Integer(3), Integer(5), Integer(2),
↪Integer(4), Integer(3)]) # indirect doctest
[1, 4, 3, 5, 2, 4, 3]
>>> FC([Integer(4), Integer(1), Integer(3), Integer(5), Integer(2),
↪Integer(4), Integer(3)]) # indirect doctest
[1, 4, 3, 5, 2, 4, 3]
>>> FC([Integer(4), Integer(3), Integer(1), Integer(5), Integer(4),
↪Integer(2), Integer(3)]) # indirect doctest
[1, 4, 3, 5, 2, 4, 3]
```

Note

The Cartier–Foata form of a reduced word of an FC element w can be found recursively by repeatedly moving left descents of elements to the left and ordering the left descents from small to large. In the above example, the left descents of the element are 4 and 1, therefore the Cartier–Foata form of the element is the concatenation of [1,4] with the Cartier–Foata form of the remaining part of the word. See [Gre2006].

See also

descents()

plot_heap()

Display the Hasse diagram of the heap of `self`.

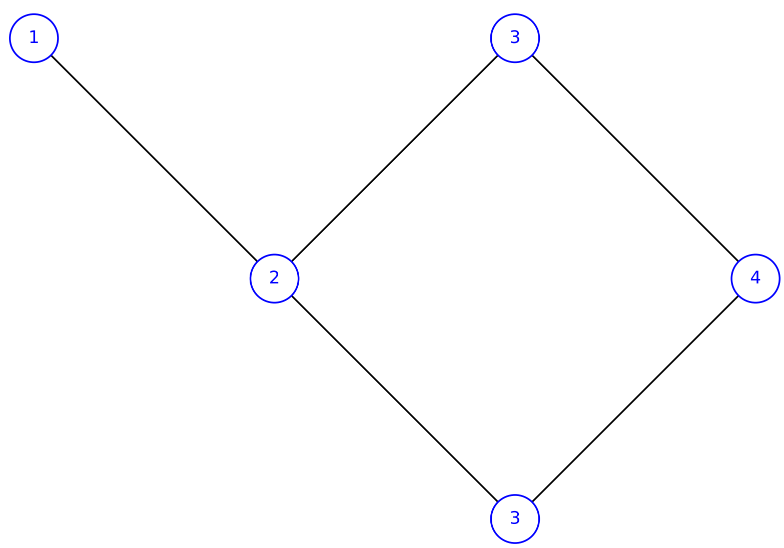
The Hasse diagram is rendered in the lattice $S \times \mathbf{N}$, with every element i in the poset drawn as a point labelled by its label s_i. Every point is placed in the column for its label at a certain level. The levels start at 0 and the level k of an element i is the maximal number k such that the heap contains a chain $i_0 \prec i_1 \prec ... \prec i_k$ where $i_k = i$. See [Ste1996] and [GX2020].

OUTPUT: GraphicsObject

EXAMPLES:

```
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: FC([3,2,4,3,1]).plot_heap()                                     #␣
↪needs sage.plot
Graphics object consisting of 15 graphics primitives
```

```
>>> from sage.all import *
>>> FC = CoxeterGroup(['B', Integer(5)]).fully_commutative_elements()
>>> FC([Integer(3),Integer(2),Integer(4),Integer(3),Integer(1)]).plot_heap() ␣
↪                                   # needs sage.plot
Graphics object consisting of 15 graphics primitives
```



star_operation(*J*, *direction*, *side='left'*)

Apply a star operation on `self` relative to two noncommuting generators.

Star operations were first defined on elements of Coxeter groups by Kazhdan and Lusztig in [KL1979] with respect to pair of generators s, t such that $m(s, t) = 3$. Later, Lusztig generalized the definition in [Lus1985], via coset decompositions, to allow star operations with respect to any pair of generators s, t such that $m(s, t) \geq 3$. Given such a pair, we can potentially perform four types of star operations corresponding to all combinations of a 'direction' and a 'side': upper left, lower left, upper right and lower right; see [Gre2006].

Let w be an element in W and let J be any pair $\{s, t\}$ of noncommuting generators in S. Consider the coset decomposition $w = w_J \cdot {}^J w$ of w relative to J. Then an upper left star operation is defined on w if and only if $1 \leq l(w_J) \leq m(s, t) - 2$; when this is the case, the operation returns $x \cdot w_J \cdot w^J$ where x is the letter J different from the leftmost letter of w_J. A lower left star operation is defined on w if and only if $2 \leq l(w_J) \leq m(s, t) - 1$; when this is the case, the operation removes the leftmost letter of w_J from w. Similar facts hold for right star operations. See [Gre2006].

The facts of the previous paragraph hold in general, even if w is not FC. Note that if f is a star operation of any kind, then for every element $w \in W$, the elements w and $f(w)$ are either both FC or both not FC.

INPUT:

- `J` – set of two integers representing two noncommuting generators of the Coxeter system
- `direction` – string, `'upper'` or `'lower'`; the function performs an upper or lower star operation according to `direction`
- `side` – string (default: `'left'`); if this is set to 'right', the function performs a right star operation

OUTPUT:

The Cartier–Foata form of the result of the star operation if the operation is defined on `self`, `None` otherwise.

EXAMPLES:

We will compute all star operations on the following FC element in type B_6 relative to $J = \{5, 6\}$:

```
sage: FC = CoxeterGroup(['B', 6]).fully_commutative_elements()
sage: w = FC([1, 6, 2, 5, 4, 6, 5])
```

```
>>> from sage.all import *
>>> FC = CoxeterGroup(['B', Integer(6)]).fully_commutative_elements()
>>> w = FC([Integer(1), Integer(6), Integer(2), Integer(5), Integer(4),␣
→Integer(6), Integer(5)])
```

Whether and how a left star operations can be applied depend on the coset decomposition $w = w_J \cdot w^J$:

```
sage: w.coset_decomposition({5, 6})
([6, 5, 6], [1, 2, 4, 5])
```

```
>>> from sage.all import *
>>> w.coset_decomposition({Integer(5), Integer(6)})
([6, 5, 6], [1, 2, 4, 5])
```

Only the lower star operation is defined on the left on w:

```
sage: w.star_operation({5,6}, 'upper')

sage: w.star_operation({5,6}, 'lower')
[1, 5, 2, 4, 6, 5]
```

```
>>> from sage.all import *
>>> w.star_operation({Integer(5),Integer(6)}, 'upper')
<BLANKLINE>
>>> w.star_operation({Integer(5),Integer(6)}, 'lower')
[1, 5, 2, 4, 6, 5]
```

Whether and how a right star operations can be applied depend on the coset decomposition $w = w^J \cdot w_J$:

```
sage: w.coset_decomposition({5, 6}, side='right')
([1, 6, 2, 5, 4], [6, 5])
```

```
>>> from sage.all import *
>>> w.coset_decomposition({Integer(5), Integer(6)}, side='right')
([1, 6, 2, 5, 4], [6, 5])
```

Both types of right star operations on defined for this example:

```
sage: w.star_operation({5, 6}, 'upper', side='right')
[1, 6, 2, 5, 4, 6, 5, 6]

sage: w.star_operation({5, 6}, 'lower', side='right')
[1, 6, 2, 5, 4, 6]
```

```
>>> from sage.all import *
>>> w.star_operation({Integer(5), Integer(6)}, 'upper', side='right')
[1, 6, 2, 5, 4, 6, 5, 6]

>>> w.star_operation({Integer(5), Integer(6)}, 'lower', side='right')
[1, 6, 2, 5, 4, 6]
```

class `sage.combinat.fully_commutative_elements.`**`FullyCommutativeElements`**`(`*coxeter_group*`)`

Bases: `UniqueRepresentation`, `Parent`

Class for the set of fully commutative (FC) elements of a Coxeter system.

Coxeter systems with finitely many FC elements, or *FC-finite* Coxeter systems, are classfied by Stembridge in [Ste1996]. They fall into seven families, namely the groups of types $A_n, B_n, D_n, E_n, F_n, H_n$ and $I_2(m)$.

INPUT:

- `data` – CoxeterMatrix, CartanType, or the usual datum that can is taken in the constructors for these classes (see *`sage.combinat.root_system.coxeter_group.CoxeterGroup()`*)

OUTPUT:

The class of fully commutative elements in the Coxeter group constructed from `data`. This will belong to the category of enumerated sets. If the Coxeter data corresponds to a Cartan type, the category is further refined to either finite enumerated sets or infinite enumerated sets depending on i whether the Coxeter group is FC-finite; the refinement is not carried out if `data` is a Coxeter matrix not corresponding to a Cartan type.

Todo

It would be ideal to implement the aforementioned refinement to finite and infinite enumerated sets for all possible `data`, regardless of whether it corresponds to a Cartan type. Doing so requires determining if an arbitrary Coxeter matrix corresponds to a Cartan type. It may be best to address this issue in `sage.combinat.root_system`. On the other hand, the refinement in the general case may be unnecessary in light of the fact that Stembridge's classification of FC-finite groups contains a very small number of easily-recognizable families.

EXAMPLES:

Create the enumerate set of fully commutative elements in B_3:

```
sage: FC = CoxeterGroup(['B', 3]).fully_commutative_elements(); FC
Fully commutative elements of Finite Coxeter group over Number Field in a with␣
↪defining polynomial x^2 - 2 with a = 1.414213562373095? with Coxeter matrix:
[1 3 2]
```

(continues on next page)

(continued from previous page)

```
[3 1 4]
[2 4 1]
```

```
>>> from sage.all import *
>>> FC = CoxeterGroup(['B', Integer(3)]).fully_commutative_elements(); FC
Fully commutative elements of Finite Coxeter group over Number Field in a with
↪defining polynomial x^2 - 2 with a = 1.414213562373095? with Coxeter matrix:
[1 3 2]
[3 1 4]
[2 4 1]
```

Construct elements:

```
sage: FC([])
[]
sage: FC([1,2])
[1, 2]
sage: FC([2,3,2])
[2, 3, 2]
sage: FC([3,2,3])
[3, 2, 3]
```

```
>>> from sage.all import *
>>> FC([])
[]
>>> FC([Integer(1),Integer(2)])
[1, 2]
>>> FC([Integer(2),Integer(3),Integer(2)])
[2, 3, 2]
>>> FC([Integer(3),Integer(2),Integer(3)])
[3, 2, 3]
```

Elements are normalized to Cartier–Foata normal form upon construction:

```
sage: FC([3,1])
[1, 3]
sage: FC([2,3,1])
[2, 1, 3]
sage: FC([1,3]) == FC([3,1])
True
```

```
>>> from sage.all import *
>>> FC([Integer(3),Integer(1)])
[1, 3]
>>> FC([Integer(2),Integer(3),Integer(1)])
[2, 1, 3]
>>> FC([Integer(1),Integer(3)]) == FC([Integer(3),Integer(1)])
True
```

Attempting to create an element from an input that is not the reduced word of a fully commutative element throws a `ValueError`:

```
sage: FC([1,2,1])
Traceback (most recent call last):
...
ValueError: the input is not a reduced word of a fully commutative element
sage: FC([2,3,2,3])
Traceback (most recent call last):
...
ValueError: the input is not a reduced word of a fully commutative element
```

```
>>> from sage.all import *
>>> FC([Integer(1),Integer(2),Integer(1)])
Traceback (most recent call last):
...
ValueError: the input is not a reduced word of a fully commutative element
>>> FC([Integer(2),Integer(3),Integer(2),Integer(3)])
Traceback (most recent call last):
...
ValueError: the input is not a reduced word of a fully commutative element
```

Enumerate the FC elements in A_3:

```
sage: FCA3 = CoxeterGroup(['A', 3]).fully_commutative_elements()
sage: FCA3.category()
Category of finite enumerated sets
sage: FCA3.list()
[[],
 [1],
 [2],
 [3],
 [2, 1],
 [1, 3],
 [1, 2],
 [3, 2],
 [2, 3],
 [3, 2, 1],
 [2, 1, 3],
 [1, 3, 2],
 [1, 2, 3],
 [2, 1, 3, 2]]
```

```
>>> from sage.all import *
>>> FCA3 = CoxeterGroup(['A', Integer(3)]).fully_commutative_elements()
>>> FCA3.category()
Category of finite enumerated sets
>>> FCA3.list()
[[],
 [1],
 [2],
 [3],
 [2, 1],
 [1, 3],
 [1, 2],
```

(continues on next page)

(continued from previous page)

```
 [3, 2],
 [2, 3],
 [3, 2, 1],
 [2, 1, 3],
 [1, 3, 2],
 [1, 2, 3],
 [2, 1, 3, 2]]
```

Count the FC elements in B_8:

```
sage: FCB8 = CoxeterGroup(['B', 8]).fully_commutative_elements()
sage: len(FCB8)     # long time (7 seconds)
14299
```

```
>>> from sage.all import *
>>> FCB8 = CoxeterGroup(['B', Integer(8)]).fully_commutative_elements()
>>> len(FCB8)     # long time (7 seconds)
14299
```

Iterate through the FC elements of length up to 2 in the non-FC-finite group affine A_2:

```
sage: FCAffineA2 = CoxeterGroup(['A', 2, 1]).fully_commutative_elements()
sage: FCAffineA2.category()
Category of infinite enumerated sets
sage: list(FCAffineA2.iterate_to_length(2))
[[], [0], [1], [2], [1, 0], [2, 0], [0, 1], [2, 1], [0, 2], [1, 2]]
```

```
>>> from sage.all import *
>>> FCAffineA2 = CoxeterGroup(['A', Integer(2), Integer(1)]).fully_commutative_
↪elements()
>>> FCAffineA2.category()
Category of infinite enumerated sets
>>> list(FCAffineA2.iterate_to_length(Integer(2)))
[[], [0], [1], [2], [1, 0], [2, 0], [0, 1], [2, 1], [0, 2], [1, 2]]
```

The cardinality of the set is determined from the classification of FC-finite Coxeter groups:

```
sage: CoxeterGroup('A2').fully_commutative_elements().category()
Category of finite enumerated sets
sage: CoxeterGroup('B7').fully_commutative_elements().category()
Category of finite enumerated sets
sage: CoxeterGroup('A3~').fully_commutative_elements().category()
Category of infinite enumerated sets
sage: CoxeterGroup('F4~').fully_commutative_elements().category()
Category of finite enumerated sets
sage: CoxeterGroup('E8~').fully_commutative_elements().category()
Category of finite enumerated sets
sage: CoxeterGroup('F4~xE8~').fully_commutative_elements().category()
Category of finite enumerated sets
sage: CoxeterGroup('B4~xE8~').fully_commutative_elements().category()
Category of infinite enumerated sets
```

```
>>> from sage.all import *
>>> CoxeterGroup('A2').fully_commutative_elements().category()
Category of finite enumerated sets
>>> CoxeterGroup('B7').fully_commutative_elements().category()
Category of finite enumerated sets
>>> CoxeterGroup('A3~').fully_commutative_elements().category()
Category of infinite enumerated sets
>>> CoxeterGroup('F4~').fully_commutative_elements().category()
Category of finite enumerated sets
>>> CoxeterGroup('E8~').fully_commutative_elements().category()
Category of finite enumerated sets
>>> CoxeterGroup('F4~xE8~').fully_commutative_elements().category()
Category of finite enumerated sets
>>> CoxeterGroup('B4~xE8~').fully_commutative_elements().category()
Category of infinite enumerated sets
```

Element

alias of *FullyCommutativeElement*

coxeter_group()

Obtain the Coxeter group associated with `self`.

EXAMPLES:

```
sage: FCA3 = CoxeterGroup(['A', 3]).fully_commutative_elements()
sage: FCA3.coxeter_group()
Finite Coxeter group over Integer Ring with Coxeter matrix:
[1 3 2]
[3 1 3]
[2 3 1]
```

```
>>> from sage.all import *
>>> FCA3 = CoxeterGroup(['A', Integer(3)]).fully_commutative_elements()
>>> FCA3.coxeter_group()
Finite Coxeter group over Integer Ring with Coxeter matrix:
[1 3 2]
[3 1 3]
[2 3 1]
```

iterate_to_length(*length*)

Iterate through the elements of this class up to a maximum length.

INPUT:

- `length` – integer; maximum length of element to generate

OUTPUT: generator for elements of `self` of length up to `length`

EXAMPLES:

The following example produces all FC elements of length up to 2 in the group A_3:

```
sage: FCA3 = CoxeterGroup(['A', 3]).fully_commutative_elements()
sage: list(FCA3.iterate_to_length(2))
[[], [1], [2], [3], [2, 1], [1, 3], [1, 2], [3, 2], [2, 3]]
```

```
>>> from sage.all import *
>>> FCA3 = CoxeterGroup(['A', Integer(3)]).fully_commutative_elements()
>>> list(FCA3.iterate_to_length(Integer(2)))
[[], [1], [2], [3], [2, 1], [1, 3], [1, 2], [3, 2], [2, 3]]
```

The lists for length 4 and 5 are the same since 4 is the maximum length of an FC element in A_3:

```
sage: list(FCA3.iterate_to_length(4))
[[], [1], [2], [3], [2, 1], [1, 3], [1, 2], [3, 2], [2, 3],
 [3, 2, 1], [2, 1, 3], [1, 3, 2], [1, 2, 3], [2, 1, 3, 2]]
sage: list(FCA3.iterate_to_length(5))
[[], [1], [2], [3], [2, 1], [1, 3], [1, 2], [3, 2], [2, 3],
 [3, 2, 1], [2, 1, 3], [1, 3, 2], [1, 2, 3], [2, 1, 3, 2]]
sage: list(FCA3.iterate_to_length(4)) == list(FCA3)
True
```

```
>>> from sage.all import *
>>> list(FCA3.iterate_to_length(Integer(4)))
[[], [1], [2], [3], [2, 1], [1, 3], [1, 2], [3, 2], [2, 3],
 [3, 2, 1], [2, 1, 3], [1, 3, 2], [1, 2, 3], [2, 1, 3, 2]]
>>> list(FCA3.iterate_to_length(Integer(5)))
[[], [1], [2], [3], [2, 1], [1, 3], [1, 2], [3, 2], [2, 3],
 [3, 2, 1], [2, 1, 3], [1, 3, 2], [1, 2, 3], [2, 1, 3, 2]]
>>> list(FCA3.iterate_to_length(Integer(4))) == list(FCA3)
True
```

The following example produces all FC elements of length up to 4 in the affine Weyl group $\tilde{A}_2$:

```
sage: FCAffineA2 = CoxeterGroup(['A', 2, 1]).fully_commutative_elements()
sage: FCAffineA2.category()
Category of infinite enumerated sets
sage: list(FCAffineA2.iterate_to_length(4))
[[], [0], [1], [2], [1, 0], [2, 0], [0, 1], [2, 1], [0, 2],
 [1, 2], [2, 1, 0], [1, 2, 0], [2, 0, 1], [0, 2, 1], [1, 0, 2],
 [0, 1, 2], [0, 2, 1, 0], [0, 1, 2, 0], [1, 2, 0, 1],
 [1, 0, 2, 1], [2, 1, 0, 2], [2, 0, 1, 2]]
```

```
>>> from sage.all import *
>>> FCAffineA2 = CoxeterGroup(['A', Integer(2), Integer(1)]).fully_
↪commutative_elements()
>>> FCAffineA2.category()
Category of infinite enumerated sets
>>> list(FCAffineA2.iterate_to_length(Integer(4)))
[[], [0], [1], [2], [1, 0], [2, 0], [0, 1], [2, 1], [0, 2],
 [1, 2], [2, 1, 0], [1, 2, 0], [2, 0, 1], [0, 2, 1], [1, 0, 2],
 [0, 1, 2], [0, 2, 1, 0], [0, 1, 2, 0], [1, 2, 0, 1],
 [1, 0, 2, 1], [2, 1, 0, 2], [2, 0, 1, 2]]
```

5.1.108 Finite state machines, automata, transducers

This module adds support for finite state machines, automata and transducers.

For creating automata and transducers you can use classes

- *Automaton* and *Transducer* (or the more general class *FiniteStateMachine*)

or the generators

- *automata* and *transducers*

which contain *preconstructed and commonly used automata and transducers*. See also the *examples* below.

Contents

FiniteStateMachine and derived classes Transducer and Automaton

Accessing parts of a finite state machine

state()	Get a state by its label
states()	List of states
iter_states()	Iterator over the states
initial_states()	List of initial states
iter_initial_states()	Iterator over initial states
final_states()	List of final states
iter_final_states()	Iterator over final states
transition()	Get a transition by its states and labels
transitions()	List of transitions
iter_transitions()	Iterator over the transitions
predecessors()	List of predecessors of a state
induced_sub_finite_state_machine()	Induced sub-machine
accessible_components()	Accessible components
coaccessible_components()	Coaccessible components
final_components()	Final components (connected components which cannot be left again)

(Modified) Copies

empty_copy()	Return an empty deep copy
deepcopy()	Return a deep copy
relabeled()	Return a relabeled deep copy
Automaton.with_output()	Extend an automaton to a transducer

Manipulation

`add_state()`	Add a state
`add_states()`	Add states
`delete_state()`	Delete a state
`add_transition()`	Add a transition
`add_transitions_from_function()`	Add transitions
`input_alphabet`	Input alphabet
`output_alphabet`	Output alphabet
`on_duplicate_transition`	Hook for handling duplicate transitions
`add_from_transition_function()`	Add transitions by a transition function
`delete_transition()`	Delete a transition
`remove_epsilon_transitions()`	Remove epsilon transitions (not implemented)
`split_transitions()`	Split transitions with input words of length > `1`
`determine_alphabets()`	Determine input and output alphabets
`determine_input_alphabet()`	Determine input alphabet
`determine_output_alphabet()`	Determine output alphabet
`construct_final_word_out()`	Construct final output by implicitly reading trailing letters; cf. `with_final_word_out()`

Properties

`has_state()`	Check for a state
`has_initial_state()`	Check for an initial state
`has_initial_states()`	Check for initial states
`has_final_state()`	Check for a final state
`has_final_states()`	Check for final states
`has_transition()`	Check for a transition
`is_deterministic()`	Check for a deterministic machine
`is_complete()`	Check for a complete machine
`is_connected()`	Check for a connected machine
`Automaton.is_equivalent()`	Check for equivalent automata
`is_Markov_chain()`	Check for a Markov chain
`is_monochromatic()`	Check whether the colors of all states are equal
`number_of_words()`	Determine the number of successful paths
`asymptotic_moments()`	Main terms of expectation and variance of sums of labels
`moments_waiting_time()`	Moments of the waiting time for first true output
`epsilon_successors()`	Epsilon successors of a state
`Automaton.shannon_parry_markov_chai`	Compute Markov chain with Parry measure

Operations

disjoint_union()	Disjoint union
concatenation()	Concatenation
kleene_star()	Kleene star
Automaton.complement()	Complement of an automaton
Automaton.intersection()	Intersection of automata
Transducer.intersection()	Intersection of transducers
Transducer.cartesian_product()	Cartesian product of a transducer with another finite state machine
product_FiniteStateMachine()	Product of finite state machines
composition()	Composition (output of other is input of self)
input_projection()	Input projection (output is deleted)
output_projection()	Output projection (old output is new input)
projection()	Input or output projection
transposition()	Transposition (all transitions are reversed)
with_final_word_out()	Machine with final output constructed by implicitly reading trailing letters, cf. *construct_final_word_out()* for inplace version
Automaton.determinisation()	Determinisation of an automaton
completion()	Completion of a finite state machine
process()	Process input
__call__()	Process input with shortened output
Automaton.process()	Process input of an automaton (output differs from general case)
Transducer.process()	Process input of a transducer (output differs from general case)
iter_process()	Return process iterator
language()	Return all possible output words
Automaton.language()	Return all possible accepted words

Simplification

prepone_output()	Prepone output where possible
equivalence_classes()	List of equivalent states
quotient()	Quotient with respect to equivalence classes
merged_transitions()	Merge transitions while adding input
markov_chain_simplification()	Simplification of a Markov chain
Automaton.minimization()	Minimization of an automaton
Transducer.simplification()	Simplification of a transducer

Conversion

adjacency_matrix()	(Weighted) adjacency `matrix()`
graph()	Underlying `DiGraph`
plot()	Plot

LaTeX output

latex_options()	Set options
set_coordinates()	Set coordinates of the states
default_format_transition_label()	Default formatting of words in transition labels
format_letter_negative()	Format negative numbers as overlined number
format_transition_label_reversed()	Format words in transition labels in reversed order

See also:

LaTeX output

FSMState

final_word_out	Final output of a state
is_final	Describe whether a state is final or not
is_initial	Describe whether a state is initial or not
initial_probability	Probability of starting in this state as part of a Markov chain
label()	Label of a state
relabeled()	Return a relabeled deep copy of a state
fully_equal()	Check whether two states are fully equal (including all attributes)

FSMTransition

from_state	State in which transition starts
to_state	State in which transition ends
word_in	Input word of the transition
word_out	Output word of the transition
deepcopy()	Return a deep copy of the transition

FSMProcessIterator

next()	Make one step in processing the input tape
preview_word()	Read a word from the input tape
result()	Return the finished branches during process

Helper Functions

equal()	Check whether all elements of `iterator` are equal
full_group_by()	Group iterable by values of some key
startswith()	Determine whether list starts with the given prefix
FSMLetterSymbol()	Return a string associated to the input letter
FSMWordSymbol()	Return a string associated to a word
is_FSMState()	Test whether an object inherits from *FSMState*
is_FSMTransition()	Test whether an object inherits from *FSMTransition*
is_FiniteStateMachine()	Test whether an object inherits from *FiniteStateMachine*
duplicate_transition_ignore()	Default function for handling duplicate transitions
duplicate_transition_raise_error()	Raise error when inserting a duplicate transition
duplicate_transition_add_input()	Add input when inserting a duplicate transition

Examples

We start with a general *FiniteStateMachine*. Later there will be also an *Automaton* and a *Transducer*.

A simple finite state machine

We can easily create a finite state machine by

```
sage: fsm = FiniteStateMachine()
sage: fsm
Empty finite state machine
```

```
>>> from sage.all import *
>>> fsm = FiniteStateMachine()
>>> fsm
Empty finite state machine
```

By default this is the empty finite state machine, so not very interesting. Let's create and add some states and transitions:

```
sage: day = fsm.add_state('day')
sage: night = fsm.add_state('night')
sage: sunrise = fsm.add_transition(night, day)
sage: sunset = fsm.add_transition(day, night)
```

```
>>> from sage.all import *
>>> day = fsm.add_state('day')
>>> night = fsm.add_state('night')
>>> sunrise = fsm.add_transition(night, day)
>>> sunset = fsm.add_transition(day, night)
```

Let us look at `sunset` more closely:

```
sage: sunset
Transition from 'day' to 'night': -|-
```

```
>>> from sage.all import *
>>> sunset
Transition from 'day' to 'night': -|-
```

Note that could also have created and added the transitions directly by:

```
sage: fsm.add_transition('day', 'night')
Transition from 'day' to 'night': -|-
```

```
>>> from sage.all import *
>>> fsm.add_transition('day', 'night')
Transition from 'day' to 'night': -|-
```

This would have had added the states automatically, since they are present in the transitions.

Anyhow, we got the following finite state machine:

```
sage: fsm
Finite state machine with 2 states
```

```
>>> from sage.all import *
>>> fsm
Finite state machine with 2 states
```

We can also obtain the underlying `directed graph` by

```
sage: fsm.graph()
Looped multi-digraph on 2 vertices
```

```
>>> from sage.all import *
>>> fsm.graph()
Looped multi-digraph on 2 vertices
```

To visualize a finite state machine, we can use `latex()` and run the result through LaTeX, see the section on *LaTeX output* below.

Alternatively, we could have created the finite state machine above simply by

```
sage: FiniteStateMachine([('night', 'day'), ('day', 'night')])
Finite state machine with 2 states
```

```
>>> from sage.all import *
>>> FiniteStateMachine([('night', 'day'), ('day', 'night')])
Finite state machine with 2 states
```

See *`FiniteStateMachine`* for a lot of possibilities to create finite state machines.

A simple Automaton (recognizing NAFs)

We want to build an automaton which recognizes non-adjacent forms (NAFs), i.e., sequences which have no adjacent nonzeros. We use 0, 1, and -1 as digits:

```
sage: NAF = Automaton(
....:     {'A': [('A', 0), ('B', 1), ('B', -1)], 'B': [('A', 0)]})
sage: NAF.state('A').is_initial = True
sage: NAF.state('A').is_final = True
sage: NAF.state('B').is_final = True
sage: NAF
Automaton with 2 states
```

```
>>> from sage.all import *
>>> NAF = Automaton(
...     {'A': [('A', Integer(0)), ('B', Integer(1)), ('B', -Integer(1))], 'B': [('A',␣
↪Integer(0))]})
>>> NAF.state('A').is_initial = True
>>> NAF.state('A').is_final = True
>>> NAF.state('B').is_final = True
>>> NAF
Automaton with 2 states
```

Of course, we could have specified the initial and final states directly in the definition of `NAF` by `initial_states=['A']` and `final_states=['A', 'B']`.

So let's test the automaton with some input:

```
sage: NAF([0])
True
sage: NAF([0, 1])
True
sage: NAF([1, -1])
False
sage: NAF([0, -1, 0, 1])
True
sage: NAF([0, -1, -1, -1, 0])
False
sage: NAF([-1, 0, 0, 1, 1])
False
```

```
>>> from sage.all import *
>>> NAF([Integer(0)])
True
>>> NAF([Integer(0), Integer(1)])
True
>>> NAF([Integer(1), -Integer(1)])
False
>>> NAF([Integer(0), -Integer(1), Integer(0), Integer(1)])
True
>>> NAF([Integer(0), -Integer(1), -Integer(1), -Integer(1), Integer(0)])
False
>>> NAF([-Integer(1), Integer(0), Integer(0), Integer(1), Integer(1)])
False
```

Alternatively, we could call that by

```
sage: NAF.process([0, -1, 0, 1])
(True, 'B')
```

```
>>> from sage.all import *
>>> NAF.process([Integer(0), -Integer(1), Integer(0), Integer(1)])
(True, 'B')
```

which gives additionally the state in which we arrived.

We can also let an automaton act on a *word*:

```
sage: # needs sage.combinat
sage: W = Words([-1, 0, 1]); W
Finite and infinite words over {-1, 0, 1}
sage: w = W([1, 0, 1, 0, -1]); w
word: 1,0,1,0,-1
sage: NAF(w)
True
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> W = Words([-Integer(1), Integer(0), Integer(1)]); W
Finite and infinite words over {-1, 0, 1}
>>> w = W([Integer(1), Integer(0), Integer(1), Integer(0), -Integer(1)]); w
word: 1,0,1,0,-1
>>> NAF(w)
True
```

Recognizing NAFs via Automata Operations

Alternatively, we can use automata operations to recognize NAFs; for simplicity, we only use the input alphabet `[0, 1]`. On the one hand, we can construct such an automaton by forbidding the word `11`:

```
sage: forbidden = automata.ContainsWord([1, 1], input_alphabet=[0, 1])
sage: NAF_negative = forbidden.complement()
sage: NAF_negative([1, 1, 0, 1])
False
sage: NAF_negative([1, 0, 1, 0, 1])
True
```

```
>>> from sage.all import *
>>> forbidden = automata.ContainsWord([Integer(1), Integer(1)], input_
↪alphabet=[Integer(0), Integer(1)])
>>> NAF_negative = forbidden.complement()
>>> NAF_negative([Integer(1), Integer(1), Integer(0), Integer(1)])
False
>>> NAF_negative([Integer(1), Integer(0), Integer(1), Integer(0), Integer(1)])
True
```

On the other hand, we can write this as a regular expression and translate that into automata operations:

```
sage: zero = automata.Word([0])
sage: one = automata.Word([1])
sage: epsilon = automata.EmptyWord(input_alphabet=[0, 1])
sage: NAF_positive = (zero + one*zero).kleene_star() * (epsilon + one)
```

```
>>> from sage.all import *
>>> zero = automata.Word([Integer(0)])
>>> one = automata.Word([Integer(1)])
>>> epsilon = automata.EmptyWord(input_alphabet=[Integer(0), Integer(1)])
>>> NAF_positive = (zero + one*zero).kleene_star() * (epsilon + one)
```

We check that the two approaches are equivalent:

```
sage: NAF_negative.is_equivalent(NAF_positive)
True
```

```
>>> from sage.all import *
>>> NAF_negative.is_equivalent(NAF_positive)
True
```

See also

ContainsWord(), *Word()*, *complement()*, *kleene_star()*, *EmptyWord()*, *is_equivalent()*.

LaTeX output

We can visualize a finite state machine by converting it to LaTeX by using the usual function `latex()`. Within LaTeX, TikZ is used for typesetting the graphics, see the Wikipedia article PGF/TikZ.

```
sage: print(latex(NAF))  # abs tol 1e-3
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state, accepting, initial] (v0) at (3.000000, 0.000000) {$\text{\texttt{A}}$};
\node[state, accepting] (v1) at (-3.000000, 0.000000) {$\text{\texttt{B}}$};
\path[->] (v0) edge[loop above] node {$0$} ();
\path[->] (v0.185.00) edge node[rotate=360.00, anchor=north] {$1, -1$} (v1.355.00);
\path[->] (v1.5.00) edge node[rotate=0.00, anchor=south] {$0$} (v0.175.00);
\end{tikzpicture}
```

```
>>> from sage.all import *
>>> print(latex(NAF))  # abs tol 1e-3
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state, accepting, initial] (v0) at (3.000000, 0.000000) {$\text{\texttt{A}}$};
\node[state, accepting] (v1) at (-3.000000, 0.000000) {$\text{\texttt{B}}$};
\path[->] (v0) edge[loop above] node {$0$} ();
\path[->] (v0.185.00) edge node[rotate=360.00, anchor=north] {$1, -1$} (v1.355.00);
\path[->] (v1.5.00) edge node[rotate=0.00, anchor=south] {$0$} (v0.175.00);
\end{tikzpicture}
```

We can turn this into a graphical representation.

```
sage: view(NAF) # not tested
```

```
>>> from sage.all import *
>>> view(NAF) # not tested
```

To actually see this, use the live documentation in the Sage notebook and execute the cells in this and the previous section.

Several options can be set to customize the output, see `latex_options()` for details. In particular, we use `format_letter_negative()` to format -1 as $\bar{1}$.

```
sage: NAF.latex_options(
....:     coordinates={'A': (0, 0),
....:                  'B': (6, 0)},
....:     initial_where={'A': 'below'},

\path[->] (v0) edge[loop above] node {$0$} ();
\path[->] (v0.5.00) edge node[rotate=0.00, anchor=south] {$1, \overline{1}$} (v1.175.
↪00);
\path[->] (v1.185.00) edge node[rotate=360.00, anchor=north] {$0$} (v0.355.00);
\end{tikzpicture}
>>> view(NAF) # not tested
```

To use the output of `latex()` in your own LaTeX file, you have to include

```
\usepackage{tikz}
\usetikzlibrary{automata}
```

into the preamble of your file.

A simple transducer (binary inverter)

Let's build a simple transducer, which rewrites a binary word by inverting each bit:

```
sage: inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
....:     initial_states=['A'], final_states=['A'])
```

```
>>> from sage.all import *
>>> inverter = Transducer({'A': [('A', Integer(0), Integer(1)), ('A', Integer(1),
↪Integer(0))]},
...     initial_states=['A'], final_states=['A'])
```

We can look at the states and transitions:

```
sage: inverter.states()
['A']
sage: for t in inverter.transitions():
....:     print(t)
Transition from 'A' to 'A': 0|1
Transition from 'A' to 'A': 1|0
```

```
>>> from sage.all import *
>>> inverter.states()
['A']
>>> for t in inverter.transitions():
...     print(t)
Transition from 'A' to 'A': 0|1
Transition from 'A' to 'A': 1|0
```

Now we apply a word to it and see what the transducer does:

```
sage: inverter([0, 1, 0, 0, 1, 1, 0, 0, 0, 1, 1, 1])
[1, 0, 1, 1, 0, 0, 1, 1, 1, 0, 0, 0]
```

```
>>> from sage.all import *
>>> inverter([Integer(0), Integer(1), Integer(0), Integer(0), Integer(1), Integer(1),
↪Integer(0), Integer(0), Integer(0), Integer(1), Integer(1), Integer(1)])
[1, 0, 1, 1, 0, 0, 1, 1, 1, 0, 0, 0]
```

`True` means, that we landed in a final state, that state is labeled `'A'`, and we also got an output.

Transducers and (in)finite Words

A transducer can also act on everything iterable, in particular, on Sage's *words*.

```
sage: W = Words([0, 1]); W
Finite and infinite words over {0, 1}
```

```
>>> from sage.all import *
>>> W = Words([Integer(0), Integer(1)]); W
Finite and infinite words over {0, 1}
```

Let us take the inverter from the previous section and feed some finite word into it:

```
sage: w = W([1, 1, 0, 1]); w
word: 1101
sage: inverter(w)
word: 0010
```

```
>>> from sage.all import *
>>> w = W([Integer(1), Integer(1), Integer(0), Integer(1)]); w
word: 1101
>>> inverter(w)
word: 0010
```

We see that the output is again a word (this is a consequence of calling `process()` with `automatic_output_type`).

We can even input something infinite like an infinite word:

```
sage: tm = words.ThueMorseWord(); tm
word: 0110100110010110100101100110100110010110...
sage: inverter(tm)
word: 1001011001101001011010011001011001101001...
```

```
>>> from sage.all import *
>>> tm = words.ThueMorseWord(); tm
word: 0110100110010110100101100110100110010110...
>>> inverter(tm)
word: 1001011001101001011010011001011001101001...
```

A transducer which performs division by 3 in binary

Now we build a transducer, which divides a binary number by 3. The labels of the states are the remainder of the division. The transition function is

```
sage: def f(state_from, read):
....:     if state_from + read <= 1:
....:         state_to = 2*state_from + read
....:         write = 0
....:     else:
....:         state_to = 2*state_from + read - 3
....:         write = 1
....:     return (state_to, write)
```

```
>>> from sage.all import *
>>> def f(state_from, read):
...     if state_from + read <= Integer(1):
...         state_to = Integer(2)*state_from + read
...         write = Integer(0)
...     else:
```

(continues on next page)

(continued from previous page)

```
...         state_to = Integer(2)*state_from + read - Integer(3)
...         write = Integer(1)
...     return (state_to, write)
```

which assumes reading a binary number from left to right. We get the transducer with

```
sage: D = Transducer(f, initial_states=[0], final_states=[0],
....:                input_alphabet=[0, 1])
```

```
>>> from sage.all import *
>>> D = Transducer(f, initial_states=[Integer(0)], final_states=[Integer(0)],
...                input_alphabet=[Integer(0), Integer(1)])
```

Let us try to divide 12 by 3:

```
sage: D([1, 1, 0, 0])
[0, 1, 0, 0]
```

```
>>> from sage.all import *
>>> D([Integer(1), Integer(1), Integer(0), Integer(0)])
[0, 1, 0, 0]
```

Now we want to divide 13 by 3:

```
sage: D([1, 1, 0, 1])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

```
>>> from sage.all import *
>>> D([Integer(1), Integer(1), Integer(0), Integer(1)])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

The raised `ValueError` means 13 is not divisible by 3.

Gray Code

The Gray code is a binary numeral system where two successive values differ in only one bit, cf. the Wikipedia article Gray_code. The Gray code of an integer n is obtained by a bitwise xor between the binary expansion of n and the binary expansion of $\lfloor n/2\rfloor$; the latter corresponds to a shift by one position in binary.

The purpose of this example is to construct a transducer converting the standard binary expansion to the Gray code by translating this construction into operations with transducers.

For this construction, the least significant digit is at the left-most position. Note that it is easier to shift everything to the right first, i.e., multiply by 2 instead of building $\lfloor n/2\rfloor$. Then, we take the input xor with the right shift of the input and forget the first letter.

We first construct a transducer shifting the binary expansion to the right. This requires storing the previously read digit in a state.

```
sage: def shift_right_transition(state, digit):
....:     if state == 'I':
....:         return (digit, None)
....:     else:
....:         return (digit, state)
sage: shift_right_transducer = Transducer(
....:     shift_right_transition,
....:     initial_states=['I'],
....:     input_alphabet=[0, 1],
....:     final_states=[0])
sage: shift_right_transducer.transitions()
[Transition from 'I' to 0: 0|-,
 Transition from 'I' to 1: 1|-,
 Transition from 0 to 0: 0|0,
 Transition from 0 to 1: 1|0,
 Transition from 1 to 0: 0|1,
 Transition from 1 to 1: 1|1]
sage: shift_right_transducer([0, 1, 1, 0])
[0, 1, 1]
sage: shift_right_transducer([1, 0, 0])
[1, 0]
```

```
>>> from sage.all import *
>>> def shift_right_transition(state, digit):
...     if state == 'I':
...         return (digit, None)
...     else:
...         return (digit, state)
>>> shift_right_transducer = Transducer(
...     shift_right_transition,
...     initial_states=['I'],
...     input_alphabet=[Integer(0), Integer(1)],
...     final_states=[Integer(0)])
>>> shift_right_transducer.transitions()
[Transition from 'I' to 0: 0|-,
 Transition from 'I' to 1: 1|-,
 Transition from 0 to 0: 0|0,
 Transition from 0 to 1: 1|0,
 Transition from 1 to 0: 0|1,
 Transition from 1 to 1: 1|1]
>>> shift_right_transducer([Integer(0), Integer(1), Integer(1), Integer(0)])
[0, 1, 1]
>>> shift_right_transducer([Integer(1), Integer(0), Integer(0)])
[1, 0]
```

The output of the shifts above look a bit weird (from a right-shift transducer, we would expect, for example, that `[1, 0, 0]` was mapped to `[0, 1, 0]`), since we write `None` instead of the zero at the left. Further, note that only 0 is listed as a final state as we have to enforce that a most significant zero is read as the last input letter in order to flush the last digit:

```
sage: shift_right_transducer([0, 1, 0, 1])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

```
>>> from sage.all import *
>>> shift_right_transducer([Integer(0), Integer(1), Integer(0), Integer(1)])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

Next, we construct the transducer performing the xor operation. We also have to take `None` into account as our `shift_right_transducer` waits one iteration until it starts writing output. This corresponds with our intention to forget the first letter.

```
sage: def xor_transition(state, digits):
....:     if digits[0] is None or digits[1] is None:
....:         return (0, None)
....:     else:
....:         return (0, digits[0].__xor__(digits[1]))
sage: from itertools import product
sage: xor_transducer = Transducer(
....:     xor_transition,
....:     initial_states=[0],
....:     final_states=[0],
....:     input_alphabet=list(product([None, 0, 1], [0, 1])))
sage: xor_transducer.transitions()
[Transition from 0 to 0: (None, 0)|-,
 Transition from 0 to 0: (None, 1)|-,
 Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|0]
sage: xor_transducer([(None, 0), (None, 1), (0, 0), (0, 1), (1, 0), (1, 1)])
[0, 1, 1, 0]
sage: xor_transducer([(0, None)])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

```
>>> from sage.all import *
>>> def xor_transition(state, digits):
...     if digits[Integer(0)] is None or digits[Integer(1)] is None:
...         return (Integer(0), None)
...     else:
...         return (Integer(0), digits[Integer(0)].__xor__(digits[Integer(1)]))
>>> from itertools import product
>>> xor_transducer = Transducer(
...     xor_transition,
...     initial_states=[Integer(0)],
...     final_states=[Integer(0)],
...     input_alphabet=list(product([None, Integer(0), Integer(1)], [Integer(0),
↪Integer(1)])))
>>> xor_transducer.transitions()
[Transition from 0 to 0: (None, 0)|-,
 Transition from 0 to 0: (None, 1)|-,
 Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|1,
```

(continues on next page)

(continued from previous page)

```
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|0]
>>> xor_transducer([(None, Integer(0)), (None, Integer(1)), (Integer(0), Integer(0)),
↪(Integer(0), Integer(1)), (Integer(1), Integer(0)), (Integer(1), Integer(1))])
[0, 1, 1, 0]
>>> xor_transducer([(Integer(0), None)])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

The transducer computing the Gray code is then constructed as a *Cartesian product* between the shifted version and the original input (represented here by the `shift_right_transducer` and the *identity transducer*, respectively). This Cartesian product is then fed into the `xor_transducer` as a *composition* of transducers.

```
sage: product_transducer = shift_right_transducer.cartesian_product(transducers.
↪Identity([0, 1]))
sage: Gray_transducer = xor_transducer(product_transducer)
```

```
>>> from sage.all import *
>>> product_transducer = shift_right_transducer.cartesian_product(transducers.
↪Identity([Integer(0), Integer(1)]))
>>> Gray_transducer = xor_transducer(product_transducer)
```

We use *construct_final_word_out()* to make sure that all output is written; otherwise, we would have to make sure that a sufficient number of trailing zeros is read.

```
sage: Gray_transducer.construct_final_word_out([0])
sage: Gray_transducer.transitions()
[Transition from (('I', 0), 0) to ((0, 0), 0): 0|-,
 Transition from (('I', 0), 0) to ((1, 0), 0): 1|-,
 Transition from ((0, 0), 0) to ((0, 0), 0): 0|0,
 Transition from ((0, 0), 0) to ((1, 0), 0): 1|1,
 Transition from ((1, 0), 0) to ((0, 0), 0): 0|1,
 Transition from ((1, 0), 0) to ((1, 0), 0): 1|0]
```

```
>>> from sage.all import *
>>> Gray_transducer.construct_final_word_out([Integer(0)])
>>> Gray_transducer.transitions()
[Transition from (('I', 0), 0) to ((0, 0), 0): 0|-,
 Transition from (('I', 0), 0) to ((1, 0), 0): 1|-,
 Transition from ((0, 0), 0) to ((0, 0), 0): 0|0,
 Transition from ((0, 0), 0) to ((1, 0), 0): 1|1,
 Transition from ((1, 0), 0) to ((0, 0), 0): 0|1,
 Transition from ((1, 0), 0) to ((1, 0), 0): 1|0]
```

There is a *prepackaged transducer* for Gray code, let's see whether they agree. We have to use *relabeled()* to relabel our states with integers.

```
sage: constructed = Gray_transducer.relabeled()
sage: packaged = transducers.GrayCode()
sage: constructed == packaged
True
```

```
>>> from sage.all import *
>>> constructed = Gray_transducer.relabeled()
>>> packaged = transducers.GrayCode()
>>> constructed == packaged
True
```

Finally, we check that this indeed computes the Gray code of the first 10 nonnegative integers.

```
sage: for n in srange(10):
....:     Gray_transducer(n.bits())
[]
[1]
[1, 1]
[0, 1]
[0, 1, 1]
[1, 1, 1]
[1, 0, 1]
[0, 0, 1]
[0, 0, 1, 1]
[1, 0, 1, 1]
```

```
>>> from sage.all import *
>>> for n in srange(Integer(10)):
...     Gray_transducer(n.bits())
[]
[1]
[1, 1]
[0, 1]
[0, 1, 1]
[1, 1, 1]
[1, 0, 1]
[0, 0, 1]
[0, 0, 1, 1]
[1, 0, 1, 1]
```

Using the hook-functions

Let's use the *previous example "division by 3"* to demonstrate the optional state and transition parameters `hook`.

First, we define what those functions should do. In our case, this is just saying in which state we are and which transition we take

```
sage: def state_hook(process, state, output):
....:     print("We are now in State %s." % (state.label(),))
sage: from sage.combinat.finite_state_machine import FSMWordSymbol
sage: def transition_hook(transition, process):
....:     print("Currently we go from %s to %s, "
....:           "reading %s and writing %s." % (
....:                transition.from_state, transition.to_state,
....:                FSMWordSymbol(transition.word_in),
....:                FSMWordSymbol(transition.word_out)))
```

```
>>> from sage.all import *
>>> def state_hook(process, state, output):
...     print("We are now in State %s." % (state.label(),))
>>> from sage.combinat.finite_state_machine import FSMWordSymbol
>>> def transition_hook(transition, process):
...     print("Currently we go from %s to %s, "
...           "reading %s and writing %s." % (
...               transition.from_state, transition.to_state,
...               FSMWordSymbol(transition.word_in),
...               FSMWordSymbol(transition.word_out)))
```

Now, let's add these hook-functions to the existing transducer:

```
sage: for s in D.iter_states():
....:     s.hook = state_hook
sage: for t in D.iter_transitions():
....:     t.hook = transition_hook
```

```
>>> from sage.all import *
>>> for s in D.iter_states():
...     s.hook = state_hook
>>> for t in D.iter_transitions():
...     t.hook = transition_hook
```

Rerunning the process again now gives the following output:

```
sage: D.process([1, 1, 0, 1], check_epsilon_transitions=False)
We are now in State 0.
Currently we go from 0 to 1, reading 1 and writing 0.
We are now in State 1.
Currently we go from 1 to 0, reading 1 and writing 1.
We are now in State 0.
Currently we go from 0 to 0, reading 0 and writing 0.
We are now in State 0.
Currently we go from 0 to 1, reading 1 and writing 0.
We are now in State 1.
(False, 1, [0, 1, 0, 0])
```

```
>>> from sage.all import *
>>> D.process([Integer(1), Integer(1), Integer(0), Integer(1)], check_epsilon_
↪transitions=False)
We are now in State 0.
Currently we go from 0 to 1, reading 1 and writing 0.
We are now in State 1.
Currently we go from 1 to 0, reading 1 and writing 1.
We are now in State 0.
Currently we go from 0 to 0, reading 0 and writing 0.
We are now in State 0.
Currently we go from 0 to 1, reading 1 and writing 0.
We are now in State 1.
(False, 1, [0, 1, 0, 0])
```

The example above just explains the basic idea of using hook-functions. In the following, we will use those hooks more seriously.

> **Warning**
>
> The hooks of the states are also called while exploring the epsilon successors of a state (during processing). In the example above, we used `check_epsilon_transitions=False` to avoid this (and also therefore got a cleaner output).

> **Warning**
>
> The arguments used when calling a hook have changed in Issue #16538 from `hook(state, process)` to `hook(process, state, output)`.

Detecting sequences with same number of 0 and 1

Suppose we have a binary input and want to accept all sequences with the same number of 0 and 1. This cannot be done with a finite automaton. Anyhow, we can make usage of the hook functions to extend our finite automaton by a counter:

```
sage: from sage.combinat.finite_state_machine import FSMState, FSMTransition
sage: C = FiniteStateMachine()
sage: def update_counter(process, state, output):
....:     try:
....:         l = process.preview_word()
....:     except RuntimeError:
....:         raise StopIteration
....:     process.fsm.counter += 1 if l == 1 else -1
....:     if process.fsm.counter > 0:
....:         next_state = 'positive'
....:     elif process.fsm.counter < 0:
....:         next_state = 'negative'
....:     else:
....:         next_state = 'zero'
....:     return FSMTransition(state, process.fsm.state(next_state),
....:                          l, process.fsm.counter)
sage: C.add_state(FSMState('zero', hook=update_counter,
....:             is_initial=True, is_final=True))
'zero'
sage: C.add_state(FSMState('positive', hook=update_counter))
'positive'
sage: C.add_state(FSMState('negative', hook=update_counter))
'negative'
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState, FSMTransition
>>> C = FiniteStateMachine()
>>> def update_counter(process, state, output):
...     try:
...         l = process.preview_word()
...     except RuntimeError:
...         raise StopIteration
```

(continues on next page)

(continued from previous page)

```
...     process.fsm.counter += Integer(1) if l == Integer(1) else -Integer(1)
...     if process.fsm.counter > Integer(0):
...         next_state = 'positive'
...     elif process.fsm.counter < Integer(0):
...         next_state = 'negative'
...     else:
...         next_state = 'zero'
...     return FSMTransition(state, process.fsm.state(next_state),
...                          l, process.fsm.counter)
>>> C.add_state(FSMState('zero', hook=update_counter,
...             is_initial=True, is_final=True))
'zero'
>>> C.add_state(FSMState('positive', hook=update_counter))
'positive'
>>> C.add_state(FSMState('negative', hook=update_counter))
'negative'
```

Now, let's input some sequence:

```
sage: C.counter = 0; C([1, 1, 1, 1, 0, 0])
(False, 'positive', [1, 2, 3, 4, 3, 2])
```

```
>>> from sage.all import *
>>> C.counter = Integer(0); C([Integer(1), Integer(1), Integer(1), Integer(1),␣
↪Integer(0), Integer(0)])
(False, 'positive', [1, 2, 3, 4, 3, 2])
```

The result is False, since there are four 1 but only two 0. We land in the state `positive` and we can also see the values of the counter in each step.

Let's try some other examples:

```
sage: C.counter = 0; C([1, 1, 0, 0])
(True, 'zero', [1, 2, 1, 0])
sage: C.counter = 0; C([0, 1, 0, 0])
(False, 'negative', [-1, 0, -1, -2])
```

```
>>> from sage.all import *
>>> C.counter = Integer(0); C([Integer(1), Integer(1), Integer(0), Integer(0)])
(True, 'zero', [1, 2, 1, 0])
>>> C.counter = Integer(0); C([Integer(0), Integer(1), Integer(0), Integer(0)])
(False, 'negative', [-1, 0, -1, -2])
```

Methods

class `sage.combinat.finite_state_machine.`**`Automaton`**`(*args, **kwargs)`

Bases: `FiniteStateMachine`

This creates an automaton, which is a finite state machine, whose transitions have input labels.

An automaton has additional features like creating a deterministic and a minimized automaton.

See class `FiniteStateMachine` for more information.

EXAMPLES:

We can create an automaton recognizing even numbers (given in binary and read from left to right) in the following way:

```
sage: A = Automaton([('P', 'Q', 0), ('P', 'P', 1),
....:                ('Q', 'P', 1), ('Q', 'Q', 0)],
....:               initial_states=['P'], final_states=['Q'])
sage: A
Automaton with 2 states
sage: A([0])
True
sage: A([1, 1, 0])
True
sage: A([1, 0, 1])
False
```

```
>>> from sage.all import *
>>> A = Automaton([('P', 'Q', Integer(0)), ('P', 'P', Integer(1)),
...                ('Q', 'P', Integer(1)), ('Q', 'Q', Integer(0))],
...               initial_states=['P'], final_states=['Q'])
>>> A
Automaton with 2 states
>>> A([Integer(0)])
True
>>> A([Integer(1), Integer(1), Integer(0)])
True
>>> A([Integer(1), Integer(0), Integer(1)])
False
```

Note that the full output of the commands can be obtained by calling *process()* and looks like this:

```
sage: A.process([1, 0, 1])
(False, 'P')
```

```
>>> from sage.all import *
>>> A.process([Integer(1), Integer(0), Integer(1)])
(False, 'P')
```

cartesian_product(*other*, *only_accessible_components=True*)

Return a new automaton which accepts an input if it is accepted by both given automata.

INPUT:

- `other` – an automaton
- `only_accessible_components` – if `True` (default), then the result is piped through *accessible_components()*. If no `new_input_alphabet` is given, it is determined by *determine_alphabets()*.

OUTPUT:

A new automaton which computes the intersection (see below) of the languages of `self` and `other`.

The set of states of the new automaton is the Cartesian product of the set of states of both given automata. There is a transition $((A, B), (C, D), a)$ in the new automaton if there are transitions (A, C, a) and (B, D, a) in the old automata.

The methods *intersection()* and *cartesian_product()* are the same (for automata).

EXAMPLES:

```
sage: aut1 = Automaton([('1', '2', 1),
....:                    ('2', '2', 1),
....:                    ('2', '2', 0)],
....:                   initial_states=['1'],
....:                   final_states=['2'],
....:                   determine_alphabets=True)
sage: aut2 = Automaton([('A', 'A', 1),
....:                    ('A', 'B', 0),
....:                    ('B', 'B', 0),
....:                    ('B', 'A', 1)],
....:                   initial_states=['A'],
....:                   final_states=['B'],
....:                   determine_alphabets=True)
sage: res = aut1.intersection(aut2)
sage: (aut1([1, 1]), aut2([1, 1]), res([1, 1]))
(True, False, False)
sage: (aut1([1, 0]), aut2([1, 0]), res([1, 0]))
(True, True, True)
sage: res.transitions()
[Transition from ('1', 'A') to ('2', 'A'): 1|-,
 Transition from ('2', 'A') to ('2', 'B'): 0|-,
 Transition from ('2', 'A') to ('2', 'A'): 1|-,
 Transition from ('2', 'B') to ('2', 'B'): 0|-,
 Transition from ('2', 'B') to ('2', 'A'): 1|-]
```

```
>>> from sage.all import *
>>> aut1 = Automaton([('1', '2', Integer(1)),
...                    ('2', '2', Integer(1)),
...                    ('2', '2', Integer(0))],
...                   initial_states=['1'],
...                   final_states=['2'],
...                   determine_alphabets=True)
>>> aut2 = Automaton([('A', 'A', Integer(1)),
...                    ('A', 'B', Integer(0)),
...                    ('B', 'B', Integer(0)),
...                    ('B', 'A', Integer(1))],
...                   initial_states=['A'],
...                   final_states=['B'],
...                   determine_alphabets=True)
>>> res = aut1.intersection(aut2)
>>> (aut1([Integer(1), Integer(1)]), aut2([Integer(1), Integer(1)]),␣
↪res([Integer(1), Integer(1)]))
(True, False, False)
>>> (aut1([Integer(1), Integer(0)]), aut2([Integer(1), Integer(0)]),␣
↪res([Integer(1), Integer(0)]))
(True, True, True)
>>> res.transitions()
[Transition from ('1', 'A') to ('2', 'A'): 1|-,
 Transition from ('2', 'A') to ('2', 'B'): 0|-,
 Transition from ('2', 'A') to ('2', 'A'): 1|-,
 Transition from ('2', 'B') to ('2', 'B'): 0|-,
 Transition from ('2', 'B') to ('2', 'A'): 1|-]
```

For automata with epsilon-transitions, intersection is not well defined. But for any finite state machine, epsilon-transitions can be removed by `remove_epsilon_transitions()`.

```
sage: a1 = Automaton([(0, 0, 0),
....:                 (0, 1, None),
....:                 (1, 1, 1),
....:                 (1, 2, 1)],
....:                 initial_states=[0],
....:                 final_states=[1],
....:                 determine_alphabets=True)
sage: a2 = Automaton([(0, 0, 0), (0, 1, 1), (1, 1, 1)],
....:                 initial_states=[0],
....:                 final_states=[1],
....:                 determine_alphabets=True)
sage: a1.intersection(a2)
Traceback (most recent call last):
...
ValueError: An epsilon-transition (with empty input)
was found.
sage: a1.remove_epsilon_transitions()  # not tested (since not implemented␣
↪yet)
sage: a1.intersection(a2)  # not tested
```

```
>>> from sage.all import *
>>> a1 = Automaton([(Integer(0), Integer(0), Integer(0)),
...                 (Integer(0), Integer(1), None),
...                 (Integer(1), Integer(1), Integer(1)),
...                 (Integer(1), Integer(2), Integer(1))],
...                 initial_states=[Integer(0)],
...                 final_states=[Integer(1)],
...                 determine_alphabets=True)
>>> a2 = Automaton([(Integer(0), Integer(0), Integer(0)), (Integer(0),␣
↪Integer(1), Integer(1)), (Integer(1), Integer(1), Integer(1))],
...                 initial_states=[Integer(0)],
...                 final_states=[Integer(1)],
...                 determine_alphabets=True)
>>> a1.intersection(a2)
Traceback (most recent call last):
...
ValueError: An epsilon-transition (with empty input)
was found.
>>> a1.remove_epsilon_transitions()  # not tested (since not implemented yet)
>>> a1.intersection(a2)  # not tested
```

complement()

Return the complement of this automaton.

OUTPUT: an `Automaton`

If this automaton recognizes language $\mathcal{L}$ over an input alphabet $\mathcal{A}$, then the complement recognizes $\mathcal{A} \setminus \mathcal{L}$.

EXAMPLES:

```
sage: A = automata.Word([0, 1])
sage: [w for w in ([], [0], [1], [0, 0], [0, 1], [1, 0], [1, 1])
```

(continues on next page)

(continued from previous page)

```
....:  if A(w)]
[[0, 1]]
sage: Ac = A.complement()
sage: Ac.transitions()
[Transition from 0 to 1: 0|-,
 Transition from 0 to 3: 1|-,
 Transition from 2 to 3: 0|-,
 Transition from 2 to 3: 1|-,
 Transition from 1 to 2: 1|-,
 Transition from 1 to 3: 0|-,
 Transition from 3 to 3: 0|-,
 Transition from 3 to 3: 1|-]
sage: [w for w in ([], [0], [1], [0, 0], [0, 1], [1, 0], [1, 1])
....:  if Ac(w)]
[[], [0], [1], [0, 0], [1, 0], [1, 1]]
```

```
>>> from sage.all import *
>>> A = automata.Word([Integer(0), Integer(1)])
>>> [w for w in ([], [Integer(0)], [Integer(1)], [Integer(0), Integer(0)],␣
↪[Integer(0), Integer(1)], [Integer(1), Integer(0)], [Integer(1),␣
↪Integer(1)])
...  if A(w)]
[[0, 1]]
>>> Ac = A.complement()
>>> Ac.transitions()
[Transition from 0 to 1: 0|-,
 Transition from 0 to 3: 1|-,
 Transition from 2 to 3: 0|-,
 Transition from 2 to 3: 1|-,
 Transition from 1 to 2: 1|-,
 Transition from 1 to 3: 0|-,
 Transition from 3 to 3: 0|-,
 Transition from 3 to 3: 1|-]
>>> [w for w in ([], [Integer(0)], [Integer(1)], [Integer(0), Integer(0)],␣
↪[Integer(0), Integer(1)], [Integer(1), Integer(0)], [Integer(1),␣
↪Integer(1)])
...  if Ac(w)]
[[], [0], [1], [0, 0], [1, 0], [1, 1]]
```

The automaton must be deterministic:

```
sage: A = automata.Word([0]) * automata.Word([1])
sage: A.complement()
Traceback (most recent call last):
...
ValueError: The finite state machine must be deterministic.
sage: Ac = A.determinisation().complement()
sage: [w for w in ([], [0], [1], [0, 0], [0, 1], [1, 0], [1, 1])
....:  if Ac(w)]
[[], [0], [1], [0, 0], [1, 0], [1, 1]]
```

```
>>> from sage.all import *
>>> A = automata.Word([Integer(0)]) * automata.Word([Integer(1)])
>>> A.complement()
Traceback (most recent call last):
...
ValueError: The finite state machine must be deterministic.
>>> Ac = A.determinisation().complement()
>>> [w for w in ([], [Integer(0)], [Integer(1)], [Integer(0), Integer(0)],
↪[Integer(0), Integer(1)], [Integer(1), Integer(0)], [Integer(1),
↪Integer(1)])
...  if Ac(w)]
[[], [0], [1], [0, 0], [1, 0], [1, 1]]
```

determinisation()

Return a deterministic automaton which accepts the same input words as the original one.

OUTPUT: a new automaton, which is deterministic

The labels of the states of the new automaton are frozensets of states of `self`. The color of a new state is the frozenset of colors of the constituent states of `self`. Therefore, the colors of the constituent states have to be hashable. However, if all constituent states have color `None`, then the resulting color is `None`, too.

The input alphabet must be specified.

EXAMPLES:

```
sage: aut = Automaton([('A', 'A', 0), ('A', 'B', 1), ('B', 'B', 1)],
....:                 initial_states=['A'], final_states=['B'])
sage: aut.determinisation().transitions()
[Transition from frozenset({'A'}) to frozenset({'A'}): 0|-,
 Transition from frozenset({'A'}) to frozenset({'B'}): 1|-,
 Transition from frozenset({'B'}) to frozenset(): 0|-,
 Transition from frozenset({'B'}) to frozenset({'B'}): 1|-,
 Transition from frozenset() to frozenset(): 0|-,
 Transition from frozenset() to frozenset(): 1|-]
```

```
>>> from sage.all import *
>>> aut = Automaton([('A', 'A', Integer(0)), ('A', 'B', Integer(1)), ('B', 'B
↪', Integer(1))],
...                 initial_states=['A'], final_states=['B'])
>>> aut.determinisation().transitions()
[Transition from frozenset({'A'}) to frozenset({'A'}): 0|-,
 Transition from frozenset({'A'}) to frozenset({'B'}): 1|-,
 Transition from frozenset({'B'}) to frozenset(): 0|-,
 Transition from frozenset({'B'}) to frozenset({'B'}): 1|-,
 Transition from frozenset() to frozenset(): 0|-,
 Transition from frozenset() to frozenset(): 1|-]
```

```
sage: A = Automaton([('A', 'A', 1), ('A', 'A', 0), ('A', 'B', 1),
....:                ('B', 'C', 0), ('C', 'C', 1), ('C', 'C', 0)],
....:               initial_states=['A'], final_states=['C'])
sage: A.determinisation().states()
[frozenset({'A'}),
 frozenset({'A', 'B'}),
```

(continues on next page)

(continued from previous page)

```
 frozenset({'A', 'C'}),
 frozenset({'A', 'B', 'C'})]
```

```
>>> from sage.all import *
>>> A = Automaton([('A', 'A', Integer(1)), ('A', 'A', Integer(0)), ('A', 'B',
↪Integer(1)),
...                    ('B', 'C', Integer(0)), ('C', 'C', Integer(1)), ('C', 'C',
↪Integer(0))],
...                   initial_states=['A'], final_states=['C'])
>>> A.determinisation().states()
[frozenset({'A'}),
 frozenset({'A', 'B'}),
 frozenset({'A', 'C'}),
 frozenset({'A', 'B', 'C'})]
```

```
sage: A = Automaton([(0, 1, 1), (0, 2, [1, 1]), (0, 3, [1, 1, 1]),
....:                    (1, 0, -1), (2, 0, -2), (3, 0, -3)],
....:                   initial_states=[0], final_states=[0, 1, 2, 3])
sage: B = A.determinisation().relabeled().coaccessible_components()
sage: sorted(B.transitions())
[Transition from 0 to 1: 1|-,
 Transition from 1 to 0: -1|-,
 Transition from 1 to 3: 1|-,
 Transition from 3 to 0: -2|-,
 Transition from 3 to 4: 1|-,
 Transition from 4 to 0: -3|-]
```

```
>>> from sage.all import *
>>> A = Automaton([(Integer(0), Integer(1), Integer(1)), (Integer(0),
↪Integer(2), [Integer(1), Integer(1)]), (Integer(0), Integer(3), [Integer(1),
↪ Integer(1), Integer(1)]),
...                    (Integer(1), Integer(0), -Integer(1)), (Integer(2),
↪Integer(0), -Integer(2)), (Integer(3), Integer(0), -Integer(3))],
...                   initial_states=[Integer(0)], final_states=[Integer(0),
↪Integer(1), Integer(2), Integer(3)])
>>> B = A.determinisation().relabeled().coaccessible_components()
>>> sorted(B.transitions())
[Transition from 0 to 1: 1|-,
 Transition from 1 to 0: -1|-,
 Transition from 1 to 3: 1|-,
 Transition from 3 to 0: -2|-,
 Transition from 3 to 4: 1|-,
 Transition from 4 to 0: -3|-]
```

Note that colors of states have to be hashable:

```
sage: A = Automaton([[0, 0, 0]], initial_states=[0])
sage: A.state(0).color = []
sage: A.determinisation()
Traceback (most recent call last):
...
```

(continues on next page)

(continued from previous page)

```
TypeError: unhashable type: 'list'
sage: A.state(0).color = ()
sage: A.determinisation()
Automaton with 1 state
```

```
>>> from sage.all import *
>>> A = Automaton([[Integer(0), Integer(0), Integer(0)]], initial_
↪states=[Integer(0)])
>>> A.state(Integer(0)).color = []
>>> A.determinisation()
Traceback (most recent call last):
...
TypeError: unhashable type: 'list'
>>> A.state(Integer(0)).color = ()
>>> A.determinisation()
Automaton with 1 state
```

If the colors of all constituent states are `None`, the resulting color is `None`, too (Issue #19199):

```
sage: A = Automaton([(0, 0, 0)],
....:               initial_states=[0],
....:               final_states=[0])
sage: [s.color for s in A.determinisation().iter_states()]
[None]
```

```
>>> from sage.all import *
>>> A = Automaton([(Integer(0), Integer(0), Integer(0))],
...               initial_states=[Integer(0)],
...               final_states=[Integer(0)])
>>> [s.color for s in A.determinisation().iter_states()]
[None]
```

intersection(*other*, *only_accessible_components=True*)

Return a new automaton which accepts an input if it is accepted by both given automata.

INPUT:

- `other` – an automaton
- `only_accessible_components` – if `True` (default), then the result is piped through *accessible_components()*. If no `new_input_alphabet` is given, it is determined by *determine_alphabets()*.

OUTPUT:

A new automaton which computes the intersection (see below) of the languages of `self` and `other`.

The set of states of the new automaton is the Cartesian product of the set of states of both given automata. There is a transition $((A, B), (C, D), a)$ in the new automaton if there are transitions (A, C, a) and (B, D, a) in the old automata.

The methods *intersection()* and *cartesian_product()* are the same (for automata).

EXAMPLES:

```
sage: aut1 = Automaton([('1', '2', 1),
....:                   ('2', '2', 1),
....:                   ('2', '2', 0)],
....:                  initial_states=['1'],
....:                  final_states=['2'],
....:                  determine_alphabets=True)
sage: aut2 = Automaton([('A', 'A', 1),
....:                   ('A', 'B', 0),
....:                   ('B', 'B', 0),
....:                   ('B', 'A', 1)],
....:                  initial_states=['A'],
....:                  final_states=['B'],
....:                  determine_alphabets=True)
sage: res = aut1.intersection(aut2)
sage: (aut1([1, 1]), aut2([1, 1]), res([1, 1]))
(True, False, False)
sage: (aut1([1, 0]), aut2([1, 0]), res([1, 0]))
(True, True, True)
sage: res.transitions()
[Transition from ('1', 'A') to ('2', 'A'): 1|-,
 Transition from ('2', 'A') to ('2', 'B'): 0|-,
 Transition from ('2', 'A') to ('2', 'A'): 1|-,
 Transition from ('2', 'B') to ('2', 'B'): 0|-,
 Transition from ('2', 'B') to ('2', 'A'): 1|-]
```

```
>>> from sage.all import *
>>> aut1 = Automaton([('1', '2', Integer(1)),
...                   ('2', '2', Integer(1)),
...                   ('2', '2', Integer(0))],
...                  initial_states=['1'],
...                  final_states=['2'],
...                  determine_alphabets=True)
>>> aut2 = Automaton([('A', 'A', Integer(1)),
...                   ('A', 'B', Integer(0)),
...                   ('B', 'B', Integer(0)),
...                   ('B', 'A', Integer(1))],
...                  initial_states=['A'],
...                  final_states=['B'],
...                  determine_alphabets=True)
>>> res = aut1.intersection(aut2)
>>> (aut1([Integer(1), Integer(1)]), aut2([Integer(1), Integer(1)]),␣
↪res([Integer(1), Integer(1)]))
(True, False, False)
>>> (aut1([Integer(1), Integer(0)]), aut2([Integer(1), Integer(0)]),␣
↪res([Integer(1), Integer(0)]))
(True, True, True)
>>> res.transitions()
[Transition from ('1', 'A') to ('2', 'A'): 1|-,
 Transition from ('2', 'A') to ('2', 'B'): 0|-,
 Transition from ('2', 'A') to ('2', 'A'): 1|-,
 Transition from ('2', 'B') to ('2', 'B'): 0|-,
 Transition from ('2', 'B') to ('2', 'A'): 1|-]
```

For automata with epsilon-transitions, intersection is not well defined. But for any finite state machine, epsilon-transitions can be removed by `remove_epsilon_transitions()`.

```
sage: a1 = Automaton([(0, 0, 0),
....:                 (0, 1, None),
....:                 (1, 1, 1),
....:                 (1, 2, 1)],
....:                 initial_states=[0],
....:                 final_states=[1],
....:                 determine_alphabets=True)
sage: a2 = Automaton([(0, 0, 0), (0, 1, 1), (1, 1, 1)],
....:                 initial_states=[0],
....:                 final_states=[1],
....:                 determine_alphabets=True)

>>> a1.intersection(a2)  # not tested
```

is_equivalent(*other*)

Test whether two automata are equivalent, i.e., accept the same language.

INPUT:

- `other` – an `Automaton`

EXAMPLES:

```
sage: A = Automaton([(0, 0, 0), (0, 1, 1), (1, 0, 1)],
....:                 initial_states=[0],
```

(continues on next page)

(continued from previous page)

```
....:                final_states=[0])
sage: B = Automaton([('a', 'a', 0), ('a', 'b', 1), ('b', 'a', 1)],
....:                initial_states=['a'],
....:                final_states=['a'])
sage: A.is_equivalent(B)
True
sage: B.add_transition('b', 'a', 0)
Transition from 'b' to 'a': 0|-
sage: A.is_equivalent(B)
False
```

```
>>> from sage.all import *
>>> A = Automaton([(Integer(0), Integer(0), Integer(0)), (Integer(0),␣
↪Integer(1), Integer(1)), (Integer(1), Integer(0), Integer(1))],
...                initial_states=[Integer(0)],
...                final_states=[Integer(0)])
>>> B = Automaton([('a', 'a', Integer(0)), ('a', 'b', Integer(1)), ('b', 'a',␣
↪Integer(1))],
...                initial_states=['a'],
...                final_states=['a'])
>>> A.is_equivalent(B)
True
>>> B.add_transition('b', 'a', Integer(0))
Transition from 'b' to 'a': 0|-
>>> A.is_equivalent(B)
False
```

language(*max_length=None*, ***kwargs*)

Return all words accepted by this automaton.

INPUT:

- `max_length` – integer or `None` (default). Only inputs of length at most `max_length` will be considered. If `None`, then this iterates over all possible words without length restrictions.
- `kwargs` – will be passed on to the *process iterator*. See *process()* for a description.

OUTPUT: an iterator

EXAMPLES:

```
sage: NAF = Automaton(
....:     {'A': [('A', 0), ('B', 1), ('B', -1)],
....:      'B': [('A', 0)]},
....:     initial_states=['A'], final_states=['A', 'B'])
sage: list(NAF.language(3))
[[],
 [0], [-1], [1],
 [-1, 0], [0, 0], [1, 0], [0, -1], [0, 1],
 [-1, 0, 0], [0, -1, 0], [0, 0, 0], [0, 1, 0], [1, 0, 0],
 [-1, 0, -1], [-1, 0, 1], [0, 0, -1],
 [0, 0, 1], [1, 0, -1], [1, 0, 1]]
```

```
>>> from sage.all import *
>>> NAF = Automaton(
...     {'A': [('A', Integer(0)), ('B', Integer(1)), ('B', -Integer(1))],
...      'B': [('A', Integer(0))]},
...     initial_states=['A'], final_states=['A', 'B'])
>>> list(NAF.language(Integer(3)))
[[],
 [0], [-1], [1],
 [-1, 0], [0, 0], [1, 0], [0, -1], [0, 1],
 [-1, 0, 0], [0, -1, 0], [0, 0, 0], [0, 1, 0], [1, 0, 0],
 [-1, 0, -1], [-1, 0, 1], [0, 0, -1],
 [0, 0, 1], [1, 0, -1], [1, 0, 1]]
```

See also

FiniteStateMachine.language(), *process()*.

minimization (*algorithm=None*)

Return the minimization of the input automaton as a new automaton.

INPUT:

- `algorithm` – either Moore's algorithm (by `algorithm='Moore'` or as default for deterministic automata) or Brzozowski's algorithm (when `algorithm='Brzozowski'` or when the automaton is not deterministic) is used.

OUTPUT: a new automaton

The resulting automaton is deterministic and has a minimal number of states.

EXAMPLES:

```
sage: A = Automaton([('A', 'A', 1), ('A', 'A', 0), ('A', 'B', 1),
....:                ('B', 'C', 0), ('C', 'C', 1), ('C', 'C', 0)],
....:               initial_states=['A'], final_states=['C'])
sage: B = A.minimization(algorithm='Brzozowski')
sage: B_trans = B.transitions(B.states()[1])
sage: B_trans # random
[Transition from frozenset({frozenset({'B', 'C'}),
                            frozenset({'A', 'C'}),
                            frozenset({'A', 'B', 'C'})})
            to frozenset({frozenset({'C'}),
                          frozenset({'B', 'C'}),
                          frozenset({'A', 'C'}),
                          frozenset({'A', 'B', 'C'})}):
            0|-,
 Transition from frozenset({frozenset({'B', 'C'}),
                            frozenset({'A', 'C'}),
                            frozenset({'A', 'B', 'C'})})
            to frozenset({frozenset({'B', 'C'}),
                          frozenset({'A', 'C'}),
                          frozenset({'A', 'B', 'C'})}):
            1|-]
sage: len(B.states())
```

(continues on next page)

(continued from previous page)

```

```

process(**args*, ***kwargs*)

Return whether the automaton accepts the input and the state where the computation stops.

INPUT:

- `input_tape` – the input tape can be a list or an iterable with entries from the input alphabet. If we are working with a multi-tape machine (see parameter `use_multitape_input` and notes below), then the tape is a list or tuple of tracks, each of which can be a list or an iterable with entries from the input alphabet.
- `initial_state` or `initial_states` – the initial state(s) in which the machine starts. Either specify a single one with `initial_state` or a list of them with `initial_states`. If both are given, `initial_state` will be appended to `initial_states`. If neither is specified, the initial states of the finite state machine are taken.
- `list_of_outputs` – (default: `None`) a boolean or `None`. If `True`, then the outputs are given in list form (even if we have no or only one single output). If `False`, then the result is never a list (an exception is raised if the result cannot be returned). If `list_of_outputs=None` the method determines automatically what to do (e.g. if a non-deterministic machine returns more than one path, then the output is returned in list form).
- `only_accepted` – boolean (default: `False`); if set, then the first argument in the output is guaranteed to be `True` (if the output is a list, then the first argument of each element will be `True`).
- `full_output` – boolean (default: `True`); if set, then the full output is given, otherwise only whether the sequence is accepted or not (the first entry below only).
- `always_include_output` – if set (not by default), always return a triple containing the (non-existing) output. This is in order to obtain output compatible with that of `FiniteStateMachine.process()`. If this parameter is set, `full_output` has no effect.
- `format_output` – a function that translates the written output (which is in form of a list) to something more readable. By default (`None`) identity is used here.
- `check_epsilon_transitions` – boolean (default: `True`); a boolean. If `False`, then epsilon transitions are not taken into consideration during process.
- `write_final_word_out` – boolean (default: `True`); whether the final output words should be written or not

- `use_multitape_input` – boolean (default: `False`); if `True`, then the multi-tape mode of the process iterator is activated. See also the notes below for multi-tape machines.
- `process_all_prefixes_of_input` – boolean (default: `False`); if `True`, then each prefix of the input word is processed (instead of processing the whole input word at once). Consequently, there is an output generated for each of these prefixes.
- `process_iterator_class` – (default: `None`) a class inherited from *FSMProcessIterator*. If `None`, then *FSMProcessIterator* is taken. An instance of this class is created and is used during the processing.

OUTPUT:

The full output is a pair (or a list of pairs, cf. parameter `list_of_outputs`), where

- the first entry is `True` if the input string is accepted and
- the second gives the state reached after processing the input tape (This is a state with label `None` if the input could not be processed, i.e., if at one point no transition to go on could be found.).

If `full_output` is `False`, then only the first entry is returned.

If `always_include_output` is set, an additional third entry `[]` is included.

Note that in the case the automaton is not deterministic, all possible paths are taken into account. You can use *determinisation()* to get a deterministic automaton machine.

This function uses an iterator which, in its simplest form, goes from one state to another in each step. To decide which way to go, it uses the input words of the outgoing transitions and compares them to the input tape. More precisely, in each step, the iterator takes an outgoing transition of the current state, whose input label equals the input letter of the tape.

If the choice of the outgoing transition is not unique (i.e., we have a non-deterministic finite state machine), all possibilities are followed. This is done by splitting the process into several branches, one for each of the possible outgoing transitions.

The process (iteration) stops if all branches are finished, i.e., for no branch, there is any transition whose input word coincides with the processed input tape. This can simply happen when the entire tape was read.

Also see *__call__()* for a version of *process()* with shortened output.

Internally this function creates and works with an instance of *FSMProcessIterator*. This iterator can also be obtained with *iter_process()*.

If working with multi-tape finite state machines, all input words of transitions are words of k-tuples of letters. Moreover, the input tape has to consist of k tracks, i.e., be a list or tuple of k iterators, one for each track.

> **Warning**
>
> Working with multi-tape finite state machines is still experimental and can lead to wrong outputs.

EXAMPLES:

In the following examples, we construct an automaton which accepts non-adjacent forms (see also the example on *non-adjacent forms* in the documentation of the module *Finite state machines, automata, transducers*) and then test it by feeding it with several binary digit expansions.

```
sage: NAF = Automaton(
....:     {'_': [('_', 0), ('1', 1)], '1': [('_', 0)]},
....:     initial_states=['_'], final_states=['_', '1'])
```

(continues on next page)

(continued from previous page)

```
sage: [NAF.process(w) for w in [[0], [0, 1], [1, 1], [0, 1, 0, 1],
....:                           [0, 1, 1, 1, 0], [1, 0, 0, 1, 1]]]
[(True, '_'), (True, '1'), (False, None),
 (True, '1'), (False, None), (False, None)]
```

```
>>> from sage.all import *
>>> NAF = Automaton(
...     {'_': [('_', Integer(0)), ('1', Integer(1))], '1': [('_',␣
↪Integer(0))]},
...     initial_states=['_'], final_states=['_', '1'])
>>> [NAF.process(w) for w in [[Integer(0)], [Integer(0), Integer(1)],␣
↪[Integer(1), Integer(1)], [Integer(0), Integer(1), Integer(0), Integer(1)],
...                           [Integer(0), Integer(1), Integer(1), Integer(1),
↪ Integer(0)], [Integer(1), Integer(0), Integer(0), Integer(1), Integer(1)]]]
[(True, '_'), (True, '1'), (False, None),
 (True, '1'), (False, None), (False, None)]
```

If we just want a condensed output, we use:

```
sage: [NAF.process(w, full_output=False)
....:     for w in [[0], [0, 1], [1, 1], [0, 1, 0, 1],
....:               [0, 1, 1, 1, 0], [1, 0, 0, 1, 1]]]
[True, True, False, True, False, False]
```

```
>>> from sage.all import *
>>> [NAF.process(w, full_output=False)
...     for w in [[Integer(0)], [Integer(0), Integer(1)], [Integer(1),␣
↪Integer(1)], [Integer(0), Integer(1), Integer(0), Integer(1)],
...               [Integer(0), Integer(1), Integer(1), Integer(1),␣
↪Integer(0)], [Integer(1), Integer(0), Integer(0), Integer(1), Integer(1)]]]
[True, True, False, True, False, False]
```

It is equivalent to:

```
sage: [NAF(w) for w in [[0], [0, 1], [1, 1], [0, 1, 0, 1],
....:                   [0, 1, 1, 1, 0], [1, 0, 0, 1, 1]]]
[True, True, False, True, False, False]
```

```
>>> from sage.all import *
>>> [NAF(w) for w in [[Integer(0)], [Integer(0), Integer(1)], [Integer(1),␣
↪Integer(1)], [Integer(0), Integer(1), Integer(0), Integer(1)],
...                   [Integer(0), Integer(1), Integer(1), Integer(1),␣
↪Integer(0)], [Integer(1), Integer(0), Integer(0), Integer(1), Integer(1)]]]
[True, True, False, True, False, False]
```

The following example illustrates the difference between non-existing paths and reaching a non-final state:

```
sage: NAF.process([2])
(False, None)
sage: NAF.add_transition(('_', 's', 2))
Transition from '_' to 's': 2|-
```

(continues on next page)

(continued from previous page)

```
sage: NAF.process([2])
(False, 's')
```

```
>>> from sage.all import *
>>> NAF.process([Integer(2)])
(False, None)
>>> NAF.add_transition(('_', 's', Integer(2)))
Transition from '_' to 's': 2|-
>>> NAF.process([Integer(2)])
(False, 's')
```

A simple example of a (non-deterministic) multi-tape automaton is the following: It checks whether the two input tapes have the same number of ones:

```
sage: M = Automaton([('=', '=', (1, 1)),
....:                ('=', '=', (None, 0)),
....:                ('=', '=', (0, None)),
....:                ('=', '<', (None, 1)),
....:                ('<', '<', (None, 1)),
....:                ('<', '<', (None, 0)),
....:                ('=', '>', (1, None)),
....:                ('>', '>', (1, None)),
....:                ('>', '>', (0, None))],
....:               initial_states=['='],
....:               final_states=['='])
sage: M.process(([1, 0, 1], [1, 0]), use_multitape_input=True)
(False, '>')
sage: M.process(([0, 1, 0], [0, 1, 1]), use_multitape_input=True)
(False, '<')
sage: M.process(([1, 1, 0, 1], [0, 0, 1, 0, 1, 1]),
....:           use_multitape_input=True)
(True, '=')
```

```
>>> from sage.all import *
>>> M = Automaton([('=', '=', (Integer(1), Integer(1))),
...                ('=', '=', (None, Integer(0))),
...                ('=', '=', (Integer(0), None)),
...                ('=', '<', (None, Integer(1))),
...                ('<', '<', (None, Integer(1))),
...                ('<', '<', (None, Integer(0))),
...                ('=', '>', (Integer(1), None)),
...                ('>', '>', (Integer(1), None)),
...                ('>', '>', (Integer(0), None))],
...               initial_states=['='],
...               final_states=['='])
>>> M.process(([Integer(1), Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]), use_multitape_input=True)
(False, '>')
>>> M.process(([Integer(0), Integer(1), Integer(0)], [Integer(0), Integer(1),␣
↪Integer(1)]), use_multitape_input=True)
(False, '<')
>>> M.process(([Integer(1), Integer(1), Integer(0), Integer(1)], [Integer(0),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(0), Integer(1), Integer(0), Integer(1), Integer(1)]),
...            use_multitape_input=True)
(True, '=')
```

Alternatively, we can use the following (non-deterministic) multi-tape automaton for the same check:

```
sage: N = Automaton([('=', '=', (0, 0)),
....:                  ('=', '<', (None, 1)),
....:                  ('<', '<', (0, None)),
....:                  ('<', '=', (1, None)),
....:                  ('=', '>', (1, None)),
....:                  ('>', '>', (None, 0)),
....:                  ('>', '=', (None, 1))],
....:                 initial_states=['='],
....:                 final_states=['='])
sage: N.process(([1, 0, 1], [1, 0]), use_multitape_input=True)
(False, '>')

shannon_parry_markov_chain()

Compute a time homogeneous Markov chain such that all words of a given length recognized by the original automaton occur as the output with the same weight; the transition probabilities correspond to the Parry measure.

OUTPUT:

A Markov chain. Its input labels are the transition probabilities, the output labels the labels of the original automaton. In order to obtain equal weight for all words of the same length, an "exit weight" is needed. It is stored in the attribute `color` of the states of the Markov chain. The weights of the words of the same length sum up to one up to an exponentially small error.

The stationary distribution of this Markov chain is saved as the initial probabilities of the states.

The transition probabilities correspond to the Parry measure (see [S1948] and [P1964]).

The automaton is assumed to be deterministic, irreducible and aperiodic. All states must be final.

EXAMPLES:

```
sage: NAF = Automaton([(0, 0, 0), (0, 1, 1), (0, 1, -1),
....:                  (1, 0, 0)], initial_states=[0],
....:                 final_states=[0, 1])
sage: P_NAF = NAF.shannon_parry_markov_chain()                          #␣
↪needs sage.symbolic
sage: P_NAF.transitions()                                               #␣
↪needs sage.symbolic
[Transition from 0 to 0: 1/2|0,
 Transition from 0 to 1: 1/4|1,
 Transition from 0 to 1: 1/4|-1,
 Transition from 1 to 0: 1|0]
sage: for s in P_NAF.iter_states():                                     #␣
↪needs sage.symbolic
....:     print(s.color)
3/4
3/2
```

```
>>> from sage.all import *
>>> NAF = Automaton([(Integer(0), Integer(0), Integer(0)), (Integer(0),␣
↪Integer(1), Integer(1)), (Integer(0), Integer(1), -Integer(1)),
...                  (Integer(1), Integer(0), Integer(0))], initial_
↪states=[Integer(0)],
...                 final_states=[Integer(0), Integer(1)])
>>> P_NAF = NAF.shannon_parry_markov_chain()                            #␣
↪needs sage.symbolic
>>> P_NAF.transitions()                                                 #␣
↪needs sage.symbolic
[Transition from 0 to 0: 1/2|0,
 Transition from 0 to 1: 1/4|1,
 Transition from 0 to 1: 1/4|-1,
 Transition from 1 to 0: 1|0]
>>> for s in P_NAF.iter_states():                                       #␣
↪needs sage.symbolic
...     print(s.color)
3/4
3/2
```

The stationary distribution is also computed and saved as the initial probabilities of the returned Markov chain:

```
sage: for s in P_NAF.states():                                          #␣
↪needs sage.symbolic
....:     print("{} {}".format(s, s.initial_probability))
0 2/3
1 1/3
```

```
>>> from sage.all import *
>>> for s in P_NAF.states():                                          #␣
↪needs sage.symbolic
...     print("{} {}".format(s, s.initial_probability))
0 2/3
1 1/3
```

The automaton is assumed to be deterministic, irreducible and aperiodic:

```
sage: A = Automaton([(0, 0, 0), (0, 1, 1), (1, 1, 1), (1, 1, 0)],
....:               initial_states=[0])
sage: A.shannon_parry_markov_chain()
Traceback (most recent call last):
...

```

```
>>> from sage.all import *
>>> A = Automaton([(Integer(0), Integer(1), Integer(0)), (Integer(0),␣
↪Integer(0), Integer(1)), (Integer(1), Integer(0), Integer(0))],
...                 initial_states=[Integer(0)])
>>> A.shannon_parry_markov_chain()
Traceback (most recent call last):
...
NotImplementedError: All states must be final.
```

ALGORITHM:

See [HKP2015a], Lemma 4.1.

REFERENCES:

with_output(*word_out_function=None*)

Construct a transducer out of this automaton.

INPUT:

- `word_out_function` – (default: `None`) a function. It transforms a *transition* to the output word for this transition.

  If this is `None`, then the output word will be equal to the input word of each transition.

OUTPUT: a transducer

EXAMPLES:

```
sage: A = Automaton([(0, 0, 'A'), (0, 1, 'B'), (1, 2, 'C')])
sage: T = A.with_output(); T
Transducer with 3 states
sage: T.transitions()
[Transition from 0 to 0: 'A'|'A',
 Transition from 0 to 1: 'B'|'B',
 Transition from 1 to 2: 'C'|'C']
```

```
>>> from sage.all import *
>>> A = Automaton([(Integer(0), Integer(0), 'A'), (Integer(0), Integer(1), 'B
↪'), (Integer(1), Integer(2), 'C')])
>>> T = A.with_output(); T
```

(continues on next page)

(continued from previous page)

```
Transducer with 3 states
>>> T.transitions()
[Transition from 0 to 0: 'A'|'A',
 Transition from 0 to 1: 'B'|'B',
 Transition from 1 to 2: 'C'|'C']
```

This result is in contrast to:

```
sage: Transducer(A).transitions()
[Transition from 0 to 0: 'A'|-,
 Transition from 0 to 1: 'B'|-,
 Transition from 1 to 2: 'C'|-]
```

```
>>> from sage.all import *
>>> Transducer(A).transitions()
[Transition from 0 to 0: 'A'|-,
 Transition from 0 to 1: 'B'|-,
 Transition from 1 to 2: 'C'|-]
```

where no output labels are created.

Here is another example:

```
sage: T2 = A.with_output(lambda t: [c.lower() for c in t.word_in])
sage: T2.transitions()
[Transition from 0 to 0: 'A'|'a',
 Transition from 0 to 1: 'B'|'b',
 Transition from 1 to 2: 'C'|'c']
```

```
>>> from sage.all import *
>>> T2 = A.with_output(lambda t: [c.lower() for c in t.word_in])
>>> T2.transitions()
[Transition from 0 to 0: 'A'|'a',
 Transition from 0 to 1: 'B'|'b',
 Transition from 1 to 2: 'C'|'c']
```

We can obtain the same result by composing two transducers. As inner transducer of the composition, we use *with_output()* without the optional argument `word_out_function` (which makes the output of each transition equal to its input); as outer transducer we use a *map-transducer* (for converting to lower case). This gives

```
sage: L = transducers.map(lambda x: x.lower(), ['A', 'B', 'C'])
sage: L.composition(A.with_output()).relabeled().transitions()
[Transition from 0 to 0: 'A'|'a',
 Transition from 0 to 1: 'B'|'b',
 Transition from 1 to 2: 'C'|'c']
```

```
>>> from sage.all import *
>>> L = transducers.map(lambda x: x.lower(), ['A', 'B', 'C'])
>>> L.composition(A.with_output()).relabeled().transitions()
[Transition from 0 to 0: 'A'|'a',
 Transition from 0 to 1: 'B'|'b',
 Transition from 1 to 2: 'C'|'c']
```

input_projection(), *output_projection()*, *Transducer*, *transducers.map()*.

sage.combinat.finite_state_machine.**FSMLetterSymbol**(*letter*)

Return a string associated to the input letter.

INPUT:

- `letter` – the input letter or `None` (representing the empty word)

OUTPUT:

If `letter` is `None` the symbol for the empty word `FSMEmptyWordSymbol` is returned, otherwise the string associated to the letter.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMLetterSymbol
sage: FSMLetterSymbol(0)
'0'
sage: FSMLetterSymbol(None)
'-'
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMLetterSymbol
>>> FSMLetterSymbol(Integer(0))
'0'
>>> FSMLetterSymbol(None)
'-'
```

class sage.combinat.finite_state_machine.**FSMProcessIterator**(*fsm*, *input_tape=None*, *initial_state=None*, *initial_states=[]*, *use_multitape_input=False*, *check_epsilon_transitions=True*, *write_final_word_out=True*, *format_output=None*, *process_all_prefixes_of_input=False*, ***kwargs*)

Bases: `SageObject`, `Iterator`

This class takes an input, feeds it into a finite state machine (automaton or transducer, in particular), tests whether this was successful and calculates the written output.

INPUT:

- `fsm` – the finite state machine on which the input should be processed
- `input_tape` – the input tape can be a list or an iterable with entries from the input alphabet. If we are working with a multi-tape machine (see parameter `use_multitape_input` and notes below), then the tape is a list or tuple of tracks, each of which can be a list or an iterable with entries from the input alphabet.
- `initial_state` or `initial_states` – the initial state(s) in which the machine starts. Either specify a single one with `initial_state` or a list of them with `initial_states`. If both are given, `initial_state` will be appended to `initial_states`. If neither is specified, the initial states of the finite state machine are taken.

- `format_output` – a function that translates the written output (which is in form of a list) to something more readable. By default (`None`) identity is used here.
- `check_epsilon_transitions` – boolean (default: `True`); if `False`, then epsilon transitions are not taken into consideration during process
- `write_final_word_out` – boolean (default: `True`); whether the final output words should be written or not
- `use_multitape_input` – boolean (default: `False`); if `True`, then the multi-tape mode of the process iterator is activated. See also the notes below for multi-tape machines.
- `process_all_prefixes_of_input` – boolean (default: `False`); if `True`, then each prefix of the input word is processed (instead of processing the whole input word at once). Consequently, there is an output generated for each of these prefixes.

OUTPUT: an iterator

In its simplest form, it behaves like an iterator which, in each step, goes from one state to another. To decide which way to go, it uses the input words of the outgoing transitions and compares them to the input tape. More precisely, in each step, the process iterator takes an outgoing transition of the current state, whose input label equals the input letter of the tape. The output label of the transition, if present, is written on the output tape.

If the choice of the outgoing transition is not unique (i.e., we have a non-deterministic finite state machine), all possibilities are followed. This is done by splitting the process into several branches, one for each of the possible outgoing transitions.

The process (iteration) stops if all branches are finished, i.e., for no branch, there is any transition whose input word coincides with the processed input tape. This can simply happen when the entire tape was read. When the process stops, a `StopIteration` exception is thrown.

Warning: Processing an input tape of length n usually takes at least $n+1$ iterations, since there will be $n+1$ states visited (in the case the taken transitions have input words consisting of single letters).

An instance of this class is generated when *FiniteStateMachine.process()* or *FiniteStateMachine.iter_process()* of a finite state machine, an automaton, or a transducer is invoked.

When working with multi-tape finite state machines, all input words of transitions are words of k-tuples of letters. Moreover, the input tape has to consist of k tracks, i.e., be a list or tuple of k iterators, one for each track.

Warning: Working with multi-tape finite state machines is still experimental and can lead to wrong outputs.

EXAMPLES:

The following transducer reads binary words and outputs a word, where blocks of ones are replaced by just a single one. Further only words that end with a zero are accepted.

```
sage: T = Transducer({'A': [('A', 0, 0), ('B', 1, None)],
....:                 'B': [('B', 1, None), ('A', 0, [1, 0])]},
....:     initial_states=['A'], final_states=['A'])
sage: input = [1, 1, 0, 0, 1, 0, 1, 1, 1, 0]
```

(continues on next page)

(continued from previous page)

```
sage: T.process(input)
(True, 'A', [1, 0, 0, 1, 0, 1, 0])
```

```
>>> from sage.all import *
>>> T = Transducer({'A': [('A', Integer(0), Integer(0)), ('B', Integer(1), None)],
...                 'B': [('B', Integer(1), None), ('A', Integer(0), [Integer(1),
↪Integer(0)])]},
...     initial_states=['A'], final_states=['A'])
>>> input = [Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),
↪Integer(0), Integer(1), Integer(1), Integer(1), Integer(0)]
>>> T.process(input)
(True, 'A', [1, 0, 0, 1, 0, 1, 0])
```

The function `FiniteStateMachine.process()` (internally) uses a `FSMProcessIterator`. We can do that manually, too, and get full access to the iteration process:

```
sage: from sage.combinat.finite_state_machine import FSMProcessIterator
sage: it = FSMProcessIterator(T, input_tape=input)
sage: for current in it:
....:     print(current)
process (1 branch)
+ at state 'B'
+-- tape at 1, [[]]
process (1 branch)
+ at state 'B'
+-- tape at 2, [[]]
process (1 branch)
+ at state 'A'
+-- tape at 3, [[1, 0]]
process (1 branch)
+ at state 'A'
+-- tape at 4, [[1, 0, 0]]
process (1 branch)
+ at state 'B'
+-- tape at 5, [[1, 0, 0]]
process (1 branch)
+ at state 'A'
+-- tape at 6, [[1, 0, 0, 1, 0]]
process (1 branch)
+ at state 'B'

class Current

Bases: dict

This class stores the branches which have to be processed during iteration and provides a nicer formatting of them.

This class is derived from dict. It is returned by the next-function during iteration.

EXAMPLES:

In the following example you can see the dict directly and then the nicer output provided by this class:

```
sage: from sage.combinat.finite_state_machine import FSMProcessIterator
sage: inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
....:     initial_states=['A'], final_states=['A'])
sage: it = FSMProcessIterator(inverter, input_tape=[0, 1])
sage: for current in it:
....:     print(dict(current))
....:     print(current)
{((1, 0),): {'A': Branch(tape_cache=tape at 1, outputs=[[1]])}}
process (1 branch)
+ at state 'A'
+-- tape at 1, [[1]]
{((2, 0),): {'A': Branch(tape_cache=tape at 2, outputs=[[1, 0]])}}
process (1 branch)
+ at state 'A'
+-- tape at 2, [[1, 0]]
{}
process (0 branches)
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMProcessIterator
>>> inverter = Transducer({'A': [('A', Integer(0), Integer(1)), ('A',␣
↪Integer(1), Integer(0))]},
...     initial_states=['A'], final_states=['A'])
>>> it = FSMProcessIterator(inverter, input_tape=[Integer(0), Integer(1)])
>>> for current in it:
...     print(dict(current))
...     print(current)
{((1, 0),): {'A': Branch(tape_cache=tape at 1, outputs=[[1]])}}
process (1 branch)
+ at state 'A'
+-- tape at 1, [[1]]
{((2, 0),): {'A': Branch(tape_cache=tape at 2, outputs=[[1, 0]])}}
process (1 branch)
```

(continues on next page)

(continued from previous page)

```
+ at state 'A'
+-- tape at 2, [[1, 0]]
{}
process (0 branches)
```

class FinishedBranch(*accept*, *state*, *output*)

Bases: `tuple`

A `named tuple` representing the attributes of a branch, once it is fully processed.

accept

Alias for field number 0

output

Alias for field number 2

state

Alias for field number 1

next()

Makes one step in processing the input tape.

OUTPUT:

It returns the current status of the iterator (see below). A `StopIteration` exception is thrown when there is/was nothing to do (i.e. all branches ended with previous call of `next()`).

The current status is a dictionary (encapsulated into an instance of `Current`). The keys are positions on the tape. The value corresponding to such a position is again a dictionary, where each entry represents a branch of the process. This dictionary maps the current state of a branch to a pair consisting of a tape cache and a list of output words, which were written during reaching this current state.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMProcessIterator
sage: inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
....:     initial_states=['A'], final_states=['A'])
sage: it = FSMProcessIterator(inverter, input_tape=[0, 1])
sage: next(it)
process (1 branch)
+ at state 'A'
+-- tape at 1, [[1]]
sage: next(it)
process (1 branch)
+ at state 'A'
+-- tape at 2, [[1, 0]]
sage: next(it)
process (0 branches)
sage: next(it)
Traceback (most recent call last):
...
StopIteration
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMProcessIterator
```

(continues on next page)

(continued from previous page)

```
>>> inverter = Transducer({'A': [('A', Integer(0), Integer(1)), ('A',␣
↪Integer(1), Integer(0))]},
...     initial_states=['A'], final_states=['A'])
>>> it = FSMProcessIterator(inverter, input_tape=[Integer(0), Integer(1)])
>>> next(it)
process (1 branch)
+ at state 'A'
+-- tape at 1, [[1]]
>>> next(it)
process (1 branch)
+ at state 'A'
+-- tape at 2, [[1, 0]]
>>> next(it)
process (0 branches)
>>> next(it)
Traceback (most recent call last):
...
StopIteration
```

See also

FiniteStateMachine.process(), *Automaton.process()*, *Transducer.process()*, *FiniteStateMachine.iter_process()*, *FiniteStateMachine.__call__()*, *FSMProcessIterator*.

preview_word(*track_number=None*, *length=1*, *return_word=False*)

Read a word from the input tape.

INPUT:

- `track_number` – integer (default: `None`); if `None`, then a tuple of words (one from each track) is returned
- `length` – (default: `1`) the length of the word(s)
- `return_word` – boolean (default: `False`); if set, then a word is returned, otherwise a single letter (in which case `length` has to be `1`)

OUTPUT: a single letter or a word

An exception `StopIteration` is thrown if the tape (at least one track) has reached its end.

Typically, this method is called from a hook-function of a state.

EXAMPLES:

```
sage: inverter = Transducer({'A': [('A', 0, 'one'),
....:                              ('A', 1, 'zero')]},
....:     initial_states=['A'], final_states=['A'])
sage: def state_hook(process, state, output):
....:     print("We are now in state %s." % (state.label(),))
....:     try:
....:         w = process.preview_word()
....:     except RuntimeError:
....:         raise StopIteration
```

(continues on next page)

(continued from previous page)

```
....:     print("Next on the tape is a %s." % (w,))
sage: inverter.state('A').hook = state_hook
sage: it = inverter.iter_process(
....:     input_tape=[0, 1, 1],
....:     check_epsilon_transitions=False)
sage: for _ in it:
....:     pass
We are now in state A.
Next on the tape is a 0.
We are now in state A.
Next on the tape is a 1.
We are now in state A.
Next on the tape is a 1.
We are now in state A.
sage: it.result()
[Branch(accept=True, state='A', output=['one', 'zero', 'zero'])]
```

```
>>> from sage.all import *
>>> inverter = Transducer({'A': [('A', Integer(0), 'one'),
...                              ('A', Integer(1), 'zero')]},
...     initial_states=['A'], final_states=['A'])
>>> def state_hook(process, state, output):
...     print("We are now in state %s." % (state.label(),))
...     try:
...         w = process.preview_word()
...     except RuntimeError:
...         raise StopIteration
...     print("Next on the tape is a %s." % (w,))
>>> inverter.state('A').hook = state_hook
>>> it = inverter.iter_process(
...     input_tape=[Integer(0), Integer(1), Integer(1)],
...     check_epsilon_transitions=False)
>>> for _ in it:
...     pass
We are now in state A.
Next on the tape is a 0.
We are now in state A.
Next on the tape is a 1.
We are now in state A.
Next on the tape is a 1.
We are now in state A.
>>> it.result()
[Branch(accept=True, state='A', output=['one', 'zero', 'zero'])]
```

result (*format_output=None*)

Return the already finished branches during process.

INPUT:

- `format_output` – a function converting the output from list form to something more readable (default: output the list directly).

OUTPUT:

A list of triples (accepted, state, output).

See also the parameter format_output of *FSMProcessIterator*.

EXAMPLES:

```
sage: inverter = Transducer({'A': [('A', 0, 'one'), ('A', 1, 'zero')]},
....:     initial_states=['A'], final_states=['A'])
sage: it = inverter.iter_process(input_tape=[0, 1, 1])
sage: for _ in it:
....:     pass
sage: it.result()
[Branch(accept=True, state='A', output=['one', 'zero', 'zero'])]
sage: it.result(lambda L: ', '.join(L))
[(True, 'A', 'one, zero, zero')]
```

```
>>> from sage.all import *
>>> inverter = Transducer({'A': [('A', Integer(0), 'one'), ('A', Integer(1),
↪'zero')]},
...     initial_states=['A'], final_states=['A'])
>>> it = inverter.iter_process(input_tape=[Integer(0), Integer(1),␣
↪Integer(1)])
>>> for _ in it:
...     pass
>>> it.result()
[Branch(accept=True, state='A', output=['one', 'zero', 'zero'])]
>>> it.result(lambda L: ', '.join(L))
[(True, 'A', 'one, zero, zero')]
```

Using both the parameter format_output of *FSMProcessIterator* and the parameter format_output of *result()* leads to concatenation of the two functions:

```
sage: it = inverter.iter_process(input_tape=[0, 1, 1],
....:                            format_output=lambda L: ', '.join(L))
sage: for _ in it:
....:     pass
sage: it.result()
[Branch(accept=True, state='A', output='one, zero, zero')]
sage: it.result(lambda L: ', '.join(L))
[(True, 'A', 'o, n, e, ,,  , z, e, r, o, ,,  , z, e, r, o')]
```

```
>>> from sage.all import *
>>> it = inverter.iter_process(input_tape=[Integer(0), Integer(1),␣
↪Integer(1)],
...                            format_output=lambda L: ', '.join(L))
>>> for _ in it:
...     pass
>>> it.result()
[Branch(accept=True, state='A', output='one, zero, zero')]
>>> it.result(lambda L: ', '.join(L))
[(True, 'A', 'o, n, e, ,,  , z, e, r, o, ,,  , z, e, r, o')]
```

class sage.combinat.finite_state_machine.**FSMState**(*label*, *word_out=None*, *is_initial=False*, *is_final=False*, *final_word_out=None*, *initial_probability=None*, *hook=None*, *color=None*, *allow_label_None=False*)

Bases: SageObject

Class for a state of a finite state machine.

INPUT:

- label – the label of the state
- word_out – (default: None) a word that is written when the state is reached
- is_initial – (default: False)
- is_final – (default: False)
- final_word_out – (default: None) a word that is written when the state is reached as the last state of some input; only for final states.
- initial_probability – (default: None) the probability of starting in this state if it is a state of a Markov chain
- hook – (default: None) a function which is called when the state is reached during processing input. It takes two input parameters: the first is the current state (to allow using the same hook for several states), the second is the current process iterator object (to have full access to everything; e.g. the next letter from the input tape can be read in). It can output the next transition, i.e. the transition to take next. If it returns None the process iterator chooses. Moreover, this function can raise a StopIteration exception to stop processing of a finite state machine the input immediately. See also the example below.
- color – (default: None) in order to distinguish states, they can be given an arbitrary "color" (an arbitrary object). This is used in *FiniteStateMachine.equivalence_classes()*: states of different colors are never considered to be equivalent. Note that *Automaton.determinisation()* requires that color is hashable.
- allow_label_None – boolean (default: False); if True allows also None as label. Note that a state with label None is used in *FSMProcessIterator*.

OUTPUT: a state of a finite state machine

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('state 1', word_out=0, is_initial=True)
sage: A
'state 1'
sage: A.label()
'state 1'
sage: B = FSMState('state 2')
sage: A == B
False
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('state 1', word_out=Integer(0), is_initial=True)
>>> A
'state 1'
>>> A.label()
'state 1'
>>> B = FSMState('state 2')
>>> A == B
False
```

We can also define a final output word of a final state which is used if the input of a transducer leads to this state. Such final output words are used in subsequential transducers.

```
sage: C = FSMState('state 3', is_final=True, final_word_out='end')
sage: C.final_word_out
['end']
```

```
>>> from sage.all import *
>>> C = FSMState('state 3', is_final=True, final_word_out='end')
>>> C.final_word_out
['end']
```

The final output word can be a single letter, `None` or a list of letters:

```
sage: A = FSMState('A')
sage: A.is_final = True
sage: A.final_word_out = 2
sage: A.final_word_out
[2]
sage: A.final_word_out = [2, 3]
sage: A.final_word_out
[2, 3]
```

```
>>> from sage.all import *
>>> A = FSMState('A')
>>> A.is_final = True
>>> A.final_word_out = Integer(2)
>>> A.final_word_out
[2]
>>> A.final_word_out = [Integer(2), Integer(3)]
>>> A.final_word_out
[2, 3]
```

Only final states can have a final output word which is not `None`:

```
sage: B = FSMState('B')
sage: B.final_word_out is None
True
sage: B.final_word_out = 2
Traceback (most recent call last):
...
ValueError: Only final states can have a final output word,
but state B is not final.
```

```
>>> from sage.all import *
>>> B = FSMState('B')
>>> B.final_word_out is None
True
>>> B.final_word_out = Integer(2)
Traceback (most recent call last):
...
ValueError: Only final states can have a final output word,
but state B is not final.
```

Setting the `final_word_out` of a final state to `None` is the same as setting it to `[]` and is also the default for a final state:

```
sage: C = FSMState('C', is_final=True)
sage: C.final_word_out
[]
sage: C.final_word_out = None
sage: C.final_word_out
[]
sage: C.final_word_out = []
sage: C.final_word_out
[]
```

```
>>> from sage.all import *
>>> C = FSMState('C', is_final=True)
>>> C.final_word_out
[]
>>> C.final_word_out = None
>>> C.final_word_out
[]
>>> C.final_word_out = []
>>> C.final_word_out
[]
```

It is not allowed to use `None` as a label:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: FSMState(None)
Traceback (most recent call last):
...
ValueError: Label None reserved for a special state,
choose another label.
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> FSMState(None)
Traceback (most recent call last):
...
ValueError: Label None reserved for a special state,
choose another label.
```

This can be overridden by:

```
sage: FSMState(None, allow_label_None=True)
None
```

```
>>> from sage.all import *
>>> FSMState(None, allow_label_None=True)
None
```

Note that *`Automaton.determinisation()`* requires that `color` is hashable:

```
sage: A = Automaton([[0, 0, 0]], initial_states=[0])
sage: A.state(0).color = []
sage: A.determinisation()
Traceback (most recent call last):
...
TypeError: unhashable type: 'list'
sage: A.state(0).color = ()
sage: A.determinisation()
Automaton with 1 state
```

```
>>> from sage.all import *
>>> A = Automaton([[Integer(0), Integer(0), Integer(0)]], initial_
↪states=[Integer(0)])
>>> A.state(Integer(0)).color = []
>>> A.determinisation()
Traceback (most recent call last):
...
TypeError: unhashable type: 'list'
>>> A.state(Integer(0)).color = ()
>>> A.determinisation()
Automaton with 1 state
```

We can use a hook function of a state to stop processing. This is done by raising a `StopIteration` exception. The following code demonstrates this:

```
sage: T = Transducer([(0, 1, 9, 'a'), (1, 2, 9, 'b'),
....:                  (2, 3, 9, 'c'), (3, 4, 9, 'd')],
....:                 initial_states=[0],
....:                 final_states=[4],
....:                 input_alphabet=[9])
sage: def stop(process, state, output):
....:     raise StopIteration()
sage: T.state(3).hook = stop
sage: T.process([9, 9, 9, 9])
(False, 3, ['a', 'b', 'c'])
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(1), Integer(9), 'a'), (Integer(1),␣
↪Integer(2), Integer(9), 'b'),
...                  (Integer(2), Integer(3), Integer(9), 'c'), (Integer(3),␣
↪Integer(4), Integer(9), 'd')],
...                 initial_states=[Integer(0)],
...                 final_states=[Integer(4)],
...                 input_alphabet=[Integer(9)])
>>> def stop(process, state, output):
...     raise StopIteration()
>>> T.state(Integer(3)).hook = stop
>>> T.process([Integer(9), Integer(9), Integer(9), Integer(9)])
(False, 3, ['a', 'b', 'c'])
```

copy()

Return a (shallow) copy of the state.

OUTPUT: a new state

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: A.is_initial = True
sage: A.is_final = True
sage: A.final_word_out = [1]
sage: A.color = 'green'
sage: A.initial_probability = 1/2
sage: B = copy(A)
sage: B.fully_equal(A)
True
sage: A.label() is B.label()
True
sage: A.is_initial is B.is_initial
True
sage: A.is_final is B.is_final
True
sage: A.final_word_out is B.final_word_out
True
sage: A.color is B.color
True
sage: A.initial_probability is B.initial_probability
True
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('A')
>>> A.is_initial = True
>>> A.is_final = True
>>> A.final_word_out = [Integer(1)]
>>> A.color = 'green'
>>> A.initial_probability = Integer(1)/Integer(2)
>>> B = copy(A)
>>> B.fully_equal(A)
True
>>> A.label() is B.label()
True
>>> A.is_initial is B.is_initial
True
>>> A.is_final is B.is_final
True
>>> A.final_word_out is B.final_word_out
True
>>> A.color is B.color
True
>>> A.initial_probability is B.initial_probability
True
```

deepcopy (*memo=None*)

Return a deep copy of the state.

INPUT:

- memo – (default: None) a dictionary storing already processed elements

OUTPUT: a new state

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState((1, 3), color=[1, 2],
....:              is_final=True, final_word_out=3,
....:              initial_probability=1/3)
sage: B = deepcopy(A)
sage: B
(1, 3)
sage: B.label() == A.label()
True
sage: B.label is A.label
False
sage: B.color == A.color
True
sage: B.color is A.color
False
sage: B.is_final == A.is_final
True
sage: B.is_final is A.is_final
True
sage: B.final_word_out == A.final_word_out
True
sage: B.final_word_out is A.final_word_out
False
sage: B.initial_probability == A.initial_probability
True
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState((Integer(1), Integer(3)), color=[Integer(1), Integer(2)],
...              is_final=True, final_word_out=Integer(3),
...              initial_probability=Integer(1)/Integer(3))
>>> B = deepcopy(A)
>>> B
(1, 3)
>>> B.label() == A.label()
True
>>> B.label is A.label
False
>>> B.color == A.color
True
>>> B.color is A.color
False
>>> B.is_final == A.is_final
True
>>> B.is_final is A.is_final
True
>>> B.final_word_out == A.final_word_out
True
```

(continues on next page)

(continued from previous page)

```
>>> B.final_word_out is A.final_word_out
False
>>> B.initial_probability == A.initial_probability
True
```

property final_word_out

The final output word of a final state which is written if the state is reached as the last state of the input of the finite state machine. For a non-final state, the value is None.

final_word_out can be a single letter, a list or None, but for a final-state, it is always saved as a list.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_final=True, final_word_out=2)
sage: A.final_word_out
[2]
sage: A.final_word_out = 3
sage: A.final_word_out
[3]
sage: A.final_word_out = [3, 4]
sage: A.final_word_out
[3, 4]
sage: A.final_word_out = None
sage: A.final_word_out
[]
sage: B = FSMState('B')
sage: B.final_word_out is None
True
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('A', is_final=True, final_word_out=Integer(2))
>>> A.final_word_out
[2]
>>> A.final_word_out = Integer(3)
>>> A.final_word_out
[3]
>>> A.final_word_out = [Integer(3), Integer(4)]
>>> A.final_word_out
[3, 4]
>>> A.final_word_out = None
>>> A.final_word_out
[]
>>> B = FSMState('B')
>>> B.final_word_out is None
True
```

A non-final state cannot have a final output word:

```
sage: B.final_word_out = [3, 4]
Traceback (most recent call last):
...
```

(continues on next page)

(continued from previous page)

```
ValueError: Only final states can have a final
output word, but state B is not final.
```

```
>>> from sage.all import *
>>> B.final_word_out = [Integer(3), Integer(4)]
Traceback (most recent call last):
...
ValueError: Only final states can have a final
output word, but state B is not final.
```

fully_equal(*other*, *compare_color=True*)

Check whether two states are fully equal, i.e., including all attributes except `hook`.

INPUT:

- `self` – a state
- `other` – a state
- `compare_color` – boolean (default: `True`); if `True` colors are compared as well, otherwise not

OUTPUT: boolean

Note that usual comparison by == does only compare the labels.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: B = FSMState('A', is_initial=True)
sage: A.fully_equal(B)
False
sage: A == B
True
sage: A.is_initial = True; A.color = 'green'
sage: A.fully_equal(B)
False
sage: A.fully_equal(B, compare_color=False)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('A')
>>> B = FSMState('A', is_initial=True)
>>> A.fully_equal(B)
False
>>> A == B
True
>>> A.is_initial = True; A.color = 'green'
>>> A.fully_equal(B)
False
>>> A.fully_equal(B, compare_color=False)
True
```

initial_probability = None

property is_final

Describe whether the state is final or not.

`True` if the state is final and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_final=True, final_word_out=3)
sage: A.is_final
True
sage: A.is_final = False
Traceback (most recent call last):
...
ValueError: State A cannot be non-final, because it has a
final output word. Only final states can have a final output
word.
sage: A.final_word_out = None
sage: A.is_final = False
sage: A.is_final
False
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('A', is_final=True, final_word_out=Integer(3))
>>> A.is_final
True
>>> A.is_final = False
Traceback (most recent call last):
...
ValueError: State A cannot be non-final, because it has a
final output word. Only final states can have a final output
word.
>>> A.final_word_out = None
>>> A.is_final = False
>>> A.is_final
False
```

is_initial = False

label()

Return the label of the state.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('state')
sage: A.label()
'state'
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('state')
>>> A.label()
'state'
```

relabeled(*label*, *memo=None*)

Return a deep copy of the state with a new label.

INPUT:

- `label` – the label of new state
- `memo` – (default: `None`) a dictionary storing already processed elements

OUTPUT: a new state

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: A.relabeled('B')
'B'
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('A')
>>> A.relabeled('B')
'B'
```

class sage.combinat.finite_state_machine.**FSMTransition**(*from_state*, *to_state*, *word_in=None*, *word_out=None*, *hook=None*)

Bases: `SageObject`

Class for a transition of a finite state machine.

INPUT:

- `from_state` – state from which transition starts
- `to_state` – state in which transition ends
- `word_in` – the input word of the transitions (when the finite state machine is used as automaton)
- `word_out` – the output word of the transitions (when the finite state machine is used as transducer)

OUTPUT: a transition of a finite state machine

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState, FSMTransition
sage: A = FSMState('A')
sage: B = FSMState('B')
sage: S = FSMTransition(A, B, 0, 1)
sage: T = FSMTransition('A', 'B', 0, 1)
sage: T == S
True
sage: U = FSMTransition('A', 'B', 0)
sage: U == T
False
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState, FSMTransition
>>> A = FSMState('A')
>>> B = FSMState('B')
```

(continues on next page)

(continued from previous page)

```
>>> S = FSMTransition(A, B, Integer(0), Integer(1))
>>> T = FSMTransition('A', 'B', Integer(0), Integer(1))
>>> T == S
True
>>> U = FSMTransition('A', 'B', Integer(0))
>>> U == T
False
```

copy()

Return a (shallow) copy of the transition.

OUTPUT: a new transition

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: t = FSMTransition('A', 'B', 0)
sage: copy(t)
Transition from 'A' to 'B': 0|-
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMTransition
>>> t = FSMTransition('A', 'B', Integer(0))
>>> copy(t)
Transition from 'A' to 'B': 0|-
```

deepcopy(*memo=None*)

Return a deep copy of the transition.

INPUT:

- `memo` – (default: `None`) a dictionary storing already processed elements

OUTPUT: a new transition

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: t = FSMTransition('A', 'B', 0)
sage: deepcopy(t)
Transition from 'A' to 'B': 0|-
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMTransition
>>> t = FSMTransition('A', 'B', Integer(0))
>>> deepcopy(t)
Transition from 'A' to 'B': 0|-
```

from_state = None

State from which the transition starts. Read-only.

to_state = None

State in which the transition ends. Read-only.

word_in = None

Input word of the transition. Read-only.

word_out = None

Output word of the transition. Read-only.

sage.combinat.finite_state_machine.**FSMWordSymbol**(*word*)

Return a string of `word`. It may returns the symbol of the empty word `FSMEmptyWordSymbol`.

INPUT:

- `word` – the input word

OUTPUT: string of `word`

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMWordSymbol
sage: FSMWordSymbol([0, 1, 1])
'0,1,1'
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMWordSymbol
>>> FSMWordSymbol([Integer(0), Integer(1), Integer(1)])
'0,1,1'
```

class sage.combinat.finite_state_machine.**FiniteStateMachine**(*data=None*, *initial_states=None*, *final_states=None*, *input_alphabet=None*, *output_alphabet=None*, *determine_alphabets=None*, *with_final_word_out=None*, *store_states_dict=True*, *on_duplicate_transition=None*)

Bases: `SageObject`

Class for a finite state machine.

A finite state machine is a finite set of states connected by transitions.

INPUT:

- `data` – can be any of the following:
  1. a dictionary of dictionaries (of transitions),
  2. a dictionary of lists (of states or transitions),
  3. a list (of transitions),
  4. a function (transition function),
  5. an other instance of a finite state machine.
- `initial_states` and `final_states` – the initial and final states of this machine
- `input_alphabet` and `output_alphabet` – the input and output alphabets of this machine
- `determine_alphabets` – if `True`, then the function `determine_alphabets()` is called after `data` was read and processed, if `False`, then not. If it is `None`, then it is decided during the construction of the finite state machine whether `determine_alphabets()` should be called.

- `with_final_word_out` – if given (not `None`), then the function `with_final_word_out()` (more precisely, its inplace pendant `construct_final_word_out()`) is called with input `letters=with_final_word_out` at the end of the creation process.
- `store_states_dict` – if `True`, then additionally the states are stored in an internal dictionary for speed up
- `on_duplicate_transition` – a function which is called when a transition is inserted into `self` which already existed (same `from_state`, same `to_state`, same `word_in`, same `word_out`).

  This function is assumed to take two arguments, the first being the already existing transition, the second being the new transition (as an `FSMTransition`). The function must return the (possibly modified) original transition.

  By default, we have `on_duplicate_transition=None`, which is interpreted as `on_duplicate_transition=duplicate_transition_ignore`, where `duplicate_transition_ignore` is a predefined function ignoring the occurrence. Other such predefined functions are `duplicate_transition_raise_error` and `duplicate_transition_add_input`.

OUTPUT: a finite state machine

The object creation of `Automaton` and `Transducer` is the same as the one described here (i.e. just replace the word `FiniteStateMachine` by `Automaton` or `Transducer`).

Each transition of an automaton has an input label. Automata can, for example, be determinised (see `Automaton.determinisation()`) and minimized (see `Automaton.minimization()`). Each transition of a transducer has an input and an output label. Transducers can, for example, be simplified (see `Transducer.simplification()`).

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState, FSMTransition
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState, FSMTransition
```

See documentation for more examples.

We illustrate the different input formats:

1. The input-data can be a dictionary of dictionaries, where

   - the keys of the outer dictionary are state-labels (from-states of transitions),
   - the keys of the inner dictionaries are state-labels (to-states of transitions),
   - the values of the inner dictionaries specify the transition more precisely.

   The easiest is to use a tuple consisting of an input and an output word:

   ```
   sage: FiniteStateMachine({'a':{'b':(0, 1), 'c':(1, 1)}})
   Finite state machine with 3 states
   ```

   ```
   >>> from sage.all import *
   >>> FiniteStateMachine({'a':{'b':(Integer(0), Integer(1)), 'c':(Integer(1),␣
   ↪Integer(1))}})
   Finite state machine with 3 states
   ```

   Instead of the tuple anything iterable (e.g. a list) can be used as well.

   If you want to use the arguments of `FSMTransition` directly, you can use a dictionary:

```
sage: FiniteStateMachine({'a':{'b':{'word_in':0, 'word_out':1},
....:                          'c':{'word_in':1, 'word_out':1}}})
Finite state machine with 3 states
```

```
>>> from sage.all import *
>>> FiniteStateMachine({'a':{'b':{'word_in':Integer(0), 'word_out':Integer(1)}
↪,
...                          'c':{'word_in':Integer(1), 'word_out':Integer(1)}
↪}})
Finite state machine with 3 states
```

In the case you already have instances of *FSMTransition*, it is possible to use them directly:

```
sage: FiniteStateMachine({'a':{'b':FSMTransition('a', 'b', 0, 1),
....:                          'c':FSMTransition('a', 'c', 1, 1)}})
Finite state machine with 3 states
```

```
>>> from sage.all import *
>>> FiniteStateMachine({'a':{'b':FSMTransition('a', 'b', Integer(0),␣
↪Integer(1)),
...                          'c':FSMTransition('a', 'c', Integer(1),␣
↪Integer(1))}})
Finite state machine with 3 states
```

2. The input-data can be a dictionary of lists, where the keys are states or label of states.

   The list-elements can be states:

```
sage: a = FSMState('a')
sage: b = FSMState('b')
sage: c = FSMState('c')
sage: FiniteStateMachine({a:[b, c]})
Finite state machine with 3 states
```

```
>>> from sage.all import *
>>> a = FSMState('a')
>>> b = FSMState('b')
>>> c = FSMState('c')
>>> FiniteStateMachine({a:[b, c]})
Finite state machine with 3 states
```

   Or the list-elements can simply be labels of states:

```
sage: FiniteStateMachine({'a':['b', 'c']})
Finite state machine with 3 states
```

```
>>> from sage.all import *
>>> FiniteStateMachine({'a':['b', 'c']})
Finite state machine with 3 states
```

   The list-elements can also be transitions:

```
sage: FiniteStateMachine({'a':[FSMTransition('a', 'b', 0, 1),
....:                          FSMTransition('a', 'c', 1, 1)]})
Finite state machine with 3 states
```

```
>>> from sage.all import *
>>> FiniteStateMachine({'a':[FSMTransition('a', 'b', Integer(0), Integer(1)),
...                          FSMTransition('a', 'c', Integer(1), Integer(1))]}
↪)
Finite state machine with 3 states
```

Or they can be tuples of a label, an input word and an output word specifying a transition:

```
sage: FiniteStateMachine({'a':[('b', 0, 1), ('c', 1, 1)]})
Finite state machine with 3 states
```

```
>>> from sage.all import *
>>> FiniteStateMachine({'a':[('b', Integer(0), Integer(1)), ('c', Integer(1),␣
↪Integer(1))]})
Finite state machine with 3 states
```

3. The input-data can be a list, where its elements specify transitions:

```
sage: FiniteStateMachine([FSMTransition('a', 'b', 0, 1),
....:                     FSMTransition('a', 'c', 1, 1)])
Finite state machine with 3 states
```

```
>>> from sage.all import *
>>> FiniteStateMachine([FSMTransition('a', 'b', Integer(0), Integer(1)),
...                     FSMTransition('a', 'c', Integer(1), Integer(1))])
Finite state machine with 3 states
```

It is possible to skip `FSMTransition` in the example above:

```
sage: FiniteStateMachine([('a', 'b', 0, 1), ('a', 'c', 1, 1)])
Finite state machine with 3 states
```

```
>>> from sage.all import *
>>> FiniteStateMachine([('a', 'b', Integer(0), Integer(1)), ('a', 'c',␣
↪Integer(1), Integer(1))])
Finite state machine with 3 states
```

The parameters of the transition are given in tuples. Anyhow, anything iterable (e.g. a list) is possible.

You can also name the parameters of the transition. For this purpose you take a dictionary:

```
sage: FiniteStateMachine([{'from_state':'a', 'to_state':'b',
....:                      'word_in':0, 'word_out':1},
....:                     {'from_state':'a', 'to_state':'c',
....:                      'word_in':1, 'word_out':1}])
Finite state machine with 3 states
```

```
>>> from sage.all import *
>>> FiniteStateMachine([{'from_state':'a', 'to_state':'b',
```

(continues on next page)

(continued from previous page)

```
...                          'word_in':Integer(0), 'word_out':Integer(1)},
...                         {'from_state':'a', 'to_state':'c',
...                          'word_in':Integer(1), 'word_out':Integer(1)}])
Finite state machine with 3 states
```

Other arguments, which `FSMTransition` accepts, can be added, too.

4. The input-data can also be function acting as transition function:

   This function has two input arguments:

   1. a label of a state (from which the transition starts),
   2. a letter of the (input-)alphabet (as input-label of the transition).

   It returns a tuple with the following entries:

   1. a label of a state (to which state the transition goes),
   2. a letter of or a word over the (output-)alphabet (as output-label of the transition).

   It may also output a list of such tuples if several transitions from the from-state and the input letter exist (this means that the finite state machine is non-deterministic).

   If the transition does not exist, the function should raise a `LookupError` or return an empty list.

   When constructing a finite state machine in this way, some initial states and an input alphabet have to be specified.

```
sage: def f(state_from, read):
....:     if int(state_from) + read <= 2:
....:         state_to = 2*int(state_from)+read
....:         write = 0
....:     else:
....:         state_to = 2*int(state_from) + read - 5
....:         write = 1
....:     return (str(state_to), write)
sage: F = FiniteStateMachine(f, input_alphabet=[0, 1],
....:                        initial_states=['0'],
....:                        final_states=['0'])
sage: F([1, 0, 1])
(True, '0', [0, 0, 1])
```

```
>>> from sage.all import *
>>> def f(state_from, read):
...     if int(state_from) + read <= Integer(2):
...         state_to = Integer(2)*int(state_from)+read
...         write = Integer(0)
...     else:
...         state_to = Integer(2)*int(state_from) + read - Integer(5)
...         write = Integer(1)
...     return (str(state_to), write)
>>> F = FiniteStateMachine(f, input_alphabet=[Integer(0), Integer(1)],
...                        initial_states=['0'],
...                        final_states=['0'])
>>> F([Integer(1), Integer(0), Integer(1)])
(True, '0', [0, 0, 1])
```

5. The input-data can be an other instance of a finite state machine:

```
sage: F = FiniteStateMachine()
sage: G = Transducer(F)
sage: G == F
True
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine()
>>> G = Transducer(F)
>>> G == F
True
```

The other parameters cannot be specified in that case. If you want to change these, use the attributes *FSMState.is_initial*, *FSMState.is_final*, *input_alphabet*, *output_alphabet*, *on_duplicate_transition* and methods *determine_alphabets()*, *construct_final_word_out()* on the new machine, respectively.

The following examples demonstrate the use of `on_duplicate_transition`:

```
sage: F = FiniteStateMachine([['a', 'a', 1/2], ['a', 'a', 1/2]])
sage: F.transitions()
[Transition from 'a' to 'a': 1/2|-]
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine([['a', 'a', Integer(1)/Integer(2)], ['a', 'a',␣
↪Integer(1)/Integer(2)]])
>>> F.transitions()
[Transition from 'a' to 'a': 1/2|-]
```

```
sage: from sage.combinat.finite_state_machine import duplicate_transition_raise_
↪error
sage: F1 = FiniteStateMachine([['a', 'a', 1/2], ['a', 'a', 1/2]],
....:                         on_duplicate_transition=duplicate_transition_raise_
↪error)
Traceback (most recent call last):
...
ValueError: Attempting to re-insert transition Transition from 'a' to 'a': 1/2|-
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import duplicate_transition_raise_
↪error
>>> F1 = FiniteStateMachine([['a', 'a', Integer(1)/Integer(2)], ['a', 'a',␣
↪Integer(1)/Integer(2)]],
...                         on_duplicate_transition=duplicate_transition_raise_
↪error)
Traceback (most recent call last):
...
ValueError: Attempting to re-insert transition Transition from 'a' to 'a': 1/2|-
```

Use `duplicate_transition_add_input` to emulate a Markov chain, the input labels are considered as transition probabilities:

```
sage: from sage.combinat.finite_state_machine import duplicate_transition_add_
↪input
sage: F = FiniteStateMachine([['a', 'a', 1/2], ['a', 'a', 1/2]],
....:                        on_duplicate_transition=duplicate_transition_add_
↪input)
sage: F.transitions()
[Transition from 'a' to 'a': 1|-]
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import duplicate_transition_add_input
>>> F = FiniteStateMachine([['a', 'a', Integer(1)/Integer(2)], ['a', 'a',␣
↪Integer(1)/Integer(2)]],
...                        on_duplicate_transition=duplicate_transition_add_input)
>>> F.transitions()
[Transition from 'a' to 'a': 1|-]
```

Use `with_final_word_out` to construct final output:

```
sage: T = Transducer([(0, 1, 0, 0), (1, 0, 0, 0)],
....:                initial_states=[0],
....:                final_states=[0],
....:                with_final_word_out=0)
sage: for s in T.iter_final_states():
....:     print("{} {}".format(s, s.final_word_out))
0 []
1 [0]
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(1), Integer(0), Integer(0)), (Integer(1),
↪ Integer(0), Integer(0), Integer(0))],
...                initial_states=[Integer(0)],
...                final_states=[Integer(0)],
...                with_final_word_out=Integer(0))
>>> for s in T.iter_final_states():
...     print("{} {}".format(s, s.final_word_out))
0 []
1 [0]
```

`__call__`(**args, **kwargs*)

Call either method *`composition()`* or *`process()`* (with `full_output=False`). If the input is not finite (`is_finite` of input is `False`), then *`iter_process()`* (with `iterator_type='simple'`) is called. Moreover, the flag `automatic_output_type` is set (unless `format_output` is specified). See the documentation of these functions for possible parameters.

EXAMPLES:

The following code performs a *`composition()`*:

```
sage: F = Transducer([('A', 'B', 1, 0), ('B', 'B', 1, 1),
....:                 ('B', 'B', 0, 0)],
....:                initial_states=['A'], final_states=['B'])
sage: G = Transducer([(1, 1, 0, 0), (1, 2, 1, 0),
....:                 (2, 2, 0, 1), (2, 1, 1, 1)],
```

(continues on next page)

(continued from previous page)

```
....:                   initial_states=[1], final_states=[1])
sage: H = G(F)
sage: H.states()
[('A', 1), ('B', 1), ('B', 2)]
```

```
>>> from sage.all import *
>>> F = Transducer([('A', 'B', Integer(1), Integer(0)), ('B', 'B', Integer(1),
↪ Integer(1)),
...                  ('B', 'B', Integer(0), Integer(0))],
...                 initial_states=['A'], final_states=['B'])
>>> G = Transducer([(Integer(1), Integer(1), Integer(0), Integer(0)),␣
↪(Integer(1), Integer(2), Integer(1), Integer(0)),
...                  (Integer(2), Integer(2), Integer(0), Integer(1)),␣
↪(Integer(2), Integer(1), Integer(1), Integer(1))],
...                 initial_states=[Integer(1)], final_states=[Integer(1)])
>>> H = G(F)
>>> H.states()
[('A', 1), ('B', 1), ('B', 2)]
```

An automaton or transducer can also act on an input (a list or other iterable of letters):

```
sage: binary_inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
....:                              initial_states=['A'], final_states=['A'])
sage: binary_inverter([0, 1, 0, 0, 1, 1])
[1, 0, 1, 1, 0, 0]
```

```
>>> from sage.all import *
>>> binary_inverter = Transducer({'A': [('A', Integer(0), Integer(1)), ('A',␣
↪Integer(1), Integer(0))]},
...                              initial_states=['A'], final_states=['A'])
>>> binary_inverter([Integer(0), Integer(1), Integer(0), Integer(0),␣
↪Integer(1), Integer(1)])
[1, 0, 1, 1, 0, 0]
```

We can also let them act on *words*:

```
sage: # needs sage.combinat
sage: W = Words([0, 1]); W
Finite and infinite words over {0, 1}
sage: binary_inverter(W([0, 1, 1, 0, 1, 1]))
word: 100100
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> W = Words([Integer(0), Integer(1)]); W
Finite and infinite words over {0, 1}
>>> binary_inverter(W([Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(1), Integer(1)]))
word: 100100
```

Infinite words work as well:

```
sage: # needs sage.combinat
sage: words.FibonacciWord()
word: 0100101001001010010100100101001001010010...
sage: binary_inverter(words.FibonacciWord())
word: 1011010110110101101011011010110110101101...
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> words.FibonacciWord()
word: 0100101001001010010100100101001001010010...
>>> binary_inverter(words.FibonacciWord())
word: 1011010110110101101011011010110110101101...
```

When only one successful path is found in a non-deterministic transducer, the result of that path is returned.

```
sage: T = Transducer([(0, 1, 0, 1), (0, 2, 0, 2)],
....:                initial_states=[0], final_states=[1])
sage: T.process([0])
[(False, 2, [2]), (True, 1, [1])]
sage: T([0])
[1]
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(1), Integer(0), Integer(1)),␣
→(Integer(0), Integer(2), Integer(0), Integer(2))],
...                initial_states=[Integer(0)], final_states=[Integer(1)])
>>> T.process([Integer(0)])
[(False, 2, [2]), (True, 1, [1])]
>>> T([Integer(0)])
[1]
```

See also

composition(), *process()*, *iter_process()*, *Automaton.process()*, *Transducer.process()*.

accessible_components()

Return a new finite state machine with the accessible states of `self` and all transitions between those states.

OUTPUT:

A finite state machine with the accessible states of `self` and all transitions between those states.

A state is accessible if there is a directed path from an initial state to the state. If `self` has no initial states then a copy of the finite state machine `self` is returned.

EXAMPLES:

```
sage: F = Automaton([(0, 0, 0), (0, 1, 1), (1, 1, 0), (1, 0, 1)],
....:               initial_states=[0])
sage: F.accessible_components()
Automaton with 2 states
```

```
>>> from sage.all import *
>>> F = Automaton([(Integer(0), Integer(0), Integer(0)), (Integer(0),␣
↪Integer(1), Integer(1)), (Integer(1), Integer(1), Integer(0)), (Integer(1),␣
↪Integer(0), Integer(1))],
...               initial_states=[Integer(0)])
>>> F.accessible_components()
Automaton with 2 states
```

```
sage: F = Automaton([(0, 0, 1), (0, 0, 1), (1, 1, 0), (1, 0, 1)],
....:               initial_states=[0])
sage: F.accessible_components()
Automaton with 1 state
```

```
>>> from sage.all import *
>>> F = Automaton([(Integer(0), Integer(0), Integer(1)), (Integer(0),␣
↪Integer(0), Integer(1)), (Integer(1), Integer(1), Integer(0)), (Integer(1),␣
↪Integer(0), Integer(1))],
...               initial_states=[Integer(0)])
>>> F.accessible_components()
Automaton with 1 state
```

See also

coaccessible_components()

add_from_transition_function(*function*, *initial_states=None*, *explore_existing_states=True*)

Construct a finite state machine from a transition function.

INPUT:

- `function` may return a tuple (new_state, output_word) or a list of such tuples
- `initial_states` – if no initial states are given, the already existing initial states of `self` are taken
- `explore_existing_states` – boolean (default: `True`); if `True` (default), then already existing states in `self` (e.g. already given final states) will also be processed if they are reachable from the initial statess

OUTPUT: nothing

EXAMPLES:

```
sage: F = FiniteStateMachine(initial_states=['A'],
....:                        input_alphabet=[0, 1])
sage: def f(state, input):
....:     return [('A', input), ('B', 1-input)]
sage: F.add_from_transition_function(f)
sage: F.transitions()
[Transition from 'A' to 'A': 0|0,
Transition from 'A' to 'B': 0|1,
Transition from 'A' to 'A': 1|1,
Transition from 'A' to 'B': 1|0,
Transition from 'B' to 'A': 0|0,
Transition from 'B' to 'B': 0|1,
```

(continues on next page)

(continued from previous page)

```
Transition from 'B' to 'A': 1|1,
Transition from 'B' to 'B': 1|0]
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine(initial_states=['A'],
...                        input_alphabet=[Integer(0), Integer(1)])
>>> def f(state, input):
...     return [('A', input), ('B', Integer(1)-input)]
>>> F.add_from_transition_function(f)
>>> F.transitions()
[Transition from 'A' to 'A': 0|0,
Transition from 'A' to 'B': 0|1,
Transition from 'A' to 'A': 1|1,
Transition from 'A' to 'B': 1|0,
Transition from 'B' to 'A': 0|0,
Transition from 'B' to 'B': 0|1,
Transition from 'B' to 'A': 1|1,
Transition from 'B' to 'B': 1|0]
```

Initial states can also be given as a parameter:

```
sage: F = FiniteStateMachine(input_alphabet=[0,1])
sage: def f(state, input):
....:     return [('A', input), ('B', 1-input)]
sage: F.add_from_transition_function(f,initial_states=['A'])
sage: F.initial_states()
['A']
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine(input_alphabet=[Integer(0),Integer(1)])
>>> def f(state, input):
...     return [('A', input), ('B', Integer(1)-input)]
>>> F.add_from_transition_function(f,initial_states=['A'])
>>> F.initial_states()
['A']
```

Already existing states in the finite state machine (the final states in the example below) are also explored:

```
sage: F = FiniteStateMachine(initial_states=[0],
....:                        final_states=[1],
....:                        input_alphabet=[0])
sage: def transition_function(state, letter):
....:     return 1 - state, []
sage: F.add_from_transition_function(transition_function)
sage: F.transitions()
[Transition from 0 to 1: 0|-,
 Transition from 1 to 0: 0|-]
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine(initial_states=[Integer(0)],
...                        final_states=[Integer(1)],
...                        input_alphabet=[Integer(0)])
```

(continues on next page)

(continued from previous page)

```
>>> def transition_function(state, letter):
...     return Integer(1) - state, []
>>> F.add_from_transition_function(transition_function)
>>> F.transitions()
[Transition from 0 to 1: 0|-,
 Transition from 1 to 0: 0|-]
```

If `explore_existing_states=False`, however, this behavior is turned off, i.e., already existing states are not explored:

```
sage: F = FiniteStateMachine(initial_states=[0],
....:                        final_states=[1],
....:                        input_alphabet=[0])
sage: def transition_function(state, letter):
....:     return 1 - state, []
sage: F.add_from_transition_function(transition_function,
....:                                explore_existing_states=False)
sage: F.transitions()
[Transition from 0 to 1: 0|-]
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine(initial_states=[Integer(0)],
...                        final_states=[Integer(1)],
...                        input_alphabet=[Integer(0)])
>>> def transition_function(state, letter):
...     return Integer(1) - state, []
>>> F.add_from_transition_function(transition_function,
...                                explore_existing_states=False)
>>> F.transitions()
[Transition from 0 to 1: 0|-]
```

add_state(*state*)

Add a state to the finite state machine and returns the new state. If the state already exists, that existing state is returned.

INPUT:

- `state` is either an instance of *FSMState* or, otherwise, a label of a state.

OUTPUT: the new or existing state

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: F = FiniteStateMachine()
sage: A = FSMState('A', is_initial=True)
sage: F.add_state(A)
'A'
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> F = FiniteStateMachine()
>>> A = FSMState('A', is_initial=True)
```

(continues on next page)

(continued from previous page)

```
>>> F.add_state(A)
'A'
```

add_states(*states*)

Add several states. See add_state for more information.

INPUT:

- `states` – list of states or iterator over states

OUTPUT: nothing

EXAMPLES:

```
sage: F = FiniteStateMachine()
sage: F.add_states(['A', 'B'])
sage: F.states()
['A', 'B']
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine()
>>> F.add_states(['A', 'B'])
>>> F.states()
['A', 'B']
```

add_transition(**args*, ***kwargs*)

Add a transition to the finite state machine and returns the new transition.

If the transition already exists, the return value of `self.on_duplicate_transition` is returned. See the documentation of `FiniteStateMachine`.

INPUT:

The following forms are all accepted:

```
sage: from sage.combinat.finite_state_machine import FSMState, FSMTransition
sage: A = FSMState('A')
sage: B = FSMState('B')

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition(FSMTransition(A, B, 0, 1))
Transition from 'A' to 'B': 0|1

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition(A, B, 0, 1)
Transition from 'A' to 'B': 0|1

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition(A, B, word_in=0, word_out=1)
Transition from 'A' to 'B': 0|1

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition('A', 'B', {'word_in': 0, 'word_out': 1})
Transition from 'A' to 'B': {'word_in': 0, 'word_out': 1}|-
```

(continues on next page)

(continued from previous page)

```
sage: FSM = FiniteStateMachine()
sage: FSM.add_transition(from_state=A, to_state=B,
....:                    word_in=0, word_out=1)
Transition from 'A' to 'B': 0|1

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition({'from_state': A, 'to_state': B,
....:                    'word_in': 0, 'word_out': 1})
Transition from 'A' to 'B': 0|1

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition((A, B, 0, 1))
Transition from 'A' to 'B': 0|1

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition([A, B, 0, 1])
Transition from 'A' to 'B': 0|1
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState, FSMTransition
>>> A = FSMState('A')
>>> B = FSMState('B')

>>> FSM = FiniteStateMachine()
>>> FSM.add_transition(FSMTransition(A, B, Integer(0), Integer(1)))
Transition from 'A' to 'B': 0|1

>>> FSM = FiniteStateMachine()
>>> FSM.add_transition(A, B, Integer(0), Integer(1))
Transition from 'A' to 'B': 0|1

>>> FSM = FiniteStateMachine()
>>> FSM.add_transition(A, B, word_in=Integer(0), word_out=Integer(1))
Transition from 'A' to 'B': 0|1

>>> FSM = FiniteStateMachine()
>>> FSM.add_transition('A', 'B', {'word_in': Integer(0), 'word_out':
↪Integer(1)})
Transition from 'A' to 'B': {'word_in': 0, 'word_out': 1}|-

>>> FSM = FiniteStateMachine()
>>> FSM.add_transition(from_state=A, to_state=B,
...                    word_in=Integer(0), word_out=Integer(1))
Transition from 'A' to 'B': 0|1

>>> FSM = FiniteStateMachine()
>>> FSM.add_transition({'from_state': A, 'to_state': B,
...                    'word_in': Integer(0), 'word_out': Integer(1)})
Transition from 'A' to 'B': 0|1

>>> FSM = FiniteStateMachine()
>>> FSM.add_transition((A, B, Integer(0), Integer(1)))
```

(continues on next page)

(continued from previous page)

```
Transition from 'A' to 'B': 0|1

>>> FSM = FiniteStateMachine()
>>> FSM.add_transition([A, B, Integer(0), Integer(1)])
Transition from 'A' to 'B': 0|1
```

If the states `A` and `B` are not instances of `FSMState`, then it is assumed that they are labels of states.

OUTPUT:

The new transition.

add_transitions_from_function(*function*, *labels_as_input=True*)

Add one or more transitions if `function(state, state)` says that there are some.

INPUT:

- `function` – a transition function. Given two states `from_state` and `to_state` (or their labels if `label_as_input` is true), this function shall return a tuple `(word_in, word_out)` to add a transition from `from_state` to `to_state` with input and output labels `word_in` and `word_out`, respectively. If no such addition is to be added, the transition function shall return `None`. The transition function may also return a list of such tuples in order to add multiple transitions between the pair of states.
- `label_as_input` – (default: `True`)

OUTPUT: nothing

EXAMPLES:

```
sage: F = FiniteStateMachine()
sage: F.add_states(['A', 'B', 'C'])
sage: def f(state1, state2):
....:     if state1 == 'C':
....:         return None
....:     return (0, 1)
sage: F.add_transitions_from_function(f)
sage: len(F.transitions())
6
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine()
>>> F.add_states(['A', 'B', 'C'])
>>> def f(state1, state2):
...     if state1 == 'C':
...         return None
...     return (Integer(0), Integer(1))
>>> F.add_transitions_from_function(f)
>>> len(F.transitions())
6
```

Multiple transitions are also possible:

```
sage: F = FiniteStateMachine()
sage: F.add_states([0, 1])
sage: def f(state1, state2):
....:     if state1 != state2:
```

(continues on next page)

(continued from previous page)

```
....:           return [(0, 1), (1, 0)]
....:     else:
....:           return None
sage: F.add_transitions_from_function(f)
sage: F.transitions()
[Transition from 0 to 1: 0|1,
 Transition from 0 to 1: 1|0,
 Transition from 1 to 0: 0|1,
 Transition from 1 to 0: 1|0]
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine()
>>> F.add_states([Integer(0), Integer(1)])
>>> def f(state1, state2):
...     if state1 != state2:
...         return [(Integer(0), Integer(1)), (Integer(1), Integer(0))]
...     else:
...         return None
>>> F.add_transitions_from_function(f)
>>> F.transitions()
[Transition from 0 to 1: 0|1,
 Transition from 0 to 1: 1|0,
 Transition from 1 to 0: 0|1,
 Transition from 1 to 0: 1|0]
```

adjacency_matrix(*input=None*, *entry=None*)

Return the adjacency matrix of the underlying graph.

INPUT:

- `input` – only transitions with input label `input` are respected
- `entry` – the function `entry` takes a transition and the return value is written in the matrix as the entry `(transition.from_state, transition.to_state)`. The default value (`None`) of entry takes the variable `x` to the power of the sum of the output word of the transition.

OUTPUT: a matrix

If any label of a state is not an integer, the finite state machine is relabeled at the beginning. If there are more than one transitions between two states, then the different return values of `entry` are added up.

EXAMPLES:

```
sage: B = FiniteStateMachine({0:{0:(0, 0), 'a':(1, 0)},
....:                         'a':{2:(0, 0), 3:(1, 0)},
....:                         2:{0:(1, 1), 4:(0, 0)},
....:                         3:{'a':(0, 1), 2:(1, 1)},
....:                         4:{4:(1, 1), 3:(0, 1)}},
....:                        initial_states=[0])
sage: B.adjacency_matrix()                                              #␣
↪needs sage.symbolic
[1 1 0 0 0]
[0 0 1 1 0]
[x 0 0 0 1]
```

(continues on next page)

(continued from previous page)

```
[0 x x 0 0]
[0 0 0 x x]
```

```
>>> from sage.all import *
>>> B = FiniteStateMachine({Integer(0):{Integer(0):(Integer(0), Integer(0)),
↪'a':(Integer(1), Integer(0))},
...                          'a':{Integer(2):(Integer(0), Integer(0)),␣
↪Integer(3):(Integer(1), Integer(0))},
...                          Integer(2):{Integer(0):(Integer(1), Integer(1)),␣
↪Integer(4):(Integer(0), Integer(0))},
...                          Integer(3):{'a':(Integer(0), Integer(1)),␣
↪Integer(2):(Integer(1), Integer(1))},
...                          Integer(4):{Integer(4):(Integer(1), Integer(1)),␣
↪Integer(3):(Integer(0), Integer(1))}},
...                         initial_states=[Integer(0)])
>>> B.adjacency_matrix()                                                    #␣
↪needs sage.symbolic
[1 1 0 0 0]
[0 0 1 1 0]
[x 0 0 0 1]
[0 x x 0 0]
[0 0 0 x x]
```

This is equivalent to:

```
sage: matrix(B)                                                               #␣
↪needs sage.symbolic
[1 1 0 0 0]
[0 0 1 1 0]
[x 0 0 0 1]
[0 x x 0 0]
[0 0 0 x x]
```

```
>>> from sage.all import *
>>> matrix(B)                                                                #␣
↪needs sage.symbolic
[1 1 0 0 0]
[0 0 1 1 0]
[x 0 0 0 1]
[0 x x 0 0]
[0 0 0 x x]
```

It is also possible to use other entries in the adjacency matrix:

```
sage: B.adjacency_matrix(entry=(lambda transition: 1))
[1 1 0 0 0]
[0 0 1 1 0]
[1 0 0 0 1]
[0 1 1 0 0]
[0 0 0 1 1]
sage: var('t')                                                                #␣
↪needs sage.symbolic
```

(continues on next page)

(continued from previous page)

```
t
sage: B.adjacency_matrix(1, entry=(lambda transition:                          #␣
↪needs sage.symbolic
....:     exp(I*transition.word_out[0]*t)))
[      0       1       0       0       0]
[      0       0       0       1       0]
[e^(I*t)       0       0       0       0]
[      0       0 e^(I*t)       0       0]
[      0       0       0       0 e^(I*t)]
sage: a = Automaton([(0, 1, 0),
....:                (1, 2, 0),
....:                (2, 0, 1),
....:                (2, 1, 0)],
....:               initial_states=[0],
....:               final_states=[0])
sage: a.adjacency_matrix()                                                     #␣
↪needs sage.symbolic
[0 1 0]
[0 0 1]
[1 1 0]
```

```

...                (Integer(2), Integer(1), Integer(0))],
...               initial_states=[Integer(0)],
...               final_states=[Integer(0)])
>>> a.adjacency_matrix()                                                      #␣
↪needs sage.symbolic
[0 1 0]
[0 0 1]
[1 1 0]
```

asymptotic_moments(*variable=None*)

Return the main terms of expectation and variance of the sum of output labels and its covariance with the sum of input labels.

INPUT:

- `variable` – a symbol denoting the length of the input, (default: n)

OUTPUT: a dictionary consisting of

- `expectation` – $en + \mathrm{Order}(1)$,
- `variance` – $vn + \mathrm{Order}(1)$,
- `covariance` – $cn + \mathrm{Order}(1)$

for suitable constants e, v and c.

Assume that all input and output labels are numbers and that `self` is complete and has only one final component. Assume further that this final component is aperiodic. Furthermore, assume that there is exactly one initial state and that all states are final.

Denote by X_n the sum of output labels written by the finite state machine when reading a random input word of length n over the input alphabet (assuming equidistribution).

Then the expectation of X_n is $en + O(1)$, the variance of X_n is $vn + O(1)$ and the covariance of X_n and the sum of input labels is $cn + O(1)$, cf. [HKW2015], Theorem 3.9.

In the case of non-integer input or output labels, performance degrades significantly. For rational input and output labels, consider rescaling to integers. This limitation comes from the fact that determinants over polynomial rings can be computed much more efficiently than over the symbolic ring. In fact, we compute (parts) of a trivariate generating function where the input and output labels are exponents of some indeterminates, see [HKW2015], Theorem 3.9 for details. If those exponents are integers, we can use a polynomial ring.

EXAMPLES:

1. A trivial example: write the negative of the input:

```
sage: T = Transducer([(0, 0, 0, 0), (0, 0, 1, -1)],
....:                initial_states=[0],
....:                final_states=[0])
sage: T([0, 1, 1])
[0, -1, -1]

sage: # needs sage.symbolic
sage: moments = T.asymptotic_moments()
sage: moments['expectation']
-1/2*n + Order(1)
sage: moments['variance']
1/4*n + Order(1)
sage: moments['covariance']
-1/4*n + Order(1)
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(0), Integer(0), Integer(0)),
↪(Integer(0), Integer(0), Integer(1), -Integer(1))],
...                initial_states=[Integer(0)],
...                final_states=[Integer(0)])
>>> T([Integer(0), Integer(1), Integer(1)])
[0, -1, -1]
```

(continues on next page)

(continued from previous page)

```
>>> # needs sage.symbolic
>>> moments = T.asymptotic_moments()
>>> moments['expectation']
-1/2*n + Order(1)
>>> moments['variance']
1/4*n + Order(1)
>>> moments['covariance']
-1/4*n + Order(1)
```

2. For the case of the Hamming weight of the non-adjacent-form (NAF) of integers, cf. the Wikipedia article Non-adjacent_form and the *example on recognizing NAFs*, the following agrees with the results in [HP2007].

   We first use the transducer to convert the standard binary expansion to the NAF given in [HP2007]. We use the parameter `with_final_word_out` such that we do not have to add sufficiently many trailing zeros:

```
sage: NAF = Transducer([(0, 0, 0, 0),
....:                     (0, '.1', 1, None),
....:                     ('.1', 0, 0, [1, 0]),
....:                     ('.1', 1, 1, [-1, 0]),
....:                     (1, 1, 1, 0),
....:                     (1, '.1', 0, None)],
....:                    initial_states=[0],
....:                    final_states=[0],
....:                    with_final_word_out=[0])
```

```
>>> from sage.all import *
>>> NAF = Transducer([(Integer(0), Integer(0), Integer(0), Integer(0)),
...                     (Integer(0), '.1', Integer(1), None),
...                     ('.1', Integer(0), Integer(0), [Integer(1),␣
↪Integer(0)]),
...                     ('.1', Integer(1), Integer(1), [-Integer(1),␣
↪Integer(0)]),
...                     (Integer(1), Integer(1), Integer(1), Integer(0)),
...                     (Integer(1), '.1', Integer(0), None)],
...                    initial_states=[Integer(0)],
...                    final_states=[Integer(0)],
...                    with_final_word_out=[Integer(0)])
```

   As an example, we compute the NAF of 27 by this transducer.

```
sage: binary_27 = 27.bits()
sage: binary_27
[1, 1, 0, 1, 1]
sage: NAF_27 = NAF(binary_27)
sage: NAF_27
[-1, 0, -1, 0, 0, 1, 0]
sage: ZZ(NAF_27, base=2)
27
```

```
>>> from sage.all import *
```

(continues on next page)

(continued from previous page)

```
>>> binary_27 = Integer(27).bits()
>>> binary_27
[1, 1, 0, 1, 1]
>>> NAF_27 = NAF(binary_27)
>>> NAF_27
[-1, 0, -1, 0, 0, 1, 0]
>>> ZZ(NAF_27, base=Integer(2))
27
```

Next, we are only interested in the Hamming weight:

```
sage: def weight(state, input):
....:     if input is None:
....:         result = 0
....:     else:
....:         result = ZZ(input != 0)
....:     return (0, result)
sage: weight_transducer = Transducer(weight,
....:                                input_alphabet=[-1, 0, 1],
....:                                initial_states=[0],
....:                                final_states=[0])
sage: NAFweight = weight_transducer.composition(NAF)
sage: NAFweight.transitions()
[Transition from (0, 0) to (0, 0): 0|0,
 Transition from (0, 0) to ('.1', 0): 1|-,
 Transition from ('.1', 0) to (0, 0): 0|1,0,
 Transition from ('.1', 0) to (1, 0): 1|1,0,
 Transition from (1, 0) to ('.1', 0): 0|-,
 Transition from (1, 0) to (1, 0): 1|0]
sage: NAFweight(binary_27)
[1, 0, 1, 0, 0, 1, 0]
```

```
>>> from sage.all import *
>>> def weight(state, input):
...     if input is None:
...         result = Integer(0)
...     else:
...         result = ZZ(input != Integer(0))
...     return (Integer(0), result)
>>> weight_transducer = Transducer(weight,
...                                input_alphabet=[-Integer(1),␣
↪Integer(0), Integer(1)],
...                                initial_states=[Integer(0)],
...                                final_states=[Integer(0)])
>>> NAFweight = weight_transducer.composition(NAF)
>>> NAFweight.transitions()
[Transition from (0, 0) to (0, 0): 0|0,
 Transition from (0, 0) to ('.1', 0): 1|-,
 Transition from ('.1', 0) to (0, 0): 0|1,0,
 Transition from ('.1', 0) to (1, 0): 1|1,0,
 Transition from (1, 0) to ('.1', 0): 0|-,
 Transition from (1, 0) to (1, 0): 1|0]
```

(continues on next page)

(continued from previous page)

```
>>> NAFweight(binary_27)
[1, 0, 1, 0, 0, 1, 0]
```

Now, we actually compute the asymptotic moments:

```
sage: # needs sage.symbolic
sage: moments = NAFweight.asymptotic_moments()
sage: moments['expectation']
1/3*n + Order(1)
sage: moments['variance']
2/27*n + Order(1)
sage: moments['covariance']
Order(1)
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> moments = NAFweight.asymptotic_moments()
>>> moments['expectation']
1/3*n + Order(1)
>>> moments['variance']
2/27*n + Order(1)
>>> moments['covariance']
Order(1)
```

3. This is Example 3.16 in [HKW2015], where a transducer with variable output labels is given. There, the aim was to choose the output labels of this very simple transducer such that the input and output sum are asymptotically independent, i.e., the constant c vanishes.

```
sage: # needs sage.symbolic
sage: var('a_1, a_2, a_3, a_4')
(a_1, a_2, a_3, a_4)
sage: T = Transducer([[0, 0, 0, a_1], [0, 1, 1, a_3],
....:                  [1, 0, 0, a_4], [1, 1, 1, a_2]],
....:                 initial_states=[0], final_states=[0, 1])
sage: moments = T.asymptotic_moments()
verbose 0 (...) Non-integer output weights lead to
significant performance degradation.
sage: moments['expectation']
1/4*(a_1 + a_2 + a_3 + a_4)*n + Order(1)
sage: moments['covariance']
-1/4*(a_1 - a_2)*n + Order(1)
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> var('a_1, a_2, a_3, a_4')
(a_1, a_2, a_3, a_4)
>>> T = Transducer([[Integer(0), Integer(0), Integer(0), a_1],
↪[Integer(0), Integer(1), Integer(1), a_3],
...                 [Integer(1), Integer(0), Integer(0), a_4],
↪[Integer(1), Integer(1), Integer(1), a_2]],
...                initial_states=[Integer(0)], final_states=[Integer(0),
↪Integer(1)])
```

(continues on next page)

(continued from previous page)

```
>>> moments = T.asymptotic_moments()
verbose 0 (...) Non-integer output weights lead to
significant performance degradation.
>>> moments['expectation']
1/4*(a_1 + a_2 + a_3 + a_4)*n + Order(1)
>>> moments['covariance']
-1/4*(a_1 - a_2)*n + Order(1)
```

Therefore, the asymptotic covariance vanishes if and only if $a_2 = a_1$.

4. This is Example 4.3 in [HKW2015], dealing with the transducer converting the binary expansion of an integer into Gray code (cf. the Wikipedia article Gray_code and the *example on Gray code*):

```
sage: # needs sage.symbolic
sage: moments = transducers.GrayCode().asymptotic_moments()
sage: moments['expectation']
1/2*n + Order(1)
sage: moments['variance']
1/4*n + Order(1)
sage: moments['covariance']
Order(1)
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> moments = transducers.GrayCode().asymptotic_moments()
>>> moments['expectation']
1/2*n + Order(1)
>>> moments['variance']
1/4*n + Order(1)
>>> moments['covariance']
Order(1)
```

5. This is the first part of Example 4.4 in [HKW2015], counting the number of 10 blocks in the standard binary expansion. The least significant digit is at the left-most position:

```
sage: block10 = transducers.CountSubblockOccurrences(
....:     [1, 0],
....:     input_alphabet=[0, 1])
sage: sorted(block10.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from (1,) to (): 0|1,
 Transition from (1,) to (1,): 1|0]

sage: # needs sage.symbolic
sage: moments = block10.asymptotic_moments()
sage: moments['expectation']
1/4*n + Order(1)
sage: moments['variance']
1/16*n + Order(1)
sage: moments['covariance']
Order(1)
```

```
>>> from sage.all import *
>>> block10 = transducers.CountSubblockOccurrences(
...     [Integer(1), Integer(0)],
...     input_alphabet=[Integer(0), Integer(1)])
>>> sorted(block10.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from (1,) to (): 0|1,
 Transition from (1,) to (1,): 1|0]

>>> # needs sage.symbolic
>>> moments = block10.asymptotic_moments()
>>> moments['expectation']
1/4*n + Order(1)
>>> moments['variance']
1/16*n + Order(1)
>>> moments['covariance']
Order(1)
```

6. This is the second part of Example 4.4 in [HKW2015], counting the number of 11 blocks in the standard binary expansion. The least significant digit is at the left-most position:

```
sage: block11 = transducers.CountSubblockOccurrences(
....:     [1, 1],
....:     input_alphabet=[0, 1])
sage: sorted(block11.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from (1,) to (): 0|0,
 Transition from (1,) to (1,): 1|1]

sage: # needs sage.symbolic
sage: var('N')
N
sage: moments = block11.asymptotic_moments(N)
sage: moments['expectation']
1/4*N + Order(1)
sage: moments['variance']
5/16*N + Order(1)
sage: correlation = (moments['covariance'].coefficient(N) /
....:                (1/2 * sqrt(moments['variance'].coefficient(N))))
sage: correlation
2/5*sqrt(5)
```

```
>>> from sage.all import *
>>> block11 = transducers.CountSubblockOccurrences(
...     [Integer(1), Integer(1)],
...     input_alphabet=[Integer(0), Integer(1)])
>>> sorted(block11.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from (1,) to (): 0|0,
 Transition from (1,) to (1,): 1|1]
```

(continues on next page)

(continued from previous page)

```
>>> # needs sage.symbolic
>>> var('N')
N
>>> moments = block11.asymptotic_moments(N)
>>> moments['expectation']
1/4*N + Order(1)
>>> moments['variance']
5/16*N + Order(1)
>>> correlation = (moments['covariance'].coefficient(N) /
...                 (Integer(1)/Integer(2) * sqrt(moments['variance'].
↪coefficient(N))))
>>> correlation
2/5*sqrt(5)
```

7. This is Example 4.5 in [HKW2015], counting the number of 01 blocks minus the number of 10 blocks in the standard binary expansion. The least significant digit is at the left-most position:

```
sage: block01 = transducers.CountSubblockOccurrences(
....:     [0, 1],
....:     input_alphabet=[0, 1])
sage: product_01x10 = block01.cartesian_product(block10)
sage: block_difference = transducers.sub([0, 1])(product_01x10)
sage: T = block_difference.simplification().relabeled()
sage: T.transitions()
[Transition from 0 to 2: 0|-1,
 Transition from 0 to 0: 1|0,
 Transition from 1 to 2: 0|0,
 Transition from 1 to 0: 1|0,
 Transition from 2 to 2: 0|0,
 Transition from 2 to 0: 1|1]

sage: # needs sage.symbolic
sage: moments = T.asymptotic_moments()
sage: moments['expectation']
Order(1)
sage: moments['variance']
Order(1)
sage: moments['covariance']
Order(1)
```

```
>>> from sage.all import *
>>> block01 = transducers.CountSubblockOccurrences(
...     [Integer(0), Integer(1)],
...     input_alphabet=[Integer(0), Integer(1)])
>>> product_01x10 = block01.cartesian_product(block10)
>>> block_difference = transducers.sub([Integer(0), Integer(1)])(product_
↪01x10)
>>> T = block_difference.simplification().relabeled()
>>> T.transitions()
[Transition from 0 to 2: 0|-1,
 Transition from 0 to 0: 1|0,
```

(continues on next page)

(continued from previous page)

```
 Transition from 1 to 2: 0|0,
 Transition from 1 to 0: 1|0,
 Transition from 2 to 2: 0|0,
 Transition from 2 to 0: 1|1]

>>> # needs sage.symbolic
>>> moments = T.asymptotic_moments()
>>> moments['expectation']
Order(1)
>>> moments['variance']
Order(1)
>>> moments['covariance']
Order(1)
```

8. The finite state machine must have a unique final component:

```
sage: T = Transducer([(0, -1, -1, -1), (0, 1, 1, 1),
....:                  (-1, -1, -1, -1), (-1, -1, 1, -1),
....:                  (1, 1, -1, 1), (1, 1, 1, 1)],
....:                 initial_states=[0],
....:                 final_states=[0, 1, -1])
sage: T.asymptotic_moments()
Traceback (most recent call last):
...
NotImplementedError: asymptotic_moments is only
implemented for finite state machines with one final
component.
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), -Integer(1), -Integer(1), -Integer(1)), (Integer(0), Integer(1), Integer(1), Integer(1)),
...                 (-Integer(1), -Integer(1), -Integer(1), -Integer(1)), (-Integer(1), -Integer(1), Integer(1), -Integer(1)),
...                 (Integer(1), Integer(1), -Integer(1), Integer(1)), (Integer(1), Integer(1), Integer(1), Integer(1))],
...                initial_states=[Integer(0)],
...                final_states=[Integer(0), Integer(1), -Integer(1)])
>>> T.asymptotic_moments()
Traceback (most recent call last):
...
NotImplementedError: asymptotic_moments is only
implemented for finite state machines with one final
component.
```

In this particular example, the first letter of the input decides whether we reach the loop at -1 or the loop at 1. In the first case, we have $X_n = -n$, while we have $X_n = n$ in the second case. Therefore, the expectation $E(X_n)$ of X_n is $E(X_n) = 0$. We get $(X_n - E(X_n))^2 = n^2$ in all cases, which results in a variance of n^2.

So this example shows that the variance may be non-linear if there is more than one final component.

ALGORITHM:

See [HKW2015], Theorem 3.9.

REFERENCES:

coaccessible_components()

Return the sub-machine induced by the coaccessible states of this finite state machine.

OUTPUT:

A finite state machine of the same type as this finite state machine.

EXAMPLES:

```
sage: A = automata.ContainsWord([1, 1],
....:     input_alphabet=[0, 1]).complement().minimization().relabeled()
sage: A.transitions()
[Transition from 0 to 0: 0|-,
 Transition from 0 to 0: 1|-,
 Transition from 1 to 2: 0|-,
 Transition from 1 to 0: 1|-,
 Transition from 2 to 2: 0|-,
 Transition from 2 to 1: 1|-]
sage: A.initial_states()
[2]
sage: A.final_states()
[1, 2]
sage: C = A.coaccessible_components()
sage: C.transitions()
[Transition from 1 to 2: 0|-,
 Transition from 2 to 2: 0|-,
 Transition from 2 to 1: 1|-]
```

```
>>> from sage.all import *
>>> A = automata.ContainsWord([Integer(1), Integer(1)],
...     input_alphabet=[Integer(0), Integer(1)]).complement().minimization().
↪relabeled()
>>> A.transitions()
[Transition from 0 to 0: 0|-,
 Transition from 0 to 0: 1|-,
 Transition from 1 to 2: 0|-,
 Transition from 1 to 0: 1|-,
 Transition from 2 to 2: 0|-,
 Transition from 2 to 1: 1|-]
>>> A.initial_states()
[2]
>>> A.final_states()
[1, 2]
>>> C = A.coaccessible_components()
>>> C.transitions()
[Transition from 1 to 2: 0|-,
 Transition from 2 to 2: 0|-,
 Transition from 2 to 1: 1|-]
```

See also

accessible_components(), *induced_sub_finite_state_machine()*

completion(*sink=None*)

Return a completion of this finite state machine.

INPUT:

- `sink` – either an instance of `FSMState` or a label for the sink (default: `None`); if `None`, the least available nonzero integer is used

OUTPUT:

A `FiniteStateMachine` of the same type as this finite state machine.

The resulting finite state machine is a complete version of this finite state machine. A finite state machine is considered to be complete if each transition has an input label of length one and for each pair (q, a) where q is a state and a is an element of the input alphabet, there is exactly one transition from q with input label a.

If this finite state machine is already complete, a deep copy is returned. Otherwise, a new non-final state (usually called a sink) is created and transitions to this sink are introduced as appropriate.

EXAMPLES:

```
sage: F = FiniteStateMachine([(0, 0, 0, 0),
....:                         (0, 1, 1, 1),
....:                         (1, 1, 0, 0)])
sage: F.is_complete()
False
sage: G1 = F.completion()
sage: G1.is_complete()
True
sage: G1.transitions()
[Transition from 0 to 0: 0|0,
 Transition from 0 to 1: 1|1,
 Transition from 1 to 1: 0|0,
 Transition from 1 to 2: 1|-,
 Transition from 2 to 2: 0|-,
 Transition from 2 to 2: 1|-]
sage: G2 = F.completion('Sink')
sage: G2.is_complete()
True
sage: G2.transitions()
[Transition from 0 to 0: 0|0,
 Transition from 0 to 1: 1|1,
 Transition from 1 to 1: 0|0,
 Transition from 1 to 'Sink': 1|-,
 Transition from 'Sink' to 'Sink': 0|-,
 Transition from 'Sink' to 'Sink': 1|-]
sage: F.completion(1)
Traceback (most recent call last):
...
ValueError: The finite state machine already contains a state
'1'.
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine([(Integer(0), Integer(0), Integer(0), Integer(0)),
...                         (Integer(0), Integer(1), Integer(1), Integer(1)),
...                         (Integer(1), Integer(1), Integer(0), Integer(0))])
```

(continues on next page)

(continued from previous page)

```
>>> F.is_complete()
False
>>> G1 = F.completion()
>>> G1.is_complete()
True
>>> G1.transitions()
[Transition from 0 to 0: 0|0,
 Transition from 0 to 1: 1|1,
 Transition from 1 to 1: 0|0,
 Transition from 1 to 2: 1|-,
 Transition from 2 to 2: 0|-,
 Transition from 2 to 2: 1|-]
>>> G2 = F.completion('Sink')
>>> G2.is_complete()
True
>>> G2.transitions()
[Transition from 0 to 0: 0|0,
 Transition from 0 to 1: 1|1,
 Transition from 1 to 1: 0|0,
 Transition from 1 to 'Sink': 1|-,
 Transition from 'Sink' to 'Sink': 0|-,
 Transition from 'Sink' to 'Sink': 1|-]
>>> F.completion(Integer(1))
Traceback (most recent call last):
...
ValueError: The finite state machine already contains a state
'1'.
```

An input alphabet must be given:

```
sage: F = FiniteStateMachine([(0, 0, 0, 0),
....:                           (0, 1, 1, 1),
....:                           (1, 1, 0, 0)],
....:                          determine_alphabets=False)
sage: F.is_complete()
Traceback (most recent call last):
...
ValueError: No input alphabet is given. Try calling
determine_alphabets().
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine([(Integer(0), Integer(0), Integer(0), Integer(0)),
...                           (Integer(0), Integer(1), Integer(1), Integer(1)),
...                           (Integer(1), Integer(1), Integer(0), Integer(0))],
...                          determine_alphabets=False)
>>> F.is_complete()
Traceback (most recent call last):
...
ValueError: No input alphabet is given. Try calling
determine_alphabets().
```

Non-deterministic machines are not allowed.

```
sage: F = FiniteStateMachine([(0, 0, 0, 0), (0, 1, 0, 0)])
sage: F.is_complete()
False
sage: F.completion()
Traceback (most recent call last):
...
ValueError: The finite state machine must be deterministic.
sage: F = FiniteStateMachine([(0, 0, [0, 0], 0)])
sage: F.is_complete()
False
sage: F.completion()
Traceback (most recent call last):
...
ValueError: The finite state machine must be deterministic.
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine([(Integer(0), Integer(0), Integer(0), Integer(0)), (Integer(0), Integer(1), Integer(0), Integer(0))])
>>> F.is_complete()
False
>>> F.completion()
Traceback (most recent call last):
...
ValueError: The finite state machine must be deterministic.
>>> F = FiniteStateMachine([(Integer(0), Integer(0), [Integer(0), Integer(0)], Integer(0))])
>>> F.is_complete()
False
>>> F.completion()
Traceback (most recent call last):
...
ValueError: The finite state machine must be deterministic.
```

See also

is_complete(), *split_transitions()*, *determine_alphabets()*, *is_deterministic()*.

composition(*other*, *algorithm=None*, *only_accessible_components=True*)

Return a new transducer which is the composition of `self` and `other`.

INPUT:

- `other` – a transducer
- `algorithm` – can be one of the following
  - `direct` – the composition is calculated directly

    There can be arbitrarily many initial and final states, but the input and output labels must have length 1.

Warning

The output of `other` is fed into `self`.

- `explorative` – an explorative algorithm is used

  The input alphabet of `self` has to be specified.

  Warning

  The output of `other` is fed into `self`.

If algorithm is `None`, then the algorithm is chosen automatically (at the moment always `direct`, except when there are output words of `other` or input words of `self` of length greater than 1).

OUTPUT: a new transducer

The labels of the new finite state machine are pairs of states of the original finite state machines. The color of a new state is the tuple of colors of the constituent states.

EXAMPLES:

```
sage: F = Transducer([('A', 'B', 1, 0), ('B', 'A', 0, 1)],
....:                initial_states=['A', 'B'], final_states=['B'],
....:                determine_alphabets=True)
sage: G = Transducer([(1, 1, 1, 0), (1, 2, 0, 1),
....:                 (2, 2, 1, 1), (2, 2, 0, 0)],
....:                initial_states=[1], final_states=[2],
....:                determine_alphabets=True)
sage: Hd = F.composition(G, algorithm='direct')
sage: Hd.initial_states()
[(1, 'B'), (1, 'A')]
sage: Hd.transitions()
[Transition from (1, 'B') to (1, 'A'): 1|1,
 Transition from (1, 'A') to (2, 'B'): 0|0,
 Transition from (2, 'B') to (2, 'A'): 0|1,
 Transition from (2, 'A') to (2, 'B'): 1|0]
sage: He = F.composition(G, algorithm='explorative')
sage: He.initial_states()
[(1, 'A'), (1, 'B')]
sage: He.transitions()
[Transition from (1, 'A') to (2, 'B'): 0|0,
 Transition from (1, 'B') to (1, 'A'): 1|1,
 Transition from (2, 'B') to (2, 'A'): 0|1,
 Transition from (2, 'A') to (2, 'B'): 1|0]
sage: Hd == He
True
```

```
>>> from sage.all import *
>>> F = Transducer([('A', 'B', Integer(1), Integer(0)), ('B', 'A', Integer(0),
↪ Integer(1))],
...                initial_states=['A', 'B'], final_states=['B'],
...                determine_alphabets=True)
>>> G = Transducer([(Integer(1), Integer(1), Integer(1), Integer(0)),␣
↪(Integer(1), Integer(2), Integer(0), Integer(1)),
```

(continues on next page)

(continued from previous page)

```
...                   (Integer(2), Integer(2), Integer(1), Integer(1)),␣
↪(Integer(2), Integer(2), Integer(0), Integer(0))],
...                  initial_states=[Integer(1)], final_states=[Integer(2)],
...                  determine_alphabets=True)

[Transition from (1, 'B') to (1, 'A'): 1|1,
 Transition from (1, 'A') to (2, 'B'): 0|0,
 Transition from (2, 'B') to (2, 'A'): 0|1,
 Transition from (2, 'A') to (2, 'B'): 1|0]
>>> He = F.composition(G, algorithm='explorative')
>>> He.initial_states()
[(1, 'A'), (1, 'B')]
>>> He.transitions()
[Transition from (1, 'A') to (2, 'B'): 0|0,
 Transition from (1, 'B') to (1, 'A'): 1|1,
 Transition from (2, 'B') to (2, 'A'): 0|1,
 Transition from (2, 'A') to (2, 'B'): 1|0]
>>> Hd == He
True
```

The following example has output of length > 1, so the explorative algorithm has to be used (and is selected automatically).

```
sage: F = Transducer([('A', 'B', 1, [1, 0]), ('B', 'B', 1, 1),
....:                  ('B', 'B', 0, 0)],
....:                 initial_states=['A'], final_states=['B'])
sage: G = Transducer([(1, 1, 0, 0), (1, 2, 1, 0),
....:                  (2, 2, 0, 1), (2, 1, 1, 1)],
....:                 initial_states=[1], final_states=[1])
sage: He = G.composition(F, algorithm='explorative')
sage: He.transitions()
[Transition from ('A', 1) to ('B', 2): 1|0,1,
 Transition from ('B', 2) to ('B', 2): 0|1,
 Transition from ('B', 2) to ('B', 1): 1|1,
 Transition from ('B', 1) to ('B', 1): 0|0,
 Transition from ('B', 1) to ('B', 2): 1|0]
sage: Ha = G.composition(F)
sage: Ha == He
True
```

```
>>> from sage.all import *
>>> F = Transducer([('A', 'B', Integer(1), [Integer(1), Integer(0)]), ('B', 'B
↪', Integer(1), Integer(1)),
...                   ('B', 'B', Integer(0), Integer(0))],
...                  initial_states=['A'], final_states=['B'])
>>> G = Transducer([(Integer(1), Integer(1), Integer(0), Integer(0)),␣
↪(Integer(1), Integer(2), Integer(1), Integer(0)),
...                   (Integer(2), Integer(2), Integer(0), Integer(1)),␣
↪(Integer(2), Integer(1), Integer(1), Integer(1))],
```

(continues on next page)

(continued from previous page)

```
...                 initial_states=[Integer(1)], final_states=[Integer(1)])
>>> He = G.composition(F, algorithm='explorative')
>>> He.transitions()
[Transition from ('A', 1) to ('B', 2): 1|0,1,
 Transition from ('B', 2) to ('B', 2): 0|1,
 Transition from ('B', 2) to ('B', 1): 1|1,
 Transition from ('B', 1) to ('B', 1): 0|0,
 Transition from ('B', 1) to ('B', 2): 1|0]
>>> Ha = G.composition(F)
>>> Ha == He
True
```

Final output words are also considered:

```
sage: F = Transducer([('A', 'B', 1, 0), ('B', 'A', 0, 1)],
....:                initial_states=['A', 'B'],
....:                final_states=['A', 'B'])
sage: F.state('A').final_word_out = 0
sage: F.state('B').final_word_out = 1
sage: G = Transducer([(1, 1, 1, 0), (1, 2, 0, 1),
....:                 (2, 2, 1, 1), (2, 2, 0, 0)],
....:                initial_states=[1], final_states=[2])
sage: G.state(2).final_word_out = 0
sage: Hd = F.composition(G, algorithm='direct')
sage: Hd.final_states()
[(2, 'B')]
sage: He = F.composition(G, algorithm='explorative')
sage: He.final_states()
[(2, 'B')]
```

```
>>> from sage.all import *
>>> F = Transducer([('A', 'B', Integer(1), Integer(0)), ('B', 'A', Integer(0),
↪ Integer(1))],
...                 initial_states=['A', 'B'],
...                 final_states=['A', 'B'])
>>> F.state('A').final_word_out = Integer(0)
>>> F.state('B').final_word_out = Integer(1)
>>> G = Transducer([(Integer(1), Integer(1), Integer(1), Integer(0)),␣
↪(Integer(1), Integer(2), Integer(0), Integer(1)),
...                  (Integer(2), Integer(2), Integer(1), Integer(1)),␣
↪(Integer(2), Integer(2), Integer(0), Integer(0))],
...                 initial_states=[Integer(1)], final_states=[Integer(2)])
>>> G.state(Integer(2)).final_word_out = Integer(0)
>>> Hd = F.composition(G, algorithm='direct')
>>> Hd.final_states()
[(2, 'B')]
>>> He = F.composition(G, algorithm='explorative')
>>> He.final_states()
[(2, 'B')]
```

Note that `(2, 'A')` is not final, as the final output 0 of state 2 of G cannot be processed in state `'A'` of F.

```
sage: [s.final_word_out for s in Hd.final_states()]
[[1, 0]]
sage: [s.final_word_out for s in He.final_states()]
[[1, 0]]
sage: Hd == He
True
```

```
>>> from sage.all import *
>>> [s.final_word_out for s in Hd.final_states()]
[[1, 0]]
>>> [s.final_word_out for s in He.final_states()]
[[1, 0]]
>>> Hd == He
True
```

Here is a non-deterministic example with intermediate output length > 1.

```
sage: F = Transducer([(1, 1, 1, ['a', 'a']), (1, 2, 1, 'b'),
....:                 (2, 1, 2, 'a'), (2, 2, 2, 'b')],
....:                initial_states=[1, 2])
sage: G = Transducer([('A', 'A', 'a', 'i'),
....:                 ('A', 'B', 'a', 'l'),
....:                 ('B', 'B', 'b', 'e')],
....:                initial_states=['A', 'B'])
sage: G(F).transitions()
[Transition from (1, 'A') to (1, 'A'): 1|'i','i',
 Transition from (1, 'A') to (1, 'B'): 1|'i','l',
 Transition from (1, 'B') to (2, 'B'): 1|'e',
 Transition from (2, 'A') to (1, 'A'): 2|'i',
 Transition from (2, 'A') to (1, 'B'): 2|'l',
 Transition from (2, 'B') to (2, 'B'): 2|'e']
```

```
>>> from sage.all import *
>>> F = Transducer([(Integer(1), Integer(1), Integer(1), ['a', 'a']),
↪(Integer(1), Integer(2), Integer(1), 'b'),
...                 (Integer(2), Integer(1), Integer(2), 'a'), (Integer(2),
↪Integer(2), Integer(2), 'b')],
...                initial_states=[Integer(1), Integer(2)])
>>> G = Transducer([('A', 'A', 'a', 'i'),
...                 ('A', 'B', 'a', 'l'),
...                 ('B', 'B', 'b', 'e')],
...                initial_states=['A', 'B'])
>>> G(F).transitions()
[Transition from (1, 'A') to (1, 'A'): 1|'i','i',
 Transition from (1, 'A') to (1, 'B'): 1|'i','l',
 Transition from (1, 'B') to (2, 'B'): 1|'e',
 Transition from (2, 'A') to (1, 'A'): 2|'i',
 Transition from (2, 'A') to (1, 'B'): 2|'l',
 Transition from (2, 'B') to (2, 'B'): 2|'e']
```

Be aware that after composition, different transitions may share the same output label (same python object):

```
sage: F = Transducer([ ('A','B',0,0), ('B','A',0,0)],
....:                 initial_states=['A'],
....:                 final_states=['A'])
sage: F.transitions()[0].word_out is F.transitions()[1].word_out
False
sage: G = Transducer([('C','C',0,1)],
....:                 initial_states=['C'],
....:                 final_states=['C'])
sage: H = G.composition(F)
sage: H.transitions()[0].word_out is H.transitions()[1].word_out
True
```

```
>>> from sage.all import *
>>> F = Transducer([ ('A','B',Integer(0),Integer(0)), ('B','A',Integer(0),
↪Integer(0))],
...                 initial_states=['A'],
...                 final_states=['A'])
>>> F.transitions()[Integer(0)].word_out is F.transitions()[Integer(1)].word_
↪out
False
>>> G = Transducer([('C','C',Integer(0),Integer(1))],
...                 initial_states=['C'],
...                 final_states=['C'])
>>> H = G.composition(F)
>>> H.transitions()[Integer(0)].word_out is H.transitions()[Integer(1)].word_
↪out
True
```

concatenation(*other*)

Concatenate this finite state machine with another finite state machine.

INPUT:

- `other` – a *FiniteStateMachine*

OUTPUT:

A *FiniteStateMachine* of the same type as this finite state machine.

Assume that both finite state machines are automata. If $\mathcal{L}_1$ is the language accepted by this automaton and $\mathcal{L}_2$ is the language accepted by the other automaton, then the language accepted by the concatenated automaton is $\{w_1w_2 \mid w_1 \in \mathcal{L}_1, w_2 \in \mathcal{L}_2\}$ where w_1w_2 denotes the concatenation of the words w_1 and w_2.

Assume that both finite state machines are transducers and that this transducer maps words $w_1 \in \mathcal{L}_1$ to words $f_1(w_1)$ and that the other transducer maps words $w_2 \in \mathcal{L}_2$ to words $f_2(w_2)$. Then the concatenated transducer maps words w_1w_2 with $w_1 \in \mathcal{L}_1$ and $w_2 \in \mathcal{L}_2$ to $f_1(w_1)f_2(w_2)$. Here, w_1w_2 and $f_1(w_1)f_2(w_2)$ again denote concatenation of words.

The input alphabet is the union of the input alphabets (if possible) and `None` otherwise. In the latter case, try calling *determine_alphabets()*.

Instead of `A.concatenation(B)`, the notation `A * B` can be used.

EXAMPLES:

Concatenation of two automata:

```
sage: A = automata.Word([0])
sage: B = automata.Word([1])
sage: C = A.concatenation(B)
sage: C.transitions()
[Transition from (0, 0) to (0, 1): 0|-,
 Transition from (0, 1) to (1, 0): -|-,
 Transition from (1, 0) to (1, 1): 1|-]
sage: [w
....:  for w in ([0, 0], [0, 1], [1, 0], [1, 1])
....:  if C(w)]
[[0, 1]]
sage: from sage.combinat.finite_state_machine import (
....:     Automaton, Transducer)
sage: isinstance(C, Automaton)
True
```

```
>>> from sage.all import *
>>> A = automata.Word([Integer(0)])
>>> B = automata.Word([Integer(1)])
>>> C = A.concatenation(B)
>>> C.transitions()
[Transition from (0, 0) to (0, 1): 0|-,
 Transition from (0, 1) to (1, 0): -|-,
 Transition from (1, 0) to (1, 1): 1|-]
>>> [w
...  for w in ([Integer(0), Integer(0)], [Integer(0), Integer(1)],
↪[Integer(1), Integer(0)], [Integer(1), Integer(1)])
...  if C(w)]
[[0, 1]]
>>> from sage.combinat.finite_state_machine import (
...     Automaton, Transducer)
>>> isinstance(C, Automaton)
True
```

Concatenation of two transducers:

```
sage: A = Transducer([(0, 1, 0, 1), (0, 1, 1, 2)],
....:                initial_states=[0],
....:                final_states=[1])
sage: B = Transducer([(0, 1, 0, 1), (0, 1, 1, 0)],
....:                initial_states=[0],
....:                final_states=[1])
sage: C = A.concatenation(B)
sage: C.transitions()
[Transition from (0, 0) to (0, 1): 0|1,
 Transition from (0, 0) to (0, 1): 1|2,
 Transition from (0, 1) to (1, 0): -|-,
 Transition from (1, 0) to (1, 1): 0|1,
 Transition from (1, 0) to (1, 1): 1|0]
sage: [(w, C(w)) for w in ([0, 0], [0, 1], [1, 0], [1, 1])]
[([0, 0], [1, 1]),
 ([0, 1], [1, 0]),
 ([1, 0], [2, 1]),
```

(continues on next page)

(continued from previous page)

```
 ([1, 1], [2, 0])]
sage: isinstance(C, Transducer)
True
```

```
>>> from sage.all import *
>>> A = Transducer([(Integer(0), Integer(1), Integer(0), Integer(1)),␣
↪(Integer(0), Integer(1), Integer(1), Integer(2))],
...                initial_states=[Integer(0)],
...                final_states=[Integer(1)])
>>> B = Transducer([(Integer(0), Integer(1), Integer(0), Integer(1)),␣
↪(Integer(0), Integer(1), Integer(1), Integer(0))],
...                initial_states=[Integer(0)],
...                final_states=[Integer(1)])
>>> C = A.concatenation(B)
>>> C.transitions()
[Transition from (0, 0) to (0, 1): 0|1,
 Transition from (0, 0) to (0, 1): 1|2,
 Transition from (0, 1) to (1, 0): -|-,
 Transition from (1, 0) to (1, 1): 0|1,
 Transition from (1, 0) to (1, 1): 1|0]
>>> [(w, C(w)) for w in ([Integer(0), Integer(0)], [Integer(0), Integer(1)],␣
↪[Integer(1), Integer(0)], [Integer(1), Integer(1)])]
[([0, 0], [1, 1]),
 ([0, 1], [1, 0]),
 ([1, 0], [2, 1]),
 ([1, 1], [2, 0])]
>>> isinstance(C, Transducer)
True
```

Alternative notation as multiplication:

```
sage: C == A * B
True
```

```
>>> from sage.all import *
>>> C == A * B
True
```

Final output words are taken into account:

```
sage: A = Transducer([(0, 1, 0, 1)],
....:                initial_states=[0],
....:                final_states=[1])
sage: A.state(1).final_word_out = 2
sage: B = Transducer([(0, 1, 0, 3)],
....:                initial_states=[0],
....:                final_states=[1])
sage: B.state(1).final_word_out = 4
sage: C = A * B
sage: C([0, 0])
[1, 2, 3, 4]
```

```
>>> from sage.all import *
>>> A = Transducer([(Integer(0), Integer(1), Integer(0), Integer(1))],
...                initial_states=[Integer(0)],
...                final_states=[Integer(1)])
>>> A.state(Integer(1)).final_word_out = Integer(2)
>>> B = Transducer([(Integer(0), Integer(1), Integer(0), Integer(3))],
...                initial_states=[Integer(0)],
...                final_states=[Integer(1)])
>>> B.state(Integer(1)).final_word_out = Integer(4)
>>> C = A * B
>>> C([Integer(0), Integer(0)])
[1, 2, 3, 4]
```

Handling of the input alphabet:

```
sage: A = Automaton([(0, 0, 0)])
sage: B = Automaton([(0, 0, 1)], input_alphabet=[1, 2])
sage: C = Automaton([(0, 0, 2)], determine_alphabets=False)
sage: D = Automaton([(0, 0, [[0, 0]])], input_alphabet=[[0, 0]])
sage: A.input_alphabet
[0]
sage: B.input_alphabet
[1, 2]
sage: C.input_alphabet is None
True
sage: D.input_alphabet
[[0, 0]]
sage: (A * B).input_alphabet
[0, 1, 2]
sage: (A * C).input_alphabet is None
True
sage: (A * D).input_alphabet is None
True
```

```
>>> from sage.all import *
>>> A = Automaton([(Integer(0), Integer(0), Integer(0))])
>>> B = Automaton([(Integer(0), Integer(0), Integer(1))], input_
↪alphabet=[Integer(1), Integer(2)])
>>> C = Automaton([(Integer(0), Integer(0), Integer(2))], determine_
↪alphabets=False)
>>> D = Automaton([(Integer(0), Integer(0), [[Integer(0), Integer(0)]])],␣
↪input_alphabet=[[Integer(0), Integer(0)]])
>>> A.input_alphabet
[0]
>>> B.input_alphabet
[1, 2]
>>> C.input_alphabet is None
True
>>> D.input_alphabet
[[0, 0]]
>>> (A * B).input_alphabet
[0, 1, 2]
>>> (A * C).input_alphabet is None
```

(continues on next page)

(continued from previous page)

```
True
>>> (A * D).input_alphabet is None
True
```

See also:

disjoint_union(), determine_alphabets().

construct_final_word_out(*letters*, *allow_non_final=True*)

This is an inplace version of with_final_word_out(). See with_final_word_out() for documentation and examples.

copy()

Return a (shallow) copy of the finite state machine.

OUTPUT: a new finite state machine

deepcopy(*memo=None*)

Return a deep copy of the finite state machine.

INPUT:

- memo – (default: None) a dictionary storing already processed elements

OUTPUT: a new finite state machine

EXAMPLES:

```
sage: F = FiniteStateMachine([('A', 'A', 0, 1), ('A', 'A', 1, 0)])
sage: deepcopy(F)
Finite state machine with 1 state
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine([('A', 'A', Integer(0), Integer(1)), ('A', 'A',
↪Integer(1), Integer(0))])
>>> deepcopy(F)
Finite state machine with 1 state
```

default_format_letter = <sage.misc.latex.Latex object>

default_format_transition_label(*word*)

Default formatting of words in transition labels for LaTeX output.

INPUT:

- word – list of letters

OUTPUT:

String representation of word suitable to be typeset in mathematical mode.

- For a non-empty word: Concatenation of the letters, piped through self.format_letter and separated by blanks.
- For an empty word: sage.combinat.finite_state_machine.EmptyWordLaTeX.

There is also a variant *format_transition_label_reversed()* writing the words in reversed order.

EXAMPLES:

1. Example of a non-empty word:

```
sage: T = Transducer()
sage: print(T.default_format_transition_label(
....:     ['a', 'alpha', 'a_1', '0', 0, (0, 1)]))
\text{\texttt{a}} \text{\texttt{alpha}}
\text{\texttt{a{\char`\_}1}} 0 0 \left(0, 1\right)
```

```
>>> from sage.all import *
>>> T = Transducer()
>>> print(T.default_format_transition_label(
...     ['a', 'alpha', 'a_1', '0', Integer(0), (Integer(0), Integer(1))]))
\text{\texttt{a}} \text{\texttt{alpha}}
\text{\texttt{a{\char`\_}1}} 0 0 \left(0, 1\right)
```

2. In the example above, `'a'` and `'alpha'` should perhaps be symbols:

```
sage: var('a alpha a_1')                                                    #␣
↪needs sage.symbolic
(a, alpha, a_1)
sage: print(T.default_format_transition_label([a, alpha, a_1]))             #␣
↪needs sage.symbolic
a \alpha a_{1}
```

```
>>> from sage.all import *
>>> var('a alpha a_1')                                                    #␣
↪needs sage.symbolic
(a, alpha, a_1)
>>> print(T.default_format_transition_label([a, alpha, a_1]))             #␣
↪needs sage.symbolic
a \alpha a_{1}
```

3. Example of an empty word:

```
sage: print(T.default_format_transition_label([]))
\varepsilon
```

```
>>> from sage.all import *
>>> print(T.default_format_transition_label([]))
\varepsilon
```

We can change this by setting `sage.combinat.finite_state_machine.EmptyWordLaTeX`:

```
sage: sage.combinat.finite_state_machine.EmptyWordLaTeX = ''
sage: T.default_format_transition_label([])
''
```

```
>>> from sage.all import *
>>> sage.combinat.finite_state_machine.EmptyWordLaTeX = ''
```

(continues on next page)

(continued from previous page)

```
>>> T.default_format_transition_label([])
''
```

Finally, we restore the default value:

```
sage: sage.combinat.finite_state_machine.EmptyWordLaTeX = r'\varepsilon'
```

```
>>> from sage.all import *
>>> sage.combinat.finite_state_machine.EmptyWordLaTeX = r'\varepsilon'
```

4. This method is the default value for `FiniteStateMachine.format_transition_label`. That can be changed to be any other function:

```
sage: A = Automaton([(0, 1, 0)])
sage: def custom_format_transition_label(word):
....:     return "t"
sage: A.latex_options(format_transition_label=custom_format_transition_
↪label)
sage: print(latex(A))
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state] (v0) at (3.000000, 0.000000) {$0$};
\node[state] (v1) at (-3.000000, 0.000000) {$1$};
\path[->] (v0) edge node[rotate=360.00, anchor=south] {$t$} (v1);
\end{tikzpicture}
```

```
>>> from sage.all import *
>>> A = Automaton([(Integer(0), Integer(1), Integer(0))])
>>> def custom_format_transition_label(word):
...     return "t"
>>> A.latex_options(format_transition_label=custom_format_transition_
↪label)
>>> print(latex(A))
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state] (v0) at (3.000000, 0.000000) {$0$};
\node[state] (v1) at (-3.000000, 0.000000) {$1$};
\path[->] (v0) edge node[rotate=360.00, anchor=south] {$t$} (v1);
\end{tikzpicture}
```

delete_state(*s*)

Delete a state and all transitions coming or going to this state.

INPUT:

- `s` – a label of a state or an *FSMState*

OUTPUT: nothing

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: t1 = FSMTransition('A', 'B', 0)
sage: t2 = FSMTransition('B', 'B', 1)
sage: F = FiniteStateMachine([t1, t2])
sage: F.delete_state('A')
```

(continues on next page)

(continued from previous page)

```
sage: F.transitions()
[Transition from 'B' to 'B': 1|-]
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMTransition
>>> t1 = FSMTransition('A', 'B', Integer(0))
>>> t2 = FSMTransition('B', 'B', Integer(1))
>>> F = FiniteStateMachine([t1, t2])
>>> F.delete_state('A')
>>> F.transitions()
[Transition from 'B' to 'B': 1|-]
```

delete_transition(*t*)

Delete a transition by removing it from the list of transitions of the state, where the transition starts.

INPUT:

- `t` – a transition

OUTPUT: nothing

EXAMPLES:

```
sage: F = FiniteStateMachine([('A', 'B', 0), ('B', 'A', 1)])
sage: F.delete_transition(('A', 'B', 0))
sage: F.transitions()
[Transition from 'B' to 'A': 1|-]
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine([('A', 'B', Integer(0)), ('B', 'A', Integer(1))])
>>> F.delete_transition(('A', 'B', Integer(0)))
>>> F.transitions()
[Transition from 'B' to 'A': 1|-]
```

determine_alphabets(*reset=True*)

Determine the input and output alphabet according to the transitions in this finite state machine.

INPUT:

- `reset` – if reset is `True`, then the existing input and output alphabets are erased, otherwise new letters are appended to the existing alphabets.

OUTPUT: nothing

After this operation the input alphabet and the output alphabet of this finite state machine are a list of letters.

Todo

At the moment, the letters of the alphabets need to be hashable.

EXAMPLES:

```
sage: T = Transducer([(1, 1, 1, 0), (1, 2, 2, 1),
....:                 (2, 2, 1, 1), (2, 2, 0, 0)],
```

(continues on next page)

(continued from previous page)

```
....:                     final_states=[1],
....:                     determine_alphabets=False)
sage: T.state(1).final_word_out = [1, 4]
sage: (T.input_alphabet, T.output_alphabet)
(None, None)
sage: T.determine_alphabets()
sage: (T.input_alphabet, T.output_alphabet)
([0, 1, 2], [0, 1, 4])
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(1), Integer(1), Integer(1), Integer(0)),␣
↪(Integer(1), Integer(2), Integer(2), Integer(1)),
...                     (Integer(2), Integer(2), Integer(1), Integer(1)),␣
↪(Integer(2), Integer(2), Integer(0), Integer(0))],
...                   final_states=[Integer(1)],
...                   determine_alphabets=False)
>>> T.state(Integer(1)).final_word_out = [Integer(1), Integer(4)]
>>> (T.input_alphabet, T.output_alphabet)
(None, None)
>>> T.determine_alphabets()
>>> (T.input_alphabet, T.output_alphabet)
([0, 1, 2], [0, 1, 4])
```

See also

determine_input_alphabet(), *determine_output_alphabet()*.

determine_input_alphabet(*reset=True*)

Determine the input alphabet according to the transitions of this finite state machine.

INPUT:

- `reset` – boolean (default: `True`); if `True`, then the existing input alphabet is erased, otherwise new letters are appended to the existing alphabet.

OUTPUT: nothing

After this operation the input alphabet of this finite state machine is a list of letters.

Todo

At the moment, the letters of the alphabet need to be hashable.

EXAMPLES:

```
sage: T = Transducer([(1, 1, 1, 0), (1, 2, 2, 1),
....:                      (2, 2, 1, 1), (2, 2, 0, 0)],
....:                     final_states=[1],
....:                     determine_alphabets=False)
sage: (T.input_alphabet, T.output_alphabet)
(None, None)
```

(continues on next page)

(continued from previous page)

```
sage: T.determine_input_alphabet()
sage: (T.input_alphabet, T.output_alphabet)
([0, 1, 2], None)
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(1), Integer(1), Integer(1), Integer(0)),␣
↪(Integer(1), Integer(2), Integer(2), Integer(1)),
...                    (Integer(2), Integer(2), Integer(1), Integer(1)),␣
↪(Integer(2), Integer(2), Integer(0), Integer(0))],
...                   final_states=[Integer(1)],
...                   determine_alphabets=False)
>>> (T.input_alphabet, T.output_alphabet)
(None, None)
>>> T.determine_input_alphabet()
>>> (T.input_alphabet, T.output_alphabet)
([0, 1, 2], None)
```

See also

determine_output_alphabet(), *determine_alphabets()*.

determine_output_alphabet(*reset=True*)

Determine the output alphabet according to the transitions of this finite state machine.

INPUT:

- `reset` – boolean (default: `True`); if `True`, then the existing output alphabet is erased, otherwise new letters are appended to the existing alphabet.

OUTPUT: nothing

After this operation the output alphabet of this finite state machine is a list of letters.

Todo

At the moment, the letters of the alphabet need to be hashable.

EXAMPLES:

```
sage: T = Transducer([(1, 1, 1, 0), (1, 2, 2, 1),
....:                  (2, 2, 1, 1), (2, 2, 0, 0)],
....:                 final_states=[1],
....:                 determine_alphabets=False)
sage: T.state(1).final_word_out = [1, 4]
sage: (T.input_alphabet, T.output_alphabet)
(None, None)
sage: T.determine_output_alphabet()
sage: (T.input_alphabet, T.output_alphabet)
(None, [0, 1, 4])
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(1), Integer(1), Integer(1), Integer(0)),␣
↪(Integer(1), Integer(2), Integer(2), Integer(1)),
...                 (Integer(2), Integer(2), Integer(1), Integer(1)),␣
↪(Integer(2), Integer(2), Integer(0), Integer(0))],
...                final_states=[Integer(1)],
...                determine_alphabets=False)
>>> T.state(Integer(1)).final_word_out = [Integer(1), Integer(4)]
>>> (T.input_alphabet, T.output_alphabet)
(None, None)
>>> T.determine_output_alphabet()
>>> (T.input_alphabet, T.output_alphabet)
(None, [0, 1, 4])
```

See also

determine_input_alphabet(), *determine_alphabets()*.

digraph(*edge_labels='words_in_out'*)

Return the graph of the finite state machine with labeled vertices and labeled edges.

INPUT:

- **edge_label – (default: 'words_in_out') can be**
  - 'words_in_out' (labels will be strings 'i|o')
  - a function with which takes as input a transition and outputs (returns) the label

OUTPUT: a directed graph

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: T = Transducer()
sage: T.graph()
Looped multi-digraph on 0 vertices
sage: T.add_state(A)
'A'
sage: T.graph()
Looped multi-digraph on 1 vertex
sage: T.add_transition(('A', 'A', 0, 1))
Transition from 'A' to 'A': 0|1
sage: T.graph()
Looped multi-digraph on 1 vertex
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('A')
>>> T = Transducer()
>>> T.graph()
Looped multi-digraph on 0 vertices
>>> T.add_state(A)
```

(continues on next page)

(continued from previous page)

```
'A'
>>> T.graph()
Looped multi-digraph on 1 vertex
>>> T.add_transition(('A', 'A', Integer(0), Integer(1)))
Transition from 'A' to 'A': 0|1
>>> T.graph()
Looped multi-digraph on 1 vertex
```

See also

`DiGraph`

disjoint_union(*other*)

Return the disjoint union of this and another finite state machine.

INPUT:

- `other` – a *FiniteStateMachine*

OUTPUT:

A finite state machine of the same type as this finite state machine.

In general, the disjoint union of two finite state machines is non-deterministic. In the case of a automata, the language accepted by the disjoint union is the union of the languages accepted by the constituent automata. In the case of transducer, for each successful path in one of the constituent transducers, there will be one successful path with the same input and output labels in the disjoint union.

The labels of the states of the disjoint union are pairs `(i, s)`: for each state `s` of this finite state machine, there is a state `(0, s)` in the disjoint union; for each state `s` of the other finite state machine, there is a state `(1, s)` in the disjoint union.

The input alphabet is the union of the input alphabets (if possible) and `None` otherwise. In the latter case, try calling *determine_alphabets()*.

The disjoint union can also be written as `A + B` or `A | B`.

EXAMPLES:

```
sage: A = Automaton([(0, 1, 0), (1, 0, 1)],
....:               initial_states=[0],
....:               final_states=[0])
sage: A([0, 1, 0, 1])
True
sage: B = Automaton([(0, 1, 0), (1, 2, 0), (2, 0, 1)],
....:               initial_states=[0],
....:               final_states=[0])
sage: B([0, 0, 1])
True
sage: C = A.disjoint_union(B)
sage: C
Automaton with 5 states
sage: C.transitions()
[Transition from (0, 0) to (0, 1): 0|-,
 Transition from (0, 1) to (0, 0): 1|-,
```

(continues on next page)

(continued from previous page)

```
 Transition from (1, 0) to (1, 1): 0|-,
 Transition from (1, 1) to (1, 2): 0|-,
 Transition from (1, 2) to (1, 0): 1|-]
sage: C([0, 0, 1])
True
sage: C([0, 1, 0, 1])
True
sage: C([1])
False
sage: C.initial_states()
[(0, 0), (1, 0)]
```

```
>>> from sage.all import *
>>> A = Automaton([(Integer(0), Integer(1), Integer(0)), (Integer(1),␣
↪Integer(0), Integer(1))],
...                initial_states=[Integer(0)],
...                final_states=[Integer(0)])
>>> A([Integer(0), Integer(1), Integer(0), Integer(1)])
True
>>> B = Automaton([(Integer(0), Integer(1), Integer(0)), (Integer(1),␣
↪Integer(2), Integer(0)), (Integer(2), Integer(0), Integer(1))],
...                initial_states=[Integer(0)],
...                final_states=[Integer(0)])
>>> B([Integer(0), Integer(0), Integer(1)])
True
>>> C = A.disjoint_union(B)
>>> C
Automaton with 5 states
>>> C.transitions()
[Transition from (0, 0) to (0, 1): 0|-,
 Transition from (0, 1) to (0, 0): 1|-,
 Transition from (1, 0) to (1, 1): 0|-,
 Transition from (1, 1) to (1, 2): 0|-,
 Transition from (1, 2) to (1, 0): 1|-]
>>> C([Integer(0), Integer(0), Integer(1)])
True
>>> C([Integer(0), Integer(1), Integer(0), Integer(1)])
True
>>> C([Integer(1)])
False
>>> C.initial_states()
[(0, 0), (1, 0)]
```

Instead of `.disjoint_union`, alternative notations are available:

```
sage: C1 = A + B
sage: C1 == C
True
sage: C2 = A | B
sage: C2 == C
True
```

```
>>> from sage.all import *
>>> C1 = A + B
>>> C1 == C
True
>>> C2 = A | B
>>> C2 == C
True
```

In general, the disjoint union is not deterministic.:

```
sage: C.is_deterministic()
False
sage: D = C.determinisation().minimization()
sage: D.is_equivalent(Automaton([(0, 0, 0), (0, 0, 1),
....:    (1, 7, 0), (1, 0, 1), (2, 6, 0), (2, 0, 1),
....:    (3, 5, 0), (3, 0, 1), (4, 0, 0), (4, 2, 1),
....:    (5, 0, 0), (5, 3, 1), (6, 4, 0), (6, 0, 1),
....:    (7, 4, 0), (7, 3, 1)],
....:    initial_states=[1],
....:    final_states=[1, 2, 3]))
True
```

```
>>> from sage.all import *
>>> C.is_deterministic()
False
>>> D = C.determinisation().minimization()
>>> D.is_equivalent(Automaton([(Integer(0), Integer(0), Integer(0)),␣
↪(Integer(0), Integer(0), Integer(1)),
...    (Integer(1), Integer(7), Integer(0)), (Integer(1), Integer(0),␣
↪Integer(1)), (Integer(2), Integer(6), Integer(0)), (Integer(2), Integer(0),␣
↪Integer(1)),
...    (Integer(3), Integer(5), Integer(0)), (Integer(3), Integer(0),␣
↪Integer(1)), (Integer(4), Integer(0), Integer(0)), (Integer(4), Integer(2),␣
↪Integer(1)),
...    (Integer(5), Integer(0), Integer(0)), (Integer(5), Integer(3),␣
↪Integer(1)), (Integer(6), Integer(4), Integer(0)), (Integer(6), Integer(0),␣
↪Integer(1)),
...    (Integer(7), Integer(4), Integer(0)), (Integer(7), Integer(3),␣
↪Integer(1))],
...    initial_states=[Integer(1)],
...    final_states=[Integer(1), Integer(2), Integer(3)]))
True
```

Disjoint union of transducers:

```
sage: T1 = Transducer([(0, 0, 0, 1)],
....:                 initial_states=[0],
....:                 final_states=[0])
sage: T2 = Transducer([(0, 0, 0, 2)],
....:                 initial_states=[0],
....:                 final_states=[0])
sage: T1([0])
[1]
```

(continues on next page)

(continued from previous page)

```
sage: T2([0])
[2]
sage: T = T1.disjoint_union(T2)
sage: T([0])
Traceback (most recent call last):
...
ValueError: Found more than one accepting path.
sage: T.process([0])
[(True, (0, 0), [1]), (True, (1, 0), [2])]
```

```
>>> from sage.all import *
>>> T1 = Transducer([(Integer(0), Integer(0), Integer(0), Integer(1))],
...                 initial_states=[Integer(0)],
...                 final_states=[Integer(0)])
>>> T2 = Transducer([(Integer(0), Integer(0), Integer(0), Integer(2))],
...                 initial_states=[Integer(0)],
...                 final_states=[Integer(0)])
>>> T1([Integer(0)])
[1]
>>> T2([Integer(0)])
[2]
>>> T = T1.disjoint_union(T2)
>>> T([Integer(0)])
Traceback (most recent call last):
...
ValueError: Found more than one accepting path.
>>> T.process([Integer(0)])
[(True, (0, 0), [1]), (True, (1, 0), [2])]
```

Handling of the input alphabet (see Issue #18989):

```
sage: A = Automaton([(0, 0, 0)])
sage: B = Automaton([(0, 0, 1)], input_alphabet=[1, 2])
sage: C = Automaton([(0, 0, 2)], determine_alphabets=False)
sage: D = Automaton([(0, 0, [[0, 0]])], input_alphabet=[[0, 0]])
sage: A.input_alphabet
[0]
sage: B.input_alphabet
[1, 2]
sage: C.input_alphabet is None
True
sage: D.input_alphabet
[[0, 0]]
sage: (A + B).input_alphabet
[0, 1, 2]
sage: (A + C).input_alphabet is None
True
sage: (A + D).input_alphabet is None
True
```

```
>>> from sage.all import *
>>> A = Automaton([(Integer(0), Integer(0), Integer(0))])
```

(continues on next page)

(continued from previous page)

```
>>> B = Automaton([(Integer(0), Integer(0), Integer(1))], input_
↪alphabet=[Integer(1), Integer(2)])
>>> C = Automaton([(Integer(0), Integer(0), Integer(2))], determine_
↪alphabets=False)
>>> D = Automaton([(Integer(0), Integer(0), [[Integer(0), Integer(0)]])],␣
↪input_alphabet=[[Integer(0), Integer(0)]])
>>> A.input_alphabet
[0]
>>> B.input_alphabet
[1, 2]
>>> C.input_alphabet is None
True
>>> D.input_alphabet
[[0, 0]]
>>> (A + B).input_alphabet
[0, 1, 2]
>>> (A + C).input_alphabet is None
True
>>> (A + D).input_alphabet is None
True
```

See also

Automaton.intersection(), *Transducer.intersection()*, *determine_alphabets()*.

empty_copy (*memo=None*, *new_class=None*)

Return an empty deep copy of the finite state machine, i.e., `input_alphabet`, `output_alphabet`, `on_duplicate_transition` are preserved, but states and transitions are not.

INPUT:

- `memo` – dictionary storing already processed elements
- `new_class` – a class for the copy; by default (`None`), the class of `self` is used

OUTPUT: a new finite state machine

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import duplicate_transition_
↪raise_error
sage: F = FiniteStateMachine([('A', 'A', 0, 2), ('A', 'A', 1, 3)],
....:                        input_alphabet=[0, 1],
....:                        output_alphabet=[2, 3],
....:                        on_duplicate_transition=duplicate_transition_
↪raise_error)
sage: FE = F.empty_copy(); FE
Empty finite state machine
sage: FE.input_alphabet
[0, 1]
sage: FE.output_alphabet
[2, 3]
```

(continues on next page)

(continued from previous page)

```
sage: FE.on_duplicate_transition == duplicate_transition_raise_error
True
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import duplicate_transition_raise_
↪error
>>> F = FiniteStateMachine([('A', 'A', Integer(0), Integer(2)), ('A', 'A',␣
↪Integer(1), Integer(3))],
...                        input_alphabet=[Integer(0), Integer(1)],
...                        output_alphabet=[Integer(2), Integer(3)],
...                        on_duplicate_transition=duplicate_transition_raise_
↪error)
>>> FE = F.empty_copy(); FE
Empty finite state machine
>>> FE.input_alphabet
[0, 1]
>>> FE.output_alphabet
[2, 3]
>>> FE.on_duplicate_transition == duplicate_transition_raise_error
True
```

epsilon_successors(*state*)

Return the dictionary with states reachable from `state` without reading anything from an input tape as keys. The values are lists of outputs.

INPUT:

- `state` – the state whose epsilon successors should be determined

OUTPUT: a dictionary mapping states to a list of output words

The states in the output are the epsilon successors of `state`. Each word of the list of output words is a word written when taking a path from `state` to the corresponding state.

EXAMPLES:

```
sage: T = Transducer([(0, 1, None, 'a'), (1, 2, None, 'b')])
sage: T.epsilon_successors(0)
{1: [['a']], 2: [['a', 'b']]}
sage: T.epsilon_successors(1)
{2: [['b']]}
sage: T.epsilon_successors(2)
{}
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(1), None, 'a'), (Integer(1),␣
↪Integer(2), None, 'b')])
>>> T.epsilon_successors(Integer(0))
{1: [['a']], 2: [['a', 'b']]}
>>> T.epsilon_successors(Integer(1))
{2: [['b']]}
>>> T.epsilon_successors(Integer(2))
{}
```

If there is a cycle with only epsilon transitions, then this cycle is only processed once and there is no infinite loop:

```
sage: S = Transducer([(0, 1, None, 'a'), (1, 0, None, 'b')])
sage: S.epsilon_successors(0)
{0: [['a', 'b']], 1: [['a']]}
sage: S.epsilon_successors(1)
{0: [['b']], 1: [['b', 'a']]}
```

```
>>> from sage.all import *
>>> S = Transducer([(Integer(0), Integer(1), None, 'a'), (Integer(1),␣
↪Integer(0), None, 'b')])
>>> S.epsilon_successors(Integer(0))
{0: [['a', 'b']], 1: [['a']]}
>>> S.epsilon_successors(Integer(1))
{0: [['b']], 1: [['b', 'a']]}
```

equivalence_classes()

Return a list of equivalence classes of states.

Two states a and b are equivalent if and only if there is a bijection φ between paths starting at a and paths starting at b with the following properties: Let p_a be a path from a to a' and p_b a path from b to b' such that $\varphi(p_a) = p_b$, then

- $p_a.word_{in} = p_b.word_{in}$,
- $p_a.word_{out} = p_b.word_{out}$,
- a' and b' have the same output label, and
- a' and b' are both final or both non-final and have the same final output word.

The function *equivalence_classes()* returns a list of the equivalence classes to this equivalence relation.

This is one step of Moore's minimization algorithm.

See also

minimization()

EXAMPLES:

```
sage: fsm = FiniteStateMachine([("A", "B", 0, 1), ("A", "B", 1, 0),
....:                           ("B", "C", 0, 0), ("B", "C", 1, 1),
....:                           ("C", "D", 0, 1), ("C", "D", 1, 0),
....:                           ("D", "A", 0, 0), ("D", "A", 1, 1)])
sage: sorted(fsm.equivalence_classes())
[['A', 'C'], ['B', 'D']]
sage: fsm.state("A").is_final = True
sage: sorted(fsm.equivalence_classes())
[['A'], ['B'], ['C'], ['D']]
sage: fsm.state("C").is_final = True
sage: sorted(fsm.equivalence_classes())
[['A', 'C'], ['B', 'D']]
sage: fsm.state("A").final_word_out = 1
sage: sorted(fsm.equivalence_classes())
```

(continues on next page)

(continued from previous page)

```
[['A'], ['B'], ['C'], ['D']]
sage: fsm.state("C").final_word_out = 1
sage: sorted(fsm.equivalence_classes())
[['A', 'C'], ['B', 'D']]
```

```
>>> from sage.all import *
>>> fsm = FiniteStateMachine([("A", "B", Integer(0), Integer(1)), ("A", "B",
↪Integer(1), Integer(0)),
...                           ("B", "C", Integer(0), Integer(0)), ("B", "C",
↪Integer(1), Integer(1)),
...                           ("C", "D", Integer(0), Integer(1)), ("C", "D",
↪Integer(1), Integer(0)),
...                           ("D", "A", Integer(0), Integer(0)), ("D", "A",
↪Integer(1), Integer(1))])
>>> sorted(fsm.equivalence_classes())
[['A', 'C'], ['B', 'D']]
>>> fsm.state("A").is_final = True
>>> sorted(fsm.equivalence_classes())
[['A'], ['B'], ['C'], ['D']]
>>> fsm.state("C").is_final = True
>>> sorted(fsm.equivalence_classes())
[['A', 'C'], ['B', 'D']]
>>> fsm.state("A").final_word_out = Integer(1)
>>> sorted(fsm.equivalence_classes())
[['A'], ['B'], ['C'], ['D']]
>>> fsm.state("C").final_word_out = Integer(1)
>>> sorted(fsm.equivalence_classes())
[['A', 'C'], ['B', 'D']]
```

final_components()

Return the final components of a finite state machine as finite state machines.

OUTPUT:

A list of finite state machines, each representing a final component of `self`.

A final component of a transducer `T` is a strongly connected component `C` such that there are no transitions of `T` leaving `C`.

The final components are the only parts of a transducer which influence the main terms of the asymptotic behaviour of the sum of output labels of a transducer, see [HKP2015] and [HKW2015].

EXAMPLES:

```
sage: T = Transducer([['A', 'B', 0, 0], ['B', 'C', 0, 1],
....:                 ['C', 'B', 0, 1], ['A', 'D', 1, 0],
....:                 ['D', 'D', 0, 0], ['D', 'B', 1, 0],
....:                 ['A', 'E', 2, 0], ['E', 'E', 0, 0]])
sage: FC = T.final_components()
sage: sorted(FC[0].transitions())
[Transition from 'B' to 'C': 0|1,
 Transition from 'C' to 'B': 0|1]
sage: FC[1].transitions()
[Transition from 'E' to 'E': 0|0]
```

```
>>> from sage.all import *
>>> T = Transducer([['A', 'B', Integer(0), Integer(0)], ['B', 'C', Integer(0),
↪ Integer(1)],
...                 ['C', 'B', Integer(0), Integer(1)], ['A', 'D', Integer(1),
↪ Integer(0)],
...                 ['D', 'D', Integer(0), Integer(0)], ['D', 'B', Integer(1),
↪ Integer(0)],
...                 ['A', 'E', Integer(2), Integer(0)], ['E', 'E', Integer(0),
↪ Integer(0)]])
>>> FC = T.final_components()
>>> sorted(FC[Integer(0)].transitions())
[Transition from 'B' to 'C': 0|1,
 Transition from 'C' to 'B': 0|1]
>>> FC[Integer(1)].transitions()
[Transition from 'E' to 'E': 0|0]
```

Another example (cycle of length 2):

```
sage: T = Automaton([[0, 1, 0], [1, 0, 0]])
sage: len(T.final_components()) == 1
True
sage: T.final_components()[0].transitions()
[Transition from 0 to 1: 0|-,
 Transition from 1 to 0: 0|-]
```

```
>>> from sage.all import *
>>> T = Automaton([[Integer(0), Integer(1), Integer(0)], [Integer(1),␣
↪Integer(0), Integer(0)]])
>>> len(T.final_components()) == Integer(1)
True
>>> T.final_components()[Integer(0)].transitions()
[Transition from 0 to 1: 0|-,
 Transition from 1 to 0: 0|-]
```

final_states()

Return a list of all final states.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_final=True)
sage: B = FSMState('B', is_initial=True)
sage: C = FSMState('C', is_final=True)
sage: F = FiniteStateMachine([(A, B), (A, C)])
sage: F.final_states()
['A', 'C']
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('A', is_final=True)
>>> B = FSMState('B', is_initial=True)
>>> C = FSMState('C', is_final=True)
>>> F = FiniteStateMachine([(A, B), (A, C)])
```

(continues on next page)

(continued from previous page)

```
>>> F.final_states()
['A', 'C']
```

format_letter = <sage.misc.latex.Latex object>

format_letter_negative(*letter*)

Format negative numbers as overlined numbers, everything else by standard LaTeX formatting.

INPUT:

- `letter` – anything

OUTPUT:

Overlined absolute value if letter is a negative integer, `latex(letter)` otherwise.

EXAMPLES:

```
sage: A = Automaton([(0, 0, -1)])
sage: list(map(A.format_letter_negative, [-1, 0, 1, 'a', None]))
['\\overline{1}', 0, 1, \text{\texttt{a}}, \mathrm{None}]
sage: A.latex_options(format_letter=A.format_letter_negative)
sage: print(latex(A))
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state] (v0) at (3.000000, 0.000000) {$0$};
\path[->] (v0) edge[loop above] node {$\overline{1}$} ();
\end{tikzpicture}
```

```
>>> from sage.all import *
>>> A = Automaton([(Integer(0), Integer(0), -Integer(1))])
>>> list(map(A.format_letter_negative, [-Integer(1), Integer(0), Integer(1),
↪'a', None]))
['\\overline{1}', 0, 1, \text{\texttt{a}}, \mathrm{None}]
>>> A.latex_options(format_letter=A.format_letter_negative)
>>> print(latex(A))
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state] (v0) at (3.000000, 0.000000) {$0$};
\path[->] (v0) edge[loop above] node {$\overline{1}$} ();
\end{tikzpicture}
```

format_transition_label(*word*)

Default formatting of words in transition labels for LaTeX output.

INPUT:

- `word` – list of letters

OUTPUT:

String representation of `word` suitable to be typeset in mathematical mode.

- For a non-empty word: Concatenation of the letters, piped through `self.format_letter` and separated by blanks.
- For an empty word: `sage.combinat.finite_state_machine.EmptyWordLaTeX`.

There is also a variant *format_transition_label_reversed()* writing the words in reversed order.

EXAMPLES:

1. Example of a non-empty word:

```
sage: T = Transducer()
sage: print(T.default_format_transition_label(
....:     ['a', 'alpha', 'a_1', '0', 0, (0, 1)]))
\text{\texttt{a}} \text{\texttt{alpha}}
\text{\texttt{a{\char`\_}1}} 0 0 \left(0, 1\right)
```

```
>>> from sage.all import *
>>> T = Transducer()
>>> print(T.default_format_transition_label(
...     ['a', 'alpha', 'a_1', '0', Integer(0), (Integer(0), Integer(1))]))
\text{\texttt{a}} \text{\texttt{alpha}}
\text{\texttt{a{\char`\_}1}} 0 0 \left(0, 1\right)
```

2. In the example above, `'a'` and `'alpha'` should perhaps be symbols:

```
sage: var('a alpha a_1')                                                    #␣
↪needs sage.symbolic
(a, alpha, a_1)
sage: print(T.default_format_transition_label([a, alpha, a_1]))           #␣
↪needs sage.symbolic
a \alpha a_{1}
```

```
>>> from sage.all import *
>>> var('a alpha a_1')                                                    #␣
↪needs sage.symbolic
(a, alpha, a_1)
>>> print(T.default_format_transition_label([a, alpha, a_1]))           #␣
↪needs sage.symbolic
a \alpha a_{1}
```

3. Example of an empty word:

```
sage: print(T.default_format_transition_label([]))
\varepsilon
```

```
>>> from sage.all import *
>>> print(T.default_format_transition_label([]))
\varepsilon
```

We can change this by setting `sage.combinat.finite_state_machine.EmptyWordLaTeX`:

```
sage: sage.combinat.finite_state_machine.EmptyWordLaTeX = ''
sage: T.default_format_transition_label([])
''
```

```
>>> from sage.all import *
>>> sage.combinat.finite_state_machine.EmptyWordLaTeX = ''
>>> T.default_format_transition_label([])
''
```

Finally, we restore the default value:

```
sage: sage.combinat.finite_state_machine.EmptyWordLaTeX = r'\varepsilon'
```

```
>>> from sage.all import *
>>> sage.combinat.finite_state_machine.EmptyWordLaTeX = r'\varepsilon'
```

4. This method is the default value for `FiniteStateMachine.format_transition_label`. That can be changed to be any other function:

```
sage: A = Automaton([(0, 1, 0)])
sage: def custom_format_transition_label(word):
....:     return "t"
sage: A.latex_options(format_transition_label=custom_format_transition_
↪label)
sage: print(latex(A))
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state] (v0) at (3.000000, 0.000000) {$0$};
\node[state] (v1) at (-3.000000, 0.000000) {$1$};
\path[->] (v0) edge node[rotate=360.00, anchor=south] {$t$} (v1);
\end{tikzpicture}
```

```
>>> from sage.all import *
>>> A = Automaton([(Integer(0), Integer(1), Integer(0))])
>>> def custom_format_transition_label(word):
...     return "t"
>>> A.latex_options(format_transition_label=custom_format_transition_
↪label)
>>> print(latex(A))
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state] (v0) at (3.000000, 0.000000) {$0$};
\node[state] (v1) at (-3.000000, 0.000000) {$1$};
\path[->] (v0) edge node[rotate=360.00, anchor=south] {$t$} (v1);
\end{tikzpicture}
```

format_transition_label_reversed(*word*)

Format words in transition labels in reversed order.

INPUT:

- `word` – list of letters

OUTPUT:

String representation of `word` suitable to be typeset in mathematical mode, letters are written in reversed order.

This is the reversed version of *default_format_transition_label()*.

In digit expansions, digits are frequently processed from the least significant to the most significant position, but it is customary to write the least significant digit at the right-most position. Therefore, the labels have to be reversed.

EXAMPLES:

```
sage: T = Transducer([(0, 0, 0, [1, 2, 3])])
sage: T.format_transition_label_reversed([1, 2, 3])
'3 2 1'
```

(continues on next page)

(continued from previous page)

```
sage: T.latex_options(format_transition_label=T.format_transition_label_
↪reversed)
sage: print(latex(T))
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state] (v0) at (3.000000, 0.000000) {$0$};
\path[->] (v0) edge[loop above] node {$0\mid 3 2 1$} ();
\end{tikzpicture}
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(0), Integer(0), [Integer(1),␣
↪Integer(2), Integer(3)])])
>>> T.format_transition_label_reversed([Integer(1), Integer(2), Integer(3)])
'3 2 1'
>>> T.latex_options(format_transition_label=T.format_transition_label_
↪reversed)
>>> print(latex(T))
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state] (v0) at (3.000000, 0.000000) {$0$};
\path[->] (v0) edge[loop above] node {$0\mid 3 2 1$} ();
\end{tikzpicture}
```

graph(*edge_labels='words_in_out'*)

Return the graph of the finite state machine with labeled vertices and labeled edges.

INPUT:

- **edge_label – (default: 'words_in_out') can be**
  - 'words_in_out' (labels will be strings 'i|o')
  - a function with which takes as input a transition and outputs (returns) the label

OUTPUT: a directed graph

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: T = Transducer()
sage: T.graph()
Looped multi-digraph on 0 vertices
sage: T.add_state(A)
'A'
sage: T.graph()
Looped multi-digraph on 1 vertex
sage: T.add_transition(('A', 'A', 0, 1))
Transition from 'A' to 'A': 0|1
sage: T.graph()
Looped multi-digraph on 1 vertex
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('A')
>>> T = Transducer()
```

(continues on next page)

(continued from previous page)

```
>>> T.graph()
Looped multi-digraph on 0 vertices
>>> T.add_state(A)
'A'
>>> T.graph()
Looped multi-digraph on 1 vertex
>>> T.add_transition(('A', 'A', Integer(0), Integer(1)))
Transition from 'A' to 'A': 0|1
>>> T.graph()
Looped multi-digraph on 1 vertex
```

See also:

DiGraph

has_final_state(*state*)

Return whether `state` is one of the final states of the finite state machine.

INPUT:

- `state` can be a *FSMState* or a label.

OUTPUT: boolean

EXAMPLES:

```
sage: FiniteStateMachine(final_states=['A']).has_final_state('A')
True
```

```
>>> from sage.all import *
>>> FiniteStateMachine(final_states=['A']).has_final_state('A')
True
```

has_final_states()

Return whether the finite state machine has a final state.

OUTPUT: boolean

EXAMPLES:

```
sage: FiniteStateMachine().has_final_states()
False
```

```
>>> from sage.all import *
>>> FiniteStateMachine().has_final_states()
False
```

has_initial_state(*state*)

Return whether `state` is one of the initial states of the finite state machine.

INPUT:

- `state` can be a *FSMState* or a label.

OUTPUT: boolean

EXAMPLES:

```
sage: F = FiniteStateMachine([('A', 'A')], initial_states=['A'])
sage: F.has_initial_state('A')
True
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine([('A', 'A')], initial_states=['A'])
>>> F.has_initial_state('A')
True
```

has_initial_states()

Return whether the finite state machine has an initial state.

OUTPUT: boolean

EXAMPLES:

```
sage: FiniteStateMachine().has_initial_states()
False
```

```
>>> from sage.all import *
>>> FiniteStateMachine().has_initial_states()
False
```

has_state(*state*)

Return whether `state` is one of the states of the finite state machine.

INPUT:

- `state` can be a *FSMState* or a label of a state.

OUTPUT: boolean

EXAMPLES:

```
sage: FiniteStateMachine().has_state('A')
False
```

```
>>> from sage.all import *
>>> FiniteStateMachine().has_state('A')
False
```

has_transition(*transition*)

Return whether `transition` is one of the transitions of the finite state machine.

INPUT:

- `transition` has to be a *FSMTransition*.

OUTPUT: boolean

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: t = FSMTransition('A', 'A', 0, 1)
sage: FiniteStateMachine().has_transition(t)
False
sage: FiniteStateMachine().has_transition(('A', 'A', 0, 1))
Traceback (most recent call last):
...
TypeError: Transition is not an instance of FSMTransition.
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMTransition
>>> t = FSMTransition('A', 'A', Integer(0), Integer(1))
>>> FiniteStateMachine().has_transition(t)
False
>>> FiniteStateMachine().has_transition(('A', 'A', Integer(0), Integer(1)))
Traceback (most recent call last):
...
TypeError: Transition is not an instance of FSMTransition.
```

induced_sub_finite_state_machine(*states*)

Return a sub-finite-state-machine of the finite state machine induced by the given states.

INPUT:

- `states` – list (or an iterator) of states (either labels or instances of *FSMState*) of the sub-finite-state-machine

OUTPUT:

A new finite state machine. It consists (of deep copies) of the given states and (deep copies) of all transitions of `self` between these states.

EXAMPLES:

```
sage: FSM = FiniteStateMachine([(0, 1, 0), (0, 2, 0),
....:                           (1, 2, 0), (2, 0, 0)])
sage: sub_FSM = FSM.induced_sub_finite_state_machine([0, 1])
sage: sub_FSM.states()
[0, 1]
sage: sub_FSM.transitions()
[Transition from 0 to 1: 0|-]
sage: FSM.induced_sub_finite_state_machine([3])
Traceback (most recent call last):
...
ValueError: 3 is not a state of this finite state machine.
```

```
>>> from sage.all import *
>>> FSM = FiniteStateMachine([(Integer(0), Integer(1), Integer(0)),
↪(Integer(0), Integer(2), Integer(0)),
...                           (Integer(1), Integer(2), Integer(0)),
↪(Integer(2), Integer(0), Integer(0))])
>>> sub_FSM = FSM.induced_sub_finite_state_machine([Integer(0), Integer(1)])
>>> sub_FSM.states()
[0, 1]
>>> sub_FSM.transitions()
```

(continues on next page)

(continued from previous page)

```
[Transition from 0 to 1: 0|-]
>>> FSM.induced_sub_finite_state_machine([Integer(3)])
Traceback (most recent call last):
...
ValueError: 3 is not a state of this finite state machine.
```

initial_states()

Return a list of all initial states.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_initial=True)
sage: B = FSMState('B')
sage: F = FiniteStateMachine([(A, B, 1, 0)])
sage: F.initial_states()
['A']
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('A', is_initial=True)
>>> B = FSMState('B')
>>> F = FiniteStateMachine([(A, B, Integer(1), Integer(0))])
>>> F.initial_states()
['A']
```

input_alphabet = None

A list of letters representing the input alphabet of the finite state machine.

It can be set by the parameter `input_alphabet` when initializing a finite state machine, see *FiniteStateMachine*.

It can also be set by the method *determine_alphabets()*.

See also

FiniteStateMachine, *determine_alphabets()*, *output_alphabet*.

input_projection()

Return an automaton where the output of each transition of `self` is deleted.

OUTPUT: an automaton

EXAMPLES:

```
sage: F = FiniteStateMachine([('A', 'B', 0, 1), ('A', 'A', 1, 1),
....:                          ('B', 'B', 1, 0)])
sage: G = F.input_projection()
sage: G.transitions()
[Transition from 'A' to 'B': 0|-,
 Transition from 'A' to 'A': 1|-,
 Transition from 'B' to 'B': 1|-]
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine([('A', 'B', Integer(0), Integer(1)), ('A', 'A',␣
↪Integer(1), Integer(1)),
...                          ('B', 'B', Integer(1), Integer(0))])
>>> G = F.input_projection()
>>> G.transitions()
[Transition from 'A' to 'B': 0|-,
 Transition from 'A' to 'A': 1|-,
 Transition from 'B' to 'B': 1|-]
```

intersection(*other*)

is_Markov_chain(*is_zero=None*)

Check whether `self` is a Markov chain where the transition probabilities are modeled as input labels.

INPUT:

- `is_zero` – by default (`is_zero=None`), checking for zero is simply done by `is_zero()`. This parameter can be used to provide a more sophisticated check for zero, e.g. in the case of symbolic probabilities, see the examples below.

OUTPUT: boolean

on_duplicate_transition must be *duplicate_transition_add_input()*, the sum of the input weights of the transitions leaving a state must add up to 1 and the sum of initial probabilities must add up to 1 (or all be `None`).

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import duplicate_transition_add_
↪input
sage: F = Transducer([[0, 0, 1/4, 0], [0, 1, 3/4, 1],
....:                 [1, 0, 1/2, 0], [1, 1, 1/2, 1]],
....:                on_duplicate_transition=duplicate_transition_add_input)
sage: F.is_Markov_chain()
True
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import duplicate_transition_add_
↪input
>>> F = Transducer([[Integer(0), Integer(0), Integer(1)/Integer(4),␣
↪Integer(0)], [Integer(0), Integer(1), Integer(3)/Integer(4), Integer(1)],
...                 [Integer(1), Integer(0), Integer(1)/Integer(2),␣
↪Integer(0)], [Integer(1), Integer(1), Integer(1)/Integer(2), Integer(1)]],
...                on_duplicate_transition=duplicate_transition_add_input)
>>> F.is_Markov_chain()
True
```

on_duplicate_transition must be *duplicate_transition_add_input()*:

```
sage: F = Transducer([[0, 0, 1/4, 0], [0, 1, 3/4, 1],
....:                 [1, 0, 1/2, 0], [1, 1, 1/2, 1]])
sage: F.is_Markov_chain()
False
```

```
>>> from sage.all import *
>>> F = Transducer([[Integer(0), Integer(0), Integer(1)/Integer(4),␣
↪Integer(0)], [Integer(0), Integer(1), Integer(3)/Integer(4), Integer(1)],
...                 [Integer(1), Integer(0), Integer(1)/Integer(2),␣
↪Integer(0)], [Integer(1), Integer(1), Integer(1)/Integer(2), Integer(1)]])
>>> F.is_Markov_chain()
False
```

Sum of input labels of the transitions leaving states must be 1:

```
sage: F = Transducer([[0, 0, 1/4, 0], [0, 1, 3/4, 1],
....:                 [1, 0, 1/2, 0]],
....:                on_duplicate_transition=duplicate_transition_add_input)
sage: F.is_Markov_chain()
False
```

```
>>> from sage.all import *
>>> F = Transducer([[Integer(0), Integer(0), Integer(1)/Integer(4),␣
↪Integer(0)], [Integer(0), Integer(1), Integer(3)/Integer(4), Integer(1)],
...                 [Integer(1), Integer(0), Integer(1)/Integer(2),␣
↪Integer(0)]],
...                on_duplicate_transition=duplicate_transition_add_input)
>>> F.is_Markov_chain()
False
```

The initial probabilities of all states must be `None` or they must sum up to 1. The initial probabilities of all states have to be set in the latter case:

```
sage: F = Transducer([[0, 0, 1/4, 0], [0, 1, 3/4, 1],
....:                 [1, 0, 1, 0]],
....:                on_duplicate_transition=duplicate_transition_add_input)
sage: F.is_Markov_chain()
True
sage: F.state(0).initial_probability = 1/4
sage: F.is_Markov_chain()
False
sage: F.state(1).initial_probability = 7
sage: F.is_Markov_chain()
False
sage: F.state(1).initial_probability = 3/4
sage: F.is_Markov_chain()
True
```

```
>>> from sage.all import *
>>> F = Transducer([[Integer(0), Integer(0), Integer(1)/Integer(4),␣
↪Integer(0)], [Integer(0), Integer(1), Integer(3)/Integer(4), Integer(1)],
...                 [Integer(1), Integer(0), Integer(1), Integer(0)]],
...                on_duplicate_transition=duplicate_transition_add_input)
>>> F.is_Markov_chain()
True
>>> F.state(Integer(0)).initial_probability = Integer(1)/Integer(4)
>>> F.is_Markov_chain()
False
```

(continues on next page)

(continued from previous page)

```
>>> F.state(Integer(1)).initial_probability = Integer(7)
>>> F.is_Markov_chain()
False
>>> F.state(Integer(1)).initial_probability = Integer(3)/Integer(4)
>>> F.is_Markov_chain()
True
```

If the probabilities are variables in the symbolic ring, `assume()` will do the trick:

```
sage: # needs sage.symbolic
sage: var('p q')
(p, q)
sage: F = Transducer([(0, 0, p, 1), (0, 0, q, 0)],
....:                 on_duplicate_transition=duplicate_transition_add_input)
sage: assume(p + q == 1)
sage: (p + q - 1).is_zero()
True
sage: F.is_Markov_chain()
True
sage: forget()
sage: del(p, q)
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> var('p q')
(p, q)
>>> F = Transducer([(Integer(0), Integer(0), p, Integer(1)), (Integer(0),␣
↪Integer(0), q, Integer(0))],
...                 on_duplicate_transition=duplicate_transition_add_input)
>>> assume(p + q == Integer(1))
>>> (p + q - Integer(1)).is_zero()
True
>>> F.is_Markov_chain()
True
>>> forget()
>>> del(p, q)
```

If the probabilities are variables in some polynomial ring, the parameter `is_zero` can be used:

```
sage: R.<p, q> = PolynomialRing(QQ)
sage: def is_zero_polynomial(polynomial):
....:     return polynomial in (p + q - 1)*R
sage: F = Transducer([(0, 0, p, 1), (0, 0, q, 0)],
....:                 on_duplicate_transition=duplicate_transition_add_input)
sage: F.state(0).initial_probability = p + q
sage: F.is_Markov_chain()
False
sage: F.is_Markov_chain(is_zero_polynomial)                          #␣
↪needs sage.libs.singular
True
```

```
>>> from sage.all import *
>>> R = PolynomialRing(QQ, names=('p', 'q',)); (p, q,) = R._first_ngens(2)
>>> def is_zero_polynomial(polynomial):
...     return polynomial in (p + q - Integer(1))*R
>>> F = Transducer([(Integer(0), Integer(0), p, Integer(1)), (Integer(0),␣
↪Integer(0), q, Integer(0))],
...                on_duplicate_transition=duplicate_transition_add_input)
>>> F.state(Integer(0)).initial_probability = p + q
>>> F.is_Markov_chain()
False
>>> F.is_Markov_chain(is_zero_polynomial)                               #␣
↪needs sage.libs.singular
True
```

is_complete()

Return whether the finite state machine is complete.

OUTPUT: boolean

A finite state machine is considered to be complete if each transition has an input label of length one and for each pair (q, a) where q is a state and a is an element of the input alphabet, there is exactly one transition from q with input label a.

EXAMPLES:

```
sage: fsm = FiniteStateMachine([(0, 0, 0, 0),
....:                           (0, 1, 1, 1),
....:                           (1, 1, 0, 0)],
....:                          determine_alphabets=False)
sage: fsm.is_complete()
Traceback (most recent call last):
...
ValueError: No input alphabet is given. Try calling determine_alphabets().
sage: fsm.input_alphabet = [0, 1]
sage: fsm.is_complete()
False
sage: fsm.add_transition((1, 1, 1, 1))
Transition from 1 to 1: 1|1
sage: fsm.is_complete()
True
sage: fsm.add_transition((0, 0, 1, 0))
Transition from 0 to 0: 1|0
sage: fsm.is_complete()
False
```

```
>>> from sage.all import *
>>> fsm = FiniteStateMachine([(Integer(0), Integer(0), Integer(0),␣
↪Integer(0)),
...                           (Integer(0), Integer(1), Integer(1),␣
↪Integer(1)),
...                           (Integer(1), Integer(1), Integer(0),␣
↪Integer(0))],
...                          determine_alphabets=False)
>>> fsm.is_complete()
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
ValueError: No input alphabet is given. Try calling determine_alphabets().
>>> fsm.input_alphabet = [Integer(0), Integer(1)]
>>> fsm.is_complete()
False
>>> fsm.add_transition((Integer(1), Integer(1), Integer(1), Integer(1)))
Transition from 1 to 1: 1|1
>>> fsm.is_complete()
True
>>> fsm.add_transition((Integer(0), Integer(0), Integer(1), Integer(0)))
Transition from 0 to 0: 1|0
>>> fsm.is_complete()
False
```

is_connected()

is_deterministic()

Return whether the finite finite state machine is deterministic.

OUTPUT: boolean

A finite state machine is considered to be deterministic if each transition has input label of length one and for each pair (q, a) where q is a state and a is an element of the input alphabet, there is at most one transition from q with input label a. Furthermore, the finite state may not have more than one initial state.

EXAMPLES:

```
sage: fsm = FiniteStateMachine()
sage: fsm.add_transition(('A', 'B', 0, []))
Transition from 'A' to 'B': 0|-
sage: fsm.is_deterministic()
True
sage: fsm.add_transition(('A', 'C', 0, []))
Transition from 'A' to 'C': 0|-
sage: fsm.is_deterministic()
False
sage: fsm.add_transition(('A', 'B', [0,1], []))
Transition from 'A' to 'B': 0,1|-
sage: fsm.is_deterministic()
False
```

```
>>> from sage.all import *
>>> fsm = FiniteStateMachine()
>>> fsm.add_transition(('A', 'B', Integer(0), []))
Transition from 'A' to 'B': 0|-
>>> fsm.is_deterministic()
True
>>> fsm.add_transition(('A', 'C', Integer(0), []))
Transition from 'A' to 'C': 0|-
>>> fsm.is_deterministic()
False
>>> fsm.add_transition(('A', 'B', [Integer(0),Integer(1)], []))
```

(continues on next page)

(continued from previous page)

```
Transition from 'A' to 'B': 0,1|-
>>> fsm.is_deterministic()
False
```

Check that Issue #18556 is fixed:

```
sage: Automaton().is_deterministic()
True
sage: Automaton(initial_states=[0]).is_deterministic()
True
sage: Automaton(initial_states=[0, 1]).is_deterministic()
False
```

```
>>> from sage.all import *
>>> Automaton().is_deterministic()
True
>>> Automaton(initial_states=[Integer(0)]).is_deterministic()
True
>>> Automaton(initial_states=[Integer(0), Integer(1)]).is_deterministic()
False
```

is_monochromatic()

Check whether the colors of all states are equal.

OUTPUT: boolean

EXAMPLES:

```
sage: G = transducers.GrayCode()
sage: [s.color for s in G.iter_states()]
[None, None, None]
sage: G.is_monochromatic()
True
sage: G.state(1).color = 'blue'
sage: G.is_monochromatic()
False
```

```
>>> from sage.all import *
>>> G = transducers.GrayCode()
>>> [s.color for s in G.iter_states()]
[None, None, None]
>>> G.is_monochromatic()
True
>>> G.state(Integer(1)).color = 'blue'
>>> G.is_monochromatic()
False
```

iter_final_states()

Return an iterator of the final states.

OUTPUT: an iterator over all initial states

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_final=True)
sage: B = FSMState('B', is_initial=True)
sage: C = FSMState('C', is_final=True)
sage: F = FiniteStateMachine([(A, B), (A, C)])
sage: [s.label() for s in F.iter_final_states()]
['A', 'C']
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('A', is_final=True)
>>> B = FSMState('B', is_initial=True)
>>> C = FSMState('C', is_final=True)
>>> F = FiniteStateMachine([(A, B), (A, C)])
>>> [s.label() for s in F.iter_final_states()]
['A', 'C']
```

iter_initial_states()

Return an iterator of the initial states.

OUTPUT: an iterator over all initial states

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_initial=True)
sage: B = FSMState('B')
sage: F = FiniteStateMachine([(A, B, 1, 0)])
sage: [s.label() for s in F.iter_initial_states()]
['A']
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('A', is_initial=True)
>>> B = FSMState('B')
>>> F = FiniteStateMachine([(A, B, Integer(1), Integer(0))])
>>> [s.label() for s in F.iter_initial_states()]
['A']
```

iter_process(*input_tape=None*, *initial_state=None*, *process_iterator_class=None*, *iterator_type=None*, *automatic_output_type=False*, ***kwargs*)

This function returns an iterator for processing the input. See `process()` (which runs this iterator until the end) for more information.

INPUT:

- `iterator_type` – if `None` (default), then an instance of `FSMProcessIterator` is returned. If this is `'simple'` only an iterator over one output is returned (an exception is raised if this is not the case, i.e., if the process has branched).

See `process()` for a description of the other parameters.

OUTPUT: an iterator

EXAMPLES:

We can use `iter_process()` to deal with infinite words:

```
sage: inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
....:     initial_states=['A'], final_states=['A'])

sage: # needs sage.combinat
sage: words.FibonacciWord()
word: 0100101001001010010100100101001001010010...
sage: it = inverter.iter_process(
....:     words.FibonacciWord(), iterator_type='simple')
sage: Words([0,1])(it)
word: 1011010110110101101011011010110110101101...
```

```
>>> from sage.all import *
>>> inverter = Transducer({'A': [('A', Integer(0), Integer(1)), ('A',␣
→Integer(1), Integer(0))]},
...     initial_states=['A'], final_states=['A'])

>>> # needs sage.combinat
>>> words.FibonacciWord()
word: 0100101001001010010100100101001001010010...
>>> it = inverter.iter_process(
...     words.FibonacciWord(), iterator_type='simple')
>>> Words([Integer(0),Integer(1)])(it)
word: 1011010110110101101011011010110110101101...
```

This can also be done by:

```
sage: inverter.iter_process(words.FibonacciWord(),                          #␣
→needs sage.combinat
....:                       iterator_type='simple',
....:                       automatic_output_type=True)
word: 1011010110110101101011011010110110101101...
```

```
>>> from sage.all import *
>>> inverter.iter_process(words.FibonacciWord(),                          #␣
→needs sage.combinat
...                       iterator_type='simple',
...                       automatic_output_type=True)
word: 1011010110110101101011011010110110101101...
```

or even simpler by:

```
sage: inverter(words.FibonacciWord())                                       #␣
→needs sage.combinat
word: 1011010110110101101011011010110110101101...
```

```
>>> from sage.all import *
>>> inverter(words.FibonacciWord())                                       #␣
→needs sage.combinat
word: 1011010110110101101011011010110110101101...
```

To see what is going on, we use *iter_process()* without arguments:

```
sage: # needs sage.combinat
sage: from itertools import islice
sage: it = inverter.iter_process(words.FibonacciWord())
sage: for current in islice(it, 4r):
....:     print(current)
process (1 branch)
+ at state 'A'
+-- tape at 1, [[1]]
process (1 branch)
+ at state 'A'
+-- tape at 2, [[1, 0]]
process (1 branch)
+ at state 'A'
+-- tape at 3, [[1, 0, 1]]
process (1 branch)
+ at state 'A'
+-- tape at 4, [[1, 0, 1, 1]]
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> from itertools import islice
>>> it = inverter.iter_process(words.FibonacciWord())
>>> for current in islice(it, 4):
...     print(current)
process (1 branch)
+ at state 'A'
+-- tape at 1, [[1]]
process (1 branch)
+ at state 'A'
+-- tape at 2, [[1, 0]]
process (1 branch)
+ at state 'A'
+-- tape at 3, [[1, 0, 1]]
process (1 branch)
+ at state 'A'
+-- tape at 4, [[1, 0, 1, 1]]
```

The following show the difference between using the `'simple'`-option and not using it. With this option, we have

```
sage: it = inverter.iter_process(input_tape=[0, 1, 1],
....:                            iterator_type='simple')
sage: for i, o in enumerate(it):
....:     print('step %s: output %s' % (i, o))
step 0: output 1
step 1: output 0
step 2: output 0
```

```
>>> from sage.all import *
>>> it = inverter.iter_process(input_tape=[Integer(0), Integer(1),␣
↪Integer(1)],
...                            iterator_type='simple')
```

(continues on next page)

(continued from previous page)

```
>>> for i, o in enumerate(it):
...     print('step %s: output %s' % (i, o))
step 0: output 1
step 1: output 0
step 2: output 0
```

So `iter_process()` is a generator expression which gives a new output letter in each step (and not more). In many cases this is sufficient.

Doing the same without the `'simple'`-option does not give the output directly; it has to be extracted first. On the other hand, additional information is presented:

```
sage: it = inverter.iter_process(input_tape=[0, 1, 1])
sage: for current in it:
....:     print(current)
process (1 branch)
+ at state 'A'
+-- tape at 1, [[1]]
process (1 branch)
+ at state 'A'
+-- tape at 2, [[1, 0]]
process (1 branch)
+ at state 'A'
+-- tape at 3, [[1, 0, 0]]
process (0 branches)
sage: it.result()
[Branch(accept=True, state='A', output=[1, 0, 0])]
```

```
>>> from sage.all import *
>>> it = inverter.iter_process(input_tape=[Integer(0), Integer(1),
↪Integer(1)])
>>> for current in it:
...     print(current)
process (1 branch)
+ at state 'A'
+-- tape at 1, [[1]]
process (1 branch)
+ at state 'A'
+-- tape at 2, [[1, 0]]
process (1 branch)
+ at state 'A'
+-- tape at 3, [[1, 0, 0]]
process (0 branches)
>>> it.result()
[Branch(accept=True, state='A', output=[1, 0, 0])]
```

One can see the growing of the output (the list of lists at the end of each entry).

Even if the transducer has transitions with empty or multiletter output, the simple iterator returns one new output letter in each step:

```
sage: T = Transducer([(0, 0, 0, []),
....:                 (0, 0, 1, [1]),
```

(continues on next page)

(continued from previous page)

```
....:                  (0, 0, 2, [2, 2])],
....:                  initial_states=[0])
sage: it = T.iter_process(input_tape=[0, 1, 2, 0, 1, 2],
....:                     iterator_type='simple')
sage: for i, o in enumerate(it):
....:     print('step %s: output %s' % (i, o))
step 0: output 1
step 1: output 2
step 2: output 2
step 3: output 1
step 4: output 2
step 5: output 2
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(0), Integer(0), []),
...                  (Integer(0), Integer(0), Integer(1), [Integer(1)]),
...                  (Integer(0), Integer(0), Integer(2), [Integer(2),␣
↪Integer(2)])],
...                 initial_states=[Integer(0)])
>>> it = T.iter_process(input_tape=[Integer(0), Integer(1), Integer(2),␣
↪Integer(0), Integer(1), Integer(2)],
...                     iterator_type='simple')
>>> for i, o in enumerate(it):
...     print('step %s: output %s' % (i, o))
step 0: output 1
step 1: output 2
step 2: output 2
step 3: output 1
step 4: output 2
step 5: output 2
```

See also

FiniteStateMachine.process(), *Automaton.process()*, *Transducer.process()*, *__call__()*, *FSMProcessIterator*.

iter_states()

Return an iterator of the states.

OUTPUT: an iterator of the states of the finite state machine

EXAMPLES:

```
sage: FSM = Automaton([('1', '2', 1), ('2', '2', 0)])
sage: [s.label() for s in FSM.iter_states()]
['1', '2']
```

```
>>> from sage.all import *
>>> FSM = Automaton([('1', '2', Integer(1)), ('2', '2', Integer(0))])
>>> [s.label() for s in FSM.iter_states()]
['1', '2']
```

iter_transitions(*from_state=None*)

Return an iterator of all transitions.

INPUT:

- `from_state` – (default: `None`) if `from_state` is given, then a list of transitions starting there is given

OUTPUT: an iterator of all transitions

EXAMPLES:

```
sage: FSM = Automaton([('1', '2', 1), ('2', '2', 0)])
sage: [(t.from_state.label(), t.to_state.label())
....:      for t in FSM.iter_transitions('1')]
[('1', '2')]
sage: [(t.from_state.label(), t.to_state.label())
....:      for t in FSM.iter_transitions('2')]
[('2', '2')]
sage: [(t.from_state.label(), t.to_state.label())
....:      for t in FSM.iter_transitions()]
[('1', '2'), ('2', '2')]
```

```
>>> from sage.all import *
>>> FSM = Automaton([('1', '2', Integer(1)), ('2', '2', Integer(0))])
>>> [(t.from_state.label(), t.to_state.label())
...      for t in FSM.iter_transitions('1')]
[('1', '2')]
>>> [(t.from_state.label(), t.to_state.label())
...      for t in FSM.iter_transitions('2')]
[('2', '2')]
>>> [(t.from_state.label(), t.to_state.label())
...      for t in FSM.iter_transitions()]
[('1', '2'), ('2', '2')]
```

kleene_star()

Compute the Kleene closure of this finite state machine.

OUTPUT:

A *FiniteStateMachine* of the same type as this finite state machine.

Assume that this finite state machine is an automaton recognizing the language $\mathcal{L}$. Then the Kleene star recognizes the language $\mathcal{L}^* = \{w_1 \dots w_n \mid n \geq 0, w_j \in \mathcal{L} \text{ for all } j\}$.

Assume that this finite state machine is a transducer realizing a function f on some alphabet $\mathcal{L}$. Then the Kleene star realizes a function g on $\mathcal{L}^*$ with $g(w_1 \dots w_n) = f(w_1) \dots f(w_n)$.

EXAMPLES:

Kleene star of an automaton:

```
sage: A = automata.Word([0, 1])
sage: B = A.kleene_star()
sage: B.transitions()
[Transition from 0 to 1: 0|-,
 Transition from 2 to 0: -|-,
 Transition from 1 to 2: 1|-]
sage: from sage.combinat.finite_state_machine import (
```

(continues on next page)

(continued from previous page)

```
....:     is_Automaton, is_Transducer)
sage: isinstance(B, Automaton)
True
sage: [w for w in ([], [0, 1], [0, 1, 0], [0, 1, 0, 1], [0, 1, 1, 1])
....:  if B(w)]
[[],
 [0, 1],
 [0, 1, 0, 1]]
```

```
>>> from sage.all import *
>>> A = automata.Word([Integer(0), Integer(1)])
>>> B = A.kleene_star()
>>> B.transitions()
[Transition from 0 to 1: 0|-,
 Transition from 2 to 0: -|-,
 Transition from 1 to 2: 1|-]
>>> from sage.combinat.finite_state_machine import (
...     is_Automaton, is_Transducer)
>>> isinstance(B, Automaton)
True
>>> [w for w in ([], [Integer(0), Integer(1)], [Integer(0), Integer(1),␣
↪Integer(0)], [Integer(0), Integer(1), Integer(0), Integer(1)], [Integer(0),␣
↪Integer(1), Integer(1), Integer(1)])
...  if B(w)]
[[],
 [0, 1],
 [0, 1, 0, 1]]
```

Kleene star of a transducer:

```
sage: T = Transducer([(0, 1, 0, 1), (0, 1, 1, 0)],
....:                initial_states=[0],
....:                final_states=[1])
sage: S = T.kleene_star()
sage: S.transitions()
[Transition from 0 to 1: 0|1,
 Transition from 0 to 1: 1|0,
 Transition from 1 to 0: -|-]
sage: isinstance(S, Transducer)
True
sage: for w in ([], [0], [1], [0, 0], [0, 1]):
....:     print("{} {}".format(w, S.process(w)))
[]     (True, 0, [])
[0]    [(True, 0, [1]), (True, 1, [1])]
[1]    [(True, 0, [0]), (True, 1, [0])]
[0, 0] [(True, 0, [1, 1]), (True, 1, [1, 1])]
[0, 1] [(True, 0, [1, 0]), (True, 1, [1, 0])]
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(1), Integer(0), Integer(1)),␣
↪(Integer(0), Integer(1), Integer(1), Integer(0))],
...                initial_states=[Integer(0)],
```

(continues on next page)

(continued from previous page)

```
...                   final_states=[Integer(1)])
>>> S = T.kleene_star()
>>> S.transitions()
[Transition from 0 to 1: 0|1,
 Transition from 0 to 1: 1|0,
 Transition from 1 to 0: -|-]
>>> isinstance(S, Transducer)
True
>>> for w in ([], [Integer(0)], [Integer(1)], [Integer(0), Integer(0)],␣
↪[Integer(0), Integer(1)]):
...     print("{} {}".format(w, S.process(w)))
[]      (True, 0, [])
[0]     [(True, 0, [1]), (True, 1, [1])]
[1]     [(True, 0, [0]), (True, 1, [0])]
[0, 0] [(True, 0, [1, 1]), (True, 1, [1, 1])]
[0, 1] [(True, 0, [1, 0]), (True, 1, [1, 0])]
```

Final output words are taken into account:

```
sage: T = Transducer([(0, 1, 0, 1)],
....:                 initial_states=[0],
....:                 final_states=[1])
sage: T.state(1).final_word_out = 2
sage: S = T.kleene_star()
sage: sorted(S.process([0, 0]))
[(True, 0, [1, 2, 1, 2]), (True, 1, [1, 2, 1, 2])]
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(1), Integer(0), Integer(1))],
...                   initial_states=[Integer(0)],
...                   final_states=[Integer(1)])
>>> T.state(Integer(1)).final_word_out = Integer(2)
>>> S = T.kleene_star()
>>> sorted(S.process([Integer(0), Integer(0)]))
[(True, 0, [1, 2, 1, 2]), (True, 1, [1, 2, 1, 2])]
```

Final output words may lead to undesirable situations if initial states and final states coincide:

```
sage: T = Transducer(initial_states=[0], final_states=[0])
sage: T.state(0).final_word_out = 1
sage: T([])
[1]
sage: S = T.kleene_star()
sage: S([])
Traceback (most recent call last):
...
RuntimeError: State 0 is in an epsilon cycle (no input), but
output is written.
```

```
>>> from sage.all import *
>>> T = Transducer(initial_states=[Integer(0)], final_states=[Integer(0)])
>>> T.state(Integer(0)).final_word_out = Integer(1)
```

(continues on next page)

(continued from previous page)

```
>>> T([])
[1]
>>> S = T.kleene_star()
>>> S([])
Traceback (most recent call last):
...
RuntimeError: State 0 is in an epsilon cycle (no input), but
output is written.
```

language (*max_length=None*, ***kwargs*)

Return all words that can be written by this transducer.

INPUT:

- `max_length` – integer or `None` (default). Only output words which come from inputs of length at most `max_length` will be considered. If `None`, then this iterates over all possible words without length restrictions.
- `kwargs` – will be passed on to the *process iterator*. See *process()* for a description.

OUTPUT: an iterator

EXAMPLES:

```
sage: NAF = Transducer([('I', 0, 0, None), ('I', 1, 1, None),
....:                   (0, 0, 0, 0), (0, 1, 1, 0),
....:                   (1, 0, 0, 1), (1, 2, 1, -1),
....:                   (2, 1, 0, 0), (2, 2, 1, 0)],
....:                  initial_states=['I'], final_states=[0],
....:                  input_alphabet=[0, 1])
sage: sorted(NAF.language(4),
....:        key=lambda o: (ZZ(o, base=2), len(o)))
[[], [0], [0, 0], [0, 0, 0],
 [1], [1, 0], [1, 0, 0],
 [0, 1], [0, 1, 0],
 [-1, 0, 1],
 [0, 0, 1],
 [1, 0, 1]]
```

```
>>> from sage.all import *

```

See also

Automaton.language(), *process()*.

latex_options(*coordinates=None*, *format_state_label=None*, *format_letter=None*, *format_transition_label=None*, *loop_where=None*, *initial_where=None*, *accepting_style=None*, *accepting_distance=None*, *accepting_where=None*, *accepting_show_empty=None*)

Set options for LaTeX output via `latex()` and therefore `view()`.

INPUT:

- `coordinates` – dictionary or a function mapping labels of states to pairs interpreted as coordinates. If no coordinates are given, states a placed equidistantly on a circle of radius 3. See also *set_coordinates()*.
- `format_state_label` – a function mapping labels of states to a string suitable for typesetting in LaTeX's mathematics mode. If not given, `latex()` is used.
- `format_letter` – a function mapping letters of the input and output alphabets to a string suitable for typesetting in LaTeX's mathematics mode. If not given, *default_format_transition_label()* uses `latex()`.

- `format_transition_label` – a function mapping words over the input and output alphabets to a string suitable for typesetting in LaTeX's mathematics mode. If not given, *`default_format_transition_label()`* is used.
- `loop_where` – dictionary or a function mapping labels of initial states to one of `'above'`, `'left'`, `'below'`, `'right'`. If not given, `'above'` is used.
- `initial_where` – dictionary or a function mapping labels of initial states to one of `'above'`, `'left'`, `'below'`, `'right'`. If not given, TikZ' default (currently `'left'`) is used.
- `accepting_style` – one of `'accepting by double'` and `'accepting by arrow'`. If not given, `'accepting by double'` is used unless there are non-empty final output words.
- `accepting_distance` – string giving a LaTeX length used for the length of the arrow leading from a final state. If not given, TikZ' default (currently `'3ex'`) is used unless there are non-empty final output words, in which case `'7ex'` is used.
- `accepting_where` – dictionary or a function mapping labels of final states to one of `'above'`, `'left'`, `'below'`, `'right'`. If not given, TikZ' default (currently `'right'`) is used. If the final state has a final output word, it is also possible to give an angle in degrees.
- `accepting_show_empty` – if `True` the arrow of an empty final output word is labeled as well. Note that this implicitly implies `accepting_style='accepting by arrow'`. If not given, the default `False` is used.

OUTPUT: nothing

As TikZ (cf. the Wikipedia article PGF/TikZ) is used to typeset the graphics, the syntax is oriented on TikZ' syntax.

This is a convenience function collecting all options for LaTeX output. All of its functionality can also be achieved by directly setting the attributes

- `coordinates`, `format_label`, `loop_where`, `initial_where`, and `accepting_where` of *`FSMState`* (here, `format_label` is a callable without arguments, everything else is a specific value);
- `format_label` of *`FSMTransition`* (`format_label` is a callable without arguments);
- `format_state_label`, `format_letter`, `format_transition_label`, `accepting_style`, `accepting_distance`, and `accepting_show_empty` of *`FiniteStateMachine`*.

This function, however, also (somewhat) checks its input and serves to collect documentation on all these options.

The function can be called several times, only those arguments which are not `None` are taken into account. By the same means, it can be combined with directly setting some attributes as outlined above.

EXAMPLES:

See also the section on *LaTeX output* in the introductory examples of this module.

```

\end{tikzpicture}
>>> view(T) # not tested
```

markov_chain_simplification()

Consider `self` as Markov chain with probabilities as input labels and simplify it.

OUTPUT: simplified version of `self`

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import duplicate_transition_add_
↪input
sage: T = Transducer([[1, 2, 1/4, 0], [1, -2, 1/4, 0], [1, -2, 1/2, 0],
....:                  [2, 2, 1/4, 1], [2, -2, 1/4, 1], [-2, -2, 1/4, 1],
....:                  [-2, 2, 1/4, 1], [2, 3, 1/2, 2], [-2, 3, 1/2, 2]],
....:                 initial_states=[1],
....:                 final_states=[3],
....:                 on_duplicate_transition=duplicate_transition_add_input)
sage: T1 = T.markov_chain_simplification()
```

(continues on next page)

(continued from previous page)

```
sage: sorted(T1.transitions())
[Transition from ((1,),) to ((2, -2),): 1|0,
 Transition from ((2, -2),) to ((2, -2),): 1/2|1,
 Transition from ((2, -2),) to ((3,),): 1/2|2]
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import duplicate_transition_add_
↪input
>>> T = Transducer([[Integer(1), Integer(2), Integer(1)/Integer(4),␣
↪Integer(0)], [Integer(1), -Integer(2), Integer(1)/Integer(4), Integer(0)],␣
↪[Integer(1), -Integer(2), Integer(1)/Integer(2), Integer(0)],
...                 [Integer(2), Integer(2), Integer(1)/Integer(4),␣
↪Integer(1)], [Integer(2), -Integer(2), Integer(1)/Integer(4), Integer(1)],␣
↪[-Integer(2), -Integer(2), Integer(1)/Integer(4), Integer(1)],
...                 [-Integer(2), Integer(2), Integer(1)/Integer(4),␣
↪Integer(1)], [Integer(2), Integer(3), Integer(1)/Integer(2), Integer(2)], [-
↪Integer(2), Integer(3), Integer(1)/Integer(2), Integer(2)]],
...                initial_states=[Integer(1)],
...                final_states=[Integer(3)],
...                on_duplicate_transition=duplicate_transition_add_input)
>>> T1 = T.markov_chain_simplification()
>>> sorted(T1.transitions())
[Transition from ((1,),) to ((2, -2),): 1|0,
 Transition from ((2, -2),) to ((2, -2),): 1/2|1,
 Transition from ((2, -2),) to ((3,),): 1/2|2]
```

merged_transitions()

Merges transitions which have the same `from_state`, `to_state` and `word_out` while adding their `word_in`.

OUTPUT:

A finite state machine with merged transitions. If no mergers occur, return `self`.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import duplicate_transition_add_
↪input
sage: T = Transducer([[1, 2, 1/4, 1], [1, -2, 1/4, 1], [1, -2, 1/2, 1],
....:                 [2, 2, 1/4, 1], [2, -2, 1/4, 1], [-2, -2, 1/4, 1],
....:                 [-2, 2, 1/4, 1], [2, 3, 1/2, 1], [-2, 3, 1/2, 1]],
....:                on_duplicate_transition=duplicate_transition_add_input)
sage: T1 = T.merged_transitions()
sage: T1 is T
False
sage: sorted(T1.transitions())
[Transition from -2 to -2: 1/4|1,
 Transition from -2 to 2: 1/4|1,
 Transition from -2 to 3: 1/2|1,
 Transition from 1 to 2: 1/4|1,
 Transition from 1 to -2: 3/4|1,
 Transition from 2 to -2: 1/4|1,
 Transition from 2 to 2: 1/4|1,
```

(continues on next page)

(continued from previous page)

```
Transition from 2 to 3: 1/2|1]
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import duplicate_transition_add_
↪input
>>> T = Transducer([[Integer(1), Integer(2), Integer(1)/Integer(4),␣
↪Integer(1)], [Integer(1), -Integer(2), Integer(1)/Integer(4), Integer(1)],␣
↪[Integer(1), -Integer(2), Integer(1)/Integer(2), Integer(1)],
...                 [Integer(2), Integer(2), Integer(1)/Integer(4),␣
↪Integer(1)], [Integer(2), -Integer(2), Integer(1)/Integer(4), Integer(1)],␣
↪[-Integer(2), -Integer(2), Integer(1)/Integer(4), Integer(1)],
...                 [-Integer(2), Integer(2), Integer(1)/Integer(4),␣
↪Integer(1)], [Integer(2), Integer(3), Integer(1)/Integer(2), Integer(1)], [-
↪Integer(2), Integer(3), Integer(1)/Integer(2), Integer(1)]],
...                on_duplicate_transition=duplicate_transition_add_input)
>>> T1 = T.merged_transitions()
>>> T1 is T
False
>>> sorted(T1.transitions())
[Transition from -2 to -2: 1/4|1,
 Transition from -2 to 2: 1/4|1,
 Transition from -2 to 3: 1/2|1,
 Transition from 1 to 2: 1/4|1,
 Transition from 1 to -2: 3/4|1,
 Transition from 2 to -2: 1/4|1,
 Transition from 2 to 2: 1/4|1,
 Transition from 2 to 3: 1/2|1]
```

Applying the function again does not change the result:

```
sage: T2 = T1.merged_transitions()
sage: T2 is T1
True
```

```
>>> from sage.all import *
>>> T2 = T1.merged_transitions()
>>> T2 is T1
True
```

moments_waiting_time(*test=<class 'bool'>*, *is_zero=None*, *expectation_only=False*)

If this finite state machine acts as a Markov chain, return the expectation and variance of the number of steps until first writing `True`.

INPUT:

- `test` – (default: `bool`) a callable deciding whether an output label is to be considered `True`. By default, the standard conversion to boolean is used.
- `is_zero` – (default: `None`) a callable deciding whether an expression for a probability is zero. By default, checking for zero is simply done by `is_zero()`. This parameter can be used to provide a more sophisticated check for zero, e.g. in the case of symbolic probabilities, see the examples below. This parameter is passed on to `is_Markov_chain()`. This parameter only affects the input of the Markov chain.

- `expectation_only` – boolean (default: `False`); if set, the variance is not computed (in order to save time). By default, the variance is computed.

OUTPUT:

A dictionary (if `expectation_only=False`) consisting of

- `expectation`,
- `variance`.

Otherwise, just the expectation is returned (no dictionary for `expectation_only=True`).

Expectation and variance of the number of steps until first writing `True` (as determined by the parameter `test`).

ALGORITHM:

Relies on a (classical and easy) probabilistic argument, cf. [FGT1992], Eqns. (6) and (7).

For the variance, see [FHP2015], Section 2.

EXAMPLES:

1. The simplest example is to wait for the first 1 in a 0-1-string where both digits appear with probability $1/2$. In fact, the waiting time equals k if and only if the string starts with $0^{k-1}1$. This event occurs with probability 2^{-k}. Therefore, the expected waiting time and the variance are $\sum_{k\geq 1} k2^{-k} = 2$ and $\sum_{k\geq 1}(k-2)^2 2^{-k} = 2$:

```
sage: var('k')                                                              # needs sage.symbolic
k
sage: sum(k * 2^(-k), k, 1, infinity)                                       # needs sage.symbolic
2
sage: sum((k-2)^2 * 2^(-k), k, 1, infinity)                                 # needs sage.symbolic
2
```

```
>>> from sage.all import *
>>> var('k')                                                                # needs sage.symbolic
k
>>> sum(k * Integer(2)**(-k), k, Integer(1), infinity)                      # needs sage.symbolic
2
>>> sum((k-Integer(2))**Integer(2) * Integer(2)**(-k), k, Integer(1), infinity)                                           # needs sage.symbolic
2
```

We now compute the same expectation and variance by using a Markov chain:

```
sage: from sage.combinat.finite_state_machine import (
....:     duplicate_transition_add_input)
sage: T = Transducer(
....:     [(0, 0, 1/2, 0), (0, 0, 1/2, 1)],
....:     on_duplicate_transition=\
....:         duplicate_transition_add_input,
....:     initial_states=[0],
```

(continues on next page)

(continued from previous page)

```
....:     final_states=[0])
sage: T.moments_waiting_time()
{'expectation': 2, 'variance': 2}
sage: T.moments_waiting_time(expectation_only=True)
2
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import (
...     duplicate_transition_add_input)
>>> T = Transducer(
...     [(Integer(0), Integer(0), Integer(1)/Integer(2), Integer(0)),␣
↪(Integer(0), Integer(0), Integer(1)/Integer(2), Integer(1))],
...     on_duplicate_transition=        duplicate_transition_add_input,
...     initial_states=[Integer(0)],
...     final_states=[Integer(0)])
>>> T.moments_waiting_time()
{'expectation': 2, 'variance': 2}
>>> T.moments_waiting_time(expectation_only=True)
2
```

In the following, we replace the output `0` by `-1` and demonstrate the use of the parameter `test`:

```
sage: T.delete_transition((0, 0, 1/2, 0))
sage: T.add_transition((0, 0, 1/2, -1))
Transition from 0 to 0: 1/2|-1
sage: T.moments_waiting_time(test=lambda x: x<0)
{'expectation': 2, 'variance': 2}
```

```
>>> from sage.all import *
>>> T.delete_transition((Integer(0), Integer(0), Integer(1)/Integer(2),␣
↪Integer(0)))
>>> T.add_transition((Integer(0), Integer(0), Integer(1)/Integer(2), -
↪Integer(1)))
Transition from 0 to 0: 1/2|-1
>>> T.moments_waiting_time(test=lambda x: x<Integer(0))
{'expectation': 2, 'variance': 2}
```

2. Make sure that the transducer is actually a Markov chain. Although this is checked by the code, unexpected behaviour may still occur if the transducer looks like a Markov chain. In the following example, we 'forget' to assign probabilities, but due to a coincidence, all 'probabilities' add up to one. Nevertheless, 0 is never written, so the expectation is 1.

```
sage: T = Transducer([(0, 0, 0, 0), (0, 0, 1, 1)],
....:                on_duplicate_transition=\
....:                    duplicate_transition_add_input,
....:                initial_states=[0],
....:                final_states=[0])
sage: T.moments_waiting_time()
{'expectation': 1, 'variance': 0}
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(0), Integer(0), Integer(0)),␣
```

(continues on next page)

(continued from previous page)

```
↪(Integer(0), Integer(0), Integer(1), Integer(1))],
...                   on_duplicate_transition=                   duplicate_
↪transition_add_input,
...                   initial_states=[Integer(0)],
...                   final_states=[Integer(0)])
>>> T.moments_waiting_time()
{'expectation': 1, 'variance': 0}
```

3. If `True` is never written, the moments are `+Infinity`:

```
sage: T = Transducer([(0, 0, 1, 0)],
....:                   on_duplicate_transition=\
....:                       duplicate_transition_add_input,
....:                   initial_states=[0],
....:                   final_states=[0])
sage: T.moments_waiting_time()
{'expectation': +Infinity, 'variance': +Infinity}
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(0), Integer(1), Integer(0))],
...                   on_duplicate_transition=                   duplicate_
↪transition_add_input,
...                   initial_states=[Integer(0)],
...                   final_states=[Integer(0)])
>>> T.moments_waiting_time()
{'expectation': +Infinity, 'variance': +Infinity}
```

4. Let h and r be positive integers. We consider random strings of letters $1, \ldots, r$ where the letter j occurs with probability p_j. Let B be the random variable giving the first position of a block of h consecutive identical letters. Then

$$\mathbb{E}(B) = \frac{1}{\displaystyle\sum_{i=1}^{r} \frac{1}{p_i^{-1} + \cdots + p_i^{-h}}},$$

$$\mathbb{V}(B) = \frac{\displaystyle\sum_{i=1}^{r} \left(\frac{p_i + p_i^h}{1 - p_i^h} - 2h \frac{p_i^h (1 - p_i)}{(1 - p_i^h)^2} \right)}{\displaystyle\left(\sum_{i=1}^{r} \frac{1}{p_i^{-1} + \cdots + p_i^{-h}} \right)^2}$$

cf. [S1986], p. 62, or [FHP2015], Theorem 1. We now verify this with a transducer approach.

```
sage: # needs sage.libs.singular
sage: def test(h, r):
....:     R = PolynomialRing(
....:             QQ,
....:             names=['p_%d' % j for j in range(r)])
....:     p = R.gens()
....:     def is_zero(polynomial):
....:         return polynomial in (sum(p) - 1) * R
....:     theory_expectation = 1/(sum(1/sum(p[j]^(-i)
....:                         for i in range(1, h+1))
```

(continues on next page)

(continued from previous page)

```
....:                         for j in range(r)))
....:     theory_variance = sum(
....:         (p[i] + p[i]^h)/(1 - p[i]^h)
....:         - 2*h*p[i]^h * (1 - p[i])/(1 - p[i]^h)^2
....:         for i in range(r)
....:         ) * theory_expectation^2
....:     alphabet = list(range(r))
....:     counters = [
....:         transducers.CountSubblockOccurrences([j]*h,
....:                     alphabet)
....:         for j in alphabet]
....:     all_counter = counters[0].cartesian_product(
....:         counters[1:])
....:     adder = transducers.add(input_alphabet=[0, 1],
....:         number_of_operands=r)
....:     probabilities = Transducer(
....:        [(0, 0, p[j], j) for j in alphabet],
....:        initial_states=[0],
....:        final_states=[0],
....:        on_duplicate_transition=\
....:            duplicate_transition_add_input)
....:     chain = adder(all_counter(probabilities))
....:     result = chain.moments_waiting_time(
....:        is_zero=is_zero)
....:     return is_zero((result['expectation'] -

...         - Integer(2)*h*p[i]**h * (Integer(1) - p[i])/(Integer(1) -
↪p[i]**h)**Integer(2)
```

(continues on next page)

(continued from previous page)

```
...             for i in range(r)
...             ) * theory_expectation**Integer(2)
...         alphabet = list(range(r))
...         counters = [
...             transducers.CountSubblockOccurrences([j]*h,
...                         alphabet)
...             for j in alphabet]
...         all_counter = counters[Integer(0)].cartesian_product(
...             counters[Integer(1):])
...         adder = transducers.add(input_alphabet=[Integer(0), Integer(1)],
...             number_of_operands=r)
...         probabilities = Transducer(
...            [(Integer(0), Integer(0), p[j], j) for j in alphabet],
...            initial_states=[Integer(0)],
...            final_states=[Integer(0)],
...            on_duplicate_transition=           duplicate_transition_add_
↪input)
...         chain = adder(all_counter(probabilities))
...         result = chain.moments_waiting_time(
...            is_zero=is_zero)
...         return is_zero((result['expectation'] -
...                     theory_expectation).numerator())            and        ␣
↪    is_zero((result['variance'] -
...                      theory_variance).numerator())
>>> test(Integer(2), Integer(2))
True
>>> test(Integer(2), Integer(3))
True
>>> test(Integer(3), Integer(3))
True
```

5. Consider the alphabet $\{0, \ldots, r-1\}$, some $1 \leq j \leq r$ and some $h \geq 1$. For some probabilities $p_0, \ldots, p_{r-1}$, we consider infinite words where the letters occur independently with the given probabilities. The random variable B_j is the first position n such that there exist j of the r letters having an h-run. The expectation of B_j is given in [FHP2015], Theorem 2. Here, we verify this result by using transducers:

```
sage: # needs sage.libs.singular
sage: def test(h, r, j):
....:     R = PolynomialRing(
....:             QQ,
....:             names=['p_%d' % i for i in range(r)])
....:     p = R.gens()
....:     def is_zero(polynomial):
....:         return polynomial in (sum(p) - 1) * R
....:     alphabet = list(range(r))
....:     counters = [
....:         transducers.Wait([0, 1])(
....:             transducers.CountSubblockOccurrences(
....:                 [i]*h,
....:                 alphabet))
....:         for i in alphabet]
....:     all_counter = counters[0].cartesian_product(
```

(continues on next page)

(continued from previous page)

```
....:         counters[1:])
....:     adder = transducers.add(input_alphabet=[0, 1],
....:         number_of_operands=r)
....:     threshold = transducers.map(
....:         f=lambda x: x >= j,
....:         input_alphabet=srange(r+1))
....:     probabilities = Transducer(
....:         [(0, 0, p[i], i) for i in alphabet],
....:         initial_states=[0],
....:         final_states=[0],
....:         on_duplicate_transition=\
....:             duplicate_transition_add_input)
....:     chain = threshold(adder(all_counter(
....:         probabilities)))
....:     result = chain.moments_waiting_time(
....:         is_zero=is_zero,
....:         expectation_only=True)
....:     R_v = PolynomialRing(

REFERENCES:

number_of_words(*variable=None*, *base_ring=None*)

Return the number of successful input words of given length.

INPUT:

- `variable` – a symbol denoting the length of the words, by default n
- `base_ring` – ring (default: `QQbar`) in which to compute the eigenvalues

OUTPUT: a symbolic expression

EXAMPLES:

```
sage: NAFpm = Automaton([(0, 0, 0), (0, 1, 1),
....:                    (0, 1, -1), (1, 0, 0)],
....:                   initial_states=[0],
....:                   final_states=[0, 1])
sage: N = NAFpm.number_of_words(); N                                      #␣
↪needs sage.symbolic
4/3*2^n - 1/3*(-1)^n
sage: all(len(list(NAFpm.language(s)))                                   #␣
↪needs sage.symbolic
....:     - len(list(NAFpm.language(s-1))) == N.subs(n=s)
....:     for s in srange(1, 6))
True
```

```
>>> from sage.all import *
>>> NAFpm = Automaton([(Integer(0), Integer(0), Integer(0)), (Integer(0),␣
↪Integer(1), Integer(1)),
...                    (Integer(0), Integer(1), -Integer(1)), (Integer(1),␣
↪Integer(0), Integer(0))],
...                   initial_states=[Integer(0)],

>>> all(len(list(NAFp.language(s)))                                    #␣
↪needs sage.rings.number_field sage.symbolic
...     - len(list(NAFp.language(s-Integer(1)))) == N.subs(n=s)
...     for s in srange(Integer(1), Integer(6)))
True
```

We specify a suitable `base_ring` to obtain a radical expression. To do so, we first compute the characteristic polynomial and then construct a number field generated by its roots.

```
sage: # needs sage.rings.number_field sage.symbolic
sage: M = NAFp.adjacency_matrix(entry=lambda t: 1)
sage: M.characteristic_polynomial()
x^2 - x - 1
sage: R.<phi> = NumberField(x^2 - x - 1, embedding=1.6)
sage: N = NAFp.number_of_words(base_ring=R); N
1/2*(1/2*sqrt(5) + 1/2)^n*(3*sqrt(1/5) + 1)
- 1/2*(-1/2*sqrt(5) + 1/2)^n*(3*sqrt(1/5) - 1)
sage: all(len(list(NAFp.language(s)))
....:     - len(list(NAFp.language(s-1))) == N.subs(n=s)
....:     for s in srange(1, 6))
True
```

```
>>> from sage.all import *
>>> # needs sage.rings.number_field sage.symbolic
>>> M = NAFp.adjacency_matrix(entry=lambda t: Integer(1))
>>> M.characteristic_polynomial()
x^2 - x - 1
>>> R = NumberField(x**Integer(2) - x - Integer(1), embedding=RealNumber('1.6
↪'), names=('phi',)); (phi,) = R._first_ngens(1)
>>> N = NAFp.number_of_words(base_ring=R); N
1/2*(1/2*sqrt(5) + 1/2)^n*(3*sqrt(1/5) + 1)
- 1/2*(-1/2*sqrt(5) + 1/2)^n*(3*sqrt(1/5) - 1)
>>> all(len(list(NAFp.language(s)))
...     - len(list(NAFp.language(s-Integer(1)))) == N.subs(n=s)
...     for s in srange(Integer(1), Integer(6)))
True
```

In this special case, we might also use the constant `golden_ratio`:

```
sage: # needs sage.rings.number_field sage.symbolic
sage: R.<phi> = NumberField(x^2-x-1, embedding=golden_ratio)
sage: N = NAFp.number_of_words(base_ring=R); N
1/5*(3*golden_ratio + 1)*golden_ratio^n
- 1/5*(3*golden_ratio - 4)*(-golden_ratio + 1)^n
sage: all(len(list(NAFp.language(s)))
....:     - len(list(NAFp.language(s-1))) == N.subs(n=s)
....:     for s in srange(1, 6))
True
```

```
>>> from sage.all import *
>>> # needs sage.rings.number_field sage.symbolic
>>> R = NumberField(x**Integer(2)-x-Integer(1), embedding=golden_ratio,␣
↪names=('phi',)); (phi,) = R._first_ngens(1)
>>> N = NAFp.number_of_words(base_ring=R); N
1/5*(3*golden_ratio + 1)*golden_ratio^n
- 1/5*(3*golden_ratio - 4)*(-golden_ratio + 1)^n
>>> all(len(list(NAFp.language(s)))
...     - len(list(NAFp.language(s-Integer(1)))) == N.subs(n=s)
...     for s in srange(Integer(1), Integer(6)))
True
```

The adjacency matrix of the following example is a Jordan matrix of size 3 to the eigenvalue 4:

```
sage: J3 = Automaton([(0, 1, -1), (1, 2, -1)],
....:     initial_states=[0],
....:     final_states=[0, 1, 2])
sage: for i in range(3):
....:     for j in range(4):
....:         new_transition = J3.add_transition(i, i, j)
sage: J3.adjacency_matrix(entry=lambda t: 1)
[4 1 0]
[0 4 1]
[0 0 4]
sage: N = J3.number_of_words(); N                                          #␣
↪needs sage.symbolic
1/2*4^(n - 2)*(n - 1)*n + 4^(n - 1)*n + 4^n
sage: all(len(list(J3.language(s)))                                        #␣
↪needs sage.symbolic
....:     - len(list(J3.language(s-1))) == N.subs(n=s)
....:     for s in range(1, 6))
True
```

```
>>> from sage.all import *
>>> J3 = Automaton([(Integer(0), Integer(1), -Integer(1)), (Integer(1),␣
↪Integer(2), -Integer(1))],
...     initial_states=[Integer(0)],
...     final_states=[Integer(0), Integer(1), Integer(2)])
>>> for i in range(Integer(3)):
...     for j in range(Integer(4)):
...         new_transition = J3.add_transition(i, i, j)
>>> J3.adjacency_matrix(entry=lambda t: Integer(1))
```

(continues on next page)

(continued from previous page)

```
[4 1 0]
[0 4 1]

...     for s in range(Integer(1), Integer(6)))
True
```

Here is an automaton without cycles, so with eigenvalue 0.

```
sage: A = Automaton([(j, j+1, 0) for j in range(3)],
....:               initial_states=[0],
....:               final_states=list(range(3)))
sage: A.number_of_words()                                                 #␣
↪needs sage.symbolic
1/2*0^(n - 2)*(n - 1)*n + 0^(n - 1)*n + 0^n
```

```
>>> from sage.all import *
>>> A = Automaton([(j, j+Integer(1), Integer(0)) for j in range(Integer(3))],
...               initial_states=[Integer(0)],
...               final_states=list(range(Integer(3))))
>>> A.number_of_words()                                                  #␣
↪needs sage.symbolic
1/2*0^(n - 2)*(n - 1)*n + 0^(n - 1)*n + 0^n
```

on_duplicate_transition(*old_transition*, *new_transition*)

Which function to call when a duplicate transition is inserted.

It can be set by the parameter `on_duplicate_transition` when initializing a finite state machine, see *FiniteStateMachine*.

See also

FiniteStateMachine, *is_Markov_chain()*, *markov_chain_simplification()*.

output_alphabet = None

A list of letters representing the output alphabet of the finite state machine.

It can be set by the parameter `output_alphabet` when initializing a finite state machine, see *FiniteStateMachine*.

It can also be set by the method *determine_alphabets()*.

See also

FiniteStateMachine, *determine_alphabets()*, *input_alphabet*.

output_projection()

Return a automaton where the input of each transition of self is deleted and the new input is the original output.

OUTPUT: an automaton

EXAMPLES:

```
sage: F = FiniteStateMachine([('A', 'B', 0, 1), ('A', 'A', 1, 1),
....:                         ('B', 'B', 1, 0)])
sage: G = F.output_projection()
sage: G.transitions()
[Transition from 'A' to 'B': 1|-,
 Transition from 'A' to 'A': 1|-,
 Transition from 'B' to 'B': 0|-]
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine([('A', 'B', Integer(0), Integer(1)), ('A', 'A',
↪Integer(1), Integer(1)),
...                         ('B', 'B', Integer(1), Integer(0))])
>>> G = F.output_projection()
>>> G.transitions()
[Transition from 'A' to 'B': 1|-,
 Transition from 'A' to 'A': 1|-,
 Transition from 'B' to 'B': 0|-]
```

Final output words are also considered correctly:

```
sage: H = Transducer([('A', 'B', 0, 1), ('A', 'A', 1, 1),
....:                 ('B', 'B', 1, 0), ('A', ('final', 0), 0, 0)],
....:                final_states=['A', 'B'])
sage: H.state('B').final_word_out = 2
sage: J = H.output_projection()
sage: J.states()
['A', 'B', ('final', 0), ('final', 1)]
sage: J.transitions()
[Transition from 'A' to 'B': 1|-,
 Transition from 'A' to 'A': 1|-,
 Transition from 'A' to ('final', 0): 0|-,
 Transition from 'B' to 'B': 0|-,
 Transition from 'B' to ('final', 1): 2|-]
sage: J.final_states()
['A', ('final', 1)]
```

```
>>> from sage.all import *
>>> H = Transducer([('A', 'B', Integer(0), Integer(1)), ('A', 'A', Integer(1),
↪ Integer(1)),
...                 ('B', 'B', Integer(1), Integer(0)), ('A', ('final',
↪Integer(0)), Integer(0), Integer(0))],
...                final_states=['A', 'B'])
>>> H.state('B').final_word_out = Integer(2)
>>> J = H.output_projection()
>>> J.states()
['A', 'B', ('final', 0), ('final', 1)]
```

(continues on next page)

(continued from previous page)

```
>>> J.transitions()
[Transition from 'A' to 'B': 1|-,
 Transition from 'A' to 'A': 1|-,
 Transition from 'A' to ('final', 0): 0|-,
 Transition from 'B' to 'B': 0|-,
 Transition from 'B' to ('final', 1): 2|-]
>>> J.final_states()
['A', ('final', 1)]
```

plot()

Plots a graph of the finite state machine with labeled vertices and labeled edges.

OUTPUT: a plot of the graph of the finite state machine

predecessors(*state*, *valid_input=None*)

List all predecessors of a state.

INPUT:

- `state` – the state from which the predecessors should be listed
- `valid_input` – if `valid_input` is a list, then we only consider transitions whose input labels are contained in `valid_input`. `state` has to be a *FSMState* (not a label of a state). If input labels of length larger than 1 are used, then `valid_input` has to be a list of lists.

OUTPUT: list of states

EXAMPLES:

```
sage: A = Transducer([('I', 'A', 'a', 'b'), ('I', 'B', 'b', 'c'),
....:                 ('I', 'C', 'c', 'a'), ('A', 'F', 'b', 'a'),
....:                 ('B', 'F', ['c', 'b'], 'b'), ('C', 'F', 'a', 'c')],
....:                initial_states=['I'], final_states=['F'])
sage: A.predecessors(A.state('A'))
['A', 'I']
sage: A.predecessors(A.state('F'), valid_input=['b', 'a'])
['F', 'C', 'A', 'I']
sage: A.predecessors(A.state('F'), valid_input=[['c', 'b'], 'a'])
['F', 'C', 'B']
```

```
>>> from sage.all import *
>>> A = Transducer([('I', 'A', 'a', 'b'), ('I', 'B', 'b', 'c'),
...                 ('I', 'C', 'c', 'a'), ('A', 'F', 'b', 'a'),
...                 ('B', 'F', ['c', 'b'], 'b'), ('C', 'F', 'a', 'c')],
...                initial_states=['I'], final_states=['F'])
>>> A.predecessors(A.state('A'))
['A', 'I']
>>> A.predecessors(A.state('F'), valid_input=['b', 'a'])
['F', 'C', 'A', 'I']
>>> A.predecessors(A.state('F'), valid_input=[['c', 'b'], 'a'])
['F', 'C', 'B']
```

prepone_output()

For all paths, shift the output of the path from one transition to the earliest possible preceding transition of the path.

OUTPUT: nothing

Apply the following to each state s (except initial states) of the finite state machine as often as possible:

If the letter a is a prefix of the output label of all transitions from s (including the final output of s), then remove it from all these labels and append it to all output labels of all transitions leading to s.

We assume that the states have no output labels, but final outputs are allowed.

EXAMPLES:

```
sage: A = Transducer([('A', 'B', 1, 1),
....:                 ('B', 'B', 0, 0),
....:                 ('B', 'C', 1, 0)],
....:                initial_states=['A'],
....:                final_states=['C'])
sage: A.prepone_output()
sage: A.transitions()
[Transition from 'A' to 'B': 1|1,0,
 Transition from 'B' to 'B': 0|0,
 Transition from 'B' to 'C': 1|-]
```

```
>>> from sage.all import *
>>> A = Transducer([('A', 'B', Integer(1), Integer(1)),
...                 ('B', 'B', Integer(0), Integer(0)),
...                 ('B', 'C', Integer(1), Integer(0))],
...                initial_states=['A'],
...                final_states=['C'])
>>> A.prepone_output()
>>> A.transitions()
[Transition from 'A' to 'B': 1|1,0,
 Transition from 'B' to 'B': 0|0,
 Transition from 'B' to 'C': 1|-]
```

```
sage: B = Transducer([('A', 'B', 0, 1),
....:                 ('B', 'C', 1, [1, 1]),
....:                 ('B', 'C', 0, 1)],
....:                initial_states=['A'],
....:                final_states=['C'])
sage: B.prepone_output()
sage: B.transitions()
[Transition from 'A' to 'B': 0|1,1,
 Transition from 'B' to 'C': 1|1,
 Transition from 'B' to 'C': 0|-]
```

```
>>> from sage.all import *
>>> B = Transducer([('A', 'B', Integer(0), Integer(1)),
...                 ('B', 'C', Integer(1), [Integer(1), Integer(1)]),
...                 ('B', 'C', Integer(0), Integer(1))],
...                initial_states=['A'],
...                final_states=['C'])
>>> B.prepone_output()
>>> B.transitions()
[Transition from 'A' to 'B': 0|1,1,
```

(continues on next page)

(continued from previous page)

```
 Transition from 'B' to 'C': 1|1,
 Transition from 'B' to 'C': 0|-]
```

If initial states are not labeled as such, unexpected results may be obtained:

```
sage: C = Transducer([(0,1,0,0)])
sage: C.prepone_output()
verbose 0 (...: finite_state_machine.py, prepone_output)
All transitions leaving state 0 have an output label with
prefix 0.  However, there is no inbound transition and it
is not an initial state. This routine (possibly called by
simplification) therefore erased this prefix from all
outbound transitions.
sage: C.transitions()
[Transition from 0 to 1: 0|-]
```

```
>>> from sage.all import *
>>> C = Transducer([(Integer(0),Integer(1),Integer(0),Integer(0))])
>>> C.prepone_output()
verbose 0 (...: finite_state_machine.py, prepone_output)
All transitions leaving state 0 have an output label with
prefix 0.  However, there is no inbound transition and it
is not an initial state. This routine (possibly called by
simplification) therefore erased this prefix from all
outbound transitions.
>>> C.transitions()
[Transition from 0 to 1: 0|-]
```

Also the final output of final states can be changed:

```
sage: T = Transducer([('A', 'B', 0, 1),
....:                  ('B', 'C', 1, [1, 1]),
....:                  ('B', 'C', 0, 1)],
....:                 initial_states=['A'],
....:                 final_states=['B'])
sage: T.state('B').final_word_out = [1]
sage: T.prepone_output()
sage: T.transitions()
[Transition from 'A' to 'B': 0|1,1,
 Transition from 'B' to 'C': 1|1,
 Transition from 'B' to 'C': 0|-]
sage: T.state('B').final_word_out
[]
```

```
>>> from sage.all import *
>>> T = Transducer([('A', 'B', Integer(0), Integer(1)),
...                  ('B', 'C', Integer(1), [Integer(1), Integer(1)]),
...                  ('B', 'C', Integer(0), Integer(1))],
...                 initial_states=['A'],
...                 final_states=['B'])
>>> T.state('B').final_word_out = [Integer(1)]
>>> T.prepone_output()
```

(continues on next page)

(continued from previous page)

```
>>> T.transitions()
[Transition from 'A' to 'B': 0|1,1,
 Transition from 'B' to 'C': 1|1,
 Transition from 'B' to 'C': 0|-]
>>> T.state('B').final_word_out
[]
```

```
sage: S = Transducer([('A', 'B', 0, 1),
....:                  ('B', 'C', 1, [1, 1]),
....:                  ('B', 'C', 0, 1)],
....:                 initial_states=['A'],
....:                 final_states=['B'])
sage: S.state('B').final_word_out = [0]
sage: S.prepone_output()
sage: S.transitions()
[Transition from 'A' to 'B': 0|1,
 Transition from 'B' to 'C': 1|1,1,
 Transition from 'B' to 'C': 0|1]
sage: S.state('B').final_word_out
[0]
```

```
>>> from sage.all import *
>>> S = Transducer([('A', 'B', Integer(0), Integer(1)),
...                  ('B', 'C', Integer(1), [Integer(1), Integer(1)]),
...                  ('B', 'C', Integer(0), Integer(1))],
...                 initial_states=['A'],
...                 final_states=['B'])
>>> S.state('B').final_word_out = [Integer(0)]
>>> S.prepone_output()
>>> S.transitions()
[Transition from 'A' to 'B': 0|1,
 Transition from 'B' to 'C': 1|1,1,
 Transition from 'B' to 'C': 0|1]
>>> S.state('B').final_word_out
[0]
```

Output labels do not have to be hashable:

```
sage: C = Transducer([(0, 1, 0, []),
....:                  (1, 0, 0, [vector([0, 0]), 0]),
....:                  (1, 1, 1, [vector([0, 0]), 1]),
....:                  (0, 0, 1, 0)],
....:                  determine_alphabets=False,
....:                  initial_states=[0])
sage: C.prepone_output()
sage: sorted(C.transitions())
[Transition from 0 to 1: 0|(0, 0),
 Transition from 0 to 0: 1|0,
 Transition from 1 to 0: 0|0,
 Transition from 1 to 1: 1|1,(0, 0)]
```

```
>>> from sage.all import *
>>> C = Transducer([(Integer(0), Integer(1), Integer(0), []),
...                 (Integer(1), Integer(0), Integer(0), [vector([Integer(0),
↪Integer(0)]), Integer(0)]),
...                 (Integer(1), Integer(1), Integer(1), [vector([Integer(0),
↪Integer(0)]), Integer(1)]),
...                 (Integer(0), Integer(0), Integer(1), Integer(0))],
...                determine_alphabets=False,
...                initial_states=[Integer(0)])
>>> C.prepone_output()
>>> sorted(C.transitions())
[Transition from 0 to 1: 0|(0, 0),
 Transition from 0 to 0: 1|0,
 Transition from 1 to 0: 0|0,
 Transition from 1 to 1: 1|1,(0, 0)]
```

process(**args*, ***kwargs*)

Return whether the finite state machine accepts the input, the state where the computation stops and which output is generated.

INPUT:

- `input_tape` – the input tape can be a list or an iterable with entries from the input alphabet. If we are working with a multi-tape machine (see parameter `use_multitape_input` and notes below), then the tape is a list or tuple of tracks, each of which can be a list or an iterable with entries from the input alphabet.
- `initial_state` or `initial_states` – the initial state(s) in which the machine starts. Either specify a single one with `initial_state` or a list of them with `initial_states`. If both are given, `initial_state` will be appended to `initial_states`. If neither is specified, the initial states of the finite state machine are taken.
- `list_of_outputs` – (default: `None`) a boolean or `None`. If `True`, then the outputs are given in list form (even if we have no or only one single output). If `False`, then the result is never a list (an exception is raised if the result cannot be returned). If `list_of_outputs=None`, the method determines automatically what to do (e.g. if a non-deterministic machine returns more than one path, then the output is returned in list form).
- `only_accepted` – boolean (default: `False`); if set, then the first argument in the output is guaranteed to be `True` (if the output is a list, then the first argument of each element will be `True`)
- `always_include_output` – if set (not by default), always include the output. This is inconsequential for a `FiniteStateMachine`, but can be used in derived classes where the output is suppressed by default, cf. `Automaton.process()`.
- `format_output` – a function that translates the written output (which is in form of a list) to something more readable. By default (`None`) identity is used here.
- `check_epsilon_transitions` – boolean (default: `True`); if `False`, then epsilon transitions are not taken into consideration during process
- `write_final_word_out` – boolean (default: `True`); whether the final output words should be written or not
- `use_multitape_input` – boolean (default: `False`); if `True`, then the multi-tape mode of the process iterator is activated. See also the notes below for multi-tape machines.
- `process_all_prefixes_of_input` – boolean (default: `False`); if `True`, then each prefix of the input word is processed (instead of processing the whole input word at once). Consequently, there is an

output generated for each of these prefixes.

- process_iterator_class – (default: None) a class inherited from *FSMProcessIterator*. If None, then *FSMProcessIterator* is taken. An instance of this class is created and is used during the processing.
- automatic_output_type – boolean (default: False); if set and the input has a parent, then the output will have the same parent. If the input does not have a parent, then the output will be of the same type as the input.

OUTPUT:

A triple (or a list of triples, cf. parameter list_of_outputs), where

- the first entry is True if the input string is accepted,
- the second gives the reached state after processing the input tape (This is a state with label None if the input could not be processed, i.e., if at one point no transition to go on could be found.), and
- the third gives a list of the output labels written during processing (in the case the finite state machine runs as transducer).

Note that in the case the finite state machine is not deterministic, all possible paths are taken into account.

This function uses an iterator which, in its simplest form, goes from one state to another in each step. To decide which way to go, it uses the input words of the outgoing transitions and compares them to the input tape. More precisely, in each step, the iterator takes an outgoing transition of the current state, whose input label equals the input letter of the tape. The output label of the transition, if present, is written on the output tape.

If the choice of the outgoing transition is not unique (i.e., we have a non-deterministic finite state machine), all possibilities are followed. This is done by splitting the process into several branches, one for each of the possible outgoing transitions.

The process (iteration) stops if all branches are finished, i.e., for no branch, there is any transition whose input word coincides with the processed input tape. This can simply happen when the entire tape was read.

Also see *__call__()* for a version of *process()* with shortened output.

Internally this function creates and works with an instance of *FSMProcessIterator*. This iterator can also be obtained with *iter_process()*.

If working with multi-tape finite state machines, all input words of transitions are words of k-tuples of letters. Moreover, the input tape has to consist of k tracks, i.e., be a list or tuple of k iterators, one for each track.

Warning

Working with multi-tape finite state machines is still experimental and can lead to wrong outputs.

EXAMPLES:

```
sage: binary_inverter = FiniteStateMachine({'A': [('A', 0, 1), ('A', 1, 0)]},
....:                                      initial_states=['A'], final_
↪states=['A'])
sage: binary_inverter.process([0, 1, 0, 0, 1, 1])
(True, 'A', [1, 0, 1, 1, 0, 0])
```

```
>>> from sage.all import *
>>> binary_inverter = FiniteStateMachine({'A': [('A', Integer(0), Integer(1)),
```

(continues on next page)

(continued from previous page)

```
↪ ('A', Integer(1), Integer(0))]},
...                                     initial_states=['A'], final_states=[
↪'A'])
>>> binary_inverter.process([Integer(0), Integer(1), Integer(0), Integer(0),␣
↪Integer(1), Integer(1)])
(True, 'A', [1, 0, 1, 1, 0, 0])
```

Alternatively, we can invoke this function by:

```
sage: binary_inverter([0, 1, 0, 0, 1, 1])
(True, 'A', [1, 0, 1, 1, 0, 0])
```

```
>>> from sage.all import *
>>> binary_inverter([Integer(0), Integer(1), Integer(0), Integer(0),␣
↪Integer(1), Integer(1)])
(True, 'A', [1, 0, 1, 1, 0, 0])
```

Below we construct a finite state machine which tests if an input is a non-adjacent form, i.e., no two neighboring letters are both nonzero (see also the example on *non-adjacent forms* in the documentation of the module *Finite state machines, automata, transducers*):

```
sage: NAF = FiniteStateMachine(
....:     {'_': [('_', 0), (1, 1)], 1: [('_', 0)]},
....:     initial_states=['_'], final_states=['_', 1])
sage: [NAF.process(w)[0] for w in [[0], [0, 1], [1, 1], [0, 1, 0, 1],
....:                              [0, 1, 1, 1, 0], [1, 0, 0, 1, 1]]]
[True, True, False, True, False, False]
```

```
>>> from sage.all import *
>>> NAF = FiniteStateMachine(
...     {'_': [('_', Integer(0)), (Integer(1), Integer(1))], Integer(1): [('_
↪', Integer(0))]},
...     initial_states=['_'], final_states=['_', Integer(1)])
>>> [NAF.process(w)[Integer(0)] for w in [[Integer(0)], [Integer(0),␣
↪Integer(1)], [Integer(1), Integer(1)], [Integer(0), Integer(1), Integer(0),␣
↪Integer(1)],
...                              [Integer(0), Integer(1), Integer(1), Integer(1),
↪ Integer(0)], [Integer(1), Integer(0), Integer(0), Integer(1), Integer(1)]]]
[True, True, False, True, False, False]
```

Working only with the first component (i.e., returning whether accepted or not) usually corresponds to using the more specialized class `Automaton`.

Non-deterministic finite state machines can be handled as well.

```
sage: T = Transducer([(0, 1, 0, 0), (0, 2, 0, 0)],
....:     initial_states=[0])
sage: T.process([0])
[(False, 1, [0]), (False, 2, [0])]
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(1), Integer(0), Integer(0)),␣
```

(continues on next page)

(continued from previous page)

```
↪(Integer(0), Integer(2), Integer(0), Integer(0))],
...     initial_states=[Integer(0)])
>>> T.process([Integer(0)])
[(False, 1, [0]), (False, 2, [0])]
```

Here is another non-deterministic finite state machine. Note that we use `format_output` (see *FSMProcessIterator*) to convert the written outputs (all characters) to strings.

```
sage: T = Transducer([(0, 1, [0, 0], 'a'), (0, 2, [0, 0, 1], 'b'),
....:                  (0, 1, 1, 'c'), (1, 0, [], 'd'),
....:                  (1, 1, 1, 'e')],
....:                 initial_states=[0], final_states=[0, 1])
sage: T.process([0], format_output=lambda o: ''.join(o))
(False, None, None)
sage: T.process([0, 0], format_output=lambda o: ''.join(o))
[(True, 0, 'ad'), (True, 1, 'a')]
sage: T.process([1], format_output=lambda o: ''.join(o))
[(True, 0, 'cd'), (True, 1, 'c')]
sage: T.process([1, 1], format_output=lambda o: ''.join(o))
[(True, 0, 'cdcd'), (True, 0, 'ced'),
 (True, 1, 'cdc'), (True, 1, 'ce')]
sage: T.process([0, 0, 1], format_output=lambda o: ''.join(o))
[(False, 2, 'b'),
 (True, 0, 'adcd'),
 (True, 0, 'aed'),
 (True, 1, 'adc'),
 (True, 1, 'ae')]
sage: T.process([0, 0, 1], format_output=lambda o: ''.join(o),
....:           only_accepted=True)
[(True, 0, 'adcd'), (True, 0, 'aed'),
 (True, 1, 'adc'), (True, 1, 'ae')]
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(1), [Integer(0), Integer(0)], 'a'),␣
↪(Integer(0), Integer(2), [Integer(0), Integer(0), Integer(1)], 'b'),
...                  (Integer(0), Integer(1), Integer(1), 'c'), (Integer(1),␣
↪Integer(0), [], 'd'),
...                  (Integer(1), Integer(1), Integer(1), 'e')],
...                 initial_states=[Integer(0)], final_states=[Integer(0),␣
↪Integer(1)])
>>> T.process([Integer(0)], format_output=lambda o: ''.join(o))
(False, None, None)
>>> T.process([Integer(0), Integer(0)], format_output=lambda o: ''.join(o))
[(True, 0, 'ad'), (True, 1, 'a')]
>>> T.process([Integer(1)], format_output=lambda o: ''.join(o))
[(True, 0, 'cd'), (True, 1, 'c')]
>>> T.process([Integer(1), Integer(1)], format_output=lambda o: ''.join(o))
[(True, 0, 'cdcd'), (True, 0, 'ced'),
 (True, 1, 'cdc'), (True, 1, 'ce')]
>>> T.process([Integer(0), Integer(0), Integer(1)], format_output=lambda o: '
↪'.join(o))
[(False, 2, 'b'),
```

(continues on next page)

(continued from previous page)

```
 (True, 0, 'adcd'),
 (True, 0, 'aed'),
 (True, 1, 'adc'),
 (True, 1, 'ae')]
>>> T.process([Integer(0), Integer(0), Integer(1)], format_output=lambda o: '
↪'.join(o),
...             only_accepted=True)
[(True, 0, 'adcd'), (True, 0, 'aed'),
 (True, 1, 'adc'), (True, 1, 'ae')]
```

A simple example of a multi-tape finite state machine is the following: It writes the length of the first tape many letters `a` and then the length of the second tape many letters `b`:

```
sage: M = FiniteStateMachine([(0, 0, (1, None), 'a'),
....:                         (0, 1, [], []),
....:                         (1, 1, (None, 1), 'b')],
....:                        initial_states=[0],
....:                        final_states=[1])
sage: M.process(([1, 1], [1]), use_multitape_input=True)
(True, 1, ['a', 'a', 'b'])
```

```
>>> from sage.all import *
>>> M = FiniteStateMachine([(Integer(0), Integer(0), (Integer(1), None), 'a'),
...                         (Integer(0), Integer(1), [], []),
...                         (Integer(1), Integer(1), (None, Integer(1)), 'b
↪')],
...                        initial_states=[Integer(0)],
...                        final_states=[Integer(1)])
>>> M.process(([Integer(1), Integer(1)], [Integer(1)]), use_multitape_
↪input=True)
(True, 1, ['a', 'a', 'b'])
```

See also

`Automaton.process()`, *`Transducer.process()`*, *`iter_process()`*, *`__call__()`*, *`FSMProcessIterator`*.

`product_FiniteStateMachine`(*other*, *function*, *new_input_alphabet=None*, *only_accessible_components=True*, *final_function=None*, *new_class=None*)

Return a new finite state machine whose states are d-tuples of states of the original finite state machines.

INPUT:

- `other` – a finite state machine (for $d = 2$) or a list (or iterable) of $d - 1$ finite state machines
- `function` has to accept d transitions from A_j to B_j for $j \in \{1, \dots, d\}$ and returns a pair `(word_in, word_out)` which is the label of the transition $A = (A_1, \dots, A_d)$ to $B = (B_1, \dots, B_d)$. If there is no transition from A to B, then `function` should raise a `LookupError`.
- `new_input_alphabet` – (optional) the new input alphabet as a list
- `only_accessible_components` – if `True` (default), then the result is piped through *`accessible_components()`*. If no `new_input_alphabet` is given, it is determined by *`determine_alphabets()`*.

- `final_function` – a function mapping d final states of the original finite state machines to the final output of the corresponding state in the new finite state machine. By default, the final output is the empty word if both final outputs of the constituent states are empty; otherwise, a `ValueError` is raised.
- `new_class` – class of the new finite state machine. By default (`None`), the class of `self` is used

OUTPUT:

A finite state machine whose states are d-tuples of states of the original finite state machines. A state is initial or final if all constituent states are initial or final, respectively.

The labels of the transitions are defined by `function`.

The final output of a final state is determined by calling `final_function` on the constituent states.

The color of a new state is the tuple of colors of the constituent states of `self` and `other`. However, if all constituent states have color `None`, then the state has color `None`, too.

EXAMPLES:

```
sage: F = Automaton([('A', 'B', 1), ('A', 'A', 0), ('B', 'A', 2)],
....:               initial_states=['A'], final_states=['B'],
....:               determine_alphabets=True)
sage: G = Automaton([(1, 1, 1)], initial_states=[1], final_states=[1])
sage: def addition(transition1, transition2):
....:     return (transition1.word_in[0] + transition2.word_in[0],
....:             None)
sage: H = F.product_FiniteStateMachine(G, addition, [0, 1, 2, 3], only_
↪accessible_components=False)
sage: H.transitions()
[Transition from ('A', 1) to ('B', 1): 2|-,
 Transition from ('A', 1) to ('A', 1): 1|-,
 Transition from ('B', 1) to ('A', 1): 3|-]
sage: [s.color for s in H.iter_states()]
[None, None]
sage: H1 = F.product_FiniteStateMachine(G, addition, [0, 1, 2, 3], only_
↪accessible_components=False)
sage: H1.states()[0].label()[0] is F.states()[0]
True
sage: H1.states()[0].label()[1] is G.states()[0]
True
```

```
>>> from sage.all import *

↪None))
>>> H.states()
[(0, 0), (1, 0)]
```

```
sage: F = Automaton([(0,1,1/4), (0,0,3/4), (1,1,3/4), (1,0,1/4)],
....:               initial_states=[0] )
sage: G = Automaton([(0,0,1), (1,1,3/4), (1,0,1/4)],
....:               initial_states=[0] )
sage: H = F.product_FiniteStateMachine(G,
....:                                  lambda t1,t2: (t1.word_in[0]*t2.word_
↪in[0], None),
....:                                  only_accessible_components=False)
sage: H.states()
[(0, 0), (1, 0), (0, 1), (1, 1)]
```

```
>>> from sage.all import *
>>> F = Automaton([(Integer(0),Integer(1),Integer(1)/Integer(4)), (Integer(0),
↪Integer(0),Integer(3)/Integer(4)), (Integer(1),Integer(1),Integer(3)/
↪Integer(4)), (Integer(1),Integer(0),Integer(1)/Integer(4))],
...               initial_states=[Integer(0)] )
>>> G = Automaton([(Integer(0),Integer(0),Integer(1)), (Integer(1),Integer(1),
```

(continues on next page)

(continued from previous page)

```
↪Integer(3)/Integer(4)), (Integer(1),Integer(0),Integer(1)/Integer(4))],
...                     initial_states=[Integer(0)] )
>>> H = F.product_FiniteStateMachine(G,
...                                   lambda t1,t2: (t1.word_in[Integer(0)]*t2.
↪word_in[Integer(0)], None),
...                                   only_accessible_components=False)
>>> H.states()
[(0, 0), (1, 0), (0, 1), (1, 1)]
```

Also final output words are considered according to the function `final_function`:

```
sage: F = Transducer([(0, 1, 0, 1), (1, 1, 1, 1), (1, 1, 0, 1)],
....:                final_states=[1])
sage: F.state(1).final_word_out = 1
sage: G = Transducer([(0, 0, 0, 1), (0, 0, 1, 0)], final_states=[0])
sage: G.state(0).final_word_out = 1
sage: def minus(t1, t2):
....:     return (t1.word_in[0] - t2.word_in[0],
....:                t1.word_out[0] - t2.word_out[0])
sage: H = F.product_FiniteStateMachine(G, minus)
Traceback (most recent call last):
...
ValueError: A final function must be given.
sage: def plus(s1, s2):
....:     return s1.final_word_out[0] + s2.final_word_out[0]
sage: H = F.product_FiniteStateMachine(G, minus,
....:                                  final_function=plus)
sage: H.final_states()
[(1, 0)]
sage: H.final_states()[0].final_word_out
[2]
```

```
>>> from sage.all import *
>>> F = Transducer([(Integer(0), Integer(1), Integer(0), Integer(1)),␣
↪(Integer(1), Integer(1), Integer(1), Integer(1)), (Integer(1), Integer(1),␣
↪Integer(0), Integer(1))],
...                     final_states=[Integer(1)])
>>> F.state(Integer(1)).final_word_out = Integer(1)
>>> G = Transducer([(Integer(0), Integer(0), Integer(0), Integer(1)),␣
↪(Integer(0), Integer(0), Integer(1), Integer(0))], final_
↪states=[Integer(0)])
>>> G.state(Integer(0)).final_word_out = Integer(1)
>>> def minus(t1, t2):
...     return (t1.word_in[Integer(0)] - t2.word_in[Integer(0)],
...                t1.word_out[Integer(0)] - t2.word_out[Integer(0)])
>>> H = F.product_FiniteStateMachine(G, minus)
Traceback (most recent call last):
...
ValueError: A final function must be given.
>>> def plus(s1, s2):
...     return s1.final_word_out[Integer(0)] + s2.final_word_out[Integer(0)]
>>> H = F.product_FiniteStateMachine(G, minus,
```

(continues on next page)

(continued from previous page)

```
...                                          final_function=plus)
>>> H.final_states()
[(1, 0)]
>>> H.final_states()[Integer(0)].final_word_out
[2]
```

Products of more than two finite state machines are also possible:

```
sage: def plus(s1, s2, s3):
....:     if s1.word_in == s2.word_in == s3.word_in:
....:          return (s1.word_in,
....:                  sum(s.word_out[0] for s in (s1, s2, s3)))
....:     else:
....:         raise LookupError
sage: T0 = transducers.CountSubblockOccurrences([0, 0], [0, 1, 2])
sage: T1 = transducers.CountSubblockOccurrences([1, 1], [0, 1, 2])
sage: T2 = transducers.CountSubblockOccurrences([2, 2], [0, 1, 2])
sage: T = T0.product_FiniteStateMachine([T1, T2], plus)
sage: T.transitions()
[Transition from ((), (), ()) to ((0,), (), ()): 0|0,
 Transition from ((), (), ()) to ((), (1,), ()): 1|0,
 Transition from ((), (), ()) to ((), (), (2,)): 2|0,
 Transition from ((0,), (), ()) to ((0,), (), ()): 0|1,
 Transition from ((0,), (), ()) to ((), (1,), ()): 1|0,
 Transition from ((0,), (), ()) to ((), (), (2,)): 2|0,
 Transition from ((), (1,), ()) to ((0,), (), ()): 0|0,
 Transition from ((), (1,), ()) to ((), (1,), ()): 1|1,
 Transition from ((), (1,), ()) to ((), (), (2,)): 2|0,
 Transition from ((), (), (2,)) to ((0,), (), ()): 0|0,
 Transition from ((), (), (2,)) to ((), (1,), ()): 1|0,
 Transition from ((), (), (2,)) to ((), (), (2,)): 2|1]
sage: T([0, 0, 1, 1, 2, 2, 0, 1, 2, 2])
[0, 1, 0, 1, 0, 1, 0, 0, 0, 1]
```

```
>>> from sage.all import *
>>> def plus(s1, s2, s3):
...     if s1.word_in == s2.word_in == s3.word_in:
...          return (s1.word_in,
...                  sum(s.word_out[Integer(0)] for s in (s1, s2, s3)))
...     else:
...         raise LookupError
>>> T0 = transducers.CountSubblockOccurrences([Integer(0), Integer(0)],␣
↪[Integer(0), Integer(1), Integer(2)])
>>> T1 = transducers.CountSubblockOccurrences([Integer(1), Integer(1)],␣
↪[Integer(0), Integer(1), Integer(2)])
>>> T2 = transducers.CountSubblockOccurrences([Integer(2), Integer(2)],␣
↪[Integer(0), Integer(1), Integer(2)])
>>> T = T0.product_FiniteStateMachine([T1, T2], plus)
>>> T.transitions()
[Transition from ((), (), ()) to ((0,), (), ()): 0|0,
 Transition from ((), (), ()) to ((), (1,), ()): 1|0,
 Transition from ((), (), ()) to ((), (), (2,)): 2|0,
```

(continues on next page)

(continued from previous page)

```
 Transition from ((0,), (), ()) to ((0,), (), ()): 0|1,
 Transition from ((0,), (), ()) to ((), (1,), ()): 1|0,
 Transition from ((0,), (), ()) to ((), (), (2,)): 2|0,
 Transition from ((), (1,), ()) to ((0,), (), ()): 0|0,
 Transition from ((), (1,), ()) to ((), (1,), ()): 1|1,
 Transition from ((), (1,), ()) to ((), (), (2,)): 2|0,
 Transition from ((), (), (2,)) to ((0,), (), ()): 0|0,
 Transition from ((), (), (2,)) to ((), (1,), ()): 1|0,
 Transition from ((), (), (2,)) to ((), (), (2,)): 2|1]
>>> T([Integer(0), Integer(0), Integer(1), Integer(1), Integer(2), Integer(2),
↪ Integer(0), Integer(1), Integer(2), Integer(2)])
[0, 1, 0, 1, 0, 1, 0, 0, 0, 1]
```

`other` can also be an iterable:

```
sage: T == T0.product_FiniteStateMachine(iter([T1, T2]), plus)
True
```

```
>>> from sage.all import *
>>> T == T0.product_FiniteStateMachine(iter([T1, T2]), plus)
True
```

projection(*what='input'*)

Return an Automaton which transition labels are the projection of the transition labels of the input.

INPUT:

- `what` – (default: `input`) either `input` or `output`

OUTPUT: an automaton

EXAMPLES:

```
sage: F = FiniteStateMachine([('A', 'B', 0, 1), ('A', 'A', 1, 1),
....:                         ('B', 'B', 1, 0)])
sage: G = F.projection(what='output')
sage: G.transitions()
[Transition from 'A' to 'B': 1|-,
 Transition from 'A' to 'A': 1|-,
 Transition from 'B' to 'B': 0|-]
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine([('A', 'B', Integer(0), Integer(1)), ('A', 'A',␣
↪Integer(1), Integer(1)),
...                         ('B', 'B', Integer(1), Integer(0))])
>>> G = F.projection(what='output')
>>> G.transitions()
[Transition from 'A' to 'B': 1|-,
 Transition from 'A' to 'A': 1|-,
 Transition from 'B' to 'B': 0|-]
```

quotient(*classes*)

Construct the quotient with respect to the equivalence classes.

INPUT:

- `classes` is a list of equivalence classes of states.

OUTPUT: a finite state machine

The labels of the new states are tuples of states of the `self`, corresponding to `classes`.

Assume that c is a class, and a and b are states in c. Then there is a bijection φ between the transitions from a and the transitions from b with the following properties: if $\varphi(t_a) = t_b$, then

- $t_a.word_{in} = t_b.word_{in}$,
- $t_a.word_{out} = t_b.word_{out}$, and
- t_a and t_b lead to some equivalent states a' and b'.

Non-initial states may be merged with initial states, the resulting state is an initial state.

All states in a class must have the same `is_final`, `final_word_out` and `word_out` values.

EXAMPLES:

```
sage: fsm = FiniteStateMachine([("A", "B", 0, 1), ("A", "B", 1, 0),
....:                           ("B", "C", 0, 0), ("B", "C", 1, 1),
....:                           ("C", "D", 0, 1), ("C", "D", 1, 0),
....:                           ("D", "A", 0, 0), ("D", "A", 1, 1)])
sage: fsmq = fsm.quotient([[fsm.state("A"), fsm.state("C")],
....:                      [fsm.state("B"), fsm.state("D")]])
sage: fsmq.transitions()
[Transition from ('A', 'C')
             to ('B', 'D'): 0|1,
 Transition from ('A', 'C')
             to ('B', 'D'): 1|0,
 Transition from ('B', 'D')
             to ('A', 'C'): 0|0,
 Transition from ('B', 'D')
             to ('A', 'C'): 1|1]
sage: fsmq.relabeled().transitions()
[Transition from 0 to 1: 0|1,
 Transition from 0 to 1: 1|0,
 Transition from 1 to 0: 0|0,
 Transition from 1 to 0: 1|1]
sage: fsmq1 = fsm.quotient(fsm.equivalence_classes())
sage: fsmq1 == fsmq
True
sage: fsm.quotient([[fsm.state("A"), fsm.state("B"), fsm.state("C"), fsm.
↪state("D")]])
Traceback (most recent call last):
    ...
AssertionError: Transitions of state 'A' and 'B' are incompatible.
```

```
>>> from sage.all import *
>>> fsm = FiniteStateMachine([("A", "B", Integer(0), Integer(1)), ("A", "B",␣
↪Integer(1), Integer(0)),
...                           ("B", "C", Integer(0), Integer(0)), ("B", "C",␣
↪Integer(1), Integer(1)),
...                           ("C", "D", Integer(0), Integer(1)), ("C", "D",␣
↪Integer(1), Integer(0)),
...                           ("D", "A", Integer(0), Integer(0)), ("D", "A",␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(1), Integer(1))])
>>> fsmq = fsm.quotient([[fsm.state("A"), fsm.state("C")],
...                      [fsm.state("B"), fsm.state("D")]])
>>> fsmq.transitions()
[Transition from ('A', 'C')
              to ('B', 'D'): 0|1,
 Transition from ('A', 'C')
              to ('B', 'D'): 1|0,
 Transition from ('B', 'D')
              to ('A', 'C'): 0|0,
 Transition from ('B', 'D')
              to ('A', 'C'): 1|1]
>>> fsmq.relabeled().transitions()
[Transition from 0 to 1: 0|1,
 Transition from 0 to 1: 1|0,
 Transition from 1 to 0: 0|0,
 Transition from 1 to 0: 1|1]
>>> fsmq1 = fsm.quotient(fsm.equivalence_classes())
>>> fsmq1 == fsmq
True
>>> fsm.quotient([[fsm.state("A"), fsm.state("B"), fsm.state("C"), fsm.state(
↪"D")]])
Traceback (most recent call last):
    ...
AssertionError: Transitions of state 'A' and 'B' are incompatible.
```

relabeled(*memo=None*, *labels=None*)

Return a deep copy of the finite state machine, but the states are relabeled.

INPUT:

- `memo` – (default: `None`) a dictionary storing already processed elements
- `labels` – (default: `None`) a dictionary or callable mapping old labels to new labels. If `None`, then the new labels are integers starting with 0.

OUTPUT: a new finite state machine

EXAMPLES:

```
sage: FSM1 = FiniteStateMachine([('A', 'B'), ('B', 'C'), ('C', 'A')])
sage: FSM1.states()
['A', 'B', 'C']
sage: FSM2 = FSM1.relabeled()
sage: FSM2.states()
[0, 1, 2]
sage: FSM3 = FSM1.relabeled(labels={'A': 'a', 'B': 'b', 'C': 'c'})
sage: FSM3.states()
['a', 'b', 'c']
sage: FSM4 = FSM2.relabeled(labels=lambda x: 2*x)
sage: FSM4.states()
[0, 2, 4]
```

```
>>> from sage.all import *
>>> FSM1 = FiniteStateMachine([('A', 'B'), ('B', 'C'), ('C', 'A')])
>>> FSM1.states()
['A', 'B', 'C']
>>> FSM2 = FSM1.relabeled()
>>> FSM2.states()
[0, 1, 2]
>>> FSM3 = FSM1.relabeled(labels={'A': 'a', 'B': 'b', 'C': 'c'})
>>> FSM3.states()
['a', 'b', 'c']
>>> FSM4 = FSM2.relabeled(labels=lambda x: Integer(2)*x)
>>> FSM4.states()
[0, 2, 4]
```

remove_epsilon_transitions()

set_coordinates(*coordinates*, *default=True*)

Set coordinates of the states for the LaTeX representation by a dictionary or a function mapping labels to coordinates.

INPUT:

- `coordinates` – dictionary or a function mapping labels of states to pairs interpreted as coordinates
- `default` – if `True`, then states not given by `coordinates` get a default position on a circle of radius 3.

OUTPUT: nothing

EXAMPLES:

```
sage: F = Automaton([[0, 1, 1], [1, 2, 2], [2, 0, 0]])
sage: F.set_coordinates({0: (0, 0), 1: (2, 0), 2: (1, 1)})
sage: F.state(0).coordinates
(0, 0)
```

```
>>> from sage.all import *
>>> F = Automaton([[Integer(0), Integer(1), Integer(1)], [Integer(1),␣
↪Integer(2), Integer(2)], [Integer(2), Integer(0), Integer(0)]])
>>> F.set_coordinates({Integer(0): (Integer(0), Integer(0)), Integer(1):␣
↪(Integer(2), Integer(0)), Integer(2): (Integer(1), Integer(1))})
>>> F.state(Integer(0)).coordinates
(0, 0)
```

We can also use a function to determine the coordinates:

```
sage: F = Automaton([[0, 1, 1], [1, 2, 2], [2, 0, 0]])
sage: F.set_coordinates(lambda l: (l, 3/(l+1)))
sage: F.state(2).coordinates
(2, 1)
```

```
>>> from sage.all import *
>>> F = Automaton([[Integer(0), Integer(1), Integer(1)], [Integer(1),␣
↪Integer(2), Integer(2)], [Integer(2), Integer(0), Integer(0)]])
>>> F.set_coordinates(lambda l: (l, Integer(3)/(l+Integer(1))))
```

(continues on next page)

(continued from previous page)

```
>>> F.state(Integer(2)).coordinates
(2, 1)
```

split_transitions()

Return a new transducer, where all transitions in `self` with input labels consisting of more than one letter are replaced by a path of the corresponding length.

OUTPUT: a new transducer

EXAMPLES:

```
sage: A = Transducer([('A', 'B', [1, 2, 3], 0)],
....:                initial_states=['A'], final_states=['B'])
sage: A.split_transitions().states()
[('A', ()), ('B', ()),
 ('A', (1,)), ('A', (1, 2))]
```

```
>>> from sage.all import *
>>> A = Transducer([('A', 'B', [Integer(1), Integer(2), Integer(3)],␣
↪Integer(0))],
...                initial_states=['A'], final_states=['B'])
>>> A.split_transitions().states()
[('A', ()), ('B', ()),
 ('A', (1,)), ('A', (1, 2))]
```

state(*state*)

Return the state of the finite state machine.

INPUT:

- `state` – if `state` is not an instance of *FSMState*, then it is assumed that it is the label of a state.

OUTPUT: the state of the finite state machine corresponding to `state`

If no state is found, then a `LookupError` is thrown.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: FSM = FiniteStateMachine([(A, 'B'), ('C', A)])
sage: FSM.state('A') == A
True
sage: FSM.state('xyz')
Traceback (most recent call last):
...
LookupError: No state with label xyz found.
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('A')
>>> FSM = FiniteStateMachine([(A, 'B'), ('C', A)])
>>> FSM.state('A') == A
True
>>> FSM.state('xyz')
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
LookupError: No state with label xyz found.
```

states()

Return the states of the finite state machine.

OUTPUT: the states of the finite state machine as list

EXAMPLES:

```
sage: FSM = Automaton([('1', '2', 1), ('2', '2', 0)])
sage: FSM.states()
['1', '2']
```

```
>>> from sage.all import *
>>> FSM = Automaton([('1', '2', Integer(1)), ('2', '2', Integer(0))])
>>> FSM.states()
['1', '2']
```

transition(*transition*)

Return the transition of the finite state machine.

INPUT:

- `transition` – if `transition` is not an instance of `FSMTransition`, then it is assumed that it is a tuple `(from_state, to_state, word_in, word_out)`

OUTPUT: the transition of the finite state machine corresponding to `transition`

If no transition is found, then a `LookupError` is thrown.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: t = FSMTransition('A', 'B', 0)
sage: F = FiniteStateMachine([t])
sage: F.transition(('A', 'B', 0))
Transition from 'A' to 'B': 0|-
sage: id(t) == id(F.transition(('A', 'B', 0)))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMTransition
>>> t = FSMTransition('A', 'B', Integer(0))
>>> F = FiniteStateMachine([t])
>>> F.transition(('A', 'B', Integer(0)))
Transition from 'A' to 'B': 0|-
>>> id(t) == id(F.transition(('A', 'B', Integer(0))))
True
```

transitions(*from_state=None*)

Return a list of all transitions.

INPUT:

- `from_state` – (default: `None`) if `from_state` is given, then a list of transitions starting there is given

OUTPUT: list of all transitions

EXAMPLES:

```
sage: FSM = Automaton([('1', '2', 1), ('2', '2', 0)])
sage: FSM.transitions()
[Transition from '1' to '2': 1|-,
 Transition from '2' to '2': 0|-]
```

```
>>> from sage.all import *
>>> FSM = Automaton([('1', '2', Integer(1)), ('2', '2', Integer(0))])
>>> FSM.transitions()
[Transition from '1' to '2': 1|-,
 Transition from '2' to '2': 0|-]
```

transposition(*reverse_output_labels=True*)

Return a new finite state machine, where all transitions of the input finite state machine are reversed.

INPUT:

- `reverse_output_labels` – boolean (default: `True`); whether to reverse output labels

EXAMPLES:

```
sage: aut = Automaton([('A', 'A', 0), ('A', 'A', 1), ('A', 'B', 0)],
....:                 initial_states=['A'], final_states=['B'])
sage: aut.transposition().transitions('B')
[Transition from 'B' to 'A': 0|-]
```

```
>>> from sage.all import *
>>> aut = Automaton([('A', 'A', Integer(0)), ('A', 'A', Integer(1)), ('A', 'B
↪', Integer(0))],
...                 initial_states=['A'], final_states=['B'])
>>> aut.transposition().transitions('B')
[Transition from 'B' to 'A': 0|-]
```

```
sage: aut = Automaton([('1', '1', 1), ('1', '2', 0), ('2', '2', 0)],
....:                 initial_states=['1'], final_states=['1', '2'])
sage: aut.transposition().initial_states()
['1', '2']
```

```
>>> from sage.all import *
>>> aut = Automaton([('1', '1', Integer(1)), ('1', '2', Integer(0)), ('2', '2
↪', Integer(0))],
...                 initial_states=['1'], final_states=['1', '2'])
>>> aut.transposition().initial_states()
['1', '2']
```

```
sage: A = Automaton([(0, 1, [1, 0])],
....:     initial_states=[0],
....:     final_states=[1])
sage: A([1, 0])
```

(continues on next page)

(continued from previous page)

```
True
sage: A.transposition()([0, 1])
True
```

```
>>> from sage.all import *
>>> A = Automaton([(Integer(0), Integer(1), [Integer(1), Integer(0)])],
...     initial_states=[Integer(0)],
...     final_states=[Integer(1)])
>>> A([Integer(1), Integer(0)])
True
>>> A.transposition()([Integer(0), Integer(1)])
True
```

```
sage: T = Transducer([(0, 1, [1, 0], [1, 0])],
....:     initial_states=[0],
....:     final_states=[1])
sage: T([1, 0])
[1, 0]
sage: T.transposition()([0, 1])
[0, 1]
sage: T.transposition(reverse_output_labels=False)([0, 1])
[1, 0]
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(1), [Integer(1), Integer(0)],
↪[Integer(1), Integer(0)])],
...     initial_states=[Integer(0)],
...     final_states=[Integer(1)])
>>> T([Integer(1), Integer(0)])
[1, 0]
>>> T.transposition()([Integer(0), Integer(1)])
[0, 1]
>>> T.transposition(reverse_output_labels=False)([Integer(0), Integer(1)])
[1, 0]
```

with_final_word_out (*letters*, *allow_non_final=True*)

Construct a new finite state machine with final output words for all states by implicitly reading trailing letters until a final state is reached.

INPUT:

- `letters` – either an element of the input alphabet or a list of such elements. This is repeated cyclically when needed.
- `allow_non_final` – boolean (default: `True`); whether we allow that some states may be non-final in the resulting finite state machine. I.e., if `False` then each state has to have a path to a final state with input label matching `letters`.

OUTPUT: a finite state machine

The inplace version of this function is *construct_final_word_out()*.

Suppose for the moment a single element `letter` as input for `letters`. This is equivalent to `letters = [letter]`. We will discuss the general case below.

Let `word_in` be a word over the input alphabet and assume that the original finite state machine transforms `word_in` to `word_out` reaching a possibly non-final state `s`. Let further k be the minimum number of letters `letter` such that there is a path from `s` to some final state `f` whose input label consists of k copies of `letter` and whose output label is `path_word_out`. Then the state `s` of the resulting finite state machine is a final state with final output `path_word_out + f.final_word_out`. Therefore, the new finite state machine transforms `word_in` to `word_out + path_word_out + f.final_word_out`.

This is e.g. useful for finite state machines operating on digit expansions: there, it is sometimes required to read a sufficient number of trailing zeros (at the most significant positions) in order to reach a final state and to flush all carries. In this case, this method constructs an essentially equivalent finite state machine in the sense that it not longer requires adding sufficiently many trailing zeros. However, it is the responsibility of the user to make sure that if adding trailing zeros to the input anyway, the output is equivalent.

If `letters` consists of more than one letter, then it is assumed that (not necessarily complete) cycles of `letters` are appended as trailing input.

example on Gray code

EXAMPLES:

1. A simple transducer transforming 00 blocks to 01 blocks:

```
sage: T = Transducer([(0, 1, 0, 0), (1, 0, 0, 1)],
....:                initial_states=[0],
....:                final_states=[0])
sage: T.process([0, 0, 0])
(False, 1, [0, 1, 0])
sage: T.process([0, 0, 0, 0])
(True, 0, [0, 1, 0, 1])
sage: F = T.with_final_word_out(0)
sage: for f in F.iter_final_states():
....:     print("{} {}".format(f, f.final_word_out))
0 []
1 [1]
sage: F.process([0, 0, 0])
(True, 1, [0, 1, 0, 1])
sage: F.process([0, 0, 0, 0])
(True, 0, [0, 1, 0, 1])
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(1), Integer(0), Integer(0)),␣
↪(Integer(1), Integer(0), Integer(0), Integer(1))],
...                initial_states=[Integer(0)],
...                final_states=[Integer(0)])
>>> T.process([Integer(0), Integer(0), Integer(0)])
(False, 1, [0, 1, 0])
>>> T.process([Integer(0), Integer(0), Integer(0), Integer(0)])
(True, 0, [0, 1, 0, 1])
>>> F = T.with_final_word_out(Integer(0))
>>> for f in F.iter_final_states():
...     print("{} {}".format(f, f.final_word_out))
0 []
```

(continues on next page)

(continued from previous page)

```
1 [1]
>>> F.process([Integer(0), Integer(0), Integer(0)])
(True, 1, [0, 1, 0, 1])
>>> F.process([Integer(0), Integer(0), Integer(0), Integer(0)])
(True, 0, [0, 1, 0, 1])
```

2. A more realistic example: Addition of 1 in binary. We construct a transition function transforming the input to its binary expansion:

```
sage: def binary_transition(carry, input):
....:     value = carry + input
....:     if value.mod(2) == 0:
....:         return (value/2, 0)
....:     else:
....:         return ((value-1)/2, 1)
```

```
>>> from sage.all import *
>>> def binary_transition(carry, input):
...     value = carry + input
...     if value.mod(Integer(2)) == Integer(0):
...         return (value/Integer(2), Integer(0))
...     else:
...         return ((value-Integer(1))/Integer(2), Integer(1))
```

Now, we only have to start with a carry of 1 to get the required transducer:

```
sage: T = Transducer(binary_transition,
....:                input_alphabet=[0, 1],
....:                initial_states=[1],
....:                final_states=[0])
```

```
>>> from sage.all import *
>>> T = Transducer(binary_transition,
...                input_alphabet=[Integer(0), Integer(1)],
...                initial_states=[Integer(1)],
...                final_states=[Integer(0)])
```

We test this for the binary expansion of 7:

```
sage: T.process([1, 1, 1])
(False, 1, [0, 0, 0])
```

```
>>> from sage.all import *
>>> T.process([Integer(1), Integer(1), Integer(1)])
(False, 1, [0, 0, 0])
```

The final carry 1 has not be flushed yet, we have to add a trailing zero:

```
sage: T.process([1, 1, 1, 0])
(True, 0, [0, 0, 0, 1])
```

```
>>> from sage.all import *
>>> T.process([Integer(1), Integer(1), Integer(1), Integer(0)])
(True, 0, [0, 0, 0, 1])
```

We check that with this trailing zero, the transducer performs as advertised:

```
sage: all(ZZ(T(k.bits()+[0]), base=2) == k + 1
....:     for k in srange(16))
True
```

```
>>> from sage.all import *
>>> all(ZZ(T(k.bits()+[Integer(0)]), base=Integer(2)) == k + Integer(1)
...     for k in srange(Integer(16)))
True
```

However, most of the time, we produce superfluous trailing zeros:

```
sage: T(11.bits()+[0])
[0, 0, 1, 1, 0]
```

```
>>> from sage.all import *
>>> T(Integer(11).bits()+[Integer(0)])
[0, 0, 1, 1, 0]
```

We now use this method:

```
sage: F = T.with_final_word_out(0)
sage: for f in F.iter_final_states():
....:     print("{} {}".format(f, f.final_word_out))
1 [1]
0 []
```

```
>>> from sage.all import *
>>> F = T.with_final_word_out(Integer(0))
>>> for f in F.iter_final_states():
...     print("{} {}".format(f, f.final_word_out))
1 [1]
0 []
```

The same tests as above, but we do not have to pad with trailing zeros anymore:

```
sage: F.process([1, 1, 1])
(True, 1, [0, 0, 0, 1])
sage: all(ZZ(F(k.bits()), base=2) == k + 1
....:     for k in srange(16))
True
```

```
>>> from sage.all import *
>>> F.process([Integer(1), Integer(1), Integer(1)])
(True, 1, [0, 0, 0, 1])
>>> all(ZZ(F(k.bits()), base=Integer(2)) == k + Integer(1)
...     for k in srange(Integer(16)))
True
```

No more trailing zero in the output:

```
sage: F(11.bits())
[0, 0, 1, 1]
sage: all(F(k.bits())[-1] == 1
....:     for k in srange(16))
True
```

```
>>> from sage.all import *
>>> F(Integer(11).bits())
[0, 0, 1, 1]
>>> all(F(k.bits())[-Integer(1)] == Integer(1)
...     for k in srange(Integer(16)))
True
```

3. Here is an example, where we allow trailing repeated 10:

```
sage: T = Transducer([(0, 1, 0, 'a'),
....:                 (1, 2, 1, 'b'),
....:                 (2, 0, 0, 'c')],
....:                initial_states=[0],
....:                final_states=[0])
sage: F = T.with_final_word_out([1, 0])
sage: for f in F.iter_final_states():
....:     print(str(f) + ' ' + ''.join(f.final_word_out))
0
1 bc
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(1), Integer(0), 'a'),
...                 (Integer(1), Integer(2), Integer(1), 'b'),
...                 (Integer(2), Integer(0), Integer(0), 'c')],
...                initial_states=[Integer(0)],
...                final_states=[Integer(0)])
>>> F = T.with_final_word_out([Integer(1), Integer(0)])
>>> for f in F.iter_final_states():
...     print(str(f) + ' ' + ''.join(f.final_word_out))
0
1 bc
```

Trying this with trailing repeated 01 does not produce a `final_word_out` for state `1`, but for state `2`:

```
sage: F = T.with_final_word_out([0, 1])
sage: for f in F.iter_final_states():
....:     print(str(f) + ' ' + ''.join(f.final_word_out))
0
2 c
```

```
>>> from sage.all import *
>>> F = T.with_final_word_out([Integer(0), Integer(1)])
>>> for f in F.iter_final_states():
...     print(str(f) + ' ' + ''.join(f.final_word_out))
0
```

(continues on next page)

(continued from previous page)

```
2 c
```

4. Here another example with a more-letter trailing input:

```
sage: T = Transducer([(0, 1, 0, 'a'),
....:                  (1, 2, 0, 'b'), (1, 2, 1, 'b'),
....:                  (2, 3, 0, 'c'), (2, 0, 1, 'e'),
....:                  (3, 1, 0, 'd'), (3, 1, 1, 'd')],
....:                 initial_states=[0],
....:                 final_states=[0],
....:                 with_final_word_out=[0, 0, 1, 1])
sage: for f in T.iter_final_states():
....:     print(str(f) + ' ' + ''.join(f.final_word_out))
0
1 bcdbcdbe
2 cdbe
3 dbe
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(1), Integer(0), 'a'),
...                  (Integer(1), Integer(2), Integer(0), 'b'),␣
↪(Integer(1), Integer(2), Integer(1), 'b'),
...                  (Integer(2), Integer(3), Integer(0), 'c'),␣
↪(Integer(2), Integer(0), Integer(1), 'e'),
...                  (Integer(3), Integer(1), Integer(0), 'd'),␣
↪(Integer(3), Integer(1), Integer(1), 'd')],
...                 initial_states=[Integer(0)],
...                 final_states=[Integer(0)],
...                 with_final_word_out=[Integer(0), Integer(0),␣
↪Integer(1), Integer(1)])
>>> for f in T.iter_final_states():
...     print(str(f) + ' ' + ''.join(f.final_word_out))
0
1 bcdbcdbe
2 cdbe
3 dbe
```

class sage.combinat.finite_state_machine.**Transducer**(*data=None*, *initial_states=None*, *final_states=None*, *input_alphabet=None*, *output_alphabet=None*, *determine_alphabets=None*, *with_final_word_out=None*, *store_states_dict=True*, *on_duplicate_transition=None*)

Bases: `FiniteStateMachine`

This creates a transducer, which is a finite state machine, whose transitions have input and output labels.

A transducer has additional features like creating a simplified transducer.

See class `FiniteStateMachine` for more information.

EXAMPLES:

We can create a transducer performing the addition of 1 (for numbers given in binary and read from right to left) in the following way:

```
sage: T = Transducer([('C', 'C', 1, 0), ('C', 'N', 0, 1),
....:                 ('N', 'N', 0, 0), ('N', 'N', 1, 1)],
....:                initial_states=['C'], final_states=['N'])
sage: T
Transducer with 2 states
sage: T([0])
[1]
sage: T([1,1,0])
[0, 0, 1]
sage: ZZ(T(15.digits(base=2)+[0]), base=2)
16
```

```
>>> from sage.all import *
>>> T = Transducer([('C', 'C', Integer(1), Integer(0)), ('C', 'N', Integer(0),
↪Integer(1)),
...                 ('N', 'N', Integer(0), Integer(0)), ('N', 'N', Integer(1),
↪Integer(1))],
...                initial_states=['C'], final_states=['N'])
>>> T
Transducer with 2 states
>>> T([Integer(0)])
[1]
>>> T([Integer(1),Integer(1),Integer(0)])
[0, 0, 1]
>>> ZZ(T(Integer(15).digits(base=Integer(2))+[Integer(0)]), base=Integer(2))
16
```

Note that we have padded the binary input sequence by a 0 so that the transducer can reach its final state.

cartesian_product(*other*, *only_accessible_components=True*)

Return a new transducer which can simultaneously process an input with the machines `self` and `other` where the output labels are d-tuples of the original output labels.

INPUT:

- `other` – a finite state machine (if $d = 2$) or a list (or other iterable) of $d - 1$ finite state machines
- `only_accessible_components` – if `True` (default), then the result is piped through *accessible_components()*. If no `new_input_alphabet` is given, it is determined by *determine_alphabets()*.

OUTPUT:

A transducer which can simultaneously process an input with `self` and the machine(s) in `other`.

The set of states of the new transducer is the Cartesian product of the set of states of `self` and `other`.

Let (A_j, B_j, a_j, b_j) for $j \in \{1, \dots, d\}$ be transitions in the machines `self` and in `other`. Then there is a transition $((A_1, \dots, A_d), (B_1, \dots, B_d), a, (b_1, \dots, b_d))$ in the new transducer if $a_1 = \cdots = a_d =: a$.

EXAMPLES:

```
sage: transducer1 = Transducer([('A', 'A', 0, 0),
....:                           ('A', 'A', 1, 1)],
....:                          initial_states=['A'],
```

(continues on next page)

(continued from previous page)

```
....:                          final_states=['A'],
....:                          determine_alphabets=True)
sage: transducer2 = Transducer([(0, 1, 0, ['b', 'c']),
....:                           (0, 0, 1, 'b'),
....:                           (1, 1, 0, 'a')],
....:                          initial_states=[0],
....:                          final_states=[1],
....:                          determine_alphabets=True)
sage: result = transducer1.cartesian_product(transducer2)
sage: result
Transducer with 2 states
sage: result.transitions()
[Transition from ('A', 0) to ('A', 1): 0|(0, 'b'),(None, 'c'),
 Transition from ('A', 0) to ('A', 0): 1|(1, 'b'),
 Transition from ('A', 1) to ('A', 1): 0|(0, 'a')]
sage: result([1, 0, 0])
[(1, 'b'), (0, 'b'), (None, 'c'),  (0, 'a')]
sage: (transducer1([1, 0, 0]), transducer2([1, 0, 0]))
([1, 0, 0], ['b', 'b', 'c', 'a'])
```

```
>>> from sage.all import *
>>> transducer1 = Transducer([('A', 'A', Integer(0), Integer(0)),
...                           ('A', 'A', Integer(1), Integer(1))],
...                          initial_states=['A'],
...                          final_states=['A'],
...                          determine_alphabets=True)
>>> transducer2 = Transducer([(Integer(0), Integer(1), Integer(0), ['b', 'c
↪']),
...                           (Integer(0), Integer(0), Integer(1), 'b'),
...                           (Integer(1), Integer(1), Integer(0), 'a')],
...                          initial_states=[Integer(0)],
...                          final_states=[Integer(1)],
...                          determine_alphabets=True)
>>> result = transducer1.cartesian_product(transducer2)
>>> result
Transducer with 2 states
>>> result.transitions()
[Transition from ('A', 0) to ('A', 1): 0|(0, 'b'),(None, 'c'),
 Transition from ('A', 0) to ('A', 0): 1|(1, 'b'),
 Transition from ('A', 1) to ('A', 1): 0|(0, 'a')]
>>> result([Integer(1), Integer(0), Integer(0)])
[(1, 'b'), (0, 'b'), (None, 'c'),  (0, 'a')]
>>> (transducer1([Integer(1), Integer(0), Integer(0)]),
↪transducer2([Integer(1), Integer(0), Integer(0)]))
([1, 0, 0], ['b', 'b', 'c', 'a'])
```

Also final output words are correctly processed:

```
sage: transducer1.state('A').final_word_out = 2
sage: result = transducer1.cartesian_product(transducer2)
sage: result.final_states()[0].final_word_out
[(2, None)]
```

```
>>> from sage.all import *
>>> transducer1.state('A').final_word_out = Integer(2)
>>> result = transducer1.cartesian_product(transducer2)
>>> result.final_states()[Integer(0)].final_word_out
[(2, None)]
```

The following transducer counts the number of 11 blocks minus the number of 10 blocks over the alphabet `[0, 1]`.

```
sage: count_11 = transducers.CountSubblockOccurrences(
....:     [1, 1],
....:     input_alphabet=[0, 1])
sage: count_10 = transducers.CountSubblockOccurrences(
....:     [1, 0],
....:     input_alphabet=[0, 1])
sage: count_11x10 = count_11.cartesian_product(count_10)
sage: difference = transducers.sub([0, 1])(count_11x10)
sage: T = difference.simplification().relabeled()
sage: T.initial_states()
[1]
sage: sorted(T.transitions())
[Transition from 0 to 1: 0|-1,
 Transition from 0 to 0: 1|1,
 Transition from 1 to 1: 0|0,
 Transition from 1 to 0: 1|0]
sage: input =  [0, 1, 1,  0, 1,  0, 0, 0, 1, 1, 1,  0]
sage: output = [0, 0, 1, -1, 0, -1, 0, 0, 0, 1, 1, -1]
sage: T(input) == output
True
```

```
>>> from sage.all import *
>>> count_11 = transducers.CountSubblockOccurrences(
...     [Integer(1), Integer(1)],
...     input_alphabet=[Integer(0), Integer(1)])
>>> count_10 = transducers.CountSubblockOccurrences(
...     [Integer(1), Integer(0)],
...     input_alphabet=[Integer(0), Integer(1)])
>>> count_11x10 = count_11.cartesian_product(count_10)
>>> difference = transducers.sub([Integer(0), Integer(1)])(count_11x10)
>>> T = difference.simplification().relabeled()
>>> T.initial_states()
[1]
>>> sorted(T.transitions())
[Transition from 0 to 1: 0|-1,
 Transition from 0 to 0: 1|1,
 Transition from 1 to 1: 0|0,
 Transition from 1 to 0: 1|0]
>>> input =  [Integer(0), Integer(1), Integer(1),  Integer(0), Integer(1), 
↪Integer(0), Integer(0), Integer(0), Integer(1), Integer(1), Integer(1), 
↪Integer(0)]
>>> output = [Integer(0), Integer(0), Integer(1), -Integer(1), Integer(0), -
↪Integer(1), Integer(0), Integer(0), Integer(0), Integer(1), Integer(1), -
↪Integer(1)]
```

(continues on next page)

(continued from previous page)

```
>>> T(input) == output
True
```

If `other` is an automaton, then `cartesian_product()` returns `self` where the input is restricted to the input accepted by `other`.

For example, if the transducer transforms the standard binary expansion into the non-adjacent form and the automaton recognizes the binary expansion without adjacent ones, then the Cartesian product of these two is a transducer which does not change the input (except for changing `a` to `(a, None)` and ignoring a leading 0).

```
sage: NAF = Transducer([(0, 1, 0, None),
....:                   (0, 2, 1, None),
....:                   (1, 1, 0, 0),
....:                   (1, 2, 1, 0),
....:                   (2, 1, 0, 1),
....:                   (2, 3, 1, -1),
....:                   (3, 2, 0, 0),
....:                   (3, 3, 1, 0)],
....:                  initial_states=[0],
....:                  final_states=[1],
....:                  determine_alphabets=True)
sage: aut11 = Automaton([(0, 0, 0), (0, 1, 1), (1, 0, 0)],
....:                   initial_states=[0],
....:                   final_states=[0, 1],
....:                   determine_alphabets=True)
sage: res = NAF.cartesian_product(aut11)
sage: res([1, 0, 0, 1, 0, 1, 0])
[(1, None), (0, None), (0, None), (1, None), (0, None), (1, None)]
```

```
>>> from sage.all import *
>>> NAF = Transducer([(Integer(0), Integer(1), Integer(0), None),
...                   (Integer(0), Integer(2), Integer(1), None),
...                   (Integer(1), Integer(1), Integer(0), Integer(0)),
...                   (Integer(1), Integer(2), Integer(1), Integer(0)),
...                   (Integer(2), Integer(1), Integer(0), Integer(1)),
...                   (Integer(2), Integer(3), Integer(1), -Integer(1)),
...                   (Integer(3), Integer(2), Integer(0), Integer(0)),
...                   (Integer(3), Integer(3), Integer(1), Integer(0))],
...                  initial_states=[Integer(0)],
...                  final_states=[Integer(1)],
...                  determine_alphabets=True)
>>> aut11 = Automaton([(Integer(0), Integer(0), Integer(0)), (Integer(0),␣
↪Integer(1), Integer(1)), (Integer(1), Integer(0), Integer(0))],
...                   initial_states=[Integer(0)],
...                   final_states=[Integer(0), Integer(1)],
...                   determine_alphabets=True)
>>> res = NAF.cartesian_product(aut11)
>>> res([Integer(1), Integer(0), Integer(0), Integer(1), Integer(0),␣
↪Integer(1), Integer(0)])
[(1, None), (0, None), (0, None), (1, None), (0, None), (1, None)]
```

This is obvious because if the standard binary expansion does not have adjacent ones, then it is the same as the non-adjacent form.

Be aware that *cartesian_product()* is not commutative.

```
sage: aut11.cartesian_product(NAF)
Traceback (most recent call last):
...
TypeError: Only an automaton can be intersected with an automaton.
```

```
>>> from sage.all import *
>>> aut11.cartesian_product(NAF)
Traceback (most recent call last):
...
TypeError: Only an automaton can be intersected with an automaton.
```

The Cartesian product of more than two finite state machines can also be computed:

```
sage: T0 = transducers.CountSubblockOccurrences([0, 0], [0, 1, 2])
sage: T1 = transducers.CountSubblockOccurrences([1, 1], [0, 1, 2])
sage: T2 = transducers.CountSubblockOccurrences([2, 2], [0, 1, 2])
sage: T = T0.cartesian_product([T1, T2])
sage: T.transitions()

intersection(*other*, *only_accessible_components=True*)

Return a new transducer which accepts an input if it is accepted by both given finite state machines producing the same output.

INPUT:

- `other` – a transducer
- `only_accessible_components` – if `True` (default), then the result is piped through *accessible_components()*. If no `new_input_alphabet` is given, it is determined by *determine_alphabets()*.

OUTPUT:

A new transducer which computes the intersection (see below) of the languages of `self` and `other`.

The set of states of the transducer is the Cartesian product of the set of states of both given transducer. There is a transition $((A, B), (C, D), a, b)$ in the new transducer if there are transitions (A, C, a, b) and (B, D, a, b) in the old transducers.

EXAMPLES:

```
sage: transducer1 = Transducer([('1', '2', 1, 0),
....:                           ('2', '2', 1, 0),
....:                           ('2', '2', 0, 1)],
....:                          initial_states=['1'],
....:                          final_states=['2'])
sage: transducer2 = Transducer([('A', 'A', 1, 0),
....:                           ('A', 'B', 0, 0),
```

(continues on next page)

(continued from previous page)

```
....:                            ('B', 'B', 0, 1),
....:                            ('B', 'A', 1, 1)],
....:                           initial_states=['A'],
....:                           final_states=['B'])
sage: res = transducer1.intersection(transducer2)
sage: res.transitions()
[Transition from ('1', 'A') to ('2', 'A'): 1|0,
 Transition from ('2', 'A') to ('2', 'A'): 1|0]
```

```
>>> from sage.all import *
>>> transducer1 = Transducer([('1', '2', Integer(1), Integer(0)),
...                           ('2', '2', Integer(1), Integer(0)),
...                           ('2', '2', Integer(0), Integer(1))],
...                          initial_states=['1'],
...                          final_states=['2'])
>>> transducer2 = Transducer([('A', 'A', Integer(1), Integer(0)),
...                           ('A', 'B', Integer(0), Integer(0)),
...                           ('B', 'B', Integer(0), Integer(1)),
...                           ('B', 'A', Integer(1), Integer(1))],
...                          initial_states=['A'],
...                          final_states=['B'])
>>> res = transducer1.intersection(transducer2)
>>> res.transitions()
[Transition from ('1', 'A') to ('2', 'A'): 1|0,
 Transition from ('2', 'A') to ('2', 'A'): 1|0]
```

In general, transducers are not closed under intersection. But for transducer which do not have epsilon-transitions, the intersection is well defined (cf. [BaWo2012]). However, in the next example the intersection of the two transducers is not well defined. The intersection of the languages consists of $(a^n, b^n c^n)$. This set is not recognizable by a *finite* transducer.

```
sage: t1 = Transducer([(0, 0, 'a', 'b'),
....:                  (0, 1, None, 'c'),
....:                  (1, 1, None, 'c')],
....:                 initial_states=[0],
....:                 final_states=[0, 1])
sage: t2 = Transducer([('A', 'A', None, 'b'),
....:                  ('A', 'B', 'a', 'c'),
....:                  ('B', 'B', 'a', 'c')],
....:                 initial_states=['A'],
....:                 final_states=['A', 'B'])
sage: t2.intersection(t1)
Traceback (most recent call last):
...
ValueError: An epsilon-transition (with empty input or output)
was found.
```

```
>>> from sage.all import *
>>> t1 = Transducer([(Integer(0), Integer(0), 'a', 'b'),
...                  (Integer(0), Integer(1), None, 'c'),
...                  (Integer(1), Integer(1), None, 'c')],
...                 initial_states=[Integer(0)],
```

(continues on next page)

(continued from previous page)

```
...                  final_states=[Integer(0), Integer(1)])
>>> t2 = Transducer([('A', 'A', None, 'b'),
...                   ('A', 'B', 'a', 'c'),
...                   ('B', 'B', 'a', 'c')],
...                  initial_states=['A'],
...                  final_states=['A', 'B'])
>>> t2.intersection(t1)
Traceback (most recent call last):
...
ValueError: An epsilon-transition (with empty input or output)
was found.
```

REFERENCES:

process(**args*, ***kwargs*)

Return whether the transducer accepts the input, the state where the computation stops and which output is generated.

INPUT:

- `input_tape` – the input tape can be a list or an iterable with entries from the input alphabet. If we are working with a multi-tape machine (see parameter `use_multitape_input` and notes below), then the tape is a list or tuple of tracks, each of which can be a list or an iterable with entries from the input alphabet.
- `initial_state` or `initial_states` – the initial state(s) in which the machine starts. Either specify a single one with `initial_state` or a list of them with `initial_states`. If both are given, `initial_state` will be appended to `initial_states`. If neither is specified, the initial states of the finite state machine are taken.
- `list_of_outputs` – (default: `None`) a boolean or `None`. If `True`, then the outputs are given in list form (even if we have no or only one single output). If `False`, then the result is never a list (an exception is raised if the result cannot be returned). If `list_of_outputs=None` the method determines automatically what to do (e.g. if a non-deterministic machine returns more than one path, then the output is returned in list form).
- `only_accepted` – boolean (default: `False`); if set, then the first argument in the output is guaranteed to be `True` (if the output is a list, then the first argument of each element will be `True`).
- `full_output` – boolean (default: `True`); if set, then the full output is given, otherwise only the generated output (the third entry below only). If the input is not accepted, a `ValueError` is raised.
- `always_include_output` – if set (not by default), always include the output. This is inconsequential for a *Transducer*, but can be used in other classes derived from *FiniteStateMachine* where the output is suppressed by default, cf. *Automaton.process()*.
- `format_output` – a function that translates the written output (which is in form of a list) to something more readable. By default (`None`) identity is used here.
- `check_epsilon_transitions` – boolean (default: `True`); if `False`, then epsilon transitions are not taken into consideration during process
- `write_final_word_out` – boolean (default: `True`); whether the final output words should be written or not
- `use_multitape_input` – boolean (default: `False`); if `True`, then the multi-tape mode of the process iterator is activated. See also the notes below for multi-tape machines.

- `process_all_prefixes_of_input` – boolean (default: `False`); if `True`, then each prefix of the input word is processed (instead of processing the whole input word at once). Consequently, there is an output generated for each of these prefixes.
- `process_iterator_class` – (default: `None`) a class inherited from `FSMProcessIterator`. If `None`, then `FSMProcessIterator` is taken. An instance of this class is created and is used during the processing.
- `automatic_output_type` – boolean (default: `False`); if set and the input has a parent, then the output will have the same parent. If the input does not have a parent, then the output will be of the same type as the input.

OUTPUT:

The full output is a triple (or a list of triples, cf. parameter `list_of_outputs`), where

- the first entry is `True` if the input string is accepted,
- the second gives the reached state after processing the input tape (This is a state with label `None` if the input could not be processed, i.e., if at one point no transition to go on could be found.), and
- the third gives a list of the output labels written during processing.

If `full_output` is `False`, then only the third entry is returned.

Note that in the case the transducer is not deterministic, all possible paths are taken into account.

This function uses an iterator which, in its simplest form, goes from one state to another in each step. To decide which way to go, it uses the input words of the outgoing transitions and compares them to the input tape. More precisely, in each step, the iterator takes an outgoing transition of the current state, whose input label equals the input letter of the tape. The output label of the transition, if present, is written on the output tape.

If the choice of the outgoing transition is not unique (i.e., we have a non-deterministic finite state machine), all possibilities are followed. This is done by splitting the process into several branches, one for each of the possible outgoing transitions.

The process (iteration) stops if all branches are finished, i.e., for no branch, there is any transition whose input word coincides with the processed input tape. This can simply happen when the entire tape was read.

Also see `__call__()` for a version of `process()` with shortened output.

Internally this function creates and works with an instance of `FSMProcessIterator`. This iterator can also be obtained with `iter_process()`.

If working with multi-tape finite state machines, all input words of transitions are words of k-tuples of letters. Moreover, the input tape has to consist of k tracks, i.e., be a list or tuple of k iterators, one for each track.

Warning: Working with multi-tape finite state machines is still experimental and can lead to wrong outputs.

EXAMPLES:

```
sage: binary_inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
....:                              initial_states=['A'], final_states=['A'])
sage: binary_inverter.process([0, 1, 0, 0, 1, 1])
(True, 'A', [1, 0, 1, 1, 0, 0])
```

```
>>> from sage.all import *
>>> binary_inverter = Transducer({'A': [('A', Integer(0), Integer(1)), ('A',␣
↪Integer(1), Integer(0))]},
...                               initial_states=['A'], final_states=['A'])
>>> binary_inverter.process([Integer(0), Integer(1), Integer(0), Integer(0),␣
↪Integer(1), Integer(1)])
(True, 'A', [1, 0, 1, 1, 0, 0])
```

If we are only interested in the output, we can also use:

```
sage: binary_inverter([0, 1, 0, 0, 1, 1])
[1, 0, 1, 1, 0, 0]
```

```
>>> from sage.all import *
>>> binary_inverter([Integer(0), Integer(1), Integer(0), Integer(0),␣
↪Integer(1), Integer(1)])
[1, 0, 1, 1, 0, 0]
```

This can also be used with words as input:

```
sage: # needs sage.combinat
sage: W = Words([0, 1]); W
Finite and infinite words over {0, 1}
sage: w = W([0, 1, 0, 0, 1, 1]); w
word: 010011
sage: binary_inverter(w)
word: 101100
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> W = Words([Integer(0), Integer(1)]); W
Finite and infinite words over {0, 1}
>>> w = W([Integer(0), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(1)]); w
word: 010011
>>> binary_inverter(w)
word: 101100
```

In this case it is automatically determined that the output is a word. The call above is equivalent to:

```
sage: binary_inverter.process(w,                                            #␣
↪needs sage.combinat
....:                          full_output=False,
....:                          list_of_outputs=False,
....:                          automatic_output_type=True)
word: 101100
```

```
>>> from sage.all import *
>>> binary_inverter.process(w,                                            #␣
↪needs sage.combinat
...                          full_output=False,
...                          list_of_outputs=False,
```

(continues on next page)

(continued from previous page)

```
...                             automatic_output_type=True)
word: 101100
```

The following transducer transforms $0^n 1$ to $1^n 2$:

```
sage: T = Transducer([(0, 0, 0, 1), (0, 1, 1, 2)])
sage: T.state(0).is_initial = True
sage: T.state(1).is_final = True
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(0), Integer(0), Integer(1)),␣
↪(Integer(0), Integer(1), Integer(1), Integer(2))])
>>> T.state(Integer(0)).is_initial = True
>>> T.state(Integer(1)).is_final = True
```

We can see the different possibilities of the output by:

```
sage: [T.process(w) for w in [[1], [0, 1], [0, 0, 1], [0, 1, 1],
....:                         [0], [0, 0], [2, 0], [0, 1, 2]]]
[(True, 1, [2]), (True, 1, [1, 2]),
 (True, 1, [1, 1, 2]), (False, None, None),
 (False, 0, [1]), (False, 0, [1, 1]),
 (False, None, None), (False, None, None)]
```

```
>>> from sage.all import *
>>> [T.process(w) for w in [[Integer(1)], [Integer(0), Integer(1)],␣
↪[Integer(0), Integer(0), Integer(1)], [Integer(0), Integer(1), Integer(1)],
...                         [Integer(0)], [Integer(0), Integer(0)],␣
↪[Integer(2), Integer(0)], [Integer(0), Integer(1), Integer(2)]]]
[(True, 1, [2]), (True, 1, [1, 2]),
 (True, 1, [1, 1, 2]), (False, None, None),
 (False, 0, [1]), (False, 0, [1, 1]),
 (False, None, None), (False, None, None)]
```

If we just want a condensed output, we use:

```
sage: [T.process(w, full_output=False)
....:      for w in [[1], [0, 1], [0, 0, 1]]]
[[2], [1, 2], [1, 1, 2]]
sage: T.process([0], full_output=False)
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
sage: T.process([0, 1, 2], full_output=False)
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

```
>>> from sage.all import *
>>> [T.process(w, full_output=False)
...      for w in [[Integer(1)], [Integer(0), Integer(1)], [Integer(0),␣
↪Integer(0), Integer(1)]]]
```

(continues on next page)

(continued from previous page)

```
[[2], [1, 2], [1, 1, 2]]
>>> T.process([Integer(0)], full_output=False)
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
>>> T.process([Integer(0), Integer(1), Integer(2)], full_output=False)
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

It is equivalent to:

```
sage: [T(w) for w in [[1], [0, 1], [0, 0, 1]]]
[[2], [1, 2], [1, 1, 2]]
sage: T([0])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
sage: T([0, 1, 2])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

```
>>> from sage.all import *
>>> [T(w) for w in [[Integer(1)], [Integer(0), Integer(1)], [Integer(0),␣
↪Integer(0), Integer(1)]]]
[[2], [1, 2], [1, 1, 2]]
>>> T([Integer(0)])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
>>> T([Integer(0), Integer(1), Integer(2)])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

A cycle with empty input and empty output is correctly processed:

```
sage: T = Transducer([(0, 1, None, None), (1, 0, None, None)],
....:                initial_states=[0], final_states=[1])
sage: T.process([])
[(False, 0, []), (True, 1, [])]
sage: _ = T.add_transition(-1, 0, 0, 'r')
sage: T.state(-1).is_initial = True
sage: T.state(0).is_initial = False
sage: T.process([0])
[(False, 0, ['r']), (True, 1, ['r'])]
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(1), None, None), (Integer(1),␣
↪Integer(0), None, None)],
...                 initial_states=[Integer(0)], final_states=[Integer(1)])
```

(continues on next page)

(continued from previous page)

```
>>> T.process([])
[(False, 0, []), (True, 1, [])]
>>> _ = T.add_transition(-Integer(1), Integer(0), Integer(0), 'r')
>>> T.state(-Integer(1)).is_initial = True
>>> T.state(Integer(0)).is_initial = False
>>> T.process([Integer(0)])
[(False, 0, ['r']), (True, 1, ['r'])]
```

If there is a cycle with empty input but non-empty output, the possible outputs would be an infinite set:

```
sage: T = Transducer([(0, 1, None, 'z'), (1, 0, None, None)],
....:                initial_states=[0], final_states=[1])
sage: T.process([])
Traceback (most recent call last):
...
RuntimeError: State 0 is in an epsilon cycle (no input),
but output is written.
```

```
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(1), None, 'z'), (Integer(1),␣
↪Integer(0), None, None)],
...                initial_states=[Integer(0)], final_states=[Integer(1)])
>>> T.process([])
Traceback (most recent call last):
...
RuntimeError: State 0 is in an epsilon cycle (no input),
but output is written.
```

But if this cycle with empty input and non-empty output is not reached, the correct output is produced:

```
sage: _ = T.add_transition(-1, 0, 0, 'r')
sage: T.state(-1).is_initial = True
sage: T.state(0).is_initial = False
sage: T.process([])
(False, -1, [])
sage: T.process([0])
Traceback (most recent call last):
...
RuntimeError: State 0 is in an epsilon cycle (no input),
but output is written.
```

```
>>> from sage.all import *
>>> _ = T.add_transition(-Integer(1), Integer(0), Integer(0), 'r')
>>> T.state(-Integer(1)).is_initial = True
>>> T.state(Integer(0)).is_initial = False
>>> T.process([])
(False, -1, [])
>>> T.process([Integer(0)])
Traceback (most recent call last):
...
RuntimeError: State 0 is in an epsilon cycle (no input),
but output is written.
```

If we set `check_epsilon_transitions=False`, then no transitions with empty input are considered anymore. Thus cycles with empty input are no problem anymore:

```
sage: T.process([0], check_epsilon_transitions=False)
(False, 0, ['r'])
```

```
>>> from sage.all import *
>>> T.process([Integer(0)], check_epsilon_transitions=False)
(False, 0, ['r'])
```

A simple example of a multi-tape transducer is the following: It writes the length of the first tape many letters `a` and then the length of the second tape many letters `b`:

```
sage: M = Transducer([(0, 0, (1, None), 'a'),
....:                  (0, 1, [], []),
....:                  (1, 1, (None, 1), 'b')],
....:                 initial_states=[0],
....:                 final_states=[1])
sage: M.process(([1, 1], [1]), use_multitape_input=True)
(True, 1, ['a', 'a', 'b'])
```

```
>>> from sage.all import *
>>> M = Transducer([(Integer(0), Integer(0), (Integer(1), None), 'a'),
...                  (Integer(0), Integer(1), [], []),
...                  (Integer(1), Integer(1), (None, Integer(1)), 'b')],
...                 initial_states=[Integer(0)],
...                 final_states=[Integer(1)])
>>> M.process(([Integer(1), Integer(1)], [Integer(1)]), use_multitape_
↪input=True)
(True, 1, ['a', 'a', 'b'])
```

simplification()

Return a simplified transducer.

OUTPUT: a new transducer

This function simplifies a transducer by Moore's algorithm, first moving common output labels of transitions leaving a state to output labels of transitions entering the state (cf. *prepone_output()*).

The resulting transducer implements the same function as the original transducer.

EXAMPLES:

```
sage: fsm = Transducer([("A", "B", 0, 1), ("A", "B", 1, 0),
....:                          ("B", "C", 0, 0), ("B", "C", 1, 1),
....:                          ("C", "D", 0, 1), ("C", "D", 1, 0),
....:                          ("D", "A", 0, 0), ("D", "A", 1, 1)])
sage: fsms = fsm.simplification()
sage: fsms
```

(continues on next page)

(continued from previous page)

 Transition from ('B', 'C') to ('A',): 1|0]
```

Illustrating the use of colors in order to avoid identification of states:

```
sage: T = Transducer( [[0,0,0,0], [0,1,1,1],
....:                  [1,0,0,0], [1,1,1,1]],
....:                 initial_states=[0],
....:                 final_states=[0,1])
sage: sorted(T.simplification().transitions())
[Transition from (0, 1) to (0, 1): 0|0,
```

(continues on next page)

(continued from previous page)

```
 Transition from (0, 1) to (0, 1): 1|1]
sage: T.state(0).color = 0
sage: T.state(0).color = 1
sage: sorted(T.simplification().transitions())
[Transition from (0,) to (0,): 0|0,
 Transition from (0,) to (1,): 1|1,
 Transition from (1,) to (0,): 0|0,
 Transition from (1,) to (1,): 1|1]
```

```
>>> from sage.all import *
>>> T = Transducer( [[Integer(0),Integer(0),Integer(0),Integer(0)],␣
↪[Integer(0),Integer(1),Integer(1),Integer(1)],
...                      [Integer(1),Integer(0),Integer(0),Integer(0)],␣
↪[Integer(1),Integer(1),Integer(1),Integer(1)]],
...                     initial_states=[Integer(0)],
...                     final_states=[Integer(0),Integer(1)])
>>> sorted(T.simplification().transitions())
[Transition from (0, 1) to (0, 1): 0|0,
 Transition from (0, 1) to (0, 1): 1|1]
>>> T.state(Integer(0)).color = Integer(0)
>>> T.state(Integer(0)).color = Integer(1)
>>> sorted(T.simplification().transitions())
[Transition from (0,) to (0,): 0|0,
 Transition from (0,) to (1,): 1|1,
 Transition from (1,) to (0,): 0|0,
 Transition from (1,) to (1,): 1|1]
```

sage.combinat.finite_state_machine.**duplicate_transition_add_input**(*old_transition*, *new_transition*)

Alternative function for handling duplicate transitions in finite state machines. This implementation adds the input label of the new transition to the input label of the old transition. This is intended for the case where a Markov chain is modelled by a finite state machine using the input labels as transition probabilities.

See the documentation of the `on_duplicate_transition` parameter of *FiniteStateMachine*.

INPUT:

- `old_transition` – a transition in a finite state machine
- `new_transition` – a transition, identical to `old_transition`, which is to be inserted into the finite state machine

OUTPUT:

A transition whose input weight is the sum of the input weights of `old_transition` and `new_transition`.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import duplicate_transition_add_
↪input
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: duplicate_transition_add_input(FSMTransition('a', 'a', 1/2),
....:                                FSMTransition('a', 'a', 1/2))
Transition from 'a' to 'a': 1|-
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import duplicate_transition_add_input
>>> from sage.combinat.finite_state_machine import FSMTransition
>>> duplicate_transition_add_input(FSMTransition('a', 'a', Integer(1)/Integer(2)),
...                                FSMTransition('a', 'a', Integer(1)/Integer(2)))
Transition from 'a' to 'a': 1|-
```

Input labels must be lists of length 1:

```
sage: duplicate_transition_add_input(FSMTransition('a', 'a', [1, 1]),
....:                                FSMTransition('a', 'a', [1, 1]))
Traceback (most recent call last):
...
TypeError: Trying to use duplicate_transition_add_input on
"Transition from 'a' to 'a': 1,1|-" and
"Transition from 'a' to 'a': 1,1|-",
but input words are assumed to be lists of length 1
```

```
>>> from sage.all import *
>>> duplicate_transition_add_input(FSMTransition('a', 'a', [Integer(1),
↪Integer(1)]),
...                                FSMTransition('a', 'a', [Integer(1),
↪Integer(1)]))
Traceback (most recent call last):
...
TypeError: Trying to use duplicate_transition_add_input on
"Transition from 'a' to 'a': 1,1|-" and
"Transition from 'a' to 'a': 1,1|-",
but input words are assumed to be lists of length 1
```

sage.combinat.finite_state_machine.**duplicate_transition_ignore**(*old_transition*, *new_transition*)

Default function for handling duplicate transitions in finite state machines. This implementation ignores the occurrence.

See the documentation of the `on_duplicate_transition` parameter of `FiniteStateMachine`.

INPUT:

- `old_transition` – a transition in a finite state machine
- `new_transition` – a transition, identical to `old_transition`, which is to be inserted into the finite state machine

OUTPUT: the same transition, unchanged

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import duplicate_transition_ignore
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: duplicate_transition_ignore(FSMTransition(0, 0, 1),
....:                             FSMTransition(0, 0, 1))
Transition from 0 to 0: 1|-
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import duplicate_transition_ignore
```

(continues on next page)

(continued from previous page)

```
>>> from sage.combinat.finite_state_machine import FSMTransition
>>> duplicate_transition_ignore(FSMTransition(Integer(0), Integer(0), Integer(1)),
...                             FSMTransition(Integer(0), Integer(0), Integer(1)))
Transition from 0 to 0: 1|-
```

sage.combinat.finite_state_machine.**duplicate_transition_raise_error**(*old_transition*, *new_transition*)

Alternative function for handling duplicate transitions in finite state machines.

This implementation raises a `ValueError`.

See the documentation of the `on_duplicate_transition` parameter of *FiniteStateMachine*.

INPUT:

- `old_transition` – a transition in a finite state machine
- `new_transition` – a transition, identical to `old_transition`, which is to be inserted into the finite state machine

OUTPUT: nothing. A `ValueError` is raised

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import duplicate_transition_raise_
↪error
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: duplicate_transition_raise_error(FSMTransition(0, 0, 1),
....:                                  FSMTransition(0, 0, 1))
Traceback (most recent call last):
...
ValueError: Attempting to re-insert transition Transition from 0 to 0: 1|-
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import duplicate_transition_raise_
↪error
>>> from sage.combinat.finite_state_machine import FSMTransition
>>> duplicate_transition_raise_error(FSMTransition(Integer(0), Integer(0),␣
↪Integer(1)),
...                                  FSMTransition(Integer(0), Integer(0),␣
↪Integer(1)))
Traceback (most recent call last):
...
ValueError: Attempting to re-insert transition Transition from 0 to 0: 1|-
```

sage.combinat.finite_state_machine.**equal**(*iterator*)

Check whether all elements of `iterator` are equal.

INPUT:

- `iterator` – an iterator of the elements to check

OUTPUT: boolean

This implements https://stackoverflow.com/a/3844832/1052778.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import equal
sage: equal([0, 0, 0])
True
sage: equal([0, 1, 0])
False
sage: equal([])
True
sage: equal(iter([None, None]))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import equal
>>> equal([Integer(0), Integer(0), Integer(0)])
True
>>> equal([Integer(0), Integer(1), Integer(0)])
False
>>> equal([])
True
>>> equal(iter([None, None]))
True
```

We can test other properties of the elements than the elements themselves. In the following example, we check whether all tuples have the same lengths:

```
sage: equal(len(x) for x in [(1, 2), (2, 3), (3, 1)])
True
sage: equal(len(x) for x in [(1, 2), (1, 2, 3), (3, 1)])
False
```

```
>>> from sage.all import *
>>> equal(len(x) for x in [(Integer(1), Integer(2)), (Integer(2), Integer(3)),
→(Integer(3), Integer(1))])
True
>>> equal(len(x) for x in [(Integer(1), Integer(2)), (Integer(1), Integer(2),
→Integer(3)), (Integer(3), Integer(1))])
False
```

sage.combinat.finite_state_machine.**full_group_by**(*l*, *key=None*)

Group iterable `l` by values of `key`.

INPUT:

- iterable `l`
- key function `key`

OUTPUT:

A list of pairs `(k, elements)` such that `key(e)=k` for all `e` in `elements`.

This is similar to `itertools.groupby()` except that lists are returned instead of iterables and no prior sorting is required.

We do not require

- that the keys are sortable (in contrast to the approach via `sorted()` and `itertools.groupby()`) and

- that the keys are hashable (in contrast to the implementation proposed in https://stackoverflow.com/a/15250161).

However, it is required

- that distinct keys have distinct `str`-representations.

The implementation is inspired by https://stackoverflow.com/a/15250161, but non-hashable keys are allowed.

EXAMPLES:

```
sage: # needs sage.symbolic
sage: from sage.combinat.finite_state_machine import full_group_by
sage: t = [2/x, 1/x, 2/x]
sage: r = full_group_by([0, 1, 2], key=lambda i: t[i])
sage: sorted(r, key=lambda p: p[1])
[(2/x, [0, 2]), (1/x, [1])]
sage: from itertools import groupby
sage: for k, elements in groupby(sorted([0, 1, 2],
....:                              key=lambda i:t[i]),
....:                              key=lambda i:t[i]):
....:     print("{} {}".format(k, list(elements)))
2/x [0]
1/x [1]
2/x [2]
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> from sage.combinat.finite_state_machine import full_group_by
>>> t = [Integer(2)/x, Integer(1)/x, Integer(2)/x]
>>> r = full_group_by([Integer(0), Integer(1), Integer(2)], key=lambda i: t[i])
>>> sorted(r, key=lambda p: p[Integer(1)])
[(2/x, [0, 2]), (1/x, [1])]
>>> from itertools import groupby
>>> for k, elements in groupby(sorted([Integer(0), Integer(1), Integer(2)],
...                              key=lambda i:t[i]),
...                              key=lambda i:t[i]):
...     print("{} {}".format(k, list(elements)))
2/x [0]
1/x [1]
2/x [2]
```

Note that the behavior is different from `itertools.groupby()` because neither $1/x < 2/x$ nor $2/x < 1/x$ does hold.

Here, the result `r` has been sorted in order to guarantee a consistent order for the doctest suite.

`sage.combinat.finite_state_machine.`**`is_Automaton`**`(`*FSM*`)`

Test whether or not `FSM` inherits from *Automaton*.

`sage.combinat.finite_state_machine.`**`is_FSMProcessIterator`**`(`*PI*`)`

Test whether or not `PI` inherits from *FSMProcessIterator*.

`sage.combinat.finite_state_machine.`**`is_FSMState`**`(`*S*`)`

Test whether or not `S` inherits from *FSMState*.

`sage.combinat.finite_state_machine.`**`is_FSMTransition`**`(`*T*`)`

Test whether or not `T` inherits from *FSMTransition*.

sage.combinat.finite_state_machine.**is_FiniteStateMachine**(*FSM*)

Test whether or not FSM inherits from *FiniteStateMachine*.

sage.combinat.finite_state_machine.**is_Transducer**(*FSM*)

Test whether or not FSM inherits from *Transducer*.

sage.combinat.finite_state_machine.**setup_latex_preamble**()

This function adds the package tikz with support for automata to the preamble of Latex so that the finite state machines can be drawn nicely.

See the section on *LaTeX output* in the introductory examples of this module.

sage.combinat.finite_state_machine.**startswith**(*list_*, *prefix*)

Determine whether list starts with the given prefix.

INPUT:

- list_ – list
- prefix – list representing the prefix

OUTPUT: boolean

Similar to str.startswith().

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import startswith
sage: startswith([1, 2, 3], [1, 2])
True
sage: startswith([1], [1, 2])
False
sage: startswith([1, 3, 2], [1, 2])
False
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import startswith
>>> startswith([Integer(1), Integer(2), Integer(3)], [Integer(1), Integer(2)])
True
>>> startswith([Integer(1)], [Integer(1), Integer(2)])
False
>>> startswith([Integer(1), Integer(3), Integer(2)], [Integer(1), Integer(2)])
False
```

sage.combinat.finite_state_machine.**tupleofwords_to_wordoftuples**(*tupleofwords*)

Transposes a tuple of words over the alphabet to a word of tuples.

INPUT:

- tupleofwords – tuple of a list of letters

OUTPUT: list of tuples

Missing letters in the words are padded with the letter None (from the empty word).

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import (
....:     tupleofwords_to_wordoftuples)
sage: tupleofwords_to_wordoftuples(
```

(continues on next page)

(continued from previous page)

```
....:     ([1, 2], [3, 4, 5, 6], [7]))
[(1, 3, 7), (2, 4, None), (None, 5, None), (None, 6, None)]
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import (
...     tupleofwords_to_wordoftuples)
>>> tupleofwords_to_wordoftuples(
...     ([Integer(1), Integer(2)], [Integer(3), Integer(4), Integer(5),␣
↪Integer(6)], [Integer(7)]))
[(1, 3, 7), (2, 4, None), (None, 5, None), (None, 6, None)]
```

sage.combinat.finite_state_machine.**wordoftuples_to_tupleofwords**(*wordoftuples*)

Transposes a word of tuples to a tuple of words over the alphabet.

INPUT:

- `wordoftuples` – list of tuples of letters

OUTPUT: a tuple of lists

Letters `None` (empty word) are removed from each word in the output.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import (
....:     wordoftuples_to_tupleofwords)
sage: wordoftuples_to_tupleofwords(
....:     [(1, 2), (1, None), (1, None), (1, 2), (None, 2)])
([1, 1, 1, 1], [2, 2, 2])
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import (
...     wordoftuples_to_tupleofwords)
>>> wordoftuples_to_tupleofwords(
...     [(Integer(1), Integer(2)), (Integer(1), None), (Integer(1), None),␣
↪(Integer(1), Integer(2)), (None, Integer(2))])
([1, 1, 1, 1], [2, 2, 2])
```

5.1.109 Common Automata and Transducers (Finite State Machines Generators)

Automata and Transducers in Sage can be built through the `automata` and `transducers` objects, respectively. It contains generators for common finite state machines. For example,

```
sage: I = transducers.Identity([0, 1, 2])
```

```
>>> from sage.all import *
>>> I = transducers.Identity([Integer(0), Integer(1), Integer(2)])
```

generates an identity transducer on the alphabet $\{0, 1, 2\}$.

To construct automata and transducers manually, you can use the classes `Automaton` and `Transducer`, respectively. See *Finite state machines, automata, transducers* for more details and a lot of *examples*.

Automata

`AnyLetter()`	Return an automaton recognizing any letter.
`AnyWord()`	Return an automaton recognizing any word.
`EmptyWord()`	Return an automaton recognizing the empty word.
`Word()`	Return an automaton recognizing the given word.
`ContainsWord()`	Return an automaton recognizing words containing the given word.

Transducers

`Identity()`	Return a transducer realizing the identity map.
`abs()`	Return a transducer realizing absolute value.
`map()`	Return a transducer realizing a function.
`operator()`	Return a transducer realizing a binary operation.
`all()`	Return a transducer realizing logical `and`.
`any()`	Return a transducer realizing logical `or`.
`add()`	Return a transducer realizing addition.
`sub()`	Return a transducer realizing subtraction.
`CountSubblockOccurrences()`	Return a transducer counting the occurrences of a subblock.
`Wait()`	Return a transducer writing `False` until first (or k-th) true input is read.
`weight()`	Return a transducer realizing the Hamming weight.
`GrayCode()`	Return a transducer realizing binary Gray code.
`Recursion()`	Return a transducer defined by recursions.

Functions and methods

class `sage.combinat.finite_state_machine_generators.`**`AutomatonGenerators`**

Bases: `object`

A collection of constructors for several common automata.

A list of all automata in this database is available via tab completion. Type "`automata.`" and then hit tab to see which automata are available.

The automata currently in this class include:

- `AnyLetter()`
- `AnyWord()`
- `EmptyWord()`
- `Word()`
- `ContainsWord()`

AnyLetter(*input_alphabet*)

Return an automaton recognizing any letter of the given input alphabet.

INPUT:

- `input_alphabet` – list; the input alphabet

OUTPUT: an `Automaton`

EXAMPLES:

```
sage: A = automata.AnyLetter([0, 1])
sage: A([])
False
sage: A([0])
True
sage: A([1])
True
sage: A([0, 0])
False
```

```
>>> from sage.all import *
>>> A = automata.AnyLetter([Integer(0), Integer(1)])
>>> A([])
False
>>> A([Integer(0)])
True
>>> A([Integer(1)])
True
>>> A([Integer(0), Integer(0)])
False
```

See also

`AnyWord()`

AnyWord(*input_alphabet*)

Return an automaton recognizing any word of the given input alphabet.

INPUT:

- `input_alphabet` – list; the input alphabet

OUTPUT: an `Automaton`

EXAMPLES:

```
sage: A = automata.AnyWord([0, 1])
sage: A([0])
True
sage: A([1])
True
sage: A([0, 1])
True
sage: A([0, 2])
False
```

```
>>> from sage.all import *
>>> A = automata.AnyWord([Integer(0), Integer(1)])
>>> A([Integer(0)])
True
>>> A([Integer(1)])
True
>>> A([Integer(0), Integer(1)])
True
>>> A([Integer(0), Integer(2)])
False
```

This is equivalent to taking the `kleene_star()` of `AnyLetter()` and minimizing the result. This method immediately gives a minimized version:

```
sage: B = automata.AnyLetter([0, 1]).kleene_star().minimization().relabeled()
sage: B == A
True
```

```
>>> from sage.all import *
>>> B = automata.AnyLetter([Integer(0), Integer(1)]).kleene_star().
↪minimization().relabeled()
>>> B == A
True
```

See also:

`AnyLetter()`, `Word()`.

ContainsWord(*word*, *input_alphabet*)

Return an automaton recognizing the words containing the given word as a factor.

INPUT:

- `word` – list (or other iterable) of letters; the word we are looking for
- `input_alphabet` – list or other iterable; the input alphabet

OUTPUT: an `Automaton`

EXAMPLES:

```
sage: A = automata.ContainsWord([0, 1, 0, 1, 1],
....:                           input_alphabet=[0, 1])
```

(continues on next page)

(continued from previous page)

```
sage: A([1, 0, 1, 0, 1, 0, 1, 1, 0, 0])
True
sage: A([1, 0, 1, 0, 1, 0, 1, 0])
False
```

```
>>> from sage.all import *
>>> A = automata.ContainsWord([Integer(0), Integer(1), Integer(0), Integer(1),
↪ Integer(1)],
...                              input_alphabet=[Integer(0), Integer(1)])
>>> A([Integer(1), Integer(0), Integer(1), Integer(0), Integer(1), Integer(0),
↪ Integer(1), Integer(1), Integer(0), Integer(0)])
True
>>> A([Integer(1), Integer(0), Integer(1), Integer(0), Integer(1), Integer(0),
↪ Integer(1), Integer(0)])
False
```

This is equivalent to taking the concatenation of `AnyWord()`, `Word()` and `AnyWord()` and minimizing the result. This method immediately gives a minimized version:

```
sage: B = (automata.AnyWord([0, 1]) *
....:     automata.Word([0, 1, 0, 1, 1], [0, 1]) *
....:     automata.AnyWord([0, 1])).minimization()
sage: B.is_equivalent(A)
True
```

```
>>> from sage.all import *
>>> B = (automata.AnyWord([Integer(0), Integer(1)]) *
...     automata.Word([Integer(0), Integer(1), Integer(0), Integer(1),␣
↪Integer(1)], [Integer(0), Integer(1)]) *
...     automata.AnyWord([Integer(0), Integer(1)])).minimization()
>>> B.is_equivalent(A)
True
```

See also

`CountSubblockOccurrences()`, `AnyWord()`, `Word()`.

EmptyWord(*input_alphabet=None*)

Return an automaton recognizing the empty word.

INPUT:

- `input_alphabet` – iterable or `None` (default: `None`)

OUTPUT: an `Automaton`

EXAMPLES:

```
sage: A = automata.EmptyWord()
sage: A([])
True
sage: A([0])
False
```

```
>>> from sage.all import *
>>> A = automata.EmptyWord()
>>> A([])
True
>>> A([Integer(0)])
False
```

See also

AnyLetter(), *AnyWord()*.

Word(*word*, *input_alphabet=None*)

Return an automaton recognizing the given word.

INPUT:

- `word` – an iterable
- `input_alphabet` – list or `None`; if `None`, then the letters occurring in the word are used

OUTPUT: an *Automaton*

EXAMPLES:

```
sage: A = automata.Word([0])
sage: A.transitions()
[Transition from 0 to 1: 0|-]
sage: [A(w) for w in ([], [0], [1])]
[False, True, False]
sage: A = automata.Word([0, 1, 0])
sage: A.transitions()
[Transition from 0 to 1: 0|-,
Transition from 1 to 2: 1|-,
Transition from 2 to 3: 0|-]
sage: [A(w) for w in ([], [0], [0, 1], [0, 1, 1], [0, 1, 0])]
[False, False, False, False, True]
```

```
>>> from sage.all import *
>>> A = automata.Word([Integer(0)])
>>> A.transitions()
[Transition from 0 to 1: 0|-]
>>> [A(w) for w in ([], [Integer(0)], [Integer(1)])]
[False, True, False]
>>> A = automata.Word([Integer(0), Integer(1), Integer(0)])
>>> A.transitions()
[Transition from 0 to 1: 0|-,
Transition from 1 to 2: 1|-,
Transition from 2 to 3: 0|-]
>>> [A(w) for w in ([], [Integer(0)], [Integer(0), Integer(1)], [Integer(0),
↪Integer(1), Integer(1)], [Integer(0), Integer(1), Integer(0)])]
[False, False, False, False, True]
```

If the input alphabet is not given, it is derived from the given word.

```
sage: A.input_alphabet
[0, 1]
sage: A = automata.Word([0, 1, 0], input_alphabet=[0, 1, 2])
sage: A.input_alphabet
[0, 1, 2]
```

```
>>> from sage.all import *
>>> A.input_alphabet
[0, 1]
>>> A = automata.Word([Integer(0), Integer(1), Integer(0)], input_
↪alphabet=[Integer(0), Integer(1), Integer(2)])
>>> A.input_alphabet
[0, 1, 2]
```

AnyWord(), *ContainsWord()*.

class sage.combinat.finite_state_machine_generators.**TransducerGenerators**

Bases: object

A collection of constructors for several common transducers.

A list of all transducers in this database is available via tab completion. Type "transducers." and then hit tab to see which transducers are available.

The transducers currently in this class include:

- *Identity()*
- *abs()*
- *operator()*
- *all()*
- *any()*
- *add()*
- *sub()*
- *CountSubblockOccurrences()*
- *Wait()*
- *GrayCode()*
- *Recursion()*

CountSubblockOccurrences(*block*, *input_alphabet*)

Return a transducer counting the number of (possibly overlapping) occurrences of a block in the input.

INPUT:

- block – list (or other iterable) of letters
- input_alphabet – list or other iterable

OUTPUT:

A transducer counting (in unary) the number of occurrences of the given block in the input. Overlapping occurrences are counted several times.

Denoting the block by $b_0 \dots b_{k-1}$, the input word by $i_0 \dots i_L$ and the output word by $o_0 \dots o_L$, we have $o_j = 1$ if and only if $i_{j-k+1} \dots i_j = b_0 \dots b_{k-1}$. Otherwise, $o_j = 0$.

EXAMPLES:

1. Counting the number of `10` blocks over the alphabet `[0, 1]`:

```
sage: T = transducers.CountSubblockOccurrences(
....:     [1, 0],
....:     [0, 1])
sage: sorted(T.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from (1,) to (): 0|1,
 Transition from (1,) to (1,): 1|0]
sage: T.input_alphabet
[0, 1]
sage: T.output_alphabet
[0, 1]
sage: T.initial_states()
[()]
sage: T.final_states()
[(), (1,)]
```

```
>>> from sage.all import *
>>> T = transducers.CountSubblockOccurrences(
...     [Integer(1), Integer(0)],
...     [Integer(0), Integer(1)])
>>> sorted(T.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from (1,) to (): 0|1,
 Transition from (1,) to (1,): 1|0]
>>> T.input_alphabet
[0, 1]
>>> T.output_alphabet
[0, 1]
>>> T.initial_states()
[()]
>>> T.final_states()
[(), (1,)]
```

Check some sequence:

```
sage: T([0, 1, 0, 1, 1, 0])
[0, 0, 1, 0, 0, 1]
```

```
>>> from sage.all import *
>>> T([Integer(0), Integer(1), Integer(0), Integer(1), Integer(1),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(0)])
[0, 0, 1, 0, 0, 1]
```

2. Counting the number of `11` blocks over the alphabet `[0, 1]`:

```
sage: T = transducers.CountSubblockOccurrences(
....:     [1, 1],
....:     [0, 1])
sage: sorted(T.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from (1,) to (): 0|0,
 Transition from (1,) to (1,): 1|1]
```

```
>>> from sage.all import *
>>> T = transducers.CountSubblockOccurrences(
...     [Integer(1), Integer(1)],
...     [Integer(0), Integer(1)])
>>> sorted(T.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from (1,) to (): 0|0,
 Transition from (1,) to (1,): 1|1]
```

Check some sequence:

```
sage: T([0, 1, 0, 1, 1, 0])
[0, 0, 0, 0, 1, 0]
```

```
>>> from sage.all import *
>>> T([Integer(0), Integer(1), Integer(0), Integer(1), Integer(1),␣
↪Integer(0)])
[0, 0, 0, 0, 1, 0]
```

3. Counting the number of `1010` blocks over the alphabet `[0, 1, 2]`:

```
sage: T = transducers.CountSubblockOccurrences(
....:     [1, 0, 1, 0],
....:     [0, 1, 2])
sage: sorted(T.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from () to (): 2|0,
 Transition from (1,) to (1, 0): 0|0,
 Transition from (1,) to (1,): 1|0,
 Transition from (1,) to (): 2|0,
 Transition from (1, 0) to (): 0|0,
 Transition from (1, 0) to (1, 0, 1): 1|0,
 Transition from (1, 0) to (): 2|0,
 Transition from (1, 0, 1) to (1, 0): 0|1,
 Transition from (1, 0, 1) to (1,): 1|0,
 Transition from (1, 0, 1) to (): 2|0]
```

(continues on next page)

(continued from previous page)

```
sage: input =  [0, 1, 0, 1, 0, 1, 0, 0, 1, 0, 1, 0, 2]
sage: output = [0, 0, 0, 0, 1, 0, 1, 0, 0, 0, 0, 1, 0]
sage: T(input) == output
True
```

```
>>> from sage.all import *
>>> T = transducers.CountSubblockOccurrences(
...     [Integer(1), Integer(0), Integer(1), Integer(0)],
...     [Integer(0), Integer(1), Integer(2)])
>>> sorted(T.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from () to (): 2|0,
 Transition from (1,) to (1, 0): 0|0,
 Transition from (1,) to (1,): 1|0,
 Transition from (1,) to (): 2|0,
 Transition from (1, 0) to (): 0|0,
 Transition from (1, 0) to (1, 0, 1): 1|0,
 Transition from (1, 0) to (): 2|0,
 Transition from (1, 0, 1) to (1, 0): 0|1,
 Transition from (1, 0, 1) to (1,): 1|0,
 Transition from (1, 0, 1) to (): 2|0]
>>> input =  [Integer(0), Integer(1), Integer(0), Integer(1), Integer(0),␣
↪Integer(1), Integer(0), Integer(0), Integer(1), Integer(0), Integer(1),␣
↪Integer(0), Integer(2)]
>>> output = [Integer(0), Integer(0), Integer(0), Integer(0), Integer(1),␣
↪Integer(0), Integer(1), Integer(0), Integer(0), Integer(0), Integer(0),␣
↪Integer(1), Integer(0)]
>>> T(input) == output
True
```

See also:

ContainsWord()

GrayCode()

Return a transducer converting the standard binary expansion to Gray code.

OUTPUT: a transducer

Cf. the Wikipedia article Gray_code for a description of the Gray code.

EXAMPLES:

```
sage: G = transducers.GrayCode()
sage: G
Transducer with 3 states
sage: for v in srange(10):
....:     print("{} {}".format(v, G(v.digits(base=2))))
0 []
1 [1]
2 [1, 1]
```

(continues on next page)

(continued from previous page)

```
3 [0, 1]
4 [0, 1, 1]
5 [1, 1, 1]
6 [1, 0, 1]
7 [0, 0, 1]
8 [0, 0, 1, 1]
9 [1, 0, 1, 1]
```

```
>>> from sage.all import *
>>> G = transducers.GrayCode()
>>> G
Transducer with 3 states
>>> for v in srange(Integer(10)):
...     print("{} {}".format(v, G(v.digits(base=Integer(2)))))
0 []
1 [1]
2 [1, 1]
3 [0, 1]
4 [0, 1, 1]
5 [1, 1, 1]
6 [1, 0, 1]
7 [0, 0, 1]
8 [0, 0, 1, 1]
9 [1, 0, 1, 1]
```

In the example *Gray Code* in the documentation of the *Finite state machines, automata, transducers* module, the Gray code transducer is derived from the algorithm converting the binary expansion to the Gray code. The result is the same as the one given here.

Identity(*input_alphabet*)

Return the identity transducer realizing the identity map.

INPUT:

- `input_alphabet` – list or other iterable

OUTPUT: a transducer mapping each word over `input_alphabet` to itself

EXAMPLES:

```
sage: T = transducers.Identity([0, 1])
sage: sorted(T.transitions())
[Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 1|1]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T.input_alphabet
[0, 1]
sage: T.output_alphabet
[0, 1]
sage: T([0, 1, 0, 1, 1])
[0, 1, 0, 1, 1]
```

```
>>> from sage.all import *
>>> T = transducers.Identity([Integer(0), Integer(1)])
>>> sorted(T.transitions())
[Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 1|1]
>>> T.initial_states()
[0]
>>> T.final_states()
[0]
>>> T.input_alphabet
[0, 1]
>>> T.output_alphabet
[0, 1]
>>> T([Integer(0), Integer(1), Integer(0), Integer(1), Integer(1)])
[0, 1, 0, 1, 1]
```

Recursion(*recursions, base, function=None, var=None, input_alphabet=None, word_function=None, is_zero=None, output_rings=[Integer Ring, Rational Field]*)

Return a transducer realizing the given recursion when reading the digit expansion with base `base`.

INPUT:

- `recursions` – list or iterable of equations. Each equation has either the form
  - `f(base^K * n + r) == f(base^k * n + s) + t` for some integers `0 <= k < K`, `r` and some `t`—valid for all `n` such that the arguments on both sides are nonnegative—

  or the form
  - `f(r) == t` for some integer `r` and some `t`.

  Alternatively, an equation may be replaced by a `transducers.RecursionRule` with the attributes `K`, `r`, `k`, `s`, `t` as above or a tuple `(r, t)`. Note that `t` *must* be a list in this case.
- `base` – base of the digit expansion
- `function` – symbolic function `f` occurring in the recursions
- `var` – symbolic variable
- `input_alphabet` – (default: `None`) a list of digits to be used as the input alphabet. If `None` and the base is an integer, `input_alphabet` is chosen to be `srange(base.abs())`.
- `word_function` – (default: `None`) a symbolic function. If not `None`, `word_function(arg1, ..., argn)` in a symbolic recurrence relation is interpreted as a transition with output `[arg1, ..., argn]`. This could not be entered in a symbolic recurrence relation because lists do not coerce into the `SymbolicRing`.
- `is_zero` – (default: `None`) a callable. The recursion relations are only well-posed if there is no cycle with nonzero output and input consisting of zeros. This parameter is used to determine whether the output of such a cycle is nonzero. By default, the output must evaluate to `False` as a boolean.
- `output_rings` – (default: `[ZZ, QQ]`) a list of rings. The output labels are converted into the first ring of the list in which they are contained. If they are not contained in any ring, they remain in whatever ring they are after parsing the recursions, typically the symbolic ring.

OUTPUT: a transducer `T`

The transducer is constructed such that `T(expansion) == f(n)` if `expansion` is the digit expansion of `n` to the base `base` with the given input alphabet as set of digits. Here, the `+` on the right hand side of the recurrence relation is interpreted as the concatenation of words.

The formal equations and initial conditions in the recursion have to be selected such that `f` is uniquely defined.

EXAMPLES:

- The following example computes the Hamming weight of the ternary expansion of integers.

```
sage: # needs sage.symbolic
sage: function('f')
f
sage: var('n')
n
sage: T = transducers.Recursion([
....:     f(3*n + 1) == f(n) + 1,
....:     f(3*n + 2) == f(n) + 1,
....:     f(3*n) == f(n),
....:     f(0) == 0],
....:     3, f, n)
sage: T.transitions()
[Transition from (0, 0) to (0, 0): 0|-,
 Transition from (0, 0) to (0, 0): 1|1,
 Transition from (0, 0) to (0, 0): 2|1]
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> function('f')
f
>>> var('n')
n
>>> T = transducers.Recursion([
...     f(Integer(3)*n + Integer(1)) == f(n) + Integer(1),
...     f(Integer(3)*n + Integer(2)) == f(n) + Integer(1),
...     f(Integer(3)*n) == f(n),
...     f(Integer(0)) == Integer(0)],
...     Integer(3), f, n)
>>> T.transitions()
[Transition from (0, 0) to (0, 0): 0|-,
 Transition from (0, 0) to (0, 0): 1|1,
 Transition from (0, 0) to (0, 0): 2|1]
```

To illustrate what this transducer does, we consider the example of $n = 601$:

```
sage: # needs sage.symbolic
sage: ternary_expansion = 601.digits(base=3)
sage: ternary_expansion
[1, 2, 0, 1, 1, 2]
sage: weight_sequence = T(ternary_expansion)
sage: weight_sequence
[1, 1, 1, 1, 1]
sage: sum(weight_sequence)
5
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> ternary_expansion = Integer(601).digits(base=Integer(3))
```

(continues on next page)

(continued from previous page)

```
>>> ternary_expansion
[1, 2, 0, 1, 1, 2]
>>> weight_sequence = T(ternary_expansion)
>>> weight_sequence
[1, 1, 1, 1, 1]
>>> sum(weight_sequence)
5
```

Note that the digit zero does not show up in the output because the equation `f(3*n) == f(n)` means that no output is added to `f(n)`.

- The following example computes the Hamming weight of the non-adjacent form, cf. the Wikipedia article Non-adjacent_form.

```
sage: # needs sage.symbolic
sage: function('f')
f
sage: var('n')
n
sage: T = transducers.Recursion([
....:     f(4*n + 1) == f(n) + 1,
....:     f(4*n - 1) == f(n) + 1,
....:     f(2*n) == f(n),
....:     f(0) == 0],
....:     2, f, n)
sage: T.transitions()
[Transition from (0, 0) to (0, 0): 0|-,
 Transition from (0, 0) to (1, 1): 1|-,
 Transition from (1, 1) to (0, 0): 0|1,
 Transition from (1, 1) to (1, 0): 1|1,
 Transition from (1, 0) to (1, 1): 0|-,
 Transition from (1, 0) to (1, 0): 1|-]
sage: [(s.label(), s.final_word_out)
....:  for s in T.iter_final_states()]
[((0, 0), []),
 ((1, 1), [1]),
 ((1, 0), [1])]
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> function('f')
f
>>> var('n')
n
>>> T = transducers.Recursion([
...     f(Integer(4)*n + Integer(1)) == f(n) + Integer(1),
...     f(Integer(4)*n - Integer(1)) == f(n) + Integer(1),
...     f(Integer(2)*n) == f(n),
...     f(Integer(0)) == Integer(0)],
...     Integer(2), f, n)
>>> T.transitions()
[Transition from (0, 0) to (0, 0): 0|-,
```

(continues on next page)

(continued from previous page)

```
 Transition from (0, 0) to (1, 1): 1|-,
 Transition from (1, 1) to (0, 0): 0|1,
 Transition from (1, 1) to (1, 0): 1|1,
 Transition from (1, 0) to (1, 1): 0|-,
 Transition from (1, 0) to (1, 0): 1|-]
>>> [(s.label(), s.final_word_out)
...  for s in T.iter_final_states()]
[((0, 0), []),
 ((1, 1), [1]),
 ((1, 0), [1])]
```

As we are interested in the weight only, we also output 1 for numbers congruent to 3 mod 4. The actual expansion is computed in the next example.

Consider the example of $29 = (100\bar{1}01)_2$ (as usual, the digit -1 is denoted by $\bar{1}$ and digits are written from the most significant digit at the left to the least significant digit at the right; for the transducer, we have to give the digits in the reverse order):

```
sage: NAF = [1, 0, -1, 0, 0, 1]
sage: ZZ(NAF, base=2)
29
sage: binary_expansion = 29.digits(base=2)
sage: binary_expansion
[1, 0, 1, 1, 1]
sage: T(binary_expansion)                                                    #␣
↪needs sage.symbolic
[1, 1, 1]
sage: sum(T(binary_expansion))                                               #␣
↪needs sage.symbolic
3
```

```
>>> from sage.all import *
>>> NAF = [Integer(1), Integer(0), -Integer(1), Integer(0), Integer(0),␣
↪Integer(1)]
>>> ZZ(NAF, base=Integer(2))
29
>>> binary_expansion = Integer(29).digits(base=Integer(2))
>>> binary_expansion
[1, 0, 1, 1, 1]
>>> T(binary_expansion)                                                    #␣
↪needs sage.symbolic
[1, 1, 1]
>>> sum(T(binary_expansion))                                               #␣
↪needs sage.symbolic
3
```

Indeed, the given non-adjacent form has three nonzero digits.

- The following example computes the non-adjacent form from the binary expansion, cf. the Wikipedia article Non-adjacent_form. In contrast to the previous example, we actually compute the expansion, not only the weight.

  We have to write the output 0 when converting an even number. This cannot be encoded directly by an equation in the symbolic ring, because `f(2*n) == f(n) + 0` would be equivalent to `f(2*n) ==`

f(n) and an empty output would be written. Therefore, we wrap the output in the symbolic function w and use the parameter word_function to announce this.

Similarly, we use w(-1, 0) to write an output word of length 2 in one iteration. Finally, we write f(0) == w() to write an empty word upon completion.

Moreover, there is a cycle with output [0] which—from the point of view of this method—is a contradicting recursion. We override this by the parameter is_zero.

```
sage: # needs sage.symbolic
sage: var('n')
n
sage: function('f w')
(f, w)
sage: T = transducers.Recursion([
....:       f(2*n) == f(n) + w(0),
....:       f(4*n + 1) == f(n) + w(1, 0),
....:       f(4*n - 1) == f(n) + w(-1, 0),
....:       f(0) == w()],
....:       2, f, n,
....:       word_function=w,
....:       is_zero=lambda x: sum(x).is_zero())
sage: T.transitions()
[Transition from (0, 0) to (0, 0): 0|0,
 Transition from (0, 0) to (1, 1): 1|-,
 Transition from (1, 1) to (0, 0): 0|1,0,
 Transition from (1, 1) to (1, 0): 1|-1,0,
 Transition from (1, 0) to (1, 1): 0|-,
 Transition from (1, 0) to (1, 0): 1|0]
sage: for s in T.iter_states():
....:     print("{} {}".format(s, s.final_word_out))
(0, 0) []
(1, 1) [1, 0]
(1, 0) [1, 0]
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> var('n')
n
>>> function('f w')
(f, w)
>>> T = transducers.Recursion([
...       f(Integer(2)*n) == f(n) + w(Integer(0)),
...       f(Integer(4)*n + Integer(1)) == f(n) + w(Integer(1), Integer(0)),
...       f(Integer(4)*n - Integer(1)) == f(n) + w(-Integer(1),␣
↪Integer(0)),
...       f(Integer(0)) == w()],
...       Integer(2), f, n,
...       word_function=w,
...       is_zero=lambda x: sum(x).is_zero())
>>> T.transitions()
[Transition from (0, 0) to (0, 0): 0|0,
 Transition from (0, 0) to (1, 1): 1|-,
 Transition from (1, 1) to (0, 0): 0|1,0,
```

(continues on next page)

(continued from previous page)

```
 Transition from (1, 1) to (1, 0): 1|-1,0,
 Transition from (1, 0) to (1, 1): 0|-,
 Transition from (1, 0) to (1, 0): 1|0]
>>> for s in T.iter_states():
...     print("{} {}".format(s, s.final_word_out))
(0, 0) []
(1, 1) [1, 0]
(1, 0) [1, 0]
```

We again consider the example of $n = 29$:

```
sage: T(29.digits(base=2))                                              #␣
↪needs sage.symbolic
[1, 0, -1, 0, 0, 1, 0]
```

```
>>> from sage.all import *
>>> T(Integer(29).digits(base=Integer(2)))                               ␣
↪              # needs sage.symbolic
[1, 0, -1, 0, 0, 1, 0]
```

The same transducer can also be entered bypassing the symbolic equations:

```
sage: R = transducers.RecursionRule
sage: TR = transducers.Recursion([
....:       R(K=1, r=0, k=0, s=0, t=[0]),
....:       R(K=2, r=1, k=0, s=0, t=[1, 0]),
....:       R(K=2, r=-1, k=0, s=0, t=[-1, 0]),
....:       (0, [])],
....:       2,
....:       is_zero=lambda x: sum(x).is_zero())
sage: TR == T                                                           #␣
↪needs sage.symbolic
True
```

```
>>> from sage.all import *
>>> R = transducers.RecursionRule
>>> TR = transducers.Recursion([
...       R(K=Integer(1), r=Integer(0), k=Integer(0), s=Integer(0),␣
↪t=[Integer(0)]),
...       R(K=Integer(2), r=Integer(1), k=Integer(0), s=Integer(0),␣
↪t=[Integer(1), Integer(0)]),
...       R(K=Integer(2), r=-Integer(1), k=Integer(0), s=Integer(0), t=[-
↪Integer(1), Integer(0)]),
...       (Integer(0), [])],
...       Integer(2),
...       is_zero=lambda x: sum(x).is_zero())
>>> TR == T                                                           #␣
↪needs sage.symbolic
True
```

- Here is an artificial example where some of the s are negative:

```
sage: # needs sage.symbolic
sage: function('f')
f
sage: var('n')
n
sage: T = transducers.Recursion([
....:     f(2*n + 1) == f(n-1) + 1,
....:     f(2*n) == f(n),
....:     f(1) == 1,
....:     f(0) == 0], 2, f, n)
sage: T.transitions()
[Transition from (0, 0) to (0, 0): 0|-,
 Transition from (0, 0) to (1, 1): 1|-,
 Transition from (1, 1) to (-1, 1): 0|1,
 Transition from (1, 1) to (0, 0): 1|1,
 Transition from (-1, 1) to (-1, 2): 0|-,
 Transition from (-1, 1) to (1, 2): 1|-,
 Transition from (-1, 2) to (-1, 1): 0|1,
 Transition from (-1, 2) to (0, 0): 1|1,
 Transition from (1, 2) to (-1, 2): 0|1,
 Transition from (1, 2) to (1, 2): 1|1]
sage: [(s.label(), s.final_word_out)
....:  for s in T.iter_final_states()]
[((0, 0), []),
 ((1, 1), [1]),
 ((-1, 1), [0]),
 ((-1, 2), [0]),
 ((1, 2), [1])]
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> function('f')
f
>>> var('n')
n
>>> T = transducers.Recursion([
...     f(Integer(2)*n + Integer(1)) == f(n-Integer(1)) + Integer(1),
...     f(Integer(2)*n) == f(n),
...     f(Integer(1)) == Integer(1),
...     f(Integer(0)) == Integer(0)], Integer(2), f, n)
>>> T.transitions()
[Transition from (0, 0) to (0, 0): 0|-,
 Transition from (0, 0) to (1, 1): 1|-,
 Transition from (1, 1) to (-1, 1): 0|1,
 Transition from (1, 1) to (0, 0): 1|1,
 Transition from (-1, 1) to (-1, 2): 0|-,
 Transition from (-1, 1) to (1, 2): 1|-,
 Transition from (-1, 2) to (-1, 1): 0|1,
 Transition from (-1, 2) to (0, 0): 1|1,
 Transition from (1, 2) to (-1, 2): 0|1,
 Transition from (1, 2) to (1, 2): 1|1]
>>> [(s.label(), s.final_word_out)
```

(continues on next page)

(continued from previous page)

```
...   for s in T.iter_final_states()]
[((0, 0), []),
 ((1, 1), [1]),
 ((-1, 1), [0]),
 ((-1, 2), [0]),
 ((1, 2), [1])]
```

- Abelian complexity of the paperfolding sequence (cf. [HKP2015], Example 2.8):

```
sage: # needs sage.symbolic
sage: T = transducers.Recursion([
....:     f(4*n) == f(2*n),
....:     f(4*n+2) == f(2*n+1)+1,
....:     f(16*n+1) == f(8*n+1),
....:     f(16*n+5) == f(4*n+1)+2,
....:     f(16*n+11) == f(4*n+3)+2,
....:     f(16*n+15) == f(2*n+2)+1,
....:     f(1) == 2, f(0) == 0]
....:     + [f(16*n+jj) == f(2*n+1)+2 for jj in [3,7,9,13]],
....:     2, f, n)
sage: T.transitions()
[Transition from (0, 0) to (0, 1): 0|-,
 Transition from (0, 0) to (1, 1): 1|-,

(1, 1) [2]
(1, 2) [2]
(3, 2) [2, 2]
(1, 3) [2]
(5, 3) [2, 2]
(3, 3) [2, 2]
```

(continues on next page)

(continued from previous page)

```
(7, 3) [2, 2]
(2, 1) [1, 2]
>>> list(sum(T(n.bits())) for n in srange(Integer(1), Integer(21)))
[2, 3, 4, 3, 4, 5, 4, 3, 4, 5, 6, 5, 4, 5, 4, 3, 4, 5, 6, 5]
```

- We now demonstrate the use of the `output_rings` parameter. If no `output_rings` are specified, the output labels are converted into `ZZ`:

```
sage: # needs sage.symbolic
sage: function('f')
f
sage: var('n')
n
sage: T = transducers.Recursion([
....:     f(2*n + 1) == f(n) + 1,
....:     f(2*n) == f(n),
....:     f(0) == 2],
....:     2, f, n)
sage: for t in T.transitions():
....:     print([x.parent() for x in t.word_out])
[]
[Integer Ring]
sage: [x.parent() for x in T.states()[0].final_word_out]
[Integer Ring]
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> function('f')
f
>>> var('n')
n
>>> T = transducers.Recursion([
...     f(Integer(2)*n + Integer(1)) == f(n) + Integer(1),
...     f(Integer(2)*n) == f(n),
...     f(Integer(0)) == Integer(2)],
...     Integer(2), f, n)
>>> for t in T.transitions():
...     print([x.parent() for x in t.word_out])
[]
[Integer Ring]
>>> [x.parent() for x in T.states()[Integer(0)].final_word_out]
[Integer Ring]
```

In contrast, if `output_rings` is set to the empty list, the results are not converted:

```
sage: T = transducers.Recursion([                                        #␣
↪needs sage.symbolic
....:     f(2*n + 1) == f(n) + 1,
....:     f(2*n) == f(n),
....:     f(0) == 2],
....:     2, f, n, output_rings=[])
sage: for t in T.transitions():                                          #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.symbolic
....:     print([x.parent() for x in t.word_out])
[]
[Symbolic Ring]
sage: [x.parent() for x in T.states()[0].final_word_out]                    #␣
↪needs sage.symbolic
[Symbolic Ring]
```

```
>>> from sage.all import *
>>> T = transducers.Recursion([                                           #␣
↪needs sage.symbolic
...     f(Integer(2)*n + Integer(1)) == f(n) + Integer(1),
...     f(Integer(2)*n) == f(n),
...     f(Integer(0)) == Integer(2)],
...     Integer(2), f, n, output_rings=[])
>>> for t in T.transitions():                                             #␣
↪needs sage.symbolic
...     print([x.parent() for x in t.word_out])
[]
[Symbolic Ring]
>>> [x.parent() for x in T.states()[Integer(0)].final_word_out]              ␣
↪       # needs sage.symbolic
[Symbolic Ring]
```

Finally, we use a somewhat questionable conversion:

```
sage: T = transducers.Recursion([                                           #␣
↪needs sage.rings.finite_rings sage.symbolic
....:     f(2*n + 1) == f(n) + 1,
....:     f(2*n) == f(n),
....:     f(0) == 0],
....:     2, f, n, output_rings=[GF(5)])
sage: for t in T.transitions():                                             #␣
↪needs sage.rings.finite_rings sage.symbolic
....:     print([x.parent() for x in t.word_out])
[]
[Finite Field of size 5]
```

```
>>> from sage.all import *
>>> T = transducers.Recursion([                                           #␣
↪needs sage.rings.finite_rings sage.symbolic
...     f(Integer(2)*n + Integer(1)) == f(n) + Integer(1),
...     f(Integer(2)*n) == f(n),
...     f(Integer(0)) == Integer(0)],
...     Integer(2), f, n, output_rings=[GF(Integer(5))])
>>> for t in T.transitions():                                             #␣
↪needs sage.rings.finite_rings sage.symbolic
...     print([x.parent() for x in t.word_out])
[]
[Finite Field of size 5]
```

Todo

Extend the method to

- non-integral bases,
- higher dimensions.

ALGORITHM:

See [HKP2015], Section 6. However, there are also recursion transitions for states of level $< \kappa$ if the recursion rules allow such a transition. Furthermore, the intermediate step of a non-deterministic transducer is left out by implicitly using recursion transitions. The well-posedness is checked in a truncated version of the recursion digraph.

class RecursionRule(*K*, *r*, *k*, *s*, *t*)

Bases: `tuple`

K

Alias for field number 0

k

Alias for field number 2

r

Alias for field number 1

s

Alias for field number 3

t

Alias for field number 4

Wait(*input_alphabet*, *threshold=1*)

Writes `False` until reading the `threshold`-th occurrence of a true input letter; then writes `True`.

INPUT:

- `input_alphabet` – list or other iterable
- `threshold` – positive integer specifying how many occurrences of `True` inputs are waited for

OUTPUT:

A transducer writing `False` until the `threshold`-th true (Python's standard conversion to boolean is used to convert the actual input to boolean) input is read. Subsequently, the transducer writes `True`.

EXAMPLES:

```
sage: T = transducers.Wait([0, 1])
sage: T([0, 0, 1, 0, 1, 0])
[False, False, True, True, True, True]
sage: T2 = transducers.Wait([0, 1], threshold=2)
sage: T2([0, 0, 1, 0, 1, 0])
[False, False, False, False, True, True]
```

```
>>> from sage.all import *
>>> T = transducers.Wait([Integer(0), Integer(1)])
```

(continues on next page)

(continued from previous page)

```
>>> T([Integer(0), Integer(0), Integer(1), Integer(0), Integer(1),
↪Integer(0)])
[False, False, True, True, True, True]
>>> T2 = transducers.Wait([Integer(0), Integer(1)], threshold=Integer(2))
>>> T2([Integer(0), Integer(0), Integer(1), Integer(0), Integer(1),
↪Integer(0)])
[False, False, False, False, True, True]
```

abs(*input_alphabet*)

Return a transducer which realizes the letter-wise absolute value of an input word over the given input alphabet.

INPUT:

- `input_alphabet` – list or other iterable

OUTPUT:

A transducer mapping $i_0 \dots i_k$ to $|i_0| \dots |i_k|$.

EXAMPLES:

The following transducer realizes letter-wise absolute value:

```
sage: T = transducers.abs([-1, 0, 1])
sage: T.transitions()
[Transition from 0 to 0: -1|1,
 Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 1|1]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([-1, -1, 0, 1])
[1, 1, 0, 1]
```

```
>>> from sage.all import *
>>> T = transducers.abs([-Integer(1), Integer(0), Integer(1)])
>>> T.transitions()
[Transition from 0 to 0: -1|1,
 Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 1|1]
>>> T.initial_states()
[0]
>>> T.final_states()
[0]
>>> T([-Integer(1), -Integer(1), Integer(0), Integer(1)])
[1, 1, 0, 1]
```

add(*input_alphabet*, *number_of_operands=2*)

Return a transducer which realizes addition on pairs over the given input alphabet.

INPUT:

- `input_alphabet` – list or other iterable
- `number_of_operands` – (default: 2) it specifies the number of input arguments the operator takes

OUTPUT:

A transducer mapping an input word $(i_{01}, \ldots, i_{0d}) \ldots (i_{k1}, \ldots, i_{kd})$ to the word $(i_{01} + \cdots + i_{0d}) \ldots (i_{k1} + \cdots + i_{kd})$.

The input alphabet of the generated transducer is the Cartesian product of `number_of_operands` copies of `input_alphabet`.

EXAMPLES:

The following transducer realizes letter-wise addition:

```
sage: T = transducers.add([0, 1])
sage: T.transitions()
[Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|2]
sage: T.input_alphabet
[(0, 0), (0, 1), (1, 0), (1, 1)]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([(0, 0), (0, 1), (1, 0), (1, 1)])
[0, 1, 1, 2]
```

```
>>> from sage.all import *
>>> T = transducers.add([Integer(0), Integer(1)])
>>> T.transitions()
[Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|2]
>>> T.input_alphabet
[(0, 0), (0, 1), (1, 0), (1, 1)]
>>> T.initial_states()
[0]
>>> T.final_states()
[0]
>>> T([(Integer(0), Integer(0)), (Integer(0), Integer(1)), (Integer(1),
↪Integer(0)), (Integer(1), Integer(1))])
[0, 1, 1, 2]
```

More than two operands can also be handled:

```
sage: T3 = transducers.add([0, 1], number_of_operands=3)
sage: T3.input_alphabet
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (0, 1, 1),
 (1, 0, 0), (1, 0, 1), (1, 1, 0), (1, 1, 1)]
sage: T3([(0, 0, 0), (0, 1, 0), (0, 1, 1), (1, 1, 1)])
[0, 1, 2, 3]
```

```
>>> from sage.all import *
>>> T3 = transducers.add([Integer(0), Integer(1)], number_of_
```

(continues on next page)

(continued from previous page)

```
↪operands=Integer(3))
>>> T3.input_alphabet
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (0, 1, 1),
 (1, 0, 0), (1, 0, 1), (1, 1, 0), (1, 1, 1)]
>>> T3([(Integer(0), Integer(0), Integer(0)), (Integer(0), Integer(1),␣
↪Integer(0)), (Integer(0), Integer(1), Integer(1)), (Integer(1), Integer(1),␣
↪Integer(1))])
[0, 1, 2, 3]
```

all(*input_alphabet*, *number_of_operands=2*)

Return a transducer which realizes logical `and` over the given input alphabet.

INPUT:

- `input_alphabet` – list or other iterable
- `number_of_operands` – (default: 2) specifies the number of input arguments for the `and` operation

OUTPUT:

A transducer mapping an input word $(i_{01}, \dots, i_{0d}) \dots (i_{k1}, \dots, i_{kd})$ to the word $(i_{01} \wedge \dots \wedge i_{0d}) \dots (i_{k1} \wedge \dots \wedge i_{kd})$.

The input alphabet of the generated transducer is the Cartesian product of `number_of_operands` copies of `input_alphabet`.

EXAMPLES:

The following transducer realizes letter-wise logical `and`:

```
sage: T = transducers.all([False, True])
sage: T.transitions()
[Transition from 0 to 0: (False, False)|False,
 Transition from 0 to 0: (False, True)|False,
 Transition from 0 to 0: (True, False)|False,
 Transition from 0 to 0: (True, True)|True]
sage: T.input_alphabet
[(False, False), (False, True), (True, False), (True, True)]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([(False, False), (False, True), (True, False), (True, True)])
[False, False, False, True]
```

```
>>> from sage.all import *
>>> T = transducers.all([False, True])
>>> T.transitions()
[Transition from 0 to 0: (False, False)|False,
 Transition from 0 to 0: (False, True)|False,
 Transition from 0 to 0: (True, False)|False,
 Transition from 0 to 0: (True, True)|True]
>>> T.input_alphabet
[(False, False), (False, True), (True, False), (True, True)]
>>> T.initial_states()
[0]
```

(continues on next page)

(continued from previous page)

```
>>> T.final_states()
[0]
>>> T([(False, False), (False, True), (True, False), (True, True)])
[False, False, False, True]
```

More than two operands and other input alphabets (with conversion to boolean) are also possible:

```
sage: T3 = transducers.all([0, 1], number_of_operands=3)
sage: T3([(0, 0, 0), (1, 0, 0), (1, 1, 1)])
[False, False, True]
```

```
>>> from sage.all import *
>>> T3 = transducers.all([Integer(0), Integer(1)], number_of_
↪operands=Integer(3))
>>> T3([(Integer(0), Integer(0), Integer(0)), (Integer(1), Integer(0),␣
↪Integer(0)), (Integer(1), Integer(1), Integer(1))])
[False, False, True]
```

any(*input_alphabet*, *number_of_operands=2*)

Return a transducer which realizes logical `or` over the given input alphabet.

INPUT:

- `input_alphabet` – list or other iterable
- `number_of_operands` – (default: 2) specifies the number of input arguments for the `or` operation

OUTPUT:

A transducer mapping an input word $(i_{01},\ldots,i_{0d})\ldots(i_{k1},\ldots,i_{kd})$ to the word $(i_{01}\vee\cdots\vee i_{0d})\ldots(i_{k1}\vee\cdots\vee i_{kd})$.

The input alphabet of the generated transducer is the Cartesian product of `number_of_operands` copies of `input_alphabet`.

EXAMPLES:

The following transducer realizes letter-wise logical `or`:

```
sage: T = transducers.any([False, True])
sage: T.transitions()
[Transition from 0 to 0: (False, False)|False,
 Transition from 0 to 0: (False, True)|True,
 Transition from 0 to 0: (True, False)|True,
 Transition from 0 to 0: (True, True)|True]
sage: T.input_alphabet
[(False, False), (False, True), (True, False), (True, True)]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([(False, False), (False, True), (True, False), (True, True)])
[False, True, True, True]
```

```
>>> from sage.all import *
>>> T = transducers.any([False, True])
```

(continues on next page)

(continued from previous page)

```
>>> T.transitions()
[Transition from 0 to 0: (False, False)|False,
 Transition from 0 to 0: (False, True)|True,
 Transition from 0 to 0: (True, False)|True,
 Transition from 0 to 0: (True, True)|True]
>>> T.input_alphabet
[(False, False), (False, True), (True, False), (True, True)]
>>> T.initial_states()
[0]
>>> T.final_states()
[0]
>>> T([(False, False), (False, True), (True, False), (True, True)])
[False, True, True, True]
```

More than two operands and other input alphabets (with conversion to boolean) are also possible:

```
sage: T3 = transducers.any([0, 1], number_of_operands=3)
sage: T3([(0, 0, 0), (1, 0, 0), (1, 1, 1)])
[False, True, True]
```

```
>>> from sage.all import *
>>> T3 = transducers.any([Integer(0), Integer(1)], number_of_
↪operands=Integer(3))
>>> T3([(Integer(0), Integer(0), Integer(0)), (Integer(1), Integer(0),␣
↪Integer(0)), (Integer(1), Integer(1), Integer(1))])
[False, True, True]
```

map(*f*, *input_alphabet*)

Return a transducer which realizes a function on the alphabet.

INPUT:

- `f` – function to realize
- `input_alphabet` – list or other iterable

OUTPUT:

A transducer mapping an input letter x to $f(x)$.

EXAMPLES:

The following binary transducer realizes component-wise absolute value (this transducer is also available as `abs()`):

```
sage: T = transducers.map(abs, [-1, 0, 1])
sage: T.transitions()
[Transition from 0 to 0: -1|1,
 Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 1|1]
sage: T.input_alphabet
[-1, 0, 1]
sage: T.initial_states()
[0]
sage: T.final_states()
```

(continues on next page)

(continued from previous page)

```
[0]
sage: T([-1, 1, 0, 1])
[1, 1, 0, 1]
```

```
>>> from sage.all import *
>>> T = transducers.map(abs, [-Integer(1), Integer(0), Integer(1)])
>>> T.transitions()
[Transition from 0 to 0: -1|1,
 Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 1|1]
>>> T.input_alphabet
[-1, 0, 1]
>>> T.initial_states()
[0]
>>> T.final_states()
[0]
>>> T([-Integer(1), Integer(1), Integer(0), Integer(1)])
[1, 1, 0, 1]
```

See also:

Automaton.with_output().

operator(*operator*, *input_alphabet*, *number_of_operands=2*)

Return a transducer which realizes an operation on tuples over the given input alphabet.

INPUT:

- `operator` – operator to realize; it is a function which takes `number_of_operands` input arguments (each out of `input_alphabet`)
- `input_alphabet` – list or other iterable
- `number_of_operands` – (default: 2) it specifies the number of input arguments the operator takes

OUTPUT:

A transducer mapping an input letter $(i_1, \ldots, i_n)$ to operator$(i_1, \ldots, i_n)$. Here, n equals `number_of_operands`.

The input alphabet of the generated transducer is the Cartesian product of `number_of_operands` copies of `input_alphabet`.

EXAMPLES:

The following binary transducer realizes component-wise addition (this transducer is also available as *add()*):

```
sage: import operator
sage: T = transducers.operator(operator.add, [0, 1])
sage: T.transitions()
[Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|2]
sage: T.input_alphabet
```

(continues on next page)

(continued from previous page)

```
[(0, 0), (0, 1), (1, 0), (1, 1)]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([(0, 0), (0, 1), (1, 0), (1, 1)])
[0, 1, 1, 2]
```

```
>>> from sage.all import *
>>> import operator
>>> T = transducers.operator(operator.add, [Integer(0), Integer(1)])
>>> T.transitions()
[Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|2]
>>> T.input_alphabet
[(0, 0), (0, 1), (1, 0), (1, 1)]
>>> T.initial_states()
[0]
>>> T.final_states()
[0]
>>> T([(Integer(0), Integer(0)), (Integer(0), Integer(1)), (Integer(1),␣
→Integer(0)), (Integer(1), Integer(1))])
[0, 1, 1, 2]
```

Note that for a unary operator the input letters of the new transducer are tuples of length 1:

```
sage: T = transducers.operator(abs,
....:                          [-1, 0, 1],
....:                          number_of_operands=1)
sage: T([-1, 1, 0])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
sage: T([(-1,), (1,), (0,)])
[1, 1, 0]
```

```
>>> from sage.all import *
>>> T = transducers.operator(abs,
...                          [-Integer(1), Integer(0), Integer(1)],
...                          number_of_operands=Integer(1))
>>> T([-Integer(1), Integer(1), Integer(0)])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
>>> T([(-Integer(1),), (Integer(1),), (Integer(0),)])
[1, 1, 0]
```

Compare this with the transducer generated by *map()*:

```
sage: T = transducers.map(abs,
....:                     [-1, 0, 1])
sage: T([-1, 1, 0])
[1, 1, 0]
```

```
>>> from sage.all import *
>>> T = transducers.map(abs,
...                     [-Integer(1), Integer(0), Integer(1)])
>>> T([-Integer(1), Integer(1), Integer(0)])
[1, 1, 0]
```

In fact, this transducer is also available as *abs()*:

```
sage: T = transducers.abs([-1, 0, 1])
sage: T([-1, 1, 0])
[1, 1, 0]
```

```
>>> from sage.all import *
>>> T = transducers.abs([-Integer(1), Integer(0), Integer(1)])
>>> T([-Integer(1), Integer(1), Integer(0)])
[1, 1, 0]
```

sub(*input_alphabet*)

Return a transducer which realizes subtraction on pairs over the given input alphabet.

INPUT:

- `input_alphabet` – list or other iterable

OUTPUT:

A transducer mapping an input word $(i_0, i'_0) \ldots (i_k, i'_k)$ to the word $(i_0 - i'_0) \ldots (i_k - i'_k)$.

The input alphabet of the generated transducer is the Cartesian product of two copies of `input_alphabet`.

EXAMPLES:

The following transducer realizes letter-wise subtraction:

```
sage: T = transducers.sub([0, 1])
sage: T.transitions()
[Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|-1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|0]
sage: T.input_alphabet
[(0, 0), (0, 1), (1, 0), (1, 1)]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([(0, 0), (0, 1), (1, 0), (1, 1)])
[0, -1, 1, 0]
```

```
>>> from sage.all import *
>>> T = transducers.sub([Integer(0), Integer(1)])
>>> T.transitions()
[Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|-1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|0]
>>> T.input_alphabet
[(0, 0), (0, 1), (1, 0), (1, 1)]
>>> T.initial_states()
[0]
>>> T.final_states()
[0]
>>> T([(Integer(0), Integer(0)), (Integer(0), Integer(1)), (Integer(1),␣
↪Integer(0)), (Integer(1), Integer(1))])
[0, -1, 1, 0]
```

weight(*input_alphabet*, *zero=0*)

Return a transducer which realizes the Hamming weight of the input over the given input alphabet.

INPUT:

- `input_alphabet` – list or other iterable
- `zero` – the zero symbol in the alphabet used

OUTPUT:

A transducer mapping $i_0 \ldots i_k$ to $(i_0 \neq 0) \ldots (i_k \neq 0)$.

The Hamming weight is defined as the number of nonzero digits in the input sequence over the alphabet `input_alphabet` (see Wikipedia article Hamming_weight). The output sequence of the transducer is a unary encoding of the Hamming weight. Thus the sum of the output sequence is the Hamming weight of the input.

EXAMPLES:

```
sage: W = transducers.weight([-1, 0, 2])
sage: W.transitions()
[Transition from 0 to 0: -1|1,
 Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 2|1]
sage: unary_weight = W([-1, 0, 0, 2, -1])
sage: unary_weight
[1, 0, 0, 1, 1]
sage: weight = add(unary_weight)
sage: weight
3
```

```
>>> from sage.all import *
>>> W = transducers.weight([-Integer(1), Integer(0), Integer(2)])
>>> W.transitions()
[Transition from 0 to 0: -1|1,
 Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 2|1]
>>> unary_weight = W([-Integer(1), Integer(0), Integer(0), Integer(2), -
```

(continues on next page)

(continued from previous page)

```
↪Integer(1)])
>>> unary_weight
[1, 0, 0, 1, 1]
>>> weight = add(unary_weight)
>>> weight
3
```

Also the joint Hamming weight can be computed:

```
sage: v1 = vector([-1, 0])
sage: v0 = vector([0, 0])
sage: W = transducers.weight([v1, v0])
sage: unary_weight = W([v1, v0, v1, v0])
sage: add(unary_weight)
2
```

```
>>> from sage.all import *
>>> v1 = vector([-Integer(1), Integer(0)])
>>> v0 = vector([Integer(0), Integer(0)])
>>> W = transducers.weight([v1, v0])
>>> unary_weight = W([v1, v0, v1, v0])
>>> add(unary_weight)
2
```

For the input alphabet `[-1, 0, 1]` the weight transducer is the same as the absolute value transducer *abs()*:

```
sage: W = transducers.weight([-1, 0, 1])
sage: A = transducers.abs([-1, 0, 1])
sage: W == A
True
```

```
>>> from sage.all import *
>>> W = transducers.weight([-Integer(1), Integer(0), Integer(1)])
>>> A = transducers.abs([-Integer(1), Integer(0), Integer(1)])
>>> W == A
True
```

For other input alphabets, we can specify the zero symbol:

```
sage: W = transducers.weight(['a', 'b'], zero='a')
sage: add(W(['a', 'b', 'b']))
2
```

```
>>> from sage.all import *
>>> W = transducers.weight(['a', 'b'], zero='a')
>>> add(W(['a', 'b', 'b']))
2
```

5.1.110 Free Quasi-symmetric functions

AUTHORS:

- Frédéric Chapoton, Darij Grinberg (2017)

class sage.combinat.fqsym.**FQSymBases**(*base*)

Bases: Category_realization_of_parent

The category of graded bases of $FQSym$ indexed by permutations.

class ElementMethods

Bases: object

omega_involution()

Return the image of the element self of $FQSym$ under the omega involution.

The ω involution is defined as the linear map $FQSym \to FQSym$ that sends each basis element F_u of the F-basis of $FQSym$ to the basis element $F_{u \circ w_0}$, where w_0 is the longest word (i.e., $w_0(i) = n+1-i$) in the symmetric group S_n that contains u. The ω involution is a graded algebra automorphism and a coalgebra anti-automorphism of $FQSym$. Every permutation $u \in S_n$ satisfies

$$\omega(F_u) = F_{u \circ w_0}, \qquad \omega(G_u) = G_{w_0 \circ u},$$

where standard notations for classical bases of $FQSym$ are being used (that is, F for the F-basis, and G for the G-basis). In other words, writing permutations in one-line notation, we have

$$\omega(F_{(u_1,u_2,\ldots,u_n)}) = F_{(u_n,u_{n-1},\ldots,u_1)}, \qquad \omega(G_{(u_1,u_2,\ldots,u_n)}) = G_{(n+1-u_1,n+1-u_2,\ldots,n+1-u_n)}.$$

If we also consider the ω involution (*omega_involution()*) of the quasisymmetric functions (by slight abuse of notation), and if we let π be the canonical projection $FQSym \to QSym$, then $\pi \circ \omega = \omega \circ \pi$.

Additionally, consider the ψ involution (*psi_involution()*) of the noncommutative symmetric functions, and if we let ι be the canonical inclusion $NSym \to FQSym$, then $\omega \circ \iota = \iota \circ \psi$.

Todo

Duality?

See also

psi_involution(), *star_involution()*

EXAMPLES:

```
sage: FQSym = algebras.FQSym(ZZ)
sage: F = FQSym.F()
sage: F[[2,3,1]].omega_involution()
F[1, 3, 2]
sage: (3*F[[1]] - 4*F[[]] + 5*F[[1,2]]).omega_involution()
-4*F[] + 3*F[1] + 5*F[2, 1]
sage: G = FQSym.G()
sage: G[[2,3,1]].omega_involution()
G[2, 1, 3]
sage: M = FQSym.M()
```

(continues on next page)

(continued from previous page)

```
sage: M[[2,3,1]].omega_involution()
-M[1, 2, 3] - M[2, 1, 3] - M[3, 1, 2]
```

```
>>> from sage.all import *
>>> FQSym = algebras.FQSym(ZZ)
>>> F = FQSym.F()
>>> F[[Integer(2),Integer(3),Integer(1)]].omega_involution()
F[1, 3, 2]
>>> (Integer(3)*F[[Integer(1)]] - Integer(4)*F[[]] +
↪Integer(5)*F[[Integer(1),Integer(2)]]).omega_involution()
-4*F[] + 3*F[1] + 5*F[2, 1]
>>> G = FQSym.G()
>>> G[[Integer(2),Integer(3),Integer(1)]].omega_involution()
G[2, 1, 3]
>>> M = FQSym.M()
>>> M[[Integer(2),Integer(3),Integer(1)]].omega_involution()
-M[1, 2, 3] - M[2, 1, 3] - M[3, 1, 2]
```

The omega involution is an algebra homomorphism:

```
sage: (F[1,2] * F[1]).omega_involution()
F[2, 1, 3] + F[2, 3, 1] + F[3, 2, 1]
sage: F[1,2].omega_involution() * F[1].omega_involution()
F[2, 1, 3] + F[2, 3, 1] + F[3, 2, 1]
```

```
>>> from sage.all import *
>>> (F[Integer(1),Integer(2)] * F[Integer(1)]).omega_involution()
F[2, 1, 3] + F[2, 3, 1] + F[3, 2, 1]
>>> F[Integer(1),Integer(2)].omega_involution() * F[Integer(1)].omega_
↪involution()
F[2, 1, 3] + F[2, 3, 1] + F[3, 2, 1]
```

The omega involution intertwines the antipode and the inverse of the antipode:

```
sage: all( F(I).antipode().omega_involution().antipode()
....:      == F(I).omega_involution()
....:      for I in Permutations(4) )
True
```

```
>>> from sage.all import *
>>> all( F(I).antipode().omega_involution().antipode()
...      == F(I).omega_involution()
...      for I in Permutations(Integer(4)) )
True
```

Testing the $\pi \circ \omega = \omega \circ \pi$ relation noticed above:

```
sage: all( M[I].omega_involution().to_qsym()
....:      == M[I].to_qsym().omega_involution()
....:      for I in Permutations(4) )
True
```

```
>>> from sage.all import *
>>> all( M[I].omega_involution().to_qsym()
...      == M[I].to_qsym().omega_involution()
...      for I in Permutations(Integer(4)) )
True
```

Testing the $\omega \circ \iota = \iota \circ \psi$ relation:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: all( S[I].psi_involution().to_fqsym() == S[I].to_fqsym().omega_
↪involution()
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> S = NSym.S()
>>> all( S[I].psi_involution().to_fqsym() == S[I].to_fqsym().omega_
↪involution()
...      for I in Compositions(Integer(4)) )
True
```

Todo

Check further commutative squares.

psi_involution()

Return the image of the element `self` of $FQSym$ under the psi involution.

The ψ involution is defined as the linear map $FQSym \to FQSym$ that sends each basis element F_u of the F-basis of $FQSym$ to the basis element $F_{w_0 \circ u}$, where w_0 is the longest word (i.e., $w_0(i) = n+1-i$) in the symmetric group S_n that contains u. The ψ involution is a graded coalgebra automorphism and an algebra anti-automorphism of $FQSym$. Every permutation $u \in S_n$ satisfies

$$\psi(F_u) = F_{w_0 \circ u}, \qquad \psi(G_u) = G_{u \circ w_0},$$

where standard notations for classical bases of $FQSym$ are being used (that is, F for the F-basis, and G for the G-basis). In other words, writing permutations in one-line notation, we have

$$\psi(F_{(u_1,u_2,\ldots,u_n)}) = F_{(n+1-u_1,n+1-u_2,\ldots,n+1-u_n)}, \qquad \psi(G_{(u_1,u_2,\ldots,u_n)}) = G_{(u_n,u_{n-1},\ldots,u_1)}.$$

If we also consider the ψ involution (`psi_involution()`) of the quasisymmetric functions (by slight abuse of notation), and if we let π be the canonical projection $FQSym \to QSym$, then $\pi \circ \psi = \psi \circ \pi$.

Additionally, consider the ω involution (`omega_involution()`) of the noncommutative symmetric functions, and if we let ι be the canonical inclusion $NSym \to FQSym$, then $\psi \circ \iota = \iota \circ \omega$.

omega_involution(), *star_involution()*

EXAMPLES:

```
sage: FQSym = algebras.FQSym(ZZ)
sage: F = FQSym.F()
sage: F[[2,3,1]].psi_involution()
F[2, 1, 3]
sage: (3*F[[1]] - 4*F[[]] + 5*F[[1,2]]).psi_involution()
-4*F[] + 3*F[1] + 5*F[2, 1]
sage: G = FQSym.G()
sage: G[[2,3,1]].psi_involution()
G[1, 3, 2]
sage: M = FQSym.M()
sage: M[[2,3,1]].psi_involution()
-M[1, 2, 3] - M[1, 3, 2] - M[2, 3, 1]
```

```
>>> from sage.all import *
>>> FQSym = algebras.FQSym(ZZ)
>>> F = FQSym.F()
>>> F[[Integer(2),Integer(3),Integer(1)]].psi_involution()
F[2, 1, 3]
>>> (Integer(3)*F[[Integer(1)]] - Integer(4)*F[[]] +␣
↪Integer(5)*F[[Integer(1),Integer(2)]]).psi_involution()
-4*F[] + 3*F[1] + 5*F[2, 1]
>>> G = FQSym.G()
>>> G[[Integer(2),Integer(3),Integer(1)]].psi_involution()
G[1, 3, 2]
>>> M = FQSym.M()
>>> M[[Integer(2),Integer(3),Integer(1)]].psi_involution()
-M[1, 2, 3] - M[1, 3, 2] - M[2, 3, 1]
```

The ψ involution intertwines the antipode and the inverse of the antipode:

```
sage: all( F(I).antipode().psi_involution().antipode()
....:      == F(I).psi_involution()
....:      for I in Permutations(4) )
True
```

```
>>> from sage.all import *
>>> all( F(I).antipode().psi_involution().antipode()
...      == F(I).psi_involution()
...      for I in Permutations(Integer(4)) )
True
```

Testing the $\pi \circ \psi = \psi \circ \pi$ relation above:

```
sage: all( M[I].psi_involution().to_qsym()
....:      == M[I].to_qsym().psi_involution()
....:      for I in Permutations(4) )
True
```

```
>>> from sage.all import *
>>> all( M[I].psi_involution().to_qsym()
...      == M[I].to_qsym().psi_involution()
...      for I in Permutations(Integer(4)) )
True
```

Testing the $\psi \circ \iota = \iota \circ \omega$ relation:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: all( S[I].omega_involution().to_fqsym() == S[I].to_fqsym().psi_
↪involution()
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> S = NSym.S()
>>> all( S[I].omega_involution().to_fqsym() == S[I].to_fqsym().psi_
↪involution()
...      for I in Compositions(Integer(4)) )
True
```

Todo

Check further commutative squares.

star_involution()

Return the image of the element `self` of $FQSym$ under the star involution.

The star involution is defined as the linear map $FQSym \to FQSym$ that sends each basis element F_u of the F-basis of $FQSym$ to the basis element $F_{w_0 \circ u \circ w_0}$, where w_0 is the longest word (i.e., $w_0(i) = n + 1 - i$) in the symmetric group S_n that contains u. The star involution is a graded Hopf algebra anti-automorphism of $FQSym$. It is denoted by $f \mapsto f^*$. Every permutation $u \in S_n$ satisfies

$$(F_u)^* = F_{w_0 \circ u \circ w_0}, \qquad (G_u)^* = G_{w_0 \circ u \circ w_0}, \qquad (\mathcal{M}_u)^* = \mathcal{M}_{w_0 \circ u \circ w_0},$$

where standard notations for classical bases of $FQSym$ are being used (that is, F for the F-basis, G for the G-basis, and $\mathcal{M}$ for the Monomial basis). In other words, writing permutations in one-line notation, we have

$$(F_{(u_1,u_2,\ldots,u_n)})^* = F_{(n+1-u_n,n+1-u_{n-1},\ldots,n+1-u_1)}, \qquad (G_{(u_1,u_2,\ldots,u_n)})^* = G_{(n+1-u_n,n+1-u_{n-1},\ldots,n+1-u_1)},$$

and

$$(\mathcal{M}_{(u_1,u_2,\ldots,u_n)})^* = \mathcal{M}_{(n+1-u_n,n+1-u_{n-1},\ldots,n+1-u_1)}.$$

Let us denote the star involution by $(*)$ as well.

If we also denote by $(*)$ the star involution of of the quasisymmetric functions (*star_involution()*) and if we let $\pi : FQSym \to QSym$ be the canonical projection then $\pi \circ (*) = (*) \circ \pi$. Similar for the noncommutative symmetric functions (*star_involution()*) with $\pi : NSym \to FQSym$ being the canonical inclusion and the word quasisymmetric functions (`star_involution()`) with $\pi : FQSym \to WQSym$ the canonical inclusion.

Todo

Duality?

See also

omega_involution(), *psi_involution()*

EXAMPLES:

```
sage: FQSym = algebras.FQSym(ZZ)
sage: F = FQSym.F()
sage: F[[2,3,1]].star_involution()
F[3, 1, 2]
sage: (3*F[[1]] - 4*F[[]] + 5*F[[1,2]]).star_involution()
-4*F[] + 3*F[1] + 5*F[1, 2]
sage: G = FQSym.G()
sage: G[[2,3,1]].star_involution()
G[3, 1, 2]
sage: M = FQSym.M()
sage: M[[2,3,1]].star_involution()
M[3, 1, 2]
```

```
>>> from sage.all import *
>>> FQSym = algebras.FQSym(ZZ)
>>> F = FQSym.F()
>>> F[[Integer(2),Integer(3),Integer(1)]].star_involution()
F[3, 1, 2]
>>> (Integer(3)*F[[Integer(1)]] - Integer(4)*F[[]] +␣
↪Integer(5)*F[[Integer(1),Integer(2)]]).star_involution()
-4*F[] + 3*F[1] + 5*F[1, 2]
>>> G = FQSym.G()
>>> G[[Integer(2),Integer(3),Integer(1)]].star_involution()
G[3, 1, 2]
>>> M = FQSym.M()
>>> M[[Integer(2),Integer(3),Integer(1)]].star_involution()
M[3, 1, 2]
```

The star involution commutes with the antipode:

```
sage: all( F(I).antipode().star_involution()
....:      == F(I).star_involution().antipode()
....:      for I in Permutations(4) )
True
```

```
>>> from sage.all import *
>>> all( F(I).antipode().star_involution()
...      == F(I).star_involution().antipode()
...      for I in Permutations(Integer(4)) )
True
```

Testing the $\pi \circ (*) = (*) \circ \pi$ relation:

```
sage: all( M[I].star_involution().to_qsym()
....:      == M[I].to_qsym().star_involution()
....:      for I in Permutations(4) )
True
```

```
>>> from sage.all import *
>>> all( M[I].star_involution().to_qsym()
...      == M[I].to_qsym().star_involution()
...      for I in Permutations(Integer(4)) )
True
```

Similar for $NSym$:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: all( S[I].star_involution().to_fqsym() == S[I].to_fqsym().star_
↪involution()
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> S = NSym.S()
>>> all( S[I].star_involution().to_fqsym() == S[I].to_fqsym().star_
↪involution()
...      for I in Compositions(Integer(4)) )
True
```

Similar for $WQSym$:

```
sage: WQSym = algebras.WQSym(ZZ)
sage: all( F(I).to_wqsym().star_involution()
....:      == F(I).star_involution().to_wqsym()
....:      for I in Permutations(4) )
True
```

```
>>> from sage.all import *
>>> WQSym = algebras.WQSym(ZZ)
>>> all( F(I).to_wqsym().star_involution()
...      == F(I).star_involution().to_wqsym()
...      for I in Permutations(Integer(4)) )
True
```

Todo

Check further commutative squares.

to_qsym()

Return the image of `self` under the canonical projection $FQSym \to QSym$.

The canonical projection $FQSym \to QSym$ is a surjective homomorphism of Hopf algebras. It sends a basis element F_w of $FQSym$ to the basis element $F_{\operatorname{Comp} w}$ of the fundamental basis of $QSym$, where Comp w stands for the descent composition (`sage.combinat.permutation.Permutation.descents_composition()`) of the permutation w.

See also

`QuasiSymmetricFunctions` for a definition of $QSym$.

EXAMPLES:

```
sage: G = algebras.FQSym(QQ).G()
sage: x = G[1, 3, 2]
sage: x.to_qsym()
F[2, 1]
sage: G[2, 3, 1].to_qsym()
F[1, 2]
sage: F = algebras.FQSym(QQ).F()
sage: F[2, 3, 1].to_qsym()
F[2, 1]
sage: (F[2, 3, 1] + F[1, 3, 2] + F[1, 2, 3]).to_qsym()
2*F[2, 1] + F[3]
sage: F2 = algebras.FQSym(GF(2)).F()
sage: F2[2, 3, 1].to_qsym()
F[2, 1]
sage: (F2[2, 3, 1] + F2[1, 3, 2] + F2[1, 2, 3]).to_qsym()
F[3]
```

```
>>> from sage.all import *
>>> G = algebras.FQSym(QQ).G()
>>> x = G[Integer(1), Integer(3), Integer(2)]
>>> x.to_qsym()
F[2, 1]
>>> G[Integer(2), Integer(3), Integer(1)].to_qsym()
F[1, 2]
>>> F = algebras.FQSym(QQ).F()
>>> F[Integer(2), Integer(3), Integer(1)].to_qsym()
F[2, 1]
>>> (F[Integer(2), Integer(3), Integer(1)] + F[Integer(1), Integer(3),␣
↪Integer(2)] + F[Integer(1), Integer(2), Integer(3)]).to_qsym()
2*F[2, 1] + F[3]
>>> F2 = algebras.FQSym(GF(Integer(2))).F()
>>> F2[Integer(2), Integer(3), Integer(1)].to_qsym()
F[2, 1]
>>> (F2[Integer(2), Integer(3), Integer(1)] + F2[Integer(1), Integer(3),␣
↪Integer(2)] + F2[Integer(1), Integer(2), Integer(3)]).to_qsym()
F[3]
```

to_symmetric_group_algebra(*n=None*)

Return the element of a symmetric group algebra corresponding to the element `self` of $FQSym$.

INPUT:

- `n` – integer (default: the maximal degree of `self`); the rank of the target symmetric group algebra

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).G()
sage: x = A([1,3,2,4]) + 5/2 * A([2,3,4,1])
sage: x.to_symmetric_group_algebra()
[1, 3, 2, 4] + 5/2*[4, 1, 2, 3]
```

```
>>> from sage.all import *
>>> A = algebras.FQSym(QQ).G()
>>> x = A([Integer(1),Integer(3),Integer(2),Integer(4)]) + Integer(5)/
↪Integer(2) * A([Integer(2),Integer(3),Integer(4),Integer(1)])
>>> x.to_symmetric_group_algebra()
[1, 3, 2, 4] + 5/2*[4, 1, 2, 3]
```

to_wqsym()

Return the image of `self` under the canonical inclusion map $FQSym \to WQSym$.

The canonical inclusion map $FQSym \to WQSym$ is an injective homomorphism of Hopf algebras. It sends a basis element G_w of $FQSym$ to the sum of basis elements $\mathbf{M}_u$ of $WQSym$, where u ranges over all packed words whose standardization is w.

See also

WordQuasiSymmetricFunctions for a definition of $WQSym$.

EXAMPLES:

```
sage: G = algebras.FQSym(QQ).G()
sage: x = G[1, 3, 2]
sage: x.to_wqsym()
M[{1}, {3}, {2}] + M[{1, 3}, {2}]
sage: G[1, 2].to_wqsym()
M[{1}, {2}] + M[{1, 2}]
sage: F = algebras.FQSym(QQ).F()
sage: F[3, 1, 2].to_wqsym()
M[{3}, {1}, {2}] + M[{3}, {1, 2}]
sage: G[2, 3, 1].to_wqsym()
M[{3}, {1}, {2}] + M[{3}, {1, 2}]
```

```
>>> from sage.all import *
>>> G = algebras.FQSym(QQ).G()
>>> x = G[Integer(1), Integer(3), Integer(2)]
>>> x.to_wqsym()
M[{1}, {3}, {2}] + M[{1, 3}, {2}]
>>> G[Integer(1), Integer(2)].to_wqsym()
M[{1}, {2}] + M[{1, 2}]
>>> F = algebras.FQSym(QQ).F()
>>> F[Integer(3), Integer(1), Integer(2)].to_wqsym()
M[{3}, {1}, {2}] + M[{3}, {1, 2}]
>>> G[Integer(2), Integer(3), Integer(1)].to_wqsym()
M[{3}, {1}, {2}] + M[{3}, {1, 2}]
```

class ParentMethods

Bases: `object`

basis(*degree=None*)

The basis elements (optionally: of the specified degree).

OUTPUT: Family

EXAMPLES:

```
sage: FQSym = algebras.FQSym(QQ)
sage: G = FQSym.G()
sage: G.basis()
Lazy family (Term map from Standard permutations to Free Quasi-symmetric␣
↪functions over Rational Field in the G basis(i))_{i in Standard␣
↪permutations}
sage: G.basis().keys()
Standard permutations
sage: G.basis(degree=3).keys()
Standard permutations of 3
sage: G.basis(degree=3).list()
[G[1, 2, 3], G[1, 3, 2], G[2, 1, 3], G[2, 3, 1], G[3, 1, 2], G[3, 2, 1]]
```

```
>>> from sage.all import *
>>> FQSym = algebras.FQSym(QQ)
>>> G = FQSym.G()
>>> G.basis()
Lazy family (Term map from Standard permutations to Free Quasi-symmetric␣
↪functions over Rational Field in the G basis(i))_{i in Standard␣
↪permutations}
>>> G.basis().keys()
Standard permutations
>>> G.basis(degree=Integer(3)).keys()
Standard permutations of 3
>>> G.basis(degree=Integer(3)).list()
[G[1, 2, 3], G[1, 3, 2], G[2, 1, 3], G[2, 3, 1], G[3, 1, 2], G[3, 2, 1]]
```

from_symmetric_group_algebra(*x*)

Return the element of $FQSym$ corresponding to the element x of a symmetric group algebra.

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: SGA4 = SymmetricGroupAlgebra(QQ, 4)
sage: x = SGA4([1,3,2,4]) + 5/2 * SGA4([1,2,4,3])
sage: A.from_symmetric_group_algebra(x)
5/2*F[1, 2, 4, 3] + F[1, 3, 2, 4]
sage: A.from_symmetric_group_algebra(SGA4.zero())
0
```

```
>>> from sage.all import *
>>> A = algebras.FQSym(QQ).F()
>>> SGA4 = SymmetricGroupAlgebra(QQ, Integer(4))
>>> x = SGA4([Integer(1),Integer(3),Integer(2),Integer(4)]) + Integer(5)/
↪Integer(2) * SGA4([Integer(1),Integer(2),Integer(4),Integer(3)])
>>> A.from_symmetric_group_algebra(x)
5/2*F[1, 2, 4, 3] + F[1, 3, 2, 4]
```

(continues on next page)

(continued from previous page)

```
>>> A.from_symmetric_group_algebra(SGA4.zero())
0
```

is_commutative()

Return whether this $FQSym$ is commutative.

EXAMPLES:

```
sage: F = algebras.FQSym(ZZ).F()
sage: F.is_commutative()
False
```

```
>>> from sage.all import *
>>> F = algebras.FQSym(ZZ).F()
>>> F.is_commutative()
False
```

is_field(*proof=True*)

Return whether this $FQSym$ is a field.

EXAMPLES:

```
sage: F = algebras.FQSym(QQ).F()
sage: F.is_field()
False
```

```
>>> from sage.all import *
>>> F = algebras.FQSym(QQ).F()
>>> F.is_field()
False
```

one_basis()

Return the index of the unit.

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: A.one_basis()
[]
```

```
>>> from sage.all import *
>>> A = algebras.FQSym(QQ).F()
>>> A.one_basis()
[]
```

prec()

Return the $\prec$ product.

On the F-basis of `FQSym`, this product is determined by $F_x \prec F_y = \sum F_z$, where the sum ranges over all z in the shifted shuffle of x and y with the additional condition that the first letter of the result comes from x.

The usual symbol for this operation is $\prec$.

See also

product(), succ()

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: x = A([2,1])
sage: A.prec(x, x)
F[2, 1, 4, 3] + F[2, 4, 1, 3] + F[2, 4, 3, 1]
sage: y = A([2,1,3])
sage: A.prec(x, y)
F[2, 1, 4, 3, 5] + F[2, 4, 1, 3, 5] + F[2, 4, 3, 1, 5]
 + F[2, 4, 3, 5, 1]
sage: A.prec(y, x)
F[2, 1, 3, 5, 4] + F[2, 1, 5, 3, 4] + F[2, 1, 5, 4, 3]
 + F[2, 5, 1, 3, 4] + F[2, 5, 1, 4, 3] + F[2, 5, 4, 1, 3]
```

```
>>> from sage.all import *
>>> A = algebras.FQSym(QQ).F()
>>> x = A([Integer(2),Integer(1)])
>>> A.prec(x, x)
F[2, 1, 4, 3] + F[2, 4, 1, 3] + F[2, 4, 3, 1]
>>> y = A([Integer(2),Integer(1),Integer(3)])
>>> A.prec(x, y)
F[2, 1, 4, 3, 5] + F[2, 4, 1, 3, 5] + F[2, 4, 3, 1, 5]
 + F[2, 4, 3, 5, 1]
>>> A.prec(y, x)
F[2, 1, 3, 5, 4] + F[2, 1, 5, 3, 4] + F[2, 1, 5, 4, 3]
 + F[2, 5, 1, 3, 4] + F[2, 5, 1, 4, 3] + F[2, 5, 4, 1, 3]
```

prec_by_coercion(x, y)

Return $x \prec y$, computed using coercion to the F-basis.

See *prec()* for the definition of the objects involved.

EXAMPLES:

```
sage: G = algebras.FQSym(ZZ).G()
sage: a = G([1])
sage: b = G([2, 3, 1])
sage: G.prec(a, b) + G.succ(a, b) == a * b # indirect doctest
True
```

```
>>> from sage.all import *
>>> G = algebras.FQSym(ZZ).G()
>>> a = G([Integer(1)])
>>> b = G([Integer(2), Integer(3), Integer(1)])
>>> G.prec(a, b) + G.succ(a, b) == a * b # indirect doctest
True
```

some_elements()

Return some elements of the free quasi-symmetric functions.

EXAMPLES:

```
sage: A = algebras.FQSym(QQ)
sage: F = A.F()
sage: F.some_elements()
[F[], F[1], F[1, 2] + F[2, 1], F[] + F[1, 2] + F[2, 1]]
sage: G = A.G()
sage: G.some_elements()
[G[], G[1], G[1, 2] + G[2, 1], G[] + G[1, 2] + G[2, 1]]
sage: M = A.M()
sage: M.some_elements()
[M[], M[1], M[1, 2] + 2*M[2, 1], M[] + M[1, 2] + 2*M[2, 1]]
```

```
>>> from sage.all import *
>>> A = algebras.FQSym(QQ)
>>> F = A.F()
>>> F.some_elements()
[F[], F[1], F[1, 2] + F[2, 1], F[] + F[1, 2] + F[2, 1]]
>>> G = A.G()
>>> G.some_elements()
[G[], G[1], G[1, 2] + G[2, 1], G[] + G[1, 2] + G[2, 1]]
>>> M = A.M()
>>> M.some_elements()
[M[], M[1], M[1, 2] + 2*M[2, 1], M[] + M[1, 2] + 2*M[2, 1]]
```

succ()

Return the $\succ$ product.

On the F-basis of `FQSym`, this product is determined by $F_x \succ F_y = \sum F_z$, where the sum ranges over all z in the shifted shuffle of x and y with the additional condition that the first letter of the result comes from y.

The usual symbol for this operation is $\succ$.

See also

`product()`, *prec()*

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: x = A([1])
sage: A.succ(x, x)
F[2, 1]
sage: y = A([3,1,2])
sage: A.succ(x, y)
F[4, 1, 2, 3] + F[4, 2, 1, 3] + F[4, 2, 3, 1]
sage: A.succ(y, x)
F[4, 3, 1, 2]
```

```
>>> from sage.all import *
>>> A = algebras.FQSym(QQ).F()
>>> x = A([Integer(1)])
```

(continues on next page)

(continued from previous page)

```
>>> A.succ(x, x)
F[2, 1]
>>> y = A([Integer(3),Integer(1),Integer(2)])
>>> A.succ(x, y)
F[4, 1, 2, 3] + F[4, 2, 1, 3] + F[4, 2, 3, 1]
>>> A.succ(y, x)
F[4, 3, 1, 2]
```

succ_by_coercion(*x*, *y*)

Return $x \succ y$, computed using coercion to the F-basis.

See *succ()* for the definition of the objects involved.

EXAMPLES:

```
sage: G = algebras.FQSym(ZZ).G()
sage: G.succ(G([1]), G([2, 3, 1])) # indirect doctest
G[2, 3, 4, 1] + G[3, 2, 4, 1] + G[4, 2, 3, 1]
```

```
>>> from sage.all import *
>>> G = algebras.FQSym(ZZ).G()
>>> G.succ(G([Integer(1)]), G([Integer(2), Integer(3), Integer(1)])) #␣
↪indirect doctest
G[2, 3, 4, 1] + G[3, 2, 4, 1] + G[4, 2, 3, 1]
```

super_categories()

The super categories of `self`.

EXAMPLES:

```
sage: from sage.combinat.fqsym import FQSymBases
sage: FQSym = algebras.FQSym(ZZ)
sage: bases = FQSymBases(FQSym)
sage: bases.super_categories()
[Category of realizations of Free Quasi-symmetric functions over Integer Ring,
 Join of Category of realizations of Hopf algebras over Integer Ring
   and Category of graded algebras over Integer Ring
   and Category of graded coalgebras over Integer Ring,
 Category of graded connected Hopf algebras with basis over Integer Ring]
```

```
>>> from sage.all import *
>>> from sage.combinat.fqsym import FQSymBases
>>> FQSym = algebras.FQSym(ZZ)
>>> bases = FQSymBases(FQSym)
>>> bases.super_categories()
[Category of realizations of Free Quasi-symmetric functions over Integer Ring,
 Join of Category of realizations of Hopf algebras over Integer Ring
   and Category of graded algebras over Integer Ring
   and Category of graded coalgebras over Integer Ring,
 Category of graded connected Hopf algebras with basis over Integer Ring]
```

class sage.combinat.fqsym.**FQSymBasis_abstract**(*alg*)

Bases: *CombinatorialFreeModule*, `BindableClass`

Abstract base class for bases of FQSym.

This must define two attributes:

- `_prefix` – the basis prefix
- `_basis_name` – the name of the basis and must match one of the names that the basis can be constructed from FQSym

an_element()

Return an element of `self`.

EXAMPLES:

```
sage: A = algebras.FQSym(QQ)
sage: F = A.F()
sage: F.an_element()
F[1] + 2*F[1, 2] + 2*F[2, 1]
sage: G = A.G()
sage: G.an_element()
G[1] + 2*G[1, 2] + 2*G[2, 1]
sage: M = A.M()
sage: M.an_element()
M[1] + 2*M[1, 2] + 4*M[2, 1]
```

```
>>> from sage.all import *
>>> A = algebras.FQSym(QQ)
>>> F = A.F()
>>> F.an_element()
F[1] + 2*F[1, 2] + 2*F[2, 1]
>>> G = A.G()
>>> G.an_element()
G[1] + 2*G[1, 2] + 2*G[2, 1]
>>> M = A.M()
>>> M.an_element()
M[1] + 2*M[1, 2] + 4*M[2, 1]
```

class sage.combinat.fqsym.**FreeQuasisymmetricFunctions**(*R*)

Bases: `UniqueRepresentation`, `Parent`

The free quasi-symmetric functions.

The Hopf algebra $FQSym$ of free quasi-symmetric functions over a commutative ring R is the free R-module with basis indexed by all permutations (i.e., the indexing set is the disjoint union of all symmetric groups). Its product is determined by the shifted shuffles of two permutations, whereas its coproduct is given by splitting a permutation (regarded as a word) into two (at every possible point) and standardizing the two pieces. This Hopf algebra was introduced in [MR]. See [GriRei18] (Chapter 8) for a treatment using modern notations.

In more detail: For each $n \geq 0$, consider the symmetric group S_n. Let S be the disjoint union of the S_n over all $n \geq 0$. Then, $FQSym$ is the free R-module with basis $(F_w)_{w \in S}$. This R-module is graded, with the n-th graded component being spanned by all F_w for $w \in S_n$. A multiplication is defined on $FQSym$ as follows: For any two permutations $u \in S_k$ and $v \in S_l$, we set

$$F_u F_v = \sum F_w,$$

where the sum is over all shuffles of u with $v[k]$. Here, the permutations u and v are regarded as words (by writing them in one-line notation), and $v[k]$ means the word obtained from v by increasing each letter by k (for example,

$(1, 4, 2, 3)[5] = (6, 9, 7, 8)$); and the shuffles w are translated back into permutations. This defines an associative multiplication on $FQSym$; its unity is F_e, where e is the identity permutation in S_0.

In Section 1.3 of [AguSot05], Aguiar and Sottile construct a different basis of $FQSym$. Their basis, called the *monomial basis* and denoted by $(\mathcal{M}_u)$, is also indexed by permutations. It is connected to the above F-basis by the relation

$$F_u = \sum_v \mathcal{M}_v,$$

where the sum ranges over all permutations v such that each inversion of u is an inversion of v. (An *inversion* of a permutation w means a pair (i, j) of positions satisfying $i < j$ and $w(i) > w(j)$.) The above relation yields a unitriangular change-of-basis matrix, and thus can be used to compute the $\mathcal{M}_u$ by Mobius inversion.

Another classical basis of $FQSym$ is $(G_w)_{w\in S}$, where $G_w = F_{w^{-1}}$. This is just a relabeling of the basis $(F_w)_{w\in S}$, but is a more natural choice from some viewpoints.

The algebra $FQSym$ is often identified with ("realized as") a subring of the ring of all bounded-degree noncommutative power series in countably many indeterminates (i.e., elements in $R\langle\langle x_1, x_2, x_3, \ldots\rangle\rangle$ of bounded degree). Namely, consider words over the alphabet $\{1, 2, 3, \ldots\}$; every noncommutative power series is an infinite R-linear combination of these words. Consider the R-linear map that sends each G_u to the sum of all words whose standardization (also known as "standard permutation"; see `standard_permutation()`) is u. This map is an injective R-algebra homomorphism, and thus embeds $FQSym$ into the latter ring.

As an associative algebra, $FQSym$ has the richer structure of a dendriform algebra. This means that the associative product $*$ is decomposed as a sum of two binary operations

$$xy = x \succ y + x \prec y$$

that satisfy the axioms:

$$(x \succ y) \prec z = x \succ (y \prec z),$$

$$(x \prec y) \prec z = x \prec (yz),$$

$$(xy) \succ z = x \succ (y \succ z).$$

These two binary operations are defined similarly to the (associative) product above: We set

$$F_u \prec F_v = \sum F_w,$$

where the sum is now over all shuffles of u with $v[k]$ whose first letter is taken from u (rather than from $v[k]$). Similarly,

$$F_u \succ F_v = \sum F_w,$$

where the sum is over all remaining shuffles of u with $v[k]$.

Todo

Decide what $1 \prec 1$ and $1 \succ 1$ are.

Note

The usual binary operator `*` is used for the associative product.

EXAMPLES:

```
sage: F = algebras.FQSym(ZZ).F()
sage: x,y,z = F([1]), F([1,2]), F([1,3,2])
sage: (x * y) * z
F[1, 2, 3, 4, 6, 5] + ...
```

```
>>> from sage.all import *
>>> F = algebras.FQSym(ZZ).F()
>>> x,y,z = F([Integer(1)]), F([Integer(1),Integer(2)]), F([Integer(1),Integer(3),
↪Integer(2)])
>>> (x * y) * z
F[1, 2, 3, 4, 6, 5] + ...
```

The product of $FQSym$ is associative:

```
sage: x * (y * z) == (x * y) * z
True
```

```
>>> from sage.all import *
>>> x * (y * z) == (x * y) * z
True
```

The associative product decomposes into two parts:

```
sage: x * y == F.prec(x, y) + F.succ(x, y)
True
```

```
>>> from sage.all import *
>>> x * y == F.prec(x, y) + F.succ(x, y)
True
```

The axioms of a dendriform algebra hold:

```
sage: F.prec(F.succ(x, y), z) == F.succ(x, F.prec(y, z))
True
sage: F.prec(F.prec(x, y), z) == F.prec(x, y * z)
True
sage: F.succ(x * y, z) == F.succ(x, F.succ(y, z))
True
```

```
>>> from sage.all import *
>>> F.prec(F.succ(x, y), z) == F.succ(x, F.prec(y, z))
True
>>> F.prec(F.prec(x, y), z) == F.prec(x, y * z)
True
>>> F.succ(x * y, z) == F.succ(x, F.succ(y, z))
True
```

$FQSym$ is also known as the Malvenuto-Reutenauer algebra:

```
sage: algebras.MalvenutoReutenauer(ZZ)
Free Quasi-symmetric functions over Integer Ring
```

```
>>> from sage.all import *
>>> algebras.MalvenutoReutenauer(ZZ)
Free Quasi-symmetric functions over Integer Ring
```

REFERENCES:

- [MR]
- [LR1998]
- [GriRei18]

class F(*alg*)

Bases: `FQSymBasis_abstract`

The F-basis of $FQSym$.

This is the basis (F_w), with w ranging over all permutations. See the documentation of `FreeQuasisymmetricFunctions` for details.

EXAMPLES:

```
sage: FQSym = algebras.FQSym(QQ)
sage: FQSym.F()
Free Quasi-symmetric functions over Rational Field in the F basis
```

```
>>> from sage.all import *
>>> FQSym = algebras.FQSym(QQ)
>>> FQSym.F()
Free Quasi-symmetric functions over Rational Field in the F basis
```

class Element

Bases: `IndexedFreeModuleElement`

to_symmetric_group_algebra(*n=None*)

Return the element of a symmetric group algebra corresponding to the element `self` of $FQSym$.

INPUT:

- `n` – integer (default: the maximal degree of `self`); the rank of the target symmetric group algebra

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: x = A([1,3,2,4]) + 5/2 * A([1,2,4,3])
sage: x.to_symmetric_group_algebra()
5/2*[1, 2, 4, 3] + [1, 3, 2, 4]
sage: x.to_symmetric_group_algebra(n=7)
5/2*[1, 2, 4, 3, 5, 6, 7] + [1, 3, 2, 4, 5, 6, 7]
sage: a = A.zero().to_symmetric_group_algebra(); a
0
sage: parent(a)
Symmetric group algebra of order 0 over Rational Field

sage: y = A([1,3,2,4]) + 5/2 * A([2,1])
sage: y.to_symmetric_group_algebra()
[1, 3, 2, 4] + 5/2*[2, 1, 3, 4]
sage: y.to_symmetric_group_algebra(6)
[1, 3, 2, 4, 5, 6] + 5/2*[2, 1, 3, 4, 5, 6]
```

```
>>> from sage.all import *
>>> A = algebras.FQSym(QQ).F()
>>> x = A([Integer(1),Integer(3),Integer(2),Integer(4)]) + Integer(5)/
↪Integer(2) * A([Integer(1),Integer(2),Integer(4),Integer(3)])
>>> x.to_symmetric_group_algebra()
5/2*[1, 2, 4, 3] + [1, 3, 2, 4]
>>> x.to_symmetric_group_algebra(n=Integer(7))
5/2*[1, 2, 4, 3, 5, 6, 7] + [1, 3, 2, 4, 5, 6, 7]
>>> a = A.zero().to_symmetric_group_algebra(); a
0
>>> parent(a)
Symmetric group algebra of order 0 over Rational Field

>>> y = A([Integer(1),Integer(3),Integer(2),Integer(4)]) + Integer(5)/
↪Integer(2) * A([Integer(2),Integer(1)])
>>> y.to_symmetric_group_algebra()
[1, 3, 2, 4] + 5/2*[2, 1, 3, 4]
>>> y.to_symmetric_group_algebra(Integer(6))
[1, 3, 2, 4, 5, 6] + 5/2*[2, 1, 3, 4, 5, 6]
```

coproduct_on_basis(*x*)

Return the coproduct of F_σ for σ a permutation (here, σ is x).

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: x = A([1])
sage: ascii_art(A.coproduct(A.one()))  # indirect doctest
1 # 1

sage: ascii_art(A.coproduct(x))  # indirect doctest
1 # F    + F    # 1
     [1]    [1]

sage: A = algebras.FQSym(QQ).F()
sage: x, y, z = A([1]), A([2,1]), A([3,2,1])
sage: A.coproduct(z)
F[] # F[3, 2, 1] + F[1] # F[2, 1] + F[2, 1] # F[1]
+ F[3, 2, 1] # F[]
```

```
>>> from sage.all import *
>>> A = algebras.FQSym(QQ).F()
>>> x = A([Integer(1)])
>>> ascii_art(A.coproduct(A.one()))  # indirect doctest
1 # 1

>>> ascii_art(A.coproduct(x))  # indirect doctest
1 # F    + F    # 1
     [1]    [1]

>>> A = algebras.FQSym(QQ).F()
>>> x, y, z = A([Integer(1)]), A([Integer(2),Integer(1)]), A([Integer(3),
↪Integer(2),Integer(1)])
```

(continues on next page)

(continued from previous page)

```
>>> A.coproduct(z)
F[] # F[3, 2, 1] + F[1] # F[2, 1] + F[2, 1] # F[1]
+ F[3, 2, 1] # F[]
```

degree_on_basis(*t*)

Return the degree of a permutation in the algebra of free quasi-symmetric functions.

This is the size of the permutation (i.e., the n for which the permutation belongs to S_n).

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: u = Permutation([2,1])
sage: A.degree_on_basis(u)
2
```

```
>>> from sage.all import *
>>> A = algebras.FQSym(QQ).F()
>>> u = Permutation([Integer(2),Integer(1)])
>>> A.degree_on_basis(u)
2
```

prec_product_on_basis(*x*, *y*)

Return the $\prec$ product of two permutations.

This is the shifted shuffle of x and y with the additional condition that the first letter of the result comes from x.

The usual symbol for this operation is $\prec$.

See also

product_on_basis(), *succ_product_on_basis()*

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: x = Permutation([1,2])
sage: A.prec_product_on_basis(x, x)
F[1, 2, 3, 4] + F[1, 3, 2, 4] + F[1, 3, 4, 2]
sage: y = Permutation([])
sage: A.prec_product_on_basis(x, y) == A(x)
True
sage: A.prec_product_on_basis(y, x) == 0
True
```

```
>>> from sage.all import *
>>> A = algebras.FQSym(QQ).F()
>>> x = Permutation([Integer(1),Integer(2)])
>>> A.prec_product_on_basis(x, x)
F[1, 2, 3, 4] + F[1, 3, 2, 4] + F[1, 3, 4, 2]
>>> y = Permutation([])
```

(continues on next page)

(continued from previous page)

```
>>> A.prec_product_on_basis(x, y) == A(x)
True
>>> A.prec_product_on_basis(y, x) == Integer(0)
True
```

product_on_basis(*x*, *y*)

Return the $*$ associative product of two permutations.

This is the shifted shuffle of x and y.

See also

succ_product_on_basis(), *prec_product_on_basis()*

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: x = Permutation([1])
sage: A.product_on_basis(x, x)
F[1, 2] + F[2, 1]
```

```
>>> from sage.all import *
>>> A = algebras.FQSym(QQ).F()
>>> x = Permutation([Integer(1)])
>>> A.product_on_basis(x, x)
F[1, 2] + F[2, 1]
```

succ_product_on_basis(*x*, *y*)

Return the $\succ$ product of two permutations.

This is the shifted shuffle of x and y with the additional condition that the first letter of the result comes from y.

The usual symbol for this operation is $\succ$.

See also

- *product_on_basis()*, *prec_product_on_basis()*

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: x = Permutation([1,2])
sage: A.succ_product_on_basis(x, x)
F[3, 1, 2, 4] + F[3, 1, 4, 2] + F[3, 4, 1, 2]
sage: y = Permutation([])
sage: A.succ_product_on_basis(x, y) == 0
True
sage: A.succ_product_on_basis(y, x) == A(x)
True
```

```
>>> from sage.all import *
>>> A = algebras.FQSym(QQ).F()
>>> x = Permutation([Integer(1),Integer(2)])
>>> A.succ_product_on_basis(x, x)
F[3, 1, 2, 4] + F[3, 1, 4, 2] + F[3, 4, 1, 2]
>>> y = Permutation([])
>>> A.succ_product_on_basis(x, y) == Integer(0)
True
>>> A.succ_product_on_basis(y, x) == A(x)
True
```

class G(*alg*)

Bases: *FQSymBasis_abstract*

The G-basis of $FQSym$.

This is the basis (G_w), with w ranging over all permutations. See the documentation of *FreeQuasisymmetricFunctions* for details.

EXAMPLES:

```
sage: FQSym = algebras.FQSym(QQ)
sage: G = FQSym.G(); G
Free Quasi-symmetric functions over Rational Field in the G basis

sage: G([3, 1, 2]).coproduct()
G[] # G[3, 1, 2] + G[1] # G[2, 1] + G[1, 2] # G[1]
 + G[3, 1, 2] # G[]

sage: G([3, 1, 2]) * G([2, 1])
G[3, 1, 2, 5, 4] + G[4, 1, 2, 5, 3] + G[4, 1, 3, 5, 2]
 + G[4, 2, 3, 5, 1] + G[5, 1, 2, 4, 3] + G[5, 1, 3, 4, 2]
 + G[5, 1, 4, 3, 2] + G[5, 2, 3, 4, 1] + G[5, 2, 4, 3, 1]
 + G[5, 3, 4, 2, 1]
```

```
>>> from sage.all import *
>>> FQSym = algebras.FQSym(QQ)
>>> G = FQSym.G(); G
Free Quasi-symmetric functions over Rational Field in the G basis

>>> G([Integer(3), Integer(1), Integer(2)]).coproduct()
G[] # G[3, 1, 2] + G[1] # G[2, 1] + G[1, 2] # G[1]
 + G[3, 1, 2] # G[]

>>> G([Integer(3), Integer(1), Integer(2)]) * G([Integer(2), Integer(1)])
G[3, 1, 2, 5, 4] + G[4, 1, 2, 5, 3] + G[4, 1, 3, 5, 2]
 + G[4, 2, 3, 5, 1] + G[5, 1, 2, 4, 3] + G[5, 1, 3, 4, 2]
 + G[5, 1, 4, 3, 2] + G[5, 2, 3, 4, 1] + G[5, 2, 4, 3, 1]
 + G[5, 3, 4, 2, 1]
```

degree_on_basis(*t*)

Return the degree of a permutation in the algebra of free quasi-symmetric functions.

This is the size of the permutation (i.e., the n for which the permutation belongs to S_n).

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).G()
sage: u = Permutation([2,1])
sage: A.degree_on_basis(u)
2
```

```
>>> from sage.all import *
>>> A = algebras.FQSym(QQ).G()
>>> u = Permutation([Integer(2),Integer(1)])
>>> A.degree_on_basis(u)
2
```

class M(*alg*)

Bases: *FQSymBasis_abstract*

The M-basis of $FQSym$.

This is the Monomial basis $(\mathcal{M}_w)$, with w ranging over all permutations. See the documentation of `FQSym` for details.

EXAMPLES:

```
sage: FQSym = algebras.FQSym(QQ)
sage: M = FQSym.M(); M
Free Quasi-symmetric functions over Rational Field in the Monomial basis

sage: M([3, 1, 2]).coproduct()
M[] # M[3, 1, 2] + M[1] # M[1, 2] + M[3, 1, 2] # M[]
sage: M([3, 2, 1]).coproduct()
M[] # M[3, 2, 1] + M[1] # M[2, 1] + M[2, 1] # M[1]
 + M[3, 2, 1] # M[]

sage: M([1, 2]) * M([1])
M[1, 2, 3] + 2*M[1, 3, 2] + M[2, 3, 1] + M[3, 1, 2]
```

```
>>> from sage.all import *
>>> FQSym = algebras.FQSym(QQ)
>>> M = FQSym.M(); M
Free Quasi-symmetric functions over Rational Field in the Monomial basis

>>> M([Integer(3), Integer(1), Integer(2)]).coproduct()
M[] # M[3, 1, 2] + M[1] # M[1, 2] + M[3, 1, 2] # M[]
>>> M([Integer(3), Integer(2), Integer(1)]).coproduct()
M[] # M[3, 2, 1] + M[1] # M[2, 1] + M[2, 1] # M[1]
 + M[3, 2, 1] # M[]

>>> M([Integer(1), Integer(2)]) * M([Integer(1)])
M[1, 2, 3] + 2*M[1, 3, 2] + M[2, 3, 1] + M[3, 1, 2]
```

class Element

Bases: `IndexedFreeModuleElement`

star_involution()

Return the image of the element `self` of $FQSym$ under the star involution.

See `FQSymBases.ElementMethods.star_involution()` for a definition of the involution and for examples.

See also:

`omega_involution()`, `psi_involution()`

EXAMPLES:

```
sage: FQSym = algebras.FQSym(ZZ)
sage: M = FQSym.M()
sage: M[[2,3,1]].star_involution()
M[3, 1, 2]
sage: M[[]].star_involution()
M[]
```

```
>>> from sage.all import *
>>> FQSym = algebras.FQSym(ZZ)
>>> M = FQSym.M()
>>> M[[Integer(2),Integer(3),Integer(1)]].star_involution()
M[3, 1, 2]
>>> M[[]].star_involution()
M[]
```

coproduct_on_basis(*x*)

Return the coproduct of $\mathcal{M}_\sigma$ for σ a permutation (here, σ is `x`).

This uses Theorem 3.1 in [AguSot05].

EXAMPLES:

```
sage: M = algebras.FQSym(QQ).M()
sage: x = M([1])
sage: ascii_art(M.coproduct(M.one()))  # indirect doctest
1 # 1

sage: ascii_art(M.coproduct(x))  # indirect doctest
1 # M    + M    # 1
     [1]    [1]

sage: M.coproduct(M([2, 1, 3]))
M[] # M[2, 1, 3] + M[2, 1, 3] # M[]
sage: M.coproduct(M([2, 3, 1]))
M[] # M[2, 3, 1] + M[1, 2] # M[1] + M[2, 3, 1] # M[]
sage: M.coproduct(M([3, 2, 1]))
M[] # M[3, 2, 1] + M[1] # M[2, 1] + M[2, 1] # M[1]
+ M[3, 2, 1] # M[]
sage: M.coproduct(M([3, 4, 2, 1]))
M[] # M[3, 4, 2, 1] + M[1, 2] # M[2, 1] + M[2, 3, 1] # M[1]
 + M[3, 4, 2, 1] # M[]
sage: M.coproduct(M([3, 4, 1, 2]))
M[] # M[3, 4, 1, 2] + M[1, 2] # M[1, 2] + M[3, 4, 1, 2] # M[]
```

```
>>> from sage.all import *
>>> M = algebras.FQSym(QQ).M()
>>> x = M([Integer(1)])
>>> ascii_art(M.coproduct(M.one()))  # indirect doctest
1 # 1

>>> ascii_art(M.coproduct(x))  # indirect doctest
1 # M    + M    # 1
     [1]    [1]

>>> M.coproduct(M([Integer(2), Integer(1), Integer(3)]))
M[] # M[2, 1, 3] + M[2, 1, 3] # M[]
>>> M.coproduct(M([Integer(2), Integer(3), Integer(1)]))
M[] # M[2, 3, 1] + M[1, 2] # M[1] + M[2, 3, 1] # M[]
>>> M.coproduct(M([Integer(3), Integer(2), Integer(1)]))
M[] # M[3, 2, 1] + M[1] # M[2, 1] + M[2, 1] # M[1]
+ M[3, 2, 1] # M[]
>>> M.coproduct(M([Integer(3), Integer(4), Integer(2), Integer(1)]))
M[] # M[3, 4, 2, 1] + M[1, 2] # M[2, 1] + M[2, 3, 1] # M[1]
 + M[3, 4, 2, 1] # M[]
>>> M.coproduct(M([Integer(3), Integer(4), Integer(1), Integer(2)]))
M[] # M[3, 4, 1, 2] + M[1, 2] # M[1, 2] + M[3, 4, 1, 2] # M[]
```

degree_on_basis(*t*)

Return the degree of a permutation in the algebra of free quasi-symmetric functions.

This is the size of the permutation (i.e., the n for which the permutation belongs to S_n).

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).M()
sage: u = Permutation([2,1])
sage: A.degree_on_basis(u)
2
```

```
>>> from sage.all import *
>>> A = algebras.FQSym(QQ).M()
>>> u = Permutation([Integer(2),Integer(1)])
>>> A.degree_on_basis(u)
2
```

a_realization()

Return a particular realization of `self` (the F-basis).

EXAMPLES:

```
sage: FQSym = algebras.FQSym(QQ)
sage: FQSym.a_realization()
Free Quasi-symmetric functions over Rational Field in the F basis
```

```
>>> from sage.all import *
>>> FQSym = algebras.FQSym(QQ)
>>> FQSym.a_realization()
Free Quasi-symmetric functions over Rational Field in the F basis
```

5.1.111 Free modules

class sage.combinat.free_module.**CartesianProductWithFlattening**(*flatten*)

Bases: object

A class for Cartesian product constructor, with partial flattening

class sage.combinat.free_module.**CombinatorialFreeModule**(*R*, *basis_keys=None*, *element_class=None*, *category=None*, *prefix=None*, *names=None*, ***kwds*)

Bases: UniqueRepresentation, Module, IndexedGenerators

Class for free modules with a named basis.

INPUT:

- R – base ring
- basis_keys – list; tuple, family, set, etc. defining the indexing set for the basis of this module
- element_class – the class of which elements of this module should be instances (default: None, in which case the elements are instances of IndexedFreeModuleElement)
- category – the category in which this module lies (optional, default None, in which case use the "category of modules with basis" over the base ring R); this should be a subcategory of ModulesWithBasis

For the options controlling the printing of elements, see IndexedGenerators.

Note: These print options may also be accessed and modified using the print_options() method, after the module has been defined.

EXAMPLES:

We construct a free module whose basis is indexed by the letters a, b, c:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: F
Free module generated by {'a', 'b', 'c'} over Rational Field
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ, ['a','b','c'])
>>> F
Free module generated by {'a', 'b', 'c'} over Rational Field
```

Its basis is a family, indexed by a, b, c:

```
sage: e = F.basis()
sage: e
Finite family {'a': B['a'], 'b': B['b'], 'c': B['c']}
```

```
>>> from sage.all import *
>>> e = F.basis()
>>> e
Finite family {'a': B['a'], 'b': B['b'], 'c': B['c']}
```

```
sage: [x for x in e]
[B['a'], B['b'], B['c']]
sage: [k for k in e.keys()]
['a', 'b', 'c']
```

```
>>> from sage.all import *
>>> [x for x in e]
[B['a'], B['b'], B['c']]
>>> [k for k in e.keys()]
['a', 'b', 'c']
```

Let us construct some elements, and compute with them:

```
sage: e['a']
B['a']
sage: 2*e['a']
2*B['a']
sage: e['a'] + 3*e['b']
B['a'] + 3*B['b']
```

```
>>> from sage.all import *
>>> e['a']
B['a']
>>> Integer(2)*e['a']
2*B['a']
>>> e['a'] + Integer(3)*e['b']
B['a'] + 3*B['b']
```

Some uses of `sage.categories.commutative_additive_semigroups.CommutativeAdditiveSemigroups.ParentMethods.summation()` and *sum()*:

```
sage: F = CombinatorialFreeModule(QQ, [1,2,3,4])
sage: F.summation(F.monomial(1), F.monomial(3))
B[1] + B[3]

sage: F = CombinatorialFreeModule(QQ, [1,2,3,4])
sage: F.sum(F.monomial(i) for i in [1,2,3])
B[1] + B[2] + B[3]
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ, [Integer(1),Integer(2),Integer(3),Integer(4)])
>>> F.summation(F.monomial(Integer(1)), F.monomial(Integer(3)))
B[1] + B[3]

>>> F = CombinatorialFreeModule(QQ, [Integer(1),Integer(2),Integer(3),Integer(4)])
>>> F.sum(F.monomial(i) for i in [Integer(1),Integer(2),Integer(3)])
B[1] + B[2] + B[3]
```

Note that free modules with a given basis and parameters are unique:

```
sage: F1 = CombinatorialFreeModule(QQ, (1,2,3,4))
sage: F1 is F
True
```

```
>>> from sage.all import *
>>> F1 = CombinatorialFreeModule(QQ, (Integer(1),Integer(2),Integer(3),
↪Integer(4)))
>>> F1 is F
True
```

The identity of the constructed free module depends on the order of the basis and on the other parameters, like the prefix. Note that *CombinatorialFreeModule* is a UniqueRepresentation. Hence, two combinatorial free modules evaluate equal if and only if they are identical:

```
sage: F1 = CombinatorialFreeModule(QQ, (1,2,3,4))
sage: F1 is F
True
sage: F1 = CombinatorialFreeModule(QQ, [4,3,2,1])
sage: F1 == F
False
sage: F2 = CombinatorialFreeModule(QQ, [1,2,3,4], prefix='F')
sage: F2 == F
False
```

```
>>> from sage.all import *
>>> F1 = CombinatorialFreeModule(QQ, (Integer(1),Integer(2),Integer(3),
↪Integer(4)))
>>> F1 is F
True
>>> F1 = CombinatorialFreeModule(QQ, [Integer(4),Integer(3),Integer(2),
↪Integer(1)])
>>> F1 == F
False
>>> F2 = CombinatorialFreeModule(QQ, [Integer(1),Integer(2),Integer(3),
↪Integer(4)], prefix='F')
>>> F2 == F
False
```

Because of this, if you create a free module with certain parameters and then modify its prefix or other print options, this affects all modules which were defined using the same parameters.

```
sage: F2.print_options(prefix='x')
sage: F2.prefix()
'x'
sage: F3 = CombinatorialFreeModule(QQ, [1,2,3,4], prefix='F')
sage: F3 is F2   # F3 was defined just like F2
True
sage: F3.prefix()
'x'
sage: F4 = CombinatorialFreeModule(QQ, [1,2,3,4], prefix='F', bracket=True)
sage: F4 == F2   # F4 was NOT defined just like F2
False
sage: F4.prefix()
'F'

sage: F2.print_options(prefix='F') #reset for following doctests
```

```
>>> from sage.all import *
>>> F2.print_options(prefix='x')
>>> F2.prefix()
'x'
>>> F3 = CombinatorialFreeModule(QQ, [Integer(1),Integer(2),Integer(3),
↪Integer(4)], prefix='F')
>>> F3 is F2   # F3 was defined just like F2
True
>>> F3.prefix()
'x'
>>> F4 = CombinatorialFreeModule(QQ, [Integer(1),Integer(2),Integer(3),
↪Integer(4)], prefix='F', bracket=True)
>>> F4 == F2   # F4 was NOT defined just like F2
False
>>> F4.prefix()
'F'

>>> F2.print_options(prefix='F') #reset for following doctests
```

The constructed module is in the category of modules with basis over the base ring:

```
sage: CombinatorialFreeModule(QQ, Partitions()).category()                      #␣
↪needs sage.combinat
Category of vector spaces with basis over Rational Field
```

```
>>> from sage.all import *
>>> CombinatorialFreeModule(QQ, Partitions()).category()                      #␣
↪needs sage.combinat
Category of vector spaces with basis over Rational Field
```

If furthermore the index set is finite (i.e. in the category `Sets().Finite()`), then the module is declared as being finite dimensional:

```
sage: CombinatorialFreeModule(QQ, [1,2,3,4]).category()
Category of finite dimensional vector spaces with basis over Rational Field
sage: CombinatorialFreeModule(QQ, Partitions(3),                                #␣
↪needs sage.combinat
....:                         category=Algebras(QQ).WithBasis()).category()
Category of finite dimensional algebras with basis over Rational Field
```

```
>>> from sage.all import *
>>> CombinatorialFreeModule(QQ, [Integer(1),Integer(2),Integer(3),Integer(4)]).
↪category()
Category of finite dimensional vector spaces with basis over Rational Field
>>> CombinatorialFreeModule(QQ, Partitions(Integer(3)),                         ␣
↪     # needs sage.combinat
...                         category=Algebras(QQ).WithBasis()).category()
Category of finite dimensional algebras with basis over Rational Field
```

See `sage.categories.examples.algebras_with_basis` and `sage.categories.examples.hopf_algebras_with_basis` for illustrations of the use of the `category` keyword, and see *`sage.combinat.root_system.weight_space.WeightSpace`* for an example of the use of `element_class`.

Customizing print and LaTeX representations of elements:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b'], prefix='x')
sage: original_print_options = F.print_options()
sage: sorted(original_print_options.items())
[('bracket', None),
 ('iterate_key', False),
 ('latex_bracket', False), ('latex_names', None),
 ('latex_prefix', None), ('latex_scalar_mult', None),
 ('names', None), ('prefix', 'x'),
 ('scalar_mult', '*'),
 ('sorting_key', <function ...<lambda> at ...>),
 ('sorting_reverse', False), ('string_quotes', True),
 ('tensor_symbol', None)]

sage: e = F.basis()
sage: e['a'] - 3 * e['b']
x['a'] - 3*x['b']

sage: F.print_options(prefix='x', scalar_mult=' ', bracket='{')
sage: e['a'] - 3 * e['b']
x{'a'} - 3 x{'b'}
sage: latex(e['a'] - 3 * e['b'])
x_{a} - 3 x_{b}

sage: F.print_options(latex_prefix='y')
sage: latex(e['a'] - 3 * e['b'])
y_{a} - 3  y_{b}

sage: F.print_options(sorting_reverse=True)
sage: e['a'] - 3 * e['b']
-3 x{'b'} + x{'a'}
sage: F.print_options(**original_print_options) # reset print options

sage: F = CombinatorialFreeModule(QQ, [(1,2), (3,4)])
sage: e = F.basis()
sage: e[(1,2)] - 3 * e[(3,4)]
B[(1, 2)] - 3*B[(3, 4)]

sage: F.print_options(bracket=['_{', '}'])
sage: e[(1,2)] - 3 * e[(3,4)]
B_{(1, 2)} - 3*B_{(3, 4)}

sage: F.print_options(prefix='', bracket=False)
sage: e[(1,2)] - 3 * e[(3,4)]
(1, 2) - 3*(3, 4)
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ, ['a','b'], prefix='x')
>>> original_print_options = F.print_options()
>>> sorted(original_print_options.items())
[('bracket', None),
 ('iterate_key', False),
 ('latex_bracket', False), ('latex_names', None),
```

(continues on next page)

(continued from previous page)

```
 ('latex_prefix', None), ('latex_scalar_mult', None),
 ('names', None), ('prefix', 'x'),
 ('scalar_mult', '*'),
 ('sorting_key', <function ...<lambda> at ...>),
 ('sorting_reverse', False), ('string_quotes', True),
 ('tensor_symbol', None)]

>>> e = F.basis()
>>> e['a'] - Integer(3) * e['b']
x['a'] - 3*x['b']

>>> F.print_options(prefix='x', scalar_mult=' ', bracket='{')
>>> e['a'] - Integer(3) * e['b']
x{'a'} - 3 x{'b'}
>>> latex(e['a'] - Integer(3) * e['b'])
x_{a} - 3 x_{b}

>>> F.print_options(latex_prefix='y')
>>> latex(e['a'] - Integer(3) * e['b'])
y_{a} - 3  y_{b}

>>> F.print_options(sorting_reverse=True)
>>> e['a'] - Integer(3) * e['b']
-3 x{'b'} + x{'a'}
>>> F.print_options(**original_print_options) # reset print options

>>> F = CombinatorialFreeModule(QQ, [(Integer(1),Integer(2)), (Integer(3),
↪Integer(4))])
>>> e = F.basis()
>>> e[(Integer(1),Integer(2))] - Integer(3) * e[(Integer(3),Integer(4))]
B[(1, 2)] - 3*B[(3, 4)]

>>> e[(Integer(1),Integer(2))] - Integer(3) * e[(Integer(3),Integer(4))]
B_{(1, 2)} - 3*B_{(3, 4)}

>>> F.print_options(prefix='', bracket=False)
>>> e[(Integer(1),Integer(2))] - Integer(3) * e[(Integer(3),Integer(4))]
(1, 2) - 3*(3, 4)
```

CartesianProduct

alias of *CombinatorialFreeModule_CartesianProduct*

Element

alias of IndexedFreeModuleElement

Tensor

alias of *CombinatorialFreeModule_Tensor*

change_ring(R)

Return the base change of self to R.

EXAMPLES:

```
sage: F = CombinatorialFreeModule(ZZ, ['a','b','c']); F
Free module generated by {'a', 'b', 'c'} over Integer Ring
sage: F_QQ = F.change_ring(QQ); F_QQ
Free module generated by {'a', 'b', 'c'} over Rational Field
sage: F_QQ.change_ring(ZZ) == F
True

sage: T = F.tensor(F); T
Free module generated by {'a', 'b', 'c'} over Integer Ring
 # Free module generated by {'a', 'b', 'c'} over Integer Ring
sage: T.change_ring(QQ)
Free module generated by {'a', 'b', 'c'} over Rational Field
 # Free module generated by {'a', 'b', 'c'} over Rational Field

sage: G = CombinatorialFreeModule(ZZ, ['x','y']); G
Free module generated by {'x', 'y'} over Integer Ring
sage: T = F.cartesian_product(G); T
Free module generated by {'a', 'b', 'c'} over Integer Ring
 (+) Free module generated by {'x', 'y'} over Integer Ring
sage: T.change_ring(QQ)
Free module generated by {'a', 'b', 'c'} over Rational Field
 (+) Free module generated by {'x', 'y'} over Rational Field
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(ZZ, ['a','b','c']); F
Free module generated by {'a', 'b', 'c'} over Integer Ring
>>> F_QQ = F.change_ring(QQ); F_QQ
Free module generated by {'a', 'b', 'c'} over Rational Field
>>> F_QQ.change_ring(ZZ) == F
True

>>> T = F.tensor(F); T
Free module generated by {'a', 'b', 'c'} over Integer Ring
 # Free module generated by {'a', 'b', 'c'} over Integer Ring
>>> T.change_ring(QQ)
Free module generated by {'a', 'b', 'c'} over Rational Field
 # Free module generated by {'a', 'b', 'c'} over Rational Field

>>> G = CombinatorialFreeModule(ZZ, ['x','y']); G
Free module generated by {'x', 'y'} over Integer Ring
>>> T = F.cartesian_product(G); T
Free module generated by {'a', 'b', 'c'} over Integer Ring
 (+) Free module generated by {'x', 'y'} over Integer Ring
>>> T.change_ring(QQ)
Free module generated by {'a', 'b', 'c'} over Rational Field
 (+) Free module generated by {'x', 'y'} over Rational Field
```

construction()

The construction functor and base ring for `self`.

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'],␣
↪category=AlgebrasWithBasis(QQ))
sage: F.construction()
(VectorFunctor, Rational Field)
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ, ['a','b','c'],␣
↪category=AlgebrasWithBasis(QQ))
>>> F.construction()
(VectorFunctor, Rational Field)
```

dimension()

Return the dimension of the free module (which is given by the number of elements in the basis).

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.dimension()
3
sage: F.basis().cardinality()
3
sage: F.basis().keys().cardinality()
3
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
>>> F.dimension()
3
>>> F.basis().cardinality()
3
>>> F.basis().keys().cardinality()
3
```

Rank is available as a synonym:

```
sage: F.rank()
3
```

```
>>> from sage.all import *
>>> F.rank()
3
```

```
sage: s = SymmetricFunctions(QQ).schur()                                    #␣
↪needs sage.combinat
sage: s.dimension()                                                         #␣
↪needs sage.combinat
+Infinity
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).schur()                                  #␣
↪needs sage.combinat
>>> s.dimension()                                                       #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.combinat
+Infinity
```

element_class()

The (default) class for the elements of this parent.

Overrides `Parent.element_class()` to force the construction of Python class. This is currently needed to inherit really all the features from categories, and in particular the initialization of `_mul_` in `Magmas.ParentMethods.__init_extra__()`.

EXAMPLES:

```
sage: # needs sage.combinat
sage: A = Algebras(QQ).WithBasis().example(); A
An example of an algebra with basis:
the free algebra on the generators ('a', 'b', 'c') over Rational Field
sage: A.element_class.mro()
[<class 'sage.categories.examples.algebras_with_basis.FreeAlgebra_with_
↪category.element_class'>,
 <class 'sage.modules.with_basis.indexed_element.IndexedFreeModuleElement'>,
 ...]
sage: a,b,c = A.algebra_generators()
sage: a * b
B[word: ab]
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> A = Algebras(QQ).WithBasis().example(); A
An example of an algebra with basis:
the free algebra on the generators ('a', 'b', 'c') over Rational Field
>>> A.element_class.mro()
[<class 'sage.categories.examples.algebras_with_basis.FreeAlgebra_with_
↪category.element_class'>,
 <class 'sage.modules.with_basis.indexed_element.IndexedFreeModuleElement'>,
 ...]
>>> a,b,c = A.algebra_generators()
>>> a * b
B[word: ab]
```

from_vector(*vector*, *order=None*, *coerce=True*)

Build an element of `self` from a (sparse) vector.

See also

`get_order()`, `CombinatorialFreeModule.Element._vector_()`

EXAMPLES:

```
sage: # needs sage.combinat
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: b = QS3.from_vector(vector((2, 0, 0, 0, 0, 4))); b
2*[1, 2, 3] + 4*[3, 2, 1]
```

(continues on next page)

(continued from previous page)

```
sage: a = 2*QS3([1,2,3]) + 4*QS3([3,2,1])
sage: a == b
True
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3))
>>> b = QS3.from_vector(vector((Integer(2), Integer(0), Integer(0),␣
↪Integer(0), Integer(0), Integer(4)))); b
2*[1, 2, 3] + 4*[3, 2, 1]
>>> a = Integer(2)*QS3([Integer(1),Integer(2),Integer(3)]) +␣
↪Integer(4)*QS3([Integer(3),Integer(2),Integer(1)])
>>> a == b
True
```

get_order()

Return the order of the elements in the basis.

EXAMPLES:

```
sage: QS2 = SymmetricGroupAlgebra(QQ,2)                                 #␣
↪needs sage.combinat
sage: QS2.get_order()  # note: order changed on 2009-03-13              #␣
↪needs sage.combinat
[[2, 1], [1, 2]]
```

```
>>> from sage.all import *
>>> QS2 = SymmetricGroupAlgebra(QQ,Integer(2))                          ␣
↪     # needs sage.combinat
>>> QS2.get_order()  # note: order changed on 2009-03-13              #␣
↪needs sage.combinat
[[2, 1], [1, 2]]
```

get_order_key()

Return a comparison key on the basis indices that is compatible with the current term order.

EXAMPLES:

```
sage: A = FiniteDimensionalAlgebrasWithBasis(QQ).example()
sage: A.set_order(['x', 'y', 'a', 'b'])
sage: Akey = A.get_order_key()
sage: sorted(A.basis().keys(), key=Akey)
['x', 'y', 'a', 'b']
sage: A.set_order(list(reversed(A.basis().keys())))
sage: Akey = A.get_order_key()
sage: sorted(A.basis().keys(), key=Akey)
['b', 'a', 'y', 'x']
```

```
>>> from sage.all import *
>>> A = FiniteDimensionalAlgebrasWithBasis(QQ).example()
>>> A.set_order(['x', 'y', 'a', 'b'])
>>> Akey = A.get_order_key()
```

(continues on next page)

(continued from previous page)

```
>>> sorted(A.basis().keys(), key=Akey)
['x', 'y', 'a', 'b']
>>> A.set_order(list(reversed(A.basis().keys())))
>>> Akey = A.get_order_key()
>>> sorted(A.basis().keys(), key=Akey)
['b', 'a', 'y', 'x']
```

is_exact()

Return `True` if elements of `self` have exact representations, which is true of `self` if and only if it is true of `self.basis().keys()` and `self.base_ring()`.

EXAMPLES:

```
sage: GroupAlgebra(GL(3, GF(7))).is_exact()                                  #␣
↪needs sage.groups sage.rings.finite_rings
True
sage: GroupAlgebra(GL(3, GF(7)), RR).is_exact()                              #␣
↪needs sage.groups sage.rings.finite_rings
False
sage: GroupAlgebra(GL(3, pAdicRing(7))).is_exact()   # not implemented, needs␣
↪sage.groups sage.rings.padics
False
```

```
>>> from sage.all import *
>>> GroupAlgebra(GL(Integer(3), GF(Integer(7)))).is_exact()                   ␣
↪                # needs sage.groups sage.rings.finite_rings
True
>>> GroupAlgebra(GL(Integer(3), GF(Integer(7))), RR).is_exact()               ␣
↪                # needs sage.groups sage.rings.finite_rings
False
>>> GroupAlgebra(GL(Integer(3), pAdicRing(Integer(7)))).is_exact()   # not␣
↪implemented, needs sage.groups sage.rings.padics
False
```

linear_combination(*iter_of_elements_coeff*, *factor_on_left=True*)

Return the linear combination $\lambda_1 v_1 + \cdots + \lambda_k v_k$ (resp. the linear combination $v_1 \lambda_1 + \cdots + v_k \lambda_k$) where `iter_of_elements_coeff` iterates through the sequence $((v_1, \lambda_1), ..., (v_k, \lambda_k))$.

INPUT:

- `iter_of_elements_coeff` – iterator of pairs `(element, coeff)` with `element` in `self` and `coeff` in `self.base_ring()`
- `factor_on_left` – (optional) if `True`, the coefficients are multiplied from the left if `False`, the coefficients are multiplied from the right

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, [1,2])
sage: f = F.an_element(); f
2*B[1] + 2*B[2]
sage: F.linear_combination( (f,i) for i in range(5) )
20*B[1] + 20*B[2]
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ, [Integer(1),Integer(2)])
>>> f = F.an_element(); f
2*B[1] + 2*B[2]
>>> F.linear_combination( (f,i) for i in range(Integer(5)) )
20*B[1] + 20*B[2]
```

monomial()

Return the basis element indexed by `i`.

INPUT:

- `i` – an element of the index set

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.monomial('a')
B['a']
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
>>> F.monomial('a')
B['a']
```

`F.monomial` is in fact (almost) a map:

```
sage: F.monomial
Term map from {'a', 'b', 'c'} to Free module generated by {'a', 'b', 'c'}␣
↪over Rational Field
```

```
>>> from sage.all import *
>>> F.monomial
Term map from {'a', 'b', 'c'} to Free module generated by {'a', 'b', 'c'}␣
↪over Rational Field
```

rank()

Return the dimension of the free module (which is given by the number of elements in the basis).

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.dimension()
3
sage: F.basis().cardinality()
3
sage: F.basis().keys().cardinality()
3
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
>>> F.dimension()
3
>>> F.basis().cardinality()
```

(continues on next page)

(continued from previous page)

```
3
>>> F.basis().keys().cardinality()
3
```

Rank is available as a synonym:

```
sage: F.rank()
3
```

```
>>> from sage.all import *
>>> F.rank()
3
```

```
sage: s = SymmetricFunctions(QQ).schur()                                    #␣
↪needs sage.combinat
sage: s.dimension()                                                         #␣
↪needs sage.combinat
+Infinity
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).schur()                                    #␣
↪needs sage.combinat
>>> s.dimension()                                                         #␣
↪needs sage.combinat
+Infinity
```

set_order(*order*)

Set the order of the elements of the basis.

If `set_order()` has not been called, then the ordering is the one used in the generation of the elements of `self`'s associated enumerated set.

> **Warning**
>
> Many cached methods depend on this order, in particular for constructing subspaces and quotients. Changing the order after some computations have been cached does not invalidate the cache, and is likely to introduce inconsistencies.

EXAMPLES:

```
sage: # needs sage.combinat
sage: QS2 = SymmetricGroupAlgebra(QQ,2)
sage: b = list(QS2.basis().keys())
sage: b.reverse()
sage: QS2.set_order(b)
sage: QS2.get_order()
[[2, 1], [1, 2]]
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> QS2 = SymmetricGroupAlgebra(QQ,Integer(2))
```

(continues on next page)

(continued from previous page)

```
>>> b = list(QS2.basis().keys())
>>> b.reverse()
>>> QS2.set_order(b)
>>> QS2.get_order()
[[2, 1], [1, 2]]
```

sum(*iter_of_elements*)

Return the sum of all elements in `iter_of_elements`.

Overrides method inherited from commutative additive monoid as it is much faster on dicts directly.

INPUT:

- `iter_of_elements` – iterator of elements of `self`

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ,[1,2])
sage: f = F.an_element(); f
2*B[1] + 2*B[2]
sage: F.sum( f for _ in range(5) )
10*B[1] + 10*B[2]
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ,[Integer(1),Integer(2)])
>>> f = F.an_element(); f
2*B[1] + 2*B[2]
>>> F.sum( f for _ in range(Integer(5)) )
10*B[1] + 10*B[2]
```

sum_of_terms(*terms*, *distinct=False*)

Construct a sum of terms of `self`.

INPUT:

- `terms` – list (or iterable) of pairs `(index, coeff)`
- `distinct` – boolean (default: `False`); whether the indices are guaranteed to be distinct

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.sum_of_terms([('a',2), ('c',3)])
2*B['a'] + 3*B['c']
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
>>> F.sum_of_terms([('a',Integer(2)), ('c',Integer(3))])
2*B['a'] + 3*B['c']
```

If `distinct` is True, then the construction is optimized:

```
sage: F.sum_of_terms([('a',2), ('c',3)], distinct = True)
2*B['a'] + 3*B['c']
```

```
>>> from sage.all import *
>>> F.sum_of_terms([('a',Integer(2)), ('c',Integer(3))], distinct = True)
2*B['a'] + 3*B['c']
```

Warning

Use `distinct=True` only if you are sure that the indices are indeed distinct:

```
sage: F.sum_of_terms([('a',2), ('a',3)], distinct = True)
3*B['a']
```

```
>>> from sage.all import *
>>> F.sum_of_terms([('a',Integer(2)), ('a',Integer(3))], distinct = True)
3*B['a']
```

Extreme case:

```
sage: F.sum_of_terms([])
0
```

```
>>> from sage.all import *
>>> F.sum_of_terms([])
0
```

term(*index*, *coeff=None*)

Construct a term in `self`.

INPUT:

- `index` – the index of a basis element
- `coeff` – an element of the coefficient ring (default: one)

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.term('a',3)
3*B['a']
sage: F.term('a')
B['a']
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
>>> F.term('a',Integer(3))
3*B['a']
>>> F.term('a')
B['a']
```

Design: should this do coercion on the coefficient ring?

zero()

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.zero()
0
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
>>> F.zero()
0
```

class sage.combinat.free_module.**CombinatorialFreeModule_CartesianProduct**(*modules*, ***options*)

Bases: *CombinatorialFreeModule*

An implementation of Cartesian products of modules with basis.

EXAMPLES:

We construct two free modules, assign them short names, and construct their Cartesian product:

```
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.rename('F')
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.rename('G')
sage: H = CombinatorialFreeModule(ZZ, [4,7]); H.rename('H')
sage: S = cartesian_product([F, G])
sage: S
F (+) G
sage: S.basis()
Lazy family (Term map
 from Disjoint union of Family ({4, 5}, {4, 6})
   to F (+) G(i))_{i in Disjoint union of Family ({4, 5}, {4, 6})}
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(ZZ, [Integer(4),Integer(5)]); F.rename('F')
>>> G = CombinatorialFreeModule(ZZ, [Integer(4),Integer(6)]); G.rename('G')
>>> H = CombinatorialFreeModule(ZZ, [Integer(4),Integer(7)]); H.rename('H')
>>> S = cartesian_product([F, G])
>>> S
F (+) G
>>> S.basis()
Lazy family (Term map
 from Disjoint union of Family ({4, 5}, {4, 6})
   to F (+) G(i))_{i in Disjoint union of Family ({4, 5}, {4, 6})}
```

Note that the indices of the basis elements of F and G intersect non trivially. This is handled by forcing the union to be disjoint:

```
sage: list(S.basis())
[B[(0, 4)], B[(0, 5)], B[(1, 4)], B[(1, 6)]]
```

```
>>> from sage.all import *
>>> list(S.basis())
[B[(0, 4)], B[(0, 5)], B[(1, 4)], B[(1, 6)]]
```

We now compute the Cartesian product of elements of free modules:

```
sage: f =   F.monomial(4) + 2*F.monomial(5)
sage: g = 2*G.monomial(4) +   G.monomial(6)
sage: h =   H.monomial(4) +   H.monomial(7)
sage: cartesian_product([f, g])
B[(0, 4)] + 2*B[(0, 5)] + 2*B[(1, 4)] + B[(1, 6)]
sage: cartesian_product([f, g, h])
B[(0, 4)] + 2*B[(0, 5)] + 2*B[(1, 4)] + B[(1, 6)] + B[(2, 4)] + B[(2, 7)]
sage: cartesian_product([f, g, h]).parent()
F (+) G (+) H
```

```
>>> from sage.all import *
>>> f =   F.monomial(Integer(4)) + Integer(2)*F.monomial(Integer(5))
>>> g = Integer(2)*G.monomial(Integer(4)) +   G.monomial(Integer(6))
>>> h =   H.monomial(Integer(4)) +   H.monomial(Integer(7))
>>> cartesian_product([f, g])
B[(0, 4)] + 2*B[(0, 5)] + 2*B[(1, 4)] + B[(1, 6)]
>>> cartesian_product([f, g, h])
B[(0, 4)] + 2*B[(0, 5)] + 2*B[(1, 4)] + B[(1, 6)] + B[(2, 4)] + B[(2, 7)]
>>> cartesian_product([f, g, h]).parent()
F (+) G (+) H
```

TODO: choose an appropriate semantic for Cartesian products of Cartesian products (associativity?):

```
sage: S = cartesian_product([cartesian_product([F, G]), H])  # todo: not␣
↪implemented
F (+) G (+) H
```

```
>>> from sage.all import *
>>> S = cartesian_product([cartesian_product([F, G]), H])  # todo: not implemented
F (+) G (+) H
```

class Element

Bases: `IndexedFreeModuleElement`

cartesian_embedding(*i*)

Return the natural embedding morphism of the `i`-th Cartesian factor (summand) of `self` into `self`.

INPUT:

- `i` – integer

EXAMPLES:

```
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.rename('F')
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.rename('G')
sage: S = cartesian_product([F, G])
sage: phi = S.cartesian_embedding(0)
sage: phi(F.monomial(4) + 2 * F.monomial(5))
B[(0, 4)] + 2*B[(0, 5)]
sage: phi(F.monomial(4) + 2 * F.monomial(6)).parent() == S
True
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(ZZ, [Integer(4),Integer(5)]); F.rename('F')
```

(continues on next page)

(continued from previous page)

```
>>> G = CombinatorialFreeModule(ZZ, [Integer(4),Integer(6)]); G.rename('G')
>>> S = cartesian_product([F, G])
>>> phi = S.cartesian_embedding(Integer(0))
>>> phi(F.monomial(Integer(4)) + Integer(2) * F.monomial(Integer(5)))
B[(0, 4)] + 2*B[(0, 5)]
>>> phi(F.monomial(Integer(4)) + Integer(2) * F.monomial(Integer(6))).
↪parent() == S
True
```

cartesian_factors()

Return the factors of the Cartesian product.

EXAMPLES:

```
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.rename('F')
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.rename('G')
sage: S = cartesian_product([F, G])
sage: S.cartesian_factors()
(F, G)
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(ZZ, [Integer(4),Integer(5)]); F.rename('F')
>>> G = CombinatorialFreeModule(ZZ, [Integer(4),Integer(6)]); G.rename('G')
>>> S = cartesian_product([F, G])
>>> S.cartesian_factors()
(F, G)
```

cartesian_projection(i)

Return the natural projection onto the i-th Cartesian factor (summand) of `self`.

INPUT:

- `i` – integer

EXAMPLES:

```
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.rename('F')
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.rename('G')
sage: S = cartesian_product([F, G])
sage: x = S.monomial((0,4)) + 2 * S.monomial((0,5)) + 3 * S.monomial((1,6))
sage: S.cartesian_projection(0)(x)
B[4] + 2*B[5]
sage: S.cartesian_projection(1)(x)
3*B[6]
sage: S.cartesian_projection(0)(x).parent() == F
True
sage: S.cartesian_projection(1)(x).parent() == G
True
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(ZZ, [Integer(4),Integer(5)]); F.rename('F')
>>> G = CombinatorialFreeModule(ZZ, [Integer(4),Integer(6)]); G.rename('G')
>>> S = cartesian_product([F, G])
```

(continues on next page)

(continued from previous page)

```
>>> x = S.monomial((Integer(0),Integer(4))) + Integer(2) * S.
↪monomial((Integer(0),Integer(5))) + Integer(3) * S.monomial((Integer(1),
↪Integer(6)))
>>> S.cartesian_projection(Integer(0))(x)
B[4] + 2*B[5]
>>> S.cartesian_projection(Integer(1))(x)
3*B[6]
>>> S.cartesian_projection(Integer(0))(x).parent() == F
True
>>> S.cartesian_projection(Integer(1))(x).parent() == G
True
```

summand_embedding(*i*)

Return the natural embedding morphism of the `i`-th Cartesian factor (summand) of `self` into `self`.

INPUT:

- `i` – integer

EXAMPLES:

```
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.rename('F')
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.rename('G')
sage: S = cartesian_product([F, G])
sage: phi = S.cartesian_embedding(0)
sage: phi(F.monomial(4) + 2 * F.monomial(5))
B[(0, 4)] + 2*B[(0, 5)]
sage: phi(F.monomial(4) + 2 * F.monomial(6)).parent() == S
True
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(ZZ, [Integer(4),Integer(5)]); F.rename('F')
>>> G = CombinatorialFreeModule(ZZ, [Integer(4),Integer(6)]); G.rename('G')
>>> S = cartesian_product([F, G])
>>> phi = S.cartesian_embedding(Integer(0))
>>> phi(F.monomial(Integer(4)) + Integer(2) * F.monomial(Integer(5)))
B[(0, 4)] + 2*B[(0, 5)]
>>> phi(F.monomial(Integer(4)) + Integer(2) * F.monomial(Integer(6))).
↪parent() == S
True
```

summand_projection(*i*)

Return the natural projection onto the i-th Cartesian factor (summand) of `self`.

INPUT:

- `i` – integer

EXAMPLES:

```
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.rename('F')
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.rename('G')
sage: S = cartesian_product([F, G])
sage: x = S.monomial((0,4)) + 2 * S.monomial((0,5)) + 3 * S.monomial((1,6))
sage: S.cartesian_projection(0)(x)
```

(continues on next page)

(continued from previous page)

```
B[4] + 2*B[5]
sage: S.cartesian_projection(1)(x)
3*B[6]
sage: S.cartesian_projection(0)(x).parent() == F
True
sage: S.cartesian_projection(1)(x).parent() == G
True
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(ZZ, [Integer(4),Integer(5)]); F.rename('F')
>>> G = CombinatorialFreeModule(ZZ, [Integer(4),Integer(6)]); G.rename('G')
>>> S = cartesian_product([F, G])
>>> x = S.monomial((Integer(0),Integer(4))) + Integer(2) * S.
↪monomial((Integer(0),Integer(5))) + Integer(3) * S.monomial((Integer(1),
↪Integer(6)))
>>> S.cartesian_projection(Integer(0))(x)
B[4] + 2*B[5]
>>> S.cartesian_projection(Integer(1))(x)
3*B[6]
>>> S.cartesian_projection(Integer(0))(x).parent() == F
True
>>> S.cartesian_projection(Integer(1))(x).parent() == G
True
```

class sage.combinat.free_module.**CombinatorialFreeModule_Tensor**(*modules*, ***options*)

Bases: *CombinatorialFreeModule*

Tensor Product of Free Modules.

EXAMPLES:

We construct two free modules, assign them short names, and construct their tensor product:

```
sage: F = CombinatorialFreeModule(ZZ, [1,2]); F.rename('F')
sage: G = CombinatorialFreeModule(ZZ, [3,4]); G.rename('G')
sage: T = tensor([F, G]); T
F # G

sage: T.category()
Category of tensor products of
 finite dimensional modules with basis over Integer Ring

sage: T.construction() # todo: not implemented
[tensor, ]
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(ZZ, [Integer(1),Integer(2)]); F.rename('F')
>>> G = CombinatorialFreeModule(ZZ, [Integer(3),Integer(4)]); G.rename('G')
>>> T = tensor([F, G]); T
F # G

>>> T.category()
Category of tensor products of
```

(continues on next page)

(continued from previous page)

```
 finite dimensional modules with basis over Integer Ring

>>> T.construction() # todo: not implemented
[tensor, ]
```

T is a free module, with same base ring as F and G:

```
sage: T.base_ring()
Integer Ring
```

```
>>> from sage.all import *
>>> T.base_ring()
Integer Ring
```

The basis of T is indexed by tuples of basis indices of F and G:

```
sage: T.basis().keys()
Image of Cartesian product of {1, 2}, {3, 4}
      by The map <class 'tuple'> from Cartesian product of {1, 2}, {3, 4}
sage: T.basis().keys().list()
[(1, 3), (1, 4), (2, 3), (2, 4)]
```

```
>>> from sage.all import *
>>> T.basis().keys()
Image of Cartesian product of {1, 2}, {3, 4}
      by The map <class 'tuple'> from Cartesian product of {1, 2}, {3, 4}
>>> T.basis().keys().list()
[(1, 3), (1, 4), (2, 3), (2, 4)]
```

FIXME: Should elements of a CartesianProduct be tuples (making them hashable)?

Here are the basis elements themselves:

```
sage: T.basis().cardinality()
4
sage: list(T.basis())
[B[1] # B[3], B[1] # B[4], B[2] # B[3], B[2] # B[4]]
```

```
>>> from sage.all import *
>>> T.basis().cardinality()
4
>>> list(T.basis())
[B[1] # B[3], B[1] # B[4], B[2] # B[3], B[2] # B[4]]
```

The tensor product is associative and flattens sub tensor products:

```
sage: H = CombinatorialFreeModule(ZZ, [5,6]); H.rename('H')
sage: tensor([F, tensor([G, H])])
F # G # H
sage: tensor([tensor([F, G]), H])
F # G # H
sage: tensor([F, G, H])
F # G # H
```

```
>>> from sage.all import *
>>> H = CombinatorialFreeModule(ZZ, [Integer(5),Integer(6)]); H.rename('H')
>>> tensor([F, tensor([G, H])])
F # G # H
>>> tensor([tensor([F, G]), H])
F # G # H
>>> tensor([F, G, H])
F # G # H
```

We now compute the tensor product of elements of free modules:

```
sage: f =   F.monomial(1) + 2 * F.monomial(2)
sage: g = 2*G.monomial(3) +     G.monomial(4)
sage: h =   H.monomial(5) +     H.monomial(6)
sage: tensor([f, g])
2*B[1] # B[3] + B[1] # B[4] + 4*B[2] # B[3] + 2*B[2] # B[4]
```

```
>>> from sage.all import *
>>> f =   F.monomial(Integer(1)) + Integer(2) * F.monomial(Integer(2))
>>> g = Integer(2)*G.monomial(Integer(3)) +     G.monomial(Integer(4))
>>> h =   H.monomial(Integer(5)) +     H.monomial(Integer(6))
>>> tensor([f, g])
2*B[1] # B[3] + B[1] # B[4] + 4*B[2] # B[3] + 2*B[2] # B[4]
```

Again, the tensor product is associative on elements:

```
sage: tensor([f, tensor([g, h])]) == tensor([f, g, h])
True
sage: tensor([tensor([f, g]), h]) == tensor([f, g, h])
True
```

```
>>> from sage.all import *
>>> tensor([f, tensor([g, h])]) == tensor([f, g, h])
True
>>> tensor([tensor([f, g]), h]) == tensor([f, g, h])
True
```

Note further that the tensor product spaces need not preexist:

```
sage: t = tensor([f, g, h])
sage: t.parent()
F # G # H
```

```
>>> from sage.all import *
>>> t = tensor([f, g, h])
>>> t.parent()
F # G # H
```

tensor_constructor(*modules*)

INPUT:

- `modules` – tuple $(F_1, \ldots, F_n)$ of free modules whose tensor product is self

Returns the canonical multilinear morphism from $F_1 \times \cdots \times F_n$ to $F_1 \otimes \cdots \otimes F_n$

EXAMPLES:

```
sage: F = CombinatorialFreeModule(ZZ, [1,2]); F.rename('F')
sage: G = CombinatorialFreeModule(ZZ, [3,4]); G.rename('G')
sage: H = CombinatorialFreeModule(ZZ, [5,6]); H.rename('H')

sage: f =   F.monomial(1) + 2*F.monomial(2)
sage: g = 2*G.monomial(3) +   G.monomial(4)
sage: h =   H.monomial(5) +   H.monomial(6)
sage: FG = tensor([F, G])
sage: phi_fg = FG.tensor_constructor((F, G))
sage: phi_fg(f, g)
2*B[1] # B[3] + B[1] # B[4] + 4*B[2] # B[3] + 2*B[2] # B[4]

sage: FGH = tensor([F, G, H])
sage: phi_fgh = FGH.tensor_constructor((F, G, H))
sage: phi_fgh(f, g, h)
2*B[1] # B[3] # B[5] + 2*B[1] # B[3] # B[6] + B[1] # B[4] # B[5]
+ B[1] # B[4] # B[6] + 4*B[2] # B[3] # B[5] + 4*B[2] # B[3] # B[6]
+ 2*B[2] # B[4] # B[5] + 2*B[2] # B[4] # B[6]

sage: phi_fg_h = FGH.tensor_constructor((FG, H))
sage: phi_fg_h(phi_fg(f, g), h)
2*B[1] # B[3] # B[5] + 2*B[1] # B[3] # B[6] + B[1] # B[4] # B[5]
+ B[1] # B[4] # B[6] + 4*B[2] # B[3] # B[5] + 4*B[2] # B[3] # B[6]
+ 2*B[2] # B[4] # B[5] + 2*B[2] # B[4] # B[6]
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(ZZ, [Integer(1),Integer(2)]); F.rename('F')
>>> G = CombinatorialFreeModule(ZZ, [Integer(3),Integer(4)]); G.rename('G')
>>> H = CombinatorialFreeModule(ZZ, [Integer(5),Integer(6)]); H.rename('H')

>>> f =   F.monomial(Integer(1)) + Integer(2)*F.monomial(Integer(2))
>>> g = Integer(2)*G.monomial(Integer(3)) +   G.monomial(Integer(4))
>>> h =   H.monomial(Integer(5)) +   H.monomial(Integer(6))
>>> FG = tensor([F, G])
>>> phi_fg = FG.tensor_constructor((F, G))
>>> phi_fg(f, g)
2*B[1] # B[3] + B[1] # B[4] + 4*B[2] # B[3] + 2*B[2] # B[4]

>>> FGH = tensor([F, G, H])
>>> phi_fgh = FGH.tensor_constructor((F, G, H))
>>> phi_fgh(f, g, h)
2*B[1] # B[3] # B[5] + 2*B[1] # B[3] # B[6] + B[1] # B[4] # B[5]
+ B[1] # B[4] # B[6] + 4*B[2] # B[3] # B[5] + 4*B[2] # B[3] # B[6]
+ 2*B[2] # B[4] # B[5] + 2*B[2] # B[4] # B[6]

>>> phi_fg_h = FGH.tensor_constructor((FG, H))
>>> phi_fg_h(phi_fg(f, g), h)
2*B[1] # B[3] # B[5] + 2*B[1] # B[3] # B[6] + B[1] # B[4] # B[5]
+ B[1] # B[4] # B[6] + 4*B[2] # B[3] # B[5] + 4*B[2] # B[3] # B[6]
+ 2*B[2] # B[4] # B[5] + 2*B[2] # B[4] # B[6]
```

tensor_factors()

Return the tensor factors of this tensor product.

EXAMPLES:

```
sage: F = CombinatorialFreeModule(ZZ, [1,2])
sage: F.rename('F')
sage: G = CombinatorialFreeModule(ZZ, [3,4])
sage: G.rename('G')
sage: T = tensor([F, G]); T
F # G
sage: T.tensor_factors()
(F, G)
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(ZZ, [Integer(1),Integer(2)])
>>> F.rename('F')
>>> G = CombinatorialFreeModule(ZZ, [Integer(3),Integer(4)])
>>> G.rename('G')
>>> T = tensor([F, G]); T
F # G
>>> T.tensor_factors()
(F, G)
```

5.1.112 Free Dendriform Algebras

AUTHORS:

Frédéric Chapoton (2017)

class sage.combinat.free_dendriform_algebra.**DendriformFunctor**(*vars*)

Bases: ConstructionFunctor

A constructor for dendriform algebras.

EXAMPLES:

```
sage: P = algebras.FreeDendriform(ZZ, 'x,y')
sage: x,y = P.gens()
sage: F = P.construction()[0]; F
Dendriform[x,y]

sage: A = GF(5)['a,b']
sage: a, b = A.gens()
sage: F(A)
Free Dendriform algebra on 2 generators ['x', 'y']
 over Multivariate Polynomial Ring in a, b over Finite Field of size 5

sage: f = A.hom([a+b,a-b],A)
sage: F(f)
Generic endomorphism of Free Dendriform algebra on 2 generators ['x', 'y']
 over Multivariate Polynomial Ring in a, b over Finite Field of size 5

sage: F(f)(a * F(A)(x))
(a+b)*B[x[., .]]
```

```
>>> from sage.all import *
>>> P = algebras.FreeDendriform(ZZ, 'x,y')
>>> x,y = P.gens()
>>> F = P.construction()[Integer(0)]; F
Dendriform[x,y]

>>> A = GF(Integer(5))['a,b']
>>> a, b = A.gens()
>>> F(A)
Free Dendriform algebra on 2 generators ['x', 'y']
 over Multivariate Polynomial Ring in a, b over Finite Field of size 5

>>> f = A.hom([a+b,a-b],A)
>>> F(f)
Generic endomorphism of Free Dendriform algebra on 2 generators ['x', 'y']
 over Multivariate Polynomial Ring in a, b over Finite Field of size 5

>>> F(f)(a * F(A)(x))
(a+b)*B[x[., .]]
```

merge(*other*)

Merge `self` with another construction functor, or return `None`.

EXAMPLES:

```
sage: F = sage.combinat.free_dendriform_algebra.DendriformFunctor(['x','y'])
sage: G = sage.combinat.free_dendriform_algebra.DendriformFunctor(['t'])
sage: F.merge(G)
Dendriform[x,y,t]
sage: F.merge(F)
Dendriform[x,y]
```

```
>>> from sage.all import *
>>> F = sage.combinat.free_dendriform_algebra.DendriformFunctor(['x','y'])
>>> G = sage.combinat.free_dendriform_algebra.DendriformFunctor(['t'])
>>> F.merge(G)
Dendriform[x,y,t]
>>> F.merge(F)
Dendriform[x,y]
```

Now some actual use cases:

```
sage: R = algebras.FreeDendriform(ZZ, 'x,y,z')
sage: x,y,z = R.gens()
sage: 1/2 * x
1/2*B[x[., .]]
sage: parent(1/2 * x)
Free Dendriform algebra on 3 generators ['x', 'y', 'z'] over Rational Field

sage: S = algebras.FreeDendriform(QQ, 'zt')
sage: z,t = S.gens()
sage: x + t
B[t[., .]] + B[x[., .]]
```

(continues on next page)

(continued from previous page)

```
sage: parent(x + t)
Free Dendriform algebra on 4 generators ['z', 't', 'x', 'y'] over Rational
↪Field
```

```
>>> from sage.all import *
>>> R = algebras.FreeDendriform(ZZ, 'x,y,z')
>>> x,y,z = R.gens()
>>> Integer(1)/Integer(2) * x
1/2*B[x[., .]]
>>> parent(Integer(1)/Integer(2) * x)
Free Dendriform algebra on 3 generators ['x', 'y', 'z'] over Rational Field

>>> S = algebras.FreeDendriform(QQ, 'zt')
>>> z,t = S.gens()
>>> x + t
B[t[., .]] + B[x[., .]]
>>> parent(x + t)
Free Dendriform algebra on 4 generators ['z', 't', 'x', 'y'] over Rational
↪Field
```

rank = 9

class sage.combinat.free_dendriform_algebra.**FreeDendriformAlgebra**(*R*, *names=None*)

Bases: *CombinatorialFreeModule*

The free dendriform algebra.

Dendriform algebras are associative algebras, where the associative product $*$ is decomposed as a sum of two binary operations

$$x * y = x \succ y + x \prec y$$

that satisfy the axioms:

$$(x \succ y) \prec z = x \succ (y \prec z),$$

$$(x \prec y) \prec z = x \prec (y * z).$$

$$(x * y) \succ z = x \succ (y \succ z).$$

The free Dendriform algebra on a given set E has an explicit description using (planar) binary trees, just as the free associative algebra can be described using words. The underlying vector space has a basis indexed by finite binary trees endowed with a map from their vertices to E. In this basis, the associative product of two (decorated) binary trees $S * T$ is the sum over all possible ways of identifying (glueing) the rightmost path in S and the leftmost path in T.

The decomposition of the associative product as the sum of two binary operations $\succ$ and $\prec$ is made by separating the terms according to the origin of the root vertex. For $x \succ y$, one keeps the terms where the root vertex comes from y, whereas for $x \prec y$ one keeps the terms where the root vertex comes from x.

The free dendriform algebra can also be considered as the free algebra over the Dendriform operad.

Note

The usual binary operator $*$ is used for the associative product.

EXAMPLES:

```
sage: F = algebras.FreeDendriform(ZZ, 'xyz')
sage: x,y,z = F.gens()
sage: (x * y) * z
B[x[., y[., z[., .]]]] + B[x[., z[y[., .], .]]] + B[y[x[., .], z[., .]]]
 + B[z[x[., y[., .]], .]] + B[z[y[x[., .], .], .]]
```

```
>>> from sage.all import *
>>> F = algebras.FreeDendriform(ZZ, 'xyz')
>>> x,y,z = F.gens()
>>> (x * y) * z
B[x[., y[., z[., .]]]] + B[x[., z[y[., .], .]]] + B[y[x[., .], z[., .]]]
 + B[z[x[., y[., .]], .]] + B[z[y[x[., .], .], .]]
```

The free dendriform algebra is associative:

```
sage: x * (y * z) == (x * y) * z
True
```

```
>>> from sage.all import *
>>> x * (y * z) == (x * y) * z
True
```

The associative product decomposes in two parts:

```
sage: x * y == F.prec(x, y) + F.succ(x, y)
True
```

```
>>> from sage.all import *
>>> x * y == F.prec(x, y) + F.succ(x, y)
True
```

The axioms hold:

```
sage: F.prec(F.succ(x, y), z) == F.succ(x, F.prec(y, z))
True
sage: F.prec(F.prec(x, y), z) == F.prec(x, y * z)
True
sage: F.succ(x * y, z) == F.succ(x, F.succ(y, z))
True
```

```
>>> from sage.all import *
>>> F.prec(F.succ(x, y), z) == F.succ(x, F.prec(y, z))
True
>>> F.prec(F.prec(x, y), z) == F.prec(x, y * z)
True
>>> F.succ(x * y, z) == F.succ(x, F.succ(y, z))
True
```

When there is only one generator, unlabelled trees are used instead:

```
sage: F1 = algebras.FreeDendriform(QQ)
sage: w = F1.gen(0); w
B[[., .]]
sage: w * w * w
B[[., [., [., .]]]] + B[[., [[., .], .]]] + B[[[., .], [., .]]]
 + B[[[., [., .]], .]] + B[[[[., .], .], .]]
```

```
>>> from sage.all import *
>>> F1 = algebras.FreeDendriform(QQ)
>>> w = F1.gen(Integer(0)); w
B[[., .]]
>>> w * w * w
B[[., [., [., .]]]] + B[[., [[., .], .]]] + B[[[., .], [., .]]]
 + B[[[., [., .]], .]] + B[[[[., .], .], .]]
```

The set E can be infinite:

```
sage: F = algebras.FreeDendriform(QQ, ZZ)
sage: w = F.gen(1); w
B[1[., .]]
sage: x = F.gen(2); x
B[-1[., .]]
sage: w*x
B[-1[1[., .], .]] + B[1[., -1[., .]]]
```

```
>>> from sage.all import *
>>> F = algebras.FreeDendriform(QQ, ZZ)
>>> w = F.gen(Integer(1)); w
B[1[., .]]
>>> x = F.gen(Integer(2)); x
B[-1[., .]]
>>> w*x
B[-1[1[., .], .]] + B[1[., -1[., .]]]
```

REFERENCES:

- [LR1998]

algebra_generators()

Return the generators of this algebra.

These are the binary trees with just one vertex.

EXAMPLES:

```
sage: A = algebras.FreeDendriform(ZZ, 'fgh'); A
Free Dendriform algebra on 3 generators ['f', 'g', 'h']
 over Integer Ring
sage: list(A.algebra_generators())
[B[f[., .]], B[g[., .]], B[h[., .]]]

sage: A = algebras.FreeDendriform(QQ, ['x1','x2'])
sage: list(A.algebra_generators())
[B[x1[., .]], B[x2[., .]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreeDendriform(ZZ, 'fgh'); A
Free Dendriform algebra on 3 generators ['f', 'g', 'h']
 over Integer Ring
>>> list(A.algebra_generators())
[B[f[., .]], B[g[., .]], B[h[., .]]]

>>> A = algebras.FreeDendriform(QQ, ['x1','x2'])
>>> list(A.algebra_generators())
[B[x1[., .]], B[x2[., .]]]
```

an_element()

Return an element of `self`.

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ, 'xy')
sage: A.an_element()
B[x[., .]] + 2*B[x[., x[., .]]] + 2*B[x[x[., .], .]]
```

```
>>> from sage.all import *
>>> A = algebras.FreeDendriform(QQ, 'xy')
>>> A.an_element()
B[x[., .]] + 2*B[x[., x[., .]]] + 2*B[x[x[., .], .]]
```

change_ring(R)

Return the free dendriform algebra in the same variables over R.

INPUT:

- `R` – a ring

EXAMPLES:

```
sage: A = algebras.FreeDendriform(ZZ, 'fgh')
sage: A.change_ring(QQ)
Free Dendriform algebra on 3 generators ['f', 'g', 'h'] over
Rational Field
```

```
>>> from sage.all import *
>>> A = algebras.FreeDendriform(ZZ, 'fgh')
>>> A.change_ring(QQ)
Free Dendriform algebra on 3 generators ['f', 'g', 'h'] over
Rational Field
```

construction()

Return a pair `(F, R)`, where `F` is a *DendriformFunctor* and R is a ring, such that `F(R)` returns `self`.

EXAMPLES:

```
sage: P = algebras.FreeDendriform(ZZ, 'x,y')
sage: x,y = P.gens()
sage: F, R = P.construction()
sage: F
```

(continues on next page)

(continued from previous page)

```
Dendriform[x,y]
sage: R
Integer Ring
sage: F(ZZ) is P
True
sage: F(QQ)
Free Dendriform algebra on 2 generators ['x', 'y'] over Rational Field
```

```
>>> from sage.all import *
>>> P = algebras.FreeDendriform(ZZ, 'x,y')
>>> x,y = P.gens()
>>> F, R = P.construction()
>>> F
Dendriform[x,y]
>>> R
Integer Ring
>>> F(ZZ) is P
True
>>> F(QQ)
Free Dendriform algebra on 2 generators ['x', 'y'] over Rational Field
```

coproduct_on_basis(*x*)

Return the coproduct of a binary tree.

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: x = A.gen(0)
sage: ascii_art(A.coproduct(A.one()))  # indirect doctest
1 # 1

sage: ascii_art(A.coproduct(x))  # indirect doctest
1 # B  + B  # 1
     o    o

sage: A = algebras.FreeDendriform(QQ, 'xyz')
sage: x, y, z = A.gens()
sage: w = A.under(z,A.over(x,y))
sage: A.coproduct(z)
B[.] # B[z[., .]] + B[z[., .]] # B[.]
sage: A.coproduct(w)
B[.] # B[x[z[., .], y[., .]]] + B[x[., .]] # B[z[., y[., .]]] +
B[x[., .]] # B[y[z[., .], .]] + B[x[., y[., .]]] # B[z[., .]] +
B[x[z[., .], .]] # B[y[., .]] + B[x[z[., .], y[., .]]] # B[.]
```

```
>>> from sage.all import *
>>> A = algebras.FreeDendriform(QQ)
>>> x = A.gen(Integer(0))
>>> ascii_art(A.coproduct(A.one()))  # indirect doctest
1 # 1

>>> ascii_art(A.coproduct(x))  # indirect doctest
```

(continues on next page)

(continued from previous page)

```
1 # B  + B  # 1
     o     o

>>> A = algebras.FreeDendriform(QQ, 'xyz')
>>> x, y, z = A.gens()
>>> w = A.under(z,A.over(x,y))
>>> A.coproduct(z)
B[.] # B[z[., .]] + B[z[., .]] # B[.]
>>> A.coproduct(w)
B[.] # B[x[z[., .], y[., .]]] + B[x[., .]] # B[z[., y[., .]]] +
B[x[., .]] # B[y[z[., .], .]] + B[x[., y[., .]]] # B[z[., .]] +
B[x[z[., .], .]] # B[y[., .]] + B[x[z[., .], y[., .]]] # B[.]
```

degree_on_basis(*t*)

Return the degree of a binary tree in the free Dendriform algebra.

This is the number of vertices.

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ,'@')
sage: RT = A.basis().keys()
sage: u = RT([], '@')
sage: A.degree_on_basis(u.over(u))
2
```

```
>>> from sage.all import *
>>> A = algebras.FreeDendriform(QQ,'@')
>>> RT = A.basis().keys()
>>> u = RT([], '@')
>>> A.degree_on_basis(u.over(u))
2
```

gen(*i*)

Return the i-th generator of the algebra.

INPUT:

- i – integer

EXAMPLES:

```
sage: F = algebras.FreeDendriform(ZZ, 'xyz')
sage: F.gen(0)
B[x[., .]]

sage: F.gen(4)
Traceback (most recent call last):
...
IndexError: argument i (= 4) must be between 0 and 2
```

```
>>> from sage.all import *
>>> F = algebras.FreeDendriform(ZZ, 'xyz')
>>> F.gen(Integer(0))
```

(continues on next page)

(continued from previous page)

```
B[x[., .]]

>>> F.gen(Integer(4))
Traceback (most recent call last):
...
IndexError: argument i (= 4) must be between 0 and 2
```

gens()

Return the generators of `self` (as an algebra).

EXAMPLES:

```
sage: A = algebras.FreeDendriform(ZZ, 'fgh')
sage: A.gens()
(B[f[., .]], B[g[., .]], B[h[., .]])
```

```
>>> from sage.all import *
>>> A = algebras.FreeDendriform(ZZ, 'fgh')
>>> A.gens()
(B[f[., .]], B[g[., .]], B[h[., .]])
```

one_basis()

Return the index of the unit.

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ, '@')
sage: A.one_basis()
.
sage: A = algebras.FreeDendriform(QQ, 'xy')
sage: A.one_basis()
.
```

```
>>> from sage.all import *
>>> A = algebras.FreeDendriform(QQ, '@')
>>> A.one_basis()
.
>>> A = algebras.FreeDendriform(QQ, 'xy')
>>> A.one_basis()
.
```

over()

Return the over product.

The over product x/y is the binary tree obtained by grafting the root of y at the rightmost leaf of x.

The usual symbol for this operation is $/$.

See also

`product()`, *succ()*, *prec()*, *under()*

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = A.gen(0)
sage: A.over(x, x)
B[[., [., .]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreeDendriform(QQ)
>>> RT = A.basis().keys()
>>> x = A.gen(Integer(0))
>>> A.over(x, x)
B[[., [., .]]]
```

prec()

Return the $\prec$ dendriform product.

This is the sum over all possible ways to identify the rightmost path in x and the leftmost path in y, with the additional condition that the root vertex of the result comes from x.

The usual symbol for this operation is $\prec$.

See also

product(), *succ()*, *over()*, *under()*

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = A.gen(0)
sage: A.prec(x, x)
B[[., [., .]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreeDendriform(QQ)
>>> RT = A.basis().keys()
>>> x = A.gen(Integer(0))
>>> A.prec(x, x)
B[[., [., .]]]
```

prec_product_on_basis(*x*, *y*)

Return the $\prec$ dendriform product of two trees.

This is the sum over all possible ways of identifying the rightmost path in x and the leftmost path in y, with the additional condition that the root vertex of the result comes from x.

The usual symbol for this operation is $\prec$.

See also

- *product_on_basis()*, *succ_product_on_basis()*

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = RT([])
sage: A.prec_product_on_basis(x, x)
B[[., [., .]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreeDendriform(QQ)
>>> RT = A.basis().keys()
>>> x = RT([])
>>> A.prec_product_on_basis(x, x)
B[[., [., .]]]
```

product_on_basis(x, y)

Return the $*$ associative dendriform product of two trees.

This is the sum over all possible ways of identifying the rightmost path in x and the leftmost path in y. Every term corresponds to a shuffle of the vertices on the rightmost path in x and the vertices on the leftmost path in y.

See also

- *succ_product_on_basis()*, *prec_product_on_basis()*

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = RT([])
sage: A.product_on_basis(x, x)
B[[., [., .]]] + B[[[., .], .]]
```

```
>>> from sage.all import *
>>> A = algebras.FreeDendriform(QQ)
>>> RT = A.basis().keys()
>>> x = RT([])
>>> A.product_on_basis(x, x)
B[[., [., .]]] + B[[[., .], .]]
```

some_elements()

Return some elements of the free dendriform algebra.

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: A.some_elements()
[B[.],
 B[[., .]],
 B[[., [., .]]] + B[[[., .], .]],
 B[.] + B[[., [., .]]] + B[[[., .], .]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreeDendriform(QQ)
>>> A.some_elements()
[B[.],
 B[[., .]],
 B[[., [., .]]] + B[[[., .], .]],
 B[.] + B[[., [., .]]] + B[[[., .], .]]]
```

With several generators:

```
sage: A = algebras.FreeDendriform(QQ, 'xy')
sage: A.some_elements()
[B[.],
 B[x[., .]],
 B[x[., x[., .]]] + B[x[x[., .], .]],
 B[.] + B[x[., x[., .]]] + B[x[x[., .], .]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreeDendriform(QQ, 'xy')
>>> A.some_elements()
[B[.],
 B[x[., .]],
 B[x[., x[., .]]] + B[x[x[., .], .]],
 B[.] + B[x[., x[., .]]] + B[x[x[., .], .]]]
```

succ()

Return the $\succ$ dendriform product.

This is the sum over all possible ways of identifying the rightmost path in x and the leftmost path in y, with the additional condition that the root vertex of the result comes from y.

The usual symbol for this operation is $\succ$.

See also

product(), *prec()*, *over()*, *under()*

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = A.gen(0)
sage: A.succ(x, x)
B[[[., .], .]]
```

```
>>> from sage.all import *
>>> A = algebras.FreeDendriform(QQ)
>>> RT = A.basis().keys()
>>> x = A.gen(Integer(0))
>>> A.succ(x, x)
B[[[., .], .]]
```

succ_product_on_basis(*x*, *y*)

Return the $\succ$ dendriform product of two trees.

This is the sum over all possible ways to identify the rightmost path in x and the leftmost path in y, with the additional condition that the root vertex of the result comes from y.

The usual symbol for this operation is $\succ$.

See also

- *product_on_basis()*, *prec_product_on_basis()*

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = RT([])
sage: A.succ_product_on_basis(x, x)
B[[[., .], .]]
```

```
>>> from sage.all import *
>>> A = algebras.FreeDendriform(QQ)
>>> RT = A.basis().keys()
>>> x = RT([])
>>> A.succ_product_on_basis(x, x)
B[[[., .], .]]
```

under()

Return the under product.

The over product $x\backslash y$ is the binary tree obtained by grafting the root of x at the leftmost leaf of y.

The usual symbol for this operation is $\backslash$.

See also

product(), *succ()*, *prec()*, *over()*

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = A.gen(0)
sage: A.under(x, x)
B[[[., .], .]]
```

```
>>> from sage.all import *
>>> A = algebras.FreeDendriform(QQ)
>>> RT = A.basis().keys()
>>> x = A.gen(Integer(0))
>>> A.under(x, x)
B[[[., .], .]]
```

variable_names()

Return the names of the variables.

EXAMPLES:

```
sage: R = algebras.FreeDendriform(QQ, 'xy')
sage: R.variable_names()
{'x', 'y'}
```

```
>>> from sage.all import *
>>> R = algebras.FreeDendriform(QQ, 'xy')
>>> R.variable_names()
{'x', 'y'}
```

5.1.113 Free Pre-Lie Algebras

AUTHORS:

- Florent Hivert, Frédéric Chapoton (2011)

class sage.combinat.free_prelie_algebra.**FreePreLieAlgebra**(*R*, *names=None*)

Bases: *CombinatorialFreeModule*

The free pre-Lie algebra.

Pre-Lie algebras are non-associative algebras, where the product $*$ satisfies

$$(x * y) * z - x * (y * z) = (x * z) * y - x * (z * y).$$

We use here the convention where the associator

$$(x, y, z) := (x * y) * z - x * (y * z)$$

is symmetric in its two rightmost arguments. This is sometimes called a right pre-Lie algebra.

They have appeared in numerical analysis and deformation theory.

The free Pre-Lie algebra on a given set E has an explicit description using rooted trees, just as the free associative algebra can be described using words. The underlying vector space has a basis indexed by finite rooted trees endowed with a map from their vertices to E. In this basis, the product of two (decorated) rooted trees $S * T$ is the sum over vertices of S of the rooted tree obtained by adding one edge from the root of T to the given vertex of S. The root of these trees is taken to be the root of S. The free pre-Lie algebra can also be considered as the free algebra over the PreLie operad.

Warning

The usual binary operator `*` can be used for the pre-Lie product. Beware that it but must be parenthesized properly, as the pre-Lie product is not associative. By default, a multiple product will be taken with left parentheses.

EXAMPLES:

```
sage: F = algebras.FreePreLie(ZZ, 'xyz')
sage: x,y,z = F.gens()
sage: (x * y) * z
```

(continues on next page)

(continued from previous page)

```
B[x[y[z[]]]] + B[x[y[], z[]]]
sage: (x * y) * z - x * (y * z) == (x * z) * y - x * (z * y)
True
```

```
>>> from sage.all import *
>>> F = algebras.FreePreLie(ZZ, 'xyz')
>>> x,y,z = F.gens()
>>> (x * y) * z
B[x[y[z[]]]] + B[x[y[], z[]]]
>>> (x * y) * z - x * (y * z) == (x * z) * y - x * (z * y)
True
```

The free pre-Lie algebra is non-associative:

```
sage: x * (y * z) == (x * y) * z
False
```

```
>>> from sage.all import *
>>> x * (y * z) == (x * y) * z
False
```

The default product is with left parentheses:

```
sage: x * y * z == (x * y) * z
True
sage: x * y * z * x == ((x * y) * z) * x
True
```

```
>>> from sage.all import *
>>> x * y * z == (x * y) * z
True
>>> x * y * z * x == ((x * y) * z) * x
True
```

The NAP product as defined in [Liv2006] is also implemented on the same vector space:

```
sage: N = F.nap_product
sage: N(x*y,z*z)
B[x[y[], z[z[]]]]
```

```
>>> from sage.all import *
>>> N = F.nap_product
>>> N(x*y,z*z)
B[x[y[], z[z[]]]]
```

When `None` is given as input, unlabelled trees are used instead:

```
sage: F1 = algebras.FreePreLie(QQ, None)
sage: w = F1.gen(0); w
B[[]]
sage: w * w * w * w
B[[[[[]]]]] + B[[[[], []]]] + 3*B[[[], [[]]]] + B[[[], [], []]]
```

```
>>> from sage.all import *
>>> F1 = algebras.FreePreLie(QQ, None)
>>> w = F1.gen(Integer(0)); w
B[[]]
>>> w * w * w * w
B[[[[[]]]]] + B[[[[], []]]] + 3*B[[[], [[]]]] + B[[[], [], []]]
```

However, it is equally possible to use labelled trees instead:

```
sage: F1 = algebras.FreePreLie(QQ, 'q')
sage: w = F1.gen(0); w
B[q[]]
sage: w * w * w * w
B[q[q[q[q[]]]]] + B[q[q[q[], q[]]]] + 3*B[q[q[], q[q[]]]] + B[q[q[], q[], q[]]]
```

```
>>> from sage.all import *
>>> F1 = algebras.FreePreLie(QQ, 'q')
>>> w = F1.gen(Integer(0)); w
B[q[]]
>>> w * w * w * w
B[q[q[q[q[]]]]] + B[q[q[q[], q[]]]] + 3*B[q[q[], q[q[]]]] + B[q[q[], q[], q[]]]
```

The set E can be infinite:

```
sage: F = algebras.FreePreLie(QQ, ZZ)
sage: w = F.gen(1); w
B[1[]]
sage: x = F.gen(2); x
B[-1[]]
sage: y = F.gen(3); y
B[2[]]
sage: w*x
B[1[-1[]]]
sage: (w*x)*y
B[1[-1[2[]]]] + B[1[-1[], 2[]]]
sage: w*(x*y)
B[1[-1[2[]]]]
```

```
>>> from sage.all import *
>>> F = algebras.FreePreLie(QQ, ZZ)
>>> w = F.gen(Integer(1)); w
B[1[]]
>>> x = F.gen(Integer(2)); x
B[-1[]]
>>> y = F.gen(Integer(3)); y
B[2[]]
>>> w*x
B[1[-1[]]]
>>> (w*x)*y
B[1[-1[2[]]]] + B[1[-1[], 2[]]]
>>> w*(x*y)
B[1[-1[2[]]]]
```

Elements of a free pre-Lie algebra can be lifted to the universal enveloping algebra of the associated Lie algebra. The universal enveloping algebra is the Grossman-Larson Hopf algebra:

```
sage: F = algebras.FreePreLie(QQ,'abc')
sage: a,b,c = F.gens()
sage: (a*b+b*c).lift()
B[#[a[b[]]]] + B[#[b[c[]]]]
```

```
>>> from sage.all import *
>>> F = algebras.FreePreLie(QQ,'abc')
>>> a,b,c = F.gens()
>>> (a*b+b*c).lift()
B[#[a[b[]]]] + B[#[b[c[]]]]
```

Note

Variables names can be `None`, a list of strings, a string or an integer. When `None` is given, unlabelled rooted trees are used. When a single string is given, each letter is taken as a variable. See *sage.combinat.words.alphabet.build_alphabet()*.

Warning

Beware that the underlying combinatorial free module is based either on `RootedTrees` or on `LabelledRootedTrees`, with no restriction on the labellings. This means that all code calling the `basis()` method would not give meaningful results, since `basis()` returns many "chaff" elements that do not belong to the algebra.

REFERENCES:

- [ChLi]
- [Liv2006]

class Element

Bases: `IndexedFreeModuleElement`

lift()

Lift element to the Grossman-Larson algebra.

EXAMPLES:

```
sage: F = algebras.FreePreLie(QQ,'abc')
sage: elt = F.an_element().lift(); elt
B[#[a[a[a[a[]]]]]] + B[#[a[a[], a[a[]]]]]
sage: parent(elt)
Grossman-Larson Hopf algebra on 3 generators ['a', 'b', 'c']
over Rational Field
```

```
>>> from sage.all import *
>>> F = algebras.FreePreLie(QQ,'abc')
>>> elt = F.an_element().lift(); elt
B[#[a[a[a[a[]]]]]] + B[#[a[a[], a[a[]]]]]
```

(continues on next page)

(continued from previous page)

```
>>> parent(elt)
Grossman-Larson Hopf algebra on 3 generators ['a', 'b', 'c']
over Rational Field
```

valuation()

Return the valuation of `self`.

EXAMPLES:

```
sage: a = algebras.FreePreLie(QQ).gen(0)
sage: a.valuation()
1
sage: (a*a).valuation()
2

sage: a, b = algebras.FreePreLie(QQ,'ab').gens()
sage: (a+b).valuation()
1
sage: (a*b).valuation()
2
sage: (a*b+a).valuation()
1
```

```
>>> from sage.all import *
>>> a = algebras.FreePreLie(QQ).gen(Integer(0))
>>> a.valuation()
1
>>> (a*a).valuation()
2

>>> a, b = algebras.FreePreLie(QQ,'ab').gens()
>>> (a+b).valuation()
1
>>> (a*b).valuation()
2
>>> (a*b+a).valuation()
1
```

algebra_generators()

Return the generators of this algebra.

These are the rooted trees with just one vertex.

EXAMPLES:

```
sage: A = algebras.FreePreLie(ZZ, 'fgh'); A
Free PreLie algebra on 3 generators ['f', 'g', 'h']
 over Integer Ring
sage: list(A.algebra_generators())
[B[f[]], B[g[]], B[h[]]]

sage: A = algebras.FreePreLie(QQ, ['x1','x2'])
sage: list(A.algebra_generators())
[B[x1[]], B[x2[]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(ZZ, 'fgh'); A
Free PreLie algebra on 3 generators ['f', 'g', 'h']
 over Integer Ring
>>> list(A.algebra_generators())
[B[f[]], B[g[]], B[h[]]]

>>> A = algebras.FreePreLie(QQ, ['x1','x2'])
>>> list(A.algebra_generators())
[B[x1[]], B[x2[]]]
```

an_element()

Return an element of `self`.

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, 'xy')
sage: A.an_element()
B[x[x[x[x[]]]]] + B[x[x[], x[x[]]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(QQ, 'xy')
>>> A.an_element()
B[x[x[x[x[]]]]] + B[x[x[], x[x[]]]]
```

bracket_on_basis(x, y)

Return the Lie bracket of two trees.

This is the commutator $[x, y] = x * y - y * x$ of the pre-Lie product.

See also

pre_Lie_product_on_basis()

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([RT([])])
sage: y = RT([x])
sage: A.bracket_on_basis(x, y)
-B[[[[], [[]]]]] + B[[[], [[[]]]]] - B[[[[]], [[]]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(QQ, None)
>>> RT = A.basis().keys()
>>> x = RT([RT([])])
>>> y = RT([x])
>>> A.bracket_on_basis(x, y)
-B[[[[], [[]]]]] + B[[[], [[[]]]]] - B[[[[]], [[]]]]
```

change_ring(R)

Return the free pre-Lie algebra in the same variables over R.

INPUT:

- `R` – a ring

EXAMPLES:

```
sage: A = algebras.FreePreLie(ZZ, 'fgh')
sage: A.change_ring(QQ)
Free PreLie algebra on 3 generators ['f', 'g', 'h'] over
Rational Field
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(ZZ, 'fgh')
>>> A.change_ring(QQ)
Free PreLie algebra on 3 generators ['f', 'g', 'h'] over
Rational Field
```

construction()

Return a pair `(F, R)`, where `F` is a *PreLieFunctor* and R is a ring, such that `F(R)` returns `self`.

EXAMPLES:

```
sage: P = algebras.FreePreLie(ZZ, 'x,y')
sage: x,y = P.gens()
sage: F, R = P.construction()
sage: F
PreLie[x,y]
sage: R
Integer Ring
sage: F(ZZ) is P
True
sage: F(QQ)
Free PreLie algebra on 2 generators ['x', 'y'] over Rational Field
```

```
>>> from sage.all import *
>>> P = algebras.FreePreLie(ZZ, 'x,y')
>>> x,y = P.gens()
>>> F, R = P.construction()
>>> F
PreLie[x,y]
>>> R
Integer Ring
>>> F(ZZ) is P
True
>>> F(QQ)
Free PreLie algebra on 2 generators ['x', 'y'] over Rational Field
```

corolla(x, y, n, N)

Return the corolla obtained with `x` as root and `y` as leaves.

INPUT:

- `x`, `y` – two elements
- `n` – integer; width of the corolla
- `N` – integer; truncation order (up to order `N` included)

OUTPUT:

the sum over all possible ways to graft `n` copies of `y` on top of `x` (with at most `N` vertices in total)

This operation can be defined by induction starting from the pre-Lie product.

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ)
sage: a = A.gen(0)
sage: b = A.corolla(a,a,1,4); b
B[[[]]]
sage: A.corolla(b,b,2,7)
B[[[[[]], [[]]]]] + 2*B[[[[]], [[[]]]]] + B[[[], [[]], [[]]]]

sage: A = algebras.FreePreLie(QQ, 'o')
sage: a = A.gen(0)
sage: b = A.corolla(a,a,1,4)

sage: A = algebras.FreePreLie(QQ,'ab')
sage: a, b = A.gens()
sage: A.corolla(a,b,1,4)
B[a[b[]]]
sage: A.corolla(b,a,3,4)
B[b[a[], a[], a[]]]

sage: A.corolla(a+b,a+b,2,4)
B[a[a[], a[]]] + 2*B[a[a[], b[]]] + B[a[b[], b[]]] + B[b[a[], a[]]] +
2*B[b[a[], b[]]] + B[b[b[], b[]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(QQ)
>>> a = A.gen(Integer(0))
>>> b = A.corolla(a,a,Integer(1),Integer(4)); b
B[[[]]]
>>> A.corolla(b,b,Integer(2),Integer(7))
B[[[[[]], [[]]]]] + 2*B[[[[]], [[[]]]]] + B[[[], [[]], [[]]]]

>>> A = algebras.FreePreLie(QQ, 'o')
>>> a = A.gen(Integer(0))
>>> b = A.corolla(a,a,Integer(1),Integer(4))

>>> A = algebras.FreePreLie(QQ,'ab')
>>> a, b = A.gens()
>>> A.corolla(a,b,Integer(1),Integer(4))
B[a[b[]]]
>>> A.corolla(b,a,Integer(3),Integer(4))
B[b[a[], a[], a[]]]

>>> A.corolla(a+b,a+b,Integer(2),Integer(4))
B[a[a[], a[]]] + 2*B[a[a[], b[]]] + B[a[b[], b[]]] + B[b[a[], a[]]] +
2*B[b[a[], b[]]] + B[b[b[], b[]]]
```

degree_on_basis(*t*)

Return the degree of a rooted tree in the free Pre-Lie algebra.

This is the number of vertices.

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: A.degree_on_basis(RT([RT([])]))
2
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(QQ, None)
>>> RT = A.basis().keys()
>>> A.degree_on_basis(RT([RT([])]))
2
```

gen(*i*)

Return the `i`-th generator of the algebra.

INPUT:

- `i` – integer

EXAMPLES:

```
sage: F = algebras.FreePreLie(ZZ, 'xyz')
sage: F.gen(0)
B[x[]]

sage: F.gen(4)
Traceback (most recent call last):
...
IndexError: argument i (= 4) must be between 0 and 2
```

```
>>> from sage.all import *
>>> F = algebras.FreePreLie(ZZ, 'xyz')
>>> F.gen(Integer(0))
B[x[]]

>>> F.gen(Integer(4))
Traceback (most recent call last):
...
IndexError: argument i (= 4) must be between 0 and 2
```

gens()

Return the generators of `self` (as an algebra).

EXAMPLES:

```
sage: A = algebras.FreePreLie(ZZ, 'fgh')
sage: A.gens()
(B[f[]], B[g[]], B[h[]])
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(ZZ, 'fgh')
>>> A.gens()
(B[f[]], B[g[]], B[h[]])
```

group_product(*x*, *y*, *n*, *N=10*)

Return the truncated group product of `x` and `y`.

This is a weighted sum of all corollas with up to `n` leaves, with `x` as root and `y` as leaves.

The result is computed up to order `N` (included).

When considered with infinitely many terms and infinite precision, this is an analogue of the Baker-Campbell-Hausdorff formula: it defines an associative product on the completed free pre-Lie algebra.

INPUT:

- `x`, `y` – two elements
- `n` – integer; the maximal width of corollas
- `N` – integer (default: 10); truncation order

EXAMPLES:

In the free pre-Lie algebra with one generator:

```
sage: PL = algebras.FreePreLie(QQ)
sage: a = PL.gen(0)
sage: PL.group_product(a, a, 3, 3)
B[[]] + B[[[]]] + 1/2*B[[[], []]]
```

```
>>> from sage.all import *
>>> PL = algebras.FreePreLie(QQ)
>>> a = PL.gen(Integer(0))
>>> PL.group_product(a, a, Integer(3), Integer(3))
B[[]] + B[[[]]] + 1/2*B[[[], []]]
```

In the free pre-Lie algebra with several generators:

```
sage: PL = algebras.FreePreLie(QQ,'@O')
sage: a, b = PL.gens()
sage: PL.group_product(a, b, 3, 3)
B[@[]] + B[@[O[]]] + 1/2*B[@[O[], O[]]]
sage: PL.group_product(a, b, 3, 10)
B[@[]] + B[@[O[]]] + 1/2*B[@[O[], O[]]] + 1/6*B[@[O[], O[], O[]]]
```

```
>>> from sage.all import *
>>> PL = algebras.FreePreLie(QQ,'@O')
>>> a, b = PL.gens()
>>> PL.group_product(a, b, Integer(3), Integer(3))
B[@[]] + B[@[O[]]] + 1/2*B[@[O[], O[]]]
>>> PL.group_product(a, b, Integer(3), Integer(10))
B[@[]] + B[@[O[]]] + 1/2*B[@[O[], O[]]] + 1/6*B[@[O[], O[], O[]]]
```

nap_product()

Return the NAP product.

See also

nap_product_on_basis()

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = A(RT([RT([])]))
sage: A.nap_product(x, x)
B[[[], [[]]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(QQ, None)
>>> RT = A.basis().keys()
>>> x = A(RT([RT([])]))
>>> A.nap_product(x, x)
B[[[], [[]]]]
```

nap_product_on_basis(*x*, *y*)

Return the NAP product of two trees.

This is the grafting of the root of y over the root of x. The root of the resulting tree is the root of x.

See also

nap_product()

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([RT([])])
sage: A.nap_product_on_basis(x, x)
B[[[], [[]]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(QQ, None)
>>> RT = A.basis().keys()
>>> x = RT([RT([])])
>>> A.nap_product_on_basis(x, x)
B[[[], [[]]]]
```

pre_Lie_product()

Return the pre-Lie product.

See also

pre_Lie_product_on_basis()

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = A(RT([RT([])]))
```

(continues on next page)

(continued from previous page)

```
sage: A.pre_Lie_product(x, x)
B[[[[[]]]]] + B[[[], [[]]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(QQ, None)
>>> RT = A.basis().keys()
>>> x = A(RT([RT([])]))
>>> A.pre_Lie_product(x, x)
B[[[[[]]]]] + B[[[], [[]]]]
```

pre_Lie_product_on_basis(x, y)

Return the pre-Lie product of two trees.

This is the sum over all graftings of the root of y over a vertex of x. The root of the resulting trees is the root of x.

See also

pre_Lie_product()

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([RT([])])
sage: A.product_on_basis(x, x)
B[[[[[]]]]] + B[[[], [[]]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(QQ, None)
>>> RT = A.basis().keys()
>>> x = RT([RT([])])
>>> A.product_on_basis(x, x)
B[[[[[]]]]] + B[[[], [[]]]]
```

product_on_basis(x, y)

Return the pre-Lie product of two trees.

This is the sum over all graftings of the root of y over a vertex of x. The root of the resulting trees is the root of x.

See also

pre_Lie_product()

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([RT([])])
```

(continues on next page)

(continued from previous page)

```
sage: A.product_on_basis(x, x)
B[[[[[]]]]] + B[[[], [[]]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(QQ, None)
>>> RT = A.basis().keys()
>>> x = RT([RT([])])
>>> A.product_on_basis(x, x)
B[[[[[]]]]] + B[[[], [[]]]]
```

some_elements()

Return some elements of the free pre-Lie algebra.

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: A.some_elements()
[B[[]], B[[[]]], B[[[[[]]]]] + B[[[], [[]]]], B[[[[]]]] + B[[[], []]],␣
↪B[[[]]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(QQ, None)
>>> A.some_elements()
[B[[]], B[[[]]], B[[[[[]]]]] + B[[[], [[]]]], B[[[[]]]] + B[[[], []]],␣
↪B[[[]]]]
```

With several generators:

```
sage: A = algebras.FreePreLie(QQ, 'xy')
sage: A.some_elements()
[B[x[]],
 B[x[x[]]],
 B[x[x[x[x[]]]]] + B[x[x[], x[x[]]]],
 B[x[x[x[]]]] + B[x[x[], x[]]],
 B[x[x[y[]]]] + B[x[x[], y[]]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(QQ, 'xy')
>>> A.some_elements()
[B[x[]],
 B[x[x[]]],
 B[x[x[x[x[]]]]] + B[x[x[], x[x[]]]],
 B[x[x[x[]]]] + B[x[x[], x[]]],
 B[x[x[y[]]]] + B[x[x[], y[]]]]
```

variable_names()

Return the names of the variables.

EXAMPLES:

```
sage: R = algebras.FreePreLie(QQ, 'xy')
sage: R.variable_names()
```

(continues on next page)

(continued from previous page)

```
{'x', 'y'}

sage: R = algebras.FreePreLie(QQ, None)
sage: R.variable_names()
{'o'}
```

```
>>> from sage.all import *
>>> R = algebras.FreePreLie(QQ, 'xy')
>>> R.variable_names()
{'x', 'y'}

>>> R = algebras.FreePreLie(QQ, None)
>>> R.variable_names()
{'o'}
```

class sage.combinat.free_prelie_algebra.**PreLieFunctor**(*vars*)

Bases: ConstructionFunctor

A constructor for pre-Lie algebras.

EXAMPLES:

```
sage: P = algebras.FreePreLie(ZZ, 'x,y')
sage: x,y = P.gens()
sage: F = P.construction()[0]; F
PreLie[x,y]

sage: A = GF(5)['a,b']
sage: a, b = A.gens()
sage: F(A)
Free PreLie algebra on 2 generators ['x', 'y'] over Multivariate Polynomial Ring␣
↪in a, b over Finite Field of size 5

sage: f = A.hom([a+b,a-b],A)
sage: F(f)
Generic endomorphism of Free PreLie algebra on 2 generators ['x', 'y']
over Multivariate Polynomial Ring in a, b over Finite Field of size 5

sage: F(f)(a * F(A)(x))
(a+b)*B[x[]]
```

```
>>> from sage.all import *
>>> P = algebras.FreePreLie(ZZ, 'x,y')
>>> x,y = P.gens()
>>> F = P.construction()[Integer(0)]; F
PreLie[x,y]

>>> A = GF(Integer(5))['a,b']
>>> a, b = A.gens()
>>> F(A)
Free PreLie algebra on 2 generators ['x', 'y'] over Multivariate Polynomial Ring␣
↪in a, b over Finite Field of size 5
```

(continues on next page)

(continued from previous page)

```
>>> f = A.hom([a+b,a-b],A)
>>> F(f)
Generic endomorphism of Free PreLie algebra on 2 generators ['x', 'y']
over Multivariate Polynomial Ring in a, b over Finite Field of size 5

>>> F(f)(a * F(A)(x))
(a+b)*B[x[]]
```

merge(*other*)

Merge `self` with another construction functor, or return None.

EXAMPLES:

```
sage: F = sage.combinat.free_prelie_algebra.PreLieFunctor(['x','y'])
sage: G = sage.combinat.free_prelie_algebra.PreLieFunctor(['t'])
sage: F.merge(G)
PreLie[x,y,t]
sage: F.merge(F)
PreLie[x,y]
```

```
>>> from sage.all import *
>>> F = sage.combinat.free_prelie_algebra.PreLieFunctor(['x','y'])
>>> G = sage.combinat.free_prelie_algebra.PreLieFunctor(['t'])
>>> F.merge(G)
PreLie[x,y,t]
>>> F.merge(F)
PreLie[x,y]
```

Now some actual use cases:

```
sage: R = algebras.FreePreLie(ZZ, 'xyz')
sage: x,y,z = R.gens()
sage: 1/2 * x
1/2*B[x[]]
sage: parent(1/2 * x)
Free PreLie algebra on 3 generators ['x', 'y', 'z'] over Rational Field

sage: S = algebras.FreePreLie(QQ, 'zt')
sage: z,t = S.gens()
sage: x + t
B[t[]] + B[x[]]
sage: parent(x + t)
Free PreLie algebra on 4 generators ['z', 't', 'x', 'y'] over Rational Field
```

```
>>> from sage.all import *
>>> R = algebras.FreePreLie(ZZ, 'xyz')
>>> x,y,z = R.gens()
>>> Integer(1)/Integer(2) * x
1/2*B[x[]]
>>> parent(Integer(1)/Integer(2) * x)
Free PreLie algebra on 3 generators ['x', 'y', 'z'] over Rational Field
```

(continues on next page)

(continued from previous page)

```
>>> S = algebras.FreePreLie(QQ, 'zt')
>>> z,t = S.gens()
>>> x + t
B[t[]] + B[x[]]
>>> parent(x + t)
Free PreLie algebra on 4 generators ['z', 't', 'x', 'y'] over Rational Field
```

rank = 9

sage.combinat.free_prelie_algebra.**corolla_gen**(*tx*, *list_ty*, *labels=True*)

Yield the terms in the corolla with given bottom tree and top trees.

These are the possible terms in the simultaneous grafting of the top trees on vertices of the bottom tree.

INPUT:

- `tx` – a tree
- `list_ty` – list of trees

EXAMPLES:

```
sage: from sage.combinat.free_prelie_algebra import corolla_gen
sage: a = algebras.FreePreLie(QQ).gen(0)
sage: ta = a.support()[0]
sage: list(corolla_gen(ta,[ta],False))
[[[]]]

sage: a, b = algebras.FreePreLie(QQ,'ab').gens()
sage: ta = a.support()[0]
sage: tb = b.support()[0]
sage: ab = (a*b).support()[0]
sage: list(corolla_gen(ta,[tb]))
[a[b[]]]
sage: list(corolla_gen(tb,[ta,ta]))
[b[a[], a[]]]
sage: list(corolla_gen(ab,[ab,ta]))
[a[a[], b[], a[b[]]], a[a[b[]], b[a[]]], a[a[], b[a[b[]]]],
a[b[a[], a[b[]]]]]
```

```
>>> from sage.all import *
>>> from sage.combinat.free_prelie_algebra import corolla_gen
>>> a = algebras.FreePreLie(QQ).gen(Integer(0))
>>> ta = a.support()[Integer(0)]
>>> list(corolla_gen(ta,[ta],False))
[[[]]]

>>> a, b = algebras.FreePreLie(QQ,'ab').gens()
>>> ta = a.support()[Integer(0)]
>>> tb = b.support()[Integer(0)]
>>> ab = (a*b).support()[Integer(0)]
>>> list(corolla_gen(ta,[tb]))
[a[b[]]]
```

(continues on next page)

(continued from previous page)

```
>>> list(corolla_gen(tb,[ta,ta]))
[b[a[], a[]]]
>>> list(corolla_gen(ab,[ab,ta]))
[a[a[], b[], a[b[]]], a[a[b[]], b[a[]]], a[a[], b[a[b[]]]],
a[b[a[], a[b[]]]]]
```

sage.combinat.free_prelie_algebra.**tree_from_sortkey**(*ch*, *labels=True*)

Transform a list of `(valence, label)` into a tree and a remainder.

This is like an inverse of the `sort_key` method.

INPUT:

- `ch` – list of pairs `(integer, label)`
- `labels` – boolean (default: `True`); whether to use labelled trees

OUTPUT:

a pair `(tree, remainder of the input)`

EXAMPLES:

```
sage: from sage.combinat.free_prelie_algebra import tree_from_sortkey
sage: a = algebras.FreePreLie(QQ).gen(0)
sage: t = (a*a*a*a).support()
sage: all(tree_from_sortkey(u.sort_key(), False)[0] == u for u in t)
True

sage: a, b = algebras.FreePreLie(QQ,'ab').gens()
sage: t = (a*b*a*b).support()
sage: all(tree_from_sortkey(u.sort_key())[0] == u for u in t)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.free_prelie_algebra import tree_from_sortkey
>>> a = algebras.FreePreLie(QQ).gen(Integer(0))
>>> t = (a*a*a*a).support()
>>> all(tree_from_sortkey(u.sort_key(), False)[Integer(0)] == u for u in t)
True

>>> a, b = algebras.FreePreLie(QQ,'ab').gens()
>>> t = (a*b*a*b).support()
>>> all(tree_from_sortkey(u.sort_key())[Integer(0)] == u for u in t)
True
```

5.1.114 Fully packed loops

AUTHORS:

- Vincent Knight, James Campbell, Kevin Dilks, Emily Gunawan (2015): Initial version
- Vincent Delecroix (2017): cleaning and enhanced plotting function

class sage.combinat.fully_packed_loop.**FullyPackedLoop**(*parent*, *generator*)

Bases: `Element`

A class for fully packed loops.

A fully packed loop is a collection of non-intersecting lattice paths on a square grid such that every vertex is part of some path, and the paths are either closed internal loops or have endpoints corresponding to alternate points on the boundary [Pro2001]. They are known to be in bijection with alternating sign matrices.

See also

AlternatingSignMatrix

To each fully packed loop, we assign a link pattern, which is the non-crossing matching attained by seeing which points on the boundary are connected by open paths in the fully packed loop.

We can create a fully packed loop using the corresponding alternating sign matrix and also extract the link pattern:

```
sage: A = AlternatingSignMatrix([[0, 0, 1], [0, 1, 0], [1, 0, 0]])
sage: fpl = FullyPackedLoop(A)
sage: fpl.link_pattern()
[(1, 4), (2, 3), (5, 6)]
sage: fpl
    |         |
    |         |
    + -- +    +
         |    |
         |    |
 -- +    +    + --
    |    |
    |    |
    +    + -- +
    |         |
    |         |
sage: B = AlternatingSignMatrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
sage: fplb = FullyPackedLoop(B)
sage: fplb.link_pattern()
[(1, 6), (2, 5), (3, 4)]
sage: fplb
    |         |
    |         |
    +    + -- +
    |    |
    |    |
 -- +    +    + --
         |    |
         |    |
    + -- +    +
    |         |
    |         |
```

```
>>> from sage.all import *
>>> A = AlternatingSignMatrix([[Integer(0), Integer(0), Integer(1)], [Integer(0),␣
↪Integer(1), Integer(0)], [Integer(1), Integer(0), Integer(0)]])
>>> fpl = FullyPackedLoop(A)
>>> fpl.link_pattern()
```

(continues on next page)

(continued from previous page)

```
[(1, 4), (2, 3), (5, 6)]
>>> fpl
   |         |
   |         |
   + -- +    +
        |    |
        |    |
-- +    +    + --
   |    |
   |    |
   +    + -- +
   |         |
   |         |
>>> B = AlternatingSignMatrix([[Integer(1), Integer(0), Integer(0)], [Integer(0),␣
↪Integer(1), Integer(0)], [Integer(0), Integer(0), Integer(1)]])
>>> fplb = FullyPackedLoop(B)
>>> fplb.link_pattern()
[(1, 6), (2, 5), (3, 4)]
>>> fplb
   |         |
   |         |
   +    + -- +
   |    |
   |    |
-- +    +    + --
        |    |
        |    |
   + -- +    +
   |         |
   |         |
```

The class also has a plot method:

```
sage: fpl.plot()                                                            #␣
↪needs sage.plot
Graphics object consisting of 3 graphics primitives
```

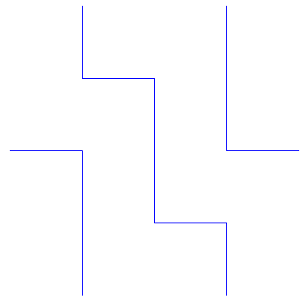
```
>>> from sage.all import *
>>> fpl.plot()                                                            #␣
↪needs sage.plot
Graphics object consisting of 3 graphics primitives
```

which gives:

Note that we can also create a fully packed loop from a six vertex model configuration:

```
sage: S = SixVertexModel(3, boundary_conditions='ice').from_alternating_sign_
↪matrix(A)
sage: S
    ^    ^    ^
    |    |    |
--> # -> # -> # <--
    ^    ^    |
```

(continues on next page)



(continued from previous page)

```
     |     |     V
--> # -> # <- # <--
     ^     |     |
     |     V     V
--> # <- # <- # <--
     |     |     |
     V     V     V
sage: fpl = FullyPackedLoop(S)
sage: fpl
    │         │
    │         │
    + ── +    +
         │    │
         │    │
── +     +    + ──
    │    │
    │    │
    +    + ── +
    │         │
    │         │
```

```
>>> from sage.all import *
>>> S = SixVertexModel(Integer(3), boundary_conditions='ice').from_alternating_
↪sign_matrix(A)
>>> S
     ^     ^     ^
     |     |     |
--> # -> # -> # <--
     ^     ^     |
     |     |     V
--> # -> # <- # <--
     ^     |     |
     |     V     V
--> # <- # <- # <--
     |     |     |
     V     V     V
>>> fpl = FullyPackedLoop(S)
>>> fpl
    │         │
    │         │
    + ── +    +
```

(continues on next page)

(continued from previous page)

```
         |     |
         |     |
── +     +     + ──
   |     |
   |     |
   +     + ── +
   |          |
   |          |
```

Once we have a fully packed loop we can obtain the corresponding alternating sign matrix:

```
sage: fpl.to_alternating_sign_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
```

```
>>> from sage.all import *
>>> fpl.to_alternating_sign_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
```

Here are some more examples using bigger ASMs:

```
sage: A = AlternatingSignMatrix([[0,1,0,0],[0,0,1,0],[1,-1,0,1],[0,1,0,0]])
sage: S = SixVertexModel(4, boundary_conditions='ice').from_alternating_sign_
↪matrix(A)
sage: fpl = FullyPackedLoop(S)
sage: fpl.link_pattern()
[(1, 2), (3, 6), (4, 5), (7, 8)]
sage: fpl
   |          |
   |          |
   + ── + ── +     + ──
                   |
                   |
── +     + ── + ── +
   |     |
   |     |
   +     +     + ── + ──
   |     |     |
   |     |     |
── +     +     + ── +
         |          |
         |          |

sage: m = AlternatingSignMatrix([[0,0,1,0,0,0],
....:                            [1,0,-1,0,1,0],
....:                            [0,0,0,1,0,0],
....:                            [0,1,0,0,-1,1],
....:                            [0,0,0,0,1,0],
....:                            [0,0,1,0,0,0]])
```

(continues on next page)

(continued from previous page)

```
sage: fpl = FullyPackedLoop(m)
sage: fpl.link_pattern()
[(1, 12), (2, 7), (3, 4), (5, 6), (8, 9), (10, 11)]
sage: fpl
   |         |         |

More examples:

We can initiate a fully packed loop using an alternating sign matrix:

```
sage: A = AlternatingSignMatrix([[0, 0, 1], [0, 1, 0], [1, 0, 0]])
sage: fpl = FullyPackedLoop(A)
sage: fpl
    |         |
    |         |
    + -- +    +
         |    |
         |    |
 -- +    +    + --
    |    |
    |    |
    +    + -- +
    |         |
    |         |
sage: FullyPackedLoops(3)(A) == fpl
True
```

```
>>> from sage.all import *
>>> A = AlternatingSignMatrix([[Integer(0), Integer(0), Integer(1)], [Integer(0),␣
↪Integer(1), Integer(0)], [Integer(1), Integer(0), Integer(0)]])
>>> fpl = FullyPackedLoop(A)
>>> fpl
    |         |
    |         |
    + -- +    +
         |    |
         |    |
 -- +    +    + --
```

(continues on next page)

(continued from previous page)

```
    |     |
    |     |
    +     + ── +
    |          |
    |          |
>>> FullyPackedLoops(Integer(3))(A) == fpl
True
```

We can also input a matrix:

```
sage: FullyPackedLoop([[0, 0, 1], [0, 1, 0], [1, 0, 0]])
    |          |
    |          |
    + ── +     +
         |     |
         |     |
 ── +    +     + ──
    |    |
    |    |
    +    + ── +
    |          |
    |          |
sage: FullyPackedLoop([[0, 0, 1], [0, 1, 0], [1, 0, 0]]) ==\
....: FullyPackedLoops(3)([[0, 0, 1], [0, 1, 0], [1, 0, 0]])
True
```

```
>>> from sage.all import *
>>> FullyPackedLoop([[Integer(0), Integer(0), Integer(1)], [Integer(0),
↪Integer(1), Integer(0)], [Integer(1), Integer(0), Integer(0)]])
    |          |
    |          |
    + ── +     +
         |     |
         |     |
 ── +    +     + ──
    |    |
    |    |
    +    + ── +
    |          |
    |          |
>>> FullyPackedLoop([[Integer(0), Integer(0), Integer(1)], [Integer(0),
↪Integer(1), Integer(0)], [Integer(1), Integer(0), Integer(0)]])
↪==FullyPackedLoops(Integer(3))([[Integer(0), Integer(0), Integer(1)],
↪[Integer(0), Integer(1), Integer(0)], [Integer(1), Integer(0), Integer(0)]])
True
```

Otherwise we initiate a fully packed loop using a six vertex model:

```
sage: S = SixVertexModel(3, boundary_conditions='ice').from_alternating_sign_
↪matrix(A)
sage: fpl = FullyPackedLoop(S)
sage: fpl
```

(continues on next page)

(continued from previous page)

```
    |         |
    |         |
    + -- +    +
         |    |
         |    |
 -- +    +    + --
    |    |
    |    |
    +    + -- +
    |         |
    |         |

sage: FullyPackedLoops(3)(S) == FullyPackedLoop(S)
True

sage: fpl.six_vertex_model().to_alternating_sign_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
```

```
>>> from sage.all import *
>>> S = SixVertexModel(Integer(3), boundary_conditions='ice').from_alternating_
↪sign_matrix(A)
>>> fpl = FullyPackedLoop(S)
>>> fpl
    |         |
    |         |
    + -- +    +
         |    |
         |    |
 -- +    +    + --
    |    |
    |    |
    +    + -- +
    |         |
    |         |

>>> FullyPackedLoops(Integer(3))(S) == FullyPackedLoop(S)
True

>>> fpl.six_vertex_model().to_alternating_sign_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
```

We can also input the matrix associated to a six vertex model:

```
sage: SixVertexModel(2)([[3,1],[5,3]])
    ^    ^
    |    |
--> # <- # <--
    |    ^
```

(continues on next page)

(continued from previous page)

```
    V     |
--> # -> # <--
    |     |
    V     V

sage: FullyPackedLoop([[3,1],[5,3]])
    |
    |
    +     + ——
    |     |
    |     |
 —— +     +
          |
          |

sage: FullyPackedLoops(2)([[3,1],[5,3]]) == FullyPackedLoop([[3,1],[5,3]])
True
```

```
>>> from sage.all import *
>>> SixVertexModel(Integer(2))([[Integer(3),Integer(1)],[Integer(5),Integer(3)]])
    ^     ^
    |     |
--> # <- # <--
    |     ^
    V     |
--> # -> # <--
    |     |
    V     V

>>> FullyPackedLoop([[Integer(3),Integer(1)],[Integer(5),Integer(3)]])
    |
    |
    +     + ——
    |     |
    |     |
 —— +     +
          |
          |

>>> FullyPackedLoops(Integer(2))([[Integer(3),Integer(1)],[Integer(5),
↪Integer(3)]]) == FullyPackedLoop([[Integer(3),Integer(1)],[Integer(5),
↪Integer(3)]])
True
```

Note that the matrix corresponding to a six vertex model without the ice boundary condition is not allowed:

```
sage: SixVertexModel(2)([[3,1],[5,5]])
    ^     ^
    |     |
--> # <- # <--
    |     ^
    V     V
```

(continues on next page)

(continued from previous page)

```
--> # -> # -->
    |     |
    V     V

sage: FullyPackedLoop([[3,1],[5,5]])
Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix

sage: FullyPackedLoops(2)([[3,1],[5,5]])
Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix
```

```
>>> from sage.all import *
>>> SixVertexModel(Integer(2))([[Integer(3),Integer(1)],[Integer(5),Integer(5)]])
    ^     ^
    |     |
--> # <- # <--
    |     ^
    V     V
--> # -> # -->
    |     |
    V     V

>>> FullyPackedLoop([[Integer(3),Integer(1)],[Integer(5),Integer(5)]])
Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix

>>> FullyPackedLoops(Integer(2))([[Integer(3),Integer(1)],[Integer(5),
↪Integer(5)]])
Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix
```

Note that if anything else is used to generate the fully packed loop an error will occur:

```
sage: fpl = FullyPackedLoop(5)
Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix

sage: fpl = FullyPackedLoop((1, 2, 3))
Traceback (most recent call last):
...
ValueError: the alternating sign matrices must be square

sage: SVM = SixVertexModel(3)[0]
sage: FullyPackedLoop(SVM)
Traceback (most recent call last):
...
```

(continues on next page)

(continued from previous page)

```
ValueError: invalid alternating sign matrix
```

```
>>> from sage.all import *
>>> fpl = FullyPackedLoop(Integer(5))
Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix

>>> fpl = FullyPackedLoop((Integer(1), Integer(2), Integer(3)))
Traceback (most recent call last):
...
ValueError: the alternating sign matrices must be square

>>> SVM = SixVertexModel(Integer(3))[Integer(0)]
>>> FullyPackedLoop(SVM)
Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix
```

- [Str2015]

gyration()

Return the fully packed loop obtained by applying gyration to the alternating sign matrix in bijection with `self`.

Gyration was first defined in [Wie2000] as an action on fully-packed loops.

EXAMPLES:

```
sage: A = AlternatingSignMatrix([[1, 0, 0],[0, 1, 0],[0, 0, 1]])
sage: fpl = FullyPackedLoop(A)
sage: fpl.gyration().to_alternating_sign_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
sage: asm = AlternatingSignMatrix([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: f = FullyPackedLoop(asm)
sage: f.gyration().to_alternating_sign_matrix()
[0 1 0]
[0 0 1]
[1 0 0]
```

```
>>> from sage.all import *
>>> A = AlternatingSignMatrix([[Integer(1), Integer(0), Integer(0)],
↪[Integer(0), Integer(1), Integer(0)],[Integer(0), Integer(0), Integer(1)]])
>>> fpl = FullyPackedLoop(A)
>>> fpl.gyration().to_alternating_sign_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
```

(continues on next page)

(continued from previous page)

```
>>> asm = AlternatingSignMatrix([[Integer(0), Integer(0), Integer(1)],
↪[Integer(1), Integer(0), Integer(0)],[Integer(0), Integer(1), Integer(0)]])
>>> f = FullyPackedLoop(asm)
>>> f.gyration().to_alternating_sign_matrix()
[0 1 0]
[0 0 1]
[1 0 0]
```

link_pattern()

Return a link pattern corresponding to a fully packed loop.

Here we define a link pattern LP to be a partition of the list $[1, ..., 2k]$ into 2-element sets (such a partition is also known as a perfect matching) such that the following non-crossing condition holds: Let the numbers $1, ..., 2k$ be written on the perimeter of a circle. For every 2-element set (a, b) of the partition LP, draw an arc linking the two numbers a and b. We say that LP is non-crossing if every arc can be drawn so that no two arcs intersect.

Since every endpoint of a fully packed loop fpl is connected to a different endpoint, there is a natural surjection from the fully packed loops on an nxn grid onto the link patterns on the list $[1, \dots, 2n]$. The pairs of connected endpoints of a fully packed loop fpl correspond to the 2-element tuples of the corresponding link pattern.

See also

PerfectMatching

Note

by convention, we choose the top left vertex to be even. See [Pro2001] and [Str2015].

EXAMPLES:

We can extract the underlying link pattern (a non-crossing partition) from a fully packed loop:

```
sage: A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: fpl = FullyPackedLoop(A)
sage: fpl.link_pattern()
[(1, 2), (3, 6), (4, 5)]

sage: B = AlternatingSignMatrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
sage: fpl = FullyPackedLoop(B)
sage: fpl.link_pattern()
[(1, 6), (2, 5), (3, 4)]
```

```
>>> from sage.all import *
>>> A = AlternatingSignMatrix([[Integer(0), Integer(1), Integer(0)],␣
↪[Integer(1), -Integer(1), Integer(1)], [Integer(0), Integer(1),␣
↪Integer(0)]])
>>> fpl = FullyPackedLoop(A)
>>> fpl.link_pattern()
[(1, 2), (3, 6), (4, 5)]
```

(continues on next page)

(continued from previous page)

```
>>> B = AlternatingSignMatrix([[Integer(1), Integer(0), Integer(0)],␣
↪[Integer(0), Integer(1), Integer(0)], [Integer(0), Integer(0), Integer(1)]])
>>> fpl = FullyPackedLoop(B)
>>> fpl.link_pattern()
[(1, 6), (2, 5), (3, 4)]
```

Gyration on an alternating sign matrix/fully packed loop `fpl` corresponds to a rotation (i.e. a becomes a-1 mod 2n) of the link pattern corresponding to `fpl`:

```
sage: ASMs = AlternatingSignMatrices(3).list()
sage: ncp = FullyPackedLoop(ASMs[1]).link_pattern()
sage: rotated_ncp=[]
sage: for (a,b) in ncp:
....:     for i in range(5):
....:         a,b=a%6+1,b%6+1;
....:     rotated_ncp.append((a,b))
sage: PerfectMatching(ASMs[1].gyration().to_fully_packed_loop().link_
↪pattern()) ==\
....:     PerfectMatching(rotated_ncp)
True

sage: fpl = FullyPackedLoop(ASMs[0])
sage: ncp = fpl.link_pattern()
sage: rotated_ncp=[]
sage: for (a,b) in ncp:
....:     for i in range(5):
....:         a,b=a%6+1,b%6+1;
....:     rotated_ncp.append((a,b))
sage: PerfectMatching(ASMs[0].gyration().to_fully_packed_loop().link_
↪pattern()) ==\
....:     PerfectMatching(rotated_ncp)
True

sage: mat = AlternatingSignMatrix([[0,0,1,0,0,0,0],[1,0,-1,0,1,0,0],[0,0,1,0,
↪0,0,0],
....:     [0,1,-1,0,0,1,0],[0,0,1,0,0,0,0],[0,0,0,1,0,0,0],[0,0,0,0,0,0,1]])
sage: fpl = FullyPackedLoop(mat) # n=7
sage: ncp = fpl.link_pattern()
sage: rotated_ncp=[]
sage: for (a,b) in ncp:
....:     for i in range(13):
....:         a,b=a%14+1,b%14+1;
....:     rotated_ncp.append((a,b))
sage: PerfectMatching(mat.gyration().to_fully_packed_loop().link_pattern())␣
↪==\
....:     PerfectMatching(rotated_ncp)
True

sage: mat = AlternatingSignMatrix([[0,0,0,1,0,0], [0,0,1,-1,1,0], [0,1,0,0,-1,
↪1], [1,0,-1,1,0,0],
....:     [0,0,1,0,0,0], [0,0,0,0,1,0]])
sage: fpl = FullyPackedLoop(mat)
```

>>> PerfectMatching(mat.gyration().to_fully_packed_loop().link_pattern()) ==
→ PerfectMatching(rotated_ncp)
True
```

plot(*link=True*, *loop=True*, *loop_fill=False*, ***options*)

Return a graphical object of the Fully Packed Loop.

Each option can be specified separately for links (the curves that join boundary points) and the loops. In order to do so, you need to prefix its name with either `'link_'` or `'loop_'`. As an example, setting `color='red'` will color both links and loops in red while setting `link_color='red'` will only apply the color option for the links.

INPUT:

- `link`, `loop` – boolean (default: `True`); whether to plot the links or the loops
- `color`, `link_color`, `loop_color` – (optional) string or RGB triple
- `colors`, `link_colors`, `loop_colors` – (optional) list of colors
- `color_map`, `link_color_map`, `loop_color_map` – (string, optional) a name of a matplotlib color map for the link or the loop
- `link_color_randomize` – boolean (default: `False`); when `link_colors` or `link_color_map` is specified it randomizes its order. Setting this option to `True` makes it unlikely to have two neighboring links with the same color.
- `loop_fill` – (boolean, optional) whether to fill the interior of the loops

EXAMPLES:

To plot the fully packed loop associated to the following alternating sign matrix

$$\begin{pmatrix} 0 & 1 & 1 \\ 1 & -1 & 1 \\ 0 & 1 & 0 \end{pmatrix}$$

simply do:

```
sage: A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: fpl = FullyPackedLoop(A)
```

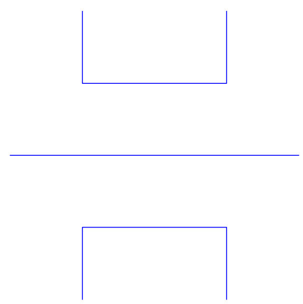
(continues on next page)

(continued from previous page)

```
sage: fpl.plot()                                                  #␣
↪needs sage.plot
Graphics object consisting of 3 graphics primitives
```

```
>>> from sage.all import *
>>> A = AlternatingSignMatrix([[Integer(0), Integer(1), Integer(0)],␣
↪[Integer(1), -Integer(1), Integer(1)], [Integer(0), Integer(1),␣
↪Integer(0)]])
>>> fpl = FullyPackedLoop(A)
>>> fpl.plot()                                                   #␣
↪needs sage.plot
Graphics object consisting of 3 graphics primitives
```

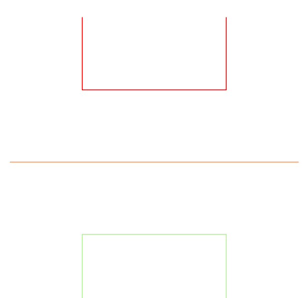
The resulting graphics is as follows



You can also have the three links in different colors with:

```
sage: A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: fpl = FullyPackedLoop(A)
sage: fpl.plot(link_color_map='rainbow')                          #␣
↪needs sage.plot
Graphics object consisting of 3 graphics primitives
```

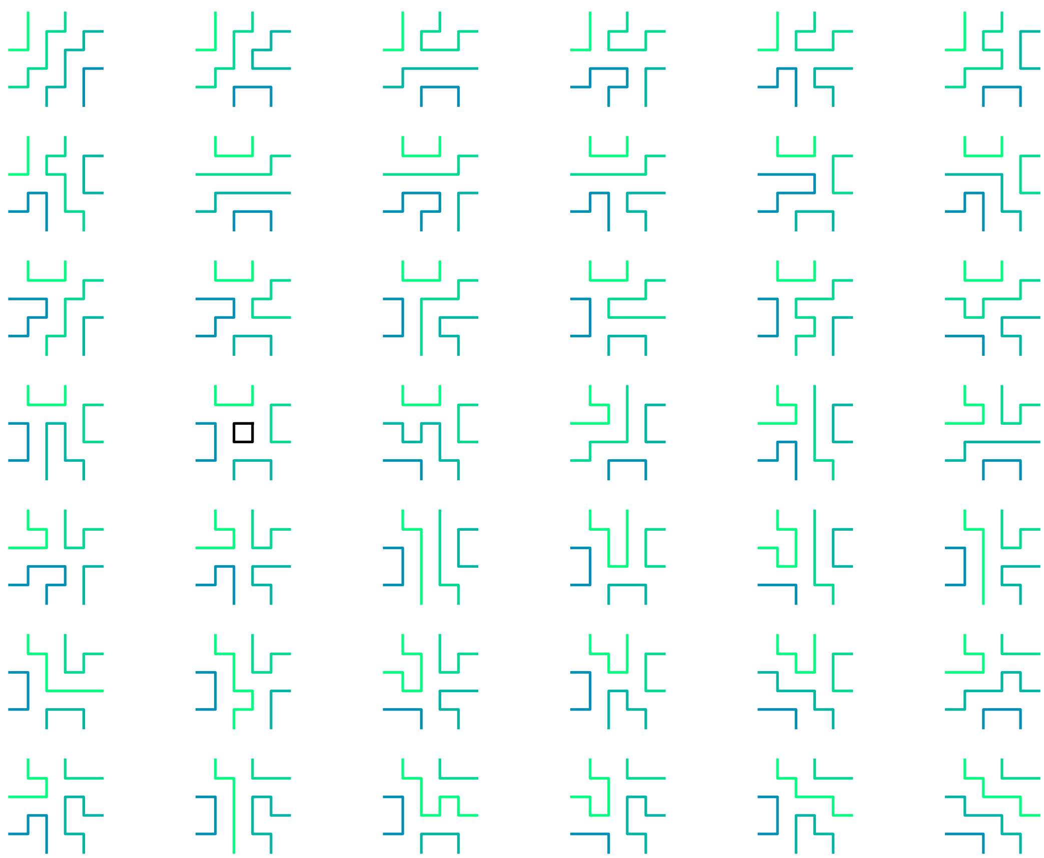
```
>>> from sage.all import *
>>> A = AlternatingSignMatrix([[Integer(0), Integer(1), Integer(0)],␣
↪[Integer(1), -Integer(1), Integer(1)], [Integer(0), Integer(1),␣
↪Integer(0)]])
>>> fpl = FullyPackedLoop(A)
>>> fpl.plot(link_color_map='rainbow')                           #␣
↪needs sage.plot
Graphics object consisting of 3 graphics primitives
```



You can plot the 42 fully packed loops of size 4×4 using:

```
sage: G = [fpl.plot(link_color_map='winter', loop_color='black')            #␣
↪needs sage.plot
....:      for fpl in FullyPackedLoops(4)]
sage: graphics_array(G, 7, 6)                                               #␣
↪needs sage.plot
Graphics Array of size 7 x 6
```

```
>>> from sage.all import *
>>> G = [fpl.plot(link_color_map='winter', loop_color='black')             #␣
↪needs sage.plot
...      for fpl in FullyPackedLoops(Integer(4))]
>>> graphics_array(G, Integer(7), Integer(6))                               ␣
↪              # needs sage.plot
Graphics Array of size 7 x 6
```



Here is an example of a 20×20 fully packed loop:

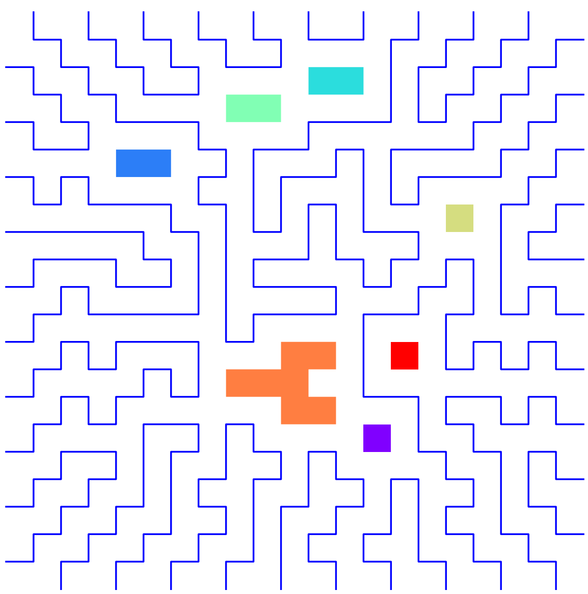
```
sage: s = "00000000000+0000000000000000+00-0+00000000000+00-00+0-+00000\
....: 0000+-00+00-+00000000+00-0000+0000-+00000000+000-0+0-+0-+000\
....: 000+-000+-00+0000000+-+-000+00-+0-000+000+-000+-0+000000-0+\
....: 0000+0-+0-+00000-+00000+-+0-0+-00+0000000000+-0000+0-00+0000\
....: 000000+0-000+000000000000000+0000-00+00000000+0000-000+00000\
```

(continues on next page)

(continued from previous page)

```
....: 00+0-00+000000000000000+-0000+000000-+000000+00-0000+-00+00\
....: 00000000+-0000+00000000000000+0000000000"
sage: a = matrix(20, [{'0':0, '+':1, '-': -1}[i] for i in s])
sage: fpl = FullyPackedLoop(a)
sage: fpl.plot(loop_fill=True, loop_color_map='rainbow')                    #␣
↪needs sage.plot
Graphics object consisting of 27 graphics primitives
```

```
>>> from sage.all import *
>>> s = "00000000000+0000000000000000+00-0+00000000000+00-00+0-+00000\
... 0000+-00+00-+00000000+00-0000+0000-+00000000+000-0+0-+0-+000\
... 000+-000+-00+0000000+-+-000+00-+0-000+000+-000+-0+0000000-0+\
... 0000+0-+0-+00000-+00000+-+0-0+-00+0000000000+-0000+0-00+0000\
... 000000+0-000+000000000000000+0000-00+00000000+0000-000+00000\
... 00+0-00+000000000000000+-0000+000000-+000000+00-0000+-00+00\
... 00000000+-0000+00000000000000+0000000000"
>>> a = matrix(Integer(20), [{'0':Integer(0), '+':Integer(1), '-': -
↪Integer(1)}[i] for i in s])
>>> fpl = FullyPackedLoop(a)
>>> fpl.plot(loop_fill=True, loop_color_map='rainbow')                    #␣
↪needs sage.plot
Graphics object consisting of 27 graphics primitives
```



six_vertex_model()

Return the underlying six vertex model configuration.

EXAMPLES:

```
sage: B = AlternatingSignMatrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
sage: fpl = FullyPackedLoop(B)
sage: fpl
    |         |
```

    V     V     V
```

to_alternating_sign_matrix()

Return the alternating sign matrix corresponding to this class.

> **See also**
>
> *AlternatingSignMatrix*

EXAMPLES:

```
sage: A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: S = SixVertexModel(3, boundary_conditions='ice').from_alternating_sign_
↪matrix(A)
sage: fpl = FullyPackedLoop(S)
sage: fpl.to_alternating_sign_matrix()
[ 0  1  0]
[ 1 -1  1]
[ 0  1  0]
sage: A = AlternatingSignMatrix([[0,1,0,0],[0,0,1,0],[1,-1,0,1],[0,1,0,0]])
sage: S = SixVertexModel(4, boundary_conditions='ice').from_alternating_sign_
↪matrix(A)
sage: fpl = FullyPackedLoop(S)
sage: fpl.to_alternating_sign_matrix()
[ 0  1  0  0]
[ 0  0  1  0]
[ 1 -1  0  1]
[ 0  1  0  0]
```

```
>>> from sage.all import *
>>> A = AlternatingSignMatrix([[Integer(0), Integer(1), Integer(0)],␣
↪[Integer(1), -Integer(1), Integer(1)], [Integer(0), Integer(1),␣
↪Integer(0)]])
>>> S = SixVertexModel(Integer(3), boundary_conditions='ice').from_
↪alternating_sign_matrix(A)
>>> fpl = FullyPackedLoop(S)
>>> fpl.to_alternating_sign_matrix()
[ 0  1  0]
[ 1 -1  1]
[ 0  1  0]
>>> A = AlternatingSignMatrix([[Integer(0),Integer(1),Integer(0),Integer(0)],
↪[Integer(0),Integer(0),Integer(1),Integer(0)],[Integer(1),-Integer(1),
↪Integer(0),Integer(1)],[Integer(0),Integer(1),Integer(0),Integer(0)]])
>>> S = SixVertexModel(Integer(4), boundary_conditions='ice').from_
↪alternating_sign_matrix(A)
>>> fpl = FullyPackedLoop(S)
>>> fpl.to_alternating_sign_matrix()
[ 0  1  0  0]
[ 0  0  1  0]
[ 1 -1  0  1]
[ 0  1  0  0]
```

class sage.combinat.fully_packed_loop.**FullyPackedLoops**(*n*)

Bases: Parent, UniqueRepresentation

Class of all fully packed loops on an $n \times n$ grid.

They are known to be in bijection with alternating sign matrices.

See also

AlternatingSignMatrices

INPUT:

- `n` – the number of row (and column) or grid

EXAMPLES:

This will create an instance to manipulate the fully packed loops of size 3:

```
sage: FPLs = FullyPackedLoops(3)
sage: FPLs
Fully packed loops on a 3x3 grid
sage: FPLs.cardinality()
7
```

```
>>> from sage.all import *
>>> FPLs = FullyPackedLoops(Integer(3))
>>> FPLs
Fully packed loops on a 3x3 grid
>>> FPLs.cardinality()
7
```

When using the square ice model, it is known that the number of configurations is equal to the number of alternating sign matrices:

```
sage: M = FullyPackedLoops(1)
sage: len(M)
1
sage: M = FullyPackedLoops(4)
sage: len(M)
42
sage: all(len(SixVertexModel(n, boundary_conditions='ice'))
....:     == FullyPackedLoops(n).cardinality() for n in range(1, 7))
True
```

```
>>> from sage.all import *
>>> M = FullyPackedLoops(Integer(1))
>>> len(M)
1
>>> M = FullyPackedLoops(Integer(4))
>>> len(M)
42
>>> all(len(SixVertexModel(n, boundary_conditions='ice'))
...     == FullyPackedLoops(n).cardinality() for n in range(Integer(1),
↪Integer(7)))
True
```

Element

alias of *FullyPackedLoop*

cardinality()

Return the cardinality of `self`.

The number of fully packed loops on $n \times n$ grid

$$\prod_{k=0}^{n-1} \frac{(3k+1)!}{(n+k)!} = \frac{1!4!7!10! \cdots (3n-2)!}{n!(n+1)!(n+2)!(n+3)! \cdots (2n-1)!}.$$

EXAMPLES:

```
sage: [AlternatingSignMatrices(n).cardinality() for n in range(10)]
[1, 1, 2, 7, 42, 429, 7436, 218348, 10850216, 911835460]
```

```
>>> from sage.all import *
>>> [AlternatingSignMatrices(n).cardinality() for n in range(Integer(10))]
[1, 1, 2, 7, 42, 429, 7436, 218348, 10850216, 911835460]
```

size()

Return the size of the matrices in `self`.

5.1.115 Gelfand-Tsetlin Patterns

AUTHORS:

- Travis Scrimshaw (2013-15-03): Initial version

REFERENCES:

class sage.combinat.gelfand_tsetlin_patterns.**GelfandTsetlinPattern**

Bases: `ClonableArray`

A Gelfand-Tsetlin (sometimes written as Gelfand-Zetlin or Gelfand-Cetlin) pattern. They were originally defined in [GC50].

A Gelfand-Tsetlin pattern is a triangular array:

$$\begin{array}{ccccccccc} a_{1,1} & & a_{1,2} & & a_{1,3} & & \cdots & & a_{1,n} \\ & a_{2,2} & & a_{2,3} & & \cdots & & a_{2,n} & \\ & & a_{3,3} & & \cdots & & a_{3,n} & & \\ & & & \ddots & & & & & \\ & & & & a_{n,n} & & & & \end{array}$$

such that $a_{i,j} \geq a_{i+1,j+1} \geq a_{i,j+1}$.

Gelfand-Tsetlin patterns are in bijection with semistandard Young tableaux by the following algorithm. Let G be a Gelfand-Tsetlin pattern with $\lambda^{(k)}$ being the $(n-k+1)$-st row (note that this is a partition). The definition of G implies

$$\lambda^{(0)} \subseteq \lambda^{(1)} \subseteq \cdots \subseteq \lambda^{(n)},$$

where $\lambda^{(0)}$ is the empty partition, and each skew shape $\lambda^{(k)}/\lambda^{(k-1)}$ is a horizontal strip. Thus define $T(G)$ by inserting k into the squares of the skew shape $\lambda^{(k)}/\lambda^{(k-1)}$, for $k = 1, \ldots, n$.

To each entry in a Gelfand-Tsetlin pattern, one may attach a decoration of a circle or a box (or both or neither). These decorations appear in the study of Weyl group multiple Dirichlet series, and are implemented here following the exposition in [BBF].

Note

We use the "right-hand" rule for determining circled and boxed entries.

Warning

The entries in Sage are 0-based and are thought of as flushed to the left in a matrix. In other words, the coordinates of entries in the Gelfand-Tsetlin patterns are thought of as the matrix:

$$\begin{bmatrix} g_{0,0} & g_{0,1} & g_{0,2} & \cdots & g_{0,n-2} & g_{n-1,n-1} \\ g_{1,0} & g_{1,1} & g_{1,2} & \cdots & g_{1,n-2} \\ g_{2,0} & g_{2,1} & g_{2,2} & \cdots \\ \vdots & \vdots & \vdots \\ g_{n-2,0} & g_{n-2,1} \\ g_{n-1,0} \end{bmatrix}.$$

However, in the discussions, we will be using the **standard** numbering system.

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[3, 2, 1], [2, 1], [1]]); G
[[3, 2, 1], [2, 1], [1]]
sage: G.pp()
  3     2     1
     2     1
        1
sage: G = GelfandTsetlinPattern([[7, 7, 4, 0], [7, 7, 3], [7, 5], [5]]); G.pp()
  7     7     4     0
     7     7     3
        7     5
           5
sage: G.to_tableau().pp()
  1  1  1  1  1  2  2
  2  2  2  2  2  3  3
  3  3  3  4
```

```
>>> from sage.all import *
>>> G = GelfandTsetlinPattern([[Integer(3), Integer(2), Integer(1)], [Integer(2),
↪Integer(1)], [Integer(1)]]); G
[[3, 2, 1], [2, 1], [1]]
>>> G.pp()
  3     2     1
     2     1
        1
>>> G = GelfandTsetlinPattern([[Integer(7), Integer(7), Integer(4), Integer(0)],
↪[Integer(7), Integer(7), Integer(3)], [Integer(7), Integer(5)], [Integer(5)]]);
↪G.pp()
  7     7     4     0
     7     7     3
        7     5
```

(continues on next page)

(continued from previous page)

```
            5
>>> G.to_tableau().pp()
  1  1  1  1  1  2  2
  2  2  2  2  2  3  3
  3  3  3  4
```

Tokuyama_coefficient (*name='t'*)

Return the Tokuyama coefficient attached to `self`.

Following the exposition of [BBF], Tokuyama's formula asserts

$$\sum_G (t+1)^{s(G)} t^{l(G)} z_1^{d_{n+1}} z_2^{d_n - d_{n+1}} \cdots z_{n+1}^{d_1 - d_2} = s_\lambda(z_1, \ldots, z_{n+1}) \prod_{i<j} (z_j + t z_i),$$

where the sum is over all strict Gelfand-Tsetlin patterns with fixed top row $\lambda + \rho$, with λ a partition with at most $n+1$ parts and $\rho = (n, n-1, \ldots, 1, 0)$, and s_λ is a Schur function.

INPUT:

- `name` – (default: `'t'`) an alternative name for the variable t

EXAMPLES:

```
sage: P = GelfandTsetlinPattern([[3,2,1],[2,2],[2]])
sage: P.Tokuyama_coefficient()
0
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[2]])
sage: G.Tokuyama_coefficient()
t^2 + t
sage: G = GelfandTsetlinPattern([[2,1,0],[1,1],[1]])
sage: G.Tokuyama_coefficient()
0
sage: G = GelfandTsetlinPattern([[5,3,2,1,0],[4,3,2,0],[4,2,1],[3,2],[3]])
sage: G.Tokuyama_coefficient()
t^8 + 3*t^7 + 3*t^6 + t^5
```

```
>>> from sage.all import *
>>> P = GelfandTsetlinPattern([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(2)],[Integer(2)]])
>>> P.Tokuyama_coefficient()
0
>>> G = GelfandTsetlinPattern([[Integer(3),Integer(2),Integer(1)],[Integer(3),
↪Integer(1)],[Integer(2)]])
>>> G.Tokuyama_coefficient()
t^2 + t
>>> G = GelfandTsetlinPattern([[Integer(2),Integer(1),Integer(0)],[Integer(1),
↪Integer(1)],[Integer(1)]])
>>> G.Tokuyama_coefficient()
0
>>> G = GelfandTsetlinPattern([[Integer(5),Integer(3),Integer(2),Integer(1),
↪Integer(0)],[Integer(4),Integer(3),Integer(2),Integer(0)],[Integer(4),
↪Integer(2),Integer(1)],[Integer(3),Integer(2)],[Integer(3)]])
>>> G.Tokuyama_coefficient()
t^8 + 3*t^7 + 3*t^6 + t^5
```

bender_knuth_involution(*i*)

Return the image of `self` under the i-th Bender-Knuth involution.

If the triangle `self` has size n then this is defined for $0 < i < n$.

The entries of `self` can take values in any ordered ring. Usually, this will be the integers but can also be the rationals or the real numbers.

This implements the construction of the Bender-Knuth involution using toggling due to Berenstein-Kirillov.

This agrees with the Bender-Knuth involution on semistandard tableaux.

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[5,3,2,1,0],[4,3,2,0],[4,2,1],[3,2],[3]])
sage: G.bender_knuth_involution(2)
[[5, 3, 2, 1, 0], [4, 3, 2, 0], [4, 2, 1], [4, 1], [3]]

sage: G = GelfandTsetlinPattern([[3,2,0],[2.2,0],[2]])
sage: G.bender_knuth_involution(2)
[[3, 2, 0], [2.80000000000000, 2], [2]]
```

```
>>> from sage.all import *
>>> G = GelfandTsetlinPattern([[Integer(5),Integer(3),Integer(2),Integer(1),
↪Integer(0)],[Integer(4),Integer(3),Integer(2),Integer(0)],[Integer(4),
↪Integer(2),Integer(1)],[Integer(3),Integer(2)],[Integer(3)]])
>>> G.bender_knuth_involution(Integer(2))
[[5, 3, 2, 1, 0], [4, 3, 2, 0], [4, 2, 1], [4, 1], [3]]

>>> G = GelfandTsetlinPattern([[Integer(3),Integer(2),Integer(0)],[RealNumber(
↪'2.2'),Integer(0)],[Integer(2)]])
>>> G.bender_knuth_involution(Integer(2))
[[3, 2, 0], [2.80000000000000, 2], [2]]
```

boxed_entries()

Return the position of the boxed entries of `self`.

Using the *right-hand* rule, an entry $a_{i,j}$ is boxed if $a_{i,j} = a_{i-1,j-1}$; i.e., $a_{i,j}$ has the same value as its neighbor to the northwest.

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.boxed_entries()
((1, 0),)
```

```
>>> from sage.all import *
>>> G = GelfandTsetlinPattern([[Integer(3),Integer(2),Integer(1)],[Integer(3),
↪Integer(1)],[Integer(1)]])
>>> G.boxed_entries()
((1, 0),)
```

check()

Check that this is a valid Gelfand-Tsetlin pattern.

EXAMPLES:

```
sage: G = GelfandTsetlinPatterns()
sage: G([[3,2,1],[2,1],[1]]).check()
```

```
>>> from sage.all import *
>>> G = GelfandTsetlinPatterns()
>>> G([[Integer(3),Integer(2),Integer(1)],[Integer(2),Integer(1)],
↪[Integer(1)]]).check()
```

circled_entries()

Return the circled entries of `self`.

Using the *right-hand* rule, an entry $a_{i,j}$ is circled if $a_{i,j} = a_{i-1,j}$; i.e., $a_{i,j}$ has the same value as its neighbor to the northeast.

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.circled_entries()
((1, 1), (2, 0))
```

```
>>> from sage.all import *
>>> G = GelfandTsetlinPattern([[Integer(3),Integer(2),Integer(1)],[Integer(3),
↪Integer(1)],[Integer(1)]])
>>> G.circled_entries()
((1, 1), (2, 0))
```

is_strict()

Return `True` if `self` is a strict Gelfand-Tsetlin pattern.

A Gelfand-Tsetlin pattern is said to be *strict* if every row is strictly decreasing.

EXAMPLES:

```
sage: GelfandTsetlinPattern([[7,3,1],[6,2],[4]]).is_strict()
True
sage: GelfandTsetlinPattern([[3,2,1],[3,1],[1]]).is_strict()
True
sage: GelfandTsetlinPattern([[6,0,0],[3,0],[2]]).is_strict()
False
```

```
>>> from sage.all import *
>>> GelfandTsetlinPattern([[Integer(7),Integer(3),Integer(1)],[Integer(6),
↪Integer(2)],[Integer(4)]]).is_strict()
True
>>> GelfandTsetlinPattern([[Integer(3),Integer(2),Integer(1)],[Integer(3),
↪Integer(1)],[Integer(1)]]).is_strict()
True
>>> GelfandTsetlinPattern([[Integer(6),Integer(0),Integer(0)],[Integer(3),
↪Integer(0)],[Integer(2)]]).is_strict()
False
```

number_of_boxes()

Return the number of boxed entries. See `boxed_entries()`.

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.number_of_boxes()
1
```

```
>>> from sage.all import *
>>> G = GelfandTsetlinPattern([[Integer(3),Integer(2),Integer(1)],[Integer(3),
↪Integer(1)],[Integer(1)]])
>>> G.number_of_boxes()
1
```

number_of_circles()

Return the number of boxed entries. See *circled_entries()*.

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.number_of_circles()
2
```

```
>>> from sage.all import *
>>> G = GelfandTsetlinPattern([[Integer(3),Integer(2),Integer(1)],[Integer(3),
↪Integer(1)],[Integer(1)]])
>>> G.number_of_circles()
2
```

number_of_special_entries()

Return the number of special entries. See *special_entries()*.

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[4,2,1],[4,1],[2]])
sage: G.number_of_special_entries()
1
```

```
>>> from sage.all import *
>>> G = GelfandTsetlinPattern([[Integer(4),Integer(2),Integer(1)],[Integer(4),
↪Integer(1)],[Integer(2)]])
>>> G.number_of_special_entries()
1
```

pp()

Pretty print `self`.

EXAMPLES:

```
sage: G = GelfandTsetlinPatterns()
sage: G([[3,2,1],[2,1],[1]]).pp()
  3     2     1
     2     1
        1
```

```
>>> from sage.all import *
>>> G = GelfandTsetlinPatterns()
```

(continues on next page)

(continued from previous page)

```
>>> G([[Integer(3),Integer(2),Integer(1)],[Integer(2),Integer(1)],
↪[Integer(1)]]).pp()
  3     2     1
     2     1
        1
```

row_sums()

Return the list of row sums.

For a Gelfand-Tsetlin pattern G, the i-th row sum d_i is

$$d_i = d_i(G) = \sum_{j=i}^{n} a_{i,j}.$$

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[5,3,2,1,0],[4,3,2,0],[4,2,1],[3,2],[3]])
sage: G.row_sums()
[11, 9, 7, 5, 3]
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[2]])
sage: G.row_sums()
[6, 4, 2]
```

```
>>> from sage.all import *
>>> G = GelfandTsetlinPattern([[Integer(5),Integer(3),Integer(2),Integer(1),
↪Integer(0)],[Integer(4),Integer(3),Integer(2),Integer(0)],[Integer(4),
↪Integer(2),Integer(1)],[Integer(3),Integer(2)],[Integer(3)]])
>>> G.row_sums()
[11, 9, 7, 5, 3]
>>> G = GelfandTsetlinPattern([[Integer(3),Integer(2),Integer(1)],[Integer(3),
↪Integer(1)],[Integer(2)]])
>>> G.row_sums()
[6, 4, 2]
```

special_entries()

Return the special entries.

An entry $a_{i,j}$ is special if $a_{i-1,j-1} > a_{i,j} > a_{i-1,j}$, that is to say, the entry is neither boxed nor circled and is **not** in the first row. The name was coined by [Tok88].

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.special_entries()
()
sage: G = GelfandTsetlinPattern([[4,2,1],[4,1],[2]])
sage: G.special_entries()
((2, 0),)
```

```
>>> from sage.all import *
>>> G = GelfandTsetlinPattern([[Integer(3),Integer(2),Integer(1)],[Integer(3),
↪Integer(1)],[Integer(1)]])
>>> G.special_entries()
```

(continues on next page)

(continued from previous page)

```
()
>>> G = GelfandTsetlinPattern([[Integer(4),Integer(2),Integer(1)],[Integer(4),
↪Integer(1)],[Integer(2)]])
>>> G.special_entries()
((2, 0),)
```

to_tableau()

Return `self` as a semistandard Young tableau.

The conversion from a Gelfand-Tsetlin pattern to a semistandard Young tableaux is as follows. Let G be a Gelfand-Tsetlin pattern with $\lambda^{(k)}$ being the $(n-k+1)$-st row (note that this is a partition). The definition of G implies

$$\lambda^{(0)} \subseteq \lambda^{(1)} \subseteq \cdots \subseteq \lambda^{(n)},$$

where $\lambda^{(0)}$ is the empty partition, and each skew shape $\lambda^{(k)}/\lambda^{(k-1)}$ is a horizontal strip. Thus define $T(G)$ by inserting k into the squares of the skew shape $\lambda^{(k)}/\lambda^{(k-1)}$, for $k = 1, \ldots, n$.

EXAMPLES:

```
sage: G = GelfandTsetlinPatterns()
sage: elt = G([[3,2,1],[2,1],[1]])
sage: T = elt.to_tableau(); T
[[1, 2, 3], [2, 3], [3]]
sage: T.pp()
  1  2  3
  2  3
  3
sage: G(T) == elt
True
```

```
>>> from sage.all import *
>>> G = GelfandTsetlinPatterns()
>>> elt = G([[Integer(3),Integer(2),Integer(1)],[Integer(2),Integer(1)],
↪[Integer(1)]])
>>> T = elt.to_tableau(); T
[[1, 2, 3], [2, 3], [3]]
>>> T.pp()
  1  2  3
  2  3
  3
>>> G(T) == elt
True
```

weight()

Return the weight of `self`.

Define the weight of G to be the content of the tableau to which G corresponds under the bijection between Gelfand-Tsetlin patterns and semistandard tableaux. More precisely,

$$\mathrm{wt}(G) = (d_n, d_{n-1} - d_n, \ldots, d_1 - d_2),$$

where the d_i are the row sums.

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[2,1,0],[1,0],[1]])
sage: G.weight()
(1, 0, 2)
sage: G = GelfandTsetlinPattern([[4,2,1],[3,1],[2]])
sage: G.weight()
(2, 2, 3)
```

```
>>> from sage.all import *
>>> G = GelfandTsetlinPattern([[Integer(2),Integer(1),Integer(0)],[Integer(1),
↪Integer(0)],[Integer(1)]])
>>> G.weight()
(1, 0, 2)
>>> G = GelfandTsetlinPattern([[Integer(4),Integer(2),Integer(1)],[Integer(3),
↪Integer(1)],[Integer(2)]])
>>> G.weight()
(2, 2, 3)
```

class sage.combinat.gelfand_tsetlin_patterns.**GelfandTsetlinPatterns**(*n*, *k*, *strict*)

Bases: UniqueRepresentation, Parent

Gelfand-Tsetlin patterns.

INPUT:

- n – the width or depth of the array, also known as the rank
- k – (default: None) if specified, this is the maximum value that can occur in the patterns
- top_row – (default: None) if specified, this is the fixed top row of all patterns
- strict – (default: False) set to True if all patterns are strict patterns

Element

alias of *GelfandTsetlinPattern*

random_element()

Return a uniformly random Gelfand-Tsetlin pattern.

EXAMPLES:

```
sage: g = GelfandTsetlinPatterns(4, 5)
sage: x = g.random_element()
sage: x in g
True
sage: len(x)
4
sage: all(y in range(5+1) for z in x for y in z)
True
sage: x.check()
```

```
>>> from sage.all import *
>>> g = GelfandTsetlinPatterns(Integer(4), Integer(5))
>>> x = g.random_element()
>>> x in g
True
>>> len(x)
```

(continues on next page)

(continued from previous page)

```
4
>>> all(y in range(Integer(5)+Integer(1)) for z in x for y in z)
True
>>> x.check()
```

```
sage: g = GelfandTsetlinPatterns(4, 5, strict=True)
sage: x = g.random_element()
sage: x in g
True
sage: len(x)
4
sage: all(y in range(5+1) for z in x for y in z)
True
sage: x.check()
sage: x.is_strict()
True
```

```
>>> from sage.all import *
>>> g = GelfandTsetlinPatterns(Integer(4), Integer(5), strict=True)
>>> x = g.random_element()
>>> x in g
True
>>> len(x)
4
>>> all(y in range(Integer(5)+Integer(1)) for z in x for y in z)
True
>>> x.check()
>>> x.is_strict()
True
```

class sage.combinat.gelfand_tsetlin_patterns.**GelfandTsetlinPatternsTopRow**(*top_row*, *strict*)

Bases: *GelfandTsetlinPatterns*

Gelfand-Tsetlin patterns with a fixed top row.

Tokuyama_formula(*name='t'*)

Return the Tokuyama formula of `self`.

Following the exposition of [BBF], Tokuyama's formula asserts

$$\sum_G (t+1)^{s(G)} t^{l(G)} z_1^{d_{n+1}} z_2^{d_n - d_{n+1}} \cdots z_{n+1}^{d_1 - d_2} = s_\lambda(z_1, \ldots, z_{n+1}) \prod_{i<j} (z_j + t z_i),$$

where the sum is over all strict Gelfand-Tsetlin patterns with fixed top row $\lambda + \rho$, with λ a partition with at most $n+1$ parts and $\rho = (n, n-1, \ldots, 1, 0)$, and s_λ is a Schur function.

INPUT:

- `name` – (default: `'t'`) an alternative name for the variable t

EXAMPLES:

```
sage: GT = GelfandTsetlinPatterns(top_row=[2,1,0],strict=True)
sage: GT.Tokuyama_formula()
t^3*x1^2*x2 + t^2*x1*x2^2 + t^2*x1^2*x3 + t^2*x1*x2*x3 + t*x1*x2*x3 + t*x2^
```

(continues on next page)

(continued from previous page)

```
↪2*x3 + t*x1*x3^2 + x2*x3^2
sage: GT = GelfandTsetlinPatterns(top_row=[3,2,1],strict=True)
sage: GT.Tokuyama_formula()
t^3*x1^3*x2^2*x3 + t^2*x1^2*x2^3*x3 + t^2*x1^3*x2*x3^2 + t^2*x1^2*x2^2*x3^2 +␣
↪t*x1^2*x2^2*x3^2 + t*x1*x2^3*x3^2 + t*x1^2*x2*x3^3 + x1*x2^2*x3^3
sage: GT = GelfandTsetlinPatterns(top_row=[1,1,1],strict=True)
sage: GT.Tokuyama_formula()
0
```

```
>>> from sage.all import *
>>> GT = GelfandTsetlinPatterns(top_row=[Integer(2),Integer(1),Integer(0)],
↪strict=True)
>>> GT.Tokuyama_formula()
t^3*x1^2*x2 + t^2*x1*x2^2 + t^2*x1^2*x3 + t^2*x1*x2*x3 + t*x1*x2*x3 + t*x2^
↪2*x3 + t*x1*x3^2 + x2*x3^2
>>> GT = GelfandTsetlinPatterns(top_row=[Integer(3),Integer(2),Integer(1)],
↪strict=True)
>>> GT.Tokuyama_formula()
t^3*x1^3*x2^2*x3 + t^2*x1^2*x2^3*x3 + t^2*x1^3*x2*x3^2 + t^2*x1^2*x2^2*x3^2 +␣
↪t*x1^2*x2^2*x3^2 + t*x1*x2^3*x3^2 + t*x1^2*x2*x3^3 + x1*x2^2*x3^3
>>> GT = GelfandTsetlinPatterns(top_row=[Integer(1),Integer(1),Integer(1)],
↪strict=True)
>>> GT.Tokuyama_formula()
0
```

random_element()

Return a uniformly random Gelfand-Tsetlin pattern with specified top row.

EXAMPLES:

```
sage: g = GelfandTsetlinPatterns(top_row = [4, 3, 1, 1])
sage: x = g.random_element()
sage: x in g
True
sage: x[0] == [4, 3, 1, 1]
True
sage: x.check()

sage: g = GelfandTsetlinPatterns(top_row=[4, 3, 2, 1], strict=True)
sage: x = g.random_element()
sage: x in g
True
sage: x[0] == [4, 3, 2, 1]
True
sage: x.is_strict()
True
sage: x.check()
```

```
>>> from sage.all import *
>>> g = GelfandTsetlinPatterns(top_row = [Integer(4), Integer(3), Integer(1),␣
↪Integer(1)])
>>> x = g.random_element()
```

(continues on next page)

(continued from previous page)

```
>>> x in g
True
>>> x[Integer(0)] == [Integer(4), Integer(3), Integer(1), Integer(1)]
True
>>> x.check()

>>> g = GelfandTsetlinPatterns(top_row=[Integer(4), Integer(3), Integer(2),␣
↪Integer(1)], strict=True)
>>> x = g.random_element()
>>> x in g
True
>>> x[Integer(0)] == [Integer(4), Integer(3), Integer(2), Integer(1)]
True
>>> x.is_strict()
True
>>> x.check()
```

top_row()

Return the top row of `self`.

EXAMPLES:

```
sage: G = GelfandTsetlinPatterns(top_row=[4,4,3,1])
sage: G.top_row()
(4, 4, 3, 1)
```

```
>>> from sage.all import *
>>> G = GelfandTsetlinPatterns(top_row=[Integer(4),Integer(4),Integer(3),
↪Integer(1)])
>>> G.top_row()
(4, 4, 3, 1)
```

5.1.116 Paths in Directed Acyclic Graphs

sage.combinat.graph_path.**GraphPaths**(*g*, *source=None*, *target=None*)

Return the combinatorial class of paths in the directed acyclic graph g.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
```

If source and target are not given, then the returned class contains all paths (including trivial paths containing only one vertex).

```
sage: p = GraphPaths(G); p
Paths in Multi-digraph on 5 vertices
sage: p.cardinality()
```

(continues on next page)

(continued from previous page)

```
37
sage: path = p.random_element()
sage: all(G.has_edge(*path[i:i+2]) for i in range(len(path) -1))
True
```

```
>>> from sage.all import *
>>> p = GraphPaths(G); p
Paths in Multi-digraph on 5 vertices
>>> p.cardinality()
37
>>> path = p.random_element()
>>> all(G.has_edge(*path[i:i+Integer(2)]) for i in range(len(path) -Integer(1)))
True
```

If the source is specified, then the returned class contains all of the paths starting at the vertex source (including the trivial path).

```
sage: p = GraphPaths(G, source=3); p
Paths in Multi-digraph on 5 vertices starting at 3
sage: p.list()
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]
```

```
>>> from sage.all import *
>>> p = GraphPaths(G, source=Integer(3)); p
Paths in Multi-digraph on 5 vertices starting at 3
>>> p.list()
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]
```

If the target is specified, then the returned class contains all of the paths ending at the vertex target (including the trivial path).

```
sage: p = GraphPaths(G, target=3); p
Paths in Multi-digraph on 5 vertices ending at 3
sage: p.cardinality()
5
sage: p.list()
[[3], [1, 3], [2, 3], [1, 2, 3], [1, 2, 3]]
```

```
>>> from sage.all import *
>>> p = GraphPaths(G, target=Integer(3)); p
Paths in Multi-digraph on 5 vertices ending at 3
>>> p.cardinality()
5
>>> p.list()
[[3], [1, 3], [2, 3], [1, 2, 3], [1, 2, 3]]
```

If both the target and source are specified, then the returned class contains all of the paths from source to target.

```
sage: p = GraphPaths(G, source=1, target=3); p
Paths in Multi-digraph on 5 vertices starting at 1 and ending at 3
sage: p.cardinality()
3
```

(continues on next page)

(continued from previous page)

```
sage: p.list()
[[1, 2, 3], [1, 2, 3], [1, 3]]
```

```
>>> from sage.all import *
>>> p = GraphPaths(G, source=Integer(1), target=Integer(3)); p
Paths in Multi-digraph on 5 vertices starting at 1 and ending at 3
>>> p.cardinality()
3
>>> p.list()
[[1, 2, 3], [1, 2, 3], [1, 3]]
```

Note that G must be a directed acyclic graph.

```
sage: G = DiGraph({1:[2,2,3,5], 2:[3,4], 3:[4], 4:[2,5,7], 5:[6]},
↪multiedges=True)
sage: GraphPaths(G)
Traceback (most recent call last):
...
TypeError: g must be a directed acyclic graph
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3),Integer(5)],
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],
↪Integer(4):[Integer(2),Integer(5),Integer(7)], Integer(5):[Integer(6)]},
↪multiedges=True)
>>> GraphPaths(G)
Traceback (most recent call last):
...
TypeError: g must be a directed acyclic graph
```

class sage.combinat.graph_path.**GraphPaths_all**(*g*)

Bases: `Parent`, *`GraphPaths_common`*

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G)
sage: p.cardinality()
37
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> p = GraphPaths(G)
>>> p.cardinality()
37
```

list()

Return a list of the paths of `self`.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: len(GraphPaths(G).list())
37
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> len(GraphPaths(G).list())
37
```

class sage.combinat.graph_path.**GraphPaths_common**

Bases: object

incoming_edges(*v*)

Return a list of v's incoming edges.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G)
sage: p.incoming_edges(2)
[(1, 2, None), (1, 2, None)]
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> p = GraphPaths(G)
>>> p.incoming_edges(Integer(2))
[(1, 2, None), (1, 2, None)]
```

incoming_paths(*v*)

Return a list of paths that end at v.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: gp.incoming_paths(2)
[[2], [1, 2], [1, 2]]
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> gp = GraphPaths(G)
>>> gp.incoming_paths(Integer(2))
[[2], [1, 2], [1, 2]]
```

outgoing_edges(*v*)

Return a list of v's outgoing edges.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G)
sage: p.outgoing_edges(2)
[(2, 3, None), (2, 4, None)]
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> p = GraphPaths(G)
>>> p.outgoing_edges(Integer(2))
[(2, 3, None), (2, 4, None)]
```

outgoing_paths(*v*)

Return a list of the paths that start at v.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: gp.outgoing_paths(3)
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]
sage: gp.outgoing_paths(2)
[[2],
 [2, 3],
 [2, 3, 4],
 [2, 3, 4, 5],
 [2, 3, 4, 5],
 [2, 4],
 [2, 4, 5],
 [2, 4, 5]]
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> gp = GraphPaths(G)
>>> gp.outgoing_paths(Integer(3))
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]
>>> gp.outgoing_paths(Integer(2))
[[2],
 [2, 3],
 [2, 3, 4],
 [2, 3, 4, 5],
 [2, 3, 4, 5],
 [2, 4],
 [2, 4, 5],
 [2, 4, 5]]
```

paths()

Return a list of all the paths of `self`.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: len(gp.paths())
37
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> gp = GraphPaths(G)
>>> len(gp.paths())
37
```

paths_from_source_to_target(*source*, *target*)

Return a list of paths from source to target.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: gp.paths_from_source_to_target(2,4)
[[2, 3, 4], [2, 4]]
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> gp = GraphPaths(G)
>>> gp.paths_from_source_to_target(Integer(2),Integer(4))
[[2, 3, 4], [2, 4]]
```

class sage.combinat.graph_path.**GraphPaths_s**(*g*, *source*)

Bases: Parent, *GraphPaths_common*

list()

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G, 4)
sage: p.list()
[[4], [4, 5], [4, 5]]
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> p = GraphPaths(G, Integer(4))
>>> p.list()
[[4], [4, 5], [4, 5]]
```

class sage.combinat.graph_path.**GraphPaths_st**(*g*, *source*, *target*)

Bases: Parent, *GraphPaths_common*

 [1, 2, 3, 4]]
```

5.1.117 Gray codes

Functions

sage.combinat.gray_codes.**combinations**(*n*, *t*)

Iterator through the switches of the revolving door algorithm.

The revolving door algorithm is a way to generate all combinations of a set (i.e. the subset of given cardinality) in such way that two consecutive subsets differ by one element. At each step, the iterator output a pair (i,j) where the item i has to be removed and j has to be added.

The ground set is always $\{0, 1, ..., n-1\}$. Note that n can be infinity in that algorithm.

See [Knu2011] Section 7.2.1.3, "Generating All Combinations".

INPUT:

- n – integer or Infinity; size of the ground set
- t – integer; size of the subsets

EXAMPLES:

```
sage: from sage.combinat.gray_codes import combinations
sage: b = [1, 1, 1, 0, 0]
sage: for i,j in combinations(5,3):
....:     b[i] = 0; b[j] = 1
....:     print(b)
[1, 0, 1, 1, 0]
[0, 1, 1, 1, 0]
[1, 1, 0, 1, 0]
[1, 0, 0, 1, 1]
[0, 1, 0, 1, 1]
[0, 0, 1, 1, 1]
[1, 0, 1, 0, 1]
[0, 1, 1, 0, 1]
[1, 1, 0, 0, 1]

sage: s = set([0,1])
sage: for i,j in combinations(4,2):
....:     s.remove(i)
....:     s.add(j)
....:     print(sorted(s))
[1, 2]
[0, 2]
[2, 3]
[1, 3]
[0, 3]
```

```
>>> from sage.all import *
>>> from sage.combinat.gray_codes import combinations
>>> b = [Integer(1), Integer(1), Integer(1), Integer(0), Integer(0)]
>>> for i,j in combinations(Integer(5),Integer(3)):
...     b[i] = Integer(0); b[j] = Integer(1)
...     print(b)
[1, 0, 1, 1, 0]
[0, 1, 1, 1, 0]
[1, 1, 0, 1, 0]
[1, 0, 0, 1, 1]
[0, 1, 0, 1, 1]
[0, 0, 1, 1, 1]
[1, 0, 1, 0, 1]
[0, 1, 1, 0, 1]
```

(continues on next page)

(continued from previous page)

```
[1, 1, 0, 0, 1]

>>> s = set([Integer(0),Integer(1)])
>>> for i,j in combinations(Integer(4),Integer(2)):
...     s.remove(i)
...     s.add(j)
...     print(sorted(s))
[1, 2]
[0, 2]
[2, 3]
[1, 3]
[0, 3]
```

Note that n can be infinity:

```
sage: c = combinations(Infinity,4)
sage: s = set([0,1,2,3])
sage: for _ in range(10):
....:     i,j = next(c)
....:     s.remove(i); s.add(j)
....:     print(sorted(s))
[0, 1, 3, 4]
[1, 2, 3, 4]
[0, 2, 3, 4]
[0, 1, 2, 4]
[0, 1, 4, 5]
[1, 2, 4, 5]
[0, 2, 4, 5]
[2, 3, 4, 5]
[1, 3, 4, 5]
[0, 3, 4, 5]
sage: for _ in range(1000):
....:     i,j = next(c)
....:     s.remove(i); s.add(j)
sage: sorted(s)
[0, 4, 13, 14]
```

```
>>> from sage.all import *
>>> c = combinations(Infinity,Integer(4))
>>> s = set([Integer(0),Integer(1),Integer(2),Integer(3)])
>>> for _ in range(Integer(10)):
...     i,j = next(c)
...     s.remove(i); s.add(j)
...     print(sorted(s))
[0, 1, 3, 4]
[1, 2, 3, 4]
[0, 2, 3, 4]
[0, 1, 2, 4]
[0, 1, 4, 5]
[1, 2, 4, 5]
[0, 2, 4, 5]
[2, 3, 4, 5]
```

(continues on next page)

(continued from previous page)

```
[1, 3, 4, 5]
[0, 3, 4, 5]
>>> for _ in range(Integer(1000)):
...     i,j = next(c)
...     s.remove(i); s.add(j)
>>> sorted(s)
[0, 4, 13, 14]
```

sage.combinat.gray_codes.**product**(*m*)

Iterator over the switch for the iteration of the product $[m_0] \times [m_1] \ldots \times [m_k]$.

The iterator return at each step a pair `(p,i)` which corresponds to the modification to perform to get the next element. More precisely, one has to apply the increment `i` at the position `p`. By construction, the increment is either `+1` or `-1`.

This is algorithm H in [Knu2011] Section 7.2.1.1, “Generating All n-Tuples”: loopless reflected mixed-radix Gray generation.

INPUT:

- `m` – list or tuple of positive integers that correspond to the size of the sets in the product

EXAMPLES:

```
sage: from sage.combinat.gray_codes import product
sage: l = [0,0,0]
sage: for p,i in product([3,3,3]):
....:     l[p] += i
....:     print(l)
[1, 0, 0]
[2, 0, 0]
[2, 1, 0]
[1, 1, 0]
[0, 1, 0]
[0, 2, 0]
[1, 2, 0]
[2, 2, 0]
[2, 2, 1]
[1, 2, 1]
[0, 2, 1]
[0, 1, 1]
[1, 1, 1]
[2, 1, 1]
[2, 0, 1]
[1, 0, 1]
[0, 0, 1]
[0, 0, 2]
[1, 0, 2]
[2, 0, 2]
[2, 1, 2]
[1, 1, 2]
[0, 1, 2]
[0, 2, 2]
[1, 2, 2]
```

(continues on next page)

(continued from previous page)

```
[2, 2, 2]
sage: l = [0,0]
sage: for i,j in product([2,1]):
....:     l[i] += j
....:     print(l)
[1, 0]
```

```
>>> from sage.all import *
>>> from sage.combinat.gray_codes import product
>>> l = [Integer(0),Integer(0),Integer(0)]
>>> for p,i in product([Integer(3),Integer(3),Integer(3)]):
...     l[p] += i
...     print(l)
[1, 0, 0]
[2, 0, 0]
[2, 1, 0]
[1, 1, 0]
[0, 1, 0]
[0, 2, 0]
[1, 2, 0]
[2, 2, 0]
[2, 2, 1]
[1, 2, 1]
[0, 2, 1]
[0, 1, 1]
[1, 1, 1]
[2, 1, 1]
[2, 0, 1]
[1, 0, 1]
[0, 0, 1]
[0, 0, 2]
[1, 0, 2]
[2, 0, 2]
[2, 1, 2]
[1, 1, 2]
[0, 1, 2]
[0, 2, 2]
[1, 2, 2]
[2, 2, 2]
>>> l = [Integer(0),Integer(0)]
>>> for i,j in product([Integer(2),Integer(1)]):
...     l[i] += j
...     print(l)
[1, 0]
```

5.1.118 Growth diagrams and dual graded graphs

AUTHORS:

- Martin Rubey (2016-09): Initial version
- Martin Rubey (2017-09): generalize, more rules, improve documentation
- Travis Scrimshaw (2017-09): switch to rule-based framework

Todo

- provide examples for the P and Q-symbol in the skew case
- implement a method providing a visualization of the growth diagram with all labels, perhaps as LaTeX code
- when shape is given, check that it is compatible with filling or labels
- optimize rules, mainly for `RuleRSK` and `RuleBurge`
- implement backward rules for `GrowthDiagram.rules.Domino`
- implement backward rule from [LLMSSZ2013], [LS2007]
- make semistandard extension generic
- accommodate dual filtered graphs

A guided tour

Growth diagrams, invented by Sergey Fomin [Fom1994], [Fom1995], provide a vast generalization of the Robinson-Schensted-Knuth (RSK) correspondence between matrices with nonnegative integer entries and pairs of semi-standard Young tableaux of the same shape.

The main fact is that many correspondences similar to RSK can be defined by providing a pair of so-called local rules: a 'forward' rule, whose input are three vertices y, t and x of a certain directed graph (in the case of Robinson-Schensted: the directed graph corresponding to Young's lattice) and an integer (in the case of Robinson-Schensted: 0 or 1), and whose output is a fourth vertex z. This rule should be invertible in the following sense: there is a so-called 'backward' rule that recovers the integer and t given y, z and x.

As an example, the growth rules for the classical RSK correspondence are provided by `RuleRSK`. To produce a growth diagram, pass the desired rule and a permutation to `GrowthDiagram`:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: w = [2,3,6,1,4,5]; G = GrowthDiagram(RuleRSK, w); G
0  0  0  1  0  0
1  0  0  0  0  0
0  1  0  0  0  0
0  0  0  0  1  0
0  0  0  0  0  1
0  0  1  0  0  0
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> w = [Integer(2),Integer(3),Integer(6),Integer(1),Integer(4),Integer(5)]; G =␣
↪GrowthDiagram(RuleRSK, w); G
0  0  0  1  0  0
1  0  0  0  0  0
0  1  0  0  0  0
0  0  0  0  1  0
0  0  0  0  0  1
0  0  1  0  0  0
```

The forward rule just mentioned assigns 49 partitions to the corners of each of the 36 cells of this matrix (i.e., 49 the vertices of a $(6 + 1) \times (6 + 1)$ grid graph), with the exception of the corners on the left and top boundary, which are initialized with the empty partition. More precisely, for each cell, the `forward_rule()` computes the partition z labelling the lower right corner, given the content c of a cell and the other three partitions:

```
t --- x
|  c  |
y --- z
```

Warning: Note that a growth diagram is printed with matrix coordinates, the origin being in the top-left corner. Therefore, the growth is from the top left to the bottom right!

The partitions along the boundary opposite of the origin, reading from the bottom left to the top right, are obtained by using the method *out_labels()*:

```
sage: G.out_labels()
[[],
 [1],
 [2],
 [3],
 [3, 1],
 [3, 2],
 [4, 2],
 [4, 1],
 [3, 1],
 [2, 1],
 [1, 1],
 [1],
 []]
```

```
>>> from sage.all import *
>>> G.out_labels()
[[],
 [1],
 [2],
 [3],
 [3, 1],
 [3, 2],
 [4, 2],
 [4, 1],
 [3, 1],
 [2, 1],
 [1, 1],
 [1],
 []]
```

However, in the case of a rectangular filling, it is more practical to split this sequence of labels in two. Interpreting the sequence of partitions along the right boundary as a standard Young tableau, we then obtain the so-called *P_symbol()*, the partitions along the bottom boundary yield the so-called *Q_symbol()*. These coincide with the output of the classical *RSK()* insertion algorithm:

```
sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[   1  3  4  5     1  2  3  6 ]
[   2  6      ,    4  5       ]
```

(continues on next page)

(continued from previous page)

```
sage: ascii_art(RSK(w))
[   1  3  4  5    1  2  3  6 ]
[   2  6       ,  4  5       ]
```

```
>>> from sage.all import *
>>> ascii_art([G.P_symbol(), G.Q_symbol()])
[   1  3  4  5    1  2  3  6 ]
[   2  6       ,  4  5       ]
>>> ascii_art(RSK(w))
[   1  3  4  5    1  2  3  6 ]
[   2  6       ,  4  5       ]
```

The filling can be recovered knowing the partitions labelling the corners of the bottom and the right boundary alone, by repeatedly applying the *backward_rule()*. Therefore, to initialize a *GrowthDiagram*, we can provide these labels instead of the filling:

```
sage: GrowthDiagram(RuleRSK, labels=G.out_labels())
0  0  0  1  0  0
1  0  0  0  0  0
0  1  0  0  0  0
0  0  0  0  1  0
0  0  0  0  0  1
0  0  1  0  0  0
```

```
>>> from sage.all import *
>>> GrowthDiagram(RuleRSK, labels=G.out_labels())
0  0  0  1  0  0
1  0  0  0  0  0
0  1  0  0  0  0
0  0  0  0  1  0
0  0  0  0  0  1
0  0  1  0  0  0
```

Invocation

In general, growth diagrams are defined for $0-1$-fillings of arbitrary skew shapes. In the case of the Robinson-Schensted-Knuth correspondence, even arbitrary nonnegative integers are allowed. In other cases, entries may be either zero or an r-th root of unity - for example, *RuleDomino* insertion is defined for signed permutations, that is, $r=2$. Traditionally, words and permutations are also used to specify a filling in special cases.

To accommodate all this, the filling may be passed in various ways. The most general possibility is to pass a dictionary of coordinates to (signed) entries, where zeros can be omitted. In this case, when the parameter `shape` is not explicitly specified, it is assumed to be the minimal rectangle containing the origin and all coordinates with nonzero entries.

For example, consider the following generalized permutation:

```
1 2 2 2 4 4
4 2 3 3 2 3
```

that we encode as the dictionary:

```
sage: P = {(1-1,4-1): 1, (2-1,2-1): 1, (2-1,3-1): 2, (4-1,2-1): 1, (4-1,3-1): 1}
```

```
>>> from sage.all import *
>>> P = {(Integer(1)-Integer(1),Integer(4)-Integer(1)): Integer(1), (Integer(2)-
↪Integer(1),Integer(2)-Integer(1)): Integer(1), (Integer(2)-Integer(1),Integer(3)-
↪Integer(1)): Integer(2), (Integer(4)-Integer(1),Integer(2)-Integer(1)): Integer(1),␣
↪(Integer(4)-Integer(1),Integer(3)-Integer(1)): Integer(1)}
```

Note that we are subtracting 1 from all entries because of zero-based indexing, we obtain:

```
sage: GrowthDiagram(RuleRSK, P)
0  0  0  0
0  1  0  1
0  2  0  1
1  0  0  0
```

```
>>> from sage.all import *
>>> GrowthDiagram(RuleRSK, P)
0  0  0  0
0  1  0  1
0  2  0  1
1  0  0  0
```

Alternatively, we could create the same growth diagram using a matrix.

Let us also mention that one can pass the arguments specifying a growth diagram directly to the rule:

```
sage: RuleRSK(P)
0  0  0  0
0  1  0  1
0  2  0  1
1  0  0  0
```

```
>>> from sage.all import *
>>> RuleRSK(P)
0  0  0  0
0  1  0  1
0  2  0  1
1  0  0  0
```

In contrast to the classical insertion algorithms, growth diagrams immediately generalize to fillings whose shape is an arbitrary skew partition:

```
sage: GrowthDiagram(RuleRSK, [3,1,2], shape=SkewPartition([[3,3,2],[1,1]]))
.  1  0
.  0  1
1  0
```

```
>>> from sage.all import *
>>> GrowthDiagram(RuleRSK, [Integer(3),Integer(1),Integer(2)],␣
↪shape=SkewPartition([[Integer(3),Integer(3),Integer(2)],[Integer(1),Integer(1)]]))
.  1  0
.  0  1
1  0
```

As an important example, consider the Stanley-Sundaram correspondence between oscillating tableaux and (partial) perfect matchings. Perfect matchings of $\{1, \ldots, 2r\}$ are in bijection with $0-1$-fillings of a triangular shape with $2r-1$ rows, such that for each k there is either exactly one nonzero entry in row k or exactly one nonzero entry in column $2r-k$. Explicitly, if (i, j) is a pair in the perfect matching, the entry in column $i-1$ and row $2r-j$ equals 1. For example:

```
sage: m = [[1,5],[3,4],[2,7],[6,8]]
sage: G = RuleRSK({(i-1, 8-j): 1 for i,j in m}, shape=[7,6,5,4,3,2,1]); G
0  0  0  0  0  1  0
0  1  0  0  0  0
0  0  0  0  0
1  0  0  0
0  0  1
0  0
0
```

```
>>> from sage.all import *
>>> m = [[Integer(1),Integer(5)],[Integer(3),Integer(4)],[Integer(2),Integer(7)],
↪[Integer(6),Integer(8)]]
>>> G = RuleRSK({(i-Integer(1), Integer(8)-j): Integer(1) for i,j in m},␣
↪shape=[Integer(7),Integer(6),Integer(5),Integer(4),Integer(3),Integer(2),
↪Integer(1)]); G
0  0  0  0  0  1  0
0  1  0  0  0  0
0  0  0  0  0
1  0  0  0
0  0  1
0  0
0
```

The partitions labelling the bottom-right corners along the boundary opposite of the origin then form a so-called oscillating tableau - the remaining partitions along the bottom-right boundary are redundant:

```
sage: G.out_labels()[1::2]
[[1], [1, 1], [2, 1], [1, 1], [1], [1, 1], [1]]
```

```
>>> from sage.all import *
>>> G.out_labels()[Integer(1)::Integer(2)]
[[1], [1, 1], [2, 1], [1, 1], [1], [1, 1], [1]]
```

Another great advantage of growth diagrams is that we immediately have access to a skew version of the correspondence, by providing different initialization for the labels on the side of the origin. We reproduce the original example of Bruce Sagan and Richard Stanley, see also Tom Roby's thesis [Rob1991]:

```
sage: w = {(1-1,4-1): 1, (2-1,2-1): 1, (4-1,3-1): 1}
sage: T = SkewTableau([[None, None], [None, 5], [1]])
sage: U = SkewTableau([[None, None], [None, 3], [5]])
sage: labels = T.to_chain()[::-1] + U.to_chain()[1:]
sage: G = GrowthDiagram(RuleRSK, filling=w, shape=[5,5,5,5,5], labels=labels); G
0  0  0  0  0
0  1  0  0  0
0  0  0  1  0
1  0  0  0  0
0  0  0  0  0
```

(continues on next page)

(continued from previous page)

```
sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[   .  .  2  3    .  .  1  4 ]
[   .  .          .  .       ]
[   .  4          .  2       ]
[   1             3          ]
[   5        ,    5          ]
```

```
>>> from sage.all import *
>>> w = {(Integer(1)-Integer(1),Integer(4)-Integer(1)): Integer(1), (Integer(2)-
↪Integer(1),Integer(2)-Integer(1)): Integer(1), (Integer(4)-Integer(1),Integer(3)-
↪Integer(1)): Integer(1)}
>>> T = SkewTableau([[None, None], [None, Integer(5)], [Integer(1)]])
>>> U = SkewTableau([[None, None], [None, Integer(3)], [Integer(5)]])
>>> labels = T.to_chain()[::-Integer(1)] + U.to_chain()[Integer(1):]
>>> G = GrowthDiagram(RuleRSK, filling=w, shape=[Integer(5),Integer(5),Integer(5),
↪Integer(5),Integer(5)], labels=labels); G
0  0  0  0  0
0  1  0  0  0
0  0  0  1  0
1  0  0  0  0
0  0  0  0  0
>>> ascii_art([G.P_symbol(), G.Q_symbol()])
[   .  .  2  3    .  .  1  4 ]
[   .  .          .  .       ]
[   .  4          .  2       ]
[   1             3          ]
[   5        ,    5          ]
```

Similarly, there is a correspondence for skew oscillating tableau. Let us conclude by reproducing Example 4.2.6 from [Rob1991]. The oscillating tableau, as given, is:

```
sage: o = [[2,1],[2,2],[3,2],[4,2],[4,1],[4,1,1],[3,1,1],[3,1],[3,2],[3,1],[2,1]]
```

```
>>> from sage.all import *
>>> o = [[Integer(2),Integer(1)],[Integer(2),Integer(2)],[Integer(3),Integer(2)],
↪[Integer(4),Integer(2)],[Integer(4),Integer(1)],[Integer(4),Integer(1),Integer(1)],
↪[Integer(3),Integer(1),Integer(1)],[Integer(3),Integer(1)],[Integer(3),Integer(2)],
↪[Integer(3),Integer(1)],[Integer(2),Integer(1)]]
```

From this, we have to construct the list of labels of the corners along the bottom-right boundary. The labels with odd indices are given by the oscillating tableau, the other labels are obtained by taking the smaller of the two neighbouring partitions:

```
sage: l = [o[i//2] if is_even(i) else min(o[(i-1)//2],o[(i+1)//2])
....:      for i in range(2*len(o)-1)]
sage: la = list(range(len(o)-2, 0, -1))
sage: G = RuleRSK(labels=l[1:-1], shape=la); G
0  0  0  0  0  0  0  1  0
0  1  0  0  0  0  0  0
0  0  0  0  0  0  0
0  0  0  0  0  0
0  0  1  0  0
```

(continues on next page)

(continued from previous page)

```
0  0  0  0
0  0  0
0  0
0
```

```
>>> from sage.all import *
>>> l = [o[i//Integer(2)] if is_even(i) else min(o[(i-Integer(1))//Integer(2)],
↪o[(i+Integer(1))//Integer(2)])
...      for i in range(Integer(2)*len(o)-Integer(1))]
>>> la = list(range(len(o)-Integer(2), Integer(0), -Integer(1)))
>>> G = RuleRSK(labels=l[Integer(1):-Integer(1)], shape=la); G
0  0  0  0  0  0  0  1  0
0  1  0  0  0  0  0  0
0  0  0  0  0  0  0
0  0  0  0  0  0
0  0  1  0  0
0  0  0  0
0  0  0
0  0
0
```

The skew tableaux can now be read off the partitions labelling the left and the top boundary. These can be accessed using the method *in_labels()*:

```
sage: ascii_art(SkewTableau(chain=G.in_labels()[len(o)-2:]),
....:           SkewTableau(chain=G.in_labels()[len(o)-2::-1]))
.  1  .  7
5     4
```

```
>>> from sage.all import *
>>> ascii_art(SkewTableau(chain=G.in_labels()[len(o)-Integer(2):]),
...           SkewTableau(chain=G.in_labels()[len(o)-Integer(2)::-Integer(1)]))
.  1  .  7
5     4
```

Rules currently available

As mentioned at the beginning, the Robinson-Schensted-Knuth correspondence is just a special case of growth diagrams. In particular, we have implemented the following local rules:

- RSK (*RuleRSK*).
- A variation of RSK originally due to Burge (*RuleBurge*).
- A correspondence producing binary words originally due to Viennot (*RuleBinaryWord*).
- A correspondence producing domino tableaux (*RuleDomino*) originally due to Barbasch and Vogan.
- A correspondence for shifted shapes (*RuleShiftedShapes*), where the original insertion algorithm is due to Sagan and Worley, and Haiman.
- The Sylvester correspondence, producing binary trees (*RuleSylvester*).
- The Young-Fibonacci correspondence (*RuleYoungFibonacci*).
- LLMS insertion (*RuleLLMS*).

Background

At the heart of Fomin's framework is the notion of dual graded graphs. This is a pair of digraphs P, Q (multiple edges being allowed) on the same set of vertices V, that satisfy the following conditions:

- the graphs are graded, that is, there is a function $\rho : V \to \mathbf{N}$, such that for any edge (v, w) of P and also of Q we have $\rho(w) = \rho(v) + 1$,
- there is a vertex 0 with rank zero, and
- there is a positive integer r such that $DU = UD + rI$ on the free $\mathbf{Z}$-module $\mathbf{Z}[V]$, where D is the down operator of Q, assigning to each vertex the formal sum of its predecessors, U is the up operator of P, assigning to each vertex the formal sum of its successors, and I is the identity operator.

Note that the condition $DU = UD + rI$ is symmetric with respect to the interchange of the graphs P and Q, because the up operator of a graph is the transpose of its down operator.

For example, taking for both P and Q to be Young's lattice and $r = 1$, we obtain the dual graded graphs for classical Schensted insertion.

Given such a pair of graphs, there is a bijection between the r-colored permutations on k letters and pairs (p, q), where p is a path in P from zero to a vertex of rank k and q is a path in Q from zero to the same vertex.

It turns out that - in principle - this bijection can always be described by so-called local forward and backward rules, see [Fom1995] for a detailed description. Knowing at least the forward rules, or the backward rules, you can implement your own growth diagram class.

Implementing your own growth diagrams

The class `GrowthDiagram` is written so that it is easy to implement growth diagrams you come across in your research. Moreover, the class tolerates some deviations from Fomin's definitions. For example, although the general Robinson-Schensted-Knuth correspondence between integer matrices and semistandard tableaux is, strictly speaking, not a growth on dual graded graphs, it is supported by our framework.

For illustration, let us implement a growth diagram class with the backward rule only. Suppose that the vertices of the graph are the nonnegative integers, the rank is given by the integer itself, and the backward rule is $(y, z, x) \mapsto (\min(x, y), 0)$ if $y = z$ or $x = z$ and $(y, z, x) \mapsto (\min(x, y), 1)$ otherwise.

We first need to import the base class for a rule:

```
sage: from sage.combinat.growth import Rule
```

```
>>> from sage.all import *
>>> from sage.combinat.growth import Rule
```

Next, we implement the backward rule and the rank function and provide the bottom element `zero` of the graph. For more information, see `Rule`.

```
sage: class RulePascal(Rule):
....:     zero = 0
....:     def rank(self, v): return v
....:     def backward_rule(self, y, z, x):
....:         return (min(x,y), 0 if y==z or x==z else 1)
```

```
>>> from sage.all import *
>>> class RulePascal(Rule):
...     zero = Integer(0)
...     def rank(self, v): return v
```

(continues on next page)

(continued from previous page)

```
...     def backward_rule(self, y, z, x):
...         return (min(x,y), Integer(0) if y==z or x==z else Integer(1))
```

We can now compute the filling corresponding to a sequence of labels as follows:

```
sage: GrowthDiagram(RulePascal(), labels=[0,1,2,1,2,1,0])
1  0  0
0  0  1
0  1
```

```
>>> from sage.all import *
>>> GrowthDiagram(RulePascal(), labels=[Integer(0),Integer(1),Integer(2),Integer(1),
↪Integer(2),Integer(1),Integer(0)])
1  0  0
0  0  1
0  1
```

Of course, since we have not provided the forward rule, we cannot compute the labels belonging to a filling:

```
sage: GrowthDiagram(RulePascal(), [3,1,2])
Traceback (most recent call last):
...
AttributeError: 'RulePascal' object has no attribute 'forward_rule'...
```

```
>>> from sage.all import *
>>> GrowthDiagram(RulePascal(), [Integer(3),Integer(1),Integer(2)])
Traceback (most recent call last):
...
AttributeError: 'RulePascal' object has no attribute 'forward_rule'...
```

We now re-implement the rule where we provide the dual graded graphs:

```
sage: class RulePascal(Rule):
....:     zero = 0
....:     def rank(self, v): return v
....:     def backward_rule(self, y, z, x):
....:         return (min(x,y), 0 if y==z or x==z else 1)
....:     def vertices(self, n): return [n]
....:     def is_P_edge(self, v, w): return w == v + 1
....:     def is_Q_edge(self, v, w): return w == v + 1
```

```
>>> from sage.all import *
>>> class RulePascal(Rule):
...     zero = Integer(0)
...     def rank(self, v): return v
...     def backward_rule(self, y, z, x):
...         return (min(x,y), Integer(0) if y==z or x==z else Integer(1))
...     def vertices(self, n): return [n]
...     def is_P_edge(self, v, w): return w == v + Integer(1)
...     def is_Q_edge(self, v, w): return w == v + Integer(1)
```

Are they really dual?

```
sage: RulePascal()._check_duality(3)
Traceback (most recent call last):
...
ValueError: D U - U D differs from 1 I for vertex 3:
D U = [3]
U D + 1 I = [3, 3]
```

```
>>> from sage.all import *
>>> RulePascal()._check_duality(Integer(3))
Traceback (most recent call last):
...
ValueError: D U - U D differs from 1 I for vertex 3:
D U = [3]
U D + 1 I = [3, 3]
```

With our current definition, duality fails - in fact, there are no dual graded graphs on the integers without multiple edges. Consequently, also the backward rule cannot work as `backward_rule` requires additional information (the edge labels as arguments).

Let us thus continue with the example from Section 4.7 of [Fom1995] instead, which defines dual graded graphs with multiple edges on the integers. The color `self.zero_edge`, which defaults to `0` is reserved for degenerate edges, but may be abused for the unique edge if one of the graphs has no multiple edges. For greater clarity in this example we set it to `None`:

```
sage: class RulePascal(Rule):
....:     zero = 0
....:     has_multiple_edges = True
....:     zero_edge = None
....:     def rank(self, v): return v
....:     def vertices(self, n): return [n]
....:     def is_P_edge(self, v, w): return [0] if w == v + 1 else []
....:     def is_Q_edge(self, v, w): return list(range(w)) if w == v+1 else []
```

```
>>> from sage.all import *
>>> class RulePascal(Rule):
...     zero = Integer(0)
...     has_multiple_edges = True
...     zero_edge = None
...     def rank(self, v): return v
...     def vertices(self, n): return [n]
...     def is_P_edge(self, v, w): return [Integer(0)] if w == v + Integer(1) else []
...     def is_Q_edge(self, v, w): return list(range(w)) if w == v+Integer(1) else []
```

We verify these are 1 dual at level 5:

```
sage: RulePascal()._check_duality(5)
```

```
>>> from sage.all import *
>>> RulePascal()._check_duality(Integer(5))
```

Finally, let us provide the backward rule. The arguments of the rule are vertices together with the edge labels now, specifying the path from the lower left to the upper right of the cell. The horizontal edges come from Q, whereas the vertical edges come from P.

Thus, the definition in Section 4.7 of [Fom1995] translates as follows:

```
sage: class RulePascal(Rule):
....:     zero = 0
....:     has_multiple_edges = True
....:     zero_edge = None
....:     def rank(self, v): return v
....:     def vertices(self, n): return [n]
....:     def is_P_edge(self, v, w): return [0] if w == v + 1 else []
....:     def is_Q_edge(self, v, w): return list(range(w)) if w == v+1 else []
....:     def backward_rule(self, y, g, z, h, x):
....:         if g is None:
....:             return (0, x, None, 0)
....:         if h is None:
....:             return (None, y, g, 0)
....:         if g == 0:
....:             return (None, y, None, 1)
....:         else:
....:             return (0, x-1, g-1, 0)
```

```
>>> from sage.all import *
>>> class RulePascal(Rule):
...     zero = Integer(0)
...     has_multiple_edges = True
...     zero_edge = None
...     def rank(self, v): return v
...     def vertices(self, n): return [n]
...     def is_P_edge(self, v, w): return [Integer(0)] if w == v + Integer(1) else []
...     def is_Q_edge(self, v, w): return list(range(w)) if w == v+Integer(1) else []
...     def backward_rule(self, y, g, z, h, x):
...         if g is None:
...             return (Integer(0), x, None, Integer(0))
...         if h is None:
...             return (None, y, g, Integer(0))
...         if g == Integer(0):
...             return (None, y, None, Integer(1))
...         else:
...             return (Integer(0), x-Integer(1), g-Integer(1), Integer(0))
```

The labels are now alternating between vertices and edge-colors:

```
sage: GrowthDiagram(RulePascal(), labels=[0,0,1,0,2,0,1,0,0])
1  0
0  1

sage: GrowthDiagram(RulePascal(), labels=[0,0,1,1,2,0,1,0,0])
0  1
1  0
```

```
>>> from sage.all import *
>>> GrowthDiagram(RulePascal(), labels=[Integer(0),Integer(0),Integer(1),Integer(0),
↪Integer(2),Integer(0),Integer(1),Integer(0),Integer(0)])
1  0
```

(continues on next page)

(continued from previous page)

```
0  1

>>> GrowthDiagram(RulePascal(), labels=[Integer(0),Integer(0),Integer(1),Integer(1),
↪Integer(2),Integer(0),Integer(1),Integer(0),Integer(0)])
0  1
1  0
```

class sage.combinat.growth.**GrowthDiagram**(*rule*, *filling=None*, *shape=None*, *labels=None*)

Bases: SageObject

A generalized Schensted growth diagram in the sense of Fomin.

Growth diagrams were introduced by Sergey Fomin [Fom1994], [Fom1995] and provide a vast generalization of the Robinson-Schensted-Knuth (RSK) correspondence between matrices with nonnegative integer entries and pairs of semistandard Young tableaux of the same shape.

A growth diagram is based on the notion of *dual graded graphs*, a pair of digraphs P, Q (multiple edges being allowed) on the same set of vertices V, that satisfy the following conditions:

- the graphs are graded, that is, there is a function $\rho : V \to \mathbf{N}$, such that for any edge (v, w) of P and also of Q we have $\rho(w) = \rho(v) + 1$,
- there is a vertex 0 with rank zero, and
- there is a positive integer r such that $DU = UD + rI$ on the free $\mathbf{Z}$-module $\mathbf{Z}[V]$, where D is the down operator of Q, assigning to each vertex the formal sum of its predecessors, U is the up operator of P, assigning to each vertex the formal sum of its successors, and I is the identity operator.

Growth diagrams are defined by providing a pair of local rules: a 'forward' rule, whose input are three vertices y, t and x of the dual graded graphs and an integer, and whose output is a fourth vertex z. This rule should be invertible in the following sense: there is a so-called 'backward' rule that recovers the integer and t given y, z and x.

All implemented growth diagram rules are available by `GrowthDiagram.rules.<tab>`. The current list is:

- *RuleRSK* – RSK
- *RuleBurge* – a variation of RSK originally due to Burge
- *RuleBinaryWord* – a correspondence producing binary words originally due to Viennot
- *RuleDomino* – a correspondence producing domino tableaux originally due to Barbasch and Vogan
- *RuleShiftedShapes* – a correspondence for shifted shapes, where the original insertion algorithm is due to Sagan and Worley, and Haiman.
- *RuleSylvester* – the Sylvester correspondence, producing binary trees
- *RuleYoungFibonacci* – the Young-Fibonacci correspondence
- *RuleLLMS* – LLMS insertion

INPUT:

- `rule` – *Rule*; the growth diagram rule
- `filling` – (optional) a dictionary whose keys are coordinates and values are integers, a list of lists of integers, or a word with integer values; if a word, then negative letters but without repetitions are allowed and interpreted as coloured permutations
- `shape` – (optional) a (possibly skew) partition
- `labels` – (optional) a list that specifies a path whose length in the half-perimeter of the shape; more details given below

If `filling` is not given, then the growth diagram is determined by applying the backward rule to `labels` decorating the boundary opposite of the origin of the `shape`. In this case, `labels` are interpreted as labelling the boundary opposite of the origin.

Otherwise, `shape` is inferred from `filling` or `labels` if possible and `labels` is set to `rule.zero` if not specified. Here, `labels` are labelling the boundary on the side of the origin.

For `labels`, if `rule.has_multiple_edges` is `True`, then the elements should be of the form $(v_1, e_1, \ldots, e_{n-1}, v_n)$, where n is the half-perimeter of `shape`, and (v_{i-1}, e_i, v_i) is an edge in the dual graded graph for all i. Otherwise, it is a list of n vertices.

Note

Coordinates are of the form `(col, row)` where the origin is in the upper left, to be consistent with permutation matrices and skew tableaux (in English convention). This is different from Fomin's convention, who uses a Cartesian coordinate system.

Conventions are chosen such that for permutations, the same growth diagram is constructed when passing the permutation matrix instead.

EXAMPLES:

We create a growth diagram using the forward RSK rule and a permutation:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: pi = Permutation([4, 1, 2, 3])
sage: G = GrowthDiagram(RuleRSK, pi); G
0  1  0  0
0  0  1  0
0  0  0  1
1  0  0  0
sage: G.out_labels()
[[], [1], [1, 1], [2, 1], [3, 1], [3], [2], [1], []]
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> pi = Permutation([Integer(4), Integer(1), Integer(2), Integer(3)])
>>> G = GrowthDiagram(RuleRSK, pi); G
0  1  0  0
0  0  1  0
0  0  0  1
1  0  0  0
>>> G.out_labels()
[[], [1], [1, 1], [2, 1], [3, 1], [3], [2], [1], []]
```

Passing the permutation matrix instead gives the same result:

```
sage: G = GrowthDiagram(RuleRSK, pi.to_matrix())                        #␣
↪needs sage.modules
sage: ascii_art([G.P_symbol(), G.Q_symbol()])                           #␣
↪needs sage.modules
[   1  2  3     1  3  4 ]
[   4       ,   2       ]
```

```
>>> from sage.all import *
>>> G = GrowthDiagram(RuleRSK, pi.to_matrix())                              #␣
↪needs sage.modules
>>> ascii_art([G.P_symbol(), G.Q_symbol()])                                 #␣
↪needs sage.modules
[   1  2  3    1  3  4 ]
[   4      ,   2       ]
```

We give the same example but using a skew shape:

```
sage: shape = SkewPartition([[4,4,4,2],[1,1]])
sage: G = GrowthDiagram(RuleRSK, pi, shape=shape); G
.  1  0  0
.  0  1  0
0  0  0  1
1  0
sage: G.out_labels()
[[], [1], [1, 1], [1], [2], [3], [2], [1], []]
```

```
>>> from sage.all import *
>>> shape = SkewPartition([[Integer(4),Integer(4),Integer(4),Integer(2)],
↪[Integer(1),Integer(1)]])
>>> G = GrowthDiagram(RuleRSK, pi, shape=shape); G
.  1  0  0
.  0  1  0
0  0  0  1
1  0
>>> G.out_labels()
[[], [1], [1, 1], [1], [2], [3], [2], [1], []]
```

We construct a growth diagram using the backwards RSK rule by specifying the labels:

```
sage: GrowthDiagram(RuleRSK, labels=G.out_labels())
0  1  0  0
0  0  1  0
0  0  0  1
1  0
```

```
>>> from sage.all import *
>>> GrowthDiagram(RuleRSK, labels=G.out_labels())
0  1  0  0
0  0  1  0
0  0  0  1
1  0
```

P_chain()

Return the labels along the vertical boundary of a rectangular growth diagram.

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: G = GrowthDiagram(BinaryWord, [4, 1, 2, 3])
```

(continues on next page)

(continued from previous page)

```
sage: G.P_chain()
[word: , word: 1, word: 11, word: 111, word: 1011]
```

```
>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> G = GrowthDiagram(BinaryWord, [Integer(4), Integer(1), Integer(2),␣
↪Integer(3)])
>>> G.P_chain()
[word: , word: 1, word: 11, word: 111, word: 1011]
```

Check that Issue #25631 is fixed:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord(filling = {}).P_chain()
[word: ]
```

```
>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> BinaryWord(filling = {}).P_chain()
[word: ]
```

P_symbol()

Return the labels along the vertical boundary of a rectangular growth diagram as a generalized standard tableau.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[   1  2  2    1  3  3 ]
[   2      ,   2       ]
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> G = GrowthDiagram(RuleRSK, [[Integer(0),Integer(1),Integer(0)],␣
↪[Integer(1),Integer(0),Integer(2)]])
>>> ascii_art([G.P_symbol(), G.Q_symbol()])
[   1  2  2    1  3  3 ]
[   2      ,   2       ]
```

Q_chain()

Return the labels along the horizontal boundary of a rectangular growth diagram.

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: G = GrowthDiagram(BinaryWord, [[0,1,0,0], [0,0,1,0], [0,0,0,1], [1,0,0,
↪0]])
sage: G.Q_chain()
[word: , word: 1, word: 10, word: 101, word: 1011]
```

```
>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> G = GrowthDiagram(BinaryWord, [[Integer(0),Integer(1),Integer(0),
↪Integer(0)], [Integer(0),Integer(0),Integer(1),Integer(0)], [Integer(0),
↪Integer(0),Integer(0),Integer(1)], [Integer(1),Integer(0),Integer(0),
↪Integer(0)]])
>>> G.Q_chain()
[word: , word: 1, word: 10, word: 101, word: 1011]
```

Check that Issue #25631 is fixed:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord(filling = {}).Q_chain()
[word: ]
```

```
>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> BinaryWord(filling = {}).Q_chain()
[word: ]
```

Q_symbol()

Return the labels along the horizontal boundary of a rectangular growth diagram as a generalized standard tableau.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[   1  2  2     1  3  3 ]
[   2       ,   2       ]
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> G = GrowthDiagram(RuleRSK, [[Integer(0),Integer(1),Integer(0)],
↪[Integer(1),Integer(0),Integer(2)]])
>>> ascii_art([G.P_symbol(), G.Q_symbol()])
[   1  2  2     1  3  3 ]
[   2       ,   2       ]
```

conjugate()

Return the conjugate growth diagram of `self`.

This is the growth diagram with the filling reflected over the main diagonal.

The sequence of labels along the boundary on the side of the origin is the reversal of the corresponding sequence of the original growth diagram.

When the filling is a permutation, the conjugate filling corresponds to its inverse.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: Gc = G.conjugate()
```

(continues on next page)

(continued from previous page)

```
sage: (Gc.P_symbol(), Gc.Q_symbol()) == (G.Q_symbol(), G.P_symbol())
True
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> G = GrowthDiagram(RuleRSK, [[Integer(0),Integer(1),Integer(0)],␣
↪[Integer(1),Integer(0),Integer(2)]])
>>> Gc = G.conjugate()
>>> (Gc.P_symbol(), Gc.Q_symbol()) == (G.Q_symbol(), G.P_symbol())
True
```

filling()

Return the filling of the diagram as a dictionary.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: G.filling()
{(0, 1): 1, (1, 0): 1, (2, 1): 2}
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> G = GrowthDiagram(RuleRSK, [[Integer(0),Integer(1),Integer(0)],␣
↪[Integer(1),Integer(0),Integer(2)]])
>>> G.filling()
{(0, 1): 1, (1, 0): 1, (2, 1): 2}
```

half_perimeter()

Return half the perimeter of the shape of the growth diagram.

in_labels()

Return the labels along the boundary on the side of the origin.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, labels=[[2,2],[3,2],[3,3],[3,2]]); G
1 0
sage: G.in_labels()
[[2, 2], [2, 2], [2, 2], [3, 2]]
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> G = GrowthDiagram(RuleRSK, labels=[[Integer(2),Integer(2)],[Integer(3),
↪Integer(2)],[Integer(3),Integer(3)],[Integer(3),Integer(2)]]); G
1 0
>>> G.in_labels()
[[2, 2], [2, 2], [2, 2], [3, 2]]
```

is_rectangular()

Return `True` if the shape of the growth diagram is rectangular.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: GrowthDiagram(RuleRSK, [2,3,1]).is_rectangular()
True
sage: GrowthDiagram(RuleRSK, [[1,0,1],[0,1]]).is_rectangular()
False
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> GrowthDiagram(RuleRSK, [Integer(2),Integer(3),Integer(1)]).is_
↪rectangular()
True
>>> GrowthDiagram(RuleRSK, [[Integer(1),Integer(0),Integer(1)],[Integer(0),
↪Integer(1)]]).is_rectangular()
False
```

out_labels()

Return the labels along the boundary opposite of the origin.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: G.out_labels()
[[], [1], [1, 1], [3, 1], [1], []]
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> G = GrowthDiagram(RuleRSK, [[Integer(0),Integer(1),Integer(0)],
↪[Integer(1),Integer(0),Integer(2)]])
>>> G.out_labels()
[[], [1], [1, 1], [3, 1], [1], []]
```

rotate()

Return the growth diagram with the filling rotated by 180 degrees.

The rotated growth diagram is initialized with `labels=None`, that is, all labels along the boundary on the side of the origin are set to `rule.zero`.

For RSK-growth diagrams and rectangular fillings, this corresponds to evacuation of the P- and the Q-symbol.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: Gc = G.rotate()
sage: ascii_art([Gc.P_symbol(), Gc.Q_symbol()])
[   1  1  1    1  1  2 ]
[   2      ,   3       ]

sage: ascii_art([Tableau(t).evacuation()
....:            for t in [G.P_symbol(), G.Q_symbol()]])
[   1  1  1    1  1  2 ]
[   2      ,   3       ]
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> G = GrowthDiagram(RuleRSK, [[Integer(0),Integer(1),Integer(0)],
→[Integer(1),Integer(0),Integer(2)]])
>>> Gc = G.rotate()
>>> ascii_art([Gc.P_symbol(), Gc.Q_symbol()])
[   1  1  1     1  1  2 ]
[   2       ,   3       ]

>>> ascii_art([Tableau(t).evacuation()
...            for t in [G.P_symbol(), G.Q_symbol()]])
[   1  1  1     1  1  2 ]
[   2       ,   3       ]
```

rules

alias of *Rules*

shape()

Return the shape of the growth diagram as a skew partition.

> **Warning**
>
> In the literature the label on the corner opposite of the origin of a rectangular filling is often called the shape of the filling. This method returns the shape of the region instead.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: GrowthDiagram(RuleRSK, [1]).shape()
[1] / []
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> GrowthDiagram(RuleRSK, [Integer(1)]).shape()
[1] / []
```

to_biword()

Return the filling as a biword, if the shape is rectangular.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: P = Tableau([[1,2,2],[2]])
sage: Q = Tableau([[1,3,3],[2]])
sage: bw = RSK_inverse(P, Q); bw
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: G = GrowthDiagram(RuleRSK, labels=Q.to_chain()[:-1]+P.to_chain()[::-1]);
→ G
0  1  0
1  0  2

sage: P = SemistandardTableau([[1, 1, 2], [2]])
```

(continues on next page)

(continued from previous page)

```
sage: Q = SemistandardTableau([[1, 2, 2], [2]])
sage: G = GrowthDiagram(RuleRSK, labels=Q.to_chain()[:-1]+P.to_chain()[::-1]);
↪ G
0  2
1  1
sage: G.to_biword()
([1, 2, 2, 2], [2, 1, 1, 2])
sage: RSK([1, 2, 2, 2], [2, 1, 1, 2])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> P = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(2)]])
>>> Q = Tableau([[Integer(1),Integer(3),Integer(3)],[Integer(2)]])
>>> bw = RSK_inverse(P, Q); bw
[[1, 2, 3, 3], [2, 1, 2, 2]]
>>> G = GrowthDiagram(RuleRSK, labels=Q.to_chain()[:-Integer(1)]+P.to_
↪chain()[::-Integer(1)]); G
0  1  0
1  0  2

>>> P = SemistandardTableau([[Integer(1), Integer(1), Integer(2)],␣
↪[Integer(2)]])
>>> Q = SemistandardTableau([[Integer(1), Integer(2), Integer(2)],␣
↪[Integer(2)]])
>>> G = GrowthDiagram(RuleRSK, labels=Q.to_chain()[:-Integer(1)]+P.to_
↪chain()[::-Integer(1)]); G
0  2
1  1
>>> G.to_biword()
([1, 2, 2, 2], [2, 1, 1, 2])
>>> RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2),␣
↪Integer(1), Integer(1), Integer(2)])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

to_word()

Return the filling as a word, if the shape is rectangular and there is at most one nonzero entry in each column, which must be 1.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: w = [3,3,2,4,1]; G = GrowthDiagram(RuleRSK, w)
sage: G
0  0  0  0  1
0  0  1  0  0
1  1  0  0  0
0  0  0  1  0
sage: G.to_word()
[3, 3, 2, 4, 1]
```

```
>>> from sage.all import *
```

(continues on next page)

(continued from previous page)

```
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> w = [Integer(3),Integer(3),Integer(2),Integer(4),Integer(1)]; G =␣
↪GrowthDiagram(RuleRSK, w)
>>> G
0  0  0  0  1
0  0  1  0  0
1  1  0  0  0
0  0  0  1  0
>>> G.to_word()
[3, 3, 2, 4, 1]
```

class sage.combinat.growth.**Rule**

Bases: UniqueRepresentation

Generic base class for a rule for a growth diagram.

Subclasses may provide the following attributes:

- zero – the zero element of the vertices of the graphs
- r – (default: 1) the parameter in the equation $DU - UD = rI$
- has_multiple_edges – boolean (default: False); if the dual graded graph has multiple edges and therefore edges are triples consisting of two vertices and a label
- zero_edge – (default: 0) the zero label of the edges of the graphs used for degenerate edges. It is allowed to use this label also for other edges.

Subclasses may provide the following methods:

- normalize_vertex – a function that converts its input to a vertex
- vertices – a function that takes a nonnegative integer as input and returns the list of vertices on this rank
- rank – the rank function of the dual graded graphs
- forward_rule – a function with input (y, t, x, content) or (y, e, t, f, x, content) if has_multiple_edges is True. (y, e, t) is an edge in the graph P, (t, f, x) an edge in the graph Q. It should return the fourth vertex z, or, if has_multiple_edges is True, the path (g, z, h) from y to x.
- backward_rule – a function with input (y, z, x) or (y, g, z, h, x) if has_multiple_edges is True. (y, g, z) is an edge in the graph Q, (z, h, x) an edge in the graph P. It should return the fourth vertex and the content (t, content), or, if has_multiple_edges is True, the path from y to x and the content as (e, t, f, content).
- is_P_edge, is_Q_edge – functions that take two vertices as arguments and return True or False, or, if multiple edges are allowed, the list of edge labels of the edges from the first vertex to the second in the respective graded graph. These are only used for checking user input and providing the dual graded graph, and are therefore not mandatory.

Note that the class *GrowthDiagram* is able to use partially implemented subclasses just fine. Suppose that MyRule is such a subclass. Then:

- GrowthDiagram(MyRule, my_filling) requires only an implementation of forward_rule, zero and possibly has_multiple_edges.
- GrowthDiagram(MyRule, labels=my_labels, shape=my_shape) requires only an implementation of backward_rule and possibly has_multiple_edges, provided that the labels my_labels are given as needed by backward_rule.

- `GrowthDiagram(MyRule, labels=my_labels)` additionally needs an implementation of `rank` to deduce the shape.

In particular, this allows to implement rules which do not quite fit Fomin's notion of dual graded graphs. An example would be Bloom and Saracino's variant of the RSK correspondence [BS2012], where a backward rule is not available.

Similarly:

- `MyRule.P_graph` only requires an implementation of `vertices`, `is_P_edge` and possibly `has_multiple_edges` is required, mutatis mutandis for `MyRule.Q_graph`.
- `MyRule._check_duality` requires `P_graph` and `Q_graph`.

In particular, this allows to work with dual graded graphs without local rules.

P_graph(*n*)

Return the first `n` levels of the first dual graded graph.

The non-degenerate edges in the vertical direction come from this graph.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: Domino.P_graph(3)
Finite poset containing 8 elements
```

```
>>> from sage.all import *
>>> Domino = GrowthDiagram.rules.Domino()
>>> Domino.P_graph(Integer(3))
Finite poset containing 8 elements
```

Q_graph(*n*)

Return the first `n` levels of the second dual graded graph.

The non-degenerate edges in the horizontal direction come from this graph.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: Q = Domino.Q_graph(3); Q
Finite poset containing 8 elements

sage: Q.upper_covers(Partition([1,1]))
[[1, 1, 1, 1], [3, 1], [2, 2]]
```

```
>>> from sage.all import *
>>> Domino = GrowthDiagram.rules.Domino()
>>> Q = Domino.Q_graph(Integer(3)); Q
Finite poset containing 8 elements

>>> Q.upper_covers(Partition([Integer(1),Integer(1)]))
[[1, 1, 1, 1], [3, 1], [2, 2]]
```

has_multiple_edges = False

normalize_vertex(*v*)

Return v as a vertex of the dual graded graph.

This is a default implementation, returning its argument.

EXAMPLES:

```
sage: from sage.combinat.growth import Rule
sage: Rule().normalize_vertex("hello") == "hello"
True
```

```
>>> from sage.all import *
>>> from sage.combinat.growth import Rule
>>> Rule().normalize_vertex("hello") == "hello"
True
```

r = 1

zero_edge = 0

class sage.combinat.growth.**RuleBinaryWord**

Bases: *Rule*

A rule modelling a Schensted-like correspondence for binary words.

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: GrowthDiagram(BinaryWord, [3,1,2])
0  1  0
0  0  1
1  0  0
```

```
>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> GrowthDiagram(BinaryWord, [Integer(3),Integer(1),Integer(2)])
0  1  0
0  0  1
1  0  0
```

The vertices of the dual graded graph are binary words:

```
sage: BinaryWord.vertices(3)
[word: 100, word: 101, word: 110, word: 111]
```

```
>>> from sage.all import *
>>> BinaryWord.vertices(Integer(3))
[word: 100, word: 101, word: 110, word: 111]
```

Note that, instead of passing the rule to *GrowthDiagram*, we can also use call the rule to create growth diagrams. For example:

```
sage: BinaryWord([2,4,1,3]).P_chain()
[word: , word: 1, word: 10, word: 101, word: 1101]
sage: BinaryWord([2,4,1,3]).Q_chain()
[word: , word: 1, word: 11, word: 110, word: 1101]
```

```
>>> from sage.all import *
>>> BinaryWord([Integer(2),Integer(4),Integer(1),Integer(3)]).P_chain()
[word: , word: 1, word: 10, word: 101, word: 1101]
>>> BinaryWord([Integer(2),Integer(4),Integer(1),Integer(3)]).Q_chain()
[word: , word: 1, word: 11, word: 110, word: 1101]
```

The Kleitman Greene invariant is the descent word, encoded by the positions of the zeros:

```
sage: pi = Permutation([4,1,8,3,6,5,2,7,9])
sage: G = BinaryWord(pi); G
0  1  0  0  0  0  0  0  0
0  0  0  0  0  0  1  0  0
0  0  0  1  0  0  0  0  0
1  0  0  0  0  0  0  0  0
0  0  0  0  0  1  0  0  0
0  0  0  0  1  0  0  0  0
0  0  0  0  0  0  0  1  0
0  0  1  0  0  0  0  0  0
0  0  0  0  0  0  0  0  1
sage: pi.descents()
[1, 3, 5, 6]
```

```
>>> from sage.all import *
>>> pi = Permutation([Integer(4),Integer(1),Integer(8),Integer(3),Integer(6),
↪Integer(5),Integer(2),Integer(7),Integer(9)])
>>> G = BinaryWord(pi); G
0  1  0  0  0  0  0  0  0
0  0  0  0  0  0  1  0  0
0  0  0  1  0  0  0  0  0
1  0  0  0  0  0  0  0  0
0  0  0  0  0  1  0  0  0
0  0  0  0  1  0  0  0  0
0  0  0  0  0  0  0  1  0
0  0  1  0  0  0  0  0  0
0  0  0  0  0  0  0  0  1
>>> pi.descents()
[1, 3, 5, 6]
```

backward_rule(y, z, x)

Return the content and the input shape.

See [Fom1995] Lemma 4.6.1, page 40.

- `y, z, x` – three binary words from a cell in a growth diagram, labelled as:

```
  x
y z
```

OUTPUT:

A pair `(t, content)` consisting of the shape of the fourth word and the content of the cell according to Viennot's bijection [Vie1983].

forward_rule(y, t, x, *content*)

Return the output shape given three shapes and the content.

See [Fom1995] Lemma 4.6.1, page 40.

INPUT:

- y, t, x – three binary words from a cell in a growth diagram, labelled as:

```
t x
y
```

- content – 0 or 1; the content of the cell

OUTPUT:

The fourth binary word z according to Viennot's bijection [Vie1983].

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()

sage: BinaryWord.forward_rule([], [], [], 1)
word: 1

sage: BinaryWord.forward_rule([1], [1], [1], 1)
word: 11
```

```
>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()

>>> BinaryWord.forward_rule([], [], [], Integer(1))
word: 1

>>> BinaryWord.forward_rule([Integer(1)], [Integer(1)], [Integer(1)],␣
↪Integer(1))
word: 11
```

if x != y append last letter of x to y:

```
sage: BinaryWord.forward_rule([1,0], [1], [1,1], 0)
word: 101
```

```
>>> from sage.all import *
>>> BinaryWord.forward_rule([Integer(1),Integer(0)], [Integer(1)],␣
↪[Integer(1),Integer(1)], Integer(0))
word: 101
```

if x == y != t append 0 to y:

```
sage: BinaryWord.forward_rule([1,1], [1], [1,1], 0)
word: 110
```

```
>>> from sage.all import *
>>> BinaryWord.forward_rule([Integer(1),Integer(1)], [Integer(1)],␣
↪[Integer(1),Integer(1)], Integer(0))
word: 110
```

is_P_edge(*v*, *w*)

Return whether `(v, w)` is a P-edge of `self`.

`(v, w)` is an edge if `v` is obtained from `w` by deleting a letter.

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: v = BinaryWord.vertices(2)[1]; v
word: 11
sage: [w for w in BinaryWord.vertices(3) if BinaryWord.is_P_edge(v, w)]
[word: 101, word: 110, word: 111]
sage: [w for w in BinaryWord.vertices(4) if BinaryWord.is_P_edge(v, w)]
[]
```

```
>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> v = BinaryWord.vertices(Integer(2))[Integer(1)]; v
word: 11
>>> [w for w in BinaryWord.vertices(Integer(3)) if BinaryWord.is_P_edge(v, w)]
[word: 101, word: 110, word: 111]
>>> [w for w in BinaryWord.vertices(Integer(4)) if BinaryWord.is_P_edge(v, w)]
[]
```

is_Q_edge(*v*, *w*)

Return whether `(v, w)` is a Q-edge of `self`.

`(w, v)` is an edge if `w` is obtained from `v` by appending a letter.

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: v = BinaryWord.vertices(2)[0]; v
word: 10
sage: [w for w in BinaryWord.vertices(3) if BinaryWord.is_Q_edge(v, w)]
[word: 100, word: 101]
sage: [w for w in BinaryWord.vertices(4) if BinaryWord.is_Q_edge(v, w)]
[]
```

```
>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> v = BinaryWord.vertices(Integer(2))[Integer(0)]; v
word: 10
>>> [w for w in BinaryWord.vertices(Integer(3)) if BinaryWord.is_Q_edge(v, w)]
[word: 100, word: 101]
>>> [w for w in BinaryWord.vertices(Integer(4)) if BinaryWord.is_Q_edge(v, w)]
[]
```

normalize_vertex(*v*)

Return `v` as a binary word.

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord.normalize_vertex([0,1]).parent()
Finite words over {0, 1}
```

```
>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> BinaryWord.normalize_vertex([Integer(0),Integer(1)]).parent()
Finite words over {0, 1}
```

rank(*v*)

Return the rank of `v`: number of letters of the word.

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord.rank(BinaryWord.vertices(3)[0])
3
```

```
>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> BinaryWord.rank(BinaryWord.vertices(Integer(3))[Integer(0)])
3
```

vertices(*n*)

Return the vertices of the dual graded graph on level `n`.

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord.vertices(3)
[word: 100, word: 101, word: 110, word: 111]
```

```
>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> BinaryWord.vertices(Integer(3))
[word: 100, word: 101, word: 110, word: 111]
```

zero = word:

class sage.combinat.growth.**RuleBurge**

Bases: *RulePartitions*

A rule modelling Burge insertion.

EXAMPLES:

```
sage: Burge = GrowthDiagram.rules.Burge()
sage: GrowthDiagram(Burge, labels=[[],[1,1,1],[2,1,1,1],[2,1,1],[2,1],[1,1],[]])
1  1
0  1
1  0
1  0
```

```
>>> from sage.all import *
>>> Burge = GrowthDiagram.rules.Burge()
>>> GrowthDiagram(Burge, labels=[[],[Integer(1),Integer(1),Integer(1)],
↪[Integer(2),Integer(1),Integer(1),Integer(1)],[Integer(2),Integer(1),
↪Integer(1)],[Integer(2),Integer(1)],[Integer(1),Integer(1)],[]])
```

(continues on next page)

(continued from previous page)

```
1  1
0  1
1  0
1  0
```

The vertices of the dual graded graph are integer partitions:

```
sage: Burge.vertices(3)
Partitions of the integer 3
```

```
>>> from sage.all import *
>>> Burge.vertices(Integer(3))
Partitions of the integer 3
```

The local rules implemented provide Burge's correspondence between matrices with nonnegative integer entries and pairs of semistandard tableaux, the `P_symbol()` and the `Q_symbol()`. For permutations, it reduces to classical Schensted insertion.

Instead of passing the rule to `GrowthDiagram`, we can also call the rule to create growth diagrams. For example:

```
sage: m = matrix([[2,0,0,1,0],[1,1,0,0,0], [0,0,0,0,3]])
sage: G = Burge(m); G
2  0  0  1  0
1  1  0  0  0
0  0  0  0  3

sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[   1  2  3     1  2  5 ]
[   1  3        1  5    ]
[   1  3        1  5    ]
[   2       ,   4       ]
```

```
>>> from sage.all import *
>>> m = matrix([[Integer(2),Integer(0),Integer(0),Integer(1),Integer(0)],
↪[Integer(1),Integer(1),Integer(0),Integer(0),Integer(0)], [Integer(0),
↪Integer(0),Integer(0),Integer(0),Integer(3)]])
>>> G = Burge(m); G
2  0  0  1  0
1  1  0  0  0
0  0  0  0  3

>>> ascii_art([G.P_symbol(), G.Q_symbol()])
[   1  2  3     1  2  5 ]
[   1  3        1  5    ]
[   1  3        1  5    ]
[   2       ,   4       ]
```

For rectangular fillings, the Kleitman-Greene invariant is the shape of the `P_symbol()`. Put differently, it is the partition labelling the lower right corner of the filling (recall that we are using matrix coordinates). It can be computed alternatively as the transpose of the partition $(\mu_1, \dots, \mu_n)$, where $\mu_1 + \dots + \mu_i$ is the maximal sum of entries in a collection of i pairwise disjoint sequences of cells with weakly decreasing row indices and weakly increasing column indices.

backward_rule(*y*, *z*, *x*)

Return the content and the input shape.

See [Kra2006] $(B^4 0) - (B^4 2)$. (In the arXiv version of the article there is a typo: in the computation of carry in $(B^4 2)$, ρ must be replaced by λ).

INPUT:

- `y`, `z`, `x` – three partitions from a cell in a growth diagram, labelled as:

```
  x
y z
```

OUTPUT:

A pair `(t, content)` consisting of the shape of the fourth partition according to the Burge correspondence and the content of the cell.

EXAMPLES:

```
sage: Burge = GrowthDiagram.rules.Burge()
sage: Burge.backward_rule([1,1,1],[2,1,1,1],[2,1,1])
([1, 1], 0)
```

```
>>> from sage.all import *
>>> Burge = GrowthDiagram.rules.Burge()
>>> Burge.backward_rule([Integer(1),Integer(1),Integer(1)],[Integer(2),
↪Integer(1),Integer(1),Integer(1)],[Integer(2),Integer(1),Integer(1)])
([1, 1], 0)
```

forward_rule(*y*, *t*, *x*, *content*)

Return the output shape given three shapes and the content.

See [Kra2006] $(F^4 0) - (F^4 2)$.

INPUT:

- `y`, `t`, `x` – three from a cell in a growth diagram, labelled as:

```
t x
y
```

- `content` – nonnegative integer; the content of the cell

OUTPUT: the fourth partition according to the Burge correspondence

EXAMPLES:

```
sage: Burge = GrowthDiagram.rules.Burge()
sage: Burge.forward_rule([2,1],[2,1],[2,1],1)
[3, 1]

sage: Burge.forward_rule([1],[],[2],2)
[2, 1, 1, 1]
```

```
>>> from sage.all import *
>>> Burge = GrowthDiagram.rules.Burge()
>>> Burge.forward_rule([Integer(2),Integer(1)],[Integer(2),Integer(1)],
```

(continues on next page)

(continued from previous page)

```
↪[Integer(2),Integer(1)],Integer(1))
[3, 1]

>>> Burge.forward_rule([Integer(1)],[],[Integer(2)],Integer(2))
[2, 1, 1, 1]
```

class sage.combinat.growth.**RuleDomino**

Bases: *Rule*

A rule modelling domino insertion.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: GrowthDiagram(Domino, [[1,0,0],[0,0,1],[0,-1,0]])
1  0  0
0  0  1
0 -1  0
```

```
>>> from sage.all import *
>>> Domino = GrowthDiagram.rules.Domino()
>>> GrowthDiagram(Domino, [[Integer(1),Integer(0),Integer(0)],[Integer(0),
↪Integer(0),Integer(1)],[Integer(0),-Integer(1),Integer(0)]])
1  0  0
0  0  1
0 -1  0
```

The vertices of the dual graded graph are integer partitions whose Ferrers diagram can be tiled with dominoes:

```
sage: Domino.vertices(2)
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> Domino.vertices(Integer(2))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

Instead of passing the rule to *GrowthDiagram*, we can also call the rule to create growth diagrams. For example, let us check Figure 3 in [Lam2004]:

```
sage: G = Domino([[0,0,0,-1],[0,0,1,0],[-1,0,0,0],[0,1,0,0]]); G
 0  0  0 -1
 0  0  1  0
-1  0  0  0
 0  1  0  0

sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[   1  2  4     1  2  2 ]
[   1  2  4     1  3  3 ]
[   3  3   ,    4  4    ]
```

```
>>> from sage.all import *
>>> G = Domino([[Integer(0),Integer(0),Integer(0),-Integer(1)],[Integer(0),
```

(continues on next page)

(continued from previous page)

```
↪Integer(0),Integer(1),Integer(0)],[-Integer(1),Integer(0),Integer(0),
↪Integer(0)],[Integer(0),Integer(1),Integer(0),Integer(0)]]); G
 0  0  0 -1
 0  0  1  0
-1  0  0  0
 0  1  0  0

>>> ascii_art([G.P_symbol(), G.Q_symbol()])
[   1  2  4     1  2  2 ]
[   1  2  4     1  3  3 ]
[   3  3   ,    4  4    ]
```

The spin of a domino tableau is half the number of vertical dominoes:

```
sage: def spin(T):
....:     return sum(2*len(set(row)) - len(row) for row in T)/4
```

```
>>> from sage.all import *
>>> def spin(T):
...     return sum(Integer(2)*len(set(row)) - len(row) for row in T)/Integer(4)
```

According to [Lam2004], the number of negative entries in the signed permutation equals the sum of the spins of the two associated tableaux:

```
sage: pi = [3,-1,2,4,-5]
sage: G = Domino(pi)
sage: list(G.filling().values()).count(-1) == spin(G.P_symbol()) + spin(G.Q_
↪symbol())
True
```

```
>>> from sage.all import *
>>> pi = [Integer(3),-Integer(1),Integer(2),Integer(4),-Integer(5)]
>>> G = Domino(pi)
>>> list(G.filling().values()).count(-Integer(1)) == spin(G.P_symbol()) + spin(G.
↪Q_symbol())
True
```

Negating all signs transposes all the partitions:

```
sage: G.P_symbol() == Domino([-e for e in pi]).P_symbol().conjugate()
True
```

```
>>> from sage.all import *
>>> G.P_symbol() == Domino([-e for e in pi]).P_symbol().conjugate()
True
```

P_symbol(*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a (skew) domino tableau.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: G = Domino([[0,1,0],[0,0,-1],[1,0,0]])
sage: G.P_symbol().pp()
1  1
2  3
2  3
```

```
>>> from sage.all import *
>>> Domino = GrowthDiagram.rules.Domino()
>>> G = Domino([[Integer(0),Integer(1),Integer(0)],[Integer(0),Integer(0),-
↪Integer(1)],[Integer(1),Integer(0),Integer(0)]])
>>> G.P_symbol().pp()
1  1
2  3
2  3
```

Q_symbol(*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a (skew) domino tableau.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: G = Domino([[0,1,0],[0,0,-1],[1,0,0]])
sage: G.P_symbol().pp()
1  1
2  3
2  3
```

```
>>> from sage.all import *
>>> Domino = GrowthDiagram.rules.Domino()
>>> G = Domino([[Integer(0),Integer(1),Integer(0)],[Integer(0),Integer(0),-
↪Integer(1)],[Integer(1),Integer(0),Integer(0)]])
>>> G.P_symbol().pp()
1  1
2  3
2  3
```

forward_rule(*y*, *t*, *x*, *content*)

Return the output shape given three shapes and the content.

See [Lam2004] Section 3.1.

INPUT:

- `y`, `t`, `x` – three partitions from a cell in a growth diagram, labelled as:

```
t  x
y
```

- `content` – -1, 0 or 1; the content of the cell

OUTPUT: the fourth partition according to domino insertion

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
```

```
>>> from sage.all import *
>>> Domino = GrowthDiagram.rules.Domino()
```

Rule 1:

```
sage: Domino.forward_rule([], [], [], 1)
[2]

sage: Domino.forward_rule([1,1], [1,1], [1,1], 1)
[3, 1]
```

```
>>> from sage.all import *
>>> Domino.forward_rule([], [], [], Integer(1))
[2]

>>> Domino.forward_rule([Integer(1),Integer(1)], [Integer(1),Integer(1)],␣
↪[Integer(1),Integer(1)], Integer(1))
[3, 1]
```

Rule 2:

```
sage: Domino.forward_rule([1,1], [1,1], [1,1], -1)
[1, 1, 1, 1]
```

```
>>> from sage.all import *
>>> Domino.forward_rule([Integer(1),Integer(1)], [Integer(1),Integer(1)],␣
↪[Integer(1),Integer(1)], -Integer(1))
[1, 1, 1, 1]
```

Rule 3:

```
sage: Domino.forward_rule([1,1], [1,1], [2,2], 0)
[2, 2]
```

```
>>> from sage.all import *
>>> Domino.forward_rule([Integer(1),Integer(1)], [Integer(1),Integer(1)],␣
↪[Integer(2),Integer(2)], Integer(0))
[2, 2]
```

Rule 4:

```
sage: Domino.forward_rule([2,2,2], [2,2], [3,3], 0)
[3, 3, 2]

sage: Domino.forward_rule([2], [], [1,1], 0)
[2, 2]

sage: Domino.forward_rule([1,1], [], [2], 0)
[2, 2]

```

(continues on next page)

(continued from previous page)

```
sage: Domino.forward_rule([2], [], [2], 0)
[2, 2]

sage: Domino.forward_rule([4], [2], [4], 0)
[4, 2]

sage: Domino.forward_rule([1,1,1,1], [1,1], [1,1,1,1], 0)
[2, 2, 1, 1]

sage: Domino.forward_rule([2,1,1], [2], [4], 0)
[4, 1, 1]
```

```
>>> from sage.all import *
>>> Domino.forward_rule([Integer(2),Integer(2),Integer(2)], [Integer(2),
↪Integer(2)], [Integer(3),Integer(3)], Integer(0))
[3, 3, 2]

>>> Domino.forward_rule([Integer(2)], [], [Integer(1),Integer(1)], Integer(0))
[2, 2]

>>> Domino.forward_rule([Integer(1),Integer(1)], [], [Integer(2)], Integer(0))
[2, 2]

>>> Domino.forward_rule([Integer(2)], [], [Integer(2)], Integer(0))
[2, 2]

>>> Domino.forward_rule([Integer(4)], [Integer(2)], [Integer(4)], Integer(0))
[4, 2]

>>> Domino.forward_rule([Integer(1),Integer(1),Integer(1),Integer(1)],␣
↪[Integer(1),Integer(1)], [Integer(1),Integer(1),Integer(1),Integer(1)],␣
↪Integer(0))
[2, 2, 1, 1]

>>> Domino.forward_rule([Integer(2),Integer(1),Integer(1)], [Integer(2)],␣
↪[Integer(4)], Integer(0))
[4, 1, 1]
```

is_P_edge(*v*, *w*)

Return whether `(v, w)` is a P-edge of `self`.

`(v, w)` is an edge if `v` is obtained from `w` by deleting a domino.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: v = Domino.vertices(2)[1]; ascii_art(v)
***
*
sage: ascii_art([w for w in Domino.vertices(3) if Domino.is_P_edge(v, w)])
[              *** ]
[              *   ]
[ *****   ***  *   ]
```

(continues on next page)

(continued from previous page)

```
[ *     , ***, *    ]
sage: [w for w in Domino.vertices(4) if Domino.is_P_edge(v, w)]
[]
```

```
>>> from sage.all import *
>>> Domino = GrowthDiagram.rules.Domino()
>>> v = Domino.vertices(Integer(2))[Integer(1)]; ascii_art(v)
***
*
>>> ascii_art([w for w in Domino.vertices(Integer(3)) if Domino.is_P_edge(v,␣
↪w)])
[               *** ]
[               *   ]
[ *****   ***   *   ]
[ *     , ***, *    ]
>>> [w for w in Domino.vertices(Integer(4)) if Domino.is_P_edge(v, w)]
[]
```

is_Q_edge(*v*, *w*)

Return whether `(v, w)` is a P-edge of `self`.

`(v, w)` is an edge if `v` is obtained from `w` by deleting a domino.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: v = Domino.vertices(2)[1]; ascii_art(v)
***
*
sage: ascii_art([w for w in Domino.vertices(3) if Domino.is_P_edge(v, w)])
[               *** ]
[               *   ]
[ *****   ***   *   ]
[ *     , ***, *    ]
sage: [w for w in Domino.vertices(4) if Domino.is_P_edge(v, w)]
[]
```

```
>>> from sage.all import *
>>> Domino = GrowthDiagram.rules.Domino()
>>> v = Domino.vertices(Integer(2))[Integer(1)]; ascii_art(v)
***
*
>>> ascii_art([w for w in Domino.vertices(Integer(3)) if Domino.is_P_edge(v,␣
↪w)])
[               *** ]
[               *   ]
[ *****   ***   *   ]
[ *     , ***, *    ]
>>> [w for w in Domino.vertices(Integer(4)) if Domino.is_P_edge(v, w)]
[]
```

normalize_vertex(*v*)

Return `v` as a partition.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: Domino.normalize_vertex([3,1]).parent()
Partitions
```

```
>>> from sage.all import *
>>> Domino = GrowthDiagram.rules.Domino()
>>> Domino.normalize_vertex([Integer(3),Integer(1)]).parent()
Partitions
```

r = 2

rank(*v*)

Return the rank of `v`.

The rank of a vertex is half the size of the partition, which equals the number of dominoes in any filling.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: Domino.rank(Domino.vertices(3)[0])
3
```

```
>>> from sage.all import *
>>> Domino = GrowthDiagram.rules.Domino()
>>> Domino.rank(Domino.vertices(Integer(3))[Integer(0)])
3
```

vertices(*n*)

Return the vertices of the dual graded graph on level `n`.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: Domino.vertices(2)
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> Domino = GrowthDiagram.rules.Domino()
>>> Domino.vertices(Integer(2))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

zero = []

class sage.combinat.growth.**RuleLLMS**(*k*)

Bases: `Rule`

A rule modelling the Schensted correspondence for affine permutations.

EXAMPLES:

```
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: GrowthDiagram(LLMS3, [3,1,2])
0  1  0
```

(continues on next page)

(continued from previous page)

```
0  0  1
1  0  0
```

```
>>> from sage.all import *
>>> LLMS3 = GrowthDiagram.rules.LLMS(Integer(3))
>>> GrowthDiagram(LLMS3, [Integer(3),Integer(1),Integer(2)])
0  1  0
0  0  1
1  0  0
```

The vertices of the dual graded graph are `Cores`:

```
sage: LLMS3.vertices(4)
3-Cores of length 4
```

```
>>> from sage.all import *
>>> LLMS3.vertices(Integer(4))
3-Cores of length 4
```

Let us check example of Figure 1 in [LS2007]. Note that, instead of passing the rule to `GrowthDiagram`, we can also call the rule to create growth diagrams:

```
sage: G = LLMS3([4,1,2,6,3,5]); G
0  1  0  0  0  0
0  0  1  0  0  0
0  0  0  0  1  0
1  0  0  0  0  0
0  0  0  0  0  1
0  0  0  1  0  0
```

```
>>> from sage.all import *
>>> G = LLMS3([Integer(4),Integer(1),Integer(2),Integer(6),Integer(3),
↪Integer(5)]); G
0  1  0  0  0  0
0  0  1  0  0  0
0  0  0  0  1  0
1  0  0  0  0  0
0  0  0  0  0  1
0  0  0  1  0  0
```

The `P_symbol()` is a `StrongTableau`:

```
sage: G.P_symbol().pp()
-1 -2 -3 -5
 3  5
-4 -6
 5
 6
```

```
>>> from sage.all import *
>>> G.P_symbol().pp()
```

(continues on next page)

(continued from previous page)

```
-1 -2 -3 -5
 3  5
-4 -6
 5
 6
```

The `Q_symbol()` is a `WeakTableau`:

```
sage: G.Q_symbol().pp()
1  3  4  5
2  5
3  6
5
6
```

```
>>> from sage.all import *
>>> G.Q_symbol().pp()
1  3  4  5
2  5
3  6
5
6
```

Let us also check Example 6.2 in [LLMSSZ2013]:

```
sage: G = LLMS3([4,1,3,2])
sage: G.P_symbol().pp()
-1 -2  3
-3
-4

sage: G.Q_symbol().pp()
1  3  4
2
3
```

```
>>> from sage.all import *
>>> G = LLMS3([Integer(4),Integer(1),Integer(3),Integer(2)])
>>> G.P_symbol().pp()
-1 -2  3
-3
-4

>>> G.Q_symbol().pp()
1  3  4
2
3
```

P_symbol(*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a skew `StrongTableau`.

EXAMPLES:

```
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: G = LLMS4([3,4,1,2])
sage: G.P_symbol().pp()
-1 -2
-3 -4
```

```
>>> from sage.all import *
>>> LLMS4 = GrowthDiagram.rules.LLMS(Integer(4))
>>> G = LLMS4([Integer(3),Integer(4),Integer(1),Integer(2)])
>>> G.P_symbol().pp()
-1 -2
-3 -4
```

Q_symbol(*Q_chain*)

Return the labels along the horizontal boundary of a rectangular growth diagram as a skew `WeakTableau`.

EXAMPLES:

```
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: G = LLMS4([3,4,1,2])
sage: G.Q_symbol().pp()
1 2
3 4
```

```
>>> from sage.all import *
>>> LLMS4 = GrowthDiagram.rules.LLMS(Integer(4))
>>> G = LLMS4([Integer(3),Integer(4),Integer(1),Integer(2)])
>>> G.Q_symbol().pp()
1 2
3 4
```

forward_rule(*y*, *e*, *t*, *f*, *x*, *content*)

Return the output path given two incident edges and the content.

See [LS2007] Section 3.4 and [LLMSSZ2013] Section 6.3.

INPUT:

- `y, e, t, f, x` – a path of three partitions and two colors from a cell in a growth diagram, labelled as:

```
t f x
e
y
```

- `content` – 0 or 1; the content of the cell

OUTPUT:

The two colors and the fourth partition g, z, h according to LLMS insertion.

EXAMPLES:

```
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)

sage: Z = LLMS3.zero
```

(continues on next page)

(continued from previous page)

(None, [2, 2], 0)
```

has_multiple_edges = True

is_P_edge(*v*, *w*)

Return whether `(v, w)` is a P-edge of `self`.

For two k-cores v and w containing v, there are as many edges as there are components in the skew partition w/v. These components are ribbons, and therefore contain a unique cell with maximal content. We index the edge with this content.

EXAMPLES:

```
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: v = LLMS4.vertices(2)[0]; v
[2]
sage: [(w, LLMS4.is_P_edge(v, w)) for w in LLMS4.vertices(3)]
[([3], [2]), ([2, 1], [-1]), ([1, 1, 1], [])]
sage: all(LLMS4.is_P_edge(v, w) == [] for w in LLMS4.vertices(4))
True
```

```
>>> from sage.all import *
>>> LLMS4 = GrowthDiagram.rules.LLMS(Integer(4))
>>> v = LLMS4.vertices(Integer(2))[Integer(0)]; v
[2]
>>> [(w, LLMS4.is_P_edge(v, w)) for w in LLMS4.vertices(Integer(3))]
[([3], [2]), ([2, 1], [-1]), ([1, 1, 1], [])]
>>> all(LLMS4.is_P_edge(v, w) == [] for w in LLMS4.vertices(Integer(4)))
True
```

is_Q_edge(*v*, *w*)

Return whether `(v, w)` is a Q-edge of `self`.

`(v, w)` is an edge if `w` is a weak cover of `v`, see *weak_covers()*.

EXAMPLES:

```
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: v = LLMS4.vertices(3)[1]; v
[2, 1]
sage: [w for w in LLMS4.vertices(4) if len(LLMS4.is_Q_edge(v, w)) > 0]
[[2, 2], [3, 1, 1]]
sage: all(LLMS4.is_Q_edge(v, w) == [] for w in LLMS4.vertices(5))
True
```

```
>>> from sage.all import *
>>> LLMS4 = GrowthDiagram.rules.LLMS(Integer(4))
>>> v = LLMS4.vertices(Integer(3))[Integer(1)]; v
[2, 1]
>>> [w for w in LLMS4.vertices(Integer(4)) if len(LLMS4.is_Q_edge(v, w)) >␣
↪Integer(0)]
[[2, 2], [3, 1, 1]]
>>> all(LLMS4.is_Q_edge(v, w) == [] for w in LLMS4.vertices(Integer(5)))
True
```

normalize_vertex(*v*)

Convert `v` to a k-core.

EXAMPLES:

```
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS3.normalize_vertex([3,1]).parent()
3-Cores of length 3
```

```
>>> from sage.all import *
>>> LLMS3 = GrowthDiagram.rules.LLMS(Integer(3))
>>> LLMS3.normalize_vertex([Integer(3),Integer(1)]).parent()
3-Cores of length 3
```

rank(*v*)

Return the rank of `v`: the length of the core.

EXAMPLES:

```
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS3.rank(LLMS3.vertices(3)[0])
3
```

```
>>> from sage.all import *
>>> LLMS3 = GrowthDiagram.rules.LLMS(Integer(3))
>>> LLMS3.rank(LLMS3.vertices(Integer(3))[Integer(0)])
3
```

vertices(*n*)

Return the vertices of the dual graded graph on level `n`.

EXAMPLES:

```
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS3.vertices(2)
3-Cores of length 2
```

```
>>> from sage.all import *
>>> LLMS3 = GrowthDiagram.rules.LLMS(Integer(3))
>>> LLMS3.vertices(Integer(2))
3-Cores of length 2
```

zero_edge = None

class sage.combinat.growth.**RulePartitions**

Bases: *Rule*

A rule for growth diagrams on Young's lattice on integer partitions graded by size.

P_symbol(*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a (skew) tableau.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = RuleRSK([[0,1,0], [1,0,2]])
sage: G.P_symbol().pp()
1  2  2
2
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> G = RuleRSK([[Integer(0),Integer(1),Integer(0)], [Integer(1),Integer(0),
↪Integer(2)]])
>>> G.P_symbol().pp()
1  2  2
2
```

Q_symbol(*Q_chain*)

Return the labels along the horizontal boundary of a rectangular growth diagram as a skew tableau.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = RuleRSK([[0,1,0], [1,0,2]])
sage: G.Q_symbol().pp()
1  3  3
2
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> G = RuleRSK([[Integer(0),Integer(1),Integer(0)], [Integer(1),Integer(0),
↪Integer(2)]])
>>> G.Q_symbol().pp()
1  3  3
2
```

normalize_vertex(*v*)

Return v as a partition.

EXAMPLES:

```
sage: RSK = GrowthDiagram.rules.RSK()
sage: RSK.normalize_vertex([3,1]).parent()
Partitions
```

```
>>> from sage.all import *
>>> RSK = GrowthDiagram.rules.RSK()
>>> RSK.normalize_vertex([Integer(3),Integer(1)]).parent()
Partitions
```

rank(*v*)

Return the rank of v: the size of the partition.

EXAMPLES:

```
sage: RSK = GrowthDiagram.rules.RSK()
sage: RSK.rank(RSK.vertices(3)[0])
3
```

```
>>> from sage.all import *
>>> RSK = GrowthDiagram.rules.RSK()
>>> RSK.rank(RSK.vertices(Integer(3))[Integer(0)])
3
```

vertices(*n*)

Return the vertices of the dual graded graph on level n.

EXAMPLES:

```
sage: RSK = GrowthDiagram.rules.RSK()
sage: RSK.vertices(3)
Partitions of the integer 3
```

```
>>> from sage.all import *
>>> RSK = GrowthDiagram.rules.RSK()
```

(continues on next page)

(continued from previous page)

```
>>> RSK.vertices(Integer(3))
Partitions of the integer 3
```

zero = []

class sage.combinat.growth.**RuleRSK**

Bases: *RulePartitions*

A rule modelling Robinson-Schensted-Knuth insertion.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: GrowthDiagram(RuleRSK, [3,2,1,2,3])
0  0  1  0  0
0  1  0  1  0
1  0  0  0  1
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> GrowthDiagram(RuleRSK, [Integer(3),Integer(2),Integer(1),Integer(2),
↪Integer(3)])
0  0  1  0  0
0  1  0  1  0
1  0  0  0  1
```

The vertices of the dual graded graph are integer partitions:

```
sage: RuleRSK.vertices(3)
Partitions of the integer 3
```

```
>>> from sage.all import *
>>> RuleRSK.vertices(Integer(3))
Partitions of the integer 3
```

The local rules implemented provide the RSK correspondence between matrices with nonnegative integer entries and pairs of semistandard tableaux, the *P_symbol()* and the *Q_symbol()*. For permutations, it reduces to classical Schensted insertion.

Instead of passing the rule to *GrowthDiagram*, we can also call the rule to create growth diagrams. For example:

```
sage: m = matrix([[0,0,0,0,1],[1,1,0,2,0], [0,3,0,0,0]])
sage: G = RuleRSK(m); G
0  0  0  0  1
1  1  0  2  0
0  3  0  0  0

sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[   1  2  2  2  3    1  2  2  2  2 ]
[   2  3             4  4          ]
[   3           ,    5             ]
```

```
>>> from sage.all import *
>>> m = matrix([[Integer(0),Integer(0),Integer(0),Integer(0),Integer(1)],
↪[Integer(1),Integer(1),Integer(0),Integer(2),Integer(0)], [Integer(0),
↪Integer(3),Integer(0),Integer(0),Integer(0)]])
>>> G = RuleRSK(m); G
0  0  0  0  1
1  1  0  2  0
0  3  0  0  0

>>> ascii_art([G.P_symbol(), G.Q_symbol()])
[   1  2  2  2  3    1  2  2  2  2 ]
[   2  3             4  4          ]
[   3           ,    5             ]
```

For rectangular fillings, the Kleitman-Greene invariant is the shape of the `P_symbol()` (or the `Q_symbol()`). Put differently, it is the partition labelling the lower right corner of the filling (recall that we are using matrix coordinates). It can be computed alternatively as the partition $(\mu_1, \ldots, \mu_n)$, where $\mu_1 + \cdots + \mu_i$ is the maximal sum of entries in a collection of i pairwise disjoint sequences of cells with weakly increasing coordinates.

For rectangular fillings, we could also use the (faster) implementation provided via `RSK()`. Because the of the coordinate conventions in `RSK()`, we have to transpose matrices:

```
sage: [G.P_symbol(), G.Q_symbol()] == RSK(m.transpose())
True

sage: n = 5; l = [(pi, RuleRSK(pi)) for pi in Permutations(n)]
sage: all([G.P_symbol(), G.Q_symbol()] == RSK(pi) for pi, G in l)
True

sage: n = 5; l = [(w, RuleRSK(w)) for w in Words([1,2,3], 5)]
sage: all([G.P_symbol(), G.Q_symbol()] == RSK(pi) for pi, G in l)
True
```

```
>>> from sage.all import *
>>> [G.P_symbol(), G.Q_symbol()] == RSK(m.transpose())
True

>>> n = Integer(5); l = [(pi, RuleRSK(pi)) for pi in Permutations(n)]
>>> all([G.P_symbol(), G.Q_symbol()] == RSK(pi) for pi, G in l)
True

>>> n = Integer(5); l = [(w, RuleRSK(w)) for w in Words([Integer(1),Integer(2),
↪Integer(3)], Integer(5))]
>>> all([G.P_symbol(), G.Q_symbol()] == RSK(pi) for pi, G in l)
True
```

backward_rule(*y*, *z*, *x*)

Return the content and the input shape.

See [Kra2006] $(B^1 0) - (B^1 2)$.

INPUT:

- `y`, `z`, `x` – three partitions from a cell in a growth diagram, labelled as:

```
  x
y z
```

OUTPUT:

A pair `(t, content)` consisting of the shape of the fourth word according to the Robinson-Schensted-Knuth correspondence and the content of the cell.

forward_rule(*y*, *t*, *x*, *content*)

Return the output shape given three shapes and the content.

See [Kra2006] $(F^1 0) - (F^1 2)$.

INPUT:

- `y`, `t`, `x` – three partitions from a cell in a growth diagram, labelled as:

```
t x
y
```

- `content` – nonnegative integer; the content of the cell

OUTPUT:

The fourth partition according to the Robinson-Schensted-Knuth correspondence.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: RuleRSK.forward_rule([2,1],[2,1],[2,1],1)
[3, 1]

sage: RuleRSK.forward_rule([1],[],[2],2)
[4, 1]
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> RuleRSK.forward_rule([Integer(2),Integer(1)],[Integer(2),Integer(1)],
↪[Integer(2),Integer(1)],Integer(1))
[3, 1]

>>> RuleRSK.forward_rule([Integer(1)],[],[Integer(2)],Integer(2))
[4, 1]
```

class sage.combinat.growth.**RuleShiftedShapes**

Bases: *Rule*

A class modelling the Schensted correspondence for shifted shapes.

This agrees with Sagan [Sag1987] and Worley's [Wor1984], and Haiman's [Hai1989] insertion algorithms, see Proposition 4.5.2 of [Fom1995].

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: GrowthDiagram(Shifted, [3,1,2])
0  1  0
```

(continues on next page)

(continued from previous page)

```
0  0  1
1  0  0
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> GrowthDiagram(Shifted, [Integer(3),Integer(1),Integer(2)])
0  1  0
0  0  1
1  0  0
```

The vertices of the dual graded graph are shifted shapes:

```
sage: Shifted.vertices(3)
Partitions of the integer 3 satisfying constraints max_slope=-1
```

```
>>> from sage.all import *
>>> Shifted.vertices(Integer(3))
Partitions of the integer 3 satisfying constraints max_slope=-1
```

Let us check the example just before Corollary 3.2 in [Sag1987]. Note that, instead of passing the rule to `GrowthDiagram`, we can also call the rule to create growth diagrams:

```
sage: G = Shifted([2,6,5,1,7,4,3])
sage: G.P_chain()
[[], 0, [1], 0, [2], 0, [3], 0, [3, 1], 0, [3, 2], 0, [4, 2], 0, [5, 2]]
sage: G.Q_chain()
[[], 1, [1], 2, [2], 1, [2, 1], 3, [3, 1], 2, [4, 1], 3, [4, 2], 3, [5, 2]]
```

```
>>> from sage.all import *
>>> G = Shifted([Integer(2),Integer(6),Integer(5),Integer(1),Integer(7),
↪Integer(4),Integer(3)])
>>> G.P_chain()
[[], 0, [1], 0, [2], 0, [3], 0, [3, 1], 0, [3, 2], 0, [4, 2], 0, [5, 2]]
>>> G.Q_chain()
[[], 1, [1], 2, [2], 1, [2, 1], 3, [3, 1], 2, [4, 1], 3, [4, 2], 3, [5, 2]]
```

P_symbol(*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a shifted tableau.

EXAMPLES:

Check the example just before Corollary 3.2 in [Sag1987]:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: G = Shifted([2,6,5,1,7,4,3])
sage: G.P_symbol().pp()
1  2  3  6  7
   4  5
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> G = Shifted([Integer(2),Integer(6),Integer(5),Integer(1),Integer(7),
```

(continues on next page)

(continued from previous page)

```
↪Integer(4),Integer(3)])
>>> G.P_symbol().pp()
1  2  3  6  7
   4  5
```

Check the example just before Corollary 8.2 in [SS1990]:

```
sage: T = ShiftedPrimedTableau([[4],[1],[5]], skew=[3,1])
sage: T.pp()
 .  .  .  4
    .  1
       5
sage: U = ShiftedPrimedTableau([[1],[3.5],[5]], skew=[3,1])
sage: U.pp()
 .  .  .  1
    .  4'
       5
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: labels = [mu if is_even(i) else 0
....:           for i, mu in enumerate(T.to_chain()[::-1])] + U.to_chain()[1:]
sage: G = Shifted({(1,2):1, (2,1):1}, shape=[5,5,5,5,5], labels=labels)
sage: G.P_symbol().pp()
 .  .  .  .  2
    .  .  1  3
       .  4  5
```

```
>>> from sage.all import *
>>> T = ShiftedPrimedTableau([[Integer(4)],[Integer(1)],[Integer(5)]],␣
↪skew=[Integer(3),Integer(1)])
>>> T.pp()
 .  .  .  4
    .  1
       5
>>> U = ShiftedPrimedTableau([[Integer(1)],[RealNumber('3.5')],[Integer(5)]],␣
↪skew=[Integer(3),Integer(1)])
>>> U.pp()
 .  .  .  1
    .  4'
       5
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> labels = [mu if is_even(i) else Integer(0)
...           for i, mu in enumerate(T.to_chain()[::-Integer(1)])] + U.to_
↪chain()[Integer(1):]
>>> G = Shifted({(Integer(1),Integer(2)):Integer(1), (Integer(2),
↪Integer(1)):Integer(1)}, shape=[Integer(5),Integer(5),Integer(5),Integer(5),
↪Integer(5)], labels=labels)
>>> G.P_symbol().pp()
 .  .  .  .  2
    .  .  1  3
       .  4  5
```

Q_symbol(*Q_chain*)

Return the labels along the horizontal boundary of a rectangular growth diagram as a skew tableau.

EXAMPLES:

Check the example just before Corollary 3.2 in [Sag1987]:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: G = Shifted([2,6,5,1,7,4,3])
sage: G.Q_symbol().pp()
1  2  4' 5  7'
   3  6'
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> G = Shifted([Integer(2),Integer(6),Integer(5),Integer(1),Integer(7),
↪Integer(4),Integer(3)])
>>> G.Q_symbol().pp()
1  2  4' 5  7'
   3  6'
```

Check the example just before Corollary 8.2 in [SS1990]:

```
sage: T = ShiftedPrimedTableau([[4],[1],[5]], skew=[3,1])
sage: T.pp()
 .  .  .  4
    .  1
       5
sage: U = ShiftedPrimedTableau([[1],[3.5],[5]], skew=[3,1])
sage: U.pp()
 .  .  .  1
    .  4'
       5
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: labels = [mu if is_even(i) else 0
....:           for i, mu in enumerate(T.to_chain()[::-1])] + U.to_chain()[1:]
sage: G = Shifted({(1,2):1, (2,1):1}, shape=[5,5,5,5,5], labels=labels)
sage: G.Q_symbol().pp()

    .  1
       5
>>> U = ShiftedPrimedTableau([[Integer(1)],[RealNumber('3.5')],[Integer(5)]],␣
↪skew=[Integer(3),Integer(1)])
>>> U.pp()
 .  .  .  1
    .  4'
       5
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> labels = [mu if is_even(i) else Integer(0)
```

(continues on next page)

(continued from previous page)

```
...             for i, mu in enumerate(T.to_chain()[::-Integer(1)])] + U.to_
↪chain()[Integer(1):]
>>> G = Shifted({(Integer(1),Integer(2)):Integer(1), (Integer(2),
↪Integer(1)):Integer(1)}, shape=[Integer(5),Integer(5),Integer(5),Integer(5),
↪Integer(5)], labels=labels)
>>> G.Q_symbol().pp()
 .  .  .  .  2
    .  .  1  4'
       .  3' 5'
```

backward_rule(*y*, *g*, *z*, *h*, *x*)

Return the input path and the content given two incident edges.

See [Fom1995] Lemma 4.5.1, page 38.

INPUT:

- y, g, z, h, x – a path of three partitions and two colors from a cell in a growth diagram, labelled as:

```
    x
    h
y g z
```

OUTPUT:

A tuple (e, t, f, content) consisting of the shape t of the fourth word, the colours of the incident edges and the content of the cell according to Sagan - Worley insertion.

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.backward_rule([], 1, [1], 0, [])
(0, [], 0, 1)

sage: Shifted.backward_rule([1], 2, [2], 0, [1])
(0, [1], 0, 1)
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> Shifted.backward_rule([], Integer(1), [Integer(1)], Integer(0), [])
(0, [], 0, 1)

>>> Shifted.backward_rule([Integer(1)], Integer(2), [Integer(2)], Integer(0),␣
↪[Integer(1)])
(0, [1], 0, 1)
```

if x != y:

```
sage: Shifted.backward_rule([3], 1, [3, 1], 0, [2,1])
(0, [2], 1, 0)

sage: Shifted.backward_rule([2,1], 2, [3, 1], 0, [3])
(0, [2], 2, 0)
```

```
>>> from sage.all import *
>>> Shifted.backward_rule([Integer(3)], Integer(1), [Integer(3), Integer(1)],␣
↪Integer(0), [Integer(2),Integer(1)])
(0, [2], 1, 0)

>>> Shifted.backward_rule([Integer(2),Integer(1)], Integer(2), [Integer(3),␣
↪Integer(1)], Integer(0), [Integer(3)])
(0, [2], 2, 0)
```

if `x == y != t`:

```
sage: Shifted.backward_rule([3], 1, [3, 1], 0, [3])
(0, [2], 2, 0)

sage: Shifted.backward_rule([3,1], 2, [3, 2], 0, [3,1])
(0, [2, 1], 2, 0)

sage: Shifted.backward_rule([2,1], 3, [3, 1], 0, [2,1])
(0, [2], 1, 0)

sage: Shifted.backward_rule([3], 3, [4], 0, [3])
(0, [2], 3, 0)
```

```
>>> from sage.all import *
>>> Shifted.backward_rule([Integer(3)], Integer(1), [Integer(3), Integer(1)],␣
↪Integer(0), [Integer(3)])
(0, [2], 2, 0)

>>> Shifted.backward_rule([Integer(3),Integer(1)], Integer(2), [Integer(3),␣
↪Integer(2)], Integer(0), [Integer(3),Integer(1)])
(0, [2, 1], 2, 0)

>>> Shifted.backward_rule([Integer(2),Integer(1)], Integer(3), [Integer(3),␣
↪Integer(1)], Integer(0), [Integer(2),Integer(1)])
(0, [2], 1, 0)

>>> Shifted.backward_rule([Integer(3)], Integer(3), [Integer(4)], Integer(0),␣
↪[Integer(3)])
(0, [2], 3, 0)
```

forward_rule(*y*, *e*, *t*, *f*, *x*, *content*)

Return the output path given two incident edges and the content.

See [Fom1995] Lemma 4.5.1, page 38.

INPUT:

- `y`, `e`, `t`, `f`, `x` – a path of three partitions and two colors from a cell in a growth diagram, labelled as:

```
t f x
e
y
```

- `content` – 0 or 1; the content of the cell

OUTPUT:

The two colors and the fourth partition `g`, `z`, `h` according to Sagan-Worley insertion.

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.forward_rule([], 0, [], 0, [], 1)
(1, [1], 0)

sage: Shifted.forward_rule([1], 0, [1], 0, [1], 1)
(2, [2], 0)
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> Shifted.forward_rule([], Integer(0), [], Integer(0), [], Integer(1))
(1, [1], 0)

>>> Shifted.forward_rule([Integer(1)], Integer(0), [Integer(1)], Integer(0),␣
→[Integer(1)], Integer(1))
(2, [2], 0)
```

if `x != y`:

```
sage: Shifted.forward_rule([3], 0, [2], 1, [2,1], 0)
(1, [3, 1], 0)

sage: Shifted.forward_rule([2,1], 0, [2], 2, [3], 0)
(2, [3, 1], 0)
```

```
>>> from sage.all import *
>>> Shifted.forward_rule([Integer(3)], Integer(0), [Integer(2)], Integer(1),␣
→[Integer(2),Integer(1)], Integer(0))
(1, [3, 1], 0)

>>> Shifted.forward_rule([Integer(2),Integer(1)], Integer(0), [Integer(2)],␣
→Integer(2), [Integer(3)], Integer(0))
(2, [3, 1], 0)
```

if `x == y != t`:

```
sage: Shifted.forward_rule([3], 0, [2], 2, [3], 0)
(1, [3, 1], 0)

sage: Shifted.forward_rule([3,1], 0, [2,1], 2, [3,1], 0)
(2, [3, 2], 0)

sage: Shifted.forward_rule([2,1], 0, [2], 1, [2,1], 0)
(3, [3, 1], 0)

sage: Shifted.forward_rule([3], 0, [2], 3, [3], 0)
(3, [4], 0)
```

```
>>> from sage.all import *
>>> Shifted.forward_rule([Integer(3)], Integer(0), [Integer(2)], Integer(2),␣
↪[Integer(3)], Integer(0))
(1, [3, 1], 0)

>>> Shifted.forward_rule([Integer(3),Integer(1)], Integer(0), [Integer(2),
↪Integer(1)], Integer(2), [Integer(3),Integer(1)], Integer(0))
(2, [3, 2], 0)

>>> Shifted.forward_rule([Integer(2),Integer(1)], Integer(0), [Integer(2)],␣
↪Integer(1), [Integer(2),Integer(1)], Integer(0))
(3, [3, 1], 0)

>>> Shifted.forward_rule([Integer(3)], Integer(0), [Integer(2)], Integer(3),␣
↪[Integer(3)], Integer(0))
(3, [4], 0)
```

has_multiple_edges = True

is_P_edge(*v*, *w*)

Return whether `(v, w)` is a P-edge of `self`.

`(v, w)` is an edge if `w` contains `v`.

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: v = Shifted.vertices(2)[0]; v
[2]
sage: [w for w in Shifted.vertices(3) if Shifted.is_P_edge(v, w)]
[[3], [2, 1]]
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> v = Shifted.vertices(Integer(2))[Integer(0)]; v
[2]
>>> [w for w in Shifted.vertices(Integer(3)) if Shifted.is_P_edge(v, w)]
[[3], [2, 1]]
```

is_Q_edge(*v*, *w*)

Return whether `(v, w)` is a Q-edge of `self`.

`(v, w)` is an edge if `w` is obtained from `v` by adding a cell. It is a black (color 1) edge, if the cell is on the diagonal, otherwise it can be blue or red (color 2 or 3).

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: v = Shifted.vertices(2)[0]; v
[2]
sage: [(w, Shifted.is_Q_edge(v, w)) for w in Shifted.vertices(3)]
[([3], [2, 3]), ([2, 1], [1])]
sage: all(Shifted.is_Q_edge(v, w) == [] for w in Shifted.vertices(4))
True
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> v = Shifted.vertices(Integer(2))[Integer(0)]; v
[2]
>>> [(w, Shifted.is_Q_edge(v, w)) for w in Shifted.vertices(Integer(3))]
[([3], [2, 3]), ([2, 1], [1])]
>>> all(Shifted.is_Q_edge(v, w) == [] for w in Shifted.vertices(Integer(4)))
True
```

normalize_vertex(*v*)

Return v as a partition.

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.normalize_vertex([3,1]).parent()
Partitions
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> Shifted.normalize_vertex([Integer(3),Integer(1)]).parent()
Partitions
```

rank(*v*)

Return the rank of v: the size of the shifted partition.

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.rank(Shifted.vertices(3)[0])
3
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> Shifted.rank(Shifted.vertices(Integer(3))[Integer(0)])
3
```

vertices(*n*)

Return the vertices of the dual graded graph on level n.

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.vertices(3)
Partitions of the integer 3 satisfying constraints max_slope=-1
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> Shifted.vertices(Integer(3))
Partitions of the integer 3 satisfying constraints max_slope=-1
```

zero = []

class sage.combinat.growth.**RuleSylvester**

Bases: *Rule*

A rule modelling a Schensted-like correspondence for binary trees.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: GrowthDiagram(Sylvester, [3,1,2])
0  1  0
0  0  1
1  0  0
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> GrowthDiagram(Sylvester, [Integer(3),Integer(1),Integer(2)])
0  1  0
0  0  1
1  0  0
```

The vertices of the dual graded graph are *BinaryTrees*:

```
sage: Sylvester.vertices(3)
Binary trees of size 3
```

```
>>> from sage.all import *
>>> Sylvester.vertices(Integer(3))
Binary trees of size 3
```

The *P_graph()* is also known as the bracket tree, the *Q_graph()* is the lattice of finite order ideals of the infinite binary tree, see Example 2.4.6 in [Fom1994].

For a permutation, the *P_symbol()* is the binary search tree, the *Q_symbol()* is the increasing tree corresponding to the inverse permutation. Note that, instead of passing the rule to *GrowthDiagram*, we can also call the rule to create growth diagrams. From [Nze2007]:

```
sage: pi = Permutation([3,5,1,4,2,6]); G = Sylvester(pi); G
0  0  1  0  0  0
0  0  0  0  1  0
1  0  0  0  0  0
0  0  0  1  0  0
0  1  0  0  0  0
0  0  0  0  0  1
sage: ascii_art(G.P_symbol())
  __3__
 /     \
1       5
 \     / \
  2   4   6
sage: ascii_art(G.Q_symbol())
  __1__
 /     \
3       2
 \     / \
  5   4   6
```

(continues on next page)

(continued from previous page)

```
sage: all(Sylvester(pi).P_symbol() == pi.binary_search_tree()
....:     for pi in Permutations(5))
True

sage: all(Sylvester(pi).Q_symbol() == pi.inverse().increasing_tree()
....:     for pi in Permutations(5))
True
```

```
>>> from sage.all import *
>>> pi = Permutation([Integer(3),Integer(5),Integer(1),Integer(4),Integer(2),
↪Integer(6)]); G = Sylvester(pi); G
0  0  1  0  0  0
0  0  0  0  1  0
1  0  0  0  0  0
0  0  0  1  0  0
0  1  0  0  0  0
0  0  0  0  0  1
>>> ascii_art(G.P_symbol())
  __3__
 /     \
1       5
 \     / \
  2   4   6
>>> ascii_art(G.Q_symbol())
  __1__
 /     \
3       2
 \     / \
  5   4   6

>>> all(Sylvester(pi).P_symbol() == pi.binary_search_tree()
...     for pi in Permutations(Integer(5)))
True

>>> all(Sylvester(pi).Q_symbol() == pi.inverse().increasing_tree()
...     for pi in Permutations(Integer(5)))
True
```

P_symbol(*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a labelled binary tree.

For permutations, this coincides with the binary search tree.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: pi = Permutation([2,4,3,1])
sage: ascii_art(Sylvester(pi).P_symbol())
  _2_
 /   \
1     4
     /
```

(continues on next page)

(continued from previous page)

```
    3
sage: Sylvester(pi).P_symbol() == pi.binary_search_tree()
True
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> pi = Permutation([Integer(2),Integer(4),Integer(3),Integer(1)])
>>> ascii_art(Sylvester(pi).P_symbol())
  _2_
 /   \
1     4
     /
    3
>>> Sylvester(pi).P_symbol() == pi.binary_search_tree()
True
```

We can also do the skew version:

```
sage: B = BinaryTree; E = B(); N = B([])
sage: ascii_art(Sylvester([3,2], shape=[3,3,3], labels=[N,N,N,E,E,E,N]).P_
↪symbol())
  __1___
 /      \
None     3
        /
       2
```

```
>>> from sage.all import *
>>> B = BinaryTree; E = B(); N = B([])
>>> ascii_art(Sylvester([Integer(3),Integer(2)], shape=[Integer(3),Integer(3),
↪Integer(3)], labels=[N,N,N,E,E,E,N]).P_symbol())
  __1___
 /      \
None     3
        /
       2
```

Q_symbol(*Q_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a labelled binary tree.

For permutations, this coincides with the increasing tree.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: pi = Permutation([2,4,3,1])
sage: ascii_art(Sylvester(pi).Q_symbol())
  _1_
 /   \
4     2
     /
    3
```

(continues on next page)

(continued from previous page)

```
sage: Sylvester(pi).Q_symbol() == pi.inverse().increasing_tree()
True
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> pi = Permutation([Integer(2),Integer(4),Integer(3),Integer(1)])
>>> ascii_art(Sylvester(pi).Q_symbol())
  _1_
 /   \
4     2
     /
    3
>>> Sylvester(pi).Q_symbol() == pi.inverse().increasing_tree()
True
```

We can also do the skew version:

```
sage: B = BinaryTree; E = B(); N = B([])
sage: ascii_art(Sylvester([3,2], shape=[3,3,3], labels=[N,N,N,E,E,E,N]).Q_
↪symbol())
  _None_
 /      \
3        1
        /
       2
```

```
>>> from sage.all import *
>>> B = BinaryTree; E = B(); N = B([])
>>> ascii_art(Sylvester([Integer(3),Integer(2)], shape=[Integer(3),Integer(3),
↪Integer(3)], labels=[N,N,N,E,E,E,N]).Q_symbol())
  _None_
 /      \
3        1
        /
       2
```

backward_rule(*y*, *z*, *x*)

Return the output shape given three shapes and the content.

See [Nze2007], page 9.

INPUT:

- `y, z, x` – three binary trees from a cell in a growth diagram, labelled as:

```
  x
y z
```

OUTPUT:

A pair `(t, content)` consisting of the shape of the fourth binary tree t and the content of the cell.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: B = BinaryTree; E = B(); N = B([]); L = B([[],None])
sage: R = B([None,[]]); T = B([[],[]])

sage: ascii_art(Sylvester.backward_rule(E, E, E))
( , 0 )
sage: ascii_art(Sylvester.backward_rule(N, N, N))
( o, 0 )
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> B = BinaryTree; E = B(); N = B([]); L = B([[],None])
>>> R = B([None,[]]); T = B([[],[]])

>>> ascii_art(Sylvester.backward_rule(E, E, E))
( , 0 )
>>> ascii_art(Sylvester.backward_rule(N, N, N))
( o, 0 )
```

forward_rule(*y*, *t*, *x*, *content*)

Return the output shape given three shapes and the content.

See [Nze2007], page 9.

INPUT:

- `y`, `t`, `x` – three binary trees from a cell in a growth diagram, labelled as:

```
t x
y
```

- `content` – 0 or 1; the content of the cell

OUTPUT: the fourth binary tree `z`

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: B = BinaryTree; E = B(); N = B([]); L = B([[],None])
sage: R = B([None,[]]); T = B([[],[]])

sage: ascii_art(Sylvester.forward_rule(E, E, E, 1))
o
sage: ascii_art(Sylvester.forward_rule(N, N, N, 1))
o
 \
  o
sage: ascii_art(Sylvester.forward_rule(L, L, L, 1))
  o
 / \
o   o
sage: ascii_art(Sylvester.forward_rule(R, R, R, 1))
o
 \
  o
```

(continues on next page)

(continued from previous page)

```
    \
     o
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> B = BinaryTree; E = B(); N = B([]); L = B([[],None])
>>> R = B([None,[]]); T = B([[],[]])

>>> ascii_art(Sylvester.forward_rule(E, E, E, Integer(1)))
o
>>> ascii_art(Sylvester.forward_rule(N, N, N, Integer(1)))
o
 \
  o
>>> ascii_art(Sylvester.forward_rule(L, L, L, Integer(1)))
  o
 / \
o   o
>>> ascii_art(Sylvester.forward_rule(R, R, R, Integer(1)))
o
 \
  o
   \
    o
```

If `y != x`, obtain `z` from `y` adding a node such that deleting the right most gives `x`:

```
sage: ascii_art(Sylvester.forward_rule(R, N, L, 0))
  o
 / \
o   o

sage: ascii_art(Sylvester.forward_rule(L, N, R, 0))
  o
 /
o
 \
  o
```

```
>>> from sage.all import *
>>> ascii_art(Sylvester.forward_rule(R, N, L, Integer(0)))
  o
 / \
o   o

>>> ascii_art(Sylvester.forward_rule(L, N, R, Integer(0)))
  o
 /
o
 \
  o
```

If `y == x != t`, obtain `z` from `x` by adding a node as left child to the right most node:

```
sage: ascii_art(Sylvester.forward_rule(N, E, N, 0))
  o
 /
o
sage: ascii_art(Sylvester.forward_rule(T, L, T, 0))
  _o_
 /   \
o     o
     /
    o
sage: ascii_art(Sylvester.forward_rule(L, N, L, 0))
    o
   /
  o
 /
o
sage: ascii_art(Sylvester.forward_rule(R, N, R, 0))
o
 \
  o
 /
o
```

```
>>> from sage.all import *
>>> ascii_art(Sylvester.forward_rule(N, E, N, Integer(0)))
  o
 /
o
>>> ascii_art(Sylvester.forward_rule(T, L, T, Integer(0)))
  _o_
 /   \
o     o
     /
    o
>>> ascii_art(Sylvester.forward_rule(L, N, L, Integer(0)))
    o
   /
  o
 /
o
>>> ascii_art(Sylvester.forward_rule(R, N, R, Integer(0)))
o
 \
  o
 /
o
```

is_P_edge(*v*, *w*)

Return whether `(v, w)` is a P-edge of `self`.

`(v, w)` is an edge if `v` is obtained from `w` by deleting its right-most node.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: v = Sylvester.vertices(2)[1]; ascii_art(v)
  o
 /
o

sage: ascii_art([w for w in Sylvester.vertices(3) if Sylvester.is_P_edge(v,␣
↪w)])
[    o   ,      o ]
[   / \        /  ]
[ o    o     o    ]
[          /      ]
[         o       ]

sage: [w for w in Sylvester.vertices(4) if Sylvester.is_P_edge(v, w)]
[]
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> v = Sylvester.vertices(Integer(2))[Integer(1)]; ascii_art(v)
  o
 /
o

>>> ascii_art([w for w in Sylvester.vertices(Integer(3)) if Sylvester.is_P_
↪edge(v, w)])
[    o   ,      o ]
[   / \        /  ]
[ o    o     o    ]
[          /      ]
[         o       ]

>>> [w for w in Sylvester.vertices(Integer(4)) if Sylvester.is_P_edge(v, w)]
[]
```

is_Q_edge(*v*, *w*)

Return whether `(v, w)` is a Q-edge of `self`.

`(v, w)` is an edge if `v` is a sub-tree of `w` with one node less.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: v = Sylvester.vertices(2)[1]; ascii_art(v)
  o
 /
o
sage: ascii_art([w for w in Sylvester.vertices(3) if Sylvester.is_Q_edge(v,␣
↪w)])
[    o   ,   o,        o ]
[   / \     /         /  ]
[ o    o  o         o    ]
[          \       /     ]
```

(continues on next page)

(continued from previous page)

```
[           o   o      ]
sage: [w for w in Sylvester.vertices(4) if Sylvester.is_Q_edge(v, w)]
[]
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> v = Sylvester.vertices(Integer(2))[Integer(1)]; ascii_art(v)
  o
 /
o
>>> ascii_art([w for w in Sylvester.vertices(Integer(3)) if Sylvester.is_Q_
↪edge(v, w)])
[   o  ,    o,      o ]
[  / \     /       /  ]
[ o   o  o       o    ]
[          \    /     ]
[           o  o      ]
>>> [w for w in Sylvester.vertices(Integer(4)) if Sylvester.is_Q_edge(v, w)]
[]
```

normalize_vertex(*v*)

Return v as a binary tree.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: Sylvester.normalize_vertex([[],[]]).parent()
Binary trees
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> Sylvester.normalize_vertex([[],[]]).parent()
Binary trees
```

rank(*v*)

Return the rank of v: the number of nodes of the tree.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: Sylvester.rank(Sylvester.vertices(3)[0])
3
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> Sylvester.rank(Sylvester.vertices(Integer(3))[Integer(0)])
3
```

vertices(*n*)

Return the vertices of the dual graded graph on level n.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: Sylvester.vertices(3)
Binary trees of size 3
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> Sylvester.vertices(Integer(3))
Binary trees of size 3
```

zero = .

class sage.combinat.growth.**RuleYoungFibonacci**

Bases: *Rule*

A rule modelling a Schensted-like correspondence for Young-Fibonacci-tableaux.

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: GrowthDiagram(YF, [3,1,2])
0  1  0
0  0  1
1  0  0
```

```
>>> from sage.all import *
>>> YF = GrowthDiagram.rules.YoungFibonacci()
>>> GrowthDiagram(YF, [Integer(3),Integer(1),Integer(2)])
0  1  0
0  0  1
1  0  0
```

The vertices of the dual graded graph are Fibonacci words - compositions into parts of size at most two:

```
sage: YF.vertices(4)
[word: 22, word: 211, word: 121, word: 112, word: 1111]
```

```
>>> from sage.all import *
>>> YF.vertices(Integer(4))
[word: 22, word: 211, word: 121, word: 112, word: 1111]
```

Note that, instead of passing the rule to *GrowthDiagram*, we can also use call the rule to create growth diagrams. For example:

```
sage: G = YF([2, 3, 7, 4, 1, 6, 5]); G
0  0  0  0  1  0  0
1  0  0  0  0  0  0
0  1  0  0  0  0  0
0  0  0  1  0  0  0
0  0  0  0  0  0  1
0  0  0  0  0  1  0
0  0  1  0  0  0  0
```

```
>>> from sage.all import *
>>> G = YF([Integer(2), Integer(3), Integer(7), Integer(4), Integer(1),␣
↪Integer(6), Integer(5)]); G
0  0  0  0  1  0  0
1  0  0  0  0  0  0
0  1  0  0  0  0  0
0  0  0  1  0  0  0
0  0  0  0  0  0  1
0  0  0  0  0  1  0
0  0  1  0  0  0  0
```

The Kleitman Greene invariant is: take the last letter and the largest letter of the permutation and remove them. If they coincide write 1, otherwise write 2:

```
sage: G.P_chain()[-1]
word: 21211
```

```
>>> from sage.all import *
>>> G.P_chain()[-Integer(1)]
word: 21211
```

backward_rule(*y*, *z*, *x*)

Return the content and the input shape.

See [Fom1995] Lemma 4.4.1, page 35.

- y, z, x – three Fibonacci words from a cell in a growth diagram, labelled as:

```
  x
y z
```

OUTPUT:

A pair (t, content) consisting of the shape of the fourth word and the content of the cell.

forward_rule(*y*, *t*, *x*, *content*)

Return the output shape given three shapes and the content.

See [Fom1995] Lemma 4.4.1, page 35.

INPUT:

- y, t, x – three Fibonacci words from a cell in a growth diagram, labelled as:

```
t x
y
```

- content – 0 or 1; the content of the cell

OUTPUT: the fourth Fibonacci word

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()

sage: YF.forward_rule([], [], [], 1)
word: 1
```

(continues on next page)

(continued from previous page)

```
sage: YF.forward_rule([1], [1], [1], 1)
word: 11

sage: YF.forward_rule([1,2], [1], [1,1], 0)
word: 21

sage: YF.forward_rule([1,1], [1], [1,1], 0)
word: 21
```

```
>>> from sage.all import *
>>> YF = GrowthDiagram.rules.YoungFibonacci()

>>> YF.forward_rule([], [], [], Integer(1))
word: 1

>>> YF.forward_rule([Integer(1)], [Integer(1)], [Integer(1)], Integer(1))
word: 11

>>> YF.forward_rule([Integer(1),Integer(2)], [Integer(1)], [Integer(1),
↪Integer(1)], Integer(0))
word: 21

>>> YF.forward_rule([Integer(1),Integer(1)], [Integer(1)], [Integer(1),
↪Integer(1)], Integer(0))
word: 21
```

is_P_edge(*v*, *w*)

Return whether `(v, w)` is a P-edge of `self`.

`(v, w)` is an edge if `v` is obtained from `w` by deleting a `1` or replacing the left-most `2` by a `1`.

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: v = YF.vertices(5)[5]; v
word: 1121
sage: [w for w in YF.vertices(6) if YF.is_P_edge(v, w)]
[word: 2121, word: 11121]
sage: [w for w in YF.vertices(7) if YF.is_P_edge(v, w)]
[]
```

```
>>> from sage.all import *
>>> YF = GrowthDiagram.rules.YoungFibonacci()
>>> v = YF.vertices(Integer(5))[Integer(5)]; v
word: 1121
>>> [w for w in YF.vertices(Integer(6)) if YF.is_P_edge(v, w)]
[word: 2121, word: 11121]
>>> [w for w in YF.vertices(Integer(7)) if YF.is_P_edge(v, w)]
[]
```

is_Q_edge(*v*, *w*)

Return whether `(v, w)` is a P-edge of `self`.

(v, w) is an edge if v is obtained from w by deleting a 1 or replacing the left-most 2 by a 1.

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: v = YF.vertices(5)[5]; v
word: 1121
sage: [w for w in YF.vertices(6) if YF.is_P_edge(v, w)]
[word: 2121, word: 11121]
sage: [w for w in YF.vertices(7) if YF.is_P_edge(v, w)]
[]
```

```
>>> from sage.all import *
>>> YF = GrowthDiagram.rules.YoungFibonacci()
>>> v = YF.vertices(Integer(5))[Integer(5)]; v
word: 1121
>>> [w for w in YF.vertices(Integer(6)) if YF.is_P_edge(v, w)]
[word: 2121, word: 11121]
>>> [w for w in YF.vertices(Integer(7)) if YF.is_P_edge(v, w)]
[]
```

normalize_vertex(*v*)

Return v as a word with letters 1 and 2.

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: YF.normalize_vertex([1,2,1]).parent()
Finite words over {1, 2}
```

```
>>> from sage.all import *
>>> YF = GrowthDiagram.rules.YoungFibonacci()
>>> YF.normalize_vertex([Integer(1),Integer(2),Integer(1)]).parent()
Finite words over {1, 2}
```

rank(*v*)

Return the rank of v: the size of the corresponding composition.

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: YF.rank(YF.vertices(3)[0])
3
```

```
>>> from sage.all import *
>>> YF = GrowthDiagram.rules.YoungFibonacci()
>>> YF.rank(YF.vertices(Integer(3))[Integer(0)])
3
```

vertices(*n*)

Return the vertices of the dual graded graph on level n.

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: YF.vertices(3)
[word: 21, word: 12, word: 111]
```

```
>>> from sage.all import *
>>> YF = GrowthDiagram.rules.YoungFibonacci()
>>> YF.vertices(Integer(3))
[word: 21, word: 12, word: 111]
```

5.1.119 Grossman-Larson Hopf Algebras

AUTHORS:

- Frédéric Chapoton (2017)

class sage.combinat.grossman_larson_algebras.**GrossmanLarsonAlgebra**(*R*, *names=None*)

Bases: *CombinatorialFreeModule*

The Grossman-Larson Hopf Algebra.

The Grossman-Larson Hopf Algebras are Hopf algebras with a basis indexed by forests of decorated rooted trees. They are the universal enveloping algebras of free pre-Lie algebras, seen as Lie algebras.

The Grossman-Larson Hopf algebra on a given set E has an explicit description using rooted forests. The underlying vector space has a basis indexed by finite rooted forests endowed with a map from their vertices to E (called the "labeling"). In this basis, the product of two (decorated) rooted forests $S * T$ is a sum over all maps from the set of roots of T to the union of a singleton $\{\#\}$ and the set of vertices of S. Given such a map, one defines a new forest as follows. Starting from the disjoint union of all rooted trees of S and T, one adds an edge from every root of T to its image when this image is not the fake vertex labelled `#`. The coproduct sends a rooted forest T to the sum of all tensors $T_1 \otimes T_2$ obtained by splitting the connected components of T into two subsets and letting T_1 be the forest formed by the first subset and T_2 the forest formed by the second. This yields a connected graded Hopf algebra (the degree of a forest is its number of vertices).

See [Pana2002] (Section 2) and [GroLar1]. (Note that both references use rooted trees rather than rooted forests, so think of each rooted forest grafted onto a new root. Also, the product is reversed, so they are defining the opposite algebra structure.)

Warning

For technical reasons, instead of using forests as labels for the basis, we use rooted trees. Their root vertex should be considered as a fake vertex. This fake root vertex is labelled `'#'` when labels are present.

EXAMPLES:

```
sage: G = algebras.GrossmanLarson(QQ, 'xy')
sage: x, y = G.single_vertex_all()
sage: ascii_art(x*y)
B  + B
 #      #_
 |     / /
 x    x y
 |
 y

sage: ascii_art(x*x*x)
B  + B      + 3*B     + B
 #      #         #_      _#__
 |      |        / /     / / /
 x      x_      x x     x x x
 |     / /        |
 x    x x         x
 |
 x
```

```
>>> from sage.all import *
>>> G = algebras.GrossmanLarson(QQ, 'xy')
>>> x, y = G.single_vertex_all()
>>> ascii_art(x*y)
B  + B
 #      #_
 |     / /
 x    x y
 |
 y

>>> ascii_art(x*x*x)
B  + B      + 3*B     + B
 #      #         #_      _#__
 |      |        / /     / / /
```

(continues on next page)

(continued from previous page)

```
 x       x_      x x     x x x
 |      / /        |
 x     x x         x
 |
 x
```

The Grossman-Larson algebra is associative:

```
sage: z = x * y
sage: x * (y * z) == (x * y) * z
True
```

```
>>> from sage.all import *
>>> z = x * y
>>> x * (y * z) == (x * y) * z
True
```

It is not commutative:

```
sage: x * y == y * x
False
```

```
>>> from sage.all import *
>>> x * y == y * x
False
```

When `None` is given as input, unlabelled forests are used instead; this corresponds to a 1-element set E:

```
sage: G = algebras.GrossmanLarson(QQ, None)
sage: x = G.single_vertex_all()[0]
sage: ascii_art(x*x)
B  + B
 o       o_
 |      / /
 o     o o
 |
 o
```

```
>>> from sage.all import *
>>> G = algebras.GrossmanLarson(QQ, None)
>>> x = G.single_vertex_all()[Integer(0)]
>>> ascii_art(x*x)
B  + B
 o       o_
 |      / /
 o     o o
 |
 o
```

Note

Variables names can be `None`, a list of strings, a string or an integer. When `None` is given, unlabelled rooted forests are used. When a single string is given, each letter is taken as a variable. See *sage.combinat.words.alphabet.build_alphabet()*.

> **Warning:** Beware that the underlying combinatorial free module is based either on `RootedTrees` or on `LabelledRootedTrees`, with no restriction on the labellings. This means that all code calling the `basis()` method would not give meaningful results, since `basis()` returns many "chaff" elements that do not belong to the algebra.

REFERENCES:

- [Pana2002]
- [GroLar1]

an_element()

Return an element of `self`.

EXAMPLES:

```
sage: A = algebras.GrossmanLarson(QQ, 'xy')
sage: A.an_element()
B[#[x[]]] + 2*B[#[x[x[]]]] + 2*B[#[x[], x[]]]
```

```
>>> from sage.all import *
>>> A = algebras.GrossmanLarson(QQ, 'xy')
>>> A.an_element()
B[#[x[]]] + 2*B[#[x[x[]]]] + 2*B[#[x[], x[]]]
```

antipode_on_basis(*x*)

Return the antipode of a forest.

EXAMPLES:

```
sage: G = algebras.GrossmanLarson(QQ,2)
sage: x, y = G.single_vertex_all()
sage: G.antipode(x)   # indirect doctest
-B[#[0[]]]

sage: G.antipode(y*x)   # indirect doctest
B[#[0[1[]]]] + B[#[0[], 1[]]]
```

```
>>> from sage.all import *
>>> G = algebras.GrossmanLarson(QQ,Integer(2))
>>> x, y = G.single_vertex_all()
>>> G.antipode(x)   # indirect doctest
-B[#[0[]]]

>>> G.antipode(y*x)   # indirect doctest
B[#[0[1[]]]] + B[#[0[], 1[]]]
```

change_ring(*R*)

Return the Grossman-Larson algebra in the same variables over R.

INPUT:

- R – a ring

EXAMPLES:

```
sage: A = algebras.GrossmanLarson(ZZ, 'fgh')
sage: A.change_ring(QQ)
Grossman-Larson Hopf algebra on 3 generators ['f', 'g', 'h']
over Rational Field
```

```
>>> from sage.all import *
>>> A = algebras.GrossmanLarson(ZZ, 'fgh')
>>> A.change_ring(QQ)
Grossman-Larson Hopf algebra on 3 generators ['f', 'g', 'h']
over Rational Field
```

coproduct_on_basis(*x*)

Return the coproduct of a forest.

EXAMPLES:

```
sage: G = algebras.GrossmanLarson(QQ,2)
sage: x, y = G.single_vertex_all()
sage: ascii_art(G.coproduct(x))  # indirect doctest
1 # B  + B  # 1
     #    #
     |    |
     0    0

sage: Delta_xy = G.coproduct(y*x)
sage: ascii_art(Delta_xy)  # random indirect doctest
1 # B     + 1 # B  + B  # B  + B     # 1 + B  # B  + B  # 1
       #_         #    #    #      #_         #    #    #
      / /         |    |    |     / /         |    |    |
     0 1          1    0    1    0 1          1    0    1
                  |                                     |
                  0                                     0
```

```
>>> from sage.all import *
>>> G = algebras.GrossmanLarson(QQ,Integer(2))
>>> x, y = G.single_vertex_all()
>>> ascii_art(G.coproduct(x))  # indirect doctest
1 # B  + B  # 1
     #    #
     |    |
     0    0

>>> Delta_xy = G.coproduct(y*x)
>>> ascii_art(Delta_xy)  # random indirect doctest
1 # B     + 1 # B  + B  # B  + B     # 1 + B  # B  + B  # 1
       #_         #    #    #      #_         #    #    #
```

(continues on next page)

(continued from previous page)

```
      / /          |     |     |      / /          |     |     |
     0 1           1     0     1     0 1           1     0     1
                   |                                           |
                   0                                           0
```

counit_on_basis(*x*)

Return the counit on a basis element.

This is zero unless the forest x is empty.

EXAMPLES:

```
sage: A = algebras.GrossmanLarson(QQ, 'xy')
sage: RT = A.basis().keys()
sage: x = RT([RT([],'x')],'#')
sage: A.counit_on_basis(x)
0
sage: A.counit_on_basis(RT([],'#'))
1
```

```
>>> from sage.all import *
>>> A = algebras.GrossmanLarson(QQ, 'xy')
>>> RT = A.basis().keys()
>>> x = RT([RT([],'x')],'#')
>>> A.counit_on_basis(x)
0
>>> A.counit_on_basis(RT([],'#'))
1
```

degree_on_basis(*t*)

Return the degree of a rooted forest in the Grossman-Larson algebra.

This is the total number of vertices of the forest.

EXAMPLES:

```
sage: A = algebras.GrossmanLarson(QQ, '@')
sage: RT = A.basis().keys()
sage: A.degree_on_basis(RT([RT([])]))
1
```

```
>>> from sage.all import *
>>> A = algebras.GrossmanLarson(QQ, '@')
>>> RT = A.basis().keys()
>>> A.degree_on_basis(RT([RT([])]))
1
```

one_basis()

Return the empty rooted forest.

EXAMPLES:

```
sage: A = algebras.GrossmanLarson(QQ, 'ab')
sage: A.one_basis()
```

(continues on next page)

(continued from previous page)

```
#[]

sage: A = algebras.GrossmanLarson(QQ, None)
sage: A.one_basis()
[]
```

```
>>> from sage.all import *
>>> A = algebras.GrossmanLarson(QQ, 'ab')
>>> A.one_basis()
#[]

>>> A = algebras.GrossmanLarson(QQ, None)
>>> A.one_basis()
[]
```

product_on_basis(*x*, *y*)

Return the product of two forests x and y.

This is the sum over all possible ways for the components of the forest y to either fall side-by-side with components of x or be grafted on a vertex of x.

EXAMPLES:

```
sage: A = algebras.GrossmanLarson(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([RT([])])
sage: A.product_on_basis(x, x)
B[[[[]]]] + B[[[], []]]
```

```
>>> from sage.all import *
>>> A = algebras.GrossmanLarson(QQ, None)
>>> RT = A.basis().keys()
>>> x = RT([RT([])])
>>> A.product_on_basis(x, x)
B[[[[]]]] + B[[[], []]]
```

Check that the product is the correct one:

```
sage: A = algebras.GrossmanLarson(QQ, 'uv')
sage: RT = A.basis().keys()
sage: Tu = RT([RT([],'u')],'#')
sage: Tv = RT([RT([],'v')],'#')
sage: A.product_on_basis(Tu, Tv)
B[#[u[v[]]]] + B[#[u[], v[]]]
```

```
>>> from sage.all import *
>>> A = algebras.GrossmanLarson(QQ, 'uv')
>>> RT = A.basis().keys()
>>> Tu = RT([RT([],'u')],'#')
>>> Tv = RT([RT([],'v')],'#')
>>> A.product_on_basis(Tu, Tv)
B[#[u[v[]]]] + B[#[u[], v[]]]
```

single_vertex(*i*)

Return the i-th rooted forest with one vertex.

This is the rooted forest with just one vertex, labelled by the i-th element of the label list.

See also:

single_vertex_all().

INPUT:

- i – nonnegative integer

EXAMPLES:

```
sage: F = algebras.GrossmanLarson(ZZ, 'xyz')
sage: F.single_vertex(0)
B[#[x[]]]

sage: F.single_vertex(4)
Traceback (most recent call last):
...
IndexError: argument i (= 4) must be between 0 and 2
```

```
>>> from sage.all import *
>>> F = algebras.GrossmanLarson(ZZ, 'xyz')
>>> F.single_vertex(Integer(0))
B[#[x[]]]

>>> F.single_vertex(Integer(4))
Traceback (most recent call last):
...
IndexError: argument i (= 4) must be between 0 and 2
```

single_vertex_all()

Return the rooted forests with one vertex in self.

They freely generate the Lie algebra of primitive elements as a pre-Lie algebra.

See also:

single_vertex().

EXAMPLES:

```
sage: A = algebras.GrossmanLarson(ZZ, 'fgh')
sage: A.single_vertex_all()
(B[#[f[]]], B[#[g[]]], B[#[h[]]])

sage: A = algebras.GrossmanLarson(QQ, ['x1','x2'])
sage: A.single_vertex_all()
(B[#[x1[]]], B[#[x2[]]])
```

(continues on next page)

(continued from previous page)

```
sage: A = algebras.GrossmanLarson(ZZ, None)
sage: A.single_vertex_all()
(B[[[]]],)
```

```
>>> from sage.all import *
>>> A = algebras.GrossmanLarson(ZZ, 'fgh')
>>> A.single_vertex_all()
(B[#[f[]]], B[#[g[]]], B[#[h[]]])

>>> A = algebras.GrossmanLarson(QQ, ['x1','x2'])
>>> A.single_vertex_all()
(B[#[x1[]]], B[#[x2[]]])

>>> A = algebras.GrossmanLarson(ZZ, None)
>>> A.single_vertex_all()
(B[[[]]],)
```

some_elements()

Return some elements of the Grossman-Larson Hopf algebra.

EXAMPLES:

```
sage: A = algebras.GrossmanLarson(QQ, None)
sage: A.some_elements()
[B[[[]]], B[[]] + B[[[[]]]] + B[[[], []]],
4*B[[[[]]]] + 4*B[[[], []]]]
```

```
>>> from sage.all import *
>>> A = algebras.GrossmanLarson(QQ, None)
>>> A.some_elements()
[B[[[]]], B[[]] + B[[[[]]]] + B[[[], []]],
4*B[[[[]]]] + 4*B[[[], []]]]
```

With several generators:

```
sage: A = algebras.GrossmanLarson(QQ, 'xy')
sage: A.some_elements()
[B[#[x[]]],
 B[#[]] + B[#[x[x[]]]] + B[#[x[], x[]]],
 B[#[x[x[]]]] + 3*B[#[x[y[]]]] + B[#[x[], x[]]] + 3*B[#[x[], y[]]]]
```

```
>>> from sage.all import *
>>> A = algebras.GrossmanLarson(QQ, 'xy')
>>> A.some_elements()
[B[#[x[]]],
 B[#[]] + B[#[x[x[]]]] + B[#[x[], x[]]],
 B[#[x[x[]]]] + 3*B[#[x[y[]]]] + B[#[x[], x[]]] + 3*B[#[x[], y[]]]]
```

variable_names()

Return the names of the variables.

This returns the set E (as a family).

EXAMPLES:

```
sage: R = algebras.GrossmanLarson(QQ, 'xy')
sage: R.variable_names()
{'x', 'y'}

sage: R = algebras.GrossmanLarson(QQ, ['a','b'])
sage: R.variable_names()
{'a', 'b'}

sage: R = algebras.GrossmanLarson(QQ, 2)
sage: R.variable_names()
{0, 1}

sage: R = algebras.GrossmanLarson(QQ, None)
sage: R.variable_names()
{'o'}
```

```
>>> from sage.all import *
>>> R = algebras.GrossmanLarson(QQ, 'xy')
>>> R.variable_names()
{'x', 'y'}

>>> R = algebras.GrossmanLarson(QQ, ['a','b'])
>>> R.variable_names()
{'a', 'b'}

>>> R = algebras.GrossmanLarson(QQ, Integer(2))
>>> R.variable_names()
{0, 1}

>>> R = algebras.GrossmanLarson(QQ, None)
>>> R.variable_names()
{'o'}
```

5.1.120 Hall Polynomials

`sage.combinat.hall_polynomial.`**`hall_polynomial`**(*nu*, *mu*, *la*, *q=None*)

Return the (classical) Hall polynomial $P^{\nu}_{\mu,\lambda}$ (where ν, μ and λ are the inputs `nu`, `mu` and `la`).

Let ν, μ, λ be partitions. The Hall polynomial $P^{\nu}_{\mu,\lambda}(q)$ (in the indeterminate q) is defined as follows: Specialize q to a prime power, and consider the category of $\mathbf{F}_q$-vector spaces with a distinguished nilpotent endomorphism. The morphisms in this category shall be the linear maps commuting with the distinguished endomorphisms. The *type* of an object in the category will be the Jordan type of the distinguished endomorphism; this is a partition. Now, if N is any fixed object of type ν in this category, then the polynomial $P^{\nu}_{\mu,\lambda}(q)$ specialized at the prime power q counts the number of subobjects L of N having type λ such that the quotient object N/L has type μ. This determines the values of the polynomial $P^{\nu}_{\mu,\lambda}$ at infinitely many points (namely, at all prime powers), and hence $P^{\nu}_{\mu,\lambda}$ is uniquely determined. The degree of this polynomial is at most $n(\nu) - n(\lambda) - n(\mu)$, where $n(\kappa) = \sum_i (i-1)\kappa_i$ for every partition κ. (If this is negative, then the polynomial is zero.)

These are the structure coefficients of the `(classical) Hall algebra`.

If $|\nu| \neq |\mu| + |\lambda|$, then we have $P^{\nu}_{\mu,\lambda} = 0$. More generally, if the Littlewood-Richardson coefficient $c^{\nu}_{\mu,\lambda}$ vanishes, then $P^{\nu}_{\mu,\lambda} = 0$.

The Hall polynomials satisfy the symmetry property $P^{\nu}_{\mu,\lambda} = P^{\nu}_{\lambda,\mu}$.

ALGORITHM:

If $\lambda = (1^r)$ and $|\nu| = |\mu| + |\lambda|$, then we compute $P^{\nu}_{\mu,\lambda}$ as follows (cf. Example 2.4 in [Sch2006]):

First, write $\nu = (1^{l_1}, 2^{l_2}, \ldots, n^{l_n})$, and define a sequence $r = r_0 \geq r_1 \geq \cdots \geq r_n$ such that

$$\mu = \left(1^{l_1 - r_0 + 2r_1 - r_2}, 2^{l_2 - r_1 + 2r_2 - r_3}, \ldots, (n-1)^{l_{n-1} - r_{n-2} + 2r_{n-1} - r_n}, n^{l_n - r_{n-1} + r_n}\right).$$

Thus if $\mu = (1^{m_1}, \ldots, n^{m_n})$, we have the following system of equations:

$$\begin{aligned} m_1 &= l_1 - r + 2r_1 - r_2, \\ m_2 &= l_2 - r_1 + 2r_2 - r_3, \\ &\vdots, \\ m_{n-1} &= l_{n-1} - r_{n-2} + 2r_{n-1} - r_n, \\ m_n &= l_n - r_{n-1} + r_n \end{aligned}$$

and solving for r_i and back substituting we obtain the equations:

$$\begin{aligned} r_n &= r_{n-1} + m_n - l_n, \\ r_{n-1} &= r_{n-2} + m_{n-1} - l_{n-1} + m_n - l_n, \\ &\vdots, \\ r_1 &= r + \sum_{k=1}^{n} (m_k - l_k), \end{aligned}$$

or in general we have the recursive equation:

$$r_i = r_{i-1} + \sum_{k=i}^{n} (m_k - l_k).$$

This, combined with the condition that $r_0 = r$, determines the r_i uniquely (recursively). Next we define

$$t = (r_{n-2} - r_{n-1})(l_n - r_{n-1}) + (r_{n-3} - r_{n-2})(l_{n-1} + l_n - r_{n-2}) + \cdots + (r_0 - r_1)(l_2 + \cdots + l_n - r_1),$$

and with these notations we have

$$P^{\nu}_{\mu,(1^r)} = q^t \binom{l_n}{r_{n-1}}_q \binom{l_{n-1}}{r_{n-2} - r_{n-1}}_q \cdots \binom{l_1}{r_0 - r_1}_q.$$

To compute $P^{\nu}_{\mu,\lambda}$ in general, we compute the product $I_\mu I_\lambda$ in the Hall algebra and return the coefficient of I_ν.

EXAMPLES:

```
sage: from sage.combinat.hall_polynomial import hall_polynomial
sage: hall_polynomial([1,1],[1],[1])
q + 1
sage: hall_polynomial([2],[1],[1])
1
sage: hall_polynomial([2,1],[2],[1])
q
sage: hall_polynomial([2,2,1],[2,1],[1,1])
q^2 + q
sage: hall_polynomial([2,2,2,1],[2,2,1],[1,1])
q^4 + q^3 + q^2
```

(continues on next page)

(continued from previous page)

```
sage: hall_polynomial([3,2,2,1], [3,2], [2,1])
q^6 + q^5
sage: hall_polynomial([4,2,1,1], [3,1,1], [2,1])
2*q^3 + q^2 - q - 1
sage: hall_polynomial([4,2], [2,1], [2,1], 0)
1
```

```
>>> from sage.all import *
>>> from sage.combinat.hall_polynomial import hall_polynomial
>>> hall_polynomial([Integer(1),Integer(1)],[Integer(1)],[Integer(1)])
q + 1
>>> hall_polynomial([Integer(2)],[Integer(1)],[Integer(1)])
1
>>> hall_polynomial([Integer(2),Integer(1)],[Integer(2)],[Integer(1)])
q
>>> hall_polynomial([Integer(2),Integer(2),Integer(1)],[Integer(2),Integer(1)],
↪[Integer(1),Integer(1)])
q^2 + q
>>> hall_polynomial([Integer(2),Integer(2),Integer(2),Integer(1)],[Integer(2),
↪Integer(2),Integer(1)],[Integer(1),Integer(1)])
q^4 + q^3 + q^2
>>> hall_polynomial([Integer(3),Integer(2),Integer(2),Integer(1)], [Integer(3),
↪Integer(2)], [Integer(2),Integer(1)])
q^6 + q^5
>>> hall_polynomial([Integer(4),Integer(2),Integer(1),Integer(1)], [Integer(3),
↪Integer(1),Integer(1)], [Integer(2),Integer(1)])
2*q^3 + q^2 - q - 1
>>> hall_polynomial([Integer(4),Integer(2)], [Integer(2),Integer(1)], [Integer(2),
↪Integer(1)], Integer(0))
1
```

5.1.121 The Hillman-Grassl correspondence

This module implements weak reverse plane partitions and four correspondences on them: the Hillman-Grassl correspondence and its inverse, as well as the Sulzgruber correspondence and its inverse (the Pak correspondence).

Fix a partition λ (see `Partition()`). We draw all partitions and tableaux in English notation.

A λ*-array* will mean a tableau of shape λ whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A *weak reverse plane partition of shape* λ (short: λ*-rpp*) will mean a λ-array whose entries weakly increase along each row and weakly increase along each column. (The name "weak reverse plane partition" comes from Stanley in [EnumComb2] Section 7.22; other authors – such as Pak [Sulzgr2017], or Hillman and Grassl in [HilGra1976] – just call it a reverse plane partition.)

The Hillman-Grassl correspondence is a bijection from the set of λ-arrays to the set of λ-rpps. For its definition, see `hillman_grassl()`; for its inverse, see `hillman_grassl_inverse()`.

The Sulzgruber correspondence Φ_λ and the Pak correspondence ξ_λ are two further mutually inverse bijections between the set of λ-arrays and the set of λ-rpps. They appear (sometimes with different definitions, but defining the same maps) in [Pak2002], [Hopkins2017] and [Sulzgr2017]. For their definitions, see `sulzgruber_correspondence()` and `pak_correspondence()`.

EXAMPLES:

We construct a λ-rpp for $\lambda = (3, 3, 1)$ (note that λ needs not be specified explicitly):

```
sage: p = WeakReversePlanePartition([[0, 1, 3], [2, 4, 4], [3]])
sage: p.parent()
Weak Reverse Plane Partitions
```

```
>>> from sage.all import *
>>> p = WeakReversePlanePartition([[Integer(0), Integer(1), Integer(3)], [Integer(2),
→Integer(4), Integer(4)], [Integer(3)]])
>>> p.parent()
Weak Reverse Plane Partitions
```

(This is the example in Section 7.22 of [EnumComb2].)

Next, we apply the inverse of the Hillman-Grassl correspondence to it:

```
sage: HGp = p.hillman_grassl_inverse(); HGp
[[1, 2, 0], [1, 0, 1], [1]]
sage: HGp.parent()
Tableaux
```

```
>>> from sage.all import *
>>> HGp = p.hillman_grassl_inverse(); HGp
[[1, 2, 0], [1, 0, 1], [1]]
>>> HGp.parent()
Tableaux
```

This is a λ-array, encoded as a tableau. We can recover our original λ-rpp from it using the Hillman-Grassl correspondence:

```
sage: HGp.hillman_grassl() == p
True
```

```
>>> from sage.all import *
>>> HGp.hillman_grassl() == p
True
```

We can also apply the Pak correspondence to our rpp:

```
sage: Pp = p.pak_correspondence(); Pp
[[2, 0, 1], [0, 2, 0], [1]]
sage: Pp.parent()
Tableaux
```

```
>>> from sage.all import *
>>> Pp = p.pak_correspondence(); Pp
[[2, 0, 1], [0, 2, 0], [1]]
>>> Pp.parent()
Tableaux
```

This is undone by the Sulzgruber correspondence:

```
sage: Pp.sulzgruber_correspondence() == p
True
```

```
>>> from sage.all import *
>>> Pp.sulzgruber_correspondence() == p
True
```

These four correspondences can also be accessed as standalone functions (`hillman_grassl_inverse()`, `hillman_grassl()`, `pak_correspondence()` and `sulzgruber_correspondence()`) that transform lists of lists into lists of lists; this may be more efficient. For example, the above computation of `HGp` can also be obtained as follows:

```
sage: from sage.combinat.hillman_grassl import hillman_grassl_inverse
sage: HGp_bare = hillman_grassl_inverse([[0, 1, 3], [2, 4, 4], [3]])
sage: HGp_bare
[[1, 2, 0], [1, 0, 1], [1]]
sage: isinstance(HGp_bare, list)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.hillman_grassl import hillman_grassl_inverse
>>> HGp_bare = hillman_grassl_inverse([[Integer(0), Integer(1), Integer(3)],
↪[Integer(2), Integer(4), Integer(4)], [Integer(3)]])
>>> HGp_bare
[[1, 2, 0], [1, 0, 1], [1]]
>>> isinstance(HGp_bare, list)
True
```

class sage.combinat.hillman_grassl.**WeakReversePlanePartition**(*parent*, *t*)

Bases: `Tableau`

A weak reverse plane partition (short: rpp).

A weak reverse plane partition is a tableau with nonnegative entries that are weakly increasing in each row and weakly increasing in each column.

EXAMPLES:

```
sage: x = WeakReversePlanePartition([[0, 1, 1], [0, 1, 3], [1, 2, 2], [1, 2, 3],
↪[2]]); x
[[0, 1, 1], [0, 1, 3], [1, 2, 2], [1, 2, 3], [2]]
sage: x.pp()
  0  1  1
  0  1  3
```

(continues on next page)

(continued from previous page)

```
  1  2  2
  1  2  3
  2
sage: x.shape()
[3, 3, 3, 3, 1]
```

```
>>> from sage.all import *
>>> x = WeakReversePlanePartition([[Integer(0), Integer(1), Integer(1)],
↪[Integer(0), Integer(1), Integer(3)], [Integer(1), Integer(2), Integer(2)],
↪[Integer(1), Integer(2), Integer(3)], [Integer(2)]]); x
[[0, 1, 1], [0, 1, 3], [1, 2, 2], [1, 2, 3], [2]]
>>> x.pp()
  0  1  1
  0  1  3
  1  2  2
  1  2  3
  2
>>> x.shape()
[3, 3, 3, 3, 1]
```

conjugate()

Return the conjugate of `self`.

EXAMPLES:

```
sage: c = WeakReversePlanePartition([[1,1],[1,3],[2]]).conjugate(); c
[[1, 1, 2], [1, 3]]
sage: c.parent()
Weak Reverse Plane Partitions
```

```
>>> from sage.all import *
>>> c = WeakReversePlanePartition([[Integer(1),Integer(1)],[Integer(1),
↪Integer(3)],[Integer(2)]]).conjugate(); c
[[1, 1, 2], [1, 3]]
>>> c.parent()
Weak Reverse Plane Partitions
```

hillman_grassl_inverse()

Return the image of the λ-rpp `self` under the inverse of the Hillman-Grassl correspondence (as a `Tableau`).

Fix a partition λ (see `Partition()`). We draw all partitions and tableaux in English notation.

A λ-*array* will mean a tableau of shape λ whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A *weak reverse plane partition of shape* λ (short: λ-*rpp*) will mean a λ-array whose entries weakly increase along each row and weakly increase along each column.

The inverse H^{-1} of the Hillman-Grassl correspondence (see (`hillman_grassl()` for the latter) sends a λ-rpp π to a λ-array $H^{-1}(\pi)$ constructed recursively as follows:

- If all entries of π are 0, then $H^{-1}(\pi) = \pi$.
- Otherwise, let s be the index of the leftmost column of π containing a nonzero entry. Write the λ-array M as $(m_{i,j})$.

- Define a sequence $((i_1, j_1), (i_2, j_2), \ldots, (i_n, j_n))$ of boxes in the diagram of λ (actually a lattice path made of northward and eastward steps) as follows: Let (i_1, j_1) be the bottommost box in the s-th column of π. If (i_k, j_k) is defined for some $k \geq 1$, then (i_{k+1}, j_{k+1}) is constructed as follows: If q_{i_k-1, j_k} is well-defined and equals q_{i_k, j_k}, then we set $(i_{k+1}, j_{k+1}) = (i_k - 1, j_k)$. Otherwise, we set $(i_{k+1}, j_{k+1}) = (i_k, j_k + 1)$ if this is still a box of λ. Otherwise, the sequence ends here.
- Let π' be the λ-rpp obtained from π by subtracting 1 from the (i_k, j_k)-th entry of π for each $k \in \{1, 2, \ldots, n\}$.
- Let N' be the image $H^{-1}(\pi')$ (which is already constructed by recursion). Then, $H^{-1}(\pi)$ is obtained from N' by adding 1 to the (i_n, s)-th entry of N'.

This construction appears in [HilGra1976] Section 6 (where λ-arrays are re-encoded as sequences of "hook number multiplicities") and [EnumComb2] Section 7.22.

See also

hillman_grassl_inverse() for the inverse of the Hillman-Grassl correspondence as a standalone function.

hillman_grassl() for the inverse map.

EXAMPLES:

```
sage: a = WeakReversePlanePartition([[2, 2, 4], [2, 3, 4], [3, 5]])
sage: a.hillman_grassl_inverse()
[[2, 1, 1], [0, 2, 0], [1, 1]]
sage: b = WeakReversePlanePartition([[1, 1, 2, 2], [1, 1, 2, 2], [2, 2, 3, 3],
↪ [2, 2, 3, 3]])
sage: B = b.hillman_grassl_inverse(); B
[[1, 0, 1, 0], [0, 1, 0, 1], [1, 0, 1, 0], [0, 1, 0, 1]]
sage: b.parent(), B.parent()
(Weak Reverse Plane Partitions, Tableaux)
```

```
>>> from sage.all import *
>>> a = WeakReversePlanePartition([[Integer(2), Integer(2), Integer(4)],
↪[Integer(2), Integer(3), Integer(4)], [Integer(3), Integer(5)]])
>>> a.hillman_grassl_inverse()
[[2, 1, 1], [0, 2, 0], [1, 1]]
>>> b = WeakReversePlanePartition([[Integer(1), Integer(1), Integer(2),
↪Integer(2)], [Integer(1), Integer(1), Integer(2), Integer(2)], [Integer(2),
↪Integer(2), Integer(3), Integer(3)], [Integer(2), Integer(2), Integer(3),
↪Integer(3)]])
>>> B = b.hillman_grassl_inverse(); B
[[1, 0, 1, 0], [0, 1, 0, 1], [1, 0, 1, 0], [0, 1, 0, 1]]
>>> b.parent(), B.parent()
(Weak Reverse Plane Partitions, Tableaux)
```

Applying the inverse of the Hillman-Grassl correspondence to the transpose of a λ-rpp M yields the same result as applying it to M and then transposing the result ([Gans1981] Corollary 3.4):

```
sage: a = WeakReversePlanePartition([[1,3,5],[2,4]])
sage: aic = a.hillman_grassl_inverse().conjugate()
sage: aic == a.conjugate().hillman_grassl_inverse()
True
```

```
>>> from sage.all import *
>>> a = WeakReversePlanePartition([[Integer(1),Integer(3),Integer(5)],
↪[Integer(2),Integer(4)]])
>>> aic = a.hillman_grassl_inverse().conjugate()
>>> aic == a.conjugate().hillman_grassl_inverse()
True
```

pak_correspondence()

Return the image of the λ-rpp `self` under the Pak correspondence (as a *Tableau*).

See *hillman_grassl*.

The Pak correspondence is the map ξ_λ from [Sulzgr2017] Section 7, and is the map ξ_λ from [Pak2002] Section 4. It is the inverse of the Sulzgruber correspondence (*sulzgruber_correspondence()*). The following description of the Pak correspondence follows [Hopkins2017] (which denotes it by $\mathcal{RSK}^{-1}$):

Fix a partition λ (see *Partition()*). We draw all partitions and tableaux in English notation.

A *λ-array* will mean a tableau of shape λ whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A *weak reverse plane partition of shape λ* (short: *λ-rpp*) will mean a λ-array whose entries weakly increase along each row and weakly increase along each column.

We shall also use the following notation: If (u, v) is a cell of λ, and if π is a λ-rpp, then:

- the *lower bound* of π at (u, v) (denoted by $\pi_{<(u,v)}$) is defined to be $\max\{\pi_{u-1,v}, \pi_{u,v-1}\}$ (where $\pi_{0,v}$ and $\pi_{u,0}$ are understood to mean 0).
- the *upper bound* of π at (u, v) (denoted by $\pi_{>(u,v)}$) is defined to be $\min\{\pi_{u+1,v}, \pi_{u,v+1}\}$ (where $\pi_{i,j}$ is understood to mean $+\infty$ if (i, j) is not in λ; thus, the upper bound at a corner cell is $+\infty$).
- *toggling* π at (u, v) means replacing the entry $\pi_{u,v}$ of π at (u, v) by $\pi_{<(u,v)} + \pi_{>(u,v)} - \pi_{u,v}$ (this is well-defined as long as (u, v) is not a corner of λ).

Note that every λ-rpp π and every cell (u, v) of λ satisfy $\pi_{<(u,v)} \leq \pi_{u,v} \leq \pi_{>(u,v)}$. Note that toggling a λ-rpp (at a cell that is not a corner) always results in a λ-rpp. Also, toggling is an involution).

Note also that the lower bound of π at (u, v) is defined (and finite) even when (u, v) is not a cell of λ, as long as both $(u - 1, v)$ and $(u, v - 1)$ are cells of λ.

The Pak correspondence Φ_λ sends a λ-array $M = (m_{i,j})$ to a λ-rpp $\Phi_\lambda(M)$. It is defined by recursion on λ (that is, we assume that Φ_μ is already defined for every partition μ smaller than λ), and its definition proceeds as follows:

- If $\lambda = \varnothing$, then Φ_λ is the obvious bijection sending the only $\varnothing$-array to the only $\varnothing$-rpp.
- Pick any corner $c = (i, j)$ of λ, and let μ be the result of removing this corner c from the partition λ. (The exact choice of c is immaterial.)
- Let M' be what remains of M when the corner cell c is removed.
- Let $\pi' = \Phi_\mu(M')$.
- For each positive integer k such that $(i - k, j - k)$ is a cell of λ, toggle π' at $(i - k, j - k)$. (All these togglings commute, so the order in which they are made is immaterial.)
- Extend the μ-rpp π' to a λ-rpp π by adding the cell c and writing the number $m_{i,j} - \pi'_{<(i,j)}$ into this cell.
- Set $\Phi_\lambda(M) = \pi$.

See also

`pak_correspondence()` for the Pak correspondence as a standalone function.

`sulzgruber_correspondence()` for the inverse map.

EXAMPLES:

```
sage: a = WeakReversePlanePartition([[1, 2, 3], [1, 2, 3], [2, 4, 4]])
sage: A = a.pak_correspondence(); A
[[1, 0, 2], [0, 2, 0], [1, 1, 0]]
sage: a.parent(), A.parent()
(Weak Reverse Plane Partitions, Tableaux)
```

```
>>> from sage.all import *
>>> a = WeakReversePlanePartition([[Integer(1), Integer(2), Integer(3)],␣
↪[Integer(1), Integer(2), Integer(3)], [Integer(2), Integer(4), Integer(4)]])
>>> A = a.pak_correspondence(); A
[[1, 0, 2], [0, 2, 0], [1, 1, 0]]
>>> a.parent(), A.parent()
(Weak Reverse Plane Partitions, Tableaux)
```

Applying the Pak correspondence to the transpose of a λ-rpp M yields the same result as applying it to M and then transposing the result:

```
sage: a = WeakReversePlanePartition([[1,3,5],[2,4]])
sage: acc = a.pak_correspondence().conjugate()
sage: acc == a.conjugate().pak_correspondence()
True
```

```
>>> from sage.all import *
>>> a = WeakReversePlanePartition([[Integer(1),Integer(3),Integer(5)],
↪[Integer(2),Integer(4)]])
>>> acc = a.pak_correspondence().conjugate()
>>> acc == a.conjugate().pak_correspondence()
True
```

class sage.combinat.hillman_grassl.**WeakReversePlanePartitions**

Bases: `Tableaux`

The set of all weak reverse plane partitions.

Element

alias of `WeakReversePlanePartition`

an_element()

Return a particular element of the class.

sage.combinat.hillman_grassl.**hillman_grassl**(M)

Return the image of the λ-array `M` under the Hillman-Grassl correspondence.

The Hillman-Grassl correspondence is a bijection between the tableaux with nonnegative entries (otherwise arbitrary) and the weak reverse plane partitions with nonnegative entries. This bijection preserves the shape of the tableau. See `hillman_grassl`.

See *hillman_grassl()* for a description of this map.

See also:

hillman_grassl_inverse()

EXAMPLES:

```
sage: from sage.combinat.hillman_grassl import hillman_grassl
sage: hillman_grassl([[2, 1, 1], [0, 2, 0], [1, 1]])
[[2, 2, 4], [2, 3, 4], [3, 5]]
sage: hillman_grassl([[1, 2, 0], [1, 0, 1], [1]])
[[0, 1, 3], [2, 4, 4], [3]]
sage: hillman_grassl([])
[]
sage: hillman_grassl([[3, 1, 2]])
[[3, 4, 6]]
sage: hillman_grassl([[2, 2, 0], [1, 1, 1], [1]])
[[1, 2, 4], [3, 5, 5], [4]]
sage: hillman_grassl([[1, 1, 1, 1]]*3)
[[1, 2, 3, 4], [2, 3, 4, 5], [3, 4, 5, 6]]
```

```
>>> from sage.all import *
>>> from sage.combinat.hillman_grassl import hillman_grassl
>>> hillman_grassl([[Integer(2), Integer(1), Integer(1)], [Integer(0), Integer(2),
↪ Integer(0)], [Integer(1), Integer(1)]])
[[2, 2, 4], [2, 3, 4], [3, 5]]
>>> hillman_grassl([[Integer(1), Integer(2), Integer(0)], [Integer(1), Integer(0),
↪ Integer(1)], [Integer(1)]])
[[0, 1, 3], [2, 4, 4], [3]]
>>> hillman_grassl([])
[]
>>> hillman_grassl([[Integer(3), Integer(1), Integer(2)]])
[[3, 4, 6]]
>>> hillman_grassl([[Integer(2), Integer(2), Integer(0)], [Integer(1), Integer(1),
↪ Integer(1)], [Integer(1)]])
[[1, 2, 4], [3, 5, 5], [4]]
>>> hillman_grassl([[Integer(1), Integer(1), Integer(1), Integer(1)]]*Integer(3))
[[1, 2, 3, 4], [2, 3, 4, 5], [3, 4, 5, 6]]
```

sage.combinat.hillman_grassl.**hillman_grassl_inverse**(M)

Return the image of the λ-rpp `M` under the inverse of the Hillman-Grassl correspondence.

See *hillman_grassl*.

See *hillman_grassl_inverse()* for a description of this map.

See also:

hillman_grassl()

EXAMPLES:

```
sage: from sage.combinat.hillman_grassl import hillman_grassl_inverse
sage: hillman_grassl_inverse([[2, 2, 4], [2, 3, 4], [3, 5]])
[[2, 1, 1], [0, 2, 0], [1, 1]]
sage: hillman_grassl_inverse([[0, 1, 3], [2, 4, 4], [3]])
[[1, 2, 0], [1, 0, 1], [1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.hillman_grassl import hillman_grassl_inverse
>>> hillman_grassl_inverse([[Integer(2), Integer(2), Integer(4)], [Integer(2),
↪Integer(3), Integer(4)], [Integer(3), Integer(5)]])
[[2, 1, 1], [0, 2, 0], [1, 1]]
>>> hillman_grassl_inverse([[Integer(0), Integer(1), Integer(3)], [Integer(2),
↪Integer(4), Integer(4)], [Integer(3)]])
[[1, 2, 0], [1, 0, 1], [1]]
```

Applying the inverse of the Hillman-Grassl correspondence to the transpose of a λ-rpp M yields the same result as applying it to M and then transposing the result ([Gans1981] Corollary 3.4):

```
sage: hillman_grassl_inverse([[1,3,5],[2,4]])
[[1, 2, 2], [1, 1]]
sage: hillman_grassl_inverse([[1,2],[3,4],[5]])
[[1, 1], [2, 1], [2]]
sage: hillman_grassl_inverse([[1, 2, 3], [1, 2, 3], [2, 4, 4]])
[[1, 2, 0], [0, 1, 1], [1, 0, 1]]
sage: hillman_grassl_inverse([[1, 2, 3, 4], [2, 3, 4, 5], [3, 4, 5, 6]])
[[1, 1, 1, 1], [1, 1, 1, 1], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> hillman_grassl_inverse([[Integer(1),Integer(3),Integer(5)],[Integer(2),
↪Integer(4)]])
[[1, 2, 2], [1, 1]]
>>> hillman_grassl_inverse([[Integer(1),Integer(2)],[Integer(3),Integer(4)],
↪[Integer(5)]])
[[1, 1], [2, 1], [2]]
>>> hillman_grassl_inverse([[Integer(1), Integer(2), Integer(3)], [Integer(1),
↪Integer(2), Integer(3)], [Integer(2), Integer(4), Integer(4)]])
[[1, 2, 0], [0, 1, 1], [1, 0, 1]]
>>> hillman_grassl_inverse([[Integer(1), Integer(2), Integer(3), Integer(4)],
↪[Integer(2), Integer(3), Integer(4), Integer(5)], [Integer(3), Integer(4),
↪Integer(5), Integer(6)]])
[[1, 1, 1, 1], [1, 1, 1, 1], [1, 1, 1, 1]]
```

sage.combinat.hillman_grassl.**pak_correspondence**(*M*, *copy=True*)

Return the image of a λ-rpp `M` under the Pak correspondence.

The Pak correspondence is the map ξ_λ from [Sulzgr2017] Section 7, and is the map ξ_λ from [Pak2002] Section 4. It is the inverse of the Sulzgruber correspondence (`sulzgruber_correspondence()`).

See `pak_correspondence()` for a description of this map.

INPUT:

- `copy` – boolean (default: `True`); if set to `False`, the algorithm will mutate the input (but be more efficient)

EXAMPLES:

```
sage: from sage.combinat.hillman_grassl import pak_correspondence
sage: pak_correspondence([[1, 2, 3], [1, 2, 3], [2, 4, 4]])
[[1, 0, 2], [0, 2, 0], [1, 1, 0]]
sage: pak_correspondence([[1, 1, 4], [2, 3, 4], [4, 4, 4]])
[[1, 1, 2], [0, 1, 0], [3, 0, 0]]
sage: pak_correspondence([[0, 2, 3], [1, 3, 3], [2, 4]])
[[1, 0, 2], [0, 2, 0], [1, 1]]
sage: pak_correspondence([[1, 2, 4], [1, 3], [3]])
[[0, 2, 2], [1, 1], [2]]
sage: pak_correspondence([[1, 2, 3, 4], [2, 3, 4, 5], [3, 4, 5, 6]])
[[1, 1, 1, 1], [1, 1, 1, 1], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.hillman_grassl import pak_correspondence
>>> pak_correspondence([[Integer(1), Integer(2), Integer(3)], [Integer(1),␣
↪Integer(2), Integer(3)], [Integer(2), Integer(4), Integer(4)]])
[[1, 0, 2], [0, 2, 0], [1, 1, 0]]
>>> pak_correspondence([[Integer(1), Integer(1), Integer(4)], [Integer(2),␣
↪Integer(3), Integer(4)], [Integer(4), Integer(4), Integer(4)]])
[[1, 1, 2], [0, 1, 0], [3, 0, 0]]
>>> pak_correspondence([[Integer(0), Integer(2), Integer(3)], [Integer(1),␣
↪Integer(3), Integer(3)], [Integer(2), Integer(4)]])
[[1, 0, 2], [0, 2, 0], [1, 1]]
>>> pak_correspondence([[Integer(1), Integer(2), Integer(4)], [Integer(1),␣
↪Integer(3)], [Integer(3)]])
[[0, 2, 2], [1, 1], [2]]
>>> pak_correspondence([[Integer(1), Integer(2), Integer(3), Integer(4)],␣
↪[Integer(2), Integer(3), Integer(4), Integer(5)], [Integer(3), Integer(4),␣
↪Integer(5), Integer(6)]])
[[1, 1, 1, 1], [1, 1, 1, 1], [1, 1, 1, 1]]
```

The Pak correspondence can actually be extended (by the same definition) to "rpps" of nonnegative reals rather than nonnegative integers. This implementation supports this:

```
sage: pak_correspondence([[0, 1, 3/2], [1/2, 3/2, 3/2], [1, 2]])
[[1/2, 0, 1], [0, 1, 0], [1/2, 1/2]]
```

```
>>> from sage.all import *
>>> pak_correspondence([[Integer(0), Integer(1), Integer(3)/Integer(2)],␣
↪[Integer(1)/Integer(2), Integer(3)/Integer(2), Integer(3)/Integer(2)],␣
↪[Integer(1), Integer(2)]])
[[1/2, 0, 1], [0, 1, 0], [1/2, 1/2]]
```

sage.combinat.hillman_grassl.**sulzgruber_correspondence**(M)

Return the image of a λ-array M under the Sulzgruber correspondence.

The Sulzgruber correspondence is the map Φ_λ from [Sulzgr2017] Section 7, and is the map ξ_λ^{-1} from [Pak2002] Section 5. It is denoted by $\mathcal{RSK}$ in [Hopkins2017]. It is the inverse of the Pak correspondence (*pak_correspondence()*).

See *sulzgruber_correspondence()* for a description of this map.

EXAMPLES:

```
sage: from sage.combinat.hillman_grassl import sulzgruber_correspondence
sage: sulzgruber_correspondence([[1, 0, 2], [0, 2, 0], [1, 1, 0]])
[[1, 2, 3], [1, 2, 3], [2, 4, 4]]
sage: sulzgruber_correspondence([[1, 1, 2], [0, 1, 0], [3, 0, 0]])
[[1, 1, 4], [2, 3, 4], [4, 4, 4]]
sage: sulzgruber_correspondence([[1, 0, 2], [0, 2, 0], [1, 1]])
[[0, 2, 3], [1, 3, 3], [2, 4]]
sage: sulzgruber_correspondence([[0, 2, 2], [1, 1], [2]])
[[1, 2, 4], [1, 3], [3]]
sage: sulzgruber_correspondence([[1, 1, 1, 1]]*3)
[[1, 2, 3, 4], [2, 3, 4, 5], [3, 4, 5, 6]]
```

```
>>> from sage.all import *
>>> from sage.combinat.hillman_grassl import sulzgruber_correspondence
>>> sulzgruber_correspondence([[Integer(1), Integer(0), Integer(2)], [Integer(0),␣
↪Integer(2), Integer(0)], [Integer(1), Integer(1), Integer(0)]])
[[1, 2, 3], [1, 2, 3], [2, 4, 4]]
>>> sulzgruber_correspondence([[Integer(1), Integer(1), Integer(2)], [Integer(0),␣
↪Integer(1), Integer(0)], [Integer(3), Integer(0), Integer(0)]])
[[1, 1, 4], [2, 3, 4], [4, 4, 4]]
>>> sulzgruber_correspondence([[Integer(1), Integer(0), Integer(2)], [Integer(0),␣
↪Integer(2), Integer(0)], [Integer(1), Integer(1)]])
[[0, 2, 3], [1, 3, 3], [2, 4]]
>>> sulzgruber_correspondence([[Integer(0), Integer(2), Integer(2)], [Integer(1),␣
↪Integer(1)], [Integer(2)]])
[[1, 2, 4], [1, 3], [3]]
>>> sulzgruber_correspondence([[Integer(1), Integer(1), Integer(1),␣
↪Integer(1)]]*Integer(3))
[[1, 2, 3, 4], [2, 3, 4, 5], [3, 4, 5, 6]]
```

The Sulzgruber correspondence can actually be extended (by the same definition) to arrays of nonnegative reals rather than nonnegative integers. This implementation supports this:

```
sage: sulzgruber_correspondence([[1/2, 0, 1], [0, 1, 0], [1/2, 1/2]])
[[0, 1, 3/2], [1/2, 3/2, 3/2], [1, 2]]
```

```
>>> from sage.all import *
>>> sulzgruber_correspondence([[Integer(1)/Integer(2), Integer(0), Integer(1)],␣
↪[Integer(0), Integer(1), Integer(0)], [Integer(1)/Integer(2), Integer(1)/
↪Integer(2)]])
[[0, 1, 3/2], [1/2, 3/2, 3/2], [1, 2]]
```

sage.combinat.hillman_grassl.**transpose**(M)

Return the transpose of a λ-array.

The transpose of a λ-array $(m_{i,j})$ is the λ^t-array $(m_{j,i})$ (where λ^t is the conjugate of the partition λ).

EXAMPLES:

```
sage: from sage.combinat.hillman_grassl import transpose
sage: transpose([[1, 2, 3], [4, 5]])
[[1, 4], [2, 5], [3]]
sage: transpose([[5, 0, 3], [4, 1, 0], [7]])
[[5, 4, 7], [0, 1], [3, 0]]
```

```
>>> from sage.all import *
>>> from sage.combinat.hillman_grassl import transpose
>>> transpose([[Integer(1), Integer(2), Integer(3)], [Integer(4), Integer(5)]])
[[1, 4], [2, 5], [3]]
>>> transpose([[Integer(5), Integer(0), Integer(3)], [Integer(4), Integer(1),␣
↪Integer(0)], [Integer(7)]])
[[5, 4, 7], [0, 1], [3, 0]]
```

5.1.122 Enumerated set of lists of integers with constraints: base classes

- *IntegerListsBackend*: base class for the Cython back-end of an enumerated set of lists of integers with specified constraints.
- *Envelope*: a utility class for upper (lower) envelope of a function under constraints.

class sage.combinat.integer_lists.base.**Envelope**

Bases: object

The (currently approximated) upper (lower) envelope of a function under the specified constraints.

INPUT:

- f – a function, list, or tuple; if f is a list, it is considered as the function f(i)=f[i], completed for larger i with f(i)=max_part.
- min_part, max_part, min_slope, max_slope, … as for *IntegerListsLex* (please consult for details).
- sign – (+1 or -1) multiply the input values with sign and multiply the output with sign. Setting this to -1 can be used to implement a lower envelope.

The *upper envelope* $U(f)$ of f is the (pointwise) largest function which is bounded above by f and satisfies the max_part and max_slope conditions. Furthermore, for i,i+1<min_length, the upper envelope also satisfies the min_slope condition.

Upon computing $U(f)(i)$, all the previous values for $j \leq i$ are computed and cached; in particular $f(i)$ will be computed at most once for each i.

Todo

- This class is a good candidate for Cythonization, especially to get the critical path in __call__ super fast.
- To get full envelopes, we would want both the min_slope and max_slope conditions to always be satisfied. This is only properly defined for the restriction of f to a finite interval $0, .., k$, and depends on k.
- This is the core "data structure" of IntegerListsLex. Improving the lookahead there essentially depends on having functions with a good complexity to compute the area below an envelope; and in particular how it evolves when increasing the length.

EXAMPLES:

```
sage: from sage.combinat.integer_lists import Envelope
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_lists import Envelope
```

Trivial upper and lower envelopes:

```
sage: f = Envelope([3,2,2])
sage: [f(i) for i in range(10)]
[3, 2, 2, inf, inf, inf, inf, inf, inf, inf]
sage: f = Envelope([3,2,2], sign=-1)
sage: [f(i) for i in range(10)]
[3, 2, 2, 0, 0, 0, 0, 0, 0, 0]
```

```
>>> from sage.all import *
>>> f = Envelope([Integer(3),Integer(2),Integer(2)])
>>> [f(i) for i in range(Integer(10))]
[3, 2, 2, inf, inf, inf, inf, inf, inf, inf]
>>> f = Envelope([Integer(3),Integer(2),Integer(2)], sign=-Integer(1))
>>> [f(i) for i in range(Integer(10))]
[3, 2, 2, 0, 0, 0, 0, 0, 0, 0]
```

A more interesting lower envelope:

```
sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1)
sage: [f(i) for i in range(10)]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]
```

```
>>> from sage.all import *
>>> f = Envelope([Integer(4),Integer(1),Integer(5),Integer(3),Integer(5)], sign=-
↪Integer(1), min_part=Integer(2), min_slope=-Integer(1))
>>> [f(i) for i in range(Integer(10))]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]
```

Currently, adding `max_slope` has no effect:

```
sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0)
sage: [f(i) for i in range(10)]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]
```

```
>>> from sage.all import *
>>> f = Envelope([Integer(4),Integer(1),Integer(5),Integer(3),Integer(5)], sign=-
↪Integer(1), min_part=Integer(2), min_slope=-Integer(1), max_slope=Integer(0))
>>> [f(i) for i in range(Integer(10))]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]
```

unless `min_length` is large enough:

```
sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0,␣
↪min_length=2)
sage: [f(i) for i in range(10)]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]

sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0,␣
↪min_length=4)
sage: [f(i) for i in range(10)]
[5, 5, 5, 4, 5, 4, 3, 2, 2, 2]
```

(continues on next page)

(continued from previous page)

```
sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0,␣
↪min_length=5)
sage: [f(i) for i in range(10)]
[5, 5, 5, 5, 5, 4, 3, 2, 2, 2]
```

```
>>> from sage.all import *
>>> f = Envelope([Integer(4),Integer(1),Integer(5),Integer(3),Integer(5)], sign=-
↪Integer(1), min_part=Integer(2), min_slope=-Integer(1), max_slope=Integer(0),␣
↪min_length=Integer(2))
>>> [f(i) for i in range(Integer(10))]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]

>>> f = Envelope([Integer(4),Integer(1),Integer(5),Integer(3),Integer(5)], sign=-
↪Integer(1), min_part=Integer(2), min_slope=-Integer(1), max_slope=Integer(0),␣
↪min_length=Integer(4))
>>> [f(i) for i in range(Integer(10))]
[5, 5, 5, 4, 5, 4, 3, 2, 2, 2]

>>> f = Envelope([Integer(4),Integer(1),Integer(5),Integer(3),Integer(5)], sign=-
↪Integer(1), min_part=Integer(2), min_slope=-Integer(1), max_slope=Integer(0),␣
↪min_length=Integer(5))
>>> [f(i) for i in range(Integer(10))]
[5, 5, 5, 5, 5, 4, 3, 2, 2, 2]
```

A non trivial upper envelope:

```
sage: f = Envelope([9,1,5,4], max_part=7, max_slope=2)
sage: [f(i) for i in range(10)]
[7, 1, 3, 4, 6, 7, 7, 7, 7, 7]
```

```
>>> from sage.all import *
>>> f = Envelope([Integer(9),Integer(1),Integer(5),Integer(4)], max_
↪part=Integer(7), max_slope=Integer(2))
>>> [f(i) for i in range(Integer(10))]
[7, 1, 3, 4, 6, 7, 7, 7, 7, 7]
```

adapt (m, j)

Return this envelope adapted to an additional local constraint.

INPUT:

- `m` – nonnegative integer (starting value)
- `j` – nonnegative integer (position)

This method adapts this envelope to the additional local constraint imposed by having a part m at position j. Namely, this returns a function which computes, for any $i > j$, the minimum of the ceiling function and the value restriction given by the slope conditions.

EXAMPLES:

```
sage: from sage.combinat.integer_lists import Envelope
sage: f = Envelope(3)
sage: g = f.adapt(1,1)
```

(continues on next page)

(continued from previous page)

```
sage: g is f
True
sage: [g(i) for i in range(10)]
[3, 3, 3, 3, 3, 3, 3, 3, 3, 3]

sage: f = Envelope(3, max_slope=1)
sage: g = f.adapt(1,1)
sage: [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_lists import Envelope
>>> f = Envelope(Integer(3))
>>> g = f.adapt(Integer(1),Integer(1))
>>> g is f
True
>>> [g(i) for i in range(Integer(10))]
[3, 3, 3, 3, 3, 3, 3, 3, 3, 3]

>>> f = Envelope(Integer(3), max_slope=Integer(1))
>>> g = f.adapt(Integer(1),Integer(1))
>>> [g(i) for i in range(Integer(10))]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]
```

Note that, in both cases above, the adapted envelope is only guaranteed to be valid for $i > j$! This is to leave potential room in the future for sharing similar adapted envelopes:

```
sage: g = f.adapt(0,0)
sage: [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]

sage: g = f.adapt(2,2)
sage: [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]

sage: g = f.adapt(3,3)
sage: [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]
```

```
>>> from sage.all import *
>>> g = f.adapt(Integer(0),Integer(0))
>>> [g(i) for i in range(Integer(10))]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]

>>> g = f.adapt(Integer(2),Integer(2))
>>> [g(i) for i in range(Integer(10))]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]

>>> g = f.adapt(Integer(3),Integer(3))
>>> [g(i) for i in range(Integer(10))]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]
```

Now with a lower envelope:

```
sage: f = Envelope(1, sign=-1, min_slope=-1)
sage: g = f.adapt(2,2)
sage: [g(i) for i in range(10)]
[4, 3, 2, 1, 1, 1, 1, 1, 1, 1]
sage: g = f.adapt(1,3)
sage: [g(i) for i in range(10)]
[4, 3, 2, 1, 1, 1, 1, 1, 1, 1]
```

```
>>> from sage.all import *
>>> f = Envelope(Integer(1), sign=-Integer(1), min_slope=-Integer(1))
>>> g = f.adapt(Integer(2),Integer(2))
>>> [g(i) for i in range(Integer(10))]
[4, 3, 2, 1, 1, 1, 1, 1, 1, 1]
>>> g = f.adapt(Integer(1),Integer(3))
>>> [g(i) for i in range(Integer(10))]
[4, 3, 2, 1, 1, 1, 1, 1, 1, 1]
```

limit()

Return a bound on the limit of `self`.

OUTPUT: nonnegative integer or ∞

This returns some upper bound for the accumulation points of this upper envelope. For a lower envelope, a lower bound is returned instead.

In particular this gives a bound for the value of `self` at i for i large enough. Special case: for a lower envelop, and when the limit is ∞, the envelope is guaranteed to tend to ∞ instead.

When `s=self.limit_start()` is finite, this bound is guaranteed to be valid for $i >= s$.

Sometimes it's better to have a loose bound that starts early; sometimes the converse holds. At this point which specific bound and starting point is returned is not set in stone, in order to leave room for later optimizations.

EXAMPLES:

```
sage: from sage.combinat.integer_lists import Envelope
sage: Envelope([4,1,5]).limit()
inf
sage: Envelope([4,1,5], max_part=2).limit()
2
sage: Envelope([4,1,5], max_slope=0).limit()
1
sage: Envelope(lambda x: 3, max_part=2).limit()
2
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_lists import Envelope
>>> Envelope([Integer(4),Integer(1),Integer(5)]).limit()
inf
>>> Envelope([Integer(4),Integer(1),Integer(5)], max_part=Integer(2)).limit()
2
>>> Envelope([Integer(4),Integer(1),Integer(5)], max_slope=Integer(0)).limit()
1
```

(continues on next page)

(continued from previous page)

```
>>> Envelope(lambda x: Integer(3), max_part=Integer(2)).limit()
2
```

Lower envelopes:

```
sage: Envelope(lambda x: 3, min_part=2, sign=-1).limit()
2
sage: Envelope([4,1,5], min_slope=0, sign=-1).limit()
5
sage: Envelope([4,1,5], sign=-1).limit()
0
```

```
>>> from sage.all import *
>>> Envelope(lambda x: Integer(3), min_part=Integer(2), sign=-Integer(1)).
↪limit()
2
>>> Envelope([Integer(4),Integer(1),Integer(5)], min_slope=Integer(0), sign=-
↪Integer(1)).limit()
5
>>> Envelope([Integer(4),Integer(1),Integer(5)], sign=-Integer(1)).limit()
0
```

See also

limit_start()

limit_start()

Return from which i on the bound returned by `limit` holds.

See also

limit() for the precise specifications.

EXAMPLES:

```
sage: from sage.combinat.integer_lists import Envelope
sage: Envelope([4,1,5]).limit_start()
3

class sage.combinat.integer_lists.base.**IntegerListsBackend**

Bases: `object`

Base class for the Cython back-end of an enumerated set of lists of integers with specified constraints.

This base implements the basic operations, including checking for containment using `_contains()`, but not iteration. For iteration, subclass this class and implement an `_iter()` method.

EXAMPLES:

```
sage: from sage.combinat.integer_lists.base import IntegerListsBackend
sage: L = IntegerListsBackend(6, max_slope=-1)
```

(continues on next page)

(continued from previous page)

```
sage: L._contains([3,2,1])
True
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_lists.base import IntegerListsBackend
>>> L = IntegerListsBackend(Integer(6), max_slope=-Integer(1))
>>> L._contains([Integer(3),Integer(2),Integer(1)])
True
```

5.1.123 Enumerated set of lists of integers with constraints: front-end

- *IntegerLists*: class which models an enumerated set of lists of integers with certain constraints. This is a Python front-end where all user-accessible functionality should be implemented.

class sage.combinat.integer_lists.lists.**IntegerList**

Bases: ClonableArray

Element class for *IntegerLists*.

check()

Check to make sure this is a valid element in its *IntegerLists* parent.

EXAMPLES:

```
sage: C = IntegerListsLex(4)
sage: C([4]).check()
True
sage: C([5]).check()
False
```

```
>>> from sage.all import *
>>> C = IntegerListsLex(Integer(4))
>>> C([Integer(4)]).check()
True
>>> C([Integer(5)]).check()
False
```

class sage.combinat.integer_lists.lists.**IntegerLists**(**args*, ***kwds*)

Bases: `Parent`

Enumerated set of lists of integers with constraints.

Currently, this is simply an abstract base class which should not be used by itself. See *IntegerListsLex* for a class which can be used by end users.

`IntegerLists` is just a Python front-end, acting as a `Parent`, supporting element classes and so on. The attribute `.backend` which is an instance of *sage.combinat.integer_lists.base.IntegerListsBackend* is the Cython back-end which implements all operations such as iteration.

The front-end (i.e. this class) and the back-end are supposed to be orthogonal: there is no imposed correspondence between front-ends and back-ends.

For example, the set of partitions of 5 and the set of weakly decreasing sequences which sum to 5 might be implemented by the same back-end, but they will be presented to the user by a different front-end.

EXAMPLES:

```
sage: from sage.combinat.integer_lists import IntegerLists
sage: L = IntegerLists(5)
sage: L
Integer lists of sum 5 satisfying certain constraints

sage: IntegerListsLex(2, length=3, name="A given name")
A given name
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_lists import IntegerLists
>>> L = IntegerLists(Integer(5))
>>> L
Integer lists of sum 5 satisfying certain constraints

>>> IntegerListsLex(Integer(2), length=Integer(3), name="A given name")
A given name
```

5.1.124 Enumerated set of lists of integers with constraints, in inverse lexicographic order

- *IntegerListsLex*: the enumerated set of lists of nonnegative integers with specified constraints, in inverse lexicographic order.
- *IntegerListsBackend_invlex*: Cython back-end for *IntegerListsLex*.

HISTORY:

This generic tool was originally written by Hivert and Thiery in MuPAD-Combinat in 2000 and ported over to Sage by Mike Hansen in 2007. It was then completely rewritten in 2015 by Gillespie, Schilling, and Thiery, with the help of many, to deal with limitations and lack of robustness w.r.t. input.

class sage.combinat.integer_lists.invlex.**IntegerListsBackend_invlex**

Bases: *IntegerListsBackend*

Cython back-end of a set of lists of integers with specified constraints enumerated in inverse lexicographic order.

check

class sage.combinat.integer_lists.invlex.**IntegerListsLex**(**args*, ***kwds*)

Bases: *IntegerLists*

Lists of nonnegative integers with constraints, in inverse lexicographic order.

An *integer list* is a list l of nonnegative integers, its *parts*. The slope (at position i) is the difference `l[i+1]-l[i]` between two consecutive parts.

This class allows to construct the set S of all integer lists l satisfying specified bounds on the sum, the length, the slope, and the individual parts, enumerated in *inverse* lexicographic order, that is from largest to smallest in lexicographic order. Note that, to admit such an enumeration, S is almost necessarily finite (see *On finiteness and inverse lexicographic enumeration*).

The main purpose is to provide a generic iteration engine for all the enumerated sets like *Partitions*, *Compositions*, *IntegerVectors*. It can also be used to generate many other combinatorial objects like Dyck paths, Motzkin paths, etc. Mathematically speaking, this is a special case of set of integral points of a polytope (or union thereof, when the length is not fixed).

INPUT:

- `min_sum` – nonnegative integer (default: 0); a lower bound on `sum(l)`
- `max_sum` – nonnegative integer or ∞ (default: ∞); an upper bound on `sum(l)`
- `n` – nonnegative integer (optional); if specified, this overrides `min_sum` and `max_sum`
- `min_length` – nonnegative integer (default: 0); a lower bound on `len(l)`
- `max_length` – nonnegative integer or ∞ (default: ∞); an upper bound on `len(l)`
- `length` – integer (optional); overrides `min_length` and `max_length` if specified
- `min_part` – nonnegative integer; a lower bounds on all parts: `min_part <= l[i]` for `0 <= i < len(l)`
- `floor` – list of nonnegative integers or a function; lower bounds on the individual parts $l[i]$

  If `floor` is a list of integers, then `floor<=l[i]` for `0 <= i < min(len(l), len(floor))`. Similarly, if `floor` is a function, then `floor(i) <= l[i]` for `0 <= i < len(l)`.
- `max_part` – nonnegative integer or ∞; an upper bound on all parts: `l[i] <= max_part` for `0 <= i < len(l)`
- `ceiling` – upper bounds on the individual parts `l[i]`; this takes the same type of input as `floor`, except that ∞ is allowed in addition to integers, and the default value is ∞.
- `min_slope` – integer or $-\infty$ (default: $-\infty$); a lower bound on the slope between consecutive parts: `min_slope <= l[i+1]-l[i]` for `0 <= i < len(l)-1`
- `max_slope` – integer or $+\infty$ (defaults: $+\infty$); an upper bound on the slope between consecutive parts: `l[i+1]-l[i] <= max_slope` for `0 <= i < len(l)-1`
- `category` – a category (default: `FiniteEnumeratedSets`)
- `check` – boolean (default: `True`); whether to display the warnings raised when functions are given as input to `floor` or `ceiling` and the errors raised when there is no proper enumeration.

- `name` – string or `None` (default: `None`); if set, this will be passed down to `Parent.rename()` to specify the name of `self`. It is recommended to use rename method directly because this feature may become deprecated.
- `element_constructor` – a function (or callable) that creates elements of `self` from a list. See also `Parent`
- `element_class` – a class for the elements of `self` (default: $ClonableArray$). This merely sets the attribute `self.Element`. See the examples for details.

Note

When several lists satisfying the constraints differ only by trailing zeroes, only the shortest one is enumerated (and therefore counted). The others are still considered valid. See the examples below.

This feature is questionable. It is recommended not to rely on it, as it may eventually be discontinued.

EXAMPLES:

We create the enumerated set of all lists of nonnegative integers of length 3 and sum 2:

```
sage: C = IntegerListsLex(2, length=3)
sage: C
Integer lists of sum 2 satisfying certain constraints
sage: C.cardinality()
6
sage: [p for p in C]
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]

sage: [2, 0, 0] in C
True
sage: [2, 0, 1] in C
False
sage: "a" in C
False
sage: ["a"] in C
False
sage: C.first()
[2, 0, 0]
```

```
>>> from sage.all import *
>>> C = IntegerListsLex(Integer(2), length=Integer(3))
>>> C
Integer lists of sum 2 satisfying certain constraints
>>> C.cardinality()
6
>>> [p for p in C]
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]

>>> [Integer(2), Integer(0), Integer(0)] in C
True
>>> [Integer(2), Integer(0), Integer(1)] in C
False
>>> "a" in C
```

(continues on next page)

(continued from previous page)

```
False
>>> ["a"] in C
False
>>> C.first()
[2, 0, 0]
```

One can specify lower and upper bounds on each part:

```
sage: list(IntegerListsLex(5, length=3, floor=[1,2,0], ceiling=[3,2,3]))
[[3, 2, 0], [2, 2, 1], [1, 2, 2]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(5), length=Integer(3), floor=[Integer(1),
↪Integer(2),Integer(0)], ceiling=[Integer(3),Integer(2),Integer(3)]))
[[3, 2, 0], [2, 2, 1], [1, 2, 2]]
```

When the length is fixed as above, one can also use *IntegerVectors*:

```
sage: IntegerVectors(2,3).list()
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

```
>>> from sage.all import *
>>> IntegerVectors(Integer(2),Integer(3)).list()
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

Using the slope condition, one can generate integer partitions (but see *Partitions*):

```
sage: list(IntegerListsLex(4, max_slope=0))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(4), max_slope=Integer(0)))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

The following is the list of all partitions of 7 with parts at least 2:

```
sage: list(IntegerListsLex(7, max_slope=0, min_part=2))
[[7], [5, 2], [4, 3], [3, 2, 2]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(7), max_slope=Integer(0), min_part=Integer(2)))
[[7], [5, 2], [4, 3], [3, 2, 2]]
```

floor and ceiling conditions

Next we list all partitions of 5 of length at most 3 which are bounded below by `[2,1,1]`:

```
sage: list(IntegerListsLex(5, max_slope=0, max_length=3, floor=[2,1,1]))
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(5), max_slope=Integer(0), max_length=Integer(3),␣
↪floor=[Integer(2),Integer(1),Integer(1)]))
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1]]
```

Note that `[5]` is considered valid, because the floor constraints only apply to existing positions in the list. To obtain instead the partitions containing `[2,1,1]`, one needs to use `min_length` or `length`:

```
sage: list(IntegerListsLex(5, max_slope=0, length=3, floor=[2,1,1]))
[[3, 1, 1], [2, 2, 1]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(5), max_slope=Integer(0), length=Integer(3),␣
↪floor=[Integer(2),Integer(1),Integer(1)]))
[[3, 1, 1], [2, 2, 1]]
```

Here is the list of all partitions of 5 which are contained in `[3,2,2]`:

```
sage: list(IntegerListsLex(5, max_slope=0, max_length=3, ceiling=[3,2,2]))
[[3, 2], [3, 1, 1], [2, 2, 1]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(5), max_slope=Integer(0), max_length=Integer(3),␣
↪ceiling=[Integer(3),Integer(2),Integer(2)]))
[[3, 2], [3, 1, 1], [2, 2, 1]]
```

This is the list of all compositions of 4 (but see *Compositions*):

```
sage: list(IntegerListsLex(4, min_part=1))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(4), min_part=Integer(1)))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

This is the list of all integer vectors of sum 4 and length 3:

```
sage: list(IntegerListsLex(4, length=3))
[[4, 0, 0], [3, 1, 0], [3, 0, 1], [2, 2, 0], [2, 1, 1],
 [2, 0, 2], [1, 3, 0], [1, 2, 1], [1, 1, 2], [1, 0, 3],
 [0, 4, 0], [0, 3, 1], [0, 2, 2], [0, 1, 3], [0, 0, 4]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(4), length=Integer(3)))
[[4, 0, 0], [3, 1, 0], [3, 0, 1], [2, 2, 0], [2, 1, 1],
 [2, 0, 2], [1, 3, 0], [1, 2, 1], [1, 1, 2], [1, 0, 3],
 [0, 4, 0], [0, 3, 1], [0, 2, 2], [0, 1, 3], [0, 0, 4]]
```

For whatever it is worth, the `floor` and `min_part` constraints can be combined:

```
sage: L = IntegerListsLex(5, floor=[2,0,2], min_part=1)
sage: L.list()
[[5], [4, 1], [3, 2], [2, 3], [2, 1, 2]]
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(5), floor=[Integer(2),Integer(0),Integer(2)], min_
↪part=Integer(1))
>>> L.list()
[[5], [4, 1], [3, 2], [2, 3], [2, 1, 2]]
```

This is achieved by updating the floor upon constructing `L`:

```
sage: [L.floor(i) for i in range(5)]
[2, 1, 2, 1, 1]
```

```
>>> from sage.all import *
>>> [L.floor(i) for i in range(Integer(5))]
[2, 1, 2, 1, 1]
```

Similarly, the `ceiling` and `max_part` constraints can be combined:

```
sage: L = IntegerListsLex(4, ceiling=[2,3,1], max_part=2, length=3)
sage: L.list()
[[2, 2, 0], [2, 1, 1], [1, 2, 1]]
sage: [L.ceiling(i) for i in range(5)]
[2, 2, 1, 2, 2]
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(4), ceiling=[Integer(2),Integer(3),Integer(1)],␣
↪max_part=Integer(2), length=Integer(3))
>>> L.list()
[[2, 2, 0], [2, 1, 1], [1, 2, 1]]
>>> [L.ceiling(i) for i in range(Integer(5))]
[2, 2, 1, 2, 2]
```

This can be used to generate Motzkin words (see Wikipedia article Motzkin_number):

```
sage: def motzkin_words(n):
....:     return IntegerListsLex(length=n+1, min_slope=-1, max_slope=1,
....:                 ceiling=[0]+[+oo for i in range(n-1)]+[0])
sage: motzkin_words(4).list()
[[0, 1, 2, 1, 0],
 [0, 1, 1, 1, 0],
 [0, 1, 1, 0, 0],
 [0, 1, 0, 1, 0],
 [0, 1, 0, 0, 0],
 [0, 0, 1, 1, 0],
 [0, 0, 1, 0, 0],
 [0, 0, 0, 1, 0],
 [0, 0, 0, 0, 0]]
sage: [motzkin_words(n).cardinality() for n in range(8)]
[1, 1, 2, 4, 9, 21, 51, 127]
sage: oeis(_)                  # optional -- internet
0: A001006: Motzkin numbers: number of ways of drawing any number
of nonintersecting chords joining n (labeled) points on a circle.
1: ...
2: ...
```

```
>>> from sage.all import *
>>> def motzkin_words(n):
...     return IntegerListsLex(length=n+Integer(1), min_slope=-Integer(1), max_
↪slope=Integer(1),
...                  ceiling=[Integer(0)]+[+oo for i in range(n-
↪Integer(1))]+[Integer(0)])
>>> motzkin_words(Integer(4)).list()
[[0, 1, 2, 1, 0],
 [0, 1, 1, 1, 0],
 [0, 1, 1, 0, 0],
 [0, 1, 0, 1, 0],
 [0, 1, 0, 0, 0],
 [0, 0, 1, 1, 0],
 [0, 0, 1, 0, 0],
 [0, 0, 0, 1, 0],
 [0, 0, 0, 0, 0]]
>>> [motzkin_words(n).cardinality() for n in range(Integer(8))]
[1, 1, 2, 4, 9, 21, 51, 127]
>>> oeis(_)                    # optional -- internet
0: A001006: Motzkin numbers: number of ways of drawing any number
of nonintersecting chords joining n (labeled) points on a circle.
1: ...
2: ...
```

or Dyck words (see also *DyckWords*), through the bijection with paths from $(0,0)$ to (n,n) with left and up steps that remain below the diagonal:

```
sage: def dyck_words(n):
....:     return IntegerListsLex(length=n, ceiling=list(range(n+1)), min_slope=0)
sage: [dyck_words(n).cardinality() for n in range(8)]
[1, 1, 2, 5, 14, 42, 132, 429]
sage: dyck_words(3).list()
[[0, 1, 2], [0, 1, 1], [0, 0, 2], [0, 0, 1], [0, 0, 0]]
```

```
>>> from sage.all import *
>>> def dyck_words(n):
...     return IntegerListsLex(length=n, ceiling=list(range(n+Integer(1))), min_
↪slope=Integer(0))
>>> [dyck_words(n).cardinality() for n in range(Integer(8))]
[1, 1, 2, 5, 14, 42, 132, 429]
>>> dyck_words(Integer(3)).list()
[[0, 1, 2], [0, 1, 1], [0, 0, 2], [0, 0, 1], [0, 0, 0]]
```

On finiteness and inverse lexicographic enumeration

The set of all lists of integers cannot be enumerated in inverse lexicographic order, since there is no largest list (take $[n]$ for n as large as desired):

```
sage: IntegerListsLex().first()
Traceback (most recent call last):
...
ValueError: could not prove that the specified constraints yield a finite set
```

```
>>> from sage.all import *
>>> IntegerListsLex().first()
Traceback (most recent call last):
...
ValueError: could not prove that the specified constraints yield a finite set
```

Here is a variant which could be enumerated in lexicographic order but not in inverse lexicographic order:

```
sage: L = IntegerListsLex(length=2, ceiling=[Infinity, 0], floor=[0,1])
sage: for l in L: print(l)
Traceback (most recent call last):
...
ValueError: infinite upper bound for values of m
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(length=Integer(2), ceiling=[Infinity, Integer(0)],␣
↪floor=[Integer(0),Integer(1)])
>>> for l in L: print(l)
Traceback (most recent call last):
...
ValueError: infinite upper bound for values of m
```

Even when the sum is specified, it is not necessarily possible to enumerate *all* elements in inverse lexicographic order. In the following example, the list `[1, 1, 1]` will never appear in the enumeration:

```
sage: IntegerListsLex(3).first()
Traceback (most recent call last):
...
ValueError: could not prove that the specified constraints yield a finite set
```

```
>>> from sage.all import *
>>> IntegerListsLex(Integer(3)).first()
Traceback (most recent call last):
...
ValueError: could not prove that the specified constraints yield a finite set
```

If one wants to proceed anyway, one can sign a waiver by setting `check=False` (again, be warned that some valid lists may never appear):

```
sage: L = IntegerListsLex(3, check=False)
sage: it = iter(L)
sage: [next(it) for i in range(6)]
[[3], [2, 1], [2, 0, 1], [2, 0, 0, 1], [2, 0, 0, 0, 1], [2, 0, 0, 0, 0, 1]]
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(3), check=False)
>>> it = iter(L)
>>> [next(it) for i in range(Integer(6))]
[[3], [2, 1], [2, 0, 1], [2, 0, 0, 1], [2, 0, 0, 0, 1], [2, 0, 0, 0, 0, 1]]
```

In fact, being inverse lexicographically enumerable is almost equivalent to being finite. The only infinity that can occur would be from a tail of numbers $0, 1$ as in the previous example, where the 1 moves further and further to the right. If there is any list that is inverse lexicographically smaller than such a configuration, the iterator would not reach it and hence would not be considered iterable. Given that the infinite cases are very specific, at this point only the finite cases are supported (without signing the waiver).

The finiteness detection is not complete yet, so some finite cases may not be supported either, at least not without disabling the checks. Practical examples of such are welcome.

On trailing zeroes, and their caveats

As mentioned above, when several lists satisfying the constraints differ only by trailing zeroes, only the shortest one is listed:

```
sage: L = IntegerListsLex(max_length=4, max_part=1)
sage: L.list()
[[1, 1, 1, 1],
 [1, 1, 1],
 [1, 1, 0, 1],
 [1, 1],
 [1, 0, 1, 1],
 [1, 0, 1],
 [1, 0, 0, 1],
 [1],
 [0, 1, 1, 1],
 [0, 1, 1],
 [0, 1, 0, 1],
 [0, 1],
 [0, 0, 1, 1],
 [0, 0, 1],
 [0, 0, 0, 1],
 []]
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(max_length=Integer(4), max_part=Integer(1))
>>> L.list()
[[1, 1, 1, 1],
 [1, 1, 1],
 [1, 1, 0, 1],
 [1, 1],
 [1, 0, 1, 1],
 [1, 0, 1],
 [1, 0, 0, 1],
 [1],
 [0, 1, 1, 1],
 [0, 1, 1],
 [0, 1, 0, 1],
 [0, 1],
 [0, 0, 1, 1],
 [0, 0, 1],
 [0, 0, 0, 1],
 []]
```

and counted:

```
sage: L.cardinality()
16
```

```
>>> from sage.all import *
>>> L.cardinality()
16
```

Still, the others are considered as elements of L:

```
sage: L = IntegerListsLex(4,min_length=3,max_length=4)
sage: L.list()
[..., [2, 2, 0], ...]

sage: [2, 2, 0] in L       # in L.list()
True
sage: [2, 2, 0, 0] in L    # not in L.list() !
True
sage: [2, 2, 0, 0, 0] in L
False
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(4),min_length=Integer(3),max_length=Integer(4))
>>> L.list()
[..., [2, 2, 0], ...]

>>> [Integer(2), Integer(2), Integer(0)] in L       # in L.list()
True
>>> [Integer(2), Integer(2), Integer(0), Integer(0)] in L    # not in L.list() !
True
>>> [Integer(2), Integer(2), Integer(0), Integer(0), Integer(0)] in L
False
```

Specifying functions as input for the floor or ceiling

We construct all lists of sum 4 and length 4 such that `l[i] <= i`:

```
sage: list(IntegerListsLex(4, length=4, ceiling=lambda i: i, check=False))
[[0, 1, 2, 1], [0, 1, 1, 2], [0, 1, 0, 3], [0, 0, 2, 2], [0, 0, 1, 3]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(4), length=Integer(4), ceiling=lambda i: i,␣
→check=False))
[[0, 1, 2, 1], [0, 1, 1, 2], [0, 1, 0, 3], [0, 0, 2, 2], [0, 0, 1, 3]]
```

Warning

When passing a function as `floor` or `ceiling`, it may become undecidable to detect improper inverse lexicographic enumeration. For example, the following example has a finite enumeration:

```
sage: L = IntegerListsLex(3, floor=lambda i: 1 if i>=2 else 0, check=False)
sage: L.list()
[[3],
 [2, 1],
 [2, 0, 1],
 [1, 2],
```

```
 [1, 1, 1],
 [1, 0, 2],
 [1, 0, 1, 1],
 [0, 3],
 [0, 2, 1],
 [0, 1, 2],
 [0, 1, 1, 1],
 [0, 0, 3],
 [0, 0, 2, 1],
 [0, 0, 1, 2],
 [0, 0, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(3), floor=lambda i: Integer(1) if i>
↪=Integer(2) else Integer(0), check=False)
>>> L.list()
[[3],
 [2, 1],
 [2, 0, 1],
 [1, 2],
 [1, 1, 1],
 [1, 0, 2],
 [1, 0, 1, 1],
 [0, 3],
 [0, 2, 1],
 [0, 1, 2],
 [0, 1, 1, 1],
 [0, 0, 3],
 [0, 0, 2, 1],
 [0, 0, 1, 2],
 [0, 0, 1, 1, 1]]
```

but one cannot decide whether the following has an improper inverse lexicographic enumeration without computing the floor all the way to `Infinity`:

```
sage: L = IntegerListsLex(3, floor=lambda i: 0, check=False)
sage: it = iter(L)
sage: [next(it) for i in range(6)]
[[3], [2, 1], [2, 0, 1], [2, 0, 0, 1], [2, 0, 0, 0, 1], [2, 0, 0, 0, 0, 1]]
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(3), floor=lambda i: Integer(0), check=False)
>>> it = iter(L)
>>> [next(it) for i in range(Integer(6))]
[[3], [2, 1], [2, 0, 1], [2, 0, 0, 1], [2, 0, 0, 0, 1], [2, 0, 0, 0, 0, 1]]
```

Hence a warning is raised when a function is specified as input, unless the waiver is signed by setting `check=False`:

```
sage: L = IntegerListsLex(3, floor=lambda i: 1 if i>=2 else 0)
doctest:...
A function has been given as input of the floor=[...] or ceiling=[...]
arguments of IntegerListsLex. Please see the documentation for the caveats.
If you know what you are doing, you can set check=False to skip this warning.
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(3), floor=lambda i: Integer(1) if i>
↪=Integer(2) else Integer(0))
doctest:...
A function has been given as input of the floor=[...] or ceiling=[...]
arguments of IntegerListsLex. Please see the documentation for the caveats.
If you know what you are doing, you can set check=False to skip this warning.
```

Similarly, the algorithm may need to search forever for a solution when the ceiling is ultimately zero:

```
sage: L = IntegerListsLex(2,ceiling=lambda i:0, check=False)
sage: L.first()           # not tested: will hang forever
sage: L = IntegerListsLex(2,ceiling=lambda i:0 if i<20 else 1, check=False)
sage: it = iter(L)
sage: next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 1]
sage: next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 1]
sage: next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 1]
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(2),ceiling=lambda i:Integer(0), check=False)
>>> L.first()           # not tested: will hang forever
>>> L = IntegerListsLex(Integer(2),ceiling=lambda i:Integer(0) if i
↪<Integer(20) else Integer(1), check=False)
>>> it = iter(L)
>>> next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 1]
>>> next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 1]
>>> next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 1]
```

Tip: using disjoint union enumerated sets for additional flexibility

Sometimes, specifying a range for the sum or the length may be too restrictive. One would want instead to specify a list, or iterable L, of acceptable values. This is easy to achieve using a `disjoint union of enumerated sets`. Here we want to accept the values $n = 0, 2, 3$:

```
sage: C = DisjointUnionEnumeratedSets(Family([0,2,3],
....:         lambda n: IntegerListsLex(n, length=2)))
sage: C
Disjoint union of Finite family
{0: Integer lists of sum 0 satisfying certain constraints,
 2: Integer lists of sum 2 satisfying certain constraints,
 3: Integer lists of sum 3 satisfying certain constraints}
sage: C.list()
[[0, 0],
 [2, 0], [1, 1], [0, 2],
 [3, 0], [2, 1], [1, 2], [0, 3]]
```

```
>>> from sage.all import *
>>> C = DisjointUnionEnumeratedSets(Family([Integer(0),Integer(2),Integer(3)],
...         lambda n: IntegerListsLex(n, length=Integer(2))))
>>> C
Disjoint union of Finite family
{0: Integer lists of sum 0 satisfying certain constraints,
 2: Integer lists of sum 2 satisfying certain constraints,
 3: Integer lists of sum 3 satisfying certain constraints}
>>> C.list()
[[0, 0],
 [2, 0], [1, 1], [0, 2],
 [3, 0], [2, 1], [1, 2], [0, 3]]
```

The price to pay is that the enumeration order is now *graded lexicographic* instead of lexicographic: first choose the value according to the order specified by L, and use lexicographic order within each value. Here is we reverse L:

```
sage: DisjointUnionEnumeratedSets(Family([3,2,0],
....:     lambda n: IntegerListsLex(n, length=2))).list()
[[3, 0], [2, 1], [1, 2], [0, 3],
 [2, 0], [1, 1], [0, 2],
 [0, 0]]
```

```
>>> from sage.all import *
>>> DisjointUnionEnumeratedSets(Family([Integer(3),Integer(2),Integer(0)],
...     lambda n: IntegerListsLex(n, length=Integer(2)))).list()
[[3, 0], [2, 1], [1, 2], [0, 3],
 [2, 0], [1, 1], [0, 2],
 [0, 0]]
```

Note that if a given value appears several times, the corresponding elements will be enumerated several times, which may, or not, be what one wants:

```
sage: DisjointUnionEnumeratedSets(Family([2,2],
....:     lambda n: IntegerListsLex(n, length=2))).list()
[[2, 0], [1, 1], [0, 2], [2, 0], [1, 1], [0, 2]]
```

```
>>> from sage.all import *
>>> DisjointUnionEnumeratedSets(Family([Integer(2),Integer(2)],
...     lambda n: IntegerListsLex(n, length=Integer(2)))).list()
[[2, 0], [1, 1], [0, 2], [2, 0], [1, 1], [0, 2]]
```

Here is a variant where we specify acceptable values for the length:

```
sage: DisjointUnionEnumeratedSets(Family([0,1,3],
....:     lambda l: IntegerListsLex(2, length=l))).list()
[[2],
 [2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

```
>>> from sage.all import *
>>> DisjointUnionEnumeratedSets(Family([Integer(0),Integer(1),Integer(3)],
...     lambda l: IntegerListsLex(Integer(2), length=l))).list()
```

(continues on next page)

(continued from previous page)

```
[[2],
 [2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

This technique can also be useful to obtain a proper enumeration on infinite sets by using a graded lexicographic enumeration:

```
sage: C = DisjointUnionEnumeratedSets(Family(NN,
....:             lambda n: IntegerListsLex(n, length=2)))
sage: C
Disjoint union of Lazy family (<lambda>(i))_{i in Non negative integer semiring}
sage: it = iter(C)
sage: [next(it) for i in range(10)]
[[0, 0],
 [1, 0], [0, 1],
 [2, 0], [1, 1], [0, 2],
 [3, 0], [2, 1], [1, 2], [0, 3]]
```

```
>>> from sage.all import *
>>> C = DisjointUnionEnumeratedSets(Family(NN,
...             lambda n: IntegerListsLex(n, length=Integer(2))))
>>> C
Disjoint union of Lazy family (<lambda>(i))_{i in Non negative integer semiring}
>>> it = iter(C)
>>> [next(it) for i in range(Integer(10))]
[[0, 0],
 [1, 0], [0, 1],
 [2, 0], [1, 1], [0, 2],
 [3, 0], [2, 1], [1, 2], [0, 3]]
```

Specifying how to construct elements

This is the list of all monomials of degree 4 which divide the monomial $x^3y^1z^2$ (a monomial being identified with its exponent vector):

```
sage: R.<x,y,z> = QQ[]
sage: m = [3,1,2]
sage: def term(exponents):
....:     return x^exponents[0] * y^exponents[1] * z^exponents[2]
sage: list( IntegerListsLex(4, length=len(m), ceiling=m, element_
↪constructor=term) )
[x^3*y, x^3*z, x^2*y*z, x^2*z^2, x*y*z^2]
```

```
>>> from sage.all import *
>>> R = QQ['x, y, z']; (x, y, z,) = R._first_ngens(3)
>>> m = [Integer(3),Integer(1),Integer(2)]
>>> def term(exponents):
...     return x**exponents[Integer(0)] * y**exponents[Integer(1)] *␣
↪z**exponents[Integer(2)]
>>> list( IntegerListsLex(Integer(4), length=len(m), ceiling=m, element_
↪constructor=term) )
[x^3*y, x^3*z, x^2*y*z, x^2*z^2, x*y*z^2]
```

Note the use of the `element_constructor` option to specify how to construct elements from a plain list.

A variant is to specify a class for the elements. With the default element constructor, this class should take as input the parent `self` and a list.

> **Warning**
>
> The protocol for specifying the element class and constructor is subject to changes.

ALGORITHM:

The iteration algorithm uses a depth first search through the prefix tree of the list of integers (see also *Lexicographic generation of lists of integers*). While doing so, it does some lookahead heuristics to attempt to cut dead branches.

In most practical use cases, most dead branches are cut. Then, roughly speaking, the time needed to iterate through all the elements of S is proportional to the number of elements, where the proportion factor is controlled by the length l of the longest element of S. In addition, the memory usage is also controlled by l, which is to say negligible in practice.

Still, there remains much room for efficiency improvements; see Issue #18055, Issue #18056.

> **Note**
>
> The generation algorithm could in principle be extended to deal with non-constant slope constraints and with negative parts.

TESTS from comments on Issue #17979

Comment 191:

```
sage: list(IntegerListsLex(1, min_length=2, min_slope=0, max_slope=0))
[]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(1), min_length=Integer(2), min_slope=Integer(0),␣
↪max_slope=Integer(0)))
[]
```

Comment 240:

```
sage: L = IntegerListsLex(min_length=2, max_part=0)
sage: L.list()
[[0, 0]]
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(min_length=Integer(2), max_part=Integer(0))
>>> L.list()
[[0, 0]]
```

Tests on the element constructor feature and mutability

Internally, the iterator works on a single list that is mutated along the way. Therefore, you need to make sure that the `element_constructor` actually **copies** its input. This example shows what can go wrong:

```
sage: P = IntegerListsLex(n=3, max_slope=0, min_part=1, element_
↪constructor=lambda x: x)
sage: list(P)
[[], [], []]
```

```
>>> from sage.all import *
>>> P = IntegerListsLex(n=Integer(3), max_slope=Integer(0), min_part=Integer(1),␣
↪element_constructor=lambda x: x)
>>> list(P)
[[], [], []]
```

However, specifying `list()` as constructor solves this problem:

```
sage: P = IntegerListsLex(n=3, max_slope=0, min_part=1, element_constructor=list)
sage: list(P)
[[3], [2, 1], [1, 1, 1]]
```

```
>>> from sage.all import *
>>> P = IntegerListsLex(n=Integer(3), max_slope=Integer(0), min_part=Integer(1),␣
↪element_constructor=list)
>>> list(P)
[[3], [2, 1], [1, 1, 1]]
```

Same, step by step:

```
sage: it = iter(P)
sage: a = next(it); a
[3]
sage: b = next(it); b
[2, 1]
sage: a
[3]
sage: a is b
False
```

```
>>> from sage.all import *
>>> it = iter(P)
>>> a = next(it); a
[3]
>>> b = next(it); b
[2, 1]
>>> a
[3]
>>> a is b
False
```

Tests from MuPAD-Combinat:

```
sage: IntegerListsLex(7, min_length=2, max_length=6, floor=[0,0,2,0,0,1],␣
↪ceiling=[3,2,3,2,1,2]).cardinality()

```

(continues on next page)

(continued from previous page)

```
↪Integer(2)]).cardinality()
0
```

This used to hang (see comment 389 and fix in `Envelope.__init__()`):

```
sage: IntegerListsLex(7, max_part=0, ceiling=lambda i:i, check=False).list()
[]
```

```
>>> from sage.all import *
>>> IntegerListsLex(Integer(7), max_part=Integer(0), ceiling=lambda i:i,␣
↪check=False).list()
[]
```

backend_class

alias of *IntegerListsBackend_invlex*

class sage.combinat.integer_lists.invlex.**IntegerListsLexIter**(*backend*)

Bases: `object`

Iterator class for IntegerListsLex.

Let `T` be the prefix tree of all lists of nonnegative integers that satisfy all constraints except possibly for `min_length` and `min_sum`; let the children of a list be sorted decreasingly according to their last part.

The iterator is based on a depth-first search exploration of a subtree of this tree, trying to cut branches that do not contain a valid list. Each call of `next` iterates through the nodes of this tree until it finds a valid list to return.

Here are the attributes describing the current state of the iterator, and their invariants:

- `backend` – the `IntegerListsBackend` object this is iterating on;
- `_current_list` – the list corresponding to the current node of the tree;
- `_j` – the index of the last element of `_current_list`: `self._j == len(self._current_list) - 1`;
- `_current_sum` – the sum of the parts of `_current_list`;
- `_search_ranges` – list of same length as `_current_list`: the range for each part

Furthermore, we assume that there is no obvious contradiction in the constraints:

- `self.backend.min_length <= self.backend.max_length`;
- `self.backend.min_slope <= self.backend.max_slope` unless `self.backend.min_length <= 1`.

Along this iteration, `next` switches between the following states:

- LOOKAHEAD: determine whether the current list could be a prefix of a valid list;
- PUSH: go deeper into the prefix tree by appending the largest possible part to the current list;
- ME: check whether the current list is valid and if yes return it
- DECREASE: decrease the last part;
- POP: pop the last part of the current list;
- STOP: the iteration is finished.

The attribute `_next_state` contains the next state `next` should enter in.

5.1.125 Counting, generating, and manipulating nonnegative integer matrices

Counting, generating, and manipulating nonnegative integer matrices with prescribed row sums and column sums.

AUTHORS:

- Franco Saliola

class sage.combinat.integer_matrices.**IntegerMatrices**(*row_sums*, *column_sums*)

Bases: UniqueRepresentation, Parent

The class of nonnegative integer matrices with prescribed row sums and column sums.

An *integer matrix* m with column sums $c := (c_1, ..., c_k)$ and row sums $l := (l_1, ..., l_n)$ where $c_1 + ... + c_k$ is equal to $l_1 + ... + l_n$, is a $n \times k$ matrix $m = (m_{i,j})$ such that $m_{1,j} + \cdots + m_{n,j} = c_j$, for all j and $m_{i,1} + \cdots + m_{i,k} = l_i$, for all i.

EXAMPLES:

There are 6 integer matrices with row sums $[3, 2, 2]$ and column sums $[2, 5]$:

```
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IM = IntegerMatrices([3,2,2], [2,5]); IM
Non-negative integer matrices with row sums [3, 2, 2] and column sums [2, 5]
sage: IM.list()
[
[2 1]  [1 2]  [1 2]  [0 3]  [0 3]  [0 3]
[0 2]  [1 1]  [0 2]  [2 0]  [1 1]  [0 2]
[0 2], [0 2], [1 1], [0 2], [1 1], [2 0]
]
sage: IM.cardinality()
6
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_matrices import IntegerMatrices
>>> IM = IntegerMatrices([Integer(3),Integer(2),Integer(2)], [Integer(2),
↪Integer(5)]); IM
Non-negative integer matrices with row sums [3, 2, 2] and column sums [2, 5]
>>> IM.list()
[
[2 1]  [1 2]  [1 2]  [0 3]  [0 3]  [0 3]
[0 2]  [1 1]  [0 2]  [2 0]  [1 1]  [0 2]
[0 2], [0 2], [1 1], [0 2], [1 1], [2 0]
]
>>> IM.cardinality()
6
```

cardinality()

The number of integer matrices with the prescribed row sums and columns sums.

EXAMPLES:

```
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IntegerMatrices([2,5], [3,2,2]).cardinality()
6
sage: IntegerMatrices([1,1,1,1,1], [1,1,1,1,1]).cardinality()
120
```

(continues on next page)

(continued from previous page)

```
sage: IntegerMatrices([2,2,2,2], [2,2,2,2]).cardinality()
282
sage: IntegerMatrices([4], [3]).cardinality()
0
sage: len(IntegerMatrices([0,0], [0]).list())
1
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_matrices import IntegerMatrices
>>> IntegerMatrices([Integer(2),Integer(5)], [Integer(3),Integer(2),
↪Integer(2)]).cardinality()
6
>>> IntegerMatrices([Integer(1),Integer(1),Integer(1),Integer(1),Integer(1)],␣
↪[Integer(1),Integer(1),Integer(1),Integer(1),Integer(1)]).cardinality()
120
>>> IntegerMatrices([Integer(2),Integer(2),Integer(2),Integer(2)],␣
↪[Integer(2),Integer(2),Integer(2),Integer(2)]).cardinality()
282
>>> IntegerMatrices([Integer(4)], [Integer(3)]).cardinality()
0
>>> len(IntegerMatrices([Integer(0),Integer(0)], [Integer(0)]).list())
1
```

This method computes the cardinality using symmetric functions. Below are the same examples, but computed by generating the actual matrices:

```
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: len(IntegerMatrices([2,5], [3,2,2]).list())
6
sage: len(IntegerMatrices([1,1,1,1,1], [1,1,1,1,1]).list())
120
sage: len(IntegerMatrices([2,2,2,2], [2,2,2,2]).list())
282
sage: len(IntegerMatrices([4], [3]).list())
0
sage: len(IntegerMatrices([0], [0]).list())
1
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_matrices import IntegerMatrices
>>> len(IntegerMatrices([Integer(2),Integer(5)], [Integer(3),Integer(2),
↪Integer(2)]).list())
6
>>> len(IntegerMatrices([Integer(1),Integer(1),Integer(1),Integer(1),
↪Integer(1)], [Integer(1),Integer(1),Integer(1),Integer(1),Integer(1)]).
↪list())
120
>>> len(IntegerMatrices([Integer(2),Integer(2),Integer(2),Integer(2)],␣
↪[Integer(2),Integer(2),Integer(2),Integer(2)]).list())
282
>>> len(IntegerMatrices([Integer(4)], [Integer(3)]).list())
0
```

(continues on next page)

(continued from previous page)

```
>>> len(IntegerMatrices([Integer(0)], [Integer(0)]).list())
1
```

column_sums()

The column sums of the integer matrices in `self`.

OUTPUT: Composition

EXAMPLES:

```
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IM = IntegerMatrices([3,2,2], [2,5])
sage: IM.column_sums()
[2, 5]
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_matrices import IntegerMatrices
>>> IM = IntegerMatrices([Integer(3),Integer(2),Integer(2)], [Integer(2),
↪Integer(5)])
>>> IM.column_sums()
[2, 5]
```

row_sums()

The row sums of the integer matrices in `self`.

OUTPUT: Composition

EXAMPLES:

```
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IM = IntegerMatrices([3,2,2], [2,5])
sage: IM.row_sums()
[3, 2, 2]
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_matrices import IntegerMatrices
>>> IM = IntegerMatrices([Integer(3),Integer(2),Integer(2)], [Integer(2),
↪Integer(5)])
>>> IM.row_sums()
[3, 2, 2]
```

to_composition(x)

The composition corresponding to the integer matrix.

This is the composition obtained by reading the entries of the matrix from left to right along each row, and reading the rows from top to bottom, ignore zeros.

INPUT:

- `x` – matrix

EXAMPLES:

```
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IM = IntegerMatrices([3,2,2], [2,5]); IM
```

(continues on next page)

(continued from previous page)

```
Non-negative integer matrices with row sums [3, 2, 2] and column sums [2, 5]
sage: IM.list()
[
[2 1]  [1 2]  [1 2]  [0 3]  [0 3]  [0 3]
[0 2]  [1 1]  [0 2]  [2 0]  [1 1]  [0 2]
[0 2], [0 2], [1 1], [0 2], [1 1], [2 0]
]
sage: for m in IM: print(IM.to_composition(m))
[2, 1, 2, 2]
[1, 2, 1, 1, 2]
[1, 2, 2, 1, 1]
[3, 2, 2]
[3, 1, 1, 1, 1]
[3, 2, 2]
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_matrices import IntegerMatrices
>>> IM = IntegerMatrices([Integer(3),Integer(2),Integer(2)], [Integer(2),
↪Integer(5)]); IM
Non-negative integer matrices with row sums [3, 2, 2] and column sums [2, 5]
>>> IM.list()
[
[2 1]  [1 2]  [1 2]  [0 3]  [0 3]  [0 3]
[0 2]  [1 1]  [0 2]  [2 0]  [1 1]  [0 2]
[0 2], [0 2], [1 1], [0 2], [1 1], [2 0]
]
>>> for m in IM: print(IM.to_composition(m))
[2, 1, 2, 2]
[1, 2, 1, 1, 2]
[1, 2, 2, 1, 1]
[3, 2, 2]
[3, 1, 1, 1, 1]
[3, 2, 2]
```

sage.combinat.integer_matrices.**integer_matrices_generator**(*row_sums*, *column_sums*)

Recursively generate the integer matrices with the prescribed row sums and column sums.

INPUT:

- `row_sums` – list or tuple
- `column_sums` – list or tuple

OUTPUT: an iterator producing a list of lists

EXAMPLES:

```
sage: from sage.combinat.integer_matrices import integer_matrices_generator
sage: iter = integer_matrices_generator([3,2,2], [2,5]); iter
<generator object ...integer_matrices_generator at ...>
sage: for m in iter: print(m)
[[2, 1], [0, 2], [0, 2]]
[[1, 2], [1, 1], [0, 2]]
[[1, 2], [0, 2], [1, 1]]
```

(continues on next page)

(continued from previous page)

```
[[0, 3], [2, 0], [0, 2]]
[[0, 3], [1, 1], [1, 1]]
[[0, 3], [0, 2], [2, 0]]
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_matrices import integer_matrices_generator
>>> iter = integer_matrices_generator([Integer(3),Integer(2),Integer(2)],␣
↪[Integer(2),Integer(5)]); iter
<generator object ...integer_matrices_generator at ...>
>>> for m in iter: print(m)
[[2, 1], [0, 2], [0, 2]]
[[1, 2], [1, 1], [0, 2]]
[[1, 2], [0, 2], [1, 1]]
[[0, 3], [2, 0], [0, 2]]
[[0, 3], [1, 1], [1, 1]]
[[0, 3], [0, 2], [2, 0]]
```

5.1.126 (Non-negative) Integer vectors

AUTHORS:

- Mike Hansen (2007) - original module
- Nathann Cohen, David Joyner (2009-2010) - Gale-Ryser stuff
- Nathann Cohen, David Joyner (2011) - Gale-Ryser bugfix
- Travis Scrimshaw (2012-05-12) - Updated doc-strings to tell the user of that the class's name is a misnomer (that they only contains non-negative entries).
- Federico Poloni (2013) - specialized `rank()`
- Travis Scrimshaw (2013-02-04) - Refactored to use `ClonableIntArray`

class sage.combinat.integer_vector.**IntegerVector**

Bases: `ClonableArray`

An integer vector.

check()

Check to make sure this is a valid integer vector by making sure all entries are nonnegative.

EXAMPLES:

```
sage: IV = IntegerVectors()
sage: elt = IV([1,2,1])
sage: elt.check()
```

```
>>> from sage.all import *
>>> IV = IntegerVectors()
>>> elt = IV([Integer(1),Integer(2),Integer(1)])
>>> elt.check()
```

Check Issue #34510:

```
sage: IV3 = IntegerVectors(n=3)
sage: IV3([2,2])
Traceback (most recent call last):
...
ValueError: [2, 2] doesn't satisfy correct constraints
sage: IVk3 = IntegerVectors(k=3)
sage: IVk3([2,2])
Traceback (most recent call last):
...
ValueError: [2, 2] doesn't satisfy correct constraints
sage: IV33 = IntegerVectors(n=3, k=3)
sage: IV33([2,2])
Traceback (most recent call last):
...
ValueError: [2, 2] doesn't satisfy correct constraints
```

```
>>> from sage.all import *
>>> IV3 = IntegerVectors(n=Integer(3))
>>> IV3([Integer(2),Integer(2)])
Traceback (most recent call last):
...
ValueError: [2, 2] doesn't satisfy correct constraints
>>> IVk3 = IntegerVectors(k=Integer(3))
>>> IVk3([Integer(2),Integer(2)])
Traceback (most recent call last):
...
ValueError: [2, 2] doesn't satisfy correct constraints
>>> IV33 = IntegerVectors(n=Integer(3), k=Integer(3))
>>> IV33([Integer(2),Integer(2)])
Traceback (most recent call last):
...
ValueError: [2, 2] doesn't satisfy correct constraints
```

specht_module(*base_ring=None*)

Return the Specht module corresponding to `self`.

EXAMPLES:

```
sage: SM = IntegerVectors()([2,0,1,0,2]).specht_module(QQ); SM              #␣
↪needs sage.combinat sage.modules
Specht module of [(0, 0), (0, 1), (2, 0), (4, 0), (4, 1)] over Rational Field
sage: s = SymmetricFunctions(QQ).s()                                        #␣
↪needs sage.combinat sage.modules
sage: s(SM.frobenius_image())                                               #␣
↪needs sage.combinat sage.modules
s[2, 2, 1]
```

```
>>> from sage.all import *
>>> SM = IntegerVectors()([Integer(2),Integer(0),Integer(1),Integer(0),
↪Integer(2)]).specht_module(QQ); SM             # needs sage.combinat sage.
↪modules
Specht module of [(0, 0), (0, 1), (2, 0), (4, 0), (4, 1)] over Rational Field
>>> s = SymmetricFunctions(QQ).s()                                        #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.combinat sage.modules
>>> s(SM.frobenius_image())                                                  #␣
↪needs sage.combinat sage.modules
s[2, 2, 1]
```

specht_module_dimension(*base_ring=None*)

Return the dimension of the Specht module corresponding to `self`.

INPUT:

- `BR` – (default: **Q**) the base ring

EXAMPLES:

```
sage: IntegerVectors()([2,0,1,0,2]).specht_module_dimension()                  #␣
↪needs sage.combinat sage.modules
5
sage: IntegerVectors()([2,0,1,0,2]).specht_module_dimension(GF(2))             #␣
↪needs sage.combinat sage.modules sage.rings.finite_rings
5
```

```
>>> from sage.all import *
>>> IntegerVectors()([Integer(2),Integer(0),Integer(1),Integer(0),
↪Integer(2)]).specht_module_dimension()                  # needs sage.combinat␣
↪sage.modules
5
>>> IntegerVectors()([Integer(2),Integer(0),Integer(1),Integer(0),
↪Integer(2)]).specht_module_dimension(GF(Integer(2)))          # needs sage.
↪combinat sage.modules sage.rings.finite_rings
5
```

trim()

Remove trailing zeros from the integer vector.

EXAMPLES:

```
sage: IV = IntegerVectors()
sage: IV([5,3,5,1,0,0]).trim()
[5, 3, 5, 1]
sage: IV([5,0,5,1,0]).trim()
[5, 0, 5, 1]
sage: IV([4,3,3]).trim()
[4, 3, 3]
sage: IV([0,0,0]).trim()
[]

sage: IV = IntegerVectors(k=4)
sage: v = IV([4,3,2,0]).trim(); v
[4, 3, 2]
sage: v.parent()
Integer vectors
```

```
>>> from sage.all import *
>>> IV = IntegerVectors()
>>> IV([Integer(5),Integer(3),Integer(5),Integer(1),Integer(0),Integer(0)]).
↪trim()
[5, 3, 5, 1]
>>> IV([Integer(5),Integer(0),Integer(5),Integer(1),Integer(0)]).trim()
[5, 0, 5, 1]
>>> IV([Integer(4),Integer(3),Integer(3)]).trim()
[4, 3, 3]
>>> IV([Integer(0),Integer(0),Integer(0)]).trim()
[]

>>> IV = IntegerVectors(k=Integer(4))
>>> v = IV([Integer(4),Integer(3),Integer(2),Integer(0)]).trim(); v
[4, 3, 2]
>>> v.parent()
Integer vectors
```

class sage.combinat.integer_vector.**IntegerVectors**(*category=None*)

Bases: Parent

The class of (nonnegative) integer vectors.

INPUT:

- n – if set to an integer, returns the combinatorial class of integer vectors whose sum is n; if set to None (default), no such constraint is defined
- k – the length of the vectors; set to None (default) if you do not want such a constraint

Note

The entries are nonnegative integers.

EXAMPLES:

If n is not specified, it returns the class of all integer vectors:

```
sage: IntegerVectors()
Integer vectors
sage: [] in IntegerVectors()
True
sage: [1,2,1] in IntegerVectors()
True
sage: [1, 0, 0] in IntegerVectors()
True
```

```
>>> from sage.all import *
>>> IntegerVectors()
Integer vectors
>>> [] in IntegerVectors()
True
>>> [Integer(1),Integer(2),Integer(1)] in IntegerVectors()
True
```

(continues on next page)

(continued from previous page)

```
>>> [Integer(1), Integer(0), Integer(0)] in IntegerVectors()
True
```

Entries are nonnegative:

```
sage: [-1, 2] in IntegerVectors()
False
```

```
>>> from sage.all import *
>>> [-Integer(1), Integer(2)] in IntegerVectors()
False
```

If `n` is specified, then it returns the class of all integer vectors which sum to `n`:

```
sage: IV3 = IntegerVectors(3); IV3
Integer vectors that sum to 3
```

```
>>> from sage.all import *
>>> IV3 = IntegerVectors(Integer(3)); IV3
Integer vectors that sum to 3
```

Note that trailing zeros are ignored so that `[3, 0]` does not show up in the following list (since `[3]` does):

```
sage: IntegerVectors(3, max_length=2).list()
[[3], [2, 1], [1, 2], [0, 3]]
```

```
>>> from sage.all import *
>>> IntegerVectors(Integer(3), max_length=Integer(2)).list()
[[3], [2, 1], [1, 2], [0, 3]]
```

If `n` and `k` are both specified, then it returns the class of integer vectors that sum to `n` and are of length `k`:

```
sage: IV53 = IntegerVectors(5,3); IV53
Integer vectors of length 3 that sum to 5
sage: IV53.cardinality()
21
sage: IV53.first()
[5, 0, 0]
sage: IV53.last()
[0, 0, 5]
sage: IV53.random_element().parent() is IV53
True
```

```
>>> from sage.all import *
>>> IV53 = IntegerVectors(Integer(5),Integer(3)); IV53
Integer vectors of length 3 that sum to 5
>>> IV53.cardinality()
21
>>> IV53.first()
[5, 0, 0]
>>> IV53.last()
[0, 0, 5]
```

(continues on next page)

(continued from previous page)

```
>>> IV53.random_element().parent() is IV53
True
```

Further examples:

```
sage: IntegerVectors(-1, 0, min_part=1).list()
[]
sage: IntegerVectors(-1, 2, min_part=1).list()
[]
sage: IntegerVectors(0, 0, min_part=1).list()
[[]]
sage: IntegerVectors(3, 0, min_part=1).list()
[]
sage: IntegerVectors(0, 1, min_part=1).list()
[]
sage: IntegerVectors(2, 2, min_part=1).list()
[[1, 1]]
sage: IntegerVectors(2, 3, min_part=1).list()
[]
sage: IntegerVectors(4, 2, min_part=1).list()
[[3, 1], [2, 2], [1, 3]]
```

```
>>> from sage.all import *
>>> IntegerVectors(-Integer(1), Integer(0), min_part=Integer(1)).list()
[]
>>> IntegerVectors(-Integer(1), Integer(2), min_part=Integer(1)).list()
[]
>>> IntegerVectors(Integer(0), Integer(0), min_part=Integer(1)).list()
[[]]
>>> IntegerVectors(Integer(3), Integer(0), min_part=Integer(1)).list()
[]
>>> IntegerVectors(Integer(0), Integer(1), min_part=Integer(1)).list()
[]
>>> IntegerVectors(Integer(2), Integer(2), min_part=Integer(1)).list()
[[1, 1]]
>>> IntegerVectors(Integer(2), Integer(3), min_part=Integer(1)).list()
[]
>>> IntegerVectors(Integer(4), Integer(2), min_part=Integer(1)).list()
[[3, 1], [2, 2], [1, 3]]
```

```
sage: IntegerVectors(0, 3, outer=[0,0,0]).list()
[[0, 0, 0]]
sage: IntegerVectors(1, 3, outer=[0,0,0]).list()
[]
sage: IntegerVectors(2, 3, outer=[0,2,0]).list()
[[0, 2, 0]]
sage: IntegerVectors(2, 3, outer=[1,2,1]).list()
[[1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1]]
sage: IntegerVectors(2, 3, outer=[1,1,1]).list()
[[1, 1, 0], [1, 0, 1], [0, 1, 1]]
sage: IntegerVectors(2, 5, outer=[1,1,1,1,1]).list()
[[1, 1, 0, 0, 0],
```

(continues on next page)

(continued from previous page)

```
 [1, 0, 1, 0, 0],
 [1, 0, 0, 1, 0],
 [1, 0, 0, 0, 1],
 [0, 1, 1, 0, 0],
 [0, 1, 0, 1, 0],
 [0, 1, 0, 0, 1],
 [0, 0, 1, 1, 0],
 [0, 0, 1, 0, 1],
 [0, 0, 0, 1, 1]]
```

```
>>> from sage.all import *
>>> IntegerVectors(Integer(0), Integer(3), outer=[Integer(0),Integer(0),
↪Integer(0)]).list()
[[0, 0, 0]]
>>> IntegerVectors(Integer(1), Integer(3), outer=[Integer(0),Integer(0),
↪Integer(0)]).list()
[]
>>> IntegerVectors(Integer(2), Integer(3), outer=[Integer(0),Integer(2),
↪Integer(0)]).list()
[[0, 2, 0]]
>>> IntegerVectors(Integer(2), Integer(3), outer=[Integer(1),Integer(2),

 [0, 0, 1, 1, 0],
 [0, 0, 1, 0, 1],
 [0, 0, 0, 1, 1]]
```

```
sage: iv = [ IntegerVectors(n,k) for n in range(-2, 7) for k in range(7) ]
sage: all(map(lambda x: x.cardinality() == len(x.list()), iv))
True
sage: essai = [[1,1,1], [2,5,6], [6,5,2]]
sage: iv = [ IntegerVectors(x[0], x[1], max_part = x[2]-1) for x in essai ]
sage: all(map(lambda x: x.cardinality() == len(x.list()), iv))
True
```

```
>>> from sage.all import *
>>> iv = [ IntegerVectors(n,k) for n in range(-Integer(2), Integer(7)) for k in␣
↪range(Integer(7)) ]
>>> all(map(lambda x: x.cardinality() == len(x.list()), iv))
```

(continues on next page)

(continued from previous page)

```
True
>>> essai = [[Integer(1),Integer(1),Integer(1)], [Integer(2),Integer(5),
↪Integer(6)], [Integer(6),Integer(5),Integer(2)]]
>>> iv = [ IntegerVectors(x[Integer(0)], x[Integer(1)], max_part = x[Integer(2)]-
↪Integer(1)) for x in essai ]
>>> all(map(lambda x: x.cardinality() == len(x.list()), iv))
True
```

An example showing the same output by using IntegerListsLex:

```
sage: IntegerVectors(4, max_length=2).list()
[[4], [3, 1], [2, 2], [1, 3], [0, 4]]
sage: list(IntegerListsLex(4, max_length=2))
[[4], [3, 1], [2, 2], [1, 3], [0, 4]]
```

```
>>> from sage.all import *
>>> IntegerVectors(Integer(4), max_length=Integer(2)).list()
[[4], [3, 1], [2, 2], [1, 3], [0, 4]]
>>> list(IntegerListsLex(Integer(4), max_length=Integer(2)))
[[4], [3, 1], [2, 2], [1, 3], [0, 4]]
```

sage.combinat.integer_lists.invlex.IntegerListsLex

Element

alias of *IntegerVector*

class sage.combinat.integer_vector.**IntegerVectorsConstraints**(*n=None*, *k=None*, ***constraints*)

Bases: *IntegerVectors*

Class of integer vectors subject to various constraints.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: IntegerVectors(3, 3, min_part=1).cardinality()
1
sage: IntegerVectors(5, 3, min_part=1).cardinality()
6
sage: IntegerVectors(13, 4, max_part=4).cardinality()
20
sage: IntegerVectors(k=4, max_part=3).cardinality()
256
sage: IntegerVectors(k=3, min_part=2, max_part=4).cardinality()
27
sage: IntegerVectors(13, 4, min_part=2, max_part=4).cardinality()
16
```

```
>>> from sage.all import *
>>> IntegerVectors(Integer(3), Integer(3), min_part=Integer(1)).cardinality()
1
>>> IntegerVectors(Integer(5), Integer(3), min_part=Integer(1)).cardinality()
6
>>> IntegerVectors(Integer(13), Integer(4), max_part=Integer(4)).cardinality()
20
>>> IntegerVectors(k=Integer(4), max_part=Integer(3)).cardinality()
256
>>> IntegerVectors(k=Integer(3), min_part=Integer(2), max_part=Integer(4)).
↪cardinality()
27
>>> IntegerVectors(Integer(13), Integer(4), min_part=Integer(2), max_
↪part=Integer(4)).cardinality()
16
```

class sage.combinat.integer_vector.**IntegerVectors_all**

Bases: UniqueRepresentation, *IntegerVectors*

Class of all integer vectors.

class sage.combinat.integer_vector.**IntegerVectors_k**(*k*)

Bases: UniqueRepresentation, *IntegerVectors*

Integer vectors of length k.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: IntegerVectors(k=0).cardinality()
1
sage: IntegerVectors(k=10).cardinality()
+Infinity
```

```
>>> from sage.all import *
>>> IntegerVectors(k=Integer(0)).cardinality()
1
>>> IntegerVectors(k=Integer(10)).cardinality()
+Infinity
```

rank(*x*)

Return the rank of a given element.

INPUT:

- `x` – list with `len(x) == k`

EXAMPLES:

```
sage: IntegerVectors(k=5).rank([0,0,0,0,0])
0
sage: IntegerVectors(k=5).rank([1,1,0,0,0])
7
```

```
>>> from sage.all import *
>>> IntegerVectors(k=Integer(5)).rank([Integer(0),Integer(0),Integer(0),
↪Integer(0),Integer(0)])
0
>>> IntegerVectors(k=Integer(5)).rank([Integer(1),Integer(1),Integer(0),
↪Integer(0),Integer(0)])
7
```

unrank(*x*)

Return the element at given rank x.

INPUT:

- `x` – integer such that `x < self.cardinality()`

EXAMPLES:

```
sage: IntegerVectors(k=5).unrank(10)
[1, 0, 0, 0, 1]
sage: IntegerVectors(k=5).unrank(15)
[0, 0, 2, 0, 0]
sage: IntegerVectors(k=0).unrank(0)
[]
```

```
>>> from sage.all import *
>>> IntegerVectors(k=Integer(5)).unrank(Integer(10))
[1, 0, 0, 0, 1]
>>> IntegerVectors(k=Integer(5)).unrank(Integer(15))
[0, 0, 2, 0, 0]
>>> IntegerVectors(k=Integer(0)).unrank(Integer(0))
[]
```

class sage.combinat.integer_vector.**IntegerVectors_n**(*n*)

Bases: `UniqueRepresentation`, *`IntegerVectors`*

Integer vectors that sum to n.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: IntegerVectors(n=0).cardinality()
1
sage: IntegerVectors(n=10).cardinality()
+Infinity
```

```
>>> from sage.all import *
>>> IntegerVectors(n=Integer(0)).cardinality()
1
>>> IntegerVectors(n=Integer(10)).cardinality()
+Infinity
```

rank(*x*)

Return the rank of a given element.

INPUT:

- `x` – list with `sum(x) == n`

EXAMPLES:

```
sage: IntegerVectors(n=5).rank([5,0])
1
sage: IntegerVectors(n=5).rank([3,2])
3
```

```
>>> from sage.all import *
>>> IntegerVectors(n=Integer(5)).rank([Integer(5),Integer(0)])
1
>>> IntegerVectors(n=Integer(5)).rank([Integer(3),Integer(2)])
3
```

unrank(*x*)

Return the element at given rank x.

INPUT:

- `x` – integer

EXAMPLES:

```
sage: IntegerVectors(n=5).unrank(2)
[4, 1]
sage: IntegerVectors(n=10).unrank(10)
[1, 9]
```

```
>>> from sage.all import *
>>> IntegerVectors(n=Integer(5)).unrank(Integer(2))
[4, 1]
>>> IntegerVectors(n=Integer(10)).unrank(Integer(10))
[1, 9]
```

class sage.combinat.integer_vector.**IntegerVectors_nk**(*n*, *k*)

Bases: `UniqueRepresentation`, *IntegerVectors*

Integer vectors of length k that sum to n.

AUTHORS:

- Martin Albrecht
- Mike Hansen

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: IntegerVectors(3,5).cardinality()
35
sage: IntegerVectors(99, 3).cardinality()
5050
sage: IntegerVectors(10^9 - 1, 3).cardinality()
500000000500000000
```

```
>>> from sage.all import *
>>> IntegerVectors(Integer(3),Integer(5)).cardinality()
35
>>> IntegerVectors(Integer(99), Integer(3)).cardinality()
5050
>>> IntegerVectors(Integer(10)**Integer(9) - Integer(1), Integer(3)).
↪cardinality()
500000000500000000
```

rank(*x*)

Return the rank of a given element.

INPUT:

- `x` – list with `sum(x) == n` and `len(x) == k`

unrank(*x*)

Return the element at given rank x.

INPUT:

- `x` – integer such that `x < self.cardinality()`

EXAMPLES:

```
sage: IntegerVectors(4,5).unrank(30)
[1, 0, 1, 0, 2]
sage: IntegerVectors(2,3).unrank(5)
[0, 0, 2]
```

```
>>> from sage.all import *
>>> IntegerVectors(Integer(4),Integer(5)).unrank(Integer(30))
[1, 0, 1, 0, 2]
>>> IntegerVectors(Integer(2),Integer(3)).unrank(Integer(5))
[0, 0, 2]
```

class sage.combinat.integer_vector.**IntegerVectors_nnondescents**(*n*, *comp*)

Bases: `UniqueRepresentation`, *IntegerVectors*

Integer vectors graded by two parameters.

The grading parameters on the integer vector v are:

- `n` – the sum of the parts of v
- `c` – the non descents composition of v

In other words: the length of v equals $c_1 + \cdots + c_k$, and v is decreasing in the consecutive blocs of length $c_1, \ldots, c_k$,

INPUT:

- `n` – the positive integer n
- `comp` – the composition c

Those are the integer vectors of sum n that are lexicographically maximal (for the natural left-to-right reading) in their orbit by the Young subgroup $S_{c_1} \times \cdots \times S_{c_k}$. In particular, they form a set of orbit representative of integer vectors with respect to this Young subgroup.

sage.combinat.integer_vector.**gale_ryser_theorem**(*p1*, *p2*, *algorithm*, *solver*, *integrality_tolerance='gale'*)

Return the binary matrix given by the Gale-Ryser theorem.

The Gale Ryser theorem asserts that if p_1, p_2 are two partitions of n of respective lengths k_1, k_2, then there is a binary $k_1 \times k_2$ matrix M such that p_1 is the vector of row sums and p_2 is the vector of column sums of M, if and only if the conjugate of p_2 dominates p_1.

INPUT:

- `p1`, `p2` – list of integers representing the vectors of row/column sums
- `algorithm` – two possible string values:
  - `'ryser'` implements the construction due to Ryser [Ryser63].
  - `'gale'` (default) implements the construction due to Gale [Gale57].
- `solver` – (default: `None`) specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`

OUTPUT: a binary matrix if it exists, `None` otherwise

Gale's Algorithm:

(Gale [Gale57]): A matrix satisfying the constraints of its sums can be defined as the solution of the following Linear Program, which Sage knows how to solve.

$$\forall i \sum_{j=1}^{k_2} b_{i,j} = p_{1,j}$$
$$\forall i \sum_{j=1}^{k_1} b_{j,i} = p_{2,j}$$
$$b_{i,j} \text{ is a binary variable}$$

Ryser's Algorithm:

(Ryser [Ryser63]): The construction of an $m \times n$ matrix $A = A_{r,s}$, due to Ryser, is described as follows. The construction works if and only if have $s \preceq r^*$.

- Construct the $m \times n$ matrix B from r by defining the i-th row of B to be the vector whose first r_i entries are 1, and the remainder are 0s, $1 \le i \le m$. This maximal matrix B with row sum r and ones left justified has column sum r^*.
- Shift the last 1 in certain rows of B to column n in order to achieve the sum s_n. Call this B again.
  - The 1's in column n are to appear in those rows in which A has the largest row sums, giving preference to the bottom-most positions in case of ties.
  - Note: When this step automatically "fixes" other columns, one must skip ahead to the first column index with a wrong sum in the step below.
- Proceed inductively to construct columns $n-1$, …, 2, 1. Note: when performing the induction on step k, we consider the row sums of the first k columns.
- Set $A = B$. Return A.

EXAMPLES:

Computing the matrix for $p_1 = p_2 = 2 + 2 + 1$:

```
sage: # needs sage.combinat sage.modules
sage: from sage.combinat.integer_vector import gale_ryser_theorem
sage: p1 = [2,2,1]
sage: p2 = [2,2,1]
sage: print(gale_ryser_theorem(p1, p2))         # not tested
[1 1 0]
[1 0 1]
[0 1 0]
sage: A = gale_ryser_theorem(p1, p2)
sage: rs = [sum(x) for x in A.rows()]
sage: cs = [sum(x) for x in A.columns()]
sage: p1 == rs; p2 == cs
True
True
```

```
>>> from sage.all import *
>>> # needs sage.combinat sage.modules
>>> from sage.combinat.integer_vector import gale_ryser_theorem
>>> p1 = [Integer(2),Integer(2),Integer(1)]
>>> p2 = [Integer(2),Integer(2),Integer(1)]
>>> print(gale_ryser_theorem(p1, p2))         # not tested
[1 1 0]
[1 0 1]
[0 1 0]
>>> A = gale_ryser_theorem(p1, p2)
>>> rs = [sum(x) for x in A.rows()]
>>> cs = [sum(x) for x in A.columns()]
>>> p1 == rs; p2 == cs
True
True
```

Or for a non-square matrix with $p_1 = 3+3+2+1$ and $p_2 = 3+2+2+1+1$, using Ryser's algorithm:

```
sage: # needs sage.combinat sage.modules
sage: from sage.combinat.integer_vector import gale_ryser_theorem
sage: p1 = [3,3,1,1]
sage: p2 = [3,3,1,1]
sage: gale_ryser_theorem(p1, p2, algorithm='ryser')
[1 1 1 0]
[1 1 0 1]
[1 0 0 0]
[0 1 0 0]
sage: p1 = [4,2,2]
sage: p2 = [3,3,1,1]
sage: gale_ryser_theorem(p1, p2, algorithm='ryser')
[1 1 1 1]
[1 1 0 0]
[1 1 0 0]
sage: p1 = [4,2,2,0]
sage: p2 = [3,3,1,1,0,0]
sage: gale_ryser_theorem(p1, p2, algorithm='ryser')
[1 1 1 1 0 0]
[1 1 0 0 0 0]
```

(continues on next page)

(continued from previous page)

```
[1 1 0 0 0 0]
[0 0 0 0 0 0]
sage: p1 = [3,3,2,1]
sage: p2 = [3,2,2,1,1]
sage: print(gale_ryser_theorem(p1, p2, algorithm='gale'))       # not tested
[1 1 1 0 0]
[1 1 0 0 1]
[1 0 1 0 0]
[0 0 0 1 0]
```

```
>>> from sage.all import *
>>> # needs sage.combinat sage.modules
>>> from sage.combinat.integer_vector import gale_ryser_theorem
>>> p1 = [Integer(3),Integer(3),Integer(1),Integer(1)]
>>> p2 = [Integer(3),Integer(3),Integer(1),Integer(1)]
>>> gale_ryser_theorem(p1, p2, algorithm='ryser')
[1 1 1 0]
[1 1 0 1]
[1 0 0 0]
[0 1 0 0]
>>> p1 = [Integer(4),Integer(2),Integer(2)]
>>> p2 = [Integer(3),Integer(3),Integer(1),Integer(1)]
>>> gale_ryser_theorem(p1, p2, algorithm='ryser')
[1 1 1 1]
[1 1 0 0]
[1 1 0 0]
>>> p1 = [Integer(4),Integer(2),Integer(2),Integer(0)]
>>> p2 = [Integer(3),Integer(3),Integer(1),Integer(1),Integer(0),Integer(0)]
>>> gale_ryser_theorem(p1, p2, algorithm='ryser')
[1 1 1 1 0 0]
[1 1 0 0 0 0]
[1 1 0 0 0 0]
[0 0 0 0 0 0]
>>> p1 = [Integer(3),Integer(3),Integer(2),Integer(1)]
>>> p2 = [Integer(3),Integer(2),Integer(2),Integer(1),Integer(1)]
>>> print(gale_ryser_theorem(p1, p2, algorithm='gale'))       # not tested
[1 1 1 0 0]
[1 1 0 0 1]
[1 0 1 0 0]
[0 0 0 1 0]
```

With 0 in the sequences, and with unordered inputs:

```
sage: from sage.combinat.integer_vector import gale_ryser_theorem
sage: gale_ryser_theorem([3,3,0,1,1,0], [3,1,3,1,0], algorithm='ryser')       #␣

↪needs sage.combinat sage.modules
[1 1 1 0]
[1 0 0 0]
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
```

REFERENCES:

sage.combinat.integer_vector.**integer_vectors_nk_fast_iter**(*n*, *k*)

A fast iterator for integer vectors of `n` of length `k` which yields Python lists filled with Sage Integers.

EXAMPLES:

```
sage: from sage.combinat.integer_vector import integer_vectors_nk_fast_iter
sage: list(integer_vectors_nk_fast_iter(3, 2))
[[3, 0], [2, 1], [1, 2], [0, 3]]
sage: list(integer_vectors_nk_fast_iter(2, 2))
[[2, 0], [1, 1], [0, 2]]
sage: list(integer_vectors_nk_fast_iter(1, 2))
[[1, 0], [0, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_vector import integer_vectors_nk_fast_iter
>>> list(integer_vectors_nk_fast_iter(Integer(3), Integer(2)))
[[3, 0], [2, 1], [1, 2], [0, 3]]
>>> list(integer_vectors_nk_fast_iter(Integer(2), Integer(2)))
[[2, 0], [1, 1], [0, 2]]
>>> list(integer_vectors_nk_fast_iter(Integer(1), Integer(2)))
[[1, 0], [0, 1]]
```

We check some corner cases:

```
sage: list(integer_vectors_nk_fast_iter(5, 1))
[[5]]
sage: list(integer_vectors_nk_fast_iter(1, 1))
[[1]]
sage: list(integer_vectors_nk_fast_iter(2, 0))
[]
sage: list(integer_vectors_nk_fast_iter(0, 2))
[[0, 0]]
sage: list(integer_vectors_nk_fast_iter(0, 0))
[[]]
```

```
>>> from sage.all import *
>>> list(integer_vectors_nk_fast_iter(Integer(5), Integer(1)))
[[5]]
>>> list(integer_vectors_nk_fast_iter(Integer(1), Integer(1)))
[[1]]
>>> list(integer_vectors_nk_fast_iter(Integer(2), Integer(0)))
[]
>>> list(integer_vectors_nk_fast_iter(Integer(0), Integer(2)))
[[0, 0]]
>>> list(integer_vectors_nk_fast_iter(Integer(0), Integer(0)))
[[]]
```

sage.combinat.integer_vector.**is_gale_ryser**(*r*, *s*)

Test whether the given sequences satisfy the condition of the Gale-Ryser theorem.

Given a binary matrix B of dimension $n \times m$, the vector of row sums is defined as the vector whose i^{th} component is equal to the sum of the i^{th} row in A. The vector of column sums is defined similarly.

If, given a binary matrix, these two vectors are easy to compute, the Gale-Ryser theorem lets us decide whether, given two nonnegative vectors r, s, there exists a binary matrix whose row/column sums vectors are r and s.

This functions answers accordingly.

INPUT:

- r, s – lists of nonnegative integers

ALGORITHM:

Without loss of generality, we can assume that:

- The two given sequences do not contain any 0 (which would correspond to an empty column/row)
- The two given sequences are ordered in decreasing order (reordering the sequence of row (resp. column) sums amounts to reordering the rows (resp. columns) themselves in the matrix, which does not alter the columns (resp. rows) sums.

We can then assume that r and s are partitions (see the corresponding class *Partition*)

If r^* denote the conjugate of r, the Gale-Ryser theorem asserts that a binary Matrix satisfying the constraints exists if and only if $s \preceq r^*$, where $\preceq$ denotes the domination order on partitions.

EXAMPLES:

```
sage: from sage.combinat.integer_vector import is_gale_ryser
sage: is_gale_ryser([4,2,2], [3,3,1,1])                                        #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.combinat
True
sage: is_gale_ryser([4,2,1,1], [3,3,1,1])                                  #␣
↪needs sage.combinat
True
sage: is_gale_ryser([3,2,1,1], [3,3,1,1])                                  #␣
↪needs sage.combinat
False
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_vector import is_gale_ryser
>>> is_gale_ryser([Integer(4),Integer(2),Integer(2)], [Integer(3),Integer(3),
↪Integer(1),Integer(1)])                                          # needs sage.
↪combinat
True
>>> is_gale_ryser([Integer(4),Integer(2),Integer(1),Integer(1)], [Integer(3),
↪Integer(3),Integer(1),Integer(1)])                                        #␣
↪needs sage.combinat
True
>>> is_gale_ryser([Integer(3),Integer(2),Integer(1),Integer(1)], [Integer(3),
↪Integer(3),Integer(1),Integer(1)])                                        #␣
↪needs sage.combinat
False
```

REMARK: In the literature, what we are calling a Gale-Ryser sequence sometimes goes by the (rather generic-sounding) term "realizable sequence".

sage.combinat.integer_vector.**list2func**(*l*, *default=None*)

Given a list `l`, return a function that takes in a value `i` and return `l[i]`. If default is not `None`, then the function will return the default value for out of range `i`'s.

EXAMPLES:

```
sage: f = sage.combinat.integer_vector.list2func([1,2,3])
sage: f(0)
1
sage: f(1)
2
sage: f(2)
3
sage: f(3)
Traceback (most recent call last):
...
IndexError: list index out of range
```

```
>>> from sage.all import *
>>> f = sage.combinat.integer_vector.list2func([Integer(1),Integer(2),Integer(3)])
>>> f(Integer(0))
1
>>> f(Integer(1))
2
>>> f(Integer(2))
```

(continues on next page)

(continued from previous page)

```
3
>>> f(Integer(3))
Traceback (most recent call last):
...
IndexError: list index out of range
```

```
sage: f = sage.combinat.integer_vector.list2func([1,2,3], 0)
sage: f(2)
3
sage: f(3)
0
```

```
>>> from sage.all import *
>>> f = sage.combinat.integer_vector.list2func([Integer(1),Integer(2),Integer(3)],
↪ Integer(0))
>>> f(Integer(2))
3
>>> f(Integer(3))
0
```

5.1.127 Weighted Integer Vectors

AUTHORS:

- Mike Hansen (2007): initial version, ported from MuPAD-Combinat
- Nicolas M. Thiery (2010-10-30): WeightedIntegerVectors(weights) + cleanup

class sage.combinat.integer_vector_weighted.**WeightedIntegerVectors**(*n*, *weight*)

Bases: Parent, UniqueRepresentation

The class of integer vectors of n weighted by `weight`, that is, the nonnegative integer vectors $(v_1, \ldots, v_\ell)$ satisfying $\sum_{i=1}^{\ell} v_i w_i = n$ where ℓ is `length(weight)` and w_i is `weight[i]`.

INPUT:

- `n` – nonnegative integer (optional)
- `weight` – tuple (or list or iterable) of positive integers

EXAMPLES:

```
sage: WeightedIntegerVectors(8, [1,1,2])
Integer vectors of 8 weighted by [1, 1, 2]
sage: WeightedIntegerVectors(8, [1,1,2]).first()
[0, 0, 4]
sage: WeightedIntegerVectors(8, [1,1,2]).last()
[8, 0, 0]
sage: WeightedIntegerVectors(8, [1,1,2]).cardinality()
25
sage: w = WeightedIntegerVectors(8, [1,1,2]).random_element()
sage: w.parent() is WeightedIntegerVectors(8, [1,1,2])
True

sage: WeightedIntegerVectors([1,1,2])
```

(continues on next page)

(continued from previous page)

```
Integer vectors weighted by [1, 1, 2]
sage: WeightedIntegerVectors([1,1,2]).cardinality()
+Infinity
sage: WeightedIntegerVectors([1,1,2]).first()
[0, 0, 0]
```

```
>>> from sage.all import *
>>> WeightedIntegerVectors(Integer(8), [Integer(1),Integer(1),Integer(2)])
Integer vectors of 8 weighted by [1, 1, 2]
>>> WeightedIntegerVectors(Integer(8), [Integer(1),Integer(1),Integer(2)]).first()
[0, 0, 4]
>>> WeightedIntegerVectors(Integer(8), [Integer(1),Integer(1),Integer(2)]).last()
[8, 0, 0]
>>> WeightedIntegerVectors(Integer(8), [Integer(1),Integer(1),Integer(2)]).
↪cardinality()
25
>>> w = WeightedIntegerVectors(Integer(8), [Integer(1),Integer(1),Integer(2)]).
↪random_element()
>>> w.parent() is WeightedIntegerVectors(Integer(8), [Integer(1),Integer(1),
↪Integer(2)])
True

>>> WeightedIntegerVectors([Integer(1),Integer(1),Integer(2)])
Integer vectors weighted by [1, 1, 2]
>>> WeightedIntegerVectors([Integer(1),Integer(1),Integer(2)]).cardinality()
+Infinity
>>> WeightedIntegerVectors([Integer(1),Integer(1),Integer(2)]).first()
[0, 0, 0]
```

Todo

Should the order of the arguments `n` and `weight` be exchanged to simplify the logic?

`Element`

alias of *`IntegerVector`*

class `sage.combinat.integer_vector_weighted.`**`WeightedIntegerVectors_all`**(*weight*)

Bases: `DisjointUnionEnumeratedSets`

Set of weighted integer vectors.

EXAMPLES:

```
sage: W = WeightedIntegerVectors([3,1,1,2,1]); W
Integer vectors weighted by [3, 1, 1, 2, 1]
sage: W.cardinality()
+Infinity

sage: W12 = W.graded_component(12)
sage: W12.an_element()
[4, 0, 0, 0, 0]
```

(continues on next page)

(continued from previous page)

```
sage: W12.last()
[0, 12, 0, 0, 0]
sage: W12.cardinality()
441
sage: for w in W12: print(w)
[4, 0, 0, 0, 0]
[3, 0, 0, 1, 1]
[3, 0, 1, 1, 0]
...
[0, 11, 1, 0, 0]
[0, 12, 0, 0, 0]
```

```
>>> from sage.all import *
>>> W = WeightedIntegerVectors([Integer(3),Integer(1),Integer(1),Integer(2),
↪Integer(1)]); W
Integer vectors weighted by [3, 1, 1, 2, 1]
>>> W.cardinality()
+Infinity

>>> W12 = W.graded_component(Integer(12))
>>> W12.an_element()
[4, 0, 0, 0, 0]
>>> W12.last()
[0, 12, 0, 0, 0]
>>> W12.cardinality()
441
>>> for w in W12: print(w)
[4, 0, 0, 0, 0]
[3, 0, 0, 1, 1]
[3, 0, 1, 1, 0]
...
[0, 11, 1, 0, 0]
[0, 12, 0, 0, 0]
```

grading(*x*)

EXAMPLES:

```
sage: C = WeightedIntegerVectors([2,1,3])
sage: C.grading((2,1,1))
8
```

```
>>> from sage.all import *
>>> C = WeightedIntegerVectors([Integer(2),Integer(1),Integer(3)])
>>> C.grading((Integer(2),Integer(1),Integer(1)))
8
```

subset(*size=None*)

EXAMPLES:

```
sage: C = WeightedIntegerVectors([2,1,3])
sage: C.subset(4)
Integer vectors of 4 weighted by [2, 1, 3]
```

```
>>> from sage.all import *
>>> C = WeightedIntegerVectors([Integer(2),Integer(1),Integer(3)])
>>> C.subset(Integer(4))
Integer vectors of 4 weighted by [2, 1, 3]
```

sage.combinat.integer_vector_weighted.**iterator_fast**(*n*, *l*)

Iterate over all `l` weighted integer vectors with total weight `n`.

INPUT:

- `n` – integer
- `l` – the weights in weakly decreasing order

EXAMPLES:

```
sage: from sage.combinat.integer_vector_weighted import iterator_fast
sage: list(iterator_fast(3, [2,1,1]))
[[1, 1, 0], [1, 0, 1], [0, 3, 0], [0, 2, 1], [0, 1, 2], [0, 0, 3]]
sage: list(iterator_fast(2, [2]))
[[1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_vector_weighted import iterator_fast
>>> list(iterator_fast(Integer(3), [Integer(2),Integer(1),Integer(1)]))
[[1, 1, 0], [1, 0, 1], [0, 3, 0], [0, 2, 1], [0, 1, 2], [0, 0, 3]]
>>> list(iterator_fast(Integer(2), [Integer(2)]))
[[1]]
```

Test that Issue #20491 is fixed:

```
sage: type(list(iterator_fast(2, [2]))[0][0])
<class 'sage.rings.integer.Integer'>
```

```
>>> from sage.all import *
>>> type(list(iterator_fast(Integer(2), [Integer(2)]))[Integer(0)][Integer(0)])
<class 'sage.rings.integer.Integer'>
```

5.1.128 Integer vectors modulo the action of a permutation group

AUTHORS:

- Nicolas Borie (2010-2012) - original module
- Jukka Kohonen (2023) - fast cardinality method, Issue #36787, Issue #36681

class sage.combinat.integer_vectors_mod_permgroup.**IntegerVectorsModPermutationGroup**

Bases: `UniqueRepresentation`

Return an enumerated set containing integer vectors which are maximal in their orbit under the action of the permutation group `G` for the lexicographic order.

In Sage, a permutation group G is viewed as a subgroup of the symmetric group S_n of degree n and n is said to be the degree of G. Any integer vector v is said to be canonical if it is maximal in its orbit under the action of G. v is canonical if and only if

$$v = \max_{\text{lex order}} \{g \cdot v | g \in G\}$$

The action of G is on position. This means for example that the simple transposition $s_1 = (1, 2)$ swaps the first and the second entries of any integer vector $v = [a_1, a_2, a_3, \dots, a_n]$

$$s_1 \cdot v = [a_2, a_1, a_3, \dots, a_n]$$

This function returns a parent which contains, from each orbit orbit under the action of the permutation group G, a single canonical vector. The canonical vector is the one that is maximal within the orbit according to lexicographic order.

INPUT:

- `G` – a permutation group
- `sum` – (default: `None`) - a nonnegative integer
- `max_part` – (default: `None`) - a nonnegative integer setting the maximum value for every element
- `sgs` – (default: `None`) - a strong generating system of the group G. If you do not provide it, it will be calculated at the creation of the parent

OUTPUT:

- If `sum` and `max_part` are None, it returns the infinite enumerated set of all integer vectors (lists of integers) maximal in their orbit for the lexicographic order. Exceptionally, if the domain of `G` is empty, the result is a finite enumerated set that contains one element, namely the empty vector.
- If `sum` is an integer, it returns a finite enumerated set containing all integer vectors maximal in their orbit for the lexicographic order and whose entries sum to `sum`.

EXAMPLES:

Here is the set enumerating integer vectors modulo the action of the cyclic group of 3 elements:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3)]]))
sage: I.category()
Category of infinite enumerated quotients of sets
sage: I.cardinality()
+Infinity
sage: I.list()
Traceback (most recent call last):
...
NotImplementedError: cannot list an infinite set
sage: p = iter(I)
sage: for i in range(10): next(p)
[0, 0, 0]
[1, 0, 0]
[2, 0, 0]
[1, 1, 0]
[3, 0, 0]
[2, 1, 0]
[2, 0, 1]
[1, 1, 1]
[4, 0, 0]
[3, 1, 0]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3))]]))
```

(continues on next page)

(continued from previous page)

```
>>> I.category()
Category of infinite enumerated quotients of sets
>>> I.cardinality()
+Infinity
>>> I.list()
Traceback (most recent call last):
...
NotImplementedError: cannot list an infinite set
>>> p = iter(I)
>>> for i in range(Integer(10)): next(p)
[0, 0, 0]
[1, 0, 0]
[2, 0, 0]
[1, 1, 0]
[3, 0, 0]
[2, 1, 0]
[2, 0, 1]
[1, 1, 1]
[4, 0, 0]
[3, 1, 0]
```

The method `is_canonical()` tests if an integer vector is maximal in its orbit. This method is also used in the containment test:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: I.is_canonical([5,2,0,4])
True
sage: I.is_canonical([5,0,6,4])
False
sage: I.is_canonical([1,1,1,1])
True
sage: [2,3,1,0] in I
False
sage: [5,0,5,0] in I
True
sage: 'Bla' in I
False
sage: I.is_canonical('bla')
Traceback (most recent call last):
...
AssertionError: bla should be a list or an integer vector
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> I.is_canonical([Integer(5),Integer(2),Integer(0),Integer(4)])
True
>>> I.is_canonical([Integer(5),Integer(0),Integer(6),Integer(4)])
False
>>> I.is_canonical([Integer(1),Integer(1),Integer(1),Integer(1)])
True
>>> [Integer(2),Integer(3),Integer(1),Integer(0)] in I
```

(continues on next page)

(continued from previous page)

```
False
>>> [Integer(5),Integer(0),Integer(5),Integer(0)] in I
True
>>> 'Bla' in I
False
>>> I.is_canonical('bla')
Traceback (most recent call last):
...
AssertionError: bla should be a list or an integer vector
```

If you give a value to the extra argument `sum`, the set returned will be a finite set containing only canonical vectors whose entries sum to `sum`.:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3)]]), sum=6)
sage: I.cardinality()
10
sage: I.list()
[[6, 0, 0], [5, 1, 0], [5, 0, 1], [4, 2, 0], [4, 1, 1],
 [4, 0, 2], [3, 3, 0], [3, 2, 1], [3, 1, 2], [2, 2, 2]]
sage: I.category()
Join of Category of finite enumerated sets
    and Category of subquotients of finite sets
    and Category of quotients of sets
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3))]]), sum=Integer(6))
>>> I.cardinality()
10
>>> I.list()
[[6, 0, 0], [5, 1, 0], [5, 0, 1], [4, 2, 0], [4, 1, 1],
 [4, 0, 2], [3, 3, 0], [3, 2, 1], [3, 1, 2], [2, 2, 2]]
>>> I.category()
Join of Category of finite enumerated sets
    and Category of subquotients of finite sets
    and Category of quotients of sets
```

To get the orbit of any integer vector v under the action of the group, use the method `orbit()`; we convert the returned set of vectors into a list in increasing lexicographic order, to get a reproducible test:

```
sage: sorted(I.orbit([6,0,0]))
[[0, 0, 6], [0, 6, 0], [6, 0, 0]]
sage: sorted(I.orbit([5,1,0]))
[[0, 5, 1], [1, 0, 5], [5, 1, 0]]
sage: I.orbit([2,2,2])
{[2, 2, 2]}
```

```
>>> from sage.all import *
>>> sorted(I.orbit([Integer(6),Integer(0),Integer(0)]))
[[0, 0, 6], [0, 6, 0], [6, 0, 0]]
>>> sorted(I.orbit([Integer(5),Integer(1),Integer(0)]))
[[0, 5, 1], [1, 0, 5], [5, 1, 0]]
```

(continues on next page)

(continued from previous page)

```
>>> I.orbit([Integer(2),Integer(2),Integer(2)])
{[2, 2, 2]}
```

Even without constraints, for an empty domain the result is a singleton set:

```
sage: G = PermutationGroup([], domain=[])
sage: sgs = tuple(tuple(s) for s in G.strong_generating_system())
sage: list(IntegerVectorsModPermutationGroup(G, sgs=sgs))
[[]]
```

```
>>> from sage.all import *
>>> G = PermutationGroup([], domain=[])
>>> sgs = tuple(tuple(s) for s in G.strong_generating_system())
>>> list(IntegerVectorsModPermutationGroup(G, sgs=sgs))
[[]]
```

Warning

Because of Issue #36527, permutation groups that have different domains but similar generators can be erroneously treated as the same group. This will silently produce erroneous results. To avoid this issue, compute a strong generating system for the group as:

```
sgs = tuple(tuple(s) for s in G.strong_generating_system())
```

and provide it as the optional `sgs` argument to the constructor.

class sage.combinat.integer_vectors_mod_permgroup.**IntegerVectorsModPermutationGroup_All**(*G*, *sgs=None*)

Bases: `UniqueRepresentation`, `RecursivelyEnumeratedSet_forest`

A class for integer vectors enumerated up to the action of a permutation group.

A Sage permutation group is viewed as a subgroup of the symmetric group S_n for a certain n. This group has a natural action by position on vectors of length n. This class implements a set which keeps a single vector for each orbit. We say that a vector is canonical if it is the maximum in its orbit under the action of the permutation group for the lexicographic order.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]])); I
Integer vectors of length 4 enumerated up to the action of
 Permutation Group with generators [(1,2,3,4)]
sage: I.cardinality()
+Infinity
sage: TestSuite(I).run()
sage: it = iter(I)
sage: [next(it), next(it), next(it), next(it), next(it)]
[[0, 0, 0, 0],
 [1, 0, 0, 0],
 [2, 0, 0, 0],
 [1, 1, 0, 0],
 [1, 0, 1, 0]]
```

(continues on next page)

(continued from previous page)

```
sage: x = next(it); x
[3, 0, 0, 0]
sage: I.first()
[0, 0, 0, 0]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]])); I
Integer vectors of length 4 enumerated up to the action of
 Permutation Group with generators [(1,2,3,4)]
>>> I.cardinality()
+Infinity
>>> TestSuite(I).run()
>>> it = iter(I)
>>> [next(it), next(it), next(it), next(it), next(it)]
[[0, 0, 0, 0],
 [1, 0, 0, 0],
 [2, 0, 0, 0],
 [1, 1, 0, 0],
 [1, 0, 1, 0]]
>>> x = next(it); x
[3, 0, 0, 0]
>>> I.first()
[0, 0, 0, 0]
```

class Element

Bases: `ClonableIntArray`

Element class for the set of integer vectors of given sum enumerated modulo the action of a permutation group. These vectors are clonable lists of integers which must satisfy conditions coming from the parent appearing in the method `check()`.

check()

Check that `self` verify the invariants needed for living in `self.parent()`.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,
↪4)]]))
sage: v = I.an_element()
sage: v.check()
sage: w = I([0,4,0,0], check=False); w
[0, 4, 0, 0]
sage: w.check()
Traceback (most recent call last):
...
AssertionError
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> v = I.an_element()
>>> v.check()
```

(continues on next page)

(continued from previous page)

```
>>> w = I([Integer(0),Integer(4),Integer(0),Integer(0)], check=False); w
[0, 4, 0, 0]
>>> w.check()
Traceback (most recent call last):
...
AssertionError
```

ambient()

Return the ambient space from which `self` is a quotient.

EXAMPLES:

```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: S.ambient()
Integer vectors of length 4
```

```
>>> from sage.all import *
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> S.ambient()
Integer vectors of length 4
```

children(*x*)

Return the list of children of the element `x`. This method is required to build the tree structure of `self` which inherits from the class `RecursivelyEnumeratedSet_forest`.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: I.children(I([2,1,0,0], check=False))
[[2, 2, 0, 0], [2, 1, 1, 0], [2, 1, 0, 1]]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> I.children(I([Integer(2),Integer(1),Integer(0),Integer(0)], check=False))
[[2, 2, 0, 0], [2, 1, 1, 0], [2, 1, 0, 1]]
```

is_canonical(*v*, *check=True*)

Return `True` if the integer list `v` is maximal in its orbit under the action of the permutation group given to define `self`. Such integer vectors are said to be canonical. A vector v is canonical if and only if

$$v = \max_{\text{lex order}} \{g \cdot v | g \in G\}$$

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: I.is_canonical([4,3,2,1])
True
sage: I.is_canonical([4,0,0,1])
True
sage: I.is_canonical([4,0,3,3])
True
```

(continues on next page)

(continued from previous page)

```
sage: I.is_canonical([4,0,4,4])
False
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> I.is_canonical([Integer(4),Integer(3),Integer(2),Integer(1)])
True
>>> I.is_canonical([Integer(4),Integer(0),Integer(0),Integer(1)])
True
>>> I.is_canonical([Integer(4),Integer(0),Integer(3),Integer(3)])
True
>>> I.is_canonical([Integer(4),Integer(0),Integer(4),Integer(4)])
False
```

lift (*elt*)

Lift the element `elt` inside the ambient space from which `self` is a quotient.

EXAMPLES:

```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: v = S.lift(S([4,3,0,1])); v
[4, 3, 0, 1]
sage: type(v)
<class 'list'>
```

```
>>> from sage.all import *
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> v = S.lift(S([Integer(4),Integer(3),Integer(0),Integer(1)])); v
[4, 3, 0, 1]
>>> type(v)
<class 'list'>
```

orbit (*v*)

Return the orbit of the integer vector `v` under the action of the permutation group defining `self`. The result is a set.

EXAMPLES:

In order to get reproducible doctests, we convert the returned sets into lists in increasing lexicographic order:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: sorted(I.orbit([2,2,0,0]))
[[0, 0, 2, 2], [0, 2, 2, 0], [2, 0, 0, 2], [2, 2, 0, 0]]
sage: sorted(I.orbit([2,1,0,0]))
[[0, 0, 2, 1], [0, 2, 1, 0], [1, 0, 0, 2], [2, 1, 0, 0]]
sage: sorted(I.orbit([2,0,1,0]))
[[0, 1, 0, 2], [0, 2, 0, 1], [1, 0, 2, 0], [2, 0, 1, 0]]
sage: sorted(I.orbit([2,0,2,0]))
[[0, 2, 0, 2], [2, 0, 2, 0]]
sage: I.orbit([1,1,1,1])
{[1, 1, 1, 1]}
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> sorted(I.orbit([Integer(2),Integer(2),Integer(0),Integer(0)]))
[[0, 0, 2, 2], [0, 2, 2, 0], [2, 0, 0, 2], [2, 2, 0, 0]]
>>> sorted(I.orbit([Integer(2),Integer(1),Integer(0),Integer(0)]))
[[0, 0, 2, 1], [0, 2, 1, 0], [1, 0, 0, 2], [2, 1, 0, 0]]
>>> sorted(I.orbit([Integer(2),Integer(0),Integer(1),Integer(0)]))
[[0, 1, 0, 2], [0, 2, 0, 1], [1, 0, 2, 0], [2, 0, 1, 0]]
>>> sorted(I.orbit([Integer(2),Integer(0),Integer(2),Integer(0)]))
[[0, 2, 0, 2], [2, 0, 2, 0]]
>>> I.orbit([Integer(1),Integer(1),Integer(1),Integer(1)])
{[1, 1, 1, 1]}
```

permutation_group()

Return the permutation group given to define `self`.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: I.permutation_group()
Permutation Group with generators [(1,2,3,4)]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> I.permutation_group()
Permutation Group with generators [(1,2,3,4)]
```

retract(*elt*)

Return the canonical representative of the orbit of the integer `elt` under the action of the permutation group defining `self`.

If the element `elt` is already maximal in its orbit for the lexicographic order, `elt` is thus the good representative for its orbit.

EXAMPLES:

```
sage: [0,0,0,0] in IntegerVectors(0,4)
True
sage: [1,0,0,0] in IntegerVectors(1,4)
True
sage: [0,1,0,0] in IntegerVectors(1,4)
True
sage: [1,0,1,0] in IntegerVectors(2,4)
True
sage: [0,1,0,1] in IntegerVectors(2,4)
True
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: S.retract([0,0,0,0])
[0, 0, 0, 0]
sage: S.retract([1,0,0,0])
[1, 0, 0, 0]
sage: S.retract([0,1,0,0])
```

(continues on next page)

(continued from previous page)

```
[1, 0, 0, 0]
sage: S.retract([1,0,1,0])
[1, 0, 1, 0]
sage: S.retract([0,1,0,1])
[1, 0, 1, 0]
```

```
>>> from sage.all import *
>>> [Integer(0),Integer(0),Integer(0),Integer(0)] in␣
↪IntegerVectors(Integer(0),Integer(4))
True
>>> [Integer(1),Integer(0),Integer(0),Integer(0)] in␣
↪IntegerVectors(Integer(1),Integer(4))
True
>>> [Integer(0),Integer(1),Integer(0),Integer(0)] in␣
↪IntegerVectors(Integer(1),Integer(4))
True
>>> [Integer(1),Integer(0),Integer(1),Integer(0)] in␣
↪IntegerVectors(Integer(2),Integer(4))
True
>>> [Integer(0),Integer(1),Integer(0),Integer(1)] in␣
↪IntegerVectors(Integer(2),Integer(4))
True
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> S.retract([Integer(0),Integer(0),Integer(0),Integer(0)])
[0, 0, 0, 0]
>>> S.retract([Integer(1),Integer(0),Integer(0),Integer(0)])
[1, 0, 0, 0]
>>> S.retract([Integer(0),Integer(1),Integer(0),Integer(0)])
[1, 0, 0, 0]
>>> S.retract([Integer(1),Integer(0),Integer(1),Integer(0)])
[1, 0, 1, 0]
>>> S.retract([Integer(0),Integer(1),Integer(0),Integer(1)])
[1, 0, 1, 0]
```

roots()

Return the root of generation of `self`. This method is required to build the tree structure of `self` which inherits from the class `RecursivelyEnumeratedSet_forest`.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: I.roots()
[[0, 0, 0, 0]]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> I.roots()
[[0, 0, 0, 0]]
```

subset(*sum=None*, *max_part=None*)

Return the subset of `self` containing integer vectors whose entries sum to `sum`.

EXAMPLES:

```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: S.subset(4)
Integer vectors of length 4 and of sum 4 enumerated up to
the action of Permutation Group with generators
[(1,2,3,4)]
```

```
>>> from sage.all import *
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> S.subset(Integer(4))
Integer vectors of length 4 and of sum 4 enumerated up to
the action of Permutation Group with generators
[(1,2,3,4)]
```

class sage.combinat.integer_vectors_mod_permgroup.**IntegerVectorsModPermutationGroup_with_constraints**

Bases: UniqueRepresentation, RecursivelyEnumeratedSet_forest

This class models finite enumerated sets of integer vectors with constraint enumerated up to the action of a permutation group. Integer vectors are enumerated modulo the action of the permutation group. To implement that, we keep a single integer vector by orbit under the action of the permutation group. Elements chosen are vectors maximal in their orbit for the lexicographic order.

For more information see *IntegerVectorsModPermutationGroup*.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                       max_part=1)
sage: I.list()
[[0, 0, 0, 0], [1, 0, 0, 0], [1, 1, 0, 0], [1, 0, 1, 0], [1, 1, 1, 0],
 [1, 1, 1, 1]]
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                       sum=6, max_part=4)
sage: I.list()
[[4, 2, 0, 0], [4, 1, 1, 0], [4, 1, 0, 1], [4, 0, 2, 0], [4, 0, 1, 1],
 [4, 0, 0, 2], [3, 3, 0, 0], [3, 2, 1, 0], [3, 2, 0, 1], [3, 1, 2, 0],
 [3, 1, 1, 1], [3, 1, 0, 2], [3, 0, 3, 0], [3, 0, 2, 1], [3, 0, 1, 2],
 [2, 2, 2, 0], [2, 2, 1, 1], [2, 1, 2, 1]]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                       max_part=Integer(1))
>>> I.list()
[[0, 0, 0, 0], [1, 0, 0, 0], [1, 1, 0, 0], [1, 0, 1, 0], [1, 1, 1, 0],
 [1, 1, 1, 1]]
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                       sum=Integer(6), max_part=Integer(4))
```

(continues on next page)

(continued from previous page)

```
>>> I.list()
[[4, 2, 0, 0], [4, 1, 1, 0], [4, 1, 0, 1], [4, 0, 2, 0], [4, 0, 1, 1],
 [4, 0, 0, 2], [3, 3, 0, 0], [3, 2, 1, 0], [3, 2, 0, 1], [3, 1, 2, 0],
 [3, 1, 1, 1], [3, 1, 0, 2], [3, 0, 3, 0], [3, 0, 2, 1], [3, 0, 1, 2],
 [2, 2, 2, 0], [2, 2, 1, 1], [2, 1, 2, 1]]
```

Here is the enumeration of unlabeled graphs over 5 vertices:

```
sage: G = IntegerVectorsModPermutationGroup(TransitiveGroup(10,12), max_part=1)
sage: G.cardinality()
34
```

```
>>> from sage.all import *
>>> G = IntegerVectorsModPermutationGroup(TransitiveGroup(Integer(10),
↪Integer(12)), max_part=Integer(1))
>>> G.cardinality()
34
```

class Element

Bases: `ClonableIntArray`

Element class for the set of integer vectors with constraints enumerated modulo the action of a permutation group. These vectors are clonable lists of integers which must satisfy conditions coming from the parent as in the method *check()*.

check()

Check that `self` meets the constraints of being an element of `self.parent()`.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,
↪4)]]), 4)
sage: v = I.an_element()
sage: v.check()
sage: w = I([0,4,0,0], check=False); w
[0, 4, 0, 0]
sage: w.check()
Traceback (most recent call last):
...
AssertionError
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]), Integer(4))
>>> v = I.an_element()
>>> v.check()
>>> w = I([Integer(0),Integer(4),Integer(0),Integer(0)], check=False); w
[0, 4, 0, 0]
>>> w.check()
Traceback (most recent call last):
...
AssertionError
```

ambient()

Return the ambient space from which `self` is a quotient.

EXAMPLES:

```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),␣
↪6)
sage: S.ambient()
Integer vectors that sum to 6
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                       6, max_part=12)
sage: S.ambient()
Integer vectors that sum to 6 with constraints: max_part=12
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                       max_part=12)
sage: S.ambient()
Integer vectors with constraints: max_part=12
```

```
>>> from sage.all import *
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]), Integer(6))
>>> S.ambient()
Integer vectors that sum to 6
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                       Integer(6), max_part=Integer(12))
>>> S.ambient()
Integer vectors that sum to 6 with constraints: max_part=12
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                       max_part=Integer(12))
>>> S.ambient()
Integer vectors with constraints: max_part=12
```

an_element()

Return an element of `self`.

Raises an `EmptySetError` when `self` is empty.

EXAMPLES:

```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                       sum=0, max_part=1)
sage: S.an_element()
[0, 0, 0, 0]
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                       sum=1, max_part=1)
sage: S.an_element()
[1, 0, 0, 0]
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                       sum=2, max_part=1)
sage: S.an_element()
[1, 1, 0, 0]
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
```

(continues on next page)

(continued from previous page)

```
....:                                          sum=3, max_part=1)
sage: S.an_element()
[1, 1, 1, 0]
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                          sum=4, max_part=1)
sage: S.an_element()
[1, 1, 1, 1]
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                          sum=5, max_part=1)
sage: S.an_element()
Traceback (most recent call last):
...
EmptySetError
```

```
>>> from sage.all import *
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                          sum=Integer(0), max_part=Integer(1))
>>> S.an_element()
[0, 0, 0, 0]
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                          sum=Integer(1), max_part=Integer(1))
>>> S.an_element()
[1, 0, 0, 0]
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                          sum=Integer(2), max_part=Integer(1))
>>> S.an_element()
[1, 1, 0, 0]
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                          sum=Integer(3), max_part=Integer(1))
>>> S.an_element()
[1, 1, 1, 0]
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                          sum=Integer(4), max_part=Integer(1))
>>> S.an_element()
[1, 1, 1, 1]
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                          sum=Integer(5), max_part=Integer(1))
>>> S.an_element()
Traceback (most recent call last):
...
EmptySetError
```

cardinality()

Return the number of integer vectors in the set.

The algorithm utilises Cycle Index Theorem, allowing for a faster than a plain enumeration computation.

EXAMPLES:

With a trivial group all vectors are canonical:

```
sage: G = PermutationGroup([], domain=[1,2,3])
sage: IntegerVectorsModPermutationGroup(G, 5).cardinality()
21
sage: IntegerVectors(5, 3).cardinality()
21
```

```
>>> from sage.all import *
>>> G = PermutationGroup([], domain=[Integer(1),Integer(2),Integer(3)])
>>> IntegerVectorsModPermutationGroup(G, Integer(5)).cardinality()
21
>>> IntegerVectors(Integer(5), Integer(3)).cardinality()
21
```

With two interchangeable elements, the smaller one ranges from zero to `sum//2`:

```
sage: G = PermutationGroup([(1,2)])
sage: IntegerVectorsModPermutationGroup(G, 1000).cardinality()
501
```

```
>>> from sage.all import *
>>> G = PermutationGroup([(Integer(1),Integer(2))])
>>> IntegerVectorsModPermutationGroup(G, Integer(1000)).cardinality()
501
```

Binary vectors up to full symmetry are first some ones and then some zeros:

```
sage: G = SymmetricGroup(10)
sage: I = IntegerVectorsModPermutationGroup(G, max_part=1)
sage: I.cardinality()
11
```

```
>>> from sage.all import *
>>> G = SymmetricGroup(Integer(10))
>>> I = IntegerVectorsModPermutationGroup(G, max_part=Integer(1))
>>> I.cardinality()
11
```

Binary vectors of constant weight, up to PGL(2,17), which is 3-transitive, but not 4-transitive:

```
sage: G=PGL(2,17)
sage: I = IntegerVectorsModPermutationGroup(G, sum=3, max_part=1)
sage: I.cardinality()
1
sage: I = IntegerVectorsModPermutationGroup(G, sum=4, max_part=1)
sage: I.cardinality()
3
```

```
>>> from sage.all import *
>>> G=PGL(Integer(2),Integer(17))
```

(continues on next page)

(continued from previous page)

```
>>> I = IntegerVectorsModPermutationGroup(G, sum=Integer(3), max_
↪part=Integer(1))
>>> I.cardinality()
1
>>> I = IntegerVectorsModPermutationGroup(G, sum=Integer(4), max_
↪part=Integer(1))
>>> I.cardinality()
3
```

children(*x*)

Return the list of children of the element x.

This method is required to build the tree structure of self which inherits from the class RecursivelyEnumeratedSet_forest.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: I.children(I([2,1,0,0], check=False))
[[2, 2, 0, 0], [2, 1, 1, 0], [2, 1, 0, 1]]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> I.children(I([Integer(2),Integer(1),Integer(0),Integer(0)], check=False))
[[2, 2, 0, 0], [2, 1, 1, 0], [2, 1, 0, 1]]
```

is_canonical(*v*, *check=True*)

Return True if the integer list v is maximal in its orbit under the action of the permutation group given to define self. Such integer vectors are said to be canonical. A vector v is canonical if and only if

$$v = \max_{\text{lex order}} \{g \cdot v | g \in G\}$$

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                        max_part=3)
sage: I.is_canonical([3,0,0,0])
True
sage: I.is_canonical([1,0,2,0])
False
sage: I.is_canonical([2,0,1,0])
True
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                       max_part=Integer(3))
>>> I.is_canonical([Integer(3),Integer(0),Integer(0),Integer(0)])
True
>>> I.is_canonical([Integer(1),Integer(0),Integer(2),Integer(0)])
False
>>> I.is_canonical([Integer(2),Integer(0),Integer(1),Integer(0)])
True
```

lift(*elt*)

Lift the element `elt` inside the ambient space from which `self` is a quotient.

EXAMPLES:

```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                        max_part=1)
sage: v = S.lift([1,0,1,0]); v
[1, 0, 1, 0]
sage: v in IntegerVectors(2,4,max_part=1)
True
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                        sum=6)
sage: v = S.lift(S.list()[5]); v
[4, 1, 1, 0]
sage: v in IntegerVectors(n=6)
True
```

```
>>> from sage.all import *
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                        max_part=Integer(1))
>>> v = S.lift([Integer(1),Integer(0),Integer(1),Integer(0)]); v
[1, 0, 1, 0]
>>> v in IntegerVectors(Integer(2),Integer(4),max_part=Integer(1))
True
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                        sum=Integer(6))
>>> v = S.lift(S.list()[Integer(5)]); v
[4, 1, 1, 0]
>>> v in IntegerVectors(n=Integer(6))
True
```

orbit(*v*)

Return the orbit of the vector `v` under the action of the permutation group defining `self`. The result is a set.

INPUT:

- `v` – an element of `self` or any list of length the degree of the permutation group

EXAMPLES:

We convert the result in a list in increasing lexicographic order, to get a reproducible doctest:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),␣
↪4)
sage: I.orbit([1,1,1,1])
{[1, 1, 1, 1]}
sage: sorted(I.orbit([3,0,0,1]))
[[0, 0, 1, 3], [0, 1, 3, 0], [1, 3, 0, 0], [3, 0, 0, 1]]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]), Integer(4))
```

(continues on next page)

(continued from previous page)

```
>>> I.orbit([Integer(1),Integer(1),Integer(1),Integer(1)])
{[1, 1, 1, 1]}
>>> sorted(I.orbit([Integer(3),Integer(0),Integer(0),Integer(1)]))
[[0, 0, 1, 3], [0, 1, 3, 0], [1, 3, 0, 0], [3, 0, 0, 1]]
```

permutation_group()

Return the permutation group given to define `self`.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3)]]), 5)
sage: I.permutation_group()
Permutation Group with generators [(1,2,3)]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3))]]), Integer(5))
>>> I.permutation_group()
Permutation Group with generators [(1,2,3)]
```

retract(*elt*)

Return the canonical representative of the orbit of the integer `elt` under the action of the permutation group defining `self`.

If the element `elt` is already maximal in its orbits for the lexicographic order, `elt` is thus the good representative for its orbit.

EXAMPLES:

```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                       sum=2, max_part=1)
sage: S.retract([1,1,0,0])
[1, 1, 0, 0]
sage: S.retract([1,0,1,0])
[1, 0, 1, 0]
sage: S.retract([1,0,0,1])
[1, 1, 0, 0]
sage: S.retract([0,1,1,0])
[1, 1, 0, 0]
sage: S.retract([0,1,0,1])
[1, 0, 1, 0]
sage: S.retract([0,0,1,1])
[1, 1, 0, 0]
```

```
>>> from sage.all import *
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                       sum=Integer(2), max_part=Integer(1))
>>> S.retract([Integer(1),Integer(1),Integer(0),Integer(0)])
[1, 1, 0, 0]
>>> S.retract([Integer(1),Integer(0),Integer(1),Integer(0)])
[1, 0, 1, 0]
>>> S.retract([Integer(1),Integer(0),Integer(0),Integer(1)])
```

(continues on next page)

(continued from previous page)

```
[1, 1, 0, 0]
>>> S.retract([Integer(0),Integer(1),Integer(1),Integer(0)])
[1, 1, 0, 0]
>>> S.retract([Integer(0),Integer(1),Integer(0),Integer(1)])
[1, 0, 1, 0]
>>> S.retract([Integer(0),Integer(0),Integer(1),Integer(1)])
[1, 1, 0, 0]
```

roots()

Return the root of generation of `self`.

This method is required to build the tree structure of `self` which inherits from the class `RecursivelyEnumeratedSet_forest`.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: I.roots()
[[0, 0, 0, 0]]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> I.roots()
[[0, 0, 0, 0]]
```

5.1.129 Tamari Interval-posets

This module implements Tamari interval-posets: combinatorial objects which represent intervals of the Tamari order. They have been introduced in [CP2015] and allow for many combinatorial operations on Tamari intervals. In particular, they are linked to *DyckWords* and *BinaryTrees*. An introduction into Tamari interval-posets is given in Chapter 7 of [Pons2013].

The Tamari lattice can be defined as a lattice structure on either of several classes of Catalan objects, especially binary trees and Dyck paths [Tam1962] [HT1972] [Sta-EC2]. An interval can be seen as a pair of comparable elements. The number of intervals has been given in [Cha2008].

`sage.combinat.interval_posets.`**TIP**

alias of *TamariIntervalPoset*

class `sage.combinat.interval_posets.`**TamariIntervalPoset**(*parent*, *size*, *relations=None*, *check=True*)

Bases: `Element`

The class of Tamari interval-posets.

An interval-poset is a labelled poset of size n, with labels $1, 2, \ldots, n$, satisfying the following conditions:

- if $a < c$ (as integers) and a precedes c in the poset, then, for all b such that $a < b < c$, b precedes c,

- if $a < c$ (as integers) and c precedes a in the poset, then, for all b such that $a < b < c$, b precedes a.

We use the word "precedes" here to distinguish the poset order and the natural order on numbers. "Precedes" means "is smaller than with respect to the poset structure"; this does not imply a covering relation.

Interval-posets of size n are in bijection with intervals of the Tamari lattice of binary trees of size n. Specifically, if P is an interval-poset of size n, then the set of linear extensions of P (as permutations in S_n) is an interval in the right weak order (see *permutohedron_lequal()*), and is in fact the preimage of an interval in the Tamari lattice (of binary trees of size n) under the operation which sends a permutation to its right-to-left binary search tree (*binary_search_tree()* with the `left_to_right` variable set to `False`) without its labelling.

INPUT:

- `size` – integer; the size of the interval-posets (number of vertices)
- `relations` – list (or tuple) of pairs `(a,b)` (themselves lists or tuples), each representing a relation of the form 'a precedes b' in the poset
- `check` – boolean (default: `True`); whether to check the interval-poset condition or not

Warning

The `relations` input can be a list or tuple, but not an iterator (nor should its entries be iterators).

NOTATION:

Here and in the following, the signs $<$ and $>$ always refer to the natural ordering on integers, whereas the word "precedes" refers to the order of the interval-poset. "Minimal" and "maximal" refer to the natural ordering on integers.

The *increasing relations* of an interval-poset P mean the pairs (a, b) of elements of P such that $a < b$ as integers and a precedes b in P. The *initial forest* of P is the poset obtained by imposing (only) the increasing relations on the ground set of P. It is a sub-interval poset of P, and is a forest with its roots on top. This forest is usually given the structure of a planar forest by ordering brother nodes by their labels; it then has the property that if its nodes are traversed in post-order (see *post_order_traversal()*, and traverse the trees of the forest from left to right as well), then the labels encountered are $1, 2, \ldots, n$ in this order.

The *decreasing relations* of an interval-poset P mean the pairs (a, b) of elements of P such that $b < a$ as integers and a precedes b in P. The *final forest* of P is the poset obtained by imposing (only) the decreasing relations on the ground set of P. It is a sub-interval poset of P, and is a forest with its roots on top. This forest is usually given the structure of a planar forest by ordering brother nodes by their labels; it then has the property that if its nodes are traversed in pre-order (see *pre_order_traversal()*, and traverse the trees of the forest from left to right as well), then the labels encountered are $1, 2, \ldots, n$ in this order.

EXAMPLES:

```
sage: TamariIntervalPoset(0,[])
The Tamari interval of size 0 induced by relations []
sage: TamariIntervalPoset(3,[])
The Tamari interval of size 3 induced by relations []
sage: TamariIntervalPoset(3,[(1,2)])

↪Integer(3)]])
The Tamari interval of size 3 induced by relations [(1, 2), (2, 3)]
>>> TamariIntervalPoset(Integer(3),[[Integer(1),Integer(2)],[Integer(2),
↪Integer(3)],[Integer(1),Integer(2)],[Integer(1),Integer(3)]])
The Tamari interval of size 3 induced by relations [(1, 2), (2, 3)]

>>> TamariIntervalPoset(Integer(3),[(Integer(3),Integer(4))])
Traceback (most recent call last):
...
ValueError: the relations do not correspond to the size of the poset

>>> TamariIntervalPoset(Integer(2),[(Integer(2),Integer(1)),(Integer(1),
↪Integer(2))])
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
ValueError: The graph is not directed acyclic

>>> TamariIntervalPoset(Integer(3),[(Integer(1),Integer(3))])
Traceback (most recent call last):
...
ValueError: this does not satisfy the Tamari interval-poset condition
```

It is also possible to transform a poset directly into an interval-poset:

```
sage: TIP = TamariIntervalPosets()
sage: p = Poset(([1,2,3], [(1,2)]))
sage: TIP(p)
The Tamari interval of size 3 induced by relations [(1, 2)]
sage: TIP(Poset({1: []}))
The Tamari interval of size 1 induced by relations []
sage: TIP(Poset({}))
The Tamari interval of size 0 induced by relations []
```

```
>>> from sage.all import *
>>> TIP = TamariIntervalPosets()
>>> p = Poset(([Integer(1),Integer(2),Integer(3)], [(Integer(1),Integer(2))]))
>>> TIP(p)
The Tamari interval of size 3 induced by relations [(1, 2)]
>>> TIP(Poset({Integer(1): []}))
The Tamari interval of size 1 induced by relations []
>>> TIP(Poset({}))
The Tamari interval of size 0 induced by relations []
```

binary_trees()

Return an iterator on all the binary trees in the interval represented by `self`.

See also

interval_cardinality()

EXAMPLES:

```
sage: list(TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)]).binary_trees())
[[., [[., [., .]], .]],
 [[., [., [., .]]], .],
 [., [[[., .], .], .]],
 [[., [[., .], .]], .]]
sage: set(TamariIntervalPoset(4,[]).binary_trees()) == set(BinaryTrees(4))
True
```

```
>>> from sage.all import *
>>> list(TamariIntervalPoset(Integer(4),[(Integer(2),Integer(4)),(Integer(3),
↪Integer(4)),(Integer(2),Integer(1)),(Integer(3),Integer(1))]).binary_
↪trees())
[[., [[., [., .]], .]],
```

(continues on next page)

(continued from previous page)

```
 [[., [., [., .]]], .],
 [., [[[., .], .], .]],
 [[., [[., .], .]], .]]
>>> set(TamariIntervalPoset(Integer(4),[]).binary_trees()) ==␣
↪set(BinaryTrees(Integer(4)))
True
```

complement()

Return the complement of the interval-poset `self`.

If P is a Tamari interval-poset of size n, then the *complement* of P is defined as the interval-poset Q whose base set is $[n] = \{1, 2, \ldots, n\}$ (just as for P), but whose order relation has a precede b if and only if $n+1-a$ precedes $n+1-b$ in P.

In terms of the Tamari lattice, the *complement* is the symmetric of `self`. It is formed from the left-right symmetrized of the binary trees of the interval (switching left and right subtrees, see `left_right_symmetry()`). In particular, initial intervals are sent to final intervals and vice-versa.

EXAMPLES:

```
sage: TamariIntervalPoset(3, [(2, 1), (3, 1)]).complement()
The Tamari interval of size 3 induced by relations [(1, 3), (2, 3)]
sage: TamariIntervalPoset(0, []).complement()
The Tamari interval of size 0 induced by relations []
sage: ip = TamariIntervalPoset(4, [(1, 2), (2, 4), (3, 4)])
sage: ip.complement() == TamariIntervalPoset(4, [(2, 1), (3, 1), (4, 3)])
True
sage: ip.lower_binary_tree() == ip.complement().upper_binary_tree().left_
↪right_symmetry()
True
sage: ip.upper_binary_tree() == ip.complement().lower_binary_tree().left_
↪right_symmetry()
True
sage: ip.is_initial_interval()
True
sage: ip.complement().is_final_interval()
True
```

```
>>> from sage.all import *
>>> TamariIntervalPoset(Integer(3), [(Integer(2), Integer(1)), (Integer(3),␣
↪Integer(1))]).complement()
The Tamari interval of size 3 induced by relations [(1, 3), (2, 3)]
>>> TamariIntervalPoset(Integer(0), []).complement()
The Tamari interval of size 0 induced by relations []
>>> ip = TamariIntervalPoset(Integer(4), [(Integer(1), Integer(2)),␣
↪(Integer(2), Integer(4)), (Integer(3), Integer(4))])
>>> ip.complement() == TamariIntervalPoset(Integer(4), [(Integer(2),␣
↪Integer(1)), (Integer(3), Integer(1)), (Integer(4), Integer(3))])
True
>>> ip.lower_binary_tree() == ip.complement().upper_binary_tree().left_right_
↪symmetry()
True
>>> ip.upper_binary_tree() == ip.complement().lower_binary_tree().left_right_
```

(continues on next page)

(continued from previous page)

```
↪symmetry()
True
>>> ip.is_initial_interval()
True
>>> ip.complement().is_final_interval()
True
```

contains_binary_tree(*binary_tree*)

Return whether the interval represented by `self` contains the binary tree `binary_tree`.

INPUT:

- `binary_tree` – a binary tree

See also:

contains_dyck_word()

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)])
sage: ip.contains_binary_tree(BinaryTree([[None,[None,[]]],None]))
True
sage: ip.contains_binary_tree(BinaryTree([None,[[[],None],None]]))
True
sage: ip.contains_binary_tree(BinaryTree([[],[[],None]]))
False
sage: ip.contains_binary_tree(ip.lower_binary_tree())
True
sage: ip.contains_binary_tree(ip.upper_binary_tree())
True
sage: all(ip.contains_binary_tree(bt) for bt in ip.binary_trees())
True
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(2),Integer(4)),(Integer(3),
↪Integer(4)),(Integer(2),Integer(1)),(Integer(3),Integer(1))])
>>> ip.contains_binary_tree(BinaryTree([[None,[None,[]]],None]))
True
>>> ip.contains_binary_tree(BinaryTree([None,[[[],None],None]]))
True
>>> ip.contains_binary_tree(BinaryTree([[],[[],None]]))
False
>>> ip.contains_binary_tree(ip.lower_binary_tree())
True
>>> ip.contains_binary_tree(ip.upper_binary_tree())
True
>>> all(ip.contains_binary_tree(bt) for bt in ip.binary_trees())
True
```

contains_dyck_word(*dyck_word*)

Return whether the interval represented by `self` contains the Dyck word `dyck_word`.

INPUT:

- `dyck_word` – a Dyck word

See also

`contains_binary_tree()`

EXAMPLES:

```
sage: # needs sage.combinat
sage: ip = TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)])
sage: ip.contains_dyck_word(DyckWord([1,1,1,0,0,0,1,0]))
True
sage: ip.contains_dyck_word(DyckWord([1,1,0,1,0,1,0,0]))
True
sage: ip.contains_dyck_word(DyckWord([1,0,1,1,0,1,0,0]))
False
sage: ip.contains_dyck_word(ip.lower_dyck_word())
True
sage: ip.contains_dyck_word(ip.upper_dyck_word())
True
sage: all(ip.contains_dyck_word(bt) for bt in ip.dyck_words())
True
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(2),Integer(4)),(Integer(3),
↪Integer(4)),(Integer(2),Integer(1)),(Integer(3),Integer(1))])
>>> ip.contains_dyck_word(DyckWord([Integer(1),Integer(1),Integer(1),
↪Integer(0),Integer(0),Integer(0),Integer(1),Integer(0)]))
True
>>> ip.contains_dyck_word(DyckWord([Integer(1),Integer(1),Integer(0),
↪Integer(1),Integer(0),Integer(1),Integer(0),Integer(0)]))
True
>>> ip.contains_dyck_word(DyckWord([Integer(1),Integer(0),Integer(1),
↪Integer(1),Integer(0),Integer(1),Integer(0),Integer(0)]))
False
>>> ip.contains_dyck_word(ip.lower_dyck_word())
True
>>> ip.contains_dyck_word(ip.upper_dyck_word())
True
>>> all(ip.contains_dyck_word(bt) for bt in ip.dyck_words())
True
```

contains_interval(*other*)

Return whether the interval represented by `other` is contained in `self` as an interval of the Tamari lattice.

In terms of interval-posets, it means that all relations of `self` are relations of `other`.

INPUT:

- `other` – an interval-poset

EXAMPLES:

```
sage: ip1 = TamariIntervalPoset(4,[(1,2),(2,3),(4,3)])
sage: ip2 = TamariIntervalPoset(4,[(2,3)])
sage: ip2.contains_interval(ip1)
True
sage: ip3 = TamariIntervalPoset(4,[(2,1)])
sage: ip2.contains_interval(ip3)
False
sage: ip4 = TamariIntervalPoset(3,[(2,3)])
sage: ip2.contains_interval(ip4)
False
```

```
>>> from sage.all import *
>>> ip1 = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
→Integer(3)),(Integer(4),Integer(3))])
>>> ip2 = TamariIntervalPoset(Integer(4),[(Integer(2),Integer(3))])
>>> ip2.contains_interval(ip1)
True
>>> ip3 = TamariIntervalPoset(Integer(4),[(Integer(2),Integer(1))])
>>> ip2.contains_interval(ip3)
False
>>> ip4 = TamariIntervalPoset(Integer(3),[(Integer(2),Integer(3))])
>>> ip2.contains_interval(ip4)
False
```

cubical_coordinates()

Return the cubical coordinates of `self`.

This provides a fast and natural way to order the set of interval-posets of a given size.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3)])
sage: ip.cubical_coordinates()
(-1, -2, 0)
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
→Integer(3))])
>>> ip.cubical_coordinates()
(-1, -2, 0)
```

REFERENCES:

- [Com2019]

decomposition_to_triple()

Decompose an interval-poset into a triple (`left`, `right`, `r`).

For the inverse method, see *TamariIntervalPosets.recomposition_from_triple()*.

OUTPUT:

a triple (`left`, `right`, `r`) where `left` and `right` are interval-posets and `r` (an integer) is the parameter of the decomposition.

EXAMPLES:

```
sage: tip = TamariIntervalPoset(8, [(1,2), (2,4), (3,4), (6,7),
....:                             (3,2), (5,4), (6,4), (8,7)])
sage: tip.decomposition_to_triple()
(The Tamari interval of size 3 induced by relations [(1, 2), (3, 2)],
 The Tamari interval of size 4 induced by relations [(2, 3), (4, 3)],
 2)
sage: tip == TamariIntervalPosets.recomposition_from_triple(
....:           *tip.decomposition_to_triple())
True
```

```
>>> from sage.all import *
>>> tip = TamariIntervalPoset(Integer(8), [(Integer(1),Integer(2)),␣
↪(Integer(2),Integer(4)), (Integer(3),Integer(4)), (Integer(6),Integer(7)),
...                             (Integer(3),Integer(2)), (Integer(5),
↪Integer(4)), (Integer(6),Integer(4)), (Integer(8),Integer(7))])
>>> tip.decomposition_to_triple()
(The Tamari interval of size 3 induced by relations [(1, 2), (3, 2)],
 The Tamari interval of size 4 induced by relations [(2, 3), (4, 3)],
 2)
>>> tip == TamariIntervalPosets.recomposition_from_triple(
...           *tip.decomposition_to_triple())
True
```

REFERENCES:

- [CP2015]

decreasing_children(*v*)

Return the children of `v` in the final forest of `self`.

INPUT:

- `v` – integer representing a vertex of `self` (between 1 and `size`)

OUTPUT:

The list of all children of `v` in the final forest of `self`, in increasing order.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,5)]);
↪ ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),␣
↪(6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.decreasing_children(2)
[3, 5]
sage: ip.decreasing_children(3)
[4]
sage: ip.decreasing_children(1)
[]
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(6),[(Integer(3),Integer(2)),(Integer(4),
↪Integer(3)),(Integer(5),Integer(2)),(Integer(6),Integer(5)),(Integer(1),
↪Integer(2)),(Integer(3),Integer(5)),(Integer(4),Integer(5))]); ip
```

(continues on next page)

(continued from previous page)

```
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),
↪(6, 5), (5, 2), (4, 3), (3, 2)]
>>> ip.decreasing_children(Integer(2))
[3, 5]
>>> ip.decreasing_children(Integer(3))
[4]
>>> ip.decreasing_children(Integer(1))
[]
```

decreasing_cover_relations()

Return the cover relations of the final forest of `self`.

This is the poset formed by keeping only the relations of the form a precedes b with $a > b$.

The final forest of `self` is a forest with its roots being on top. It is also called the decreasing poset of `self`.

Warning

This method computes the cover relations of the final forest. This is not identical with the cover relations of `self` which happen to be decreasing!

See also

final_forest()

EXAMPLES:

```
sage: TamariIntervalPoset(4,[(2,1),(3,2),(3,4),(4,2)]).decreasing_cover_
↪relations()
[(4, 2), (3, 2), (2, 1)]
sage: TamariIntervalPoset(4,[(2,1),(4,3),(2,3)]).decreasing_cover_relations()
[(4, 3), (2, 1)]
sage: TamariIntervalPoset(3,[(2,1),(3,1),(3,2)]).decreasing_cover_relations()
[(3, 2), (2, 1)]
```

```
>>> from sage.all import *
>>> TamariIntervalPoset(Integer(4),[(Integer(2),Integer(1)),(Integer(3),
↪Integer(2)),(Integer(3),Integer(4)),(Integer(4),Integer(2))]).decreasing_
↪cover_relations()
[(4, 2), (3, 2), (2, 1)]
>>> TamariIntervalPoset(Integer(4),[(Integer(2),Integer(1)),(Integer(4),
↪Integer(3)),(Integer(2),Integer(3))]).decreasing_cover_relations()
[(4, 3), (2, 1)]
>>> TamariIntervalPoset(Integer(3),[(Integer(2),Integer(1)),(Integer(3),
↪Integer(1)),(Integer(3),Integer(2))]).decreasing_cover_relations()
[(3, 2), (2, 1)]
```

decreasing_parent(*v*)

Return the vertex parent of `v` in the final forest of `self`.

This is the highest (as integer!) vertex $a < v$ such that `v` precedes `a`. If there is no such vertex (that is, v is a decreasing root), then `None` is returned.

INPUT:

- `v` – integer representing a vertex of `self` (between 1 and `size`)

EXAMPLES:

```
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,5)]);
↪ ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),␣
↪(6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.decreasing_parent(4)
3
sage: ip.decreasing_parent(3)
2
sage: ip.decreasing_parent(5)
2
sage: ip.decreasing_parent(2) is None
True
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(6),[(Integer(3),Integer(2)),(Integer(4),
↪Integer(3)),(Integer(5),Integer(2)),(Integer(6),Integer(5)),(Integer(1),
↪Integer(2)),(Integer(3),Integer(5)),(Integer(4),Integer(5))]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),␣
↪(6, 5), (5, 2), (4, 3), (3, 2)]
>>> ip.decreasing_parent(Integer(4))
3
>>> ip.decreasing_parent(Integer(3))
2
>>> ip.decreasing_parent(Integer(5))
2
>>> ip.decreasing_parent(Integer(2)) is None
True
```

decreasing_roots()

Return the root vertices of the final forest of `self`.

These are the vertices b such that there is no $a < b$ with b preceding a.

OUTPUT:

The list of all roots of the final forest of `self`, in increasing order.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,5)]);
↪ ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),␣
↪(6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.decreasing_roots()
[1, 2]
sage: ip.final_forest().decreasing_roots()
[1, 2]
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(6),[(Integer(3),Integer(2)),(Integer(4),
→Integer(3)),(Integer(5),Integer(2)),(Integer(6),Integer(5)),(Integer(1),
→Integer(2)),(Integer(3),Integer(5)),(Integer(4),Integer(5))]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),␣
→(6, 5), (5, 2), (4, 3), (3, 2)]
>>> ip.decreasing_roots()
[1, 2]
>>> ip.final_forest().decreasing_roots()
[1, 2]
```

dyck_words()

Return an iterator on all the Dyck words in the interval represented by `self`.

EXAMPLES:

```
sage: list(TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)]).dyck_words())    #␣
→needs sage.combinat
[[1, 1, 1, 0, 0, 1, 0, 0],
 [1, 1, 1, 0, 0, 0, 1, 0],
 [1, 1, 0, 1, 0, 1, 0, 0],
 [1, 1, 0, 1, 0, 0, 1, 0]]
sage: set(TamariIntervalPoset(4,[]).dyck_words()) == set(DyckWords(4))       #␣
→needs sage.combinat
True
```

```
>>> from sage.all import *
>>> list(TamariIntervalPoset(Integer(4),[(Integer(2),Integer(4)),(Integer(3),
→Integer(4)),(Integer(2),Integer(1)),(Integer(3),Integer(1))]).dyck_words())␣
→   # needs sage.combinat
[[1, 1, 1, 0, 0, 1, 0, 0],
 [1, 1, 1, 0, 0, 0, 1, 0],
 [1, 1, 0, 1, 0, 1, 0, 0],
 [1, 1, 0, 1, 0, 0, 1, 0]]
>>> set(TamariIntervalPoset(Integer(4),[]).dyck_words()) ==␣
→set(DyckWords(Integer(4)))       # needs sage.combinat
True
```

factor()

Return the unique decomposition as a list of connected components.

EXAMPLES:

```
sage: factor(TamariIntervalPoset(2,[]))  # indirect doctest
[The Tamari interval of size 1 induced by relations [],
 The Tamari interval of size 1 induced by relations []]
```

```
>>> from sage.all import *
>>> factor(TamariIntervalPoset(Integer(2),[]))  # indirect doctest
[The Tamari interval of size 1 induced by relations [],
 The Tamari interval of size 1 induced by relations []]
```

See also

is_connected()

final_forest()

Return the final forest of `self`, i.e., the interval-poset formed with only the decreasing relations of `self`.

See also

initial_forest()

EXAMPLES:

```
sage: TamariIntervalPoset(4,[(2,1),(3,2),(3,4),(4,2)]).final_forest()
The Tamari interval of size 4 induced by relations [(4, 2), (3, 2), (2, 1)]
sage: ip = TamariIntervalPoset(3,[(2,1),(3,1)])
sage: ip.final_forest() == ip
True
```

```
>>> from sage.all import *
>>> TamariIntervalPoset(Integer(4),[(Integer(2),Integer(1)),(Integer(3),
↪Integer(2)),(Integer(3),Integer(4)),(Integer(4),Integer(2))]).final_forest()
The Tamari interval of size 4 induced by relations [(4, 2), (3, 2), (2, 1)]
>>> ip = TamariIntervalPoset(Integer(3),[(Integer(2),Integer(1)),(Integer(3),
↪Integer(1))])
>>> ip.final_forest() == ip
True
```

ge(*e1*, *e2*)

Return whether `e2` precedes or equals `e1` in `self`.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3)])
sage: ip.ge(2,1)
True
sage: ip.ge(3,1)
True
sage: ip.ge(3,2)
True
sage: ip.ge(4,3)
False
sage: ip.ge(1,1)
True
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
↪Integer(3))])
>>> ip.ge(Integer(2),Integer(1))
True
>>> ip.ge(Integer(3),Integer(1))
```

(continues on next page)

(continued from previous page)

```
True
>>> ip.ge(Integer(3),Integer(2))
True
>>> ip.ge(Integer(4),Integer(3))
False
>>> ip.ge(Integer(1),Integer(1))
True
```

grafting_tree()

Return the grafting tree of the interval-poset.

For the inverse method, see *TamariIntervalPosets.from_grafting_tree()*.

EXAMPLES:

```
sage: tip = TamariIntervalPoset(8, [(1,2), (2,4), (3,4), (6,7),
....:                              (3,2), (5,4), (6,4), (8,7)])
sage: tip.grafting_tree()
2[1[0[., .], 0[., .]], 0[., 1[0[., .], 0[., .]]]]
sage: tip == TamariIntervalPosets.from_grafting_tree(tip.grafting_tree())
True
```

```
>>> from sage.all import *
>>> tip = TamariIntervalPoset(Integer(8), [(Integer(1),Integer(2)),␣
↪(Integer(2),Integer(4)), (Integer(3),Integer(4)), (Integer(6),Integer(7)),
...                              (Integer(3),Integer(2)), (Integer(5),
↪Integer(4)), (Integer(6),Integer(4)), (Integer(8),Integer(7))])
>>> tip.grafting_tree()
2[1[0[., .], 0[., .]], 0[., 1[0[., .], 0[., .]]]]
>>> tip == TamariIntervalPosets.from_grafting_tree(tip.grafting_tree())
True
```

REFERENCES:

- [Pons2018]

gt(*e1*, *e2*)

Return whether `e2` strictly precedes `e1` in `self`.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3)])
sage: ip.gt(2,1)
True
sage: ip.gt(3,1)
True
sage: ip.gt(3,2)
True
sage: ip.gt(4,3)
False
sage: ip.gt(1,1)
False
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
↪Integer(3))])
>>> ip.gt(Integer(2),Integer(1))
True
>>> ip.gt(Integer(3),Integer(1))
True
>>> ip.gt(Integer(3),Integer(2))
True
>>> ip.gt(Integer(4),Integer(3))
False
>>> ip.gt(Integer(1),Integer(1))
False
```

increasing_children(v)

Return the children of v in the initial forest of self.

INPUT:

- v – integer representing a vertex of self (between 1 and size)

OUTPUT:

The list of all children of v in the initial forest of self, in decreasing order.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,5)]);
↪ ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),␣
↪(6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.increasing_children(2)
[1]
sage: ip.increasing_children(5)
[4, 3]
sage: ip.increasing_children(1)
[]
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(6),[(Integer(3),Integer(2)),(Integer(4),
↪Integer(3)),(Integer(5),Integer(2)),(Integer(6),Integer(5)),(Integer(1),
↪Integer(2)),(Integer(3),Integer(5)),(Integer(4),Integer(5))]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),␣
↪(6, 5), (5, 2), (4, 3), (3, 2)]
>>> ip.increasing_children(Integer(2))
[1]
>>> ip.increasing_children(Integer(5))
[4, 3]
>>> ip.increasing_children(Integer(1))
[]
```

increasing_cover_relations()

Return the cover relations of the initial forest of self.

This is the poset formed by keeping only the relations of the form a precedes b with $a < b$.

The initial forest of `self` is a forest with its roots being on top. It is also called the increasing poset of `self`.

Warning: This method computes the cover relations of the initial forest. This is not identical with the cover relations of `self` which happen to be increasing!

See also:

initial_forest()

EXAMPLES:

```
sage: TamariIntervalPoset(4,[(1,2),(3,2),(2,4),(3,4)]).increasing_cover_
↪relations()
[(1, 2), (2, 4), (3, 4)]
sage: TamariIntervalPoset(3,[(1,2),(1,3),(2,3)]).increasing_cover_relations()
[(1, 2), (2, 3)]
```

```
>>> from sage.all import *
>>> TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(3),
↪Integer(2)),(Integer(2),Integer(4)),(Integer(3),Integer(4))]).increasing_
↪cover_relations()
[(1, 2), (2, 4), (3, 4)]
>>> TamariIntervalPoset(Integer(3),[(Integer(1),Integer(2)),(Integer(1),
↪Integer(3)),(Integer(2),Integer(3))]).increasing_cover_relations()
[(1, 2), (2, 3)]
```

increasing_parent(*v*)

Return the vertex parent of `v` in the initial forest of `self`.

This is the lowest (as integer!) vertex $b > v$ such that v precedes b. If there is no such vertex (that is, v is an increasing root), then `None` is returned.

INPUT:

- `v` – integer representing a vertex of `self` (between 1 and `size`)

EXAMPLES:

```
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,5)]);
↪ ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),␣
↪(6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.increasing_parent(1)
2
sage: ip.increasing_parent(3)
5
sage: ip.increasing_parent(4)
5
sage: ip.increasing_parent(5) is None
True
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(6),[(Integer(3),Integer(2)),(Integer(4),
↪Integer(3)),(Integer(5),Integer(2)),(Integer(6),Integer(5)),(Integer(1),
↪Integer(2)),(Integer(3),Integer(5)),(Integer(4),Integer(5))]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),␣
↪(6, 5), (5, 2), (4, 3), (3, 2)]
>>> ip.increasing_parent(Integer(1))
2
>>> ip.increasing_parent(Integer(3))
5
>>> ip.increasing_parent(Integer(4))
5
>>> ip.increasing_parent(Integer(5)) is None
True
```

increasing_roots()

Return the root vertices of the initial forest of `self`.

These are the vertices a of `self` such that there is no $b > a$ with a precedes b.

OUTPUT:

The list of all roots of the initial forest of `self`, in decreasing order.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,5)]);
↪ ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),␣
↪(6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.increasing_roots()
[6, 5, 2]
sage: ip.initial_forest().increasing_roots()
[6, 5, 2]
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(6),[(Integer(3),Integer(2)),(Integer(4),
↪Integer(3)),(Integer(5),Integer(2)),(Integer(6),Integer(5)),(Integer(1),
↪Integer(2)),(Integer(3),Integer(5)),(Integer(4),Integer(5))]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),␣
↪(6, 5), (5, 2), (4, 3), (3, 2)]
>>> ip.increasing_roots()
[6, 5, 2]
>>> ip.initial_forest().increasing_roots()
[6, 5, 2]
```

initial_forest()

Return the initial forest of `self`, i.e., the interval-poset formed from only the increasing relations of `self`.

See also

final_forest()

EXAMPLES:

```
sage: TamariIntervalPoset(4,[(1,2),(3,2),(2,4),(3,4)]).initial_forest()
The Tamari interval of size 4 induced by relations [(1, 2), (2, 4), (3, 4)]
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3)])
sage: ip.initial_forest() == ip
True
```

```
>>> from sage.all import *
>>> TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(3),
↪Integer(2)),(Integer(2),Integer(4)),(Integer(3),Integer(4))]).initial_
↪forest()
The Tamari interval of size 4 induced by relations [(1, 2), (2, 4), (3, 4)]
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
↪Integer(3))])
>>> ip.initial_forest() == ip
True
```

insertion(i)

Return the Tamari insertion of an integer i into the interval-poset `self`.

If P is a Tamari interval-poset of size n and i is an integer with $1 \leq i \leq n+1$, then the Tamari insertion of i into P is defined as the Tamari interval-poset of size $n+1$ which corresponds to the interval $[C_1, C_2]$ on the Tamari lattice, where the binary trees C_1 and C_2 are defined as follows: We write the interval-poset P as $[B_1, B_2]$ for two binary trees B_1 and B_2. We label the vertices of each of these two trees with the integers $1, 2, \ldots, i-1, i+1, i+2, \ldots, n+1$ in such a way that the trees are binary search trees (this labelling is unique). Then, we insert i into each of these trees (in the way as explained in *binary_search_insert()*). The shapes of the resulting two trees are denoted C_1 and C_2.

An alternative way to construct the insertion of i into P is by relabeling each vertex u of P satisfying $u \geq i$ (as integers) as $u+1$, and then adding a vertex i which should precede $i-1$ and $i+1$.

Todo

To study this, it would be more natural to define interval-posets on arbitrary ordered sets rather than just on $\{1, 2, \ldots, n\}$.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4, [(2, 3), (4, 3)]); ip
The Tamari interval of size 4 induced by relations [(2, 3), (4, 3)]
sage: ip.insertion(1)
The Tamari interval of size 5 induced by relations [(1, 2), (3, 4), (5, 4)]
sage: ip.insertion(2)
The Tamari interval of size 5 induced by relations [(2, 3), (3, 4), (5, 4),␣
↪(2, 1)]
sage: ip.insertion(3)
The Tamari interval of size 5 induced by relations [(2, 4), (3, 4), (5, 4),␣
↪(3, 2)]
sage: ip.insertion(4)
The Tamari interval of size 5 induced by relations [(2, 3), (4, 5), (5, 3),␣
↪(4, 3)]
sage: ip.insertion(5)
The Tamari interval of size 5 induced by relations [(2, 3), (5, 4), (4, 3)]
```

(continues on next page)

(continued from previous page)

```
sage: ip = TamariIntervalPoset(0, [])
sage: ip.insertion(1)
The Tamari interval of size 1 induced by relations []

sage: ip = TamariIntervalPoset(1, [])
sage: ip.insertion(1)
The Tamari interval of size 2 induced by relations [(1, 2)]
sage: ip.insertion(2)
The Tamari interval of size 2 induced by relations [(2, 1)]
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4), [(Integer(2), Integer(3)),␣
↪(Integer(4), Integer(3))]); ip
The Tamari interval of size 4 induced by relations [(2, 3), (4, 3)]
>>> ip.insertion(Integer(1))
The Tamari interval of size 5 induced by relations [(1, 2), (3, 4), (5, 4)]
>>> ip.insertion(Integer(2))
The Tamari interval of size 5 induced by relations [(2, 3), (3, 4), (5, 4),␣
↪(2, 1)]
>>> ip.insertion(Integer(3))
The Tamari interval of size 5 induced by relations [(2, 4), (3, 4), (5, 4),␣
↪(3, 2)]
>>> ip.insertion(Integer(4))
The Tamari interval of size 5 induced by relations [(2, 3), (4, 5), (5, 3),␣
↪(4, 3)]
>>> ip.insertion(Integer(5))
The Tamari interval of size 5 induced by relations [(2, 3), (5, 4), (4, 3)]

>>> ip = TamariIntervalPoset(Integer(0), [])
>>> ip.insertion(Integer(1))
The Tamari interval of size 1 induced by relations []

>>> ip = TamariIntervalPoset(Integer(1), [])
>>> ip.insertion(Integer(1))
The Tamari interval of size 2 induced by relations [(1, 2)]
>>> ip.insertion(Integer(2))
The Tamari interval of size 2 induced by relations [(2, 1)]
```

intersection(*other*)

Return the interval-poset formed by combining the relations from both `self` and `other`. It corresponds to the intersection of the two corresponding intervals of the Tamari lattice.

INPUT:

- `other` – an interval-poset of the same size as `self`

EXAMPLES:

```
sage: ip1 = TamariIntervalPoset(4,[(1,2),(2,3)])
sage: ip2 = TamariIntervalPoset(4,[(4,3)])
sage: ip1.intersection(ip2)
The Tamari interval of size 4 induced by relations [(1, 2), (2, 3), (4, 3)]
```

(continues on next page)

(continued from previous page)

```
sage: ip3 = TamariIntervalPoset(4,[(2,1)])
sage: ip1.intersection(ip3)
Traceback (most recent call last):
...
ValueError: this intersection is empty, it does not correspond to an interval-
↪poset
sage: ip4 = TamariIntervalPoset(3,[(2,3)])
sage: ip2.intersection(ip4)
Traceback (most recent call last):
...
ValueError: intersections are only possible on interval-posets of the same␣
↪size
```

```
>>> from sage.all import *
>>> ip1 = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
↪Integer(3))])
>>> ip2 = TamariIntervalPoset(Integer(4),[(Integer(4),Integer(3))])
>>> ip1.intersection(ip2)
The Tamari interval of size 4 induced by relations [(1, 2), (2, 3), (4, 3)]
>>> ip3 = TamariIntervalPoset(Integer(4),[(Integer(2),Integer(1))])
>>> ip1.intersection(ip3)
Traceback (most recent call last):
...
ValueError: this intersection is empty, it does not correspond to an interval-
↪poset
>>> ip4 = TamariIntervalPoset(Integer(3),[(Integer(2),Integer(3))])
>>> ip2.intersection(ip4)
Traceback (most recent call last):
...
ValueError: intersections are only possible on interval-posets of the same␣
↪size
```

interval_cardinality()

Return the cardinality of the interval, i.e., the number of elements (binary trees or Dyck words) in the interval represented by `self`.

Not to be confused with *size()* which is the number of vertices.

See also

binary_trees()

EXAMPLES:

```
sage: TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)]).interval_cardinality()
4
sage: TamariIntervalPoset(4,[]).interval_cardinality()
14
sage: TamariIntervalPoset(4,[(1,2),(2,3),(3,4)]).interval_cardinality()
1
```

```
>>> from sage.all import *
>>> TamariIntervalPoset(Integer(4),[(Integer(2),Integer(4)),(Integer(3),
↪Integer(4)),(Integer(2),Integer(1)),(Integer(3),Integer(1))]).interval_
↪cardinality()
4
>>> TamariIntervalPoset(Integer(4),[]).interval_cardinality()
14
>>> TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
↪Integer(3)),(Integer(3),Integer(4))]).interval_cardinality()
1
```

is_connected()

Return whether `self` is a connected Tamari interval.

This means that the Hasse diagram is connected.

This condition is invariant under complementation.

See also

is_indecomposable(), *factor()*

EXAMPLES:

```
sage: len([T for T in TamariIntervalPosets(3) if T.is_connected()])
8
```

```
>>> from sage.all import *
>>> len([T for T in TamariIntervalPosets(Integer(3)) if T.is_connected()])
8
```

is_dexter()

Return whether `self` is a dexter Tamari interval.

This is defined by an exclusion pattern in the Hasse diagram. See the code for the exact description.

This condition is not invariant under complementation.

EXAMPLES:

```
sage: len([T for T in TamariIntervalPosets(3) if T.is_dexter()])
12
```

```
>>> from sage.all import *
>>> len([T for T in TamariIntervalPosets(Integer(3)) if T.is_dexter()])
12
```

is_exceptional()

Return whether `self` is an exceptional Tamari interval.

This is defined by exclusion of a simple pattern in the Hasse diagram, namely there is no configuration `y <-- x --> z` with $1 \leq y < x < z \leq n$.

This condition is invariant under complementation.

EXAMPLES:

```
sage: len([T for T in TamariIntervalPosets(3)
....:     if T.is_exceptional()])
12
```

```
>>> from sage.all import *
>>> len([T for T in TamariIntervalPosets(Integer(3))
...     if T.is_exceptional()])
12
```

is_final_interval()

Return if `self` corresponds to a final interval of the Tamari lattice.

This means that its upper end is the largest element of the lattice. It consists of checking that `self` does not contain any increasing relations.

See also

is_initial_interval()

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4, [(4, 3), (3, 1), (2, 1)])
sage: ip.is_final_interval()
True
sage: ip.upper_dyck_word()                                                  #␣
↪needs sage.combinat
[1, 1, 1, 1, 0, 0, 0, 0]
sage: ip = TamariIntervalPoset(4, [(4, 3), (3, 1), (2, 1), (2, 3)])
sage: ip.is_final_interval()
False
sage: ip.upper_dyck_word()                                                  #␣
↪needs sage.combinat
[1, 1, 0, 1, 1, 0, 0, 0]
sage: all(dw.tamari_interval(DyckWord([1, 1, 1, 0, 0, 0]))                  #␣
↪needs sage.combinat
....:           .is_final_interval()
....:     for dw in DyckWords(3))
True
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4), [(Integer(4), Integer(3)),␣
↪(Integer(3), Integer(1)), (Integer(2), Integer(1))])
>>> ip.is_final_interval()
True
>>> ip.upper_dyck_word()                                                  #␣
↪needs sage.combinat
[1, 1, 1, 1, 0, 0, 0, 0]
>>> ip = TamariIntervalPoset(Integer(4), [(Integer(4), Integer(3)),␣
↪(Integer(3), Integer(1)), (Integer(2), Integer(1)), (Integer(2),␣
↪Integer(3))])
>>> ip.is_final_interval()
False
```

(continues on next page)

(continued from previous page)

```
>>> ip.upper_dyck_word()                                                    #␣
↪needs sage.combinat
[1, 1, 0, 1, 1, 0, 0, 0]
>>> all(dw.tamari_interval(DyckWord([Integer(1), Integer(1), Integer(1),␣
↪Integer(0), Integer(0), Integer(0)]))                    # needs sage.combinat
...            .is_final_interval()
...     for dw in DyckWords(Integer(3)))
True
```

is_indecomposable()

Return whether `self` is an indecomposable Tamari interval.

This is the terminology of [Cha2008].

This means that the upper binary tree has an empty left subtree.

This condition is not invariant under complementation.

See also

is_connected()

EXAMPLES:

```
sage: len([T for T in TamariIntervalPosets(3)
....:      if T.is_indecomposable()])
8
```

```
>>> from sage.all import *
>>> len([T for T in TamariIntervalPosets(Integer(3))
...      if T.is_indecomposable()])
8
```

is_infinitely_modern()

Return whether `self` is an infinitely-modern Tamari interval.

This is defined by the exclusion of the configuration $i \rightarrow i+1$ and $j+1 \rightarrow j$ with $i < j$.

This condition is invariant under complementation.

See also

is_new(), *is_modern()*

EXAMPLES:

```
sage: len([T for T in TamariIntervalPosets(3)
....:     if T.is_infinitely_modern()])
12
```

```
>>> from sage.all import *
>>> len([T for T in TamariIntervalPosets(Integer(3))
```

(continues on next page)

(continued from previous page)

```
...     if T.is_infinitely_modern()])
12
```

REFERENCES:

- [Rog2018]

is_initial_interval()

Return if `self` corresponds to an initial interval of the Tamari lattice.

This means that its lower end is the smallest element of the lattice. It consists of checking that `self` does not contain any decreasing relations.

See also:

is_final_interval()

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4, [(1, 2), (2, 4), (3, 4)])
sage: ip.is_initial_interval()
True
sage: ip.lower_dyck_word()                                              #␣
↪needs sage.combinat
[1, 0, 1, 0, 1, 0, 1, 0]
sage: ip = TamariIntervalPoset(4, [(1, 2), (2, 4), (3, 4), (3, 2)])
sage: ip.is_initial_interval()
False
sage: ip.lower_dyck_word()                                              #␣
↪needs sage.combinat
[1, 0, 1, 1, 0, 0, 1, 0]
sage: all(DyckWord([1,0,1,0,1,0]).tamari_interval(dw)                  #␣
↪needs sage.combinat
....:         .is_initial_interval()
....:     for dw in DyckWords(3))
True
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4), [(Integer(1), Integer(2)),␣
↪(Integer(2), Integer(4)), (Integer(3), Integer(4))])
>>> ip.is_initial_interval()
True
>>> ip.lower_dyck_word()                                                #␣
↪needs sage.combinat
[1, 0, 1, 0, 1, 0, 1, 0]

↪Integer(2))])
>>> ip.is_initial_interval()
False
>>> ip.lower_dyck_word()                                                #␣
↪needs sage.combinat
```

(continues on next page)

(continued from previous page)

```
[1, 0, 1, 1, 0, 0, 1, 0]
>>> all(DyckWord([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
↪Integer(0)]).tamari_interval(dw)                          # needs sage.combinat
...         .is_initial_interval()
...     for dw in DyckWords(Integer(3)))
True
```

is_linear_extension(*perm*)

Return whether the permutation `perm` is a linear extension of `self`.

INPUT:

- `perm` – a permutation of the size of `self`

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3),(4,3)])
sage: ip.is_linear_extension([1,4,2,3])
True
sage: ip.is_linear_extension(Permutation([1,4,2,3]))
True
sage: ip.is_linear_extension(Permutation([1,4,3,2]))
False
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
↪Integer(3)),(Integer(4),Integer(3))])
>>> ip.is_linear_extension([Integer(1),Integer(4),Integer(2),Integer(3)])
True
>>> ip.is_linear_extension(Permutation([Integer(1),Integer(4),Integer(2),
↪Integer(3)]))
True
>>> ip.is_linear_extension(Permutation([Integer(1),Integer(4),Integer(3),
↪Integer(2)]))
False
```

is_modern()

Return whether `self` is a modern Tamari interval.

This is defined by exclusion of a simple pattern in the Hasse diagram, namely there is no configuration $y \to x \leftarrow z$ with $1 \leq y < x < z \leq n$.

This condition is invariant under complementation.

See also

is_new(), *is_infinitely_modern()*

EXAMPLES:

```
sage: len([T for T in TamariIntervalPosets(3) if T.is_modern()])
12
```

```
>>> from sage.all import *
>>> len([T for T in TamariIntervalPosets(Integer(3)) if T.is_modern()])
12
```

REFERENCES:

- [Rog2018]

is_new()

Return whether `self` is a new Tamari interval.

Here 'new' means that the interval is not contained in any facet of the associahedron. This condition is invariant under complementation.

They have been considered in section 9 of [Cha2008].

See also

is_modern()

EXAMPLES:

```
sage: TIP4 = TamariIntervalPosets(4)
sage: len([u for u in TIP4 if u.is_new()])
12

sage: TIP3 = TamariIntervalPosets(3)
sage: len([u for u in TIP3 if u.is_new()])
3
```

```
>>> from sage.all import *
>>> TIP4 = TamariIntervalPosets(Integer(4))
>>> len([u for u in TIP4 if u.is_new()])
12

>>> TIP3 = TamariIntervalPosets(Integer(3))
>>> len([u for u in TIP3 if u.is_new()])
3
```

is_simple()

Return whether `self` is a simple Tamari interval.

Here 'simple' means that the interval contains a unique binary tree.

These intervals define the simple modules over the incidence algebras of the Tamari lattices.

See also

is_final_interval(), *is_initial_interval()*

EXAMPLES:

```
sage: TIP4 = TamariIntervalPosets(4)
sage: len([u for u in TIP4 if u.is_simple()])
```

(continues on next page)

(continued from previous page)

```
14

sage: TIP3 = TamariIntervalPosets(3)
sage: len([u for u in TIP3 if u.is_simple()])
5
```

```
>>> from sage.all import *
>>> TIP4 = TamariIntervalPosets(Integer(4))
>>> len([u for u in TIP4 if u.is_simple()])
14

>>> TIP3 = TamariIntervalPosets(Integer(3))
>>> len([u for u in TIP3 if u.is_simple()])
5
```

is_synchronized()

Return whether `self` is a synchronized Tamari interval.

This means that the upper and lower binary trees have the same canopee. This condition is invariant under complementation.

This has been considered in [FPR2015]. The numbers of synchronized intervals are given by the sequence OEIS sequence A000139.

EXAMPLES:

```
sage: len([T for T in TamariIntervalPosets(3)
....:      if T.is_synchronized()])
6
```

```
>>> from sage.all import *
>>> len([T for T in TamariIntervalPosets(Integer(3))
...      if T.is_synchronized()])
6
```

latex_options()

Return the latex options for use in the `_latex_` function as a dictionary.

The default values are set using the options.

- `tikz_scale` – (default: 1) scale for use with the tikz package
- `line_width` – (default: 1) value representing the line width (additionally scaled by `tikz_scale`)
- `color_decreasing` – (default: `'red'`) the color for decreasing relations
- `color_increasing` – (default: `'blue'`) the color for increasing relations
- `hspace` – (default: 1) the difference between horizontal coordinates of adjacent vertices
- `vspace` – (default: 1) the difference between vertical coordinates of adjacent vertices

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)])
sage: ip.latex_options()['color_decreasing']
'red'
```

(continues on next page)

(continued from previous page)

```
sage: ip.latex_options()['hspace']
1
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(2),Integer(4)),(Integer(3),
↪Integer(4)),(Integer(2),Integer(1)),(Integer(3),Integer(1))])
>>> ip.latex_options()['color_decreasing']
'red'
>>> ip.latex_options()['hspace']
1
```

le(*e1*, *e2*)

Return whether `e1` precedes or equals `e2` in `self`.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3)])
sage: ip.le(1,2)
True
sage: ip.le(1,3)
True
sage: ip.le(2,3)
True
sage: ip.le(3,4)
False
sage: ip.le(1,1)
True
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
↪Integer(3))])
>>> ip.le(Integer(1),Integer(2))
True
>>> ip.le(Integer(1),Integer(3))
True
>>> ip.le(Integer(2),Integer(3))
True
>>> ip.le(Integer(3),Integer(4))
False
>>> ip.le(Integer(1),Integer(1))
True
```

left_branch_involution()

Return the image of `self` by the left-branch involution.

OUTPUT: an interval-poset

See also

rise_contact_involution()

EXAMPLES:

```
sage: tip = TamariIntervalPoset(8, [(1,2), (2,4), (3,4), (6,7), (3,2), (5,4),
↪(6,4), (8,7)])
sage: t = tip.left_branch_involution(); t
The Tamari interval of size 8 induced by relations [(1, 6), (2, 6),
(3, 5), (4, 5), (5, 6), (6, 8), (7, 8), (7, 6), (4, 3), (3, 1),
(2, 1)]
sage: t.left_branch_involution() == tip
True
```

```
>>> from sage.all import *
>>> tip = TamariIntervalPoset(Integer(8), [(Integer(1),Integer(2)),
↪(Integer(2),Integer(4)), (Integer(3),Integer(4)), (Integer(6),Integer(7)),
↪(Integer(3),Integer(2)), (Integer(5),Integer(4)), (Integer(6),Integer(4)),
↪(Integer(8),Integer(7))])
>>> t = tip.left_branch_involution(); t
The Tamari interval of size 8 induced by relations [(1, 6), (2, 6),
(3, 5), (4, 5), (5, 6), (6, 8), (7, 8), (7, 6), (4, 3), (3, 1),
(2, 1)]
>>> t.left_branch_involution() == tip
True
```

REFERENCES:

- [Pons2018]

linear_extensions()

Return an iterator on the permutations which are linear extensions of `self`.

They form an interval of the right weak order (also called the right permutohedron order – see *permutohedron_lequal()* for a definition).

EXAMPLES:

```
sage: ip = TamariIntervalPoset(3, [(1,2),(3,2)])
sage: list(ip.linear_extensions())                                       #
↪needs sage.modules sage.rings.finite_rings
[[3, 1, 2], [1, 3, 2]]
sage: ip = TamariIntervalPoset(4, [(1,2),(2,3),(4,3)])
sage: list(ip.linear_extensions())                                       #
↪needs sage.modules sage.rings.finite_rings
[[4, 1, 2, 3], [1, 2, 4, 3], [1, 4, 2, 3]]
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(3), [(Integer(1),Integer(2)),(Integer(3),
↪Integer(2))])
>>> list(ip.linear_extensions())                                       #
↪needs sage.modules sage.rings.finite_rings
[[3, 1, 2], [1, 3, 2]]
>>> ip = TamariIntervalPoset(Integer(4), [(Integer(1),Integer(2)),(Integer(2),
↪Integer(3)),(Integer(4),Integer(3))])
>>> list(ip.linear_extensions())                                       #
↪needs sage.modules sage.rings.finite_rings
[[4, 1, 2, 3], [1, 2, 4, 3], [1, 4, 2, 3]]
```

lower_binary_tree()

Return the lowest binary tree in the interval of the Tamari lattice represented by `self`.

This is a binary tree. It is the shape of the unique binary search tree whose left-branch ordered forest (i.e., the result of applying *to_ordered_tree_left_branch()* and cutting off the root) is the final forest of `self`.

See also:

lower_dyck_word()

EXAMPLES:

```
sage: ip = TamariIntervalPoset(6, [(3,2),(4,3),(5,2),(6,5),(1,2),(4,5)]); ip
The Tamari interval of size 6 induced by relations
 [(1, 2), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.lower_binary_tree()
[[., .], [[., [., .]], [., .]]]
sage: ff = TamariIntervalPosets.final_forest(ip.lower_binary_tree())
sage: ff == ip.final_forest()
True
sage: ip == TamariIntervalPosets.from_binary_trees(ip.lower_binary_tree(),
....:                                              ip.upper_binary_tree())
True
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(6), [(Integer(3),Integer(2)),(Integer(4),
↪Integer(3)),(Integer(5),Integer(2)),(Integer(6),Integer(5)),(Integer(1),
↪Integer(2)),(Integer(4),Integer(5))]); ip
The Tamari interval of size 6 induced by relations
 [(1, 2), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
>>> ip.lower_binary_tree()
[[., .], [[., [., .]], [., .]]]
>>> ff = TamariIntervalPosets.final_forest(ip.lower_binary_tree())
>>> ff == ip.final_forest()
True
>>> ip == TamariIntervalPosets.from_binary_trees(ip.lower_binary_tree(),
...                                              ip.upper_binary_tree())
True
```

lower_contained_intervals()

If `self` represents the interval $[t_1, t_2]$ of the Tamari lattice, return an iterator on all intervals $[t_1, t]$ with $t \leq t_2$ for the Tamari lattice.

In terms of interval-posets, it corresponds to adding all possible relations of the form n precedes m with $n < m$.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4, [(2,4),(3,4),(2,1),(3,1)])
sage: list(ip.lower_contained_intervals())
[The Tamari interval of size 4 induced by relations
  [(2, 4), (3, 4), (3, 1), (2, 1)],
 The Tamari interval of size 4 induced by relations
```

(continues on next page)

(continued from previous page)

```
 [(1, 4), (2, 4), (3, 4), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations
 [(2, 3), (3, 4), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations
 [(1, 4), (2, 3), (3, 4), (3, 1), (2, 1)]]
sage: ip = TamariIntervalPoset(4,[])
sage: len(list(ip.lower_contained_intervals()))
14
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4), [(Integer(2),Integer(4)),(Integer(3),
↪Integer(4)),(Integer(2),Integer(1)),(Integer(3),Integer(1))])
>>> list(ip.lower_contained_intervals())
[The Tamari interval of size 4 induced by relations
 [(2, 4), (3, 4), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations
 [(1, 4), (2, 4), (3, 4), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations
 [(2, 3), (3, 4), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations
 [(1, 4), (2, 3), (3, 4), (3, 1), (2, 1)]]
>>> ip = TamariIntervalPoset(Integer(4),[])
>>> len(list(ip.lower_contained_intervals()))
14
```

lower_contains_interval(*other*)

Return whether the interval represented by `other` is contained in `self` as an interval of the Tamari lattice and if they share the same lower bound.

As interval-posets, it means that `other` contains the relations of `self` plus some extra increasing relations.

INPUT:

- `other` – an interval-poset

EXAMPLES:

```
sage: ip1 = TamariIntervalPoset(4,[(1,2),(2,3),(4,3)])
sage: ip2 = TamariIntervalPoset(4,[(4,3)])
sage: ip2.lower_contains_interval(ip1)
True
sage: ip2.contains_interval(ip1) and ip2.lower_binary_tree() == ip1.lower_
↪binary_tree()
True
sage: ip3 = TamariIntervalPoset(4,[(4,3),(2,1)])
sage: ip2.contains_interval(ip3)
True
sage: ip2.lower_binary_tree() == ip3.lower_binary_tree()
False
sage: ip2.lower_contains_interval(ip3)
False
```

```
>>> from sage.all import *
>>> ip1 = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
↪Integer(3)),(Integer(4),Integer(3))])
>>> ip2 = TamariIntervalPoset(Integer(4),[(Integer(4),Integer(3))])
>>> ip2.lower_contains_interval(ip1)
True
>>> ip2.contains_interval(ip1) and ip2.lower_binary_tree() == ip1.lower_
↪binary_tree()
True
>>> ip3 = TamariIntervalPoset(Integer(4),[(Integer(4),Integer(3)),(Integer(2),
↪Integer(1))])
>>> ip2.contains_interval(ip3)
True
>>> ip2.lower_binary_tree() == ip3.lower_binary_tree()
False
>>> ip2.lower_contains_interval(ip3)
False
```

lower_dyck_word()

Return the lowest Dyck word in the interval of the Tamari lattice represented by `self`.

See also

lower_binary_tree()

EXAMPLES:

```
sage: # needs sage.combinat
sage: ip = TamariIntervalPoset(6, [(3,2),(4,3),(5,2),(6,5),(1,2),(4,5)]); ip
The Tamari interval of size 6 induced by relations
 [(1, 2), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.lower_dyck_word()
[1, 0, 1, 1, 1, 0, 0, 1, 1, 0, 0, 0]
sage: ldw_ff = TamariIntervalPosets.final_forest(ip.lower_dyck_word())
sage: ldw_ff == ip.final_forest()
True
sage: ip == TamariIntervalPosets.from_dyck_words(ip.lower_dyck_word(),
....:                                             ip.upper_dyck_word())
True
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> ip = TamariIntervalPoset(Integer(6), [(Integer(3),Integer(2)),(Integer(4),
↪Integer(3)),(Integer(5),Integer(2)),(Integer(6),Integer(5)),(Integer(1),
↪Integer(2)),(Integer(4),Integer(5))]); ip
The Tamari interval of size 6 induced by relations
 [(1, 2), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
>>> ip.lower_dyck_word()
[1, 0, 1, 1, 1, 0, 0, 1, 1, 0, 0, 0]
>>> ldw_ff = TamariIntervalPosets.final_forest(ip.lower_dyck_word())
>>> ldw_ff == ip.final_forest()
True
```

(continues on next page)

(continued from previous page)

```
>>> ip == TamariIntervalPosets.from_dyck_words(ip.lower_dyck_word(),
...                                              ip.upper_dyck_word())
True
```

lt(*e1*, *e2*)

Return whether `e1` strictly precedes `e2` in `self`.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3)])
sage: ip.lt(1,2)
True
sage: ip.lt(1,3)
True
sage: ip.lt(2,3)
True
sage: ip.lt(3,4)
False
sage: ip.lt(1,1)
False
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
↪Integer(3))])
>>> ip.lt(Integer(1),Integer(2))
True
>>> ip.lt(Integer(1),Integer(3))
True
>>> ip.lt(Integer(2),Integer(3))
True
>>> ip.lt(Integer(3),Integer(4))
False
>>> ip.lt(Integer(1),Integer(1))
False
```

max_linear_extension()

Return the maximal permutation for the right weak order which is a linear extension of `self`.

This is also the maximal permutation in the sylvester class of `self.upper_binary_tree()` and is a 132-avoiding permutation.

The right weak order is also known as the right permutohedron order. See `permutohedron_lequal()` for its definition.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3),(4,3)])
sage: ip.max_linear_extension()
[4, 1, 2, 3]
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(4,5)]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (4, 5), (6, 5),␣
↪(5, 2), (4, 3), (3, 2)]
sage: ip.max_linear_extension()
[6, 4, 5, 3, 1, 2]
```

(continues on next page)

(continued from previous page)

```
sage: ip = TamariIntervalPoset(0,[]); ip
The Tamari interval of size 0 induced by relations []
sage: ip.max_linear_extension()
[]
sage: ip = TamariIntervalPoset(5, [(1, 4), (2, 4), (3, 4), (5, 4)]); ip
The Tamari interval of size 5 induced by relations [(1, 4), (2, 4), (3, 4),␣
↪(5, 4)]
sage: ip.max_linear_extension()
[5, 3, 2, 1, 4]
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
↪Integer(3)),(Integer(4),Integer(3))])
>>> ip.max_linear_extension()
[4, 1, 2, 3]
>>> ip = TamariIntervalPoset(Integer(6),[(Integer(3),Integer(2)),(Integer(4),
↪Integer(3)),(Integer(5),Integer(2)),(Integer(6),Integer(5)),(Integer(1),
↪Integer(2)),(Integer(4),Integer(5))]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (4, 5), (6, 5),␣
↪(5, 2), (4, 3), (3, 2)]
>>> ip.max_linear_extension()
[6, 4, 5, 3, 1, 2]
>>> ip = TamariIntervalPoset(Integer(0),[]); ip
The Tamari interval of size 0 induced by relations []
>>> ip.max_linear_extension()
[]
>>> ip = TamariIntervalPoset(Integer(5), [(Integer(1), Integer(4)),␣
↪(Integer(2), Integer(4)), (Integer(3), Integer(4)), (Integer(5),␣
↪Integer(4))]); ip
The Tamari interval of size 5 induced by relations [(1, 4), (2, 4), (3, 4),␣
↪(5, 4)]
>>> ip.max_linear_extension()
[5, 3, 2, 1, 4]
```

maximal_chain_binary_trees()

Return an iterator on the binary trees forming a longest chain of `self` (regarding `self` as an interval of the Tamari lattice).

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)])
sage: list(ip.maximal_chain_binary_trees())
[[[., [[., .], .]], .], [., [[[., .], .], .]], [., [[., [., .]], .]]]
sage: ip = TamariIntervalPoset(4,[])
sage: list(ip.maximal_chain_binary_trees())
[[[[[., .], .], .], .],
 [[[., [., .]], .], .],
 [[., [[., .], .]], .],
 [., [[[., .], .], .]],
 [., [[., [., .]], .]],
 [., [., [[., .], .]]],
 [., [., [., [., .]]]]]
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(2),Integer(4)),(Integer(3),
↪Integer(4)),(Integer(2),Integer(1)),(Integer(3),Integer(1))])
>>> list(ip.maximal_chain_binary_trees())
[[[., [[., .], .]], .], [., [[[., .], .], .]], [., [[., [., .]], .]]]
>>> ip = TamariIntervalPoset(Integer(4),[])
>>> list(ip.maximal_chain_binary_trees())
[[[[[., .], .], .], .],
 [[[., [., .]], .], .],
 [[., [[., .], .]], .],
 [., [[[., .], .], .]],
 [., [[., [., .]], .]],
 [., [., [[., .], .]]],
 [., [., [., [., .]]]]]
```

maximal_chain_dyck_words()

Return an iterator on the Dyck words forming a longest chain of `self` (regarding `self` as an interval of the Tamari lattice).

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)])
sage: list(ip.maximal_chain_dyck_words())                              #␣
↪needs sage.combinat
[[1, 1, 0, 1, 0, 0, 1, 0], [1, 1, 0, 1, 0, 1, 0, 0], [1, 1, 1, 0, 0, 1, 0, 0]]
sage: ip = TamariIntervalPoset(4,[])
sage: list(ip.maximal_chain_dyck_words())                              #␣
↪needs sage.combinat
[[1, 0, 1, 0, 1, 0, 1, 0],

 [1, 1, 0, 1, 0, 1, 0, 0],
 [1, 1, 1, 0, 0, 1, 0, 0],
 [1, 1, 1, 0, 1, 0, 0, 0],
 [1, 1, 1, 1, 0, 0, 0, 0]]
```

maximal_chain_tamari_intervals()

Return an iterator on the upper contained intervals of one longest chain of the Tamari interval represented by `self`.

If `self` represents the interval $[T_1, T_2]$ of the Tamari lattice, this returns intervals $[T', T_2]$ with T' following one longest chain between T_1 and T_2.

To obtain a longest chain, we use the Tamari inversions of `self`. The elements of the chain are obtained by adding one by one the relations (b, a) from each Tamari inversion (a, b) to `self`, where the Tamari inversions are taken in lexicographic order.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4, [(2,4),(3,4),(2,1),(3,1)])
sage: list(ip.maximal_chain_tamari_intervals())
[The Tamari interval of size 4 induced by relations
  [(2, 4), (3, 4), (3, 1), (2, 1)],
 The Tamari interval of size 4 induced by relations
  [(2, 4), (3, 4), (4, 1), (3, 1), (2, 1)],
 The Tamari interval of size 4 induced by relations
  [(2, 4), (3, 4), (4, 1), (3, 2), (2, 1)]]
sage: ip = TamariIntervalPoset(4, [])
sage: list(ip.maximal_chain_tamari_intervals())
[The Tamari interval of size 4 induced by relations [],
 The Tamari interval of size 4 induced by relations [(2, 1)],
 The Tamari interval of size 4 induced by relations [(3, 1), (2, 1)],
 The Tamari interval of size 4 induced by relations [(4, 1), (3, 1), (2, 1)],
 The Tamari interval of size 4 induced by relations [(4, 1), (3, 2), (2, 1)],
 The Tamari interval of size 4 induced by relations [(4, 2), (3, 2), (2, 1)],
 The Tamari interval of size 4 induced by relations [(4, 3), (3, 2), (2, 1)]]
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4), [(Integer(2),Integer(4)),(Integer(3),
↪Integer(4)),(Integer(2),Integer(1)),(Integer(3),Integer(1))])
>>> list(ip.maximal_chain_tamari_intervals())
[The Tamari interval of size 4 induced by relations
  [(2, 4), (3, 4), (3, 1), (2, 1)],
 The Tamari interval of size 4 induced by relations
  [(2, 4), (3, 4), (4, 1), (3, 1), (2, 1)],
 The Tamari interval of size 4 induced by relations
  [(2, 4), (3, 4), (4, 1), (3, 2), (2, 1)]]
>>> ip = TamariIntervalPoset(Integer(4), [])
>>> list(ip.maximal_chain_tamari_intervals())
[The Tamari interval of size 4 induced by relations [],
 The Tamari interval of size 4 induced by relations [(2, 1)],
 The Tamari interval of size 4 induced by relations [(3, 1), (2, 1)],
 The Tamari interval of size 4 induced by relations [(4, 1), (3, 1), (2, 1)],
 The Tamari interval of size 4 induced by relations [(4, 1), (3, 2), (2, 1)],
 The Tamari interval of size 4 induced by relations [(4, 2), (3, 2), (2, 1)],
 The Tamari interval of size 4 induced by relations [(4, 3), (3, 2), (2, 1)]]
```

min_linear_extension()

Return the minimal permutation for the right weak order which is a linear extension of `self`.

This is also the minimal permutation in the sylvester class of `self.lower_binary_tree()` and is a 312-avoiding permutation.

The right weak order is also known as the right permutohedron order. See `permutohedron_lequal()` for its definition.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3),(4,3)])
sage: ip.min_linear_extension()
[1, 2, 4, 3]
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(4,5)])
sage: ip.min_linear_extension()
[1, 4, 3, 6, 5, 2]
sage: ip = TamariIntervalPoset(0,[])
sage: ip.min_linear_extension()
[]
sage: ip = TamariIntervalPoset(5, [(1, 4), (2, 4), (3, 4), (5, 4)]); ip
The Tamari interval of size 5 induced by relations [(1, 4), (2, 4), (3, 4),␣
↪(5, 4)]
sage: ip.min_linear_extension()
[1, 2, 3, 5, 4]
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
↪Integer(3)),(Integer(4),Integer(3))])
>>> ip.min_linear_extension()
[1, 2, 4, 3]
>>> ip = TamariIntervalPoset(Integer(6),[(Integer(3),Integer(2)),(Integer(4),
↪Integer(3)),(Integer(5),Integer(2)),(Integer(6),Integer(5)),(Integer(1),
↪Integer(2)),(Integer(4),Integer(5))])
>>> ip.min_linear_extension()
[1, 4, 3, 6, 5, 2]
>>> ip = TamariIntervalPoset(Integer(0),[])
>>> ip.min_linear_extension()
[]
>>> ip = TamariIntervalPoset(Integer(5), [(Integer(1), Integer(4)),␣
↪(Integer(2), Integer(4)), (Integer(3), Integer(4)), (Integer(5),␣
↪Integer(4))]); ip
The Tamari interval of size 5 induced by relations [(1, 4), (2, 4), (3, 4),␣
↪(5, 4)]
>>> ip.min_linear_extension()
[1, 2, 3, 5, 4]
```

new_decomposition()

Return the decomposition of the interval-poset into new interval-posets.

Every interval-poset has a unique decomposition as a planar tree of new interval-posets, as explained in [Cha2008]. This function computes the terms of this decomposition, but not the planar tree.

For the number of terms, you can use instead the method `number_of_new_components()`.

OUTPUT: list of new interval-posets

See also

`number_of_new_components()`, `is_new()`

EXAMPLES:

```
sage: ex = TamariIntervalPosets(4)[11]
sage: ex.number_of_new_components()
3
sage: ex.new_decomposition()                                              #␣
↪needs sage.combinat
[The Tamari interval of size 1 induced by relations [],
 The Tamari interval of size 2 induced by relations [],
 The Tamari interval of size 1 induced by relations []]
```

```
>>> from sage.all import *
>>> ex = TamariIntervalPosets(Integer(4))[Integer(11)]
>>> ex.number_of_new_components()
3
>>> ex.new_decomposition()                                              #␣
↪needs sage.combinat
[The Tamari interval of size 1 induced by relations [],
 The Tamari interval of size 2 induced by relations [],
 The Tamari interval of size 1 induced by relations []]
```

number_of_new_components()

Return the number of terms in the decomposition in new interval-posets.

Every interval-poset has a unique decomposition as a planar tree of new interval-posets, as explained in [Cha2008]. This function just computes the number of terms, not the planar tree nor the terms themselves.

See also:

is_new(), *new_decomposition()*

EXAMPLES:

```
sage: TIP4 = TamariIntervalPosets(4)
sage: nb = [u.number_of_new_components() for u in TIP4]
sage: [nb.count(i) for i in range(1, 5)]
[12, 21, 21, 14]
```

```
>>> from sage.all import *
>>> TIP4 = TamariIntervalPosets(Integer(4))
>>> nb = [u.number_of_new_components() for u in TIP4]
>>> [nb.count(i) for i in range(Integer(1), Integer(5))]
[12, 21, 21, 14]
```

number_of_tamari_inversions()

Return the number of Tamari inversions of `self`.

This is also the length the longest chain of the Tamari interval represented by `self`.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)])
sage: ip.number_of_tamari_inversions()
```

(continues on next page)

(continued from previous page)

```
2
sage: ip = TamariIntervalPoset(4,[])
sage: ip.number_of_tamari_inversions()
6
sage: ip = TamariIntervalPoset(3,[])
sage: ip.number_of_tamari_inversions()
3
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(2),Integer(4)),(Integer(3),
↪Integer(4)),(Integer(2),Integer(1)),(Integer(3),Integer(1))])
>>> ip.number_of_tamari_inversions()
2
>>> ip = TamariIntervalPoset(Integer(4),[])
>>> ip.number_of_tamari_inversions()
6
>>> ip = TamariIntervalPoset(Integer(3),[])
>>> ip.number_of_tamari_inversions()
3
```

plot(***kwds*)

Return a picture.

The picture represents the Hasse diagram, where the covers are colored in blue if they are increasing and in red if they are decreasing.

This uses the same coordinates as the latex view.

EXAMPLES:

```
sage: ti = TamariIntervalPosets(4)[2]
sage: ti.plot()                                                              #␣
↪needs sage.plot
Graphics object consisting of 6 graphics primitives
```

```
>>> from sage.all import *
>>> ti = TamariIntervalPosets(Integer(4))[Integer(2)]
>>> ti.plot()                                                              #␣
↪needs sage.plot
Graphics object consisting of 6 graphics primitives
```

poset()

Return `self` as a labelled poset.

An interval-poset is indeed constructed from a labelled poset which is stored internally. This method allows to access the poset and all the associated methods.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(1,2),(3,2),(2,4),(3,4)])
sage: pos = ip.poset(); pos
Finite poset containing 4 elements
sage: pos.maximal_chains()
[[3, 2, 4], [1, 2, 4]]
```

(continues on next page)

(continued from previous page)

```
sage: pos.maximal_elements()
[4]
sage: pos.is_lattice()
False
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(3),
↪Integer(2)),(Integer(2),Integer(4)),(Integer(3),Integer(4))])
>>> pos = ip.poset(); pos
Finite poset containing 4 elements
>>> pos.maximal_chains()
[[3, 2, 4], [1, 2, 4]]
>>> pos.maximal_elements()
[4]
>>> pos.is_lattice()
False
```

rise_contact_involution()

Return the image of `self` by the rise-contact involution.

OUTPUT: an interval-poset

This is defined by conjugating the complement involution by the left-branch involution.

See also

left_branch_involution(), *complement()*

EXAMPLES:

```
sage: tip = TamariIntervalPoset(8, [(1,2), (2,4), (3,4), (6,7),
....:                               (3,2), (5,4), (6,4), (8,7)])
sage: t = tip.rise_contact_involution(); t
The Tamari interval of size 8 induced by relations [(2, 8), (3, 8),
(4, 5), (5, 7), (6, 7), (7, 8), (8, 1), (7, 2), (6, 2), (5, 3),
(4, 3), (3, 2), (2, 1)]
sage: t.rise_contact_involution() == tip
True
sage: (tip.lower_dyck_word().number_of_touch_points()                    #␣
↪needs sage.combinat
....:     == t.upper_dyck_word().number_of_initial_rises())
True
sage: tip.number_of_tamari_inversions() == t.number_of_tamari_inversions()
True
```

```
>>> from sage.all import *
>>> tip = TamariIntervalPoset(Integer(8), [(Integer(1),Integer(2)),␣
↪(Integer(2),Integer(4)), (Integer(3),Integer(4)), (Integer(6),Integer(7)),
...                               (Integer(3),Integer(2)), (Integer(5),
↪Integer(4)), (Integer(6),Integer(4)), (Integer(8),Integer(7))])
>>> t = tip.rise_contact_involution(); t
The Tamari interval of size 8 induced by relations [(2, 8), (3, 8),
```

(continues on next page)

(continued from previous page)

```
(4, 5), (5, 7), (6, 7), (7, 8), (8, 1), (7, 2), (6, 2), (5, 3),
(4, 3), (3, 2), (2, 1)]
>>> t.rise_contact_involution() == tip
True
>>> (tip.lower_dyck_word().number_of_touch_points()                    #␣
↪needs sage.combinat
...      == t.upper_dyck_word().number_of_initial_rises())
True
>>> tip.number_of_tamari_inversions() == t.number_of_tamari_inversions()
True
```

REFERENCES:

- [Pons2018]

set_latex_options(*D*)

Set the latex options for use in the `_latex_` function.

The default values are set in the `__init__` function.

- `tikz_scale` – (default: 1) scale for use with the tikz package
- `line_width` – (default: 1 * `tikz_scale`) value representing the line width
- `color_decreasing` – (default: red) the color for decreasing relations
- `color_increasing` – (default: blue) the color for increasing relations
- `hspace` – (default: 1) the difference between horizontal coordinates of adjacent vertices
- `vspace` – (default: 1) the difference between vertical coordinates of adjacent vertices

INPUT:

- `D` – dictionary with a list of latex parameters to change

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)])
sage: ip.latex_options()["color_decreasing"]
'red'
sage: ip.set_latex_options({"color_decreasing":'green'})
sage: ip.latex_options()["color_decreasing"]
'green'
sage: ip.set_latex_options({"color_increasing":'black'})
sage: ip.latex_options()["color_increasing"]
'black'
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(2),Integer(4)),(Integer(3),
↪Integer(4)),(Integer(2),Integer(1)),(Integer(3),Integer(1))])
>>> ip.latex_options()["color_decreasing"]
'red'
>>> ip.set_latex_options({"color_decreasing":'green'})
>>> ip.latex_options()["color_decreasing"]
'green'
>>> ip.set_latex_options({"color_increasing":'black'})
```

(continues on next page)

(continued from previous page)

```
>>> ip.latex_options()["color_increasing"]
'black'
```

To change the default options for all interval-posets, use the parent's latex options:

```
sage: ip = TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)])
sage: ip2 = TamariIntervalPoset(4,[(1,2),(2,3)])
sage: ip.latex_options()["color_decreasing"]
'red'
sage: ip2.latex_options()["color_decreasing"]
'red'
sage: TamariIntervalPosets.options(latex_color_decreasing='green')
sage: ip.latex_options()["color_decreasing"]
'green'
sage: ip2.latex_options()["color_decreasing"]
'green'
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(2),Integer(4)),(Integer(3),
↪Integer(4)),(Integer(2),Integer(1)),(Integer(3),Integer(1))])
>>> ip2 = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
↪Integer(3))])
>>> ip.latex_options()["color_decreasing"]
'red'
>>> ip2.latex_options()["color_decreasing"]
'red'
>>> TamariIntervalPosets.options(latex_color_decreasing='green')
>>> ip.latex_options()["color_decreasing"]
'green'
>>> ip2.latex_options()["color_decreasing"]
'green'
```

Next we set a local latex option and show the global option does not override it:

```
sage: ip.set_latex_options({"color_decreasing": 'black'})
sage: ip.latex_options()["color_decreasing"]
'black'
sage: TamariIntervalPosets.options(latex_color_decreasing='blue')
sage: ip.latex_options()["color_decreasing"]
'black'
sage: ip2.latex_options()["color_decreasing"]
'blue'
sage: TamariIntervalPosets.options._reset()
```

```
>>> from sage.all import *
>>> ip.set_latex_options({"color_decreasing": 'black'})
>>> ip.latex_options()["color_decreasing"]
'black'
>>> TamariIntervalPosets.options(latex_color_decreasing='blue')
>>> ip.latex_options()["color_decreasing"]
'black'
>>> ip2.latex_options()["color_decreasing"]
```

(continues on next page)

(continued from previous page)

```
'blue'
>>> TamariIntervalPosets.options._reset()
```

size()

Return the size (number of vertices) of the interval-poset.

EXAMPLES:

```
sage: TamariIntervalPoset(3,[(2,1),(3,1)]).size()
3
```

```
>>> from sage.all import *
>>> TamariIntervalPoset(Integer(3),[(Integer(2),Integer(1)),(Integer(3),
↪Integer(1))]).size()
3
```

sub_poset(*start*, *end*)

Return the renormalized subposet of `self` consisting solely of integers from `start` (inclusive) to `end` (not inclusive).

"Renormalized" means that these integers are relabelled $1, 2, \ldots, k$ in the obvious way (i.e., by subtracting `start - 1`).

INPUT:

- `start` – integer; the starting vertex (inclusive)
- `end` – integer; the ending vertex (not inclusive)

EXAMPLES:

```
sage: ip = TamariIntervalPoset(6, [(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,
↪5)]); ip
The Tamari interval of size 6 induced by relations
 [(1, 2), (3, 5), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.subposet(1,3)
The Tamari interval of size 2 induced by relations [(1, 2)]
sage: ip.subposet(1,4)
The Tamari interval of size 3 induced by relations [(1, 2), (3, 2)]
sage: ip.subposet(1,5)
The Tamari interval of size 4 induced by relations [(1, 2), (4, 3), (3, 2)]
sage: ip.subposet(1,7) == ip
True
sage: ip.subposet(1,1)
The Tamari interval of size 0 induced by relations []
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(6), [(Integer(3),Integer(2)),(Integer(4),
↪Integer(3)),(Integer(5),Integer(2)),(Integer(6),Integer(5)),(Integer(1),
↪Integer(2)),(Integer(3),Integer(5)),(Integer(4),Integer(5))]); ip
The Tamari interval of size 6 induced by relations
 [(1, 2), (3, 5), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
>>> ip.subposet(Integer(1),Integer(3))
The Tamari interval of size 2 induced by relations [(1, 2)]
```

(continues on next page)

(continued from previous page)

```
>>> ip.subposet(Integer(1),Integer(4))
The Tamari interval of size 3 induced by relations [(1, 2), (3, 2)]
>>> ip.subposet(Integer(1),Integer(5))
The Tamari interval of size 4 induced by relations [(1, 2), (4, 3), (3, 2)]
>>> ip.subposet(Integer(1),Integer(7)) == ip
True
>>> ip.subposet(Integer(1),Integer(1))
The Tamari interval of size 0 induced by relations []
```

subposet (*start*, *end*)

Return the renormalized subposet of `self` consisting solely of integers from `start` (inclusive) to `end` (not inclusive).

"Renormalized" means that these integers are relabelled $1, 2, \ldots, k$ in the obvious way (i.e., by subtracting `start - 1`).

INPUT:

- `start` – integer; the starting vertex (inclusive)
- `end` – integer; the ending vertex (not inclusive)

EXAMPLES:

```
sage: ip = TamariIntervalPoset(6, [(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,
↪5)]); ip
The Tamari interval of size 6 induced by relations
 [(1, 2), (3, 5), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.subposet(1,3)
The Tamari interval of size 2 induced by relations [(1, 2)]
sage: ip.subposet(1,4)
The Tamari interval of size 3 induced by relations [(1, 2), (3, 2)]
sage: ip.subposet(1,5)
The Tamari interval of size 4 induced by relations [(1, 2), (4, 3), (3, 2)]
sage: ip.subposet(1,7) == ip
True
sage: ip.subposet(1,1)
The Tamari interval of size 0 induced by relations []
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(6), [(Integer(3),Integer(2)),(Integer(4),
↪Integer(3)),(Integer(5),Integer(2)),(Integer(6),Integer(5)),(Integer(1),
↪Integer(2)),(Integer(3),Integer(5)),(Integer(4),Integer(5))]); ip
The Tamari interval of size 6 induced by relations
 [(1, 2), (3, 5), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
>>> ip.subposet(Integer(1),Integer(3))
The Tamari interval of size 2 induced by relations [(1, 2)]
>>> ip.subposet(Integer(1),Integer(4))
The Tamari interval of size 3 induced by relations [(1, 2), (3, 2)]
>>> ip.subposet(Integer(1),Integer(5))
The Tamari interval of size 4 induced by relations [(1, 2), (4, 3), (3, 2)]
>>> ip.subposet(Integer(1),Integer(7)) == ip
True
>>> ip.subposet(Integer(1),Integer(1))
```

(continues on next page)

(continued from previous page)

```
The Tamari interval of size 0 induced by relations []
```

tamari_inversions()

Return the Tamari inversions of `self`.

A Tamari inversion is a pair of vertices (a, b) with $a < b$ such that:

- the decreasing parent of b is strictly smaller than a (or does not exist), and
- the increasing parent of a is strictly bigger than b (or does not exist).

"Smaller" and "bigger" refer to the numerical values of the elements, not to the poset order.

This method returns the list of all Tamari inversions in lexicographic order.

The number of Tamari inversions is the length of the longest chain of the Tamari interval represented by `self`.

Indeed, when an interval consists of just one binary tree, it has no inversion. One can also prove that if a Tamari interval $I' = [T_1', T_2']$ is a proper subset of a Tamari interval $I = [T_1, T_2]$, then the inversion number of I' is strictly lower than the inversion number of I. And finally, by adding the relation (b, a) to the interval-poset where (a, b) is the first inversion of I in lexicographic order, one reduces the inversion number by exactly 1.

See also

tamari_inversions_iter(), *number_of_tamari_inversions()*

EXAMPLES:

```
sage: ip = TamariIntervalPoset(3,[])
sage: ip.tamari_inversions()
[(1, 2), (1, 3), (2, 3)]
sage: ip = TamariIntervalPoset(3,[(2,1)])

True
```

tamari_inversions_iter()

Iterate over the Tamari inversions of `self`, in lexicographic order.

See *tamari_inversions()* for the definition of the terms involved.

EXAMPLES:

```
sage: T = TamariIntervalPoset(5, [[1,2],[3,4],[3,2],[5,2],[4,2]])
sage: list(T.tamari_inversions_iter())
[(4, 5)]

sage: T = TamariIntervalPoset(8, [(2, 7), (3, 7), (4, 7), (5, 7), (6, 7),
....:                             (8, 7), (6, 4), (5, 4), (4, 3), (3, 2)])
sage: list(T.tamari_inversions_iter())
[(1, 2), (1, 7), (5, 6)]

sage: T = TamariIntervalPoset(1, [])
```

(continues on next page)

(continued from previous page)

```
sage: list(T.tamari_inversions_iter())
[]

sage: T = TamariIntervalPoset(0, [])
sage: list(T.tamari_inversions_iter())
[]
```

```
>>> from sage.all import *
>>> T = TamariIntervalPoset(Integer(5), [[Integer(1),Integer(2)],[Integer(3),
↪Integer(4)],[Integer(3),Integer(2)],[Integer(5),Integer(2)],[Integer(4),
↪Integer(2)]])
>>> list(T.tamari_inversions_iter())
[(4, 5)]

>>> T = TamariIntervalPoset(Integer(8), [(Integer(2), Integer(7)),␣
↪(Integer(3), Integer(7)), (Integer(4), Integer(7)), (Integer(5),␣
↪Integer(7)), (Integer(6), Integer(7)),
...                                  (Integer(8), Integer(7)), (Integer(6),␣
↪Integer(4)), (Integer(5), Integer(4)), (Integer(4), Integer(3)),␣
↪(Integer(3), Integer(2))])
>>> list(T.tamari_inversions_iter())
[(1, 2), (1, 7), (5, 6)]

>>> T = TamariIntervalPoset(Integer(1), [])
>>> list(T.tamari_inversions_iter())
[]

>>> T = TamariIntervalPoset(Integer(0), [])
>>> list(T.tamari_inversions_iter())
[]
```

upper_binary_tree()

Return the highest binary tree in the interval of the Tamari lattice represented by `self`.

This is a binary tree. It is the shape of the unique binary search tree whose right-branch ordered forest (i.e., the result of applying *to_ordered_tree_right_branch()* and cutting off the root) is the initial forest of `self`.

See also

upper_dyck_word()

EXAMPLES:

```
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(4,5)]); ip
The Tamari interval of size 6 induced by relations
 [(1, 2), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.upper_binary_tree()
[[., .], [., [[., .], [., .]]]]

sage: TamariIntervalPosets.initial_forest(ip.upper_binary_tree()) == ip.
```

(continues on next page)

(continued from previous page)

```
↪initial_forest()
True
sage: ip == TamariIntervalPosets.from_binary_trees(ip.lower_binary_tree(),ip.
↪upper_binary_tree())
True
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(6),[(Integer(3),Integer(2)),(Integer(4),
↪Integer(3)),(Integer(5),Integer(2)),(Integer(6),Integer(5)),(Integer(1),
↪Integer(2)),(Integer(4),Integer(5))]); ip
The Tamari interval of size 6 induced by relations
 [(1, 2), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
>>> ip.upper_binary_tree()
[[., .], [., [[., .], [., .]]]]

>>> TamariIntervalPosets.initial_forest(ip.upper_binary_tree()) == ip.initial_
↪forest()
True
>>> ip == TamariIntervalPosets.from_binary_trees(ip.lower_binary_tree(),ip.
↪upper_binary_tree())
True
```

upper_contains_interval(*other*)

Return whether the interval represented by `other` is contained in `self` as an interval of the Tamari lattice and if they share the same upper bound.

As interval-posets, it means that `other` contains the relations of `self` plus some extra decreasing relations.

INPUT:

- `other` – an interval-poset

EXAMPLES:

```
sage: ip1 = TamariIntervalPoset(4,[(1,2),(2,3),(4,3)])
sage: ip2 = TamariIntervalPoset(4,[(1,2),(2,3)])
sage: ip2.upper_contains_interval(ip1)
True
sage: ip2.contains_interval(ip1) and ip2.upper_binary_tree() == ip1.upper_
↪binary_tree()
True
sage: ip3 = TamariIntervalPoset(4,[(1,2),(2,3),(3,4)])
sage: ip2.upper_contains_interval(ip3)
False
sage: ip2.contains_interval(ip3)
True
sage: ip2.upper_binary_tree() == ip3.upper_binary_tree()
False
```

```
>>> from sage.all import *
>>> ip1 = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
↪Integer(3)),(Integer(4),Integer(3))])
>>> ip2 = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
```

(continues on next page)

(continued from previous page)

```
↪Integer(3))])
>>> ip2.upper_contains_interval(ip1)
True
>>> ip2.contains_interval(ip1) and ip2.upper_binary_tree() == ip1.upper_
↪binary_tree()
True
>>> ip3 = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
↪Integer(3)),(Integer(3),Integer(4))])
>>> ip2.upper_contains_interval(ip3)
False
>>> ip2.contains_interval(ip3)
True
>>> ip2.upper_binary_tree() == ip3.upper_binary_tree()
False
```

upper_dyck_word()

Return the highest Dyck word in the interval of the Tamari lattice represented by `self`.

See also

upper_binary_tree()

EXAMPLES:

```
sage: # needs sage.combinat
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(4,5)]); ip
The Tamari interval of size 6 induced by relations
 [(1, 2), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.upper_dyck_word()
[1, 0, 1, 1, 1, 0, 1, 1, 0, 0, 0, 0]
sage: udw_if = TamariIntervalPosets.initial_forest(ip.upper_dyck_word())
sage: udw_if == ip.initial_forest()
True
sage: ip == TamariIntervalPosets.from_dyck_words(ip.lower_dyck_word(),
....:                                             ip.upper_dyck_word())
True
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> ip = TamariIntervalPoset(Integer(6),[(Integer(3),Integer(2)),(Integer(4),
↪Integer(3)),(Integer(5),Integer(2)),(Integer(6),Integer(5)),(Integer(1),
↪Integer(2)),(Integer(4),Integer(5))]); ip
The Tamari interval of size 6 induced by relations
 [(1, 2), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
>>> ip.upper_dyck_word()
[1, 0, 1, 1, 1, 0, 1, 1, 0, 0, 0, 0]
>>> udw_if = TamariIntervalPosets.initial_forest(ip.upper_dyck_word())
>>> udw_if == ip.initial_forest()
True
>>> ip == TamariIntervalPosets.from_dyck_words(ip.lower_dyck_word(),
...                                             ip.upper_dyck_word())
```

(continues on next page)

(continued from previous page)

```
True
```

class sage.combinat.interval_posets.**TamariIntervalPosets**

Bases: UniqueRepresentation, Parent

Factory for interval-posets.

INPUT:

- size – integer (optional)

OUTPUT:

- the set of all interval-posets (of the given size if specified)

EXAMPLES:

```
sage: TamariIntervalPosets()
Interval-posets

sage: TamariIntervalPosets(2)
Interval-posets of size 2
```

```
>>> from sage.all import *
>>> TamariIntervalPosets()
Interval-posets

>>> TamariIntervalPosets(Integer(2))
Interval-posets of size 2
```

Note

This is a factory class whose constructor returns instances of subclasses.

static check_poset(*poset*)

Check if the given poset poset is a interval-poset, that is, if it satisfies the following properties:

- Its labels are exactly $1, \ldots, n$ where n is its size.
- If $a < c$ (as numbers) and a precedes c, then b precedes c for all b such that $a < b < c$.
- If $a < c$ (as numbers) and c precedes a, then b precedes a for all b such that $a < b < c$.

INPUT:

- poset – a finite labeled poset

EXAMPLES:

```
sage: p = Poset(([1,2,3],[(1,2),(3,2)]))
sage: TamariIntervalPosets.check_poset(p)
True
sage: p = Poset(([2,3],[(3,2)]))
sage: TamariIntervalPosets.check_poset(p)
False
sage: p = Poset(([1,2,3],[(3,1)]))
```

(continues on next page)

(continued from previous page)

```
sage: TamariIntervalPosets.check_poset(p)
False
sage: p = Poset(([1,2,3],[(1,3)]))
sage: TamariIntervalPosets.check_poset(p)
False
```

```
>>> from sage.all import *
>>> p = Poset(([Integer(1),Integer(2),Integer(3)],[(Integer(1),Integer(2)),
↪(Integer(3),Integer(2))]))
>>> TamariIntervalPosets.check_poset(p)
True
>>> p = Poset(([Integer(2),Integer(3)],[(Integer(3),Integer(2))]))
>>> TamariIntervalPosets.check_poset(p)
False
>>> p = Poset(([Integer(1),Integer(2),Integer(3)],[(Integer(3),Integer(1))]))
>>> TamariIntervalPosets.check_poset(p)
False
>>> p = Poset(([Integer(1),Integer(2),Integer(3)],[(Integer(1),Integer(3))]))
>>> TamariIntervalPosets.check_poset(p)
False
```

static final_forest(*element*)

Return the final forest of a binary tree, an interval-poset or a Dyck word.

A final forest is an interval-poset corresponding to a final interval of the Tamari lattice, i.e., containing only decreasing relations.

It can be constructed from a binary tree by its binary search tree labeling with the rule: b precedes a in the final forest iff b is in the right subtree of a in the binary search tree.

INPUT:

- `element` – a binary tree, a Dyck word or an interval-poset

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3),(4,3)])
sage: TamariIntervalPosets.final_forest(ip)
The Tamari interval of size 4 induced by relations [(4, 3)]
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
↪Integer(3)),(Integer(4),Integer(3))])
>>> TamariIntervalPosets.final_forest(ip)
The Tamari interval of size 4 induced by relations [(4, 3)]
```

From binary trees:

```
sage: bt = BinaryTree(); bt
.
sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 0 induced by relations []
sage: bt = BinaryTree([]); bt
[., .]
```

(continues on next page)

(continued from previous page)

```
sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 1 induced by relations []
sage: bt = BinaryTree([[],None]); bt
[[., .], .]
sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 2 induced by relations []
sage: bt = BinaryTree([None,[]]); bt
[., [., .]]
sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 2 induced by relations [(2, 1)]
sage: bt = BinaryTree([[],[]]); bt
[[., .], [., .]]
sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 3 induced by relations [(3, 2)]
sage: bt = BinaryTree([[None,[[],None]],[]]); bt
[[., [[., .], .]], [., .]]
sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 5 induced by relations [(5, 4), (3, 1), (2, 1)]
```

```
>>> from sage.all import *
>>> bt = BinaryTree(); bt
.
>>> TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 0 induced by relations []
>>> bt = BinaryTree([]); bt
[., .]
>>> TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 1 induced by relations []
>>> bt = BinaryTree([[],None]); bt
[[., .], .]
>>> TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 2 induced by relations []
>>> bt = BinaryTree([None,[]]); bt
[., [., .]]
>>> TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 2 induced by relations [(2, 1)]
>>> bt = BinaryTree([[],[]]); bt
[[., .], [., .]]
>>> TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 3 induced by relations [(3, 2)]
>>> bt = BinaryTree([[None,[[],None]],[]]); bt
[[., [[., .], .]], [., .]]
>>> TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 5 induced by relations [(5, 4), (3, 1), (2, 1)]
```

From Dyck words:

```
sage: # needs sage.combinat
sage: dw = DyckWord([1,0])
sage: TamariIntervalPosets.final_forest(dw)
The Tamari interval of size 1 induced by relations []
sage: dw = DyckWord([1,1,0,1,0,0,1,1,0,0])
```

(continues on next page)

(continued from previous page)

```
sage: TamariIntervalPosets.final_forest(dw)
The Tamari interval of size 5 induced by relations [(5, 4), (3, 1), (2, 1)]
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> dw = DyckWord([Integer(1),Integer(0)])
>>> TamariIntervalPosets.final_forest(dw)
The Tamari interval of size 1 induced by relations []
>>> dw = DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(0),Integer(0)])
>>> TamariIntervalPosets.final_forest(dw)
The Tamari interval of size 5 induced by relations [(5, 4), (3, 1), (2, 1)]
```

static from_binary_trees(*tree1*, *tree2*)

Return the interval-poset corresponding to the interval [`tree1`, `tree2`] of the Tamari lattice.

Raise an exception if `tree1` is not $\leq$ `tree2` in the Tamari lattice.

INPUT:

- `tree1` – a binary tree
- `tree2` – a binary tree greater or equal than `tree1` for the Tamari lattice

EXAMPLES:

```
sage: tree1 = BinaryTree([[],None])
sage: tree2 = BinaryTree([None,[]])
sage: TamariIntervalPosets.from_binary_trees(tree1,tree2)
The Tamari interval of size 2 induced by relations []
sage: TamariIntervalPosets.from_binary_trees(tree1,tree1)
The Tamari interval of size 2 induced by relations [(1, 2)]
sage: TamariIntervalPosets.from_binary_trees(tree2,tree2)
The Tamari interval of size 2 induced by relations [(2, 1)]

sage: tree1 = BinaryTree([[],[[None,[]],[]]])
sage: tree2 = BinaryTree([None,[None,[None,[[],[]]]]])
sage: TamariIntervalPosets.from_binary_trees(tree1,tree2)
The Tamari interval of size 6 induced by relations
 [(4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]

sage: tree3 = BinaryTree([None,[None,[[],[None,[]]]]])
sage: TamariIntervalPosets.from_binary_trees(tree1,tree3)
Traceback (most recent call last):
...
ValueError: the two binary trees are not comparable on the Tamari lattice
sage: TamariIntervalPosets.from_binary_trees(tree1,BinaryTree())
Traceback (most recent call last):
...
ValueError: the two binary trees are not comparable on the Tamari lattice
```

```
>>> from sage.all import *
>>> tree1 = BinaryTree([[],None])
>>> tree2 = BinaryTree([None,[]])
```

(continues on next page)

(continued from previous page)

```
>>> TamariIntervalPosets.from_binary_trees(tree1,tree2)
The Tamari interval of size 2 induced by relations []
>>> TamariIntervalPosets.from_binary_trees(tree1,tree1)
The Tamari interval of size 2 induced by relations [(1, 2)]
>>> TamariIntervalPosets.from_binary_trees(tree2,tree2)
The Tamari interval of size 2 induced by relations [(2, 1)]

>>> tree1 = BinaryTree([[],[[None,[]],[]]])
>>> tree2 = BinaryTree([None,[None,[None,[[],[]]]]])
>>> TamariIntervalPosets.from_binary_trees(tree1,tree2)
The Tamari interval of size 6 induced by relations
 [(4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]

>>> tree3 = BinaryTree([None,[None,[[],[None,[]]]]])
>>> TamariIntervalPosets.from_binary_trees(tree1,tree3)
Traceback (most recent call last):
...
ValueError: the two binary trees are not comparable on the Tamari lattice
>>> TamariIntervalPosets.from_binary_trees(tree1,BinaryTree())
Traceback (most recent call last):
...
ValueError: the two binary trees are not comparable on the Tamari lattice
```

static from_dyck_words(*dw1*, *dw2*)

Return the interval-poset corresponding to the interval [`dw1`, `dw2`] of the Tamari lattice.

Raise an exception if the two Dyck words `dw1` and `dw2` do not satisfy `dw1` $\leq$ `dw2` in the Tamari lattice.

INPUT:

- `dw1` – a Dyck word
- `dw2` – a Dyck word greater or equal than `dw1` for the Tamari lattice

EXAMPLES:

```
sage: # needs sage.combinat
sage: dw1 = DyckWord([1,0,1,0])
sage: dw2 = DyckWord([1,1,0,0])
sage: TamariIntervalPosets.from_dyck_words(dw1, dw2)
The Tamari interval of size 2 induced by relations []
sage: TamariIntervalPosets.from_dyck_words(dw1,dw1)
The Tamari interval of size 2 induced by relations [(1, 2)]
sage: TamariIntervalPosets.from_dyck_words(dw2,dw2)
The Tamari interval of size 2 induced by relations [(2, 1)]

sage: # needs sage.combinat
sage: dw1 = DyckWord([1,0,1,1,1,0,0,1,1,0,0,0])
sage: dw2 = DyckWord([1,1,1,1,0,1,1,0,0,0,0,0])
sage: TamariIntervalPosets.from_dyck_words(dw1,dw2)
The Tamari interval of size 6 induced by relations
 [(4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
sage: dw3 = DyckWord([1,1,1,0,1,1,1,0,0,0,0,0])
sage: TamariIntervalPosets.from_dyck_words(dw1,dw3)
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
ValueError: the two Dyck words are not comparable on the Tamari lattice
sage: TamariIntervalPosets.from_dyck_words(dw1,DyckWord([1,0]))

↪Integer(0)]))
Traceback (most recent call last):
...
ValueError: the two Dyck words are not comparable on the Tamari lattice
```

static from_grafting_tree(*tree*)

Return an interval-poset from a grafting tree.

For the inverse method, see *TamariIntervalPoset.grafting_tree()*.

EXAMPLES:

```
sage: tip = TamariIntervalPoset(8, [(1,2), (2,4), (3,4), (6,7), (3,2), (5,4),␣
↪(6,4), (8,7)])
sage: t = tip.grafting_tree()
sage: TamariIntervalPosets.from_grafting_tree(t) == tip
```

(continues on next page)

(continued from previous page)

```
True
```

```
>>> from sage.all import *
>>> tip = TamariIntervalPoset(Integer(8), [(Integer(1),Integer(2)),
↪(Integer(2),Integer(4)), (Integer(3),Integer(4)), (Integer(6),Integer(7)),
↪(Integer(3),Integer(2)), (Integer(5),Integer(4)), (Integer(6),Integer(4)),
↪(Integer(8),Integer(7))])
>>> t = tip.grafting_tree()

static from_minimal_schnyder_wood(*graph*)

Return a Tamari interval built from a minimal Schnyder wood.

This is an implementation of Bernardi and Bonichon's bijection [BeBo2009].

INPUT:

- `graph` – a minimal Schnyder wood, given as a graph with colored and oriented edges, without the three exterior unoriented edges

The three boundary vertices must be -1, -2 and -3.

One assumes moreover that the embedding around -1 is the list of neighbors of -1 and not just a cyclic permutation of that.

Beware that the embedding convention used here is the opposite of the one used by the plot method.

OUTPUT: a Tamari interval-poset

EXAMPLES:

A small example:

```
sage: TIP = TamariIntervalPosets
sage: G = DiGraph([(0,-1,0),(0,-2,1),(0,-3,2)], format='list_of_edges')
sage: G.set_embedding({-1:[0],-2:[0],-3:[0],0:[-1,-2,-3]})
sage: TIP.from_minimal_schnyder_wood(G)                                    #
↪needs sage.combinat
The Tamari interval of size 1 induced by relations []
```

```
>>> from sage.all import *
>>> TIP = TamariIntervalPosets
>>> G = DiGraph([(Integer(0),-Integer(1),Integer(0)),(Integer(0),-Integer(2),
↪Integer(1)),(Integer(0),-Integer(3),Integer(2))], format='list_of_edges')
>>> G.set_embedding({-Integer(1):[Integer(0)],-Integer(2):[Integer(0)],-
↪Integer(3):[Integer(0)],Integer(0):[-Integer(1),-Integer(2),-Integer(3)]})
>>> TIP.from_minimal_schnyder_wood(G)                                     #
↪needs sage.combinat
The Tamari interval of size 1 induced by relations []
```

An example from page 14 of [BeBo2009]:

```
sage: c0 = [(0,-1),(1,0),(2,0),(4,3),(3,-1),(5,3)]
sage: c1 = [(5,-2),(3,-2),(4,5),(1,3),(2,3),(0,3)]
sage: c2 = [(0,-3),(1,-3),(3,-3),(4,-3),(5,-3),(2,1)]
sage: ed = [(u,v,0) for u,v in c0]
sage: ed += [(u,v,1) for u,v in c1]
sage: ed += [(u,v,2) for u,v in c2]
sage: G = DiGraph(ed, format='list_of_edges')
sage: embed = {-1:[3,0],-2:[5,3],-3:[0,1,3,4,5]}
sage: data_emb = [[3,2,1,-3,-1],[2,3,-3,0],[3,1,0]]
sage: data_emb += [[-2,5,4,-3,1,2,0,-1],[5,-3,3],[-2,-3,4,3]]
sage: for k in range(6):
....:     embed[k] = data_emb[k]
sage: G.set_embedding(embed)
sage: TIP.from_minimal_schnyder_wood(G)                                         #␣

↪needs sage.combinat
The Tamari interval of size 3 induced by relations [(2, 3), (2, 1)]
```

static initial_forest(*element*)

Return the initial forest of a binary tree, an interval-poset or a Dyck word.

An initial forest is an interval-poset corresponding to an initial interval of the Tamari lattice, i.e., containing only increasing relations.

It can be constructed from a binary tree by its binary search tree labeling with the rule: a precedes b in the initial forest iff a is in the left subtree of b in the binary search tree.

INPUT:

- `element` – a binary tree, a Dyck word or an interval-poset

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3),(4,3)])
sage: TamariIntervalPosets.initial_forest(ip)
The Tamari interval of size 4 induced by relations [(1, 2), (2, 3)]
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
→Integer(3)),(Integer(4),Integer(3))])
>>> TamariIntervalPosets.initial_forest(ip)
The Tamari interval of size 4 induced by relations [(1, 2), (2, 3)]
```

with binary trees:

```
sage: bt = BinaryTree(); bt

False
>>> TamariIntervalPosets().le(ip2,ip1)
True
```

options = Current options for TamariIntervalPosets - latex_color_decreasing: red - latex_color_increasing: blue - latex_hspace: 1 - latex_line_width_scalar: 0.5 - latex_tikz_scale: 1 - latex_vspace: 1

static recomposition_from_triple(*left*, *right*, *r*)

Recompose an interval-poset from a triple (`left`, `right`, `r`).

For the inverse method, see *TamariIntervalPoset.decomposition_to_triple()*.

INPUT:

- `left` – an interval-poset
- `right` – an interval-poset
- `r` – the parameter of the decomposition, an integer

OUTPUT: an interval-poset

EXAMPLES:

```
sage: T1 = TamariIntervalPoset(3, [(1, 2), (3, 2)])
sage: T2 = TamariIntervalPoset(4, [(2, 3), (4, 3)])
sage: TamariIntervalPosets.recomposition_from_triple(T1, T2, 2)
The Tamari interval of size 8 induced by relations [(1, 2), (2, 4),
(3, 4), (6, 7), (8, 7), (6, 4), (5, 4), (3, 2)]
```

```
>>> from sage.all import *
>>> T1 = TamariIntervalPoset(Integer(3), [(Integer(1), Integer(2)),
↪(Integer(3), Integer(2))])
>>> T2 = TamariIntervalPoset(Integer(4), [(Integer(2), Integer(3)),
↪(Integer(4), Integer(3))])
>>> TamariIntervalPosets.recomposition_from_triple(T1, T2, Integer(2))
The Tamari interval of size 8 induced by relations [(1, 2), (2, 4),
(3, 4), (6, 7), (8, 7), (6, 4), (5, 4), (3, 2)]
```

REFERENCES:

- [Pons2018]

class sage.combinat.interval_posets.**TamariIntervalPosets_all**

Bases: `DisjointUnionEnumeratedSets`, *TamariIntervalPosets*

The enumerated set of all Tamari interval-posets.

Element

alias of *TamariIntervalPoset*

one()

Return the unit of the monoid.

This is the empty interval poset, of size 0.

EXAMPLES:

```
sage: TamariIntervalPosets().one()
The Tamari interval of size 0 induced by relations []
```

```
>>> from sage.all import *
>>> TamariIntervalPosets().one()
The Tamari interval of size 0 induced by relations []
```

class sage.combinat.interval_posets.**TamariIntervalPosets_size**(*size*)

Bases: *TamariIntervalPosets*

The enumerated set of interval-posets of a given size.

cardinality()

The cardinality of `self`. That is, the number of interval-posets of size n.

The formula was given in [Cha2008]:

$$\frac{2(4n+1)!}{(n+1)!(3n+2)!} = \frac{2}{n(n+1)}\binom{4n+1}{n-1}.$$

EXAMPLES:

```
sage: [TamariIntervalPosets(i).cardinality() for i in range(6)]
[1, 1, 3, 13, 68, 399]
```

```
>>> from sage.all import *
>>> [TamariIntervalPosets(i).cardinality() for i in range(Integer(6))]
[1, 1, 3, 13, 68, 399]
```

element_class()

random_element()

Return a random Tamari interval of fixed size.

This is obtained by first creating a random rooted planar triangulation, then computing its unique minimal Schnyder wood, then applying a bijection of Bernardi and Bonichon [BeBo2009].

Because the random rooted planar triangulation is chosen uniformly at random, the Tamari interval is also chosen according to the uniform distribution.

EXAMPLES:

```
sage: # needs sage.combinat
sage: T = TamariIntervalPosets(4).random_element()
sage: T.parent()
Interval-posets
sage: u = T.lower_dyck_word(); u   # random
[1, 1, 0, 1, 0, 0, 1, 0]
sage: v = T.lower_dyck_word(); v   # random
[1, 1, 0, 1, 0, 0, 1, 0]
sage: len(u)
8
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> T = TamariIntervalPosets(Integer(4)).random_element()
>>> T.parent()
Interval-posets
>>> u = T.lower_dyck_word(); u    # random
[1, 1, 0, 1, 0, 0, 1, 0]
>>> v = T.lower_dyck_word(); v    # random
[1, 1, 0, 1, 0, 0, 1, 0]
>>> len(u)
8
```

5.1.130 Strong and weak tableaux

There are two types of k-tableaux: strong k-tableaux and weak k-tableaux. Standard weak k-tableaux correspond to saturated chains in the weak order, whereas standard strong k-tableaux correspond to saturated chains in the strong Bruhat order. For semistandard tableaux, the notion of weak and strong horizontal strip is necessary. More information can be found in [LLMS2006] .

See also

sage.combinat.k_tableau.StrongTableau(), *sage.combinat.k_tableau.WeakTableau()*

Authors:

- Anne Schilling and Mike Zabrocki (2013): initial version
- Avi Dalal and Nate Gallup (2013): implementation of k-charge

class sage.combinat.k_tableau.**StrongTableau**(*parent*, *T*)

Bases: ClonableList

A (standard) strong k-tableau is a (saturated) chain in Bruhat order.

Combinatorially, it is a sequence of embedded $k+1$-cores (subject to some conditions) together with a set of markings.

A strong cover in terms of cores corresponds to certain translated ribbons. A marking corresponds to the choice of one of the translated ribbons, which is indicated by marking the head (southeast most cell in French notation) of the chosen ribbon. For more information, see [LLMS2006] and [LLMSSZ2013].

In Sage, a strong k-tableau is created by specifying k, a standard strong tableau together with its markings, and a weight μ. Here the standard tableau is represented by a sequence of $k+1$-cores

$$\lambda^{(0)} \subseteq \lambda^{(1)} \subseteq \cdots \subseteq \lambda^{(m)}$$

where each of the $\lambda^{(i)}$ is a $k+1$-core. The standard tableau is a filling of the diagram for the core $\lambda^{(m)}/\lambda^{(0)}$ where a strong cover is represented by letters $\pm i$ in the skew shape $\lambda^{(i)}/\lambda^{(i-1)}$. Each skew $(k+1)$-core $\lambda^{(i)}/\lambda^{(i-1)}$ is a ribbon or multiple copies of the same ribbon which are separated by $k+1$ diagonals. Precisely one of the copies of the ribbons will be marked in the largest diagonal of the connected component (the 'head' of the ribbon). The marked cells are indicated by negative signs.

The strong tableau is stored as a standard strong marked tableau (referred to as the standard part of the strong tableau) and a vector representing the weight.

EXAMPLES:

```
sage: StrongTableau( [[-1, -2, -3], [3]], 2, [3] )
[[-1, -1, -1], [1]]
sage: StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,1])
[[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4]]
```

```
>>> from sage.all import *
>>> StrongTableau( [[-Integer(1), -Integer(2), -Integer(3)], [Integer(3)]],␣
↪Integer(2), [Integer(3)] )
[[-1, -1, -1], [1]]
>>> StrongTableau([[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-Integer(3),
↪Integer(6),-Integer(6),Integer(8)],[Integer(4),Integer(7)],[-Integer(5),-
↪Integer(8)]], Integer(3), [Integer(2),Integer(2),Integer(3),Integer(1)])
[[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4]]
```

Alternatively, the strong k-tableau can also be entered directly in semistandard format and then the standard tableau and the weight are computed and stored:

```
sage: T = StrongTableau([[-1,-1,-1],[1]], 2); T
[[-1, -1, -1], [1]]
sage: T.to_standard_list()
[[-1, -2, -3], [3]]
sage: T.weight()
(3,)
sage: T = StrongTableau([[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4]], 3);␣
↪T
[[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4]]
sage: T.to_standard_list()
[[-1, -2, -4, -7], [-3, 6, -6, 8], [4, 7], [-5, -8]]
sage: T.weight()
(2, 2, 3, 1)
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1),-Integer(1),-Integer(1)],[Integer(1)]],␣
↪Integer(2)); T
[[-1, -1, -1], [1]]
>>> T.to_standard_list()
[[-1, -2, -3], [3]]
>>> T.weight()
(3,)
>>> T = StrongTableau([[-Integer(1), -Integer(1), -Integer(2), -Integer(3)], [-
↪Integer(2), Integer(3), -Integer(3), Integer(4)], [Integer(2), Integer(3)], [-
↪Integer(3), -Integer(4)]], Integer(3)); T
[[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4]]
>>> T.to_standard_list()
[[-1, -2, -4, -7], [-3, 6, -6, 8], [4, 7], [-5, -8]]
>>> T.weight()
(2, 2, 3, 1)
```

cell_of_highest_head(*v*)

Return the cell of the highest head of label `v` in the standard part of `self`.

Return the cell where the head of the ribbon in the highest row is located in the underlying standard tableau. If there is no cell with entry `v` then the cell returned is $(0, r)$ where r is the length of the first row.

This cell is calculated by iterating through the diagonals of the tableau.

INPUT:

- `v` – integer indicating the label in the standard tableau

OUTPUT: a pair of integers indicating the coordinates of the head of the highest ribbon with label `v`

EXAMPLES:

```
sage: T = StrongTableau([[-1,2,-3],[-2,3],[3]], 1)
sage: [T.cell_of_highest_head(v) for v in range(1,5)]
[(0, 0), (1, 0), (2, 0), (0, 3)]
sage: T = StrongTableau([[None,None,-3,4],[3,-4]],2)
sage: [T.cell_of_highest_head(v) for v in range(1,5)]
[(1, 0), (1, 1), (0, 4), (0, 4)]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1),Integer(2),-Integer(3)],[-Integer(2),
↪Integer(3)],[Integer(3)]], Integer(1))
>>> [T.cell_of_highest_head(v) for v in range(Integer(1),Integer(5))]
[(0, 0), (1, 0), (2, 0), (0, 3)]
>>> T = StrongTableau([[None,None,-Integer(3),Integer(4)],[Integer(3),-
↪Integer(4)]],Integer(2))
>>> [T.cell_of_highest_head(v) for v in range(Integer(1),Integer(5))]
[(1, 0), (1, 1), (0, 4), (0, 4)]
```

cell_of_marked_head(*v*)

Return location of marked head labeled by `v` in the standard part of `self`.

Return the coordinates of the `v`-th marked cell in the strong standard tableau `self`. If there is no mark, then the value returned is $(0, r)$ where r is the length of the first row.

INPUT:

- `v` – integer representing the label in the standard tableau

OUTPUT: a pair of the coordinates of the marked cell with entry `v`

EXAMPLES:

```
sage: T = StrongTableau([[-1, -3, 4, -5], [-2], [-4]], 3)
sage: [ T.cell_of_marked_head(i) for i in range(1,7)]
[(0, 0), (1, 0), (0, 1), (2, 0), (0, 3), (0, 4)]
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: [ T.cell_of_marked_head(i) for i in range(1,7)]
[(2, 0), (0, 2), (2, 1), (0, 3), (4, 0), (0, 4)]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1), -Integer(3), Integer(4), -Integer(5)], [-
↪Integer(2)], [-Integer(4)]], Integer(3))
>>> [ T.cell_of_marked_head(i) for i in range(Integer(1),Integer(7))]
[(0, 0), (1, 0), (0, 1), (2, 0), (0, 3), (0, 4)]
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],␣
↪[-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))
```

(continues on next page)

(continued from previous page)

```
>>> [ T.cell_of_marked_head(i) for i in range(Integer(1),Integer(7))]
[(2, 0), (0, 2), (2, 1), (0, 3), (4, 0), (0, 4)]
```

cells_head_dictionary()

Return a dictionary with the locations of the heads of all markings.

Return a dictionary of values and lists of cells where the heads with the values are located.

OUTPUT:

- a dictionary with keys the entries in the tableau and values are the coordinates of the heads with those entries

EXAMPLES:

```
sage: T = StrongTableau([[-1,-2,-4,7],[-3,6,-6,8],[4,-7],[-5,-8]], 3)
sage: T.cells_head_dictionary()
{1: [(0, 0)],
 2: [(0, 1)],
 3: [(1, 0)],
 4: [(2, 0), (0, 2)],
 5: [(3, 0)],
 6: [(1, 2)],
 7: [(2, 1), (0, 3)],
 8: [(3, 1), (1, 3)]}
sage: T = StrongTableau([[None, 4, -4, -6, -7, 8, 8, -8], [None, -5, 8, 8, 8],
↪ [-3, 6]],3)
sage: T.cells_head_dictionary()
{1: [(2, 0)],
 2: [(0, 2)],
 3: [(1, 1)],
 4: [(2, 1), (0, 3)],
 5: [(0, 4)],
 6: [(1, 4), (0, 7)]}
 sage: StrongTableau([[None, None], [None, -1]], 4).cells_head_dictionary()
 {1: [(1, 1)]}
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1),-Integer(2),-Integer(4),Integer(7)],[-
↪Integer(3),Integer(6),-Integer(6),Integer(8)],[Integer(4),-Integer(7)],[-
↪Integer(5),-Integer(8)]], Integer(3))
>>> T.cells_head_dictionary()
{1: [(0, 0)],
 2: [(0, 1)],
 3: [(1, 0)],
 4: [(2, 0), (0, 2)],
 5: [(3, 0)],
 6: [(1, 2)],
 7: [(2, 1), (0, 3)],
 8: [(3, 1), (1, 3)]}
>>> T = StrongTableau([[None, Integer(4), -Integer(4), -Integer(6), -
↪Integer(7), Integer(8), Integer(8), -Integer(8)], [None, -Integer(5),␣
↪Integer(8), Integer(8), Integer(8)], [-Integer(3), Integer(6)]],Integer(3))
>>> T.cells_head_dictionary()
```

(continues on next page)

(continued from previous page)

```
{1: [(2, 0)],
 2: [(0, 2)],
 3: [(1, 1)],
 4: [(2, 1), (0, 3)],
 5: [(0, 4)],
 6: [(1, 4), (0, 7)]}
>>> StrongTableau([[None, None], [None, -Integer(1)]], Integer(4)).cells_head_
↪dictionary()
 {1: [(1, 1)]}
```

cells_of_heads(*v*)

Return a list of cells of the heads with label v in the standard part of self.

A list of cells which are heads of the ribbons with label v in the standard part of the tableau self. If there is no cell labelled by v then return the empty list.

INPUT:

- v – integer label

OUTPUT: a list of pairs of integers of the coordinates of the heads of the ribbons with label v

EXAMPLES:

```
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: T.cells_of_heads(1)
[(2, 0)]
sage: T.cells_of_heads(2)
[(3, 0), (0, 2)]
sage: T.cells_of_heads(3)
[(2, 1)]
sage: T.cells_of_heads(4)
[(3, 1), (0, 3)]
sage: T.cells_of_heads(5)
[(4, 0)]
sage: T.cells_of_heads(6)
[]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],
↪[-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))
>>> T.cells_of_heads(Integer(1))
[(2, 0)]
>>> T.cells_of_heads(Integer(2))
[(3, 0), (0, 2)]
>>> T.cells_of_heads(Integer(3))
[(2, 1)]
>>> T.cells_of_heads(Integer(4))
[(3, 1), (0, 3)]
>>> T.cells_of_heads(Integer(5))
[(4, 0)]
>>> T.cells_of_heads(Integer(6))
```

(continues on next page)

(continued from previous page)

```
[]
```

cells_of_marked_ribbon(*v*)

Return a list of all cells the marked ribbon labeled by `v` in the standard part of `self`.

Return the list of coordinates of the cells which are in the marked ribbon with label `v` in the standard part of the tableau. Note that the result is independent of the weight of the tableau.

The cells are listed from largest content (where the mark is located) to the smallest. Hence, the first entry in this list will be the marked cell.

INPUT:

- `v` – the entry of the standard tableau

OUTPUT:

- a list of pairs representing the coordinates of the cells of the marked ribbon

EXAMPLES:

```
sage: T = StrongTableau([[-1, -1, -2, -2, 3], [2, -3], [-3]],3)
sage: T.to_standard_list()
[[-1, -2, -3, -4, 6], [4, -6], [-5]]
sage: T.cells_of_marked_ribbon(1)
[(0, 0)]
sage: T.cells_of_marked_ribbon(4)
[(0, 3)]
sage: T = StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3)
sage: T.cells_of_marked_ribbon(6)
[(1, 2), (1, 1)]
sage: T.cells_of_marked_ribbon(9)
[]
sage: T = StrongTableau([[None, None, -1, -1, 3], [1, -3], [-3]],3)
sage: T.to_standard_list()
[[None, None, -1, -2, 4], [2, -4], [-3]]
sage: T.cells_of_marked_ribbon(1)
[(0, 2)]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1), -Integer(1), -Integer(2), -Integer(2),␣
↪Integer(3)], [Integer(2), -Integer(3)], [-Integer(3)]],Integer(3))
>>> T.to_standard_list()
[[-1, -2, -3, -4, 6], [4, -6], [-5]]
>>> T.cells_of_marked_ribbon(Integer(1))
[(0, 0)]
>>> T.cells_of_marked_ribbon(Integer(4))
[(0, 3)]
>>> T = StrongTableau([[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-
↪Integer(3),Integer(6),-Integer(6),Integer(8)],[Integer(4),Integer(7)],[-
↪Integer(5),-Integer(8)]], Integer(3))
>>> T.cells_of_marked_ribbon(Integer(6))
[(1, 2), (1, 1)]
>>> T.cells_of_marked_ribbon(Integer(9))
[]
```

(continues on next page)

(continued from previous page)

```
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(1), Integer(3)],
↪[Integer(1), -Integer(3)], [-Integer(3)]],Integer(3))
>>> T.to_standard_list()
[[None, None, -1, -2, 4], [2, -4], [-3]]
>>> T.cells_of_marked_ribbon(Integer(1))
[(0, 2)]
```

check()

Check that `self` is a valid strong k-tableau.

This function verifies that the outer and inner shape of the parent class is equal to the outer and inner shape of the tableau, that the tableau portion of `self` is a valid standard tableau, that the marks are placed correctly and that the size and weight agree.

EXAMPLES:

```
sage: T = StrongTableau([[-1, -1, -2], [2]], 2)
sage: T.check()
sage: T = StrongTableau([[None, None, 2, -4, -4], [-1, 4], [-2]], 3)
sage: T.check()
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1), -Integer(1), -Integer(2)], [Integer(2)]],
↪ Integer(2))
>>> T.check()
>>> T = StrongTableau([[None, None, Integer(2), -Integer(4), -Integer(4)], [-
↪Integer(1), Integer(4)], [-Integer(2)]], Integer(3))
>>> T.check()
```

content_of_highest_head(*v*)

Return the diagonal of the highest head of the cells labeled `v` in the standard part of `self`.

Return the content of the cell of the head in the highest row of all ribbons labeled by `v` of the underlying standard tableau. If there is no cell with entry `v` then the value returned is the length of the first row.

INPUT:

- `v` – integer representing the label in the standard tableau

OUTPUT: an integer representing the content of the head of the highest ribbon with label `v`

EXAMPLES:

```
sage: [StrongTableau([[-1,2,-3],[-2,3],[3]], 1).content_of_highest_head(v)
↪for v in range(1,5)]
[0, -1, -2, 3]
```

```
>>> from sage.all import *
>>> [StrongTableau([[-Integer(1),Integer(2),-Integer(3)],[-Integer(2),
↪Integer(3)],[Integer(3)]], Integer(1)).content_of_highest_head(v) for v in
↪range(Integer(1),Integer(5))]
[0, -1, -2, 3]
```

content_of_marked_head(*v*)

Return the diagonal of the marked label `v` in the standard part of `self`.

Return the content (the $j - i$ coordinate of the cell) of the v-th marked cell in the strong standard tableau self. If there is no mark, then the value returned is the size of first row.

INPUT:

- v – integer representing the label in the standard tableau

OUTPUT: integer representing the residue of the location of the mark

EXAMPLES:

```
sage: [ StrongTableau([[-1, -3, 4, -5], [-2], [-4]], 3).content_of_marked_
↪head(i) for i in range(1,7)]
[0, -1, 1, -2, 3, 4]
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: [ T.content_of_marked_head(i) for i in range(1,7)]
[-2, 2, -1, 3, -4, 4]
```

```
>>> from sage.all import *
>>> [ StrongTableau([[-Integer(1), -Integer(3), Integer(4), -Integer(5)], [-
↪Integer(2)], [-Integer(4)]], Integer(3)).content_of_marked_head(i) for i in␣
↪range(Integer(1),Integer(7))]
[0, -1, 1, -2, 3, 4]
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],␣
↪[-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))
>>> [ T.content_of_marked_head(i) for i in range(Integer(1),Integer(7))]
[-2, 2, -1, 3, -4, 4]
```

contents_of_heads(*v*)

A list of contents of the cells which are heads of the ribbons with label v.

If there is no cell labelled by v then return the empty list.

INPUT:

- v – integer label

OUTPUT: list of integers of the content of the heads of the ribbons with label v

EXAMPLES:

```
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: T.contents_of_heads(1)
[-2]
sage: T.contents_of_heads(2)
[-3, 2]
sage: T.contents_of_heads(3)
[-1]
sage: T.contents_of_heads(4)
[-2, 3]
sage: T.contents_of_heads(5)
[-4]
sage: T.contents_of_heads(6)
[]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],␣
↪[-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))
>>> T.contents_of_heads(Integer(1))
[-2]
>>> T.contents_of_heads(Integer(2))
[-3, 2]
>>> T.contents_of_heads(Integer(3))
[-1]
>>> T.contents_of_heads(Integer(4))
[-2, 3]
>>> T.contents_of_heads(Integer(5))
[-4]
>>> T.contents_of_heads(Integer(6))
[]
```

entries_by_content(*diag*)

Return the entries on the diagonal of `self`.

Return the entries in the tableau that are in the cells (i, j) with $j - i$ equal to `diag` (that is, with content equal to `diag`).

INPUT:

- `diag` – integer indicating the diagonal

OUTPUT: list (perhaps empty) of labels on the diagonal `diag`

EXAMPLES:

```
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: T.entries_by_content(0)
[]
sage: T.entries_by_content(1)
[]
sage: T.entries_by_content(2)
[-1]
sage: T.entries_by_content(-2)
[-1, 2]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],␣
↪[-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))
>>> T.entries_by_content(Integer(0))
[]
>>> T.entries_by_content(Integer(1))
[]
>>> T.entries_by_content(Integer(2))
[-1]
>>> T.entries_by_content(-Integer(2))
[-1, 2]
```

entries_by_content_standard(*diag*)

Return the entries on the diagonal of the standard part of `self`.

Return the entries in the tableau that are in the cells (i, j) with $j - i$ equal to `diag` (that is, with content equal to `diag`) in the standard tableau.

INPUT:

- `diag` – integer indicating the diagonal

OUTPUT: list (perhaps empty) of labels on the diagonal `diag`

EXAMPLES:

```
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: T.entries_by_content_standard(0)
[]
sage: T.entries_by_content_standard(1)
[]
sage: T.entries_by_content_standard(2)
[-2]
sage: T.entries_by_content_standard(-2)
[-1, 4]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],
↪[-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))
>>> T.entries_by_content_standard(Integer(0))
[]
>>> T.entries_by_content_standard(Integer(1))
[]
>>> T.entries_by_content_standard(Integer(2))
[-2]
>>> T.entries_by_content_standard(-Integer(2))
[-1, 4]
```

follows_tableau()

Return a list of strong marked tableaux with length one longer than `self`.

Return list of all strong tableaux obtained from `self` by extending to a core which follows the shape of `self` in the strong order.

OUTPUT: list of strong tableaux which follow `self` in strong order

EXAMPLES:

```
sage: T = StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,
↪1])
sage: T.follows_tableau()
[[[-1, -1, -2, -3, 5, 5, -5], [-2, 3, -3, 4], [2, 3], [-3, -4]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [-5]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, -5], [-3, -4], [5]],
 [[-1, -1, -2, -3, -5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [5]],
 [[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4], [-5], [5], [5]]]
sage: StrongTableau([[-1,-2],[-3,-4]],3).follows_tableau()
```

(continues on next page)

(continued from previous page)

```
[[[-1, -2, 5, 5, -5], [-3, -4]], [[-1, -2, 5], [-3, -4], [-5]],
 [[-1, -2, -5], [-3, -4], [5]], [[-1, -2], [-3, -4], [-5], [5], [5]]]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-
↪Integer(3),Integer(6),-Integer(6),Integer(8)],[Integer(4),Integer(7)],[-
↪Integer(5),-Integer(8)]], Integer(3), [Integer(2),Integer(2),Integer(3),
↪Integer(1)])
>>> T.follows_tableau()
[[[-1, -1, -2, -3, 5, 5, -5], [-2, 3, -3, 4], [2, 3], [-3, -4]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [-5]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, -5], [-3, -4], [5]],
 [[-1, -1, -2, -3, -5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [5]],
 [[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4], [-5], [5], [5]]]
>>> StrongTableau([[-Integer(1),-Integer(2)],[-Integer(3),-Integer(4)]],
↪Integer(3)).follows_tableau()
[[[-1, -2, 5, 5, -5], [-3, -4]], [[-1, -2, 5], [-3, -4], [-5]],
 [[-1, -2, -5], [-3, -4], [5]], [[-1, -2], [-3, -4], [-5], [5], [5]]]
```

height_of_ribbon(*v*)

The number of rows occupied by one of the ribbons with label `v`.

The number of rows occupied by the marked ribbon with label `v` (and by consequence the number of rows occupied by any ribbon with the same label) in the standard part of `self`.

INPUT:

- `v` – the label of the standard marked tableau

OUTPUT: nonnegative integer representing the number of rows occupied by the ribbon which is marked

EXAMPLES:

```
sage: T = StrongTableau([[-1, -1, -2, -2, 3], [2, -3], [-3]],3)
sage: T.to_standard_list()
[[-1, -2, -3, -4, 6], [4, -6], [-5]]
sage: T.height_of_ribbon(1)
1
sage: T.height_of_ribbon(4)
1
sage: T = StrongTableau([[None,None,1,-2],[None,-3,4,-5],[-1,3],[-4,5]], 3)
sage: T.height_of_ribbon(3)
2
sage: T.height_of_ribbon(6)
0
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1), -Integer(1), -Integer(2), -Integer(2),␣
↪Integer(3)], [Integer(2), -Integer(3)], [-Integer(3)]],Integer(3))
>>> T.to_standard_list()
[[-1, -2, -3, -4, 6], [4, -6], [-5]]
>>> T.height_of_ribbon(Integer(1))
1
>>> T.height_of_ribbon(Integer(4))
```

(continues on next page)

(continued from previous page)

```
1
>>> T = StrongTableau([[None,None,Integer(1),-Integer(2)],[None,-Integer(3),
↪Integer(4),-Integer(5)],[-Integer(1),Integer(3)],[-Integer(4),Integer(5)]],␣
↪Integer(3))
>>> T.height_of_ribbon(Integer(3))
2
>>> T.height_of_ribbon(Integer(6))
0
```

inner_shape()

Return the inner shape of `self`.

If `self` is a strong skew tableau, then this method returns the inner shape (the shape of the cells labelled with `None`). If `self` is not skew, then the inner shape is empty.

OUTPUT:

- a $(k+1)$-core

EXAMPLES:

```
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
↪3], [3], [3], [3]], 4).inner_shape()
[2, 2]
sage: StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,1]).
↪inner_shape()
[]
```

```
>>> from sage.all import *
>>> StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None], [-
↪Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4)).inner_shape()
[2, 2]
>>> StrongTableau([[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-
↪Integer(3),Integer(6),-Integer(6),Integer(8)],[Integer(4),Integer(7)],[-
↪Integer(5),-Integer(8)]], Integer(3), [Integer(2),Integer(2),Integer(3),
↪Integer(1)]).inner_shape()
[]
```

intermediate_shapes()

Return the intermediate shapes of `self`.

A (skew) tableau with letters $1, 2, \ldots, \ell$ can be viewed as a sequence of shapes, where the i-th shape is given by the shape of the subtableau on letters $1, 2, \ldots, i$.

The output is the list of these shapes. The marked cells are ignored so to recover the strong tableau one would need the intermediate shapes and the *content_of_marked_head()* for each pair of adjacent shapes in the list.

OUTPUT: list of lists of integers representing $k+1$-cores

EXAMPLES:

```
sage: T = StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,
↪1])
sage: T.intermediate_shapes()
```

(continues on next page)

(continued from previous page)

```
[[], [2], [3, 1, 1], [4, 3, 2, 1], [4, 4, 2, 2]]
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: T.intermediate_shapes()
[[2, 2], [3, 2, 1, 1], [4, 2, 2, 2], [4, 2, 2, 2, 1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-
↪Integer(3),Integer(6),-Integer(6),Integer(8)],[Integer(4),Integer(7)],[-
↪Integer(5),-Integer(8)]], Integer(3), [Integer(2),Integer(2),Integer(3),
↪Integer(1)])
>>> T.intermediate_shapes()
[[], [2], [3, 1, 1], [4, 3, 2, 1], [4, 4, 2, 2]]
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],␣
↪[-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))
>>> T.intermediate_shapes()
[[2, 2], [3, 2, 1, 1], [4, 2, 2, 2], [4, 2, 2, 2, 1, 1, 1, 1]]
```

is_column_strict_with_weight(*mu*)

Test if `self` is a column strict tableau with respect to the weight `mu`.

INPUT:

- `mu` – a vector of weights

OUTPUT: boolean; `True` means the underlying column strict strong marked tableau is valid

EXAMPLES:

```
sage: StrongTableau([[-1, -2, -3], [3]], 2).is_column_strict_with_weight([3])
True
sage: StrongTableau([[-1, -2, 3], [-3]], 2).is_column_strict_with_weight([3])
False
```

```
>>> from sage.all import *
>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3)], [Integer(3)]],␣
↪Integer(2)).is_column_strict_with_weight([Integer(3)])
True
>>> StrongTableau([[-Integer(1), -Integer(2), Integer(3)], [-Integer(3)]],␣
↪Integer(2)).is_column_strict_with_weight([Integer(3)])
False
```

left_action(*tij*)

Action of transposition `tij` on `self` by adding marked ribbons.

Computes the left action of the transposition `tij` on the tableau. If `tij` acting on the element of the affine Grassmannian raises the length by 1, then this function will add a cell to the standard tableau.

INPUT:

- `tij` – a transposition represented as a pair (i, j)

OUTPUT: `self` after it has been modified by the action of the transposition `tij`

EXAMPLES:

```
sage: StrongTableau( [[None, -1, -2, -3], [3], [-4]], 3, weight=[1,1,1,1] ).
↪left_action([0,1])
[[None, -1, -2, -3, 5], [3, -5], [-4]]
sage: StrongTableau( [[None, -1, -2, -3], [3], [-4]], 3, weight=[1,1,1,1] ).
↪left_action([4,5])
[[None, -1, -2, -3, -5], [3, 5], [-4]]
sage: T = StrongTableau( [[None, -1, -2, -3], [3], [-4]], 3, weight=[1,1,1,1]␣
↪)
sage: T.left_action([-3,-2])
[[None, -1, -2, -3], [3], [-4], [-5]]
sage: T = StrongTableau( [[None, -1, -2, -3], [3], [-4]], 3, weight=[3,1] )
sage: T.left_action([-3,-2])
[[None, -1, -1, -1], [1], [-2], [-3]]
sage: T
[[None, -1, -1, -1], [1], [-2]]
sage: T.check()
sage: T.weight()
(3, 1)
```

```
>>> from sage.all import *
>>> StrongTableau( [[None, -Integer(1), -Integer(2), -Integer(3)],␣
↪[Integer(3)], [-Integer(4)]], Integer(3), weight=[Integer(1),Integer(1),
↪Integer(1),Integer(1)] ).left_action([Integer(0),Integer(1)])
[[None, -1, -2, -3, 5], [3, -5], [-4]]
>>> StrongTableau( [[None, -Integer(1), -Integer(2), -Integer(3)],␣
↪[Integer(3)], [-Integer(4)]], Integer(3), weight=[Integer(1),Integer(1),
↪Integer(1),Integer(1)] ).left_action([Integer(4),Integer(5)])
[[None, -1, -2, -3, -5], [3, 5], [-4]]
>>> T = StrongTableau( [[None, -Integer(1), -Integer(2), -Integer(3)],␣
↪[Integer(3)], [-Integer(4)]], Integer(3), weight=[Integer(1),Integer(1),
↪Integer(1),Integer(1)] )
>>> T.left_action([-Integer(3),-Integer(2)])
[[None, -1, -2, -3], [3], [-4], [-5]]
>>> T = StrongTableau( [[None, -Integer(1), -Integer(2), -Integer(3)],␣
↪[Integer(3)], [-Integer(4)]], Integer(3), weight=[Integer(3),Integer(1)] )
>>> T.left_action([-Integer(3),-Integer(2)])
[[None, -1, -1, -1], [1], [-2], [-3]]
>>> T
[[None, -1, -1, -1], [1], [-2]]
>>> T.check()
>>> T.weight()
(3, 1)
```

number_of_connected_components(*v*)

Number of connected components of ribbons with label `v` in the standard part.

The number of connected components is calculated by finding the number of cells with label `v` in the standard part of the tableau and dividing by the number of cells in the ribbon.

INPUT:

- `v` – the label of the standard marked tableau

OUTPUT: nonnegative integer representing the number of connected components

EXAMPLES:

```
sage: T = StrongTableau([[-1, -1, -2, -2, 3], [2, -3], [-3]],3)
sage: T.to_standard_list()
[[-1, -2, -3, -4, 6], [4, -6], [-5]]
sage: T.number_of_connected_components(1)
1
sage: T.number_of_connected_components(4)
2
sage: T = StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3)
sage: T.number_of_connected_components(6)
1
sage: T.number_of_connected_components(9)
0
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1), -Integer(1), -Integer(2), -Integer(2),␣
→Integer(3)], [Integer(2), -Integer(3)], [-Integer(3)]],Integer(3))
>>> T.to_standard_list()
[[-1, -2, -3, -4, 6], [4, -6], [-5]]
>>> T.number_of_connected_components(Integer(1))
1
>>> T.number_of_connected_components(Integer(4))
2
>>> T = StrongTableau([[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-
→Integer(3),Integer(6),-Integer(6),Integer(8)],[Integer(4),Integer(7)],[-
→Integer(5),-Integer(8)]], Integer(3))
>>> T.number_of_connected_components(Integer(6))
1
>>> T.number_of_connected_components(Integer(9))
0
```

outer_shape()

Return the outer shape of `self`.

This method returns the outer shape of `self` as viewed as a `Core`. The outer shape of a strong tableau is always a $(k+1)$-core.

OUTPUT:

- a $(k+1)$-core

EXAMPLES:

```
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
→3], [3], [3], [3]], 4).outer_shape()
[4, 2, 2, 2, 1, 1, 1, 1]
sage: StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,1]).
→outer_shape()
[4, 4, 2, 2]
```

```
>>> from sage.all import *
>>> StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None], [-
→Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
→[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4)).outer_shape()
```

(continues on next page)

(continued from previous page)

```
[4, 2, 2, 2, 1, 1, 1, 1]
>>> StrongTableau([[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-
↪Integer(3),Integer(6),-Integer(6),Integer(8)],[Integer(4),Integer(7)],[-
↪Integer(5),-Integer(8)]], Integer(3), [Integer(2),Integer(2),Integer(3),
↪Integer(1)]).outer_shape()
[4, 4, 2, 2]
```

pp()

Print the strong tableau self in pretty print format.

EXAMPLES:

```
sage: T = StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,
↪1])
sage: T.pp()
-1 -1 -2 -3
-2  3 -3  4
 2  3
-3 -4
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: T.pp()
  .  . -1 -2
  .  .

  .  .
  .  . -1 -2
>>> Tableaux.options(convention='English')
```

restrict(*r*)

Restrict the standard part of the tableau to the labels $1, 2, \ldots, r$.

Return the tableau consisting of the labels of the standard part of `self` restricted to the labels of 1 through `r`. The result is another `StrongTableau` object.

INPUT:

- `r` – integer

OUTPUT: a strong tableau

EXAMPLES:

```
sage: T = StrongTableau([[None, None, -4, 5, -5], [None, None], [-1, -3], [-
↪2], [2], [2], [3]], 4, weight=[1,1,1,1,1])
sage: T.restrict(3)
[[None, None], [None, None], [-1, -3], [-2], [2], [2], [3]]
sage: TT = T.restrict(0)
sage: TT
[[None, None], [None, None]]
sage: TT == StrongTableau( [[None, None], [None, None]], 4 )
True
sage: T.restrict(5) == T
True
```

```
>>> from sage.all import *
>>> T = StrongTableau([[None, None, -Integer(4), Integer(5), -Integer(5)],␣
↪[None, None], [-Integer(1), -Integer(3)], [-Integer(2)], [Integer(2)],␣
↪[Integer(2)], [Integer(3)]], Integer(4), weight=[Integer(1),Integer(1),
```

(continues on next page)

(continued from previous page)

```
↪Integer(1),Integer(1),Integer(1)])
>>> T.restrict(Integer(3))
[[None, None], [None, None], [-1, -3], [-2], [2], [2], [3]]
>>> TT = T.restrict(Integer(0))
>>> TT
[[None, None], [None, None]]
>>> TT == StrongTableau( [[None, None], [None, None]], Integer(4) )
True
>>> T.restrict(Integer(5)) == T
True
```

ribbons_above_marked(*v*)

Number of ribbons of label `v` higher than the marked ribbon in the standard part.

Return the number of copies of the ribbon with label `v` in the standard part of `self` which are in a higher row than the marked ribbon. Note that the result is independent of the weight of the tableau.

INPUT:

- `v` – the entry of the standard tableau

OUTPUT:

- an integer representing the number of copies of the ribbon above the marked ribbon

EXAMPLES:

```
sage: T = StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3)
sage: T.ribbons_above_marked(4)
1
sage: T.ribbons_above_marked(6)
0
sage: T.ribbons_above_marked(9)
0
sage: StrongTableau([[-1,-2,-3,-4],[2,3,4],[3,4],[4]], 1).ribbons_above_
↪marked(4)
3
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-
↪Integer(3),Integer(6),-Integer(6),Integer(8)],[Integer(4),Integer(7)],[-
↪Integer(5),-Integer(8)]], Integer(3))
>>> T.ribbons_above_marked(Integer(4))
1
>>> T.ribbons_above_marked(Integer(6))
0
>>> T.ribbons_above_marked(Integer(9))
0
>>> StrongTableau([[-Integer(1),-Integer(2),-Integer(3),-Integer(4)],
↪[Integer(2),Integer(3),Integer(4)],[Integer(3),Integer(4)],[Integer(4)]],␣
↪Integer(1)).ribbons_above_marked(Integer(4))
3
```

set_weight(*mu*)

Set a new weight `mu` for `self`.

This method first tests if the underlying standard tableau is column-strict with respect to the weight `mu`. If it is, then it changes the weight and returns the tableau; otherwise it raises an error.

INPUT:

- `mu` – list of nonnegative integers representing the new weight

EXAMPLES:

```
sage: StrongTableau( [[-1, -2, -3], [3]], 2 ).set_weight( [3] )
[[-1, -1, -1], [1]]
sage: StrongTableau( [[-1, -2, -3], [3]], 2 ).set_weight( [0,3] )
[[-2, -2, -2], [2]]
sage: StrongTableau( [[-1, -2, 3], [-3]], 2 ).set_weight( [2, 0, 1] )
[[-1, -1, 3], [-3]]
sage: StrongTableau( [[-1, -2, 3], [-3]], 2 ).set_weight( [3] )
Traceback (most recent call last):
...
ValueError: [[-1, -2, 3], [-3]] is not a semistandard strong tableau with␣
↪respect to the partition [3]
```

```
>>> from sage.all import *
>>> StrongTableau( [[-Integer(1), -Integer(2), -Integer(3)], [Integer(3)]],␣
↪Integer(2) ).set_weight( [Integer(3)] )
[[-1, -1, -1], [1]]
>>> StrongTableau( [[-Integer(1), -Integer(2), -Integer(3)], [Integer(3)]],␣
↪Integer(2) ).set_weight( [Integer(0),Integer(3)] )
[[-2, -2, -2], [2]]
>>> StrongTableau( [[-Integer(1), -Integer(2), Integer(3)], [-Integer(3)]],␣
↪Integer(2) ).set_weight( [Integer(2), Integer(0), Integer(1)] )
[[-1, -1, 3], [-3]]
>>> StrongTableau( [[-Integer(1), -Integer(2), Integer(3)], [-Integer(3)]],␣
↪Integer(2) ).set_weight( [Integer(3)] )
Traceback (most recent call last):
...
ValueError: [[-1, -2, 3], [-3]] is not a semistandard strong tableau with␣
↪respect to the partition [3]
```

shape()

Return the shape of `self`.

If `self` is a skew tableau then return a pair of $k+1$-cores consisting of the outer and the inner shape. If `self` is strong tableau with no inner shape then return a $k+1$-core.

INPUT:

- `form` – argument to indicate `'inner'`, `'outer'` or `'skew'` (default: `'outer'`)

OUTPUT: a $k+1$-core or a pair of $k+1$-cores if form is not `'inner'` or `'outer'`

EXAMPLES:

```
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: T.shape()
([4, 2, 2, 2, 1, 1, 1, 1], [2, 2])
sage: StrongTableau([[-1, -2, 3], [-3]], 2).shape()
```

(continues on next page)

(continued from previous page)

```
[3, 1]
sage: type(StrongTableau([[-1, -2, 3], [-3]], 2).shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
```

```
>>> from sage.all import *
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],␣
↪[-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))
>>> T.shape()
([4, 2, 2, 2, 1, 1, 1, 1], [2, 2])
>>> StrongTableau([[-Integer(1), -Integer(2), Integer(3)], [-Integer(3)]],␣
↪Integer(2)).shape()
[3, 1]
>>> type(StrongTableau([[-Integer(1), -Integer(2), Integer(3)], [-
↪Integer(3)]], Integer(2)).shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
```

size()

Return the size of the strong tableau.

The size of the strong tableau is the sum of the entries in the *weight()*. It will also be equal to the length of the outer shape (as a $k+1$-core) minus the length of the inner shape.

See also

sage.combinat.core.Core.length()

OUTPUT: nonnegative integer

EXAMPLES:

```
sage: StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3).size()
5
sage: StrongTableau([[None, None, -1, 2], [-2], [-3]], 3).size()
3
```

```
>>> from sage.all import *
>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-
↪Integer(4)], [-Integer(5)]], Integer(3)).size()
5
>>> StrongTableau([[None, None, -Integer(1), Integer(2)], [-Integer(2)], [-
↪Integer(3)]], Integer(3)).size()
3
```

spin()

Return the spin statistic of the tableau `self`.

The spin is an integer statistic on a strong marked tableau. It is the sum of $(h-1)r$ plus the number of connected components above the marked one where h is the height of the marked ribbon and r is the number of connected components.

See also

height_of_ribbon(), *number_of_connected_components()*, *ribbons_above_marked()*

The k-Schur functions with a parameter t can be defined as

$$s_\lambda^{(k)}[X;t] = \sum_T t^{spin(T)} m_{weight(T)}[X]$$

where the sum is over all column strict marked strong k-tableaux of shape λ and partition content.

OUTPUT: integer value representing the spin

EXAMPLES:

```
sage: StrongTableau([[-1,-2,5,6],[-3,-4,-7,8],[-5,-6],[7,-8]], 3, [2,2,3,1]).
↪spin()
1
sage: StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,1]).
↪spin()
2
sage: StrongTableau([[None,None,-1,-3],[-2,3,-3,4],[2,3],[-3,-4]], 3).spin()
2
sage: ks3 = SymmetricFunctions(QQ['t'].fraction_field()).kschur(3)
sage: t = ks3.realization_of().t
sage: m = ks3.ambient().realization_of().m()
sage: myks221 = sum(sum(t**T.spin() for T in StrongTableaux(3,[3,2,1],
↪weight=mu))*m(mu) for mu in Partitions(5, max_part=3))
sage: myks221 == m(ks3[2,2,1])
True
sage: h = ks3.ambient().realization_of().h()
sage: Core([4,4,2,2],4).to_bounded_partition()
[2, 2, 2, 2]
sage: ks3[2,2,2,2].lift().scalar(h[3,3,2]) == sum( t**T.spin() for T in␣
↪StrongTableaux(3, [4,4,2,2], weight=[3,3,2]) )
True
```

```
>>> from sage.all import *
>>> StrongTableau([[-Integer(1),-Integer(2),Integer(5),Integer(6)],[-
↪Integer(3),-Integer(4),-Integer(7),Integer(8)],[-Integer(5),-Integer(6)],
↪[Integer(7),-Integer(8)]], Integer(3), [Integer(2),Integer(2),Integer(3),
↪Integer(1)]).spin()
1
>>> StrongTableau([[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-
↪Integer(3),Integer(6),-Integer(6),Integer(8)],[Integer(4),Integer(7)],[-

↪StrongTableaux(Integer(3), [Integer(4),Integer(4),Integer(2),Integer(2)],␣
↪weight=[Integer(3),Integer(3),Integer(2)]) )
True
```

spin_of_ribbon(*v*)

Return the spin of the ribbon with label `v` in the standard part of `self`.

The spin of a ribbon is an integer statistic. It is the sum of $(h-1)r$ plus the number of connected components above the marked one where h is the height of the marked ribbon and r is the number of connected components.

See also

height_of_ribbon(), *number_of_connected_components()*, *ribbons_above_marked()*

INPUT:

- `v` – a label of the standard part of the tableau

OUTPUT: integer value representing the spin of the ribbon with label `v`

EXAMPLES:

```
sage: T = StrongTableau([[-1,-2,5,6],[-3,-4,-7,8],[-5,-6],[7,-8]], 3)
sage: [T.spin_of_ribbon(v) for v in range(1,9)]
[0, 0, 0, 0, 0, 0, 1, 0]
sage: T = StrongTableau([[None,None,-1,-3],[-2,3,-3,4],[2,3],[-3,-4]], 3)
sage: [T.spin_of_ribbon(v) for v in range(1,7)]
[0, 1, 0, 0, 1, 0]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1),-Integer(2),Integer(5),Integer(6)],[-
↪Integer(3),-Integer(4),-Integer(7),Integer(8)],[-Integer(5),-Integer(6)],
↪[Integer(7),-Integer(8)]], Integer(3))
>>> [T.spin_of_ribbon(v) for v in range(Integer(1),Integer(9))]
[0, 0, 0, 0, 0, 0, 1, 0]
>>> T = StrongTableau([[None,None,-Integer(1),-Integer(3)],[-Integer(2),
↪Integer(3),-Integer(3),Integer(4)],[Integer(2),Integer(3)],[-Integer(3),-
↪Integer(4)]], Integer(3))
>>> [T.spin_of_ribbon(v) for v in range(Integer(1),Integer(7))]
[0, 1, 0, 0, 1, 0]
```

to_list()

Return the marked column strict (possibly skew) tableau as a list of lists.

OUTPUT: list of lists of integers or None

EXAMPLES:

```
sage: StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3).set_weight([2,1,1,1]).
↪to_list()
[[-1, -1, -2, 3], [-3], [-4]]
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
↪3], [3], [3], [3]], 4).to_list()
[[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], [3]]
sage: StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1]).to_list()
[[-1, -1, -1, 2], [-2], [-3]]
```

```
>>> from sage.all import *
>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-
↪Integer(4)], [-Integer(5)]], Integer(3)).set_weight([Integer(2),Integer(1),
↪Integer(1),Integer(1)]).to_list()
[[-1, -1, -2, 3], [-3], [-4]]
>>> StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None], [-
↪Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4)).to_list()
[[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], [3]]
>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-
↪Integer(4)], [-Integer(5)]], Integer(3), [Integer(3),Integer(1),
↪Integer(1)]).to_list()
[[-1, -1, -1, 2], [-2], [-3]]
```

to_standard_list()

Return the underlying standard strong tableau as a list of lists.

Internally, for a strong tableau the standard strong tableau and its weight is stored separately. This method returns the underlying standard part.

OUTPUT: list of lists of integers or None

EXAMPLES:

```
sage: StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1]).to_standard_
↪list()
[[-1, -2, -3, 4], [-4], [-5]]
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
↪3], [3], [3], [3]], 4).to_standard_list()
[[None, None, -2, -4], [None, None], [-1, -3], [2, 4], [-5], [5], [5], [5]]
```

```
>>> from sage.all import *
>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-
↪Integer(4)], [-Integer(5)]], Integer(3), [Integer(3),Integer(1),
↪Integer(1)]).to_standard_list()
[[-1, -2, -3, 4], [-4], [-5]]
>>> StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None], [-
↪Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4)).to_standard_list()
[[None, None, -2, -4], [None, None], [-1, -3], [2, 4], [-5], [5], [5], [5]]
```

to_standard_tableau()

Return the underlying standard strong tableau as a `StrongTableau` object.

Internally, for a strong tableau the standard strong tableau and its weight is stored separately. This method returns the underlying standard part as a `StrongTableau`.

OUTPUT: a strong tableau with standard weight

EXAMPLES:

```
sage: T = StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1])
sage: T.to_standard_tableau()
[[-1, -2, -3, 4], [-4], [-5]]
sage: T.to_standard_tableau() == T.to_standard_list()
False
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
↪3], [3], [3], [3]], 4).to_standard_tableau()
[[None, None, -2, -4], [None, None], [-1, -3], [2, 4], [-5], [5], [5], [5]]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-
↪Integer(4)], [-Integer(5)]], Integer(3), [Integer(3),Integer(1),Integer(1)])
>>> T.to_standard_tableau()
[[-1, -2, -3, 4], [-4], [-5]]
>>> T.to_standard_tableau() == T.to_standard_list()
False
>>> StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None], [-
↪Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4)).to_standard_tableau()
[[None, None, -2, -4], [None, None], [-1, -3], [2, 4], [-5], [5], [5], [5]]
```

to_transposition_sequence()

Return a list of transpositions corresponding to `self`.

Given a strong column strict tableau `self` returns the list of transpositions which when applied to the left of an empty tableau gives the corresponding strong standard tableau.

OUTPUT: list of pairs of values `[i,j]` representing the transpositions t_{ij}

EXAMPLES:

```
sage: T = StrongTableau([[-1, -1, -1], [1]],2)
sage: T.to_transposition_sequence()
[[2, 3], [1, 2], [0, 1]]
sage: T = StrongTableau([[-1, -1, 2], [-2]],2)
sage: T.to_transposition_sequence()
[[-1, 0], [1, 2], [0, 1]]
sage: T = StrongTableau([[None, -1, 2, -3], [-2, 3]],2)
sage: T.to_transposition_sequence()
[[3, 4], [-1, 0], [1, 2]]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1), -Integer(1), -Integer(1)], [Integer(1)]],
↪Integer(2))
>>> T.to_transposition_sequence()
[[2, 3], [1, 2], [0, 1]]
```

(continues on next page)

(continued from previous page)

```
>>> T = StrongTableau([[-Integer(1), -Integer(1), Integer(2)], [-Integer(2)]],
↪Integer(2))
>>> T.to_transposition_sequence()
[[-1, 0], [1, 2], [0, 1]]
>>> T = StrongTableau([[None, -Integer(1), Integer(2), -Integer(3)], [-
↪Integer(2), Integer(3)]],Integer(2))
>>> T.to_transposition_sequence()
[[3, 4], [-1, 0], [1, 2]]
```

to_unmarked_list()

Return the tableau as a list of lists with markings removed.

Return the list of lists of the rows of the tableau where the markings have been removed.

OUTPUT: list of lists of integers or `None`

EXAMPLES:

```
sage: T = StrongTableau( [[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1])
sage: T.to_unmarked_list()
[[1, 1, 1, 2], [2], [3]]
sage: TT = T.set_weight([2,1,1,1])
sage: TT.to_unmarked_list()
[[1, 1, 2, 3], [3], [4]]
sage: StrongTableau( [[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
↪3], [3], [3], [3]], 4).to_unmarked_list()
[[None, None, 1, 2], [None, None], [1, 2], [1, 2], [3], [3], [3], [3]]
```

```
>>> from sage.all import *
>>> T = StrongTableau( [[-Integer(1), -Integer(2), -Integer(3), Integer(4)],␣
↪[-Integer(4)], [-Integer(5)]], Integer(3), [Integer(3),Integer(1),
↪Integer(1)])
>>> T.to_unmarked_list()
[[1, 1, 1, 2], [2], [3]]
>>> TT = T.set_weight([Integer(2),Integer(1),Integer(1),Integer(1)])
>>> TT.to_unmarked_list()
[[1, 1, 2, 3], [3], [4]]
>>> StrongTableau( [[None, None, -Integer(1), -Integer(2)], [None, None], [-
↪Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4)).to_unmarked_list()
[[None, None, 1, 2], [None, None], [1, 2], [1, 2], [3], [3], [3], [3]]
```

to_unmarked_standard_list()

Return the standard part of the tableau as a list of lists with markings removed.

Return the list of lists of the rows of the tableau where the markings have been removed.

OUTPUT: list of lists of integers or `None`

EXAMPLES:

```
sage: StrongTableau( [[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1]).to_unmarked_
↪standard_list()
[[1, 2, 3, 4], [4], [5]]
sage: StrongTableau( [[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
```

(continues on next page)

(continued from previous page)

```
↪3], [3], [3], [3]], 4).to_unmarked_standard_list()
[[None, None, 2, 4], [None, None], [1, 3], [2, 4], [5], [5], [5], [5]]
```

```
>>> from sage.all import *
>>> StrongTableau( [[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-
↪Integer(4)], [-Integer(5)]], Integer(3), [Integer(3),Integer(1),
↪Integer(1)]).to_unmarked_standard_list()
[[1, 2, 3, 4], [4], [5]]
>>> StrongTableau( [[None, None, -Integer(1), -Integer(2)], [None, None], [-
↪Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4)).to_unmarked_standard_
↪list()
[[None, None, 2, 4], [None, None], [1, 3], [2, 4], [5], [5], [5], [5]]
```

weight()

Return the weight of the tableau.

The weight is a list of nonnegative integers indicating the number of 1s, number of 2s, number of 3s, etc.

OUTPUT: list of nonnegative integers

EXAMPLES:

```
sage: T = StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3); T.weight()
(1, 1, 1, 1, 1)
sage: T.set_weight([3,1,1]).weight()
(3, 1, 1)
sage: StrongTableau([[-1,-1,-2,-3],[-2,3,-3,4],[2,3],[-3,-4]], 3).weight()
(2, 2, 3, 1)
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-
↪Integer(4)], [-Integer(5)]], Integer(3)); T.weight()
(1, 1, 1, 1, 1)
>>> T.set_weight([Integer(3),Integer(1),Integer(1)]).weight()
(3, 1, 1)
>>> StrongTableau([[-Integer(1),-Integer(1),-Integer(2),-Integer(3)],[-
↪Integer(2),Integer(3),-Integer(3),Integer(4)],[Integer(2),Integer(3)],[-
↪Integer(3),-Integer(4)]], Integer(3)).weight()
(2, 2, 3, 1)
```

class sage.combinat.k_tableau.**StrongTableaux**(*k*, *shape*, *weight*)

Bases: UniqueRepresentation, Parent

Element

alias of *StrongTableau*

classmethod add_marking(*unmarkedT*, *marking*, *k*, *weight*)

Add markings to a partially marked strong tableau.

Given a partially marked standard tableau and a list of cells where the marks should be placed along with a weight, return the semi-standard marked strong tableau. The marking should complete the marking so that the result is a strong standard marked tableau.

INPUT:

- `unmarkedT` – list of lists which is a partially marked strong k-tableau
- `marking` – list of pairs of coordinates where cells are to be marked
- `k` – positive integer
- `weight` – tuple of the weight of the output tableau

OUTPUT: a `StrongTableau` object

EXAMPLES:

```
sage: StrongTableaux.add_marking([[None,1,2],[2]], [(0,1), (1,0)], 2, [1,1])
[[None, -1, 2], [-2]]
sage: StrongTableaux.add_marking([[None,1,2],[2]], [(0,1), (1,0)], 2, [2])
Traceback (most recent call last):
...
ValueError: The weight=(2,) and the markings on the standard tableau=[[None, -
↪1, 2], [-2]] do not agree.
sage: StrongTableaux.add_marking([[None,1,2],[2]], [(0,1), (0,2)], 2, [2])
[[None, -1, -1], [1]]
```

```
>>> from sage.all import *
>>> StrongTableaux.add_marking([[None,Integer(1),Integer(2)],[Integer(2)]],
↪[(Integer(0),Integer(1)), (Integer(1),Integer(0))], Integer(2), [Integer(1),
↪Integer(1)])
[[None, -1, 2], [-2]]
>>> StrongTableaux.add_marking([[None,Integer(1),Integer(2)],[Integer(2)]],
↪[(Integer(0),Integer(1)), (Integer(1),Integer(0))], Integer(2),
↪[Integer(2)])
Traceback (most recent call last):
...
ValueError: The weight=(2,) and the markings on the standard tableau=[[None, -
↪1, 2], [-2]] do not agree.
>>> StrongTableaux.add_marking([[None,Integer(1),Integer(2)],[Integer(2)]],
↪[(Integer(0),Integer(1)), (Integer(0),Integer(2))], Integer(2),
↪[Integer(2)])
[[None, -1, -1], [1]]
```

an_element()

Return the first generated element of the class of `StrongTableaux`.

EXAMPLES:

```
sage: ST = StrongTableaux(3, [3], weight=[3])
sage: ST.an_element()
[[-1, -1, -1]]
```

```
>>> from sage.all import *
>>> ST = StrongTableaux(Integer(3), [Integer(3)], weight=[Integer(3)])
>>> ST.an_element()
[[-1, -1, -1]]
```

classmethod cells_head_dictionary(T)

Return a dictionary with the locations of the heads of all markings.

Return a dictionary of values and lists of cells where the heads with the values are located in a strong standard unmarked tableau `T`.

INPUT:

- `T` – a strong standard unmarked tableau as a list of lists

OUTPUT:

- a dictionary with keys the entries in the tableau and values are the coordinates of the heads with those entries

EXAMPLES:

```
sage: StrongTableaux.cells_head_dictionary([[1,2,4,7],[3,6,6,8],[4,7],[5,8]])
{1: [(0, 0)],
 2: [(0, 1)],
 3: [(1, 0)],
 4: [(2, 0), (0, 2)],
 5: [(3, 0)],
 6: [(1, 2)],
 7: [(2, 1), (0, 3)],
 8: [(3, 1), (1, 3)]}
sage: StrongTableaux.cells_head_dictionary([[None, 2, 2, 4, 5, 6, 6, 6],
↪[None, 3, 6, 6, 6], [1, 4]])
{1: [(2, 0)],
 2: [(0, 2)],
 3: [(1, 1)],
 4: [(2, 1), (0, 3)],
 5: [(0, 4)],
 6: [(1, 4), (0, 7)]}
```

```
>>> from sage.all import *
>>> StrongTableaux.cells_head_dictionary([[Integer(1),Integer(2),Integer(4),
↪Integer(7)],[Integer(3),Integer(6),Integer(6),Integer(8)],[Integer(4),
↪Integer(7)],[Integer(5),Integer(8)]])
{1: [(0, 0)],
 2: [(0, 1)],
 3: [(1, 0)],
 4: [(2, 0), (0, 2)],
 5: [(3, 0)],
 6: [(1, 2)],
 7: [(2, 1), (0, 3)],
 8: [(3, 1), (1, 3)]}
>>> StrongTableaux.cells_head_dictionary([[None, Integer(2), Integer(2),
↪Integer(4), Integer(5), Integer(6), Integer(6), Integer(6)], [None,
↪Integer(3), Integer(6), Integer(6), Integer(6)], [Integer(1), Integer(4)]])
{1: [(2, 0)],
 2: [(0, 2)],
 3: [(1, 1)],
 4: [(2, 1), (0, 3)],
 5: [(0, 4)],
 6: [(1, 4), (0, 7)]}
```

classmethod follows_tableau_unsigned_standard(*Tlist*, *k*)

Return a list of strong tableaux one longer in length than `Tlist`.

Return list of all standard strong tableaux obtained from `Tlist` by extending to a core which follows the shape of `Tlist` in the strong order. It does not put the markings on the last entry that it adds but it does keep the markings on all entries smaller. The objects returned are not `StrongTableau` objects (and cannot be) because the last entry will not properly marked.

INPUT:

- `Tlist` – a filling of a $k+1$-core as a list of lists
- `k` – integer

OUTPUT: list of strong tableaux which follow `Tlist` in strong order

EXAMPLES:

```
sage: StrongTableaux.follows_tableau_unsigned_standard([[-1, -1, -2, -3], [-2,
↪ 3, -3, 4], [2, 3], [-3, -4]], 3)
[[[-1, -1, -2, -3, 5, 5, 5], [-2, 3, -3, 4], [2, 3], [-3, -4]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [5]],
 [[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4], [5], [5], [5]]]
sage: StrongTableaux.follows_tableau_unsigned_standard([[None,-1],[-2,-3]],3)
[[[None, -1, 4, 4, 4], [-2, -3]], [[None, -1, 4], [-2, -3], [4]],
 [[None, -1], [-2, -3], [4], [4], [4]]]
```

```
>>> from sage.all import *
>>> StrongTableaux.follows_tableau_unsigned_standard([[-Integer(1), -
↪Integer(1), -Integer(2), -Integer(3)], [-Integer(2), Integer(3), -
↪Integer(3), Integer(4)], [Integer(2), Integer(3)], [-Integer(3), -
↪Integer(4)]], Integer(3))
[[[-1, -1, -2, -3, 5, 5, 5], [-2, 3, -3, 4], [2, 3], [-3, -4]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [5]],
 [[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4], [5], [5], [5]]]
>>> StrongTableaux.follows_tableau_unsigned_standard([[None,-Integer(1)],[-
↪Integer(2),-Integer(3)]],Integer(3))
[[[None, -1, 4, 4, 4], [-2, -3]], [[None, -1, 4], [-2, -3], [4]],
 [[None, -1], [-2, -3], [4], [4], [4]]]
```

inner_shape()

Return the inner shape of the class of strong tableaux.

OUTPUT: a $k+1$-core

EXAMPLES:

```
sage: StrongTableaux( 2, [3,1] ).inner_shape()
[]
sage: type(StrongTableaux( 2, [3,1] ).inner_shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: StrongTableaux( 4, [[2,1], [1]] ).inner_shape()
[1]
```

```
>>> from sage.all import *
>>> StrongTableaux( Integer(2), [Integer(3),Integer(1)] ).inner_shape()
[]
>>> type(StrongTableaux( Integer(2), [Integer(3),Integer(1)] ).inner_shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
```

(continues on next page)

(continued from previous page)

```
>>> StrongTableaux( Integer(4), [[Integer(2),Integer(1)], [Integer(1)]] ).
↪inner_shape()
[1]
```

classmethod marked_CST_to_transposition_sequence(T, k)

Return a list of transpositions corresponding to `T`.

Given a strong column strict tableau `T` returns the list of transpositions which when applied to the left of an empty tableau gives the corresponding strong standard tableau.

INPUT:

- `T` – a non-empty column strict tableau as a list of lists
- `k` – positive integer

OUTPUT: list of pairs of values `[i,j]` representing the transpositions t_{ij}

EXAMPLES:

```
sage: CST_to_trans = StrongTableaux.marked_CST_to_transposition_sequence
sage: CST_to_trans([[-1, -1, -1], [1]], 2)
[[2, 3], [1, 2], [0, 1]]
sage: CST_to_trans([], 2)
[]
sage: CST_to_trans([[-2, -2, -2], [2]], 2)
[[2, 3], [1, 2], [0, 1]]
sage: CST_to_trans([[-1, -2, -2, -2, -2], [-2, 2], [2]], 3)
[[4, 5], [3, 4], [2, 3], [1, 2], [-1, 0], [0, 1]]
sage: CST_to_trans([[-1, -2, -5, 5, -5, 5, -5], [-3, -4, 5, 5], [5]],3)
[[5, 7], [3, 5], [2, 3], [0, 1], [-1, 0], [1, 2], [0, 1]]
sage: CST_to_trans([[-1, -2, -3, 4, -7], [-4, -6], [-5, 6]],3)
[[4, 5], [-1, 1], [-2, -1], [-1, 0], [2, 3], [1, 2], [0, 1]]
```

```
>>> from sage.all import *
>>> CST_to_trans = StrongTableaux.marked_CST_to_transposition_sequence
>>> CST_to_trans([[-Integer(1), -Integer(1), -Integer(1)], [Integer(1)]],␣
↪Integer(2))
[[2, 3], [1, 2], [0, 1]]
>>> CST_to_trans([], Integer(2))
[]
>>> CST_to_trans([[-Integer(2), -Integer(2), -Integer(2)], [Integer(2)]],␣
↪Integer(2))
[[2, 3], [1, 2], [0, 1]]
>>> CST_to_trans([[-Integer(1), -Integer(2), -Integer(2), -Integer(2), -
↪Integer(2)], [-Integer(2), Integer(2)], [Integer(2)]], Integer(3))
[[4, 5], [3, 4], [2, 3], [1, 2], [-1, 0], [0, 1]]
>>> CST_to_trans([[-Integer(1), -Integer(2), -Integer(5), Integer(5), -
↪Integer(5), Integer(5), -Integer(5)], [-Integer(3), -Integer(4), Integer(5),
↪ Integer(5)], [Integer(5)]],Integer(3))
[[5, 7], [3, 5], [2, 3], [0, 1], [-1, 0], [1, 2], [0, 1]]
>>> CST_to_trans([[-Integer(1), -Integer(2), -Integer(3), Integer(4), -
↪Integer(7)], [-Integer(4), -Integer(6)], [-Integer(5), Integer(6)]],
↪Integer(3))
[[4, 5], [-1, 1], [-2, -1], [-1, 0], [2, 3], [1, 2], [0, 1]]
```

classmethod marked_given_unmarked_and_weight_iterator(*unmarkedT*, *k*, *weight*)

An iterator generating strong marked tableaux from an unmarked strong tableau.

Iterator which lists all marked tableaux of weight `weight` such that the standard unmarked part of the tableau is equal to `unmarkedT`.

INPUT:

- `unmarkedT` – list of lists representing a strong unmarked tableau
- `k` – positive integer
- `weight` – list of nonnegative integers indicating the weight

OUTPUT: an iterator that returns `StrongTableau` objects

EXAMPLES:

```
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[1,2,3],
↪[3]], 2, [3])
sage: list(ST)
[[[-1, -1, -1], [1]]]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[1,2,3],
↪[3]], 2, [0,3])
sage: list(ST)
[[[-2, -2, -2], [2]]]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[1,2,3],
↪[3]], 2, [1,2])
sage: list(ST)
[[[-1, -2, -2], [2]]]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[1,2,3],
↪[3]], 2, [2,1])
sage: list(ST)
[[[-1, -1, 2], [-2]], [[-1, -1, -2], [2]]]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[None,␣
↪None, 1, 2, 4], [2, 4], [3]], 3, [3,1])
sage: list(ST)
[]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[None,␣
↪None, 1, 2, 4], [2, 4], [3]], 3, [2,2])
sage: list(ST)
[[[None, None, -1, -1, 2], [1, -2], [-2]],
 [[None, None, -1, -1, -2], [1, 2], [-2]]]
```

```
>>> from sage.all import *
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_
↪iterator([[Integer(1),Integer(2),Integer(3)],[Integer(3)]], Integer(2),␣
↪[Integer(3)])
>>> list(ST)
[[[-1, -1, -1], [1]]]
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_
↪iterator([[Integer(1),Integer(2),Integer(3)],[Integer(3)]], Integer(2),␣
↪[Integer(0),Integer(3)])
>>> list(ST)
[[[-2, -2, -2], [2]]]
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_
```

(continues on next page)

(continued from previous page)

```
↪iterator([[Integer(1),Integer(2),Integer(3)],[Integer(3)]], Integer(2),␣
↪[Integer(1),Integer(2)])
>>> list(ST)
[[[-1, -2, -2], [2]]]
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_
↪iterator([[Integer(1),Integer(2),Integer(3)],[Integer(3)]], Integer(2),␣
↪[Integer(2),Integer(1)])
>>> list(ST)
[[[-1, -1, 2], [-2]], [[-1, -1, -2], [2]]]
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[None,␣
↪None, Integer(1), Integer(2), Integer(4)], [Integer(2), Integer(4)],␣
↪[Integer(3)]], Integer(3), [Integer(3),Integer(1)])
>>> list(ST)
[]
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[None,␣

```

options = Current options for Tableaux - ascii_art: repr - convention: English - display: list - latex: diagram

outer_shape()

Return the outer shape of the class of strong tableaux.

OUTPUT: a $k + 1$-core

EXAMPLES:

```
sage: StrongTableaux( 2, [3,1] ).outer_shape()
[3, 1]
sage: type(StrongTableaux( 2, [3,1] ).outer_shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: StrongTableaux( 4, [[2,1], [1]] ).outer_shape()
[2, 1]
```

```
>>> from sage.all import *
>>> StrongTableaux( Integer(2), [Integer(3),Integer(1)] ).outer_shape()
[3, 1]
>>> type(StrongTableaux( Integer(2), [Integer(3),Integer(1)] ).outer_shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
>>> StrongTableaux( Integer(4), [[Integer(2),Integer(1)], [Integer(1)]] ).
↪outer_shape()
[2, 1]
```

shape()

Return the shape of `self`.

If the `self` has an inner shape return a pair consisting of an inner and an outer shape. If the inner shape is empty then return only the outer shape.

OUTPUT: a $k + 1$-core or a pair of $k + 1$-cores

EXAMPLES:

```
sage: StrongTableaux( 2, [3,1] ).shape()
[3, 1]
sage: type(StrongTableaux( 2, [3,1] ).shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: StrongTableaux( 4, [[2,1], [1]] ).shape()
([2, 1], [1])
```

```
>>> from sage.all import *
>>> StrongTableaux( Integer(2), [Integer(3),Integer(1)] ).shape()
[3, 1]
>>> type(StrongTableaux( Integer(2), [Integer(3),Integer(1)] ).shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
>>> StrongTableaux( Integer(4), [[Integer(2),Integer(1)], [Integer(1)]] ).
→shape()
([2, 1], [1])
```

classmethod standard_marked_iterator(*k*, *size*, *outer_shape=None*, *inner_shape=[]*)

An iterator for generating standard strong marked tableaux.

An iterator which generates all standard marked k-tableaux of a given `size` which are contained in `outer_shape` and contain the `inner_shape`. If `outer_shape` is `None` then there is no restriction on the shape of the tableaux which are created.

INPUT:

- `k` – positive integer
- `size` – positive integer
- `outer_shape` – list which is a $k + 1$-core (default: `None`)
- `inner_shape` – list which is a $k + 1$-core (default: `[]`)

OUTPUT:

- an iterator which returns the standard marked tableaux with `size` cells and that are contained in `outer_shape` and contain `inner_shape`

EXAMPLES:

```
sage: list(StrongTableaux.standard_marked_iterator(2, 3))
[[[-1, -2, 3], [-3]], [[-1, -2, -3], [3]], [[-1, -2], [-3], [3]], [[-1, 3, -
→3], [-2]], [[-1, 3], [-2], [-3]], [[-1, -3], [-2], [3]]]
sage: list(StrongTableaux.standard_marked_iterator(2, 1, inner_shape=[1,1]))
[[[None, 1, -1], [None]], [[None, 1], [None], [-1]], [[None, -1], [None],
→[1]]]
sage: len(list(StrongTableaux.standard_marked_iterator(4,4)))
10
sage: len(list(StrongTableaux.standard_marked_iterator(4,6)))
140
sage: len(list(StrongTableaux.standard_marked_iterator(4,4, inner_shape=[2,
→2])))
200
sage: len(list(StrongTableaux.standard_marked_iterator(4,4, outer_shape=[5,2,
→2,1], inner_shape=[2,2])))
24
```

```
>>> from sage.all import *
>>> list(StrongTableaux.standard_marked_iterator(Integer(2), Integer(3)))
[[[-1, -2, 3], [-3]], [[-1, -2, -3], [3]], [[-1, -2], [-3], [3]], [[-1, 3, -
↪3], [-2]], [[-1, 3], [-2], [-3]], [[-1, -3], [-2], [3]]]
>>> list(StrongTableaux.standard_marked_iterator(Integer(2), Integer(1),␣
↪inner_shape=[Integer(1),Integer(1)]))
[[[None, 1, -1], [None]], [[None, 1], [None], [-1]], [[None, -1], [None],␣
↪[1]]]
>>> len(list(StrongTableaux.standard_marked_iterator(Integer(4),Integer(4))))
10
>>> len(list(StrongTableaux.standard_marked_iterator(Integer(4),Integer(6))))
140
>>> len(list(StrongTableaux.standard_marked_iterator(Integer(4),Integer(4),␣
↪inner_shape=[Integer(2),Integer(2)])))
200
>>> len(list(StrongTableaux.standard_marked_iterator(Integer(4),Integer(4),␣
↪outer_shape=[Integer(5),Integer(2),Integer(2),Integer(1)], inner_
↪shape=[Integer(2),Integer(2)])))
24
```

classmethod standard_unmarked_iterator(*k*, *size*, *outer_shape=None*, *inner_shape=[]*)

An iterator for standard unmarked strong tableaux.

An iterator which generates all unmarked tableaux of a given `size` which are contained in `outer_shape` and which contain the `inner_shape`.

These are built recursively by building all standard marked strong tableaux of size `size` -1 and adding all possible covers.

If `outer_shape` is `None` then there is no restriction on the shape of the tableaux which are created.

INPUT:

- `k`, `size` – positive integers
- `outer_shape` – list representing a $k+1$-core (default: `None`)
- `inner_shape` – list representing a $k+1$-core (default: `[]`)

OUTPUT:

- an iterator which lists all standard strong unmarked tableaux with `size` cells and which are contained in `outer_shape` and contain `inner_shape`

EXAMPLES:

```
sage: list(StrongTableaux.standard_unmarked_iterator(2, 3))
[[[1, 2, 3], [3]], [[1, 2], [3], [3]], [[1, 3, 3], [2]], [[1, 3], [2], [3]]]
sage: list(StrongTableaux.standard_unmarked_iterator(2, 1, inner_shape=[1,1]))
[[[None, 1, 1], [None]], [[None, 1], [None], [1]]]
sage: len(list(StrongTableaux.standard_unmarked_iterator(4,4)))
10
sage: len(list(StrongTableaux.standard_unmarked_iterator(4,6)))
98
sage: len(list(StrongTableaux.standard_unmarked_iterator(4,4, inner_shape=[2,
↪2])))
92
sage: len(list(StrongTableaux.standard_unmarked_iterator(4,4, outer_shape=[5,
```

(continues on next page)

(continued from previous page)

```
↪2,2,1], inner_shape=[2,2])))
10
```

```
>>> from sage.all import *
>>> list(StrongTableaux.standard_unmarked_iterator(Integer(2), Integer(3)))
[[[1, 2, 3], [3]], [[1, 2], [3], [3]], [[1, 3, 3], [2]], [[1, 3], [2], [3]]]
>>> list(StrongTableaux.standard_unmarked_iterator(Integer(2), Integer(1),␣
↪inner_shape=[Integer(1),Integer(1)]))
[[[None, 1, 1], [None]], [[None, 1], [None], [1]]]
>>> len(list(StrongTableaux.standard_unmarked_iterator(Integer(4),
↪Integer(4))))
10
>>> len(list(StrongTableaux.standard_unmarked_iterator(Integer(4),
↪Integer(6))))
98
>>> len(list(StrongTableaux.standard_unmarked_iterator(Integer(4),Integer(4),␣
↪inner_shape=[Integer(2),Integer(2)])))
92
>>> len(list(StrongTableaux.standard_unmarked_iterator(Integer(4),Integer(4),␣
↪outer_shape=[Integer(5),Integer(2),Integer(2),Integer(1)], inner_
↪shape=[Integer(2),Integer(2)])))
10
```

classmethod transpositions_to_standard_strong(*transeq*, *k*, *emptyTableau=[]*)

Return a strong tableau corresponding to a sequence of transpositions.

This method returns the action by left multiplication on the empty strong tableau by transpositions specified by `transeq`.

INPUT:

- `transeq` – a sequence of transpositions t_{ij} (a list of pairs)
- `emptyTableau` – (default: `[]`) an empty list or a skew strong tableau possibly consisting of `None` entries

OUTPUT: a `StrongTableau` object

EXAMPLES:

```
sage: StrongTableaux.transpositions_to_standard_strong([[0,1]], 2)
[[-1]]
sage: StrongTableaux.transpositions_to_standard_strong([[-2,-1], [2,3]], 2,␣
↪[[None, None]])
[[None, None, -1], [1], [-2]]
sage: StrongTableaux.transpositions_to_standard_strong([[2, 3], [1, 2], [0,␣
↪1]], 2)
[[-1, -2, -3], [3]]
sage: StrongTableaux.transpositions_to_standard_strong([[-1, 0], [1, 2], [0,␣
↪1]], 2)
[[-1, -2, 3], [-3]]
sage: StrongTableaux.transpositions_to_standard_strong([[3, 4], [-1, 0], [1,␣
↪2]], 2, [[None]])
[[None, -1, 2, -3], [-2, 3]]
```

```
>>> from sage.all import *
>>> StrongTableaux.transpositions_to_standard_strong([[Integer(0),
↪Integer(1)]], Integer(2))
[[-1]]
>>> StrongTableaux.transpositions_to_standard_strong([[-Integer(2),-
↪Integer(1)], [Integer(2),Integer(3)]], Integer(2), [[None, None]])
[[None, None, -1], [1], [-2]]
>>> StrongTableaux.transpositions_to_standard_strong([[Integer(2),
↪Integer(3)], [Integer(1), Integer(2)], [Integer(0), Integer(1)]],
↪Integer(2))
[[-1, -2, -3], [3]]
>>> StrongTableaux.transpositions_to_standard_strong([[-Integer(1),
↪Integer(0)], [Integer(1), Integer(2)], [Integer(0), Integer(1)]],
↪Integer(2))
[[-1, -2, 3], [-3]]
>>> StrongTableaux.transpositions_to_standard_strong([[Integer(3),
↪Integer(4)], [-Integer(1), Integer(0)], [Integer(1), Integer(2)]],
↪Integer(2), [[None]])
[[None, -1, 2, -3], [-2, 3]]
```

`sage.combinat.k_tableau.`**`WeakTableau`**`(`*t*, *k*, *inner_shape=[]*, *representation='core'*`)`

This is the dispatcher method for the element class of weak k-tableaux.

Standard weak k-tableaux correspond to saturated chains in the weak order. There are three formulations of weak tableaux, one in terms of cores, one in terms of k-bounded partitions, and one in terms of factorizations of affine Grassmannian elements. For semistandard weak k-tableaux, all letters of the same value have to satisfy the conditions of a horizontal strip. In the affine Grassmannian formulation this means that all factors are cyclically decreasing elements. For more information, see for example [LLMSSZ2013].

INPUT:

- `t` – a weak k-tableau in the specified representation:
  - for the 'core' representation `t` is a list of lists where each subtableaux should have a $k + 1$-core shape; `None` is allowed as an entry for skew weak k-tableaux
  - for the 'bounded' representation `t` is a list of lists where each subtableaux should have a k-bounded shape; `None` is allowed as an entry for skew weak k-tableaux
  - for the 'factorized_permutation' representation `t` is either a list of cyclically decreasing Weyl group elements or a list of reduced words of cyclically decreasing Weyl group elements; to indicate a skew tableau in this representation, `inner_shape` should be the inner shape as a $(k + 1)$-core
- `k` – positive integer
- `inner_shape` – this entry is only relevant for the 'factorized_permutation' representation and specifies the inner shape in case the tableau is skew (default: `[]`)
- `representation` – 'core', 'bounded', or 'factorized_permutation' (default: `'core'`)

EXAMPLES:

Here is an example of a weak 3-tableau in core representation:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.shape()
[5, 2, 1]
sage: t.weight()
```

(continues on next page)

(continued from previous page)

```
(2, 2, 2)
sage: type(t)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2), Integer(3)],
↪ [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> t.shape()
[5, 2, 1]
>>> t.weight()
(2, 2, 2)
>>> type(t)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
```

And now we give a skew weak 3-tableau in core representation:

```
sage: ts = WeakTableau([[None, 1, 1, 2, 2], [None, 2], [1]], 3)
sage: ts.shape()
([5, 2, 1], [1, 1])
sage: ts.weight()
(2, 2)
sage: type(ts)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
```

```
>>> from sage.all import *
>>> ts = WeakTableau([[None, Integer(1), Integer(1), Integer(2), Integer(2)],
↪[None, Integer(2)], [Integer(1)]], Integer(3))
>>> ts.shape()
([5, 2, 1], [1, 1])
>>> ts.weight()
(2, 2)
>>> type(ts)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
```

Next we create the analogue of the first example in bounded representation:

```
sage: tb = WeakTableau([[1,1,2],[2,3],[3]], 3, representation='bounded')
sage: tb.shape()
[3, 2, 1]
sage: tb.weight()
(2, 2, 2)
sage: type(tb)
<class 'sage.combinat.k_tableau.WeakTableaux_bounded_with_category.element_class'>
sage: tb.to_core_tableau()
[[1, 1, 2, 2, 3], [2, 3], [3]]
sage: t == tb.to_core_tableau()
True
```

```
>>> from sage.all import *
>>> tb = WeakTableau([[Integer(1),Integer(1),Integer(2)],[Integer(2),Integer(3)],
↪[Integer(3)]], Integer(3), representation='bounded')
>>> tb.shape()
```

(continues on next page)

(continued from previous page)

```
[3, 2, 1]
>>> tb.weight()
(2, 2, 2)
>>> type(tb)
<class 'sage.combinat.k_tableau.WeakTableaux_bounded_with_category.element_class'>
>>> tb.to_core_tableau()
[[1, 1, 2, 2, 3], [2, 3], [3]]
>>> t == tb.to_core_tableau()
True
```

And the analogue of the skew example in bounded representation:

```
sage: tbs = WeakTableau([[None, 1, 2], [None, 2], [1]], 3, representation =
↪"bounded")
sage: tbs.shape()
([3, 2, 1], [1, 1])
sage: tbs.weight()
(2, 2)
sage: tbs.to_core_tableau()
[[None, 1, 1, 2, 2], [None, 2], [1]]
sage: ts.to_bounded_tableau() == tbs
True
```

```
>>> from sage.all import *
>>> tbs = WeakTableau([[None, Integer(1), Integer(2)], [None, Integer(2)],
↪[Integer(1)]], Integer(3), representation = "bounded")
>>> tbs.shape()
([3, 2, 1], [1, 1])
>>> tbs.weight()
(2, 2)
>>> tbs.to_core_tableau()
[[None, 1, 1, 2, 2], [None, 2], [1]]
>>> ts.to_bounded_tableau() == tbs
True
```

Finally we do the same examples for the factorized permutation representation:

```
sage: tf = WeakTableau([[2,0],[3,2],[1,0]], 3, representation = "factorized_
↪permutation")
sage: tf.shape()
[5, 2, 1]
sage: tf.weight()
(2, 2, 2)
sage: type(tf)
<class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_category.
↪element_class'>
sage: tf.to_core_tableau() == t
True

sage: tfs = WeakTableau([[0,3],[2,1]], 3, inner_shape = [1,1], representation =
↪'factorized_permutation')
sage: tfs.shape()
```

(continues on next page)

(continued from previous page)

```
([5, 2, 1], [1, 1])
sage: tfs.weight()
(2, 2)
sage: type(tfs)
<class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_category.
↪element_class'>
sage: tfs.to_core_tableau()
[[None, 1, 1, 2, 2], [None, 2], [1]]
```

```
>>> from sage.all import *
>>> tf = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)],[Integer(1),
↪Integer(0)]], Integer(3), representation = "factorized_permutation")
>>> tf.shape()
[5, 2, 1]
>>> tf.weight()
(2, 2, 2)
>>> type(tf)
<class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_category.
↪element_class'>
>>> tf.to_core_tableau() == t
True

>>> tfs = WeakTableau([[Integer(0),Integer(3)],[Integer(2),Integer(1)]],
↪Integer(3), inner_shape = [Integer(1),Integer(1)], representation = 'factorized_
↪permutation')
>>> tfs.shape()
([5, 2, 1], [1, 1])
>>> tfs.weight()
(2, 2)
>>> type(tfs)
<class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_category.
↪element_class'>
>>> tfs.to_core_tableau()
[[None, 1, 1, 2, 2], [None, 2], [1]]
```

Another way to pass from one representation to another is as follows:

```
sage: ts
[[None, 1, 1, 2, 2], [None, 2], [1]]
sage: ts.parent()._representation
'core'
sage: ts.representation('bounded')
[[None, 1, 2], [None, 2], [1]]
```

```
>>> from sage.all import *
>>> ts
[[None, 1, 1, 2, 2], [None, 2], [1]]
>>> ts.parent()._representation
'core'
>>> ts.representation('bounded')
[[None, 1, 2], [None, 2], [1]]
```

To test whether a given semistandard tableau is a weak k-tableau in the bounded representation, one can ask:

```
sage: t = Tableau([[1,1,2],[2,3],[3]])
sage: t.is_k_tableau(3)
True
sage: t = SkewTableau([[None, 1, 2], [None, 2], [1]])
sage: t.is_k_tableau(3)
True
sage: t = SkewTableau([[None, 1, 1], [None, 2], [2]])
sage: t.is_k_tableau(3)
False
```

```
>>> from sage.all import *
>>> t = Tableau([[Integer(1),Integer(1),Integer(2)],[Integer(2),Integer(3)],
↪[Integer(3)]])
>>> t.is_k_tableau(Integer(3))
True
>>> t = SkewTableau([[None, Integer(1), Integer(2)], [None, Integer(2)],␣
↪[Integer(1)]])
>>> t.is_k_tableau(Integer(3))
True
>>> t = SkewTableau([[None, Integer(1), Integer(1)], [None, Integer(2)],␣
↪[Integer(2)]])
>>> t.is_k_tableau(Integer(3))
False
```

class sage.combinat.k_tableau.**WeakTableau_abstract**

Bases: `ClonableList`

Abstract class for the various element classes of WeakTableau.

intermediate_shapes()

Return the intermediate shapes of `self`.

A (skew) tableau with letters $1, 2, \ldots, \ell$ can be viewed as a sequence of shapes, where the i-th shape is given by the shape of the subtableau on letters $1, 2, \ldots, i$. The output is the list of these shapes.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]],3)
sage: t.intermediate_shapes()
[[], [2], [4, 1], [5, 2, 1]]

sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.intermediate_shapes()
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]

sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.intermediate_shapes()
[[], [3], [3, 2], [3, 2, 1]]

sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation =
↪'bounded')
sage: t.intermediate_shapes()
[[2], [3], [3, 1], [3, 1, 1], [3, 2, 1]]
```

(continues on next page)

(continued from previous page)

```
sage: t = WeakTableau([[0],[3],[2],[3]], 3, inner_shape = [2], representation␣
↪= 'factorized_permutation')
sage: t.intermediate_shapes()
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]],Integer(3))
>>> t.intermediate_shapes()
[[], [2], [4, 1], [5, 2, 1]]

>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> t.intermediate_shapes()
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]

>>> t = WeakTableau([[Integer(1),Integer(1),Integer(1)],[Integer(2),
↪Integer(2)],[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.intermediate_shapes()
[[], [3], [3, 2], [3, 2, 1]]

>>> t = WeakTableau([[None, None, Integer(1)], [Integer(2), Integer(4)],␣
↪[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.intermediate_shapes()
[[2], [3], [3, 1], [3, 1, 1], [3, 2, 1]]

>>> t = WeakTableau([[Integer(0)],[Integer(3)],[Integer(2)],[Integer(3)]],␣
↪Integer(3), inner_shape = [Integer(2)], representation = 'factorized_
↪permutation')
>>> t.intermediate_shapes()
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]
```

pp()

Return a pretty print string of the tableau.

EXAMPLES:

```
sage: t = WeakTableau([[None, 1, 1, 2, 2], [None, 2], [1]], 3)
sage: t.pp()
.  1  1  2  2
.  2
1
sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation =
↪'factorized_permutation')
sage: t.pp()
[s2*s0, s3*s2]
```

```
>>> from sage.all import *
>>> t = WeakTableau([[None, Integer(1), Integer(1), Integer(2), Integer(2)],␣
↪[None, Integer(2)], [Integer(1)]], Integer(3))
>>> t.pp()
```

(continues on next page)

(continued from previous page)

```
.  1  1  2  2
.  2
1
>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)]],␣
↪Integer(3), inner_shape = [Integer(2)], representation = 'factorized_
↪permutation')
>>> t.pp()
[s2*s0, s3*s2]
```

representation(*representation='core'*)

Return the analogue of `self` in the specified representation.

INPUT:

- `representation` – 'core', 'bounded', or 'factorized_permutation' (default: `'core'`)

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4,␣
↪7], [5, 6], [6], [7]], 4)
sage: t.parent()._representation
'core'
sage: t.representation('bounded')
[[1, 1, 2, 4], [2, 3, 5], [3, 4], [5, 6], [6], [7]]
sage: t.representation('factorized_permutation')
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]

sage: tb = WeakTableau([[1, 1, 2, 4], [2, 3, 5], [3, 4], [5, 6], [6], [7]], 4,
↪ representation = 'bounded')
sage: tb.parent()._representation
'bounded'
sage: tb.representation('core') == t
True
sage: tb.representation('factorized_permutation')
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]

sage: tp = WeakTableau([[0],[3,1],[2,1],[0,4],[3,0],[4,2],[1,0]], 4,␣
↪representation = 'factorized_permutation')
sage: tp.parent()._representation
'factorized_permutation'
sage: tp.representation('core') == t
True
sage: tp.representation('bounded') == tb
True
```

```
>>> from sage.all import *

↪'factorized_permutation')
>>> tp.parent()._representation
'factorized_permutation'
>>> tp.representation('core') == t
True
>>> tp.representation('bounded') == tb
True
```

shape()

Return the shape of `self`.

When the tableau is straight, the outer shape is returned. When the tableau is skew, the tuple of the outer and inner shape is returned.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.shape()
[5, 2, 1]
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.shape()
([5, 2, 1], [2])

sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.shape()
[3, 2, 1]
sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation =
↪'bounded')
sage: t.shape()
([3, 2, 1], [2])

sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_
↪permutation')
sage: t.shape()
```

(continues on next page)

(continued from previous page)

```
[5, 2, 1]
sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation =
↪'factorized_permutation')
sage: t.shape()
([5, 2, 1], [2])
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> t.shape()
[5, 2, 1]
>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> t.shape()
([5, 2, 1], [2])

>>> t = WeakTableau([[Integer(1),Integer(1),Integer(1)],[Integer(2),
↪Integer(2)],[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.shape()
[3, 2, 1]
>>> t = WeakTableau([[None, None, Integer(1)], [Integer(2), Integer(4)],␣
↪[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.shape()
([3, 2, 1], [2])

>>> t = WeakTableau([[Integer(2)],[Integer(0),Integer(3)],[Integer(2),
↪Integer(1),Integer(0)]], Integer(3), representation = 'factorized_
↪permutation')
>>> t.shape()
[5, 2, 1]
>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)]],␣
↪Integer(3), inner_shape = [Integer(2)], representation = 'factorized_
↪permutation')
>>> t.shape()
([5, 2, 1], [2])
```

size()

Return the size of the shape of `self`.

In the bounded representation, the size of the shape is the number of boxes in the outer shape minus the number of boxes in the inner shape. For the core and factorized permutation representation, the size is the length of the outer shape minus the length of the inner shape.

See also

sage.combinat.core.Core.length()

EXAMPLES:

```
sage: t = WeakTableau([[None, 1, 1, 2, 2], [None, 2], [1]], 3)
sage: t.shape()
```

(continues on next page)

(continued from previous page)

```
([5, 2, 1], [1, 1])
sage: t.size()
4
sage: t = WeakTableau([[1,1,2],[2,3],[3]], 3, representation='bounded')
sage: t.shape()
[3, 2, 1]
sage: t.size()
6
```

```
>>> from sage.all import *
>>> t = WeakTableau([[None, Integer(1), Integer(1), Integer(2), Integer(2)],
↪[None, Integer(2)], [Integer(1)]], Integer(3))
>>> t.shape()
([5, 2, 1], [1, 1])
>>> t.size()
4
>>> t = WeakTableau([[Integer(1),Integer(1),Integer(2)],[Integer(2),
↪Integer(3)],[Integer(3)]], Integer(3), representation='bounded')
>>> t.shape()
[3, 2, 1]
>>> t.size()
6
```

weight()

Return the weight of `self`.

The weight is a tuple whose i-th entry is the number of labels i in the bounded representation of `self`.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.weight()
(2, 2, 2)
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.weight()
(1, 1, 1, 1)
sage: t = WeakTableau([[None,2,3],[3]],2)
sage: t.weight()
(0, 1, 1)

sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.weight()
(3, 2, 1)
sage: t = WeakTableau([[1,1,2],[2,3],[3]], 3, representation = 'bounded')
sage: t.weight()
(2, 2, 2)
sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation =
↪'bounded')
sage: t.weight()
(1, 1, 1, 1)

sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_
↪permutation')
```

(continues on next page)

(continued from previous page)

```
sage: t.weight()
(3, 2, 1)
sage: t = WeakTableau([[2,0],[3,2],[1,0]], 3, representation = 'factorized_
↪permutation')
sage: t.weight()
(2, 2, 2)
sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation =
↪'factorized_permutation')
sage: t.weight()
(2, 2)
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> t.weight()
(2, 2, 2)
>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> t.weight()
(1, 1, 1, 1)
>>> t = WeakTableau([[None,Integer(2),Integer(3)],[Integer(3)]],Integer(2))
>>> t.weight()
(0, 1, 1)

>>> t = WeakTableau([[Integer(1),Integer(1),Integer(1)],[Integer(2),
↪Integer(2)],[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.weight()
(3, 2, 1)
>>> t = WeakTableau([[Integer(1),Integer(1),Integer(2)],[Integer(2),
↪Integer(3)],[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.weight()
(2, 2, 2)
>>> t = WeakTableau([[None, None, Integer(1)], [Integer(2), Integer(4)],␣
↪[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.weight()
(1, 1, 1, 1)

>>> t = WeakTableau([[Integer(2)],[Integer(0),Integer(3)],[Integer(2),
↪Integer(1),Integer(0)]], Integer(3), representation = 'factorized_
↪permutation')
>>> t.weight()
(3, 2, 1)
>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)],
↪[Integer(1),Integer(0)]], Integer(3), representation = 'factorized_
↪permutation')
>>> t.weight()
(2, 2, 2)
>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)]],␣
↪Integer(3), inner_shape = [Integer(2)], representation = 'factorized_
↪permutation')
>>> t.weight()
(2, 2)
```

class sage.combinat.k_tableau.**WeakTableau_bounded**(*parent*, *t*)

Bases: *WeakTableau_abstract*

A (skew) weak k-tableau represented in terms of k-bounded partitions.

check()

Check that self is a valid weak k-tableau.

EXAMPLES:

```
sage: t = WeakTableau([[1,1],[2]], 2, representation = 'bounded')
sage: t.check()

sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation =
↪'bounded')
sage: t.check()
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1),Integer(1)],[Integer(2)]], Integer(2),␣
↪representation = 'bounded')
>>> t.check()

>>> t = WeakTableau([[None, None, Integer(1)], [Integer(2), Integer(4)],␣
↪[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.check()
```

classmethod from_core_tableau(*t*, *k*)

Construct weak k-bounded tableau from in k-core tableau.

EXAMPLES:

```
sage: from sage.combinat.k_tableau import WeakTableau_bounded
sage: WeakTableau_bounded.from_core_tableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
[[1, 1, 2], [2, 3], [3]]

sage: WeakTableau_bounded.from_core_tableau([[None, None, 2, 3, 4], [1, 4],␣
↪[2]], 3)
[[None, None, 3], [1, 4], [2]]

sage: WeakTableau_bounded.from_core_tableau([[None,2,3],[3]], 2)
[[None, 2], [3]]
```

```
>>> from sage.all import *
>>> from sage.combinat.k_tableau import WeakTableau_bounded
>>> WeakTableau_bounded.from_core_tableau([[Integer(1), Integer(1),␣
↪Integer(2), Integer(2), Integer(3)], [Integer(2), Integer(3)],␣
↪[Integer(3)]], Integer(3))
[[1, 1, 2], [2, 3], [3]]

>>> WeakTableau_bounded.from_core_tableau([[None, None, Integer(2),␣
↪Integer(3), Integer(4)], [Integer(1), Integer(4)], [Integer(2)]],␣
↪Integer(3))
[[None, None, 3], [1, 4], [2]]
```

(continues on next page)

(continued from previous page)

```
>>> WeakTableau_bounded.from_core_tableau([[None,Integer(2),Integer(3)],
↪[Integer(3)]], Integer(2))
[[None, 2], [3]]
```

k_charge(*algorithm='I'*)

Return the k-charge of `self`.

INPUT:

- `algorithm` – (default: `'I'`) if "I", computes k-charge using the I algorithm, otherwise uses the J-algorithm

OUTPUT: nonnegative integer

For the definition of k-charge and the various algorithms to compute it see Section 3.3 of [LLMSSZ2013].

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2], [2, 3], [3]], 3, representation = 'bounded')
sage: t.k_charge()
2
sage: t = WeakTableau([[1, 3, 5], [2, 6], [4]], 3, representation = 'bounded')
sage: t.k_charge()
8
sage: t = WeakTableau([[1, 1, 2, 4], [2, 3, 5], [3, 4], [5, 6], [6], [7]], 4,␣
↪representation = 'bounded')
sage: t.k_charge()
12
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2)], [Integer(2),␣
↪Integer(3)], [Integer(3)]], Integer(3), representation = 'bounded')
>>> t.k_charge()
2
>>> t = WeakTableau([[Integer(1), Integer(3), Integer(5)], [Integer(2),␣
↪Integer(6)], [Integer(4)]], Integer(3), representation = 'bounded')
>>> t.k_charge()
8
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(4)],␣
↪[Integer(2), Integer(3), Integer(5)], [Integer(3), Integer(4)], [Integer(5),
↪ Integer(6)], [Integer(6)], [Integer(7)]], Integer(4), representation =
↪'bounded')
>>> t.k_charge()
12
```

shape_bounded()

Return the shape of `self` as k-bounded partition.

When the tableau is straight, the outer shape is returned as a k-bounded partition. When the tableau is skew, the tuple of the outer and inner shape is returned as k-bounded partitions.

EXAMPLES:

```
sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.shape_bounded()
```

(continues on next page)

(continued from previous page)

```
[3, 2, 1]

sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation =
↪'bounded')
sage: t.shape_bounded()
([3, 2, 1], [2])
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1),Integer(1),Integer(1)],[Integer(2),
↪Integer(2)],[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.shape_bounded()
[3, 2, 1]

>>> t = WeakTableau([[None, None, Integer(1)], [Integer(2), Integer(4)],␣
↪[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.shape_bounded()
([3, 2, 1], [2])
```

shape_core()

Return the shape of `self` as $(k+1)$-core.

When the tableau is straight, the outer shape is returned as a $(k+1)$-core. When the tableau is skew, the tuple of the outer and inner shape is returned as $(k+1)$-cores.

EXAMPLES:

```
sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.shape_core()
[5, 2, 1]

sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation =
↪'bounded')
sage: t.shape_core()
([5, 2, 1], [2])
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1),Integer(1),Integer(1)],[Integer(2),
↪Integer(2)],[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.shape_core()
[5, 2, 1]

>>> t = WeakTableau([[None, None, Integer(1)], [Integer(2), Integer(4)],␣
↪[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.shape_core()
([5, 2, 1], [2])
```

to_core_tableau()

Return the weak k-tableau `self` where the shape of each restricted tableau is a $(k+1)$-core.

EXAMPLES:

```
sage: t = WeakTableau([[1,1,2,4],[2,3,5],[3,4],[5,6],[6],[7]], 4,␣
↪representation = 'bounded')
```

(continues on next page)

(continued from previous page)

```
sage: c = t.to_core_tableau(); c
[[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]]
sage: type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class
→'>
sage: t = WeakTableau([], 4, representation = 'bounded')
sage: t.to_core_tableau()
[]

sage: from sage.combinat.k_tableau import WeakTableau_bounded
sage: t = WeakTableau([[1,1,2],[2,3],[3]], 3, representation = 'bounded')
sage: WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),3)
[[1, 1, 2], [2, 3], [3]]
sage: t == WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),3)
True

sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation =
→'bounded')
sage: t.to_core_tableau()
[[None, None, 1, 2, 4], [2, 4], [3]]
sage: t == WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),3)
True
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1),Integer(1),Integer(2),Integer(4)],
→[Integer(2),Integer(3),Integer(5)],[Integer(3),Integer(4)],[Integer(5),
→Integer(6)],[Integer(6)],[Integer(7)]], Integer(4), representation =
→'bounded')
>>> c = t.to_core_tableau(); c
[[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]]
>>> type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class
→'>
>>> t = WeakTableau([], Integer(4), representation = 'bounded')
>>> t.to_core_tableau()
[]

>>> from sage.combinat.k_tableau import WeakTableau_bounded
>>> t = WeakTableau([[Integer(1),Integer(1),Integer(2)],[Integer(2),
→Integer(3)],[Integer(3)]], Integer(3), representation = 'bounded')
>>> WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),Integer(3))
[[1, 1, 2], [2, 3], [3]]
>>> t == WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),Integer(3))
True

>>> t = WeakTableau([[None, None, Integer(1)], [Integer(2), Integer(4)],␣
→[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.to_core_tableau()
[[None, None, 1, 2, 4], [2, 4], [3]]
>>> t == WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),Integer(3))
True
```

class sage.combinat.k_tableau.**WeakTableau_core**(*parent*, *t*)

Bases: `WeakTableau_abstract`

A (skew) weak k-tableau represented in terms of $(k + 1)$-cores.

check()

Check that `self` is a valid weak k-tableau.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2], [2]], 2)
sage: t.check()
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.check()
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2)], [Integer(2)]],␣
↪Integer(2))
>>> t.check()
>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> t.check()
```

dictionary_of_coordinates_at_residues(*v*)

Return a dictionary assigning to all residues of `self` with label `v` a list of cells with the given residue.

INPUT:

- `v` – a label of a cell in `self`

OUTPUT: dictionary assigning coordinates in `self` to residues

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]],3)
sage: t.dictionary_of_coordinates_at_residues(3)
{0: [(0, 4), (1, 1)], 2: [(2, 0)]}

sage: t = WeakTableau([[None, None, 1, 1, 4], [1, 4], [3]], 3)
sage: t.dictionary_of_coordinates_at_residues(1)
{2: [(0, 2)], 3: [(0, 3), (1, 0)]}

sage: t = WeakTableau([], 3)
sage: t.dictionary_of_coordinates_at_residues(1)
{}
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]],Integer(3))
>>> t.dictionary_of_coordinates_at_residues(Integer(3))
{0: [(0, 4), (1, 1)], 2: [(2, 0)]}

>>> t = WeakTableau([[None, None, Integer(1), Integer(1), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(3)]], Integer(3))
>>> t.dictionary_of_coordinates_at_residues(Integer(1))
{2: [(0, 2)], 3: [(0, 3), (1, 0)]}
```

(continues on next page)

(continued from previous page)

```
>>> t = WeakTableau([], Integer(3))
>>> t.dictionary_of_coordinates_at_residues(Integer(1))
{}
```

k_charge(*algorithm='I'*)

Return the k-charge of `self`.

INPUT:

- `algorithm` – (default: `'I'`) if "I", computes k-charge using the I algorithm, otherwise uses the J-algorithm

OUTPUT: nonnegative integer

For the definition of k-charge and the various algorithms to compute it see Section 3.3 of [LLMSSZ2013].

See also:

k_charge_I() and *k_charge_J()*

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.k_charge()
2
sage: t = WeakTableau([[1, 3, 4, 5, 6], [2, 6], [4]], 3)
sage: t.k_charge()
8
sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4,
→7], [5, 6], [6], [7]], 4)
sage: t.k_charge()
12
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),
→Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> t.k_charge()
2
>>> t = WeakTableau([[Integer(1), Integer(3), Integer(4), Integer(5),
→Integer(6)], [Integer(2), Integer(6)], [Integer(4)]], Integer(3))
>>> t.k_charge()
8
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(3),
→Integer(4), Integer(4), Integer(5), Integer(5), Integer(6)], [Integer(2),
→Integer(3), Integer(5), Integer(5), Integer(6)], [Integer(3), Integer(4),
→Integer(7)], [Integer(5), Integer(6)], [Integer(6)], [Integer(7)]],
→Integer(4))
>>> t.k_charge()
12
```

k_charge_I()

Return the k-charge of `self` using the I-algorithm.

For the definition of k-charge and the I-algorithm see Section 3.3 of [LLMSSZ2013].

OUTPUT: nonnegative integer

See also:

k_charge() and *k_charge_J()*

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.k_charge_I()
2
sage: t = WeakTableau([[1, 3, 4, 5, 6], [2, 6], [4]], 3)
sage: t.k_charge_I()
8
sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4,
→7], [5, 6], [6], [7]], 4)
sage: t.k_charge_I()
12
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),
→Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> t.k_charge_I()
2
>>> t = WeakTableau([[Integer(1), Integer(3), Integer(4), Integer(5),
→Integer(6)], [Integer(2), Integer(6)], [Integer(4)]], Integer(3))
>>> t.k_charge_I()
8
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(3),
→Integer(4), Integer(4), Integer(5), Integer(5), Integer(6)], [Integer(2),
→Integer(3), Integer(5), Integer(5), Integer(6)], [Integer(3), Integer(4),
→Integer(7)], [Integer(5), Integer(6)], [Integer(6)], [Integer(7)]],
→Integer(4))
>>> t.k_charge_I()
12
```

k_charge_J()

Return the k-charge of `self` using the J-algorithm.

For the definition of k-charge and the J-algorithm see Section 3.3 of [LLMSSZ2013].

OUTPUT: nonnegative integer

See also:

k_charge() and *k_charge_I()*

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.k_charge_J()
```

(continues on next page)

(continued from previous page)

```
2
sage: t = WeakTableau([[1, 3, 4, 5, 6], [2, 6], [4]], 3)
sage: t.k_charge_J()
8
sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4,␣
→7], [5, 6], [6], [7]], 4)
sage: t.k_charge_J()
12
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
→Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> t.k_charge_J()
2
>>> t = WeakTableau([[Integer(1), Integer(3), Integer(4), Integer(5),␣
→Integer(6)], [Integer(2), Integer(6)], [Integer(4)]], Integer(3))
>>> t.k_charge_J()
8
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(3),␣
→Integer(4), Integer(4), Integer(5), Integer(5), Integer(6)], [Integer(2),␣
→Integer(3), Integer(5), Integer(5), Integer(6)], [Integer(3), Integer(4),␣
→Integer(7)], [Integer(5), Integer(6)], [Integer(6)], [Integer(7)]],␣
→Integer(4))
>>> t.k_charge_J()
12
```

list_of_standard_cells()

Return a list of lists of the coordinates of the standard cells of `self`.

INPUT:

- `self` – a weak k-tableau in core representation with partition weight

OUTPUT: list of lists of coordinates

> **Warning**
>
> This method currently only works for straight weak tableaux with partition weight.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.list_of_standard_cells()
[[(0, 1), (1, 0), (2, 0)], [(0, 0), (0, 2), (1, 1)]]
sage: t = WeakTableau([[1, 1, 1, 2], [2, 2, 3]], 5)
sage: t.list_of_standard_cells()
[[(0, 2), (1, 1), (1, 2)], [(0, 1), (1, 0)], [(0, 0), (0, 3)]]
sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4,␣
→7], [5, 6], [6], [7]], 4)
sage: t.list_of_standard_cells()
[[(0, 1), (1, 0), (2, 0), (0, 5), (3, 0), (4, 0), (5, 0)], [(0, 0), (0, 2),␣
→(1, 1), (2, 1), (1, 2), (3, 1)]]
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> t.list_of_standard_cells()
[[(0, 1), (1, 0), (2, 0)], [(0, 0), (0, 2), (1, 1)]]
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(1), Integer(2)],␣
↪[Integer(2), Integer(2), Integer(3)]], Integer(5))
>>> t.list_of_standard_cells()
[[(0, 2), (1, 1), (1, 2)], [(0, 1), (1, 0)], [(0, 0), (0, 3)]]
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(3),␣
↪Integer(4), Integer(4), Integer(5), Integer(5), Integer(6)], [Integer(2),␣
↪Integer(3), Integer(5), Integer(5), Integer(6)], [Integer(3), Integer(4),␣
↪Integer(7)], [Integer(5), Integer(6)], [Integer(6)], [Integer(7)]],␣
↪Integer(4))
>>> t.list_of_standard_cells()
[[(0, 1), (1, 0), (2, 0), (0, 5), (3, 0), (4, 0), (5, 0)], [(0, 0), (0, 2),␣
↪(1, 1), (2, 1), (1, 2), (3, 1)]]
```

residues_of_entries(*v*)

Return a list of residues of cells of weak k-tableau `self` labeled by `v`.

INPUT:

- `v` – a label of a cell in `self`

OUTPUT: list of residues

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]],3)
sage: t.residues_of_entries(1)
[0, 1]

sage: t = WeakTableau([[None, None, 1, 1, 4], [1, 4], [3]], 3)
sage: t.residues_of_entries(1)
[2, 3]
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]],Integer(3))
>>> t.residues_of_entries(Integer(1))
[0, 1]

>>> t = WeakTableau([[None, None, Integer(1), Integer(1), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(3)]], Integer(3))
>>> t.residues_of_entries(Integer(1))
[2, 3]
```

shape_bounded()

Return the shape of `self` as a k-bounded partition.

When the tableau is straight, the outer shape is returned as a k-bounded partition. When the tableau is skew, the tuple of the outer and inner shape is returned as k-bounded partitions.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]],3)
sage: t.shape_bounded()
[3, 2, 1]

sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.shape_bounded()
([3, 2, 1], [2])
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]],Integer(3))
>>> t.shape_bounded()
[3, 2, 1]

>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> t.shape_bounded()
([3, 2, 1], [2])
```

shape_core()

Return the shape of `self` as a $(k+1)$-core.

When the tableau is straight, the outer shape is returned as a core. When the tableau is skew, the tuple of the outer and inner shape is returned as cores.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]],3)
sage: t.shape_core()
[5, 2, 1]

sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.shape_core()
([5, 2, 1], [2])
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]],Integer(3))
>>> t.shape_core()
[5, 2, 1]

>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> t.shape_core()
([5, 2, 1], [2])
```

to_bounded_tableau()

Return the bounded representation of the weak k-tableau `self`.

Each restricted subtableau of the output is a k-bounded partition.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: c = t.to_bounded_tableau(); c
[[1, 1, 2], [2, 3], [3]]
sage: type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_bounded_with_category.element_
↪class'>

sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.to_bounded_tableau()
[[None, None, 3], [1, 4], [2]]
sage: t.to_bounded_tableau().to_core_tableau() == t
True
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> c = t.to_bounded_tableau(); c
[[1, 1, 2], [2, 3], [3]]
>>> type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_bounded_with_category.element_
↪class'>

>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> t.to_bounded_tableau()
[[None, None, 3], [1, 4], [2]]
>>> t.to_bounded_tableau().to_core_tableau() == t
True
```

to_factorized_permutation_tableau()

Return the factorized permutation representation of the weak k-tableau `self`.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: c = t.to_factorized_permutation_tableau(); c
[s2*s0, s3*s2, s1*s0]
sage: type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_
↪category.element_class'>
sage: c.to_core_tableau() == t
True

sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: c = t.to_factorized_permutation_tableau(); c
[s0, s3, s2, s3]
sage: c._inner_shape
[2]
sage: c.to_core_tableau() == t
True
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> c = t.to_factorized_permutation_tableau(); c
[s2*s0, s3*s2, s1*s0]
>>> type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_
↪category.element_class'>
>>> c.to_core_tableau() == t
True

>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> c = t.to_factorized_permutation_tableau(); c
[s0, s3, s2, s3]
>>> c._inner_shape
[2]
>>> c.to_core_tableau() == t
True
```

class sage.combinat.k_tableau.**WeakTableau_factorized_permutation**(*parent*, *t*)

Bases: *WeakTableau_abstract*

A weak (skew) k-tableau represented in terms of factorizations of affine permutations into cyclically decreasing elements.

check()

Check that self is a valid weak k-tableau.

EXAMPLES:

```
sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_
↪permutation')
sage: t.check()
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(2)],[Integer(0),Integer(3)],[Integer(2),
↪Integer(1),Integer(0)]], Integer(3), representation = 'factorized_
↪permutation')
>>> t.check()
```

classmethod from_core_tableau(*t*, *k*)

Construct weak factorized affine permutation tableau from a k-core tableau.

EXAMPLES:

```
sage: from sage.combinat.k_tableau import WeakTableau_factorized_permutation
sage: WeakTableau_factorized_permutation.from_core_tableau([[1, 1, 2, 2, 3],␣
↪[2, 3], [3]],3)
[s2*s0, s3*s2, s1*s0]
sage: WeakTableau_factorized_permutation.from_core_tableau([[1, 1, 2, 3, 4, 4,
↪ 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]], 4)
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]
sage: WeakTableau_factorized_permutation.from_core_tableau([[None, 1, 1, 2,␣
↪2], [None, 2], [1]], 3)
[s0*s3, s2*s1]
```

```
>>> from sage.all import *
>>> from sage.combinat.k_tableau import WeakTableau_factorized_permutation
>>> WeakTableau_factorized_permutation.from_core_tableau([[Integer(1),␣
→Integer(1), Integer(2), Integer(2), Integer(3)], [Integer(2), Integer(3)],␣
→[Integer(3)]],Integer(3))
[s2*s0, s3*s2, s1*s0]
>>> WeakTableau_factorized_permutation.from_core_tableau([[Integer(1),␣
→Integer(1), Integer(2), Integer(3), Integer(4), Integer(4), Integer(5),␣
→Integer(5), Integer(6)], [Integer(2), Integer(3), Integer(5), Integer(5),␣
→Integer(6)], [Integer(3), Integer(4), Integer(7)], [Integer(5), Integer(6)],
→ [Integer(6)], [Integer(7)]], Integer(4))
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]
>>> WeakTableau_factorized_permutation.from_core_tableau([[None, Integer(1),␣
→Integer(1), Integer(2), Integer(2)], [None, Integer(2)], [Integer(1)]],␣
→Integer(3))
[s0*s3, s2*s1]
```

k_charge(*algorithm='I'*)

Return the k-charge of `self`.

OUTPUT: nonnegative integer

EXAMPLES:

```
sage: t = WeakTableau([[2,0],[3,2],[1,0]], 3, representation = 'factorized_
→permutation')
sage: t.k_charge()
2
sage: t = WeakTableau([[0],[3],[2],[1],[3],[0]], 3, representation =
→'factorized_permutation')
sage: t.k_charge()
8
sage: t = WeakTableau([[0],[3,1],[2,1],[0,4],[3,0],[4,2],[1,0]], 4,␣
→representation = 'factorized_permutation')
sage: t.k_charge()
12
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)],
→[Integer(1),Integer(0)]], Integer(3), representation = 'factorized_
→permutation')
>>> t.k_charge()
2
>>> t = WeakTableau([[Integer(0)],[Integer(3)],[Integer(2)],[Integer(1)],
→[Integer(3)],[Integer(0)]], Integer(3), representation = 'factorized_
→permutation')
>>> t.k_charge()
8
>>> t = WeakTableau([[Integer(0)],[Integer(3),Integer(1)],[Integer(2),
→Integer(1)],[Integer(0),Integer(4)],[Integer(3),Integer(0)],[Integer(4),
→Integer(2)],[Integer(1),Integer(0)]], Integer(4), representation =
→'factorized_permutation')
>>> t.k_charge()
12
```

shape_bounded()

Return the shape of `self` as a k-bounded partition.

When the tableau is straight, the outer shape is returned as a k-bounded partition. When the tableau is skew, the tuple of the outer and inner shape is returned as k-bounded partitions.

EXAMPLES:

```
sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_
↪permutation')
sage: t.shape_bounded()
[3, 2, 1]

sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation =
↪'factorized_permutation')
sage: t.shape_bounded()
([3, 2, 1], [2])
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(2)],[Integer(0),Integer(3)],[Integer(2),
↪Integer(1),Integer(0)]], Integer(3), representation = 'factorized_
↪permutation')
>>> t.shape_bounded()
[3, 2, 1]

>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)]],␣
↪Integer(3), inner_shape = [Integer(2)], representation = 'factorized_
↪permutation')
>>> t.shape_bounded()
([3, 2, 1], [2])
```

shape_core()

Return the shape of `self` as a $(k+1)$-core.

When the tableau is straight, the outer shape is returned as a core. When the tableau is skew, the tuple of the outer and inner shape is returned as cores.

EXAMPLES:

```
sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_
↪permutation')
sage: t.shape_core()
[5, 2, 1]

sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation =
↪'factorized_permutation')
sage: t.shape()
([5, 2, 1], [2])
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(2)],[Integer(0),Integer(3)],[Integer(2),
↪Integer(1),Integer(0)]], Integer(3), representation = 'factorized_
↪permutation')
>>> t.shape_core()
[5, 2, 1]
```

(continues on next page)

(continued from previous page)

```
>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)]],␣
↪Integer(3), inner_shape = [Integer(2)], representation = 'factorized_
↪permutation')
>>> t.shape()
([5, 2, 1], [2])
```

static straighten_input(*t*, *k*)

Straightens input.

INPUT:

- `t` – list of reduced words or a list of elements in the Weyl group of type $A_k^{(1)}$
- `k` – positive integer

EXAMPLES:

```
sage: from sage.combinat.k_tableau import WeakTableau_factorized_permutation
sage: WeakTableau_factorized_permutation.straighten_input([[2,0],[3,2],[1,0]],
↪ 3)
(s2*s0, s3*s2, s1*s0)
sage: W = WeylGroup(['A',4,1])
sage: WeakTableau_factorized_permutation.straighten_input([W.an_element(),W.
↪an_element()], 4)
(s0*s1*s2*s3*s4, s0*s1*s2*s3*s4)
```

```
>>> from sage.all import *
>>> from sage.combinat.k_tableau import WeakTableau_factorized_permutation
>>> WeakTableau_factorized_permutation.straighten_input([[Integer(2),
↪Integer(0)],[Integer(3),Integer(2)],[Integer(1),Integer(0)]], Integer(3))
(s2*s0, s3*s2, s1*s0)
>>> W = WeylGroup(['A',Integer(4),Integer(1)])
>>> WeakTableau_factorized_permutation.straighten_input([W.an_element(),W.an_
↪element()], Integer(4))
(s0*s1*s2*s3*s4, s0*s1*s2*s3*s4)
```

to_core_tableau()

Return the weak k-tableau `self` where the shape of each restricted tableau is a $(k + 1)$-core.

EXAMPLES:

```
sage: t = WeakTableau([[0], [3,1], [2,1], [0,4], [3,0], [4,2], [1,0]], 4,␣
↪representation = 'factorized_permutation'); t
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]
sage: c = t.to_core_tableau(); c
[[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]]
sage: type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class
↪'>
sage: t = WeakTableau([[]], 4, representation = 'factorized_permutation'); t
[1]
sage: t.to_core_tableau()
[]
```

(continues on next page)

(continued from previous page)

```
sage: from sage.combinat.k_tableau import WeakTableau_factorized_permutation
sage: t = WeakTableau([[2,0],[3,2],[1,0]], 3, representation = 'factorized_
↪permutation')
sage: WeakTableau_factorized_permutation.from_core_tableau(t.to_core_
↪tableau(), 3)
[s2*s0, s3*s2, s1*s0]
sage: t == WeakTableau_factorized_permutation.from_core_tableau(t.to_core_
↪tableau(), 3)
True

sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation =
↪'factorized_permutation')
sage: t.to_core_tableau()
[[None, None, 1, 1, 2], [1, 2], [2]]
sage: t == WeakTableau_factorized_permutation.from_core_tableau(t.to_core_
↪tableau(), 3)
True
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(0)], [Integer(3),Integer(1)], [Integer(2),
↪Integer(1)], [Integer(0),Integer(4)], [Integer(3),Integer(0)], [Integer(4),
↪Integer(2)], [Integer(1),Integer(0)]], Integer(4), representation =
↪'factorized_permutation'); t
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]
>>> c = t.to_core_tableau(); c
[[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]]
>>> type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class
↪'>
>>> t = WeakTableau([[]], Integer(4), representation = 'factorized_permutation
↪'); t
[1]
>>> t.to_core_tableau()
[]

>>> from sage.combinat.k_tableau import WeakTableau_factorized_permutation
>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)],
↪[Integer(1),Integer(0)]], Integer(3), representation = 'factorized_
↪permutation')
>>> WeakTableau_factorized_permutation.from_core_tableau(t.to_core_tableau(),␣
↪Integer(3))
[s2*s0, s3*s2, s1*s0]
>>> t == WeakTableau_factorized_permutation.from_core_tableau(t.to_core_
↪tableau(), Integer(3))
True

>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)]],␣
↪Integer(3), inner_shape = [Integer(2)], representation = 'factorized_
↪permutation')
>>> t.to_core_tableau()
[[None, None, 1, 1, 2], [1, 2], [2]]
```

(continues on next page)

(continued from previous page)

```
>>> t == WeakTableau_factorized_permutation.from_core_tableau(t.to_core_
↪tableau(), Integer(3))
True
```

sage.combinat.k_tableau.**WeakTableaux**(*k*, *shape*, *weight*, *representation='core'*)

This is the dispatcher method for the parent class of weak k-tableaux.

INPUT:

- `k` – positive integer
- `shape` – shape of the weak k-tableaux; for the 'core' and 'factorized_permutation' representation, the shape is inputted as a $(k+1)$-core; for the 'bounded' representation, the shape is inputted as a k-bounded partition; for skew tableaux, the shape is inputted as a tuple of the outer and inner shape
- `weight` – the weight of the weak k-tableaux as a list or tuple
- `representation` – `'core'`, `'bounded'`, or `'factorized_permutation'` (default: `'core'`)

EXAMPLES:

```
sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1,1])
sage: T.list()
[[[1, 3, 4, 5, 6], [2, 6], [4]],
[[1, 2, 4, 5, 6], [3, 6], [4]],
[[1, 2, 3, 4, 6], [4, 6], [5]],
[[1, 2, 3, 4, 5], [4, 5], [6]]]
sage: T.cardinality()
4

sage: T = WeakTableaux(3, [[5,2,1], [2]], [1,1,1,1])
sage: T.list()
[[[None, None, 2, 3, 4], [1, 4], [2]],
[[None, None, 1, 2, 4], [2, 4], [3]],
[[None, None, 1, 2, 3], [2, 3], [4]]]

sage: T = WeakTableaux(3, [3,2,1], [1,1,1,1,1,1], representation = 'bounded')
sage: T.list()
[[[1, 3, 5], [2, 6], [4]],
[[1, 2, 5], [3, 6], [4]],
[[1, 2, 3], [4, 6], [5]],
[[1, 2, 3], [4, 5], [6]]]

sage: T = WeakTableaux(3, [[3,2,1], [2]], [1,1,1,1], representation = 'bounded')
sage: T.list()
[[[None, None, 3], [1, 4], [2]],
[[None, None, 1], [2, 4], [3]],
[[None, None, 1], [2, 3], [4]]]

sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1,1], representation = 'factorized_
↪permutation')
sage: T.list()
[[s0, s3, s2, s1, s3, s0],
[s0, s3, s2, s3, s1, s0],
[s0, s2, s3, s2, s1, s0],
```

(continues on next page)

(continued from previous page)

```
[s2, s0, s3, s2, s1, s0]]

sage: T = WeakTableaux(3, [[5,2,1], [2]], [1,1,1,1], representation = 'factorized_
↪permutation')
sage: T.list()
[[s0, s3, s2, s3], [s0, s2, s3, s2], [s2, s0, s3, s2]]
```

class sage.combinat.k_tableau.**WeakTableaux_abstract**

Bases: UniqueRepresentation, Parent

Abstract class for the various parent classes of WeakTableaux.

representation(*representation='core'*)

Return the analogue of `self` in the specified representation.

INPUT:

- `representation` – 'core', 'bounded', or 'factorized_permutation' (default: `'core'`)

EXAMPLES:

```
sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1,1])
sage: T._representation
'core'
sage: T.representation('bounded')
Bounded weak 3-Tableaux of (skew) 3-bounded shape [3, 2, 1] and weight (1, 1,␣
↪1, 1, 1, 1)
sage: T.representation('factorized_permutation')
Factorized permutation (skew) weak 3-Tableaux of shape [5, 2, 1] and weight␣
↪(1, 1, 1, 1, 1, 1)

sage: T = WeakTableaux(3, [3,2,1], [1,1,1,1,1,1], representation = 'bounded')
sage: T._representation
'bounded'
sage: T.representation('core')
Core weak 3-Tableaux of (skew) core shape [5, 2, 1] and weight (1, 1, 1, 1, 1,
↪ 1)
sage: T.representation('bounded')
Bounded weak 3-Tableaux of (skew) 3-bounded shape [3, 2, 1] and weight (1, 1,␣
↪1, 1, 1, 1)
sage: T.representation('bounded') == T
True
sage: T.representation('factorized_permutation')
Factorized permutation (skew) weak 3-Tableaux of shape [5, 2, 1] and weight␣
↪(1, 1, 1, 1, 1, 1)
sage: T.representation('factorized_permutation') == T
False

sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1,1], representation =
↪'factorized_permutation')
sage: T._representation
'factorized_permutation'
sage: T.representation('core')
Core weak 3-Tableaux of (skew) core shape [5, 2, 1] and weight (1, 1, 1, 1, 1,
↪ 1)
sage: T.representation('bounded')
```

(continues on next page)

(continued from previous page)

```
Bounded weak 3-Tableaux of (skew) 3-bounded shape [3, 2, 1] and weight (1, 1,␣
↪1, 1, 1, 1)
sage: T.representation('factorized_permutation')
Factorized permutation (skew) weak 3-Tableaux of shape [5, 2, 1] and weight␣
↪(1, 1, 1, 1, 1, 1)
```

```
>>> from sage.all import *

>>> T.representation('bounded') == T
True
>>> T.representation('factorized_permutation')
Factorized permutation (skew) weak 3-Tableaux of shape [5, 2, 1] and weight␣
↪(1, 1, 1, 1, 1, 1)
>>> T.representation('factorized_permutation') == T
False

>>> T = WeakTableaux(Integer(3), [Integer(5),Integer(2),Integer(1)],␣
↪[Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),Integer(1)],␣
↪representation = 'factorized_permutation')
>>> T._representation
'factorized_permutation'
>>> T.representation('core')
Core weak 3-Tableaux of (skew) core shape [5, 2, 1] and weight (1, 1, 1, 1, 1,
↪ 1)
>>> T.representation('bounded')
Bounded weak 3-Tableaux of (skew) 3-bounded shape [3, 2, 1] and weight (1, 1,␣
↪1, 1, 1, 1)
>>> T.representation('factorized_permutation')
Factorized permutation (skew) weak 3-Tableaux of shape [5, 2, 1] and weight␣
↪(1, 1, 1, 1, 1, 1)
```

shape()

Return the shape of the tableaux of `self`.

When `self` is the class of straight tableaux, the outer shape is returned. When `self` is the class of skew tableaux, the tuple of the outer and inner shape is returned.

Note that in the 'core' and 'factorized_permutation' representation, the shapes are $(k+1)$-cores. In the 'bounded' representation, the shapes are k-bounded partitions.

If the user wants to access the skew shape (even if the inner shape is empty), please use `self._shape`.

EXAMPLES:

```
sage: T = WeakTableaux(3, [5,2,2], [2,2,2,1])
sage: T.shape()
[5, 2, 2]
sage: T._shape
([5, 2, 2], [])
sage: T = WeakTableaux(3, [[5,2,2], [1]], [2,1,2,1])
sage: T.shape()
([5, 2, 2], [1])

sage: T = WeakTableaux(3, [3,2,2], [2,2,2,1], representation = 'bounded')
sage: T.shape()
[3, 2, 2]
sage: T._shape
([3, 2, 2], [])
sage: T = WeakTableaux(3, [[3,2,2], [1]], [2,1,2,1], representation = 'bounded
↪')
sage: T.shape()
([3, 2, 2], [1])

sage: T = WeakTableaux(3, [4,1], [2,2], representation = 'factorized_
↪permutation')
sage: T.shape()
[4, 1]
sage: T._shape
([4, 1], [])
sage: T = WeakTableaux(4, [[6,2,1], [2]], [2,1,1,1], representation =
↪'factorized_permutation')
sage: T.shape()
([6, 2, 1], [2])
```

```
>>> from sage.all import *
>>> T = WeakTableaux(Integer(3), [Integer(5),Integer(2),Integer(2)],␣
↪[Integer(2),Integer(2),Integer(2),Integer(1)])
>>> T.shape()
[5, 2, 2]
>>> T._shape
([5, 2, 2], [])
>>> T = WeakTableaux(Integer(3), [[Integer(5),Integer(2),Integer(2)],␣
↪[Integer(1)]], [Integer(2),Integer(1),Integer(2),Integer(1)])
>>> T.shape()
([5, 2, 2], [1])
```

(continues on next page)

(continued from previous page)

```
>>> T = WeakTableaux(Integer(3), [Integer(3),Integer(2),Integer(2)],␣
↪[Integer(2),Integer(2),Integer(2),Integer(1)], representation = 'bounded')
>>> T.shape()
[3, 2, 2]
>>> T._shape
([3, 2, 2], [])
>>> T = WeakTableaux(Integer(3), [[Integer(3),Integer(2),Integer(2)],␣
↪[Integer(1)]], [Integer(2),Integer(1),Integer(2),Integer(1)],␣
↪representation = 'bounded')
>>> T.shape()
([3, 2, 2], [1])

>>> T = WeakTableaux(Integer(3), [Integer(4),Integer(1)], [Integer(2),
↪Integer(2)], representation = 'factorized_permutation')
>>> T.shape()
[4, 1]
>>> T._shape
([4, 1], [])
>>> T = WeakTableaux(Integer(4), [[Integer(6),Integer(2),Integer(1)],␣
↪[Integer(2)]], [Integer(2),Integer(1),Integer(1),Integer(1)],␣
↪representation = 'factorized_permutation')
>>> T.shape()
([6, 2, 1], [2])
```

size()

Return the size of the shape.

In the bounded representation, the size of the shape is the number of boxes in the outer shape minus the number of boxes in the inner shape. For the core and factorized permutation representation, the size is the length of the outer shape minus the length of the inner shape.

EXAMPLES:

```
sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1,1])
sage: T.size()
6
sage: T = WeakTableaux(3, [3,2,1], [1,1,1,1,1,1], representation = 'bounded')
sage: T.size()
6
sage: T = WeakTableaux(4, [[6,2,1], [2]], [2,1,1,1], 'factorized_permutation')
sage: T.size()
5
```

```
>>> from sage.all import *
>>> T = WeakTableaux(Integer(3), [Integer(5),Integer(2),Integer(1)],␣
↪[Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),Integer(1)])
>>> T.size()
6
>>> T = WeakTableaux(Integer(3), [Integer(3),Integer(2),Integer(1)],␣
↪[Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),Integer(1)],␣
↪representation = 'bounded')
>>> T.size()
6
```

(continues on next page)

(continued from previous page)

```
>>> T = WeakTableaux(Integer(4), [[Integer(6),Integer(2),Integer(1)],␣
↪[Integer(2)]], [Integer(2),Integer(1),Integer(1),Integer(1)], 'factorized_
↪permutation')
>>> T.size()
5
```

class sage.combinat.k_tableau.**WeakTableaux_bounded**(*k*, *shape*, *weight*)

Bases: *WeakTableaux_abstract*

The class of (skew) weak k-tableaux in the bounded representation of shape `shape` (as k-bounded partition or tuple of k-bounded partitions in the skew case) and weight `weight`.

INPUT:

- `k` – positive integer
- `shape` – the shape of the k-tableaux represented as a k-bounded partition; if the tableaux are skew, the shape is a tuple of the outer and inner shape each represented as a k-bounded partition
- `weight` – the weight of the k-tableaux

EXAMPLES:

```
sage: T = WeakTableaux(3, [3,1], [2,2], representation = 'bounded')
sage: T.list()
[[[1, 1, 2], [2]]]

sage: T = WeakTableaux(3, [[3,2,1], [2]], [1,1,1,1], representation = 'bounded')
sage: T.list()
[[[None, None, 3], [1, 4], [2]],
[[None, None, 1], [2, 4], [3]],
[[None, None, 1], [2, 3], [4]]]
```

```
>>> from sage.all import *
>>> T = WeakTableaux(Integer(3), [Integer(3),Integer(1)], [Integer(2),Integer(2)],
↪ representation = 'bounded')
>>> T.list()
[[[1, 1, 2], [2]]]

>>> T = WeakTableaux(Integer(3), [[Integer(3),Integer(2),Integer(1)],␣
↪[Integer(2)]], [Integer(1),Integer(1),Integer(1),Integer(1)], representation =
↪'bounded')
>>> T.list()
[[[None, None, 3], [1, 4], [2]],
[[None, None, 1], [2, 4], [3]],
[[None, None, 1], [2, 3], [4]]]
```

Element

alias of *WeakTableau_bounded*

class sage.combinat.k_tableau.**WeakTableaux_core**(*k*, *shape*, *weight*)

Bases: *WeakTableaux_abstract*

The class of (skew) weak k-tableaux in the core representation of shape `shape` (as $k+1$-core) and weight `weight`.

INPUT:

- k – positive integer
- shape – the shape of the k-tableaux represented as a $(k+1)$-core; if the tableaux are skew, the shape is a tuple of the outer and inner shape (both as $(k+1)$-cores)
- weight – the weight of the k-tableaux

EXAMPLES:

```
sage: T = WeakTableaux(3, [4,1], [2,2])
sage: T.list()
[[[1, 1, 2, 2], [2]]]

sage: T = WeakTableaux(3, [[5,2,1], [2]], [1,1,1,1])
sage: T.list()
[[[None, None, 2, 3, 4], [1, 4], [2]],
[[None, None, 1, 2, 4], [2, 4], [3]],
[[None, None, 1, 2, 3], [2, 3], [4]]]
```

```
>>> from sage.all import *
>>> T = WeakTableaux(Integer(3), [Integer(4),Integer(1)], [Integer(2),Integer(2)])
>>> T.list()
[[[1, 1, 2, 2], [2]]]

>>> T = WeakTableaux(Integer(3), [[Integer(5),Integer(2),Integer(1)],
↪[Integer(2)]], [Integer(1),Integer(1),Integer(1),Integer(1)])
>>> T.list()
[[[None, None, 2, 3, 4], [1, 4], [2]],
[[None, None, 1, 2, 4], [2, 4], [3]],
[[None, None, 1, 2, 3], [2, 3], [4]]]
```

Element

alias of *WeakTableau_core*

circular_distance(*cr*, *r*)

Return the shortest counterclockwise distance between cr and r modulo $k+1$.

INPUT:

- cr, r – nonnegative integers between 0 and k

OUTPUT: positive integer

EXAMPLES:

```
sage: T = WeakTableaux(10, [], [])
sage: T.circular_distance(8, 6)
2
sage: T.circular_distance(8, 8)
0
sage: T.circular_distance(8, 9)
10
```

```
>>> from sage.all import *
>>> T = WeakTableaux(Integer(10), [], [])
>>> T.circular_distance(Integer(8), Integer(6))
2
```

(continues on next page)

(continued from previous page)

```
>>> T.circular_distance(Integer(8), Integer(8))
0
>>> T.circular_distance(Integer(8), Integer(9))
10
```

diag(*c*, *ha*)

Return the number of diagonals strictly between cells `c` and `ha` of the same residue as `c`.

INPUT:

- `c` – a cell in the lattice
- `ha` – another cell in the lattice with bigger row and smaller column than c

OUTPUT: nonnegative integer

EXAMPLES:

```
sage: T = WeakTableaux(4, [5,2,2], [2,2,2,1])
sage: T.diag((1,2),(4,0))
0
```

```
>>> from sage.all import *
>>> T = WeakTableaux(Integer(4), [Integer(5),Integer(2),Integer(2)],␣
↪[Integer(2),Integer(2),Integer(2),Integer(1)])
>>> T.diag((Integer(1),Integer(2)),(Integer(4),Integer(0)))
0
```

class sage.combinat.k_tableau.**WeakTableaux_factorized_permutation**(*k*, *shape*, *weight*)

Bases: *WeakTableaux_abstract*

The class of (skew) weak k-tableaux in the factorized permutation representation of shape `shape` (as $k+1$-core or tuple of $(k+1)$-cores in the skew case) and weight `weight`.

INPUT:

- `k` – positive integer
- `shape` – the shape of the k-tableaux represented as a $(k+1)$-core; in the skew case the shape is a tuple of the outer and inner shape both as $(k+1)$-cores
- `weight` – the weight of the k-tableaux

EXAMPLES:

```
sage: T = WeakTableaux(3, [4,1], [2,2], representation = 'factorized_permutation')
sage: T.list()
[[s3*s2, s1*s0]]

sage: T = WeakTableaux(4, [[6,2,1], [2]], [2,1,1,1], representation = 'factorized_
↪permutation')
sage: T.list()
[[s0, s4, s3, s4*s2], [s0, s3, s4, s3*s2], [s3, s0, s4, s3*s2]]
```

```
>>> from sage.all import *
>>> T = WeakTableaux(Integer(3), [Integer(4),Integer(1)], [Integer(2),Integer(2)],
↪ representation = 'factorized_permutation')
```

(continues on next page)

(continued from previous page)

```
>>> T.list()
[[s3*s2, s1*s0]]

>>> T = WeakTableaux(Integer(4), [[Integer(6),Integer(2),Integer(1)],
↪[Integer(2)]], [Integer(2),Integer(1),Integer(1),Integer(1)], representation =
↪'factorized_permutation')
>>> T.list()
[[s0, s4, s3, s4*s2], [s0, s3, s4, s3*s2], [s3, s0, s4, s3*s2]]
```

Element

alias of *WeakTableau_factorized_permutation*

sage.combinat.k_tableau.**intermediate_shapes**(*t*)

Return the intermediate shapes of tableau `t`.

A (skew) tableau with letters $1, 2, \ldots, \ell$ can be viewed as a sequence of shapes, where the i-th shape is given by the shape of the subtableau on letters $1, 2, \ldots, i$. The output is the list of these shapes.

OUTPUT: list of lists representing partitions

EXAMPLES:

```
sage: from sage.combinat.k_tableau import intermediate_shapes
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]],3)
sage: intermediate_shapes(t)
[[], [2], [4, 1], [5, 2, 1]]

sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: intermediate_shapes(t)
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.k_tableau import intermediate_shapes
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2), Integer(3)],
↪ [Integer(2), Integer(3)], [Integer(3)]],Integer(3))
>>> intermediate_shapes(t)
[[], [2], [4, 1], [5, 2, 1]]

>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> intermediate_shapes(t)
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]
```

sage.combinat.k_tableau.**nabs**(*v*)

Return the absolute value of `v` or `None`.

INPUT:

- `v` – either an integer or `None`

OUTPUT: either a nonnegative integer or `None`

EXAMPLES:

```
sage: from sage.combinat.k_tableau import nabs
sage: nabs(None)
sage: nabs(-3)
3
sage: nabs(None)
```

```
>>> from sage.all import *
>>> from sage.combinat.k_tableau import nabs
>>> nabs(None)
>>> nabs(-Integer(3))
3
>>> nabs(None)
```

5.1.131 Kazhdan-Lusztig Polynomials

AUTHORS:

- Daniel Bump (2008): initial version
- Alan J.X. Guo (2014-03-18): `R_tilde()` method.

class `sage.combinat.kazhdan_lusztig.`**`KazhdanLusztigPolynomial`**(*W*, *q*, *trace=False*)

Bases: `UniqueRepresentation`, `SageObject`

A Kazhdan-Lusztig polynomial.

INPUT:

- `W` – a Weyl Group
- `q` – an indeterminate

OPTIONAL:

- `trace` – if `True`, then this displays the trace: the intermediate results. This is instructive and fun.

The parent of `q` may be a `PolynomialRing` or a `LaurentPolynomialRing`.

EXAMPLES:

```
sage: W = WeylGroup("B3",prefix='s')
sage: [s1,s2,s3] = W.simple_reflections()
sage: R.<q> = LaurentPolynomialRing(QQ)
sage: KL = KazhdanLusztigPolynomial(W,q)
sage: KL.P(s2,s3*s2*s3*s1*s2)
1 + q
```

```
>>> from sage.all import *
>>> W = WeylGroup("B3",prefix='s')
>>> [s1,s2,s3] = W.simple_reflections()
>>> R = LaurentPolynomialRing(QQ, names=('q',)); (q,) = R._first_ngens(1)
>>> KL = KazhdanLusztigPolynomial(W,q)
>>> KL.P(s2,s3*s2*s3*s1*s2)
1 + q
```

A faster implementation (using the optional package Coxeter 3) is given by:

```
sage: W = CoxeterGroup(['B', 3], implementation='coxeter3') # optional - coxeter3
sage: W.kazhdan_lusztig_polynomial([2], [3,2,3,1,2])        # optional - coxeter3
q + 1
```

```
>>> from sage.all import *
>>> W = CoxeterGroup(['B', Integer(3)], implementation='coxeter3') # optional -␣
↪coxeter3
>>> W.kazhdan_lusztig_polynomial([Integer(2)], [Integer(3),Integer(2),Integer(3),
↪Integer(1),Integer(2)])        # optional - coxeter3
q + 1
```

P(*x*, *y*)

Return the Kazhdan-Lusztig P polynomial.

If the rank is large, this runs slowly at first but speeds up as you do repeated calculations due to the caching.

INPUT:

- x, y – elements of the underlying Coxeter group

See also

kazhdan_lusztig_polynomial for a faster implementation using Fokko Ducloux's Coxeter3 C++ library.

EXAMPLES:

```
sage: R.<q> = QQ[]
sage: W = WeylGroup("A3", prefix='s')
sage: [s1,s2,s3] = W.simple_reflections()
sage: KL = KazhdanLusztigPolynomial(W, q)
sage: KL.P(s2,s2*s1*s3*s2)
q + 1
```

```
>>> from sage.all import *
>>> R = QQ['q']; (q,) = R._first_ngens(1)
>>> W = WeylGroup("A3", prefix='s')
>>> [s1,s2,s3] = W.simple_reflections()
>>> KL = KazhdanLusztigPolynomial(W, q)
>>> KL.P(s2,s2*s1*s3*s2)
q + 1
```

R(*x*, *y*)

Return the Kazhdan-Lusztig R polynomial.

INPUT:

- x, y – elements of the underlying Coxeter group

EXAMPLES:

```
sage: R.<q>=QQ[]
sage: W = WeylGroup("A2", prefix='s')
sage: [s1,s2]=W.simple_reflections()
```

(continues on next page)

(continued from previous page)

```
sage: KL = KazhdanLusztigPolynomial(W, q)
sage: [KL.R(x,s2*s1) for x in [1,s1,s2,s1*s2]]
[q^2 - 2*q + 1, q - 1, q - 1, 0]
```

```
>>> from sage.all import *
>>> R = QQ['q']; (q,) = R._first_ngens(1)
>>> W = WeylGroup("A2", prefix='s')
>>> [s1,s2]=W.simple_reflections()
>>> KL = KazhdanLusztigPolynomial(W, q)
>>> [KL.R(x,s2*s1) for x in [Integer(1),s1,s2,s1*s2]]
[q^2 - 2*q + 1, q - 1, q - 1, 0]
```

R_tilde (*x*, *y*)

Return the Kazhdan-Lusztig $\tilde{R}$ polynomial.

Information about the $\tilde{R}$ polynomials can be found in [Dy1993] and [BB2005].

INPUT:

- `x`, `y` – elements of the underlying Coxeter group

EXAMPLES:

```
sage: R.<q> = QQ[]
sage: W = WeylGroup("A2", prefix='s')
sage: [s1,s2] = W.simple_reflections()
sage: KL = KazhdanLusztigPolynomial(W, q)
sage: [KL.R_tilde(x,s2*s1) for x in [1,s1,s2,s1*s2]]
[q^2, q, q, 0]
```

```
>>> from sage.all import *
>>> R = QQ['q']; (q,) = R._first_ngens(1)
>>> W = WeylGroup("A2", prefix='s')
>>> [s1,s2] = W.simple_reflections()
>>> KL = KazhdanLusztigPolynomial(W, q)
>>> [KL.R_tilde(x,s2*s1) for x in [Integer(1),s1,s2,s1*s2]]
[q^2, q, q, 0]
```

5.1.132 Key polynomials

Key polynomials (also known as type A Demazure characters) are defined by applying the divided difference operator π_σ, where σ is a permutation, to a monomial corresponding to an integer partition $\mu \vdash n$.

See also

For Demazure characters in other types, see

- *sage.combinat.root_system.weyl_characters.WeylCharacterRing.demazure_character()*

- Trevor K. Karn (2022-08-17): initial version

class sage.combinat.key_polynomial.**KeyPolynomial**

Bases: IndexedFreeModuleElement

A key polynomial.

Key polynomials are polynomials that form a basis for a polynomial ring and are indexed by weak compositions.

Elements should be created by first creating the basis *KeyPolynomialBasis* and passing a list representing the indexing composition.

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: f = k([4,3,2,1]) + k([1,2,3,4]); f
k[1, 2, 3, 4] + k[4, 3, 2, 1]
sage: f in k
True
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> f = k([Integer(4),Integer(3),Integer(2),Integer(1)]) + k([Integer(1),
↪Integer(2),Integer(3),Integer(4)]); f
k[1, 2, 3, 4] + k[4, 3, 2, 1]
>>> f in k
True
```

divided_difference(*w*)

Apply the divided difference operator ∂_w to self.

The convention is to apply from left to right so if w = [w1, w2, ..., wm] then we apply $\partial_{w_2 \cdots w_m} \circ \partial_{w_1}$

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: k([3,2,1]).divided_difference(2)
k[3, 1, 1]
sage: k([3,2,1]).divided_difference([2,3])
k[3, 1]

sage: k = KeyPolynomials(QQ, 4)
sage: k([3,2,1,0]).divided_difference(2)
k[3, 1, 1, 0]
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k([Integer(3),Integer(2),Integer(1)]).divided_difference(Integer(2))
k[3, 1, 1]
>>> k([Integer(3),Integer(2),Integer(1)]).divided_difference([Integer(2),
↪Integer(3)])
k[3, 1]

>>> k = KeyPolynomials(QQ, Integer(4))
>>> k([Integer(3),Integer(2),Integer(1),Integer(0)]).divided_
↪difference(Integer(2))
k[3, 1, 1, 0]
```

expand()

Return `self` written in the monomial basis (i.e., as an element in the corresponding polynomial ring).

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: f = k([4,3,2,1])
sage: f.expand()
z_3*z_2^2*z_1^3*z_0^4

sage: f = k([1,2,3])
sage: f.expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^2*z_1^3*z_0
 + 2*z_2^2*z_1^2*z_0^2 + z_2^2*z_1*z_0^3 + z_2*z_1^3*z_0^2
 + z_2*z_1^2*z_0^3
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> f = k([Integer(4),Integer(3),Integer(2),Integer(1)])
>>> f.expand()
z_3*z_2^2*z_1^3*z_0^4

>>> f = k([Integer(1),Integer(2),Integer(3)])
>>> f.expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^2*z_1^3*z_0
 + 2*z_2^2*z_1^2*z_0^2 + z_2^2*z_1*z_0^3 + z_2*z_1^3*z_0^2
 + z_2*z_1^2*z_0^3
```

isobaric_divided_difference(*w*)

Apply the operator π_w to `self`.

`w` may be either a `Permutation` or a list of indices of simple transpositions (1-based).

The convention is to apply from left to right so if `w = [w1, w2, ..., wm]` then we apply $\pi_{w_2 \cdots w_m} \circ \pi_{w_1}$

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: k([3,2,1]).pi(2)
k[3, 1, 2]
sage: k([3,2,1]).pi([2,1])
k[1, 3, 2]
sage: k([3,2,1]).pi(Permutation([3,2,1]))
k[1, 2, 3]
sage: f = k([3,2,1]) + k([3,2,1,1])
sage: f.pi(2)
k[3, 1, 2] + k[3, 1, 2, 1]
sage: k.one().pi(1)
k[]

sage: k([3,2,1,0]).pi(2).pi(2)
k[3, 1, 2]
sage: (-k([3,2,1,0]) + 4*k([3,1,2,0])).pi(2)
3*k[3, 1, 2]
```

(continues on next page)

(continued from previous page)

```
sage: k = KeyPolynomials(QQ, 4)
sage: k([3,2,1,0]).pi(2)
k[3, 1, 2, 0]
sage: k([3,2,1,0]).pi([2,1])
k[1, 3, 2, 0]
sage: k([3,2,1,0]).pi(Permutation([3,2,1,4]))
k[1, 2, 3, 0]
sage: f = k([3,2,1,0]) + k([3,2,1,1])
sage: f.pi(2)
k[3, 1, 2, 0] + k[3, 1, 2, 1]
sage: k.one().pi(1)
k[0, 0, 0, 0]
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k([Integer(3),Integer(2),Integer(1)]).pi(Integer(2))
k[3, 1, 2]
>>> k([Integer(3),Integer(2),Integer(1)]).pi([Integer(2),Integer(1)])
k[1, 3, 2]
>>> k([Integer(3),Integer(2),Integer(1)]).pi(Permutation([Integer(3),
↪Integer(2),Integer(1)]))
k[1, 2, 3]
>>> f = k([Integer(3),Integer(2),Integer(1)]) + k([Integer(3),Integer(2),
↪Integer(1),Integer(1)])
>>> f.pi(Integer(2))
k[3, 1, 2] + k[3, 1, 2, 1]
>>> k.one().pi(Integer(1))
k[]

>>> k([Integer(3),Integer(2),Integer(1),Integer(0)]).pi(Integer(2)).
↪pi(Integer(2))
k[3, 1, 2]
>>> (-k([Integer(3),Integer(2),Integer(1),Integer(0)]) +␣
↪Integer(4)*k([Integer(3),Integer(1),Integer(2),Integer(0)])).pi(Integer(2))
3*k[3, 1, 2]

>>> k = KeyPolynomials(QQ, Integer(4))
>>> k([Integer(3),Integer(2),Integer(1),Integer(0)]).pi(Integer(2))
k[3, 1, 2, 0]
>>> k([Integer(3),Integer(2),Integer(1),Integer(0)]).pi([Integer(2),
↪Integer(1)])
k[1, 3, 2, 0]
>>> k([Integer(3),Integer(2),Integer(1),Integer(0)]).
↪pi(Permutation([Integer(3),Integer(2),Integer(1),Integer(4)]))
k[1, 2, 3, 0]
>>> f = k([Integer(3),Integer(2),Integer(1),Integer(0)]) + k([Integer(3),
↪Integer(2),Integer(1),Integer(1)])
>>> f.pi(Integer(2))
k[3, 1, 2, 0] + k[3, 1, 2, 1]
>>> k.one().pi(Integer(1))
k[0, 0, 0, 0]
```

pi(*w*)

Apply the operator π_w to `self`.

`w` may be either a `Permutation` or a list of indices of simple transpositions (1-based).

The convention is to apply from left to right so if `w = [w1, w2, ..., wm]` then we apply $\pi_{w_2 \cdots w_m} \circ \pi_{w_1}$

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: k([3,2,1]).pi(2)
k[3, 1, 2]
sage: k([3,2,1]).pi([2,1])
k[1, 3, 2]
sage: k([3,2,1]).pi(Permutation([3,2,1]))
k[1, 2, 3]
sage: f = k([3,2,1]) + k([3,2,1,1])
sage: f.pi(2)
k[3, 1, 2] + k[3, 1, 2, 1]
sage: k.one().pi(1)
k[]

sage: k([3,2,1,0]).pi(2).pi(2)
k[3, 1, 2]
sage: (-k([3,2,1,0]) + 4*k([3,1,2,0])).pi(2)
3*k[3, 1, 2]

sage: k = KeyPolynomials(QQ, 4)
sage: k([3,2,1,0]).pi(2)
k[3, 1, 2, 0]
sage: k([3,2,1,0]).pi([2,1])
k[1, 3, 2, 0]
sage: k([3,2,1,0]).pi(Permutation([3,2,1,4]))
k[1, 2, 3, 0]
sage: f = k([3,2,1,0]) + k([3,2,1,1])
sage: f.pi(2)
k[3, 1, 2, 0] + k[3, 1, 2, 1]
sage: k.one().pi(1)
k[0, 0, 0, 0]
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k([Integer(3),Integer(2),Integer(1)]).pi(Integer(2))
k[3, 1, 2]
>>> k([Integer(3),Integer(2),Integer(1)]).pi([Integer(2),Integer(1)])
k[1, 3, 2]
>>> k([Integer(3),Integer(2),Integer(1)]).pi(Permutation([Integer(3),
↪Integer(2),Integer(1)]))
k[1, 2, 3]
>>> f = k([Integer(3),Integer(2),Integer(1)]) + k([Integer(3),Integer(2),
↪Integer(1),Integer(1)])
>>> f.pi(Integer(2))
k[3, 1, 2] + k[3, 1, 2, 1]
>>> k.one().pi(Integer(1))
k[]
```

(continues on next page)

(continued from previous page)

```
>>> k([Integer(3),Integer(2),Integer(1),Integer(0)]).pi(Integer(2)).
→pi(Integer(2))
k[3, 1, 2]
>>> (-k([Integer(3),Integer(2),Integer(1),Integer(0)]) +␣
→Integer(4)*k([Integer(3),Integer(1),Integer(2),Integer(0)])).pi(Integer(2))
3*k[3, 1, 2]

>>> k = KeyPolynomials(QQ, Integer(4))
>>> k([Integer(3),Integer(2),Integer(1),Integer(0)]).pi(Integer(2))
k[3, 1, 2, 0]
>>> k([Integer(3),Integer(2),Integer(1),Integer(0)]).pi([Integer(2),
→Integer(1)])
k[1, 3, 2, 0]
>>> k([Integer(3),Integer(2),Integer(1),Integer(0)]).
→pi(Permutation([Integer(3),Integer(2),Integer(1),Integer(4)]))
k[1, 2, 3, 0]
>>> f = k([Integer(3),Integer(2),Integer(1),Integer(0)]) + k([Integer(3),
→Integer(2),Integer(1),Integer(1)])
>>> f.pi(Integer(2))
k[3, 1, 2, 0] + k[3, 1, 2, 1]
>>> k.one().pi(Integer(1))
k[0, 0, 0, 0]
```

to_polynomial()

Return `self` written in the monomial basis (i.e., as an element in the corresponding polynomial ring).

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: f = k([4,3,2,1])
sage: f.expand()
z_3*z_2^2*z_1^3*z_0^4

sage: f = k([1,2,3])
sage: f.expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^2*z_1^3*z_0
 + 2*z_2^2*z_1^2*z_0^2 + z_2^2*z_1*z_0^3 + z_2*z_1^3*z_0^2
 + z_2*z_1^2*z_0^3
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> f = k([Integer(4),Integer(3),Integer(2),Integer(1)])
>>> f.expand()
z_3*z_2^2*z_1^3*z_0^4

>>> f = k([Integer(1),Integer(2),Integer(3)])
>>> f.expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^2*z_1^3*z_0
 + 2*z_2^2*z_1^2*z_0^2 + z_2^2*z_1*z_0^3 + z_2*z_1^3*z_0^2
 + z_2*z_1^2*z_0^3
```

class sage.combinat.key_polynomial.**KeyPolynomialBasis**(*R=None*, *k=None*, *poly_ring=None*)

Bases: *CombinatorialFreeModule*

The key polynomial basis for a polynomial ring.

For a full definition, see SymmetricFunctions.com. Key polynomials are indexed by weak compositions with no trailing zeros, and σ is the permutation of shortest length which sorts the indexing composition into a partition.

EXAMPLES:

Key polynomials are a basis, indexed by (weak) compositions, for polynomial rings:

```
sage: k = KeyPolynomials(QQ)
sage: k([3,0,1,2])
k[3, 0, 1, 2]
sage: k([3,0,1,2])/2
1/2*k[3, 0, 1, 2]
sage: R = k.polynomial_ring(); R
Infinite polynomial ring in z over Rational Field

sage: K = KeyPolynomials(GF(5)); K
Key polynomial basis over Finite Field of size 5
sage: 2*K([3,0,1,2])
2*k[3, 0, 1, 2]
sage: 5*(K([3,0,1,2]) + K([3,1,1]))
0
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k([Integer(3),Integer(0),Integer(1),Integer(2)])
k[3, 0, 1, 2]
>>> k([Integer(3),Integer(0),Integer(1),Integer(2)])/Integer(2)
1/2*k[3, 0, 1, 2]
>>> R = k.polynomial_ring(); R
Infinite polynomial ring in z over Rational Field

>>> K = KeyPolynomials(GF(Integer(5))); K
Key polynomial basis over Finite Field of size 5
>>> Integer(2)*K([Integer(3),Integer(0),Integer(1),Integer(2)])
2*k[3, 0, 1, 2]
>>> Integer(5)*(K([Integer(3),Integer(0),Integer(1),Integer(2)]) + K([Integer(3),
↪Integer(1),Integer(1)]))
0
```

We can expand them in the standard monomial basis:

```
sage: k([3,0,1,2]).expand()
z_3^2*z_2*z_0^3 + z_3^2*z_1*z_0^3 + z_3*z_2^2*z_0^3
 + 2*z_3*z_2*z_1*z_0^3 + z_3*z_1^2*z_0^3 + z_2^2*z_1*z_0^3
 + z_2*z_1^2*z_0^3

sage: k([0,0,2]).expand()
z_2^2 + z_2*z_1 + z_2*z_0 + z_1^2 + z_1*z_0 + z_0^2
```

```
>>> from sage.all import *
>>> k([Integer(3),Integer(0),Integer(1),Integer(2)]).expand()
z_3^2*z_2*z_0^3 + z_3^2*z_1*z_0^3 + z_3*z_2^2*z_0^3
 + 2*z_3*z_2*z_1*z_0^3 + z_3*z_1^2*z_0^3 + z_2^2*z_1*z_0^3
 + z_2*z_1^2*z_0^3

>>> k([Integer(0),Integer(0),Integer(2)]).expand()
z_2^2 + z_2*z_1 + z_2*z_0 + z_1^2 + z_1*z_0 + z_0^2
```

If we have a polynomial, we can express it in the key basis:

```
sage: z = R.gen()
sage: k.from_polynomial(z[2]^2*z[1]*z[0])
k[1, 1, 2] - k[1, 2, 1]

sage: f = z[3]^2*z[2]*z[0]^3 + z[3]^2*z[1]*z[0]^3 + z[3]*z[2]^2*z[0]^3 + \
....: 2*z[3]*z[2]*z[1]*z[0]^3 + z[3]*z[1]^2*z[0]^3 + z[2]^2*z[1]*z[0]^3 + \
....: z[2]*z[1]^2*z[0]^3
sage: k.from_polynomial(f)
k[3, 0, 1, 2]
```

```
>>> from sage.all import *
>>> z = R.gen()
>>> k.from_polynomial(z[Integer(2)]**Integer(2)*z[Integer(1)]*z[Integer(0)])
k[1, 1, 2] - k[1, 2, 1]

>>> f = z[Integer(3)]**Integer(2)*z[Integer(2)]*z[Integer(0)]**Integer(3) +␣
↪z[Integer(3)]**Integer(2)*z[Integer(1)]*z[Integer(0)]**Integer(3) +␣
↪z[Integer(3)]*z[Integer(2)]**Integer(2)*z[Integer(0)]**Integer(3) +␣
↪Integer(2)*z[Integer(3)]*z[Integer(2)]*z[Integer(1)]*z[Integer(0)]**Integer(3)␣
↪+ z[Integer(3)]*z[Integer(1)]**Integer(2)*z[Integer(0)]**Integer(3) +␣
↪z[Integer(2)]**Integer(2)*z[Integer(1)]*z[Integer(0)]**Integer(3) +␣
↪z[Integer(2)]*z[Integer(1)]**Integer(2)*z[Integer(0)]**Integer(3)
>>> k.from_polynomial(f)
k[3, 0, 1, 2]
```

Since the ring of key polynomials may be regarded as a different choice of basis for a polynomial ring, it forms an algebra, so we have multiplication:

```
sage: k([10,5,2])*k([1,1,1])
k[11, 6, 3]
```

```
>>> from sage.all import *
>>> k([Integer(10),Integer(5),Integer(2)])*k([Integer(1),Integer(1),Integer(1)])
k[11, 6, 3]
```

We can also multiply by polynomials in the monomial basis:

```
sage: k([10,9,1])*z[0]
k[11, 9, 1]
sage: z[0] * k([10,9,1])
k[11, 9, 1]
```

(continues on next page)

(continued from previous page)

```
sage: k([10,9,1])*(z[0] + z[3])
k[10, 9, 1, 1] + k[11, 9, 1]
```

```
>>> from sage.all import *
>>> k([Integer(10),Integer(9),Integer(1)])*z[Integer(0)]
k[11, 9, 1]
>>> z[Integer(0)] * k([Integer(10),Integer(9),Integer(1)])
k[11, 9, 1]
>>> k([Integer(10),Integer(9),Integer(1)])*(z[Integer(0)] + z[Integer(3)])
k[10, 9, 1, 1] + k[11, 9, 1]
```

When the sorting permutation is the longest element, the key polynomial agrees with the Schur polynomial:

```
sage: s = SymmetricFunctions(QQ).schur()
sage: k([1,2,3]).expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^2*z_1^3*z_0
 + 2*z_2^2*z_1^2*z_0^2 + z_2^2*z_1*z_0^3 + z_2*z_1^3*z_0^2
 + z_2*z_1^2*z_0^3
sage: s[3,2,1].expand(3)
x0^3*x1^2*x2 + x0^2*x1^3*x2 + x0^3*x1*x2^2 + 2*x0^2*x1^2*x2^2
 + x0*x1^3*x2^2 + x0^2*x1*x2^3 + x0*x1^2*x2^3
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).schur()
>>> k([Integer(1),Integer(2),Integer(3)]).expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^2*z_1^3*z_0
 + 2*z_2^2*z_1^2*z_0^2 + z_2^2*z_1*z_0^3 + z_2*z_1^3*z_0^2
 + z_2*z_1^2*z_0^3
>>> s[Integer(3),Integer(2),Integer(1)].expand(Integer(3))
x0^3*x1^2*x2 + x0^2*x1^3*x2 + x0^3*x1*x2^2 + 2*x0^2*x1^2*x2^2
 + x0*x1^3*x2^2 + x0^2*x1*x2^3 + x0*x1^2*x2^3
```

The polynomial expansions can be computed using crystals and expressed in terms of the key basis:

```
sage: T = crystals.Tableaux(['A',3],shape=[2,1])
sage: f = T.demazure_character([3,2,1])
sage: k.from_polynomial(f)
k[1, 0, 0, 2]
```

```
>>> from sage.all import *
>>> T = crystals.Tableaux(['A',Integer(3)],shape=[Integer(2),Integer(1)])
>>> f = T.demazure_character([Integer(3),Integer(2),Integer(1)])
>>> k.from_polynomial(f)
k[1, 0, 0, 2]
```

The default behavior is to work in a polynomial ring with infinitely many variables. One can work in a specicfied number of variables:

```
sage: k = KeyPolynomials(QQ, 4)
sage: k([3,0,1,2]).expand()
z_0^3*z_1^2*z_2 + z_0^3*z_1*z_2^2 + z_0^3*z_1^2*z_3
 + 2*z_0^3*z_1*z_2*z_3 + z_0^3*z_2^2*z_3 + z_0^3*z_1*z_3^2 + z_0^3*z_2*z_3^2
```

(continues on next page)

(continued from previous page)

```
sage: k([0,0,2,0]).expand()
z_0^2 + z_0*z_1 + z_1^2 + z_0*z_2  + z_1*z_2 + z_2^2

sage: k([0,0,2,0]).expand().parent()
Multivariate Polynomial Ring in z_0, z_1, z_2, z_3 over Rational Field
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ, Integer(4))
>>> k([Integer(3),Integer(0),Integer(1),Integer(2)]).expand()
z_0^3*z_1^2*z_2 + z_0^3*z_1*z_2^2 + z_0^3*z_1^2*z_3
 + 2*z_0^3*z_1*z_2*z_3 + z_0^3*z_2^2*z_3 + z_0^3*z_1*z_3^2 + z_0^3*z_2*z_3^2

>>> k([Integer(0),Integer(0),Integer(2),Integer(0)]).expand()
z_0^2 + z_0*z_1 + z_1^2 + z_0*z_2  + z_1*z_2 + z_2^2

>>> k([Integer(0),Integer(0),Integer(2),Integer(0)]).expand().parent()
Multivariate Polynomial Ring in z_0, z_1, z_2, z_3 over Rational Field
```

If working in a specified number of variables, the length of the indexing composition must be the same as the number of variables:

```
sage: k([0,0,2])
Traceback (most recent call last):
 ...
TypeError: do not know how to make x (= [0, 0, 2]) an element of self
 (=Key polynomial basis over Rational Field)
```

```
>>> from sage.all import *
>>> k([Integer(0),Integer(0),Integer(2)])
Traceback (most recent call last):
 ...
TypeError: do not know how to make x (= [0, 0, 2]) an element of self
 (=Key polynomial basis over Rational Field)
```

One can also work in a specified polynomial ring:

```
sage: k = KeyPolynomials(QQ['x0', 'x1', 'x2', 'x3'])
sage: k([0,2,0,0])
k[0, 2, 0, 0]
sage: k([4,0,0,0]).expand()
x0^4
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ['x0', 'x1', 'x2', 'x3'])
>>> k([Integer(0),Integer(2),Integer(0),Integer(0)])
k[0, 2, 0, 0]
>>> k([Integer(4),Integer(0),Integer(0),Integer(0)]).expand()
x0^4
```

If one wishes to use a polynomial ring as coefficients for the key polynomials, pass the keyword argument `poly_coeffs=True`:

```
sage: k = KeyPolynomials(QQ['q'], poly_coeffs=True)
sage: R = k.base_ring(); R
Univariate Polynomial Ring in q over Rational Field
sage: R.inject_variables()
Defining q
sage: (q^2 + q + 1)*k([0,2,2,0,3,2])
(q^2+q+1)*k[0, 2, 2, 0, 3, 2]
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ['q'], poly_coeffs=True)
>>> R = k.base_ring(); R
Univariate Polynomial Ring in q over Rational Field
>>> R.inject_variables()
Defining q
>>> (q**Integer(2) + q + Integer(1))*k([Integer(0),Integer(2),Integer(2),
↪Integer(0),Integer(3),Integer(2)])
(q^2+q+1)*k[0, 2, 2, 0, 3, 2]
```

Element

alias of *KeyPolynomial*

degree_on_basis(*alpha*)

Return the degree of the basis element indexed by `alpha`.

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: k.degree_on_basis([2,1,0,2])
5

sage: k = KeyPolynomials(QQ, 5)
sage: k.degree_on_basis([2,1,0,2,0])
5
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k.degree_on_basis([Integer(2),Integer(1),Integer(0),Integer(2)])
5

>>> k = KeyPolynomials(QQ, Integer(5))
>>> k.degree_on_basis([Integer(2),Integer(1),Integer(0),Integer(2),
↪Integer(0)])
5
```

from_polynomial(*f*)

Expand a polynomial in terms of the key basis.

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: z = k.poly_gens(); z
z_*
sage: p = z[0]^4*z[1]^2*z[2]*z[3] + z[0]^4*z[1]*z[2]^2*z[3]
```

(continues on next page)

(continued from previous page)

```
sage: k.from_polynomial(p)
k[4, 1, 2, 1]

sage: all(k(c) == k.from_polynomial(k(c).expand()) for c in␣
↪IntegerVectors(n=5, k=4))
True

sage: T = crystals.Tableaux(['A', 4], shape=[4,2,1,1])
sage: k.from_polynomial(T.demazure_character([2]))
k[4, 1, 2, 1]
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> z = k.poly_gens(); z
z_*
>>> p = z[Integer(0)]**Integer(4)*z[Integer(1)]**Integer(2)*z[Integer(2)]*z[In
↪teger(3)] + z[Integer(0)]**Integer(4)*z[Integer(1)]*z[Integer(2)]**Integer(2
↪)*z[Integer(3)]
>>> k.from_polynomial(p)
k[4, 1, 2, 1]

>>> all(k(c) == k.from_polynomial(k(c).expand()) for c in␣
↪IntegerVectors(n=Integer(5), k=Integer(4)))
True

>>> T = crystals.Tableaux(['A', Integer(4)], shape=[Integer(4),Integer(2),
↪Integer(1),Integer(1)])
>>> k.from_polynomial(T.demazure_character([Integer(2)]))
k[4, 1, 2, 1]
```

from_schubert_polynomial(*x*)

Expand a Schubert polynomial in the key basis.

EXAMPLES:

```
sage: k = KeyPolynomials(ZZ)
sage: X = SchubertPolynomialRing(ZZ)
sage: f = X([2,1,5,4,3])
sage: k.from_schubert_polynomial(f)
k[1, 0, 2, 1] + k[2, 0, 2] + k[3, 0, 0, 1]
sage: k.from_schubert_polynomial(2)
2*k[]
sage: k(f)
k[1, 0, 2, 1] + k[2, 0, 2] + k[3, 0, 0, 1]

sage: k = KeyPolynomials(GF(7), 4)
sage: k.from_schubert_polynomial(f)
k[1, 0, 2, 1] + k[2, 0, 2, 0] + k[3, 0, 0, 1]
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(ZZ)
>>> X = SchubertPolynomialRing(ZZ)
```

(continues on next page)

(continued from previous page)

```
>>> f = X([Integer(2),Integer(1),Integer(5),Integer(4),Integer(3)])
>>> k.from_schubert_polynomial(f)
k[1, 0, 2, 1] + k[2, 0, 2] + k[3, 0, 0, 1]
>>> k.from_schubert_polynomial(Integer(2))
2*k[]
>>> k(f)
k[1, 0, 2, 1] + k[2, 0, 2] + k[3, 0, 0, 1]

>>> k = KeyPolynomials(GF(Integer(7)), Integer(4))
>>> k.from_schubert_polynomial(f)
k[1, 0, 2, 1] + k[2, 0, 2, 0] + k[3, 0, 0, 1]
```

one_basis()

Return the basis element indexing the identity.

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: k.one_basis()
[]

sage: k = KeyPolynomials(QQ, 4)
sage: k.one_basis()
[0, 0, 0, 0]
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k.one_basis()
[]

>>> k = KeyPolynomials(QQ, Integer(4))
>>> k.one_basis()
[0, 0, 0, 0]
```

poly_gens()

Return the polynomial generators for the polynomial ring associated to `self`.

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: k.poly_gens()
z_*

sage: k = KeyPolynomials(QQ, 4)
sage: k.poly_gens()
(z_0, z_1, z_2, z_3)
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k.poly_gens()
z_*

```

(continues on next page)

(continued from previous page)

```
>>> k = KeyPolynomials(QQ, Integer(4))
>>> k.poly_gens()
(z_0, z_1, z_2, z_3)
```

polynomial_ring()

Return the polynomial ring associated to `self`.

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: k.polynomial_ring()
Infinite polynomial ring in z over Rational Field

sage: k = KeyPolynomials(QQ, 4)
sage: k.polynomial_ring()
Multivariate Polynomial Ring in z_0, z_1, z_2, z_3 over Rational Field
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k.polynomial_ring()
Infinite polynomial ring in z over Rational Field

>>> k = KeyPolynomials(QQ, Integer(4))
>>> k.polynomial_ring()
Multivariate Polynomial Ring in z_0, z_1, z_2, z_3 over Rational Field
```

sage.combinat.key_polynomial.**divided_difference**(f, i)

Apply the `i`-th divided difference operator to the polynomial `f`.

EXAMPLES:

```
sage: from sage.combinat.key_polynomial import divided_difference
sage: k = KeyPolynomials(QQ)
sage: z = k.poly_gens()
sage: f = z[1]*z[2]^3 + z[1]*z[2]*z[3]
sage: divided_difference(f, 3)
z_3^2*z_1 + z_3*z_2*z_1 + z_2^2*z_1

sage: k = KeyPolynomials(QQ, 4)
sage: z = k.poly_gens()
sage: f = z[1]*z[2]^3 + z[1]*z[2]*z[3]
sage: divided_difference(f, 3)
z_1*z_2^2 + z_1*z_2*z_3 + z_1*z_3^2

sage: k = KeyPolynomials(QQ)
sage: R = k.polynomial_ring(); R
Infinite polynomial ring in z over Rational Field
sage: z = R.gen()
sage: divided_difference(z[1]*z[2]^3, 2)
-z_2^2*z_1 - z_2*z_1^2
sage: divided_difference(z[1]*z[2]*z[3], 3)
0
sage: divided_difference(z[1]*z[2]*z[3], 4)
```

(continues on next page)

(continued from previous page)

```
z_2*z_1
sage: divided_difference(z[1]*z[2]*z[4], 4)
-z_2*z_1

sage: k = KeyPolynomials(QQ, 5)
sage: z = k.polynomial_ring().gens()
sage: divided_difference(z[1]*z[2]^3, 2)
-z_1^2*z_2 - z_1*z_2^2
sage: divided_difference(z[1]*z[2]*z[3], 3)
0
sage: divided_difference(z[1]*z[2]*z[3], 4)
z_1*z_2
sage: divided_difference(z[1]*z[2]*z[4], 4)
-z_1*z_2
```

```
>>> from sage.all import *
>>> from sage.combinat.key_polynomial import divided_difference
>>> k = KeyPolynomials(QQ)
>>> z = k.poly_gens()
>>> f = z[Integer(1)]*z[Integer(2)]**Integer(3) +␣
↪z[Integer(1)]*z[Integer(2)]*z[Integer(3)]
>>> divided_difference(f, Integer(3))
z_3^2*z_1 + z_3*z_2*z_1 + z_2^2*z_1

>>> k = KeyPolynomials(QQ, Integer(4))
>>> z = k.poly_gens()
>>> f = z[Integer(1)]*z[Integer(2)]**Integer(3) +␣
↪z[Integer(1)]*z[Integer(2)]*z[Integer(3)]
>>> divided_difference(f, Integer(3))
z_1*z_2^2 + z_1*z_2*z_3 + z_1*z_3^2

>>> k = KeyPolynomials(QQ)
>>> R = k.polynomial_ring(); R
Infinite polynomial ring in z over Rational Field
>>> z = R.gen()
>>> divided_difference(z[Integer(1)]*z[Integer(2)]**Integer(3), Integer(2))
-z_2^2*z_1 - z_2*z_1^2
>>> divided_difference(z[Integer(1)]*z[Integer(2)]*z[Integer(3)], Integer(3))
0
>>> divided_difference(z[Integer(1)]*z[Integer(2)]*z[Integer(3)], Integer(4))
z_2*z_1
>>> divided_difference(z[Integer(1)]*z[Integer(2)]*z[Integer(4)], Integer(4))
-z_2*z_1

>>> k = KeyPolynomials(QQ, Integer(5))
>>> z = k.polynomial_ring().gens()
>>> divided_difference(z[Integer(1)]*z[Integer(2)]**Integer(3), Integer(2))
-z_1^2*z_2 - z_1*z_2^2
>>> divided_difference(z[Integer(1)]*z[Integer(2)]*z[Integer(3)], Integer(3))
0
>>> divided_difference(z[Integer(1)]*z[Integer(2)]*z[Integer(3)], Integer(4))
z_1*z_2
```

(continues on next page)

(continued from previous page)

```
>>> divided_difference(z[Integer(1)]*z[Integer(2)]*z[Integer(4)], Integer(4))
-z_1*z_2
```

sage.combinat.key_polynomial.**isobaric_divided_difference**(*f*, *w*)

Apply the isobaric divided difference operator π_w to the polynomial f.

w may be either a single index or a list of indices of simple transpositions.

> **Warning**
>
> The simple transpositions should be applied from left to right.

EXAMPLES:

```
sage: from sage.combinat.key_polynomial import isobaric_divided_difference as idd
sage: R.<z> = InfinitePolynomialRing(GF(3))
sage: idd(z[1]^4*z[2]^2*z[4], 4)
0

sage: idd(z[1]^4*z[2]^2*z[3]*z[4], 3)
z_4*z_3^2*z_2*z_1^4 + z_4*z_3*z_2^2*z_1^4

sage: idd(z[1]^4*z[2]^2*z[3]*z[4], [3, 4])
z_4^2*z_3*z_2*z_1^4 + z_4*z_3^2*z_2*z_1^4 + z_4*z_3*z_2^2*z_1^4

sage: idd(z[1]^4*z[2]^2*z[3]*z[4], [4, 3])
z_4*z_3^2*z_2*z_1^4 + z_4*z_3*z_2^2*z_1^4

sage: idd(z[1]^2*z[2], [3, 2])
z_3*z_2^2 + z_3*z_2*z_1 + z_3*z_1^2 + z_2^2*z_1 + z_2*z_1^2
```

```
>>> from sage.all import *
>>> from sage.combinat.key_polynomial import isobaric_divided_difference as idd
>>> R = InfinitePolynomialRing(GF(Integer(3)), names=('z',)); (z,) = R._first_
↪ngens(1)
>>> idd(z[Integer(1)]**Integer(4)*z[Integer(2)]**Integer(2)*z[Integer(4)],␣
↪Integer(4))
0

>>> idd(z[Integer(1)]**Integer(4)*z[Integer(2)]**Integer(2)*z[Integer(3)]*z[Inte-
ger(4)], Integer(3))
z_4*z_3^2*z_2*z_1^4 + z_4*z_3*z_2^2*z_1^4

>>> idd(z[Integer(1)]**Integer(4)*z[Integer(2)]**Integer(2)*z[Integer(3)]*z[Inte-
ger(4)], [Integer(3), Integer(4)])
z_4^2*z_3*z_2*z_1^4 + z_4*z_3^2*z_2*z_1^4 + z_4*z_3*z_2^2*z_1^4

>>> idd(z[Integer(1)]**Integer(4)*z[Integer(2)]**Integer(2)*z[Integer(3)]*z[Inte-
ger(4)], [Integer(4), Integer(3)])
z_4*z_3^2*z_2*z_1^4 + z_4*z_3*z_2^2*z_1^4
```

(continues on next page)

(continued from previous page)

```
>>> idd(z[Integer(1)]**Integer(2)*z[Integer(2)], [Integer(3), Integer(2)])
z_3*z_2^2 + z_3*z_2*z_1 + z_3*z_1^2 + z_2^2*z_1 + z_2*z_1^2
```

sage.combinat.key_polynomial.**sorting_word**(*alpha*)

Get a reduced word for the permutation which sorts `alpha` into a partition.

The result is a list `l = [i0, i1, i2, ...]` where each `ij` is a positive integer such that it applies the simple transposition $(i_j, i_j + 1)$. The transpositions are applied starting with `i0`, then `i1` is applied, followed by `i2`, and so on. See *sage.combinat.permutation.Permutation.reduced_words()* for the convention used.

EXAMPLES:

```
sage: IV = IntegerVectors()
sage: from sage.combinat.key_polynomial import sorting_word
sage: list(sorting_word(IV([2,3,2]))[0])
[1]
sage: sorting_word(IV([2,3,2]))[1]
[3, 2, 2]
sage: list(sorting_word(IV([5,6,7]))[0])
[1, 2, 1]
sage: list(sorting_word(IV([0,3,2]))[0])
[2, 1]
sage: list(sorting_word(IV([0,3,0,2]))[0])
[2, 3, 1]
sage: list(sorting_word(IV([3,2,1]))[0])
[]
sage: list(sorting_word(IV([2,3,3]))[0])
[2, 1]
```

```
>>> from sage.all import *
>>> IV = IntegerVectors()
>>> from sage.combinat.key_polynomial import sorting_word
>>> list(sorting_word(IV([Integer(2),Integer(3),Integer(2)]))[Integer(0)])
[1]
>>> sorting_word(IV([Integer(2),Integer(3),Integer(2)]))[Integer(1)]
[3, 2, 2]
>>> list(sorting_word(IV([Integer(5),Integer(6),Integer(7)]))[Integer(0)])
[1, 2, 1]
>>> list(sorting_word(IV([Integer(0),Integer(3),Integer(2)]))[Integer(0)])
[2, 1]
>>> list(sorting_word(IV([Integer(0),Integer(3),Integer(0),
↪Integer(2)]))[Integer(0)])
[2, 3, 1]
>>> list(sorting_word(IV([Integer(3),Integer(2),Integer(1)]))[Integer(0)])
[]
>>> list(sorting_word(IV([Integer(2),Integer(3),Integer(3)]))[Integer(0)])
[2, 1]
```

5.1.133 Knutson-Tao Puzzles

This module implements a generic algorithm to solve Knutson-Tao puzzles. An instance of this class will be callable: the arguments are the labels of north-east and north-west sides of the puzzle boundary; the output is the list of the fillings of the puzzle with the specified pieces.

Acknowledgements

This code was written during Sage Days 45 at ICERM with Franco Saliola, Anne Schilling, and Avinash Dalal in discussions with Allen Knutson. The code was tested afterwards by Liz Beazley and Ed Richmond.

Todo

Functionality to add:

- plotter will not plot edge labels higher than 2; e.g. in BK puzzles, the labels are 1,…, n and so in 3-step examples, none of the edge labels with 3 appear
- we should also have a 3-step puzzle pieces constructor, taken from p22 of arXiv math/0610538
- implement the bijection from puzzles to tableaux; see for example R. Vakil, A geometric Littlewood-Richardson rule, arXiv math/0302294 or K. Purbhoo, Puzzles, Tableaux and Mosaics, arXiv 0705.1184.

sage.combinat.knutson_tao_puzzles.**BK_pieces**(*max_letter*)

The puzzle pieces used in computing the Belkale-Kumar coefficients for any partial flag variety in type A.

There are two types of puzzle pieces:

- a triangle, with each edge labeled with the same letter;
- a rhombus, with edges labeled i, j, i, j in clockwise order with $i > j$.

Each of these is rotated by 60 degrees, but not reflected.

We model the rhombus pieces as two triangles: a delta piece north-west label i, north-east label j and south label $i(j)$; and a nabla piece with south-east label i, south-west label j and north label $i(j)$.

INPUT:

- max_letter – positive integer specifying the number of steps in the partial flag variety, equivalently, the number of elements in the alphabet for the edge labels. The smallest label is 1.

REFERENCES:

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import BK_pieces
sage: BK_pieces(3)
Nablas : [1\1/1, 1\2(1)/2, 1\3(1)/3, 2(1)\2/1, 2\1/2(1), 2\2/2, 2\3(2)/3, 3(1)\3/
↪1, 3(2)\3/2, 3\1/3(1), 3\2/3(2), 3\3/3]
Deltas : [1/1\1, 1/2\2(1), 1/3\3(1), 2(1)/1\2, 2/2(1)\1, 2/2\2, 2/3\3(2), 3(1)/1\
↪3, 3(2)/2\3, 3/3(1)\1, 3/3(2)\2, 3/3\3]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import BK_pieces
>>> BK_pieces(Integer(3))
Nablas : [1\1/1, 1\2(1)/2, 1\3(1)/3, 2(1)\2/1, 2\1/2(1), 2\2/2, 2\3(2)/3, 3(1)\3/
↪1, 3(2)\3/2, 3\1/3(1), 3\2/3(2), 3\3/3]
```

(continues on next page)

(continued from previous page)

```
Deltas : [1/1\1, 1/2\2(1), 1/3\3(1), 2(1)/1\2, 2/2(1)\1, 2/2\2, 2/3\3(2), 3(1)/1\
↪3, 3(2)/2\3, 3/3(1)\1, 3/3(2)\2, 3/3\3]
```

class sage.combinat.knutson_tao_puzzles.**DeltaPiece**(*south*, *north_west*, *north_east*)

Bases: *PuzzlePiece*

Delta Piece takes as input three labels, inputted as strings. They label the South, Northwest and Northeast edges, respectively.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: DeltaPiece('a','b','c')
b/a\c
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> DeltaPiece('a','b','c')
b/a\c
```

clockwise_rotation()

Rotate the Delta piece by 120 degree clockwise.

OUTPUT: Delta piece

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('1','2','3')
sage: delta.clockwise_rotation()
1/3\2
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> delta = DeltaPiece('1','2','3')
>>> delta.clockwise_rotation()
1/3\2
```

edges()

Return the tuple of edge names.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('1','2','3')
sage: delta.edges()
('south', 'north_west', 'north_east')
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> delta = DeltaPiece('1','2','3')
>>> delta.edges()
('south', 'north_west', 'north_east')
```

half_turn_rotation()

Rotate the Delta piece by 180 degree.

OUTPUT: Nabla piece

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('1','2','3')
sage: delta.half_turn_rotation()
3\1/2
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> delta = DeltaPiece('1','2','3')
>>> delta.half_turn_rotation()
3\1/2
```

sage.combinat.knutson_tao_puzzles.**HT_grassmannian_pieces**()

Define the puzzle pieces used in computing the torus-equivariant cohomology of the Grassmannian.

REFERENCES:

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import HT_grassmannian_pieces
sage: HT_grassmannian_pieces()
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1, 1\T0|1/0]
Deltas : [0/0\0, 0/1\10, 0/T0|1\1, 1/10\0, 1/1\1, 10/0\1]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import HT_grassmannian_pieces
>>> HT_grassmannian_pieces()
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1, 1\T0|1/0]
Deltas : [0/0\0, 0/1\10, 0/T0|1\1, 1/10\0, 1/1\1, 10/0\1]
```

sage.combinat.knutson_tao_puzzles.**HT_two_step_pieces**()

Define the puzzle pieces used in computing the equivariant two step puzzle pieces.

For the puzzle pieces, see Figure 26 on page 22 of [CoskunVakil06].

REFERENCES:

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import HT_two_step_pieces
sage: HT_two_step_pieces()
Nablas : [(21)0\21/0, 0\(21)0/21, 0\0/0, 0\10/1, 0\20/2, 10\1/0, 10\2(10)/2,

```

sage.combinat.knutson_tao_puzzles.**H_two_step_pieces**()

Define the puzzle pieces used in two step flags.

This rule is currently only conjecturally true. See [BuchKreschTamvakis03].

```

class sage.combinat.knutson_tao_puzzles.**KnutsonTaoPuzzleSolver**(*puzzle_pieces*)

Bases: `UniqueRepresentation`

Return puzzle solver function used to create all puzzles with given boundary conditions.

This class implements a generic algorithm to solve Knutson-Tao puzzles. An instance of this class will be callable: the arguments are the labels of north-east and north-west sides of the puzzle boundary; the output is the list of the fillings of the puzzle with the specified pieces.

INPUT:

- `puzzle_pieces` – takes either a collection of puzzle pieces or a string indicating a pre-programmed collection of puzzle pieces:
  - `H` – cohomology of the Grassmannian
  - `HT` – equivariant cohomology of the Grassmannian
  - `K` – K-theory
  - `H2step` – cohomology of the *2-step* Grassmannian
  - `HT2step` – equivariant cohomology of the *2-step* Grassmannian
  - `BK` – Belkale-Kumar puzzle pieces
- `max_letter` – `None` or a positive integer(default: `None`); this is only required for Belkale-Kumar puzzles

EXAMPLES:

Each puzzle piece is an edge-labelled triangle oriented in such a way that it has a south edge (called a *delta* piece) or a north edge (called a *nabla* piece). For example, the puzzle pieces corresponding to the cohomology of the Grassmannian are the following:

```
sage: from sage.combinat.knutson_tao_puzzles import H_grassmannian_pieces
sage: H_grassmannian_pieces()
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import H_grassmannian_pieces
>>> H_grassmannian_pieces()
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

In the string representation, the nabla pieces are depicted as `c\a/b`, where a is the label of the north edge, b is the label of the south-east edge, c is the label of the south-west edge. A similar string representation exists for the delta pieces.

To create a puzzle solver, one specifies a collection of puzzle pieces:

```
sage: KnutsonTaoPuzzleSolver(H_grassmannian_pieces())
Knutson-Tao puzzle solver with pieces:
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

```
>>> from sage.all import *
>>> KnutsonTaoPuzzleSolver(H_grassmannian_pieces())
Knutson-Tao puzzle solver with pieces:
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

The following shorthand to create the above puzzle solver is also supported:

```
sage: KnutsonTaoPuzzleSolver('H')
Knutson-Tao puzzle solver with pieces:
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

```
>>> from sage.all import *
>>> KnutsonTaoPuzzleSolver('H')
Knutson-Tao puzzle solver with pieces:
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

The solver will compute all fillings of the puzzle with the given puzzle pieces. The user specifies the labels of north-east and north-west sides of the puzzle boundary and the output is a list of the fillings of the puzzle with the specified pieces. For example, there is one solution to the puzzle whose north-west and north-east edges are both labeled '0':

```
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: ps('0', '0')
[{(1, 1): 0/0\0}]
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver('H')
```

(continues on next page)

(continued from previous page)

```
>>> ps('0', '0')
[{(1, 1): 0/0\0}]
```

There are two solutions to the puzzle whose north-west and north-east edges are both labeled '0101':

```
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: solns = ps('0101', '0101')
sage: len(solns)
2
sage: solns.sort(key=str)
sage: solns
[{(1, 1): 0/0\0,
  (1, 2): 1/\0  0\/1,
  (1, 3): 0/\0  0\/0,
  (1, 4): 1/\0  0\/1,
  (2, 2): 1/1\1,
  (2, 3): 0/\10  1\/1,
  (2, 4): 1/\1  10\/0,
  (3, 3): 1/1\1,
  (3, 4): 0/\0  1\/10,
  (4, 4): 10/0\1}, {(1, 1): 0/1\10,
  (1, 2): 1/\1  10\/0,
  (1, 3): 0/\0  1\/10,
  (1, 4): 1/\0  0\/1,
  (2, 2): 0/0\0,
  (2, 3): 10/\1  0\/0,
  (2, 4): 1/\1  1\/1,
  (3, 3): 0/0\0,
  (3, 4): 1/\0  0\/1,
  (4, 4): 1/1\1}]
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver('H')
>>> solns = ps('0101', '0101')
>>> len(solns)
2
>>> solns.sort(key=str)
>>> solns
[{(1, 1): 0/0\0,
  (1, 2): 1/\0  0\/1,
  (1, 3): 0/\0  0\/0,
  (1, 4): 1/\0  0\/1,
  (2, 2): 1/1\1,
  (2, 3): 0/\10  1\/1,
  (2, 4): 1/\1  10\/0,
  (3, 3): 1/1\1,
  (3, 4): 0/\0  1\/10,
  (4, 4): 10/0\1}, {(1, 1): 0/1\10,
  (1, 2): 1/\1  10\/0,
  (1, 3): 0/\0  1\/10,
  (1, 4): 1/\0  0\/1,
  (2, 2): 0/0\0,
```

(continues on next page)

(continued from previous page)

```
 (2, 3): 10/\1  0\/0,
 (2, 4): 1/\1  1\/1,
 (3, 3): 0/0\0,
 (3, 4): 1/\0  0\/1,
 (4, 4): 1/1\1}]
```

The pieces in a puzzle filling are indexed by pairs of nonnegative integers (i, j) with $1 \leq i \leq j \leq n$, where n is the length of the word labelling the triangle edge. The pieces indexed by (i, i) are the triangles along the south edge of the puzzle.

```
sage: f = solns[0]
sage: [f[i, i] for i in range(1,5)]
[0/0\0, 1/1\1, 1/1\1, 10/0\1]
```

```
>>> from sage.all import *
>>> f = solns[Integer(0)]
>>> [f[i, i] for i in range(Integer(1),Integer(5))]
[0/0\0, 1/1\1, 1/1\1, 10/0\1]
```

The pieces indexed by (i, j) for $j > i$ are a pair consisting of a delta piece and nabla piece glued together along the south edge and north edge, respectively (these pairs are called *rhombi*).

```
sage: f = solns[0]
sage: f[1, 2]
1/\0  0\/1
```

```
>>> from sage.all import *
>>> f = solns[Integer(0)]
>>> f[Integer(1), Integer(2)]
1/\0  0\/1
```

There are various methods and options to display puzzle solutions. A single puzzle can be displayed using the plot method of the puzzle:

```
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: puzzle = ps('0101','1001')[0]
sage: puzzle.plot()  #not tested
sage: puzzle.plot(style='fill')  #not tested
sage: puzzle.plot(style='edges')  #not tested
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver("H")
>>> puzzle = ps('0101','1001')[Integer(0)]
>>> puzzle.plot()  #not tested
>>> puzzle.plot(style='fill')  #not tested
>>> puzzle.plot(style='edges')  #not tested
```

To plot several puzzle solutions, use the plot method of the puzzle solver:

```
sage: ps = KnutsonTaoPuzzleSolver('K')
sage: solns = ps('0101', '0101')
sage: ps.plot(solns)        # not tested
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver('K')
>>> solns = ps('0101', '0101')
>>> ps.plot(solns)         # not tested
```

The code can also generate a PDF of a puzzle (using LaTeX and *tikz*):

```
sage: latex.extra_preamble(r'''\usepackage{tikz}''')
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: solns = ps('0101', '0101')
sage: view(solns[0], viewer='pdf')   # not tested
```

```
>>> from sage.all import *
>>> latex.extra_preamble(r'''\usepackage{tikz}''')
>>> ps = KnutsonTaoPuzzleSolver('H')
>>> solns = ps('0101', '0101')
>>> view(solns[Integer(0)], viewer='pdf')   # not tested
```

Below are examples of using each of the currently supported puzzles.

Cohomology of the Grassmannian:

```
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: solns = ps('0101', '0101')
sage: sorted(solns, key=str)
[{(1, 1): 0/0\0,
  (1, 2): 1/\0  0\/1,
  (1, 3): 0/\0  0\/0,
  (1, 4): 1/\0  0\/1,
  (2, 2): 1/1\1,
  (2, 3): 0/\10  1\/1,
  (2, 4): 1/\1  10\/0,
  (3, 3): 1/1\1,
  (3, 4): 0/\0  1\/10,
  (4, 4): 10/0\1}, {(1, 1): 0/1\10,
  (1, 2): 1/\1  10\/0,
  (1, 3): 0/\0  1\/10,
  (1, 4): 1/\0  0\/1,
  (2, 2): 0/0\0,
  (2, 3): 10/\1  0\/0,
  (2, 4): 1/\1  1\/1,
  (3, 3): 0/0\0,
  (3, 4): 1/\0  0\/1,
  (4, 4): 1/1\1}]
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver("H")
>>> solns = ps('0101', '0101')
>>> sorted(solns, key=str)
[{(1, 1): 0/0\0,
  (1, 2): 1/\0  0\/1,
  (1, 3): 0/\0  0\/0,
  (1, 4): 1/\0  0\/1,
```

(continues on next page)

(continued from previous page)

```
  (2, 2): 1/1\1,
  (2, 3): 0/\10  1\/1,
  (2, 4): 1/\1  10\/0,
  (3, 3): 1/1\1,
  (3, 4): 0/\0  1\/10,
  (4, 4): 10/0\1}, {(1, 1): 0/1\10,
  (1, 2): 1/\1  10\/0,
  (1, 3): 0/\0  1\/10,
  (1, 4): 1/\0  0\/1,
  (2, 2): 0/0\0,
  (2, 3): 10/\1  0\/0,
  (2, 4): 1/\1  1\/1,
  (3, 3): 0/0\0,
  (3, 4): 1/\0  0\/1,
  (4, 4): 1/1\1}]
```

Equivariant puzzles:

```
sage: ps = KnutsonTaoPuzzleSolver("HT")
sage: solns = ps('0101', '0101')
sage: sorted(solns, key=str)
[{(1, 1): 0/0\0,
  (1, 2): 1/\0  0\/1,
  (1, 3): 0/\0  0\/0,
  (1, 4): 1/\0  0\/1,
  (2, 2): 1/1\1,
  (2, 3): 0/\1  1\/0,
  (2, 4): 1/\1  1\/1,
  (3, 3): 0/0\0,
  (3, 4): 1/\0  0\/1,
  (4, 4): 1/1\1}, {(1, 1): 0/0\0,
  (1, 2): 1/\0  0\/1,
  (1, 3): 0/\0  0\/0,

  (2, 5): 3(2)/\3  2(1)\/1,
  (3, 3): 1/1\1,
  (3, 4): 2/\1  1\/2,
  (3, 5): 1/\1  1\/1,
  (4, 4): 2/2\2,
  (4, 5): 1/\1  2\/2(1),
  (5, 5): 2(1)/1\2}]
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver('BK', Integer(3))
>>> solns = ps('12132', '23112')
>>> len(solns)
1
>>> solns[Integer(0)].south_labels()
('3', '2', '1', '2', '1')
```

(continues on next page)

(continued from previous page)

```
>>> solns
[{(1, 1): 1/3\3(1),
  (1, 2): 2/\3(2)  3(1)\/1,
  (1, 3): 1/\3(1)  3(2)\/2,
  (1, 4): 3/\3  3(1)\/1,
  (1, 5): 2/\2  3\/3(2),
  (2, 2): 1/2\2(1),
  (2, 3): 2/\2  2(1)\/1,
  (2, 4): 1/\2(1)  2\/2,
  (2, 5): 3(2)/\3  2(1)\/1,
  (3, 3): 1/1\1,
  (3, 4): 2/\1  1\/2,
  (3, 5): 1/\1  1\/1,
  (4, 4): 2/2\2,
  (4, 5): 1/\1  2\/2(1),
  (5, 5): 2(1)/1\2}]
```

plot(*puzzles*)

Return plot of puzzles.

INPUT:

- `puzzles` – list of puzzles

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver('K')
sage: solns = ps('0101', '0101')
sage: ps.plot(solns)        # not tested
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
>>> ps = KnutsonTaoPuzzleSolver('K')
>>> solns = ps('0101', '0101')
>>> ps.plot(solns)        # not tested
```

puzzle_pieces()

The puzzle pieces used for filling in the puzzles.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: ps.puzzle_pieces()
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
>>> ps = KnutsonTaoPuzzleSolver('H')
>>> ps.puzzle_pieces()
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

solutions(*lamda*, *mu*, *algorithm='strips'*)

structure_constants(*lamda*, *mu*, *nu=None*)

Compute cohomology structure coefficients from puzzles.

INPUT:

- `pieces` – puzzle pieces to be used
- `lambda`, `mu` – edge labels of puzzle for northwest and north east side
- `nu` – (default: `None`) if `nu` is not specified a dictionary is returned with the structure coefficients corresponding to all south labels; if `nu` is given, only the coefficients with the specified label is returned

OUTPUT: dictionary

EXAMPLES:

Note: In order to standardize the output of the following examples, we output a sorted list of items from the dictionary instead of the dictionary itself.

Grassmannian cohomology:

```
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: cp = ps.structure_constants('0101', '0101')
sage: sorted(cp.items(), key=str)
[(('0', '1', '1', '0'), 1), (('1', '0', '0', '1'), 1)]
sage: ps.structure_constants('001001', '001010', '010100')
1
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver('H')
>>> cp = ps.structure_constants('0101', '0101')
>>> sorted(cp.items(), key=str)
[(('0', '1', '1', '0'), 1), (('1', '0', '0', '1'), 1)]
>>> ps.structure_constants('001001', '001010', '010100')
1
```

Equivariant cohomology:

```
sage: ps = KnutsonTaoPuzzleSolver('HT')
sage: cp = ps.structure_constants('0101', '0101')
sage: sorted(cp.items(), key=str)
[(('0', '1', '0', '1'), y2 - y3),
(('0', '1', '1', '0'), 1),
(('1', '0', '0', '1'), 1)]
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver('HT')
>>> cp = ps.structure_constants('0101', '0101')
>>> sorted(cp.items(), key=str)
[(('0', '1', '0', '1'), y2 - y3),
(('0', '1', '1', '0'), 1),
(('1', '0', '0', '1'), 1)]
```

K-theory:

```
sage: ps = KnutsonTaoPuzzleSolver('K')
sage: cp = ps.structure_constants('0101', '0101')
sage: sorted(cp.items(), key=str)
[(('0', '1', '1', '0'), 1), (('1', '0', '0', '1'), 1), (('1', '0', '1', '0'),␣
↪-1)]
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver('K')
>>> cp = ps.structure_constants('0101', '0101')
>>> sorted(cp.items(), key=str)
[(('0', '1', '1', '0'), 1), (('1', '0', '0', '1'), 1), (('1', '0', '1', '0'),␣
↪-1)]
```

Two-step:

```
sage: ps = KnutsonTaoPuzzleSolver('H2step')
sage: cp = ps.structure_constants('01122', '01122')
sage: sorted(cp.items(), key=str)
[(('0', '1', '1', '2', '2'), 1)]
sage: cp = ps.structure_constants('01201', '01021')
sage: sorted(cp.items(), key=str)
[(('0', '2', '1', '1', '0'), 1),
 (('1', '2', '0', '0', '1'), 1),
 (('2', '0', '1', '0', '1'), 1)]
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver('H2step')
>>> cp = ps.structure_constants('01122', '01122')
>>> sorted(cp.items(), key=str)
[(('0', '1', '1', '2', '2'), 1)]
>>> cp = ps.structure_constants('01201', '01021')
>>> sorted(cp.items(), key=str)
[(('0', '2', '1', '1', '0'), 1),
 (('1', '2', '0', '0', '1'), 1),
 (('2', '0', '1', '0', '1'), 1)]
```

Two-step equivariant:

```
sage: ps = KnutsonTaoPuzzleSolver('HT2step')
sage: cp = ps.structure_constants('10212', '12012')
sage: sorted(cp.items(), key=str)
[(('1', '2', '0', '1', '2'), y1*y2 - y2*y3 - y1*y4 + y3*y4),
 (('1', '2', '0', '2', '1'), y1 - y3),
 (('1', '2', '1', '0', '2'), y2 - y4),
 (('1', '2', '1', '2', '0'), 1),
 (('1', '2', '2', '0', '1'), 1),
 (('2', '1', '0', '1', '2'), y1 - y3),
 (('2', '1', '1', '0', '2'), 1)]
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver('HT2step')
>>> cp = ps.structure_constants('10212', '12012')
```

(continues on next page)

(continued from previous page)

```
>>> sorted(cp.items(), key=str)
[(('1', '2', '0', '1', '2'), y1*y2 - y2*y3 - y1*y4 + y3*y4),
 (('1', '2', '0', '2', '1'), y1 - y3),
 (('1', '2', '1', '0', '2'), y2 - y4),
 (('1', '2', '1', '2', '0'), 1),
 (('1', '2', '2', '0', '1'), 1),
 (('2', '1', '0', '1', '2'), y1 - y3),
 (('2', '1', '1', '0', '2'), 1)]
```

class sage.combinat.knutson_tao_puzzles.**NablaPiece**(*north*, *south_east*, *south_west*)

Bases: *PuzzlePiece*

Nabla Piece takes as input three labels, inputted as strings. They label the North, Southeast and Southwest edges, respectively.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: NablaPiece('a','b','c')
c\a/b
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import NablaPiece
>>> NablaPiece('a','b','c')
c\a/b
```

clockwise_rotation()

Rotate the Nabla piece by 120 degree clockwise.

OUTPUT: Nabla piece

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: nabla = NablaPiece('1','2','3')
sage: nabla.clockwise_rotation()
2\3/1
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import NablaPiece
>>> nabla = NablaPiece('1','2','3')
>>> nabla.clockwise_rotation()
2\3/1
```

edges()

Return the tuple of edge names.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: nabla = NablaPiece('1','2','3')
sage: nabla.edges()
('north', 'south_east', 'south_west')
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import NablaPiece
>>> nabla = NablaPiece('1','2','3')
>>> nabla.edges()
('north', 'south_east', 'south_west')
```

half_turn_rotation()

Rotate the Nabla piece by 180 degree.

OUTPUT: Delta piece

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: nabla = NablaPiece('1','2','3')
sage: nabla.half_turn_rotation()
2/1\3
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import NablaPiece
>>> nabla = NablaPiece('1','2','3')
>>> nabla.half_turn_rotation()
2/1\3
```

class sage.combinat.knutson_tao_puzzles.**PuzzleFilling**(*north_west_labels*, *north_east_labels*)

Bases: `object`

Create partial puzzles and provides methods to build puzzles from them.

add_piece(*piece*)

Add `piece` to partial puzzle.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
sage: piece = DeltaPiece('0','1','0')
sage: P = PuzzleFilling('0101','0101'); P
{}
sage: P.add_piece(piece); P
{(1, 4): 1/0\0}
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
>>> piece = DeltaPiece('0','1','0')
>>> P = PuzzleFilling('0101','0101'); P
{}
>>> P.add_piece(piece); P
{(1, 4): 1/0\0}
```

add_pieces(*pieces*)

Add `piece` to partial puzzle.

INPUT:

- `pieces` – tuple of pieces

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
sage: P = PuzzleFilling('0101','0101'); P
{}
sage: piece = DeltaPiece('0','1','0')
sage: pieces = [piece,piece]
sage: P.add_pieces(pieces)
sage: P
{(1, 4): 1/0\0, (2, 4): 1/0\0}
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
>>> P = PuzzleFilling('0101','0101'); P
{}
>>> piece = DeltaPiece('0','1','0')
>>> pieces = [piece,piece]
>>> P.add_pieces(pieces)
>>> P
{(1, 4): 1/0\0, (2, 4): 1/0\0}
```

contribution()

Return equivariant contributions from `self` in polynomial ring.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver("HT")
sage: puzzles = ps('0101','1001')
sage: sorted([p.contribution() for p in puzzles], key=str)
[1, y1 - y3]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
>>> ps = KnutsonTaoPuzzleSolver("HT")
>>> puzzles = ps('0101','1001')
>>> sorted([p.contribution() for p in puzzles], key=str)
[1, y1 - y3]
```

copy()

Return copy of `self`.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
sage: piece = DeltaPiece('0','1','0')
sage: P = PuzzleFilling('0101','0101'); P
{}
sage: PP = P.copy()
sage: P.add_piece(piece); P
{(1, 4): 1/0\0}
sage: PP
{}
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
>>> piece = DeltaPiece('0','1','0')
>>> P = PuzzleFilling('0101','0101'); P
{}
>>> PP = P.copy()
>>> P.add_piece(piece); P
{(1, 4): 1/0\0}
>>> PP
{}
```

is_completed()

Whether partial puzzle is complete (completely filled) or not.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P.is_completed()
False

sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: puzzle = ps('0101','1001')[0]
sage: puzzle.is_completed()
True
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzleFilling
>>> P = PuzzleFilling('0101','0101')
>>> P.is_completed()
False

>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
>>> ps = KnutsonTaoPuzzleSolver("H")
>>> puzzle = ps('0101','1001')[Integer(0)]
>>> puzzle.is_completed()
True
```

is_in_south_edge()

Check whether kink coordinates of partial puzzle is in south corner.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P.is_in_south_edge()
False
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzleFilling
>>> P = PuzzleFilling('0101','0101')
```

(continues on next page)

(continued from previous page)

```
>>> P.is_in_south_edge()
False
```

kink_coordinates()

Provide the coordinates of the kinks.

The kink coordinates are the coordinates up to which the puzzle has already been built. The kink starts in the north corner and then moves down the diagonals as the puzzles is built.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P
{}
sage: P.kink_coordinates()
(1, 4)
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzleFilling
>>> P = PuzzleFilling('0101','0101')
>>> P
{}
>>> P.kink_coordinates()
(1, 4)
```

north_east_label_of_kink()

Return north east label of kink.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P.north_east_label_of_kink()
'0'
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzleFilling
>>> P = PuzzleFilling('0101','0101')
>>> P.north_east_label_of_kink()
'0'
```

north_west_label_of_kink()

Return north-west label of kink.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P.north_west_label_of_kink()
'1'
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzleFilling
>>> P = PuzzleFilling('0101','0101')
>>> P.north_west_label_of_kink()
'1'
```

plot (*labels=True*, *style='fill'*)

Plot completed puzzle.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: puzzle = ps('0101','1001')[0]
sage: puzzle.plot()  #not tested
sage: puzzle.plot(style='fill')  #not tested
sage: puzzle.plot(style='edges')  #not tested
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
>>> ps = KnutsonTaoPuzzleSolver("H")
>>> puzzle = ps('0101','1001')[Integer(0)]
>>> puzzle.plot()  #not tested
>>> puzzle.plot(style='fill')  #not tested
>>> puzzle.plot(style='edges')  #not tested
```

south_labels ()

Return south labels for completed puzzle.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: ps('0101','1001')[0].south_labels()
('1', '0', '1', '0')
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
>>> ps = KnutsonTaoPuzzleSolver("H")
>>> ps('0101','1001')[Integer(0)].south_labels()
('1', '0', '1', '0')
```

class sage.combinat.knutson_tao_puzzles.**PuzzlePiece**

Bases: `object`

Abstract class for puzzle pieces.

This abstract class contains information on how to test equality of puzzle pieces, and sets color and plotting options.

border ()

Return the border of `self`.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('a','b','c')
sage: sorted(delta.border())
['a', 'b', 'c']
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> delta = DeltaPiece('a','b','c')
>>> sorted(delta.border())
['a', 'b', 'c']
```

color()

Return the color of `self`.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('a','b','c')
sage: delta.color()
'white'
sage: delta = DeltaPiece('0','0','0')
sage: delta.color()
'red'
sage: delta = DeltaPiece('1','1','1')
sage: delta.color()
'blue'
sage: delta = DeltaPiece('2','2','2')
sage: delta.color()
'green'
sage: delta = DeltaPiece('2','K','2')
sage: delta.color()
'orange'
sage: delta = DeltaPiece('2','T1/2','2')
sage: delta.color()
'yellow'
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> delta = DeltaPiece('a','b','c')
>>> delta.color()
'white'
>>> delta = DeltaPiece('0','0','0')
>>> delta.color()
'red'
>>> delta = DeltaPiece('1','1','1')
>>> delta.color()
'blue'
>>> delta = DeltaPiece('2','2','2')
>>> delta.color()
'green'
>>> delta = DeltaPiece('2','K','2')
>>> delta.color()
'orange'
```

(continues on next page)

(continued from previous page)

```
>>> delta = DeltaPiece('2','T1/2','2')
>>> delta.color()
'yellow'
```

edge_color(*edge*)

Color of the specified edge of `self` (to be used when plotting the piece).

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('1','0','10')
sage: delta.edge_color('south')
'blue'
sage: delta.edge_color('north_west')
'red'
sage: delta.edge_color('north_east')
'white'
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> delta = DeltaPiece('1','0','10')
>>> delta.edge_color('south')
'blue'
>>> delta.edge_color('north_west')
'red'
>>> delta.edge_color('north_east')
'white'
```

edge_label(*edge*)

Return the edge label of `edge`.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('2','K','2')
sage: delta.edge_label('south')
'2'
sage: delta.edge_label('north_east')
'2'
sage: delta.edge_label('north_west')
'K'
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> delta = DeltaPiece('2','K','2')
>>> delta.edge_label('south')
'2'
>>> delta.edge_label('north_east')
'2'
>>> delta.edge_label('north_west')
'K'
```

class sage.combinat.knutson_tao_puzzles.**PuzzlePieces**(*forbidden_border_labels=None*)

Bases: `object`

Construct a valid set of puzzle pieces.

This class constructs the set of valid puzzle pieces. It can take a list of forbidden border labels as input. These labels are forbidden from appearing on the south edge of a puzzle filling. The user can add valid nabla or delta pieces and specify which rotations of these pieces are legal. For example, `rotations=0` does not add any additional pieces (only the piece itself), `rotations=60` adds six pieces (the pieces and its rotations by 60, 120, 180, 240, 300), etc..

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, NablaPiece
sage: forbidden_border_labels = ['10']
sage: pieces = PuzzlePieces(forbidden_border_labels)
sage: pieces.add_piece(NablaPiece('0','0','0'), rotations=60)
sage: pieces.add_piece(NablaPiece('1','1','1'), rotations=60)
sage: pieces.add_piece(NablaPiece('1','0','10'), rotations=60)
sage: pieces
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces, NablaPiece
>>> forbidden_border_labels = ['10']
>>> pieces = PuzzlePieces(forbidden_border_labels)
>>> pieces.add_piece(NablaPiece('0','0','0'), rotations=Integer(60))
>>> pieces.add_piece(NablaPiece('1','1','1'), rotations=Integer(60))
>>> pieces.add_piece(NablaPiece('1','0','10'), rotations=Integer(60))
>>> pieces
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

The user can obtain the list of valid rhombi pieces as follows:

```
sage: sorted([p for p in pieces.rhombus_pieces()], key=str)
[0/\0  0\/0, 0/\0  1\/10, 0/\10  10\/0, 0/\10  1\/1, 1/\0  0\/1,
1/\1  10\/0, 1/\1  1\/1, 10/\1  0\/0, 10/\1  1\/10]
```

```
>>> from sage.all import *
>>> sorted([p for p in pieces.rhombus_pieces()], key=str)
[0/\0  0\/0, 0/\0  1\/10, 0/\10  10\/0, 0/\10  1\/1, 1/\0  0\/1,
1/\1  10\/0, 1/\1  1\/1, 10/\1  0\/0, 10/\1  1\/10]
```

add_T_piece(*label1*, *label2*)

Add a nabla and delta piece with `label1` and `label2`.

This method adds a nabla piece with edges `label2`T``label1``|``label2`` / `label1`. and a delta piece with edges `label1`/ T``label1``|``label2`` `label2`. It also adds T``label1``|``label2`` to the forbidden list.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces
sage: pieces = PuzzlePieces()
```

(continues on next page)

(continued from previous page)

```
sage: pieces.add_T_piece('1','3')
sage: pieces
Nablas : [3\T1|3/1]
Deltas : [1/T1|3\3]
sage: pieces._forbidden_border_labels
['T1|3']
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces
>>> pieces = PuzzlePieces()
>>> pieces.add_T_piece('1','3')
>>> pieces
Nablas : [3\T1|3/1]
Deltas : [1/T1|3\3]
>>> pieces._forbidden_border_labels
['T1|3']
```

add_forbidden_label(*label*)

Add forbidden border labels.

INPUT:

- `label` – string specifying a new forbidden label

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces
sage: pieces = PuzzlePieces()
sage: pieces.add_forbidden_label('1')
sage: pieces._forbidden_border_labels
['1']
sage: pieces.add_forbidden_label('2')
sage: pieces._forbidden_border_labels
['1', '2']
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces
>>> pieces = PuzzlePieces()
>>> pieces.add_forbidden_label('1')
>>> pieces._forbidden_border_labels
['1']
>>> pieces.add_forbidden_label('2')
>>> pieces._forbidden_border_labels
['1', '2']
```

add_piece(*piece*, *rotations=120*)

Add `piece` to the list of pieces.

INPUT:

- `piece` – a nabla piece or a delta piece
- `rotations` – (default: 120) 0, 60, 120, 180

The user can add valid nabla or delta pieces and specify which rotations of these pieces are legal. For example, `rotations=0` does not add any additional pieces (only the piece itself), `rotations=60` adds six pieces (namely three delta and three nabla pieces), while `rotations=120` adds only delta or nabla (depending on which piece `self` is). `rotations=180` adds the piece and its 180 degree rotation, i.e. one delta and one nabla piece.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: delta = DeltaPiece('a','b','c')
sage: pieces = PuzzlePieces()
sage: pieces
Nablas : []
Deltas : []
sage: pieces.add_piece(delta)
sage: pieces
Nablas : []
Deltas : [a/c\b, b/a\c, c/b\a]

sage: pieces = PuzzlePieces()
sage: pieces.add_piece(delta,rotations=0)
sage: pieces
Nablas : []
Deltas : [b/a\c]

sage: pieces = PuzzlePieces()
sage: pieces.add_piece(delta,rotations=60)
sage: pieces
Nablas : [a\b/c, b\c/a, c\a/b]
Deltas : [a/c\b, b/a\c, c/b\a]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
>>> delta = DeltaPiece('a','b','c')
>>> pieces = PuzzlePieces()
>>> pieces
Nablas : []
Deltas : []
>>> pieces.add_piece(delta)
>>> pieces
Nablas : []
Deltas : [a/c\b, b/a\c, c/b\a]

>>> pieces = PuzzlePieces()
>>> pieces.add_piece(delta,rotations=Integer(0))
>>> pieces
Nablas : []
Deltas : [b/a\c]

>>> pieces = PuzzlePieces()
>>> pieces.add_piece(delta,rotations=Integer(60))
>>> pieces
Nablas : [a\b/c, b\c/a, c\a/b]
Deltas : [a/c\b, b/a\c, c/b\a]
```

boundary_deltas()

Return deltas with south edges not in the forbidden list.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: pieces = PuzzlePieces(['a'])
sage: delta = DeltaPiece('a','b','c')
sage: pieces.add_piece(delta,rotations=60)
sage: sorted([p for p in pieces.boundary_deltas()], key=str)
[a/c\b, c/b\a]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
>>> pieces = PuzzlePieces(['a'])
>>> delta = DeltaPiece('a','b','c')
>>> pieces.add_piece(delta,rotations=Integer(60))
>>> sorted([p for p in pieces.boundary_deltas()], key=str)
[a/c\b, c/b\a]
```

delta_pieces()

Return the delta pieces as a set.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: pieces = PuzzlePieces()
sage: delta = DeltaPiece('a','b','c')
sage: pieces.add_piece(delta,rotations=60)
sage: sorted([p for p in pieces.delta_pieces()], key=str)
[a/c\b, b/a\c, c/b\a]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
>>> pieces = PuzzlePieces()
>>> delta = DeltaPiece('a','b','c')
>>> pieces.add_piece(delta,rotations=Integer(60))
>>> sorted([p for p in pieces.delta_pieces()], key=str)
[a/c\b, b/a\c, c/b\a]
```

nabla_pieces()

Return the nabla pieces as a set.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: pieces = PuzzlePieces()
sage: delta = DeltaPiece('a','b','c')
sage: pieces.add_piece(delta,rotations=60)
sage: sorted([p for p in pieces.nabla_pieces()], key=str)
[a\b/c, b\c/a, c\a/b]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
>>> pieces = PuzzlePieces()
```

(continues on next page)

(continued from previous page)

```
>>> delta = DeltaPiece('a','b','c')
>>> pieces.add_piece(delta,rotations=Integer(60))
>>> sorted([p for p in pieces.nabla_pieces()], key=str)
[a\b/c, b\c/a, c\a/b]
```

rhombus_pieces()

Return a set of all allowable rhombus pieces.

Allowable rhombus pieces are those where the south edge of the delta piece equals the north edge of the nabla piece.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: pieces = PuzzlePieces()
sage: delta = DeltaPiece('a','b','c')
sage: pieces.add_piece(delta,rotations=60)
sage: sorted([p for p in pieces.rhombus_pieces()], key=str)
[a/\b  b\/a, b/\c  c\/b, c/\a  a\/c]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
>>> pieces = PuzzlePieces()
>>> delta = DeltaPiece('a','b','c')
>>> pieces.add_piece(delta,rotations=Integer(60))
>>> sorted([p for p in pieces.rhombus_pieces()], key=str)
[a/\b  b\/a, b/\c  c\/b, c/\a  a\/c]
```

class sage.combinat.knutson_tao_puzzles.**RhombusPiece**(*north_piece*, *south_piece*)

Bases: *PuzzlePiece*

Class of rhombi pieces.

To construct a rhombus piece we input a delta and a nabla piece. The delta and nabla pieces are joined along the south and north edge, respectively.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,␣
↪RhombusPiece
sage: delta = DeltaPiece('1','2','3')
sage: nabla = NablaPiece('4','5','6')
sage: RhombusPiece(delta,nabla)
2/\3  6\/5
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,␣
↪RhombusPiece
>>> delta = DeltaPiece('1','2','3')
>>> nabla = NablaPiece('4','5','6')
>>> RhombusPiece(delta,nabla)
2/\3  6\/5
```

edges()

Return the tuple of edge names.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,
↪RhombusPiece
sage: delta = DeltaPiece('1','2','3')
sage: nabla = NablaPiece('4','5','6')
sage: RhombusPiece(delta,nabla).edges()
('north_west', 'north_east', 'south_east', 'south_west')
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,
↪RhombusPiece
>>> delta = DeltaPiece('1','2','3')
>>> nabla = NablaPiece('4','5','6')
>>> RhombusPiece(delta,nabla).edges()
('north_west', 'north_east', 'south_east', 'south_west')
```

north_piece()

Return the north piece.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,
↪RhombusPiece
sage: delta = DeltaPiece('1','2','3')
sage: nabla = NablaPiece('4','5','6')
sage: r = RhombusPiece(delta,nabla)
sage: r.north_piece()
2/1\3
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,
↪RhombusPiece
>>> delta = DeltaPiece('1','2','3')
>>> nabla = NablaPiece('4','5','6')
>>> r = RhombusPiece(delta,nabla)
>>> r.north_piece()
2/1\3
```

south_piece()

Return the south piece.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,
↪RhombusPiece
sage: delta = DeltaPiece('1','2','3')
sage: nabla = NablaPiece('4','5','6')
sage: r = RhombusPiece(delta,nabla)
sage: r.south_piece()
6\4/5
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,␣
↪RhombusPiece
>>> delta = DeltaPiece('1','2','3')
>>> nabla = NablaPiece('4','5','6')
>>> r = RhombusPiece(delta,nabla)
>>> r.south_piece()
6\4/5
```

5.1.134 Combinatorics on matrices

- *Dancing Links internal pyx code*
- *Dancing links C++ wrapper*
- *Hadamard matrices*
- *Latin Squares*

5.1.135 Dancing Links internal pyx code

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: x = dlx_solver(rows)
sage: x
Dancing links solver for 6 columns and 6 rows
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),Integer(5)],␣
↪[Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),Integer(5)],␣
↪[Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)]]
>>> x = dlx_solver(rows)
>>> x
Dancing links solver for 6 columns and 6 rows
```

The number of solutions:

```
sage: x.number_of_solutions()
3
```

```
>>> from sage.all import *
>>> x.number_of_solutions()
3
```

Iterate over the solutions:

```
sage: sorted(map(sorted, x.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> sorted(map(sorted, x.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

All solutions (computed in parallel):

```
sage: sorted(map(sorted, x.all_solutions()))
[[0, 1], [2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> sorted(map(sorted, x.all_solutions()))
[[0, 1], [2, 3], [4, 5]]
```

Return the first solution found when the computation is done in parallel:

```
sage: sorted(x.one_solution(ncpus=2)) # random
[0, 1]
```

```
>>> from sage.all import *
>>> sorted(x.one_solution(ncpus=Integer(2))) # random
[0, 1]
```

Find all solutions using some specific rows:

```
sage: x_using_row_2 = x.restrict([2])
sage: x_using_row_2
Dancing links solver for 7 columns and 6 rows
sage: sorted(map(sorted, x_using_row_2.solutions_iterator()))
[[2, 3]]
```

```
>>> from sage.all import *
>>> x_using_row_2 = x.restrict([Integer(2)])
>>> x_using_row_2
Dancing links solver for 7 columns and 6 rows
>>> sorted(map(sorted, x_using_row_2.solutions_iterator()))
[[2, 3]]
```

The two basic methods that are wrapped in this class are `search` which returns `1` if a solution is found or `0` otherwise and `get_solution` which return the current solution:

```
sage: x = dlx_solver(rows)
sage: x.search()
1
sage: x.get_solution()
[0, 1]
sage: x.search()
1
sage: x.get_solution()
[2, 3]
sage: x.search()
1
sage: x.get_solution()
[4, 5]
```

(continues on next page)

(continued from previous page)

```
sage: x.search()
0
```

```
>>> from sage.all import *
>>> x = dlx_solver(rows)
>>> x.search()
1
>>> x.get_solution()
[0, 1]
>>> x.search()
1
>>> x.get_solution()
[2, 3]
>>> x.search()
1
>>> x.get_solution()
[4, 5]
>>> x.search()
0
```

There is also a method `reinitialize` to reinitialize the algorithm:

```
sage: x.reinitialize()
sage: x.search()
1
sage: x.get_solution()
[0, 1]
```

```
>>> from sage.all import *
>>> x.reinitialize()
>>> x.search()
1
>>> x.get_solution()
[0, 1]
```

class `sage.combinat.matrices.dancing_links.`**`dancing_linksWrapper`**

Bases: `object`

A simple class that implements dancing links.

The main methods to list the solutions are *`search()`* and *`get_solution()`*. You can also use *`number_of_solutions()`* to count them.

This class simply wraps a C++ implementation of Carlo Hamalainen.

`all_solutions`(*ncpus=None*, *column=None*)

Return all solutions found after splitting the problem to allow parallel computation.

INPUT:

- `ncpus` – integer (default: `None`); maximal number of subprocesses to use at the same time. If `None`, it detects the number of effective CPUs in the system using `sage.parallel.ncpus.ncpus()`.
- `column` – integer (default: `None`); the column used to split the problem, if `None` a random column is chosen

OUTPUT: list of solutions

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: S = d.all_solutions()
sage: sorted(sorted(s) for s in S)
[[0, 1], [2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
↪Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
↪Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)]]
>>> d = dlx_solver(rows)
>>> S = d.all_solutions()
>>> sorted(sorted(s) for s in S)
[[0, 1], [2, 3], [4, 5]]
```

The number of CPUs can be specified as input:

```
sage: S = Subsets(range(4))
sage: rows = map(list, S)
sage: dlx = dlx_solver(rows)
sage: dlx
Dancing links solver for 4 columns and 16 rows
sage: dlx.number_of_solutions()
15
sage: sorted(sorted(s) for s in dlx.all_solutions(ncpus=2))
[[1, 2, 3, 4],
 [1, 2, 10],
 [1, 3, 9],
 [1, 4, 8],
 [1, 14],
 [2, 3, 7],
 [2, 4, 6],
 [2, 13],
 [3, 4, 5],
 [3, 12],
 [4, 11],
 [5, 10],
 [6, 9],
 [7, 8],
 [15]]
```

```
>>> from sage.all import *
>>> S = Subsets(range(Integer(4)))
>>> rows = map(list, S)
>>> dlx = dlx_solver(rows)
>>> dlx
Dancing links solver for 4 columns and 16 rows
```

(continues on next page)

(continued from previous page)

```
>>> dlx.number_of_solutions()
15
>>> sorted(sorted(s) for s in dlx.all_solutions(ncpus=Integer(2)))
[[1, 2, 3, 4],
 [1, 2, 10],
 [1, 3, 9],
 [1, 4, 8],
 [1, 14],
 [2, 3, 7],
 [2, 4, 6],
 [2, 13],
 [3, 4, 5],
 [3, 12],
 [4, 11],
 [5, 10],
 [6, 9],
 [7, 8],
 [15]]
```

If ncpus=1, the computation is not done in parallel:

```
sage: sorted(sorted(s) for s in dlx.all_solutions(ncpus=1))
[[1, 2, 3, 4],
 [1, 2, 10],
 [1, 3, 9],
 [1, 4, 8],
 [1, 14],
 [2, 3, 7],
 [2, 4, 6],
 [2, 13],
 [3, 4, 5],
 [3, 12],
 [4, 11],
 [5, 10],
 [6, 9],
 [7, 8],
 [15]]
```

```
>>> from sage.all import *
>>> sorted(sorted(s) for s in dlx.all_solutions(ncpus=Integer(1)))
[[1, 2, 3, 4],
 [1, 2, 10],
 [1, 3, 9],
 [1, 4, 8],
 [1, 14],
 [2, 3, 7],
 [2, 4, 6],
 [2, 13],
 [3, 4, 5],
 [3, 12],
 [4, 11],
 [5, 10],
```

(continues on next page)

(continued from previous page)

```
[6, 9],
[7, 8],
[15]]
```

get_solution()

Return the current solution.

After a new solution is found using the method *search()* this method return the rows that make up the current solution.

ncols()

Return the number of columns.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [1,2], [0], [3,4,5]]
sage: dlx = dlx_solver(rows)
sage: dlx.ncols()
6
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(1),Integer(2)],␣
↪[Integer(0)], [Integer(3),Integer(4),Integer(5)]]
>>> dlx = dlx_solver(rows)
>>> dlx.ncols()
6
```

nrows()

Return the number of rows.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [1,2], [0], [3,4,5]]
sage: dlx = dlx_solver(rows)
sage: dlx.nrows()
4
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(1),Integer(2)],␣
↪[Integer(0)], [Integer(3),Integer(4),Integer(5)]]
>>> dlx = dlx_solver(rows)
>>> dlx.nrows()
4
```

number_of_solutions(*ncpus=None*, *column=None*)

Return the number of distinct solutions.

INPUT:

- ncpus – integer (default: None); maximal number of subprocesses to use at the same time. If ncpus>1 the dancing links problem is split into independent subproblems to allow parallel computation. If None, it detects the number of effective CPUs in the system using sage.parallel.ncpus.ncpus().
- column – integer (default: None); the column used to split the problem, if None a random column is chosen (this argument is ignored if ncpus is 1)

OUTPUT: integer

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2]]
sage: rows += [[0,2]]
sage: rows += [[1]]
sage: rows += [[3]]
sage: x = dlx_solver(rows)
sage: x.number_of_solutions()
2
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)]]
>>> rows += [[Integer(0),Integer(2)]]
>>> rows += [[Integer(1)]]
>>> rows += [[Integer(3)]]
>>> x = dlx_solver(rows)
>>> x.number_of_solutions()
2
```

The number of CPUs can be specified as input:

```
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: x = dlx_solver(rows)
sage: x.number_of_solutions(ncpus=2, column=3)
3
```

```
>>> from sage.all import *
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
↪Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
↪Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)]]
>>> x = dlx_solver(rows)
>>> x.number_of_solutions(ncpus=Integer(2), column=Integer(3))
3
```

```
sage: S = Subsets(range(5))
sage: rows = map(list, S)
sage: d = dlx_solver(rows)
sage: d.number_of_solutions()
52
```

```
>>> from sage.all import *
>>> S = Subsets(range(Integer(5)))
```

(continues on next page)

(continued from previous page)

```
>>> rows = map(list, S)
>>> d = dlx_solver(rows)
>>> d.number_of_solutions()
52
```

one_solution(*ncpus=None*, *column=None*)

Return the first solution found.

This method allows parallel computations which might be useful for some kind of problems when it is very hard just to find one solution.

INPUT:

- `ncpus` – integer (default: `None`); maximal number of subprocesses to use at the same time. If `None`, it detects the number of effective CPUs in the system using `sage.parallel.ncpus.ncpus()`. If `ncpus=1`, the first solution is searched serially.
- `column` – integer (default: `None`); the column used to split the problem (see `restrict()`). If `None`, a random column is chosen. This argument is ignored if `ncpus=1`.

OUTPUT: list of rows or `None` if no solution is found

Note

For some case, increasing the number of cpus makes it faster. For other instances, `ncpus=1` is faster. It all depends on problem which is considered.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: solutions = [[0,1], [2,3], [4,5]]
sage: sorted(d.one_solution()) in solutions
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
→Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
→Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
→Integer(5)]]
>>> d = dlx_solver(rows)
>>> solutions = [[Integer(0),Integer(1)], [Integer(2),Integer(3)],
→[Integer(4),Integer(5)]]
>>> sorted(d.one_solution()) in solutions
True
```

The number of CPUs can be specified as input:

```
sage: sorted(d.one_solution(ncpus=2)) in solutions
True
```

```
>>> from sage.all import *
>>> sorted(d.one_solution(ncpus=Integer(2))) in solutions
True
```

The column used to split the problem for parallel computations can be given:

```
sage: sorted(d.one_solution(ncpus=2, column=4)) in solutions
True
```

```
>>> from sage.all import *
>>> sorted(d.one_solution(ncpus=Integer(2), column=Integer(4))) in solutions
True
```

When no solution is found:

```
sage: rows = [[0,1,2], [2,3,4,5], [0,1,2,3]]
sage: d = dlx_solver(rows)
sage: d.one_solution() is None
True
```

```
>>> from sage.all import *
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(2),Integer(3),
↪Integer(4),Integer(5)], [Integer(0),Integer(1),Integer(2),Integer(3)]]
>>> d = dlx_solver(rows)
>>> d.one_solution() is None
True
```

one_solution_using_milp_solver(*solver=None*, *integrality_tolerance=0.001*)

Return a solution found using a MILP solver.

INPUT:

- `solver` – string or `None` (default: `None`); possible values include `'GLPK'`, `'GLPK/exact'`, `'Coin'`, `'CPLEX'`, `'Gurobi'`, `'CVXOPT'`, `'PPL'`, `'InteractiveLP'`

OUTPUT: list of rows or `None` if no solution is found

Note

When comparing the time taken by method `one_solution`, have in mind that `one_solution_using_milp_solver` first creates (and caches) the MILP solver instance from the dancing links solver. This copy of data may take many seconds depending on the size of the problem.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: solutions = [[0,1], [2,3], [4,5]]
sage: d.one_solution_using_milp_solver() in solutions                    #␣
↪needs sage.numerical.mip
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
↪Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
↪Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)]]
>>> d = dlx_solver(rows)
>>> solutions = [[Integer(0),Integer(1)], [Integer(2),Integer(3)],␣
↪[Integer(4),Integer(5)]]
>>> d.one_solution_using_milp_solver() in solutions                    #␣
↪needs sage.numerical.mip
True
```

Using optional solvers:

```
sage: # optional - gurobi sage_numerical_backends_gurobi, needs sage.
↪numerical.mip
sage: s = d.one_solution_using_milp_solver('gurobi')
sage: s in solutions
True
```

```
>>> from sage.all import *
>>> # optional - gurobi sage_numerical_backends_gurobi, needs sage.numerical.
↪mip
>>> s = d.one_solution_using_milp_solver('gurobi')
>>> s in solutions
True
```

When no solution is found:

```
sage: rows = [[0,1,2], [2,3,4,5], [0,1,2,3]]
sage: d = dlx_solver(rows)
sage: d.one_solution_using_milp_solver() is None                       #␣
↪needs sage.numerical.mip
True
```

```
>>> from sage.all import *
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(2),Integer(3),
↪Integer(4),Integer(5)], [Integer(0),Integer(1),Integer(2),Integer(3)]]
>>> d = dlx_solver(rows)
>>> d.one_solution_using_milp_solver() is None                         #␣
↪needs sage.numerical.mip
True
```

one_solution_using_sat_solver(*solver=None*)

Return a solution found using a SAT solver.

INPUT:

- `solver` – string or `None` (default: `None`), possible values include `'picosat'`, `'cryptominisat'`, `'LP'`, `'glucose'`, `'glucose-syrup'`.

OUTPUT: list of rows or `None` if no solution is found

Note

When comparing the time taken by method `one_solution`, have in mind that `one_solution_using_sat_solver` first creates the SAT solver instance from the dancing links solver. This copy of data may take many seconds depending on the size of the problem.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: solutions = [[0,1], [2,3], [4,5]]
sage: d.one_solution_using_sat_solver() in solutions                           #␣
↪needs sage.sat
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
↪Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
↪Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)]]
>>> d = dlx_solver(rows)
>>> solutions = [[Integer(0),Integer(1)], [Integer(2),Integer(3)],␣
↪[Integer(4),Integer(5)]]
>>> d.one_solution_using_sat_solver() in solutions                            #␣
↪needs sage.sat
True
```

Using optional solvers:

```
sage: s = d.one_solution_using_sat_solver('glucose')                    #␣
↪optional - glucose, needs sage.sat
sage: s in solutions                                                    #␣
↪optional - glucose, needs sage.sat
True
```

```
>>> from sage.all import *
>>> s = d.one_solution_using_sat_solver('glucose')                  # optional -
↪ glucose, needs sage.sat
>>> s in solutions                                                  # optional -
↪ glucose, needs sage.sat
True
```

When no solution is found:

```
sage: rows = [[0,1,2], [2,3,4,5], [0,1,2,3]]
sage: d = dlx_solver(rows)
sage: d.one_solution_using_sat_solver() is None                                #␣
↪needs sage.sat
True
```

```
>>> from sage.all import *
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(2),Integer(3),
↪Integer(4),Integer(5)], [Integer(0),Integer(1),Integer(2),Integer(3)]]
>>> d = dlx_solver(rows)
>>> d.one_solution_using_sat_solver() is None                               #␣
↪needs sage.sat
True
```

reinitialize()

Reinitialization of the search algorithm.

This recreates an empty `dancing_links` object and adds the rows to the instance of `dancing_links`.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: x = dlx_solver(rows)
sage: x.get_solution() if x.search() else None
[0, 1]
sage: x.get_solution() if x.search() else None
[2, 3]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
↪Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
↪Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)]]
>>> x = dlx_solver(rows)
>>> x.get_solution() if x.search() else None
[0, 1]
>>> x.get_solution() if x.search() else None
[2, 3]
```

Reinitialization of the algorithm:

```
sage: x.reinitialize()
sage: x.get_solution() if x.search() else None
[0, 1]
sage: x.get_solution() if x.search() else None
[2, 3]
sage: x.get_solution() if x.search() else None
[4, 5]
sage: x.get_solution() if x.search() else None
```

```
>>> from sage.all import *
>>> x.reinitialize()
>>> x.get_solution() if x.search() else None
[0, 1]
>>> x.get_solution() if x.search() else None
[2, 3]
>>> x.get_solution() if x.search() else None
```

(continues on next page)

(continued from previous page)

```
[4, 5]
>>> x.get_solution() if x.search() else None
```

Reinitialization works after solutions are exhausted:

```
sage: x.reinitialize()
sage: x.get_solution() if x.search() else None
[0, 1]
sage: x.get_solution() if x.search() else None
[2, 3]
sage: x.get_solution() if x.search() else None
[4, 5]
sage: x.get_solution() if x.search() else None
```

```
>>> from sage.all import *
>>> x.reinitialize()
>>> x.get_solution() if x.search() else None
[0, 1]
>>> x.get_solution() if x.search() else None
[2, 3]
>>> x.get_solution() if x.search() else None
[4, 5]
>>> x.get_solution() if x.search() else None
```

restrict(*indices*)

Return a dancing links solver solving the subcase which uses some given rows.

For every row that is wanted in the solution, we add a new column to the row to make sure it is in the solution.

INPUT:

- `indices` – list; row indices to be found in the solution

OUTPUT: dancing links solver

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: d
Dancing links solver for 6 columns and 6 rows
sage: sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
↪Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
↪Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)]]
>>> d = dlx_solver(rows)
>>> d
Dancing links solver for 6 columns and 6 rows
```

(continues on next page)

(continued from previous page)

```
>>> sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

To impose that the 0-th row is part of the solution, the rows of the new problem are:

```
sage: d_using_0 = d.restrict([0])
sage: d_using_0
Dancing links solver for 7 columns and 6 rows
sage: d_using_0.rows()
[[0, 1, 2, 6], [3, 4, 5], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
```

```
>>> from sage.all import *
>>> d_using_0 = d.restrict([Integer(0)])
>>> d_using_0
Dancing links solver for 7 columns and 6 rows
>>> d_using_0.rows()
[[0, 1, 2, 6], [3, 4, 5], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
```

After restriction the subproblem has one more columns and the same number of rows as the original one:

```
sage: d.restrict([1]).rows()
[[0, 1, 2], [3, 4, 5, 6], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
sage: d.restrict([2]).rows()
[[0, 1, 2], [3, 4, 5], [0, 1, 6], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
```

```
>>> from sage.all import *
>>> d.restrict([Integer(1)]).rows()
[[0, 1, 2], [3, 4, 5, 6], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
>>> d.restrict([Integer(2)]).rows()
[[0, 1, 2], [3, 4, 5], [0, 1, 6], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
```

This method allows to find solutions where the 0-th row is part of a solution:

```
sage: sorted(map(sorted, d.restrict([0]).solutions_iterator()))
[[0, 1]]
```

```
>>> from sage.all import *
>>> sorted(map(sorted, d.restrict([Integer(0)]).solutions_iterator()))
[[0, 1]]
```

Some other examples:

```
sage: sorted(map(sorted, d.restrict([1]).solutions_iterator()))
[[0, 1]]
sage: sorted(map(sorted, d.restrict([2]).solutions_iterator()))
[[2, 3]]
sage: sorted(map(sorted, d.restrict([3]).solutions_iterator()))
[[2, 3]]
```

```
>>> from sage.all import *
>>> sorted(map(sorted, d.restrict([Integer(1)]).solutions_iterator()))
[[0, 1]]
```

(continues on next page)

(continued from previous page)

```
>>> sorted(map(sorted, d.restrict([Integer(2)]).solutions_iterator()))
[[2, 3]]
>>> sorted(map(sorted, d.restrict([Integer(3)]).solutions_iterator()))
[[2, 3]]
```

Here there are no solutions using both 0th and 3rd row:

```
sage: list(d.restrict([0,3]).solutions_iterator())
[]
```

```
>>> from sage.all import *
>>> list(d.restrict([Integer(0),Integer(3)]).solutions_iterator())
[]
```

rows()

Return the list of rows.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [1,2], [0]]
sage: x = dlx_solver(rows)
sage: x.rows()
[[0, 1, 2], [1, 2], [0]]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(1),Integer(2)],
→[Integer(0)]]
>>> x = dlx_solver(rows)
>>> x.rows()
[[0, 1, 2], [1, 2], [0]]
```

search()

Search for a new solution.

Return 1 if a new solution is found and 0 otherwise. To recover the solution, use the method *get_solution()*.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2]]
sage: rows+= [[0,2]]
sage: rows+= [[1]]
sage: rows+= [[3]]
sage: x = dlx_solver(rows)
sage: print(x.search())
1
sage: print(x.get_solution())
[3, 0]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)]]
>>> rows+= [[Integer(0),Integer(2)]]
>>> rows+= [[Integer(1)]]
>>> rows+= [[Integer(3)]]
>>> x = dlx_solver(rows)
>>> print(x.search())
1
>>> print(x.get_solution())
[3, 0]
```

solutions_iterator()

Return an iterator of the solutions.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
↪Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
↪Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)]]
>>> d = dlx_solver(rows)
>>> sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

split(*column*)

Return a dict of independent solvers.

For each `i`-th row containing a `1` in the `column`, the dict associates the solver giving all solution using the `i`-th row.

This is used for parallel computations.

INPUT:

- `column` – integer; the column used to split the problem into independent subproblems

OUTPUT: dict where keys are row numbers and values are dlx solvers

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: d
Dancing links solver for 6 columns and 6 rows
sage: sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
↪Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
↪Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)]]
>>> d = dlx_solver(rows)
>>> d
Dancing links solver for 6 columns and 6 rows
>>> sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

After the split each subproblem has one more column and the same number of rows as the original problem:

```
sage: D = d.split(0)
sage: D
{0: Dancing links solver for 7 columns and 6 rows,
 2: Dancing links solver for 7 columns and 6 rows,
 4: Dancing links solver for 7 columns and 6 rows}
```

```
>>> from sage.all import *
>>> D = d.split(Integer(0))
>>> D
{0: Dancing links solver for 7 columns and 6 rows,
 2: Dancing links solver for 7 columns and 6 rows,
 4: Dancing links solver for 7 columns and 6 rows}
```

The (disjoint) union of the solutions of the subproblems is equal to the set of solutions shown above:

```
sage: for x in D.values(): sorted(map(sorted, x.solutions_iterator()))
[[0, 1]]
[[2, 3]]
[[4, 5]]
```

```
>>> from sage.all import *
>>> for x in D.values(): sorted(map(sorted, x.solutions_iterator()))
[[0, 1]]
[[2, 3]]
[[4, 5]]
```

to_milp(*solver=None*)

Return the mixed integer linear program (MILP) representing an equivalent problem.

See also `sage.numerical.mip.MixedIntegerLinearProgram`.

INPUT:

- `solver` – string or `None` (default: `None`); possible values include `'GLPK'`, `'GLPK/exact'`, `'Coin'`, `'CPLEX'`, `'Gurobi'`, `'CVXOPT'`, `'PPL'`, `'InteractiveLP'`

OUTPUT:

- MixedIntegerLinearProgram instance
- MIPVariable with binary components

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [0,2], [1], [3]]
sage: d = dlx_solver(rows)
sage: p,x = d.to_milp()                                                     #␣
↪needs sage.numerical.mip
sage: p                                                                     #␣
↪needs sage.numerical.mip
Boolean Program (no objective, 4 variables, ... constraints)
sage: x                                                                     #␣
↪needs sage.numerical.mip
MIPVariable with 4 binary components
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(0),Integer(2)],␣
↪[Integer(1)], [Integer(3)]]
>>> d = dlx_solver(rows)
>>> p,x = d.to_milp()                                                       #␣
↪needs sage.numerical.mip
>>> p                                                                       #␣
↪needs sage.numerical.mip
Boolean Program (no objective, 4 variables, ... constraints)
>>> x                                                                       #␣
↪needs sage.numerical.mip
MIPVariable with 4 binary components
```

In the reduction, the boolean variable x_i is `True` if and only if the i-th row is in the solution:

```
sage: p.show()                                                              #␣
↪needs sage.numerical.mip
Maximization:

Constraints:...
  one 1 in 0-th column: 1.0 <= x_0 + x_1 <= 1.0
  one 1 in 1-th column: 1.0 <= x_0 + x_2 <= 1.0
  one 1 in 2-th column: 1.0 <= x_0 + x_1 <= 1.0
  one 1 in 3-th column: 1.0 <= x_3 <= 1.0
Variables:
  x_0 is a boolean variable (min=0.0, max=1.0)
  x_1 is a boolean variable (min=0.0, max=1.0)
  x_2 is a boolean variable (min=0.0, max=1.0)
  x_3 is a boolean variable (min=0.0, max=1.0)
```

```
>>> from sage.all import *
>>> p.show()                                                                #␣
↪needs sage.numerical.mip
Maximization:
<BLANKLINE>
<BLANKLINE>
Constraints:...
  one 1 in 0-th column: 1.0 <= x_0 + x_1 <= 1.0
```

(continues on next page)

(continued from previous page)

```
  one 1 in 1-th column: 1.0 <= x_0 + x_2 <= 1.0
  one 1 in 2-th column: 1.0 <= x_0 + x_1 <= 1.0
  one 1 in 3-th column: 1.0 <= x_3 <= 1.0
Variables:
  x_0 is a boolean variable (min=0.0, max=1.0)
  x_1 is a boolean variable (min=0.0, max=1.0)
  x_2 is a boolean variable (min=0.0, max=1.0)
  x_3 is a boolean variable (min=0.0, max=1.0)
```

Using some optional MILP solvers:

```
sage: d.to_milp('gurobi')            # optional - gurobi sage_numerical_
↪backends_gurobi, needs sage.numerical.mip
(Boolean Program (no objective, 4 variables, 4 constraints),
 MIPVariable with 4 binary components)
```

```
>>> from sage.all import *
>>> d.to_milp('gurobi')            # optional - gurobi sage_numerical_backends_
↪gurobi, needs sage.numerical.mip
(Boolean Program (no objective, 4 variables, 4 constraints),
 MIPVariable with 4 binary components)
```

to_sat_solver(*solver=None*)

Return the SAT solver solving an equivalent problem.

Note that row index i in the dancing links solver corresponds to the boolean variable index $+1$ for the SAT solver to avoid the variable index 0.

See also `sage.sat.solvers.satsolver`.

INPUT:

- `solver` – string or `None` (default: `None`), possible values include `'picosat'`, `'cryptominisat'`, `'LP'`, `'glucose'`, `'glucose-syrup'`.

OUTPUT: SAT solver instance

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [0,2], [1], [3]]
sage: x = dlx_solver(rows)
sage: s = x.to_sat_solver()                                              #␣
↪needs sage.sat
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(0),Integer(2)],␣
↪[Integer(1)], [Integer(3)]]
>>> x = dlx_solver(rows)
>>> s = x.to_sat_solver()                                              #␣
↪needs sage.sat
```

Using some optional SAT solvers:

```
sage: x.to_sat_solver('cryptominisat')      # optional - pycryptosat        #␣
↪needs sage.sat
CryptoMiniSat solver: 4 variables, 7 clauses.
```

```
>>> from sage.all import *
>>> x.to_sat_solver('cryptominisat')      # optional - pycryptosat        #␣
↪needs sage.sat
CryptoMiniSat solver: 4 variables, 7 clauses.
```

sage.combinat.matrices.dancing_links.**dlx_solver**(*rows*)

Internal-use wrapper for the dancing links C++ code.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2]]
sage: rows+= [[0,2]]
sage: rows+= [[1]]
sage: rows+= [[3]]
sage: x = dlx_solver(rows)
sage: print(x.search())
1
sage: print(x.get_solution())
[3, 0]
sage: print(x.search())
1
sage: print(x.get_solution())
[3, 1, 2]
sage: print(x.search())
0
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)]]
>>> rows+= [[Integer(0),Integer(2)]]
>>> rows+= [[Integer(1)]]
>>> rows+= [[Integer(3)]]
>>> x = dlx_solver(rows)
>>> print(x.search())
1
>>> print(x.get_solution())
[3, 0]
>>> print(x.search())
1
>>> print(x.get_solution())
[3, 1, 2]
>>> print(x.search())
0
```

sage.combinat.matrices.dancing_links.**make_dlxwrapper**(*s*)

Create a dlx wrapper from a Python *string* s.

This was historically used in unpickling and is kept for backwards compatibility. We expect s to be `dumps(rows)` where rows is the list of rows used to instantiate the object.

5.1.136 Dancing links C++ wrapper

sage.combinat.matrices.dlxcpp.**AllExactCovers**(*M*)

Solve the exact cover problem on the matrix M (treated as a dense binary matrix).

EXAMPLES: No exact covers:

```
sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]])                                 #␣
↪needs sage.modules
sage: [cover for cover in AllExactCovers(M)]                                #␣
↪needs sage.modules
[]
```

```
>>> from sage.all import *
>>> M = Matrix([[Integer(1),Integer(1),Integer(0)],[Integer(1),Integer(0),
↪Integer(1)],[Integer(0),Integer(1),Integer(1)]])                           ␣
↪      # needs sage.modules
>>> [cover for cover in AllExactCovers(M)]                                #␣
↪needs sage.modules
[]
```

Two exact covers:

```
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]])                         #␣
↪needs sage.modules
sage: [cover for cover in AllExactCovers(M)]                                #␣
↪needs sage.modules
[[(1, 1, 0), (0, 0, 1)], [(1, 0, 1), (0, 1, 0)]]
```

```
>>> from sage.all import *
>>> M = Matrix([[Integer(1),Integer(1),Integer(0)],[Integer(1),Integer(0),
↪Integer(1)],[Integer(0),Integer(0),Integer(1)],[Integer(0),Integer(1),
↪Integer(0)]])                              # needs sage.modules
>>> [cover for cover in AllExactCovers(M)]                                #␣
↪needs sage.modules
[[(1, 1, 0), (0, 0, 1)], [(1, 0, 1), (0, 1, 0)]]
```

sage.combinat.matrices.dlxcpp.**DLXCPP**(*rows*)

Solve the Exact Cover problem by using the Dancing Links algorithm described by Knuth.

Consider a matrix M with entries of 0 and 1, and compute a subset of the rows of this matrix which sum to the vector of all 1s.

The dancing links algorithm works particularly well for sparse matrices, so the input is a list of lists of the form:

```
[
 [i_11,i_12,...,i_1r]
 ...
 [i_m1,i_m2,...,i_ms]
]
```

where M[j][i_jk] = 1.

The first example below corresponds to the matrix:

```
1110
1010
0100
0001
```

which is exactly covered by:

```
1110
0001
```

and

```
1010
0100
0001
```

If soln is a solution given by DLXCPP(rows) then

[rows[soln[0]], rows[soln[1]], … rows[soln[len(soln)-1]]]

is an exact cover.

Solutions are given as a list.

EXAMPLES:

```
sage: rows = [[0,1,2]]
sage: rows+= [[0,2]]
sage: rows+= [[1]]
sage: rows+= [[3]]
sage: [x for x in DLXCPP(rows)]
[[3, 0], [3, 1, 2]]
```

```
>>> from sage.all import *
>>> rows = [[Integer(0),Integer(1),Integer(2)]]
>>> rows+= [[Integer(0),Integer(2)]]
>>> rows+= [[Integer(1)]]
>>> rows+= [[Integer(3)]]
>>> [x for x in DLXCPP(rows)]
[[3, 0], [3, 1, 2]]
```

sage.combinat.matrices.dlxcpp.**OneExactCover**(*M*)

Solve the exact cover problem on the matrix M (treated as a dense binary matrix).

EXAMPLES:

```
sage: # needs sage.modules
sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]])   # no exact covers
sage: print(OneExactCover(M))
None
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]]) # two exact covers
sage: OneExactCover(M)
[(1, 1, 0), (0, 0, 1)]
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> M = Matrix([[Integer(1),Integer(1),Integer(0)],[Integer(1),Integer(0),
↪Integer(1)],[Integer(0),Integer(1),Integer(1)]])  # no exact covers
>>> print(OneExactCover(M))
None
>>> M = Matrix([[Integer(1),Integer(1),Integer(0)],[Integer(1),Integer(0),
↪Integer(1)],[Integer(0),Integer(0),Integer(1)],[Integer(0),Integer(1),
↪Integer(0)]]) # two exact covers
>>> OneExactCover(M)
[(1, 1, 0), (0, 0, 1)]
```

5.1.137 Hadamard matrices

A Hadamard matrix is an $n \times n$ matrix H whose entries are either $+1$ or -1 and whose rows are mutually orthogonal. For example, the matrix H_2 defined by

$$\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$$

is a Hadamard matrix. An $n \times n$ matrix H whose entries are either $+1$ or -1 is a Hadamard matrix if and only if:

(a) $|det(H)| = n^{n/2}$ or

(b) $H * H^t = n \cdot I_n$, where I_n is the identity matrix.

In general, the tensor product of an $m \times m$ Hadamard matrix and an $n \times n$ Hadamard matrix is an $(mn) \times (mn)$ matrix. In particular, if there is an $n \times n$ Hadamard matrix then there is a $(2n) \times (2n)$ Hadamard matrix (since one may tensor with H_2). This particular case is sometimes called the Sylvester construction.

The Hadamard conjecture (possibly due to Paley) states that a Hadamard matrix of order n exists if and only if $n = 1, 2$ or n is a multiple of 4.

The module below implements constructions of Hadamard and skew Hadamard matrices for all known orders ≤ 1200, plus some more greater than 1200. It also allows you to pull a Hadamard matrix from the database at [SloaHada].

The following code will test that a construction for all known orders $\leq 4k$ is implemented. The assertion above can be verified by setting `k=300` (note that it will take a long time to run):

```
sage: from sage.combinat.matrices.hadamard_matrix import (hadamard_matrix,
....:                                     skew_hadamard_matrix, is_hadamard_matrix,
....:                                     is_skew_hadamard_matrix)
sage: k = 20
sage: unknown_hadamard = [668, 716, 892, 1132]
sage: unknown_skew_hadamard = [356, 404, 428, 476, 596, 612, 668, 708, 712, 716,
....:                          764, 772, 804, 808, 820, 836, 856, 892, 900, 916,
....:                          932, 940, 952, 980, 996, 1004, 1012, 1028, 1036,
....:                          1044, 1060, 1076, 1100, 1108, 1132, 1140, 1148,
....:                          1156, 1180, 1192, 1196]
sage: for n in range(1, k+1):
....:   if 4*n not in unknown_hadamard:
....:       H = hadamard_matrix(4*n, check=False)
....:       assert is_hadamard_matrix(H)
....:   if 4*n not in unknown_skew_hadamard:
....:       H = skew_hadamard_matrix(4*n, check=False)
....:       assert is_skew_hadamard_matrix(H)
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import (hadamard_matrix,
...                                  skew_hadamard_matrix, is_hadamard_matrix,
...                                  is_skew_hadamard_matrix)
>>> k = Integer(20)
>>> unknown_hadamard = [Integer(668), Integer(716), Integer(892), Integer(1132)]
>>> unknown_skew_hadamard = [Integer(356), Integer(404), Integer(428), Integer(476),
↪Integer(596), Integer(612), Integer(668), Integer(708), Integer(712), Integer(716),
...                          Integer(764), Integer(772), Integer(804), Integer(808),
↪Integer(820), Integer(836), Integer(856), Integer(892), Integer(900), Integer(916),
...                          Integer(932), Integer(940), Integer(952), Integer(980),
↪Integer(996), Integer(1004), Integer(1012), Integer(1028), Integer(1036),
...                          Integer(1044), Integer(1060), Integer(1076),
↪Integer(1100), Integer(1108), Integer(1132), Integer(1140), Integer(1148),
...                          Integer(1156), Integer(1180), Integer(1192),
↪Integer(1196)]
>>> for n in range(Integer(1), k+Integer(1)):
...   if Integer(4)*n not in unknown_hadamard:
...       H = hadamard_matrix(Integer(4)*n, check=False)
...       assert is_hadamard_matrix(H)
...   if Integer(4)*n not in unknown_skew_hadamard:
...       H = skew_hadamard_matrix(Integer(4)*n, check=False)
...       assert is_skew_hadamard_matrix(H)
```

AUTHORS:

- David Joyner (2009-05-17): initial version
- Matteo Cati (2023-03-18): implemented more constructions for Hadamard and skew Hadamard matrices, to cover all known orders up to 1200.

REFERENCES:

`sage.combinat.matrices.hadamard_matrix.`**`GS_skew_hadamard_smallcases`**(*n*, *existence=False*, *check=True*)

Data for Williamson-Goethals-Seidel construction of skew Hadamard matrices.

Here we keep the data for this construction. Namely, it needs 4 circulant matrices with extra properties, as described in `sage.combinat.matrices.hadamard_matrix.williamson_goethals_seidel_skew_hadamard_matrix()` Matrices are taken from:

- $n = 36, 52$: [GS70s]
- $n = 92$: [Wall71]
- $n = 188$: [Djo2008a]
- $n = 236$: [FKS2004]
- $n = 276$: [Djo2023a]

Additional data is obtained from skew supplementary difference sets contained in *sage.combinat.designs.difference_family.skew_supplementary_difference_set()*, using the construction described in [Djo1992a].

INPUT:

- `n` – integer; the order of the matrix
- `existence` – boolean (default: `True`); if `True`, only check that we can do the construction
- `check` – boolean (default: `False`); if `True`, check the result

`sage.combinat.matrices.hadamard_matrix.`**`RSHCD_324`**`(e)`

Return a size 324x324 Regular Symmetric Hadamard Matrix with Constant Diagonal.

We build the matrix M for the case $n = 324$, $\epsilon = 1$ directly from `JankoKharaghaniTonchevGraph` and for the case $\epsilon = -1$ from the "twist" M' of M, using Lemma 11 in [HX2010]. Namely, it turns out that the matrix

$$M' = \begin{pmatrix} M_{12} & M_{11} \\ M_{11}^\top & M_{21} \end{pmatrix}, \quad \text{where} \quad M = \begin{pmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{pmatrix},$$

and the M_{ij} are 162x162-blocks, also RSHCD, its diagonal blocks having zero row sums, as needed by [loc.cit.]. Interestingly, the corresponding $(324, 152, 70, 72)$-strongly regular graph has a vertex-transitive automorphism group of order 2592, twice the order of the (intransitive) automorphism group of the graph corresponding to M. Cf. [CP2016].

INPUT:

- `e` – -1 or $+1$; the value of ϵ

REFERENCE:

- [CP2016]

`sage.combinat.matrices.hadamard_matrix.`**`amicable_hadamard_matrices`**`(n, existence=False, check=True)`

Construct amicable Hadamard matrices of order `n` using the available methods.

INPUT:

- `n` – positive integer; the order of the amicable Hadamard matrices
- `existence` – boolean (default: `False`); if `True`, only return whether amicable Hadamard matrices of order n can be constructed
- `check` – boolean (default: `True`); if `True`, check that the matrices are amicable Hadamard matrices before returning them

OUTPUT:

If `existence` is true, the function returns a boolean representing whether amicable Hadamard matrices of order n can be constructed. If `existence` is false, returns two amicable Hadamard matrices, or raises an error if the matrices cannot be constructed.

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import amicable_hadamard_
↪matrices
sage: amicable_hadamard_matrices(2)
(
[ 1  1]  [ 1  1]
[-1  1], [ 1 -1]
)
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import amicable_hadamard_matrices
>>> amicable_hadamard_matrices(Integer(2))
(
[ 1  1]  [ 1  1]
[-1  1], [ 1 -1]
)
```

If `existence` is true, the function returns a boolean:

```
sage: amicable_hadamard_matrices(16, existence=True)
False
```

```
>>> from sage.all import *
>>> amicable_hadamard_matrices(Integer(16), existence=True)
False
```

`sage.combinat.matrices.hadamard_matrix.`**`amicable_hadamard_matrices_wallis`**`(`*n*, *check=True*`)`

Construct amicable Hadamard matrices of order $n = q + 1$ where q is a prime power.

If q is a prime power $\equiv 3 \mod 4$, then amicable Hadamard matrices of order $q+1$ can be constructed as described in [Wal1970b].

INPUT:

- `n` – integer; the order of the matrices to be constructed
- `check` – boolean (default: `True`); if `True`, check that the resulting matrices are amicable Hadamard before returning them

OUTPUT:

The function returns two amicable Hadamard matrices, or raises an error if such matrices cannot be created using this construction.

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import amicable_hadamard_
↪matrices_wallis
sage: M, N = amicable_hadamard_matrices_wallis(28)
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import amicable_hadamard_matrices_
↪wallis
>>> M, N = amicable_hadamard_matrices_wallis(Integer(28))
```

`sage.combinat.matrices.hadamard_matrix.`**`are_amicable_hadamard_matrices`**`(`*M*, *N*, *verbose=False*`)`

Check if `M` and `N` are amicable Hadamard matrices.

Two matrices M and N of order n are called amicable if they satisfy the following conditions (see [Seb2017]):

- M is a skew Hadamard matrix
- N is a symmetric Hadamard matrix
- $MN^T = NM^T$

INPUT:

- `M` – a square matrix
- `N` – a square matrix
- `verbose` – boolean (default: `False`); whether to be verbose when the matrices are not amicable Hadamard matrices

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import are_amicable_hadamard_
↪matrices
sage: M = matrix([[1, 1], [-1, 1]])
sage: N = matrix([[1, 1], [1, -1]])
sage: are_amicable_hadamard_matrices(M, N)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import are_amicable_hadamard_
↪matrices
>>> M = matrix([[Integer(1), Integer(1)], [-Integer(1), Integer(1)]])
>>> N = matrix([[Integer(1), Integer(1)], [Integer(1), -Integer(1)]])
>>> are_amicable_hadamard_matrices(M, N)
True
```

If `verbose` is true, the function will be verbose when returning False:

```
sage: N = matrix([[1, 1], [1, 1]])
sage: are_amicable_hadamard_matrices(M, N, verbose=True)
The second matrix is not Hadamard
False
```

```
>>> from sage.all import *
>>> N = matrix([[Integer(1), Integer(1)], [Integer(1), Integer(1)]])
>>> are_amicable_hadamard_matrices(M, N, verbose=True)
The second matrix is not Hadamard
False
```

`sage.combinat.matrices.hadamard_matrix.`**`construction_four_symbol_delta_code_I`**`(`X, Y, Z, W`)`

Construct 4-symbol δ code of length $2n + 1$.

The 4-symbol δ code is constructed from sequences X, Y, Z, W of length $n + 1$, $n + 1$, n, n satisfying for all $s > 0$:

$$N_X(s) + N_Y(s) + N_Z(s) + N_W(s) = 0$$

where $N_A(s)$ is the nonperiodic correlation function:

$$N_A(s) = \sum_{i=1}^{n-s} a_i a_{i+s}$$

The construction (detailed in [Tur1974]) is as follows:

$$\begin{aligned} T_1 &= X; Z \\ T_2 &= X; -Z \\ T_3 &= Y; W \\ T_4 &= Y; -W \end{aligned}$$

INPUT:

- X – list; the first sequence (length $n+1$)
- Y – list; the second sequence (length $n+1$)
- Z – list; the third sequence (length n)
- W – list; the fourth sequence (length n)

OUTPUT: tuple containing the 4-symbol δ code of length $2n+1$

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import construction_four_symbol_
↪delta_code_I
sage: construction_four_symbol_delta_code_I([1, 1], [1, -1], [1], [1])
([1, 1, 1], [1, 1, -1], [1, -1, 1], [1, -1, -1])
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import construction_four_symbol_
↪delta_code_I
>>> construction_four_symbol_delta_code_I([Integer(1), Integer(1)], [Integer(1), -
↪Integer(1)], [Integer(1)], [Integer(1)])
([1, 1, 1], [1, 1, -1], [1, -1, 1], [1, -1, -1])
```

sage.combinat.matrices.hadamard_matrix.**construction_four_symbol_delta_code_II**(X, Y, Z, W)

Construct 4-symbol δ code of length $4n+3$.

The 4-symbol δ code is constructed from sequences X, Y, Z, W of length $n+1$, $n+1$, n, n satisfying for all $s>0$:

$$N_X(s)+N_Y(s)+N_Z(s)+N_W(s)=0$$

where $N_A(s)$ is the nonperiodic correlation function:

$$N_A(s)=\sum_{i=1}^{n-s}a_ia_{i+s}$$

The construction (detailed in [Tur1974]) is as follows (writing A/B to mean A alternated with B):

$$\begin{aligned}T_1&=X/Z;Y/W;1\\T_2&=X/Z;Y/-W;-1\\T_3&=X/Z;-Y/-W;1\\T_4&=X/Z;-Y/W;-1\end{aligned}$$

INPUT:

- X – list; the first sequence (length $n+1$)
- Y – list; the second sequence (length $n+1$)
- Z – list; the third sequence (length n)
- W – list; the fourth sequence (length n)

OUTPUT: tuple containing the four 4-symbol δ code of length $4n+3$

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import construction_four_symbol_
↪delta_code_II
sage: construction_four_symbol_delta_code_II([1, 1], [1, -1], [1], [1])
([1, 1, 1, 1, 1, -1, 1],
 [1, 1, 1, 1, -1, -1, -1],
 [1, 1, 1, -1, -1, 1, 1],
 [1, 1, 1, -1, 1, 1, -1])
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import construction_four_symbol_
↪delta_code_II
>>> construction_four_symbol_delta_code_II([Integer(1), Integer(1)], [Integer(1),␣
↪-Integer(1)], [Integer(1)], [Integer(1)])
([1, 1, 1, 1, 1, -1, 1],
 [1, 1, 1, 1, -1, -1, -1],
 [1, 1, 1, -1, -1, 1, 1],
 [1, 1, 1, -1, 1, 1, -1])
```

sage.combinat.matrices.hadamard_matrix.**four_symbol_delta_code_smallcases**(*n*, *existence=False*)

Return the 4-symobl δ code of length `n` if available.

The 4-symbol δ codes are constructed using *construction_four_symbol_delta_code_I()* or *construction_four_symbol_delta_code_II()*. The base sequences used are taken from [Tur1974].

INPUT:

- `n` – integer; the length of the desired 4-symbol δ code
- `existence` – boolean (default: `False`); if `True`, only check if the sequences are available

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import four_symbol_delta_code_
↪smallcases
sage: four_symbol_delta_code_smallcases(3)
([1, -1, 1], [1, -1, -1], [1, 1, 1], [1, 1, -1])
sage: four_symbol_delta_code_smallcases(3, existence=True)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import four_symbol_delta_code_
↪smallcases
>>> four_symbol_delta_code_smallcases(Integer(3))
([1, -1, 1], [1, -1, -1], [1, 1, 1], [1, 1, -1])
>>> four_symbol_delta_code_smallcases(Integer(3), existence=True)
True
```

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix**(*n*, *existence=False*, *check=True*, *construction_name=False*)

This function is available as hadamard_matrix(…) and matrix.hadamard(…).

Try to construct a Hadamard matrix using the available methods.

Currently all orders ≤ 1200 for which a construction is known are implemented. For $n > 1200$, only some orders are available.

INPUT:

- `n` – integer; dimension of the matrix
- `existence` – boolean (default: `False`); whether to build the matrix or merely query if a construction is available in Sage. When set to `True`, the function returns:
  - `True` – meaning that Sage knows how to build the matrix
  - `Unknown` – meaning that Sage does not know how to build the matrix, although the matrix may exist (see `sage.misc.unknown`).
  - `False` – meaning that the matrix does not exist
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.
- `construction_name` – boolean (default: `False`); if it is `True`, `existence` is `True`, and a matrix exists, output the construction name. It has no effect if `existence` is set to `False`.

EXAMPLES:

```
sage: hadamard_matrix(12).det()
2985984
sage: 12^6
2985984
sage: hadamard_matrix(1)
[1]
sage: hadamard_matrix(2)
[ 1  1]
[ 1 -1]
sage: hadamard_matrix(8) # random
[ 1  1  1  1  1  1  1  1]
[ 1 -1  1 -1  1 -1  1 -1]
[ 1  1 -1 -1  1  1 -1 -1]
[ 1 -1 -1  1  1 -1 -1  1]
[ 1  1  1  1 -1 -1 -1 -1]
[ 1 -1  1 -1 -1  1 -1  1]
[ 1  1 -1 -1 -1 -1  1  1]
[ 1 -1 -1  1 -1  1  1 -1]
sage: hadamard_matrix(8).det() == 8^4
True
```

```
>>> from sage.all import *
>>> hadamard_matrix(Integer(12)).det()
2985984
>>> Integer(12)**Integer(6)
2985984
>>> hadamard_matrix(Integer(1))
[1]
>>> hadamard_matrix(Integer(2))
[ 1  1]
[ 1 -1]
>>> hadamard_matrix(Integer(8)) # random
[ 1  1  1  1  1  1  1  1]
[ 1 -1  1 -1  1 -1  1 -1]
[ 1  1 -1 -1  1  1 -1 -1]
```

(continues on next page)

(continued from previous page)

```
[ 1 -1 -1  1  1 -1 -1  1]
[ 1  1  1  1 -1 -1 -1 -1]
[ 1 -1  1 -1 -1  1 -1  1]
[ 1  1 -1 -1 -1 -1  1  1]
[ 1 -1 -1  1 -1  1  1 -1]
>>> hadamard_matrix(Integer(8)).det() == Integer(8)**Integer(4)
True
```

We note that `hadamard_matrix()` returns a normalised Hadamard matrix (the entries in the first row and column are all +1)

```
sage: hadamard_matrix(12) # random
[ 1  1| 1  1| 1  1| 1  1| 1  1| 1  1]
[ 1 -1|-1  1|-1  1|-1  1|-1  1|-1  1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1| 1 -1| 1  1|-1 -1|-1 -1| 1  1]
[ 1  1|-1 -1| 1 -1|-1  1|-1  1| 1 -1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1| 1  1| 1 -1| 1  1|-1 -1|-1 -1]
[ 1  1| 1 -1|-1 -1| 1 -1|-1  1|-1  1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1|-1 -1| 1  1| 1 -1| 1  1|-1 -1]
[ 1  1|-1  1| 1 -1|-1 -1| 1 -1|-1  1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1|-1 -1|-1 -1| 1  1| 1 -1| 1  1]
[ 1  1|-1  1|-1  1| 1 -1|-1 -1| 1 -1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1| 1  1|-1 -1|-1 -1| 1  1| 1 -1]
[ 1  1| 1 -1|-1  1|-1  1| 1 -1|-1 -1]
```

```
>>> from sage.all import *
>>> hadamard_matrix(Integer(12)) # random
[ 1  1| 1  1| 1  1| 1  1| 1  1| 1  1]
[ 1 -1|-1  1|-1  1|-1  1|-1  1|-1  1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1| 1 -1| 1  1|-1 -1|-1 -1| 1  1]
[ 1  1|-1 -1| 1 -1|-1  1|-1  1| 1 -1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1| 1  1| 1 -1| 1  1|-1 -1|-1 -1]
[ 1  1| 1 -1|-1 -1| 1 -1|-1  1|-1  1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1|-1 -1| 1  1| 1 -1| 1  1|-1 -1]
[ 1  1|-1  1| 1 -1|-1 -1| 1 -1|-1  1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1|-1 -1|-1 -1| 1  1| 1 -1| 1  1]
[ 1  1|-1  1|-1  1| 1 -1|-1 -1| 1 -1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1| 1  1|-1 -1|-1 -1| 1  1| 1 -1]
[ 1  1| 1 -1|-1  1|-1  1| 1 -1|-1 -1]
```

To find how the matrix is obtained, use `construction_name`

```
sage: matrix.hadamard(476, existence=True, construction_name=True)
'cooper-wallis small cases: 476'
```

```
>>> from sage.all import *
>>> matrix.hadamard(Integer(476), existence=True, construction_name=True)
'cooper-wallis small cases: 476'
```

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix_156**()

Construct a Hadamard matrix of order 156.

The matrix is created using the construction detailed in [BH1965]. This uses four circulant matrices of size 13×13, which are composed into a 156×156 block matrix.

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix_cooper_wallis_construction**(*x1*, *x2*, *x3*, *x4*, *A*, *B*, *C*, *D*, *check=True*)

Create a Hadamard matrix using the construction detailed in [CW1972].

Given four circulant matrices X_1, X_2, X_3, X_4` of order n with entries (0, 1, -1) such that the entrywise product of two distinct matrices is always equal to 0 and that $\sum_{i=1}^{4} X_iX_i^\top = nI_n$ holds, and four matrices A, B, C, D of order m with elements (1, -1) such that $MN^\top = NM^\top$ for all distinct M, N and $AA^\top + BB^\top + CC^\top + DD^\top = 4mI_n$ holds, we construct a Hadamard matrix of order $4nm$.

INPUT:

- `x1` – list or vector; the first row of the circulant matrix X_1
- `x2` – list or vector; the first row of the circulant matrix X_2
- `x3` – list or vector; the first row of the circulant matrix X_3
- `x4` – list or vector; the first row of the circulant matrix X_4
- `A` – the matrix described above
- `B` – the matrix described above
- `C` – the matrix described above
- `D` – the matrix described above
- `check` – boolean (default: `True`); if `True`, check that the resulting matrix is Hadamard before returning it

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_cooper_
↪wallis_construction
sage: from sage.combinat.t_sequences import T_sequences_smallcases
sage: seqs = T_sequences_smallcases(19)
sage: hadamard_matrix_cooper_wallis_construction(seqs[0], seqs[1], seqs[2],␣
↪seqs[3], matrix([1]), matrix([1]), matrix([1]), matrix([1]))
76 x 76 dense matrix over Integer Ring...
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_cooper_
↪wallis_construction
>>> from sage.combinat.t_sequences import T_sequences_smallcases
```

(continues on next page)

(continued from previous page)

```
>>> seqs = T_sequences_smallcases(Integer(19))
>>> hadamard_matrix_cooper_wallis_construction(seqs[Integer(0)], seqs[Integer(1)],
↪ seqs[Integer(2)], seqs[Integer(3)], matrix([Integer(1)]), matrix([Integer(1)]),
↪ matrix([Integer(1)]), matrix([Integer(1)]))
76 x 76 dense matrix over Integer Ring...
```

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix_cooper_wallis_smallcases**(*n*, *check=True*, *existence=False*)

Construct Hadamard matrices using the Cooper-Wallis construction for some small values of n.

This function calls the function *hadamard_matrix_cooper_wallis_construction()* with the appropriate arguments. It constructs the matrices X_1, X_2, X_3, X_4 using either T-matrices or the T-sequences from *sage.combinat.t_sequences.T_sequences_smallcases()*. The matrices A, B, C, D are taken from *williamson_type_quadruples_smallcases()*.

Data for T-matrices of order 67 is taken from [Saw1985].

INPUT:

- `n` – integer; the order of the matrix to be constructed
- `check` – boolean (default: `True`); if `True`, check that the matrix is a Hadamard matrix before returning
- `existence` – boolean (default: `False`); if `True`, only check if the matrix exists

OUTPUT:

If `existence=False`, returns the Hadamard matrix of order n. It raises an error if no data is available to construct the matrix of the given order. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

See also

hadamard_matrix_cooper_wallis_construction()

EXAMPLES:

By default The function returns the Hadamard matrix

```
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_cooper_
↪wallis_smallcases
sage: hadamard_matrix_cooper_wallis_smallcases(28)
28 x 28 dense matrix over Integer Ring...
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_cooper_
↪wallis_smallcases
>>> hadamard_matrix_cooper_wallis_smallcases(Integer(28))
28 x 28 dense matrix over Integer Ring...
```

If `existence` is set to True, the function returns a boolean

```
sage: hadamard_matrix_cooper_wallis_smallcases(20, existence=True)
True
```

```
>>> from sage.all import *
>>> hadamard_matrix_cooper_wallis_smallcases(Integer(20), existence=True)
True
```

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix_from_sds**(*n*, *existence=False*, *check=True*)

Construction of Hadamard matrices from supplementary difference sets.
